FACTORS ASSOCIATED WITH SEVERE SARS-COV-2 INFECTION IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES IN MADRID: RESULTS FROM REUMA-COVID SORCOM REGISTRY

A. Boteanu[1], A. García Fernández[1], N. De la Torre[2], M. Pavia Pascual[2], O. Sanchez Pernaute[3], S. Recuero Diaz[3], S. Perez Esteban[3], G. Bonilla[4], L. Nuño[4], J. J. Sanmartin Martinez[5], C. Bonilla Gonzalez-Leganá[6], D. Clemente Garulo[7], L. Lojo Oliveira[8], J. M. Rodríguez Herredia[9], J. Bachiller-Corral[1]on behalf of REUMA-COVID SORCOM. [1]*H. U. Ramón y Cajal, Rheumatology, Madrid, Spain*; [2]*H.U. Puerta de Hierro, Rheumatology, Madrid, Spain*; [3]*H.U Fundación Jiménez Diaz, Rheumatology, Madrid, Spain*; [4]*H.U La Paz, Rheumatology, Madrid, Spain*; [5]*H.U Severo Ochoa, Rheumatology, Madrid, Spain*; [6]*H.U del Tajo, Rheumatology, Madrid, Spain*; [7]*H.U. Niño Jesus, Rheumatology, Madrid, Spain*; [8]*H.U Infanta Leonor, Rheumatology, Madrid, Spain*; [9]*H.U. Getafe, Rheumatology, Madrid, Spain*

Background: Patients with inflammatory rheumatic diseases (IRD) infected with SARS-CoV-2 may be at risk to develop a severe course of COVID-19 due to the immune dysregulation or the influence of immunomodulating drugs on the course of the infection. For a better understanding of SARS-CoV-2 infections in patients with IRD and due to the high incidence of COVID-19 in Madrid from the beginning of this pandemic infection in Spain, the Society of Rheumatology from Madrid (SORCOM) established a registry (REUMA-COVID SORCOM) shortly after the beginning of the pandemic in Spain.

Objectives: To determine factors associated with severity of infection with SARS-CoV-2 in patients with inflammatory rheumatic diseases in Madrid
Methods: The REUMA-COVID SORCOM registry is a multicenter, retrospective, observational cohort study conducted in Madrid, a SORCOM initiative. All rheumatology departments from Madrid were invited to participate. The study includes patients with IRD presenting with a confirmed or highly suspected diagnosis of COVID-19 between March 1, 2020, and November 10, 2020. We consider severe infection death or need of hospitalization. Inclusion criteria was having an IRD and at least 1 of the following 4 criteria: (1) a biologically confirmed COVID-19 diagnosis based on a positive result of a SARS-CoV-2 polymerase chain reaction (PCR) test on a nasopharyngeal swab; (2) Detection of IgM or IgG anti SARS-CoV2 in a symptomatic or asymptomatic patients (3)typical thoracic computed tomography (CT) abnormalities (ground-glass opacities) in epidemic areas; (4) COVID19–typical symptoms in an epidemic zone of COVID-19.
Results: As of November 10, 2020, 417 patients with IRD were included in the REUMA-COVID SORCOM registry. 5 patients were discharged for incomplete data. Of 412 patients (mean age 57 years, 87.4% Caucasian race, 66.3% female) 174 need hospitalization (42.2%) and 33 patients died (18.4% mortality in hospitalized patients). 82.3% had comorbidities. 234 (56.8%) patients were classified as inflammatory arthropathy, 133 (32.3%) had connective tissue diseases (CTD). 41.1% of the patients had a large history of IRD (> 10 years). 10.4% of patients had previously pulmonary involvement. The study includes 143 patients taking Methotrexate, 89 patients taking anti-TNFα therapy and 27 Rituximab. In the univariant analysis, no differences were seen in the severity of COVID-19 infection in patients taking methotrexate. 63% of the all patients taking Rituximab included in the registry need hospitalization and 22% of them died. Hypertension, COPD or cardiovascular disease was associated with hospitalization.
Independent factors associated with COVID-19 hospitalization in the multivariate analysis was: age (>62 years), male sex, IMC >30, previous cardiovascular comorbidities and the IRD disease duration (> 10 years). Independent factors associated with COVID-19 related death was: age (> 62 years), having a CTD diagnose, pulmonary involvement before infection and chronical GC treatment.
Conclusion: Patients with IRD represent a population of particular interest in the pandemic context because the baseline immunological alteration and the treated with immunosuppressants agents they receive, comorbidities and the well-known risk of severe infection. Older age, male sex, cardiovascular comorbidities were factors associated with high risk of hospitalization in IRD patients. CTD diseases, previously pulmonary involvement and chronical GC treatment with more than 10mg/day were associated with high risk of death. Neither anti TNF-α treatment nor Methotrexate were risk factor for hospitalization or death COVID-19 related in IRD patients.

Background: The current pandemic constitutes an entirely new situation for patients as well as physicians. The insecurity of the early phase, shutdowns, increasing infection rate and appearing SARS-CoV2 mutations have created a situation that makes live difficult especially for chronic diseases i.e. patients with rheumatic and musculoskeletal diseases (RMD) and their treating physicians. The psychosocial burden that is created by this special situation is completely unknown and is estimated to be higher in patients than in the general population.
Objectives: In order to measure the impact on our patients, the German COVID19-Rheuma patient survey was set up in April 2020, during Germany's first shut down.
Methods: The German COVID19-Rheuma patient survey is a patient reported longitudinal online survey where patients with RMD who registered between April and July 2020 are asked on a monthly base using an online survey on social, personal, medical factors, whether a COVID19 infection occurred, isolation measures were changed and scores regarding stress and anxiety are recorded. Between April and July 2020, 637 patients registered and completed a first survey. Up to January 2021, about 400 patients are still enrolled.
Here we present an interim analysis of the first 6 months regarding patients that were enrolled in April and May during the first shut-down. This first analysis compares the situation in the first lockdown to July, a phase with very low infection numbers in Germany, and to November, the beginning of the second lockdown.
Results: 150 patients (87% female) were enrolled in April/early May 2020. Mean age was 48 years (range 11-89). The majority of patients suffered from rheumatoid arthritis (51%), followed by psoriatic arthritis (17%), other spondyloarthropathies (10%) and connective tissue diseases (10%).
The majority of patients received antirheumatic therapies: 32% glucocorticoids (GC), 31% cDMARDs, 21% TNF inhibitors, 7% Jak inhibitors, and 9% other biologicals. Of the patients treated with GC, 25% were on GC monotherapy.
In the first lockdown, 26% of patients were working remotely and 24% were self-isolating (doubles included). Additionally, 48% were using masks that were not mandatory at that time and 41% were using disinfection in a regular manner. The rates for remote work and self-isolation did not change significantly over time while the mask use increased to 98% with the official obligation to do so. The use of disinfectants increased to 88% in November.
Regarding disease activity, no change in patient global assessment could be observed over time (4.3 ± 2.5 vs. 4.0 ±2.6 and 4.0 ± 2.5). Self-reported pain was also stable over time as were sleep disturbances. While 48.2% of patients who were receiving physiotherapy paused in April, only 10 and 14% did so in July and November, respectively. 11% of the patients paused their medication in the first lockdown, whereas only 2.75% did so in July and 3.4% in November. Contact with the treating rheumatologist was maintained over time in the majority of cases.
Conclusion: While in the beginning of the pandemic the insecurity was considerable and the concern that the fear for infection would lead to inadequately treated patients with RMDs, we here show for the first time that on the one hand our patients were timely in taking adequate measures to keep themselves safe (e.g. self-isolating, mask use) and adapted to the clinical situation in not pausing their medication. Altogether, in this alert cohort, the pandemic did not lead to an increase of patient-reported disease activity in the first six months.
Acknowledgements: Thanks goes to all patients who participated in the study.

POS1262

A COHORT STUDY OF COVID-19 RELATED MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN AND ADOLESCENTS FROM MULTIPLE TERTIARY CARE CENTRES IN SOUTH INDIA

A. Tiwari[1], A. Rauf[2], S. Kesavan[3], M. Kappanayil[4], S. Sivadas[5], S. Balan[1], P. Chickermane[1]. [1]*Amrita Institute of Medical Sciences, Rheumatology and Clinical Immunology, Kochi, India*; [2]*Baby Memorial Hospital, Pediatric Intensivist, Kozhikode, India*; [3]*Amrita Institute of Medical Scinces, Pediatric Pulmonology and Intensive Care, Kochi, India*; [4]*Amrita Institute of Medical Sciences, Pediatric Cardiology, Kochi, India*; [5]*Amrita Institute of Medical Sciences, Pediatrics, Kochi, India*

Background: After the peak of COVID 19 pandemic, a surge of cases with multi-system involvement and hyperinflammatory state was reported in children, at multiple tertiary care centers across the world. (1) This COVID-19 associated multisystem inflammatory syndrome in children and adolescents is also known as multisystem inflammatory syndrome in children (MIS-C). There is a paucity of literature of clinical profile of MIS-C patients from India.
Objectives: To study the clinical manifestations and treatment outcomes of COVID-19 related multisystem inflammatory syndrome in children (MIS-C) and adolescents.
Methods: It was a cohort study including cases defnied as per the case definitions of MIS-C by World Health Organisation (WHO) or Centre for Disease Control and Prevention(CDC).(2)The clinical parameters, laboratory parameters (including inflammatory markers, D dimer and NT ProBNP), electrocardiogram, 2D echocardiogram, course in hospital, and immediate outcomes were noted.

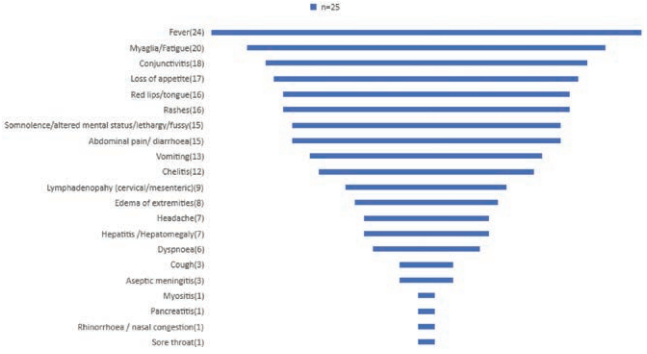

Figure 1. Frequency of clinical features in our MIS-C cohort patients

Table 1. Clinical characteristics of MIS-C patients (n)=25

Clinical Phenotypes:	
Incomplete/ Atypical Kawasaki Disease (KD)	18 (72%)
Macrophage activation syndrome (MAS)	11 (44%)
Unexplained Shock	13 (52%)
Fever with gastrointestinal symptoms	17 (68%)
Fever with neurological symptoms	9 (36%)
Fever with respiratory symptoms	5 (20%)
COVID chronology:	
MISC with acute COVID 19 with MAS	1 (4%)
MISC with acute COVID 19 with incomplete/atypical KD	1 (4%)
COVID 19 tests:	
COVID 19 RTPCR positive	2 (8%)
COVID 19 RTPCR negative	23 (92%)
COVID 19 IgG positive	20 (80%)
COVID 19 IgM positive	6 (24%)
COVID 19 IgG and IgM both positive	2 (8%)
COVID 19 IgG and IgM not done	4 (16%)
Other laboratory investigations	
(Peak/ trough values):	
Anaemia	20 (80%)
Leukopenia	2 (8%)
Thrombocytopenia	6 (24%)
Pancytopenia	2 (8%)
Positive CRP	23 (92%)
High Procalcitonin	9 (36%)
High ferritin	10 (40%)
High D- dimer	17 (68%)
High NT ProBNP	23 (92%)
Hypoalbuminemia	14 (56%)
Sterile pyuria	7 (28%)
Proteinuria	4 (16%)
Cardiac assessment:	
Abnormal Electrocardiogram (ECG)	5 (20%)
Abnormal Echocardiography	15 (60%)
Coronary dilation/prominence/non-tapering	9 (36%)
Coronary aneurysm	1 (4%)
LAD Z score (Mean±SD)	2.12 ± 1.11
Decreased Ejection fraction (EF)	5 (20%)
Systolic Dysfunction	5 (20%)
Pericardial effusion	9 (36%)
Global/septal hypokinesia	4 (16%)
Mitral Valve regurgitation	3 (12%)
Complete heart block	1 (4%)

Results: Twenty five patients (male-14) with a mean age of 6.22 ±4.25 years and a mean body mass index of 16.21 ±3.36 kg/m^2 were enrolled on the study. Average length of hospital stay was 8.12±5.76 days. Associated comorbidities were present in 4 of our patients (16%). Figure 1 shows the frequency of clinical features in our study patients. Table 1 shows the clinical, laboratory, imaging findings, disease course and outcomes.

Twenty patients (80%) had severe illness requiring intensive care. Fourteen patients (56%) required inotropic support, 8 patients (32%) required supplemental oxygen, 5 patients (20%) required mechanical ventilation and 2 patients (8%) expired. A total of 23 patients (92%) received pulse steroids followed by oral/iv steroids, 22 patients (88%) received IVIG (2g/kg) and 3 patients (12%) required anticoagulation.

Conclusion: Our MIS-C cohort had varied clinical manifestations ranging from the mild cutaneous and gastrointestinal symptoms to fatal multiorgan dysfunctions. In contrast to western cohorts, our study cohort had higher number of patients from younger age group and lower BMI.

POS1263 COVID-19 FROM THE PATIENTS'S P ERSPECTIVE: PRELIMINARY RESULTS OF ONLINE SURVEY

D. Karateev[1], P. Pchelnikova[2], E. Luchikhina[1], T. Boboshko[3]. [1]*Moscow Regional Research and Clinical Institute n.a. M.F. Vladimirsky (MONIKI), Moscow Regional Rheumatology Center and Department of Rheumatology, Moscow, Russian Federation*; [2]*EULAR Standing Committee of People with Arthritis/Rheumatism in Europe, PARE, Zurich, Switzerland*; [3]*Russian Rheumatology Association "Nadezhda", Moscow Branch, Moscow, Russian Federation*

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), also known as COVID-19, is now in the spotlight of the medical community. Obtaining the most complete data on COVID-19 in the rheumatic diseases (RD) is an urgent task, and the data received directly from patients seems to be is extremely important.

Objectives: To study the factors, associated with the possibility of COVID-19 in patients with RDs.

Methods: We conduct COVID-19 Russian rheumatology patient experience survey to create a registry of "Patient's Opinion on Covid-19 in Rheumatic Diseases (POPCORD)". This ongoing project is based on the data collected directly from Russian-speaking patients with different RDs who fill out a special questionnaire via the https://revmo-covid.ru/. The questionnaire was developed by the national patient organization – Russian Rheumatology Association "Nadezhda" in collaboration with Moscow regional rheumatology center and department of rheumatology of Moscow Regional Research and clinical institute n.a. M.F. Vladimirsky (MONIKI). The anonymous questionnaire includes information on whether the patient had COVID-19, as well as information on rheumatic disease, its treatment, and information on social distancing and compliance with other anti-epidemic measures.

Results: At the moment, 1050 patients (92% from Russia, 8% from other countries) completed the survey, including residents of 74 regions of Russia, most of them from Moscow (20%), Moscow region (8%) and St. Petersburg (8%). In total, there were 93% females, with mean age 40,28±11,26 (M±SD, median 38 [32;48]), BMI 24,52±5,38 (median 23,42 [21;27]), disease duration 7,91±8,46 (median 5,00 [2;11]). The main diagnoses reported: rheumatoid arthritis (49%), ankylosing spondylitis (14%), systemic lupus erythematosus (13%), psoriatic arthritis (6%), Sjogren's disease (5%), systemic sclerosis (3%), other (10%). 344 (31,8%) patients reported COVID-19 or suspected SASR-CoV-2 viral pneumonia. Relatives or physicians reported 3 cases of death related to COVID-19. The most important results of the survey presented in Table 1.

Table 1. Main results of the patients survey, n=1050.

Item	Results (n, %)		
	No COVID-19/ pneumonia reported (n=716)	*COVID-19/ pneumonia (n=334)*	*p, chi-square*
Smoking status			0,003
• Current smoker	118, 16,5%	25, 7,5%	
• Never smoke	359, 50,1%	199, 59,6%	
• Quit smoking	239, 33,4%	110, 32,9%	
Vaccination during last 3 years against Influenza, Pneumococcus and others			0,265
• No	531, 74,2%	236, 70,7%	
• Yes	185, 25,8%	98, 29,3%	
Social distancing			0,003
• I avoid crowds and large gatherings of people	412, 57,5%	172, 51,5%	
• Self-isolation	219, 30,6%	96, 28,7%	
• No social distancing	85, 11,9%	66, 19,9%	
Hygiene			0,031
• wearing a mask, hand washing/ using a sanitizer, gloves etc.	705, 98,5%	321, 96,1%	
• nothing	11, 1,5%	13, 3,9%	
Withdrawal of anti-rheumatic medication last weeks for fear of infection			<0,001
• Yes	124, 17,3%	104, 31,1%	
• No	592, 82,7%	230, 68,9%	
Possible contacts with COVID-19 infected persons			<0,001
• Yes	203, 28,4%	205, 61,4%	
• No	299, 41,8%	65, 19,5%	
• Don't know	214, 29,9%	64, 19,1%	

Conclusion: According to patient-reported data, lack of adherence to social distancing and hygienic measures, higher possibility of contacts with infected persons, as well as withdrawal of anti-rheumatic medication for fear of infection and smoking status were the factors, significantly associated with the possibility of COVID-19/viral pneumonia in patients with rheumatic diseases.

POS1264 IMMUNE-MEDIATED DISEASES (IMID) AND CORONAVIRUS DISEASE 2019 (COVID-19): RESULTS FROM AN OBSERVATIONAL RETROSPECTIVE MULTICENTER STUDY

R. Dos-Santos[1], C. Calviño[2], I. Bastón[2], R. Ferreiro[2], F. Montero[3], C. Gonzalez[3], I. Marín-Jiménez[4], M. Barreiro-de-Acosta[2], E. Perez-Pampín[1]. [1]*Clinical University Hospital in Santiago de Compostela, Rheumatology Department, Santiago de Compostela, Spain*; [2]*Clinical University Hospital in Santiago de Compostela, Gastroenterology Department, Santiago de Compostela, Spain*; [3]*Gregorio Marañón Hospital, Rheumatology Department, Madrid, Spain*; [4]*Gregorio Marañón Hospital, Gastroenterology Department, Madrid, Spain*

Background: The novel coronavirus emerged in 2019 in Wuhan has caused a global pandemic of coronavirus disease (COVID-19). Immune-mediated diseases (IMID), as inflammatory arthritis or inflammatory bowel disease (IBD), have some special implications due to their pathogenesis and treatments. Some treatments employed in IMID are now being used in the treatment of severe COVID-19. There still exists controversy about IMID behavior and its complications.[1, 2]

Objectives: To assess COVID-19 severity in IMID patients and its prognosis predictors.

Methods: An observational retrospective multicenter study was performed in two Spanish Hospitals (Clinical University Hospital in Santiago de Compostela

and Gregorio Marañón Hospital). Patients were selected if they were diagnosed of an IMID (rheumatoid arthritis, psoriatic arthritis, espondyloarthritis, ulcerative colitis and Crohn's disease) and had COVID-19 infection between February and April 2020.
Demographic, clinical, analytical and treatment data were collected. Logistic regression was used to evaluate potential predictors.
Stata 15.1 was used to perform statistical analysis.
Results: 91 patients were recruited. 55 suffered from a rheumatic disease and 36 suffer IBD. Baseline characteristics are shown in Table 1.
Univariable analysis reached age, comorbidity, female gender, flu vaccine, arthropathy, basal classical synthetic anti-rheumatic drugs (csDMARD), pneumonia and basal C-reactive protein (CRP) as potential predictors of non-severe (absence of death, respiratory insufficiency, intensive care unit admission or sepsis) COVID-19 disease ($p < 0.2$). After multivariable analysis, only female gender (OR 4.60 [CI95% 1.00, 21.2] p=0.050), lower age (OR 0.94 [CI95% 0.88, 1.00] p=0.042) and lower basal levels of CRP (OR 0.87 [CI95% 0.77, 0.97] p=0.010) were predictors for non-severe disease ($p < 0.005$).
Mean time of healing (symptoms solved in outpatient and hospital discharge in admitted) from COVID-19 was 13.8 days (SD 16.3). Univariable analysis showed arthropathy, COVID-19 symptomatic and basal glucocorticoids (GC) dose as potential predictors of higher time-to-healing from COVID-19 disease ($p < 0.2$). After multivariable analysis, only lower GC basal dose predicts higher time-to-healing (OR -1.83 [CI95% -2.81, -0.84] p=0.001).
11 patients deceased because of COVID-19. Univariable analysis reached age, basal csDMARD, pneumonia and basal CRP as potential predictors of COVID-19 mortality ($p < 0.2$). After multivariable analysis, only higher age was a predictor for mortality (OR 1.14 [CI95% 1.04,1.25] p=0.006).
Conclusion: IMID patients showed similar predictors of mortality than general population involving COVID-19. Immune-modulating agents did not seem to overshadow the prognosis of COVID-19 infection. Female gender, lower age and lower basal CRP could select a cohort of "good" prognosis patients with mild COVID-19 disease as well higher age points out the worst prognosis. Even that, each case should be individiualized.

POS1265 CHALLENGES OF EGYPTIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS DURING COVID-19 PANDEMIC

S. Tharwat[1], S. Zohdy[2]. [1]*Mansoura University, Internal Medicine, Rheumatology & Immunology, Mansoura, Egypt*; [2]*Faculty of Medicine, Horus University, Internal Medicine Department, Mansoura, Egypt*

Background: Coronavirus disease 2019 (COVID-19) pandemic in Egypt is part of worldwide COVID-19 pandemic caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)[1]. The current COVID-19 pandemic has contributed to substantial deterioration to healthcare systems worldwide [2].Systemic lupus erythematosus (SLE) patients may have several barriers as medications access during the pandemic.
Objectives: The aim of this study was to assess the tremendous challenges faced by the Egyptian SLE patients during COVID-19 pandemic either in the drug shortage, hospitalization or COVID-19 infection through a questionnaire-based study.
Methods: This questionnaire-based study was carried out on 200 patients with SLE from Egypt. The questionnaire provided covered socioeconomic status, lupus disease data, knowledge about COVID-19 infection and medical and family history of COVID-19 infection.
Results: The mean age of the participants was 30.1 years (with SD 8.4). Among the participants,180 (90 %) were females and 172 (86%) were from urban areas. Corticosteroids and mycophenolate mofetil and antimalarials were the most used medications (87%,87% and 70 % respectively). 140/200 (70 %) of the participants reported difficulty in obtaining medications during COVID-19 pandemic particularly antimalarials (60%). Lupus disease activity was affected by the drug shortage in half of the participants. Twenty-eight (14%) patients lost their jobs while 26 patients (13%) reported that their work was severely impacted by the crisis. Among the precautions taken for prophylaxis against infection wearing protective masks (74%) and using disinfectants of the hands several times per day (67%) were the most reported measures. Forty patients (20%) had to stop or reduce taking NSAIDs to guard against COVID-19 infection while 10 patients (5%) had to start taking antimalarials as a prophylaxis. Among 34 patients (17%) who needed hospitalization,26 (76%) were mainly due to lupus activity and 24 (71%) of them found difficulty on hospital admission because of COVID-19 pandemics. About 40 % of the participants reported that they had at least one close relative had confirmed COVID-19 infection. In addition, thirty-two patients (16%) had confirmed COVID-19 infection. Most of them became clinically free after treatment. However, about half of them had lupus flare and had to change the medications used for treatment of lupus.
Figure 1 shows the differences between males and females in response to the questionnaire. 58.6% of females versus 20 % of males would use telemedicine for remote contact with the rheumatologist. Most of females were more keen than males to wear the masks (76.7% versus 50 % respectively).
Conclusion: The current COVID-19 pandemic has negative impact on the healthcare provided to SLE patients in Egypt. Patients with SLE faced shortage their medications especially antimalarials.

POS1266 COVID-19 IN PATIENTS WITH RHEUMATIC DISEASES: SURVEY-BASED ASSESSMENT OF THE RISK OF HOSPITALIZATION

D. Karateev[1], P. Pchelnikova[2], E. Luchikhina[1], T. Boboshko[3]. [1]*Moscow Regional Research and Clinical Institute n.a. M.F. Vladimirsky (MONIKI), Moscow Regional Rheumatology Center and Department of Rheumatology, Moscow, Russian Federation*; [2]*EULAR Standing Committee of People with Arthritis/ Rheumatism in Europe, PARE, Zurich, Switzerland*; [3]*Russian Rheumatology Association "Nadezhda", Moscow Branch, Moscow, Russian Federation*

Background: Prognosis of the need for in-hospital treatment in patients suffered with COVID-19 is crucial to optimize the use of medical resources. Risk factors of hospitalization due to COVID-19 are not sufficiently studied in patients with rheumatic diseases (RD).
Objectives: To reveal factors associated with the risk of hospitalization of patients with RD due to SARS-CoV-2 (COVID-19) infection.

Methods: We analyzed data based on the preliminary results of the patients registry from the ongoing project "Patient's Opinion on Covid-19 in Rheumatic Diseases (POPCORD)". The registry contains data collected directly from Russian-speaking patients with different RD who completed a special questionnaire, located on the website https://revmo-covid.ru/. The questionnaire includes information on whether the patient had COVID-19 and related information, as well as information on rheumatic disease and its treatment.
Results: 1050 patients (92% from Russian Federation, 8% from other locations) completed the survey - 93% females, mean age 40,28±11,26 (M±SD, median 38 [32;48]), BMI 24,52±5,38 (median 23,42 [21;27]), disease duration 7,91±8,46 (median 5,00 [2;11]). Diagnoses reported: rheumatoid arthritis (49%), ankylosing spondylitis (14%), systemic lupus erythematosus (13%), psoriatic arthritis (6%), Sjogren's disease (5%), systemic sclerosis (3%), other (10%). 51% of respondents indicated concomitant conditions: arterial hypertension (19%), obesity (15%), kidney disease (11%), cardiovascular disease (7%), liver disease (6%), IBD (5%), other lung diseases, including ILD (5%). 96% of patients reported constant intake of antirheumatic drugs: steroids (37%), NSAIDs (46%), hydroxychloroquine (22%), csDMARDs (66%), bDMARDs (17%), tsDMARDs (2%). 344 (31,8%) patients reported COVID-19 or suspected SASR-CoV2 viral pneumonia, 282 (84,4%) were treated as outpatients, 52 (15,6%) were hospitalized. Relatives or physicians reported 3 cases of death related to COVID-19 (0,9% of total mortality, 5,8% of in-hospital mortality). Table 1 contains odds ratios for the main factors, related to hospitalization, based on the results of the survey. Analysis of the survey participants' parameters (patients' characteristics, treatments etc.) did not reveal any significant variables, related to increased risk of hospitalization. No increased risk related to any groups of anti-rheumatic drugs or any particular medications was found either. Risk of hospitalization was significantly lower in patients with ankylosing spondylitis.

Table 1. Factors, related to hospitalization due to COVID-19 in patients with RD.

Factor	*OR [95% CI]*	*p*
Age ≥50 y.o.	2,12 [1,14;3,94]	0,99
Age ≥65 y.o.	9,04 [2,10;38,98]	1,00
Female	1,73 [0,70;4,25]	0,92
Body mass index ≥35	2,09 [0,71;6,10]	0,88
Current smoking	0,47 [0,11;2,06]	0,24
Smoking in the past	1,43 [0,83;2,48]	0,92
Diagnosis of ankylosing spondylitis	0,25 [0,06;1,05]	0,02
Comorbid conditions:		
• Diabetes mellitus	3,39 [1,07;10,77]	0,99
• Cardiovascular disease	1,91 [0,72;5,08]	0,94
• Asthma	5,42 [1,07;27,61]	0,99
• COPD	0,42 [0,05;3,26]	0,34
• Kidney disease	1,57 [0,71;3,50]	0,91
• Liver disease	0,90 [0,26;3,18]	0,57
• Neurological disorders	5,42 [0,75;39,36]	0,99
• No concomitant conditions	0,70 [0,40;1,25]	0,14
Therapy:		
• Oral steroids	1,37 [0,82;2,29]	0,91
• NSAIDs	1,12 [0,67;1,87]	0,72
• Traditional DMARDs	1,39 [0,89;2,17]	0,94
• Biologic DMARDs	1,15 [0,55;2,43]	0,72
• Targeted synthetic DMARDs (JAK-inhibitors, apremilast)	3,25 [0,75;14,03]	0,97
Level of concern about COVID-19:		
• Low level / no concern about COVID-19	0,57 [0,28;1,17]	0,08
• Medium level of concern	0,60 [0,28;1,28]	0,12
• High level of concern	1,69 [1,03;2,76]	0,99

Conclusion: Survey of patients with RD did not show significantly increased risk for hospitalization due to COVID-19 in relation with specific diagnosis, any anti-rheumatic medications, as well as comorbid conditions and main patient characteristics. Diagnosis of ankylosing spondylitis related to significantly lower risk of hospitalization.

POS1267 CLINICAL COURSE OF NEW SARS-COV-2 INFECTION IN CHILDREN WITH RHEUMATIC DISEASES: RETROSPECTIVE STUDY OF SINGLE PEDIATRIC RHEUMATOLOGY CENTER

I. Nikishina[1], Z. Kolkhidova[1], V. Matkava[1], A. Shapovalenko[1], S. Arsenyeva[1], M. Kaleda[1], E. Fedorov[1], S. Salugina[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*

Background: About one year ago at the beginning of the new SARS-CoV-2 infection pandemic, it was expected, that rheumatic disease (RD) and immunosuppressive therapy could predispose to a more severe course of the Covid-19 infection. At that time, it was unspeakable how this infection would occur in children with RB in compare to adults. Now it's time to draw preliminary conclusions.
Objectives: to analyze all features of COVID19 infection in children with RD
Methods: The retrospective single center study of all patients with pediatric RD who had the COVID19 infection up to the end of January 2021. It was analyzed all variety of clinical manifestations, changing in therapy at the time of COVID-19 and after it, the dynamics of the RD and consequences of the new viral disease.
Results: The study included 66 patients under the age of 18 with various RS, including autoinflammatory disease (AIDs). The diagnostic distribution, sex ratio, age and previous therapy present in the Table 1. There were patients treated with DMARDS (methotrexate -47, hydroxychloroquine -3, mycophenolate mofetil -2, colchicine -1), NSAID monotherapy -6, systemic steroids -10; 29 patients recived Biologics, including combination with methotrexate. None of our patients had a severe course of the COVID-19, none of 66 patients was hospitalized for emergency indications in the intensive care unit or in other specialized departments. The diagnosis of Covid-19 infection was based on different evidences: positive PCR in 15 (23%) cases, high levels of immunoglobulins G and M - in 64 (97%) and 7 (11%) respectively, viral pneumonia was confirmed by CT in 2 (10%) cases. A manifest clinical picture presented just in 21 (32 %) of patients, the others were carried the disease asymptomatically. Among the clinical manifestations of SARS-CoV-2 that were observed in our patients were the following: fever, as the most frequent symptom - 19 (90%), rhinitis - 12 (57%), anosmia - 10 (48%), sore throat - 3 (14%), arthralgia/myalgia in 4 (19%), rash - 1 (5%) case, cough - 4 (19%) cases. it is important to note that until July 2020, only 4 patients were registered, and in the next 6 months – 62. The treatment against Covid-19 in our patients with clinical symptoms included: NSAID monotherapy -4 (19%), Systemic steroids -2 (10%), Hydroxychloroquine -2(10%), Antibiotics-5 (24%).

Table 1. Clinical characteristics of children with RD according to presence of symptoms of Covid-19

Parameter		Covid-19 symptomatic course (n=21)	Covid-19 asymptomatic course (n=45)	p-values
Sex ratio (F/M)		9/12	30/15	ns
Duration of RD (Me. Years)		4 (2;6)	4 (2;7)	ns
Age	Me	15 (13; 17)	11 (8;13.5)	**<0,001**
(years)	<10 yrs	1	19	**<0,05**
	>10 yrs	20	26	**<0,001**
Covid-19 evidences	IgG Covid-19 +	19	45	ns
	IgM Covid-19 +	3	4	ns
	PCR Covid-19 +	11	0	ns
Diagnosis of RD	JIA non-systemic	14	31	ns
	sJIA	1	3	ns
	SLE	4	1	ns
	JDM	1	1	ns
	Scleroderma		6	ns
	AIDs (CAPS, FMF, FOP)	1	3	ns
Previous therapy	NSAID monotherapy	3	6	ns
	DMARDs	16	33	ns
	Systemic steroids	4	7	ns
	TNF-inhibitors	5	12	ns
	Abatacept	1	3	ns
	IL6-inhibitors (Tocilizumab, Sarilumab)	0	2	ns
	JAK-kinase inhibitors	1	2	ns
Worsening/flare of RD after Covid-19 infection		5	0	p<0,05

Conclusion: Our study suggests that the presence of RD and immunosuppression therapy does not lead to an increased frequency or severe course of Covid-19 infection in children. The final conclusion will be drawn as the data accumulates.

POS1268 COVID-19 VACCINE HESITANCY AMONG RHEUMATOLOGY PATIENTS RECEIVING INFLUENZA VACCINE

V. Valerio[1], H. C. Shen[2], E. Field[1], E. G. Mcdonald[3], A. Turner[4], S. Bernatsky[3], M. Hudson[5], I. Colmegna[3]. *[1]The Research Institute of the McGill University Health Care Centre, Medicine, Montreal, Canada*; *[2]University of Montreal, Medicine, Montreal, Canada*; *[3]McGill University Health Care Centre, Medicine, Montreal, Canada*; *[4]McGill University Health Care Centre, Nursing, Montreal, Canada*; *[5]Jewish General Hospital, Medicine, Montreal, Canada*

Background: Adults with rheumatic diseases are a COVID-19 vulnerable population with potential increased risk for severe infection. COVID-19 vaccines are a key strategy to ending the pandemic. Unfortunately, fears about vaccines, some of which are propagated by misinformation, are common and may prevent or inappropriately delay vaccination. *Refusal or uncertainty to get a vaccine despite its availability* is known as vaccine hesitancy.
Objectives: This study aims at defining causes of COVID-19 vaccine hesitancy among rheumatology patients.
Methods: Between November and December 2020, a cross-sectional survey was completed by rheumatology patients presenting to a large Canadian tertiary-care center for influenza immunization. COVID-19 risk factors, previous COVID-19 infection, the likelihood of getting a future COVID-19 vaccine (scale 0-10), and contextual, individual, and vaccine-specific potential determinants of vaccine hesitancy were assessed. Patients were classified into 5 groups based on how likely they were to get a future COVID-19 vaccine (0= not likely at all; 2.5= unlikely; 5= intermediate; 7.5= likely; 10= highly likely). A machine learning approach (XgBoost) was used to fit univariate models for a multi-class correlation.
Results: 157 rheumatology patients completed the survey. Most were females (n=112, 71%) with a mean age of 54.6 (standard deviation 17.9). The majority (73%) had tertiary-education, and 46% were employed at the time of the survey. The most common rheumatology diagnoses were rheumatoid arthritis (n=90, 58%), systemic lupus erythematosus/vasculitis (n=41, 26%) and spondyloarthropathies (n=39, 25%). Most patients were on immunosuppressors (n=93, 59%). Only half (n=85, 54%) were highly likely to accept a future COVID vaccine, 17% (n=26) likely, 19% (n=30) intermediate, 6% (n=10) unlikely, and 4% (n=6) not likely at all. One hundred thirty-five patients (86%) previously received the flu vaccine, whereas 6% (n=10) previously rejected it. Only three patients were previously diagnosed with COVID-19 (2%) one of whom was hospitalized. Eighty-seven patients (56%) considered that the COVID-19 vaccine should be mandatory, and 101 (65%) that they should receive it. Most respondents were somewhat concerned about receiving a future COVID-19 vaccine (n=116, 76%) despite that 65% believed that vaccines benefits outweighed their risks. Almost all, (n=145, 96%) believed that governmental decisions about vaccines are in the best interest of the population, while less than half (n=70, 45%) were confident that pharmaceutical companies would provide safe and effective vaccines. One hundred participants (65%) denied feeling social pressure to get the vaccine, and 55% (n=81) were willing to pay for the vaccine. Feeling social pressure about getting a COVID-19 vaccine, having severe concerns about receiving a future COVID-19 vaccine, distrust in pharmaceutical companies, lower education, and doubts of whether vaccines benefits outweigh their risks, were negatively associated with COVID vaccine acceptance.
Conclusion: Forty six percent of rheumatology patients being immunized against influenza showed at least some hesitancy towards COVID-19 vaccination. Multiple contextual, individual, and vaccine-related factors may contribute. Targeted educational strategies, including producing and communicating data on vaccine safety, may help promote vaccine uptake in this potentially vulnerable population.

Spine, mechanical musculoskeletal problems, local soft tissue disorders

POS1269 **THE UTILITY OF ULTRASOUND TO PREDICT PATIENT OUTCOMES IN SHOULDER PAIN: A PROSPECTIVE OBSERVATIONAL STUDY OF 500 PATIENTS**

G. Tran[1,2,3], S. Kingsbury[1,2], E. Hensor[1,2], P. G. Conaghan[1,2]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, Chapel Allerton Hospital, Leeds, United Kingdom*; [2]*National Institute for Health Research Leeds Biomedical Research Centre, Chapel Allerton Hospital, Leeds, United Kingdom*; [3]*Harrogate and District NHS Foundation Trust, Department of Rheumatology, Harrogate, United Kingdom*

Background: Shoulder pain is common and persistent, with a large socioeconomic burden. Ultrasound (US) scans are used for diagnosing and managing shoulder pain, but the extent to which it informs management and improves outcomes is unknown. A recent retrospective study identified groups with different patterns of US pathologies.
Objectives: To confirm the existence of US-based groups of shoulder pain and determine if US-detected pathology (grouped or individual) predicts outcomes in the context of usual care. Response to local steroid injection was also evaluated.
Methods: This was a 6 month, prospective, single centred, community based, observational cohort study. Inclusion: shoulder pain, ≥18 years, first shoulder US. Exclusion: shoulder surgery, inflammatory arthritis, steroid/physiotherapy in prior 6 weeks. Standardised reporting for 10 US pathologies was employed. Latent class analysis (LCA) identified pathology-based groups. Multiple linear regression analysis explored associations between baseline pathologies, subsequent treatment and 6-month Shoulder Pain and Disability Index (SPADI). Growth mixture modelling (GMM) identified groups with common trajectories of change.
Results: Of 500 patients (mean age 53.6; 52% female), 330 completed follow-up. LCA identified 4 groups: bursitis without acromioclavicular joint degeneration (ACJD) (group 1), bursitis with ACJD (group 2), rotator cuff tear (group 3), no bursitis/tear (group 4). SPADI was higher at baseline for tears (55.1 vs. 49.7-51.3) (overall p=0.005), but groups did not differ at 6 months (p=0.379) (Table 1). No individual pathologies predicted 6-month outcomes. Response to baseline injection at week 2 did not differ between groups (p=0.423). GMM found 4 trajectories; the majority of patients followed trajectory 1 (little change), irrespective of US pathology group (79%, 77%, 87%, 70% of US groups 1-4 respectively) (Figure 1).
Conclusion: This is the largest prospective study involving US of symptomatic shoulders, and the first to investigate groups with distinct patterns of US pathologies in predicting outcome. US-based classification of pathology (as groups or individually) did not predict 6-month outcomes with current treatments and there were no differences in short-term response to steroids between groups. The role of routine diagnostic US for shoulder pain needs consideration; it may be useful if evidence-based therapies for specific pathologies are established.

Table 1. Predictors of SPADI score at 6 months

Baseline characteristic	Coefficient* (95% CI), p-value
Pathology group:Bursitis w/o ACJ degeneration (group 1)	Reference
Bursitis with ACJ degeneration (group 2)	0.08 (-5.15, 5.32), p=0.975
RC tear (group 3)	5.01 (-1.48, 11.50), p=0.130
No bursitis, no RC tear (group 4)	1.98 (-4.00, 7.96), p=0.516
Injection at scan	4.87 (0.40, 9.34), p=0.033
Age, years	-0.01 (-0.17, 0.15), p=0.898
Female	-1.51 (-5.42, 2.40), p=0.448
Symptom duration, months	0.00 (-0.04, 0.05), p=0.879
Uses arms to rise from chair	2.65 (-1.50, 6.81), p=0.210
Physiotherapy before baseline	-0.23 (-4.78, 4.31), p=0.920
1 injection before baseline	2.35 (-2.87, 7.56), p=0.377
≥2 injections before baseline	6.53 (-2.50, 15.57), p=0.156
Total SPADI	0.62 (0.35, 0.89), p<0.001
Shoulder activity score	-0.59 (-1.15, -0.04), p=0.037
P-SEQ score	-0.20 (-0.46, 0.07), p=0.141
Brief IPQ score	0.19 (-0.16, 0.54), p=0.298
HADS score	0.01 (-0.38, 0.41), p=0.947
Constant**	35.44 (29.50, 41.38), p<0.001

*Interpreted as unit difference in Rasch-transformed SPADI score per 1 additional unit of the independent variable **Estimated SPADI at 26 weeks in patients in the reference category for all categorical variables and with mean values for continuous covariates. ACJ=acromioclavicular joint; HADS=hospital anxiety and depression scale; IPQ=illness perception questionnaire; P-SEQ=pain self-efficacy questionnaire; RC=rotator cuff; SPADI=shoulder pain and disability index

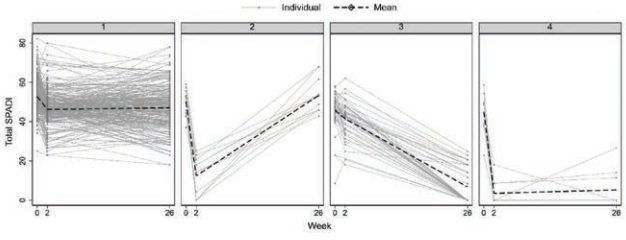

Figure 1. Trajectories of total SPADI over time by the pathology groups found and response to injections

POS1270 **MUSCULOSKELETAL MANIFESTATIONS IN A COHORT OF 234 INFLAMMATORY BOWEL DISEASE PATIENTS**

B. M. Fernandes[1], M. Bernardes[1], D. R. Gonçalves[2], F. Magro[3], L. Costa[1]. [1]*Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal*;

[2]*Centro Hospitalar Entre Douro e Vouga, Rheumatology, Santa Maria da Feira, Portugal*; [3]*Centro Hospitalar Universitário São João, Gastroenterology, Porto, Portugal*

Background: Musculoskeletal symptoms represent the most common extraintestinal manifestations of inflammatory bowel disease (IBD) and a major cause of impaired quality of life in these patients. Spondyloarthritis (SpA) is classically associated with IBD, but other rheumatic manifestations may occur.
Objectives: To characterize musculoskeletal symptoms and rheumatic diseases in an IBD cohort.
Methods: Retrospective monocentric descriptive study including all the patients with IBD consecutively reffered from Gastroenterology to the Rheumatology Department between January of 2013 and December 2020 in a tertiary university hospital. Demographic and clinical data and musculoskeletal symptoms were collected at the time of the first visit in the Rheumatology outpatient center and the rheumatic diseases diagnosed during the entire follow-up were registered.
Results: A total of 234 patients were included, 136 (58.1%) females, 20 (8.5%) smokers. At the first Rheumatology consultation the mean age was 43.6 (±13.7) years and the mean IBD duration was 11.7 (±9.7) years. Concerning IBD: 172 (73.5%) had Crohn's disease and 62 (26.5%) had ulcerative colitis; azathioprine (39.7%), infliximab (28.2%) and mesalazine (26.5%) were the most frequently used drugs; eleven patients (4.7%) were taking glucocorticoids and 106 (45.3%) had already been treated with glucocorticoids.
Regarding musculoskeletal symptoms: 76 (32.5%) patients had peripheral symptoms and 98 (41.9%) had axial symptoms (Table 1).

Table 1. Characterization of peripheral and axial musculoskeletal symptoms in patients with Inflammatory Bowel Disease.

		N (%)
Peripheral symptoms	**No**	158 (67.5%)
	Arthritis / "inflammatory" joint pain	24 (10.3%)
	"Mixed" rhythm joint pain	15 (6.4%)
	"Mechanical" joint pain	29 (12.4%)
	Enthesopathy	8 (3.4%)
Axial symptoms	No	136 (58.1%)
	"Inflammatory" back pain	46 (19.7%)
	"Mixed" rhythm back pain	35 (14.9%)
	"Mechanical" back pain	17 (7.3%)
Total		234 (100%)

Twenty-six (11.1%) patients had radiographic sacroiliitis, 14 (6.0%) had sacroiliitis in computed tomography and 9 (3.8%) in magnetic resonance. Forty-four (18.8%) patients fulfilled *Assessment of SpondyloArthritis international Society* (ASAS) criteria for axial SpA and 5 (2.1%) for peripheral SpA. Also of note, 16 (6.8%) patients had a previous diagnosis of psoriasis and 5 (2.1%) had uveitis in the past.
Concerning other rheumatic diagnosis, we observed: osteoarthritis in 64 (27.3%), osteoporosis in 16 (6.9%), diffuse idiopathic skeletal hyperostosis in 6 (2.6%), systemic lupus erythematosus in 4 (1.7%), rotator cuff tendinopathy in 2 (0.9%), rheumatoid arthritis, gout, calcium pyrophosphate deposition disease, fibromyalgia, drug-induced lupus, osteitis condensans ilii, Dupuytren's contracture and avascular necrosis of the femoral head in 1 (0.4%), each.
Conclusion: Our results demonstrate a high prevalence of musculoskeletal symptoms and rheumatic diseases in patients with IBD. These diagnoses are not limited to the group of SpA and osteoporosis, emphasizing the importance of rheumatologists being alert to other rheumatic diagnoses in patients with IBD.

POS1271 PREVALENCE OF JOINT EFFUSION, HYPERPERFUSION AND ENTHESITIS IN YOUNG HEALTHY INDIVIDUALS

J. K. Schreiner[1], D. Scheicht[2], P. Karakostas[1], C. Behning[3], P. Preuss[4], P. Brossart[1], V. Schäfer[1]. [1]*University Hospital Bonn, Clinic of Internal Medicine III, Oncology, Hematology, Rheumatology and Clinical Immunology, Bonn, Germany*; [2]*Porz am Rhein Hospital, Department for Rheumatology, Cologne, Germany*; [3]*University Hospital Bonn, Department of Medical Biometry, Informatics and Epidemiology, Bonn, Germany*; [4]*University of Bonn, University Sport, Bonn, Germany*

Background: The European League Against Rheumatism (EULAR) recommends using ultrasound (US) in patients with rheumatoid arthritis and psoriatic arthritis in diagnosis (1). In addition, US examination is crucial for detecting enthesitis in the above mentioned rheumatic diseases. However, abnormal findings on US may also occur in healthy individuals as indicated by recent studies focusing on small joints like metacarpophalangeal joint, metatarsophalangeal joint or the elbow. (2,3)
Ultrasound assessment of large joints in healthy individuals has not been extensively studied so far, causing a lack of information concerning normal values in musculoskeletal US examination.
Objectives: The purpose of this study was to determine the prevalence of joint effusion, hyperperfusion of the synovia and enthesitis in large and medium-sized joints of healthy individuals.
Methods: Ultrasound assessment of shoulder, elbow, wrist, hip, knee and ankle joints as well as corresponding entheseal sites including the Achilles tendon and the plantar aponeurosis was performed in healthy individuals below the age of 30 years. Additionally, participants filled out a survey on their physical activity level, underwent a bioelectrical impedance analysis (BIA) and conducted a supervised weight training to determine their training volume. Prevalence of US findings was calculated, and a binary logistic regression model was applied to determine the association between the present findings and sex, age, handedness, hours of sports activity per week, BMI, amount of skeletal muscle mass (SMM) or training volume of strength training.
Results: We included 51 healthy individuals with a mean age of 23.7 years, 52.9% were female with a mean BMI of 22.5 kg/m^2. Ultrasound examination detected joint effusion in one joint in 25.5% (n=13), 29.4% (n=15) showed effusion in two of twelve examined joints. Joint effusion in three, four and five joints was detected in 9.8% (n=5), 3.9% (n=2) and 3.9% (n=2) of the cases, respectively. In 27.5% (n=14) of the individuals no joint effusion was observed. The most frequently affected joint was the elbow joint. Synovial hyperperfusion was not detected in any participant. Enthesitis was observed in one, two and three examined entheseal sites in 19.5% (n=10), 5.9% (n=3) and 2% (n=1), respectively. In 72% (n=37) of the examined individuals no pathology of the entheseal sites was found. Hyperperfusion presented to be the most frequent pathology observed in enthesitis (23%), followed by calcification (6%).
Binary logistic regression model demonstrated a significant association between reported hours of sports activity per week and the prevalence of effusion in the knee (p = 0.017). The odds of joint effusion in the knee increased with the hours of sports activity by 34.1% (Exp(B)= 1.341, 95%-CI(1.054, 1.705)). Additionally, the odds of enthesitis in any entheseal site increased with BMI (p= 0.015, Exp(B) = 1.407, 95%-CI(1.068, 1.852).
Binary logistic regression model did not show any significant association between sex, age, handedness, amount of SMM or training volume of strength training and the prevalence of joint effusion or enthesis pathology in the examined participants.
Conclusion: Joint effusion in large and mid-sized joints as well as enthesitis are not only detected in patients with rheumatic diseases but also in healthy individuals. Hours of sports activity and BMI have a significant association with the findings and should be considered during ultrasound examination.

POS1272 DIFFERENCES IN RANGE OF MOTION AND MECHANICAL MUSCLE CHARACTERISTICS AMONG INFLAMMATORY AND MECHANICAL SPINAL PAIN: A CASE-CONTROL STUDY

S. Alcaraz-Clariana[1], L. García-Luque[1], I. C. Aranda-Valera[2], M. L. Ladehesa Pineda[2], C. López-Medina[2], C. Gonzalez-Navas[3], F. Alburquerque Sendin[1], D. P. Rodrigues-de-Sousa[1], C. Garrido-González[1], J. L. Garrido-Castro[3], E. Collantes Estevez[2]on behalf of CASTRO. [1]*University of Cordoba, Medicine, Nursing and Physiotherapy Faculty, Cordoba, Spain*; [2]*Hospital Universitario Reina Sofia, Rheumatology, Córdoba, Spain*; [3]*Maimónides Biomedical Research Institute of Córdoba, Motion Analysis Lab, Cordoba, Spain*

Background: The spinal range of motion (ROM) and the mechanical muscle properties (MMPs) at rest are defined as relevant clinical factors in inflammatory (i.e. axial Spondyloarthritis -axSpA) and mechanical spinal pain (i.e. Mechanical

Neck pain -NP- or Mechanical Low Back pain -LBP-). Nevertheless, there is not enough evidence regarding if ROM and MMPs are different in both types of spinal pain.

Objectives: To identify differences between axSpA patients and NP or LBP subjects, in cervical and lumbar ROMs and MMPs at rest.

Methods: Subjects with axSpA and with NP or LBP composed the Inflammatory pain Group (IG) and the Mechanical pain Group (MG), respectively. For the analysis of the spinal mobility, two Inertial Measurement Units (IMU) were used. For both spinal regions (cervical and lumbar - Figure 1A,B) 3 repetitions of flexion-extension, lateral-flexion, and rotation were executed separately[1]. A record of the MMPs using a hand myotonometer was made in both lumbar (muscular belly of the erector spinal – Figure 1D) and cervical (the semispinalis capitis muscles at C4 - Figure 1C) spine in prone position with both arms along the body. The MMPs recorded in this study included: frequency (tone), stiffness, decrement (elasticity), relaxation and creep (viscosity). The order of assessments (right/left) was randomized. Since no side-to-side differences in either group were observed, the mean of both sides was considered. Student-t tests were used to compare the groups, and Cohen-d effect size index was estimated as a measure of the size of difference. P<0.05 was considered statistically significant.

Results: 61 subjects in IG (42% women, age 41±12 years, BMI 25±3) and 66 in MG (51% women, age 38±13 years, BMI 25±3) participated in this study. No significant differences were identified in sociodemographic data between both groups. Table 1 shows ROM and MMPs between groups. All lumbar ROMs were significantly lower in the IG, with the different between means achieving the minimum clinical important difference (>8º) for flexion-extension and lateroflexion. On the contrary, the cervical ROMs were not different between groups, and showed the highest variability, probably related to compensatory mechanisms due to lumbar ROMs restrictions. The IG showed greater Lumbar stiffness than the MG with large effect size (d=0.94). No other difference in MMPs was identified in this region (p>0.05). Regarding the cervical region, all MMPs showed differences between groups. Thus, tone, stiffness and elasticity were higher in the IG, while relaxation and viscosity were lower. In all cases, except for decrement, the effect size was from moderate to large (0.6<d<0.8).

	IG (n=61)	MG (n=66)	p-value	Cohen-d
Lumbar flexion- extension (°)	62.7 ± 20.2	70.8 ± 17.9	0.019 *	0.42
Lumbar rotation (°)	25.6 ± 8.3	30.1 ± 10.1	0.007 *	0.48
Lumbar lateral-flexion (°)	46.6 ± 12.3	54.8 ± 10.8	<0.001 *	0.70
Cervical flexion- extension (°)	96.5 ± 21.6	96.2 ± 18.8	0.941	0.01
Cervical rotation (°)	130.9 ± 27.3	131.9 ± 25.6	0.817	0.01
Cervical lateral-flexion (°)	66.4 ± 21.5	71.6 ± 15.6	0.122	0.27
Lumbar tone (Hz)	15.32 ± 3.40	14.52 ± 1.93	0.129	0.29
Lumbar stiffness (N/m)	330.85 ± 56.93	272.48 ± 65.59	0.001 *	0.94
Lumbar decrement	1.33 ± 0.41	1.29 ± 0.32	0.480	0.10)
Lumbar relaxation (ms)	19.11 ± 7.58	20.23 ± 4.29	0.312	0.18
Lumbar creep	1.16 ± 0.43	1.21 ± 0.22	0.519	0.14
Cervical tone (Hz)	17.27 ± 1.93	16.17 ± 1.84	0.001 *	0.58
Cervical stiffness (N/m)	313.93 ± 54.17	282.61 ± 50.07	0.001 *	0.59
Cervical decrement	1.34 ± 0.23	1.42 ± 0.18	0.020 *	0.39
Cervical relaxation (ms)	16.66 ± 2.52	18.49 ± 2.74	<0.001 *	0.69
Cervical creep	1.02 ± 0.14	1.13 ± 0.14	<0.001 *	0.80

Conclusion: AxSpA patients present lower lumbar ROMs than NP and LBP subjects. Further, posterior cervical MMPs of axSpA are more rigid and less viscoelastic than those of NP and LBP subjects. ROMs and MMPs show a different behavior pattern in cervical and lumbar regions when spinal pain from different origin is assessed.

POS1273 A CHANGE IN A REHABILITATION MODEL INCREASES WORK CAPACITY AT 36 MONTHS IN LOW BACK PAIN

M. Norberg[1]. [1]*Lavey Medical Center, Rehabilitation, Lavey-les-Bains, Switzerland*

Background: In chronic low back pain, the most expensive patients are them with long-standing sick-leave of more than 6 months. Several studies have showed the importance of rehabilitation models working with kinesiophobia (fear of movement). One possibility of treating chronic low back pain is a multidisciplinary rehabilitation program.

Objectives: The aim of this study was to analyze the impact of a change in a rehabilitation program for chronic lumbar pain by introducing a progressive exposure procedure to decrease apprehension associated with low back pain. We studied its impact on work capacity after 3 years, compared to our classic program.

Methods: We have compared the results of 1004 of our patients that have accomplished a multi-disciplinary program and that have been followed over 12 months. They were divided in two groups: one before the implantation of PHODA (PHOto of Daily Activity: photos showing activites) associated with occupational training and work exposure. Then a second one including 200 patients that followed the new program. The program contained physical training, occupational tasks developed on the basis of the apprehension following a cogntivo-comportemental approach.

We have analyzed the evolution of apprehension according to different questionnaires (FABQ, Tampa scale (TSK) and PACT (evaluating the subjective work capacity)), the Phoda results and the official work capacity at beginning of the program and after 36 months.

Results: We saw a clear increase in the global work capacity at 12 months after completing the program: passing from 40 to 79% (p < 0.01) in the old program comparing to the new one with an increase of 86% (p< 0.01). These results were confirmed at 36 months, with stabilized results. In parallel there was an increase in the subjective sensation of physical capacity (Pact), but less in the new program. This increase was correlated with a decrease in fear-avoidance according to the Fabq, and in the TSK

Conclusion: In chronic low back, a multidisciplinary rehabilitation program, gives a global work capacity of 79%. This capacity could be increased on focalising on patient's apprehensions with gradual exposure according the fear-avoidance model developed by Waddell and explored by Vlayen. The correlation were confirmed on the psychological part, with less apprehension and less anxiety. Finally, the SF 36 showed an increase in body confidence as an important factor in these functional restoration programs.

POS1274 THERAPEUTIC MANAGEMENT OF RHEUMATOLOGISTS VERSUS OTORHINOLARYNGOLOGISTS OF CERVICOGENIC DIZZINESS

M. Yasmine[1], K. Maatallah[1], H. Ferjani[1], W. Triki[1], D. Ben Nsib[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia*

Background: The treatment of patients presenting with cervicogenic dizziness (CGD) may be challenging. Indeed, there is no consensual treatment approach for CGD, nor is there no gold-standard assessment for diagnosis.

Objectives: Our study aimed to assess the management of CGD by rheumatologists versus otorhinolaryngologists.

Methods: We conducted a cross-sectional study including Tunisian doctors dealing with CGD. Rheumatologists (RTO) and otorhinolaryngologists (ORL) were invited to answer a questionnaire via google form about CGD daily management. Outcomes of interest were treatment modalities.

Results: The study included 30 RTO and 32 ORL. Most of the doctors (RTO, vs ORL) were females (88.3%, vs 56.3%), aged between 35 and 45 (43.3%, vs 62.5%), and worked at a private practice (33.3%, vs 59.4%). The number of patients diagnosed with CGD by RTO was as follows: 1-2 per year (33.3%), 1-2 per month (18.8%), 1-2 per week (20%), less than one patient a year (10%) and none in 3.3% of cases. The number of patients diagnosed with CGD by ORL was as follows: 1-2 per year (50%), 1-2 per month (33.3%), 1-2 per week (6.2%), less than one patient a year (15.7%) and none (9.4%). Most patients presenting with CGD were females in both groups (93.1%, vs 82.8% respectively) with a mean

age between 36 and 65 (79.3%, vs 82.1%). Most of the respondents declared treating patients with CGD (93.1%, vs 79.1%). Regarding treatment modalities, physical therapy was the most prescribed in both specialties (81.5% and 48.3%, respectively). Only RTO (18.5%) prescribed manual therapy. Concerning medical treatment, anti-inflammatory were the most prescribed drugs in both groups (92.6, and 34.5%, respectively). Sixty-seven percent of RTO prescribed anti-vertigo medication. Interestingly, it was the least prescribed drug by ORL (6.9%). Only RTO (59.3%) prescribed Muscle relaxants.

Conclusion: Despite the disparities in the management of CGD, physical therapy remains the first prescribed treatment by Tunisian doctors. Further studies are needed to establish a consensus to treat CGD.

POS1275 PERITENON THICKENING IS ASSOCIATED WITH THE INTENSITY OF MANUAL SPORTS ACTIVITY

C. Guillén-Astete[1], P. Zurita-Prada[2], C. Urrego-Laurín[1], N. García-Montes[3], H. García-López[2]. [1]*Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*; [2]*University Hospital Moncloa, Rheumatology, Madrid, Spain*; [3]*Hospital Ramón y Cajal, Emergency, Madrid, Spain*

Background: Peritenon enlargement has been considered as a specific ultrasound finding associated with psoriatic arthritis based on studies in patients. Recent observations in athletes have demonstrated the existence of this finding although its relationship with the type of physical activity performed has not been determined.

Objectives: To determine to what extent manual physical activity is associated with the prevalence of peritenon thickening in the fingers of healthy athletic subjects.

Methods: Thirty-five healthy young male volunteers were recruited from a local sports centre in the community of Madrid. All of them performed sports activities with their hands for more than 12 hours a week.A digital dynamometer was used to determine the flexion strength of the fingers of the dominant hand. A single observer performed an ultrasound scan of this hand to determine the presence or absence of a hypoechoic image surrounding the extensor digitorum tendon of the 2nd, 3rd, 4th and 5th fingers, according to previous definitions. Mean flexion strengths were compared with the number of positive ultrasound findings.

Results: Fifteen volunteers (mean age 24.3 years, BMI 24.4) did not present peritenon enlargement (42.8%). The mean ± standard deviation of the fingers flexor strength according to the number of peritenon enlargement detected were 43.5 ± 6.2, 49.2 ± 3.8, 53.2 ± 1.64 and 63.0 ± 4.83 Kg for volunteers with none, 1, 2, 3 and 4 peritenon enlargements, respectively. (ANOVA P<0.001; Pearson's coefficient 0.827, P<0.001). Correlation between BMI, body fat percentage or training hours per week and the number of peritenon enlargement detected was not demonstrated.

Conclusion: Peritenon enlargement, also knew as peritenon tendon inflammation, is detectable by ultrasound scan in healthy subjects and it seems to be associated to the physical activity intensity, indirectly measured by the flexor strength of the fingers.

POS1276 LONG TERM OUTCOME OF MULTIPLE ULTRASOUND GUIDED SUPRASCAPULAR NERVE BLOCK IN TREATMENT OF FROZEN SHOULDER IN DIABETIC PATIENTS

M. A. Mortada[1], R. Hassan[1], Y. A. Amer[1]. [1]*Faculty of Medicine, Zagazig University, Rheumatology and Rehabilitation, zagazig, Egypt*

Background: Frozen shoulder is prevalent among diabetic patients, and usually has aggressive course, with more tendency to be bilateral and resistant to treatment. Suprascapular nerve block (SSNB) is used with increasing frequency by anesthetists and rheumatologists in the management of frozen shoulder. We previously introduced a protocol of nine injections for SSNB with better short term outcome than single SSNB injection (1). Long term outcome of SSNB in management of frozen shoulder is still not detected.

Objectives: To evaluate the long term effect of multiple (nine) ultrasound guided supra-scapular nerve block in treatment of diabetic frozen shoulder.

Methods: A retrospective cohort study followed up 40 diabetic patients who received a course of ultrasound guided multiple supra-scapular nerve block (9 injections) on 2014. In this study we retrospectively assessed the patients from previously recorded data at a mean duration of 6 years after completing the 9 injection course SSNB clinically by measuring the shoulder active range of motion (using a goniometer in three planes: abduction, internal, and external rotation). Visual analogue scale and Functional assessment by shoulder pain and disability index (SPADI).

Results: Thirty four patients (85% of original cohort) completed the long term follow up.

The patients were 19 (55.9%) females, 60.6 y mean age, and the mean of disease duration was 85.6 months. The majority of patients (33 patients 97.05%) continues improvement and gained within normal complete range of motions in all directions and excellent grades of shoulder function (Table 1).

Table 1.

Clinical Parameters	At base line	At 4 months	Last follow up at (72months±4)	**P value
SPADI pain score (100)	(68.8 ± 0.5)a	(10.3 ± 7.4)b	(0.9±1.9)c	0.00*
SPADI disability score (100)	(69.2 ± 7.7)a	(6.25 ± 2.25)b	(0.4±0.8)c	0.00*
SPADI total (100)	(69.1 ± 8.5)a	(8.15 ± 5.4)b	(1.1±0.9)c	0.00*
Patient global assessment (100)	(90.2 ± 8.2)a	(8.2 ± 4.2)b	(0.4±2.1)c	0.00*
Night pain (100)	(55.4±10.2)a	(10.3 ± 4.9)b	(2.3±1.1)c	0.00*
Abduction (180°)	(77.5 ± 4.7)a	(170.3 ± 10.3)b	(174.2±6.2)b	0.00*
External rotation (100 °)	(46 ± 12.6)a	(80.1 ± 10.2)b	(86.4±10.3)b	0.00*
Internal rotation (70 °)	(34.5 ± 2.4)a	(55.4 ± 10.1)b	(60.2±9.5)b	0.00*

* P <0.05 there was a statistical significant difference**•A,b,c**--- the alphabet of different symbols ---means a significant statistical difference between groups**SPADI:** shoulder pain and disability index

Conclusion: The multiple injection courses for supra-scapular nerve block has an excellent long term efficacy as treatment of diabetic frozen shoulder. This method should be the treatment of choice in patients of diabetic frozen shoulder who do not respond to physiotherapy.

POS1277 NON-CONTIGUOUS MULTIFOCAL SPONDYLODISCITIS: A CASE SERIES AND REVIEW OF LITERATURE

A. Feki[1], I. Sellami[2], R. Akrout[1], S. Ben Jemaa[1], A. Hriz[1], M. Ezzeddine[1], M. H. Kallel[1], H. Fourati[1], S. Baklouti[1]. [1]*Hedi Chaker Hospital, Rheumatology, Sfax, Tunisia*; [2]*Hedi Chaker Hospital, Occupational Medicine, Sfax, Tunisia*

Background: Spondylodiscitis is an infective process of the disc and the two adjacent vertebrae. It is quite a rare disease accounting for 2–7% of all cases of septic osteomyelitis. These spinal infections touch commonly a single level, the lumbar spine being the most affected. Non-contiguous spine level involvement is seldom reported in the literature. This last group is for the most part imputable to granulomatous organisms [1,2].

Objectives: Study the clinical, microbiological, radiological, therapeutic and evolutional characteristics of non-contiguous multi-levels spondylodiscitis.

Methods: We conducted a retrospective descriptive study over twenty-one years in the Department of Rheumatology. The diagnosis of spondylodiscitis was based on combination of clinical, biological and radiological arguments.

Results: Eight patients had non-contiguous multi-levels infectious spondylodiscitis. There were 6 men and 2 women. The mean age was 53.3±26.2 years. The mean delay from onset of symptoms to diagnosis was 134.6±77.6 days. Back pain was the most common symptom. All patients had spinal syndrome. The Signs of spinal cord compression were observed in 3 patients. C-reactive protein levels were elevated in 6 patients (mean: 56 ± 30.8 mg/L). Plain radiography, performed in all cases, showed pathological pictures in 7 patients. Magnetic resonance imaging was performed in 6 patients. Vertebral levels affected were thoracic / lumbar in 6 cases, cervical/thoracic in 1 case and cervical/lumbar in 1 case. The paravertebral abscess was associated to the disc involvement in 3 cases. Epiduritis was associated in 3 cases. Pathogens were isolated in all cases. Tuberculosis was the most common cause. The leading causative agents in non-tuberculosis spondylodiscitis were staphylococcus aureus, brucella and streptococcus B. Two microorganisms combined were found in two cases (mycobacterium tuberculosis associated to Escherichia coli in one case and mycobacterium tuberculosis associated to Brucella in another). Medical treatment was adapted to the microbial culture and the sensitivity profile of the etiological agent.

After therapy, 7 patients had regression of symptoms and 1 patient had a permanent neurological impairment.

Conclusion: Multilevel spondylodiscitis involving non-contiguous spine segments is rare. Although atypical organisms are generally held to be responsible, the common bacteria such as Streptococcus B or Staphylococcus aureus should not be overlooked.

POS1278 THE PREVALENCE AND CLINICAL SIGNIFICANCE OF ULTRASONOGRAPHIC FINDINGS OF DISTAL MEDIAL HAMSTRING TENDONS IN PATIENTS WITH POSTEROMEDIAL KNEE PAIN

H. Saad[1], Y. Gazar[1], S. Ghanem[1], A. Maaty[2,3]. [1]*Al-Azhar University, Cairo, Egypt, Rheumatology and Rehabilitation, Cairo, Egypt*; [2]*Faculty of Medicine, Suez Canal University, Ismailia, Egypt, Physical Medicine, Rheumatology, and Rehabilitation, Ismailia, Egypt*; [3]*Armed Forces Center of Health Rehabilitation, Taif, Saudi Arabia, Physical Medicine and Rehabilitation, Taif, Saudi Arabia*

Background: Periarticular abnormalities are common ultrasonographic (U/S) findings in individuals with knee pain. Incidental U/S observations, including thickening of the distal hamstring tendons, require explanations for their clinical importance. Tendon thickness may be a good indicator of tendinopathy and tendon dysfunction. Also, it is uncertain whether these tendon changes are correlated with knee pain or not?

Objectives: The aim of this study was to determine U/S findings of distal medial hamstring tendons in patients with posteromedial (PM) knee pain and assess the diagnostic values of tendon thickness in predicting tendinopathy.

Methods: We studied distal medial hamstring tendons (semimembranosus [SM] and semitendinosus [ST]) of 104 patients (104 knees) with non-traumatic unilateral PM knee pain and 118 healthy controls (236 knees). U/S evaluations included tendon thickness, echogenicity, the presence of intrasubstance tears, calcification, and vascularity.

Results: The mean age (standard deviation) of the patients and control groups were 51.7 (10.4) years and 49.8 (9.9) years, respectively. The mean visual analogue scale (VAS) for pain among patients was 5.1 and 58.6% of them located the pain at medial joint line. The studied patients had significantly higher mean SM thickness (7.17 mm *vs.* 5.46 mm, respectively) and ST thickness (3.93 mm *vs.* 3.45 mm, respectively) than the controls. U/S abnormalities among patients were hypoechogenicity (62.5%), intrasubstance tears (31.7%), loss of fibrillar pattern (23.1%), Baker cyst (20.2%), calcification (18.3%), Anserine bursitis (11.5%), and neovascularization (6.7%). We found significant correlations between tendon thickness and VAS (r=0.752, p=0.004), and pain location (r=0.680, p=0.008). SM thickness had higher accuracy to predict tendinopathy than ST thickness (80.6% *vs.* 68.9%, respectively).

Table 1. Diagnostic values of tendon thickness in predicting tendinopathy.

Tendons	Cutoff	Sensitivity	Specificity	+PV	-PV	Accuracy	AUC
SM	>6.6	70.2	89.8	85.7	76.8	80.6	0.835
ST	>3.7	56.7	79.6	71.1	67.6	68.9	0.696

SM: semimembranosus, ST: semitendinosus, +PV: positive predictive value, -PV: negative predictive value, AUC: area under curve.

Conclusion: U/S changes are frequently present in patients with PM knee pain. Tendon thickness is an accurate predictor of tendinopathy. These findings suggest that U/S screening of all individuals with PM knee pain is a useful tool for improving patients' outcomes and decreasing tendon-related disability.

POS1279 ADVERSE DRUG REACTIONS IN TUBERCULOSIS AND MANAGEMENT

R. Grassa[1], N. El Amri[1], S. Lataoui[1], O. Jomaa[1], H. Zeglaoui[1], K. Baccouche[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumathology, Sousse, Tunisia*

Background: Around 10 million people worldwide contract tuberculosis (TB) every year. According to the World Health Organization (WHO), approximately one-quarter of the world's population is latently infected with Mycobacterium tuberculosis. Its treatment is extremely long and patients may experience a variety of adverse reactions.

Objectives: The aim of this study was to assess the different adverse drug reactions (ADR's) in patients treated with first-line anti-tubercular drugs.

Methods: This retrospective study included 45 cases of TB followed in the Rheumatology department of Farhat Hached hospital in Sousse, Tunisia, over a period of 22 years (1998-2020).

Results: The mean age was 52.2 ± 17.72 years [14-95 years]. These were 19 men (42.2%) and 26 women (57.8%).The different locations of tuberculosis were as follows: pulmonary for 5 patients (11.1%), spinal for 26 patients (57.8%), articular for one patient (2.2%), urinary for two (4.4%), and multifocal for 8 patients (17.8%). An anti-tuberculosis treatment (based on quadrytherapy: Rifadine(R), Isoniazide(I), Pyrazinamide (Z) and Ethambutol (E)during 2 months, followed by biotherapy based on (R)and (I) was prescribed for an average duration of 10.85 months [6-24 months]. ADR's were observed in 53.33% of patients. Abdominal pain and nausea were detected in 5 cases (11.1%). Hepatic cytolyse was noticed in 8 cases (17.8%) under (R). Cholestatic hepatitis occurred in 9 cases (20%) under (R). Asymptomatic Hyperuricemia was detected in 15 cases (33.3%) with (E). Two cases of toxiderma were detected: the first under (E) and the second under (E) + (Z). Ethambutol was responsible for a case of DRESS syndrome and a case of drug-induced hepatitis. One case of hemolytic anemia had occurred under (R). A sensorineural hearing loss was noted under streptomycin in one case. No fatal side effects were observed. These ADR's were reversible in all cases.

Conclusion: The treatment of TB can cause a variety of ADRs'. Early recognition by active surveillance and appropriate management of these ADRs' might improve adherence and treatment success.

POS1280 SPINAL LOCATION OF TUBERCULOSIS: WHAT HAS CHANGED OVER THE LAST YEARS?

S. Boussaid[1], M. Mrabet[1], S. Jemmali[1], H. Sahli[1], H. Ajlani[1], E. Cheour[1], S. Rekik[1], M. Elleuch[1]. [1]*Rabta Hospital, Rheumatology, Tunis, Tunisia*

Background: Tuberculosis (TB) is no longer a disease limited to developing nations and is still a major cause of significant morbidity and mortality worldwide. It can affect the different parts of the spine.

Objectives: The aim of this study was to determine the preferred spinal location of TB.

Methods: We conduct a retrospective and descriptive study in a single rheumatology department. Data were collected from observations of patients hospitalized in the past 20 years (2000-2020) who have been diagnosed with tuberculous spondylodiscitis (TS).

Results: Fifty-two patients were included (37F/15M). Their mean age was 55.21 years ± 17.79 [19-91]. TS was more frequently unifocal (75%) than multifocal (25%). Lumbar spine involvement was the most common (57.7%) and more frequent in women (63.3%) but with no statistically significant difference (p = 0.2). Other localizations were described such as: dorso-lumbar (21.2%), dorsal (15.4%), lumbosacral (3.8%) and cervical (1.9%). Lumbar pain was present in 34 patients (65.4%) and 29 patients (55.8%) suffered from segmental lumbar stiffness. Imaging was contributive by showing the vertebral location using standard X-rays, computed tomography and magnetic resonance imaging. Disc pinch, erosion of vertebral plateaus and vertebral collapse were the major signs (82.7%, 65.4% and 67.3%, respectively).

Conclusion: TS is a rare but serious clinical condition which may lead to severe deformity and early or late neurological complications. Spinal involvement is often unifocal and mostly diagnosed with lumbar pain or stiffness. Multifocal forms, touching several parts of the spine, however remain rare. Our findings remain consistent with those of the literature.

POS1281 HOW DOES OBESITY INFLUENCE THE FEATURES OF KNEE OSTEOARTHRITIS?

H. Hachfi[1], D. Khalifa[1], M. Brahem[1], N. Ben Chekaya[1], M. Younes[1]. [1]*Taher Sfar Hospital, Rheumatology, Mahdia, Tunisia*

Background: Knee osteoarthritis and obesity are both major health problems. It is now admitted that the prevalence of knee osteoarthritis gets higher with obesity and that weight loss helps knee function and allows patients to avoid surgery.

Objectives: The aim of this study was to study the influence of obesity on knee osteoarthritis features.

Methods: A cross-sectional study was conducted in the university hospital Taher Sfar of Tunisia over a period of 6 months. Patients who had knee osteoarthritis confirmed by radiographs were included. Sociodemographic, clinical, radiological and therapeutic data were collected from medical records and visits. Obesity was

defined by a body mass index (BMI) ≥30. Functional impairment was assessed by the Womac index and Lequesne index.
Results: The study included 186 patients. There were 31 males and 155 femmes. The mean age was 60±10 years. The percentage of obese patients was 53,8%. The mean age was similar in both groups obese and non obese. There were more women in the obese group compared to the non obese group (p=0.0001), more patients who had diabetes mellitus and dyslipidemia (p=0.002). Non-obese patients had a shorter duration of symptoms with no statistical significance (p=0.151). Obese patients had more involvement of both knees (p<0.0001). Obesity did not have an impact on pain severity. Severity of radiological images (p=0,0001) were more frequent in obese patients. Functional impairment was similar in both groups. However, the percentage of patients having a very important functional impairment with Lequesne index was higher in obese patients (p<0.029). Obese patients also needed more physical therapy sessions (p=0.035).
Conclusion: Knee osteoarthritis in obese patients is characterized with the femlae gender predominance, bilateral knee involvement, and a more severe images on radiographs. Thus the need for better control of weight and the importance of physical activity.

POS1282 VERIFICATION OF MANIFESTATIONS OF SARCOPENIA IN OBESE PATIENTS WITH THREE METHODS FOR BODY COMPOSITION ASSESSMENT

V. Vasileva[1], L. Marchenkova2, V. Sergeev2. [1]*National Medical Center for Rehabilitation and Balneology, Department of Somatic Rehabilitation, Reproductive Health and Active Longevity, Moscow, Russian Federation*; [1]*National Medical Center for Rehabilitation and Balneology, Department of Somatic Rehabilitation, Reproductive Health and Active Longevity, Moscow, Russian Federation*

Background: With new technologies for body composition assessment determining changes learn, muscle and fat mass. Prevention of sarcopenic obesity is timely detection of decrease.
Objectives: Aim of the study was to compare the effectiveness of three methods of body composition assessment such as bioimpedans analysis (BIA), air-replacement bodyplatismography (BodPod) and Dual X-ray absorptiometry Total body program (DXA Total Body) in the verification of reducing of skeletal muscle mass as sign of sarcopenic obesity in obese patients.
Methods: The study group included 95 patients aged 21-69 y.o. (average age 53,9±11,05 years) with BMI≥30.0 kg/m2. The control group included 37 patients aged 37-69 y.o (average age 50,73±10,6 years) of the same age without obesity with BMI 20.0-29.9 kg/m2. Body composition was tested using BIA, BodPod and DXA with calculating fat, lean and skeletal muscles mass (kg) and % in all the patients.
Results: According to BIA the groups differ only in fat mass (FM) 42.75 (4.8;6.3) vs. 33.15 (28.4;35.5) kg; p=0.036 and did not differ (p>0.05) in lean (LM), skeletal muscle mass (SMM) and in % of FM and SMM. According to BodPod analyses groups differed in the FM 3.4 [36.81;69.94] vs 31.02 [23.22;38] kg, p=0.007, % FM 45.4 [42.1;53.8] vs 37.7 [28.6;41.1], p=0.003 and % LM - 54.6 [46.2;57.9] vs 62.3 [58.9;71.4], p=0.003, but had statistically equivalent values of LM 55 [49.48;67.77] vs 40.36 [33.12;49.06] kg, p=0.19. According to DXA Total Body analyses statistically significant differences (p<0.05) have been identified between the groups in FM and % FM of the hands, feet, trunk, total body (p>0.05), but not in LM and % LM (p>0.05) (Table 1).

Table 1. Effectiveness of three methods for body composition assessment

INDICATORS	STUDY GROUP	CONTROL GROUP	p
Weight (kg)	106 [96;122]	80 [77;81]	0.00251
BMI (kg/m2)	37.6 [104;124]	26.8 [24;30]	0.000000
Bod Pod			
% fat mass	45.4 [42.1;53.8]	37.7 [28.6;41.1]	0.003424
% lean mass	54.6 [46.2;57.9]	62.3 [58.9;71.4]	0.003424
fat mass (kg)	43.4 [36.81;69.935]	31.016 [23.223;38.004]	0.006836
lean mass (kg)	55.002 [49.48;67.77]	40.359 [33.122;49.058]	0.185377
BIA			
fat mass (kg)	42.75 [4.8;6.3]	33.150 [28.4;35.5]	0.035771
lean mass (kg)	59.5 [53.95;71.05]	54.850 [49.9;62.6]	0.458312
skeletal muscle mass (kg)	27.9 [23.9;33.2]	25.6 [22;29.3]	0.701678
skeletal muscle mass (%)	45.3 [43.3;47.7]	47.1 [42.3;48.1]	0.415687
DXA Total Body			
total body lean mass (g)	97276 [86062; 109154]	62628 [57839; 85068]	0.602523
total body fat mass (g)	47030 [39300; 56729]	25652 [22164; 36396]	0.009796
total body muscle mass (g)	49861 [42793; 57088]	36426 [32273; 43341]	0.973711

Conclusion: From methods of body composition assessment, air-replacement bodyplatismography (BodPod) is the most sensitive in the verification of skeletal muscle mass reduction in obese patients. This method shows that patients with obesity have a significantly reduced muscle mass compared with normal weight or overweight subjects.

POS1283 SPONDILODISCITIS WITHOUT DOCUMENTED GERM: WHAT THERAPEUTIC MANAGEMENT?

R. Grassa[1], N. El Amri[1], K. Baccouche[1], S. Lataoui[1], H. Zeglaoui[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumathology, Sousse, Tunisia*

Background: Spondylodiscitis (SD) is an infectious inflammation that affects the vertebrae, vertebral discs and adjacent structures. It may have a bacterial or non-bacterial etiology. Although analysis has improved and identification of pathogens is highly pursued, in one third of cases, no organism can be identified.
Objectives: The objective of our work is to describe the epidemiological, clinical and evolutionary profile of SD with no germ identified and management.
Methods: This is a retrospective study including 37 cases of SD with no germ identified, collected in the Rheumatology Department of Farhat Hached hospital in Sousse, Tunisia over a period of 22 years (1998-2020).
Results: The mean age was 59.7 years [18-97 years]. These were 21 men (56.76 %) and 16 women (43.24 %).Spinal pain was the major symptom. The lumbar location was the most frequent in 56.76% of cases. It was a multifocal localization in 21.62%. The imaging allowed the detection of para abscesses -vertebral in 43.24%. An epiduritis was objectified in 54.05%.CT-guided biopsy was performed in 59.46% and it was not conclusive. A bacteriological survey was carried out and came back negative. Spondylodiscitis was presumed to be tubercular and staphylococcal in respectively 62.16 % and 18.92 %. The tuberculosis origin was retained in view of the chronic evolution, the multi-stage damage in the radiological assessment. While staphylococcal SD was retained due to the presence of cutaneous lesion and subacute evolution. Large-spectrum antibiotic therapy was initiated in the other cases.One case was initially considered to be staphylococcal but with epidural and soft tissue extension tuberculosis was then considered to be the cause. The evolution after initiation of adequate antibiotic treatment was interspersed with neurological complications in one case of tuberculosis SD.
Conclusion: Our results show a higher frequency of presumed tuberculosis SD considering the endemicity of our country and the improvement under anti tuberculosis treatment.

POS1284 FASCIAL ULTRASOUND: THE CONTEXT FOR DRY NEEDLING TRIGGER POINTS IN TREATMENT OF MYOFASCIAL PAIN, POSTURAL IMBALANCE

R. Bubnov[1], L. Kalika[2]. [1]*Clinical Hospital "Pheophania", Ultrasound, Kyiv, Ukraine*; [2]*NYDNRehab: Physical Therapy Clinic & Chiropractic NYC, Rehabilitation, New York, United States of America*

Background: Muscles and fascia are the major source of pain in rheumatic diseases. Dry needling under ultrasound guidance (DN-US) is a crucial therapeutic approach to treat muscle pain [1,2], the definition `myo-fascial` calls for searching trigger points (TrPs) in fascia to improve the treatment effectiveness.
Objectives: Aim was to evaluate the relevance of fascial ultrasound for DN-US in myo-fascial pain.
Methods: We included 36 patients (21 females, 20-69 years old) with myofascial pain different localisations (low back, limbs, shoulder, neck pain), postural imbalance; did DN-US protocol according to R. Bubnov [1]: trigger points were identified according, fine (28G) steel needle DN-US was applied. Additionally considered fascial structures for detecting areas of abnormalities (hypervascularity, heterogeinity, hypomotility, adhesions) aka `trigger points` and potental nerve compression/irritation and did precise DN-US where appropriate.
Results: In all patients movement restored and pain decreaed after muscles DN; in 30 patients additionally we detected and did successful DN-US the

major fascial points as follows: thoracolumbar fascia, sacroiliac joint, pelvis ligaments, rotator cuff; potential nerve compressions (e.g., arcade of Frochse, soleus arcade); nerve sheath surrounding nerves (sciatic nerve, brachial plexus) and vessels (thoracic outlet syndrome), smaller fascia, joint capsule thickening. We detected higher rates of motility, improvement postural balance and pain decrease, fewer sessions needed in patients after extensive protocol.

Conclusion: Fascia dry needling is accessible and effective method for myo-fascial pain treatment, may provide additional mechanical benefit and help to maintain treatment effect. Affected fascia can be considered as relevant trigger points, specific ultrasound symptoms should be validated.

POS1285 FOOT DISORDERS AND FALLS RISK IN OLDER PERSONS

N. Fani[1], E. Toulgui[1], D. Khalifa[2], S. Mtaoua[3], W. Ouanes[1], S. Jemni[1]. *[1]Hôpital Sahloul, Physical Medicine and Rehabilitation, Sousse, Tunisia*; *[2]Hospital Farhat Hached, Rhumatologie, Sousse, Tunisia*; *[3]Hospital Ibn El Jazzar, Physical Medicine and Rehabilitation, Kairouan, Tunisia*

Background: Falls are major problems in older people, leading to serious morbidity and mortality. Many studies have identified intrinsic and extrinsic fall risk factors in order to develop preventive strategies and guidelines. There are few reports which studied the impacts of aging feet on falls [1].

Objectives: The present study aimed to explore foot musculoskeletal disorders and their relationship to falls in a healthy aging population.

Methods: This was a cross-sectional descriptive study involving the patients aged 65 years and over who were independent in self-care and walking followed at the physical medicine and rehabilitation department of the university hospital of sousse over 3 months. The analysed data focused on the epidemiological and clinical characteristics.Trained physicians evaluated health status, foot problems, and fall(s) history of all subjects. Walking performance was assessed using the 'Timed Get Up & Go' test and the unipedal stance test was used for the assessment of balance. Footprints were taken from the standing position. Associated factors of foot disorders and falls were analyzed.

Results: There were 45 subjects: 18 men, 27 women with a mean age of 69.6 [65-86] years. Foot deformities presented in 87% and were a significantly associated with walking performance or falls (p=0.01, p=0.02). The most common foot musculoskeletal disorder were Halux valgus 31%, followed by Mallet toe 15%. Arch of foot classified by physical examination revealed that pes planus was presented in 35% of cases. There was a significant correlation between BMI and an arch index (p=0.04). Foot problems remained significantly associated with impaired timed up and go test and the unipedal stance test. The causes of pain were plantar fasciitis, hallux valgus, callus, metatarsalgia, and inappropriate footwear. Falls were reported in 33.3 of patients. Falls were significantly associated with Hallux valgus, mallet toe and pain (p<0.05).

Conclusion: Independent of the influence of age, gender, common conditions; foot problems have a significant impact on the ability to perform functional tasks integral to independent living.

POS1286 SHORT-TERM AND MID-TERM EFFICACY OF CAUDAL EPIDURAL STEROID INJECTIONS IN THE MANAGEMENT OF DEGENERATIVE SCIATICA

D. Khalifa[1], N. El Fani[1], R. Moncer[1], E. Toulgui[1], W. Ouanes[1], S. Jemni[1]. *[1]Sahloul Hospital, Physical Therapy and Rehabilitation, Sousse, Tunisia*

Background: Epidural steroid injections are largely used in the management of osteoarthritis-related sciatica. Three possible sites of injection are possible: the caudal through the sacral hiatus, the interlaminar and the transforaminal site. The caudal technique is known to be the most simple one. However, doubts still persist about this infiltration's efficacy.

Objectives: The aim of this work was to study the short-term and mid-term efficacy of caudal epidural steroid injections in patients suffering from sciatica related to a degenerative etiology and to study the determining factors of its efficacy.

Methods: A retroscpective, descriptive and monocentric study was conducted in Sahloul university hospital of Tunisia. Medical records of patients who suffered from sciatica due to disc herniation or spinal stenosis were analysed. Only patients who benefited from at least one caudal epidural steroid injection were included. Other etiologies were ruled out by CT-scan or MRI and laboratory tests. Efficacy of the injection was evaluated by the visual analog scale of pain (VAS) at the first week post infiltration, 3 months and 6 months later. The infiltration was considered effective if the difference of pain scoe by VAS was ≥50% compared to baseline's score. The presence of anxiety and depression was also tracked down with the hospital anxiety and depression scale. Data was collected and analysed using the statistical tool SPSS.20.

Results: Twenty-five patients were included. They were 7 males and 18 females. The mean age at diagnosis was 51.88± 15.28 years. Eleven patients had another osteoarthritis site. Five patients had previous back surgery: 2 dissectomies, 1 arthrodesis, and 2 laminectomies. Median duration of sciatica was 30 months. Sciatica was bilateral in 41.7% of the cases, impulsive during efforts in 52% of the cases and with claudication in 92% of the cases. The median VAS score at baseline was 7 out of 10 (min=4; max=9). All patients had tried medical treatment using NSAIDS and painkillers, and physical therapy before prescribing the infiltration. The technique was similar in all patients: Lidocaine 1% was first injected at a median volume of 5ml, followed by corticosteroids and finally a saline solution (median volume of 20ml). The median number of epidural caudal injections was 3 injections (min=1; max=3). The caudal epidural steroid injections were effective in 60% of the patients at the first week, 56% in the cases at 3 months and 56% of the cases at 6 months. Factors associated with efficacy of the injection at the first week were greater total volume injected (p=0.001), and greater saline solution volumes (p=0.016). At 3 months, factors significantly associated with efficacy of the infiltration were having unilateral pain (p=0.05), a positive straight leg raise test sign (p=0.028), a lower anxiety score (0.014) and a lower depression (0.000) score. At 6 months, factors associated with efficacy were not having cervical osteoarthritis (p=0.03), unilateral pain (p=0.05), low anxiety (p=0.014) and low depression (p=0.001) scores and a higher number of steroid injections (p=0.05).

Conclusion: Caudal epidural steroid injections seem effective on the short-term and this efficacy is maintained till the mid-term. Greater volumes may help with pain by possible adhesiolyse-like mechanisms and having unilateral pain, positive straight leg raise sign, a higher number of injections, no anxiety or depression and no other osteoarthritis sites makes the infiltration more effective.

POS1287 ANXIETY, DEPRESSION, FIBROMYALGIA SYNDROME AND PAIN INTENSITY IN PATIENTS WITH LOW BACK PAIN

R. Dhahri[1], A. Dghaies[1], M. Slouma[1], L. Metoui[1], I. Gharsallah[1], I. Dorgham[2], R. Ayari[2], Y. Mallat[2], K. Amri[2]. *[1]The Military Hospital of Tunis, Rheumatology, Tunis, Tunisia*; *[2]The Military Hospital of Tunis, Traumatology-Orthopedic Department, Tunis, Tunisia*

Background: Common low back pain (LBP) is a common health problem affecting 50 to 80% of working age adults resulting in significant personal, social and occupational impairment. Chronic pain has a negative impact on quality of life and psychological well-being.

Objectives: The aim of this study was to examine the relationship between anxiety, depression and pain intensity in patients with low back pain in a population made of military agents.

Methods: It was an analytical cross-sectional study including 50 patients with at least three months of LBP, in the department of rheumatology and orthopedics at the Military Hospital of Tunis between January 1st and March 31, 2020. All patients had a standardized clinical assessment. Patients completed the «hospital anxiety and depression scale» (HADS) and the «Fibromyalgia Rapid Screening Tool» (FIRST) to evaluate psychological impact of chronic LBP. Pain intensity was assessed using a visual analog scale (VAS).

Results: The mean age of the patients was 41.9 ± 8.4 years and the sex ratio was 4.5. LBP duration was 66.4 months. The mean lumbar visual analog scale (VAS) was 4.5 ± 1.9, and the root VAS was 2.6 ± 2.5. Neuropathic pain was found in 26% of patients. Abnormal level of anxiety and depression were found in 58% and 62% of the patients respectively. Out of them 20% and 26% were borderline abnormal for anxiety and depression respectively, while 38% (16.4%) and 36% were certainly abnormal for anxiety and depression respectively. Twelve percent of the patients had fibromyalgia syndrome associated with LBP as they had a FIRST score ≥5. Positive correlations were found between lumbar VAS and HAD anxiety/depression scores (r = 0.35; p<0.01/ r = 0.3; p = 0.04). Positive correlations were also found between root VAS and HAD anxiety/depression (R= 0.38;

P<0.01/ R=0.29; P=0.03). There was positive correlations between Fibromyalgia syndrome (FIRST scale) and lumbar VAS (r= 0.42; p=0.01) and root VAS (R= 0.29; P<0.01).
Conclusion: The results of this study showed that anxiety, depression and fibromyalgia syndrome are not only frequent with patient suffering from chronic LBP but they are also correlated to the pain intensity. As a consequence, assessment of and intervention in anxiety, depression symptoms and fibromyalgia syndrome is crucial in the provision of pain-relief nursing treatment in patients with low back pain.

POS1288 TUBERCULOUS SPONDYLODISCITIS IN ELDERLY: EPIDEMIOLOGY, CLINICAL, FEATURES, TREATMENT AND OUTCOMES

M. Mrabet[1], S. Boussaid[1], S. Jemmali[1], H. Sahli[1], H. Ajlani[1], E. Cheour[1], S. Rekik[1], M. Elleuch[1]. [1]*Rabta Hospital, Rheumatology, Tunis, Tunisia*

Background: Tuberculosis is still endemic all over the world. The incidence of tuberculous spondylodiscitis (TS) is steadily increasing. Clinical features and outcomes of this affection are various and depending on various parameters, including age.
Objectives: Our objective was to explore the differences in presentation and the results of further investigations and the prognosis of TS between young and elderly subjects.
Methods: We conduct a retrospective and descriptive study in a single rheumatology department. Data were collected from files of patients hospitalized in the past 20 years (2000-2020) who have been diagnosed with TS. We carried out a comparative study concerning the clinical biological, imaging features and outcomes between young subjects and subjects aged over 65 years.
Results: Fifty-two cases of TS were collected (37F/15M). The mean age of the population was 55.21 years ± 17.79 [19-91]. Thirty-three patients (69.2%) were classified as young versus 16 elderly patients (30.8%), with female predominance in both groups (69.4% and 75% respectively, p = 0.57). Young subjects was more frequently vaccinated (88.9%) by Bacillus Calmette–Guérin (BCG) (p < 0.001). A delayed diagnosis was noted in both groups (p = 0.24). Lumbar spine involvement was the most common (57.7%). In the two age ranges, the onset of the disease was progressive (p = 0.22), characterized by segmental spine stiffness (p = 0.57) and lumbar pain with general signs (p = 0.27), such as: impaired general condition, fever, night sweats and weight loss. Biological inflammatory syndrome and normochrome normocytic anemia were encountered in both cases (p = 0.08 and p = 0.2, respectively). Standard X-rays and Computed tomography were more performed in young subjects (94.4% and 69.4%, respectively; p < 0.001), unlike magnetic resonance imaging which was more common in elderly subjects but with no statistically significant difference (p = 0.22). Disc pinch, erosion of vertebral plateaus and vertebral collapse were the major signs (82.7%, 65.4% and 67.3%, respectively). Clinical, biological and imaging arguments contributed to positive diagnosis in both groups (p = 0.24). Common medical treatment was anti-tuberculosis: Isoniazid (H), Rifampicin (R), Pyrazinamide (Z), Ethambutol (E) and physical treatment such as immobilization witch was more common in the eldery (56.3%, p = 0.16). The evolution of the disease was characterized by a clear improvement of young subjects during the second week of treatment (p < 0.001). A more frequent clinical improvement in older subjects was during the fourth week but with no statistically significant difference (p = 0.13). The occurrence of immediate complications was more frequent in the elderly (p = 0.23) with a predominance for drug complications (56.3%) such as: hepatic cytolysis (12.5%), hyperuricemia (18.8%) and major intolerance to anti-tuberculosis (18.8%).
Conclusion: TS is a frequent condition that needs to be treated rapidly. the clinical presentation of TS in the elderly is less noisy which leads to more frequent complications and mortality.

POS1289 CHRONIC LOW BACK PAIN: THERAPEUTIC STRATEGIES AND CLINICAL OUTCOMES IN A MILITARY POPULATION

R. Dhahri[1], A. Dghaies[1], M. Slouma[1], L. Metoui[1], I. Gharsallah[1], I. Dorgham[2], Y. Mallat[2], R. Ayari[2], K. Amri[2]. [1]*Military Hospital of Tunis, Rheumatology, Tunis, Tunisia*; [2]*Military Hospital of Tunis, Orthopedics, Tunis, Tunisia*

Background: Low back pain is an extremely common patient complaint. Most cases resolve quickly after the acute episode. However, a significant number of patients develop chronic low back pain; a persistent disabling condition. Patients suffer from unremitting pain and often become functionally impaired.
Objectives: The aim of this study is to describe the characteristics of chronic LBP, physical examination abnormalities, treatment strategies and the impact of LBP on the professional life of the patients.
Methods: It was a an analytical cross-sectional study including 50 patients with at least three months of LBP, in the department of rheumatology and orthopedics at the Military Hospital of Tunis between January 1st and March 31, 2020. All patients had a standardized investigation and clinical assessment.
Results: The study included 80% of active military serving members and 20% of administrative officers. The mean age of the patients was 41.9 ± 8.4 years and the sex ratio was 4.5. Four patients were suffering from diabetes; two patients were suffering from high blood pressure. All the patients were suffering from chronic LBP lasting for an average of 66.4 months. LBP was associated with radicular pain in 78% of the cases. It was a unilateral radicular pain in 72% of the cases and bilateral in 28% of the cases. The main triggering factors were: carrying heavy loads in 98% of the cases, standing or sitting for long periods in 90% and 76% of the cases, tremors in 74% of the cases. Neuropathic pain was found in 26% of patients. Physical examination showed paravertebral muscle tenderness in 66% of the cases and slack abdominal muscles in 56% of the cases. Assessement of range of flexion of the lumbar spine showed: fingertip to floor test was 18 ±12.2 cm [054cm], schober test was +3.8±1.2cm [16cm]. The extension of lumbar spine was painful in 80% of the cases. A trigger point was found in 28% of the cases. Lasegue sign was positive in 18% of the cases. Leri's test was positive in 8% of the cases. Required treatments during the last episode of LBP were: Paracetamol (62%), nonsteroidal antiinflammatory drugs (26%), tramadol (4%), myorelaxant (4%) and pregabalin (2%). Half of the patients needed functional rehabilitation. Forty percent of the patients reported improvement; 46% of them reported improvement then recurrence of the pain, 8% of them reported no improvement and 4% reported worsening of the symptoms. Thirty six percent of the patients needed an average of 21 days of leave and 35% of them needed exemption from work for LBP problems. One patient needed an outplacement from his original work and one patient needed an early retirement.
Conclusion: Chronic low back pain can cause significant functional disability, and commonly becomes frustrating for both patients and physicians to cope with and treat. There is still no consensus on the best way to manage chronic low back pain, and clinical guidelines are scarce. A combination of pharmacological agents and non-pharmacological methods is the most appropriate therapeutic regimen.

POS1290 CYTOKINE BIOMARKERS IN COMMON LOW BACK PAIN

R. Dhahri[1], A. Dghaies[1], M. Slouma[1], L. Metoui[1], I. Gharsallah[1], I. Dorgham[2], R. Ayari[2], Y. Mallat[2], K. Amri[2], A. Tezeghdenti[3], W. Dkhili[3], R. Kochkar[3], E. Ghazouani[3]. [1]*Military Hospital of Tunis, Rheumatology, Tunis, Tunisia*; [2]*Military Hospital of Tunis, Orthopedics, Tunis, Tunisia*; [3]*The Military Hospital of Tunis, Immunology, Tunis, Tunisia*

Background: Common low back pain (LBP) is a common health problem affecting 50 to 80% of working age adults. It is one of the common and costly health problems in Tunisia. Actually, the role of the immune response and inflammatory cytokines in the pathogenesis of chronic pain has been of growing interest.
Objectives: The aim of this study was to assess whether pro and anti-inflammatory cytokines could be detected in serum in patients with LBP compared with healthy subjects and whether they could be related to pain severity and to clinical findings.
Methods: It was a an analytical cross-sectional study including 50 patients with at least three months of LBP, in the department of rheumatology, orthopedics and immunology at the Military Hospital of Tunis between January 1st and March 31, 2020. All patients had a standardized clinical assessment.
Levels of serum cytokines IL-6, IL-8, IL-1β and TNF- α, were measured using the chimiluminescence technique. Serum concentration of IL-10 was assayed by the enzyme-linked immunosorbent assay technique (ELISA). The normal levels of cytokines were determined in 50 healthy controls.
Results: The mean age of the patients was 41.9 ± 8.4 years and the sex ratio was 4.5. LBP duration was 66.4 months. The mean lumbar visual analog scale (VAS) was 4.5 ± 1.9, and the root VAS was 2.6 ± 2.5. Neuropathic pain was found in 26% of patients. The average BMI was 27 ± 3.7 kg/m^2. Only serum level of IL-8 was significantly higher in subjects with LBP compared to healthy controls (p <10-3). IL-1β was indetectable in both patients and controls. Positive correlations were found between IL-8 levels and anxiety/functional scores (r = 0.3; p = 0.02/ r = 0.3; p = 0.04). IL-6 was positively correlated with BMI, and negatively correlated with the Schober test. No correlations were found between serum levels of IL-6, IL-8, IL-10, TNF-α and pain intensity (VAS), neuropathic pain (DN4), fibromyalgia (FIRST), depression (HAD) and various radiological data.
Conclusion: Interleukin-8 is a biomarker of common low back pain and correlate with anxiety and functional disability. These results suggest that IL-8 may be a therapeutic target to reduce chronic back pain and reduce the social and profession impact.

POS1291

PROFILE OF LUMBAR SPINE DEGENERATIVE PATHOLOGY IN RHEUMATOLOGIC CONSULTATION IN NORTHEN TOGO

P. Houzou[1], V. E. S. Koffi-Tessio[2], E. Fianyo[2], K. Tagbor[2], K. Kakpovi[3], O. Onianikitan[2], M. Mijiyaw[2]. [1]*University of Kara, Rheumatology, Kara, Togo*; [2]*University of Lomé, Rheumatology, Lomé, Togo*; [3]*University of Lomé, Rheumatology, Kara, Togo*

Background: Degenerative spine pathology is a common reason for consultation in rheumatology. The lumbar spine is the first seat.
Objectives: To determine the epidemiological and semiological profile of degenerative lumbar spine damage in Kara.
Methods: It was a cross-sectional study based on patient records who had consulted for a degenerative lumbar spine pathology in the rheumatology department of the CHU-Kara (Northen Togo) over a three-year period.
Results: Of the 1,767 patients examined during the study period, 745 (42.16%) suffered from a degenerative pathology of lumbar spine. They were 285 men (38.3%), and 460 women (61.7%) H/F ratio of 0.62. Traders (30%), civil servants (12.5%), teachers (9.5%), and housewives (8.7%) were the most affected occupational categories. The average age of patients at the consultation was 50.6 ± 12.3 years, and the average duration of disease progression was 4.3 years ± 1.8 years. The clinical forms of degenerative lumbar spine damage were: common low back pain (194 cases; 26.04%), common lomboradiculalgia by probable disco-radicular conflict (457 cases; 61.34%) and the narrowed lumbar canal (94 cases; 12.62%). Common low back pain was acute in 56.7% of cases. The path of radiculalgia during the probable herniated disc was truncated in 19.2% of cases, L5 in 46.4% of cases, S1 in 32.9% of cases, and L4 in 2.7% of cases. The walking perimeter was less than 500 meters in 48% of patients with narrowed lumbar canal. Signs of degenerative disc disease (536 cases), spondylolisthesis (102 cases) and isthmic lysis (37 cases) were the main radiological lesions observed.
Conclusion: Degenerative damage to lumbar spine is dominated in North Togo by common lomboradiculalgia by probable herniated disc.

Background: Biologic therapies have revolutionised treatment pathways and outcomes for patients with juvenile idiopathic arthritis (JIA). Although there is a choice of approved TNF inhibitors available as a first biologic, there lacks data to inform treatment choices in clinical practice.
Objectives: To compare short-term outcomes on etanercept and adalimumab in children and young people with JIA without uveitis, including drug survival, arthritis disease activity and function ability at 1 year.
Methods: All patients starting a first biologic (etanercept/adalimumab including biosimilars) from 2010 in the UK JIA biologic registers (BCRD and BSPAR ETN) were included. Those with systemic JIA or with any history of uveitis were excluded. Data were collected at start of therapy, 6 months, 1 year, and then annually, including patient demographic, disease activity and drug therapy. In this analysis, drug survival and arthritis disease activity / function ability at 1 year (range 3-15 months) were investigated; comparing between therapies using logistic / linear regression, adjusted for propensity deciles.
Results: There were 550 patients with outcome data available (to 30 Sept 2020); 384 etanercept, 166 adalimumab. At registration, 68% female, median age 12 years old (IQR 8-14), median disease duration 1 year (IQR 1-4), 72% on concomitant methotrexate. Disease activity was similar between both therapies at baseline and one year. At one year, 70% were still on biologic therapy; most stopping therapy for ineffectiveness (45%), adverse events (31%), or patient / family choice (15%). Inactive disease and minimal disease activity was achieved in 26% and 46% respectively, 48% achieved a minimally clinical important improvement in their functional ability (CHAQ improvement >0.13).

*Childhood Health Assessment Questionnaire (CHAQ), confidence interval (CI), International League Against Rheumatism (ILAR), interquartile range (IQR), odds ratio (OR), propensity decile (PD), rheumatoid factor (RF), standard error (SE). *p<0.05*

Conclusion: This is the first comparative effectiveness analysis of adalimumab and etanercept within UK children receiving TNFi therapies for JIA. Despite large patient numbers, there was no evidence of difference between adalimumab and etanercept regarding arthritis disease control or treatment persistence. For children without uveitis, both adalimumab and etanercept can be considered as effective treatment options for children and young people with JIA.

POS1293

RISK FACTORS OF NON-PROTECTIVE LEVELS OF ANTIBODIES TO VACCINES IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

N. Lybimova[1], I. Fridman[2], O. Goleva[3], S. Kharit4, M. Kostik[5,6]. [1]*Almazov National Medical Research Centre, Saint Petersburg, Russian Federation, Department of Pediatrics and Medical Rehabilitation N 1,*

Saint Petersburg, Russian Federation; [2]*Pediatric Research and Clinical Center for Infection Diseases, Saint-Petersburg, Russia, Prevention of Infectious Diseases and Immunodeficiency States, Saint Petersburg, Russian Federation*; [3]*Pediatric Research and Clinical Center for Infection Diseases, Saint-Petersburg, Russia, Department of Virology and Molecular Biological Research Methods, Saint Petersburg, Russian Federation*; [2]*Pediatric Research and Clinical Center for Infection Diseases, Saint-Petersburg, Russia, Prevention of Infectious Diseases and Immunodeficiency States, Saint Petersburg, Russian Federation*; [5]*Saint Petersburg State Pediatric Medical University, Hospital Pediatry, Saint-Petersburg, Russian Federation*; [6]*Almazov National Medical Research Centre, Autoimmune and Autoinflammatory Diseases, Saint-Petersburg, Russian Federation*

Background: Immunosuppressive drugs, decreased vaccine coverage, aberrant immunity might be factors of low anti-vaccine antibodies in JIA patients.
Objectives: The study aimed to evaluate risk factors of non-protective levels of antibodies against measles, mumps, rubella, hepatitis B and diphtheria in JIA patients.
Methods: A prospective study included 170 children diagnosed with JIA aged 2 to 17 years, who received routine vaccinations against measles, rubella, mumps, diphtheria and hepatitis B. In all patients, the levels of post-vaccination antibodies (IgG) for measles, rubella, mumps, hepatitis B and diphtheria measured with ELISA.
Results: Protective level of antibodies were 50% against hepatitis B, 52% diphtheria, 58% measles, 80% mumps, 98%rubella. The best coverage for MMR had patients with enthesytis-related arthritis85%, compare to oligoarthritis70%, polyarthritis69%, systemic arthritis63%. Diphtheria coverage was 50%, 51%, 46%, 63%, respectively. Incomplete MMR vaccination had 39%patients, treated with biologics, 22%with methotrexate and 14%with NSAID(p=0.025), and 61%, 46%, 36% for diphtheria (p=0.021). Incomplete vaccination was a risk factor of non-protective level of antibodies against measles (HR=2.03[95%CI: 1.02; 4.0], p=0.042), parotitis (HR=6.25[95%CI: 2.13; 17.9], p=0.0008) and diphtheria (HR=2.39[95%CI:1.18; 4.85], p=0.016) vaccines. The lowest probability of having a protective level of antibodies was observed in systemic arthritis compared to oligoarthritis (p=0.008) and polyarthritis (p=0.005). JIA patients, with non-protective levels of antibodies against measles, had more extended methotrexate treatment (2.8 [1.3; 6.4] vs 2.2 [0.9; 3.9] years, p<0.05) and increased applying of the biologics (76% vs 52%, p<0.05). Patients treated with biologics had the lowest probability of having protective levels of antibodies against measles, mumps, hepatitis B, and diphtheria than MTX and NSAID. Patients with non-protective antibodies had lower vaccine coverage against mumps (56% vs 67%, p<0.05) and diphtheria (38% vs 61%, p<0.01), longer duration of methotrexate 3.3 [1.4; 6.7] vs 1.8 [1.0; 2.9] years, p<0.01) and biologic treatment 3.1 [1.1; 5.4] vs 0.9 [0.0; 1.9] years, p<0.05) compare to patients with protective levels. The main risk factors to have non-protective levels of antibodies against specific vaccines are in Table 1 below.
Conclusion: Children with JIA may have lower anti-vaccine antibodies levels and required routine check, especially in children with incomplete vaccination, biologics, systemic arthritis and long-term methotrexate treatment. Funding statement:
Footnotes: CI confidence interval, GCS glucocorticosteroids, HR hazard ratio, MTX methotrexate, na not applicable, soJIA systemic onset of juvenile idiopathic arthritis.
* Data were not calculated due to a small number of patients with a non-protective level of antibodies against rubella and no patients with incomplete vaccination against hepatitis

EFFECT OF EMOTIONAL TRIGGERS ON THE FREQUENCY OF PFAPA ATTACKS - A MULTICENTER STUDY

Y. Levinsky[1,2], Y. Butbul[3], M. Gafner[2], M. Broide[2], S. Kagan[2], R. Tal[1], M. Natur[4], K. Kaidar[4], N. Dagan[4], G. Amarilyo[4,5], L. Harel[1,5]. [1]*Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel*; [2]*Schneider Children's Medical Center of Israel, Pediatrics, Petach Tikva, Israel*; [3] *Technion - Israel Institute of Technology, Haifa, Israel, Pediatric Rheumatology Service, Ruth Rappaport Children's Hospital, Rambam Health Care Campus, Haifa, Israel, Haifa, Israel*; [4]*Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel*; [5]*Schneider Children's Medical Center of Israel, Pediatric Rheumatology Clinic, Petah Tikva, Israel*

Background: The fact that mental state may serve as a trigger for attacks of periodic fever diseases is known in Familial Mediterranean fever (FMF). There is a lack of information regarding the role of emotional triggers for PFAPA attacks.
Objectives: To examine whether emotional distress may trigger PFAPA attacks.
Methods: Enrolled were patients with active PFAPA, from two Israeli medical centers. Researchers contacted their parents by phone in two occasions: a. within the two weeks of returning to school after the first COCID-19 lockdown; b. during the summer vacation (i.e., non-stressful period). Parents were asked regarding the occurrence of PFAPA attacks within the two weeks preceding the calls. The relative stress levels of the two periods were validated by an emotional distress scale questionnaire. Differences between occurrences of attacks during these two periods of time were recorded.
Results: One-hundred and six pediatric patients enrolled in the study. Mean age was 7.37± 2.9. In the stressful period, 41 (38.7%) reported at least one attack during the preceding 2 weeks, compared to 24 (22.6%) in the non-stressful period (p = 0.017). Scores for the mean emotional distress questionnaire were higher in the stressful period compared to the non-stressful period (35.6± 8.1 vs. 32.1± 7.7, respectively, P = 0.047).
Conclusion: This study shows that during a period of stress for children there were more PFAPA attacks compared to a relaxed period. These findings indicate that mental factors such as stress or excitement may be triggers for PFAPA attacks.

Table 1. Attacks status during prior 2 weeks during stressful or non-stressful event

Outcome	First call (May 2020)	Second call (August 2020)	P-value
Pediatric emotional distress score (PEDS), mean (±SD)	35.6 (±8.1)	32.1 (±7.7)	0.047
Any attacks during last 2 week, n (%)	41 (39.8%)	24 (24.2%)	0.017
Number of attacks			0.04
One, n (%)	27 (25.5%)	19 (17.9%)	
Two, n (%)	14 (13.2%)	5 (4.7%)

PERFORMANCE OF 2019 EULAR/ACR CLASSIFICATION CRITERIA FOR SYSTEMIC LUPUS ERYTHEMATOSUS IN A PEDIATRIC POPULATION – A MULTICENTER STUDY

Y. Levinsky[1,2], M. Broide[1], S. Kagan[1], O. Goldberg[1], O. Scheuerman[1], R. Tal[3], I. Tirosh[4], Y. Butbul[5], L. Harel[2,3], G. Amarilyo[2,3]. *[1]Schneider Children's Medical Center of Israel, Pediatrics, Petach Tikva, Israel*; *[2] Tel Aviv University, Tel Aviv, Israel, Sackler Faculty of Medicine, Tel Aviv, Israel*; *[3]Schneider Children's Medical Center of Israel, Pediatric Rheumatology Unit, Petach Tikva, Israel*; *[4]Sheba Medical Center, Tel Hashomer, Pediatric Rheumatology Service, Edmond and Lily Safra Children's Hospital, Ramat Gan, Israel*; *[5]Rambam Health Care Campus, Haifa, Israel, Pediatric Rheumatology Service, Ruth Rappaport Children's Hospital, Haifa, Israel*

Background: The "European League Against Rheumatism" and "American College of Rheumatology" 2019 (EULAR/ACR-19) criteria for the diagnosis of Systemic Lupus Erythematosus (SLE) were recently published, with the stated goal of maintaining the level of sensitivity and raising the level of specificity for classification of SLE in adults.
Objectives: We aimed to examine the function of the new EULAR/ACR-19 criteria in a population of children and compare them to the SLICC-12 and ACR-97 criteria.
Methods: In this multicenter study the charts of jSLE patients from three tertiary medical centers were reviewed and compared to patients with non-jSLE diagnosis. Pediatric rheumatologists, blinded to the original diagnosis, reviewed and diagnosed all cases. Pediatric patients' clinical and laboratory data were retrospectively extracted and then examined with regard to how they met the new and old criteria.
Results: Included were 225 patients (112 jSLE, 113 non-SLE). When applied to juvenile SLE classification, the sensitivity of the new EULAR/ACR-19 criteria was 0.96 (0.9-.0.99) and the specificity was 0.89 (0.82-0.94). These were comparable to the Systemic Lupus International Collaborating Clinics (SLICC) criteria. The sensitivity of the EULAR/ACR-19 criteria improves over time and was 0.83 twelve months following disease onset, reaching 0.96 after longer than 24 months.
Conclusion: Among a cohort of jSLE patients, sensitivity of the new EULAR/ACR-19 criteria was found to be high and specificity may have improved slightly compared to the SLICC-12 criteria. We support the use of the new classification criteria for pediatric patients in future jSLE studies, but it should be noted that its specificity is lower than for adults.

	ACR-97	SLICC-12	EULAR/ ACR-19
Sensitivity (95% CI)	0.79 (0.70-0.86)	0.96 (0.9-0.99)	0.96 (0.9-.0.99)
Specificity (95% CI)	0.94 (0.88-0.97)	0.85 (0.77-0.91)	0.89 (0.82-0.94)
Accuracy (95% CI)	0.86 (0.81-0.9)	0.9 (0.86-0.94)	0.92 (0.88-.0.96)
Positive Likelihood Ratio (95% CI)	12.7(6.1-26.2)	6.35(4.1-9.9)	9.0 (5.3-15.4)
Negative Likelihood Ratio (95% CI)	0.23(0.16-0.33)	0.05(0.02-0.12)	0.05(0.02-0.12)
Diagnostic odds ratio (95% CI)	55.5(22.80-135.0)	120.85(43.0-340.0)	180.1(61.3-529.4)

POS1296

JIA PATIENTS DO NOT HAVE MORE OSTEOPOROSIS THAN HEALTHY AGE AND SEX-MATCHED CONTROLS BUT LOWER BONE MASS DENSITY IS FOUND AT TOTAL HIP AND CORTICAL COMPARTMENT

M. Lopez Corbeto[1], M. Barcelo Bru[2], E. Moreno Ruzafa[1], M. Pasqual Pastor[2]. *[1]Vall d'Hebron University Hospital, Pediatric Rheumatology, Barcelona, Spain*; *[2]Vall d'Hebron University Hospital, Rheumatology, Barcelona, Spain*

Background: Achievement of a normal peak bone mass is an especially important consideration in young adults with juvenile idiopathic arthritis (JIA), because interference with attainment of peak bone mass may not be repaired later in life. It has been suggested that children with JIA cortical appendicular skeletal bone is more affected by disease activity than axial trabecular bone. To evaluate bone mineral density (BMD) DXA measurements are widely used. Although, DXA is limited to two-dimensional evaluation of integral BMD and cannot differentiate between trabecular and cortical bone compartments. Alternatively, 3D-DXA analysis is a new method based on DXA scans of proximal femur that provides accurate estimates of trabecular and cortical volumetric BMD.
Objectives: The aim of the study was to analyze the trabecular and cortical bone using 3D-DXA in young adults with JIA compared to age-matched healthy controls.
Methods: This cross-sectional study was aimed to analyze the differences in 3D-DXA proximal femur compartments. The patients were recruited from the specialized transitional unit of the Vall d'Hebron University Hospital. JIA patients older than 18 yo without previous bisphosphonates intake were included. Age and sex-matched healthy controls were selected. DXA scans (Lunar Prodigy, General Electric Medical Systems, v.15) were acquired. OP was defined according to the WHO criteria. The 3D-DXA software was used to assess in 3D the trabecular density and cortical thickness from DXA scans as reported previously

[1]. The 3D-DXA and DXA measurements were compared using Student's *t* test. Categorical variables were compared using Chi-squared test. All hypothesis tests with p value lower than 5% were considered significant.

Results: Forty-six patients and 46 age and sex-matched controls were evaluated. The mean time of disease's duration was 7.37 years, and the most frequent JIA subtype was Oligoarticular ANA positive. More than 21% of the patients had an active disease. OP was present in 5 patients and 1 control. Despite not finding significant differences in the prevalence of osteoporosis, JIA patients had lower aBMD at total hip by DXA and lower cortical sBMD by 3D-DXA than controls (Table 1).

Table 1. Comparison of DXA and 3D-DXA measurements between JIA and healthy controls

Variable	JIA patients (n=46)	Healthy controls (n=46)	*P value*
DXA			
Lumbar aBMD (g/cm^2), mean ± sd	1.097 ± 0.02	1.155 ± 0.02	0.042
Right femoral neck aBMD (g/cm^2), mean ± sd	0.930 ± 0.02	1.014 ± 0.01	0.041
Right total hip aBMD (g/cm^2), mean ± sd	0.932 ± 0.02	1.001 ± 0.01	**0.008**
Lumbar T-score, mean ± sd	-0.716 ± 0.16	-0.212 ± 0.16	0.037
Right femoral neck T-score, mean ± sd	-0.563 ± 0.17	0.087 ± 0.12	0.036
Right total hip T-score, mean ± sd	-0.721 ± 0.18	-0.12 ± 0.13	0.008
3D-DXA			
Trabecular vBMD (mg/cm^3), mean ± sd	180.44 ± 5.54	194.57 ± 5.11	0.064
Cortical sBMD (mg/cm^2), mean ± sd	147.23 ± 3.41	161.52 ± 2.89	**0.002**
Osteoporosis (WHO definition)			
Yes, n (%)	5 (10.87)	1 (2.17)	0.091
No, n (%)	41 (89.13)	45 (97.83)	

DXA dual-energy X-ray absorptiometry, *sd* standard deviation, *aBMD* areal bone mineral density, *3D-DXA* three-dimensional dual-energy X-ray absorptiometry, *vBMD* volumetric bone mineral density, *sBMD* superficial cortical bone mineral density

Conclusion: JIA patients do not have more OP than controls in our cohort but there are differences in BMD in the different locations and greater involvement of the cortical bone in JIA.

POS1297 HOW HLA B27 PREVALENCE IN THE POPULATION INFLUENCE ON FEATURES OF JUVENILE IDIOPATHIC ARTHRITIS: DATA FROM SAKHA REPUBLIC (YAKUTIA)

F. Vinokurova[1], L. Sorokina[2], V. Argunova[3], P. Sleptsova[3], T. Bourtseva[4,5], V. Chasnyk[2], M. Kostik[2]. [1]*Yakut Science Center of Complex Medical Problems, Laboratory of Immunological Researches, Yakutsk, Russian Federation*; [2]*Saint-Petersburg State Pediatric Medical University, Department of Hospital Pediatrics, St. Petersburg, Russian Federation*; [3]*Republic Hospital № 1 - National Center of Medicine, Pediatric Center, Department of Cardio-Rheumatology, Yakutsk, Russian Federation*; [4]*North-Eastern Federal University (NEFU), Department of Pediatrics and Pediatric Surgery of Medical Institute NEFU, Yakutsk, Russian Federation*; [5]*Yakut Science Center of Complex Medical Problems, Laboratory of Children Health Monitoring and Medical and Environmental Research, Yakutsk, Russian Federation*

Background: Sakha Republic (Yakutia) - SR(Y) is a bid arctic region of Russia with high proportion of aboriginals - Yakutians (50%), intra-national marriages, increased level of inbreeding and high distribution of HLAB27 among aboriginals – 33%, according the epidemiological studies. The main type of arthritis is ankylosing spondylitis in adults and enthesytis-related arthritis (ERA) of juvenile idiopathic arthritis (JIA) in children. The pattern of arthritis distribution in adults and children in SR(Y) is differ from Caucasians and similar to Native Americans.

Objectives: Our study aimed to evaluate the features of JIA in aboriginals of SR(Y), associated with high prevalence of HLAB27 antigen.

Methods: In the retrospective study we included 144 Yakutians who were admitted in the rheumatology department of Yakutsk in 2007-2016 years and 753 JIA patients Caucasian origin in Saint-Petersburg in the same years. We evaluated routine clinical and laboratorial features. HLA B27 was evaluated according the clinical judgement of the attending physicians.

Results: ERA is a main JIA category in Yakutians. The main features the male predominance, higher onset age, high inflammatory activity, lower number of active joints, high incidence of hip and sacroiliac joints involvement, lower levels of psoriasis and uveitis. Yakutians have rare the involvement of cervical spine (6% vs 14%, p=0.0000001), TMJ (1% vs 6%, p=0.027), elbow (8% vs 16%, p=0.012), wrist (18% vs 28%, p=0.017), MCP (7% vs 21%, p=0.00005), PIP (8% vs 25%, p=0.00005). The treatment rates of methotrexate and biologics were similar between groups, but in Yakutians the biologics were administered earlier, because methotrexate failed and often was ineffective. The cumulative probability to receive biologics was higher in Yakutians compare to Caucasians: HR=3.4 [2.6; 4.4], p=0.000001 (Figure 1). The main biologic in Yakutians was etanercept (49/70; 70%). Yakutians received corticosteroids and cyclosporine A rarely, due to low incidence of systemic onset JIA and oligoarthritis with uveitis. It was observed, that the HLA B27 as a risk factors had different significance in Yakutians and Caucasians. HLA B27 presence increased the risk of ERA OR=2.72 (1.3; 5.6) p=0.01 in Yakutians and OR=69.2 (29.5; 162.3), p=0.00001 for Caucasians; for biologic administration: 0,86 (0,4; 1,8), p=0.529 and 2,45 (1,5; 4,0), p=0.0003, respectively.

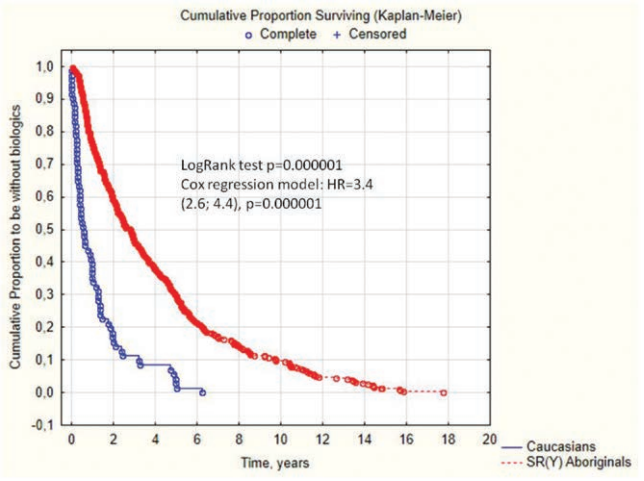

Figure 1. Cumulative probability to leave without biologics between Yakutian and Caucasian JIA patients.

Conclusion: High distribution of HLA B27 antigene in Yakutians, lead to different pattern of JIA categories distributions and patient's management.

POS1298 COMPARISON OF FMF CLINICAL FEATURES BETWEEN TURKISH AND CRIMEAN TATAR CHILDREN

O. Zhogova[1], U. Kaya Akca[2], E. Suspitsin[3,4], E. Sag[2], V. Nizhnik[3], A. Tumakova[3], S. Ivanoskiy[1], N. Lagunova[1], Y. Bilginer[2], S. Özen[2], M. Kostik[3,5]. [1]*Crimean Federal University named after V.I. Vernadsky, Pediatry, Simferopol, Russian Federation*; [2]*Hacettepe University, Department of Pediatric Rheumatology, Faculty of Medicine, Ankara, Turkey*; [3]*Saint Petersburg State Pediatric Medical University, Hospital Pediatry, Saint-Petersburg, Russian Federation*; [4]*N.N. Petrov National Research Center of Oncology, Molecular Diagnostics, Saint-Petersburg, Russian Federation*; [5]*Almazov National Medical Research Centre,*

Autoimmune and Autoinflammatory Diseases, Saint-Petersburg, Russian Federation

Background: Crimean Tatars is an ethnic group in Russia. The presence of familial Mediterranean fever (FMF) has been recognized since 2016.

Objectives: The study aimed to evaluate the prevalence and clinical features as well as genetic aspects of FMF in children of Crimean Tatar (CT) origin and compare them with a cohort from Turkey.

Methods: This retrospective study included all FMF cases in patients of CT origin (n=18) diagnosed in Children's Regional Hospital in Simferopol since 2016. We included 40 consecutive FMF cases between February-March 2020, diagnosed and followed at Hacettepe University, Ankara, Turkey. All children were less than 18 years old at the time of inclusion. The diagnosis of FMF was based on the EULAR criteria (2019). We excluded other autoinflammatory diseases and any doubtful cases. For assessment of MEFV alleles prevalence 127 healthy unrelated CT adults from different parts of Crimea peninsula were included. Sanger sequencing of MEFV exons 2 and 10 was performed in all the patients and controls.

Results: FMF in CT was diagnosed with nearly 5 year-delay, despite the earlier age at onset. CT children had more frequent and prolonged fever, joint involvement (arthritis and arthralgia) and erysipeloid rash compared to Turkish, who had more attacks with chest pain and abdominal pain which last longer. (Table 1) CT had higher white blood cell count, C-reactive protein, erythrocyte sedimentation rate and lower hemoglobin. It might be explained by the fact that the majority of Crimean Tatars were admitted to the clinic during an attack, which was not always the case with Turkish children. Distribution of MEFV pathogenic alleles p.M694V, p.M680I, p.V726A in CT children was 81%, 9.5% and 9.5%, respectively, while in Turks it was 68.6%, 14.3% and 12.9%. Among the CT patients, proportion of homozygotes, compound-heterozygotes and heterozygotes were 11%, 6% and 83%, and among Turkish patients were 45%; 30%; and 25%, respectively. MEFV pathogenic variants were detected in 10.2% of healthy CT donors: 7.1% individuals had p.M694V, 1.6% - p.M680I, 1.6% - p.V726A. Comorbid diseases including IgA vasculitis, sacroiliitis, JIA, autoimmune hepatitis and inflammatory bowel disease were reported in 5.6% of CT and 10% of Turks. The colchicine treatment rate and regimen were similar, but CT received biologics more frequently (44%) than Turks (22.5%).

Conclusion: CT is an ethnic group with a significant number of MEFV mutation carriers assuming the expected prevalence of FMF to be as high as 1:385. Thus, any periodic fever in CT patients should be considered as a sign of possible FMF. The clinical course of FMF has some peculiarities in CT patients.

POS1299 RISK FACTORS OF TOTAL HIP ARTHROPLASTY IN JUVENILE ARTHRITIS WITH HIP INVOLVEMENT

L. Sorokina[1], I. Avrusin[1], R. Raupov[1], N. Garipova[2], M. Gharabaghtsyan[3], S. Khrypov[4], E. Isupova[1], E. Gaidar[1], I. Chikova[1], M. Dubko[1], V. Masalova[1], T. Likhacheva[1], L. Snegireva[1], M. Kostik[1,5]. [1]*Saint-Petersburg State Pediatric Medical University, Department of Hospital Pediatrics, St. Petersburg, Russian Federation*; [2]*Almazov National Medical Research Centre, Pediatric Department, St. Petersburg, Russian Federation*; [3]*Institute of Child and Adolescent Health (ICAH) with the Arabkir Medical Center, Pediatric Department, Yerevan, Armenia*; [4]*Saint-Petersburg Clinical Research-Practical Center for Specialized Healthcare (Oncology), Surgical Department, St. Petersburg, Russian Federation*; [5]*Almazov National Medical Research Centre, Autoimmune and Autoinflammatory Diseases, St. Petersburg, Russian Federation*

Background: Hip osteoarthritis (HOA) is a severe outcome of juvenile idiopathic arthritis (JIA) itself and also can be result of corticosteroid (CS) treatment, if it was used. Total hip arthroplasty (THA) is the last step in JIA treatment and indicates ineffectiveness of conservative treatment.

Objectives: We aimed to evaluate risk factors which lead to THA in JIA patients with HOA.

Methods: 753 patients aged 2-17 years were included in our retrospective study during the last 10 years. Diagnosis was made according to ILAR criteria. Clinical, laboratory and radial examinations were evaluated. Diagnosis of HOA was made on MRI, CT and planar radiograms and confirmed by morphological examination of removed femoral heads.

Results: Total 153/753 (20.3%) patients with JIA had hip involvement. HOA developed in 48/153 (31.4%) of JIA patients and 16/48 (33.3%) of them had THA was undergone. Prevalence of HOA and THA (%) in JIA subtypes: in polyarticular (5/32 (15.6%) and 8/16 (50%), systemic (6/32 (18.7%) and 5/16 (31.2%)), enthesitis-related (19/32 (59.4%) and 3/16 (18.8%)) and psoriatic (2/32 (6.7%) and 0/16) subtypes respectively, p=0,0000001. Patients who underwent THA initially had higher level of inflammation: elevated ESR (33 vs 5 mm/h, p=0.002) and CRP (14.7 vs 1.9 mg/l, p=0.03), more active joint, and especially involvement of joints of upper limbs: elbows (p=0.004) and proximal interphalangeal joints (p=0.001), arthritis of subtalar joint (p=0.02). Delayed biologic treatment (7.5 vs 3.4 years, p=0.043) and delayed achievement of remission (9.2 vs 5.6 years, p=0.047) were main predictors of THA. Patients with HOA without biologics had increased cumulative probability of THA: HR=1.99 (1.01; 3.98), p=0.049 (Figure 1). Patients with THA received corticosteroids (93.7 vs 50%, p=0.003) more often including high dose pulse-therapy regimes, but differences in the cumulative doses were not observed (5000 vs 4500 mg, p=0.54) between groups, CS administration was independent risk factor of HOA and THA.

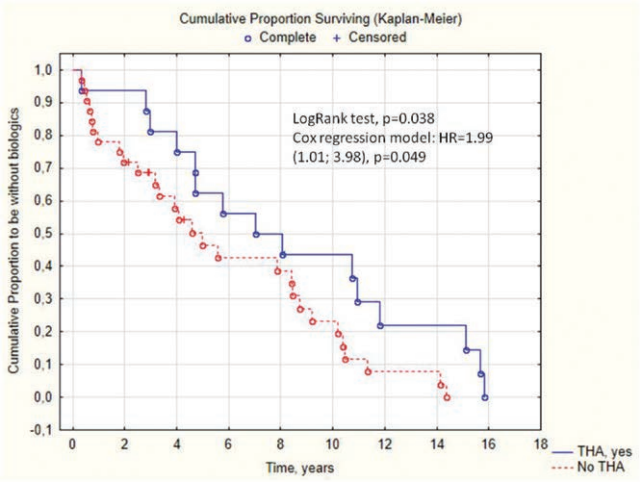

Figure 1. Cumulative probability of THA in JIA patients with hip osteoarthritis.

Conclusion: the main risk factors of THA are systemic and polyarticular course because of their activity, systemic CS and delayed biologic treatment. Corticosteroids should be avoided in those group of patients because of risk of avascular pathway HOA formation.

Background: Juvenile Idiopathic Arthritis (JIA) is the most common auto-immune disease in children and pain is a common symptom. Despite treatment advances in recent years, pain often persists when the disease is inactive. Treating JIA to target has been widely recommended[1], but effectiveness in pain reduction has not been proven yet[2].
Objectives: To compare pain scores over two years in three treatment arms in JIA patients that were treated to target and to identify baseline characteristics predicting unfavorable pain outcomes.
Methods: DMARD naïve children who participated in the BeSt for kids study[3] with oligoarticular JIA, RF negative polyarticular JIA and juvenile psoriatic arthritis were included. Patient were treated to target aimed at inactive disease according to 1 of 3 different treatment groups; 1) initial sequential DMARD monotherapy 2) initial methotrexate (MTX) with prednisolone bridging or 3) initial MTX with etanercept. Pain intensity was measured using a 100 mm Visual Analogue Scale during 24 months of follow up with 3-monthly intervals. Potential differences in VAS pain scores over time between treatment arms were compared using linear mixed models with random intercept and random slope for visits clustered within patients. A similar multivariable mixed model was used to assess the ability of several baseline characteristics to predict the chance of high pain levels during follow-up.
Results: 92 patients were randomized into the three treatment groups. Overall, pain scores over time reduced from mean 55.3 (SD 21.7) at baseline to 19.5 (SD 25.3) after 24 months. When comparing pain over time per arm, pain scores decreased significantly over time β -1.37 (95% CI -1.726; -1.022). No significant difference was found in pain over time between treatment groups (interaction term treatment arm*time (months) β (95% CI) arm 1 0.13 (-0.36; 0.62) and arm 2 0.37 (-0.12; 0.86) compared to arm 3), Figure 1. Correction for sex and symptom duration as possible confounders yielded similar results. Multiple baseline characteristics demonstrated a significant predictive value for pain over time: VAS pain (scale 0-100) with β 0.44 (95% CI 0.25; 0.65), VAS physician (scale 0-100) with β -0.34 (-0.55; -0.06), number of active joints with β 0.77 (0.19; 1.34), Child Health Questionnaire Physical summary Score with β -0.42 (-0.72; -0.11) and Psychosocial summary Score β -0.42 (-0.77; -0.06). Symptom duration, VAS patient/parent and NSAID use were no significant predictors, Table 1.
Conclusion: Treatment to target seems effective in pain reduction in non-systemic JIA patients irrespective of initial treatment strategy. Several baseline predictors for pain over time were identified, which could serve as an initial indication for non-systemic JIA-patients with a high risk of pain despite a strict treat-to-target strategy.

POS1301

DRUG SURVIVAL OF BIOLOGICS WITH RESPECT TO COMBINATION WITH METHOTREXATE IN TREATMENT OF POLYARTICULAR JIA

G. Horneff[1], D. Windschall[2], K. Minden[3], T. Hospach[4], F. Dressler[5], F. Weller-Heinemann[6], B. Huegle[7], I. Foeldvari[8], A. Klein[1]on behalf of BIKER registry. [1]*Asklepios Clinic, Paediatics, Sankt Augustin, Germany*; [2]*St. Josef Stift, Paediatric Rheumatology, Sendenhorst, Germany*; [3]*Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology, Berlin, Germany*; [4]*Klinikum Stuttgart - Olga Hospital / Women's Hospital, Paediatrics, Stuttgart, Germany*; [5]*MHH Kinderklinik Station 61b, Paediatrics, Hannover, Germany*; [6]*Prof Hess Childrens Hospital, Paediatrics, Bremen, Germany*; [7]*Deutsche Zentrum, Kinder- und Jugendrheumatologie, Garmisch-Partenkirchen, Germany*; [8]*Zentrum, Kinderheumatologie, Hamburg, Germany*

Background: In polyarticular juvenile idiopathic arthritis (pJIA) biologic therapies are often combined with methotrexate (MTX). This combination was shown to increase efficacy in adult rheumatoid arthritis patients. MTX may also have a protective effect on the formation of anti-drug antibodies and thus may prolong drug survival. In pJIA, there are few and sometimes controversial data available.
Objectives: To compare the effect of combination treatment with MTX on discontinuation due to inefficacy and on drug survival discontinuation of biologics approved for first line treatment of pJIA.
Methods: Patients from the German BIKER registry with their first treatment course with Adalimumab, Etanercept, Golimumab or Tocilizumab were selected. Rates of ineffectiveness-related withdrawal were analysed and compared using $\chi 2$-test, Wald-test and Kaplan-Meier analysis of patients receiving biologic monotherapy or concomitant methotrexate. Cases were censored if MTX was discontinued before the biologic.
Results: 2173 pJIA patients were identified who for the first time received a biologic. Etanercept (ETA) was by far the most frequently used biologic for first line biologic treatment in pJIA (77%) followed by Adalimumab (ADA, 16%). Patients on Golimumab (GOL) received most frequently a combination with MTX (86.5%), while patients on Tocilizumab (TOC) had the lowest rate of combination treatment (53%).
ETA/ADA/GOL/TOC was given as monotherapy in 500(30%)/89(26%)/5(13.5%)/46(47%) and combined with MTX in 1179 (70%)/259(74%)/32(86.5%)/51(53

%) cases. More patients with rheumatoid-factor negative (54 vs 50%; p=0.04) and rheumatoid-factor positive pJIA (13 vs 10%, p=0.04) received combination with MTX, while more patients in the monotherapy cohort had extended oligoarthritis (40 vs 32%, p<0.001). Patients with MTX had a shorter disease duration (4 vs 5.5years, p<0.001) and received concomitant steroid more often (34 vs 24%), p<0.001). There was no statistical difference regarding disease activity parameters (active joint count, patient assessment and physician assessment of disease activity, ESR, CRP, CHAQ-DI, JADAS10). Discontinuation due to ineffectiveness was reported for ETA/ADA/GOL/TOC in 20%/18%/14%/28% of patients, respectively in 3.7/4.9/6/10.5 patients/100 treatment years. Thus discontinuation due to inefficacy was reported less frequently with ETA compared to ADA (p=0.046) and TOC (p<0.001) and with ADA compared to TOC (p<0.001).

Patients on ETA and ADA had a slightly, but not statistically significant lower rate of withdrawal for ineffectiveness if on methotrexate (Figure 1). There was no difference regarding baseline disease activity parameters in patients with ETA/ADA monotherapy compared with combination with MTX, apart from patients with ETA+MTX receiving more often systemic steroids at baseline (36vs 24%,p<0-001). For both GOL and TOC treatment, no baseline differences in disease activity between cohorts with monotherapy and MTX combination could be shown. The combination with MTX led to significantly lower rates of discontinuation due to inefficacy (p<0.05) with GOL and TOC (Figure 1).

Conclusion: Patients with pJIA mostly were treated with a combination of the biologic and MTX rather than with biologic monotherapy. Treatment was discontinued due to lack of efficacy in 14% to 28%. No statistically significant effect of combination treatment with MTX versus monotherapy could be observed regarding the rate of treatment failures in patients treated with ETA or ADA. However, combination treatment with MTX significantly prolonged the survival of GOL and TOC in patients with polyarticular JIA. The results are limited by low patient numbers in the GOL cohort and possible bias by JIA category.

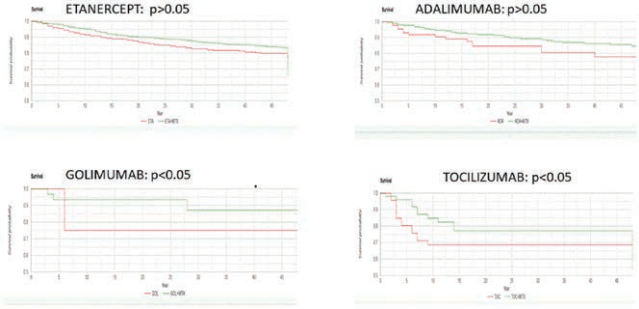

Figure 1. Kaplan Meier plot of drug survival in patients with monotherapy or with combination with MTX of the indicated biologic

POS1302 THE MUSCULOSKELETAL SYSTEM MANIFESTATIONS IN CHILDREN WITH FAMILIAL MEDITERRANEAN FEVER

F. Demir[1], S. Canbek[2], B. Sözeri[1]. [1]*Health Sciences University, Umraniye Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey*; [2]*Health Sciences University, Umraniye Training and Research Hospital, Medical Genetics, Istanbul, Turkey*

Background: Familial Mediterranean fever (FMF) is a monogenic inherited periodic fever syndrome presenting with episodes of self-limiting fever and inflammation of serosal membranes. The attacks emerge with arthritis were defined as one of the major diagnostic criteria besides involvement of serosal membranes. Non-specific musculoskeletal findings such as myalgia, arthralgia, transient synovitis, and more rare manifestations like protracted febrile myalgia can also be seen in FMF patients attacks

Objectives: We aim to reveal the frequency and genotype association of musculoskeletal manifestations in children with FMF.

Methods: The patients diagnosed with FMF between January 1, 2017 and June 1, 2019, and followed for at least 6 months in our pediatric rheumatology clinic were included in the study. Musculoskeletal manifestations of patients were enrolled. The patients were grouped according to the "Mediterranean Fever" (MEFV) gene variants. Musculoskeletal manifestations of the patients were compared between the groups

Results: The study group included 634 children with FMF (336 female and 298 male, F/M: 1.13/1). The clinical manifestations of patients in attack period were as follows: 99% of the patients had fever, 87.3% had abdominal pain, 20.7% had chest pain, 11.3% had vomiting, 10.7% had erysipelas like erythema, and 9.3% had headache. The musculoskeletal symptoms were accompanied by 58.6% (n: 372) of the patients during the attack period. The most common musculoskeletal manifestation was found as arthralgia (32.6%, n: 206). Also, the other musculosceletal manifestations were found as follows during attacks; arthritis in 23.7% (n: 150), myalgia in 20.5% (n: 130), exertional calf pain in 6.5% (n: 41), and protracted febrile myalgia in 1% (n: 7) of the patients. It was observed that the musculoskeletal manifestations were significantly higher in patients with homozygous M694V variant in exon-10 (p=0.017). Also, it was found that the musculoskeletal manifestations are more common in the attack periods of patients carrying the M694V variant in at least one allele (p = 0.019).

Conclusion: It was determined that the musculoskeletal manifestations were seen as an attack symptom in more than half of FMF patients. Also, homozygous and compound heterozygous *MEFV* mutations including M694V variant found as a risk factor for emerge of musculoskeletal manifestations. In children with unexplained and recurrent musculoskeletal symptoms, especially in ethnicities with the high frequency of FMF, analysis of *MEFV* gene can help reveal the underlying cause.

POS1303 EXPERIENCE WITH ADALIMUMAB BIOSIMILAR USE IN CLINICAL PRACTICE: DATA FROM THE GERMAN BIKER-REGISTRY

G. Horneff[1], F. Dressler[2], M. Rühlmann[3], T. Geikowski[4], S. Mrusek[5], A. Klein[1]. [1]*Asklepios Clinic Sankt Augustin, General Paediatrics, Sankt Augustin, Germany*; [2]*MHH, Paediatrics, Hannover, Germany*; [3]*Office, Paedaitrics, Goettingen, Germany*; [4]*Office, Paediatrics, Bad Honnef, Germany*; [5]*Office, Paediatrics, Baden-Baden, Germany*

Background: In 2017, Adalimumab Biosimilars became approved. Comparative studies to the originator have been performed in adult patients with rheumatoid arthritis, ankylosing spondylitis and psoriasis and extrapolation led to approval for juvenile idiopathic arthritis (JIA).

Objectives: So far there is limited experience with biosimilars in JIA: The large national data base of the BIKER-registry was used to describe experience with Adalimumab biosimilars in clinical practice

Methods: This retrospective analysis used data of the German BIKER-registry. The data basis war screened for patients exposed to Adalimumab. Subcohorts with initiation of treatment after 2017, use of the originator and of biosimilars were built. The course of JADAS10, Physician global assessment VAS 0–100-mm, Parent/patient global assessment VAS 0–100-cm, Active joint count 0-71, truncated at 10, ESR and CHAQ-DI was analyzed. Descriptive statistics was used for demographic, clinical data, drug exposure, adverse events (AEs) and events of special interest (ESI).

Results: Until 31.10.2020, 1173 JIA patients were reported to have received Adalimumab. 352 treatments have been started after January 1, 2017. A biosimilar was used first line in 44 patients. Further 55 patients switched for the originator to a biosimilar. 2 patient switched from a biosimilar to the originator. 3 patients switched to a second biosimilar while 5 patients who switched from the originator to a biosimilar reswitched back to the originator.

After 2017, 33 pediatric rheumatology centres reported initiation of Adalimumab treatment. 17 have used a biosimilar. 15 centres have swichted at least 1 patient from the originator to a biosimilar and 14 have used first line a biosimilar in at least 1 patient. In a single centre, initiation of a biosimilar was used more frequently (8 versus 7).

The patients' characteristics and disease activity parameters were brightly comparable. The JIA category rheumatoid factor (RF) negative polyarthritis was less frequent in the biosimilar first cohort while RF positive polyarthritis and psoriatic arthritis was more frequent. In patients with idiopathic uveitis the originator was used more often. In the switching cohort, more patients had RF negative polyarthritis, persistent oligoarthritis but less had psoriatic arthritis and no had RF positive polyarthritis.

No difference in disease activity parameters between patients receiving the originator or biosimilars were noted, neither at baseline, during the course of treatment nor at last observation upon treatment (Figure 1). At the time of switching, 46 (92%) had JADAS minimal disease activity (MDA) and 30 (69%) were in JASDAS remission. At last observation, those numbers were comparable with 42 (86%) with JADAS MDA and 28 (57%) with JADAS remission.
In total, 45 adverse events (AE) were reported in 45 patients upon biosimilar treatment. 26 patients had 1, 12 patients had 2 and 6 patients reported 3 and 1 reported 4 events. Adverse event of special interest were Infection associated leukopenia (n=1), COVID 19 infection (n=1), Uveitis flare (n=8), other disease deterioration (arthritis flare) (n=20), injection site reaction n=2. A single serious AE was reported. A 16 year old female adolescent was admitted for unexpected CK elevation. In 10 patients, Adalimumab was discontinued, in 2 it was temporarily paused.
Conclusion: This article is the first attempt to present a large sample of data on JIA patients exposed to Adalimumab biosimilars. Since approval of Adalimumab-Biosimilars, limited experience from clinical practice is available. Biosimilars are used in a minority of patients and by a minority of centers although no difference in efficacy or safety was noted from our analysis.

Opsahl Hetlevik[3], Y. Uziel[3], N. Helmus[1]. *[1]Hamburg Centre for Pediatric and Adolescence Rheumatology, Schön Klinik Hamburg Eilbek, Hamburg, Germany*; *[2]German Rheumatism Research Center, German Rheumatism Research Center, Berlin, Germany*; *[3]JSSC Collaborative Group, Hamburg Centre for Pediatric and Adolescence Rheumatology, Hamburg, Germany*

Background: Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence of around 3 in 1, 000,000 children. It is known that in pediatric jSSc cohorts, there are a significant number of patients with overlap features, such as arthritis and myositis. However, the disease burden between those with and without overlap features in jSSc has not been defined.
Objectives: Compare the clinical phenotype between children with and without overlap features in the juvenile systemic scleroderma inception cohort (jSScC).
Methods: A cross-sectional study was performed using baseline visit data. Demographic, organ system evaluation, autoantibody profile, treatment, and patient and physician reported outcome variables were extracted from jSScC. Comparison between patients with and without overlap features was performed using chi-square test and Mann Whitney U-test.
Results: At the time of data extraction, 175 jSSc patients were enrolled in the cohort, 81% were Caucasian and 81% female. Mean disease duration was 3.1 year (±2.7). Mean age at Raynaud´s onset was 10 years (±3.8) and mean age of first non-Raynaud´s was 10.2 years (±3.8). Overlap features occurred 17% (n=30) of the cohort, 12.5% in the diffuse cutaneous (dc) jSSc and in 30% in the limited cutaneous (lc) jSSc. Significant differences in clinical characteristics were found between those patients with compared to without overlap characteristics. Patients with overlap features presented more frequently with Gottron papules (p=0.007), swollen joints (p=0.019), muscle weakness (p=0.003), and lung involvement documented by decreased DLCO < 80% (p=0.06) and/or abnormal high resolution computed tomography (p=0.049). Anti-PM/Scl autoantibodies were also more common in this group (p=0.001). Significantly more patients without overlap features had Raynaud´s (p=0.006). Physician Global Assessment of disease activity was significantly higher in patients with overlap features (41 vs 34; p=0.041). (Table 1.)

Table 1. Demographic and clinical characteristics of jSSc patients with and without overlap features.

	Whole Cohort N=175	Patients without overlap N=145	Patients with overlap N=30	P value
Female to Male Ratio	4.3:1 (142/33)	4:1 (116/29)	6.5:1 (26/4)	0.395
Cutaneous subtype				
Diffuse subtype (N)	73% (128)	112	16	
Limited subtype (N)	27% (47)	33	17	
Mean disease duration (years)	3.1 (± 2.7)	3.2 (± 2.8)	3.1 (± 2.2)	0.291
Mean age of onset of Raynaud´s (years)	10.0 (± 3.8) 17 non-Raynaud	10.0 (± 3.8) 10 non-Raynaud	10.0 (± 3.7) 7 non-Raynaud	0.931
Mean age of onset of non-Raynaud´s (years)	10.2 (± 3.8)	10.2 (± 3.9)	9.8 (± 3.7)	
Disease modifying drugs (N)	88% (154)	89% (129)	83% (25)	0.388
Raynaud´s phenomenon	90% (158)	93% (135)	77% (23)	0.006
Anti-PMScl	18% (12/68)	9% (5/53)	47% (7/15)	0.001
Gottron Papules (N)	27% (46/171)	23% (33/144)	48% (13/27)	0.007
DLCO <80% (N)	44% (39/88)	39% (28/71)	65% (11/17)	0.06
Abnormal findings in HRCT (N)	44% (59/133)	40% (43/107)	62% (16/26)	0.049
Proportion of patients with swollen joints	18% (32)	14% (21)	37% (11)	0.019
Muscle Weakness (N)	21% (31/149)	16% (20/123)	42% (11/26)	0.003
Physician global disease activity (0-100) min -max	35 (0-90) n=141	34 (0-90) n=114	41 (0-80) n=27	0.041

Conclusion: Results from this large international cohort of jSSc patients demonstrate significant differences between patients with and without overlap features. Patients with overlap have significantly more interstitial lung disease and more physician rated disease activity and should not be considered to have more "mild disease".

POS1305 TREATMENT RESPONSE TO TUMOR NECROSIS FACTOR INHIBITORS IN ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS: DATA FROM THE NOR-DMARD STUDY

I. Bardan[1], K. M. Fagerli[2], J. Sexton[2], G. Bakland[3], P. Mielnik[4], L. M. Paucar Loli[5], T. K. Kvien[1,2], E. Kristianslund[2], A. B. Aga[2,6]. *[1]University of Oslo, Faculty of Medicine, Oslo, Norway*; *[2]Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*; *[3]University Hospital Northern Norway, Department of Rheumatology, Oslo, Norway*; *[4]Helse Førde, Section for Rheumatology, Department for Neurology, Rheumatology and Physical Medicine, Førde, Norway*; *[5]Lillehammer Hospital for Rheumatic Diseases, Department of Rheumatology, Lillehammer, Norway*; *[6]Oslo University Hospital, Department of Rheumatology, Oslo, Norway*

Background: Juvenile idiopathic arthritis (JIA) can cause considerable pain and disability in childhood and adulthood. Studies exploring the efficacy of medications in adult JIA patients are limited, although tumor necrosis factor inhibitors (TNFi) have been increasingly used in this patient group.
Objectives: To explore the efficacy of TNFi ± comedication on disease activity in adult JIA patients, compared to a weighted rheumatoid arthritis (RA) cohort.
Methods: Data from NOR-DMARD, a longitudinal observational study including patients > 18 years starting or switching DMARD treatment, was used [1]. Patients with a clinical JIA diagnosis, or patients with other inflammatory joint diseases diagnosed before 16 years were identified from the study population. RA patients were included for comparative purposes.
Disease activity measurements and remission rates among patients starting treatment with TNFi ± comedication were collected at baseline, 3 and 6 months.

Changes in disease activity and absolute remission rates after 3 and 6 months were calculated. Remission rates and change in disease activity from baseline were compared between JIA patients and a weighted RA cohort with weights based on age and gender, using linear and logistic regression for continuous and categorical variables, respectively.

Results: 281 JIA patients (68.9% female, mean (SD) age 32.1 (11.1) years, mean (SD) diagnosis duration 23.5 (12.2) years) and 1374 RA patients (71.6% female, mean (SD) age 52.7 (14.5) years, mean (SD) diagnosis duration 9.5 (10.0) years) were included in the analyses. Age, gender distribution and disease duration differed significantly between cohorts.

Both groups had a significant improvement across all disease activity measures after 3 months (Table 1), which was maintained after 6 months across all measures except MHAQ. The RA group had a significantly greater 3- and 6-month improvement in SJC28. Both groups had an overall 6-month increase in absolute remission rates. The JIA group had a significantly higher 3-month DAS28 remission rate (Figure 1). This difference was not significant after 6 months, as remission rates from 3 to 6 months in the JIA group declined across all measures.

Table 1.

	Baseline			Change to 3 months			Change to 6 months		
	JIA*	RA*	Diff.§	JIA*	RA*	Diff.§	JIA*	RA*	Diff.§

*Mean (SD)§ Weighted group difference, RA coefficient (95 % confidence interval)

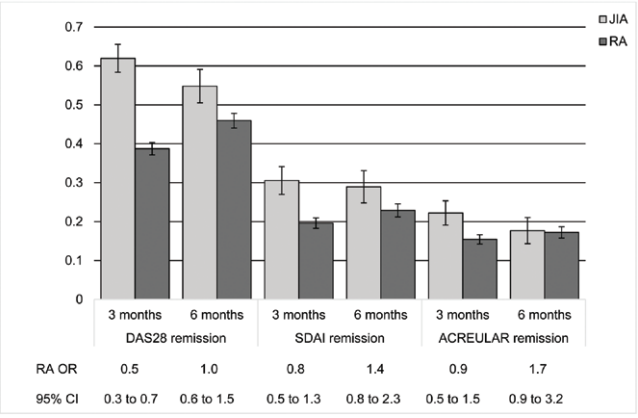

Figure 1. Mean 3- and 6-month remission rates with error bars (SE)

Conclusion: TNFi was equally effective in reducing disease activity in the JIA and RA cohort after 3 and 6 months, and in inducing remission after 6 months. Absolute remission rates in the JIA group declined from 3 to 6 months across all measures, and studies with longer duration are needed to explore the long-term efficacy of TNFi in the patient groups.

POS1306 TREATMENT STRATEGIES IN CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS (CMRO) OR CHRONIC NON-BACTERIAL OSTEOMYELITIS (CNO): SYSTEMATIC REVIEW AND META-ANALYSIS

R. Dos-Santos[1], C. Gomez-Vieites[1], D. Fernández Fernández[1], I. González Fernández[1], A. Souto Vilas[1], E. Perez-Pampín[1], A. Mera Varela[1]. [1]*Clinical University Hospital in Santiago de Compostela, Rheumatology Department, Santiago de Compostela, Spain*

Background: Glucocorticoids (GC), bisphosphonates (BP), non-steroidal anti-inflammatory drugs (NSAID) and classical synthetic or biological disease-modifying antirheumatic drugs (cs/bDMARD) have been employed in the treatment of chronic recurrent multifocal osteomyelitis (CRMO) or chronic non-bacterial osteomyelitis (CNO).[1, 2] This one is a rare bone childhood illness and none treatment guidelines have been carried out till present.[3]

Objectives: To asses which treatment schedule employed in CRMO had the best response rates and try to expose a treatment recommendation.

Methods: A systematic literature review was made using Medline, Embase, Cochrane library and the Web of Science databases. The search strategy focused on synonyms of CRMO. A prevalence meta-analysis was performed to evaluate each treatment response. Stata 15.1 was used to perform statistical analysis.

Results: The search identified 1883 articles, of which 43 were finally selected. Complete response rate reached with NSAIDs was acceptable [50% (CI95% 40-60)]. Lower response rates were reached by GC treatment [44% (CI95% 25-63)] or csDMARD [38% (CI95% 28-48)]. The best complete response rates were reached by bDMARD and BP treatments [69% (CI95% 56-82) and 73% (CI95% 62-84), respectively].

Conclusion: This review and meta-analysis supports, taking into account its remission rates and its risk-benefit profile, NSAIDs as potential first-line agents in CRMO treatment. bDMARD and BP have reached the higher remission rates, turning into helpful treatment alternatives. There is not any treatment guidelines driving CRMO patients, but this analysis could help to select a suitable agent for each patient. Decision-making should be individualized.

POS1307 ULTRASOUND-DETECTED TENOSYNOVITIS IN ANKLES WITH CLINICALLY ACTIVE DISEASE OF CHILDREN WITH NEW-ONSET JUVENILE IDIOPATHIC ARTHRITIS DOES NOT AFFECT THE CHANCE TO ACHIEVE DISEASE REMISSION

S. Lanni[1], O. De Lucia[2], S. Orsi[1], S. Costi[2,3], G. Beretta[1], T. Giani[4,5], G. Filocamo[1], C. V. Agostoni[1,3], R. Pini-CTO, Milano, Italy, Department of Rheumatology and Medical Sciences, Milano, Italy*

Background: The ankle is one of the most commonly affected sites in juvenile idiopathic arthritis (JIA). This region has a complex anatomical structure owing to the presence of multiple joint recesses and surrounding tendons. While the prognostic value of ultrasound (US)-detected arthritis has been investigated in recent studies, the role of tenosynovitis in JIA remains still unexplored.
Objectives: To investigate: 1) US features of ankle involvement in JIA at disease onset; 2) the predictive value of US-detected tenosynovitis in ankles with clinically active disease of children with new-onset JIA.
Methods: The clinical charts of all consecutive patients with new-onset JIA between May 2018 and January 2020 at study centres (Policlinico and G.Pini Hospitals of Milan) and with clinically active ankle disease among the joints affected were reviewed retrospectively. Data on ankle US assessment were retrieved and patients were then stratified as follows: 1) patients with detection on US of isolated arthritis in at least one of the joint recesses of the ankle region; 2) patients with detection on US of tenosynovitis in at least one of the tendon compartments of the ankle irrespective of the presence of concomitant arthritis. For each of these two categories, estimation of patients who were able to achieve clinical disease remission at 12 months since disease onset was evaluated.
Results: Twenty-seven new-onset JIA patients were found to have clinical involvement of the ankle among the joints affected. Nine of them (33.3%) showed on US isolated arthritis of the ankle, whereas US-detected tenosynovitis was found in 18 (66.7%) patients. The amount of patients who were able to achieve disease remission at 12-months was the same (66.7%) for both patients with and without US-detected tenosynovitis in the ankle (12/18 and 6/9 patients, respectively). In patients with US-detected tenosynovitis and clinical disease remission at 12 months, the lateral tendon compartment (LTC) was the tendon site more frequently affected by pathology (75.0%). Patients with US-detected tenosynovitis that did not achieve clinical disease remission at follow-up had the highest frequency of tendon pathology on US in the medial tendon compartment (MTC) (83.3%). The anterior tendon compartment was the less frequently affected tendon compartment of the ankle in all patients (33.3% in both patients with and without clinical remission of disease at the 12-months follow-up visit).
Conclusion: US-detected tenosynovitis of the ankle is a common finding in patients with new-onset JIA with clinically ankle disease activity and is more frequent than the detection on US of isolated arthritis. The MTC and LTC are the tendon compartments more commonly affected on US. The detection on US of tenosynovitis at disease onset in ankles with clinical disease activity did not seem to affect the change to achieve the overall clinical disease remission compared to patients without tendon pathology but with joint disease in the ankle region.

POS1308 PREDICTORS OF DISEASE PROGRESSION IN A MONOCENTRIC COHORT OF 100 PATIENTS WITH CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

C. Chighizola[1,2], I. Pontikaki[2], S. Costi[1,2], G. Armentaro[1,2], M. Gattinara[2], T. Giani[3], R. Cimaz[1,2,4]. [1]*University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*; [2]*ASST G. Pini & CTO, Pediatric Rheumatology Unit, Milan, Italy*; [3]*Azienda Ospedaliero Universitaria Meyer, Rheumatology, Florence, Italy*; [4]*University of Milan, RECAP_RD, Milan, Italy*

Background: Childhood-onset systemic lupus erythematosus (cSLE) accounts for 10-20% of overall cases, usually presenting in early adolescence. SLE in children is characterized by a severe clinical course.
Objectives: This study describes the evolution of clinical manifestations of cSLE, with the aims of i) identifying biomarkers predictive of disease progression and ii) assessing the effects of treatment on disease course.
Methods: Laboratory and clinical data of cSLE patients followed in our Paediatric Rheumatology Unit were retrospectively collected at diagnosis and during follow-up. Continuous data were expressed as median (interquartile range [IQR]) and categorical data as percentages. The association between categorical variables was assessed by chi-squared test, the correlation between variables was tested by Pearson's test. Univariate linear regression analyses were performed to investigate the relationship between the rate of new disease manifestations at follow-up and candidate predictors. Statistical analysis was performed using GraphPadPrism v6. P values <0.05 were regarded statistically significant.
Results: One-hundred patients (89% of female gender) with cSLE were included in this study, with a median age at disease onset of 13 years (10.5-15). Clinical details are presented in Table 1. Complement levels were reduced in 71 patients (C3 in 62 and C4 in 65). At a median follow-up of 118 months (57-239), the disease progressed in 93 patients, with a median of two new manifestations per patient (1-3). No correlation emerged between the number of new disease manifestations and both age at diagnosis and disease duration. Among serological biomarkers, a reduction in complement fractions at diagnosis emerged as the only predictor of new clinical manifestations due to cSLE (p=0.013 for low C3 and p=0.0004 for low C4). Among the several different pharmacological tools, hydroxychloroquine (HCQ, p=0.021, 95% confidence interval (CI) 0.0084-0.1007), azathioprine (AZA, p=0.0217, 95%CI 0.013-0.1703) and cyclophosphamide (CTX, p=0.0305, 95%CI 0.013-0.170) were identified as protective.
At follow-up, patients most commonly developed new haematological and cutaneous involvements, which were diagnosed in 43 and 11 patients, respectively. A trend towards statistical significance emerged for low C4 levels to predict new haematological involvement at follow-up (p=0.064, chi-squared: 3.42). Differently, positivity for antibodies against dsDNA emerged as the only predictor of the onset of cutaneous manifestations during follow-up (p=0.022, chi-squared: 7.62). Low C3 levels approached statistical significance in the prediction of skin involvement (p=0.058, chi-squared 5.68).
Conclusion: According to the data from our monocentric cohort of 100 patients, complement and anti-dsDNA antibodies are the most accurate tools to predict disease progression in cSLE. HCQ, AZA and CTX reduce the rate of disease progression.

POS1309 PREVALENCE AND CORRELATES OF UNDERWEIGHT, OVERWEIGHT AND OBESITY AMONG PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA): EVIDENCE FROM THE NATIONAL PAEDIATRIC RHEUMATOLOGIC DATABASE (NPRD)

F. Milatz[1], J. Klotsche[1], M. Niewerth[1], J. Hörstermann[1], D. Windschall[2], F. Weller-Heinemann[3], F. Dressler[4], R. Berendes[5], J. P. Haas[6], G. Horneff[7,8], K. Minden[1,9]. Medicine Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany

Background: In patients with JIA, growth impairment and variance in body composition are well-known long-term complications that may be associated with prolonged drug therapy (e.g. glucocorticoids) as well as impaired physical and psychosocial well-being. An increased accumulation of body fat represents a significant risk factor for metabolic abnormalities and a modifiable variable for a number of comorbidities. Recently, evidence has emerged in favour of the potential negative influence of overweight on the course of the disease and treatment response [1].

Objectives: The study aimed a) to estimate the prevalence of underweight, overweight and obesity in children and adolescents with JIA compared to the general population, and b) to investigate correlates of patients' weight status.

Methods: A cross-sectional analysis of physicians' recorded body weights and heights of patients with JIA enrolled in the NPRD in the year 2019 was performed. Underweight (BMI <10th), overweight (BMI >90th) and obesity (BMI >97th) were defined according to age- and sex-specific percentiles used in the German reference system. For comparison with data from the general population [2], sex- and age-matched pairs of 3-17-year-old patients and controls were generated. A multinomial logistic regression analysis was performed to examine the association between weight status and patients' clinical and self-reported outcomes.

Results: In total, data from 6.515 children and adolescents with JIA (age 11.2 ± 4.1 years, disease duration 4.9 ± 3.8 years, 67% girls, 40% persistent oligoarthritis) were included. Of these, 3.334 (age 5.9 ± 2.1 years, 52.5% girls) could be considered for matched-pair analysis. Compared with the general population, patients underweight, overweight and obesity rates were 10.6% (vs. 8.1%), 8.8% (vs. 8.5%) and 6.1% (vs. 5.7%), respectively. No significant sex differences were found in either group. Largest difference in prevalence was registered for underweight, specifically in the age group 3-6 years (12.9% patients vs. 5.9% controls). Similar to the general population, higher rates of overweight were observed in adolescent patients than in affected children (19.1% age group 11-13 vs. 8.4% age group 3-6). While the highest underweight prevalence was registered in patients with RF+ polyarthritis (16%), patients with Enthesitis-related arthritis (22%), psoriatic arthritis (21%) and systemic JIA (20%) showed the highest overweight rates (including obesity). Younger age (OR = 0.51, 95% CI = 0.31-0.83), more frequent physical activity (OR = 0.92, 95% CI = 0.85-0.99) and high parental vocational education (OR = 0.39, 95% CI = 0.18-0.80) were independently associated with a lower likelihood of being overweight/obese.

Conclusion: The overall prevalence of underweight, overweight and obesity in children and adolescents with JIA is comparable to that found in the general population. Behavioural health promotion, including regular physical activity, as part of the treatment strategy in JIA should preventively already begin at preschool age and necessarily be made accessible to patients of all educational levels.

POS1310 CANAKINUMAB IS A RESCUE TREATMENT FOR MACROPHAGE ACTIVATION SYNDROME IN PATIENTS WITH SYSTEMIC ONSET JUVENILE IDIOPATHIC ARTHRITIS: SINGLE CENTER EXPERIENCE

M. Kostik[1], E. Isupova[1], I. Chikova[1], T. Likhacheva[1], V. Masalova[1], L. Snegireva[1], M. Dubko[1], E. Gaidar[1], M. Kaneva[1], T. Kornishina[1], O. Kalashnikova[1], V. Chasnyk[1]. *[1]Saint Petersburg State Pediatric Medical University, Hospital Pediatry, Saint-Petersburg, Russian Federation*

Background: Macrophage activation syndrome (MAS) is a severe life-threatening complication of the systemic-onset juvenile idiopathic arthritis (soJIA). The treatment options included high-dose of the corticosteroids (CS), cyclosporine A (CsA), intravenous immunoglobulin (IVIG) and biologics, predominantly IL-1 antagonist – anakinra. In Russia anakinra has not approved yet, so canakinumab (CAN) is a single anti-IL-1 option, available in Russia.

Objectives: To evaluate the safety and efficacy of canakinumab in patients with severe MAS in soJIA, who failed the previous treatment.

Methods: In the retrospective case series study were included 9 soJIA patients (4 boys and 5 girls) with severe MAS, resistant to combination of high-dose CS, IVIG and CsA.

Results: All patients had a MAS during the onset of JIA. The main clinical features of disease onset included: fever 9 (100%), active arthritis 5 (56%), pleuritis 7 (78%), pericarditis – 5 (56%), peritonitis 2 (22%), rash 6 (67%), hepatomegaly 9 (100%), splenomegaly 9 (100%), lymphadenopathy 7 (78%), bleeding 4 (44%), CNS involvement – 3 (33%). Initial treatment included high doses CS 8 (89%), oral CS 9 (100%), methotrexate 5 (56%), tocilizumab 4 (44%), and canakinumab 5 (56%), CsA 4 (44%), IVIG 6 (67%). TCZ was discontinued due to infusion reaction (n=2), TCZ inefficacy (n=3) and presence of MAS in all patients (n=5). In children whom TCZ was switched on CAN we used the standard dose of CAN 4 mg/kg, but if MAS occurred on the CAN we temporally increased the doses since 8 to 25 mg/kg (300 mg). In all cases MAS episodes were successfully resolved during CAN treatment. In 5 (56%) MAS had repeated course during the CAN which lead to temporally increasing the doses of CAN (pt3, pt5, pt8, pt 9) or required to increase immunosupression with abatacept or tofacitinib. Three patients with repeated MAS developed interstitial lung disease (ILD). Two patients who successfully resolved MAS after CAN had relapses of arthritis and switched CAN to TCZ.

ID	Sex	JIA onset, y	Repeated MAS	Initial bio-logic	MAS on CAN	Experience of increased CAN doses	Outcomes	Current treatment
1	F	7.7	N	TCZ	N	N	Remission	CAN
2	F	11.5	N	CAN	N	N	soJIA flare, ILD	TCZ
3	F	7.9	Y	CAN	Y	Y	Remission	CAN
4	F	3.4	N	TCZ	N	Y	Remission, ILD	CAN, CS, MMF
5	M	0.8	Y	TCZ	Y	Y	Remission, ILD	CAN, abatacept, CsA, CS
6	M	14.2	Y	CAN	N	N	Remission	TCZ
7	M	1.1	Y	CAN	N	N	Remission	N
8	M	1.3	N	CAN	Y	Y	Remission	CAN every 12 months
9	F	9.1	N	TCZ	Y	Y	Minimal disease activity	CAN, tofacitinib

Footnotes: CAN – canakinumab, CS – corticosteroids, CsA – cyclosporine A, ID – identification, ILD – interstitial lung disease, F – females, M – males, N- no, TCZ – tocilizumab, Y – yes.

Conclusion: Canakinumab is an effective rescue treatment either soJIA either MAS. In patients with MAS developed on CAN required the temporal increasing of the doses.

POS1311 SCLERODERMA PATTERN IN NAILFOLD CAPILLARIES OF (CHILDHOOD-ONSET) SYSTEMIC LUPUS ERYTHEMATOSUS: LESSONS FROM LONGITUDINAL FOLLOW-UP

D. Schonenberg-Meinema[1], S. Bergkamp[1], A. Nassar-Sheikh Rashid[1], M. Gruppen[1], A. E. Hak[2], P. C. E. Hissink Muller[3], M. Middelkamp[4], M. Van Onna[2], T. Kuijpers[5], V. Smith[6], J. M. Van den Berg[1]on behalf of EULAR study group on Microcirculation in Rheumatic Diseases. *[1]Amsterdam UMC, locatie AMC, Pediatric Immunology, Rheumatology and Infectious Diseases, Amsterdam, Netherlands*; *[2]Amsterdam UMC, locatie AMC, Amsterdam Rheumatology and Immunology Centre, Department of Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[3]Leiden University Medical Center (LUMC), Department of Pediatric Rheumatology, Leiden, Netherlands*; *[4]Amsterdam UMC, locatie AMC, Department of Dermatology, Amsterdam, Netherlands*; *[5]Amsterdam UMC, locatie AMC, Department of Pediatric Immunology, Rheumatology and Infectious diseases, Amsterdam,*

Netherlands; [6]*Ghent University Hospital, Department of Rheumatology, Gent, Belgium*

Background: It has been suggested that a capillary scleroderma pattern in patients with systemic lupus erythematosus (SLE)-patients predisposes for clinical signs of systemic sclerosis (SSc) or overlap disease (1). However, this was previously shown not to be the case in a cross-sectional study in childhood-onset SLE (cSLE) (2).
Objectives: To assess if nailfold capillary patterns in cSLE change over time and if a capillary scleroderma pattern is associated with prospective development of clinical SSc-features, higher SLE disease activity or –damage.
Methods: Prospective clinical and capillaroscopy data were used from a longitudinal cohort of cSLE patients. Patients with a disease onset before the age of 18 years and diagnosis according to SLICC 2012 criteria were included. Disease activity was defined by SLEDAI score and disease damage by the SLICC damage index. Nailfold images from eight fingers (excluding thumbs) were obtained by videocapillaroscopy. A scleroderma pattern was defined according to the 'fast track algorithm' (3). An abnormal capillary pattern that did not match the criteria for a scleroderma pattern was defined as 'microangiopathy'.
Results: Our longitudinal study cohort consisted of n=53 cSLE patients with a median disease onset of 14 years (IQR 12.5-15.5 years) and a median SLEDAI score at diagnosis of 11 (IQR 8-15.5). Clinical follow-up data were available from 0.5-16 years after disease onset. Median disease duration at first capillaroscopy was 17 months (IQR 5.5-51.5 months) and 17/53 (32.1%) of patients had Raynaud's phenomenon. In total, n=9 (17%) showed a scleroderma pattern (at some point in time), n=37 (70%) had microangiopathy and n=7 (13%) showed a normal capillary pattern. N=27 patients had follow up with capillaroscopy (1-7 times over 1-5 years). In most patients (23/27) we did not observe any change in capillary pattern during follow-up. Two patients showed changes from microangiopathy to a scleroderma pattern, one patient from a scleroderma pattern to microangiopathy and one patient from microangiopathy to a normal pattern. Raynaud's phenomenon was equally distributed among patients with different capillaroscopy patterns (p=0.487), as was median SLEDAI score at diagnosis (p=0.285). Follow-up patients with a capillary scleroderma pattern did not show any clinical features for SSc over time (follow-up over 1-5 years, Table 1 below. Patients with a capillary scleroderma pattern showed significantly more disease damage (Chi-square, p=0.008), also indicated by a survival analysis for disease damage (Figure 1, p=0.042).
Conclusion: Our study indicates that a capillary scleroderma pattern in cSLE correlates with disease damage but not with clinical SSc features during follow-up period.

Background: The efficacy of tocilizumab for treatment patients with systemic juvenile idiopathic arthritis (sJIA) was demonstrated before. We want to describe tocilizumab drug survival based on data from a single-center observation.
Objectives: To analyze the drug survival of tocilizumab in patients with sJIA treated at the National Medical Research Center of Children`s health, Moscow, Russia.
Methods: Medical records from sJIA patients treated with tocilizumab (TOC) were analyzed retrospectively from the National Medical Research Center of Children`s health, Moscow, Russia.
Results: One hundred ninety-two patients presenting with sJIA were included in this observation, with a median age at treatment initiation of 7,2 (interquartile range, IQR 3,9-10,8) years and a median disease duration of 1,9 (IQR 0,4-5,9) years. All patients had been bio-naive. TOC therapy was highly effective in patients with sJIA. At 6 month of follow-up 148/172 (86%) patients achieved inactive disease according the criteria C. Wallace, disease activity persisted in 24/172 (14%) patients. At 1 year of medication 139/150 (92%) patients had inactive disease. We analyzed the reason of TOC withdrawal retrospectively. A total of 82/192 drug withdrawals were performed. TOC was discontinued due to primary ineffectiveness in 4 patients, due to secondary ineffectiveness in 39 patients. 33 patients achieved drug-free remission.

Table 1. Clinical characteristics of cSLE-patients (n=9/53) with a nailfold capillary scleroderma pattern

	Butterfly rash	Photosensitive rash	Lupus nephritis	Autoimmune cytopenia	Positive Coombs	Low C3/C4	Serositis	Damage	Type of auto-antibodies	Follow-up in years
1	+	+	-	+	+	+	-	+	ANA, Anti-ds-DNA, anti-Sm, anti-RNP, anti-Ro52, anti-SS-A	5
2	+	+	-	+	+	+	-	+	ANA, Anti-ds-DNA, anti-Sm, anti-RNP, anti-SS-A	5
3	-	+	+	+	+	+	+	+	ANA, Anti-ds-DNA, anti-Sm, anti-RNP, anti-SS-A	10
4	-	+	+	-	+	+	+	+	ANA, Anti-ds-DNA, anti-Sm, anti-RNP, anti-Ro52, anti-SS-A	9
5	-	+	-	-	+	-	+	-	ANA	1 (lost)
6	-	+	+	+	+	+	+	-	ANA, Anti-ds-DNA, anti-c1q	3
7	-	-	-	+	-	-	-	-	ANA, Anti-ds-DNA, anti-Sm, anti-RNP	1
8	+	+	-	+	-	-	-	-	ANA	9
9	-	+	+	+	+	+	+	+	ANA, Anti-ds-DNA, anti-RNP, anti-SS-A	8

Six patients developed side effects that required discontinuation of TOC therapy (4 patients had allergic reactions, 1 patient developed tuberculosis, 1 patient had severe neutropenia). 47/82 patients were switched on other biologic drug: on canakinumab (31), on TNF-inhibitors (11), on rituximab (5). In summary, TOC was canceled in 49/192 (25%) patients due to ineffectiveness or AEs in our cohort.
Conclusion: These results demonstrated that TOC is highly effective as the first biologic drug in patients with sJIA. Our observations have shown a good tolerability and survival of the IL-6 inhibitor TOC in patients with sJIA treated in a real-world clinical setting.

POS1313 PSYCHIATRIC DISORDERS IN JUVENILE IDIOPATHIC ARTHRITIS - A POPULATION-BASED COHORT STUDY

B. Delcoigne[1], A. Horne[2,3], S. Omarsdottir[3,4], J. Reutfors[1], J. Askling[1].
[1]Karolinska Institutet of Medecine, Division of Clinical Epidemiology, Stockholm, Sweden; *[2]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden*; *[3]Karolinska University Hospital, Pediatric Rheumatology Unit, Theme of Children's Health, Stockholm, Sweden*; *[4]Pediatric Rheumatology Registry, Pediatric Rheumatology Registry, Stockholm, Sweden*

Background: Juvenile idiopathic arthritis (JIA) may have substantial consequences for quality of life, for instance due to chronic pain, restriction of activities, concern about physical appearance, and treatment protocols that may limit interactions with peers. However, it remains unclear whether children and adolescents with JIA sow a higher incidence of psychiatric disorders compared with the general population.
Objectives: To examine the incidence of psychiatric disorders during childhood in JIA patients in Sweden relative to general population controls.
Methods: We performed a register- and population-based cohort study including new-onset JIA patients aged 0 to 17 years 1st January 2012 through 31st December 2017. Incident JIA patients were followed-up from the date of their 2nd JIA diagnosis. At this date, five sex-age-region matched individuals were sampled from the general population. Nine psychiatric disorders were defined with ICD-10 codes and associated drugs (ATC codes): psychotic disorders (ICD-10: F20-29; ATC: N05A), mood and anxiety disorders (F30-F43; N05B, N06A, R06AD01, R06AD02, N03AX16), sleeping disorders (F51; N05C, N03AE01), eating and personality disorders (F50, F60-61, F69), neuropsychiatric disorders (F70-F79, F84, F90; N06BA, C02AC02), substance misuse (F10-F19; N07B), suicide attempts (X60-X84, Y10-34) and death by suicide or substance abuse, and all these combined. The follow-up stopped at date of first outcome, migration, death, 18th birthday or end of the study period, whichever occurred first. Incidence rates were calculated and compared by Cox regression analyses, adjusted for age, sex, calendar year, patient's and family's history of psychiatric disorder, country of birth, parents' education level, and comorbidities (IBD, obesity and celiac disease). In sensitivity analyses, we (1.) excluded children with a history of a psychiatric diagnosis at start of follow-up, and (2.) defined the psychiatric disorders based on ICD-10 codes only.
Results: We identified 2224 JIA patients (64% girls, mean age: 9.8 years) and 10,264 matched controls. In the JIA cohort, 309 patients developed a psychiatric disorder (all outcomes combined) during 4998 person-years (pyrs), which corresponded to a crude incidence rate (IR) of 6.2 per 100 pyrs (95% confidence interval (CI): 5.5-6.9). The corresponding crude IR for the general population matched controls was 3.6 (3.4-3.9). Comparing these incidence rates resulted in a sex-age adjusted hazard ratio (HR) of 1.66 (95% CI: 1.46-1.89) and a fully adjusted HR of 1.68 (1.47-1.91). Considering specific outcomes, the IRs per 100 pyrs in the JIA population ranged from 0.1 (suicide attempt) to 3.7 (mood and anxiety disorders) (Table 1). No death from suicide was recorded. There was an overlap across the seven outcomes: among all individuals diagnosed with at least one of the psychiatric outcomes during follow-up, 58% were diagnosed with one outcome only, 25% with two and 19% with three or more outcome conditions. The Cox analyses of the 7 outcome groups demonstrated four statistically significant increased risks for psychotic, mood and anxiety, sleeping and neuropsychiatric disorders (Figure 1). The three latter outcomes were correlated to each other (with Cramer's V coefficient between 0.3 and 0.5). The sensitivity analyses did not substantially modify these findings.
Conclusion: The burden of psychiatric illness in individuals with JIA is increased compared to the general population.

Table 1. Risk of psychiatric disorders in JIA patients and general population controls.

Disorders	N events JIA	N events controls	IR JIA (95% CI)	IR controls (95% CI)
All combined	309	918	6.2 (5.5-6.9)	3.6 (3.4-3.9)
Psychotic	25	44	0.5 (0.3-0.7)	0.2 (0.1-0.2)
Mood	194	534	3.7 (3.2-4.3)	2.0 (1.9-2.2)
Sleeping	148	348	2.8 (2.4-3.3)	1.3 (1.2-1.5)
Neuropsychiatric	126	442	2.4 (2.0-2.8)	1.7 (1.5-1.9)
Eating	13	55	0.2 (0.1-0.4)	0.2 (0.2-0.3)
Substance misuse	14	49	0.3 (0.2-0.4)	0.2 (0.1-0.2)
Suicide attempt	7	55	0.1 (0.1-0.3)	0.2 (0.2-0.3)

IR: crude incidence rate per 100 person-years; CI: confidence interval[1] adjustment: see text.

Devauchelle-Pensec[9]. *[1]Hospital La Cavale Blanche, Rheumatology, Brest, France*; *[2]CHRU de Nancy - Hôpitaux de Brabois, Paediatric Onco-Haematology, Vandœuvre-lès-Nancy, France*; *[3]Hospital Nord Franche-Comté, Rheumatology, Trévenans, France*; *[4]Hôpital Pellegrin Bordeaux, Paediatrics, Rheumatology and Paediatric Internal Medicine, Bordeaux, France*; *[5]Hôpital de la Robertsau - Hôpitaux Universitaires de Strasbourg, Rheumatology, Strasbourg, France*; *[6]South Hospital, Paediatric, Rennes, France*; *[7]Bicetre Hospital AP-HP, Paediatric Rheumatology, Le Kremlin-Bicêtre, France*; *[8]Poitiers University Hospital, Rheumatology, Poitiers, France*; *[9]Hospital La Cavale Blanche, Rheumatology, Brest, France*

Background: The SARS-CoV-2 pandemic has induced an exceptional sanitary crisis, potentially having an impact on treatment continuation, for juvenile idiopathic arthritis (JIA) patients receiving immunosuppressive therapies. In France, after the first lockdown from March to May 2020, many parents and children were then also concerned about whether reopening plans for school could ensure the safety of students, despite data concerning children with COVID-19 seem reassuring, and very few of them develop severe forms of the disease (1, 2, 3).
Objectives: Our objectives were to evaluate the impact of the COVID-19 pandemic on the therapeutic management of JIA, the frequency of returning to school after the first lockdown period and the prevalence of SARS-CoV-2 infection at the time of the survey.
Methods: JIA patients under 18 years of age, usually treated with disease-modifying anti-rheumatic drugs (DMARDs) were prospectively included during their outpatient visit and completed a standardized questionnaire. Data regarding the general characteristics of the participants, medical history, SARS-CoV-2 infection, characteristics of JIA subtypes and treatment modifications were collected.
Results: A total of 173 patients from 8 different expert centers were included between May and August 2020. Their mean age was 11.6 years (± 4.1 years), and most of them 31.2% (54/173) had a rheumatoid factor-negative polyarticular JIA. Fifty percent (86/172) were treated with methotrexate, and 72.5% (124/171) were treated with bDMARDs. DMARD treatment modification in relation to the pandemic was observed in 4.0% (7/173) of participants, our results reflect good adherence of the patient/parents to their immunosuppressive treatments. 49.1% (81/165) of the patients did not return to school due to a personal/parental decision in 69.9% (55/81) of cases, due to anxiety of the patient/parents regarding COVID-19. Two patients were diagnosed positive for SARS-CoV-2 infection.

Conclusion: This study suggests that JIA patients treated with DMARDs continued their treatment during the pandemic. In contrast, parents' reluctance was a major obstacle for returning to school. Therefore, more solidified school reopening strategies should be developed.

POS1315 USEFULNESS OF SYNOVIAL BIOPSY IN THE DIFFERENTIAL DIAGNOSIS AND AS POSSIBLE PREDICTOR OF RESPONSE TO TREATMENT IN JUVENILE IDIOPATHIC ARTHRITIS

S. Costi[1], F. Pregnolato[2], A. Parafioriti[3], E. Armiraglio[3], T. Giani[4,5], R. Cimaz[6,7]. *[1]University of Milan, Rheumatology, Milan, Italy*; *[2]Auxologico Italiano, Experimental Laboratory of Immunological and Rheumatologic Researches, Milan, Italy*; *[3]ASST G.Pini-CTO, Pathological Anatomy, Milan, Italy*; *[4]Meyer Children's Hospital, Pediatric Rheumatology, Florence, Italy*; *[5]University of Siena, Department of Medical Biotechnology, Siena, Italy*; *[6]University of Milan, Department of Clinical Sciences and Community Health, and Research Center for Adult and Pediatric Rheumatic Diseases, Milan, Italy*; *[7]ASST G.Pini-CTO, Pediatric Rheumatology, Milan, Italy*

Background: While synovial biopsy is an invasive procedure and is not required for the diagnosis of juvenile idiopathic arthritis (JIA), it may be useful in doubtful cases.

Objectives: Aims of the study were i.to verify the role of synovial biopsy in the differential diagnosis of JIA and ii. to review the pathology slides in order to evaluate possible associations of a histologic pattern with response to treatment.

Methods: We reviewed data from medical records of patients under the age of 18 years who underwent a synovial biopsy requested by our Pediatric Rheumatology Unit over the last 10 years. We collected information on demographic, clinical, laboratory, radiological, histopathological characteristics, as well as treatment response (in particular, remission at the last visit and number of examination, number of biologic drugs used). Among variables in the histologic score, number of layers in the synovial lining and inflammatory infiltrate (0-5) were compared to clinical status at last visit. Potential differences in variables between responders and non responders were assessed by unpaired t-test or non-parametric Mann-Whitney test, as appropriate.

Results: We identified 64 patients (40F, 24M) with a median age at disease onset of 9 years (range 1-15) and a median follow-up time of 161 months (range 8-1160). We recognized two groups of interest: patients with a known JIA diagnosis (28/64) and patients with unknown diagnosis (36/64) at the moment of synovial biopsy. In the group with known JIA, most underwent the procedure during orthopedic surgery, and in all cases the histology was consistent with JIA. Among the unknown diagnosis group, in 19 cases results were consistent with a chronic synovitis, while among the other 17 histology could lead to a diagnosis of other conditions in 6 cases (foreign body and villonodular synovitis n=2 each, sarcoidosis and osteochondromatosis n=1 each). In the remaining 11 the final diagnoses were varied (mostly genetic forms eg skeletal dysplasia, CACP, Thiemann disease).

Between the two groups we identified 46 patients with a definite JIA diagnosis. At the last follow-up visit 29 of them were in clinical remission, albeit on medication. The remaining 17 had a severe course of disease, with persistent activity and use of at least two biologic drugs. In 26 cases we could evaluate the correlation between status at last visit and number of layers/inflammatory infiltrate, but no statistical significant correlation was found.

Conclusion: Despite its limited use nowadays, synovial biopsy may still be a useful tool in patients whose diagnosis is unclear. In our study, while it confirmed the suspicion in most cases, in other instances it allowed the diagnosis of rare conditions that would have been otherwise missed. No association between disease course and histological features in a small JIA cohort was found. We are currently expanding the study with a larger series.

POS1316 VISUAL FUNCTION AND QUALITY OF LIFE: PRELIMINARY RESULTS FROM A PIVOTAL CROSS-SECTIONAL STUDY ON ONE HUNDRED PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS-ASSOCIATED AND IDIOPATHIC UVEITIS

G. B. Beretta[1], F. Minoia[1], L. Marelli[2], C. Mapelli[3], G. Leone[3], T. Giani[4], P. Nucci[2,5], E. Miserocchi[6], R. Cimaz[7,8]on behalf of Pediatric Rheumatology Associated Group of the Milan Area. *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Pediatric Rheumatology, Milan, Italy*; *[2]Ospedale San Giuseppe, IRCCS Multimedica, Ophthalmology, Milan, Italy*; *[3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Ophthalmology, Milan, Italy*; *[4]Università degli Studi di Siena, Pediatric Rheumatology, Siena, Italy*; *[5] Università degli Studi di Milano, Ophthalmology, Milan, Italy*; *[6]IRCCS Ospedale San Raffaele, Ophthalmology, Milan, Italy*; *[7]ASST Gaetano Pini-CTO, Milan, Italy, Pediatric Rheumatology, Milan, Italy*; *[8]Università degli Studi di Milano, Pediatric Rheumatology, Milan, Italy*

Background: Juvenile idiopathic arthritis (JIA) is the main cause of chronic uveitis in childhood and JIA associated uveitis (JIA-U) is the most common extraarticular complication of JIA. Despite continuous improvement in its management, pediatric uveitis still represents a serious condition with potential sight-threatening complications and a significant impact on quality of life (QoL).

Objectives: To evaluate visual function (VF) and QoL in children with JIA-U and idiopathic uveitis

Methods: A cross-sectional study was conducted in two tertiary Pediatric Rheumatology Centres, enrolling all patients seen with JIA-U, JIA without uveitis and idiopathic uveitis. VF was assessed by a translated form of the available EYE-Q, adapted for cross-cultural feasibility into a 10-question tool, while QoL was evaluated by the Italian version of the Pediatric Rheumatology Quality of Life scale part of the Juvenile Arthritis Multidimensional Report (JAMAR), shortened for feasibility to a 8-question tool. JAMAR section on treatment compliance and school attendance was also included. Parents, and patients when appropriate, were asked to complete each patient/parent-reporting outcome measure, answering on a 4-point Likert scale, with a total score ranging from 0 to 72 (worst condition). Medical charts were reviewed regarding JIA and uveitis features and outcome. Quantitative and qualitative variables were compared by means of Mann-Whitney U test or chi-square/Fisher exact test, as appropriate; correlations among quantitative non-parametric variables were evaluated by Spearman's test.

Results: We herein describe results from the first 100 patients enrolled (76% female), with a median age at study time of 12.8 (9.0-17.6) years. Forty-nine had JIA-U, 37 JIA without uveitis and 14 idiopathic uveitis. Uveitis was active in 14/63 patients (22.2%), with a median of uveitis duration of 9.0 years (3.6-14.8). Almost all children with uveitis were on systemic treatment (58/63, 92%) at the time of interview; 54.0% of patients presented an ocular damage, with 8.0% having a best corrected visual acuity (BCVA) < 4/10. Total score, VF and QoL scores resulted significantly higher in JIA-U patients compared to JIA without uveitis, while no differences were noticed among children with uveitis with or without JIA (Table 1). School absence was reported more frequently in JIA-U compared to JIA only (32.7% vs 10.8%, p 0.0211). VF was significantly worse in patients with ocular damage and BCVA < 4/10 (p 0.0351 and 0.0123, respectively). In patients with uveitis, VF and QoL showed a significant correlation (r 0.50, p <0.0001) especially in patients with idiopathic uveitis (r 0.74, p <0.0001).

Conclusion: Visual function is a crucial component of QoL in children with uveitis and it correlates with ocular damage. Since eye involvement significantly affect QoL in patients with JIA, a specific tool widely validated and cross-cultural adapted is highly demanded in the clinical care of JIA-U patients.

POS1317 PREDICTIVE FACTORS FOR RESPONSE TO TREATMENT IN A LONG-TERM COHORT OF PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS-ASSOCIATED UVEITIS

L. Marelli[1], F. Minoia[2], G. Beretta[2], C. Mapelli[3], G. Leone[3], G. Cincinelli[4], T. Giani[5], P. Nucci[6], R. Cimaz[4,6], E. Miserocchi[7]. *[1]Ospedale San Giuseppe, IRCCS Multimedica, Ophthalmology, Milan, Italy*; *[2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Pediatric Rheumatology, Milan, Italy*; *[3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Ophthalmology, Milan, Italy*; *[4]ASST Gaetano Pini CTO, Pediatric Rheumatology, Milan, Italy*; *[5]Università degli Studi di Siena, Pediatric Rheumatology, Siena, Italy*; *[6]Università degli Studi di Milano, Dipartimento di Scienze Cliniche e di Comunità, Milan, Italy*; *[7]IRCCS Ospedale San Raffaele, Ophthalmology, Milan, Italy*

Background: Uveitis is the main extraarticular complication of juvenile idiopathic arthritis (JIA) with still a significant impact on JIA morbidity, despite continuous improvement in systemic treatment. Although antinuclear antibody positivity and early onset of JIA have been associated with a high risk of uveitis onset, so far no clinical features have been widely recognized as predictive factors for JIA-associated uveitis (JIA-U) response to treatment.
Objectives: To investigate clinical features associated with response to systemic treatment in a long-term cohort of patients with JIA-U
Methods: Clinical records of patients with JIA-U were retrospectively reviewed with regard to clinical features, therapeutic choices and outcome. Clinical and laboratory variables were compared by means of Mann-Whitney U test or chi-square/Fisher exact test, as appropriate.
Results: Data from 164 JIA-U patients were analysed (81.7% female), with a median follow up of 12.1 years (7.1-17.3). Median age at JIA and uveitis onset was 2.6 (1.6-4.8) and 4.8 (2.9 – 7.0) years, respectively. Monotherapy with a conventional disease-modifying antirheumatic drug (DMARD) was used in 25.0% of patients, while 111 patients (67.7%) received at least one biologic DMARD (bDMARDs). Compared to patients responsive to DMARDs, children requiring a bDMARDs for uveitis had a lower median age at both JIA (2.4 vs 4.3 years, p 0.0234) and uveitis onset (4.1 vs 6.2 years, p 0.0023). Despite no differences in ocular damage at onset and median disease duration, patients not responsive to conventional DMARDs showed a higher frequency of ocular damage at the last visit (66.2% vs 33.3%, p 0.011). Children requiring more than one bDMARD for uveitis presented a more frequent polyarticular course (87.0% vs 20.2%, p 0.0022), a longer disease duration (median follow-up: 14.2 vs 10.4 years, p 0.0397) and a higher frequency of visual loss (best corrected visual acuity < 4/10: 23.3% vs 6.3%, p 0.0069).
Conclusion: JIA-U patients with a lack of response to conventional DMARDs were significantly younger both at JIA and uveitis onset. Severe JIA-U requiring more than one bDMARDs was associated with polyarticular JIA course and longer disease duration. Children resistant to conventional treatment need prompt recognition and additional strategies to improve long-term outcome.

POS1318 A NATIONWIDE COHORT STUDY ON CLINICAL AND LABORATORY MANIFESTATIONS IN CHILDREN WITH MULTISYSTEM INFLAMMATORY SYNDROME (MIS-C)

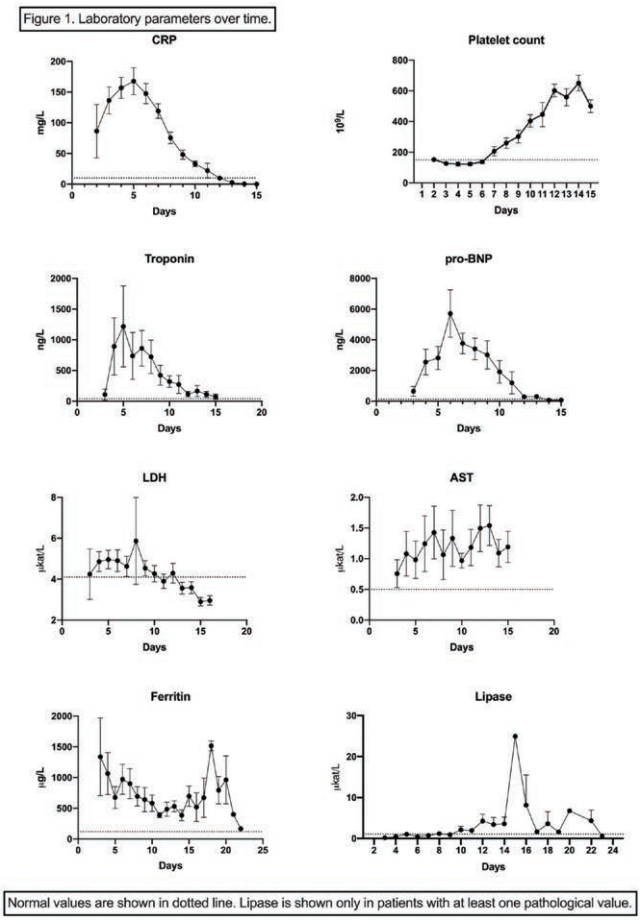
M. Zajc Avramovic[1,2], K. Vincek[3], G. Mlakar[4], N. Emersic[1], T. Plankar Srovin[3], T. Avsic-Zupanc[5], A. Ihan[5], T. Avcin[1,2]. *[1]University Medical Center Ljubljana, Children's Hospital, Department for Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia*; *[2]University of Ljubljana, Faculty of Medicine, Pediatrics, Ljubljana, Slovenia*; *[3]University Medical Center Ljubljana, Clinic of Infectious Diseases, Ljubljana, Slovenia*; *[4]University Medical Center Ljubljana, Children's Hospital, Department for Cardiology, Ljubljana, Slovenia*; *[5]University of Ljubljana, Faculty of Medicine, Institute of Microbiology and Immunology, Ljubljana, Slovenia*

Background: Multisystem inflammatory syndrome in children (MIS-C) was recognized during the 2020 pandemic of SARS-CoV-2. Because of the relative rarity current knowledge is limited, especially in the European Caucasian population.
Objectives: To report the epidemiology, clinical and laboratory characteristics of patients with MIS-C in a nationwide cohort study in Slovenia.
Methods: This is a nationwide prospective cohort study of all consecutive patients with MIS-C, admitted from the beginning of epidemics to 31st December 2020 to University Medical Centre Ljubljana, Slovenia, the only tertiary care pediatric rheumatology center in the country. The inclusion criteria were meeting the CDC criteria for MIS-C. Infection with SARS-CoV-2 was confirmed in all patients by positive antibodies for SARS-CoV-2. Data were collected from the patients' medical records. Data on the COVID-19 epidemics in Slovenia were collected from National Institute of Public Health. Population data were provided by the Statistical Office of the Republic of Slovenia.
Results: Twenty-three patients with MIS-C were diagnosed nationwide in Slovenia, all of them in the second wave of epidemics from 14th September to 31st December 2020. All patients were Caucasian and the estimated prevalence of MIS-C was 5.8/100 000 persons younger than 19 years of age. Detailed analyses were available in 20 patients of which 14 were boys (70 %), median age was 12.4 years (4 months to 17.7 years). Two patients (10 %) were treated in the intensive care unit and none of the patients died. Troponin was elevated in 15/20 (75 %) patients during the disease course, and 7/15 (47 %) of these had normal troponin level at admission. The serum level of troponin closely followed the serum level of CRP. Six out of 20 (30 %) patients had elevated pancreatic enzymes in the second week of the disease after treatment was already given,and one patient developed asymptomatic acute pancreatitis with serum lipase level reaching the maximum of 25μkat/L. All patients had elevated levels of D-dimer with no signs of thrombosis. Five patients (5/20; 25 %) had pleural effusions and five patients (5/20, 25 %) had ascites. Half of the patients (10/20; 50 %) had hepatosplenomegaly and eight (8/20; 40 %) had mesenterial lymphadenopathy. Three patients (3/20; 15 %) had radiologic signs of cholecystitis. Two patients had thickened lung parenchyma. All patients received IVIG and systemic glucocorticosteroids. Because of resistant or organ threatening disease 4 patients (4/20, 20%) received high dose methylprednisolone pulse therapy. Biologic therapy with anakinra was started in 2 patients. Nineteen patients (19/20, 95%) received acetylsalicylic acid and prophylactic anticoagulation was prescribed in 15/20 (75%) of patients.
The mean follow up was 50 days (14 – 122). At the last follow-up visit all patients had normal laboratory parameters of inflammation, troponin, pro-BNP, d-dimer values and normal heart function.

Table 1. Clinical characteristics.

	n *(%)*
Fever n *(%)*	20 (100)
Fever duration (days) [min; max]	*5.9 [4; 8]*
Headache	8 (40)
Lymphadenopathy	15 (75)
Chest pain	6 (30)
Tachycardia	16 (80)
Gastrointestinal involvement	19 (95)
• Abdominal pain	16 (80)
• Vomiting	11 (55)
• Diarrhoea	9 (45)
• Loss of apetite	18 (90)
Cough	7 (35)
Skin and mucous involvement	14 (70)
• Rash	12 (60)
• Palmar/plantar oedema	3 (15)
• Lip and mouth changes	12 (60)
• Bilateral conjunctivitis	14 (70)
Myocarditis	19 (95)

Conclusion. A very high incidence of MIS-C, estimated 5.8/100 000 persons under the age of 19 with a predominantly cardiac involvement but very good outcome was noted in European Caucasian population in a nationwide cohort study in Slovenia. Attention to newly described pancreatic involvement should be raised.



Conclusion: A very high incidence of MIS-C, estimated 5.8/100 000 persons under the age of 19 with a predominantly cardiac involvement but very good outcome was noted in European Caucasian population in a nationwide cohort study in Slovenia. Attention to newly described pancreatic involvement should be raised.

POS1319 RAYNAUD'S PHENOMENON IN A SINGLE CENTER COHORT OF TURKISH CHILDREN

Ş. Çağlayan[1], F. Demir[1], B. Sancar[1], K. Ulu[1], T. Coşkuner[1], B. Sözeri[1]. [1]*Health Sciences University, Umraniye Traning and Research Hospita, Pediatric Rheumatology, Istanbul, Turkey*

Background: Raynaud's phenomenon (RF) is a vasospastic condition characterized by episodic color changes of blanching, cyanosis, and hyperemia of the extremities of the body

Objectives: We aim to examine the clinical presentation, capillaroscopic findings and disease associations of Raynaud's phenomenon (RP) in pediatric patients

Methods: We retrospectively enrolled a single-center cohort of 247 consecutive pediatric patients with RP admitted to Umraniye Training and Research Hospital, Pediatric Rheumatology Clinic, Istanbul, Turkey, since 2016. Medical records were analyzed for clinical presentation, disease associations, and physical examination and laboratory findings.

Results: We reported 247 patients (152 female, 95 male) with RP. Their mean age at disease onset was 14.5±2.55 years and median age at diagnosis was 15.4± 2.21 years. In patients with secondary RP syndrome (10.9%), the age of complaint was found to be lower than others (p=0.03). Although most patients have affected upper extremity (hand and fingers), lower extremity (toes) involvement was also detected in 50 (20%) patients. In both the patients with primary and secondary RP, main triggering factor was found as cold exposure. Biphasic (53.6%) color changes were more seen in primary RP, although triphasic (51.8%) color changes were more in patients with secondary RP (p=0.00). The presence of antinuclear antibodies and abnormal nailfold capillaries were more seen in patients with secondary RP (28% vs 74% and 35.3% vs 66.7, respectively p=0.00). Digital ulcer was detected 5.2% of patients (mostly secondary). Out of 247, 31 patients were treated with low-dose aspirin, 47 with calcium blockers, 25 with low-dose aspirin and calcium blockers, 16 with iloprost and/or bosentan, while the remaining 140 did not receive any drug.

Conclusion: Similar to adults, RP is more common in girls without an underlying disease. In patients with secondary RP, the symptoms. It has been shown that in patients with secondary RP, symptoms begin at a younger age and the ANA positivity and abnormal nailfold capillaries correlate.

POS1320 DIFFERENCES IN CLINICAL MANIFESTATION AND DISEASE ACTIVITY OF PEDIATRIC BEHÇET DISEASE: A CROSS-SECTIONAL COHORT COMPARISON BETWEEN TURKEY AND UNITED STATES

E. Demirkaya[1], M. Romano[1], C. Swearingen[2], O. Kasapcopur[3], B. Makay[4], S. Özen[5], Y. Yazici[6]. [1]*Schulich School of Medicine & Dentistry, University of Western Ontario, Paediatric Rheumatology, LONDON, Canada*; [2]*NYU Hospital for Joint Disease, Rheumatology, New YorK, United States of America*; [3]*Istanbul University-Cerrahpasa, Paediatric Rheumatology, Instanbul, Turkey*; [4]*Dokuz Eylul University, Paediatric Rheumatology, Izmir, Turkey*; [5]*Hacettepe University, Ankara, Paediatric Rheumatology, Ankara, Turkey*; [6]*New York University School of Medicine, Rheumatology, New YorK, United States of America*

Background: Behçet disease (BD) is a systemic inflammatory disease which is rare in children. It is also known a higher prevalence along the ancient Silk Road and the eastern Mediterranean, especially in Turkey. Despite the presence of diagnostic criteria, the diagnosis of pediatric BD is still difficult due to atypical findings and the heterogeneity of the disease. While descriptive cohort studies in pediatric BD exist, direct comparison studies of clinical manifestations and disease activity between patients from different countries are scarce.

Objectives: We aimed to compare the main clinical features and activity of pediatric BD patients from Turkey versus United States (US).

Methods: The BD was diagnosed before 18 years of age and based on expert opinion. Disease activity was assessed with Physician Global Assessment (PhGA), Parents/Patient Global Assessment (PWPGA) and Behçet's Syndrome Activity Scale (BSAS) were administered to patients from both countries.

Results: A total of 161 patients were included (61 from Turkey; 100 from US). Males were more prevalent among patients from Turkey than among patients from US (63.9% vs. 32%, respectively, $p < 0.001$). Disease duration at the diagnosis was significantly longer in US p=0.002). Oral aphthosis was the most common symptom in both groups (96.7% for Turkey and 73% for US), however a significant difference was found (p<0.001). Genital ulcers were documented in 47% of US patients and in 41.4% of Turkish patients (p=0.5). There were significant difference between two groups with regards to the ocular involvement: uveitis and posterior uveitis were more frequently in Turkish patients (p=<0.001 respectively) while retinal vasculitis was no seen in US patients (p<0.001). Erythema nodosum occurred more frequently in Turkish group (p<0.001). The pathergy test was reported as positive in 22 (37.3%) patients in Turkey and 2 (2.3%) in USA in our study (p<0.001). Gastrointestinal and neurological involvement did not differ between cohorts. The rate of colchicine and oral steroids was similar. Azathioprine, cyclosporine and methotrexate usage was more frequent in Turkey (p=0.005, p=0.007, p=0.033, respectively) and infliximab was administered just in the US cohort ($p = 0.002$). PhGA and BSAS scores were higher in patients from Turkey (p=0.003 and p=0.017 respectively) and no significant differences were seen in PWPGA scores.

Conclusion: Disease activity and clinical features seem to be different between the two countries which may be linked to the environmental factors, referral patterns and immune system responses in the expression of this disease. The diagnosis of BD in the US was based on both fulfilling the ISBD criteria and in cases when criteria were not met, based on treating physician assessment, which can explain some of the differences in disease presentation. In addition, there were differences in regard to clinical practice and treatment patterns between two countries. Increasing knowledge about heterogeneity of BD will improve the ability of diagnosis, development of new diagnostic criteria, and management of BD.

Biometrie, Ulm, Germany*

Background: Mental disorders often begin in the vulnerable phase of adolescence and young adulthood. Young people with chronic diseases are particularly at risk. Early recognition of mental health problems is necessary in order to be able to support those affected in a timely and adequate manner. By implementing a web-based generic screening tool for mental health in routine care, patients with juvenile idiopathic arthritis (JIA) and mental health conditions can be identified and provided with targeted treatment.
Objectives: To investigate the prevalence of mental health conditions in young people with JIA in routine rheumatology care.
Methods: Mental health screening is implemented as an add-on module to the National Paediatric Rheumatology Database (NPRD). The current data was gathered over a period of 24 months. Patients complete the screening tool which includes the Patient Health Questionnaire[1] (PHQ-9, score 0-27) and the Generalized Anxiety Disorder scale[2] (GAD-7, score 0-21) via a web-based questionnaire. The cut-off for critical values in PHQ-9 and GAD-7 were defined as values ≥ 10. Simultaneously, other data, such as sociodemographic data, disease activity (cJADAS10, score 0-30), functional status (CHAQ, score 0-3) were collected as well.
Results: The analysis included 245 patients (75% female) with a mean age of 15.7 years and a mean disease duration of 8.8 years. 38.8% of the patients had oligoarthritis (18.0% OA, persistent/20.8% OA, extended) and 23.3% RF negative polyarthritis. At the time of documentation 49 patients (30.6%) had an inactive disease (cJADAS10 ≤ 1) and 120 (49.4%) no functional limitations (CHAQ = 0). In total, 53 patients (21.6%) had screening values in either GAD-7 or PHD-9 ≥10. Patients with critical mental health screening values showed higher disease activity and more frequent functional limitations than inconspicuous patients (cJADAS10 (mean ± SD): 9.3 ± 6 vs. 4.9 ± 4.9; CHAQ: 0.66 ± 0.6 vs. 0.21 ± 0.42). When compared to males, females were significantly more likely to report either depression or anxiety symptoms (11.7% vs. 24.9%, p = 0.031).
17.6% of all patients with valid items for these data reported to receive psychological support, meaning psychotherapeutic support (14.5%) and/or drug therapy (8.6%). Among those with a critical mental health screening score, 38.7% received psychological support (psychotherapeutic support (35.5%) and/or drug therapy (16.1%)).
Conclusion: Every fifth young person with JIA reported mental health problems, however, not even every second of them stated to receive psychological support. The results show that screening for mental health problems during routine adolescent rheumatology care is necessary to provide appropriate and targeted support services to young people with a high burden of illness.

POS1322 A DATA SCIENCE EVALUATION OF THE JUVENILE ARTHRITIS MULTIDIMENSIONAL ASSESSMENT REPORT (JAMAR) QUESTIONNAIRE FOR IMPROVING MANAGEMENT OF JIA PATIENTS

H. Quesada-Masachs[1], M. Faloutsos[1], M. López- Corbetó[2], S. Ghose[3], S. Marsal[4], E. Quesada-Masachs[2]. *[1]University of California Riverside, Computer Science & Engineering, Riverside, United States of America*; *[2]Hospital Universitari Vall d'Hebron, Rheumatology, Pediatric Rheumatology Unit, Barcelona, Spain*; *[3]University of California Berkeley, University of California Berkeley, Berkeley, United States of America*; *[4]Hospital Universitari Vall d'Hebron, Rheumatology, Barcelona, Spain*

Background: The Juvenile Arthritis Multidimensional Assessment Report (JAMAR) is a questionnaire developed to comprehensively assess Juvenile Idiopathic Arthritis (JIA) patients. Despite being translated into 54 languages, there is still limited literature about it. The length of the questionnaire could have been influencing its clinical practicality.
Objectives: The purpose of this study is to answer the following questions:
a)"Which are the most informative questions?";
b)"How well do the collected data correlate with other clinical variables?";
c)"Are there discrepancies between the perceptions of patients and parents?";
Methods: We included 71 children with JIA according to ILAR criteria, all of them receiving treatment and we followed them up for a year. JAMAR questionnaires were answered by both children and parents at baseline, 6 and 12 months. Also, a thorough clinical examination was performed in every visit: all the joints were clinically assessed for swelling, tenderness, and limited range of motion, and Juvenile Arthritis Disease Activity Score (JADAS), disease activity state, parents and patients assessment through Visual Analogue Scale (VAS), physician's VAS, Erythrocyte Sedimentation Rate (ESR) and C-reactive protein (CRP) were recorded. We applied state of the art machine learning methods in order to find the most relevant questions in JAMAR. Additionally, we utilized tensor decomposition to identify relevant patient clusters. Furthermore, we correlated these critical questions with clinical and biological parameters recorded. We have compared the discordance rate between patients vs parents responses in 5 of JAMAR parameters as previously reported [1]. We explored the relation between discordance and demographic and clinical variables.
Results: A total of 374 JAMAR questionnaires are analyzed with our Machine Learning algorithms. First, we identify a small group of questions as the most relevant for patients and parents. The identified questions exhibit better correlations with the JADAS scores than the non-relevant ones. Second, 96% of the pairs (child-parent) are discordant for at least one item, but the differences are small and VAS well being is the only score with a statistically significant difference ($P < 0.0001$). We observe a higher rate of activity in the patients exhibiting discordant evaluations with their parents. In addition, the observation patient-parent agreement in Juvenile Arthritis Functionality Scale (JAFS) is better than Pediatric Rheumatology Quality of Life Scale (PRQL).
Conclusion: In this study, we revisited the JAMAR questionnaire by applying modern data mining techniques in a longitudinal dataset. Our results suggest that a small number of questions in the JAMAR questionnaire provide significant information and correlate well with the JADAS scores. We argue that this reduced set of questions could make the data collection easier by trading off the number of questions for frequency and ease of self-reported data collection.

Background: Preliminary definitions for SIJ lesions in the OMERACT Juvenile Idiopathic Arthritis Magnetic Resonance Imaging score has been reported[1]. Investigators identified the need to revise the JAMRIS-SIJ item definitions.
Objectives: To update the JAMRIS-SIJ definitions and scoring method.
Methods: The OMERACT JAMRI working group was convened to discuss the performance of the score in a reliability exercise using 30 patients. Twenty investigators (12 radiologists, 8 rheumatologists) decided which definitions and scoring methods to be revised, retained or added.
Results: The revised JAMRI-SIJ is in the Table 1.

Table 1. Revised OMERACT JAMRIS-SIJ.

Component	Definition	Segmentation/ slice	Score range/ slice
Bone Marrow Edema (BME)	An ill-defined area of high bone marrow signal intensity within the subchondral bone in the ilium or sacrum on fluid sensitive images	4 quadrants/ SIJ	0-8
BME Intensity	Presence of hyperintensity of the marrow on fluid sensitive images using the signal of the presacral veins or cerebrospinal fluid as reference	1 score/SIJ	0-2
BME Depth	Continuing increased signal on fluid sensitive images of depth ≥ 5mm/ ≥ 1cm from the articular surface using the signal of the presacral veins or cerebrospinal fluid as reference	1 score/SIJ	0-2
Osteitis	An ill-defined area of high bone marrow signal intensity within the subchondral bone in the ilium or sacrum on contrast enhanced T1 weighted sequences	4 quadrants/ SIJ	0-8
Capsulitis	Increased signal on fluid sensitive or contrast enhanced T1 weighted sequences involving the superior portion of the SIJ capsule	superior halves/SIJ	0-2
Joint space fluid	High signal intensity equivalent to the CSF on fluid sensitive sequences within the joint space of the cartilaginous portion of the SIJ	halves/SIJ	0-4
Joint space enhancement	Increased signal intensity on contrast enhanced T1 weighted sequences within the joint space of the cartilaginous portion of the SIJ	halves/SIJ	0-4
Inflammation in erosion cavity	Increased signal intensity on fluid sensitive or contrast enhanced T1 weighted sequences in an erosion cavity of the cartilaginous portion of the SIJ	halves/SIJ	0-4
Enthesitis	Increased signal intensity in bone marrow and/or adjacent soft tissue on fluid sensitive or contrast enhanced T1 weighted sequences at sites where ligaments and tendons attach to a bone excluding retroarticular enthesitis	Score per case	0-1
Damage Domain			
Sclerosis	A substantially wider than normal area of very low bone marrow signal intensity within the subchondral bone in the ilium or sacrum on a non-fat suppressed sequence, preferably a non-fat suppressed T1 weighted sequence. This feature must also be present on all other sequences, as available	4 quadrants/ SIJ	0-8
Erosion	A focal loss of the low signal of cortical bone at the osteochondral interface and adjacent marrow matrix on T1 weighted images	4 quadrants/ SIJ	0-8
Fat metaplasia lesion	Homogeneous increased signal intensity within the subchondral bone marrow on T1weighted images	4 quadrants/ SIJ	0-8
Backfill	A high signal on non-contrast enhanced T1 weighted sequences in a typical location for an erosion, with signal intensity greater than normal bone marrow, clearly demarcated from adjacent bone marrow by an irregular band of low signal reflecting sclerosis at the border of the original erosion	halves/SIJ	0-4
Ankylosis	Presence of signal equivalent to regional bone marrow continuously bridging a portion of the joint space between the iliac and sacral bones	halves/SIJ	0-4

Statement of overarching consideration for all definitions: "[…] in comparison to physiological changes normally seen on MRI examinations of age- and sex-matched children, and visible in 2 planes wherever available."

Conclusion: Revised JAMRIS-SIJ has been developed. Validation steps are underway.

POS1324 TREATMENT OF UVEITIS ASSOCIATED WITH JUVENILE IDIOPATHIC ARTHRITIS: A SEVEN YEARS' SINGLE-CENTRE EXPERIENCE

E. Gaidar[1], A. Kononov[2], E. Isupova[2], M. Kostik[3], O. Kalashnikova[4], T. Nikitina[5], E. Sinelnikova[4], V. Chasnyk[4]. [1]*Saint-Petersburg State Pediatric Medical University, Hospital Pediatrics, Sankt-Peterburg, Russian Federation*; [2]*Saint-Petersburg State Pediatric Medical University, Hospital Pediatrics, Sankt-Peterburg, Russian Federation*; [3]*Saint-Petersburg State Pediatric Medical University, Hospital Pediatrics, Sankt-Peterburg, Russian Federation*; [4]*Saint-Petersburg State Pediatric Medical University, Hospital Pediatrics, Sankt-Peterburg, Russian Federation*; [5]*Saint-Petersburg State Pediatric Medical University, Ophthalmology, Sankt-Peterburg, Russian Federation*

Background: Uveitis (U) is one of the most common extra-articular manifestation of juvenile idiopathic arthritis (JIA). It is usually revealed in 10-20% of children with JIA, often asymptomatic and sometimes the onset of U precedes the onset of arthritis. Being inappropriately treated, U leads to vision loss in up to 20% of children. Despite the efforts of the Standardization of Uveitis Nomenclature (SUN) Working Group and the European initiative Single Hub and Access point for pediatric Rheumatology in Europe (SHARE) which optimized management of JIA-associated U [1], the actual treatment is mostly based on physicians' experience. Initial treatment typically includes topical glucocorticoids (G) or systemic immunosuppressive therapy if topical G don't work. Methotrexate (MTX) is the first-line systemic immunosuppressive agent, followed by tumor necrosis factor inhibitors (TNFi) [1,2].
Objectives: To provide treatment recommendations for JIA-associated U based on monitoring of 221 patients during 7 years.
Methods: Data collected during 2240 hospitalisations of 221 patients aged 3 - 17 years treated at the State Pediatric Medical University in years 2014 - 2020 were analyzed. U and JIA were diagnosed according to the SUN and ACR recommendations. Initial treatment of U included topical G or non-steroidal anti-inflammatory drugs (NSAIDs). Treatment of JIA included systemic NSAIDs, cytostatics (MTX, Cyclosporine or Cyclophosphamide) and biologics: Adalimumab (Ada), Infliximab (Inf), Etanercept (Eta), Abatacept (Aba), Tocilizumab (Toc), Golimumab (Gol). Statistical analysis included traditional Descriptive Statistics, Spearman Rank Order Correlation (SROC) and Multivariate Exploratory Techniques [Statistica for Windows, Statsoft].
Results: Of all patients with JIA-associated U the proportion of those treated with biologics during the monitoring increased from 60 to 70% (of them, Ada 79 - 93%, Inf 7 - 1%, Eta 5 - 1%, Aba 7 - 3%, Toc 7 - 0%, Gol 0 - 3%). Of all children in whom U was diagnosed later than arthritis 36% were treated with systemic NSAIDs, 25% - with cytostatics (MTX - 84%, Cyclosporine - 8%, Cyclophosphamide - 8%), 23% - with systemic G, 6% - with biologics (Eta - 83%, Toc - 17%). Of patients in whom U and arthritis were diagnosed simultaneously, 95% were treated with cytostatics (MTX - 95%, Cyclosporine - 15%), 93% - with topical G, 91% - with topical NSAIDs, 81% - with systemic G, 60% - with systemic NSAIDs. Efficacy of treatment in terms of SROK showed evidence of steady improvement already after 1 month of therapy with TNFi or with MTX (increase of r during the first year from 0.37 to 0,62, $p<0.02$; from 0.37 to 0.55, $p<0.05$ respectively), though r was never higher than 0.84 during the first 3 years of treatment. Topical NSAIDs and G were less effective: improvement was revealed after 3 months of treatment, it was not so steady and r was never higher than 0.35. Systemic NSAID's were not effective at all.
Conclusion: 1. The likelihood of improvement of U treated with TNFi (Eta excepted) after one month, after 1 and after 3 years of therapy was 37%, 62% and 84% respectively. For MTX this likelihood was 37% after 1 month and 55% after 3 months.
2. TNFi (Eta excepted) in treatment of JIA prevents the onset of U, thereby supposing its early administration.

3. Eta neither prevents nor treats U.
4. Topical NSAIDs and G can hardly be recommended as a reliable means for treatment of U without TNFi and MTX.
5. Systemic NSAIDs neither prevent nor treat JIA-associated U.

Tenbrock[12], M. Niewerth[1], C. Sengler[1], D. Foell[13], J. Klotsche[1]. *[1]Deutsches Rheuma-Forschungszentrum Berlin, Epidemiology, Berlin, Germany*; *[2]Charité Universitätsmedizin Berlin, Paediatric Rheumatology, Berlin, Germany*; *[3]St-Josef-Stift Sendenhorst, Paediatric Rheumatology, Sendenhorst, Germany*; *[4]MHH, Kinderklinik, Hannover, Germany*; *[5]Hamburg Center for Pediatric and Adolescent Rheumatology, Pediatric and Adolescent Rheumatology, Hamburg, Germany*; *[6]Deutsches Zentrum für Kinder- und Jugendrheumatologie, Kinder- und Jugendrheumatologie, Garmisch-Partenkirchen, Germany*; *[7]Asklepios Kinderklinik, Paediatric Rheumatology, St. Augustin, Germany*; *[8]Olgahospital Stuttgart, Paediatric Rheumatology, Stuttgart, Germany*; *[9]Universitätskinderklinik Tübingen, Paediatric Rheumatology, Tübingen,*; *[10]Kinderkrankenhaus Amsterdamer Straße, Paediatric Rheumatology, Köln, Germany*; *[11]Klinikum Bremen Mitte, Prof. Hess Kinderklinik, Bremen, Germany*; *[12]Universitätsklinikum Aachen, Kinder- und Jugendmedizin, Aachen, Germany*; *[13]Universitätsklinikum Münster, Klinik für Pädiatrische Rheumatologie und Immunologie, Münster, Germany*

Background: Various treatment strategies are used for children with newly diagnosed polyarticular JIA. MTX is usually prescribed, sometimes in combination with high-dose intravenous glucocorticoid pulses (HDGC) or multiple intra-articular GC injections (IAGC). These different approaches were considered in the German consensus-based treatment protocols for polyarticular JIA[1], they were also the leading therapies in patients with rheumatoid factor-negative polyarthritis (RF- PA) included in the JIA inception cohort ICON.

Objectives: To compare the effectiveness of three different treatment strategies in nearly DMARD-naïve patients with RF- PA.

Methods: Patients with RF- PA who were included in the ICON cohort and received one of the following treatments within the first three months were considered for the analysis: Group 1: MTX + IAGC in >4 joints, Group 2: MTX + HDGC, Group 3: MTX, no IAGC in >4 joints, no HDGC. Propensity score-adjusted group differences in outcomes after one and two years were analysed by linear and logistic regression analyses.

Results: The analysis included data from 150 patients (79% female, mean age 6.7±4.8 years) enrolled in ICON 1.6±1.9 months after the diagnosis of RF- PA, of whom 52 were in Group 1, 54 in Group 2 and 44 in Group 3. Disease activity did not differ significantly between the groups at treatment start (cJADAS-10 16.7±4.7, 15.8±5.7, 15.9±6.5, respectively).

Of the total group, at 1- and 2-year follow-up (FU), 60.9%/60.1% and 52.3%/58.8% of patients had inactive disease (cJADAS ≤1/Wallace criteria[2]), 21.3% and 35.6% were in remission off drug[2], and mean cJADAS-10 scores were 2.6±3.9 and 3.0±3.5, respectively. 60.5% and 67.0% had no functional limitations (CHAQ=0).

Patients in Group 1 more often had an inactive disease (according to Wallace[2]) at the 1-year FU and tended to have inactive disease more often at 2-year FU than patients in Group 3 (78.1% vs. 45.2%, p=0.025; 73.3 vs. 49.1%, p=0.075, respectively). Group 2 patients (inactive disease in 56.1% and 53.4% at 1- and 2-year FU) did not differ significantly from either Group 1 or Group 3. In addition, Group 1 patients had a significantly better quality of life than patients of Group 2 at the 2-year FU (mean PedsQL 4.0 total score 90.4±9.3 vs. 83.8±11.2, p=0.031). At that time, Group 3 patients had a mean PedsQL 4.0 total score of 85.0±14.6, which was not significantly different from either Group 1 or 2.

On the other hand, Group 1 patients tended to develop new uveitis more frequently within the first two years of treatment than patients in Groups 2 and 3 (13% vs. 2.2% and 3.6%, p=0.101 and 0.131, respectively). At the 2-year FU, patients in Group 1 also had a significantly lower mean height SDS than patients of Group 3 (-0.3±1.1 vs. 0.2±1.1, p=0.038). Mean height SDS was lowest (-0.5±0.8) in patients in Group 2 and significantly lower than in Group 3 (0.019). Mean body mass index SDS also differed significantly between the groups at 2-year follow-up. The mean BMI SDS was highest in Group 1 patients (0.2±0.8), differing significantly from Group 2 (-0.3±0.7, p=0.014) and Group 3 (-0.4±1.1, p=0.023).

There were no significant differences in inactive disease (according to cJADAS) and functional status (CHAQ) between the three groups at 1- and 2-year FU. Over time, treatments were very different in the three groups. In Group 3, biologics were used significantly more often over time than in group 1 (54.0% vs. 18.3%, p=0.014), and Group 2 patients received bDMARDs in 36.1%.

Conclusion: While patients with numerous early joint injections seem to achieve inactive disease more frequently and earlier, they have a slightly smaller body height and tend to develop uveitis slightly more often than patients with more intensive DMARD therapy. However, the differences are small between the groups. Further comparative effectiveness studies with higher patient numbers are needed to identify particularly effective and safe treatment strategies.

POS1326 FAMILIAL PERIODIC FEVER, APHTHOUS STOMATITIS, PHARYNGITIS AND ADENITIS (PFAPA)SYNDROME; IS IT A SEPARATE DISEASE?

Y. Butbul[1]. *[1]1The Ruth and Bruce Rappaport Faculty of Medicine,Technion - Israel Institute of Technology, Haifa, Israel, Pediatric Rheumatology unit, Haifa, Israel*

Background: Periodic fever, aphthous stomatitis, pharyngitis, and adenitis syndrome (PFAPA) is the most common periodic fever syndrome in the pediatric population. Unlike other periodic fever syndromes, the pathogenesis and genetics of PFAPA is unknown. Until recently, PFAPA was believed to be a sporadic disease, yet family clustering has been widely observed and current research indicates that heredity is likely.

Objectives: To identify demographic and clinical differences between patients with PFAPA who have a positive family history (FH+) compared to those with PFAPA with no family history (FH-) that can reveal if heritable and sporadic subtypes of this disorder exist.

Methods: In a database comprising demographic and clinical data of 273 pediatric PFAPA patients treated at two tertiary centers in Israel, 31(14.3%) of patients were PFAPA FH+. Data from patients with FH+ for PFAPA was compared to data from those with FH- of the disorder. Furthermore, family members (FMs) of those with FH+ were contacted via telephone for more demography and clinical details.

Results: FH+ group had more headaches (32% vs.2%; p= 0.016), myalgia (56% vs. 19%; p= 0.001), higher carrier frequency of M694V mutation (54% vs. 25%; p=0.053), greater family history of FMF (30% vs. 15%; p=0.096) and better outcomes with colchicine (82% vs. 52%; p=0.096) compared to those with FH-. FMs displayed almost identical characteristics to the FH+ group except for greater arthralgia during flares (64% vs. 23%; p=0.008) and compared to the FH- group, more oral aphthae (68% vs. 43%; p=0.002), myalgia/arthralgia (64% vs. 19%/16%; p<0.0001), and higher rates of FH of FMF (45% vs.15%; p=0.003).

Conclusion: Our findings suggest that FH+ had probably different subset of disease with higher frequency of family history of FMF arthralgia, myalgia and better response to colchicine. Colchicine prophylaxis for PFAPA should be considered in FH+.

POS1327 DO JIA PATIENTS RESPONSE TO RE-TREATMENT AFTER A FLARE DURING TAPERING OF BDMARDS? A DESCRIPTIVE STUDY

A. García Fernández[1], A. Briones-Figueroa[1], L. Calvo Sanz[1], Á. Andreu-Suárez[1], A. Boteanu[1]. [1]*Hospital Universitario Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: Tapering and withdrawal of biological DMARDs (bDMARDs) is often attempted in Juvenile Idiopathic Arthritis (JIA) patients but data about response to re-treatment after an unsuccessful tapering are scarce.
Objectives: Our aim is to assess response to re-treatment after a disease flare during tapering or withdrawal of bDMARDs and to describe re-treatment strategies.
Methods: A retrospective, descriptive study was conducted in a cohort of JIA patients followed up in a referral hospital and who had received bDMARDs between 2000 and 2019. All JIA patients with at least one flare during tapering or withdrawal were included. Response to re-treatment was defined as achieving Wallace criteria for remission for 6 months.
Results: A total of 142 flares during tapering or withdrawal were identified and included. In 3/142 (2.1%) patients bDMARDS were not re-started after a flare, 1 due to patient refusal, 2 due to unplanned pregnancy. Main characteristics according to tapering strategies are reported in Table 1.

Table 1. Main characteristics according to tapering strategies. Apso, Psoriatic Arthritis; ERA, Enthesitis related Arthritis; OligE, Oligoarticular Extended; OligP, oligoarticular persistent; Poly RF+, polyarticular rheumatoid factor positive; PolyRF-, polyarticular rheumatoid factor negative; sJIA, Systemic JIA; Und, Undifferenciated.

	Tapering	Withdrawal
Cases, n (%)	80 (57.5)	59 (42.4)
Female, n (%)	57 (71.3)	36 (61)
Age at diagnosis,years, median (IQR)	5 (2-11)	4 (2-11)
Age at start of tapering or withdrawal, years, median (IQR)	17 (11-25)	16 (8-29)
Categories, n (%)		
OligP	19 (23.8)	12 (20.3)
OligE	15 (18.8)	13 (22)
sJIA	10 (12.5)	11 (18.6)
ERA	12 (15)	8 (13.6)
Apso	7 (8.8)	6 (10.2)
Poly RF+	9 (11.3)	4 (6.8)
Poly RF-	7 (8.8)	3 (5.1)
Und	1 (1.3)	2 (3.4)
Uveitis, n (%)	24 (30)	16 (27.1)
Laboratory values, n (%)		
- RF	15 (18.8)	5 (8.5)
- ANA	45 (56.3)	33 (55.9)
cDMARDs at start of tapering, n (%)	40 (50)	20 (33.9)
bDMARD target, n (%)		
- TNF inhibitors	63 (78.8)	45 (76.3)
- IL6-blockers	14 (17.5)	5 (8.5)
- IL1-blockers	2 (2.5)	7 (11.9)
- Rituximab	1 (1.3)	2 (3.4)
Line of bDMARD, n (%)		
- First	50 (62.5)	45 (76.3)
- Second	18 (22.5)	10 (16.9)
- Third	5 (6.3)	2 (3.4)
- Forth	6 (7.5)	2 (3.4)
- Fifth	1 (1.3)	0 (0)
Time in bDMARD treatment, months median (IQR)	28.4 (13.3-52.5)	28.2 (13.9-44.6)
Remission prior tapering or withdrawal,months median (IQR)	8 (6-12)	8 (6-12)

Fifty-nine out of 80 (73.8%) tapering cases were on remission at 6 months (6m) and 42/80 (52.5%) at 12 months (12m). Regarding dosage schedule adjustments, interval widening was the most frequent in 70/80 (87.5%) followed by combined strategy in 7/80 (8.8%) and lower dosage in 3/80 (3.8%). Median remaining dosage administrated was 54.9% IQR(50-75). Median time to flare was 14.9 months IQR (5.6-24.7). Median time to re-start of bDMARDs was 0 months min-max(0-13).
After withdrawal of bDMARDs 23/59 (39%)cases at 6m and 14/59 (23.7%) cases at 12m were on remission. Median time to flare was 4.7 months IQR (2.8-11.4). Median time to re-start of bDMARDs was 1 month min-max (1-6).
Most frequent re-treatment strategies were re-start of standard dosage [tapering 42/80 (52.5%), withdrawal 34/59 (57.6%)], re-start of previous effective dosage [tapering 28/80 (35%), withdrawal 11/59 (18.6%)], change of bDMARD [tapering 6/80 (7.5%), withdrawal 6/59 (10.2), re-start of bDMARD and cDMARD [tapering 4/80 (5%), withdrawal 6/59 (10.2)] and re-start of cDMARD [tapering 0/80 (0), withdrawal 1/59 (1.7%)].
Overall response to re-treatment was 75/80 (93.8%) and 53/58 (91.4%) among tapering and withdrawal, respectively. In 12/139 (8.6%) patients bDMARD was changed, achieving remission in 11/12 (91.7%) cases. No factors were associated with response to re-treatment and there were no differences between re-treatment strategies and re-achieving remission (p=0.596).
Conclusion: Response to re-treatment was high (92.7%), no risk factors were identified. Most frequent retreatment strategy was re-start of standard bDMARD dosage in 76/139 (54.7%) followed up by restart of previous effective bDMARD dosage in 39/139 (28.1%).

POS1328 HAVE THE CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS AN EXCESS OF ADIPOSITY?

G. Diaz-Cordobes[1], S. Aguado Henche[2], L. Martín Pedraz[3], R. Galindo Zavala[3], N. Mena-Vázquez[4], E. Núñez Cuadros[3]. [1]*Instituto de Investigación Biomédica de Málaga (IBIMA). Hospital Regional Universitario de Malaga. Universidad de Malaga, Reumatología, Málaga, Spain*; [2]*Universidad de Alcalá. Facultad de Medicina, Departamento de Anatomía y Embriología Humana, Madrid, Spain*; [3]*Hospital Materno Infantil. Hospital Regional Universitario de Mälaga, Pediatria., Málaga, Spain*; [4]*Instituto de Investigación Biomédica de Málaga (IBIMA). Hospital Regional Universitario de Malaga. Universidad de Malaga, Reumatología, Màlaga, Spain*

Background: In recent years, several studies show contradictory results regarding body composition in juvenile idiopathic arthritis. Adiposity in Rheumatoid Arthritis and Psoriasic Arthritis has been associated to inflammatory activity, but it is not clear what happens in JIA.
Objectives: To describe the body composition and anthropometric parameters of patients with JIA compared with healthy controls and analyze associated risk factors in JIA patients.
Methods: Observational cross-sectional study in spanish children aged 4-15 years with JIA compared with healthy controls matched for age and sex. We recorded epidemiological variablesanthropometric parameters, clinical data and validated physical activity questionnaires. Body composition was measured using dual-energy x-ray absorptiometry (DXA), and included total mass (kg), fat mass (g), lean mass (g), and lean mass and android and gynoid fat mass. The fat mass index (FMI) was defined as fat mass (kg)/height squared (m^2) and fat-free mass index (FFMI) as fat-free mass (kg)/height squared (m^2). Descriptive, bivariete and two multivariate models were constructed to identify factors associated with obesity and fat mass in JIA patients.
Results: We analyze 160 subjects: 80 patients with JIA and 80 healthy controls. The baseline characteristics of both groups are shown in Table 1. No differences were found between both groups in BMI (p=0.936), fat mass (p = 0.449), lean mass (p = 0.793) and in fat and lean mass of legs, arms and trunk, or in physical activity questionnaire (p = 0.582). The factors associated with obesity in patients with JIA were: time with biological drug (OR [95% CI] = 1.12 [1.01-1.04]; p = 0.042) and sedentary lifestyle (OR [95% CI] = 3.50 [1.18-7.35]; p = 0.023); while the factors associated with the fat mass index were: age (ß [95% CI] = 0.30 [0.16-1.41]; p= 0.014), inflammatory activity (JDAS) (ß [95% CI] = 0.44 [0.16-1.08]; p= 0.009) and physical activity (ß [95% CI] = -0.22 [-0.10,-0.28]; p = 0.031).

Table 1. Baseline characteristics of patients with JIA and controls

Variable	JIA (n=80)	Controls (n=80)	P-value
Sex, girls n (%)	56 (70.0)	57 (71.3)	0.862
Age, mean (SD)	10.7 (3.2)	10.2 (3.2)	0.893
Disease duration (years) JIA, mean (SD)	6.5 (3.7)		
JIA subtype			
Systemic, n (%)	9 (11.3)		
Oligoarticular persistent, n (%)	38 (47.5)		
Oligoarticular extended, n (%)	13 (16.3)		
Rheumatoid Factor-positive polyarticular, n (%)	1 (1.3)		
Rheumatoid Factor-negative polyarticular, n (%)	19(23.8)		
CRP (mg/l), mean (SD)	4,8 (9,5)		
ESR (mm/h), mean (SD)	8.8 (7,3)		
JADAS27, mean (SD)	2 (4.0)		
CHAQ, mean (SD)	0.17 (0.4)		
Treatment			
DMARDs (synthetic), n (%)	42 (52.5)		
DMARDs (biological), n (%)	24 (30.0)		
Anti IL-1, n (%)	4 (16.7)		
Anti IL-6, n (%)	2 (8.3)		
Anti TNF-α, n (%)	18 (75.0)		
Treatment duration			
DMARDs synthetic, (months), mean (±SD)	51 (37.5)		
DMARDs biological, (months), mean (±SD)	19.7 (28.4)		
DMARDs total (months), mean (±SD)	55.8 (38.0)		
Cumulative corticoisteroids dose, median (range)	11.3 (0.12-870)		

Abreviaturas; JIA: juvenile idhipathic arthritis; SD: standart deviation; CRP: C-reactive protein; VSG:erytrocyte sedimentation rate; JADAS27: Juvenile Arthritis Disease Activity Score; CHAQ: Childhood Health Assessment; DMARD: disease-modifyng anti-rheumatic drug.

Conclusion: Children with JIA have adiposity similar to healthy controls. Inflammatory activity measured by JDAS is associated with fat mass but not to anthropometric measurements such as body mass index (BMI).

POS1329 A COHORT STUDY ON THE RISK OF DEVELOPING OBSTRUCTIVE SLEEP APNEA, TEMPOROMANDIBULAR JOINT DISORDERS AND CRANIOFACIAL DEFORMITIES IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

K. S. K. MA[1], L. T. Wang[2]. *[1]National Taiwan University,Taipei,Taiwan, ROC, Department of Life Science,Taipei,Taiwan, Republic of China*; *[2] National Taiwan University Hospital, Department of Obstetrics & Gynecology,Taipei,Taiwan, Republic of China*

Background: Juvenile Idiopathic Arthritis (JIA), an autoimmune disease, has been proposed to be comorbid with obstructive sleep apnea (OSA).

Objectives: We aimed at identifying the relationship between JIA and OSA.

Methods: We performed a cohort study including JIA and OSA patients from 1999 to 2013. A total of 2791 patients diagnosed with OSA after JIA onset were recruited, which 11,164 eligible individuals without JIA history were selected as matched-controls. A Cox proportional hazard model was developed to estimate the risk of OSA in JIA patients. A cumulative probability model was adopted to assess the time-dependent effect of JIA on OSA development, implying the casual link of the association. To identify whether JIA patients have higher risks for developing temporomandibular joint (TMJ) disorders, craniofacial anomalies and deformities than non-JIA individuals, subgroup analyses was conducted. Finally, Ingenuity Systems Pathway Analysis (IPA) was conducted to identify underlying mechanisms of the above disease correlation among peripheral blood mononuclear cells (PBMCs) from rheumatic factor (RF)-positive and RF-negative JIA patients, and subcutaneous fat tissues from OSA patients, using p-value visualization for RNA-seq analyses.

Results: The Cox proportional hazard model showed that JIA patients were more likely to have OSA than non-JIA individuals (adjusted hazard ratio =1.949, 95% CI =1.264–3.005). The incidence of developing OSA was particularly high among patients who developed JIA aged 18-30 years old (aHR= 2.034, 95% CI=1.305-3.169) and males (aHR=1.82, 95% CI=1.121-2.954). The risk of developing OSA increased within 0-36 months (aHR = 2.216, 95% CI = 1.001 – 4.907) and over 60 months (aHR = 2.558, 95% CI = 1.346 – 4.860) of follow-up duration after JIA onset. Subgroup analyses showed that JIA patients were more likely to have TMJ disorders (relative risk = 2.047, 95% CI = 1.446-2.898) and to receive treatment for craniofacial deformities (RR = 1.722, 95% CI = 1.38-2.148) than non-JIA controls. IPA analyses suggested that the underlying mechanisms involved activation of antigen presentation pathway followed by antigen presentation to CD4+ and CD8+ T lymphocytes, as well as B cell development.

Conclusion: Our findings identified high risks of developing OSA, TMJ disorders, and craniofacial deformities following JIA onset, which the underlying mechanisms may involve both cellular and humoral immunity.

Background: Cryopyrin associated periodic syndromes (CAPS) are a group of ultra-rare autoinflammatory diseases caused by mutations in the *NLRP3* gene, leading to overproduction of IL-1β. CAPS includes the following subdiagnoses: familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS) and chronic infantile neurological cutaneous articular syndrome/neonatal-onset multisystem inflammatory disease (CINCA/NOMID), where FCAS is the mildest form of CAPS and CINCA/NOMID the most severe. A graduated pre-filled syringe of the IL-1 receptor antagonist anakinra was introduced to meet the need of smaller and varying doses when treating children with CAPS.

Objectives: To evaluate the safety of anakinra in CAPS patients using the novel pre-filled syringe.

Methods: Investigators managing patients with CAPS treated with anakinra were identified via the Eurofever registry. Follow-up data of at least 3 years for each patient were prospectively collected and analyzed (EUPAS6366). The primary study endpoints were the occurrence of adverse events (AEs) with focus on serious infections, malignancies, injection site reactions, allergic reactions and medication errors, including re-use of the syringe. Secondary endpoints included dose at specific time points, discontinuations, and switch to other IL-1 blocking treatment.

Results: 12 patients with CAPS were included in the study, 8 with MWS, 2 with FCAS and 2 with CINCA/NOMID. The majority were male (75%) and white (83.3%). At baseline, all but one patient were already using the graduated pre-filled syringe with anakinra. 5 patients required a median dose of 2 to 3 mg/kg/day and 6 patients below 2 mg/kg/day. During a total of 26.1 patient years of treatment, there were 7 AEs with rate of 26.8 (95% CI 4.2-169.6) per 100 patient years. All AEs were infections from 1 patient with CINCA/NOMID and were considered unrelated to anakinra by the investigator. Two of the AEs were considered serious as hospitalization was required (1 tonsillitis and 1 urinary tract infection). No AEs were severe, 6 of the AEs were of moderate severity and 1 was of mild severity. In total, 6 patients discontinued anakinra permanently, 2 during the first year of treatment, 3 during the second year and 1 after the third year of follow-up. The reasons for discontinuation included switch to canakinumab (4 patients), switch to canakinumab and inefficacy (1 patient) and non-compliance (1 patient). The remaining 5 patients continued anakira until the end of the study. 1 patient discontinued anakinra temporarily during the second year of treatment due to non-compliance. No deaths, malignancies, injection site reactions, allergic reactions or medication errors, including re-use of the pre-filled syringe, were observed.

Table 1. Study results

Patients	12 (100)
Gender, M:F	9:3 (75:25)
Ethnicity, white:black	10:2 (83.3:16.7)
Age at baseline, median (range), years	25.3 (1.4-54.9)
Age at disease onset, median (range), years	2.5 (0-29.5)
Age at diagnosis, median (range), years	24.4 (0.6-54.6)
Disease duration, median (range), years	15.5 (1.4-51.3)
Patients already using anakinra at baseline	11 (91.7)
Patients with history of other IL-1 blocking treatments at baseline	3 (25)
Anakinra dose at baseline, median (range), mg/kg/day	1.7 (1.1-2.5)
Anakinra dose during follow-up years 1:2:3:>3, median (range), mg/kg/day	1.6:1.6:2.6:1.4 (1.1-3.9:1-4.4:1.7-3.7:1-3.2)
Patients with AEs	1 (8.3)
Patients with permanent discontinuation of anakinra	6 (50)
Patients with continuation of anakinra until the end of the study	5 (41.7)
Patients with temporary discontinuation of anakinra	1 (8.3)
Total duration of anakinra exposure, median (range), years	1.3 (0.5-7)
Any AE	7 (100)
Urinary tract infection	1 (14.3)
Upper respiratory tract infection	1 (14.3)
Tonsillitis	5 (71.4)

Results are shown as number (%) unless stated otherwise.

Conclusion: The results of the present study confirm the safety profile of anakinra treatment in CAPS patients using the graduated pre-filled syringe. No new safety findings were identified.

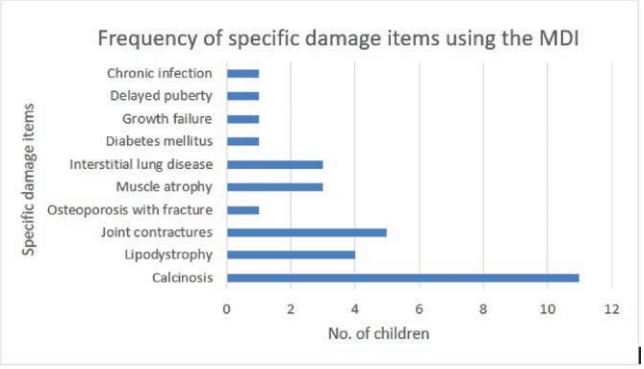
POS1331 LONG-TERM OUTCOME IN CHILDREN WITH JUVENILE DERMATOMYOSITIS FROM SOUTHERN INDIA

P. R. Chickermane[1], M. Kuriakose2, A. Tiwari2, A. Shahul2, S. Balan2. [1]*Amrita Institute of Medical Sciences, Clinical Immunology and Rheumatology, Kochi, India*; [1]*Amrita Institute of Medical Sciences, Clinical Immunology and Rheumatology, Kochi, India*

Background: There is paucity of data regarding long-term outcome and cumulative damage in children with juvenile dermatomyositis (JDM) from the Indian subcontinent.
Objectives: To assess the long-term outcome and cumulative damage in children with JDM receiving treatment at a tertiary hospital in southern India.
Methods: Retrospective review of records and cross-sectional assessment of outcome and damage in 29 patients with JDM at a tertiary hospital in Kochi, India. The disease course was categorized as monocyclic, polycyclic and chronic progressive. Cumulative damage was assessed using the IMACS myositis damage index (MDI).
Results: Twenty-nine patients (male-16) diagnosed with definite or probable juvenile dermatomyositis based on the Bohan and Peter criteria and having a minimum follow-up period of 3 years each were enrolled. Of these, 20 children were diagnosed and initiated on treatment at our institute (inceptional) and 9 were diagnosed elsewhere and referred to our centre for further management (non-inceptional). The mean age at disease onset was 7.01 ± 3.34 years (range 1.0 to 13.5 years). The median interval from onset to diagnosis was 3 months (range- 3 weeks to 8.75 years). Delayed diagnosis defined as interval from onset to diagnosis exceeding 6 months was noted in case of 8 children. Among patients in the non-inceptional group, six were considered to have not received standard of care treatment prior to referral to our centre. Standard of care treatment was defined as initiation of a treatment regimen comprising of a combination of glucocorticoids with an immunosuppressive agent within 4 weeks of diagnosis. A total of 11 children had a delayed diagnosis and/or had not received standard of care treatment prior to referral.
At our centre, all patients received oral steroids and subcutaneous methotrexate as standard therapy. Pulse steroids were used to induce remission in 12 patients and as a rescue for relapses in 2 patients. Intravenous immunoglobulin was used in 10 children with severe myositis, oropharyngeal weakness, refractory cutaneous disease including calcinosis and concomitant infection, where affordable with good results. Hydroxychloroquine was added in 15 patients with dominant cutaneous manifestations. Mycophenolate mofetil, azathioprine and tacrolimus were used in patients refractory or intolerant to methotrexate. Cyclophosphamide and rituximab were used in 4 patients each with refractory disease and extra-muscular manifestations such as interstitial lung disease. Seven patients with refractory calcinosis received pamidronate infusions.



The total follow-up duration was 121.06 patient-years. A monocyclic course was observed in 11/29 (37.9%), chronic progressive course in 16/29 (55.2%) and polycyclic course in 2/29(6.9 %). Nearly half of the patients (14/29) had damage in at least one organ using the MDI (MDI ≥1). 38% of the patients (11/29) had at least one sign of cutaneous damage, the most common being calcinosis (n=11) and lipodystrophy (n=4). This was followed by skeletal damage (n=6, joint contractures-5, osteoporosis with fracture-1), muscle and pulmonary (pulmonary fibrosis) damage in 3 patients each, endocrine damage in 2 patients (diabetes mellitus-1, growth failure and delayed development of secondary sexual characteristics-1) and chronic infection in one patient. All patients with damage in at least one organ had a chronic progressive course, indicating damage accrual. Delayed diagnosis and lack of standard of care treatment prior to referral (i.e., longer duration of untreated/ sub-optimally treated disease) were associated with an increased risk of cumulative damage ($p< 0.05$).
Conclusion: Nearly half of the patients had damage in at least one organ using the MDI. Cutaneous damage was the most common, followed by skeletal, muscle, pulmonary and endocrine damage. Longer duration of untreated/ sub-optimally treated disease significantly increases the risk of cumulative damage, highlighting the need for an early diagnosis and referral to pediatric rheumatology services.

POS1332 ETANERCEPT-ASSOCIATED NEW ONSET UVEITIS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS UNDER BIOLOGICAL THERAPY: SINGLE CENTER EXPERIENCE

I. Nikishina[1], S. Arsenyeva[1], M. Kaleda[1], O. Kostareva[1], A. Shapovalenko[1], E. Denisova[2], A. Panova[1,2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*; [2]*Helmgoltz Moscow Research Institute of Eye Diseases, Pediatric Department, Moscow, Russian Federation*

Background: Biological agents (BA), especially TNF inhibitors, are high efficacy options for current therapy for patients (pts) with juvenile idiopathic arthritis (JIA). They are successfully used not only for the arthritis but also for JIA-associated uveitis, however, development of uveitis *de novo* in pts treated with BA is a well-established paradoxical phenomenon.
Objectives: to evaluate the frequency of new onset (*no*-) uveitis, occurring under BA therapy in JIA pts, to establish clinical features, which may be associated with development of such effects.
Methods: retrospective cohort study involved all JIA pts (1136) who were treated with BA in our clinic from 2004 to 2020. All cases of *no*-uveitis were collected for the describing of their clinical features in disease onset and course, activity level, JIA category, exposure to Methotrexate (MTX) and BA, presence of ANA, HLA B27.
Results: among of 1136 pts treated with different BA we identified 36 (3.3%) pts (19 female/17 male) with *no*-uveitis under BA. Mostly during etanercept (ETA) therapy (34 cases from 488 ETA courses, 7%), 1/166 - in abatacept (ABA) and 1/372 - in adalimumab (ADA). 30 pts (83%) with *no*-uveitis developed it on the 1st line of BA treatment (29 ETA vs 1 ADA). 4pts (11%) developed *no*-uveitis on 2 nd line (3 ETA vs 1 ABA). 2 pts (6%) on third line (all ETA, both pts had also psoriasis). There are no cases of *no*-uveitis under other BA. Frequency of *no*-uveitis was much higher in ETA group. ETA exposure was 26.8±28.8 months (mo). It means there are no "safe" period of therapy from paradoxical phenomenon of no-uveitis. JIA subtypes were as follows: RF-neg polyarthritis 9 (25%), persistent oligoarthritis 3 (8%), extended oligoarthritis 21 (59%), enthesitis-related arthritis (ERA) - 3 (8%). Average age at JIA onset was 4.6±3.9 yrs. 20/36 patients had high laboratory activity (CRP 54±23 mg/l; ESR 41±19 mm/h) and severe arthritis before BA initiation. However most of pts (25/36) achieved 90-100% ACRpedi-response by the uveitis development. 23/36 pts were ANA-positive, 17/36 pts had HLAB27, including 7 pts who had the both features. Uveitis was occurred earlier in ANA plus HLAB27 positive pts (mean exposure - 15.3 mo) than in only ANA-positive or HLAB27-positive pts (27.7 mo and 27.6 mo accordingly). 29/36 (81%) of pts received methotrexate (MTX) in mean dosage 11.5 mg/m^2/week. There are no differences in time of uveitis development depending of MTX. In all cases of *no*-uveitis BA was switched.
Conclusion: Our study suggested that new onset of uveitis is rare adverse event during BA therapy in JIA. Uveitis can develop despite the excellent effect of therapy on joint manifestation. The most typical development of *no*-uveitis is under ETA therapy, especially in the predisposed cases (certain variants of JIA, ANF positivity, HLAB27 presence) and in patients with very high disease activity at the time of the start of biological therapy.

POS1333 ANKLE ARTHRITIS IN JUVENILE IDIOPATHIC ARTHRITIS: DON'T MISS TENOSYNOVITIS. CLINICAL AND SONOGRAPHIC FEATURES OF ANKLE TENOSYNOVITIS IN JIA

S. Pastore[1], S. Della Paolera[1], A. Zabotti[2,3], A. Tommasini[1,4], A. Taddio[1,4]. [1]*IRCCS Burlo Garofolo, Pediatric Department, Trieste, Italy*; [2]*Azienda Sanitaria*

Universitaria Friuli Centrale, Rheumatology Clinic, Udine, Italy; [3]*University of Udine, Department of Medical and Biological Sciences, Udine, Italy*; [4]*University of Trieste, Department of Medicine, Surgery and Health Sciences, Trieste, Italy*

Background: Tenosynovitis can occur in patients with Juvenile Idiopathic Arthritis (JIA) and may be clinically difficult to distinguish from joint synovitis. The role of musculoskeletal ultrasound (msk-US) is still discussed in the management of JIA but recent studies supported the utility of msk-US especially in detection of tenosynovitis. There is no consensus treatment for tenosynovitis in children with JIA and almost all studies focused on tendon sheath injection with glucocorticoids.
Objectives: The aims of the study were: i) to define the prevalence of tenosynovitis of the ankle in JIA patients and ankle swelling; ii) to describe the clinical characteristics of patient with tenosynovitis and to analyze different response to treatment.
Methods: We conducted an observational cross-sectional study of a group of patients with JIA followed at the Rheumatology Service of the Maternal and Child Institute "Burlo Garofolo" of Trieste. We enrolled all the patients who reported a swelling of the ankle at least once during the follow-up period and, among these patients, we included only those who underwent msk-US. Based on both clinical and sonographic examination, we identified patients with tenosynovitis and we described their demographical and clinical characteristics as well as the therapeutic approach undertaken in this group of patients.
Results: On December 31st 2019, 56 swollen ankles of 48 patients were assessed with msk-US: 22 ankles showed sonographic signs of synovitis (39%), 16 ankles of both synovitis and tenosynovitis (28%), 14 ankles of tenosynovitis only (25%). Overall, tenosynovitis was detected on twenty-seven (56%) out of 48 children with at least a swollen ankle. The majority of patient were females (70%) and the most affected tendon was the tibialis posterior (66%). Twenty-five patients with tenosynovitis (92%) achieved clinical and radiological remission: seven out of 26 patients (26%) treated with methotrexate achieved clinical and radiological remission without the addition of other therapies; fifteen out of seventeen patients (88%) treated with a biological drug responded to the therapy, of which eleven (73%) were in combination therapy with methotrexate.
Conclusion: We observed that more than 50% of the patients with a swelling of the ankle presented a tenosynovitis and among these patients about 50% did not show sonographic sign of synovitis. Msk-US was decisive in order to identify tenosynovitis and to characterize ankle swelling in JIA patients. Among patients with tenosynovitis biological therapy alone or in association with immunomodulating therapy showed effectiveness in inducing disease remission.

POS1334 **RHEUMATOLOGY PATIENT ATTENDANCE TO THE PAEDIATRIC EMERGENCY DEPARTMENT**

M. Al-Attar[1]. [1]*Paediatric Emergency Department, Royal Manchester Children's Hospital, Manchester, United Kingdom*

Background: A large proportion of patients present to the paediatric emergency department (PED) with non-urgent problems [1]. With growing pressures on services, there is a need to reduce unnecessary attendances. Children with rheumatological conditions may attend PED with flares of their condition or unrelated presentations. These patients may be immunosuppressed due to steroid, disease-modifying or biologic therapy; PED attendance may therefore pose a serious infection risk.
Objectives: To evaluate why children with rheumatological conditions attend the PED and whether these attendances are avoidable.
Methods: This study was run in Royal Manchester Children's Hospital, a UK hospital with a PED and tertiary paediatric rheumatology services. Patients under rheumatology who attend PED are usually seen directly. A dataset of all patients referred directly to paediatric rheumatology between 01/01/19 and 31/12/19 was obtained from electronic records (n=59). The age, sex and reason for attendence were collected, as well whether they were admitted/discharged. Further data on management was collected from discharge letters for those with joint pain/swelling.
Results: This cohort had 36 females and 23 males, with an average age of 11.9 years (range 1-18). 28 were discharged (47.5%) and 30 were admitted (50.8%). One patient left before being seen. The average waiting time was 3.97 hours.
Table 1 summarises reasons for attendance to PED and final outcome. The most common reason for attendance was joint pain/swelling (n=14, 23.7%). Of these, nine were discharged with advice on analgesia or steroid dosing and for early review in clinic. There was no documentation on whether there had been any attempt to access the available rheumatology helpline prior to attending PED.
Non-rheumatology-related reasons for attendance are also shown in Table 1, and notably include 20 patients with infections, 75% of whom were admitted to hospital. Chicken pox was the second most common reason for attendance (n=5, 8.5%); all patients attending with chicken pox or shingles (n=6) were admitted.

Table 1. Reasons for attendance to PED and final outcome

Reason for attendance	Number admitted	Number discharged
Joint pain/swelling	5	9
Chicken pox	5	0
Viral URTI	1	4
Rash	0	4
Pneumonia	3	0
SLE flare	3	0
Influenza A	2	0
GPA flare	2	0
Asked to attend due to blood results from clinic	2	0
Drug reaction	0	2
Minor injury	0	2
Shingles	1	0
Oral herpes simplex	1	1
Orbital inflammation	1	0
Urinary tract infection	1	0
Dysphagia	1	0
Gastroenteritis	1	0
Cerebral infarcts	1	0
Constipation	0	1
Chest pain	0	1
Abdominal pain	0	1
Enlarged lymph node	0	1
Picking up prescription	0	1
Unresponsive episode	0	1

Conclusion: Our study shows that attendance to PED with joint pain/swelling is usually avoidable in patients known to paediatric rheumatology services. Appropriate alternative services are needed to reduce hospital attendances; nurse-led helplines are beneficial, but still face some challenges in both availability and accessibility [2]. It is also important that patients and parents are given action plans for acute flares, which would ideally involve early clinic review rather than PED attendance. Our data also showed that patients are spending a long time waiting in PED, which needs to be avoided particularly in the context of immunosuppression. This is especially poignant now in light of the Covid-19 pandemic. Direct referral to rheumatology with non-rheumatological problems likely reflects a desire for specialist advice in the context of complex conditions and medications, for example with regards to infections whilst on immunosuppressive medications, or uncertainty about whether new symptoms are related to the underlying condition. Expansion of helpline services and new approaches such as remote consultations should be explored.

POS1335 **CLINICAL CHARACTERISTICS OF THE PULMONARY ARTERY INVOLVEMENT IN PATIENTS WITH BEHÇET'S SYNDROME: A SINGLE-CENTRE EXPERIENCE OF 61 PATIENTS**

D. Sahin Eroglu[1], M. Torgutalp[1], S. Baysal[2], A. Colaklar[3], S. Sezer[1], M. E. Yayla[1], C. Uzun[3], T. M. Turgay[1], G. Kınıklı[1], A. Ates[1]. [1]*Ankara University Faculty of Medicine, Department of Internal Medicine, Division of*

Rheumatology, Ankara, Turkey; [2]*Ankara University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey*; [3]*Ankara University Faculty of Medicine, Department of Radiology, Ankara, Turkey*

Background: Behçet's Syndrome (BS) is a vasculitis of unknown origin. Vascular involvement, so-called vascular Behçet's syndrome (VBS), may involve blood vessels of all sizes belonging to both venous and arterial system, with pulmonary artery involvement (PAI) being the most frequent form of arterial involvement. PAI in BS occurs in the form of aneurysms or thrombosis, and results in significant mortality.

Objectives: To report the clinical characteristics of PAI in patients with BS and to define the predictors of relapses.

Methods: We performed a retrospective analysis of BS patients with PAI who fulfilled international study group criteria. Among 460 patients with VBS, 66 were diagnosed with PAI. For final analyses, 61 patients with PAI, who had at least 2 follow-up visits (72.1% male, mean age at BS diagnosis 29.34 (SD 10.1) years), were included. The data of the patients were recorded. Relapse was defined as the reoccurrence of vascular event at any vascular structure. Factors associated with relapse were assessed by logistic regression analysis.

Results: There were not any differences considering demographic and clinical features of the patients with and without PAI in VBS group except for that intracardiac thrombosis was more common in the patients with PAI than the patients without (19.7% vs 0.3%, respectively) (Figure 1). Among 61 patients with PAI, 50 (82.0%) had isolated pulmonary artery thrombosis (PAT), whereas 11 (18.0%) had pulmonary artery aneurysm (PAA) with or without PAT. The characteristics of 61 patients with PAI were shown in Table 1. A total of 37 relapses occurred in 24 (39.3%) patients during follow-up a median of 65.9 (IQR 20.1-109.0) months. To define the factors associated with relapses, the patients with isolated PAT were analysed. In multivariable logistic regression analysis, older age at BS diagnosis and anticoagulation usage seemed to be protective, even though they could not reach statistical significance (OR: 0.92 95% CI 0.86-1.02, OR: 0.34 95% CI 0.09-1.33, respectively).

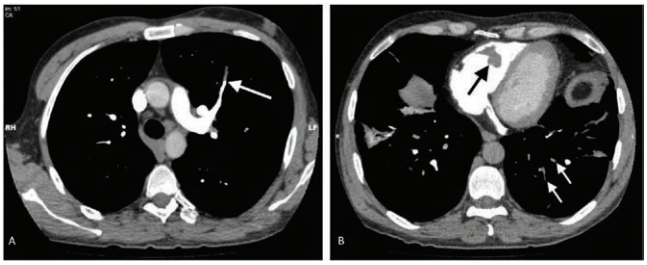

Figure 1. A) Axial CT image shows thrombus formation in the left upper lobe pulmonary artery branch. **B)** Giant thrombus is seen in the right ventricle (black arrow). Note the thrombus formation in the left lower lobe pulmonary artery branches (white arrows).

Table 1. Characteristics of the patients with pulmonary artery involvement

	All n= 61	Isolated PAT n= 50	PAA n= 11
Sex (male), n (%)	44 (72.1)	35 (70.0)	9 (81.8)
Age at diagnosis of BS, years (SD)	29.3 (10.1)	28.8 (10.4)	31.9 (8.0)
Age at diagnosis of PAI, years (SD)	36.3 (12.83)	36.7 (13.8)	34.7 (6.7)
Symptoms, n (%)			
Dyspnea	28 (45.9)	23 (46.0)	5 (45.5)
Hemoptysis	26 (42.6)	19 (38.0)	7 (63.6)
Vascular event before PAI, n (%)	21 (34.4)	20 (40.0)	1 (9.1)
Other vascular events at PAI, n (%)	33 (54.1)	28 (56.0)	5 (45.5)
Thrombophlebitis, n (%)	7 (21.2)	6 (21.4)	1 (20.0)
Upper and/or lower extremity DVT, n (%)	20 (60.6)	16 (57.1)	4 (80.0)
SVCS, n (%)	1 (3.0)	1 (3.6)	0 (0)
IVCS, n (%)	3 (9.1)	1 (3.6)	2 (40.0)
Intracranial thrombosis, n (%)	4 (12.1)	4 (14.3)	0 (0)
Intracardiac thrombosis, n (%)	8 (24.2)	7 (25.0)	1 (20.0)
Arterial event other than PAI, n (%)	4 (12.1)	3 (10.7)	1 (20.0)
Relapse, n (%)	24 (39.3)	20 (40.0)	4 (36.4)
Time to the first relapse, median (IQR), month	49.8 (13.2-102.6)	54.1 (24.4-117.9)	3.9 (1.7-67.9)
Death, n (%)	2 (3.3)	0 (0)	2 (18.2)

BS= Behçet Syndrome, PAI= pulmonary artery involvement, PAT= pulmonary artery thrombosis, PAA= pulmonary artery aneurysm, DVT= deep vein thrombosis, SVCS= superior vena cava syndrome, IVCS= inferior vena cava syndrome

Conclusion: Our results indicate that there is a higher frequency of intracardiac thrombosis in BS patients with PAI and an increasing current trend of PAT in patients with PAI. In addition, there might be a possible efficacy of anticoagulation usage in preventing relapses, which needs confirmation with further studies.

POS1336

RETROPERITONEAL FIBROSIS IN ERDHEIM-CHESTER DISEASE HAS UNIQUE PRESENTING AND PROGNOSTIC FEATURES: A SINGLE CENTRE RETROSPECTIVE COMPARATIVE COHORT STUDY

A. Tomelleri[1], C. Campochiaro[1], M. Lanzillotta[1], G. De Luca[1], G. Cavalli[1], E. Della Torre[1], L. Dagna[1]. [1]*IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: Erdheim-Chester disease (ECD) is a multisystemic non-Langerhans cell histiocytosis. Retroperitoneal fibrosis (RPF) is a common ECD feature, found in up to 60% of patients. Besides ECD, RPF differential diagnosis includes other clinical entities of rheumatological interest, such as idiopathic RPF and IgG4-related disease (IgG4-RD). Since ECD management does not include glucocorticoids and mainly relies on the use of anti-neoplastic small molecules, a prompt diagnosis is critical.

Objectives: To characterize the main differential clinical, radiologic and prognostic features of a monocentric cohort of patients with RPF. To provide practical learning points useful to recognize ECD among patients with RPF.

Methods: Medical records of ECD patients with radiologic signs of RPF and of patients with non ECD-related RPF followed up at our Rheumatology Clinic were retrospectively reviewed. Final diagnosis relied either on analysis of histologic samples or on fulfilment of appropriate classification criteria. Main clinical, radiologic and laboratory features at diagnosis and long-term outcomes were evaluated and compared between the two groups. Non parametric tests were used for comparison.

Results: 31 (41%) ECD and 45 (59%) non-ECD patients (IgG4-RD, n=28; idiopathic RPF, n=11; peri-aortitis with large-vessel involvement, n=6) were included. All but one (97%) ECD patients and 56% non-ECD patients had a biopsy-proven diagnosis. ECD patients were younger at disease onset (51±14 vs 59±10 years, P=0.024) and diagnosed with a greater delay (48 [IQR, 13-92] vs 4 [IQR, 2-7] months, P<0.001). In the majority of ECD patients (84%), RPF was clinically silent and was disclosed in the context of the diagnostic work-up; conversely, 82% non-ECD patients had at least one RPF-related symptom (mainly, abdominal pain, n=19, and low-back pain, n=16). At diagnosis, C-reactive protein (50±34 vs 33±31 mg/L, P=0.052) and serum creatinine (1.31±0.53 vs 1.34±0.79, P=0.76) levels were not statistically different. In all ECD patients, fibrotic tissue surrounded both kidneys symmetrically, involving the ureters in half of the cases (Table 1); signs of hydronephrosis were present in 55% of patients (mostly bilaterally, 77%). In the non-ECD group, kidneys were rarely affected, and ureteral involvement was mostly asymmetric; hence, hydronephrosis incidence was similar (76%), but more frequently monolateral (65%). In non-ECD patients, fibrotic tissue more frequently involved inferior vena cava and iliac arteries. FDG uptake by RPF was disclosed in 39/40 (98%) non-ECD and 5/12 (42%) ECD patients who underwent a PET before therapy start (P<0.001). Ureteral stenting was required by a similar fraction of patients (ECD, 29%; non-ECD, 38%, P=0.47), but it was bilateral in 100% of ECD vs 29% of non-ECD patients (P<0.001). No differences in the rate of chronic kidney failure was found (26% vs 18%, P=0.41), but only ECD patients progressed to a terminal stage requiring hemodialysis (13% vs 0%, P=0.025).

Table 1.

	ECD patients (n=31)	Non-ECD patients (n=45)	*P-value*
Left kidney	30 (97%)	4 (9%)	<0.001
Right kidney	31 (100%)	6 (13%)	<0.001
Left ureter	16 (52%)	16 (36%)	0.24
Right ureter	16 (52%)	24 (53%)	1
Abdominal aorta	21 (68%)	40 (89%)	0.04
Inferior vena cava	5 (16%)	29 (64%)	<0.001
Left iliac artery	10 (32%)	27 (60%)	0.02
Right iliac artery	10 (32%)	29 (64%)	0.001
Left renal artery	9 (29%)	6 (13%)	0.14
Right renal artery	6 (19%)	4 (9%)	0.3
Mesenteric artery	8 (26%)	4 (9%)	0.06
Celiac trunk	7 (23%)	3 (7%)	0.08

Conclusion: Our retrospective study suggests that ECD-related RPF has a significantly worse renal prognosis than non ECD-related RPF. A complete baseline work-up including a critical evaluation of the extension of the fibrotic tissue and the sites involved is fundamental to avoid patients' misdiagnosis and mistreatment.

POS1337 BEHÇET`S DISEASE AND COURSE OF PREGNANCY - RESULTS FROM THE NATIONWIDE PREGNANCY REGISTER REVNATUS

H. S. Koksvik[1], B. Jakobsen[1], H. Bjørngaard[1], C. Skorpen[2,3], M. Wallenius[1,2]. [1]*St. Olavs Hospital, Trondheim University Hospital, Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases, Trondheim, Norway*; [2]*NTNU, Department of Neuromedicine and Movement Science, Trondheim, Norway*; [3]*Alesund Hospital, Department of Rheumatology, Alesund, Norway*

Background: Behçets disease (BD) is a complex and multisystemic disorder of unknown etiology. It is characterized by recurrent oral and genital ulcers and inflammatory eye involvement. It can also affect the cardiovascular, pulmonary and skeletal system. BD is commonly diagnosed in women in reproductive age. Pregnancy outcomes are reported in previous studies with discrepancies in the rate of pregnancy-related complications.
Objectives: To describe the course of pregnancy in patients with BD.
Methods: We prospectively collected data on pregnancy outcome in women with BD through the nationwide Norwegian registry on pregnancy and rheumatic diseases (RevNatus) from 2016-2020. All women were diagnosed with ICD-10 code M35.2. 13 pregnancies in 11 women were recorded. One women had two pregnancies including one twin birth.
Results: Median age at conception was 30 years (range 25-32), with median disease duration 7 years (range 1-15). There were no serious organ manifestations. Tnf-alpha-inhibitors were used in 2nd trimester in 3 pregnancies. All pregnancies resulted in live births with median gestational age at delivery of 38 weeks (range 36-41). No preeclampsia or HELLP were recorded.

Table 1. Pregnancy outcome in 13 BD pregnancies

Patient #	Pregnancy #	Medication at 2.nd trimester	Oral or genital ulcers during pregnancy	Disease activity during pregnancy	CRP value at 2nd trimester	Gestational age at delivery, week	Mode of delivery	Birth weight, gram
A	1	Azathioprine Colchicine LMWH	no	persistent*	13	38	SVD	3475
B	2	Adalimumab Colchicine LDPrednisolon	yes	persistent *	4	40	SVD	3215
C	3	no	yes	persistent*	5	41	SVD	3355
D	4	Adalimumab LDPrednisolon	yes	persistent*	23	36	SVD	1940
E	5	Etanercept ASA	no		2	41	SVD	3410
	6a (twin)	Etanercept ASA	no		5	37	Elective Sectio	2400
	6b (twin)							2410
F	7	LDPrednisolon	yes	flare**	15	38	SVD	3180
	8	Adalimumab LDPrednisolon	yes	flare**	4	37	Acute Sectio	3049
G	9	no	no	remission***	1	41	SVD	3150
H	10	LDPrednisolon	yes	persistent *	10	38	SVD	2480
I	11	ASA	no	persistent*	3	39	SVD	3410
J	12	no	yes	persistent*	1	37	SVD	3115
K	13	Ciklosporine	no	remission***	3	37	SVD	3130

SVD = spontaneous vaginal delivery, ASA = acetylsalicylic acid, LDPrednisolon = Low dose Prednisolon <10 mg/day, *= persistent throughout pregnancy, **= flare once during pregnancy, ***= remission throughout pregnancy

Conclusion: Pregnancies in women with BD in this cohort were uncomplicated. We did not reveal any serious events, and they all resulted in live births. However, BD is a very heterogeneous disease, and the women in our cohort did not have any serious organ manifestations. Larger cohorts representing the heterogeneity are needed to study the course and outcome of pregnancies in BD.

POS1338 INCIDENCE, PREVALENCE, AND MORTALITY OF CHRONIC PERIAORTITIS: A POPULATION-BASED STUDY

U. Ghaffar[1], K. J. Warrington[1], S. Duong[2], C. S. Crowson[1,2], M. Burke[1], B. Viers[3], A. Potretzke[3], H. Bjarnason[4], M. Koster[1]. [1]*Mayo Clinic College of Medicine and Science, Rheumatology, Rochester, United States of America*; [2]*Mayo Clinic School of Health Sciences, Biomedical Statistics and Informatics, Rochester, United States of America*; [3]*Mayo Clinic College of Medicine and Science, Urology, Rochester, United States of America*; [4]*Mayo Clinic College of Medicine and Science, Vascular and Interventional Radiology, Rochester, United States of America*

Background: Chronic periaortitis is an inflammatory condition that typically involves the infrarenal portion of the abdominal aorta. Few studies are available to outline the epidemiology of this rare condition. To date, no epidemiologic studies on periaoritis have been performed in North America.
Objectives: To evaluate the epidemiology, presentation and outcomes of patients with chronic periaortitis from 1998 through 2018.
Methods: An inception cohort of patients with incident chronic periaortitis from January 1, 1998 through December 31, 2018, in Olmsted County, Minnesota, USA, was identified based on comprehensive individual medical record review utilizing the Rochester Epidemiology Project medical record linkage system. Inclusion required radiographic and/or histologic confirmation of periarterial soft tissue thickening around at least part of the infra-renal abdominal aorta or the common iliac arteries. Data were collected on demographic characteristics, clinical presentation, renal and radiographic outcomes, and mortality. Incidence rates were age and sex adjusted to the 2010 United States white population.
Results: Eleven incident cases of chronic periaortitis were identified during the study period. Mean±SD age at diagnosis was 61.8±13.4 years. The cohort included 9 men (82%) and 2 women (18%). The most common presenting symptom was pain with 55% (6/11) reporting abdominopelvic-pelvic pain, 36% (4/11) back pain, and 18% (2/11) flank pain. Obstructive uropathy was present in 73% (8/11) subjects: 3 (27%) unilateral left, 1 (9%) unilateral right, and 4 (36%) bilateral. Mean creatinine at presentation was 2.7±3.4 mg/dL. Ureteral stenting was required at diagnosis in seven patients: unilateral left in 2, unilateral right in 1 and bilateral in 4. All 11 patients received glucocorticoids with a median (IQR) dose of 40 (30, 60) mg/day. Additional non-glucocorticoid therapeutics were used in 10 patients.
Renal function stage at last follow up declined in 2 patients, remained the same in 3 patients and improved in 6 patients. Mean creatinine at last follow-up was 1.2±0.2 mg/dL. Among the seven patients requiring baseline indwelling ureteral stent placement only two required ongoing ureteral stenting at last follow up. None of the four patients without ureteral stenting at diagnosis progressed to require stenting during the follow-up period. No patient underwent ureterolysis surgery in this cohort. Periarterial soft tissue thickening at last follow up had increased in thickness in 1 (9%), was unchanged in 2 (18%), decreased in size but did not resolve in 6 (55%), and fully resolved in 18%.
Age- and sex-adjusted incidence rates per 100,000 population were 0.26 for females, 1.56 for males and 0.87 overall. Overall prevalence on January 1, 2015 was 8.98 per 100,000 population. Median (IQR) length of follow-up was 10.1 (2.5, 13.8) years. Overall mortality was similar to the expected age, sex, and calendar estimates of the Minnesota population with standardized mortality ratio (95% CI) for the entire cohort 2.07 (0.67, 4.84).
Conclusion: This study reports the first epidemiologic data on chronic periaortitis in the United States. In this cohort of patients with chronic periaortitis, men were approximately 4 times more commonly affected than women. Mortality was not increased compared to the general population.

POS1339 MORE FREQUENT AND EARLIER HIP INVOLVEMENT IN SPONDYLOARTHRITIS ASSOCIATED WITH FAMILIAL MEDITERRANEAN FEVER

M. Bektaş[1], S. Sarı[1], C. Cetin[1], B. Ç. Yalçın Dulundu[1], N. Koca[1], B. Ince[1], Y. Yalçınkaya[1], B. Artim-Esen[1], M. Inanc[1], M. L. Ocal[1], A. Gül[1]. [1]*Istanbul Faculty of Medicine, Internal Medicine, Rheumatology Division, Istanbul, Turkey*

Background: Familial Mediterranean fever (FMF) is a hereditary autoinflammatory disorder caused by the *MEFV* gene variants. Although association between FMF and spondyloarthritis (SpA) has previously been reported, clinical and laboratory features of patients with FMF and SpA have not been defined in detail.
Objectives: We aimed to evaluate clinical and laboratory characteristics, disease outcome and biologic responses of patients with FMF+SpA compared to patients with only SpA who were followed-up in our tertiary referral center.
Methods: Database of FMF Clinic was screened for FMF patients with coexistent SpA and 113 patients were identified fulfilling Tel Hashomer and ASAS criteria for FMF and SpA, respectively. A group of patients with SpA without FMF matched for age, gender and disease duration were selected as the control group.
Results: Thirteen patients were excluded because of missing data, and 100 patients (F/M: 52/48) were included into the analysis. Mean follow-up time was 93.6 ± 77 (range[r]: 3-324) months and mean patient age was 43.3 ± 12 (r: 20-87) years. Mean age of onset for FMF was 12.5 ± 8 (r: 1-36) and for SpA was 25 ± 11 (r: 7-72) years. SpA findings was classified as axial in 35.4%, axial and peripheral in 47.9% and only peripheral in 16.7% in FMF+SpA group. Half (49%) of the

patients had hip involvement (70% bilaterally), and 21.5% of them needed total hip joint replacement (TJR), which were significantly more frequent compared to control group. Two exon 10 MEFV variants were found in 69.4%, and most (69.8%) had homozygous M694V. Hip involvement was more frequent in patients with two exon 10 variants (p=0.036; OR=4.4) compared to those with one variant; and TJR was more frequent in those with homozygous M694V compared to other exon 10 variants (p=0.001; OR=10). Radiographic sacroiliitis was less frequent in patients with homozygous M694V (p=0.019; OR=5.48). HLA-B27 positivity was not associated with hip or axial involvement in patients with FMF+SpA.
Biologics were used in 60 patients (anti-TNF in 43, secukinumab in 1, and tocilizumab in 2). Anti-IL-1 drugs were used in 23 patients for refractory FMF. In 9 patients, anti-TNF and anti-IL-1 drugs were tried for refractory joint involvement: 5 switched to anti-TNFs from anti-IL-1, 4 patients switched to anti-IL-1 from anti-TNFs. Biologic DMARD requirement was more frequent in patients with two exon 10 variants (p=0.006; OR=7.4), especially in those with homozygous M694V (p=0.006; OR=7.6). Although anti-IL-1 usage did not differ among MEFV variants, anti-TNF was used more frequently in patients with homozygous M694V (p=0.007; OR=7.2). FMF+SpA patients had higher serum CRP and developed amyloidosis more frequently than those patients with SpA.

Table 1. Comparison of clinical and laboratory findings between the patients with FMF+SpA and SpA control

	FMF + SpA (n=100)	SpA (n=217)	P value
Age (years)*	43.3 ± 12	43.4 ± 11	0.6
Sex (n, %)			
Male	48	104 (47.9)	0.99
Female	52	113 (52.1)	
Duration of SpA (monnths)*	181.6 ± 108	180.2 ± 112	0.8
Age onset of SpA (years)*	25.1±11	28.4±8	0.008
Peripheral arthritis (n, %)	35/80 (43.8)	79/212 (37.3)	0.3
HLA-B27 positivity (n, %)	6/21 (28.6)	105/139 (75.5)	<0.001 (OR=18.9)
CRP (mg/dL)*	26.7 ± 25**	18.96±29	0.001
ESR (mm/hour)*	39.7 ± 27	39.4 ± 28	0.8
Hip involvement (n, %)	47/96 (49)	23/118 (19.5)	<0.001 (OR=20.9)
TJR (n, %)	20/93 (21.5)	8/205 (3.9)	<0.001 (OR=23.3)
Fulfilling mNY criteria (n, %)	52/81 (64.2)	164/199 (82.4)	0.001 (OR=10.8)
Biologic DMARD (n, %)	60	68/214 (31.8)	<0.001 (OR=22.5)
Anti-TNF (n, %)	46	68/214 (31.8)	0.015 (OR=5.96)
Amyloidosis (n, %)	16	5/205 (2.4)	<0.001 (OR=19.3)

* mean±standard deviation, **during the attack-free period

Conclusion: In this group of FMF+SpA patients, hip involvement and need for TJR were more frequent and associated with penetrant MEFV variants rather than HLA-B27 positivity. These patients had higher inflammatory response and risk of developing amyloidosis, and they needed biologics more frequently compared to SpA group. More severe disease course in FMF+SpA patients requires further attention and analysis in larger cohorts.

Background: Prognosis of non-infectious refractory uveitis has improved markedly with biologic therapy (BT) **(1-5)**. Most data are with monoclonal anti-TNF drugs, especially Adalimumab (ADA) and Infliximab (IFX). However, there is not enough evidence for the use of Certolizumab Pegol (CZP).
Objectives: To evaluate the efficacy and safety of CZP in refractory uveitis secondary to Immune-Mediated Inflammatory Diseases (IMID).
Methods: Multicenter study of 71 patients with uveitis due to IMID refractory to glucocorticoids and conventional immunosuppressants. Efficacy was assessed with the following ocular parameters: best corrected visual acuity (BCVA), anterior chamber cells, vitritis, macular thickness and presence of retinal vasculitis. These outcomes were compared between baseline, 1st week, 1st and 6th month, and 1st and 2nd year. Statistical analysis was performed with IBM SPSS Statistics v.23.
Results: 71 patients/100 affected eyes (29 men/42 women) with mean age of 40.0±11.3 years were studied. Underlying IMIDs were: spondyloarthritis (n=38), Behçet (10), psoriatic arthritis (8), Crohn disease (3), sarcoidosis (2), JIA (1), reactive arthritis (1), rheumatoid arthritis (1), relapsing polychondritis (1), TINU (1), pars planitis (1), Birdshot (1) and idiopathic uveitis (3). Uveitis pattern was anterior (n=55), posterior (6), panuveitis (6) and intermediate (4).
Prior to CZP, patients had received: methotrexate (37), sulfasalazine (26), azathioprine (14), cyclosporine (10), leflunomide (3), mycophenolate mofetil (3) and cyclophosphamide (1). Previous BT was administered in 48 (67.6%) patients, with a mean of 1.4±1.3 drugs per patient as follows: ADA (n=56), IFX (27), golimumab (14), tocilizumab (5) and etanercept (3). Pregnancy was the reason for prescribing CZP in 19 patients. CZP was administered in monotherapy (n=39) or combined with conventional immunosuppressants (n=32).
After a mean follow-up of 27.1±21.1 months, most of the ocular variables showed a rapid and significantly improvement (Table 1). A decrease in the median number [IQR] of flares of uveitis before and after CZP, (3 [1-4] vs. 0 [0-1], p<0.001) was observed. CZP was discontinued in 15 patients due to remission (n=2), ocular insufficient response (2) and incomplete response of extraocular manifestations (11). No serious adverse events were reported.
Conclusion: CZP seems to be effective and safe in patients with refractory uveitis due to IMID.

POS1341

TOCILIZUMAB FOR THE TREATMENT OF IMMUNE-RELATED ADVERSE EVENTS TO IMMUNE CHECKPOINT INHIBITORS: A CASE SERIES

C. Campochiaro[1], N. Farina[1], A. Tomelleri[1], G. De Luca[1], G. Cavalli[1], C. Lazzari[2], R. Ferrara[3], M. Garassino[3], V. Gregorc[2], L. Dagna[1]. [1]*IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*; [2]*IRCCS San Raffaele Hospital, Department of Oncology, Division of Experimental Medicine, Milan, Italy*; [3] *Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Oncology Department, Milan, Italy*

Background: Immune checkpoint inhibitors (ICI) are pharmacological agents effectively used in the treatment of several malignant tumors. The hyperactivation of the immune system induced by ICI may trigger an inflammatory involvement of healthy tissues, a phenomenon referred to as immune-related adverse event (irAE). No clinical trials are available to guide the management of irAEs. Observational data suggest tocilizumab might be effective in severe cases of irAEs, but data are scant. The possibility of continuing ICI treatment despite the development of irAE and the subsequent initiation of tocilizumab has never been evaluated.
Objectives: To evaluate the efficacy and safety of tocilizumab, as monotherapy or alongside the continuation of ICI treatment, in the management of irAEs.
Methods: We retrospectively identified patients who developed irAEs and were referred to our specialized Clinic between May 2018 and December 2020. Among these patients, we identified those who had been treated with tocilizumab and collected information about their oncologic history and outcome, ICI therapy and irAEs.
Results: Thirty-nine patients were referred to our outpatient Clinic following the development of irAEs. Five of them were treated with tocilizumab. Disease and demographic features are reported in Table 1. At irAEs onset all patients were treated with glucocorticoids. A steroid-sparing agent was started to permit an adequate prednisone tapering without the irAE relapsing. Before tocilizumab start, two patients were treated with methotrexate monotherapy, one with anakinra monotherapy, and one with methotrexate and anakinra combination therapy. A significant therapeutic effect was confirmed in all patients and no significant adverse reactions were reported. ICI therapy was permanently discontinued in two patients. In the other three cases, cancer immunotherapy was safely continued alongside tocilizumab without further irAEs occurring. Only one patient experienced tumor progression two years after ICI suspension and subsequently died despite the improvement of his myocardial inflammatory involvement.
Conclusion: In our cohort, tocilizumab proved to be an effective and safe therapy for the management of irAEs.
Our case series also supports the possibility of maintaining ICI while introducing tocilizumab for irAE treatment. This combined approach might represent a suitable therapeutic option to guarantee a significant anti-inflammatory activity without losing the oncologic response.

POS1342

CHEMOPROPHYLAXIS IN LATENT TUBERCULOSIS ASSOCIATED WITH RHEUMATIC IMMUNE-MEDIATED DISEASES. STUDY OF 240 PATIENTS FROM A SINGLE UNIVERSITY HOSPITAL

D. Martínez-López[1], J. Rueda-Gotor[1], J. Osorio-Chavez[1], C. Álvarez-Reguera[1], V. Portilla[1], M. A. González-Gay[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*

Background: Tuberculosis (TB) may be increased with biologic therapy (BT). Diagnosis and treatment of latent TB infection (LTBI) is the best strategy to prevent TB. In Rheumatic Immune-Mediated Diseases (R-IMID) and LTBI, chemoprophylaxis must be used before BT. The drugs more frequently used are Isoniazid (INH), Rifampicin (RIF) and Fluoroquinolones (FQ). These drugs may be associated with side-effects, especially hepatotoxicity.
Objectives: To assess, in a single University Hospital, **a)** used chemoprophylactic drugs and, **b)** adverse events with these drugs.
Methods: We included all consecutive patients in the last five years (2016-2020) with a diagnosis of R-IMID and a positive LTBI test (positive tuberculin skin test and/or interferon-γ–release assay), who received chemoprophylaxis prior to BT. Dose of chemoprophylactic drugs were **a)** INH (5 mg/kg/d, maximum, 300 mg; for 9 months with vitamin B6), **b)** RIF (10 mg/kg/d, maximum, 600 mg for 4 months) and **c)** FQ levofloxacin (500 mg/day for 9 months).
In all patients analytic controls that included liver enzymes were performed at the 1st and 3rd month and then at a variable time.
Results: 240 patients were analyzed (165 women/ 75 men), mean age of 56±11 years. The underlying R-IMID of patients receiving chemoprophylaxis were rheumatoid arthritis (n=74, 30.8%), axial spondyloarthritis (n=59, 24.6%), psoriatic arthritis (n=62, 25.8%), conectivopathies (n=17, 7.1%), vasculitis (n=12, 5%), sarcoidosis (n=2, 0.8%), Behçet's disease (n=1, 0.4%), inflammatory myopathies (n=1, 0.4%) and other (n=12, 5%).
At the onset of chemoprophylaxis they were taking: Prednisone in 61 patients (24 of them above 10 mg/day) and the following conventional DMARD, methotrexate (n=109, 45.4%), hydroxychloroquine (n=20, 8.3%), sulfasalazine (n=11, 4.6%), leflunomide (n=4, 1.7%) and azathioprine (n=2, 0.8%).
The first-line chemoprophylactic drug was INH in 232 (96.7%) patients and RIF in the remaining 8 (3.3%). Due to adverse events, second-line therapy was used in 18 (RIF, n=17 and Levofloxacin, n=1) patients previously treated with INH.
Adverse events were more frequent with INH, being observed in 55 patients (23.7%) out of 232. (Table 1 next page, Figure 1 below). By contrast, only 1 out of 25 (4%) receiving RIF presented an adverse event, which was hepatotoxicity, requiring suspension of RIF. No adverse events were described in the only patient receiving levofloxacin.

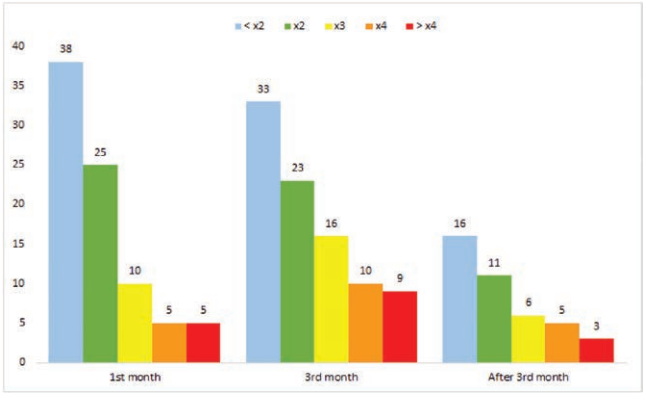

Figure 1. Liver enzyme elevation over baseline in patients in treatment with isoniazid.* Patients with higher liver enzyme elevation are included in the previous groups.

Conclusion: INH is the most used first-line treatment for LTBI. RIF was mainly used as second-line therapy if an adverse event with INH was observed. Treatment was generally well tolerated and most adverse events did not require the withdrawal of the treatment. Hepatotoxicity was the most frequent adverse event with INH and the most frequent cause of treatment withdrawal.

Table 1. Adverse events with isoniazid at months 1 and 3 and after month 3

	Month 1 (n=232)			Month 3 (n=222)			After month 3 (n=214)

POS1343 ABNORMAL ELECTROCHEMICAL SKIN CONDUCTANCE VALUES IN PATIENTS WITH AA AMYLOIDOSIS

S. Deshayes[1], R. Bourguiba[2], J. P. Haymann[3], L. S. F. Lea.Savey@aphp.Fr>;[2], A. Aouba[1], G. Grateau[2], S. Georgin-Lavialle[2]. *[1]CHU de Caen Normandie, Internal Medicine, Caen, France*; *[2]Hôpital Tenon, Internal Medicine, Paris, France*; *[3]Hôpital Tenon, Physiology, Paris, France*

Background: Clinical manifestations are scarce in AA amyloidosis (AAA) and, contrary to other types of amyloidosis, involvement of the peripheral nervous system was rarely reported in AAA. However, the usual absence of hypertension despite chronic renal failure and the digestive involvement may be secondary to dysautonomia, but the autonomic nervous system has rarely been studied in AAA (1). Measure of the electrochemical skin conductance (ESC) is a simple and reproducible method to evaluate the function of eccrine sweat glands, which are innervated by small non-myelinated C fibers, and patients with AL and hereditary transthyretin amyloidoses show decreased ESC values (2,3).
Objectives: To evaluate ESC values by Sudoscan in patients with AAA.
Methods: Patients diagnosed as having AAA based on positive immunohistochemistry with an anti-serum amyloid A antibody followed at the national reference center for AAA in Tenon Hospital between July, 2017 and September, 2020, were routinely assessed for ESC with FDA approved Sudoscan (Impeto Medical, Paris, France). An ESC value above 60 microSiemens (µS) or 70 µS were considered normal for hands or feet, respectively. Categorical variables are reported as percentages and continuous variables are expressed as means±standard deviation. Correlations between age, body mass index (BMI), hemoglobin levels, C-reactive protein levels, estimated glomerular filtration rate using the Chronic Kidney Disease Epidemiology Collaboration equation (defined as 0 for dialysis patients) and ESC values were calculated using the nonparametric Spearman test. GraphPad Prism Version 7 software (GraphPad Software, San Diego, California, USA) was used for statistical analyses. A p-value <0.05 was considered as statistically significant.
Results: Overall, 32 patients (16 women) were included, with a mean age of 57.4±13.6 years and a mean BMI of 25.2±6.8 kg/m^2. Six (19%) had diabetes mellitus, and 5 (16%) had a kidney transplantation. The main causes of AAA were: monogenic autoinflammatory diseases (n=11, 34%, including 9 patients with familial Mediterranean fever), chronic and/or recurrent infections (n=5, 16%), obesity (n=3, 9%) and undefined (n=3, 9%). The mean hands' ESC values was normal at 65.5±21.1 µS, although 8 (25%) patients had ESC values below 60 µS, including 2 diabetic patients. In contrast, the mean feet's ESC values was abnormal at 62.7±23.7 µS, including half of the patients with ESC values below 70 µS (2 diabetic patients). Eight patients had abnormal ESC values only for feet, and 1 had abnormal values only for hands. Apart from a significant correlation between feet and hands' ESC values (p<0.0001), only the estimated glomerular filtration rate was significantly associated with hands' ESC values (p<0.01).
Conclusion: To our knowledge, this is the first study to assess ESC in AAA. Feet's ESC values were moderately impaired in half of the patients with AAA. Therefore, this study reinforces the previously reported alterations in the autonomic nervous system in patients with AAA that should probably be searched for in these patients. In addition, the identification of an alteration of the ESC values cannot allow to distinguish the type of amyloidosis.

POS1344 EVALUATING THE MULTIVISCERAL INVOLVEMENT ON ADULT-ONSET STILL'S DISEASE TO RETRIEVE IMAGING-BASED DIFFERENCES IN PATIENTS WITH AND WITHOUT MACROPHAGE ACTIVATION SYNDROME; RESULTS FROM A SINGLE-CENTRE OBSERVATIONAL STUDY

I. DI Cola[1], F. Bruno[1], O. Berardicurti[1], R. Monti[1], A. Conforti[1], A. DI Sibio[1], V. Pavlych[1], F. Sensini[1], C. Masciocchi[1], A. Barile[1], P. Cipriani[1], P. Ruscitti[1]. *[1]University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy*

Background: Adult-onset Still's disease (AOSD) is a rare systemic inflammatory disorder usually affecting young adults, burdened by life-threatening complications, mainly macrophage activation syndrome (MAS), a secondary form of hemophagocytic lymphohistiocytosis [1]. In this context, the importance of an accurate assessment of AOSD is suggested to promptly recognise the multivisceral involvement of the disease which is associated with life-threatening complications. The assessment of the most aggressive subsets of the disease could guide the clinicians when to apply additional resources but avoiding unnecessary expenditures in patients with a less severe clinical picture.
Objectives: In this study, we aimed at describing the multivisceral involvement of the disease to retrieve imaging-based differences in AOSD patients with and without MAS.
Methods: The present evaluation has been designed as a cross-sectional study to descriptively compare the multivisceral involvement in AOSD patients with and without MAS. Patients admitted to our Institution, who underwent a total body CT scan, were selected from our historical cohort and assessed. Clinical and CT scan characteristics of AOSD patients with and without MAS were compared. Clinical and CT scan characteristics of AOSD patients with and without MAS were analysed by parametric or non-parametric t tests for all continuous variables, and chi squared test was used for categorical ones, as appropriate. Furthermore, possible correlations among radiological outcomes with laboratory markers and systemic score were estimated by using a point-biserial coefficient correlation.
Results: This study evaluated 39 AOSD patients (men 64.1%), mean age of 48.8±16.6 years). Out of those, 14 patients (35.9%) were complicated by MAS. These patients showed higher values of ferritin [AOSD: 770.0 (1306.5) ng/mL vs MAS: 2926.3 (4918.5) ng/mL p=0.003] and systemic score (AOSD: 4.6±1.4 vs MAS: 6.9±1.7, p<0.0001). AOSD patients with MAS presented a higher prevalence of lung disease than others (AOSD: 56.0% vs MAS 85.7% p=0.048). Lung disease correlated with the systemic score (coefficient 0.491, p=0.003). AOSD patients with MAS were more frequently characterised by hepatomegaly (AOSD: 12.0% vs MAS: 50.0% p=0.019) and splenomegaly (AOSD: 16.0% vs MAS 50.0% p=0.033), respectively, than others. Hepatomegaly correlated with CRP (coefficient 0.421, p=0.016), ferritin (coefficient 0.397, p=0.020), and systemic score (coefficient 0.391, p=0.022). Furthermore, the presence of splenomegaly correlated with the systemic score (coefficient 0.439, p=0.009). CT scan features of abdominal effusions were more frequently observed in AOSD patients with MAS than those without this complication (AOSD: 12.0% vs 57.1% p=0.007).

Finally, a higher percentage of AOSD patients with MAS showed a significant lymph node enlargement, either mediastinal or abdominal, than others on CT scan (AOSD: 36.0% vs MAS 71.4% p=0.048). The presence of lymphadenomegaly correlated with the systemic score (coefficient 0.368, p=0.032).
Conclusion: Our findings showed a higher prevalence of multiorgan involvement in AOSD patients with MAS, suggesting imaging-based differences, although other studies are needed to fully assess this issue. Pulmonary disease, hepatomegaly, splenomegaly, lymph nodes enlargement, and abdominal effusions were associated with these more aggressive patients.

POS1345 PULMONARY ARTERY PSEUDOANEURYSMS IN BEHCET'S DISEASE

O. Jomaa[1], O. Berriche[1], S. Arfa[1], A. Fraj[1], W. Romdhane[1], M. Belkhiri[1], M. Hermassi[1], R. Makhloufi[1]. [1]*University Hospital Tahar Sfar Mahdia, Tunisia, Internal Medicine Department, Mahdia, Tunisia*

Background: Pulmonary artery pseudoaneurysms (PAP) is a serious complication of Behcet's Disease (BD).
Objectives: The aim of this work is to analyze, through 4 observations, the clinical, para-clinical and therapeutic aspects of PAP.
Methods: Matériels et méthodes:
Retrospective study including 4 cases of PAA among 150 patients who satisfied the criteria of the International Study Group on BD, followed in the Internal Medicine and Radiology Departments at Tahar Sfar Hospital Mahdia TUNISIA.
Results: Résultats:
Four men, with an average age of 27 years (20-34). PAPs were inaugural, and multiple (>3) in 3 cases and associated with pulmonary embolism in 2 cases. Hemoptysis was the main clinical symptom. All patients were treated with high-dose corticosteroid therapy combined with monthly boluses of cyclophosphamide in addition to colchicine. Two patients had undergone arterial embolization. Surgery was indicated for 2 patients, one of whom died after surgery as a result of massive hemoptysis. The others had a favorable outcome.
Conclusion: PAP severity justifies the necessity of early diagnosis and management. The thoracic angio-CT is the imaging of choice for diagnosis. The treatment is based on a corticosteroid therapy and immunosuppressive association with possibly a selective embolization.

POS1346 CLINICAL ASSOCIATIONS OF ANTI-RO52 ANTIBODIES IN PATIENTS WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES

D. Prieto-Peña[1], B. Atienza-Mateo[1], M. A. González-Gay[1], R. Blanco[1], M. Lopez-Hoyos[2]. [1]*Hospital Universitario Marques de Valdecilla, IDIVAL, Rheumatology, Santander, Spain*; [2]*Hospital Universitario Marques de Valdecilla, IDIVAL, Immunology, Santander, Spain*

Background: Anti-SSA/Ro antibodies (Abs) can target Ro60 and Ro52 antigens. The presence of anti-Ro60 Abs has been widely described in patients with systemic autoimmune rheumatic diseases (SARDs). However, the clinical implication of anti-Ro52 Abs for the diagnosis and management of SARDs remains unclear.
Objectives: To assess the clinical associations of anti-Ro52 antibodies in patients with high clinical suspicion of SARDs.
Methods: We retrieved the clinical records of all patients with positive anti-Ro52 Abs tested in our hospital between November 2017 and September 2020. Patients were divided into 3 groups: 1) anti-Ro52+Ro60+2) antiRo52+Ro60-3) antiRo52+Ro60+ with other Abs. A comparative study between groups was performed.
Results: 57 patients (43 women/14 men; mean age 62.1±13.6 years) with antiRo52+ Abs were identified. Final diagnosis were: undifferentiated connective tissue disease (UCTD) (n=13), anti-synthetase/overlap myositis (n=12), Sjögren's syndrome (n=7), interstitial pneumonia with autoimmune features (IPAF) (n=6), scleroderma (n=4), systemic lupus erythematosus (n=2), dermatomyositis (n=2), other systemic inflammatory diseases (n=3). In 8 (14%) patients the diagnosis of inflammatory diseases was finally ruled out. 27 patients were classified in the Ro52+Ro60+ group, 11 in the Ro52+Ro60- group and 19 Ro52+ with other Abs. Patients with Ro52+Ro60- were younger and more often women than patients with Ro52+Ro60+.Interstitial lung disease (ILD) was less frequent in patients with Ro52+Ro60-(Table 1**).** Isolated Ro52 Abs were more frequently associated with UCTD, while IPAF was more commonly found in patients with anti-Ro52+Ro60+ Abs (Table 1 **and** Figure 1).

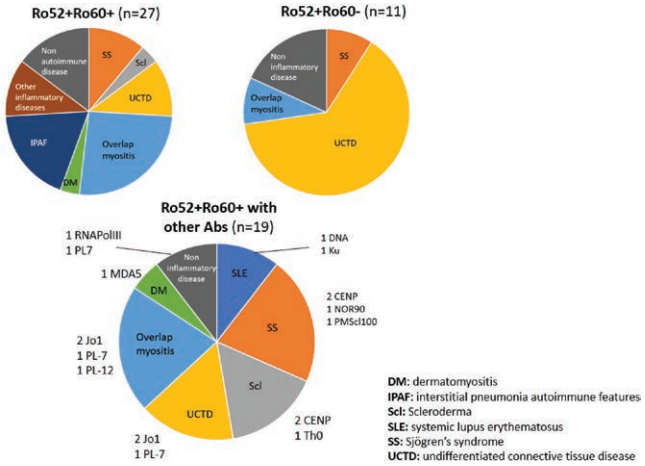

Figure 1.

Conclusion: Anti Ro52 Abs determination has clinical implications in the diagnosis of SARDs.

Table 1.

POS1347 IMPACT OF CANAKINUMAB AND ANAKINRA ON PATIENT-REPORTED OUTCOMES IN ADULT-ONSET STILL'S DISEASE PATIENTS

N. Farina[1], C. Campochiaro[1], A. Tomelleri[1], G. De Luca[1], G. Cavalli[1], E. Baldissera[1], L. Dagna[1]. [1]*IRCCS San Raffaele Hospital, Milan, Italy, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: Adult-onset still's disease (AOSD) is a rare systemic inflammatory disease. Interleukin-1 (IL1) blockade has shown to be crucial for the management of refractory AOSD patients. The IL1 inhibitors anakinra and canakinumab are both effectively used in clinical practice for the management of AOSD. No data are available on the impact of these therapies on patient-reported outcomes (PROs).
Objectives: To assess the impact of ANK and CNK therapies on PROs of AOSD patients.
Methods: Medical records of AOSD patients followed up at our Institution who had been treated with both ANK and CNK were identified. Disease features were retrospectively collected. All patients were initially treated with ANK and

subsequently with CNK. At the moment of CNK introduction and at their latest visit while on CNK, patients were asked to fill a questionnaire investigating their experience with either ANK or CNK. The questionnaire included 4 different domains that were assessed through means of Visual Analogue Scales (VAS) ranging from 0 to 10. The following domains were considered: injection-related pain, satisfaction with the frequency of administration, concern for drug-related adverse events including infections, and overall drug tolerability. VAS values for each of the domains were compared between ANK and CNK with Mann-Whitney U test.

Results: Ten AOSD patients treated with both ANK and CNK were included in the analysis. Disease characteristics are shown in Table 1 below. ANK was discontinued due to inefficacy in 6 patients and due to adverse reactions in 4. As shown in Figure 1, CNK overall tolerability significantly exceeded ANK one (p=0.021). Only 1 AOSD patient reported a greater tolerability with ANK compared to CNK because she felt more comfortable with pre-filled syringes. The reasons for higher CNK tolerability were the lower pain at injection site (median 1, IQR 1-1 vs median 4.5, IQR 1.25-7; p=0.015) and the greater level of satisfaction with the frequency of administration (median 10, IQR 9.25-10 vs median 3.5, IQR 2.25-4.75, p<0.001). The concern for drug-related adverse events was not significantly different between ANK and CNK (p=0.549) and overall low among AOSD patients. CNK led to a satisfying control of systemic inflammation and steroid-sparing effect in most of patients and it was discontinued in only one case (*Patient 5*), due to ineffective disease control.

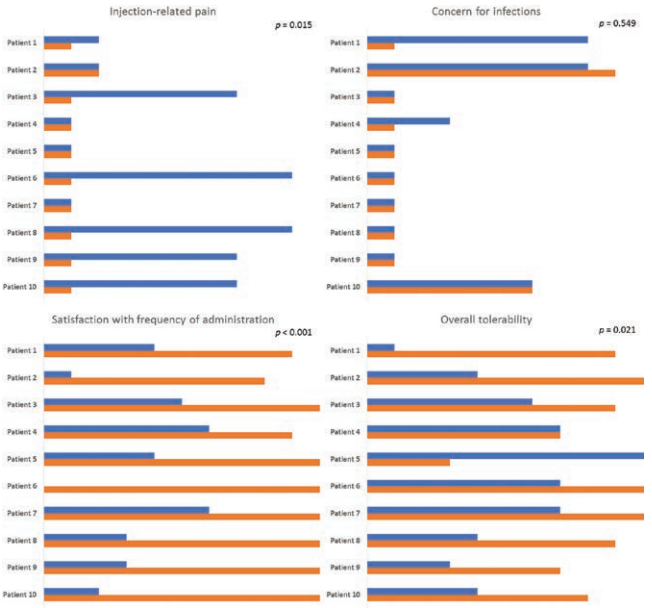

Figure 1. Comparative tolerability of anakinra (blue line) and canakinumab (orange line) in our study population, expressed as Visual Analogue Scale values (range from 1 to 10). Reported p-values refer to the comparative analysis between the two drugs.

Conclusion: In our cohort of AOSD patients, CNK proved not only to be effective in controlling systemic inflammation in ANK refractory cases, but its use was associated with greater patients' satisfaction and tolerability.

POS1348 MORTALITY AND ITS RELATED FACTORS IN PATIENTS WITH IGG4-RELATED DISEASE: A JAPANESE SINGLE-CENTER STUDY

I. Mizushima[1], H. Kawahara[1], T. Yoshinobu[1], S. Shin[1], R. Hoshiba[1], R. Nishioka[1], T. Zoshima[1], S. Hara[1], Y. Suzuki[1], K. Ito[1], M. Kawano[1]. [1]*Kanazawa University Hospital, Rheumatology, Kanazawa, Japan*

Background: In recent years, IgG4-related disease (IgG4-RD) has become a widely recognized disorder. However, mortality and its related factors in this disease are not well known.

Objectives: This study aimed to clarify mortality and its related factors in patients with IgG4-RD.

Methods: We retrospectively reviewed the medical records of patients with IgG4-RD diagnosed by experts based on fulfillment of the Japanese comprehensive diagnostic criteria and/or the 2019 ACR/EULAR classification criteria for IgG4-RD at a single center in Japan. Using the collected data, we calculated the crude mortality rate and the standardized mortality ratio (SMR) using national Japan mortality statistics and investigated the cause of death. We performed Cox regression analyses to assess mortality-related factors.

Results: A total of 179 patients with IgG4-RD were included: 124 were male (69.3%); the median age was 68 years (interquartile range [IQR] 60-75 years); and the median follow-up from diagnosis was 47 months (IQR 17-84). Ten patients (5.6%) in our cohort died during the follow-up period. Five died of malignancy, one of respiratory failure, two of infectious pneumonia, one of sudden cardiac event, and one of suspected aortic aneurysmal rupture. The crude mortality rate was 11.1 per 1,000 person-years. According to national Japan mortality statistics, 11.6 age- and sex-matched deaths were expected to occur within the follow-up period, resulting in a SMR of 0.86 (95% confidence interval [CI] 0.41-1.59). Univariate Cox regression analyses indicated that the number of affected organs at diagnosis (hazard ratio [HR] 1.45, 95% CI 1.02-2.05), serum creatinine levels at diagnosis (HR 1.82, 95% CI 1.06-3.12), and the presence of malignancy during the clinical course (HR 3.93, 95% CI 1.10-14.02) had a significant impact on the time to death, whereas the other factors including age at diagnosis and serum C-reactive protein and IgG4 levels at diagnosis did not.

Conclusion: Our findings suggest that the mortality rate of patients with IgG4-RD does not significantly differ from that of the Japanese general

Background: Adult onset Still's disease (AOSD) is a rare systemic autoinflammatory disease and joint involvement is one of its clinical manifestations [1]. Arthritis, either oligoarthritis or bilateral symmetrical rheumatoid arthritis-like polyarthritis, is another common clinical feature of AOSD, with a migrating pattern at the beginning and becoming stable over the time [1].

Objectives: The aims of the study were to assess joint involvement in AOSD by using magnetic resonance imaging (MRI), to describe main patterns of involvement, and associated clinical characteristics, and to evaluate the global transcriptomic profile of synovial tissues in AOSD to elucidate possible pathogenic pathways involved with.

Methods: AOSD patients, who underwent to magnetic resonance imaging (MRI) exam on joints, were assessed to describe patterns of joint involvement and associated clinical characteristics. Some synovial tissues were collected for RNA-sequencing purposes.

Results: In this study, 31 patients with AOSD (mean age 42.3 ± 15.2 years, 54.8% male gender), who underwent to at least one MRI exam on joints, were assessed. The most common MRI finding was the presence of synovitis on 60.5%, mainly in peripheral affected joints. MRI revealed a mild to moderate proliferative synovitis, as thickening of the synovial membrane, with low to intermediate signal intensity on T1-weighted images and intermediate to high signal intensity on T2-fat saturated weighted and STIR images, suggesting the presence of a hyperplastic than of a hypertrophied synovial tissue. Bone oedema and bone erosions were reported on 34.9% and 25.6% MRI exams, respectively. In all patients but one, bone erosions were synchronous with bone oedema, overlapping completely the locations. Assessing clinical characteristics in patients with MRI-erosions, a higher prevalence of splenomegaly, a more frequent chronic disease course, lower levels of erythrocyte sedimentation rate and ferritin was observed.

Assessing the synovial tissues of some AOSD patients, a moderate perivascular mononuclear infiltrate in the sub-lining stroma of hip synovial tissues was observed, whereas the lining cells were relatively unremarkable. In addition, interleukin (IL)-1β, IL-6, TNF, and heavy ferritin subunit (FeH) were found on AOSD synovial tissues.

An RNA-sequencing analysis assessed the global transcriptomic profile of synovial tissues on AOSD patients and matched-controls. Assessing IL-1 pathway, we found an increased expression of *il1a*, *il1b*, *il1rap*, *il1r1*, *il18r1*, and *Il18bp* on AOSD tissues when compared with controls. In IL-6 pathway, we found an increased expression of *il6* and *il6st*/*gp130* on AOSD synovial tissues whereas an increased expression of *il6r* was shown on the controls. Among genes involved in TNF pathway, *tnf*, *traf1*, *traf2*, *tnfaip3* and *tnfrsf1a* resulted to be more expressed in AOSD synovial tissues than in controls. Finally, *fth1* and *ftl* were more expressed in AOSD patients than controls, when we explored the iron uptake and transport pathway.

Conclusion: A peculiar MRI pattern of joint involvement in AOSD was reported; the most common finding was the presence of synovitis, characterised by intermediate to high signal intensity on T2-fat-saturated weighted and STIR images. Bone erosions and bone oedema were also observed. This MRI pattern was associated with a hyper-activation of IL-1, IL-6, and TNF pathways together with a hyper-expression of ferritin genes on AOSD synovial tissues.

POS1350 FAMILIAL MEDITERRANEAN FEVER DURING PREGNANCY: A 26 CASE SERIES WITH 38 PREGNANCIES

Y. Karabulut[1]. [1]*Private Yıldırım Doruk Hospital, Division of Rheumatology, Bursa, Turkey*

Background: Familial Mediterranean Fever (FMF) is an autoinflammatory disease characterized by recurrent attacks with autosomal recessive inheritance. FMF usually occurs in young age; most patients (90%) begin to suffer from their first attack before 20 years of age. Pregnancy can occur frequently during the course of the disease, as women of reproductive age are affected by the disease.

Objectives: In this study, it was aimed to retrospectively examine the demographic, genetic, and clinical features (frequency of attacks during pregnancy, duration of attacks, treatment of attacks) of 26 cases who were followed up with a diagnosis of FMF in the last five years and experienced pregnancy.

Methods: A total of twenty-six female FMF cases experienced pregnancy and diagnosed or followed up in our rheumatology center between 2015-2020 were included in the study. All patients were diagnosed according to Tel-Heshomer criteria. All data and follow-up visit records of the patients were retrospectively recorded by the rheumatologist. Patients were followed up by an obstetrician working in the same center during pregnancy. The demographic and genetic characteristics of the patients, the treatment used, the duration and characteristics of the attack during pregnancy, and the treatment they received during the attack were recorded retrospectively. Data processing and analysis conducted with SPSS 22 for Windows.

Results: During the follow-up period, a total of 38 pregnancies were observed in 26 female cases. When the genetic mutation tests of all patients were examined, 61% were M694, 15% were V726, 11% were M680I positive and compound mutation was detected in 42% of the patients. The mean age of the patients was 30±7.8, the disease duration was 9.8± 5.4 years, the follow-up period was 38±14 months, the attack frequency during pregnancy was 3.6± 1.7 and the attack duration was 14± 9.8 hours. Considering the clinical features, fever was seen in 92.3%, abdominal pain 96.1%, chest pain 88.4%, arthritis 11.5% and other symptoms seen in 26% during attacks of pregnant FMF patients. All patients used 1 gram of colchicine regularly throughout pregnancy. Steroids were used in 11.5% of patients and non-steroid anti-inflammatory drugs in 53.8% of patients during the attack. Anakinra was used in 11.5% of the cases except for the first trimester following a written consent obtained from the patients.

In 10.5% of 38 pregnancies, spontaneous abortion was observed in the early period, 7.8% of pregnancies resulted in preterm delivery before 32 weeks. In addition, 81.5% of pregnancy completed the planned period and resulted in a healthy birth. Cesarean section was performed in 4 patients and normal delivery procedure in 27 patients. Major malformation-anomaly was not observed in any baby. When patients using colchicine (73%) irregularly and less than 1 gram (26.9%) before pregnancy were compared in terms of attack frequency and duration, the group using regular medication had significantly fewer and shorter attacks ($p<0.05$).

Three colchicine resistant patients with M694 homozygous mutation became pregnant under anakinra treatment. A total of five pregnancies were followed in three cases. No medication was used in these patients in the first trimester. As of the second trimester, 100mg/day for 3 days of anakinra was administered in these patients after obtaining an informed consent. In this patient group, no obstetric problem was observed during and after pregnancy, and healthy deliveries were realized.

Conclusion: Pregnancy is common in FMF patients of reproductive age. Disease and relapse treatment during pregnancy is still a problem due to the limited number of medications that can be used for treatment. Further studies required to verify safety of Anakinra in refractory FMF cases. There is a need to develop options for the prevention and treatment of attacks during pregnancy.

POS1351 CAUSES OF HOSPITALIZATION IN BEHÇET SYNDROME

Y. Ozguler[1,2], G. Hatemi[1,2], A. S. Pala[3], S. N. Esatoglu[1,2], S. Ugurlu[1,2], E. Seyahi[1,2], M. Melikoglu[1,2], I. Fresko[1,2], H. Ozdogan[1], S. Yurdakul[1,2], H. Yazici[1,2], V. Hamuryudan[1,2]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; [2]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behcet Disease Center, Istanbul, Turkey*; [3]*Prof. Dr. Cemil Taşcıoğlu City Hospital, Department of Internal Medicine, Istanbul, Turkey*

Background: The causes of hospitalization may provide important information on the course of diseases and treatment-related adverse effects.
Objectives: We aimed to determine the causes and outcome of hospitalizations among patients with Behçet Syndrome (BS) in a dedicated center.
Methods: We surveyed hospitalization records in our clinic between January 2002 and December 2019 and identified those with a diagnosis of BS. The records of these patients were reviewed for demographic and clinical features, causes of hospitalization and outcome. We divided hospitalization causes into 2 as being BS related (organ involvement or deterioration) and non-BS related (treatment complication or others).
Results: Three-hundred and thirty BS patients (75% men, mean age 37.7 ±11.4 SD years) were hospitalized for a total of 456 times during 18 years. The mean disease duration was 10.8± 8.8 SD years. Two-hundred and ninety-one (64%) patients were using immunosuppressives (IS) with or without corticosteroids (CSs) and 72 (16%) of them were under biologic treatment at the time of hospitalization. The mean duration of hospitalization was 12.7±10.7 SD days. The reasons for hospitalization were directly related to BS in 259 patients (57%) and non-related to BS in 191 (42%). Six patients were hospitalized for both BS and non-BS related reasons at the same time. The most common reasons were vascular involvement (n=169, 64%) for BS related reasons and infections (n=64, 32%) for non-BS related reasons (Table 1). Patients hospitalized for BS related causes were younger (35.2±10.6 vs 41.1±11.7, p<0.001), had short mean disease duration (8.5±7.5 vs. 13.6±9.4 years, p<0.001), stayed shorter in the hospital (11.6±8.6 vs 14.0±12.9 days p=0.03) and had less frequent IS±CSs use (59% vs 70%, p=0.02) compared to those with non-BS related hospitalizations. There were no differences between the groups regarding gender distribution (203 M/62 F vs. 143 M/54 F) and use of biologic agents (15% vs 17%). Three patients died during hospitalization. The reasons were malignancy, infection and right heart failure due to pulmonary artery thrombosis and pulmonary hypertension, respectively.
Conclusion: Vascular involvement is the leading cause of hospitalization among BS patients, followed by infections. The predominance of men among hospitalized patients underlines the relatively severe course of BS in men. The retrospective design and inclusion of patients who were hospitalized only in the rheumatology unit are limitations of this study.

Table 1. Distributions of BS related and non-BS related reasons of hospitalizations

	BS patients hospitalized with BS related reasons (n of pts=195, n of hospitalizations=265)*	BS patients hospitalized with non-BS related reasons (n of pts=170, n of hospitalizations=197)*
Causes of hospitalizations (per hospitalization)	Vascular inv. (n=169, 64 %)	Infection (n=64, 32%)
	Pulmonary artery inv. (n=64, 24 %)	*Pneumonia (n=17, 8%)*
	Deep vein thrombosis (n=39, 15 %)	*Tuberculosis (n=8, 4%)*
	Budd-Chiari synd. (n=24, 9%)	*Urinary tract inf (n=7, 4%)*
	Vena cava inf. thrombosis (n=19, 7 %)	*Gastroenteritis (n=4, 2%)*
	Peripheral artery inv. (n=15, 6 %)	*Osteomyelitis (n=3, 2%)*
	Vena cava sup. thrombosis (n=14, 5 %)	*Septic arthritis (n=3, 2%)*
	Aorta inv. (n=14, 5%)	*Aspergillosis (n=2, 1%)*
	Coronary artery inv. (n=4, 2 %)	*Nocardia (n=1, 1%)*
	Neurologic inv. (n=50, 19 %)	*Salmonella (n=1, 1%)*
	Parenchymal inv. (n=37, 14%)	*Others (n=18, 9%)*
	Dural sinus thrombosis (n=13, 5%)	Drug side effects other than infections (n=29, 15 %)
		Interferon (n=10, 5%)
		Azathioprine (n=7, 4%)
		Cyclosporine (n=5, 3%)
		Steroid (n=3, 2%)
		TNF antagonists (n=3, 2%)
		IVIG (n=1, 1%)
	GI inv. (n=18, 7%)	Additional rheumatologic diseases (n=17, 9%)
	Joint inv. (n=12, 5%)	Renal disease (n=16, 8 %)
	Mucocutaneous inv. (n=10, 4%)	Cardiovascular dis. (n=12, 6%)
	Eye inv. (n=8, 3%)	Avascular necrosis (n=4, 2%)
	Others (n=8, 3%)	Malignancy (n=11, 6%)
		Others (n=40, 20%)

*Some patients were hospitalized more than one times and for both BS related and non-BS related reasons at different time and had more than one type of BS related and/or non-BS related reasons.

POS1352 ANTIINFLAMMATORY, ANTIOXIDANT AND ANTI-ATHEROSCLEROTIC EFFECTS OF A COMBINATION OF NATURAL SUPPLEMENTS ON PATIENTS WITH FMF RELATED AA AMYLOIDOSIS: A NON-RANDOMIZED 24 WEEKS OPEN LABEL INTERVENTIONAL STUDY

M. Romano[1], F. Garcia-Bournissen[2], D. Piskin[2], R. Cimaz[3], M. Yilmaz[4], E. Demirkaya[1]. [1]*Schulich School of Medicine & Dentistry, University of Western Ontario, Paediatric Rheumatology, London, Canada*; [2]*Western University, London, Ontario, Canada, Paediatrics, London, Canada*; [3]*University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*; [4]*Epigenetic Health Solutions, Unit of Nephrology, Ankara, Turkey*

Background: Few studies have focused on Familial Mediterranean Fever (FMF)-related AA amyloidosis and cardiovascular disease event risk. Systemic inflammation stimulates the development and progression of atherosclerosis which is accelerated by vascular endothelial inflammation and enhanced oxidative stress. Excessive reactive oxygen species (ROS) generation has been reported in FMF, which correlated with attack severity. ROS may also be involved in amyloid formation, and in the pathogenesis of progressive renal injury.
Objectives: In this non-randomized, 24 weeks open label interventional study, we aimed to evaluate the effect of a combination of natural products on parameters related to inflammation, endothelial dysfunction and oxidative stress in a cohort of FMF patients with AA amyloidosis.
Methods: Morinda citrifolia (anti-atherosclerotic liquid- AAL), omega-3 (anti-inflammatory capsules- AIC) and extract with Alaskan blueberry (anti-oxidant liquid- AOL) were given to patients with FMF related AA amyloidosis. We included patients with biopsy proven AA amyloidosis, older than 18 years who have normal estimated glomerular filtration rate (eGFR) and proteinuria [>3500mg/day]. Flow-mediated dilatation (FMD), asymmetric dimethylarginine (ADMA), hs-CRP, serum PTX3, Carotis intima media thickness (CIMT), malondialdehyde (MDA), Cu/Zn-superoxide dismutase (Cu/Zn-SOD), glutathione peroxidase (GSH-Px) levels were studied in baseline and after 24 weeks.
Results: 67 FMF-related amyloidosis [52 male (77.6%); median recruitment age 36 years (range 21-66)] were enrolled. M694V mutation was the most common mutation found (74%), with 50.7% of the patients in homozygosity. All patients were treated with colchicine, and most of them (83.6%) has been on colchicine treatment at the time of enrollment. Serum ADMA, MDA, PTX3, hsCRP, cholesterol, and proteinuria were significantly decreased compared to baseline, while CuZn-SOD, GSH-Px and FMD levels were significantly increased following AAL, AIC and AOL therapies (Table 1). The change of the inflammatory markers PTX3, and hsCRP were negatively correlated with the change in FMD and positively correlated with the change of proteinuria, ADMA, MDA, cholesterol and CIMT.
Conclusion: 24 weeks of AAL, AIC and AOL combined supplementation was significantly associated with reduction in serum inflammatory markers (PTX3 and hsCRP), improved endothelial functions (FMD, ADMA), and oxidative state (MDA). Our findings highlight the link among the three pathogenetic mechanisms including inflammation, endothelial function and oxidative status in progression of atherosclerosis and renal injury in patients with FMF related AA amyloidosis. Efficient control of these three mechanisms can have long term benefits from the cardiovascular and renal perspective of the patients with AA amyloidosis.

POS1353 SERUM PROTEOMICS REVEALS INSULIN-LIKE GROWTH FACTOR BINDING PROTEINS-1 AS BIOMARKERS FOR IDIOPATHIC MULTICENTRIC CASTLEMAN'S DISEASE

R. Sumiyoshi[1], T. Koga[1], A. Kawakami[1]. [1]*Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan*

Background: Castleman's disease (CD) is a lymphoproliferative disorder[1] and presents as two distinct clinical entities: the localized form, unicentric CD (UCD) and the multicentric form, multicentric CD (MCD)[2]. MCD without human herpesvirus-8 (HHV-8) infection is defined idiopathic MCD (iMCD)[3] and most MCDs in Japan are iMCDs. TAFRO syndrome is a group of disease that present with T: thrombocytopenia, A: anasarca, F: fever, R: reticulin fibrosis/renal dysfunction, O: organomegaly[4]. iMCD-TAFRO is present in the TAFRO syndrome and it is thought that pathology of lymph node biopsy shows an MCD-like appearance, and some clinical features overlap with MCD[5]. That do not belong to any of the above categories is classified as iMCD-not otherwise specified (iMCD-NOS). No biomarkers stratifying iMCD-NOS and iMCD-TAFRO have been identified, and no biomarkers defining treatment response have been identified for iMCD.
Objectives: We will identify biomarkers that discriminate iMCD-NOS and iMCD-TAFRO or predict the treatment responsiveness.
Methods: We performed a comprehensive analysis of serum proteins using the L-Series Human Antibody Array L-507 on the 4 iMCD-NOS and 2 iMCD-TAFRO patients from which pre- and post-tocilizumab treatment samples were obtained. An analysis by L-507 identified insulin-like growth factor binding proteins-1 (IGFBP-1) as a protein with a high rate of reduction post treatment. Sera from 28 healthy controls, 8 patients with iMCD-NOS, and 6 patients with iMCD-TAFRO were used to validate IGFBP-1 by ELISA. The mean ages of healthy controls, iMCD-NOS, and iMCD-TAFRO used in the validation ELISA were 50, 56, and 47 years, respectively, with no significant differences among the groups. The ratio of male to female was almost 1:1.
Results: The 4 patients who responded well to treatment with tocilizumab all had a high rate of IGFBP-1 reduction by L-507 serum protein arrays. In ELISA, serum IGFBP-1 was significantly higher (p=0.0016) before the introduction of treatment in iMCD patients than healthy controls. In addition, serum IGFBP-1 level of iMCD-TAFRO was significantly higher than iMCD-NOS (p=0.024). Furthermore, post-treatment serum IGFBP-1 was decreased in many cases.
Conclusion: Serum IGFBP-1 may play a particularly important role in the pathogenesis of iMCD-TAFRO and may be useful in discriminating between iMCD-NOS and iMCD-TAFRO. In the future, we will accumulate more cases, compare it with other inflammatory diseases, and examine the difference in response to treatment.

POS1354 GENDER DIFFERENCES IN CLINICAL FEATURES AND BURDEN IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER: PRELIMINARY REPORT

M. T. Duruöz[1], A. Ozer[1], H. H. Gezer[1], M. Alkan Melikoglu[2], S. Hizmetli[3], H. S. Baklacioglu[4], N. Sahin[5], N. Öz[1], D. Erdem Gürsoy[6], D. Altıntaş[7], P. Oba[8], S. Acer Kasman[1]. [1]*Marmara University School of Medicine, PMR Department, Rheumatology Division, İstanbul, Turkey*; [2]*Ataturk University School of Medicine, PMR Department, Rheumatology Division, Erzurum, Turkey*; [3]*Cumhuriyet University School of Medicine, PMR Department, Rheumatology Division, Sivas, Turkey*; [4]*Samsun Training and Research Hospital, Rheumatology Clinic, Samsun, Turkey*; [5]*Balikesir University School of Medicine, PMR Department, Balıkesir, Turkey*; [6] *Adıyaman Training and Research Hospital, Rheumatology Clinic, Adıyaman, Turkey*; [7]*Ataturk University School of Medicine, PMR Department, Erzurum, Turkey*; [8] *Cumhuriyet University School of Medicine, PMR Department, Sivas, Turkey*

Background: Familial Mediterranean fever (FMF) is the most common hereditary auto-inflammatory disease, which is more common in groups in the Mediterranean basin, characterized by recurrent attacks of febrile peritonitis, pleuritis and arthritis.
Objectives: The aim of this study is to investigate the gender differences in clinical and demographic features in patients with familial Mediterranean fever (FMF).
Methods: Patients with FMF diagnosed according to Tel-Hashomer criteria were included in this multi-center study. Data about age, sex, disease duration, symptom duration, age at diagnosis, comorbid diseases and medications were noted. All patients were screen with Hospital Anxiety and Depression Scale (HADS), Health Assessment Questionnaires (HAQ), Short Form 36 (SF-36). The severity of FMF was assessed by the PRASS scoring system.
Results: Of the 286 patients, 199 (69,6%) were female with the mean age 36,2(SD:12.32) years and 87 (30,4%) were male with the mean age 32,9(SD:12,6) years (p=0,017). Age of diagnosis in male patients was lower than in females (p=0,008). The most common genetic mutation in both genders was M694V gene mutation. Homozygous M694V positivity was higher in males (31,79% vs 17,4%). More than 90% of patients were receiving colchicine,10 (3,5%) patients were receiving anakinra and 5(1,75%) patients were receiving canakinumab. Among the patients regularly taking colchicine, 86.2% were females and 86% were males (p=0,981). There were no differences between male and females in terms of clinical findings, frequency and duration of attacks, presence of colchicine resistance, and the presence of amyloidosis (p>0.05). ESR was detected higher in female group (p=0,011). Headache (p=0,001), migraine (p=0,031), and concomitant diseases (p=0,017) were also more common in females than males. Anxiety and depression scores were higher in females (p<0,05). The PRASS activity scores were similar between genders (p>0,05). All parameters of SF-36 were higher in male patients, while HAQ score was higher in females (p<0,05).
Conclusion: Although clinical findings, disease severity and treatment compliance are similar in both genders, males are diagnosed with FMF earlier than females, but findings such as anxiety, depression, migraine, and headache are more common in female patients.

POS1355 THE REMITTING SERONEGATIVE SYMMETRICAL SYNOVITIS WITH PITTING EDEMA SYNDROME (RS3PE): REVIEW OF TEN YEARS AT A REFERENCE HOSPITAL

S. Garcia Perez[1], J. L. Modesto Dos Santos[2], J. Mendizabal[1], M. López I Gómez[1], G. Sada[1], J. Restrepo Vélez[1], J. I. Elejalde[2], L. Garrido Courel[1], V. Aldasoro[1], I. Paniagua Zudaire[1], R. Gutierrez[1], L. Horcada[1], F. J. Anniccherico[2], N. Del Val del Amo[1], M. C. Fito Manteca[1], J. Sanchez Alvarez[2]. *[1]Complejo Hospitalario de Navarra (CHN), Rheumatology, Pamplona, Spain*; *[2]Complejo Hospitalario de Navarra (CHN), Internal Medicine, Pamplona, Spain*

Background: The Remitting Seronegative Symmetrical Synovitis with Pitting Edema Syndrome (RS3PE) is a rare rheumatological disease, considered a benign process.
Objectives: This study aims to describe its clinical features and serological markers, and also to analyze its possible association with neoplasms.
Methods: An observational retrospective study was performed to assess demographic and clinical characteristics of patients diagnosed from RS3PE at a reference hospital amongst the Rheumatology and Internal Medicine departments, from 2010 to 2021.
Results: Twenty-seven patients were included, with a mean age of 82.74 y.o. (IC95% 80.45-85.04; range 66 to 93), and a 51.85% proportion of males. Only 22.22% were from rural areas.
All patients presented bilateral hand edema although some associated feet edema (40.74%) or morning stiffness (70.37%). Blood tests demonstrated anemia in 44.44% of patients. Inflammatory markers were elevated, such as C-Reactive Protein (29.23 mg/L, IC95% 18.17-40.29), erythrocyte-sedimentation rate (33.74 mm/hour, IC95% 24.22-43.26) and fibrinogen (531.6 mg/dL, IC95% 482.91-580.30). Only a few patients presented any autoimmune serological marker such as antinuclear antibodies (18.18%) or rheumatoid factor (8.70%).
X-ray screening was realized to 22 patients. 14 showed of osteoarthritis radiologic presentation, 4 had radiological findings of chondrocalcinosis and one of them presented both. Only one patient had bone erosion.
Malignancy screening was performed at diagnosis in only 29.63% of patients (all negative). During follow-up only two tumors were detected (mean accumulated follow-up: 40.37 months, IC95% 26.70-54.04; range 1 to 122) and there were adenocarcinoma primary neoplasms.
All but one patient received low-dose corticosteroids, with a good and rapid response in all cases. Three patients received treatment with methotrexate (2) or leflunomide (1).
Conclusion: RS3PE must be contemplated in elderly patients presenting with bilateral hand pitting edema and articular symptoms. No specific biomarkers have been described, but inflammatory reaction is often found in the absence of rheumatoid arthritis biomarkers. Rapid response to corticosteroids is prevalent. Only two neoplasms were detected during follow-up.

POS1356 PERSISTENCE OF TFH CELLS AFTER RITUXIMAB IS ASSOCIATED WITH IGG4-RELATED DISEASE RELAPSE

G. Mancuso[1,2], T. Jofra[3], M. Lanzillotta[4], J. Gerosa[3], G. DI Colo[2], L. Dagna[2], G. Fousteri[3], E. Della Torre[2]. *[1]Università Vita-Salute San Raffaele, Allergologia ed Immunologia clinica, Milano, Italy*; *[2]Ospedale San Raffaele, Immunologia, Reumatologia, Allergologia e Malattie Rare, Milano, Italy*; *[3]Università Vita-Salute San Raffaele, Diabetes Research Institute (DRI), Milano, Italy*; *[4]Università Vita-Salute San Raffaele, Internal medicine, Milano, Italy*

Background: Clinical improvement after B-cell depletion with rituxmab suggests a prominent pathogenic role of B-lymphcytes in IgG4-related disease (IgG4-RD). IgG4-RD, however, relapses in most cases together with re-expansion of clonally divergent plasmablasts indicating that treatment with rituximab does not completely abrogates T follicular helper (Tfh)-cells dependent germinal center reactions leading to de-novo plasmablast differentiation.
Objectives: In the present work we aim to study the effects of B-cell depletion therapy with rituximab on circulating Tfh cells and on the levels of CXCL13 - a chemotactic factor for B-lymphocytes produced by Tfh cells - in patients with IgG4-RD.
Methods: Thirty patients with IgG4-RD, diagnosed according to the "Consensus Statement on the Pathology of IgG4-RD" and fulfilling the "2019 ACR/EULAR Classification Criteria" were included in the present study. Ten patients with relapsing disease were treated with the anti-CD20 monoclonal antibody rituximab (two 1g infuxions 15 days apart). Peripheral blood mononuclear cells and serum were collected before rituximab and three months after infusion. Tfh cells subsets in the peripheral blood were measured by flow cytometry and CXCL13 plasma levels were measured by ELISA assay.
Results: No changes in total Tfh cells and Tfh cells subsets were observed three months after rituximab neither in absolute counts nor in percentage of CD4+ T cells. In particular, no difference in Tfh1, Tfh2, Tfh17, T follicular regulatory and highly functional Tfh cells counts was observed before and after treatment. The serum level of CXCL13 was significantly higher in active untreated IgG4-RD patients compared to healthy controls (151.94 pg/ml vs 66.98 pg/ml, p value = 0.0026), but was not affected by rituximab treatment (p value = 0.41).
Conclusion: In relapsing patients with IgG4-RD rituximab does not affect circulating Tfh cells numbers and serum levels of CXCL13. Persistence of Tfh cells after rituximab and reconstitution of germinal center reactions likely drives IgG4-RD flare.

POS1357 OCULAR SCLERAL PATHOLOGY. UNDERLYING DISEASES AND SYSTEMIC TREATMENT. STUDY OF 175 PATIENTS FROM A SINGLE UNIVERSITY CENTER

L. Sanchez-Bilbao[1], V. Calvo-Río[1], J. L. Martín-Varillas[2], C. Álvarez-Reguera[1], A. Herrero-Morant[1], I. González-Mazón[1], R. Demetrio-Pablo[3], M. A. González-Gay[1], R. Blanco[1]. *[1]H.U. Marqués de Valdecilla, Rheumatology, Santander, Spain*; *[2]H.Sierrallana, Rheumatology, Torrelavega, Spain*; *[3]H.U. Marqués de Valdecilla, Ophthalmology, Santander, Spain*

Background: Ocular scleral pathology (OSP) includes episcleritis and scleritis. Episcleritis is generally a benign disease with a self-limited course, while scleritis is a more severe ocular condition. In some severe and refractory cases systemic therapy may be required.
Objectives: In a wide series with OSP our aim was to assess **a)** underlying diseases and **b)** systemic treatment.
Methods: Study of unselected all consecutive patients studied in a single University Hospital during the last ten years with**: a)** episcleritis and **b)** scleritis diagnosed by clinical features and slit-lamp (Watson and Hayreh criteria). Best corrected visual acuity (BCVA) and intraocular pressure (IOP) were measured at diagnosis and after systemic treatment.
Results: We studied 175 patients (106 women/ 69 men) /212 affected eyes with OSP (episcleritis=135; scleritis=40); mean age 48.9±14.2 years.
OSP was unilateral in 138 (78.9%), recurrent in 74 (42.9%) and chronic in 21 (12%). Most of them were idiopathic (n=81, 46.3%) while associated with IMID were 43.4% (Table 1). The most important underlying IMID were spondyloarthritis and inflammatory bowel disease, without significant differences between scleritis and episcleritis. Granulomatosis with polyangiits and systemic lupus erythematosus were more frequent in scleritis, not reaching statistical significance.
Regarding treatment, topical treatment was used in all patients. 41.1% received systemic treatment, including systemic glucocorticoids, cDMARDS and

bDMARDs. Systemic glucocorticoids and Methotrexate were used more frequently in scleritis (Table 1). The main indication for biologic therapy was related to underlying IMID in both groups, but 7 bDMARDs in scleritis were indicated for systemic and ocular compromise.
BVCA and IOP improved significantly after systemic treatment in scleritis (Figure 1).

Table 1. Underlying diseases and systemic treatment.

	Overall (n =175)	Episcleritis (n=135)	Scleritis (n=40)	p

POS1358 THE EFFECTS AND SAFETY OF APREMILAST AND CYTOKINE EXPRESSION IN BEHCET'S DISEASE PATIENTS

Y. Ushio[1], R. Wakiya[1], K. Ueeda[1], T. Kameda[1], S. Nakashima[1], H. Shimada[1], M. Mahmoud Fahmy Mansour[1], M. Kato[1], T. Miyagi[1], K. Sugihara[1], R. Senba[1], M. Mizusaki[1], H. Dobashi[1]. *[1]Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Takamatsu, Japan*

Background: Apremilast, the small-molecule phosphodiesterase (PDE) -4 inhibitor, was approved for the treatment of recurrent oral ulcers associated with Behcet's disease (BD) in Japan from September 2019, following the success of the phase 3 RELIEF study (1). However, the efficacy of apremilast on domains other than oral ulcers in BD patients is unclear. On the other hand, it has been reported that apremilast may decrease the production of proinflammatory cytokine and increase the production of anti-inflammatory mediators in psoriasis (PS) and psoriatic arthritis (PsA) (2).
Objectives: To evaluate the effects and safty of apremilast on clinical symptoms and the changing of serum cytokine expression.
Methods: BD patients who had treated with apremilast for active oral ulcers were included in the study. We investigated the improvement rate of oral and genital ulcers, skin lesions, arthritis. In addition, serum cytokines (IFN-γ, IL-10, IL-8, and TNF-α) before and after apremilast treatment were measured using a multiplex immunoassay (Luminex Assay, R&D Systems).
Results: Fourteen patients (3 males and 11 females) were enrolled in this study. The mean age was 46.6 ± 13.0 years and the mean duration of disease was 10.2 ± 8.8 years. All patients had active oral ulcers, five had genital ulcers, six had skin lesions, and four had arthritis. Three months after the treatment with apremilast, oral ulcers improved in 13 patients (92.9%). The improvement rates of genital ulcers, skin lesions and arthritis were 60%, 25% and 25%, respectively. Changes in serum cytokines were different from those previously reported in PS. Adverse events were gastrointestinal symptoms such as nausea and diarrhea in 6 patients and sensorineural deafness in 1 patient. Medication was reduced in 2 patients, and discontinued in 1 patient due to nausea and diarrhea.
Conclusion: Apremilast is useful not only for oral ulcers, but also for other lesions in BD patients. The effect of apremilast for other domain such as genital ulcers, skin lesions, arthritis was not comparable to that of active oral ulcers. Additionally, BD may have different cytokine profile from PS and PsA.

POS1359 REGIONAL DIFFERENCES IN DISEASE CHARACTERISTICS OF FAMILIAL MEDITERRANEAN FEVER IN TURKEY: PRELIMINARY REPORT

M. T. Duruöz[1], H. H. Gezer[1], M. Alkan Melikoglu[2], S. Hizmetli[3], H. S. Baklacioglu[4], N. Sahin[5], A. Ozer[1], N. Öz[1], D. Erdem Gürsoy[6], D. Altıntaş[7], P. Oba[8], S. Acer Kasman[1]. *[1]Marmara University School of Medicine, PMR Department, Rheumatology Division, Istanbul, Turkey*; *[2]Ataturk University School of Medicine, PMR Department, Rheumatology Division, Erzurum, Turkey*; *[3]Cumhuriyet University School of Medicine, PMR Department, Rheumatology Division, Sivas, Turkey*; *[4]Samsun Training and Research Hospital, Rheumatology Clinic, Samsun, Turkey*; *[5]Balıkesir University School of Medicine, PMR Department, Balıkesir, Turkey*; *[6]Adıyaman Training and Research Hospital, Rheumatology Clinic, Adıyaman, Turkey*; *[7]Ataturk University School of Medicine, PMR Department, Erzurum, Turkey*; *[8]Cumhuriyet University School of Medicine, PMR Department, Sivas, Turkey*

Background: Familial Mediterranean fever (FMF) is a hereditary autoinflammatory disease accompanied by recurrent attacks of fever and serositis. It is prevalent among Mediterranean populations, mainly Turks, Armenians; Jews and Arabs. As genetic factors are variable in the population, environmental factors can also affect phenotypic characteristics.
Objectives: This study aimed to determine the geographic differences in disease characteristics and burden in patients with FMF in Turkey.
Methods: Patients diagnosed with FMF according to the Tel-Hashomer criteria were included in this multi-center study. Patients were included from the different regions of Turkey. Demographic features and clinic characteristics of the patients including disease duration, medications, comorbid conditions, attack characteristics, amyloidosis, acute phase reactants, FMF gene mutations, arthritis, sacroiliitis, and febrile myalgia were recorded. PRASS disease activity score, FMF-QoL, HAD, and HAQ were assessed. Patients from different parts of Turkey were divided into 3 groups the Central Anatolia, Western, and Eastern. Disease activity, characteristics and burden were also investigated among 3 distinct geographic regions.
Results: A total of 281 patients with FMF (195 women, 86 men) were enrolled in this study. The mean age of the patients was 34.9 (SD:12.3) years. While the patients in the eastern areas of Turkey were diagnosed earlier age (*p<0.001*), the patients in the western area had a longer diagnostic delay time (*p<0.001*). Patients enrolled from western regions tended to have higher ESR and PRASS scores than those from eastern and central Anatolian regions, but attack numbers per 6 months were similar among the regions. The highest proportion of patients who were M694V/M694V homozygous patients were in western, and then eastern and central Anatolia (19.5%, 18%, and 5.4%). While fever and arthritis were more common in the eastern, pleuritis and sacroiliitis were more common in the central anatolia. Peritonitis and erysipelas like erythema rates were similar among the regions. The majority of patients were receiving colchicine treatment in all three regions. FMF-QoL scores were highest in the eastern and lowest in the western (*p=0.006*). Patients enrolled in the central Anatolia region experienced more functional disability than those from the western and eastern regions (p=0.009). Anxiety and depression scores were similar between groups (p=0.385 vs p=0.549).
Conclusion: These findings suggest that patients with FMF have diversity concerning the age at diagnosis, diagnostic delay time, disease activity, quality of

life, and functional disability among the 3 regions. In the genotypic analysis, the M694V mutation is the most common pathogenic mutation in all regions. Regional genetic and environmental varieties may explain the areal differences. These relationships can occur more clearly in larger patient populations.

POS1360 MONOGENIC AUTO-INFLAMMATORY DISEASES IN ADULTS IN THE PRACTICE OF A RHEUMATOLOGIST

S. Salugina[1], E. Fedorov[1], T. Dubinina[2], S. Palshina[3]. [1]*V.A.Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*; [2]*V.A.Nasonova Research Institute of Rheumatology, Laboratory of Medical and Social Problems of Rheumatology, Moscow, Russian Federation*; [3]*V.A.Nasonova Research Institute of Rheumatology, Laboratory of Intensive Therapy Methods, Moscow, Russian Federation*

Background: The group of the most common monogenic auto-inflammatory diseases (mAIDs) includes FMF, TRAPS, HIDS, CAPS. Descriptions of these diseases are widely presented in the literature, but they are not well covered among adults. MAIDs in the adult rheumatological practice are found: 1) in pts with the onset and diagnostics of the disease in their childhood; 2) in pts with juvenile onset, but diagnostics of the disease in their adulthood; 3) in pts with the onset of the disease in adulthood. Adult specialists, in contrast to pediatricians, are not very well aware of the clinical and laboratory picture, course, age characteristics, approaches to treatment, consequences of mAID, which leads to late diagnostics and untimely prescription of targeted therapy, development of complications (amyloidosis) and damage to organs, life quality impairment.

Objectives: To characterize adult patients with mAIDs in the practice of a rheumatologist.

Methods: Within the period from 2009 to 2020, 123 patients with mAIDs (FMF-53, CAPS-44, TRAPS-21, HIDS-5) were diagnosed, of which 50 were adults. All pts underwent a standard rheumatological examination, including ESR, CRP, ophthalmological and other instrumental examinations, audiogram, if required. Molecular genetic analysis of genes MEFV, TNFRSF1A, MVK, NLRP3 was performed in all pts. All but one patient with CAPS (CINCA / NOMID) showed feature genetic mutations.

Results: The study included 50 pts aged 18 to 66 years, 35 women, 15 men. The age of onset was from 0 to 53 years, in 88% of cases the onset of the disease was noted in childhood, 6 pts debuted at the age over 18 years (4 with FMF - 23-35 years; 2 CAPS - 51 and 53 years). As of the time of inclusion into the study, the duration of the disease ranged from 6 months to 59 years. All patients had fever, skin rashes were present in the majority (72%) of pts with CAPS (urticaria), TRAPS (erythematous and anulyariform) and HIDS (spotted), in half of pts with FMF (erysipeloid erythema). Articular manifestations were present in the majority of pts (80%), oligoarthritis in 38%, mainly in pts with CAPS (35%) and FMF (47.8%). Polyarthritis occurred in 18% of pts. Ophthalmic changes (32%) in the form of conjunctivitis and/or uveitis were more common in patients with CAPS (65%), sensorineural deafness only in pts with CAPS (40%), stomatitis in 16% in pts, more often in case of CAPS (35%). Family history is aggravated in almost half of pts. All pts showed an increase in ESR and CRP performance. Colchicine treatment was used mainly in patients with FMF. Glucocorticoids (GC) and biological agents (IL-1 inhibitors) were more often received by pts with CAPS (55% and 60%).

Table 1. Clinical and demographic characteristics of adult patients with mAIDs

AIDs	FMF (23)	CAPS (20)	TRAPS (5)	HIDS (2)	N (%)
Fever	23(100)	20 (100)	5 (100)	2 (100)	50 (100)

POS1361 EVALUATION OF PATIENTS WITH (SUSPECTED) BEHÇET SYNDROME; DIAGNOSTIC VALUE OF PATHERGY TESTING AND OPHTHALMOLOGIC EXAMINATION

G. Duttenhofer[1], I. Visman[1], F. Kerstens[1], G. Piskin[2], F. Turkstra[1]. [1]*Reade, Rheumatology, Amsterdam, Netherlands*; [2]*BovenIJ ziekenhuis, Dermatology, Amsterdam, Netherlands*

Background: Behçet syndrome (BS) is a multisystem vasculitis of unknown etiology. A positive pathergy test (PT) is part of the ISG criteria for the classification of BS [1]. The added value of PT in the diagnostic workup is unknown. Also, it is unknown whether real time assessment of the pathergy reaction after 48 hours by a physician can be replaced by patient assessment.

The diagnostic value of routine eye examination in patients with suspected BS is unclear.

Objectives: Assess the diagnostic value of PT and ophthalmologic examination in (suspected) BS patients. Examine the correlation between physician and patient assessment of PT results.

Methods: This prospective cohort study in (suspected) BS patients was conducted from 2009 to 2020.

At baseline, patients were classified as "true" (≥3 criteria), "probable" (2 criteria) or "no" (0-1 criteria) BS according to ISG criteria and were referred to a dermatologist and/or ophthalmologist for PT and/or eye examination. The percentage of positive PT and eye examination in each group was assessed and the percentage of patients with a changed classification (probable to true BS) was determined.

PT results were scored by both patients and physicians.

Results: Baseline characteristics are reported in Table 1. Figure 1 displays the flowchart of diagnostic value of PT.

Table 1. Baseline characteristics of (suspected) BS patients.

	All patients n=153	ISG +[1] n=59	ISG+ after FU[2] n=11	ISG –[3] n=83	P-value (+ vs -)
Age (mean ± SD[4] years)	39.5 (12)	41.8 (11.6)	33.6 (7.5)	38.5 (12.6)	0.294

1.patients fulfilling the ISG criteria at enrollment2.patients who fulfilled the ISG criteria during FU3.patients did not fulfill the ISG criteria after FU4.standard deviation5.Turkey, Asia, Middle and Far Eastern, Arabic countries and Northern Africa

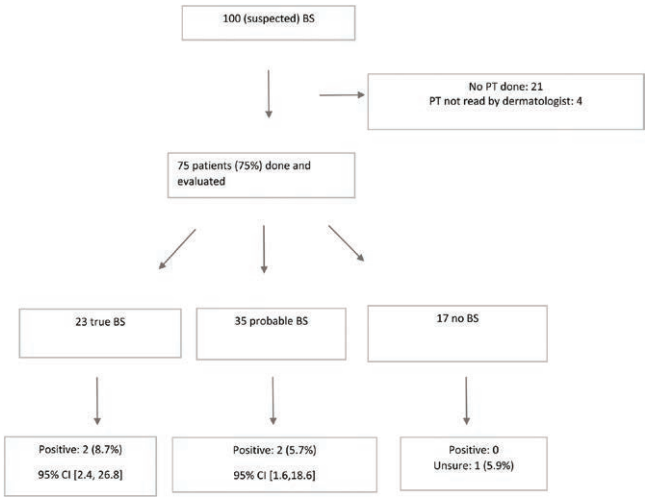

Figure 1. Flowchart of the results of PT in (suspected) BS patients

In 22 patients with two ISG criteria, grade I uveitis was diagnosed in 1 patient (4.5%, 95% CI [0.8,21.8]) and retinal vasculitis in 1 patient (4.5%, 95% CI [0.8,21.8]). He had shortly experienced photophobia 3 months earlier. Both patients (9%, 95% CI [2.5,27.8]) changed from "probable" to "true" BS, the latter also had a positive PT.

47 patients assessed the results of their own PT. The dermatologist scored PT as positive in one patient. This patient scored the results as unsure on all six PT points. In 46 patients, the dermatologist scored PT as negative, a total of 26 patients (56.5%, 95% CI [42.2,69.7]) scored their results negative as well.

Conclusion: The added diagnostic value of PT in patients fulfilling 2 features of the ISG criteria was limited in our study, i.e. 5.7% 95% CI [1.6,18.6]. Furthermore, half of patients scored their true negative PT result as negative. The added diagnostic value of routine eye examination in probable BS patients was limited in our study.

POS1362 NEUROSARCOIDOSIS. STUDY OF 30 PATIENTS FROM A SERIES OF 384 SYSTEMIC SARCOIDOSIS FROM A TERTIARY UNIVERSITY HOSPITAL

A. Herrero-Morant[1], L. Sanchez-Bilbao[1], I. González-Mazón[1], D. Martínez-López[1], J. L. Martín-Varillas[2], R. Fernández-Ramón[1], M. Á. González-Gay[1], R. Blanco[1]. *[1]Hospital Universitario Marqués de Valdecilla, Rheumatology and Ophtalmology, Santander, Spain*; *[2]Hospital de Sierrallana, Rheumatology, Torrelavega, Spain*

Background: Neurosarcoidosis is a serious and infrequent complication of sarcoidosis. Data on Biologic Therapy (BT) efficacy is scarce.

Objectives: To assess in neurosarcoidosis a) its prevalence and associations of clinical clusters and b) efficacy and safety of BT.

Methods: Study of neurosarcoidosis from a large cohort (n=384) of all consecutive patients diagnosed with sarcoidosis from January 1, 1999 to December 31, 2019 in a single University hospital.

Results: 30 (19 women/ 11 men) out of 384 (7.8%) patients had neurosarcoidosis. Mean age at diagnosis was 41.8±15.8 years. Clusters of clinical associations were lungs (n=23, 76.7%) and joints (n=15, 50.0%) (Figure 1). The underlying neurological manifestations were chronic headache (n=13, 43.4%), peripheral neuropathy (n=6, 20.0%), cranial neuropathy (n=5, 16.7%), spinal cord abnormalities (n=3, 10.0%) and aseptic meningitis (n=3, 10.0%). 26 (86.7%) patients received oral corticosteroids (mean maximum dose 50±19.2mg) and 7 (23.3%) iv corticosteroids. In addition, 18 (60.0%) patients received conventional immunosuppressants and 12 (40.0%) BT. 4 (13.3%) did not have any treatment. Table 1 shows the main clinical features and treatment.

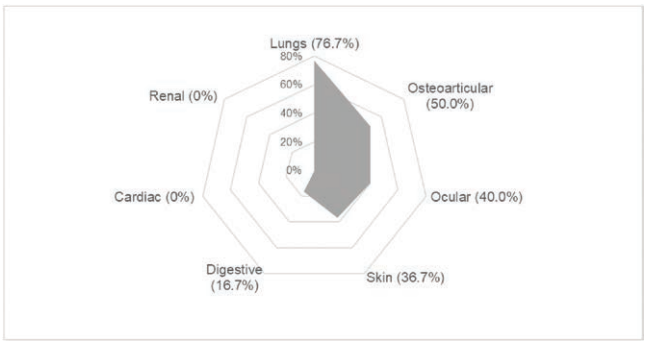

Figure 1. Clusters of clinical associations in neurosarcoidosis

12 patients received treatment with 14 BT. Monoclonal anti-TNFα (n=10, 83.3%) was the most used BT. 10 (83.3%) patients treated with BT achieved clinical remission. No serious adverse effects were observed.

Conclusion: Neurosarcoidosis was observed in 7.8% of systemic sarcoidosis. Most patients treated with BT, especially monoclonal anti-TNFα, achieved clinical remission.

Table 1. Main clinical features and treatment of 30 patients with neurosarcoidosis.

	n (%)	Conventional immunosuppressant, n (%)	monoclonal anti-TNFα, n (%)	Etarnecept, n (%)	Tocilizumab, n (%)	Secukinumab, n (%)	Rituximab, n (%)
Chronic headache	13 (43.4)	5 (38.5)	2 (15.4)	0 (0)	0	1 (7.7)	1 (7.7)
Peripheral neuropathy	6 (20.0)	4 (66.7)	3 (50.0)	1 (16.7)	0	0	0
Cranial neuropathy	5 (16.7)	4 (80.0)	3 (60.0)	0	0	0	0
Spinal cord abnormalities	3 (10.0)	1 (33.3)	1 (33.3)	0	0	0	0
Aseptic meningitis	3 (10.0)	2 (66.7)	2 (66.7)	0	1 (33.3)	0	0

POS1363 CHONDROCALCINOSIS AS PREDICTOR OF DEVELOPMENT OF PRIMARY HYPERPARATHYROIDISM: RESULTS OF THE FOLLOW-UP OBSERVATION

A. Novikova[1], M. Eliseev[1], O. Sheliabina[1], M. Chikina[1]. *[1]VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation*

Background: The association between chondrocalcinosis and primary hyperparathyroidism (PHPT) is known, but chondrocalcinosis is considered as a late complication of PHPT.

Objectives: To investigate whether calcium pyrophosphate crystal deposition is an early clinical sign of PHPT.

Methods: The prospective study included 113 patients aged ≥18 years, 42 (37.2%) men and 71 (62.8%) women, with a crystal-verified diagnosis of calcium pyrophosphate crystal deposition disease (CPPD) (McCarty criteria). Exclusion criteria were the presence of other rheumatic diseases with symptoms of arthritis, the presence of hyperparathyroidism (HPT). Patients were examined at their enrollment and over time, the median follow-up was 3.86 [2.07; 8.36] years. The examination of the patients included assessment of anthropometric parameters, information about the affected joints and the time of onset of symptoms.

Table 1. Results of patients with PHPT at screening and in dynamics.

	Crystals of calcium pyrophosphate in synovial fluid	Chondrocalcinosis by ultrasound	Chondrocalcinosis by X-ray	Convulsions	ECG changes (shortening of the QT interval)	Arthralgias / arthritis	PTH, pg/ml (15,0-65,0)	Ca, μmol/l (2.10-2.62)	Ca^{++}, μmol/l (1.10-1.33)	vitamin D (25-OH), ng/ml (30-100)
	screening / dynamics									
Patient A.	yes/yes	yes/yes	not/yes	not/not	not/not	yes/yes	61.6/96.2	2.73/2.67	1.37/1.24	-/31
Patient B.	yes/yes	yes/yes	yes/yes	not/yes	not/yes	yes/yes	40.7/252	2.63/2.56	1.34/1.77	19.1/14.2
Patient C.	yes/yes	yes/yes	not/yes	not/not	not/not	yes/yes	26.6/102.4	2.60/2.65	1.25/1.26	-/40

Laboratory tests included determination of the following in blood serum: creatinine (with estimating glomerular filtration rate (eGFR) according to the MDRD formula), total and ionized calcium (Ca and Ca^{++}), phosphorus (P), parathyroid hormone (PTH), vitamin D (25-OH); ultrasound and X-ray investigations of the target joints (hands, knee joints) were made for all patients. Scintigraphy and ultrasound of the parathyroid glands were performed if medically required. Statistica 12.0 package was used for statistical data processing.

Results: 113 patients were examined, the average age was 58.4±12.4 years. 10 patients were excluded due to diagnosed HPT at screening. 41 patients dropped out of observation: 5 - died, 36 were not available for dynamic examination. 62 patients were examined in dynamics, 4 (6.5%) of those had HPT. In 1 (1.6%) case, HPT was associated with chronic renal failure, 3 (4.8) patients were diagnosed PHPT. The results of the examination of patients who developed PHPT during screening and in dynamics are presented in Table 1 above.

In all three patients, chondrocalcinosis was revealed by ultrasound and Crystals of calcium pyrophosphate in synovial fluid during the screening examination, in one patient chondrocalcinosis was revealed by X-ray. In two out of three cases, the level of serum Ca and Ca^{++} was minimally increased at a normal level of PTH, no other disorders of calcium metabolism were observed during the screening.

Interestingly, the first clinical manifestation of HPT in all patients was damage of the musculoskeletal system - mainly arthralgia, as well as arthritis of large and small joints. Moreover, all patients had a different CPPD phenotype: patient A - asymptomatic chondrocalcinosis, patient B - chronic arthritis (pseudo-rheumatoid form) and patient C - chronic arthritis (pseudosteoarthritis).

Conclusion: The deposition of calcium pyrophosphate crystals may be an early predictor of the development of PHPT and precedes other manifestations.

POS1364 MUSCULOSKELETAL VARIANT OF FAMILIAL MEDITERRANEAN FEVER MAY HAVE MORE SEVERE DISEASE

M. E. Tezcan[1], R. Mercan[2], Ö. Volkan[1], N. Şen[1], S. Yilmaz-Oner[1]. [1]*Kartal Dr. Lütfi Kırdar Şehir Hastanesi, Rheumatology, Istanbul, Turkey*; [2]*Tekirdağ Namık Kemal Üniversitesi, Rheumatology, Tekirdag, Turkey*

Background: Familial Mediterranean fever (FMF) is one of the prototypes of auto inflammatory diseases. Besides recurrent serositis, some patients also have musculoskeletal involvement similar to spondyloarthropathies (SpA) (1). These patients usually have more severe disease (2). In addition, some experts think FMF can be considered a variant of SpA.

Objectives: There is handful of studies in literature that evaluated the disease severity, FMF complications and treatment variations in FMF patients with individual musculoskeletal features separately (3). However, these patients can be considered as musculoskeletal/SpA variants of FMF. Here, we evaluated the validity of hypothesis: "The patients with any of musculoskeletal symptoms or SpA variant of FMF have more severe disease."

Methods: We included 218 FMF patients who met Modified Tel- Hashomer criteria. We divided the patients according to suffering from any of the musculoskeletal symptoms (arthritis, enthesitis, arthralgia/myalgia, sacroiliitis,standing myalgia).Here, arthritis, enthesitis were diagnosed with physical examination according to appropriate methods. Standing myalgia diagnosis was depending upon patients' history. Lastly, sacroiliitis was demonstrated in radiological screening. The patients with any of the musculoskeletal symptoms were considered musculoskeletal variants of FMF. In this study we compare disease characteristics and treatment differences between the groups. We used Mann-Whitney-U or chi-square tests where appropriate.

Results: There were 126 (57.7%) patients in the musculoskeletal group. FMF patients in both groups had similar demographic and disease characteristics except musculoskeletal signs. Musculoskeletal variant group had higher The International Severity Score for FMF (ISSF) (p<0.001); more frequent (p=0.009), intense (p=0.009) and longer attacks (p=0.001) than the others. Also, patients with musculoskeletal variant received higher colchicine dose (p=0.006).

Table 1. Demographic, disease and treatment characteristics of the patients

	Musculoskeletal variant n=126	Non-musculoskeletal group n=92	p
Gender (M/F)	45/81	34/58	0.85
Disease duration(year)	9.6±7.3	8.3±6.9	0.08
Fever (%)	81 (64.3)	53 (57.6)	0.37
Abdominal pain (%)	106 (84.1)	83 (90.2)	0.19
Plevritis (%)	46 (36.5)	28 (30.4)	0.35
Number of attack region	1.7±0.8	1.3±0.5	**<0.001**
Attack frequency (/year)	3.4±5.0	2.1±3.5	**0.009**
Attack duration (day)	1.6±1.7	0.9±1.5	**0,001**
Attack VAS score (0-100)	33.3±32.7	23.1±31.5	**0,009**
ISSF score	1.6±1.3	0.6±0.9	**<0.001**
Exon 10 homozygote (%)	33 (26.2)	19 (20.7)	0.42
Amyloidosis (%)	6 (4.8)	2 (2.2)	0.47
Colchicine dose (mg/day)	1.4±04	1.2±0.4	**0.006**
Il-1 blocker (%)	1 (0.8)	2 (2.2)	0.57

M: Male; F: Female; ISSF: The International **Severity** Score for FMF; VAS: Visual analog score. All continuous variables shown as mean±SD. p<0.05 is significant.

Conclusion: We showed that FMF patients with musculoskeletal signs have more severe disease and received higher colchicine dose as compared to non-musculoskeletal group and can be considered as the SpA variant of FMF or a distinct variant of SpA.

POS1365 ANNALYSIS OF PRO-INFLAMMATORY BIOMARKERS IN A POLYMYALGIA RHEUMATICA COHORT DURING THE ACUTE ONSET OF THE DISEASE

F. M. Ortiz Sanjuan[1], E. Grau García[1], C. Riesco Barcena[1], A. V. Huaylla Quispe[1], C. Pávez Perales[1], S. Leal Rodriguez[1], M. De la Rubia Navarro[1], I. Martínez Cordellat[1], C. Nájera Herranz[1], R. Negueroles Albuixech[1], J. E. Oller Rodríguez[1], E. Vicens Bernabeu[1], C. Alcañiz Escandell[1], I. Cánovas Olmos[1], I. Chalmeta Verdejo[1], J. J. Fragío Gil[1], L. Gonzalez Puig[1], J. Ivorra Cortés[1], J. A. Román Ivorra[1]. [1]*HUP La Fe, Rheumatology Department, Valencia, Spain*

Background: Polymyalgia Rheumatica (PMR) is a common inflammatory disease found in elderly patients and results in a high burden of long-term CS-based therapies. Most patients diagnosed with PMR have a good evolution following the introduction of medium-dose glucocorticoid treatment. However, the need to maintain corticosteroid treatment for an extended period (around 12-15 months) is often the norm in standard clinical practice. Activation of Th-17 lymphocytes with the consequent action of pro-inflammatory cytokines such as IL-1, IL-6, IL-17, or IL-23 is well known in the acute phase of this disease and treated by glucocorticoids or IL-6 blockers satisfactorily. However, activation of Th-1 lymphocytes appears to play a leading role in a chronic phase of the disease through the activation of INF-gamma and IL-12.

Objectives: Our aim was to assess proinflammatory biomarkers in a cohort of patients with PMR during the acute onset of the disease and its possibly relationship with corticosteroid dose.

Methods: Prospective study of a wide and unselected series of patients classified as PMR following 2012 ACR/EULAR classification criteria for PMR. Patient evaluations were performed at baseline and at 3 and 6 months after initiation of corticosteroid therapy. Serum levels of the proinflammatory biomarkers interleukin-6 (IL-6), interleukin-8 (IL-8), CXC motif ligand 10 chemokine (CXCL10), CXC motif ligand 9 chemokine (CXCL9), CXC motif ligand 2 chemokine (CXCL2) and

CC motif ligand 2 chemokine (CCL2) were measured in PMR patients and in healthy controls.
Results: A total of 25 patients with PMR were studied (32% men; 68% women). The mean age was 72.72 ±9.32 years (range 65-79). We also included 35 healthy controls. In reference to laboratory parameters and proinflammatory biomarkers at the onset of PMR, the mean values (± standard deviation) were as follows: C reactive protein (CRP): 28.4±26.6 mg/dL; erythrocyte sedimentation rate (ESR): 54.3±21.3 mm/h; haemoglobin: 12.6±1.6 g/dL; IL-6: 17.6±30.1 pg/mL; IL-8: 10.1±6.9 pg/mL; CXCL10: 259.4±290.7 pg/mL; CXCL9:5175±4396.8 pg/mL;, CXCL2: 25.9±12.5 pg/mL; CCL2: 471.3±152.9 pg/mL.
IL-6, IL-8 and CXCL9 levels were significantly increased in PMR patients comparing with the healthy control group.
The Health Assessment Questionnaire (HAQ) performed at the onset of the PMR yielded a mean value of 1.6±0.6. The mean dose of prednisone employed at the onset of PMR was 14.8±5.6 mg/day.
After 6 months, the mean dose of prednisone employed was 6.7±3.9 mg/day, the median [range] value for CRP was 3.1 [1.75-7.2] mg/dl and the mean value for ESR was 22±14 mm/h. Regarding relationship between proinflammatory biomarkers studied and doses of prednisone employed, no differences were observed.
Regarding pain perception and disability, we observed higher visual analogic scale values (VAS) in association with higher IL-6 levels (P=0.03) and higher HAQ values in association with higher IL-6 and CXCL2 values.
After 6 months, our patients showed an excellent evolution, and no complications were observed.
Conclusion: During the acute onset of PMR, IL-6, IL-8 and CXCL9 levels were significantly increased in our population of PMR patients. No differences were observed between proinflammatory biomarkers studied and doses of prednisone employed.

POS1366 THE RELATIONSHIP OF MAST CELL ACTIVATION SYNDROME AND HYPERMOBILE EHLERS-DANLOS SYNDROME IN HOSPITALIZED PATIENTS IN THE UNITED STATES

K. Mathias[1], A. Mantha[2], L. Mathias[3], D. Arkfeld[3]. [1]*University of Chicago, Internal Medicine, Chicago, United States of America*; [2]*USC Keck School of Medicine, Internal Medicine, Los Angeles, United States of America*; [3]*USC Keck School of Medicine, Rheumatology, Los Angeles, United States of America*

Background: Patients with hypermobile Ehlers-Danlos syndrome (hEDS) often report symptoms of cutaneous flushing, pruritis, vomiting, diarrhea and anaphylactoid responses to environmental, food, and mechanical stimuli. There is a growing body of literature investigating the possible link between disorders of mast cell regulation including mast cell activation syndrome (MCAS) and connective tissue disorders including hEDS. The evidence for such a relationship, however, remains limited[1].
Objectives: We aimed to evaluate the association between hEDS and MCAS among hospitalized patients using a nationally representative cohort.
Methods: Hospitalized patients with a diagnosis of hEDS or MCAS were identified in the 2016-2018 National Inpatient Sample (NIS) using the International Classification of Diseases 10 system (ICD-10). The NIS is an all-payer inpatient database that estimates over 37 million annual U.S. hospitalizations and is maintained by the Healthcare Cost and Utilization Project. The primary outcomes were prevalence of EDS and MCAS among hospitalized patients. Secondary outcomes included cause of admission, mortality, length of stay, and cost of care. Multivariate hierarchical regression analysis was using adjusting for demographics, hospital factors, and comorbid conditions.
Results: Among 37,665 patients identified in this study, 35,115 (95.9%) patients had hEDS and 3,630 (9.6%) patients had MCAS. 1080 patients had concomitant diagnosis of hEDS (3.1%) and MCAS (29.8%), of whom 555 (51.4%) were diagnosed in 2018 compared with 100 (9.3%) patients in 2016 (P<0.001). The mean age of patients with both conditions was significantly lower than those diagnosed with hEDS (29.5 vs 36.6 years, P<0.001) or MCAS (29.5 vs 39.8 years, P<0.001) alone. Those with comorbid hEDS and MCAS were more likely female (95.8% vs 84.5%, P<0.001), had private insurance (67.6% vs 52.4%, P<0.001) and were among the highest income quartile (47.4% vs 31.9%, P<0.001). There were no significant differences in mortality or overall comorbidity burden. Patients with hEDS and MCAS had higher adjusted hospitalization charges ($64,445 vs $54,782, β=0.15, P<0.05) and longer adjusted lengths of stay (6.4 vs 4.9 days, IRR 1.35, P<0.001).
Conclusion: Nearly 1 in 3 patients diagnosed with MCAS have comorbid diagnosis of hEDS. This association appeared to increase over time with the increasing diagnosis of MCAS. Social determinants of disease such as health insurance status and income appeared to be associated with the identification of the overlap syndrome. These findings merit further investigation into the co-occurrence of these disease entities and development of consistent clinical diagnostic criteria.

POS1367 PROCALCITONIN IN RHEUMATOLOGY

K. Erraoui[1], K. Nassar[2], S. Janani[1]. [1]*CHU Ibn Rochd, Department of Rheumatology, Casablanca, Morocco*; [2]*CHU Ibn Rochd, Department of Rheumatology, Casablanca, Morocco*

Background: The differentiation between infection and aseptic inflammation is difficult and often a challenge in the daily practice of rheumatology.Procalcitonin (PCT) is a preferred marker for bacterial infections that allows the rheumatologist to make an early diagnosis, choose an appropriate antibiotic therapy for bacterial infection, and avoid unnecessary antibiotic therapy for inflammation.
Objectives: To study the levels of PCT in various inflammatory states observed in a rheumatology department, and to assess its possible discriminating role in the differentiation of bacterial infection from other inflammatory processes.
Methods: This is a preliminary monocentric retrospective study conducted from January 2018 to December 2020 in our rheumatology department. The inclusion criteria were all patients hospitalized in rheumatology for a rheumatic or autoimmune disease or a bone and joint infection.PCT samples from patients were analyzed along with general signs (fever/chills) and with routine assessment (blood count including white blood cell count(WBC), erythrocyte sedimentation rate (ESR)and C reactive protein(CRP)) in patients admitted to hospitalfor a fever or a biological inflammatory syndrome, or both, with a laboratory cut-off value of 0.5 ng/ml.
Results: 20 patients were included. Their mean age was 46.1 (extremes 19 – 66) and the with sex ratio was 1. Three patients had a history of autoimmune disease, 2 of neoplasia, 1 with chronic terminal kidney failure and hemodialysis, and 4 patients took antibiotics before hospitalization. The mean PCT was 100.01ng/ml (extremes 0.01-200), and Sensitivity at 57.44% and specificity at 100%, PPV: 100%, NPV: 81.25%.
The patients were divided according to their final diagnosis into 3 groups: bacterial or fungal infection; inflammatory abacterian disease (autoimmune or rheumatic flare, neoplasia, metabolic, reactive arthritis); infection + inflammatory abacterian disease. Group 1 included 4 patients, their mean PCT was 6.92ng/ml (0.16-26.80),mean CRP was 131.725 mg/L, and mean ESR was 50 mm,

	Group 1(n=4)	Group 2(n=13)	Group 3(n=3)
Mean age	45	46.77	44.67
Sex ratio M/F	2/2	8/5	0/3
Reason for hospitalization	Phlegmon of the left shoulder and inflammatory gonalgia in a feverish context 25% Multiple vertebral fractures 25% Acute monoarthritis of the left knee 25% Pain in the left hip with functional impairment 25%	Inflammatory polyarthralgia15.38% Inflammatory back pain 23.07% Activity of his autoimmune 15.38% disease Chronic hip pain 7.69% Acute febrile polyarthralgia 30.77% Biarthritis 7.69%	Acute febrile polyarthralgia 66.67% Flare of polymyalgia rheumatica 33.33%
History	Neoplasia 25%	Autoimmune disease 23.07%	End-stage chronic renal disease with hemodialysis 33.33%
PCT indication	Suspected septic arthritis 75% Exploration of inflammatory syndrome 25%	Suspicion of arthritis 46.15% Exploration of inflammatory syndrome 53.85%	Suspicion of sepsis 33.33% Exploration of inflammatory syndrome 66.67%
Mean PCT value (ng/ml)	6.92	0.025	66.88
fever/chills	75%	30.77%	33.33%
Biological parameters	25%	30.77 %	33.33%
Hyperleukocytosis	50	84.38	107.33
ESR (mm)	131.725	132.25	560
CRP (mg/L)			

and 25% had hyperleukocytosis.2 patients had already taken antibiotics before admission. Group 2 included 13 patients, their mean PCT was 0.025 ng/mL (0.01-0.13), mean CRP was 132.25mg/L, mean ESR was 84.38mm, and 30.77% of them had hyperleukocytosis. Group 3 included 3 patients, their mean PCT was 66.88 ng/mL (0.02-200), mean CRP was 560 mg/L, mean ESR was 107.33 mm, and 33.33% had hyperleucocytosis. The patient with the highest PCT was admitted for a sepsis with uremic encephalopathy that improved after hemodialysis. A control PCT was made in 2 patients with infection who received antibiotics,showing a decrease or negativation compared to the initial value of PCT.

Conclusion: Our study showed that PCT levels only increased significantly in bacterial infections. The PCT values were more discriminating than the level of WBC and CRP in differentiating a bacterial infection from another inflammatory process, hence the value of using this marker in case diagnosis doubt.

POS1368 ANTI-IL-1 THERAPIES IN COLCHICINE-RESISTANT OR İNTOLERANT PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER: SINGLE CENTER EXPERIENCE

M. E. Derin[1], B. Karakaş[2], B. Karataş[2], N. Çabuk Çelik[2], İ. Yalçın[2], A. Şahin[2]. [1]*Sivas Numune Hospital, Internal Medicine – Rheumatology, Sivas, Turkey*; [2]*Sivas Cumhuriyet University, Internal Medicine – Rheumatology, Sivas, Turkey*

Background: Familial Mediterranean Fever (FMF) is a hereditary auto-inflammatory disease characterized by recurrent fever and serosal inflammation (1). The goal of FMF treatment is to prevent the attacks and to minimize subclinical inflammation between attacks The main treatment of FMF is colchicine however anti-interleukin-1 treatments are recommended in colchicine resistant and/or intolerant FMF patients (2).

Objectives: The aim of this study is to evaluate the efficacy of anti-interleukin-1 (anti-IL-1) agents in 81 FMF patients with resistant/intolareted to colchicine or complicated with amyloidosis.

Methods: Between January 2014 and December 2020, eighty-one patients who were diagnosed as FMF according to the criteria of Tel-Hashomer that following-up at Cumhuriyet University Medical Faculty Rheumatology-Internal Medicine Department were included in to the study.

Results: 45 (55.6%) male and 36 (44.4%) female were included in the study. The median age of the patients was 25 years (min:17-max: 60) and the median age at diagnosis was 15 years (min 3-max 46). 44 patients (54.3%) used Anakinra (100 mg/day), and 27 (45.7%) canakinumab (150mg/8month) were used. 49 cases were resistant to colchicine,16 were intolerant to colchicine, 16 (20%) cases were comlicated with amyloidosis. 10 patients had renal transplantation. MEFV gene mutations are shown in Table 1. Median duration of anti-IL-1 agent use was 24 month (min:4-max 52). 9 patients were resistant to anakinra, 18 patients had side effects which anakinra related. After a median follow up 12 months overall clinical response was %95 (frequency of attacks <1/6months). median proteinuria decreased from 3500 mg /day to median 1500 mg /day (p: 0.04) (Table 2). IL-6 treatment was started in 4 patients because of ineffective canakinumab. Five pregnant patients were followed up with anakinra during pregnancy and there were no problems.

Conclusion: Anti-interleukin-1 agents are effectively and safely in the treatment of FMF patients. There are still unanswered questions in FMF treatment such as other factors affecting the frequency of attacks, colchicine resistance is not defined precisely and the importance of some mutations. The effect of anti IL-1 agents on FMF patients with amyloidosis is not clearly. According to our experience, these treatments are effective in patients with glomerular filtration rate> 60 ml/min. For answers to these and similar questions, Large and long follow-up studies are needed for long-term effects.

POS1369 ADULT-ONSET STILL'S DISEASE: A SINGLE-CENTER EXPERIENCE

B. Egeli[1], S. Ugurlu[2]. [1]*Boston Children's Hospital, Immunology, Boston, United States of America*; [2]*Istanbul University-Cerrahpasa, Internal Medicine, Istanbul, Turkey*

Background: Adult-Onset Still's disease (AOSD) is an autoinflammatory condition characterized by fever, rash, and arthritis. The diagnosis of AOSD is made by excluding common causes of fever of unknown origin which are infections, malignancies, autoimmune conditions and medication adverse effects. As it is a diagnostic challenge, further data on highlighting clinical and laboratory findings are necessary on guiding clinicians.

Objectives: Our main objective is to present our single tertiary center experience of patients diagnosed with AOSD.

Methods: This retrospective study was conducted at a tertiary rheumatology center. Patients were diagnosed with AOSD using Yamaguchi's criteria and followed between 2007 and 2020. Demographic, clinical and laboratory information was retrieved from the patient chars. Treatment-related and prognostic information were also noted with additional information from phone call interviews.

Results: The study includes 69 patients (23 M, 46 F). The mean age of diagnosis was 33.86±14.3. The presenting signs and symptoms of the patients are shown in Figure 1. The laboratory findings supporting the diagnosis at initial encounter are summarized in Table 1. The mean corticosteroid dose at initial diagnosis was 29.7±18 mg. In addition to corticosteroid treatment these patients were followed with different glucocorticoid-sparing agents. Methotrexate was the choice of treatment in 54 patients with the mean dose of 14.5±3.43 mg. Eight patients were treated with leflunomide, seven with anti-TNF agents, seven with tocilizumab, nineteen with anakinra and four with canakinumab.

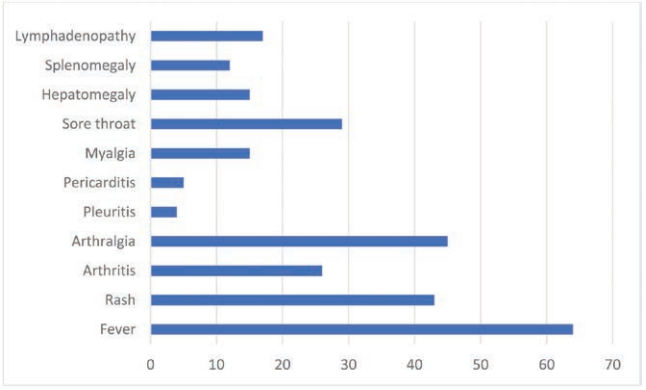

Figure 1. The presenting signs and symptoms of the patients

Conclusion: In conclusion, the most common presenting symptoms in our AOSD cohort were fever and salmon-colored rash. In the differential diagnosis of fever of unknown origin especially with rash, AOSD should be considered. Corticosteroid was the main treatment modality. In patients who are unresponsive to conventional immunosuppressive treatment, biologic agents can be an alternative.

Table 1. The laboratory findings at initial encounter

	Mean ± Standard Deviation
Ferritin (ng/mL)	3179.46±6503.56

POS1370 HYDROXYCLOROQUINE-INDUCED ATRIOVENTRICULAR BLOCK IN IMMUNE-MEDIATED DISEASES. SINGLE UNIVERSITY CENTER STUDY OF 293 PATIENTS

A. Herrero-Morant[1], A. Margarida-de Castro[1], R. Pérez-Barquín[1], J. Zubiaur-Zamacola[1], M. Á. González-Gay[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology and Cardiology, Santander, Spain*

Background: Hydroxychloroquine (HCQ) is an extensively used drug in immune-mediated diseases (IMID). Despite its general safety, HCQ can cause serious toxicity such as heart conduction disorders. Atrioventricular block (AVB)

is an underrecognized adverse effect that can potentially cause significant morbidity and mortality.
Objectives: To study incidence, presentation, and characteristics of HCQ-induced AVB in IMID.
Methods: Open-label single center study of 293 patients with IMID treated with HCQ for at least 3 months. Electrocardiograms were analyzed at baseline and during HCQ treatment. In addition, a comparative study between patients with and without AVB was conducted.
Results: We studied 293 patients (270 women/ 23 men; mean age 59.7±14.7 years). Underlying IMID were Systemic Lupus Erythematosus (SLE) (n=109, 40.6%); undifferentiated connective-tissue disease (n=70, 23.9%), Sjögren's syndrome (SS) (n=70, 23.9%), antiphospholipid syndrome (n=31,10.6%) and other IMID (n=13, 4.4%). HCQ was used for 4.1±3.5 years.
After 11.8±8.9 years of follow-up (HCQ mean cumulative dose: 979.7±272.1 g). AVB was observed in 19 out of 293 (6.5%) patients: 16 (84.2%) were first-degree AVB and 3 (15.8%) complete AVB. 4 (21.2%) patients with AVB were treated with a permanent pacemaker.
Presentation of atrioventricular block according to hydroxychloroquine incidence rate and treatment duration is shown in Figure 1. Most of AVB happened in the first 40 months, regardless of HCQ cumulative dose.

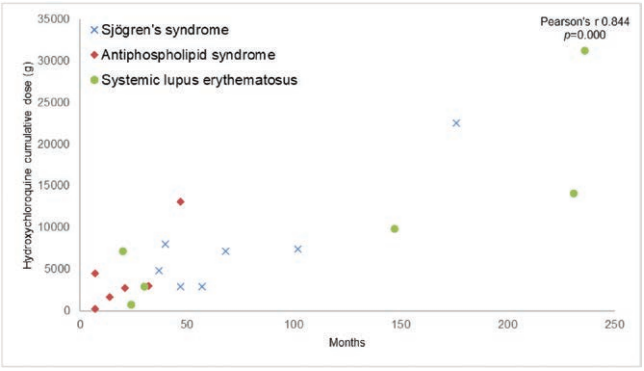

Figure 1. Presentation of atrioventricular block according to hydroxychloroquine incidence rate and treatment duration.

A comparative study between patients with and without AVB was performed (Table 1). Patients with AVB were older (p=0.014) and had a higher incidence of diabetes mellitus (p=0.033). HCQ cumulative dose and duration of IMID were similar in both groups (p>0.05).
Other HCQ adverse effects were retinopathy (n=16, 5.4%), gastrointestinal alterations (n=14, 4.8%), cutaneous alterations (n=14, 4.8%), allergic reactions (n=4, 1.4%) and myopathy (n=1, 0.3%).
Conclusion: AVB was observed in 6.5% of patients with IMID treated with HCQ. Most AVB were first-degree AVB. HCQ increased the risk of developing an AVB in patients with IMID regardless of HCQ cumulative dose or underlying disease duration. Older patients with diabetes mellitus had a higher risk of developing an AVB.

Background: Neuro-Behçet's disease (NBD) is a severe complication of Behcet's disease (BD). Despite well-established therapies with glucocorticoids and conventional immunosuppressants (cIS), a significant proportion of patients are refractory.
Objectives: To assess efficacy and safety of biologic therapy (BT) in NBD refractory to glucocorticoids and at least one cIS.
Methods: Open-label multicenter study of refractory NBD from 23 different referral Spanish Hospitals. Main outcome was neurological response. Secondarily, analytical efficacy was measured by Erythrocyte Sedimentation Rate (ESR), C-Reactive Protein (CRP) and Hemoglobin (Hb) at baseline, 6 months, 1 year and 2 years.
Results: We studied 42 patients (21 women/ 21 men; mean age 40.4±10.8 years). HLA B51 was positive in 15 out of 37 (40.5%) patients tested. Non-neurological manifestations were oral ulcers (n=41, 97.6%), genital ulcers (n=31, 73.8%), skin lesions (n=28, 66.7%), arthralgia (n=27, 64.3%), uveitis (n=21, 50.0%), arthritis (n=9, 21.4%), venous thrombosis (n=9, 21.4%) and arterial thrombosis (n=4, 9.5%). The underlying neurologic manifestation were parenchymal (n=34, 81.0 %) and non-parenchymal (n=17, 40.5%) involvement (Table 1). The first BT used was infliximab (n=20), adalimumab (n=13), golimumab (n=3), tocilizumab (n=3) and etanercept (n=2).
After 58.2±51.4 months since initiation of BT, neurological response was complete (n=27; 64.3%), or partial (n=11, 26.1%) (Figure 1). Only 4 (9.5%) patients did not respond. After 6 months of BT, ESR improved from.31.5±25.6 to 15.3±11.9 mm/h (p=0.005), CRP from 1.4 [0.2-12.8] to 0.3[0.1-3] mg/dL (p= 0.002) and Hb from 13.1±1.6 to 13.8±1.3 g/dL (p=0.005).

Table 1. Neurologic manifestation of 42 patients with refractory neurobehçet's disease treated with biologic therapy.

Parenchymal subtype, n (%)	**34 (81.0)**
-Hemiparesis	8 (19.1)
-Polineuropathy	8 (19.1)
-Encephalopathy	6 (14.3)
-Cognitive impairments	4 (9.5)
-Optic neuropathy	4 (9.5)
-Ophtalmoparesis	4 (9.5)
-Other cranial nerve involvement	3 (7.1)
-Hemihypoesthesia	3 (7.1)
-Cerebellar dysphasia	1 (2.4)
-Cerebellar involvement	1 (2.4)
-Non-steroidal psicosis	1 (2.4)
Non-parenchymal subtype, n (%)	**17 (40.5)**
-Aseptic meningitis	12(28.6)
-Thrombosis	4 (9.5)
-Intracranial hypertension	1 (2.4)

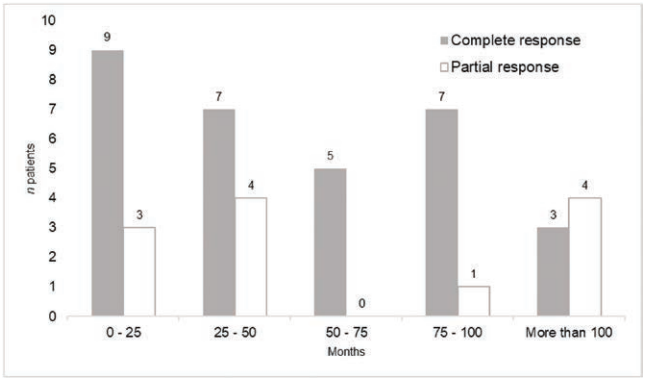

Figure 1. Neurological clinical response to biological therapy.

Primary failure was observed in 16 (38.1%) patients due to inefficacy (n=11, 68.8%) or adverse effects (n=5, 31.3%). Similarly, causes of secondary failure (n=6, 14.3%) were inefficacy (n=5, 83.3%) and adverse effects (n=1, 16.7%). No serious adverse effects were observed.

Conclusion: BT, especially monoclonal anti-TNF drugs, seems to be effective and safe in refractory NBD.

POS1372 EVALUATION OF E148Q AND CONCOMITANT AA AMYLOIDOSIS SECONDARY TO FAMILIAL MEDITERRANEAN FEVER AFTER ADJUSTED CLINICAL-DEMOGRAPHIC CHARACTERISTICS

Z. S. Arici[1], M. Romano[2], D. Piskin[3], F. Guzel[4], M. Yilmaz[5], E. Demirkaya[2]. *[1]Sanliurfa Training and Research Hospital, Paediatric Rheumatology, Sanliurfa, Turkey*; *[2]Schulich School of Medicine & Dentistry, University of Western Ontario, Paediatric Rheumatology, London, Canada*; *[3]Lawson Health Research Institute, Pediatrics, London, Canada*; *[4]Gentera Biotechnology, Biotechnology, Istanbul, Turkey*; *[5]Epigenetic Health Solutions, Unit of Nephrology, Ankara, Turkey*

Background: Amyloid A (AA) amyloidosis, previously known as secondary or reactive amyloidosis, is a long-recognized severe complication of some chronic inflammatory diseases. The pathogenesis and risk factors for amyloidosis in Familial Mediterranean Fever (FMF) remain partially understood (1). The development of AA amyloidosis is dependent on ethnicity and country of residence (2). In the pre-colchicine era, renal AA-amyloidosis was largely reported patients of Turkish (67%) and Sephardic Jewish ancestry (26.5%) (2,3). Currently it's well known that the MEFV M694V variant associated with high risk of amyloidosis however, mutations on exon 2, specifically E148Q variant remained controversial.

Objectives: To evaluate the E148Q mutation variant and concomitant AA Amyloidosis secondary to FMF after adjusted clinical-demographic characteristics.

Methods: Patients were recruited from the renal unit at Epigenetic Health Center outpatient clinic in Turkey between September 2003 and February 2020. Patients who had biopsy confirmed FMF related AA amyloidosis were included the study. Tel-Hashomer criteria were applied in the diagnosis of FMF. The clinical characteristics of FMF patients and medication history were recorded by the physician at the time of registry entry. All patients had detailed baseline assessment of clinical features, renal functions, genetic testing, histopathological diagnosis of amyloidosis, and treatment received. We performed multiple comparisons according to the age of diagnosis, demographic features, disease phenotype, allele frequency, type of mutation and mortality. Statistical analysis was performed with Statistical Package of Social Science (SPSS) for Windows, version 15.0 (SPSS Inc, Chicago, IL).

Results: Our registry consists of 195 patients with a diagnosis of AA amyloidosis. Complete information on 169 patients (lost to follow up, n=26) were included. The median age was 36 (19-49) years; male/female ratio was 1.6 (104/65). The median follow-up duration was 15.0 years (4-17 years). There were 101 patients diagnosed with FMF <18 years of age and 68 patients diagnosed ≥18 years of age. All participants developed renal amyloidosis before the age of 32 years. Family history of FMF was documented in 56 patients (33.1%) and family history of amyloidosis was present in 41 patients (24.3%). The three most common clinical symptoms were fever (84,6%), abdominal pain (71.6%) and arthritis (66.9%). During the follow-up, 5 patients started dialysis treatment and 9 patients had kidney transplantation. The most common allele frequency across patients was M694V (60.6%), E148Q (21.4%) and M680I (10.3%). The most frequent mutations were M694V/M694V (63.3%), M694V/E148Q (20.8%) and E148Q/E148Q (15.8%). During the follow up period, 15 patients (10 male, 5 female) died. In those that died, the mutations in 14 had M694V/M694Vand one demonstrated E148Q/E148Q.

Conclusion: Patients with FMF related AA amyloidosis have an increased risk for mortality. This study confirmed the association between M694V and FMF-associated AA amyloidosis, which has been reported in many studies. Close clinical follow-up and further evaluation of patients with the E148Q mutation is warranted specifically if residing in FMF endemic areas. The possible relationship between E148Q and AA amyloidosis need to be confirmed in other cohorts.

POS1373 DEFINING EAR CHONDRITIS: DATA FROM 685 PATIENTS WITH RELAPSING POLYCHONDRITIS

M. Ferrada[1], N. Costedoat-Chalumeau[2], G. Moulis[3], N. Linn[4], E. Rose[1], P. Grayson[1]. *[1]NIH, NIAMS, Bethesda, United States of America*; *[2]APHP, Université de Paris, Paris, France*; *[3]Toulouse University Hospital, Department of Internal Medicine, Toulouse, France*; *[4]Relapsing Polychondritis Foundation, Relapsing Polychondritis Foundation, New York, United States of America*

Background: Ear chondritis is often considered the pathognomonic feature of relapsing polychondritis (RP). Although painful redness and swelling of the pinna and a resultant cauliflower ear are universally recognized as chondritis, the complete spectrum of symptoms associated with ear chondritis have not been well described.

Objectives: The study objective was to seek patient input to help characterize ear chondritis An online survey was administered in English or Spanish to participants with self-reported RP.
Methods: Participants were asked questions about their ear pain, including quality, location, duration, aggravating/alleviating factors, timing of onset and duration. Participants were included who reported age ≥ 18 years, a diagnosis of RP confirmed by a physician, and sufficient symptoms to meet McAdams or Damiani's diagnostic criteria. Participants were categorized as having "typical ear chondritis" if they reported ear pain localized to the pinna with associated redness and swelling. Atypical presentations of ear chondritis were also considered.
Results: A total of 685 participants from five continents completed the survey. Among them, 659 met inclusion criteria for subsequent analysis. Most participants were female (n=574; 87%), white (n=548; 83%) and from the United States (n=484;74%). The median age was 50 years (interquartile range = 41-58). In total, 593 (90%) patients reported ear pain, 227 (38%) had "typical ear chondritis", and 98 (16%) had cauliflower ear.
Ear pain was most commonly described as burning (n=334, 56%) or throbbing (n=295, 50%). The most common location of pain was the pinna (n=373, 63%). Participants reported ear redness (n=454, 60%) and swelling (n=405, 62%). Some patients experienced only ear redness without swelling (n=286, 48%) or only ear swelling without redness (n=71, 12%). The most common aggravating factors were minor trauma (n=371, 62%) and stress (n=358, 60%). The most common alleviating factor was avoidance of touching the ear (n=374, 63%). Pain was most frequently reported during the daytime (n=355, 60%) and most likely to occur in either ear at different times (n=310, 52%). Onset could be gradual (n=198, 33%) or sudden (n=155, 26%). Pain typically lasted a few hours (n=175, 30%) or 2-3 days (n=130, 22%). The majority of patients who had pinna pain also had pain in other parts of the ear (e.g. mastoid process, inner ear, whole ear) at some point (n=394, 67%). In patients with cauliflower ear, the most common location of pain was the pinna (n=57, 58%) followed by pain inside the ear (n=53, 54%). Most participants reported at least two different types of pain (n=420, 64%).
Conclusion: Ear chondritis in patients with RP has a wide range of clinical presentations and characteristics beyond the typical triad of redness, swelling, and pain localized to the pinna. The description of pain often significantly varies within the same patient. Knowledge of the various distinct characteristics of ear involvement in RP may help physicians recognize and monitor the disease more effectively.

POS1374 RHEUMATOLOGIC DISEASES AS PRESENTATIONS OF PRIMARY IMMUNODEFICIENCY DISEASES

S. Kudryashov[1], L. Karzakova[1], N. Zhuravleva[1], I. Sidorov[1], T. Lutkova[1].
[1]*Federal State Budgetary Educational Institution of Higher Education "The Chuvash State University named after I.N. Ulyanov", Department of Internal Medicine, Cheboksary, Russian Federation*

Background: Primary immunodeficiency diseases (PID) occur on average with a frequency of 1: 100 000 of the population. In accordance with the classification of PIDS of the International Union of Immunological Societies (IUIS) 9 different groups of innate errors of immunity are distinguished [1]. The polymorphism of the clinical picture, difficulties in recognizing PID cause their late diagnosis and the associated development of irreversible organ damage, complications and high mortality. According to the traditional view, the clinical marker of PID is an infectious syndrome. However, in some cases, PID is detected as a rheumatologic disease.
Objectives: The aim of the study is to analyze the frequency of rheumatologic diseases in adult patients with PID living in one of the subjects of Russia –Chuvashia.
Methods: The material of the study was patient data obtained during a retrospective analysis of 49 outpatient records included in the Republican Register of PID. Diagnosis of various forms of PIDS was carried out in accordance with the criteria developed by the IUIS [1].
Results: During the period from 1993 to January 2020, 49 cases of PID were registered in the adult population of Chuvashia. According to the frequency of PID, common variable immunodeficiency (CVID) is the most common in Chuvashia (26 people). In the second place there is selective IgA deficiency (10 people); in third place there are X-linked agammaglobulinemia (4 people) and hereditary angioedema (4 people). The remaining forms of PID account for 5 cases: 2 cases of Louis-Bar syndrome, 1 case of DiGeorge syndrome, 1 case of Wiskott-Aldrich syndrome and 1 case of Hyper IgE syndrome. The main symptom of PID in 35 (71.4%) patients was heightened susceptibility to infection. In 14 (28.6%) patients, the clinical picture was dominated by non-infectious presentations (autoimmune, lymphoproliferative and oncological diseases). In 9 patients (18.3%), it was manifested by rheumatologic diseases (rheumatoid arthritis, psoriatic arthritis, scleroderma-like syndrome). These symptoms were more characteristic of CVID. With selective IgA deficiency and X-linked agammaglobulinemia, rheumatic symptoms were observed only in isolated cases. CVID debuted in 2 cases as rheumatoid arthritis, resulting in the delay in the diagnosis of an average of 5.2 years. Only the detailed immunological and genetic study made it possible to diagnose PID and prescribe adequate treatment – replacement immunoglobulin therapy. This treatment reduced the frequency of infectious manifestations of the disease and it did not significantly improve the course of rheumatological diseases. Therefore, the use of methotrexate and targeted therapy was continued.
Conclusion: In the clinical picture of PID, rheumatic symptoms predominate in 28.6% of cases, which requires a thorough immunological and genetic examination of patients with rheumatic diseases in order to diagnose PID in a timely manner.

POS1375 THE EFFECT OF M694V HOMOZYGOSITY ON THE CAROTID INTIMA-MEDIA THICKNESS AND FLOW MEDIATED DILATATION IN PATIENTS WITH FMF RELATED AMYLOIDOSIS

S. Sahin[1], M. Romano[2], F. Guzel[3], O. Kasapcopur[1], D. Piskin[4], I. Yilmaz[5], E. Demirkaya[6]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa School of Medicine, Department of Pediatric Rheumatology, Istanbul, Turkey*; [2]*Schulich School of Medicine & Dentistry, University of Western Ontario, Department of Paediatrics, Division of Paediatric Rheumatology, London, Canada*; [3]*Gentera Biotechnology, Biotechnology, Istanbul, Turkey*; [4]*Schulich School of Medicine & Dentistry, University of Western Ontario, Department of Epidemiology and Biostatistics, London, Canada*; [5]*Epigenetic Health Solutions, Unit of Nephrology, Ankara, Turkey*; [6]*Schulich School of Medicine & Dentistry, University of Western Ontario, Department of Paediatrics, Division of Paediatric Rheumatology and Department of Epidemiology and Biostatistics, London, Canada*

Background: There are limited data in FMF associated AA amyloidosis patients regarding the vascular abnormalities including atherosclerosis and endothelial dysfunction, all of which are contributors of cardiovascular disease (CVD) risk. And, this risk assessment for future CV events have not yet been evaluated between FMF amyloidosis patients with different genotypes.
Objectives: We aimed to compare early markers of endothelial dysfunction and atherosclerosis, mortality and other disease characteristics in FMF-related amyloidosis patients with a homozygous M694V genotype and in patients with other genotypes with this cross-sectional comparative study.
Methods: For this purpose, patients with FMF-related amyloidosis were assigned according to the *MEFV* gene mutation to one of the two groups. **Group 1:** Patients homozygous for M694V (which is the most common genotype associated with the most severe clinical phenotype in FMF) **Group 2:** Patients homozygous (other than M694V) or compound heterozygous (including M694V) for other *MEFV* variants. Potential confounders were controlled by excluding the patients with untreated hypertension, diabetes mellitus, obesity, smoking, previous history of CVD low glomerular filtration rate (eGFR <70 mL/min). Flow-mediated dilatation (FMD), pentraxin-3 (PTX3) as early markers of endothelial dysfunction and carotid intima-media thickness (cIMT), fibroblast Growth Factor 23 (FGF23) as an indicator of atherosclerotic vascular disease, all of which are non-invasive tests that are also used to identify subjects at increased risk for future CV events were measured in these 2 groups.
Results: We analyzed demographic, clinical, genetic, survival data and these non-invasive markers of endothelial dysfunction (FMD and PTX3) and atherosclerosis (cIMT and FGF23) in 76 FMF amyloidosis patients with homozygous M694V mutations (Group 1) and 93 FMF amyloidosis patients with two pathogenic mutations apart from M694V homozygosity (Group 2) (Table 1). Brachial artery FMD was significantly lower in Group 1 when compared with Group 2 subjects (6.0 vs. 6.5%, p<0.001). cIMT, FGF23 and PTX3 levels were higher in Group 1 when compared with Group 2 (cIMT: 0.84 vs. 0.67 mm, p<0.001; FGF23: 52.4 vs. 38.0 pg/dL, p=0.01; PTX3: 14.0 vs. 3.2 ng/mL, p<0.001). Time to develop amyloidosis was similar in patients homozygous for M694V (median 10.0 years, 95%CI: 8.99-11.0) and in Group 2 (median 10.0 years, 95%CI: 8.97-11.0) (p>0.05). Mortality rate was significantly higher in Group 1 compared to Group 2 (18.4% vs. 1.1%, p<0.001) over a median of 7.8 years of follow-up. FMF amyloidosis patients homozygous for M694V had reduced survival (mean survival: 97 months, 95%CI: 94.9 to 101.0 months) as compared to Group 2 (mean survival: 100.7 months, 95%CI: 100.0 to 101.3 months) (p<0.001) (Figure 1). The proportion of the clinical manifestations including fever, serositis, erysipelas-like

erythema, all of which are associated with an FMF attack did not differ between two groups (p>0.05) apart from arthritis (76.3% in Group 1 and 59.1% in Group 2, p<0.05) (Table 1).

Conclusion: In patients with FMF related amyloidosis, M694V homozygosity is associated with lower FMD values and higher cIMT, FGF23 and PTX3 levels. In summary, the data demonstrate that a genotype-phenotype association exists in terms of endothelial dysfunction and atherosclerosis in FMF patients with amyloidosis.

POS1376

UVEITIS IN 1449 PATIENTS WITH INFLAMMATORY BOWEL DISEASE. STUDY FROM A SINGLE UNIVERSITY CENTER

L. Sanchez-Bilbao[1], M. J. García-García[2], D. Martínez-López[1], M. Rivero-Tirado[2], B. Castro[2], I. González-Mazón[1], J. Crespo[2], M. A. González-Gay[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*; [2]*Hospital Universitario Marqués de Valdecilla, Gastroenterology, Santander, Spain*

Background: Inflammatory bowel disease (IBD), which includes Crohn's disease (CD), and Ulcerative colitis (UC) are related to Spondyloarthritis (SpA). Ocular manifestations (OM) are well-stablished in axial SpA but not in IBD. It has been classically reported that whereas uveitis with axial SpA is predominantly anterior, unilateral, acute, and non-recurrent; in IBD it is bilateral, posterior, insidious, and chronic **(1).**

Objectives: In a large unselected series of IBD, our aim was to assess **a)** epidemiology and clinical features of uveitis associated to IBD, **b)** to compare patients who developed uveitis and those who did not, and **c)** its relationship with biological treatment used in IBD.

Methods: Study of all consecutive patients from a single University Hospital during the last 40 years with**: a)** IBD (CD and UC), and **b)** uveitis according to Standarization Uveitis Nomenclature (SUN) Working Group. Demographic features, clinical findings, occurrence of other extraintestinal manifestations and treatment were recorded.

Results: We studied 1449 (714 women/735 men) patients with IBD, mean age of 55.2±15.9 years.

Uveitis was present in 23 (1.6 %) (38 eyes) of 1448 IBD patients. The most common pattern of uveitis was typically anterior (n=18; 78.3%), unilateral (n=19; 82.6%), acute (n=19; 82.6%), and non-recurrent (n=12; 52.2%).

The comparative study between patients with and without uveitis showed a significant predominance of women (Table 1) in patients with uveitis, as well as erythema nodosum, hidradenitis suppurativa and joint involvement.

Regarding IBD severity, in terms of surgical interventions, and conventional and biological immunosuppressive treatments, there were no significant differences.

Conclusion: Although uveitis is more infrequent in IBD than in axial SpA, it is also anterior, unilateral, acute, and non-recurrent in contrast with published data from selected series. Patients with uveitis do not seem to represent more severe phenotype of IBD.

POS1377

SOME PARAMETERS OF ENDOTHELIAL FUNCTION IN PATIENTS WITH IDIOPATHIC AVASCLAR NECROSIS

K. Gudkevich[1], N. Martusevitch[2], E. Dashkevich[3]. [1]*Minsk City Clinical Hospital No.6, Rheumatology, Minsk, Belarus*; [2]*Belarusian State Medical University, Cardiology and Internal Diseases, Minsk, Belarus*; [3]*Minsk City Clinical Hospital No.10, Central Hormonal Laboratory, Minsk, Belarus*

Background: Avascular necrosis (AN) is a disease, which is the result of blood flow disturbance and necrosis of the bone tissue. It affects predominantly men of working age and steadily progresses to secondary osteoarthritis. AN is a multifactorial disease. In the context of vascular hypothesis it is of particular interest to evaluate homocysteine and its metabolism in patients with AN.

Objectives: The aim of the present study was to evaluate some parameters of endothelial function in patients with AN of the femoral head or femoral condyles in order to determine possible treatment and prevention options.

Methods: We included 53 patients with AN of the femoral head or femoral condyles into the study. The patients were aged 49 (35-62) years, 58,49% (n=31) were male. The inclusion criteria was diagnosis of AN confirmed by X-Ray, CT or MRI. The exclusion criteria were: traumatic AN, Legg-Calve-Pertes disease, connective tissue systemic diseases. We recruited 51 patients into the control group. The groups were comparable by age and gender. In order to analyse engothelial function in the groups we investigated the following serum parameters: homocysteine, vitamin B12, folate. In order to analyse the data obtained we used non-parametric statistics.

Results: We determined a higher level of homocysteine in patients with AN (12,15 (7,55-14,60) vs. 8,18 (6,57-10,70) mcmol/l in the control group, p=0,04). Also we observed almost equal levels of vitamin B12 in patients with AN an in the control group (531,95 (340,80-793,55) vs. 532,75 (417,60-669,7) pg/ml, p=0,99). The level of folate was lower in the study group (5,66 (3,83-6,83) vs. 6,99 (5,02-10,38) ng/ml, p=0,01).

Conclusion: The data obtained show that homocysteine level in patients with AN is higher. This can be a consequence of folate deficiency, which takes part in homocysteine metabolism. Therefore, homocysteine metabolism disturbances can lead to endothelial dysfunction, which results in cardiovascular events in the heart, brain, kidneys [1] as well as in the bone, according to the study results. Folate supplement is the possible way of AN treatment and prevention.

POS1378 COMPARISON OF DEMOGRAPHIC AND CLINICAL FEATURES OF FAMILIAL MEDITERRANEAN FEVER PATIENTS AND PATIENTS WITH AXIAL SPONDYLOARTHRITIS ACCOMPANYING FAMILIAL MEDITERRANEAN FEVER

M. Kiracı[1], E. Bilgin[2], E. Duran[2], B. Farisoğulları[2], E. C. Bolek[2], G. K. Yardımcı[2], Z. Özsoy[2], G. Ayan[2], G. Sandal Uzun[2], B. Balci Peynircioglu[3], O. Karadag[2], A. Akdoğan[2], Ş. A. Bilgen[2], S. Kiraz[2], A. İ. Ertenli[2], U. Kalyoncu[2], L. Kılıç[2]. *[1]Hacettepe University, Internal Medicine, Ankara, Turkey*; *[2]Hacettepe University, Internal Medicine, Rheumatology, Ankara, Turkey*; *[3]Hacettepe University, Medical Biology, Ankara, Turkey*

Background: The rate of co-occurrence of Familial Mediterranean Fever (FMF) and axial spondyloarthritis (axSpA) in adults is reported ranging from 0.5% to 7.5%. The clinical implications of this co-occurrence in the course of FMF is still a research question.

Objectives: To compare of demographic and clinical features of patients with FMF and FMF+axSpA.

Methods: A total of 9630 FMF patients was detected according to the ICD-10 code (E85.0) of FMF in Hacettepe University Hospital database. 241 of these patients also had axSpA according to the ICD-10 code (M45). FMF diagnosis was confirmed by Tel-Hashomer criteria. AxSpA was diagnosis was confirmed by either presence of sacroiliitis on sacroiliac radiography according to the Modified New York Criteria (mNY) or presence of active sacroiliitis according to ASAS criteria on magnetic resonance imaging. 136 patients were confirmed according to these criterias as having FMF+axSpA. As a control group, 231 consequent FMF patients without axSpA recorded on the "FMF in Central Anatolia (FiCA) database" and followed up at our center were included in the analysis. Demographic and clinical features of those patients in both groups were compared. p<0.05 was considered as statistically significant, correction for multiple comparisons was not performed.

Results: 136 patients were included in FMF+axSpA group and 231 patients were included in FMF group. 114 (83.8%) patients in FMF+axSpA group had radiographic sacroiliitis according to mNY criteria; median cervical mSASSS was 0 (available for 49 patients, min-max, 0-36), median lumber mSASSS was 4 (available for 121 patients, min-max, 0-36), 33 (27%) patients had cervical or lumber syndesmophyte. Twenty-six (19.1%) of these patients had radiologically documented inflammatory hip disease 12 (8.8%) of these patients underwent total hip replacement. Female gender was more prevalent in FMF+axSpA group (53.7% vs 32.5%, p<0.001). Age at FMF symptom onset and diagnosis were earlier in FMF patients; however, symptom and disease durations were longer in FMF+axSpA group in our study cohort (Table 1). Frequency of FMF signs and symptoms were comparable except the rate of pleuritis was higher in FMF patients compared to FMF+axSpA group (p=0.003). Amyloidosis was more prevalent in FMF+axSpA group (6.6% vs. 1.7%, p=0.014). Results of MEFV gene analysis were available for 273 patients. Although presence of M694V mutation (either in 1 allele or 2 alleles) was comparable in 2 groups, homozygous M694V mutation was more prevalent in FMF+axSpA group (39.8% vs. 28.9%, p=0.02).

Conclusion: The coexistence of spondyloarthritis in FMF patients appears to be associated with the increased prevalence of amyloidosis. The inflammatory burden of a second disease and the increased prevalence of the homozygous M694V mutation may explain this risk.

Table 1. Comparison of demographic and clinical features of two groups.

	FMF+AxSpA (n=136, 37.1%)	FMF (n=231, 62.9%)	p

Background: Familial Mediterranean Fever (FMF) is characterized by recurrent attacks of fever and serositis as well as elevated inflammatory markers. FMF treatment goals according to EULAR are to control acute attacks and subclinical inflammation and to improve patients´ quality of life[1]. In a phase 3 pivotal study (*CLUSTER* study), FMF patients treated with the interleukin-1β inhibitor canakinumab met all these goals[2].

Objectives: The present study explores the long-term efficacy and safety of canakinumab (CAN) in routine clinical practice in pediatric (age ≥2 years) and adult FMF patients.

Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany with a three-year follow-up period. Patients with clinically confirmed diagnosis of FMF who routinely receive CAN were enrolled in order to evaluate effectiveness and safety of CAN under standard clinical practice conditions. Disease activity and remission by physicians´ assessment, disease activity, fatigue and impact on social life by patients' assessment, inflammatory markers and AIDAI (Auto-Inflammatory Diseases Activity Index) score were recorded at baseline and were assessed at 6-monthly intervals within the three-year observation period of the study.

Table 1. Baseline characteristics and third interim analysis data of patients with FMF

Baseline			6 months		12 months		18 months		
								Number of patients, N	54
All patients | patients without prior CAN therapy

11					16.23			Arthritis	5
7.38				SARS-CoV-2 infection		2			2.95
Familial Mediterranean Fever			1			1.48			Intestinal Hemorrhage
1					1.48			Pyrexia	1
1.48				Tonsillectomy (SADR)		1			1.48

*not reported for all patientsCRP, c-reactive protein; ESR, erythrocyte sedimentation rate; n. a., not annotated; SAA, serum amyloid A; SADR, serious adverse drug reaction; SAE, serious adverse event

Results: This interim analysis of FMF patients (N=54) enrolled by December 2020 includes baseline as well as 6-, 12- and 18-month data. Mean age in this cohort was 25 years (4–56 years) and the proportion of female patients was 46 % (N=25). At baseline, median duration of prior CAN treatment was 2.0 years (0–6 years).

While physician ratings report around 62% of patients in disease remission, 52% with absent and 34% with mild-moderate disease activity, patient-reported disease activity decreased from moderate (PPA 3.0) to low (PPA 2.0) during the observation period. A decrease was observed regarding disease activity parameters, in particular in patients without prior CAN therapy (Table 1, Figure 1). A total of 11 serious adverse events was reported, of which one case of tonsillectomy was classified as drug-related.

Conclusion: Interim data of FMF patients from the RELIANCE study, the longest running real-life CAN registry, confirm efficacy and safety of long-term CAN treatment.

Background: Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is a rare autoinflammatory condition characterized by severe systemic and organ inflammation. In a phase 3 pivotal trial (*CLUSTER* study), TRAPS patients have been successfully treated with the interleukin-1β inhibitor canakinumab. 45% of patients reached clinical remission after 16 weeks (primary endpoint)[1]. Canakinumab has been approved and applied for the treatment of TRAPS patients since 2017[2].

Objectives: The present study explores the long-term efficacy and safety of canakinumab under routine clinical practice conditions in pediatric (age ≥2 years) and adult TRAPS patients.

Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany with a 3-year follow-up period. Patients with clinically confirmed diagnoses of TRAPS, CAPS, FMF or HIDS/MKD who routinely receive canakinumab are enrolled in order to evaluate efficacy and safety of canakinumab under standard clinical practice conditions. Disease activity and remission by physician assessment, disease activity and fatigue by patient assessment, days absent from school/work due to study indication, inflammatory markers, and AIDAI (Auto-Inflammatory Diseases Activity Index) score were assessed at baseline and at 6-monthly intervals.

Results: The interim analysis of TRAPS patients enrolled by December 2020 includes baseline (N=16, including 1 patient with atypical TRAPS) and preliminary 18-month data. Mean age in this cohort was 23 years (3–43 years) and the median duration of prior CAN treatment was 1.0 year (0–4 years).

Physician assessment indicated 60-80% remission and laboratory parameters were within normal range. Disease control by patient assessment showed no major changes regarding the analyzed parameters (Table 1, Figure 1). Of the three serious adverse events reported none was classified as drug-related.

Conclusion: Preliminary analysis of 18 month interim data of TRAPS patients treated with CAN available from the RELIANCE study indicate stable efficacy and safety of CAN long-term treatment.

POS1381 BIOLOGIC TREATMENT OF ADULT-ONSET STILL'S DISEASE: A SINGLE CENTER EXPERIENCE

B. Yurttas[1], B. Egeli[2], G. Guzelant Ozkose[1], S. Ugurlu[1]. [1]*Istanbul University-Cerrahpasa, Rheumatology, Istanbul, Turkey*; [2]*Boston Children's Hospital, Immunology, Boston, United States of America*

Background: Even though corticosteroids and cDMARDs are effective for inducing remission in patients with Adult-Onset Still Disease (AOSD), relapse is common. Hence, maintaining the clinical stability is challenging. Almost all of the patients face side effects because of high dose steroid treatment. Biological DMARDs have been reported to be effective in refractory patients.
Objectives: We aimed to evaluate the patients' outcomes who were diagnosed with AOSD and treated with at least one bDMARDs in our tertiary center.
Methods: Patients with AOSD who were followed in our clinic between 2007 and 2020 were screened retrospectively. For the diagnosis of AOSD, all of the patients fulfilled Yamaguchi criteria. The demographic characteristics, baseline and post-treatment clinical findings and outcomes were reported.
Results: Twenty-eight patients (21 F, 7 M) were screened (Figure 1). The mean disease duration of the first bDMARD was 21,76 ± 28,05 months (mean ± SD). The mean duration of bDMARD treatment was 37,04 ± 30,75 months. The reasons for starting a bDMARD were systemic symptoms (%80) and chronic arthritis (%20). All of the patients used methotrexate (MTX) except one. This patient had macrophage activation syndrome during diagnosis and was treated with cyclosporine. All of the patients were treated with corticosteroids (34,28 ± 26,70 mg/d) and a cDMARD at initiation (22 of them MTX, 1 of them azathioprine, 2 of them cyclosporine and 1 of them IVIg). Anakinra was the most preferred biologic as a first-line treatment modality (TNF inhibitors=5, tocilizumab=4). The main reason for switching was loss of efficacy (8/22). Tocilizumab was the most used agent in 2nd line and canakinumab was in 3rd line. Twenty-two patients were in remission at last visit. Also, 15 patients were steroid-free, 14 patients were MTX-free. Patient global visual analogue scale, acute phase reactants and daily steroid dose were reduced significantly at last visit compared to the initial visit (Table 1).

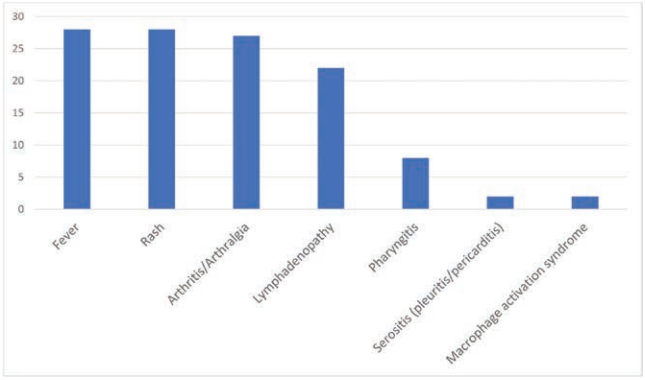

Figure 1. Presenting signs and the symptoms of the patients

Table 1. Comparison of important laboratory findings and the mean steroid dose

Clinical finding	At initiation of bDMARD mean ± SD	At the last visit mean ± SD
PG-VAS	9.8 ± 0.8	2.3 ± 2.3
ESR (mm/h)	34,28 ± 33,95	18.82 ± 11.60
CRP (mg/l)	70,76 ± 67,80	13.44 ± 27.33
Ferritin (ng/mL)	1662 ± 1239	275.7 ± 381.4
Daily steroid dose (prednisolone, mg/d)	34.28 ± 26.70	5.60 ± 8.60

bDMARD treatment was terminated in 5 patients due to complete remission (n=2) and side effects (1 of them pneumonia, 1 of them EBER (+) Hodgkin Lymphoma and 1 of them tuberculosis). Six patients experienced local injection site reaction, none of them stopped treatment. Also, one patient died while she was in remission under anakinra treatment with an unknown cause.
Conclusion: The most common presenting symptoms in our cohort were fever and salmon-colored rash. Tocilizumab is an alternative treatment modality in cases with chronic arthritis and IL-1 inhibitors are an alternative for systemic course of disease. bDMARDs, especially IL-1 inhibitors are highly effective for refractory patients with AOSD.

POS1382 RITUXIMAB FOR INDUCTION OF REMISSION IN TYPE 1 AUTOIMMUNE PANCREATITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Lanzillotta[1], G. Capurso[2], Z. Wallace[3], O. Karadag[4], L. Dagna5, E. Della Torre5. [1]*San Raffaele Scientific Institute, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*; [2]*San Raffaele Scientific Institute, PancreatoBiliary Endoscopy and EUS Division, Milan, Italy*; [3]*Massachusetts General Hospital, Clinical Epidemiology Unit, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America*; [4]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; [1]*San Raffaele Scientific Institute, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: Type I autoimmune pancreatitis (AIP) is a rare form of pancreatitis that belongs to the IgG4-related disease (IgG4-RD) spectrum (1). Autoimmune pancreatitis responds brilliantly to glucocorticoids, but iatrogenic toxicity associated with prolonged steroid therapy represents a relevant clinical concern in the long-term (2). B cell depletion therapy proved to be effective in inducing IgG4-RD remission, yet most evidence are derived from small and heterogenous cohorts.
Objectives: We performed a systematic review and meta-analysis to estimate the remission rate following rituximab-based induction treatment.
Methods: Two reviewers searched MEDLINE, SCOPUS, and EMBASE until December 2020 to identify studies on remission rate and relapse rate of Type I AIP after induction of remission with rituximab. Studies involving three or more patients were included, including the most recent or most numerous cohorts in case of duplicates This study was conducted in accordance with Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. Pooled effects were calculated using a random-effects model and expressed in terms of pooled remission, relapse and adverse effects (AEs) rates.
Results: Seven cohort studies met inclusion criteria for the meta-analysis for a total of 101 patients. Reasons for rituximab administration were relapsing disease (63.5%), new diagnosis (18.5%) or glucorticoids intolerance (17.9%). The median follow-up time was 18.5 months. The pooled rate of complete response at 6 months from induction of remission was 88.9% (95% CI 80.5%-93.9%) without heterogeneity (I^2=0%) (Figure 1). The median time to relapse was 9.75 months. The pooled estimate of relapse rate was 21% (95% CI 10.5%-40.3%) with moderate heterogeneity (I^2=51%), being 35.9% (95% CI 17.3%-60.1%) in the 4 studies with rate of other organs involvement (OOI)>80% and as low as 10.1% (4.8%-20.3%) in the others. The pooled estimate of rituximab-related AEs was 25% (95% CI 8.8%53%) with substantial heterogeneity (I^2=73.6%). There was no publication bias.
Conclusion: Treatment of type I AIP with rituximab is associated with high remission rate, a higher relapse rate in presence of OOI and limited AEs. Randomized controlled trials with adequate power are needed to confirm these findings.

POS1383 THE ASSOCIATION BETWEEN BARIATRIC SURGERY AND DUPUYTREN DISEASE: A COHORT STUDY FROM SWEDISH NATIONWIDE HEALTHCARE REGISTRIES

T. Burkard[1], J. Lane[2], D. Holmberg[3], A. M. Burden[1,4], D. Furniss[2]. [1]*ETH Zurich, Department of Chemistry and Applied Biosciences, Zurich, Switzerland*; [2]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology, and*

Musculoskeletal Sciences, Oxford, United Kingdom; [3]*Karolinska Institutet and Karolinska University Hospital, Department of Molecular medicine and Surgery, Stockholm, Sweden*; [4]*Maastricht University Medical Center+, 4 Department of Clinical Pharmacy and Toxicology, Maastricht, Netherlands*

Background: Dupuytren disease (DD) is multifactorial, with several genetic and environmental risk factors contributing to disease susceptibility. High body mass index, however, was suggested to be protective of DD.[1] The impact of weight loss among obese patients on DD has not been assessed to date.
Objectives: To assess the association between bariatric surgery and DD in a secondary care setting.
Methods: We performed a propensity score (PS)-matched cohort study using data from Swedish nationwide healthcare registries (patient registry [secondary care], causes of death registry, prescribed drug registry). Patients aged 30-79 years who underwent bariatric surgery between 2006 and 2019 were matched to up to 2 obese bariatric surgery-free patients (called unexposed patients) based on their PS. PS-matching was carried out in risk set sampling to reduce selection bias, within 4 sequential cohort entry blocks to account for time trend biases. The outcome DD was defined as a diagnosis of DD in secondary care or partial or total fasciotomy of wrist or hand. After a 1-year run-in period, patients were followed in an "as-treated" approach. We applied Cox proportional hazard regression to calculate hazard ratios (HR) with 95% confidence intervals (CIs) of incident DD among bariatric surgery patients when compared to obese unexposed patients overall, and in subgroups of age, sex, bariatric surgery type, and by duration of follow-up.
Results: A total of 34 959 bariatric surgery patients were PS-matched to 54 769 obese unexposed patients. A total of 71.6% of bariatric surgery patients were women. Bariatric surgery patients had a mean age of 45.5 years and a mean follow-up of 6.9 years. All patient characteristics in obese unexposed patients were highly similar. We observed 126 and 136 severe DD cases among bariatric surgery and obese unexposed patients, respectively. The risk of DD was significantly increased in bariatric surgery patients compared to obese unexposed patients (HR = 1.30, 95% CI 1.02-1.65). The risk of DD was higher in women (HR = 1.36, 95% CI 1.00-1.84) than in men (HR = 1.05, 95% CI 0.70-1.58). Age did not modify the risk of DD among bariatric surgery patients compared to obese unexposed patients. Malabsorptive bariatric surgery yielded an increased risk of DD when compared to obese unexposed patients (HR = 1.33, 95% CI 1.04-1.71), while restrictive bariatric surgery yielded a null result. The risk of DD increased with duration of follow-up (>5 years of follow-up: HR = 1.63, 95% CI 1.14-2.34, null result in earlier follow-up).
Conclusion: Our results suggest that substantial weight loss is associated with a latent increased risk of severe DD in an obese population. This observation further strengthens current evidence that high body mass index is protective against DD. The latency of risk increase of DD after bariatric surgery may suggest that slowly adapting metabolic changes may be part of the mechanism of DD emergence.

POS1384 DIFFERENT CLINICAL CHARACTERISTICS OF IGG4-RRD PATIENTS AND NON-IGG4-RRD PATIENTS: A LARGE CHINESE COHORT STUDY

Z. Wang[1], L. Jiaxi[1], Y. Liu[1]. [1]*Peking University People's Hospital, Department of Rheumatology and Immunology, Beijing, China*

Background: IgG4-related disease (IgG4-RD) is an autoimmune disorder and frequently involve multiple organs. The respiratory tract is one of the most frequently involved sites.
Objectives: This study aimed to compare the demographic and clinical characteristics of IgG4-related respiratory disease (IgG4-RRD) and non-IgG4-RRD patients in a large cohort.
Methods: We carried out a retrospective study of 452 cases of IgG4-RD (104 IgG4-RRD patients and 348 non-IgG4-RRD patients) diagnosed at Peking University People's Hospital between 2003 and 2020.
Results: IgG4-RRD patients had an elder age of disease onset and diagnosis. Multiorgan involvement and hypocomplementemia were more common in IgG4-RRD. Besides, the level of ESR, eosinophilia, IgG and IgG4 were higher in IgG4-RRD patients. In IgG4-RRD group, salivary gland, lacrimal gland, lymph nodes, biliary system and kidney were more commonly involved than those in the non-IgG4-RRD group. Also, more numbers of organ involvement and biliary involvement were independent risk factors for the development of respiratory involvement in IgG4-RD patients.
Conclusion: Our study revealed demographic, clinical, laboratory and imaging features of IgG4-RRD patients and the underlying differences in pathogenesis between the two phenotypes, which have important implications for the diagnosis and treatment of the disease.

POS1385 AUTOIMMUNE DISEASES ASSOCIATED WITH CHRONIC LIVER DISEASES

N. Trad[1], G. Mohamed[2], B. Ben Slimen[1], K. Boughoula[2], S. Bizid[1], H. Ben Abdallah[2], R. Bouali[1], M. N. Abdelli[2]. [1]*Military Hospital of Tunis, Gastroenterology, Tunis, Tunisia*; [2]*Military Hospital of Tunis, Gastroenterology, Tunis, Tunisia*

Background: Chronic liver diseases whatever their etiologies could be associated with immunological disturbances.
Objectives: Our aim was to evaluate the prevalence and the characteristics of autoimmune diseases associated with chronic liver diseases.
Methods: We performed a retrospective analysis of data from consecutive patients followed in our department for chronic liver diseases recruited from January 2010 to December 2019. Demographic, clinical, and paraclinical data were collected.
Results: A total of 224 patients were included. The mean age was 61.02 ±13.2 years and the sex-ratio was 1.6. The main etiology of chronic liver diseases was viral infection C (32.1%) followed by viral infection B (22.8%) and non-alcoholic steatohepatitis (21.4%). The prevalence of autoimmune chronic liver diseases was 7.58%: autoimmune hepatitis (AIH) in four cases, primary biliary cholangitis (PBC) in huit cases, primary sclerosing cholangitis (PSC) in three cases and overlap syndrome (AIH-PBC) in two cases. Autoimmune diseases were noted in 31 cases (13.9%): autoimmune hemolytic anemia in 15 cases, autoimmune thyroiditis in 12 cases, one case of psoriasis, one case of CREST syndrome, one case of Sjögren's syndrome and one case of autoimmune thrombocytopenia. Autoimmune pathologies were more associated with autoimmune chronic liver disease than other causes of chronic liver disease (47% vs 11.1%, p <0.001). Autoimmune pathologies were not statistically associated with female gender (p = 0.085) or young age (p = 0.483).
Conclusion: In our study, the prevalence of autoimmune diseases during chronic liver diseases was 13.9%. This prevalence was higher in the case of autoimmune chronic liver diseases (47%), which would underline the importance of systematic screening for clinical and biological immune manifestations in those patients.

Diagnostics and imaging procedures

POS1386 ANGIOGRAPHIC CHARACTERISTICS OF VASCULOPATHY IN PATIENTS WITH CONNECTIVE TISSUE DISEASES

J. Yeo[1], E. A. Park[2,3], E. B. Lee[1,4], Y. W. Song[1,4], J. K. Park[1,4]. [1]*Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*Seoul National University Hospital, Department of Radiology, Seoul, Korea, Rep. of (South Korea)*; [3]*Seoul National University College of Medicine, Department of Radiology, Seoul, Korea, Rep. of (South Korea)*; [4]*Seoul National University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Vasculopathies are a heterogeneous group of morphologically and pathogenetically distinct vascular diseases. They include both non-inflammatory and inflammatory vasculopathies. Patients with connective tissue disease (CTD), including systemic sclerosis (SSc), dermatomyositis (DM), and polymyositis (PM), can develop a non-thrombotic proliferative vasculopathy (NTPV), a distinctive disease entity characterized by vascular wall proliferation without overt evidence of vascular inflammation and intraluminal thrombosis.
Objectives: This study aimed to analyze the angiographic features of NTPV in patients with CTD, including SSc, DM, and PM in comparison to polyarteritis nodosa (PAN).
Methods: Angiograms of 47 extremities (24 upper and 23 lower extremities) of 11 patients with CTD (6 SSc, 4 DM, and 1 PM), and 12 patients with PAN who presented with critical digital ischemia between January 2001 and May 2020 were analyzed. The degree and pattern of stenosis, occlusion, aneurysms, and neovascularization in proximal arteries (defined as arteries above the wrist and ankle) and distal arteries (defined as those at or below the wrist and ankle) were compared between CTD-vasculopathy and PAN.
Results: Diffuse narrowing was significantly more frequent (66.1% vs. 38.0%; p=0.001), whereas multifocal stenosis was significantly less frequent (6.5% vs. 26.8%, p=0.002) in the CTD group than in the PAN group. All patients with CTD and 72.0% with PAN had diffuse narrowing in the distal arteries (p =0.010). Tapered occlusion was more frequent than abrupt occlusion in patients with CTD (43.5% vs. 11.3%). Abrupt occlusion (11.3% vs. 29.6%, p=0.010) and aneurysm formation (1.6% vs. 11.3%; p=0.037) were significantly less frequent in the CTD than in the PAN group. After 1 year, three patients (27.3%) in the CTD group and seven (58.3%) in the PAN group showed improvements in digital ischemia. Moreover, four patients (36.4%) in the CTD group and two (16.7%) in the PAN group underwent auto- or surgical amputation.
Conclusion: Patients with CTD-vasculopathy exhibit more frequently diffuse smooth narrowing, tapered occlusion and delayed distal blood flow on conventional angiograms and worse outcomes than with PAN patients. Larger studies are needed to confirm the current findings.

POS1387 QUANTIFICATION OF BONE MARROW EDEMA BY MRI OF THE SACROILIAC JOINTS IN PATIENTS DIAGNOSED WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE ESPERANZA COHORT

R. Almodovar[1], P. Zarco-Montejo[1], A. Bueno[2], C. Garcia-Monco[2], E. De Miguel[3], C. Tornero[3], M. Moreno Martinez Losa[4], J. Gratacos-Masmitja[4], R. Mazzucchelli[1]. [1]*Hospital Universitario Fundación Alcorcón, Rheumatology Unit, Alcorcón, Spain*; [2]*Hospital Universitario Fundación Alcorcón, Radiology Department, Alcorcón, Spain*; [3]*Hospital Universitario La Paz, Rheumatology Unit, Madrid, Spain*; [4]*Hospital Universitario Parc Taulí, Rheumatology Unit, Sabadell. Barcelona, Spain*

Background: The present study analyzes the added value of quantification by MRI of SI joints by comparing it to the standard interpretation with ASAS criteria for the classification of patients with axSpA of recent onset and a six-year follow-up.
Objectives: To evaluate if the quantification of bone marrow edema (BME) of the sacroiliac (SI) joints by magnetic resonance imaging (MRI) improves capacity for axial spondyloarthritis (axSpA) classification in comparison to the assessment of sacroiliitis by means of ASAS classification criteria.
Methods: Prospective study from the ESPeranza cohort involving 66 subjects with an available MRI of the SI joints at baseline. This subgroup includes patients with axSpA (n=28), peripheral spondyloarthritis (n=10) and a group with other diagnoses that were not spondyloarthritis (n=28). Measures of diagnostic usefulness (area under the curve (AUC), sensitivity, specificity, Youden's J statistic, LR+ and LR-) were calculated for MRI of the SI joints according to ASAS criteria and for MRI quantified by means of SCAISS (Spanish tool for semi-automatic quantification of sacroiliac inflammation by MRI in spondyloarthritis). This analysis was stratified in patients who were HLA-B27 positive and negative.
Results: Out of a total of 66 MRI of the SI joints, 20 (30.3%) were positive according to ASAS criteria. Out of these 20 subjects, 18 patients with final diagnosis of axSpA had a positive MRI, and 2 patients did not have axSpA. Out of the 66 patients of the cohort, 23 (34.8%) patients were HLA-B27 positive and 42 (63,6%) were negative. AUC value with bone marrow edema (BME) quantification was 0.919 (CI95% 0.799-1) for HLA-B27 positive patients and 0.884 (CI95% 0.764-1) for HLA-B27 negative patients. A SCAISS cutoff point of 80 units obtained a specificity of 94.4% and LR+ 7.5, while assessment by ASAS criteria showed a specificity value of 90% and LR+ 6.4.
Conclusion: For patients with suspected axSpA, quantification of BME improves the predictive capacity of MRI of the SI joints, for both HLA-B27 positive and negative patients.

POS1388 ULTRASOUND FOR PANNICULITIS

A. Potapova[1], O. Egorova[1], O. Alekseeva[1], A. Volkov[1], S. Radenska-Lopovok[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*; *[2]I.M. Sechenov First Moscow State Medical University (Sechenov University), Pathomorphology, Moscow, Russian Federation*

Background: Ultrasound (US) is a non-invasive and safe imaging method that allows in vivo differentiation of the morphological structures of subcutaneous fat (SCF) tissue in in normal and pathology.
Objectives: Reveal features of ultrasound changes in SCF in panniculitis (Pn).
Methods: 57 patients (f – 45, m - 12) aged 18 - 67 years with an initial diagnosis of erythema nodosum and a disease duration of 3.6 ± 1.4 years were examined. In addition to the general clinical examination, a computed tomography of the chest organs and a pathomorphological examination of a skin biopsy from the site of the node were performed. Ultrasound was performed on a MyLabTwice apparatus (ESAOTE, Italy) using a multi-frequency linear transducer (10-18 MHz) with the PD technique, the parameters of which were adapted for recording low-speed flows (PRF 300-600 Hz, low filter, dynamic range - 20-40 dB), the presence of vascularization was assessed not only in the affected area, but also on the contralateral side using high-energy Doppler.
Results: 33 patients were diagnosed with septal Pn (SPn), 24 - lobular Pn (LPn). In all cases, the diagnosis was verified by histological examination. Ultrasound made it possible to assess the thickness, echoicity and vascularization of the SCF. In 35 patients, significant thickening of the SCF was revealed (as compared to the contralateral side), of which in 14 cases with SPn, in 21 - with LPn. Significant diffuse thickening of the SCF with the contralateral side was observed in 18 patients, incl. in 12 (66%) patients with LPn. Limited thickening was more typical for SPn (73%). A significant increase in the echoicity of the SCF was noted in all forms of Pn. A "lobular" echo pattern with an anechogenic environment was observed in 25 patients, of which 18 (72%) had LPn. An increase in vascularization compared to the contralateral side was recorded in 30 cases (SPn-17, LPn-13).
Conclusion: The obtained preliminary results indicate the important role of ultrasound in assessing the depth and prevalence of the inflammatory process at Pn. To clarify the diagnostic value of this method, further studies are needed on a larger sample of patients.

POS1389 IDIOPATHIC, RHEUMATOID ARTHRITIS AND DIABETES MELLITUS ASSOCIATED CARPAL TUNNEL SYNDROME: EVALUATION OF THE DEPTH OF THE CARPAL TUNNEL BY ULTRASONOGRAPHY

A. Elsaman[1], Y. Alzahrani[2], H. Alzahrani[2], A. Radwan[1]. *[1]Sohag University Hospital, Rheumatology and Rehabilitation, Sohag, Egypt*; *[2]Armed Forces Specialized Center for Health Rehabilitation, Altaif, Kingdom of Saudi Arabia, Rehabilitation Depatment, Taif, Saudi Arabia*

Background: The depth of the carpal tunnel is a relatively new sonographic parameter for evaluation of carpal tunnel syndrome (CTS). It showed a sensitivity and specificity comparable to cross-sectional area measurement. So far it is not clear how the depth can changes with different types of CTS [1, 2].
Objectives: is to assess the depth in 3 different types of CTS including idiopathic, rheumatoid arthritis, and diabetes mellitus associated CTS and to compare it with other sonographic and electro-physiologic scales.
Methods: We included a total number of 360 participants; including 289 with CTS (60 idiopathic, 106 diabetes associated, and 123 rheumatoid arthritis associated CTS), all fulfilled the criteria for electro-physiologic diagnosis according to the American Association of Electro Diagnostic Medicine; along with 71 non-CTS cases (20 healthy controls, 20 RA and 31 diabetic patients). Median nerve cross-sectional area (CSA); flattening ratio (FR); and depth of the carpal tunnel (DCT) were measured for all participants.
Results: We found the mean age 35.6±9.48 years. The female-to-male ratio was 47:13. The sensitivities for CSA, FR and DCT were 74.7%, 68.9%, and 75.1%; respectively, and the specificities were 91.6%, 63.4% and 87.3%; respectively. DCT was the best sonographic parameter with rheumatoid arthritis associated CTS (giving an accuracy of 88.6%) and CSA was the best in the other two types (giving an accuracy of 87.5% for idiopathic CTS and 83.4% for diabetes associated CTS). Table 1 summarizes the sensitivity statistics among each of the three groups and all over the study participants.
Conclusion: The depth of the CTS showed the best accuracy in rheumatoid arthritis associated CTS followed by idiopathic CTS and finally diabetes mellitus associated CTS.

Background: Anterior uveitis (AU) is one of the most frequent extra articular manifestations of axial spondyloarthritis (axSpA), present in around 25% of patients. As with axSpA, AU has also been associated with the development of accelerated atherosclerosis[1]. If the presence of AU confers an increased cardiovascular (CV) risk or specific disease-related features to patients with axSpA remains unclear.
Objectives: To compare the atherosclerotic burden, CV events, CV risk factors and disease related factors including structural damage in axSpA patients with and without AU.
Methods: Cross-sectional analysis of the AtheSpAin cohort, a Spanish multicenter cohort designed for the study of atherosclerosis in axSpA, comparing axSpA patients with and without concomitant uveitis. Background information on CV and disease-related factors was reviewed. Data on CV risk and disease status at the time of the study were also obtained, including the structural damage assessed by the presence of syndesmophytes, the severity of the sacroiliitis (defined as grade 3 or 4 according to New York criteria), and the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Carotid ultrasound (US) was performed in all patients at the time of the study, including measurement of carotid intima-media wall thickness (cIMT) and plaque detection according to the Mannhein consensus criteria.
Results: A set of 886 axSpA patients were included. 709 (80.0%) of them had no history of concomitant AU, which was present in the remaining 177 (20.0%). The group with AU was older (50 ± 11 vs 48 ± 13 years, p=0.05), had a higher proportion of patients with AS (90.1% vs 76.3%, p=0.00) (Table 1) and a longer disease duration 13(7-23) vs 7(2-16) years, p=0.00]. The prevalence of HLA-B27 was higher in AU patients (82% vs 67%).
Remarkably, structural damage showed interesting differences between both groups (Table 1). AU patients had a higher prevalence of severe sacroiliits (69% vs 49%, p=0.00), which remained significant after adjustment for age, disease duration and AS/nr-axSpA ratio. Furthermore, a non-significant trend towards a

higher prevalence of syndesmophytes (44% vs 36%, p=0.06) and hip involvement (20% vs 15%, p=0.09) was observed in the group of AU.
Regarding CV risk features, no differences were observed in the prevalence of CV risk factors and events (Table 1). Patients with AU showed a higher cIMT in the crude analysis (665 ± 156 mm vs 640 ± 142 mm, p = 0.047), but no significant differences were observed after adjustment by age and sex (p=0.6). Prevalence of carotid plaques was comparable in both groups (32% Vs 32%, p=0.84).

Table 1.

	axSpA without uveitis (n=709)	axSpA with uveitis (n=177)	p	P (adjusted model)
Men/Women, n	477/232	122/55	0.68	
Mean age (years) ±SD at the time of study	48 ± 13	50 ± 11	**0.049**	
AS/nr-AxSpa	541/168	160/17	**0.000**	
History of CV risk factors, n (%)				
Current smoker	247 (35)	50 (28)	0.096	
Obesitty				
Dyslipemia	233 (33)	63 (36)	0.48	
Hypertension	188 (27)	50 (28)	0.63	
Diabetes Mellitus	50 (7)	14 (8)	0.69	
Chronic Kidney Disease	18 (3)	4 (2)	0.99	
History of cardiovascular events, n (%)	29 (4)	12 (7)	0.13	
Structural damage at the time of study				
Presence of syndesmophytes, n (%)	253 (36)	77 (44)	0.063	
mSASSS	5 (1-15)	6 (0-16)	0.31	
Severe sacroiliitis (grade 3,4), n (%)	348 (49)	122 (69)	**0.000**	0.000*
Carotid US data at the time of study				
Carotid plaques, n (%)	225 (32)	57 (32)	0.84	
IMT (mm)	640 ± 142	665 ± 156	**0.047**	0.6**
IMT >= 0.900 mm	36 (5)	10 (6)	0.72	

*: adjusted by age, disease duration and AS/nr-axSpA ratio
**: adjusted by age and sex
Abbreviations: AS = ankylosing spondylitis. AxSpA= axial spondylitis. CV = cardiovascular. IMT = intima-media wall thickness. Nr-axSpA = no-radiographic axial spondylitis.

Conclusion: The presence of AU does not confer additional CV risk to axSpA patients, although it is associated with a more severe structural damage in our series.

POS1391 MEASURING SUBCLINICAL INFLAMMATION IN HAND AND FOREFOOT IN PATIENTS WITH ARTHRALGIA USING 1.5T OR 3.0T MRI: DOES FIELD STRENGTH MATTER?

D. Krijbolder[1], M. Verstappen[1], F. Wouters[1], L. R. Lard[2], P. D. De Buck[3], J. Veris-van Dieren[4], M. Reijnierse[5], H. Bloem[5], A. Van der Helm - van Mil[1,6]. *[1]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*; *[2]LangeLand Ziekenhuis, Department of Rheumatology, Zoetermeer, Netherlands*; *[3]Haaglanden Medical Center, Department of Rheumatology, Den Haag, Netherlands*; *[4]Reumazorg Zuid West Nederland, Department of Rheumatology, Goes, Netherlands*; *[5]Leiden University Medical Center, Department of Radiology, Leiden, Netherlands*; *[6]Erasmus Medical Center, Department of Rheumatology, Rotterdam, Netherlands*

Background: Magnetic resonance imaging (MRI) of small joints sensitively detects inflammation. MRI-detected subclinical inflammation, and tenosynovitis in particular, has been shown predictive for RA development in patients with arthralgia. These scientific data are mostly acquired on 1.0T-1.5T MRI scanners. However, 3.0T MRI is nowadays increasingly used in practice. Evidence on the comparability of these field strengths is scarce and it has never been studied in arthralgia where subclinical inflammation is subtle. Moreover, comparisons never included tenosynovitis, which is, of all imaging features, the strongest predictor for progression to RA.
Objectives: To determine if there is a difference between 1.5T and 3.0T MRI in detecting subclinical inflammation in arthralgia patients.
Methods: 2968 locations (joints, bones or tendon sheaths) in hands and forefeet of 28 arthralgia patients were imaged on both 1.5T and 3.0T MRI. Two independent readers scored for erosions, osteitis, synovitis (according to RAMRIS) and tenosynovitis (as described by Haavaardsholm et al.). Scores were also summed as total inflammation (osteitis, synovitis and tenosynovitis) and total RAMRIS (erosions, osteitis, synovitis and tenosynovitis) scores. Interreader reliability (comparing both readers) and field strength agreement (comparing 1.5T and 3.0T) was assessed with interclass correlation coefficients (ICCs). Next, field strength agreement was assessed after dichotomization into presence or absence of inflammation. Analyses were performed on patient- and location-level.
Results: ICCs between readers were excellent (>0.90). Comparing 1.5 and 3.0T revealed excellent ICCs of 0.90 (95% confidence interval 0.78-0.95) for the total inflammation score and 0.90 (0.78-0.95) for the total RAMRIS score. ICCs for individual inflammation features were: tenosynovitis: 0.87 (0.74-0.94), synovitis 0.65 (0.24-0.84) and osteitis 0.96 (0.91-0.98). The field strength agreement on dichotomized scores was 83% for the total inflammation score and 89% for the total RAMRIS score. Of the individual features, agreement for tenosynovitis was the highest (89%). Analyses on location- level showed similar results.
Conclusion: Agreement of subclinical inflammation scores on 1.5T and 3.0T were good to excellent, in particular for tenosynovitis. This suggests that scientific evidence on predictive power of MRI in arthralgia patients, obtained on 1.5T, can be generalized to 3.0T when this field strength would be used for diagnostic purposes in daily practice.

POS1392 ECHOCARDIOGRAPHIC FINDINGS IN PSORIATIC ARTHRITIS, RHEUMATOID ARTHRITIS AND CONTROLS

A. B. Rodriguez-Romero[1], J. R. Azpiri-López[2], I. J. Colunga-Pedraza[1], D. Á. Galarza-Delgado[1], N. Guajardo-Jauregui[1], S. Lugo-Perez[2], A. Cárdenas[1], H. Azpiri-Diaz[2], O. A. Cepeda-Ayala[2]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology Service, Monterrey, Mexico*; *[2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology Service, Monterrey, Mexico*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthropathy associated with cardiovascular abnormalities (1). The echocardiography is a non-invasive tool useful in the detection of cardiac abnormalities, which may be the only manifestation of cardiac involvement preceding a global dysfunction. However, echocardiographic differences between PsA patients, rheumatoid arthritis (RA) patients, and controls have not yet been well described.
Objectives: To analyze the echocardiographic parameters in PsA patients and to compare them with RA patients and controls.
Methods: This cross-sectional, observational and comparative study, included thirty-six patients (nineteen in each group), aged 40-75 years, with PsA and RA who fulfilled the CASPAR (Classification criteria for Psoriatic Arthritis) and ACR/EULAR 2010 classification criteria, respectively, matched by age, gender and comorbidities with nineteen healthy controls. Exclusion criteria were a poor echocardiographic window, patients with a previous atherosclerotic cardiovascular disease (ischemic heart disease, cerebrovascular accident or peripheral arterial disease), and pregnancy. Transthoracic echocardiogram was performed and reviewed by 2 board-certified cardiologists, in all study subjects. Comparisons were done with X2, Kruskall Wallis or ANOVA.
Results: There were not differences in the demographic characteristics between groups (Table 1). When comparing echocardiographic findings a statistically significant difference was found in the prevalence of diastolic dysfunction, being more prevalent in PsA and RA patients compared with controls (52.6% vs 52.6% vs 5.3%, p=0.002), likewise the presence of mild mitral valve regurgitation was higher (84.2% vs 53.6% vs 10.5%, p=0.001) and mild pulmonary valve regurgitation (68.4% vs 10.5% vs 0%, p=0.001). Prevalence of abnormal left ventricular geometry was higher in PsA and RA patients than controls (68.4% vs 63.2% vs 21.1%, p=0.006).

Table 1. Comparison of demographic characteristics and echocardiographic findings between patients with PsA, RA and controls.

	PsA (n=19)	RA (n=19)	Controls (n=19)	*p*
Age, years ± SD	54.7 ± 7.7	55.4 ± 9.9	55.3 ± 5.9	NS
Female, n (%)	11 (57.9)	11 (57.9)	11 (57.9)	NS
Diabetes Mellitus	4 (21.1)	3 (15.8)	2 (10.5)	NS
Hypertension	10 (52.6)	8 (42.1)	7 (36.8)	NS
Dyslipidemia	10 (52.6)	4 (21.1)	7 (36.8)	NS
Active smoking	4 (21.1)	2 (10.5)	5 (26.3)	NS
Disease duration, years (p25-p75)	6 (4-14)	7 (5-18)	-	NS
DAS28-CRP, mean ± SD	2.2 ± 0.8	3.1 ± .8	-	**0.003**
Echocardiographic findigs				
Diastolic dysfunction, n (%)	10 (52.6)	10 (52.6)	1 (5.3)	**0.002**
LV mass index, g/m^2 (p25-p75)	78.9 (55.9-86.9)	73.7 (61.0-85.7)	69.5 (52.0-98.7)	**NS**
LVEF, ± mean SD	62.3 ± 6.1	59.7 ± 8.6	62.9 ± 6.1	NS
TAPSE, cm ± SD	21.8 ± 2.7	22.4 ± 2.7	23.7 ± 3.1	NS
Mild aortic regurgitation, n (%)	5 (26.3)	4 (21.1)	1 (5.3)	NS
Mild mitral regurgitation, n (%)	16 (84.2)	10 (52.6)	2 (10.5)	**<0.001**
Mild pulmonary regurgitation, n (%)	13 (68.4)	2 (10.5)	0 (0)	**<0.001**
Mild tricuspid regurgitation, n (%)	15 (83.3)	13 (76.5)	11 (57.9)	NS
LV geometry alterations, n (%)	13 (68.4)	12 (63.2)	4 (21.1)	**0.006**
Concentric remodeling, n (%)	12 (63.2)	10 (52.6)	4 (21.1)	**0.025**

NS, non-significant; DAS28-CRP, disease activity score using 28 joints and C reactive protein; LV, left ventricular; LVEF, left ventricular ejection fraction; TAPSE, tricuspid annular plane systolic excursion.

Conclusion: This study shows the high prevalence of echocardiographic alterations in PsA patients compared to the general population, of the same magnitude as patients with RA. We emphasize the value of an echocardiogram for a complete cardiovascular evaluation and early detection of cardiac abnormalities in these patients.

POS1393 QUANTITATIVE AUTOFLUORESCENCE FINDINGS IN PATIENTS UNDERGOING HYDROXYCHLOROQUINE TREATMENT

S. Parrulli[1], M. Cozzi[1], M. Airaldi[1], F. Romano[1], F. Viola[2], P. Sarzi-Puttini[3], G. Staurenghi[1], A. Invernizzi[1,4]. *[1]Sacco Hospital, University of Milan, Eye Clinic, Department of Biomedical and Clinical Science "Luigi Sacco", Milan, Italy*; *[2]University of Milan, IRCCS-Ca Granda Fondazione Ospedale Maggiore Policlinico, Ophthalmological Unit, Department of Clinical Sciences and Community Health, Milan, Italy*; *[3]ASST Fatebenefratelli L.Sacco University Hospital, Rheumatology Unit, Milan, Italy*; *[4]Sydney Medical School, The University of Sydney, Save Sight Institute, Discipline of Ophthalmology, Sydney, Australia*

Background: Hydroxychloroquine (HCQ) is a relatively safe and effective drug widely used as primary or adjunctive treatment for several rheumatological and dermatological disorders[1]. HCQ modulates immune response through several mechanisms and has a tropism for pigmented ocular tissues, particularly retinal pigment epithelium (RPE)[2]. Its accumulation within RPE cells can lead to sight threatening retinal toxicity, with bull's eye maculopathy (BEM) representing its advanced phenotype. [3] Quantitative Auto-Fluorescence (qAF) is an imaging modality that allows the measurement of retinal auto-fluorescence following short-wavelength light (488nm) excitation of retinal fluorophores (lipofuscin). [4] Two recent studies have focused on qAF values in patients treated with HCQ [5,6]. In both cases qAF was increased in eyes with BEM. Furthermore, Reichel et al.[6] were able to detect increased values of qAF in patients without BEM as early as 6 months after the start of HCQ treatment using an experimental imaging analysis procedure.

Objectives: To measure quantitative autofluorescence (qAF) in patients under treatment with hydroxychloroquine (HCQ) with no apparent signs of retinal toxicity and to compare it with that of untreated subjects.

Methods: Consecutive patients at risk for the development of HCQ retinal toxicity (duration of treatment >5 years or daily HCQ dose >5 mg/kg of actual body weight (ABW) and/or renal insufficiency)[7] but no alterations on Spectral Domain - Optical Coherence Tomography, Short-Wavelength Autofluorescence and 10-2 Visual Field examination were recruited. Healthy subject matched by age and sex were also enrolled in the study. All subjects underwent qAF measurements in one eye. Images were analyzed using the conventional qAF grid by Delori calculating the qAF of 8 sectors of the intermediate ring and the mean of those values (qAF_8).

Results: Thirty-nine patients treated with HCQ (38 females, mean age 52,1 ± 8,6 years) and 39 untreated subjects (38 females, mean age 51,2 ± 8,6 years). In both HCQ patients and untreated subjects, qAF_8 was positively correlated with age (p=0.004) (Figure 1). Although HCQ patients showed a higher mean qAF_8 compared to untreated subjects (294,7 ±65,3 vs 268,9 ± 57,5), the difference was not significant (p=0.068). HCQ patients showed significantly higher mean qAF values in the inferior-temporal, inferior and inferior-nasal sectors of the intermediate ring of qAF grid compared to untreated subjects (all p<0.05).

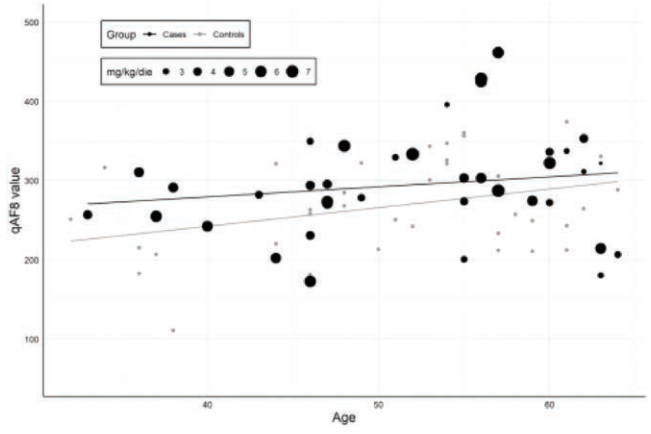

Figure 1. Visual representation of a model predicting the standardized qAF values as influenced by age and HCQ daily dose/ABW, calculated for a treatment duration of 15 years.

Conclusion: These results suggest a possible preclinical increase of qAF values in inferior parafoveal sectors probably induced by HCQ exposure. Further studies are required to improve our understanding of preclinical stages of HCQ retinopathy and the possible role of qAF in the HCQ toxicity screening.

POS1394 ACCURACY AND PERFORMANCE OF A HANDHELD ULTRASOUND DEVICE TO ASSESS ARTICULAR AND PERIARTICULAR PATHOLOGIES IN PATIENTS WITH INFLAMMATORY ARTHRITIS

G. Corte[1,2], S. Bayat[1,2], K. Tascilar[1,2], L. Valor[1,2], L. Schuster[1,2], J. Knitza[1,2], G. Schett[1,2], A. Kleyer[1,2], D. Simon[1,2]on behalf of https://www.medizin3.uk-erlangen.de/en/research/research-main-focus/digital-rheumatology-and-experimental-imaging/. *[1]Friedrich-Alexander-Universität (FAU) and Universitätsklinikum Erlangen, Internal Medicine 3, Rheumatology and Immunology, Erlangen, Germany*; *[2]Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Deutsches Zentrum Immuntherapie, Erlangen, Germany*

Background: Handheld ultrasound (HHUS) devices have increasingly found their way into clinical practice due to several advantages (e.g. portability, significantly lower purchase cost). However, there is no evidence to date on the accuracy and performance of HHUS in patients with inflammatory arthritis (IA).

Objectives: To assess accuracy and performance of a new HHUS machine in comparison to a conventional cart-based sonographic machine in patients with IA.

Methods: Consecutive IA patients of our outpatient clinic with at least one tender and swollen joint in the 66/68 joint count were enrolled. US was performed on clinically affected joints with corresponding tendons/entheses using a cart-based sonographic device ("Samsung HS40") and a HHUS device ("Butterfly iQ") in standard scan positions. One blinded reader scored all images for the presence of following pathologic findings: erosions, bony enlargement, synovial hyperthrophy, joint effusion, bursitis, tenosynovitis and enthesitis. In addition, synovitis was graded (B Mode and power Doppler (PD)) by the 4-level EULAR-OMERACT scale [1]. To avoid bias by the blinded reader, who otherwise would have been tempted to identify pathological findings for each examined joint, we also included 67 joints of two healthy volunteers into the evaluation. We calculated the overall concordance and the concordance by type of joint and type of pathological finding between the two devices (percentage of observation pairs in which the same rating was given by both devices). The Cohen's kappa coefficient (κ) with 95% bootstrap confidence intervals was used to assess the agreement between the two US devices. We also measured the time required for the US examination of one joint with both devices.

Results: 32 patients (20 rheumatoid arthritis, 10 psoriatic arthritis, 1 gouty arthritis, 1 systemic lupus erythematosus) were included in this study. Mean age of patients was 58.2±13.7 years, 63% were females. In total 186 joints were examined. The overall raw concordance in B-mode between the two devices was 97 %, with an overall κappa for agreement of 0.90, 95% CI (0.89, 0.94). No significant differences were found in relation to type of joint or pathological finding examined. The PD-mode of the HHUS device did not detect any PD-signal, whereas the cart-based device detected a PD-signal in 61 joints (33%). The portable device did not offer any time saving compared to the cart-based device (mean time in seconds per examined region: 47 seconds for the HHUS device versus 46.3 seconds for the cart-based device).

Conclusion: The HHUS device "Butterfly iQ" has been shown to be accurate in the assessment of structural joint damage and inflammation in patients with IA,

but only in B-mode. Significant improvements are still needed to reliable demonstrate blood flow detection by PD mode.

Table 1. Concordance between a handheld and a conventional cart-based US device in B-mode

	Agreement by site		
	N joints (%)	Concordance (%)	Kappa 95%CI
Overall	186	97	0.90 (0.89 to 0.94)
Wrist	32 (17.2)	96	0.86 (0.77 to 0.93)
Finger/toe joint (MCP, PIP, DIP, MTP)	114 (61.3)	97	0.92 (0.88 to 0.95)
Elbows	11 (5.9)	95	0.87 (0.75 to 0.97)
Shoulder	4 (2.2)	100	1.00 (NA to NA) *
Knee	20 (10.7)	98	0.96 (0.90 to 1.00)
Ankle	5 (2.7)	100	1.00 (NA to NA) *
Agreement by pathological finding			
Joint effusion		95	0.81 (0.68 to 0.92)
Synovitis		94	0.87 (0.79 to 0.93)
Synovitis OMERACT grade (0– 3)		90	0.84 (0.76 to 0.91)
Bone enlargement		98	0.88 (0.71 to 1.00)
Erosion		98	0.89 (0.77 to 0.89)
Tenosynovitis		98	0.83 (0.61 to 0.96)
Entheseopathy		100	1.00 (NA to NA) *
Bursitis		97	0.90 (0.89 to 0.94)

** unreliable kappa statistics because of small number of shoulders/ankles examined and small number of entheseopathies*

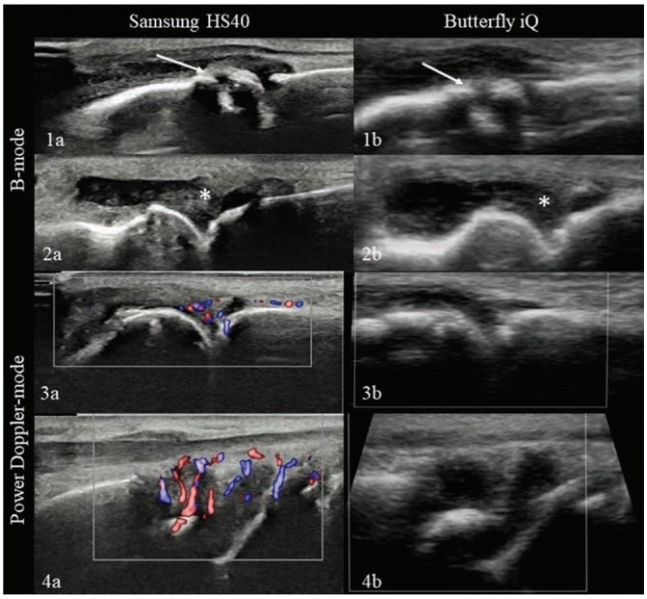

Figure 1. Pathological US findings in MCP joints (1, 2, 3) and wrist (4) depicted by the two different ultrasound devices

B-mode erosive (arrow) and synovial (asterisk) changes could be detected by both devices (1-2), while PD changes of different grades only by the conventional US device (3-4).

ASSESSMENT OF MICROVASCULAR INVOLVEMENT IN LUPUS NEPHRITIS PATIENTS BY RETINAL OCT-ANGIOGRAPHY AND KIDNEY BIOPSIES

S. Ferrigno[1], P. Conigliaro[1], C. Giannini[2], C. Nesi[2], G. L. Fonti[1], M. Cesareo[2], R. Perricone[1]. [1]*University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Department of "Medicina dei Sistemi", Rome, Italy*; [2]*University of Rome Tor Vergata, Ophthalmology Unit, Department of Experimental Medicine and Surgery, Rome, Italy*

Background: Lupus Nephritis (LN) and retinopathy are organ-threatening manifestation of Systemic Lupus Erythematosus (SLE) and both share common pathophysiology represented by microvascular damage. Optical coherence tomography angiography (OCTA) is a recent non-invasive technique showing retinal vascular damage.

Objectives: To analyze retinal microvascular alterations in SLE-LN patients and investigate correlations between ocular and renal involvement.

Methods: We recruited SLE-LN patients and healthy controls (HC), age and sex -matched. Patients underwent rheumatological evaluation, including clinical, laboratory, kidney function and kidney biopsies examination.

Patients and HC underwent a complete ophthalmological evaluation including eye definition color retinography and OCTA whole image, parafovea and fovea vessel density assessment of superficial and deep retinal capillary plexus. Parafovea and fovea thickness, fovea avascular zone (FAZ) area and perimeter were detected.

Statistical analysis was performed using: $\chi 2$ test, unpaired t-test, Mann Whitney U test, Pearson or Spearman rank correlation and ROC curve analysis.

Results: 48 eyes of 24 SLE-LN patients and 44 eyes of 21 HC were evaluated. Table 1 shows demographic, clinical, laboratory and histological parameters.

Figure 1 shows results of OCTA data and relative AUC curves and ROC analysis. Analysis of OCTA data showed a significative reduction of vessel density in SLE-LN compared to HC regarding the following parameters: superficial whole en face, parafovea and fovea density (Figure 1A-C), deep whole en face and deep fovea density, (Figure 1D-E), parafovea and fovea thickness (Figure 1F-G), FAZ area and perimeter (Figure 1H-I).

OCTA data were correlated with demographic, clinical and histologic features of patients showing negative correlation between: SLE duration and both superficial (p=0.03; r=-0.3) and deep (p= 0.004; r=-0.4) whole en face density; LN duration and superficial whole en face (p=0,05; r=-0.4) and parafovea (p=0.007; r=-0.4) density, deep whole en face (p=0.004; r=-0.4) and fovea (p=0.01; r=-0.4) density and parafovea thickness (p=0.004; r=-0.3); SLEDAI-2K and both superficial and deep fovea density (p<0.0001, r=-0.6 and p=0.0, r=-0.4 respectively); BUN and superficial whole en face density (p=0.003; r=-0.5) and parafovea (p=0.004; r=-0.4) density and deep fovea density (p=0.03; r=-0.3); serum creatinine and deep whole en face density (p=0.004; r=-0.4).

Positive correlation was found between LN duration and FAZ area (p= 0.01; r= 0.4); creatinine clearance and both deep whole en face (p=0.05; r= 0.3) and fovea (p=0.0007; r= 0.5) density.

OCTA data analysis showed a reduction in superficial (p=0.02) and deep (p=0.009) whole en face density in patients with LN-vascular lesions assessed by kidney biopsy. In this group, patients with intimal hyalinosis showed a reduction in deep whole en face density (p=0.04) compared to those without intimal hyalinosis.

Conclusion: Preliminary results suggest a correlation between retinal microvascular alterations and kidney function and histologic lesions encouraging the use of OCTA measurement as a potential biomarker of systemic vascular involvement.

POS1396 DAMAGE PROGRESSION OF FINGER JOINT CARTILAGE EVALUATED BY ULTRASOUND AND X-RAY IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

T. Ogura[1], A. Hirata[1], Y. Inoue[1], T. Kagtagiri[1], Y. Takakura[1], H. Kameda[1]. [1]*Toho University, Division of Rheumatology, Department of Internal medicine, Tokyo, Japan*

Background: Cartilage damage in RA has been evaluated by joint space narrowing (JSN) in X-ray, while it is not a direct evaluation of cartilage. Previously we have confirmed the usefulness of the direct imaging of finger joint cartilage by ultrasound (US) in patients with RA [1].
Objectives: We aimed to examine the temporal changes of US cartilage thickness in RA patients.
Methods: We enrolled 53 RA patients in whom the cartilage thickness of finger joints was measured by US and had radiographs of both hands at baseline and 1-year later. The cartilage of metacapophalangeal and proximal interphalangeal joints of 2nd to 5th fingers were bilaterally visualized at the middle portion from a longitudinal dorsal view. Cartilage thickness was measured from the base of the cartilage to the interface artefact at the cartilage surface by static images. In addition, the JSN of the corresponding joints was scored using a hand X-ray by van der Heijde-modified Sharp method. Continuous variables from the two groups were analyzed using the Mann-Whitney U test or Wilcoxon signed-rank test. The relationships among the continuous variables were assessed using the Spearman's rank correlation coefficient.
Results: The median age of the patients was 68 years and the median disease duration was 6.3 years. The sum of total cartilage thickness from 16 joints per patient ranged from 3.1 to 9.1mm (median 6.5mm) at baseline, and it was significantly correlated with total JSN score of the same joints (ρ=-0.63, p<0.001). The cartilage thickness was inversely correlated with disease duration (rho=-0.40, p=0.003), but not associated with age nor height. The decrease in cartilage thickness over 1 year was evident in patients with persistent moderate to high disease activity by the DAS28-CRP (n=10; median -6.2%) as compared with other patients (n=43; median -1.2%, p=0.004 versus active patients).
Conclusion: This pilot study demonstrated the progression of cartilage damage by sustained RA activity, supporting the validity and usefulness of joint cartilage thickness evaluation by ultrasound in patients with RA.

POS1397 HYDROXYCHLOROQUINE INDUCED RETINAL TOXICITY IN PATIENTS WITH RHEUMATIC DISEASES

R. Maheshwari[1], R. Sankaralingam2, S. Chinnadurai2, J. Antony2, B. Chilukuri2, M. Mani2. [1]*Sri Ramachandra Institute of Higher Education and Research, Clinical Immunology and Rheumatology, Chennai, India*; [1]*Sri Ramachandra Institute of Higher Education and Research, Clinical Immunology and Rheumatology, Chennai, India*

Background: Retinal toxicity from hydroxychloroquine (HCQ) is rare, but the vision loss maybe irreversible and could have medicolegal consequences.
Objectives: To determine the prevalence and assess the predictors of retinal toxicity due to HCQ in patients with rheumatic diseases. There is paucity of literature on retinal toxicity due to HCQ in rheumatic diseases.
Methods: A retrospective observational study was conducted in the Department of Clinical Immnuology and Rheumatology, Sri Ramachandra Institute of Higher Education and Research,Chennai, India from November 2018-May 2020, on patients taking HCQ for more than 6 months. All patients underwent ophthalmological screening at baseline and every 6 months, and thereafter by modern day screening methods-Humphrey Visual Field (HVF)10-2, Spectral Domain Optical Coherence Tomography(SD-OCT), except for patients with evidence of suspected retinal toxicity at baseline.Fundus autofluorescence (FAF) was done in feasible patients.
Results: 9 out of 743(1.2%) patients were identified to have retinal toxicity, detected via fundus examination (n=9), SD-OCT (n=8/9), HVF 10-2 (n=6/9), FAF (n=1/9). 55.5% (n=5/9) had Rheumatoid Arthritis(RA) and 44.4% (n=4/9) had Systemic Lupus Erythematosus(SLE) as their primary diagnosis. 77.7% (n=7/9) were females. The mean age was 47.5 years (20-72 years).75%(n=3/4) of SLE patients were below 30 years of age. The average daily and cumulative dose of HCQ in these 9 patients were 244mg (200-400mg) and 311.22g(73-730g) respectively, whereas the mean recommended dose as per real body weight was 287.2mg/day. Average duration of HCQ consumption was 3.6 years (1-10 years). Only 11.1% (n=1/9) had presented with visual complaints of black floaters.
Conclusion: The asymptomatic nature of this irreversible toxicity, warrants frequent screening.Retinal toxicity was not age-related.Toxicity was manifested at low daily and cumulative doses.Screening should be done atleast every 6 months by fundus examination.Objective tests like HVF and SD-OCT should be done annually, especially in patients with underlying rheumatic diseases.The early manifestation of retinal toxicity in young SLE patients could have a genetic association and needs further evaluation.

Table 1. SALIENT FEATURES OF THE 9 PATIENTS PRESENTING WITH RETINAL TOXICITY DUE TO HCQ

					Dose				Detection Method Used			
Sl. No	Age	Gender	Weight (Kg)	Primary Diagnosis	Recommended Dose (mg/Day)	Received Dose (mg/Day)	Cumulative Dose (grams)	Duration (Years)	FUNDUS EXAM.	SD-OCT	HVF 10-2	F AF

POS1398 RHEUMATOLOGICAL PATIENTS PERFORMING BLOOD SELF-SAMPLING FOR DMARD THERAPY SAFETY: A PROOF OF CONCEPT STUDY COMPARING WITH VENOUS BLOOD SAMPLES

S. A. Just[1,2], P. Toftegaard[1], U. Jakobsen[3], T. R. Larsen[2,3]. [1]*Svendborg Hospital - Odense University Hospital, Section of Rheumatology, Department of Medicine, Svendborg, Denmark*; [2]*University of Southern Denmark, Department of Clinical Research, Odense, Denmark*; [3]*Svendborg Hospital - Odense University Hospital, Department of Biochemistry, Svendborg, Denmark*

Background: Regular blood sampling is a requirement for rheumatological patients receiving csDMARD, bDMARD or tsDMARD therapies (1). The frequent blood sampling affects the patient's life as they use a substantial amount of time at hospitals or by the general practitioner. Often visits are time-consuming with transport, waiting time, and for some patient's costly long travels. Giving patients the option of taking the blood samples themself in their own home, as part of a patient-centred monitoring approach, could provide the patient much higher degree of independence. Further, it may increase the quality of life, cause higher compliance with taking the control samples and possibly reduce health care costs.
Objectives: 1. To investigate if rheumatological patients can take capillary blood samples and describe patient-reported outcomes (PRO) about the procedure. 2. Compare the venous and capillary samples' results. 3. Test if the laboratory automated analysis equipment can handle the small capillary samples.
Methods: 21 rheumatological patients, underwent capillary and venous blood sampling at up to 4 occasions (1-2 months between). Instructions were available on a pictogram. PRO data were assessed by questionnaires. The patient performed blood extraction to the capillary samples from a finger after using a device making a small incision (2 mm depth and 3 mm width). Two capillary tubes (one Microtainer K2-EDTA and one Microtainer lithium heparin with gel) were filled with a total volume of approximately 1.0 mL blood. A phlebotomist took the venous sample. Blood samples were analyzed for alanine aminotransferase (ALAT), albumin, alkaline phosphatase (ALP), calcium, C-reactive protein (CRP), creatinine, potassium, lactate dehydrogenase (LDH), urate, hemolysis index, erythrocyte corpuscular volume (MCV), haemoglobin, leukocytes, differential count and platelets.
Results: A total of 53 paired capillary (C) and venous (V) samples were taken. The average perceived pain of the procedure of C sampling was VAS: 10.3 (SD:14.4) (0-100) versus V sampling VAS: 8.5 (SD:11.7). 90% of patients would accept it as a future form of blood sampling.
Differences in blood samples (C versus V) were: CRP (-3.4%); Hemoglobin (-1.4%); Creatinine (-4.4%), ALAT (-2.9%), neutrophils (1.43%), platelets (-16.9%). The index of hemolysis was on average 128.9 mg/dL (SD: 203) in C versus 6.7 mg/dL (SD: 4.6) in V. Results was evaluated by a rheumatologist, and 92.5% of capillary samples could be used to evaluate the safety of DMARD treatment based on the most critical samples for this: ALAT, creatinine, neutrophils and platelets (1). The 7.5 % not accepted were all due to aggregated platelets leading to low platelet count. There was hemolysis in 18% of the samples, but the analysis results could be used despite this.
Conclusion: In the majority of rheumatological patients, capillary self-sampling is well tolerated.
We show that it is possible to extract the needed results from the capillary samples to evaluate DMARD treatment safety, despite higher hemolysis index. Using capillary samples taken at home could be a central instrument in future rheumatological patient-centred monitoring.

POS1399 ALGORITHM FOR DIFFERENTIAL DIAGNOSIS OF ARTHROPATHIES USING OSTEOSCINTIGRAPHY

E. Prokhorova[1], E. Zhilyaev[2], G. Zhilyaev[3]. [1]*Main Hospital of Police, Nuclear Imaging, Moscow, Russian Federation*; [2]*JSC European Medical Center, Medical Administration, Moscow, Russian Federation*; [3]*Moscow State University of Medicine and Dentistry named after A.I. Evdokimov, Student, Moscow, Russian Federation*

Background: Joint bone scintigraphy is a promising method for diagnosing of inflammatory joint diseases. However, its scintigraphic semiotics remains to be developed.
Objectives: To develop an algorithm for the differential diagnosis of the most common arthropathies based on quantitative osteoscintigraphy.
Methods: This single-center study included inpatients with clinical diagnoses of rheumatoid arthritis (RA), axial spondyloarthritis (including ankylosing spondylitis - aSPA), peripheral spondyloarthritis (including reactive arthritis - pSpA), psoriatic arthritis (PsA), and osteoarthritis (OA) established by a rheumatologist and meeting the relevant criteria, Three hours after the injection of pyrophosphate, labeled with Tc-99m, scintigraphy of the skeletal bones was carried out according to the "whole body" program. The joint / bone accumulation ratio (AR) was calculated as the ratios of counts in relevant areas. All AR were recalculated into T-score for each joint based on data from control group. The CHAID algorithm for classification trees constructing was used. The significance of the division in the nodes was estimated with Bonferroni adjustment.
Results: 266 patients were included in the study aged 46.6±14.3 years, men - 134 (50.4%). aSPA was diagnosed in 40 patients, pSpA in 87, RA in 45, OA in 68, PsA in 26. 2279 joints were analyzed. A classification tree for differential diagnosis of arthropathies has been built (Pict.). Key indicators for identifying subgroups in the algorithm: AR in the wrist, knee and hip joints.
At the first step of the classification tree, the sum of the T-scores of the wrist joints is determined. If this amount exceeds 7.76 (node 2), the most likely diagnosis is RA (58.5% of patients in the subgroup of this node). Patients with the sum of the T-scores in the wrist joints less than 7.76 (node 1), in turn, were divided depending on the sum of the T-scores of hip joints. Those with this value less than 3.25 (node 3), mainly suffered from OA (48.7%), less often in this subgroup were diagnosed pSpA (16.7%) and PsA (14.1%). Patients in whom the sum of the T-score in the hips was more than 3.245 (node 4) were further subdivided depending on the sum of the T-scores in the shoulder joints. If it was more than 4.21 (node 8), then pSpA was most likely (58.7%). If the sum of the T-scores of the shoulder joints was in the range from 2.05 to 4.21 (node 7), then these are mainly patients with spondyloarthritides (56.2% with aSPA and 31.2% with pSpA) and a small number of patients (10%) with PsA. In the subgroup with the sum of T-scores of the shoulder joints <2.05 (node 6), patients with PSA (40%) prevailed, with a significant proportion of persons with OA (27.5%). Thus, out of the final branches formed by the tree (node 2, 3, nodes 6-8), four correspond to certain diseases (node 2 - PA, node 3 - OA, node 7 - aSPA, node 8 - pSpA). Node 6 includes patients with various diseases with a predominance of PsA. The level of significance of differences between the formed groups at all branch points of the tree is p = 0.001 or less (Bonferroni adjusted). In the training sample, 51.5% of observations are correctly classified. According to cross-validation data, the expected rate of correct classifications in real application of the algorithm is 38.0%.
Conclusion: An algorithm for the differential diagnosis of the most common inflammatory diseases of the joints has been developed, which makes it possible to use the data of quantitative osteoscintigraphy in the process of diagnosing arthritis.

POS1400 A SYSTEMATIC REVIEW OF INTERNATIONAL GUIDELINES REGARDING THE ROLE OF RADIOGRAPHY IN THE DIAGNOSIS OF OSTEOARTHRITIS

C. Henry-Blake[1], K. Treadwell[1], S. Parmar[1], J. Higgs[1], M. Marshall[1], J. Edwards[1], G. Peat[1]. *[1]Keele University, Department of Primary, Community and Social Care, Keele, United Kingdom*

Background: A substantial proportion of primary care osteoarthritis (OA) consultations are associated with an X-ray request [(1,2)]. Uncertainty exists regarding the ability of radiography to improve a clinical OA diagnosis, and the over-use of radiography may lead to inappropriate referrals due to severe radiographic features that do not correlate with patients' symptoms. Additionally, there are cost implications of unnecessarily imaging such a prevalent disease. As evidence questions the utility of routine radiography in OA, the extent to which radiography is supported by international guidelines is unknown.
Objectives: To undertake a systematic review and narrative synthesis of UK and international guideline recommendations on the role of radiography in the diagnosis of OA.
Methods: A systematic search of eleven electronic databases (including EMBASE, MEDLINE CINAHL, Epistemonikos and Guideline Central) and the websites of nine professional organisations (including NICE, Royal College of Radiologists (RCR), EULAR, and the American College of Radiology (ACR)) identified the most recent evidence-based guidelines produced by professional organisations on the role of imaging in OA. Guidelines not addressing the role of radiography in the diagnosis of OA were excluded, as were non-English and spinal OA guidelines. Each title was screened by one reviewer whilst each abstract and full text underwent dual screening. A single reviewer, using a standard proforma, undertook data extraction. Each guideline was independently appraised by two reviewers using the AGREE II tool. A narrative synthesis of the nature and consistency of OA radiographic recommendations was performed.
Results: 18 evidence-based OA guidelines published between 1998-2019 were included. These guidelines considered OA at any joint (n=8), or at the knee (n=3), hip (n=2), hand (n=2), wrist (n=1), foot (n=1), and ankle (n=1). Seven guidelines were produced by European organisations; four guidelines were produced by EULAR. Guidelines were targeted at general practitioners (n=11), radiologists (n=7), rheumatologist (n=4) and orthopaedic surgeons (n=3). Using the AGREE II tool, the identified guidelines scored highly on rigour of development (mean score 69%) but poorly on applicability (32%). All 18 guidelines recommended X-rays as the first-line modality, where imaging was indicated. A clinical diagnosis of OA without radiographic confirmation was recommended by all eleven guidelines produced by organisations represented general practitioners, with seven guidelines justifying this due to a poor correlation between radiographic features and clinical symptoms. Only three guidelines explicitly discouraged the routine use of radiography for the diagnosis of OA and only two guidelines reassured practitioners of a low probability of missing serious pathology when not routinely requesting radiographs. Guidelines produced by organisations representing radiologists were more supportive of radiography. The ACR recommended radiographic confirmation in patients suspected to have OA at the hand, wrist, hip, knee, ankle, and foot. Conversely, the RCR recommended radiographic confirmation in patients suspected to have OA at the hand, feet, and hip, but not the knee.
Conclusion: Differences in guideline recommendations on the utility of radiography in OA appear related to country/region, professional organisation, and joint. The use and utility of radiography in OA may need to be reviewed in light of a shift towards remote consultations, a change that has been accelerated by COVID-19 in many countries.

POS1401 ASSESSMENT OF INTERREADER RELIABILITY IN SCORING PATIENTS WITH HAND OSTEOARTHRITIS AND PSORIATIC ARTHRITIS BY FLUORESCENCE OPTICAL IMAGING

B. Drude[1], Ø. Maugesten[2], S. G. Werner[3], G. R. Burmester[1], J. Berger[4], I. K. Haugen[2], S. Ohrndorf[1]. *[1]Charité Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[2]Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway*; *[3]RHIO (Rheumatology, Immunology, Osteology) Duesseldorf, RHIO Research Institute, Duesseldorf, Germany*; *[4]Xiralite GmbH, Head Development and Produktion, Berlin, Germany*

Background: Fluorescence Optical Imaging (FOI) utilises the fluorophore indocyanine green (ICG) to reflect enhanced microcirculation in hand and finger joints due to inflammation.
Objectives: We wanted to assess the interreader reliability of FOI enhancement in patients with hand osteoarthritis (OA) and psoriatic arthritis (PsA). Furthermore, predefined typical morphologic patterns were included to determine the ability of FOI to discriminate between both diagnoses.
Methods: An atlas with example images of grade 0-3 in different joint groups and typical morphologic patterns ('streaky signals'[1], 'green/blue nail sign'[2], 'Werner sign'[3,4], and 'Bishop's crozier sign') of PsA and hand OA was created. Two readers scored all joints in both hands (30 in total) of 20 cases with hand OA and PsA. The cases were randomly mixed and both readers were blinded to diagnosis. Each joint was rated on a semiquantitative scale from 0 to 3 in five different images (PrimaVista Mode (PVM), phase 1, 2 (first and middle image), and 3) during the FOI sequence according to the scoring method FOIAS (fluorescence optical imaging activity score) [1,3]. Interreader reliability on scoring joint enhancement was calculated using linear weighted Cohen's kappa (κ). Agreement on diagnosis (hand OA vs. PsA) and different morphologic patterns was assessed by calculating (regular) Cohen's kappa.
Results: Overall agreement on scoring joint enhancement (all phases) was substantial (κ = 0.75), with greatest consensus in phase 2 first (κ = 0.75) and lowest agreement in phase 1 (κ = 0.46). Reliability varied in different joint groups (wrist, MCP, (P)IP, DIP), with almost perfect overall agreement on PIP joint affection (κ = 0.81), substantial agreement on wrist (κ = 0.69) and DIP joint affection (κ = 0.63), and moderate agreement on MCP joint affection (κ = 0.49) across all phases. Consensus on morphologic patterns showed overall fair agreement (κ = 0.37) with a similar kappa value on the ability to discriminate between both diagnoses (κ = 0.3).
Conclusion: Joint enhancement in FOI can be reliably assessed using a predefined scoring method. The ability of FOI to differentiate between hand OA and PsA seems to be limited. Clearer definition and more training might be needed to better agree on morphologic patterns in FOI.

POS1402 HIGHER PREVALENCE OF SUBCLINICAL ATHEROSCLEROSIS IN PSORIATIC ARTHRITIS PATIENTS

S. Lugo-Perez[1], I. J. Colunga-Pedraza[2], D. Á. Galarza-Delgado[2], J. R. Azpiri-López[1], A. B. Rodriguez-Romero[2], N. Guajardo-Jauregui[2], D. E. Flores Alvarado[2], A. Cárdenas[2], A. C. Garza Acosta[3], O. Ilizaliturri Guerra[2], G. García-Arellano[2]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*; *[2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*; *[3]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Radiology, Monterrey, Mexico*

Background: Psoriatic arthritis (PsA) patients have a higher risk of developing a cardiovascular (CV) event than the general population due to an increased prevalence of traditional CV risk factors and to disease characteristics such as disease duration and activity. The carotid ultrasound (US) is a non-invasive diagnostic tool that can detect the presence of subclinical atherosclerosis which is directly associated with the risk of developing a CV event.
Objectives: The aim of this study is to compare the prevalence of subclinical atherosclerosis detected by carotid US in PsA patients and controls.

Methods: This is a cross-sectional, observational, and comparative study. A total of seventy-five PsA patients aged 40-75 years old, who fulfilled the 2006 CASPAR criteria and seventy-five matched controls by age (±5 years), gender and comorbidities were recruited for this study. Patients with history of a previous CV event and pregnant women were excluded from this study. A high-resolution B mode carotid US was performed in all study subjects by a certified radiologist. Subclinical atherosclerosis was defined as the presence of a carotid plaque (CP) or an increased carotid intima media thickness (cIMT). The presence of CP was defined as a cIMT ≥1.2mm or a focal narrowing ≥0.5mm in the surrounding lumen. An increased cIMT was considered as a value ≥0.8mm. Distribution was evaluated with the Kolmogorov-Smirnov test. Comparisons were done with $\chi 2$ test for qualitative variables and Student´s t test and Mann-Whitney's U test for quantitative variables. A *p* value <0.05 was considered statistically significant.

Results: There were no differences when comparing the demographic characteristics between both groups (Table 1). When comparing the carotid US findings, a statistically significant difference was found in the prevalence of CP, which was higher in the PsA group (44.0% vs 26.7%, *p*=0.026), in the presence of unilateral CP (25.3% vs 10.7%, *p*=0.019) and in the presence of subclinical atherosclerosis (52.0% vs 34.7%, *p*=0.032) (Figure 1).

Conclusion: The prevalence of subclinical atherosclerosis was higher in PsA patients than controls, and this could be attributed to an increase in the inflammatory burden of these patients. The carotid US should be considered as part of the CV evaluation in all PsA patients, identifying those who would benefit from an opportune treatment preventing the development of a CV event.

POS1403 RADIOSYNOVECTOMY IN A CLINICAL SETTING: AN UNDEREXPLOITED TOOL AT OUR DISPOSAL

L. R. Caballero Motta[1], A. M. Anzola Alfaro[1], J. Molina Collada[1], I. Janta[1], Y. K. Henao[2], R. Perez Pascual[2], F. J. López-Longo[1], J. M. Alvaro Gracia[1], J. C. Nieto González[1]. [1]*Gregorio Marañón Hospital, Rheumatology, Madrid, Spain*; [2]*Gregorio Marañón Hospital, Nuclear Medicin, Madrid, Spain*

Background: Radiosynovectomy (RS) is a useful for treating inflammatory arthritis that fail conventional treatments. The main isotope used is Yttrium-90 on large joints as knees, whereas Erbium-169 and Renium-186 are more common in small and medium sized joints respectively.

RS is a safe procedure since the isotopes cannot escape the synovial capsule or be absorbed into circulation. It is, however, lethal against cells within the inflamed joint. The most common rheumatic disease treated with RS is rheumatoid arthritis (RA), followed by axial spondyloarthritis (SpA) and idiopathic juvenile arthritis (JIA). It has also been used on persistent synovitis after joint replacements, pigmented villonodular synovitis (PVNS) and undifferentiated arthritis.

Objectives: To describe the experience in RS of a tertiary rheumatology center and compare patients with and without clinical response to treatment in the following 12 months.

Methods: Observational retrospective study between May 31st 2013 and October 31st 2019. We collected demographic variables, data about the disease of the patient, the joints affected, isotope utilized, presence of Baker's cyst, systemic treatment received, need of additional infiltrations (before and after), complications and any changes in medication up to a year after the procedure.

All the RS were performed ambulatory and the radioisotope infiltration was guided by ultrasound, with 40mg of triamcinolone infiltrated after.

SPSS v23 was used for statistical analysis; with Chi2 for qualitative variables and Student's T distribution for quantitative variables.

Results: We evaluated 67 joints in 49 patients in total. All of them were refractory to conventional treatment. 44 patients (65.7%) were women, median of 53.4 years of age (IQ 43.4-67.1).

The median disease duration was 12.5 years and RS seemed to fare better the longer the patient had the disease (median of 13.5 years vs 6.5 years p<0.001).

The joints infiltrated where 46 (68.6%) knees, 14 (20.9%) wrists and 7 (15.2%) elbows. Out of the knees, 16 (34.8%) belonged to RA patients with effective response in 14 (87,5%). 100% of elbows had an effective response, of them 6 (85.7%) had RA. However, even when 9 (64.2%) wrists also had RA as diagnosis, only 3 (21.4%) were effective.

Of the PVNS, 6 out of 8 (75%) had no clinical response, as shown in Table 1.

Table 1. RS response compared to clinical diagnosis.

	TOTAL	EFFECTIVE	INEFFECTIVE	p
	67 (100%)	46 (68.6%)	21 (31.3%)	
Inflammatory Arthritides	52 (77.6)	**39 (75%)**	13 (25%)	<0.0001
(RA + PsA + SpA + sJIA), (%)				
RA (%)	30 (44.7)	**22 (73.3)**	8 (26.6)	<0.001
RA *positive ACPA/FR*	21 (70)	**15 (71.4)**	6 (28.6)	<0.0001
Psoriasic arthritis (PsA) (%)	6 (9)	4 (66.6)	2 (33.3)	0.42
SpA (%)	10 (14.9)	8 (80)	2 (20)	0.45
sJIA (%)	6 (9)	5 (83.3)	1 (16.6)	0.55
PVNS (%)	8 (11.9)	2 (25)	**6 (75)**	<0.001
Inespecific monoarthritis (%)	3 (4.4)	3 (100)	0 (0)	0.23
OA + Calcium Pyrophosphate Deposition (CPPD) (%)	4 (5.9)	2 (50)	2 (50)	0.33

Intra articular corticosteroids were needed before RS, with no differences in effective and ineffective joints; however after RS it was significantly lower in effective joints in the first six months (0% vs 43% p<0.0001) and remained so in the following 6 months (0% vs 19% p<0.0001)Only 13 (28%) patients with effective RS needed to change systemic treatment compared to 10 (43%) of those ineffective (p<0.0001). None of the patients with RS had any complication after the procedure during follow up.

Conclusion: Our study showed that knees were the main joint infiltrated and they had an overall good response to treatment, especially if the diagnosis was RA.

Patients with effective procedures needed leest treatment changes and significantly less corticosteroids infiltrations.

In our study, RS in PVNS was significantly less effective than in inflammatory arthritis (25% vs 75% p<0.0001) and RA seemed to have the best response overall.

Background: Systemic lupus erythematosus (SLE) is a chronic and autoimmune disease characterized by systemic involvement. Patients with SLE have accelerated atherosclerosis, resulting in an up to nine-fold increased risk of cardiovascular disease, compared to the general population (1), being the leading cause of death for these patients. Speckle tracking echocardiography (STE) is an accurate technique to estimate myocardial function and deformation.
Objectives: This study aims to determine the association between echocardiographic findings and the presence of antibodies in SLE patients.
Methods: This was a cross-sectional and observational study. A total of forty-three patients ≥18 years with a diagnosis of SLE according to EULAR/ACR 2019 criteria were included for this study. Those with a history of cardiovascular disease (myocardial infarction, cerebrovascular accident, or peripheral arterial disease) and pregnancy were excluded. Transthoracic echocardiogram was performed and reviewed by 2 board-certified cardiologists, in all study subjects. Blood samples obtained from all patients were analyzed for the following: anti-nuclear antibodies (ANA), anti, SSA/Ro, SSB/La antibodies, anti-cardiolipin antibodies (IgA, IgM, IgG), and complement levels. Distribution was evaluated with the Kolmogorov-Smirnov test. Correlations between numerical variables were done using Spearman's rho, considering two-tailed p-values <0.05 as statistically significant.
Results: The 39 female patients (90.7%) and 4 male patients (9.3%) had a mean age of 35.5 ± 12.0 years and a median disease duration of 72 months (14-132). At the time of inclusion, 90.7% of the patients were being treated with glucocorticoids and antimalarials. Concerning traditional cardiovascular risk factors; 20.9% of the patients had hypertension, 7.0% had dyslipidemia, 2.3% had diabetes mellitus and 18.6% were active smokers. Correlations between echocardiographic findings and antibodies are shown in Table 1. We found a moderate positive correlation between global circumferential strain and IgA anticardiolipin antibody (r=0.507, p=0.002), a low positive correlation in left ventricular ejection fraction with anti-Ro (r=0.397, p=0.012) and anti-La (r=0.397, p=0.012) and a low positive correlation between TAPSE and C3 levels (r=0.396, p=0.013).
Conclusion: There is an association between anticardiolipin antibody titers, anti-Ro, and anti-La with echocardiographic alterations. All SLE patients especially those who had positive antibodies should be screened for the presence of structural cardiac abnormalities. STE can be helpful as a noninvasive diagnostic tool, that could result in earlier treatment and prognosis.

POS1405 OPTICAL SPECTRAL TRANSMISSION (HANDSCAN) IN PATIENTS WITH PSORIATIC ARTHRITIS: FIRST DATA ON DIAGNOSTIC VALUE AND ASSOCIATIONS WITH CLINICAL AND ULTRASOUND DISEASE ACTIVITY MARKERS

K. Triantafyllias[1], S. Liverakos[2], C. Noack[3], A. Schwarting[1,2]. [1]*ACURA Clinics, Rheumatology, Bad Kreuznach, Germany*; [2]*Johannes Gutenberg University Medical Center, Internal Medicine I, Deparmtnet of Rheumatology and Clinical Immunology, Mainz, Germany*; [3]*University of Mannheim, Graduate School of Economics and Social Sciences, Mannheim, Germany*

Background: Valid assessment of disease activity leads to improvement of long-term outcomes in patients with inflammatory arthritis (1). Optical spectral transmission (OST) is a modern diagnostic tool able to assess the blood-specific absorption of light transmitted through a tissue, promising quantification of inflammation in the finger and wrist joints of patients with rheumatoid arthritis (RA) (commercial device: HandScan – Demcon/Hemics, The Netherlands) (2). Even though an increasing number of studies have evaluated diagnostic value of this new technology in RA patients (2,3), no data exist regarding psoriatic arthritis (PsA).
Objectives: To examine for the first time the diagnostic value of OST in detecting inflammation in patients with PsA and to evaluate its relationship with disease activity markers and various epidemiological and anthropometric patient characteristics.
Methods: OST-Measurements were performed in a group of PsA patients and a group of healthy controls. The difference between OST in the two groups was statistically examined and relationships of OST with clinical (tender / swollen joint counts, disease activity on a visual analogue scale) and serological disease activity markers were evaluated. Moreover, joint ultrasound (US) examinations were performed in a subgroup of PsA patients and OST associations with a Power Doppler- and a Grey Scale-US score were examined. Finally, relationships of OST with various anthropometric and epidemiologic parameters (BMI, handsize, gender, age) were assessed.
Results: We recruited 49 PsA patients [65.3% female; mean age 53.3 years (± 11.8 SD)] and 114 control subjects [77.2% female; mean age 46 years (± 12.8 SD)]. OST was statistically significantly higher in the patient group, compared to the control group [14.95 (12.04 - 17.18, IQR) vs. 10.31 (7.84 – 13.79, IQR); p<0.001]. OST correlated moderately-strongly with both examined US scores (Power Doppler-score: r = 0.5; p = 0.026 and Grey Scale-score: r = 0.52; p = 0.028). Moreover, OST showed a moderate, statistically significant association with C-reactive protein (CRP) (r = 0,298; p = 0,037). Finally, males had significantly higher OST values than females and OST associated moderately-weakly with body mass index (BMI) in the control group (rho = 0.24; p< 0.001).
Conclusion: This is the first report of a possible diagnostic value of OST in patients with PsA. OST correlated with ultrasound and serological activity markers and may thus prove to be a useful tool of disease activity assessment, next to well established diagnostic modalities, such as the joint US. Correlations of OST with patient characteristics implicate the need to take also anthropometric and epidemiological patient characteristics into account when interprenting OST results in order to avoid confounding.

POS1406 DEVELOPMENT OF A DIAGNOSTIC ALGORITHM FOR THE DIFFERENTIAL DIAGNOSIS OF INTERSTITIAL LUNG DISEASE: PRELIMINARY DATA FROM A MULTICENTER RETROSPECTIVE CASE-CONTROL STUDY

B. Maranini[1], T. Chiodin[1], C. A. Scirè[1], M. Govoni[1], E. Lucioni[2], S. Chiarello[2], F. Scabbia[2], I. Marchi[3], G. Zanframundo[4], L. Cavagna[4], E. Bellis[4], M. Silva[5], G. Tringali[5], A. Carnevale[2]. [1]*Rheumatology Unit, University of Ferrara and Azienda Ospedaliero-Universitaria S. Anna, Department of Medical Sciences, Ferrara, Italy*; [2]*Radiology Unit, Azienda Ospedaliero-Universitaria S. Anna, Department of Radiology, Ferrara, Italy*; [3]*Pneumology Unit, University of Ferrara and Azienda Ospedaliero-Universitaria S. Anna, Department of Medical Sciences, Ferrara, Italy*; [4]*University and IRCCS Policlinico S. Matteo Foundation of Pavia, Department of Rheumatology, Pavia, Italy*; [5]*Department of Medicine and Surgery (DiMeC), University of Parma, Scienze Radiologiche, Parma, Italy*

Background: Interstitial lung diseases (ILDs) represent a heterogeneous group of disorders with different treatment and prognosis. ILD may be the presenting or

the dominant manifestation of a connective tissue disease (CTD). Multidisciplinary team (MDT) discussion is currently the diagnostic standard. However, there is no consensus on how MDT diagnosis is validated and on the core elements of discussion.

Objectives: To explore the performance of a diagnostic algorithm for the differential diagnosis of ILD based on clinical, serological and radiological data, supporting clinician decision-making.

Methods: In this retrospective study, analysis was performed on clinical, serological and radiological features at diagnosis and 1-year follow-up in 71 patients, including 41 with CTD-ILD and 30 with idiopathic interstitial pneumonias (IIPs). In order to identify robust hallmarks, we conducted the Receiver Operating Characteristic (ROC) curve analyses in logistic regression, to discriminate significantly different features between CTD-ILD and non-CTD-ILD groups.

Results: Out of 71 patients 46% were women, with a mean age of 66±11 years. History of smoking (8.8% current and 39.8% former smokers), was more associated with IIPs. 54% of patients had dyspnea on exertion and 39% dry cough, both more frequently associated with IIPs (p = 0.016). Among radiological features, NSIP pattern was more frequent in CTD-ILD, while UIP was associated with IIP. Lung fibrosis extent was greater in IIP (p = 0.063), in which CT is generally performed in symptomatic patients at diagnosis and rarely for screening purpose. Baseline features with good performance (OR p-value ≤ 0.05) were eligible as potential candidate discriminators: age, sex, smoking habit, rheumatological signs and symptoms, autoantibodies, ILD patterns were selected, to build a multivariate model with high discrimination accuracy (AUC 0.971). The model has a sensitivity of 100% and specificity of 89.7%. The most relevant correlations between population features and CTD-ILD are presented in Table 1.

Table 1. Correlation analysis of the most significant discriminative features.

Features	Odds ratio	P value	Area under ROC curve
Sex (female)	3.29	0.019*	0.643
Age	0.91	0.001*	0.736
Smoke	0.12	<0.001*	0.738
Respiratory symptoms (dyspnea and/or dry cough)	0.26	0.016*	0.644
Rheumatological symptoms (any)	28.8	<0.001*	0.839
• Raynaud's phenomenon	15.04	0.011	0.654
• Cutaneous manifestations	8.16	0.053	0.593
Autoantibodies (ANA, ENA, RF, ACPA, myositis-specific antibodies or aPL) positivity	33.68	<0.001*	0.792
Lung function test			
• Forced vital capacity (%FVC)	0.97	0.175	0.638
• Diffusing capacity of carbon monoxide (%DLCO)	0.96	0.072	0.665
High-resolution computed tomography (HRCT) imaging			
• Honeycombing	0.34	0.068	0.593
• Emphysema	0.14	0.005*	0.647
• Extent of lung involvement (%)	0.97	0.063	0.668
HRCT pattern			
• NSIP vs UIP	3	0.033*	0.625

Abbreviations: ANA, antinuclear antibody; ENA, extractable nuclear antigen; RF, rheumatoid factor; ACPA, anti-citrullinated peptide antibody; aPL, antiphospholipid antibody; NSIP, non-specific interstitial pneumonia; UIP, usual interstitial pneumonia.

Conclusion: Our study shows that the most important variables in the differential diagnosis between CTD-ILD versus IIPs include, as expected, autoimmune features (rheumatological symptoms and serological data). Questionnaire tool containing these specific hallmarks may be relevant during MDT discussion, limiting the number of misdiagnosed CTD-ILDs and potentially avoiding further unnecessary investigations. However, only prospective cohort studies of early onset ILD are needed to fully validate the relative importance of clinical, serological, functional and radiological data.

Background: The prevalence of inflammatory bowel disease (IBD) in ankylosing spondylitis (AS) has been reported to range between 6%-15%. As occurs with axial spondyloarthrtitis (axSpA), patients with IBD have an increased risk of cardiovascular (CV) events because of a process of accelerated atherosclerosis[1]. However, it is unknown whether the presence of IBD confers an increased cardiovascular CV risk in patients with axSpA.

Objectives: To compare the atherosclerotic burden, CV events, CV risk factors and disease related factors including structural damage in axSpA patients with and without IBD.

Methods: Cross-sectional analysis of the AtheSpAin cohort, a Spanish multicenter cohort designed for the study of atherosclerosis in axSpA, comparing axSpA patients with and without concomitant IBD. Background information on CV and disease-related factors was reviewed. Data on CV risk and disease status at the time of the study were also obtained, including the structural damage assessed by the presence of syndesmophytes, the severity of the sacroiliitis (defined as grade 3 or 4 according to New York criteria), and the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Carotid ultrasound (US) was performed in all patients at the time of the study, including measurement of carotid intima-media wall thickness (cIMT) and plaque detection according to the Mannhein consensus criteria.

Results: A set of 886 axSpA patients were included. 829 (93.6%) of them had no concomitant IBD, which was present in 57 (6.4%) patients. Age, sex and AS/nr-axSpA ratio were comparable in both groups (Table 1. next page). Patients with IBD were characterised by a lower prevalence of HLA B27 (46% vs 72%, p=0.01) and a higher presence of concomitant psoriasis (21% vs 10%, p=0.01) Regarding peripheral disease (history of synovitis, enthesitis, dactylitis) and hip involvement, no differences were found between both groups. There were either no differences in the structural damage found in patients with and without IBD (Table 1. next page). With respect to the management of the disease, prednisone (21% vs 13%, p = 0.03), DMARDs (54% vs 35%, p = 0.01) and anti-TNFα therapy (54% vs 31%, p = 0.00) were more commonly used in the group with IBD, while treatment with NSAIDs was more frequent in patients without IBD (81% vs 70%, p = 0.04). Regarding CV risk features, smoking was more frequent in patients without IBD (34% vs 21%, p = 0.045) (Table 1. next page). No differences were observed neither in the lipid profile or blood pressure at the time of the study, nor in the prevalence of CV events (5% vs 4%, p=0.99) (Table 1) and the subclinical atherogenic burden assessed both by the presence of carotid plaques (31% vs 37%, p=0.45) and the cIMT (645 ± 147 mm vs 636 ± 112 mm, p = 0.64) (Table 1. next page).

Conclusion: The presence of IBD does not confer additional CV risk to axSpA. In our series, patients with axSpA and IBD showed a lower frequency of HLA B27 and a higher prevalence of psoriasis.

Table 1.

	axSpA without IBD (n=829)	axSpA with IBD (n=57)	p

Background: Nailfold Capillaroscopy is a simple, inexpensive and non-invasive technique that allows microvascular damage to be observed, gaining recent importance in the diagnosis, monitoring and prognosis of many diseases with microangiopathy. However, the variability in the results interpretation has led to the development of new computerized systems that allow the automatic analysis of capillaroscopic images.

Objectives: to compare the degree of agreement between the automatic system Capillary.io and a gold standard obtained from the agreement of 9 expert capillaroscopists and to know the degree of the interobserver reliability To demonstrate the validity of the system to detect normal and enlarged capillaries, hemorrhages, megacapillaries, ramifications and tortuosities.

Methods: a cross-sectional study was performed in which 300 random and anonymous nailfold capillaroscopic images (1165 capillaries) were analyzed by 9 experienced observers. The degree of interobserver agreement was calculated from the 5 users. Likewise, the system performed an automatic assessment of the images and their agreement with the gold standard was calculated (interobserver agreement greater than 5, 6, 7, 8 and 9 successively). The validity of the program for each variable was also analyzed using sensitivity and specificity, positive and negative predictive values, and likelihood ratios, as well as their degree of agreement using the weighted kappa statistic (95% CI, p <0.05). The programs used for statistical calculations were SPSS 22.0 and EPIDAT 3.0.

Results: the degree of interobserver agreement was 76.5% for the agreement of 5 or more observers, progressively decreasing to 15.4% for the 9 observers. Capillary.io obtained higher levels of agreement, reaching 97.7% for the 9 observers. Statistically significant results were obtained in the automated detection of all the morphological alterations analyzed Capillary.io presented a sensitivity (S) of 79.82% and a specificity (E) of 82% in the recognition of normal capillaries. The automatized system was able to recognize enlarged capillaries with a sensitivity of 86.97% and a specificity of 81.38%. Megacapillaries were detected with 89.41% sensitivity and 78.75% specificity. Similarly, the system was able to detect tortuosities (S 66.94%; E 67.71%), ramifications (S 54.34%; E 58.61%) and hemorrhages (S 71.36; E 73.97%).

Conclusion: Capillary.io demonstrated a high degree of agreement with the gold standard, stronger with greater consensus among observers. It was able to detect with great sensitivity and specificity hemorrhages and megacapillaries, very relevant alterations in microangiopathies.

Background: A nailfold capillaroscopy procedure is a non-invasive, low-cost, and well-established examination that can be used to diagnose several rheumatic autoimmune diseases and support the necessary follow-up of patients. While the clinical implications of the technique are known, a rigorous and in-depth examination of nailfold capillaries remains as one of the major challenges to produce new advances in research and diagnosis, due to practical limitations for analysing the whole nailfold area of each patient. The difference between the different patterns established by Maricq and Cutolo makes it possible to predict the evolution that the patient will present. We introduce Capillary.io, an automatic image reading system able to recognize capillaries in images obtained with any microscope, generate automatic measurements of each capillary and take advantage of this information to report capillary morphology and patterns.

Objectives: to determine the ability to detect active and early sclerodermiform patterns of Capillary.io.

Methods: Forty-nine complete capillaroscopies, reported by expert capillaroscopists according to the different patterns manually (gold standard), were compared with the pattern detection capability of Capillary.io. A scoring system based on the algorithm of the Spanish Capillaroscopy Study Group (GREC) was performed and interpreted by capillary.io for the global interpretation of each of the capillaroscopies analyzed.
Results: Overall, 37 of the 49 capillaroscopies reported agreed with the diagnosed pattern (75.51%). Separately, the early pattern presented a concordance of 77.27% and the active pattern of 74.07%. In reference to the findings detected by the Capillary.io system, the mean overall density was 5.01 capillaries/mm in the group with the active pattern compared to 6.46 capillaries/mm in the early pattern. The density of dilations and megacapillaries was 2.81/mm and 1.21/mm in the active pattern group versus 4.69/mm and 0.4/mm in the early pattern group. Global diameters were greater in the active pattern group with an apical mean of 37.3 μm compared to 28.5 μm in the early pattern subgroup.
Conclusion: Capillary.io is a simple, easy-to-learn web system for interpreting capillaroscopic images of nail folds. It can be a very useful tool to standardize the interpretation of capillaroscopic images, not only individually for each capillary, but also jointly through the detection of different patterns.

POS1410

FLUORESCENCE OPTICAL IMAGING (FOI) DETECTS SUBCLINICAL INFLAMMATION IN HANDS OF PATIENTS DIAGNOSED WITH FIBROMYALGIA SYNDROME AND OTHER RHEUMATIC DISEASES

P. Welker[1], J. Ferl[2], S. Ohrndorf[3], A. Briel[4], V. Failli[5]. [1]*Charité, Functional Anatomy, Berlin, Germany*; [2]*Medical Faculty University Hospital Magdeburg, Clinical Chemistry and Pathobiochemistry, Magdeburg, Germany*; [3]*Charité, Rheumatology and Clinical Imunology, Berlin, Germany*; [4]*nanoPET GmbH, Pharma, Berlin, Germany*; [5]*Xiralite, GmbH, Berlin, Germany*

Background: Myalgias are a common symptom of infections and diseases of the rheumatic type but can also occur in the case of physical overstress or as an undesirable drug side effect. Anamnesis, clinical examination and determination of specific laboratory parameters are usually helpful for diagnosis, but do not always lead to correct results. Particularly, differentiation between the diagnoses of fibromyalgia syndrome (FMS), polymyalgia rheumatica (PMR), and other myalgic diseases of the rheumatic type is often difficult. FOI are playing an increasingly role as quantifiable and sensitive diagnostic imaging methods. After injecting a fluorescent dye, the signal intensity enables visualization of the microcirculation. This can be used for the differential diagnosis of inflammatory, degenerative, muscular and connective tissue-associated diseases.
Objectives: The present work investigates the potential of this method for the detection of subclinical inflammatory processes to differentiate between FMS and various rheumatic diseases which are accompanied by myalgia.
Methods: Analyses of subjects without clinical symptoms (n = 59) were compared with patients with a clinical diagnosis of FMS (n = 63), PMR (n = 5), or polymyalgia as a consequence of other diseases (PM, n = 6), Sjogren's syndrome (SS, n = 20), and erosive rheumatoid arthritis (RA, n = 162). The FMS patients were stratified according to primary (n = 31) and secondary (n = 32) pathology. FOI signal intensity (SI) was defined by ratio of areas with SI in patients and controls. Clinical and FOI examinations were carried out under the conditions of standard outpatient rheumatological care. The laboratory parameters were created in certified medical laboratories.
Results: Only 21% of all patients diagnosed with FMS are seropositive for rheumatic factors. Secondary FMS have higher values than primary FMS (26 versus 13%). In contrast, 79% of the patients with RA, 75% of the SS patients, and 100% of the patients with PMR are seropositive. On average, both the CRP values and the ESR of FMS patients were in the normal range, whereas in the other cohort the mean values were significantly increased. X-ray examinations showed erosions in all patients with RA and in 80% with PMR, whereas this was only the case in less than 15% of FMS and SS patients. However, in nearly 80% of patients both with primary and secondary FMS, increased SI value as a sign of inflammation could be detected by FOI. While in patients with RA or PMR an accumulation of the dye in the metacarpophalangeal joints can be detected in an early phase of the FOI examination, in the FMS or SS patients signal increases can be detected in the later phases in the area of connective tissue, tendons and muscles (Figure 1).
Conclusion: The examination with FOI gives more precise information on the localization and extent of an inflammation in the hands and can thus make an important contribution to differential diagnosis and optimization of therapy. The present work demonstrates a high potential in the detection and localization of subclinical inflammatory processes which cannot be detected in FMS patients with other methods, often leading to a psychosomatic diagnosis. In future, there will a requirement for diagnostic technologies that can be used widely and are suitable for interlinking therapy with diagnostics more closely than before.

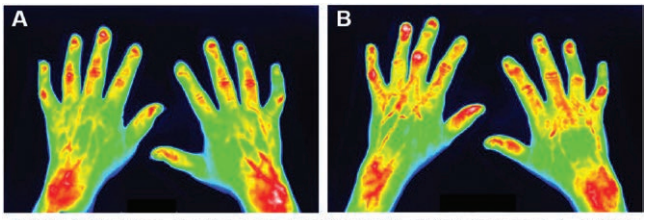

Figure 1: Examples of FOI images in patients with clinical diagnosed: A. primary FMS or, B. secondary FMS as an accompanying syndrome of RA. Analysis of intermediate/late phase (P2/3) of fluorescence dye (indocyanine green) distribution.

POS1411 EARLY IDENTIFICATION OF AXIAL SPONDYLOARTHRITIS IN A MULTI-ETHNIC ASIAN POPULATION

L. Xiang[1,2], W. Fong[1,2,3], A. Low[1,2,3], Y. Y. Leung[1,2,3], M. Gandhi[4,5,6], X. Xin[7], E. Uy[1], L. Hamilton[8], J. Thumboo[1,2,3]. *[1]Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore*; *[2]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore*; *[3]Duke-NUS Medical School, NA, Singapore, Singapore*; *[4]Duke-NUS Medical School, Centre for Quantitative Medicine, Singapore, Singapore*; *[5]Singapore Clinical Research Institute, Biostatistics, Singapore, Singapore*; *[6]Tampere University, The Center for Child Health Research, Tampere, Finland*; *[7]Singapore General Hospital, Academic Clinical Program for Medicine, Singapore, Singapore*; *[8]Norfolk and Norwich University Hospitals NHS Foundation Trust, Department of Rheumatology, Norforlk, United Kingdom*

Background: To facilitate earlier diagnosis of spondyloarthritis (SpA), we have previously cross-culturally adapted a self-administered screening questionnaire.
Objectives: We aimed to improve the sensitivity of this questionnaire as a screening tool by comparing various scoring methods.
Methods: Subjects newly referred to a rheumatology clinic self-administered the questionnaire before seeing a rheumatologist. Identification of axial SpA by the questionnaire using original scoring (Method A) and scoring based on Assessment of SpondyloArthritis International Society (ASAS) inflammatory back pain (IBP) criteria (Method B), ASAS referral criteria (Method C), ASAS classification criteria (Method D) and a combination of ASAS referral and classification criteria (Method E) were compared to classification by the ASAS classification criteria and diagnosis by rheumatologist. Since Methods B-E were based on SpA features, we compared self-reported vs rheumatologist-documented features in subjects with axial SpA.
Results: Of 1418 subjects (age: 54 ± 14 years, female: 73%), 39 were classified as axial SpA cases by classification criteria. Methods A-E yielded sensitivities of 39%, 72%, 67%, 49% and 85%, respectively, among patients newly referred to the rheumatology clinic (Table 1). Rheumatologist-documented clinical SpA features exceeded self-report for IBP (62 vs 44%) and uveitis (15 vs 5%). The reverse was true for arthritis (21 vs 80%), enthesitis (28 vs 33%), dactylitis (3 vs 18%), good response to NSAIDs (33 vs 41%) and family history for SpA (5 vs 10%).

Table 1. Performance of the five scoring methods for the cross-culturally adapted Hamilton axial SpA questionnaire.

Scoring method	Sensitivity (95% confidence interval)	Specificity (95% confidence interval)	Positive predictive value (95% confidence interval)	Negative predictive value (95% confidence interval)
Method A	38.5	93.7	14.7	98.2
	(23.4 – 55.4)	(92.3 – 94.9)	(8.5 – 23.1)	(97.3 – 98.8)
Method B	71.8	73.1	7.0	98.9
	(55.1 – 85.0)	(70.7 – 75.4)	(4.7 – 10.0)	(98.1 – 99.5)
Method C	66.7	77.8	7.8	98.8
	(49.8 – 80.9)	(75.5 – 80.0)	(5.2 – 11.3)	(98.0 – 99.4)
Method D	48.7	74.9	5.2	98.1
	(32.4 – 65.2)	(72.5 – 77.2)	(3.2 – 8.0)	(97.1 – 98.8)
Method E	84.6	37.2	3.7	98.8
	(69.5 – 94.1)	(34.6 – 39.8)	(2.5 – 5.1)	(97.5 – 99.6)

Method A: the original scoring defined by the questionnaire developers; Method B: a scoring based on the ASAS IBP criteria; Method C: a scoring based on the ASAS referral criteria; Method D: a scoring based on the ASAS classification criteria for axial and peripheral SpA; Method E: a scoring based on a combination of the ASAS referral and classification criteria.

Conclusion: A self-administered questionnaire scored based on a combination of ASAS referral and classification criteria achieved high sensitivity in identifying axial SpA in subjects referred to a rheumatology clinic. This supports its evaluation as a screening tool for axial SpA in the general population.

POS1412 IDENTIFYING HIGH-COST DRUGS FOR RARE RHEUMATIC DISEASES IN ROUTINELY COLLECTED NHS DATA. RESULTS FROM A PILOT STUDY OF RITUXIMAB USE IN VASCULITIS USING DATA FROM THE NATIONAL DISEASE REGISTRATION SERVICE AND THE REGISTRATION OF COMPLEX RARE DISEASES-EXEMPLARS IN RHEUMATOLOGY (RECORDER) PROJECT

C. Godsave[1], M. Chakravorty[2], M. Rutter[2,3,4], P. Lanyon[2,3,4,5], J. Aston[4], M. Bythell[4], S. Stevens[4], F. Pearce[2,3,4,5]. *[1]Royal Derby Hospital, Rheumatology, Derby, United Kingdom*; *[2]Nottingham University Hospitals NHS Trust, Rheumatology, Nottingham, United Kingdom*; *[3]University of Nottingham, Division of Epidemiology and Public Health, Nottingham, United Kingdom*; *[4]Public Health England, National Congenital Anomaly and Rare Disease Registration Service, London, United Kingdom*; *[5]National Institute for Health Research (NIHR), Nottingham Biomedical Research Centre, Nottingham, United Kingdom*

Background: Understanding real-world usage of high-cost drugs is crucial to support planning, adoption of innovation and reduce unwarranted variation in treatment. Hospital Episode Statistics (HES) contain diagnoses (coded by ICD-10) and procedures/treatments (coded by OPCS) for all daycase or inpatient care in England. However, OPCS codes are not specific for individual drugs, for example X921 (cytokine inhibitors band 1) includes rituximab (RTX) and 15 other drugs.
Objectives: We aimed to validate the accurate identification of patients treated with RTX for ANCA-associated vasculitis (AAV) using HES data.
Methods: We used data from the National Congenital Anomaly and Rare Disease Registration Service (NCARDRS) at Public Health England and their legal permissions (CAG 10-02(d)/2015). We extracted records from HES of all patients treated at two hospitals during financial year 2018/19 who ever had a coded diagnosis of granulomatosis with polyangiitis (GPA, M313), eosinophilic granulomatosis with polyangiitis (EGPA, M301), microscopic polyangiitis (MPA, M317), polyarteritis nodosa (PAN, M300) or arteritis unspecified (I776). Where people had multiple diagnoses of vasculitis, the most specific was considered their diagnosis. Enabled by data sharing agreements, we reviewed hospital records of those patients to validate diagnoses and whether X921 reliably identified RTX. We report the positive predictive value and sensitivity of the coding for X921 and GPA/EGPA/MPA for identifying people with AAV who are treated with RTX.
Results: At Trust 1 records ever coded with GPA/EGPA/MPA identified 74 people, 69 of whom had AAV confirmed in their medical notes. Among these 74 patients there were 59 episodes coded with X921 procedure codes, of which 56 correctly identified a RTX infusion given for AAV. A total of 64 RTX infusions were given to people with AAV – 3 missed infusions were X921 procedures in patients who had coded diagnoses of PAN or I776 but never GPA/EGPA/MPA and 5 infusions were not coded as X921.
The same analysis at Trust 2 identified 46 people, 44 of whom had AAV confirmed in their medical notes. Among patients identified with AAV there were 17 episodes coded as X921, of which 15 correctly identified a RTX infusion. A total of 23 infusions were given to people with AAV: 4 infusions were X921 procedures in patients who had coded diagnoses of PAN or I776 but never GPA/EGPA/MPA, and 4 infusions were not coded as X921.

Table 1. Summary of Positive Predictive Values (PPV) applying our algorithm to identify AAV diagnoses and RTX use

	Trust 1	Trust 2	Combined
Diagnosis of AAV and coded as AAV	69	44	113
AAV coded	74	46	120
Diagnosis of AAV under any code	73	55	128
PPV AAV ascertainment (95% CI)	93.2% (84.9-97.8)	95.7% (85.2-99.5)	94.2% (88.4-97.6)
Sensitivity of AAV ascertainment (95% CI)	94.5% (86.8-98.5)	80.0% (67.0-89.6)	88.3% (81.4-93.3)
RTX given in people coded as AAV	56	15	71
RTX coded in people coded as AAV	59	17	76
RTX given for AAV under any diagnostic or procedure code	64	23	87
PPV RTX ascertainment (95% CI)	94.9% (85.9-98.9)	88.2% (63.6-98.5)	93.4% (85.3-97.8)
Sensitivity of RTX ascertainment (95% CI)	87.5% (76.8-94.4)	65.2% (42.7-83.6)	81.6% (71.9-89.1)

Conclusion: HES data identified patients treated with RTX for AAV with a PPV of 93.4% (85.3-97.8) and sensitivity of 81.6% (71.9-89.1). This demonstrates the utility of national data to identify people receiving RTX for AAV. The RECORDER project, within the National Disease Registration Service plans to conduct real-world studies of the high-cost drug RTX, given for AAV, across the whole of England, and assess whether geography, demographics or socioeconomic factors influence frequency of prescription of this, and potentially other, high-cost drugs in line with the NHS long term plan.

POS1413 INTERVAL BETWEEN SYMPTOM ONSET AND DIAGNOSIS AMONG PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES IN A MULTI-ETHNIC ASIAN POPULATION

L. Xiang[1,2], A. Low[1,2,3], Y. Y. Leung[1,2,3], W. Fong[1,2,3], M. Gandhi[3,4], S. Yoon[3], T. C. Lau[2,5], D. R. Koh[2,5], J. Thumboo[1,2,3]. [1]*Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore*; [2]*National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore*; [3]*Duke-NUS Medical School, NA, Singapore, Singapore*; [4]*Singapore Clinical Research Institute, Biostatistics, Singapore, Singapore*; [5]*National University Hospital, Department of Medicine, Singapore, Singapore*

Background: The interval between symptom onset and diagnosis can often be longer than is ideal in autoimmune rheumatic diseases (ARDs).

Objectives: We aimed to characterise this interval among patients newly diagnosed with ARDs in a multi-ethnic Asian population and to identify factors associated with a longer interval.

Methods: We used Scott's model of pathways to treatment to characterise the interval between symptom onset and diagnosis into 4 intervals: #1 between symptom onset and first seeking medical attention, #2 between first medical attention and rheumatology referral, #3 between rheumatology referral and first rheumatology assessment, and #4 between first rheumatology assessment and diagnosis. Linear regression models were used to identify factors associated with a longer the overall interval between symptom onset and diagnosis and Interval #1.

Results: Among 259 patients (age: 51±15 years, female: 71%, most common three ARDs: rheumatoid arthritis (n = 75), axial spondyloarthritis (n = 40) and psoriatic arthritis (n = 35)), the median overall interval was 11.5 months. Interval #1 (median = 4.9 months) was significantly longer than the other intervals (Table 1). Patients with axial spondyloarthritis had a significantly longer overall interval (median = 38.7 months) and Interval #1 (median = 26.6 months) compared to patients with RA (median = 7.6 and 3.5 months, respectively), PsA (median = 7.0 and 2.6 months, respectively) and the other ARDs. Gender was the only patient-related factor significantly associated with the overall interval (reference = male, coefficient = -15.3, p = 0.033) in regression models.

Conclusion: A longer than ideal interval between symptom onset and diagnosis was observed among patients with ARDs. This was primarily due to a relatively long interval between symptom onset and first seeking medical attention, and highlights the importance of interventions targeting patients prior to first medical attention in reducing the duration between symptom onset and diagnosis.

POS1414 RHEUMATOID ARTHRITIS AND INTERSTITIAL LUNG DISEASE: PREVALENCE AND DRUG PRESCRIPTIONS IN GERMAN CLAIMS DATA

K. Albrecht[1], A. Strangfeld[1], U. Marschall[2], J. Callhoff[1]. [1]*German Rheumatism Research Centre, Epidemiology, Berlin, Germany*; [2]*BARMER Institute for Health System Research, Department Medicine and Health Services Research, Berlin, Germany*

Background: Persons with rheumatoid arthritis (RA) have an increased risk of interstitial lung disease (ILD). ILD is a serious extraarticular manifestation in RA with a significantly increased mortality but without evidence-based drug therapy (1).

Objectives: The aim of this analysis was to investigate the frequency of ILD diagnosis in RA using claims data and to identify the medications prescribed.

Methods: Data from a large German statutory health insurance fund were used to identify persons with one inpatient or two outpatient diagnoses of RA (ICD-10: M05, M06) and ILD (J84.1, J84.8, J84.9 and M05.1+J99.0) in 2019. Specialist care by rheumatologists and/or pulmonologists was identified using physician specialty numbers. Drug prescriptions of glucocorticoids, conventional synthetic disease modifying antirheumatic drugs (csDMARDs: methotrexate, leflunomide, sulfasalazine, hydroxychloroquine, mycophenolate), biologic (b) DMARDs (abatacept, rituximab, TNF inhibitors, tocilizumab) or targeted synthetic (ts) DMARDs (tofacitinib) were identified by ATC codes. Prescriptions were included if a person received at least one prescription of the respective drug in 2019.

Results: Among 7,479,000 persons over 18 years of age and insured in 2019 a total of 2.0% (n=148,000) had a diagnosis of RA and 1.1% (n=1,600) of those had an additional diagnosis of ILD. The majority of persons with RA+ILD

diagnosis was older than 70 years (59%), mean age was 72 years, 68% were female and 41% had a diagnosis of serpositive RA (M05). 4 out of 5 patients were in rheumatologist or pulmonologist care (36% both, 22% only rheumatologist, 22% only pulmonologist). In total, 67% received glucocorticoids, 49% csDMARDs and 19% bDMARDs and 1.8% tofacitinib. TNF inhibitors were the most frequently prescribed bDMARDs followed by abatacept and tocilizumab. Persons without specialized care received considerably less DMARD therapy (Table 1). Nintedanib was prescribed to 14 patients, pirfenidon to 10 patients, all of them were in specialist care.

Table 1. Demographics and treatment of persons with RA and ILD diagnosis, numbers are percentages unless indicated otherwise.

Variable	Not treated by rheumatologist or pulmonologist	Treated by rheumatologist and/or pulmonologist	All
N (%)	326 (20%)	1274 (80%)	1,600 (100%)
Age, mean years (std)	75 (10)	72 (10)	72 (10)
<70 years	35	43	41
70 to 80 years	31	39	37
>80 years	35	18	22
Female sex	67	69	68
Glucocorticoids	49	72	67
csDMARDs	**24**	**56**	**49**
MTX	13	30	27
Leflunomide	4.9	10	8.9
(Hydroxy-)chloroquine	2.8	9.0	7.8
Mycophenolate	1.2	2.2	2.0
Sulfasalazine	2.1	3.8	3.4
bDMARDs	**7**	**22**	**19**
TNF-alpha Inhibitors	3.4	9.0	7.9
Abatacept	2.1	5.6	4.9
Tocilizumab	1.2	3.6	3.1
Rituximab	0.9	2.9	2.5
Tofacitinib	1.5	1.9	1.8

Conclusion: ILD was diagnosed in one of 100 persons with RA diagnosis. Specialist care is necessary to provide disease-specific therapies. While methotrexate is the most commonly used DMARD, the bDMARD prescription is heterogeneous.

POS1415 SOCIO-ECONOMIC IMPACT OF SJÖGREN'S SYNDROME IN WESTERN SWITZERLAND: A CROSS-SECTIONAL STUDY

K. Cunha Rodrigues[1], A. Grosjean[2], T. Hügle[1], A. Dumusc[1]. *[1]University Hospital Lausanne, Rheumatology, Lausanne, Switzerland*; *[2]Sjögren's Patients Association for Western Switzerland, (ARSYS), Vevey, Switzerland*

Background: Several studies investigated the socio-economic impact of Sjögren's syndrome (SS) showing an increased risk of work disability and a reduced health-related quality of life. SS is also associated with increased direct and indirect healthcare costs. There are no published data about Switzerland, a country with high resources and easy access to healthcare except dental care, which is rarely reimbursed.

Objectives: To evaluate the professional and economic impact of SS in patients living in Western Switzerland.

Methods: Cross-sectional survey-based study conducted in December 2020, during the pandemic. Patients suffering from SS and living in Western Switzerland (Geneva and Lausanne region) were invited by the regional association of patients with SS to complete a survey assessing the socio-economic impact of SS.

Results: Among the 86 patients who were contacted, 55 (64%) completed the survey. Participants were predominantly female (95%) with a mean (SD) age of 54.2 (12.3). Mean (SD) EULAR SS Patient Reported Index (ESSPRI) was 6.5 (1.6), assessing pain, fatigue and dryness.

In the working age population (under 65, n=39), 64% of the participants reported to be employed, 88% of whom working part-time. They reported to work 23.3 (10.1) hours per week (mean, SD). 60% reported SS-related work incapacity periods during the past year. 72% of participants had to reduce their working hours and 27% had to change careers due to their medical condition. 16% benefited from an adaptation of their workstation to their health status.

In terms of work disability, 27% of the participants depended on disability insurance pension, of whom 38% received a full pension. 16% of the participants applied for a disability pension and were waiting for an administrative decision. A minority of participants (11%) reported to receive a minimum subsistence allowance from the local social service.

Participants estimated to pay 2752 CHF (3000) per year (median, IQR) out of their own pocket (Swiss monthly median wage: 6500 CHF) for health care not covered by health insurances. 95% of the patients had to pay for dental medicine costs, at least partially. Public health insurance contributed to dental costs for 44% of the patients and private health insurance for 28% of them. 22% of the patients reported to limit dental care for financial reasons.

Conclusion: Two-thirds of the patients with SS remained in active employment, but the majority of them working in part-time, with a substantial loss of income. One third of the patients are work disabled and depend on a disability pension. Dental care was not reimbursed in half of the patients by their health insurance, leading to dental care access restriction for 20% of the patients with SS. Despite a relatively high wage level in Switzerland, SS represents a substantial financial burden for most of the patients.

POS1416 THE IMPACT OF NON-PERSISTENCE ON RESOURCE UTILIZATION COSTS IN IMMUNE-MEDIATED RHEUMATIC DISEASES

N. Carballo[1], E. Garcia-Alzorriz Morral[2], O. Ferrández-Quirante[1], C. Perez-Garcia[3], M. E. Navarrete-Rouco[1], X. Duran[4], J. Monfort[3], F. Cots[2], S. Grau[1]. *[1]Hospital del Mar, Pharmacy Department, Barcelona, Spain*; *[2]Hospital del Mar, Management Control Department, Barcelona, Spain*; *[3]Hospital del Mar, Rheumatology Department, Barcelona, Spain*; *[4] Institute Hospital del Mar for Medical Research (IMIM), Methodology and Biostatistics Support Unit, Barcelona, Spain*

Background: Rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) are chronic progressive immune-mediated rheumatic diseases (IMRD) that can cause a progressive disability and joint deformation and thus can impact in healthcare resource utilization (HCRU) and costs.

Objectives: To describe the HCRU and treatment costs in IMRD patients initiating subcutaneous tumour necrosis factor-alpha inhibitors (SC-TNFi) therapy, based on treatment persistence.

Methods: Retrospective cohort study including all naïve patients initiating SC-TNFi therapy for IMRD from 2015-2018 in a tertiary university hospital.

Patients were divided into two cohorts: persistent and non-persistent. Treatment persistence was estimated as the duration of time from SC-TNFi therapy initiation to discontinuation during one year of follow-up.

SC-TNFi therapy and HCRU costs (outpatient care, rheumatology specialized outpatient care, inpatient care, emergency care, laboratory testing and other non- biological therapies) were calculated one year before and after initiation of SC-TNFi and compared between persistence and non-persistence groups.

Results: 110 patients were identified.

Baseline characteristics: Non-persistent cohort (n=25) versus Persistent cohort (n=85): median age 48.6(12.7) vs 47.3(15.4) (p=0.692). Female (n=12;48%) vs (n=49;57.6%) (p=0.493). Race: Caucasian (n=22;88%), Asiatic (n=3;12%), Other (n=0;0%) vs Caucasian (n=75;88.2%), Asiatic (n=5;5.9%), Other (n=5;5.9%) (p=0.351).IMRD: RA (n=14;56%),PsA (n=2;8%), AS (n=4;16%), other spondyloarthropathy (n=5;20%) vs RA (n=34;40%),PsA (n=11;12.9%), AS (n=24;28.3%), other spondyloarthropathy (n=16;18.8%) (p=0.470). SC-TNFi therapy: adalimumab (n=4;16%), etanercept commercial (n=4;16%), etanercept biosimilar1 (n=5;20%), etanercept biosimilar2 (n=5;20%), golimumab (n=5;20%), certolizumab (n=2;8%) vs adalimumab (n=22;25.9%), etanercept commercial (n=11;12.9%), etanercept biosimilar1 (n=7;8.3%), etanercept biosimilar2 (n=10;11.8%), golimumab (n=24;28.2%), certolizumab (n=11;12.9%) (p=0.398).

Overall cost of SC-TNFi treatment: Non-persistent 11218.81€ (6444.32), persistent 10470.19€ (3465.48); p= 0.658.

Table 1. HCRU costs

	Non-persistent(n=25)	Persistent(n=85)	Total(n=110)	P
HCRU costs 12 months prior to SC-TNFi initiation,€(SD)				
Outpatient care	243.48(828.86)	87.17(293.61)	122.70(471.20)	0.204
Rheumatology outpatient care	216.39(169.88)	174.79(101.06)	184.24(120.55)	0.224
Inpatient care	500.41(1542.93)	170.34(846.47)	245.36(1046.74)	0.571
Emergency care	37.77(66.00)	39.30(83.16)	38.95(79.31)	0.850
Laboratory testing	376.12(195.59)	388.20(207.07)	385.46(203.70)	0.458
Other non-biological therapies	10.77(39.83)	36.79(250.55)	30.88(221.01)	0.803
Total	1384.94(1816.17)	896.60(1247.60)	1007.59(1402.87)	0.299
HCRU costs 12 months post SC-TNFi initiation,€(SD)				
Outpatient care	106.11 (172.85)	76.67 (112.90)	83.36 (128.67)	0.682
Rheumatology outpatient care	327.29(170.10)	195.58(100.05)	225.52(130.99)	**<0.001**
Inpatient care	89.35(446.77)	80.86(466.54)	82.79(460.11)	0.969
Emergency care	89.14(171.89)	36.06(106.23)	48.12(125.31)	0.198
Laboratory testing	182.14(128.62)	146.86(141.48)	154.88(138.89)	0.061
Other non-biological therapies	3859.80(4043.86)	25.89(116.05)	897.24(2493.21)	**<0.001**
Total	4653.84(4269.61)	561.93(682.14)	1491.91(2709.23)	**<0.001**

Conclusion: - Non-persistence was observed in less than a quarter of the patients.
- No differences in the costs of SC-TNFi treatment were observed between the persistent and non-persistent groups, leading us to believe that persistence may not be associated with SC-TNFi costs offsets for patients with IMRD.
- During the period post SC-TNFi initiation, the costs of rheumatologic outpatient care and treatment with other non-biological therapies as well as total costs were statistically significantly lower in the persistent cohort. These results suggest that persistence may be associated with HCRU cost savings for IMRD patients.

Background:
Objectives: The aim of this study was to estimate the annual direct cost of biologics in rheumatoid arthritis and to evaluate the impact of social factors on biological use and costs.
Methods: Patients in the Moroccan register of biologicals (RBSMR) with available 1-year data were included. Variables related to socio-economic status, disease and biological were collected. Direct costs included prices of biologics, costs of infusions, and subcutaneous injections. Biological use and costs were compared based on social factors.
Results: Our study included 197 patients (female sex of 86.8%, mean age of 52.3 ± 11 years). Patients were on one of the following therapies: Rituximab (n=132), Tocilizumab (n=37) or TNF-blockers (n=28). 44.2% of included patients have the RAMED medical assistance (health insurance scheme for the economically underprivileged). Illiteracy was noted in 45.7% of cases. Median one-year direct costs per patient were €1,665 [€1,472 - €9,879].
There was no statistically significant difference in costs between men and women (p>0.05), between illiterate and literate (p>0.05). There was a statistically significant difference in costs between patients with the RAMED medical assistance scheme and other health insurances (p<0.01).
Conclusion: This study showed that Moroccan RA patients had equal access to biologics regardless of their gender or level of education. Indeed, the insurance system influence the costs of biologics. Accessibility of those expensive treatments in a developing country seems be explained by efforts of the Moroccan ministry of health who has allocated a substantial budget for biologic DMARDs for patients with RAMED in the tertiary structures in our country.

Epidemiology, risk factors for disease or disease progression

POS1418 REALIZING EARLY RECOGNITION OF ARTHRITIS IN TIMES OF INCREASED TELEMEDICINE: THE VALUE OF PATIENT-REPORTED SWOLLEN JOINTS

C. Rogier[1], B. Van Dijk[2], E. Brouwer[3], P. De Jong[1], A. Van der Helm - van Mil[1,2]. *[1]Erasmus MC, Department of Rheumatology, Rotterdam, Netherlands*; *[2]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*; *[3]University Medical Center Groningen, Department of Rheumatology, Groningen, Netherlands*

Background: Early diagnosis and management of patients with inflammatory arthritis(IA) are critical to improve long-term patient-outcomes. Assessment of joint swelling at joint examination is the reference of IA-identification; early access clinics are constructed to promote this early recognition of IA. However, due to the COVID-19 pandemic the face-to-face capacity of such services is severely reduced. The accuracy of patient-reported swelling in comparison to joint examination has been extensively evaluated in established RA (ρ 0.31-0.67), but not in patients suspected for IA.[1]
Objectives: To promote evidence based care in the era of telemedicine, we determined the accuracy of patient-reported joint swelling for actual presence of IA in persons suspected of IA by general practitioners(GP).
Methods: Data from two Dutch Early Arthritis *Recognition* Clinics were studied. These are screening clinics (1.5-lines-setting) where GPs send patients in case of doubt on IA. At this clinic patients were asked to mark the presence of swollen joints on a mannequin with 52 joints. For this study the DIP joints and the metatarsal joints were excluded and, therefore, a total of 42 joints were assessed for self-reported joint swelling. Clinically apparent IA of ≥1 joint determined by the physician was the reference to calculate sensitivity, specificity, positive and negative likelihood ratios (LR+,LR-), and positive and negative predictive values (PPV, NPV) on patient-level. Pearson correlation coefficients(ρ) were determined. Predictive values depend on the prevalence of a disease in a population. Because the prevalence of IA in a 1.5-lines-setting will differ from a primary care setting, post-test probabilities of IA were estimated for two lower prior-test probabilities as example, namely 20% (estimated probability in patients GPs belief IA is likely) and 2% (prior-test probability with less preselection by GPs), using likelihood ratios and nomograms.
Results: A total of 1637 consecutive patients were studied. Median symptom duration was 13 weeks. 76% of patients marked ≥1swollen joint at the mannequin. 41% of patients had ≥1swollen joint at examination by rheumatologists. ρ was 0.20(patient-level)-0.26(joint-level).
The sensitivity of patients-reported joint swelling was high, 87%, indicating that the majority of patients with IA had marked swelling on the mannequin. However the specificity was 31%, indicating that 69% of persons without IA had also done so. The LR+ was 1.25; the LR- 0.43. The PPV was 46%, the NPV 77%. Thus the PPV increased hardly (from 41% to 46%) and the NPV somewhat (from 59% to 77%). Also in settings with prior-test probabilities of 20% and 2%, estimated PPVs (from respectively 20% and 2% to 24% and 2%) and NPVs (from respectively 80% and 98% to 90% and 99%) hardly increased.
Conclusion: Patient-reported joint swelling had little value in distinguishing patients with/without IA for different prior-test probabilities, and is less valuable in comparison to self-reported flare detection in established RA.

POS1419

PREDICTIVE FACTORS FOR PULMONARY PROGRESSION IN PATIENTS WITH CONNECTIVE TISSUE DISEASE AND INTERSTITIAL LUNG DISEASE

Y. H. Chiu[1,2], J. Spierings[1], P. De Jong[3], F. Mohamed Hoesein[3], J. M. Van Laar[1], M. Voortman[4]. *[1]University Medical Centre Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands*; *[2]National Defense Medical Center, Division of Rheumatology/Immunology/Allergy, Taipei, Taiwan, Republic of China*; *[3]University Medical Centre Utrecht, Department of Radiology, Utrecht, Netherlands*; *[4]University Medical Centre Utrecht, Department of Heart and Lung, Utrecht, Netherlands*

Background: Interstitial lung disease (ILD) is associated with decreased quality of life and higher mortality risk in patients with connective tissue disease (CTD). Outcome and treatment response to immunosuppressive therapies is unpredictable, and therefore the management of CTD-ILD can be challenging.
Objectives: Our study aimed to identify clinical and imaging factors that are predictive for outcome in patients with CTD-ILD.
Methods: We performed a retrospective cohort study in patients with CTD-ILD who were treated in our centre between 2004 and 2018. Clinical, biochemical data as well as pulmonary function test (PFT) and high-resolution computed tomography (HRCT) results were recorded. Two experienced chest radiologists independently and blindly reviewed the HRCT's. When the two chest radiologists assessed the ILD pattern differently, a diagnosis was made by consultation of a third expert. The ILD patterns were classified as fibrotic or inflammatory. Overall survival and progressive fibrosing interstitial lung disease (PF-ILD, defined as a significant decline of PFT and HRCT) after two years of treatment were assessed using a Kaplan-Meier plot. Multivariable Cox regression was including for treatment, comorbidity, and age as variables. Factors with a p value < 0.2 in the univariate analysis were included in the multivariate analysis. The correlation between the variation of serum markers and PFT over-time was evaluated with Spearman's Rho.
Results: In total, 150 patients with CTD-ILD were included, of which 53 (35.3%) had systemic sclerosis, 19 (12.7%) Sjogren's syndrome, 29 (19.3%) inflammatory myopathy, 24 (16%) rheumatoid arthritis, 5 (3.3%) systemic lupus erythematosus, 4 (2.7%) mixed connective tissue disease, and 16 (10.7%) undifferentiated connective tissue disease patients. Median disease duration of CTD was 14 months (IQR 2–73) in patients with CTD diagnosis before ILD onset. The median follow-up duration was 40 months (IQR 27.3–60.8). Thirty (20%) deaths occurred, in which the cause of death was a pulmonary infection in 6 (4%) patients and a respiratory failure due to ILD in 10 (6.7%) patients. PF-ILD occurred in 82 (54.7%) patients, which was associated with poor overall survival (HR 3.03, 95%CI 1.15–7.98) (Figure 1). Age, smoking, and steroid usage were associated with increased mortality risk as well (Table 1). There was no dose-related effect of smoking on mortality.

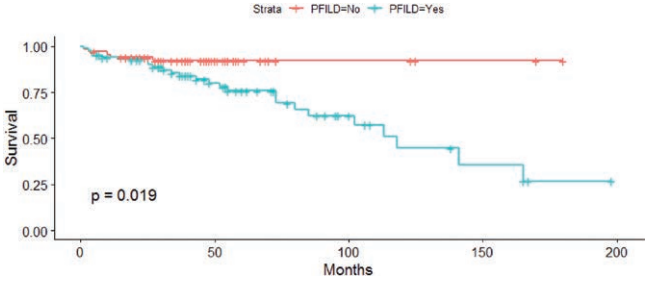

Figure 1. The Kaplan-Meier plot for progressive fibrosing interstitial lung diseases (PF-ILD). PF-ILF was defined as pulmonary function decline or high-resolution computed tomography progression after two years of treatment.

Inflammatory patterns on baseline HRCT were correlated with a lower risk of FVC decline than fibrotic patterns (OR 0.24, 95%CI 0.09–0.64). The increase in CA15.3 level was associated with the decline in FVC (Rho -0.308, p=0.037). Besides, the elevation in CRP was associated with the reduction in FVC (Rho -0.302, p=0.006) and DLCO (Rho -0.268, p=0.019).
Conclusion: Our study identified several factors associated with outcomes. Age, smoking, and steroid treatment increased the risk of mortality in patient with CTD-ILD. Inflammatory HRCT pattern at baseline revealed a better pulmonary outcome than a fibrotic pattern. The patients having PF-ILD after two years of treatment showed a higher mortality risk.

Table 1. Multivariable Cox-regression for the clinical risk of mortality.

Clinical factor	Crude HR (95%CI)	P	Adjusted HR (95%CI)	p
Age	1.11 (1.06–1.15)	$1.7*10^{-6}$	1.12 (1.07–1.17)	$3.54*10^{-6}$
Smoking	1.64 (0.79–3.43)	0.187	2.53 (1.11–5.78)	0.028
Congestive heart failure	1.86 (0.75–4.58)	0.179	1.17 (0.47–2.91)	0.737
MMF	0.55 (0.23–1.35)	0.195	0.73 (0.29–1.85)	0.512
Steroid	4.37 (1.67–11.45)	0.003	4.96 (1.84–13.40)	0.002

POS1420

RISK OF SERIOUS INFECTIONS IN OFFSPRING EXPOSED IN UTERO TO USTEKINUMAB OR VEDOLIZUMAB

J. Gorodensky[1], S. Bernatsky[1,2], W. Afif[3], Y. St-Pierre[2], K. Filion[1,4], E. Vinet[1,2]. *[1]McGill University, Epidemiology, Montréal, Canada*; *[2]Research Institute of the McGill University Health Centre, CORE, Montréal, Canada*; *[3]McGill University, Gastroenterology and Hepatology, Montreal, Canada*; *[4]Lady Davis Institure for Medical Research, Center for Clinical Epidemiology, Montreal, Canada*

Background: Ustekinumab, an IL-12/23 inhibitor, is indicated in adult patients with inflammatory bowel disease (IBD), psoriasis (PsO), and psoriatic arthritis (PsA) and vedolizumab, an $\alpha_4\beta_7$ receptor antagonist is indicated in IBD only. Both are monoclonal antibodies harbouring an Fc portion, which are actively transported across the placenta, often reaching higher fetal than maternal levels. As fetuses could be exposed to therapeutic or supra-therapeutic levels of these drugs, there are concerns that these agents could cause immunosuppression after birth. However, evidence is lacking.
Objectives: We compared the risk of serious infections in offspring exposed to ustekinumab, vedolizumab, tumour necrosis factor inhibitors (TNFi), and non-biologic immunosupressives versus offspring unexposed during pregnancy among women with IBD, PsO and/or PsA.
Methods: We conducted a retrospective cohort study using the US MarketScan database, an employment insurance database. We included live births (01/2011-12/2018) among women with PsO, PsA, and/or IBD. Drug exposure was defined as ≥1 filled prescrip tion or infusion procedure code during pregnancy. In offspring, we evaluated serious infections within the first year of life as any single inpatient infection code. We performed multivariate analyses using logistic regression, adjusting for maternal age, co-morbidities, corticosteroid use, concomitant drug use, and preterm birth.
Results: We included 16,115 offspring born to 7,612 women with PsO/PsA, 8,315 with IBD, and 188 with PsO/PsA and IBD. A total of 52 offspring were exposed to ustekinumab, 43 to vedolizumab (including 7 to both TNFi and vedolizumab),1,578 to TNFi, 1,857 to non-biologic immunosuppressives alone, and 12,585 unexposed to any drug. The percentage of serious infections in offspring exposed to ustekinumab was 3.9% (95% CI 0.5-13.9), versus 2.7% (95% CI 1.9-3.6) for TNFi, 2.3% (95% CI 0.06-13.0) for vedolizumab and 2.6 (95% CI 2.3-2.8) for those unexposed to any drug, though all estimates had wide, overlapping confidence intervals. Compared to children unexposed to any drug, there was a potential trend for increased risk with ustekinumab (OR 1.54, 0.37-6.45), but CIs were wide and included the null. For those exposed to vedolizumab (OR 0.82, 0.15-5.91) or TNFi (OR 0.98, 0.68-1.40) there was no clear excess risk.
Conclusion: In a large cohort, we did not detect a clear excess risk for offspring exposed in-utero to, vedolizumab or anti-TNF's, compared to unexposed patients; there was a signal for more events with ustekinumab, but confidence intervals were wide. Ongoing caution, as well as more research on short and long-term effects, is warranted for biologics actively transported across the placenta

HIGHER SERUM URIC ACID IS ASSOCIATED WITH INCREASED RISK OF OBESITY IN CHINESE ADULTS: A LONGITUDINAL DATA ANALYSIS

J. Zeng[1], W. R. Lawrence[2], J. Yang[3]. *[1]Department of Ultrasonography, Institute of Ultrasound in Musculoskeletal Sports Medicine, Guangdong Second Provincial General Hospital, Guangzhou, China, Department of*

Ultrasonography, Guangzhou, China; [2]*Department of Epidemiology and Biostatistics, School of Public Health, University at Albany, State University of New York, One University Place, Rensselaer, New York., Department of Epidemiology and Biostatistics, New York, United States of America*; [3]*Institute for Environmental and Climate Research, Jinan University, Guangzhou, 511443, China, Jinan University, Guangzhou, China*

Background: Hyperuricemia has been reported to be significantly associated with risk of obesity. However, previous studies on the association between serum uric acid (SUA) and body mass index (BMI) yielded conflicting results.
Objectives: The present study examined the relationship between SUA and obesity among Chinese adults.
Methods: Data were collected at Guangdong Second Provincial General Hospital in Guangzhou City, China between January 2010 and December 2018. Participants with ≥2 medical checkup times were included in our analyses. Logistic regression model (LRM) was performed for data at baseline. For all participants, generalized estimation equation (GEE) model was used to assess the association between SUA and obesity, where the data were repeatedly measured over the nine-year study period. We calculated the cut-off values for SUA of obesity using the receiver operating characteristic curves (ROC) technique.
Results: A total of 15,959 participants (10,023 males and 5,936females) were included in this study, with an average age of 37.38 years (SD: 13.27) and average SUA of 367.05 μmol/L (SD: 97.97) at baseline, respectively. Finally, 1078 participants developed obesity over the 9-year period. The prevalence of obesity was approximately 14.2% for high SUA level. In logistic regression analysis at baseline, we observed a positive association between SUA and risk of obesity: OR=1.84 (95% CI: 1.77,1.90) for per-SD increase in SUA. Considering repeated measures over 9-year for all participants in the GEE model, the per-SD OR was 1.85 (95% CI:1.77,1.91) for SUA and the increased risk of obesity were greater for male (OR=1.45) and elderly participants (OR=1.01). The SUA cutoff points for risk of obesity using ROC curves were approximately consistent with the international standard.
Conclusion: Our study observed higher SUA level was associated with increased risk of obesity. More high-quality research is needed to further support these findings.

POS1422 CORRELATES OF TESTING POSITIVE FOR SARS-COV-2 IN PATIENTS WITH RHEUMATIC AD MUSCULOSKELETAL DISEASES

N. Singh[1,2], I. Huang[2], M. Singleton[2], A. Bays[2], J. Sabo[2], S. Chung[2], G. Gardner[2], J. Schaeffer[2], K. Wysham[2], J. Andrews[2], R. Patel[2], J. Simard[3], J. Liew[4]. [1]*University of Washington, Rheumatology, Bellevue*; [2]*1959 NE Pacific St, Internal Medicine, Seattle, United States of America*; [3]*450 Serra Mall, Internal Medicine, Stanford, United States of America*; [4]*233 Bay State Rd, Internal Medicine, Boston, United States of America*

Background: Many studies on COVID-19 outcomes in patients with RMD have either restricted to COVID positive RMD patients or compared them to the general clinic population as a comparator. Given heterogeneity in behaviors and risks, clinical characteristics associated with a positive diagnosis among patients with RMD seeking testing for Sars-CoV-2 remain less well studied.
Objectives: Among patients with RMD receiving a Sars-CoV-2 PCR test, we aimed to identify RMD-related factors associated with a positive test result.
Methods: Among patients seen at least once in the University of Washington (UW) rheumatology clinics between March 2018 to March 2020, we reviewed electronic medical records to identify patients undergoing Sars-CoV-2 PCR testing from March 1 through October 31, 2020. Patients with RMD were categorized into two groups: those who tested positive for Sars-CoV-2 and those who tested negative. We randomly selected patients from the negative group in a 2:1 ratio for further data abstraction. Student's *t*-test and Chi-squared tests were used to compare continuous and categorical variables, respectively, between the groups. To determine the correlates of testing positive for Sars-CoV-2, specifically RMD medication use and disease activity, we constructed different multivariable logistic regression models adjusted for age, sex, race/ethnicity, presence of comorbidities, body mass index, and smoking.
Results: A total of 2768 RMD patients underwent SARS-CoV-2 PCR testing within the UW system, of whom 43 (1.5%) were positive at least once. Three patients with incomplete information were excluded. Patients who tested positive had higher prevalence of end stage renal disease (ESRD)/chronic kidney disease (CKD) (24% versus 11%), had higher rates of active disease (24% versus 20%), were older (>55 years) (mean age 57.3 versus 54.8 years), male (63% versus 55%), non-white race/ethnicity (32% versus 26%), and higher prevalence of multiple comorbidities (42% versus 31%) (Table 1). In the multivariable models, neither RMD medication use (versus no use, Table 1) nor high disease activity (vs low disease activity/remission) were statistically significantly associated with COVID-19 positivity. Among the 41 COVID-19 positive patients, a majority recovered without specific treatments, although approximately one third of the positive patients were hospitalized and three deaths were observed.
Conclusion: In this study, patients who tested positive did not differ in many ways from those who tested negative.

Table 1. Baseline characteristics of the patients prior to COVID testing

Variables	All (N=126)	COVID Positive (N=41)	COVID Negative (N=85)	P value
Age in years – mean (SD)	55.6 (15.3)	57.3 (16.3)	54.8 (14.9)	0.40

POS1423 LIFESTYLE HABITS IN PATIENTS WITH RHEUMATOID ARTHRITIS – A CROSS SECTIONAL STUDY ON TWO SCANDINAVIAN COHORTS

J. K. Karstensen[1,2,3], J. Primdahl[1,2,4], M. Andersson[5,6], J. Reffstrup Christensen[7,8], A. Bremander[1,2,3,5,6]. [1]*Department of Regional Health Research, University of Southern Denmark, Odense, Denmark*; [2]*Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark*; [3]*The DANBIO Registry, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark*; [4]*Hospital of Southern Jutland, University Hospital*

of Southern Denmark, Aabenraa, Denmark; [5]*Section of Rheumatology, Department of Clinical Sciences Lund, Lund University, Lund, Denmark*; [6]*Spenshult, Research and Development Centre, Halmstad, Sweden*; [7]*Research Initiative for Activity Studies and Occupational Therapy, Research Unit of General Practice, Department of Public Health, University of Southern Denmark, Odense, Denmark*; [8]*Research Unit of User Perspectives, Department of Public Health, University of Southern Denmark, Odense, Denmark*

Background: In people with rheumatoid arthritis (RA), modifiable lifestyle factors such as smoking, being overweight/obese, alcohol overuse and physical inactivity may not only affect treatment response and quality of life, but can also increase the risk for cardio-vascular diseases and other comorbidities (1,2). Evidence and EULAR guidelines (3) support lifestyle changes in patients with RA. If a patient need to change several habits, the challenge may seem overwhelming and substantial support will be needed. There is little information concerning the prevalence of a combined number of unhealthy lifestyle (UL) factors in people with RA.
Objectives: I) To study the prevalence of unhealthy lifestyle factors in two Scandinavian RA cohorts. II) To study the association between disease impact and two or more unhealthy lifestyle factors.
Methods: Patients diagnosed with RA who participated in a cardiovascular screening consultation at a specialist clinic during 2016-2018 and responded to four lifestyle questions, constituted the Danish cohort (data retrieved from the national registry DANBIO). Patients with RA belonging to the BARFOT cohort, and who in a 2017 survey responded to four lifestyle questions, constituted the Swedish cohort. Lifestyle information was dichotomized as present tobacco use or not, BMI <25 kg/m2 vs. ≥25 kg/m2, alcohol overuse or not, and health enhancing physical activity (≥ 150 minutes/week) or less. The combined number of UL factors (0, 1, 2, 3, 4) were calculated. Crude logistic regression analyses were performed to determine the association between disease impact and two or more UL factors (controlled for age, gender and disease duration). Independent factors (disease impact) were pain (NRS 0-10, best to worst), fatigue (NRS 0-10, best to worst), function (HAQ, 0-3, best to worst) and quality of life (EQ-5D-3L 0-1, worst to best).
Results: The 566 included Danish patients had a mean age of 61.82 (SD 11.13) years, a disease duration of mean 12.40 (SD 10.95) years, and 72% were women. The 995 Swedish patients had a mean age of 66.38 (SD 12.90) years, a disease duration of mean 15.55 (SD 3.85) years, and 72% were women. 95% of the Danish patients and 82% of the Swedish patients reported at least one UL factor, while 66% and 47% respectively reported two or more (Figure 1). The most common ones were overweight/obesity and physical inactivity in both cohorts. Male gender OR 1.86 95% CI [1.21-2.85] and shorter disease duration OR 0.97 95% CI [0.95-0.99] were associated with two or more UL factors in the Danish cohort. In the Swedish cohort, male gender OR 1.42 95% CI [1.07 – 1.89], worse pain OR 1.10 95% CI [1.04 – 1.15], fatigue OR 1.09 95% CI [1.04 – 1.15], function OR 1.64 95% CI [1.28 – 2.10], and worse quality of life OR 0.35 95% CI [0.20 – 0.60] were associated with two or more UL factors.
Conclusion: Every other patient with RA had two or more UL factors in both the Danish and Swedish cohort, and more often they were men. The combined number of UL factors was not necessarily associated with disease impact. The findings are important for health professionals working with lifestyle interventions in patients with RA.

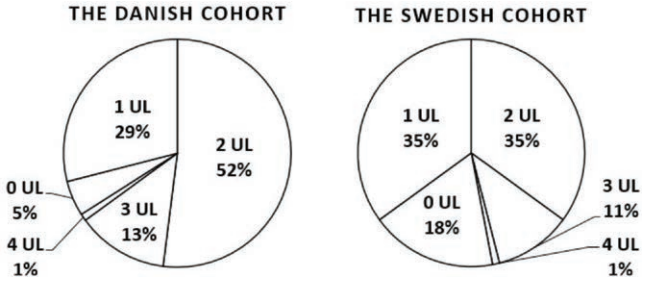

Figure 1. The combined number of unhealthy lifestyle (UL) factors in two Scandinavian RA cohorts.

POS1424 PREGNANCY COURSE IN A COHORT OF WOMEN WITH MYOSITIS - RESULTS FROM REVNATUS

B. Jakobsen[1], H. Bjørngaard[1], H. S. Koksvik[1], T. T. Pedersen[1], M. Wallenius[1,2]. [1]*St. Olavs Hospital, Trondheim University Hospital, Norwegian National Advisory Unit on Pregancy and Rheumatic Diseases, Trondheim, Norway*; [2]*Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Trondheim, Norway*

Background: Myositis is a rare autoimmune disease characterized by proximal and symmetrical muscle weakness and inflammatory infiltrates on muscle biopsy, and may affect women in reproductive age. Only few reports exist on pregnancy outcomes in women with myositis. Well-controlled disease at time of conception seems to give better outcome for the mother and the fetus (1). Inflammatory active disease before and during pregnancy has been associated with preterm birth and infant small for gestational age (1).
Objectives: To describe the course of pregnancy in patients with myositis.
Methods: We prospectively collected data on pregnancy in women with myositis in the nationwide Norwegian quality registry - RevNatus. ICD-10 codes: ICD-10 M33.0 (5), M33.1 (2), M33.2 (1), M33.9 (3). Eleven pregnancies in ten women with a known pregnancy outcome from 2016 – 2020 were included.
Results: Median disease duration was 10 years (range 3-26), and median age at conception was 29 years (range 25-43). Five women had juvenile myositis. Two pregnancies ended in spontaneous abortions, one in 1st trimester and one in 2nd trimester. Nine pregnancies ended with live birth at median pregnancy week 39 (range 35-41) and a median birth weight of 3355 gram (range 2580-4750). None of the women experienced preeclampsia or HELLP. Three women was positive for ANA. Median CRP in second trimester was three (range 0-7). Among nine women with live births, seven were in remission, and two women had persistent disease in second trimester, defined by rheumatologist. Seven women used DMARDs in pregnancy, and two women used prednisolone 5 mg throughout pregnancy.

Patient #	Pregnancy #	Maternal age at conception	Disease duration years	Medication during pregnancy	Disease activity 2nd trimester	Gestational age at delivery	Infant birth weight (gram)	Delivery mode
A	1	29	25	none	Remission	38	3355	Standard vaginal delivery
B	2	34	7	azathioprine	Persistent	39	3725	Standard vaginal delivery
C	3	29	15	azathioprine				Spontaneous abortion week 7
D	4	35	3	ciclosporin prednisolone 5mg	Persistent	40	3000	Standard vaginal delivery
E	5	28	13	none	Remission	37	2765	Operational vaginal delivery
F	6	25	10	azathioprine hydroxy-chloroquine	Remission	41	4085	Standard vaginal delivery
F	7	27	13	azathioprine hydroxy-chloroquine	Remission	41	3815	Standard vaginal delivery
G	8	36	13	prednisolone 5mg				Spontaneous abortion > week 12
H	9	29	9	azathioprine	Remission	35	2580	Standard vaginal delivery
I	10	43	5	azathioprine prednisolone 5mg	Remission	37	3140	Sectio
J	11	36	28	none	Remission	41	4750	Acute sectio

Conclusion: We did not observe disease flare during pregnancy and no serious adverse outcomes in the pregnancies ending with live births. However, data are sparse, and larger cohorts are necessary to evaluate possible risk factors.

POS1425 ANTIBODIES TO PORPHYROMONAS GINGIVALIS ASSOCIATE WITH THE PRESENCE OF RHEUMATOID ARTHRITIS-RELATED AUTOANTIBODIES IN PATIENTS WITH PERIODONTITIS

C. De Vries[1], G. Ruacho[1], N. Sippl[1], B. A. Potempa[2], L. Ryden[3], J. S. Potempa[2], B. Klinge[4], E. Svenungsson[1], K. Lundberg[1]. *[1]Karolinska Institute, Department of Medicine, Division of Rheumatology, Stockholm, Sweden*; *[2]University of Louisville, Department of Oral Immunology & Infectious Diseases, Louisville, United States of America*; *[3]Nya Karolinska, Department of Medicine, Stockholm, Sweden*; *[4]Huddinge Hospital, Department of Dental Medicine, Division of Oral Diseases, Huddinge, Sweden*

Background: Epidemiologic studies have demonstrated a link between periodontitis (PD) and rheumatoid arthritis (RA), specifically RA characterized by anti-citrullinated protein antibodies (ACPA). The keystone pathogen driving PD, *Porphyromonas gingivalis (Pg),* is the only pathogen known to express peptidylarginine deiminase (PAD), a citrullinating enzyme. Hence, *Pg* has been proposed to be involved in triggering the ACPA response, by generating citrullinated antigens in an inflammatory milieu(1). Another major virulence factor of *Pg* is arginine gingipain B (RgpB), a proteinase which cleaves proteins so that *P.*PAD can access the site where citrullination takes place. We have previously shown elevated anti-RgpB IgG levels in ACPA+ RA patients, even before clinical onset(2, 3), and we hypothesize that anti-RgpB IgG could serve as a serological marker to identify PD patients with increased risk of developing ACPA+ RA.
Objectives: Based on this hypothesis, we set out to investigate whether anti-RgpB IgG was associated with PD, PD severity, autoimmunity in general, and the ACPA response in particular.
Methods: Anti-RgpB IgG, as well as RA- and systemic lupus erythematosus (SLE)-related autoantibodies targeting cyclic citrullinated peptide(s) (CCP2), rheumatoid factor (RF), dsDNA, cardiolipin, and β2 glycoprotein, were measured by ELISA in serum samples from the ParoKrank study, which is a well-characterized cohort of 805 patients with a first myocardial infarction and 805 matched controls, where periodontal status has been determined by dentists(4). In this study, individuals with PD (n=941) were compared to individuals without PD (n=557).
Results: We detected significantly elevated (p<0,0001) anti-RgpB IgG levels in PD compared to non-PD individuals, with highest levels recorded in severe PD. Anti-RgpB IgG levels were significantly increased in PD patients positive for CCP2 and/or RF (n=50), when compared to PD patients negative for CCP2 and RF (n=507), p<0,05, and when compared to non-PD individuals positive for CCP2 and/or RF (n=62), p < 0,05. Notably, these differences were not seen for SLE-related autoantibodies. In addition, anti-RgpB IgG levels were significantly elevated amongst MI patients versus controls (p < 0,05), supporting the previous finding that PD is more common among MI patients(4).
Conclusion: Our data demonstrates a specific association between severe PD, elevated anti-RgpB IgG levels and RA-related autoantibodies, supporting a role for *Pg* in linking PD to ACPA+ RA. Further investigation will be needed to confirm whether anti-RgpB IgG can be used as a serological marker to identify PD patients with increased risk of developing ACPA+ RA.

POS1426 PATIENTS WITH IMMUNE MEDIATED INFLAMMATORY DISEASES ARE OVERREPRESENTED IN LOW-FREQUENCY VIRAL SYMPTOM CLUSTERS

K. Tascilar[1,2], D. Simon[1,2], G. Krönke[1,2], A. Kleyer[1,2], A. Ramming[1,2], R. Atreya[2,3], M. Tenbusch[4], K. Überla[4], C. Berking[2,5], M. Sticherling[2,5], M. F. Neurath[2,3], G. Schett[1,2]. *[1]Friedrich Alexander University of Erlangen Nuremberg and Universitätsklinikum Erlangen, Department of Medicine-3, Rheumatology and Immunology, Erlangen, Germany*; *[2]Friedrich Alexander University of Erlangen Nuremberg and Universitätsklinikum Erlangen, Deutsches Zentrum für Immuntherapie, Erlangen, Germany*; *[3]Friedrich Alexander University of Erlangen Nuremberg and Universitätsklinikum Erlangen, Department of Medicine-1, Gastroenterology, Pneumology and Endorcrinology, Erlangen, Germany*; *[4]Friedrich Alexander University of Erlangen Nuremberg and Universitätsklinikum Erlangen, Institute of Clinical and Molecular Virology, Erlangen, Germany*; *[5]Friedrich Alexander University of Erlangen Nuremberg and Universitätsklinikum Erlangen, Department of Dermatology, Erlangen, Germany*

Background: Viral respiratory infections are common in the general population and result in a spectrum of outcomes ranging from effective viral clearance with no symptoms, to a maladaptive immune response that can result in severe symptomatic disease and death. Although patients with immune-mediated inflammatory diseases (IMID) are considered susceptible to poor outcomes from infectious syndromes, it is not known whether IMID patients are overall more prone to manifest common viral infection symptoms.
Objectives: To explore frequency patterns of common viral infection symptoms in IMID patients.
Methods: We previously recruited patients with IMIDs and individuals with no IMIDs for a seroprevalence study between February 1st and April 30th 2020 (1). Participants were questioned for the presence of eleven common viral disease symptoms. We clustered these data using an unsupervised binary data clustering algorithm (2) into 6 symptom clusters based on symptom frequency. Three major clusters (broadly symptomatic, intermediately symptomatic and oligo-/asymptomatic) and 2 sub-clusters (higher and lower frequency) for each major cluster. In addition, qualitative symptom clustering was done. We estimated standardized residuals to quantify the over/underrepresentation of IMID diagnosis frequencies in each subject cluster. We used Poisson regression to compare symptom counts by diagnosis.
Results: We analyzed 1909 participants (757 with IMIDs; 1152 non-IMID controls; Table 1). Within each major subject cluster (Figure 1A), IMID patients showed the highest positive deviation from the expected frequencies in lower frequency sub-clusters while non IMID controls showed the highest positive deviations in the higher frequency sub-clusters (Figure 1B). Inflammatory bowel disease and psoriasis were remarkably overrepresented in the lower frequency sub-cluster of the broadly-symptomatic cluster while RA was overrepresented in the lower frequency sub-clusters of intermediate and oligo-/asymptomatic clusters. X axis of Figure 1A presents qualitative symptom clusters. Regression analysis shows that RA patients among other IMIDs reported overall less symptoms (RR= 0.69, 95%CI, 0.58 - 0.80) compared to non-IMID controls.

Table 1. Participant characteristics and distribution of IMID diagnoses across subject clusters.

		Clusters					
		Broad Symptomatic		Intermediate Symptomatic		Oligo-Asymptomatic	
	Overall	Higher	Lower	Higher	Lower	Higher	Lower
N	1909	101	85	412	259	283	769
Age, years, mean (SD)	45.4 (15.2)	42.4 (13.3)	47.3 (15.2)	42.4 (12.9)	50.4 (15.5)	41.8 (14.9)	46.8 (15.9)
Male	1080 (56.6)	42 (41.6)	38 (44.7)	196 (47.6)	137 (52.9)	178 (62.9)	489 (63.6)
Diagnosis, n(%)							
No-IMID	1152 (60.3)	72 (71.3)	44 (51.8)	280 (68.0)	112 (43.2)	207 (73.1)	437 (56.8)
RA	226 (11.8)	7 (6.9)	5 (5.9)	29 (7.0)	56 (21.6)	17 (6.0)	112 (14.6)

SpA	142 (7.4)	7 (6.9)	5 (5.9)	23 (5.6)	25 (9.7)	14 (4.9)	68 (8.8)
Psoriasis	89 (4.7)	4 (4.0)	9 (10.6)	14 (3.4)	8 (3.1)	13 (4.6)	41 (5.3)
Other	122 (6.4)	6 (5.9)	7 (8.2)	20 (4.9)	29 (11.2)	13 (4.6)	47 (6.1)
Symptom count/ patient, mean (SD)	1.2 (1.7)	6.0 (1.3)	3.9 (1.1)	2.2 (1.0)	1.5 (0.6)	0.5 (0.5)	0.0 (0.0)

IBD, inflammatory bowel disease.

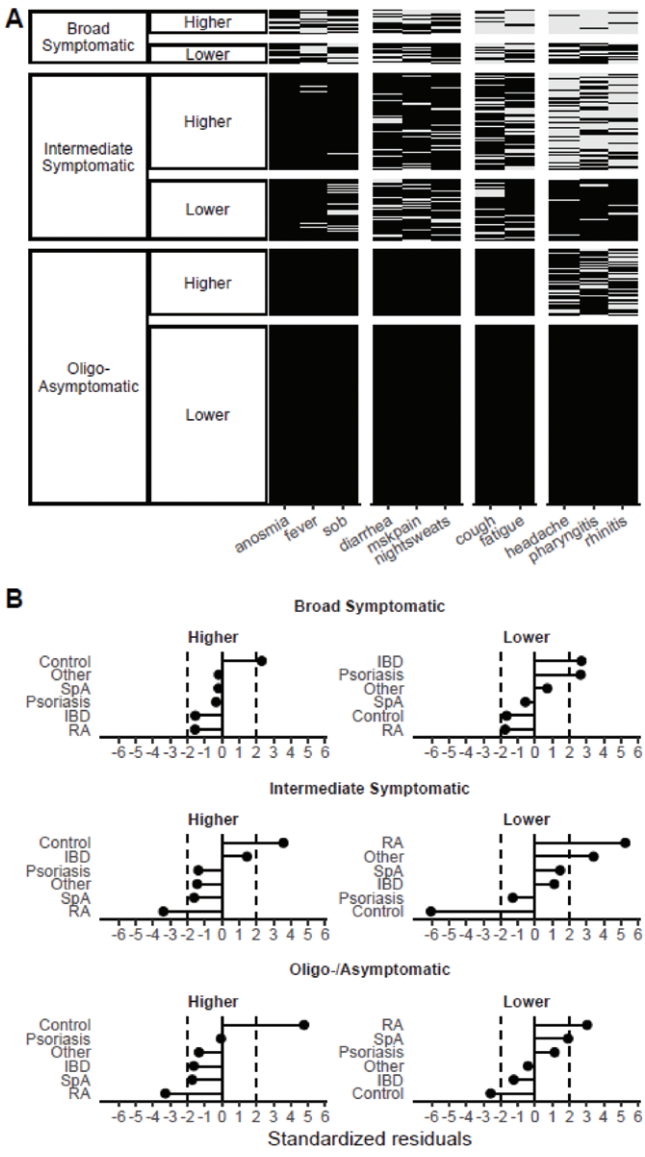

Figure 1. A) distribution of common viral respiratory disease symptoms across patient and symptom clusters. B) Standardized residuals indicating deviation from expected frequencies of IMID diagnoses across patient clusters. sob: shortness of breath, mskpain: musculoskeletal pain

Conclusion: This analysis shows that symptoms of common respiratory viral infections are less frequent in RA patients and to a lesser extent in other IMID patient. As major clusters in this analysis can also be considered to represent exposure categories, these data suggest that IMIDs or their treatments may mitigate common respiratory viral infection symptoms.

POS1427 NATIONAL BURDEN OF RHEUMATOID ARTHRITIS IN CANADA 1990-2017: FINDINGS FROM THE GLOBAL BURDEN OF DISEASE STUDY 2017

N. Hassen[1], D. Lacaille[1], A. Xu[1], S. Sidi[1], A. Alandejani[1], M. Mansourian[2], N. Sarrazadegan[1], J. Kopec[1]. [1]*The University of British Columbia, Faculty of Medicine, Vancouver, Canada*; [2]*Isfahan University of Medical Sciences, Isfahan, Iran (Islamic Republic of)*

Background: According to the Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) 2017, over 120,000 individuals currently have rheumatoid arthritis (RA) in Canada, yet a study that evaluates the combined effect of RA on the longevity and quality of life in the country is lacking.

Objectives: The objectives of this study are three: 1) to describe burden of RA levels and trends from 1990-2017 using GBD data, 2) to describe age and sex differences, and 3) to compare Canada RA burden to other countries.

Methods: We obtained publicly available data from GBD Study 2017 from the Institute for Health Metrics and Evaluation interactive visualization tool (http://vizhub.healthdata.org/gbd-compare). Disease burden indicators include prevalence, mortality, years of life lost (YLLs), years lived with disability (YLDs), and disability-adjusted life years (DALYs). Estimates were presented as non age-standardized and age-standardized rates per 100,000 population. GBD estimated prevalence using published literature, survey data, patient records, and health insurance claims, and mortality using cause of death ensemble modelling technique. YLLs measure premature death calculated as the sum of each death multiplied by the standard life expectancy at each age. YLDs measure amount of time in a year an individual lives with a short- or long-term health condition, calculated by combining prevalence with disability weights for each age/sex/year. DALYs were calculated as the sum of YLLs and YLDs. DALYs for Canada were compared to DALYs of countries with similar socio-demographic index (SDI) values. SDI combines income per capita, average educational attainment, and fertility rates. Data were analysed by DisMod-MR 2.1, a Bayesian meta-regression tool.

Results: In Canada, RA mortality (mortality and YLLs) improved over time, with a steeper decline after the year 2002. However, the population burden of quality of life (YLDs and DALYs) increased due to increasing prevalence. The disease burden was higher in females (prevalence, mortality, YLLs, YLDs, DALYs), and DALY rates were higher among older populations. Compared to other countries, Canada had greater improvement in mortality and YLLs over time and had a lower age-standardized DALYs rate compared to countries of similar SDI values. A weak association was found between global age-standardized DALYs and SDI (R^2 = 0.0138).

Conclusion: RA is a major public health challenge. Canada fares better than other countries with regards to national RA burden. Early identification and management are critical to reducing the overall burden of RA in Canada, especially in women. More data from multiple provincial RA databases would increase the accuracy of our estimates for Canada.

POS1428 VALIDATION OF ANCA-ASSOCIATED VASCULITIS AS THE CAUSE OF END-STAGE RENAL DISEASE IN THE UNITED STATES RENAL DATA SYSTEM

C. Cook[1], H. Choi[1,2], Z. Wallace[1,2]. [1]*Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America*; [2]*Harvard, Medical School, Boston, United States of America*

Background: Glomerulonephritis and other renal manifestations are common in ANCA-associated vasculitis (AAV). Renal involvement in AAV is associated with adverse outcomes, including end-stage renal disease (ESRD) in up to 25% of patients (1). The United States Renal Data System (USRDS), a national registry of ESRD patients, represents a unique nationwide data source for studying AAV patients with ESRD. Prior research has assessed how often patients with ESRD attributed to AAV have biopsy-proven glomerulonephritis in USRDS (2), but the validity of the diagnosis of AAV as the cause of ESRD in the USRDS remains unknown.

Objectives: We aim to validate the diagnosis of AAV as the primary cause of ESRD listed in USRDS.

Methods: We identified all patients in the Mass General Brigham (MGB) healthcare system with a billing code for advanced chronic kidney disease or end-stage renal disease or procedure code for dialysis or renal transplantation. We identified all MGB patients fulfilling these criteria to records in the USRDS by name, sex, date of birth, and social security number. From this cohort of patients, we identified those with AAV or related diagnoses listed as the primary disease causing ESRD (ICD9: 446.0, 446.4 or ICD10: M31.3X, M31.7). Two authors reviewed medical records to collect information on whether or not a physician had diagnosed AAV, details of AAV history, renal and non-renal biopsies, and antineutrophil cytoplasmic antibody (ANCA) tests. Discrepancies were resolved through consensus. Details regarding initial ESRD onset date were obtained from the USRDS. To calculate the positive predictive value (PPV) for AAV as the primary cause of ESRD a definite physician diagnosis of AAV (a diagnosis confirmed by two physicians based on available data) in the MGB medical record was used as the gold standard. To calculate sensitivity, we linked the Partners (MGB) AAV Cohort to USRDS records using the same methods. A diagnosis code of AAV as the cause of ESRD was considered a true positive and a diagnosis code for other types of nephritis was considered a false negative.

Results: We identified 89 USRDS records linked to MGB medical records in which the primary cause of ESRD was attributed to AAV. Of these, 85 were confirmed to be true cases of AAV after medical record review (PPV=96%) (Table 1). Among the cases classified as AAV, 84 (99%) had a positive ANCA test, which was predominantly MPO/P-ANCA (47, 55%); 36 (42%) had a renal biopsy, all of which were supportive of the diagnosis. The majority of cases were identified as AAV by ICD9 or 10 codes for Wegener's granulomatosis (446.4 or M313.1). Within the Partners (MGB) AAV cohort linked to USRDS records, 33 (55%) of 60 identified cases had AAV listed as the cause of ESRD; in the remainder, ESRD was attributed to non-specific nephritis codes.

Table 1. AAV and non-AAV patients in the USRDS with ESRD due to AAV (N=89)

	Physician-Diagnosed AAV (N=85)
ANCA type n (%)	84 (98.8)
MPO/P-ANCA+	47 (55.3)
PR3/C-ANCA+	33 (38.8)
Renal biopsy n (%)	36 (42.4)
Pauci-Immune Glomerulonephritis n (%)	16 (44%)
Non-renal biopsy n (%)	
Yes	10 (11.8)
No	74 (87.1)
Years from AAV diagnosis to ESRD median [IQR]	1 [0, 6]
Principal diagnosis code (ICD9/ICD10) n (%)	
Wegener's granulomatosis (446.4, 446.4B, or M313.1)	81 (95.3)

Conclusion: We found that the diagnosis of AAV as the primary cause of ESRD in the USRD had a high PPV, suggesting accurate classification of ESRD due to AAV in the USRDS, but that sensitivity was moderate. These findings support the past and future use of the USRDS for research with ESRD attributed to AAV.

POS1429

ORAL DYSBIOSIS REFLECTS THE IMMUNOLOGICAL ALTERATION OF RA REGARDING TO HLA DRB1*SE, ACPA AND CIGARETTE SMOKING: NAGASAKI ISLAND STUDY

Y. Tsuji[1], M. Tamai[2], S. Morimoto[3], D. Sasaki[2], S.Y. Kawashiri[1], K. Yanagihara[2], K. Aoyagi[4], T. Maeda[1], F. Matsuda[5], A. Kawakami[4], T. Saito[6]. *[1]Nagasaki University, Department of Community Medicine, Graduate School of Biomedical Sciences, Nagasaki, Japan*; *[2]Nagasaki University, Department of Laboratory Medicine, Nagasaki, Japan*; *[3]Nagasaki University, Department of Public Health, Graduate School of Biomedical Sciences, Nagasaki, Japan*; *[4]Nagasaki University, Department of Immunology and Rheumatology, Nagasaki, Japan*; *[5]Kyoto University, Center for Genomic Medicine, Kyoto, Japan*; *[6]Nagasaki University, Department of Oral Health, Medical and Dental Sciences, Nagasaki, Japan*

Background: Anti-citrullinated protein antibody (ACPA) production is observed in several organs even prior to the onset of rheumatoid arthritis (RA), and oral mucosa is considered to be one of the important tissues. Saliva is considered to reflect the oral microbiota(oralMB) including periodontal disease. A gene-environment interaction between cigarette smoking and shared epitope genes in HLA-DRB1*shared epitope (SE) provides a high risk of ACPA-positive RA. However, the interaction of HLA-DRB1*SE, ACPA, cigarette smoking and oralMB of RA patients remains to be elucidated.

Objectives: We investigated that the difference of oralMB among RA patients and healthy subjects(HS) regarding to ACPA, HLA-DRB1*SE and cigarette smoking.

Methods: The Nagasaki Island Study, which had started in 2014 collaborating with Goto City, Nagasaki Prefecture, Japan, is intended for research of the preclinical stage of RA, including ACPA, HLA genotype screening, oralMB and lifestyle habit. Both of blood and salivary samples were obtained from 1422 subjects out of 4276 participants in this study from 2016 to 2018. ACPA positivity was 1.7 % in total 4276 subjects. At this point, we selected 291 subjects, who were ACPA positive non-RA HS(n=22) and patients with RA (n=33, 11 subjects were ACPA positive and 22 ACPA negative, respectively) as the case, age and gender matched ACPA negative non-RA HS (n=236) as the control. In RA subjects, current smoker was n=1(3.0%) and ever smoker was n=8(24.2%). In HS, current smoker was n=29(11.2%) and ever smoker was n=55(21.3%). ACPA was measured by ELISA, and HLA genotyping was quantified by next-generation sequencing (Ref.1). The operational taxonomic unit (OTU) analysis using 16S rRNA gene sequencing were performed. The richness of microbial diversity within subject (α-diversity) was scaled via Shannon entropy. The dissimilarity between microbial community composition was calculated using Bray-Curtis distance as a scale, and differences between groups (β-diversity) were tested by permutational multivariate analysis of variance (PERMANOVA). In addition, UniFrac distance calculated in consideration of the distance on the phylogenetic tree were performed.

Results: Median age 71 y.o., % Female 58.4 %. Among RA and non-RA subjects, not α-diversity but β-diversity was statistically smaller significantly in RA (p=0.022). In the HS, there was no decrease in α-diversity between the ACPA-positive and HLA-DRB1*SE-positive groups, but in the ACPA-positive group, there was a decrease in α-diversity in the HLA-DRB1*SE-positive group. When we compared α-diversity stratified by the presence or absence of three factors (RA, ACPA, and HLA-DRB1*SE), the RA group with ACPA and HLA-DRB1*SE positive tended to have the lowest diversity (Figure 1 lower right). RA subjects, presence of HLA-DRB1*SE did not show the difference but the tendency of lower α-diversity (p=0.29).

Conclusion: HS with ACPA-positive HLA-DRB1*SE tended to show lower α-diversity than ACPA-positive HS and HLA-DRB1*SE positive HS. Furthermore, RA subjects with ACPA-positive HLA-DRB1*SE showed lower α-diversity than HS with ACPA-positive HLA-DRB1*SE.

Our study suggested that the oral dysbiosis may reflect the immunological status of patients with RA. Because of the small number of ACPA-positive patients, stratification by smoking history was difficult. Further examination is needed to clarify the gene-environment interaction and microbiome.

EPIDEMIOLOGY OF LUPUS NEPHRITIS IN BRAZIL: FINDINGS FROM THE MACUNAÍMA STUDY - A NATIONWIDE MULTICENTRIC STUDY

M. Abreu[1,2], O. Monticielo[3], V. Fernandes[4], A. Cristovão Maiorano[2], F. Dos Santos Beserra[2], F. Lamarao[5], N. David[5], B. De Veras[5], B. Bica[1], D. Sávio Nunes de Lima[6], M. Maria Das Chagas Medeiros[7]. Background: Lupus nephritis (LN) is one of the most serious organic manifestations of systemic lupus erythematosus (SLE). Ethnicity can contribute to disparities in the prevalence and disease activity of LN.
Objectives: To assess the prevalence of LN in Brazilian patients with SLE and to determine factors associated with LN activity across the country.
Methods: This cross-sectional study (GSK Study 207353) was carried out through face-to-face interviews and review of medical records (12-month study period). Adult patients with SLE (American College of Rheumatology [ACR] criteria, 1997) were included. Five SLE reference teaching centres were selected: North (NO), Northeast (NE), Midwest (CO), Southeast (SE), and South (SU). Patients with another disease whose morbidity surpassed SLE were excluded. LN was defined as reported in the medical record or history of confirmed renal biopsy; disease activity by pre-defined changes in SLE Disease Activity Index (SLEDAI) or the patient's kidney disease during the study. Activity was assessed during (T0), 6 months before (T6), and 12 months before (T12) the interview. Systemic Lupus International Collaborating Clinics/ACR Damage Index score mapped damage accrual. Two pairings were performed, aiming to discriminate factors associated with LN and its activity, respectively. Matching technique was used to select similar individuals based on propensity scores, obtained from a logistic regression model. A bootstrapping method explored characteristic variables associated with the risk of progressing to LN.
Results: Overall, 300 Brazilian patients with SLE were included in the study. Two groups were paired: LN group (N=150) and non-LN group (N = 141). The prevalence of LN in the paired sample (N=291) was 51.5%, with a disparity between centres (p<0.001; Figure 1A). Most patients were female (LN: 92.7%; non-LN: 94.3%) and the mean (standard deviation [SD]) age for the LN and non-LN groups was 39.46 (11.86) and 43.96 (12.18), respectively. History of serositis was associated with the presence of LN (42 [28.0%] vs 21 [14.9%] non-LN; p=0.010). Type IV histological class predominated in both groups, with no disparity between centres. Social disparities were noted between groups. Non-active workers prevailed among the LN group (115 [76.7%] vs 98 [69.5%] for non-LN, p=0.024).
When pairing for disease activity at T12, 73 (50.3%) patients with LN (N=145) had active disease. There was regional disparity in terms of disease activity (Figure 1B), with a predominance of active LN in the NO (28 [68.3%]) and SU (16 [55.2%], p=0.026). Type IV histological class was the component most associated with active LN (active: 32 [43.8%]; non-active: 11 [15.3%], p<0.001). Variation in SLEDAI during the study period discriminated between active and non-active LN. The mean (SD) SLEDAI score at T12 was substantially higher in those with active LN compared with non-active LN (7.18 [4.83] vs 2.47 [4.63], p<0.001). As for the pattern of care, corticosteroids users prevailed in those with active LN (62 [84.9%] vs 45 [62.5%] for non-active LN, p=0.004). There was no disparity in the use of immunosuppressants, with the exception of cyclophosphamide use, noted among 16 (21.9%) patients with active LN and 6 (8.3%) patients with non-active LN (p=0.041). Psychotropic or anticonvulsant use was higher in patients with non-active LN (32 [44.4%] vs 17 [23.3%] patients with active LN, p=0.012). Consultation with a neurologist was verified in 15 (20.8%) patients with non-active LN and 6 (8.2%) with active LN (p=0.055). Hospitalisation occurred in 17 patients with non-active (23.6%) and active (23.3%) LN.
Conclusion: Disparities in the prevalence of LN and its activity were evident between the regions across Brazil, highlighting differences in clinical factors, regional factors, and patterns of care.

POS1431

THE ASSOCIATION OF CLINICAL AND STRUCTURAL KNEE OSTEOARTHRITIS WITH PHYSICAL ACTIVITY IN THE MIDDLE-AGED POPULATION: THE NEO STUDY

S. Terpstra[1], J. Van der Velde[2], R. De Mutsert[2], D. Schiphof[3], M. Reijnierse[4], F. Rosendaal5, M. Kloppenburg5,6, M. Loef6. [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [2]*Leiden University Medical Center, Clinical Epidemiology, Leiden, Netherlands*; [3]*Erasmus Medical Center, General Practice, Rotterdam, Netherlands*; [4]*Leiden University Medical Center, Radiology, Leiden, Netherlands*; [2]*Leiden University Medical Center, Clinical Epidemiology, Leiden, Netherlands*; [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*

Background: Lack of physical activity in individuals with knee OA has shown to be associated with increased cardiovascular risk and mortality. Consequently, physical activity is a potential target for interventions in knee OA. However, most of the available studies concerning physical activity in individuals with knee OA were performed in relatively old populations with an inactive lifestyle. It is unclear

how previous results can be generalized to other populations with different lifestyle and physical activity habits.

Objectives: To investigate if knee OA is associated with lower physical activity in a general middle-aged Dutch population. Furthermore, to investigate the association of physical activity with patient reported outcomes such as knee pain and function, and health-related quality of life in individuals with knee OA.

Methods: We used cross-sectional data from the Netherlands Epidemiology of Obesity (NEO) study, in which participants aged 45-65 years were included. Clinical knee OA was defined using the ACR criteria. Structural knee OA was defined on MRI using the modified criteria by Hunter et al. in a random subset of 1,285 individuals of our study population.

We assessed knee pain and function with the Knee injury and Osteoarthritis Score (KOOS), and health-related quality of life (HRQoL) with the Short Form (SF)-36. Physical activity (in Metabolic Equivalent of Task (MET) hours per week) was assessed using the Short Questionnaire to Assess Health-enhancing physical activity (SQUASH).

We used linear regression analyses to investigate 1) the association of knee OA with physical activity, and 2) of physical activity with knee pain, function, and HRQoL in participants with clinical knee OA. All analyses were adjusted for age, sex, body mass index (BMI), ethnicity, educational level and comorbidities. To account for possible information bias, we performed a sensitivity analysis to assess the association between clinical knee OA and physical activity measured by an accelerometer in a random subset of 15% of the study population.

Results: Of 6,212 participants, we observed clinical knee OA in 14%, and structural knee OA in 12%. The general population characteristics and median physical activity of our study population are presented in Table 1. In comparison to participants without knee OA, participants with clinical knee OA had on average 9.60 (95% CI 3.70;15.50) MET hours per week more total physical activity (Figure 1). Structural knee OA was associated with 3.97 (-7.82; 15.76) MET hours per week more physical activity, compared with no structural knee OA.

Sensitivity analysis showed a weak positive association of clinical knee OA with physical activity measured by an accelerometer: 2.37 (-6.05; 10.80) MET hours per week more physical activity in participants with clinical knee OA, compared with participants without clinical knee OA.

In the subpopulation of participants with clinical knee OA, physical activity was not associated with knee pain, function or HRQoL.

Conclusion: Knee OA was not associated with lower physical activity in this middle-aged Dutch population. This contrasts previous findings and warrants caution when generalizing physical activity outcomes to other populations. Furthermore, it stresses the need of more insight in the barriers and facilitators of physical activity in the middle-aged population.

Table 1. Characteristics of the NEO study population

	All n = 6,214	No clinical knee OA 86%	Clinical knee OA 14%
General population characteristics			
Age (year)	55.7 (6.0)	55.4 (6.1)	57.5 (5.0)
Sex (% women)	55	54	67
BMI (kg/m^2)	26.3 (4.4)	26.1 (4.3)	27.6 (5.1)
Comorbidities (% present)	24	23	32
Physical activity			
Total^ (MET-hours per week)	118.8 (76.8;155.0)	118.4 (76.6;154.4)	123.5 (77.8;157.2)

SHORT-TERM RISK OF OSTEOPOROSIS IN ADULTS TREATED WITH CORTICOSTEROIDS: AN OBSERVATIONAL STUDY

E. Berni[1], P. Ambery[2], S. Adamsson Eryd[3], S. Jenkins-Jones[1], M. Brown[4], C. Astbury[5], P. Hunt[6], C. Currie[1,7]. [1]*Pharmatelligence, Epidemiology, Cardiff, United Kingdom*; [2]*AstraZeneca, Late-Stage Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals R&D, Gothenburg, Sweden*; [3]*AstraZeneca, BioPharmaceuticals Medical, CVRM Evidence, Gothenburg, Sweden*; [4]*AstraZeneca, Research and Early Development, Respiratory & Immunology, BioPharmaceuticals R&D, Boston, United States of America*; [5]*AstraZeneca, Research and Early Development, Respiratory & Immunology, BioPharmaceuticals R&D, Cambridge, United Kingdom*; [6]*AstraZeneca, BioPharmaceuticals Medical, CVRM Evidence, Gaithersburg, United States of America*; [7]*Cardiff University, School of Medicine, Cardiff, United Kingdom*

Background: Exposure to corticosteroids is recognised to increase the risk of osteoporosis.

Objectives: Our aim was to evaluate patients' short-term absolute risk of osteoporosis over the course of their first continuous exposure to corticosteroids.

Methods: This was an observational study using UK data from the Clinical Practice Research Datalink. Adult patients were selected if exposed to systemic corticosteroids for any condition and had no prior osteoporosis. Non-exposed adults matched on age, sex, and disease burden were selected from the general population. Patients were followed from their first exposure to corticosteroid to the earlier of 90 days following the end of continuous prescribing or for a maximum of three years. Cohorts were categorised by age (18-42 years, 43-67 and 68-92 years), BMI (underweight, normal overweight, obese and obese+) and gender. Absolute risk rates were calculated for each of these categories.

Results: In total, 573,056 exposed patients were matched 1:1 to non-exposed controls. Mean age was 52 years; 57% were female. The mean and median days' supply were 50.9 and 13 days, respectively. Underweight females aged 68-92 years exposed to corticosteroids had the highest absolute risk of osteoporosis (70.9 per 1000 patient years (PKPY)); in matched non-exposed controls this was 26.6 PKPY. Generally, following their first continuous exposure to corticosteroids, patients taking steroids had greater risk of osteoporosis compared with those in the same age, sex and BMI category never exposed to corticosteroids.

Conclusion: Whilst it is understood that exposure to corticosteroids increases the risk of osteoporosis, there are large differences in risk in accordance with age, sex and BMI. Alternatives to corticosteroids are urgently needed.

POS1433 IMPACT OF RHEUMATOID ARTHRITIS ON STRESS: A SYSTEMATIC SCOPING REVIEW

C. Vervloesem[1], D. De Cock[1], A. Van Breda[1], D. Bertrand[1], M. Doumen[1,2], S. Pazmino[1], R. Westhovens[1,2], P. Verschueren[1,2]. *[1]KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium*; *[2]University Hospitals Leuven, Rheumatology, Leuven, Belgium*

Background: The literature about the impact of Rheumatoid Arthritis (RA) on mental health is mostly focused on depression and anxiety. Yet, patients can experience stress without depressed mood or anxiety.
Objectives: To examine the impact of RA on psychological stress excluding depression and anxiety focusing on 3 questions: 1) What is the stress level of RA patients compared to a control group? 2) Which types of stress do RA patients experience? 3) Which are risk factors to develop stress as an RA patient?
Methods: Four scientific databases, EMBASE, PubMed (including MEDLINE), Web of Science Core Collection and Cochrane Library, were systematically searched from inception until 19/04/2020. Eligible studies included psychological stress in RA patients as outcome. Two reviewers (CV&AVB) independently screened titles and abstracts, and later full texts for eligibility. Full-text screening excluded studies without a separate RA population, with a focus on only anxiety and/or depression or not answering at least 1/3 research questions. Quality was appraised by MINORS/AXIS tools.
Results: From 11 115 potentially relevant studies, 16 studies met the inclusion criteria (Table 1). Remarkably, 13 different stress measurement instruments were picked-up in this review. Work stress and interpersonal stress seem more prevalent in RA patients compared to healthy controls. Stress at disease onset was more prevalent in RA compared to osteoarthritis. Psychological stress was higher in patients with chronic pain compared to RA. Role stress, social stress and work stress were induced by RA. More disability, more pain, less social support, lower income, younger age and personality factors like excessive worrying, pessimism, and sensitivity to anxiety, seem to increase the risk for increased stress levels.
Conclusion: This scoping review is to our knowledge the first to address the heterogeneity of measurement tools and definitions of stress in RA research. It provides the basis for further research, which is needed to predict different stress trajectories and respond to these with patient-centered interventions.

POS1434 WHICH PROGNOSTIC FACTORS MIGHT PREDICT THE NEED FOR TREATMENT ADAPTATION IN EARLY RHEUMATOID ARTHRITIS? A COMPARISON OF MACHINE LEARNING, SURVIVAL ANALYSIS AND REGRESSION METHODS

G. Verhavert[1,2], T. Verdonck[2], S. Pazmino[1], V. Stouten[1], D. Bertrand[1], M. Doumen[1], R. Westhovens[1,3], P. Verschueren[1,3], D. De Cock[1]. *[1]KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium*; *[2]KU Leuven, Department of Mathematics, Leuven, Belgium*; *[3]University Hospitals Leuven, Rheumatology, Leuven, Belgium*

Background: Current EULAR guidelines recommend treating RA early, intensively and to-target. A data-driven tool for planning the optimal moment for subsequent visits might adapt visit schedules more to the patient's needs, without losing treatment quality.
Objectives: To determine the optimal statistical model and clinical factors to predict the time to a treatment adaptation in early RA patients.
Methods: This study included 379 patients from the treat-to-target Care in Rheumatoid Arthritis (CareRA) trial. The CareRA protocol included 2 predefined treatment adaptation steps for patients not reaching low disease activity (DAS-28CRP<3.2). The 1st adaptation was an MTX dose increase and the second one was adding/increasing the dose of a 2nd csDMARD. Three predictive models (Cox Proportional Hazards, Linear Multi-Task Regression and Random Survival Forest) were trained and validated to predicting time until these 2 adaptations. Factor selection for these models was performed by applying Cox Proportional Hazards with LASSO penalty to each set of demographic and clinical variables recorded at baseline, w4 and w8. Models used these factors at these 3 time points to predict future treatment adaptations. Model performance was estimated by the Uno Concordance Index with five-fold cross-validation. Missing data were imputed by interpolation or mean score.
Results: Factors selected to predict the first per protocol change included TJC, SJC, HAQ, CRP, pain and morning stiffness>15min. Factors selected to predict the second per protocol change included TJC, SJC, PGA, PhGA. Uno Concordance indices showed similar scores per different statistical model but higher scores at w4 and w8 compared to baseline indicating a better predictive performance (Table 1. next page).

Table 1. ***Uno Concordance Scores. Format 'mean (min-max)'.***

		Baseline	Week 4	Week 8
Cox Proportional Hazards	Change 1	0.63 (0.59-0.69)	0.72 (0.68-0.80)	0.75 (0.69-0.82)
	Change 2	0.58 (0.50-0.66)	0.75 (0.65-0.87)	0.78 (0.65-0.93)
Linear Multi-Task Regression	Change 1	0.65 (0.62-0.68)	0.72 (0.68-0.78)	0.75 (0.69-0.79)
	Change 2	0.58 (0.51-0.68)	0.72 (0.67-0.82)	0.77 (0.68-0.89)
Random Survival Forest	Change 1	0.64 (0.58-0.67)	0.71 (0.66-0.78)	0.76 (0.68-0.80)
	Change 2	0.56 (0.50-0.68)	0.72 (0.60-0.82)	0.77 (0.64-0.92)

Conclusion: Our data-driven approach identified predictive clinical factors with a high face validity including joint counts, functionality scores and global health indicators. The different model approaches did not seem to increase the predictive capacity performance. However, our results underline that not so much the baseline disease status but rather the early response to initial treatment reflected in the selected predictive factors can be used for prediction of the need for further treatment adaptation. These models will have to be enriched with patient reported outcomes to further improve predictive performance.

POS1435 CLINICAL CHARACTERIZATION AND PREDICTIVE FACTORS FOR PROGRESSION IN A COHORT OF ILD PATIENTS WITH FEATURES OF AUTOIMMUNITY: ARE IPAF CRITERIA SUFFICIENT?

F. Bozzao[1], P. Tomietto[2], E. Baratella[3,4], F. Giudici[4], M. Kodric[5], R. Della Porta[5], I. Prearo[6], S. M. G. Pirronello[7], F. Fischetti[2,4], M. Confalonieri[4,5], B. Fabris[4,8]on behalf of ILD multidisciplinary unit of the "Azienda sanitaria universitaria Giuliano Isontina" (Trieste). *[1]Azienda ULSS 2 Marca Trevigiana, Internal Medicine, Treviso, Italy*; *[2]Azienda Sanitaria Universitaria Giuliano Isontina, Internal Medicine - Rheumatology Unit, Trieste, Italy*; *[3]Azienda Sanitaria Universitaria Giuliano Isontina, Radiology, Trieste, Italy*; *[4]University of Trieste, Medicine, Surgery and Health Sciences, Trieste, Italy*; *[5]Azienda Sanitaria Universitaria Giuliano Isontina, Pneumology, Trieste, Italy*; *[6]University Hospital, LMU Munich, Vascular Medicine, Munich, Germany*; *[7]Azienda Ospedaliera Cannizzaro, Emergency Medicine, Catania, Italy*; *[8]Azienda Sanitaria Universitaria Giuliano Isontina, Internal Medicine, Trieste, Italy*

Background: It is unknown whether patients with interstitial lung disease (ILD) and only some features of autoimmunity have a different natural history from those with a defined connective tissue disease (CTD-ILD). The classification criteria for "ILD with autoimmune features" (IPAF) may not be able to characterize all these patients, especially those with a usual interstitial pneumonia (UIP) pattern [1].

Objectives: To determine clinical characteristics and predictive factors for progression in a cohort of ILD patients with features of autoimmunity, through the application of classification criteria for IPAF and specific CTD, whenever possible.

Methods: We retrospectively selected a cohort of consecutive patients with ILD as onset manifestation and features of autoimmunity (at least 1 autoantibody and/or 1 clinical sign/symptom), evaluated by our multidisciplinary unit from March 2009 to March 2020. All the final diagnoses were revised according to the latest CTD and IPAF criteria. Patients were followed up for 33 (16.5-69.5) months.

Results: Of the 101 patients enrolled (67.4±10.9 yrs, F/M ratio 65/36), 53 (52.5%) and 37 (36.6%) respectively satisfied the CTD and IPAF criteria. Eleven patients (10.9%) did not satisfy IPAF criteria because of only 1 item (clinical or serologic) within the IPAF domains and a UIP pattern; we defined this group as "autoimmune" UIP (AI-UIP). All the 8 patients initially classified as undifferentiated CTD had sufficient IPAF criteria. Among the IPAF patients (68.2±10.1 years, F/M ratio 20/17), the most common findings were: Nonspecific interstitial pneumonia pattern (56.8%), antinuclear antibodies positivity (43.2%) and arthritis (24.3%). The combination of a positive morphologic and serologic domain was the most common to reach the diagnosis (48.6%). Some IPAF patients had features not included in IPAF criteria, such as non-anti-synthetase myositis-specific antibodies (21.6%), objective sicca syndrome (13.5%) and anti-myeloperoxidase antibodies (2.7%). Over a median of 17 months, 2 IPAF patients (5.4%) developed a definite UIP pattern, while 4 (10.8%) a specific CTD. Comparing the IPAF, CTD-ILD and AI-UIP groups, no statistically significant differences were found in the mean age, sex distribution, smoking habits and mean duration of the disease. However, IPAF patients had a significantly higher prevalence of arterial hypertension and left-sided heart failure and a lower predominance of UIP pattern as expected (10.8% vs. 32.1% vs. 100%, $p<0.01$). Although no differences were found at the diagnosis, at 1 year the proportion of IPAF patients with radiological progression of the fibrosis and/or functional deterioration (defined by a decline in FVC of ≥ 10% and/or DLCO of ≥ 15% predicted) was lower to that of CTD-ILD and AI-UIP (17.1% vs. 31.4% vs. 63.6%, p 0.01). Fewer IPAF patients needed oxygen support (8.6% vs. 31.4% vs. 36.4, p 0.02). Considering the overall 101 patients, having an IPAF and a UIP pattern respectively predicted a slower (OR: 0.37, p 0.04) and a faster (OR: 3.56, p 0.01) ILD progression at the multivariate analysis.

Conclusion: In our cohort, IPAF criteria were useful to identify a subset of patients with a slower ILD progression and a possible evolution to CTD (10-15% of cases) [2]. These criteria do not characterize all the patients with a UIP pattern and limited features of autoimmunity, which seem to have a worse prognosis, independently from the final diagnosis. Further studies are needed to clarify if the prognosis of AI-UIP is different from that of idiopathic pulmonary fibrosis.

POS1436 EPIDEMIOLOGY OF LATENT TUBERCULOSIS INFECTION IN PATIENTS WITH RHEUMATIC IMMUNE-MEDIATED DISEASES. SINGLE UNIVERSITY STUDY OF 1117 PATIENTS

D. Martínez-López[1], J. Osorio-Chavez[2], C. Álvarez-Reguera[3], V. Portilla[3], M. A. González-Gay[3], R. Blanco[3]. *[1]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander (SPAIN), Spain*; *[2]Hospital Universitario Marqués de Valdecilla, Pulmonology, Santander (SPAIN), Spain*; *[3]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*

Background: Patients with rheumatologic immune-mediated diseases (R-IMID) with Latent tuberculosis infection (LTBI) requiring biologic therapy (BT) are at an increased risk of active tuberculosis (TB). Screening of LTBI with tuberculin skin test (TST) and/or Interferon (IFN)-γ release assays (IGRA) is recommended before starting of BT.

Objectives: In patients with R-IMID previously to BT our aim was to assess **a)** prevalence of LTBI, **b)** importance of using a booster test in negative TST and **c)** to compare TST with the IGRA test.

Methods: Cross-sectional single University Hospital study including all patients diagnosed with R-IMID who underwent a TST and/or IGRA in the last five years (2016-2020).

TST was performed by a subcutaneous injection of 0.1 ml of purified protein derivative (PPD) with a reading after 72 hours. TST was considered positive with an induration of more than 5 mm of diameter. If the first TST was negative, a new TST (Booster) was performed between 1 and 2 weeks after the first TST.

LTBI was diagnosed by a positive IGRA and/or TST and absence of active TB (Chest radiograph). Diagnosis with IGRA vs TST was compared (Cohen's kappa coefficient).

Results: We included 1117 patients (741 women/376 men), mean age 53±15 years with LTBI. Chest radiograph was normal in most of the patients, only 39 patients (3.5%) presented signs of previous TB infection, mostly granuloma. Total LTBI prevalence was 31.7% (354/1117). LTBI prevalence in different underlying R-IMID ranges from 35% in vasculitis up to 26.5% in conectivopathies (Figure 1**).**

Booster was positive in 66 patients (7.7%) out of 859 patients with a negative simple TST. Results of TST (+booster) and IGRA tests are shown in Table 1. TST (+booster) was positive in 187 patients (22.9%) out of 817 with a negative or indeterminate IGRA test. IGRA test was positive in 30 (3.8%) out of 793 patients with a negative TST (+booster). Cohen's Kappa coefficient between TST (+booster) and IGRA (QFT-plus), was 0.381.

Conclusion: LTBI is frequent between patients with R-IMID. Booster after negative simple TST may be useful, since it can detect false negatives for LTBI. IGRA and TST(+booster) show a low grade of agreement. Therefore, performing both tests before BT may be recommendable.

Table 1. Results of TST (+booster) and IGRA test

		IGRA (QFT-Plus)				
		Positive	**Negative**	**Indeterminate**	**Unavailable**	**Total**
TST (+Booster)	**Positive**	89	142	45	48	324
	Negative	30	500	130	133	793
	Total	119	642	175	181	1117

* Cohen's kappa coefficient: 0.381

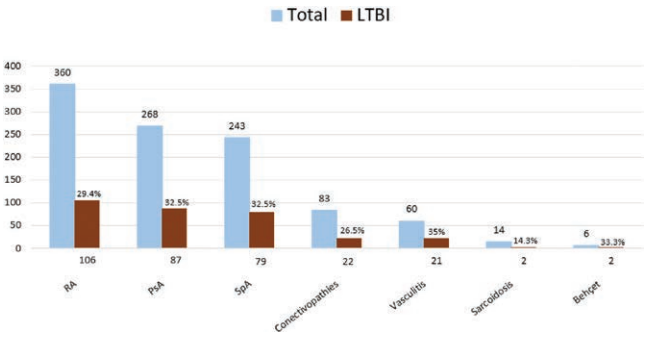

Figure 1. Prevalence of LTBI in different underlying R-IMID

POS1437 LATENT TUBERCULOSIS INFECTION IN RHEUMATIC DISEASES: A REAL-LIFE STUDY OF THREE APULIAN CENTRES. DATA FROM BIOPURE REGISTRY

M. Fornaro[1], D. Goletti[2], A. Abbruzzese[1], M. G. Anelli[1], A. Semeraro[3], N. Maruotti[4], F. P. Cantatore[4], F. Cacciapaglia[1], F. Iannone[1]on behalf of BIOlogic aPUlian REgistry (BIOPURE). [1]*Rheumatology Unit, Department of Emergence and Transplantation (DETO), University of Bari, Bari, Italy*; [2]*Translational Research Unit, Department of Epidemiology and Preclinical Research, National Institute for Infectious Diseases, L. Spallanzani, Roma, Italy*; [3]*Rheumatology Unit, ASL Taranto, Taranto, Italy*; [4]*UOC Reumatologia Universitaria, University of Foggia, Foggia, Italy*

Background: Latent tuberculous infection (LTBI) is very common in the world and screening for it is essential before starting treatment with biotechnological drugs
Objectives: The aims of our study were to assess the prevalence in Apulia of LTBI among patients affected with rheumatic disease and to record the cases of tuberculosis (TB) infection among patients treated with biologic agents.
Methods: We analysed data of patients included in BIOPURE registry from 2008 to 2018, who underwent Quantiferon (QTF) test as routinely screening for biologic treatment. Demographic and clinical data were recorded at the time of the first QTF assessment and this time point was considered the "baseline" of the study. Data regarding further QTF tests performed during follow-up was also acquired by electronic charts. Prophylaxis administration and bDMARD treatments were recorded for patients with positive QTF test. All tuberculosis infections were recorded during the entire time of follow-up.
Results: Three thousand thirty-five patients (female 67.2%, mean age 52 ± 18.3 years) were included in these study, 2692 patients (88.7%) had inflammatory arthritis (28.2% rheumatoid arthritis, 33% psoriatic arthritis and 27.4% spondyloarthritis), 129 (4.2%) patients had connective tissue disease, whereas 214 (7.1%) patients were affected by others rheumatic diseases. The prevalence of LTBI was 10.7% (326 patients) at baseline. Comparisons between positive and negative patients for QTF are reported in Table 1. We acquired data of LTBI prophylaxis of 284 patients; 235 out 265 patients treated with isoniazid completed the treatment, whereas 19 out 19 patients treated with rifampicin completed the prophylaxis regimen. The main cause of isoniazid withdrawal was hypertransaminasemia, but 8 patients then completed prophylaxis with rifampicin. During the entire follow-up (42.6±30.5 months), we recorded 5 (0.02%) cases of primary TB infection in patients on anti-TNFα agents treatment, which had baseline screening negative for LTBI. Data and outcome of these patients are reported in Table 2. The mean time of follow-up of patients on bDMARDs treatment with positive QTF at baseline was 52.7±35.2 months. bDMARD treatment regimens are reported in Table 3. No case of TB reactivation was found among patients with positive baseline QTF. Moreover, of 1563 (51.5%) patients who repeated QTF during follow-up, 62 (4%) of them showed a change in the test result. We observed a change to a positive state in 36 patients with previous negative QTF test, whereas 26 patients with previous positive QTF showed a shift to a negative test during follow-up.
Conclusion: Our study shows a prevalence of LTBI of 10.7% in Apulian patients affected with rheumatic disease. bDMARDs therapy appears to be safe in patients with positive QTF test treated according to current recommendations[1]. However, cases of primary TB infections, especially in patients receiving anti-TNFα drugs, have been observed.

POS1438 EARLY FACTORS ASSOCIATED WITH THE INITIATION OF TREATMENT WITH BIOLOGICS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS – RESULTS FROM A SINGLE CENTRE RETROSPECTIVE COHORT STUDY

E. Costa[1,2], L. Lages[3], D. Esperança Almeida[1,2], A. M. Gomes Correia[1], M. Cerqueira[1], J. Silva[1], A. R. Ribeiro[1], J. Redondo Costa[1], J. Neves[1]. [1]*Hospital de Braga, Rheumatology, Braga, Portugal*; [2]*Unidade Local de Saúde do Alto Minho, Rheumatology, Ponte de Lima, Portugal*; [3]*University of Minho, School of Medicine, Braga, Portugal*

Background: Axial Spondyloarthritis (axSpA) refers to a group of rheumatic diseases that mainly affect the axial skeleton. Treatment with Biological Disease Modifying Anti-Rheumatic Drug (bDMARDs) is indicated when low disease activity is not achieved with Non-Steroid Anti-inflammatory Drugs. Some studies reported that some clinical and socio-demographic were associated with biologics initiation[1,2]. However, early factors associated with the initiation of bDMARDs have not been extensively studied.
The authors speculate that certain features early in disease presentation may be associated with future need for treatment with bDMARDs in patients with axSpA.
Objectives: To study a population of patients with axSpA and determine whether the presence of certain factors at diagnosis is associated with a later need for biological treatment.
Methods: A single centre retrospective study was conducted comprising patients fulfilling the ASAS criteria for axSpA that attended the Rheumatology Outpatient Clinic from January to December 2019. Patients with psoriatic arthritis and enteropathic spondyloarthritis were excluded. All data, except regarding use of bDMARD, refers to the two initial appointments. Between group comparisons were performed through independent sample t-test or Chi-Square as applicable. Logistic Multivariate Regression was performed to understand which factors independently contributed to the use of bDMARDs.
Results: One hundred and fifty patients were included, and 52 patients (34,7%) were under biological treatment. In comparison to the group that was not under treatment with bDMARDs, these were significantly more likely to be *hard-workers* (57,8% *vs* 29,7%; p =,003), to have had elevated C-Reactive Protein (81,6% *vs* 48,9%; p <,001), to have had a grade of sacroiliitis greater than 2 (67,4% *vs* 29,5%; p <,001) and to have history of enthesitis, (32,7% *vs* 13,3%; p =,006). No differences between groups were found in sex, age, HLA-B27 positivity, state of employment, diagnostic delay, smoking status, history of dactylitis and history of uveitis. In multivariate regression analysis, only the *hard-worker* type and the highest grade of sacroiliitis were found to be independently associated with the use of bDMARDs as presented in Table 1. Although not statistically significant, a trend to association was found between elevated CRP at diagnosis and use of bDMARDs.

Table 1. Multivariate logistic regression of variables associated with initiation of bDMARDs.

Conclusion: In our study, the performance of work associated with greater biomechanical stress and the presence of greater structural damage at diagnosis were shown to be associated with the latter use of bDMARDs. The authors highlight the importance of recognizing these factors that seem to relate to more aggressive disease, with more structural damage, thus suggesting a need for a tighter control management strategy in these patients accordingly current guidelines. More studies still needed to better depict the influence of certain early clinical and patient related variables in management of axSpA patients.

POS1439 A MULTI-PREDICTOR MODEL TO PREDICT RISK OF SCLERODERMA RENAL CRISIS IN SYSTEMIC SCLEROSIS

D. Xu[1], R. Mu[1]. [1]*Peking University Third Hopsital, Department of Rheumatology and Immunology, Beijing, China*

Background: Scleroderma renal crisis (SRC) is a life-threatening syndrome. The early identification of patients at risk is essential for timely treatment to improve the outcome[1].

Objectives: We aimed to provide a personalized tool to predict risk of SRC in systemic sclerosis (SSc).

Methods: We tried to set up a SRC prediction model based on the PKUPH-SSc cohort of 302 SSc patients. The least absolute shrinkage and selection operator (Lasso) regression was used to optimize disease features. Multivariable logistic regression analysis was applied to build a SRC prediction model incorporating the features of SSc selected in the Lasso regression. Then, a multi-predictor nomogram combining clinical characteristics was constructed and evaluated by discrimination and calibration.

Results: A multi-predictor nomogram for evaluating the risk of SRC was successfully developed. In the nomogram, four easily available predictors were contained including disease duration <2 years, cardiac involvement, anemia and corticosteroid >15mg/d exposure. The nomogram displayed good discrimination with an area under the curve (AUC) of 0.843 (95% CI: 0.797-0.882) and good calibration.

Conclusion: The multi-predictor nomogram for SRC could be reliably and conveniently used to predict the individual risk of SRC in SSc patients, and be a step towards more personalized medicine.

POS1440 ASSOCIATION BETWEEN SERUM URATE AND INFLAMMATORY MARKERS IN YOUNG ADULTS: CROSS-SECTIONAL FINDINGS FROM A BIRTH COHORT

T. Loyola Correa[1], I. Oliveira de Oliveira[2]. [1]*Universidade Federal de Pelotas, Faculty of Medicine, Pelotas, Brazil*; [2]*Universidade Federal de Pelotas, Postgraduate Program in Epidemiology, Pelotas, Brazil*

Background: Uric acid is the end product of purine metabolism and an abruptly increase or decrease on its serum concentrations can form free urate crystals and precipitate a gout attack. Serum urate (SU) has been positively and independently associated with cardiometabolic diseases in observational studies, but causal roles remain unclear.[1] In addition, inflammatory markers are deeply associated with cardiometabolic diseases, such as essential hypertension and type 2 diabetes mellitus.[2] However, little has been published about the association of SU and subclinical inflammation.

Objectives: To assess the associations of SU with interleukin 6 (IL-6), C-reactive protein (CRP), and adiponectin at 22-year-old individuals belonging to the 1993 birth cohort of Pelotas (Brazil).

Methods: During 1993, all live born babies in the city were invited to take part in a prospective study and sub-samples of this cohort were followed-up since then. At the 22-year follow-up, interviews and clinical measurements were performed and non-fasting blood samples were drawn from the participants. SU was evaluated by enzymatic-colorimetric assay; IL-6 and adiponectin, by immunoassay; and CRP by immunoturbidimetric assay. The co-variables taken into consideration were skin color; asset index at 22 years; cardiometabolic risk factors (body mass index, systolic and diastolic blood pressure); presence of cardiometabolic diseases (hypertension, diabetes and dyslipidemia); and behavioral variables (alcohol use disorder, smoking status and physical inactivity). Exposition variables were categorized into tertiles. Sex-stratified linear regressions have been performed using STATA 13 and p<0.05 was considered statistically significant.

Results: The sample was composed by 1657 (46.3%) men and 1921 (53.7%) women of 22 years old. The median (25-75 IQR) for IL-6 (pg/mL) was higher in women than in men [1.26 (0.85; 2.02) *vs.* 1.07 (0.76; 1.69)]; the same was observed for CRP (mg/dL) [1.6 (0.6; 4.1) *vs.* 0.6 (0.3; 1.4)]. The mean (95%CI) for adiponectin (µg/mL) was also higher in women [10.72 (10.50; 10.94) *vs.* 7.97 (7.78; 8.16)]. As expected, the mean (±SD) for SU (mg/dL) was higher in men (5.2±1.2 *vs.* 3.9±1.1). In adjusted analysis, IL-6 was positively associated with SU only in women; p=0.018 (Table 1). CRP was positively associated with SU in crude and adjusted analyses for both sexes; p=0.002 (Table 1). In addition, higher adiponectin was independently associated with lower concentrations of SU for men (p<0.001) and women (p=0.013) (Table 1).

Conclusion: The increase of SU is associated with IL-6 and CRP increasing and adiponectin decreasing since early adult age.

POS1441

SYMPTOMS CHARACTERISTICS OF SEROPOSITIVE INDIVIDUALS AT-RISK FOR DEVELOPING RHEUMATOID ARTHRITIS ARE VERSATILE AND COMPARABLE TO THOSE IN PEOPLE WITH EARLY RHEUMATOID ARTHRITIS

P. Studenic[1,2], A. Circiumaru[1,3], D. Aletaha[2], K. Chatzidionysiou[1,4], A. Hensvold[1,3], A. Catrina[1,4]. [1]*Karolinska Institute, Department of Medicine (Solna), Division of Rheumatology, Stockholm, Sweden*; [2]*Medical University of Vienna, Department of Internal Medicine 3, Division of Rheumatology, Wien, Austria*; [3]*Academic Specialist Center - Stockholm Health Care Services, Center for Rheumatology, Stockholm, Sweden*; [4]*Karolinska University Hospital, Rheumatology Unit, Stockholm, Sweden*

Background: The symptom burden of typical rheumatoid arthritis (RA) symptoms in those at risk for developing RA - positive for anti-citrullinated peptide antibodies (ACPA) and musculoskeletal complaints - has not been explored.
Objectives: To evaluate patient-reported symptoms in individuals at-risk to develop RA in comparison to people with newly diagnosed, early seropositive RA.
Methods: Two datasources from the region of Stockholm were used: The RISK RA cohort follows up ACPA positive individuals with arthralgia, but without signs of joint inflammation in a structured program over 3 years. The baseline visit of this cohort was used. Patients with early seropositive (ACPA and/or rheumatoid factor positive) RA (symptom duration of 12 months maximum) reported in the Swedish Rheumatology Quality Register (SRQ) at their closest visit to their diagnosis date before receiving DMARD treatment have been identified. At-risk individuals were matched 1:3 by sex and age using the nearest neighbour method utilizing Mahalanobis distance, corrected for sample bias and exact matches on sex. Effect estimates of being at-risk compared to early RA for pain, patient global (GH), fatigue (all visual analogue scales), health assessment questionnaire (HAQ), TJC28 and the EuroQol-5D (EQ5D; range: 0-1) have been derived. Propensity score matching was used as sensitivity analyses.
Results: A total of 223 individuals at risk for developing RA were compared to 820 matched early RA patients. The summary of distribution of variables and effect estimates of differences between at-risk and early RA individuals are shown in the Figure 1. At-risk individuals show 24mm of lower pain scores than early RA. This difference is even less (-17mm, 95%CI: -24 to -11) when the estimate is additionally matched for the number of tender joints. The TJC28 was on average 5.4 joints lower than in early RA patients. People at-risk show 22mm lower GH scores (rate themselves better) and 17mm lower fatigue scores than early RA patients. Fatigue was scored highest (mean:35mm, 95%CI: 30 to 29) among the three VAS. HAQ was on average lower by 0.6 points in at-risk individuals and EQ5D showed 0.24 higher index-values, outlining a better health status. Still the mean EQ5D in at-risk individuals was only 0.74 (95%CI: 0.71 to 0.77), which is lower than average values of an age-matched general population (0.92 to 0.96). Sensitivity analyses revealed similar results.

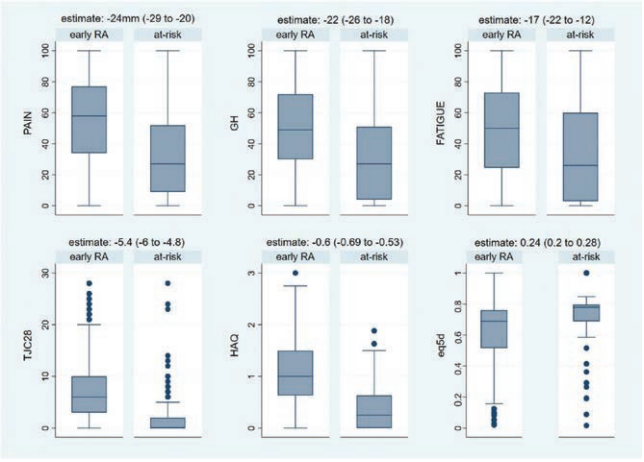

Figure 1. Boxplots of pain, global health, fatigue, TJC28, EQ5D and HAQ, separately displayed for people with early seropositive RA and individuals at-risk. Population effect estimates (all p<0.001) comparing at-risk to early RA are provided for every pair, with 95% confidence interval in brackets.

Conclusion: Not surprisingly, individuals at risk for RA report less symptom burden then early diagnosed RA patients. However, these differences only range around minimal clinically important differences and for fatigue even below, which stresses the need for medical attention and management strategies for symptomatic at-risk individuals.

Validation of outcome measures and biomarkers

POS1442

THE SUBGROUP OF ACPA-NEGATIVE RHEUMATOID ARTHRITIS PATIENTS ACHIEVING SUSTAINED DMARD-FREE REMISSION IS CHARACTERIZED BY A DIFFERENT RESPONSE IN SEROLOGICAL MARKERS WITHIN THE FIRST YEAR OF DMARD-INITIATION

M. Verstappen[1], A. Van der Helm - van Mil[1,2]. [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [2]*Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands*

Background: Whilst ~40% of ACPA-negative RA-patients achieve sustained DMARD-free remission (SDFR; the sustained absence of synovitis after DMARD-cessation), the biological pathways involved in SDFR-development are incompletely understood. Previously, high baseline levels of MMP-3, SAA and CRP were found in ACPA-negative RA-patients achieving SDFR. Differences in biomarker levels might reflect distinct underlying biological pathways leading towards disease resolution in this subgroup of ACPA-negative RA-patients. Subsequently, the course of specific biomarkers after treatment-initiation could attain more insight in the understanding of SDFR-development in ACPA-negative RA.
Objectives: We explored whether the response of specific biomarkers after treatment-initiation could increase the understanding of SDFR-development in ACPA-negative RA.
Methods: One-hundred-thirty-one consecutive ACPA-negative RA-patients were studied on SDFR-development during (median) 7.2-years follow-up. Twelve biomarkers (SAA/CRP/MMP-1/MMP-3/resistin/leptin/IL-6/TNF-R1/YKL-40/EGF/VEGF/VCAM-1) were measured at diagnosis and 1-, and 2-years after DMARD-initiation and compared between patients achieving and not achieving SDFR. To extend on previous findings on baseline levels, correlations between baseline levels and change in levels within year-1 were determined using spearman's rho (ρ).
Results: RA-patients that achieved SDFR (n=63) were characterized by a stronger decline in MMP-1, MMP-3, SAA and CRP in the first 12-months after DMARD-start, compared to RA-patients not achieving SDFR. MMP-1 and MMP-3 declined 1.30-times (95%CI; 1.08-1.57) and 1.44-times (95%CI; 1.00-2.06) stronger in SDFR-patients. In SAA and CRP, this decline was 2.12-times (95%CI; 1.08-4.14) and 2.24-times (95%CI; 1.16-4.35) stronger. Baseline levels of MMP-3, SAA and CRP and strongly correlated with decline in 12-months; ρ -0.6991, ρ -0.9205 respectively ρ -0.9008. RA-patients with high baseline levels characterized the subgroup with the strongest decline in biomarker levels in the first year after DMARD-initiation.
Conclusion: The subgroup ACPA-negative RA-patients achieving SDFR are characterized by higher baseline levels and a stronger serological response of MMP-3, SAA and CRP after DMARD-initiation. Because MMP-3 and SAA are expressed by fibroblast-like synoviocytes, these cells may differ in RA-patients achieving disease resolution; molecular studies on synovial tissue could be a next step.

POS1443

RELATIONSHIP BETWEEN FIBRINOGEN TO ALBUMIN RATIO AND DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Liu[1], Y. Huang[1], Z. Huang[1], Q. Huang[1], T. W. Li[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Systemic lupus erythematosus (SLE) is a systemic inflammatory autoimmune disease characterized by excessive production of immune complexes and proinflammatory cytokine. Low complement, neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) have been used as inflammatory biomarkers to assess the disease activity of SLE. Recently, the fibrinogen to albumin ratio (FAR) has emerged as an effective indicator to reflect the systemic inflammation in many diseases. However, the role of FAR in SLE has been scarcely studied.
Objectives: This study was to investigate the association between FAR and SLE Disease Activity Index 2000 (SLEDAI-2K) in SLE.

Methods: This retrospective study included 74 SLE patients and 79 age- and sex-matched healthy subjects. According to the SLEDAI-2K score, SLE patients were divided into Group 1 with a score ≤ 9 (patients with mild disease activity, *N* = 41) and Group 2 with a score > 9 (patients with moderate to severe disease activity, *N* = 33). Neutrophil, lymphocyte, monocyte, platelet, albumin, fibrinogen, NLR, PLR, monocyte to lymphocyte ratio (MLR), FAR, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), complement 3 (C3), complement 4 (C4) and SLEDAI-2K were collected. Receiver operation characteristic (ROC) curves were conducted to discriminate SLE patients from healthy controls and SLE patients with different disease activity. Correlations between the inflammatory markers and SLEDAI-2K were analyzed.
Results: FAR, NLR, PLR, MLR and fibrinogen in SLE patients were higher compared to those of the healthy controls ($P < 0.05$), while albumin was lower ($P < 0.05$). Patients in Group 2 had higher levels of FAR, NLR, PLR, fibrinogen and CRP than those in Group 1 ($P < 0.05$) except MLR ($P = 0.579$) and ESR ($P = 0.130$), albumin and C3 were lower ($P < 0.05$). Furthermore, FAR were higher in SLE patients with nephritis than those without nephritis ($P = 0.009$). The ROC curve for differentiating SLE patients from healthy individuals showed that the area under curve (AUC) of FAR (0.801, 95%CI: 0.728 - 0.874) and albumin (0.833, 95%CI: 0.764-0.903) were higher than NLR (0.798, 95%CI: 0.725 - 0.871), PLR (0.680, 95%CI: 0.588 - 0.771), MLR (0.785, 95%CI: 0.712 - 0.859) and fibrinogen (0.645, 95%CI: 0.556 - 0.733). Besides, the ROC curve for predicting the disease activity of SLE patients indicated that the AUC of FAR (0.911, 95%CI: 0. 842 - 0.980) was higher than NLR (0.697, 95%CI: 0.574 - 0.821), PLR (0.695, 95%CI: 0.571 - 0.820), MLR (0.553, 95%CI: 0.415 - 0.691), fibrinogen (0.718, 95%CI: 0.590 - 0.847), CRP (0.672, 95%CI: 0.540 - 0.803), ESR (0.640, 95%CI: 0.510 - 0.770), C3 (0.644, 95%CI: 0.515 - 0.773), C4 (0.544, 95%CI: 0.407 - 0.681) and albumin (0.894, 95%CI: 0.819 - 0.969). FAR was positively correlated with SLEDAI-2K ($r = 0.682$, $P < 0.001$), yielding a highest relevance than other inflammatory parameters.
Conclusion: FAR was significantly elevated in SLE patients compared with healthy subjects and related with the disease activity of SLE. FAR might be a useful inflammatory index to evaluate disease activity in patients with SLE.

POS1444 ADOPTION OF DIGITAL MANIKINS TO SELF-REPORT PAIN: A SYSTEMATIC REVIEW

S. Mustafa Ali[1], R. Lee[1], A. Chiarotto[2], J. Mcbeth[1], S. Van der Veer[3], W. Dixon[1]. [1]*University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [2]*Erasmus University Medical Centre, Department of General Practice, Rotterdam, Netherlands*; [3]*University of Manchester, Centre for Health Informatics, Manchester, United Kingdom*

Background: Chronic pain is common in rheumatic and musculoskeletal conditions, and a major driver of disability worldwide. Knowledge gaps exist with respect to correct estimates of chronic pain [1], what causes it and how best to manage it [2]. To address this, researchers need validated methods to measure pain in large, representative populations. Though many authors have recognised the potential benefits of paper-based and digital pain manikins [3]–[5], it is unknown to what extent studies have adopted digital manikins as a data collection tool.
Objectives: The objective of our review was to identify and characterise published studies that have used digital pain manikins as a data collection tool.
Methods: We systematically searched six electronic databases, including Medline, CINAHL, Embase, Scopus, IEEE Xplore digital library, ACM Digital Library, on 3-4 of November 2020 by using a pre-defined search strategy. We included a study in our review if it used a digital manikin for self-reporting any pain aspect (e.g., intensity, type) by people suffering from pain, and if its full text was published in English. We conducted this review by following the PRISMA reporting guidelines and conducted a descriptive synthesis of findings, including manikin-derived outcome measures.
Results: Our search yielded 4,685 unique studies. After full text screening of 705 articles, we included 14 studies in our review. Most articles were excluded because they used either paper-based manikins or didn't include enough details to determine that the manikin was digital (n=386). The majority of included studies were published in Europe (n=11). Most studies collected data on a manikin once (n=11); from people with pain conditions (n=9); and in clinical settings (n=9). There was only one study that collected digital pain manikin data in a large sized (i.e., ~20,000) population-based survey.
In most studies participants shaded any painful area on manikin (n=9) and did not enable participants to record location-specific pain aspects (n=11). None of the manikins enabled participants to record location-specific pain intensity. Pain distribution (i.e. number or percentage of pre-defined body areas or locations experiencing pain) and pain extent (i.e. number or percentage of shaded pixels) were commonly used manikin-derived outcome measures. In six studies, a heat map was used to summarise the extent of pain across the population.
Conclusion: Digital pain manikins have been available since the 1990s but their adoption in research has been slow. Few manikins enabled location-specific pain recording suggesting that the digital nature of the manikin is not yet fully utilised. Future development of a validated digital pain manikin supporting self-reporting of the location and intensity of pain, usable across any device and screen size, may increase uptake and value.

POS1445 RETINOL BINDING PROTEIN 4 AS AN ACUTE PHASE REACTANT AND BIOMARKER IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER AND AMYLOIDOSIS COMPARED TO INFECTIONS

N. Koca[1], R. Deniz[1], M. Erdugan[1], Y. Yalçınkaya[1], B. Artim-Esen[1], M. L. Ocal[1], M. Inanc[1], A. Gül[1]. [1]*Istanbul Faculty of Medicine, Istanbul University, Division of Rheumatology, Department of Internal Medicine, Istanbul, Turkey*

Background: Retinol binding protein 4 (RBP4) is a plasma retinol transporter that transports retinol from liver to periphery. RBP4 has been studied as a biomarker in metabolic and neoplastic conditions, however its association with inflammation is not clear. Serum amyloid A (SAA), another retinol binding protein, has been known as a sensitive biomarker of inflammation in familial Mediterranean fever (FMF) and other autoinflammatory disorders. C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and SAA are commonly used as acute phase reactants, but they are not successful in differentiating non-infectious inflammatory conditions from infections.
Objectives: We aimed to evaluate the potential of serum RBP4 as a biomarker of acute phase response and to determine its performance in differentiation of inflammation of patients with FMF and AA amyloidosis from infections.
Methods: A total of 169 participants in 5 groups, consisting of FMF (n = 60), FMF with AA amyloidosis (n = 58), non-FMF AA amyloidosis (n = 23), infections (n = 10, 3 pneumonia, 3 sepsis, 1 pyelonephritis, 1 fungal infection, 1 cellulitis, 1 disseminated zoster), and healthy controls (HC) (n = 18), were included and evaluated cross sectionally. Hemogram and serum CRP, ESR, SAA, ferritin, creatinine, AST, ALT, albumin levels were recorded from the patient charts. FMF and FMF + amyloidosis patients were evaluated during attack-free period. Serum RBP4 levels were investigated by ELISA (Elabscience, USA). Mean values and relative changes compared to healthy controls were evaluated for SAA, CRP, RBP4 levels in all groups.
Results: Serum RBP4 level was found to be higher in FMF group compared to the patients with infection ($p = 0.002$) and HC ($p < 0.001$) as well as in patients with amyloidosis. Compared to HC, 47%, 28% and 27% increase was observed in mean RBP4 levels in FMF, FMF + amyloidosis and non-FMF amyloidosis patients, despite no significant change in patients with infections. However, CRP and SAA elevations were much more prominent in patients with infections (58 and 134 times, respectively) compared to the patients with FMF (13 and 35 times, respectively), FMF + amyloidosis and non-FMF amyloidosis (Table 1). There was no significant difference in RBP4 levels between FMF, FMF-amyloidosis and non-FMF amyloidosis groups. CRP, ESR, ferritin and SAA levels were higher in the infection group compared to HCs.

Table 1. Demographic features and laboratory findings of the participants

Variables	FMF (n=60)	FMF-Amyloidosis (n=58)	Non-FMF-AA Amyloidosis (n=23)	Infection (n=10)	Healthy control (n=18)
Female/Male	46/14	33/25	8/15	3/7	8/10
Age (SD)*	38±13	43±11	53±13	65±15	33±9
	(18-74)	(21-69)			
Creatinine (mg/dL)*	0,8±0,2	1,7±1,7	2,0±1,6	1,7±1,0	0,7±0,2
Albumin(mg/dL)*	4,7±0,4	4,3±0,6	3,3±0,9	3,0±0,9	4,8±0,2
Ferritin (ng/mL)*	70±94	245±315	139±168	554±38	83±72
RBP4 (ng/mL)*	772±183	671±214	666±256	512±204	524±117
RBP4 (median)	770	653	645	487	498
	(434-1142)	(227-1259)	(331-1214)	(226-876)	(566-738)
CRP (mg/L)*	16±47,1	12,8±32,8	25,7±36,4	69±36,8	1,2±1,2
SAA (mg/dL)*	10,3±31,4	5,0±13,9	7,1±14,1	40,2±18,5	0,3±0,1
ESR*	15±13	19±16	41±29	45±42	7±5
Relative RBP4 increase	1,47±0,35	1,28±0,41	1,27±0,49	0,98±0,39	
Relative CRP increase	13,4±39,2	10,6±27,3	21,4±30,3	57,7±30,6	
Relative SAA increase	34,5±104,8	16,0±45,7	23,7±47,1	133,9±61,7	

*mean, RBP4 (Retinol Binding Protein 4), C-Reactive Protein (CRP), Erythrocyte Sedimentation Rate (ESR), Serum Amyloid A (SAA).

Conclusion: This preliminary study showed that RBP4 levels may be increased about 1.5 times in FMF and to lesser extent in AA amyloidosis patients despite no significant change during acute phase response of different infections. Patients with infections show strong CRP and SAA response, and the differential response of RBP4 in FMF patients warrants further analysis in larger group of patients with different clinical characteristics.

Rehabilitation

POS1446

ANTHROPOMETRIC MEASUREMENTS IN UPPER EXTREMITY REHABILITATION OF PATIENTS WITH RHEUMATIC DISEASES

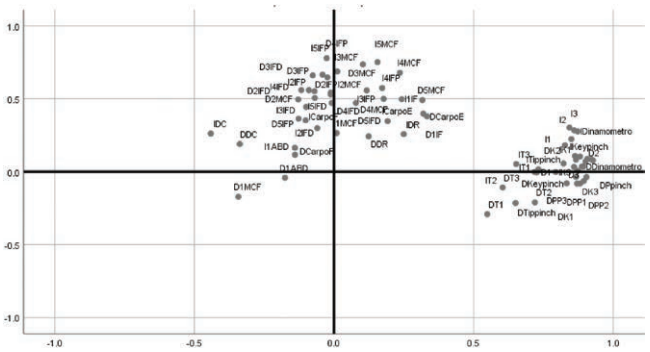
P. Herrera-Sandate[1], D. Vega-Morales[1], A. L. De-Leon-Ibarra[1], P. Valdes-Torres[2], L. A. Chavez-Alvarez[1], I. D. J. Hernandez-Galarza[1], R. Pineda-Sic[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology Service, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Sports Medicine and Physical Rehabilitation Department, Monterrey, Mexico*

Background: The chronic nature of rheumatic diseases has a negative impact in quality of life. Pain and loss of function in the upper extremity cause a progressive difficulty to perform daily activities, often requiring integral physical rehabilitation programs. Anthropometric measurements habitually take prolonged periods of time, given the extensive nature of physical examination in rheumatic patients. It is unknown which factors are most efficient to better reflect the functional status of the rheumatic patient.

Objectives: Determine the most efficient anthropometric measurements in the upper extremity to assess the functional status of rheumatic patients in rehabilitation programs.

Methods: Thirty-six patients were recruited from Rheumatology consultation of University Hospital "Dr. José Eleuterio González" in Monterrey, Mexico. Patients had a complete physical examination by a board-certified rheumatologist, which referred patients to Physical Rehabilitation consultation if necessary. A cross-sectional study was carried out in these patients with Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire (1), measurement of ranges of motion (ROM) and hand strength with the Mathiowetz protocol (2). Analysis was performed through Principal Components Analysis including Total Variance Explained (TVE), Rotated Component Matrix (RCM) and dendrograms.

Results: From the total of patients, 34 (94.4%) were women with a mean age of 34 years (SD 11.33). The most common diagnosis was rheumatoid arthritis (47.2%) followed by osteoarthritis (8.3%). The mean disability score in DASH was 29.3% (DE 23.36). The TVE analysis found that 3 elements explained 48.6% of the total variance, and 13 elements explained 89.4%. RCM correlations among hand strength parameters ranged from 0.51 to 0.93, whereas ROM correlation values were below 0.4. Graph 1 depicts data dispersion for ROM, grip strength and pinch gauge by dynamometer.



Graph 1. Two main clusters are observed in the RCM plot of the data. In the center and superior to the x axis, a conglomeration corresponding to ROM is shown, consisting of radial and ulnar deviation; flexion, extension, abduction and adduction in carpal bones, metacarpophalangeal joints, and proximal and distal interphalangeal joints of the five fingers of both hands, accordingly. To the right and across the x axis, another cluster depicts the grip strength and tip, key, and lateral pinch gauge of the fingers according to the Mathiowetz protocol. Closeness of data points portray a higher similarity among variances in the second cluster.

Conclusion: Hand strength is the most efficient parameter to assess the functional status of the upper extremity in rheumatic patients in rehabilitation programs.

POS1447

LOW-INTENSITY PULSED ELECTROMAGNETIC FIELDS IMPROVE PHYSICAL PERFORMANCE IN A DOSE-DEPENDENT MANNER: AN OBSERVATIONAL STUDY IN OLDER ADULTS WITH RHEUMATIC DISEASES

M. Giovale[1], G. Tramontano[1], R. Galli[1], S. Rando[1], A. Giusti[1], L. Bandi[1], F. Russo[1], S. Rampoldi[2], L. C. Bottaro[3], G. Bianchi[1]. [1]*Local Health Trust 3, Rheumatology Unit, Department of Medical Specialties, Genoa, Italy*; [2]*THS Therapeutic Solutions, Department of Engineering, Milano, Italy*; [3]*Local Health Trust 3, Executive Board, Genoa, Italy*

Background: Low-intensity pulsed electromagnetic fields (PEMF) have been shown to improve gait parameters in frail older adults.[1] Furthermore, the continuous exposure to PEMF (up to 1 year) have been demonstrated to produce progressive improvements in self-selected gait speed in older adults at risk of falling.[2]

Objectives: To investigate the effects of two different treatment regimens of PEMF on physical performances in older adults presenting with rheumatoid arthritis (RA), osteoarthritis (OA) or severe osteoporosis (OP).

Methods: Older adults presenting with RA, OA or OP, at increased risk of falls, evaluated in our Falls Prevention Clinic, were considered for a prospective observational study investigating the effects of PEMF on physical performances. PEMF were supplied by the THS 280 E device (THS-Therapeutic Solutions Srl, Milan, Italy). It provides a new therapeutic approach, named TEPS (Triple Energy Postural Stabilization), that represents an evolution of physical therapy.[1,2] On the basis of the physician judgment, PEMF were administered following an intensive protocol, every 45 days (PEMF-45), or a standard validated protocol[1,2], every 60 days (PEMF-60). All subjects were assessed at baseline and every 3 months with the following tests: 4 meters gait speed test [4MGS, seconds (sec)], timed up and go test (TUG, sec), chair stand test (CST, sec), short physical performance battery (SPPB, score), and hand grip strength (HGS) by hand dynamometer (Kg). Demographic, anthropometric and clinical characteristics, including pharmacological treatments and functional status were evaluated at baseline. Clinical and adverse events were assessed every 45 or 60 days after PEMF administration.

Results: Overall, 94 patients were enrolled between January and December 2020. Of these, 43 subjects (N=33 PEMF-45, N=11 PEMF-60) with a valid 6-month follow-up assessment were considered for the current analysis. The two groups were comparable regarding the main baseline characteristics, and similar

% of patients presented with RA, OA or OP. Mean age (±SE) was 78±7 in PEMF-45 and 77±7 in PEMF-60. As expected, all physical performance tests improved significantly from baseline to 6 months in both groups. Mean (±SE) 4MGS increased significantly more in PEMF-45 (from 3.24±0.12 sec to 2.83±0.18 sec) compared to PEMF-60 (from 3.22±0.21 sec to 3.02±0.30 sec, p=.018). Likewise, mean (±SE) CST improved more in PEMF-45 (from 12.4±0.9 sec to 8.7±0.4 sec) compared to PEMF-60 (from 11.1±1.5 sec to 9.8±0.7 sec, p=.002). No significant difference between groups was found for the other tests, although a trend toward better results in PEMF-45 was manifest: SPPB improved by 6.4% in PEMF-45 and by 3.0% in PEMF-60, and TUG decreased by 7.8% in PEMF-45 and by 6.1% in PEMF-60. During the 6 months observation period no adverse event was observed.

Conclusion: Preliminary results of our ongoing prospective observational study suggest that a more frequent administration of PEMF produces greater improvements in some but not all physical performance parameters compared to a standard validated regimen[1,2].

Education

POS1448 EVIDENCE BASED PRACTICE: WHAT IS THE EVIDENCE THAT BRITISH SOCIETY FOR RHEUMATOLOGY GUIDELINES ARE EVIDENCE BASED?

M. Lee[1], G. Reynolds[2], M. Yates[3], J. Galloway[3]. [1]*Mohammed Bin Rashid University Of Medicine and Health Sciences, Rheumatology, Dubai, United Arab Emirates*; [2]*Newcastle University, Translational and Clinical Research Institute, Newcastle, United Kingdom*; [3]*King's College London, Rheumatology, London, United Kingdom*

Background: Clinical practice guidelines are designed to ensure that patients are treated according to best evidence, with the goal of optimizing clinical outcomes and reducing unwarranted variation in care. They compile, rate and translate the data available into recommendations that form the basis of evidence-based practice for most clinicians. Despite their importance, the evidence base informing different guidelines varies in quality. A recent study of American College of Rheumatology (ACR) Practice Guidelines demonstrated only 17 of 35 class I (strong benefit to harm ratio) recommendations were supported by level A evidence (high quality randomized controlled trails or meta-analyses)[1].

Objectives: To review the evidence supporting the British Society for Rheumatology (BSR) guidelines.

Methods: Thirteen sets of guidelines that were available on the BSR website as of October 16th 2019 were reviewed (https://www.rheumatology.org.uk/practice-quality/guidelines). A range of methodologies (including Grading of Recommendations Assessment, Development and Evaluation (GRADE), Scottish Intercollegiate Guidelines Network (SIGN), EULAR and Royal College of Physicians (RCP) recommendations) were used to assess the quality of evidence and strength of recommendation. For comparability between guidelines the level of evidence was converted to a score between I (highest quality) and IV (lowest quality) and the strength of recommendation was converted to a rating between A and D. The polymyalgia rheumatica guideline was not assessed due to unclear methodology and lack of level of evidence for all recommendations.

Results: Of the 12 BSR guidelines assessed, there were 554 recommendations in total. The number of recommendations per guideline ranged between 13 and 80. Across all assessed guidelines, 94 recommendations (17.0%) were classified as level I, 161 (29.1%) as level 2 and 299 (54.0%) as level 3 or 4. These figures are similar to those reported in the ACR guidelines (23%, 19% and 58% respectively)[1]. The proportion of level I evidence varied from 46.2% (Axial Spondyloarthropathy guideline) to 0% (Hot Swollen Joint guideline).

Conclusion: Over half of all BSR guideline recommendations have level of supporting evidence of III/IV. A wide range of methodologies are used to generate BSR guidelines (GRADE, SIGN, RCP / EULAR). This makes it challenging for readers unfamiliar with these approaches to interpret evidence and hinders comparisons between guidelines. A standardized methodology for future guideline development would overcome these barriers.

POS1449 SEGMENTED SHORT-FORMAT ONLINE EDUCATION SIGNIFICANTLY INCREASES PREDICTION, PROGNOSIS, AND MANAGEMENT OF FIBROSING INTERSTITIAL LUNG DISEASE ASSOCIATED WITH CONNECTIVE TISSUE DISEASE

C. Rohani-Montez[1], M. Calle[1], C. Allen[1], T. Maher[2], V. Smith[3], J. Jacob[4], G. Riemekasten[5], M. Kolb[6]. [1]*Medscape Education Global, Medscape Education Global, London, United Kingdom*; [2]*Keck Medicine of USC, Clinical Medicine, Los Angeles, United States of America*; [3]*Ghent University Hospital, Department of Rheumatology, Gent, Belgium*; [4]*University College London, UCL Respiratory, CMIC UCL, London, United Kingdom*; [5]*University Medical Center Schleswig-Holstein, Department of Rheumatology and Clinical Immunology, Lubuck, Germany*; [6]*McMaster University, Division of Respirology, Department of Medicine, Hamilton, Canada*

Background: Identifying fibrosing interstitial lung disease (ILD) at the earliest opportunity remains one of the most urgent challenges for the effective management of this potentially rapidly progressive and burdensome condition, which is frequently associated with several connective tissue diseases (CTDs). However, knowledge on how to identify early hallmarks and predictors of fibrosing ILD, as well as knowing which steps to take next is frequently lacking in clinical practice.

Objectives: This study was conducted to determine whether online independent medical education could improve rheumatologists' and pulmonologists' knowledge and competence in identifying and managing progressive fibrosing ILDs earlier in the disease course.

Methods: Rheumatologists and pulmonologists participated in five ~10-min presentations about the early identification of fibrosing ILD in patients with or without CTDs and completed all pre- and post-questions.[1] The effects of the education on knowledge and competence were assessed using a 3-question, repeated pairs, pre-assessment/post-assessment study design. For all questions combined, the chi-square test assessed differences from pre- to post-assessment. P values <.05 are statistically significant. The activity launched on October 9, 2020, and data were collected through December 18, 2020.

Results: Overall significant improvements were seen after participation for both rheumatologists (average correct response rate of 28% at pre-assessment vs 74% at post-assessment; P<.001, representing a 165% relative percentage change [RPC]; N=39), and pulmonologists (average correct response rate of 39% at pre-assessment vs 67% at post-assessment; P<.001, representing a 72% RPC; N=102). Specifically, significant improvements were observed in clinicians' knowledge of predictors of fibrosing ILD in patients with CTD, as well as competence in selecting the right HRCT parameters to assess prognosis and select a treatment approach to reduce the risk of disease progression (Figure 1).

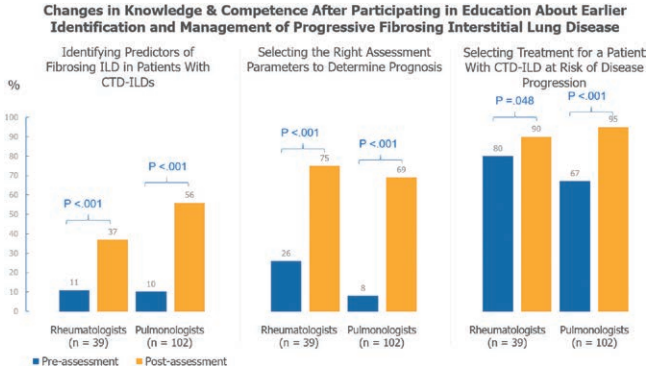

Figure 1.

After participating in the activity, 59% of rheumatologists and 50% of pulmonologists had measurable improved confidence related to identifying early disease progression in patients with progressive fibrosing ILDs.

Given the very low rates of correct responses at baseline regarding predictors of fibrosing ILD and assessing prognosis, it will be important to continue to reinforce these learnings in ongoing educational programs.

Conclusion: This study demonstrates the success of segmented online education in improving rheumatologists' and pulmonologists' knowledge and competence in evaluating risk and prognosis of fibrosing ILD and managing patients with CTD-ILDs. This could lead to earlier changes in therapeutic approach for those with signs of progression and result in improved overall outcomes for these patients.

POS1450 PATIENTS' SAFETY SKILLS ASSESSMENT WITH BIOLOGICS AND JAK INHIBITORS: UPDATE OF THE BIOSECURE QUESTIONNAIRE

C. Beauvais[1], V. Gaud-Listrat[2], J. Sellam[3], F. Fayet[4], M. Beranger[5], N. Deparis[6], M. Antignac[7], C. Sordet[8], M. Rodere[4], L. Gossec[9]on behalf of On the behalf of the therapeutic patient education section of the French Rheumatology Society. *[1]Centre Hospitalier Universitaire Saint Antoine, Sorbonne Université, Rheumatology Department, Paris, France*; *[2]Cochin Hospital, Rheumatology Department, Paris, France*; *[3]Hospital Saint-Antoine Ap-Hp, Rheumatology Department, Paris, France*; *[4]Centre Hospitalier Universitaire Gabriel Montpied, Rheumatology Department, Clermont-Ferrand, France*; *[5]Centre Hospitalier Universitaire Orléans, Rheumatology Department, Orleans, France*; *[6]Association Nationale de Défense Contre l'Arthrite Rhumatoïde, ANDAR, Paris, France*; *[7]Centre Hospitalier Universitaire Saint Antoine, Sorbonne Université APHP, Pharmacy Department, Paris, France*; *[8]Hôpitaux Universitaires de Strasbourg, Rheumatology Department, Strasbourg, France*; *[9]Sorbonne Université, Hopital Pitié Salpetrière, Rheumatology Department, Paris, France*

Background: Biologic disease-modifying anti-rheumatic drug (bDMARDs) and JAK inhibitors (JAKi) may lead to an increased risk of infections, which could be prevented by enhancing patients' safety skills (ref). We developed a self-administered questionnaire (BioSecure1, ref) in 2013 to assess the patients' safety skills (Table 1). Following the appearance of new bDMARDs and JAKi and new information on safety, this questionnaire needed updating.

Table 1. Nine domains of core safety skills and number of corresponding questions in BioSecure questionnaires.

Domain of competence	BioSecure1	BioSecure2
General knowledge	4	2
Dealing with infectious symptoms and fever	10	11
Dealing with other infectious symptoms	4	4
Dealing with injuries, preventing infectious complications, vaccinations	8	8
Dental hygiene, preventing infectious complications, information to share with the dentist	2	2
Planning surgery, information to share with the surgeon/ anesthesiologist	7	7
Planning child conception	2	1
Communication: who to contact?	2	2
Subcutaneous treatments: cold chain/cold storage, subcutaneous injection techniques	3	0

Objectives: To update the BioSecure questionnaire assessing patients' safety skills

Methods: Four steps by a 10 participants multidisciplinary steering committee. Step1: critical analysis of content and formulations of BioSecure1 on the basis of i) the participants' own experience of the questionnaire use in current practice (5/10 participants) or research (6/10 participants) ii) assessment of BioSecure1 consistency with current guidelines for management of targeted drugs. Step2: development of a first updated version by a core group of 10 persons. Step3: comments by an extended panel of rheumatology teams interested in therapeutic patient education (TPE). Step4: testing of the final version (Biosecure2) by ten patients through cognitive debriefing.

Results: In total, 10 rheumatologists, 6 rheumatology nurses, 1 pharmacist and 1 patient from a patient association participated. Inadequate formulations were reported regarding some situations for which recommendations had the most shifted since Biosecure1 development such as planning pregnancy, remission management and prevention measures before surgery. Features of some infectious conditions were clarified; barriers measures against infection and complications such as sigmoiditis and Herpes Zoster infection were added. BioSecure2 continues to assess the 9 domains of core safety skills (Table 1). The questionnaire was shortened to 50 items (mean filling in time is 10 minutes) with a good understanding and scoring was simplified (mean scoring time 3.5 minutes).

Conclusion: BioSecure2 represents an updated outcome measure to evaluate the patient's skills to prevent adverse events with targeted therapies. This questionnaire can be useful in the context of patient-health professional communication, and as a tool to measure TPE on safety issues.

POS1451 DEVELOPING A TOOL TO MEASURE THE LEARNING CURVE: ENTHESITIS ULTRASOUND IN PSORIASIS ARTHRITIS

S. Brådland[1], P. Andel[1,2,3], A. Diamandopoulos[4,5], G. Haugeberg[1,6]. *[1]Hospital of Southern Norway, Department of Rheumatology, Kristiansand, Norway*; *[2]Østfold Hospital Trust, Department of Cardiology, Kalnes, Norway*; *[3]University of Oslo, Department of Clinical Medicine, Oslo, Norway*; *[4]Akershus University Hospital, Department of Rheumatology, Oslo, Norway*; *[5]Martina Hansens Hospital, Department of Rheumatology, Bærum, Norway*; *[6]Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Trondheim, Norway*

Background: Enthesitis is defined as inflammation of the tendon inserting the bone encompassing the adjacent trabecular bone network, the fascia and surrounding soft tissues as the cartilage, the bursa and the fat pad. In enthesitis clinical examination alone is a method with significant limitations in terms of diagnostic accuracy and does not correlate strongly with imaging diagnostics (1,2).

Ultrasound (US) is a widely used imaging technique in Rheumatology. But while learning curricula and standardization for joint US are available, other US techniques as vascular-, enthesis- or serosa-US gets usually less attention in rheumatologic US curricula. Though both OMERACT (4) and GRAPPA (3) have recently published qualitative and semi quantitative criteria in enthesitis US, few publications explicitly address the learning curves in these particular domain.

Objectives: To describe the development of a tool to measure the learning curve for enthesitis US.

Methods: 3237 US images of 561 enthesis were obtained by one experienced ultrasonographer (PMA) in B- and color Doppler (CD) mode in longstanding psoriasis arthritis patients of different disease activity. Due to duplicity and poorer image quality 2115 images were eliminated. The remaining fully anonymized 1122 images (561 enthesis) were afterward implemented in a random multiple choice algorithm presenting a B-mode and a CD image of the same enthesis at the same time without timely limitation. Rating follows qualitative GRAPPA criteria as well as semiquantitative OMERACT criteria (3, 4). The enthesitis scoring application was than written in.NET/ C#, TypeScript and ReactJS and is hosted in Azure Cloud platform. The scoring is stored in a database allowing extraction to SPSS for statistical analysis.

Results: The interface of the functional program is shown in image 1 (Screenshot). In a next step the program will be presented to different raters of different ultrasound experience (>10 years, 5-10 years, 1-5 years, <1 years). The program will be presented a multitude of times in different order to every rater to adjust for inter-rater reliability. Correlation between raters will be given to depict a learning curve on enthesitis ultrasound assuming the rater with the highest experience as gold standard.

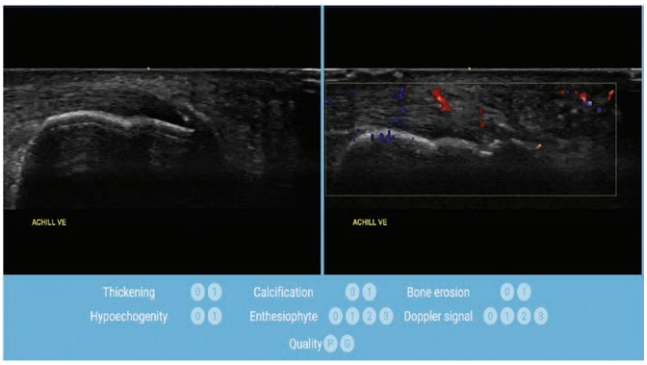

Image 1. Screenshot of grafical user interface of the scoring program.

Conclusion: In this presentation we outline the successful development of a tool to measure the learning curve in enthesitis. We hypothesize that knowledge about the learning curve and inter-rater reliability in enthesitis US obtained by our tool might contribute to future US curricula, structured reporting and deep learning algorithms.

Educational cases

POS1452 DE NOVO LUPUS NEPHRITIS FOLLOWING THE INTRODUCTION OF BELIMUMAB

J. Pinnell[1], S. Tosounidou[1]. [1]*Birmingham City Hospital, Rheumatology, Birmingham, United Kingdom*

Background: Belimumab inhibits the activity of the soluble cytokine BLyS (B lymphocyte stimulator) and is recommended for use in moderate refractory systemic lupus erythematosus (SLE). A recent randomised controlled trial reported that Belimumab improves the outcomes for patients with lupus nephritis when used with standard therapy.

Objectives: We present two cases of lupus nephritis that developed in SLE patients without pre-existing renal disease shortly after commencing treatment with Belimumab.

Methods: Both patients are Afro-Caribbean females with similar immunological profiles, including ANA, dsDNA, anti-Sm, anti- Ro and anti-RNP antibodies. The first was 59 years old with a long standing diagnosis of SLE since 1996 that had required previous Cyclophosphamide for neuropsychiatric lupus. She was most recently taking Hydroxychloroquine, Mycophenolate and Prednisolone having previously failed with Azathioprine twice. Belimumab was commenced in February 2020 due to worsening arthritis, mouth ulcers, pleuritis and systemic features associated with a significant rise in her dsDNA and low complement. Her SLEDAI score was 13. After six months of treatment she developed proteinuria for the first time. Her urine protein creatinine ratio (uPCR) was measured at 205mg/mmol and a subsequent renal biopsy revealed features of active Class IV and V lupus nephritis. Belimumab was changed to Rituximab. Mycophenolate was stopped due to persistent neutropenia and Tacrolimus was introduced instead. After 5 months treatment her uPCR is now 33mg/mmol.

The second patient was 37 years old with a recent diagnosis of SLE in 2018. She presented with inflammatory arthritis, oral and nasal ulcers, and cytopenia. She responded poorly to Azathioprine and was intolerant of Mycophenolate. Her most recent treatment was Hydroxychloroquine and Prednisolone. She was commenced on Belimumab in February 2020 due to active mucocutaneous and musculoskeletal features of lupus with a SLEDAI score of 12. The mucocutaneous features of lupus responded well but she developed proteinuria seven months later, and by November 2020 her uPCR was 149mg/mmol. Belimumab was switched to Rituximab and initially her uPCR continued to rise but it has now fallen to 43mg/mmol.

Results: The occurrence of new lupus nephritis soon after the initiation of Belimumab monotherapy has been reported previously and our cases raise further concerns. A prospective observational study recently reported significantly increased rates of new lupus nephritis developing in patients receiving Belimumab in addition to standard care compared to those receiving standard treatment. An association between Belimumab and the development of de novo lupus nephritis has not yet been conclusively established but it would create a significant challenge in how Belimumab is used and consented for in SLE, especially if it becomes more widely used to treat lupus nephritis. The mechanism by which Belimumab may increase the risk of, or trigger, lupus nephritis is currently unclear but may result from increased activity in BLyS associated pathways following the blockade of the BLyS pathway.

Conclusion: These two cases raise questions about the role of using Belimumab in patients at risk of developing lupus nephritis. We therefore recommend caution in its use and recommend active monitoring of renal parameters especially in patients with poor clinical and serological response to Belimumab.

POS1453 OVERLAPPING FEATURES OF RELAPSING POLYCHONDRITIS AND SWEET'S SYNDROME: COULD THIS BE VEXAS (VACUOLES, UBIQUITIN A1E MUTATION, X-LINKED, AUTOINFLAMMATORY, SOMATIC) SYNDROME?

A. Vivekanantham[1,2], M. Kesavan[3], J. Evans[4], R. N. Matin[5], I. Elliott[6], R. Luqmani[1,2]. [1]*Oxford University Hospitals NHS Foundation Trust, Nuffield Orthopaedic Centre, Rheumatology, Oxford, United Kingdom*; [2]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Botnar Research Centre, Oxford, United Kingdom*; [3]*Oxford University Hospitals NHS Foundation Trust, Churchill Hospital, Haematology, Oxford, United Kingdom*; [4]*Oxford University Hospitals NHS Foundation Trust, Churchill Hospital, Haematology, Oxford, United Kingdom*; [5]*Oxford University Hospitals NHS Foundation Trust, Churchill Hospital, Dermatology, Oxford, United Kingdom*; [6]*Oxford University Hospitals NHS Foundation Trust, John Radcliffe Hospital, Infectious Diseases, Oxford, United Kingdom*

Background: An 83-year-old male presented to the infectious diseases team with intermittent fevers associated with tension headaches, malaise and fatigue for two years, with recent worsening. He had noted a progressive decline in his mobility over the past year following replacement of his right knee for osteoarthritis. His past medical history included atopic eczema, malaria and bilateral cataract extractions.

On examination, he had a widespread non-scaly annular urticated rash. He had persistently raised inflammatory markers (CRP 40mg/L, ESR 82mm/hour), normocytic anaemia (Hb 102 g/L, MCV 101.9 fL), lymphopenia (0.70 x10^9/L), fluctuating eosinophilia (0.88-1.25 x10^9/L) and a mildly elevated lactate dehydrogenase (243IU/L). A thorough work up for pyrexia of unknown origin showed no evidence of infection/ vasculitis/ immune pathology. The only positive finding was prior exposure to schistosomiasis, treated with a single dose of praziquantel. An echocardiogram and serial PET-CT scans were normal. Given the deterioration in mobility since the right knee replacement, an MRI knee was performed, and cobalt/ chromium levels to look for allergic responses to the prosthesis, but these tests did not reveal any findings of significance.

An initial haematology work-up did not identify an abnormality of concern (screening for a myeloproliferative neoplasm including BCR-ABL studies were negative and mast cell tryptase was not elevated). Due to a worsening skin rash, he was reviewed by dermatology where a skin biopsy showed features of superficial neutrophilic dermatosis which can be observed with Sweet's syndrome. However, it was felt that this was an unlikely explanation for the persistent systemic symptoms. He proceeded to a bone marrow biopsy which showed reactive features including vacuolation of myeloid precursors with normal cytogenics.

During follow up appointments, the patient described new recurrent violaceous patches with episodes of inflammation of the pinna of the ear, suggesting a diagnosis of relapsing polychondritis and so the patient was started on high dose prednisolone (80mg per day [1mg per kg]) and referred for rheumatological assessment. He had an excellent response to prednisolone (fever, ear swelling and rash subsided). The overlapping features of relapsing polychondritis and Sweet's syndrome in an elderly man suggested a diagnosis of VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory and somatic) syndrome. The prednisolone dose was rapidly reduced to 10mg per day and the patient was commenced on methotrexate, as a steroid-sparing agent. Further blood tests have been sent for genetic analysis for VEXAS syndrome but results are pending.

Objectives: N/A

Methods: N/A

Results: N/A

Conclusion: VEXAS syndrome is a newly identified genetically defined syndrome, described by Beck et al in October 2020 consisting of somatic mutations in the *UBA1* gene, affecting bone marrow stem cells. In a study of 25 patients with this mutation, diagnostic/ classification criteria for relapsing polychondritis (n=15), Sweet's syndrome (n=8), polyarteritis nodosa (n=3) or giant cell arteritis (n=1) were met and patients often had severe refractory disease with overlapping systemic inflammatory and haematologic features. Features of VEXAS include the presence of vacuoles in myeloid cells, somatic mutations in the UBA1 (ubiquitin-activating enzyme) gene, X-linkage (therefore only occurring in males), in older people with autoinflammatory syndromes. Although VEXAS syndrome is a relatively rare condition, it was a relevant consideration in this case.

Background: Systemic sclerosis (SSc) is a fibrotic autoimmune disease characterized by dermatological involvement. Skin involvement can alter appearance, which can have a psychological impact(1). Assessment of body image could be central in optimizing care. Yet, data are scarce(2).

Objectives: The main objective of our study was to assess aesthetic impairment measured on a visual aesthetic scale (AES) (3) in patients with SSc compared to a group of healthy subjects. Secondary objectives were to assess associations between aesthetic impairment and standardized questionnaires for aesthetic impairment as well as clinical, biological, psychological/quality of life, and functional parameters of SSc.

Methods: The "Sclero-esthet" study is a descriptive single-center study of two populations: patients with SSc, included in a referral center for systemic and autoimmune diseases at Lille Hospital, France, and healthy controls.

Results: This study, from January 2017 to October 2017, included 88 patients (69 [78.4%] women) with a median age of 52 years (range: 43 to 59) and 88 controls (49 [55.7%] women) with a median age of 45 years (range: 32 to 55). Perception of physical changes assessed using the AES was greater in cases than in controls (3.7 ± 0.3 vs 2.8 ± 0.3, p=0.028), with statistical correlation with ASWAP. SSc patients with anxiety or depressive symptoms had significantly higher AES scores. Cases presented poorer quality of life than controls.

Conclusion: The AES appears to be a good tool to evaluate aesthetic impairment. Correlations found with psychological and quality of life parameters support the need to improve patient management in this field.

POS1455-HPR RELATIONSHIP BETWEEN PSYCHOLOGICAL FACTORS AND MEASURES OF RHEUMATOID ARTHRITIS ACTIVITY

Y. Olyunin[1], V. Rybakova[2], E. Likhacheva[3], E. Nasonov[4,5]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Early Arthritis, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Outpatient Department, Moscow, Russian Federation*; *[3]Institute of Psychology and Pedagogy, Russian New University, Department of General Psychology and Labor Psychology, Moscow, Russian Federation*; *[4]V.A. Nasonova Research Institute of Rheumatology, Scientific Supervisor, Moscow, Russian Federation*; *[5]I.M. Sechenov First Moscow State Medical University, Ministry of Health of Russia (Sechenov University), Department of Therapy and Occupational Diseases, Moscow, Russian Federation*

Background: The patient-reported outcomes are important components of quantitative methods of rheumatoid arthritis (RA) activity assessment which are used to choose the appropriate drug therapy. The value of these parameters can be significantly affected not only by the inflammatory process, but also by the psychological characteristics of the patient and, in particular, by hardiness [1].

Objectives: To study the relationship between psychological factors and signs of RA activity.

Methods: Patients with RA who met the EULAR/ACR 2010 criteria, and observed at the V. A. Nasonova Research Institute of Rheumatology were included. Clinical examination was performed including patient global assessment (PGA), physician global assessment (PhGA), pain measurement on a visual analog scale, tender joint count (TJC), swollen joint count (SJC). The functional status was determined by HAQ, the quality of life – by SF-36 EQ-5D, the nature of pain – by painDETECT, the presence of anxiety and depression – by HADS. Patients also completed Hardiness Survey questionnaire to assess hardiness (HDS) and 3 components of the HDS – commitment (CMT), control (CT) and challenge (CLN). Disease activity was evaluated with DAS28, CDAI, and RAPID3. All patients signed informed consent to participate in the study. Analysis of the data was performed using Spearman's rank test, Fisher exact test, qui-square and t-tests.

Results: 85 patients with RA were included. There were 69 women and 16 men. Mean age was 56.7±13.1 years, disease duration – 7.6±2.7 years. 72 patients were positive for rheumatoid factor, 75 – for anti-cyclic citrullinated peptide antibody. CDAI showed high activity in 15, moderate – in 37, low – in 30, and remission in 3 patients, DAS 28 – in 10, 55, 12, and 8, and RAPID3 – in 24, 25, 15, and 21, respectively. 24 patients had subclinically or clinically expressed anxiety and 15 –subclinically or clinically expressed depression (≥8 according to HADS). In 31 patients, the painDETECT questionnaire revealed possible or probable neuropathic pain. Mean HDS was 84.8±21.7, CMT – 38.9±9.2, CT – 29.4±8.6, CLN – 17.3±7.1. These values were comparable with the corresponding population data for this age group. There was a significant inverse correlation between HDS and RA activity measures, including SJC, TJC, DAS28 ($p<0.05$), pain, PGA, PhGA, CDAI, RAPID3, and HAQ ($p<0.01$). In addition, HDS and all its components positively correlated with quality of life, assessed by SF-36 and EQ-5D ($p<0.01$). In patients with subclinically and clinically expressed anxiety and depression, HDS, CMT, and CT were significantly lower than in patients without anxiety and depression ($p<0.01$), while the values of CLN in these groups did not differ significantly.

Conclusion: The results of the present study suggest that low HDS may be one of the significant factors determining RA activity level because it does not allow patients to adapt adequately to a stressful situation produced by the disease.

POS1456-HPR THE SERUM IRON LEVEL MIGHT BE USEFUL IN DETERMINING THE SEVERITY OF MALNUTRITION IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Matsumoto[1,2], Y. Sugioka[3], M. Tada[4], T. Okano[5], K. Mamoto[5], K. Inui[6], D. Habu[2], T. Koike[1,3]. [1]*Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease, Shirahama, Japan*; [2]*Osaka City University Graduate School of Human Life Science, Medical Nutrition, Osaka, Japan*; [3]*Osaka City University Medical School, Center for Senile Degenerative Disorders, Osaka, Japan*; [4]*Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan*; [5]*Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan*; [6]*Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan*

Background: The Global Leadership Initiative on Malnutrition (GLIM) criteria, the first international criteria for diagnosis of malnutrition, was released in 2018 [1]. Patients with rheumatoid arthritis (RA) are thought to be prone to malnutrition due to decreased food intake and increased muscle catabolism caused by chronic inflammation or pain. However, there has been no report to assess the nutritional status of RA patients in accordance with the GLIM criteria. In addition, commonly used blood nutrient indicators such as albumin might not be appropriate as nutritional indicators for RA because these values are affected by inflammation.

Objectives: This study aims to examine the rates of malnutrition in RA patients according to GLIM criteria, and the relationship between blood nutrient indicators and the severity of malnutrition.

Methods: In this study, we conducted a cross-sectional survey of 135 female RA patients in 2020. According to the GLIM criteria, patients were considered to be malnourished if patients had one of the following phenotypic: (1) low body mass index, (2) non-volitional weight loss, (3) reduced muscle mass, and one of the following etiologic: (1) reduced food intake or assimilation, (2) disease burden/inflammatory condition. Reduced muscle mass was evaluated by measuring calf circumference, and inflammatory condition was evaluated by Disease Activity Score (DAS) 28. In accordance with the GLIM criteria, the severity of malnutrition was judged as three levels: no problem, moderate, and severe malnutrition. Albumin, transthyretin, transferrin, retinol binding protein, zinc, iron, ceruloplasmin, and total cholesterol were assessed as blood nutrition indicators. Also grip strength was assessed. We compared each nutritional indicator among the three groups according to the severity of malnutrition using age-adjusted analysis of covariance, and examined the relationship between each nutritional indicator and the severity of malnutrition using receiver operating characteristic (ROC) analysis.

Results: In RA patients, 20% were classified as severe malnutrition, and 40% were moderate or more. Serum iron levels were significantly lower in the severe malnutrition group compared to the no problem group ($p = 0.001$). In ROC analysis, serum iron, zinc, albumin, and grip strength (area under curve; AUC; 0.680, 0.696, 0.636, 0.790, respectively) were significant parameters for classification of moderate and severe malnutrition. Serum iron and grip strength (AUC for respective parameters were 0.741, 0.747) were significant parameters for classification of severe malnutrition.

Conclusion: Evaluation based on the GLIM criteria showed that about 40% of RA patients were under moderate or severe malnutrition. It was suggested that serum iron and grip strength might be useful to predict the severity of malnutrition.

POS1457-HPR GASTROINTESTINAL SYMPTOMS AND RHEUMATIC DISEASES: TWO SIDES OF THE SAME COIN

R. Spagnuolo[1], F. S. Iaquinta[2], S. Naty[3], R. D. Grembiale[3], P. Doldo[1]. [1]*University "Magna Graecia" of Catanzaro - AOU Mater Domini - Gastroenterology Unit, Department of Experimental and Clinical Medicine, Catanzaro, Italy*; [2]*University "Magna Graecia" of Catanzaro, Rheumatology Research Unit, Department of Health Sciences, Catanzaro, Italy*; [3]*University "Magna Graecia" of Catanzaro, Rheumatology Research Unit, Department of Health Sciences, Catanzaro, Italy*

Background: Patients with Rheumatic Diseases (RD) often show different symptoms besides the osteoarticular ones. Healthcare workers can evaluate the impact of specific symptoms on RD patients' quality of life in order to improve global management.

Objectives: The aim of this study was to assess the presence of gastrointestinal symptoms in RD patients through Patients Reported Outcomes.

Methods: We carried out a cross-sectional study of 101 RD patients compared with 202 healthy volunteers. Healthcare workers invited patients and volunteers to complete questionnaires on gastrointestinal symptoms, through seven domains (belly pain, constipation, diarrhea, disrupted swallowing, gas and bloating, nausea and vomiting, gastroesophageal reflux) of the Patient-Reported Outcomes Measurement Information System (PROMIS®).

Results: Among 101 RD patients, 34 (33.6%) had a diagnosis of Rheumatoid Arthritis, 23 (22.7%) had a diagnosis of Psoriatic Arthritis, 12 (11.8%) had axial spondyloarthritis; 18 (17.8%) had Systemic Sclerosis, 8 (7.9%) were classified as Connectivitis (i.e.Lupus, Sjögren Syndrome), and finally 6 (5.9%) had vasculitis. Median disease duration was 7±5 years and just under half (45.5%) of RD patients had active disease according to specific disease activity index. As shown in Table 1, no significant differences were found between patients and controls with regard to demographic and anthropometric characteristics except for sex, since males were 25.7% (n=26) in RD patients and 125 (61,8%) in healthy volunteers. In our study, Patients reported significantly greater gastrointestinal symptoms than healthy controls. More specifically, as shown in Figure 1A, median T score for belly pain, constipation, diarrhea and disrupted swallowing were significantly higher in the RD patients than in healthy controls (50.2 ± 14 vs 41.7 ± 12 $p<0.001$; 51.5 ± 10 vs 42.2 ± 9 $p <0.001$; 45.3 ± 8 vs 42 ± 5 $p <0.001$; 51.1 ± 10 vs 44.6 ± 7 $p <0.001$) respectively. Moreover, also regarding others domains (gas and bloating, nausea and vomiting and gastroesophageal reflux), patients reported a median T score worse than healthy controls (Figure 1B).

Table 1.

	Patients (N= 101)	Healthy (N= 202)	*p*
Demographic and Anthropometric			
Age (years)	60±13	54.2 ±15	ns
Gender n male (%)	26 (25,7)	125 (61,8)	<0,001
BMI (Kg/m2)	26,4±4	25,5±4	ns
Smoke n (%)	51(50,5)	97(48)	ns
Physical Activity (%)	27(26,7)	62(30,7)	ns
Rheumatoid Arthritis	34(33,6)	-	
Psoriatic Arthritis	23(22,7)	-	
Spondyloarthritis	12(11,8)	-	
Systemic Sclerosis	18(17,8)	-	
Connectivitis	8(7,9)	-	
Vasculitis	6(5,9)	-	
Disease duration (years)	7±5	-	
Disease Activity n yes (%)	46(45,5)	-	
Medications n (% patients)		-	
NSAID	11(10,9)	-	
Steroids	26(25,7)	-	
Biological Treatment	54(53,5)	-	
Methotrexate	34(33,7)	-	

Continuous variables are shown as mean ± standard deviation. Categorical variables are presented as number and proportion. The overall p-value was calculated by the Mann–Whitney non-parametric test for independent samples and by Chi-square test as appropriate.

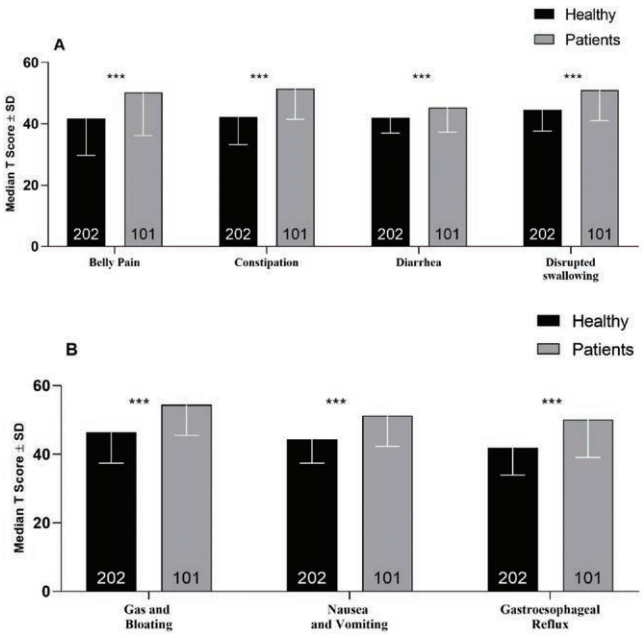

Figure 1. Median T Score stratified by study group. Data are shown as mean and standard deviation. The overall p-value was calculated by the Mann–Whitney non-parametric test for independent samples.

Conclusion: Firstly, this study highlights the need to investigate further the association between Rheumatic Diseases and gastrointestinal symptoms as potential patterns of underlying diseases and, secondly, the need to adopt validated questionnaires in clinical practice that can help healthcare professionals to detect underestimated symptoms.

DIGITAL RHEUMATOLOGY IN THE ERA OF COVID-19: RESULTS OF A NATIONAL PATIENT AND PHYSICIAN SURVEY

A. Kernder[1,2], H. Morf[2,3], P. Klemm[2,4], D. Vossen[2,5], M. Meyer[2,6], I. Haase[2,7], J. Mucke[1,2], A. Kleyer[2,3], P. Sewerin[1,2], G. Bendzuck[8], S. Eis[8], J. Knitza[2,3], M. Krusche[2,9]. *[1]Heinrich-Heine-University Düsseldorf, Department of Rheumatology & Hiller-Research Unit Rheumatology, Düsseldorf, Germany*; *[2]German Society for Rheumatology (Working Group Young Rheumatology), Rheumatology, Berlin, Germany*; *[3]Friedrich-Alexander University Erlangen-Nürnberg, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany*; *[4]Department of Rheumatology, Immunology, Osteology and Physical Medicine, Department of Rheumatology, Immunology, Osteology and Physical Medicine, Bad Nauheim, Germany*; *[5]St. Elisabeth Hospital, Rheinisches Rheumazentrum Meerbusch, Rheumatology, Meerbusch, Germany*; *[6]Universitätsklinikum Hamburg-Eppendorf, Rheumatology, Hamburg, Germany*; *[7]Department of Rheumatology & Hiller-Research Unit Rheumatology, Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany*; *[8]German League against Rheumatism, German League against Rheumatism, Bonn, Germany*; *[9]Charité- Universitätsmedizin, Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Digital health applications (DHAs) are gaining influence and promise great potential for the monitoring and management of rheumatic and musculoskeletal diseases (RMDs).

Objectives: To analyse the impact of the COVID-19 pandemic on RMD patients' and rheumatologists' usage, preferences, and perception of digital health applications (DHAs) in Germany.

Methods: A web-based national survey was developed by the Working Group Young Rheumatology of the German Society for Rheumatology and the German League against Rheumatism. The prospective survey was distributed via social media, QR-code, and email. Descriptive statistics were calculated, and regression analyses were performed to show correlations.

Results: We analysed the responses of 299 patients and 129 rheumatologists. Most patients (74%) and rheumatologists (76%) believed that DHAs are useful in the management of RMDs and felt confident in their own usage thereof (90%; 86%). 38% of patients and 71% of rheumatologists reported that their attitude had changed positively towards DHAs and that their usage had increased due to COVID-19 (29%; 48%).

Usage and recommendation of DHAs for both groups are shown in Figure 1:

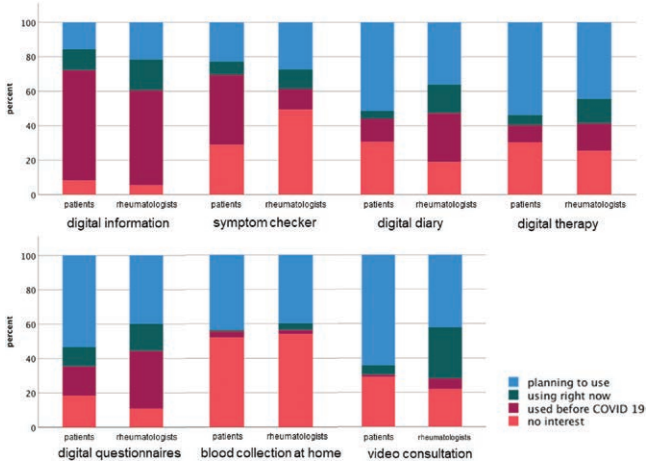

Figure 1. Usage or recommendation of digital health applications. Patients and rheumatologists were asked to indicate the specific digital health applications (DHAs) they used or were recommended.

The majority in both groups agreed on implementing virtual visits for follow-up appointments in stable disease conditions. The most reported advantages of DHAs were usage independent of time and place (76.6%; 77.5%). The main barriers were a lack of information on suitable, available DHAs (58.5%; 41.9%), poor usability (42.1% of patients) and a lack of evidence supporting the effectiveness of DHAs (23.2% of rheumatologists) (Table 1).

Table 1. Advantages and Barriers of DHA, n (%).

Advantages			Barriers		
	Patients	Rheumatologists		Patients	Rheumatologists

Patients and rheumatologists were asked about the advantages and barriers of DHAs. Multiple answers were allowed. Patients had two additional potential advantages and potential barriers to choose from*.

Only a minority (<10% in both groups) believed that digitalisation has a negative impact on the patient-doctor relationship.

Conclusion: The COVID-19 pandemic instigated an increase in patients' and rheumatologists' acceptance and usage of DHAs, possibly introducing a permanent paradigm shift in the management of RMDs.

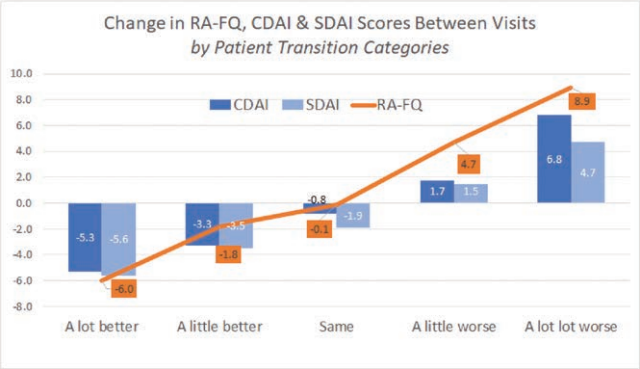
Sinai Hospital, Rheumatology, Toronto, Canada*; [12]*Hospital for Special Surgery, Rheumatology, New York, United States of America*

Background: The RA-FQ is a patient-reported measure of current disease activity in RA that can be used to identify disease flares. The RA-FQ queries pain, physical function, fatigue, stiffness, and participation and yields a score from 0-50. We previously reported on reliability, validity, and responsiveness.

Objectives: To identify changes in RA-FQ that represent minimal and meaningful improvement or worsening from the perspective of people with RA, treating rheumatologists, and in relation to disease activity indices. We hypothesized that

Methods: Data were from adults with early RA (sx <1 year) enrolled in the Canadian Early Arthritis Cohort, a prospective study of real-world patients treated across Canada. Participants completed the RA-FQ, Patient Global, and RA transition item since last visit (a little vs. a lot better or worse or same) between consecutive 3- and 6-month visits. Rheumatologists recorded joint counts, MD Global, and change in RA. We compared mean change across improvement and worsening using patient anchors and disease activity indicators.

Results: The 808 adults were mostly white (84%) women (71%) with a mean (SD) age of 55 (15) and moderate-high CDAI level (85%) at enrollment. Most (79%) reported their RA had changed; 59% were better and 20% worse. Patients who were *a lot worse* had a mean increase of 8.9 points whereas those who rated themselves as *a lot better* had a -6.0 decrease on the RA-FQ (Figure 1). Minimal worsening and improvement were associated with 4.7 and -1.8 change in RA-FQ scores, respectively, while patients who rated their RA unchanged had stable RA-FQ scores (Table 1).



Similar changes were evident in CDAI, SDAI, and DAS indices (Table 1). Larger differences were observed with patient vs. physician global scores and tender vs. swollen joints. Across measures, the change associated with worsening was greater than for improvement. Results supported all prespecified hypotheses ab.

Table 1. Change in RA-FQ scores between visits by patient rating of RA status.

	A Lot Better (N=346; 43%)			A Little Better (N=132; 16%)			The Same (N=174; 21%)			A Little Worse (N=94; 12%)			A Lot Worse (N=62; 8%)

DAS28-CRP	-0.7	(-0.8, -0.6)	1.01	-0.5	(-0.7, -0.2)	1.2	-0.2	(-0.4, 0.0)	1.0	0.3	(0.1, 0.5)	1.0	0.5	(0.2, 0.9)	1.2
Patient Global (0-10)	-1.3	(-1.5, -1.0)	2.7	-0.5	(-0.9, -0.1)	2.1	-0.1	(-0.4, 0.2)	2.1	1.3	(0.8, 1.8)	2.4	2.9	(2.1, 3.6)	3.1
MD Global (0-10)	-1.2	(-1.4, -1.0)	1.9	-0.7	(-1.1, -0.3)	-0.1	-0.1	(-0.4, 0.2)	1.9	0.1	(-0.3, 0.5)	2.8	0.7	(0.0, 1.5)	2.8
Swollen Joints (28)	-1.4	(-1.7, 1.0)	3.2	-1.0	(-1.8, -0.2)	4.6	-0.4	(-0.9, 0.0)	3.0	0.0	(-0.7, 0.7)	3.4	1.3	(0.2, 2.5)	4.6
Tender Joints (28)	-1.5	(-1.9, -1.1)	3.9	-1.3	(-2.2, -0.3)	5.5	0.0	(-0.7, 0.6)	4.3	0.3	(-0.7, 1.2)	4.5	2.2	(0.8, 3.5)	5.4

Conclusion: In this large cohort of adults with ERA, the RA-FQ was responsive to change and generally distinguish between minimal and meaningful improvement and worsening. These data add to a growing evidence demonstrating robust psychometric properties of the RA-FQ and offer

initial guidance about the amount of change associated with improvement or worsening, supporting its use in RA care, research and decision-making.

POS1460-HPR MYRA TOUCH FOR DISEASE ACTIVITY EVALUATION IN RHEUMATOID ARTHRITIS: A COMPARISON OF PATIENT-REPORTED OUTCOMES WITH PHYSICIAN'S ASSESSMENT

L. H. Eow[1], J. Yew[1], K. H. Lee2, S. Selvadurai2, S. M. Liau2, N. Mohd Noor2, A. Mohd2, Y. L. Loh2, S. C. Gun2. *[1]Hospital Tuanku Ja'afar, Medical Department, Seremban, Malaysia*; *[1]Hospital Tuanku Ja'afar, Medical Department, Seremban, Malaysia*

Background: Patient-reported outcomes (PROs) have become an essential component of patients' assessment in the management of Rheumatoid Arthritis(RA).They have been reported to be at least as informative if not more than physician assessed outcomes.

MyRA Touch was pioneered by the Rheumatology Unit of Hospital Tuanku Jaa'far in Seremban Malaysia in March 2018,to engage and empower all RA patients on their own disease activity monitoring. It is an electronic platform, designed to enhanced the application of electronic patient reported outcomes (ePROs) among RA patients where they examine and record their own painful and/or swollen joints for DAS28 calculation and report their health assessment through Routine Assessment of Patient Index Data with 3 Measures (RAPID 3).MyRA Touch is an applications (App) that is user friendly and available in four major spoken languages (English, Chinese, Malay and Tamil) with an animated version for patients who are illiterate.

Objectives: The objectives of this study are to determine the correlation between:

I)Patient-reported and physician reported DAS28 ESR/CRP

II)RAPID3 and Clinical Disease activity Index (CDAI)

III)RAPID3 and DAS28 ESR/CRP assessed by physician and patient

IV)RAPID3 and inflammatory markers ESR/CRP.

Methods: This was a cross-sectional study carried out in the Rheumatology Unit of Hospital Tuanku Jaa'far. All data entered through MyRA Touch App from April 2018 till April 2020 was analysed.

Results: There were a total of 562 patients who entered the data in the App, 87.9% were women. The ethnic compositions of the study subjects comprised of Indians (36.7%) followed by the Malays (34.7%),Chinese (26.3%) and other ethnics (2.3%). About half of patients (59.8%) were in the 51-70 age group whereas 22.9%,1.8% and 15.5% were in the 31-50,18-30 and above 70 age groups respectively. The majority of our patients (96%) were literate. A total of 54.3% of them received secondary education, 27% primary, 12.2% tertiary and 6.6% did not receive any formal education.

There was a high level of correlation between DAS28 ESR/CRP performed by patient and DAS28 ESR/CRP assessed by physician, (r=0.808 for DAS28 ESR and r=0.804 for DAS28 CRP). RAPID3 also showed high level of correlation with CDAI and DAS28 CRP assessed by patient (r=0.700 and r=0.718 respectively). There was a moderate correlation between DAS28 ESR/CRP done by physician with RAPID3 (r=0.656 and r=0.696 respectively).RAPID3 demonstrated little correlation with inflammatory markers ESR and CRP (r=0.141 and r=0.171 respectively).

Conclusion: PROs via DAS 28 (ESR/CRP) and RAPID3 showed moderate to high correlation with disease activity assessed by physician. We can empower patients to perform their own disease assessment by using the MyRA Touch App before seeing their physician and the information provided in the App, can help to reduced consultation time. During the COVID-19 pandemic, telemedicine is very much encouraged. By using the MyRA Touch, patients can assess their own tender and swollen joint count on a homunculus, evaluate their own physical function, health and pain using the RAPID3 parameters. The information obtained from the PROs in the MyRA touch App enables the physician to make a more comprehensive virtual assessment of the patient's condition which helps in treatment decision making. In conclusion, MyRA Touch is an useful tool for disease activity measurement by patient.

POS1461-HPR THE DEVELOPMENT OF A NOVEL EPRO DELIVERY SYSTEM TO MEASURE PATIENT QUALITY OF LIFE IN ROUTINE CLINICAL CARE: AN ANALYSIS OF 5 YEARS OF EXPERIENCE

K. Tymms[1,2], T. Smith[1], C. Deakin[1], T. Freeman[3], D. Hoffman[3], D. Segelov[3], H. Griffiths[1,4], S. Ciciriello[1,5], P. Youssef[1,6], D. Mathers[1,7], C. Osullivan[1], G. Littlejohn[1,8]. *[1]OPAL Rheumatology, Ltd, Sydney, Australia*; *[2]Canberra Rheumatology, Canberra, Australia*; *[3]Software 4 Specialists (S4S), Pty Ltd, Sydney, Australia*; *[4]Barwon Rheumatology, Services, Geelong, Australia*; *[5]Dept. of Rheumatology, Royal Melbourne Hospital, Melbourne, Australia*; *[6]Dept. of Rheumatology, Royal Prince Alfred Hospital, Sydney, Australia*; *[7]Georgetown Arthritis, Georgetown, Australia*; *[8]Dept. of Medicine, Monash University, Clayton, Australia*

Background: Registry studies and clinical trials are increasingly incorporating patient reported outcomes (PROs) to measure the full burden of disease and better measure the efficacy and value of medicines; however, the burden of paper-based surveys, time constraints, and privacy concerns impede the widespread use of PROs in routine clinical care.

Objectives: To develop a simple and secure technological solution to incorporate validated PROs into routine clinical care for patients with rheumatic diseases, and to assess the patient response to functional assessment of chronic illness therapy fatigue (FACIT-F), patient health questionnaire-2 (PHQ-2), and healthcare resource utilization (HCRU) questionnaires delivered using this ePRO method.

Methods: A novel ePRO questionnaire delivery system was developed by Software4Specialists in partnership with OPAL Rheumatology. Validated PRO questionnaires were sent from the patient's electronic medical record (Audit4, Software4Specialists) and delivered to the patient's email address at time intervals specified by the rheumatologist (defaults to quarterly) or completed in the clinic waiting room prior to the consultation using a tablet or the patient's smart phone (in-practice). Completed questionnaires were encrypted and returned directly to the patient's Audit4 electronic medical record held on the clinician's server for review at the next clinical consultation. The link to the PRO questionnaire expired within 28 days if the questionnaire was not completed, and the questionnaires were automatically cancelled if 2 consecutive links expired. This technology was made available to up to 111 rheumatologists located in 42 clinics in 6 states/territories in Australia, and the use of this technology to furnish the clinical consultation was voluntary for clinicians and patients. Deidentified clinical data was extracted from the servers of participating rheumatologists and aggregated across all sites.[1] Data collected between April 2016-Dec 2020 was analysed descriptively.

Results: Between April 2016-Dec 2020, 99,505 FACIT-F, PHQ-2 and HCRU questionnaires have been delivered to 5,784 patients from 39 of 42 contributing clinics (93%). 85% of questionnaires were delivered via email and 15% in-practice. Overall, 85% of patients completed at least one questionnaire, and of all questionnaires sent, 73% were completed. These rates have remained consistent over time. The completion rates were higher when questionnaires were delivered to patients in-practice compared to email (96% vs 69%). Females were more likely to engage with the questionnaires than males (87% vs 81%), and older patients were slightly more likely to complete all questionnaires delivered. 69% of questionnaires sent via email were completed on the day they were delivered and 94% were completed within 7 days. The median (IQR) number of questionnaires completed per patient was 3 (1,7) and the median (IQR) time since the first questionnaire was completed was 13 months (5,26).

Conclusion: The novel Audit4 ePRO delivery system is an effective tool for incorporating PROs into routine clinical care to capture data directly from the patient on the impact of their condition on their quality of life. The data generated provides a unique opportunity to understand the full burden of disease for patients in the real-world setting and the impact of interventions.

POS1462-HPR VALIDITY AND PSYCHOMETRIC CHARACTERISTICS OF THE PSORIATIC ARTHRITIS QUALITY OF LIFE (PSAQOL) QUESTIONNAIRE IN TURKISH POPULATION

M. T. Duruöz[1], K. Nas[2], S. Acer Kasman[1], E. Uzun[3], H. H. Gezer[1]. *[1]Marmara University, School of Medicine, Physical Medicine and Rehabilitation Department, Rheumatology Division, Istanbul, Turkey*; *[2]Sakarya University School of Medicine, Division of Rheumatology and Immunology, Department of Physical Medicine and Rehabilitation, Sakarya, Turkey*; *[3]Sakarya University School of Medicine, Department of Physical Medicine and Rehabilitation, Sakarya, Turkey*

Background: Psoriatic Arthritis Quality of Life (PsAQoL) questionnaire was developed to measure quality of life (QoL) in patients with psoriatic arthritis (PsA) (1).
Objectives: The aim of the study was to assess validity and psychometric properties of the PsAQoL questionnaire.
Methods: The translation-back translation method by a bilingual panel was used to translate the original PsAQoL into Turkish (2). Face and content validities were evaluated via cognitive debriefing interviews with 10 PsA patients. Then, patients with PsA according to CASPAR criteria were recruited to assess feasibility, missing data, floor and ceiling effect, reliability, and construct validity. Reliability was assessed by internal consistency. Construct validity was investigated by convergent and divergent validity by assessing the PsAQoL's relations with QoL and non-QoL parameters. For this purpose, demographics, clinical characteristics (shown in Table 1), survey data including PsAQoL, Short form 36, visual analog scales for pain and fatigue, Health Assessment Questionnaire, and Hospital Anxiety and Depression Scale results were recorded.
Results: One hundred and sixty-two patients were recruited and 74 of them had axial PsA. Cognitive debriefing showed the Turkish version of PsAQoL to be clear, understandable, and relevant. It was easy to complete and calculate, with the 3 minutes and 20 seconds, respectively. The Cronbach's alpha coefficient for internal consistency was 0.930. The questionnaire presented no floor or ceiling effect (<15% for both) and no missing data. PsAQoL showed good correlations with the QoL scales indicating its convergent validity and moderate to non-significant correlations with the non-QoL parameters supporting its divergent validity (Table 1).

Table 1. Spearman's correlation coefficients of PsAQoL with the other parameters for construct validity

POS1463-HPR IMPACT OF COVID-19 PANDEMIC ON DISEASE ACTIVITY AND EMOTIONAL WELL-BEING AMONG RHEUMATOID ARTHRITIS PATIENTS: A TELEMEDICINE STUDY

B. Lucchino[1], C. Iannuccelli[1], C. Gioia[1], G. Dolcini[1], M. DI Franco[1]. *[1]Sapienza University of Rome, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Rome, Italy*

Background: By the beginning of March 2020, the pandemic of the novel coronavirus disease (COVID-19) imposed severe lockdown measures opposing the viral spread, limiting non-COVID patients' access to hospitals. Previous reports suggest that Rheumatoid Arthritis (RA) patients may experience a worsening of self-reported disease activity following natural disasters. Moreover, RA patients are at increased risk of mood disorders, such as depression and anxiety. An increase of depressive symptoms, anxiety and suicidal rate has been recently reported as result of the lockdown in response to COVID-19.
Objectives: Aims of this study were to investigate the impact of the lockdown measures on disease activity and emotional well-being among patients affected by RA, through a telemedicine approach.
Methods: Patients followed in the "Early Arthritis Clinic" of our hospital were invited to participate to an online survey. They were asked also to invite their best friend (BF), matched for age and sex, to participate the survey, as control group. Moreover, clinical records from the same "Early Arthritis Clinic" cohort were used as pre-pandemic group. The online survey included demographic questions and, for RA patients, the evaluation of perceived pain (P-VAS) and disease activity (DA-VAS) on a scale of 1-10 as well as Rheumatoid Arthritis Disease Activity Index-5 (RADAI-5), a validated self-reported disease activity measure. Both RA patients and BF responded also to validated, psychometric scales for stress vulnerability (Stress Vulnerability Scale-SVS), resilience (Resilience Scale-RS), depression (Zung's depression questionnaire-Zung-D) and anxiety (Zung's anxiety questionnaire-Zung-A) evaluation.
Results: The cohort was composed by 76 RA patients who answered the survey, 32 BF and 170 RA patients from historical cohort. There were no differences in demographic characteristics, SVS, RS, Zung-D and Zung-A between RA patients and BF. RADAI-5 correlated positively with SVS (r=0,29;p=0,01), P-VAS (r=0,8;p<0,0001) and DA-VAS (r=0,8;p<0,0001) and negatively with RS (r=-0,23;p=0,04). Patients with higher disease activity showed higher classes of Zung-D (p=0,03) and SVS (p=0,006), and lower classes of RS(p=0,001). P-VAS was the only significant predictor of RADAI-5 (β=0,83;CI=0,53-0,76;p<0,001), and the concordance between RADAI-5, P-VAS and DA-VAS was high (K=0,94;p<0,001). Compared with the historical cohort, RA patients involved in the survey showed higher frequencies of moderate and elevated disease activity classes (p<0,001;Figure 1) despite there were no differences in P-VAS and DA-VAS.
Conclusion: These results suggest that lockdown did not affect differently emotional well-being of RA patients compared to healthy subjects. RA patients with elevated disease activity report higher stress and depressive symptoms, and SVS and RS may be useful to identify patients at higher risk. The higher self-reported disease activity measured through RADAI-5 may be the result of an overestimation of disease severity by patients, which depends mostly from pain. This should be considered in the assessment of disease activity through telemedicine.

POS1464-HPR **ASSESSMENT OF EMOTIONAL WELL-BEING IN RHEUMATIC PATIENTS DURING COVID-19 LOCKDOWN THROUGH A WEB-BASED SURVEY APPROACH**

C. Iannuccelli[1], B. Lucchino[1], C. Gioia[1], A. Gattamelata[1], F. Giardina[1], M. Dl Franco[1], R. Priori[1], F. Conti[1]. [1]*Sapienza University of Rome, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Rome, Italy*

Background: The severe measures of lockdown imposed in Italy to limit the SARS coronavirus 2 disease (COVID-19) spread caused an increase of reported anxiety, depression and suicidal rate among general population. Patients affected by rheumatic disorders feature an increased risk of mood disorders for the chronic course of the disease itself and for the related disability.
Objectives: Aim of this study was to investigate the impact of COVID-19 lockdown on emotional well-being of a large cohort of rheumatic patients through a telemedicine approach.
Methods: Patients in follow-up in rheumatologic out-patient clinics of our hospital were invited to participate to an online survey. They were asked also to invite their best friend, matched for age and sex, to participate the survey, as control group. The online survey included demographic questions and validated, psychometric scales for stress vulnerability (Stress Vulnerability Scale-SVS), resilience (Resilience Scale-RS), depression (Zung's depression questionnaire-Zung-D) and anxiety (Zung's anxiety questionnaire-Zung-A) evaluation.
Results: The cohort was composed by 484 subjects (84,1% F, 15,9% M). The number of subjects and the frequency of various diagnosis are shown in Table 1. According to the psychometric scales, 55,5% and 43,3% of subject showed respectively an increased stress vulnerability and a reduced resiliency. Moreover, 64% and 40,5% of the enrolled subjects reported respectively anxiety and depressive symptoms worthy of psychiatric attention. There was a significant different distribution of scores for SVS (p<0,0001), Zung-A (p<0,0001) and Zung-D (p<0,0001) among the various diagnosis. In comparison with controls, higher scores of SVS were present in connective tissue diseases (CTD) (p=0,007), Sjogren's Syndrome (SSJ) (p=0,0029) and fibromyalgia (FM) (p<0,0001) patients, higher scores of Zung-A were present in SSJ (p=0,006) and FM (p<0,0001) patients and higher scores of Zung-D were present in FM (p<0,0001) patients (Figure 1). Ordinal regression analysis showed that higher classes of anxiety were independently predicted by the Tension (β=0,32;CI=0,13-0,52;p=0,003) and Demoralization (β=0,22;CI=0,04-0,44;p=0,046) components of SVS and by the Zung-D score (β=0,09;CI=0,05-0,1;p<0,001), while higher classes of depression were independently predicted by SVS total (β=0,17;CI=0,03-0,30;p=0,012), by its subcomponent Demoralization (β=0,22;CI=0,01-0,43;p=0,038), by a lower absolute RS score (β=-0,083;CI=-0,1--0,06;p<0,001) and by the Zung-A score (β=0,11;CI=0,06-0,15;p<0,001). In both cases, a specific diagnosis was not associated to a higher risk of advanced anxiety and depression classes.
Conclusion: Rheumatic patients developed a high frequency of anxiety and depressive symptoms following COVID-19 lockdown, of which a large part should be referred for specialist attention according to their severity. There was a large variability of the symptoms reported among the various diagnosis. CTD, SSJ and FM patients were the most susceptible to the development of anxiety, depression and stress vulnerability. The application of psycometric scales through a telemedicine approach represents a useful tool to identify patients with higher levels of anxiety and depression.

Table 1.

DIAGNOSIS

	Frequency	Percent
Controls	45	9,3

HPR Epidemiology and public health (including prevention)

POS1465-HPR **THE RELATIONSHIP BETWEEN SEDENTARY BEHAVIOR AND SLEEP IN RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY**

N. Kelly[1], E. Hawkins[1], H. O'leary[2], K. Quinn[3], G. Murphy[4], L. Larkin[5]. [1]*University of Limerick, School of Allied Health, Limerick, Ireland*; [2]*University Hospital Kerry, Physiotherapy, Kerry, Ireland*; [3]*Cork University Hospital, Physiotherapy, Cork, Ireland*; [4]*Cork University Hospital, Rheumatology, Cork, Ireland*; [5]*University of Limerick, School of Allied Health and Health Research Institute, Limerick, Ireland*

Background: Rheumatoid arthritis (RA) is a chronic, autoimmune inflammatory condition that affects 0.5% of the adult population worldwide (1). Sedentary behavior (SB) is any waking behavior characterized by an energy expenditure of ≤1.5 METs (metabolic equivalent) and a sitting or reclining posture, e.g. computer use (2) and has a negative impact on health in the RA population (3). Sleep is an important health behavior, but sleep quality is an issue for people living with RA (4, 5). Poor sleep quality is associated with low levels of physical activity in RA (4) however the association between SB and sleep in people who have RA has not been examined previously.
Objectives: The aim of this study was to investigate the relationship between SB and sleep in people who have RA.
Methods: A cross-sectional study was conducted. Patients were recruited from rheumatology clinics in a large acute public hospital serving a mix of urban and rural populations. Inclusion criteria were diagnosis of RA by a rheumatologist according to the American College of Rheumatology criteria age ≥ 18 and ≤ 80 years; ability to mobilize independently or aided by a stick; and to understand written and spoken English. Demographic data on age, gender, disease duration

and medication were recorded. Pain and fatigue were measured by the Visual Analogue Scale (VAS), anxiety and depression were assessed using the Hospital Anxiety and Depression Scale (HADS), and sleep quality was assessed using the Pittsburgh Sleep Quality Index. SB was measured using the ActivPAL4™ activity monitor, over a 7-day wear period. Descriptive statistics were calculated to describe participant characteristics. Relationships between clinical characteristics and SB were examined using Pearson's correlation coefficients and regression analyses.

Results: N=76 participants enrolled in the study with valid data provided by N=72 participants. Mean age of participants was 61.5years (SD10.6) and the majority 63% (n = 47) were female. Participant mean disease duration was 17.8years (SD10.9). Mean SB time was 533.7 (SD100.1) minutes (8.9 hours per day/59.9% of waking hours). Mean sleep quality score was 7.2 (SD5.0) (Table 1). Correlation analysis and regression analysis found no significant correlation between sleep quality and SB variables. Regression analysis demonstrated positive statistical associations for SB time and body mass index (p-value=0.03846, R^2 = 0.05143), SB time and pain VAS (p-value=0.009261, R^2 = 0.07987), SB time and HADS (p-value = 0.009721, R^2 = 0.08097) and SB time and HADSD (p-value = 0.01932, R^2 = 0.0643).

Conclusion: We found high levels of sedentary behavior and poor sleep quality in people who have RA, however no statistically significant relationship was found in this study. Future research should further explore the complex associations between sedentary behavior and sleep quality in people who have RA.

POS1466-HPR IMPACT OF COVID-19 PANDEMIC ON ADHERENCE BEHAVIOR OF LATIN-AMERICAN PATIENTS WITH RHEUMATIC DISEASES

I. A. Moreno-Arquieta[1], G. G. Sánchez Mendieta[1], D. E. Flores Alvarado[1], J. A. Esquivel Valerio[1], D. Á. Galarza-Delgado[1]. [1]*Dr. José Eleuterio González (Gonzalitos) 235, Rheumatology, Monterrey, Mexico*

Background: One of the greatest challenges of the COVID-19 pandemic for rheumatologists concerns the patient's adherence to treatment (1). The impact of poor adherence on the effectiveness of chronic disease treatment is severe in terms of poorer health outcomes and increased health care costs (2). Information regarding covid-19 on adherence behavior in Latin-American is scarce.

Objectives: The aim of this study is to describe impact of COVID-19 outbreak on adherence behavior in Latin-American population with rheumatic diseases.

Methods: We carried out a descriptive, cross-sectional, self-report study through voluntary telephonic survey, to determine adherence behaviors during the COVID-19 pandemic, from September 9th, 2020 to November 19th, 2020, for consecutive patients of the outpatient rheumatology clinic in the Hospital Universitario (Monterrey, Nuevo Leon, Mexico), which serves a resource limited population that lack access to health insurance, from five neighboring states. A 17-items survey was designed. Baseline demographics that were collected included age, sex, rheumatologic diagnosis, current medications and patient perception of disease control. Patients were asked if they continued follow-up care, last prescribed therapy and reasons. Also, the survey assessed whether patients had any issues with medication supply and where they were obtaining information about covid-19 (could choose as many options as applicable). Transferred to SPSS for analysis for descriptive statistics.

Results: A total of 150 patients were called, the survey response rate was 54.6% (n=82), with a mean completion time of 10 minutes. The mean +/- SD age of the participants was 52 +/- 15.9 years, and 95% were female. The most common self-reported diagnoses were rheumatoid arthritis (RA) (13.4%) and systemic lupus erythematosus (SLE) (13.4%) [Table 1]. Patient perception of disease control was primary good 37.8% and regular 35.4%.

Patients that continued their follow-up with their rheumatologist (on the clinic face-to-face, electronically or telehealth) or in another clinic were 26.9%, the majority were nonadherent 73%. Persistence to treatment was 82.9%, the main reason to discontinue therapy was lack of prescriptions or medical advice 8.5% and overall 58.5% had trouble finding their medicine.

Information regarding covid-19 was mainly obtained by television (health secretary conference) 90.2%, and the least directly from their doctor 4.8%.

Table 1. Survey Results

		N (%)
Age, mean +/- SD years 52 +/- 15.9		
Female/ Male	78 (95.1) / 4 (4.9)	
Diagnoses	RA	50(61)
	SLE	11(13.4)
	Osteoarthritis	10(12.2)
	Other	11(13.4)
Disease Control during covid-19	Excellent	8 (9.8)
	Good	31 (37.8)
	Regular	29 (35.4)
	Bad	14 (17.1)
Continued follow-up		22 (26.9)
(face-to-face, telehealth, other)		
Continued last prescribed treatment		68 (82.9)
Reasons to discontinue treatment	Lack of prescriptions/ medical advice	7 (8.5)
	Lack of availability	6(7.3)
	Economic disadvantage	3 (3.6)
	Fear of getting sick of COVID-19	2(2.4)
"Trouble" finding medicine		48 (58.5)
COVID-19 information	Television (Health Secretary conference)	74 (90.2)
	Social network	27 (32.9)
	Newspaper/ magazines	14 (17)
	Internet	9 (10.9)
	From a doctor	4 (4.8)

Conclusion: Patients continue their therapeutic regimen, still many of them have trouble finding their medications, which affects the disease control. Also, despite having a poor disease control (majority between regular and bad) they are not continuing their follow-up care, more objective studies are needed to determine a specific cause.

POS1467-HPR SEVERE RESPIRATORY INFECTIONS IN RHEUMATOID ARTHRITIS PATIENTS WITH BIOLOGIC THERAPY. COMPARATIVE STUDY BETWEEN VACCINATED AND NON VACCINATED PATIENTS

L. Domínguez[1], P. Rodriguez Cundin[2], T. Dierssen-Sotos[3], V. Calvo-Río[1], N. Vegas-Revenga[1], A. Corrales[1], N. Palmou-Fontana[1], D. Prieto-Peña[1], M. Calderón-Goercke[1], M. A. González-Gay[1], R. Blanco[1]. [1]*HUMV,*

Rheumatology, Santander, Spain; [2]*HUMV, Preventive Medicine, Santander, Spain*; [3]*University of Cantabria, Santander, Spain*

Background: Rheumatoid arthritis (RA) patients are at increased risk of severe infections due to the disease itself, and the immunosuppressive treatment. Vaccination programs are designed to decrease the risk of infections.
Objectives: In patients with RA treated with biologic therapy (BT) our aim was to assess a) the incidence of severe respiratory infections and b) to compare the risk between vaccinated and non vaccinated patients.
Methods: Observational study of 431 patients diagnosed with RA that iniciated BT. One group of patients participated in a vaccination program from October 2011 to October 2016 (Group 1). The other group was not included in the vaccination program (Group 2). The follow-up was made until June 2017 with a minimum follow-up period of 8 months and a maximum of 5.5 years.
Information on severe respiratory infections, defined as those that required hospitalization or at least one dose of intravenous antibiotic treatment at the emergency room, was retrieved from the hospital medical records.
Results: We studied 431 patients (335 women/96 men); mean age 63.4±13.7 years. In the vaccination program *(group 1)* were included 299 (69.37%) patients and in the *group 2* 132 patients (30.63%). The main features of both groups are summarized in Table 1**.**
During the follow-up, we registered 299 hospital admissions due to severe respiratory infections in both groups (incidence density 9.9 (95% CI: 6.9-13.6).
In group 1, vaccinated patients, this incidence density was reduced to 7.1 (95% CI: 4.1-11.6). Figure 1**.**
The vaccination program reduced the general incidence of severe respiratory infection in 44%.
Conclusion: RA patients with BT included in the vaccination program present a lower incidence of severe respiratory infections compared with non vaccinated patients.

Table 1. Main general features at BT onset

POS1468-HPR **THE IMPACT OF COVID-19 ON RHEUMATOLOGY HEALTH CARE WORKERS AND THEIR SCIENTIFIC OUTPUT: HEAVY LIES THE CROWN ON FEMALE RHEUMATOLOGISTS**

C. Kirchler[1], M. R. Andrews[2], E. Mosor[2], K. Thaler[3], T. Stamm[2], R. Fritsch-Stork[1,3,4], C. Duftner[5]. [1]*School of Medicine, Sigmund Freud University Vienna, Austria, Rheumatology, Vienna, Austria*; [2]*Medical University of Vienna, Section for Outcomes Research, Center for Medical Statistics, Informatics, and Intelligent Systems, Vienna, Austria*; [3]*Hanusch Hospital of the Austrian Health Insurance Fund, 1st Medical Department of Internal Medicine, Vienna, Austria*; [4]*Ludwig Boltzmann Institute of Osteology, Hanusch Hospital and AUVA Trauma Center Meidling, Vienna, Austria*; [5]*Medical University Innsbruck, Clinical Division of Internal Medicine II, Innsbruck, Austria*

Background: COVID-19 has changed daily practice in medicine and affected teaching as well as research activities of medical personnel. Meanwhile, the pandemic´s impact on private life and responsibilities for dependents also affected health care workers in rheumatology.
Objectives: To examine the adaptability of clinician-researchers in rheumatology in a time of crisis focusing on academic output in the first six months of the COVID-19 pandemic and to investigate the professional and private burden experienced by health care workers in rheumatology.
Methods: A systematic search in PubMed, medRxiv and bioRxiv for reports of rheumatic diseases *and* COVID-19/SARS-CoV-2 submitted (or published) from January 1 to June 30 2020 was carried out. As comparison, publications from April 6 to 13 2019 of the same rheumatic diseases *without* COVID-19 were analysed in terms of author characteristics and journal metrics. Additionally, a questionnaire was circulated via EULAR countries rheumatology societies and individual working group members. The participants were asked to answer 43 questions regarding their family situation, professional background, research output, changes in work and private responsibilities during the pandemic as well as the burden experienced. Responses were collected using an online survey tool and data analyses performed with SPSS Statistics 25; missing variable analysis was performed, excluding records with >15% missing responses. Descriptive and summary statistics were calculated for the entire dataset and split by gender.
Results: Whereas the overall number of publications and authors was equal between 2020 and 2019, the portion of female first authors of review articles and original studies decreased substantially in the first phase of the pandemic (Table 1). The numerical contribution of female authors in highly ranked journals (impact factor>6) was comparable in 2019 and 2020, however, the percentage of female first authors dropped from 50% to 32% (P=0.07).

Table 1. Author and journal metrics of publications

	Authors		
	2019 (%)	2020 (%)	
Proportion female	**N=1386**	**N=1361**	**P-value**
overall	46,8	41.1	n.s.
first authorships			
all publications	46,8	35,3	0.021
reviews	56,7	30	n.s.
original studies	46,2	18,2	0.004
other reports*	42,6	39,9	n.s.
last authorships			
all publications	34,7	27,9	n.s.
reviews	33,3	15	n.s.
original studies	32,1	30,3	n.s.
other reports*	40,7	29,1	n.s.

*other reports: letters/editorials/case reports

In the survey, a total dataset was available for N=180 responders. On average, female respondents (52.5%) were younger, more likely to live alone (19,1% vs 10,5%) and have no caring responsibilities (51.1% vs. 36.3%) than male respondents.

Male doctors were more often tenure-track/tenured or chairmen (31.4% vs 12.8% female) and worked less often part-time (9,3% vs. 19.1%). Unpaid overtime hours of all participants were striking with 46.3/44,2% (female/male) reporting to accumulate >10 hours/ week.
Regarding gender differences in scientific output, male respondents more frequently revealed >20 publications as first (57,6% vs. 26,9%) or last authors (34.1% vs. 10,1%). Similarly, 44,7% of male respondents reported a last author publication during COVID-19 vs. 26,4% of female respondents.
While female and male respondents reported similar experience of burden during the pandemic, more female respondents reported increased family care as a major source of this (38,2% vs. 22,2%). Both genders would like to see increased support from superiors and official institutions.

Conclusion: In a time of acute crisis, the adaptability of scientifically active female health care workers in rheumatology is lower than that of their male counterparts. This is reflected in a lower scientific output, especially as first or last authors. However, the burden experienced in the current pandemic is similar between the genders.

POS1469-HPR **THE ASSESSMENT OF FRACTURE RISK AND OSTEOPOROSIS RATE AMONG PATIENTS OVER 50 YEARS OLD UNDERGOING MEDICAL REHABILITATION**

L. Marchenkova[1]. [1]*National Medical Research Center for Rehabilitation and Balneology of Ministry of Health of Russian Federation, Rehabilitation Department for Somatic Patients, Moscow, Russian Federation*

Background: Taking a course of physical rehabilitation creates the prerequisites for falls and injuries in patients at high risk of fractures. Data on fracture risk and prevalence of osteoporosis in older patients starting medical rehabilitation can change the approach of doctors to the development of rehabilitation programs and the management of such patients.

Objectives: To assess the prevalence of osteoporosis, individual risk factors for osteoporosis as well as the proportion of people with high risk of osteoporotic low-energy fractures among patients over 50 years old undergoing treatment according to the "medical rehabilitation" profile.

Methods: The study group comprised of 600 patients (426 women and 174 men) aged 50 to 84 years, average age 64.25 ± 10.17 years, undergoing treatment in a rehabilitation department. This was a cross-sectional study in the form of unified questionnaire, including data concerning age, weight, height, BMI, clinical and rehabilitation diagnosis, anamnesis of the main disease, anamnesis vitae, presence of osteoporosis diagnosis in the anamnesis, its treatment, osteoporosis risk factors estimation. An assessment of 10-year probability of osteoporotic fractures was carried out using Russian model of online FRAX® calculator.

Results: 41.8% patients in the study sample had osteoporosis risk factors, including 31.2% of subjects had 3 risk factors or more. 38.0% patients showed a high fracture risk according to the FRAX calculator. 34.1% had a diagnosis of osteoporosis, and 45.8% already had osteoporotic fractures. Among those who did not undergo densitometry examination, 69.9% had a history of low-traumatic fractures, and only 58.5% of patients with an established diagnosis of osteoporosis and 26.8% of those at high risk of fractures received effective therapy for osteoporosis.

Conclusion: Population of patients over 50 years old undergoing rehabilitation is characterized by high frequency of osteoporosis and probability of fractures, and insufficient quality of osteoporosis verification and anti-osteoporotic therapy administration at the same time.

HPR Interventions (educational, physical, social and psychological)

POS1470-HPR **BARRIERS AND FACILITATORS OF A NEW MODEL OF STRATIFIED EXERCISE THERAPY IN KNEE OSTEOARTHRITIS: A QUALITATIVE STUDY**

J. Knoop[1], W. Van Berkel-de Joode[1], H. Brandt[1], J. Dekker[2], R. Ostelo[1]. [1]*Vrije Universiteit Amsterdam, Health Sciences, Amsterdam, Netherlands*; [2]*Amsterdam UMC (VUmc), Department of Rehabilitation, Amsterdam, Netherlands*

Background: We have developed a model of stratified exercise therapy, in which three knee osteoarthritis (OA) subgroups (i.e., 'high muscle strength subgroup', 'low muscle strength subgroup' and 'obesity subgroup') can be distinguished and provided a subgroup-specific intervention. Currently, the (cost-)effectiveness of this model compared to usual exercise therapy is tested in a large-scaled randomized controlled trial (OCTOPuS-study [1]). Alongside this trial, we performed a qualitative study to explore perceived barriers and facilitators of the application of this model in primary care.

Objectives: To explore barriers and facilitators of the application of this model in primary care, as perceived by patients, physiotherapists and dieticians.

Methods: Qualitative data were collected through semi-structured interviews in a random sample of 15 patients (5 from each subgroup), 11 physiotherapists and 5 dieticians, from the experimental arm of the OCTUPuS trial. A thematic analysis of the data was performed.

Results: We identified 14 themes in 5 categories. In general, patients and therapists were positive about the added value and applicability of the model, although some physiotherapists would prefer more flexibility. Regarding the 'high muscle strength subgroup', both patients and physiotherapists reported mixed feelings on the low number of supervised sessions, with some perceiving this low number as advantageous for stimulating the patient's own responsibility, whereas others as hindering an optimally guided treatment. Regarding the 'obesity subgroup', dieticians and physiotherapists acknowledged the added value of the combined intervention, but both were disappointed by the lack of interdisciplinary collaboration. Moreover, those patients in this subgroup already following a diet restriction, therefore not perceiving any added value of the diet intervention.

Conclusion: This qualitative study revealed relevant barriers and facilitators of our new model of stratified exercise therapy, which will help us interpreting the upcoming results on its (cost-) effectiveness [1]. If proven to be (cost-)effective, implementation strategies should specifically focus on guidance of patients from the 'high muscle strength subgroup' within only a few sessions, collaboration between physiotherapist and dietician in the 'obesity subgroup', and adequate use of booster sessions after the supervised period to optimize treatment adherence.

POS1471-HPR **EVALUATION OF THE EFFECTIVENESS OF MOBILE APP-BASED EXERCISES PROGRAMME IN PATIENTS WITH NECK PAIN: THE RANDOMIZED CONTROLLED TRIAL**

L. Beyaztaş[1], E. Tonga[1]. [1]*Marmara University Faculty of Health Sciences, Physical Therapy and Rehabilitation, İstanbul, Turkey*

Background: Mobile health applications are frequently used to increase exercise adherence in patients with musculoskeletal problems. However, the usability of these health mobile applications mostly has not been proven. In our previous study, the usability of the mobile app, which includes postural correction and neck spinal stabilization exercises, has been proven. (M.U-NeckExercise application)
Objectives: The aim of this study is to evaluate the effectiveness of the mobile application-based home exercise program for patients with chronic neck pain.
Methods: 60 people with chronic neck pain were participated in the our study. They were randomized into two groups. The first group (n:30) received home exercises via the novel mobile app, and the second group (n:30) received the same home exercises via the brochure. The exercise program consisted of neck and thoracic postural correction and neck spinal stabilization exercises. Participants has been requested to do the exercises 3 days in a week for 6 weeks. Participants' pain levels were assessed by using the Visual Analogue Scale (VAS), their neck-related functional limitations were evaluated by Neck Pain and Disability Index (BADI). Exercise adherence was meausered with a ratio of total participated sessions compared with the target defined by patient activation monitor and exercise adherance questionnaire. Targeted participation were %60 of total sessions.
Results: In both groups, the improvement in VAS and BADI scores was statistically significant ($p<0.05$). It was found that the pain parameters of VAS score decreased statistically more in the mobile application-based exercise group ($p<0.05$). While there was no statistically significant difference between the groups in the BADI score, the effect size results was higher in the mobile app group (effect size= 0.411). Our exercise commitment target in the mobile app group was an average of 10.5 sessions. The target session number has been reached 11.25 sessions.
Conclusion: It has been observed that the mobile application-based exercise program is effective in reducing pain and increasing exercise adherence in people with chronic neck pain. The findings support M.U-NeckExercise-App could be recommended to health professionals for exercise prescription in patients with cronic neck pain.

POS1472-HPR **CLINICIANS' PERSPECTIVES ON PSYCHOLOGICAL DISTRESS AND MEETING PATIENTS' SUPPORT NEEDS IN RHEUMATOLOGY CARE SETTINGS**

C. Silverthorne[1,2], J. Daniels[3], M. Thompson[1], J. Robson[1,2], M. Ndosi[1,2], C. Swales[2], K. Wilkins[2], E. Dures[1,2]. [1]*University of the West of England, Faculty of Health and Applied Sciences, Bristol, United Kingdom*; [2]*University Hospitals Bristol and Weston NHS Foundation Trust, Academic Rheumatology, Bristol, United Kingdom*; [3]*University of Bath, Department of Psychology, Bath, United Kingdom*

Background: People with inflammatory rheumatic diseases (IRDs) face challenges that include fluctuations in pain, fatigue and flares of disease activity, complex medical regimens, and decisions about when to seek clinical help with symptoms [1,2]. Evidence suggests levels of anxiety and depression are higher in people with IRDs compared to the general population [3]. Rheumatology teams report that psychologically distressed patients can have additional support needs and require more time. Patients' concerns include health-related anxiety and difficulty accepting the diagnosis. This group can have poor outcomes and poor adherence to treatments. However, little is currently known about optimal ways to meet these patients' support needs.
Objectives: To understand rheumatology clinicians' perspectives on psychological distress in care settings with the long-term aim to develop a proposed model/pathway of support.
Methods: Telephone interviews were conducted with members of UK rheumatology teams who have clinical experience with patients experiencing distress. The semi-structured interviews explored both 'what happens now' (current clinical practice) and 'what should happen' (acceptable models of future psychological support provision). The semi-structured format provided flexibility to probe more deeply and develop new lines of enquiry based on participants' responses.
Results: Fourteen interviews were conducted with rheumatology clinicians including 2 consultants, 4 nurses, 1 physiotherapist, 4 occupational therapists, 2 clinical psychologists and 1 podiatrist. Inductive thematic analysis was used to analyse the data. Two main themes represent the data (Table 1).

Table 1.

Main Theme	Sub-themes
1. 'No one shoe fits all' – the many manifestations of distress in patients. 'I pick up on distress as increased emotion…tearfulness and sadness I suppose, but also frustration, anger...A lot of helplessness comments'	1. 'Distress can be quite emotive and quite obvious, but then it can also hide away' 2. 'They're [patients] trying to manage their own conditions, but they're also trying to manage life'
2. 'If Rheumatology could be interwoven with psychological principles' – the need to attend to the psychological impact of IRDs, alongside the physical impact. 'The physical and mental health side of things are so closely linked because one affects the other…after a while they [patients] don't really know what's affecting what'	1. 'Prioritising physical health…sometimes the stress gets not thought about' 2. 'Make best use of everyone in the team to work with patients who are struggling' 3. 'For the psychological side of things we don't measure anything about that at all'

Conclusion: Distress can be obvious or hidden and cause issues for both patient and clinician. It can lead to poor engagement with care provision. Clinicians differ in their perceptions of distress and in their thresholds for dealing with distress and have described the inconsistency of support offered for distressed patients. They described the powerful link between physical and mental distress, the vicious cycle that can develop, and the benefits of incorporating a psychological approach to treatment. This study suggests psychological support should be embedded within the team as it is felt there is a need for speciality understanding and for patients' emotional wellbeing to consistently be given equal priority to their physical wellbeing.

POS1473-HPR **SELF- AND SHARED-MANAGEMENT INTERVENTIONS FOR CHILDREN, YOUNG PEOPLE, AND FAMILIES LIVING WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: AN INTEGRATIVE REVIEW**

S. Stones[1] on behalf of iSMART Research Group. [1]*University of Leeds, School of Healthcare, Leeds, United Kingdom*

Background: Self-management refers to the manner in which individuals manage the symptoms, treatment, physical and psychosocial impact of long-term conditions (LTCs). The importance of equipping children and young people living with LTCs, like rheumatic and musculoskeletal diseases (RMDs) with the capacity to self-manage is increasingly recognised in the literature, and in conversation. In addition, there is a strong case to support families who assume a shared-management role for their child. However, there is a limited understanding of interventions designed to improve self- and shared-management capacity in this population, prompting for a review of the literature, across multiple study designs.
Objectives: The aim of this integrative review was to identify and describe interventions promoting self-management of RMDs by children and young people, and shared-management of RMDs by families.
Methods: The integrative review followed a six-stage process [1]. Studies published since 2010 were identified through a search of eight bibliographic databases. Studies reporting on any paediatric-onset RMD were included, as were those in multiple condition areas where RMDs were included in the analysis. Twenty-six articles met the inclusion criteria: 24 research articles reporting on 17 interventions, and two review articles containing a further four research articles. The methodological quality of included articles was assessed using the Mixed Methods Appraisal Tool, and a thematic synthesis was undertaken.
Results: Most study participants were CYP and families living with JIA. A minority of studies included CYP and families living with other RMDs, as well as chronic pain, type 1 diabetes mellitus, epilepsy, sleeping disorder, and cancer. Around half of the articles reported a specific theory and/or model or framework guiding the intervention. Interventions tended to be focussed at either CYP or families, with few designed to span the lifecourse from birth to young adulthood, while supporting all members of the family unit. Intervention types included: decisional aids; comic educational book; family retreat weekend; internet- and group-based cognitive behavioural programme; internet-based peer mentoring intervention; internet-based self-guided self-management intervention with weekly social support; internet-based electronic patient-reported outcome platform; smartphone applications; telenursing intervention; therapeutic recreational camp; therapeutic family nursing conversations; transition programme/clinic; and video games-based task-orientated activity training.
Conclusion: This integrative review identified a range of interventions that have been evaluated to promote self- and shared management of RMDs by CYP and their families. There is a noticeable lack of emphasis on targeting the whole lifecourse for CYP, as well as supporting both CYP and families as they manage their RMD. Further work is needed to explore the underlying mechanisms which dictate how self- and shared-management interventions influence outcomes for CYP and families, under differing contexts, since this was overlooked by the majority of included studies.

HPR Patients' perspectives, functioning and health (descriptive: qualitative or quantitative)

POS1474-HPR **PERSONAL EXPERIENCES WITH DIAGNOSTIC DELAY AMONG AXIAL SPONDYLOARTHRITIS PATIENTS – A QUALITATIVE STUDY**

C. Dubé[1], K. Lapane[1], K. Ferrucci[1,2], A. Beccia[1], S. Khan[1], E. Yi[3], J. Kay[1,4,5], K. A. Kuhn[6], A. Ogdie[7], S. H. Liu[1]. [1]*University of Massachusetts Medical School, Population and Quantitative Health Sciences, Worcester, United States of America*; [2]*University of Massachusetts Medical School, Clinical and Population Health Research Program, Graduate School of Biomedical Sciences, Worcester, United States of America*; [3]*Novartis Pharmaceuticals Corporation, HE&OR and Medical Access, East Hanover, United States of America*; [4]*University of Massachusetts Medical School, Division of Rheumatology, Department of Medicine, Worcester, United States of America*; [5]*UMass Memorial Medical Center, Rheumatology Center, Worcester, United States of America*; [6]*University of Colorado School of Medicine, Department of Medicine, Denver, United States of America*; [7]*University of Pennsylvania Perelman School of Medicine, Epidemiology and Biostatistics, Center for Clinical Epidemiology and Biostatistics, Philadelphia, United States of America*

Background: The estimated prevalence of axial Spondyloarthritis (axSpA) in the U.S. is 0.4 to 1.3 percent. Undiagnosed axSpA patients suffer from symptoms on average 7 to 10 years, which can also contribute to psychological suffering and healthcare burden due to the prolonged search for diagnosis and treatment.
Objectives: To explore the experiences of diagnostic delay of axSpA patients as part of the SpondyloArthritis Screening and Early Detection (SpA-SED) Study.
Methods: We conducted exploratory semi-structured patient focus groups. English-speaking participants ≥18 years of age with a rheumatologist-verified clinical diagnosis of axSpA were recruited from three rheumatology practices in Massachusetts, Colorado, and Pennsylvania. Six focus groups were conducted with 26 total participants (16 men, 10 women, age range 21-76 years). Discussions ranged from 1.33 to 2.13 hours. Verbatim transcripts were deidentified, cleaned and coded using NVivo qualitative software. A coding list was generated and summary themes were constructed.
Results: Participants described meandering and frustrating journeys in search of a diagnosis. When doctors gave up, it was experienced by patients as profoundly negative. Intermittent axSpA symptoms confused some physicians and caused some patients to either delay seeking medical care (e.g., sporadic flare-up) or use dramatic language to convey the magnitude of the impact on their symptoms. Patients explained their experiences where physicians presumed that patients were trying to obtain narcotics or were "imagining/exaggerating" symptoms. Early symptom stories fell into five areas of importance for patients: pain, stiffness and lack of mobility, impact on sleep, impact on daily life, and changes with weather. Tenacity on the part of the patient and/or their family, patient research and confidence to challenge their physicians were important. Self-advocacy was challenging but necessary and particularly difficult when patients were sick. During the typically lengthy time that participants waited to be diagnosed, they experienced frustration and mental suffering due to lack of answers and/or not being heard, believed, or taken seriously. Some participants described the fatigue they experienced after trying without success to obtain a diagnosis or receive treatment. Early administration of a definitive diagnostic test or screening tools for axSpA would have alleviated both physical and emotional suffering for these participants.
Conclusion: Overall, participants expressed satisfaction with physicians who sought to understand them and believed them, took them seriously, and did not give up even with long delays. Patients with axSpA described significant suffering prior to diagnosis which could have been prevented and treated. Further research is needed with axSpA patients who are early in their diagnostic journey to determine best practices to support patients and reduce diagnostic delay.

POS1475-HPR **EFFECT OF ARGENTINE TANGO PRACTICE ON TOTAL PHYSICAL ACTIVITY TIME IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISM: A PILOT STUDY**

N. Darmant[1], F. Fayet[1], C. Lambert[2], B. Pereira[2], M. Rodere[1], A. Fan[1], M. Soubrier[1], M. Duclos[3]. [1]*CHU Gabriel-Montpied, Rhumatologie, Clermont-Ferrand, France*; [2]*CHU Gabriel-Montpied, Biostatistics Unit, Clermont-Ferrand, France*; [3]*CHU Gabriel-Montpied, Sports Medicine, Clermont-Ferrand, France*

Background: Most patients with chronic inflammatory rheumatism (CIR) have a physical activity (PA) level below recommendations [1,2]. Currently, adapted structures offer a range of activities supervised by adapted physical activity educators. To the best of our knowledge, Argentinean tango is not yet offered in these structures.
Objectives: The objective of this pilot study was to study the effect of 24 consecutive sessions of Argentinean tango on the total PA level in patients with CIR, including rheumatoid arthritis (RA) and spondyloarthritis (AS).
Methods: In this controlled, randomized, open-label, clinical trial with two parallel arms, patients were required to attend two tango sessions per week,

48 sessions from 0 (M0) to 6 months (M6) for the intervention group (IG) and 24 sessions from 3 months (M3) to M6 for the control group (CG). Total PA time was measured at M3 using the Global Physical Activity Questionnaire (GPAQ) [3].

Results: A total of 27 patients (23 women) were included, including 15 with RA and 12 with AS. Mean age was 59 ± 12 years, and median disease duration was 10 years (IQR: 3-19). The majority of patients had background treatment (conventional and/or biological). At M3, 22 patients could be evaluated (11 GC patients and 11 GI patients), as 3 patients were lost to follow-up and 2 were unable to come in due to health or professional reasons. The 11 GI patients attended a median of 16 sessions (IQR: 8-22), i.e., approximately one session per week. At M3, the total PA time was not increased, regardless of the measurement method, GPAQ questionnaire (effect size and 95% confidence interval (CI): 0.03 [-0.60; 0.67], p=0.91) or accelerometer (effect size and 95% CI: 0.43 [-0.37; 1.24], p=0.26), and regardless of the intensity of the PA. No significant change was found for sedentary time, disease activity, fatigue, or anxiety. However, improvements were found in body appreciation as assessed by the Body Appreciation Scale 2 questionnaire (p=0.016), balance (p=0.053), wrist bending angle (p=0.092), and shoulder amplitude (p=0.093). The few participants in this study is explained by the geographic distance of the classes and their homes, the lack of availability of patients in professional activity, fatigue, or not liking dance (mainly among men).

Conclusion: The results of this pilot study suggest that one Argentinean tango session per week in CIR patients is more achievable than two sessions as originally planned. As the practice of classes in hospitals is constrained due to geographic distance, the sessions could be offered in adapted structures. Nevertheless, our pilot study shows that the Argentinean tango is beneficial for body appreciation in patients with CIR. A qualitative study is needed to better understand these effects.

POS1476-HPR THE NEED FOR INFORMATION AMONG PATIENTS WITH ANCA ASSOCIATED VASCULITIS DIFFERS BETWEEN GROUPS

S. Brolin[1], B. Lövström[1], E. Welin[2], I. Gunnarsson[1,3], S. Pettersson[1]. [1]*Karolinska University Hospital, Department of Gastroenterology, Dermatology and Rheumatology, Stockholm, Sweden*; [2]*Örebro University, School of Health Sciences, Örebro, Sweden*; [3]*Karolinska Institutet, Rheumatology, Stockholm, Sweden*

Background: Being diagnosed with ANCA associated vasculitis (AAV) can be a frightening experience and means facing changes that involves adapting to new situations1. Patients that are provided adequate information are better equipped to make well informed decisions regarding their care and stay compliant to the treatment plan. In order to provide adequate patient-centered information at the appropriate time and to identify those who may need extra support, the information needs must be explored2. There have been several studies on the information needs of rheumatological patients, although very few studies for patients with AAV.

Objectives: The aim of this study was to explore what information patients with AAV need from their rheumatological team and how it differs between groups (gender, disease duration).

Methods: Men and women over 18 years were included through a consecutive sample from a Rheumatology or Nephrology Clinic at Karolinska University Hospital in Sweden during 2008-2019. Patients with all forms of AAV (GPA, MPA and EGPA), that had the Rheumatology clinic as primary contact, were included.

The participants were given Educational Needs Assessment Tool (ENAT) that measures the patient's information needs3. The initial question, 'Do you need information right now about something that can help you with your rheumatic disease?' is answered yes/no. ENAT then includes 7 domains (Managing pain, Movement, Feelings, Disease process, Treatments, Self-help measures and Support systems) each containing 4-7 items (4-point Likert scale, 'not at all important = 0' to 'extremely important = 3'). The total sum is divided by the maximum score and gives the percentage response of maximum score (0-100%), 0% meaning no information need and 100% highest information need. The responses are presented as "mean % of the domain score". Independent-sample t-test was used to compare the mean between groups. One way ANOVA was used to compare the mean domain score between the different diagnoses and age groups.

Results: 178 individuals completed the questionnaire, equally divided by gender. Age ranged from 18-85, median 61. 33,7% had been diagnosed within 2 years.

The mean total score was 56,8 % of the highest possible score (0-100%). The highest information need was found in the domains 'Disease process' (78,1%), 'Self-help measures' (68,5%) and 'Treatments' (63,6%) whereas lesser need for information was found in the domains 'Managing pain' (47,5%), 'Support systems' (46,5%) and 'Movement' (41,1%). The domain 'Feelings' was scored as moderate (55,5%).

Those who acknowledge a present information need also scored significantly higher overall in all the domains. Disease duration and gender showed significantly affect the information need. Highest scores were found among women with a disease duration < 2 years with significant difference in 3/7 domains. Age, disease activity, diagnosis and social status did not affect the ENAT scores.

Conclusion: Even though only 38% of participants stated a current need for information, the results indicate that there are certain areas that patients with AAV consider important to receive more information about. Special consideration needs to be taken to women with short disease duration since they were shown to have a significantly higher need for information.

POS1477-HPR GOUT PATIENTS IN REMISSION, AND THEIR PERSPECTIVES ON URATE LOWERING THERAPY TREATMENT STOP OR CONTINUATION STRATEGIES

I. R. Peeters[1,2], S. A. C. Wanten[1,2], L. M. Verhoef[1], A. Den Broeder[1,2], N. Van Herwaarden[1,2], M. Flendrie[1]. [1]*Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands*; [2]*Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*

Background: Urate lowering therapies (ULT) are used to reduce hyperuricemia in gout patients (1). When gout remission is reached, patients often ask if ULT should be continued lifelong (treat to target strategy, T2T), or if tapering or stopping (a treat to symptom approach, T2S) can be attempted. In fact, although current rheumatology guidelines (1,2) suggest continuation, conclusive evidence for this is absent. Since ULT therapy adherence also remains suboptimal, exploring gout patients' beliefs on different long term ULT treatment strategies is of great value.

Objectives: To identify cognitions and emotions on ULT treatment strategies (T2T continuation and T2S cessation) of gout patients in remission with current or previous ULT use.

Methods: Purposive sampling (3) was used to recruit patients from a general practice and a rheumatology department (Nijmegen, the Netherlands), with a clinical diagnosis of gout, current or previous ULT use and remission according to adapted (without serum urate criterion) preliminary gout remission criteria(4). Semi-structured interviews were conducted by two interviewers and audio-records were fully transcribed. Inductive thematic analysis (5) was used to analyse and interpret our data using the ATLAS.ti. software.

Results: From a total of 18 patients (16 male/2 female), 14 patients were treated by a rheumatologist (10 currently using ULT, 1 intermittent and 3 previously) and 4 were treated by a general practitioner (all currently using ULT). Patients were satisfied with a T2T strategy, due to the absence of flares, a feeling of certainty and the reassurance of serum urate monitoring. Reluctance towards medication was reported, the importance of indefinite ULT use was questioned and its chronic use was addressed as a drawback. Reducing medication use by a T2S strategy was assessed positively and this strategy was considered less burdensome. A wish for and the willingness to follow a T2S approach was expressed. Fear and concerns of flaring after ULT cessation were expressed and were deemed both acceptable and unacceptable. See Table 1 for a schematic overview of the results.

Table 1. ***Overview of patients' perspectives on ULT treatment strategies***

Motivation for a T2T strategy	Drawbacks of a T2T strategy
1. Being free of flares	1. Resistance to (any) medication use
2. Acceptance of and contentment with chronic ULT use	2. Side effects of ULT
3. Feels secure due to regular SU monitoring	3. Possibly detrimental to healthcare costs
4. No desire for change	
Motivation for a T2S strategy	**Drawbacks of a T2S strategy**
1. Doubt if chronic ULT use is necessary	1. Fear and insecurities on
a. Possible restorative capacity of the body	a. Flaring and not being able to function
b. Curious to effects of ULT cessation	b. Joint damage
2. Being free of ULT side effects	2. Feels uncontrolled
3. Long term damage ULT unknown	3. Hassle with visits, blood tests and medication adjustments when a flare occurs.
4. Less burdensome for patient and body	
5. Wish for minimization of (any) medication use	

Conclusion: This study provides an overview of perspectives on ULT treatment strategies of gout patients in remission. These results must be considered in developing educational material for patients and in future research on gout management, particularly in designing randomised clinical trials on this subject.

POS1478-HPR NURSE LED REMOTE MANAGEMENT OF OSTEOPOROSIS – DO PATIENTS APPROVE?

J. Begum[1], J. Fourmy[1], M. K. Nisar[1]. [1]*Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom*

Background: Specialist services are heavily reliant on consultant delivered models however lack of sufficient consultant appointments pose a significant operational challenge. Clinical nurse specialists (CNSs) are highly trained and can fill this gap whilst maintaining a high standard of care.
Objectives: We designed an innovative proof-of-concept osteoporosis service with patients only consulting a metabolic bone CNS and a consultant providing remote oversight. The aim of the project was to improve the efficiency of the service by eliminating consultant appointments and reducing unnecessary hospital visits whilst continuing to deliver high-quality care.
Methods: A new pathway was implemented where a consultant rheumatologist and a CNS virtually triaged women over the age of 65 into the service. A dedicated proforma provided the template for the CNS to undertake new patient telephone consultation. Relevant investigations were requested during the telephone clinic and treatment related information was despatched to help with shared decision making. All patients were then reviewed in a consultant-CNS virtual MDT. Appropriate parenteral treatment option was agreed and confirmed to each individual. The CNS worked through a safety checklist and provided further advice and support to the patient as necessary. We surveyed 100 consecutive patients to gain their feedback regarding the service using a ten-item questionnaire employing binary and Likert scale options.
Results: The questionnaire was posted to 100 patients. Mean age of participants was 77.2 years (65-92). 75 returned the survey. 67 (89%) were happy with the waiting time and seventy (93%) found thirty-minute appointment acceptable. 66 (88%) were happy with the phone consultation and agreed that the care plan was adequately explained. 73 (97%) were happy for the CNS review in future and would recommend the service. 67 (89%) were satisfied with the overall service. Though most (95%) were able to take the call maintaining privacy, eleven (15%) participants would've found physical appointment more convenient. When asked which medium they would prefer for future reviews, only fifty (66%) patients would keep telephone as their choice. Sixteen (21%) would prefer face to face consultation, seven (9%) a combination of the two and only two would choose online option.
Conclusion: To our knowledge, this is the first successful example of an innovative service wholly provided by CNSs. Most patients were satisfied with this model of care and would highly recommend it. They were happy to be reviewed by CNS in the future. However a significant minority did not like the remote element and a higher proportion would choose physical review in future if offered. Interestingly, telephone consultation still scored substantially higher than online platform despite being physically visible in the latter. This is intriguing as most remote services strive for online consultations assuming its preference to phone. Our study suggests against this notion certainly in older patient group. Overall, a nurse-delivered osteoporosis treatment pathway is highly effective, safe and provides an innovative solution though remote consultations may not be the optimal delivery model.

POS1479-HPR PATIENTS' PERCEPTIONS OF PERSON-CENTRED CARE IN EARLY RA: A QUALITATIVE STUDY

E. Landgren[1,2,3], A. Bremander[1,3,4,5], E. Lindqvist[1,2], M. Nylander[3,6], I. Larsson[1,3,7]. [1]*Lunds University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden*; [2]*Skåne University Hospital, Department of Rheumatology, Lund, Sweden*; [3]*Spenshult Research and Development Centre, Halmstad, Sweden*; [4]*University of Southern Denmark, Department of Regional Health Research, Odense, Denmark*; [5]*University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sonderborg, Denmark*; [6]*Swedish Rheumatism Association, Stockholm, Sweden*; [7]*Halmstad University, School of Health and Welfare, Halmstad, Sweden*

Background: Data on patients' experience can identify strengths and weaknesses with given care, why a person-centred care will improve health care quality. In rheumatology care, most research on patient preferences for and experiences of RA care is performed in patients with established RA and less often in patients with early RA. In the early course of RA patients often struggle to manage their new life situation with a chronic disease and its treatment. Expectations and experiences of health care may change over time why it is important to understand how newly diagnosed patients perceive person-centred care.
Objectives: To explore patients' perceptions of person-centred care early in the RA disease course within the framework of person-centred care.
Methods: In this qualitative study 31 patients with early RA from four rheumatology specialist outpatient clinics were interviewed. An abductive qualitative content analysis was conducted based on the framework of McCormack and McCance (2006, 2016). The four constructs; prerequisites, care environment, person-centred processes, and person-centred outcomes constituted the four categories in the deductive part of the study. An inductive analysis revealed eleven sub-categories exploring the content of person-centred care for patients with early RA.
Results: For patients with early RA person-centred care was described as; *1. Prerequisites* were to be treated with respect, to meet dedicated healthcare professionals, and to meet professional competence. *2. The care environment* was to have access to a multidisciplinary team, to have access to health care, and a supportive organization. *3. Person-centred processes* were to be listened to, to be supported, and to be involved in decision-making. *4. The person-centred outcomes* were to be satisfied with received health care and to achieve optimal health.
Conclusion: A true person-centred care is important to patients early in the RA disease course, supporting the relevance to implement person-centred approach at all stages in the health care system. This study contributes to information about how to further develop person-centredness in rheumatology care also early in the disease course.

POS1480-HPR IMPLEMENTATION OF TELEMEDICINE IN RHEUMATOLOGY: VIRTUAL CONSULTATION AS A TOOL FOR DIRECT COMMUNICATION WITH PRIMARY CARE

I. Garcia Hernandez[1], D. V. Mendoza Mendoza[1], P. Muñoz Reinoso[1], J. J. Pérez Venegas[1]. [1]*Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain*

Background: Virtual consultation is defined as the provision of a healthcare service when there is a distance between the subjects and information and communication technologies are used to carry out the consultation. This tool has been successfully implemented in different specialties. It is useful for providing quick solutions, improving the overload of the medical care and for the early detection of inflammatory diseases[1]. In our centre, virtual consultation from Primary Care (PC) to Hospital Care (HC) has been implemented.
Objectives: The main objective is to describe our experience with the use of virtual consultation and its value as a new modality of specialised medical care.

The second aim is to identify the most frequent reasons for consultation and diagnoses, to assess the concordance between the two and to analyse the trend over time of the number of virtual consultations and their relationship with the different waves of the COVID 19 pandemic.

Methods: Retrospective observational study. The virtual consultations made from PC (47 centres) to Rheumatology during 2020 were analysed. They were carried out through a computer programme, using the "Andalusian Health Service Virtual Consultation Platform" tool. A specific agenda was established for virtual consultations. The reason for the referral and the rheumatologist's diagnosis were collected. The response given to the PC was divided into four models: NON-TRIBUTARY (not related to the speciality), DISCHARGE (a diagnosis and therapeutic response is concluded), APPOINTMENT FOR CONSULTATION and FOLLOW-UP (new contact is requested, completing the information). The reasons for consultation, diagnoses, time and type of response were analysed.

Results: 47 virtual consultations were carried out. 54.5% (n 298) were closed as DISCHARGE. 27.4% (n 150) were APPOINTMENT FOR CONSULTATION, and 17.7% (n 97) indicated FOLLOW-UP. Only 0.4% (n 2) were NOT TRIBUTARY.

The average response time was 2 days 15 hours and 56 min.

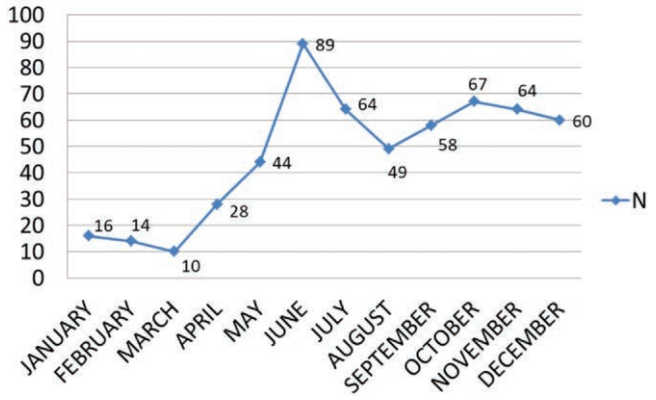
The most frequent reason for consultation was polyarthralgias (26.7%, n 146) and after the rheumatologist's assessment a diagnosis was established in 89% of them. Inflammatory arthropathy accounted for 30.8% (n 45), osteoarthritis for 19.9% (n 29), fibromyalgia for 12.3% (n 18), polymyalgia rheumatica (PMR) for 6.9% (n 10), osteoporosis for 2.7% (n 4) and connective tissue disease for 2.1% (n 3).

Another frequent reason for consultation was osteoporosis (13.5% n 74), of which 85.1% (n 63) had a confirmed diagnosis and/or need for revision.

A diagnosis could be made via telematics in 89.6% of the consultations. 15.5% were osteoporosis (n 85), 14.9% osteoarthritis (n 81), 10.5% soft tissue injuries, 8.8% mechanical/nonspecific pain (n 47), 7.1% rheumatoid arthritis (n 39), 6.5% fibromyalgia (n 34), 6.2% connective tissue disease (n 34), 5.7% PMR (n 31), 4.9% suspected spondyloarthritis (n 26), 4.2% psoriatic arthritis (n 23) and 4.2% microcrystalline arthritis (n 23).

27.4% (n 150) of the virtual consultations were required for assessment in a face-to-face appointment. We analysed the distribution over time (Figure 1). In the COVID 19 confinement phase (14 March - 21 June), the number of consultations increased, peaking in June, a behaviour that has persisted in the other mobility phases (October/November).

Figure 1. ANNUAL PROGRESS OF VIRTUAL CONSULTATIONS TO RHEUMATOLOGY



Conclusion: More than half of the virtual consultations carried out were resolved without face-to-face assessment, with a diagnosis being established in almost 90%. It is an effective tool for rapid access to Rheumatology, detecting pathology requiring preferential attention, with a face-to-face appointment, as well as for the early diagnosis of inflammatory arthropathy, which was detected in a quarter of the consultations, as well as for the diagnosis and follow-up of osteoporosis. Virtual consultation facilitates a quick response, playing an even more relevant role in the current SARS CoV-2 pandemic situation.

POS1481-HPR SEXUAL EXPERIENCE IN MALE PATIENTS WITH ANKYLOSING SPONDYLITIS: RESULTS FROM A CROSS-SECTIONAL STUDY OF 113 PATIENTS

L. Hu[1], D. Gao[1], Y. MA[1], Y. Wang[1], X. Ji[1], F. Huang[1]. *[1]Chinese PLA General Hospital, Rheumatology, Beijing, China*

Background: The expression and experience of sexuality is a key part of an individual self-identity[1], so it is essential for both healthy individuals and patients. Patients with ankylosing spondylitis (AS) may be susceptible to sexual issues due to disease activity, dysfunction and comorbid emotional problems. However, sexuality, especially sexual experience, are rarely paid attention in patients with AS.

Objectives: Our study aims to assess sexual experience in male patients with AS, and analyze the factors affecting sexual experience.

Methods: This is a cross-sectional study. A total of 113 patients with AS and 46 healthy people were investigated, matched according to age and body mass index. The Sexual Experience Questionnaire is used to assess male sexual experience. Linear regression analysis is used to explore the contributions of clinical variables to worse sexual experience.

Results: There is a significant difference in the total sexual experience score between AS patients and healthy controls (41.92±8.83 vs 46.98±8.10, *P*=0.0013). Also, patients with AS have a worse score in all dimensions of sexual experience, including erectile function, individual satisfaction and couple satisfaction, comparing to healthy people. In the regression model after controlling for the effects of age, disease duration and body mass index, disease activity (BASDAI), function (BASFI), mobility (BASMI, chest expansion and finger-floor distance), health index (ASAS HI), sleep quality (PSQI) and psychological status (HADS, HADS-A and HADS-D) are significant determinants of sexual experience, including erectile function (except for chest expansion), individual satisfaction (except for BASMI) and couple satisfaction (except for BASMI). See Table 1 for details.

Table 1. Multivariable regression analysis of association between sexual experience and clinical outcomes

Independent	Sexual experience total score		Erectile function		Individual satisfaction		Couple satisfaction	
	β (95%CI)	*P*	β (95%CI)	*P*	β (95%CI)	*P*	β (95%CI)	*P*
Pain total	-0.09 (-0.25,0.28 0.07)		-0.27 (-0.58, 0.073 0.03)		-0.51 (-0.91, 0.014 -0.10		-0.15 (-0.32, 0.077 0.02)	
BASDAI	1.35 (-2.24, 0.003 -0.45)		-0.42 (-0.75, 0.014 -0.09)		-0.72 (-1.16, 0.001 -0.28)		-0.21 (-0.40, 0.028 -0.02)	
BASFI	-1.80 (-2.59, <0.001 -1.01)		-0.62 (-0.91, <0.001 -0.32)		-0.89 (-1.28, <0.001 -0.50)		-0.30 (-0.47, 0.001 -0.13)	
BASMI	-1.04 (-2.01, 0.036 -0.07)		-0.47 (-0.82, 0.008 -0.12)		-0.48 (-0.96, 0.051 0.001)		-0.09 (-0.29, 0.413 0.12)	
Chest expansion	1.60 (0.24, 2.96)	0.021	0.50 (-0.004,0.052 0.99)		0.74 (0.07, 1.42)	0.032	0.36 (0.08, 0.64)	0.011
Finger-floor distance	-0.20 (-0.33,0.003 -0.07)		-0.07 (-0.11, 0.009 -0.02)		-0.10 (-0.17, 0.003 -0.03)		-0.04 (-0.06, 0.011 -0.01)	
ASAS HI	-1.27 (-1.64, <0.001 -0.91)		-0.42 (-0.55, <0.001 -0.28)		-0.62 (-0.80, <0.001 -0.43)		-0.24 (-0.32, <0.001 -0.16)	
PSQI	-0.60 (-1.11, 0.021 -0.09)		-0.19 (-0.38, 0.045 -0.004)		-0.28 (-0.54, 0.03 -0.03)		-0.13 (-0.23, 0.019 -0.02)	
HADS	-0.53 (-0.76,<0.001 -0.29)		-0.18 (-0.27, <0.001 -0.09)		-0.24 (-0.36, <0.001 -0.13)		-0.10 (-0.15, <0.001 -0.05)	
HADS-A	-0.86 (-1.30, <0.001 -0.42)		-0.28 (-0.44, 0.001 -0.12)		-0.42 (-0.63, <0.001 -0.20)		-0.17 (-0.26, <0.001 -0.07)	
HADS-D	-0.99 (-1.45, <0.001 -0.53)		-0.35 (-0.52, <0.001 -0.19)		-0.44 (-0.67, <0.001 -0.21)		-0.20 (-0.29, <0.001 -0.10)	

Conclusion: Worse sexual experience is associated with increased disease activity, decreased function, poor mobility, decreased health index, poor sleep quality and psychological status. Therefore, special attention to worse sexual experience in patients with AS is essential to assess disease-related suffering and develop new patient management strategies.

POS1482-HPR PAIN CATASTROPHIZING IS ASSOCIATED WITH RESIDUAL PAIN AFTER REACHING IMPROVED CONDITIONS OF SWOLLEN/TENDER JOINTS AND SERUM C-REACTIVE PROTEIN LEVEL

T. Yoshida[1,2], M. Hashimoto[3], K. Murakami[4], K. Murata[3,5], K. Nishitani[3,5], R. Watanabe[3], T. Koyama[1], R. Uehara[1], M. Tanaka[3], H. Ito[3,5], S. Matsuda6. *[1]Kyoto Prefectural University of Medicine, Department of Epidemiology for Community Health and Medicine, Kyoto, Japan*; *[2]Kyoto Prefectural University of Medicine, Department of Nursing, Kyoto, Japan*; *[3]Graduate School of Medicine, Kyoto University, Department of Advanced Medicine for Rheumatic Diseases, Kyoto, Japan*; *[4]Graduate School of Medicine, Kyoto University, Department of Rheumatology and Clinical Immunology, Kyoto, Japan*; *[5]Graduate School of Medicine, Kyoto University, Department of Orthopaedic Surgery, Kyoto, Japan*; *[5]Graduate School of Medicine, Kyoto University, Department of Orthopaedic Surgery, Kyoto, Japan*

Background: It has long been recognized that immune-mediated inflammatory diseases, such as rheumatoid arthritis (RA), are prone to coexist with depression due to the effects of cytokines, and that these two illnesses lead to an elevation in patients' pain. However, we often encounter patients with RA who suffer from residual pain despite an improvement in disease activity and inflammation. The specific psychological factors associated with residual pain have not yet been clarified. In addition to the traditional psychological factors, such as depression and anxiety, we focused on pain catastrophizing due to the distortion of pain perception and explored its association with residual pain.
Objectives: To examine whether psychological factors, such as pain catastrophizing, depression, and anxiety, are associated with self-reported pain visual analogue scale (pain-VAS) scores in RA patients with 1 or less on 28joints- swollen/tender counts (SJC/TJC) and CRP.
Methods: This was a cross-sectional study of 290 RA outpatients (85% of whom were women) with scores of less than 1 on SJC, TJC, and CRP, with a median (IQR) age of 66 (57–73) years. The participants completed questionnaires, including pain VAS (0–100 mm), Pain Catastrophizing Scale (PCS, 0–52 scale), and Hospital Depression and Anxiety Scale (HADS, 0–42 scale). Using linear regression analyses, we analysed whether PC (PCS ≥30), depression (HADS-D ≥11), and anxiety (HADS-A ≥11) (independent variables) were associated with pain VAS scores (dependent variable). After univariate regression analysis, multivariate analysis adjusted for confounding factors was performed.
Results: Patients reported a wide range of pain severity with a median (range) pain VAS score of 9 (0–96mm). The prevalence of anxiety and depression were 5.5% and 5.9%, respectively. Meanwhile, 24.1% of the patients experienced pain catastrophizing. Pain catastrophizing was associated with pain VAS scores in univariate and multivariate analyses (Table 1). The presence of anxiety and depression was not associated with pain VAS scores in any model. Multivariate analysis of other covariates showed that age, disease duration, and presence of SJC/TJC of joints other than the 28 joints were positively correlated with pain VAS scores.

Table 1. Univariate and multivariate regression analysis for independent variables associated with pain-VAS scores

		Univariate	Multivariate	
independent variables			Model 1*	Model 2**
Pain catastrophizing	Estimate	3.7	4.1	3.6
	95%CI	0.7 to 6.6	1.1 to 7.0	0.5 to 6.6
	p-value	0.015	0.006	0.021
Anxiety	Estimate	3.7	4.4	0.5
	95%CI	-1.9 to 9.2	-1.0 to 9.9	-3.5 to 7.9
	p value	0.198	0.108	0.453
Depression	Estimate	3.5	4.2	3.9
	95%CI	-1.9 to 8.9	-1.1 to 9.5	-1.9 to 8.7
	p-value	0.204	0.119	0.210

The covariates in multivariate analysis are as follows: age, sex, body mass index, disease duration, Steinbrocker's Stage, prednisolone dosage, biologic agents use, and presence of swollen joint counts/tender joint counts of joints other than the 28 joints. *Model 1: each psychological independent variable and the above covariates.**Model 2: all psychological independent variables and the above covariates.

Conclusion: Pain catastrophizing was associated with pain VAS scores in RA patients with 1 or less on 28joints-SJC/TJC and CRP, emphasising that residual pain in the patients should be treated in a biopsychosocial framework focussing on pain catastrophizing.

POS1483-HPR A QUANTITATIVE ASSESSMENT OF THE LIKELIHOOD THAT PATIENTS WITH RHEUMATOID ARTHRITIS WILL COMMUNICATE INFORMATION ABOUT RHEUMATOID ARTHRITIS RISK TO RELATIVES

I. Wells[1], P. Nightingale[2], G. Simons[1], C. Mallen[3], K. Raza[1], M. Falahee[1].
[1]*Rheumatology Research Group, University of Birmingham, Birmingham, United Kingdom*; [2]*Institute of Translational Medicine, Queen Elizabeth Hospital, Birmingham, United Kingdom*; [3]*Primary Care Centre Versus Arthritis, School of Medicine, David Weatherall Building, Keele University, Keele, United Kingdom*

Background: First-degree relatives (FDRs) of patients with rheumatoid arthritis (RA) are at increased risk of RA and are being recruited to studies of predictive and preventive approaches. Access to FDRs is usually via the proband with RA. Qualitative investigations have shown that communication of RA risk to FDRs is a complex and selective process. However, quantitative data are needed to develop a robust understanding of this process and its determinants to develop effective communication strategies and support for RA patients and their relatives.
Objectives: To identify predictors of the RA patients' reported likelihood of communicating RA risk information to their FDRs.
Methods: Patients with RA were invited to anonymously complete a survey assessing patient characteristics including age, gender, duration of RA, information seeking and decision making preferences (Autonomy Preference Index[1]), interest in FDRs taking a predictive test for RA, dispositional openness, and the general functioning subscale of the McMaster Family Assessment Device[2]. Reported likelihood of communicating RA risk to each of the patients' FDRs was assessed using a Likert scale ranging from extremely unlikely (0) to extremely likely (4). The median score across all FDRs was calculated for each patient. The association between patient characteristics and the median score was examined using univariate approaches.
Results: Surveys were completed by 482 patients (median age 65 years, 72% female). Most patients reported being likely to communicate RA risk to their FDRs (median score=3). Those who reported their likelihood of communicating RA risk to both children and siblings were more likely to communicate risk to children than siblings (p<0.001). No significant difference was found for FDRs' gender, or patients' gender, on reported likelihood to communicate about RA risk (p=0.32 and p=0.87, respectively). Patients who were older and who had had RA for longer were less likely to communicate about RA risk with their relatives. Patients who had higher interest in their FDRs taking a predictive test for RA, information seeking preferences, openness to communicate, and family functioning were more likely to communicate about risk (Table 1).

Table 1. Descriptive statistics and Spearman's rank-order correlations for the association between patients' characteristics and their median reported likelihood of communicating to their FDRs about RA risk

Patient characteristics	Descriptive statistics	Association with median likelihood to communicate risk to relatives	
		Test statistic	P value
Age; median (IQR)	65 (55-72)	-0.19	<0.001*
RA duration; median (IQR)	10 (4-20)	-0.18	0.001*
Autonomy preferences			
Information seeking; median (IQR)	84 (75-97)	0.26	<0.001*
Decision making; median (IQR)	54 (42-67)	0.09	0.048
Interest in children taking a test; median (IQR)	3 (2-3)	0.44	<0.001*
Interest in siblings taking a test; median (IQR)	2 (2-3)	0.44	<0.001*
Openness; median (IQR)	2 (1-3)	0.13	0.004*
Family functioning; median (IQR)	2 (2-3)	0.23	<0.001*

* p values significant at the Bonferroni adjusted value of 0.006.

Conclusion: Respondents were willing to communicate RA risk to their FDRs, and were more likely to communicate about risk to their children than their siblings. Factors including information seeking preferences, dispositional openness, interest in FDRs taking a predictive test, and family functioning were associated with increased likelihood of communicating RA risk information to FDRs. Patients' age and RA duration were associated with decreased likelihood. These findings increase understanding of communication about RA risk in families, and

will inform the development of informational approaches to support family communication and access to FDRs.

POS1484-HPR THE ASSOCIATION OF STIGMA WITH DISEASE VARIABLES IN PATIENTS WITH FIBROMYALGIA (FM)

M. Offenbächer[1], L. Toussaint[2], M. Weigl[3], J. Dezutter[4], N. Kohls[5], M. Vallejo[6], J. Rivera[7], F. Sirois[8], J. Hirsch[9]. *[1]Gasteiner Heilstollen, Medical Department, Bad Gastein, Austria*; *[2]Luther College, Psychology, Decorah, United States of America*; *[3]University Hospital, Department of Orthopaedics, Physical Medicine and Rehabilitation, München, Germany*; *[4]University of Leuven, School Psychology and Development in Context, Leuven, Belgium*; *[5]Coburg University of Applied Sciences, Health Promotion, Coburg, Germany*; *[6]UNED, Psychology, Madrid, Spain*; *[7]Gregorio Marañón Hospital, Rheumatology, Madrid, Spain*; *[8]The University of Sheffield, Psychology, Sheffield, United Kingdom*; *[9]East Tennessee State University, Psychology, Johnson City, United States of America*

Background: Stigma, defined as social devaluation of an individual, can be an important stressor for chronic pain patients [1]. Not every condition is stigmatized. A relevant factor for illness stigmatization seems to be whether the cause is mental-behavioural or physical. Chronic pain is often regarded as an imaginary illness or caused by psychological problems [2]. Sources of stigma for chronic pain patients are perceived negative attitudes from family members, the general public, and physicians [1]..

Objectives: To assess perceived stigma and the associations with disease variables in a cohort of patients with FM.

Methods: We invited 18 FM self-help groups in Germany to participate anonymously in our survey, and we sent the survey battery to 192 potential participants via postal mail. To measure perceived stigma, we used the Chronic Pain Stigma Scale (CPSS) developed by Reed [3], which has 30 items and 3 subscales (public, physicians, family). We also assessed sociodemographic characteristics, disease related variables (e.g., pain, stress, depression, anxiety), and other health-related factors, including health related quality of life [Healthy Days Core Module (CDC HDQOL-4)], disease specific impact (FIQ), fear avoidance belief questionnaire (physical activity subscale) (FABQ-PA), pain catastrophizing scale (PCS) and pain self-efficacy questionnaire (PSEQ).

Results: In total 162 FM patients participated (=84% response rate). Their mean age was 58 years (SD=10), 84% (N=135) were female. Highest level of education was: Elementary School 29%, Junior High School 35%, High School 15%, College 12%, and other 10%. Duration of chronic pain was 18.2 years (SD=12.0). There was no significant gender difference in the stigma subscales, nor was there an association with duration of chronic pain. Table 1 presents the significant Pearson correlations.

Table 1. Correlations of CPSS stigma subscales with health variables. *<.05; **<.01; ns=not significant.

	CPSS-public	CPSS-physician	CPSS-family
Regional pain scale	ns	.19*	.20*
VAS pain today	ns	ns	Ns
FIQ	.20*	.16*	.22**
HADS-anxiety	.37*	.20*	.24*
HADS-depression	.41**	.16*	.25**
CDC-HDQOL-4			
General health	.19*	.18*	.22**
Physical health	.19*	ns	ns
Mental health	.20*	ns	.21*
Impairment	.24*	ns	ns
Perceived stress scale	.44**	.24**	.37**
FABQ-PA	ns	-.17*	ns
PCS	.21*	ns	ns
PSEQ	.19*	ns	.18*

Conclusion: Perceived stigma in our FM patient cohort has an important impact on a variety of different disease variables including mental and general health, physical functioning, and on pain coping. Stigmatizing attitudes perceived from the general public exhibited the greatest association with most variables in our chronic pain patients. Perceived stigma from physicians and the family were also related to negative disease consequences in our FM patients. To conclude, we assert that assessing and addressing multi-source perceived stigmatization in routine clinical care may improve the management and wellbeing of patients with FM.

POS1485-HPR PATIENTS' PERSPECTIVE ON CONTINUATION VERSUS TEMPORARY INTERRUPTION OF IMMUNOMODULATORY AGENTS DURING INFECTIONS IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASES: AN INTERVIEW STUDY

M. Opdam[1], L. M. Verhoef[1], J. Vriezekolk[1], B. Van den Bemt[2,3], A. Den Broeder[1]. *[1]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands*; *[2]Sint Maartenskliniek, Pharmacy, Ubbergen, Netherlands*; *[3]Radboud University Medical Center, Pharmacy, Nijmegen, Netherlands*

Background: Immune mediated inflammatory diseases (IMIDs) like rheumatoid arthritis (RA) are often treated with immunomodulatory agents (IA). Infection risks appear to be slightly increased in IMID patients using IA[1]. However, it remains uncertain whether it is best to continue or temporary interrupt IA in case of an infection For this decision, it is essential to know patient's perceptions about both strategies. Unfortunately, little is known about the patients' perceptions on this topic.

Objectives: To explore the patients' perspectives on continuation and temporary interruption of IA in case of an infection and assess possible barriers and facilitators.

Methods: Semi-structured interviews were conducted in IMID patients using IA. Patients were recruited from the rheumatology, dermatology and gastroenterology departments of two hospitals in the Netherlands. Purposive sampling was used to select a diverse patient population. Semi-structured interviews were performed until data saturation was reached and analyzed using inductive thematic analysis.

Results: 19 patients with 6 different IMIDs and 17 different IA were interviewed. The majority was female, mean age 51 years and mean disease duration 17 years. Four had experienced a severe infection (requiring hospitalization). 15 patients indicated that they would prefer to continue their IA in case of an infection, however, for most patients this would depend on the infection severity. Several facilitators and barriers were identified (Table 1). Patients mentioned disease flare as a barrier for temporary interruption. Beliefs about susceptibility to infections form barriers and facilitators for both temporary interruption and continuation. Patients also mentioned that they would follow their physician's advice on continuation/temporary interruption.

Table 1. Identified barriers and facilitators

Temporary interruption	
Barriers	Disease flare and its impact
	Loss of IA effects or increased side effects after restarting
	Long duration of interruption
	Belief: IA has no/a positive effect on infection (risk)
	Belief: not more susceptible for infections
	Practical barriers
	Not aware of possibility of interruption
	Not following physician's advice
Facilitators	More severe and/or longer lasting infection
	Interactions with medication needed for infection
	Positive effect of interruption on immune system
	Short duration of interruption
	Belief: more susceptible for infections
	Belief: IA has a negative effect on infection (risk)
	Concerned about infections
	Current stable disease
	Physician's advice
	Long duration of IA effects
	Wish to taper/stop IA in general
	Negative impact of infection on daily activities
Continuation	
Barriers	Belief: more susceptible for infections
	Belief: IA has a negative effect on infection (risk)
	Negative previous experiences during infection
	Loss of IA effects after long use
	Interactions with medication needed for infection
Facilitators	Belief: not more susceptible for infections
	Belief: IA has no/a positive effect on infection (risk)
	Not concerned about infections
	IA needed to control IMID
	Mild infection
	Positive previous experiences with continuation
	Physician's advice

Conclusion: Interviewed patients seemed to prefer continuation of IA during an infection if possible. The concern of disease flare might form a barrier for temporary interruption, this is in line with a previous study, showing that RA patients fear disease flare after dose reduction [2].

POS1486-HPR DAILY ACTIVITY IMPAIRMENT IS MEDIATED BY BOTH ORAL DRYNESS AND ORAL HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

Y. Yenisoy[1], A. Kapusuz[1], E. N. Çakır[1], K. Abacar[2], İ. Tatlı[3], F. Türe-Özdemir[3], M. Yay[4], Ü. Karaçaylı[5], N. Inanc[2], H. Direskeneli[2], G. Mumcu[6]. [1]*Marmara University, Institute of Health Sciences, Istanbul, Turkey*; [2]*Marmara University, Division of Rheumatology, Istanbul, Turkey*; [3]*Marmara University, Department of Hematology and Immunology, Istanbul, Turkey*; [4]*Mimar Sinan Fine Arts University, Department of Statistics, Istanbul, Turkey*; [5]*Health Sciences University, Department of Oral and Dental Surgery, Ankara, Turkey*; [6]*Marmara University, Department of Health Management, Istanbul, Turkey*

Background: Both oral functions and oral health-related quality of life (OHRQoL) are poorly affected by low salivary flow rate in patients with primary Sjögren's syndrome (pSS).

Objectives: The aim of the study was to evaluate the effects of oral dryness and OHRQoL on daily life in patients with primary Sjögren's syndrome (pSS).

Methods: In this cross-sectional study, 86 patients with pSS (M/F: 5/81; mean age: 52.4 ± 11.6 years) were included. The data were collected by clinical examination and a questionnaire regarding patient-reported outcome measures (PROMs). Patient filled PROMs regarding Oral Health Impact Profile-14 (OHIP-14) for OHRQoL, Work Productivity and Activity Impairment scale (WPAI) for Daily life and the EULAR Sjogren's Syndrome Patient Reported Index (ESSPRI) for their symptoms. Unstimulated whole saliva flow rates (U-WSFR) of patients were calculated as ml/min. Increases in PROMs and decreases in U-WSFR reflected poor conditions. After preliminary analysis, a mediation analysis was used to evaluate the relations among variables.

Results: WPAI-Daily activity impairment score was higher in patients with low U-WSFR (≤0,1 ml/min) than the others (67±29,8 vs 52,5±28,6) (p=0.042). Both U-WSFR (0,43±0,57 ml/min) and ESSPRI-Dryness score (6.31 ± 2.71) were correlated with scores of OHIP-14 (25,96±17,13)(r:- 0,38 p=0.000; r: 0,37 p=0.000) and WPAI-Daily activity impairment (57,96±29,71)(r: -0,36 p=0.004; r: 0,53 p=0.000). Moreover, scores of ESSPRI-Pain (5,16±3,12) and ESSPRI-Fatigue (5,41±2,97) were also related to WPAI-Daily activity impairment score (r: 0,41 p=0.001; r:0,49 p=0.000, respectively).

In the mediation analysis, WPAI-Daily activity impairment score (57.9 ± 29.7) was directly mediated by ESSPRI-Dryness score (p=0.0010) and indirectly mediated by OHIP-14 score (25.9 ± 17.1) (p=0.0357). After mediation analysis, a bootstrap analysis with 5000 replications was applied to estimate the mediation effect to generate 95% CI. Percentile bootstrap of OHIP-14 score was found to be an effective mediator for Daily activity impairment based on 5000 bootstrap samples.

Conclusion: Both oral dryness and poor OHRQoL in patients with pSS affected daily activity impairment. Therefore, the patients' needs for improving oral health were critical components of treatment plans to improve the daily activity of SjS patients.

HPR Service developments, innovation and economics in healthcare

POS1487-HPR NEXT-GENERATION ONLINE TELEMEDICINE SYSTEM UTILIZING MIXED REALITY FOR RHEUMATOID ARTHRITIS

S. Y. Kawashiri[1], F. Nonaka[2], S. Chiba[3], T. Honda[4], T. Nakajima[4], T. Ishikawa[3], A. Kawakami[5]. [1]*Nagasaki University Graduate School of Medical Sciences, Departments of Community Medicine, Nagasaki, Japan*; [2]*Nagasaki University Graduate School of Medical Sciences, Department of Island and Community Medicine, Nagasaki, Japan*; [3]*Microsoft Japan Co., Ltd., N/A, Tokyo, Japan*; [4]*Rocket Studio, Inc., N/A, Tokyo, Japan*; [5]*Nagasaki University Graduate School of Medical Sciences, Departments of Immunology and Rheumatology, Nagasaki, Japan*

Background: Telemedicine can be performed using a conventional videophone or web conferencing system. Then, joint lesions can only be observed and inferred from two-dimensional images, and it is difficult to perform accurate joint assessments, which is essential for the management of rheumatoid arthritis (RA).

Objectives: To develop the next-generation online telemedicine system utilizing mixed reality for RA.

Methods: We have developed a system that can assess joints accurately in three-dimensions images in real-time, using Azure Kinect DK (depth sensor)/ HoloLens 2 (headset), which are mixed reality technologies, and Teams (online interview/chat) provided by Microsoft. Furthermore, by applying artificial intelligence (AI), we plan to implement additionally to this system 1) a function to quickly catch and automatically evaluate the patient's anxiety and changes in facial expressions at the time of examination, 2) a function to record dialogue with the patient in chronological order, 3) a function to support the detection of swollen joints, and 4) function to automatically analyze the questionnaire.

Results: This system remotely connects a rheumatologist in the Nagasaki University Hospital (Nagasaki City, urban area) and a patient with RA and a non- rheumatologist in the Goto Central Hospital (Goto Island, rural area). A three-dimensional hologram of the patient's hand projected in front of a rheumatologist. Using this system, we are able to evaluate joints more accurately than using a conventional videophone or web conferencing system.

Conclusion: It is expected that this system will enable remote medical care specializing in rheumatology, which is standardized at a high level even in areas without rheumatologists such as remote islands and remote areas. This system remotely connects Nagasaki City and Goto Island, but due to the performance of the system, it is not limited to these areas and it is possible to connect rheumatologists to any area that can be connected to the network. It is also effective for the purpose of avoiding the risk of infection during long-distance hospital visits under the epidemic of COVID-19 infection.

POS1488-HPR CAN A SPECIALIST NURSE LEAD A COMPREHENSIVE OSTEOPOROSIS SERVICE WITH REMOTE SUPERVISION – AN INNOVATIVE CONCEPT

D. Masieh[1], J. Begum[1], J. Fourmy[1], M. K. Nisar[1]. [1]*Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom*

Background: Specialist services traditionally rely on a consultant to lead a multidisciplinary team and provide patient facing activities. However, demand

outstrips the limited expertise available and therefore significant delays occur in treatment pathways. There is an urgent need to expand the skill set of the employed workforce and think 'outside the box'. A service run by clinical nurse specialists (CNS) can be an effective solution. CNS are already an integral part of multidisciplinary teams caring for a diverse range of patients including those with chronic conditions such as osteoporosis.

Objectives: We designed an innovative osteoporosis service with patients consulting only a metabolic bone CNS with a consultant rheumatologist providing remote oversight. The aim of the project was to improve the efficiency of the service by eliminating consultant appointments and reducing unnecessary hospital visits while continuing to deliver a high-quality and safe service.

Methods: A new pathway was implemented where a consultant rheumatologist and a CNS virtually triaged post menopausal women over the age of 65 into the service. A dedicated proforma provided the template for the CNS to undertake new patient telephone consultation. Relevant investigations were requested during the telephone clinic and treatment related information was despatched to help with shared decision making. All patients were then reviewed in a Rheumatologist-CNS virtual MDT. An appropriate parenteral treatment option was agreed and confirmed to each individual. The CNS worked through a safety checklist and provided further advice and support to the patient as necessary. Using the database, we compared the timelines for the patient journey to the conventional pathway, obtained the number of consultant follow-up appointments saved by implementing this service, and calculated total savings.

Results: In the pilot phase, 116 patients were triaged into the new service. The patient cohort was a combination of new referrals and patients taken from the consultants' waiting lists. The mean age of the participants was 78 years (65-93). The median time: from referral to virtual triage was 20 days (0-308); from triage to new patient CNS telephone consultation was 20 days (0-137); and from virtual MDT to treatment authorisation was zero days (0-331 days). 45 patients had anabolic therapy commenced via home care. The remainder had anti resorptive therapy. No patient requested face-to-face review. Only one patient fed back that they would've preferred to see the consultant once. 116 new patient consultant appointments were saved and the median delay in treatment commencement was reduced from 84 to 38 days.

Conclusion: To our knowledge, this is the first successful example of an innovative service wholly provided by CNS for commencing parenteral anti-osteoporotic therapy with only remote consultant supervision. Our service redesign has significantly improved the efficiency of the parenteral osteoporosis pathway with reduction in treatment delay and a more streamlined patient journey. A nurse-delivered osteoporosis treatment pathway is highly effective, safe and provides an innovative solution to address thinly stretched health care resources for people with chronic conditions.

POS1489-HPR TELEMEDICINE CONSULTATIONS IN RHEUMATOLOGY: IDENTIFIED PROBLEMS OF NEW TECHNOLOGY

Y. Livshits[1], O. Teplyakova[1], A. Sarapulova[1]. [1]*Ural State Medical University, All Patient Department, Yekaterinburg, Russian Federation*

Background: Telemedicine counseling (TMC) has gained rapid development during the COVID-19 pandemic. The prospect of using this technology in rheumatology was based on the possibility of getting maximum information about the patient during the survey, examination and interpretation of laboratory and instrumental data, that is excepting direct contact with the patient. Several rheumatological clinics have reported on the success of using TMC. However, there is very little data of the difficulties that can be encountered when organizing this process.

Objectives: To characterize the identified problems during TMC in rheumatology, to suggest potential directions for their elimination.

Methods: Since June 2021, on the basis of the Medical Association "New Hospital", Yekaterinburg, Russian Federation, 76 TMCs have been performed on the profile of rheumatology in patients aged 29 to 71 years. Of these, 13 applied to the primary TMC, the other patients were preliminarily examined in person. The consultation included the preliminary acquaintance with the examination results, a 20-minute video communication and writing of a conclusion. After each TMC, a survey was conducted between the doctor and the patient, including the identified deficiencies in counseling. The frequency of identified problems is presented as an absolute indicator and as a percentage of the total number of TMCs performed.

Results: We noted a high degree of patient satisfaction: 74 (97.4%) responded that they received answers to all. However, according to the doctor, the following groups of problems were identified.

[1] Technical problems in 29 (38.2%): most often there were various problems with the Internet, but there were also registered: the end of the charge on the patient's tablet, the patient was not registered in the electronic queue. Elimination of these violations depends on the work of IT-specialists, but each consulting physician should be prepared for an immediate transition to an alternative form of communication (for example - telephone).

[2] Lack of objective examination, leading to the impossibility of correct remote diagnosis - 8 (10.5%). This problem was identified due to the inability to establish the presence or absence of arthritis during the initial diagnosis (6 cases) and to clarify the nature of the rash (2 cases). All patients are invited for a face-to-face consultation.

[3] The need to write prescriptions for psychotropic drugs - 12 (15.8%), which under the conditions of national legislation cannot be done in the TMC regime.

[4] The time spent directly on remote communication with the patient was 17.2 minutes (from 8 to 31), however, taking into account the study data and writing the conclusion, the total time was 40.7 minutes (from 21 to 73). Thus, it turned out that the average time for remote and face-to-face consultations is the same, while TMC's payment is only about 50% of the face-to-face consultation. This situation reduces the doctor's interest in carrying out TMC. The solution to the problem is associated with reducing the time for the documentation process through technical improvements. In addition, of the 9 patients in whom the TMC process lasted 60 minutes or more, 5 were diagnosed with fibromyalgia. It is possible that with a previously established diagnosis of fibromyalgia, only face-to-face counseling should be recommended to patients.

Conclusion: The TMC system is promising, however, there are a number of problems that need to be improved, since they can reduce the doctor's interest in using this technology.

HPR Professional education, training and competencies

POS1490-HPR "WHERE DOES IT HURT?": IDENTIFYING PAIN CONTENT AND ITS CONTEXT WITHIN PAEDIATRIC AND ADOLESCENT RHEUMATOLOGY TRAINING

R. Lee[1,2], J. Mcdonagh[1,2,3], M. Connelly[4], S. Peters[5], L. Cordingley[6]. [1]*Centre for Epidemiology Versus Arthritis, Centre for Musculoskeletal Research, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom*; [2]*NIHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom*; [3]*Department of Paediatric and Adolescent Rheumatology, Royal Manchester Children's Hospital, Manchester University NHS Foundation Trust, Manchester, United Kingdom*; [4]*Division of Developmental and Behavioral Sciences, Section of Psychology, Children's Mercy Kansas City, Kansas City, United States of America*; [5]*Manchester Centre for Health Psychology, Division of Psychology and Mental Health, University of Manchester, Manchester, United Kingdom*; [6]*Division of Musculoskeletal and Dermatological Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom*

Background: Complex pain symptoms present across a wide spectrum of long-term musculoskeletal conditions in paediatric rheumatology. Pain training should therefore be part of a core curriculum for the professionals working in this speciality, but it is unclear to what extent this is the case currently.

Objectives: To identify the extent of pain-specific content included in the training of healthcare professionals in paediatric and adolescent rheumatology in the UK.

Methods: A systematic search of documental data using key internet search engines was conducted using combinations of the following terms: 'training', 'curriculum', 'competency', 'paediatric', 'adolescent' and 'rheumatology'. A targeted search of online content from the main professional organisations followed; doctors (Royal College of Paediatric and Child Health [RCPCH]), nurses (Royal College of Nursing [RCN]), physiotherapists (Chartered Society of Physiotherapy), occupational therapists (Royal College of Occupational Therapists) and psychologists (British Psychological Society). Documents from professional learned societies such as The British Society of Paediatric and Adolescent Rheumatology (BSPAR) and The Scottish Paediatric and Adolescent Rheumatology Network (SPARN) were also included. Document search strategies were designed by the authors in partnership with healthcare professionals. Data were extracted and analysed following a summative content analysis. Pain-related terms were quantified. Latent content was interpreted qualitatively to explore the context in which pain-related phrases were presented.

Results: Nine documents were identified. Pain-related terms represented 0.17% of all words across texts (used 55 times in total). Most pain terms were found in documents aimed at doctors (n=40, 72.7%). Of the pain terms used, most were used in the context of referring to specific pain syndromes such as chronic regional pain, generalized idiopathic pain and pain amplification. Content around

the assessment and management of pain was vague and no detail was given as to how health professionals should perform these tasks. There was no reference to pain intensity, location or emotion. There were several problematic conceptual issues in the way pain was presented, with pain mostly portrayed either in the context of inflammatory or non-inflammatory pain and rarely in the context of both. Musculoskeletal pain was also positioned as a 'somatic' symptom, potentially conveying an interpretation of pain as being psychologically mediated.
Conclusion: Training for healthcare professionals in paediatric rheumatology would benefit from updates informed by contemporary pain theories and evidence-based practices. This is key to ensuring that children and young people with chronic pain receive effective pain care from tertiary care services focused on treating musculoskeletal disease.

Table 1. Documents and pain terms identified

POS1491-HPR MENTAL HEALTH OUTCOMES AMONG HEALTH CARE WORKERS DURING THE CORONAVIRUS-19 PANDEMIC

O. Hamdi[1], M. Sellami[1], S. Miladi[1], A. Fazaa[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia*

Background: The coronavirus-19 (COVID-19) pandemic is having negative effects on societies' mental health, particularly health care workers who are exposed to tremendous psychological stress.
Objectives: To assess the magnitude of mental health outcomes among health care workers treating patients exposed to COVID-19.
Methods: This cross-sectional study collected demographic data and mental health measurements from health workers in different hospitals using an online questionnaire. Participants were also asked to complete the 9-item Patient Health Questionnaire (PHQ-9), the 7-item Insomnia Severity Index (ISI), and the 7-item Generalized Anxiety Disorder scale (GAD-7). The total scores of these measurement tools were interpreted as follows: PHQ-9 normal (0-4), mild (5-9), moderate (10-14), and severe (15-21) depression; ISI normal (0-7), mild (8-14), moderate (15-21), and severe (22-28) insomnia; GAD-7 normal (0-4), mild (5-9), moderate (10-14), and severe (15-21) anxiety.
Results: A total of 155 health care workers with a mean age of 31.3 ± 25 years [26-45] and a sex-ratio of 0.3 completed the online questionnaire. All participants were directly engaged in diagnosing, treating, or caring for patients with or suspected to have COVID-19. Participants were divided into two groups: 79% medical (61% doctors in training and 18% hospital doctors) and 21% paramedical staff. Twenty-two participants (14.2%) had a chronic disease and 21(13.5%) had a history of depression. Nineteen (12.2%) of the participants were infected with COVID-19, 4 of whom contracted the infection in the hospital (50% during October 2020). A statement to the department of occupational medicine was made in 70% of cases. Ninety-one percent of the participants were fit for treating patients with COVID-19. The mean number of nightshifts in the COVID unit per month was 5.3. The mean number of hours of work in the COVID unit was 5 hours per day, 36 hours per week, and 62 hours per month. An increase in workload compared to the pre-epidemic was noted in 62.9% of cases. Thirteen percent of participants experienced the same anxiety level as the first time of taking care of COVID patients while 65% were rather at ease compared to the first time. Forty-seven percent of participants felt the need for psychological support and 16.7% of whom had consulted a psychiatrist. Participants were diagnosed with depression (9 cases), anxiety (13 cases), and burn-out (3 cases). The prescribed treatment was: antidepressants (5 cases), anxiolytic (10 cases), and psychotherapy (12 cases). Mild depression was detected in 13% of cases, moderate depression in 4% of cases, and severe depression in 2% of cases. Mild insomnia was detected in 41% of cases, moderate insomnia in 14% of cases, and severe insomnia in 9% of cases. As for anxiety, 33% of participants suffered from mild anxiety, 14% moderate anxiety, and 5% severe anxiety.
Conclusion: Participants reported experiencing psychological burden and a high rate of anxiety, depression, and insomnia. It is important to protect health care workers and to promote mental well-being to survive this pandemic.

POS1492-HPR EVALUATION OF A VIRTUAL REALITY-BASED APPLICATION TO EDUCATE HEALTHCARE PROFESSIONALS AND MEDICAL STUDENTS ABOUT INFLAMMATORY ARTHRITIS

P. Klemm[1], A. Kleyer[2], K. Tascilar[2], L. Schuster[2], T. Meinderink[2], F. Steiger[2], U. Lange[1], U. Müller-Ladner[1], J. Knitza[2], P. Sewerin[3], J. Mucke[3], A. Pfeil[4], G. Schett[2], F. Hartmann[2], A. Hueber[5], D. Simon[2]. [1]*Justus-Liebig University Gießen, Campus Kerckhoff, Department of Rheumatology, Immunology, Osteology and Physical Medicine, Gießen, Germany*; [2]*Universitätsklinikum Erlangen, Department of Internal Medicine 3, Rheumatology and Immunology, Erlangen, Germany, Erlangen, Germany*; [3]*Heinrich Heine University Düsseldorf, Department and Hiller Research Unit for Rheumatology, Düsseldorf, Germany*; [4]*Jena University Hospital - Friedrich Schiller University, Department of Internal Medicine 3, Jena, Germany*; [5]*Sozialstiftung Bamberg, Sektion Rheumatologie, Bamberg, Germany*

Background: Inflammatory arthritides (IA), such as rheumatoid arthritis or psoriatic arthritis, are disorders that can be difficult to comprehend for health professionals and students in terms of the heterogeneity of clinical symptoms and pathologies. New didactic approaches using innovative technologies such as Virtual Reality (VR) applications could be helpful to demonstrate disease manifestations as well as joint pathologies in a more comprehensive way. However, the potential of using a VR education concept in IA has not yet been evaluated.
Objectives: We evaluated the feasibility of a VR application to educate healthcare professionals and medical students about IA.
Methods: We developed a VR application using IA patients data as well as two- and three-dimensional visualized pathological joints from X-ray and computed tomography generated images (1). This VR application (called Rheumality) allows the user to interact with representative arthritic joint and bone pathologies of IA patients (Figure 1 A, B). In a consensus meeting an online questionnaire was designed to collect basic demographic data (age, sex), profession of the participants, and their feedback on the general impression, knowledge gain and potential areas of application of the VR application. The VR application was subsequently tested and evaluated by healthcare professionals (physicians, researchers, and other healthcare professionals) and medical students at predefined events (two annual rheumatology conferences and academic teaching seminars at two sites in Germany).
Results: 125 individuals participated in this study (56% female, 43% male, 1% non-binary). 59% of the participants were between 18-30 years of age, 18% between 31-40, 10% between 41-50, 8% between 51-60 and 5% were between 61-70. Of the participants, 50 were physicians, five researchers and four other health care professionals, the remaining were medical students (66). The participants rated the application as excellent (Figure 1 C, D), the mean rating of the VR application was 9.0/10 (SD 1.2) and many participants would recommend the use of the application, with a mean recommendation score of 3.2/4 (SD 1.1). A large majority stated that the presentation of pathological bone formation improves the understanding of the disease (120 out of 125 (96%)).
Conclusion: The data show that IA-targeting innovative teaching approaches based on VR technology are feasible. The use of VR applications enables a disease-specific knowledge visualization and may add a new educational pillar to conventional educational approaches.

POS1493-HPR **IMPACT OF THE EULAR HCP CORE COMPETENCIES ON RHEUMATOLOGY PHYSIOTHERAPISTS IN THE UK: SURVEY RESULTS**

W. J. Gregory[1,2], S. Burchett[3], C. Mccrum[4,5]. [1]*Salford Royal NHS Foundation Trust, Rheumatology Directorate, Manchester, United Kingdom*; [2]*Manchester Metropolitan University, Department of Health Professionals; Faculty of Health, Psychology and Social Care, Manchester, United Kingdom*; [3]*East Sussex Healthcare NHS Trust, Information Management and Performance, Hastings, United Kingdom*; [4]*East Sussex Healthcare NHS Trust, Physiotherapy Department, Hastings, United Kingdom*; [5]*University Of Brighton, Research Centre for Healthcare Professionals, Brighton, United Kingdom*

Background: A European Alliance of Associations for Rheumatology (EULAR) initiative in 2019 saw the first-ever publication of Core Competencies for Health Care Professionals (HCPs) working in Rheumatology (Edelaar et al 2019). This document sets the tone for how HCPs in Rheumatology should be working. One of the listed research agenda items created as a part of this project was to define discipline-specific competencies related to each of the HCPs unique roles in the multidisciplinary team.

Objectives: In response to this call for discipline-specific application, a recent national survey of physiotherapists working in rheumatology in the UK included a section looking at the comfort these clinicians feel in the day-to-day application of these Core Competencies.

Methods: In late 2019, an internet-based survey was emailed, and shared via other digital platforms, aiming to target all UK-based rheumatology physiotherapists. Other areas were covered and have been published (Gregory, Burchett and McCrum 2021), but there are unpublished data from Question 8 on this survey which involved listing the EULAR HCP Core Competencies and asking responders to rate on a 5-point Likert scale their comfort with these statements in relation to their day-to-day practice.

Results: Ninety-seven UK-based physiotherapists working at least some of their job in rheumatology completed the survey. Overall the EULAR HACP core competency statements with the highest scores were statements 2 and 5; those statements with the lowest comfort response were statements 4 and 6.

Statement 2 relates to assessment and statement 5 to non-pharmacological management; it is in line with the traditional physiotherapy job role that these are the two areas identified by survey responders as their strongest areas.

Statement 4 relates to pharmacological management, and as this is not a formal part of expected specialist rheumatology physiotherapist job role at banding levels below band 8, this result was lower level of comfort probably to be expected.

Statement 6 relates to patient education and whilst this is clearly a big part of the physiotherapist role, we expect the lower score here represents respondents awareness that broader disease education may sit better with other members of the rheumatology multi-disciplinary team.

Conclusion: Written for all HCPs, the competency statements do show less comfort on this survey of physiotherapists with regards to less profession-specific statements, namely medication management and disease education. Team working means these areas will be picked up by other rheumatology HCPs.

Generally there is a good amount of familiarity with and comfort in application of these new core competencies. An alternative conclusion is that the EULAR working group creating the competencies achieved a strong understanding of the HCP roles and the competencies are hence seen to fit well in this survey. As per the concluding statements of the 2019 EULAR core competencies document, there does remain a requirement to work on profession specific competencies in rheumatology.

HPR Interdisciplinary research

POS1494-HPR **THE COLLABORATION OF RHEUMATOLOGY-DERMATOLOGY IN THE EVALUATION OF RHEUMATIC DISEASES PATIENTS: EXPERIENCE IN A UNIVERSITY HOSPITAL**

G. Figueroa-Parra[1], A. Moreno-Salinas[1], C. M. Gamboa-Alonso[1], M. A. Villarreal-Alarcón[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Universidad Autónoma de Nuevo León, Servicio de Reumatología, Monterrey, Mexico*

Background: Dermatological manifestations are not rare in patients with rheumatic diseases (RD). Multidisciplinary management and direct interaction between these disciplines are essential. According to Dermatology-Rheumatology clinics, most diagnoses evaluated are systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA), with dermatitis being the most common manifestation. It is important to be aware that skin problems in RD patients are not always related to the underlying condition(1). Nowadays, there is significant evidence to support the manifold advantages of the joint dermatology-rheumatology clinics, including improved quality of care for patients and multidisciplinary training for new physicians(2). This ongoing trend is intended to highlight the important interaction between specialties that treat overlapping conditions, and it has been incorporated in academic health centers to give a comprehensive approach to patients.

Objectives: Our purpose was to describe the collaboration between the Rheumatology and Dermatology services during the evaluation of RD patients.

Methods: An observational, retrospective study was performed in the Rheumatology Service of the University Hospital “Dr. Jose Eleuterio Gonzalez” in Monterrey, Mexico, between March 2019 and February 2020. All the patients with a Rheumatology or Dermatology consultation requested were included (hospitalized and outpatients). Demographic (age, gender, baseline diagnosis), the reason for consultation, specialty requested, type of treatment, final diagnoses, and agreement in final diagnosis were registered. Results are shown in descriptive statistics.

Results: One hundred and seventy-four patients were included, 142 (81.6%) patients from the outpatient clinic and 32 (18.4%) patients hospitalized. The mean age was 45.1 (SD±15.8) years, 135 (77.6%) were females, 54 (31%) patients were under initial diagnosis evaluation, 30 (17.2%) had RA, 25 (14.4%) patients had SLE, 15 (8.6%) patients had psoriatic arthritis, 12 (6.9%) patients had systemic sclerosis, 6 (3.4%) patients had dermatomyositis. The main reasons for consultation in hospitalized patients were acute lupus (15.6%), subacute lupus (12.5%), purpura (12.5%), cutaneous vasculitis (9.4%), urticarial dermatitis (9.4%), dermatomyositis (6.3%) and others (34.3%). The consultation requested was: 156 (89.7%) to Dermatology and 18 (10.3%) to Rheumatology. The type of treatment prescribed was topic/local in 37 (21.3%) patients, systemic in 25 (14.4%) and both in 92 (52.9%) patients. The final diagnoses were related to the underlying disease in 102 (77%) patients and unrelated in 40 (23%) patients. The agreement between initial clinical suspicion and final diagnoses reached 75.9% between Rheumatology and Dermatology services. Figure 1.

Conclusion: The collaboration between Rheumatology and Dermatology services are very important. Most of the patients were under initial evaluation. All the rheumatologists and dermatologists should be aware of the interdependence from both specialties to give the best quality of care to the patients.

POS1495-HPR THE EXPERIENCE OF A RHEUMATOLOGY UNIT DURING THE COVID19 LOCKDOWN: TELEMEDICINE ALLOWS A SAFE FOLLOW UP OF PATIENTS WITH RHEUMATIC DISEASES

K. El Aoufy[1,2], M. R. Melis[1,2], S. Bellando Randone[1,2], J. Blagojevic[1,2], F. Bartoli[1,2], G. Fiori[1,2], F. Nacci[1,2], M. L. Conforti[1,2], L. Cometi[1,2], C. Bruni[1,2], A. Moggi Pignone[1,3], L. Rasero[4], S. Guiducci[1,2], M. Matucci-Cerinic[1,2].
[1]University of Florence, Clinical and Experimental Medicine, Florence, Italy; *[2]Careggi University Hospital, Department of Geriatric Medicine, Division of Rheumatology, Firenze, Italy*; *[3]Careggi University Hospital, of Emergency Medicine, Division of Internal Medicine, Firenze, Italy*; *[4]University of Florence, Departement of Health Science, Florence, Italy*

Background: In March this year, most of the routine activities were cancelled during the streaming of the pandemic in Italy. This prompted a pragmatic reorganization of the traditional care model of nursing and medicine, to quickly give an efficient clinical response. During the first phase of the pandemic, outpatient visits dropped by more than 60%, forcefully shifting to telemedicine to assure continuity of care despite the lockdown.

Objectives: The **aim** of the present work was to describe the strategy adopted during and immediately after the lockdown to assure the follow up of patients and the maintenance of their treatment in an outpatient "virtual" *telemedicine clinic* dedicated to RDs.

Methods: the patient flow to a rheumatology division during the lockdown was evaluated retrospectively from March to September 2020 in accordance with local restrictions, and three periods are described.

Results: 653/913 (71.5%), 542/542 (100%) and 1.048/1.048 (100%) infusion activities scheduled were performed at the centre for daily infusion and pre-infusion assessment, respectively during the 1st, 2nd and 3rd period. In the outpatient clinic during the 1st period, 96.96% of the cases was shifted to Telemedicine, which decreased to 52.45% in the 2nd period; while in the 3rd period, 97.6% of the performances were carried out at the clinic. Diagnostic procedures, such as ultrasound, capillaroscopy, and joint injection were generally postponed during the 1st period, reduced drastically during the 2nd and performed regularly during 3rd period. Ulcer treatment and the Clinical Trial Unit never stopped their activity. The flow of the activity of the outpatient clinic and the day hospital is represented as monthly trends in graph 1 (See Graph 1).

Conclusion: Our data show the feasibility of Telemedicine in a lockdown condition. Shifting stable patients to Telemedicine has the potentiality to minimize the risk of contagion and allow continuity of care. In the future, the use of Telemedicine for specific clinical uses might assure patient assistance also in non-pandemic conditions.

POS1496-HPR IS NUTRITIONAL FOLLOW-UP IN PATIENTS LIVING WITH RHEUMATOID ARTHRITIS BETTER WITH TELECONSULTATION? - EXPERIENCE BEFORE AND AFTER PANDEMIC

I. Mozo[1], M. Marquez[2], O. Valencia[3]. *[1]Fundación Santa Fé de Bogotá, Centro de Cuidado Clínico en Artritis Reumatoide, Bogotá, Colombia*; *[2]Fundación Santa Fé de Bogotá, Nutrition, Bogotá, Colombia*; *[3]Fundación Santa Fé de Bogotá, Research, Bogotá, Colombia*

Background: Nutritional follow-up as part of the integral attention for patients living with rheumatoid arthritis (RA) has been limited due to the COVID-19 pandemic. It made necessary to implement a remote monitoring for the care of the patients and to evaluate the outcomes of the changes in the care model.

Objectives: To identify the effects of the telemonitoring intervention within the pandemic scenario and the outcomes of the traditional face-to-face nutrition consultation.

Methods: A retrospective analysis of health records and the administrative data base of the patient's follow-up, between 2019 and 2020, was developed at the arthritis specialized center of the Santa Fe de Bogotá Foundation in Bogotá, Colombia. The outcomes measured include the number of visits per year and the proportion of patients who attend their nutritional follow-up by telemonitoring in 2020 vs patients attending to face-to-face nutrition consultation. Differences in the Body Max Index (BMI) and the changes based on eating habits, defined by the quality of food consumption per day, were also measured.

Results: A total of 212 patients from 2020 and 179 from 2019 were analyzed; An increase of 61.5% in the number of consultations, using nutritional telemonitoring per year, was identified in 2020 (n=412) compared to 2019 (n=255). In patients followed from 2019 to 2020, 13% (10/77) experienced an increase of more than 2 units of their BMI, while 22% (17/77) showed a decrease; in 2% of patients was not possible to evaluate their current weight; in the same way, 49% (103/212) in 2020 showed a positive change in their feeding habits compared with a 12% (21/179) in 2019. 135 new patients were recruited for nutritional telemonitoring 2020.

Conclusion: Nutritional telemonitoring to follow-up patients with RA has increased considerably in terms of consultations per year and changes in the feeding habits. However, more evaluation is required for this model.

Patient information and education

POS1497-PARE POST-TRIAL SURVEY OF PARTICIPANTS OF A PHASE 3 CLINICAL TRIAL IN SSC-ILD

I. Galetti[1,2], E. Brown[1,3], A. Kennedy[2], R. J. Riggs[4], A. Roennow[5], M. Sauvé[6], J. Welling[7], H. Finnern[8], A. Gilbert[9], M. Gahlemann[10], W. Sauter[11]. [1]*Gruppo Italiano per la Lotta alla Sclerodermia, n/a, Milan, Italy*; [2]*FESCA aisbl, n/a, Saint Maur, Belgium*; [3]*Scleroderma and Raynaud's UK, n/a, London, United Kingdom*; [4]*Scleroderma Foundation, Inc, n/a, Danvers, United States of America*; [5]*Sklerodermiforeningen, n/a, Rødovre, Denmark*; [6]*Scleroderma Canada, n/a, Hamilton, Canada*; [7]*Nationale Vereniging Voorlupus, APS, Sclerodermie en MCTD, n/a, UTRECHT, Netherlands*; [8]*Boehringer Ingelheim International GmbH, n/a, Ingelheim, Germany*; [9]*AK Gilbert Ltd, n/a, Brighton, United Kingdom*; [10]*Boehringer Ingelheim Schweiz GmbH, n/a, Basel, Switzerland*; [11]*Boehringer Ingelheim International GmbH, n/a, Biberach, Germany*

Background: The SENSCIS® trial (2015–18) was a large clinical trial (n=576) investigating the efficacy and safety of nintedanib in patients with systemic sclerosis-associated interstitial lung disease.1 The clinical research sponsors (CRS) collaborated with the scleroderma patient community advisory board (CAB) regarding the design, implementation and conduct of the trial.2 As part of this collaboration, the CRS and CAB developed a post-trial survey for SENSCIS® participants. The use of the developed patient-centric materials was optional for the sites.
Objectives: The objectives of the SENSCIS® post-trial survey were to gain experience in collecting real-world information and trial satisfaction data from patients to inform and improve future patient centric clinical research.
Methods: SENSCIS® trial participants who were involved in the extension trial SENSCIS®-ON completed a post-trial survey covering nine multiple-choice questions about three main topics:

[1] Recruitment – Where do patients usually search for clinical trials and how did they become aware of SENSCIS®?
[2] Motivation & Retention – What motivated patients to start and continue participation in SENSCIS®?
[3] Challenges & Wishes – What were the challenges during trial participation and how can future clinical trials be improved regarding patient centricity?

Results: A total of 125 participants completed all survey questions. Participants could select more than one option. A total of 51 patients reported that they are usually not actively looking for trials. For those actively searching, the most common sources to learn about trials were specialists/general practitioners (GPs) (46 patients) and internet search engines (20 patients), followed by patient organisations (12 patients). Of note, 78 patients would pay attention to printed materials, such as a card/flyer/poster in a doctor's office and get in touch with a trial/study site. Back in 2015–2017, during recruitment for the SENSCIS® trial, the majority of the patients who answered the survey were made aware via their specialist/GP (116 patients), whereas 5 were made aware via patient organisations and 4 via the internet.
The most frequent motivations to join the trial were 'hope to receive an improved therapy' (98 patients), to help other patients (64 patients), and on the recommendation of their specialist/GP (81 patients). Similarly, the most liked aspects of the trial were the 'opportunity to receive an improved therapy' (92 patients) and 'to support the development of an improved therapy for my illness' (90 patients). More than half of patients reported 'continuous observation of general health' (72 patients) and 'advice from GPs/specialists' (71 patients) as motivation to stay in the trial (Figure 1).
'Concerns about side effects' (72 patients) and 'not knowing whether the trial medication will work for me' (63 patients) were reported as the least liked aspects of the trial. Travel to the site was reported as a challenge by 21 patients.
To improve clinical trials, patients requested more patient-friendly information (50 patients) and multiple formats of information material (46 patients). Finally, 48 patients expressed the desire to communicate with other trial participants.
Conclusion: The SENSCIS® post-trial survey is a unique approach to receive real-world feedback from trial participants, and these pilot data will help improve future clinical trials and communication. The results highlight the importance of reaching patients who may not be actively looking for clinical trials.

Building patient led organisations

POS1498-PARE LAUNCHING A NEW RELAPSING POLYCHONDRITIS ("RP") PROGRAM

N. Linn[1]. [1]*Relapsing Polychondritis Foundation, Rare Diseases, New York, United States of America*

Background: In 2011, I was diagnosed with relapsing polychondritis ("RP"), a debilitating and sometimes fatal rheumatic disease that is characterized by inflammation of cartilage and other tissues. The disease affects multiple organs, particularly cartilaginous structures such as the ears, nose, airways, and joints as well as eyes, skin, heart valves and brain. The cause of RP remains unknown and there currently is no cure for the disease.
As a patient, I had the opportunity to be evaluated by an incredible team of multidisciplinary expert medical professionals. While interacting with these experts, it was evident that there were tremendous unmet needs in the areas of diagnosis and treatments. As a retired Registered Nurse, it was clear that targeted research initiatives would be required to combat RP.
Objectives: After diagnosis, I realized that I could focus on my specific case or combat RP more broadly and help others. I decided to live my life with the purpose of helping others.
Methods: While fighting RP, I met many highly skilled, collaborative research scientists, especially at annual gatherings of rheumatology professionals.
In 2017 in San Diego, I participated in an RP study group that received a tremendous response from participating clinicians, clinical and basic scientist researchers, patients, and patient advocacy groups.

In 2018 in Chicago, I helped organize the RP Foundation's reception, co-hosted an event with the University of Michigan Division of Rheumatology, participated on a podcast of a news source dedicated to the rheumatology field, and facilitated two exhibitor booths at a prominent rheumatology conference.
In 2019 in Atlanta, I participated in an RP investigator meeting, which provided an update on a classification criteria project, introduced a new project to modify the disease activity index, and summarized RP-related projects.
With knowledge gleaned at these sessions, my husband and I collaborated with the RP Foundation to provide a substantial gift in 2020 to establish the Penn RP Fund, which will support a unique partnership between the University of Pennsylvania and the National Institutes of Health sponsored Vasculitis Clinical Research Consortium.
Results: Living with the purpose of helping other patients continues to improve the quality of my life. It affords me the ability to be excited about the extraordinary advances in patient care and cutting-edge research.
Participating in these conferences has provided exceptional opportunities to learn and collaborate with highly skilled research scientists. Further, I was able to build relationships with these scientists, which played a key role in the launch of the Penn RP Program.
This program will allow researchers to pursue important projects, including the development of a world-class referral center to examine the impact of the microbiome on RP disease activity. Additionally, patients with RP will have the opportunity to be evaluated by multiple subspecialties in a coordinated patient-centered manner.
Conclusion: The RP Foundation, University of Pennsylvania, and the Vasculitis Clinical Research Consortium (VCRC) Created a Powerhouse Healthcare Coalition. The Penn RP program will significantly improve the quality of my life and other RP patients for years to come.

Arthritis research

POS1499-PARE **PATIENT PERSPECTIVES OF BIOLOGIC TREATMENTS FOR AXIAL SPONDYLOARTHRITIS: SATISFACTION, WEAR-OFF BETWEEN DOSES, AND USE OF SUPPLEMENTAL MEDICATIONS**

W. B. Nowell[1], K. Gavigan[1], T. Hunter[2], W. Malatestinic[3], R. Bolce[3], J. Lisse[3], C. Himelein[3], J. Curtis[4], J. A. Walsh[5,6]. [1]*Global Healthy Living Foundation, Patient-Centered Research, Upper Nyack, United States of America*; [2]*Eli Lilly and Company, Global Patient Outcomes and Real World Evidence, Indianapolis, United States of America*; [3]*Eli Lilly and Company, Medical Affairs, Indianapolis, United States of America*; [4]*University of Alabama at Birmingham, Rheumatology, Birmingham, United States of America*; [5]*University of Utah, Rheumatology, Salt Lake City, United States of America*; [6]*George E. Wahlen Veterans Affairs Medical Center, Rheumatology, Salt Lake City, United States of America*

Background: Biologic disease-modifying antirheumatic drug (bDMARD) therapy has been shown to be effective in the treatment of axial spondyloarthritis (axSpA).[1,2] Little is understood about patients' experience of axSpA treatment from their own perspective.
Objectives: To characterize patient experiences and perspectives with bDMARD treatments for axSpA, including satisfaction, and use of supplementary treatments when wear-off between doses is perceived among those currently treated with bDMARD therapy.
Methods: Adult US participants (pts) within the ArthritisPower registry with physician-diagnosed axSpA were invited to complete electronic PRO measures, such as the BASDAI (0-10 scale, score ≥4 indicates suboptimal disease control), and an online survey about their perspectives of treatment. Analysis compared pt characteristics and treatment satisfaction by whether or not pt reported wear-off between bDMARD doses.
Results: 128 pts with axSpA and on bDMARD therapy met inclusion criteria of whom 82.8% were female, with mean age of 47 years. Mean BASDAI scores indicated poor disease control (6.4, SD 1.8), worse for those perceiving wear-off between doses compared with those who did not [6.8 (1.6) vs. 5.9 (2.0), p=0.01]. A majority of pts on a bDMARD reported being somewhat (57.8%) or very satisfied (26.6%) with their current axSpA treatment, and about 53.1% were satisfied with how well it controls axSpA-related pain. However, 60.9% (n=78) of pts reported that their current bDMARD typically wears off before the next dose. Treatment satisfaction was lower for pts experiencing wear-off compared to pts without wear-off (highly satisfied: 21.8% vs. 34%; somewhat satisfied: 60.3% vs. 54%; dissatisfied: 17.9% vs. 12%). 82.1% (n=64) of pts reporting wear-off used additional medications or supplements when that happened, chiefly NSAIDs (68.8%, n=44), muscle relaxers (42.2%, n=27) and/or opioids (37.5%, n=24). Among the 20 pts not satisfied with current axSpA treatment, side effects (6/20, 30.0%), or worry about risk of side effects (2/20, 10%) were the main reasons.
Conclusion: In a predominantly female sample of bDMARD-treated axSpA patients with high disease activity, most expressed satisfaction with treatment. However, most experienced wear-off between doses and took supplementary medications, including opioids, to manage.

AB0001 INTERFERON SIGNATURE IN CHILDREN WITH CHRONIC NON-BACTERIAL OSTEOMYELITIS AND IT'S DYNAMIC AFTER BISPHOSPHONATES TREATMENT

M. Kostik[1], R. Raupov[1], R. Mulkidzhan[2], A. Kosmin[2], E. Suspitsin[1,2]. [1]*Saint-Petersburg State Pediatric Medical University, Hospital Pediatry, Sankt-Peterburg, Russian Federation*; [2]*N.N.Petrov Institute of Oncology, Molecular Diagnostics, Saint-Petersburg, Russian Federation*

Background: Chronic non-bacterial osteomyelitis (CNO) is an immune-mediated chronic inflammatory bone disease which predominantly affects children and adolescents. The pathogenesis of CNO related to imbalance between pro-inflammatory and anti-inflammatory cytokines. Interferon-I mediated pathway is associated with pathogenesis of different pediatric rheumatic diseases, such as juvenile systemic lupus erythematosus (jSLE), juvenile dermatomyositis (JDM), systemic onset of juvenile idiopathic arthritis (soJIA), and, most of all, with macrophage activation syndrome. The data on interferon-I- regulated pathway in CNO is absent. NSAIDs, non-biologic and biologic anti-inflammatory drugs and bisphosphonates (BF) are treatment options for patients with CNO. The main adverse event of BF is a flu-like syndrome probably caused by the excessive cytokine release stimulated by BF.
Objectives: The aim of our study was to evaluate activity of Interferon-I mediated pathway in CNO patients and it's dynamics after BF treatment.
Methods: This prospective study included children with CNO requiring BF treatment (n=9), patients with soJIA (n=8), JDM (n=11) and jSLE (n=40) and healthy controls (HC, n=21). The activity of Interferon-I mediated pathway was assessed using interferon I score (IFN1 score). The score represented the median expression of 5 IFN1-regulated genes (IFI44L, IFI44, IFIT3, LY6E, MX1) measured by quantitative real-time PCR. Patients with CNO were treated with standard 3-day regimen (1 mg/kg/day). We measured interferon score before pamidronate (Day 0, n=9) and after (Day 3, n=7).
Results: Median interferon score was 1.09 (0.96; 1.67) in CNO patients, 1.95 (1.3; 5.75) in soJIA, 7.6 (1.78; 29.0) in JDM and 16.9 (2.55; 40.3) in jSLE and 0.95 (0.82; 1.17) in HC (p=0.00001). Where were no difference in the IFN1 score between CNO and HC (p=0.222). In 6/7 CNO patients interferon score increased after pamidronate (p=0.015). The median interferon score after pamidronate increased and became 3.06 (0.87; 4,9, p=0.043); this may possibly explain the development of BF-related flu-like symptoms (cytokine release syndrome).
Conclusion: While interferon I-regulated pathway is not directly associated with CNO pathogenesis, BF likely activates interferon-I-regulated pathway and thus could be a possible cause of flu-like syndrome.

AB0002 ASSOCIATION OF C1Q GENETIC POLYMORPHISMS WITH SUSCEPTIBILITY TO RHEUMATOID ARTHRITIS IN BULGARIAN COHORT

M. Kosturkova[1], G. Mihaylova[2], M. Radanova[2]. [1]*Varna Medical University, Propedeutics of Internal Diseases, Varna*; [2]*Varna Medical University, Biochemistry, Molecular Medicine and Nutrigenomics, Varna, Bulgaria*

Background: Complement is strongly implicated in the pathogenesis of autoimmune diseases like systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). Its component C1q plays a dualistic role, triggering the inflammatory cascade on one hand and directing the clearance of immune complexes on the other. Homozygous genetic deficiency of C1q is strongly associated with SLE and SLE-like phenotype as almost 90% of C1q deficient individuals develop SLE or similar disease. Nevertheless, there are few and inconsistent studies exploring the single nucleotide polymorphisms (SNPs) of the C1q gene cluster in relation to the pathogenesis of SLE and RA.
Objectives: The aim of the study was to evaluate the possible association of five SNPs – rs292001, rs172378, rs294179, rs665691 and rs682658 in complement C1q gene cluster with susceptibility to SLE and RA in Bulgarian cohort.
Methods: Fifty patients with SLE, sixty-one patients with RA and sixty-seven healthy controls were genotyped for the five SNPs by TaqMan allelic discrimination assay.
Results: Frequency of genotypes and alleles of rs294179, rs665691 and rs682658 SNPs was similar between patients with SLE, RA and healthy controls. For rs172378 SNP, the minor G allele (OR = 2.73; 95% CI, 1.59-4.67, p=0.0003) and GG genotype (OR = 5.12; 95% CI, 1.60-16.49, p=0.006) were associated with susceptibility to RA. In our cohort in accordance with others, AA rs292001 SNP genotype was associated with increased risk for RA (OR = 3.32; 95% CI, 1.19-9.20, p=0.021). For SLE patients, AA rs292001 SNP genotype was low presented and did not associate with disease.
Conclusion: GG genotype of rs172378 SNP in C1q gene cluster could be considered as a new risk factor for RA.

AB0003 HLA-ALLELES IN SUSCEPTIBILITY TO SYSTEMIC AND OLIGOARTICULAR JUVENILE IDIOPATHIC ARTHRITIS IN THE BELARUSIAN POPULATION

H. Yatskiu[1], A. Sukalo[2], R. Goncharova[1]. [1]*Institute of Genetics and Cytology of NAS of Belarus, Laboratory of Molecular Basis of Genomic Stability, Minsk, Belarus*; [2]*Belarusian State Medical University, 1st Department of Pediatric Diseases, Minsk, Belarus*

Background: Juvenile idiopathic arthritis (JIA) is a complex trait, the most common rheumatic disease in children. Considering clinical heterogeneity of the disease, the genetic background of particular JIA subtypes may also vary significantly.
Objectives: This work was aimed to reveal characteristic patterns of HLA associations within 11 loci for two clinically different forms of JIA in the Belarusian population.
Methods: 24 patients diagnosed with systemic JIA, 24 patients with oligoarticular JIA and 24 healthy controls were included into the study. The JIA patients were divided into subgroups according to IIAR classification criteria. High-throughput HLA typing was performed using TruSight HLA v2 Sequencing Panel (Illumina) on MiSeq system. Sample analysis was performed using Assign TruSight HLA v2.0 software.
Results: *DQA1**05:01:01 and *DQB1**02:01:01 alleles showed protective effect against both systemic (p = 0.007; OR=0.08; 95% CI=[0.009–0.65] and p = 0.01; OR=0.09; 95% CI=[0.01–0.83]) and oliarticular JIA

(p = 0.026; OR=0.16; 95% CI=[0.03–0.79] and p = 0.046; OR=0.2; 95% CI=[0.04–1.00], while for *DRB1**03:01 negative association was revealed only for systemic JIA (p = 0.03; OR=0.11; 95% CI=[0.01–0.88]). At the same time the *DQB1**04:02:01 (p=0.026; OR=5.88; 95% CI=[1.20–28.72]) and *DRB1**08:01:01 (p=0.07; OR=3.94; 95% CI=[1.01–15.39]) allele frequencies were significantly higher in patients with oligoarthritis but not systemic JIA when compared with controls.

Conclusion: High-throughput HLA typing revealed distinct HLA-alleles associated with different JIA subtypes in the Belarusian population as well as some alleles protective both for oligoartricular and systemic JIA.

AB0004 THE ASSOCIATION OF THE RARE RS35667974 IFIH1 GENE POLYMORPHISM WITH SIX AUTOIMMUNE DISEASES: STRUCTURAL BIOLOGICAL INSIGHTS

M. Zervou[1], A. Andreou[2], G. Goulielmos[1], E. Eliopoulos[2]. [1]*University of Crete, Heraklion, Greece, Section of Molecular Pathology and Human Genetics, Department of Internal Medicine, School of Medicine, Heraklion, Greece*; [2]*Agricultural University of Athens, Department of Biotechnology, Athens, Greece*

Background: Genome wide association studies (GWAS) have successfully identified novel autoimmune disease-associated loci, with many of them shared by multiple disease-associated pathways but much of the genetics and pathophysiological mechanisms remain still obscure. Considering that most of the potential causal variants are still unknown, many studies showed that the missense variant rs35667974 at interferon induced with helicase C domain 1 (*IFIH1*) gene is protective for type 1 diabetes (T1D), psoriasis (PS) and psoriatic arthritis (PsA), while it was found to be also associated with ankylosing spondylitis (AS), Crohn's disease (CD) and ulcerative colitis (UC). *IFIH1* gene encodes a cytoplasmic RNA helicase that recognizes viral RNA and is involved in innate immunity through recognition of viral RNA [1].

Objectives: To investigate the role of the rare rs35667974 variant of *IFIH1* gene, which resides in exon 14 and changes a conserved isoleucine at position #923 to valine in T1D, PS, PsA, AS, CD and UC [2-4] as well as the mechanism that may affect the function in the protein structure.

Methods: Evolutionary analysis revealed heavily conserved sequence elements among species, indicating structural/functional importance of the mutation at position #923. *In silico* mutagenesis and three-dimensional (3D) homology modeling was used to localize the polymorphism under study on the IFIH1 protein. The mutant was constructed using molecular modeling with the program Maestro (Schrodinger, LLC) [5]. Molecular mechanics/dynamics studies were applied to validate structural/functional changes caused by the Ile923V substitution. All figures depicting 3D models were generated using the PyMOL molecular-graphics system V.2.2 [6].

Results: Evolutionary and **s**tructural analysis revealed that the position of residue Ile923 is located on a protein loop (921-927) directly interacting with mRNA both to the phosphoribose chain and the base pairs. Mutation of Ile to Val at position #923 will directly affect the said interaction with mRNA [7] (Figure 1). Moreover, it has been reported that pre-mRNA or mRNA levels did not correlate with Ile923Val, suggesting that, Ile923Val did not alter the expression of *IFIH1* in a major way [7].

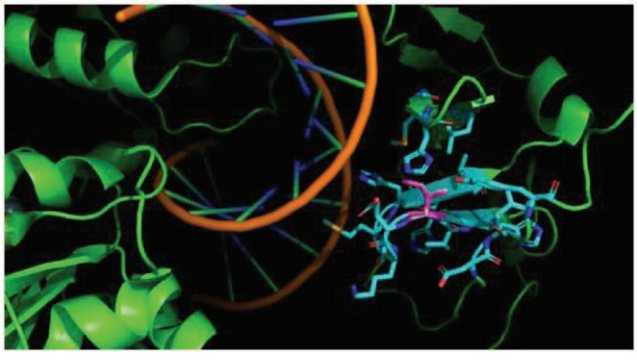

Figure 1. Structural representation of the interferon-induced helicase C domain-containing protein 1 [Homo sapiens] structure (4GL2 from Protein Data Bank) (in green) bound to the double stranded RNA (in orange-yellow). The location of the mutation (I923V) is highlighted in pink. The proximity of the aminoacid 923 to the nucleotide is apparent.

Conclusion: This study represents a comprehensive evaluation of the role of the shared rs35667974 variant of autoimmune locus *IFIH1*, reported to lead to a loss of function phenotype and, as a consequence, reduced levels of IFIH1 protein and activity that protect against autoimmunity. Structural analysis of rare shared genetic susceptibility or protection loci may provide insight to our understanding of the pathophysiology of autoimmune diseases and the research findings may affect the better management of the diseases under study.

Background: Psoriasis is an immune-mediated, genetic disease manifesting in the skin or joints or both, and also has a strong genetic predisposition and autoimmune pathogenic traits[1]. The hallmark of psoriasis is sustained inflammation that leads to uncontrolled keratinocyte proliferation and dysfunctional differentiation. And it's also a chronic relapsing disease, which often necessitates a long-term therapy[2].

Objectives: To investigate the molecular mechanisms of psoriasis and find the potential gene targets for diagnosis and treating psoriasis.

Methods: Total 334 gene expression data of patients with psoriasis research (GSE13355 GSE14905 and GSE30999) were obtained from the Gene Expression Omnibus database. After data preprocessing and screening of differentially expressed genes (DEGs) by R software. Online toll Metascape[3] was used to analyze Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis of DEGs. Interactions of proteins encoded by DEGs were discovered by Protein-protein interaction network (PPI) using STRING online software. Cytoscape software was utilized to visualize PPI and the degree of each DEGs was obtained by analyzing the topological structure of the PPI network.

Results: A total of 611 DEGs were found to be differentially expressed in psoriasis. GO analysis revealed that up-regulated DEGs were mostly associated with defense and response to external stimulus while down-regulated DEGs were mostly associated with metabolism and synthesis of lipids. KEGG enrichment analysis suggested they were mainly enriched in IL-17 signaling, Toll-like receptor signaling and PPAR signaling pathways, Cytokine-cytokine receptor interaction and lipid metabolism. In addition, top 9 key genes (CXCL10, OASL, IFIT1, IFIT3, RSAD2, MX1, OAS1, IFI44 and OAS2) were identified through Cytoscape.

Conclusion: DEGs of psoriasis may play an essential role in disease development and may be potential pathogeneses of psoriasis.

AB0006 GENETIC RISK PROFILE FOR PSORIATIC ARTHRITIS PREDISPOSITION IN ITALIAN PATIENTS

M. S. Chimenti[1], C. Ciccacci[2], G. De Benedittis[3], A. Latini[3], P. Conigliaro[1], G. L. Fonti[1], P. Triggianese[1], P. Borgiani[3], R. Perricone[1]. [1]*University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Rome, Italy*; [2]*UniCamillus - Saint Camillus International University of Health Sciences, Genetics Unit, Rome, Italy*; [3]*University of Rome Tor Vergata, Genetics Unit, Rome, Italy*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory joint disease typically associated with psoriasis and classified in the group of spondyloarthritis (1). The pathogenesis is based on an interplay of different genes interacting with several environmental factors including stress, trauma, infections, triggering an inflammatory response related to the activation of innate and acquired immunity in different tissues and organs (2). However, the risk for the development of PsA is not clearly understood.
Objectives: The aim of this study was to evaluate, in a cohort of Italian PsA out-patients of the Rheumatology Unit of the University of Rome Tor Vergata, the association of genetic variants in candidate genes for PSA susceptibility and their possible contribute in the modulation of clinical and laboratory features.
Methods: The genes were selected according to previous studies describing these genes as involved in susceptibility to rheumatoid arthritis (RA) (3), since a common genetic background can be shared between these diseases. Nine SNPs (single nucleotide polymorphism) in eight candidate genes were analysed: STAT4 (rs7574865), TRAF3IP2 (rs33980500), TNFAIP3 (rs6920220 and rs2230926), MIR146A (rs2910164), PSORS1C1 (rs2233945), IL-10 (rs1800872), HCP5 (rs3099844) and ERAP1 (rs27524). Polymorphisms were analysed in 163 consecutive PsA out-patients and 198 healthy controls (HC). Genotyping was performed by allelic discrimination by TaqMan assay. Alleles frequencies differences between cases and controls or between phenotypic groups were compared using Pearson's χ 2 test.
Results: We have observed an association between PSA susceptibility and the variant alleles of STAT4 [OR= 1.60 (1.15-2.21), P= 0.005], TRAF3IP2 [OR= 1.65 (1.01-2.65), P= 0.04], ERAP1 [OR= 1.40 (1.05-1.85), P= 0.02] and TNFAIP3 (rs6920220) [OR= 1.75 (1.19-2.57), P= 0.004]. On the contrary, the variant allele of IL-10 polymorphism seems to play a protective role [OR= 0.74 (1.05-1.85), P= 0.05]. Moreover, in order to define a genetic risk profile, we have counted the total number of risk alleles in each subject, considering as risk alleles the allelic variant of rs7574865 (STAT4), rs33980500 (TRAF3IP2), rs6920220 (TNFAIP3) and rs27524 (ERAP1) SNPs. Then, we have compared the risk allele number distribution between patients and HC (Fig.1). Classes with 3 or more risk alleles are significantly more represented in patients than in HC (OR= 2.03, P=0.004). The risk to develop the disease increases significantly in subjects with at least four risk alleles (OR= 2.96, P=0.002).

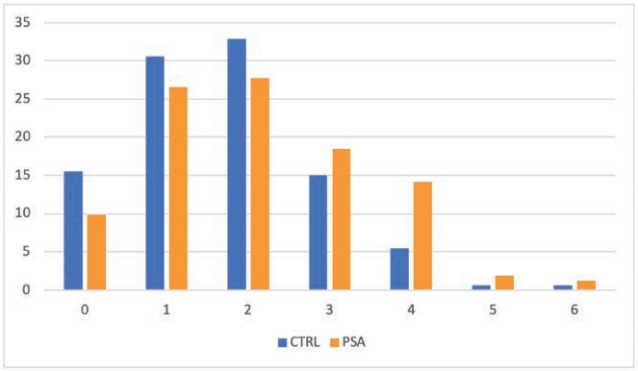

Figure 1. Number of risk alleles in patients and controls: rs7574865 (STAT4), rs33980500 (TRAF3IP2), rs6920220 (TNFAIP3) and rs27524 (ERAP1) SNPs.

Conclusion: We confirm the associations between five SNPs, already studied in RA, and PSA susceptibility, suggesting a common inflammatory pathway in chronic inflammatory rheumatological diseases. Moreover, we show how the genotyping of only few associated SNPs could help to define a genetic risk profile for PSA development.

AB0007 STAT4 RS7574865 G/T POLYMORPHISM AS MARKER OF PREDISPOSITION TO SYSTEMIC LUPUS ERYTHEMATOSUS WITH JUVENILE ONSET

M. Kaleda[1], M. Krylov[2], I. Nikishina[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Genetic Department, Moscow, Russian Federation*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with a significant genetic predisposition. Recent studies have identified STAT4 (signal transducers and transcription activators 4) as a susceptibility gene for SLE.
Objectives: To investigate the hypothesis of the association of STAT4 rs7574865 G/T polymorphism with the predisposition to SLE in children and its relationship with some of SLE manifestations.

Methods: The case-control pilot study included 143 children (39 with SLE and 103 healthy unrelated volunteers as a control group). Diagnosis of SLE was based on 2012 SLICC criteria. STAT4 rs7574865 G/T polymorphism was investigated using allele-specific real-time polymerase chain reaction (RT-PCR).
Results: The group of pts with SLE consisted of 29 girls and 10 boys, with an average age of 11.8±3.7 years (from 3 to 17 years) and an average disease duration of 4.1±2.4 years. 79.5% pts had acute cutaneous lupus at the onset, 46.1% - nonscarring alopecia, 71.8% - arthritis, 23.1% - oral and nasal ulcers, 23.1% - serositis, 43.6% - renal involvement, 35.9% –neuropsychiatric disorders. Leucopenia/lymphopenia was found in 71.8% of pts, thrombocytopenia – in 23,1%. ANA were detected in 100% pts, anti-dsDNA – in 79.5%, anti-Sm – in 31.6%, antiphospholipid antibodies - in 7,3%, hypocomplementemia – in 61.5%, positive direct Coombs test – in 35.9 %. Macrophage activation syndrome at the onset was documented in 15.4 % of pts. The distribution of rs7574865 genotypes in the control group showed no significant deviations from the Hardy-Weinberg equilibrium. The distribution of genotype frequencies among pts had statistically significant differences compared to the control (χ2=12.95, p=0.0015): GG-30.8% and 63.1% (p=0.001), GT-56.4% and 33.0% (p=0.018), TT-12.8% and 3.9% (p=0.114), GT+TT - 69.2% and 36.9% (p=0.0005). The frequency of the mutant STAT 4 allele T (polymorphism), was significantly higher in the SLE group than in the control group (41% and 20.4%, respectively; p=0.0007). We identified an association of the T allele with some clinical, laboratory, and immunological disorders in SLE: arthritis (OR 3.9, p=0.0002), acute cutaneous lupus (OR 2.47, p=0.003), nonscarring alopecia (OR 3.12, p=0.002), renal involvement (OR 2.42, p=0.022), leucopenia (OR 2.72, p=0.003), thrombocytopenia (OR 4.88, p=0.002), anti-dsDNA (OR 2.82, p=0.0006), hypocomplementemia (OR 2.34, p=0.012), positive direct Coombs test (OR 3.38, p=0.002).
Conclusion: Our pilot study confirmed that the STAT4 rs7574865 G/T polymorphism was associated with the risk of SLE in children and some of SLE manifestations.

AB0008 APPLYING WHOLE EXOME SEQUENCING TO FAMILIAL ANTIPHOSPHOLIPID SYNDROME: NEW PLAYERS IN A RARE DISEASE?

A. Barinotti[1], M. Radin[1], I. Cecchi[1], S. G. Foddai[1], E. Rubini[1], D. Roccatello[1], S. Sciascia[1], E. Menegatti[1]. [1]*University of Turin, Clinical and Biological Sciences, Turin, Italy*

Background: Antiphospholipid Syndrome (APS) is an autoimmune disease whose precise aetiology is still unknown, but the high heterogeneity of its manifestations and clinical course is presumably due to the occurrence of different mechanisms and alterations at different levels and pathways [1]. The first genetic studies in APS focused primarily on the human leukocytes antigen system region, but more recent data highlighted a role of other genes in APS susceptibility, primarily those involved in the immune response and in the haemostatic process.
Objectives: We aimed to deepen the investigation of APS genetic background starting from a case of familial APS, analysing two siblings with thrombotic APS (Table 1), both triple positive for antiphospholipid antibodies (aPL).

Table 1. ***Main clinical and laboratory characteristics of the patients included in the study.***

Patient	Age	aPL Profile	Relevant Clinical History
1 (F)	51	Triple positive (LA, aCL IgG, aβ2GPI IgG)	Two episodes of ischemic stroke, one episode of CAPS (renal thrombotic microangiopathy, visual impairment, ischemic stroke)
2 (M)	47	Triple positive (LA, aCL IgG, aβ2GPI IgG)	Three episodes of deep vein thrombosis, regardless ongoing well conducted therapy vitamin k antagonist and additional retinal vein thrombosis

LA: lupus anticoagulant; aCL: anti-cardiolipin antibodies; aβ2GPI: anti- β2 glycoprotein I antibodies; CAPS: catastrophic APS.

Methods: Genomic DNA was extracted from peripheral blood and the samples underwent Whole Exome Sequencing (WES). Sequencing was done on a 100X coverage, and reads have been aligned to the human reference genome (GRCh37/hg19 assembly) using the Burrows–Wheeler Alignment tool (BWA). The mean sequencing depth on target regions was 170X for patient 1, 205X for patient 2, moreover, 99.50% of the targeted bases had at least 10X coverage for all the three donors. The resulting single nucleotide polymorphisms (SNPs) have been analysed through a step-by-step process based on their frequency population (using Genome Aggregation Database), their predicted effects on the protein (using VarSome) and a literature research about the genes carrying them. Moreover, genes previously associated with a pro-thrombotic tendency and with APS have been analysed in the two patients.
Results: Starting from more than 120000 SNPs for each patients, the analysis led to reduce the list of SNPs of interest to 27 missense mutations. The complete literature research regarding the genes carrying these mutations allowed to further reduce the number of selected genes, focusing on those that exert a role potentially involved in APS pathogenesis and development. In particular, these genes (*PLA2G6*, *HSPG2*, *BCL3*, *ZFAT*, *ATP2B2*, *CRTC3* and *ADCY3*) take part in the immune response and the vascular homeostasis. The list of the DNA missense variants of interest found in our cases of familial APS is resumed in Figure 2.

Figure 2. List of DNA missense variants of interest found in patient 1 and 2.Genes potentially involved in APS pathogenesis and development are highlighted in bold.

No mutations on genes known to be associated with a pro-thrombotic state (*F5*, *F2*, *MTHFR*, *F13A1*, *PROC*, *PROS1*, *FGB* and *SERPINE1*), or on genes previously associated with APS (*B2GPI*, *PF4V1*, *SELP*, *TLR2*, *TLR4*, *GP Ia*, *GP1BA*, *F2R*, *F2RL1*, *TFPI*, *F3*, *VEGFA*, *FLT1*, and *TNF*) have been found in the WES analysis.
Conclusion: To some extent, this can be seen as a proof of concept of the complexity of APS. Efforts to interpret the genetic risk factors involved in the heterogeneous clinical features of the syndrome, for instance, the integration of WES and network-based approaches might help to identify and stratify patients at risk of developing APS.

AB0009 ASSOCIATION OF STAT4 RS7574865, RUNX1 RS9979383, IL6 RS1800795, IL6R RS2228145, IL6R RS4845618 WITH SYSTEMIC LUPUS ERYTHEMATOSUS SUSCEPTIBILITY AND SOME LUPUS MANIFESTATIONS IN BELARUSIAN POPULATION

N. Dostanko[1], V. Yagur[1], R. Goncharova[2], E. Siniauskaya[2], T. Zybalova[1]. [1]*Belarusian State Medical University, 2-nd Department of Internal Medicine, Minsk, Belarus*; [2]*National Academy of Sciences of Belarus, Institute of Genetics and Cytology, Minsk, Belarus*

Background: Systemic lupus erythematosus (SLE) has a significant genetic predisposition. Many genetic variants of susceptibility to SLE have been published and analyzed, but the clinical and functional significance of the various genotypes has not yet been clearly defined [1].
Objectives: To estimate the association between some of non-HLA gene polymorphisms such as STAT4 rs7574865, RUNX1 rs9979383, IL6 rs1800795, IL6R rs2228145, IL6R rs4845618 and susceptibility to SLE in Belarusian population as well as some disease manifestations.
Methods: We examined 383 healthy blood donors and 54 SLE patients (18-72 years old, median age 35) classified according to the 1997 American College of Rheumatology (ACR) revised classification criteria [2]. Deoxyribonucleic acid was extracted from peripheral blood samples by phenol-chloroform method. Genotyping was performed by real-time PCR with fluorescent probes. Differences of distribution of all the single nucleotide polymorphism (SNP) genotypes and their associations with secondary antiphospholipid syndrom (APS) and lupus arthritis were analyzed using Pearson χ^2 (χ^2) and two-way Fisher exact test (F, $p_{2\text{-}t}$). Diagnostic odds ratio (dOR), likelihood ratio of positive (LR^+) and negative (LR^-) tests and corresponding 95% confidence intervals (CI) were also calculated.
Results: We revealed significant difference in STAT4 rs7574865 genotypes in SLE patients and healthy donors (χ^2=8,27, p=0,016) with significant increase of TT genotype frequency in SLE patients vs healthy donors (χ^2=6.83 p=0.009; $p_{2\text{-}t}$ =0.020; dOR=3.78 ($CI_{95\%}$ 1.36-10.55); LR^+ =3.44 ($CI_{95\%}$ 1.35-8.71); LR^- =0.91

($CI_{95\%}$ 0.83-0.98)). Lupus arthritis was more common in risk TT-genotype SLE carriers than in other SLE patients (χ^2=5.902 p=0.015; $p_{2\text{-}t}$ =0.027).
We revealed significant increase of CT genotype (RUNX1 rs9979383) in healthy donors vs SLE patients (χ^2=4.14; p=0.042; dOR=0.53 ($CI_{95\%}$ 0.29-0.98); LR^+ =0.69 ($CI_{95\%}$ 0.45-0.99); LR^- =1.3 ($CI_{95\%}$ 1.01-1,56)). Lupus arthritis was more common in SLE CT-genotype carriers than in other SLE patients (χ^2=4.66 p=0.031; $p_{2\text{-}t}$ =0.058).
Significant differences in IL6 rs1800795, IL6R rs2228145 and IL6R rs4845618 genotypes distribution between studied groups were not found (χ^2, p=0.427, p=0.559 and p=0.407, correspondingly) but GG-genotype (IL6 rs1800795) carriership in SLE patients was associated with increased APS frequency (χ^2=4.45, p=0.035; dOR=0.19 ($CI_{95\%}$ 0.04-0.9); LR^+ =0.28 ($CI_{95\%}$ 0.07-0.93); LR^- =1.41 ($CI_{95\%}$ 1.03-1.64).
Conclusion: Our data suggest the susceptibility to SLE in TT genotype of STAT4 rs7574865 polymorphism, protective role of CT genotype of RUNX1 rs9979383 for SLE and association between GG-genotype of IL6 rs1800795 and APS in SLE patients in Belarusian population. Lupus arthritis was associated with TT genotype of STAT4 rs7574865 and CT genotype of RUNX1 rs9979383.

AB0010 ASSOCIATION OF SAA1 GENE POLYMORPHISM -13T/C (RS12218) WITH ANKYLOSING SPONDYLITIS IN RUSSIAN POPULATION

I. Guseva[1], K. Sakharova[2], M. Krylov[1], E. Samarkina[1], S. Erdes[2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Spondyloarthritis, Moscow, Russian Federation*

Background: Ankylosing spondylitis is a chronic systemic inflammatory disease. Inflammation and high levels of serum amyloid A (SAA) protein are predisposing factors for secondary AA amyloidosis. The role of *SAA1* gene polymorphisms in AS is not well understood.
Objectives: To investigate the association of *SAA1* gene polymorphism -13T/C (rs12218) with ankylosing spondylitis and to evaluate the influence of this polymorphism on SAA protein concentration.
Methods: 123 AS patients (72 males, 51 females; age - M (SD) 37.51 (12.77) years; disease duration - 14.28 (11.22) years; BASDAI – 5.59 (1.13); B27-positive - 111 (90.2%) pts) and 95 gender, age matched healthy individuals (control group) were included in this study. *SAA1* gene polymorphism -13T/C was genotyped using allele-specific RT-PCR assay. SAA protein concentration was measured using nephelometry in AS patients.
Results: The distribution of genotypes TT, TC and CC differed statistically between AS and control groups (24.4%, 56.1%, 19.5% and 41.1%, 44.2%, 14.7% respectively, χ^2=6.9, p=0.03).
The presence of the C allele was associated with the development of AS (OR=1.55 [CI 1.04-2.33], p=0.03). The *SAA1* -13T/C polymorphism tended to be associated with SAA protein value in AS patients: TT+TC genotypes -13.8 mg/l [4.2; 91.0], CC genotype -7.8 mg/l [1.6; 29.6], p=0.07. ESR, CRP and BASDAI values did not correlated with *SAA1* - 13T/C polymorphism (p=0.6, p=0.4, p=0.4 respectively).
Conclusion: The results of our study demonstrated for the first time that *SAA1* gene polymorphism -13T/C (rs12218) is associated with susceptibility to AS. It is also shown that this polymorphism can affect the SAA protein level. Our findings need to be verified in AS patients with high levels of SAA protein in various ethnic and population groups.

AB0011 EXPRESSION PROFILE AND POTENTIAL FUNCTION OF CIRCRNAS IN PERIPHERAL BLOOD MONONUCLEAR CELLS FROM PATIENTS WITH PRIMARY GOUT

Y. F. Qing[1], F. Dai[1], Q. B. Zhang[2], Y. P. Tang[1], Z. R. Dong[1], Y. X. He[1], Y. Jiang[1], Y. Q. Huang[2], J. Zheng[1]. [1]*Institute of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Department of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Nanchong, China*; [2]*Institute of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Department of Geriatrics, Affiliated Hospital of North Sichuan Medical College, Nanchong, China*

Background: Autophagy is a phenomenon of "self-phagocytosis" in eukaryotic cells, which maintains cell homeostasis by transporting intracellular materials to lysosomes for degradation and recycling. In recent years, studies have shown that autophagy may be involved in the pathogenesis of rheumatoid arthritis(RA) [1], but its specific mechanism is still unclear.
Objectives: The expression levels of autophagy-related genes(ATG) unc-51-like kinase 1(ULK1), ATG13, ATG17, microtubule associated protein 1 light chain 3 (LC3), and P62 in peripheral blood mononuclear cells (PBMC) of patients with RA were detected, and their role and clinical significance in the pathogenesis of RA were explored.
Methods: Real-time fluorescent quantitative PCR was performed to detect the expression levels of ULK1, ATG13, ATG17, LC3, and P62 in PBMCs of 50 RA patients, 50 healthy controls (HC), and 25 moderate to severe RA patients before and after treatment. Then, t test, χ2 test, Mann-Whitney U test, Pearson test were used for statistical analysis.
Results: 1.The levels of hsCRP, white blood cell(WBC), neutrophils(GR), platelet(PLT) and plateletcrit(PCT) in RA group were higher than those in HC group (P <0.05). Lymphocytes (LY), red blood cell(RBC), hemoglobin(HGB), hematocrit(HCT), mean corpuscular hemoglobin(MCH), mean red blood cell volume(MCV) and mean red blood cell hemoglobin concentration(MCHC) in RA group were lower than those in HC group (P <0.05). 2.The expressions of ULK1, ATG17, and LC3 in RA group were higher than those in HC group, while the expressions of P62 was lower than those in HC group(P<0.05) (Figure 1). The correlation analysis suggested that ATG17 was positively correlated with tender joint count (TJC), swollen joint count (SJC), and health assessment questionnaire (HAQ) (P<0.05); ULK1 and HAQ were negatively correlated (P<0.05).3. Compared with before treatment with TNFi, ATG17, HAQ, DAS-28, ESR, hsCRP, WBC, GR, PLT and PCT were significantly reduced after treatment (P<0.05); the expressions of RBC, HCT, MCV and MCH were significantly increased after treatment,(P<0.05); ULK1, ATG13, LC3, P62 and other related clinical and laboratory indicators were not significantly different before and after treatment with TNFi (P>0.05).

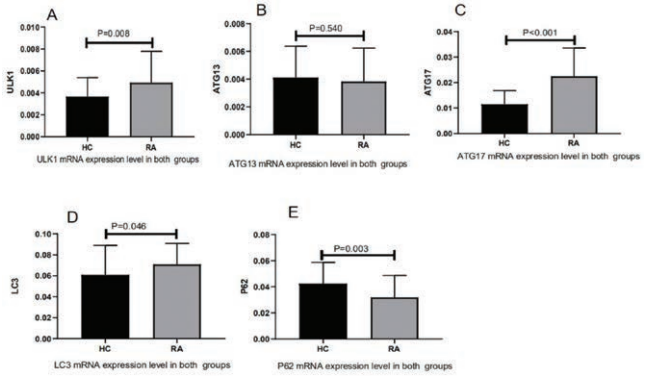

Figure 1. The expression levels of ATGs in HC and RA groups.

Conclusion: There is abnormal expression of autophagy genes in the peripheral blood of RA patients. ULK1, ATG17, LC3 and P62 may be related to the pathogenesis of RA, among them, ATG17 may regulate the pathogenesis of RA by participating in the TNF-α pathway.

AB0012 THE EFFECTS OF COMMON THERAPEUTICS ON AIRE METHYLATION STATUS AND THE LEVELS OF IL-16, IL-1B, AND IFN-Γ IN LPS-INDUCED MACROPHAGE CELLS CAN SULPHASALAZINE'S INFLUENCE ON METHYLATION STATUS OF AIRE EXPLAIN ITS AUTOIMMUNE SIDE EFFECTS?

Z. B. Çelik[1], C. Gunaydin[2], A. K. Cengiz[3]. [1]*19 Mayis University Medical Faculty, Medical Biology, Samsun, Turkey*; [2]*19 Mayis University Medical Faculty, Pharmacology, Samsun, Turkey*; [3]*19 Mayis University Medical Faculty, Physical Medicine and Rehabilitation-Rheumatology, Samsun, Turkey*

Background: The autoimmune regulator gene (*AIRE*) has very important role in self-tolerance. Estrogen induced hypermethylation of *AIRE* promoter was put forward as one of the reasons for susceptibility to autoimmunity in females. [1] Sulphasalazine is a commonly used drug in rheumatology and is known to be responsible for various autoimmune side effects.
Objectives: We aimed to investigate the effects of commonly used treatments on the methylation status of *AIRE* and levels of interleukin-16 (IL16), interleukin-1β (IL1β), and interferon-γ (IFNγ), in lipopolysaccharides (LPS)-induced RAW264.7 macrophage cells which mimic inflammatory state in rheumatoid arthritis in vitro.[2]
Methods: RAW264.7 cells were stimulated by LPS (1μ/mL). Cell viability test was performed to determine drug concentrations. Following drug treatments, cell media was isolated for the determination of IL16, IL1β, and IFNγ levels by ELISA. Also, the cells detached by trypsin-EDTA were used for DNA isolation and bisulfite modification. Then, the promoter methylation status of AIRE was analyzed with methylation-specific PCR and agarose jel electrophoresis.
Results: Our results demonstrated that the *AIRE* promoter is highly methylated in absence of any inflammatory stimulus.LPS treatment changed methylation status to unmethylated form. Leflunomide(LEF), sulfasalazine(SLZ) and methotrexate(MTX) significantly altered methylation status as the methylated (p=0.041,p<0.001,p<0.001, respectively). Surprisingly, SLZ treatment caused significantly more methylation in AIRE promoter than other drugs (p<0.001,-Fig 1A). Analysis of IL16, IL1β and IFNγ levels demonstrated that LPS caused potent increase in all three cytokines (p<0.001, Fig 1B-D). LEF and SLZ significantly prevented LPS-induced increase in these cytokines (p=0.025, p<0.001 for IL-16, p<0.001 for IL-1β and IFNγ, Fig 1B-D). Although MTX exacerbated LPS-induced increase in IL16 levels, it inhibited LPS induced increase in IL1β and IFNγ levels (p<0.001, Fig 1B-D).

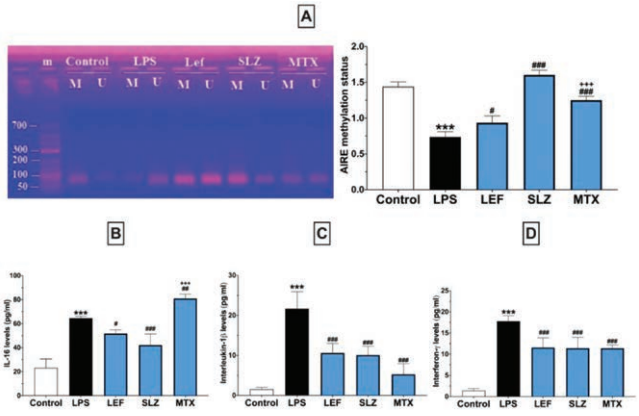

Figure 1. PCR gel image. All data expressed as mean±SD. ***p<0.001 versus control, ###p<0.001, #p<0.05 versus LPS, +++p<0.001 versus sulfasalazine.

Conclusion: Our results suggest that although LEF,SLZ and MTX potently suppresses LPS-induced inflammatory cytokines, they affect *AIRE* methylation differently.Changes in the methylation status of *AIRE* are important for autoimmunity. Relative increase in methylation of *AIRE* promoter by SLZ usage can be responsible for its autoimmune side effects, like drug induced lupus or hypersensitivity reactions, which are not common in MTX and LEF usage.
IL16 is a key regulator of biological properties of CD4+T cells, it also regulates migration of CD4+CD25+Treg cells.[3] MTX treatment was shown to increase Treg cells in early rheumatoid arthritis patients. LEF and SLZ's effect on Treg cells was shown to be different from that of MTX.[4] Our results demonstrated that MTX exacerbated LPS-induced increase in IL16 levels in contrary to LEF and SLZ. This difference may also be responsible for the different effect of these medications on Treg functions.
The different effect of commonly used disease modifying drugs on IL16 levels and methylation of *AIRE* promoter is interesting and deserves attention.

AB0013 ASSOCIATION BETWEEN STAT4 POLYMORPHISM AND MANIFESTATIONS OF SLE

V. Agarwal[1], S. Kakati[1], P. Debbaruah[2]. [1]*Assam Medical College and Hospital, Medicine, Dibrugarh, India*; [2]*Assam Medical College and Hospital, Anatomy, Dibrugarh, India*

Background: SNP rs7574865, located within the third intron of STAT4 gene at chromosome 2, has been associated with susceptibility to SLE among different ethnic groups.[1,2] Interestingly, we recently have documented an association between this gene and susceptibility to systemic lupus erythematosus (SLE) in Indian population.[3]
Objectives: To determine whether the STAT4 (rs7574865) SNP is associated with clinical and immunological manifestations in SLE.
Methods: The study was carried out on 100 unrelated SLE (SLICC criteria 2012) patients from North-East India. Genotyping of STAT4 rs7574865 SNP was done using Taqman probe and Real-Time Polymerase chain reaction. An association study was performed between the alleles and genotypes of STAT4 rs7574865 with the clinical and immunological manifestations included in the SLE SLICC classification criteria. For all analysis, the statistical significance was fixed at 5% level of significance ($p < 0.05$).
Results: The mean duration of illness was 2.69±2.55 years. Cases and Controls remained in Hardy-Weinberg equilibrium.The occurrence of Photosensitivity and hyperpigmentation was significantly higher in TT genotype group (97.22% and 77.77%, respectively) with p <0.001 in each case.SLE patients with nephritis (Albuminuria >500mg/24 hours) and elevated serum creatinine were both significantly higher in TT genotype group as compared to GT and GG (p< 0.001 and p=0.001 respectively).The Anti-dsDNA antibody was significantly associated with TT genotype (p <0.001).
Conclusion: Our study provides evidence regarding the association between STAT4 rs7574865 gene polymorphism is risk factor for cutaneous manifestations, Lupus nephritis and Anti ds-DNA positivity in SLE. So, our findings reinforce the need for further association studies including prospective studies with larger subjects in order to replicate such findings.

AB0014 METHOTREXATE - IMPLICATIONS OF PHARMACOGENETICS IN THE TREATMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS

R. Pinheiro Torres[1,2], F. Pimentel Dos Santos[1,2,3], J. Branco[1,2,3]. [1]*Hospital Egas Moniz, Rheumatology, Lisboa, Portugal*; [2]*CEDOC, Rheumatology, Lisboa, Portugal*; [3]*Nova Medical School, Rheumatology, Lisboa, Portugal*

Background: Methotrexate (MTX) is an anti-folate drug with anti-proliferative and anti-inflammatory effects. MTX proved to be the most highly effective, fast-acting disease modifying anti-rheumatic drug (DMARD), being widely used for the treatment of rheumatoid arthritis (RA) (1).
Objectives: This review aims to describe the main genetic variants identified concerning proteins that play a role in methotrexate's kinetics and efficiency profile.
Methods: A literature review was conducted since January of 2000 until December 2020, by searching the PubMed and Embase bibliographic databases, employing the following MeSH terms: methotrexate, pharmacogenetics, pharmacokinetics and rheumatoid arthritis. The search was limited to articles in English language. Two independent reviewers screened the titles and abstracts followed by a full-text review to assess papers regarding their eligibility. A total of 48 articles matched the research criteria and were analysed.
Results: Genetic variants of four main proteins, with different functions, have been consistently described.
Reduced folate carrier 1 (RFC1), a constitutively expressed folate transport protein that has high affinity for MTX is responsible, almost exclusively, for the transport of folate and MTX into the cell. The most commonly studied variant of the gene is the 80G > A variant (rs1051266), mapped within exon 2, on chromosome 21. It seems to improve RA responses to MTX, clinical efficacy with long disease remission (2).

ABC transporters are involved in the eflux of MTX from cells. An increased expression and function of these transporters should decrease MTX concentrations in target cells, resulting in lack of therapeutic response. *ABCB1 3435* C/T (rs1045642) is a high frequency polymorphism, significantly associated with RA good responses, symptom remission and reduced adverse events, due to MTX treatment (3).
Thymidylate synthase (TYMS) is involved in thymidine synthesis. MTX decreases TYMS activity by inhibition and decreasing the access to tetrahydrofolate (THF) cofactors (1). The most common genetic variant of the TYMS gene consists of a 28 bp tandem repeat (rs34743033), with double and triple number of repeats (2R and 3R). The 3R allele genotype was associated with decreased efficacy and increased toxicity (4).
The 5,10-methylenetetrahydrofolate reductase (MTHFR) enzyme is indirectly inhibited by MTX. The most common SNPs of the MTHFR gene are C677T (rs1801133) and A1298C (rs1801131). Both are associated with a decreased efficacy and an increased toxicity of MTX (5).
Conclusion: MTX response is affected by many gene variants; the effect of each variant separately is likely to be small. Additionally, gene-gene interaction, enhancing the potential role of linkage disequilibrium. This shows the emerging need for a better gene characterization and to improve the knowledge about variants distribution according to ethnicity, to explain different responses to MTX at an individual level.

AB0015 **STUDY OF VDR AND VDBP GENES AS CANDIDATE SUSCEPTIBILITY GENES FOR THE DEVELOPMENT OF IMMUNE-MEDIATED DISEASES IN THE PARAGUAYAN POPULATION**

I. Acosta-Colman[1], M. Vazquez[1], S. Cabrera-Villalba[1], A. Ayala-Lugo[2], M. E. Acosta[2], I. Arevalo de Guillen[2], V. Jolie[2], M. Duarte[1], V. Valinotti[1], R. Contreras[3], G. Avila[1], T. Martinez[4], A. Juliá[5], S. Marsal[5]. [1]*Hospital de Clinicas, Universidad Nacional de Asuncion, Rheumatology, Asunción, Paraguay*; [2]*Insituto de Investigaciones en Ciencias de la Salud, UNA, Asunción, Paraguay*; [3]*Hospital de Clinicas, Universidad Nacional de Asuncion, Dermatology, Asunción, Paraguay*; [4]*Laboratorio Curie, Laboratorio Curie, Asunción, Paraguay*; [5]*Hospital General Vall d'Hebron, Vall d'Hebron Institut de Recerca, Barcelona, Spain*

Background: Immune Mediated Inflammatory Diseases (IMIDs) are complex diseases that are believed to have a strong interaction between the genome and the environment as part of their aetiology. In studies using the candidate gene strategy, genetic variation in a gene where functionality has been associated with the pathophysiology of the disease under study is being analyzed. In the last decade, polymorphisms of the vitamin D receptor (VDR) and VDBP genes have been more emphatically studied in IMIDs in different populations, but the results reported have not yet been conclusive.
Objectives: To identify an association between vitamin D receptor (VDR) and vitamin D-binding protein (VDBP) gene polymorphisms, and IMIDs in Paraguayan patients.
Methods: Association study of VDR (SNPs rs731236, rs7975232, rs2228570) and VDBP (rs4588) gene polymorphisms with susceptibility to IMIDs in Paraguayan population. A total of 399 patients with IMIDs (i.e. Systemic Lupus Erythematosus (SLE), Scleroderma (ES), Rheumatoid Arthritis (RA), and Cutaneous Psoriasis (CPS) and 100 hypernormal controls (HC) from the same population were included in this study. Genotyping was performed using Taqman real-time PCR-based technology (Life Technologies, USA). Statistical analysis was performed using Rv3.0.1 statistical language software (www.R-project.org). A p value ≤ 0.05 was used for statistical significance.
Results: A total of 399 individuals, 100 controls and 299 patients (99 RA, 100 SLE, 50 ES, and 50 PSO) were included. Seventy-six percent were female and 24% were male. The mean age was 43.7±14 years. Four SNPs were genotyped: rs731236, rs7975232, rs2228570, rs4588. The HWE test was not statistically significant for any of the 4 SNPs considered (P>0.05), confirming the quality of genotyping and the absence of technical bias. (Table 1).

Table 1. Genotyping of SNPs of the VDR and VDBP gene in Paraguayan population with IMIDs.

SNP	IMID	Minor Allele	Major Allele	MAF Control	MAF Case	OR	IC.L	IC.H	p allelic	P.Genetic
rs731236	SLE	G	A	0.5	0.4	0.64	0.42	0.97	0.035	0.08
rs731236	RA	G	A	0.5	0.41	0.69	0.46	1.05	0.071	0.12
rs731236	SS	G	A	0.5	0.42	0.71	0.42	1.18	0.18	0.37
rs731236	CPS	G	A	0.5	0.38	0.6	0.36	1.01	**0.049**	**0.042**

Adaptive immunity (T cells and B cells) in rheumatic diseases

AB0016 **THE IMPACT OF IL-17A THERAPY ON IGG SIALYLATION IN HUMANS**

R. Pfeifle[1,2], J. Kittler[1], M. Wuhrer[3], G. Schett[1], G. Krönke[1]. [1]*University Hospital Erlangen, Department of Internal Medicine 3 and Institute of Clinical Immunology, Erlangen, Germany*; [2]*Friedrich-Alexander University, Nikolaus-Fiebiger Center of Molecular Medicine, Erlangen, Germany*; [3]*Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*

Background: Rheumatoid arthritis (RA) is characterized by autoreactive B- and T cells. Autoantibodies are a hallmark of RA and contribute to synovial inflammation. We have recently demonstrated that Th17 cells suppress the enzyme ST6 a-galactoside b-2,6-sialyltransferase (ST6GAL1) in developing plasma cells. Thereby, Th17 cells regulate the degree of autoantibody sialylation leading to the increased inflammatory activity of autoantibodies. These events correlate with the onset of RA, arguing for a crucial role of the IL-23/Th17 axis during the transition of asymptomatic autoimmunity into active RA. Therefore, treatment against the IL-23/TH17-axis might present an attractive therapeutic approach to halt or delay RA's onset. However, the effects of Th17 cytokines like IL-17 on IgG glycosylation in humans are so far poorly studied.
Objectives: To explore whether anti-IL17A treatment can inhibit pro-inflammatory IgG glycosylation patterns in humans.
Methods: Total IgG from patient cohorts suffering from psoriatic arthritis (PsA) treated with Secukinumab (anti-IL-17 blockade, n=26) or Ustekinumab (anti-IL12/23 blockade, n=14) was compared with patients treated with anti-TNFa blockade as a control (n=20). The cohorts were age- and sex-matched and included patients being on therapy for at least six months. Total IgG was isolated using Protein G columns, and IgG glycopeptides of IgG1, IgG2, and IgG4 were analyzed using the LC-MS technique. The effect of IL-17 depletion on IgG glycosylation was analyzed in psoriatic arthritis patients who have been treated with secukinumab for at least six months. Furthermore, in a longitudinal approach, IgG1, IgG2, and IgG4 glycosylation were analyzed from samples, isolated before the beginning of anti-IL-17 blockade and after at least six months of therapy (n=16).
Results: Cross-sectional comparison of cohorts treated with Ustekinumab, Sekukinumab, and anti-TNFa therapy did not show any significant differences in sialylation, galactosylation, or fucosylation of IgG1 and IgG2. IgG4 from anti-TNFa treated patients displayed a small increase of sialylation when compared to the Ustekinumab treated cohort.
Longitudinal analyses, however, showed that IL-17A blockade during Secukinumab therapy caused a significant increase of sialic acid-rich IgG glycoforms on IgG1, IgG2 IgG4 patients, while the galactosylation, fucosylation remained unaffected.
Conclusion: This data indicates that IL-17A blockade specifically affects IgG sialylation, while other Fc-glycan modifications remain unaltered. This data confirms our recent findings in mice, where cytokines of the IL-23/Th17 axis specifically induce the production of hypo-sialylated, proinflammatory autoantibodies in

rheumatoid arthritis (RA) [2]. Therefore, neutralizing IL-17 might be a therapeutic option during the asymptomatic autoimmune prodromal phase in autoimmune diseases like RA, where TH17 cytokines orchestrate the emergence of a pro-inflammatory autoantibody response and the transition into active RA.

AB0017 IMMUNE CHARACTERISTICS OF PERIPHERAL BLOOD IN SECONDARY SJOGREN'S SYNDROME PATIENTS WITH RHEUMATOID ARTHRITIS

R. Su[1], Y. Y. Wang[1], C. Wang[1]. [1]*The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China*

Background: Secondary Sjogren's Syndrome (sSS) is diagnosed when symptoms of SS coexist with other systemic connective tissue disease, often secondary to rheumatoid arthritis(RA).The occurrence of SS secondary with RA will worsen the course of disease and increase the high incidence and mortality of RA. At present, the immune characteristics of peripheral blood of sSS with RA are not clear.

Objectives: To observe the difference of immune Immune characteristics in peripheral blood between sSS secondary to RA, primary Sjogren's syndrome(pSS) and RA patients.

Methods: 20 sSS with RA patients, 20 pSS paients and 20 RA pateints hospitalized in ShanXi medical university the second Hospital were enrolled. The percentage and absolute numbers of lymphocyte phenotypes and CD4+ T subsets in peripheral blood were examined by flow cytometry.

Results: As for the percentage and absolute number of total T, B, NK, CD4+T,CD8+ T and the ratio of CD4 + T to CD8+ T cells, there was no significant difference between the sSS with RA, RA, and SS group. There was also no statistical difference in the percentage of CD4+T subsets(Th1,Th2,Th17 and Treg) between the three groups. But the ratio of Th17 and Treg in sSS with RA group was increased than pSS group.About comparison of absolute number of CD4+T subsets, there was no statistical difference among the three groups except that the Th1 cells in RA group was significantly higher than SS group.

Conclusion: Elevated Th17/Treg may be an immunological feature that differentiates sSS with RA patients from pSS patients. In addition, in general, peripheral blood of patients with RA and SS have similar immune characteristics.

AB0018 ACCUMULATION OF FUNCTIONALLY MATURE CD1C+ DENDRITIC CELLS CONTRIBUTES TO SYNOVIAL INFLAMMATION IN INFLAMMATORY ARTHRITIS

M. Canavan[1,2], V. Marzaioli[1,2], V. Bhargava[3], S. Nagpal[3], P. Gallagher[4], C. Hurson[4], R. Mullan[5], D. Veale[2], U. Fearon[1,2]. [1]*Trinity College Dublin, Molecular Rheumatology, Dublin, Ireland*; [2]*St Vincent's University Hospital, Centre for Arthritis and Rheumatic Diseases, Dublin, Ireland*; [3]*Janssen Research and Development, Immunology and Discovery Sciences, Pennsylvania, United States of America*; [4]*St Vincent's University Hospital, Department of Rheumatology, Dublin, Ireland*; [5]*Adelaide and Meath Hospital, Department of Rheumatology, Dublin, Ireland*

Background: Myeloid Dendritic Cells (DC) are potent antigen presenting cells that can be subdivided into CD141 and CD1c$^+$ DC. We have previously reported an unacknowledged role for CD141$^+$DC in the IA synovium. However, the identification and function of CD1c$^+$ DC in the IA synovium has yet to be fully elucidated.

Objectives: To investigate if CD1c$^+$DC reside in the IA synovium and ascertain if they represent a unique population, distinct from peripheral CD1c$^+$DC and if they contribute to synovial inflammation.

Methods: Synovial tissue (ST) biopsies and synovial fluid mononuclear cells (SFMC) were obtained via arthroscopy and healthy control (HC) ST was obtained during ACL surgery. Synovial tissue single cells suspensions were generated following enzymatic and mechanical digestion. Single cell analysis of synovial tissue cell suspensions, along with PBMC and SFMC was performed by multicolour flow cytometry. CD1c$^+$DC were sorted from IA synovial fluid and peripheral blood and bulk RNA sequencing was performed. CD1c$^+$DC functionality and maturation was assessed using OVA DQ phagocytosis assays, multiplex ELISA and DC: T cell cocultures.

Results: Within the circulation the frequency of CD1c$^+$DC are significantly decreased in IA peripheral blood compared to HC ($p<0.01$) in addition to expressing significantly higher levels of the maturation markers CD80 ($p<0.01$) and CD40 ($p=0.08$). IA peripheral blood DC also express significantly higher levels of CXCR3 ($p<0.01$) and CCR7 ($p<0.05$) compared to HC - suggestive of DC migration from the periphery to the synovium. Following RNA-seq analysis, IPA and differentially expressed gene (DEG) analysis revealed an enrichment in genes involved in DC maturation, TLR signalling and chemokine signalling in IA peripheral blood compared to HC. In support of the hypothesis that DC migrate and accumulate in the IA synovium, CD1c$^+$ DC were identified in IA ST and were significantly enriched compared to IA peripheral blood ($p<0.01$). IA ST CD1c$^+$DC express significantly higher levels of the activation marker CD80 compared to IA peripheral blood ($p<0.05$) or HC ST ($p<0.05$). Upon examination of IA synovial fluid, we report similar findings to ST, whereby CD1c$^+$DC are enriched in synovial fluid compared to PB ($p<0.001$). Moreover, RNA sequencing and PCA analysis of synovial versus blood CD1c$^+$DC revealed distinct transcriptional variation between both sites. Functionally, synovial CD1c$^+$DC express higher levels of the maturation markers CD80, CD83, CD40, PD-L1 and BTLA (all $p<0.05$) and have distinct coexpression of these maturation markers which is unique to the synovium. Synovial CD1c$^+$DC are less phagocytic compared to peripheral blood DC, have decreased production of MMP1 and MMP9 and importantly are still capable of additional activation *in-vitro*. Finally, synovial CD1c$^+$DC induce the proinflammatory cytokines TNFα, GMCSF, IL-17a and IFNγ from CD4$^+$ T-cells in allogeneic DC: T cells cocultures.

Conclusion: Mature circulatory CD1c$^+$DC migrate and accumulate in the IA synovium. Synovial DC are present in the IA synovium in a mature state, have distinct tissue specific characteristics and can induce proinflammatory CD4$^+$T cell responses.

AB0019 TREATMENT OF AUTOIMMUNE AND INFLAMMATORY SKIN DISEASES USING SKIN-TARGETING BIFUNCTIONAL ANTIBODIES: A LOCALIZED IMMUNOMODULATION APPROACH

S. Borthakur[1], P. Mande[2], D. Rios[2], P. Halvey[2], A. Boisvert[1], M. Rowe[2], A. Agrawal[1], M. Borah[2], M. Cianci[2], J. L. Viney[2], K. Kis-Toth[2], K. L. Otipoby[2], I. Mascanfroni[2], N. Higginson-Scott[1]. [1]*Pandion Therapeutics Inc., Biotherapeutics, Watertown, United States of America*; [2]*Pandion Therapeutics Inc., Immunology, Watertown, United States of America*

Background: Current treatment approaches for autoimmune conditions comprise primarily of systemic immunosuppressants or cytokine blockade. The concentration of therapeutic molecules to the tissues that are the sites of autoimmune and inflammatory diseases is a promising approach with the potential to induce therapeutic benefit and avert risks associated with systemic immunotherapies. Pandion Therapeutics is developing a bifunctional antibody platform that can drive localized immune modulation by combining a "tether antibody" that targets a tissue of choice and "an effector end" that activates specific regulatory immune pathways to restore immune-homeostasis.
Objectives: Here we report the engineering of a skin-tethered PD-1 agonist and a skin-tethered CD39 that inhibit T cell activation and function and deplete local ATP, respectively, modulating different arms of the immune system in a tissue specific manner.
Methods: Biophysical assays were performed to characterize Skin-tethered immune effectors for drug-like properties and *in vitro* and *in vivo* assays for target binding, cellular activity and tissue specific-localization. Moreover, these bifunctionals were tested in pathway-relevant preclinical models such as Vitiligo and Contact Hypersensitivity.
Results: Biophysical characterization of the bifunctional molecules showed desired drug like properties including specificity, stability, and manufacturability. The skin tethered bifunctionals showed effector activity in *in vitro* assays and selectively localized to the skin. Skin localization strikingly correlated with a tether-dependent efficacy compared to a non-tether control.
Conclusion: We believe that this therapeutic approach has the potential to drive the resolution of cutaneous inflammation, providing an opportunity for developing new targeted therapies for autoimmune and inflammatory skin diseases.

Background: Fc neonatal receptor (FcRn) is crucial for IgG half-life and transplacental transport. Different sites of IgG carry glycans which may affect binding to FcRn. While the effect of Fc-glycans has been investigated, the impact of Fab-glycosylation (~14% IgG) on IgG-FcRn interaction remains unclear. Anti-citrullinated protein antibodies (ACPA) of rheumatoid arthritis patients exhibit remarkably high Fab-glycosylation (~90%). This makes ACPA an ideal model to investigate how Fab-glycosylation influences IgG-FcRn interaction.
Objectives: To investigate the potential impact of IgG Fab-glycosylation on IgG transplacental transfer and interaction with FcRn.
Methods: To investigate transplacental transport of ACPA and total IgG, serum of ACPA-positive RA patients (mothers) as well as of healthy mothers and their respective newborns was analyzed. IgG Fab- and Fc-glycosylation was investigated with liquid chromatography and mass-spectrometry. Furthemore, ACPA monoclonal IgG were produced and glycoengineered to acquire several variants of the same monoclonal antibody differing only in their glycosylation profile. These glycovariants were then used to investigate the impact of Fab-glycans on the affinity of IgG for FcRn. Surface plasmon resonance (SPR) and affinity chromatography were implemented.
Results: When measured in mothers' serum and cord blood samples, Fab-glycosylation of IgG antibodies was ~20% lower in newborns compared to their mothers, which was observed for ACPA IgG, non-ACPA IgG in RA patients and total IgG of healthy controls (Figure 1). This may indicate that transplacental transfer of Fab-glycosylated antibodies is impaired. SPR results suggested that presence of Fab-glycans slightly lowered the affinity of IgG for FcRn. However, presence of Fab-glycans did not have a significant effect on the results of FcRn affinity chromatography. Together, these results suggest that Fab-glycans may impair association of IgG with FcRn, while dissociation likely stays intact.
Conclusion: Our results suggest that Fab-glycans inhibit IgG-FcRn binding which negatively affects the transplacental transfer of Fab-glycosylated IgG. The impact of Fab-glycosylation on IgG half-life requires further investigation.

AB0021 CHARACTERISATION OF AGE-ASSOCIATED B CELLS IN EARLY, DRUG NAÏVE RHEUMATOID ARTHRITIS

G. Vidal-Pedrola[1], N. Naamane[1], D. Scheel-Toellner[2], A. Pratt[1], A. Mellor[1], J. D. Isaacs[1], A. E. Anderson[1]. [1]*Newcastle University, Translational and Clinical Research Institute, Newcastle upon Tyne, United Kingdom*; [2]*University of Birmingham, Centre for Translational Inflammation Research, Birmingham, United Kingdom*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease of immune dysregulation affecting the joints. While T cells play a recognised role in disease pathogenesis, the presence of autoantibodies years before the clinical onset of disease, and the efficacy of the B cell-depleting therapy rituximab, highlight a pathogenic role for these functionally diverse lymphocytes. A novel subset, termed age-associated B cells (ABCs), are described as $CD19^{high}$ $CD21^{-}$ $CD11c^{+}$, with a high proportion expressing the transcription factor T-bet; they are elevated in murine models of autoimmunity and produce autoantibodies characteristic of autoimmune disease. A detailed characterisation of ABCs in early, drug naïve RA has not yet been conducted.
Objectives: We aimed to characterise peripheral blood (PB) and synovial fluid (SF) ABCs in patients suffering from early drug naïve RA. As a secondary objective we sought to determine whether this population differs between RA patients and age-matched early psoriatic arthritis (PsA; disease controls) and healthy controls.
Methods: Newly presenting early RA and other inflammatory arthritis patients, naïve to immunomodulatory treatment, were recruited from the Newcastle Early Arthritis Clinic. Patients with established RA (≥1 year duration on treatment and age-matched healthy controls were recruited in parallel. B cell subsets (naïve ($CD19^{+}IgD^{+}CD27^{-}$), switched memory ($CD19^{+}IgD^{-}CD27^{+}$) and ABC ($CD19^{+}CD21^{-}CD11c^{+}$)) in PB and SF were characterised by flow cytometry. FACS sorted PB B cell subset gene expression profiles were assessed using a customised NanoString nCounter Human Immunology v2 Panel.
Results: Transcriptionally, ABC differed from both naïve and switched memory B cells. In keeping with published studies ABCs had an activated memory phenotype, exemplified by elevated expression of CD69, CD80, and CD86, as well as Ki67, HLA-DR, IgG and T-bet. Interestingly, ABC had high expression of the Fc Receptor Like (FcRL) family (FcRL1-5), and an inflammatory homing profile (high levels of CXCR3 and low levels of CXCR4 and CXCR5). We found no difference in the proportion of PB ABC between RA patients and control groups, and no association of ABC frequencies with age. Focussing on RA ABCs specifically, we observed elevated ABC frequencies in females, but no association with disease activity. In keeping with their chemokine receptor profile, cross-sectional analysis also demonstrated ABC enrichment in SF compared to PB, with SF frequencies higher in established than early disease. The transcriptome of ABCs from early RA patients differed from both age-matched disease controls and healthy donors (Figure 1 next page).
Conclusion: These data demonstrate that ABCs have a unique, activated, class-switched proliferative phenotype that is transcriptionally distinct from switched memory and naïve B cells. Interestingly, at the transcriptome level early RA ABCs differ to their counterparts in health and other inflammatory arthritides, suggesting they may differ functionally and contribute to pathogenesis. Of note,

their high expression of MHC class II (HLA-DR) and co-stimulatory (CD80 and CD86) molecules suggests an important antigen-presentation function of ABC, which together with their unique FcRL family expression pattern, warrants further functional characterisation.

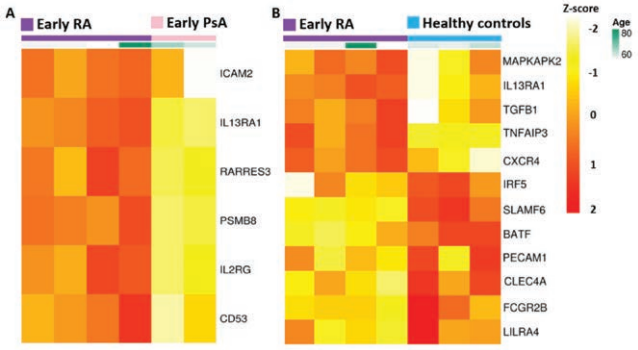

Figure 1. Differential gene expression in ABCs from early RA patients compared to early PsA patients (A) and healthy controls (B). A NanoString nCounter Technologies chip was used to assess gene expression. Raw counts were normalised to the housekeeping genes. Sample quality was then assessed using the arrayQualityMetrics package. Gene expression profiles between different donor groups was assessed using the DESeq2 R package. In both hierarchical clustering heatmaps gene expression intensities were log2 transformed and their z-scores are displayed as colours ranging from yellow (low expression) to red (high expression) as shown in the key.

AB0022 AUTOREACTIVE B CELLS IN RHEUMATOID ARTHRITIS DISPLAY AN ACTIVATED PHENOTYPE OF RECENT ANTIGEN EXPOSURE

N. Blomberg[1], H. Kristyanto[1], T. Huizinga[1], R. Toes[1], H. U. Scherer[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: Rheumatoid arthritis, in particular ACPA+ RA, is characterized by frequent disease flares and poor chances to achieve DMARD-free sustained remission. Recently, we have shown that ACPA-expressing memory B cells (MBC) remain in a persistently activated state throughout disease, even in patients in DMARD-induced clinical remission.(1) The reasons why the ACPA B cell response is continuously activated are unknown, as well as why the response does not revert to a resting, 'quiescent' state. We hypothesized that continuous antigen exposure in germinal centres drives ACPA B cell activation, leading to a 'recent germinal centre emigrant' phenotype of these cells in the circulation.

Objectives: To understand whether the activated phenotype of ACPA-expressing B cells could be induced by recent antigen exposure, to thereby discern the processes of immune activation that remain active in patients even in clinical remission and to argue whether these processes could be targets for therapeutic intervention.

Methods: ACPA-expressing B cells were identified in peripheral blood of RA patients by flow cytometry during different stages of disease and characterized by a panel of activation- and germinal centre related markers (CD80, CD86, CD32, CD95, Ki-67). In addition, three healthy donors received a TT booster vaccination. TT-specific MBC were identified in blood at different timepoints (before vaccination and up to 22 weeks after vaccination) and analysed phenotypically over time.

Results: The majority of ACPA-expressing B cells strongly expressed CD95 and the co-stimulatory marker CD80. A part was also positive for the proliferation marker Ki-67 (on average 30%), and most cells downregulated the inhibitory marker CD32. TT-specific MBC adopted a comparable phenotype after booster vaccination, but most markers returned to the pre-vaccination expression level gradually over time. These effects were antigen-dependent because the phenotype of TT-negative B cells remained unchanged. The phenotypic composition of the proliferating ACPA-positive B cell pool most closely corresponded to a stimulation history of 1-2 weeks after antigen exposure. Notably, none of the Ki-67 negative ACPA-specific MBC showed phenotypic quiescence, indicating either a short life-time (in circulation) after antigen encounter or persistent additional factors of activation.

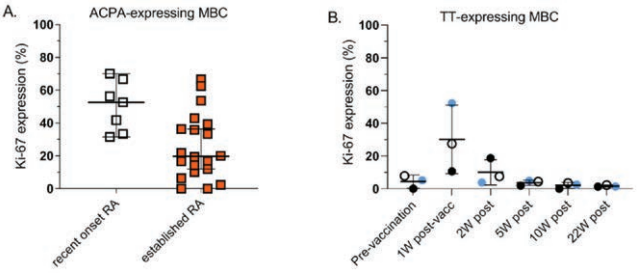

Figure 1. Ki-67 expression on ACPA-specific MBC in RA (A) and on TT-specific MBC in 3 healthy donors before and after booster vaccination (B).

Conclusion: ACPA-expressing MBC phenotypically resemble TT-specific MBC after recent (1-2 weeks) booster vaccination, reflecting the phenotype of recent germinal centre emigrants, and remain activated, whereas TT-specific MBC lose this marker profile over time. These observations suggest that ACPA-expressing MBC either home to tissue or survive shortly in the circulation, or that additional factors drive or program these cells to persistent activation. Transcriptomic profiling and analysis of the homing marker profile may help to answer these questions. Furthermore, it will be important to understand the association of persistent activation of ACPA-expressing B cells in clinical remission and the risk for disease flares upon treatment discontinuation.

AB0023 DENDRITIC CELLS AS A PROMINENT MARKERS OF AUTOIMMUNE DISEASES

M. Korolev[1], Y. Kurochkina[1], N. Banshhikova[1], V. Omelchenko[1], A. Akimova[1], E. Letyagina[1], O. Poveschenko[2]. [1]*Research Institute of Clinical and Experimental Lymphology - Branch of the Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Science, Rheumatology, Novosibirsk, Russian Federation*; [2]*Research Institute of Clinical and Experimental Lymphology - Branch of the Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Science, Cells Technologies, Novosibirsk, Russian Federation*

Background: Dendritic cells (DCs) are known to contribute to the pathogenesis of different autoimmune diseases. It is clear nowadays the role of DCs in rheumatoid arthritis (RA) but not well investigated in Axial spondylitis (AxSpA). DCs are a heterogeneous population and can be divided into groups: myeloid (mDCs) and plasmacytoid (pDCs). DCs can induce both immune response and tolerance.

Objectives: To investigate the subpopulations of peripheral blood myeloid and plasmacytoid DCs in patients with early stage of RA (duration of illness up to 12 months) and AS.

Methods: The study include sixty five patients with early forms of diseases including 55 patients with RA and 10 patients with AxSpA. Diagnosis RA was established according ACR/EULAR criteria (2010). Diagnosis AxSpA was established according ASAS criteria. All patients received conventional synthetic DMARDs. Thirty patients with osteoarthritis (OA) used as a control group. Analysis of the content of the B-lymphocytes, myeloid and plasmacytoid DCs was carried out by flow cytometry. B-lymphocytes, subtypes of peripheral blood DCs were characterized by the following phenotypes: myeloid DCs (CD3-CD14-CD19-HLA-DR + CD11c + CD123-), plasmacytoid DCs (CD3-CD14-CD19-HLA-DR + CD11c-CD123 +), B-lymphocytes (CD19 +). Analyses were performed before treatment and after 3 and 6 months.

Results: Patients with early RA are characterized by significant evaluation of the population of myeloid DCs in comparison of patients with osteoarthritis (25.3% vs 21.5, p=0.005). Furthermore, the difference was found in the number of cells with the phenotype B-lymphocytes: 5.7% vs 3.1%, p = 0.0007). No significant differences were observed in the number of plasmocytoid DCs. After 3 and 6 month of observation we detected reducing amount of myeloid DCs 26.7% vs 20.1% vs 16.4% respectively. Disease activity according to DAS28 droped to low (4.32 to3.06, p=0.03). Patients with AxSpA are characterized a lower mDCs levels in compared with RA (19.3% vs 26.7, p=0.07). After 6 month of investigation we detected decreasing mDCs (19.3% to 14.2%, p=0.05). The percent of pDCs were constant and did not differ from the level of healthy donors.

Conclusion: The data obtained indicate that early form of rheumatic diseases namely rheumatoid arthritis and axial spondylitis have the common features such as the dominance of mDCs and their decreasing in reduction of activity of disease.

AB0024

IN VITRO CHARACTERIZATION OF CENERIMOD, A POTENT AND SELECTIVE SPHINGOSINE 1-PHOSPHATE RECEPTOR 1 (S1P1) MODULATOR IN PREVENTING MIGRATION OF NON-ACTIVATED AND ACTIVATED PRIMARY HUMAN B CELLS IN THE PRESENCE OR ABSENCE OF GLUCOCORTICOIDS

L. Schlicher[1], P. Kulig[1], M. Murphy[1], M. Keller[1]. [1]*Idorsia Pharmaceuticals Ltd, Immunology, Basel, Switzerland*

Background: Cenerimod is a potent, selective, and orally active sphingosine 1-phosphate receptor 1 ($S1P_1$) modulator that is currently being evaluated in a Phase 2b study in patients with systemic lupus erythematosus (SLE) (NCT03742037). $S1P_1$ receptor modulators sequester circulating lymphocytes within lymph nodes, thereby reducing pathogenic autoimmune cells (including B lymphocytes) in the blood stream and in inflamed tissues. Extensive clinical experience has become available for the nonselective S1P receptor modulator fingolimod in relapsing forms of multiple sclerosis, supporting this therapeutic concept for the treatment of autoimmune disorders.
Objectives: Although the effect of S1P-receptor modulators in reducing peripheral B cells is well documented[1,2], the role of the $S1P_1$ receptor on this cell type is only incompletely understood. In this study, the mode of action of cenerimod on primary human B cells was investigated in a series of *in vitro* experiments, including $S1P_1$ receptor cell surface expression and chemotaxis towards S1P. Moreover, $S1P_1$ expression following B cell activation *in vitro* was studied. As glucocorticoids (GC) are frequently used in the treatment of patients with autoimmune disorders including SLE, the potential influence of GC on the mode of action of cenerimod was evaluated.
Methods: Primary human B lymphocytes from healthy donors were isolated from whole blood. In one set of experiments, cells were treated with different concentrations of cenerimod to measure $S1P_1$ receptor internalization by flow cytometry. In a second set of experiments, isolated B cells were activated using different stimuli or left untreated. Cells were then analysed for $S1P_1$ and CD69 cell surface expression and tested in a novel real-time S1P-mediated migration assay. In addition, the effect of physiological concentrations of GCs (prednisolone and prednisone) on cenerimod activity in preventing S1P mediated migration was tested.
Results: *In vitro,* cenerimod led to a dose-dependent internalization of the $S1P_1$ receptor on primary human B lymphocytes. Cenerimod also blocked migration of nonactivated and activated B lymphocytes towards S1P in a concentration-dependent manner, which is in line with the retention of lymphocytes in the lymph node and the reduction of circulating lymphocytes observed in the clinical setting. Upon B cell activation, which was monitored by CD69 upregulation, a simultaneous downregulation of $S1P_1$ expression was detected, leading to less efficient S1P-directed cell migration. Importantly, physiological concentrations of GC did not affect the inhibitory activity of cenerimod on B cell migration.
Conclusion: These results show that cenerimod, by modulating $S1P_1$, blocks B lymphocyte migration towards its natural chemoattractant S1P and demonstrate compatibility of cenerimod with GC. These results are consistent with results of comparable experiments done previously using primary human T lymphocytes.

CITRULLINATED-PEPTIDE SPECIFIC CD4+ T CELL RESPONSES IN RHEUMATOID ARHRITIS

J. Swift[1], J. Stanway[1], I. Nicorescu[1], C. Hilkens[1], F. Stevenaert[2], A. Anderson[1], A. Pratt[1], J. D. Isaacs[1]. [1]*Newcastle University, Translational and Clinical Research Institute, Newcastle-upon-Tyne, United Kingdom*; [2]*Janssen Pharmaceutica, Immunosciences, Beerse, Belgium*

Background: CD4+ T cells reacting to post-translationally modified, citrullinated self-antigens are thought to play a central role in the pathogenesis of rheumatoid arthritis (RA)[1]. This is evidenced by a strong HLA class II association, the success of therapeutic co-stimulation blockade and the detection of autoantigen specific T-cells using HLA class II multimers[2]. These cells may represent a target for antigen-specific, tolerogenic therapies and their in-depth phenotyping may provide the means by which to monitor such treatment.
Objectives: To identify the citrullinated-peptide (cit-peptide) induced cytokine repertoire of antigen-specific memory CD4+ T cells in both healthy controls (HCs) and ACPA positive RA patients using intracellular cytokine staining and flow cytometry. Of note, the HLA-types of both HCs and RA patients were not known.
Methods: Cryopreserved peripheral blood mononuclear cells (PBMC) from both HCs (n = 8) and RA patients (n = 13) with both early (untreated) and established disease were thawed and labelled with a proliferation tracking dye (PTD). Labelled PBMC were then either incubated alone or with a pool of cit-peptides for 9-days, followed by a 5-hour restimulation with PMA and ionomycin, where cytokine secretion was blocked for the final 4-hours using brefeldin-A. Cells were then harvested, permeabilised and stained for T cell surface markers and intracellular cytokines including IFN-γ, IL-4, IL-21 and IL-17. Stained cells were immediately acquired using a BD Fortessa X20, where antigen-specific CD4+ T cells were identified as the viable CD45RO+ (memory) CD4+ T cell population that had proliferated (PTDlow) in response to the cit-peptides. Stimulation indices (SI) were calculated as the percentage of proliferated memory CD4+ T cells in the stimulated wells divided by the percentage in the unstimulated conditions, and cit-peptide responders were defined as those with an SI > 2.0. Net cytokine production was measured by subtracting the percentage cytokine production from unstimulated CD4+ CD45RO+ PTDlow cells, from those stimulated with the cit-peptides.
Results: Comparable proliferative responses were observed in both donor groups in response to stimulation with the cit-peptide pool, where 37 % of HCs and 31 % of RA patients responded with an SI > 2.0 (Fig. 1A). While little cytokine production was observed in the cit-peptide responding HC T cells, for responding RA donors, cit-peptide responsive CD4+ memory T cells were predominantly IFN-γ and IL-21 producing (Fig. 1B and 1C). In contrast, these donors did not produce significant levels of either IL-17 or IL-4 (Fig. 1D and 1E).
Conclusion: Cit-peptides were able to induce proliferation in both HCs and RA memory CD4+ T cells which, amongst the RA donors only, were of a Th1/Tfh subtype. In contrast, and while based only on a small sample, cit-peptides did not induce either IL-17 or IL-4 production in either donor group, suggesting a lack of Th17/Th2 responses. Not all donors responded to the peptide pool, possibly reflecting the limited number of pooled cit-peptides or to a lack of confirmed HLA-DRB1*04:01 positive donors, as peptides were selected for their specificity on this basis. Future work will therefore include HLA-typing, as well as the inclusion of additional citrullinated-epitopes to demonstrate autoreactivity in a wider cross-section of patients. Further phenotyping of the cit-peptide specific T cells will be performed, and future plans will be to study the assay data alongside clinical outcomes to assess its value for immune monitoring.

Background: Interstitial lung disease (ILD) is one of the most significant complications of connective tissue diseases (CTD), leading to an increase of the morbidity and mortality in patients with CTD [1]. A specific T cell subset termed angiogenic T cells (TAng), that promote endothelial repair and revascularization, have been involved in the pathogenesis of CTD [2-4]. However, to the best of our knowledge, no information regarding the role of TAng in CTD-ILD$^+$ is available.
Objectives: To study, for the first time, the potential role of TAng related to vascular damage in CTD-ILD$^+$.
Methods: Peripheral venous blood was collected from 40 patients with CTD-ILD$^+$ and three comparative groups: 44 CTD-ILD$^-$ patients, 21 idiopathic pulmonary fibrosis (IPF) patients and 20 healthy controls (HC). All subjects were recruited from the Rheumatology and Pneumology departments of Hospital Universitario Marqués de Valdecilla, Santander, Spain. Quantification of TAng was performed by flow cytometry. TAng were considered as triple-positive for CD3, CD31 and CXCR4.
Results: Patients with CTD-ILD$^+$ exhibited a significantly lower TAng frequency than CTD-ILD$^-$ patients ($p<0.001$). Similar results were obtained when patients with CTD-ILD$^+$ were compared with HC ($p=0.004$) although no difference was observed between CTD-ILD$^+$ and IPF. In addition, a significant increase of TAng frequency was shown in patients with CTD-ILD$^-$ in relation to IPF patients ($p<0.001$), while no difference was observed between CTD-ILD$^-$ and HC.
Conclusion: Our results reveal a decrease of TAng frequency related to vascular damage in CTD-ILD$^+$. Furthermore, we disclose that the presence of ILD is associated with lower TAng frequency.

AB0027 INCREASED CIRCULATING CD39+FOXP3+CD4+ TREG CELLS IN EARLY RHEUMATOID ARTHRITIS FACILITATE THE ANTIINFLAMMATORY ACTION OF METHOTREXATE

L. Nuño[1], A. Villalva[1], M. Novella-Navarro[1], I. Monjo[1], D. Peiteado[1], S. García-Carazo[1], A. Puig-Kröger[2], A. Balsa[1], M. E. Miranda-Carus[1]. *[1]Hospital Universitario La Paz, Rheumatology, Madrid, Spain*; *[2]Gregorio Marañón Hospital, Immunology, Madrid, Spain*

Background: Methotrexate (MTX) remains the first line of treatment in Rheumatoid Arthritis (RA)[1,2]. Inhibition of AICAR transformylase by MTX results in augmented release of adenine nucleotides to the extracellular space[1]; these are rapidly hydrolysed by the combined action of ectonucleotidases CD39 and CD79 rendering the antiinflammatory agent adenosine[1]. CD39, the rate-limiting enzyme in this cascade, is highly expressed by a subset of human FoxP3+CD4+ regulatory T cells (Treg39+)[2-4] and MTX may act synergistically with Tregs in the control of inflammation.
Objectives: To study the expression of CD39 on circulating Treg cells of untreated early Rheumatoid Arthritis (ERA) patients and its relation with the ex vivo effect of MTX.
Methods: Peripheral blood was drawn from 22 DMARD- and steroid- naïve ERA patients with a disease duration < 24 weeks, 15 longstanding RA patients (LRA, disease duration > 2 years) and 37 age and gender-matched healthy controls (HC). LRA patients were receiving low-dose weekly MTX and were naïve for biologicals. 10 ERA patients who had achieved remission 12 months after initiating MTX donated blood for a second time (ERA-R). The frequency of Treg and Treg cell subsets was assessed by flow cytometry. CD4+CD25+CD127- (total T reg), CD4+CD27+CD127-CD39+ Treg (Treg39+) and CD4+CD25-CD39- responder T (Tresp39-) cells were isolated by Ficoll-Hypaque, followed by sorting. The suppressor potency of Tregs was assessed in cocultures of isolated Tregs with Tresp, established at different Treg/Tresp ratios. Proliferation was determined by CFSE dilution; cytokine secretion was measured by ELISA of culture supernatants.
Results: As previously described[5], ERA but not LRA patients demonstrated a superior frequency of circulating Treg (CD4+CD25+CD127-FoxP3+) cells. In addition, the proportion of Tregs that expressed CD39 (Treg39+) was significantly increased in ERA but not LRA. Total ERA Tregs were significantly more potent suppressors of proliferation, TNFα and IFNγ secretion when compared with HC or LRA Tregs, and this difference was partially and significantly abrogated in the presence of adenosine deaminase, or the adenosine A2A receptor (A2AR) antagonists DMPX (3,7-dimethyl-1-propargylxanthine) or ZM 241385, but not in the presence of the adenosine A1 receptor antagonist DPCPX (8-cyclopentyl-dipropylxanthine). When MTX was added to the culture medium, the suppressor potency of total Tregs was further enhanced in all 3 groups of patients, and this enhancement was significantly higher in ERA total Treg/Tresp39- cocultures as compared with HC or LRA total Treg/Tresp39- cocultures. The effect of MTX was also partially and significantly abrogated by adenosine deaminase, DMPX or ZM 241385 but not by DPCPX. We then tested the suppressor potency of isolated Treg39+ together with the enhancer effect of MTX on this potency, and observed that there were no longer differences among ERA, LRA and HC; this further suggests that the differences observed in assays using total Tregs can be attributable to the increased Treg39+ proportions present in ERA. The frequency and function of ERA-R Treg cells were not different from HC or LRA Tregs.
Conclusion: The suppressor action of CD39+Tregs is mediated at least in part by adenosine trough A2AR ligation, and the superior suppressive potency of total ERA Tregs is associated with their higher proportion of TregCD39+ cells as compared with HC or LRA. In addition, the augmented suppressor effect observed in the presence of MTX is partly mediated by an increased adenosine production acting on A2AR and is more marked in ERA patients reflecting again their higher proportion of Treg39+ cells. This indicates that MTX cooperates with Treg39+ cells in the control of inflammation.

AB0028 EXPRESSION OF FATTY ACID TRANSPORTERS AND FREE FATTY ACID UPTAKE IN CD8+ T CELLS IN AUTOIMMUNE ARTHRITIS PATIENTS

S. Keck[1], F. V. Kraus[1], H. M. Lorenz[1], M. Souto-Carneiro[1]. *[1]University Hospital Heidelberg, Department of Rheumatology, Heidelberg, Germany*

Background: RA CD8+ T cells (CD8s) have been shown to vastly contribute to tissue damage and RA disease activity by presenting and maintaining an active effector phenotype promoting autoinflammation. In order to meet their high metabolic requirements RA CD8s alter not only their glycolytic and glutaminolytic profiles, but also rely on increased lipid metabolism characterized by increased free fatty acid (FFA) uptake and lipid biosynthesis.
Objectives: In order to classify the importance of lipid metabolism in RA CD8s in terms of initiation and perpetuation of effector functions and therefore exploring potential novel therapy targeting points or biomarkers additional investigations have to been made. By analysing FFA uptake and the expression of free fatty acid transporters (FAT) upon TCR-stimulation in RA, PsA, SpA patients and healthy controls (HC), we aimed to further characterize the importance of RA CD8s´ lipid metabolism.
Methods: Blood samples from 23 RA patients, 22 SpA patients, 20 PsA patients and 7 HC recruited at Heidelberg University Hospital were processed via negative magnetic separation selection to obtain purified CD8s. CD8s were cultured for 72 hours in [1,6-13C] glucose containing medium in the presence of anti-CD3 and anti-CD28. FFA uptake was measured by Palmitate-Bodipy 488 staining (ThermoFisher), the expression of FAT CD36, FABP4 and GPR84 besides CD69, CD36, CD45RA, CD3 and CD8 were assessed by FACS analysis.

Ethic approval NR: S-096/2016.
Results: The intake of the FFA palmitate by CD8s was higher in all patients groups than in HC ($p < 0,05$). In all three diseases´ stimulated CD8s, unlike in the HC group, the expression of GPR84 was inversely correlating to the expression of CD69 (Spearman $r < -0,62$). In patient´s stimulated CD8s the expression of GPR84 tended to be lower in RA and PSA effector memory (EM) CD8s. In RA and HC the expression of FABP4 tended to be lower in the naive CD8+ subset when compared to the effector subset. HC naive and effector CD8+ subsets had a higher expression of CD36 than in the patient groups. In RA and SPA patients the expression of FAT correlated with clinical variables. In RA DAS28 and CRP inversely correlated with CD36 (MFI), and disease duration with FABP4 as well. In SPA CRP and BASDAI inversely correlated with FABP4 while disease duration had a negative correlation with CD36 (MFI). GPR84 (MFI) had an inverted relationship to BASDAI. While the BMI was directly correlated with the expression of CD36 in RA, this relationship was inverted in SPA.
Conclusion: A high free fatty acid uptake seems to characterize autoimmune arthritis CD8+ T cells. The gain of effector functions appears to be connected to changes in the expression of different fatty acid transporters on the surface of CD8+ T cells. The correlation between the expression of fatty acid transporters and clinical parameters (specially disease activity scores) in RA and SPA suggests that they could potentially be used as biomarkers for disease activity and progression.

Innate immunity in rheumatic diseases

AB0029 THE METABOLIC HIERARCHY OF IMMUNE PROCESSES IN HUMAN MONOCYTES

P. L. Krauß[1], F. Buttgereit[1], T. Gaber[1], M. Pfeiffenberger[1], Y. Chen[1], T. Buttgereit[2]. [1]*Charite Universitaetsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany*; [2]*Charite Universitaetsmedizin Berlin, Dermatology, Venerology, and Allergology, Berlin, Germany*

Background: At sites of inflammation, monocytes carry out specific immunological functions while facing challenging bioenergetic restrictions.
Objectives: Here, we investigated the potential of human monocytes to adapt under conditions of reduced energy supply by gradually inhibiting oxidative phosphorylation (OXPHOS) under glucose free conditions.
Methods: We modelled this reduced energy supply with myxothiazol, an inhibitor of mitochondrial respiration, at 0, 2 and 4 pmol/10^6 cells to decrease mitochondrial ATP production for 0%, 25% and 66% under glucose free conditions. For the three energy levels, we assessed (i) phagocytosis of FITC-labelled *E.coli* using flow cytometry, (i) production of reactive oxygen species (ROS) through NADPH oxidase (NOX) as determined by VAS2870-sensitive OCR using a Clark-type electrode, (iii) ATP generation and steady state level using a Clark-type electrode and luminometric assessment (iv) expression of surface activation markers CD16, CD80, CD11b, HLA-DR and (v) production of the inflammatory cytokines IL-1β, IL-6 and TNF-α using flow cytometry in peripheral blood-derived human monocytes with and without LPS-stimulation.
Results: As a prerequisite for our study, we demonstrate that human monocytes survived strong inhibition of mitochondrial respiration without any sign of apoptosis as determined by flow cytometry. As a result of the inhibition of OXPHOS, we demonstrate a reduction of VAS2870-sensitive OCR (ROS production through NOX), ATPase-dependent OCR and ATP steady-state levels. Focusing on immune function, we observed that phagocytosis and the production of IL-6 were the least sensitive to reduced energy supply while surface expression of CD11b, HLA-DR, production of TNF-α and IL-1β were most affected by inhibition of OXPHOS.
Conclusion: Our data demonstrate an energy-dependent hierarchy of immune functions in monocytes, which may represent a potential therapeutic target in monocyte-mediated inflammatory diseases.

AB0030 BETA BOSWELLIC ACID BLOCKS INNATE IMMUNE RESPONSES IN MULTIPLE OA JOINT CELLS

E. Franco-Trepat[1], A. Lois-Iglesias[1], A. Alonso-Pérez[1], M. Guillán-Fresco[1], M. López-Fagúndez[1], J. P. Cerón-Carrasco[2], A. Pazos-Pérez[1], A. Crespo-Golmar[1], A. Jorge-Mora[1], S. Belén Bravo[3], R. Gómez[1]. [1]*Institute IDIS, Musculoskeletal Pathology Group, Santiago de Compostela, Spain*; [2]*Universidad Católica de Murcia (UCAM), Bioinformatics and High Performance Computing (BIO-HPC), Murcia, Spain*; [3]*Institute IDIS, Proteomics Unit, Santiago de Compostela, Spain*

Background: Osteoarthritis (OA) incidence has skyrocketed in the last decade and yet a definitive treatment has still to be found. This worldwide disease is depriving our society from their life quality and has become a grave economic burden. Research on anti-inflammatory tools has been done on traditional Asian medicine. Boswellic acid is a plant-derived molecule from the *Boswellia* species that has shown to prevent cartilage loss in an OA mouse model[1]. However, the specific mechanism of action is still unclear. The activation of innate immune receptors, such Toll-like receptor 4 (TLR4) has been involved in chondrocyte-mediated inflammatory responses and OA development. Although, boswellic acid has shown an inhibitory effect on TLR4-mediated inflammatory responses little is known about its role on TLR4-mediated chondrocyte inflammatory and catabolic responses.
Objectives: Determine the ability of beta boswellic acid (BBA) to block TLR4-mediated innate immune responses in chondrocytes and synoviocytes.
Methods: *In silico*
The binding affinity of beta boswellic acid (BBA) to TLR4 complex signalling was determined by optimized docking algorithm in the BIO-HPC Research Group facilities.
In vitro
Cellular proteome and secretome profiling (LC-MALDI/TOFF) was used to study inflammatory pathways induced by the agonist of TLR4 (LPS [100ng/ml]) and IL1R (IL1β [0.1ng/ml]). The effect of BBA on TLR4-mediated innate immune responses was determined by RT-PCR, Western Blot and ELISA in primary human OA chondrocytes (hOC), murine ATDC5 chondrocytes, human synoviocytes (SW982) and primary human osteoblasts (hOB). Cell viability was tested using the methyl-thiazolyl-tetrazolium (MTT) reagent. Nitric oxide production in cell culture media was assessed by Griess reaction. Green Malachite Assay was used to semi-quantify the whole phosphoproteome.
Ethics
This study was approved by the CEIC (CAEIG 2014/310).
Results: Cellular proteome and secretome profiling validated the activation of TLR4 and IL1R signalling by LPS and IL1β ligands and revealed an enrichment in innate immune responses (NF-Kβ, NLRP3, MMPs, Interleukins, etc).
Non-toxic doses of BBA [0.5-1000nM] prevented the activation of TLR4 in multiple articular joint cells and inhibited TLR4 & IL1R-dependant innate immune responses at the mRNA and protein level such as inflammatory factors IL6, NOS2, COX2, LCN2, MMP1, -3, -9, -13 and ADAMTS4, among others. Furthermore, NF-Kβ/IKBα and NLRP3/PYCARD/IL1β axis were also severely inhibited after BBA treatment. Moreover, these results were validated by in silico docking analysis that showed BBA interacted with TLR4/NF-Kβ.
Conclusion: We prove that BBA inhibit TLR4 & IL1R -dependent innate immune responses in multiple human joint cells (Figure 1). We show that NF-Kβ & NLRP3 signalling, both associated to OA, are blocked (mRNA and protein) after BBA treatment (Figure 1).
Our data support previous studies showing the prevention of cartilage loss in an OA animal models by BBA might come from its ability to inhibit TLR4 signalling. In the clinical practice of rheumatologists, *Boswellia Serrata* could be a useful nutraceutical to manage OA inflammation due to its content in BBA.

AB0031

METABOLIC ADAPTATION OF HUMAN NEUTROPHILS TO GLUCOSE DEPRIVATION IS IMPAIRED WITH INCREASING AGE

M. Pfeiffenberger[1,2], P. L. Krauß[1,2], T. Buttgereit[3], Y. Chen[1], A. Damerau[1,2], T. Gaber[1,2], F. Buttgereit[1,2]. [1]*Charité Universitaetsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany*; [2]*German Rheumatism Research Center, Rheumatism Research, Berlin, Germany*; [3]*Charité Universitaetsmedizin Berlin, Venerology and Allergology, Berlin, Germany*

Background: Age-related impairment of classical neutrophil functions is well described (Fortin, McDonald et al. 2008). However, experimental evidence for age-related alterations of neutrophil metabolic adaptation towards nutrient deprivation -a feature of neutrophil battlefields- remains elusive. Moreover, age-related differences in neutrophil metabolic adaptation may contribute to age-related pathologies such as atherosclerosis, cancer, and autoimmune diseases including rheumatoid arthritis.
Objectives: Therefore, we hypothesized that metabolic adaptation of human neutrophils to glucose deprivation is impaired with increasing age.
Methods: We isolated human peripheral CD15+ neutrophils from four healthy young donors (mean age: 23.4 ± 2.7) and four healthy donors with a mean age of 58.7 ± 2.4. First, we analyzed the survival of neutrophils either stimulated with PMA or left untreated and subsequently incubated for 0 h and 6 h under varying glucose concentrations (0, 0.5, 1, 5, and 10 mM). To address this, we used 7-AAD staining and flow cytometry. Using Seahorse™ technology, we determined basal respiration, ATP-bound respiration, and maximal and spare capacity.
Results: We show that neutrophils (purity > 95%) survived for 6 hours *in vitro*, independent of treatment with PMA or concentrations of glucose in the culture medium. With negligible differences between the various concentrations of glucose used, the percentage of living cells after 6 h was 95% ± 2.5 without PMA and 75% ± 4.7 with PMA stimulation. No differences were uncovered in this respect between the two age groups. However, Seahorse™ technology revealed significant differences in basal, maximal, and spare respiratory capacity. Briefly, OCR (pmol/min/cell count) with respect to basal, maximal and reserve respiratory capacity was lower in the elderly donors compared to the young donors. For instance, with a concentration of 5 mM glucose, the basal respiration (OCR) was 17 ± 0.7 in elderly donors compared to 22.5 ± 1 in young donors, while the maximal respiration was 25 ± 0.8 in elderly and 41 ± 0.6 in the young donor group. Interestingly, these differences were independent of glucose concentration in the medium.
Conclusion: Our data show that basal metabolic parameters differ between neutrophils from young and older donors. Further experiments are needed to understand in detail the mechanisms and effects of age-related differences in metabolism on neutrophil functions.

AB0032

DIFFERENTIAL IMPACT OF BIOLOGICS AND GLUCOCORTICOIDS ON TNF SECRETION AND CD14+CD16+ MONOCYTES PERCENTAGE IN CULTURE DERIVED FROM SYNOVIAL FLUIDS OF PATIENTS WITH PSORIATIC ARTHRITIS-IN VITRO RESEARCH

S. Gertel[1], A. Polachek[1], V. Furer[1], D. Levartovsky[1], R. Tzemach[1], K. Meridor[1], D. Caspi[1], O. Elkayam[1]. [1]*Tel Aviv Sourasky Medical Center, Department of Rheumatology and the Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel*

Background: Inflammatory joint diseases, such as psoriatic arthritis (PsA), are frequently treated by biologics. Assessment of treatment efficacy is based upon change in clinical activity scores and in tender and swollen joint counts. Although the response to these agents may be attributed to their central anti-inflammatory effects, synovial response may be operating in parallel. The potential beneficial role of intra-articular injection of tumor necrosis factor (TNF) blockers compared to glucocorticoids (GCs) in reducing synovitis was shown by means of clinical and instrumental validated measures (1). The inflamed synovial fluid is rich in mononuclear cells, however, the different mode of action of the in vitro response of these cells to drugs may contribute to the understanding of cellular response to therapeutic agents in central as opposed to peripheral compartments.
Objectives: To evaluate the effect of biologics used in the management of PsA on synovial fluid mononuclear cells (SFMCs) in vitro, and to compare their modes of action to GCs that are used to locally alleviate synovial inflammation.
Methods: SFMCs were obtained from PsA patients (n=11) during therapeutic knee arthrocentesis. The cells were cultured in vitro for 7 days in the presence of biologics (adalimumab, infliximab, secukinumab and ustekinumab, 10ug/ml) and GCs (betamethasone and methylprednisolone, 1 ug/ml and 10ug/ml) or medium as control. Levels of the secreted TNF were measured by ELISA. Changes in %$CD14^+CD16^+$ monocytes were analyzed by flow cytometry.
Results: Both TNF inhibitors (adalimumab $p<0.01$, infliximab $p=0.0003$) and GCs (betamethasone and methylprednisolone at 1ug/ml $p<0.01$ and at 10ug/ml $p<0.04$) significantly reduced TNF levels in cultured media derived from SFMCs of PsA patients (n=8) compared to medium. None of the other biologics reduced TNF levels in culture (Fig. 1A). Additionally, %$CD14^+CD16^+$ SFMCs derived from PsA patients (n=11) were significantly reduced by TNF inhibitors ($p=0.0003$) compared to medium, however, other biologics and GCs did not display similar activity (Fig. 1B).

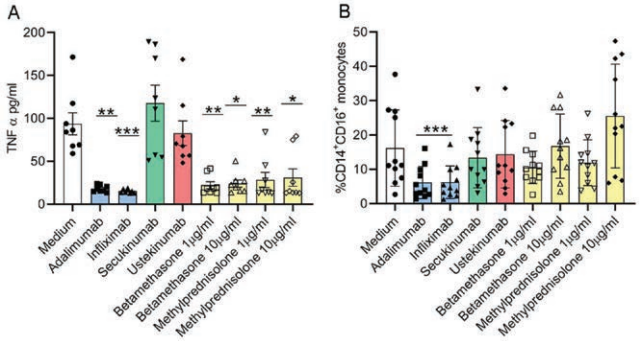

Figure 1. Both TNF inhibitors and GCs block TNF secretion but exhibit different activity on inflammatory $CD14^+CD16^+$ monocytes derived from SFMCs of PsA patients. SFMCs were co-cultured for 7 days in the presence of adalimumab, infliximab, secukinumab and ustekinumab at 10ug/ml or with betamethasone and methylprednisolone at 1ug/ml and 10ug/ml. Medium alone was used as a control. (A) Culture supernatants were analyzed for TNF levels by ELISA (n=8). (B) Cells were analyzed for %$CD14^+CD16^+$ monocytes by flow cytometry (n=11). All *p* values were calculated by the non-parametric one-way ANOVA Kruskal-Wallis test and Dunn's multiple comparison test, *$p<0.04$, **$p<0.01$ and ***$p=0.0003$.

Conclusion: Our data demonstrated marked activity mediated by TNF inhibitors in comparison with other biologics tested for their ability to suppress TNF secretion and inflammatory $CD14^+CD16^+$ monocytes. In contrast, GCs suppressed TNF secretion but did not significantly change the proportion of inflammatory $CD14^+CD16^+$ monocytes. These findings suggest an additional mechanism of action exerted directly by TNF inhibitors on synovial monocytes and which differs from that of GCs. These results warrant further studies of the therapeutic potential of local peripheral activity of TNF inhibitors for clinical application.

MACROPHAGE ACTIVATION IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS (PRELIMINARY DATA)

E. Gerasimova[1], T. Popkova[1], T. Kirichenko[2], A . Markin[2], Y. Markina[2], D. Gerasimova[3], A. Bogatyreva[2], A. Orekhov[2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Systemic Rheumatic Diseases, Moscow, Russian Federation*; [2]*Research Institute of Human Morphology, Laboratory of Cellular and Molecular Pathology of the Cardiovascular System, Moscow, Russian Federation*; [3]*I.M. Sechenov First Moscow State Medical University (Sechenov University), Department of Pharmaceutical Economics, Moscow, Russian Federation*

Background: The study of the ability of monocytes to activate associated with the clinical activity of immunological markers of inflammation in rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) will provide important and fundamentally new information on the involvement of these cells in the development of autoimmune rheumatic diseases (ARDs).
Objectives: To study macrophage activation in rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) patients (pts).
Methods: A total of 21 active ARDs pts (11 RA, 10 SLE) were enrolled in the study (median age was 55[44; 63] years; disease duration was 8 [2; 14] months). There are 11 pts with early RA (disease duration was ≤12 months), moderate to high activity (DAS28 was 6.1[4.9;6.7]; SDAI was 25(22;31); ACCP was positive in 73% and RF in 87% cases) and 10 pts with active SLE (SLADAI-2K was 7 [6;8])

in the study. All early RA pts and 4 SLE pts were not treated with glucocorticoids and disease-modifying antirheumatic drugs. Six SLE pts received low-dose glucocorticoids and hydroxychloroquine.
All pts were assessed for macrophage activation and laboratory data: ESR, RF, ACCP, CRP, ANA, anti-dsDNA. Isolation of monocytes was carried out according to the standard procedure for obtaining a leukocyte fraction in a Ficoll gradient and subsequent selection of CD14 + cells using magnetic separation. After isolation, the cells were cultured in X-Vivo medium. To assess the degree of monocyte activation, cells were stimulated by the addition of LPS. The value of monocyte activation was expressed as a ratio of the level of secretion of proinflammatory cytokines by monocytes cultured with and without LPS addition. Secretion levels were determined by ELISA. The belonging of the isolated cells to CD14 + monocytes was additionally confirmed by flow cytometry.
Results: Macrophage activation was 2.6 (2.0;5.4) and 4.8 (2.8;7.3) in RA and SLE pts, respectively (p>0.05). In RA and SLE pts macrophage activation was independent of age, sex, body mass index, traditional risk factors (arterial hypertension, overweight, smoking, family history of cardiovascular diseases), RA activity scores (DAS28, SDAI), and SLADAI-2K. No association was found between macrophage activation and levels of ESR, RF, ACCP, CRP, ANA, and anti-dsDNA.
Conclusion: No differences in macrophage activation were found in RA and SLE pts. Macrophage activation was independent of age, sex, traditional risk factors, and ARD-related parameters. A study on a larger number of pts will clarify the link between macrophage activation and autoimmune disorders.

AB0034 **PD-1 AGONISM INHIBITS ACTIVATION OF PLASMACYTOID DENDRITIC CELLS**

I. Banerjee[1], L. Edwards[1], P. Halvey[1], S. Alioto[1], D. Cluckley[1], C. Mitchell[1], C. Cox[1], E. Lurier[1], M. Cianci[1], S. Bengeri[1], S. Borthakur[1], K. Kis-Toth[1], N. Higginson-Scott[1], J. Viney[1], K. L. Otipoby[1]. [1]*Pandion Therapeutics, Immunology, Watertown MA, United States of America*

Background: T cell function is regulated by complex signaling networks of interconnected activators and inhibitors. Blockade of inhibitory receptors such as programmed death-1 (PD-1) has emerged as a novel treatment for multiple forms of cancer. One of the most common adverse events associated with blockade of the endogenous PD-1/PD-L1 pathway is the induction of autoimmune pathology in multiple tissues, demonstrating that PD-1 activation is necessary for normal immune homeostasis in humans (Kostine, et al., 2018). Given this body of clinical data, we sought to develop a PD-1 agonist antibody as a therapeutic approach to restore immune homeostasis in patients living with autoimmune diseases. PD-1 expression and function has been primarily described on T cells (Ishida, et al., 1992), with additional data available from several other immune cell populations (Ohaegbulam, et al., 2015).
Objectives: To study the effect of PD-1 agonism on plasmacytoid dendritic cell (pDC) function.
Methods: Human PBMCs stimulated with or without toll-like receptor (TLR)-9 agonist, CpG were analyzed by flow cytometry for PD-1 expression on immune cell subsets. To assess the impact of PD-1 agonist on pDC function human PBMCs were activated by CpG in the presence or absence of PD-1 agonist. Type-I interferon (IFN) levels were quantified using ELISA from culture supernatants. The expression of interferon stimulated genes was analyzed by qPCR as a measure of type-I IFN activation.
Results: We have discovered that TLR9 activation can induce PD-1 expression on plasmacytoid dendritic cells, which has not been previously reported. Further, we have demonstrated that PD-1 agonism inhibits TLR9-mediated activation and the effector functions of plasmacytoid dendritic cells.
Conclusion: These data suggest the potential of PD-1 as a target for regulating diseases with pathology generated by type-I IFN.

Osteo arthritis, aetiology, pathology and animal models

AB0035 **A REVIEW OF THE CLINICAL AND ECONOMIC BURDEN OF OSTEOARTHRITIS PAIN BY SEVERITY IN THE UNITED STATES**

A. Sadosky[1], P. Schepman[2], S. Thakkar[2], R. Robinson[3], C. Beck[4]. [1]*Apperture LLC, HEOR, Westerly, United States of America*; [2]*Pfizer Inc, PHI, New York, United States of America*; [3]*Eli Lilly and Company, Global Patient Outcomes & Real World Evidence, Indianapolis, United States of America*; [4]*Pfizer Inc, Medical Affairs, Tadworth, United Kingdom*

Background: The development of new therapies to treat symptomatic osteoarthritis (OA) often requires targeting patient subgroups such as mild and/or moderate and/or severe. Multiple assessments for pain are used in clinical and research settings, yet to quantify patient burden with increasing pain severity it is important to understand the potential variability in outcomes based on definitions of severity used[1].
Objectives: The objective of this study was to examine studies in the published literature that report the burden of OA pain by severity to assess similarities and/or differences across study methodologies and outcomes.
Methods: A targeted literature review of PubMed and Google Scholar was conducted January 2021 and included search terms: osteoarthritis, severity, United States (US), burden, quality of life, medication/treatment, and healthcare resource utilization. The search was limited to the English language, full-text articles, and no restriction on publication date. Results included a recent study of the burden of symptomatic OA pain respondents by severity level in the US[2,3]. Over 100 publication titles were reviewed. Comparison of findings was descriptive in nature.
Results: Nine publications were identified representing 7 unique studies, 6 being patient and/or healthcare provider surveys. Two studies focused on OA severity: the remaining 5 stratified patients by pain severity, and all but 2 of the 5 identified and confirmed pain as OA-related. Pain measures included numeric rating scales (generic 0-10, Western Ontario and McMaster Universities Arthritis Index [WOMAC] NRS 3.1), visual analog scales (generic 0-100, Short-Form McGill Pain Questionnaire Visual Analog Scale [SF-MPQ-VAS]) or Pain Interference with Activities (PIA) scale derived from the 12-Item Short Form Health Survey [SF-12v2] developed for the Medical Outcomes Study, with recall periods varying from 48 hours to 7 days to 4 weeks. Only one study exclusively assessed symptomatic patients only i.e., patients with pain scores of 0 were excluded; the remainder compared cohorts of no/mild pain with increasing severity cohorts. Four of the 7 studies examined pairwise differences among mild, moderate, and severe patients (1 study vs. a non-OA cohort); 2 compared no/mild vs. moderate-to-severe OA pain and 1 study compared mild to moderate-to-severe OA pain. For most outcomes examined like clinical comorbidities, quality of life, and healthcare resource utilization, increasing burden was observed with increasing OA and/or pain severity despite study variability.
Conclusion: Pain severity levels represent an important and distinguishing factor that contributes to health outcomes in OA patients in the US. Considerable heterogeneity across studies may impact how OA pain is defined, perceived by patients, and treated. Selecting appropriate OA pain severity assessments, including cut-points, may contribute to the successful monitoring of outcomes or comparisons of therapies to manage symptomatic OA pain, especially those that target specific pain severity subgroups.

AB0036 APPA (APOCYNIN AND PAEONOL) REDUCES ROS PRODUCTION AND SENESCENCE IN HUMAN ARTICULAR CHONDROCYTES

M. Fernandez-Moreno[1], N. Larkins[2], A. Reynolds[2], T. Hermida Gómez[1,3], F. J. Blanco[1]. *[1] Instituto de Investigación Biomédica de A Coruña (INIBIC). Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC). CICA-INIBIC., Servicio de Reumatología., A Coruña, Spain*; *[2]AKL Research & Development, Stevenage Bioscience, Stevenage SG1 2FX., United Kingdom*; *[3]Centro de Investigación Biomédica en Red, Bioingenieria, Biomatereial y Nanomedicina, (CIBER-BBN)., Madrid, Spain*

Background: Disease modification is not yet possible for osteoarthritis (OA). Mitochondrial ROS and pro-inflammatory cytokines are involved in the pathogenesis of OA and are potential therapeutic targets. APPA, a combination of apocynin (AP) and paeonol (PA), has the potential capacity to modulate synthesis of pro-inflammatory stimuli.
Objectives: To investigate the anti-inflammatory effect of APPA in human articular chondrocytes and cartilage.
Methods: Tissue and chondrocytes from human OA cartilage were isolated. The effect of APPA on chondrocyte viability was analyzed using MTT. IL-1β 10 ng/mL and LPS 10 ng/mL were used as pro-inflammatory stimuli. ROS production was evaluated by flow cytometry using DCFH-DA and MitoSoxRed. The percentage of senescent cells was evaluated through the quantification of Fluorescein di-β-D-galactopyranoside (FDG) by flow cytometry. The effect of APPA on gene expression of pro-inflammatory cytokines (IL-8 and TNF-α) and enzymes degrading cartilage (MMP-13 and MMP-3) were analyzed in chondrocyte and cartilage by RT-PCR. Quantification of Toluidine Blue (TB) staining in cartilage was performed to evaluate proteoglycans content using software ImageJ/Fiji. Release of Glycosaminoglycan (GAGs) into the supernatant was quantified using BlyscanTM Glycosaminoglycan assay. Statistical analyses were performed with GraphPad Prism v6.
Results: *Chondrocytes*, incubated in presence of APPA 10 µg/mL for 24 h had viability >85%, reduced cytoplasmic ROS (p=0.028) and mitochondrial anion superoxide production induced by LPS 10 ng/mL (p=0.057). Chondrocytes incubated in presence of APPA 10 µg/mL for 2 hours contained significantly fewer senescent cells (p=0.0079). APPA significantly reduced the gene expression induced by IL-1β 10 ng/mL in chondrocytes of *IL-8*, *TNF-α*, *MMP-13* and *MMP-3*. *Cartilage* incubated with APPA 60 and 100 µg/mL for 48 h showed decreased the *MMP-3* gene expression induced by IL-1β (p=0.021 and p<0.0001 respectively). Quantification of TB showed that APPA 60 and 100 µg/mL during 48h increased the proteoglycans in intermedial layer, which had been decreased through the incubation with IL-1β (p=0.0018 and p=0.018 respectively). Quantification of release GAGs into the supernatant decreased significantly when the cartilage explants were incubated for 48h in presence of APPA 100 µg/mL (p=0.028).
Conclusion: APPA has a clear anti-inflammatory effect on human articular chondrocytes, and could reduce extracellular matrix degradation of cartilage. This could be mediated by the capacity to modulate ROS production and reduce senescence.

AB0037 UNDIFFERENTIATED ARTHRITIS

O. Jomaa[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. *[1]University Hospital Fattouma Bourguiba Monastir, TUNISIA, Rheumatology Department, Monastir, Tunisia*

Background: Early recognition and treatment of inflammatory arthritis is imperative for the further course of the disease.
Objectives: This study aims to determine the evolution of undifferentiated arthritis observed in rheumatology.
Methods: Retrospective descriptive study which collects patients files identified as undifferentiated Arthritis and followed in the Rheumatology Department at Fattouma Bourguiba Hospital Monastir TUNISIA over a period of 15 years (2005, 2019). Epidemiological, clinical, paraclinical, and evolutionary data were collected and analyzed.
Results: 99 files were analyzed. The average age was 42.06±15.56; they were 42 males and 57 females with an average body mass index of 27±6.1 Kg/m2. The reason leading to consultation was, polyarthritis (37), oligoarthritis (27), mono-arthritis (21), and polyarthralgia (15). The median time to visit was 60 days [15 days, 3 months]. The median number of painful joints and swollen joints was 4 [2, 8], and 2 [1, 4] respectively. The mean duration of morning derusting was 34.8 ±24.4 minutes. Extra-articular manifestations were: a dry syndrome (22), a rheumatoid nodule (2), and serosal damage (1). Anemia (52 patients), leukopenia (6 patients), and lymphopenia (13 patients) were found in the blood cell count with a biological inflammatory syndrome in most patients (72/99). The immunology results showed: positive anti-nuclear antibodies (15/99), positive Anti-Citrullinated Protein Antibodies (9/99) and positive rheumatoid factor (8/99). 31 patients had standard radiological signs represented mainly by joint pinching and erosions. A joint puncture was done in 36/99 revealing inflammatory fluid in most cases. After an average follow-up of 1047 days [365, 1460]. undifferentiated arthritis was classified as rheumatoid arthritis (RA) (23), spondyloarthritis (SpA) (10), connective tissue disease (11), Crystalline Arthritis (5), and paraneoplastic arthritis (2). One patient had self resolution of symptoms and 38 remain undifferentiated.we found that the more the patients were seropositive, the more likely to develop Rheumatoid Arthritis (p=0.001), the more there was disorder in the blood cell count, the more the evolution was towards connective tissue disease (0.01), The more male patients were, the more likely to develop SpA (p=0.04). The patients management was mainly based on: analgesics (94), systemic corticosteroids (57) with a mean dose of 10.89± 5.8 mg/day. The use of Methotrexate and antimalarial drugs was noted in 18 and 15 patients respectively.
Conclusion: Follow-up of patients with undifferentiated arthritis leads to a definite inflammatory rheumatism diagnosis in 61.6% of cases. Our data indicate that seropositive patients with chronic symptoms carry an increased risk of developing Rheumatoid Arthritis (P=0,001). Clinical, biological and genetic data can help the health care provider to predict future outcomes.

AB0038 CIRCULATING MICRORNAS IN HAND OSTEOARTHRITIS

A. Pekacova[1,2], J. Baloun[1], O. Sleglova[1,2], O. Růžičková[1,2], J. Vencovský[1,2], K. Pavelka[1,2], L. Šenolt[1,2]. *[1]Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic*; *[2]First Faculty of Medicine Charles University, Department of Rheumatology, Prague, Czech Republic*

Background: microRNAs (miRNAs) are small non-coding RNAs that can ignite the degradation of mRNAs or inhibit the protein translation and are therefore essential for several physiological and pathological functions. miRNAs can regulate up to 60 % of human mRNA, including genes related to cartilage development, homeostasis, and OA pathology. For example, miR-9 inhibits matrix metalloproteinase 13

or miR-140 expression level correlates with the disease progression of knee OA (Zhang et al.; Chao et al.). Under certain circumstances, miRNAs can be released into the body fluids and easily be detected in the blood samples. Therefore, miRNAs are hot candidates as biomarkers for early diagnosis or structural progression of OA.

Objectives: The aim of this study was to evaluate circulating miRNAs in patients with hand osteoarthritis (HOA) and healthy individuals. Simultaneously, we studied specific miRNAs in order to differentiate between erosive and non-erosive subsets of the disease.

Methods: Eight patients with HOA (erosive: n=4, 3 females, mean age=63.7±7 yrs; non-erosive: n=4, 3 females, mean age= 62.4±6 yrs) and 4 healthy controls (3 females, mean age=63.5±7 yrs) were included in this study. Firstly, Advance TaqMan low-density assay (TLDA) was performed for the purpose of miRNA high-throughput screening. Differently expressed miRNAs were further verified by real-time qPCR on the validation cohort in 31 patients with hand OA (19 females, mean age=66.2±7 yrs, erosive: n=9, non-erosive: n=10, healthy controls: n=12).

Results: TLDA profiling displayed 346 circulating miRNAs in plasma of patients with HOA and healthy controls. We demonstrated 40 differently expressed circulating miRNAs in patients with HOA compared with healthy controls. Using a real-time qPCR, we verified increased expression levels of 10 circulating miRNAs in patients with HOA compared with healthy controls, e.g. miR-191-5p (3.4 fold), miR-151a-3p (3.4 fold) or miR-222-3p (2.4 fold). We did not find any specific miRNA, which could distinct erosive from a non-erosive subset of the disease.

Conclusion: Extensive profiling of circulating miRNAs revealed several miRNAs that can be associated with HOA and can help to better understand OA pathogenesis.

AB0039 AGRIN REPAIRS BONE AND CARTILAGE IN VIVO

Background: Cartilage defects in the joints are reported in 61% of all arthroscopies[1&2]. The size of the cartilage repair market is estimated to be $2.195 million by 2025[3]. Cartilage defects can evolve into osteoarthritis, in which abnormal load results in cartilage breakdown, joint pain and reduced mobility. Osteoarthritis is the leading cause of permanent disability and absenteeism and affects up to 1/3 of the people over 60yrs. In western countries osteoarthritis costs 1.5-2% of the GDP[4]. Joint replacement with a prosthesis restores some degree of independence but in up to 20% of patients it does not meet expectations [5] and has a limited life span. There is no pharmacological intervention that arrests or reverts the course of osteoarthritis, despite the desperate need.

We previously published that agrin plays an important role in cartilage homeostasis[6]. The addition of agrin to chondrocytes *in vivo* resulted in enhanced cartilage formation, suggesting a potential role for agrin in cartilage repair.

Objectives: Investigate the potential of agrin for use in cartilage repair.

Methods: Critical size osteochondral defects were generated in mice and sheep and injected intraarticularly with type I collagen gel containing agrin or vehicle. Animals were monitored for 8 weeks or 6 months respectively. MicroCT, histological analysis, qPCR, linage tracking, reporter assays, chondrogenesis assay, immunohistochemistry were performed.

Results: A single intraarticular administration of agrin induced regeneration of critical-size osteochondral defects in mice, restoring the tissue architecture and bone-cartilage interface. Agrin stem cells to the site of injury and, through simultaneous activation of CREB and suppression of canonical WNT signalling, induced GDF5 expression and differentiation into stable articular chondrocytes, forming stable articular cartilage. In sheep, agrin treatment resulted in regeneration of bone and cartilage, which promoted increased ambulatory activity.

Conclusion: Agrin orchestrates repair morphogenesis at the joint surface by modulating multiple signalling pathways, supporting the therapeutic use of agrin for joint surface regeneration.

AB0040 PYRUVATE DEHYDROGENASE KINASES AS A POTENTIAL TARGET IN THE TREATMENT OF OSTEOARTHRITIS TO UNLEASH THE METABOLIC FLOW?

A. Damerau[1,2], M. Kirchner[3], M. Pfeiffenberger[1,2], A. Lang[1,2], F. Buttgereit[1,2], T. Gaber[1,2]. [1]*Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; [2]*German Rheumatism Research Centre (DRFZ) Berlin, a Leibniz Institute, Berlin, Germany, Rheumatism Research, Berlin, Germany*; [3]*Berlin Institute of Health (BIH) and Max-Delbrück-Centrum für Molekulare Medizin (MDC), Proteomics Core Facility, Berlin, Germany*

Background: While osteoarthritis (OA) is the most common joint disease worldwide, rheumatoid arthritis (RA) represents the most common type of autoimmune arthritis. In both diseases, fibroblast-like synoviocytes (FLS), which maintain the structural and dynamic integrity of the joint, have been identified as key drivers of cartilage degradation. FLS can be divided into two major populations. The destructive phenotype which is restricted to the THY1- FLS of the synovial lining promotes bone erosion, while THY1+ FLS of the sublining layer drives synovitis. The FLS phenotype is shaped by glucose metabolism, which promotes disease progression in patients with synovitis. However, profound knowledge about the contribution of FLS to pathogenic mechanisms in cartilage degradation is limited.

Objectives: Here, we present the phenotypic features of FLS obtained from patients with OA (OA-FLS) compared to bone marrow-derived mesenchymal stromal cells (MSC) on transcriptomic, proteomic and metabolic levels with the aims (i) to identify novel targets for the development of disease-modifying osteoarthritis drugs and (ii) to distinguish both cell types.

Methods: To this end, we comprehensively compared human bone marrow-derived MSC with OA-FLS isolated from human knee joint sections. MSC and OA-FLS were characterized in detail according to their multipotency, surface marker pattern, cell viability, proliferation rate, morphology and expression of fibroblast- and metabolic-related markers using flow cytometry, immunofluorescence and Seahorse™. More in-depth, selected gene and protein expression patterns were analyzed using qPCR and mass spectrometry.

Results: We observed a similar phenotype of OA-FLS and MSC with regard to the minimal criteria that define a MSC phenotype. In-depth comparison of

OA-FLS and MSC on proteome level revealed 598 differentially expressed proteins. We observed no differences in the expression of classical fibroblast markers such as vimentin, tenascin C and decorin as confirmed on RNA level. Remarkably, fibronectin, which is mainly produced by fibroblasts, is significantly lower expressed at both protein and RNA levels in OA-FLS together with collagen type 1 and CD106. Conversely, CD9, CD54 and fibroblast-specific protein-1 were expressed significantly higher in FLS at both levels, while hyaluronan synthase 1-3 remained unchanged. Of note, in terms of mitochondrial function, human OA-FLS show a significantly lower basal respiration and ATP production than MSC, but a comparable spare respiratory capacity and cellular mitochondrial dehydrogenase activity (NADH amount) per cell. Additionally, we identified the pyruvate dehydrogenase kinase (PDK) 3 to be highly expressed in OA-FLS, while the expression of mitochondrial ATP synthase subunits, electron transport chain complexes and glycolytic enzymes was comparable with MSC. Finally, inhibition of PDK by using DCA resulted in a significant increase in oxygen consumption rate and ATP production in OA-FLS. Thus, our data newly suggest, that PDKs may play a crucial role in the pathogenesis of OA and possibly RA.
Conclusion: Our data provide evidence that, although the classical fibroblast markers do not discriminate between MSC and FLS, the latter demonstrate a significantly higher expression of PDKs, known to inhibit the pyruvate entry into the TCA cycle which finally limits the mitochondrial ATP production. Therefore, shifting the metabolism of FLS from glycolysis to mitochondrial respiration via inhibition of PDKs might be a novel approach in OA for the development of disease-modifying osteoarthritis drugs in order to unleash the metabolic flow.

AB0041

TO ESTIMATE THE PREVALENCE OF ACETABULAR OSSIFICATIONS IN THE ADULT POPULATION WITH ASYMPTOMATIC, MORPHOLOGICALLY NORMAL HIPS AT CT AND TO DETERMINE WHETHER THE PRESENCE OF LABRAL OSSIFICATIONS IS ASSOCIATED WITH PATIENT-RELATED OR HIP-RELATED PARAMETERS

C. Valente[1], L. Haefliger[2], J. Favre[2], P. Omoumi[2]. [1]*CHV, Radiology, Versailles, France*; [2]*CHUV, Radiology, Lausanne, Switzerland*

Background: In clinical practice, ossifications adjoining the acetabular rim are frequently seen in healthy-appearing hip joints, at all ages. The origin of these acetabular rim ossifications (ARO) is unclear. While ARO have been described by some authors as variants that may mimic marginal acetabular osteophytes, others have hypothesized that ARO may be the cause or the consequence of femoroacetabular impingement. Overall, the literature on ARO is limited, in particular in the healthy population, and their characteristics and origin not fully understood.
Objectives: To estimate the prevalence of acetabular rim ossifications in the adult population with asymptomatic, morphologically normal hips at CT and to determine whether the presence of these ossifications is associated with patient-, or hip-related parameters.
Methods: We prospectively included all patients undergoing thoracoabdominal CT over a 3-month period. After exclusion of patients with a clinical history of hip pathology and/or with signs of osteoarthritis on CT, we included a total of 150 hips from 75 patients. We analyzed the presence and the size of ossifications around the acetabular rim. The relationships between the size of acetabular rim ossifications and patient-related (sex, age, BMI), or hip-related parameters (joint space width, and cam- and pincer-type femoroacetabular impingement morphology) were tested using multiple regression analysis.
Results: The prevalence of acetabular rim ossifications in this population of asymptomatic, non-osteoarthritic hips was 96% (95%CI=[80.1;100.0]). The presence of ossifications and their size were correlated between right and left hips (Spearman coefficient=0.64 (95%CI=[0.46;0.79]),p<0.05)).The size of acetabular rim ossifications was significantly associated with age (p<0.0001) but not with BMI (p=0.35), gender (p=0.05), joint space width (p≥0.53 for all locations) or any of the qualitative or quantitative parameters associated with femoroacetabular morphology (p≥0.34).
Conclusion: Acetabular rim ossifications are highly prevalent in asymptomatic, non-osteoarthritic adult hips at all ages. Their size is not correlated with any patient-, or hip-related parameters except for the age. These findings suggest that ossifications at the acetabular rim, when present in isolation, should not be considered as signs of osteoarthritis or femoroacetabular impingement morphology.

Rheumatoid arthritis - aetiology, pathogenesis and animal models

AB0042

THREE HEMATOLOGIC/IMMUNE SYSTEM-SPECIFIC EXPRESSED GENES ARE CONSIDERED AS THE POTENTIAL BIOMARKERS FOR THE DIAGNOSIS OF EARLY RHEUMATOID ARTHRITIS THROUGH BIOINFORMATICS ANALYSIS

Q. Cheng[1], X. Chen[1], H. Wu[1], Y. Du[1]. [1]*The Second Affiliated Hospital of Zhejiang University School of Medicine, Rheumatology, Hangzhou, China*

Background: Rheumatoid arthritis (RA) is a common chronic autoimmune connective tissue disease that mainly involves the joints. The incidence of RA is 5 to 10 per 1000 people[1]. Early diagnosis and treatment of RA can effectively prevent disease progression, joint damage, and other complications in 90% of patients[2]. At present, serum biomarkers used in the diagnosis of established RA are rheumatoid factor and anti-cyclic citrullinated peptide antibody[3]. However, early RA especially serum RF and anti-CCP antibody-negative is difficult to diagnose due to the lack of effective biomarkers. Therefore, it is vital to identify new and effective biomarkers for the early diagnosis and treatment of RA.
Objectives: This study aimed to identify new biomarkers and mechanisms for RA disease progression at the transcriptome level through a combination of microarray and bioinformatics analyses.
Methods: Microarray datasets for synovial tissue in RA or osteoarthritis (OA) were downloaded from the Gene Expression Omnibus (GEO) database, and differentially expressed genes (DEGs) were identified by R software. Tissue/organ-specific genes were recognized by BioGPS. Enrichment analyses were performed and protein-protein interaction (PPI) networks were constructed to understand the functions and enriched pathways of DEGs and to identify hub genes. Cytoscape was used to construct the co-expressed network and competitive endogenous RNA (ceRNA) networks. Biomarkers with high diagnostic value for the early diagnosis of RA were validated by GEO datasets. The ggpubr package was used to perform statistical analyses with Student's t-test.
Results: A total of 275 DEGs were identified between 16 RA samples and 10 OA samples from the datasets GSE77298 and GSE82107. Among these DEGs, 71 tissue/organ-specific expressed genes were recognized. Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analysis indicated that DEGs are mostly enriched in immune response, immune-related biological process, immune system, and cytokine signal pathways. Fifteen hub genes and gene cluster modules were identified by Cytoscape. Eight haematologic/immune system-specific expressed hub genes were verified by GEO datasets. GZMA, PRC1, and TTK may be biomarkers for diagnosis of early RA through combined the analysis of the verification results and the receiver operating characteristic (ROC) curve. NEAT1-miR-212-3p/miR-132-3p/miR-129-5p-TTK, XIST-miR-25-3p/miR-129-5p-GZMA,

and TTK_hsa_circ_0077158- miR-212-3p/miR-132-3p/miR-129-5p-TTK might be potential RNA regulatory pathways to regulate the disease progression of early RA.

Conclusion: This work identified three haematologic/immune system-specific expressed genes, namely, GZMA, PRC1, and TTK, as potential biomarkers for the early diagnosis and treatment of RA and provided insight into the mechanisms of disease development in RA at the transcriptome level. In addition, we proposed that NEAT1-miR-212-3p/miR-132-3p/miR-129-5p-TTK, XIST-miR-25-3p/miR-129-5p-GZMA, and TTK_hsa_circ_0077158-miR-212-3p/miR-132-3p/miR-129-5p-TTK are potential RNA regulatory pathways that control disease progression in early RA.

AB0043 EFFECT OF ANTI-INFLAMMATORY MEDICATION ON INTERACTION OF SYNOVIAL FIBROBLASTS WITH MACROPHAGES IN RHEUMATOID ARTHRITIS

M. Schmeller[1], M. Diller[1], R. Hasseli[1], A. Knothe[1], S. Rehart[2], I. Tarner[1], W. Hermann[1], U. Lange[1], U. Müller-Ladner[1], E. Neumann[1]. [1]*Justus Liebig University Giessen, Campus Kerckhoff, Department of Rheumatology and Clinical Immunology, Bad Nauheim, Germany*; [2]*Agaplesion Markus Hospital, Department of Orthopaedics and Trauma Surgery, Frankfurt, Germany*

Background: One of the key mechanisms in the pathogenesis of rheumatoid arthritis (RA) is the interaction of macrophages and synovial fibroblasts during joint inflammation. Increased synergistic proinflammatory activity of both cell types leads to the release of high levels of proinflammatory cytokines, especially of interleukin-6 (IL-6), and of matrix degrading enzymes. If this mechanism is uncontrolled, progressive destruction of articular cartilage and bone will take place.

In active disease, immediate anti-inflammatory treatment with glucocorticoids is usually replaced by disease-modifying anti-rheumatic drugs (DMARDS), especially by methotrexate (MTX) and biologics such as TNF-α- or IL-6-inhibitors. This led to great improvements in prognosis and outcome for RA patients. However, about 40% of patients experience no remission or suffer from side effects of medication. To optimize established substances and to develop new treatment strategies, it is necessary to understand the mechanisms underlying the limited therapeutic effects.

Objectives: Evaluation of the effect of prednisolone, MTX, adalimumab, tocilizumab on IL-6 secretion by RA synovial fibroblasts (RASF) and macrophages.

Methods: RA synovium was used for RASF isolation. Peripheral blood mononuclear cells (PBMCs) were isolated from blood of healthy donors and RA patients by using Ficoll© medium followed by density gradient centrifugation. Mononuclear cells were seeded on six well plates (6x10^6/well) and incubated for one week. Then they were stimulated with Interferon-γ (20 ng/ml) and LPS (50 ng/ml) for 48h to initiate differentiation into proinflammatory M1 macrophages. The M1 macrophages were co-cultured with RASF (100.000/well) and different treatments added (prednisolone: 10, 25, 50, 75, 100 nM, 1 µM; adalimumab: 100, 500 µg/ml; tocilizumab: 1, 5 µg/ml; MTX: 0,5, 1, 5, 10, 100 nM, 1µM). After 24h culture supernatants were collected and IL-6- and TNFα-ELISAs were performed.

Results: IL-6 concentrations of untreated controls were comparable, regardless whether M1 macrophages from healthy donors or RA-patients were used for co-culture. Prednisolone reduced co-culture-induced IL-6 up to 56% ($p<0.001$) in co-culture of RASF and M1 macrophages of healthy donors and up to 60% ($p<0.001$) in co-culture of RASF and RA M1 macrophages. Adalimumab reduced IL-6 up to 28% ($p<0.05$) in M1 of healthy donors and up to 45% ($p<0.01$) in RA M1 macrophage co-cultures. A minor reduction by 10-20% of IL-6 was observed with tocilizumab and no significant effect could be achieved after treatment with MTX.

Conclusion: Prednisolone and adalimumab clearly decrease but do not eliminate proinflammatory synergistic activity of RASF and M1 macrophages. These results confirm the clinical observation, that there is a large number of RA-patients that independent of anti-inflammatory treatment still suffer from low-level joint inflammation.

The synergistic proinflammatory activity of M1 macrophages and RASF seems to be a complex and multifactorial mechanism that is difficult to eliminate by a single treatment substance. Since it is one of the key mechanisms in RA pathogenesis, there is a critical need to investigate how therapy effects could be optimized. This study confirmed RASFs as one of the leading effector cells of increased synergistic proinflammatory activity, thus underlining their promising role as a treatment target in rheumatoid arthritis.

AB0044 ENDOTHELIAL CELL AND RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLAST MIGRATION AND ADHESION ARE ALTERED BY ACTIVIN/FOLLISTATIN

H. M. Scholz[1], I. Aykara[1], K. Frommer[1], S. Rehart[2], U. Müller-Ladner[1], E. Neumann[1]. [1]*Kerckhoff-Klinik GmbH, Rheumatologie und Klinische Immunologie, Bad Nauheim, Germany*; [2]*Agaplesion Markus Krankenhaus, Klinik für Orthopädie und Unfallchirurgie, Frankfurt am Main, Germany*

Background: Activin A and follistatin belong to an anti-inflammatory auto-regulatory cycle. Patients with rheumatoid arthritis (RA) have increased activin A levels in the synovial fluid and tissue. During inflammation, activin A is released systemically, then inducing its antagonist follistatin. This negative feedback is active in different cell types but not RA synovial fibroblasts (SF). Fibroblasts interact with endothelial cells in inflamed tissues inducing angiogenesis.

Objectives: Evaluation of the role of activin A and follistatin on RASF and endothelial cell interactions.

Methods: RA synovium was used for RASF isolation, HUVEC were commercially obtained. RASF and HUVEC were stimulated in mono- and coculture. Direct: RASF together with HUVEC; indirect: inserts with HUVEC separated by a membrane from RASF. Stimuli: activin A 15ng/ml, follistatin 500ng/ml, IL-1β 1ng/ml. Proliferation was analyzed by BrdU assay. RASF were Calcein-AM stained. Cells were transferred to 24-well plates after 18h stimulation. After adhesion for 1h, non-adherent cells were removed by shaking 3x for 5 min. Afterwards, fluorescent cells were quantified. For the flow-adhesion assay, HUVEC were cultured on rattail collagen coated capillary slides. HUVEC and RASF were stimulated for 4h with TNFα, TNFα+activin A or TNFα+follistatin. After stimulation, 2x10^6 RASF were resuspended in 20ml medium and sent through the capillaries. Two 1min videos were recorded (18.4ml/h, 30.5ml/h). Settings: TNFα-stimulated RASF on HUVEC stimulated wit TNFα or activin A+TNFα or follistatin+ TNFα. For migration assays, 2% FCS medium with 1x10^5 cells were placed in inserts (8µm membrane) into wells with 10% FCS (control: 2%FCS vs. 2%FCS) and stimulated with, IL-1, IL-1+activinA and IL-1+follistatin. After 16h, migrated cells were quantified. For scratch-assay 4x10^5 cells were cultured overnight, then cells were scratched and stimulated, afterwards 3 pictures per scratch were taken at start, after 10h and every 1.5h. Cells migrating into the scratch area were quantified.

Results: IL-1 induced activin A in RASF and HUVEC in all settings. IL-1-induced activin A release was reduced by follistatin in HUVEC monoculture and both cocultures compared to IL-1 alone but not in RASF monoculture. IL-1-induced IL-6 release was reduced by activin A in HUVEC and indirect coculture but not in RASF monoculture and direct coculture. Follistatin did not alter IL-6 responses. IL-1 induced VEGF in RASF but not in HUVEC and was not altered by activin A. Short-term adhesion showed no significant influence of activin A or follistatin (n=4). Flow adhesion assay showed reduced adherence/rolling of RASF on HUVEC stimulated with TNFα and activin A (n=4). Migration assays showed that IL-1 decreased migration but without significant difference between the induced effects mediated by IL-1+activinA and IL-1+follistatin (n=4). Scratch assay showed increased migration in dicrect coculture with greater difference between stimulated and unstimulated cells in RASF monoculture and indirect coculture (n=4). Proliferation was not altered by activin A or follistatin.

Conclusion: In direct and indirect coculture of HUVEC with RASF the effect on HUVEC was dominant leading to reduced IL-1-induced activin A release. However, the IL-1-induced IL-6 release in RASF or HUVECs was decreased by activin A in HUVEC monoculture and indirect coculture but not during cell-contact between both cell types. The direct interaction of RASF with HUVEC seems to prevent the reducing activin A effect on IL-6 release in HUVECs. Activin A seems to not to have an impact on short-term cell adhesion but first observations show, that activin A alters selectin-mediated adhesion under flow conditions. The migration assay shows that IL-1-induced effects on cell migration were enhanced by activin

A and follistatin. Migration assay shows that IL-1-induced decrease on migration more prominent in indirect coculture and RASF monoculture than in direct coculture although in gap migration in the scratch assay was highest in direct coculture.

AB0045 THE RELATIONSHIP BETWEEN CD14 AND VIMENTIN-POSITIVE SYNOVIAL DENDRITIC-SHAPED CELLS AND SYNOVITIS IN RHEUMATOID ARTHRITIS

R. Kurose[1,2], T. Satoh[3], K. Murakami[4], A. Kurose[5], Y. I. Satoh[6], Y. Ishibashi[2], K. Ishida[7], K. Ogasawara[7], A. Morikawa[8], T. Sawai[9]. [1]*Hirosaki Memorial Hospital, Orthopedic Surgery, Hirosaki, Japan*; [2]*Hirosaki University, Orthopedic Surgery, Hirosaki, Japan*; [3]*Iwate Medical University, Pathology, Morioka, Japan*; [4]*Iwate Medical University, Orthopaedic Surgery, Morioka, Japan*; [5]*Hirosaki University, Pathology, Hirosaki, Japan*; [6]*Iwate Medical University, Medical Education, Morioka, Japan*; [7]*Iwate Medical University, Technical Support Center, Morioka, Japan*; [8]*Hitachi High-Technologies Corporation, Electron Microscope Application Group, Hitachinaka, Japan*; [9]*Tohoku University, Pathology, Sendai, Japan*

Background: Inflammation in rheumatoid arthritis (RA) is caused by multiple cell types, including infiltrating inflammatory cells, such as lymphocytes, neutrophils, macrophages, and spindle-shaped fibroblasts. Especially, we are focusing on fibroblast-like synoviocytes (FLSs). In our previous study, we have reported that FLSs were positive for multiple markers including CD14, CD68 and HLA-DR, and were dendritic-shaped cells constituting nursing phenomenon between lymph or plasma cells. In addition, in our recent study, we found that CD14+FLSs were positive for vimentin (VIM), which is a marker for mesenchymal cells. There are still many issues to be discussed regarding CD14+VIM+ cells.
Objectives: To investigate the relationship between CD14+VIM+ cells and the degree of synovitis in rheumatoid arthritis.
Methods: Synovial tissues collected from RA patients who underwent joint surgeries were prepared for this study. First, the proportions of CD14+ cells in RA synovial tissue and control were analyzed using flow cytometry and the concentrations of inflammatory cytokines released by CD14+ cells in RA synovial tissue and control were examined by ELISA. Next, the proportions of CD14+VIM+ cells in RA synovial tissue and control were examined immunohistologically and then we analyzed the results using image analysis software. Also, we statistically analyzed the relationship between the proportion of CD14+VIM+ cells, the degree of synovitis, and clinical data.
Results: Results of flow cytometry showed that CD14+ cells were frequently observed in RA synovial tissue than control. Cultured CD14+ cells released more inflammatory cytokines than cultured CD14- cells. Also, results of immunohistological staining showed that many CD14+VIM+ cells were observed in RA synovial tissue than in control. The proportion of CD14+VIM+ cells was correlated with Krenn synovitis score. High proportion cases significantly showed high level of CRP and MMP-3.
Conclusion: CD14+VIM+ cells might be involved in the mechanism of chronic immunological inflammation in RA and the proportion of these cells might influence the clinical data.

AB0046 THE EXPRESSION AND CLINICAL SIGNIFICANCE OF TAM RECEPTOR TYROSINE KINASE ON MONOCYTE SUBSETS IN RHEUMATOID ARTHRITIS

J. Xue[1], L. Xu[1], F. Hu[1], Y. Su[1]. [1]*Peking University People's Hospital, Department of Rheumatology and Immunology, Beijing, China*

Background: The TAM receptor tyrosine kinases (Tyro3/Axl/Mer TK) are a subfamily of receptor tyrosine kinases, the role of which in autoimmune diseases such as systemic lupus erythematosus has been well explored, while their functions in rheumatoid arthritis (RA) remain largely unknown [1].
Objectives: The study aimed to investigate the expression and clinical significance of Tyro3, Axl and MerTK on monocyte subsets in rheumatoid arthritis (RA).
Methods: The expression of Tyro3, Axl and MerTK on CD14+ monocytes, nonclassical monocytes (NCM, $CD14^{+}CD16^{++}$), intermediate monocytes (IM, $CD14^{++}CD16^{+}$), and classical monocytes (CM, $CD14^{++}CD16^{-}$) were evaluated in peripheral blood of RA by flow cytometry and qPCR. And the correlation between the expression of Tyro3TK and MerTK on NCM, IM, and CM with RA patient clinical feature were further analyzed.
Results: The results revealed that the expression of Tyro3TK on CD14+ monocytes was significantly upregulated in RA patients ($F = 9.18$, $P < 0.0001$), while there was no significant difference of the expression MerTK on HC, OA, and RA, and the expression of AxlTK was minimal (Fig 1). The expression of Tyro3TK on CM was significantly upregulated in RA patients as compared with HC and osteoarthritis (OA) patients ($P < 0.05$, Fig 2-3), and positively correlated with the disease manifestations, such as swollen joint count (SJC), tender joint count (TJC) and the disease activity score (Fig 4).

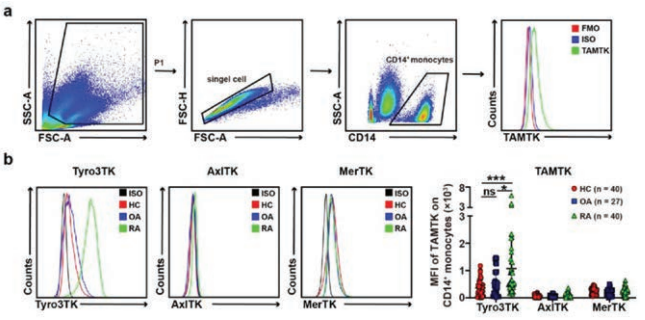

Figure 1. The expression of Tyro3, Axl and MerTK on CD14+ monocytes is increased in RA. (a) Gating strategy for flow cytometry of Tyro3, Axl and MerTK on CD14+ monocytes. **(b)** The expression of Tyro3, Axl and MerTK on CD14+ monocytes were compared between HC (n = 40), OA (n = 27), and RA patients (n = 40). **P* < 0.05, ***P* < 0.01, ns, not significant.

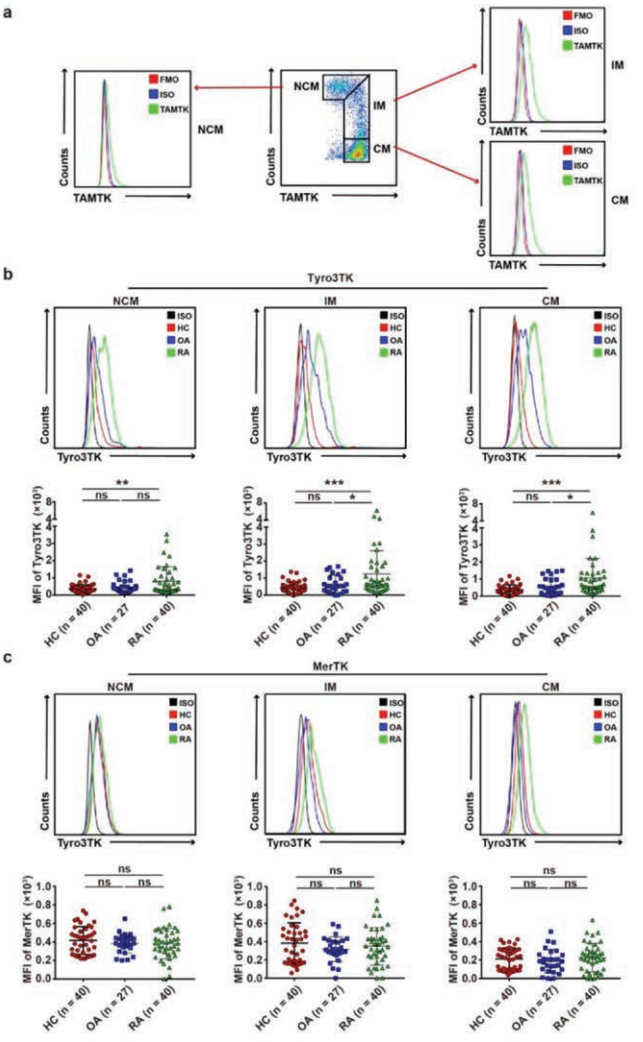

Figure 2. The expression of Tyro3TK on IM and CM were increased in RA. (a) Gating strategy for flow cytometry of TAMTK on monocyte subsets. The expression of **(b)** Tyro3TK and **(c)** MerTK on NCM, IM, and CM were compared between HC (n = 40), OA (n = 27), and RA patients (n = 40). *P < 0.05, ***P* < 0.01, ****P* < 0.001, ns, not significant.

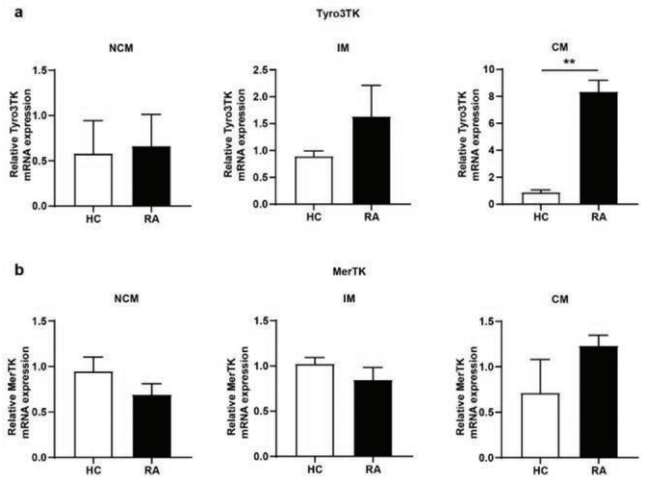

Figure 3. The mRNA expression of Tyro3TK on CM is increased in RA. (a) The mRNA expression of Tyro3TK on NCM, IM, and CM in HC (n = 3) and RA (n = 3) patients. **(b)** The mRNA expression of MerTK on NCM, IM, and CM in HC (n = 3) and RA (n = 3) patients. $^{**}P < 0.01$.

Conclusion: These findings indicate that Tyro3TK on CM was elevated in RA patients and correlated positively with disease activity, which may serves as an important participant in RA pathogenesis.

CLINICAL AND RADIOLOGICAL CHARACTERISTICS AND TREATMENTS OF A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS AND DIFFUSE INTERSTICIAL PULMONARY DISEASE FOLLOWED AT THE VIRGEN MACARENA UNIVERSITY HOSPITAL

P. Muñoz Reinoso[1], F. J. Toyos Sáenz de Miera[1], D. Ruiz-Montesinos[1], I. García Hernández[1], P. Guerrero Zamora[2], J. J. Pérez Venegas[1]. *[1]Hospital Universitario Virgen Macarena, Reumatología, Sevilla, Spain*; *[2]Hospital Universitario Virgen Macarena, Neumología, Sevilla, Spain*

Background: Diffuse interstitial lung disease (ILD) is an extra-articular manifestation of rheumatoid arthritis (RA)[1,2]. The most common pattern is the usual interstitial pneumonia (UIP), conditioning a worse prognosis[3].

Objectives: To describe epidemiological, clinical, and radiological characteristics and treatment used in a cohort of patients diagnosed with RA and ILD.

Methods: Retrospective descriptive study, including patients with a diagnosis of RA and ILD, reviewed in the Rheumatology and Pneumology consultations of the Virgen Macarena University Hospital, from 2010 to 2019. Data obtained from medical records are analyzed. SPSS statistical software is used.

Results: 26 patients were included, 18 women (69.2%). Median age at diagnosis of ILD was 62 years (53-73). Twelve patients (46.6%) used to smoke. The mean time from RA diagnosis to ILD diagnosis was 79 months (8-264). The RF was positive in 91.3% cases (21) and 87% of them (20) were ACPA positive. Fourteen patients (53.8%) had erosions and 3 (11.5%) had an associated Sjögren's Syndrome. When ILD was diagnosed, the RA activity by DAS28PCR was moderate (3.28; 2.34-3.28) and 13 patients (54.1%) suffered from dyspnea. The mean value of FVC and DLCO in the first assessment was 84% (63-108) and 71.7% (64-86), respectively. The most frequent radiological pattern of ILD was NINE in 15 patients (57.7%), 6 of them (23.1%) had UIP and 5 (19.3%) presented other patterns. Prior to ILD diagnosis, 24 (92.3%) patients received oral glucocorticoids, 18 (69.2%) cases started treatment with c-DMARD and 11 (42.3%) of them with b-DMARD; the most widely used were methotrexate (MTX) in 17 patients (65.4%) and anti-TNFα in 10 (38.5%). After diagnosis, treatment was changed to 12 patients (46.6%); the most used DMARD was leflunomide, in 11 (42.3%), MTX was maintained in 7 patients (26.9%); the number of anti-TNFα used decreased to 4 cases (15.4%), using instead drugs such as rituximab 5 (19.2%), abatacept 3 (11.5%), baricitinib 2 (7.7%) and anti-IL6 2 (7, 7%). During follow-up, 11 cases (57.9%) remained radiologically stable. A slight deterioration in DLCO was observed (66%; 51-80) and there was one death due to lung disease (UIP).

Conclusion: In this study, the most frequent radiological pattern was NINE. Half of the patients used to smoke. At the diagnosis of ILD (at ILD diagnosis), dyspnea was the most relevant clinical symptom, with a slight deterioration in the? respiratory function tests. This represented a change in the therapeutic strategy.

AB0048

ENZYMATIC PATTERN OF CIRCULATING PRO- AND ANTIOXIDANT ENZYMES IN RHEUMATOID ARTHRITIS PATIENTS

S. Bedina[1], E. Mozgovaya[1], A. Trofimenko[1], S. Spitsina[1], M. Mamus[1]. *[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Clinical Biochemistry Lab, Volgograd, Russian Federation*

Background: Rheumatoid arthritis (RA) is an autoimmune rheumatic disease of unknown etiology characterized by chronic erosive arthritis and systemic organ involvement resulting in early disability and shorter life expectancy. Neutrophils are suggested to play a substantial role in the induction and promotion of autoimmune inflammation in RA. This ability can be based on newly discovered feature of neutrophils to release neutrophil extracellular traps (NETs) during specific type cell death called NETosis. Hyperproduction of reactive oxygen species (ROS) is one of the factors promoting NETs production. With this background, the study of pro- and antioxidant enzymatic activities in RA patients can be of great interest.

Objectives: To assess plasma activities of essential prooxidant and antioxidant enzymes in RA patients.

Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles. 71 RA patients (46 women and 25 men) were enrolled in the study. The diagnosis was verified using ACR/EULAR criteria (2010). RA activity was measured using the Disease Activity Score of 28 joints (DAS28). 30 healthy persons comprise control group. Plasma xanthine oxidase (XO; EC 1.17.3.2), xanthine dehydrogenase (XDH; EC 1.17.1.4) and superoxide dismutase (SOD; EC 1.15.1.1) activities were measured using spectrophotometric technique. XO and XDG activities were expressed as nmol/ml/min, SOD activity – as units of action. Statistical analysis was performed using Statistica 6.0 software package. Differences were considered significant when p<0.05. Reference ranges were calculated as means ±2SD.

Results: Mean age of patients was 43.2±3.6 years, mean RA duration was 11.9±2.6 years. 24 (33.8%) RA patients had low disease activity, and 6 (8.5%) patients had high one. Extra-articular manifestations were found in 30 (42.2%) patients. 30% of them had cardiovascular involvement, 23.3% – pulmonary lesions, and 23.3% had renal involvement. Reference ranges for XO, XDG, and SOD activities were 2.28-5.12 nmol/min/ml, 3,96-7,24 nmol/min/ml, and 3,13-6,58 units, respectively. We examined activities of these enzymes in circulation

of RA patients with different patterns of clinical manifestations as well as relationship between RA activity and XO, XDG, and SOD activities. RA patients had increased both mean XO and mean SOD activities ($p<0.001$ for both enzymes). XO activity reached its highest values at maximum disease activity and overt extra-articular involvements, while SOD activity did it in moderate and high disease activities as well as in patients with joint manifestations. XDG activity was increased in low disease activity ($p<0.001$) and solely joint lesions ($p=0.011$), while moderate or high disease activities ($p=0.008$) and extra-articular involvements ($p=0.025$) were characterized by decreased activity of this enzyme.

Conclusion: We have revealed substantial multidirectional changes of plasma XO and XDG activities in RA. Plasma enzymatic pattern in RA patients is characterized by activation of both oxidant and antioxidant metabolic pathways. Activities of XO and SOD were positively correlated with RA activity, while XDG activity was negative correlated with RA activity. The differences between selective articular RA type and RA form with extraarticular manifestations were also revealed. Changes in oxidant and antioxidant enzyme activities can be connected with anticitrulline autoimmunity in RA via production of citrulline-rich neutrophil extracellular traps, thus enhancing rheumatoid autoimmunity.

AB0049 RELATIONSHIP OF RHEUMATOID FACTOR AND XANTHINE OXIDOREDUCTASE ENZYMATIC CONSTITUENTS IN SEVERAL BLOOD COMPARTMENTS OF RHEUMATOID ARTHRITIC PATIENTS

S. Bedina[1], A. Trofimenko[1], E. Mozgovaya[1], M. Mamus[1], S. Spitsina[1].
[1]*Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Clinical Biochemistry Lab, Volgograd, Russian Federation*

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by the presence of rheumatoid factor (RF) and anticitrulline autoantibodies. Recent evidences suggest that impairment of neutrophil extracellular traps (NETs) could exert substantial influence on RA pathogenesis. The production of NETs depends heavily on the ROS generation. One of its mechanisms is xanthine oxidoreductase (XOR) mediated degradation of purine metabolites. Analysis of pro-oxidant activity of the enzymatic complex XOR and its constituents, xanthine oxidase (XO) and xanthine dehydrogenase (XDG), is an issue of considerable interest in this context.

Objectives: Evaluation of XO and XDG activities in RF-positive and RF-negative RA using both plasma and lysed lymphocyte samples.

Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles. Diagnosis of RA had been verified using ACR/EULAR 2010 criteria. Enzymatic activities in plasma and lymphocytes were measured spectrophotometrically and expressed as nmol/min/ml. Enzymatic activities in lymphocytes were also normalized to 1×107 cells/ml. Statistical tests were selected in line with common guidelines. Differences were considered significant when $p<0.05$. Reference ranges were calculated as means ±2SD.

Results: 75 adult RA patients (52 females and 23 males, mean age 43.9±0.97 years, mean disease duration 8.5±0.3 years) from the rheumatology unit of Volgograd Clinical Emergency Hospital #25 as well as 35 healthy controls were included in the study. RF-positive RA and RF-negative RA were observed in 49 (65.3%) and 26 (34.7%) patients, respectively. Reference ranges for plasma and lymphocyte XO activities were 2.60-3.96 and 14.2-27.8 nmol/min/ml, respectively. Similar ranges for XDG activities were 4.49-5.93 and 22.5-40.7 nmol/min/ml, respectively. Enzymatic profile of RA patients is characterized by significantly increased XO activity in plasma and decreased XO and XDG activities in lymphocytes ($p<0.001$). XO activity is increased ($p<0.001$), XDG activity is decreased ($p<0.001$) in blood plasma of patients with RF-negative RA, while the activity of both enzymes is decreased in lymphocytes ($p<0.001$). XO activity ($p<0.001$) and XDG activity ($p<0.05$) is increased in blood plasma, XO activity and XDG activity are decreased ($p<0.001$) in lymphocytes of patients with RF-positive RA. Plasma XO and XDG activities are also higher, and lymphocyte XO and XDG activities are lower in patients with RF-positive RA than in patients with RF-negative RA ($p<0.001$).

Conclusion: Our study revealed the relationship between enzyme parameters and rheumatoid factor presence. More pronounced changes in the enzyme activities were observed in patients with RF-positive RA. These results demonstrate that activation of the xanthine oxidase/xanthine dehydrogenase enzyme complex is an substantial factor of induction and continuation of the autoimmune rheumatoid inflammation.

AB0050 A NOVEL METHOD FOR ISOLATION OF EXOSOMES FROM SYNOVIAL FLUID

Y. Liu[1,2], Y. Huang[1], Q. Huang[1], S. Sun[1], Z. Ji[1], W. Deng[1], T. W. LI[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China*; [2]*University of South China, Guangdong Second Provincial General Hospital, Guangzhou, China*

Background: Exosomes in synovial fluid (SF) has a close relationship with the pathogenesis of rheumatiod arthritis. As a complex biological fluid, SF presents challenges for exosomes isolation using standard methods, such as Exoquick™ kit and ultracentrifugation.

Objectives: The study aims to compared the quality of exosomes separated by Exoquick™ kit (TM), Exoquick™ kit+Exoquick™ kit (TM-TC), ultracentrifugation (UC) and TM-TC+UC(TM-TC-UC) from SF.

Methods: Exosomes was separated by TM, TM-TC, UC and TM-TC-UC respectively. The size and concentrations of exosomes were detected by high sensitivity flow cytometry for nanoparticle analysis. Total protein and RNA were extracted from exosomes. SDS-PAGE was used to detect the protein distribution of exosomes. Western blot was used to examine the level of albumin and exosomes marker (TSG101 and CD81).

Results: There was no statistic difference in the diameters of exosomes separated by the four methods. The concentrations of exosomes in TM, TM-TC, TM-TC-UC and UC were (5.65±0.93), (3.02±1.19), (1.67±0.25) and (4.61±0.73) $*10^9$Particles/mL. The protein concentrations of exosomes separated by the four methods were consistent with the concentrations of exosomes. SDS-PAGE showed that the protein distribution of exosomes separated by the four methods were different. Low levels of albumin were detected in TM-TC and TM-TC-UC, while high levels of albumin in TM and UC. Total RNA concentrations from exosomes in TM-TC was higher than other groups.

Conclusion: TM-TC can be used to obtain higher quality exosomes from SF for the study of exosome-enriched components.

AB0051 THE EFFECTS OF NON-INVASIVE VAGUS NERVE STIMULATION ON IMMUNOLOGICAL RESPONSES AND PATIENT REPORTED OUTCOME MEASURES OF FATIGUE IN PATIENTS WITH CHRONIC FATIGUE SYNDROME, FIBROMYALGIA, AND RHEUMATOID ARTHRITIS

E. Traianos[1], B. Dibnah[2], D. Lendrem[3], Y. Clark[4], V. Macrae[4], V. Slater[4], K. Wood[1], D. Storey[1], B. Simon[5], J. Blake[5], J. Tarn[3], W. F. Ng[3,4]. [1]*Newcastle University, FMS Professional Services, Newcastle upon Tyne, United Kingdom*; [2]*University of Glasgow, Institute of Molecular Cell & Systems Biology, Glasgow, United Kingdom*; [3]*Newcastle University, Translational & Clinical Research, Newcastle upon Tyne, United Kingdom*; [4]*National Institute for Health Research (NIHR), Newcastle Biomedical Research Centre (BRC), Newcastle upon Tyne, United Kingdom*; [5]*electroCore, Inc., NJ, United States of America*

Background: Fatigue is reported as a common symptom among autoimmune and other chronic diseases such as fibromyalgia (FM), a long-term condition with uncertain pathophysiology. Previous studies from our group suggest that non-invasive vagus nerve stimulation (nVNS) may contribute to the improvement of patient reported outcome measures (PROMs) of fatigue in patients with primary Sjögren's Syndrome (1).

Objectives: This follow-up study uses the gammaCore device (electroCore) to assess the effect of nVNS on PROMs of fatigue and immune responses in chronic fatigue syndrome (CFS), FM and rheumatoid arthritis (RA).

Methods: The study included thirteen CFS, fourteen FM and fifteen RA patients who used the gammaCore nVNS device twice daily over a 26-day period. Pre- and post- nVNS bloods were drawn at baseline and final visits. Whole blood

samples were stimulated with 2ng/mL lipopolysaccharide (LPS) and the IL-6 and TNF-α cytokine concentrations were quantified at 24 hours. In addition, the epidermal growth factor (EGF), IFN-γ, IL-6, IP-10, MIP-1α, and TNF-α levels were measured in 'pre-nVNS' serum and flow cytometric profiles of whole blood immune cells were analysed. The patient reported outcome measures (PROMs) recorded at each visit were the Visual Analogue Scale (VAS) (0-100cm) of abnormal fatigue, Hospital Anxiety and Depression (HAD) Scale, Orthostatic Grading Scale, Epworth Sleepiness Scale (daytime sleepiness), and Profile of fatigue (PRO-F) for Physical and Mental fatigue. Paired t-tests were performed to assess for changes in PROMs, cytokine levels, and cell subset distribution and associations of cytokine response with PROMs were investigated by correlation analyses.
Results: Eleven CFS, twelve FM and fourteen RA patients completed the study. There was a significant reduction in daytime sleepiness in CFS (p =0.0321) and FM (p =0.0294) patients between the final and baseline visits and a significant reduction in HAD depression (p =0.0413) in FM (Fig.1). Improvement in VAS for abnormal fatigue, HAD-Anxiety, HAD-Depression, PRO-F Physical and Mental fatigue was observed in all three groups over the study period with a reduction in VAS fatigue in 64% of CFS, 67% of FM and 62% of RA patients. There were no significant changes in the immune cell subsets or in cytokine response. Finally, higher baseline pre-nVNS supernatant IL-6 levels were predictive of an improvement in VAS fatigue (p =0.0006), Daytime Sleepiness (p =0.0466) and PRO-F Physical fatigue (p =0.0196) in RA, while higher baseline TNF-α levels were predictive of an improvement in VAS fatigue (p =0.0003), Daytime Sleepiness (p =0.0380), Orthostatic (p =0.0281) and PRO-F Physical fatigue (p =0.0007) in FM.
Conclusion: Our findings suggest that nVNS may contribute to the improvement of PROMs of fatigue in CFS, FM and RA. NVNS led to significant reductions in daytime sleepiness in CFS and FM, and depression in FM. Further studies and a larger sample size are needed to investigate the potential effects of nVNS on diseases characterised by persistent fatigue.

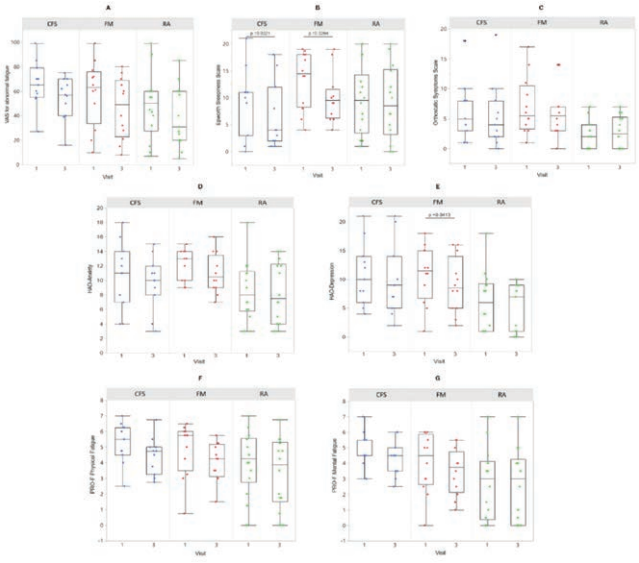

Figure 1. VAS for abnormal fatigue and PROMs recorded at baseline and final visits in patients with chronic fatigue syndrome (CFS), fibromyalgia (FM) and rheumatoid arthritis (RA). Boxplots show the median, upper, and lower quartiles for PROMs at visit 1 and visit 3 in each disease group. Paired-t tests revealed a significant reduction in daytime sleepiness in CFS and FM (B), and a significant reduction in HAD depression in FM (E). Improvement trends were observed in VAS for abnormal fatigue, HAD-Anxiety, HAD-Depression, PRO-F Physical fatigue and PRO-F Mental fatigue in all three groups over the 26-day study period.

AB0052 **INFLAMMATORY PROTEOMIC SIGNATURE RELATED TO DECREASED FERTILITY IN WOMEN WITH RHEUMATOID ARTHRITIS**

M. Bongenaar[1], H. T. Smeele[1], E. Lubberts[1], R. Dolhain[1]. [1]*Erasmus University Medical Centre, Department of Rheumatology, Rotterdam, Netherlands*

Background: Fertility issues are common in women with rheumatoid arthritis (RA). Decreased fertility in these patients is associated with high disease activity and the use of certain medication [1]. However, immunological mechanisms behind this phenomenon remain unresolved.
Objectives: This study aims to identify inflammation-related proteins associated with decreased fertility in women with rheumatoid arthritis and a wish to conceive.
Methods: Patients were derived from the PARA-study, a prospective cohort on RA and pregnancy. High-multiplex immunoassay technology with qPCR readout (Olink Proteomics, Uppsala, Sweden) was used to assess 92 inflammation-related proteins in serum obtained before pregnancy of 186 women with RA and a wish to conceive. Measured protein levels were imputed into multivariable cox regression models with time to pregnancy (TTP) as dependent variable. This model was corrected for known confounders age, nulliparity, NSAID use, prednisone use and past methotrexate use [2].
Results: Our analyses show prolonged TTP to be associated with increased expression of pro-inflammatory cytokines (TNF, IL-6, IL-18), chemokines (CCL23, CCL19, CXCL10, MCP-3, CXCL9) and T cell stimulating factors (TNFRSF9, CDCP-1). Furthermore, increased factors associated with angiogenesis (VEGF-A) and bone and collagen damage (RANKL, MMP-1) were found. Lastly, decreased fertility is associated with increased immune regulatory factors (IL-10, IL10RB, PD-L1). After false discovery rate (FDR) correction for multiple testing, IL-10, CCL23, MCP-3 and CDCP-1 remained statistically significant (adjusted P<0.05). Results are depicted in table 1.
Conclusion: This study shows a pro-inflammatory proteomic signature, including a counterbalance of increased immune regulatory proteins, to be associated with prolonged TTP. These findings provide more insight into the immunological pathways involved in fertility in RA patients.

THE ROLE OF ANGIOPOIETIN-LIKE PROTEINS TYPES 3 AND 4 IN THE DEVELOPMENT OF RENAL DYSFUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

V. Aleksandrov[1,2], L. Shilova[1], A. Aleksandrov[1,2]. [1]*Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation*; [2]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Department of Clinical and Laboratory Diagnostics, Volgograd, Russian Federation*

Background: Rheumatoid arthritis (RA) often contributes to the development of kidney disease. Angiopoietin-like proteins can be target markers for studying cardiorenal complications of RA [1].

Objectives: Assessment of the correlation of serum concentrations of angiopoietin-like proteins types 3 and 4 (ANGPTL 3 and 4) with the progression of renal dysfunction in RA patients.

Methods: 114 patients with reliable RA (90.4% of women, 9.6% of men) aged 21 to 80 years (mean age 55.4 ± 11.2 years old), disease duration - 11.18 ± 9.03 years, positive for rheumatoid factor (RF-IgM) - 63.2%, positive for anti-citrullinated protein antibody (ACPA) - 59.7%) were examined. The laboratory examination included the determination of serum concentrations of angiopoietin-like protein type 3 (Human Angiopoietin-like Protein 3 ELISA, Bio Vendor, Czech Republic) and type 4 (RayBio Human ANGPTL4 ELISA Kit; RayBiotech, USA). To assess renal function in RA patients we used the calculated glomerular filtration rate (GFR) according to the CKD-EPI formula [2], taking into account the height and weight of a particular patient without indexing by body surface area. GFR values <60 ml / min / 1.73 m2 were regarded as a certain decrease, and GFR values from 60 to 89 ml / min / 1.73 m2 - as a slight decrease in global kidney function.

Results: The concentration of ANGPTL3 in the blood serum of RA patients (n = 158) was 641.9 ± 224.5 ng / ml, and that of ANGPTL4 (n = 158) - 3.15 [0.77; 12.1] ng / ml. 74.7% (n = 118) were considered positive for the presence of ANGPTL3; 49.4% (n = 78) of RA patients were recognized as positive for the presence of ANGPTL4. The average glomerular filtration rate in RA patients was 74.0 ± 18.6 ml / min. More than a half of the examined RA patients had GFR ranging from 89 to 60 ml / min / 1.73 m2 (C1 - 21.5%; C2 - 58.9%; C3 - 19.6%). No sharp reduce of renal function (GFR <30 ml / min / 1.73 m2) corresponding to CKD C4-5 stages was recorded. Negative correlations of average strength were found between GFR and the level of ANGPTL 3 (r = -0.32, p <0.001) and ANGPTL 4 (rS = -0.31, p <0.001), as well as with age (rS = -0.28, p <0.001), the duration of RA (rS = -0.22, p = 0.005) and blood pressure increase (rS = -0.25, p = 0.001). On the basis of GFR measurements, patients were divided into three groups: group I - optimal renal function (> 90 ml / min); group II - a slight decrease in renal function (89-60 ml / min); group III - reduced renal function (<59 ml / min).

Table 1. Content of ANGPTL 3 and 4 in RA patients with different GFR, ng / ml

	Group I (n=34)	Group II (n=93)	Group III (n=31)
ANGPTL 3	533,4±161,7 [I-III]	650,0±223,9	733,2±244,1
ANGPTL 4	0,77 [0,28;3,6] [I-II, I-III]	3,3 [0,93;12,1]	6,48 [1,52;19,3]

Note: upper case indicates intergroup differences at p <0.05.

There was a significant difference in the content of ANGPTL3 in patients of the first group and the patients of the third group (H-test = 6.55, p = 0.032) and ANGPTL4 in the group of patients with normal renal function (group I) and groups of RA patients with decreased GFR (group I- II: H-test = 10.7, p = 0.001; groups I-III: H-test = 20.1, p <0.001). ANGPTL4 indices also had intergroup differences (groups II-III: H-test = 7.2, p = 0.007) with GFR less than 90 ml / min.

Conclusion: Chronic rheumatoid inflammation potentiates the development of renal dysfunction according to our data in 78.5% of patients. It is also accompanied by an increase in the content of ANGPTL types 3 and 4 in the blood of RA patients. A better understanding of the actions and mechanisms of ANGPTL may be of paramount importance for the development of effective ways of treatment for cardiorenal complications in RA.

AB0054

IS TEA CONSUMPTION ASSOCIATED WITH RISK OF RHEUMATOID ARTHRITIS?

H. Westerlind[1], I. Palmqvist[1], S. Saevarsdottir[1,2], L. Alfredsson[3], L. Klareskog[1], D. DI Giuseppe[1]. [1]*Karolinska Institute, Department of Medicine Solna, Stockholm, Sweden*; [2]*School of Health Sciences, University of Iceland, Faculty of Medicine, Reykjavik, Iceland*; [3]*Karolinska Institute, Institute of Environmental Medicine, Stockholm, Sweden*

Background: Only few studies have looked at the association between tea consumption and risk of rheumatoid arthritis (RA) with inconclusive results.

Objectives: To estimate the association between tea consumption and risk of RA in a large population-based case-control study.

Methods: We used data from the Swedish Epidemiological Investigation of RA (EIRA), a population-based case-control study including incident RA cases with 2 controls randomly matched from the general population, based on age, sex and residential area at the date of diagnosis. All participants filled in a comprehensive questionnaire on lifestyle factors, including a 124-item food frequency questionnaire (FFQ). Data from October 2005 - May 2018 was used.

Odds ratios (ORs) with 95% confidence intervals (CIs) were estimated using conditional logistic regression, overall and stratified by anti-citrullinated protein antibody (ACPA) and smoking status. We adjusted for smoking status, coffee and alcohol consumption, educational level and BMI. The dose-response trend of the association between tea consumption and risk of rheumatoid arthritis was estimated using restricted cubic spline with knots at 0, 0.29, and 2.29 cups per day. Missing tea values (44.8%) were imputed based on the zero-consumption assumption. A sensitivity analysis was performed to evaluate the influence of the assumption on the main result, with 70% of the missing randomly imputed as no consumption, and the remaining 30% randomly assigned to the other categories (10% per category).

Results: We included 2237 cases and 4661 controls. Controls were more likely to drink ≥2 tea cups/day compared to RA cases (22.1% vs. 19.7%).

The crude odds of developing RA was 22% lower (OR=0.78, 95% CI: 0.66-0.92) among those who consumed ≥2 tea cups/day compared to those who drank <1 cup/day (irregular drinkers). After adjustment for covariates, the inverse association was less pronounced and only borderline significant (OR=0.85, 95% CI: 0.71-1.01). A similar OR was observed among non-tea consumer (OR=0.82, 95% CI: 0.70-0.95). The odds of developing ACPA positive RA (but not ACPA negative) was statistically significant lower among participants drinking >=2 cups/day compared to irregular tea drinkers (OR=0.76, 95% CI: 0.62-0.94). In analyses stratified by smoking, an inverse association between tea intake and RA was found only among current smokers (OR=0.58, 95% CI: 0.37-0.92), while no association was found in never smoker. The sensitivity analysis showed results similar to the main analysis, although the OR in the no consumption category was not significant (OR=0.88, 95% CI: 0.76-1.02) while the OR in the highest category was statistically significant (OR=0.85, 95% CI: 0.73-0.99).

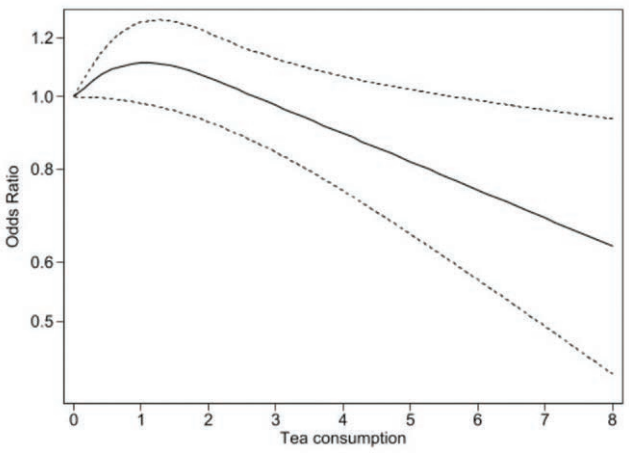

Figure 1. Dose-response odds ratio for risk of rheumatoid arthritis (RA) by tea consumption.

Conclusion: In this large population-based case-control study, high tea consumption, as well as no consumption, was associated with a decreased risk to develop ACPA positive, but not negative, RA, when compared to irregular tea drinking (<1 cup/day). The inverse association between high tea consumption and RA was lowest in analyses restricted to current smokers.

AB0055 AUTOIMMUNE RESPONSE AGAINST THE SHARED EPITOPE SEQUENCE IN RHEUMATOID ARTHRITIS

E. Graell[1], J. F. Delgado de la Poza[2], A. D. Gomez Centeno[1], M. Garcia Manrique de Lara[1], M. J. Amengual Guedan[2], E. Nuez Zaragoza[2], M. Aliste Fernandez[2], S. Rodriguez Navarro[2], M. Arevalo Salaet[1], S. Garcia-Cirera[1], M. Rusiñol[1], E. Costa Moya[1], C. Orellana[1], J. Calvet Fontova[1], M. Moreno Martinez-Losa[1], E. Casado[1], C. Galisteo[1], N. Navarro[1], M. Llop Vilaltella[1], J. Gratacos Masmitja[1]. [1]*Hospital de Sabadell, Rheumatology, Sabadell, Spain*; [2]*Hospital de Sabadell, Inmunology, Sabadell, Spain*

Background: Rheumatoid Arthritis (RA) is a systemic autoimmune disease, associated with hiperproduction of autoantibodies (AAb), in which the most specific are the AAb against citrullinated peptides (ACPA). RA is influenced by genetic factors, specifically, there is a strong genetic association with the shared epitope (SE), a five amino acid sequence motif in positions 70–74 of HLA-DRβ1 chains encoded by HLA-DRB1 alleles: QKRAA, QRRAA and RRRAA.
The present study aims to analyze whether SE-peptides (SE-p) can be a target of the autoimmune response in RA.
Objectives: To analyze the presence of AAb against the unmodified (*Un*) SE-p, citrullinated (*Cit*) SE-p and carbamylated (*Car*) SE-p.
Methods: Sera from consecutive 117 RA patients and 21 psoriasic arthritis (PsA) from our outpatient clinic were collected by venopunture. Also 138 sera from blood donors were obtained as healthy controls (HC). All participants signed the informed consent.
We perfomed a homemade ELISA test using a sequence of 15 aminoacid peptides from positions 65-79 of HLA-DRB1 containing the 3 different SE sequences, in the *Un*, *Cit* and *Car* SE-p, synthesized in a linear and cycled form. We established a 90% of specificity using a ROC curve obtained from HC and PsA for each ELISA test.
HLA-DRB1 polymorphism was performed using a HLA-DRB1 sequence specific oligonucleotide typing kit (Lifecodes) in 95 RA and in 15 PsA.
ACPA and RF were determined with commercial assays (Inova Diagnostics and Binding Site, respectively).
Results: The overall sensitivity of the different SE-p AAb tests ranged from 5.1-21.4%.
RRRAA SE polymorphism was associated with AAb against cycled CitCitCitAA SE-p (p=0.025), QKRAA polymorphism was almost significantly associated with AAb against cycled QKCitAA SE-p (p=0.067), whereas there was no association between QRRAA polymorphism and AAb against cycled QCitCitAA SE-p (p=0.690). On the other hand, there was no association between SE polymorphisms and AAb to any other peptide used in the ELISA test.
Significant differences were observed in the presence of AAb against lineal RRRAA, lineal CitCitCitAA and cycled CitCitCitAA SE-p when comparing RA vs. HC patients (p=0.022, 0.044, 0.022, respectively). Moreover, there also were significant differences in the presence of AAb against cycled CitCitCitAA SE-p between RA and PsA patients (sensitivity 21.4%, specificity 100%; p=0.014).
It must be highlighted that cycled CitCitCitAA SE-p AAb were detected in 20.0% of RA patient sera that were negative for RF and ACPA.
There was no association between RF or ACPA with the presence of any SE-p AAb.
Conclusion: RA patients have autoantibodies against the Shared Epitope (SE). The cycled CitCitCitAA SE peptide (SE-p) shows the best performance among all the peptides tested and could identify patients seronegative for ACPA and RF, both analyzed by commercial assays.
Additional studies must be performed to verify the diagnostic and utility of these new autoantibodies against SE-p in RA.

AB0056 TNFR2 PROMOTES INFLAMMATORY PROGRAMS IN FIBROBLAST-LIKE SYNOVIOCYTES

T. Suto[1], K. Von Dalwigk[1], A. Platzer[1], B. Niederreiter[1], T. M. Karonitsch[1]. [1]*Medical University of Vienna, Division of Rheumatology, Vienna, Austria*

Background: TNF-mediated fibroblast-like synoviocyte (FLS) activation is important for inflammation and joint destruction in rheumatoid arthritis (RA). The role of TNF-receptor 1 (TNFR1) in FLS activation has thoroughly been characterized. The functions of TNFR2 are, however, largely unknown.
Objectives: To investigate the contribution of TNFR2 to the TNF-mediated activation of FLS.
Methods: RA-FLS were transfected with TNFR2-targeting siRNA pools and transcriptional changes were determined by RNA-seq. QPCR, ELISA and immunoblotting were used to confirm the RNA-seq results and to gain insights into the pathways that regulate TNFR2-mediated changes in FLS.
Results: TNF stimulation of FLS resulted in a strong upregulation of proinflammatory cytokines, chemokines, tissue-degrading enzymes and other genes that are associated with synovial inflammation in RA. Silencing of TNFR2 markedly diminished the TNF-response of RA-FLS. Especially, "interferon"-stimulated-genes (ISGs) including putative master regulators of joint inflammation, such as the CXCR3 chemokines CXCL9, CXCL10 and CXCL11 were affected by the knockdown of TNFR2. Consistently, immunoblots showed that TNFR2 was required for the TNF-induced phosphorylation of the transcription factor STAT1, which is known to mediate the transcription of ISGs, such as CXCR3 chemokines.
Conclusion: TNFR2 regulates proinflammatory gene expression in RA-FLS via STAT1 and thereby contributes to the detrimental effects of TNF in synovial joint inflammation.

AB0057 IN VITRO EFFECT OF CTLA4-IGG ON M1-M2 SHIFT OF MACROPHAGES FROM RHEUMATOID ARTHRITIS PATIENTS

S. Tardito[1], S. Soldano[1], E. Gotelli[1], P. Montagna[1], S. Paolino[1], V. Smith[2,3,4], M. Cutolo[1]. [1]*University of Genova, IRCCS San Martino Polyclinic Hospital, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, Genoa, Italy*; [2]*Ghent University Hospital, Department of Rheumatology, Ghent, Belgium*; [3]*Ghent University, Department of Internal Medicine, Ghent, Belgium*; [4]*VIB Inflammation Research Center (IRC), Unit for Molecular Immunology and Inflammation, Ghent, Belgium*

Background: Among the cells involved in the inflammatory process of rheumatoid arthritis (RA) [1], macrophages play a key role through their capacity to polarize into "classically" or "alternatively" activated phenotypes (M1 or M2) and making macrophages important players for the inflammatory cascade or for the anti-inflammatory reaction, respectively [2]. CTLA4-Ig fusion protein (abatacept) has been shown to contribute to macrophage shift from M1 to M2 [3].
Objectives: We aimed to investigate the effects of abatacept to induce the polarization from the pro-inflammatory M1 phenotype into the anti-inflammatory M2 phenotype in cultured human macrophages obtained from RA patients' and healthy subjects'(HS) circulating monocytes.
Methods: Cultured monocytes were isolated from peripheral blood mononuclear cells (PBMCs) of three early RA patients and ten HS, after signing informed consent and Ethics Committee approval. Cells were treated with phorbol myristate acetate (PMA) [5ng/ml] for 24 hours (hrs) to induce their differentiation into monocyte-derived macrophages (MDMs). Therefore, cultured HS MDMs were stimulated with lipopolysaccharides [LPS, 1mg/mL] for 4hrs [4] in order to induce their polarization into a pro-inflammatory M1 phenotype and then treated or not with abatacept at the concentrations of 100mg/mL and 500mg/mL for 3, 12, 24 and 48hrs. Cultured RA MDMs, were directly treated with abatacept as previous described. Cultured HS and RA MDMs without any pro-inflammatory stimuli and abatacept treatment were used as respective control.
The transition of MDMs from M1 to M2 phenotype was evaluated through gene expression and protein synthesis of M2 macrophage markers, namely scavenger receptors (CD163 and CD204), and mannose receptor-1 (CD206) by quantitative real-time polymerase chain reaction (PCR) and by Western blotting. The statistical analysis evaluation was carried out by GraphPad Prism 8 analysis software using the Wilcoxon non-parametric t-test. Any p-value lower than 0.05 was considered as statistically significant. Results were indicated as median±standard deviation (SD).
Results: In cultured RA MDMs (three cases), abatacept upregulated the gene expression of all investigated M2 markers, specifically after 12hrs of treatment with the concentration of 100mg/mL. In these cells, abatacept upregulated only the CD204 protein synthesis with more evidence at 24hrs of treatment and with the 500mg/mL concentration. In cultured HS MDMs (ten cases), abatacept upregulated the gene expression of M2 markers, significantly for that of CD206 [at 3hrs with 100mg/mL concentration, p= 0.0312] and CD163 [at 12hrs with 500mg/mL concentration, p= 0.0312]. Moreover, in these cells, abatacept significantly upregulated the protein synthesis of CD206 [at 48hrs with 500mg/mL concentration, p= 0.0195] and CD204 [at 24hrs with 100mg/mL concentration, p= 0.0156; both at 24 and 48hrs with 500mg/mL concentration, p= 0.0234].

Conclusion: Preliminary data seem to indicate that abatacept can promote the in vitro shift from the M1 into the M2 macrophage phenotype, by upregulating specific markers (CD163, CD204, CD206) in cultured M1-MDMs from RA patients and in M1 macrophages induced from HS.

AB0058 ASSOCIATION BETWEEN HLA-DRB1*04:01, RHEUMATOID NODULES AND PARTICULAR EPITOPES OF CITRULLINATED FIBRIN IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Larid[1], M. Pancarte[2], G. Offer[2], C. Clavel[2,3], M. Martin[4], V. Pradel[5], I. Auger[4], P. Lafforgue[1], G. Serre[2], J. Roudier[1,4], N. Balandraud[1,4]. [1]*AP-HM, Rheumatology, Marseille, France*; [2]*UDEAR, Toulouse 2 University, INSERM U1056, Toulouse, France*; [3]*Centre Hospitalier Universitaire (CHU) de Toulouse, Institut Fédératif de Biologie, Laboratory of Cell Biology and Cytology, Toulouse, France*; [4]*Aix-Marseille-University, INSERM UMRs1097 Arthrites Auto Immunes, Marseille, France*; [5]*AP-HM, Public Health Laboratory, Marseille, France*

Background: Rheumatoid arthritis (RA) is associated with HLA-DRB1 genes encoding the shared epitope (SE), a 5 amino acid motive. RA is usually preceded by the emergence of anti-citrullinated protein antibodies (ACPAs) detected by anti-CCP2 tests. Citrullin is a neutral amino acid resulting from post translational modification of arginin by Peptidyl Arginyl Deiminases (PADs). ACPAs recognize epitopes from citrullinated human fibrinogen (Fib-cit) and can be specifically detected by the AhFibA assay. Five peptides derived from Fib-cit together represent almost all of the epitopes recognized by patients with ACPA-positive RA: β60–74cit, α36–50cit, α621–635cit, α501–515cit and α171–185cit. As RA is a pleiomorphic disease, whose evolution is difficult to predict, the use of antibody fine specificity as a marker of clinical phenotypes has become a major challenge.

Objectives: Our objective was to study whether clinical characteristics and HLA-DRB1 genetic background were associated with a specific reactivity against these epitopes.

Methods: 184 ACPA positive RA patients fulfilling the 2010 ACR/EULAR criteria were studied. Patients characteristics, including HLA-DRB1 genotype, were collected from their medical files. Anti-CCP2, AhFibA, Rheumatoid Factors (RF), and antibodies against the five major Fib-cit peptides were analyzed using ELISA assays.

Results: Anti-CCP2 and AhFibA titres were strongly correlated (rs: 0.7037; $p = 5.69x10^{-29}$, Pearson's). Anti-α505-515cit antibodies were associated with HLA-DRB1*04:01 (OR = 5.52 [2.00 – 13.64]; p = 0.0003). High level anti-α505-515cit antibodies were significantly associated with rheumatoid nodules (OR = 2.71 [1.00 – 7.16], p= 0.044). Anti α501–515cit antibodies were associated with RF (OR=2.31 [1.10 – 4.78], p= 0.026).

Conclusion: Immune complexes containing anti-α501–515cit antibodies and rheumatoid factors might be involved in the development of rheumatoid nodules on the HLA-DRB1*04:01 background. These findings highlight the role played by the HLA-DRB1*04:01 molecule and its rapid intracellular route into the lysosomes, enabling original antigen processing. Finally, purifying these epitope specific antibodies might be a new therapeutic opportunity for rheumatoid nodules.

AB0059 STUDY OF THE ANTI-INFLAMMATORY EFFECT OF CINNAMOMUM VERUM IN RATS

R. Dhouibi[1], A. Hanène[1], S. Ben Youssef[2], M. Ben Salem[3], R. Marrakchi[4], S. Charfi[5], S. Hammami[1], K. Ksouda[1]. [1]*Medecine School of Sfax, Pharmacology Department, Sfax, Tunisia*; [2]*University of Sfax, Higher Institute of Biotechnology of Sfa, Sfax, Tunisia*; [3]*University of Sfax, Laboratory of Biochimie, Hedi Chaker Hospital Sfax, Sfax, Tunisia*; [4]*Hedi Chaker Hopital, Laboratory of Biochimie, Sfax, Tunisia*; [5]*Habib Bourguiba Hopital, Laboratory of Histology, Sfax, Tunisia*

Background: Inflammatory response is a common physiological response that protects the host of many harmful stimuli such as toxins, local injuries and pathogens. Today, non-steroidal anti-inflammatory drugs are the most commonly prescribed for the treatment of many inflammatory treatments. However, long term administration of these NSAIDs causes many adverse effects, including gastrointestinal ulcers and bleeding and kidney damage. Therefore, the need for new anti-inflammatory drugs with fewer side effects is required.

Objectives: The aim of our study was to evaluate the anti-inflammatory activity of *Cinnamomum verum* (*C. Verum*) on rats while testing the dose effect and the typical effect of the solvent.

Methods: The edema was induced by injection of carrageenan solution (CARR) in paw of rats according to the method of Winter et al, 1963. The measurements of volumes of right hind paw of each rat were taken before induction of edema and each 1 h, 2 h, 3 h, 4 h and 5 h after the injection of carrageenan. 7 groups of 6 rats received, one hour before the injection of the carrageenan, different treatment: G1= witness, G2=CARR + saline solution, G3= CARR+ Acetylsalicylic acid, G4= CARR + *C. verum*- MeOH 100, G5= CARR + *C. verum*- MeOH 300, G6= CARR + CARR + *C. verum*- EtOH 100 and G7= CARR + *C.verum*- EtOH 300.

Results: For this test, the volume of edema increases with time, this increase is greater in the group treated with saline solution than with the extracts of *C.Verum* and with Acetylsalicylic acid. The extracts of *C. Verum* administered intraperitoneally one hour before the injection of the carrageenan, reduced the edema in the third hour after.

Conclusion: The interesting anti-inflammatory activity of *Cinnamomum verum* recorded in this work may at least in part support its popular use in traditional medicine [1, 2].

AB0060 INCREASED AGE/AUTOIMMUNE-ASSOCIATED B CELLS IN RA AND CLINICAL IMPLICATIONS

Y. QIN[1], **Z. CHEN[1].** [1]*THE FIRST AFFILIATED HOSPITAL OF USTC, RHEUMATOLOGY AND IMMUNOLOGY, HEFEI, CHINA*

Background: Age/Autoimmune-associated B cells (ABCs) are an emerging B cell subset that accumulate in aged and autoimmune-prone mice. Expansion of human ABCs has been observed in patients with autoimmune diseases like SLE and correlated with disease activity. However, it is less known whether ABCs contribute to the pathogenesis of RA.

Objectives: The aim of this work was to explore the role of ABCs in RA.

Methods: 83 RA patients who met the 2010 ACR classification criteria for RA, 42 sex and age matched healthy control (HC), 35 Spondyloarthritis (SpA) and 31 Osteoarthritis (OA) patients were enrolled and blood samples were collected. The proportion of circulating ABCs was detected by flow cytometry and association with clinical and laboratory parameters were analyzed. Expression of characteristic proteins and inflammatory cytokines on ABCs were examined by quantitative real-time PCR.

Results: The proportion of ABCs, defined as $CD19^+CD27^-IgD^-CD21^-CD11c^+$, was significantly elevated in RA patients, compared with HC, SpA and OA patients. The frequency of ABCs was higher in patients with high disease activity (DAS28>3.2) compared with remission and low disease activity (DAS28<3.2). There was a positive correlation of ABCs with SJC, TJC, DAS28 whereas no association with RF and anti-CCP titer were observed. In addition, increased mRNA expression levels of T-bet, IL-21, MAF and IL-17 were noted on ABCs compared with $CD19^+CD27^-CD11c^-$ B cells.

Conclusion: ABCs were expanded in RA patients and associated with active disease status. It might contribute to RA development by production of IL-17.

AB0061

ALTERATIONS OF XANTHINE OXIDOREDUCTASE ACTIVITY IN RED BLOOD CELLS AFTER GLUCOCORTICOID TREATMENT IN RHEUMATOID ARTHRITIS

E. Mozgovaya[1], S. Bedina[1], A. Trofimenko[1], M. Mamus[1], S. Spitsina[1], I. Zborovskaya[1]. [1]*Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Clinical Biochemistry Lab, Volgograd, Russian Federation*

Background: According to modern concepts, rheumatoid arthritis (RA) refers to severe autoimmune rheumatic diseases. The activation of free radical oxidation processes is essential in the development of this disease [1]. Xanthine oxidoreductase is a significant reactive oxygen species source [2]. Despite the great advances in the treatment of rheumatoid arthritis (RA) associated with the introduction of innovative drugs and especially the improvement of the strategy for their use into clinical practice, glucocorticoids still remain an important component of RA pharmacotherapy in actual clinical practice.
Objectives: to evaluate the changes in activities of xanthine oxidoreductase interconvertible forms (xanthine oxidase, EC 1.17.3.2 and xanthine dehydrogenase, EC 1.17.1.4) in lysed red blood cells of RA patients in relation with glucocorticoid treatment.
Methods: 47 RA patients with verified RA and 30 healthy controls were enrolled in the study. The diagnosis was verified using the 2010 ACR/EULAR criteria 2010. All patients have moderate DAS28 scores. RA patients were randomized into 2 groups comparable in gender, age and the principal clinical manifestations. Methylprednisolone (Metipred, Orion Corp.), average dose 30 mg/day, and betamethasone (Diprospan, Schering-Plough), single dose7 mg, were administered intramuscularly in the respective groups. Xanthine oxidase (XO) and xanthine dehydrogenase (XDG) activities were measured in lysed red blood cells by spectrophotometric method as previously described [3]. The changes of these enzymes activities were studied in RA patients before and after the injection of glucocorticoids. Statistical comparison tests were selected in according to common guidelines, differences were considered significant when $p<0.05$. Central tendencies were expressed as means±SEM.
Results: Mean age of patients in methylprednisolone group was 41.8±1.05 years, and mean RA duration (± SEM) was 7.9±0.21 years. Mean age of patients in diprospan group was 40.9±1.07 years, and mean RA duration was 8.0±0.33 years. Significant decreases of XO activity and increase of XDG activity were observed in lysed red blood cells of RA patients just after the injection of each glucocorticoid drug. Changes of the enzymatic activities in lysed red blood cells were more pronounced in methylprednisolone group. However enzymatic activity did not reach the level of healthy controls. As described previously, decreased XO activity and increased XDG activity were observed in plasma of RA patients just after the injection of the average therapeutic doses of glucocorticoids, as well as in lysed lymphocytes just after the injection of methylprednisolone [4].
Conclusion: Treatment with methylprednisolone and betamethasone can affect the balance of XO/XDG activity and increase the antioxidant potential of the blood. This effect can exert beneficial influence on autoimmune inflammation in RA.

TIME COURSE OF INTESTINAL PERMEABILITY AND BACTERIAL TRANSLOCATION IN THE MODEL OF ADJUVANT-INDUCED ARTHRITIS

S. Hecquet[1], P. Totoson[2], H. Martin[2], C. Peyronnel[2], M. Tournier[2], P. Saas[3], J. P. Pais-De-Barros[4], D. Wendling[1], C. Demougeot[2], F. Verhoeven[1]. [1]*Centre hospitalier régional universitaire de Besançon, Rheumatology, Besançon, France*; [2]*EA4267 PEPITE LAB, Physiology, Besançon, France*; [3]*UMR 1098, Interactions Hôte Greffon Tumeur, Besançon, France*; [4]*UMR 1231, Plateforme de lipidomique, Dijon, France*

Background: Intestinal inflammation, dysbiosis, intestinal permeability (IP) and bacterial translocation (BT) have been identified in patients with spondyloarthritis but the time at which they appear and their contribution to the pathogenesis of the disease is still a matter of debate.
Objectives: To investigate the time-course of intestinal inflammation, IP and BT in a rat model of reactive arthritis, a subgroup of SpA, the adjuvant-induced arthritis model.
Methods: Adjuvant-induced arthritis (AIA) was induced in 6-week-old male Lewis rats by an injection at the base of the tail of *Mycobacterium butyricum* with incomplete Freund's adjuvant (Day (D) 0). Control rats received saline using the same procedure. Body weights and a clinical arthritis score were daily assessed. A group of AIA and control rats (n=15 per group) were euthanized at three different times of arthritis: D4 for the pre-arthritic phase (AIA-preclinical), D11 for the onset of arthritis (AIA-onset) and D28 for the acute phase (AIA-acute). In each group (AIA and control, n=15 per group)), IP was assessed by measuring plasma levels of zonulin (ELISA) and ileal mRNA expression of zonulin and occludin (RT-qPCR), BT was studied by measuring bacterial endotoxins (or LPS, by $LCMS^2$ method), soluble CD-14 (sCD14, ELISA) and ileal mRNA expression of TLR-4, and intestinal inflammation was assessed by measuring ileal mRNA expression of IL-8, IL-33, IL-17, IL-23p19 and TNF-α (RT-qPCR). Joint damage was assessed by the determination of a clinical and radiographic score of hind paws.
Results: Body weights of AIA rats decreased from D4 to D28 as compared to controls, in parallel to the development of a severe clinical and radiographic arthritic disease from D11 and D28. Compared to control rats, AIA induced an increase in plasma zonulin levels at D4, D11 but not at D28. Ileal mRNA zonulin overexpression occurred at D11 while occludin was unchanged. As early as Day 4 (preclinical phase), mRNA of IL-8, IL-33 and IL-17 were overexpressed in ileum from AIA. At Day 11 (onset), overexpression of IL-8 persisted and mRNA of TNF-α and IL-23p19 increased in AIA. Neither LPS levels nor ileal mRNA expression of TLR-4 were changed by arthritis whatever the phase of arthritis. By contrast, blood levels of sCD-14 was significantly increased in the AIA group at all stages of arthritis. No correlation was found between clinical and radiographic arthritis scores and zonulin or LPS levels. Conversely, a negative correlation was observed between intestinal IL-8 mRNA expression and arthritis score ($r=-0.3$, $p=0.02$).
Conclusion: In an animal model of SpA, intestinal inflammation and increased intestinal permeability occur prior to joint inflammation, suggesting a role of these disorders in the pathogenesis of this disease.

DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS: A BIOMARKER SCREENING PILOT STUDY

J. Baloun[1], A. Pekacova[2,3], H. Mann[1,2], J. Vencovský[1,2], K. Pavelka[1,2], L. Šenolt[2,3]. [1]*Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic*; [2]*1st Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic*; [3]*Institute of Rheumatology, Department of Experimental Rheumatology, Prague, Czech Republic*

Background: Despite modern therapeutic approaches, many patients with rheumatoid arthritis (RA) remain symptomatic after several cycles of treatment and may become so called Difficult-To-Treat (D2T)1. D2T RA is a multifactorial condition in which different factors may be major determinants of the persistence of signs and symptoms, which is seldom caused by drug resistance only2. Discovering new biomarkers is necessary to develop tailored therapies that will be effective in an individual patient at each stage of the disease.
Objectives: The primary aim of this pilot study was to validate a target proteomic technique for the proteome profiling of the two cohorts of RA patients and controls. Moreover, we searched for potential plasma biomarker(s) predicting D2T RA.
Methods: Seven RA patients with persistent remission on biological therapy in two consecutive examinations 12 wks apart (mean age 59.6±14 yrs), seven D2T RA patients fulfilling proposed EULAR definition of D2T RA1 (mean age 59.3±13 yrs), and six healthy controls (mean age 58.8±15 yrs) were included in this study. All subjects were females and their samples were collected before starting biological therapy. We employed Thermo Orbitrap Fusion paired with nano-flow UHPLC Dionex Ultimate 3000. Prior to quantification, 125 plasma proteins were modified by Peptiquant Plus Human kit to increase the sensitivity. Data were analysed by ANOVA and Tukey`s posthoc test with false-discovery-rate adjustment.
Results: The target proteome profiling reliably quantified 92 from 125 labelled proteins. Our follow-up statistical analysis revealed ten plasma proteins, which significantly differed among groups. Notably, we found significantly different plasma levels of paraoxonase/arylesterase 1 (PON1), an esterase with an antioxidant characteristic preventing lipid peroxidation[3], between RA patients and controls and between RA patients with persistent remission and D2T RA patients.

Conclusion: Using target proteome profiling technique, we demonstrated PON1 as a potential biomarker of D2T RA. However, these results have to be validated on a larger cohort.

AB0064 EVALUATION OF QUALITY OF LIFE IN RHEUMATOID ARTHRITIS USING SF-36 AND HAQ SCALES

M. Brahem[1], M. Hassayoun[1,1], H. Hachfi[1], R. Sarraj[1], M. Ardhaoui[1], A. Ben Salem[1], S. Abdellatif[1], R. Ben Tekaya[1], Y. Mohamed[1]. *[1]Taher Sfar Hospital, Rheumatology, Mahdia, Tunisia*

Background: The assessment of health-related quality-of-life (HRQoL) in rheumatoid arthritis (RA) is becoming a common tool in clinical practice. The medical outcomes survey short form 36 (SF- 36) is one of the most widely used tools for measuring HRQoL in RA as well as the HAQ scale.
Objectives: The aim of our study is to evaluate the impact of the RA in the quality of life (QoL) of our patients using the SF-36 and the HAQ questionnaires.
Methods: This is a cross-sectional study during a period of the year 2020, including 70 patients followed in the department of Rheumatology in Mahdia, Tunisia. All patients were diagnosed with RA based in ACR 1987/EULAR 2010. We evaluated for each patient, the mean global scale and the eight domains of SF-36 (physical functioning (PF), role physical (RP), bodily pain (BP), general health (GH), vitality (VT), a social functioning (SF), role emotional (RE) and mental health (MH)), scored from 0 (worst) to 100 (best).
Results: Our study included 70 patients (59 females/11males) with an age ranged from 21 to 76 years. The mean age was 54 ± 12 years. The mean duration of the disease was 11 ± 10 years [1-40]. The mean number of tender joints was 9.7 ±9.4 and swollen joints were 4.2 ±6.1. The mean disease activity score (DAS28) was 4.6 ±1.9 [1.2-8.4]. The mean HAQ score was 1.5±1.3, 47.1% of patients had specific joint deformations, 82.9% had radiologic involvement and 31.4% had osteoporosis. The biologic analysis showed that the mean ESR was 46.7 ± 30.5 and the CRP was 15.8 ±23.3. Rheumatoid factors were positive in 42.9% of cases, the ACPA were positive in 50% of cases. 84.3% of RA patients were treated by methotrexate, 4.3% were treated by salazopyrin and 11.4% were treated by biologic treatments.
The SF-36 global score was 50.4 ± 26.3 [15.3-92.8]. 46 patients (65.7% of cases) had impaired QoL (SF-36<66.7). The means of different domains (PF, RP, BP, GH, VT, SF, RE, MH) were respectively 51; 41.4; 51.4; 50; 51.2; 57.7; 41.9; 59.2. The most severely impacted domains were the RP and RE.
Our study showed a significant correlation between the SF-36 global score and the number of tender joints (p=0.002), the DAS28 (p=0.017) and the HAQ(p=0.000).
Conclusion: Our study showed that 65.7% of RA patients presented impaired QoL (SF-36<66.7), which is associated with high disease activity. So it's important to jugulate the disease, in order to ameliorate the quality of life of our patients.

Background: Hepatocyte growth factor (HGF) binds to the receptor tyrosine kinase c-Met and is a multifunctional cytokine that promotes processes such as cell proliferation, survival, differentiation, migration and angiogenesis [1]. We previously reported that HGF is produced by inflammation in the RA synovium, and activates monocyte migration to the synovium and promotes bone destruction through its own chemotactic effect and enhanced chemokine production in the synovium [2].
Objectives: Therefore, we next aimed to determine the role of HGF in RA angiogenesis.
Methods: The expression of HGF / c-Met in the serum and synovial tissues (STs) of RA patients and controls and human umbilical vein endothelial cells (HUVECs) was evaluated by ELISA and immunostaining. The effect of HGF/c-Met signaling on the promotion of CXCL16 production from HUVECs and RA fibroblast-like synoviocytes (FLSs) was determined by ELISA. To examine the role of HGF in angiogenesis, we performed in vitro Matrigel assays using HUVECs treated with HGF.
Results: HGF in serum in treatment-naive RA patients was significantly higher than that in controls and HGF in serum in treatment-resistant RA showed a significant positive correlation with CXCL16. c-Met were expressed on vascular endothelial cells of RA STs and HUVECs. Stimulation of HUVECs with HGF dose-dependently increased CXCL16 production. c-Met signal inhibition by SU11274 suppressed TNF-α stimulation-enhanced CXCL16 production by RA FLSs in a dose-dependent manner. Furthermore, HGF induced HUVEC tube formation by 1.8-fold.
Conclusion: HGF is produced by inflammation in the RA synovium, and activates angiogenesis through its own potent angiogenic effect and enhanced production of CXCL16 in the synovium. These results indicate that a strategy targeting c-Met signalling may be important for resolving treatment-resistant RA.

AB0066 MECHANISMS OF TOTAL SAPONINS OF PANAX JAPONICUS MITIGATES COLLAGEN-INDUCED ARTHRITIS

Z. Feng[1], X. Guo[1], J. Ji[1], X. Hou[2], Y. Luo[1], X. Fu[1]. *[1] Medical College of China Three Gorges University, Third-Grade Pharmacological Laboratory on Chinese Medicine Approved by State Administration of Traditional Chinese Medicine, Yichang, China*; *[2] Medical College of China Three Gorges University, Institute of Rheumatology, The First College of Clinical Medical Sciences, Yichang, China*

Background: Total saponins of *Panax japonicus* (TSPJ) are extracted from *Panax japonicus (T.Nees) C.A.Mey* and have achieved a good therapeutic effect in the treatment of rheumatoid arthritis (RA). Unfortunately, the mechanism of TSPJ acting on RA is not clear.
Objectives: To investigate the potential mechanisms and key targets of TSPJ on RA.
Methods: The raw data were downloaded from the Gene Expression Omnibus (GEO) database, and the RStudio3.6.1 software was used to identify differentially expressed genes (DEGs). The potential targets of active compounds from TSPJ were predicted by the Pharmmapper and SwissTargetPrediction databases. Based on the overlapping genes, we used Cytoscape 3.7.2 software to construct a protein-protein interactions (PPI) network and to determine the mechanisms of the treatment by Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis. Collagen-induced arthritis (CIA) model was established and treated with different doses of TSPJ. Arthritis index (AI) and histology score were used to evaluate the symptoms of CIA. The levels of vascular endothelial growth factor (VEGF), hypoxia-inducible factor 1 (HIF-1), IL-1β, and IL-17A tested by enzyme linked immunosorbent assay and real time-quantitative Polymerase Chain Reaction.

Results: A total of 2670 DEGs and 371 TSPJ targets were obtained, including 52 overlapping genes. 41 genes had protein interactions that are used to build the PPI network. The results of the KEGG enrichment analysis included VEGF and HIF-1 signaling pathway. Seven negative correlation genes and 16 positive correlation genes were obtained by correlational analysis of DEGs in VEGF and HIF-1 signaling pathway. SRC proto-oncogene, nonreceptor tyrosine kinase (SRC), and the signal transducer and the activator of transcription 3 (STAT 3) had a higher value of degree in PPI and showed a significant correlation in the pathways; they were regarded as key targets. Compared with the CIA model group, TSPJ significantly decreased the AI and histology scores. Moreover, the expression of VEGF-A, HIF-1α, IL-1β, and IL-17A in serum or spleens significantly reduced in a dose-dependent.

Conclusion: Present study show that SRC and STAT 3 may be the key targets of TSPJ acting on the VEGF and HIF-1 signaling pathways, thus inhibiting angiogenesis and improving RA.

AB0067 RHEUMATOID ARTHRITIS IS DRIVEN NOT ONLY BY INFLAMMATION BUT ALSO BY FIBROGENESIS

A. C. Bay-Jensen[1], S. F. Madsen[1,2], K. Gehring[3], K. Musa[3], M. Karsdal[1]. [1]*Nordic Bioscience, ImmunoScience, Herlev, Denmark*; [2]*University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark*; [3]*Nordic Bioscience, Clinical Laboratory, H, Denmark*

Background: Rheumatoid arthritis (RA) is a chronic, autoimmune disease characterized by inflammation of the synovium, cartilage and bone leading to joint swelling, tenderness, and dysfunction. The destruction of the joint tissue involves degradation of the extracellular matrix (ECM). The ECM consist of collagens and other connective proteins[1]. Studies have shown that elevated levels of collagen metabolites, such as those of type I, II, III and VI, are highly elevated in RA, correlated to disease activity and modulated in response to, for example tocilizumab[2], baricitinib[3] and methotrexate[4]. However, little is known about the formation of collagen, fibroblast activity, the fibrotic component of RA and how this influence likelihood of response to treatment.

Objectives: We investigated the level of active fibrogenesis in a population of moderate to severe RA patients (in contrast healthy controls) by assessing blood-levels of PRO-C3 and PRO-C6 (type III and VI collagen formation markers), which have been reported to be associated with the degree and extent of fibrosis5.

Methods: PRO-C3 and PRO-C6 was measured in serum of 166 RA patients (age; 54 (20-82), 83 % females, 91% white) at baseline and week 16 after treatment with an anti-IL6 receptor antibody in combination with MTX, as well as in serum of 77 donors (age; 42 (20-69), 51 % females, 66% white). Marker data was LN transformed. A general linear model was used when comparing groups.

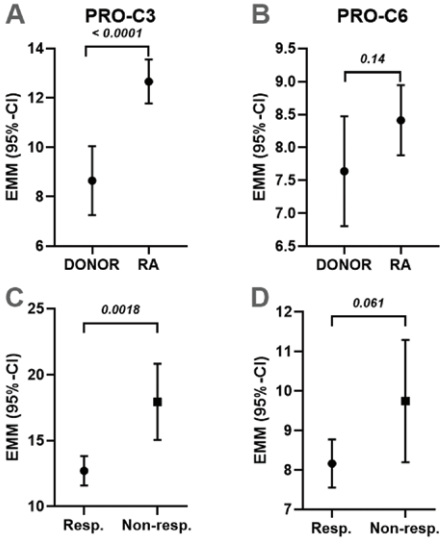

Fig. Difference in active fibrogenesis assessed by serum PRO-C3 and PRO-C6 between donors and RA patients at baseline (A,B) and between resp. and non-resp. at week 16 (C,D). Data is shown as back-transformed estimated marginal means (EMM) with 95%-CI adjusted for age, gender, and race (all), and BMI, disease duration and baseline marker level (C,D).

Results: The serum fibrogenesis marker PRO-C3, but not PRO-C6, was significantly elevated in RA compared to donors (2.1 vs. 2.4 ≈ 30% difference, p<0.0001, fig. 1A). None of the markers were correlated with disease measures such as DAS28, CRP, VASpain. None of the markers were modulated significantly in response to treatment. Interestingly, PRO-C3 levels were significantly higher at in non-responders (resp.) at week 16 compared to resp. (2.8 vs. 2.4 ≈ 40% difference, p=0.0018, fig. 1C). Similar trend was observed for PRO-C6 (2.2 vs. 2.0 ≈ 20% difference, p=0.061 fig. 1D).

Conclusion: Active fibrosis, with activated fibroblasts, may play an unseen role in RA. Patients will elevated levels of the fibrosis markers PRO-C3 and PRO-C6 were less likely to respond to an anti-IL6R. This may also give clue why such treatment are less efficacious in diseases with a clear fibrotic component.

AB0068 B- AND T- LYMPHOCYTE SUBSETS IN PATIENTS WITH EARLY AND PROGRESSED RHEUMATOID ARTHRITIS

A. Martynova[1], T. Popkova[1], A. Aleksankin[1], E. Gerasimova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases, Moscow, Russian Federation*

Background: Role of B- and T- lymphocytes is well established in pathogenesis of rheumatoid arthritis (RA). Self-containing activation of B-cells in ectopic germinative centers is followed by auto-activation of T-lymphocytes while T-cells themselves are antigen-presenting cells for B-lymphocytes [1-2]. As these processes continue with the duration of RA, different subsets of B- and T-cell might be prevalent at different stages of RA.

Objectives: Evaluate differences in dynamics of B- and T- cell subsets in early and progressed RA.

Methods: 53 patients with diagnosed RA(ACR/EULAR 2010 criteria) were included in research in October 2019 - May 2020. Age median 54,2 [47; 62] yrs. 2 groups were formed: 1st (n = 27 pts., 25 female and 2 male) with early arthritis, median duration of RA 6 [5; 12] months prior to therapy, mediane DAS28-CRP - 5,8 [5,15-6,2]; and 2nd group (n=26 pts., 22 female and 4 male) - patients with progressed RA, duration of RA 84 [24; 121] months, on DMARDs (methotrexate 20 [15; 20] mg/week or leflunomide 20 mg/day), mediane DAS28-CRP - 6,31 [5,64-6,88]. Control group included 29 individuals (23 female and 6 male), age median 58,5 [53; 62] yrs. Blood of all patients underwent standart flow cytometry with T- and B-cell immunotyping.

Results: B and C-cells subsets were studied. B-cells subsets are presented in table 1 below.

Conclusion: As disease activity was high in both groups, therefore therapy was ineffective, and results could be interpreted as natural progression of RA, resulting mainly in dynamics of switched B-memory cells, transitioning B-cells and plasmoblasts. These subsets might be indicating disease development patterns but further research is required.

AB0069

ANTIBODIES AGAINST PHOSPHORYLCHOLINE AS PROTECTION MARKERS IN AUTOIMMUNITY, ATHEROSCLEROSIS, CARDIOVASCULAR DISEASE AND CHRONIC INFLAMMATION – IMPLICATIONS FOR TREATMENT

J. Frostegård[1]. [1]*Karolinska Institutet, IMM, Stockholm, Sweden*

Background: Autoimmunity, atherosclerosis and cardiovascular disease (CVD) are chronic inflammatory conditions and represent a major part of global burden of morbidity and also mortality. The immune system plays an important role in these conditions. Further, the risk of CVD and atherosclerosis is raised in several autoimmune conditions, where SLE is an important example. Its major cause, atherosclerosis (where activated immune competent cells producing cytokines are abundant), for example, active and passive immunization can influence the degree of atherosclerosis in animal experiments, but no treatment developed to specifically ameliorate inflammation is presently available. The cause of the chronic inflammation and immune activation in atherosclerosis has not been fully defined, and there are different, non-mutually exclusive and potentially synergistic possibilities including oxidized LDL (oxLDL) heat shock proteins (HSP) and infections. We focused on the lipid moiety in OxLDL, especially phosphorylcholine (PC) which is a small hapten, immunogenic when exposed and reported that OxLDL´s immunological effects is to some extent caused by PC. Antibodies against PC (anti-PC) are abundant, about 5-10% of circulating IgM is IgM anti-PC.
This is thus a theranostic concept, combining novel risk markers with possible underlying mechanisms and potentially immunization to raise anti-PC.
Objectives: We reported that anti-PC, especially IgM (and Ig1) anti-PC is negatively associated with atherosclerosis progress, CVD (including both MI and stroke) in different populations, and also with autoimmune diseases, especially systemic rheumatic diseases as SLE. Potential mechanisms include anti-inflammatory effects, inhibition of uptake of OxLDL in the vascular wall, promotion of T regulatory cells, inhibition of cell death, and increased clearance of dead cells.
Methods: We have used a combination of experimental and translational/clinical studies.
Results: Based on our findings, we have proposed a novel hypothesis which is a development of the hygiene/old friends-hypothesis, namely that low exposure to microorganisms as nematodes, parasites and some bacteria which from an evolutionary point of view has been with humanity for millions of years, leads to low levels of the antibodies described and a lack of ability to prevent autoimmune conditions. Indeed, individuals from Kitava, New Guinea leading a traditional life as hunter-gatherers and horticulturalists appear not to have CVD or rheumatic disease, but strikingly high anti-PC levels.
Conclusion: anti-PC could be a novel factor protecting against rheumatic disease.
Disclosure of Interests: Johan Frostegård Shareholder of: I am named as inventor on patents related to antibodies against phosphorylcholine, Grant/research support from: From Amgen, related to PCSK9 and inflammation, unrelated to this topic

Background: Vaspin is a novel anti-inflammatory adipokine associated with cardiovascular (CV) disease and inflammation in chronic inflammatory conditions different from axial spondyloarthritis (axSpA).[1] Given the high incidence of CV disease (mainly due to accelerated atherosclerosis) exhibited by axSpA patients,[2] we wondered if vaspin could also be a key molecule in this process. However, data on the role of vaspin regarding atherosclerotic disease in the context of axSpA is scarce.[3]
Objectives: To evaluate the implication of vaspin, at the genetic and serological level, in subclinical atherosclerosis and CV risk in axSpA.
Methods: 510 patients who fulfilled the ASAS criteria for axSpA[4] were included in this study. Carotid ultrasound (US) was performed to evaluate the presence of subclinical atherosclerosis. Three *vaspin* gene variants (rs2236242 T/A, rs7159023 G/A and rs35262691 T/C) were genotyped by TaqMan probes. Serum vaspin levels were assessed by Enzyme-Linked ImmunoSorbent Assay. Analysis was performed using a statistical software.
Results: Serum vaspin levels were significantly higher in female patients than in males and also in obese patients when compared to those with normal weight (p<0.05). At the genetic level, we disclosed that the minor allele of rs2236242 (A) was associated with lower serum vaspin levels in axSpA, while the rs7159023 minor allele (A) was linked to higher serum levels (p<0.05). When the three polymorphisms assessed were combined conforming haplotypes, we disclosed that the TGC haplotype related to high serum levels of vaspin (p=0.01). However, no statistically significant association was observed between vaspin and markers of subclinical atherosclerosis, both at the genetic and serological level.
Conclusion: Our results revealed that vaspin is linked to CV risk factors that may influence on the atherosclerotic process in axSpA. Additionally, we disclosed that serum vaspin concentration is genetically modulated in a large cohort of patients with axSpA.

AB0071 RELATIONSHIP BETWEEN PRO-INFLAMMATORY CYTOKINE AND ATHEROGENIC INDEXES IN AXIAL RADIOGRAPHIC SPONDYLOARTHRITIS

K. Ben Ali[1], M. Slouma[1], L. Kharrat[1], A. Tezeghdenti[2], R. Dhahri[1], E. Ghazouani[2], I. Gharsallah[1], L. Metoui[1], B. Louzir[1]. *[1]The Military Hospital of Tunis, Rheumatology, Tunis, Tunisia*; *[2]The Military Hospital of Tunis, Immunology, Tunis, Tunisia*

Background: The cardiovascular burden in inflammatory rheumatic diseases is well recognized. This burden has been reported in spondyloarthritis. Atherogenic indexes are known with their role of predicting cardiovascular risk.
Objectives: The aim of our study was to determine the relation between pro-inflammatory cytokines and atherogenic indexes in spondyloarthritis.
Methods: We performed a cross sectional study including 38 patients with spondyloarthritis according to ASAS criteria. For each patient we measured interleukin (IL)1, IL6, IL17, IL23 and tumor necrosis factor (TNF) alpha, total Cholesterol (CT), Triglycerides (TG), High density lipoprotein Cholesterol (HDLc) and Low density lipoprotein cholesterol (LDLc). We also calculated the following ratios: CT/HDLc, TG/HDLc, LDLc/HDLc, and LogTG/HDLc.
Disease activity was measured using ASDAS (Ankylosing Spondylitis Disease Activity Score) and BASDAI (Bath Ankylosing Spondylitis Disease Activity Index). Statistical analysis was performed using IBM SPSS Statistics 25.
Results: The mean age were 45.4±12.5 years. There were 33 Male (sex ratio were 6.6).
The mean C-reactive protein(CRP) were 29.6 ±40.34mg/L, mean erythrocyte sedimentation rate(ESR) were 41±33.9mm.
The mean ASDASCRP, BASDAI were 2.8±1.24, 3.7±2.12, respectively.
Active disease were noted in 68 % of patients using ASDASCRP score.
The mean IL1, IL6, IL17, IL23, TNF alpha were 11.6 ±25pg/ml, 15.4±45.9pg/ml, 84.6±77.9pg/ml, 15.3±15.26pg/ml, 25.3± 47.9pg/ml respectively.
The mean CT,HDLc,LDLc, TG were 4.47±0.93mmol/l, 1.09±0.3mmol/L, 2.77±0.78mmol/L, 1.29±0.54mmol/L respectively.
The mean CT/HDLc, TG/HDLc, LDL/HDLc, LogTG/HDLc were 4.28±1.26, 1.22±0.6, 2.7±1.06, 0.03±0.23, respectively.
Correlations were found between TG/HDLC ratio and IL1 (p<0.01, r=0.515), IL6(p<0.05; r=0.407), Log TG/HDLc and IL1 (p< 0.05, r=0.369), and IL6(p<0.05; r=0.333)
However, no correlations were noted between atherogenic indexes and IL7, IL17, IL23, TNFalpha.
Conclusion: Our study showed a correlations between atherogenic indexes and both IL1 and IL6.
These findings suggests that serum IL-6 and IL1 levels in spondyloarthritis contribute to the development of cardiovascular disease atherosclerosis.

AB0072 SERUM AMYLOID A PROTEIN (SAA) IN ANKYLOSING SPONDYLITIS AND THE RELATIONSHIP WITH SYSTEMIC INFLAMMATION

K. Sakharova[1], M. Cherkasova[1], S. Erdes[1]. *[1]V.A. Nasonova Scientific Research Institute of Rheumatology, Spondyloarthritis and PsA, Moscow, Russian Federation*

Background: Serum amyloid A protein (SAA) likely has a critical role in control and possibly propagation of the primordial acute phase response and is the precursor of AA amyloid fibrils. Prolonged elevations in SAA are the major inciting factor for AA amyloidosis developing in chronic inflammatory diseases. In Russia 2-4% of patients with ankylosing spondylitis (AS) have secondary (AA) amyloidosis.
Objectives: To study the level of SAA in AS its relationship with indicators of disease activity.
Methods: 124 patients with AS (according to mNYC 1984) 70 men, 54 women, of whom HLA B 27 positive 91.1% mean age 38.1 (± 12.9), age at the onset of the disease 23.5 (± 9.9) consecutively admitted to the clinic of the Research Institute rheumatology from February to November 2020. In addition to the standard examination (the median CRP 6.7 mg/l [1.4; 24.9], ESR 13 mm/h [7; 27], SAA was studied in all patients by the nephelometric method.
Results: The median SAA in 124 patients was 12.5 mg/l [4;71.6]. Among them, 31% had normal SAA level (<5 mg/l), and 69 % - more than 5 mg/l. In 21 (17.5 %) cases, the level of SAA was increased at normal CRP levels, and only in 2 cases an increase in the level of CRP at normal SAA levels; 50 patients (40.3 %) with normal ESR had elevated SAA levels, and 7 (5.6%) - ESR exceeded the upper limits of the norm with normal SAA levels. Comparison of the average values of the levels of SAA, CRP, ESR in men and women did not reveal significant differences between them. The SAA level was weakly correlated with ESR (r = 0.2; p=0.002) and BASDAI (r=0.3; p=0.002), moderately with ASDAS-CRP (r=0.5; r<0.0001), but showed a strong association with CRP (r = 0.80; p<0.00001). Patients with elevated SAA levels (>5 mg/l) had a shorter disease duration (10 and 12 year; p<0.0004), higher ASDAS-CRP (2.9 and 2.4; p<0.003), blood CRP level (14.6 and 1.3; p<0.00001), and significantly more peripheral arthritis (60% and 39%; p<0.05) than patients with normal indicators.
Conclusion: The level of SAA correlates well with indicators of AS activity, especially with the level of CRP, and can be used as an alternative indicator of disease activity.

INTESTINAL PERMEABILITY IN SPONDYLOARTHRITIS: A SYSTEMATIC REVIEW OF THE LITERATURE

S. Hecquet[1], P. Totoson[2], H. Martin[2], C. Prati[1], D. Wendling[1], C. Demougeot[2], F. Verhoeven[1]. [1]*Centre hospitalier régional universitaire de Besançon, Rheumatology, Besançon, France*; [2]*EA4267 PEPITE LAB, Physiology, Besançon, France*

Background: Growing evidence argue for a role of the gut in the pathophysiology of various chronic rheumatic diseases such as spondyloarthritis (SpA). This so-called "gut-joint axis" involves dysbiosis, bacterial translocation, intestinal inflammation and increase in intestinal permeability. Recent data from clinical and basic research suggested that the integrity of the intestinal barrier might be a key determinant in translating autoimmunity to inflammation, making intestinal permeability a potential marker or a target for future therapies.
Objectives: To analyse the available data on intestinal permeability in SpA patients and the effects of drugs such as non-steroidal anti-inflammatory drugs (NSAIDs) on intestinal permeability.
Methods: A systematic review was conducted. Without date restriction, the following databases were searched through September 1, 2020: Medline, Embase and Cochrane. Studies with patients with SpA assessing the intestinal permeability were selected. Some of the included studies have assessed the effect of NSAIDs on intestinal permeability.
Results: A total of 12 studies were included in the final analysis. The 12 studies involved a total of 268 SpA patients, including 240 ankylosing spondylitis (AS). Among the studies included, four studies used the lactulose/mannitol test, four studies used the 51Cr-ethylenediaminetetraacetic test and two studies used the polyethylene glycols test. Nine of the 12 studies reported increased intestinal permeability regardless on the method used for intestinal permeability evaluation. Four studies evaluated the link between disease activity, assessed by CRP and ESR levels, and intestinal permeability and showed no correlation between increased intestinal permeability and markers of disease activity in AS patients. As regards the effects of NSAIDs on intestinal permeability, data are controversial. Two studies, including one evaluating indomethacin, did not show any influence of NSAIDs in AS patients, one study showed an increase in intestinal permeability under NSAIDs in only 60% of the patients, another study reported increased intestinal permeability. When comparing the effect of NSAIDs in patients with AS to healthy subjects, one study reported a comparable NSAIDs-induced increase in intestinal permeability in both groups.
Conclusion: The results of our review suggest that increased intestinal permeability is present in SpA patients even in the absence of NSAIDs use and regardless of the method used to assess intestinal permeability. The effects of NSAIDs on intestinal permeability in SpA patients is more controversial and further studies are needed to clarify them.

NO DIFFERENCE BETWEEN THE SEROLOGIES OF DENTAL GERMS AND THE PHENOTYPES OF SPONDYLOARTHRITIS WITHIN THE DESIR COHORT

T. Neel[1], A. Tournadre[2], M. Paul[3], M. Norman[3], S. Paul[4], H. Marotte[1]. [1]*CHU, Rhumatology, Saint-Etienne, France*; [2]*CHU, Rhumatology, Clermont-Ferrand, France*; [3]*SAINBIOSE INSERM U1059, Research, Saint-Etienne, France*; [4]*GIMAP EA3064, Immunology, Saint-Etienne, France*

Background: Porphyromonas gingivalis (PG) and Prevotella Intermedia (PI) are two oral pathogens involved in the pathophysiology of chronic periodontopathies. Several studies have determined a role of these periodontal pathologies in the pathophysiology of rheumatoid arthritis (1) while the link with spondyloarthritis is not clearly established with currently contradictory studies (2,3,4).
Objectives: The purpose of this work is to investigate a link between spondylarthritis and the presence of chronic periodontopathy evaluated by PG and IP serologies.
Methods: The positivity and quantity of anti-PG and anti-PI antibodies were determined by ELISA method in patients from the DESIR cohort with one of the spondyloarthritis phenotypes compared to patients with common low back pain (n=50) (population control). Patients with spondyloarthritis were classified according to the following phenotypes (diagnosis chosen at 3 years in the DESIR cohort): axial spondylarthritis (n=126), psoriatic rheumatism (n=101), spondyloarthritis associated with chronic inflammatory bowel disease (n=36), undifferentiated spondylitis (n=241), reactive arthritis (n=2), SAPHO (acronym for Synovite, Acne, Pustulose, Hyperostosis and Osteitis. Correlations between patients' serological status, and smoking status, body mass index and age were sought.
Results: According to the general characteristics, the control group was significantly older than the axial spondylarthritis (p<0.001), and the psoriatic rheumatism group had a higher body mass index than the control population (p<0.05). The positivity and concentration of anti-PG and anti-PI antibodies were similar between different groups of spondyloarthritis compared to the control group. However, the subgroups "reactive arthritis" and "SAPHO" could not be analyzed due to insufficient staffing. Smoking status and body mass index were not related to antibody concentrations, however there was a statistical correlation between anti-PG antibody concentrations and age. After adjusting on age, there was no difference between the axial spondylarthritis and control groups.
Conclusion: Our results therefore suggest the absence of a link between periodontal germs involved in chronic periodontopathies and spondyloarthritis, provided that the two phenotypes involving germs in their pathophysiology could not be analyzed. Our results from a population of beginner spondylitis are therefore not in favour of the involvement of oral flora in the pathophysiology of spondyloarthritis, as is the case in rheumatoid arthritis (1). The associations found previously could therefore be favoured by a systemic inflammatory phenomenon. In conclusion, our study suggests no link between chronic periodontopathy and the occurrence of spondyloarthritis. However, the effect of chronic periodontopathy on the evolution of spondylarthritis remains to be explored.

HSA_CIRC_0012732, HSA_CIRC_0008961, HSA_CIRC_0405239 AND HSA_CIRC_0068784 MIGHT BE INVOLVED IN THE PATHOGENESIS AND DEVELOPMENT OF ANKYLOSING SPONDYLITIS

Y. P. Tang[1], Y. F. Qing[1], Z. R. Dong[1], F. Dai[1], J. Zheng[1], Y. Jiang[1], Y. X. He[1], Q. B. Zhang[2]. [1]*Institute of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Department of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Nanchong, China*; [2]*Institute of Rheumatology and Immunology, Affiliated Hospital of North Sichuan Medical College, Department of Geriatrics, Affiliated Hospital of North Sichuan Medical College, Nanchong, China*

Background: CircRNAs have been found to be involved in the occurrence and development of many rheumatic diseases[1-2]. Are circRNAs involved in the pathogenesis of ankylosing spondylitis (AS)? How do these circRNAs participate in the pathogenesis of AS? This all needs further study.
Objectives: This study is to clarify the expression levels of hsa_circ_0012732, hsa_circ_0008961, hsa_circ_0405239 and hsa_circ_0068784 in the peripheral blood of AS patients, and to explore whether these circRNAs are involved in the pathogenesis of AS.
Methods: To collected 60 cases of AS (30 cases of active AS (ASA): BASDA> 6 or 6> BASDAI> 4, ESR> 22mm / h or 6> BASDAI> 4, hsCRP> 9mg / L; 30 cases of stable AS (ASS): BASDAI <4) and 30 health control (HC) peripheral blood samples, related clinical and laboratory indicators. The relative expression levels of hsa_circ_0012732, hsa_circ_0008961, hsa_circ_0405239 and hsa_circ_0068784 in each group were detected by real-time quantitative polymerase chain reaction (qPCR). The relationships between the 4 circRNAs and clinical and laboratory indicators were explored by correlation analysis.
Results: 1. The qPCR results suggested that the expression of hsa_circ_0012732 between the ASA and ASS groups was statistically significant (p<0.05), and the expression of hsa_circ_0008961 was statistically significant between the ASA and HC groups (p<0.05). Howeverthere was no statistical significance among other groups (p>0.05)Figure 1. Similarly, the expression level of hsa_circ_0405239 was not statistically significant among the groups (p>0.05), and the same was true for hsa_circ_0068784 (p>0.05).
2. Correlation analysis results (Figure 2) showed that hsa_circ_0012732 is positively correlated with lymphocyte count (LY), mean corpusular volume (MCV), albumin (ALB), and negatively correlated with Bath ankylosing spondylitis disease activity index (BASDAI), Bath ankylosing spondylitis functional index (BASFI), high sensitivity C-reactive protein (hsCRP), Globulin (GLOB) (p<0.05); hsa_circ_0008961 is negatively correlated with platelet (PLT) (p<0.05); hsa_circ_0405239 is negatively correlated with BASDAI and BASFI; hsa_circ_0068784 was negatively correlated with BASDAI (p<0.05); and there was no statistically significant (p>0.05) between these 4 circRNAs and other indicators.

Conclusion: Hsa_circ_0012732, hsa_circ_0008961, hsa_circ_0405239 and hsa_circ_0068784 may be related to the pathogenesis of AS. Among them, hsa_circ_0012732 may be involved in AS inflammation and has the potential to participate in the judgment of disease activity.

THE ROLE OF MACROPHAGE MIGRATION INHIBITORY FACTOR IN ACTIVITY AND PROGRESSION OF ANKYLOSING SPONDYLITIS

Y. Gazar[1], M. Hanafy[1], M. Elrefi[2]. *[1]Faculty of Medicine, AL-Azhar university, Rheumatology and Rehabilitation, cairo, Egypt*; *[2]Military Hospitals, Rheumatology, cairo, Egypt*

Background: Ankylosing Spondylitis (AS) is a chronic inflammatory form of arthritis that predominantly affects the axial joints and has a global prevalence of 1%. Disease progression is marked by osteoproliferation and bone fusion in the axial joints, causing considerable loss of mobility. Migration Inhibitory Factor (MIF) is a potent pro-inflammatory cytokine implicated in several diseases. Elevated serum MIF levels have been reported in AS the role of MIF in bone formation has been a subject of controversy.

Objectives: Detection the level of Migration Inhibitory Factor in Ankylosing Spondylitis patients and correlate the level with disease activity and progression.

Methods: This cross-sectional case-control study were concluded upon 70 randomly selected people from internal medicine department in Kobry El-kobba Military Hospital and from rheumatology and rehabilitation department in EL-Hussein university hospital. The population study were divided into two groups: Group A: (50) Patients with Ankylosing Spondylitis (AS) who met the European Spondyloarthropathy Study Group (ESSG) criteria for AS (30) and Group B: (20) Healthy controls. Serum MIF by ELISA were measured. X-rays cervical &lumbosacral vertebrae (dorsal, lateral) views were obtained. m-SASS score (based on radiographic findings to detect progression) were assessed. MSK U/S on Tendo Achilles affected in AS patients were done.

Results: the mean age of all patients was (38.2 ± 8.4) years. Regarding gender of the patients, the majority (65.7%) of patients were males, while (34.3%) were females. (88%) of AS patients had cervical erosion or sclerosis, (46%) had dorsal erosion or sclerosis, (92%) had lumbosacral erosion or sclerosis, with m-SASS score of (11 ± 6.1). Regarding musculoskeletal U/S, (72%) had evidence of inflammation and erosion. Highly significant increase in ESR, CRP and MIF levels in A group; compared to control B group; with highly significant statistical difference ($p < 0.01$). the increase in smoking, ESR and MIF level; had an independent effect on increasing the probability of progression occurrence; with significant statistical difference ($p < 0.05$ respectively). MIF level at a cutoff point (>51) predicted patients with progression, with fair accuracy (74%), sensitivity= 53% and specificity= 94% ($p = 0.0056$).

Conclusion: MIF ply an important role in the pathogenesis of Ankylosing Spondylitis and has a link between chronic inflammation, new bone formation and disease progression and can be used as indicator for activity and disease progression.

ASSOCIATION BETWEEN VITAMIN D RECEPTOR GENE POLYMORPHISMS AND SYSTEMIC LUPUS ERYTHEMATOSUS IN MALTESE PATIENTS

R. Magro[1], J. A. Grech Meli[2], J. Debattista3, N. Aquilina[4], K. Gatt5, A. Borg6, C. Scerri[2]. *[1]Mater Dei Hospital, Rheumatology, Msida, Malta*; *[2]University of Malta, Faculty of Medicine and Surgery, Msida, Malta*; *[2]University of Malta, Faculty of Medicine and Surgery, Msida, Malta*; *[4]Mater Dei Hospital, Medicine, Msida, Malta*; *[4]Mater Dei Hospital, Medicine, Msida, Malta*; *[1]Mater Dei Hospital, Rheumatology, Msida, Malta*

Background: Vitamin D deficiency is highly prevalent in patients with systemic lupus erythematosus (SLE). Vitamin D acts through the vitamin D receptor (VDR) that is present in most cells, and it can regulate the transcription of over 200 genes. The expression of vitamin D receptors by a variety of cells belonging to the innate and adaptive immune systems has created interest with regards to the role of vitamin D in the pathogenesis of SLE. Several polymorphisms of the VDR gene have been described, namely BsmI, ApaI, TaqI and FokI. A number of VDR gene polymorphism genotypes have been associated with increased risk of SLE mostly in Asians and Africans.[1]

Objectives: The aim of this study was to establish whether an association was present between VDR gene polymorphisms and SLE susceptibility in a cohort of SLE patients living in Malta. A further aim was to assess the relationship between these VDR gene polymorphisms and SLE disease characteristics.

Methods: 59 SLE patients living in Malta and attending Rheumatology clinic at Mater Dei Hospital were recruited for the study after providing informed consent. The patients were over the age of 18 years and fulfilled the SLICC classification criteria for SLE. The patients were interviewed and blood samples were taken. RNA extraction was performed from whole blood. QuantiGene Plex technology was used to measure the expression of 12 interferon (IFN) signature genes in the extracted RNA. 93 cord blood samples obtained from individuals living in Malta were used as a control. DNA extraction was carried out from the blood samples obtained from the patients and controls. The VDR gene was screened and the regions containing the VDR polymorphisms were amplified for each patient. The amplified regions were then digested with their respective restriction enzymes in order to view the patient's genotype via restriction fragment length polymorphism. Statistical analysis, including odds ratio (OR), was carried out to gauge the significance in the association of these polymorphisms with SLE.

Results: 94.9% of SLE patients were female and they had a mean age of 44.5 years. All the patients were of Caucasian ethnicity. 13.6% had vitamin D deficiency (serum 25-hydroxyvitamin D <20ng/ml) and 25.4% were vitamin D insufficient (serum 25-hydroxyvitamin D 20-29ng/ml). The results showed that when ApaI polymorphism was present as a homozygote for the variant allele there was a significant decrease in SLE prevalence (OR=0.39, CI 0.17-0.87, p=0.02). The results were also analysed by placing the polymorphs into haplotypes. The haplotype containing all wild-type alleles for the VDR gene and the haplotype containing all wild-type alleles with the variant allele for FokI had an increased prevalence of SLE (OR= 1.95, CI 1.12-3.38, p=0.01 and OR= 2.36, CI 1.13-4.91, p=0.02 respectively). The patients who were homozygous for the variant allele for BsmI had a significantly higher SLE disease activity index-2K (SLEDAI-2K) (mean 5.00) compared to those that were heterozygous (mean 2.66; p=0.010). No significant difference was noted in damage, IFN signature gene expression, organ manifestation and autoantibody profile between the different genotypes for the 4 VDR polymorphisms. SLE patients who were homozygous variant for the ApaI or TaqI polymorphisms had an increased prevalence of fibromyalgia (OR=7.50, CI 1.47-38.16, p=0.02 and OR=12.00, CI 1.80-80.05, p=0.02 respectively).

Conclusion: The study showed that in the Maltese population the presence of the VDR gene polymorphism haplotype containing all wild-type alleles and the haplotype containing all wild-type alleles with the variant allele for FokI are associated with an increased risk of SLE. Moreover the homozygous variant genotype for BsmI was associated with a higher SLE disease activity. The homozygous

variant genotype for ApaI and TaqI was associated with a higher risk of fibromyalgia in SLE patients.

AB0078 LIPID IMMOBILIZATION AS A METHOD TO OBTAIN ANTIGENIC NANO-OBJECTS

O. Rusanova[1], O. Emelyanova[1,2], N. Emelyanov[2]. [1]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», 1, Волгоград, Russian Federation*; [2]*Federal State Budgetary Educational Institution of Higher Education «Volgoorad State Medical University» of the Ministry of Healthcare of the Russian Federation, 2, Волгоград, Russian Federation*

Objectives: Objective of the study is to research the effect of emulsion polymerization on active sites of cardiolipin antigen determinant in antiphospholipid syndrome (APS) in patients with systemic lupus erythematosus (SLE).

Methods: Having integrated antigen nanoobjects we developed immobilized magnetocontrollable antigen nanosystems and put them to an evaluation test. The nanosystems are polyacrylamide granules with a built in antigen. To obtain stable immobilized multi–use biopharmaceuticals with targeted properties (shape, particle diameter, pore size, density) we used a modified version of emulsion polymerization method using polyacrylamide carrier gel. This method permitted a greater sorptive capacity, preserving the antigen in maximum native state, and opened up the possibility of controllable modification of nanoobjects. Cardiolipin was used as the antigen in question.

Results: Following the method described above we performed sorption of anticardiolipin antibodies from blood plasma of SLE patients who showed clinical presentations of antiphospholipid syndrome. Blood serum from 10 apparently healthy individuals served as control. The level of cardiolipin antibodies was determined before and after sorption by indirect solid phase immunoenzyme method. In the eluate we estimated total protein by Lowry method. In vitro testing showed that the obtained antigen nanosystems based on immobilized cardiolipin could effectively remove cardiolipin antibodies from whole blood of SLE patients with clinical presentations of APS to achieve the values of healthy individuals (before sorption cardiolipin antibodies 0.328 ± 0.028; after sorption 0.059 ± 0.017; p<0.001; sorption capacity 8.00 ± 0.390 mg/ml).

Conclusion: The method of emulsion polymerization with consideration to hydrophobic and hydrophilic properties of lipid molecules permits obtaining and modifying biomolecules with certain properties, in a controlled fashion.

AB0079 ENDOTHELIAL FUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: IMPACT OF CAFFEINE CONSUMPTION ON ENDOTHELIAL PROGENITOR CELLS

V. Orefice[1], F. Ceccarelli[1], C. Barbati[1], E. Putro[1], C. Pirone[1], F. R. Spinelli[1], C. Alessandri[1], F. Conti[1]. [1]*Lupus Clinic, Sapienza University of Rome, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rome, Italy*

Background: As widely demonstrated, circulating endothelial progenitor cells (EPCs) could be considered biomarkers of endothelial dysfunction. Their frequency and function varied in systemic lupus erythematosus (SLE) patients, with a significant association with subclinical atherosclerosis[1]. Caffeine, one of the most widely consumed products in the world, seems to interact with multiple components of the immune system by acting as a non-specific phosphodiesterase inhibitor[2]. In terms of cardiovascular disease (CVD), data from the literature showed a U-shaped association between habitual coffee intake and CVD[3]. In this view, Spyridopoulos et al. demonstrated a significant improvement in mature endothelial cells and EPCs migration in relation to coffee consumption in coronary artery disease both in mouse models and in patients[4]. Finally, caffeine seems to play a positive effect on SLE disease activity status, as demonstrated by the inverse association between its intake and SLE Disease Activity Index 2000 (SLEDAI-2K) and the serum levels of inflammatory cytokines[5]. At the best of our knowledge, there are no data about the effect of caffeine on cardiovascular risk in SLE patients.

Objectives: The aim of this study was to evaluate the possible role of caffeine intake on endothelial function in SLE patients, by evaluating its effect on circulating EPCs.

Methods: We performed a cross-sectional study enrolling SLE patients, fulfilling the revised 1997 ACR criteria. According with the protocol study, we excluded patients with history of smoking, CVD, chronic kidney failure, dyslipidaemia, and/or diabetes. At recruitment, the clinical and laboratory data were collected and disease activity was assessed using the SLEDAI-2k. Caffeine intake was evaluated using a 7-day food frequency questionnaire, previously employed in SLE cohort[5]. At the end of questionnaire filling, blood samples were collected. EPCs were isolated from peripheral blood mononuclear cells (PBMC) by a flow cytometry analysis and they were defined as early EPCs CD34+KDR+CD133+ cells and late EPCs CD34+KDR+CD133-, expressed as a percentage within the lymphocyte gate.

Results: We enrolled 19 patients (F:M 18:1, median age 45 years, IQR 15; median disease duration 240 months, IQR 168). In this cohort, we observed a mean±SD SLEDAI-2k value of 1.3±3.3 and the most frequent disease-related feature was joint involvement (73.7%). Concerning treatment at the time of enrolment, the majority of patients were receiving treatment with hydroxychloroquine (78.9%) and seven with glucocorticoids (36.8%). The median intake of caffeine was 163 mg/day (IQR 138) and we used this value as cut-off to categorize SLE patients in 2 groups: group 1 (N=10, caffeine intake ≤ 163 mg/day) and group 2 (N=9, caffeine intake > 163 mg/day). Patients with less intake of caffeine showed a significantly more frequent history of lupus nephritis (p=0.03), haematological manifestations (p=0.0003) and anti-dsDNA positivity (p=0.0003). Moving on EPCs, a positive correlation between caffeine intake and EPCs percentage was observed (p=0.04, r=0.4) (Figure 1A). Moreover, patients with more caffeine intake showed higher levels of early EPCs (p=0.02) (Figure 1B).

Conclusion: This is the first report analysing the impact of caffeine on EPCs frequency in SLE patients. We found a positive correlation between its intake and both early and late EPCs percentage, suggesting a caffeine influence on endothelial function in SLE patients. Nonetheless, these results support the possible impact of dietary habits on autoimmune diseases.

AB0080 ALTERED CONCENTRATIONS OF DIFFERENT SMALL EXTRACELLULAR VESICLE POPULATIONS IN PLASMA OF PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

U. Stok[1,2], A. Shephard[3], S. Cucnik[1,2], S. Sodin-Šemrl[1,4], P. Zigon[1,4]. [1]*University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia*; [2]*University of Ljubljana, Faculty of Pharmacy, Ljubljana, Slovenia*; [3]*Nanoview Biosciences, Research and Development, Malvern, United Kingdom*; [4]*University of Primorska, Faculty of Mathematics, Natural Sciences and Information Technologies, Koper, Slovenia*

Background: Antiphospholipid syndrome (APS) is a systemic autoimmune disorder characterized by thrombosis, obstetric complications, and the presence of antiphospholipid antibodies (aPL) that cause endothelial injury and thrombophilia [1]. Extracellular vesicles (EVs) are involved in various thrombotic disorders [2], including APS [3, 4], and therefore may influence the prothrombotic status of APS patients. One of the hallmarks of activated endothelium is the expression of adhesion molecules, such as ICAM-1 (CD54) and E-selectin (CD62E), that play a key function in the interactions with leukocytes and platelets.

Objectives: To determine the level of total tetraspanin (CD81/CD63/CD9)-positive vesicles and specific EV populations (CD54- and CD62E-positive EVs) in plasma from APS patients.

Methods: Whole blood was collected from 4 APS patients and 3 healthy blood donors (HBDs) and processed to obtain platelet-depleted plasma. The size and concentration of EVs were determined using ExoView platform (NanoView

Biosciences, MA, USA). In brief, EVs were captured and immobilized on ExoView Tetraspanin chips using the capture antibodies CD81, CD63, and CD9. Size was determined using SP-IRIS technology. Concentration measurements were performed with fluorescently labeled detection antibodies, specifically tetraspanins (CD81/CD63/CD9) for total EVs and CD54 and CD62E for specific EV populations.

Results: Analysis of EVs size confirmed the presence of small EVs (sEVs, < 70 nm) in both study groups. The size of EVs did not vary significantly between study groups (mean size ± SD in APS vs. HBD; CD81 (63.1 ± 1.5 nm vs. 66.6 ± 10.6 nm), CD63 (63.3 ± 1.64 nm vs. 69.2 ± 13.2 nm), and CD9 capture spot (61.8 ± 1.18 nm vs. 64.1 ± 7.64 nm)). The levels of total EVs (tetraspanin-positive) were increased 1.7-fold, 1.4-fold, and 2.2-fold for CD81, CD63, and CD9 capture spots, respectively, in APS patients compared to HBDs (Figure 1A). In addition, CD54- and CD62E-positive EVs represented a small population (< 2 %) of the total EVs (Figure 1B). The levels of CD54 were increased 2.9-fold, 3.0-fold, and 2.5-fold on CD81, CD63, and CD9 capture spots, respectively, and similarly, the levels of CD62E were increased 2.2-fold, 2.7-fold, and 2.0-fold on CD81, CD63, and CD9 capture spots, respectively, in APS patients compared to HBDs (Figure 1A).

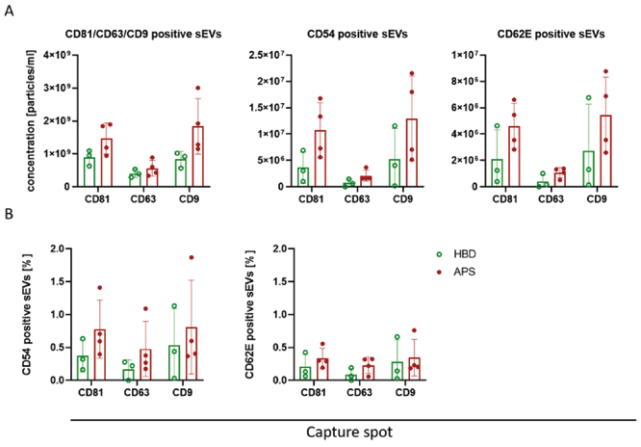

Figure 1. Concentration of tetraspanin- (CD81/CD63/CD9), CD54- and CD62- positive sEVs in APS patients and HBDs.

Conclusion: Higher levels of sEVs and increased percentage of CD54- and CD62E-positive sEVs in plasma of APS patients could indicate an altered and activated endothelium in those patients.

AB0081 ENDOTHELIAL MARKERS WITH DYSREGULATION IN SYSTEMIC LUPUS ERYTHEMATOSUS: A SYSTEMATIC LITERATURE REVIEW

S. Bergkamp[1], M. J. Wahadat[2], V. Smith[3,4,5], S. Kamphuis[2], J. M. Van den Berg[1], D. Schonenberg-Meinema[1]. *[1]Amsterdam UMC, Paediatric Rheumatology, Amsterdam, Netherlands*; *[2]Erasmus MC, Paediatric Rheumatology, Rotterdam, Netherlands*; *[3]Ghent University, Internal Medicine, Gent, Belgium*; *[4]Ghent University Hospital, Rheumatology, Gent, Belgium*; *[5]VIB Inflammation Research Centre (IRC), Unit for Molecular Immunology and Inflammation, Ghent, Belgium*

Background: Systemic lupus erythematosus (SLE) is a severe, lifelong autoimmune disease known for its multisystem organ involvement. SLE patients are known to be at risk for premature atherosclerosis at a relatively young age (1). Endothelial dysregulation is one of the pathophysiologic mechanisms that can lead to the higher risk for cardiovascular disease in SLE (2). Multiple endothelial markers with dysregulation in SLE have been described so far, of which some are associated with disease activity.

Objectives: To report a systematic literature review regarding endothelial markers that are dysregulated in SLE and search for associations with disease activity.

Methods: The search was performed according to the Preferred Reporting Items for Systematic review and Meta-analysis Protocols (PRISMA-P) 2015 (3). In July 2020, the search terms were used in Embase, MEDLINE, Web of Science, Google Scholar and Cochrane. Inclusion criteria were 1) published studies after the year 2000 that reported measurements of endothelial cell markers in serum and/or plasma of SLE patients (diagnosed according to ACR/SLICC criteria), 2) English language peer reviewed articles and 3) disease activity measurement (i.e. SLEDAI, BILAG, SLAM, ECLAM or PGA). Exclusion criteria were 1) case reports or editorials, 2) studies performed in animals and 3) studies with microRNA/cytokine biomarkers. There was no minimum count for study population. The screening process is shown in figure 1.

Results: From 1892 hits, we identified 110 eligible articles. Table 1 shows an overview of the most frequently studied endothelial markers. These identified endothelial markers are involved in endothelial cell (EC) activation, EC apoptosis, disturbed angiogenesis, defective vascular tone control, immune dysregulation and coagulopathy. In most studies, dysregulation of the endothelial marker was associated with disease activity. The majority of the studies had a cross-sectional design, longitudinal data on endothelial markers in SLE are scarce.

Conclusion: We identified multiple endothelial markers that are dysregulated in SLE and this dysregulation was often associated with disease activity in cross-sectional studies. Our future plan is to test the identified endothelial markers in (longitudinally collected) samples of (childhood onset) SLE patients, disease- and healthy controls. This will be a next step in unravelling the pathophysiology of premature atherosclerosis and cardiovascular events in SLE-patients in young adulthood.

Table 1.

Endothelial marker	Articles (no. of studies)	Significant correlation with SLEDAI (no. of studies)			Studies with control groups (no. of studies)		Longitudinal data (no. of studies)
		Yes	No	Unknown	Healthy controls	Diseased controls

AB0082 PERSISTENT LOW COMPLEMENT LEVELS AND INTERFERON GENE UPREGULATION ARE PREDICTIVE FOR DISEASE PROGRESSION IN PATIENTS WITH INCOMPLETE SYSTEMIC LUPUS ERYTHEMATOSUS

W. Lambers[1], J. Westra[2], S. Arends[2], B. Doornbos- van der Meer[2], B. Horvath[3], H. Bootsma[2], K. De Leeuw[2]. [1]*University Medical Centre Groningen, Rheumatology/Clinical Immunology, Groningen, Netherlands*; [2]*University Medical Center Groningen, Rheumatology/Clinical Immunology, Groningen, Netherlands*; [3]*University Medical Center Groningen, Dermatology, Groningen, Netherlands*

Background: A subgroup of lupus patients present with mild symptoms and immunologic features, while they do not meet classification criteria for SLE. This disease state can be referred to as "incomplete systemic lupus erythematosus" (iSLE). Up to 55% of iSLE patients progress to SLE. Furthermore, previous research has shown that iSLE might overlap with early primary Sjögren's disease (pSS).(1) Unfortunately, there are no predictive markers available for progression to classifiable disease. Type-I interferon (IFN) plays an important role in disease initiation of both SLE and pSS.(2,3) Myxovirus-resistance protein A (MxA) is a GTP-ase that has previously be demonstrated to correlate strongly with IFN-type I expression. Furthermore, interferon-inducible chemokines IFN-γ induced protein 10 (IP-10), and B-cell activating factor (BAFF), that are both inducible by IFN, are of interest, because it is demonstrated that these proteins are increased prior to the diagnosis of SLE.(4)
Objectives: To find predictive markers that identify patients with incomplete systemic lupus erythematosus (iSLE) who are at the highest risk to progress to classifiable systemic lupus erythematosus (SLE) or primary Sjögren's syndrome (pSS).
Methods: Patients with iSLE (ANA ≥ 1:80, ≥ 1 clinical SLICC criterion, but not fulfilling the criteria, and disease manifestation <5 years) were included in a longitudinal observational study. Every half year, clinical status was evaluated and regular immunological serologic assessment was performed. Annually, interferon (IFN)-gene expression was determined by RT-PCR in whole blood using 14 genes. These genes represented 3 IFN-related modules. Some genes were mainly inducible by IFN-type I, others by IFN-type II. Furthermore, IFN-related mediators Myxovirus resistance protein A (MxA), interferon-gamma-induced protein 10 (IP-10) and B-cell activating factor (BAFF) were measured.
Results: Of 38 included iSLE patients, 6 had developed SLE and 1 develop pSS (18%) after median follow up of 36 months. The 7 patients who developed SLE/pSS were all women, and were younger at baseline than those who remained having iSLE (median 26 years, IQR 20-29 vs. median 42 years, IQR 30-56, p=0.0009). Over time, these patients had significantly lower complement 3 (p<0.0001) and complement 4 levels (p=0.005), higher IFN-gene expression (p=0.007), and lower neutrophil counts (p=0.033) (see Figure 1.). No difference was found between IFN-type I and IFN-type II inducible genes. Levels of MxA, IP-10 and BAFF did not differ between patients who remained iSLE and who progressed to SLE/pSS.

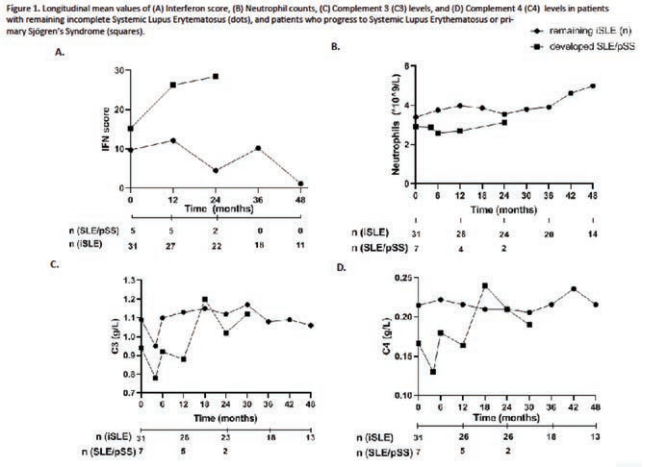

Figure 1.

Conclusion: Gender, age at diagnosis, persistent low complement levels, and high IFN-gene expression can help to identify iSLE patients at the highest risk of progressing to classifiable disease.

AB0083 SIGNALING OF PSGL-1 IN HUMAN NEUTROPHILS MIGHT CONTROL NET GENERATION AND APOPTOSIS AND MIGHT BE ALTERED IN SLE PATIENTS

A. Muñoz-Callejas[1], E. González Sánchez[1], E. F. Vicente-Rabaneda[2], J. Garcia Perez[3], S. Castañeda[2], A. Urzainqui[1]. [1]*Instituto de Investigación Sanitaria-Hospital de la Princesa, Inmunologia, Madrid, Spain*; [2]*Hospital de la Princesa, Reumatologia, Madrid, Spain*; [3]*Hospital de la Princesa, Neumologia, Madrid, Spain*

Background: Neutrophil extracellular traps (NETs) are extracellular chromatin fibers decorated with neutrophil antimicrobial proteins and histones, which are formed by neutrophils to trap invading pathogens and facilitate their removal. Excessive presence of NETs has been reported in autoimmune diseases like Systemic Lupus Erythematosus (SLE) and has been related with disease pathogenesis [1]. Our previous work showed that P-selectin KO mice develop an autoimmune syndrome similar to human lupus and that patients with cutaneous lupus have reduced expression of P-selectin in skin vessels [2]. Although it has been reported that P-selectin might induce NET generation in mouse neutrophils [3], there are no studies performed with human neutrophils.
Objectives: 1)To analyze the contribution of PSGL-1/P-Selectin interaction to control the generation of NETs by human neutrophils from healthy donors and patients with SLE.
2)To study the implication of PSGL-1/P-Selectin interaction in the control of other types of neutrophil death.
Methods: Human neutrophils were isolated from healthy donors and patients with SLE. After incubation *in* vitro with BSA or P-Selectin in rolling-like conditions (60 rpm shaking at 37^{0}C) for 10 min, neutrophils were left to adhere for 1 hour. Then, NETs were labeled with Sytox Green and quantified by fluorimetry and by flow cytometry (FACSCanto II, BD Biosciences). For quantification of necrosis and apoptosis, cells were labeled with propidium iodide and annexing V and analyzed by flow cytometry. Data were analyzed with two-sided Student, two-sided Mann-Whitney U or two-sided Wilcoxon signed rank test using GraphPad Prism software (Version 8.0.1, La Jolla, CA). Results were considered significant at P<.05.
Results: Our results show that rolling on BSA, compared to adhesion, induces NET generation and apoptosis of neutrophils isolated from blood of healthy donors. Rolling on P-selectin reduces apoptosis of neutrophils and increase the percentage of NET events, although reducing NET intensity. Comparing to healthy donors, neutrophils from active SLE patients generate NETs with higher intensity in adhesion and do not respond to P-Selectin.
Conclusion: The interaction of PSGL-1 with P-Selectin preserves neutrophil death from apoptosis and controls NET generation. Our results suggest that this control might be altered in patients with active SLE.

AB0084

INCREASED LEVEL OF NEUROPILIN-1 IN CD4+ T CELL AND ITS CORRELATION WITH DISEASE ACTIVITY OF SYSTEMIC LUPUS ERYTHEMATOSUS

Y. J. Choi[1], E. K. Lee[1], M. S. Lee[2], C. H. Lee[2], C. H. Chung[2], W. H. Yoo[1]. [1]*Research Institute of Clinical Medicine of Jeonbuk National University-Biomedical Research Institute of Jeonbuk National University Hospital, Internal Medicine, Jeonju, Korea, Rep. of (South Korea)*; [2]*Wonkwang University Hospital, Internal Medicine, Iksan, Korea, Rep. of (South Korea)*

Background: Semaphorin has been found as a neuronal guidance molecule, but has recently been called "immune semaphorin", as their critical role in immune cell activation, differentiation and migration has been revealed. In particular, class 4 semaphorin has been shown to contribute to lymphocyte activation and immune homeostasis.
Objectives: This study was aimed to investigate the expression of neuropilin-1 (NRP-1), the receptor of class 4 semaphorin, in the murine mouse model of systemic lupus erythematosus (SLE) and the patients with SLE and the correlation between the expression of NRP-1 and disease activity of SLE.
Methods: The expression of NRP-1 was measured in T cells in spleen and renal tissue in control mouse and TLR-7 agonist-induced lupus mouse by flow cytometry, PCR, and immunofluorescence (IF). CD4+ T cells from human peripheral blood were isolated to investigate the expression of NRP-1 in healthy control and the patients with SLE (n=40).
Results: The frequency of NRP-1 positivity in CD4+ T cells in spleen was significantly higher in lupus mouse group (median [interquartile range]: 15.34 [14.84] %) compared to vehicle mouse group (4.0 [2.77]%). The quantitative analysis of fluorescense intensity in kidney stained for NRP-1 revealed the increased level in lupus group compared to vehicle group. The CD4+ T cells from peripheral blood mononuclear cells in the patients with lupus also showed significantly higher frequency of NRP-1 positive CD4+ T cells than those from healthy controls. Comparing the correlation of the expression of NRP-1 and disease activity with SLEDAI, C3, C4, and anti-DNA antibodies, the significant correlation between NRP-1 and disease activity markers were confirmed.
Conclusion: Our results demonstrate that higher expression of NRP-1 in CD4+ T cells and its significant correlation with disease activity of SLE. These results indicate that pathologic contribution of NRP-1 in the pathogenesis of SLE and potential of targeting NRP-1 for the treatment of SLE.

AB0085

ANTI-MULLERIAN HORMONE IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Z. Alekberova[1], R. Goloeva[1], M. Cherkasova[1], A. Lila[1]. [1]*VA Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases, Moscow, Russian Federation*

Background: Anti-Mullerian hormone (AMH) is one of the key parameters for assessing reproductive function and ovarian reserve. The level of AMH correlates with the residual follicular pool in women of reproductive age.
Objectives: To assess AMH levels in SLE female patients of child-bearing potential, and analyze the relationship between AMH levels and disease severity, as well as relationship between serum AMH levels and different therapeutic regimens.
Methods: The study group included 12 women with SLE aged 20-40 years, and the control group - 15 age-matching healthy women. SLE diagnosis was established based on the EULAR/ACR classification criteria, 2019. The SLEDAI 2K was used to evaluate disease activity, and the SLICC index – to evaluate damage. AMH levels was measured using ELISA. AMH reference values ranged within 1.0-10.6 ng / ml. Values <1.0 were interpreted as a decreased ovarian reserve.
Results: SLE patients' mean age was 33.5 [29;38] years, and control group subjects' - 32.0 [26;35] years. Mean disease duration was 11.5 [2.8;18] years. Acute, subacute and chronic SLE was established in 33%, 17%, and 50%, respectively. Disease activity according to SLEDAI 2K was low in 25%, moderate – in 33%, and high – in 42% of pts. The SLICC damage baseline evaluation: no damage – 17%, low – 50%, medium – 16.5%, high-16.5%.
Mean AMH level was 3.5 ng/ml in SLE pts, and 3.1 ng/ml - in the control group, showing no statistical difference. A decrease in ovarian reserve (AMH less than 1.0 ng / ml) was significantly more common in SLE pts - 42% vs 13% in the control group. No correlation was found between AMH levels and the SLICC damage index, AMH and SLEDAI 2K, as well as AMH and SLE duration or clinical course. Detailed analysis showed that all pts with reduced ovarian function had CP included into their therapeutic regimens; the only exclusion within this subgroup – i.e., normal AMH level-6 ng/ml and preserved ovarian function - was documented in a patient who received a cumulative CP dose of 5.6 g. In all other patients a cumulative CP dose was higher, i.e.: 7.2 g, 7.8 g, 10.6 g, and 18.4 g – 1 patient per each dose value. Three pts with low AMH levels within 0.1 -0.3 ng/ml were 39 years old, while AMH reference values in 33-39y age group are 0.77-5.24 ng / ml. Analysis of gynecological history indicate that episodes of menstrual disorders were significantly more often reported in SLE pts (50% vs 20% in controls, p=0.001), similarly, gynecological diseases were also documented in 50% of SLE pts (chronic salpyngo-oophoritis, colpitis, endometriosis and uterine endometrioma, subserous uterine myoma, cervical dysplasia, cervical erosion), meanwhile low AMH was found only in 4 SLE pts; there was only 1 subject with gynecological condition – teratoma of the ovaries – in the control group (favorable outcome – surgical removal, preserved fertility and two births after surgery).
Conclusion: Ovarian reserve was significantly more often reduced in women with SLE compared to healthy controls. CP therapy negatively affects ovarian function, and most likely in a dose-dependent manner. In this study, 4 out of 5 patients with reduced ovarian function had gynecological diseases additionally compromising the ovarian reserve. Further studies are needed to clarify potential contribution of both - autoimmune inflammation and SLE therapy – into development of gynecological diseases and loss of fertility.

AB0086

PREGNANCY OUTCOMES IN SYSTEMIC LUPUS ERYTEMATOSUS (SLE)

Z. Alekberova[1], R. Goloeva[1], T. Popkova[1]. [1]*V A Nasonova Research Institute of Rheumatology, systemic rheumatic disease, Moscow, Russian Federation*

Background: There's no doubt that SLE has negative effect not only on the course of pregnancy, but also on maternal and fetal outcomes.
Objectives: To clarify pregnancy outcomes in patients with SLE by means of retrospective analysis.
Methods: The study group included 12 women with SLE aged 20-40 years, and the control group - 15 age-matching healthy women. SLE diagnosis was established based on the EULAR/ACR classification criteria, 2019. The SLEDAI 2K was used to evaluate disease activity, and the SLICC index – to evaluate damage. Completed by all women issue-specific questionnaire covered clinical symptoms of SLE and details of obstetric history (characteristics of menstrual and reproductive function, presence of genital and extragenital pathology, previous pregnancies outcomes; previous intrauterine interventions, a history of coagulopathy).
Results: SLE patients' mean age was 33.5 [29;38] years, and control group subjects' - 32.0 [26;35] years. Mean disease duration was 11.5 [2.8;18] years. Acute, subacute and chronic SLE was established in 33%, 17%, and 50%, respectively. Disease activity according to SLEDAI 2K was low in 25%, moderate – in 33%, and high – in 42% of pts. The SLICC damage baseline evaluation: no damage – 17%, low – 50%, medium – 16.5%, high-16.5%. Past pregnancies were documented in 7 out of 12 SLE patients and 6 healthy subjects from the control group. Spontaneous vaginal delivery of a full-term baby was documented in both groups. Unfavorable pregnancy outcomes were significantly more frequent in SLE pts (31% vs 13% in the control group, p= 0.001). Two SLE pts after cyclophosphane therapy (10.6 and 18.4 g cumulative dose) and low AMH levels (< 1 ng/ml) failed to become pregnant, although never used contraception.

Table 1. Pregnancy outcomes

Pregnancy, n	SLE, n=16	Control, n=15	*p*
Birth	9 (56,3%)	13 (87%)	0,00
Abortion	2 (12,5%)	0	0,00
Unfavorable pregnancy outcome	5 (31,2%)	2 (13%)	0,00
Missed miscarriage	4 (25%)	0	0,00
Spontaneous abortion	1 (6%)	2 (13%)	ns

Analysis of gynecological history indicate that episodes of menstrual disorders were significantly more often reported in SLE pts (50% vs 20% in controls, *p*=0.001), similarly, gynecological diseases were also documented in 50% of SLE pts (chronic salpyngo-oophoritis, colpitis, endometriosis and uterine endometrioma, subserous uterine myoma, cervical dysplasia, cervical erosion), meanwhile low AMH was found only in 4 SLE pts; there was only 1 subject with gynecological condition – teratoma of the ovaries – in the control group (favorable outcome – surgical removal, preserved fertility and two births after surgery).
Conclusion: The incidence of unfavorable pregnancy outcomes is significantly higher in patients with SLE compared to the control group of healthy women.

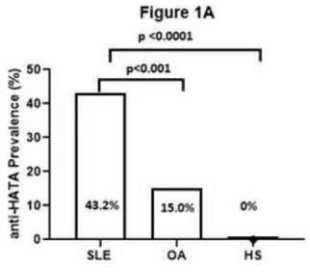
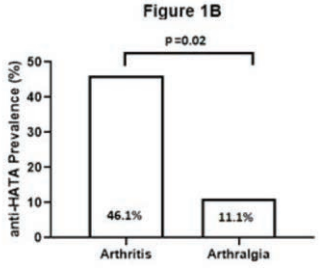
AB0087 AUTOANTIBODIES DIRECTED AGAINST HOMOCYSTEINYLATED ALPHA 1 ANTITRYPSIN AS A POTENTIAL NEW BIOMARKER FOR ARTHRITIS IN PATIENTS AFFECTED BY SYSTEMIC LUPUS ERYTHEMATOSUS

F. Natalucci[1,1], F. Ceccarelli[1], T. Colasanti[1], G. Olivieri[1], A. I. Celia[1], C. Barbati[1], M. Speziali[1], F. Ucci[1], C. Pirone[1], C. Ciancarella[1], F. R. Spinelli[1], C. Alessandri[1], F. Conti[1]. [1]*Policlinico Umberto I, Sapienza University of Rome, Department of Clinical, Internal Medicine, Anesthesiology and Cardiovascular Sciences, Rome, Italy*

Background: Joint involvement represents one of the most frequent features in patients affected by Systemic Lupus Erythematosus (SLE). This manifestation is characterized by a great heterogeneity in phenotype and severity: the application of more sensitive imaging techniques identified an erosive damage in about 25% of patients (1). This damage has been associated with autoantibodies, such as anti-citrullinated (ACPA) and anti-carbamylated proteins (antiCarP), previously identified in patients Rheumatoid Arthritis (RA) patients. Recently, homocysteinylated alpha 1 antitrypsin (Hcy-1A1AT) has been identified as a new antigenic target of autoantibodies in seronegative RA patients: in detail, anti-homocysteinylated alpha 1 antitrypsin (anti – HATA) antibodies have been identified in 75.7% of patients (2).
Objectives: In the present study, we aimed at determining the prevalence of anti – HATA in a cohort of SLE patients.
Methods: We evaluated patients affected by SLE according to the 1997 ACR criteria. Demographic, clinical, and laboratory data were collected in a standardized computerized electronically filled form. Each subject underwent peripheral blood sample collection. Hcy-A1AT was obtained by in vitro modification of native A1AT and used as antigens by ELISA to test the presence of anti–HATA in sera obtained from enrolled subjects. Finally, we investigated the presence of ACPA and Rheumatoid Factor (RF) commercial ELISA kits and of anti-CarP (home-made ELISA) by a home-made ELISA in SLE patients' sera. As control, we enrolled 40 patients affected by Osteoarthritis (OA) and 41 healthy subjects (HS).
Results: The present analysis included 88 SLE patients (M/F 6/82 median age 47 years (IQR 17), median disease duration 156 months (IQR 180). Joint involvement was observed in 75 SLE patients (85.2%): in detail, 65 patients referred arthritis and the remaining 10 inflammatory arthralgias. We identified the presence of anti–HATA IgG in 38 SLE patients (43.2%). This prevalence was significantly higher in comparison with OA and HS subjects [15.0% (p<0.001) and 0% (p<0.0001), respectively; Figure 1A]. Focusing on the SLE cohort, no differences were observed between patients with and without joint involvement in anti–HATA IgG prevalence (41.3% versus 34.7%, respectively; p=0.34). However considering SLE patients according to the presence of arthralgia and arthritis, the prevalence of anti-HATA was significantly higher in patients with arthritis in comparison with those patients with arthralgias (46.1% versus 11.1%, p=0.02; figure 1B). Finally, no significant association between anti-HATA and the other tested autoantibodies (RF, ACPA, anti-CarP) was found.





Conclusion: We evaluated the prevalence of anti-HATA in a cohort of SLE patients. The prevalence of these autoantibodies was significantly higher in SLE patients than in OA patients and in HS. The association with arthritis suggests a possible role for anti-HATA as biomarkers of SLE-related joint involvement.

AB0088 QUALITY OF LIFE IN PATIENTS WITH ANTIPHOSPHOLIPID ANTIBODIES DIFFERS ACCORDING TO ANTIPHOSPHOLIPID SYNDROME DAMAGE INDEX (DIAPS)

S. G. Foddai[1,2], M. Radin[1,2], A. Barinotti[1,2], I. Cecchi[1,2], E. Rubini[1,2], S. Sciascia[1,2], D. Roccatello[1,2]. [1]*Turin, Università di Torino, Turin, Italy*; [2]*Turin, Center of Research of Immunopathology and Rare Diseases - Coordinating Center of Piemonte and Valle d'Aosta Network for Rare Diseases, Department of Clinical and Biological Sciences, Turin, Italy*

Background: Antiphospholipid syndrome (APS) is a rare autoimmune disorder that mainly affects young individuals. Due to the potentially devasting effects of some of its clinical manifestations, such as ischemic stroke and thrombotic microangiopathy, APS can have a deep negative impact on the quality of life (QoL) of the affected patients due to damage accrual (2).
To capture the full consequences of the disease, including both thrombotic and extra-criteria APS specific features, the antiphospholipid syndrome (APS) damage index (DIAPS), a 37-item score, was conceived.
Objectives: The aim of this study was to validate the DIAPS in a cohort of antiphospholipid antibodies (aPL) positive subjects, comparing it to the risk stratification score for the development of clinical manifestations of APS (Global APS Score -GAPSS) and QoL questionnaires filled out by APS patients.
Methods: This retrospective study included a total of 84 consecutive persistent aPL positive patients who attended the San Giovanni Bosco Hospital (Turin, Italy). Patients were then divided based on their diagnosis in 3 groups: primary APS (PAPS), secondary APS (SAPS) and aPL positive patients without clinical manifestations of APS, according to Miyakis criteria (1). Demographic, clinical and laboratory characteristics, were retrieved from electronic medical records and are summarized in Table 1. DIAPS was calculated as previously reported by adding together all points corresponding to the clinical manifestations of the patients (3).
Results: A total of consecutive 84 patients were enrolled in the study: 39 primary APS patients (PAPS), 28 secondary APS patients (SAPS) and 17 aPL positive patients without APS-related clinical manifestations. APS patients had significantly higher levels of DIAPS when compared to aPL asymptomatic patients (mean DIAPS 2.6 ±1.8 vs. 1.5 ±1.9, respectively; p<0.05). Moreover, SAPS patients had significantly higher levels of DIAPS when compared to PAPS patients (mean DIAPS 3.1 ±1.9 vs. 2.2 ±1.7, respectively; p<0.05). When comparing GAPSS and DIAPS levels in all the patients, we found a significantly positive correlation between these two scores (mean GAPSS 11.9 ±5.2 and mean DIAPS 2.4 ±1.9; Pearson 0.241; p<0.05). Finally, when applying the SF-12 score to our cohort, the mean physical component score and mental component score were lower than the average population (39.3 ±11.3 and 42.3 ±8, respectively) and we observed a negative correlation trend between DIAPS and both PCS and MCS (Pearson -0.133 and -0.183).

Table 1. Clinical and laboratory characteristics of the patients

	PAPS (n=39)	SAPS (n=28)	aPL asymptomatic (n=17)
Anagraphic			
Mean age (S.D.) at data collection	50.6±13.7	47.4±12.1	48.6±11.3
Sex (females), n	29 (74.4%)	29 (74.4%)	29 (74.4%)
Secondary diagnosis, n	N/A	SLE 24 (85.7%) SSJ 1 (3.6%) UCTD 1 (3.6%) MCTD 2 (7.1%)	SLE 8 (45.1%)
Clinical manifestations of APS			
Thrombosis, n	30 (76.9%)	26 (92.9%)	N/A
Arterial thrombosis, n	20 (51.3%)	14 (50%)	N/A
Venous thrombosis, n	17 (43.6%)	15 (53.6%)	N/A
Pregnancy morbidity, n	11 (28.2%)	4 (14.3%)	N/A
aPL profile at diagnosis			
LA, n	31 (79.5%)	23 (82.1%)	12 (70.6%)
aCL (IgG/M), n	22 (56.4%)	18 (64.3%)	10 (58.9%)
Anti-β2GPI (IgG/M), n	18 (46.2.%)	16 (57.1%)	3 (17.6%)
aPS/PT (IgG/M), n	23 (59%)	21 (75%)	8 (47.1%)

Conclusion: The DIAPS might be a valid score system for the assessment of APS-related damage and QoL.

SILDENAFIL COUNTERACTS THE ACTIVATION OF CXCR3/CXCL10, -11 AXIS IN SCLERODERMA FIBROBLASTS EXPOSED TO REACTIVE OXYGEN SPECIES

C. Antinozzi[1], I. Dimauro[1], P. Sgrò[1], D. Caporossi[1], F. Del Galdo[2,3], L. DI Luigi[1]. *[1]University of Rome Foro Italico, Movement, Human and Health Sciences, Rome, Italy*; *[2]University of Leeds, Institute of Rheumatic and Musculoskeletal Diseases, Leeds, United Kingdom*; *[3]NIHR Biomedical Research Centre, University of Leeds, Leeds, United Kingdom*

Background: Oxidative stress associated with vascular damage represents one the major contributor in the pathogenesis of systemic sclerosis (SSc) [1]. Indeed, different studies demonstrated that excessive free radicals production can contribute to the activation of fibrotic process in the skin and visceral organs [1]. CXCL10 and CXCL11, together with their receptor CXCR3, are involved in vascular damage and in fibrosis [2]. Furthermore, these chemokines have been proposed as biomarkers of vascular damage progression and severe SSc prognosis [3].
Emerging evidences highlight the beneficial effects of the phosphodiesterase type 5 (PDE5) inhibitor, sildenafil, to protect different cell types from reactive oxygen species (ROS)-induced DNA damage, *in vitro* [3]. This effect has been linked to modulation of CXCL10 concentration in different pathological conditions [4,5].
Objectives: Here we set out to investigate the effects of sildenafil, in modulating the CXCR3/CXCL10, -11 inflammatory axis in dermal fibroblasts exposed to oxidative stress, *in vitro*.
Methods: Human dermal fibroblasts isolated by SSc skin biopsies were treated for 24h with 100µM of hydrogen peroxide (H_2O_2), in the presence or not of sildenafil (1µM). Dermal fibrobalsts from healthy skin were used as controls. CXCL10 and CXCL11 were evaluated in cell medium by luminex technology assay; expression of chemokine receptor (CXCR)3 and peroxisome proliferator-activated receptor (PPARγ) (a regulator of CXCL10,-11 mRNA) was evaluated by western blot assay.
Results: As showed in figure 1, SSc fibroblasts (grey bar) showed similar basal levels of CXCL10 (A) and CXCL11 (B) to healthy controls (black bar). H_2O_2 induced a significant increase of both chemokines only in SSc fibroblasts (by 4.6 fold for CXCL10 and by 4.2 fold for CXCL11) (*P<0.05 and **P<0.01 *vs.* c; #P<0.05 *vs*. healthy controls). Sildenal pre-incubation reduced by approximatively 50% the effects of H_2O_2 on chemokines release (Figure 1A and B) (§P<0.05 vs. H_2O_2), and reduced the expression of CXCR3 and PPARγ induced by hydrogen peroxyde exposure (data not shown).
Conclusion: *In vitro* study on dermal fibroblasts support clinical studies to determine the efficacy of sildenafil in the preventing tissue damage and fibrosis in SSc, by reducing the pro-inflammatory activation induced by oxidative stress.

THE BIOCHEMICAL BASIS OF ANIMAL MODEL OF SYSTEMIC SCLEROSIS

B. Doskaliuk[1], L. Zaiats[1], R. Yatsyshyn[2]. *[1]Ivano-Frankivsk National Medical University, Pathophysiology, Ivano-Frankivsk, Ukraine*; *[2]Ivano-Frankivsk National Medical University, Internal Medicine #1 Clinical Immunology and Allergology, Ivano-Frankivsk, Ukraine*

Background: Systemic sclerosis (SSc) is a heterogeneous autoimmune pathology, which detailed pathogenetic mechanisms of initiation and progression still require further investigations. It could be achieved with implementation of reliable experimental modeling techniques.
Objectives: This study was aimed to determine the state of oxidant/antioxidant system, dysregulation of collagen synthesis in laboratory animals and evaluate effectiveness of the considered model of SSc induction.
Methods: Thirty adult Wistar rats (220-240 g) were included in the study. The experimental group consisted of 20 animals, which received 3 subcutaneous injections of 0.5 ml of 5% sodium hypochlorite solution (NaClO) with an active chlorine concentration of 190 g / dm^3 for 6 consecutive weeks. The control group consisted of 10 rats injected with isotonic solution according to the previously described scheme.
Results: The level of catalase in the experimental group was lower than in the control 9.69 ± 0.67 g / l and 11.1 ± 0.87 g / l respectively (p = 0.002). Protein oxidative modification (POM) products were higher in the experimental group (0.0722 ± 0.023 vs 0.0527 ± 0.023, p = 0.014). Malondialdehyde (MDA) was also higher in the experimental group compared to the control (4.30 ± 0.26 and 3.85 ± 0.23, respectively, p = 0.010). The concentration of oxyproline in the serum of laboratory animals subjected to repeated administration of NaClO was significantly higher compared to the control group (34.03 ± 5.01 and 33.23 ± 2.40, p = 0.020).
Conclusion: As a result of the use of NaClO for the reproduction of SSc in laboratory animals, there is a violation of oxidative-antioxidant homeostasis and increased fibrotic processes. These changes are comparable with those in SSc patients, which makes this modeling technique a promising tool for a detailed investigation of SSc pathogenesis.

INHIBITION OF AUTOPHAGY PREVENTS PROGRESSION OF FIBROSIS IN MURINE MODELS OF SYSTEMIC SCLEROSIS

A. Zehender[1], Y. N. Li[1], N. Y. Lin[1], A. H. Györfi[1], A. Soare[1], C. Bergmann[1], A. Ramming[1], G. Schett[1], J. H. W. Distler[1]. [1]*Medicine 3 of the University Clinic Erlangen, Medizin 3, Erlangen, Germany*

Background: Autophagy is catabolic process allowing cells to degrade unnecessary or dysfunctional cellular organelles. Failure of appropriate regulation of autophagy, however, can severely perturb tissue homeostasis. Recent studies demonstrate that autophagy is activated in several fibrotic diseases such as liver fibrosis, renal interstitial fibrosis, cardiac fibrosis.
Objectives: The objective of this work was to characterize the activation of autophagy in systemic sclerosis (SSc) and to decipher its role in the pathogenesis of SSc.
Methods: Activation of autophagy in skin samples of patients and murine models of SSc was assessed by co-staining of LC3B and P62 with the lysosomal marker LAMP2. The role of the autophagy was investigated in the model of bleomycin-induced dermal fibrosis. Beclin1 was overexpressed using adenovirus encoding for *Beclin1*. To knockdown *Atg7 in vivo* was achieved by subcutaneous injections of *Atg7* siRNA or non-targeting siRNA. *In vivo*, 3-methyladenine (3-MA) was administered i.p. in a concentration of 15 mg/kg ones daily. Protein expression was measured by Western blot. Target genes were analyzed by qPCR. To monitor the autophagic flux, we generated adenoviral vectors encoding for tandem fluorescent-tagged *LC3* (mRFP-EGFP-LC3).
Results: In the present study, we demonstrate that autophagy is activated in fibroblasts in SSc skin and also in experimental fibrosis models as compared to respective non-fibrotic control tissue with enhanced activity in *in vivo* and *in vitro* autophagy reporter studies. The aberrant activation of autophagy had profound stimulatory effects on fibroblasts. Activation of autophagy by forced expression of BECLIN1 promoted fibroblast-to-myofibroblast transition and stimulated the collagen release by cultured human fibroblasts and induced fibrosis in murine model. Nevertheless, inhibition of autophagy can deactivate myofibroblasts and induce regression of tissue fibrosis. Knockdown of *ATG7* or *BECLIN1* in human fibroblasts reduced the expression of αSMA and the number of stress fibers in myofibroblasts, indicating re-differentiation of myofibroblasts into resting fibroblasts upon inhibition of autophagy. Similar results were obtained with the autophagy inhibitors CQ and 3-MA. *In vivo*, siRNA mediated knockdown of *Atg7* effectively prevented progression of fibrosis in a model of established bleomycin-induced skin fibrosis. Inactivation of autophagy decreased dermal thickness, myofibroblast counts and hydroxyproline content to below pretreatment levels, indicating regression of bleomycin-induced skin fibrosis. In addition, treatment of mice with the autophagy inhibitor 3-MA ameliorated bleomycin-induced skin fibrosis.
Conclusion: We demonstrate that autophagy activity is enhanced in fibroblasts of SSc patients and in murine models of SSc. The increased activation of autophagy induces fibroblast-to-myofibroblast transition and promotes fibrotic tissue remodeling. However, inhibition of autophagy can deactivate myofibroblasts and induce regression of tissue fibrosis.

ANTISYNTHETASE SYNDROME: CLINICAL PROFILE, SEROLOGIC AND TREATMENTS USED IN A COHORT OF PATIENTS FOLLOWED AT THE VIRGEN MACARENA HOSPITAL

P. Muñoz Reinoso[1], I. García Hernández[1], M. Ferrer Galván[2], F. J. Toyos Sáenz de Miera[1], L. Fernández de la Fuente Bursón[1], J. J. Pérez Venegas[1]. [1]*Hospital Universitario Virgen Macarena, Reumatología, Sevilla, Spain*; [2]*Hospital Universitario Virgen Macarena, Neumología, Sevilla, Spain*

Background: The antisynthetase syndrome (SAS) is characterized by the presence of antisynthetase antibodies, anti-JO1, PL7 y PL12 are the most common; and the classic triad of myositis, arthritis, and diffuse interstitial lung disease (ILD)[1]. Most patients present incomplete forms and the severity of the ILD determines the prognosis of the disease[2].
Objectives: to analyze epidemiological, clinical and serological characteristics and treatments used in a cohort of patients with SAS.
Methods: descriptive study of review of medical records. Data were collected from 15 patients with SAS followed in the Rheumatology and Pneumology consultations of the Virgen Macarena Hospital (Seville) in the last 10 years. The analysis was carried out using the R software.
Results: 15 patients were included, 8 men and 7 women. The median age was 56 years (33-77). Seven patients (47%) used to smoke. Four patients (27%) met the classical triad. All of them presented ILD and 8 patients (53%) had arthritis and / or myositis. Five (33%) had mechanic's hands and six of them (40%) presented Raynaud. Seven (47%) suffered from dyspnea before the SAS diagnosis. The median diagnostic delay was 1 month (0-43). Seven (47%) patients had anti-JO1, 1 (7%) anti-PL7, 2 (13%) anti-PL12 and 2 (13%) patients anti-Ro52. Radiological patterns detected by HRCT were: 5 (33%) NINE, 4 (37%) NIU and 6 (40%) others. The initial treatment included mostly (66%) glucocorticoids (GC) and one or more cFAME. In maintenance, mycophenolate was used in 7 patients (47%), cyclosporine 5 (33%), cyclophosphamide in 3 cases (20%), azathioprine in 3 patients (20%) and methotrexate in 3 of them (20%). Four (37%) patients required a combination of DMARDs and 2 cases needed (13%) biological therapy, Rituximab and Tocilizumab. Changes in the mean value of the initial respiratory function tests (FVC1 and DLCO1) and during follow-up (FVC2 and DLCO2) were not relevant (FVC1 81.5% [42-110], FVC2 81% [59-115]; DLCO1 83% [10-112], DLCO2 80.5% [47-108]). Nine patients (60%) remained clinically stable and 3 patients (20%) progressed radiologically. Four patients died from ILD progression.
Conclusion: In this study, the incomplete diagnosis of SAS predominated. The most detected antibody was anti-JO1. ILD is present in all cases, with NINE being the most frequent pattern so multidisciplinary management is necessary. Most used treatments were GC and FAMES combined, some cases required biological therapy.

CLINICAL AND SEROLOGICAL CHARACTERISTICS OF SYSTEMIC SCLEROSIS: EXPERIENCE FROM A TERTIARY CARE CENTER IN PAKISTAN

S. Asif[1,2,2], M. Haroon[1], A. Khan2, M. Faiq[1]. [1]*Fatima Memorial Hospital, Lahore, Rheumatology, Lahore, Pakistan*; [1]*Fatima Memorial Hospital, Lahore, Rheumatology, Lahore, Pakistan*

Background: Systemic sclerosis (SS) is less studied Connective tissue disease in our population. It is characterized by different manifestations which if left undiagnosed and untreated lead to serious complications. The hallmark of this disease is fibrosis of various organs including skin and also involving pulmonary, gastrointestinal and cardiovascular system. We aim to evaluate the clinical and serological characteristics of SS in our population. In addition, we evaluated the prevalence of Fibromyalgia and Depression in patients with SS.
Objectives: We aimed to determine Clinical and Serological Characteristics of Systemic Sclerosis visiting our department of Rheumatology, Fatima Memorial hospital, Lahore.
Methods: It is a cross-sectional study of 38 patients visiting outdoor and indoor in Rheumatology department of Fatima Memorial Hospital from September 2019 to January 2020. All systemic sclerosis patients with age 16 years or above were included in this study. After taking informed consent, we filled the performas to record all the required information. We evaluated the clinical, serological and radiological features of Systemic Sclerosis.
Results: A total of 38 patients were included in the study with mean age was 34.47 ± 1.53 years. Female gender comprised of 32(84.2%), with male to female ratio of 1:5.3. Thirty-four (89.5%) had developed Raynaud phenomenon and sclerodactyly was found in 34(89.5%), digital ulcers in 25 (65.8%), and tendon friction rub in 12 (31.6%) patients. Skin tightness proximal to elbow was present in 9 (23.7%). Microstomia (decreased mouth opening) was present in 32(84.2%) patients. Twenty-eight (73.7%) patients had arthritis.Respiratory symptoms comprised of shortness of breath in 36(94.7%), palpitation in 24 (63.2%) and chest

pain in 7(18.4%). Gastrointestinal (GI) symptoms comprised of regurgitation in 31 (81.5%) and dysphagia in 14 (36.8%). Interstitial lung disease was present in 30 (78.9%) patients, with higher prevalence in diffuse scleroderma (100%) than in limited scleroderma (70%) (p=0.01). Pulmonary hypertension was present in 18 patients, with significantly higher prevalence in diffuse disease (57.1%), that was secondary to interstitial lung disease and in limited disease it was found in (11.8%) (p<0.01). Thirty (78.9%) patients were found to have restricted disease on pulmonary function tests.

Obstetric history showed a higher prevalence of primary infertility in at least 6 (15.8%) patients, with significantly higher prevalence in limited systemic sclerosis disease as compared to diffuse disease (23.5% vs 9.5%, and p=0.05). Fibromyalgia diagnosed as per ACR criteria was present in 7 (18.4%) patients, and depression assessed by Hospital Anxiety and depression (HADS) score was present in 10 (26.3%) patients.

Anti nucleic acid antibody (ANA) was found positive in 30 (78.9%) patients. Anti Scl-70 antibodies were in 24 (63.2%) patients, with significant association with diffuse disease (85% vs 35.3% and p<0.01), while anti centromere antibodies were present in 20 (52.6%) patients; significantly higher in limited disease (94.2% vs 19.0%, and p<0.01).

Conclusion: Scleroderma is a very important, autoimmune multisystem disease. It has female preponderence. Raynaud phenomenon is the most initial clinical feature followed by other manifestations of variable course and disease severity. Interstitial lung disease and pulmonary hypertension were the most important complication found in our patients which has poor prognosis. So, It is imperative to early diagnose and treat the disease manifesations to prevent future complications.

Keywords: Scleroderma, Systemic sclerosis.

Background: Endothelial progenitor cells (EPC), involved in vasculogenesis and endothelial tissue repair, have been described as relevant players in vascular and connective tissue diseases [1-2]. In this regard, a previous study of our group disclosed that the degree of EPC frequency may help to identify the presence of interstitial lung disease (ILD) in rheumatoid arthritis patients [3]. Given that ILD is the main cause of mortality in patients with systemic sclerosis (SSc) [1, 4-6], the understanding of the role of EPC in the mechanism of SSc-ILD$^+$ vasculopathy is crucial.

Objectives: To assess the potential role of EPC on vascular dysfunction associated with the presence of ILD in patients with SSc.

Methods: Peripheral venous blood was collected from a total of 39 patients with SSc, 20 with ILD (SSc-ILD$^+$) and 19 without ILD (SSc-ILD$^-$). All subjects were recruited from the Rheumatology and Pneumology departments of Hospital Universitario Marqués de Valdecilla, Santander, Spain. Quantification of EPC was analyzed by flow cytometry. EPC were considered as CD34$^+$, CD45^{Low}, CD309$^+$ and CD133$^+$.

Results: Statistically significant differences in EPC frequency between patients with SSc-ILD$^+$ and patients with SSc-ILD$^-$ were disclosed. Specifically, an increase of EPC frequency was observed in SSc-ILD$^+$ patients when compared to patients with SSc-ILD$^-$ (mean ± standard deviation: 0.033 ± 0.012 *versus* 0.021 ± 0.017, respectively, p=0.012).

Conclusion: Our results suggest a potential role of EPC on vascular damage associated with the manifestation of ILD in patients with SSc.

AB0095 EXPRESSION AND PATHOGENIC ROLES OF INTEGRIN FAMILY GENE IN SYSTEMIC SCLEROSIS

D. Xu[1], T. Li[1], R. Mu[1]. *[1]Peking University Third Hopsital, Department of Rheumatology and Immunology, Beijing, China*

Background: Emerging evidence have shown that some integrin members are associated with inflammation and fibrosis in systemic sclerosis (SSc) patients[1-2]. However, the expression patterns and pathogenic significance of the whole integrin family in SSc are still unclear.

Objectives: This study aimed at evaluating the integrin family gene expression in skin lesion from SSc patients and exploring its potential pathogenic mechanism.

Methods: We utilized the public datasets of SSc skin tissue from Gene Expression Omnibus (GEO) database to analyze the expression and clinical significance of integrin family genes in SSc. In addition, functional enrichment and pathway analysis were also conducted.

Results: Compared with healthy controls, ITGA5, ITGA7, ITGA8, ITGB2, ITGB5, ITGAE and ITGB3BP were abnormally overexpressed in the skin of SSc. Further analysis indicated that ITGA5, ITGA7, ITGA8, ITGB2 and ITGB5 were positively correlated with modified Rodnan skin thickness score (mRSS), while ITGAE and ITGB3BP were negatively correlated with mRSS in SSc. Increased ITGB5 expression was associated with positive of anti-centromere antibody (ACA). Functional enrichment and pathway analysis showed that integrin members had multiple functions in SSc. Among them, ITGA5, ITGB2 and ITGB5 might synergistically promote SSc through affecting extracellular matrix (ECM) turn over, ECM-receptor interaction, focal adhesion and leukocyte trans-endothelial migration. ITGA5 and ITGB5 also affected angiogenesis and endothelial cell function. In addition, ITGA5 was uniquely enriched for actin organization, ITGB5 was uniquely enriched for TGF-β signaling, and ITGB2 was uniquely associated with immune cells activation.

Conclusion: Our results implied that integrins, especially ITGA5, ITGB5, ITGB2 participated in the process of inflammation, vasculopathy and fibrosis in SSc. Together, they might render important therapeutic targets for SSc.

Background: IgA vasculitis (IgAV) and IgA nephropathy (IgAN) are inflammatory conditions that share pathogenic and molecular mechanisms [1] and may represent different outcomes of a continuous spectrum of disease [2]. *Interleukin (IL)17A* has been identified as a common genetic risk *locus* for several immune-mediated diseases [3, 4].

Objectives: To determine whether IgAV and IgAN exhibit a different *IL17A* association pattern.

Methods: Five *IL17A* tag polymorphisms (rs4711998, rs8193036, rs3819024, rs2275913 and rs7747909) were genotyped in 388 Caucasian patients with IgAV, 99 patients with IgAN and 1,003 sex and ethnically matched healthy controls.

Results: No statistically significant differences between patients with IgAV and healthy controls and between patients with IgAN and healthy controls were observed when each *IL17A* genetic variant was analyzed independently (Table 1). Similarly, IgAV patients exhibited similar genotype and allele *IL17A* frequencies than those with IgAN (Table 1). Moreover, no genotype or allele differences between IgAV patients who developed nephritis and patients with IgAN were detected. Furthermore, haplotype frequencies were similar in patients with IgAV, IgAV and nephritis and those with IgAN.

Table 1. Genotype and allele frequencies of *IL17A* gene in patients with IgA vasculitis, patients with IgA nephropathy and healthy controls.

Polymorphism	Change	Data set	1/1	1/2	2/2	1	2
rs4711998	G/A	IgAV	53.4 (207)	38.9 (151)	7.7 (30)	72.8 (565)	27.2 (211)
		IgAN	49.0 (48)	42.9 (42)	8.2 (8)	70.4 (138)	29.6 (58)
		Controls	52.7 (529)	41.2 (413)	6.1 (61)	73.3 (1471)	26.7 (535)
rs8193036	T/C	IgAV	57.0 (221)	38.4 (149)	4.6 (18)	76.2 (591)	23.8 (185)
		IgAN	64.3 (63)	31.6 (31)	4.1 (4)	80.1 (157)	19.9 (39)
		Controls	60.3 (605)	35.2 (353)	4.5 (45)	77.9 (1563)	22.1 (443)
rs3819024	A/G	IgAV	44.1 (171)	43.3 (168)	12.6 (49)	65.7 (510)	34.3 (266)
		IgAN	39.4 (39)	54.5 (54)	6.1 (6)	66.7 (132)	33.3 (66)
		Controls	45.6 (457)	44.6 (447)	9.9 (99)	67.8 (1361)	32.2 (645)
rs2275913	G/A	IgAV	44.6 (172)	43.3 (167)	12.2 (47)	66.2 (511)	33.8 (261)
		IgAN	39.8 (39)	53.1 (52)	7.1 (7)	66.3 (130)	33.7 (66)
		Controls	44.8 (449)	44.2 (443)	11.1 (111)	66.8 (1341)	33.2 (665)
rs7747909	G/A	IgAV	53.9 (209)	39.4 (153)	6.7 (26)	73.6 (571)	26.4 (205)
		IgAN	41.1 (39)	54.7 (52)	4.2 (4)	68.4 (130)	31.6 (60)
		Controls	53.0 (532)	39.4 (395)	7.6 (76)	72.7 (1459)	27.3 (547)

Conclusion: Our results revealed that IgAV and IgAN share a similar *IL17A* association pattern.

AB0097

DIAGNOSTIC ACCURACY OF SERUM MARKERS IN LARGE VESSEL VASCULITIS AND CORRELATION WITH PET IMAGING

R. Bilici Salman[1], H. Satış2, A. Avanoglu Guler3, H. Karadeniz3, H. Küçük[1], S. Haznedaroglu[1], A. Tufan[1], B. Goker[1], U. O. Akdemir[4], L. O. Atay[4], H. Paşaoğlu[5], M. A. Ozturk[1]. *[1]Gazi University School of Medicine, Rheumatology, Ankara, Turkey*; *[1]Gazi University School of Medicine, Rheumatology, Ankara, Turkey*; *[1]Gazi University School of Medicine, Rheumatology, Ankara, Turkey*; *[4]Gazi University School of Medicine, Nuclear Medicine, Ankara, Turkey*; *[5]Gazi University School of Medicine, Biochemistry, Ankara, Turkey*

Background: The onset of symptoms in large-vessel vasculitis (LVV) tends to be subacute, which often leads to a delay in diagnosis, during which time vascular disease may start and progress to become symptomatic. PET/CT has been recognised since the 2003s as a promising tool in evaluating of LVV. There is no gold standard diagnostic laboratory tests for this patient group, novel markers for active LVV is needed.

Objectives: to investigate the association between vascular inflammation, as detected by PET imaging and interleukin-6 (IL-6), pentraxin3 (PTX3), and B-cell-activating-factor (BAFF) in subjects with LVV.

Methods: The study included 67 patients patients with newly diagnosed GCA (n= 27) or TA (n=9) and healthy control (n= 31) who had been referred to the Rheumatology Unit at Gazi University, between December 2017 and August 2020. PET images obtained from an 29 patients (22 with GCA and 7 with TA) who had not received any corticosteroid treatment prior to PET imaging and blood sampling. IL-6, PTX3, and BAFF levels were determined quantitatively by enzyme-linked immunosorbent assay (ELISA) kits.

Results: 36 patients with LVV (20 females,16 males; age 64,5±16,6) and 31 HC (14 females,17 males; age37,1±9,6) were analysed. Serum levels of IL-6,PTX3, BAFF, ESR and CRP are increased in patients with newly diagnosed LVV compared with those in control subjects. In a ROC analysis, serum IL-6 provided excellent discrimination of newly diagnosed LVV patients from HC, as indicated by AUCs>0.90. Serum BAFF also accurately distinguished newly diagnosed LVV patients from HC with AUCs>0.80. Serum PTX3 did not provide an AUC>0.80. In this study, we correlate vascular inflammation, as detected by PET imaging in newly diagnosed LVV patients, with the ESR, CRP. PTX3, IL-6 and BAFF. As a result, none of these markers has been associated with vascular inflammation as measured using PET.

Conclusion: In conclusion, our study shows that serum levels of PTX3, IL-6 and BAFF are increased in most LVV patients. The diagnostic value of BAFF and IL-6, both separately and in combination, should be further evaluated in larger cohorts of LVV patients, as well as in patients with infections or other inflammatory conditions. However, none of these markers has been associated with vascular inflammation as measured using PET.

AB0098 **ASSOCIATED FACTORS IN ONE-YEAR MORTALITY IN PATIENTS WITH SMALL VESSEL SYSTEMIC VASCULITIS**

E. M. Escudero Tepale[1], M. A. Saavedra[1], D. Miranda[1], Z. Castro[1], M. J. R. Arriga Torres[2]. [1]*Hospital La Raza Puerta 4, Reumatología, Ciudad de México, Mexico*; [2]*Hospital De Cardiologia Hospital siglo XXI, Cardiología, Mexico City, Mexico*

Background: The highest mortality rates in patients with small vessel systemic vasculitis occur within the first year after the diagnosis, however associated factors have been scarcely studied in our population.
Objectives: To identify mortality associated factors at the time of diagnosis in patients with small vessel systemic vasculitis.
Methods: Retrospective cohort (2009-2020) involving 81 patients diagnosed with systemic small vessel vasculitis. Demographic, clinical and biochemical parameters were studied as potential factors associated with one-year mortality.
Results: Of the total of patients (n=81), 36 (44.4%) had generalized granulomatosis with polyangiitis, 32 (39.5%) had localized granulomatosis with polyangiitis and 5 (6.2%) had early systemic granulomatosis with polyangiitis, 7 (8.6%) had microscopic polyangiitis and 1 (1.25%) had eosinophilic granulomatosis with polyangiitis. Twenty-two deaths (27%) were observed, 14 of them (63.6%) happened within the first year of diagnosis. The leading cause of death was infection (64%). Patients who died within the first year of diagnosis had a higher frequency of hypoalbuminemia (p=0.05) and also presented hemoglobin lower than 10.8 g/dL (p=0.035) in comparison with those who died after the first year of diagnosis. Remission induction treatment did not differ between both groups.
Conclusion: Our study suggests that hypoalbuminemia and anemia are factors associated with a higher mortality within the first year after the diagnosis in patients with systemic small vessel vasculitis which contrast with previously reported data. The study design and the reduced number of patients are two major limitations of the study.

Rheumatoid arthritis - prognosis, predictors and outcome

AB0099 **IN VIVO BONE MICROARCHITECTURE ANALYSIS IN A PSORIATIC ARTHRITIC PATIENT BEFORE AND AFTER ANTI-TNFA TREATMENT**

E. Soldati[1,2,3], L. Escoffier[4], S. Gabrie[5], J. P. Mattei[1,4], S. Camilleri[5], D. Bendahan[1], S. Guis[1,4]. [1]*AixMarseille University, CNRS, CRMBM-CEMEREM, UMR CNRS 7339, Marseille, France*; [2]*Aix-Marseille University, CNRS, IUSTI, UMR CNRS 7343, Marseille, France*; [3]*Aix-Marseille University, CNRS, ISM, UMR CNRS 7287, Marseille, France*; [4]*Aix-Marseille University, Service de Rhumatologie, AP-HM, Marseille, France*; [5]*Institut Fresnel, Aix-Marseille Université, Service de Médecine Nucléaire, AP-HM, CNRS UMR 7249, Marseille, France*

Background: In psoriatic arthritis (PA), a systemic inflammatory phenomenon, mainly mediated by TNFα, is characterized by a bone loss due to osteoclastic stimulation. Anti-TNFα treatment should inhibit this phenomenon having a role on systemic bone loss. Ultra-high field MRI (UHF MRI) may be a tool of choice for the quantification of bone microarchitecture (BM) *in vivo*.
Objectives: The purpose of the present study was to quantify BM using UHF MRI in a PA patient and to follow up changes related to anti-TNFα treatment.
Methods: An 18 years-old untreated PA patient with knee arthritis and 7 gender-matched healthy controls [21.6±0.8 years] were scanned using a gradient echo sequence at UHF MRI (TR/TE = 15/4.36ms). After a year of Adalimumab treatment, the patient underwent a second UHF MRI. BM analysis was performed on sagittal planes in regions corresponding to tendon insertion: proximal and distal patellar, and posterior tibial. A PET-FNa imaging was also performed before and after treatment. BM was characterized using the bone volume fraction (BVF), the trabecular thickness (TbTh) and the spacing (TbSp) and number of trabeculae (TbN). Student T-test was used for the statistical analysis and a p-value < 0.01 was considered as significative.
Results: PET-FNa recorded before the treatment illustrated hypermetabolic areas which resumed after the treatment while the patient was in remission. The BM parameters are shown in figure 1. The BM parameters quantified before the treatment were very different as compared to controls. BVF was significatively lower (-33±23%), TbSp and TbN were significatively distinct (-27±3% and +27±9%) for all ROIs but proximal patellar, while TbTh was in the normal range (-2±2%). After 1 year of treatment, BM parameters were significantly improved. BVF was no longer different than controls (-8±6%). Similarly, TbSp and TbN were in the normal range (+13±12% and -15±10%) for all ROIs but posterior tibial. TbTh (-5±3%) was only significantly decreased for the distal patella.

		Healthy	P. before treatment	P. after treatment
Proximal Patella	BVF	0.393±0.008	0.339±0.018 *	0.401±0.010
	TbTh	0.254±0.013	0.254±0.022	0.266±0.014
	TbSp	0.364±0.032	0.477±0.058	0.365±0.008
	TbN	1.550±0.074	1.301±0.136	1.493±0.073
Distal Patella	BVF	0.355±0.035	0.222±0.064 *	0.328±0.027
	TbTh	0.261±0.010	0.250±0.015	0.285±0.004 *
	TbSp	0.469±0.117	0.651±0.057 *	0.532±0.064
	TbN	1.366±0.114	0.994±0.090 *	1.116±0.083
Posterior Tibia	BVF	0.381±0.009	0.307±0.016 *	0.335±0.018
	TbTh	0.258±0.008	0.260±0.009	0.267±0.012
	TbSp	0.426±0.060	0.594±0.012 *	0.570±0.016 *
	TbN	1.468±0.073	1.185±0.047 *	1.241±0.029 *

Table 1. Data are presented as mean ± SD. "P." refers as patient. BVF: Bone volume fraction, TbTh: Trabecular Thickness, TbSp: Trabecular Space, TbN: Trabecular number. * indicates a statistically significant difference (p < 0.01) with the Healthy reference values.
Conclusion: Our results illustrated knee microstructure alterations in a PA patient and a normalization after a year of treatment. The abnormalities initially observed were not only localized in the hypermetabolic regions identified by PET-FNa, suggesting that the bone loss was global and not related to inflammatory sites.
Using UHF MRI, we highlighted and quantified *in vivo* BM anomalies in a patient with an inflammatory rheumatism together with the reversibility after one year of treatment.

AB0100 **EVALUATION OF PGA LEVEL FOR CLINICAL REMISSION WITH BOOLEAN CRITERIA, 10MM OR 20MM?**

I. Yoshii[1]. [1]*Yoshii Hospital, Rheumatology and Musculoskeletal Medicine, Shimanto City, Japan*

Background: Patient's global assessment (PGA) is one important component of Boolean composite criteria for remission in treat with rheumatoid arthritis (RA). However, PGA no more than 10mm is sometimes obstacle to attain clinical remission. In recent few years, one opinion that PGA no more than 20mm may be comparable as no more than 10mm.
Objectives: The aim of this study is to analyze how difference of these PGA level affect disease activity and daily activities in living, and evaluate which is optimal for the remission with Boolean remission criteria from real world setting.
Methods: RA patients who were followed up for more than three years in the institute were picked up in the study. Each patient was monitored with tenderness joint count (TJC), swollen joint count (SJC), PGA, evaluator's global assessment (EGA), serum C-reactive protein level (CRP), calculated disease activity score with simplified disease activity index(SDAI), Health Assessment Questionnaire Disability Index (HAQ-DI), and pain score using visual analog scale (PS-VAS) every consulted time from the first encounter (Baseline). Patients were classified according to achievement of Boolean remission criteria. Group 1: a patient group who attained Boolean remission wih TJC≦1, SJC≦1, CRP≦1mg/dl, and PGA≦1 (G-1), Group 2: a patient group who could not attained the Boolean remission used in the G-1 evaluation, but could attained another Boolean remission with TJC≦1, SJC≦1, CRP≦1mg/dl, and PGA≦2 (G-2), and Group 3: a patient group who could not attain Boolean remission for neither criterion.
Mean values of measured parameters at Baseline and after the Baseline were compared statistically with Student T-test. Mean values of the same parameters in the G-1 and G-2 at the time of attain Boolean remission for each criteria, mean values of each of these parameters thereafter, and changes of these parameters were compared statistically with Student T-test.
Results: A total of 438 patients 385 in the G-1 group, 16 in the G-2 group, and 37 in the G-3 group, were recruited. In parameters at Baseline, level of TJC, SJC, PGA, EGA, SDAI, and HAQ-DI in the G-1 was significantly lower than in the G-3, whereas no significant differences in any parameters demonstrated between in the G-2 and G-3. Level of HAQ-DI, and PS-VAS after Baseline in the G-1 was

lower than in the G-3, whereas no significant difference of these parameters after Baseline demonstrated between in the G-2 and G-3. TJC, SJC, PGA, and EGA demonstrated significant less level in the G-1 than in the other two groups. The mean SDAI score at the time of first achievement of Boolean remission in the G-1 and G-2 were 1.08 and 2.57, respectively. The mean value of SDAI score after remission in the G-1 and G-2 were 3.35 and 6.44, respectively. These values and PS-VAS including change of the SDAI score demonstrated significant difference between the two groups (p<0.01), whereas HAQ-DI in the two groups demonstrated no significant difference.

Conclusion: These results suggested that setting PGA as no more than 10mm should be reasonable for the evaluation of clinical remission with the Boolean criteria.

AB0101 THE IMPACT OF TIME SPAN TO ACHIEVE BOOLEAN REMISSION FOR MAINTAINING DISEASE ACTIVITY AFTER ACQUISITION IN RHEUMATOID ARTHRITIS PATIENT

I. Yoshii[1]. [1]*Yoshii Hospital, Rheumatology and Musculoskeletal Medicine, Shimanto City, Japan*

Background: Boolean remission criteria is one most popular and stringent criteria in treating patient with rheumatoid arthritis (RA), because it may guarantees a stable clinical course after attaining remission.

Objectives: Impact of time span from initiation to achieving Boolean remission on maintaining disease activity, daily activities, and quality of life after attaining Boolean remission was investigated from daily clinical practice data.

Methods: 685 patients with RA since August 2010 under the T2T strategy were treated. They were monitored for their TJC, SJC, PGA, EGA, CRP, and disease activity indices such as CDAI, SDAI, DAS28, and Boolean criteria at every visit. HAQ-DI score, pain score using visual analog scale (PS-VAS), and EQ-5D were also monitored, and the quality of life score (QOLS) calculated from EQ-5D was determined at every visit from the time of diagnosis (baseline).

Of 685 patients, 465 patients had achieved Boolean remission >1 times, and were consecutively followed up for >3 years. These patients were enrolled in the study. Time span from the first visit to first Boolean remission was calculated. The relationship between the time span and each of background parameters, and the relationship between the time span and each of the mean values of the SDAI score, HAQ score, PS-VAS, SHS, and QOLS at the first Boolean remission and thereafter was evaluated statistically.

Patients were subsequently divided into the G ≤ 6 and G > 6 groups based on the achievement of first Boolean remission within two groups: time span G ≤ 6 months and G > 6 months. The two groups were compared with regard to the SDAI score, HAQ score, PS-VAS, SHS, and QOLS at first visit and at the time of first Boolean remission, and the mean values of these parameters after remission were evaluated statistically. Moreover, changes of these parameters and the mean Boolean remission rate after the first remission, and SDAI remission rate at the first Boolean remission to thereafter were compared between the two groups statistically.

Results: Out of 465 patients, females comprised 343 (73.7%), and the mean age was 67.8 years (range, from 21–95 years). The mean disease duration at first visit was 6.1 years (range, from 1 months–45 years). The mean follow up length was 88.1 months (range: 36–122 months; median: 85 months) and mean time span from the first visit to the first Boolean remission was 8.1 months. The mean SDAI score, HAQ score, PS-VAS, and the QOLS at first visit were 13.3, 0.467, 33.2, and 0.834, respectively. Among the study parameters, PS-VAS and QOLS were significantly correlated with the time span. For parameters at the first Boolean remission, HAQ-DI score, PS-VAS, and QOLS demonstrated significant correlation with the time span, whereas SDAI, HAQ-DI score, PS-VAS, SHS, and QOLS after the Boolean remission demonstrated significant correlation with the time span.

The comparison between the G ≤ 6 and the G > 6 groups revealed that the disease duration, HAQ score, and PS-VAS at baseline in the G > 6 were significantly higher than that in the G ≤ 6 group, and QOLS in the G ≤ 6 group was significantly higher than that in the G > 6 group at baseline. Similarly, the HAQ score and PS-VAS at the first Boolean remission in the G > 6 group were significantly higher than that in the G ≤ 6 group, whereas QOLS in the G ≤ 6 group demonstrated no significant difference compared with that in the G > 6 group.

The mean value of the SDAI score after the first Boolean remission in the G > 6 group was significantly higher than that in the G ≤ 6 group. Similarly, the SDAI score, HAQ score, and PS-VAS after the first Boolean remission in the G > 6 group were also significantly higher than those in the G ≤ 6 group, and the mean value of the QOLS in the G ≤ 6 group were significantly higher than that in the G > 6 group. The Boolean remission rate and SDAI remission rate after the first Boolean remission were significantly higher in the G ≤ 6 group than those in the G > 6 group.

Conclusion: Attaining Boolean remission ≤ 6 months for RA has significant benefit for more stable disease control, that leads good maintenance of ADL.

AB0102 EVALUATOR'S GLOBAL ASSESSMENT REFLECTS DISEASE ACTIVITY BUT NOT LINEARLY CORRELATES WITH DAILY ACTIVITY OR QUALITY OF LIFE COMPARED TO PATIENT' GLOBAL ASSESSMENT

I. Yoshii[1]. [1]*Yoshii Hopital, Rheumatology and Musculoskeletal Medicine, Shimanto City, Japan*

Background: Evaluator's global assessment (EGA) is the one component of indexed disease activity evaluation assessed by the rheumatologist for treatment of rheumatoid arthritis (RA). It does not included in the Boolean remission criteria nor 28-joints disease activity score (DAS28), however it is widely recognized among rheumatologist as an only comprehensive and objective assessment parameter.

Objectives: The aim of this study is to evaluate how EGA correlates with other components and the influence of EGA on disease activity and daily activity, and quality of life.

Methods: A total of 24,075 times of monitoring out of 683 RA patients who were followed up for more than three consecutive years was performed. Contents of monitoring included tenderness joint count (TJC), swollen joint count (SJC), patient's global assessment (PGA), EGA, C-reactive protein (CRP), and calculated values of DAS28, SDAI, composite index of Boolean evaluation, pain score with visual analog scale (PS-VAS), Health Assessment Questionnaire Disability Index (HAQ-DI), and quality of life score (QOLS) calculated from Euro-QOL questionnaire with 5th dimensions. Each measurement was classified with the EGA score divided by one increment from zero to ten. Mean values of DAS28, CDAI, SDAI, remission rate of these indices and Boolean remission rate, and mean values of PS-VAS, HAQ-DI, and QOLS were statistically evaluated. Results were compared to the results that was analyzed in according to the PGA score substituted with the EGA score.

Moreover, EGA at the time of Boolean remission of the patients who achieved Boolean remission at least once during treating were picked up. Patients were classified according to the EGA level with 0.5 increment from zero. Mean value of TJC, SJC, PGA, EGA, SDAI, Boolean remission rate, HAQ-DI, and PS-VAS after attaining Boolean remission were compared statistically.

Results: Number of measures counted 15424, 2001, 3688, 1731, 664, 293, 144, 88, 29, 2, and 11 for each level of EGA. The EGA score tended to concentrate more in zero to two in comparing to the PGA score. Mean DAS28, CDAI, and SDAI demonstrated significant increase as the EGA level increased, and remission rate of the all indices including Boolean demonstrated significant decrease as the EGA level increases (p<0.01%). CDAI, SDAI, and Boolean remission rate demonstrated zero percent from two. Mean value of PS-VAS and HAQ-DI score demonstrated also significant decrease as the EGA level increases, and QOLS demonstrated significant decrease as the EGA level increases (p<0.01%). However, these tendency showed more irregular compared to that analyzed with the PGA score. Correlation coefficients with regarding to the EGA score was always less than that with regarding to the PGA score.

In the patients who achieved Boolean remission, EGA levels were divided with 294 with zero (G-0) and 118 with 0.5 (G-.5), whereas 71 could not achieve Boolean remission. Average TJC (p<0.05), SJC (p<0.001), EGA (p<0.001), CRP (p<0.05), and SDAI (p<0.01) level in the G-0 group demonstrated significant less than in the G-.5 group, whereas PGA, Boolean remission rate, HAQ-DI, and PS-VAS demonstrated no significant difference in between the two groups.

Conclusion: It is more reliable to estimate daily activity and quality of life from the PGA score than to estimate from the EGA score. EGA correlates with SJC and CRP more strongly than with TJC and CRP. EGA does not reflect HAQ-DI and PS-VAS.

AB0103 THE ACCURACY OF ADMINISTRATIVE HEALTH DATA FOR IDENTIFYING PATIENTS WITH RHEUMATOID ARTHRITIS: A VALIDATION STUDY USING MEDICAL RECORDS IN WESTERN AUSTRALIA

K. Almutairi[1], J. Nossent[1], D. Preen[2], H. Keen[1], K. Roger[3], C. Inderjeeth[1]. [1]*The University of Western Australia, School of Medicine, Perth, Australia*; [2]*University of Western Australia, School of Population and Global Health, Perth, Australia*; [3]*Sir Charles Gairdner Hospital, General Medicine, Perth, Australia*

Background: The use of large administrative health datasets is increasingly important in Rheumatology for disease trends and outcome research (1). We established the West Australian Rheumatic Disease Epidemiological Registry

containing longitudinal health data for over 10000 patients with Rheumatoid Arthritis (RA) in Western Australia (WA). Accuracy of coding for RA is essential to validity of the datasets.

Objectives: Investigate the diagnostic accuracy of International Classification of Diseases (ICD) based discharge codes for RA at WA's largest tertiary hospital.

Methods: Medical records for RA patients randomly selected from the hospital discharge database with ICD 10 codes (M05.00–M06.99) from 2008–2020 were retrospectively reviewed. Rheumatologist reported diagnosis and ACR/EULAR classification were used as gold standards to determine positive predictive value (PPV) with 95% Confidence Interval (CI) for RA primary diagnostic codes.

Results: Medical chart review was completed for 87 patients (mean age 64.7 years, 67% female). Total of 80 (92%) patients had specialist confirmed RA diagnoses, while seven patients (8%) had alternate clinical diagnoses providing a PPV of 93.5% (95%CI: 89.9 to 95.86). Overall, 69 out 87 patients (79.3%) fulfilled ACR/EULAR classification criteria based on RA primary diagnostic codes with a PPV of 80.5% (95%CI: 76.81 to 83.7). A combination of a diagnostic RA code with biologic infusion codes in two or more codes increased the PPV to 97.9%.

Conclusion: Hospital discharge diagnostic codes in WA identify RA patients with a high degree of accuracy. Combining a primary diagnostic code for RA with biological infusion codes can further increase the PPV.

Background: Involving the patients with rheumatoid arthritis (RA) in the assessment of their disease may increase their adherence to treatment, improve the disease outcomes and facilitate the application of telehealth. We previously reported an excellent concordance between the Disease Activity Score (DAS-28) performed by physicians and patients at the baseline visit of this prospective study (1).

Objectives: To evaluate the persistence of the concordance between the physician' and the patient's assessment of disease activity in RA using DAS-28 after one year.

Methods: At the baseline visit, patients with RA from 7 Middle Eastern Arab Countries (MEAC) were briefed about DAS-28 by their rheumatologist during a routine consultation and given smartphone access to a video in Arabic language explaining the performance of DAS-28. At 3, 6 and 12 months (± 3 months), the patients were asked to self-report DAS-28, blinded to the physician's assessment. Concordance between the continuous DAS-28 at each visit was calculated using paired t-test numerically and the Bland-Altman method graphically. Agreement between physician- and patient-DAS categories (remission, low-, moderate- and high disease activity) was calculated at each visit using weighted kappa for category comparison. Weighted kappa of the different agreements were compared over time using their respective confidence intervals (CIs). Predictive factors of positive concordance between physician and patient-DAS were identified using binary logistic regression.

Results: The study included 428 patients over a period of three years (2018 to 2020). The mean age of participants was 49.8 years, 82.5% were females, 44.3% had a university degree and the mean disease duration was 11.4 years.

At baseline, the average patient-DAS was higher (4.06 (±1.52)) than the physician-DAS (3.97 (±1.52)). The mean difference was -0.09 [95%CI -0.14; -0.04] and most of the pairs were within the limit of agreement in the Bland-Altman graph, indicating a good concordance, particularly in cases of remission.

During the study follow-up, 299 patients consulted for visit 2 (69.9% of the total population), 232 for visit 3 (54.2%) and 199 for visit 4 (46.5%). The weighted kappa was 0.80 [95%CI 0.76;0.85] at visit 1 and 0.79 [95%CI 0.72;0.88] at visit 4 (Figure 1 showing kappa for DAS-28, CDAI and SDAI as well). A minor numerical decrease in kappa was observed over time; however, the CIs were overlapping over the four visits and the agreement was considered stable, remaining in the excellent range. At visit 4, a positive concordance between the physician- and the patient-DAS was associated with the profession (lower in blue collar, p=0.001), the educational level (higher in high school and university, p=0.034) and the baseline physician's DAS (higher in high disease activity, p=0.46).

Conclusion: The agreement between the DAS-28 performed by the physician and by the patient was excellent at baseline and remained stable over one year. A positive concordance was associated with the profession, the educational level and the level of disease activity. The present study can help the rheumatologist make informed decisions about the patients who may be suitable for a remote evaluation of their disease activity, that can be of particular interest in the context of the COVID-19 pandemic.

AB0105

A SYSTEMATIC REVIEW OF THE MULTI-BIOMARKER DISEASE ACTIVITY SCORE FOR THE DIAGNOSIS AND TREATMENT IN RHEUMATOID ARTHRITIS

D. Abdelhafiz[1], M. Bukhari[2]. [1]*Lancaster, Lancaster Medical School, Lancaster, United Kingdom*; [2]*University Hospitals of Morecambe Bay NHS Trust, Rheumatology, Lancaster, United Kingdom*

Background: Biomarkers are important tools that can be used in the diagnosis and monitoring of rheumatoid arthritis (RA). The multi-biomarker disease activity (MBDA) score has shown a clinical value in the overall management of patients with RA.
Objectives: To systematically explore the role of MBDA score for diagnosis and treatment of RA.
Methods: A systematic review was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) recommendations. Key words used included: 'Rheumatoid Arthritis', 'Biomarkers', 'Diagnosis', 'Treatment', 'Outcome', 'Response to treatment', 'Disease Activity', and 'MBDA' The literature search included papers published in 2020 and in the English language.
Results: This literature search has yielded 5 studies that investigated the impact of MBDA score on the diagnosis, treatment or disease progression of RA and have reported clear and clinically validated diagnostic or therapeutic effects. The first study prospectively investigated 130 patients with RA, and has shown that the MBDA score moderately correlated with disease activity at baseline (r = 0.36 for adjusted MBDA score, r = 0.44 for unadjusted MBDA score) and at 16 weeks follow up (r = 0.20 for adjusted MBDA, r = 0.30 unadjusted MBDA) but did not predict treatment response to methotrexate. There was also moderate correlation between MBDA scores and erythrocyte sedimentation rate (ESR) at baseline (r = 0.54 and 0.59) and week 16 (r = 0.42 and 0.51). The second was a cross-sectional study, which included 104 patients (50% female) and demonstrated that adjusted and unadjusted MBDA score correlated similarly with clinical disease activity. Adjustment for leptin reduced the influence of adiposity, particularly among women but significantly estimated higher disease activity in thin men and women. However, MBDA score predicted disease activity and response to tofacitinib treatment, measured by musculoskeletal ultrasound score (MSUS), in RA patients as demonstrated by the third prospective study that included 25 patients (all $p < 0.05$). Correlation was found between baseline MSUS and MBDA score, and with 12-week changes in clinical disease activity ($r = 0.45–0.62$, $p < 0.05$). Regression analysis showed associations between baseline MBDA score and 6-week (all $p < 0.05$) and 12-week change in change in clinical disease activity ($p = 0.03$). The fourth prospective study which included 92 patients with RA, showed that MBDA could predict response to treatment of methotrexate with or without prednisolone. The improvement was faster in the first month of treatment followed by gradual improvement over the following 6 months. Changes from baseline to 12 months for disease activity and MBDA score showed a significant correlation for methotrexate and prednisolone ($r = 0.57$, $p = 0.002$), methotrexate and placebo ($r = 0.57$, $p = 0.001$) and for all groups ($r = 0.56$, $p < 0.001$). The final prospective study which included 148 patients, showed that MBDA predicted remission in RA and could differentiate between small differences in disease activity (low disease activity vs remission states). Baseline MBDA score discriminated baseline remission, area under the curve (AUC) 0.68-0.75, and intermittent/sustained remission (AUC 0.65-0.74). MBDA also predicted long term remission after one year.
Conclusion: MBDA appears to be a useful tool in day-to-day clinical practice that can be used in the diagnosis, monitoring of treatment and prediction of outcomes of patients with RA. MBDA correlated well with disease activity and response to treatment. It is also a good predictor of long-term disease remission.

AB0106

ASSOCIATED FACTORS FOR PRESENTING WITH MODERATE TO HIGH DISEASE ACTIVITY ON THE FIRST RHEUMATOLOGY VISIT IN AN OUTPATIENT CLINIC-BASED COHORT OF COLOMBIAN RA PATIENTS: A REAL-WORLD CROSS-SECTIONAL STUDY

K. Maldonado-Cañón[1,2], P. Coral Alvarado[2,3], P. A. Mendez Patarroyo[2,3], E. Bermúdez[2], G. Quintana Lopez[1,2,3]on behalf of Reumavance Research Group. [1]*School of Medicine - National University of Colombia, Reumavance Research Group. Internal Medicine Department, Bogotá, Colombia*; [2]*Fundacion Santa Fe de Bogota University Hospital, Reumavance Research Group. Internal Medicine Department, Bogotá, Colombia*; [3] *School of Medicine - Universidad de Los Andes, Reumavance Research Group. Internal Medicine Department, Bogota, Colombia*

Background: Rheumatoid arthritis (RA) is characterized by autoantibody formation and expansion such as the rheumatoid factor (RF), anti-citrullinated protein antibodies (ACPA), and antinuclear antibodies (ANA). Autoantibody identification has been considered as crucial not only for the diagnosis but also for its eventual association with the disease activity, to the extent of playing a pivotal role as a poor prognostic factor among patients[1].
Objectives: Our aim was to assess the eventual association between certain clinical-epidemiological factors and presenting with moderate to high disease activity on the first rheumatology visit in an outpatient clinic-based cohort of Colombian RA patients.
Methods: We conducted a cross-sectional analytic study utilizing the database of an outpatient clinic based in the Rheumatology Department at *Fundación Santa Fe de Bogotá University Hospital*. Data were collected from May 2013 until Sep. 2020 and included age, gender, autoimmune- and non-autoimmune comorbidities, family history of autoimmunity (including RA), smoking and alcoholism personal history, previous DMARD and oral steroid use, nutritional status, disease duration defined as established or early RA (disease duration of ≤1 year before starting a DMARD), autoantibody profile information (RF, ACPA, and ANA), and disease activity, assessed by the DAS28- ESR. Multiple logistic regression with backward selection was performed to build the final fitted model.
Results: Data from a total of 1229 patients were included in the analysis. Our population was primarily female (n=938, 76,3%), the majority had an initial diagnosis of established RA (n=952 (77,5%), and presentation on the first consultation with moderate to high disease activity was seen on 65,2% of the cases (n=801). Being male and having an autoimmune comorbidity were statistically significant associated protective factors whereas strongly positive RF and ACPA levels, positive high ANA titres, and established RA were recognized as risk factors after adjustment for the effects of possible confounders such as age, smoking status, previous DMARD use, and family history of RA. Table 1 provides the complete results obtained from the multiple logistic regression model.

Table 1. Multiple logistic regression analysis's results.

	OR (95% CI)	p-value
Male	**0,52 (0,39 – 0,69)**	**< 0,0001**
Age	0,99 (0,99 – 1)	0,24
Autoimmune Comorbidities	**0,41 (0,21 – 0,80)**	**0,009**
Family History of RA	0,85 (0,61 – 1,14)	0,26
Current Smoking	1,26 (0,78 – 2,07)	0,29
History of Smoking	1,26 (0,81 – 2)	0,30
Previous DMARD use	0,91 (0,70 – 1,18)	0,45
RF strong titers i.e., > 80 U/ml	**1,56 (1,21 – 2,02)**	**0,0007**
ACPA strong titers i.e., > 80 U/ml	**1,59 (1,19 – 2,11)**	**0,0016**
ANA low positive titers i.e., < 1:640 dil.	0,94 (0,72 – 1,12)	0,67
ANA strong titers i.e., > 1:640 dil.	**1,98 (1,23 – 3,27)**	**0,0063**
Disease duration (established RA)	**1,41 (1,05 – 1,90)**	**0,0277**

Bold values indicate statistically significant.

Conclusion: These findings have significant implications for the understanding of the disease activity evaluated on the first contact of a RA patient with a rheumatologist. Our data supports the consideration of being male as a protective factor; however, suggest that autoimmune comorbidities could also condition a lower disease activity for such scenarios, which may be explained by the fact that such patients were referred from- and already being treated by- other practitioners. Additionally, our research provides insights for the consideration of high ANA titers as a potentially poor prognosis factor to be identified as early as on the first visit. ANA's use on daily practice is an intriguing matter which could be usefully explored in further research with distinct methodological approaches.

CHANGES IN EXTRACELLULAR MATRIX BIOMARKER C3M CORRELATE WITH ABATACEPT RESPONSE IN SEROPOSITIVE EARLY RA

S. L. Bridges[1], J. Buckner[2], M. A. Maldonado[3], V. Bykerk[4], N. Ray[5], S. Mukherjee[6], N. Ohtsuka[7]. [1]*Hospital for Special Surgery, Department of Medicine, New York, United States of America*; [2]*Benaroya Research Institute at Virginia Mason, Center for Translational Immunology, Seattle, United States of America*; [3]*Bristol Myers Squibb, Clinical R&D, Immunoscience, Princeton, United States of America*; [4]*Hospital for Special Surgery, Rheumatology, New York, United States of America*; [5]*Bristol Myers Squibb, Global Drug*

Development, Princeton, United States of America; [6]*Bristol Myers Squibb (at the time of analysis), Translational Medicine, Princeton, United States of America*; [7]*Bristol Myers Squibb, Japan Translational Medicine, Research and Development, Tokyo, Japan*

Background: Effective biomarkers are needed to guide RA treatment selection, and the importance of evaluating synovial tissue is increasingly recognised.[1] Markers of extracellular matrix (ECM) turnover (e.g. C3M, a marker of interstitial tissue degradation)[2] may have clinical utility as disease-relevant and surrogate biomarkers of synovial joint pathophysiology.
Objectives: To evaluate baseline (BL) correlations of ECM biomarkers with disease activity and the predictive value of ECM biomarkers in patients (pts) with seropositive early RA in the exploratory head-to-head Early AMPLE study (NCT02557100), and to explore the impact of shared epitope (SE) status.
Methods: Biologic-naive, MTX-inadequate responder adults with early (≤12 months' duration), active, moderate-to-severe RA were enrolled if they were anti-cyclic citrullinated peptide 2+ and RF+. Pts were randomised 1:1 to receive SC abatacept (ABA) 125 mg weekly or SC adalimumab (ADA) 40 mg every 2 weeks (wks) for 24 wks (single-blind period). Linear correlations between levels of ECM serum biomarkers (Nordic Biosciences) and disease activity (DAS28 [CRP], SDAI) at BL and change from BL (CfB) at Wk 24 were assessed in the overall population and by SE status (+/–); early (Wk 4) changes in biomarkers were also assessed.
Results: For SE+ (n=61) and SE– (n=18) pts at BL, mean (SD) DAS28 (CRP) was 5.3 (1.2) and 5.0 (1.0), and SDAI was 35.9 (16.2) and 34.0 (13.8), respectively. At BL in the overall population, significant medium correlations between C1M, C3M and C4M and disease activity were seen (Table 1). Correlations were generally higher in SE+ vs SE– pts, with C1M highly correlated with DAS28 (CRP) in SE+; correlations between C1M, C3M and C4M and disease activity were all significant in SE+ but not SE– pts. At Wk 24, overall CfB in C3M showed higher correlation with CfB in disease activity in pts receiving ABA (n=36; DAS28 [CRP]: 0.66 [p<0.0001]; SDAI: 0.53 [p=0.0009]) vs ADA (n=32; DAS28 [CRP]: 0.33 [p=0.0644]; SDAI: 0.39 [p=0.0267]); this was more pronounced in SE+ pts (ABA, n=27; DAS28 [CRP]: 0.70 [p=0.0001]; SDAI: 0.63 [p=0.0005] vs ADA, n=25; DAS28 [CRP]: 0.33 [p=0.1120]; SDAI: 0.41 [p=0.0445]). Changes at Wk 4 in C3M showed higher correlation with response to ABA vs ADA (Figure 1). Correlations between CfB (at Wks 4 and 24) in other biomarkers and response were generally similar between treatment groups.

Table 1. BL correlation of ECM biomarkers with BL disease activity

	Overall (N=77)		SE+ (n=60)		SE– (n=17)

Data are Spearman correlation coefficient, p value. Linear correlations by shading: light grey, low (0–<0.3); medium grey, medium (0.3–<0.6); dark grey, high (0.6–1). Pts with missing SE allele data not included.[a]n=75.[b]n=58.C1M, C2M, C3M, C4M=MMP-mediated degradation products of collagen type I, II, III and IV, respectively; CRPM=neo-epitope of MMP-mediated degradation of CRP; CTX-1=neo-epitope of cathepsin-mediated degradation of type I collagen; MMP=matrix metalloproteinase; SE–=0 SE alleles; SE+=≥1 SE allele.

Conclusion: Significant BL correlation between C1M, C3M and C4M and disease activity was seen and was generally numerically higher in SE+ vs SE– pts. Early (Wk 4) change in C3M and later (Wk 24) treatment response were more highly correlated in pts receiving abatacept vs adalimumab. The predictive value of ECM biomarkers for treatment response warrants study in a larger population.

AB0108 USING RNA SEQUENCING TO IDENTIFY GENE EXPRESSION SIGNATURES ASSOCIATED WITH RESPONSE TO ABATACEPT IN PATIENTS WITH RHEUMATOID ARTHRITIS

H. H. Chen[1], W. C. Chao[2], J. R. Wang[3], T. M. Ko[3]. [1]*Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China*; [2]*Taichung Veterans General Hospital, Department of Critical Care Medicine, Taichung, Taiwan, Republic of China*; [3]*National Chiao Tung University, Department of Biological Science and Technology, Hsinchu, Taiwan, Republic of China*

Background: Rheumatoid arthritis (RA) is a common chronic autoimmune disease. Abatacept (CTLA4-immunoglobulin) is one of the biological disease-modifying antirheumatic drug (bDMARD) for RA patients with indequate response to methotrexate. Recently, Yokoyama-Kokuryo et al. compared gene expression levels between abatacept responders and non-responders in RA patients using a microarray and found that type I IFN score and expression levels of nine genes may be used as a biomarker to predict response to abatacept. However, little study used RNA sequencing (RNA-seq) to identify whole blood gene expression signatures to predict therapeutic response to abatacept.
Objectives: The aim of this study is to identify gene expression signatures to predict therapeutic responses to abatacept in RA patients using RNA-seq.
Methods: This study is a single-center, prospective study. We used a PAX gene Blood RNA kit to collect whole blood at baseline and 4 weeks after abatacept treatment from RA patients. We also measured DAS28, physician global assessment, HAQ, ESR, CRP at baseline and 12 week to calculate EULAR response at 12 week. Patients with good EULAR response were defined as responders and those with moderate or no EULAR response were defined as non-responders.
Results: We finally conducted RNA-seq for whole blood from 7 RA patients initiating abatacept therapy. Of the 7 RA patients, one was non-responder and 6 were responders. We first use DESeq2 to analyze the differentially expressed genes of non-responder and responder before taking the drug. We used hierarchical clustering and PCA to evaluate the overall similarity of the samples, and group the patient data, and find that the nonresponder can be distinguished from responders. Subsequently, we analyzed the differentially expressed genes of the two groups of non-responder and responder patients before taking the drug. Before treatment, we found that 72 genes had a higher expression in the non-responder,

and 23 genes had a higher expression level in responders. Figure 1 showed the top 20 DEG Heatmap between the non-responder and responders.
Using these two sets of genes for GO analysis, we found that most of the pathways in the non-responder are related to immune response and cytokine production, and most of the pathways in the responders are related to antigen processing and MHC class II.

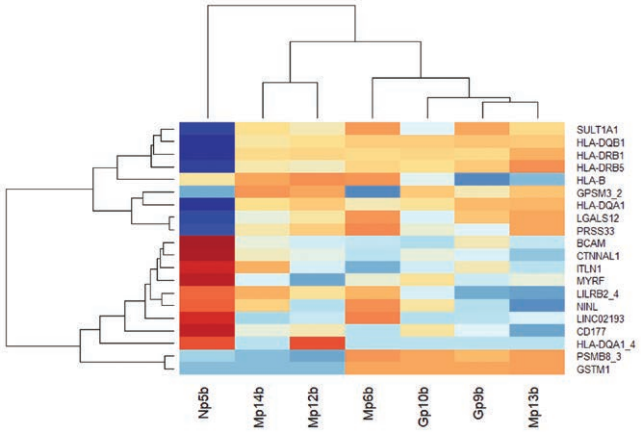

Figure 1. Top 20 DEG Heatmap between non-responder and responders

Conclusion: The study showed that most of the pathways in RA patients with no EULAR response to abatacept are related to immune response and cytokine production; while most of the pathways in RA patients with moderate/good response to abatacept are related to antigen processing and MHC class II.

AB0109 VALIDATION OF SEPARATE PATIENT-REPORTED, CLINICAL AND LABORATORY FACTOR SCORES AS REPRESENTATION OF DISEASE BURDEN IN A POPULATION WITH ESTABLISHED RHEUMATOID ARTHRITIS

S. Pazmino[1], A. Lovik[2], D. De Cock[1], V. Stouten[1], D. Bertrand[1], J. Joly[3], M. Doumen[1], R. Westhovens[1,3], P. Verschueren[1,3]on behalf of TapERA study group. [1]*Katholieke Universiteit Leuven, Skeletal Biology and Engineering Research Centre, Department of Development and Regeneration, Leuven, Belgium*; [2]*Katholieke Universiteit Leuven, I-Biostat, Leuven, Belgium*; [3]*UZ Gasthuisberg Campus, Department of Rheumatology, Leuven, Belgium*

Background: Rheumatoid arthritis (RA) can cause important bio-psychosocial burden. When exploring disease burden evolution in the 2-year Care in early RA (CareRA) trial, 3 factor scores were extracted via exploratory factor analysis (EFA).[1] EFA uncovers the fact that multiple observed variables have similar patterns of responses because they are all associated with a latent, not directly observable, variable.
Objectives: To validate in a population with established RA, the 3 factors scores and their individual components originally extracted in CareRA.
Methods: Patients with established RA in sustained remission under treatment with etanercept (≥1 year) were enrolled in the TapERA (Tapering Etanercept in RA) trial between 2012 and 2014. Patients completed the Flare Assessment in RA (FLARE-RA) questionnaire.[2]
Components of disease activity scores (swollen/tender joint count, physician and patient global health assessment, CRP and ESR), as well as pain (question 2) and fatigue evaluation (question 8), from the FLARE-RA questionnaire, and HAQ were recorded at every visit (v=5).
Missingness on previously mentioned variables was handled with multiple imputation (100 imputations). Pain and fatigue were re-scaled from their original Likert scale of 1-6 to 0-100 to match CareRA data. Next, timepoint clustering was removed with multiple outputation (1000x) and each of the 100 000 datasets was analyzed by EFA with principal component extraction and oblimin rotation. The analyses were combined after re-ordering the factors by maximizing factor congruence.
Results: Sixty-six patients with a mean disease duration of 14.8 years (SD 9.03), mean age of 55.21 years (SD12.87), 96% (63/66) positive to RF or ACPA, 77% (51/66) with erosions and 68% (45/66) female were included in this analysis.
Table 1 provides the results of the EFAs from CareRA and TapERA. The factor structure and factor components remained the same in both datasets. The factor loadings, indicating how strongly a variable relates to its factor (correlation between observed and latent score), were also comparable. The HAQ, however; did have a stronger factor loading in TapERA (0.57 vs 0.92).

Table 1. Results from the exploratory factor analyses in CareRA and TapERA

Variable	CareRA			TapERA		
	PRF	CF	LF	PRF	CF	LF
Fatigue	0.90			0.80		
PaGH	0.87			0.81		
Pain	0.86			0.75		
HAQ	0.57			0.92		
SJC28		0.92			0.82	
TJC28		0.89			0.84	
PhGH		0.76			0.60	
CRP			0.87			0.85
ESR			0.78			0.82

Factor loadings presented (correlation between the observed score and the latent factor). Cross-loadings were negligible (<0.3) -not presented. The factor order is by % of variance explained.PRF: patient-reported factor, CF: clinical factor, LF: laboratory factor, PaGH: patient's global health assessment, HAQ: health assessment questionnaire, SJC28: 28 swollen joint count, TJC28: 28 tender joint count, PhGH: physician's global health assessment, CRP: C-reactive protein, ESR: erythrocyte sedimentation rate

Conclusion: The latent factor structure for disease burden originally found in CareRA was successfully validated in the TapERA dataset, underlining the robustness of the PRF, CF and LF scores. HAQ seems to take "greater importance" on established RA. However, deviations in factor loadings (e.g., HAQ) could be attributed to differences between study populations (e.g., early vs. established RA, sample size). Apart from traditional clinical and laboratory factors, patient-reported pain, fatigue, functionality and overall well-being determine disease burden, both in early and established RA. Using these factor scores could facilitate detection and management of patient's unmet needs.

AB0110 DETERMINING THE AMOUNT OF COPPER–CONTAINING PROTEIN, ITS BIOCHEMICAL AND IMMUNOLOGIC ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS

O. Rusanova[1], A. Trofimenko[1], N. Emelyanov[2], O. Emelyanova[1]. [1]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», 1, Волгоград, Russian Federation*; [2]*Federal State Budgetary Educational Institution of Higher Education «Volgoorad State Medical University» of the Ministry of Healthcare of the Russian Federation, 2, Волгоград, Russian Federation*

Background: Production of antibodies to ceruloplasmin (CP) in rheumatoid arthritis is an issue that has not been studied well enough. It was not by chance that this copper–containing alpha 2-glycorpoteid of blood plasma showing multienzymatic properties was chosen as an object of investigation. Data on the content and activity of CP in the blood of rheumatoid arthritis patients are contradictory, which has to do with different approaches to selection of patients and different measuring methods.
Objectives: Improving diagnosis of rheumatoid arthritis by determination of antibodies to CP as well as its amount and enzymatic activity.

Methods: We studied the serum from 30 apparently healthy individuals, and 108 rheumatoid arthritis patients. Antibodies to CP were determined by enzyme immunoassay using immobilized granulated antigen preparations (modification by Gontar et al, 2002). The amount of CP was determined by enzyme immunoassay according to the method of I.S. Kuzmina et al (1991) using commercial diagnostic agent manufactured by Mechnikov Research Institute for Vaccines and Sera.
Results: Enzyme immunoassay showed a mean level of CP antibodies in donor sera of 0,020±0,006 optical density units. The level of normal values of specific antibodies determined as M±2σ included an extinction value in the range 0 – 0,086. The mean value of oxidase activity and the amount of CP in healthy people was 716±26,3 and 921±32 ng/ml, correspondingly. In the process of study we revealed a reliable increase in CP antibody count, the activity and amount of CP in patients with rheumatoid arthritis while in all cases the parameters under study correlated with the degree of disease activity ($p<0,05$): at activity degree I CP antibodies were 0,098±0,011; CP activity was 954±48,1; CP amount was 1292±73,4. At activity degree II CP antibodies were 0,138±0,007; CP activity was 1163±39,6; CP amount was 1763±69,3. At activity degree III, CP antibodies were 0,182±0,015; CP activity was 1368±89,5; CP amount was 1794±102,8. After a course of hospital treatment was completed, we noted a reliable decrease in the activity and amount of CP (at degree I of rheumatoid arthritis activity $p<0,001$, at degree II of rheumatoid arthritis activity $p<0,01$for both parameters; at degree III, $p<0,05$) compared with baseline findings. A decrease in CP antibodies shows decelerated dynamics, especially in patients with pronounced disease activity, which indicates severe disorders in the immunity that cannot be cured completely within 30 – 40 days of hospital treatment course.
Conclusion: Determination of CP antibodies, as well as quantitative content of CP and its oxidase activity can serve as indicators of the activity of rheumatoid arthritis, as well as an accessory criterion of the effectiveness of administered therapy.

AB0111 FAMILIAL RHEUMATOID ARTHRITIS WITH LATE ONSET (50 YEARS AND OLDER) IN CLINICAL PRACTICE ACCORDING TO THE ALL-RUSSIAN ARTHRITIS REGISTER (OREL)

A. Satybaldyev[1], O. Rumyantseva[2], N. Demidova[2], E. Gerasimova[1], E. Strebkova[3], J. Murtazalieva[4], E. Koltsova[4], M. Nikolenko[4], G. Lukina[4], E. Zhilyaev[4], E. Nasonov[5]. *[1]V A Nasonova Research Institute of Rheumatology, Department of Early Arthritis, Moscow, Russian Federation*; *[2]V A Nasonova Research Institute of Rheumatology, Clinical Department, Moscow, Russian Federation*; *[3]V A Nasonova Research Institute of Rheumatology, Osteoarthritis Laboratory, Moscow, Russian Federation*; *[4]Moscow Research and Practical Center, Moscow Healthcare Department Clinical Moscow, Moscow, Russian Federation*; *[5]V A Nasonova Research Institute of Rheumatology, Scientifical Department, Moscow, Russian Federation*

Background: Relatives of the 1st degree of relationship (RFDR) of a patient with rheumatoid arthritis (RA) have the higher risk for the development of RA, associated with a 2-5 fold increase.
Objectives: Clinical characteristics of probands with RA onset at an older age (50 yrs and older) and their RFDR, which had RA, other rheumatic diseases (RD) and other autoimmune diseases (AID).
Methods: 2766 RA pts with onset of the disease at the age of 50 yrs and older, residents of Moscow and the Moscow region, were included in the Russian register of arthritis OREL in the period from 01.06.2012 to 31.12.2018. 67 probands with RA (2.4%) had RFDRs with RA, other RDs, other AIDs (86 RFDRs in total). Disease activity (by DAS-28), X-ray stage - (by modified Steinbrocker), functional disorders (by functional class - FC), immunological characteristics (RF, ACPA), etc., characterizing the clinical manifestations of RA were evaluated in accordance with the requirements of the current national working RA classification. RFDRs were divided into groups depending on relation to proband father, mother and siblings with RA, RFDRs withr other RD and RFDR with other AID; serological affiliation to RF and ACPA; association with concordant and discordant RFDR, as well as on number of RFDRs (1 and 2 or more).
Results: 67 probands with RA were investigated: 9 men, 58 women, average age in debut (m ± δ) 58.78 ± 6.23 yrs; the average age at the time of the last study was 68.8 ± 6.38 yrs, average duration of RA was 10.14 ± 5.69 yrs. 6 (9%) probands had FC1, 45 (69%) - FC2, 13 (20%) - FC3, 1 (2%) - FC4, 2 - without data; 34 (53%) had high activity, 23 (36%) -medium, 6 (9%) - minimal, 1 (2%) - remission, 3 without data; RF-positive (RF+) - 77.6%, ACPA-positive (ACPA+) - 71.7%. 19 probands (32%) had 1-2a X-ray stage, 27 (46%) - stage 2b, 10(17%) - stage 3, 3 (5%) - stage 4, 8 - without data. 61 (91%) had advanced clinical stage, 6 (9%) - late. Among 86 RFDRs (67 - RF+, 19 - RF-) 10 had father with RA (8 RF+ probands, 2 - RF-), 2 - father with other RDs (all RF+), 10 - mother with RA (all RF+), 7 - mother with other RDs (4 - RF+, 3 - RF-), 26 - siblings with RA (20 - RF+, 6 - RF-), 11 - siblings with other RDs (9 - RF+, 2 - RF-), 20 - RFDR with other AIDs (14 - RF+, 6 - RF-). Probands with concordant RFDRs had more pronounced changes: high activity (56% versus 32%), X-ray erosive stages (67% versus 60%) and stages III and IV (32% versus 6%); FC3 and FC4 (23% versus 12%) and a tendency towards more frequent development of the late clinical stage (11% versus 2%). Comparison of clinical signs in probands with 1 RFDR (49 cases) and probands with 2 or more RFDRs (17 cases) showed a significant predominance of high inflammatory activity (61% versus 41%), erosive arthritis (77% versus 57%), and a tendency to development of a late clinical stage (10% versus 6%) in probands with 1 RFDR. In probands with RF-positive RA, the predominance becomes more significant: high inflammatory activity (69% versus 43%), erosive arthritis (90% versus 54%), late clinical stage (13% versus 7%), and a tendency to severe functional impairment - FC3 and FC4 (22% vs. 15%). ACPA-positive probands showed the same tendency as RF-positive.
Conclusion: The clinical picture of probands with RFDRs with RA, other RDs, other AIDs is generally characterized by more pronounced changes in probands with RA who have RFDRs with concordant diseases in the form of more often high inflammatory activity, less often moderate, erosive arthritis, more frequent development of advanced 3 and 4 X-ray stages (every fifth). Also, more pronounced changes develop in probands with RA who have only 1 RFDR compared to probands with 2 or more RPSRs. In this group, the differences are even more pronounced in the case of RF-positive probands. In cases with ACPA-positive probands, the same trends persist. Careful interview of a proband with RA about the presence of RFDRs with RA, other RDs and other AIDs will make it possible to predict its course more correctly and facilitate planning of rational therapy.

AB0112 TNF INHIBITOR MONOTHERAPY IN RHEUMATOID ARTHRITIS: IS THERE REALLY A DIFFERENCE IN COMPARISON WITH COMBINATION THERAPY WITH CSDMARDS IN REAL-LIFE?

B. M. Fernandes[1], S. Garcia[1], F. Oliveira Pinheiro[1], M. Rato[1], D. Fonseca[2], D. Santos Oliveira[1,3], A. Martins[1], F. R. Martins[4], M. Bernardes[1,5], L. Costa[1]. *[1]Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal*; *[2]Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal*; *[3]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; *[4]Centro Hospitalar Universitário do Algarve, Rheumatology, Faro, Portugal*; *[5]Faculty of Medicine, University of Porto, Departamento de Medicina, Porto, Portugal*

Background: In Rheumatoid Arthritis (RA), tumor necrosis factor inhibitors (TNFi) in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) has shown advantages concerning efficacy and immunogenicity in comparison with monotherapy. However, in clinical practice, up to 40% of patients under biological DMARDs (bDMARDs) are on monotherapy.
Objectives: To compare the efficacy outcomes of TNFi in monotherapy and in combination therapy in a RA monocentric cohort.
Methods: Retrospective, cross-sectional study including all the RA patients under TNFi followed at our Rheumatology Department and registered in the national database. Demographic, clinical and laboratorial data and disease activity measures were collected at the last visit of 2019 from each patient. Mann-Whitney U and chi-square tests were used to the comparison analysis between the two groups (continuous and categorical variables, respectively).
Results: A total of 144 patients were included: 84% were females; at the last visit of 2019, the mean age was 56.3±10.9 years and the mean disease duration was 18.3±10.2 years; 73.6% were positive for rheumatoid factor (RF), 81.9% for anti-citrullinated protein autoantibodies (ACPA) and 45.1% had erosive disease. There were no statistically significant differences in these variables between the monotherapy and the combination therapy groups (table 1).

Table 1. Demographic and disease-related variables in the monotherapy and the combination therapy group.

	Monotherapy (n=31)	Combination therapy (n=113)
Age - mean±SD	59.1±14.0 years	55.5±9.8 years
Disease duration - mean±SD	20.5±11.2 years	17.7±9.7 years
RF positive - n (%)	20 (60.4%)	86 (76.8%)
ACPA positive - n (%)	25 (80.6%)	93 (85.3%)
Erosive disease - n (%)	15 (48.4%)	50 (44.6%)

Thirty-one patients (21.5%) were under monotherapy with TNFi and etanercept was the most frequent TNFi in both groups (54.8% vs 50.0%; monotherapy and combination therapy groups, respectively). At the start of the first bDMARD, the monotherapy group had a higher disease activity score 28 - 4 variables (DAS 28 4V; 6.083±0.930 vs 5.605±1.043, p=0.039) and a higher simple disease activity score (SDAI; 36.12±11.77 vs 28.76±9.98, p=0.035); also, in the monotherapy group more patients had already started the bDMARD in monotherapy (22.6% vs 2.7%, p<0.001), less patients were under (38.7% vs 73.2%, p=0.001) or had already been treated with (77.4% vs 93.8%, p=0.007) methotrexate, in comparison with the combination group therapy.

At the last visit of 2019, the monotherapy group had a higher mean years of duration of iTNF treatment (5.5±5.8 vs 3.4±4.5, p=0.048), a higher mean patient global assessment - visual analogue scale (PGA-VAS; 49±18 vs 39±25, p=0.023), a higher mean prednisolone equivalent dose in mg/day (7.6±6.3 vs 5.6±3.2, p=0.045) and a lower proportion of American College of Rheumatology 50 and 70 responses (ACR 50: 12.9% vs 17.0%, p=0.023; ACR 70: 3.2% vs 10.7%, p=0.045) in comparison with the combination therapy group.

Conclusion: In line with the literature, our real-life results demonstrate some direct (higher PGA-VAS and lower ACR 50 and 70 responses) and indirect (higher current prednisolone equivalent dose) data that suggest that patients with TNFi monotherapy may have a worst disease activity control in comparison with combination therapy.

ANTI-CARBAMYLATED PROTEIN ANTIBODIES POSITIVITY AND DISEASE ACTIVITY IN HISPANIC PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS: AN OBSERVATIONAL STUDY

D. Vega-Morales[1], M. A. Garza Elizondo[1], L. A. Trouw[2], K. I. González Márquez[1], E. Torres-Lopez[3], M. Eguia Bernal[1], S. A. Loredo Alanis[1], T. S. Gracia-Arechiga[1], B. R. Vázquez Fuentes[1], D. D. Castañeda Martínez[1], M. M. Castañeda-Martínez[1], C. V. Solis[1], A. Mendiola-Jimenez[1], M. C. Salinas-Carmona[3], P. Herrera-Sandate[1], A. Cárdenas[1], G. E. Rodriguez-Sanchez[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology Service, Monterrey, Mexico*; [2]*Leiden University Medical Center (LUMC), Department of Immunohematology and Bloodtransfusion, Leiden, Netherlands*; [3]*Hospital Universitario Dr. José Eleuterio González, Immunology Department, Monterrey, Mexico*

Background: Clinically relevant anti-carbamylated (anti-CarP) antibodies are detected in up to 45% of rheumatoid arthritis (RA) patients and are associated with severe radiological progression, higher disease activity, and significantly more disability when studied in early phases of arthritis.

Objectives: We aimed to determine the prevalence of anti-CarP antibodies in Mexican Hispanics with established RA and to assess their relationship with disease activity.

Methods: A cohort study was conducted in 278 patients with established RA during an 18-month follow-up. We measured IgG/IgM/IgA rheumatoid factor (RF), IgG anticitrullinated protein antibodies (ACPA) and IgG/IgM/IgA anti-CarP antibodies using enzyme-linked immunosorbent assay (ELISA). For disease activity, we performed the 28-joint disease activity score with erythrocyte sedimentation rate (DAS28-ESR). Repeated measures one-way ANOVA was used to test the association between anti-CarP IgG antibody status and longitudinal DAS28-ESR scores. Patients were evaluated at baseline and at 6, 12, and 18 months during follow-up.

Results: Anti-CarP IgG antibodies were positive in 47.8% of patients and, accounting for all isotypes, in 9.5% of patients with negative RF and ACPA. Triple antibody positivity was present in 42.6% of patients in our sample. Anti-CarP IgG antibody positivity did not show statistically significant differences in mean DAS28-ESR when compared to anti-CarP IgG antibody negative patients at baseline, 6, 12 or 18 months.

Conclusion: Anti-CarP IgG antibodies are present in almost 50% of RA patients and, accounting for all isotypes, in 9% of RF and ACPA negative patients. Anti-CarP IgG antibody positivity was not associated to a higher disease activity measured by DAS28-ESR in Hispanic patients with established RA.

References: Shi J, Knevel R, Suwannalai P, Van Der Linden MP, Janssen GMC, Van Veelen PA, et al. Autoantibodies recognizing carbamylated proteins are present in sera of patients with rheumatoid arthritis and predict joint damage. Proc Natl Acad Sci U S A. 2011;108:17372–17377.

Table 1. Anti-CarP antibody status by isotype in a cohort of 278 patients with established RA.

	Mean (SD)	Antibody positivity, n (%)	95% CI
RF IgA[a]	266.9 (460.5)	155 (58.9)	53.0 to 64.9
RF IgM[a]	406.8 (611.9)	188 (71.5)	66.0 to 77.0
RF IgG[a]	36.1 (249.6)	44 (16.7)	12.2 to 21.3
ACPA IgG[a]	191.01 (411.1)	144 (54.8)	48.7 to 60.8
Anti-CarP IgA[b]	212.9 (464.2)	74 (26.6)	21.4 to 31.8
Anti-CarP IgM[b]	381.6 (762)	89 (32)	26.5 to 37.5
Anti-CarP IgG[b]	227.5 (402.5)	133 (47.8)	41.9 to 53.8

[a]Data were available for 263 patients. Units are RU/mL. [b]Data were available for 278 patients. Units are AU/mL. RF, rheumatoid factor; ACPA, anticitrullinated protein antibodies; Anti-CarP, anti-carbamylated protein antibodies; IgG, immunoglobulin; SD, standard deviation; 95% CI, 95% confidence intervals.

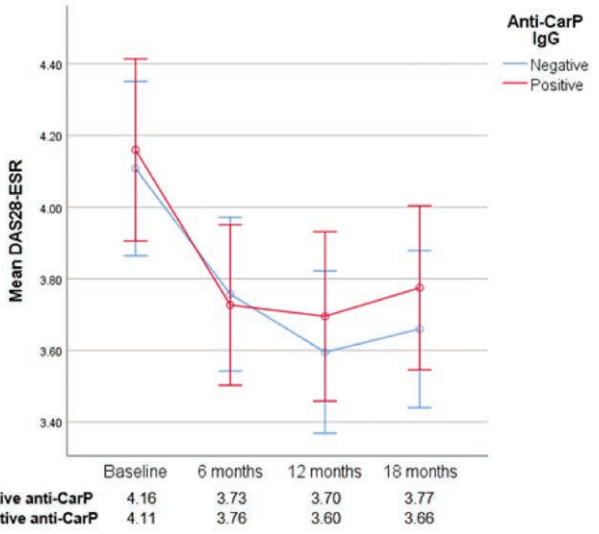

Figure 1. Mean DAS28-ESR scores over an 18-month follow-up by anti-CarP antibody status with error bars corresponding to 95% CI. With the non-sphericity assumed by Greenhouse-Geisser analysis, a non-significant statistical difference was found among groups in the repeated measures one-way ANOVA (p = 0.829). DAS28-ESR, 28-joint disease activity score with erythrocyte sedimentation rate; Anti-CarP, anti-carbamylated protein antibodies; Ig, immunoglobulin.

AB0114 INVESTIGATION OF THE EFFECTS OF EXERCISE ON MIRNA EXPRESSIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Z. B. Özcan[1], F. S. Karaahmetoğlu[2], M. Z. Çıracı[3], H. H. Pençe[4], M. Vural[5], E. I. Üstün[5], A. Kural[6], S. Kuraş[4], B. Erdoğan[4]. *[1]Hamidiye Faculty of Health Sciences, Medical Biochemistry, Istanbul, Turkey*; *[2]Hamidiye Faculty of Health Sciences, Physical Therapy and Rehabilitation, Istanbul, Turkey*; *[3]Sakarya University Education and Research Hospital, Department of Biochemistry, Sakarya, Turkey*; *[4]Istanbul Hamidiye Faculty of Health Sciences, Medical Biochemistry, Istanbul, Turkey*; *[5]Istanbul SBU Dr. Sadi Konuk Education and Research Hospital, Physical Medicine and Rehabilitation, Istanbul, Turkey*; *[6]Istanbul SBU Dr. Sadi Konuk Education and Research Hospital, Department of Biochemistry, Istanbul, Turkey*

Background: The goal of treatment for patients with RA is achieve to remission, or at least a state of low disease activity. Exercise is recommended for patients with RA in addition to drug therapy. It has been found to be effective in greatly improving functionality and reducing cardiovascular risk without exacerbating disease activity. Therefore, it is recommended that all RA patients should be encouraged to include aerobic and resistant exercise training as part of their routine treatment (1).
miRNAs(miRNA) are known to protect the pathophysiological process specific to RA. miRNA-146a is one of the miRNAs extensively studied in RA, its expression was found to be higher in the synovial fluid and synovial tissue of RA patients compared to healthy individuals (2).
Many studies have found that miRNA-146a, along with miRNA-16 and miRNA155 may be related to disease pathology. It has also been found that high levels of miRNA-16 expression correlate with active disease and low levels of expression with inactive disease. It has been found that the increased level of miRNA-155 causes a problem in the modulation of arthritis It has been found that the expression level of miRNA-145 is increased in peripheral blood mononuclear cells of RA patients and synovium supporting osteoclastogenesis (3,4,5).
Objectives: It is aimed to investigate the effect of exercise on microRNA expressions in patients with rheumatoid arthritis (RA).
Methods: 30 patients and 30 healthy controls aged 18-60 years who met the 2010 ACR / EULAR RA criteria were included in the study. A program consisting of strengthening and stretching exercises 2 days a week was applied to the study group for 8 weeks. One day a week, 30 minutes of mild moderate walking was requested. Of the cases at the beginning and at the end of the treatment; 5-10 cc peripheral blood samples were taken into one EDTA tube. Then Numeric Rating Scale (NRS) was used for pain, 28-joint Disease Activity Score (DAS28) was used to calculate disease activity, Health Assessment Questionnaire (HAQ) was used to assess general health and Short Form-36 (SF-36) was used to evaluate quality of life. 5-10 cc peripheral blood samples were taken to only 1 EDTA tube of the control group. In the samples taken, gene expressions of miRNA-146a, miRNA-155, miRNA-16, miRNA-145 were determined by real-time PZR method.
Results: There was a significant difference in DAS28, SF-36, NRS, HAQ scales before and after treatment in the RA group of patients (p 0.05). The expression level of MiRNA-146a does not differ significantly before and after treatment (p> 0.05). However, these two groups differ significantly with the control group (p 0.05). No significant difference was observed in the miRNA-155 and miRNA-16 expression levels in the pretreatment, posttreatment, and control groups (p> 0.05).
Conclusion: Exercise therapy has a good effect on pain, disease activity, quality of life and general health in patients with RA. It has been found that exercise can affect vii some of the miRNAs involved in disease pathogenesis. However, more comprehensive studies are needed.

AB0115 COMPARISON OF ULTRASOUND FINDINGS BETWEEN TNF INHIBITORS AND NON-TNF INHIBITORS AT FIRST BIOLOGICS IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Okano[1], T. Koike[2,3], K. Inui[4], K. Mamoto[1], Y. Yamada[1], K. Mandai[4], S. Anno[1], H. Nakamura[1] on behalf of Team RA. *[1]Osaka City University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka, Japan*; *[2]Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan*; *[3]Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama, Japan*; *[4]Osaka Saiseikai Nakatsu Hospital, Department of Orthopedic Surgery, Osaka, Japan*

Background: In rheumatoid arthritis (RA), biologics treatment is one of the effective treatment options. Usually, there is no difference in therapeutic effect regardless of which biologics is used, but the effect for joint synovitis is unknown. Recently, ultrasound (US) has played a role of sensitive imaging modality in the diagnosis and follow-up of patients with RA.
Objectives: The aim of this study was to compare the improvement of US findings between TNF inhibitors and non-TNF inhibitors at first biologics in patients with RA.
Methods: Fifty-four RA patients who started the first biologics from September 2016 to December 2018 were included in this longitudinal study (SPEEDY study, UMIN000028260). All the patients were performed clinical examination, blood test and US examination at baseline, 4, 12, 24, 36 and 52 weeks. A US examination was performed at the bilateral first to fifth metacarpophalangeal (MCP) joints, first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) joints, wrist joints (three part of radial, medial and ulnar) and first to fifth metatarsophalangeal (MTP) joints, by using HI VISION Ascendus (Hitachi Medical Corporation, Japan) with a multifrequency linear transducer (18-6 MHz). The gray scale (GS) and power Doppler (PD) findings were assessed by the semi-quantitative method (0-3). GS score and PD score (both 0-108 points) were defined as the sum of each score. The change of disease activity and US findings were compared between TNF group and non-TNF group.
Results: Among 54 cases, 32 patients were used TNF inhibitor and 22 were non-TNF inhibitor. Age and duration of RA were significantly higher in the non-TNF group, and MTX dose was significantly lower in the non-TNF group. The baseline inflammatory markers tended to be higher in the non-TNF group and the disease activity was also higher in the non-TNF group. However, the US findings showed no significant difference in both GS and PD between two groups at baseline. US improvement ratio was no difference between TNF group and non-TNF group at 4, 12, 24, 36 and 52 weeks in both GS and PD score. Regardless of the type of biologics, patients with long-term disease duration tended to have poor improvement in US synovial fingings.

Table 1. Baseline patient and disease characteristics

	TNF (n=32)	non-TNF (n=22)	P value
Female patients, n (%)	21 (65.6)	16 (72.7)	0.767
Age (years)	63.5±15.4	71.0±9.0	0.030
Disease duration (years)	6.5±8.2	13.0±11.7	0.032
CRP (mg/dl)	1.8±2.5	3.0±3.2	0.170
DAS28-ESR	5.0±1.4	5.8±1.2	0.022
GS score	26.1±18.8	31.8±21.1	0.313
PD score	17.6±11.4	23.1±14.6	0.150

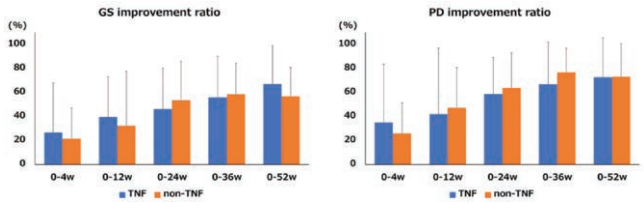

Figure 1. GS and PD improvement ratio at 4, 12, 24, 36 and 52 weeks

Conclusion: There was no difference in the US findings improvement between patients with TNF inhibitor and non-TNF inhibitor at first biologics in patients with RA.

AB0116 THE EFFECTS OF DISEASE MODIFYING ANTI-RHEUMATIC DRUGS ON PATIENT REPORTED OUTCOMES; PRELIMINARY RESULTS OF A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

M. Van den Dikkenberg, Msc[1], N. Luurssen-Masurel[2], M. Kuijper[1], M. R. Kok[1], P. De Jong[2], J. Hazes[2], D. Lopes Barreto[1], A. Weel[1,3]. *[1]Maasstad Hospital, Rheumatology, Rotterdam, Netherlands*; *[2]Erasmus MC, Rheumatology, Rotterdam, Netherlands*; *[3]Erasmus School of Health Policy & Management, Health Technology Assessment, Rotterdam, Netherlands*

Background: The need to involve patient reported outcomes (PROs) in the management of rheumatoid arthritis (RA) increases, since PROs quantify patient relevant outcomes. Although PROs have been incorporated in the core-outcome sets in clinical trials, knowledge about the treatment effects on these PROs is scarce. Therefore, we performed a systematic review on the effects of disease modifying anti-rheumatic drugs (DMARDs), of any type, on relevant PRO domains mentioned in the ICHOM standard set. This might support rheumatologists and RA patients during treatment decisions.

Objectives: To get insight in the treatment effects of DMARDs of any type on three PRO domains that matter to patients (pain, activity limitations and fatigue).

Methods: A systematic review was performed in Embase, Medline, Web of Science, Cochrane and Google Scholar. Included were all studies that were published before August 2019 and showed DMARD treatment effects in RA on PROs that are part of the ICHOM standard set. Three Bayesian network meta-analyses were performed for the PRO domains pain, activity limitations and fatigue. Preliminary results of DMARDs (in)directly compared to placebo were visualized by forest plots using R.

Results: The search strategy yielded n=5974 articles. After selection was performed by 2 independent researchers, n=70 individual articles representing n=53 studies were extracted, over the three PRO domains; pain (n=31), activity limitations (n=41) and fatigue (n=21). In all RCTs, PROs were only reported as secondary or tertiary endpoints. In figure 1, we show the effects on PROs for any type of DMARD investigated compared to placebo. Overall, DMARDs show a greater reduction in pain (standardized mean difference (SMD); -0.97 – -0.22) and most of them in activity limitations (SMD; -0.81 – 0.56). In fatigue, this clear direction is lacking (SMD; -0.86 – 3.5). csDMARDs and anti-TNF seem to perform slightly, but nog significantly, worse than other bDMARDs and tsDMARDs in the first two domains.

Conclusion: Within in this systematic review we report a reduction for DMARDs of any type on the domains of pain and activity limitations compared to placebo. However, results are still preliminary and should be interpreted with care. A more comprehensive network analysis might give a more definitive answer which DMARD performs best.

AB0117 CARDIOVASCULAR MORBIMORTALITY IN RHEUMATOID ARTHRITIS: A 5 YEAR FOLLOW-UP STUDY

A. B. Rodriguez-Romero[1], D. Á. Galarza-Delgado[1], I. J. Colunga-Pedraza[1], J. R. Azpiri-López[2], N. Guajardo-Jauregui[1], S. Lugo-Perez[2], A. Cárdenas[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology Service, Monterrey, Mexico*; *[2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology Service, Monterrey, Mexico*

Background: Rheumatoid arthritis (RA) is characterized by elevated cardiovascular morbimortality. RA patients have a higher risk to develop cardiovascular comorbidities when compared to the general population, being the main cause of mortality in these patients. Cardiovascular risk factors (CVRF) are well known, but their management is not optimal, increasing the risk of having a major heart disease (1).

Objectives: To assess the prevalence of the main causes of morbimortality and development of CVRF in RA patients during a five-year follow-up period.

Methods: A longitudinal and prospective study of a RA cohort from 2014-2019 was performed in a Cardio Rheumatology outpatient clinic at the University Hospital "Dr. Jose E. Gonzalez", UANL. Patients aged 40-75 years with RA according to ACR/EULAR 2010 criteria were recruited. At both visits, demographic, clinical variables, and lipid profile were recorded. Outcomes included the development of cardiovascular comorbidity: hypertension, diabetes mellitus (DM), dyslipidemia, myocardial infarction, stroke. Survival probabilities and outcomes cumulative frequencies were calculated according to the Kaplan-Meier lifetime analysis method. Descriptive analysis: frequencies (%), mean (SD), or median (q25-q75). Comparisons with McNemar and Student's t test.

Results: A follow-up was done in a total of 92 patients. During the follow-up, 9 patients (9.8%) died, 3 died of cardiovascular death (one myocardial infarction and two strokes). The mean age of death was 67.2 ± 10.5 years. CVRF at baseline (T0) and after five years (T5) are shown in table 1. Of the remain 83 patients, 11 patients (13.3%) developed hypertension (p=0.001), 8 (9.6%) patients developed DM (p=0.031). The number of patients with dyslipidemia decreased significantly to 14 (16.9%) (p=0.031), 4 (4.8%) developed a stroke. A survival probability of 95.7% was found at the five-year follow-up from the time of entry into the cardio rheumatology clinic (Figure 1 next page) and a 30.1% probability of developing cardiovascular comorbidity.

Conclusion: This long-term study provides updated information on RA morbimortality characteristics in our population. Patients with RA still develop significant cardiovascular comorbidities despite current treatment. In this cohort, hypertension and DM became more prevalent, and a 96% cardiovascular death-free survival was found. Is imperative to increase the effort in determining optimal markers and therapeutic measures to continue with the prevention of these comorbidities.

AB0118

REMISSION OF ANXIETY AND DEPRESSIVE DISORDERS IMPROVES HAQ TREATMENT RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS

A. Abramkin[1], T. Lisitsyna[1], D. Veltishchev[2], O. Seravina[2], O. Kovalevskaya[2], S. Glukhova[1], E. Nasonov[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Vascular Rheumatology, Moscow, Russian Federation; [2]Moscow Research Institute of Psychiatry, Serbsky NMRC PN MoH, Stress Disorders, Moscow, Russian Federation*

Background: Anxiety and depressive disorders (ADD) significantly affect disease activity and functional disability in rheumatoid arthritis (RA) patients. Psychopharmacotherapy (PPT) of ADD attempts to improve RA disease activity and lower progression of functional limitations.
Objectives: To determine factors associated with HAQ treatment response in antidepressants-treated RA-patients at five years endpoint.
Methods: 128 RA-patients (pts) were enrolled, 86% were women with a mean age of 47,4±11,3 (M±SD) yrs. All patients met the full ACR/EULAR 2010 criteria for RA. Functional limitations were assessed using Health Assessment Questionnaire (HAQ), mean HAQ was 1,42±0,78 at baseline. 69,4% RA-pts were already taking prednisone (9 [5; 10] mg/day (Me (25%; 75%)), 84,4% - cDMARDs, 7,8% - bDMARDs (anti-TNF-α – 6,3%, rituximab – 1,6%). ADD were diagnosed by psychiatrist in 123 (96,1%) of RA-pts in accordance with ICD-10 in semi-structured interview. Severity of depression and anxiety was evaluated with Montgomery–Asberg Depression Rating Scale (MADRS) and Hamilton Anxiety Rating Scale (HAM-A). RA-pts with ADD were divided into the following treatment groups: 1 – cDMARDs (n=39), 2 – cDMARDs + PPT (sertraline or mianserine) (n=43), 3 – cDMARDs + bDMARDs (n=32), 4 – cDMARDs + bDMARDs + PPT (sertraline or mianserine) (n=9). Biologics treatment duration varied from 1 to 6 years, antidepressants – from 6 to 96 weeks. Baseline HAQ scores were 1,39±0,75, 1,42±0,9, 1,58±0,76 and 1,38±0,83 in groups 1-4, respectively. At 5-yrs endpoint in 83 RA-pts differences between baseline and endpoint HAQ scores (Δ HAQ = endpoint HAQ – baseline HAQ) were assessed as HAQ treatment response with minimal clinically important difference (MCID) (Δ HAQ ≥ 0,22). HAQ response rates were 4,2%, 65,5%, 47,6% and 76,7% in groups 1-4, respectively, with the lowest response rate in group 1 (p<0,0001). Logistic regression analysis was conducted to determine factors associated with RA remission rate.
Results: By univariate logistic regression, anxiety and depressive symptoms remission at 5-yrs endpoint, baseline HAQ and major depression, lower baseline age, BMI and DAS28, no minor depression and cardiovascular diseases at baseline were significantly (p≤0,2) associated with HAQ treatment response (table 1). These variables were subjected to multivariate stepwise logistic regression. Only remission of anxiety and depressive symptoms at 5-yrs endpoint (OR 6,6 (95%CI 1,78 – 24,43), p=0,005), higher baseline HAQ (OR 2,61 (95%CI 1,12 – 6,11), p=0,027) and lower baseline BMI (OR 0,9 (95%CI 0,85 – 0,96), p=0,001) were independently associated with HAQ treatment response at 5-years follow-up.

Table 1. Factors associated with RA remission at 5 years (univariate logistic regression).

Factor	p	OR	95%CI low	95%CI up
Anxiety and depressive symptoms remission at 5-yrs endpoint	0,007	5,0	1,561	16,016
Baseline HAQ	0,01	2,657	1,264	5,588
Baseline major depression	0,142	2,082	0,782	5,542
Baseline age	0,098	0,992	0,982	1,002
Body mass index (BMI)	0,048	0,981	0,963	1,0
Baseline minor depression	0,167	0,563	0,249	1,273
Cardiovascular diseases	0,1	0,417	0,147	1,183
Baseline DAS28	0,008	0,077	1,071	2,096

Conclusion: higher HAQ and lower BMI at baseline and remission of anxiety and depressive symptoms at 5-yrs endpoint are independently associated with HAQ treatment response (MCID) at 5-years follow-up.
Disclosure of Interests: None declared

AB0119

DISCORDANCE OF RAPID3 AND CDAI IN RHEUMATOID ARTHRITIS

L. A. Ramrattan[1], Z. Vaghaiwalla[1], S. Singh[1], K. Ramsubeik[1], M. Thway[1], G. Kaeley[1]. *[1]University of Florida, Rheumatology, Jacksonville, United States of America*

Background: The Clinical Disease Activity Index (CDAI) and the Routine Assessment of Patient Index Data 3 (RAPID3) ascertain rheumatoid arthritis (RA) disease activity and inform treatment decisions. The CDAI has provider and patient components, whilst the RAPID3 only has patient driven measures. During the COVID-19 pandemic, telemedicine visits relied on RAPID3 as a clinical outcome measure and subsequently was incorporated into all clinical visits in addition to the CDAI. On an ad-hoc basis, discrepancies were noted for the disease activity level generated by these two measures. The purpose of this retrospective study was to formally analyze the relationship between these measures.
Objectives: To determine the concordance of the outcome measures RAPID3 with CDAI in patients with established RA as a quality improvement project.
Methods: This is a retrospective study of 49 patients that fulfilled the American College of Rheumatology 2010 criteria for Rheumatoid Arthritis. IRB approval was obtained. The medical records of patients seen between June to October 2020 at the rheumatology department at UF health were reviewed. Data collected included age, gender, race, number of years with RA, Rheumatoid factor (RF) and anti-citrullinated protein antibody (CCP Ab) positivity, disease modifying treatments, ESR and CRP as well as CDAI and RAPID3 scores as calculated by clinic staff. The charts were reviewed by the authors and RAPID3 scores were verified.

Table 1. Patient Population

Age	35-90 years
Race	African American-13 Caucasian-10 Hispanic-3 Not Hispanic=13
RF Positive	35/49 (71)%
CCP Ab	37/49 (75%)
Both RF and CCP Ab Positive	32/49 (65%)
Patients on monotherapy	14/48 (29%)
Patients on dual therapy	29/48 (60%)
Patients on triple therapy	5/48 (10)
Antirheumatic Drugs used	Plaquenil, methotrexate, leflunomide, etanercept, adalimumab, infliximab, tofacitinib, upadacitinib, rituximab
CDAI and RAPID3 Concordance	18/49 (37%)
RAPID 3 Higher than CDAI	22/49 (45%)
RAPID 3 lower than CDAI	7/49 (14%)
Incorrect Calculation of RAPID3 by clinic staff	11/42 (26%)

Results: The population ranged from 35- 90 years and duration of RA from 1- 30 years. CCP Ab was present in 75% of patients and RF in 71%. Patients were on DMARDs either monontherapy (29%), dual therapy (60%) or triple therapy (10%). Antirheumatic medications used were plaquenil, methotrexate, leflunomide, etanercept, adalimumab, infliximab, tofacitinib, upadacitinib and rituximab. ESR range was 2-110 and CRP 0.2-83.1. The CDAI and RAPID3 concordance was found to be 37% with RAPID3 being higher in 45% of patients. RAPID3 was lower only in 14% of patients. There was incorrect calculation of the RAPID3 26% of the time by clinic staff. Table 1 summarizes this data. Figure 1 shows RAPID3 and CDAI compared in scatterplots.

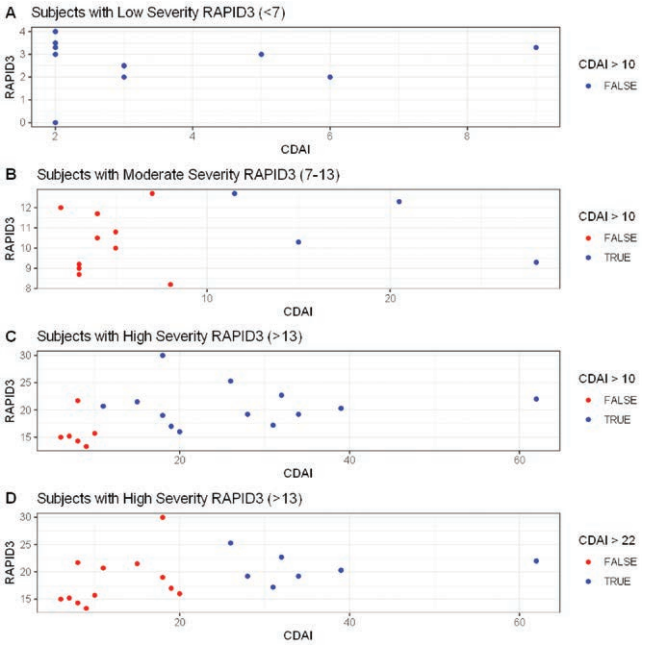

Figure 1. Scatterplots of three RAPID3 strata. Red dots represent discordant subjects when compared to CDAI.Note: Panel C demonstrates the subjects that were in low disease activity in red that had a high severity RAPID3 score

Conclusion: This study shows that RAPID3 may overestimate disease activity level for patients above low disease activity. Treatment escalation based on RAPID3 in discordant patients may be inappropriate. When making treatment decisions, a measure that includes objective physical examination and provider judgment is desirable.

AB0120

IDENTIFYING CORE VARIABLES TO DEVELOP A SEVERITY INDEX IN RHEUMATOID ARTHRITIS: A NATIONWIDE DELPHI CONSENSUS

S. C. Rodriguez-García[1], E. Toledano Martinez[2], M. J. García de Yébenes[3], L. Carmona[3], I. González-Álvaro[1]. [1]*Hospital de La Princesa, Rheumatology, Madrid, Spain*; [2]*Hospital Clinico Universitario San Carlos, Rheumatology, Madrid, Spain*; [3]*Instituto de Salud Musculoesquelética (InMusc), Research Unit, Madrid, Spain*

Background: Early interventions during the "window of opportunity" have been shown to improve clinical outcomes in rheumatoid arthritis (RA). However, intensive treatment can induce toxicity so identifying patients most likely to benefit from it is of great importance. Hence, tools for guiding therapeutic decisions in early disease stages are needed.

Objectives: To identify core variables to develop a RA severity index according to an expert panel.

Methods: An expert panel was prompted to analyze relevant variables to define a "severity" construct, specified as "early severe disease", able to classify patients with data collected on the first 2 years of the disease. They were also asked to identify potential modifying factors and external criteria to evaluate criterion validity.

An anonymous nationwide 2-round Delphi survey was applied to look for consensus about: (1) the priority of inclusion of each variable, (2) the feasibility to obtain them from usual sources (e.g., medical records) and (3) their definition. Each item was rated on a 10-point (priority) or 5-point (feasibility and definition) Likert scales were 0=complete disagreement and 5-10=complete agreement.

After the 1st round, any item rated from 5 to 10 in priority and 3 to 5 for feasibility by at least 70% of responders was included in the final variable list. Items not reaching at least 20% consensus were discarded. The remaining ones would be voted again in the 2nd round and adopted if they reached at least 50% consensus or else discarded.

Results: The task force identified 17 variables to define the "severity" construct (Table 1). Socio-economic status, knowledge of their own disease, type or work adherence to treatment, among others were proposed modifying factors. Rheumatoid factor or anti-citrullinated peptide antibody seropositivity as predictive factors The physician global assessment and the "burden of treatment" (lines of treatment, number and dose of DMARDs and cumulative steroid dose received) were proposed for evaluating criterion validity.

A total of 61 stakeholders from across Spain took the survey, 56% were female and had 19.8 years of average experience after training. All variables were included after 1st round. Nonetheless, definitions were submitted for a 2nd round after rephrasing, including comments received on the survey. The final list was reduced to 15 items after merging 3 of the initial variables into a new one called "refractoriness"(Table 1).

Conclusion: The consensus process resulted in a list of variables and modifying factors deemed of relevance for the severity construct as we defined it. These items will be used to develop a severity index to guide treatment decisions in early disease stages.

Table 1. Variables proposed for the severity construct.

N	Initially proposed variables	N	Final variables after Delphi
1	Polyarthritis	1	Polyarthritis
2	Big joint involvement	2	Big joint involvement
3	High disease activity at 2 years of follow-up	3	High disease activity at 2 years of follow-up
4	Maintained disease activity in the first 2 years	4	Maintained disease activity in the first 2 years
5	Acute phase reactants persistently elevated	5	Acute phase reactants persistently elevated
6	Extra-articular manifestations	6	Extra-articular manifestations
7	Failure to reach remission	7	Failure to reach remission
8	Need for aggressive therapy in the first 2 years	*8*	Need for aggressive therapy in the first 2 years
9	Presence of erosions at diagnosis	9	Presence of erosions by at diagnosis
10	Number of erosions at 2 years of follow-up	10	Number of erosions at 2 years of follow-up
11	Lack of improvement in the HAQ-DI	11	Lack of improvement in the HAQ-DI
12	Need for prosthetic surgery	12	Need for prosthetic surgery
13	Hospital Admissions	13	Hospital Admissions
14	Cortico-dependence	14	Cortico-dependence
15	MTX withdrawal due to loss of efficacy	15	*Refractoriness*
16	Completely absent response to MTX		
17	Number of drugs with lack of efficacy		

Underlined variables on the left were merged into a new variable called "Refractoriness". HAQ-DI: Health Assessment Questionnaire-Disability Index

AB0121 DOES CIGARETTE SMOKING INFLUENCE DISEASE ACTIVITY IN SEROPOSITIVE (ACPA POSITIVE) PATIENTS WITH EARLY RHEUMATOID ARTHRITIS?

N. Papadopoulos[1], N. Koletsos[2], D. Pantelidis[1], L. Mentesidou[3], V. Galanopoulou[1]. [1]*Papageorgiou General Hospital, Rheumatology Unit, Thessaloniki, Greece*; [2]*Papageorgiou General Hospital, Aristotle University of Thessaloniki, ESH Hypertension Excellence Center, 3rd Department of Internal Medicine, Thessaloniki, Greece*; [3]*Panagiotis and Aglaia Kyriakou Children's Hospital, First Department of Pediatrics, Athens, Greece*

Background: Many studies revealed that cigarette smoking is correlated with more active and severe Rheumatoid Arthritis (RA), mainly through the presence of positive RF or ACPA [1].
Objectives: To investigate the influence of cigarette smoking, in disease activity, in a cohort of Greek patients with ACPA positive early RA.
Methods: From January 2000 until December 2019, 137 patients with seropositive early RA (disease duration ≤ 3 months), and under the age of 75 years old, were diagnosed and subsequently were followed-up as outpatients in Rheumatology Unit of our hospital. All of them were treated by the same therapeutic protocol, were followed-up every 3 months and had at least one visit during 2019. Demographic, therapeutic, clinical and laboratory parameters were evaluated at the time of diagnosis and in every follow-up. At the end of the study we re-evaluated the above parameters, dividing patients in smokers and non smokers.
Analysis were performed using Student's t-test and non-parametric Mann-Whitney was used to estimate differences between mean values. Pearson's and Spearman's correlations were used, based on the variable's normality of distribution with the "Enter" method was used to identify the statistically significant predicting factors of DAS28/associations with DAS28.
Results: Mean age of our cohort were 57±10.2 years and 76.6% were females. From 137 patients 55 were current smokers.
Univariable analysis at the time of diagnosis revealed, that current smokers presented with more tender ($p<0.001$), more swollen joints ($p<0.001$) and higher levels of CRP ($p<0.001$). Also current smokers presented with higher disease activity measuring by DAS-28 4v, than non smokers (6.2±1.0 vs 5.6±0.9 respective, $p<0.001$). At the end of the study there were not found differences between the two groups.
Multivariable analysis revealed that high DAS-28 was correlated with the intensity of smoking ($p=0.049$).
Concerning the presence of extra-articular manifestations, smokers were presented more often with rheumatoid nodes ($p=0.026$).
Conclusion: Current smokers presented with more active disease at the time of diagnosis and have more often rheumatoid nodes. After the establishment of treatment there were no differences in disease activity between smokers and non smokers.

AB0122 THE NORA PROJECT - PREDICTION OF THERAPY RESPONSE IN RHEUMATOID ARTHRITIS

L. Mathsson-Alm[1], I. Gehring[2], M. Poorafshar[1], J. Rönnelid[3], J. Askling[4], E. Haavardsholm[5], H. Berner Hammer[5]on behalf of NORA consortium. [1]*Thermo Fisher Scientific, Research and Development, Uppsala, Sweden*; [2]*Thermo Fisher Scientific, Research and Development, Freiburg, Germany*; [3]*Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, Sweden*; [4]*Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden*; [5]*Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway*

Background: Personalized medicine in Rheumatoid arthritis (RA) especially regarding therapy response is still in early stages. The Nordic RA (NORA) project is aiming to improve the prediction of therapy outcome by combining established serologic marker with new markers, genetic information and patient-derived data.
Objectives: As an initial step in the project the aim was to select clinically characterized patient cohorts and evaluate if changes or patterns in serological markers could predict therapy response and/or disease progress.
Methods: The ARCTIC (**A**iming for **R**emission in rheumatoid arthritis: a randomised trial examining the benefit of ultrasound in a **C**linical **TI**ght **C**ontrol regimen) study [1] was designed to compare two tight control treatment strategies for early Rheumatoid arthritis and was used as a first cohort. Plasma samples (n=1622) from 224 RA patients from the ARCTIC study were included and taken at baseline and 3, 4, 6, 8, 10, 12, 14, 16, 20, and 24 months from trial start, and analyzed for the presence of EliA™ RF (IgM, IgA, IgG), anti-CCP (IgG, IgA) and anti-RA33 (IgM, IgA, IgG) autoantibodies, as well as Calprotectin using the EliA instrument platform (Phadia AB, Uppsala, Sweden). In addition, a custom-made multiplex chip (Thermo Fisher Scientific, Sweden) [2] was used for measurement of anti-IgG antibodies against RA-specific antigens (citrullinated, acetylated and carbamylated), and established CTD-markers (Connective Tissue Disease), e.g. Ro52/60 and dsDNA. The citrullinated peptides on the multiplex chip were both multiple as well as single citrullinated at different positions within the peptide sequence. Additionally, we included an ELISA to measure antibodies against native human collagen II [3].
Results: The different single assays in the baseline samples varied between 7 – 80% positive test results, e.g. anti-CCP IgG 80%. For some patients we could see changes in levels for anti-CCP, RF and anti-RA33 in the follow up samples, which varied from negative to more than 3-10xULN (Upper Limit of Normal). For anti-CCP IgG we found 9 patients (4%), who changed from negative to positive (patient 1-5) or from positive to negative (patient 6-8), while patient 9 had a peak at visit 6 (=12 months) and declined afterwards (figure 1). In addition, the above mentioned 9 patients showed clear changes in signal strength for the markers included on the multiplex chip and followed a similar pattern as the anti-CCP IgG signal. Different antibody patterns against single citrullinated peptides were observed and number of ACPA-positive peptides correlated with IgG anti-CCP levels.

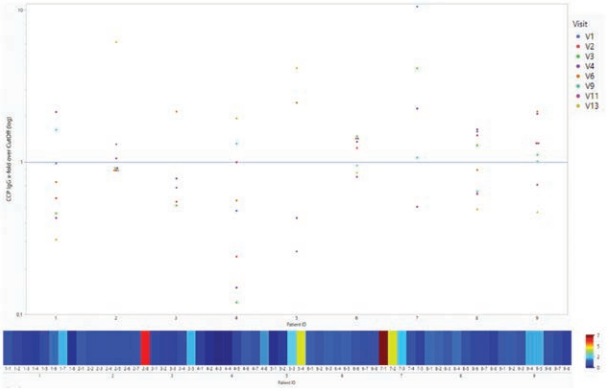

Figure 1. Anti-CCP IgG value normalised to cutoff (blue line) for patient 1 to 9. The heatmap visualizes the change over time in anti-CCP IgG signal with dark blue showing negative results and orange/red showing results >5xULN.

Anti-Collagen II antibodies (anti-CII) were detected in 15% of the baseline samples and in most cases declined over time. Two patients showed low baseline anti-CII levels that increased in the follow up samples. The changes in serological markers and the different reactivity patterns could possibly correlate with clinical outcome and define subgroups of patients with different response to therapy.
Results could be repeated in RA patients from the NOR-VEAC [4] cohort. At baseline 73% of the 106 RA patients had a positive anti-CCP IgG result and 11 patients (10%) showed a significant change of anti-CCP IgG level over time.
Conclusion: Different response patterns and changes in serological antibody levels over the first 24 months after RA diagnosis could possibly reveal subgroups of patients with different prognosis and response to treatment. Further evaluations in additional treatment cohorts and correlation with clinical data are ongoing.

AB0123 ANXIETY AND DEPRESSION DURING RHEUMATOID ARTHRITIS

L. Ben Ammar[1], S. Rekik[1], S. Boussaid[1], S. Jemmali[1], E. Cheour[2], H. Sahli[1], M. Elleuch[1]. [1]*La Rabta Hospital, Rheumatology, Tunis, Tunisia*; [2]*La Rabta Hospital, Department of Pain Management, Tunis, Tunisia*

Background: Although the management of rheumatoid arthritis (RA) has been booming since the advent of biological treatments, the consequences of this disease remain multiple, both physical and psychological.

Objectives: The aim of our work was to investigate the factors influencing anxiety and depression in RA.
Methods: This was a cross-sectional study of 49 RA patients. We used the Hospital Anxiety and Depression scale (HAD) to assess anxiety disorders.
Results: We included 24 women and 5 men with an average age of 54.1 years. Sixty-nine percent of patients were unemployed and 81% had health insurance coverage. RA had been evolving for an average of 11.43 ± 7.32 years and the mean time to diagnosis was 2.35 years. It was erosive in 93.8% of cases. An atlanto-axial dislocation was found in 4.1% of cases and coxitis in 8.2% of cases. Eighty-three percent of patients were on cs-DMARDs and 14.2% were on biotherapy. Most patients had low active disease (53%) with a mean DAS28CRP score of 2.74 ± 0.81. Twelve percent of patients had a probable anxiety and 18% had a probable depression.
A long delay in diagnosis was associated with a higher risk of anxiety disorders. Working patients had a lower risk of depression while patients from rural areas had a higher risk. The risk of anxiety and depression disorders was associated with increased VAS pain, EGP, and DAS28. In the multivariate study, EGP was the independent risk factor for the development of anxiety and depression disorders.
Conclusion: Anxiety and depression disorders are a frequent yet underestimated consequence in RA. Appropriate care in psychiatry is required as soon as the diagnosis is announced.

DOI: 10.1136/annrheumdis-2021-eular.2066

AB0124 STRUCTURAL DAMAGE IN THE FOOT IN RHEUMATOID ARTHRITIS: DON'T MISS THE OTHER METATARSOPHALANGEAL JOINTS

M. Yasmine[1], H. Ferjani[1], D. Kaffel[1], K. Maatallah[1], S. Rahmouni[1], W. Hamdi[1]. [1]*Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia*

Background: The foot involvement in rheumatoid arthritis (RA) affects the functionality and the quality of life in patients. Despite this, the clinicians do not give enough care to the foot in RA patients, especially if asymptomatic, resulting in joint damage, deformity, and disability. The distribution of erosions of the other MTP joints (excluding the 5th) has not previously been studied.
Objectives: This study aimed to investigate the distribution of erosions in MTP joints and their clinical implications.
Methods: We conducted a retrospective study including patients with RA according to the American college of rheumatology/ the European league against rheumatism classification criteria. Sociodemographic data, as well as disease activity related characteristics, were recorded.
Posterior–anterior radiographs of the hands and feet of each patient were assessed for erosions.
All patients were assessed by Ultrasonography (US) of the hands. US erosions were scored 0-3 according to Szkudlarek [1]. We divided patients into two groups (G1 without MTPs erosions and G2 with MTPs erosions).
Results: We enrolled forty-two females and eleven males in our studies. The mean age was 58.6 years ±12.7 [23-77], and the mean disease duration was 8.4 years [1-47]. Rheumatoid factor or cyclic citrullinated peptide antibodies (Anti-CCP) were positive in 62.3% of cases. The mean DAS28ESR score was 5.1±1.16 [2.5-7.7]. Half of the patients had the active disease (52.8%). Hand erosions evaluated with plain radiographs and the US were found in 43.1% and 50.9% of cases, respectively. The distribution of foot erosions (15.1%) was at follows: 5th right MTP (7.5%), the 5th right IPP (2%), the 1st left MTP (2%), 3th left MTP (3.8%), 4th left MTP (5.7%) and the 5th left MTP (9.4%). Erosions on MTPs with the exclusion of the 5th MTP were present in 9.4% of cases. The presence of MTPs erosion was more frequent in males (p=0.01) but was not associated with age (p=0.6) or disease duration (p=0.2). Seropositivity was similar between the two groups (p=0.06). Similarly, the inflammatory markers (ESR and CRP), as well as DAS28 ESR, did not differ between the two groups (p>0.05). MTPs erosion was not associated with the presence of hand erosions on a plain radiograph (p=0.445). However, MTPs erosion was significantly more frequent in patients with less erosive hands-on US (p=0.034).
Conclusion: Our study showed that screening of other MTPs (excluding the 5th) is mandatory in RA diagnosis. Interestingly, in our result, MTPs erosion is more frequent in males with less erosive hands.

AB0125 CLINICAL CHARACTERISTICS OF RHEUMATOID ARTHRITIS PATIENTS WITH IGG4-RELATED SYNOVITIS

L. F. Chen[1], X. Zhang[1], C. Chen[1], J. D. Ma[1], Y. Mo[1], J. Lin[1], Y. Y. Zou[1], D. H. Zheng[1], L. Dai[1]. [1]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Rheumatology, Guangzhou, China*

Background: Elevated serum IgG4 (sIgG4) and IgG4+ plasma cell tissue infiltration are outstanding features of IgG4-related disease (IgG4-RD). However, elevated IgG4 is not specific for IgG4-RD. Our previous study reported elevated sIgG4 in 46% of rheumatoid arthritis (RA) patients (*Mediators Inflamm 2014*). Whether synovium from RA patients show similar characteristics of IgG4-RD and how about the clinical characteristics of RA patients with IgG4-related synovitis have not been reported yet.
Objectives: To explore the serum and synovial IgG4 level and their correlation with disease indicators in RA.
Methods: Active RA patients who underwent needle synovial biopsy with qualified synovium tissue were recruited. Demographic and clinical data were collected simultaneously. Synovium tissue were stained with H&E for Krenn synovitis score and immunohistochemistry for positive cell densities of CD20, CD38, IgG and IgG4. Serum IgG4 level was detected by immunonephelometry.
Results: Among 96 RA patients recruited, 74 (77.1%) were female, the median age was 55.0 (46.0~61.0) years, disease duration was 42.0 (12.0~120.0) months and SDAI was 31.2 (22.1~42.8).
The median sIgG4 was 1.38 (0.86~2.42) g/L and 49(51.0%) patients had elevated sIgG4. Compared with those with normal sIgG4, RA patients with elevated sIgG4 had significantly higher levels of PrGA [7 (5~8) vs. 6 (4~7)], ESR [90 (64~116) mm/h vs. 61 (38~75) mm/h], CRP [46.20 (17.20~74.20) mg/L vs. 18.90 (9.46~49.20) mg/L], DAS28-ESR [6.3 (5.6~7.4) vs. 5.7 (4.7~6.4)], SDAI [34.2 (25.3~48.8) vs. 27.8 (18.9~35.9)] and HAQ-DI [1.70 (0.61~2.28) vs. 0.88 (0.40~1.75), all $P<0.05$]. Meanwhile, they also showed significantly higher synovial counts of CD38+ plasma cells [1240(559~2290) /mm^2 vs. 1020(354~1777) /mm^2], IgG4+ plasma cells [106 (39~249) /mm^2 vs. 68 (3~123) /mm^2], and higher ratio of IgG4+/IgG+ plasma cells [26.3 (15.5~38.0) % vs. 15.2 (0.9~24.7) %, all $P<0.05$].
The median IgG4+ plasma cells count was 83 (10~192) /mm^2 and median ratio of IgG4+/IgG+ plasma cells was 19.1 (8.4~31.5)%. Both of them correlated positively with ESR, CRP and sIgG4 (r=0.216~0.394, all $P<0.05$). There were 46 (47.9%) patients with IgG4+ plasma cells >10/HPF, who had significant higher ESR [86 (50~109) mm/h vs. 65 (40~84) mm/h] and CRP [43.35 (16.93~77.85) mg/L vs. 26.15 (9.54~52.53) mg/L, both $P<0.05$] than those with IgG4+ plasma cells ≤10/HPF. There were 13 (13.5%) patients with the ratio of IgG4+/IgG+ plasma cells >40%, and 11 (11.5%) patients with both IgG4+ plasma cells >10/HPF and IgG4+/IgG+ plasma cells ratio >40% (IgG4-related synovitis). RA patients with IgG4-related synovitis had significant higher ESR than the others [106 (53~125) mm/h vs. 69 (41~91) mm/h, $P<0.05$].
There were 10 (10.4%) patients showing elevated sIgG4 and IgG4-related synovitis. Four patients completed 1-year follow-up and all of them achieved remission at 6th month (SDAI≤3.3, Figure 1). Only one patient had radiographic progression at 12th month.

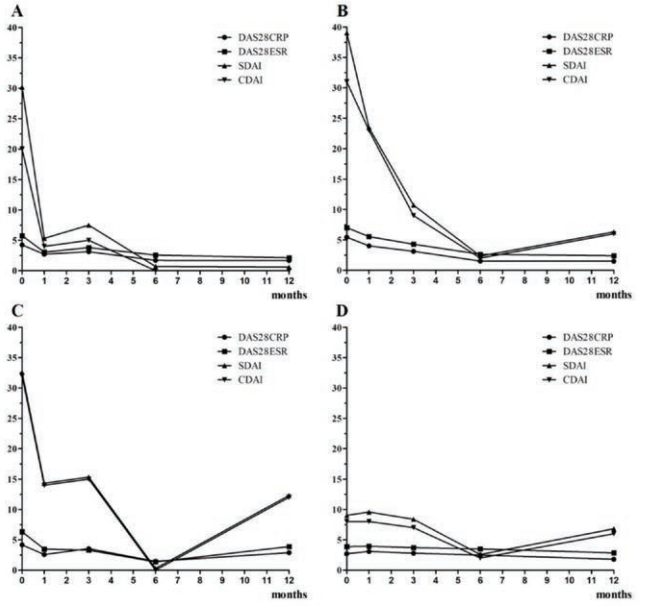

Figure 1. Dynamic disease activity of 4 RA patients with elevated sIgG4 and IgG4-related synovitis during 1-year follow-up.

Conclusion: IgG4-related synovitis can be found in RA patients. Their clinical significance in disease characteristics and outcomes are worth further study.

AB0126 METHOTREXATE MAINTENANCE THERAPY DURING THE TARGETED THERAPY ERA IN RHEUMATOID ARTHRITIS

S. Abdellaoui[1], S. Lefkir[1]. [1]*Issad Hassani Beni Messous Hospital, Rheumatology, Algiers, Algeria*

Background: The persistence with methotrexate (MTX) at 1 year or 5 years in rheumatoid arthritis (RA) is very variable and intolerance remains the main cause of discontinuation of treatment. Changes in treatment with the strategy of adding "add-on" to a targeted therapy when the conventional DMARD becomes insufficient to optimally control the disease may decrease the maintenance MTX therapy rates, particularly for biologics with a Marketing Authorization as monotherapy.
Objectives: The main objective of this study was to determine the rate of maintenance at 1 year of the combination therapy with different biologics, to compare the evaluation scores in patients receiving treatment as monotherapy (biological only) versus combination therapy with methotrexate and to analyze predictive factors for MTX maintenance therapy.
Methods: We performed a descriptive study of 56 patients with RA meeting the criteria of the ACR 2010. Statistical analysis SPSS.20 Software.
Results: These were 56 patients: 93% women and 7% men, mean age 46.74 years with an average duration of the disease of 14.74 years. 71.42% of patients were under corticosteroids taken for a period of 13 years with an average dose of 5.04 mg / day. BMI was highin 23.80% of patients, 30.95% had at least one associated comorbidity. The RF was positive in 61.90% and ACPA positive in 78.57% of cases. 47.62% were under MTX taken for 6.55 years with a dose of 13.03 mg / week on average: 68.75% by oral intake and 31.25% by subcutaneous intake with an average duration of setting before the switch of 8 years. 28 patients were on rituximab, 19 patients on tocilizumab and 9 patients on TNFi. 88.09% did not havenot received from bDMARD before. The mean ESR was 36.57 mm H1 and CRP was 8.56 mg / L. DAS28 at baseline was 6.81 and the current DAS 28 was 2.95 and the HAQ was 1.11. The rate of MTX maintenance therapy at 1 year was 36.84%, with rituximab, 64.28% with tocilizumab and 88% with TNFi. The comparison between the combination therapy with MTX and monotherapy groups showed a significant difference for the number of tender joints NTJ (3.5 vs 2.61), however, no significant difference concerning DAS28 value (2.98 vs 3.06), number of swollen joints NSJ (0.29 vs 0.22) and HAQ (1.09 vs 1.15). Regarding predictive factors of MTX maintenance therapy: Significant correlation was found with a high DAS 28 at baseline, however no correlation concerning the positivity of ACPA, duration of the disease, NTJ, NSJ, ESR, HAQ and the high dose of MTX. Reduction in persistence has found a significant correlation with non-naive RA of ≥ 1 bDMARD, disease activity score, type of biotherapy (antiTNF / rituximab vs Tocilizumab), young age, however no influence was found with a high BMI, HAQ, the presence of comorbidities or the withdrawal of corticosteroids. The increase in the persistence of combination therapy was associated with male gender and RF seropositivity only.
Conclusion: Drug persistence is an important aspect of treatment effectiveness. For rheumatologists, knowledge of the factors that predict whether to maintain the combination therapy with methotrexate, increase or reduce the persistence is of great interest when choosing a new treatment to initiate in patients with RA.

AB0127 COMBINATION THERAPY WITH METHOTREXATE AND QUALITY OF LIFE IN RHEUMATOID ARTHRITIS

S. Abdellaoui[1], S. Lefkir[1]. [1]*Issad Hassani Beni Messous Hospital, Rheumatology, Algiers, Algeria*

Background: The level of quality of life in patients with rheumatoid arthritis (RA) is often overlooked. These patients suffer from an often-precarious quality of life resulting in pain, joint destruction and fatigue.
Objectives: The main objective of this study was to compare the level of quality of life in patients with RA receiving treatment with disease-modifying anti-rheumatic drugs (DMARDs): monotherapy (biological only) versus combination therapy with methotrexate.
Methods: We performed a descriptive study of 56 patients with RA meeting the criteria of the ACR 2010. The SPSS.20 software was used for statistical analyses.
Results: These were 56 patients: 93% women and 7% men, mean age 46.74 years with an average duration of the disease of 14.74 years. 28 patients were on rituximab, 19 patients on tocilizumab and 9 patients on TNFi. The mean HAQ was 1.11. 52.38% of patients were on biological alone as monotherapy. The Compliance Questionnaire Rheumatology score (CQR19) was 55.15 / 100, the RAID (Rheumatoid Arthritis Impact of Disease) score was 3.08 / 10, the SF36 of 56.01 / 100, the AIMS score of 2.10 / 10 for social activity, 2.44 / 10 for pain, 3.32 / 10 for depression and 4.06 for physical activity.
The comparison between the 2 groups (Combination therapy vs monotherapy) did not find any significant difference in terms of quality of life parameters: An SF-36 score> 55 was found in 56% in patients on combination therapy vs. 44% on monotherapy, the RAID score was 3.02 vs. 3.12, AIMS social activity 2.08 vs 2.13, AIMS pain 2.33 vs 2.59, AIMS activity physics of 4 vs 4.11.
Conclusion: Our study did not demonstrate any superiority of the combination with methotrexate in improving quality of life. The use of biotherapy in patients with RA has been shown to be an important pharmacological strategy for the overall management of the disease.

AB0128 CONSTRUCTION OF THE VETERANS AFFAIRS NATIONAL RHEUMATOID ARTHRITIS DATABASE (VANRAD)

A. Joseph[1,2], J. Yanagida[2], X. Huang[1,2], P. Ranganathan[1,2], M. Laurie[3], H. Xian[2,4], S. Eisen[1,2]. [1]*Washington University School of Medicine, Rheumatology, Saint Louis, Missouri, United States of America*; [2]*VA St. Louis Health Care System, Rheumatology, Saint Louis, Missouri, United States of America*; [3]*Bristol Myers Squibb, Health Economics & Outcomes Research, Lawrence Township, United States of America*; [4]*Saint Louis University College for Public Health & Social Justice, Epidemiology & Biostatics, Saint Louis, Missouri, United States of America*

Background: The Department of Veterans Affairs (DVA) provides comprehensive medical care at minimal or no cost to 9 million veterans annually through 170 medical centers and 1074 outpatient clinics across the United States. In 1999, the DVA established a national, fully integrated electronic health record (EHR), which now includes approximately 24 million veterans. However, few studies have used VA EHR data to examine the validity of diagnoses of rheumatoid arthritis (RA).
Objectives: Develop a validated, national database (VANRAD) of patients with RA who received VA care since International Classification of Diseases, tenth revision (ICD-10) coding was introduced in 2015. The database will provide infrastructure for retrospective and prospective research to address the 'real-world' care of patients with RA.
Methods: Patients with the following criteria were identified from the VA EHR as of October 2, 2020: (a) ≥1 ICD-10 diagnosis code of RA; (b) treatment with ≥1 disease-modifying anti-rheumatic drug (DMARD); (c) ≥2 VA rheumatology clinic visits; and (d) ≥1 rheumatoid factor (RF) or anti-cyclic citrullinated peptide (aCCP) antibody test result. From this group, 553 EHRs were randomly selected for review. The 'gold standard' for the diagnosis of RA was the treating rheumatologist's diagnosis, documented in the EHR.
Results: 27,482 patients met eligibility criteria. Sociodemographic characteristics were: 85.6% male, mean age of 69.7 years (y) (SD=10.9 y; range=21.9 y to 100.5 y), 76.4% white, 17.0% African American; and mean VA care duration 14.1 y (SD=5.3 y, range=0.04 y to 20.0 y).
For patients with ≥1 RF or aCCP test, the positive predictive value (PPV) for RA ranged from 65.3% (aCCP-/RF-) to 95.8% (aCCP+/RF+); rheumatologists' likelihood of a 'possible' diagnosis was higher if the aCCP test result was negative or not available (Table 1). Excluding patients with a second rheumatologic diagnosis did not improve PPV results (data not shown).

Table 1. Proportion of patients with a valid RA diagnosis[1] as a function of RF and aCCP laboratory results

Test Result	aCCP			
	Not Available (0)[2]	Negative (-)	Positive (+)	Total
Rheumatoid Factor	Not Available (0) (N = 1253)[3]	N 427 RA[4] 89.7% Poss[5] RA 5.9%	N 1,159 RA 98.2% Poss RA 0.0%	N 1,586 RA 93.5% Poss RA 3.2%
	Negative (-) N 810 RA 86.3% Poss RA 3.9%	N 5,308 RA 65.3% Poss RA 11.9%	N 2,005 RA 94.5% Poss RA 0.0%	N 8,123 RA 80.7% Poss RA 5.8%
	Positive (+) N 2,229 RA 94.6% Poss RA 0.0%	N 2,566 RA 78.0% Poss RA 8.5%	N 12,978 RA 95.8% Poss RA 2.1%	N 17,773 RA 87.6% Poss RA 4.3%
	Total N 3,039 RA 90.7% Poss RA 1.9%	N 8.301 RA 76.1% Poss RA 9.2%	N 16,142 RA 95.9% Poss RA 0.5%	N 27,482 RA 85.9% Poss RA 4.7%

[1]Diagnosis given by the treating rheumatologist.[2]No test results available or test results available but without normal range values.[3]1,253 patients without available or interpretable RF or aCCP excluded from initial cohort.[4]Percent of 553 charts reviewed confirmed as RA.[5]Poss RA = Possible RA. Patients met our inclusion criteria but the treating rheumatologist never made definitive diagnosis of RA or alternative diagnosis (from 553 charts reviewed).

The percentage of RA-confirmed patients with one test not available, whose complementary test was negative (RF0/aCCP- or RF-/aCCP0), was greater than of patients for whom both tests were negative (RF-/aCCP-). This suggests our data extraction methods may be incomplete or that unidentified bias may be present and warrants further study.

Conclusion: Our methodology for constructing an RA database by selecting patients with ≥2 rheumatology clinic visits, ≥1 ICD-10 diagnosis of RA, and treatment with ≥1 DMARD, has high positive predictive value for RA. Positive RF and aCCP test results were strong predictors of rheumatologists' diagnostic certainty for an RA diagnosis. Thus, the VANRAD database and the associated EHR provide opportunity for a wide range of retrospective observational and prospective longitudinal studies based on 'real-world' patient care.

AB0129 IL-6R GENETIC VARIANTS AS PREDICTORS OF CLINICAL RESPONSE TO TOCILIZUMAB IN RHEUMATOID ARTHRITIS PATIENTS

L. Sainz Comas[1], P. Riera[2], P. Moya[1], S. Bernal[3], A. Lasa[3], S. Jeria Navarro[1], D. Lobo Prat[1], H. Codes[1], I. Castellví[1], C. Díaz-Torné[1], A. Laiz[1], B. Magallares[1], A. M. Millán Arciniegas[1], H. Park[1], H. Corominas[1]. [1]*Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; [2]*Hospital de la Santa Creu i Sant Pau, Pharmacy/Genetics, Barcelona, Spain*; [3]*Hospital de la Santa Creu i Sant Pau, Genetics, Barcelona, Spain*

Background: Rheumatoid arthritis (RA) is a chronic, systemic, inflammatory autoimmune disease of unknown etiology. Tocilizumab (TCZ) is a first-line biological disease-modifying anti-rheumatic drug (bDMARD) which inhibits Interleukin 6 (IL-6) pathway through blockade of its receptor. At present, there is a lack of evidence to recommend the treatment of one bDMARD over another.(1) Seeking for genetic biomarkers to predict response to treatment could be key towards a personalized treatment strategy in rheumatology.(2)

Objectives: We aimed to evaluate whether functional single nucleotide polymorphisms (SNPs) in the *IL6R* gene could predict response and/or toxicity to TZC in Caucasian patients diagnosed with RA.

Methods: Retrospective analytical preliminar study of a cohort of 31 patients diagnosed with RA (ACR/EULAR 2010 criteria) who received treatment with TCZ within the last 10 years. Epidemiological, clinical and laboratory data were collected. DNA was extracted from EDTA blood samples. Three SNPs in the IL-6 receptor gene (rs12083537, rs2228145, rs4329505) were genotyped by real-time PCR with TaqMan probes. The associations between polymorphisms and clinicopathological features were evaluated using parametric tests. Efficacy was assessed as the difference of DAS-28 CRP at 6 months. The toxicities recorded were hepatotoxicity, infections, hypersensibility, gastrointestinal, hematological and dyslipidemia.

Results: The 31 DNA samples from patients included were mainly female (83.9%) and had a mean age at diagnosis of 46.8 years. The mean duration of treatment was 51.3 months and, previously to initiate TCZ, they received a mean of 2,6 csDMARD and 1,7 bDMARD.

The more frequent adverse effects were hypertransaminasemia (22.6%) and neutropenia (32.3%). Most relevant epidemiologic and clinical data is shown in Table 1.

Table 1. ***Clinical characteristics. RA=Rheumatoid Arthritis. CCP= anti-Cyclic Citrullinated Peptides. RF=Rheumatoid factor. csDMARDs= conventional synthetic Disease-modifying antirheumatic drug. bDMARD= biological Disease-modifying antirheumatic drug. BMI=Body Mass Index. Sc=subcutaneous. Ev=endovenous. DAS28= Disease Activity Score in 28 joints***

Sex (n=31), n (% women/men)	26/5 (83,9%/16,1%)
Age at diagnosis (n=31), years +- SD	46,8+- 12,8
Erosive RA (n=31), n(%)	14 (45,2%)
Anti-CCP positive (n=31), n(%)	23 (74,2%)
UI+- SD	259,7 +- 137,3
RF positive (n=31), n (%)	21 (67,7%)
UI+-SD	189,4+- 114
Previous csDMARD (n=31), nº+-SD	2,6 +-1,3
Previous bDMARD (n=31), nº+- SD	1,7 +- 1,4
BMI (n=29), mean +- SD	29,3+- 5,1
Duration of treatment (n=31), months +-SD	51,3 +- 36,3
-Active treatment (n=12)	-80,9+- 18,3
-Finished treatment (n=19)	-32,6+- 32,2
Route of administration (n=31), n (%) sc/ev	11/20 (35,5/64,5)
Basal DAS28 (n=30), mean+- SD	5,3 +- 1,1
DAS28 reduction at 6 months (n=28), mean+-SD	2,9 +-1,1

The univariate analyses showed that the rs2228145 variant was statistically associated with differences in DAS28 reduction at 6 months (p=0.042). Regarding efficacy, we also found a trend with the SNP rs4329505 (p=0.173), which could achieve statistical significance with the projected inclusion of more patients. No associations were found regarding adverse effects.

Conclusion: The rs2228145 polymorphisms in the *IL6R* gene may be considered as a pharmacogenetic biomarker of TCZ response in RA patients. More studies are required in order to investigate the clinical use of pharmacogenetic biomarkers in rheumatic diseases.

AB0130 QUESTIONING THE USEFULNESS OF CDAI AS A MEASURE OF DISEASE ACTIVITY IN A TREAT TO TARGET PROGRAMME

C. Lally[1], I. Ali[1], C. Silke[1], B. Whelan[1], M. O'sullivan[1]. [1]*Manorhamilton, Rheumatology, Manorhamilton, Ireland*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune condition which if not treated can lead to joint destruction and long term disability. In RA, the concept of T2T is recommended as the appropriate method to manage early arthritis [1]. It has shown promising results to achieve clinical **remission** (CR) or **low disease activity** (LDA) [2].

Objectives: The objective of this study was to investigate the potential to achieve remission or LDA according to the Clinical Disease Activity Index (CDAI) for RA, during treatment with Disease-Modifying Anti-Rheumatic Drugs (DMARDs) and Biologics, and the factors that affect the remission/LDA outcome.

Methods: We performed an observational prospective study on patients' data available from our Early Arthritis Cohort. All patients with newly diagnosed RA who met the American College of Rheumatology (ACR) criteria were enrolled. Patients are managed by an Advanced Nurse Practitioner (ANP) with consultant supervision. To assess their response to treatment, we used the Clinical Disease Activity Index[3]. Analysis was performed using SPSS.

Results: Out of a total of 459 patients, 353 completed the programme. 217 patients (61.5%) were female and (136) 38.5 % were male. Mean age was 53.98 (SD 14.66). 195 patients were on monotherapy, 40 on combination DMARDs and

115 were on Biologics/Janus Kinase Inhibitors (JAK-Inh). Remission-rates in the monotherapy and combination DMARDs groups were approximately 60%, whilst the remission rate in the Biologics/JAK-Inh group was 41.7%. Amongst female patients 15.9% had erosions on X-ray at the time of diagnosis whilst the equivalent figure for male patients was 29.6%.

Conclusion: An association between male gender and the likelihood of erosions on X-Ray was observed. In addition an association between final medication and outcome was observed. An increased likelihood of non-remission was noted in patients that required escalation to Biologics/JAKs. A possible explanation for the lower levels of remission seen throughout the groups is the difficulty in achieving remission under the CDAI score as compared to DAS-28.

AB0131 DIFFERENCES IN CLINICAL PARAMETERS AND LABORATORY DATA OF RHEUMATOID ARTHRITIS PATIENTS IN REMISSION OR WITH LOW DISEASE ACTIVITY TREATED WITH BIOLOGIC AGENTS OR JANUS KINASE INHIBITORS

Y. Hirano[1], J. Hasegawa[1], H. Kosugiyama[2], D. Kihira[2], K. Hattori[2]. [1]*Toyohashi Municipal Hospital, Rheumatology,Toyohashi, Japan*; [2]*Nagoya University Graduate School of Medicine, Orthopaedic Surgery and Rheumatology, Nagoya, Japan*

Background: There are four kinds of drugs for rheumatoid arthritis (RA) patients who are refractory or intolerant to methotrexate (MTX) or other conventional synthetic disease-modifying anti-rheumatic drugs, namely, tumor necrosis factor inhibitors (TNFi), inteleukin-6 inhibitors (IL-6i), abatacept (ABT) and Janus kinase inhibitors (JAKi). Although these drugs have distinct mechanism of action (MOA) to reduce disease activity of RA, the effects of these drugs of reducing disease activity or inhibiting joint damage are similar according past clinical trials. However, their different MOA may induce different change in body of RA patients. If there are some differences in body of RA patients treated different drugs which have different MOA, some differences may appear in clinical parameters and laboratory data we clinician are able to know in daily clinical practice.

Objectives: This retrospective cross-sectional study assessed differences in clinical parameters and laboratory data in RA patients who met the treatment goal with biologic agents (BIO) or JAKi.

Methods: Data from the Toyohashi RA database (TRAD) was used. The TRAD is a collection of single-center retrospective data. Participants were BIO- or JAK-treated RA patients with clinical disease activity remission (REM) or low disease activity (LDA) [clinical disease activity index (CDAI) ≤ 10]categorized by BIO treatment with TNFi (reference), IL-6i, or ABT, and JAKi treatment. Clinical parameters [tender joint counts (TJ), swollen joint counts (SJ), patient's global assessment (PtGA), patient's pain assessment (PainVAS), physician's global assessment (PhGA) and modified health assessment questionnaire (mHAQ)] and laboratory data [C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), matrix metalloprotease-3 (MMP-3), white blood cell counts (WBC), hemoglobin (Hb), platelet cell counts (PLT), neutrophils counts (Neut), lymphocyte counts (Lymph) and estimated glomerular filtration rate (eGFR)] were investigated in cross-sectional manner. They are statistically compared using the Dunnett test.

Results: 171 TNFi, 71 IL-6i, 50 ABT, and 18 JAKi cases are categorized in REM or LDA. Patients' characteristics (means) are as follows (TNFi/IL-6i/ABT/JAKi). Age (63.1/63.7/72.4/60.6; years old), RA duration (17.0/12.7/18.2/11.3; years), %female (83.0/71.8/88.0/83.3), %rheumatoid factor positive (81.9/80.3/90.0/88.9), %anti-cyclic citrullinated peptide antibody (84.6/74.6/97.9/73.3), %prednisolone (PSL) concomitant (3.5/4.2/18.0/11.1) and %MTX concomitant (77.2/15.5/26.0/83.3). Parameters with statistical significance (means) were: TNFi/IL-6i-ESR 34.5/14.0 mm/hr, MMP-3 47.5/71.9 ng/mL, WBC 6124/5404 /μL, Lymph 2112/1646 μL; TNFi/ABT-TJ 0.4/1.0, PtGA 13.3/20.0 mm, PainVAS 15.7/21.6 mm, PhGA 7.4/11.1 mm, CRP 0.1/0.4 mg/dL, ESR 34.5/44.2 mm/hr, MMP-3: 47.5/72.9 ng/mL, Lymph 2112/1816 μL, Neut 3364/4233 μL, eGFR 75.4/65.3 mL/min/1.73m^2; and TNFi/JAKi-PLT 21.7/29.3 104/μL, Lymph 2112/1326 μL.

Conclusion: Although differences of rates of administering concomitant PSL or MTX should be considered, clinical parameter and laboratory data differences result from differences in the targeted cytokine between TNFi and IL-6i, differences in patient characteristics between TNFi and ABT, and differences in the MOA between TNFi and JAKi.

AB0132 THE STUDY OF SUBCLINICAL SYNOVITIS DETECTED BY ULTRASONOGRAPHY AND MRI IN RA PATIENTS AFTER REACHING CLINICAL REMISSION ON PATIENT'S SUBJECTIVE SYMPTOMS

M. Nawata[1,2], K. Someya[1,2], T. Aritomi[1,2], M. Funada[2], K. Nakamura[3], S. Kazuyoshi[1,2], Y. Tanaka[2]. [1]*Tobata General Hospital, Department of Clinical Immunology and Rheumatology, Kitakyushu, Japan*; [2]*School of Medicine, University of Occupational and Environmental Health, Japan,The First Department of Internal Medicine, Kitakyushu, Japan*; [3]*Tobata General Hospital, Department of Radiology, Kitakyushu, Japan*

Background: The goal of treatment in rheumatoid arthritis (RA) is to achieve remission. There is the patient with residual symptoms in the Japanese RA patient who achieved clinical remission. There are not many studies to examine the relation between everyday life, social activity and evaluation of disease activities using high-sensitivity image examinations (musculoskeletal ultrasound (MSKUS) and MRI).

Objectives: To examine the relationship between subjective residual symptoms and imaging examinations in RA patients who have achieved clinical remission.

Methods: 30 RA patients who achieved SDAI remission during RA treatment. Age, sex, disease duration, physical findings, serological markers, disease activity, HAQ, EQ-5D-5L, FACIT-F, Patient Reported Outcomes (PROs), EGA and medications were evaluated. 44 joints were assessed by MSKUS with gray scale (GS) and power doppler (PD) and contrast-enhanced bilateral joint MRI scoring with OMERACT-RAMRIS scoring.

Results: 1. The mean SDAI of the 30 RA patients was 1.3. 2.In the analysis of the presence or absence of subjective residual symptoms that led to remission of SDAI (Table 1).

Table 1.

	Subjective residual symptoms/presence (**N=17**)	Subjective residual symptoms/ absence (**N=13**)	Univariate analysis **p value**	Multivariate logistic analysis **p value**
TJC	0.0±0.0	0.3±0.5	0.0173	
HAQ	0.4±0.4	0.05±0.1	0.0095	0.00181
EQ5D-5L	0.8±0.1	0.9±0.0	0.0001	
FACIT-F	14.5±9.8	4.6±4.3	0.0233	
Morning stiffness (min)	256.5±564.8	0.0±0.0	0.0210	
Pain (VAS) (mm)	9.2±9.5	0.9±1.5	0.0044	0.0455
PGA (mm)	7.7±9.0	0.5±1.1	0.0013	

(1). In the univariate analysis, the number of tender joints, HAQ, EQ-5D-5L, FACIT-F, morning stiffness, and pain VAS were extracted with significant differences. (2). In multivariate logistic analysis, HAQ and pain VAS were extracted as independent factors with significant differences. 3.In univariate analysis of the association between HAQ and pain VAS extracted in multivariate logistic analysis and imaging examinations (MSKUS/MRI), MRI-synovitis was extracted with a significant difference in HAQ.

Conclusion: 1. It was suggested that Pain VAS and HAQ due to RA could be identified in patients reaching SDAI remission. 2. In patients reaching SDAI remission, Pain VAS ≤10 or HAQ ≤0.5 suggested that subjective residual symptoms may be eliminated. 3. HAQ ≤ 0.5 suggests that synovitis is less likely to be detected on MRI. 4. In patients who have reached SDAI remission, little residual inflammation was observed on US, suggesting that induction of remission is important not only to prevent joint destruction, but also to improve and maintain long-term QoL.

AB0133

LATE-ONSET AND BONE LOSS IN RHEUMATOID ARTHRITIS: WHAT FACTORS SHOULD WE CONSIDER?

K. Maatallah[1], M. Yasmine[1], H. Ferjani[1], W. Triki[1], D. Ben Nsib[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is an inflammatory rheumatism that causes alterations in bone components through the increased production of pro-inflammatory cytokines. Besides traditional risk factors of osteoporosis (OP), elderly RA patients are at higher risk of progressive decline in bone mineral density resulting from the disease.
Objectives: This study aimed to determine factors associated with bone loss in late-onset RA patients.
Methods: A cross-sectional study including patients with RA (according to ACR/EULAR classification criteria) in whom disease onset was after age 65 years. Sociodemographic data, daily calcium intake, and menopausal state were recorded. The characteristics of the disease were transcribed, including inflammatory markers (erythrocyte sedimentation rate (ESR) and C- reactive protein (CRP)), the disease activity assessed by Disease Activity Score 28 (DAS28), seropositivity for anti-cyclic citrullinated peptide antibody (ACPA) and rheumatoid factor (RF), and treatment modalities (cumulative dose of corticosteroids and Methotrexate). Bone mineral density (BMD) was assessed by Dual-energy X-ray absorptiometry. The risk of hip fracture (HF) and major osteoporotic fracture (MOF) after ten years were assessed using the fracture risk assessment tool (FRAX). Patients were divided into two groups (G1 with bone mineral loss (BML) and G2 without BML). Statistical analysis was performed using Kruskal-Wallis Test and chi-square. The level of significance was fixed for $p< 0.05$.
Results: The study included 58 late-onset RA patients with a female predominance (sex ratio M/F=0.3). The mean age was 71.6 ± 5.9 years [65-85], and the mean disease duration was 3.1 ±2.9 years [0-15]. The mean calcium intake was 416.4± 168.6 mg per day [168-1043]. The mean BMD was 1.5 g/cm^2[0.1-28.3] at the vertebral site and 0.7±0.2 g/cm [-0.1,1.2] at the femoral site. Bone loss was found in 55.2% of cases and was significantly associated with age (p=0.022) and longer disease duration (p=0.015). Similarly, there was a positive correlation between CRP and BML (p=0.023). However, bone loss was not correlated to sex (p=0.865), RF and ACPA positivity (p=0.9, p=0.1 respectively), or to coxitis (p=1). Similarly, disease activity, body mass index, and calcium intake were comparable between the two groups (p=0.311, p=0.179, p=0.099, respectively). G1 had a higher incidence of fractures without reaching a statistically significant correlation (63.2% in G1 and 51.3% in G2, p=0.393). Also, G1 had a higher risk of MOF (p=0.003) but not with a higher risk of HP (p=0.127). Regarding treatment modalities, the BML was significantly correlated to non-steroidal anti-inflammatory drug (NSAIDs) intake (85.7% in G1 and 37.8% in G2, p=0.001), but was not correlated to the cumulative dose of corticosteroids (p=0.384) and Methotrexate (p=0.054).
Conclusion: Our study showed that age, disease duration, NSAIDs, and inflammation were risk factors for a bone mineral loss in late-onset RA. Screening for these factors would be useful as part of an ideal form of fracture risk management.

AB0134

RELATIONSHIP BETWEEN INFLAMMATORY RATIOS AND RADIOGRAPHIC JOINT DAMAGE IN RHEUMATOID ARTHRITIS

F. Maatoug[1,2], M. Slouma[1,2], R. Dhahri[1,2], O. Beskri[1,2], I. Gharsallah[1,2], L. Metoui[1,2], B. Louzir[2,3]. [1]*Military Hospital of Tunis, Department of Rheumatology, Tunis, Tunisia*; [2]*University of Tunis El Manar, Faculty of Medicine of Tunis, Tunis, Tunisia*; [3]*Military Hospital of Tunis, Department of Internal Medicine, Tunis, Tunisia*

Background: The tight control strategy is recommended in rheumatoid arthritis to tailor treatment for patients. This strategy requires regular monitoring of both disease activity and structural damage. However, radiographic assessement cannot be performed frequently and the modified Sharp score is rarely evaluated in current practice. Besides, no biomarker was able to mirror structural damage (1).
Objectives: Our study aimed to assess the relationship between the modified Sharp score and the inflammatory ratios (platelet to lymphocyte ratio (PLR), neutrophil to lymphocyte ratio (NLR), lymphocyte to monocyte ratio (LMR), fibrinogen to albumin ratio (FAR) and CRP to albumin ratio (CAR)).
Methods: We performed a cross-sectional study including 53 patients with rheumatoid arthritis (RA). A cell blood count, fibrinogen and an albumin blood test were measured for each patient. Inflammatory ratios were also measured (PLR, NLR, LMR, FAR, and CAR). Modified Sharp score and its components (erosion score and joint space narrowing score) were evaluated using the radiograph of hand and foot.
Patients with infectious or hematological diseases were excluded from the study. Statistical analysis was performed using SPSS (Statistical Package for Social Sciences).
Results: Of the 53 patients, 39 were female (Sex Ratio: 2.8). The mean age was 53.9 ± 12.7 years. The mean disease duration was 10.1 ± 8.2 years.The average age of the onset of the disease was 43.8±13.5 years.
The mean DAS 28-ESR score was 4.64 ± 1.23. Forty three patients had a score higher than 3.2 (patients with moderate or high disease activity).
The mean values of PLR, NLR, LMR, FAR and CAR were 161.62 ± 86.59, 2.84 ± 2.39, 4.99 ± 3.23, 0.12 ± 0.06 and 1.15 ± 1.38.
The mean scores of joint erosion and joint space narrowing were respectively 12.76 ± 15.05 and 33.57 ± 25.80. The mean modified Sharp score was 46.33 ± 37.74.
There was a positive correlation between modified Sharp score and following ratios: PLR (r: 0.501; $p <10^{-3}$), NLR (r: 0.302; p:0.031), FAR (r: 0.300; p:0.030), CAR (r:0.286; p:0.042).
Moreover, a positive correlation between joint space narrowing score and these ratios was identified: PLR (r: 0.558; $p <10^{-3}$), NLR (r: 0.428; p:0.002), FAR (r: 0.371; p:0.007), CAR (r:0.387; p:0.005).
Joint erosion score correlated with PLR (r: 0.299; p:0.033).
No correlation was found between LMR and radiographic score.
Conclusion: Our study showed that the modified Sharp score correlated with PLR, NLR, FAR and CAR in patients with RA. This finding suggests that these ratios could be used as inexpensive and reliable markers to reflect radiographic joint damage. Longitudinal studies are necessary to confirm our results.

Background: JAK inhibitors block intracellular signaling pathways responsible for the synthesis of cytokines and mediators involved in the development of chronic pain and central sensitization (CS). This determines a very rapid clinical response to JAK inhibitors. However, it is not clear how the significant pain reduction in the first weeks of therapy is associated with the achievement of low rheumatoid arthritis (RA) activity.
Objectives: to assess the relationship between the early clinical response to tofacitinib and the decrease in RA activity after 3 and 6 months.

Methods: Study group included 88 patients with RA, their age was 53±11,5, 79.3% of women, 89.8% of RF "+," DAS28 5.2±1.2, receiving DMARDs (methotrexate 59.5% and leflunomide 19.8%), who were administered with tofacitinib 5mg 2 times a day due to inefficacy or intolerance of biological DMARDs. There were assessed the pain severity using Brief pain inventory (BPI) questionnaire, the presence of neuropathic pain component (NPC) using PainDETECT questionnaire and signs of CS using Central Sensitisation Inventory (CSI) questionnaire at early time after tofacitinib administration, RA activity using DAS28 after 3 and 6 months.
Results: The mean pain severity at baseline was 5.3±2.0 according to the visual analogue scale (VAS 0-10), 51.1% of patients had signs of central sensitization (CSI ≥ 40), 15.9% had NPC (PainDETECT ≥18). 7 days after tofacitinib intake there was statistically reliable reduction of pain severity – up to 4.1±1.8 ($p<0.05$) and CS – CSI from 40.4±13.5 to 36.5±12.5 (p=0.01). After 28 days, the effect was higher: the pain level (VAS) was 2.8±1.6 (p=0.000), PainDETECT decreased from 11.8±5.6 to 6.8±3.1 (p=0.000), CSI – to 31.6±13.9 (p=0.000). DAS28 after 3 and 6 months was 3.7±1.3 and 3.6±1.2. The number of patients with pain decrease of ≥50% after 28 days of therapy was 59.9%. Low RA activity after 3 months. (DAS28 ≤3.2) was achieved in 64.4% of patients. There was a clear correlation between the number of patients with significant pain reduction at 28 days and the number of patients with low RA activity after 3 and 6 months (r_S=0.548, p=0.000; r_S=0.790, p=0.000). Six patients withdrew from the study due to inefficacy or social reasons. There were no serious adverse reactions.
Conclusion: The application of JAK inhibitor tofacitinib allows to reach a fast analgesic effect and reduce CS signs. An early clinical response to tofacitinib (pain relief) predicts a decrease in RA activity after 3 and 6 months of the therapy. Limitation: Open-label observatory study.

AB0136 ASSESSING THE RELATIONSHIP AMONG OBESITY, GENETIC POLYMORPHISM, AND CLINICAL PARAMETERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Yoshida[1], S. Hatachi[1], S. Takahashi[1], N. Amano[1], M. Katayama[1], M. Sibata[2], T. Saito[2], S. Kumagai[1,2]. [1]*Shinko Hospital, Center for Rheumatic Diseases, Kobe, Japan*; [2]*Shinko Institute for Medical Research, Kobe, Japan*

Background: Several study suggested body mass index(BMI) may influence development of rheumatoid arthritis(RA). There are conflicting reports concerning the impact of high BMI on development of RA, but several reports of obese on drug resistance and functional impairment. The relationship of genetic polymorphism on obesity is unclear in RA.
Objectives: To examine the relationship among BMI, genetic polymorphism of obesity, disease activity of RA, laboratory parameters, and therapeutic agent of RA.
Methods: We have carried out a retrospective observational study by systematically analyzing medical records of total 289 patients diagnosed with RA in Shinko Hospital between March 2016 and December 2019. We also conducted genotyping single nucleotide polymorphisms (SNPs) including FTO (rs1558902 and rs9939609), UCP1 (rs1800592), ADR2(rs1042713) and ADR3(rs4994) after informed consent. Obesity was defined as BMI over than 25 and patients were divided between obese ("Ob") and non-obese ("non-Ob"). These SNPs, DAS-28CRP, laboratory parameters, methotrexate dose, use of biological DMARDs were compared between Ob and non-Ob patients.
Results: Of these 289 patients, 82.7% was female, mean age was 61.9 years and BMI was 22.4. Univariate logistic regression showed differences ($p<0.1$) between Ob and non Ob groups in UCP1 gene mutation(63.6% vs 78%, P=0.018), DAS(2.24 vs 1.99, P=0.033),triglyceride abnormality(23.8% vs 9.3%, P=0.021), HDL(56 vs 71, P=0.00009), HbA1c abnormality(26.5% vs 12.1%, P=0.019),γGTP(32 vs 21, P=0.00037), ALP (253 vs 230, P=0.0058), ALT (26.5 vs 20, P=0.029),and MTX dose(6 vs 8, P=0.066). Multivariate logistic regression showed that Ob group was significantly associated with HDL(OR=0.976, 95%CI 0.958 to 0.995), UCP1 gene mutation(OR=0.446, 95%CI 0.202 to 0.984), γGTP(OR=2.321, 95%CI 1.269 to 4.245), and MTX dose(OR=0.866, 0.784 to 0.957).
Conclusion: Obesity in patients with RA had significant positive correlation with γGTP, and negative correlation with HDL, UCP gene mutation and MTX dose.

AB0137 THE ASSOCIATION BETWEEN AUTOANTIBODY LEVELS AND THE OUTCOMES OF ANTI-TUMOUR NECROSIS FACTOR ALPHA TREATMENT IN RHEUMATOID ARTHRITIS - A RETROSPECTIVE COHORT STUDY WITH TWO YEARS FOLLOW-UP

D. Santos Oliveira[1,2], A. Martins[1], F. R. Martins[3], M. Rato[1], F. Oliveira Pinheiro[1], D. Fonseca[4], S. Garcia[1], B. M. Fernandes[1], C. Vaz[1,2,5], M. Bernardes[1,5], L. Costa[1]. [1]*Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal*; [2]*Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; [3]*Centro Hospitalar Universitário do Algarve, Rheumatology Department, Faro, Portugal*; [4]*Centro Hospitalar Vila Nova de Gaia / Espinho, Rheumatology Department, Vila Nova de Gaia, Portugal*; [5]*Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal*

Background: In rheumatoid arthritis (RA), autoantibodies namely anticitrullinated protein antibodies (Anti-CCP) have prognostic value, independently predicting radiologic progression. However, the evidence is still controversial about how the autoantibody levels change over time and their role in treatments outcomes and in monitoring disease activity in RA.
Objectives: This study aimed to characterize the changes of autoantibodies levels (rheumatoid factor (RF) and Anti-CCP) over time and to explore the association between these autoantibodies and the outcomes of the first anti-tumour necrosis factor alfa (anti-TNF-α) therapy as first biologic agent in RA.
Methods: An observational retrospective cohort study was conducted with two years of follow-up. Patients with diagnosis of RA according to American College of Rheumatology (ACR) criteria and registered on Rheumatic Diseases Portuguese Register (Reuma.pt) who started their first anti-TNFα agent (as first biologic) between 2003 and 2018 were included. Patients with positive RA (>30 UI/mL) and/or positive Anti-CCP (>10 U/mL) at their first visit were included. Demographic, clinical and laboratory data were obtained by consulting Reuma.pt. Disease Activity Score for 28 joints [DAS28(3v); DAS28(4v); DAS28(3v; C-Reactive Protein (CRP)), DAS28(4v; CRP), delta DAS28(4v)], Health Assessment Questionnaire (HAQ), delta HAQ, Anti-CCP and RF levels were assessed at baseline, 12 and 24 months. Continuous variables are presented with mean, standard deviation, median, quartile 1 and quartile 3. Categorical variables are presented with absolute and relative frequencies. To examine the differences between Anti-CCP and RF levels at baseline, 12 months and 24 months the Wilcoxon test for paired samples was performed. In order to correlate the Anti-CCP and RF levels with DAS28 variables, delta DAS28(4v), HAQ and delta HAQ at baseline, 12 months and 24 months, a correlation coefficient, Spearman's coefficient, was used.
Results: A total of 116 patients (mean age of 50.2±10.4 years old; 85.3% female) with RA were included with a median disease duration of 10.5 [5-18.5] years and a follow-up time of 8 [5-14] years. About 49% of patients were FR and Anti-CCP positivity, 38% only FR positivity and 13% only Anti-CCP positivity. At baseline, 64 (55.2%) patients had an erosive disease and 50 (43.1%) had extra-articular manifestations. Compared to the baseline (160[74.8-496]), FR levels decreased significantly at 12 months (121[49.1-321.8]) and 24 months (107.5[43.3-332]) with a p=0.017 and p=0.029, respectively. There were no differences in Anti-CCP levels over time. No correlation was found between FR/Anti-CCP levels and different DAS28 variables, DAS28(4v) delta, HAQ, and HAQ delta at 12 months and 24 months.
Conclusion: We found that in patients with RA treated with a first anti-TNF-α agent as first biologic, FR levels decreased at 12 months and 24 months follow-up. However, our study failed to demonstrate a correlation between autoantibodies levels and disease activity (DAS28 variables and delta DAS28(4v)), HAQ and delta HAQ. In fact, previous research demonstrated that there is an association between autoantibodies levels and disease activity in RA, nonetheless not being static and increasing with signs of inflammation at baseline. So, further research with large samples is needed to explore this correlation considering the adjustment for confounding inflammatory variables, such as number of swollen or tender joints and morning stiffness.

AB0138 A MOLECULAR SIGNATURE RESPONSE CLASSIFIER STRATIFIES SEROPOSITIVE RHEUMATOID ARTHRITIS PATIENTS BASED ON THEIR LIKELIHOOD OF INADEQUATE RESPONSE TO TNF INHIBITOR THERAPIES

S. Cohen[1], V. Strand[2], E. Connolly-Strong[3], J. Withers[3], L. Zhang[3], T. Mellors[3], V. Akmaev[3]. [1]*Metroplex Clinical Research Center, Rheumatology, Dallas, United States of America*; [2]*Stanford University, Division of Immunology/Rheumatology, Palo Alto, United States of America*; [3]*Scipher Medicine Corporation, Science and Technology, Waltham, United States of America*

Background: There is an urgent need for precision medicine in targeted therapy selection for the treatment of rheumatoid arthritis (RA). TNF inhibitor (TNFi) therapies are the most prescribed targeted therapy for RA patients, yet the majority of patients fail to achieve a clinically meaningful response using this medication class. A blood-based molecular signature test evaluates RNA and clinical metrics to stratify RA patients based on their likelihood of having an inadequate response to TNFi therapies.[1] Patients unlikely to respond to TNFi therapies can be directed to a different treatment option such as a JAK inhibitor, thus reducing the time needed to identify an effective therapy, improving confidence in and adherence to treatment, and increasing the patients' chance of reaching treat-to-target goals.

Objectives: High-titers of anti-cyclic citrillunated protein (anti-CCP) have been independently associated with reduced response to TNFi therapy;[2] thus, we evaluated the ability of a blood-based molecular signature response classifier (MSRC) test to stratify RA patients by their likelihood of inadequate response to TNFi therapies – regardless of their positive or negative anti-CCP status.
Methods: A subset of patients enrolled in the Network-04 prospective observational trial evaluating the ability of a molecular signature response classifier to stratify patients were subdivided into two groups based upon whether they were positive (N = 72) or negative (N = 74) for anti-CCP. The odds of inadequate response to TNFi therapies were calculated based on whether or not a patient had a molecular signature of non-response to TNFi therapy at baseline before the start of treatment. Odds ratios and confidence intervals were calculated[3,4] to represent the strength of association between detecting the molecular signature of non-response and the patient's failure to achieve ACR50 at 6 months.
Results: The odds that a patient with a molecular signature of non-response failed to meet ACR50 criteria at 6 months was approximately three times greater than among those patients who lacked the signal (Table 1). No significant difference in odds ratios was observed between patients who were positive or negative for anti-CCP.

Table 1. The odds of patients with a molecular signature of non-response failing to achieve an ACR50 response 6 months after TNF inhibitor therapy initiation

	Odds ratio (95% confidence interval)
Anti-CCP positive	3.5 (1.3-9.7)
Anti-CCP negative	3.1 (1.2-8.3)

Conclusion: The MSRC test evaluates RA disease biology and accurately stratifies patients based on their likelihood of having an inadequate response to TNFi therapies, regardless of being negative or positive for anti-CCP autoantibodies. Rheumatologists can use the results of the MSRC test to inform targeted therapy selection for RA patients, instead of their anti-CCP serostatus, eliminating the variability inherent to the anti-CCP measurement and its inability to consistently predict TNFi therapy incompatibility. With the MSRC test, providers can rely on a more predictable and accurate assessment of TNFi therapy success or failure when coordinating patient management.

AB0139 RHEUMATOID ARTHRITIS AND SLEEP QUALITY

S. Rekik[1], L. Ben Ammar[1], S. Boussaid[1], S. Jemmali[1], E. Cheour[2], H. Sahli[1], M. Elleuch[1]. [1]*La Rabta Hospital, Rheumatology, Tunis, Tunisia*; [2]*La Rabta Hospital, Department of Pain Management, Tunis, Tunisia*

Background: Consequences of rheumatoid arthritis (RA) are many and varied: physical, psycho-affective and financial.
Objectives: The objective of our study is to evaluate the impact of RA on sleep quality.
Methods: We conducted a cross-sectional study including 49 RA patients. An evaluation of sleep quality using the MOS-Sleep Scale was performed.
Results: The mean age of patients was 54.1 years, with a female predominance (89.8%). The mean duration of RA was 11.43 ± 7.32 years with a mean time to diagnosis of 2.35 years. Rheumatoid factor was positive in 77.6% of cases. A atlanto-axial dislocation was found in 4.1% of cases and coxitis in 8.2% of cases. All patients were on symptomatic treatment, 57.1% of whom were on corticosteroid therapy. 83.67% of patients were on cs-DMARDs and 14.2% were on biologics. At inclusion, sleep was optimal in 63.2% of cases and the mean Sleep Problem Index was 26.19 ± 22.77. The index of sleep problems was higher in older subjects and in those with long diagnostic delays. The presence of co-morbidities and atlanto-axial dislocation and/or coxitis was associated with impaired sleep quality. Also, VAS pain and EGP were associated with an increase in the sleep problem index. In the multivariate study, EGP, the presence of co-morbidities and atlanto-axial dislocation and/or coxitis were the independent factors affecting sleep quality.
Conclusion: The impact of RA on the patient's quality of life and especially the quality of sleep is confirmed by several studies in the literature. A global management of the patient is necessary in order to adapt well to his disease.

AB0140 A HIGH-CONFIDENCE DEFINITION OF THERAPEUTIC RESPONSE IN RHEUMATOID ARTHRITIS USING A MONTE CARLO SIMULATION APPROACH

V. Strand[1], S. Cohen[2], L. Zhang[3], T. Mellors[3], A. Jones[3], J. Withers[3], V. Akmaev[3]. [1]*Stanford University, Division of Immunology/Rheumatology, Palo Alto, United States of America*; [2]*Metroplex Clinical Research Center, Dallas, TX, Rheumatology, Dallas, United States of America*; [3]*Scipher Medicine Corporation, Science and Technology, Waltham, United States of America*

Background: Therapy choice and therapy change depend on the ability to accurately assess patients' disease activity. The clinical assessments used to evaluate treatment response in rheumatoid arthritis have inherent variability, normally considered as measurement error, intra-observer variability or within subject variability. Each contribute to variability in deriving response status as defined by composite measures such as the ACR or EULAR criteria, particularly when a one-time observed measurement lies near the boundary defining response or non-response. To select an optimal therapeutic strategy in the burgeoning age of precision medicine in rheumatology, achieve the lowest disease activity and maximize long-term health outcomes for each patient, improved treatment response definitions are needed.
Objectives: Develop a high-confidence definition of treatment response and non-response in rheumatoid arthritis that exceeds the expected variability of subcomponents in the composite response criteria.
Methods: A Monte Carlo simulation approach was used to assess ACR50 and EULAR response outcomes in 100 rheumatoid arthritis patients who had been treated for 6 months with a TNF inhibitor therapy. Monte Carlo simulations were run with 2000 iterations implemented with measurement variability derived for each clinical assessment: tender joint count, swollen joint count, Health Assessment Questionnaire disability index (HAQ-DI), patient pain assessment, patient global assessment, physician global assessment, serum C-reactive protein level (CRP) and disease activity score 28-joint count with CRP.[1-3] Each iteration of the Monte Carlo simulation generated one outcome with a value of 0 or 1 indicating non-responder or responder, respectively.
Results: A fidelity score, calculated separately for ACR50 and EULAR response, was defined as an aggregated score from 2000 iterations reported as a fraction that ranges from 0 to 1. The fidelity score depicted a spectrum of response covering strong non-responders, inconclusive statuses and strong responders. A fidelity score around 0.5 typified a response status with extreme variability and inconclusive clinical response to treatment. High-fidelity scores were defined as >0.7 or <0.3 for responders and non-responders, respectively, meaning that the simulated clinical response status label among all simulations agreed at least 70% of the time. High-confidence true responders were considered as those patients with high-fidelity outcomes in both ACR50 and EULAR outcomes.
Conclusion: A definition of response to treatment should exceed the expected variability of the clinical assessments used in the composite measure of therapeutic response. By defining high-confidence responders and non-responders, the true impact of therapeutic efficacy can be determined, thus forging a path to development of better treatment options and advanced precision medicine tools in rheumatoid arthritis.

AB0141 THE DYNAMICAL TRAJECTORY OF GLUCOCORTICOIDS TAPERING AND DISCONTINUATION IN RHEUMATOID ARTHRITIS PATIENTS COMMENCING GLUCOCORTICOIDS WITH CSDMARDS: A REAL-WORLD DATA FROM 2009 TO 2020

W. Xie[1], H. Huang[1], Z. Zhang[1]. [1]*Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Glucocorticoids (GC) are currently recommended as bridging therapy in combination with csDMARDs in rheumatoid arthritis (RA) and should be tapered as rapidly as clinically feasible for safety concerns about their long-term use [1-3].
Objectives: To unravel the dynamical trajectory and characteristics of GCs tapering and discontinuation in RA patients commencing GCs with concomitant csDMARDs.
Methods: We used data from longitudinal real-world TARRA (Treat-to-TARget in RA) cohort in Peking University First Hospital. RA patient who started GCs and contaminant csDMARDs therapy over 1-year follow-up were included. The changes in GCs dose and disease activity in the context of csDMARDs were evaluated. GCs discontinuation rate was analyzed using Kaplan-Meier analysis. The relapse profiles within 6 months after GCs discontinuation were also analyzed.
Results: A total of 207 RA patients were included. During a median follow-up duration of 38.6 months, 124 (59.9%) patients discontinued GC. The median oral prednisolone dose of 10 (5-10) mg/d at initiation was reduced by 50% in the first 6 months and then more slowly reduced, finally to zero by 48 months. The cumulative probability of GCs discontinuation was 26.6% at year 1, 48.0% at year 2, 58.6% at year 3, with calculated median time of 27 months (Figure 1). Of the 124 patients who discontinued GCs, add of other csDMARDs or increment of current csDMARDs was required in 29.0% of them. Approximately half of 124 patients were in clinical remission at the time point of GCs discontinuation. Within 6 months after GCs withdrawal, 79.1% (91/115) of participants maintained relapse-free.

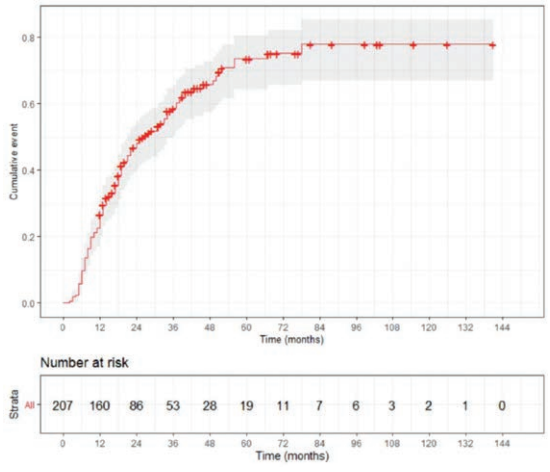

Figure 1. Kaplan-Meier curve with cumulative probability of glucocorticoids discontinuation in RA patients who start glucocorticoids with concomitant csDMARDs during the follow-up period. csDMARDs: conventional synthetic disease modifying antirheumatic drugs.

Conclusion: In RA patients commencing GCs in addition to csDMARDs, GCs are feasibly discontinued with favorable control of disease activity in real-life setting, mostly without short-term flare. Adding targeted therapies are sometimes required to attain GCs discontinuation within the time frame of 3 months in current guidelines.

AB0142 SOCIOECONOMIC STATUS (SES) AND MEDICATION USE IN RHEUMATOID ARTHRITIS (RA): A SCOPING REVIEW

O. Russell[1], S. Lester[1], R. Black[1,2,3], C. Hill[1,2,3]. [1]*The University of Adelaide, Adelaide Medical School, Adelaide, Australia*; [2]*Royal Adelaide Hospital, Rheumatology Unit, Adelaide, Australia*; [3]*The Queen Elizabeth Hospital, Rheumatology Unit, Woodville South, Australia*

Background: Socioeconomic status (SES) influences disease outcomes in rheumatoid arthritis (RA) patients. (1, 2) Differences in medication use could partly explain this association. (3) A scoping review was used to identify research conducted on this topic and determine what knowledge gaps remain.
Objectives: To determine what research has been conducted on this topic, how this research has defined SES and medication use, and establish what knowledge gaps remain.
Methods: MEDLINE, EMBASE and PsychInfo were searched from their inception until May 2019 for studies which assessed SES and medication use as outcome variables. Studies were included if they measured medication use and incorporated an SES measure as a comparator variable.
SES was defined using any of the "PROGRESS" framework variables (4) including patients' stated gender, age, educational attainment, employment, occupational class, personal income, marital status, health insurance coverage, area- (neighbourhood) level SES, or patients' stated race and/or ethnicity. Medication use was broadly defined as either prescription or dispensation of a medicine, medication adherence, or delays in treatment. Data was extracted on studies' primary objectives, measurement of specific SES measures, patients' medication use, and whether studies assessed for differences in patients' medication use according to SES variables.
Results: 1464 studies were identified by this search from which 74 studies were selected for inclusion, including 52 published articles. Studies' publication year ranged from 1994-2019, and originated from 20 countries; most commonly from the USA.
Studies measured a median of 4 SES variables (IQR 3-6), with educational achievement, area level SES and race/ethnicity the most frequently recorded.
Likelihood of disease modifying antirheumatic drug (DMARD) prescription was the most frequent primary objective recorded.
96% of studies reported on patients' use of DMARDs, with glucocorticoids and analgesics being reported in fewer studies (51% and 23% respectively.)
Most included studies found at least one SES measure to be significantly associated with differences in patients' medication use. In some studies, however, this result was not necessarily drawn from the primary outcome and therefore may not have been adjusted for covariates.
70% of published studies measuring patients' income (n=14 of 20) and 58% of those that measured race/ethnicity (n=14 of 24) documented significant differences in patients' medication use according to these SES variables, although the direction of this effect – whether it led to 'greater' or 'lesser' medication use – varied between studies.
Conclusion: Multiple definitions of SES are used in studies of medication use in RA patients. Despite this, most identified studies found evidence of a difference in medication use by patient groups that differed by an SES variable, although how medication use differed was found to vary between studies. This latter observation may relate to contextual factors pertaining to differences in countries' healthcare systems. Further prospective studies with clearly defined SES and medication use measures may help confirm the apparent association between SES and differences in medication use.

AB0143 THE EFFECT OF RHEUMATOID ARTHRITIS AND SPONDILOARTHRITIS ON PREGNANCY: A LONGITUDINAL RETROSPECTIVE COHORT STUDY

F. Pistillo[1], A. La Rosa[2], P. De Sandre[3], E. Fracassi[1], G. Scanelli[3], A. Carletto[1], A. Hoxha[3]. *[1]University of Verona, Rheumatology Unit, Verona, Italy*; *[2]San Bortolo Hospital, Department of Obstetrics and Gynecology, Vicenza, Italy*; *[3]San Bortolo Hospital, Department of Medicine, Vicenza, Italy*

Background: Many patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA) are in their childbearing years. Concerns exist regarding the interplay between the rheumatic diseases and the pregnancy (1).
Objectives: Actually, there are contradictory data regarding the pregnancy outcome in patients with RA and SpA (2). Thus, we performed this longitudinal retrospective study to evaluate the effect of RA and SpA on pregnancy outcome.
Methods: The data of 78 pregnancies of 60 women followed from April 2017 to December 2020 at pregnancy clinic of Internal Medicine Unit, San Bortolo Hospital, Vicenza and Rheumatology Unit, University of Verona were reviewed. Fifty (64.1%) women were affected by RA and 28 (35.9%) by SpA. Information regarding demographic data, disease activity, drug exposure and maternal/foetal outcomes were collected in an electronic database. Details concerning pregnancy complications and congenital malformation were also collected. We compared pregnancy and foetal/neonatal outcome, medication use and disease activity between women affected by RA and SpA. Moreover, we evaluated the effect of disease activity on pregnancy outcome.
Results: Overall, there were 70 (86.4%) live births, 10 (12.3%) miscarriages and 1 (1.2%) foetal death. There were three twin pregnancies. Even there was a higher rate of glucocorticoids and bDMARDs use in RA than in SpA group, respectively 40% *vs* 21% and 70% *vs* 57,1%, there were no statistical differences regarding drug exposure at conception. Moreover, there were no differences concerning disease activity at conception. Still, a higher rate of glucocorticoids and bDMARDs, respectively 26% *vs* 10.7% and 46% *vs* 39.3% were used in RA than in SpA patients during pregnancy. Furthermore, we did not find any statistical differences regarding maternal and foetal/neonatal outcome between pregnancies in the RA and those in the SpA groups. There were four (4.9%), congenital malformation, two (3.8%) in RA group and two (6.9%) in SpA group. About one-third of patients 24 (30.7%) presented a moderate disease activity at conception as evaluated by DAS28PCR and BASDAI. However, there were no significant differences, on maternal and foetal/neonatal outcome in patients with moderate activity disease with respect of those in clinical remission.
Conclusion: Even a higher rate of glucocorticoids and bDMARDs were used in RA than in SpA patients, there was no differences on pregnancy outcome between them.

AB0144 PREDICTIVE FACTORS OF SUSTAINED CLINICAL REMISSION IN RHEUMATOID ARTHRITIS

R. Fakhfakh[1], N. El Amri[1], K. Baccouche[1], H. Zeglaoui[1], E. Bouajina[1]. *[1]Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: Sustained remission (SR) is an ultimate treatment goal in the management of patients with rheumatoid arthritis (RA) (1) and is associated with better RA prognosis, reflected by the quality of life, physical function and radiographic progression (2).
Objectives: To investigate the prevalence and predictors of SR in RA patients.
Methods: A longitudinal prospective study of patients with RA. At the inclusion, the patients were in remission DAS28 ESR≤ 2.6 for at least 6 months. A B-mode and power doppler (PD) ultrasound of 42 joints and 20 tendons was performed. Synovial hypertrophy (SH) and tenosynovitis in B-mode and PD were defined and scored from 0 to 3 using the OMERACT. The CDAI, SDAI, Boolean remission criteria, the health assessment questionnaire (HAQ) and the radiological Sharp score were calculated. Then, the $DAS28_{\text{erythrocyte sedimentation rate (ESR)}}$ was evaluated at 6 and 12 months. SR was defined as the persistence of a $DAS28_{ESR}$≤2.6 at 6 or 12 months without any change in RA therapy during the follow-up. Unstable remission (UR) was defined either as $DAS28_{ESR}$ > 2.6 at 6 or 12 months or an increase in RA therapy because of a relapse during the follow-up.
Results: At baseline, thirty-seven patients were included. At 6 and 12 months, 28 and 24 patients completed follow-up, respectively. In decreasing order, Boolean remission (92.2%), $DAS28_{ESR}$remission (85.7%), SDAI remission (85%) and CDAI remission (83.3%) achieved SR at 6 months. At 12 months, SR was found in 100% in Boolean remission, 87.5% in SDAI remission, 86.7% in CDAI remission and in 79.7% in $DAS28_{ESR}$ remission. At 6 months, only the ESR (17mm/1h in SR versus 32mm/1h in UR, p=0.04) was associated with SR. The disease duration, remission duration, swollen and tender joints, $DAS28_{ESR}$, HAQ, rheumatoid factor, radiological Sharp score and ultrasound parameters weren't associated with SR. At 12 months, the squeeze test (15% in SR vs 80% in UR, P=0.01), the ESR (15mm/1h in SR versus 30mm/1h in UR, p=0.03), the Boolean remission (61.1% in SR versus 0% in UR, p=0.04) and the $DAS28_{ESR}$ (mean: 1.8 in SR versus 2.5 in UR, P=0.01) were associated with SR. However, no association was found with radiological Sharp score and ultrasound parameters. On multivariate analysis, the ESR (OR=1.13, CI95%=1.01-1.2, p=0.03) and the Squeeze test (OR=21.3, CI95%=1.7-263, p=0.01) were predictors of SR, at 12 months.
Conclusion: At 6 and 12 months, 79.7%-85.7% of patients in $DAS28_{ESR}$ remission achieved sustained remission, respectively. Boolean and $DAS28_{ESR}$ remission were associated with SR. Unlike $DAS28_{ESR,}$ Boolean remission seems to reflect more the SR. The squeeze test and the ESR were predictors' factor. However, the radiological and the ultrasound parameters didn't show any association.

AB0145 SMARTPHONE- AND SMARTWATCH-ACQUIRED DAILY STEPS, ACTIVITY, AND BAROMETRIC PRESSURES ASSOCIATED WITH SUBJECTIVE MEASURES OF RHEUMATOID ARTHRITIS: A PROSPECTIVE STUDY FOR RA DIGITAL PHENOTYPING

K. Izumi[1,2,3], D. Moriwaki[3,4,5], T. Toda[5,6], M. Higashida-Konishi[2], M. Koyama[2], H. Oshima[2], Y. Okano[2], Y. Kaneko[1], S. Ko[3,5], T. Takeuchi[1]. *[1]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*; *[2]National Hospital Organization Tokyo Medical Center, Division of Connective Tissue Diseases, Tokyo, Japan*; *[3]Keio University School of Medicine, Medical AI Center, Tokyo, Japan*; *[4]CyberAgent, Inc., AI Division, Tokyo, Japan*; *[5]Keio University School of Medicine, Department of Systems Medicine, Tokyo, Japan*; *[6]AI Shift, Inc., Machine Learning Engineering, Tokyo, Japan*

Background: Symptoms in patients with rheumatoid arthritis (RA) are potentially influenced by exercise load and meteorological change, and often vary from day to day, especially in unstable condition of RA. Patients with RA not infrequently experience worsening of joint symptoms when the load on the joint, such as walking and doing housework, exceeds a moderate range. However, the worsening of joint symptoms is often not observed in the midst of the loading of the joint, but often becomes apparent after a few hours or days.
Objectives: To elucidate the relationship between smartphone- and smartwatch-acquired daily objective data (barometric pressures, steps, and activity) and daily subjective patient reported outcomes of RA.
Methods: A smartphone (iPhone 8) and a wristband-type smartwatch (Fitbit Versa 2) were lent to each patient for free. A mobile app was developed and installed into the smartphones to collect patients' daily subjective RA symptoms including Pt-P-VAS (patient-pain-visual analogue scale), Pt-G-VAS (pt-general-VAS), PtTJCount(68)(patient self-determined tender joint count among 68 joints), PtTJCount(28), PtSJCount(66)(patient self-determined swollen joint count among 66 joints), PtSJCount(28). Also, the smartwatch data and physicians' assessment were collected from the same subject. Physicians' and patients' assessment of TJC, SJC, and G-VAS was independently performed without seeing each other's assessment. We conducted a simple linear regression analysis with outcome variables of Pt-P-VAS, Pt-G-VAS, PtTJCount(68), PtTJCount(28), PtSJCount(66), and PtSJCount(28). The independent variables included smartphone-acquired daily steps and barometric pressure of the reported day and the previous day, and smartwatch-acquired minutes of "lightly active (1-3 METs equivalent)", "fairly active(3-6 METs equivalent)", and "very active(>6 METs equivalent)" of the reported day and previous day. We defined low barometric pressure as below 1000 hPa. The level of activity was measured by the smartwatch. Patients were blinded to daily barometric pressure data and their daily active time when the patients answered daily symptom questions on the smartphones.

Results: A total of five patients were enrolled. At baseline, mean (± standard deviation (SD)) age was 50.8±14.8 years; all patients were females; mean disease duration was 6.6±4.9 years; mean SDAI was 18.6±25.5; mean DAS28-CRP was 3.23±1.85; mean morning stiffness was 134±116 min; mean HAQ-DI was 0.7±0.9. Mean observation period was 77.8 days. Because of the missing data, the sample size (N) for the regression analysis varies with the outcomes: Pt-P-VAS and Pt-G-VAS are 250 while PtTJCount and PtSJCount are 260.
The table 1 showed that the patients' assessment of TJC, SCJ, and G-VAS was correlated well with the physicians' assessment.

Table 1.

Evaluation item	Correlation between physicians and patients (ρ)
Tender Joint Count (68)	0.909
Tender Joint Count(28)	0.913
Swollen Joint Count(66)	0.896
Swollen Joint Count(28)	0.890
General VAS	0.688

The figure 1 showed the change associated with one SD increment in each independent variable with 90% confidence intervals. Low barometric pressure was associated with bad health conditions (high Pt-G-VAS, Pt-P-VAS, and SJCount). Moreover, longer very active time in the previous day ("veryactive_1" in the Figure 1) was associated with bad health condition (high SJCount). Many steps were associated with good health conditions (low Pt-G-VAS, Pt-P-VAS, and SJCount).

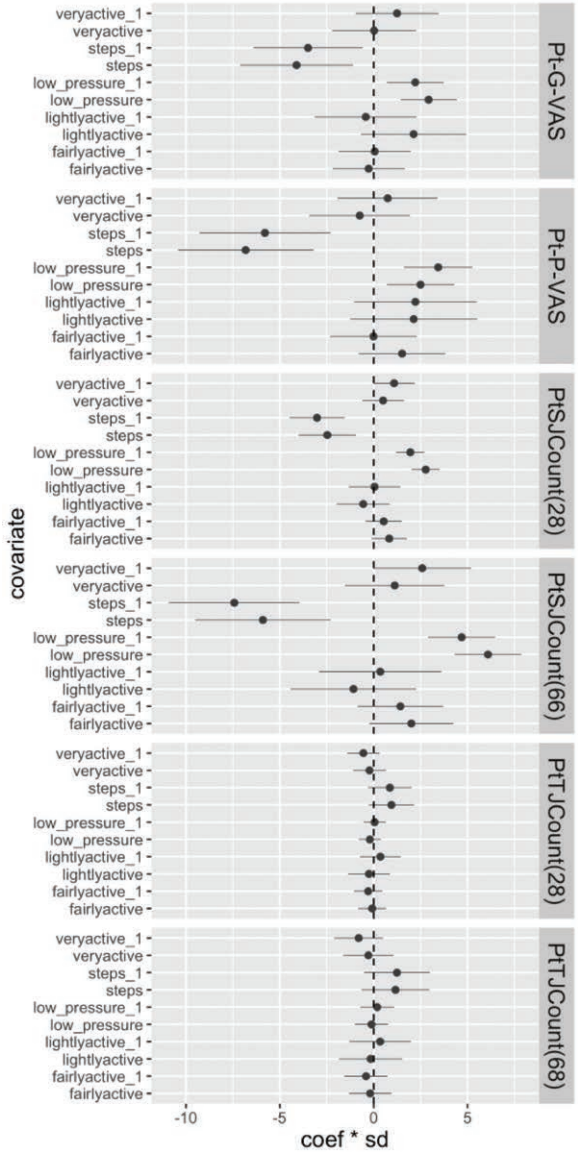

Figure 1.

Conclusion: High barometric pressure was associated with good health conditions, and longer very active time in the previous day was associated with bad health condition. Barometric pressure data and physical activity data acquired by mobile digital devices may predict the change in RA symptoms. Further investigation in larger patient numbers is warranted.

AB0146

HAND AND WRIST ACTIVE RANGE OF MOTIONS AND CONTRIBUTING FACTORS IN RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY

M. He[1], W. Zhou[1], J. Guo[1], J. Liu[1], C. Dong[1], R. Zhao[1], Z. Gu[1]. [1]*Affiliated Hospital of Nantong University, Department of Rheumatology, Nantong, China*

Background: Patients with rheumatoid arthritis (RA) usually impaired range of motions (ROMs), especially hand and wrist active ROMs (AROMs), thus influencing their ability to perform daily activities and health-related quality of life (HR-QoL). However, little is known about the potential factors of reduced hand and wrist AROMs and their relations to quality of life in Chinese RA patients.
Objectives: To explore the contributing factors of hand and wrist AROMs and their associations with HR-QoL and functional limitation in Chinese RA population.
Methods: In this cross-sectional study, 108 patients were enrolled from Affiliated Hospital of Nantong University between November 2018 and July 2019. We measured all the participants' AROMs with different directions of the hand and wrist in both sides, including volar flexion, ulnar deviation, radial deviation and radial deviation of the wrist joint, the first metacarpophalangeal (MCP1) flexion, interphalangeal (IP) flexion, volar abduction, radial abduction and thumb opposition (cm) in the thumb, average flexion, hypertension and abduction of the MCP2-5, average proximal interphalangeal (PIP) 2-5 and distal interphalangeal (DIP) 2-5 flexions, total active range of motion (TAM) of the second to the fifth fingers (TAM2-TAM5). Their sociodemographic, physical, psychological, disease-related data, acute phase reactants, laboratory indicators, drug usage and HR-QoL were examined as well. Statistical analysis used Pearson's and Spearman's correlation analysis, univariate and multivariate linear regression analyses.
Results: In univariate analyses, we found that living in rural area, longer disease duration, comorbidity, hospitalization, more swollen joints, higher disease activity, pain level, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), red blood cell count and glucocorticoids usage were associated with most of the decreased hand and wrist AROMs ($P \leq 0.050$), while higher education and annual income were related to most of the increased hand and wrist AROMs ($P \leq 0.048$). In multivariate analyses, higher disease duration ($P \leq 0.023$) and higher disease activity ($P \leq 0.033$) were corelated with most of the decreased hand and wrist AROMs. Interestingly, the psychological factor, anxiety, was only positively associated with thumb opposition in both univariate and multivariate analyses ($P \leq 0.001$). Additionally, most of the declined hand and wrist AROMs were associated with functional impairment and poor HR-QoL, especially in physical components ($P < 0.05$).
Conclusion: Various factors, especially longer disease duration and higher disease activity, were related to decreased hand and wrist AROMs, and thus causing functional impairment and poor HR-QoL in RA patients. Clinical physicians and medical faculties should pay more attention to disease activity and disease-related symptoms of these patients in order to maintain their activity of daily living (ADL) ability and improve HR-QoL.

AB0147 OLDER AGE AT ONSET AND NOT DISEASE ACTIVITY IS ASSOCIATED WITH FUNCTIONAL DISABILITY AT RA DIAGNOSIS: RESULTS FROM AN EARLY ARTHRITIS COHORT

A. R. Prata[1], M. Sousa[1], H. Assunção[1], L. Saraiva[1], M. Luis[1], L. Brites[1], F. Campos Costa[1], J. Dinis de Freitas[1], T. Santiago[1], J. A. P. Da Silva[1], C. Duarte[1]. [1]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*

Background: Rheumatoid Arthritis (RA) is a chronic inflammatory arthropathy that potentially leads to loss of function and disability early in the disease course. (1) Optimizing physical function is one of the primary goals of RA treatment (2). Several demographic, psychosocial and clinical factors may influence the impact of RA upon physical capacity, and understanding their relative contribution to disability at disease diagnosis is key to an effective treatment approach.
Objectives: To evaluate functional disability at the time of disease diagnosis and identify its demographic and clinical correlates in an early RA cohort.
Methods: We conducted a cross-sectional study based on a Rheumatology centre early arthritis cohort. Consecutive patients with early RA – less than 12 months duration– fulfilling ACR/EULAR 2010 and/or ACR 1987 RA classification criteria, were included. Variables were collected from patients' registries at the first rheumatology appointment after symptom's onset. Functional disability was assessed using the *Health Assessment Questionnaire- Disability Index* (HAQ-DI) (range 0 to 3, higher values indicating greater disability). Independent *t*-test, one way-ANOVA and Pearson's correlation coefficient were performed to evaluate differences between groups. Variables with p<0.1 were included in a stepwise multiple linear regression analysis to assess the independent association of variables with the HAQ-DI at baseline.
Results: We included 71 patients (63.4% female, mean age 57.2 ±2.01 years). Mean HAQ-DI score was 1.42±0.08. Sociodemographic and clinical variables are described in Table 1. There was a significant difference in HAQ-DI scores between rheumatoid factor (RF) positive (mean 1.24±0.11) and RF negative (1.61±0.113) patients. HAQ-DI was positively weakly correlated with age (r=0.48; p<0.001), CDAI (r=0.43; p=0.038), SDAI (r=0.49; p=0.015), and moderately with DAS28-3V (r=0.60; p<0.001) and DAS28-3V-CRP (r=0.60; p<0.001). The number of tender (r=0.35; p=0.024) and swollen joints (r=0.42; p= 0.005), ESR (r=0.46; p=0.001), CRP (r=0.35; p=0.018), HADS-depression (r=0.46; p=0.023) and educational level (r= -0.48; p=0.002) were also associated with HAQ-DI in univariate analyses. After multivariate regression analysis, age at disease diagnosis (β= 0.022 [95 CI 0.010 to 0.034]; p= 0.001) was the only independent predictor of HAQ-DI (R^2= 0.46, p=0.001).

Table 1. Patients' baseline sociodemographic and clinical characteristics.

Age at diagnosis (years), mean (SD)	57.2±2.01
Educational level (years), mean (SD)	7.37±0.59
Employment: full-time, %	42.4
Employment: partial-time, %	3.00
Employment: retired, %	48.4
Employment: absenteeism in the last month, %	1.50
Unemployed, %	4.50
Disease duration at presentation (weeks), mean (SD)	20.4±1.70
Morning stiffness >30 minutes, %	83.0
RF positivity, %	47.9
ACPA positivity, %	53.5
Fibromyalgia, %	6.60

PtGA, mean (SD)	66.8±3.73
PhGA, mean (SD)	54.7±3.08
Pain intensity (VAS), mean (SD)	67.7±3.75
EQ-5D score, mean (SD)	0.26±0.039
HADS-depression, mean (SD)	7.17±0.87

Legend: ACPA- anti-citrullinated protein antibodies; ESR- erythrocyte sedimentation rate; CRP- c-reactive protein; DAS- disease activity score; CDAI- clinical disease activity score; SDAI-simplified disease activity score; PtGA/ PhGA – patient's/physician's global assessment of general health; VAS- visual analogic scale; EQ-5D- EuroQoL 5-Dimensional Descriptive System; HADS-Hospital Anxiety and Depression Scale.

Conclusion: Older age at disease onset is associated with greater functional impairment at diagnosis, assessed by HAQ-DI, in this cohort of early RA patients, irrespective of disease activity and other clinical variables. This result suggests that older newly diagnosed RA patients may deserve special attention regarding physical function.

AB0148 CHARACTERISTICS OF RHEUMATOID ARTHRITIS PATIENTS WITH HIP INVOLVEMENT

H. Hajji[1], K. Maatallah[1], H. Ferjani[1], W. Triki[1], D. Ben Nessib[1], D. Ameni[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Institute, Tunis;, Rheumatology, Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is an autoimmune inflammatory disease that affects both small and large joints. Hip involvement is an evolutionary turning point in RA and significantly alters the patient's quality of life.
Objectives: This study aimed to assess characteristics of RA patients with hip involvement.
Methods: It was a cross-sectional study, including patients with RA (according to 2010 ACR/European League Against Rheumatism (EULAR) criteria). We divided patients into two groups: G0 patients without hip involvement, G1 patients with hip involvement. Hip involvement was defined with a limited movement during examination with abnormalities on standard radiographs. We collected the following data: age, the disease activity score (DAS28), the inflammatory biomarkers C-reactive protein (CRP) and Erythrocyte sedimentation rate (ESR), Rheumatoid Factor (RF), and Anti Citrullinated Peptides Antibodies (ACPA), and SHARP score (A scoring system used to assess the radiological changes in patients with RA. It describes erosions and narrowing of the joint space of 27 small joints of the hands, including the carpal bones and feet).
Results: Among the 224 patients included, 25had hip involvement (11%). The male / female sex-ratio was higher in G1 (0.66 vs 0.22, p=0.017).Patients in G1 were younger at disease onset (44,16±16,11 years vs 51.9±13.9 years, p= 0.022) and had a longer disease duration (12,28 ± 11,49 years vs 6,2010 ± 6,45 years, p=0.02). They had also higher HAQ(1,7692 vs 1,3054, p=0.05).SHARP score was higher in G1 (176.32 vs. 106.88, p=0.011). Atlantoaxial subluxation was more common in G1 (32% vs 14%,p=0.035).When comparing the groups we did not find any significant difference regarding age (56.12 ± 11.88 years vs 58,24±12,26 years, p=0.341), disease activity (DAS28-ESR:5.41 vs. 5.65, p=0.380; DAS28-CRP: 5.19 vs. 5.51, p=0.290), ESR (53.88 vs. 46.95, p=0.237), CRP:23,8894 vs 22,89, p=0.975), and in the serological profile (RF; G1:68% vs G0: 70.8%, p=0.817, ACPA; G1: 60% vs G0:69%, p=0.366).
Conclusion: Patients with hip involvement were commonly male, were younger at disease onset and had more functional impairment based on the HAQ score. C1-C2 dislocation wasalso more common in this group.The SHARP score was also significantly higher in G1, which shows a severe and destructive disease.

AB0149 CHARACTERISATION OF RHEUMATOID ARTHRITIS PROGRESSION IN AN EARLY UNDIFFERENTIATED ARTHRITIS COHORT

M. Novella-Navarro[1], J. L. Cabrera-Alarcón[2], A. Martínez-Feito[3], L. Nuño[1], C. Plasencia[1], M. Juarez[4], D. Peiteado[1], A. Villalva[1], A. Balsa[1]. [1]*Hospital Universitario La Paz, Rheumatology, Madrid, Spain*; [2]*CNIC, Bioinformatics, Madrid, Spain*; [3]*Hospital Universitario La Paz, Immunology, Madrid, Spain*; [4]*Universidad Autonoma de Madrid, Medicine, Madrid, Spain*

Background: Since the publication of 2010 ACR/ELUAR classification criteria for Rheumatoid Arthritis (RA), identification of patients with RA at early stages of the disease has improved. Nevertheless, up to 56% of patients are diagnosed with undifferentiated arthritis (UA) at the first visit to Rheumatology Departments, of which about 20-30% will progress to RA. For this reason, Early Arthritis Clinics (EAC) have been progressively implemented in Rheumatology departments in order to identify and have a tight follow-up of these patients.
Objectives: a) To analyze the progression rate from UA to RA in a cohort of EAC. b) To identify differences in clinical features at baseline that characterize the progression to RA of these patients.
Methods: Prospective study from a cohort of EAC between 2010 and 2018. Patients diagnosed with UA at first consultation were included and with

a follow-up of 2-years. Final diagnosis was assessed at the end of study period defining two groups: RA progression (RA-group) *vs* no progression (non-RA-group).Baseline characteristics were recorded for both groups: sex, age, smoking habit, duration of symptoms, morning stiffness, tender joint count (TJC), swollen joint count (SJC), Rheumatoid Factor (RF), Anti-Citrullinated-Peptide-Antibodies (ACPA), DAS-28, erythrocyte sedimentation rate (ESR), C-Reactive Protein (CRP), Pain visual analogue scale (VAS). Differences in sociodemographic, clinical and serological features between groups were analyzed using T-test, chi-square test and U-Mann Whitney depending on the nature of variables.

Results: A total of 228 patients with UA were included, of which 54 (23,3%) progressed to RA (patients characteristics are shown in table 1). Regarding serological characterization, we found that in our cohort, 44.4% of patients who developed RA had FR and ACPA positivity, 13% RF positive, 7.4% ACPA positive. In contrast 35% patients were seronegative. From non-RA group, 73% of patients were seronegative, 18% RF positive, 4.5% ACPA positive and 4.5% double positive.

Table 1.

Variable	Total (n=228)	RA (n=54)	Non-RA (n=174)	p-value
Female sex n(%)	165 (71.7)	42 (77.8)	121 (69.5)	0.31*
Age (mean SD)	51.47 (16.46)	52.9 (16.15)	51.26 (16.61)	0.53§
Smoking habit n (%)				0.12*
-smokers	49 (21.2)	14 (25.9)	33 (19)	
-exsmokers	52 (22.5)	15 (27.8)	37 (21.3)	
-non-smokers	113 (48.9)	19 (35.2)	93 (53.4)	
Duration of symptoms (weeks) (median IQR)	8 (4-19)	12 (8-24)	8 (4-16)	**0.006¶**
Morning stiffnes >60min n (%)	53 (22.9)	15 (27.8)	38 (21.8)	0.26*
Patient health assessment (meadian IQR)	39 (16-68)	58 (22-75)	34 (14-64)	**0.01¶**
Pain (VAS) (median IQR)	45 (18-68.2)	54 (30-71)	39 (14.5-67.5)	**0.02¶**
Tender Joint Count (median IQR)	2 (1-6)	4 (1-9)	2 (1-6)	**0.04¶**
Swollen Joint Count (median IQR)	2 (1-4)	3 (1-6)	2 (1-4)	**0.01¶**
Baseline DAS28 (mean SD)	3.97 (1.39)	4.44 (1.54)	3.82 (1.33)	**0.006§**
HAQ (median IQR)	0.75 (0.25-1.5)	1.12 (0.37-1.56)	0.62 (0.12-1.37)	0.06¶
CRP(mean SD)	2.2 (8.01)	1.39 (3.25)	2.3 (8.9)	0.44§
ESR (mean SD)	23.74 (19.5)	24.62 (16.22)	22.8 (19.3)	0.54§
RF n (%)	70 (30.3)	31 (57.4)	39 (22.4)	**<0.001***
ACPA n (%)	44 (19)	28 (51.9)	16 (9.2)	**<0.001***

No differences between age at onset, sex an smoking habit were found. Duration of symptoms until first visit to Rheumatology Department was longer RA-group. Regarding joint involvement, TCJ and SCJ were higher in RA-group at baseline and also VAS pain and patients´global health assessment.

Conclusion: One out of four patients diagnosed with early UA are at risk of RA development within the following 2 years. This fact implies that these patients benefit from EAC in order to have a tight control of the disease and have the chance of starting treatment as soon as possible.

AB0150 **ACPA-STATUS AND RHEUMATOID ARTHRITIS: MUCH MORE TO BE REVEALED!**

K. Maatallah[1], S. Miri[1], H. Ferjani[1], D. Ben Nsib[1], W. Triki[1], A. Dallegi[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rhumatology, Manouba,Tunisia*

Background: Anti-citrullinated protein antibodies (ACPA) are commonly associated with Rheumatoid arthritis (RA). RA is, therefore, classified as immunopositive or immunonegative, with disparate mechanisms in predisposition.

Objectives: Our study aimed to determine the baseline characteristics and differences of ACPA-positive and ACPA-negative RA.

Methods: We conducted a cross-sectional study including 224 patients with RA. All patients fulfilled the 2010 American College of Rheumatology/European League Against Rheumatism RA classification criteria. The patients were divided according to their ACPA status into two groups: ACPA-positive group (G1) and ACPA-negative group (G2). We compared clinical, radiological, and *laboratory findings* between the two groups, as well as extra-articular manifestations, comorbidities including fractures and osteoporosis. The Fracture Risk Assessment Tool (FRAX) was used to estimate the 10-year probability of major osteoporotic fracture (MOF) and also hip fracture (FH).

Results: Of the 224 patients, 31.6% were negative for ACPA (n=71). Female predominance was found in both groups with a sex ratio of 0.25 (p=0.203). ACPA-negative subjects were younger (57±11 versus 59±12 years) (p= 0.305).

The initial presentation of RA was different between the two groups without reaching statistical significance. In the ACPA-negative group, alteration of general condition was more frequent (16.9% in G2 versus 13.7% in G1) (p=0.533), with a tendency to oligo-articular onset (18.5% in G2 versus 6.7% in G1) (p=0.737). ACPA-positivity was more associated with an acute start of symptoms (10.4% in G1 versus 8.4% in G2) (p=0.639)

There was no significant difference in the mean DAS28-VS (5.2±1.1 in G2 versus 5.5±1.3 in G1) and DAS28-CRP levels (5±1 in G2 versus 5.3±1.2 in G1) (p=0.069 and p=0.098 respectively).

ACPA-positive RA was, however, significantly associated with more structural joint damage: erosions (55.9±53 in G1 versus 78±36 in G2, p=0.01), joint space narrowing (50.4±45.5 in G1 versus 33.1±36.6 in G2, p=0.003), Sharp/van der Heijde radiographic score (126.6 ±103.2 in G1 versus 88.8±81.5 in G2, p=0.004). ACPA-positive RA patients had more atlantoaxial dislocation: 20.2% in G1 versus 7% in G2 (p=0.012). There was no significant difference in hip involvement (9.8% in G1 versus 14% G2) (p=0.344).

There were no significant differences in extra-articular manifestations between the two groups: Rheumatoid nodules (10.4% in G1 versus 18.3% in G2) (p=0.891), Sjögren's syndrome (16.3% in G1 versus 16.9% in G2)(p=0.715), amyloidosis (0.6% in G1) (p=1), pulmonary fibrosis (5.8% in G1 versus 4.2% in G2) (p=0.757), neurological signs (4.5% in in G1 versus 5.6% in G2) (p=0.733), anaemia (5.8% in G1 versus 1.4% in G2) (p=0.175).

When analyzing comorbidities, no significant differences were found: diabetes (10.4% in G1 versus 18.3% in G2) (p=0.103), cardiovascular diseases (19.6% in G1) (p=1), neurological diseases (0.06% in G1 versus 1.4% in G2) (p=0.534), dysthyroidism (2.6% in G1 versus 5.6% in G2) (p=0.267), dyslipidemia (3.2% in G1 versus 4.2% in G2) (p=0.711), cancer (1.3% in G1) (p=1). There were neither significant differences in the prevalence of fracture (21.5% in G1 versus 18.3% in G2) (p=0.574), and osteoporosis (23.6% in G1 versus 29.5% in G2) (p=0.347), between the two groups. However, ACPA-positive patients presented with a significantly higher FRAX score of MOF (2±2.8 in G1 versus 1.2±1 in G2) (p=0.006), and FRAX score of FH (0,9±1.8 in G1 versus 0.3±0.5 in G2) (p=0.003).

Conclusion: ACPA status appears to influence both the clinical presentation and radiological progression of RA patients. ACPA-positive patients present with an acute start of symptoms, with more structural damages and atlantoaxial dislocation. Comorbidities, including osteoporosis, does not seem affected by ACPA status. However, regardless of osteoporosis, ACPA-positivity is associated with a higher probability of major osteoporotic and hip fractures. Further research is needed to clarify this relationship.

Rheumatoid arthritis - comorbidity and clinical aspects

AB0151 FOLLOW-UP IN A MULTIDISCIPLINARY UNIT IMPROVES PREGNANCY OUTCOME IN INFLAMMATORY ARTHROPATIES ON BIOLOGICAL THERAPY

O. Ibarguengoitia[1], I. Calvo[1], D. Montero[2], L. Vega[2], C. García[2], O. Fernandez[2], I. Torre[2], A. R. Inchaurbe[2], C. E. Perez[2], J. M. Blanco[2], E. Cuende[2], E. Galindez[2], I. Gorostiza[3], J. Oraa[4], M. L. García Vivar[2], M. E. Ruiz[2].
[1]Galdakao University Hospital, Rheumatology, Galdakao, Spain; *[2]Basurto University Hospital, Rheumatology, Bilbao, Spain*; *[3]Basurto University Hospital, Investigation Unit, Bilbao, Spain*; *[4]Basurto University Hospital, Obstetrics and Gynecology, Bilbao, Spain*

Background: Women with inflammatory arthropaties have fertility problems and complications during pregnancy and frequently biological therapy (BT) is required for the disease control.
Objectives: To evaluate pregnancy in women with inflammatory arthropaties in a multidisciplinary unit composed of Rheumatologists and Obstetricians: describe disease evolution, complications and treatment used (including BT).
Methods: Retrospective and descriptive study of the evolution of pregnancy in patients with
inflammatory diseases (Rheumatoid Arthritis (RA), Spondyloarthritis (SpA) and Juvenile Idiopathic Arthritis (JIA)) and follow-up in a multidisciplinary unit for more than 15 years (until December 2020). Demographics, maternal disease, time until conception, previous abortions and presence of antibodies were collected. In addition, during follow-up, treatment, abortions, Caesarean sections (C-section), preterm births, disease activity and maternal/fetal complications were collected.
Results: We registered 41 pregnancies (32 women): 20 RA (62.5%), 9 SpA (28.1%) and 3 JIA (9.4%). Maternal average age at diagnosis was 27.1±6.6 years and average age at childbirth/abortion was 34.9±5.1 years.
It took an average time of 9.6±8.5 months to conceive. 9.8% received fertility treatment with in vitro fertilization techniques.
AntiRo antibodies were registered in 7.3% of patients and 34.1% had at least 1 antiphospholipid antibody.
At the time of gestational desire/gestation 17 women (12 RA, 4 SpA, 2 JIA) were receiving BT: 7 certolizumab (CZP), 7 adalimumab (ADA), 3 etanercept (ETN). 1 patient was being treated with baricitinib. Due to pregnancy, ADA was changed to CZP in 3 women and BT was stopped in 6 cases (3 ETN, 2 ADA, 1 CZP) as well as baricitinib. In 2 cases, ADA was stopped at week 17 of pregnancy (medical indication). Pregnancy was completed with BT (CZP) in 9 cases.
9 abortions were registered prior to follow-up in the unit (0.28 abortions/mother) and 3 during follow-up (0.09 abortions/mother): 2 of them in women with CZP.
C-section was performed in 26.8% of cases.
Preterm birth (<37 weeks) happened in 9.7% (n: 4) of the pregnancies: 1 case in a woman with CZP.
A total of 17 different fetal/maternal complications were registered during follow-up: 6 in the BT group (35.3%) compared to 11 (64.7%) in the group without BT, being Intrauterine Growth Restriction (IUGR) more frequent among women with BT. Infections were not more common in patients with BT. Complications are listed in Table 1.

Table 1.

COMPLICATIONS	WITH BT (n, %) n: 11	WITHOUT BT (n, %) n: 30
IUGR	3 (27.3%)	1 (3.3%)
LOW BIRTH WEIGHT	2 (18.2%)	2 (6.6%)
INFECTION	1 (9.1%)	4 (13.3%)
CHOLESTASIS	0 (0%)	2 (6.6%)
PREECLAMPSIA	0 (0%)	1 (3.3%)
DIABETES MELLITUS	0 (0%)	1 (3.3%)
HIGH BLOOD PRESSURE	0 (0%)	0 (0%)
NEPHROPATY	0 (0%)	0 (0%)
NEONATAL LUPUS	0 (0%)	0 (0%)
HEART BLOCK	(0%)	0 (0%)
MALFORMATION	0 (0%)	0 (0%)
HELLP SYNDROME	0/0%)	0 (0%)
TOTAL	6 (54.6%)	11 (36.4%)

Regarding concomitant treatment, low dose prednisone was used in 48.8% of pregnancies, hydroxychloroquine in 51.2%, sulfasalazine in 9.8% and acetylsalicylic acid in 51.2%. We didn´t find differences in the use of these treatments between the two groups.
Median DAS28 among RA patients and available data was under 2.6 throughout pregnancy as well as previously and posteriorly. No differences in median DAS28 were found between women with BT and without BT. SpA patients had BASDAI lower than 4 in both groups during pregnancy and previously.
Conclusion: In our series, as described in the literature, women with inflammatory arthropaties are older and are more likely to have preterm births compared to general population. Fewer abortions were registered during follow-up in the multidisciplinary unit. Appropriate disease control was maintained during pregnancy, also previously and afterwards. We registered more IUGR and low birth weight among women with BT but given the low number of patients with BT no statistically significant conclusions about complications can be drawn. Therefore, more studies among pregnant women with BT are necessary.

AB0152 PROSPECTIVE ANALYSIS OF OBSTRUCTIVE SLEEP APNEA IN NEWLY DIAGNOSED PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND PERIPHERAL SPONDYLOARTHRITIS – A SCREENING STUDY

D. Dejcman[1], D. Skowasch[2], C. Pizarro[2], P. Karakostas[1], P. Brossart[1], V. Schäfer[1]. *[1]University Hospital Bonn, Department of Internal Medicine III - Oncology, Hematology, Rheumatology and Stem Cell Transplantation, Bonn, Germany*; *[2]University Hospital Bonn, Department of Internal Medicine II - Cardiology, Angiology and Pulmonary Care, Bonn, Germany*

Background: An increased prevalence of obstructive sleep apnea (OSA) in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and partially in peripheral spondylarthritis (pSpA) has been noted and described for nearly two decades. Until now, there is no study yet on the occurrence of OSA in patients with these entities at the point of first diagnosis. Identifying and treating OSA could prove pivotal in improving cardiovascular risk and quality of life. Furthermore, clinicians require insights into whom to screen.
Objectives: To assess the prevalence of OSA in early RA, PsA and pSpA and strategies for targeted screening.
Methods: We performed a prospective study on patients with first diagnosis of RA, PsA or pSpA, who were screened for day sleepiness (assessed by the Epworth sleepiness scale) and tested for obstructive sleep disorders by out-of-center sleep apnea polygraphy (employing Embletta® MPR-PG devices) at the University Hospital of Bonn, Germany. Findings were assessed by three physicians, always including an attending physician responsible for the certified sleep laboratory.
Results: A total of 22 patients with RA (52.38%), 15 with PsA (35.7%), and 5 (11.9%) with pSpA were included. Day sleepiness screening was unremarkable (ESS <10) in 29 (69%) patients and suspicious for a sleep disorder (ESS≥10) in 13 patients (31%). Subsequent sleep studies of five patients (11.9%) were suspicious for severe sleep apnea (AHI >15/h), eight (19.1%) for low-to-moderate sleep apnea (AHI 5-15/h) and 29 (69.1%) were unremarkable (AHI <5). Of the eight low-to-moderate results, none were symptomatic as in ESS ≥10, resulting in a total of five (11.9%) guideline-confirming referrals for inpatient polysomnography/ventilation therapy. In comparison with the PsA/pSpA group, a diagnosis of RA had no significant relationship with ESS results (p≈0.23), nor AHI results ≥5/h (p≈0.14). The male cohort yielded more pathological sleep studies, but the result was not significant (16% vs. ~5.9%, p≈0.32). Higher ESS scores (≥10) were not predictive for findings which require a referral (p≈0.37). Increased BMI (≥25 kg/m^2) was not associated with an AHI > 5/h (p≈0.63).
Conclusion: From the point of screening, a number needed to screen of 8.4 (6.25 in the male, 17 in the female group), speaks in favor of overall cost-efficient screening for OSA in newly diagnosed male patients with arthritis diseases. A different study design, comparing early vs. established arthritis cohorts is necessary to assess the role of disease duration in the possible development of OSA.

AB0153 REAL LIFE SEVERE INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS ON TREATMENT WITH BIOLOGICAL THERAPY AND JAKI

L. Vega[1], I. Calvo[2], O. Ibarguengoitia[2], D. Montero[1], C. García[1], J. M. Blanco[1], M. E. Ruiz[1], A. R. Inchaurbe[1], I. Torre[1], C. E. Perez[1], O. Fernandez[1], E. Cuande[1], M. R. Exposito-Molinero[1], I. Gorostiza[3], M. L. García Vivar[1], E. Galindez[1]. [1]*Basurto University Hospital, Rheumatology Unit, Bilbao, Spain*; [2]*Galdakao University Hospital, Rheumatology Unit, Galdakao, Spain*; [3]*Basurto University Hospital, Investigation Unit, Bilbao, Spain*

Background: Infections are one of the main complications among patients with rheumatoid arthritis (RA) with immunosuppressive treatment. The differences between treatments and the influence of other factors is unclear.

Objectives: To evaluate the frequency and factors associated with serious infections in patients with RA treated with biological therapy (BT) and JAKi and the differences between treatments.

Methods: Descriptive and retrospective study (January 2015-December 2020) of patients with RA treated with BT (TNFi, non-TNFi) and JAKi (tofacitinib, bariticinib, upadacitinib) in a single center. Severe infection was considered a life-threatening infection or one that required hospitalization and intravenous treatment. Epidemiological variables, clinical characteristics, Charlson comorbidity index, type of BT or JAKi and concomitant treatment were collected.

For the analysis frequencies and percentages are used in qualitative variables and mean ± SD in the quantitative ones. Statistical analysis was performed with IBM SPSS v 23.

Results: We registered 257 patients (84.4% women) mean aged 56.1±13.4 years. RF was positive in 86.8%, anti-CCP in 75.9% and 16.5 % presented extra-articular manifestations (nodulosis 9.7%, intersticial lung disease 4.3%, other 1.5%). At the start of the study, 157 (61.1%) patients were with TNFi, 80 (31.1%) with non-TNFi and 20 (7.8%) with JAKi. Conventional synthetic DMARDs (csDMARDs) were used in 86% of cases (methotrexate 71.1%, leflunomide 21.2%, other 7.7%).

During the study, 162 (63%) patients continued with the same treatment and in 95 (37%) it was changed at least once. 3 patients discontinued the treatment. At the end of the study, 126 (49%) patients were with TNFi, 81 (31.5%) with non-TNFi and 47 (18.3%) with JAKi.

Severe infection was developed in 28 (10.9%) patients (13 respiratory, 5 urinary, 5 cellulitis, 4 sepsis, 1 osteomyelitis) among them 2 patients had severe infection and herpes zoster at the same time and 3 developed a second infection. 14 (50%) patients were with TNFi, 8 (28.6%) with non-TNFi and 6 (21.4%) with JAKi. Table 1

The inflammatory activity of RA was mild at the time of infection (DAS28: 2.6±1.1). The median time until infection was: TNFi 45.25 [4.9-202.3] months, non- TNFi 19.14 [4.9-72.5] months and JAKi 17.63 [1.1-29.2] months.

The Charlson index, concomitant use of glucocorticoids (GCC) at lower doses than 10mg/d, chronic obstructive pulmonary disease (COPD), diabetes (DM), moderate-severe renal insufficiency, congestive heart failure (CHF) and peripheral vascular disease were statistically significantly associated with infection. Table 1.

TABLE 1. CHARACTERISTICS OF PATIENTS WITH INFECTION VS. WITHOUT INFECTION

	INFECTION		
	YES n:28	**NO** n:229	**p**
FEMALE, n (%)	22 (78.6)	195 (85.2)	0.406
AGE years, (mean±SD)	57.7 ± 13.9	55.9 ± 13.4	0.507
AGE ≥ 65 n (%)	10 (35.7)	68 (29.7)	0.513
RF +, n (%)	25 (89.3)	198 (86.5)	0.677
ANTI-CCP +, n (%)	21 (75)	174 (75.1)	1.00
ILD, n (%)	1 (3.5)	10 (4.3)	0.809
ALCOHOL, n (%)	3 (10.7)	17 (7.4)	0.465
SMOKER, n (%)	10 (35.7)	60 (26.2)	0.244
COPD, n (%)	7 (25)	24 (10.5)	**0.026***
DM, n (%)	7 (25)	19 (8.3)	**0.013***
CHF, n (%)	4 (14.3)	1 (0.4)	**0.001***
RENAL INSUFFICIENCY, n (%)	3 (10.7)	2 (0.9)	**0.010***
PERIPHERAL VASCULAR DISEASE, n (%)	9 (32.1)	22 (9.6)	**0.002***
CHARLSON INDEX (mean±SD)	1.64 ± 2.1	0.63 ± 1.2	**0.001***
TNFi, n (%) NON-TNFi n (%) JAKi, n (%)	14 (50)	112 (48.9)	
	8 (28.6)	73 (31.9)	
	6 (21.4)	41 (17.9)	
csDMARDs, n (%)	22 (78.6)	159 (69.4)	**0.317**
GCC dose <10mg/d, n (%)	17 (60.8)	111 (48.5)	**0.007***

Conclusion: In our study, 10.9% of patients with RA treated with BT or JAKi developed severe infection during 5 years of follow-up. Concomitant GCC therapy and comorbidity increased the risk of presenting this complication.

AB0154 USAGE OF THE SARC-F QUESTIONNAIRE FOR SARCOPENIA SCREENING IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Dobrovolskaya[1], N. Toroptsova[1], O. Nikitinskaya[1], A. Efremova[1], N. Demin[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation*

Background: Sarcopenia, characterized by low muscle strength and low muscle quantity or quality and associated with increased risks of falling and mortality. The prevalence of sarcopenia is 37% among patients with RA [1]. However, in clinical practice settings, sarcopenia among RA patients remains underdiagnosed. The SARC-F questionnaire [2] was recommended by the European Working Group on Sarcopenia in Older People (EWGSOP) before performing muscle strength tests and assessment muscle mass.
Objectives: To evaluate the diagnostic value of the SARC-F questionnaire for the screening of sarcopenia (SP) in women with rheumatoid arthritis (RA).
Methods: 83 women (average age 59±8 years) with RA without aseptic bone necrosis, joint replacement and severe comorbidities were recruited. All patients were interviewed with the SARC-F questionnaire. The summation score ≥ 4 corresponded to cut-off for suspected sarcopenia. Sarcopenia was evaluated using the European Working Group on Sarcopenia in Older People (EWGSOP2), which included dual-energy X-ray absorptiometry (DXA), handgrip strength or chair stand test, and gait speed. The sensitivity, specificity, positive and negative prognostic values of the SARC-F questionnaire were estimated.
Results: Confirmed SP was diagnosed in 20 (24%) RA patients, who had low muscle strength and mass. When conventional cut-off point (≥4) for SARC-F questionnaire was applied, only 30% of the patients with SP met this condition (sensitivity 30%, 95% confidence interval [95% CI] 13% to 54%), and 41% of the patients without SP did not meet this condition (specificity 41%, 95% CI 29% to 54%). Positive and negative prognostic values were 14% (95% CI 6% to 29%) and 65% (95% CI 48% to 79%), respectively.
Conclusion: The SARC-F questionnaire alone is not adequate for screening of SP in RA patient. It is necessary to develop other simple screening methods that can easily be carried out in real clinical practice to identify individuals with possible SP for further diagnostic tests.

AB0155

COMPARATIVE ANALYSES OF SEROLOGICAL BIOMARKERS AND DISEASE CHARACTERISTICS BETWEEN ELDERLY ONSET RHEUMATOID ARTHRITIS (EORA) AND YOUNGER ONSET RHEUMATOID ARTHRITIS (YORA)

S. Rajalingham[1], S. S. Shaharir[1], H. Mahadzir[1]. [1]*Universiti Kebangsaan Malaysia, Medicine, CHERAS, Malaysia*

Background: Several studies have reported differences in disease characteristics between elderly onset RA (EORA: age of onset > 60 years) and younger-onset RA (YORA). However, the findings across the studies have been rather inconsistent owing partially to the genetic variation across the populations studied. While a few studies have looked into the clinical aspects of EORA, there is a profound lack of comparative data on serological findings between EORA and YORA. Seropositive RA is known to be associated with more aggressive disease and the titres of the autoantibodies may predict the disease activity and the severity of radiographic progression.

Objectives: The main aim of this study was to compare the levels of the autoantibodies namely anti–CCP (cyclic citrulinated peptide), IgA, IgM, IgG rheumatoid factors(RF) and disease characteristics between the EORA and YORA groups.

Methods: We consecutively recruited a total of 151 female RA patients who were tested for IgA RF, IgG RF, IgM RF and anti CCP antibodies. Participants were aged above 18 years and met the 2010 ACR/EULAR RA criteria. Data on the disease characteristics (age at onset, disease activity at onset, disease duration and medications)were obtained by reviewing the medical records of the subjects. Subjects were divided into 2 groups i.e EORA and YORA based on age at onset of RA. All subjects were assessed for the severity of radiographic joint damage and functional disability based on Modified Sharp Score (MSS) and Health-assessment questionnaire-disability index (HAQ- DI), respectively. The EULAR response criteria was used to determine the subjects' response to disease-modifying anti-rheumatic drugs.

Results: The EORA group had 69 patients whereas the YORA group had 82 patients. The mean anti-CCP and IgA RF levels were significantly higher in the YORA group with p values of 0.002 and 0.035, respectively. The YORA group had significantly more severe disease at onset (p value for DAS 28 at onset was 0.009) with worse radiographic joint damage (p value for MSS was 0.006). In parallel with these findings, the YORA group had significantly higher ESR and CRP at onset with higher frequency of subjects requiring advanced therapies. The differences in frequency of RF positivity, disease duration, number of DMARDs, prednisolone dose and HAQ-Di scores between the groups did not reach statistical significance.

Conclusion: EORA is characterized by lower levels of anti-CCP and IgA autoantibodies with less aggressive disease as compared to YORA.

AB0156

INCIDENCE OF CERVICAL SPINE INVOLVEMENT IN RHEUMATOID ARTHRITIS, RESULTS FROM A SINGLE CENTRE OBSERVATIONAL STUDY

A. Conforti[1], F. Bruno[1], O. Berardicurti[1], V. Pavlych[1], I. DI Cola[1], F. Sensini[1], A. Barile[1], C. Masciocchi[1], P. Cipriani[1], P. Ruscitti[1]. [1]*University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy*

Background: Rheumatoid arthritis (RA) manifests as a chronic, symmetrical articular disease; any synovial joint may be involved and the cervical spine is another possible affected site [1,2]. Although the cervical spine involvement is a very severe complication of RA, the exact incidence of cervical spine abnormalities in RA is not fully elucidated yet.

Objectives: In this work, we aimed at evaluating the incidence of a cervical spine involvement and associated clinical characteristics in patients with RA in a single centre observational study.

Methods: In this study, we performed a retrospective analysis of prospectively followed-up patients with RA attending our Rheumatologic Clinic, University of L'Aquila, L'Aquila, Italy, between January 2010 and December 2020. Patients who met the diagnostic criteria of 1987 ACR and/or ACR/EULAR 2010 criteria were assessed. Each patient was investigated for cervical spine involvement occurrence, particularly the atlas-axis cervical involvement. Instrumental imaging evaluation of the cervical spine was performed in all patients with clinical suspicion of involvement, by both MRI and CT examinations. MRI examinations were performed on a 1.5 Tesla scanner, acquiring T1, T2, and STIR sequences on sagittal, coronal and axial planes. CT examinations were performed on a multidetector 320-row CT scanner (Aquilion One,Toshiba) acquired with a thin collimation; soft tissue or bone algorithms were applied for image data reconstruction and analysis.

Incident cases of cervical spine involvement were reported as incidence proportion and incidence rate per 1000 person-years at risk.

Results: In this evaluation, 347 consecutive patients, (mostly female 87.6%, mean age of 66.1 ± 11.3 years) attending our Rheumatologic Clinic, were studied. The incidence proportion of cervical spine involvement was 2.0% [0.6 – 3.4%], occurring in 7 out of 347 patients, and identified by both MRI and CT scan. Considering over 1623 person-years, an incidence rate of 4.0 × 1000 [3.0 – 5.0] person-years was also estimated. All our patients with cervical spine involvement were characterised by female gender, rheumatoid factor, ACPA, fulfilment of ACR 1987 classificative criteria, and poorly controlled disease activity. Smoking habit and extra-articular manifestations were also frequently reported. Glucocorticoids, methotrexate, and infliximab were mainly administered in these patients. This therapeutic strategy resulted in a complete resolution of the inflammatory synovitis in all but one patient. The latter developed a cervical spinal instability resulting in neurological progression and required a subsequent surgical management.

Conclusion: The cervical spine involvement is an uncommon but serious manifestation of RA, since possibly causing severe neurologic damage. A poorly controlled inflammatory process would be an important risk factor for developing a cervical spine involvement in RA, thus, a proper management is required, from an early accurate recognition to a timely therapeutic strategy. MRI could provide a useful clinical tool to early evaluate the cervical spine involvement in RA. Finally, considering the low incidence, further studies are needed to fully estimate the exact incidence of this manifestation, mostly in poorly symptomatic patients.

PREVALENCE OF SARCOPENIA AND CLINICAL IMPLICATIONS IN NEWLY DIAGNOSED RHEUMATOID ARTHRITIS PATIENTS

R. Ekici[1], A. Erden[2], B. Özdemir[2], S. C. Güven[2], B. Armagan[2], Ö. Karakaş[2], K. Gok[2], A. Omma[2], O. Küçükşahin[2], S. Erten[2]. [1]*Ankara Şehir Hastanesi, Internal Medicine, Ankara, Turkey*; [2]*Ankara Şehir Hastanesi, Rheumatology, Ankara, Turkey*

Background: The aim of this study is to determine the frequency of sarcopenia at the time of diagnosis in RA patients, evaluate the effects of sarcopenia on RA disease activity, prognosis and examine the factors that may be associated with sarcopenia.

Objectives: To determine the frequency of sarcopenia at the time of diagnosis in rheumatoid arthritis (RA) patients, assessing disease activity and factors that may be associated with sarcopenia and observe effects of treatment on sarcopenia.

Methods: A prospective study was conducted on RA patients with newly diagnosed. Patients were evaluated twice, at the time of diagnosis and three months after the initiation of treatment. Demographic data, anthropometric measurements, disease activity scores and sarcopenia status were recorded. Sarcopenia was evaluated with grip strength and bioelectric impedance. The results were also compared with healthy volunteers.
Results: Hand grip strength (p<0.001), skeletal muscle mass (p=0.009) and skeletal muscle mass index (p=0.032) were found to be reduced in RA patients compared to the control group. The frequency of sarcopenia in RA at onset of diagnosis was found to be 31.5%. There was a significant decrease in the rate of sarcopenia after three months of treatment (31.5% versus 8.7%; p=0.046).
Conclusion: Sarcopenia was found in approximately one third of the patients with newly diagnosed RA in our study. With treatment, sarcopenia improved significantly. RA patients should be evaluated in terms of sarcopenia besides evaluating joint and extra-articular findings at the time of diagnosis. Early detection and treatment planning may improve the quality of life.

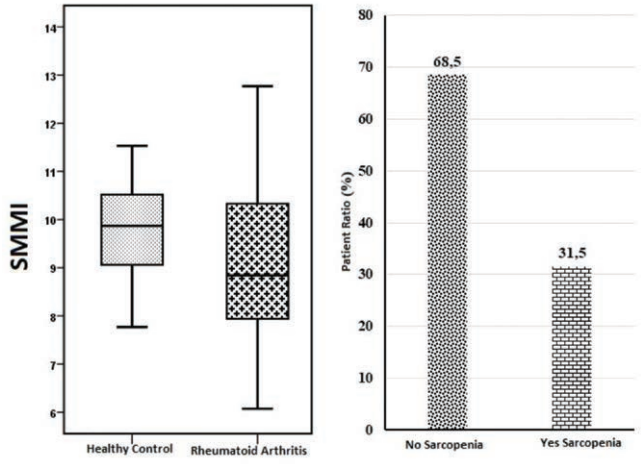

Figure 1. Distribution of skeletal muscle mass index (SMMI) and prevalence of sarcopenia in RA and control groups

AB0158 COMPARISON OF CLINICAL EXAMINATION AND ULTRASOUND OF HAND AND WRIST JOINTS IN RHEUMATOID ARTHRITIS

S. Bouden[1], B. D. Siwar[1], A. Ben Tekaya[1], O. Saidane[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Department of Rheumatology, Tunis, Tunisia*

Background: Ultrasound (US) is an accessible and non-invasive tool to assess joint involvement in rheumatoid arthritis (RA). It is used for diagnostic and prognosis purposes and for following of RA patients by evaluating the disease activity and therefore the response to treatment.
Objectives: This study investigates agreement between US of hand and wrist findings and the clinical examination and biological inflammatory parameters in RA patients.
Methods: We performed a cross sectional study including patients responding to the ACR/EULAR 2010 criteria for RA diagnosis. We collected US findings assessing synovitis and doppler signal in wrist, metacarpophalangeal (MCP) and proximal interphalangeal (PIP) articulations, and concomitant clinical examination assessing synovitis and pain in the same joints along with C reactive protein (CRP) levels and disease activity score (DAS28). The power Doppler US score (PDUS) from 6 simplified synovial sites (wrists, bilateral second and third MCP joints) was calculated [1].
Results: Forty-three patients were included with 91.7% of women. The mean age was 62±12.95 years old. The mean age at diagnosis was 52±14.79 years with a mean disease evolution of 8±8.57 years. Rheumatoid factor and anti-citrullinated antibodies were positive in respectively 78% and 83.9% of cases.
The mean disease activity (DAS28) was 1,52 with levels ranging from 1.5 to 7.33. Right wrist was the articulation in which US synovitis was most frequently detected (60.5% of patients), followed by the left wrist (53.5%). Power doppler signal was detected as frequently in the right as in the left wrist articulations (41.9%). Subsequently, clinical synovitis was most frequently detected in right and left wrist with 39,5% and 41,5% respectively. These joints were the most frequently painful, in 51.2% and 48.8% at right and left respectively.
US synovitis of the first interphalangeal joint was found in only 2.3% and 4.7% in the right and left hand respectively, with positive power doppler signal in 2.3% of the patients in the same articulations.
The overall agreement between US and clinical examination in detecting synovitis of wrist, MCP and PIP joints was of 67.3%. It was of 71.4% in wrists, 54.7% in MCP joints and 87% in PIP joints. This suggests the presence of infra-clinical synovitis. All sites combined, US synovitis were correlated to clinical synovitis (p=0.03).
A positive correlation was found between PDUS from 6 simplified joint sites and CRP levels (p value of 0.02). No correlation was found with disease activity score (DAS28).
Conclusion: US of hands and wrist articulations is more performant than clinical examination in detecting synovitis. The most frequently involved joints with clinical and US synovitis, pain and positive power doppler signal were the wrist joints. CRP level is predictive of the presence of a high simplified power doppler score which is related to clinical activity of the disease as reported by Kawashiri et al. [1].

AB0159 DIASTOLIC DYSFUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Cabrera-Villalba[1], V. Valinotti[1], L. Roman[1], A. Paats[1], P. DE Abreu Trigueros[2], M. Duarte[1], T. Martinez[3], I. Acosta-Colman[1], G. Avila[1], O. Centurion[4]. [1]*Clinicas Hospital, Universidad Nacional de Asuncion, Rheumatology, San Lorenzo, Paraguay*; [2]*Sociedad Paraguaya de Reumatología, Rheumatology, Asunción, Paraguay*; [3]*Asunción, Laboratorio Curie, Asunción, Paraguay*; [4]*Clinicas Hospital, Universidad Nacional de Asuncion, Cardiovascular Medicine, Asunción, Paraguay*

Background: Rheumatoid arthritis (RA) presents with an elevated incidence of congestive heart failure disease, which has a strong association with diastolic dysfunction, defined by left ventricular delayed relaxation pattern assessed by echocardiography.(1,2)
Objectives: To describe the frequency of left ventricular delayed relaxation pattern in patients with RA, and the relationship with its clinical and serological characteristics, as well as with traditional and non-traditional cardiovascular risk factors.

Methods: Descriptive, cross sectional, prospective study, in a Paraguayan cohort of patients with RA. This study had two phases: the first one, included a standardized questionnaire according to the variables included in the Cardiovascular Risk project (PINV15-0346), from the Consejo Nacional de Ciencias y Tecnología (CONACYT), and physical examination; the second one included laboratory sample collection performed by a specialized laboratory for serum biomarkers measurement for cardiovascular risk prediction (i.e endothelin, alpha-TNF, E-selectin, t-PA, VCAM, PAI-1 and high sensitivity-CRP levels) and echocardiographic assessment with a Doppler 7 GE USA equipment at a private facility. All patients signed informed consent. SPSS Statistics v23 was used for data analysis. Quantitative variables were presented as means and qualitative variables as frequencies. Chi square test was performed for comparisons between dichotomous variables. A p value ≤ 0.05 was used for statistical significance.

Results: 100 patients were included, 87% women, with a mean age of 51.36 ± 11.03 years, mean disease duration of 130.9 ± 102.64 months. 84.4% had positive ACPA. 43.3% had bone erosions, with an average of DAS 28-ESR 3.42 ± 1.1. 60% of patients presented with echocardiographic left ventricular delayed relaxation pattern. Regarding traditional CV risk factors, the same ones presented more frequently HBP (40% vs 19.4%, p = 0.037), DM2 (11.7% vs 0%, p = 0.036), obesity (38.3% vs 16.7%, p = 0.025), altered glycemia (27.1% vs 6.5%, p = 0.02), altered HbA1C (50.8% vs 22.6%, p = 0.01), higher mean weight (75.9 ± 17.62 p = 0.02), higher Framingham index high (20% vs 3.2%, p = 0.03). Regarding to clinical parameters, a higher frequency of erosions was found (55.8% vs 22.2%, p = 0.004), without other significant differences for disease activity, seropositivity or disease duration. As for serum biomarkers, higher levels of fibrinogen (639.71 ± 189.84, p = 0.04), homocysteine (11.74 ± 7.81, p = 0.05) and VCAM (519, 16 ± 203.68, p = 0.02) were found.

Conclusion: We found a high frequency of diastolic dysfunction in patients with RA. They presented a significant association with traditional CV risk factors, erosions, and fibrinogen, homocysteine, and VCAM biomarkers. Adequate control of cardiovascular risk factors and echocardiographic assessment of these patients is essential in order to avoid the progression of heart functional damage.

Background: Treatment with low-dose glucocorticoids (GCs) (≤7.5 mg prednisolone) in combination with standard care is highly effective in rheumatoid arthritis (RA), but despite 70 years of clinical experience, evidence-based information on its balance of benefit and harm is incomplete. This leads to an ongoing debate, with under- and over-use of GCs as result. The GLORIA pragmatic trial was developed to assess harm, benefit and costs of low-dose GCs added to the standard treatment of older RA patients.

Objectives: The objective of this abstract is to document the baseline status and frequency of comorbid conditions in the GLORIA study population. The results of the unblinded data will be submitted as late-breaking abstract.

Methods: This double-blind, randomized, placebo-controlled, multicenter trial (1) was open for patients with RA according to the 1987 or 2010 (2) criteria, age ≥65 years, and disease activity score of 28 joints (DAS28) of ≥2.6. Patients were recruited from rheumatology clinics in Germany, Hungary, Italy, The Netherlands, Portugal, Romania and Slovakia. Eligible patients were randomized to two years of treatment with daily 5 mg prednisolone or matching placebo. All other medication was allowed, except for GCs. The presented data are blinded because the database is not closed yet.

Results: The population consists of 451 patients with mean disease duration 10.6 (Q1-Q3: 3-15) years. The majority (70%) is female, mean age is 72.5 (Q1-Q3: 68-76, range: 65-88) years, 66% were positive for rheumatoid factor and 56% for ACPA. Patients had a mean of 4.3 (SD 2.8) comorbidities besides RA (3.4 active) and therefore used multiple concomitant medications (3.9 (SD 3.4)) (Table 1). The most common comorbidities (provisional data of 161 patients with complete coding) in this older population are: vascular disorders (58%), musculoskeletal and connective tissue disorders (57%) and a history of surgical and medical procedures (45%). Patients were most frequently on beta blocking agents (22%, mainly metoprolol) and HMG CoA reductase inhibitors (20%, mainly simvastatin). Most patients also have an extensive history of anti-rheumatic treatment. At the start of the trial most patients (82%) were on cDMARD treatment; 15% were on bDMARDs/tsDMARDs. Almost half of the patients previously had been treated with GCs, with a mean duration of 3.4 years and a mean last dose of 4.6 mg/day.

Conclusion: The baseline data shows that we have an older study population who have relatively many other comorbidities next to RA and who are almost all treated with multiple concomitant medications in addition to the study medication. Therefore, we expect to report a high adverse event rate. Research among older patients is urgently needed, but the frailty of this population as represented by the multiple comorbidities and concomitant medications have to be taken into account in the analyses and interpretation of the results.

Ioannina, Ioannina, Greece, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece, Ioannina, Greece; [3]*Radiology, University of Ioannina, Greece, Department of Radiology, Medical School, University of Ioannina, Ioannina, Greece, Ioannina, Greece*; [4]*Internal Medicine, University of Ioannina, Greece, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece, Ioannina, Greece*; [5]*Rheumatology Clinic, University of Ioannina, Ioannina, Greece, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece, Ioannina, Greece*

Background: The risk of cardiovascular disease in patients with rheumatoid arthritis (RA) is 1.5-2 fold higher than in people of the same age and sex of the general population.[1,2,3] This marked risk is attributed to the systemic chronic inflammation which is characteristic of the disease.
Objectives: The aim of this study is to evaluate cardiovascular risk factors and early atherosclerosis in rheumatoid arthritis patients, treated with biological agents.
Methods: This is a prospective, observational study. Thirty-five patients treated with synthetic DMARDs with no previous history of a cardiovascular event included. We compared total cholesterol (TC), high-density lipoprotein cholesterol (HDL-c), low-density lipoprotein cholesterol (LDL-c), triglycerides (TGs), Apolipoprotein A1 (ApoA1), Apolipoprotein B (ApoB) and Lipoprotein A (LpA), the titer of autoantibodies against oxidised LDL(anti-oxLDL), systolic blood pressure, inflammatory markes as C-reactive protein (CRP) and erythrocytes sedimentation rate (ESR) between baseline and after 6 months of biological agents initiation. An ultrasonographic measurement of intima-media thickness (IMT) of carotids was also performed by an experienced sonographer at baseline and after one-year follow-up.
Results: As regards the demographic characteristics of patients, the mean (SD) age was 54(14) years, disease duration 4,3(1.4) years, 22.9% were smokers and 68,6% were women. Anti-TNF was administered in 71,4% of patients while the rest non anti-TNF was given as treatment. Six months after treatment initiation, patients presented with a significant increase in mean (SD) HDL[69(19)vs58(15)] and ApoA1[177(34)vs162(31)] levels (p value <0,001) with a simultaneous significant reduction of mean (SD) systolic blood pressure [128(12)vs136(14)] and the titer of anti-oxLDL[0,132(0,042)vs0,190(0,056)]. IMT was also reduced after one-year reassessment [0,8(0,3) mm vs 0,9(0,3)mm, (p value <0,001 for all comparisons)].
Conclusion: Biological agents administration was accompanied by an improved lipid profile in a six-month period and a significant reduction of IMT, confirming that RA patients are prone to early atherosclerosis and probably biological agents initiation correlates strongly with cardiovascular risk reduction.

AB0162 OCULAR MANIFESTATIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. Monova[1], S. Monov[2], R. Shumnalieva[2], D. Dimova[3], M. Sotirova[4]. [1]*Medical Institute, Medical University - Sofia, Department of Internal Medicine, Sofia, Bulgaria*; [2]*Medical University - Sofia, Departmant of Rheumatology, Sofia, Bulgaria*; [3]*Medical Insitute-MVR, Department of Ophtalmology, Sofia, Bulgaria*; [4]*Medical Institute, Department of Ophtalmology, Sofia, Bulgaria*

Background: Rheumatoid arthritis (RA) is the most common systemic autoimmune disease and is associated with a number of extra-articular organ manifestations, including ocular complications.
Objectives: The aim of this study is to evaluate the frequency and characteristics of ocular manifestation in patients with rheumatoid arthritis (RA).
Methods: The study involved 87 patients with RA. All the study subjects underwent complete ophthalmological examination involving visual acuity assessment, examination of anterior and posterior eye segments, Schirmer's test, diameter and mobility of pupils, as well as eyeball mobility assessment of intraocular pressure. Data regarding age, gender, disease duration, age at diagnosis, systemic corticosteroid use, blood pressure, ocular symptoms and detailed ophthalmic history were recorded. The presence of rheumatoid factor in serum was evaluated by standard test methods based on principle of agglutination. All patients were seropositive.
Results: 87 patients (26 male, 59 female, mean age 45,6 ± 13,1 years; mean disease duration 7,4 ± 6,2 years) with RA were enrolled in this study. 31 (35,63 %) of them had no ocular symptoms. Among the patients with ocular symptoms, 39 (69,64 %) complained of decreased vision, 33 (58,93 %) - of dry eye, 32 (57,14 %) - of burning, 29 (51,78 %) -photophobia, 28 (50 %) - of gritty sensation, 27 (48,21 %) - of itching, 18 (32,14 %) - of redness, 13 (23,21 %) - of ocular pain, 3 (5,36 %) - of floaters. Ophthalmological examination revealed higher incidence of the following abnormalities in the study group: myopic astigmatism - in 10 (5,74 %) eyes, vascular abnormalities within fundus - in 22 (12,64 %) eyes, increased intraocular pressure (> 21 mm Hg) - in 11 (6,32 %) eyes. Mean IOP values were 17,34 ± 5,12 mm Hg. In 48 eyes Schirmer's test results were below 10 mm, and in 18 eyes - below 5 mm. Keratoconjunctivitis sicca was present in 31 (35,63 %) of all patients. Episcleritis was diagnosed in 4 patients (4,6 %), scleritis – in 3 (3,45 %). Retinal vasculitis was present in 2 (2,3 %) patients and involves veins and arteries peripheral branches. Lens opacity was found in 13 (14,94 %) patients (21 eyes), mostly in the form of posterior subcapsular cataract (in 16 eyes) and nuclear cataract (in 5 eyes). The mean age of patients with cataracts was 52,3 ± 14,2 years. 13 of the patients with cataracts were either currently taking or had previously taken systemic corticosteroids.
Conclusion: In patients with RA numerous abnormalities within the vision of organ may be found. Ocular symptoms are relatively common complications of RA, and may result in irreversible changes in the organ of vision. Regular ophthalmological examinations are essential among the patients with RA.

AB0163 ELECTROCARDIOGRAPHIC MANIFESTATIONS IN PATIENTS WITH SEROPOSITIVE RHEUMATOID ARTHRITIS

S. Spitsina[1,2], E. Mozgovaya[1], A. Trofimenko[1], S. Bedina[1], M. Mamus[1]. [1]*Federal State Budgetary Institution "Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky", Clinical Biochemical Laboratory, Volgograd, Russian Federation*; [2]*Federal State Budgetary Educational Institution of Higher Education "Volgograd State Medical University" of the Ministry of Healthcare of the Russian Federation, Department of Hospital Therapy, Volgograd, Russian Federation*

Background: Cardiovascular disease in rheumatoid arthritis (RA) is more common than in general population. Particular attention should be paid to cardiac dysfunction, as their timely diagnosis strongly affects the general outcome.
Objectives: To assess the prevalence of arrhythmias and conduction disorders in patients with seropositive RA without clinical manifestations of coronary artery disease, as well as to determine their relationship with activity and duration of RA.
Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles. 48 patients with seropositive RA were included in the study. The exclusion criteria were: age over 60 years; obesity; congenital heart defects; coronary artery disease; peripheral atherosclerosis; thyroid disease; diabetes mellitus. All patients were assessed using general physical, laboratory and instrumental survey including CBC, blood chemistry panel, as well as ECG. RA diagnosis was verified using the 2010 ACR / EULAR classification criteria. Central tendencies were expressed as mean ±SD.
Results: All the included persons were women. Their average age was 50.50 ± 7.22 years, and average duration of the disease was 8.13 ± 2.34 years. All patients had articular form (without systemic manifestations) of moderate and high activity. The patients were treated with basic and NSAIDs therapy; no glucocorticoids were applied at the time of the examination. Using 12-lead ECG arrhythmias and conduction disorders were revealed in 27 (56.25%) of RA patients. Sinus rhythm deviations had the highest (31.25%) prevalence for all arrhythmias, comprising sinus tachycardias (18.75%), sinus bradycardias (6.25%), and sinus arrhythmias (6.25%). Premature beats were registered in 12.5% cases, being supraventricular and ventricular ones in equal proportions. We have found left anterior bundle branch block in 6 (12.5%) of patients. Despite absence of any angina symptoms, 9 (18.75%) of patients had myocardial repolarization disturbances, either as ST depression deeper than 0.1 mV or as negative T wave appearance, which were quite similar to silent myocardial ischemia manifestations. All the patients with these two features had RA history of more than 10 years. There was no relationship between the prevalence of the manifestations and radiographic stage of RA.
Conclusion: Arrhythmias and conduction disorders are quite frequent finding in seropositive RA (56.25% and 18.75%, respectively). Their incidence and severity do not coincide exactly with the radiographic progression in joints, while their prevalence generally increases with disease duration.
These data highlight the importance of additional Holter ECG monitoring in RA for revelation and treatment of silent life-threatening cardiovascular complications.

AB0164 THE EFFECT OF RHEUMATOID ARTHRITIS ON FEMALE FERTILITY

S. Ben Jemaa[1], G. Mouna2, A. Hriz2, A. Feki2, H. Fourati2, S. Baklouti2. *[1]Hedi Chaker Hospital, Rheumatology, SFAX,Tunisia*; *[1]Hedi Chaker Hospital, Rheumatology, SFAX,Tunisia*

Background: Infertility is a disease of the reproductive system defined by the failure to achieve clinical pregnancy after 12 months or more of regular unprotected sexual intercourse. Although rheumatoid arthritis (RA) tends to have a late onset, the disease also occurs during child-bearing years and may interfere with procreation.
Objectives: The aim of this study was to compare fertility rates in women with RA with birth-year-matched references from the general population.
Methods: This is a case-control study. Menopausal married women who were diagnosed in the department of Rheumatology at Hedi Chaker Hospital before the age of forty were recruited into this study as cases and apparently healthy age matched married women were recruited as controls. Demographic, clinical, immunological, radiological and therapeutic data were collected from each case using the medical record of patient. Data obtained included age, age of RA onset, duration of RA, extra-articular manifestations, Rheumatoid factor (RF), anti-cyclic citrullinated peptide antibody (ACPA), the presence of erosions on radiographs of hands and feet and the therapy.
Rheumatoid arthritis and controls women were asked to state their menstrual regularity, age at menarche, age at menopause, gestity, parity, number of living children, time to first pregnancy, presence of primary or secondary infertility, the interpregnancy interval, presence of miscarriage or in utero foetal death (IUFD) or preterm delivery and their number.
Results: The mean ages of the cases and controls was 54 ± 8,11 years [39, 69]. The median duration since onset of RA in the patients was 22,5 ± 10,53 years [1, 47]. The mean age of onset of the disease was 31,4 ± 6,3 [18, 39] years. Forty-nine percent (49%) of patient had extra-articular manifestations: ocular sicca syndrome in 43,8% of cases, pulmonary fibrosis in 5,3% of cases and rheumatoid nodules in 1,8 % of cases. Rheumatoid factor (RF) was present in 61,4% of cases while anti-CCP anti-body was present in 59,6% of cases.
Erosive polyarthritis was found in 80,7% of patients. The mean rate of RF was 319,7 ± 462,4 UI/ml and the mean rate of anti-CCP was 185,8 ± 264.
Women with RA had a statistically significant mean time to pregnancy longer than the control group. Primary infertility was seen in 15 (26,3%) patients and 2 (3,5%) controls, whereas secondary infertility was seen in 31 (54,5%) patients and 2 (3,5 %) controls. The patients were significantly more likely to have primary and secondary infertility. There were no significant differences in the age at menarche, the number of children, the gestity and the parity between the two groups. The age at menopause was statistically significant lower in the group patients than controls.
Conclusion: Our study showed that RA women are more likely to have reduced fertility than general population. Although this study cannot definitively address the issue of impaired fertility among women with RA, the results are suggestive enough to warrant further research into the link between RA and fertility that takes women's childbearing choices into account.

AB0165 CENTRAL SENSITIZATION IN RHEUMATOID ARTHRITIS

E. Filatova[1], E. Pogozheva[1], V. Amirdzhanova[1], A. Karateev[1], A. Lila[1]. *[1]VA Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: Central Sensitization (CS) is a proposed physiological phenomenon in which dysregulation in the central nervous system causes neuronal dysregulation and hyperexcitability, resulting in hypersensitivity to both noxious and non-noxious stimuli. The term Central Sensitivity Syndrome (CSS) describes a group of medically indistinct (or nonspecific) disorders, such as fibromyalgia (FM) (1, 2).
The prevalence of FM has been estimated at 2-7% in general population, but 10-30% patients with several rheumatic diseases fulfill the FM criteria, which suggests that they have not only nociceptive pain, but signs of CS or nocyplastic pain. (3)
Objectives: to identify the signs of central sensitization (CS) in patients with rheumatoid arthritis (RA) with the central sensitization inventory (CSI).
Methods: We examined 43 RA patients (mean age 45.5 [29.0; 53.0] years) with chronic pain. The patients underwent rheumatological examinations; CS was diagnosed using the CSI(4).; inflammation severity (DAS28 index), pain intensity (VAS), affective disorders (HADS), and quality of life (EQ-5D) were assessed.
Results: We recruited 36 women and 7 men, mostly with moderate and high disease activity according to the DAS28 index.
Using the CSI subclinical CS was found in 9 patients (20.9%), mild in 7 (16.3%), moderate in 8 (18.6%), severe in 16 (37.2%), and extremely severe sensitization in 3 (6.7%). Thus, 62.5% of patients with RA had had clinically significant CS (CS>40 points according to the CSI questionnaire).
Patients with the presence of CS were characterized by more severe anxiety (10.0 [7.0; 11.0] vs 5.0 [3.0; 6.0], p=0.001) and lower quality of life (0.52 [-0.02; 0.52] vs 0.52 [0.52; 0.69], p= 0.02).
The CSI tests not only pain but also other diseases associated with CS. Comorbid disorders associated with CS were found in patients with RA: 34.9% had cognitive impairment, 39.5% had signs of depression.
Conclusion: Central sensitization was detected in 62.5% of patients with RA using the CSI questionnaire. CS is associated with anxiety and depression and negatively affects the patients' quality of life. Chronic pain in RA can be of a mixed nature: nociceptive and neoplastic, which must be taken into account in the selection of personalized therapy.

AB0166 MORTALITY AND COMORBIDITIES IN A COHORT OF PACIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS

J. Calvo Gutierrez[1], B. Rodríguez Jiménez[2], M. L. Ladehesa Pineda[1], M. Rojas-Giménez[1], R. Ortega Castro[1], A. Escudero Contreras[1]. *[1]Reina Sofía University Hospital, Maimónides Institute of Biomedical Research of Córdoba (IMIBIC), Rheumatology, Córdoba, Spain*; *[2]Reina Sofia University Hospital, Medicine University of Cordoba, Medicine, Córdoba, Spain*

Background: Patients diagnosed with Rheumatoid Arthritis (RA) have an increased risk of comorbidities and secondary mortality, in a large extent due to cardiovascular events.
Objectives: To identify the frequency of comorbidity, mortality and variables related to its increase in a cohort of patients with rheumatoid arthritis established (RAE).
Methods: Controlled cross-sectional observational study of a cohort of 188 patients with RAE a 10 year follow-up (5 years if not complete this period).
Results: 62.8% were women, mean age of patients at the time of inclusion was high 73.3 (+/-13.8) years and mean duration of disease was 12,8 (+/-6,99) years. Regarding CV risk factors, 26.6% smoked, 60.6% hypertension and 52.1 % diabetic. Regarding comorbidities, the most frequent were serious infections (45.2%), CVD (35.1%), Osteoporosis (31.9%), Depression (31.9%) and Kidney disease (26.6%). During follow-up, an improvement was observed inflammatory parameters and activity levels (p <0.001) Table 1. Mortality was associated to CVD and severe infection, and depression to lower mortality (p 0.05). Overall mortality was 32.4%. A logistic regression was performed in the group of patients with time greater evolution 10 years of our cohort, to be able to better represent the influence of disease carrying with her for longer, whose results are shown in Table 2. Analysand survival, men, CVD, severe infections, and Positive Rheumatoid Factor were associated with higher mortality, while treatment with Methotrexate was associated with increased

survival. Among the causes of death, the most frequent were infections, CVD and solid cancer.

Conclusion: -The incidence of comorbidities in our cohort is similar to that described in the literature.

-Relationship between mortality and CVD and severe infection is demonstrated.

-The mortality rate observed is higher than that described in the literature, which be influenced by the advanced age of the patients in the cohort and high time evolution of RA.

AB0167 PECULIARITIES OF INTERACTION OF CHRONIC INFLAMMATION AND DEPRESSION IN RHEUMATOID ARTHRITIS

A. Aleksandrov[1], N. Aleksandrova[1]. [1]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Department of Clinical and Laboratory Diagnostics, Volgograd, Russian Federation*

Background: In patients with rheumatoid arthritis (RA), a high prevalence of depression and anxiety is observed, and the severity of these conditions depends on the degree of vitamin D deficiency. The role of the main mediator, with the help of which psychological and physical stress factors can contribute to the development of depression and systemic diseases, has been attributed to inflammation in recent years.

Objectives: to assess the dependence of depressive disorders on vitamin D deficiency and the level of pro-inflammatory cytokines in patients with RA.

Methods: 88 women with a reliable diagnosis of RA (mean age 54.2 ± 12.0 years old, disease duration 9.0 [3.5; 16.0] years) were under observation. Beck's depression inventory (BDI-II) was used to assess the presence of depressive symptoms. ELISA test was used to measure serum cytokines (IL-1, IL-6) and serum 25(OH)D levels.

Results: The presence of depression was found in 66% of patients with RA. An insufficient level of 25(OH)D (<30 ng / ml) was determined in 89.8% of cases. In RA patients with no signs of depression, the level of 25(OH)D showed maximum values and significantly differed from that in the groups of patients with moderate ($p = 0.028$) and severe depression ($p < 0.001$). A negative correlation ($r = -0.38$, $n = 88$, $p < 0.05$) was established between the level of 25(OH)D and the severity of depression. A positive relationship was also found between 25(OH)D and ESR ($r = 0.29$, $n = 73$, $p < 0.05$) and a negative relationship with the number of painful joints ($r = -0.29$, $n = 76$, $p < 0.05$). Probably, vitamin D is indirectly involved in inflammatory processes in joints and in central sensitization, which provokes chronic pain and psychological disorders in patients with RA.

The level of IL-6 in patients with RA with moderate and severe depression (n=18; 14.6 ± 6.7 pg/ml) significantly exceeded the parameters of patients with RA without depressive disorders (n=30; 9.8 ± 3.7; $p = 0.003$). There was also a tendency to increase IL-6 in the group of patients with moderate and severe depression compared with patients with mild depression ($p = 0.06$). IL-1β values significantly increased with the progression of depression (without depression – mild depression, $p = 0.034$; mild – moderate, $p < 0.001$; moderate – severe depression, $p = 0.044$). A positive correlation of average severity was revealed between the degree of depression (according to BDI-II) and the dose of glucocorticoids (GC) at the time of the study ($r = 0.33$, $p = 0.002$). An increase in the GC dose in the short term can aggravate depressive disorders in RA patients (Table 1).

Table 1. Indicators of levels of depression and IL-1β depending on the dose of GC

	Group I (n=26), without GC	Group II (n=45), GC <10 mg / day	Group III (n=17), GC ≥10 mg / day
Depression level according to BDI-II, points (Me [P25; P75])	8,5[5;16]	14[9;17]	19[14;29] $^{*III-I}$
IL-1β level, pg / ml (M ± SD)	4,57 ± 1,83 $^{*I-II}$	6,04 ± 3,27	6,52 ± 5,16

* - intergroup differences are reliable, $p < 0.05$

Patients who used GC in a daily dose of ≥10 mg / day (group III) had a higher degree of depression compared to patients with RA from group I ($z = -2.98$; $p = 0.003$). In patients with RA in the first group, the level of IL-1β was significantly higher ($p_{I-II} = 0.039$) than in patients with GC prescription in minimal doses (up to 10 mg / day) (Table 1). Glucocorticoid hormones suppress pro-inflammatory cytokines. As a rule, this effect is not observed in patients with depression. This fact may indicate a violation of homeostatic mechanisms. IL-1β is thought to be the first step in the pro-inflammatory response to psychological stress and is capable of inducing a subsequent cascade of other inflammatory cytokine responses.

Conclusion: Restoring the normal level of 25(OH)D in the blood serum of patients with RA can positively affect psychological indicators by reducing the severity of depression and manifestations of pain. The activation of pro-inflammatory cytokines during stress and depression suggests that suppression of the inflammatory response can also reduce the symptoms of depression in RA patients.

AB0168 BODY MASS INDEX IS ASSOCIATED WITH SIGNIFICANT ECHOCARDIOGRAPHIC ABNORMALITIES IN RHEUMATOID ARTHRITIS

S. Hannawi[1], K. Naeem[2], H. Hannawi[3]. [1]*Ministry of Health and Prevention-UAE, Rheumatology, Dubai, United Arab Emirates*; [2]*Ministry of Health and Prevention-UAE, Internal Medicine, Dubai, United Arab Emirates*; [3]*Ministry of Health and Prevention-UAE, Research, Dubai, United Arab Emirates*

Background: Overweight/obesity is associated with a high incidence of chronic autoimmune diseases such as rheumatoid arthritis (RA). In RA, obesity represents an increasingly prevalent comorbidity even at its first presentation, with more than 60% of patients with RA classified as overweight or obese by the body mass index (BMI ≥25 kg/m^2). On the other hand, RA is related with excess

cardiovascular disease (CVD) mortality, which accounts for over 50% of premature deaths in RA. Obesity contributes to the development of inflammation *via* changes in metabolism and function of adipose tissue and it appears to coexist with other CVD risk factors such as hypertension, insulin resistance and dyslipidemia.

Objectives: For the first time, this study looks at the effect of the BMI on echocardiography parameters in established RA cases.

Methods: A cross section study was carried out to recruit patients meeting the 2010 ACR/EULAR criteria during 2019. Standard trans-thoracic echocardiography examination was performed by a specialist cardio-sonographer who was blinded to the status of the participants. The echocardiography parameters studied included left ventricular dimensions, wall geometry, systolic and diastolic parameters, ejection fraction, right ventricular size and function, valve structure and function, aortic root dimensions, pulmonary pressures and pericardium. Anthropometric measurements of BMI were carried out as weight in kilograms divided by the square of height in meters (kg/m^2). Data was analysed using the BMI as the explanatory variable and repeating the simple linear regression analysis using the echocardiography parameters as outcome variables. P value of <0.05 was considered significant.

Results: During the one-year period, 44 RA patients were recruited, of which 91% (40) were female and 4 (9 %) male. The mean (SD) of age was 50±13 years (Min 28, Max 72). The mean (SD) of BMI was 30.887 ± 6.348 Kg/m^2 (Min 21, Max 44.38). As per BMI classification of obesity, only 11% patients were found to have normal BMI. Echocardiography revealed that 14% patients had aortic regurgitation, 2% had aortic stenosis, 2% had mitral stenosis, and 7% had tricuspid regurgitation.

Using BMI as an explanatory variable, with echocardiography parameters as outcome variables, it was found that BMI contributed positively in a linear manner to the Interventricular Septal thickness in diastole (mm) (p=0.004, CI: 0.048-0.227), LV End Diastolic Diameter (mm) (p=0.033, CI: 0.033-0.722), LV mass (g) (0.04, CI: 0.022-6.339), Early Diastolic Velocity, E, by PW mitral inflow measurement (cm/s) (p=0.02, CI: 0.150-1.933), E/E' ratio by Tissue Doppler study (p=0.01, CI: 0.025-0.225), and to Right Ventricle function measured by Tricuspid Annular Plane Systolic Excursion (TAPSE) (mm) (p=0.02, CI: 0.035-0.346).

Conclusion: Obesity and Inflammation overlap syndrome may interplay to produce various cardiovascular abnormalities. Body Mass Index is shown to be associated with significant echocardiographic abnormalities including left ventricular dimension, diastolic parameters and right ventricular function. In view of the complex interrelation between obesity, rheumatoid arthritis and cardiovascular disease, measuring Body Mass Index might help predict adverse cardiovascular events in rheumatoid arthritis patients.

AB0169 INTEREST OF THE ECHOCARDIOGRAPHY IN SCREENING OF CARDIAC INVOLVEMENT IN RHEUMATOID ARTHRITIS PATIENTS

M. Brahem[1], H. Ibn Hadj Amor[2], R. Sarraj[1], R. Rouabhia[2], E. Hmaier[2], H. Hachfi[1], A. Ben Salem[1], S. Abdellatif[1], R. Ben Tekaya[1], Y. Mohamed[1]. *[1]Taher Sfar Hospital, Rheumatology, Mahdia, Tunisia*; *[2]Taher Sfar Hospital, Cardiology, Mahdia, Tunisia*

Background: Rheumatoid arthritis (RA) is the most common chronic inflammatory disease which usually affects peripheral joints.Extra-articular manifestations can occur during the course of this disease and even before the onset of arthritis, such as cardiac impairment that is a common cause of mortality in RA.

Objectives: The aim of our study is to identify the prevalence of cardiac manifestations in RA using the echocardiography exam and to elaborate its associated factors.

Methods: This is a cross-sectional study including consecutive RA's patients which consulted the rheumatology department in Taher Sfar hospital. The diagnosis of RA was elaborate according to ACR/EULAR 2010 criteria. The epidemiological, clinical and biological data were collected from patients' records. Echocardiography was performed by a trained cardiologist in the same hospital, using the transthoracic approach.

Results: Our study included 67 patients: 63 women (94%) and 4 men (6%), with an average age of 52.55 years [21-75 years] and mean disease duration of 11.85 years [10-40]. Joints deformities were present in 37 cases (55.2%) and radiographic joint damage in 49 cases (73.1%). 34 (50.7%) of the patients had an ESR greater than 30 mm/hour and 24 (35.8%) had a CRP greater than 6mg/L. The mean DAS28-CRP was 3.35 [1.24-6.7] and the mean DAS28-ESR was 4 [1.4-7.35]. Cardiac symptomatology was present in 22 cases (32.8%), dominated by dyspnea on effort in 22 cases (32.8%), dyspnea at rest in 4 cases (6%), chest pain in 8 cases (11.9%)and palpitation in 2 cases (3%). The echocardiography abnormalities were found in 44 cases. Valve damage was detected in 35 patients (52.2%), of which only 2 were significant. Valvular abnormalities were dominated by mitral valve regurgitation and mitral valve thickening in 11 cases (16.4%) each, aortic valve regurgitation in 6 cases (9%),aortic valve thickening in 2 cases (3%), aortic valve stenosis in 3 cases (4.5%),aortic valve calcification in 12 cases (17. 9%) aortic valve nodule in 1 case (1.5%), pulmonary insufficiency in 10 cases (14.9%) and tricuspid insufficiency in 25 cases (37.3%).Pericarditis was found in 2 cases (3%), pulmonary arterial hypertension (PAH) in 5 cases (7,5%) and Left ventricular hypertrophy in 14 cases (20,9%). The study of E/A and E/E' ratios revealed diastolic dysfunction in 23 cases (34.3%).The mean of longitudinal global strain measure was -17,83 [-21,9 to -10] and it revealed systolic dysfunction in 18 cases (26.86%). Cardiac impairment detected by echocardiography did not appear to be associated with the age (p=0.39) or the disease duration (p=0.62) nor the importance of biological inflammation(p=0.1). However, joints deformities and RA activity (DAS28) were significant predictors of cardiac involvement (p=0.01; p=0.03).

Conclusion: Our study shows that cardiac impairment in RA was often asymptomatic and was correlated with the disease activity. The echocardiography with the strain measure represents an excellent tool for its detection in early stages.

AB0170 RHEUMATOID ARTHRITIS ASSOCIATED LUNG DISEASE: EXPERIENCE IN A BIOLOGICAL THERAPY UNIT

L. Vega[1], I. Calvo[2], O. Ibarguengoitia[2], D. Montero[1], C. García[1], E. Galindez[1], J. M. Blanco[1], A. R. Intxaurbe[1], I. Torre[1], C. E. Perez[1], O. Fernandez[1], E. Cuande[1], M. R. Exposito-Molinero[1], E. Guerrero[3], M. L. García Vivar[1], M. E. Ruiz[1]. *[1]Basurto University Hospital, Rheumatology Unit, Bilbao, Spain*; *[2]Galdakao University Hospital, Rheumatology Unit, Galdakao, Spain*; *[3]Alto Deba Hospital, Rheumatology Unit, Arrasate, Spain*

Background: Rheumatoid arthritis (RA) associated lung disease is a relatively frequent extra articular disease manifestation, with a prevalence between 5% and 30%. The rather wide range of estimated prevalence is a result of differences in study designs and studied populations, as well as lacking diagnostic and classification criteria for lung disease in patients with RA.

Objectives: To evaluate the prevalence of RA associated lung disease in patients with biological therapy (BT), as well as its severity, treatment changes and possible associated factors.

Methods: Review of clinical records of 257 patients with RA treated with BT (TNFi, non-TNFi) between January 2015 to December 2020 in a single center. Patients with preexisting lung disease for other causes (asthma, smoking) have been excluded. RA diagnosis was performed according to ACR 2010 classification criteria. Epidemiological variables, clinical characteristics, type of pulmonary involvement, evolution, type of BT, changes in treatment and concomitant treatment were collected. For the analysis frequencies and percentages are used in qualitative variables, and mean ± SD in the quantitative ones. Statistical analysis was performed with IBM SPSS v 23.

Results: We registered 21 patients (85.7% women) mean aged 70.3±11.9 years. 52.4% were never smokers. RF was positive in 100% and 20 patients were anti-CCP positive. Erosive disease was present in 13 (61.9%) patients.

At the time of lung disease diagnosis, 15 patients (66.7%) were receiving TNFi (Etanercept 7, Adalimumab 6, Infliximab 1, Golimumab 1), 2 were with non-TNFi (Rituximab) and 4 had never received BT previously. Symptoms (cough and/or dyspnea) were reported in 10 (47.6%) patients. The median time of treatment with BT until lung disease diagnosis was 33 [15.5-95.5] months. Conventional synthetic DMARDs (csDMARDs) were used in 85.7% of cases (methotrexate 72.2%, leflunomide 22.2%, other 5.6%). The inflammatory activity was mild (DAS28: 3.22±1.6). The median time until lung disease diagnosis was 104 [56.2-156] months.

After the lung disease diagnosis, BT was only modified in 1 patient. In the 4 patients who had not previously received BT, non-TNFi was started (Rituximab 2, Abatacept 1, Tocilizumab 1). csDMARD was discontinued in 1 patient.

Interstitial lung disease (ILD) was the most frequent pulmonary involvement (16 patients, 76.2%): 8 usual interstitial pneumonia (UIP), 6 non-specific interstitial

pneumonia (NSIP), 1 organising pneumonia (OP) and 1 lymphocytic interstitial pneumonia (LIP). Other pulmonary manifestations observed in our patients were: nodular lung disease (2 patients) and small airways disease (bronchiectasis 2, obliterative bronchiolitis 1). Chest x-ray was normal in almost half of the patients (42.9%). Gold standard image diagnostic technique was high resolution CT.

In respiratory function tests (PFTs) at diagnosis, only 4 patients (19%) had a FVC<80% and 4 (19%) a DLCO<60%. In the following 2 years, in 2 patients the FVC worsened > 10% and in 5 there was a worsening of the DLCO > 15%. In 3 (14.3%) patients PFTs were never performed and in 7 (43.7%) were not repeated after the diagnosis.

We haven´t found association between different types of pulmonary involvement and the variables analysed.

Conclusion: In our series, prevalence of RA associated lung disease is similar to that described in the literature. Lung involvement is asymptomatic and chest X-ray is normal in most RA patients. High resolution CT is the gold standard for diagnosis.

ILD was the most frequent pulmonary involvement. Although in most patients the diagnosis of lung disease did not imply a BT change, it had an influence on the type of BT chosen for those who started treatment. Maintenance of csDMARD was not associated with a worsening of lung disease.

Screening and treatment protocols for lung disease in patients with RA in clinical practice are needed.

AB0171 ACHILLES ENTHESITIS AND PLANTAR FASCIITIS IN RHEUMATOID ARTHRITIS PATIENTS: IMPACT OF BODY MASS INDEX

K. Maatallah[1], H. Boussaa[1], H. Riahi[2], H. Ferjani[1], M. Habechi[1], W. Triki[1], D. Ben Nessib[1], M. Bouaziz[2], D. Kaffel[1], W. Hamdi[1]. *[1]Mohamed Kassab Institute of Orthopedics, Rheumatology, La Manouba,Tunisia*; *[2]Mohamed Kassab Institute of Orthopedics, Radiology, La Manouba,Tunisia*

Background: Enthesitis is known as a hallmark of spondyloarthitis. However, the growing use of ultrasonography (US) increased our opportunity to encounter enthesitis in rheumatoid arthritis (RA). The involvement of Achilles tendon and the plantar fascia is not rare in RA patients.

Objectives: The aims of this study were to determine the prevalence of Achilles enthesitis and plantar fasciitis in RA patients, and to identify association with clinical data.

Methods: We conducted a cross-sectional study including patients with RA (ACR/EULAR 2010). Demographic and clinical data were collected. Three groups were defined according to the BMI: normal (BMI<25kg/m^2), overweight (BMI≥25kg/m^2) and obese (BMI≥30kg/m^2). US examination of Achilles tendon and plantar aponeurosis was performed by a blinded radiologist experienced in musculoskeletal US using a Philips HD11 device with a high-frequency linear transducer. Enthesitis was defined as hypoechoic and/or thickened insertion of the tendon close to the bone (within 2 mm from the bony cortex) which exhibits Doppler signal if active and that may show erosions, enthesophytes or calcifications as sign of structural damage. A p-value <0.05 was considered significant.

Results: Sixty-two feet were examined in 31 RA patients (25 women and six men) with a mean age of 54.8±10.8 years old [32-70]. The mean disease duration was 8.5±7.2 years [1-37]. Rheumatoid Factor (RF) and Anti-Citrullinated Peptides Antibodies (ACPA) were positive in 61.3% and 83.8% of cases. The mean DAS28 ESR was 3.8±1.5 [0.6-7].

The mean BMI was 27.7±5.4 kg/m^2 [18.3-45.8]. Obesity was noted in 22.7 % of patients and overweight in 45.5% of patients. Clinical examination revealed pes planus valgus (PPV) in 55.6% of cases and pes cavus varus (PCV) in 18.5% of cases. Heel US revealed Achilles enthesitis in 79.6% of cases. The following elementary lesions were noted in the enthesis: thickness (24.1%), hypoechogenicity (37%), erosions (9.3%), enthésophytes (75.9%), and Doppler signal (3.7%). Plantar fasciitis was noted in 81.5% of cases. The following elementary lesions were found in the insertion of plantar aponeurosis: thickness (75.9%), hypoechogenicity (77.8%), erosions (16.7%), enthesophytes (13%), calcifications (1.9%), and Doppler signal (1.9%).

An association was noted between BMI and Achilles enthesitis (p=0.002). This association was not found with plantar fasciitis (p=0.224).

Achilles enthesitis was also associated with PCV (p=0.007) while plantar fasciitis was associated with PPV (p=0.039).

Conclusion: Achilles enthesitis and plantar fasciitis are common in RA patients. These lesions seem to be associated with BMI and foot deformities rather than the inflammatory process.

AB0172 ELDERLY ONSET RHEUMATOID ARTHRITIS (EORA): WHAT TO EXPECT IN REAL LIFE

I. Coman[1], I. Elisei[2], V. Bojinca[1,2], D. Mazilu[1,2], S. Daia[1,2], I. Saulescu[1,2], C. L. Constantinescu[1,2], M. Abobului[1,2], A. Borangiu[1,2], M. M. Negru[1,2], C. Cobilinschi[1,2], M. Duna[1], D. Predeteanu[1], D. Opris-Belinski[1,2], L. Groseanu[1,2], F. Berghea[1,2], A. Balanescu[1,2], R. Ionescu[1,2]. *[1]Saint Mary Hospital, Rheumatology, Bucureşti, Romania*; *[2]Carol Davila University of Medicine and Pharmacy, Medicine, Bucureşti, Romania*

Background: The term elderly onset of rheumatoid arthritis (EORA) refers to patients with rheumatoid arthritis (RA) onset after the age of 60. Data published in the literature suggest a special clinical pattern and different prognostic factors in this class of patients.

Objectives: To analyze prospectively a cohort of patients diagnosed with EORA, their disease particularities, comorbidities and treatment.

Methods: This cohort included consecutive EORA patients, diagnosed and treated in "Sfanta Maria" Clinical Hospital, Bucharest, Romania. The study was conducted for 2 years. Demographic, clinical and laboratory data was obtained. Disease activity was assessed using Disease Activity Score of 28 joints with erythrocyte sedimentation rate (DAS28-ESR). The patients were monitored using disease activity, treatment schedule modifications and possible adverse reactions.

Results: The cohort included 110 patients (88 females, 22 males). Their mean age at the beginning of disease manifestations was 70.14 years and the mean age at the diagnosis was 70.85 years. There was no statistical difference regarding the patient's residential area (urban/rural) and the period between the appearance of clinical signs and the moment of diagnosis confirmation. A great proportion of patients (77 patients, 70%) had seropositive RA, ACPA being found in 84% of the patients with seropositive RA. The mean DAS28-ESR at the diagnosis was 4.44(±1.54). A proportion of 40% of the patients had moderate disease activity, 35 patients (32.73%) - high disease activity, 11 patients (10%) - low disease activity and unexpectedly there were 19 patients (17.27%) in remission at the moment of RA diagnosis. Joint distribution was analyzed: 61.82% patients had large joint involvement, 91.82% - small joint involvement and 53.64 % had mixed joint pattern involvement. A negative significant correlation was found between the small joint involvement pattern and the body mass index (BMI) (p=0.028, R=-0.21). The mean BMI at the diagnosis was 25.81±5.358. Ninety five patients (86,36%) had at least one cardiovascular comorbidity. Hypertension was found in 70% of the patients. Only 4.55% of the patients had rheumatoid nodules and a similar proportion (4.55) had Sjogren syndrome associated. Pulmonary fibrosis was found in only 2 patients. At the moment of diagnosis 50% of patients had anemia, 36.36% had osteoporosis, 25.46% of the patients - hepatic disease, 11.82% - chronic kidney failure and 6.36% were found with a neoplasia. The main conventional synthetic disease modifying drug (csDMARD) that was recommended was methotrexate (81.8%). The second most used csDMARD was hydroxichroloquine (42 patients, 38,18%). The proportion of patients with monotherapy (50%) was similar to that with csDMARD combination (49.09%). During the follow up period only 8 patients (7.27%) had biologic therapy (4 patients - an anti TNF drug). Non steroid anti-inflammatory drugs were used in 46.63%. Cortisone therapy was used for more than 3 months in 80% of the patients. In patients with biologic therapy chronic glucocorticoids were stopped. At least one infection was documented in 20.91% of patients: 2 patients out of 6 patients (33.33%) with biologic DMARD, 14.81% of the patients with csDMARD combination and 21.81% of the patients with csDMARD monotherapy. csDMARD therapy was well tolerated with only 23.63% adverse reactions.

Conclusion: Compared to the data published in the literature, in our cohort the rate female:male was higher (4:1). A distinct feature was the high proportion of patients with seropositive RA. The joint pattern seems to be influenced by BMI: small joint pattern is less found in patients with higher BMI. As expected, the patients with EORA had multiple cardiovascular comorbidities. Arterial hypertension was the most frequent. Caution is needed in choosing treatment regarding comorbidities and the risk of infection in these patients.

AB0173 **FACTORS ASSOCIATED WITH FATIGUE AND PERSISTENT FATIGUE IN RHEUMATOID ARTHRITIS**

A. Fazaa[1], H. Boussaa[1], K. Ouenniche[1], S. Miladi[1], M. Sellami[1], L. Souabni[1], S. Chekili[1], S. Kassab[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim University Hospital, Rheumatology, Sidi Daoud, Tunisia*

Background: Fatigue is a common and debilitating symptom in patients with rheumatoid arthritis (RA). Fatigue in RA is poorly understood and appears to be multifactorial. Interactions between three factors were suggested: 'personal', 'disease processes', and 'cognitive, behavioural'.
Objectives: The aim of this study was to determine factors associated with fatigue and persistent fatigue in RA.
Methods: We conducted a longitudinal study including patients with RA (ACR/EULAR 2010). Patients with other acute or chronic diseases that may induce fatigue (such as cancer, infection or depression) were excluded. Patients were evaluated at inclusion (T0) and 12 months later (T12). Demographic and disease-related data were collected: age, gender, professional status, physical activity, disease duration, Rheumatoid Factor (RF), Anti-citrullinated peptides antibodies (ACPA), pain Visual Analog Scale (VAS), Erythrocyte Sedimentation Rate (ESR), C Protein Reactive (CRP), Disease Activity Score 28 (DAS28), and Health Assessment Questionnaire (HAQ). Fatigue was assessed using the Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) which is a short 13-item questionnaire validated in RA. The score FACIT-F ranges between 0 and 52. Fatigue was considered mild if the FACIT-F score was ≥40, moderate if 20≤FACIT-F<40 and severe if 0≤FACIT-F<20. We defined 'persistent fatigue' as reported fatigue at T0 and T12. A p value inferior to 0.05 was considered significant.
Results: We included 100 patients (84 women and 16 men) with a mean age of 49.5±10 years old [18-65]. Among them, 25% were professionally active and 15% had a regular physical activity. At inclusion, the mean disease duration was 87.3 months [1-360]. RF and ACPA were positive in 75% and 72.6% of cases respectively. The mean pain VAS was 49 cm [0-100]. The mean levels of ESR and CRP were 38.1 mm [10-120] and 10.8 mg/l [2-61] respectively. The mean DAS28 ESR was 3.68 [1.90-8.33] and the mean HAQ score was 0.90 [0-2.75].
The mean FACIT-F score was 27.1 [0-51] at T0. Fifty-seven percent of patients had moderate fatigue and 26% had severe fatigue. At T12, the mean FACIT-F score was 33.4 [5-50]. Persistent severe fatigue was noted in 17% of patients.
A significant negative correlation was noted between FACIT-F score at T0 and the following variables: age (r=-0,258, p=0.01), pain VAS (r=-0,605, p<0.001), ESR (r=-0,621, p<0.001), DAS28 ESR (r=-0.744, p<0.001), and HAQ (r=-0.634, p<0.001).
A significant negative correlation was noted between FACIT-F score at T12 and the following variables: age (r=-0,229, p=0.022), disease duration (r=-0,296, p=0.003), pain VAS (r=-0,754, p<0.001), ESR (r=-0,405, p<0.001), CRP (r=-0,468, p<0.001), DAS28 ESR (r=-0.744, p<0.001), and HAQ (r=-0.678, p<0.001). Fatigue and persistent fatigue were not associated with gender, professional status, physical activity, and immunological profile.
Multivariable analysis showed that DAS28 ESR (OR=-0.157, 95% CI [-4.614;-0.153], p=0.036) and HAQ (OR=-0.563, 95% CI [-6.916;-2.995], p<0.001) were independently associated with persistent fatigue.
Conclusion: Fatigue is a frequent and complex symptom in RA. Higher disease activity and greater disability are suggested as predictors of persistent fatigue.

AB0174 **FATIGUE IN RHEUMATOID ARTHRITIS: A CASE-CONTROL STUDY**

A. Fazaa[1], H. Boussaa[1], K. Ouenniche[1], S. Miladi[1], M. Sellami[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim University Hospital, Rheumatology, Sidi Daoud, Tunisia*

Background: Fatigue is a common symptom in many chronic inflammatory diseases, including rheumatoid arthritis (RA). It is considered one of the most frustrating, uncontrollable, and overwhelming symptoms. However, most of rheumatologists do not assess fatigue despite its clinical significance and its impact on patients' lives.
Objectives: The aims of this study were to determine whether RA patients express more fatigue than healthy controls, and to analyze its correlation with disease activity.
Methods: We conducted a cross-sectional study including patients with RA (ACR/EULAR 2010) and healthy controls matched for sex and age. Patients with other acute or chronic diseases that may induce fatigue (such as cancer, infection or depression) were excluded. Demographic data and the following clinical parameters were collected: pain Visual Analog Scale (VAS), Global Patient Assessment (GPA), tender joint count (TJC) and swollen joint count (SJC), Erythrocyte Sedimentation Rate (ESR), C Protein Reactive (CRP), Disease Activity Score 28 (DAS28), and Health Assessment Questionnaire (HAQ). Fatigue was assessed using the Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) which is a short 13-item questionnaire validated in RA. The score FACIT-F ranges between 0 and 52. Fatigue was considered mild if the FACIT-F score was ≥40, moderate if 20≤FACIT-F<40 and severe if 0≤FACIT-F<20. A p value inferior to 0.05 was considered significant.
Results: We included 100 RA patients (84 women and 16 men) with a mean age of 49.5±10 years old [18-65]. The mean disease duration was 87.3 months [1-360]. The mean pain VAS was 49 cm [0-100] and the mean GPA was 47.8 cm [0-100]. The mean TJC and SJC were 5.3 [0-36] and 1 [0-9] respectively. The mean levels of ESR and CRP were 38.1 mm [10-120] and 10.8 mg/l [2-61] respectively. The mean DAS28 ESR was 3.68 [1.90-8.33] and the mean HAQ score was 0.90 [0-2.75].
Thirty-nine healthy controls were enrolled including 35 women and 4 men with a mean age of 51.2 years old [30-64].
The mean FACIT-F score was 27.1 [0-51] in RA patients versus 46.2 [0-52] in healthy controls (p<0.001). Among RA patients, 57% had moderate fatigue and 26% had severe fatigue.
A significant negative correlation was noted between the FACIT-F score and the following parameters in RA patients: TJC (r=-0.568, p<0.001), SJC (r=-0.274, p<0.001), pain VAS (r=-0.605, p<0.001), GPA (r=-0.658, p<0.001), ESR (r=-0.405, p<0.001), CRP (r=-0.149, p<0.001), DAS28 (r=-0.837, p<0.001) and HAQ (r=-0.634, p<0.001).
Conclusion: Fatigue was significantly more observed in RA patients. This symptom was correlated with disease activity and disability. It is important to recognize and manage fatigue in order to improve patients' quality of life.

AB0175 **OPTIMAL ASSESSMENT OF FATIGUE IN RHEUMATOID ARTHRITIS: VISUAL ANALOG SCALE VERSUS FUNCTIONAL ASSESSMENT OF CHRONIC ILLNESS THERAPY – FATIGUE**

A. Fazaa[1], H. Boussaa[1], K. Ouenniche[1], S. Miladi[1], M. Sellami[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim University Hospital, Rheumatology, Sidi Daoud, Tunisia*

Background: Fatigue is an important outcome for patients with rheumatoid arthritis (RA). As recommended by the European League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) task force in 2008, fatigue should be measured in all RA clinical trials whenever possible. Despite these recommendations, it is largely ignored and rarely assessed in clinical practice.
Objectives: The aim of this study was to compare the scales being used to measure fatigue in RA.
Methods: We conducted a cross-sectional study including patients with RA (ACR/EULAR 2010). Patients with other acute or chronic diseases that may induce fatigue (such as cancer, infection or depression) were excluded. Demographic and disease-related data were collected. Fatigue was assessed using two scores. The fatigue Visual Analog Scale (VAS) ranging between 0 and 100 cm. Fatigue was considered mild if the fatigue VAS was <20 cm, moderate if 20≤VAS<50 and severe if VAS>50 cm. The Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) which is a short 13-item questionnaire validated in RA. The score FACIT-F ranges between 0 and 52. Fatigue was considered mild if the FACIT-F score was ≥40, moderate if 20≤FACIT-F<40 and severe if 0≤FACIT-F<20. We used Cohen's kappa (κ) to determine the agreement between fatigue VAS and FACIT-F. The κ result was interpreted as follows: values ≤ 0 as indicating no agreement and 0.01–0.20 as none to slight, 0.21–0.40 as fair, 0.41–0.60 as moderate, 0.61–0.80 as substantial, and 0.81–1.00 as almost perfect agreement. A p value inferior to 0.05 was considered significant.
Results: We included 100 RA patients (84 women and 16 men) with a mean age of 49.5±10 years old [18-65]. The mean disease duration was 87.3 months [1-360]. RF and ACPA were positive in 75% and 72.6% of cases respectively. The mean pain VAS was 49 cm [0-100]. The mean numbers of tender and swollen joints were 5.3 [0-36] and 1 [0-9] respectively. The mean levels of ESR and CRP were 38.1 mm [10-120] and 10.8 mg/l [2-61] respectively. The mean DAS28 ESR was 3.68 [1.90-8.33].
The mean fatigue VAS was 49.1 cm [5-100]. Fatigue was mild in 9% of patients, moderate in 31% of patients, and severe in 60% of patients.
The mean FACIT-F score was 27.1 [0-51]. Fatigue was mild in 26% of patients, moderate in 57% of patients and severe in 17% of patients.
A fair agreement was noted between the two scores (κ=0.303, p<0.001).
The fatigue VAS and FACIT-F were both correlated with the following variables: pain VAS (r=0.685, p<0.001 and r=-0.605, p<0.001), ESR (r=0.384, p<0.001 and r=-0.405, p<0.001), and DAS28 ESR (r=0.684, p<0.001 and r=-0.744, p<0.001).

Conclusion: The fatigue VAS and FACIT-F are easy, brief and valid measures for monitoring this symptom and its effects on patients with RA. A fair agreement was noted between the two scores.

AB0176 PATHOLOGICAL PHENOTYPES OF BODY COMPOSITION IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Feklistov[1], N. Toroptsova[1], O. Nikitinskaya[1], A. Efremova[1], N. Demin[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Osteoporosis, Moscow, Russian Federation*

Background: Inflammation, decreased physical activity, hormonal disorders, and the use of glucocorticoids lead to changes in the composition of the body in rheumatoid arthritis (RA). Various combinations of decreased muscle and bone mass and increased adipose tissue have led to the release of various pathological phenotypes of the composition of the body.
Objectives: To determine the frequency of pathological phenotypes of body composition in patients with RA.
Methods: The study included 79 women with RA, with a median age of 60 y.o. [55; 65]. 92% of the women were postmenopausal. The median duration of the disease was 9 years [3; 11]. Basic anti-inflammatory therapy was received by 81% of patients. Methotrexate was used most often as the basic therapy – in 52% of cases. 49% of patients were treated with glucocorticoid drugs. All patients underwent dual-energy X-ray absorptiometry. The mineral density of the tissues was determined in the standard measurement areas - the spine and the proximal thigh, and the content of muscle and adipose tissue was analyzed. We calculated appendicular muscle mass (AMM), which is the sum of upper and lower limb muscle mass and appendicular muscle index (AMI), the ratio of appendicular muscle mass to the square of height. AMM< 15 kg, AMI < 6 kg / m2 corresponds to sarcopenia.
Results: The average AMM was 17.8±3.0 kg. 18% patients had AMM <15 kg / m2. The average AMI was 6.8±1.0 kg / m2. 25% patients had AMI < 6 kg/m2. The average body mass index (BMI) was 27.6±4.8 kg/m2. 37% patients were overweight (25≤ BMI <29.9 kg/m2), 28% of women had a BMI corresponding to obesity. The average fat content was 28.2 kg. 71% of women had an obesity, according to X-ray absorptiometry, which is 2.5 times higher than the number of cases of obesity detected by BMI. A decrease a bone mineral density (BMD) was found in 73% of women, including osteoporosis in 25%. The most frequent phenotype was osteopenic obesity (Table 1), which was detected in almost 40% of patients. Isolated osteoporosis (16.5%) and obesity (17.7%) and osteosarcopenic obesity (16.5%) were found with approximately the same frequency. Osteosarcopenia was found in 9% of patients. In 4%, no changes in the compositional composition of the human body were detected.

Table 1. Pathological phenotypes of body composition

Pathological phenotypes of body composition	n=79
Osteoporosis, n (%)	13 (16,5)
Obesity, n (%)	14 (17,7)
Osteosarcopenia, n (%)	7 (8,9)
Osteopenic obesity, n (%)	29 (36,7)
Osteosarcopenic obesity, n (%)	13 (16,5)

Conclusion: The overall frequency of pathological phenotypes of body composition was high and amounted to 96.2% in women with RA. The most common pathological phenotype was an osteopenic obesity characterized by a decrease in BMD and an increase in fat mass.

AB0177 ANXIETY-DEPRESSIVE SPECTRUM IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDILITIS

M. Letaeva[1], M. Koroleva[1], J. Averkieva[1], O. Malyshenko[1], T. Raskina[1]. [1]*Kemerovo State Medical University, Department of Propedeutics of Internal Medicine, Kemerovo, Russian Federation*

Objectives: to assess the frequency of occurrence of the anxiety-depressive spectrum in patients with rheumatoid arthritis and ankylosing spondylitis.
Methods: A survey was conducted of 44 patients aged from 21 to 57 years (average age - 42.3 ± 6.7 years), who were treated at GAUZ KO OKGVV. All patients had a verified diagnosis of RA and AS according to the ACR criteria and received treatment with basic drugs. The control group consisted of 40 people comparable in age and sex, without concomitant pathology of RA and AS.
The depression screening card, the subjective well-being scale, and the hospital anxiety and depression scale (HADS) were used to assess and detect anxiety-depressive syndrome. The assessment of the condition is carried out over the last 2 weeks, which corresponds to the temporary diagnostic criterion for depression.
The Depression Screening Scale is a 35-item self-questionnaire that assesses 7 categories of signs: sleep and appetite disorders, anxiety, emotional instability, cognitive impairment, loss of self, guilt, and suicidal tendencies. A total score of 65 and above indicates a high likelihood of depression.
The Subjective Well-Being Scale is a psychodiagnostic screening tool for measuring the emotional component of subjective well-being or emotional comfort.
Hospital Anxiety and Depression Scale Zigmond A.S., Snaith R.P. was developed for the primary detection of depression and anxiety in a general medical practice. The HADS scale consists of 14 statements with 4 possible answers and includes two parts: anxiety and depression. The sum of points of 8 or more is regarded as "subclinically expressed anxiety / depression", 11 or more points - "clinically expressed anxiety / depression".
Results: According to the results of the depression screening questionnaire, 34 (77.3%) patients with RA and AS showed signs of depression, while in the control group only 6 (15%) patients tested positive for the presence of depressive disorders. According to the data obtained when assessing the scale of well-being in the main group, 26 (59.1%) patients showed signs of emotional discomfort (the indicator was 80% or more), in the control group - in 6 (15%). Using the hospital scale of anxiety and depression HADS, anxiety-depressive syndrome was detected in 36 (81.8%) patients with RA and AS: 16 (44.4%) patients had anxiety, 20 (55.6%) - depression, of them, subclinically expressed anxiety and depression were observed in 10 (27.7%) and 12 (33.3%) people, respectively. Anxiety-depressive syndrome in the control group, according to the HADS questionnaire, was detected only in 8 (20%) patients, of whom 4 (10%) patients had subclinical anxiety and 4 (10%) had signs of depression. No clinically pronounced anxiety and depression were registered in the control group.
Conclusion: In most patients with rheumatoid arthritis and ankylosing spondylitis, anxiety-depressive disorders have been identified, which can directly affect both the course of the disease itself and the development of various complications. Timely diagnosis of mental disorders and close cooperation of rheumatologists, psychiatrists and psychologists in the selection of adequate therapy can improve the course and prognosis of the disease.

AB0178 COMORBIDITIES IN RHEUMATOID ARTHRITIS: DO THEY INTERFERE WITH MYOCARDIAL FUNCTION?

R. Dhahri[1], W. Lahmar[1], Y. Ben Abderrazek[1], M. Slouma[1], B. Louzir[2], L. Metoui[1], I. Gharsallah[1], H. Mahfoudhi[3], C. Chourabi[3], W. Fehri[3]. [1]*Military Hospital of Instruction of Tunis, Department of Rheumatology, Tunis, Tunisia*; [2]*Military Hospital of Instruction of Tunis, Department of Internal Medicine, Tunis, Tunisia*; [3]*Military Hospital of Instruction of Tunis, Department of Cardiology, Tunis, Tunisia*

Background: Patients with rheumatoid arthritis are at increased risk for cardiovascular disease (CVD).The early myocardial dysfunction in RA patients may be detectable sooner using speckle-tracking echocariodgraphy to evaluate ventricular strain especially the global longitudinal strain (GLS), this has provided more comprehensive information on ventricular dysfunction in these patients.

Objectives: In the present study, we evaluated comorbidities that interfered the most with the GLS in rheumatoid arthritis patients.

Methods: The study population was comprised of a case group (36 patients with rheumatoid arthritis with no history of CVD and normal LVEF in the outpatient population of the Rheumatology department in the military hospital of Tunis) and a matched control group (individuals without a history of rheumatoid arthritis or cardiac abnormalities referred for clinical check-ups). In both groups, 2D and 3D echocardiographic examinations were performed by a single cardiologist to assess cardiac functional parameters.

Results: Anemia (36%) was found to be the most common comorbidity followed by diabetes mellitus (25%), arterial hypertension (17%) and dyslipidemia (17%).

Myocardial deformation study revealed that rheumatoid arthritis patients had a significantly worse global longitudinal strain than healthy controls (18.99±2.81% vs 20.42±1.33%; P=.015). Moreover, a third of the rheumatoid arthritis patients (and no healthy controls) exhibited subclinical left ventricular systolic dysfunction (GLS<18%).

Anemia (r=–0.368, P=.027), Age (r=–0.365, P=.029), Diabetes mellitus (r=–0.540, P=.001) and E/A (r=0.351, P=.036) were significantly correlated with

GLS in our univariate study. Receiver operating characteristic curve analysis revealed hemoglobin as the best predictor for subclinical LVSD (AUC=0.752, 95% CI: 0.577-0.927, *P*=.02) when compared to Age and E/A.

Conclusion: This prospective comparative study highlighted the diabetes mellitus and anemia burden on myocardial dysfunction in RA patients.

AB0179 INFLUENCE OF AINFLUENCE OF ANTI-CITRULLINATED PROTEIN/PEPTIDE ANTIBODIES (ACPAS)ON ARTICULAR MANIFESTATIONS, DISEASE ACTIVITY AND STRUCTURAL SEVERITY IN ALGERIAN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

F. Rahal[1], N. Brahumi[2], A. Ladjouze-Rezig[2], S. Lefkir[1]. [1]*Beni Messous University Hospital Center, Rheumatology, Algiers, Algeria*; [2]*Ben Aknoun Hospital Center, Rheumatology, Algiers, Algeria*

Background: Anti-citrullinated protein/peptide antibodies (ACPA) are highly specific and sensitive markers for rheumatoid arthritis (RA). There are also suggested to have a more severe rheumatoid arthritis.

Objectives: The aim of this study was to assess the influence of ACPA on disease activity, radiological severity, and functional disability in Algerian patient with early rheumatoid arthritis (RA).

Methods: Consecutive early RA patients (symptom duration ≤24 months) recruited were included in the descriptive, longitudinal, prospective study. Demographic, biological, immunological and radiographic data were collected at the time of inclusion in the study. Disease activity as determined by the Disease Activity Score 28-CPR (DAS28- CPR: 4 variables), functional handicap as calculated by Heath Assessment Score (HAQ), and bone and joint damage as evaluated by Sharp-Van der Heijde (SVDH) erosion and narrowing score.

Results: One hundred and sixty-one patients with RA were recruited. Patients mean age 43.71±14 years and mean symptom duration at inclusion was 10.48±7 months. Small and larges were affected in 64,3%. The mean ESR was 23,53±15,2 mm/1st hour, and the mean CRP level was 19,42±39.8 mg/l. Rheumatoid Factors (RFs) and Anti-Citrullinated Protein Antibodies (ACPAs) were present in 74% and 88% of patients, respectively. The presence of ACPAs was significantly associated with DAS28 (p=0,004) and HAQ (p=0,002). There was no significant difference in inflammatory markers and radiographic SVDH score between patients with and without ACPAs. Stepwise regression analysis showed that the presence of ACPAs was independently associated with localization when RA affected smalls and larges joint in the same time (OR=5,24; IC 95% 1,224-22,483; p=0,026).

Conclusion: These data show that in patients with early RA, ACPAs positivity was significantly associated with articular manifestations, activity disease and functional handicap, but not with structural damage.

AB0180 A MULTICENTER SELF-CONTROLLED CASE SERIES STUDY INVESTIGATING THE PREVENTIVE EFFECT OF SULFASALAZINE AGAINST PNEUMOCYSTIS PNEUMONIA

T. Nunokawa[1], T. Kakutani[1], N. Chinen[1], K. Shimada[2], M. Kimura[3], M. Tateishi[3], F. Chen[4], K. Setoguchi[4], M. Sugihara[5]. [1]*Tama Nambu Chiiki Hospital, Department of Rheumatic Diseases, Tokyo, Japan*; [2]*Tokyo Metropolitan Tama Medical Center, Department of Rheumatic Diseases, Tokyo, Japan*; [3]*Tokyo Metropolitan Ohtsuka Hospital, Department of Rheumatology, Tokyo, Japan*; [4]*Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Department of Rheumatology, Tokyo, Japan*; [5]*Tama-Hokubu Medical Center, Department of Rheumatic Diseases, Tokyo, Japan*

Background: An animal study revealed that sulfasalazine (SSZ) enhances *Pneumocystis* clearance from the lung by accelerating macrophage activity.[1] Although the preventive effect of SSZ on *Pneumocystis* pneumonia (PCP) in patients with rheumatoid arthritis (RA) is reported in case-control studies, some important confounders might remain unmeasured and distort the results. [2-3]. The self-controlled case series (SCCS) method involves only cases and controls fixed confounders automatically.[4]

Objectives: To evaluate the prophylactic effect of SSZ against PCP in patients with RA, controlling unmeasurable confounders by the SCCS method.

Methods: A retrospective study was conducted at five hospitals. Patients with RA who developed PCP between 2003 and 2019 were included. PCP was defined by the following criteria: (1) detection of *Pneumocystis jirovecii* in respiratory specimens by polymerase chain reaction; (2) clinical manifestations (pyrexia, dry cough, dyspnea, or hypoxia); (3) diffuse interstitial infiltrate on chest imaging; (4) absence of prophylaxis for PCP. Incidence rate ratio (IRR) for *Pneumocystis* pneumonia associated with sulfasalazine use was calculated by conditional Poisson regression.

Results: We identified 48 episodes of PCP in 47 cases. Of these, 15 (31.9%) died. Thirty received SSZ in certain periods of their observations (Table 1). While 46 episodes of PCP developed in the period of 168.9 person-years without SSZ use, only one episode of PCP developed in the period of 103.7 person-years with SSZ use. SSZ use had a decreased risk of PJP (adjusted IRR 0.007, 95% CI <0.001-0.067) after adjusted for age group, the use of glucocorticoid, methotrexate, and tacrolimus, and the use of biologic agent or janus kinase inhibitor (Table 2).

Table 1. Characteristic of the 47 patients enrolled in the study.

Male/female, n (%)	14 (29.8)/33 (70.2)
Observational period (years), median (IQR)	72.0 (66.3-79.1)
Lung disease, n (%)	4.7 (1.4-9.5)
Use of sulfasalazine, n (%)	23 (48.9)
Outcome of PCP, death, n (%)	30 (63.8)
Age at the onset of PCP (years), median (IQR)	15 (31.9)

EXPLORING THE ROLE OF IL-6 BLOCKADE IN PATIENTS WITH ACTIVE RHEUMATOID ARTHTITIS AND CHRONIC PERIODONTITIS

C. Ancuta[1,2], E. Ancuta[3], R. Chirieac[4], O. Tanculescu[5], C. Iordache[6]. [1]*University of Medicine and Pharmacy "GRIGORE T. POPA" IASI, Rheumatology, IASI, Romania*; [2]*Clinical Rehabilitation Hospital, Rheumatology 2, IASI, Romania*; [3]*"Elena Doamna" Clinical Hospital, Research, IASI, Romania*; [4]*Sanocare Medical and Research Center, Rheumatology, IASI, Romania*; [5]*University of Medicine and Pharmacy "GRIGORE T. POPA" IASI, Implantology, Removable Dentures, Dental Technology Department, Faculty of Dentistry, IASI, Romania*

Background: Recent data have renewed the interest in common pathobiologic pathways in autoimmune rheumatic conditions and periodontal disease, especially on dual impact of innovative anti-rheumatic drugs in modulating both inflammatory and immune articular as well as periodontal damage. Although consistent data about TNF inhibitors and chronic periodontitis are already published, the influence of IL-6 blockade.

Objectives: We aimed to explore the influence of weekly subcutaneously IL-6 receptor inhibitor tocilizumab on periodontal health in a local cohort of patients with rheumatoid arthritis (RA) and chronic periodontitis (PD).

Methods: We performed a prospective longitudinal 6 months study in 68 patients with moderate-to-severe RA starting tocilizumab (TCZ) in accordance to local recommendations. Extensive rheumatologic (clinical activity, inflammatory, serological biomarkers) and dental (plaque index PI, gingival index GI, bleeding on probing BOP, pocket probing depth PPD, clinical attachment level CAL) assessments were done. Changes in RA activity and periodontal status were reassessed after 3 and 6 months.

Results: 51 RA and concomitant t of 68 patients in our initial cohort were finally analyzed. Aggressive periodontal disease was reported particularly in disease subsets with excessive inflammatory (serum C reactive protein level) and serologic biomarkers (anti-citrullinated peptide antibodies ACPA). Furthermore, significant correlations between periodontal status, clinical disease activity and ACPA levels were also demonstrated ($p<0.05$). We also noticed consistent improvement was noticed in both RA-related parameters sand periodontal inflammation (GI and sites with bleeding of probing) after only 3 months ($p < 0.05$), while PPD improved after 6 months; overall, CAL presented only slight changes without statistical any significance as well as teeth count and plaque levels ($p > 0.05$).

Conclusion: IL-6 inhibition is able to improve periodontal outcomes in patients with RA and concomitant PD, essentially related to dramatic decrease in serum inflammatory mediators.

HEMOGLOBIN RATE AS A PREDICTOR OF SUBCLINICAL LEFT VENTRICULAR SYSTOLIC DYSFUNCTION IN RHEUMATOID ARTHRITIS

Y. Ben Abderrazek[1], R. Dhahri[1], W. Lahmar[1], M. Slouma[1], B. Louzir[2], L. Metoui[1], I. Gharsallah[1], H. Mahfoudhi[3], C. Chourabi[3], W. Fehri[3]. [1]*Military Hospital of Instruction of Tunis, Department of Rheumatology, Tunis, Tunisia*; [2]*Military Hospital of Instruction of Tunis, Department of Internal Medicine, Tunis, Tunisia*; [3]*Military Hospital of Instruction of Tunis, Department of Cardiology, Tunis, Tunisia*

Background: The role of rheumatoid arthritis as an ischemic heart disease and heart failure risk factor is well acknowledged even if the physiopathological pathways are still debated. The effect of anemia on myocardial deformation has already been established and a hemoglobin level below 9g/dL was associated with a significantly lower global longitudinal strain (GLS) patients with no history of CVD or chronic inflammatory diseases.[1]

Objectives: In the present study, we looked into the effect of anemia and hemoglobin on the myocardial impairement in RA patients.

Methods: We conducted a monocentric cross-sectional study between march 2019 and september 2019 on 36 RA patients without any history of cardiovascular disease and non-altered left ventricular ejection fraction in the outpatient population of the rheumatology department of the military hospital of Tunis matched with 36 healthy control subjects. Both groups underwent conventional echocardiography and STE to measure GLS; subclinical left ventricular systolic dysfunction was defined as a GLS > −18%, and a complete blood cell count; anemia was defined as Hemoglobin levels < 12 g/dL for women and < 13 g/dL for men.

Results: Myocardial deformation study revealed that rheumatoid arthritis patients had a significantly worse GLS than healthy controls (18.99±2.81% vs 20.42±1.33%; *P*=.015). We also observed that third of the RA patients had subclinical left ventricular systolic dysfunction.

In our report 36% of RA patients were anemic. In our univariate analysis anemia was found to be significantly correlated with GLS (r=–0.368, *P*=.027) and hemoglobin was found to be the best predictor of subclinical LVSD in our ROC curve analysis (AUC=0.752, 95% CI: 0.577-0.927, *P*=.02). In our multivariate analysis anemia was the only factor that was independently related to subclinical LVSD (OR: 11.39, 95% CI: 1.57-82.89, *P*=.016).

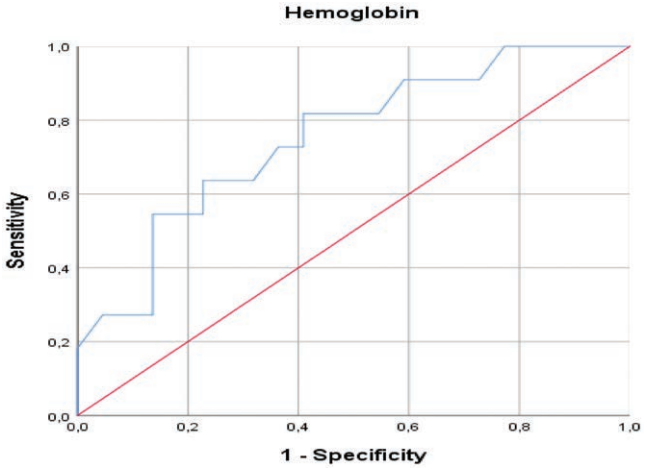

Figure 1. ***ROC curve analysis for Hemoglobin as a predictor of subclinical left ventricular systolic dysfunction***

Conclusion: To our knowledge, this is the first study to look into the relationship between GLS and anemia among RA patients, and now it is safe to say that anemia is yet another added burden on the myocardial function in RA patients that needs to be taken into account when discussing therapeutic action.

T-CELL LARGE GRANULAR LYMPHOCYTE LEUKEMIA IN PATIENTS WITH FELTY'S SYNDROME

V. Vasiliev[1], V. Gorodetskiy[2], B. Chalcev[2], S. Palshina[3], E. Sokol[2], A. Torgashina[2], J. Khvan[2]. [1]*MEDSI, Department of Rheumatic Diseases, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Intensive Care of Rheumatic Diseases, Moscow, Russian Federation*; [3]*Clinic of Heart and Joint Diseases, Department of Rheumatic Diseases, Moscow, Russian Federation*

Background: Felty's syndrome (FS) is a rare subtype of seropositive rheumatoid arthritis (RA) and is characterized by neutropenia and splenomegaly. Some researchers suggest that FS and T-cell large granular leukemia (T-LGLL) may have common pathogenetic relationships [1].

Objectives: to characterize the clinical and laboratory manifestations of FS, to evaluate the frequency of T-LGLL and Sjogren's syndrome (SS) in this group of patients with RA, neutropenia and splenomegaly (pts).

Methods: We observed 18 pts with ACCP-positive (100%) and RF-positive (94.5%) RA diagnosed according to ACR 2010 criteria, who also had neutropenia and hepatosplenomegaly. All 18 pts underwent T-LGLL diagnostics using blood smears and phenotyping of peripheral lymphocytes for the presence of granular lymphocytes, determination of T-cell clonality using the rearrangement of the γ-chain of the T-cell receptor of lymphocytes by PCR, histological/

immunohistochemical study of bone marrow biopsy specimens for the presence of LGL invasion studies, as well as the study of 4 spleens after splenectomy. SS was diagnosed in 8 out of 18 pts (44.5%) according ACR 2016 criteria.

Results: Twelve (66.6%) of 18 pts with RA, neutropenia and splenomegaly were diagnosed with T-LGLL, the patients were divided in 2 groups: FS (6 pts) and RA+T-LGL (12 pts). Pts with FS debuted with arthritis of small hand joints, extremely rarely with extra-articular manifestations, mainly at a young age (36.5±3.9 years), and developed neutropenia after 10 years of RA. Pts with T-LGLL debuted at a younger age (39,5±4,5 and 51,5+7,8 years, respectively), had a longer course of RA before the development of neutropenia (14.3±3.3 and 5±1.5 years, respectively, p=0.03), and more often had extra-articular manifestations at the onset of the disease. RA activity did not differ between groups and in most cases was characterized by a mild course of articular syndrome. Though the course of RA+T-LGLL group was characterized by low (50%) and moderate (33%) DAS28-CRP activity and active synovitis in only 41.5% of pts, severe joint deformities (stage III and IV) developed in 58.5% of pts. Pts with T-LGLL showed a higher incidence of hepatomegaly (75% and 16.5%, respectively, p=0.02) and more severe neutropenia (p=0.02). The development of severe leukopenia ($<1x10^9$) and massive hepatosplenomegaly was observed only in pts with T-LGLL, which required splenectomy in 4 cases. SS was more often detected in the FS group than in the RA+T-LGLL group (83.5% and 25%, respectively, p = 0.02).

Conclusion: Clinical and laboratory manifestations of FS and T-LGLL are extremely close, therefore, pts who are diagnosed with FS should be examined to exclude T-LGLL.

AB0184 SCREENING FOR DEPRESSION IN A GROUP OF TUNISIAN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Sellami[1], S. Kammoun[1], S. Miladi[1], A. Fazaa[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Depression is thought to be common comorbidity in patients with rheumatoid arthritis (RA), which is one of the most frequent chronic inflammatory diseases.

Objectives: This study aimed to screen for depression in RA patients, and study its relation to social and clinical parameters, as well as disease activity.

Methods: Single-center cross-sectional study, involving patients with RA, according to ACR/EULAR criteria 2010, using the original Beck Depression Inventory (BDI) as a screening tool for depression: measures of 0–9 indicated that a patient was not depressed, 10–18 indicated mild to moderate depression, 19–29 indicated moderate to severe depression and 30–63 indicated severe depression.

Results: Sixty-five patients were included (57 F / 8M). The average age was 55 years [23-73]. The mean duration of the disease was 11.75 years [1-25]. Half of the patients had precarious socioeconomic conditions and no social security. Forty-two patients were unemployed. Seventeen percent of them experienced grief by losing a close family member. Both rheumatoid factor and anti-citrullinated peptides antibodies were positive in 83.1 % of cases. RA was erosive in 78.5% of cases, and deformed in 21.5 % of cases. Almost half of the patients (52.3 %) were followed for at least another chronic disease. Forty-eight percent of patients were on Methotrexate with an average weekly dose of 15.3 mg/week [10-22.5], 10% on Leflunomide, 10% on Sulfasalazine, and 45% on biotherapy. The analysis of BDI scores showed that 64.6 % of patients suffered from depression: mild to moderate in 35.4 % of cases, moderate to severe in 21.5% of cases and severe in 7.7% of cases. Depression was significantly associated with precarious socioeconomic conditions (p=0.018). A correlation between the BDI score and the Disease Activity Score (DAS28) as well as the Health Assessment Questionnaire was noted (p = 0.045 and p = 0.02, respectively). There were no statistically significant associations with the other studied data.

Conclusion: Depression was frequent among RA patients. Our study suggests that better control of the disease may reduce the incidence of depression within this group of patients.

AB0185 ULTRASOUND IN INFLAMMATORY ARTHRALGIA: SHOULD WE ALWAYS SCAN?

K. López Gloria[1], I. Castrejon[1], J. C. Nieto González[1], J. Rivera[1], J. Martínez-Barrio[1], B. Serrano-Benavente[1], L. Trives Folguera[1], J. M. Alvaro-Gracia[1], J. Molina Collada[1]. [1]*Hospital Universitario Gregorio Marañón, Rheumatology, Madrid, Spain*

Background: Patients with inflammatory arthralgia (IA) are considered to be at increased risk for progression to RA. Ultrasound (US) has shown high sensitivity to detect synovitis compared with physical examination. Thus, US is recommended to identify subclinical synovitis in patients without clinical signs of inflammation.

Objectives: To determine the frequency and pattern of US detected active inflammation in patients with IA and investigate factors contributing to predict this outcome.

Methods: An US clinic is scheduled in an academic center running twice every week. A retrospective analysis of our US unit cohort during a period of 12 months was undertaken. Patients with IA and no previous diagnosis of inflammatory arthropathies were included for analysis. Inclusion criteria of IA definition included: severe symptoms presenting in the morning, duration of morning stiffness ≥60 min, symptoms predominantly located in MCP joints and absence of clinically detected synovitis by the referral rheumatologist. The following routinely collected variables were included in the analysis: demographics, clinical features and laboratory tests. Patients underwent bilateral US examination of hands and/or feet according to the European League Against Rheumatism (EULAR) guidelines. The presence of synovitis and tenosynovitis was assessed on a semi quantitative scale (0–3) for Grey Scale(GS)/Power Doppler(PD). Active inflammation was defined as PD synovitis and/or tenosynovitis >1 at any location. First, differences between groups were tested using chi-squared/Fisher and Student-t tests in the univariate analysis. Second, multivariate logistic regression models were employed to investigate the association between possible predictive factors of US active inflammation.

Results: A total of 110 patients were included in the analysis. Mean age was 53.6±15.6 years, 80 (72.7%) were females, and mean symptoms duration was 11.7±9.9 months (Table1). A total of 76 (69.1%) patients presented with a polyarticular arthralgia pattern. US active inflammation were present in 38 (34.5%) patients (28.2% showed PD synovitis and 19.1% PD tenosynovitis). Hands were most commonly involved with PD synovitis at wrists in 18.2% and at MCP in 14.5% of patients. For PD tenosynovitis, the flexor MCP 2-5 (4.5%) and 6th extensor tenosynovitis (5.5 %) were the most frequent affected locations. Only 9 (8.2%) patients had erosions in hands and/or feet at baseline examination. In the univariate analysis, the higher ESR values, the shorter time from symptoms onset and the presence of ACPA were significantly associated with the presence of US active inflammation (p<0.001, p=0.035 and p=0.01, respectively). In the multivariate analysis, only ACPA and ESR values (OR=1,0003; 95%CI 1,000-1,006 and OR=1.054; 95%CI 1.016-1.094), remained significantly associated with the detection of US active inflammation.

Conclusion: US features of active inflammation are found in 1 over 3 patients with IA being PD synovitis the most common finding, specially at the wrists and MCP joints. Higher ESR and ACPA values are significantly associated with the presence of US active inflammation. Thus, we strongly recommend the use of PD US to detect subclinical inflammation in at-risk patients with IA with no sign of inflammation on clinical examination, especially those with high ESR and ACPA values.

Table 1. Baseline characteristics of patients with IA

		Total n= 110	US inflammatory findings n= 38 (34.5%)	Non-US inflammatory findings n=72 (65.5%)	p

AB0186 AT WHAT LEVEL SHOULD WE MEASURE INTIMA-MEDIA THICKNESS IN RHEUMATOID ARTHRITIS?

L. Nacef[1], H. Ferjani[2], H. Riahi[3], K. Maatallah[2], Y. Mabrouk[2], E. Labbene[3], D. Kaffel[2], W. Hamdi[2], M. Bouaziz[3]. [1]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Rheumatolgy, Tunis, Tunisia*; [2]*Mohamed*

Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Rheumatolgy, Manouba, Tunisia; [3]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Radiology, Manouba, Tunisia*

Background: Rheumatoid arthritis (RA) is chronic inflammatory rheumatism characterized by an independent cardiovascular (CV) risk. The screening of carotid intima-media thickness (IMT) in the common carotid artery appears to be a marker of atherosclerosis and is used as a specific tool for CV risk assessment.
Objectives: The main of this study was to determine the most associated US sites with CV risk in RA.
Methods: The present study is a prospective study conducted on Tunisian RA patients in rheumatology department of Mohamed Kassab University Hospital (March and December 2020). The characteristics of the patients and those of the disease were collected. The measurement of cIMTwas done using high-resolution B-mode carotid US with a Philips machine with the patient in supine position, according to AmericanSociety of Echocardiography guidelines.The carotid bulb below itsbifurcation and the internal and external carotid arteries were evaluated bilaterally with gray scale, spectral and color Doppler ultra-sonography using proprietary software for carotid arterymeasurements.IMT was measured using the two inner layers of the commoncarotid artery and an increased IMT was defined as ≥0.9 mm. The CV risk at 10 years was calculated by the SCORE index.
Results: Forty-seven patients were collected, of which 78.7% were women. The mean age was 52.5 ±11.06 years. The rheumatoid factor (RF) was positive in 57.8% of cases, and anti-citrullinated peptide antibodies (ACPA) were positive in 62.2% of cases. RA was erosive in 81.6% of cases. Hypertension (hypertension) was present in 14.9% of patients and diabetes in 12.8% of patients. Nine patients were active smokers. The mean IMT in the left common carotid (LCC) was 0.069 ±0.015, in the left internal carotid (LIC) was 0.069 ±0.015, in the left external carotid (LEC) was 0.060 ±0.023. The mean IMT was 0.068 ±0.01 in the right common carotid (RCC), 0.062 ±0.02 in the right internal carotid (RIC), and 0.060 ±0.016 in the right external carotid (REC). The mean SCORE index of CV risk was 2±2.81 [0-11.6]. CV risk was significantly associated with the IMTs for LIC (p=0.029; r=0.374), LEC (p=0.04; r=0.480), and REC (p=0.016; r=0.408). No association was found between the IMT in the LCC (p=0,361; r=0,162), neither in the RCC (p=0,438; r=0,140) nor the RIC (p=0,670; r=0,077).
Conclusion: In our study, IMT is strongly associated with score index, especially in carotid bifurcation. However, IMT measured in common carotid does not reflect a cardiovascular risk at 10-years.

AB0187 PREVALENCE, RISK FACTORS, AND TREATMENT MODALITIES OF ATLANTOAXIAL DISLOCATION IN RHEUMATOID ARTHRITIS

K. Maatallah[1], S. Miri[1], H. Ferjani[1], D. Ben Nsib[1], W. Triki[1], A. Dallegi[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rhumatology, Manouba, Tunisia*

Background: Cervical spine involvement is common in patients with rheumatoid arthritis (RA). The most common abnormality is atlantoaxial dislocation (AAD). It may lead to severe neurological symptoms and even death. Currently, there is a lack of consensus on the best approach to treatment.
Objectives: We investigated the prevalence of and risk factors for AAD in patients with RA, as well as its relationship to treatment modalities.
Methods: We conducted a cross-sectional study including 224 patients with RA. All patients fulfilled the 2010 American College of Rheumatology/European League Against Rheumatism RA classification criteria. Radiographs of the cervical spine included lateral views taken in flexion, extension, neutral position of the neck, anteroposterior and odontoid projection view. Patients were divided into two groups: (G1) a group with AAD and (G2) without ADD. We compared clinical, radiological, and *laboratory findings* between the two groups, as well as the treatments used: Steroid therapy, classic and biologic disease-modifying anti-rheumatic drugs (*DMARDs*). Structural joint damage was assessed with the Sharp/van der Heijde radiographic method. Functional impairment was assessed using the Health Assessment Questionnaire (HAQ). We used Statistical Package for Social Sciences (SPSS) 22.0 to analyze the results. The level of statistical significance was set at 0.05.
Results: ADD was present in 16% of the cases (n=36). Female predominance was noted, with a sex ratio of 0.25 (p=0.530). The mean age was 58±12 years, with no significant difference between groups (p=0.146). The mean disease duration was significantly higher in G1 (11.5 ± 10.5 years versus 5.9 ± 6.3, p=0.004). A noticeable relationship between AAD and immunopositivity was found: rheumatoid factor (RF) was present in 86.1% of the cases in G1 versus 67.5% in G2 (p=0.025). Anti-citrullinated protein antibodies (ACPA) were present in 86.1% of the cases in G1 versus 64.8% in G2 (p=0.012). We found a significant difference between AAD and disease activity assessed by DAS28-VS (5.8±1.3 in G1 versus 5.3±1.6 in G2,p=0.027). AAD was significantly associated with more structural joint damage: erosions (121.1±60.9 in G1 versus 61.8±56.5 in G2,$p<10^{-3}$), joints space narrowing (77.4±47.4 in G1 versus 38.7±40 in G2, $p<10^{-3}$), Sharp/van der Heijde radiographic score (190.2±103.1 in G1 versus 100.1±90.6 in G2, $p<10^{-3}$). Hip involvement was more frequent in G1 (22.2% versus 9.4% in G2, p=0.038).
HAQ score was higher in G1 (1.8±0.7 versus 1.2±1, p=0.002).
Seventy-five percent of patients in G1 had received methotrexate versus 82.3% in G2 (p=0.301). The mean duration of methotrexate therapy was longer in G1 (24.6±23.5 versus 18±24 months, p=0.015). G1 patients received a higher mean dose and cumulative dose of methotrexate: 13.2±3.5 g/week versus 11.8±4.4 g/week (p=0.048), and 6.5±6.8 versus 4.8±8.5 (p=0.025), respectively.
Thirty-five percent of patients in G1 had received corticosteroids versus 25% in G2 (p=0.217). Patients in G1 had a significantly longer duration of steroid therapy: 17.8+20.2 versus 13.3+24.3 months (p=0.22). The mean dose of corti*costeroids was similar between the two groups: 6.9±4.3 mg/day versus 5.7±4.6 mg/day (p=0.132). The total* cumulative dose was significantly higher in G1: 6.5±6.8 *mg/day* versus 4.8±8.5 *mg/day (p=0.025).*There was no significant difference in using other DMARDs: Sulfasalazine (p=0.182) and leflunomide (p=0.276).
No significant difference was observed with patients under biologic DMARDs: 24.1% in G1 versus 17% in G2 (p=0.725).
Conclusion: Cervical spine involvement is common in RA and may be asymptomatic. Immunopositive patients seem to have more frequently ADD, as well as those with high disease activity and severe structural joint damage. The treatment modalities do not appear to be affected by AAD; however, patients with ADD seem to have higher cumulative doses of corticosteroids and methotrexate. Given the cross-sectional nature of our study, it is difficult to confirm the connection between the two. Further studies are needed.

AB0188 DO PATIENT-REPORTED OUTCOMES IN RHEUMATOID ARTHRITIS REFLECT DISEASE ACTIVITY?

K. Ben Abdelghani[1], H. Boussaa[1], S. Miladi[1], M. Sellami[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], A. Fazaa[1], A. Laatar[1]. [1]*Mongi Slim University Hospital, Rheumatology, La Marsa, Tunisia*

Background: Patient-reported outcomes (PROs) reflect the patient's perspective and are used in rheumatoid arthritis (RA) routine clinical practice. However, PROs may be associated with other aspects of health, such as psychological distress or comorbidities, which leads to situations of discordance with objective RA assessments.
Objectives: The aim of this study was to determine whether PROs were associated with objective assessment of disease activity.
Methods: We conducted a cross-sectional study including patients with RA (ACR/EULAR 2010). Demographic data were collected. The following PROs were assessed: number of nocturnal awakenings, morning stiffness duration, estimation of spontaneous pain and fatigue by Visual Analog Scale (VAS), and global patient assessment (GPA). In addition, patients rated their current satisfaction with their disease state according to the Austrian school mark system (PATSAT: 1=excellent, 2=good, 3=average, 4=moderate (fair), 5=unsatisfactory). Disease activity was assessed using the 28-joint disease activity score with erythrocyte sedimentation rate (DAS28 ESR) and C reactive protein (DAS28 CRP). We used Cohen's kappa (κ) to determine the agreement between PATSAT and DAS28 ESR. The κ result was interpreted as follows: values ≤ 0 as indicating no agreement and 0.01–0.20 as none to slight, 0.21–0.40 as fair, 0.41– 0.60 as moderate, 0.61–0.80 as substantial, and 0.81–1.00 as almost perfect agreement. A p-value inferior to 0.05 was considered significant.
Results: We included 54 patients (45 women and nine men) with a mean age of 55±11 years old [23-69]. The mean disease duration was 9.9±5.9 years [0-20]. The mean number of nocturnal awakenings was 1.1 [0-4] and the mean morning stiffness duration was 25.1 minutes [0-120]. The mean GPA was 5.3±2.2 cm [0-10]. The mean pain VAS was 5.4±2.2 cm [0-10] and the mean fatigue VAS was 4±2.5 cm [0-8]. None of the patients described his disease state as 'excellent'. It was considered 'good' in 23.1% of cases, 'average' in 36.5% of cases, and 'moderate' to 'unsatisfactory' in 40.4% of cases.

The mean ESR and CRP were 46.3±29.3 mm [5-120] and 15.8 mg/l [0.6-100] respectively. The mean DAS28 ESR was 4.68±1.35 [1.50-7.16] and the mean DAS28 CRP was 3.9±1.1 [1.02-6.05].
A significant positive correlation was noted between both DAS28 ESR and DAS28 CRP and, number of nocturnal awakenings (r=0.385, p=0.013 and r=0.448, p=0.002), morning stiffness duration (r=0.495, p=0.001 and r=0.617, p<0.001), GPA (r=0.485, p<0.001 and r=0.530, p<0.001), and pain VAS (r=0.594, p<0.001 and r=0.598, p<0.001). No correlation was found between the two scores and fatigue VAS.
No significant agreement was noted between PATSAT and DAS28 ESR (κ=0.077, p=0.478).
Conclusion: PROs showed moderate to strong correlation with disease activity scores. The timely and effective use of PROs could encourage physicians to focus more on the impact of RA on patients and how patients are feeling. This in turn would facilitate shared decision making between patients and physicians.

AB0189 LIPOPROTEIN ABNORMALITIES IN RHEUMATOID ARTHRITIS PATIENTS

L. Nacef[1], Y. Besbes[2], Y. Mabrouk[1], H. Ferjani[1], K. Maatallah[3], D. Kaffel[3], S. Besbes[2], W. Hamdi[1]. [1]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Rheumatolgy, Manouba, Tunisia*; [2]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Biology, Tunis, Tunisia*; [3]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Rheumatolgy, Tunis, Tunisia*

Background: The lipid paradox is termed the decreased cholesterol level in rheumatoid arthritis (RA). Nevertheless, the apolipoprotein levels are usually higher than a healthy person and are predictors of cardiovascular events.
Objectives: We aimed to describe lipid abnormalities in RA patients and to look for predictor factors of these changes.
Methods: The prospective study was carried out on patients with RA who met the 2010 American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) classification criteria. These patients were followed in the rheumatology department of the Kassab Institute.
We collected the socio-demographic data, biological and immunological parameters.
The lipid assessment included: a measurement of total cholesterol (TC), HDL, LDL, and triglycerides (TG). Lipoproteins APOA1 and APOB were measured. All data were collected after patient consent.
Results: Of the 47 patients recruited, 78.7% were female. The mean age was 52.5 ±11.06 [32-76]. The average RA progressed from 86.25 ±63 months [5-288] and was erosive in 81.6% of cases. The rheumatoid factor (RF) was positive in 57.8% of patients, and citrullinated antipeptide antibodies (ACPA) were present in 62.2%. Eight patients had a previous CV history.
Mean TC was 4.42 ±1.3 [1.2-7.58], mean HDL was 1.38 ±0.73 [0.18-4.10], mean LDL was 2.55 ±1.16 [0.24-5.54]. The mean TG value was 1.28 ±0.6 [0.24-5.54]. TC elevation was found in 9.1% of cases, HDL in 21.3% of cases, LDL in 5.5% of cases, and TG in 16.4% of cases. Mean APOB/APOA1 ratio was 0.67 ±0.18 [0,46-1,11]. LDL elevation was associated to a high DAS28 (p=0.06, r=0.512). APOA1 was associated to a low DAS28 (p=0.04, r=-0.642).
The mean value of APO A1 was 1.36 ±0.21 [0.84-1.81], that of APOB was 0.90 ±0.22 [0.58-1.40]. APOA1 values were lower in patients with high-level LDL (p=0.767). The APOB value was associated with lipid disturbance without significant correlation (p=0.291).
Conclusion: Lipid test abnormalities can be found in RA patients outside of any known CV risk factors. APOA1 seems to have a protective effect. Screening and treatment of these abnormalities can prevent CV risk.

AB0190 LIVER INVOLVEMENT IN RHEUMATOID ARTHRITIS

A. Ben Tekaya[1], B. D. Siwar[1], S. Bouden[1], O. Saidane[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Department of Rheumatology, Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) can be associated to extra-articular manifestations and comorbidities, including hepatic disturbances. It can be related to an underlying viral, metabolic or immune disease, or to a medical treatment toxicity [1].
Objectives: We aim to study liver involvement in a group of RA patients.
Methods: We performed a cross sectional study in 249 RA patients responding to the ACR/EULAR 2010 criteria for RA diagnosis. Hepatic enzymes, B and C hepatitis viruses screening tests, abdominal ultrasonography, biliary tract MRIs, fibrotests and fibroscans if available were collected and analysed.
Results: Two hundred and forty-nine patients were included with 83.8% of women. The mean age was 59±11.67 years. The mean age at diagnosis was 47±14.9 years with a mean disease evolution of 11±8.83 years.
The mean disease activity (DAS28) was 4,66 with levels ranging from 0.12 to 7.78.
Liver abnormalities were found in 68 patients (27.3%).
Viral disease represented 32.3% of liver abnormalities and was found in 8.8% of the total number of patients. Positive anti-HBc antibodies with negative HBs antigen were found in 8.4% of the patients, no viral reactivation with conventional or biological disease-modifying anti-rheumatic drugs was noted.
Besides, 4 of the 249 patients had positive HCV antibodies tests; one of them had a reactivation of a hepatitis C infection after treatment with leflunomide, one had a chronic C hepatitis with chronic liver disease, one had an old B and C hepatitis infection and the last one had an associated liver nodule for which an exploration was triggered. One patient had post hepatitis C cirrhosis associated with a hepatocellular carcinoma treated with surgery and an association of ledipasvir and sofosbuvir with a negative serology.
Medical treatment toxicity was responsible for 25% of liver abnormalities. Paracetamol caused both hepatic cholestasis and cytolysis in 5 patients, and isolated cholestasis in 2 patients. NSAIDs caused both hepatic cholestasis and cytolysis in 2 patients, and isolated cholestasis in one patient. Methotrexate was responsible for isolated cholestasis in 2 patients, isolated hepatic cytolysis in one patient and both cholestasis and cytolysis in one patient. An interaction between methotrexate and fluconazole caused one case of hepatic cholestasis and cytolysis. Treatment of a latent tuberculosis with isoniazid and rifampicin was responsible for cholestasis in one patient.
Immune hepatic disease was present in 3 patients: 2 patients had a primary biliary cholangitis that manifested with a cholestasis and one patient had an auto-immune hepatitis that manifested with cytolysis and cholestasis.
The prevalence of hepatic steatosis was of 4.8%, assessed with ultrasonography or microscopic examination of a liver biopsy. Hepatic enzymes test was normal in 2%, showed isolated cholestasis in 2% and both cholestasis and hepatic cytolysis in 0.8% of the patients.
One patient had a secondary hemochromatosis to multiple transfusions for sickle cell anaemia, causing cholestasis and cytolysis.
No aetiology was found for hepatic cholestasis and/or cytolysis in 7.2% of patients.
Conclusion: Liver involvement in RA is common and has different aspects. A careful monitoring of liver enzymes tests is crucial to detect hepatic disease and prevent its evolution to a chronic liver disease and cirrhosis. On the other hand, screening for viral hepatitis B and C is necessary to prevent an aggravation of a chronic infection and a reactivation of a latent one [2].

AB0191 ON WHICH FACTOR TO ACT TO REDUCE CARDIOVASCULAR RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS?

L. Nacef[1], H. Ferjani[1], H. Riahi[2], Y. Mabrouk[1], E. Labbene[2], K. Maatallah[1], D. Kaffel[1], M. Bouaziz[3], W. Hamdi[4]. [1]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Rheumatolgy, Manouba, Tunisia*; [2]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Radiology, Tunis, Tunisia*; [3]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Radiology, Manouba, Tunisia*; [4]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Rheumatolgy, Tunis, Tunisia*

Background: Patients with rheumatoid arthritis (RA) are at higher cardiovascular risk (CVR) than the general population due to chronic inflammation. Several factors, both modifiable and non-modifiable, can increase this risk. Intima-media thickness (IMT) was considered as a marker for atherosclerosis.
Objectives: This study aimed to identify predictor factors of increasing IMT.
Methods: The prospective study was carried out on patients with RA who met the 2010 American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) classification criteria. These patients were followed in the

rheumatology department of the Kassab Institute. The socio-demographic data, biological and immunological parameters were collected.
Framingham's score quantified the cardiovascular risk at 10-years. Carotid Ultrasonography (US) using a high resolution B mode carotid measured intima-media thickness (IMT) as a subclinical marker of atherosclerosis. Carotid US was performed in the supine position, according to American Society of Echocardiography guidelines. IMT was measured in the left (LCC) and right (RCC) common carotid arteries, the left (LIC) and right (RIC) internal carotid arteries, and the left (LEC) and right (RIC) internal carotid arteries. An increased IMT was defined as ≥0.9 mm.
We analyzed data by the SPSS statistical package. A p-value <0.05 was considered significant.
Results: Of the 47 patients surveyed, 78.7% were female. The mean age was 52.5 ±11.06 [32-76]. The duration disease was 86.25 ±63 months [5-288] and was erosive in 81.6% of cases. The rheumatoid factor (RF) was positive in 57.8% of patients, and citrullinated antipeptide antibodies (ACPA) were present in 62.2%. Eight patients had a previous CV history (hypertension, diabetes or dyslipidemia) and 16.4% were active smokers. Among women, 43.6% were postmenopausal. ITM was significantly higher in men at LIC (0.037) and LEC (0.025). Older age was associated with increased ITM in LIC (p=0.046; r=0.295), LEC (p=0.05; r=0.412), RCC (p=0.034; r=0.317), and REC (p=0.009; r=0.382). The ITM for LCC, LIC, LEC, RCC, RIC, and REC was higher in postmenopausal women, with no significant difference (p=0.782, p=0.208, p=0.877, r=0.734, p=0.808, p=0.437, respectively).
Among the modifiable factors, active smoking was associated with a higher ITM at the REC level (p=0.047). However, weight was not associated with an increased ITM (LCC: p=0.092; LIC: p=0.985; LEC: p=0.952; RCC: p=0.744; RIC: p=0.210; REC: p=0.510). In our study, there was no significant association between DAS28 disease activity or inflammatory marks and ITM (LCC: p=0.784; LIC: p=0.316; LEC: p=0.420; RCC: p=0.784; RIC: p=0.484; REC: p=0.754).
Conclusion: In our study, the non-modifiable factors associated with increased ITM were advanced age and male gender. The modifiable factor impacting ITM was primarily active smoking. Surprisingly, disease activity and biological inflammation did not influence ITM.

AB0192 EVALUATION OF TEMPOROMANDIBULAR JOINT INVOLVEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Brahem[1], A. Ben Salem[1], H. Hachfi[1], R. Sarraj[1], S. Abedallatif[1], R. Tekaya[1], C. Baccouche[2], Y. Mohamed[1]. [1]*Tahar Sfar Hospital, Rheumatology, Mahdia, Tunisia*; [2]*Tahar Sfar Hospital, Dentistry, Mahdia, Tunisia*

Background: Rheumatoid Arthritis (RA) is the most common chronic inflammatory disease usually involves peripheral joints with a symmetric distribution. The temporomandibular joint (TMJ) is seldom joint to be affected first in the disease course.
Objectives: The Aim of our study is to describe and to assess the prevalence of temporomandibular joint (TMJ)disorders in patients with Rheumatoid arthritis (RA).
Methods: A cross sectional study including RA patients, which consulted or were hospitalized in Rheumatology department in Taher Sfar Hospital of Mahdia Tunisia, during a period of 10 months. The diagnosis of the RA was secured by the ACR/EULAR 2010, Rheumatoid Arthritis Classification Criteria. The clinical TMJ examination was performed by a trained dentist in the same hospital. We assessed TMJ pain with VAS (visual analog scale) which varies from 0 to 10. The following key parameters were evaluated: The pain on the TMJs by bilateral palpation; The TMJ sounds (clicking or crepitus) during opening closing of the mandible; dysfunction and movement alterations. Clinical and sociodemographic parameters were also determined.
Results: Our study included 51 patients with an average age of 51.11 years ±12.4 [21-74years]. 50patients (92.6%of cases) were women and 8 patients (14.8%) were diabetic. Only one patient was a smoker. The mean duration of RA was 10.7 years 7.7± [10months-35years]. Rheumatoid factor (RF) was positive in 25 Patients (46.3%of cases). Anti-citrullinated peptide antibody (ACPA) was positive in 32 patients (59.3 %).41patients (75.4%) had radiological impairments and 28 (51.9%) had specific deformations of RA. The average disease activity score (DAS28-VS) and (DAS28-CRP) were respectively 4.1±1.5 [1.4-7.3] and 3.4±1.5 [1.24-6.71]. TMJ pain was present in 29 patients (56.9 %) which67.7% appeared before ten years. 5 patients (16.7%) had VAS more than 7 that mean a severe pain. TMJ involvement was bilateral in 64.3% and unilateral in 35.7 %. Functional difficulties were detected in 22 patients (44.9 %). TMJ examination had also revealed a limitation of mouth opening in 11 patients (21.2 %), a movement alteration in 13 patients (27.79 %), a clicking in joint mobility in 13 patients (81.3 %) and joint crepitus in 1 patient (6.3%). Disease duration was associated with TMJ pain(p=0.05) and mobility alterations (p=0.04). Functional difficulties of the TMJ were correlated with DAS28 (p=0.02). In our study we found also that duration of corticosteroid therapy had in impact on TMJ pain (p=0.01), functional difficulties (p=0.01) and movements alterations (p=0.004).
Conclusion: TMJ is very rare to be affected in the early phase of the disease, thus patient may develop signs and symptoms in the course of time. Our study showed the frequency of TMJ disorders and the most important factors were the activity of RA and the duration of the disease course.

AB0193 PRESENCE OF SUBLINICAL SYNOVITIS IN A ESTABLISHED RHEUMATOID ARTHRITIS COHORT

E. Rojas[1], V. Valinotti[1], M. Vazquez[1], L. Roman[1], M. Maidana[2], J. Ramirez[3], S. Cabrera-Villalba[1]. [1]*Clinicas Hospital, Universidad Nacional de Asuncion, Rheumatology, Asunción, Paraguay*; [2]*Maria Auxiliadora Center of Sonographic Studies, Ultrasonography, Asunción, Paraguay*; [3]*Hospital Clínic Barcelona, Rheumatology, Barcelona, Spain*

Background: Some studies prove that a significant percentage of patients with rheumatoid arthritis (RA) in sustained clinical remission has radiological progression or joint damage, and the presence of residual activity objectified by imaging studies such as ultrasonography could be related to a relapse or flare of RA.(1,2)
Objectives: To determine the presence of subclinical synovitis measured by ultrasonography in patients with RA on sustained clinical remission from the Rheumatology service at Hospital de Clínicas, San Lorenzo, Paraguay.
Materials and Methods: Prospective, cross sectional, descriptive study, in RA patients meeting ACR/EULAR 2010 criteria, older than 18 years, on sustained clinical remission (≥6 months), measured by ESR-DAS28 (<2,6), doing follow-ups on our service. A healthy control group was included. All groups signed informed consent. Synovial hypertrophy (SH) and intraarticular vascularization grades on Power Doppler (PD) mode were determined according to EULAR recommendations and OMERACT 7 group definitions. Clinical data were obtained from the service's registries.
SPSS 23rd version was used for data analysis. Quantitative variables were presented as means and qualitative as frequencies. Chi square test was performed for comparisons between dichotomous variables and t Student for continuous. For comparisons between variables the Spearman's rank correlation coefficient was performed, and p≤0.05 for statistical significance. Factors predicting subclinical synovitis were analyzed with Odds Ratio (OR) CI 95%.
Results: From 147 patients, 31 (21%) met remission criteria; 87.1% women, mean age 51.9±14.8 years. Mean disease duration was 9,06±10,81 years. 64,5% were RF and ACPA positive and 25,9% had erosions.
Ultrasonograms were made in 20 joints of both hands: radiocarpals (RC), metacarpophalangeals (MCP) and proximal interphalangeals (PIP). 12 patients (38.7%) presented subclinical synovitis (SH≥2+PD), more frequently on RC (29% right, 22.6% left), and MCP (9.7% on 2RMCP, 9.7% 4LMCP). These patients had greater CDAI (3.9±1.37 vs 2.89±1.15, p=0.03), HAQ (0.14±0.29 vs 0.00±0.00, p=0.04), CRP (9.90±7.46 vs 4.74±2.30, p=0.00) RF levels (502.67±275.66 vs 200.92±158.43, p=0,00), greater prednisone (16.5% vs 3.2%, p=0.04), and methotrexate use (20.16±5.54 vs 17.50±3.98, p=0.01). None of the healthy controls presented subclinical synovitis.
In binary logistic regression CRP levels, RF titers and methotrexate doses were associated to subclinical synovitis. This association is not found in multivariate logistic regression. Negative association was found between subclinical synovitis and two csDMARDs use.
Conclusion: This is the first study of its type in Paraguayan patients, which clearly evidenced that an important part of RA patients in clinical remission still presented subclinical synovitis (HS≥2 + PD). It was associated with CRP, RF and methotrexate dose.

AB0194 **ASSOCIATION OF MALNUTRITION WITH QUALITY OF LIFE IN ELDERLY RA PATIENTS**

W. Tański[1], J. Wójciga[2], N. Świątoniowska-Lonc[3], B. Jankowska-Polańska[3,4]. *[1]4th Military Teaching Hospital, Department of Internal Medicine, Wrocław, Poland*; *[2]Wroclaw Medical University, Student Research Club at the Division of Nursing in Internal, Wroclaw, Poland*; *[3]Wroclaw Medical University, Department of Clinical Nursing, Wroclaw, Poland*; *[4]4th Military Teaching Hospital, Research and Development Department, Wrocław, Poland*

Background: Rheumatoid arthritis (RA) is a progressive joint condition that leads to joints destruction and complications in the internal organs and significantly affects the a patient's functional ability. Elderly patients with RA complain of pain, mood and sleep disturbances, fatigue, and insomnia in addition to weakness, decreased appetite and weight loss. Chronic use of medications results in the risk of comorbidities and decreased physical functioning. All this together significantly contributes to a negative assessment of quality of life (QoL).
Objectives: Due to the chronic nature of RA and the high risk of malnutrition in this group of patients, an attempt was made to assess the QoL, activities of daily living and severity of frailty syndrome according to the results of the MNA questionnaire in a group of elderly patients with RA.
Methods: The study included 98 patients (age over 60 years) with a diagnosis of RA according to ARA. Standardized tools were used in the study: the WHO-QOL-BREF to assess quality of life, the Edmonton Frailty Scale to assess frailty syndrome, MNA to assess nutritional status and MMSE to assess cognitive function. Medical data were taken from the hospital records.
Results: Patients significantly differed in the extent of limitations in basic (ADL) and advanced activities of daily living (IADL) according to their nutritional status. The higher the level of malnutrition, the greater the limitations of undertaken activities. In addition, an adverse effect of reduced body weight on the occurrence of cognitive dysfunction was observed (33.33% of malnourished patients were diagnosed with dementia vs. 1.79% in normal weight patients). Similarly, frailty syndrome or vulnerability to frailty syndrome was associated with malnourished patients (33.3% mild, 16.67% moderate, and 16.67% severe frailty syndrome). Malnourished patients had significantly lower QoL scores in all domains of the WHOQOL-BREF questionnaire compared to normal weight patients and multivariate analysis of the effect of selected variables on QoL in the domains of the WHOQOL-BREF questionnaire showed that a significant independent determinant of lower QoL in all domains was the presence of frailty syndrome, respectively: Perception of QoL (R=-0. 069), Self-perception of health (R=-0.172), Physical domain (R=-0.425), Psychological domain (R=-0.432), Social domain (R=-0.415), Environmental domain (R=-0.317). Malnutrition was a significant independent determinant of QoL in the self-perception of health domain (R=-0.08). Additionally, in the regression analysis, a positive effect of male gender was observed on the assessment of QoL in the psychological (R=1.414) and environmental (R=1.123) domains.

Table 5. Comparative analysis of quality of life in terms of each domain of the WHOQOL-BREF questionnaire according to nutritional status.

	MNA			
WHOQOL BREF	Malnutrition (Mean±SD)	Risk of malnutrition (Mean±SD)	Normal nutrition (Mean±SD)	p
Perception of quality of life	3,33±1,03	3,33±0,68	3,68±0,58	0,029
Self-perception of health	2,67±0,82	2,47±0,84	3,14±0,98	0,004
Physical health	10,83±3,49	11,31±2,39	12,68±2,27	0,02
Psychological domain	12,5±3,89	13,28±2,73	14,45±2,24	0,056
Social domain	12,33± 2,86	12,67±2,93	14,29±2,61	0,007
Environmental domain	13,83±2,86	13,22±2,28	13,96±2,17	0,34

Conclusion: Malnourished people have a lower quality of life than people of normal weight. Malnutrition is a factor that negatively affects daily functioning, cognitive functioning, and the severity of frailty syndrome. A significant independent determinant of reduced quality of life across all domains of the WHOQOL-BREF questionnaire is frailty syndrome.

Rheumatoid arthritis - biological DMARDs

AB0195 **PHARMACOKINETIC AND PHARMACODYNAMIC EVALUATION OF A PROPOSED BIOSIMILAR MSB11456 VERSUS BOTH THE US-LICENSED AND EU-APPROVED TOCILIZUMAB: RESULTS OF A RANDOMIZED, DOUBLE-BLIND, PARALLEL-GROUP, SINGLE-DOSE TRIAL IN HEALTHY ADULTS**

C. Schwabe[1], C. Wynne[2], A. Illes[3], M. Ullmann[3], E. Vincent[3], V. Ghori[3], C. Petit-Frere[3], A. S. Racault[3], I. Morin[3]. *[1]Auckland Clinical Studies Ltd, Auckland, New Zealand*; *[2]Christchurch Clinical Studies Trust Ltd, Christchurch, New Zealand*; *[3]Biosimilars, Fresenius Kabi SwissBioSim, Eysins, Switzerland*

Background: Tocilizumab, a biologic disease-modifying antirheumatic drug, is a recombinant humanized monoclonal immunoglobulin G1 antibody against the interleukin-6 receptor (IL-6R). MSB11456 is a proposed biosimilar to the US-licensed tocilizumab and EU-approved tocilizumab. Prior to initiation of its clinical development program, MSB11456 was considered highly similar to the reference products based on extensive *in vitro* pharmacological testing and functional activity assays.
Objectives: This double-blind, parallel-group phase I study (NCT03282851) assessed the pharmacokinetic (PK) and pharmacodynamic (PD) equivalence of MSB11456 to US-licensed and EU-approved tocilizumab and provided data on the similarity of safety profiles and immunogenicity of MSB11456 and the reference products in healthy adult subjects.
Methods: Healthy adult volunteers were randomized to receive a single 162 mg subcutaneous injection of MSB11456, US-licensed tocilizumab, or EU-approved tocilizumab. Samples for PK/PD and immunogenicity analysis were taken predose, up to 29 days postdose, and at the end of study visit (day 48). Primary endpoint PK parameters were natural log transformed and analyzed using analysis of covariance (ANCOVA) methods; results were then transformed back to the original scale. Secondary PD analysis measured serum soluble IL-6R and serum C reactive protein (sCRP) parameters, and data were analyzed using a method similar to that for PK data. Safety data were collected throughout the study and analyzed descriptively.
Results: 685 subjects were randomized and treated. Results of the primary PK analysis demonstrated bioequivalence between MSB11456 and both US-licensed and EU-approved tocilizumab, as well as between the reference products, since all corresponding 90% confidence intervals (CIs) for the geometric least squares mean (LSM) ratios were within the predefined 80.00% to 125.00% equivalence margin (Table 1). PD analyses also demonstrated equivalence of MSB11456 and both US-licensed and EU-approved tocilizumab, as well as between the reference products. Safety, tolerability and immunogenicity were also comparable between treatments. The incidence of tocilizumab-specific neutralizing antibodies was low (<3% for all three products).
Conclusion: PK and PD equivalence of MSB11456, US-licensed tocilizumab, and EU-approved tocilizumab were demonstrated with comparable immunogenicity, safety, and tolerability for the three products. This study adds to the totality of evidence in support of MSB11456 as a proposed biosimilar to tocilizumab.

Table 1. Results of primary PK analysis

Parameter	Treatment	n	Ratio of geometric LSMs (%)	90% CI of ratio
MSB11456 vs US-licensed tocilizumab				
$AUC_{0-\infty}$	MSB11456	194	106.16	96.80, 116.43
	US-licensed tocilizumab	190		
AUC_{0-t}	MSB11456	230	104.15	93.58, 115.90
	US-licensed tocilizumab	226		
C_{max}	MSB11456	230	104.45	95.05, 114.77
	US-licensed tocilizumab	226		
MSB11456 vs EU-tocilizumab				
$AUC_{0-\infty}$	MSB11456	194	104.03	94.96, 113.96
	EU-approved tocilizumab	200		
AUC_{0-t}	MSB11456	230	94.78	85.15, 105.50
	EU-approved tocilizumab	224		
C_{max}	MSB11456	230	94.83	86.28, 104.22
	EU-approved tocilizumab	224		
US-licensed vs EU-approved tocilizumab				
$AUC_{0-\infty}$	US-licensed tocilizumab	190	97.99	89.40, 107.41
	EU-approved tocilizumab	200		
AUC_{0-t}	US-licensed tocilizumab	226	91.01	81.71, 101.36
	EU-approved tocilizumab	224		
C_{max}	US-licensed tocilizumab	226	90.79	82.57, 99.84
	EU-approved tocilizumab	224		

AUC, area under the serum concentration-time curve (μg·h/mL); $AUC_{0-\infty}$, AUC from time zero to infinity; AUC_{0-t}, AUC from time zero to the time of the last quantifiable concentration; C_{max}, maximum concentration (μg/mL)

AB0196 SURVIVAL ANALYSIS OF TIME TO FIRST ADVERSE DRUG REACTION AND DRUG SURVIVAL IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ADALIMUMAB AND ETANERCEPT

M. Nguyen[1], K. Velthuis[1], J. Scholl[1], J. Jansen[1], L. Kosse[1], P. Ten Klooster[2,3], N. Jessurun[1], H. Vonkeman[3,4]. *[1]Netherlands Pharmacovigilance Centre Lareb, Research Department, 's-Hertogenbosch, Netherlands*; *[2]Transparency in Healthcare B.V., Hengelo, Netherlands*; *[3]University of Twente, Department of Psychology, Health & Technology, Enschede, Netherlands*; *[4]Medisch Spectrum Twente, Department of Rheumatology and Clinical Immunology, Enschede, Netherlands*

Background: Treatment of rheumatoid arthritis (RA) with biologic disease-modifying antirheumatic drugs (bDMARDs) has been common practice in the last two decades. However, differences in patients experiencing adverse drug reactions (ADRs) between individual bDMARDs, such as adalimumab (ADA) and etanercept (ETN), during first time treatment has not been studied yet in real-world settings.
Objectives: To compare proportions of RA patients experiencing ADRs as well as survival to first ADR and drug survival during treatment with ADA and ETN.
Methods: Retrospective single centre cohort study including adult patients with RA, treated with either ADA or ETN between 1 January 2003 and 30 April 2020. The proportions of patients experiencing an ADR were compared by assessing the percentage of patients, treated with either ADA or ETN, experiencing at least one ADR during their first time treatment. Survival to first ADR and drug survival were assessed by calculating time between start of treatment and first ADR and start of treatment and discontinuation of treatment respectively. Stop and restart of treatment within 90 days was considered as continuous use. Differences in proportions were statistically tested using Fisher's Exact Test. Differences in drug survival between ADA and ETN were tested by Kaplan-Meier analysis and Log Rank tests.
Results: A total of 422 patients were included in this study (ADA 259, ETN 163). For 93 patients (21.2%) an ADR was registered during first time treatment. The proportion of patients experiencing at least one ADR during their first time treatment was 22.7% for ADA and 20.2% for ETN (p=0.628). Survival time to first ADR did not differ significantly between ADA and ETN (median survival ADA 10.34 years (95% CI [7.62-13.06], median survival ETN not reached, p=0.109, figure 1A). Median drug survival was 1.75 years for ADA (95 CI [1.38-2.11]) and 2.68 years for ETN (95% CI [1.73-3.64]). Drug survival differed significantly (p<0.001, figure 1B).

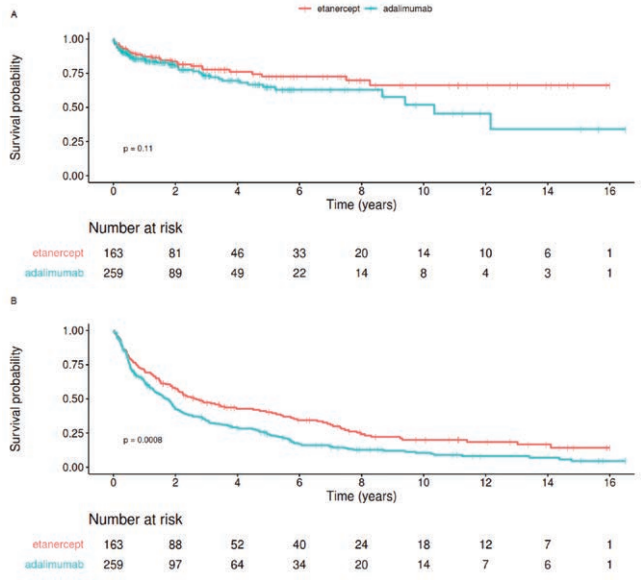

Figure 1. Kaplan-Meier survival curves for adalimumab and etanercept with (a) survival to first ADR and (b) drug survival.

Conclusion: Neither the proportion of patients experiencing ADRs nor survival to first ADR during first time treatment with ADA and ETN differed significantly. Drug survival of first time drug treatment of ADA was significantly lower compared to drug survival of first time drug treatment of ETN.

Background: Rituximab is an effective therapy for rheumatoid arthritis (RA) patients with inadequate responses to methotrexate (MTX)[1, 2]. However, it has not been registered or approved in China for the treatment of RA by far. HLX01, an approved rituximab biosimilar (demonstrated in Chinese patients with diffuse large B-cell lymphoma)[3], is thus evaluated in this study for the benefits of Chinese RA patients.
Objectives: This study aimed to evaluate the efficacy and safety of HLX01 plus MTX versus placebo plus MTX in Chinese patients with active RA who had inadequate responses to MTX.
Methods: This was a randomised, double-blind, placebo-controlled phase 3 study conducted in China (NCT03522415). Eligible patients were randomised 2:1 to receive intravenous infusion of 2×1000 mg HLX01 or placebo on day 1 and day 15. Patients with inadequate responses at week 16 and 20 were allowed to receive rescue treatments. Patients were retreated with or switched to receive (if initially assigned to placebo) 2×1000 mg rituximab at the first day of week 24 and 26. The primary endpoint of this study was the American College of Rheumatology criteria (ACR) 20 response at week 24. Secondary efficacy endpoints were evaluated at week 12, 24, 36 and 48. The safety, pharmacokinetics, pharmacodynamics and immunogenicity of HLX01 were observed and analyzed throughout the study.
Results: Between May 28, 2018 and Sep 11, 2020, a total of 275 patients (ITT set) were randomised and 263 patients without major protocol deviations were included in per-protocol set (PPS). At week 24, HLX01 showed statistically superior efficacy (p <0.001) to placebo (ACR20: 60.7% vs 35.9% in ITT set, 60.3% vs 37.1% in PPS). Secondary efficacy endpoints were also significantly improved in HLX01 group compared with placebo (Table 1). The overall incidence of serious treatment emergent adverse events (TEAEs), adverse drug reactions (ADRs), and TEAEs leading to drug discontinuation were similar among treatment groups, with the most common TEAE been upper respiratory tract infection before (18.1% vs 18.5%) or after (13.0% vs 12.3%) week 24. Serum concentrations, immunogenicity and pharmacodynamics were similar between HLX01 and placebo groups.

Table 1. Results of secondary efficacy endpoints at week 12, 24, 36 and 48 in ITT set.

	Secondary efficacy endpoints									
	ACR20 (%)		ACR50 (%)		ACR70 (%)		DAS28-CRP (mean)		HAQ-DI (mean)	
Duration	HLX01	Placebo	HLX01	Placebo	HLX01	Placebo	HLX01	Placebo	HLX01	Placebo
Baseline							5.49	5.43	1.40	1.45
Week 12	48.1	32.6	21.9	10.9	4.4	5.4	3.89	4.47	1.02	1.22
Week 24	60.7	35.9	36.6	18.5	15.3	12.0	3.39	4.37	0.87	1.22
Week 36	60.1	48.9	46.4	31.5	32.2	17.4	2.88	3.51	0.71	0.97
Week 48	73.8	62.0	55.2	40.2	39.9	27.2	2.82	3.51	0.72	1.03

Conclusion: Comparing with placebo plus MTX, HLX01 plus MTX showed significantly improved clinical outcomes and comparable safety profiles in Chinese patients with moderately to severely active RA who had inadequate responses to MTX, demonstrating HLX01 in combination with MTX as a well-tolerated, safe and efficient treatment option.

Background: Therapeutic equivalence of CT-P17 to reference adalimumab (ref-adalimumab) has been shown in patients with moderate-to-severe active rheumatoid arthritis (RA) through primary 24-week results [1]. Here, efficacy, pharmacokinetics (PK), safety and immunogenicity results up to 52-week, including transition data from ref-adalimumab to CT-P17 are presented.

Objectives: To evaluate efficacy, PK, safety and immunogenicity when switched from ref-adalimumab to CT-P17 compared to maintaining CT-P17 or ref-adalimumab.

Methods: In this study, 648 moderate-to-severe active RA patients despite methotrexate treatment were randomized (1:1) to either CT-P17 or ref-adalimumab and treated with doses of 40 mg every 2 weeks up to Week 24. Prior to dosing at Week 26, 608 patients were randomized again to either maintaining their treatments or being switched from ref-adalimumab to CT-P17. Efficacy, PK, safety, and immunogenicity were assessed up to Week 52.

Results: After the second randomization, 303 patients continued with CT-P17, 153 patients continued with ref-adalimumab and 151 patients switched from ref-adalimumab to CT-P17 treatments, up to Week 48. Demographics and baseline characteristics were similar among the 3 groups. Sustained and comparable efficacy in terms of ACR20/50/70 response rates was achieved not only in the maintenance groups (CT-P17 or ref-adalimumab) but also in the switched from ref-adalimumab to CT-P17 group up to Week 52 (Figure 1).

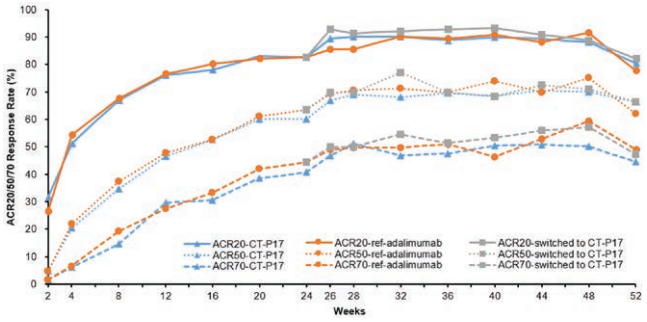

Figure 1. ACR 20/50/70 Response Rates up to 1 YearAbbreviation: ref-adalimumab, reference adalimumab.Note. There were patients who could not visit the study site due to COVID-19 pandemic and were counted as nonresponder for ACR response at Week 52.

In terms of PK, mean trough serum concentration (Ctrough) were maintained after Week 24 in all 3 groups. The observed mean Ctrough were within the reported therapeutic ranges of ref-adalimumab trough levels in RA patients (5-8 μg/mL).

The safety profile after transition was comparable among the 3 groups (Table 1). The most common treatment-emergent adverse events (TEAEs) was neutropenia. Similar proportions of patients in all 3 groups experienced at least 1 TEAE: injection site reactions, hypersensitivity/allergic reactions and infections. One malignancy (basal cell carcinoma; unrelated) was reported in the ref-adalimumab maintenance group. Safety data accumulated over 1 year also showed comparable results among the 3 groups. Anti-drug antibody (ADA) and neutralizing antibody (NAb) results were similar among the 3 groups. At Week 52, the proportions of patients who had ADA/NAbs were 28.4%/24.8% patients in CT-P17 maintenance, 27.0%/24.3% patients in ref-adalimumab maintenance and 28.3%/26.3% patients in switched to CT-P17 groups.

Conclusion: Single transition from ref-adalimumab to CT-P17 was efficacious and safe without increase in immunogenicity. Also, efficacy, PK, safety and immunogenicity profiles were comparable between CT-P17 and ref-adalimumab up to Week 52.

AB0199 PLACEBO AND NOCEBO RESPONSES IN RANDOMIZED CONTROLLED TRIALS OF NON-TUMOR NECROSIS FACTOR BIOLOGICS AND JANUS KINASE INHIBITORS IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS SHOWING INSUFFICIENT RESPONSE TO TUMOR NECROSIS FACTOR INHIBITORS: A META-ANALYSIS

Y. H. Lee[1], G. G. Song[2]. [1]*Korea University, Rheumatology, Seoul, Korea, Rep. of (South Korea)*; [2]*Korea University Guro Hospital, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Placebo and nocebo responses have important consequences for the development of pharmaceutical drugs and the design of randomized controlled trials (RCTs). They can lead to the incorrect measurement of treatment-related efficacy and adverse effects (AEs).

Objectives: The goal of this study was to evaluate the frequency and magnitude of placebo and nocebo responses in placebo-controlled RCTs of non-tumor necrosis factor (TNF) biologics and Janus kinase (JAK) inhibitors in patients with rheumatoid arthritis (RA) showing an insufficient response to TNF inhibitors.

Methods: We performed a meta-analysis on the rates of placebo response, AEs, severe AEs (SAEs), and withdrawal owing to AEs in placebo-controlled randomized clinical trials (RCTs) of non-TNF biologics and JAK inhibitors in patients with RA showing an insufficient response to TNF inhibitors.

Results: Nine RCTs contained a total of 3,442 patients (1,840 experimental subjects and 1,602 controls). The pooled incidence of an ACR20 response rate in placebo-treated patients was 22.1% (95% CI 16.4–29.1%) and 27.9% (95% CI 24.5–31.6%) in RCTs of non-TNF inhibitors and JAK inhibitors, respectively. A strong negative correlation was observed between drug efficacies (ACR20 response) and AE rates in the placebo arm, indicating that the greater the placebo response, the weaker the nocebo response (r = -0.762, P = 0.017). A strong positive correlation was observed between drug efficacies (ACR20 response) in the placebo and active comparator, indicating that the greater the placebo response, the greater the treatment response (r = 0.737, P = 0.003). The pooled estimate in placebo-treated patients with at least one AE was 71.8% (95% CI 57.4–82.7%) and 58.7% (95% CI 52.8–64.3%) in RCTs of non-TNF inhibitors and JAK inhibitors, respectively. The pooled estimate in placebo-treated patients who withdrew from treatment owing to an AE was 3.8% (95% CI 2.7–5.3%) and 4.0% (95% CI 2.7–6.0%) in RCTs of non-TNF inhibitors and JAK inhibitors, respectively. A strong positive correlation was observed between AE rates in the placebo and active arms, indicating that the greater the nocebo response, the stronger the AE rate in the active arm (r = 0.855, P = 0.003).

Conclusion: The frequency of the placebo and nocebo responses was 22.1% vs. 27.9% and 71.8% vs. 58.7% in placebo-controlled RCTs of non-TNF inhibitors and JAK inhibitors for RA, respectively, and the greater the placebo response, the weaker the nocebo response and the greater the efficacy.

Sarı[4], E. C. Bolek[1], B. Farisoğulları[1], G. K. Yardımcı[1], Z. Özsoy[1], G. Ayan[1], M. Çalgüneri[1], S. Kiraz[1]. [1]*Hacettepe University, Internal Medicine, Rheumatology, Ankara, Turkey*; [2]*Ankara City Hospital, Internal Medicine, Rheumatology, Ankara, Turkey*; [3]*Medical Park Hospital, Internal Medicine, Rheumatology, Gaziantep, Turkey*; [4]*Yenimahalle Education and Research Hospital, Internal Medicine, Rheumatology, Ankara, Turkey*

Background: In the last 20 years, there have been extraordinary improvements and practice-changing developments in the management of rheumatoid arthritis (RA). Exploring the pathogenetic mechanisms first enabled clinicians to use anti-tumor necrosis factor (TNF) alpha agents, then drugs targeting different molecules. Parallel to these developments, treatment guidelines have been changed accordingly. Meanwhile, how these developments have been reflected into the real-word practice is a question of interest.

Objectives: In this study, we aimed to explore the first biologic agent trends of our 20-years of single-center experience.

Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a single center biological disease modifying anti-rheumatic drug (DMARD) registry since 2005. Patients who were started biologics before 2005 were registered retrospectively. In brief; demographic data, treatment-related data (including adverse events) and disease-related data of RA patients have been recorded in HUR-BIO. Until the end of the 2020, 21 different rheumatologists contributed to the development of HUR-BIO. In this study, distribution of the first-line biologic agents was calculated according to 5-year periods starting from the 2001. Also, demographic and serologic data of RA patients were reported.

Results: A total of 2080 RA patients was registered in HUR-BIO by the end of 2020. Of these patients, 79.5% was female. Mean age at the starting of bDMARD was 53.3 ± 17.8 years. Rate of rheumatoid factor and anti-cyclic citrullinated peptide positivity was 67.6% and 61.0%, respectively. 65 (3.2%), 335 (16.1%), 858 (41.2%) and 822 (39.5%) patients were prescribed with their first bDMARD in 2001-2005, 2006-2010, 2011-2015 and 2016-2020, respectively. There was a trend towards the increasing prescription of non-Anti-TNF bDMARDs over time.

Table 1. Distribution of first biologic DMARDs in RA patients according to 5-years periods

	2001-2005	2006-2010	2011-2015	2016-2020	Total
Adalimumab	15 (23.1)	111 (33.0)	187 (21.8)	153 (18.6)	466 (22.4)
Etanercept	30 (46.2)	154 (45.8)	229 (26.7)	54 (6.6)	467 (22.4)
İnfliximab	20 (30.8)	58 (17.3)	64 (7.5)	7 (0.9)	149 (7.1)
Golimumab	0	0	37 (4.3)	43 (5.2)	80 (3.8)
Certolizumab	0	0	37 (4.3)	68 (8.3)	105 (5.0)
Anti-TNF	65 (100)	323 (96.4)	554 (64.5)	325 (39.5)	1267 (60.9)
Tofacitinib	0	0	6 (0.7)	212 (25.8)	218 (10.5)
Tocilizumab	0	0	9 (1.0)	102 (12.4)	111 (5.3)
Rituximab	0	12 (3.6)	136 (15.8)	84 (10.2)	232 (11.1)
Abatacept	0	0	153 (17.8)	99 (12.0)	252 (12.1)
Non-Anti-TNF	0	12 (3.6)	304 (35.5)	497 (60.5)	813 (39.1)
Total	65 (100)	335 (100)	858 (100)	822 (100)	2080 (100)

***Approval years of drugs in Turkey**; Infliximab: 2003, etanercept:2004, adalimumab: 2005, golimumab: 2013, certolizumab: 2014, abatacept: 2010, tocilizumab: 2013, rituximab:2009, tofacitinib: 2015,*

Conclusion: Real-life practice in RA seems consistent with treatment guidelines. Use of non-Anti-TNF bDMARDs becoming more frequent year-by-year. Jak kinase inhibitor has rised through the last 5 years. Next decade may be the years of Jak kinases inhibitors.

AB0201 CHANGES IN THE PRESCRIPTION PATTERNS OF THE SECOND-LINE BIOLOGIC AND TARGETED SYNTHETIC DMARD IN RHEUMATOID ARTHRITIS PATIENTS: 20-YEARS JOURNEY OF HUR-BIO REAL-LIFE REGISTRY

S. Kiraz[1], U. Kalyoncu[1], O. Karadag[1], L. Kılıç[1], A. Akdoğan[1], I. Dogan[1], Ş. A. Bilgen[1], E. Bilgin[1], E. C. Bolek[1], B. Kıcasık[2], Y. Maraş[3], A. Erden[3], B. Armagan[3], A. Sarı[4], E. Duran[1], B. Farisoğulları[1], G. K. Yardımcı[1], Z. Özsoy[1],

G. Ayan[1], M. Çalgüneri[1], A. İ. Ertenli[1]. [1]*Hacettepe University, Internal Medicine, Rheumatology, Ankara, Turkey*; [2]*Medical Park Hospital, Internal Medicine, Rheumatology, Gaziantep, Turkey*; [3]*Ankara City Hospital, Internal Medicine, Rheumatology, Ankara, Turkey*; [4]*Yenimahalle Education and Research Hospital, Internal Medicine, Rheumatology, Ankara, Turkey*

Background: In the last 20 years, anti-tumor necrosis factor (TNF) alpha agents re-designed the management of rheumatoid arthritis (RA). Despite this, unmet needs in the management of RA brought several drugs targeting different molecules and cytokines. It is still a research question that how did these developments changed daily-practice in RA patients who are intolerant/unresponsive to the first biological disease modifying anti-rheumatic drugs (bDMARD).
Objectives: In this study, we aimed to explore the second biologic agent trends of our 20-years of single-center experience.
Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a single center biological disease modifying anti-rheumatic drug (DMARD) registry since 2005. Patients who were started biologics before 2005 were registered retrospectively. Until the end of the 2020, 21 different rheumatologists contributed to the development of HUR-BIO. Distribution of the second-line biological agents (switch from first-line biological agent because of either adverse events or unresponsiveness) was calculated according to 5-year periods starting from the 2001. Also, demographic and serologic data of RA patients were reported.
Results: A total of 776 (776/2080, 37.3%) RA patients, who was prescribed a second biological agent, was registered in HUR-BIO by the end of 2020. Of these patients, 83.7% was female. Mean age at the starting of bDMARD was 53.1 ± 13.3 years. Rate of rheumatoid factor and anti-cyclic citrullinated peptid positivity was 69.1% and 60.5%, respectively. Distribution of first-line bDMARDs was as follows: adalimumab 194 (24.9%), etanercept 209 (26.9%), infliximab 105 (13.5%), golimumab 39 (5.0%), certolizumab 35 (4.5%), abatacept 78 (10.0%), rituximab 46 (5.9%), tofacitinib 37 (4.7%), tocilizumab 33 (4.2%). 11 (1.4%), 85 (11.0%), 282 (36.3%) and 398 (51.3%) patients were prescribed with their second bDMARD in 2001-2005, 2006-2010, 2011-2015 and 2016-2020, respectively. There was a trend towards the increasing prescription of non-Anti-TNF bDMARDs as second-line over time.

Table 1. Distribution of second biologic DMARDs in RA patients according to 5-years periods

	2001-2005	2006-2010	2011-2015	2016-2020	Total
Adalimumab	3 (27.3)	15 (17.6)	69 (23.9)	77 (18.9)	164 (20.8)
Etanercept	8 (72.7)	35 (41.2)	49 (17.0)	41 (10.1)	133 (16.8)
İnfliximab	0	12 (14.1)	13 (4.5)	25 (6.2)	50 (5.4)
Golimumab	0	0	19 (6.6)	8 (2.0)	27 (3.4)
Certolizumab	0	0	2 (0.7)	26 (6.4)	28 (3.5)
Anti-TNF	11 (100)	62 (72.9)	152 (53.9)	177 (44.5)	402 (51.8)
Tofacitinib	0	0	4 (1.4)	73 (17.9)	77 (9.7)
Tocilizumab	0	0	12 (4.2)	81(19.9)	93 (11.7)
Rituximab	0	22 (25.9)	53 (18.3)	32 (7.8)	107 (13.5)
Abatacept	0	1 (1.2)	61 (21.1)	35 (8.6)	97 (12.2)
Non-Anti-TNF	0	23 (27.1)	130 (46.1)	221 (55.5)	374 (48.2)
Total	11 (100)	85 (100)	282 (100)	398 (100)	776 (100)

***Approval years of drugs in Turkey**; Infliximab: 2003, etanercept:2004, adalimumab: 2005, golimumab: 2013, certolizumab: 2014, abatacept: 2010, tocilizumab: 2013, rituximab:2009, tofacitinib: 2015*

Conclusion: As the choice of second-line biologic and targeted synthetic DMARD, non-Anti-TNF bDMARDs, especially tofacitinib and tocilizumab becoming more frequent year-by-year. Despite that, anti-TNF agents as a group are still highly-prescribed options as second-line bDMARD.

AB0202

IMPROVEMENT IN CLINICAL DISEASE ACTIVITY AND PATIENT-REPORTED OUTCOMES AFTER 6 MONTHS OF TREATMENT WITH ABATACEPT, STRATIFIED BY LINE OF THERAPY, IN PATIENTS WITH RA: RESULTS FROM A LARGE, US, NATIONAL OBSERVATIONAL STUDY

L. Harrold[1], K. Wittstock[2], S. Kelly[2], S. H. Park[3], X. Han[3], Y. Shan[1], C. Roberts-Toler[1], N. Middaugh[1], V. Khaychuk[4]on behalf of Corrona. [1]*Corrona, LLC, Epidemiology & Biostatistics Department, Waltham, United States of America*; [2]*Bristol Myers Squibb, Immunology US Medical, Princeton, United States of America*; [3]*Bristol Myers Squibb, WW HEOR US Market, Princeton, United States of America*; [4]*Bristol Myers Squibb, US Medical Immunology and Fibrosis, Princeton, United States of America*

Background: RA is more responsive to treatment in the early stages of disease, and early treatment may lead to better long-term outcomes.[1,2] Data on the effectiveness of specific drugs as first or later lines of therapy will help inform treatment sequencing.
Objectives: Data from patients enrolled in the Corrona RA Registry were used to compare the effectiveness of abatacept across lines of therapy overall (primary cohort) and in a subset of patients who were anti-citrullinated protein antibody positive (ACPA+).
Methods: Patients with RA who initiated abatacept (January 2006 to October 2020), had 6 months' follow-up (within 4–9 months of starting abatacept), had baseline (BL) and follow-up CDAI scores available, and had BL CDAI >2.8 were included. Outcomes were compared for first-, second- and third or higher-line therapy: 0, 1 or ≥2 prior biologic DMARDs or Janus kinase inhibitors, respectively. Continuous outcomes included change from BL to 6 months in mean CDAI and patient-reported pain, fatigue, and HAQ. Binary outcomes included rate of achieving minimal clinically important difference (MCID) in CDAI or modified ACR20/50/70 at 6 months. Continuous and binary outcomes were analysed using multiple linear and logistic regression, respectively. The models included line of therapy, age, sex, disease duration, work status, SC nodules, history of hypertension and depression, BL CDAI, BL patient-reported pain and BL fatigue. Additional subgroup analyses were carried out in patients with moderate/high disease activity (CDAI >10) at BL.
Results: In total, 2876 patients (2327 with BL CDAI >10; 890 ACPA+) were included; 442, 911, and 1523 patients initiated first-, second- or third/higher-line abatacept, respectively. Compared with patients on second/third/higher-line abatacept therapy, those on first-line abatacept were significantly older, had shorter disease duration, and had lower BL CDAI, pain and fatigue (all p<0.001). In adjusted analyses, patients receiving abatacept as earlier lines of therapy had significantly greater improvement from BL in mean CDAI and in patient-reported fatigue and HAQ (Table 1). There was no significant difference between lines of therapy in change in patient-reported pain. Patients receiving first-line abatacept had significantly higher odds of achieving a MCID in CDAI or modified ACR20/50/70 response (Figure 1). Similar patterns were seen when the sample was limited to patients with moderate/high disease activity or in patients who were ACPA+.
Conclusion: There were significant differences in improvement in clinical disease activity and patient-reported outcomes across lines of therapy. Better treatment responses were observed with earlier lines of abatacept therapy in the overall population, in patients who were ACPA+ and in those with moderate/high BL disease activity.

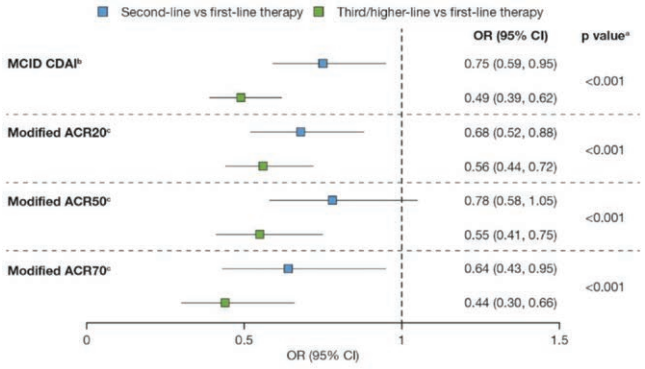
Table 1. Adjusted mean change in CDAI and patient-reported outcomes from BL to 6 months after initiation of abatacept by line of therapy (primary cohort)

Adjusted outcome, mean change (SE)	First-line (n=440)	Second-line (n=898)	Third/higher-line (n=1515)	p value[a]
CDAI	–7.96 (0.33)	–7.49 (0.27)	–5.74 (0.19)	<0.001
Patient-reported pain (VAS 0–100)	–9.43 (0.69)	–7.98 (0.47)	–7.70 (0.35)	0.074
Patient-reported fatigue (VAS 0–100)	–7.49 (0.71)	–5.87 (0.51)	–4.81 (0.36)	0.002
Patient-reported HAQ	–0.16 (0.01)	–0.12 (0.01)	–0.08 (0.01)	<0.001

[a]Estimated by multiple linear regression model adjusted for age, sex, disease duration, work status, SC nodules, history of hypertension and depression, BL CDAI, BL patient-reported pain and BL fatigue (factors that were identified *a priori* based on clinical experience or that differed significantly by line of therapy); p values reflect ANOVA overall test of differences across lines of therapy.VAS=visual analogue scale.

Figure 1. Adjusted odds ratio of achieving MCID CDAI or modified ACR20/50/70 at 6 months after initiation of abatacept by line of therapy (primary cohort)



[a]Estimated by multiple logistic regression analysis adjusted for age, sex, disease duration, work status, SC nodules, history of hypertension and depression, BL CDAI, BL patient-reported pain and BL fatigue (factors that were selected a priori based on clinical experience or differed significantly by line of therapy); p values reflect overall difference across lines of therapy.
[b]Reduction in CDAI score of 2 if BL disease activity was low (CDAI score ≤10); of 6 if BL disease activity was moderate (CDAI score >10 and ≤22); and of 11 if BL disease activity was high (CDAI score >22).
[c]Modified ACR criteria is based on 2 out of 4 measures (not using ESR or CRP).
Modified ACR20/50/70=20/50/70% improvement in modified ACR criteria; MCID=minimal clinically important difference; OR=odds ratio.

AB0203 EFFECT OF DOSE ESCALATION OF SUBCUTANEOUS TOCILIZUMAB ON DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS IN A RANDOMIZED CONTROLLED TRIAL

N. Singer[1], S. Mohan[2], J. Han[3], M. Edwardes[4], M. Michalska[2]. [1]*Case Western Reserve University and The MetroHealth System, Rheumatology, Cleveland, United States of America*; [2]*Genentech, Inc., Immunology, South San Francisco, United States of America*; [3]*Genentech, Inc., Biometrics, South San Francisco, United States of America*; [4]*Everest Clinical Research, Statistical Sciences, Markham, Canada*

Background: In patients with RA, subcutaneous tocilizumab (TCZ-SC) is administered every 2 weeks (q2w) or every week (qw), based on the patient's weight and clinical response.

Objectives: To compare the effects on disease activity at week 24, when the dosing schedule of TCZ-SC was escalated from q2w to qw, in patients who did not achieve LDA (DAS28-ESR > 3.2) at week 12 in COMP-ACT with patients who, despite not achieving LDA, continued TCZ-SC qw in SUMMACTA and q2w in BREVACTA.

Methods: US patients in COMP-ACT who weighed < 100 kg at baseline and who received TCZ-SC 162 mg q2w + methotrexate escalated to qw if they did not achieve LDA at week 12. DAS28-ESR remission (< 2.6) and LDA (≤ 3.2), CDAI remission (≤ 2.8) and LDA (≤ 10) and SDAI remission (≤ 3.3) and LDA (≤ 11) at week 24 were compared between patients who switched from q2w to qw and North American patients in SUMMACTA who initiated TCZ qw + csDMARDs and continued a qw dose (baseline body weight < 100 kg and DAS28 > 3.2 at week 12). A secondary analysis compared COMP-ACT patients who escalated from q2w to qw with all SUMMACTA patients who continued a qw dose and all BREVACTA patients who initiated a TCZ-SC q2w dose + csDMARDs and continued a q2w dose (baseline body weight < 100 kg and DAS28 > 3.2 at week 12). DAS28 was standardized to DAS28-ESR, and comparisons were calculated using a mixed model with repeated-measures logistic regression, including the following covariates: CDAI, SDAI and/or DAS28 at the reference visit (week 12), as well as study baseline values of CDAI, SDAI and/or DAS28, baseline age, sex, TNFi use prior to the study (yes or no) and weight category.

Results: A total of 328 US patients in COMP-ACT did not achieve LDA at week 12 and escalated from q2w to qw TCZ-SC. In SUMMACTA, 285 patients did not achieve LDA at week 12 and continued TCZ-SC qw, of whom 71 were from North America. Baseline demographic and clinical characteristics were comparable between patients in COMP-ACT and North American patients in SUMMACTA. A significantly higher proportion of patients in COMP-ACT achieved DAS28-ESR, CDAI and SDAI remission and LDA 12 weeks after TCZ dose escalation (week 24) than North American SUMMACTA patients (Table 1). Similar results were seen when the proportion of patients who achieved DAS28 remission and LDA was compared at week 24 between patients in COMP-ACT and patients from all geographic regions who did not escalate dosing in SUMMACTA and BREVACTA (N=196).

Conclusion: US patients with RA who did not achieve LDA and escalated from q2w to qw TCZ-SC at week 12 in COMP-ACT had better disease activity outcomes at week 24 than North American patients who did not achieve LDA and continued qw dosing in SUMMACTA. These results provide some evidence that escalation from q2w to qw has more effect than expected without dose change for patients who do not achieve LDA by week 12.

Table 1. Comparison at Week 24 of Clinical Response After Week 12 Dose Escalation or Continuation Between Patients Who Did Not Achieve LDA at Week 12

Background: SB5, a biosimilar to reference adalimumab (ADL), received EU marketing authorisation in August 2017, based on the totality of evidence from pre-clinical and clinical Phase I and III studies that demonstrated bioequivalence, similar efficacy, and comparable safety and immunogenicity to the reference. This real-world study provides data on outcomes of the transition from reference to biosimilar ADL outside the controlled, randomised, clinical trial setting.

Objectives: To evaluate candidate predictors of persistence on SB5 in EU patients (pts) across multiple indications.

Methods: This ongoing observational study enrolled 1000 pts with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), psoriatic arthritis (PsA), ulcerative colitis, or Crohn's disease who initiated SB5 as part of routine clinical practice following a minimum of 16 weeks' treatment with reference ADL, at clinics in Belgium, Germany, Ireland, Italy, Spain, and the UK. Data are captured from clinic records retrospectively for the 24 weeks prior to transition, and prospectively and/or retrospectively for 48 weeks following transition. Primary outcome measures include baseline clinical characteristics, disease activity scores and clinical management over time; data on COVID-19 infection has recently been captured. This interim analysis (IA) provides an overview of baseline characteristics, disease scores and dose regimen up to 48 weeks post-initiation of SB5, and COVID-19 infection reported to date, in subjects with RA, axSpA, or PsA enrolled at 35 specialist sites and followed up to the data extract date of 18th December 2020.

Results: Of the 504 pts included in this IA, 201 have RA, 169 have PsA, and 134 axSpA. At time of data extract, 216 pts had completed 48 weeks on SB5, 73 pts had discontinued SB5, and 8 had discontinued the study.

Conclusion: This IA provides a first insight into clinical management of pts over 48 weeks, in a contemporary cohort of EU pts with established RA, axSpA and PsA, switched from reference to biosimilar ADL SB5 in clinical practice. The majority of pts showed no meaningful difference in disease score or dose regimen of SB5 by Week 48 post-transition. As of data extract date, the proportion of pts with a known positive COVID-19 test was low (1.3%) and a small minority (1.3%) had SB5 treatment changed or interrupted as a result of the COVID-19 pandemic. With follow-up of pts ongoing to Q4 2021, the study will continue to provide pertinent information about clinical outcomes of transition from reference to biosimilar ADL in real-world practice and in indications not investigated in controlled studies.

A NOVEL METHOD FOR PREDICTING 1-YEAR RETENTION OF ABATACEPT USING MACHINE LEARNING TECHNIQUES: DIRECTIONALITY AND IMPORTANCE OF PREDICTORS

R. Alten[1], C. Behar[2], C. Boileau[3], P. Merckaert[4], E. Afari[5], V. Vannier-Moreau[6], S. Connolly[7], A. Najm[8], P. A. Juge[9], A. Rai[10], Y. Elbez[11], K. Lozenski[12].

Background: In the ACTION (NCT02109666) study, multivariable Cox proportional hazards regression models showed that the predictors of 1-year retention to abatacept treatment were: patient global pain assessment, country, reason for stopping last biologic, number of prior biologic treatments, abatacept monotherapy, RF/anti-cyclic citrullinated peptide (CCP) status, previous neoplasms, psychiatric disorders and cardiac disorders.[1] Machine learning techniques, using the gradient-boosting model, subsequently identified additional predictors of abatacept retention in patients with moderate-to-severe RA enrolled in ACTION; however, the analysis did not show the directionality of the predictors.[2]

Objectives: To improve the clinical interpretability of the machine learning model in terms of directionality and the importance of each variable in predicting retention.

Methods: Previous analyses using the gradient-boosting model to identify predictors of abatacept retention at 1 year in the ACTION study have been described.[2] This analysis used SHapley Additive exPlanations (SHAP), a mathematical framework, to show how a particular predictor value influences prediction in the context of all other predictors. Higher SHAP values indicate a higher likelihood of retention. The contribution of every variable in the model's prediction (with the exception of country variables) was computed for each data point to capture individual variable impact. This enabled interpretation for level of importance and directionality at a patient level.

Results: Using data from 2350 patients enrolled in ACTION (May 2008 to December 2013), the mean retention rate at 1 year was 59.3% (n=1393). Overall variable importance is shown in Figure 1. After removal of country variables, the top five baseline predictors of retention were: no previous corticosteroid use, ACR functional class II, ≥2 prior biologic treatments prior to abatacept initiation, abatacept monotherapy and HAQ-DI. In terms of directionality, no previous corticosteroid use, ≥2 prior biologic treatments prior to abatacept initiation, abatacept monotherapy and a higher HAQ-DI score at baseline were associated with a lower likelihood of retention; ACR functional class II was associated with a higher likelihood of retention.

Conclusion: The gradient-boosting model previously identified predictors of abatacept retention from ACTION;[2] the addition of SHAP in this analysis has provided information on the importance and directionality of those predictors. The most important predictor of abatacept retention was no previous corticosteroid use, which was associated with lower retention. The models and predictors identified could be further refined by using additional datasets from clinical trials. Machine learning offers an innovative and complementary approach to biostatistics and could be used to identify treatment response predictors at an individual patient level, leading to a more personalised treatment approach.

AB0206 DESCRIPTION AND FOLLOW-UP OF RHEUMATOID ARTHRITIS PATIENTS WHO STOPPED B/TSDMARD THERAPY, STRATIFIED BY CESSATION REASON

T. Burkard[1], E. Vallejo-Yagüe[1], T. Hügle[2], A. Finckh[3], A. M. Burden[1,4]. [1]*ETH Zurich, Department of Chemistry and Applied Biosciences, Zurich, Switzerland*; [2]*Lausanne University Hospital, Department of Rheumatology, Lausanne, Switzerland*; [3]*University Hospitals Geneva, Division of Rheumatology, Geneva, Switzerland*; [4]*Maastricht University Medical Center+, Department of Clinical Pharmacy and Toxicology, Maastricht, Netherlands*

Background: Biologic or targeted synthetic disease modifying antirheumatic drugs (b/tsDMARD) may be stopped for several reasons such as non-response, adverse events, remission, or other reasons (e.g. major surgery). Understanding the reasons and consequences of b/tsDMARD therapy cessation may contribute towards therapy decision guidance. Moreover, identifying patient characteristics leading to the re-start of b/tsDMARD therapy may guide decision-making as to which patients should remain on continuous b/tsDMARD therapy versus who may potentially stop b/tsDMARD therapy.

Objectives: To describe and follow rheumatoid arthritis (RA) patients who stopped b/tsDMARD therapy, stratified by cessation reason.

Methods: We conducted a descriptive cohort study among adult RA patients in the longitudinal Swiss Clinical Quality Management in Rheumatic Diseases (SCQM) between 1997 and 2019. RA patients who stopped their first b/tsDMARD therapy were eligible, with therapy stop date defining cohort entry. We followed all eligible patients from cohort entry until b/tsDMARD re-start (the outcome) or censoring due to end of patient record. All analyses were carried out stratified by cessation reason (non-response, adverse events, remission, other reasons, unknown reasons). We described patient characteristics (demographics, lifestyle factors, clinical information, other medication use, relevant comorbidities) at cohort entry. Furthermore, we estimated Kaplan Meier curves to describe differences in cumulative incidences of b/tsDMARD re-start. Finally, we assessed patient characteristics at b/tsDMARD re-start and compared them with those at cohort entry.

Results: Among 2559 eligible RA patients, the majority stopped their b/tsDMARD due to non-response (982, 38%), followed by adverse events (475, 19%), other reasons (445, 17%), unknown reasons (444, 17%), and remission (213, 8%). Mean age at b/tsDMARD stop was around 56.2 years except in patients who stopped due to remission (mean age of 58.1 years). The majority of patients were women (78%), stopping due to an adverse event had the highest proportion of women (84%), stopping due to remission had the lowest proportion of women (70%). Compared to patients who stopped b/tsDMARD therapy due to non-response or adverse events, patients who stopped due to remission were generally more physically active, better educated, less likely to have a family history of rheumatic diseases, and had shorter median disease duration. A total of 2086 patients (82%) re-started b/tsDMARD therapy during follow-up. Of these, the majority did so after stopping due to non-response (94%), followed by adverse events (82%), unknown reasons (79%), other reasons (74%), and remission (47%). The median cumulative incidence of re-starting b/tsDMARD therapy was shortest after non-response (30 days), followed by unknown reasons (31 days), adverse events (94 days), other reasons (212 days), and remission (1597 days). The population who stopped b/tsDMARD therapy due to remission or other reasons yielded increased RA disease activity and an increase in proportions of women, cardiac diseases, degenerative joint disease, other auto-immune diseases, and of patients with family history of rheumatic diseases at the date of b/tsDMARD re-start. However, among patients who stopped b/tsDMARD therapy due to non-response or adverse events, patient characteristics at b/tsDMARD re-start were unchanged compared to those at b/tsDMARD stop.

Conclusion: Observed differences in patient characteristics at b/tsDMARD stop may yield insight into why the patient was not responding, had an adverse event, or achieved remission. Observed changes in patient characteristics from the date of b/tsDMARD stop to re-start identified which ones may lead to a worsening of RA activity in the absence of b/tsDMARD therapy.

Background: Longer disease duration and greater number of prior DMARDs have been associated with lower treatment efficacy in patients with RA.[1] Abatacept is a biologic (b)DMARD for treatment of moderate-to-severe RA and is available in SC formulation, which may offer convenience benefits with efficacy similar to IV administration.[2] ASCORE (Abatacept SubCutaneOus in Routine Clinical PracticE; NCT02090556) was a 2-year, observational, prospective, multicentre study of SC abatacept for treatment of RA in routine clinical practice.[3]

Objectives: This *post hoc* analysis was conducted to determine if retention and efficacy of abatacept were impacted by disease duration and/or treatment line.

Methods: Eligible patients, aged ≥18 years, with active moderate-to-severe RA (ACR/EULAR 2010 criteria) who were IV abatacept-naive and initiated SC abatacept 125 mg once weekly, were enrolled into two cohorts: bDMARD-naive patients and those with ≥1 prior bDMARD treatment failure. This *post hoc* analysis evaluated abatacept retention using Kaplan-Meier estimates, as well as disease activity scores (DAS28 [ESR]), CDAI and SDAI in patients with disease duration of ≤2, 3–5, 6–10 or >10 years, and in patients taking abatacept as first-line or ≥ second-line treatment.

Results: Table 1 shows baseline (BL) characteristics. Mean age increased with disease duration; other characteristics were comparable across groups. Retention proportions (95% CIs) at Month 24 were 0.50 (0.4, 0.5), 0.47 (0.4, 0.5), 0.51 (0.5, 0.5) and 0.46 (0.4, 0.5) in the ≤2, 3–5, 6–10 and >10 years' duration groups, respectively. Proportion of patients (95% CI) with ≤2 years' duration retaining treatment at Month 24 were 0.51 (0.4, 0.6) among those using abatacept as first-line treatment and 0.44 (0.3, 0.6) among those using abatacept as a ≥ second-line treatment (Figure 1). Proportions (95% CI) at Month 24 were 0.51 (0.5, 0.6), 0.57 (0.5, 0.6) and 0.52 (0.5, 0.6) in first-line patients and 0.43 (0.4, 0.5), 0.48 (0.4, 0.5) and 0.44 (0.4, 0.5) in ≥ second-line patients in the 3–5, 6–10 and >10 years' duration groups, respectively. Mean (SE) changes from BL in DAS28 (ESR) at Month 24 were –2.12 (0.205), –1.86 (0.151), –2.07 (0.140) and –2.05 (0.115) in the ≤2, 3–5, 6–10 and >10 years' duration groups, respectively; respective mean (SE) changes in CDAI were –18.74 (1.604), –15.60 (1.099), –18.50 (1.038) and –17.68 (0.850); and respective mean (SE) changes in SDAI were –19.10 (1.873), –15.72 (1.345), –19.54 (1.103) and –17.07 (0.939).

Conclusion: In this *post hoc* analysis of the real-world ASCORE trial, patients with RA receiving abatacept in clinical practice as first-line therapy had better retention versus those receiving it as a ≥ second-line treatment, regardless of disease duration at BL. Retention rates were similar across disease duration subgroups. Improvements in disease activity were seen in all duration subgroups, without consistently greater or lesser improvement seen with longer disease duration.

Background: Adalimumab (ADL) is typically self-administered every 2 weeks (W) as a subcutaneous (s.c.) injection by patients (pts) for diverse indications, including rheumatoid arthritis (RA), psoriatic arthritis (PsA), and psoriasis (PsO). Conflicting evaluations of local tolerance to formulations containing citrate buffer have created insecurities among health care professionals and pts.[1,2]

Objectives: To evaluate local tolerance of SDZ-ADL (GP2017), a biosimilar ADL with low citrate concentration (1.2 mM),[3] in 466 healthy volunteers (HV) and 408 pts (RA: 177 and PsO: 231 including PsA: 52) from four phase I pharmacokinetic (PK) and two phase III confirmatory studies.

Methods: HV evaluated their injection site pain (ISP) using a Visual Analogue Scale (VAS) of 0–100 mm. HV received a single 40 mg/0.8 mL s.c. injection and pts received SDZ-ADL every 2W during 48–51W duration of study. Injection site reactions (ISR) as well as adverse events (AEs) were assessed by investigators during the clinical studies. Details of study designs have been reported previously.[4–7]

Results: Overall, 456 (97.9%) HV experienced no ISR. Ten HV experienced ISR. These were mostly of mild intensity; only 1 (0.2%) had an ISR of moderate intensity. 96.6% of HV experienced no pain (VAS score 0–4 mm)[8] at 1-hour post-dose (Figure 1). In the phase III studies, a low number of ISR/ISP events were observed, which decreased during the course of study. Detailed results are provided in Table 1. No ISR/ISP led to treatment or study discontinuation in any study.

Conclusion: The proportion of HV and pts experiencing ISR and ISP after administration of SDZ-ADL was low, with no events leading to treatment or study discontinuation. These results call into question the clinical impact of citrate and its concentration in ADL formulations on the incidence and intensity of ISP.

AB0209 SERIOUS INFECTIOUS COMPLICATIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICS

E. Aronova[1], G. Gridneva[1], A. Kudryavtseva[1], G. Lukina[2]. [1]*VA Nasonova Research Institute of Rheumatology, Moscow, Moscow, Russian Federation*; [2]*Moscow Clinical Scientific Center named after Loginov A. S., Moscow, Moscow, Russian Federation*

Objectives: To study infectious complications of therapy with biologics, analyze the frequency of withdrawal of bDMARDs due to infectious complications.
Methods: The ambispective analysis included data on 505 cases of prescribing biologics with different mechanism of action in 188 patients with rheumatoid arthritis (160 women, 28 men).
Results: Patients in the study group received from 2 to 5 bDMARDs, mediana (25% -75%) 2 (2-3). Biologics were discontinued 326 times, of which due to the development of serious adverse reactions - 70 times, of which due to the development of infectious complications - 16 times (5% of all cases of discontinuations, 29% of all serious adverse reactions). During treatment with the first bDMARD, infectious complications that required discontinuation of the drug developed in 5.3% of cases (N = 10), with the second bDMARD - in 5.2% of cases (N = 4), no statistical differences were found between these groups. On the background of treatment with the third bDMARD, infectious complications led to the withdrawal of treatment in 14.3% of cases (N = 1), in the fourth - 0%, and in the fifth - 33.4% of cases (N = 1). There was no correlation between the number of sequentially prescribed biologics and the incidence of infectious complications. Most often, serious infections developed during treatment with drugs of the TNF-α inhibitor group (infliximab, etanercept, adalimumab, golimumab, certolizumab pegol) and tofacitinib. Out of 16 cases of infectious complications, 5 were associated with tuberculosis infection.
Conclusion: Infectious complications make up a significant proportion (29%) of all serious adverse reactions leading to the discontinuations of biologics in patients with rheumatoid arthritis. The frequency of discontinuation of bDMARDs due to infectious complications was about 5% and did not change during treatment with both the first and second biologics. It is necessary to remain alert about tuberculosis infection and examine patients before prescribing and during treatment with bDMARDs.

AB0210 COMPARISON OF EFFICACY AND SAFETY OF BIOSIMILAR RITUXIMAB AND ORIGINATOR RITUXIMAB IN REAL CLINICAL PRACTICE

D. Kusevich[1], Y. Olyunin[2], E. Nasonov[3,4]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Early Arthritis, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Scientific Supervisor, Moscow, Russian Federation*; [4]*I.M. Sechenov First Moscow State Medical University, Ministry of Health of Russia (Sechenov University), Department of Therapy and Occupational Diseases, Moscow, Russian Federation*

Background: Due to the expiration of many originator biologics patents, their biosimilars (BS) have appeared and were put into clinical practice. The introduction of such drugs reduces the cost of treatment and thereby increases its availability. BS rituximab (RTX) Acellbia was developed by the Russian company "BIOCAD". Its effectiveness and safety have been proven in two clinical trials. It was licensed in Russia for the treatment of rheumatoid arthritis (RA) in 2017.
Objectives: To compare efficacy and safety of BSRTX and originator RTX (ORTX) in real clinical practice.
Methods: RA patients fulfilling the EULAR/ACR 2010 criteria and followed-up at the V. A. Nasonova Research Institute of Rheumatology were included. All of them had previously received methotrexate without effect. They were divided into 4 groups. The first and second groups included patients who had not previously received biologics. Treatment with BSRTX was started in the first group, ORTX was administered in the second group. The third and fourth groups included patients who received ORTX with significant improvement. Patients of the third group were switched to BSRTX, in the fourth group treatment with ORTX was continued. ORTX and BSRTX were administered twice 500 mg over 2 weeks. The indication for repeated administration of ORTX and BSRTX was an exacerbation of RA. Patients were examined before the first or regular administration of ORTX or BSRTX and before the planned repeat course of treatment with these drugs. RA activity was evaluated with the DAS28. Adverse events (AE) were recorded. Data were tested for normality using the Kolmogorov-Smirnov test. Continuous variables are presented as mean ±SD if they obey normal distribution, and as median [quartile interval] if they were not consistent with normal distribution. Mann–Whitney U test was used for comparison between groups.
Results: 127 patients with RA were included. 66 patients had not previously received biologics. BSRTX was started in 35 of them and ORTX – in 31. 61 patients already received ORTHX with clinical improvement. 31 of them were switched to BSRTX, and 30 continued therapy with ORTX. The median interval between the baseline examination and the assessment before the second treatment course in the BSRTX group was 6 [5; 13] months, in the ORTX group – 7 [7; 11] months. In group 1 median DAS28 during follow-up decreased from 5,8 [5,2; 6,9] to 3,9 [3,1; 4,5], in group 2 – from 5,7 [5,2; 6,0] to 4,1 [3,8; 4,6], respectively. These changes were comparable in both groups. The mean duration of the interval between infusion of BSRTX or ORTX and repeated examination – 11,3±8,2 and 10,1±4,8 months, respectively. These differences are not significant. In group 3 median DAS28 at the baseline examination was 5,1 [3,9; 5,9], at the second one – 4,3 [3,8; 5,3], in group 4 – 4,6 [3,7; 5,4] and 4,2 [3,5; 5,2] respectively. These values did not differ significantly. The frequency and nature of adverse events during treatment with ORTX and BSRTX did not significantly differ. We did not observe serious AE and unexpected AE.
Conclusion: The results of the present study show that efficacy and safety of BSRTX and ORTX were comparable when they were used as the first biologics and when switching from ORTX to BSRTX. BSRTX can be used in routine clinical practice for the treatment of RA.Disclosure of Interests:

AB0211 SWITCHING FROM ETANERCEPT ORIGINAL TO ETANERCEPT BIOSIMILAR: LONG TERM FOLLOW UP

G. Sada[1], M. C. Laíño Piñeiro[1], V. Aldasoro[1], J. Mendizabal[1], M. Lopez[1], S. Garcia Perez[1], L. Garrido Courel[1], N. Del-Val[1], L. Horcada[1], R. Gutiérrez Polo[1], I. Paniagua Zudaire[1], C. Fito-Manteca[1]on behalf of Complejo Hospitalario de NavarraServicio de Reumatología. [1]*Complejo Hospitalario de Navarra, Rheumatology, Pamplona, Spain*

Background: Biosimilar drugs has supposed a huge savings in our health systems and there are data that conclude that they work as original molecules when we making these switchings. There are limited studies that analize these patients across the time (1-3).
Objectives: Long term follow up of patients after switching from original etanercept to biosimilar drug.
Methods: We reviewed 187 patients who started Etanercept original in Rheumatology department at Navarra Hospital Complex and their switch to Etanercept biosimilar with a follow-up of 18 months.
Results: The switch was performed in 176 patients with rheumatoid arthritis (RA), spondyloarthritis (SpA) and psoriatic arthritis (PsA).
At 18 months of follow-up 26,1% discontinued treatment; 13% at 6 months, 9,1% at 12 months and 4% patients at 18 months. The median time in etanercept original drug before switching was 52 months.
There were 46 withdrawal patients with etanercept biosimilar: 34 inefficacy, 3 skin reaction, 2 malignancies (lymphoma and GIST), 1 injection site reaction, 1 headache, 1 diarrhea, 1 recurrent urinary infection, 1 heart failure and 2 deaths. 25 patients returned to Etanercept original but 3 did not achieve good response; all of them in RA group.
Conclusion: In our series 50 % of withdrawal happened at 6 months of follow-up. 73,9% had a good response with etanercept biosimilar at 18 months. The main reason to stop biosimilar drug was inefficacy.
Longer-term follow-up and greater number of patients are necessary to ratify these data.

AB0212 NON-ADHERENCE IN RHEUMATOLOGIC IMMUNE-MEDIATED DISEASES

A. Rodríguez-Alarcón[1], N. Carballo[1], L. Río[1], C. Pérez[2], E. González-Colominas[1], X. Duran[3], J. Monfort[2], S. Grau-Cerrato[1], O. Ferrández-Quirante[1]. [1]*Hospital del Mar, Pharmacy, Barcelona, Spain*; [2]*Hospital del Mar, Rheumatology, Barcelona, Spain*; [3]*IMIM - Hospital del Mar, Statistics, Barcelona, Spain*

Background: Patient adherence is a key determinant of treatment success in rheumatologic immune-mediated diseases. Available data about adherence to biological treatments and factors associated to non-adherence is limited in Spain. Moreover, no studies compare adherence between subcutaneous and oral drugs.
Objectives: To evaluate non-adherence to prescribed subcutaneous biologicals and oral drugs in patients with rheumatologic immune-mediated diseases and to assess possible predictor factors associated to treatment non-adherence.
Methods: Retrospective observational study including all patients with oral and subcutaneous treatment for rheumatologic immune-mediated diseases from 2017 to 2019 in the outpatient pharmaceutical care area from a tertiary university hospital. Non-adherence was evaluated by reviewing all scheduled drug-dispensing visits in the computerized application. We considered non-adherent every time that a patient missed at least one drug administration.
Data collected: demographic, total patients and patient-treatments, total dispensing visits and route of administration for drug dispensed in every visit.
We classified patients in adherent and non-adherent considering dispensing visits. Non-adherent group: number of dispensing visits, reasons for non-adherence, number of missed administrations per patient and drug and predictor factors for non-adherence.
Results: 783 patients included: 52.4(13.7) years; 427(54.5%) female; 164 (20.9%) smoker; 697 (89%) Caucasian.
A total of 79 (10.1%) of 783 patients received more than one treatment.
869 patient-treatments: 294 adalimumab (33.8%), 236 etanercept (27.2%), 78 golimumab (8.9%), 47 apremilast (5.4%), 39 certolizumab (4.5%), 34 secukinumab (3.9%), 30 tocilizumab (3.5%).
9,197 dispensing visits. Route of administration: 6,406 subcutaneous (93.2%), 374 oral (6.8%).
Non-adherence analysis: 2417 (26.3%) dispensing visits, reasons for non-adherence/ dispensing visits: 92 unjustified (97.5%), 33 infection (1.4%), 18 (surgery) 0.7%, 3 pregnancy (0.1%), 6 others (0.3%).
Number of missed administrations/patient treatment: 675 patients missed at least one administration (77.7%).Mean 2.5 (±12.9) missed administrations.
Number of missed administrations/drug: 9.9 baricitinib (±20.8), 15.8 tofacitinib (±31.2), 25.4 apremilast (±53.2).
Predictor factors for non-adherence: ethnicity (p=0.015), treatment with golimumab (p=0.006), and tocilizumab (p=0.036). Age (p=0.072).
Conclusion: - Non-adherence to the prescribed drug occurred in 77.7% of patients with rheumatologic immune-mediated diseases
- Demographic factors such as ethnicity as well as golimumab and tocilizumab treatment, despite their different frequency of administration, were predictors for non-adherence
- Route of administration did not influence non-adherence.

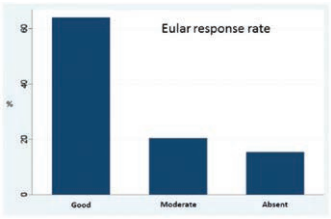
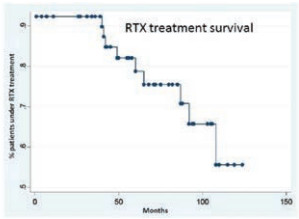
AB0213 SAVING GLUCOCORTICOIDS AFTER RITUXIMAB TREATMENT IN PATIENTS WITH REUMATOID ARTHRITIS. ANALYSIS OF A COMMON CLINICAL PRACTICE COHORT

G. Jurado Quijano[1], L. Fernández de la Fuente Bursón[1], B. Hernández-Cruz[1], P. Muñoz Reinoso[1], V. Merino Bohóquez[2], J. J. Pérez Venegas[1]. [1]*Hospital Universitario Virgen Macarena, UGC Reumatología, Sevilla, Spain*; [2]*Hospital Universitario Virgen Macarena, UGC Farmacia Hospitalaria, Sevilla, Spain*

Background: Rituximab (RTX) is a monoclonal antibody against the CD20 B cell antigen that has been used successfully in recent years for the treatment of rheumatoid arthritis (RA). It is an effective drug that reaches survival rates of 60% at 5 years of treatment as reflected in the British experience. However, survival in Spanish patients is unknown.
Objectives: To study the survival of RTX treatment and the characteristics of patients with RA treated with the drug since its commercialization in Spain.
Methods: Observational, retrospective and analytical study of a cohort of patients with RA treated with at least one dose of RTX. We reviewed the medical records of all patients with RA from January 2007 to June 2017. A total of 178 previous defined variables were collected, highlighting data about treatment (use of RTX, associated conventional synthetic disease modifying drugs [FAMEsc], doses of corticosteroids [GC] used) and activity indices. Descriptive statistics were performed (median and the 25th and 75th percentiles are shown). The comparative analysis was done with χ^2 and U of Mann Whitney for categorical variables and paired sign rank test or Student's t for continuous. Survival Kaplan Mayer curves were constructed. The study was carried out in accordance with the standards of our Clinical Research Ethics Committee.
Results: A total of 54 patients were analyzed. 74% (n = 40) of them were women, the age was 61.2 years (51.0 - 67.4). 74% (n = 40) presented some type of relevant comorbidity. Its RA was FR + in 96% (n = 52) and ACCP + in 78% (n = 42) of the cases, with an evolution time of 9.3 years (3.5-19, 2), and with radiographic erosions in up to 63% (n = 34). At the time of the start of the RTX, 100% of the patients (n = 54) received some FAMEsc, and 33 (61%) were treated with prednisone; the daily dose of prednisone was 9 (6-12) mg. The baseline DAS28-VSG was 5 (4.1 - 6.0). The duration of the follow-up was 56.6 (29.3-92.1) months. Patients received a mean of 5 (1-6) cycles of RTX at a dose of 1000 mg on days 0 and 15 in most cases. The final DAS28-VSG was 2.6 (2.1 - 4.0), p = 0.00001 compared to baseline. The delta between baseline and final DAS was -2.36 (-0.55 - -3.1). At the end of the RTX treatment, the EULAR response rate





was good in 64% (n = 25), reaching remission in 17 (31%) of the patients, and moderate response in 21% (n = 8) of them (Figure 1). Only 2 (4%) patients were treated with GCC at the end of the follow-up, p<0,00001 compared to baseline. The daily dose of PDN at the end of follow-up was 6 mg in a case and 12 mg in the other, p=00001 compared to baseline. At the end of the follow-up 24%of the patients (n = 13) changed or discontinued the drug: 9 changed due to secondary failure, 2 suspended due to adverse events, 1 due to death due to prior neoplastic process and 1 due to complete disease remission. Survival at 1, 2, 3, 4, 5, 6 and 7 years was 92%, 92%, 82% 78%, 75%, 75% and 65% respectively; with a mean survival rate of 90 months (Figure 1).

Conclusion: The results of our analysis show that patients with RA undergoing RTX treatment have adequate control of disease activity and drug survival rates, like published data. RTX treatment allowed stopped GCC treatment in 31 cases (90%).

Background: Golimumab is a human monoclonal antibody directed against TNFα in its soluble and transmembrane forms. It can be used subcutaneously or intravenously and has shown efficacy for use in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS).

Objectives: The aim of this study was to evaluate the efficacy, safety, and cumulative survival of golimumab in patients with RA, PsA and AS from different rheumatology centers in Argentina.

Methods: We performed a longitudinal study of consecutive adults with RA (ACR/EULAR 2010 criteria), PsA (CASPAR criteria) and AS (ASAS 2009 criteria), who have started treatment with subcutaneous or intravenous golimumab according to medical indication in each center. Data was obtained by review of medical records. Sociodemographic and clinical data, musculoskeletal manifestations, comorbidities, previous treatments were recorded. In reference to golimumab treatment, start date, route of administration and concomitant treatments were identified. Disease activity was assessed using DAS28 for RA patients, DAPSA and MDA for PsA and BASDAI for AS. The presence of adverse events (AE) was recorded. If golimumab was stopped, date and cause was documented. Patients were followed up until golimumab discontinuation, loss of follow-up, or study completion (November 30, 2020). *Statistical analysis:* Chi^2 test or Fischer exact test and T test or Mann Whitney and ANOVA or Kruskal Wallis, as

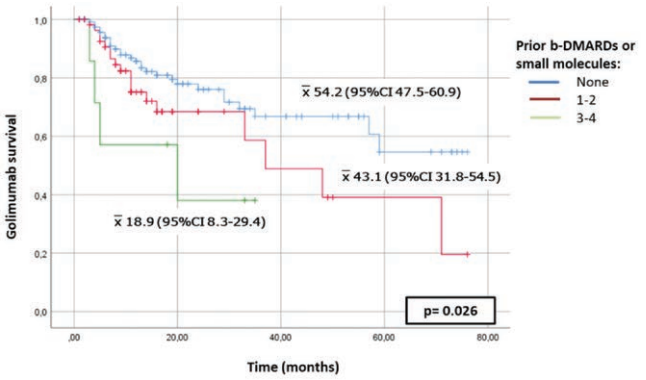

Figure 1. Golimumab survival according to prior b-DMARD o small molecule treatment.

appropriate. The incidence of EA was assessed in events every 100 patient/year. Kaplan-Meier curves and log Rank analysis. Cox proportional regression.

Results: One hundred eighty two patients were included, 116 with a diagnosis of RA, 30 with PsA and 36 with AS. Most of them (70.9%) were female with a median (m) age of 55 years (IQR 43.8-64) and m disease duration of 7 years (IQR 4-12.7) at treatment initiation. Al least one prior biological DMARD or a small molecule was received by 63 patients (34.6%). The most frequent indication cause was conventional DMARD failure. In 94.8% of the patients Golimumab was administered subcutaneously, and in 80.8% in association with conventional DMARDs, the most frequently used was methotrexate. Total follow-up was 318.1 patients/year.

Golimumab treatment showed clinical improvement in all three groups of patients. In RA patients DAS28 significantly decreased during the first 12 months of follow-up, m 5.9 (IQR 4.9-6.6) at baseline, 3.8 (IQR 2.6-4.6) at 6 months and 2.8 (IQR 2.1-3.6) at 12 months, p <0.0001. In PsA, m DAPSA-ESR value was 32.2 (IQR 24.2-47.7), 10.1 (IQR 5.8-18.3) and 11.2 (IQR 3.4-24) at baseline, 6 and 12 months, respectably (p <0.0001). In AS, m BASDAI was 6.2 (IQR 4.8-7.3), 2.8 (IQR 1.7-4.1) and 2.2 (IQR 1.1-3.2), at baseline, 6 and 12 months respectively (p <0.0001).

The incidence of adverse events was 6.6 per 100 patients/year, being infections the most frequents ones. During follow-up, 50 patients (27.5%) discontinued golimumab, the most frequent cause was treatment failure (68%), followed by lack of health insurance (16%) and adverse events (10%). Golimumab persistence was 79% and 57.6% at 12 and 24 months, respectively. Treatment survival was 50.2 months (95% CI 44.4-55.9). Patients who had received prior treatment with biological DMARDs or small molecules showed lower survival (Figure 1). In the multivariate analysis, adjusting for age, sex and disease duration, those patients showed twice the risk of suspending treatment (HR 2.01, 95% CI 1.1-3.7).

Conclusion: Golimumab treatment in real life patients in Argentina has shown good efficacy and safety. Drug survival was over 4 years and almost 80% were still using golimumab after one year. Prior treatment with other b-DMARDs o small molecules was associated with lower treatment survival.

AB0215 COMPARISON BETWEEN RITUXIMAB ORIGINATOR THERAPY AND ITS BIOSIMILAR IN THE INCIDENCE OF LATE-ONSET NEUTROPENIA IN ADULT PATIENTS WITH RHEUMATOID ARTHRITIS AND OTHER AUTOIMMUNE DISEASES

M. M. Ahmad[1], E. Mcrorie[1]. [1]*Western General Hospital, Rheumatology, Edinburgh, United Kingdom*

Background: Late-onset neutropenia (LON) occurs when the absolute neutrophil count drops below 1.5 × 10(9)/L four weeks after Rituximab infusion.[1] It is a condition recognised more in haematological malignancy patients treated with Rituximab with a reported prevalence of 8% or higher.[2] LON was reported in 6.5% of rheumatological patients[1], while a French registry found a prevalence of 1.3% in rheumatoid arthritis patients.[3]

Almost all patients receiving Rituximab originator therapy at our Rheumatology department were switched to its biosimilar starting from November 2017. Our haematology team observed LON cases in their patients after this period.

Objectives: We wanted to establish whether there is increased LON occurrence with the biosimilar than the originator therapy, requiring specific monitoring.

Methods: This is a cross-sectional retrospective review of 12 months period before and after switching to the biosimilar of all patients who received Rituximab for the first time. We reviewed the patients' blood monitoring for up to 12 months after receiving Rituximab. We used a proforma to collect the age, sex, diagnosis, date of the first infusion, use of other DMARDs, LON occurrence within 12 months after the infusion and neutropenia within the 12 months before it in addition to the frequency of the blood monitoring after the infusion.

Results: For the originator, between 1/1/2016 and 31/12/2016, 142 patients received Rituximab, 47 (33.09%) of them were given the treatment for the first time. Their median age was 62 years, 28 (59.5%) were females. The most common diagnosis was rheumatoid arthritis 38 (80.8%), and 35 (74.4%) patients were on other disease-modifying agents (DMARDs). Two patients (4.2%) developed LON. In both patients, this occurred during admission for septic arthritis whilst on antibiotics, and both had Grade 2: ≥1,000– < 1,500/mm3 neutropenia.

For the Biosimilar cohort, between 1/4/2019 and 31/3/2020, 161 patients received Rituximab, 36 (22.3%) of them were given the treatment for the first time. Their median age was 59 years, 27 (75%) of them were females. The most common diagnosis was rheumatoid arthritis 25 (69.4%), and 26 (72.2%) were on other DMARDs. One patient (2.77%) developed grade 2 LON one month after Rituximab. Another patient with known autoimmune neutropenia was excluded. In all the Three patients with LON in both groups, neutrophil count recovered in less than a month, and they had normal IgG before the infusion.

The frequency of blood monitoring after Rituximab infusion was done 1-3 monthly in 32 (68%) patients and 23 (63.8%) patients in the originator and biosimilar groups, respectively.

Four (8.5%) patients and three (8.3%) patients in the originator and biosimilar groups respectively had a frequency of blood monitoring done less than six-monthly.

Conclusion: In our patients' cohort, LON incidence following switching to the Rituximab biosimilar was not higher than the originator therapy.

AB0216 LONG-TERM RESULTS OF T2T THERAPY INITIATED AT THE ONSET OF RHEUMATOID ARTHRITIS (DATA FROM OREL REGISTRY)

V. Rybakova[1], A. Avdeeva[2], Y. Olyunin[2], E. Nasonov[3,4]. [1]*V.A. Nasonova Research Institute of Rheumatology, Outpatient Department, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Early Arthritis, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Scientific S, Moscow, Russian Federation*; [4]*I.M. Sechenov First Moscow State Medical University, Ministry of Health of Russia (Sechenov University), Department of Therapy and Occupational Diseases, Moscow, Russian Federation*

Background: Current guidelines for the treatment of rheumatoid arthritis (RA) recommend early administration of methotrexate (MTX) and addition of a biologic if MTX monotherapy does not provide remission or low activity of the disease. Efficacy of this strategy in real clinical practice was assessed using data from the Russian RA registry OREL.

Objectives: To analyze long-term results of intensive treatment initiated at RA onset in real clinical practice.

Methods: 141 RA patients with disease duration less than 3 years (29 men, 112 women) were included. 112 were positive for rheumatoid factor and 119 – for anti-cyclic citrullinated peptide antibody. Subcutaneous MTX was initiated at 10-15 mg per week with further dose escalation up to 20-30 mg per week. Therapy was adjusted every 3 months. If MTX monotherapy did not allow to achieve treatment target of remission or low disease activity, biologics were added.

Results: Median DAS 28 at baseline was 5,31 [4,79; 6,14]. Initiation of treatment resulted in steady decrease of disease activity ($p<0.05$, table1). After 1 year of follow-up 33.8% of patients received MTX monotherapy, 33.8% – MTX in combination with tumor necrosis factor alpha inhibitors, 22.0% – MTX +abatacept, 0.55% – MTX+ tocilizumab, 0.47% – MTX + rituximab. Low disease activity was achieved in 16.3% patients, and remission - in 45.8%. After 6 years median age of patients was 58 [49; 66] years, disease duration – 84 [79; 89] months, low disease activity was documented in 21.3%, and remission – in 7.8% of cases (fig. 1). 7% of patients were able to maintain remission without any treatment. Biologics were discontinued in 15 patients after achieving remission or low disease activity, and synthetic DMARDs – in 5 patients having remission.

Conclusion: Intensive therapy initiated at RA onset demonstrates high effectiveness, allowing 61.5% of patients to achieve low disease activity or remission within 12 months, and to maintain these results after 6 years of treatment in 29.2%. Adherence to this strategy allowed to discontinue biologics in 15 patients and synthetic DMARDs in 5 patients after achieving treatment target.

NON MEDICAL SWITCH FROM ETANERCEPT ORIGINATOR TO BIOSIMILAR GP2015 IN PATIENTS WITH CHRONIC INFLAMMATORY ARTHROPATHIES

M. Colaci[1], M. L. Aprile[1], A. La Rosa[2], A. DI Maggio[2], L. Malatino[1].
[1]Rheumatology Centre, Ospedale Cannizzaro, Clinical and Experimental Medicine, University of Catania, Catania, Italy; *[2]Servizio di Farmacia Ospedaliera, Ospedale Cannizzaro, Catania, Italy*

Background: In the last decades, new biologic drugs were introduced for the treatment of chronic inflammatory arthropathies, progressively leading to a relevant increase of medical costs. However, the introduction of biosimilars (biologic molecules similar to branded drugs with expired patent) permitted to optimize the financial resources. The non-medical switch (NMS) is the switch from a biologic originator to a biosimilar agent for economic reasons only, on the basis of the substantial equivalence as regards efficacy and safety between originator and biosimilar drugs.
In literature, several evidences from clinical trials and registry studies showed that the switch from etanercept originator to biosimilar SB4 was safe [1]. Instead no sufficient data may be found regarding the biosimilar GP2015.
Objectives: We aimed to evaluate efficacy, safety, and retention rate in a series of patients with chronic arthritis treated with etanercept originator who underwent to NMS towards the ETN biosimilar GP2015.
Methods: From March to June 2020, all patient referred in our Centre affected by rheumatoid arthritis (RA), psoriatic arthritis (PA) and axial spondyloarthritis (axSpA) treated with etanercept originator and in remission/low disease activity for at least 6 months underwent to NMS. Data on disease activity (DAS28-PCR/CDAI/SDAI; DAPSA; BASDAI), eventual adverse events and causes of withdrawal of therapy were collected at 2, 4 and 6 months after the switch.
Results: We recruited 71 consecutive patients (M/F: 24/47; mean age 55,8± 11,1 years; 39 RA; 15 PA; 17 axSpA; mean duration therapy 7.3±3.8 years). Disease activity was unchanged for almost all patients after 6 months from the switch (median ΔDAS28-PCR/CDAI/SDAI: 0,1/0/0,5; median ΔDAPSA: 0; median ΔBASDAI: 0) Moreover, the 6-month retention rate was 97.2%. Only 2 patients (2.8%) switched back to the originator due to loss of efficacy in one case and adverse events in the second case (paraesthesia, headache, dizziness and worsening of arthralgia).
Conclusion: Our study confirmed that the NMS from ETN originator to GP2015 represents a safe practice that maintains the efficacy of the current treatment.

AB0218

NON MEDICAL SWITCH FROM ADALIMUMAB ORIGINATOR TO THE BIOSIMILAR GP2017 IN PATIENTS AFFECTED BY CHRONIC ARTHRITIS

M. Colaci[1], M. L. Aprile[1], A. La Rosa[2], A. DI Maggio[2], L. Malatino[1].
[1]Rheumatology Centre, Ospedale Cannizzaro, Clinical and Experimental Medicine, University of Catania, Catania, Italy; *[2]Servizio di Farmacia Ospedaliera, Ospedale Cannizzaro, Catania, Italy*

Background: The non-medical switch (NMS) from originator drugs to biosimilars is a possible strategy adopted by rheumatologists in order to control the expansion of pharmaceutic costs for the treatment fo patients affected by chronic arthritis. To date, few real life data on the switch from adalimumab (ADA) originator to its biosimilars are available.
Objectives: We aimed to evaluate efficacy and safety in a single-Centre cohort of patients affected by chronic arthritis who switched from ADA originator to the biosimilar GP2017.
Methods: Patients affected by rheumatoid arthritis (RA), psoriatic arthritis (PA) and axial spondyloarthritis (axSpA) already on therapy with ADA originator in remission or low disease activity for at least 6 months were switched to GP2017 (March- June 2020). Data on disease activity (DAS28-PCR/CDAI/SDAI; DAPSA; BASDAI), eventual adverse events and causes of withdrawal of therapy were collected at 2, 4 and 6 months after the switch.
Results: 88 patients were enrolled (M/F 36/52; mean age 55.8 ± 12 years; 25 RA, 32 PA, 31 axSpA, mean duration of therapy 6.3 ± 3.8 years). No statistically significant difference was observed in median DAS28-PCR/CDAI/SDAI values at the baseline and after 6 months [1.03 (0.96-3.43) vs. 1.21 (0-3.7) / 0 (0-15) vs. 0 (0-17) / 0 (0-15) vs. 0.5 (0-17.5)], DAPSA [0 (0-12.2) vs. 0 (0-15)] and BASDAI [0 (0-4.3) vs. 0 (0-6.4)]. The retention rate was 93.2%. 6/88 patients (6.8%) switched back to the originator. The causes of discontinuation were: disease reactivation in a single case (1.1%), subjective reasons/ nocebo effect in 5/88 cases (5.7%), including: general malaise and transient increased of blood pressure (n.1), dizziness, paraesthesia, arthralgia, headache (n.1), itch *sine materia* (n.1) and subjective worsening without objective disease flare (n.2).
Conclusion: This is the first real life study showing that the NMS from ADA originator to GP2017 represents a safe practice that maintains the efficacy of the current treatment. However, a few cases of switchback were described, mainly attributed to nocebo effect [1].

AB0219

EXPLORING LONG-TERM DRUG EFFECTIVENESS AND DRUG SURVIVAL FOR RITUXIMAB REFERENCE DRUG IN TREATMENT OF RHEUMATOID ARTHRITIS PATIENTS IN ORDINARY OUTPATIENT CLINIC

K. Łosińska[1], M. Wilk[1], A. H. Pripp[2], M. Korkosz[1,3], G. Haugeberg[4,5].
[1]University Hospital, Division of Rheumatology and Immunology, Cracow, Poland; *[2]Oslo University Hospital, Oslo Centre of Biostatistics and Epidemiology, Oslo, Norway*; *[3]Jagiellonian University Medical College, Department of Rheumatology, Cracow, Poland*; *[4]Sorlandet Hospital, Division of Rheumatology, Department of Medicine, Kristiansand, Norway*; *[5]NTNU, Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Trondheim, Norway*

Background: In randomized controlled trials (RCTs) rituximab (RTX) has been shown to effectively suppress inflammation and reduce structural joint damage in rheumatoid arthritis (RA) patients [1]. There is a lack of RA data on RTX effectiveness and drug survival when used in real life practice.
Objectives: To explore long-term drug effectiveness and drug survival for RTX used to treat RA patients in ordinary clinical practice.
Methods: The study population included RA patients treated between 2006 and 2020 with RTX at an outpatient clinic in Norway. Patients were monitored using recommended measures for disease activity and patient reported outcomes (PROs). Drug effectiveness was assessed with random intercept linear mixed models. Drug survival was described using Kaplan-Meier survival analysis. Baseline predictors of drug survival were assessed with multivariable Cox proportional hazard models.
Results: In database a total of 246 RA patients (females 74.8%) were identified to have been treated with RTX. At baseline mean (SD) age was 59.1 (13.5) years, disease duration 13.0 (10.2) years, RF positive 88.8%, ACPA positive 92.1%. Majority of patients had first cycle RTX dosage of 2000 mg (82.9%). At baseline patients currently using conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) were 51.5% (methotrexate 39.4%), prednisolone 73.6% and a total of 17.1% were biologic DMARDs (bDMARDs) naïve. In table 1 mean (SE) values for disease activity and PROs are shown for baseline and subsequent years after baseline for 5 years follow up.

Table 1. Changes in disease activity and PROs at baseline and subsequent 1-year periods

	Baseline N=246	1 year N=246	2 year N=204	3 year N=163	4 year N=130	5 year N=111
CRP (mg/L)	23.1 (2.1)	21.3 (1.6)	11.7 (0.9)	8.6 (1.4)	6.2 (0.7)	6.7 (0.9)
ESR (mm/hr)	32.1 (1.4)	31.1 (1.3)	22.3 (1.1)	17.6 (1.2)	14.3 (1.0)	13.6 (1.2)
SJC28 (0-28)	6.3 (0.4)	5.4 (0.3)	3.2 (0.3)	2.2 (0.2)	1.6 (0.2)	1.5 (0.2)
TJC28 (0-28)	7.1 (0.4)	6.6 (0.3)	3.6 (0.3)	2.6 (0.3)	2.2 (0.3)	1.8 (0.3)
DAS28	4.9 (0.1)	4.7 (0.1)	3.6 (0.1)	3.1 (0.1)	2.8 (0.1)	2.7 (0.1)
CDAI	22.9 (0.9)	20.7 (0.7)	12.3 (0.7)	9.4 (0.7)	8.5 (0.6)	7.7 (0.7)
PGA (0-100mm)	57.2 (1.7)	53.7 (1.4)	38.1 (1.6)	33.7 (1.9)	35.0 (2.1)	32.8 (2.2)
MHAQ (0-3)	1.0 (0.0)	0.9 (0.0)	0.7 (0.0)	0.6 (0.0)	0.5 (0.0)	0.5 (0.0)

During follow up all disease activity and PRO measures improved significantly ($p < 0.001$). Least improvement was seen in first year and a more substantial improvement progressed since second year. Percentage of patients with no, moderate and good treatment response defined according to EULAR response criteria [2] is shown in figure 1.

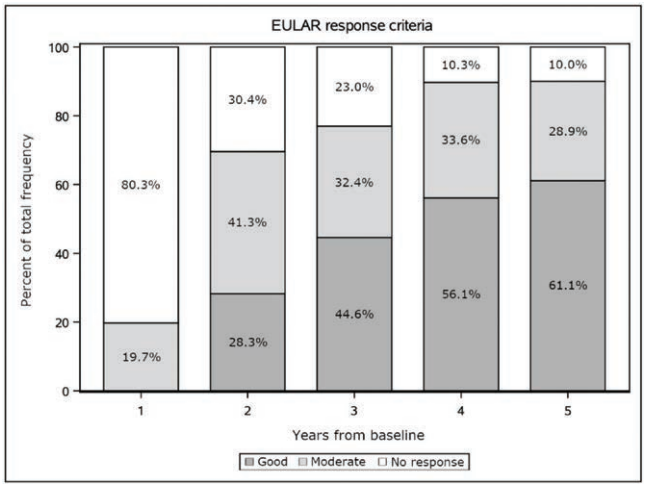

Figure 1. No, moderate and good response to RTX treatment

No significant difference during the 5-year follow-up was found regarding previous use of bDMARD or not and for concomitant use of csDMARDs or not for variables listed in the table 1.

Drug survival for the RTX was 83% (95CI 77-87%) after 1 year, 66% (95CI 60-72%) after 2 years, 53% (95CI 46-59%) after 3 years, 46% (95CI 39-52%) after 4 years and 34% (95CI 28-40%) after 5 years of follow up.

No significant difference in drug survival was found between bDMARD naïve and previous users of bDMARDs or between concomitant and non-concomitant users of csDMARDs. RF positive patients had a better drug survival.

In prediction analysis RF positive status, high baseline DAS28, low baseline CRP, previous bDMARDs use, short disease duration and low MHAQ were found to be independently associated with better drug survival.

Conclusion: Our real life data shows that RTX treated RA patients had a satisfactory treatment response and drug survival declines rather linearly over time. However, a significant treatment response was achieved primary in the second year indicating that at least 2 twin infusions should be given before identifying treatment failure.

AB0220 ANTI-CITRULLINATED PROTEIN ANTIBODY (ACPA) POSITIVITY IS ASSOCIATED WITH REDUCED WITHDRAWAL RATES OF ABATACEPT IN RHEUMATOID ARTHRITIS BUT ONLY IN PATIENTS WHO ARE ANTI-NUCLEAR ANTIBODY (ANA) NEGATIVE

J. Kimpton[1], M. Shipa[2], E. Hawkins[2], S. A. Yeoh[2], M. Greenwood[3], M. Ehrenstein[2]. *[1]University College London, Centre for Clinical Pharmacology and Therapeutics, London, United Kingdom*; *[2]University College London, Centre for Rheumatology, London, United Kingdom*; *[3]University College London Hospital, Pharmacy Department, London, United Kingdom*

Background: Abatacept, a selective inhibitor of T cell co-stimulation, is often used as a second-line biologic disease-modifying anti-rheumatic drug (bDMARD) after the failure of tumour necrosis factor inhibitor (TNFi) in Rheumatoid Arthritis (RA). However, in comparison to TNFi very few survival analyses of abatacept have been reported.[1,2]

Objectives: To investigate predictors of abatacept discontinuation due to either inefficacy or adverse events in RA patients over 5-years.

Methods: A retrospective observational analysis was conducted on a tertiary hospital dataset of RA (according to 2010 ACR/EULAR criteria) patients who started abatacept (either intravenous or subcutaneous). Time to abatacept discontinuation over 5-years was estimated using Kaplan-Meier survival analyses. A multivariate cox-regression model to predict abatacept discontinuation was chosen by elastic net regularisation.

Results: A total of 112 patients with RA [81% female, mean age 58.1 (SD 13.5) years] commenced abatacept therapy during the study period. 88 (78.6%) patients received intravenous abatacept, 14 (15.9%) of whom switched to subcutaneous injection, and 24 (21.4%) were initially treated with subcutaneous abatacept, 2 (8.3%) of whom switched to intravenous. More than half of the patients (65/112) were treated with at least one concomitant conventional synthetic DMARD (csDMARD). Methotrexate was the most commonly used (n = 37) csDMARD, followed by hydroxychloroquine (n = 23), sulfasalazine (n= 15), and leflunomide (n = 7). 42 (37.5%) patients were treated with glucocorticoids (either oral, intra-articular, or intramuscular injection) during the time they were treated with abatacept. Abatacept was most commonly used as 4th (n = 29) and 3rd line (n = 24) bDMARD but 19 patients received abatacept as their first line bDMARD. 75 (67%) patients were rheumatoid factor (RF) positive and 73 (65.2%) were anti-citrullinated protein antibody (ACPA) positive. Anti-nuclear antibody (ANA) was positive in 32 patients. Abatacept was discontinued in 54 patients (48.2%); 19 (35.2%) due to an adverse event and 35 (64.8%) due to loss of efficacy. Overall, the median time to discontinuation of abatacept was 3.8 years.

Multivariate cox regression (variables chosen by the elastic net and adjusted by whether or not abatacept was used as first-line therapy) showed that ACPA positivity was associated with a reduced risk of abatacept discontinuation with a hazard ratio (HR) of 0.40 (95% CI 0.18 to 0.85, p=0.02, N. of events 16/47) compared to ACPA negative patients (N. of events 15/23), but only if ANA was negative. In contrast, ACPA positivity did not reveal any retention benefit over ACPA negative patients, if they were ANA positive.

ACPA positive patients without positive ANA increased the time-to-discontinuation of abatacept predominantly after 3-months (unadjusted log-rank p=0.02), compared to ACPA, and ANA negative patients (Figure 1). Adding csDMARDs with abatacept, reduced the risk of discontinuation of abatacept by 59% (95% CI 24% to 77%, p = 0.004, N. of events 26/65) compared to monotherapy (N. of events 28/47).

Conclusion: Our data suggests patients who are ACPA positive and ANA negative are more likely to remain on abatacept therapy. Concomitant csDMARD use also acts as a positive predictor of abatacept treatment retention.

AB0221 CURRENT IMPLEMENTATION OF TREAT-TO-TARGET APPROACH IN RHEUMATOID ARTHRITIS TREATMENT: THE PERSPECTIVE OF CHINESE RHEUMATOLOGISTS

J. L. Zhao[1], X. Liu[2], L. Zhan[2], H. Tang[2], J. Li[2], M. Liu[2], E. Holdsworth[3], Y. Zhao[1]. *[1]Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China*; *[2]Eli Lilly and Company, Medical, Shanghai, China*; *[3]Adelphi Real World, Rheumatology, Manchester, United Kingdom*

Background: Treat-to-target (T2T) approach is recommended as a standard management strategy in rheumatoid arthritis (RA) treatment by Chinese guideline for diagnosis and treatment of RA[1]. However, there is little known about its current implementation in China.

Objectives: This study aimed to evaluate the implementation and achievement of T2T approach and explore their associated factors in Chinese RA cohort.
Methods: A comprehensive cross-sectional survey of rheumatologists and their RA patients was conducted in China. Data were collected during May-Aug 2019 via physician-completed patient record forms. 60 rheumatologists provided data on demographic, clinical characteristics, treatments, and T2T approach implementation for 600 RA patients. Two logistic regressions were used to evaluate factors associated with T2T approach implementation and T2T goal achievement, respectively. Patients with missing data were not included in the models.
Results: 600 patients were included in this study (48.8±11.7 years, 70.3% female). 39.0% (N=234) of 600 patients were being treated with T2T approach, and 64.9% (N=366) of 564 patients had achieved T2T goal. Patients with longer disease duration (>2 years diagnosis) (odds ratio (OR) [95%CI]=1.61 [1.05, 2.49], vs. diagnosis ≤2 years), higher pain score (OR [95%CI]=1.26 [1.04, 1.51]), or receiving advanced therapy (OR [95%CI]=6.91 [3.64, 13.13]) were more likely to use T2T. Patients with BMI >23.9kg/m^2 (OR [95%CI]=2.83 [1.59, 5.04], vs. BMI≤23.9kg/m^2), or who worked full-time (OR [95%CI]=2.12 [1.26, 3.57]) were more likely to achieve T2T goal, while patients with more pain (OR [95%CI]=0.77 [0.64, 0.92]) were less likely to achieve T2T goal.
Conclusion: Low implementation of T2T approach is observed in Chinese RA treatment. Longer disease duration, more pain, and receiving advanced therapy are associated with higher probability of T2T use, while higher BMI, full-time work and less pain are associated with higher probability of T2T goal achievement. Standard diagnosis and treatment according to guidelines may improve T2T approach implementation.

AB0222 COMPARISON OF SELF-INJECTION DEVICES FOR ADMINISTERING ANTI-TUMOR NECROSIS FACTOR AGENTS USING THE ORIGINAL QUESTIONNAIRE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Hirano[1], J. Hasegawa[1]. [1]*Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan*

Background: Self-injection of biological agents has become a general practice in the treatment of rheumatoid arthritis (RA). Self-injectable biological agents differ in shape, needle thickness, drug fluid volume, and so on. These differences may affect patients' evaluations of self-injection devices. Five kinds of anti-tumor necrosis factor (TNF) agents can be administered by self-injection in clinical practice in Japan. Information on patients' evaluations of self-injection devices is important in choosing the agent for the treatment of RA among several agents with the same mechanism of action.
Objectives: The aim of this retrospective cross-sectional study was to compare patient evaluations of anti-TNF self-injection devices in the treatment of RA.
Methods: RA patients in whom etanercept (ETN) pen 50 mg (Embrel Pen) was switched to ETN biosimilar (BS) 50 mg (ETN-BS [MA]), adalimumab (ADA) syringe 40 mg (Humira syringe) was switched to ADA pen 40 mg (Humira pen), golimumab (GLM) syringe 50 mg (Simponi syringe) was switched to GLM auto-injector (Simponi AI), and certolizumab pegol (CZP) syringe (Cimzia syringe) was switched to CZP autoclicks (Cimzia AC) were asked to answer an originally developed questionnaire (Toyohashi Self-injection Assessment Questionnaire [T-SAQ]; Table 1) before and after switching agents. T-SAQ included 18 questions. A score of 0 indicated "best" and 4 indicated "worst" for each question, with a highest possible score of 72. The patients' characteristics and T-SAQ scores before and after switching agents were investigated. A statistical analysis of the difference in T-SAQ score between before and after switching was performed using the Wilcoxon signed-rank test. A P value < 0.05 was considered significant.
Results: The patients were divided into groups according to the agents they received with switching as follows: switchers from ETN pen to ETN-BS, n = 32; switchers from ADA syringe to ADA pen, n = 28; switchers from GLM syringe to GLM-AI, n = 25; and switchers from CZP syringe to CZP-AC, n = 10. The total T-SAQ scores were as follows, respectively: ETN pen and ETN-BS, 23.5 and 19.0; ADA syringe and ADA pen, 25.8 and 14.9; GLM syringe and GLM-AI, 23.8 and 17.4; and CZP syringe and CZP-AC, 30.6 and 18.8. The total T-SAQ was significantly improved after switching to the pen devices in all the switching groups. In the switchers from ETN pen to ETN-BS, the scores for questions 5, 10, 11, 12, 16, 17, and 18 were significantly improved after switching. The total T-SAQ scores were significantly improved for questions 1, 2, 3, 4, 5, 7, 11, 12, 13, 15, 16, and 17 in the switchers from ADA syringe to ADA pen, for questions 1, 2, 5, 7, 10, 16, and 17 in the switchers from GLM syringe to GLM-AI, and for questions of 1, 2, 3, 4, 5, 7, 11, and 15 in the switchers from CZP syringe to GLM-AC.
Conclusion: The pen devices were favorably assessed by the RA patients in whom syringe devices were switched to pen devices for the same agent. The total T-SAQ score improved in the RA patients in whom ETN pen was switched to ETN-BS probably because the thickness of the needle was thinner in the ETN-BS than in the ETN pen. The total T-SAQ score for the ADA pen was lowest probably because the thinnest needle was used (29 gauge) and the amount of drug fluid is smallest (0.4ml). The total T-SAQ score for the CZP syringe was the lowest probably because the thickest needle was used (25 gauge).

Table 1. Toyohashi Self-injection Assessment Questionnaire (T-SAQ)

Q	Score	0	1	2	3	4
1	Ease to use	Excellent	Very Good	Fair	Poor	Unacceptable
2	Ease of learning how to use	Very easy	easy	Fair	Difficult	Very Difficult
3	Ease of abandoning	Very easy	easy	Fair	Difficult	Very Difficult
4	Ease of injection	Very easy	easy	Fair	Difficult	Very Difficult
5	Ease of holding the device	Excellent	Very Good	Fair	Poor	Unacceptable
6	Occurrence of injection fluid leak	Never	Almost not	Fair	Sometimes	Always
7	Time of injection	Very short	Short	Fair	Long	Very Long
8	Burden on leisure or travel	Very small	Small	Fair	Big	Very big
9	Burden on household affairs or child-rearing	Very small	Small	Fair	Big	Very big
10	Burden on work (only for those working)	Very small	Small	Fair	Big	Very big
11	Strain or anxiety from injection	Very small	Small	Fair	Big	Very big
12	Strain or anxiety from needle	Very small	Small	Fair	Big	Very big
13	Disgust with or anxiety from self-injection	Very small	Small	Fair	Big	Very big

AB0223 MODIFIED DOSE RITUXIMAB BIOSIMILAR IN RHEUMATOID ARTHRITIS COMPARING B-CELL DEPLETION EFFECT AND DISEASE ACTIVITY SCORES

S. Bandyopadhyay[1]. [1]*Apollo Gleneagles Hospital, Internal Medicine, Kolkata, India*

Background: In emerging economies self-funding patients opt for less costly options, influencing both compliance and maintenance of treatment for chronic illness. Studies comparing originator rituximab 1000mgx2 and 500mgx2 doses in Rheumatoid arthritis (RA) have yielded interesting results[1]. Evidence of B cell depletion, measured by CD19 count, maybe a marker for disease improvement[2]. However effect of different dose of biosimilar Rituximab (bRTX) on B cell depletion and disease activity needs exploration.
Objectives: To determine correlation of CD19 count defining B cell depletion and disease activity with different dosages of bRTX treatment.
Methods: Between April 2019 and March 2020, all RA patients with DMARD failure were screened for eligibility of biologics as routine clinical practice. Depending on individual choice, after full consent, patients received either 1000mgx2 or 500mgx2 bRTX. All patients had CD19 count before and 12 months after the first dose. Effectiveness of bRTX 1000 mg×2 and 500 mg×2 was assessed by DAS28 and EULAR response. Comparative adjusted analysis was performed by analysis of variance (ANOVA).
Results: Out of 468 eligible patient, 84 opted for biologic. Of which 27 patients consented for bRTX (17 female, mean age 39.5 years).13 patients opted for 1000mg×2 and 14 for 500mg×2 dose. 74% (20/27) patients were on concomitant methotrexate and 26% on hydroxychloroquine (7/27). Both doses led to significant reduction in ESR, CRP, and DAS28-ESR at 12 months (p<0.001) (Table 1).

Table 1. RA outcome-measurement scores at 12 months post biosimilar Rituximab therapy.

Variable	Baseline		12 months	
	RTX 1000mg x 2(n=13)	RTX 500mg x 2(n=14)	RTX 1000mg x 2(n=13)	RTX 500mg x 2(n=14)
ESR*	53.9±23.9	57.1±24.7	23.9±2.9	24.1±4.7
CRP*	6.1±3.9	6.9±2.9	2.1±0.9	2.3±0.9
DAS28-ESR*	6.1±0.3	6.1±0.2	4.0±0.4	4.1±0.2
CD 19+ Count*# (10^5/L)	1191.6±308.4	1155±289.6	128.8±90.4	139±90.6

* p<0.0001 as compared to 12 mos vs baseline; # p<0.0001 as compared amongst group

At the end of 12 months, compared to 1000mg, CD19 count was higher in 500mg group (p=0.25). Percentage of patients achieving EULAR moderate or no response was higher in 500mg group (37%vs29%, p=0.205), both complete and incomplete B cell depletion, but patients achieving good response was same in both groups (14.8%vs18.5%, p = 0.25). (Figure 1).

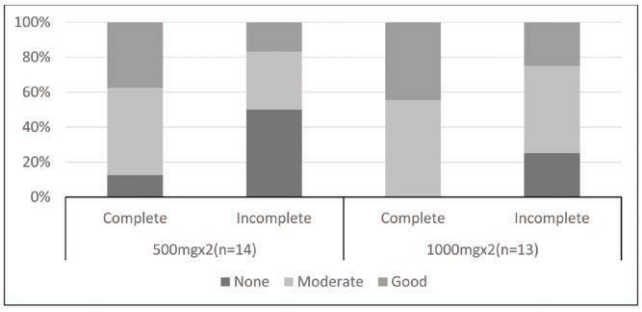

Figure 1. EULAR Response at 12 months

Conclusion: Low dose bRTX is effective in DMARD refractory RA patients with similar improvements as regular dose, although CD19 depletion was less in low dose group. A larger study to establish radiographic regression with CD19 depletion and disease activity score can help in further strengthening the use of lower dose bRTX in RA leading to significant economic advantage.

AB0224 SUSTAINABLE LOW DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: REAL-WORLD EXPERIENCE WITH TOCILIZUMAB

T. Shivacheva[1], T. Georgiev[1], S. Hristova[1], S. Dimitrov[1], S. Bogdanova-Petrova[1], G. Gerganov[2]. *[1]medical University "Prof. Dr. P. Stoyanov"- Varna, UMHAT "St. Marina", First Department of Internal Diseases, Clinic of Rheumatology, Varna, Bulgaria; [2]medical University "Prof. Dr. P. Stoyanov"- Varna, UMHAT "St.Marina", Department of Propaedeutics of Internal Medicine, Varna, Bulgaria*

Background: Sustainability, the ability of drugs to maintain remission or low disease activity (LDA) in patients with rheumatoid arthritis (RA), plays a crucial role for the prevention of structural damage to joints and thus, preserving patients' functional capacity, health-related quality of life and general sense of well-being. Therefore, studying the sustainable effectiveness of tocilizumab (TCZ) as a monotherapy or combined with methotrexate (MTX) is important (1).

Objectives: We aimed to examine to what extend TCZ, alone or combined with MTX, could achieve and further sustain LDA in patients with long-standing RA in the light of current, strictly index-based definitions of LDA and to compare the two versions of DAS28 in patients in real clinical practice

Methods: 85 RA patients treated with TCZ for at least eighteen months were consecutively enrolled in the present single-center, retrospective cohort study. All participants met the 1987 ACR classification criteria and attended the rheumatology department of University Hospital "St. Marina" Varna in an outpatient setting. Patients receiving pre-filled syringe contained 162 mg TCZ once weekly subcutaneously. Real-world data were extracted and analyzed from patient's full medical file. For each visit, disease activity score 28 with ESR and CRP (DAS28-ESR and DAS28-CRP) and simple disease activity index (SDAI) were calculated simultaneously according to generally adopted formulas. A twelve-month result was determined for sustained LDA at each of the patient's three visits (at 6-month intervals), according to DAS28 and SDAI. Descriptive statistics, Chi square test, Cochran´s Q test, kappa statistic were used, a binary logistics model was compiled to study the impact. Significance level of $p < 0.05$.

Results: Two hundred fifty-five patient visits were analyzed. The mean durations of RA and treatment with TCZ were 12.6 (±9.6) years and 3.64 (±1.8) years, respectively. The mean age of patients was 60.3 years (37-87 years), 80% were women, 24.7% were obese, 65.9% have concomitant hypertension. 61.2% of patients are treated with combination therapy TCZ with MTX.

Of all patients, these with a sustained 12-month LDA were 41.2%, 28.2% or 23.5% depending on the studied index (DAS28-CRP, SDAI, or DAS28-ESR, respectively).

A 12-month SDAI LDA was found in a significantly small proportion of patients (28.2%, p = 0.001). The DAS28 ESR determined a proportion similar to SDAI (23.5%, p> 0.05), while according to the DAS28 CRP, patients with a sustained 12-month LDA were significantly more (41.2% p = 0.005). A moderate level of agreement was found between the assessments of SDAI and the two variants of DAC28 when determining 12-month results of Tocilizumab treatment (DAS28-ESR k = 0.511, p <0.001 and DAC28-CRP k = 0.618, p <0.001). No relationship was found between the combination of TCZ with MTX and the patients' chance of a sustained 12-month LDA, regardless of which index the result was measured.

Patients with hypertension were significantly less likely to have sustained 12-month LDA according to SDAI and DAS 28 ESR (OR 0.135, 95% CI 0.048-0.386; OR 0.313, 95% CI 0.111-0.882, respectively), but not according to DAS28 CRP.

Conclusion: Sustained 12- month LDA with TCZ in patients with long-term RA remains uncommon in daily clinical practice. Co-administration of MTX is not associated with an increased likelihood of achieving a sustained LDA in the analysis of long-term responses. Patients with concomitant hypertension are less likely to be in a sustained 12-month LDA, according to SDAI and DAS28-ESR. The results according to DAS28 ESR, but not according to DAS28CRP are comparable to those of SDAI when measuring long-term results of treatment with TCZ.

AB0225 TUMOR NECROSIS FACTOR ALPHA (TNF-α) INHIBITORS IN PATIENTS WITH REFRACTORY RHEUMATOID ARTHRITIS: REASONS FOR WITHDRAWAL

V. Sygyrta[1], E. Aronova[1], A. Lila[1], S. Glukhova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Antirheumatic Drugs Safety Monitoring Laboratories, Moscow, Russian Federation*

Background: Refractory rheumatoid arthritis (RRA) is a subtype of rheumatoid arthritis (RA), in which the sequential administration of optimal methotrexate doses in combination with glucocorticoids, and at least - two biologic disease-modifying antirheumatic drugs (bDMARDs) with different mechanisms of action during 18-24 months does not lead to a significant decrease in the inflammatory activity of RA.

Objectives: to determine the reasons for the withdrawal of TNF-α inhibitors in patients with RRA.

Methods: The retrospective study included data of 95 RRA patients (80 females, 80.8%), aged 23 to 80 years (mean age 57 years), treated with TNF-α inhibitors. Mean RA duration was 11.9±7.6 years. All patients were divided into 6 groups depending on the number of the lines of therapy received. A total of 154 cases of TNF-α were studied.

Results: Infliximab (INF) was most often prescribed as the first line of therapy - 40 prescriptions. The reasons for the withdrawal of INF as the first bDMARDs were: insufficient effectiveness (IE) - 20 cases (50% of appointments), administrative reasons (AdmR) - 13 cases (32.5% of appointments), adverse reactions (AR) - 6 cases (15% of appointments), remission - 1 case (2.5% of appointments). In the 2nd line of therapy, INF was prescribed in only 3 cases, the drug was canceled in all cases due to IE. In 3 lines of therapy, INF was prescribed in 4 cases, the reasons for withdrawal in these cases were IE (50%, 2 cases) and AR (50%, 2 cases).

Etanercept (ETC) was prescribed as the first line of therapy in 10 cases. The most common reason for withdrawal was IE in 5 cases (50% of appointments), AR - 4 cases (40%), AdmR - 1 case (10%). ETC was prescribed as a 2 line in 15 cases, the reasons for withdrawal then were: IE - 11 cases (73.3%), AR - 1 case (6.7%), AdmR - 3 cases (20%). ETC was prescribed as a 3-line therapy in 20 cases. The reasons for withdrawal were as follows: IE - 8 cases (40%), AR - 4 cases (20%), AdmR - 8 cases (40%). As a drug of 4 lines of therapy, ETC was prescribed 1 time and was canceled due to the development of AR. As the 5th line, ETC was appointed in 1 case and was canceled due to IE. ETC was assigned as line 6 in 1 case. The reason for the withdrawal was AR.

Adalimumab (ADA) was prescribed as the first line of therapy in 19 cases, the reasons for withdrawal were: IE - 14 cases (73.7%), AR - 2 cases (10.5%), AdmR - 3 (15.8%). On line 2, ADA made 20 appointments, the reasons for withdrawal were: IE - 13 (65%), AR - 3 (15%), AdmR - 4 (20%). ADA was prescribed as

line 3 in 8 cases, the reasons for withdrawal were: IE - 6 (75%), AR - 1 (12.5%), AdmR - 1 (12.5%). As a 4-line drug, ADA was prescribed in 4 cases and was canceled in all cases due to IE. On line 5, ADA was assigned 1 time and was discontinuation due to IE.

Golimumab (GLM). He was appointed as the first line in 5 cases. The reasons for withdrawal were: IE - 1 case (20%), AdmR - 4 appointments (80%). As a 2-line drug, GLM was prescribed once and was canceled due to AdmR. The drug was not prescribed for the 3rd and 4th lines. As a 5-line therapy, it was prescribed once and was canceled due to IE.

When assessing the frequency of drug withdrawal due to IE or AR, no significant differences were found between the lines of therapy. Discontinuation rates were also not statistically different in the study groups.

Conclusion: The most common reason for the withdrawal of TNF-α in patients with RRA is IE. With an increase in the lines of TNF-α therapy, remission as a reason for withdrawal was not identified. As a result of the increase in the number of sequentially prescribed bDMARDs, the frequency of discontinuation of TNF-α in connection with IE did not decrease. A significant reason for cancellation is AdmR, to which we attributed the absence of the drug in the pharmacy network, financial reasons limiting the continuation o

AB0226 EVALUATION OF RITUXIMAB EFFICACY WITH VARIOUS COMPOSITE MEASURES OF INFLAMMATORY ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Olyunin[1], D. Kusevich[2], E. Nasonov[3,4]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Early Arthritis, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation*; *[3]V.A. Nasonova Research Institute of Rheumatology, Scientific Supervisor, Moscow, Russian Federation*; *[4]I.M. Sechenov First Moscow State Medical University, Ministry of Health of Russia (Sechenov University), Department of Therapy and Occupational Diseases, Moscow, Russian Federation*

Background: Disease modifying anti-rheumatic drugs (DMARD) can provide an unbalanced effect on individual components of the inflammatory process, which in some cases leads to an insufficiently correct assessment of the patient's status when using composite activity indices [1].

Objectives: To compare the results of the rituximab (RTX) efficacy assessment in patients with rheumatoid arthritis (RA) using different composite indices of disease activity.

Methods: Patients with active RA observed in 23 medical centers of the Russian Federation were included. They were randomized into 2 groups in a 2:1 ratio. In the main group methotrexate (MTX) was prescribed at 15 mg per week and RTX infusions 600 mg on days 1 and 15. Patients in the control group received MTX 15 mg per week and placebo on days 1 and 15. If after 15 weeks 20% reduction of tender joint count (TJC) and swollen joint count (SJC) was not achieved, another DMARD was prescribed.

Results: 159 RA patients (131 women and 18 men) were included. The mean age of patients was 51.4±11.8 years, the median duration of RA – 2.8 [0.6; 5.8] years. At baseline DAS28, SDAI and CDAI in all cases assessed disease activity as high. 6 months after RTX administration DAS28 showed remission in 9%, low, moderate and high activity activity in 7%, 47% and 37% of cases, SDAI – in 7%, 12%, 34% and 47%, CDAI – in 7%, 11%, 30% and 52%, respectively. In the control group remission, low, moderate and high activity by DAS28 were revealed in 2%, 2%, 38% and 58%, by SDAI – in 2%, 4%, 35%, 59%, by CDAI – in 2%, 6%, 29%, 63% of patients respectively. After 6 months, in patients achieved the treatment target (remission or low activity) according to DAS28, SJC in 12 cases was 0, in 3 – 1 and in 1 – 2. TJC was 0 in 9 cases and in 7 patients ranged from 1 to 14. The level of C-reactive protein (CRP) in 14 cases was within the normal range and in 2 – increased. Erythrocyte sedimentation rate (ESR) was normal in all cases. SDAI after 6 months showed the target activity in 18 patients treated with RTX. In 12 of them the SJC was 0, in 4 – 1 and in 2 – 2. In 9 cases TJC was 0, in the rest patients it varied from 2 to 5. The level of CRP was normal in 15 patients, ESR – in all patients. CDAI met the target activity in 17 patients. In 12 of them, SJC was 0, in 3 – 1, in 2 – 2. The level of CRP was normal in 14, ESR – in all patients.

Conclusion: Assessment of RTX efficacy with DAS28, SDAI, and CDAI in RA provided comparable number of patients who achieved remission or low disease activity 6 months after administration of the drug. The groups of patients who reached this target level of activity by DAS28, SDAI, and CDAI did not have significant differences in the values of main measures characterizing residual inflammatory activity, including SJC, TJC, ESR, and CRP.

AB0227 SAFETY AND EFFECTIVENESS OF ADALIMUMAB REFERENCE PRODUCT AND BIOSIMILAR IN PATIENTS WITH INFLAMMATORY ARTHROPATHIES

W. G. Rojas Zuleta[1], O. J. Felipe Díaz[1], C. Orozco Gonzalez[2], J. Barbosa Camacho[2], C. L. Giraldo Herrera[1], J. G. Ballesteros[1], J. H. Donado Gómez[2], N. Duque Zapata[2]on behalf of Medicarte Research Group. *[1]Medicarte SAS, Rheumatology, Medellin, Colombia*; *[2]Medicarte SAS, Research, Medellin, Colombia*

Background: Biological therapy revolutionized the treatment and prognosis of inflammatory arthropathies; however, its high cost has an economic impact on health system and limits its access. Biosimilars are products with similar molecular structure, equivalent efficacy, and comparable safety and immunogenicity, which arise as a necessity to reduce costs. Although, their long-term safety is still to be confirmed[1].

Objectives: Our aim is to compare the safety and effectiveness between adalimumab reference product and biosimilar in patients with inflammatory arthropathies.

Methods: Cohort study of 92 patients with ankylosing spondylitis (AS), rheumatoid arthritis (RA) and psoriatic arthritis (PsA) in a specialized multicenter health institution in Colombia. Ratio of incidence rates (IR) for Adverse Drug Reactions (ADR) and therapeutic failure (TF) is estimated among patients exposed to reference product and biosimilar. 95% confidence interval (CI) for the ratio is also calculated. ADR and TF Incidences in both groups were calculated using the Kaplan Meier curve.

Results: Between October 2019 and October of 2020, 92 patients started adalimumab, 64% (n = 59) reference product and 36% (n = 33) biosimilar (18 naive and 15 switch). 41.3% of patients had a diagnosis of RA, 35% AS and 24% PAs. Additionally, 62% were women, with median age of 53 years (Interquartile Range (IQR): 41-62); disease evolution time of 9 years (IQR: 5-20); and treatment time of 0.8 years (IQR: 0.4-1.04). No statistically significant differences were found according to the drug between diagnosis, evolution time, or disease activity. Of all patients 21 presented ADR; 11 events with reference product (IR 0.18 per 100 person-years), and 10 with biosimilar (IR 0.30 per 100 person-years), IR ratio of 0.61 (95%CI 0.26-1.44; p-value = 0.36). From ADR reactions, 35% were infections, 13% skin disorders and 7.4% hepatobiliary disorders; all were classified as non-serious ADR. 5 TF events were presented, 3 with reference product (IR 0.05 per 100 person-years) and 2 with biosimilar (IR 0.06 per 100 person-years); IR ratio of 0.83 (95% CI 0.09-10.04; p value= 1.00). There was no statistically significant between reference product and biosimilar in time of ADR presentation (Log Rank Test 0.74; p= 0.39) or on TF (Log Rank Test 0.55; p= 0.45).

Conclusion: Results shown that analyzed biosimilar is a safe product with a similar rate of ADR and without differences in effectiveness evaluated by TF, although 95% CIs are imprecise. This suggests that use of biosimilars in a real-life setting could be safe and with similar effectiveness, which is correlated with other studies carried out in RA and is an appropriate measure to reduce treatment costs in patients with inflammatory arthropathy.

AB0228 LONG-TERM EFFECTIVENESS, DRUG SURVIVAL OF BIOLOGIC THERAPIES IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS AND PREDICTIVE FACTORS OF DRUG DISCONTINUATION DUE TO DISEASE REMISSION

K. Preedeekanit[1], A. Koolvisoot[2]. *[1]Faculty of Medicine Siriraj Hospital, Mahidol University, Department of Medicine, Bangkok, Thailand*; *[2]Faculty of Medicine*

Table 1. Effectiveness, Drug Survival and Causes of Biologic Discontinuation in RA and SpA

RA % (87 cases)

Biologics	Total % (N)	5-year Remission rate %	5-year Drug survival rate %	Discontinuation % (N 53 cases)					
				Total % (53)	Remission	Inadequate response	Side effect	Non-adherence/ Refer	Death
Etanercept	49.4 (43)	23.9	33.6	50.9(27)	14.8(4)	44.4(12)	22.2(6)	11.1(3)	7.4(2)*
Infliximab	5.7 (5)		36	5.7 (3)	0(0)	33.3(1)	33.3(1)	33.3(1)	(0)
Rituximab	44.8 (39)		40.7	43.4 (23)	56.5(13)	17.4(4)	4.3(1)	13.0(3)	8.7(2)
SpA %(49 cases)									
Biologics	Total % (N)	5-year Remission rate %	Drug survival rate %	Discontinuation % (N 23 cases)					
				Total % (23)	Remission	Inadequate response	Side effect	Non-adherence/ Refer	Death
Etanercept	83.6 (41)	66.7	50.3	78.3(18)	22.2(4)	22.2(4)	33.3(6)	22.2(4)	0(0)
Infliximab	16.4 (8)		0	21.7 (5)	20(1)	20(1)	40(2)	20(1)	0(0)

**Cause of death: sudden cardiac death (1), intraabdominal infection (1)*
Cause of death: pneumonia (1), Lung cancer (1)

Siriraj Hospital, Mahidol University, Division of Rheumatology, Department of Medicine, Bangkok, Thailand

Background: Rheumatoid arthritis (RA) and spondyloarthropathies (SpA) are chronic rheumatic diseases that can progress to disability if left uncontrolled. Biologic therapies can induce remission in patients with inadequate response or intolerance to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs). Due to the safety and economic concern, updated treatment recommendations now consider biologics discontinuation in patients with persistent remission. However, available data are still limited.
Objectives: To evaluate the biologics effectivenss, drug survival, rate of discontinuation in real-life practice and to identify predictors of biologics discontinuation due to remission in RA and SpA.
Methods: A total of 87 patients with RA and 49 patients with SpA, starting biologics between January 2005 and October 2020, were recruited from the Rheumatic Disease Prior Authorization (RDPA) registry of Siriraj hospital. Baseline data were recorded. Time-dependent rates in achieving remission were calculated. Cumulative probability of biologics discontinuation and predictive factors of drug discontinuation due to remission were analyzed.
