POS0044 T315 SUPPRESSES OSTEOGENIC DIFFERENTIATION IN SAOS-2 CELLS BY INHIBITING PHOSPHORYLATION OF AKT

Z. Huang[1], X. Huang[1], Y. Huang[1], Z. Li[1], Q. Huang[1], T. Li[1]. [1]Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China

Background: New bone formation is common in the late stage of various inflammatory arthritis, while osteoblasts play a vital role in this process. Activation of PI3K/ Akt pathway promotes the differentiation and enhances the function of osteoblasts [1]. T315 is a novel small molecule drug, which may induce apoptosis and suppress the expression of cellular markers of chronic lymphocytic leukemia cells by disrupting PI3K/ Akt pathway [2]. However, the lack of study focuses on the influence of T31T on the other cells, except tumor cell lines.
Objectives: We aimed to assess the effect of T315 on human osteoblast-like Saos-2 cells, while its potential mechanism in PI3K/ Akt pathway was evaluated as well.
Methods: (1) Saos-2 was stimulated with an osteogenic reagent which contained L-ascorbic acid, β-glycerophosphoric acid, and dexamethasone. The concentration of T315 was adjusted to 0μg/ml, 1μg/ml, and 2μg/ml in the culture medium. (2) Alizarin red stain and alkaline phosphatase (ALP) stain were performed at d0, d7, d14, and d21 after being treated with T315. (3) Cellular protein was extracted at d0, d3, and d6 after being treated with T315, then ALP activity was tested based on a recommendation from the manufacturer of the kit. (4) Collagen type 1α2 Chain (Col1α2) and osteocalcin (OCN), two osteogenic markers, were measured through western blot, with glyceraldehyde 3-phosphate dehydrogenase (GAPDH) as an endogenous control. (5) Phospho-phosphoinositide 3-kinase (pPI3K), phospho-protein kinase B (pAkt), and runt-related transcription factor 2 (Runx2) was tested through western blot as well. GAPDH or protein kinase (Akt) was chosen as an internal reference as appropriate. (6) Analysis of variance with the least significant difference was used to analyze the data. A $P<0.05$ was considered statistically significant.
Results: (1) The higher concentration of T315 related to the less relative mineralized area and the positive area of ALP, while longer incubation time with T315 decreased these regions as well (Figure 1A-C). (2) T315 reduced the activity of ALP accordingly (Figure 1D). (3) T315 suppressed the protein expression of Col1α2 and OCN in a dose-dependent and time-dependent manner (Figure 1E, F). (4) T315 did not alter pPI3K, but it inhibited the phosphorylation of Akt (Figure 1G, H). (5) Runx2 was reduced because of the greater dose or longer incubation time with T315 (Figure 1).
Conclusion: T315 inhibits the differentiation of osteoblasts through inhibiting the phosphorylation of Akt. Surprisingly, pPI3K seldom changes in this process, so its detail mechanism should be investigated in further.

POS0045 LEAST SIGNIFICANT CHANGE IN BONE DENSITOMETRY IN PATIENTS WITH OBESITY

D. Claire[1], M. Geoffroy[1], L. Kanagaratnam[2], C. Isabelle[1], A. Hittinger[1], B. Loïs[1], C. Clément[1], J. H. Salmon[1]. [1]Centre Hospitalier Universitaire de Reims, Rheumatology, Reims, France; [2]Centre Hospitalier Universitaire de Reims, Unité d'aide méthologique, Reims, France

Background: Dual energy X-ray absoprtiometry is the reference method to mesure bone mineral density (1). Loss of bone mineral density is significant if it exceeds the least significant change. The threshold value used in general population is 0,03 g/cm^2 (2). Patients with obesity are known for having a higher bone mineral density due to metabolism and physiopathology characteristics (3,4).
Objectives: The aim of our study was to determine the least significant change in bone densitometry in patients with obesity.
Methods: We conducted an interventionnal study in 120 patients with obesity who performed a bone densitometry. We measured twice the bone mineral density at the lumbar spine, the femoral neck and the total hip in the same time (5,6). We determined the least significant change in bone densitometry from each pair of measurements, using the Bland and Altman method. We also determined the least significant change in bone densitometry according to each stage of obesity.
Results: The least significant change in bone densitometry in patients with obesity is 0,046g/cm^2 at the lumbar spine, 0.069 g/cm^2 at the femoral neck and 0.06 g/cm^2 at the total hip.

Conclusion: The least significant change in bone densitometry in patients with obesity is higher than in general population. These results may improve DXA interpretation in this specific population, and may personnalize their medical care.

POS0046 MICRO-CT ANALYSIS OF SACROILIAC JOINT AS A NEW TOOL FOR STUDYING TRABECULAR BONE AND OSTEO-ARTICULAR LESIONS IN MURINE MODELS

S. Hilliquin[1,2], V. Zhukouskaya[1,3,4], O. Fogel[2], C. Chaussain[1,4,5], C. Miceli Richard[2], C. Bardet[1]. [1]Université de Paris, Dental School, and Plateforme d'Imagerie du Vivant (PIV), Laboratory Orofacial Pathologies, Imaging and Biotherapies, URP2496 and FHU-DDS-Net, Montrouge, France; [2]Université de Paris, Department of Rheumatology, Cochin Hospital, Paris, France; [3]Université d'Evry, Université Paris-Saclay, Evry, France, INTEGRARE, Genethon, Inserm, Evry, France; [4]Hôpital de Bicêtre, Centre de référence des maladies rares du métabolisme du calcium et du phosphate, Plateforme d'expertise maladies rares Paris Saclay, filière OSCAR, EndoRare and BOND ERN, Le Kremlin-Bicêtre, France; [5]Bretonneau Hospital, GHN, AP-HP Reference Center for Rare Disorders of the Calcium and Phosphate Metabolism, Dental Medicine Department, PARIS, France

Background: Skeletal disorders affect the skeleton in different ways with some bones being very impaired while others less severely. In translational studies using murine models of human disorders, the bone phenotype is mainly evaluated at distal femur or proximal tibia. The sacroiliac joint (SIJ), which connects the spine to the pelvis, is involved in the balanced transfer of mechanical energy from the lumbar spine to the lower extremities. Its role in biomechanical stress makes it of particular interest in various bone diseases. For instance, patients with X-linked hypophosphatemia (XLH), who mainly display osteomalacia, are frequently affected with early osteoarthritis of the SIJ. Interestingly, we recently showed that the *Hyp* mouse, a murine model of XLH that greatly mimics the human disorder, displayed early and severe osteoarticular alterations of the SIJ [1].

Objectives: Here, using the *Hyp* mouse as a model, we show that the SIJ constitutes a highly reliable joint to investigate in murine models of skeletal disorders.

Methods: SIJ and distal femur were evaluated in 3-month-old *Hyp* mice compared to wild-type (WT) mice (n=10 per group). using high-resolution microCT. Measurements of trabecular and cortical bone parameters at sacral and iliac sides and trabecular bone parameters at distal femur were performed with the CTanalyzer software.

Results: *Hyp* mice displayed a significant reduction in parameters of trabecular bone at distal femur, compared to WT mice (Figure 1A). Similarly, a reduction in trabecular bone was shown in *Hyp* SIJ compared to WT at sacral side (Figure 1B). There was a significant positive correlation between trabecular bone parameters of distal femur and sacral side of SIJ in *Hyp* mice (e.g. bone volume to total volume [BV/TV]: r = 0,763 p: 0,01). Bone parameters such as sacral BV/TV were higher in comparison to femoral parameters (Figure 1C). No difference was observed on trabecular bone parameters at iliac side of Hyp and WT mice. However, regarding the cortical bone of SIJ, significant alterations were noticed especially at iliac side of SIJ in *Hyp* mice compared to WT mice. An increase in open cortical porosity, and a decrease in cortical area fraction, as well as in average cortical thickness at iliac side of SIJ in *Hyp* mice were suggestive of osteo-articular lesions, characteristic for XLH.

Conclusion: Trabecular bone parameters at the SIJ, in comparison to the femur, appear to be a relevant alternative to evaluate bone alterations in *Hyp* mice. Our study suggests that the SIJ represents a valuable tool to investigate both bone and local osteo-articular alterations for murine models of skeletal disorders.

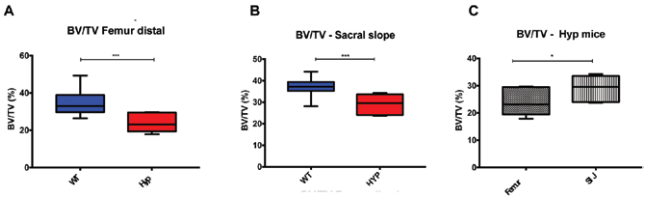

Figure 1. A) Bone to total volume ratio in the trabecular bone of distal femur, expressed in percent. **B)** Bone to total volume ratio in the trabecular bone of sacral slope of the SIJ, expressed in percent. **C)** Bone to total volume ratio in the trabecular bone of distal femur and sacral slope of the SIJ of *Hyp* mice, expressed in percent. *: p < 0,05; **: p < 0,01; ***: p< 0,001; ****: p< 0,0001.

New Developments in COVID research

POS0047 OUTCOMES IN INFLAMMATORY ARTHROPATHY PATIENTS HOSPITALIZED FOR COVID-19

T. Collins[1], V. Patel[1], A. Babajanians[2], S. Kubomoto[3]. [1]Riverside Community Hospital, Internal Medicine, Riverside, United States of America; [2]Riverside Medical Clinic, Rheumatology, Riverside, United States of America; [3]Riverside Community Hospital, Graduate Medication Education, Internal Medicine, Riverside, United States of America

Background: Covid 19 is a new and rapidly spreading corona virus which has reached pandemic proportions. As of 5/22/20 there are 5.08 million confirmed cases and 332,000 deaths worldwide. Primary manifestations are respiratory, with a subset developing severe hypoxic respiratory failure. Several risk factors predispose patients to worse outcomes including age, obesity, hypertension, chronic kidney disease, COPD, asthma, CHF, and diabetes. This is a retrospective cohort analysis of patients with Rheumatoid arthritis, Ankylosing spondylitis, or Psoriatic arthritis who were hospitalized for COVID-19 infection across 165 HCA hospitals from 1/1/2020 to 5/30/2020. We compared endpoints and calculated odds of ICU admission, invasive ventilation, mortality compared to control as well as length of stay and discharge location.

Objectives: Our objectives include measuring the outcome of Patients in two arms, the first being those with Rheumatoid arthritis, Ankylosing spondylitis, and Psoriatic arthritis who are infected with COVID 19 to an age matched and comorbidity matched arm (using the Charlson comorbidity index) for the composite endpoint of ICU admission, invasive ventilation, and death. We believe the inflammatory arthropathy arm will have a worse composite endpoint then the control arm. we will also attempt to calculate a hazard ratio of this arm vs the control to the composite endpoint. We will also examine the length of stay as well as inflammatory markers mentioned in between the two arms. We suspect initial inflammatory markers will be lower in the inflammatory arthropathy arm, particularly CRP and LDH, due to chronic immune modulating medication and these markers will not correlate as closely with severe illness represented by the composite endpoint as in the control arm.

Methods: We analyzed 86,217 patients admitted with COVID-19 comparing 751 patients who had inflammatory arthropathy to patients who did not. T tests were used for parametric outcome and chi square tests for non-parametric outcomes. Multivariate analysis included potential confounders such as age, and comorbidities such as diabetes, heart disease, etc.

Results: The odds ratio for mortality in the arthropathy arm was 1.37 with a confidence interval of 1.09 to 1.71 with a p value of 0.006. The odds ratio for ventilation was 1.35 with CI of 1.09 to 1.67 and p value of 0.006. The odds ratio of ICU admission was 1.46 with CI of 1.24 to 1.72 and P value of 0.000. The average length of stay of the arthropathy arm was 8.51 days +/- 10.02 vs 4.59 days +/- 8.26 of the control, p < 0.001. The discharge disposition of the arthropathy arm vs control group is as follows, 13.32% died inpatient vs 5.87% in the control, 56.72% were discharged home vs 77.19%, 6.79% went to hospice care vs 3.10%, 4.79% remained inpatient at the end of the study interval vs 3.45%, 17.18% were discharged to rehab vs 8.43%, and other discharges not included in the above groupings were 1.2% vs 1.96%, p<0.001. 31.29% of the arthropathy

group required ICU admission vs 16.32% and 13.98% required ventilation vs 6.9%, p <0.001. The average age was higher in the arthropathy arm vs control at 66.56 years old vs 51.53, p <0.001. Charlson comorbidity index was also higher in the arthropathy arm at 2.72 vs 0.96, p <0.001.

Conclusion: This is a large analysis of inflammatory arthropathy patients hospitalized with COVID-19. While the arthropathy group was older, and had more co-morbidities, when adjusting for potential confounders, inflammatory arthropathy patients had a higher risk of death and mechanical ventilation, as well as longer length of stay.

POS0048 SEROPREVALENCE OF ANTI-SARS-COV-2 ANTIBODIES IN RHEUMATIC PATIENTS TREATED WITH BIOLOGICAL AND TARGETED THERAPY LIVING IN LOMBARDY, ITALY (MAINSTREAM PROJECT)

E. G. Favalli[1], G. Maioli[1], M. Bombaci[2], M. Biggioggero[1], A. Favalli[2], E. Agape[1], G. Andrea[2], E. Pesce[2], E. Zagato[2], T. Fabbris[2], M. Martinovic[2], E. Marchisio[3], S. Abrignani[2,4], R. Grifantini[2], R. Caporali[1,5]. [1]ASST Gaetano Pini-CTO Institute, Division of Clinical Rheumatology, Milan, Italy; [2]Istituto Nazionale Genetica Molecolare, Padiglione Romeo ed Enrica Invernizzi, Milan, Italy; [3] Dia.Pro, Diagnostic Bioprobes srl, Milan, Italy; [4]Università degli Studi di Milano, Department of Clinical Sciences and Community Health, Milan, Italy; [5]Università degli Studi di Milano, Department of Clinical Sciences and Community Health, Research Center for Adult and Pediatric Rheumatic Diseases, Milan, Italy

Background: Emerging observational data have shown that rheumatic patients seem not to be more susceptible to SARS-CoV-2 infection neither to worse outcomes. However, the true prevalence of COVID19 is still unknown due to the high proportion of subclinical infection. In this scenario, measuring the seroprevalence of SARS-CoV-2 may be crucial to improve the knowledge about the impact of COVID19 in rheumatic patients.

Objectives: To estimate in a COVID19 high-endemic area (Lombardy, Italy) the prevalence of anti-SARS-CoV-2 antibodies in a large cohort of patients with rheumatoid arthritis (RA) or spondyloarthritis (SpA) treated with biologic (b-) or targeted synthetic (ts-) disease modifying drugs (DMARDs).

Methods: A seroprevalence cross-sectional study was conducted in the period between 4th May and 16th June 2020, including patients with confirmed RA or SpA treated with b- or tsDMARDs. Patients were tested for anti-SARS-CoV-2 IgG, IgM and IgA antibodies against main viral antigens (nucleoprotein [N], spike 1 [S1], receptor-binding domain [RBD]) using ELISA. These data were compared with those observed in the healthy population in the same period and region. Patients also answered a questionnaire on history of symptoms consistent with COVID19, risk factors and comorbidities. Serological response to RBD was evaluated according to symptom severity (asymptomatic, minor, or major [respiratory and fever >37.5°C] symptoms).

Results: The study population included 300 patients (62% females, mean age 53 years, 20% over 65 years old) diagnosed with RA (56%), psoriatic arthritis (23%), or ankylosing spondylitis (21%), treated with anti-TNF (57%), abatacept (20%), anti-IL6 (11%), or JAK inhibitors (5%). Four patients (1.3%) referred a prior diagnosis of COVID19 defined by nasopharyngeal swab. Immunoglobulin titers were evaluated resulting in 9%, 13.6%, and 13.3% positive patients for IgG, IgM and IgA, respectively (Table 1), with no significant difference to the healthy population. Among seropositive patients, 55.3% were asymptomatic, 16% had minor and 19.6% major symptoms, 7.1% were hospitalized. No deaths or admission to intensive care units occurred. IgM, IgG and IgA titers to RBD were higher in patients with both minor and major symptoms compared with asymptomatic ones (Figure 1). No differences were found between seronegative and seropositive patients in relation to age, sex, rheumatic diagnosis, and treatments with b- or tsDMARDs. A relative lower risk of seropositivity was observed in patients receiving concomitant methotrexate (RR 0.49, 95% CI 0.25-0.94; p 0.04), while an increased risk was associated with obesity (RR 2.33, 95% CI 1.26-3.79; p 0.019) and presence of at least 2 comorbidities (RR 1.94, 95% CI 1.11-3.15; p 0.037). Corticosteroids use was numerically more frequent in seropositive than seronegative patients (18% vs 14%).

Conclusion: This study confirms that, even in a cohort of rheumatic patients, the spread of SARS-CoV-2 infection is much greater than that observed by capturing only swab-diagnosed COVID19 cases. The underlying rheumatic disease and ongoing therapy with b/ts-DMARDs do not seem to impact SARS-CoV-2 antibody positivity, which conversely seems to be proportional to the intensity of COVID19 symptoms and less frequent in patients receiving concomitant methotrexate. The project was co-financed by Lombardy Region 2014-2020 Regional Operational Programme under the European Regional Development Fund.

Table 1. Prevalence of specific anti-SARS-CoV-2 antibodies.

Antibodies	Posivite(n)	Seroprevalence (%)	(95% CI)
IgG	27	9%	(6.2 – 12.7)
IgG anti-N	26	8.6%	(5.9 – 12.3)
IgG anti-RBD	20	6.6%	(4.3 – 10)
IgG anti-S1	18	6%	(3.8 – 9.2)
IgM	41	13.6%	(10.2 – 18)
IgM anti-N	35	11.6%	(8.5 – 15.7)
IgM anti-RBD	25	8.3%	(5.7 – 12)
IgA	40	13.3%	(9.9 – 17.6)
IgA anti-N	37	12.3%	(9.0 – 16.5)
IgA anti-RBD	25	8.3%	(5.7 – 12)
IgG+IgM	23	7.6%	(5.1 – 11.2)
IgG+IgM+IgA	22	7.3%	(4.9 – 10.5)
IgG+IgA	24	8%	(5.4 – 11.6)
IgG/IgM/IgA	56	18.6%	(14.6 – 23.4)

POS0049 SARS-COV-2 INFECTION IN CHILDREN WITH RHEUMATIC DISEASE: EXPERIENCE OF A TERTIARY REFERRAL CENTER

B. Sözeri[1], F. Demir[1], S. Kalın[2], C. Hasbal Akkuş[3]. [1]İstanbul Health Sciences University, Umraniye Training and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey; [2]İstanbul Health Sciences University, Umraniye Training and Research Hospital, Pediatric Radiology, Istanbul, Turkey; [3]İstanbul Health Sciences University, Umraniye Training and Research Hospital, Pediatrics, Istanbul, Turkey

Background: Patients with rheumatic diseases are considered at risk for serious infections due to their immune-compromised-status set in their primary systemic disease and the usage of immune-modulating therapies. Although various results have been reported on the subject, it is still unknown whether patients with rheumatic disease, many of whom are on immune-suppression, are at higher risk of severe COVID-19.

Objectives: We aim to share our clinical SARS-CoV-2 experience in patient with the childhood rheumatic disease during pandemic.

Methods: We evaluated 4470 patients at our pediatric-rheumatology clinic during the pandemic, from 11-March to 15-October-2020. Demographic and clinical features, treatments, laboratory results, imaging findings, and clinical outcomes of patients diagnosed with COVID-19 and/or multisystem inflammatory syndrome (MIS-C) were review from the medical records. The data of all these patients were compared between groups and presented. A p-value <0.05 was considered statistically significant.

Results: Among 4470 patients, 87 COVID-19 suspected patients were included in the study. Fifty six (64.4%) patients were hospitalized and 31 were followed without hospitalization. The most common rheumatic diseases among them were juvenile idiopathic arthritis and familial Mediterranean fever (35.6% and 34.5%). The primary disease status of these patients were; 78 (89.6%) were in remission, while 9 (10.3%) had active disease at the time of COVID-19 diagnosis. Twenty six of these patients were treated with biologic DMARDs. SARS-CoV-2 infection (RT-PCR and/or antibody test) was found positive in 84 patients (96.5%). Also, fifty one (58.6%) patients had an epidemiologic contact to a person with COVID-19. Fifty six of 87 (64.3%) had a fever and 20 (23%) had a fever for five or more days. Gastrointestinal system involvement was in 11 (12.6%), the respiratory system was in 40 (46%) and fatigue was in 57 (65.5%) patients. Cutaneous involvement was seen in 5 patients including maculopapular rash in two, vasculitic rash in two, and chilblain in one patient. 63.2% of patients had increased C-reactive protein (CRP), 40.2% had lymphocytopenia (<1500/mm3) and 26.4 % had elevated D-dimer

level. SARS-CoV-2 infection was confirmed in 84 patients (96.5%). The diagnosis was confirmed by RT-PCR in 74 patients and by antibody test in 10. 18 patients met the clinical criteria and diagnosed with MIS-C. Nine of them had also hypotension and seven patients admitted the intensive care unit because of shock and severe end-organ illness. COVID-19 outbreak also caused exacerbation of systemic disease in 56 children due to a discontinue of medication, postponed drug switch, or viral infection triggered.

Conclusion: In conclusion, children with rheumatic disease do not appear to present a higher risk of severe COVID-19. Whether these patients receive biological treatment does not affect the severity of the disease, but it is still not true to say that these drugs are protective. The immunosuppressive treatments can be adjusted in case of infection, otherwise it is not recommended interrupt the treatments. Physicians should be cautious about the hyperinflammatory syndrome associated with COVID-19 in rheumatic children, which may be severe in this group of patients and may be confused with primary diseases.

POS0050 ARE PATIENTS WITH IMMUNE MEDIATED INFLAMMATORY DISEASES (IMID) MORE LIKELY TO RECEIVE COVID-19 TESTS AND TEST POSITIVE FOR SARS-COV-2? A MATCHED POPULATION-BASED STUDY

L. Eder[1,2], R. Croxford[3], A. Drucker[2,4], A. Mendel[5], K. Bindee[4,6], Z. Touma[4,7], S. Johnson[4,7], R. Cook[8], S. Bernatsky[5], N. Haroon[1,7], J. Widdifield[3,4,9].
[1]University of Toronto - St. George Campus, Medicine and Institute of Medical Science, Toronto, Canada; [2]Women's College Hospital, Medicine, Toronto, Canada; [3]ICES, NA, Toronto, Canada; [4]University of Toronto - St. George Campus, Medicine and Institute of Health Policy Management and Evaluation, Toronto, Canada; [5]McGill University, Medicine, Montréal, Canada; [6]Sinai Health System, Medicine, Toronto, Canada; [7]Toronto Western Hospital, Medicine, Toronto, Canada; [8]University of Waterloo, Biostatistics, Waterloo, Canada; [9]Sunnybrook Health Sciences Centre, Research Institute, Toronto, Canada

Background: Population-based data about the COVID-19 risk in patients with IMID remain scarce.

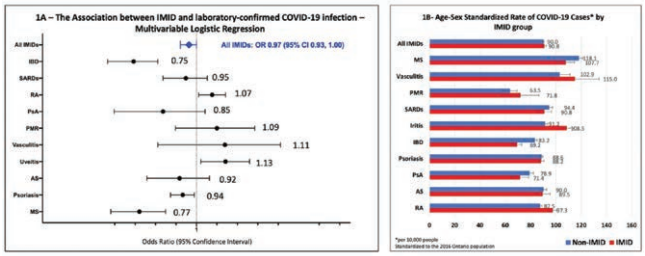
Objectives: To investigate the cumulative incidence and risk factors for laboratory-confirmed COVID-19 infection and SARS-CoV2 testing in patients with IMID compared with matched non-IMID patients from the general population.

Methods: A population-based, matched cohort study was conducted using health administrative data from adults living in Ontario, Canada from January to December 2020. Cohorts for each of the following IMID were assembled: rheumatoid arthritis (RA), psoriasis, psoriatic arthritis, ankylosing spondylitis, systemic autoimmune rheumatic diseases (including lupus, systemic sclerosis, Sjogren's, inflammatory myositis), multiple sclerosis (MS), iritis, inflammatory bowel disease (IBD), polymyalgia rheumatica (PMR) and vasculitis. Each patient was matched with 5 non-IMID comparators based on age, sex, area of residence and living in long term care (LTC). Standardized cumulative rates of testing for SARS-CoV2, and for receiving a positive test between IMID and non-IMID were compared between IMID and non-IMID patients. Multivariable logistic regression analyses assessed sociodemographic factors associated with COVID-19 testing and positivity.

Results: A total of 493,499 IMID patients and 2,466,946 non-IMID comparators were assessed. Significantly more IMID patients versus non-IMID were tested for SARS-CoV2 (27.4% vs. 22.7%), while the proportions of those positive for COVID-19 were identical (0.9% of all patients in both groups). Overall, IMID patients were more likely to undergo SARS-CoV2 testing (odds ratio (OR) 1.28, 95% CI 1.27, 1.29), but their overall risk of laboratory-confirmed COVID-19 was not elevated (OR 0.97 (95% CI 0.93, 1)). However, the risk of laboratory-confirmed COVID-19 infection was lower in IBD (OR 0.75), MS (OR 0.77) and psoriasis (OR 0.94) and marginally higher in RA (OR 1.07) and iritis (OR 1.13) compared with non-IMID comparators (Figure 1A). The highest standardized rates of COVID-19 infection were found in vasculitis (115 per 10,000 patients) and iritis (109 per 10,000 patients) (Figure 1B). Risk factors for COVID-19 infection included younger age, living in LTC, multimorbidity, urban living and lower income (Table 1).

Conclusion: Patients across all IMID were more likely to be tested for COVID-19 versus non-IMID patients. IMID patients were not at higher risk for testing positive for COVID-19 as an overall group, yet risk varied across disease subgroups.

Figure 1 – Laboratory confirmed COVID-19 Risk in IMID vs. Non-IMID by multivariable regression analysis (1A) and standardized cumulative incidence (1B)



AS – ankylosing spondylitis; IBD – inflammatory bowel disease; MS – multiple sclerosis; PsA - Psoriatic Arthritis; PMR – polymyalgia rheumatica; RA- Rheumatoid arthritis; SARDs – systemic autoimmune rheumatic disease;

Table 1. Factors associated with COVID-19 infection in IMID vs. Non-IMID – Multivariable Logistic Regression

Variable	OR	CI 95%
IMID vs. Non-IMID	0.97	0.93, 1.00
Age (10-year increase)	0.89	0.89, 0.90
Sex: Female vs. Males	0.95	0.93, 0.97
LTC	18.64	17.9, 19.42
ADG score:		
•5-9 vs. 0-4	1.40	1.35, 1.45
•10-14 vs. 0-4	1.73	1.67, 1.80
•15+ vs. 0-4	1.18	1.13, 1.23
Urban vs. Rural	3.49	3.26, 3.72
Income quintile		
•Quintile 2 vs. 1	0.92	0.89, 0.96
•Quintile 3 vs. 1	0.90	0.86, 0.93
•Quintile 4 vs. 1	0.73	0.70, 0.76
•Quintile 5 vs. 1	0.60	0.58, 0.63

ADG - Aggregated Diagnosis Groups; IMIDs – Immune medicated inflammatory disease; LTC – long term care

Background: The COVID-19 pandemic has disrupted healthcare delivery and education of physicians, including rheumatology trainees.
Objectives: To assess the impact of the COVID-19 pandemic on the clinical experiences, research opportunities, and well-being of rheumatology trainees.
Methods: A voluntary, anonymous, web-based survey was administered in English, Spanish, or French from 19/08/2020 to 05/10/2020. Adult and paediatric rheumatology trainees worldwide in training in 2020 were invited to participate via social media and email. Using multiple choice questions, Likert scales, and free text answers, we assessed trainee patient care activities, redeployment, research, and well-being.
Results: The 302 respondents were from 33 countries, with most (83%, 252/302) in adult rheumatology training. Many trainees (45%, 135/300) reported an increase in non-rheumatology clinical work (e.g. care of COVID-19 patients), with 52% of these (70/135) also continuing rheumatology clinical work. COVID-19 redeployment was not optional for 68% (91/134).
Trainees reported a negative impact of the pandemic in their growth in rheumatology (Figure 1). They also reported a substantial impact on several training areas: outpatient clinics (79%, 238/302), inpatient consultations (59%, 177/302), formal teaching (55%, 167/302), procedures (53%, 147/302), teaching opportunities (52%, 157/302), and ultrasonography (36%, 110/302), with 87-96% perceiving a negative impact on these areas. Only 54% (159/294) reported feeling comfortable with their level of clinical supervision during the pandemic (Figure 1). Many trainees (46%, 128/280) reported changes in research experiences during the pandemic; 39% (110/285) reported that COVID-19 negatively affected their ability to continue their pre-pandemic research and 50% (142/285) reported difficulty maintaining research goals (Figure 1).
Some rheumatology trainees reported having health condition(s) putting them at high risk for COVID-19 (10%, 30/302) and 14% of trainees (41/302) reported having had COVID-19 (Table 1). Only 53% (160/302) reported feeling physically safe in the workplace while 25% (76/302) reported not feeling physically safe; reasons included lack of training about COVID-19, lack of comfort in the clinical setting, insufficient personal protective equipment, immunocompromised state, and pregnancy. Half (151/302) reported burnout and 68% (204/302) an increase in stress from work during the pandemic (Figure 1), whilst 25% (75/302) reported that changes to their training programme negatively impacted their physical health.
Conclusion: The COVID-19 pandemic has negatively impacted the experience of rheumatology training as well as the well-being of trainees globally. Our data highlight concerns for rheumatology trainees including research opportunities and clinical care which should be a focus for curriculum planning.

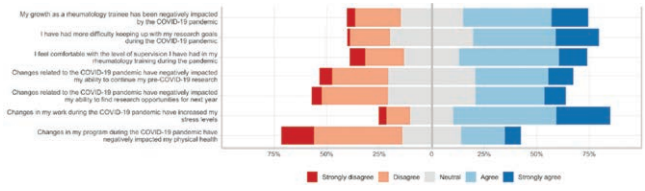

Figure 1. Rheumatology trainee perceptions of pandemic impact and changes in training programme.

Table 1. Rheumatology trainees reporting health vulnerabilities or having acquired COVID-19. Data is presented as n (%). Rest of the world (ROW) data includes the United States (116), Asia (50), Central and South America (23), Canada (12), Australia (8), and Africa (4).

	Europe n = 89	ROW n = 213	Combined n = 302
Disability	1 (1)	9 (4)	10 (3)
High risk	7 (8)	23 (11)	30 (10)

POS0052 PATHOPHYSIOLOGY OF ACUTE RESPIRATORY SYNDROME CORONAVIRUS 2 INFECTION: A SYSTEMATIC LITERATURE REVIEW TO INFORM EULAR POINTS TO CONSIDER

A. Najm[1], A. Alunno[2], X. Mariette[3], B. Terrier[4], G. De Marco[5], L. Mason[6], J. Emmel[6], D. Mcgonagle[5], P. M. Machado[7]on behalf of EULAR Task Force on pathophysiology and use of immunomodulatory therapies in COVID-19..
[1]Institute of Infection, Immunity and Inflammation, College of Medical Veterinary and Life Sciences, Rheumatology, Glasgow, United Kingdom; [2]University of Perugia, Rheumatology, Perugia, Italy; [3]Paris-Saclay University, Rheumatology, Paris, France; [4]University of Paris, Assistance Publique-Hôpitaux de Paris, Cochin Hospital, INSERM U970, Paris, France; [5]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Rheumatology, Leeds, United Kingdom; [6]Library & Evidence Research Centre, Leeds Teaching Hospitals NHS Trust, Medical Education, Leeds, United Kingdom; [7]Centre for Rheumatology & Department of Neuromuscular Diseases, University College London, Rheumatology, London, UK, United Kingdom

Background: The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic is a global health problem. Beside the specific pathogenic effect of SARS-CoV-2, incompletely understood deleterious and aberrant host immune responses play critical roles in severe disease. Rheumatologists have the best experience of studying and treating these complicated hyperinflammatory processes.
Objectives: To summarize the available information on pathophysiology of COVID-19.
Methods: As part of a EULAR taskforce, two systematic literature reviews were performed one on pathophysiology and one on immunomodulatory therapies. Two reviewers independently identified eligible studies according to the following PICO framework: P (population): patients with SARS-CoV-2 infection; I (intervention): any intervention/no intervention; C (comparator): any comparator; O (outcome) any clinical or serological outcome including but not limited to immune cell phenotype and function and serum cytokine concentration. The results pertaining to pathophysiology of COVID-19 are presented here.
Results: Of the 55496 records yielded, 85 articles were eligible for inclusion. Included studies were at variable risk of bias and exploring various aspects of disease pathogenesis from immune to non-immune cells (Table 1). Pro-inflammatory cytokines' expression including IL-6, was increased, especially in severe COVID-19, although not as high as other states with severe systemic inflammation. Innate and adaptative immune cell compartments were differentially affected by SARS-CoV-2 infection: neutrophils displayed an immature differentiation state and also increased neutrophil extracellular traps (NETs) formation. Dendritic cell number was reduced and classical monocytes was increased although displaying a reduced expression of HLA-DR. The lymphoid compartment was also affected: lymphopenia was present with a reduced number of CD4+ and CD8+ T lymphocytes and more frequent PD1+CD8+ T cells corresponding to an exhausted phenotype. Antibody response to SARS-CoV-2 infection showed a high variability across individuals and disease spectrum. Multiparametric algorithms showed variable diagnostic performances in predicting survival, hospitalization, disease progression or severity, and mortality. Differences in SARS-CoV-2 manifestations in adults and children were highlighted.
Conclusion: Overall, SARS-CoV-2 infection affects both innate and adaptative immune responses in a variable way, according to both disease severity and individual parameters. This SLR informs the EULAR points to consider on pathophysiology and use of immunomodulatory therapies in COVID-19.

POS0053

RHEUMATOID ARTHRITIS AND THE RISK OF COVID-19 DIAGNOSIS, HOSPITALISATION AND DEATH: A POPULATION-BASED MULTI-STATE COHORT ANALYSIS INCLUDING 5,586,565 PEOPLE IN CATALONIA, SPAIN

A. Vivekanantham[1,2], E. Burn[1,3], S. Fernandez-Bertolin3, M. Aragon3, T. Duarte-Salles3, D. Prieto-Alhambra[1,4]. *[1]University of Oxford, Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, Oxford, United Kingdom; [2]Nuffield Orthopaedic Centre, Rheumatology, Oxford, United Kingdom; [3]Fundació Institut Universitari per a la recerca a l'Atenció Primària de Salut Jordi Gol i Gurina, (IDIAPJGol), Barcelona, Spain; [4]Erasmus University Medical Center, Health Data Sciences, Rotterdam, Netherlands*

Background: The COVID-19 pandemic caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) virus is of particular concern for people with rheumatoid arthritis (RA), with concerns that these people may be at higher risk and have poorer outcomes. However, at present the implications of COVID-19 for people with RA remain poorly understood.

Objectives: To investigate the associations between rheumatoid arthritis and the risk of COVID-19 diagnosis, hospitalisation with COVID-19 and COVID-19-related death.

Methods: A population-based cohort study including all individuals registered in the Information System for Research in Primary Care (SIDIAP). SIDIAP includes primary care records covering over 80% of the population of Catalonia, Spain, and was linked to region-wide SARS-CoV-2 PCR testing, hospital and mortality records. Outpatient diagnoses of COVID-19, hospitalisations with COVID-19 and deaths with COVID-19 were identified as study outcomes between 1st March and 6th May 2020. A multi-state model was used, with cause-specific Cox survival models estimated for each transition, adjusted for age and sex.

Results: A total of 5,586,565 individuals were identified in SIDIAP as of the 1st March 2020, of which 16,344 had RA. RA patients were median (IQR) 63 years (52.0, 74.0) and the majority (n=11,727, 71.8%) were female. Having RA was positively associated with being diagnosed with COVID-19 (adjusted HR 1.14 (1.03 to 1.28)), with hospitalisation with COVID-19 (HR 1.66 (1.35 to 2.04)). However, we did not find an association between RA status and the risk of worsening from outpatient diagnosis to hospitalization or death, or from hospitalization to death (see Table 1).

Table 1. Estimated hazard ratios, adjusted for age and gender, for individuals with rheumatoid arthritis

Transition	Study population (RA), n	Total events (RA), n	Hazard Ratios (95% Confidence Intervals)
From general population to diagnosed with COVID-19	5,586,565 (16,344)	88,396 (324)	1.14 (1.03 to 1.28)
From general population to hospitalised with COVID-19	5,586,565 (16,344)	10,143 (90)	1.66 (1.35 to 2.04)
From diagnosed with COVID-19 to hospitalised with COVID-19	88,396 (324)	5,946 (30)	0.95 (0.66 to 1.36)
From diagnosed with COVID-19 to death	88,396 (324)	2,295 (16)	0.96 (0.58 to 1.56)
From hospitalised with COVID-19 to death	16,089 (120)	2,602 (27)	1.13 (0.77 to 1.64)

Conclusion: To our knowledge, this is the largest study performed to date looking at COVID-19 outcomes in RA patients. Individuals with RA were found to have an increased risk of COVID-19 diagnosis and hospitalisation with COVID-19, compared to the general population. Further research is needed to address factors associated with this including the presence of other co-morbidities, underlying RA disease activity and the use of immunosuppressive medications.

Disclosure of Interests: Arani Vivekanantham: None declared, Edward Burn: None declared, Sergio Fernandez-Bertolin: None declared, Maria Aragon: None declared, Talita Duarte-Salles: None declared, Daniel Prieto-Alhambra Grant/research support from: Dr. Prieto-Alhambra reports grants and other from AMGEN, grants, non-financial support and other from UCB Biopharma, grants from Les Laboratoires Servier, outside the submitted work; and Janssen, on behalf of IMI-funded EHDEN and EMIF consortiums, and Synapse Management Partners have supported training programmes organised by DPA's department and open for external participants.

Policlinico S. Marco, Rheumatology, Catania, Italy; [14]Cochin Hospital, Université de Paris, Rheumatology, Paris, France; [15]University of California in Los Angeles, Rheumatology, Los Angeles, United States of America; [16]University of Florence, Rheumatology, Florence, Italy; [17]Università Politecnica delle Marche, Scienze Cliniche e Molecolari, Ancona, Italy

Background: Coronavirus disease-19 (COVID-19) has been a major clinical challenge worldwide. Sex, age and comorbidities have been associated with worse outcome in the general population. Systemic sclerosis (SSc) is a severe, autoimmune disease with frequent multi-organ involvement.

Objectives: To assess the impact of COVID-19 and to determine factors associated with worse outcome in SSc patients from the European Scleroderma Trial and Research (EUSTAR) database.

Methods: SSc patients from the EUSTAR database with COVID-19 were prospectively collected between 15.03.-31.12.2020. Two outcomes were chosen: (1) hospitalization; and (2) severe outcome defined as either non-invasive ventilation, mechanical ventilation/extracorporeal membrane oxygenation (ECMO) or death. General risk factors assessed were sex, age and number

of comorbidities. SSc related risk factors were SSc subtype, autoantibodies, disease duration, SSc associated organ manifestations including interstitial lung disease (ILD), pulmonary arterial hypertension (PAH), cardiac, gastrointestinal (GI), and musculoskeletal involvement; digital ulcers (DU), CRP at last visit, renal disease (scleroderma renal crisis and SSc associated renal insufficiency), modified Rodnan skin score (mRSS) and immunosuppressive treatment. Descriptive statistics and logistic regression models were applied.

Results: In total, 178 European SSc patients with COVID-19 were registered with a median observation time of 5.5 weeks (Table 1). 95 patients (53%) could recall SAR-Cov-2 contact, while 47 (26%) had no contact. 156 (88%) were symptomatic at COVID-19 onset with fever, cough, malaise and dyspnea being most prevalent. Over the disease course, 63 (36%) developed pneumonia. In total, 67/176 (38%) were hospitalized which were in 84% due to COVID-19. 41/170 (24%) had a severe outcome including 21 (12%) deaths. 128 (72%) recovered completely, while 14 (8%) complained of sequela, with 7 (50%) stating respiratory complications. Age, non-SSc comorbidities, presence of ILD, PAH and SSc associated renal or cardiac disease were numerically associated with hospitalization and severe outcome (Table 1). Univariable logistic analyses for hospitalization and severe outcome are shown in Figure 1. In multivariable logistic regression, age (OR 1.03, 95%CI 1.01-1.07, p=0.019), presence of non-SSc comorbidities (OR 2.52, 95%CI 1.16-5.47, p=0.019) and SSc-related renal disease (predicting success perfectly) were associated with hospitalization and for severe outcome age (OR 1.05, 95%CI 1.01-1.08).

Conclusion: SSc patients at older age, with non-SSc comorbidities, SSc related renal disease or ILD are at risk of a more severe outcome and should follow precautions to avoid COVID-19 infections and need careful monitoring in case of COVID-19.

Table 1. SSc disease characteristics of COVID-19 patients

	All (n=172)	Hospitalized (n=67)	Severe outcome (n=41)

Gossec[8,9]. *[1]University Hospitals Pitié Salpêtrière - Charles Foix, Département de Médecine Interne et Immunologie Clinique, Centre National de Références Maladies Autoimmunes systémiques rares, Centre National de Références Maladies Autoinflammatoires et Amylose Inflammatoire, Paris, France; [2]Ruhr-Universität Bochum, Rheumazentrum Ruhrgebiet, Bochum, Germany; [3]Centro Hospitalar e Universitário de Coimbra, Rheumatology Department, Coimbra, Portugal; [4]Hospital de Santa Maria, Rheumatology Department, Lisboa, Portugal; [5]Gregorio Marañón Hospital, Rheumatology, Madrid, Spain; [6]University of Ferrara, Department of Medical Sciences, Ferrara, Italy; [7]Northwick Park Hospital, Department of Rheumatology, London, United Kingdom; [8]University Hospitals Pitié Salpêtrière - Charles Foix, Rheumatology Department, Paris, France; [9]Pierre Louis Institute of Epidemiology and Public Health, Inserm UMR 1136, PEPITES team, Paris, France; [10]Hospital Saint-Louis, URC Saint-Louis, Paris, France*

Background: Coronavirus disease 2019 (COVID-19), has raised several questions in patients with immune-mediated inflammatory diseases (IMID). Whether the seroprevalence and factors associated with symptomatic COVID-19 are similar in IMID patients and in the general population is still unknown.

Objectives: To assess the serological and clinical prevalence of COVID-19 in European IMID patients, along with the factors associated with its risk and the impacts the pandemic had on the IMID management.

Methods: Prospective multicentre cross-sectional study among patients with five IMID (i.e. systemic lupus erythematous, Sjögren's syndrome, rheumatoid arthritis, axial spondylarthritis or giant cell arteritis) from six tertiary-referral centers from France, Germany, Italy, Portugal, Spain and United Kingdom. Demographics, comorbidities, IMID, treatments, flares and COVID-19 details were collected. Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) serological tests were systematically performed.

Results: Between June 7 and December 8, 2020, 3028 patients were included (median age 58 years, 73.9% females). SARS-CoV-2 antibodies were detected in 166 (5.5%) patients. Symptomatic COVID-19 was seen in 122 patients (prevalence: 4.0%, 95% CI 3.4-4.8%); 23 (24.2%) of them were hospitalized and four (3.2%) died. In multivariate logistic regression analysis, symptomatic COVID-19 was more likely to be observed in patients with higher levels of C-reactive protein (OR: 1.18; 95% CI 1.05-1.33; p = 0.006), and increased with the number of IMID flares (OR: 1.27; 95% CI 1.02-1.58; p = 0.03). Conversely, it was less likely to occur in patients treated with biological therapy (OR: 0.51; 95% CI 0.32-0.82; p = 0.006). During the pandemic, at least one self-reported disease flare was seen in 654 (21.6%) patients. Also, 519 (20.6%) patients experienced changes in their treatment, with 125 of these (24.1%) being due to COVID-19.

Conclusion: The SARS-CoV-2 prevalence in IMID patients over the study period seems to be similar to that of the general population[1]. The IMID inflammatory status seems to be independently associated with the development of COVID-19.

POS0056 ANXIETY AND CONCERNS RELATED TO THE WORK SITUATION DURING THE COVID-19 PANDEMIC IN >5,000 PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASE FOLLOWED IN THE DANISH DANBIO REGISTRY, RESULTS FROM A NATIONWIDE QUESTIONNAIRE

B. Glintborg[1], D. V. Jensen[2], S. Engel[1], L. Terslev[1], M. Pfeiffer Jensen[1], O. Hendricks[3], M. Østergaard[1], S. H. Rasmussen[1], T. Adelsten[4], A. Colic[4], K. Danebod[1], M. Kildemand[5], A. G. Loft[6], H. L. Munk[7], J. K. Pedersen[8], R. Østgård[9], C. M. Sørensen[10], N. Steen Krogh[11], J. Nørgaard Agerbo[12], C. Ziegler[12], M. L. Hetland[1]. Background: During the COVID-19 pandemic, widespread changes in how we work have been observed. Working from home is not an option for everyone. At work it may be difficult to keep social distance, which may lead to fear and anxiety of being infected with SARS-CoV-19 or of spreading the virus.

Objectives: To explore frequency of anxiety and concerns related to work in patients with inflammatory rheumatic diseases(IRD) during the COVID-19 pandemic and to identify patient and disease characteristics associated with increased anxiety.

Methods: Patients in routine care followed in the nationwide Danish DANBIO registry were invited to answer an on-line questionnaire regarding current rheumatic disease activity, behavior and anxiety including current work-status and -concerns. Responses were linked to patient data previously recorded in DANBIO. Clinical factors associated with work-related concerns (completely/mostly agree versus neither/nor, completely/mostly disagree) were explored with multivariable logistic regression.

Results: Among 14,758 respondents (38% of eligible patients), 5,950 patients (40%) were currently working (60% full time/31% part time/9% self-employed) (61% female, 53% rheumatoid arthritis/19% psoriatic arthritis/20% axial spondyloarthritis/9% other). Although 68% reported that the workplace helped to make necessary interventions, work-related concerns and anxiety were frequent. Thus, 22% found it difficult (completely/mostly agree) to keep physical distance at work and 20% were worried about going to work (Figure 1).

Factors associated with concerns about going to work were female gender, longer education, other chronic conditions, biological therapy, and higher (=poorer) EQ-5D, whereas diagnosis was without significance. Similar patterns were found for other work-related concerns (not shown).

Conclusion: In this cohort of >5,000 patients with inflammatory rheumatic diseases followed in a nationwide registry, during the COVID-19 pandemic anxiety and concerns related to the work situation were frequent, especially in women and patients treated with biologicals, with other chronic diseases and with poor quality of life.

PARE Poster Tour

POS0057-PARE SUMMARY OF PATIENT/PARENT ORGANISATION SERVICES PROMOTING SELF- AND SHARED-MANAGEMENT OF JIA IN THE UK AND IRELAND

S. Stones[1], V. Swallow[2], L. Milnes[1]. [1]University of Leeds, School of Healthcare, Leeds, United Kingdom; [2]Sheffield Hallam University, Department of Nursing & Midwifery, Sheffield, United Kingdom

Background: Various patient/parent organisations provide information, education, and support services to children and young people with JIA and their families. Some organisations are JIA/uveitis focused, while others are umbrella rheumatic and musculoskeletal disease (RMD) organisations or have a broader remit to long-term conditions (LTCs). However, there are no summaries of such collective services offered in the UK and Ireland, which can add to confusion for children, young people, and families, while contributing to inconsistent signposting to services from healthcare professionals.
Objectives: To summarise current and recent services promoting self- and shared-management of JIA by patient/parent organisations in the UK and Ireland.
Methods: An electronic search of known patient/parent organisation platforms (website and/or social networking sites) was performed between August 2020 and January 2021. Materials provided at conference exhibitions since October 2016 were also reviewed. Services were identified, including their aims and further details, if available. These were then mapped by format (*e.g.,* educational, telemedicine, art therapy) and element (*e.g.,* informational videos, monitoring through self-report diaries, discussing art and related feelings), according to their mode of delivery (individual or group), adapted from Sattoe et al. (2015) [1].
Results: Twelve patient/parent organisations in the UK and Ireland were identified (11 of which had some form of charity/company registration): seven were JIA-specific, one was uveitis-specific, two were RMD-focused, and two were LTC-focused. In total, 48 services were identified across the twelve organisations. Generally, group mode of delivery was more popular than individual mode of delivery. Of group-based services, educational and/or support sessions and residential/excursion programmes were the most frequently observed. Of individual-based services, educational sessions including written and visual information were predominant. No one organisation provided services across all formats and elements identified. There appeared to be a limited focus on goal setting, individual level skills training, and explicitly improving self-and/or shared-management capacity. Gamification techniques were notably absent, as was the use of psychotherapeutic approaches, such as cognitive behavioural therapy and motivational interviewing.
Conclusion: Various services are offered by multiple patient/parent organisations with an interest in JIA across the UK and Ireland to promote self- and shared-management. However, no single organisation provides a comprehensive package of services to address the entire information, education, and support needs of children and young people with JIA, or their families. Furthermore, clarity of services offered across the sector is poor. Enhanced collaboration between organisations, together with a clearer focus on enhancing self- and shared-management of JIA across the lifecourse, may help to improve the offering to children, young people, and their families, so that they can more competently manage JIA.

POS0058-PARE INCREASING PREECLAMPSIA KNOWLEDGE IN SLE WITH A SPECIFIC EDUCATIONAL TOOL: PRELIMINARY RESULTS

J. Y. E. Lee[1], A. Mendel[2], I. Malhamé[3], S. Bernatsky[2], E. Vinet[2]. [1]McGill University, Experimental Medicine, Montréal, Canada; [2]McGill University Health Centre, Department of Medicine, Division of Rheumatology, Montreal, Canada; [3]McGill University Health Centre, Department of Medicine, Division of General Internal Medicine, Montreal, Canada

Background: Pregnant women with systemic lupus erythematosus (SLE) are at high risk of preeclampsia, leading to substantial maternal and fetal morbidity. Aspirin reduces preeclampsia risk but recent studies suggest aspirin is used only in a minority of SLE pregnancies. There is an urgent need to improve preeclampsia counselling and management in this vulnerable population.
Objectives: We are conducting the PREPARE (PREeclamPsia knowledge & Aspirin adheRence in lupus prEgnancies) trial, a randomized controlled trial (RCT) evaluating an educational tool on preeclampsia knowledge and aspirin adherence among pregnant women with SLE. We present preliminary analyses of the effect of this tool on preeclampsia knowledge.
Methods: Consecutive pregnant SLE women are recruited until the 16th gestational week at 5
Canadian Systemic Lupus International Collaborating Clinics centres (i.e. Montreal, Halifax, Quebec, Winnipeg, and Calgary) since 05/2018. Subjects are randomly assigned to receive either the specifically-designed educational tool (intervention group) or standard of care (control group). At baseline (i.e. first trimester) and second trimester visits, the participants complete self-administered preeclampsia knowledge questionnaires (scored out of 30 by the research team blinded to the intervention). We restricted the current analysis to participants enrolled in Montreal (accounting for nearly half of the total planned sample size). We performed a univariate linear regression analysis to assess the effect of the educational tool on preeclampsia knowledge (i.e. mean score difference between the two groups from baseline to second trimester visit).
Results: Thirty-three pregnant SLE women were included in the study, among which 16 were exposed to the intervention and 17 were unexposed. Baseline characteristics were well balanced between the two groups with similar mean maternal age between intervention group (32.2 years, standard deviation, SD, 4.6) and control group (34.1 years, SD 4.2) and identical proportion of subjects with post-secondary education (i.e. 80%). The difference in mean preeclampsia knowledge scores between second trimester and baseline visits in the intervention group was 4.4 points (95% CI -0.1, 9.0) and in the control group was 1.5 points (95% CI -2.7, 5.7). The mean difference in knowledge scores (from baseline to second trimester) for those receiving the educational tool was 2.7 points higher (95% CI -1.5, 6.9) than those receiving standard of care.
Conclusion: Approximately midway into the PREPARE trial, we observed a trend for improvement in preeclampsia knowledge from the baseline to the second trimester visit in pregnant women with SLE who received a specifically-designed educational tool compared to the control group, although the CIs included the null. Our RCT is well-poised to provide a new evidence-based approach to improve preeclampsia knowledge in pregnant women with SLE, which could help to optimize aspirin use and outcomes in this vulnerable population.

POS0059-PARE DELAY TO DIAGNOSIS IN AXIAL SPONDYLOARTHRITIS – TIME FOR A GOLD STANDARD APPROACH

D. Webb[1], K. Gaffney[2], R. Sengupta[3], S. S. Zhao[4], L. Swingler[5]. [1]National Axial Spondyloarthritis Society, CEO, London, United Kingdom; [2]Norfolk & Norwich NHS Foundation Trust, Rheumatology, Norwich, United Kingdom; [3]Royal National Hospital for Rheumatic Disease, Rheumatology, Bath, United Kingdom; [4]University of Liverpool, Rheumatology, Liverpool, United Kingdom; [5]National Axial Spondyloarthritis Society, Service Improvement, London, United Kingdom

Background: In the UK, the average time to diagnosis of axial SpA is 8.5 years (1). There is little evidence this has improved, despite the acceptance of MRI use in diagnosis (2). A recent review identified significant clinical, economic and humanistic burden from delayed diagnosis (3). Urgent action is needed to ensure delayed diagnosis is not normalized.

Objectives: We created a proposal for a Gold Standard time to diagnosis for axial SpA and a national implementation plan (4) through consensus development with patients, healthcare professionals and professional bodies.
Methods: A.A scoping literature review identifying where delays occur, from first symptom onset to diagnosis by a rheumatologist, and potential solutions. From this, a summary report / draft plan was produced for consultation
B.A national consultation survey to elicit views on the proposals from clinicians, healthcare professionals, professional societies and patients
C.Structured feedback to written proposals via e-consultation with clinicians and patients
D.A consensus development workshop to finalise the Gold Standard and implementation plan.
Results: The literature review identified four delays:
1. People do not know axial SpA may be a cause of their chronic back pain
2. Primary care practitioners may not recognise features of axial SpA
3. People may be referred to non-rheumatologists who may not recognise axial SpA promptly
4. Rheumatology and radiology teams may not optimally request or interpret investigations.
202 participants responded to the summary report (74% patients, 21% healthcare professsionals, 5% professional societies). All supported the principles behind the gold standard time to diagnosis. Qualitive analysis confirmed agreement with the proposed solutions, underscoring the importance of education and visibility for axial SpA within primary care and increased public awareness. Additional proposals were suggested, including a tool in primary care to run audits on IT systems.
40 clinicians contributed to the e-consultation and 55 clinicians, policy makers, social marketing experts, health journalists and patients attended the consensus workshop. Consensus was reached on a gold standard time to diagnosis of one year, and the principles, key components and phasing of the implemention plan. This included: public awareness about axial SpA symptoms; a primary care clinical champions programme; creating a referral pathway from primary care direct to rheumatology; a secondary care service educational programme.
Conclusion: There is consensus from UK axial SpA clinicians, patients and professional societies on the need for a Gold Standard time to diagnosis of axial SpA of one year, so that patients can live happy, healthy and productive lives.

POS0060-PARE RHEUMATOID ARTHRITIS IN NORWAY: A SURVEY-BASED PATIENT EXPERIENCE

C. P. Fjellstad[1], M. Hägg[2], M. Kautonen[3], R. Mandla[4]. *[1]Norsk Revmatikerforbund, PAG, Oslo, Norway; [2]Nordic Healthcare Group Oy, Research, Helsinki, Finland; [3]Nordic Healthcare Group Oy, Service Design, Helsinki, Finland; [4]Pfizer, Medical Affairs, Oslo, Norway*

Background: The Norwegian Association of Rheumatologists has established a national procedure for management of rheumatoid arthritis (RA) in Norway.[1] The purpose of the procedure is to support equal and evidence-based diagnosis, care and follow-up of RA patients[1]. It serves as guidance to all responsible of RA patient health care. The procedure includes recognized themes in rheumatic care.[2,3] The impact of the procedure on RA care in Norway is, however, unknown.
Objectives: To understand the patient experience through evaluating how the national procedure for RA is being followed from the patient viewpoint. To identify gaps and areas of improvement to align the national procedure and patient experience.
Methods: Members of patient organization Norwegian Rheumatism Association were invited to answer a survey on demographic and disease-specific variables, perceived health and quality of care. The survey was supported by service design patient interviews (N=14). The invitations for interviews were sent through many initiatives for a representable population.
Results: The observational RA cohort constituted of N=374. The patients were on average satisfied with shared decision-making, care and follow-ups: 71 % felt their illness was under control. Patients in centralized areas were more satisfied with well-being. Diagnosis times have shortened from on average 1.7 to 1.5 year in 10 years. Patients, especially those working, were dissatisfied with rehab support. 30 % of patients felt cooperation of primary and secondary care was not satisfactory and 32 % were worried for future treatment.
Table 1 shows the differences in awareness of comorbidities and regular vaccination need. Where applicable, the table also shows the percentage of patients screened. The results show that patients are aware of risks, but are not being screened for the conditions. Younger patients (< 50 years) with symptoms for less than five years were generally less aware.

Table 1. Awareness of comorbidity and regular vaccination need

	Comorbidities						Regular vaccine need
	Heart disease		Lung disease		Osteoporosis		
	Awareness	Screened	Awareness	Screened	Awareness	Screened	Awareness

Disease onset							
Under 5 yrs	56 % (27/48)	19 % (9/48)	29 % (14/48)	20 % (10/49)	51 % (25/49)	21 % (10/48)	59 % (29/49)
Over 5 yrs	72 % (212/294)	36 % (106/294)	38 % (113/294)	26 % (77/293)	59 % (176/295)	44 % (131/295)	55 % (162/295)

The education of patients about regular vaccines (e.g. influenza and pneumonia) could be improved. Only 56 % were aware of the need for these vaccines due to RA. When asked specifically, 73 % of patients had received an influenza vaccine and 48 % pneumonia vaccine.

Conclusion: This survey examines quality of care, shared decision-making, disease awareness and planning and provides a gap analysis of patient experience and national procedure. The results show that national procedure in RA is being followed from the patient viewpoint. Patients are satisfied with care, but information on preventive care (e.g. vaccination and comorbidity awareness and screenings) could be strengthened. This could improve planning of care and the outlook, particularly for young patients.

POS0061-PARE **HOW DO THE COMPLICATIONS OF SPONDYLOARTHRITIS (SPA*) IMPACT THE QUALITY OF LIFE (QOL) OF PATIENTS LIVING WITH SPA?**

S. Patenaude[1], W. Gerhart[2]. [1]Canadian Spondylitis Association, Intern, Phelpston, Canada; [2]Canadian Spondylitis Association, Executive Director, Phelpston, Canada

Background: SpA describes a group of chronic inflammatory arthritic diseases with common features, including inflammation of the spine, eyes, skin and gastrointestinal tract. These conditions can be painful and debilitating for many. Delayed diagnosis and treatment can lead to irreversible damage to the spine and other joints. Diagnosis of these conditions can take, on average, 7 years or more. We don't know what causes SpA and there is no cure. The onset of symptoms can be in early childhood and expands throughout one's lifespan. It affects children, women and men worldwide.
Objectives: To understand how the complications of living with SpA impacts QOL as well as what is important to patients in order to help the CSA** prioritize advocacy focus and resource development.
Methods: The CSA surveyed the community virtually from 11/19/19 to 01/21/20. The results of 838 respondents were analyzed after the survey closed. 466 participants responded to the questions regarding complications.
Results: In total, participants had an average of 3.3 complications. Those living with ankylosing spondylitis experienced an average of 3.5 while those with psoriatic arthritis reported an average of 3.9.
Sleep issues (65%), chronic pain (63%), and combined depression and anxiety (56%) were the most prevalent conditions reported among participants. In addition, 23% said they live with inflammatory bowel disease. Other complications include uveitis, weight issues, migraine, vertebral disc herniations and hypertension.
Those who reported weight issues (over 44%) consequently had increased anxiety, depression and chronic pain compared to those without weight issues.
Over 65% reported experiencing sleep issues. Many (26%) said that nothing helps with their sleep. Others used cannabis (24%), prescribed sleeping pills (20%) and exercise (19%) to cope.
36% of participants said that they suffer from chronic fatigue syndrome. When asked how they manage their fatigue, the most common answer was exercise. Most participants said they have yet to find something that helps them efficiently manage their fatigue.
Over 400 people said they suffer from either depression or anxiety, or both. When asked how they cope with this, 40% said talking to loved ones. Exercise to cope was reported by 32% and 31% take prescription medication. Those who suffer from Psoriasis experienced a higher prevalence of anxiety and depression.
Conclusion: Overall, the presence of complications is an additional stressor to SpA patients. Many pointed out that the complications are sometimes more burdensome than the actual SpA condition and some patients even prioritize the management of the complications over the actual SpA condition. These complications can lead to increased trips to the physician resulting in more healthcare interventions and medications, causing frustration to patients.
Only 59% of respondents mentioned that their rheumatologist regularly asks them about additional complications such as depression, fatigue and gut issues. Many felt that their rheumatologist seems to be more concerned with pain management and continuing function and do not necessarily address other health concerns and complications, particularly mental health. Although these are often overlooked, it is clear that complications have a significant impact on patient health and overall QOL.
The CSA is committed to developing programs and resources to help patients manage all the complications commonly experienced to improve health outcomes and overall QOL.
It doesn't have to be visible to be real. Together we are stronger!

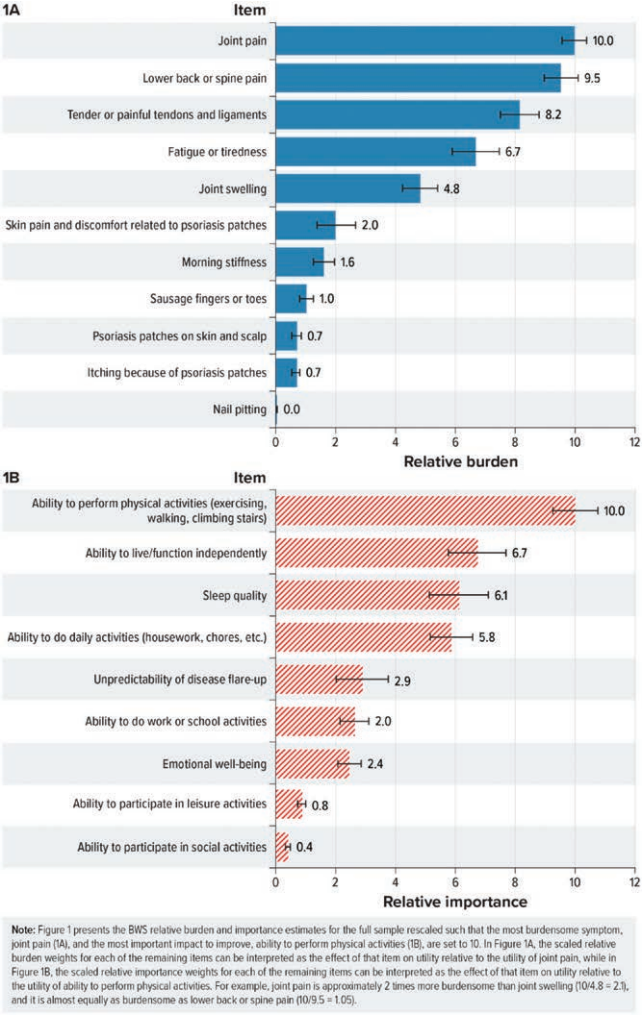
POS0062-PARE **REAL-WORLD PATIENT EXPERIENCE AND TREATMENT PREFERENCES IN PATIENTS WITH PSORIATIC ARTHRITIS**

A. Ogdie[1], C. Mansfield[2], K. Myers[2], W. Tillett[3], P. Nash[4], C. Leach[2], W. B. Nowell[5], K. Gavigan[6], P. Zueger[7], E. Mcdearmon-Blondell[8], J. A. Walsh[9,10]. [1]Perelman School of Medicine, University of Pennsylvania, Department of Medicine, Philadelphia, United States of America; [2]RTI Health Solutions, Health Preference Assessment, Research Triangle Park, United States of America; [3]Royal National Hospital for Rheumatic Diseases, Department of Rheumatology, Bath, United Kingdom; [4]Griffith University, Department of Medicine, Brisbane, Australia; [5]Global Healthy Living Foundation, Patient-Centered Research, Upper Nyack, United States of America; [6]Global Healthy Living Foundation, Research and Data Science, Upper Nyack, United States of America; [7]AbbVie, Global Rheumatology, Chicago, United States of America; [8]AbbVie, Global Medical Affairs, Chicago, United States of America; [9]University of Utah School of Medicine, Division of Rheumatology, Salt Lake City, United States of America; [10]George E. Wahlen Veteran Affairs Medical Center, Rheumatology, Salt Lake City, United States of America

Background: Despite recent advances in the treatment of psoriatic arthritis (PsA), many patients experience inadequate response or intolerance to therapy, indicating that unmet treatment-related needs remain. An understanding of patients' experience with PsA and its treatment is needed to bring the patient's perspective into treatment decision-making and development of new therapies.
Objectives: To better understand real-world PsA patients' experience with PsA via evaluation of (1) the burden and importance of common PsA symptoms and disease impacts and (2) treatment preferences.
Methods: A cross-sectional, web-based survey was developed, informed by published literature and treatment guidelines, expert clinical opinion, and cognitive debriefing interviews with PsA patients. Adults with a self-reported diagnosis of PsA were recruited from a US rheumatology patient-centered research registry and other online patient communities. Object case best-worst scaling (BWS) was used to evaluate the relative burden of 11 PsA-related symptoms and the relative importance of improvement in 9 PsA-related disease impacts. BWS data were analyzed using a random parameters logit model. Data on patient demographics and preferences for PsA treatment attributes, including experience with methotrexate and preference for route and frequency of administration, were analyzed descriptively.
Results: The sample of 247 respondents was 79% female, had a mean age of 53.4 years (range 24-79 years), and had a mean time since PsA diagnosis of 9.4 years, with 86% currently being treated by a rheumatologist. The most common PsA symptoms ever experienced were joint pain, morning



Note: Figure 1 presents the BWS relative burden and importance estimates for the full sample rescaled such that the most burdensome symptom, joint pain (1A), and the most important impact to improve, ability to perform physical activities (1B), are set to 10. In Figure 1A, the scaled relative burden weights for each of the remaining items can be interpreted as the effect of that item on utility relative to the utility of joint pain, while in Figure 1B, the scaled relative importance weights for each of the remaining items can be interpreted as the effect of that item on utility relative to the utility of ability to perform physical activities. For example, joint pain is approximately 2 times more burdensome than joint swelling (10/4.8 = 2.1), and it is almost equally as burdensome as lower back or spine pain (10/9.5 = 1.05).

stiffness and fatigue, while the least common symptom was skin pain/discomfort related to psoriasis patches. In the BWS, patients reported pain-related symptoms (i.e., joint pain and lower back or spine pain) as the most bothersome, while the least bothersome symptoms were psoriasis-related (Figure 1). Patients reported ability to perform physical activities as the most important disease impact to improve, followed by ability to live/function independently, sleep quality, and ability to do daily activities. Nearly half the sample (49%) stated they would strongly prefer a treatment for PsA that does not include methotrexate. Among patients who were not satisfied with methotrexate, the top reason was dislike of the short-term side effects after each dose. When asked to choose among four different ways of taking their PsA medication (oral once a day, oral twice a day, injection every 2 weeks, injection once a month), the most preferred method was oral once a day (38%) followed by injection once a month (26%), with 24% indicating no preference. Additionally, 49% of the sample felt that mode of administration was an important factor when deciding to start a new therapy.

Conclusion: Among real-world patients with PsA, the most bothersome PsA symptoms were related to pain while patients most wanted to improve functional impacts of their disease. Patients most preferred an oral once a day treatment option and treatment regimens that do not include methotrexate. These findings can serve to better inform development of new therapies and guide shared patient-provider treatment decision making.

POS0063-PARE IMPLEMENTING SHARED DECISION MAKING TO ADVANCE PATIENT CENTRED RHEUMATOID ARTHRITIS CARE: A ROLE FOR A PATIENT ORGANISATION

P. Pennings Msc[1], H. Voogdt-Pruis[2,3], B. Maat[4], T. Foekens[4], L. J. Kranenburg - van Koppen[5], A. Pasma[5], J. Hoes[6], I. Schoonen-Nuijten7, M. Van den Dikkenberg, Msc[8], N. Basoski[8], A. Weel[8,9], G. Willemsen- de Mey Msc[1]. [1]National Association ReumaZorg Nederland, Patientparticipation and Communication, Nijmegen, Netherlands; [2]National Association ReumaZorg Nederland, Projectmanager Project Shared Decision Making in RA Care, Nijmegen, Netherlands; [3]University Medical Centre Utrecht (UMCU), Department of Julius Global Health, Utrecht, Netherlands; [4]National Association ReumaZorg Nederland, Patientpartner for the department of Patientparticipation and Communication, Nijmegen, Netherlands; [5]Erasmus Medical Centre, Department of Rheumatology, Rotterdam, Netherlands; [6]Bravis Medical Centre, Department of Rheumatology, Roosendaal, Netherlands; [6]Bravis Medical Centre, Department of Rheumatology, Roosendaal, Netherlands; [8]Maasstad Medical Centre, Department of Rheumatology, Rotterdam, Netherlands; [9]Erasmus University, Department ESHPM (HTA), Rotterdam, Netherlands

Background: In rheumatoid arthritis (RA) care, patients and professionals face treatment decisions regularly due to the high number of treatment options, the chronic character of the disease and challenges around multi-morbidity. Recent studies have underlined the added value of shared decision making (SDM) between patients and professionals in RA care for health outcomes (i.e. disease activity, pain and joint damage) [1-4]. Therefore, effort is needed to facilitate the implementation of SDM in daily clinical practice in order to advance patient centred RA care.

Objectives: The aim of this implementation project was to improve SDM about treatment options for patients with RA. In addition the use of (Patient Reported) Outcome Measures in the process of SDM was taken into account.

Methods: An implementation programme was developed by the National Association ReumaZorg Nederland (RZN) in co-creation with patientpartners and RMD professionals. Three hospital departments of rheumatology in the Netherlands participated in the project between January 2020 and March 2021. The implementation of SDM was supported by a project team of RZN.

Results: The implementation programme started with the recording of RMD consultations in three participating departments of rheumatology. The consultations were then evaluated on the process of SDM (OPTION5) and discussed during the training of professionals that followed. Three observed improvements in SDM in RA care were: a. A more explicit introduction of choice for a patient is needed during the consultation; b. Tasks within the process of SDM should be allocated clearly among RMS specialists and nurses working together, in order to avoid unnecessary repetition of the same - or even inconsistent information; c. Besides the use of (patient reported) outcome measures in the SDM process, it is also important to include patients' values (what matters to them?) when deciding on the best fitting treatment option. After the training, implementation support for SDM was given and aids to support the SDM process (i.e. redesign of health care processes, task allocation, hand card with explanation of the 4 steps of SDM) were developed. The implementation programme was tailored to the needs and stage of change for each hospital. Implementation materials for the hospital teams were developed in co-creation with patientpartners and the professionals. At the end of the project, a second set of consultations was recorded and evaluated on SDM. The hospital teams concluded that a continuous improvement cycle is needed to further enhance SDM.

Conclusion: A continuous implementation programme on shared decision making could stimulate the enhancement of patient centred care in daily practice. Patient organisations could take a significant role in such a programme.

POS0064-PARE DESIGN OF AN INNOVATIVE MHEALTH SOLUTION FOR FIGHTING STIGMA ASSOCIATED WITH CHRONIC PAIN

Y. Koumpouros[1], K. Antonopoulou[2], A. Pappa[3], K. Tsekoura[3], N. Malliou[4], M. Salamaliki[5], E. Oikonomoula[6], S. Makri[7]. [1]University of West Attica, Department of Public and Community Health, Athens, Greece; [2]Hellenic League Against Rhuematism, Headquarters, Athens, Greece; [2]Hellenic League Against Rhuematism, Headquarters, Athens, Greece; [4]Hellenic League Against Rhuematism, Thessaloniki, Thessaloniki, Greece; [5]Hellenic League Against Rhuematism, Patras, Patras, Greece; [6]Hellenic League Against Rhuematism, Thessaly, Trikala, Greece; [7]Cyrpus League Against Rhuematism, Headquarters, Nicosia, Cyprus

Background: Pain is associated with a plethora of diseases. The statistics reveal that chronic pain affects around 100 million people across Europe and is closely associated with high unemployment rates, depression, substance abuse & social exclusion. Stigma is a significant and persistent problem for those with chronic pain. Lack of public awareness & stigma associated with pain affect not only patients but also society.

Objectives: The present research proposes a holistic solution to combat stigma using the latest technological developments. A mobile health application has been designed in order to serve the various stakeholders (patients, families, community) in the field under study. The objective of the final "StigmApp" solution is 4-fold:(i) to facilitate pain management, (ii) to aware the general public, (iii) to educate all different parties & (iv) to facilitate actions & research to combat stigma. Another innovative feature is that it delivers the required information to each party in a highly automated, personalized & digestible way making the whole experience enjoyable, while ensuring user engagement.

Methods: A multidisciplinary team was formed at the beginning of the project in order to ensure the desired outcome. Two patient organizations from Cyprus & Greece, two behavioral scientists, three physicians, one psychologist, ten

citizens, ten patients, two marketeers and two experts in mobile health applications participated. A participatory design methodology was followed in order to capture & address the whole user experience.

Results: An iterative process was followed bringing & different end-users on board. The different parties evaluated and assessed all modules implemented providing appropriate feedback. It currently runs only on Android operating system and supports: (i) pain management (intense &points of pain, medications used, underlying diseases, life style, etc.),(ii) raise awareness & education (through information nuggets & bite-sized learning), (iii) "Share your story" option to inspire others, (iv) fund raising using crowd-funding techniques, (v) become a volunteer, (vi) organize an inspiring event, (vii) networking, (viii) automatic creation of infographics on how pain affects peoples' lives. It has been awarded the first prize by BMP Innovation Grant.

Conclusion: StigmApp has been designed to support the ecosystem around chronic pain regardless of the underlying disease. Our main concern is to raise awareness in order to fight stigma associated with pain & make life easier for patients & their families. The involvement of all different potential actors in the design guarantees a product/service that could meet their needs & can be applied in real life. In the next months the final solution will be piloted by a number of different end users in order to assess it under real life conditions.

POS0065-PARE HEALTH IMPACT OF OVERWEIGHT AND OBESITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS. RESULTS FROM THE EUROPEAN MAP OF AXIAL SPONDYLOARTHRITIS (EMAS)

M. Garrido-Cumbrera[1], D. Poddubnyy[2], L. Christen[3], C. Bundy[4], R. Mahapatra[5], S. Makri[6], S. Sanz-Gómez[1], J. Correa-Fernández[1], C. J. Delgado-Domínguez[1], V. Navarro-Compán[7] on behalf of IMAS working group. *[1]Universidad de Sevilla, Health & Territory Research (HTR), Seville, Spain; [2]Charité - Universitätsmedizin Berlin, Rheumatology Department, Berlin, Germany; [3]Novartis Pharma AG, Patient Engagement, Basel, Switzerland; [4]Cardiff University, School of Healthcare Sciences, Cardiff, United Kingdom; [5]Axial Spondyloarthritis International Federation (ASIF), Patient Advocacy, London, United Kingdom; [6]Cyprus League Against Rheumatism (CYPLAR), Patient Advocacy, Nicosia, Cyprus; [7]Hospital Universitario La Paz, IdiPaz, Madrid, Spain*

Background: Growing evidence on the negative role of overweight and obesity on the health outcomes of patients with axial spondyloarthritis (axSpA) exists.

Objectives: The aim of the study is to evaluate the association between Body Mass Index (BMI) categories and sociodemographic, disease-characteristics and patient-reported outcomes (PROs) in a large sample of axSpA patients.

Methods: Data from 2,846 unselected patients of the European Map of Axial Spondyloarthritis (EMAS) through an online survey (2017-2018) across 13 European countries were analyzed. Using self-reported height and weight patients were classified into under and normal weight (<24.9 Kg/m^2), overweight (25.0-29.9Kg/m^2) or obese (>30.0Kg/m^2) following WHO guidelines. The Kruskal-Wallis test was used to compare the means of numerical variables between polytomous variables, the χ^2 test was used to compare the distribution between the categorical variables. Simple and multivariate logistic regression were used to identify possible associated factors.

Results: A total 2,846 axSpA patients participated in the EMAS survey: mean age was 43.9 years, 61.3% female, 48.1% had a university degree and 67.9% were married and 71.3% were HLA-B27 positive. The percentage of patients with obesity was 18.7%, overweight 33.5%, normal weight 44.0% and underweight 3.8% with an accumulate prevalence of overweight/obesity of 52.2% (compared to 51.6 % of the EU's population[1]). Those with obesity engage less frequently in sport (50.1% vs 33.3%; p<0.001) and in intimate relationships since disease onset (36.5% vs 20.4%; p<0.001), have higher functional limitations when tying shoe laces (46.8% vs 33.6%; p<0.001) and higher functional limitations regarding housework (52.2% vs 48.2%; p=0.024). Furthermore, they present greater disease activity (6.1±1.8 vs 5.4±2.0; p<0.001) and spinal stiffness (8.6±2.3 vs 7.4±2.5; p<0.001) compared to under and normal weight. For obese patients, the percentage of depression is higher (34.5% vs 23.7%; p<0.001), presenting a poorer mental health (5.7 ± 4.3 vs 5.0 ±4.2; p<0.001). The factors most strongly associated with obesity were higher functional limitation when tying shoe laces (OR=1.467; p<0.001), the female gender (OR=1.433; p<0.001) and lesser frequency of intimate relation (OR=1.239; p<0.001; see Table 1).

Table 1. Logistic regression analysis to predict presence of obesity (N = 1,194)

	Simple			Multivariate		
	OR	95% CI	p-value	OR	95% CI	p-value
Age	1.026	1.018, 1.034	**<0.001**	1.026	1.012, 1.040	**<0.001**
Gender (female)	1.336	1.095, 1.629	**0.004**	1.433	1.031, 1.990	**0.032**
Marital status (married)	1.384	1.184, 1.617	**<0.001**	0.982	0.746, 1.292	0.897
Educational level (university)	0.776	0.681, 0.884	**<0.001**	1.046	0.849,1.289	0.674
Employment status (employed)	1.035	0.987, 1.085	0.154	NA	NA	NA
Engage in sports (much less than before)	1.313	1.202, 1.433	**<0.001**	1.143	0.978, 1.336	0.093
Travel/ excursions (much less than before)	1.316	1.186, 1.461	**<0.001**	0.981	0.800, 1.202	0.852
Intimate relations (much less than before)	1.571	1.393, 1.772	**<0.001**	1.239	1.003, 1.530	**0.047**
Tying shoe laces (high)	1.433	1.232, 1.666	**<0.001**	1.467	1.176, 1.830	**0.001**
Housework / cleaning (high)	1.226	1.048, 1.434	**0.011**	0.760	0.596, 0.970	**0.028**
BASDAI (0-10) N:2,584	1.220	1.156, 1.288	**<0.001**	1.127	1.021, 1.244	**0.018**
Spinal Stiffness (3-12) N:2,660	1.184	1.136, 1.234	**<0.001**	1.057	0.987, 1.133	0.115
Sleep disorders diagnosis	1.558	1.284, 1.892	**<0.001**	1.045	0.753, 1.449	0.793
Depression diagnosis	1.648	1.340, 2.027	**<0.001**	1.267	0.892, 1.799	0.186
Psychological distress GHQ-12 (0-12)	1.053	1.029, 1.078	**<0.001**	0.995	0.954, 1.038	0.813

Conclusion: Results from the largest European axSpA survey reveal a similar prevalence of overweight and obesity to the general population. However, compared to normal weight, obese patients present greater disease activity, spinal stiffness and poorer mental health. Additionally, women with axSpA appear to be more vulnerable than men to obesity.

POS0066-PARE REHABILITATION WITH KINESIOTHERAPY IN MUSCLE FUNCTION AND WEIGHT LOSS IMPROVING IN OBESITY PATIENTS

V. Vasileva[1], M. Eryomushkin[1], L. Marchenkova[1]. [1]National Medical Research Center of Rehabilitation and Balneology, National Medical Research Center of Rehabilitation and Balneology, Moscow, Russian Federation

Background: exercise is one of the main factors for the successful treatment of obesity. It is known that with increasing age, muscle strength (sarcopenic obesity) decreases in an obese patient, which can lead to early disability and an increased risk of falls. Regular exercise therapy increases the functional capacity of the cardiovascular system, prevention of obesity among the population, as well as treatment for persons with sarcopenia and obesity. Therefore, it is relevant to study muscle function in obese patients while using kinesiotherapy.
Objectives: was to estimate the affect of complex 3-week treatment with 4 kinesiotherapy methods on body weight loss and muscle function in patients with obesity.
Methods: 80 men and women aged 21-69 years old with alimentary obesity were enrolled in the study (mean age 52.4±11 years, weight 111.3±24.5 kg, BMI 40.3±8.1 kg/m2, waist circumstance WC 113.4±16 cm, hip circumstance HC 124.2±16 cm). The complex kinesiotherapy administered daily for 3 week and included interactive sensorimotor trainings on double unstable platform, kinesiohydrotherapy in a pool, special complex of physical exercises in a gym and ergocycle trainings. Weight, WC, HC, fall number for last 3 weeks were measured at baseline and after the treatment was completed. Muscle strength and walking speed functional tests results assessment (10-meters-walk test, Up-and-go test, 4 special tests for back and abdomen muscle endurance to static and dynamic loading) were performed at baseline and in 3 weeks.
Results: there was a significant reduction in body weight (111.3±24.4 kg at baseline vs 107.9±23.1 kg in 3 weeks; p=0,000), in BMI (40.3±8.1 vs 39.1±7.7 kg/m^2; p=0.000), in WC (113.4±15.9 vs 109.2±15.1 cm; p=0.000) and in HC (124.1±15.5 vs 119.7±14.1 cm; p=0.000) in treated obese patients. 10-meters-walk speed increased from 0.84±0.15 m/sec at baseline to 0.88±0.17 m/sec in 3 weeks (p=0.000). Up-and-go test results improved from 8.4±2.1 to 7.9±2.09 sec (p=0.000). We registered statistically significant elevation of the endurance to static loading in abdomen muscles from 13.1±9.7 to 16.49±12.8 sec (p=0.000) and in back muscles from 14.8±11.9 sec to 18.6±14.9 sec (p=0.000). The endurance to dynamic loading increased in abdomen muscles from 29.9±11.2 to 34.84±11.93 times (p=0.000) and also in back muscles from 9.1±7.4 to 12.2±9.2 times (p=0.000). Fall number markably decreased from 0.14 ±0.34 at baseline to 0.0 (95%CI: 0.02; 0.25) after completion of treatment.
Conclusion: investigated complex treatment with 4 kinesiotherapy methods promotes body weight loss, WC and HC reduction in obesity. 3-week special training of obese patients is associated with increasing in gate speed and lower extremities muscle strength, and it also causes improvement in static and dynamic loading endurance of back and abdomen muscles. Those changes may probably improve balance function and decrease risk of falling in obese patients.

POS0067 HIGH DEGREE OF INTER-PATIENT HETEROGENEITY IN SYNOVIOCYTE HYPERPLASIA AND IMMUNE CELLS INFILTRATION IN THE SYNOVIUM OF JUVENILE IDIOPATHIC ARTHRITIS PATIENTS

C. Triaille[1,2], C. Boulanger[2,3], T. Sokolova[1], L. Meric de Bellefon[1,4], A. Nzeusseu Toukap[1,4], C. Galant[5], N. Limaye[3], B. Lauwerys[1,4], P. Durez[1,4]. [1]Université catholique de Louvain, Pôle de pathologies rhumatismales systémiques et inflammatoires, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium; [2]Cliniques Universitaires Saint-Luc, Service d'Hématologie, Oncologie et Rhumatologie pédiatrique, Brussels, Belgium; [3]Université catholique de Louvain, Genetics of Autoimmune Diseases and Cancer, de Duve Institute, Brussels, Belgium; [4]Cliniques Universitaires Saint-Luc, Service de Rhumatologie, Brussels, Belgium; [5]Cliniques Universitaires Saint-Luc, Service d'Anatomie Pathologique, Brussels, Belgium

Background: Increasing evidence indicates that synovial tissue analysis can deliver pathophysiological insights but also individual clinically-relevant information in adult-onset inflammatory arthritides. Little is known about synovial pathology in juvenile idiopathic arthritis, especially regarding inter-patient variability of histopathological features.
Objectives: To assess the heterogeneity of main synovial features (synoviocyte hyperplasia and immune cells infiltration) in juvenile idiopathic arthritis (JIA) patients and a cohort of young adults (<30 years old) with early rheumatoid arthritis (RA).
Methods: Synovial biopsies were sampled using needle arthroscopy or ultrasound (US) guided biopsy during intra-articular joint injection. Tissue was embedded in paraffin then sections were stained with hematoxylin and eosin. Synoviocyte hyperplasia (SH) and immune cells infiltration (ICI) was assessed by an experienced pathologist on a 0 – 3 scale where 0 represents the absence of the feature and 3 the highest level.
Results: 34 JIA patients (age (median ±SD): 15.5±6.47 years, oligo-articular JIA n=28/34, polyarticular JIA n=6/34, ANA-RF-ACPA positivity=56%-10%-3%) and 22 RA (age (median ±SD): 24.3±2.6 years, ANA-RF-ACPA positivity=10%-36%-32%) patients were included. Synovial tissue was obtained from knee (n=49/56), wrist (n=4/56) or metacarpophalangeal/intercarpophalangeal joints (n=3/56), using US guided biopsy in 27% of patients and needle arthroscopy in 73%.
Individual scores of SH and ICI were correlated in both JIA (Spearman's r=0.503, p value=0.0024) and RA (Spearman's r=0.636, p value=0.0015). There was no significant difference in SH and ICI scores between the 2 groups (SH score (Q25-Q50-Q75) in JIA= 0.5-1.125-2 and in RA = 0.75-2-2; ICI score (Q25-Q50-Q75) in JIA= 1-2-2 and in RA = 0.75-2-2.25). Intra-group variability of the two assessed features was comparable between the 2 groups (SH coefficient of variation: 72.2% for JIA and 68.2% for RA; ICI coefficient of variation: 52.2% for JIA and 71.2% for RA). Within JIA patients, there was no significant difference in SH/ICI scores between groups based on ANA positivity, oligo or polyarticular involvement nor ongoing treatment.
Conclusion: Studying main histological features of synovitis, we found no difference between JIA and young RA patients. Furthermore, we report a similar degree of inter-patient heterogeneity in synovial pathological features of JIA and RA patients. These variations were not explained by common clinical characteristics. Whether they relate to different molecular signatures as suggested in adult RA will be further investigated using bulk tissue RNA sequencing.

POS0068 HIGH LEVELS OF PORPHYROMONAS GINGIVALIS AND PREVOTELLA INTERMEDIA ANTIBODIES IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

F. Zekre[1], R. Cimaz[2], M. Paul[3], J. L. Stephan[4], S. Paul[5], H. Marotte[6]. [1]INSERM U1111-CNRS. INSERM U1059-SAINBIOSE, Campus Santé Innovations Faculté de Médecine Jacques Lisfranc, Saint Priest en Jarez, France; [2]Università degli studi di Milano Statale, Reumatologia pediatrica, Milano, Italy; [3]INSERM U1059, SAINBIOSE, Université de Lyon, Saint Etienne, Saint Priest en Jarez, France; [4]Hôpital Nord, Service pédiatrie, CHU Saint Etienne, Saint Priest en Jarez, France; [5]INSERM U1111-CNRS, Université de Lyon, Saint-Etienne, Saint Priest en Jarez, France; [6]INSERM U1059, SAINBIOSE, Université de Lyon, Saint-Etienne, France, Saint Priest en Jarez, France

Background: Idiopathic juvenile arthritis (JIA) is a heterogeneous group of pathologies whose origin remains unknown at present (1). They are characterised by a systemic inflammatory and joint disease affecting children under 16 years of age. The current classification groups the different forms of JIA into 7 distinct entities (systemic forms, polyarticular forms with or without rheumatoid factors, oligoarticular forms, inflammatory arthritis associated with enthesopathies (ERA), arthritis associated with psoriasis and unclassifiable arthritis). Exact etiology of JIA is still unknown. To date, the various hypotheses put forward on the occurrence of JIAs integrate the genetic and environmental framework.
The link between periodontal disease and rheumatoid arthritis (RA) is largely reported. Recently, *Porphyromonas gingivalis* (*P. gingivalis*) infection explained the occurrence of arthritis in rodent and in RA (2). Several studies mention the beneficial effect of *P. gingivalis* treatment on disease activity.
Currently, there are very few studies on the prevalence of *P. gingivalis* in patients with JIA and the possible involvement of the germ in the development of inflammatory joint diseases in the pediatric population(3)(4).
Objectives: The objective of our study is to determine presence of high IgG antibodies against *P. gingivalis* and *Prevotella Intermedia* in a cohort of patients with JIA compared to a control population and to determine variation of level according to sub-classes of JIA.

Methods: Sera were obtained from 101 patients satisfying the ILAR classification criteria for JIA and in 25 patients with two other dysimmune disorders (type 1 diabetes and juvenile inflammatory bowel disease). Level of IgG antibodies against *P. gingivalis* and *Prevotella Intermedia* were obtained by homemade ELISA already used previously (5).

Results: In the JIA group, major children were oligarthritis (47.5%), polyarthritis represents 31.7% of JIAs, ERA and systemic forms of JIA are respectively 9 and 11%. For the control group, 10 (40%) children had diabetes and 15 (60%) had IBD.

Levels of anti-*P. gingivalis* anti-*Prevotella Intermedia* antibodies were higher in AJI group compared at control groups (P<0.01, P<0.05). Theses difference are mainly related to oligoarthritis and ERA subsets for both *P. gingivalis* and *Prevotella Intermedia*.

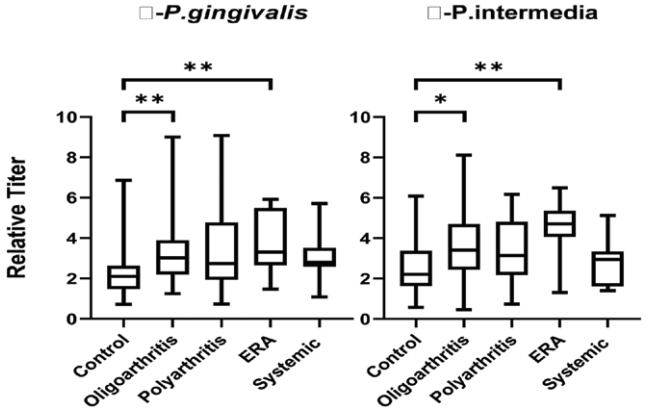

Figure 1. Relative titer of antibodies to P. gingivalis and anti Prevotella intermedia.*: P<0.05; **: P<0.01; ***: P<0.001.P. gingivalis (control vs oligoarthritis p= 0.0032. control vs ERA p= 0.0092).Prevotella intermedia (control vs oligoarthritis p= 0.0194. control vs ERA p= 0.0039).

Conclusion: We confirmed high level of anti-*P. gingivalis* and anti-*Prevotella intermedia* antibodies in JIA compared to other inflammatory disorders. For the first time, we observed that this high level was mainly in oligoarthritis and ERA. Further investigations are required to investigate involvement of oral dysbiosis in AJI pathogenesis. As observed in RA, it could be a new way to integrate in JIA therapy management.

POS0069 INCREASED T CELL RESPONSES, METABOLIC ACTIVITY AND FIBROBLAST INVASIVE CAPACITY IN CHILDREN WITH DOWN'S SYNDROME-ASSOCIATED ARTHRITIS COMPARED TO JUVENILE IDIOPATHIC ARTHRITIS

S. Foo[1,2], A. Floudas[1,2], S. Wade[1,2], A. O' Brien[1,2], S. Ansboro[1], R. Mullan[3], D. Veale[2], E. MacDermott[4], D. Deely[4], C. Foley[4], O. Killeen[4], U. Fearon[1,2]. [1]Trinity College Dublin, Molecular Rheumatology, Dublin, Ireland; [2]University College Dublin, St Vincent's Hospital, Centre for Arthritis and Rheumatic Diseases, Dublin, Ireland; [3]Tallaght University Hospital, Department of Rheumatology, Dublin, Ireland; [4]Children's Health Ireland (CHI) at Crumlin, Department of Rheumatology, Dublin, Ireland

Background: Juvenile idiopathic arthritis (JIA) was thought to be the most common inflammatory arthritis in children (Shih *et al.*, 2019). However an aggressive, erosive arthritis of little-known immunologic mechanism occurs 20 times more frequently in children with Down's syndrome (Foley *et al.*, 2019).

Objectives: This study was undertaken to characterize immune cell responses and synovial fibroblast invasiveness in children with Down's syndrome-associated arthritis (DA).

Methods: Multiparametric flow cytometric analysis was used to examine peripheral blood T cell, B cell and monocyte populations. In addition, T cell cytokine responses and their metabolic profile in children with DA, JIA, Down's Syndrome (trisomy 21 [T21]), and in healthy controls were assessed. The function of DA primary synovial fibroblasts (FLS) was assessed in response to stimulation with pro-inflammatory mediators alone and in combination (TNF-α, IL-17a, IFN-γ, GM-CSF). The two major energy pathways glycolysis (ECAR) and oxidative phosphorylation (OCR) were quantified by the Seahorse XFe96 Analyser. Migration, adhesion, invasion and cytokine/chemokine secretion were quantified by wound repair scratch assays, Transwell collagen invasion chambers, adhesion binding assays, and ELISAs.

Results: T cell frequencies were higher in DA compared to JIA and T21 in contrast to B cell frequencies which were decreased. T cell responses in DA were characterized by increased frequencies of $CD4^+$ and $CD8^+$ TNF- α, IFN- γ and GM-CSF producing T cells. The frequency of T peripheral helper (Tph) cells were elevated in children with DA compared to all other groups. In parallel, an increase in their metabolic profile evident by higher phosphorylation of mTOR pathway components AKT, mTOR and S6. Comparison of DA and JIA FLS demonstrated that DA FLS display a more invasive/migratory capacity and are more metabolically active. Based on the increased cytokine responses in DA T cells, we next examined the effect T cell derived cytokines TNF-α, IL-17A, IFN-γ and GM-CSF alone and in combination on DA FLS function. TNF-α, IL-17a and IFN-γ induced IL-6, RANTES and MCP-1 secretion, with no effect observed for GM-CSF. Furthermore, TNF-α and IL-17A induced DA FLS migration and PBMC adhesion to DA FLS. Finally IL17A and IFN-γ potentiated the effect of TNF-α on IL-6 and MCP-1 secretion compared to stimulations alone.

Conclusion: DA is a more common and aggressive form of arthritis compared to JIA. It is characterized by increased T cell responses and a more invasive FLS phenotype compared to that of JIA, with T cell derived cytokine alone and in combination further inducing DA FLS pathogenic mechanisms. These effects mirror the increased erosive disease observed clinically.

POS0070 POPULATION PHARMACOKINETICS OF INFLIXIMAB IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

A. Nassar-Sheikh Rashid[1], D. Schonenberg-Meinema[1], S. Berends[2], J. M. Van den Berg[1], R. Mathot[2]. [1]Amsterdam UMC, Locatie AMC, Department of Pediatric Immunology, Rheumatology and Infectious Diseases, Emma Children's Hospital, Amsterdam, Netherlands; [2]Amsterdam UMC, Locatie AMC, Hospital Pharmacy, Amsterdam, Netherlands

Background: Higher dosage regimes for Infliximab (IFX) have been described to be effective in partial- or non-responding adults and children with rheumatic disease and appear to be safe (1,2). To optimize IFX treatment in juvenile idiopathic arthritis (JIA) patients, therapeutic drug monitoring (TDM) might be beneficial. To support routine TDM of IFX and dose regimen optimization in JIA patients, more in-depth knowledge of the pharmacokinetic (PK) variability of IFX is needed. Ultimately, as soon as the optimal therapeutic drug ranges will be known, PK model-based simulation can be used to individualize drug dosing recommendations. Individual dosages may be adjusted by taking specific patient characteristics into account that explain inter-patient variability in pharmacokinetics (PK). Inter-patient variability can be quantified and investigated by the population approach.

Objectives: Our hypothesis is that optimizing dosage and frequency of IFX administration for individual patients will improve treatment outcome. In this current study, the population PK for IFX are described for JIA patients.

Methods: Data including IFX trough concentrations and anti-IFX antibodies of 27 JIA patients on IFX maintenance treatment were retrieved from electronic charts. Three population pharmacokinetic models from literature were validated for our dataset using nonlinear-mixed effects modeling program NONMEM (3,4,5). A novel population pharmacokinetic model was developed based on our study data.

Results: A total of 65 obtained blood samples after a median of 32 days after the last IFX infusion (IQR 28-42) were analyzed. The three published models underpredicted the observed trough concentrations. A newly developed one compartment model best described the IFX serum concentration over time data in JIA patients (see Figure 1).
Conclusion: Our study shows a novel and the first PK model for IFX in JIA patients. Our main finding was that a one- compartment model best described the IFX serum concentration over time data. Predictive performance of the known models from literature was insufficient for our patient data. Our data also show that different PK models are needed for different age categories (children or adults) and in different diseases.

POS0071 IS ANTI-NXP2 AUTOANTIBODY A RISK FACTOR FOR CALCINOSIS AND POOR OUTCOME IN JUVENILE DERMATOMYOSITIS PATIENTS?

N. Toplak[1,2], P. P. Chavan[3], S. Rosina[4], T. Dallos[5], R. Semo Oz[6], C. Aguiar[7], R. Khubchandani[8], A. Ravelli[9], A. Patwardhan[10]. Background: It has been published that the presence of NXP2 autoantibodies presents a risk for calcinosis in patients with JDM.
Objectives: To investigate the incidence of calcinosis and response to the treatment in NXP2 positive JDM patients with calcinosis.
Methods: The study design is a retrospective, multinational, multicenter study. Data on gender, race, age at disease onset and age at disease diagnosis, age at inclusion in the study, clinical presentation, muscle function tests, laboratory results, imaging, data on treatment and outcome of disease were collected
Results: we collected 26 patients (19 F, 7 M) with JDM and positive NXP2 antibodies. Fourteen patients were white, eight asian, three black and one Hispanic ethnicity. The mean age at disease presentation was 6.5 years (SD 3.7), the median diagnosis delay was 4 months (range 0.5- 27 months). Patients were divided in two groups (A and B) based on the presence of calcinosis.
Eleven patients (42%) developed calcinosis (group A) in the course of the disease, 10 females and 1 male. Four patients already had calcinosis at presentation, 1 developed after 4 months, and 6 developed calcinosis later in disease course (median 2 years, range 0,8- 7,8). Four patients developed lipodystrophy in group A (1 in group B). In group A, 3 patients developed skin ulcerations (1 in group B), 2 patients had polyarthritis (1 in group B), 2 patients had gut involvement (1 in group B) and 1 patient had lung involvement (2 in group B).
The mean age at disease presentation (5.2 / 7.5 y) and mean CK level (1548.6 / 1811.6 U/L) were lower in group A. The platelet count (306.5 / 258 10^9/L), and mean values of AST (111.4 / 103.8 U/L), ALT (72.2 / 50.8 U/L), LDH (1048.3 / 808 IU/L), and IgG (11.8 / 9.9 g/L) were higher in group A. However, the differences were not statistically significant. ANA antibodies were positive in 9/11 in group A and 12/15 in group B. One patient in group A was also positive for anti-MDA5 antibody. The data on muscle strength measurement (MMT/CMAS) were available only in a few patients.
Treatments used for patients with calcinosis includes, methotrexate and glucocorticosteroids (GCS) (all patients), hydroxychloroquine (9), IVIG (7), cyclosporine (4), bisphosphonate (4), MMF (5), rituximab (4), cyclophosphamide (1), abatacept (1) and TNF alpha blocker (1).
Disease outcome (by evaluation of the treating physician) was excellent in 4, good in 2, stable in 2 and poor in 3 patients. None of the patients from group B had a poor disease outcome. Patients with excellent disease outcomes from group A were treated with GCS and methotrexate (4), hydroxychloroquine (3), IVIG (1) and cyclosporine (1). Out of two patients who had good outcomes, one was additionally treated with MMF, bisphosphonates and rituximab and the second was treated with cyclophosphamide and rituximab. One patient with calcinosis at the presentation (age 4 years) was treated also with anti-TNF alpha therapy which not only stopped progression but partially dissolved the calcinosis. However, after 2 years of anti-TNF alpha therapy the calcinosis start to progress and the therapy was changed to MMF and rituximab, which stopped the progression of calcinosis.
Conclusion: Our preliminary results showed that calcinosis occurred in 42% of NXP2 positive JDM patients. Children with calcinosis were treated with several combinations of drugs. In four cases, rituximab and in one case, for limited time of 2 years, anti-TNF alpha agent, were used successfully.

POS0072 COMPREHENSIVE IMMUNE PROFILING OF 20 CHILDREN WITH MULTISYSTEM INFLAMMATORY SYNDROME

M. Zajc Avramovic[1,2], N. Emersic[1], A. N. Kopitar[3], M. Korva[3], T. Avsic-Zupanc[3], A. Ihan[3], T. Avcin[1,2]. [1]University Medical Center Ljubljana, Children's Hospital, Department for Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia; [2]University of Ljubljana, Faculty of Medicine, Pediatrics, Ljubljana, Slovenia; [3]University of Ljubljana, Faculty of Medicine, Institute of Microbiology and Immunology, Ljubljana, Slovenia

Background: Multisystem inflammatory syndrome in children (MIS-C) is a rare complication of SARS-CoV-2 infection in the pediatric population, caused by extensive activation of immune system. The understanding of the distorted immune response is still in the early stages.
Objectives: To analyze comprehensively immune profile in MIS-C patients including detailed serologic response to SARS-CoV-2 in comparison with control groups.
Methods: Blood samples of consecutive MIS-C patients were collected at admission. Flow cytometric analysis of all lymphocyte populations including T and B cell differentiation was performed. Immunophenotyping was performed by six-color panels for the detection of lymphocyte subpopulations. Anti-SARS-CoV-2 specific antibodies were measured in the patients serum. The IgA and IgG antibodies against S protein, the IgG S1 and S2 specific antibodies, antibodies against nucleoprotein and neutralising antibodies were measured. Patients were assessed for a wide range of auto-antibodies, namely ANA, anti-ENA (Jo-1, PL-7, PL-12, SRP, Mi-2, Ku, Pm/Scl 100, Scl-70), myositis specific antibodies (EJ, MDA-5, TIH-Y, Ro52, SAE-1, SAE-2, NXP-2), anti-dsDNA, anti-phopholipid antibodies (aCl IgA, IgG, IgM, antiβ2GPI IgG, IgM) and ANCA. Control groups to compare specific antibody response consisted of 14 healthy children and 19 healthy adults, who had SARS-CoV-2 infection in the last 2 months.
Results: Samples of 20 patients were included (14/20 boys, median age 12.4 years). Patients had higher percentage of double negative T cells and low numbers of of cytokine producing T cells Th1, Th2 and Th17. . Numbers of immune competent and CD21+ transitional B cells were also lowered. All patients had positive antibodies against SARS-CoV-2 including neutralising antibodies. Nine (9/19; 47 %) patients had high titer (≥1:160) of neutralising antibodies. Results were compared with 2 control groups; 14 healthy children (7/14 boys; median age 8 years,) and 19 healthy adults, who all experienced SARS-CoV-2 infection in the last two months. Patients with MIS-C had significantly higher levels of anti-S IgA (p<0.0001), patients with MIS-C and healthy children had significantly higher titers of anti-S1 (p=0.001) and significantly lower titers of anti-S2 (p=0.016) in comparison to adults (Figure 1). No differences were found in the titers of neutralising antibodies and anti-N antibodies. All patients were ANA negative, 19/20 patients were anti-ENA negative, whereas 1 patient had anti-Ro antibodies in low titre. Three patients had aCL IgG in medium titre and 2 patients anti-beta2GPI IgG in low titre. Patients were negative for all other autoantibodies.
Conclusion: The immune response in MIS-C patients is specific with most prominent differences in elevated percentage of double negative T cells and low numbers of Th1, Th2, Th17 and CD21+ transitional B cells. MIS-C patients have distinct serologic response with high anti-S IgA, high anti-S1 and low anti-S2 titres.

POS0073 ASSOCIATION OF SAA1 GENE POLYMORPHISM -13T/C (RS12218) WITH CRYOPYRIN ASSOCIATED PERIODIC SYNDROMES (CAPS), BUT NOT FAMILIAL MEDITERRANEAN FEVER (FMF)

I. Guseva[1], E. Fedorov[2], S. Salugina[2], M. Krylov[1], E. Samarkina[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Pediatric Rheumatic Diseases, Moscow, Russian Federation*

Background: Autoinflammatory diseases (AIDs) are a group of rare, genetically determined diseases characterized by a periodic events of inflammation, fever, and clinical symptoms that mimic rheumatic pathology. Laboratory serological markers of AIDs are C reactive protein (CRP) and serum amyloid A (SAA) protein.
Objectives: We investigated whether *SAA1* gene polymorphism -13T/C (rs12218) may affect the susceptibility to pediatric FMF and CAPS patients (pts). We also evaluate whether this polymorphism can affect CRP and SAA protein levels.
Methods: 26 FMF pts - 8 boys, 18 girls; age - M(SD) 7.37(5.32) years and 24 CAPS pts - 12 girls, 12 boys; age – 4.76(5.83) years, and 95 healthy individuals (controls) were included in this study. The diagnosis of FMF was based on Turkish paediatric criteria for the diagnosis of familial Mediterranean fever [1] and was confirmed by the detection of pathogenic mutations of the *MEFV* gene in the homozygous or compound-heterozygous states. The diagnose of CAPS was made on the basis of characteristic clinical signs and was confirmed by the detection of a pathogenic mutation in the *NLRP3* gene. *SAA1* gene polymorphism -13T/C was genotyped using allele-specific RT-PCR assay. SAA protein concentration was measured using nephelometry in FMF and CAPS pts.
Results: Table 1 shows the genotypic and allelic frequencies of *SSA1* gene in FMF, CAPS and controls. There were no significant differences between FMF pts and controls in the genotypic and allelic distributions of -13T/C gene polymorphism. The frequency of -13C allele was significantly higher in CAPS pts compared with controls (OR=2.03 [CI 1.02-4.03], p=0.03). Moreover, a statistically significant difference was revealed in the genotypic and allelic distributions between FMF and CAPS pts groups (p=0.047 and p=0.02 respectively). The CRP levels did not correlate with *SAA1* - 13T/C polymorphism. The SAA protein concentration was associated with *SAA1* gene polymorphism in FMF pts (p=0.036).

Table 1. The distribution of genotypes and alleles of *SAA1* gene polymorphism -13T/C in FMF, CAPS and control groups.

Genotypes/Alleles	FMF n=26 (%)	CAPS n=24 (%)	Controls n=95 (%)
TT	12 (46,2)	4 (16,7)	39 (41,1)
TC	12 (46,2)	14 (58,3)	42 (44,2)
CC	2 (7,7)	6 (25,0)	14 (14,7)
P (pts vs controls)	>0,05	>0,08	
T	24 (63,2)	21 (50,0)	80 (61,5)
C	14 (36,8)	21 (50,0)	50 (38,5)
P (pts vs controls)	>0,05	0.03	

Conclusion: Our preliminary study in small groups of pediatric FMF and CAPS pts revealed that *SAA1* gene polymorphism -13T/C (rs12218) is associated with susceptibility to CAPS, but not FMF. The influence of this polymorphism on SAA protein levels in FMF pts was also shown. Further investigations are required to clarify the role of *SAA1* gene polymorphism -13T/C in susceptibility to FMF and CAPS in large studies in different ethnic and population groups.

POS0074 CAN WE PREDICT THE DEVELOPMENT OF NEPHRITIS IN PEDIATRIC IGA VASCULITIS PATIENTS?

E. Sag[1,2], S. Demir[1,2], Y. Bilginer[1,2], S. Özen[1,2]. [1]*Hacettepe University Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey*; [2]*Hacettepe University Faculty of Medicine, Translational Medicine Laboratories, Pediatric Rheumatology Unit, Ankara, Turkey*

Background: IgA vasculitis (IgAV) is the most common systemic vasculitis of childhood, characterized by palpable purpura, arthritis, gastrointestinal and renal involvement [1]. It is a relatively self-limited disease apart from the renal involvement which is associated with the long term morbidity.
Objectives: We aimed to define a marker at disease onset to predict the renal involvement.
Methods: In this pilot study, we analyzed a targeted panel of vascular inflammation markers (sT2, RAGE, TIE-2, sCD40L, TIE-1, sFlt-1, LIGHT, TNF-a, PlGF, IL6, IL18, IL10 and MCP-1) in the plasma samples of eight patients IgAV at the onset of the disease, before any treatment was initiated. At the time of sample collection, none of the patients had renal involvement; four of these patients subsequently developed nephritis and were defined as the IgAVN group. The levels of the markers were studied by a cytometric bead-based multiplex assay panel according to manufacturer's instruction (LEGENDplex HU Vascular Inflammation panel 2 (13-plex); catalogue number 740966, Biolegend) and analyzed by Novocyte 3005 flow cytometer.

Results: There were no significant differences in gender, age, clinical manifestations, and laboratory findings between IgAV and IgAVN patients (Table 1). sCD40L levels were higher (median 1938.1 vs 754.9 pg/mL, p=0.04) whereas sST2 levels were lower (median 862.8 vs 2302.8 pg/mL, p=0.02) in the patients who developed IgAV nephritis (Figure 1). sRAGE levels were higher and IL18 levels were lower in IgAVN patients but did not reach statistical significance, probably due to the low number of patients. The other parameters did not show any specific pattern.

Table 1.

	IgAV (n=4)	IgAVN (n=4)	p value
Gender	2F, 2M	1F, 3M	0.49
Age at disease onset	9.0±5.4	10.3±3.4	0.68
Arthralgia/arthritis	50%	75%	0.49
GIS involvement	75%	50%	0.49
Haemoglobine (gr/dL)	12.4±2.3	12.3±0.6	0.95
White blood cells, x10^9/L	11150±1933	8525±1497	0.08
Platelets x10^9/L	290250±87328	269250±38741	0.68
Erythrocyte sedimentation rate (mm/hr)	10.5±9.1	21.0±14	0.26
C-reactive protein (mg/dL)	0.63±0.03	1.16±0.96	0.39

Data are given as mean±SD

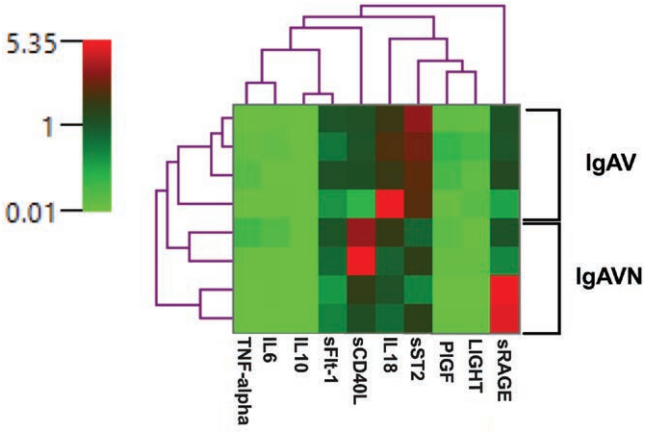

Figure 1.

Soluble CD40 ligand (sCD40L) is expressed on platelets and released on activation. It is proinflammatory for endothelial cells and promotes coagulation by inducing expression of tissue factor on monocytes and endothelial cells [2]. It was investigated in acute coronary syndrome and was suggested as a risk factor for vascular damage. [2]. Furthermore, the levels of sCD40L were shown to be correlated with disease activity in ANCA-associated vasculitis[3]. Thus in IgAV, sCD40L may be associated with the involvement of the kidney vasculature, which represents the more severe form of the disease. Receptor for advanced glycation end-products (RAGE) is another marker for endothelial damage and vasculitis which was higher in IgAVN, as well.

IL33 is expressed by epithelial and endothelial cells and overexpression of IL33 have been shown in large vessel vasculitis [4]. sST2 acts as a decoy receptor and inhibits IL33 signalling[4]. It was interesting to see that the levels of the IL-18 and sST2, which are members of IL-1 family, were lower in IgAVN patients.

Conclusion: Although the number of the patients were limited in this pilot study, we suggest that sCD40L and sRAGE might be used to predict the development of renal disease in IgAV patients. Further studies with larger number of patients are needed to confirm our findings.

Background: Golimumab (GOL) is approved for treatment of polyarticular juvenile idiopathic arthritis (pJIA) in patients 2 years and older. Data on long-term safety of GOL in this indication are limited.

Objectives: To assess long-term safety and efficacy of GOL in pJIA patients.

Methods: In this ongoing non-interventional observational study, clinical characteristics, disease activity and safety parameters were analysed using the German Biologics in Paediatric Rheumatology (BiKeR) registry. 81 pJIA-patients treated with GOL were body weight-matched with 162 patients receiving alt. tumor necrosis factor inhibitors (TNFi) and 81 biologic–naïve patients under methotrexate (MTX)-therapy.

Results: Baseline parameters of GOL patients differed from the alternative TNFi and MTX cohorts. In patients starting with GOL treatment, disease duration was longer, corticosteroid use was less and disease activity, measured by the mean number of active joints and the JADAS10, was lower (Table 1).

The long-term clinical efficacy of GOL in pJIA is highlighted by a decrease of the mean JADAS 10 from 11.6 (baseline) to 5.2 after 24 months. After 2 years, a JADAS 10 minimal disease activity was reached by 44.4 % of patients, whereas 22.2 % of patients were in remission and the JIA ACR 30/50/70/90 response rates were 77.8/72.2/66.7/55.6% respectively.

AE, SAE and infectious AE rates between the three cohorts were comparable (Table 1). In the GOL cohort, 4 SAE (1 uveitis, 1 arthritis flare, 1 fibromyalgia syndrome and 1 abscess) were reported, while in the alt. TNFi group 7 SAEs and in the MTX cohort 1 SAE were noted (Table 1). One serious infectious event (1 abscess) was documented in the GOL cohort, 2 alt. TNFi patients had influenza and no serious infectious events were seen in the MTX control group.

Few autoimmune processes occurred: 2 incident events in the GOL cohort (1 uveitis, 1 psoriasis), 3 cases in the alt. TNFi group (2 uveitis, 1 psoriasis,) and 1 event in MTX-patients (celiac disease) (Table 1). Out of the 20 GOL patients with preexisting uveitis at baseline, 6 had flare events; there were no reported uveitis flares of the 17 patients in the alt. TNFi group and no patients with preexisting uveitis in the MTX-group. No malignancies or deaths were reported.

Conclusion: Our interim results show an acceptable safety profile of GOL therapy, comparable to treatment with alt. TNFi or MTX. No new safety signals occurred. The efficacy outcome data confirm long-term benefits of GOL treatment in pJIA patients.

Acknowledgements: We greatly appreciate the kind support of Z. Huang, S. Calhoun.

Background: The calcium-binding proteins S100A8/A9 (calprotectin) and S100A12 (extracellular newly identified receptor for advanced glycation end-products binding protein [EN-RAGE]) are involved in multiple signalling pathways to mediate inflammation, can be secreted by activated monocytes/macrophages and exhibit cytokine-like extracellular functions. Circulating levels of these proteins have been associated with disease and clinical responses in systemic juvenile idiopathic arthritis (sJIA), including treatment response.[1] Studies suggest that serum S100A8/A9 and S100A12, which are released at inflammation sites, are more specific biomarkers of local inflammation (e.g. in the synovium) than systemic biomarkers such as CRP and ESR.[2,3]

Objectives: To investigate if baseline S100A8/A9 and S100A12 predict clinical response to abatacept treatment in polyarticular JIA (pJIA), and to assess whether changes from baseline in S100A8/A9 or S100A12 can be better prognostic markers for response to abatacept treatment than CRP in pJIA.

Methods: Data are from a phase III trial of SC abatacept for the treatment of pJIA (NCT01844518).[4] This 24-month, single-arm, open-label, international, multicentre, two-part study included male and female patients with pJIA aged 2–17 years. This analysis examined the correlation between biomarkers (S100A8/A9, S100A12 and high-sensitivity CRP [hsCRP]) and disease activity (measured using Juvenile Arthritis Disease Activity Score [JADAS]) at baseline, baseline biomarker values as predictors of future treatment response (ACR and JADAS endpoints), and the correlation between change from baseline in biomarker values and treatment response at Day 113.

Results: Of 219 total patients, 158 (72%) had S100A8/A9 values and 155 (71%) had S100A12 values at baseline. Median S100A8/A9 and S100A12 values were 3295 ng/mL (normal range, 716–3004 ng/mL) and 176 ng/mL (normal range, 32–385 ng/mL), respectively. S100A8/A9, S100A12 and hsCRP (median 0.20 mg/dL; normal ≤0.6 mg/dL) had a low-to-moderate but significant association with disease activity at baseline; coefficients for associations between JADAS71-CRP low disease activity (LDA) and the biomarkers S100A8/A9, S100A12 and hsCRP were 0.23 (p=0.0038), 0.16 (p=0.0448) and 0.26 (p=0.0001), respectively. Baseline S100A8/A9 level above the median was associated with lower odds of ACR100 at Day 113 (p=0.0052). Figure 1 shows the associations of baseline biomarker values with Day 113 ACR and JADAS scores in the overall population. Baseline S100A8/A9 or S100A12 did not significantly influence ACR50 or ACR70 responses at Day 113, but high baseline values were associated with reduced odds of ACR90 (p=0.01), ACR100 (p=0.005), ACR-inactive disease (ID) (p=0.0001), and JADAS71-CRP (LDA) (p=0.02). By Day 477, elevated baseline S100A12 was still significantly associated with lower odds of ACR100 overall (0.467; p=0.0248) but baseline S100A8/A9 was not; at Day 645, neither was significantly associated with ACR100 response. At Day 113, changes from baseline in S100A8/A9 and S100A12 were correlated with ACR100 (coefficients of 0.22 [p=0.0082] and 0.26 [p=0.0015], respectively) and with ACR-ID (0.22 [p=0.0067] and 0.26 [p=0.0014], respectively); change in hsCRP was not significantly correlated with disease response.

Conclusion: S100A8/A9 and S100A12 may serve as prognostic biomarkers to predict response to abatacept treatment at Day 113. Changes from baseline S100A8/A9 and S100A12 levels were more highly correlated with efficacy outcomes including ACR100 and ACR-ID at Day 113 compared with hsCRP.

POS0077 PHYSICAL ACTIVITY AND SPORT PARTICIPATION: A COMPARISON BETWEEN CHILDREN AND ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA) AND THE GERMAN GENERAL POPULATION

F. Milatz[1], M. Niewerth[1], J. Klotsche[1], J. Hörstermann[1], S. Hansmann[2], T. Kallinich[3], C. Rietschel[4], R. Trauzeddel[5], J. Peitz[6], M. Hartmann[7], H. Girschick[8], K. Minden[1,9]. *[1]German Rheumatism Research Centre, Epidemiology and Health Care Research, Berlin, Germany*; *[2]University Children's Hospital Tuebingen, Center for Pediatric Rheumatology, Autoinflammation Reference Centre Tuebingen (arcT), Tuebingen, Germany*; *[3]Charité University Medicine Berlin, Department of Pediatric Pneumology and Immunology, Berlin, Germany*; *[4]Clementine Children's Hospital, Rheumatology for Children and Adolescents, Frankfurt/Main, Germany*; *[5]Helios Klinik Berlin-Buch, Department of Paediatrics, Berlin, Germany*; *[6]Asklepios Clinic, Paediatric Rheumatology Centre, Sankt Augustin, Germany*; *[7]German Center for Paediatric and Adolescent Rheumatology, Motion Analysis, Garmisch-Partenkirchen, Germany*; *[8]Vivantes Hospital im Friedrichshain, Children's Hospital, Berlin, Germany*; *[9]Charité University Medicine Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Physical activity (PA), including sport participation is essential for children throughout their growth and maturation. It improves physiological and psychosocial health and limits the risk of developing metabolic disorders. The beneficial effect of PA specifically in patients with JIA has also been linked to its potential regulatory effect on the balance between pro- and anti-inflammatory responses [1].

Objectives: The study aimed i) to quantify the frequency of PA and participation in (organised) sports compared to the general population, ii) to determine self-reported reasons for not practicing sports, and iii) to identify clinical parameters associated with non-participation in sports.

Methods: Data from children and adolescents with JIA recorded in the National Paediatric Rheumatological Database (NPRD) in the year 2019 were considered for the analyses. In accordance with the methodology used in the general population survey (KIGGS) [2], achievement of the WHO recommendations on PA for at least 60 minutes per day as well as sport-related data were determined on the basis of self-reported outcomes in individuals aged 3 to 17 years. In order to compare PA-related data with the general population, a sex- and age-matched sample was drawn. A logistic regression model was used to explore the association between non-participation in sports and patients' clinical outcomes.

Results: Data of 5.333 matched-pairs (mean age 11.0 ± 4.3 years, female 67%, patients' disease duration 4.8 ± 3.8 years, persistent oligoarthritis 43%) were available for evaluation. Almost 38% of patients aged 3 to 17 years met the recommended PA amount (76% aged 3 to 6; 48% aged 7 to 10; 30% aged 11 to 13; 15% aged 14 to 17). In matched controls, 21% fulfilled the WHO recommendations on PA (41% aged 3 to 6; 23% aged 7 to 10; 17% aged 11 to 13; 10% aged 14 to 17). Largest differences across JIA categories were found in persistent oligoarthritis (43%) and enthesitis-related arthritis (22%). 64% of patients and 74% of controls reported participating in sports, of which 72% of patients and 58% of controls stating to participate in a formally organised way. In both groups, boys indicated organised sports participation more often than girls. Among those who declared not participating in sports, "no interest" (patients 27% vs. controls 29%), "no suitable offer nearby" (patients 25% vs. controls 31%), "health restrictions" (patients 22% vs. controls 4%) and "no time" (patients 15% vs. controls 23%) were the most frequently mentioned reasons (multiple responses possible). CJADAS-10 (OR = 1.02, 95% CI = 1.00-1.04), CHAQ (OR = 1.79, 95% CI = 1.50-2.14), DMARD use (OR = 1.32, 95% CI = 1.15-1.53) and disease duration (OR = 0.97, 95% CI = 0.95-0.99) were significantly associated with non-participation in sports.

Conclusion: Based on self-reported data, children and adolescents with JIA meet the WHO recommendation on PA more often than general population controls. Patients are less frequently engaged in sports, but more often involved in formally organised forms. In order to bring joyful, interesting PA opportunities in line with WHO recommendations, further components (e.g. intensity), facilitators and barriers to PA and sports need to be addressed in the future while controlling for JADAS and CHAQ.

POS0078 CROSS-SECTIONAL ANALYSIS OF INTERFERON SIGNATURE IN PEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

R. Raupov[1], E. Suspitsin[2,3], E. Kalashnikova[1], N. Lybimova[4], E. Kuchinskaya[4], R. Mulkidzhan[2], A. Kosmin[2], M. Kostik[1,4]. *[1]Saint-Petersburg State Pediatric Medical University, Department of Hospital Pediatrics, Saint-Petersburg, Russian Federation*; *[2]N.N.Petrov Institute of Oncology, Molecular diagnostics, Saint-Petersburg, Russian Federation*; *[3]Saint-Petersburg State Pediatric Medical University, Department of Medical Genetics, Saint-Petersburg, Russian Federation*; *[4]Almazov National Medical Research Centre, Pediatrics, Saint-Petersburg, Russian Federation*

Background: the role of interferon pathways in the pathogenesis of systemic lupus erythematosus (SLE) has been proven over the past years. Existing data suggest that interferon score (IFN I score) may serve as a useful marker of disease activity and patient clinical characteristics.

Objectives: to compare characteristics of pediatric SLE patients with high and normal IFN I score.

Methods: 40 SLE patients (33 girls, 7 boys) under 18 years old were included in the cross-sectional study. In all cases the diagnosis was made using Systemic Lupus International Collaborating Clinics (SLICC) classification criteria. The data on clinical manifestations, disease activity by SLEDAI and ECLAM, laboratory findings in the onset of the disease and at the moment of interferon signature assessment were evaluated. Interferon signature was assessed by real-time PCR quantitation of 5 IFN I-regulated transcripts; median expression of ≥2 was considered as a threshold. The patients were divided into 2 groups depending on the level of interferon score: high (group1, n=31) and normal (group2, n=9).

Results: The mean age of the disease onset was 12 (9.5; 14.0) years. The most common symptoms were skin lesions (85%), arthritis (67.5%), fever (55%), mucosa (45%), CNS (37.5%) and kidney (30%) involvement. Anemia, leukopenia and thrombocytopenia were observed in 62.5%, 27.5% and 50% of cases,

while 87.5% and 70% of patients had ANA positivity and dsDNA antibodies at the onset. The comparison between the groups with increased and normal IFN I-signature is presented in Table 1.

Table 1.

Parameters	Group 1 (High IFN-s)	Group 2 (Normal IFN-s)	p-value
Girls, n (%)	25 (80.7)	8 (88.9)	0.567
The onset age, years	12.0(10.0; 14.0)	11.0 (9.0; 13.0)	0.353
Time to IFN-signature study, months from onset	18.3 (7.0; 26.5)	0.97 (0.87;1.73)	0.987
Skin involvement, n (%)	12 (38.7)	4 (44.4)	0.837
CNS involvement, n(%)	8 (25.8)	1 (11.1)	0.353
Arthritis, n(%)	11 (35.5)	2 (22.2)	0.455
Anemia, n(%)	9 (29.0)	2 (22.20	0.687
Leucopenia, n(%)	9 (29.0)	1 (11.1)	0.274
ANA-positivity, n (%)	27 (87.1)	5 (55.6)	0.037
anti dsDNA antibodies, n(%)	12 (38.7)	2 (22.2)	0.361
Rheumatoid factor, n (%)	11 (35.5)	0 (0.0)	0.036
Hypocomplementemia, n (%)	18/28 (64.3)	2/6 (33.3)	0.162
Ferritin level, mkg/l	112.0 (39.0; 271.0)	21.0 (5.3; 23.7)	0.0008
Hematuria, n (%)	10 (32.3)	0 (0.0)	0.049
Proteinuria, n (%)	11 (35.5)	0 (0.0)	0.036
SELENA-SLEDAI, points	9 (2;15)	1 (0; 4)	0.073
ECLAM, points	3.0 (1.0; 6.0)	1.0 (0.0; 1.5)	0.048
Treatment with Rituximab or Cyclophosphamide, n (%)	22 (71.0)	3 (33.3)	0.040
GCS dose 0,2 mg/kg achievement for 6 months, n (%)	9/21 (42.9)	5/6 (83.3)	0.080

Conclusion: high IFN I-signature correlated with kidney involvement, ANA and RF-positivity, ferritinemia, proteinuria and hematuria. Patients with high IFN I-signature received more aggressive treatment and needed longer glucocorticosteroid (GCS) treatment. More meticulous dynamic evaluation of IFN-signature is needed to clarify its role as a predictive and prognostic marker.

Cimaz[3], P. Costa Reis[3], D. Eleftheriou[3], L. Harel[3], G. Horneff[3], S. Johnson[3], D. Kaiser[3], T. Kallinich[3], D. Lazarevic[3], K. Minden[2], S. Nielsen[3], F. Nuruzzaman[3], S. Opsahl Hetlevik[3], Y. Uziel[3], N. Helmus[1]. *[1]Hamburg Centre for Pediatric and Adolescent Rheumatology, Schön Klinik Hamburg Eilbek, Hamburg, Germany*; *[2]German Rheumatism Research Center, German Rheumatism Research Center, Berlin, Germany*; *[3]jSSc Collaborative Group, Hamburg Centre for Pediatric and Adolescent Rheumatology, Hamburg, Germany*

Background: Juvenile systemic sclerosis (jSSc) is a rare disease with a prevalence of around 3 in 1,000,000 children. To better capture the clinical manifestations of jSSc the juvenile systemic sclerosis inception cohort (jSScC) has been prospectively enrolling patients with predetermined clinical variables over the past 12 years. One of the goals is to study the demographic, clinical features, and physician and patient reported outcome differences between those with juvenile limited cutaneous (lc) compared to diffuse cutaneous (dc) disease subtypes, to determine if characteristics are similar or different between dc and lc jSSc.

Objectives: Evaluation of the baseline clinical characteristics of jSSc patients in the jSScC. Compare clinical phenotype between diffuse (dcjSSc) and limited cutaneous (lcjSSc) subtypes.

Methods: Demographic, physical examination, organ system evaluation, autoantibody profile, treatment, and patient and physician reported outcome variables were evaluated from the jSSc Inception cohort and summary statistics applied using chi-square test and Mann Whitney U-test comparing lcjSSc and dcjSSc subtypes.

Results: At the time of data extraction, 175 jSSc patients were enrolled in the cohort, 81% were Caucasian and 81% female. Diffuse cutaneous jSSc subtype predominated (73%). Mean disease duration was 3.1 year (±2.7). Mean age at Raynaud´s was 10 years (+3.8) and mean age of first non-Raynaud´s was 10.2 years (±3.8). Significant differences were found between dcjSSc versus lcjSSc, regarding several clinical characteristics. Patients with diffuse cutaneous subtype had significantly higher modified Rodnan skin score (p=0.001), presence of sclerodactyly (p=0.02), presence of Gottron's papules (p=0.003), presence of telangiectasia (p=0.001), history of digital tip ulceration (p=0.01), and frequency of elevated CK value (p=0.04). Cardiac involvement was significantly higher in limited cutaneous jSSc subtype (p=0.02). Diffuse cutaneous jSSc patients had significantly worse scores for Physician Global Assessment of disease activity (38 vs 25; p=0.002) and disease damage (34 vs 19; p=0.008).

Table 1. Comparison of demographic data and significant differences between dcjSSc and lcjSSc at time of inclusion

	Whole Cohort N=175	Diffuse Subtype N=128	Limited Subtype N=47	P value
Female to Male Ratio	4.3:1 (142/33)	4.1:1 (103/25)	4.8:1 (39/8)	0.829
Cutaneous subtype				
Diffuse subtype	73% (128)	128	0	
Limited subtype	27% (47)	0	47	
Mean Disease duration (years)	3.1 (± 2.7)	3.3 (± 2.9)	2.6 (± 2.2)	0.135
Mean age of onset of Raynaud´s (years)	10.0 (± 3.8) 17 non-Raynaud	9.8 (± 3.6) 10 non-Raynaud	10.6 (± 4.3) 7 non-Raynaud	0.219
Mean age of onset of non-Raynaud´s (years)	10.2 (± 3.9)	10.0 (± 3.7)	10.9 (± 4.3)	0.173
Disease modifying drugs	88% (154)	89% (114)	85% (40)	0.446
Cutaneous				
Mean modified Rodnan skin score	14.3 (0-51)	17.4 (0-51)	6.1 (0-24)	0.001
Gottron Papules	27% (46/171)	33% (41/124)	11% (5)	0.003
Sclerodactyly	78% (126/162)	82% (98/119)	65% (28/43)	0.020
Laboratory values	25% (30/122)	30% (26/88)	12% (4/34)	0.041
Elevated CK				
Vascular				
Telangiectasia	36% (56/154)	44% (49/111)	16% (7/43)	0.001
History of ulceration	53% (91/173)	61% (77/127)	30% (14/46)	0.001
Cardiac	6% (10)	2% (3)	15% (7)	0.002
Cardiac Involvement				
Patient Related Outcomes				
Physician global disease activity (0-100) min -max	35 (0-90) n=141	38 (0-90) n=108	25 (0-80) n=33	0.002
Physician global disease damage (0-100) min -max	31 (0-85) n=140	34 (0-85) n=108	19 (0-60) n=32	0.008

Conclusion: Results from this large international cohort of jSSc patients demonstrate significant differences between dcjSSc and lcjSSc patients. According to the general organ involvement and physician global scores, the dcjSSc patients had significantly more severe disease. These observations strengthen our previous findings of the unique organ pattern of pediatric patients.

POS0080 TOFACITINIB TREATMENT IN CHILDREN WITH RHEUMATIC DISEASES: SINGLE-CENTER EXPERIENCE

M. Kostik[1], R. Raupov[1], E. Suspitsin[2], E. Isupova[1], T. Gabrusskaya[3], M. Dubko[1], L. Snegireva[1], V. Masalova[1], T. Ermachenkova[2], L. Sorokina[1], T. Likhacheva[1], M. Kaneva[1], E. Gaidar[1], O. Kalashnikova[1], V. Chasnyk[1]. *[1]Saint-Petersburg State Pediatric Medical University, Hospital Pediatrics, Saint-Petersburg, Russian Federation*; *[2]N.N.Petrov Institute of Oncology, Molecular diagnostics, Saint-Petersburg, Russian Federation*; *[3]Saint-Petersburg State Pediatric Medical University, Gasrtoenterology, Saint-Petersburg, Russian Federation*

Background: While efficacy of tofacitinib (TOF) has been proven in many adult immune-mediated conditions, the information on its' safety and efficacy in the pediatric population is limited.

Objectives: to evaluate the safety and efficacy of TOF in children with immune-mediated diseases.

Methods: from 23 children whom TOF has been initiated, 17 children with treatment duration of > 6 months were extracted including 16 girls and 1 boy with the following diagnosis: JIA (n=10), autoinflammatory diseases (AID) (n=5) and juvenile dermatomyositis (JDM) (n=2) due to impossibility to taper corticosteroids (CS) or previous biologic treatment failed. The treatment outcome was classified according to the opinion of the attending physicians as complete response (CR) i.e., the absence of disease activity, partial response (PR) – a significant

Table 1.

#	Diagnosis	Indication	Previous biologics	Current treat-ment	TOF, dose, mg/kg	Duration of TOF treat-ment, months	Genetic variants detected	Efficacy
1	AID	Severe inflamma-tion, aortitis, colitis	INX, TCZ, ADA	CS, TOF	0.5	7	NOD2 c.2578G>A (p.A860T); NOD2 c.2722G>C (p.G908R) ADA2 c.927G>A (p.M309I)	PR
2	JDM	recurrent skin rash		CS, TOF, MTX	0.5	5		PR
3	JDM	skin involvement, ulceration		CS, MTX, TOF	0.7	7	NLRP12c.154G>A (p.G52S)	CR
4	AID, IFP	skin rash, recurrent inflammation, failure to thrive	CAN, TCZ	CS, TOF, CAN	0.5	32	RNASEH2B c.916dupA (p.I309Nfs*7)	CR
5	JIA, poly	severe arthritis	ETA,TCZ, ADA	TOF,TCZ	0.27	22		PR
6	soJIA	resistant to CS and biologic systemic inflammation, arthritis	TCZ, ABC, CAN	TOF, TCZ	0.4	23		PR

9	AID, IFP	systemic inflammation, ulcers	ETA	TOF, CS	0.5	13		CR
10	JIA, ERA	arthritis	ETA	TOF, MTX	0.2	44		CR
11	JIA, poly	arthritis	ABC, ETA	TOF, MTX	0.25	38		CR
12	JIA, poly	Arthritis, alopecia	ETA	TOF	0.15	31		PR
13	soJIA + MAS	systemic inflammation, arthritis	TCZ, CAN, ETA	TOF, CS	0.5	38		NR
14	JIA, poly	arthritis	INX, ETA, ADA, TCZ	TOF, MTX	0.2	24		PR
15	AID	Systemic inflammation, CS-dependency	TCZ	TOF,CS	0.5	21	STAT3, c1343A>C	PR
16	JIA, ERA	arthritis	ETA	TOF	0.25	21		PR
17	JIA, poly	arthritis	ADA, TCZ, ETA	TOF	0.15	39		CR

improvement of symptoms and disease activity or no response (NR) - no changes in disease activity.

Results: Mean duration of TOF treatment was 25.4±18.9 months. TOF was used as monotherapy in 3 cases, in combination with methotrexate (MTX) in 6, and in combination with other biologics in 3 children: tocilizumab (n=2) and canakinumab (n=1). Nine patients received CS. (Table 1). In two JIA patients with alopecia TOF induced intensive hair growth and controlled joint inflammation. 9 patients had CR: AID (n=3), JIA (n=4) and JDM(n=1): 7 patients had PR and 1 was NR. 13 patients had a previous history of several subsequent failed biologic: 4 biologics (n=1), 3 biologics (n=6), 2 biologics (n=1), 1 biologic (n=5). TOF treatment allowed discontinuation of CS in patient#6 and reducing the CS in 8/10 patients from 0.4 ±0.27 mg/kg to 0.15±0.1 mg/kg in 3.7±3.4 times: in 2 cases the tapering of steroids failed (Figure 1). 4 patients had side effects not requiring treatment discontinuation: liver enzymes elevation (n=2), hypercholesterolemia (n=1), lymphadenitis (n=1). In pt#6 after achievement of the remission the TOF dosage was decreased up to 2 times and tocilizumab intervals were increased up to 6 weeks.

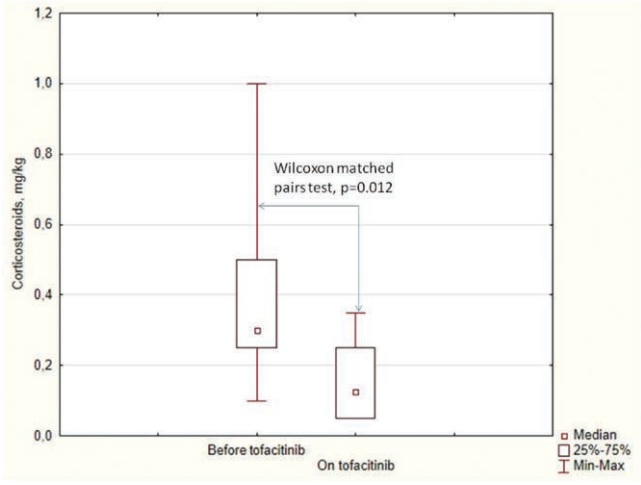

Figure 1.

Conclusion: Tofacitinib is a promising agent in treating pediatric rheumatic diseases. In our study the best results were in AID patients with rare alleles in interferon pathway genes, patients with arthritis and alopecia and in children with JDM. Future studies are needed to identify clear indications for treatment with JAK-inhibitors.

POS0081 CLINICAL FEATURES OF PEDIATRIC BEHÇET'S DISEASE IN CHINA

S. Zheng[1], Z. Huang[1], Y. Liu[1], Y. Huang[1], T. W. Li[1]. [1]*Guangdong Second Provincial General Hospital, Rheumatology, Guangzhou, China*

Background: Behçet's disease (BD) is a systemic inflammatory disease involving primarily the oral and genital mucosa, skin and eyes. Some patients exhibit broader involvement with multi-organ system inflammation, causing significant morbidity and mortality. With much of the literature focused on adult-onset BD, the clinical spectrum of BD in children is not well studied. The diagnosis of pediatric BD is difficult to make due to its rarity in childhood, the paucity of experience among pediatricians and the lack of validated diagnostic criteria.

Objectives: We aim to describe the clinical characteristic of children with Behçet's disease in China.

Methods: We performed a cross-sectional cohort analysis of patients with BD recruited between June 2017 and May 2020. We enrolled a total of 848 patients with pediatric BD (onset prior to age 18 years) and 1531 patients with adult-onset BD. Clinical data were collected by retrospective chart review.

Results: From a cohort of 848 patients with pediatric BD (412 males, 436 females), the average age of disease onset was 11.59 ± 4.11 years and the earliest case was appeared the first symptom at 7 months of age. Clinical manifestations in this group included recurrent oral aphtosis (100%), genital ulcers (77.71%), ocular involvement (30.19%), skin involvement (63.56%), neurological involvement (4.60%), gastrointestinal involvement (20.05%), vascular involvement (9.79%), heart valve involvement (3.66%), arthritis / arthralgia (32.43%), fever (0.35%) and positive pathergy test (21.11%; Table 1). The prevalence of these clinical findings was largely similar to that of adult BD patients with the exception of mild differences in the frequency of gastrointestinal, heart valve, joint involvement and fever. However, the time from symptom onset to diagnosis was significantly longer in children with BD compared to adults (13.34±9.13 years vs. 6.73±33.21 years, P<0.001). The most common initial symptom in pediatric BD was recurrent oral aphtosis (91.57% vs. 86.28% in adults, P<0.001).

In the pediatric group, clinical manifestations also differed between males and females. In addition to oral ulcers, the most common clinical manifestations in male patients were ocular involvement (42.23%), vascular involvement (15.53%), heart

valve involvement (5.10%) and epididymitis (9.95%). Among female patients, the frequency of genital ulcers is significantly higher than that of men (86.24% vs. 68.69%, P<0.001).

Conclusion: We described the clinical characteristics of a large cohort of pediatric BD patients in China. While the clinical manifestations are largely similar to adult BD, the time from symptom onset to diagnosis is significantly delayed in pediatric patients. Our study highlights the need to improve awareness of BD among pediatric providers to facilitate rapid diagnosis and treatment in children.

POS0082 PERFORMANCES OF THE RISK FACTORS AND PEDIATRIC VASCULITIS ACTIVITY SCORES FOR DISEASE SEVERITY IN CHILDREN WITH MULTISYSTEM INFLAMMATORY SYNDROME

B. Sözeri[1], Ş. Çağlayan[1], A. Akyol[2], K. Ulu[1], T. Coşkuner[1], C. Hasbal Akkuş[2], F. Demir[1]. [1]*Health Sciences University, Umraniye Traning and Research Hospita, Pediatric rheumatology, Istanbul, Turkey*; [2]*Health Sciences University, Umraniye Traning and Research Hospita, Pediatrics, Istanbul, Turkey*

Background: Multisystem Inflammatory Syndrome in Children (MIS-C) is observed by hyperinflammation and cytokine storm. The spectrum of severity ranged from standard hospitalization to pediatric intensive care unit management. There is no specific activity score that predicts whether this hyperinflammatory state will be severe or result in mortality in pediatric patients. There are activity scores used in KD and other vasculitis such as Kobayashi score (KS) and Pediatric Vasculitis Activity Score (PVAS) that determine the severity of the disease in children.

Objectives: Based on the clinical similarity of MIS-C to these disease groups, we wanted to evaluate the performance of these disease activity scores. Also, we aimed to identify the factors associated with the disease severity of patients with MISC

Methods: We retrospectively enrolled a single-center cohort of 45 consecutive pediatric patients with MISC admitted to Umraniye Training and Resrach Hospital, Pediatric Rheumatology Clinic, Istanbul, Turkey, from April 20 to December 31, 2020. Medical information of each patient including demographic data, clinical characteristics, laboratory results, and outcomes was extracted retrospectively through review of electronic medical records. We analyzed all score systems including KS, PVAS, NLR, cHIS, and C-reactive protein/albumin ratio (CAR) as assessment factors for diagnosis for severe disease and evaluation of disease activity in MISC. All scores were compared between two groups and receiver operating characteristic (ROC) curve analysis was performed to evaluate diagnostic utility.

Results: We reported 45 patients (10 female, 35male) with MISC. Their mean age was 9.65±4.93 years (7 months-18 years). All patients had fever (median 4 days), 71 % patients had acute gastrointestinal symptoms, 37.8 % of patient's conjunctivitis and only 5 patients had respiratory findings at admission. Twenty-four (46.7%) patients met criteria for classic KD. Macrophage activation syndrome and myocardial dysfunction with or without cardiogenic shock were seen 14 and 10 patients respectively. All the patients had positive serology for SARS-CoV-2, abnormal complete blood counts and coagulation tests, and elevated inflammatory markers.

We divided the disease severity into a moderate or severe group based on admission on intensive care unit (ICU). There were 15 patients with severe illness (33%). The median age of these patients was significantly older (11.3 years vs 9.16 years, p=0.05). The median hospital stay period was 10 days. The median need for intensive care was on the first day (1-14th days), and the median lasted 5 (1-9) days. The majority of MISC patients were on Intravenous immunoglobulin (IVIG) (89%), and corticosteroid (73.3%). A total of 12 patients received anakinra. In the severe group, all patients had higher values of KD, PVAS, NLR, cHIS, and CAR than the patients in moderate group. For severe MISC, the area under receiver operating characteristic curve (AUC) was 0.864 (95% confidence interval [CI], 0.729–1) for the PVAS, 0.911 (95% CI, 0.827–0.995) for the NLR, and 0.853 (95% CI, 0.744–0.963) for the CAR, with optimal cut-off values of 3.5, 9.05, and 4.86, respectively. Thirty-eight (84.4%) of the 45 patients met two or more cHIS criteria at the time of their hospitalization; 39% of these patients were identified as severe group (OR 1.62, 95% CI 1.27-2.13, p=0.04). At the time of diagnosis, 29 patients with a Kobayashi score greater than 4 were detected, of which 15 required intensive care (OR 2.07, 95% CI 1.42-3.0, p=0.00).

Conclusion: This study demonstrated that both inflammatory scores (CAR and NLR) and disease activity scores (KS, PVAS and cHIS) can be used to aid the assessment for severity of MISC

POS0083 USEFUL EXPERIENCE OF RHEUMATOLOGISTS FOR UNDERSTANDING OF THE DISEASE ORIGIN AND APPROACHES TO THERAPY IN FIBRODYSPLASIA OSSIFICANS PROGRESSIVA

I. Nikishina[1], S. Arsenyeva[1], V. Matkava[1], A. Arefieva[1], M. Kaleda[1], T. Pachkoria[1], Z. Kolkhidova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Paediatric, Moscow, Russian Federation*

Background: Many monogenic genetic conditions, such as auto-inflammatory diseases (AIDs), have similar clinical manifestations and immunopathogenesis to "classic" rheumatic diseases (RD). Such cases may include Fibrodysplasia ossificans progressiva (FOP), an extremely rare genetic disease, which, according to our previous study and data from other authors1, may represent an example of AID with catastrophic heterotopic ossification due to a mutation in the ACVR1 gene. it seems that the experience of rheumatologists, especially children's ones, will be useful in the treatment of FOP.

Objectives: To analyzed the dynamics of clinical manifestations and to therapy approaches including target anti-inflammatory drug Tofacitinib (TOFA) in the one of the world's largest groups of patients (pts) with FOP.

Methods: The study was based on the analysis retrospective and prospective observation of the 35 pts (17 males and 18 females) with a verified diagnosis of FOP for the period from 1998 to 2020. In 9 pts with severe course of FOP TOFA administration were evaluated.

Results: In all 35 pts the diagnosis was verified by "classic" FOP phenotype: malformed great toes in 33 pts (94,3%); short malformed thumbs-8 (22.8%); peripheral osteochondromas-20 (57.1%); abnormalities of the cervical spine-32 (91.4%), multiple heterotopic ossifications-32 (91,4%). Genetic tests were done in 26, it confirmed mutation in the ACVR1 gene in 100%. Long term follow-up detected a lot of spondyloarthritis-like signs similar to the manifestation of RD: ankylosis of the facet joints and vertebral bodies (by the type of syndesmophytes) in most pts, sacroiliitis, confirmed by radiological methods (X-ray, CT, MRI), gradual ankylosis in the peripheral joints in 18 (56.4%), synovitis in large joints in 8 (25%) pts (knee and hip mostly). In 9 pts with the most difficult course with rapid progression of ossification due to continuous flares despite the NSAIDs and steroids intake, we tried to use TOFA after the approval of the local Ethic Committee. We use the similar dose to randomized trial for JIA (up to 5 mg twice a day). The first patient was 16 y.o. at the time of TOFA administration in December 2019, the age of the other pts was from 2 to 12 y.o. By present time duration of TOFA therapy is from 6 to 15 mo. For the previous 6 months before TOFA initiation the number of flares was in average 8 per patient. After 6 months of TOFA treatment the number of new flares decreased to 0-1, except youngest patient of 2 y.o. in whom the number of flares decreased from 10 to 4 per the same period. In all 9 pts we minimize the dose or completely stop the steroids. New nodes formation stopped immediately in most pts and also the significant motion improvement of large (shoulder) joints were established. Drug tolerance was good in all pts, no AE were registered. But despite the good clinical effect without new heterotopic ossification in our first patient, we found continuous intraskeletal ossification between vertebral bodies, facet and sacroiliac joints in MRI.

Conclusion: We are confident that the processes of heterotopic ossification in FOP are very similar to new born formation phenomenon in spondyloarthritis and reliable suppression of inflammation can interrupt the progression of the disease. We used similar justifications to our colleagues for the use of anti-cytokine drugs, but used a JAK-kinase inhibitor, it was extremely important the oral rout of drug administration and possibility to escape any injections in FOP. TOFA demonstrated positive effect

and safety in children with severe course of FOP. It showed their advantages over the use of steroids and possibility to inhibit the rate of progression.

POS0084 SEPTIC ARTHRITIS IN CHILDREN. A LONGITUDINAL POPULATION-BASED STUDY IN WESTERN AUSTRALIA

J. Nossent[1,2], D. Preen[3], H. Keen[1,4], W. Raymond[1], C. Inderjeeth[1,2]. [1]*The University of Western Australia, Medical School, Rheumatology Section, Perth, Australia*; [2]*Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia*; [3]*The University of Western Australia, School of Population and Global Health, Bentley, Australia*; [4]*Fiona Stanley Hospital, Rheumatology, Murdoch, Australia*

Background: The incidence of Septic arthritis (SA) in adults is rising, but few data are available for children (1). SA symptomatology in young children is often atypical and delayed diagnosis can cause significant morbidity.

Objectives: To describe the incidence, risk factors and long-term outcomes in children hospitalised with septic arthritis (SA) in Western Australia (WA).

Methods: We extracted population-based longitudinally linked administrative health data for patients under 16 years with a first inpatient primary or secondary code of 711.xx (ICD9-CM) and M00.xx (ICD10-AM) in WA for the study period 1990-2010 (to allow a minimum 5 year followup). We report annual incidence rates per 100.000 (AIR), prior conditions during lookback (median 15 months, IQR 5-45) as well as joint and other comorbidities including Charlson comorbidity index (CCI) and standardised mortality rates (SMR) during a median follow-up of 10 years. Age and gender speficic population and mortality rate data were obtained from the Australian Bureau of Statistics.

Results: A total of 891 patients (62% male, median age 6.4 (IQR 1.9-10.6) years with 34% <3 years of age) had a first admission for SA. AIR was 9.85 (CI 4.79-14.41) overall with higher rates in males (11.9 vs 7, p<0.01) and no apparent period (Figure 1) or seasonal variation. Knees (43.9%), hips (34.6%), and ankles (13.3%) were most frequently affected with Staphylococci (49%) the predominant organism in patients with positive cultures (41.5%). Prior infections (40.4%) and respiratory disease (7 %) were the main preexisting morbidities. Mean hospital stay was 5.78 (± 6.4) days with ICU admission required in 1.9%, while 30-day readmittance rate was 10.4%. During follow-up 25 patients (3%) had recurrent/persistent osteomyelitis, nine patients were diagnosed with osteoarthrosis (1.1%) and five patients (0.6%) underwent joint replacement. More female patients developed new comorbidity (CCI>0, 34.6 vs 27.2%, p=0.02) including diabetes (4.2% vs 0%, p=0.001), cardiovascular events (4.2 vs 1.4%, p=0.002) and chronic arthritis (1% vs 0, p=0.05). While the crude mortality rate was low (0.3%) SMR was significantly increased for female patients (10.52, CI 1.59-41.6).

Conclusion: The statewide incidence of septic arthritis in children in WA is similar to a recent report (1) and did not change over a 20-year period. In this large population based study, subsequent bone/joint disease occured in 4.6 %, while a third of patients developed other comorbidity before the age of 18. Such (subclinical) comorbidity may thus be a contributing factor to SA development and to the increased mortality risk in female SA patients.

POS0085 EVALUATION OF DURATION OF CLINICAL REMISSION IN CHILDREN WITH NON-SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS AFTER WITHDRAWAL OF ANTI – TUMOR NECROSIS FACTOR - ALPHA THERAPY

I. Tsulukiya[1], E. Alexeeva[1,2], T. Dvoryakovskaya[1,2], K. Isaeva[1], R. Denisova[1], O. Lomakina[1], A. Mamutova[1], A. Chomakhidze[1], A. Fetisova[1], M. Gautier[1], I. Kriulin[1,2], E. Krekhova[1,2]. [1]*National Medical Research Center of Children's Health, Rheumatology, Moscow, Russian Federation*; [2]*Sechenov First Moscow State Medical University, Pediatric, Moscow, Russian Federation*

Background: Juvenile idiopathic arthritis (JIA) is the most common and prevalent rheumatic disease in childhood which is based on a chronic autoimmune inflammation. Inactive disease and remission are now the primary treatment goal in JIA and biologics have been playing an important role to reach this objective. The biologics of the first choice for the treatment of non-systemic JIA are the Tumor Necrosis Factor - alpha (TNFα) inhibitors; on this therapy patients can achieve clinically inactive disease and long-term remission.

Currently, little is known about when or how to stop TNFα inhibitors, when a good clinical response is achieved, and therefore no guidelines are available.

Objectives: To estimate the length of clinical remission after discontinuation of treatment with TNFα inhibitors in patients with non-systemic juvenile idiopathic arthritis.

Methods: A total of 393 patients with JIA who were treated with TNFα inhibitors at the Rheumatology Department of the National Medical Research Center of Children's Health (Moscow, Russia) were screened for inclusion in this retrospective study.

Patients were treated with etanercept 1 times a week, 0.8 mg per kg of body weight per dose, with adalimumab 24 mg/m2 body surface area administered every other week until the end of therapy.Treatment was terminated abruptly. Inactive disease was defined according to the preliminary criteria of Wallace et al.[1]

Results: 77 patients (27—male, 50—female) with a mean age at diagnosis of 4 years (range 1–18 years) were included in the analysis. Of those, 69 of them discontinued TNFα inhibitors due to a long-term remission on treatment, 8 patients as a result of side effects, and there were excluded from our study.:

allergic reaction (n = 5), development of uveitis (n = 1), alopecia (n = 1), recurrent infection (n=11).The clinical subtypes of JIA were RF-negative polyarticular JIA -28 (40,58%) oligoarthritis—38 (55,07%), enthesitis-related arthritis—3 (4,35%). TNFα inhibitors were started after a mean 46,43 (range 1–144) months of disease. The mean duration of therapy with TNFα inhibitors were 46,63 (range 10-113) months, with a mean duration of remission on medication 40,63 (range 6-107) months before withdrawal of TNFα inhibitors.

40/69 (57,97 %) patients did not develop a disease exacerbation and remained in long-term remission off medication—more than 24 months.

Early flares, that is less than 6 months after termination of TNFα inhibitors, were observed in 4/69 (5,8%) patients.

29 (42,03%) patients restarted TNFα inhibitors after exacerbation, due to lack of improvement after no biological DMARDs. All patients in whom TNFα inhibitors were reinitiated responded satisfactorily.

Conclusion: Among patients with JIA in whom TNFα inhibitors were discontinued after inactive disease was achieved, 57,97 % had disease in clinical remission more than 24 months after stopping anti-TNFα therapy. No association was observed between the duration of inactive disease prior to TNFα inhibitors cessation and the time to disease relapse. In addition, we also ob- served no correlation between the risk of flare and the length of anti-TNF α therapy after inactive disease was achieved. In our population, TNFα antagonists were withdrawn a median of 38 (4-107) months after inactive disease was achieved. Data from our experience with anti-TNF α agents in the treatment of JIA suggest that 57,97 % of patients can be successfully withdrawn from TNF α antagonists for at least 24 months.

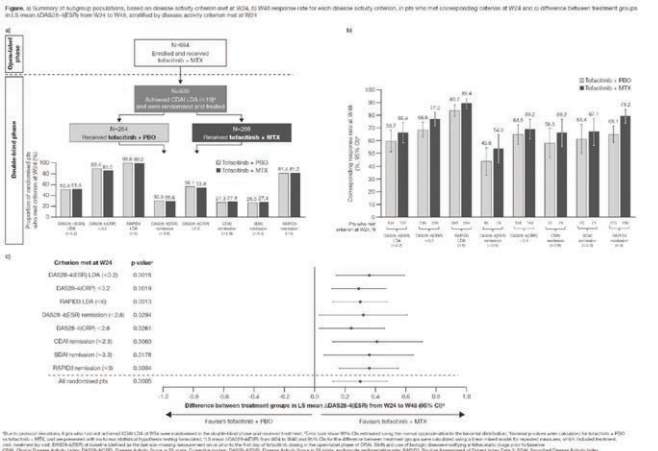
ANALYSIS OF DISEASE ACTIVITY MEASURES IN THE CONTEXT OF A METHOTREXATE WITHDRAWAL STUDY AMONG PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TOFACITINIB 11 MG ONCE DAILY + METHOTREXATE: POST HOC ANALYSIS OF DATA FROM ORAL SHIFT

R. Fleischmann[1], B. Haraoui[2], M. H. Buch[3,4], D. Gold[5], G. Sawyerr[6], H. Shi[7], A. Diehl[7], K. Lee[6]. [1]*Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Department of Medicine, Dallas, TX, United States of America*; [2]*Institut de Rhumatologie de Montréal, Montreal, QC, Canada*; [3]*School of Biological Sciences, Faculty of Biology, Medicine & Health, University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom*; [4]*NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom*; [5]*Pfizer Inc, Inflammation and Immunology, Montreal, QC, Canada*; [6]*Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; [7]*Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America*

Background: The Phase 3b/4 study ORAL Shift demonstrated sustained efficacy and safety of tofacitinib modified-release (MR) 11 mg once daily (QD) following methotrexate (MTX) withdrawal that was non-inferior to continued tofacitinib + MTX use (per DAS28-4[ESR]), in patients (pts) with rheumatoid arthritis (RA) who achieved CDAI-defined low disease activity (LDA) with tofacitinib + MTX at Week (W)24.[1]
Objectives: To assess the performance of alternative disease activity measures at W24 (randomisation) and W48 (study endpoint) in ORAL Shift.
Methods: ORAL Shift (NCT02831855) enrolled pts aged ≥18 years with moderate to severe RA and an inadequate response to MTX. Pts received open-label tofacitinib MR 11 mg QD + MTX for 24 weeks. Achievement of CDAI LDA (≤10) at W24 was set as the criteria for entry to the 24-week double-blind MTX withdrawal phase, with pts randomised 1:1 to receive tofacitinib MR 11 mg QD + placebo (PBO) (ie blinded MTX withdrawal) or continue tofacitinib + MTX. In this post hoc analysis, efficacy analyses were performed in 8 subgroups defined by achievement of various disease activity criteria at W24: DAS28-4(ESR) remission (<2.6) or LDA (≤3.2); DAS28-4(CRP) <2.6 or ≤3.2; RAPID3 remission (≤3) or LDA (≤6); CDAI remission (≤2.8); and SDAI remission (≤3.3). For each subgroup, the proportion of pts who achieved the corresponding disease activity criterion at W48 was calculated, with a 95% confidence interval (CI) estimated using the normal approximation to the binomial distribution. The change (Δ) from W24 to W48 in least squares (LS) mean DAS28-4(ESR) and DAS28-4(CRP) was also calculated in each subgroup, with a 95% CI for the difference between treatment groups estimated using a mixed model with repeated measures. Nominal p values were calculated and are presented with no formal statistical hypothesis testing formulated.
Results: Overall, 694 pts entered the open-label phase of ORAL Shift, and 530 were randomised and received treatment in the double-blind phase; 264 and 266 pts received tofacitinib + PBO and tofacitinib + MTX, respectively (Figure 1a). Considering those pts who were randomised and treated, the proportion of pts achieving each disease activity criterion at W24 varied, but was similar between treatments within each subgroup (Figure 1a). Among pts who met each disease activity criterion at W24, generally the majority of pts in both treatment groups also met the same criterion at W48 (Figure 1b). Numerically more pts receiving tofacitinib + MTX vs tofacitinib + PBO continued to meet the corresponding criterion at W48. Regardless of the disease activity criterion met at W24, differences between treatment groups in LS mean ΔDAS28-4(ESR) (Figure 1c) and ΔDAS28-4(CRP) (data not shown) from W24 to W48 favoured tofacitinib + MTX vs tofacitinib + PBO.



Conclusion: This post hoc analysis of data from pts randomised and treated in ORAL Shift demonstrated that, regardless of the disease activity state criterion met at W24, generally a majority of pts receiving tofacitinib maintained achievement of the corresponding disease activity criterion at W48, with or without continued MTX. Differences between treatment groups in LS mean ΔDAS28-4(ESR) from W24 to W48, as defined by achievement of LDA or remission with a variety of disease activity measures, were less than a change of 1.2, which is considered to be the threshold for a minimal clinically important improvement.[2]

POS0087

LONG-TERM SAFETY AND EFFICACY OF UPADACITINIB OR ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS AT 3 YEARS FROM THE SELECT-COMPARE STUDY

R. Fleischmann[1], E. Mysler[2], L. Bessette[3], C. Peterfy[4], P. Durez[5], Y. Tanaka[6], J. Swierkot[7], N. Khan[8], X. Bu[8], Y. LI[8], I. H. Song[8]. [1]*Univ of Texas Southwestern Med Center, Metroplex Clinical Research Center, Dallas, United States of America*; [2]*Organización Medica de Investigación, Rheumatology, Buenos Aires, Argentina*; [3]*Laval University, Rheumatology, Quebec, Canada*; [4]*Spire Sciences Inc, Boca Raton, United States of America*; [5]*Institut de Recherche Expérimentale et Clinique, UCL Saint-Luc, Pôle de Recherche en Rhumatologie, Brussels, Belgium*; [6]*University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan*; [7]*Wroclaw Medical University, Department of Rheumatology and Internal Medicine, Wroclaw, Poland*; [8]*AbbVie, Immunology, North Chicago, United States of America*

Background: In the SELECT-COMPARE study, the Janus kinase inhibitor, upadacitinib (UPA), demonstrated significant improvements in the signs and symptoms of rheumatoid arthritis (RA) when administered at 15 mg once daily (QD) on background methotrexate (MTX) compared with adalimumab (ADA) plus MTX at Week 12 that were maintained through 72 weeks in patients with prior inadequate response to MTX.[1]
Objectives: To assess the long-term safety and efficacy of UPA vs ADA over 3 years in the ongoing long-term extension (LTE).
Methods: Patients receiving background MTX were randomized 2:2:1 to UPA 15 mg QD, placebo (PBO), or ADA 40 mg every other week. Between Weeks 14-26, rescue was mandated for either lack of response (<20% improvement in tender or swollen joint counts: Weeks 14, 18, 22) or failure to achieve a targeted disease outcome (CDAI low disease activity: Week 26). Patients who completed the 48-week double-blind period could enter an LTE for up to 10 years total. This analysis describes patients through 3 years of treatment. Treatment-emergent adverse events (TEAEs) per 100 patient years (PY), including events of special interest (AESI), were summarized up to 3 years based on exposure to UPA and to ADA. Efficacy was analyzed by original randomized groups. Patients who were rescued or prematurely discontinued study drug were categorized as non-responders for visits after rescue or discontinuation. Descriptive analyses were performed without formal statistical comparisons.
Results: In total, 651, 651, and 327 patients were randomized at baseline to receive UPA, PBO, and ADA, respectively. Between Weeks 14-26, 252 (39%) patients were rescued from UPA to ADA, 159 (49%) were rescued from ADA to UPA, and all PBO patients were switched to UPA by Week 26.[1] A higher proportion of patients randomized to UPA completed 3 years without rescue compared to those randomized to ADA (47% vs 36%, respectively). UPA was generally well-tolerated as assessed by the rates of TEAEs, including serious AEs, AEs leading to discontinuation of study drug, and AESIs, including serious and opportunistic infections, malignancies, adjudicated major adverse cardiac events or venous thromboembolism; Figure 1). Consistent with previous analyses, the event rates of AESIs were generally comparable between the UPA and

ADA groups, while herpes zoster, lymphopenia, hepatic disorder, and CPK elevation were reported at higher rates with UPA. Consistent with earlier time points, greater proportions of patients randomized to UPA achieved low disease activity and remission at 3 years based on CDAI, as well as DAS28(CRP) ≤3.2 or <2.6, compared with patients randomized to ADA (Table 1).

Conclusion: The safety profile of UPA was consistent with the results reported previously and with the integrated Phase 3 safety analysis.[1,2] Higher levels of clinical response continued to be observed with UPA vs ADA through 3 years of treatment.

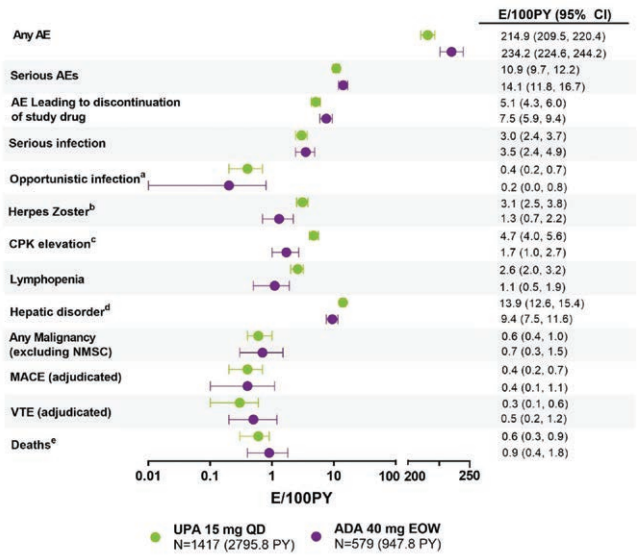
Figure. Exposure-adjusted Event and Incidence Rates of Treatment-emergent AEs Over 3 Years



ADA, adalimumab; AE, adverse event; CI, confidence interval; CPK, creatine phosphokinase; EAER, exposure-adjusted event rates; EOW, every other week; MACE, major adverse cardiovascular event; NMSC, non-melanoma skin cancer; PY, patient years; QD, once daily; UPA, upadacitinib; VTE, venous thromboembolism.
Exposure adjusted incidence rates (EAIR) are reported for malignancy, MACE, VTE, and deaths; exposure adjusted event rates (EAER) are reported for the remaining events.
[a]Excluded tuberculosis and herpes zoster.
[b]Herpes zoster: majority of cases on UPA were non-serious and involved 1 or 2 dermatomes.
[c]CPK elevation: most were mild or moderate and asymptomatic, with no reports of rhabdomyolysis.
[d]Hepatic disorders: majority were transaminase elevations.
[e]Includes treatment-emergent and non-treatment emergent deaths.

Table 1. Efficacy Endpoints at 3 Years (NRI)

Endpoints, % (95% CI)	UPA 15 mg QD N=651*	ADA 40 mg EOW N=327*
CDAI ≤10	39 (36, 43)	29 (24, 34)
CDAI ≤2.8	24 (21, 28)	17 (12, 21)
DAS28(CRP) ≤3.2	37 (33, 41)	26 (21, 31)
DAS28(CRP) <2.6	32 (29, 36)	22 (17, 26)

ADA, adalimumab; CI, confidence interval; DAS28(CRP), Disease Activity Score for 28-joints C-Reactive Protein; CDAI, clinical disease activity index; EOW, every other week; NRI, non-responder imputation; QD, once daily; UPA, upadacitinib.*Patients who were rescued prior to/at Week 26 were considered non-responders. 252/651 and 159/327 patients were rescued of those randomized to UPA and ADA, respectively.

EFFICACY OF JANUS KINASE INHIBITORS FOR DIFFICULT-TO-TREAT RA IN CLINICAL PRACTICE

M. Kamiya[1], D. Togawa[1], S. Mori[1], K. Yamazaki[1]. [1]*Nara Hospital, Kindai University, Orthopaedic Surgery and Rheumatology, Ikoma City, Japan*

Background: In 20-30% of rheumatoid arthritis (RA) patients, the first biologic disease-modifying antirheumatic drugs (bDMARDs) (generally tumour necrosis factor inhibitors (TNFis)) is ineffective, and among the patients who do respond to therapy, 20% is faced with secondary ineffectiveness within the first 2 years of treatment [1]. In practice, when refractory RA is present, of which the definition implies previous use of at least two bDMARDs (generally TNFis), the next treatment choice often made is a bDMARD of another class (non-TNFis) [2]. On the other hand, patients who are inadequately responding to bDMARDs need new treatment options because subsequent bDMARD treatment reduces their response [3]. Janus Kinase inhibitors (JAKis) are the first targeted synthetic DMARDs (tsDMARD) licensed for the treatment of RA with comparable efficacy to bDMARDs. Unlike the single cytokine targeting approach of bDMARDs, JAKis are specifically designed to inhibit intracellular signalling molecules common to the receptors of multiple inflammatory cytokines implicated in RA pathogenesis.
Objectives: Difficult-to-treat (D2T) RA is defined as refractory to two or more b/ts DMARDs with different mechanisms of action, with active and progressive disease, as published by Eular(4). We evaluated real world efficacy of approved JAKis and factors that may help to continue them in patients with D2T RA.
Methods: Patients who had inadequate response to two or more bDMARDs (including both TNFis and non-TNFis) at our hospital by December 2019 were defined as D2T RA, and patients who switched to JAKis were retrospectively investigated. The drug retention rate was determined by Kaplan-Meier method, and the difference was tested by Logrank test. Multiple regression analysis was used as the statistical method to predict continuation of JAKis for more than 1 year, with patient background (age, gender, during the disease, number of bDMARDs used, with or without methotrexate and/or glucocorticoids, disease activity score assessing 28 joints using erythrocyte sedimentation rate' presence of rheumatoid factor/anti-CCP antibody, matrix metalloproteinase 3 value, Health Assessment Questionnaire disability index) at the time of initiation as an explanatory variable.
Results: A total of 915 bDMARDs had been administered to 394 RA patients. The retention rate of bDMARDs and the number of bDMARDs used were 89.3% and 1.48 bDMARDs at 1 year, 67.7% and 2.27 bDMARDs at 5 years, and 52.0% and 3.15 bDMARDs at 10 years, respectively. The retention rate of JAKis at 1 year was 60.2% in 65 patients with tofacitinib (TOF) and 67.2% in 70 patients with baricitinib (BAR) (P=0.38). Among them, the drug retention rate in D2T RA patients was 50.8% in 38 TOF patients and 66.3% in 35 BAR patients with no significant difference (P=0.30). There were no patient background factors that significantly predicted continuation at 1 year for any JAKis.
Conclusion: Despite the limited number of patients and the retrospective nature of the study, TOF and BAR were shown to be effective options for D2T RA, regardless of patient background such as disease activity or number of bDMARDs used. Other JAKis and switches between JAKis need to be investigated in the future.

AZD9567 VERSUS PREDNISOLONE IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: A PHASE 2A, RANDOMISED, DOUBLE-BLIND, PARALLEL-GROUP EFFICACY AND SAFETY STUDY

J. M. Van Laar[1], A. Lei[2], M. Safy-Khan[1], J. Almquist[3], C. Astbury[4], M. Belvisi[5], A. Platt[6], S. Prothon[3], S. Samuelsson[7], P. Svanberg[8], C. Keen[7]on behalf of The SEMRA Study Group. *[1]University Medical Center Utrecht, Division of Internal Medicine and Dermatology, Department of Rheumatology & Clinical Immunology, Utrecht, Netherlands; [2]AstraZeneca, Patient Safety, Respiratory & Immunology, Chief Medical Office, R&D, Barcelona, Spain; [3]AstraZeneca, Clinical Pharmacology and Quantitative Pharmacology, Clinical Pharmacology & Safety Sciences, R&D, Gothenburg, Sweden; [4]AstraZeneca, Research and Early Development, Respiratory & Immunology, BioPharmaceuticals R&D, Cambridge, United Kingdom; [5]AstraZeneca, Research and Early Development, Respiratory & Immunology, BioPharmaceuticals R&D, Gothenburg, Sweden; [6]AstraZeneca, Translational Science and Experimental Medicine, Research and Early Development, Respiratory & Immunology, BioPharmaceuticals R&D, Cambridge, United Kingdom; [7]AstraZeneca, Clinical Development, Research and Early Development, Respiratory & Immunology, BioPharmaceuticals R&D, Gothenburg, Sweden; [8]AstraZeneca, Drug Metabolism and Pharmacokinetics, Research and Early Development, Respiratory & Immunology, BioPharmaceuticals R&D, Gothenburg, Sweden*

Background: Oral corticosteroids such as prednisolone are potent anti-inflammatory drugs but their use is limited by side effects caused by unwanted actions on the glucocorticoid receptor (GR), such as increased insulin resistance, and off-target actions on the mineralocorticoid receptor (MR) that disrupt electrolyte balance and increase water retention. AZD9567 is an oral, selective, non-steroidal glucocorticoid receptor modulator being developed to treat inflammatory diseases. Pre-clinical and phase 1 clinical data indicate that AZD9567 is the first GR modulator with an improved efficacy–dysglycaemic side effect profile versus prednisolone.

Objectives: To compare the efficacy, safety and tolerability of AZD9567 with prednisolone in patients with active rheumatoid arthritis (RA), at doses with predicted equivalent anti-inflammatory activity.

Methods: In this phase 2a, randomised, double-blind, parallel-group, multicentre study in RA patients with DAS28-CRP ≥ 3.2 despite stable treatment with conventional disease-modifying anti-rheumatic therapies (NCT03368235), patients were randomised 1:1 to AZD9567 40 mg or prednisolone 20 mg orally once daily for 14 days. The primary endpoint was change from baseline in DAS28-CRP at day 15. Secondary outcomes included components of DAS28-CRP, TJC68, SJC66, ACR response (ACR20, ACR50, ACR70) and safety outcomes, including serum electrolytes.

Results: All 21 randomised patients (AZD9567, n = 11; prednisolone, n = 10) completed the study. There was a slight imbalance between the treatment groups at baseline, with higher age (mean ± SD: 64.5 ± 8.4 vs 55.5 ± 13.6 years), more women (8 vs 5) and greater disease severity (DAS28-CRP, mean ± SD: 5.26 ±

Table 1. Change from baseline to day 15 in clinical disease activity measures.

SJC66 score	−6.24 (0.89)	−8.13, −4.36	−6.66 (0.86)	−8.48, −4.85	0.42 (1.14)	−1.98, 2.81	0.717

CFB, change from baseline; CRP, C-reactive protein; DAS28, 28-joint disease activity score; GH, global health; LSM(D), least-squares mean (difference); SJC, swollen joint count; TJC, tender joint count.

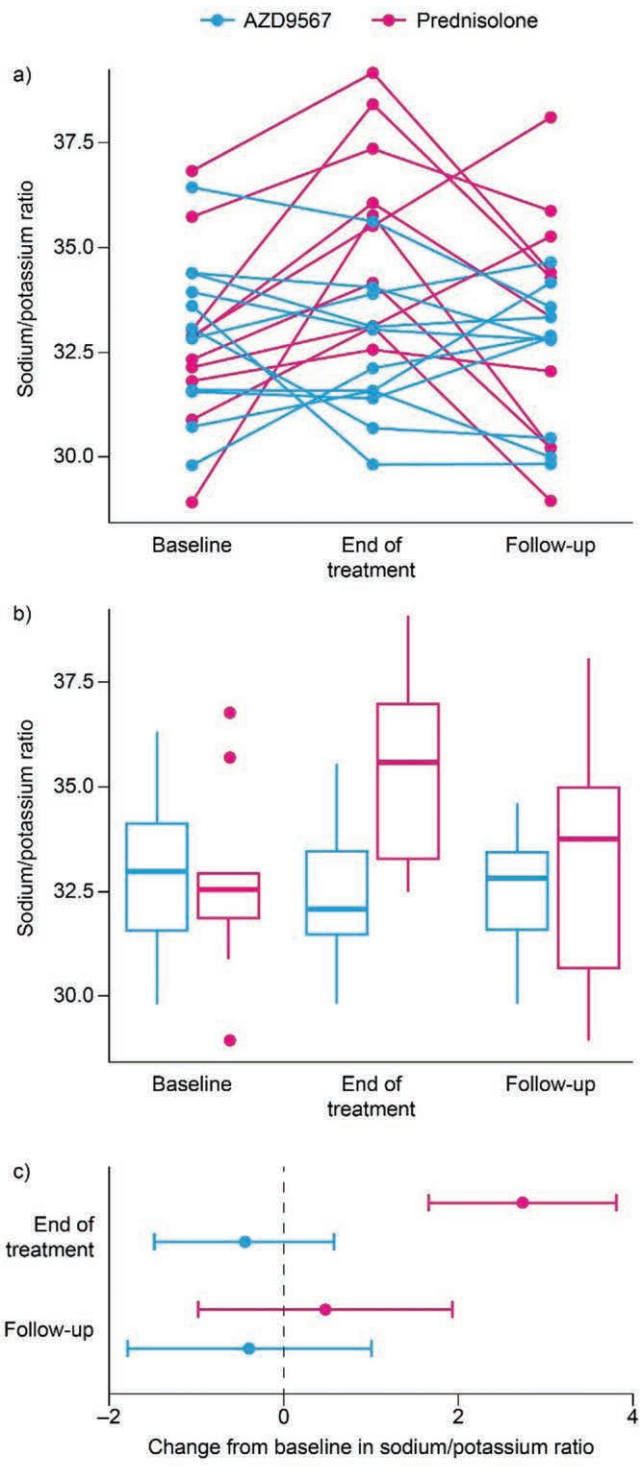

Figure. Morning serum sodium/potassium ratio with AZD9567 or prednisolone, under fasting conditions. a) Individual-level data. b) Box-and-whisker plots showing median, interquartile range and range. c) Change from baseline to day 15 (i.e. end of treatment; adjusted for baseline values) with 95% confidence intervals. Follow-up was approximately 14 days after the last dose.

0.98 vs 4.90 ± 0.74) in the AZD9567 group versus the prednisolone group. There was no statistically significant or clinically meaningful (i.e. > 1.2) difference in change from baseline to day 15 in DAS28-CRP between AZD9567 and prednisolone, although this was numerically lower with AZD9567 (Table 1). Similar results were observed for TJC68, SJC66, CRP and GH (Table 1). The proportions of patients achieving ACR20, 50 and 70 response criteria were similar in both groups, albeit numerically lower with AZD9567. Similar numbers of patients in each group reported treatment-emergent adverse events (AZD9567, n = 10, prednisolone, n = 9); most were mild in severity. One serious adverse event, suicidal depression, was reported after completing AZD9567 treatment. Morning fasting serum sodium/potassium ratio at day 15 was not altered with AZD9567 but was increased from baseline with prednisolone (Figure 1).

Conclusion: AZD9567 40 mg had a similar efficacy profile to prednisolone 20 mg in patients with active RA. Both drugs were well tolerated, with no new safety signals. Unlike prednisolone, AZD9567 had no effect on serum sodium/potassium ratio, suggesting selectivity of AZD9567 for the GR over the MR. These results support further trials of AZD9567 in patients with inflammatory disease.

RISK OF QT INTERVAL PROLONGATION ASSOCIATED WITH CHRONIC USE OF HYDROXYCHLOROQUINE IN RHEUMATIC PATIENTS AND THE EFFECT OF COTREATMENTS

M. Antivalle[1], G. La Paglia[1], M. C. Ditto[2], S. Parisi[2], E. Fusaro[2], M. Agosti[3], P. Sarzi Puttini[1]. [1]*L. Sacco University Hospital, Rheumatology, Milano, Italy*; [2]*AOU Città della Salute e della Scienza di Torino; Rheumatology Unit;, Department of Medical Science, Torino, Italy*; [3]*Azienda Socio-Sanitaria Territoriale (ASST) di Vimercate, Department of Medical Science, Vimercate, Italy*

Background: Hydroxychloroquine (HCQ) has been used safely for over 60 years in rheumatic patients. However, following its recent use in covid-19 disease, its safety has been questioned, following controversial reports of cardiac toxicity[1], possibly related to a prolongation of the QT interval[2].

Objectives: To explore the influence of chronic treatment with hydroxychloroquine on QT interval in rheumatic patients, and the possible effects of drug-to-drug interference[3].

Methods: 12-lead electrocardiogram tracings were recorded with standard equipment in 229 ambulatory patients (SLE = 53, RA = 52, SSc = 56, UCTD = 38, Others = 30). The present analysis was performed on corrected QT intervals (QTc) calculated according to Framingham formula (QTc = QT+0.154 (1–RR)), with ULN = 449 ms in males, and 467 ms in females. Estimated glomerular filtrate rate (eGFR) was calculated from serum creatinine with the CKD-EPI equation. The influence on QTc values of demographic variables, chronic (≥3 months) HCQ treatment, and of the use of selected comedications -Statins, Angiotensin Converting Enzyme inhibitors (ACEi), Angiotensin Receptor Blockers (ARBs), Selective Serotonin Reuptake Inhibitors (SSRIs), Proton-Pump Inhibitors (PPI), Calcium Channel Blockers (CCBs) – were evaluated by parametric or non parametric statistical methods, as appropriate. All statistic al analyses were performed with the IBM SPSS statistical package version 25.

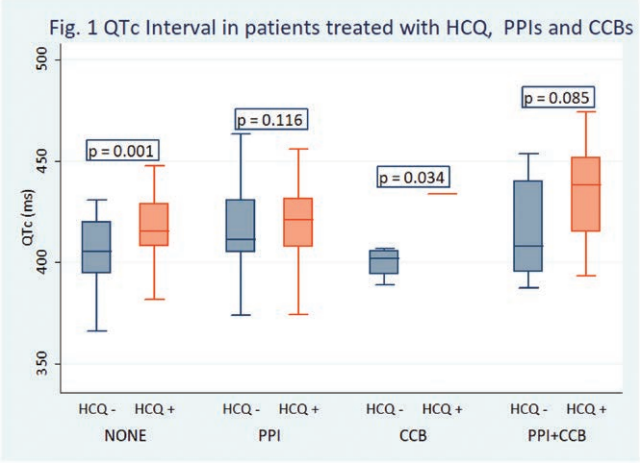
RESULTS:

Table 1. Demographic and clinical variables in patients treated with HCQ (HCQ+) and in controls (HCQ-).

	N	Age	Female	eGFR	Statins	ACEi	ARB	SSRI	PPI	CCB
		Yrs	N	mL/min/1.73m^2	N	N	N	N	N	N
		±SD	%		%	%	%	%	%	%
All	229	58.02	206	87.14	29	48	19	14	138	30
		±14.36	90.0	18.96	12.7	21.8	8.3	6.1	60.3	13.1
HCQ+	132	58.71	122	87.00	18	32	11	9	80	17
		±14.49	92.4	20.04	13.6	24.2	8.3	6.8	60.6	12.9
HCQ-	97	57.51	84	87.32	11	16	8	5	58	13
		±14.30	86.6	17.47	11.3	16.5	8.2	5.2	59.8	13.4
p		0.532	0.183	0.897	0.690	0.189	1.000	0.782	1.000	1.000

Demographic variables, and the use of evaluated comedications were not different in HCQ+ and HCQ- patients (Table 1). In the whole population, the QTc mean duration was 416.72 ± 20.70 ms, and was correlated with age (r = 0.215, p= 0.001), but not with gender (p = 0.548), eGFR (r = -0.93, p = 0.163), or disease (p = 0.092). In only 4 patients (HCQ+: 3 (2.3%) – HCQ-: 1 (1%), p = 0.639) QTc duration was above ULN.

QTc duration was not associated with the use of Statins, ACEi, ARBs, or SSRIs (p = 0.454, 0.276, 0.475, and 0.131 respectively), but was significantly prolonged in patients treated with HCQ (421.26 ± 19.19 vs 410.55 ± 21.18 msec, p < 0.001), PPIs (420.57 ± 21.45 vs 410.89 ± 18.12 ms, p < 0.001), and CCBs (424.22 ± 25.97 vs 415.59 ± 19.62 ms, p < 0.033). Furthermore, as reported in Fig. 1, our data show a trend - albeit not statistically significant - towards an additive effect on QT prolongation of the association of PPIs and CCBs with HCQ, even more evident in the case of association of the 3 drug classes.



Conclusion: In this study, the QTc interval was significantly prolonged in patients treated with hydroxychloroquine as compared to controls, although significant prolongation was extremely infrequent. Furthermore, our data revealed signs of drug-drug interference, suggesting that regular monitoring of the electrocardiogram is advisable in these patients, often undergoing cotreatment with multiple drugs.

OFF-TARGET PROFILING OF JANUS KINASE (JAK) INHIBITORS IN RHEUMATOID ARTHRITIS: A COMPUTER-BASED APPROACH FOR DRUG SAFETY STUDIES AND REPURPOSING

M. L. Faquetti[1], F. Grisoni[1], P. Schneider[2], G. Schneider[2], A. M. Burden[1]. [1]*ETH Zurich, Department of Chemistry and Applied Biosciences, Zürich, Switzerland*; [1]*ETH Zurich, Department of Chemistry and Applied Biosciences, Zürich, Switzerland*

Background: The JAK inhibitors (JAKi's) tofacitinib and baricitinib are new alternatives for treating rheumatoid arthritis. Safety concerns associated with JAKi's, such as the increased risk for thrombosis and viral infections, have emerged worldwide. The underlying explanatory mechanisms remain unknown, suggesting the elevated risk is likely due to underlying confounding or an off-target binding effect. Computational approaches can explore the potential for a small molecule drug to interact with previously unknown biological targets and identify potential safety-related concerns, and open doors for potential drug repurposing.
Objectives: To identify and characterize the off-target binding effects of baricitinib and tofacitinib, with a focus on targets related to thrombosis and viral infection
Methods: Potential targets of baricitinib and tofacitinib were predicted using two neural-network-based systems (TIGER[1] and SPiDER[2]). Targets were considered relevant if they had (1) a SPiDER confidence with p<0.05, or (2) a TIGER score >1. Selected targets related to the outcome of interest were experimentally evaluated at Eurofins Cerep (France-Celle L'Evescault, www.eurofins.com) if commercial available. Compounds were tested at (1) single concentration (30 µM) with technical replicates, using radioligand or enzymatic assays, or (2) multiple concentrations (30 µM highest concentration; dilution factor in a log-scale) with technical replicates, using calcium flux or inhibition of [cAMP] assays. Observed activity of ≥50% inhibition or stimulation on the target was considered active, between 25 to 50% inhibition (or a dissociation constant [Kd] from 1 to 10 µM) was considered as moderate activity, and lower than 25% was considered inactive. Dose-response curve were performed on active and moderate targets for IC_{50} / EC_{50} (half maximal inhibitory / effective concentration) determination.
Results: TIGER and SPiDER suggested a total of 99 off-target binding effects (baricitinib n=41; tofacitinib n=58), of which 17 targets had potential impact on thrombosis or viral infection (baricitinib n=5 and 4, respectively; tofacitinib n=5 and 3, respectively). Commercial testing was available on 11 targets (Adenosine Receptor A2A [AA2AR], Epidermal growth factor receptor, induclible NOS, PI3 Kinase (p110b/p85a), Phosphodiesterase 10A2 [PDE10A2] and Protein Kinase N2 [PKN2] for baricitinib; and Adenosine receptor A3, 15-Lipoxygenase [15-LO], PKN2, Transient receptor potential cation channel [TRPM6] and AA2AR for tofacitinib). Of these, 5 targets showed active or moderately active binding activity (baricitinib n=2; tofacitinib n=3), and were tested for dose-response curves. Test results confirmed ligand-binding activity with IC_{50} on nanomolar (PKN2), and micromolar ranges (PDE10A2 and TRPM6).
Conclusion: The results suggest both baricitinib and tofacitinib are promiscuous binders with effects on several families. Although it may lead to side effects, off-target binding also represents a potential opportunity for drug repurposing. Besides on-target effects, both drugs are under clinical investigation for the treatment of COVID-19 due to off-target interactions. The proposed pharmacological off-target effects of those with active binding include attenuation of pulmonary vascular remodeling, anti-fibrotic and anti-psychotic activities (PDE10A2), modulation of viral response (PKN2), and hypomagnesaemia (TRPM6), which is involved in cardiovascular diseases. This study supports tofacitinib and baricitinib as candidates for drug repurposing (e.g., in COVID-19, Hepatitis C virus, and pulmonary hypertension). We did not identify active off-target interactions linked to thrombosis to explain the elevated risk observed in clinical practice. Further research is required to elucidate the underlying patient-specific factors (confounders) that could explain this safety concern.

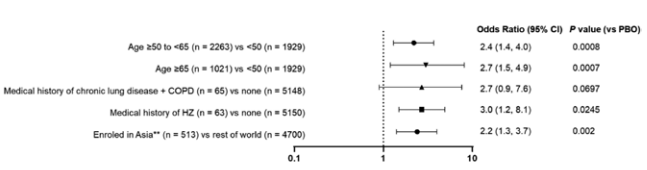
Background: The once daily, oral Janus kinase (JAK)-1 preferential inhibitor filgotinib (FIL) improved signs and symptoms of rheumatoid arthritis (RA) in phase (P)3 trials.[1-3] Patients (pts) with RA have increased herpes zoster (HZ) reactivation risk vs the general population. JAK inhibition is associated with increased infection incidence, including HZ.[4]
Objectives: To assess long-term safety of FIL across the global clinical program with respect to HZ.
Methods: Pts meeting 2010 ACR/EULAR RA criteria in a pooled analysis of P2 DARWIN 1–2 (D1–2), P3 FINCH 1–3 (F1–3), and long-term extension studies (D3, F4) were included. Placebo (PBO)-controlled as-randomised analysis included pts receiving FIL 100 mg (FIL100), FIL 200 mg (FIL200), or PBO up to week (W)12 (D1–2, F1–2); active-controlled as-randomised analysis included pts receiving FIL100, FIL200, adalimumab (ADA), or methotrexate (MTX) up to W52 (F1, F3). Long-term as-treated analysis included pts in all 7 studies receiving FIL100, FIL200, ADA, MTX, or PBO; data after re-randomisation were included and contributed to treatment received. Exposure-adjusted incidence rates (EAIR)/100 patient-years, calculated up to the last follow-up time or day, and differences with 95% confidence intervals (CIs) were calculated from the Poisson model. Logistic regression model was used for treatment-emergent (TE) HZ risk factor analysis and odds ratio (95% CI) and *P* value were provided.
Results: Table 1 shows TE HZ EAIRs in a pooled analysis. Rates of HZ were lower for FIL200 vs PBO during the 12W PBO-controlled period. At 52W, HZ rates were higher for FIL200/100 vs active control. Long-term HZ rates increased for FIL200 vs FIL100.

Table 1. EAIR of treatment-emergent herpes zoster

	N	Patient-years exposure	EAIR (95% CI)	EAIR diff (95% CI vs PBO/active control)
12W PBO-controlled				
FIL200	777	179.8	0.6 (0.1, 3.9)	–0.56 (–2.5, 1.3)
FIL100	788	181.6	1.1 (0.3, 4.4)	–0.02 (–2.2, 2.2)
PBO	781	178.4	1.1 (0.3, 4.5)	
Active-controlled, as-randomised[a]				
FIL200	475	439.7	1.4 (0.6, 3.0)	0.69 (–0.7, 2.1)
FIL100	480	443.4	0.9 (0.3, 2.4)	0.23 (–1.1, 1.5)
ADA	325	297.6	0.7 (0.2, 2.7)	
Active-controlled, as-randomised[a]				
FIL200	626	578.0	1.7 (0.9, 3.2)	0.65 (–0.8, 2.2)
FIL100	207	195.0	1.5 (0.5, 4.8)	0.46 (–1.6, 2.5)
MTX	416	372.2	1.1 (0.4, 2.9)	
Long-term as-treated[b]				
FIL200	2267	4047.7	1.8 (1.4, 2.3)	NC
FIL100	1647	2032.9	1.1 (0.8, 1.7)	NC

[a]up to W52. [b]data cut for LTE FINCH 4, Sept 19, 2019; DARWIN 3, April 26 2019.ADA, adalimumab; CI, confidence interval; EAIR, exposure-adjusted incidence rate; FIL, filgotinib; MTX, methotrexate; NC, not calculated; PBO, placebo; W week.

Figure 1 shows multivariate logistic regression model of TE risk factors.



Of 104 pts with TE HZ in long-term as-treated analysis set, 5 receiving FIL200 had history of HZ; EAIR (95% CI) was 8.7 (3.6–21.0). Of 8 pts with multiple events, 3 had events of differing severity for the same HZ episode.
EAIRs (95% CI) of TE HZ in Asia were: 3.7 (1.7–8.1) FIL200, n=197; 2.8 (1.3–6.3) FIL100, n=158; 0 ADA, n=40; 2.8 (0.4–19.6) MTX, n=43; and 3.4 (0.5–23.8) PBO, n=77 in long-term as-treated population. EAIRs (95% CI) in rest of the world were: 1.6 (1.2–2.1) FIL200, n=2070; 0.9 (0.6–1.5) FIL100, n=1489; 0.8 (0.2–3.1) ADA, n=285; 0.9 (0.3–2.9) MTX, n=373; and 0.7 (0.2–2.9) PBO, n=704 for all pts as-treated.

Most TE HZ infections were mild to moderate and non-serious; 6 were serious; 2 were recurrences. No visceral TE HZ occurred across the FIL RA program; there was 1 case each of genital, disseminated, and ophthalmic HZ. The disseminated HZ occurred in a pt with prior HZ history. Lymphopenia was not associated with HZ during the PBO-controlled W12 period.

Conclusion: HZ was more common in both FIL groups vs ADA or MTX up to 52 weeks but comparable vs PBO during the 12-week placebo-controlled period. In multivariate analyses, prior history of HZ, Asian region, and age ≥50 years were associated with increased HZ risk.

Background: Industry, regulators, and the rheumatology community have recognized the need for observational studies to monitor the safety of new anti-rheumatic agents. Registries provide a unique opportunity to understand the safety of newer therapies, but pharmacovigilance studies require large number of patients to evaluate rare drug-related adverse-events (AEs). Because JAK-inhibitors (JAKi) have only recently been approved for the treatment of rheumatoid arthritis, it makes sense to combine data from several registries in order to obtain a sufficiently large sample size to promote earlier detection of adverse events.

Objectives: The purpose of this analysis was to evaluate how AEs are assessed in the various registries in preparation for a collaborative pharmacovigilance analysis, and present preliminary results.

Methods: The "JAK-pot" collaboration includes 19 RA registries. The principal investigators of the participating registries were sent a structured questionnaire on AE assessment and 18 (94%) provided complete responses on the AE assessment procedures of their registries. We present simple descriptive statistics of the AE assessment procedures employed by the participating registries.

Results: The 19 registries represent 7186 patients initiating a JAKi (Table 1), who are on average 57 years old, with a mean disease duration 11 years, seropositive (83%), female (82%) and with moderate disease activity at treatment initiation.

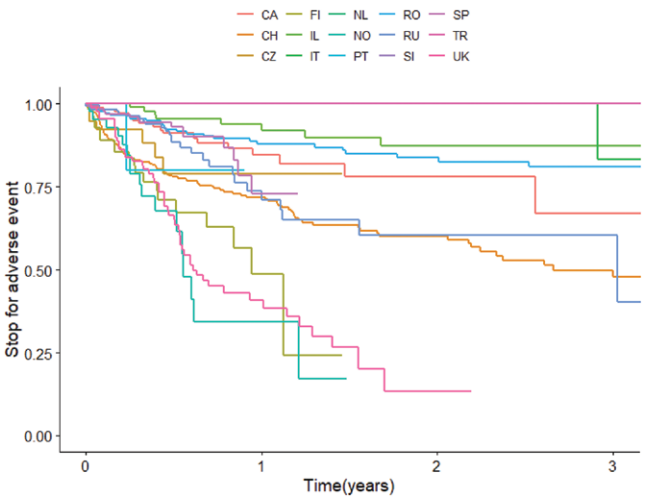
Table 1.

Country, registry	N° of patients on JAKi included
Austria, BIOREG	87
Belgium, TARDIS	2113
Canada, RHUMADATA	363
Czech Republic, ATTRA	197
Denmark, DANBIO	506
Finland, ROB-FIN	229
Germany, RABBIT	620
Italy, GISEA	244
Israel, I-RECORD	96
Netherlands, METEOR	4
Norway, NOR-DMARD	97
Portugal, REUMA.PT	44
Romania, RRBR	252
Russia, ARBITER	428
Slovenia, biorx.si	141
Spain, BIOBADASER	139
Switzerland, SCQM	738
Turkey, TURKBIO	404
UK, BSRBR	484

After ineffectiveness, AEs was the second most common reason for JAKi discontinuation (25.5%), with large differences between registries (Figure 1).

Of the participating registries, 2 registries do not collect AEs, while 16 (89%) assess incident AEs, by means of a pre-specified extraction form (3 registries), by free text (5 registries), by a combination of both (6 registries) and/or the use of linkage to external electronic records (3registries). AEs are coded using a predefined coding system by 11 registries (MeDRA (8), other (3)), but nearly all are recording the severity of the AE (15, 94%), AE related-death (15, 94%), or AE-related hospitalisation (15, 94%). AEs of special interest, such as serious infections (15, 94%), thromboembolic events (15, 94%), or shingles (9, 56%), are recorded by most registries. Incident AEs are linked by the treating physician to specific therapies in 11 registries (69%), while the other 5 registries extrapolate potential causal associations based on therapy start and stop dates. A pre-specified adjudication process for AEs is made only by 5 registries (31%).

Figure 1: Treatment discontinuation of JAKi for AEs in registries with individual patient-level information



Conclusion: Substantial heterogeneity exists among registries regarding AE assessment within the JAK-pot collaboration. These differences must be taken into account when analysing the safety of JAKi across different countries in collaborative studies. For comparative analyses, stratified analyses by country are required to account for differential AE assessment and varying degrees of potential under-reporting.

M. Lee[7], J. J. W. Lee[8], L. Qin[2], L. S. Tam[1]. *[1]The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*; *[2]The Chinese University of Hong Kong, Orthopedics & Traumatology, Hong Kong, Hong Kong (SAR)*; *[3]The Chinese University of Hong Kong, Imaging & Interventional Radiology, Hong Kong, Hong Kong (SAR)*; *[4]The Chinese University of Hong Kong, School of Pharmacy, Hong Kong, Hong Kong (SAR)*; *[5]Queen Elizabeth Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[6]Tseung Kwan O Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[7]Tai Po Hospital, Medicine and Geriatrics, Hong Kong, Hong Kong (SAR)*; *[8]The Chinese University of Hong Kong, The Jockey Club School of Public Health & Primary Care, Hong Kong, Hong Kong (SAR)*

Background: Partial repair of bone erosions in rheumatoid arthritis (RA) is known from high-resolution peripheral quantitative computer tomography (HR-pQCT) studies in patients with moderate to high disease activity using biologics [1]. Whether RANKL inhibition by denosumab is efficacious in healing existing erosions in RA patients with low disease activity or in remission on conventional synthetic DMARDs is uncertain.

Objectives: To evaluate the effects of denosumab on erosion healing at 2-4 metacarpophalangeal head as determined by HR-pQCT in patients with RA with stable disease.

Methods: This was a randomized, placebo-controlled, double-blind study. RA patients with disease activity score 28 joints (DAS28) ≤5.1 were randomized (1:1) to subcutaneous denosumab 60 mg or placebo once every six months for 24 months. The primary outcome was erosion healing at MCP 2-4 on HR-pQCT at 12 months. The effects of denosumab on erosion and joint space parameters on HR-pQCT and radiographs, disease activity and health assessment questionnaire-disability index (HAQ-DI) were also examined.

Results: At 24 months, HR-pQCT images were analyzed in 98 patients. Baseline demographic, clinical characteristics and imaging parameters were comparable between the two treatment groups (table 1). Seventeen patients in each group (placebo group: 17/52, 32.6%; denosumab group: 17/50, 34.0%) achieved sustained low disease activity (DAS28 ≤ 3.2) throughout the 24 months. At 12 months, changes in erosion parameters on HR-pQCT were similar between the two groups. At 24 months, new erosions (19% vs 9%, p=0.009) and erosion progression (34% vs 16%, p<0.001) were more common in the placebo group than the denosumab group. Erosion healing was seen in a significantly higher proportion of patients in the denosumab group (20% vs 6%, p=0.045) at 24 months. The details of the changes in HR-pQCT erosion parameters are shown in figure 1. No significant differences in the changes in joint space parameters on HR-pQCT, van der Heijde-Sharp erosion score, DAS28 and HAQ-DI were observed between the two groups at 12 and 24 months.

Conclusion: Although no differences in erosion parameters were observed at 12 months, denosumab was more efficacious than placebo in erosion repair on HR-pQCT after 24 months.

Background: Interstitial lung disease (ILD) is an extra-articular manifestation of rheumatoid arthritis (RA) detected in 20% to 60% of patients with RA on high-resolution computed-tomography (HRCT) chest scan and is clinically significant in near 10%. Despite a high morbi-mortality rate, a definite strategy for preclinical ILD screening in patients with RA remains to be determined. To date, several factors have been reported to increase the risk of RA-ILD occurrence (*i.e.* older age at RA onset, ACPA positivity, male sex, RA disease activity, the *MUC5B* rs35705950 promoter variant...). However, none of these risk factors has been validated in a prospective cohort of patients with RA. The ESPOIR prospective cohort includes patients aged 18 to 70 years with recent arthritis (less than 6 months) and a definite or probable diagnosis of RA.

Objectives: To identify in the ESPOIR cohort factors associated with ILD after at least 10 years of RA duration in order to develop a predictive score to identify patients with preclinical RA-ILD.

Methods: An ILD detection by chest HRCT scan was systematically offered to every patient with definite RA after at least 10 years-follow-up. Chest HRCT scans were centrally reviewed by an experienced radiologist. Potential predictors of ILD were prospectively collected from baseline to the date of the HRCT scan, and all included patients were genotyped for *MUC5B* rs35705950. To take into account repeated measures, trajectories were determined for disease activity, C reactive protein, smoking, treatment exposure (*i.e.* prednisone, methotrexate [MTX] and biological disease modifying anti-rheumatic drugs [bDMARDs]). A logistic model was used to identify independent predictors for the occurrence of ILD on HRCT scans. Confidence intervals were estimated using sampling methods. A predictive score for preclinical ILD occurrence was developed based on the identified predictors.

Results: 163 RA patients according to 2010 ACR/EULAR classification criteria, none of whom had pulmonary symptoms, were investigated with a chest HRCT scan (128 women (78.5%), mean RA duration 13.7 ± 1.1 years, age at inclusion 47.6 y/o ± 10.4, mean disease activity score [DAS]-28 during follow up was 3.1 ± 1.0). ILD was detected in 31 patients (19.0%). The *MUC5B* rs35705950 minor allele frequency (MAF) was 22.2% and 10.0% in the RA-ILD and RA-noILD populations, respectively (OR univariate=2.6 $CI_{95\%}$ [1.2-5.5], P=0.01). After logistic regression, independent predictors for preclinical RA-ILD were male sex (OR=3.9 $CI_{95\%}$ [1.4-11.4]), older age at RA onset (OR=1.1 per year $CI_{95\%}$ [1.0-1.2]), mean DAS-28 score during the follow-up (OR=2.0 $CI_{95\%}$ [1.2-3.4]) and *MUC5B* rs35705950 T risk allele (OR=3.7 $CI_{95\%}$ [1.4-10.4]) (Figure 1). No influence of the use of RA-related drugs (prednisone, MTX or bDMARDs) was identified as risk factor. The logistic model could predict preclinical ILD occurrence after 13 years of RA duration with an AUC=0.82 $CI_{95\%}$ (0.72-0.91). A predictive score for preclinical RA-ILD based on the 4 identified predictive risk factors was developed (Sensitivity 80%, Specificity 56%).

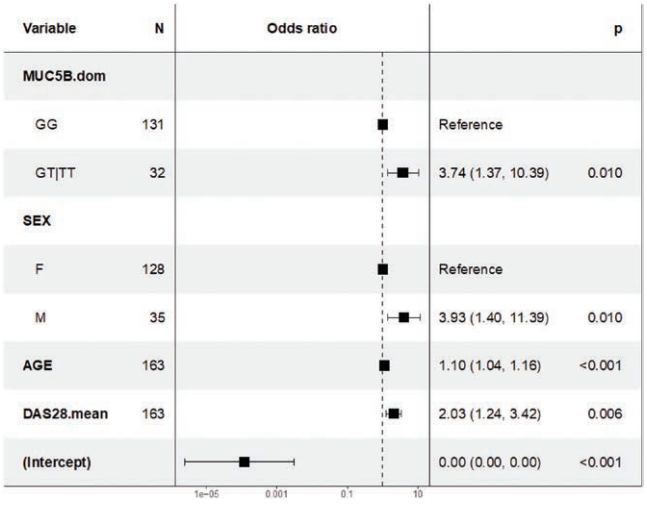

Figure 1. Factors independently associated with preclinical ILD after 13 years of RA duration

Conclusion: In this cross-sectional study of the prospective ESPOIR cohort, we identified clinical and genetic predictors for ILD after 13 years of RA duration. We developed a predictive score that could improve risk stratification for preclinical RA-ILD and help physicians identify patients with RA in whom a HRCT scan should be performed.

SPLENIC METABOLIC UPTAKE IN FDG-PET/CT PREDICTS RISK OF FUTURE CARDIOVASCULAR THROMBOSIS EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. J. Lee[1], C. M. Hong[2], Y. M. Kang[1]. *[1]School of Medicine, Kyungpook National University, Internal Medicine, Daegu, Korea, Rep. of (South Korea)*; *[2]School of*

Medicine, Kyungpook National University, Nuclear Medicine, Daegu, Korea, Rep. of (South Korea)

Background: Patients with the rheumatoid arthritis (RA) have an increased risk of cardiovascular disease (CVD) compared to general population. However there are insufficient modality to predict future CVD risk in RA.
Objectives: This study assessed whether splenic and arterial activity measured by positron emission tomography/ computed tomography (PET/CT) predict the risk of CVD thrombosis events beyond conventional risk factors in patients with RA.
Methods: We enrolled 84 patients with active RA who underwent fluorine-18-fluorodeoxyglucose (FDG) PET/CT and disease activity evaluation at the same time. CVD thrombosis events were independently evaluated, while blinded to activity of PET/CT, during follow up periods. FDG uptake by nuclear medicine physician was examined in the spleen and ascending aorta and blood pool activity of superior vena cava as SUV (standardized uptake values) and target-to-background-ratio (TBR) while blinded to CVD events.
Results: During follow-up periods, 19 patients developed CVD thrombosis events. Both splenic and arterial TBR were significantly increased in patients with subsequent CVD events compared to in patients without (2.19 ± 0.60 vs 1.80 ± 0.34, p < 0.013, 1.72 ± 0.22 vs 1.57 ± 0.22, p< 0.012). Splenic TBR was associated with an increased risk of CVD events after adjustment for conventional CVD risk factors [hazard ratio (HR): 3.15; 95% confidence interval (CI): 1.46 to 6.79; p = 0.003]. Moreover, the association between splenic TBR and CVD events remained significant after adjustment for disease activity (HR: 3.00; CI: 1.36 to 6.63; p = 0.007) and after adjustment for arterial TBR (HR: 3.00; CI: 1.36 to 6.63; p = 0.007).
Conclusion: Our results show splenic metabolic uptake in FDG-PET/CT in patients with RA provide information for subsequent CVD events beyond conventional risk factors.

POS0097 JOINT INFLAMMATION TENDS TO RECUR IN THE SAME JOINTS DURING THE RHEUMATOID ARTHRITIS DISEASE COURSE

S. Heckert[1], S. A. Bergstra[1], X. Matthijssen[1], Y. Goekoop-Ruiterman[2], F. Fodili[3], C. Allaart[1], T. Huizinga[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Hagaziekenhuis, Rheumatology, Den Haag, Netherlands*; [3]*Reumazrg Z.-W. Eng., Roosendaal, Rheumatology, Roosendaal, Netherlands*

Background: It is unknown whether in the disease course of rheumatoid arthritis (RA), inflammation recurs in the same joints over time or is more variable in joint locations. Joint involvement patterns over time might provide clues about the underlying mechanisms causing local joint inflammation.
Objectives: The aim of this study is to assess if local joint inflammation at presentation of RA tends to recur or persist in the same joints.
Methods: Data from the BeSt study were used, a treat-to-target (DAS≤2.4) trial in newly diagnosed RA (ACR 1987 criteria) patients. During 10 years, for each patient 68 joints were assessed three-monthly (41 visits) by trained nurses for swelling (yes/no) and tenderness.
We analyzed the association between local joint swelling at baseline and later swelling of the same joint using a multilevel mixed-effects logistic regression model. Models were adjusted for joint location and for timepoint, with joints clustered within patients. A sensitivity analysis was done for the 25% most affected joints (MCP 1-3, PIP 2-3, wrists and MTP 2-4).
To investigate whether later swelling of a joint is predicted by baseline swelling of that same joint specifically, rather than by baseline swelling in general, a permutation test with 1000 permutations was performed. A p-value <0.05 indicates that joint swelling is better predicted by its baseline swelling than by baseline swelling of randomly selected other joints.
In a separate model, with an interaction term between baseline swelling and previous visit swelling (yes/no), we evaluated if the association between baseline swelling and later local swelling was influenced by whether later swelling was persistent (swelling at both the current and previous visit) or recurrent (swelling at current visit but not at the previous visit).
Results: The 508 patients had a median (IQR) follow-up duration of 10 (6-10) years. At baseline, 8,137/34,423 (24%) assessed joints were scored as swollen. Baseline swelling was subsequently persistent in 21% of the joints with a median (IQR) duration of 1 (1-2) visit (± 3 months after baseline). In addition, after resolution of initial swelling, swelling recurred at least once in 46% of the joints with baseline swelling.
Baseline swelling was significantly associated with swelling in the same joint during follow-up (OR 2.37, 95% CI 2.30-2.43). A sensitivity analysis of the most affected joints showed similar results (OR 2.10 [95% CI 2.03-2.19]).
The permutation test showed a significant result with p<0.001, indicating that joint swelling is better predicted by baseline swelling of that same joint than by baseline swelling of other joints.
The association between baseline swelling and later local swelling was weaker in case of persistent swelling than in case of recurrent swelling (interaction term baseline swelling * swelling at previous timepoint 'yes': OR 0.80 [95% CI 0.75-0.85]).
Conclusion: In newly diagnosed RA, over median 10 years of treatment to target DAS≤2.4, baseline swelling persisted in 21% of the joints, for median 3 months after baseline. Local recurrence after initial resolution occurred in 46% of the joints. Baseline joint swelling was significantly associated with local joint swelling during follow-up, even when taking into account the higher a priori chance of swelling in the joints that are most often affected, and joint swelling during follow-up was better predicted by baseline swelling of that particular joint than by baseline swelling of other joints. Local persistence and recurrence of joint swelling despite DAS≤2.4 steered treatment adjustments suggest that local joint conditions or even joint memory play a role in mechanisms of joint inflammation.

POS0098 THE INFLUENCE OF THE ACTIVITY OF RHEUMATOID ARTHRITIS TO INFECTIOUS AND WOUND COMPLICATIONS AFTER TOTAL HIP AND KNEE ARTHROPLASTY

A. Khramov[1], M. Makarov[1], S. Makarov[1], S. Maglevaniy[1], E. Naryshkin[1], A. Dubinin[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Orthopaedic, Moscow, Russian Federation*

Background: Surgical treatment of patients with rheumatoid arthritis (RA) is associated with an increased risk of complications. This is due to the presence of inflammation, many variants of the disease, reduced physical activity, severity of functional disorders, prolonged therapy with glucocorticoids, disease-modifying antirheumatic drugs (DMARDs) and biological DMARDs, osteoporosis, as well as activity of the underlying disease.
Objectives: to conduct a comparative analysis of the influence of RA activity levels on infectious complications (periprosthetic infection) and wound complications (poor healing, divergence, necrosis of the wound edges) after hip and knee arthroplasty in RA patients.
Methods: 1113 arthroplasties were analyzed in patients with RA, which were performed between 2002 and 2019. Of these, 649 total knee arthroplasties and 464 total hip arthroplasties were performed.
Results: Infectious complications after total hip and knee arthroplasty did not occur at 0 grade of disease activity (remission). At the I grade of activity, periprosthetic infections were detected with a frequency of 0.31%, at the II grade – 0.89%, and at the III level in 3.06% of cases.
Complications from the operative wound occurred in 0.91% of cases with I grade of activity, at II grade with a frequency of 5.68%, and at III – 6.98%. There were no cases of complications from the wound in patients with remission of RA.
Statistical analysis of the obtained data revealed a significantly higher number of complications in the group of RA patients (p<0.005). During analyzing each type of complication, significant differences were also obtained (p<0.005).
Conclusion: Risk of periprosthetic infection and complications from the wound is several times higher in patients with a high grade of RA activity. This means that performing arthroplasty, as well as other operations, in patients with high RA activity correlates to a high risk of complications.

POS0099 CLINICAL REMISSION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOFACITINIB IS ASSOCIATED WITH LOW BASELINE EXPRESSION OF GENES RELATED TO ENERGY METABOLISM AND WITH CELLULAR CAPACITY OF THEIR UPREGULATION DURING FOLLOW-UP

E. Tchetina[1], A. Satybaldyev[2], G. Markova[1]. [1]*Nasonova Research Institute of Rheumatology, Immunology and Molecular Biology, Moscow, Russian Federation*; [2]*Nasonova Research Institute of Rheumatology, Early Arthritis, Moscow, Russian Federation*

Background: Rheumatoid arthritis (RA) is an autoimmune disease of unknown etiology, which is characterized by erosive arthritis (synovitis) and systemic inflammation. Tofacitinib (TFCN) is a small molecule Janus kinase (JAK) inhibitor that targets JAK1/JAK3. Identification of patients sensitive to TFCN before treatment could significantly improve therapy outcome. Presently it is not possible to predict TFCN efficacy in every patient while some patients are non-responsive to the drug that may produce adverse effects. TFCN function in RA patients has been recently associated with alterations in bioenergetics, mitochondrial function, and ATP production [1]. Therefore, we hypothesized that baseline metabolic status of RA patients prior to drug administration can predict the therapeutic outcome.

Objectives: To investigate the importance of baseline expression of genes involved in energy generation in RA patients, which could serve prognostic biomarkers for treatment response to tofacitinib.

Methods: Peripheral blood of 28 RA patients aged 52.2±15.6 years old, average disease duration 3.5 years (range 0.6-19) treated with TFCN (5-10 mg twice a day) during three months and 26 healthy age-matched control subjects were examined. Clinical response was assessed by disease activity score (DAS28-ESR), serum levels of ACPA antibodies, rheumatoid factor (RF), C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR). Clinical remission was assessed according to ACR criteria and DAS28 (DAS28 <2.6). Protein concentrations were measured using ELISA. Total RNA was isolated and used in gene expression studies performed with quantitative real-time RT-PCR.

Results: All of the patients were Steinbrocker's radiographic stage II-III at baseline. The majority of patients demonstrated erosive arthritis (23 out of 28), they were ACPA- (25 out of 28) and RF- (24 out of 28) positive. TFCN treatment significantly decreased the disease activity according to DAS28. At the end of the study the majority of patients demonstrated moderate disease activity (3.2< DAS28 <5.1), four patients retained high disease activity while 8, attained remission (DAS28 <2.6). This was accompanied by significant decrease in CRP and the number of swollen and tender joints. ESR values were not changed significantly. Gene and protein expression analysis revealed that RA patients, which attained clinical remission after TFCN treatment demonstrated significantly lower baseline expression of genes associated with glycolysis (pyruvate kinase), oxidative phosphorylation (succinate dehydrogenase and uncoupling protein (UCP) 2) compared to other examined RA patients and control subjects. Moreover, these gene expressions increased in RA patients who attained clinical remission in the course of follow-up while in refractory for TFCN treatment patients these gene expressions were tending to downregulate.

Conclusion: Clinical remission attainment in RA patients treated with tofacitinib is associated with lower baseline expression of genes associated with energy generation pathways (pyruvate kinase, succinate dehydrogenase, and UCP2) compared to other examined subjects. Non-responsiveness to tofacitinib is accompanied by high baseline expression of genes related to glycolysis and oxidative phosphorylation compared to controls.

POS0100 VITAMIN D LEVEL IN RHEUMATOID ARTHRITIS PATIENTS STARTING A BIOLOGIC DISEASE-MODIFYING DRUG AND ITS CORRELATION WITH DISEASE ACTIVITY AND RESPONSE TO TREATMENT

S. Garcia[1], B. M. Fernandes[1], F. Oliveira Pinheiro[1], M. Rato[1], D. Fonseca[2], A. Martins[1], D. Santos Oliveira[1,3], F. R. Martins[4], G. Terroso[1], M. Bernardes[1,5], L. Costa[1]. [1]*São João Universitary Hospital Center, Rheumatology, Porto, Portugal*; [2]*Centro Hospitalar Vila Nova de Gaia / Espinho - Unit 1, Rheumatology, Vila Nova de Gaia, Portugal*; [3]*Faculdade de Medicina da Universidade do Porto - FMUP, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; [4]*University Hospital Center of Algarve, Faro, Rheumatology, Faro, Portugal*; [5]*Faculdade de Medicina da Universidade do Porto - FMUP, Rheumatology, Porto, Portugal*

Background: Vitamin D, a fat soluble vitamin that is mainly involved in the regulation of calcium/phosphate metabolism, has a increasingly understood role in immunomodulatory activity, both in innate and adaptive immune system. In rheumatoid arthritis (RA), vitamin D showed to suppress the proliferation of synoviocytes and to reduce the production of proinfammatory cytokines, in vitro. (1) Recently the hypothesis has been raised that vitamin D has a negative association with RA activity. (2)

Objectives: This study aimed to evaluate the relationship between the 25-hydroxyvitamin D (25(OH) vitD) level, RA activity and response to a first biologic disease-modifying drug (bDMARD).

Methods: This is a longitudinal, retrospective study including consecutive patients with the diagnosis of RA followed at our rheumatology department. Demographic, clinical, and laboratorial data were collected from our national database at baseline, 6 and 12 months after initiation of a first bDMARD. Statistical analysis was performed using SPSS 23.0. Correlations between variables were studied using Spearman correlation analysis and comparison between groups was performed using Wilcoxon and Kruskal-Wallis tests; p<0.05 was considered statistically significant.

Results: Mean age of patients (n=236) was 51.5± 11.2 years old, 192 (81.4%) were females with a median disease duration of 10.1 [4.7, 16.7] years. Seropositivity for anti-citrullinated protein antibodies was present in 192 (81.4%) patients and for rheumatoid factor in 175 (74.2%). The majority exhibited a very high or high disease activity at baseline (median DAS28 5.75 [4.99 – 6.63]) and 90% (n=212) of them were concomitantly using corticosteroids and/or other disease-modifying anti-rheumatic drugs (117 with methotrexate (MTX), 62 with leflunomide and 32 with sulfasalazine). Regarding bDMARD, 56.8% (n=134) initiated an TNF alpha inhibitor.

After 6 and 12 months from a bDMARD initiation there was a significant reduction of ESR, CRP levels, TJCs, SJCs and DAS28 (all p-values < 0.001), as expected. Median baseline serum 25(OH) vitD concentrations was 25.5 [16.5, 30.0] ng/ml; notably, 34.2% of our sample was affected by hypovitaminosis D at baseline (25(OH) vitD< 20 ng/mL).

Among our study population 42.5% patients were responders to first bDMARD (23.8% good and 18.7% moderate responders) according to the EULAR response criteria. Disease remission (DAS28 < 2.6) was achieved by 17.6% of patients.

The percentage of good responders was significantly lower in the subgroup of patients with hypovitaminosis D compared to subjects with normal 25(OH) vitamin D levels at baseline (p=0.002), as it was for the percentage of disease remission (p=0.015).

The bivariate correlation analyses showed that 25(OH) vit D levels at baseline correlated with CRP levels and good response to RA treatment after 12 months (Spearman's coefficient -0.201, p = 0.028; Spearman's coefficient 0.255, p < 0.019, respectively). 25(OH) vit D levels at baseline, 6 and 12 months after bDMARD initiation did not correlate with age, BMI, ESV, number of tender or swollen joints, DAS28, HAQ or with SDAI or CDAI at 6 or 12 months of treatment.

Conclusion: In patients with RA, basal 25(OH) vit D levels correlated with response to a bDMARD. These results suggest a role of basal vitamin D status in the prediction of disease evolution and support the hypothesis that vitamin D has an immunomodulatory potential.

SLE, Sjögren's and APS - clinical

POS0101 ADVERSE HEALTH-RELATED QUALITY OF LIFE OUTCOME DESPITE ADEQUATE CLINICAL RESPONSE TO TREATMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS

A. Gomez[1,2], J. Lindblom[1,2], V. Qiu[1,2], A. Cederlund[1,2], A. Borg[1,2], S. Emamikia[1,2], Y. Enman[1,2], J. Lampa[1,2], I. Parodis[1,2]. [1]*Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden*; [2]*Karolinska University Hospital, Department of Gastroenterology, Dermatology and Rheumatology, Stockholm, Sweden*

Background: Despite improvements in medical care that have contributed to prolonged life expectancy for people living with systemic lupus erythematosus (SLE) over the past decades, they still suffer from substantial diminutions of health-related quality of life (HRQoL) compared with the general population and with other chronic diseases.

Some studies have demonstrated that conventional synthetic and biological disease-modifying agents contribute to improvements in SLE patients' HRQoL, and responders to treatment have been shown to report greater improvements than non-responders. Although these observations are clinically relevant,

improvement following a therapeutic intervention does not necessarily signify that the individual has achieved a satisfactory health state perception. In rheumatoid arthritis, significant pain and severe fatigue persist in a substantial proportion of patients who achieve a good clinical response to treatment or remission. This paradoxical observation has not been thoroughly explored in SLE.

Objectives: To determine the prevalence of adverse HRQoL outcomes in patients with SLE who achieved an adequate clinical response after a 52-week long period on standard therapy plus belimumab or placebo, within the frame of two phase III clinical trials. We further aimed to compare frequencies of adverse HRQoL outcomes across different age categories and ethnic groups, and sought to identify contributing factors.

Methods: We included patients who met the primary endpoint of the BLISS-52 (NCT00424476) and BLISS-76 (NCT00410384) trials (N=760/1684), i.e. attainment of the SLE Responder Index 4 at week 52. Accordingly, evaluation of adverse HRQoL outcomes was based on patient reports at week 52 from treatment initiation, using the Medical Outcomes Study Short Form 36 (SF-36) health survey and the Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-Fatigue) scale. Adverse HRQoL outcomes were defined as (i) SF-36 scale scores ≤ the 5th percentile derived from age- and sex-matched US population-based norms from the SF-36 health survey user manual; and (ii) FACIT-Fatigue scores <30.

Pearson's chi-square or Fisher's exact tests were used to investigate associations between dichotomous variables. Comparisons of continuous data between SLE patients and age- and sex-matched norms were performed using the Wilcoxon signed-rank test. Multivariable logistic regression models were created in order to assess independence and priority of potential factors associated with adverse HRQoL outcomes.

Results: We found clinically important diminutions of HRQoL in SLE patients compared with matched norms and high frequencies of adverse HRQoL outcomes, the highest in SF-36 general health (29.1%), followed by FACIT-Fatigue (25.8%) and SF-36 physical functioning (25.4%). Overall, frequencies were higher with increasing age. Black/African American and White/Caucasian patients reported higher frequencies than Asians and Indigenous Americans, while Hispanics experienced adverse HRQoL less frequently than non-Hispanics. Increasing organ damage was associated with adverse physical but not mental HRQoL outcomes; disease activity showed no impact. In multivariable logistic regression analysis, addition of belimumab to standard therapy was associated with lower frequencies of adverse SF-36 physical functioning (OR: 0.59; 95% CI: 0.39–0.91; P=0.016) and FACIT-F (OR: 0.53; 95% CI: 0.34–0.81; P=0.004).

Conclusion: Substantial proportions of SLE patients reported adverse HRQoL outcomes despite adequate clinical response to treatment, especially in physical aspects. Particularly high proportions were seen within Black/African American and White/Caucasian patients. Add-on belimumab may be protective against adverse physical functioning and severe fatigue. Our results corroborate that HRQoL diminutions constitute a substantial burden in patients with SLE, and highlight the limitations of current therapeutic strategies.

POS0102 GO ASK YOUR PATIENTS! PSS-QoL REPORTED PERCEPTION OF DRYNESS CORRELATES WITH LACRIMAL AND SALIVARY FLOW IN PRIMARY SJÖGREN'S SYNDROME

A. Lackner[1], P. Bosch[1], S. Zenz[1], J. Hermann[1], J. Horwath-Winter[2], D. Rabensteiner[2], M. Stradner[1]. *[1]Medical University of Graz, Department of Rheumatology, Graz, Austria*; *[2]Medical University of Graz, Department of Ophtalmology, Graz, Austria*

Background: The patient perspective is an essential outcome parameter in the quest for effective therapy in primary Sjögren's Syndrome (PSS). The EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) is recommended by EULAR to quantify patient's symptom burden and has been used in several clinical trials. Surprisingly, the patient's perception of dryness quantified with ESSPRI does not correlate with objective measures of salivary or lacrimal flow.

Objectives: Thus, we evaluated a newly developed assessment tool-the Primary Sjögren's Syndrome Quality of Life Questionnaire (PSS-QoL) - for quantifying symptoms of dryness in comparison with the ESSPRI and objective measurements of salivary and lacrimal flow.

Methods: Data of patients from the PSS registry of the Medical University of Graz fulfilling the 2016 ACR/EULAR classification criteria for PSS were analysed. The patient perspective was analyzed by PSS-QoL, ESSPRI, Xerostomia Inventory (XI) and Ocular Surface Disease Index (OSDI). Sicca signs were measured with Schirmer's test, unstimulated salivary flow test (USF) and stimulated salivary flow test (SSF). Patients were categorized into groups based on the presence of subjective and/or objective dryness: 1) objective dryness only, 2) subjective dryness only, and 3) both, subjective and objective dryness. ESSDAI (EULAR Sjögren's Syndrome Disease Activity Index) and EGA (Evaluator Global Assessment, numeric rating scale from 0 to 10) were obtained. In addition, free light chains (FLC) κ and λ, rheumatoid factor (RF) IgM and IgA were determined.

Results: Data from 123 PSS patients were analyzed; 91.9% (n=113) were female, with a mean disease duration of 6.2 (±5.3) years and mean age of 60.1 (±12.4) years. PSS-QoL-dryness revealed significant negative correlations with Schirmer's test (r=-0.31, p<0.05) and SSF-test (r=-0.39, p<0.01). In contrast, we found no significant correlation between ESSPRI-dryness and any objective dryness test. Lower perceived dryness was associated with higher immunological activity determined by increased levels of IgG, FLC and RF-IgA. Patients with objective signs and subjective symptoms of dryness had higher clinical and immunological disease activity compared to patients with subjective symptoms only (table 1).

Conclusion: Patients' perception of dryness assessed by PSS-QoL correlates with objective measurements of salivary gland function while ESSPRI-dryness did not. Based on the PSS-QoL and objective measures of dryness two distinct groups of PSS patients could be distinguished, which may have implications in daily practice and future clinical studies.

Queyrel[9], T. Goulenok[10], N. Limal[11], A. Doria[2], A. Moltó[12], E. Lazaro[13], N. Costedoat-Chalumeau[1]on behalf of GR2 Group. *[1]AP-HP, Hôpital Cochin; Centre Référence Maladies Rares, Service de médecine interne, Paris, France*; *[2]University of Padova, Rheumatology Unit, Department of Medicine-DIMED, Padova, Italy*; *[3]CHRU de Tours - Hôpital Bretonneau, Service de médecine interne, Tours, France*; *[4]CH Annecy Genevois, Service Infectiologie et médecine interne, Annecy, France*; *[5]AP-HP, Hôpital Saint-Antoine, Service de Médecine interne, Paris, France*; *[6]CHU de Poitiers – Milétrie, Service de Médecine interne, Poitiers, France*; *[7]CHU Grenoble, Service de médecine interne, Grenoble, France*; *[8]CHU de Reims-Robert Debré, Service de Médecine interne, Reims, France*; *[9]Hôpital de l'Archet, CHU de Nice, Service de Médecine interne, Nice, France*; *[10]AP-HP, Hôpital Bichat, Service de Médecine interne, Paris, France*; *[11]Hôpital Henri Mondor, Service de Médecine interne, Creteil, France*; *[12]AP-HP, Hôpital Cochin, Service de Rhumatologie B, Paris, France*; *[13]CHU-Hôpital Haut-Lévêque, Service de Médecine interne et maladies infectieuses, Bordeaux, France*

Background: Serum complement levels have been reported, as other proteins, to increase during pregnancy including in patients with systemic lupus erythematosus (SLE). Low C3/C4 levels are taken into account in disease activity scores such as the SLE-Pregnancy Disease Activity (SLEPDAI) (1) and several others. Nonetheless, their exact variations during pregnancy, especially in SLE, remain unknown, and no cut-off values per trimester of gestation have been identified.

Objectives: Our aim was to describe variations of C3 and C4 serum levels in a prospective cohort of SLE pregnancies implemented in 2014.

Methods: Inclusion criteria required that women: 1) were at least 18 years and enrolled in the French prospective observational GR2 study of pregnancies and rare autoimmune diseases; 2) diagnosed with SLE (SLICC criteria); 3) and had a pregnancy which ended before the 25th December 2020. The GR2 study is part of the European network of pregnancies registers in Rheumatology (EuNeP) supported by FOREUM (Foundation for Research in Rheumatology) (2) and follow EULAR recommendations regarding core data set for pregnancy registries in rheumatology (3).

For women with more than 1 pregnancy included in the GR2 study, only the 1st pregnancy meeting the inclusion criteria was analysed. In case of multiple C3 and C4 measures per patient, only the first measure for each trimester was considered when comparing the mean values of serum C3 and C4 levels at each trimester.

Results: This study included 290 pregnant women with SLE (mean age 32.2 years). 669 values of C3 and 648 values of C4 were available and figure 1 represents the variations in serum C3 and C4 levels during pregnancy.

Overall, mean serum C3 value increased from 0.97 g/L in the 1st trimester to 1.24 g/L in the 3rd trimester which corresponded to a 28% increase (Table 1 and figure 2). Mean C4 increased from 0.18 g/L in the 1st trimester to 0.20 g/L in the 3rd trimester which corresponded to a 11% increase (Table 1 and figure 3).

When analysing only the patients with at least one available value of serum C3 and C4 levels at each trimester (n=96 and n=101, respectively), we found very similar results (Table 1). This remained true when patients with flares were excluded (data not shown).

Conclusion: Mean C3 at third trimester increased by 28% compared to first trimester whereas mean C4 levels increased by 11% compared to first trimester. These preliminary results will lead to more precisely define which lowest cut-off value should be used to count low complement during pregnancy in SLE scores.

POS0104

ESSDAI AND ITS ASSOCIATION WITH PATIENT OUTCOMES IN SJÖGREN'S SYNDROME: A REAL-WORLD SURVEY IN THE US

B. Ndife[1], B. Hoskin[2], N. Booth[2]. [1]*Novartis Pharmaceuticals Corp., Novartis, East Hanover, United States of America*; [2]*Adelphi Real World, Adelphi Real World, Bollington, United Kingdom*

Background: The EULAR Sjögren's syndrome disease activity index (ESSDAI) is considered the gold standard for measuring Sjögren's syndrome disease activity in clinical trials, but there is limited evidence of its application in the real-world.
Objectives: To describe the distribution of ESSDAI scores in the real-world and it's association with patient outcomes.
Methods: Data were drawn from the Adelphi Primary Sjögren's syndrome (pSS) Disease Specific Programme™, a real-world point-in-time survey of rheumatologists and their consulting pSS patients in the United States. Proxy ESSDAI scores were calculated for each patient by assigning a score to the rheumatologists' perception of "not present", "mild", "moderate" or "severe" for each of the twelve domains of the ESSDAI. ESSDAI scores were then grouped according to the definitions of mild (ESSDAI 0-4), moderate (ESSDAI 5-13) and severe (ESSDAI ≥14). Rheumatologists provided data about patient demographics and clinical characteristics. Patients self-completed patient reported outcome (PRO) tools including the EuroQol 5-dimension 5-level utility score (EQ-5D), Work Productivity and Activity Impairment questionnaire (WPAI) and The Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F). Differences in clinical characteristics and patient-reported outcomes were examined according to ESSDAI severity score. Spearman's Rho association was used to assess the correlation of ESSDAI severity with PROs.
Results: Rheumatologists (n=84) provided data for 511 pSS patients, mean age 53.3 years, 88.5% female, 79.8% white/Caucasian and mean time since diagnoses 4.6 years. Of the 511 patients, 44.2% were considered to be mild, 30.9% moderate and 24.9% severe in terms of their calculated ESSDAI score. Demographic characteristics of the three ESSDAI groups were similar, Table 1. Patients with severe ESSDAI scores have been diagnosed with pSS for longer than those with mild or moderate ESSDAI scores.
Increasing ESSDAI severity was associated with worse EQ-5D utility scores (rho=-0.346, p<0.0001), worse FACIT-F scores (rho=-0.277, p<0.0001) and worse overall work impairment (rho=0.462, p<0.0001).

Table 1. Demographic characteristics of pSS patients in the US, by ESSDAI severity

	Total (n=511)	Mild ESSDAI (n=226)	Moderate ESSDAI (n=158)	Severe ESSDAI (n=127)
Patient age, mean (SD) years	53.3 (14.2)	52.6 (15.0)	53.6 (14.0)	54.2 (12.9)
% (n) female	88.5 (452)	89.4 (226)	88.6 (158)	86.6 (127)
Ethnicity, % (n)				
White/Caucasian	79.8 (408)	86.3 (195)	74.7 (118)	74.8 (95)
African-American	9.2 (47)	6.2 (14)	10.1 (16)	13.4 (17)
Hispanic/Latino	6.1 (31)	5.3 (12)	8.2 (13)	4.7 (6)
Other	4.9 (25)	2.2 (5)	7.0 (11)	7.1 (9)
Time since diagnosis, mean (SD) years [n]	4.6 (5.4) [379]	4.0 (4.9) [162]	4.9 (5.6) [118]	5.1 (5.8) [99]
Insurance type, % (n)				
Commercial (including employer provided)	59.9 (306)	62.4 (141)	56.3 (89)	59.8 (76)
Medicare	20.5 (105)	18.1 (41)	23.4 (37)	21.3 (27)
Health insurance exchange plan	9.6 (49)	10.2 (23)	10.1 (16)	7.9 (10)
Other	9.6 (49)	8.8 (20)	9.5 (15)	11.0 (14)
None	- (2)	- (1)	- (1)	- (0)
Employment status, % (n)				
Working full or part time	58.9 (301)	61.9 (140)	53.2 (84)	60.6 (77)
Long-term sick/unemployed/ retired	24.5 (125)	20.8 (47)	27.2 (43)	27.6 (35)
Homemaker	12.7 (65)	10.2 (23)	17.1 (27)	11.8 (15)
Other/unknown	3.9 (20)	7.1 (16)	2.5 (4)	- (0)
Smoking status, % (n) current smoker	6.8 (35)	3.5 (8)	5.7 (9)	14.2 (18)

Conclusion: A worsening severity on the ESSDAI scale is associated with worse outcomes for patients in the real-world. Treating systemic disease beyond symptomatic treatments is important to improve patient outcomes.

POS0105

PREDICTORS OF FLARE IN SLE PATIENTS ATTAINING LUPUS LOW DISEASE ACTIVITY STATE: A REAL-LIFE COHORT STUDY OF 292 PATIENTS WITH 36-MONTH FOLLOW-UP

A. R. Cunha[1], L. Saraiva[2], J. A. P. Da Silva[2,3], L. Inês[4,5]. [1]*Centro Hospitalar do Baixo Vouga, Rheumatology, Aveiro, Portugal*; [2]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; [3]*Coimbra Institute for Clinical and Biomedical Research(i.CIBR), Faculty of Medicine, Coimbra, Portugal*; [2]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; [5]*University of Beira Interior, Faculty of Health Sciences, Covilhã, Portugal*

Background: Lupus Low Disease Activity State (LLDAS) is a target for management of patients with SLE, that should be maintained in the long-term by preventing flares. Stratification of flare risk would be useful to optimize management.
Objectives: To identify predictors of flare in SLE patients attaining LLDAS.
Methods: Patients with SLE fulfilling classification criteria [ACR (1997) and/or SLICC and/or EULAR/ACR], followed at an academic lupus clinic from January 2017 to March 2020 were eligible. Baseline for each patient was the first visit with LLDAS within the study period. Patients never fulfilling LLDAS were excluded. Flares were identified as change from baseline by 3 instruments: revised SELENA flare index (r-SFI); SLEDAI-2K; Systemic Lupus Erythematosus Disease Activity Score (SLE-DAS). Time to first flare up to 36 months was identified separately for each instrument. Predictors of flare were sought through survival analysis, with distinct models for each of the three definitions of flare. Univariate analysis was performed using Kaplan-Meir curves and Log-Rank tests. Tested variables at baseline were: gender; age at time of SLE diagnosis; disease duration; cumulative SLE organ involvement (arthritis; mucocutaneous; renal; neurologic; haematological; anti-phospholipid syndrome); cumulative immunological features (anti-dsDNA; anti-Sm; anti-RNP, anti-phospholipid antibodies; hypocomplementemia); ongoing treatment (hydroxychloroquine; prednisone; immunosuppressants). Variables with p<0.1 were further tested in multivariate Cox regression models. Hazard ratios (HR) were determined with 95% confidence intervals (95%CI).
Results: From 322 patients in this SLE cohort, 292 (90.7%) fulfilled LLDAS and were included in the analyses (female: 87.3%; mean age: 46.2±14.5 years; previous lupus nephritis: 36.0%; receiving ongoing antimalarials, immunosuppressants, glucocorticoids: 92.8%, 34.6% and 29.8%, respectively. Over follow-up, the proportion of patients with flares according to each definition were: 28.4% (r-SFI), 24.7% (SLE-DAS) and 13.4% (SLEDAI-2K). The r-SFI flares were moderate in 28.9% and severe in 9.6% of the cases. From all patients, 54.1% maintained stable glucocorticoid-free control of the disease, without flares during follow-up. In the multivariate models, the following parameters were independent predictors of flare, as defined by any of the definitions (Table 1): anti-RNP+; oral glucocorticoids; immunosuppressants.
Conclusion: Patients attaining LLDAS but requiring ongoing treatment with immunosuppressants and/or glucocorticoids present a higher risk of flare and thus might need a tighter clinical monitoring. Anti-RNP+ was newly identified as a potential biomarker for higher risk of flares. Glucocorticoid-free, stable low disease activity is an achievable target.

Background: Low disease activity state has been defined using SLEDAI and used as treatment target in SLE. However, there has not been any such definition using BILAG-2004 index (BILAG-2004).

Objectives: This study was to determine if low disease activity state according to BILAG-2004 is valid for use as treatment target in SLE. We also assessed disease activity longitudinally using BILAG-2004 systems tally (BST). BST is an alternative way of representing BILAG-2004 scores that combines the flexibility and simplification of numerical scoring of BILAG-2004 with the clinical intuitiveness of BILAG-2004 structure.

Methods: This was a prospective multi-centre longitudinal study in the UK of an inception cohort of SLE patients (recruited within 12 months of achieving 1997 ACR revised criteria for SLE). Data were collected on disease activity (BILAG-2004 and BILAG2004-Pregnancy Index during pregnancy), SLICC/ACR DI (SDI), cumulative drug exposure and death at every visit. This study ran from 1st January 2005 to 31st December 2017. Four low disease activity states (LDA) were defined using BILAG-2004: 1) BILAG-2004 LDA when all 9 systems had scores of C, D or E on assessment (no Grade A or B), 2) BST LDA when there was persistent score of C, D or E in all 9 systems between 2 consecutive visits (equivalent to 2 consecutive visits with BILAG-2004 LDA), 3) BILAG-2004 Remission when all 9 systems had scores of D or E on assessment and 4) Persistent Remission when there was persistent score of D or E in all 9 systems between 2 consecutive visits. Longitudinal analysis using Poisson regression with random effects model was used with development of new damage as the outcome of interest. Gender, cardiovascular risk factors, antiphospholipid syndrome status and most drugs (except hydroxychloroquine, glucocorticoids, mycophenolate and cyclophosphamide) were excluded from the model as they were not associated with development of damage in univariate analysis.

Results: 273 patients were recruited (91.2% female, 59.3% Caucasian, 17.2% African/Caribbean, 17.2% South Asian) with mean age at recruitment of 38.5 years (SD 14.8). 97.8% had no damage at recruitment (2.2% had SDI score of 1). Median follow-up was 73.4 months (range: 1.8, 153.8) with total follow-up of 1767 patient-years. There were 13 deaths and 114 new damage items occurred during follow-up. There were 6674 assessments with disease activity score: 319 assessments with Grade A activity in 95 patients (84.6% had only 1 system with grade A, range: 1 - 4) and 1704 assessments with Grade A or B activity in 239 patients (78.7% had only 1 system with Grade A or B, range: 1 - 5).

BILAG-2004 LDA was achieved in 74.5% of assessments (from 271 patients). BILAG-2004 Remission occurred in 28.2% of assessments (from 234 patients). 6401 observations with BST were available (1 observation derived from change in activity between 2 consecutive assessments) and 63.7% were in BST LDA. There was no observation with Persistent Remission between consecutive visits. Table 1 summarises multivariate analysis which showed BILAG-2004 LDA to be inversely associated with damage. Similar results were obtained with BILAG-2004 Remission (RR 0.60 with 95% CI 0.38, 0.96) and BST LDA (RR 0.65 with 95% CI 0.43, 0.99). Cumulative drug exposure since recruitment for mycophenolate was protective against new damage (RR 0.99 with 95% CI 0.99, 0.99).

Table 1.

Variable	Relative Risk (95% CI) for New Damage
Ethnicity	
Afro-Caribbean	1.22 (0.68, 2.18)
South Asian	1.81 (0.97, 3.38)
Others	2.22 (0.63, 7.85)
Age at diagnosis	**1.06 (1.04, 1.08)**
Prior SDI score	0.68 (0.43, 1.06)
BILAG-2004 LDA	**0.60 (0.39, 0.94)**
Hydroxychloroquine since last visit (per g)	**0.99 (0.98, 0.99)**
Steroids since last visit (per 100mg)	**1.02 (1.01, 1.03)**
Cyclophosphamide since last visit (per g)	**1.67 (1.15, 2.41)**

Conclusion: BILAG-2004 LDA and BST LDA are valid treatment targets in SLE. BILAG-2004 Remission and Persistent Remission are uncommon, which make them unrealistic as a treatment target.

POS0107 TAPERING BELIMUMAB IN PATIENTS WITH SLE: A SINGLE CENTER EXPERIENCE

M. Fredi[1], T. Vojinovic[2], F. Regola[1], G. Babaglioni[3], D. Bettoni[3], I. Cavazzana[2], F. Franceschini[1]. *[1]UO Reumatologia e Immunologia Clinica ASST Spedali Civili e Università degli Studi di Brescia, ASST Spedali Civili, Brescia, Italy*; *[2]UO Reumatologia e Immunologia Clinica, ASST Spedali Civili, Brescia, Italy*; *[3]Farmacia Aziendale, ASST Spedali Civili, Brescia, Italy*

Background: In Italy, the use of belimumab has been authorized since 2013, in patients with active systemic lupus erythematosus (SLE) with positive anti–double-stranded DNA and low C3 or C4 levels, despite standard therapy. Belimumab is effective in reducing disease activity and number of flares and in blocking damage progression. To our knowledge, no data are available on dose tapering of belimumab in SLE patients chronically treated with it.

Objectives: The aim of this retrospective study was to analyse prevalence of tapering in a single cohort and to evaluate disease activity after tapering.

Methods: Patients, who received intravenous belimumab (10mg/kg) for at least 12 months between June 2013 and December 2020 were enrolled. The Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K), the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SLICC-SDI), Physician Global Assessment (PGA), C3 and C4 levels, and prednisone daily dose were recorded at baseline and every six-months. Follow-up was stopped when patients switched to subcutaneous belimumab or when it was discontinued for more than 6 months (interrupted). Dose tapering was defined as the prolongation of the regular dose interval, after initial treatment based on the registered dosage.

Results: Between June 2013 and December 2020, 48 patients received intravenous belimumab for at least 12 months (100% Caucasians, 94% females). All patients received standard belimumab dosage of 10mg/Kg every 4 weeks. Fourteen (29.1%) of 48 patients lengthened the dosing interval to 5 weeks; a subsequent lengthening of the interval occurred in 7 patients every 6 weeks and in 1 patient belimumab was gradually tapered to every 13 weeks.

Twelve months (T12) after belimumab introduction, 3 patients (6.2%) were receiving a tapered dosage; at T24, 9 out of the 37 (24.3%), at T36 9 out of 21 (42.8%), and at T48 8 out of 18 (44.4%). Differences in disease activity, damage, concomitant medications, disease duration at belimumab introduction (baseline) were evaluated among patients that maintained the standard interval versus the group that received a tapered dose. Notably, no differences were found among the two groups (standard dose vs tapering) concerning median age at baseline (41, IQR 31-47.5 vs 38, IQR 32.2-51.5), disease duration (median 11, IQR 7.2-16

vs 9, IQR 5.5-14.5), median prednisone daily dosage (7.1mg, IQR 5-11.9 versus 11mg, IQR 7.6-17.5) and median SLEDAI-2K (8, IQR 6-9.75 vs 8, IQR 5-10). Differences in concomitant medications or clinical manifestations are reported in Figure 1A.

Among the group that received the standard dose, 7 patients discontinued the treatment (20.6%), specifically 2 renal flares and one adverse event occurred. Whereas, in the reduced dose group, 2 discontinuations occurred (14.3%) due to a pregnancy and a renal flare. Noteworthy, the patient with the renal flare resumed subcutaneous belimumab 12 months after the flare. Finally, the disease activity was analysed in the 12 months after the first drug reduction (Figure 1B-E), with no sign of worsening of evaluated parameters (Figure 1B-1E), but with a significant reduction of steroids and SLEDAI-2K, 6 months after tapering.

Conclusion: In our single retrospective cohort, we have demonstrated that belimumab tapering seems to be safe and not associated with a worsening disease activity over the following months. However, further studies are required to identify eligibility criteria and to determine the optimal dose-tapering strategy both for the intravenous and the subcutaneous formulations.

POS0108

PLASMA MITOCHONDRIAL DNA AS A BIOMARKER IN DIAGNOSIS AND FOLLOW-UP OF SYSTEMIC LUPUS ERYTHEMATOSUS

S. Giaglis[1,2], D. Daoudlarian[1,2], D. Kyburz[1,2], N. Venhoff[3], U. Walker[1,2].
[1]University of Basel, Department of Biomedicine, Laboratory for Experimental Rheumatology, Basel, Switzerland; *[2]University Hospital Basel, Department of Rheumatology, Basel, Switzerland*; *[3]University Medical Center Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany*

Background: A fundamental role of mitochondria in systemic lupus erythematosus (SLE) was recently demonstrated (1). In brief, mitochondrial ROS participate in the formation of neutrophil extracellular traps (NETs) (2), while extrusion of cell-free mitochondria and highly oxidized interferogenic mtDNA causes disease in an animal model of SLE (3-5).

Objectives: The diagnostic and prognostic value of cell-free DNA in SLE is still unknown. The aim of the present study was therefore to examine the clinical utility of cell-free DNA quantification as a non-invasive biomarker in SLE.

Methods: Total DNA was isolated from platelet-free plasma samples of healthy individuals (HC) and consecutive SLE patients. Plasma and clinical data were collected at baseline and follow-up. Copy numbers were quantified by qPCR for mitochondrial (mt) DNA (ATP-6 gene) and nuclear (n) DNA (GAPDH gene).

Results: Fifty-six HC (median age 48.3 ± 13.5, 64% female) and 103 SLE patients (median age 46.8 ± 15.8, 99% female, mean SLEDAI: 3 ± 4) were available for analysis.

mtDNA levels were significantly elevated in SLE plasma ($1.3x10^8$ copies/ml plasma, 95% CI: $7.3x10^7$ to 1.7 $x10^{8)}$), compared to HC plasma ($8.6x10^6$ copies/ml plasma, 95% CI: $6.9x10^6$ to $1.0x10^7$, p<0.0001). nDNA levels in contrast did not differ between SLE ($8.3x10^6$ copies/ml plasma, 95%CI: $5.9x10^6$ to 1.4 $x10^7$) and HC ($1.0x10^7$ copies/ml plasma, 95%CI: $2.0x10^6$ to 1.5 $x10^7$, p=0.61). Receiver *operating characteristic* curve analysis showed that a cut-off value of $1.9x10^7$ mtDNA copy numbers differentiated between SLE and HC with 87.4% sensitivity, 94.6% specificity and an AUC of 0.95 (Figure 1a).

mtDNA levels correlated with the SLE Disease Activity Index 2000 (SLEDAI-2K) (r=0.29, p=0.0026), less so also nDNA copy numbers (r=0.24, p=0.014). There was no association of mtDNA elevation with any particular type of SLE organ involvement and no correlation between mtDNA copy numbers in SLE plasma and dsDNA antibody levels.

Follow-up data were available for 32 SLE patients (median follow-up 4.0 months, IQR: 4.0). delta mtDNA-levels robustly correlated with changes in SLEDAI-2K (r=0.51, p=0.0012, Figure 1b).

Conclusion: The quantification of cell free mtDNA, but not nDNA copy numbers allows a sensitive and specific distinction between healthy individuals and patients with SLE. mtDNA levels correlate cross sectionally with disease activity in SLE patients and within individual SLE patients longitudinally with the SLEDAI. Plasma mtDNA quantification may therefore aid in the diagnosis of SLE and in monitoring SLE activity.

IDENTIFICATION OF PRIMARY SJOGREN'S SYNDROME SUBTYPES BY MACHINE LEARNING

M. T. Qiu[1,2,3], S. X. Zhang[1,2,3], J. Qiao[1,2,3], J. Q. Zhang[1,2,3], S. Song[1,2,3], R. Zhao[1,2,3], M. J. Chang[1,2,3], Y. Zhang[1,2,3], G. Y. Liu[1], P. F. He[4], X. Li[1,2,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; *[2]Shanxi Li Xiaofeng Medical Groups, Department of Rheumatology, Taiyuan, China*; *[3]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; *[4]Shanxi Medical University, Medical Data Sciences, Taiyuan, China*

Background: Sjogren's syndrome(pSS) is a chronic, progressive, and systematic autoimmune disease characterized by lymphocytic infiltration of exocrine glands [1 2]. Sicca symptoms and abnormal fatigue are the main clinical presentation, but those symptoms are non-specific to patients, which lead to delayed diagnosis [1 3]. The heterogeneous of clinical manifestation raise challenges regarding diagnosis and therapy in pSS, thus it's necessary for us to sub-classify pSS.

Objectives: To explore new biomarkers for diagnosis and subtypes of pSS based on Machine Learning Primary.

Methods: All microarray raw datas (CEL files) were screened and downloaded from Gene Expression Omnibus (GEO). Meta-analysis to identify the consistent DEGs by MetaOmics. Weighted gene co-expression network analysis (WGCNA) was used to the modules related to SS for further analysis. Subclasses were computed using a consensus Non-negative Matrix Factorization (NMF) clustering method. Immune cell infiltration was used to evaluate the expression of immune cells and obtain various immune cell proportions from samples. *P* value < 0.05 were considered statistically significant. All the analyses were conducted under R environment (version 4.03).

Results: A total of 3715 consistent DEGs were identified from the four datasets, including 1748 up-regulated and 1967 down-regulated genes. Tour

meaningful modules, including yellow, turquoise, grey60 and bule, were identified (Figure 1A,1B). And 183 overlapping gene were screened from the DEGs and the Hub genes in the four modles for further analysis. We final divided pSS patients into three subtypes, of which yellow and turquoise in Sub1, grey60 in Sub2 and blue in Sub3. Sub1 and Sub3 were related to cell metabolism, while Sub2 had connection with virus infection (Figure 1C,1D). Infiltrated immune cells were also different among these three types (Figure 1E,1F).

Conclusion: Patients with pSS could be classified into 3 subtypes, this classification might help for assessing prognosis and guiding precise treatment.

Gemelli IRCCS, Rome, Italy*; *[6]Division of Nephrology, Università Cattolica del Sacro Cuore, Rome, Italy*

Background: Epigenetic factors such as non-coding RNA (miRNA) have been shown to be deregulated in Systemic Lupus Erythematosus (SLE). In mouse models, different miRNAs have been associated with lupus nephritis (LN), one of the most severe manifestations of the disease[1].

Objectives: To evaluate the expression of miR-155 and miR-34a in renal tissues as biomarkers of organ involvement and inflammatory tissue activity in patients with LN.

Methods: Thirty-two SLE patients with LN (age: 32.2 ± 9.2 years) with active renal involvement undergoing ultrasound-guided renal biopsy were enrolled between 2010 and 2019. The nephritic manifestation was present in 13 (41%) patients at disease onset (early-LN SLE), while 19 (59%) patients showed a renal involvement after disease onset (long-LN SLE, mean disease duration at LN onset: 7.3 ± 5.7 years). Twelve age-matched patients with IgA nephropathy were enrolled as control group. Clinical, laboratory and demographic data were collected for each patient. Disease activity was recorded using SLEDAI-2K and renal activity, using the total SLEDAI-2K fraction including the items related to the renal involvement. MiR-155 and miR-34a expression in renal tissues was carried out by extraction of total RNA from paraffin-preserved biopsies and was evaluated, after a retrotrascription protocol, using real-time PCR by relative quantification considering the ΔCt (Ct miRNA- Ct housekeeping gene)[2].

Results: MiR-155 and miR-34a expression in renal tissues was higher in LN-SLE patients as compared to IgA nephropathy patients (ΔCt miR-155: 9.4 ± 10.1 vs 21.9 ± 3.6, p<0.01; ΔCt miR-34a: 10.1 ± 9.8 vs 19.2 ± 3.1, p=0.02). MiR-155 and miR-34a expression in LN-SLE patients renal tissues was comparable in the different histological classes. Furthermore, a direct correlation was observed between the expression of miR-155 and miR-34a (r = 0.91, p <0.001). Dividing patients based on nephritic onset, SLE patients with long-LN showed higher expression of miR-155 (ΔCt 6.1 ± 8.7) and miR-34a (ΔCt 7.1 ± 9.0) as compared to patients with early-LN (miR-155: ΔCt 13.4 ± 10.6 p = 0.08; miR-34a: ΔCt 15.1 ± 9.5 p = 0.02) or patients with IgA nephropathy (miR-155 p<0.01 and miR-34a p<0.01). Moreover, in early-LN SLE it was observed an inverse correlation between miR-34a expression and C3 and C4 complement components (r=-0.7.2; p=0.05 and r=-0.86; p=0.01, respectively) and a direct correlation between miR-155 and 24h-UP (r=0,67; p=0.03). Considering SLE patients with early-LN, the expression of miR-34a was slightly significant in patients who had relapsed (ΔCt 8.2 ± 11.4 vs ΔCt 18.4 ± 7.9 p = 0.08), although no correlation emerged between the expression of miR-155 and miR-34a at the time of the biopsy and with disease activity indices.

Conclusion: MiR-155 and miR-34a may represent tissue biomarkers of inflammatory activation in SLE patients with LN; in particular, the higher expression of these miRNA in long-LN and the correlation between miR-155 expression with p24h-UP in early-LN could indicate a possible role of these biomarkers in renal involvement in patients with SLE with later renal onset. The increased expression of miR-34a could give indications of a disease recurrence suggesting a closer monitoring of patients.

Background: There had been very limited data on the development of damage and mortality in an inception cohort of SLE patients who were recruited very soon after diagnosis.

Objectives: This study aimed to analyse the development of damage and death in an inception cohort of SLE patients recruited within 1 year of diagnosis with up to 13 years of follow-up.
Methods: This was a prospective multi-centre longitudinal study in the UK of SLE patients recruited within 12 months of achieving 1997 ACR revised criteria for SLE. Data were collected on BILAG-2004, BILAG2004-Pregnancy Index (during pregnancy), SLICC/ACR DI (SDI), cumulative drug exposure and death at every visit. Information on cardiovascular risk factors and antiphospholipid syndrome status were also collected. This study ran from 1st January 2005 to 31st December 2017. Mortality and development of damage were analysed.
Results: There were 273 patients recruited (91.2% female, 59.3% Caucasian, 17.2% African/Caribbean, 17.2% South Asian) with mean age at recruitment of 38.5 years (SD 14.8). 97.8% had no damage at recruitment (2.2% had SDI score of 1). Median follow-up was 73.4 months (range: 1.8, 153.8) with total follow-up of 1767 patient-years.
There were 13 deaths (4.8%): 76.9% female, 84.6% Caucasian, 15.4% South Asian, mean age 62.6 years (± SD 15.8) and mean disease duration 3 years (± SD 1.8). Causes of death were cancer in 5 (38.5%), infection in 3 (23.1%), ischaemic heart disease in 1 (7.7%) and unknown in 4 (30.8%).
114 new damage items in 83 patients occurred during follow-up. The distribution of damage was musculoskeletal (21, 18.4%), ophthalmic (18, 15.8%), neuropsychiatric (18, 15.8%), renal (14, 12.3%), malignancy (12, 10.5%), cutaneous (7, 6.1%), GIT (7, 6.1%), cardiac (6, 5.3%), pulmonary (4, 3.5%), diabetes mellitus (4, 3.5%) and vascular (3, 2.6%). The rate of development of damage appears to be higher in the first 3 years which subsequently stabilised (Table 1).

Table 1. Incidence rate of development of damage over period of follow-up at 3 yearly intervals

Period of follow-up (year)	Person-years at risk	Number of new items of damage	Incidence rate, per 1000 person-years (95% CI)
0 – 3	753.4	60	79.6 (61.8, 102.6)
3 – 6	534.0	31	58.1 (40.8, 82.6)
6 – 9	321.2	12	37.4 (21.2, 35.8)
9 – 12	152.5	5	32.8 (13.6, 78.7)
> 12	5.9	0	-

Conclusion: Mortality is uncommon during the first 12 years of follow-up for newly diagnosed SLE patients. However, development of damage appears to be higher in the first 3 years before stabilizing to a lower rate subsequently.

Translating vasculitis

POS0112 CD8+ T-CELL INFILTRATION IS ASSOCIATED WITH LESIONAL GM-CSF OVEREXPRESSION IN GCA

W. F. Jiemy[1], R. Reitsema[2], A. Kwant[2], W. Abdulahad[1,2], A. Boots[2], P. Heeringa[1], E. Brouwer[2]. [1]*University of Groningen, University Medical Center Groningen, Department of Pathology and Medical Biology, Groningen, Netherlands*; [2]*University of Groningen, University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: Giant cell arteritis (GCA) is a large-vessel vasculitis characterized by granulomatous T cell- and macrophage infiltration. Granulocyte-macrophage colony stimulating factor (GM-CSF) is present in GCA-affected vessels where it may be involved in skewing of tissue destructive macrophages (1). Furthermore, a recent phase 2 clinical trial demonstrated that GM-CSF receptor blockade was superior to placebo at 26 weeks in GCA. However, the cellular source of GM-CSF in GCA is still unclear.
Objectives: As T cells have been identified as a major source of GM-CSF in other immune-mediated diseases such as multiple sclerosis, we investigated whether T cells are GM-CSF producers in GCA patients, both systemically and locally.
Methods: GM-CSF production capacity by PMA-stimulated PBMCs from newly diagnosed, untreated GCA patients and HCs (N=10 each) was assessed using flow cytometry. Temporal artery biopsies (TABs, N=5) were immunohistochemically stained for CD3, CD8 and GM-CSF. Colocalization of these markers was assessed with immunofluorescence.
Results: Proportions of CD4+ (median GCA=3.1%; HCs=2.76%) and CD8+ (median GCA=5.8%; HCs=5.8%) T cells produced GM-CSF after *in vitro* stimulation, but no significant differences were found between the groups. Immunofluorescence staining confirmed that CD3+ T cells (both CD8+ and CD8-) were positive for GM-CSF in TABs. Interestingly, GM-CSF positivity in TABs correlated strongly with the extent of CD8+ T-cell infiltration ($r=0.74$, $p<0.01$), but not with CD3+ T-cell infiltration ($r=0.38$, $p=0.16$).
Conclusion: Our data imply that T cells are an important source of GM-CSF in GCA lesions. The correlation of the extent of CD8+ T-cell infiltration with GM-CSF positivity suggests that CD8+ T cells are the major source of local GM-CSF overexpression in tissue.

Background: *BAFF, APRIL* and *BAFFR* are genes that encode cytokines with a key role in the development and survival of B-lymphocytes [1-4]: The B cell-activating factor (BAFF, also known as BLyS), a proliferation-inducing ligand (APRIL) and BAFF receptor (BAFF-R), respectively. Previous genetic studies have revealed that the *BAFF-APRIL-BAFFR* pathway is implicated in the genetic predisposition to several immune-mediated diseases [5].
Objectives: To determine whether the *BAFF-APRIL-BAFFR* pathway represents a novel genetic risk factor for the pathogenesis of Immunoglobulin-A vasculitis (IgAV), an inflammatory disease in which IgA deposits and B-lymphocytes are crucial [6, 7].
Methods: A functional *BAFF* polymorphism (rs374039502) and two tag variants within *APRIL* (rs11552708 and rs6608) and *BAFFR* (rs7290134 and rs77874543)

were genotyped in 386 Caucasian IgAV patients (the largest series of Caucasian patients with IgAV ever assessed for genetic studies) and 806 sex and ethnically matched healthy controls by TaqMan assays.

Results: No statistically significant differences in the genotype and allele frequencies between patients with IgAV and healthy controls were observed when each genetic variant of *BAFF APRIL* and *BAFFR* was analyzed independently (Table 1). Likewise, no statistically significant differences in genotype and allele frequencies of *BAFF APRIL* or *BAFFR* were found when patients with IgAV were stratified according to the age at disease onset or to the presence/absence of gastrointestinal or renal manifestations. Similar results were disclosed when haplotype frequencies of *APRIL* and *BAFFR* were compared between patients with IgAV and healthy controls as well as patients with IgAV stratified according to the age at disease onset or to the presence/absence of gastrointestinal or renal manifestations.

Conclusion: Our results suggest that the *BAFF-APRIL-BAFFR* pathway does not contribute to the genetic network underlying IgAV.

POS0114 ABERRANT MONOCYTE SUBSETS IN PATIENTS WITH BEHÇET’S DISEASE

C. Li[1,2], J. Liu[1], H. Chen[1], W. Zheng[1]. [1]*Peking Union Medical College Hospital, Rheumatology and Clinical Immunology, Beijing, China*; [2]*Peking University Shougang Hospital, Rheumatology, Beijing, China*

Background: Behçet’s Disease (BD) is a systemic vasculitis of unknown etiology[1]. Monocytes closely related to inflammation potentially contribute to BD’s pathogenesis. They are classified into three subsets: classical monocytes (CM), intermediate monocytes (IM) and non-classical monocytes (NCM). Abnormalities of monocyte subsets have been reported in many infectious, inflammatory and autoimmune diseases[2-6], but their implication in BD remains elusive.

Objectives: To investigate the distribution, phenotypes and functions of monocyte subsets in BD and explore their roles in BD pathogenesis.

Methods: The frequencies and phenotypes of monocyte subsets in BD and healthy controls (HC) were determined by flow cytometry, and their correlation with clinical parameters was analyzed. Intracellular cytokines and phosphorylated signal proteins [phosphorylated p65(p-p65) and phosphorylated p38(p-p38)] were determined in LPS-activated monocyte subsets by flow cytometry. Monocyte subsets of BD and HC were sorted and co-cultured with naïve CD4 + T cells, and Th1 cell frequencies were measured on day 5.

Results: A higher IM (9.0±3.6 % vs. 4.5±2.0%, p<0.01) and lower NCM (2.6±1.2% vs. 4.2±2.0%, p<0.01) population in BD patients were noted. BD IM were positively correlated with CRP (r=0.5456, $p<0.05$), ESR (r=0.4683, p=0.05), and the serum level of TNF-a (r=0.7372, $p<0.001$) and IL-6(r=0.5013, $p<0.05$). BD NCM were negatively correlated with CRP (r=0.4822, $p<0.05$) and the serum level of IgM (r=-0.7830, $p<0.001$). Moreover, BD IM decreased (12.3±3.8% vs. 5.7±3.6%, $p<0.05$), while BD NCM increased (2.6±1.3% vs. 3.5±1.5%, $p<0.01$) after BD patients achieved remission. CD11b and CD64 expression on CM, IM and NCM in BD were enhanced. BD CM promoted TNF-a (61.0±11.4% vs 48.3±9.9%, $p<0.05$) and IL-6 (7.2±5.4% vs1.9±1.7%, $p<0.05$) production and facilitated Th1 differentiation. BD IM promoted IL-6 production (6.2±3.8% vs 2.6±1.6%, $p<0.05$). Furthermore, we demonstrated a higher level of p-p65 (12.8±2.9% vs 3.3±1.1%, $p<0.01$) in BD CM and increased p-p65 (3.2±0.6% vs 0.01±0.01%, $p<0.01$) and p-p38 (1.1±0.6% vs 0.03±0.01%, $p<0.01$) in BD IM.

Conclusion: To our knowledge, our study is the first study on monocyte subsets in BD. Our data highlighted the aberrant populations of IM and CM in BD, potentially implicated in BD pathogenesis.

POS0115 RISK FACTORS FOR CORONARY HEART DISEASE AND ATHEROSCLEROSIS IN PATIENTS WITH BECHET’S DISEASE

R. Goloeva[1], Z. Alekberova[1], T. Popkova[1], S. Glukhova[1]. [1]*V A Nasonova Research Institute of Rheumatology, systemic rheumatic diseases, Moscow, Russian Federation*

Background:

Objectives: To evaluate traditional risk factors for clinically manifest and asymptomatic atherosclerosis in pts with BD.

Methods: Traditional risk factors for atherosclerosis were evaluated in 95 pts with Bechet’s disease (BD) and 40 healthy age and gender matched controls. The male-to-female ratio was 3,7:1, pts’ mean age was 29.7 (23-35) y, the mean age at the disease onset - 19,9 (14-25) y, and mean disease duration - 9,6 (4-15) y. The common carotid artery intima-media thickness (IMT) was evaluated by high resolution B-mode ultrasonography. A plaque was defined as a local intima-media thickening ≥1,2 mm, with reference IMT thickness <0,9 mm. Serum concentration of high-sensitivity C-reactive protein (hs CRP) was measured by immunonephelometric assay (BN-100 Analyzer; Dade Behring). Lipid profile evaluation included total cholesterol, TGs, HDL, LDL and atherogenic index.

Results: Traditional risk factors for atherosclerosis (one or more) were found in 85,3% of BD pts, dyslipidemia was the most common risk factor and was present in 76,84% of pts, mostly due to increased total cholesterol (TC) and

low-density lipoprotein cholesterol (LDL-C) levels. 22,1% had arterial hypertension (AH), 29,5% were current smokers, 27,4% had excess body weight, 3,1% had family history of cardiovascular diseases (CVD). Traditional risk factors for atherosclerosis were found in 80% out of 40 gender and age matching subjects from the control group, i.e., showing practically the same prevalence as in BD pts.

Table 1. The incidence-rate of traditional risk factors in BD patients and controls

Variables	BD pts (n=95)	Controls (n=40)	p
Age, years	29,0 [23,0;35,0]	29,0 [25,0;32,0]	NS
BMI, kg/m^2	23,1 [21,1;25,5]	23,8 [22,0;26,0]	NS
BMI ≥ 25 kg/m^2, n (%)	26 (27,4)	15 (37,5)	NS
Arterial hypertension, n (%)	21 (22,1)	4 (10)	NS
Family history of CVD	3 (3,1)	5 (12,5)	0,05
Cigarette smoking, n (%)	28 (29,5)	12 (30,0)	NS
Dyslipidemia, n (%)	73 (76,8)	27 (67,5)	NS
Total cholesterol, mml/l	5,0 [4,3;6,1]	5,1 [4,5;5,7]	NS
Cholesterol > 5,0 mml/l, n (%)	47 (49,5)	25 (62,5)	NS
TGs, mml/l	0,92 [0,7;1,3]	0,89 [0,60;1,08]	NS
TGs > 1,7 mml/l, n (%)	8 (8,4)	3 (7,5)	NS
LDL, mml/l	3,36 (2,8;4,0)	3,3 [2,7;3,7]	NS
LDL > 3 mml/l, n (%)	63 (66,3)	25 (62,5)	NS
HDL, mml/l	1,19 [1,0;1,5]	1,35 [1,2;1,6]	0,06
HDL ≤1 mml/l (male), ≤ 1,2 mml/l (female) n (%)	30 (31,6)	5 (12,5)	0,03

Reduced HDL levels were more common in BD pts vs the controls - 30 (31,6%) vs 5 (12,5), p=0,03 as shown in table 1. Other traditional risk factors were similarly present in both groups with no significant difference between BD pts and the controls.

Analysis showed similar incidence of CV events (nonfatal myocardial infarction, angina pectoris and stroke) in both groups. There were no differences between BD pts and healthy people in terms of lifetime risk for CVD. High lifetime risk ≥ 20% was found in 4 BD pts vs 0 in the control group; moderate lifetime risk >10% < 20% - in 6,3% of BD pts vs 2,5% in the control group, and low lifetime risk < 10% -was found in 89,5% of BD pts vs 97,5% of the controls.

Average IMT values were significantly higher in BD pts - 0.68 [0.60;0.73] vs 0.63 [0.56;0.65], p=0.008, but at the same time, IMT thinning (up to < 0.5 mm) was significantly more common in BD pts - 32.6% vs 12.5% in the control group (p=0.01). HsCRP serum levels were significantly higher in BD pts (2.42 [0.5;8.8] mg / l) than in the control group (0.37 [0.15;0.75]), p=0.001. There was a correlation between hs-CRP and BMI in BD pts (r=0.2, p<0.05), but no correlation was found between hsCRP and BD activity/BD clinical manifestations.

Conclusion: Decreased HDL cholesterol levels were more common in BD patients than in the control group, just as thinning of IMT, most likely because of vasculitis.

POS0116 HEART RATE VARIABILITY IN PATIENTS WITH BEHCETS DISEASE

R. Goloeva[1], Z. Alekberova[1], T. Popkova[1], S. Glukhova[1], D. Novikova[1]. [1]*V A Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases, Moscow, Russian Federation*

Background: Behcet's disease (BD) is a systemic vasculitis affecting all types and sizes of blood vessels. Heart rate variability (HRV) reflects sympathetic -parasympathetic imbalance in the autonomic NS regulation. Low HRV values are known as independent risk factor of death and non-fatal cardiovascular events in both - survivors of a myocardial infarction and in asymptomatic population.

Objectives: The aim of this study is to evaluate HRV in BD pts vs healthy controls.

Methods: The study group included 74 BD pts (53males/21females) with disease duration of 9,0 (5,0;15,0)/9,0 (7;20) years, and the control group - 32/15 age-matched healthy m/f. The following HRV parameters from 24h ECG ambulatory recording were assessed: MeanNN and time-domain variables, adjusted by MeanNN (SDNNn%, SDNNin%, RMSSDn%). Additionally, all traditional cardiovascular risk factors such as systolic blood pressure (SPB), smoking status, BMI values, dyslipidemia profile, ultrasonographic values of carotid intima-media thickness (IMT), and levels high sensitive CRP (hsCRP) as a marker of inflammation were evaluated.

Results: In BD patients HRV values (RMSSDn%) were significantly lower compared to healthy controls (table 1).

Table 1. HRV parameters in BD patients and control group

Parameters	Males		Females	
	BD (n=53)	Control (n=32)	BD (n=21)	Control (n=15)
Age, years	30 (24; 36)	30 (26; 35)	32 (26; 37)	28 (24; 31)
MeanNN, ms	810 (732; 849)	782 (732; 835)	776 (708; 830)	764 (694; 832)
SDNN n (%)	16,9 (13,6; 19,4)	17,2 (16,3; 21,1)	13,1 (11,3; 5,3)	12,2 (10,7; 14,6)
SDNNi n (%)	6,8 (5,1; 8,1)	6,8 (5,0; 8,3)	7,1 (6,1; 7,7)	5,2 (4,9; 5,7)
RMSSD n (%)	2,1 (1,5; 2,3)**	4,1 (2,7; 5,2)**	1,7 (1,4; 3,7)*	2,8 (2,2; 3,9)*

Data are presented in median values and interquartile range, *p<0,05, **p<0,005 vs controls.

There was a significant negative correlation in BD patients between HRV (SDNNin%) and age (r= -0,4; p=0,00), disease duration (r= -0,3; p=0,00), BMI (r= -0,2; p<0,01), cholesterol levels (r= -0,3; p=0,00), LDLP (r= -0,3; p=0,00) and increased IMT (r= -0,2; p=0,04), and also between HRV (RMSSD%) and age (r= -0,2; p=0,04), disease duration (r= -0,2; p=0,01), cholesterol levels (r= -0,3; p=0,00), HDLP (r= -0,2; p=0,04); a positive correlation was established between HRV (SNNN%) and smoking (r= -0,2; p=0,04). The control group showed positive correlation between HRV (SNNN%) and increased IMT (r= 0,4; p=0,01).

Conclusion: HRV reduction reflects impaired sympathetic -parasympathetic regulation in BD pts, associated with pts' age, disease duration and presence of traditional cardiovascular risk factors: BMI, increased cholesterol levels, LDLP, and such asymptomatic manifestation of atherosclerosis as increased IMT.

Background: Among small vessel vasculitis, double-positive patients (DPP), combining serum and/or histologic findings for glomerular basement membrane (GBM) disease, and anti-neutrophil cytoplasmic antibodies (ANCA), is a rare, newly and poorly described condition.

Objectives: We aimed to compare characteristics between DPP and ANCA-associated vasculitis patients (AAVP) with severe-renal-involvement.

Methods: Retrospective multicenter study comparing 33 DPP and 45 severe-renal-involvement (serum creatinine >300 µmol/L) AAVP, all with biopsy-proven nephropathy.

Results: Except for 2 patients (6%) who had pure renal presentation during their entire follow-up period, others exhibited at least one extrarenal manifestation: pulmonary involvement (64%), weight loss (39%), gastrointestinal involvement (33%), ENT manifestations (21%), musculoskeletal symptoms (21%), fever (18%), neurological (12%), cutaneous (6%) and/or cardiac (6%) signs. All DPP (including up to 18% exhibiting negative serum anti-GBM antibodies) presented severe acute kidney failure with histologic GBM involvement. Compared to our AAVP, they had higher serum creatinine (719 versus 501 µmol/L; p=0.006) and a higher of patients requiring initial renal replacement therapy (82% vs 36%; p<0.001). Berden classification significantly differed (p=0.003), with more crescentic glomerulonephritis and fewer sclerotic lesions in DPP. One-year renal survival was significantly lower in DPP than in AAVP (27% versus 64%; p<0.0002). With comparable proportions of ANCA subtypes (2/3 with anti-MPO autoantibodies),

numbers of extrarenal manifestations, remission-inducing immunosuppressants and median follow-ups (three years) between groups, relapse rates were similar: 9.1% of DPP and 10% of AAVP. Please, see the table 1 for more detailed data.
Conclusion: Although DPP have features of both kinds of eponymous vasculitis, the anti-GBM component is the dominant phenotype, with more severe renal presentation and prognosis compared to AAVP with severe renal failure. Simultaneous testing of both antibodies and a systematically performed renal biopsy should be recommended in all rapidly progressive glomerulonephritis patients to recognize this difficult-to-treat, rare disease.

Table 1. Comparison of clinical characteristics and outcomes between the cohorts of DPP and AAVP

	DPP n = 33	AAVP n = 45	p
Age (year)	71,5 [14 - 89]	63 [45 - 93]	0.14
Male	16 (48)	19 (42)	0.65
Birmingham Vasculitis Activity Score	18,1 ± 4,8	20,4 ± 5,4	0.07
Organ involvement (except kidney)	1,7 ± 0,8	1,9 ± 1,1	0.31
Serum creatinine (µmol/L)	719 [238 - 2412]	501 [310 - 1683]	0.006
ANCA (MPO/PR3)	22/11	34/11	0.45
Berden classification	n = 31	n = 44	0.003
s (sclerotic) / c (crescentic)	6 (19) / 22 (71)	12 (27) / 16 (37)	
f (focal) / m (mixed)	0 / 3 (10)	11 (25) / 5 (11)	
Brix renal risk score	n = 27	n = 44	0.000014
Low / Medium / High	0 (0) / 4 (15) / 23 (85)	1 (2) / 29 (66) / 14 (32)	
Initial immunosuppressive therapy			
IV Cyclophosphamide	25 (76)	40 (82)	0.14
Rituximab	1 (3)	3 (7)	0.64
Plasma exchanges	25 (76)	19 (42)	0.005
Maintenance treatment	17 (48)	40 (89)	0.046
Initial RRT requirement	27 (82)	16 (36)	0.00007
Renal recovery (% initial RRT requirement)	4 (12)	6 (38)	0.9
1 year renal survival	9 (27)	29 (64)	0.0002

Values are displayed as absolute number (%) or as median [range]. DPP: double positive patients; AAVP: ANCA associated vasculitis patients; MPO: myeloperoxidase; PR3: proteinase 3; RRT: renal replacement therapy; IV: intravenous.

POS0118 A WORLDWIDE PHARMACOEPIDEMIOLOGICAL UPDATE OF DRUG-ASSOCIATED ANCA-ASSOCIATED VASCULITIS AT THE TIME OF TARGETED THERAPIES

S. Deshayes[1], C. Dolladille[2], A. Dumont[1], N. M. Silva[1], B. Chretien[2], H. De Boysson[1], J. Alexandre[2], A. Aouba[1]. [1]*CHU de Caen Normandie, Internal Medicine, Caen, France*; [2]*CHU de Caen Normandie, Pharmacology, Caen, France*

Background: Several pharmacological classes are involved in drug-associated anti-neutrophil cytoplasmic antibody-associated vasculitis (DA-AAV). However, the literature data supporting the role a drug in the onset of DA-AAVs mainly rely on case reports or short series and implicate old treatments. Moreover, the advent of new treatments, including targeted therapies, may have modified the epidemiology of these adverse drug reactions (ADRs).
Objectives: To update this list by using a pharmacovigilance-based data mining approach.
Methods: We collected data on ADRs reported with the MedDRA preferred term "Anti-neutrophil cytoplasmic antibody positive vasculitis" up to November 2020, from the World Health Organization pharmacovigilance database. For each retrieved drug, a case/noncase analysis was performed, and disproportionate reporting was calculated by using the information component (IC). A positive IC025 value, which is the lower end of the 95% credibility interval, was considered significant.
Results: A total of 483 deduplicated individual case safety reports of DA-AAV involving 15 drugs with an IC025>0 were retrieved. DA-AAV occurred in 264 (71.2%, n=371) women, the median age at onset was 62 years [45-72], and the median time to onset between the introduction of the suspected drug and DA-AAV was 9 months [1-36]. DA-AAV occurrence was considered serious in 472 (97.7%, n=481) cases and fatal in 43 (8.9%) cases. The drugs associated with the highest disproportionate reporting were hydralazine, propylthiouracil, thiamazole, sofosbuvir, minocycline, carbimazole, mirabegron, and nintedanib (Table 1).

Table 1. List of the 15 drugs associated with ANCA-associated vasculitis in the World Health Organization pharmacovigilance database with significant disproportional reporting, sorted by decreasing IC_{025}.

Drug	$N_{observed}$	N_{fatal} (%)	IC_{025} / IC	ROR [95%CI]	Delay (in days) between the introduction of the drug and AAV, median [Q1-Q3] (n available)
Hydralazine	208	19 (9%)	8.2 / 8.4	2683.5 [2269.3-3173.3]	1277 (n=1)
Propylthiouracil	108	4 (4%)	7.2 / 7.5	1201.5 [974.8-1480.9]	1003 [425-1959] (n=19)
Thiamazole	40	5 (13%)	5.2 / 5.6	138.7 [100.7-191.1]	411 [58-966] (n=6)

Montelukast	4	4 (100%)	0.2 / 1.9	5.8 [2.2-15.5]	(n=0)
Rosuvastatin	6	0	0.1 / 1.5	3.4 [1.5-7.5]	(n=0)

IC: information component; ROR: reporting odds ratio; CI: confidence interval; AAV: ANCA-associated vasculitis

Conclusion: This study strengthens the previously suspected association but also identifies 3 new drugs that may cause DA-AAV. Particular attention should be given to these drugs by prescribers and in experimental studies.

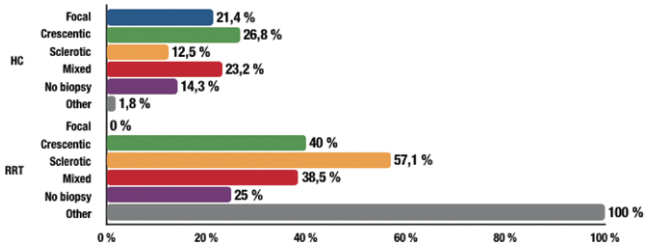
POS0119 RENAL INVOLVEMENT AND NEED OF RENAL REPLACEMENT THERAPY IN ANCA ASSOCIATED VASCULITIS IN A SPANISH SINGLE-CENTER STUDY

J. Álvarez Troncoso[1], J. C. Santacruz Mancheno[2], A. Díez Vidal[1], S. Afonso Ramos[3], A. Noblejas Mozo[1], T. Olea Tejero[3], J. J. Rios[1], B. Rivas[3], Á. Robles Marhuenda[1], M. C. Vega Cabrera[3], E. Martínez Robles[1], C. Soto Abánades[1], F. Arnalich Fernández[1]. [1]*Hospital Universitario La Paz, Internal Medicine, Madrid, Spain*; [2]*Clínica de los Riñones Menydial, Nephrology, Quito, Ecuador*; [3]*Hospital Universitario La Paz, Nephrology, Madrid, Spain*

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) include granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EPGA). Renal involvement is frequent in AAV and is an important factor for morbidity and mortality.
Objectives: The main objective of this study was to analyze the demographic, clinical, histological and therapeutic characteristics of renal involvement in patients with AAV and the risk of renal replacement therapy (RRT) or death.
Methods: Retrospective observational study of 56 patients with AAV fulfilling classificatory criteria and renal involvement diagnosed between 1995 and 2020 from a Spanish tertiary centre. We studied the histological involvement (according to the 2010 classification in focal, crescentic, mixed or sclerotic), immunofluorescence (IF) and the treatment received with the risk of RRT or death.
Results: We included 56 patients diagnosed with AAV and renal involvement. The mean age was 61.08±4.05 years; 58.9% were women. The mean follow-up

time of these patients was 16.14± 8.80 years. Only 57.1% of patients presented systemic involvement.
Most frequent non-renal AAV manifestations were lung involvement (39.3%), central nervous system (30.4%), otorhinolaryngology (ORL) (14.3%), skin (8.9%) and cardiac involvement (8.9%). Main immunological findings were ANCA-MPO+ (69.6%), ANCA-PR3+ (23.2%), ANCA-negative (5.4%). Low C3 was found in 19.6% patients. Histologic classification (HC) and need of RRT is described in table 1. Main HC in renal AAV was crescentic, mixed, focal and sclerotic respectively. Eight patients had not biopsy performed. IF was positive for C3 deposits in 20 patients (35.7%). Half of the patients presented <50% normal glomeruli.



The treatment of renal involvement in AAV in our cohort was as follows: 83.9% (47) corticosteroids (CS) and cyclophosphamide (of which 40 received intravenous and 7 oral cyclophosphamide; and 12 patients associated plasma exchange (PE) with this treatment), 5.36% CS alone, 2 patients received CS and mycophenolate; 1 CS and rituximab, 1 CS and PE, and 2 patients received no treatment. A total of 13 patients received PE and 18 RRT. The mean time to RRT was 65.44±32.72 months. Relapses were not uncommon, 33.93% of the patients presented ≥1 relapse and 10.71% presented ≥2. Infections were very frequent since they were present in 91.07% of the patients. Other frequent non-immunological complications observed in the follow-up of these patients were thrombosis in 31.14%, cardiovascular events in 28.57% and cancer in 19.64%. Patients with ANCA-PR3+ were younger at diagnosis (p<0.001), were more likely to present cardiac (p=0.045) and ORL involvement (p<0.001). However, neither ANCA-PR3+ nor ANCA-MPO+ were specifically associated with the need of RRT or higher risk of death in our cohort. Use of CS alone for the treatment of renal AAV was associated with higher mortality (p=0.006) but CS and cyclophosphamide with lower mortality (p=0.044). ANCA-negative patients were more likely to receive no treatment. Having <50% normal glomeruli and C3 deposits on IF were associated with an increased need for RRT. Presenting focal disease on HC was protective for the need of RRT. Older age at diagnosis, systemic involvement of AAV and need of RRT was associated with higher mortality.
Conclusion: AAVs are complex vasculitides with frequent renal involvement. Increased C3 deposition, non-focal histological forms, and <50% normal glomeruli were related to the need for RRT. In turn, the need for RRT, a later age at diagnosis, and systemic involvement were associated with higher mortality. Holistic and multidisciplinary early management of AAVs in experience centers can help improve renal prognosis and decrease mortality.

		OR	IC (95%)	p
RRT	Number of glomeruli <50% normal	9.66	2.56-36.39	p < 0,001
	IF: C3 deposits	6	1.69-21.26	p = 0,009
Death	Age>70	6.53	1.84-23.15	p < 0,001
	Systemic disease	1.89	0.95-3.73	p = 0,029

POS0120 INCIDENCE OF MALIGNANCIES IN PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS AND MICROSCOPIC POLYANGIITIS DIAGNOSED BETWEEN 1988 AND 2020

A. Masiak[1], M. Ziętkiewicz[1], A. Dębska-Ślizień[2], Z. Zdrojewski[1]. [1]*Medical University of Gdańsk, Department of Internal Medicine, Connective Tissue Diseases and Geriatrics, Gdańsk, Poland*; [2]*Medical University of Gdańsk, Department of Nephrology, Transplantology and Internal Diseases, Gdańsk, Poland*

Background: Antineutrophil cytoplasmic antibody-associated vasculitis (AAV) is a group of systemic necrotizing small vessel vasculitides. Microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA) are two most common types of AAV affecting mainly middle-aged and elderly people. Previous data indicated an increased occurrence of cancer in AAV patients [1], which has been mainly attributed to exposure to cyclophosphamide [2].
Objectives: The purpose of this paper was to analyze cancer incidence in unselected patients with GPA and MPA treated in one academic center since 1988 with follow-up until 2020.
Methods: With case record review, the baseline characteristics, outcomes and malignancy development in a cohort of 251 patients were assessed. Patients were followed up from time of diagnosis to their death or most recent hospital or outpatient's assessment.
Results: Twenty-eight of 251 patients with AAV (65 % cANCA, 26% pANCA, 9.0 % ANCA-negative) developed a total of 32 malignancies during a mean follow-up of 8.6 years. Patients characteristic is presented in table 1. Mean time since AAV onset to cancer diagnosis was 5.86±6.78 years. Of these malignancies, 2 melanoma, 6 were non-melanoma skin cancers, 4 gastrointestinal tract cancer (2 colon, 1 stomach, 1 liver), 3 bladder cancer, 2 breast cancer, 2 uterine cancer, 1 ovarian cancer, 2 prostate cancer, 1 testis cancer, 2 lung cancer, 6 haematological malignancies (1 lymphoma, 1 chronic myeloid leukemia, 4 monoclonal gammopathy of unknown significance), additionally 1 benign salivary gland tumor was found. Four of the 16 patients with renal transplants developed a total of 6 malignancies. There were no differences in the incidence of cancer by gender, age, severity and activity of the disease, ANCA status, smoking status, number of relapses and treatment. There was no association between cancer and cumulative dose of cyclophosphamide.
Conclusion: In the AAV group, 11% of patients developed different type of cancer. The most common was non-melanoma skin cancer. The risk of developing malignancy increased with follow-up time. We found no association of tumor development and cumulative cyclophosphamide dose.

POS0121

RESPONSE OF EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS TO MEPOLIZUMAB ACCORDING TO DISEASE MANIFESTATIONS. A SINGLE CENTRE EXPERIENCE

R. Ríos-Garcés[1], S. Prieto-González[1], J. Hernández-Rodríguez[1], M. C. Cid[1], G. Espígol-Frigolé[1]. [1]*Hospital Clínic de Barcelona, Systemic Autoimmune Diseases, Barcelona, Spain*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is a relapsing disease with frequent glucocorticoid (GC) dependence. Mepolizumab (MEPO) has been demonstrated to reduce flares and spare GC. However, EGPA is a heterogeneous disease and the effects of MEPO on specific disease manifestations has not been completely delimitated.

Objectives: To analyze the impact of MEPO on manifestations derived from small-vessel vasculitis, ENT symptoms, asthma, eosinophilic tissue infiltration and ANCA status in a single-centre cohort of EGPA patients.

Methods: Medical chart of EGPA patients treated with MEPO were reviewed to describe demographics, clinical characteristics, steroid dose at the initiation of MEPO and during follow-up, flares, disease activity, damage accrual and laboratory results.

Results: Among 52 EGPA patients regularly controlled in our department, 11 patients were treated with MEPO. MEPO was prescribed when a) patients required prednisone (PDN) at ≥ 7.5 mg/d to maintain stability, or b) when maintained with < 7.5mg/d, presented at least 4 exacerbations/year requiring an increase in PDN dose. 6 were males and 5 females, with a mean age of 54 years at MEPO initiation. Baseline characteristics of the patients and course under treatment are presented in Table 1. ENT involvement, followed by asthma and eosinophil-related tissue-infiltration (ETI) were the most common symptoms when prescribing MEPO. Regarding treatment, patients received MEPO at 100-300mg SC monthly. The definition of flare was the same used in the MIRRA trial[1]. The mean time of treatment with MEPO was 34 months. All patients achieved a BVAS score of 0 points at 12 months or earlier. In general, patients reduced the number of flares, which tended to be milder, and all related to asthma or ENT manifestations. All improved their asthma control, but 3 of them persisted with recurrent ENT symptoms in spite of treatment with MEPO. None of them had vasculitic manifestations (cutaneous, neurological, gastrointestinal, renal) manifestations during treatment. All patients were able to tapper their PDN dose to ≤5 mg/day or less, except 3 patients. Of the 3 patients who required ≥5mg/d, 1 had severe asthma, but diminished the previous PDN dose (22.5 mg/d pre-MEPO, 10 mg/d currently) and the yearly rate of flares (8.2 pre-MEPO, 0.64 under-MEPO). The other one notably improved his asthma, but had ENT symptoms that responded unsatisfactorily to MEPO and required a maintenance PDN dose of 7.5 mg/d. The last one, improved her asthma control and was able to begin PDN tapering, but persisted with ENT symptoms. Regarding damage accrual, 6 patients remained stable during treatment, and 5 worsened. Two of three ANCA positive patients remained positive in spite of treatment.

Table 1.

	Baseline characteristics at diagnosis	At mepolizumab initiation	After mepolizumab (last follow-up)
Age, median (range) years	49 (23-67)	54 (35-69)	-
Male/Female, n (%)	6/5 (54.5%/45.5%)	-	-
BVAS, median (range)	11 (2-20)	2 (0-6)	0
FFS, value (n, %)	1 (1, 9.1%)	-	-
VDI, mean (range)	-	1.7 (0-5)	2.3 (0-5)
Asthma, n (%)	11 (100%)	3 (27.3%)	0 (0%)
ENT, n (%)	10 (90%)	4 (36.4%)	3 (27.3%)
SVV, n (%)	4 (36.4%)	0 (0%)	0 (0%)
ETI signs/symptoms, n (%)	7 (63.6%)	2 (18.2%)	0 (0%)
Constitutional symptoms, n (%)	4 (36.4%)	0 (0%)	0 (0%)
Eosinophils, mean (range) cells x10^9	5500 (600-8850)	240 (0-600)	55 (0-200)
ANCA positivity (IIF)	7 (77.8%)	3	2
Anti-MPO titers, mean (range)	286 (93-740)	88 (3-739)	7 (3-37)
Yearly rate of flares	-	1,75	0.51
Immunosuppressants, n	-	3	1
Prednisone dose, mg/d (range)	8 (7.5-25)	11.4 (5-22.5)	5.125 (0-10)

Conclusion: MEPO was effective for the treatment of patients with EGPA, with a reduction in the number and severity of flares and a decrease in PDN doses. A worse response of ENT involvement was observed. No vasculitic flares were observed in spite of GC reduction. Mepolizumab did not prevent damage accrual during the treatment period.

Central pain and other extra-articular associations to KOA

POS0122

THE ASSOCIATIONS BETWEEN DISEASE MODIFYING ANTI-RHEUMATIC DRUGS AND INCIDENT, AND PROGRESSION OF, RADIOGRAPHIC HAND OSTEOARTHRITIS IN RHEUMATOID ARTHRITIS PATIENTS

T. Burkard[1], C. Lechtenboehmer[2], S. Reichenbach[3], M. Hebeisen[4], U. Walker[5], A. M. Burden[1,6], T. Hügle[7]. [1]*ETH Zurich, Department of Chemistry and Applied Biosciences, Zurich, Switzerland*; [2]*University Hospital of Basel, Department of Radiology, Basel, Switzerland*; [3]*University of Bern, Institute for Social and Preventive Medicine, Bern, Switzerland*; [4]*SCQM Foundation, SCQM Foundation, Zurich, Switzerland*; [5]*University Hospital of Basel, Department of Rheumatology, Basel, Switzerland*; [6]*Maastricht University Medical Center+, Department of Clinical Pharmacy and Toxicology, Maastricht, Switzerland*; [7]*Lausanne University Hospital (CHUV) and University Lausanne, Department of Rheumatology, Lausanne, Switzerland*

Background: Hand osteoarthritis (OA) is characterized by bone erosions, joint space remodeling, and new bone formation mainly in distal interphalangeal (DIP) joints and thereby differs from hand manifestations in rheumatoid arthritis (RA). There are conflicting data about the benefit of treatment with conventional synthetic (cs) and biologic (b) disease modifying anti-rheumatic treatment (DMARD) on DIP OA.

Objectives: To assess the associations between DMARDs and incident, and progression of, radiographic DIP OA in RA patients.

Methods: We performed two observational cohort studies in the longitudinal Swiss Clinical Quality Management in Rheumatic Diseases registry (SCQM) between 1997 and 2014. RA patients who had ≥2 eligible hand radiographs were included at their first eligible radiograph (baseline) and were followed until the outcome or their last eligible radiograph. Radiographs were eligible if all 8 DIP joints could be scored. Modified Kellgren-Lawrence scores (KLS) were obtained by evaluating DIP joints for severity of osteophytes, joint space narrowing, subchondral sclerosis, and erosions. Incident/existing DIP OA was defined as KLS ≥2 in ≥1 DIP joint. Progression of existing DIP OA was defined as an increase of ≥1 in KLS in ≥1 DIP joint. We divided the study population into two cohorts based on whether DIP OA was present or absent at cohort entry (cohorts 1 and 2, respectively). Exposure status was defined time-dependently into mutually exclusive exposure groups: csDMARD monotherapy, bDMARD monotherapy, bDMARD/csDMARD combination therapy, past bDMARD/csDMARD therapy, or never DMARD use. Cox time-varying proportional hazard regression analyses were used to estimate hazard ratios (HRs) with 95% confidence intervals (CI) of DIP OA progression (cohort 1) or DIP OA incidence (cohort 2) associated with DMARD exposure categories (csDMARD monotherapy was the reference group because it was the largest group). Exposure and covariate information were extracted at every radiograph and other visit date. Missing covariate information was imputed using multiple imputation by chained equations. In sensitivity analyses, we repeated all analyses using generalised estimation equations (GEE).

Results: Among 2234 RA patients with 5928 eligible radiographs, 1340 patients had radiographic DIP OA at cohort entry (cohort 1) and 894 were DIP OA naïve (cohort 2). In cohort 1, radiographic progression of existing DIP OA was characterized by new osteophyte formation (666, 52.4%), followed by joint space narrowing (379, 27.5%), subchondral sclerosis (238, 17.8%), and erosion (62, 4.3%). bDMARD monotherapy was associated with an increased risk of radiographic DIP OA progression compared to csDMARD monotherapy (adjusted HR 1.34, 95% CI 1.07–1.69). The risk of DIP OA progression was not significant in csDMARD/bDMARD combination therapy users (adjusted HR 1.12, 95% CI 0.96–1.31), absent in past DMARD users (adjusted HR 0.96, 95% CI 0.66–1.41), and significantly lower among never DMARD users (adjusted HR 0.54, 95% CI 0.33–0.90), compared to csDMARD monotherapy users. In cohort 2, the risk of incident OA did not differ materially between treatment groups. Results from GEE analyses corroborated all findings.

Conclusion: Our results from this real-world RA cohort suggest that monotherapy with bDMARDs is not associated with incident DIP OA but may increase the risk of radiographic progression of existing DIP OA when compared to csDMARDs.

Background: Pain is a common, difficult to manage symptom in hand osteoarthritis (OA). Multiple pain mechanisms may play a role in hand OA.

Objectives: To investigate presence of neuropathic pain symptoms in patients with inflammatory hand OA, characteristics of those patients, their impact on health related quality of life (HR-QoL), and the influence of anti-inflammatory treatment on neuropathic pain symptoms.

Methods: Data from a randomised, double-blind, placebo-controlled trial of prednisolone including 92 patients with hand OA fulfilling ACR criteria were used. At baseline patients had signs of synovial inflammation, a VAS finger pain of ≥30 mm and who flared ≥20 mm upon NSAID washout. The primary endpoint was VAS finger pain (0-100) at week 6.

Neuropathic pain symptoms were measured at baseline and week 6 using the validated painDETECT questionnaire, consisting of questions on pain quality, pain intensity over time and radiating pain. Scores range -1 to 38 and patients are classified as having unlikely (<13), indeterminate (13-18) and likely (>18) neuropathic pain. HR-QoL was measured with physical component scale (PCS) of Short-Form 36 (SF36; 0-100), comorbidities with the Self-administered Comorbidities Questionnaire (SCQ; 0-45), radiographic severity with Kellgren-Lawrence (KL) sum score (0-120), and treatment response with OMERACT-OARSI responder criteria.

Association of patient characteristics with neuropathic pain symptoms was analysed with univariate and multivariate ordinal logistic regression, with painDETECT as dependent variable. Association of neuropathic pain symptoms with HR-QoL was analysed with multivariate linear regression, adjusted for age, sex, BMI, VAS finger pain, SCQ score and KL sum score, with PCS as dependent variable. Response of neuropathic pain symptoms and VAS pain to prednisolone was analysed with generalised estimating equations. Association of neuropathic pain symptoms at baseline with response to treatment was analysed using χ^2-tests and GEE.

Results: 91 patients had complete painDETECT data at baseline (mean painDETECT score 12.8 [SD 5.9]). Scores were <13 in 53%, 13-18 in 31% and >18 in 16%. Higher painDETECT score categories were associated with less radiographic damage, more comorbidities, female sex and higher VAS finger pain in multivariate analysis. (table 1)

Patients with painDETECT scores >18 had a lower HR-QoL (PCS -6.5 [95%CI -10.4 to -2.6]) than those with painDETECT scores <13.

PainDETECT scores remained unchanged throughout the trial in both prednisolone-treated and placebo-treated patients, and there was no between-group difference at week 6. VAS pain improved more in the prednisolone group than in the placebo group (mean between-group difference -16.5 [95%CI -26.1 to -6.9]) (figure 1). No association between the presence of neuropathic pain symptoms at baseline and OMERACT-OARSI response to treatment was found.

Conclusion: Patients with inflammatory hand OA and additional neuropathic pain symptoms are more often female and have more comorbidities, and report a lower QoL, than those without. Neuropathic pain symptoms seem unresponsive to anti-inflammatory therapy. Clinicians should be aware of neuropathic pain symptoms in their patients as they might benefit from additional, specific treatment.

Table 1. Ordinal logistic regression with painDETECT categories as dependent variable

Variables	Mean (SD) N=91 (100%)	Odds ratio (95% CI)
Age	64 (9)	0.96 (0.90 to 1.02)

POS0124 QUALITY OF LIFE FOR PATIENTS WITH KNEE OSTEOARTHRITIS WITH OR WITHOUT PAIN SENSITIZATION

W. R. Goh[1], W. J. Ong[2], D. Chan[3], Y. Y. Leung[1]. *[1]Singapore General Hospital, Rheumatology & Immunology, Singapore, Singapore*; *[2]Duke-NUS Medical School, Singapore, Singapore*; *[3]Singapore General Hospital, Pain Medicine, Singapore, Singapore*

Background: Patients with central sensitization (CS) may have poorer quality of life (QOL).

Objectives: We aim to evaluate whether different ways of classifying CS have an impact on a patient's QOL among patients with knee osteoarthritis (KOA).
Methods: We use the baseline pre-operative data from a cohort of consecutive KOA patients enlisted for knee replacement surgery (1). We collected demographics, number and position of painful sites of body. Quality of life was assessed by the Medical Outcome Survey Short-Form 36 (SF-36). Pain pressure threshold was measured at volar side of right forearm. We classify CS using three sets of criteria: 1). widespread pain (pain involving both upper/ lower trunk, and both side of body), 2). lowest 10th percentile of pressure pain threshold (PPT) measured at the forearm and 3) the painDETECT questionnaire >=13/38.
Results: Of 233 patients (79.8% women) with complete data set for analysis, mean (standard deviation, SD) age was 66.0 (8.3) years. 15.5%, 25.8%, and 4.7% of patients were classified as having CS by widespread pain, low PPT and painDETECT criteria. KOA patients with CS have poorer QoL compared with those without. Low PPT identified patients with poorer general health, while widespread pain and PainDETECT criteria identified patients with poorer QoL in more domains including vitality mental health (Table 1).
Conclusion: KOA patients who have CS have poorer QoL compared to those without. Different criteria defined patients with different pattern of QoL impacts. In general, KOA patients who have CS have poorer QoL compared to those without. This highlight the importance of additional impact of CS to QoL

POS0125

CALCULATING RISK OF HAND OSTEOARTHRITIS PROGRESSION AT TEN YEARS THROUGH A PREDICTION MODEL

K. Shah[1], G. Bullock[1,2], A. Silman[1], D. Furniss[1], N. Arden[1,2], G. Collins[3,4].
[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, Oxford, United Kingdom; [2]University of Oxford, Centre for Sport, Exercise and Osteoarthritis Research, Versus Arthritis, Oxford, United Kingdom; [3]University of Oxford, Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, Oxford, United Kingdom; [4]Oxford University Hospitals NHS Foundation Trust, NIHR Oxford Biomedical Research Centre, Oxford, United Kingdom

Background: Hand osteoarthritis (OA) is a chronic, progressive disease, commonly affecting middle aged women. OA at the interphalangeal joints (IPJs) or the thumb base are considered different disease subsets (1). Few studies have investigated individual risk factors for IPJ OA progression (2). Prediction models can be used to calculate overall disease risk from multiple risk factors. This can guide prevention and treatment options.
Objectives: Develop and internally validate a prediction model for IPJ OA progression.
Methods: Data from the Chingford 1000 Women Study (Chingford Study), the largest population-based cohort worldwide assessing hand OA, was used. It is representative of the middle-aged female population in the United Kingdom (3). At baseline, 1,003 women aged 45 to 64 years' old were recruited, and 693 measurements taken. Hand radiographs were taken at baseline and after ten years, read using the Kellgren-Lawrence (KL) atlas (inter-observer correlation: ≥0.7 (4)). For the current study, participants must have had OA (KL ≥2 in ≥1 IPJ) on baseline hand radiographs. Participants with KL 4 in all 16 IPJs at baseline were excluded. Risk factors from the Chingford Study at baseline were selected by biological plausibility, literature evidence (2), and hand surgeons' consensus (5): age (years), occupation (manual versus non manual), OA in ≥1 thumb base (KL ≥2 versus KL<2), body mass index (BMI) (kg/m^2), family history of hand OA (yes versus no). The outcome was defined on an ordinal scale for the number of IPJs (up to >5 IPJs) with OA progression (increase by KL ≥1), at ten years'.
The prediction model was developed using a penalized proportional odds logistic regression. Odds ratios (95% confidence intervals) were reported for each risk factor. The model was internally validated using 2,000 bootstrap iterations. Model performance was assessed for discrimination (C-statistic), and calibration (C-slope). 3.5% of data was missing, and complete case analysis was used.
Results: 699 women had baseline hand radiographs: 38 were unreadable, 459 had no IPJ OA. Seven participants had missing data (occupation: 5, BMI: 1, family history: 1) and were excluded. 195 participants were included this study. Median age at baseline was 59 (interquartile range: 8) years.
181 (92.8%) participants had OA progression at 10 years (Figure 1). Thumb base OA (odds ratio: 1.32 (0.93 to 1.88)) was most strongly associated with IPJ OA progression (Table 1). C-statistic was 0.57, and calibration slope was 1.38 for the optimism-corrected model.
Conclusion: More stringent cut-offs for OA progression would be clinically useful. It was only weakly possible to predict which participants with IPJ OA would progress. This suggests that other risk factors, such as gender, ethnicity and genetics, may be predominant.

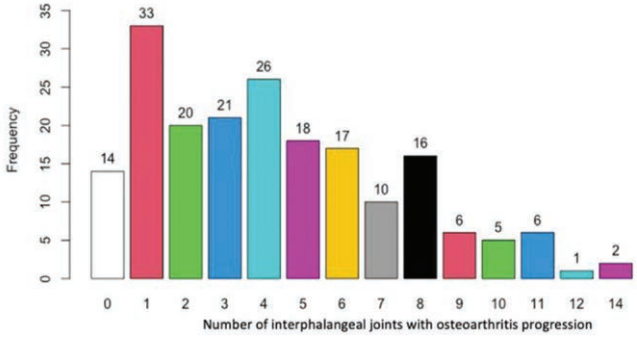

Figure 1. Hand interphalangeal joints with osteoarthritis progression (Kellgren-Lawrence grade ≥1) at 10 years' follow up

Table 1. Odds ratios for risk factors

Risk factor	Odds ratio (95% confidence interval)
Age (years)	1.02 (0.99 to 1.06)
Occupation (manual versus non manual)	0.88 (0.60 to 1.29)
Thumb base OA (Kellgren-Lawrence grade ≥2 versus <2)	1.32 (0.93 to 1.88)
Family history of hand OA (yes versus no)	1.03 (0.72 to 1.45)
Body mass index (kg/m^2)	1.04 (0.99 to 1.09)

OA: Osteoarthritis

POS0126 EARLY STAGE HAND OSTEOARTHRITIS IN PATIENTS WITH THE EHLERS-DANLOS SYNDROME: AN EXPLORATIVE STUDY

L. Rombaut[1], K. De Baere[2], E. Debacker[2], L. Decavele[2], F. Malfait[1,3], R. Wittoek[4,5]. *[1]Ghent University Hospital, Center for Medical Genetics, Gent, Belgium*; *[2]Ghent University, Rehabilitation Sciences, Ghent, Belgium*; *[3]Ghent University, Department of Biomolecular Medicine, Ghent, Belgium*; *[4]Ghent University, Internal Medicine and Pediatrics, Ghent, Belgium*; *[5]Ghent University Hospital, Department of Rheumatology, Gent, Belgium*

Background: The Ehlers-Danlos Syndromes (EDS) are a group of rare heritable connective tissue disorders caused by various defects in the biosynthesis or secretion of fibrillar collagens. The three main clinical features of EDS are joint hypermobility, skin fragility and general soft tissue fragility. 13 clinical subtypes of EDS are recognized, of which the hypermobile type (hEDS) and classical type (cEDS) are the most prevalent. It has been hypothesized that the (micro-)trauma in the joint due to typical subluxations and dislocations, make EDS patients prone to developing osteoarthritis (OA) in early stage. Conversely, it has been mentioned that joint hypermobility provides a larger joint surface area and prevents OA. Abnormal biomechanical loading has been identified as a risk factor for the development of OA in the wrist and hand. However, no studies have yet been performed in EDS patients.
Objectives: The primary aim was to investigate the presence of any degenerative features for hand OA, and if this differs between cEDS and hEDS patients. The second aim was to evaluate hand function and pain related to OA signs in EDS patients.
Methods: cEDS and hEDS patients between 35 and 50 years old were invited to participate. cEDS diagnosis was genetically confirmed and hEDS diagnosis was performed according the clinical 2017 hEDS criteria. Exclusion criteria were a body mass index ≥35, not being able to stand straight up for five minutes, suffering from an auto-immune disease or rheumatological condition, or pregnancy. Conventional X-rays of both hands were performed and scored independently by three assessors according to Kallman[1]. Presence of osteophytes (0-3), joint space narrowing (0-3), malalignment (>15°)(0/1), erosions (0/1), subchondral sclerosis (0/1), and subchondral cysts (0/1) were scored in all interphalangeal (distal and proximal), metacarpophalangeal and thumb base joints of both hands[1]. We defined early hand OA as minimally three features (≥1) were present. Several clinical assessments were made, e.g. tenderness, bony swelling and soft tissue swelling. The Michigan Hand Outcomes Questionnaire (MHOQ) and Australian/Canadian Osteoarthritis Hand Index (AUSCAN) questionnaires were completed.
Results: In total, 31 patients (mean age 41 ± 5.6 years, 13 men and 18 women) diagnosed with EDS participated, of whom 19 with cEDS and with 12 hEDS. In total, 927 joints were assessed. Level of agreement of radiographic assessments was very high (>98%). Early hand OA was found in more than 40% of the EDS patients, with a significant higher frequency in cEDS patients compared to hEDS patients (58% vs. 17%) (p=0.032). Joint space narrowing was most frequently present and significantly more in the cEDS patients compared to hEDS patients (79% vs. 21%) (p=0.003). However, radiographic changes were found in only 10% of all finger joints. Of all fingers, thumb joints were most affected. Regarding the clinical features of hand OA, all patients showed deformity in one or more finger joints, most frequently at the thumb, especially the IP joint (both hyperflexion and hyperextension). Tenderness and bony swelling was present in 36% and 45% of all patients, respectively, whereas soft tissue swelling was less frequently observed (10% of all patients). Here, no significant differences were found between cEDS and hEDS patients. Moderate disability was present (mean (SD) AUSCAN= 45.47 (27.10) and MHQ = 65.97 (14.21). cEDS showed significant less hand pain (p=0.03), a better hand function (p=0.03) and less disability (p=0.026) than hEDS.
Conclusion: This explorative study demonstrates that a high number of EDS patients present with minimal degenerative features of hand OA, but in a minority of joints. Patients with cEDS were significantly more affected, but showed a better function compared to hEDS. Possibly, cEDS patients are more susceptible to develop hand OA.

POS0127 ASSOCIATION BETWEEN HYPERURICEMIA AND OSTEOARTHRITIS

E. Taskina[1], E. Strebkova[1], L. Alekseeva[1,2], N. Kashevarova[1], K. Telyshev[1], E. Sharapova[1], S. Anikin[1], F. Bibulatova[1], A. Lila[2,3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Osteoarthritis, Moscow, Russian Federation*; *[2]Russian Medical Academy of Continuous Professional Education, Rheumatology, Moscow, Russian Federation*; *[3]V.A. Nasonova Research Institute of Rheumatology, Director, Moscow, Russian Federation*

Background:
Objectives: To evaluate the relationship of hyperuricemia (GU) with the course of knee osteoarthritis (OA) and the components of metabolic syndrome (MS).
Methods: The prospective study included 107 women aged 40-75 y.o, with a reliable diagnosis of I-III Kellgren J. - Lawrence J. stage of knee OA (ACR), who signed an informed consent. The average age of patients was 59.1 ± 8.9 y.o. (from 38 to 74), the duration of the disease was 9 (4-12) years. The average values of the body mass index (BMI) corresponded to obesity (30.6 ± 5.7 kg / m2), waist circumference (WC) - 93.9 ± 12.1 cm. An individual card was filled out for each patient, including anthropometric parameters, anamnesis and clinical examination data, an assessment of knee joint pain according to VAS, and concomitant diseases. All patients underwent standard X-ray of the knee joints, DEXA scan of the lumbar spine and total hip, and laboratory examination.
Results: Hyperuricemia was diagnosed in 26.2% of patients. Patients with GU had a higher BMI and WC (p<0.05). X-ray examination revealed significantly larger sizes of osteophytes (p = 0.02) and smaller sizes of the medial space of the knee joint (p = 0.02), while the patients of both groups were comparable in age and duration of OA (Table 1). Patients with GU had a statistically significantly higher bone mineral density (BMD) values were observed in L1-L4 and total hip (p<0.05). MS was almost 2 times more often diagnosed in patients with GU (83.3% vs. 49.2%, RR=1.71, 95%CI 1.21-2.36, p=0.01). Higher levels of CRP, COMP, leptin, triglycerides (TG), creatinine, ALT and AST were determined in patients with GU (Table 1). Spearman rank ordered correlation coefficients between GU and BMI (r=0.22, p=0.03), WC (r=0.26, p=0.02), MS (r=0.29, p=0.01), and CHD (r=0.21, p=0.04). There were a correlation between GU and the stage of knee OA (X-ray) (r=0.34, p=0.02), the size of medial osteophytes in the femur (mm) (r=0.37, p=0.01) and the medial space of the knee joint (mm) (r=-0.27, p=0.01), BMD L1-L4 (r=0.37, p=0.03) and the total hip (r=0.37, p=0.04). There were also significant positive associations with the following laboratory parameters: CRP (r=0.27, p=0.007), COMP (r=0.25, p=0.05), leptin (r=0.29, p=0.03), creatinine (r=0.45, p<0.0001), TG (r=0.44, p=0.0001), ALT (r=0.32, p=0.002), AST (r=0.25, p=0.02).

Table 1. Comparative characteristics of OA patients with and without GU

Parameter	OA Patients with GU (n = 28)	OA Patients without GU (n = 79)	p
Age, y.o.	61 (53-68)	60 (54-66)	0.33
Duration OA, years	10 (6-14)	7.5 (3-12)	0.06
WC, cm	99.3 ± 12.8	92.2 ± 11.4	0.02
BMI, kg/m^2	33.5 ± 5.6	30 ± 5.6	0.04
The size of the medial space of joint according to X-ray, mm	2.3 (1.2-3.3)	3.2 (2.0-4.3)	0.02
The size of the osteophytes of the femur, mm	5.8 (3.7-6.3)	2.9 (1.7-4.5)	0.02
BMI L1-L4, g/cm^2	1.18 (1.12-1.24)	1.0 (0.86-1.15)	0.04
BMI total hip, g/cm^2	1.05 (1.0-1.13)	0.9 (0.82-0.98)	0.04
CRP, mg/l	2.8 (1.9-6.2)	1.9 (1.2-3.6)	0.007
COMP, ng/ml	31.9 (27.6-45)	24.2 (18.9-38.7)	0.05
Leptin, ng/ml	46.2 (36.5-72)	30.5 (19.5-45.6)	0.03
TG, mmol/l	1.97 (1.61-2.41)	1.26 (0.87-1.63)	0.002
Creatinine, mmol/l	79 (74.9-86)	68 (62-74)	0.0001
ALT, mmol/l	26.5 (17.2-32.9)	17.9 (13.2-21.7)	0.003
AST, mmol/l	22.5 (18.5-27.8)	18.9 (16.8-21.9)	0.02

Conclusion: GU may be an aggravating predictor of not only MS-associated diseases such as obesity, dyslipidemia, but also OA. Thus, at high levels of uric acid, more advanced radiological stages of OA, high values of the BMD of the axial skeleton and increased values of CRP, COMP are noted. In this connection, therapeutic interventions of OA in patients with GU should also be aimed at reducing the concentration of uric acid, which may provide a slowdown in the progression of the disease. Further study of this issue is needed.

POS0128 PHYSICIAN AND PATIENT PERCEPTIONS OF SURGICAL PROCEDURES FOR KNEE OA ACROSS JAPAN, THE US AND 5 EU COUNTRIES: RESULTS OF A REAL-WORLD STUDY

N. Fukui[1], P. G. Conaghan[2], K. Togo[3], N. Ebata[3], L. Abraham[4], J. Jackson[5], J. Jackson[5], M. Berry[5], H. Pandit[2]. *[1]The University of Tokyo Komaba Campus,*

Graduate School of Arts and Sciences, Meguro City, Japan; [2]*University of Leeds, Musculoskeletal Medicine, Leeds, United Kingdom*; [3]*Pfizer, Inc., HEOR, Shibuya City, Japan*; [4]*Pfizer Ltd, HEOR, Surrey, United Kingdom*; [5]*Adelphi Real World, Real World Research, Bollington, United Kingdom*

Background: Patients with knee osteoarthritis (OA) who do not achieve adequate pain relief and functional improvement with a combination of non-pharmacologic and pharmacologic therapies are recommended an arthroplasty as an effective option to relieve severe pain and functional limitations. However, some patients are reluctant to undergo surgical interventions, and clinicians may choose to avoid or delay surgery due to safety risks and/or the financial cost. It is of interest to understand if the use and perception of surgery differs between countries, however, few published data exist.
Objectives: To demonstrate how surgery and the use of surgical procedures differs across Japan, United States of America (US) and 5 major European countries (EU5) and to evaluate patient perception towards surgery.
Methods: Data were drawn from the Adelphi OA Disease Specific Programme (2017-18), a point-in-time survey of primary care physicians (PCP), rheumatologists (rheums), orthopaedic surgeons (orthos) and their OA patients. Patients with physician-diagnosed knee OA were included and segmented into two categories: had previous surgery (PS) and never had surgery (NS). A Fisher's exact test was performed on the two groups. Physicians reported on patient demographics; whether patients had undergone surgery; type of surgery; success of surgery; how success was defined; and reasons for wanting to delay surgery. Patients reported their willingness to undergo surgery; reasons for not wanting surgery; how successful their surgery was; and how they defined this success.
Results: Physician/patient reported data were available for 302,230 (Japan), 527,283 (US) and 1487,726 (EU5) patients with diagnosed knee OA. Patients were categorised by their physicians as mild (40% Japan; 34% US; 24% EU5), moderate (49% Japan; 49% US; 56% EU5) or severe (9% Japan; 17% US; 19% EU5). Patients in Japan were more likely to be female (78% vs 54% US; 58% EU5), older (73 vs 65 US; 66 EU5) and have a lower BMI than patients in the US and EU5. Obesity and diabetes were much less prevalent among patients in Japan. One in ten patients in Japan had undergone a surgery (10%), far fewer than in the US (22%) or EU5 (17%). When surgery was performed, this was more likely to be a total joint replacement (TJR) in Japan, whereas in the EU and US, arthroscopic washout was more commonly performed.
For over half of Japanese patients (56%), successful surgery was more likely to be defined as having no more pain (vs. 35% US; 14% EU5). Improved mobility and a reduction in pain were also commonly reported reasons. Physicians (in each region) were more likely to suggest pain reduction, rather than no pain, and improved mobility as markers of success. Patients in Japan were much more likely to say they would not agree to surgery if recommended by their doctor, or were unsure (84% vs. 68% US; 62% EU5). The main reason for patient reluctance in Japan was fear of surgery, whereas in the US and EU5 the main reason given was that surgery was not needed. This finding was also evident among physicians in Japan, who frequently reported that patient reluctance was a key reason for delaying surgery. Physicians in Japan, do however, report that patient request was one of their main triggers for recommending surgery (45% vs 20% US; 16% EU5).
Conclusion: Although surgery can be an effective option for those with OA who have exhausted other treatment options, some patients are reluctant to undergo surgery out of fear, especially in Japan, possibly due to the higher patient age. Physicians aiming to delay surgery were driven by patient reluctance in Japan, whereas cost to patient was a bigger factor in the US and EU5. The higher level of TJR vs. other surgery options among patients in Japan may suggest physicians are looking for higher levels of efficacy.

POS0129 ASSOCIATION BETWEEN OSTEOARTHRITIS-RELATED SERUM BIOCHEMICAL MARKERS OVER 11 YEARS AND KNEE MRI-BASED IMAGING BIOMARKERS IN MIDDLE-AGED ADULTS

B. Antony[1], A. Singh[1], L. Blizzard[1], A. Venn[1], G. Jones[1], J. Burgess[1], V. Parameswaran[2], F. Cicuttini[3], L. March[4], C. Ding[1]. [1]*University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*; [2]*Royal Hobart Hospital, Department of Endocrinology, Hobart, Australia*; [3]*Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia*; [4]*University of Sydney, Institute of Bone and Joint Research, Kolling Institute of Medical Research, Sydney, Australia*

Background: Serum levels of osteoarthritis (OA)-related cartilage and joint-specific biochemical markers – cartilage oligomeric matrix protein (COMP), matrix metalloproteinase (MMP)-3, and hyaluronan (HA) –are shown to be associated with cartilage degradation, joint tissue degradation, and synovitis in patients with OA. Although these OA-related biochemical markers may initially precede the MRI biomarkers of joint structural changes, such changes detected in MRI can lead to biochemical marker changes later as the condition progresses. However, there is a lack of data on OA-related biochemical markers' association with MRI-based biomarkers in the middle-aged general population.
Objectives: We aimed to describe the associations between OA-related biochemical markers and MRI-based imaging biomarkers in middle-aged adults followed up over 10-13 years.
Methods: Blood samples were collected during the Childhood Determinants of Adult Health (CDAH)-1 study at baseline (year: 2004-06, age: 26–36 years) and 10-13 year follow-up (CDAH-3; year: 2014–2019, age: 36–49 years). Serum samples from baseline (n=156) and follow-up (n= 167) were analyzed for three OA-related biomarkers – namely COMP, MMP-3, and HA– using non isotopic ELISA assay methodology. Knee MRI scans were obtained during the CDAH-knee study (year: 2008-10, age: 30-40 years, n=313), and MRIs were assessed for cartilage volume, cartilage thickness, subchondral bone area, cartilage defects, and bone marrow lesions (BML). Univariable and multivariable (adjusted for age, sex, and body mass index (BMI)) linear regression and logistic regression were used to describe the association of biochemical marker at CDAH-1 and MRI-based imaging biomarkers at CDAH-knee, and Tobit regression was used to describe the association of MRI-based imaging biomarkers at CDAH-knee and biochemical markers at CDAH-3.
Results: In the multivariable model for the association of biochemical marker with MRI-based imaging biomarkers (assessed after 4 years), we found a significant negative association of COMP with medial femorotibial compartment cartilage thickness (-0.010 (-0.019, -0.000) p=0.045), and MMP-3 with patellar cartilage thickness (-9.075 (-16.344, -1.807) p=0.015) and total bone area (-0.047 (-0.086, -0.007) p=0.020). No significant association was observed between HA and MRI markers.
In the multivariable model for association of MRI-based imaging biomarkers with biochemical markers (assessed after 6-9 years), a significant negative association of total cartilage volume (-0.0005 (-0.0008, -0.0002) p=0.001) and total cartilage thickness (-0.628 (-1.143, -0.114) p=0.017) with MMP-3, and total bone area with COMP (0.270 (-0.474, -0.006) p=0.010) was observed. No significant association was observed between MRI-based imaging biomarkers and HA.
Conclusion: COMP and MMP-3 levels were negatively associated with knee cartilage thickness assessed 4-years later. Similarly, knee cartilage thickness and volume were negatively associated with COMP and MMP-3 levels assessed 6-9 years later in population-based middle-aged adults, indicating an interdependent negative association of OA-related biochemical markers and MRI-based imaging biomarkers. These results suggest that OA-related biochemical markers may predict future MRI-based imaging biomarkers in middle-aged adults and thus represent possible at-risk populations to target for structure modification interventions.

POS0130 ASSOCIATION BETWEEN HYPERTENSION AND OSTEOARTHRITIS

E. Taskina[1], E. Strebkova[1], L. Alekseeva[1,2], N. Kashevarova[1], K. Telyshev[1], S. Anikin[1], E. Sharapova[1], D. Kudinsky[1], A. Lila[2,3]. [1]*V.A. Nasonova Research Institute of Rheumatology, Osteoarthritis, Moscow, Russian Federation*; [2]*Russian Medical Academy of Continuous Professional Education, Rheumatology, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Director, Moscow, Russian Federation*

Background:
Objectives: To evaluate the relationship between arterial hypertension (AH) and the course of knee osteoarthritis (OA).

Methods: The prospective study included 109 women aged 38-75 y.o., of I-III Kellgren J. - Lawrence J. stage of knee OA (ACR), who signed an informed consent. The average age was 59.3 ± 8.7 y.o. (from 38 to 74), the average duration of the OA was 7 (4-12) years. The average values of the body mass index (BMI) corresponded to obesity (30.9 ± 5.4 kg / m^2), waist circumference (WC) – 94.4 ± 11.7 cm. An individual card was filled in for each patient, including anthropometric parameters, anamnesis and clinical examination data, assessment of knee joint pain according to VAS, WOMAC, KOOS and DN4 indices, and concomitant diseases. All patients underwent standard X-ray of the knee joints, laboratory examination.

Results: AH was diagnosed in 69.7 % patients with OA. Patients were divided into 2 groups, according to the presence or absence of AH (Table 1). Patients with AH were older, had a higher BMI, WC, a longer duration of menopause and significantly earlier its onset (p<0.05). Patients with OA and AH had a more severe course of OA: higher values of pain in VAS, total WOMAC and all its components, DN4, worse indicators of total KOOS (p<0.05). X-ray examination showed a tendency to a more significant narrowing of the medial space of the knee joints (p = 0.07). Laboratory examination showed higher values of CRP, ESR, IL-6, and leptin (p < 0.05).

Table 1. Comparative characteristics of OA patients with and without AH

Parameters	Patients with AH (n=76)	Patients without AH (n=33)	p
Age, y.o.	61 (57-68)	55.5 (49-58)	<0.01
WC, cm	92 (90-105)	86.5 (84-90)	<0.01
Age of menopause, y.o.	50 (47-52)	55.5 (49-58)	0.02
Duration of menopause, years	14 (7.5-19)	7 (4-8)	<0.01
Duration of OA, years	10 (5-15)	4 (1-6)	0.001
VAS pain score, mm	49 (40-57)	42 (24-50)	0.02
WOMAC pain, mm	189.5 (140-250)	140 (108-162)	0.001
WOMAC stiffness, mm	77.5 (42-100)	56 (33.5-71.5)	0.01
WOMAC functional impairment (FI), mm	651 (547-902)	546.5 (320-663.5)	0.002
Total WOMAC, mm	899 (728-1280)	734 (526.5-882)	0.001
KOOS, points	0.47 (0.36-0.57)	0.6 (0.53-0.75)	<0.01
DN4, points	2 (1-3)	1 (0-2)	0.01
Overall health status, mm	45 (35-55)	36.5 (28.5-48.5)	0.02
The size of the medial space of joint according to X-ray, mm	2.45 (1.35-4.35)	3.6 (2.8-4.3)	0.07
CRP, mg/l	2.38 (1.47-4.85)	1.21 (0.69-2.53)	<0.01
Leptin, ng/ml	37.4 (26.5-53.3)	23.6 (15.1-40.2)	0.01
IL-6, pg/ml	0.7 (0.4-1.2)	0.45 (0.3-0.7)	0.03
ESR, mm/h	14 (7-18)	7 (6-12)	0.02

We founded positive (p <0.05) associations between AH and a more severe, prolonged course of OA (r=-0.39, p<0.01) in the the Spearman rank-order correlation coefficient analysis. Thus, patients with AH had higher values of VAS pain (r=0.31, p<0.01), total WOMAC (r=0.31, p<0.01) and all its components (pain (r=0.33, p<0.01), FI (r=0.3, p<0.01) and stiffness (r=0.24, p<0.01), DN4 (r=0.24, p=0.01), worse indicators of total KOOS (r=-0.42, p<0.01) and overall health status (r=0.23, p=0.02), more often detected more advanced stage of OA (r=0.24, p=0.03) and synovitis (r=0.23, p=0.01). In addition, positive relationships were found with CRP (r=0.31, p<0.01), IL - 6 (r=0.3, p=0.03), ESR (r=0.3, p=0.02). Positive relationships were confirmed between AH and age (r=0.39, p<0.01), menopause duration (r=0.39, p<0.01), WC (r=0.37, p<0.01), leptin (r=0.35, p=0.01), the presence of hypertriglyceridemia (r=0.35, p=0.01) and cardiovascular risks according to SCORE (r=0.26, p=0.02), considering traditional risk factors for cardiovascular diseases (CVD).

Conclusion: Thus, we found that AH in patients with knee OA is affected by a variety of variables, both related to traditional CVD factors and to OA itself, and the correlations found are approximately equal in strength. The results obtained require further study, and it is possible that preventive measures aimed at reducing the traditional risk factors of diseases of the circulatory system, or correcting existing CVD, will contribute to a more favorable course of OA.

POS0131 10-YEAR PROBABILITY OF A MAJOR OSTEOPOROTIC FRACTURES IN WOMEN WITH OSTEOARTHRITIS OF THE KNEE JOINT

E. Usova[1], O. Malyshenko[1], M. Letaeva[1], J. Averkieva[1], M. Koroleva[1], T. Raskina[1]. [1]*State Educational Institution of Higher Education "Kemerovo State Medical University", Kemerovo, Russian Federation, Department of Internal Diseases, Kemerovo, Russian Federation*

Background: The relationship between osteoporosis and osteoarthritis (OA) is complex and contradictory. Some studies suggest a protective effect of OA in osteoporosis [1-2]. However, other studies show that increased bone mineral density (BMD) in OA not only does not reduce the risk of fractures, but can also increase it [3-4].

Objectives: To assess the 10-year probability of osteoporotic fractures using the FRAX calculator in women with OA of the knee joint.

Methods: The study included 22 women (average age 63.7±1.01 years) diagnosed with ACP of the knee joint according to the ACR criteria (1991). The Control Group included 24 conditionally healthy women without OA knee joint, with an average age of 63.6±1.37 years.

The BMD (g/cm2) and the T-criterion (standard deviation, SD) of the neck of the femur and lumbar spine (LI-LIV) were evaluated by the method of two-power X-ray absorption (DXA) (apparatus «Lunar Prodigy Primo», USA). 10-year probability of major osteoporotic fractures (clinically significant fracture of the spine, distal fracture of the forearm, fracture of the proximal femur, or fracture of the shoulder) and fracture of the proximal thigh with the FRAX calculator (version 3.5 for Russian population).

Results: An osteopenic syndrome in the cohort under investigation was found in 42 (91.3%) patients, of whom osteopenia in 24 (52.2%) women and osteoporosis in 18 (39.1%). A normal BMD is registered in 4 (8.7%) patients.

In the group of patients with knee joint OA, only 2 (9.1%) of women had a normal BMD, 11 (50.0%) of osteoporosis, and 9 (40.9%). Osteopenic syndrome is generally found in 20 (90,9%) patients.

In the control group, osteopenic syndrome has been diagnosed in 22 (91,7%) of whom: osteopenia in 13 (54.2%), osteoporosis in 9 (37.5%) patients. Two (8.3%) women had a normal BMD. There were no statistically significant differences in the structure of the osteopenic syndrome among the studied groups (p=0.961).

An analysis of the 10-year probability of major osteoporotic fractures found that women with OA knee joint had the above probability of 12.3±0.91, and in the control group 14.2±1.06 (p=0.085).

The 10-year probability of fracture of the proximal femur in women with OA was statistically less significant than in the control group: 1.55 (0.70;1.98) and 2.10 (1.20;2.95), (p=0.031), respectively.

Conclusion: The total incidence of the osteopenic syndrome in the cohort under investigation was 91.3% (90.9% in women with OA, 91.7% in the control group). The frequency of registration of osteopenia and osteoporosis in women with OA did not differ statistically significantly from the control group. The probability of major osteoporotic fractures within 10 years was comparable in these groups. The probability of a proximal femur fracture in women with OA was statistically significant, but not clinically significant, compared to the control group.

Crystal arthritis

POS0132 IS THE INTERCRITICAL GOUT REALLY ASYMPTOMATIC? THE INFLAMMATORY ROLE OF THE SILENT URATE CRYSTAL DEPOSITION

C. Diaz-Torne[1], M. A. Ortiz[2], S. Jeria Navarro[1], A. Garcia-Gullien[1], L. Sainz[1], H. Corominas[1], S. Vidal[2]. [1]*Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; [2]*Institut de Recerca Hospital de la Santa Creu i Sant Pau, Immunology, Barcelona, Spain*

Background: Gout is the most prevalent inflammatory arthritis. Gout is chronic inflammatory deposition disease related to an increase of cardiovascular (CV) events and mortality. Subclinical chronic inflammation has been demonstrated in this patients but not its relation with the monosodium urate (MSU) crystal deposit size and the number of CV risk factors.

Objectives: To study the subclinical inflammation in intercritical gout patients and its possible relation to the estimated size of the crystal deposition and the number of CV risk factors.
Methods: To analyze subclinical inflammation we performed a secretome analysis and a cytokine and adiponektine plasma levels quantification (IL-1β, IL-18, IL-6, sIL-6R, TNFα, CXCL-5, RANTES, leptin, resistin and adiponectin) in a cohort of gout patients. As nowadays it is not feasible to determinate the whole body deposit of MSU crystals we created three different MSU crystal deposit size patient groups using an indirect clinical and analytical classification to estimate it. Then we compared cytokine levels between healthy donors and gout patients. We also compared cytokine levels between the different crystal size deposition groups and studied its association to the number of CV risk factors.
Results: Ninety consecutive patients attending a Crystal Arthritis Unit were studied. Mean age was 68.27 (28-101) years. 81.1% were male. Clinical gout evolution was of 10.1±9.8 years. 77.5% were on urate lowering treatment. 24% had tophaceous gout. Mean uric acid was 6.3±2.1 mg/dl with 47.1% of them being on target. Hypertension was present in 68.9%, diabetes mellitus in 18.9%, dislipemia in 48.9%, BMI>30 in 32.9%, abdominal obesity in 50% and 16.1% suffered from ischemic heart disease. From the 102 molecules studied in the secretome analysis in 56 there was at least a 20% difference between donors group and any of the deposition groups. In 74% of them gout patients secreted lower levels. IL-18, sIL-6R, RANTES, leptin and adiponectin were higher in patients than in healthy donors. IL-18, sIL6-R, RANTES and CXCL5 levels were associated to the size of the crystal deposits. IL-18, sIL-6R, RANTES and leptin were higher in gout groups with CV risk factors. IL-18, sIL6-R, RANTES and leptin were higher in gout patients with no risk factors when compared to healthy donors with no risk factors. We found no differences when comparing urate lowering treated and non-treated patients.
Conclusion: Our results demonstrate that some proinflammatory cytokines and metabolic proteins are raised in intercritical gout patients. Some of them are different from the flare/inflammasome expected ones. In some cytokines this elevation is related to the size of the monosodium urate crystal deposit and/or to the number of cardiovascular risk factors. This cytokine changes could help to explain the increase of the cardiovascular events in gout patients.

POS0133 MONOSODIUM URATE CRYSTALS REDUCE HUMAN LIGAMENT CELLS VIABILITY THROUGH INCREASE OF ROS PRODUCTION

Y. Huang[1], Y. Liu[1], Q. Huang[1], W. Deng[1], T. W. Li[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Ligament destruction is a frequent complication of gout and is strongly associated with tophi. Ligament fibroblasts are important cellular mediators of ligament remodeling. None of study has paid attention to the effects of monosodium urate (MSU) crystals on ligament fibroblasts.
Objectives: The study aims to investigate the effects and mechanism of MSU crystals on ligament fibroblasts.
Methods: MSU crystals were added to human ligament fibroblasts(HLFs) cultures or primary ligament cells cultures. Cell counting kit-8 (CCK-8) assay, cell migration assay, Annexin V-FITC/PI assay were conducted. Reactive Oxygen Species(ROS) was tested by ROS Assay Kit.
Results: The higher concentrations of MSU crystals (0.5-1mg/mL) reduced the viability of HLFs or primary ligament cells after 24 h as assessed by CCK8 assays, with a further reduction in viability observed at the 48 h time point. When observed under light microscopy, HLFs cultured with MSU crystals (0.5mg/mL) appeared unhealthy with fewer cells present. The cell migration ability of HLFs was decreased significantly on MSU crystals (0.5mg/mL). According to the result of Annexin V-FITC/PI assay, the survival rate of HLFs on MSU crystals (0.5mg/mL) was lower than that of 0.25mg/ml and 0 mg/ml at 72h. ROS assay results showed that the production of ROS increased as the concentrations of MSU crystals increased.
Conclusion: MSU crystals inhibit human ligament cells viability through the increase of ROS production. It may contribute to disordered ligament remodeling in gout patients with ligament destruction.

POS0134 INCREASED PREVALENCE OF LUMBAR SPINE MONOSODIUM URATE DEPOSITION AMONG GOUT PATIENTS ON DUAL-ENERGY CT

M. Toprover[1,2], M. Mechlin[3], A. Slobodnick[1], V. C. Pike[1], C. Oh[4], C. Davis[5], T. Fields[6], F. Becce[7], M. H. Pillinger[1,2]. [1]*New York University Grossman School of Medicine, Medicine/Rheumatology, New York, United States of America*; [2]*New York Harbor Health Care System, US Department of Veterans Affairs, Medicine/Rheumatology, New York, United States of America*; [3]*New York University Grossman School of Medicine, Musculoskeletal Radiology, New York, United States of America*; [4]*NYU Grossman School of Medicine, Biostatistics, New York, United States of America*; [5]*NYU Grossman School of Medicine, Medicine/Rheumatology, New York, United States of America*; [6]*The Hospital for Special Surgery, Rheumatology, New York, United States of America*; [7]*Lausanne University Hospital, Radiology and Interventional Radiology, Lausanne, United States of America*

Background: Gout affecting the spine is reported as a rare event presenting with neuropathy, spinal compression and acute back pain (1). Cases are often diagnosed by tissue confirmation of monosodium urate (MSU) deposition. The frequency of gout involving the spine asymptomatically or with milder, non-specific symptoms is likely higher than reported.
Objectives: Using dual-energy CT (DECT), we are determining prevalence/extent of MSU deposition in the lumbosacral spines of patients with gout and tophaceous gout, compared to non-gout controls.

Methods: We are recruiting 25 controls, 25 non-tophaceous and 25 tophaceous gout patients, 45-80 years old. Exclusion criteria include CPPD disease, RA, spondyloarthropathy or spinal malignancy. All gout subjects meet ACR gout classification criteria with entry serum urate (sU) of >6.8 mg/dL, or sU >6.0 mg/dL on ULT for <6 months. Demographics, gout history, Aberdeen back pain scale, sU, ESR, and CRP are collected. DECT of the lumbosacral spine is used to assess MSU deposition and osteoarthritic changes.

Results: 63 subjects are enrolled and analyzed to date (25 control, 23 non-tophaceous and 15 tophaceous gout). Control, non-tophaceous gout, and tophaceous gout subjects have similar mean age in years (controls 61.8±3.8, non-tophaceous 64.0±6.2, tophaceous 63.5±9.2, p=0.45), but differ in BMI (controls 28.3±6.5 kg/m2, non-tophaceous 32.1±6.7 kg/m^2, tophaceous 29.1±4.3 kg/m^2, p=0.01) and creatinine (controls 1.0±0.2 mg/dL, non-tophaceous 1.4±0.6 mg/dL, tophaceous 1.7±0.9 mg/dL, p=0.048). Mean sU and ESR are higher in gout subjects (sU-controls 5.3±1 mg/dL, non-tophaceous 8.3±1.4 mg/dL, tophaceous 8.4±2.0 mg/dL, p<0.05; ESR-controls 13.7±13.8 mm/h, non-tophaceous 25.2±18.7 mm/h, tophaceous 22.5±15.1 mm/h, p<0.05). Using default threshold settings for MSU visualization, greater MSU deposition is observed in the spine of gout patients (controls 2.2±1.2 cm^3, non-tophaceous 4.5±4.3 cm^3, tophaceous 8.5±12.5 cm^3, p<0.05; Table 1). Reanalysis of several scans using narrower threshold settings to limit possible artifact confirms increased MSU signal among gout patients. Although many subjects in each group do not have excessive MSU deposition, deposition is more common in both gout groups. No subject demonstrated a frank spinal tophus.

Conclusion: Based on preliminary results, gout patients have higher inflammatory markers and greater spinal MSU deposition than controls. Preliminary analyes with more stringent DECT threshold settings suggests these differences are not artifact, but analysis is ongoing. These data suggest that MSU deposition in the spine occurs in a subset of gout patients.

REDUCING IMMUNOGENICITY OF PEGLOTICASE (RECIPE) WITH CONCOMITANT USE OF MYCOPHENOLATE MOFETIL IN PATIENTS WITH REFRACTORY GOUT: A PHASE II RANDOMIZED CONTROLLED TRIAL

P. Khanna[1], D. Khanna[1], G. Cutter[2], J. Foster[3], J. Melnick[3], S. Jaafar[1], S. Biggers[3], F. Rahman[2], H. C. Kuo[2], M. Feese[2], K. Saag[3]. *[1]University of Michigan, Medicine, Ann Arbor, United States of America*; *[2]University of Alabama at Birmingham, Biostatistics, Birmingham, United States of America*; *[3]University of Alabama at Birmingham, Medicine, Birmingham, United States of America*

Background: Pegloticase is a recombinant, pegylated uricase, used for treatment of gout patients who fail oral urate lowering therapy (ULT). Its use has been limited due to immunogenicity leading to infusion reactions.[1]

Objectives: We evaluated if co-administration of an immunomodulatory agent could prolong the efficacy of pegloticase.

Methods: Participants were recruited in a Phase II, double-blind, placebo-controlled trial over 18 months and randomized in a 3:1 ratio by site. Inclusion criteria were: a) Age ≥ 18 years who met 2015 ACR/EULAR gout classification criteria and b) chronic refractory gout defined as symptoms inadequately controlled with ULT or contraindications. After a 2-week run-in of mycophenolate mofetil (MMF) 1000 mg twice daily or matching placebo (PBO), they received a combination of pegloticase

8 mg biweekly with MMF or PBO for 12 weeks. Subsequent to this MMF or PBO were discontinued but pegloticase was continued for another 12 weeks. The primary endpoint was proportion of patients who sustained a serum urate (SU) level of ≤ 6 mg/dl at 12 weeks. Secondary endpoints included 24-week durability of SU ≤ 6 mg/dl and rate of adverse events (AEs). Fisher's exact test and Wilcoxon two-sample test were used for analyses along with Kaplan-Meier estimates and log-rank tests to compare survival curves between groups. Hypothesis tests were two-tailed and p-value (p) < 0.05 indicated statistical significance.

Results: Of 42 subjects screened, 35 were randomized, and 32 who received at least one dose of pegloticase were included in modified intention to treat analyses. Subjects were predominantly men (88%), mean age of 55.2 years (SD=9.7). Mean duration of gout was 13.4 years (SD=9.0), mean baseline sUA was 9.2 mg/dL (SD=1.6). Tophi were present in 88% and majority were on optimized ULT - 59% on allopurinol and 16% on febuxostat, with 63% reporting > 1 flare in the past year. At baseline both arms (MMF vs. PBO) had similar comorbidities – (82% vs 70%), diabetes mellitus/metabolic syndrome (14% vs 20%), coronary artery disease/peripheral vascular disease (41% vs.70%), BMI>30 (86% vs. 90%) and renal insufficiency (defined as eGFR < 90 mL/min; 73% vs. 70%). At 12 weeks, 19 of 22 (86%) in the MMF arm achieved SU ≤ 6 mg/dl compared to 4 of 10 (40%) in PBO arm (p-value = 0.01). At 24 weeks, the SU was ≤ 6 mg/dl in 68% of MMF arm vs. 30% in PBO (p-value = 0.06), and rates of AEs per month were similar between groups with the PBO arm having more infusion reactions (30% vs. 0%). The MMF arm had higher AEs compared to placebo: musculoskeletal (41% vs. 10%), gastrointestinal (18% vs. 10%), and infections (9% vs. 0%). Figure 1 shows that the percentage of subjects maintaining a sUA < 6 mg/dL at 12 weeks was significantly higher (p=0.02) in the MMF arm, and a significant difference (p=0.03) at 24 weeks indicates sustained benefit from MMF.

Conclusion: To our knowledge this is the first randomized-controlled proof of concept trial to demonstrate the ability of an immunomodulatory agent in prolonging the efficacy of pegloticase. Short-term concomitant use of MMF therapy with pegloticase was well tolerated and showed a clinically meaningful improvement in the targeted SU ≤6 mg/dL at 12 and 24 weeks. This study suggests an innovative approach to utilize pegloticase therapy in patients with chronic gout.

POS0136 ROLES OF AUTOPHAGY IN THE PATHOGENESIS OF PRIMARY GOUTY ARTHRITIS

Y. Q. Huang[1], Q. B. Zhang2, J. X. Zheng[3], G. L. Jian2, T. H. Liu2, X. He2, F. N. Xiao2, Q. Xiong2, Y. F. Qing[4]. *[1]The Affiliated Hospital of North Sichuan Medical College, Geriatrics, Nanchong, Sichuan, China*; *[1]The Affiliated Hospital of North Sichuan Medical College, Geriatrics, Nanchong, Sichuan, China*; *[3]The Affiliated Hospital of North Sichuan Medical College, Institute of Rheumatology and Immunology, Nanchong, Sichuan, China*; *[4]The Affiliated Hospital of North Sichuan Medical College, Rheumatology and Immunology, Nanchong, Sichuan, China*

Background: Gout is a chronic autoinflammatory disease caused by monosodium urate (MSU) crystal deposition [1].Acute gout is characterized by an acute inflammatory reaction that resolves spontaneously within a few days[2], which is one of the distinguishing features of gout compared to other arthropathies or self-inflammatory diseases. Autophagy is a lysosomal degradation pathway that is essential for cellular growth, survival, differentiation, development and homeostasis [3]. Studies have demonstrated that autophagy might play a key role in the pathogenesis of primary gouty arthritis (GA) [4-7]. However, the roles of autophagy in the development of gout have not yet been elucidated.

Objectives: The aim of our study was to investigate the changes in autophagy-related gene (ATG) mRNA and protein in patients and the clinical importance of these genes in primary gouty arthritis (GA) and to explore the roles of autophagy in the pathogenesis of GA.

Methods: The mRNA and protein expression levels of ATGs (ATG3, ATG7, ATG10, ATG5, ATG12, ATG16L1, ATG4B and LC3-2) were measured in peripheral blood mononuclear cells (PBMCs) from 196 subjects, including 57 acute gout patients (AG group), 57 intercritical gout patients (IG group) and 82 healthy control subjects (HC group). The relationship between ATG expression levels and laboratory features was analyzed in GA patients.

Results: The expression levels of ATG4B, ATG5, ATG12, ATG16L1, ATG10 and LC3-2 mRNA were much lower in the AG group than in the IG and HC groups ($p<0.05$), while the ATG7 mRNA level was much higher in the AG group than in the IG and HC groups ($p<0.05$). The protein expression levels of LC3-2, ATG3, ATG7 and ATG10 were much higher in the AG group than in the other groups, while those of ATG5, ATG12, ATG16L1 and ATG4B were far lower in the AG group than in the other groups ($p<0.05$). In GA patients, the levels of ATG mRNA and protein correlated with laboratory inflammatory and metabolic indexes.

Conclusion: Altered ATG expression suggests that autophagy is involved in the pathogenesis of GA and participates in regulating inflammation and metabolism.

POS0137 CARDIOVASCULAR RISK ASSOCIATED WITH TREATMENT OF ALLOPURINOL AND BENZBROMARONE IN PATIENTS WITH GOUT

Y. Eun[1], S. Y. Kang[1], S. Lee[1], H. Kim[2], J. Lee[1], E. M. Koh[1], H. S. Cha[1]. *[1]Samsung Medical Center, Sungkyunkwan University School of Medicine,*

Department of Medicine, Seoul, Korea, Republic of (South Korea); [2]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medical Humanities, Seoul, Korea, Republic of (South Korea)*

Background: Previous studies have shown that cardiovascular risk is increased in patients with gout. There are many studies on the effect of uric acid lowering therapy on CV risk in gout patients, but few studies have compared allopurinol and benzbromarone.
Objectives: A nationwide population-based cohort study is designed to compare cardiovascular risk according to the treatment of allopurinol and benzbromarone in Korean gout patients.
Methods: We used South Korea's database of the Health Insurance Review and Assessment service (HIRA) to identify gout patients 18 years of age or older who newly started allopurinol or benzbromarone between 2009 and 2015. The start date of allopurinol or benzbromarone is defined as the index date. We excluded patients who have been prescribed uric acid lowering agents or have been on dialysis for one year prior to the index date. During the study period, patients who used uric acid lowering agents other than allopurinol and benzbromarone or who used both drugs in combination were also excluded from the study. The primary outcome of the study was the occurrence of a composite cardiovascular endpoint, which included coronary revascularization, hospitalization due to MI, ischemic stroke, and transient ischemic attack (TIA). Cox proportional hazard regression analysis and Kaplan-Meier curves were used for the analysis.
Results: 257,097 allopurinol initiators and 7,868 benzbromarone initiators were included in the study. The mean age was 54.4 years, 86% were male. The mean adherence of drug administration was 68.2% for allopurinol initiators and 75.5% for benzbromarone initiators. In baseline, the benzbromarone initiator had more cardiovascular comorbidities and related drug administration than the allopurinol initiator. In allopurinol and benzbromarone initiators, the adjusted hazard ratio (aHR) of the composite CV endpoint was 1.01 (95% CI 0.83-1.21), which was not significantly different. No significant difference was found between the two groups in each of the items of the composite CV endpoint and hospitalization for heart failure. The results did not change even when 1:3 propensity score matching was performed for baseline characteristics. In subgroup analysis of high risk patients with cardiovascular disease, there was no significant difference between allopurinol and benzbromarone initiators. However, when the analysis was limited to the group taking allopurinol ≥200mg and benzbromarone ≥50mg, there was no difference in primary outcome and other outcomes, but the risk of coronary revascularization was higher in benzbromarone initiator (aHR 1.58, 95% CI 1.16-2.14).
Conclusion: In our study, there was no significant difference in cardiovascular risk between allopurinol initiator and benzbromarone initiator. In the high risk group of cardiovascular disease, there was no difference in risk between the two drugs.

POS0138 ALTERED RISK OF GOUT ACCORDING TO CHANGE OF METABOLIC PARAMETERS IN YOUNG ADULTS

Y. Eun[1], I. Y. Kim[2], K. D. Han[3], S. Y. Kang[1], S. Lee[1], H. S. Cha[1], E. M. Koh[1], H. Kim[4], J. Lee[1]. [1]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*National Police Hospital, Department of Medicine, Seoul, Korea, Rep. of (South Korea)*; [3]*Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea)*; [4]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medical Humanities, Seoul, Korea, Rep. of (South Korea)*

Background: Many studies have shown a link between gout and metabolic syndrome (MetS). It is well known that lifestyle modifications such as weight reduction and abstinence from alcohol are effective in the treatment of gout, but data are lacking on how exactly the change of metabolic parameters affects gout.
Objectives: The purpose of this study was to investigate the relationship between gout risk and metabolic parameters in a nationwide population based young adult cohort, and to determine whether changes in metabolic parameters affect gout risk changes.
Methods: Among adults aged 20-39 years who participated in national health check-up programs from 2009 to 2012, a total of 6,290,914 subjects were included in the study, excluding subjects who were previously diagnosed with gout. To determine the effect of changes in metabolic parameters on gout incidence, 2,701,138 subjects who participated in the health examination once more 2 years later were used for the analysis. Outcome was defined as the occurrence of gout, when the ICD-10 code (M10) was registered twice in the claim database. The Cox proportional hazard model and Kaplan Meier curve were used for the analysis.
Results: The incidence rate of gout was higher in those with MetS compared to those without (10.1 vs. 3.6 per 1,000 person-years). The risk of gout in people with MetS was 85% higher (adjusted HR 1.85, 95% CI 1.83-1.87) and was more significant in men than in women (adjusted HR 1.88 in male and 1.56 in female). Each component of MetS was also associated with increased gout risk, and hypertriglyceridemia showed the highest adjusted HR. The greater the number of MetS components, the higher the gout risk. The risk of gout was 70% higher in those who had MetS consistently (adjusted HR 1.71, 95% CI 1.67-1.75) and 44% higher in those with newly developed MetS (adjusted HR 1.47, 95% CI 1.40-1.48) than those who did not have MetS at the two health examinations. Similar risk patterns were observed according to the change of each metabolic parameter. Among the metabolic parameters, the change in hypertriglyceridemia was associated with the greatest difference in the change in gout risk.
Conclusion: In young adults, MetS was associated with a higher risk of gout, especially with more components, the higher the risk. Since the occurrence of MetS is associated with an increased risk of gout, prevention of MetS would be important to reduce gout incidence.

POS0139 TWO-YEAR REDUCTION OF URATE LOAD IN DUAL-ENERGY CT DURING A TREAT-TO-TARGET APPROACH IN GOUT PATIENTS: RESULTS FROM A LONGITUDINAL STUDY (NOR-GOUT)

T. Uhlig[1], T. Eskild[2], L. F. Karoliussen[1], T. K. Kvien[1], E. A. Haavardsholm[1], N. Dalbeth[3], H. B. Hammer[1]. [1]*Diakonhjemmet Hospital, Rheumatology, Oslo, Norway*; [2]*Diakonhjemmet Hospital, Clinical Service Radiology, Oslo, Norway*; [3]*University of Auckland, Medicine, Auckland, New Zealand*

Background: Dual-energy computed tomography (DECT) detects urate depositions, and is included in the ACR/EULAR classification criteria for gout. There is lack of longitudinal studies in large patient populations for changes in urate deposition measured by DECT during urate lowering therapy (ULT).
Objectives: To explore by DECT the longitudinal changes urate depositions during a treat-to-target approach in gout with ULT.
Methods: In a prospective observational study, patients with crystal-proven gout were included if they presented after a recent gout flare and with increased serum urate levels (>360 µmol/L/>6 mg/dl). In a treat-to-target approach they received ULT with escalating drug doses with monthly follow-up during the first year until the treatment target was met with serum urate <360 µmol/L or 360 µmol/L if tophi.
A DECT scanner (General Electric Discovery CT750 HD) acquired data from bilateral forefeet and ankles at 80 KW and 140 KV, processed with a software with a 2-material decomposition algorithm which colour codes urate. Follow-up DECT was performed after one and two years.
Images were scored with a semiquantitative method (Bayat et al. 2015) by one experienced radiologist in known order and blinded to serum urate and clinical data. Each scan assessed four regions: the first metatarsophalangeal (MTP1) joint, the other joints of the toes, the ankles and midfeet, and all visible tendons in the feet and ankles. Each region was then scored according to the maximum amount of urate deposition observed on visual inspection (0=no deposits, 1=dots, 2=single deposit, 3=more than one deposit). A total DECT sum score was derived by adding all values from the four regions, with a maximum score of 12.
Results: DECT was at baseline measured in 187 of 211 patients. 95.2% were males, mean (SD) age was 56.7 (13.7) years, disease duration 8.1 (7.9) years), and 17% had clinical tophi.
The total DECT scores and all subscores decreased from baseline to 2 years ($p<0.001$ for all comparisons versus baseline), table 1.
The mean (SD) serum urate level (µmol/L) decreased from 501 (80) at baseline to 311 (48) at 12 months and 322 (67) at 24 months. Reaching the treatment target <360 µmol/L after year 1 or 2 was only numerically but not statistically related to reductions in DECT scores. Patients with clinical tophi at baseline had larger reductions in total DECT scores after 1 (3.4 vs. 1.5, $p<0.01$) and 2 years (6.5 vs. 2.3, $p<0.001$) than patients without tophi.
Conclusion: During a treat-to-target approach urate deposition visualised by DECT were clearly reduced in ankles and feet after 1 year with further reduction after 2 years.

Table 1.

	Baseline (n=187) Mean (SD)	1 year (n=157) Mean (SD)	2 years (n=166) Mean (SD)
MTP1 (0-3)	1.4 (2.0)	1.0 (1.7)	0.6 (1.3)
Toes (0-3)	1.0 (1.8)	0.6 (1.4)	0.3 (1.0)
Ankle/Midfoot (0-3)	1.2 (2.1)	0.7 (1.6	0.3 (1.0)
Tendons (0-3)	1.0 (1.7)	0.5 (1.2)	0.3 (0.8)
Sum score (0-12)	4.6 (6.4)	2.8 (4.7)	1.5 (3.2)

POS0140 **URATE-LOWERING THERAPY REDUCES NON-EPISODIC FOOT PAIN IN PATIENTS WHO FAIL TO MEET ACR/EULAR 2015 GOUT CLASSIFICATION CRITERIA: AN EFFECT PREDICTED BY ULTRASOUND**

R. Flood[1], C. Kirby[2], Y. Alammari[2], D. Kane[2], R. Mullan[2]. [1]*Tallaght University Hospital, Rheumatology, Dublin, Ireland*; [1]*Tallaght University Hospital, Rheumatology, Dublin, Ireland*

Background: Emerging evidence that the joints of asymptomatic hyperuricaemic individuals contain monosodium urate (MSU) deposits and that alternative presentations of foot pain occur in hyperuricaemia suggests that preclinical phases may occur prior to a first episodic gout attack. (1) This case–control study evaluates urate deposition in hyperuricaemic individuals not fulfilling the current gout classification criteria, as well as a potential therapeutic role for urate lowering therapy (ULT).
Objectives: To investigate whether ULT reduces non-episodic foot pain in patients who fail to meet ACR/EULAR 2015 gout classification criteria.
Methods: Following informed consent, hyperuricaemic individuals with persistent, non-episodic foot pain (n=53) not fulfilling ACR/EULAR 2015 gout classification criteria, were compared with asymptomatic hyperuricaemic controls (n=18). Ultrasound (US) of bilateral first metatarsophalangeal (MTP) joints and features of MSU deposition including double contour (DC) sign, tophus and juxta-articular erosion were recorded. Cases only were treated with febuxostat or allopurinol daily for 6 months. Serum urate, 24-hour and 7-day visual analogue score (VAS) 0–100 mm pain scales and the Manchester Foot Pain and Disability Index (MFPDI) were recorded before treatment and after 3 and 6 months. MTP Ultrasound was repeated after a minimum of 6 months on treatment.
Results: 53 hyperuricaemic individuals with persistent, non-episodic foot pain not meeting the ACR/EULAR 2015 gout classification criteria were recruited. At baseline MTP US DC sign, erosion and tophus occurred in 62.5%, 20.8% and 49% of cases, respectively. No US features of gout occurred in controls. No significant difference was seen in baseline serum urate between cases (481±14 mg/dL) versus controls (437±14; p=NS). Serum urate in cases fell at 3 months (325±25; p<0.01) and 6 months (248±19; p<0.01). For cases, baseline 24-hour pain VAS (46±3.9) reduced at 3 months (32±4.1; p<0.05) and 6 months (21±5.2; p<0.05) of ULT. The 7-day pain VAS (59±3.9) decreased at 3 months (35±4.5; p<0.05) and 6 months (30±5.3; P<0.05). MFPDI (17±1.4) decreased at 3 month (13±1.8; p=<0.05) and 6 months (11±2.2; p=<0.05). When cases were grouped according to the presence (N=33) or absence (N=18) of DC sign on baseline US, no differences were observed for baseline pain scores. Following ULT however, 24-hour pain VAS were significantly lower in DC positive patients at 3 months (22±4.48 DC positive vs 42±6.14 DC negative; p<0.05) and 6 months (12.±5.4 vs 33±8.4; p<0.05). The 7-day pain VAS were significantly lower in DC positive patients at 3 months (23±4.6 vs 47±6.6; p<0.05) and MFDPI were significantly lower in DC positive patients at 3 months (10±1.9 DC positive vs 19±2.9 DC negative; p<0.05).
Conclusion: These findings indicate that persistent, non-episodic foot pain in hyperuricaemia is both associated with US features of MSU deposition and is responsive to ULT. Symptomatic hyperuricaemia occurring prior to episodic gout therefore represents an earlier or alternative disease presentation. Changes to the ACR/ EULAR classification criteria to include non-episodic foot pain in the presence of US features of gout may increase the sensitivity of disease classification at an early stage, leading to improved future treatment strategies and long-term outcomes.

POS0141 **ACTIVE SCREENING FOR GOUT IDENTIFIES A LARGER CARDIOVASCULAR POPULATION AT HIGH MORTALITY RISK**

S. Ruiz-Simón[1], I. Calabuig[2], M. Gomez-Garberi[3], M. Andrés[1,2]. [1]*Miguel Hernandez University, Clinical Medicine, San Juan de Alicante, Spain*; [2]*Alicante General University Hospital-ISABIAL, Rheumatology, Alicante, Spain*; [3]*San Juan de Alicante University Hospital, Urology, San Juan de Alicante, Spain*

Background: We have recently revealed by active screening that about a third of gout cases in the cardiovascular population is not registered in records [1], highlighting the value of field studies.
Objectives: To assess whether gout screening in patients hospitalized for cardiovascular events may also help identify patients at higher risk of mortality after discharge.
Methods: A retrospective cohort field study, carried out in 266 patients admitted for cardiovascular events in the Cardiology, Neurology and Vascular Surgery units of a tertiary centre in Spain. The presence of gout was established by records review and face-to-face interview, according to the 2015 ACR/EULAR criteria. The occurrence of mortality during follow-up and its causes were obtained from electronic medical records. The association between gout and subsequent mortality was tested using Cox regression models. Whether covariates affect the gout-associated mortality was also studied.
Results: Of 266 patients recruited at baseline, 17 were excluded due to loss to follow-up (>6mo), leaving a final sample of 249 patients (93.6%). Thirty-six cases (14.5% of the sample) were classified as having gout: twenty-three (63.9%) had a previously registered diagnosis, while 13 (36.1%) had not and was established by the interview.
After discharge, the mean follow-up was 19.9 months (SD ±8.6), with a mortality incidence of 21.6 deaths per 100 patient-years, 34.2% by cardiovascular causes. Gout significantly increased the risk of subsequent all-cause mortality, with a hazard ratio (HR) of 2.01 (95%CI 1.13 to 3.58). When the analysis was restricted to gout patients with registered diagnosis, the association remained significant (HR 2.89; 95%CI 1.54 to 5.41).
The adjusted HR for all-cause mortality associated with gout was 1.86 (95% CI 1.01-3.40). Regarding the causes of death, both cardiovascular and non-cardiovascular were numerically increased.
Secondary variables rising the mortality risk in those with gout were age (HR 1.07; 1.01 to 1.13) and coexistent renal disease (HR 4.70; 1.31 to 16.84), while gender, gout characteristics and traditional risk factors showed no impact.
Conclusion: Gout was confirmed an independent predictor of subsequent all-cause mortality in patients admitted for cardiovascular events. Active screening for gout allowed identifying a larger population at high mortality risk, which may help tailor optimal management to minimize the cardiovascular impact.

Fine-tuning strategies (beyond treatments) to reduce the impact of PsA

POS0142 **MINIMAL DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS AND ASSOCIATED FACTORS: REAL LIFE DATA FROM A SINGLE CENTER**

M. Bektaş[1], B. Çelik[2], B. Ince[1], Y. Yalçınkaya[1], B. Artim-Esen[1], A. Gül[1], M. L. Ocal[1], M. Inanc[1]. [1]*Istanbul Faculty of Medicine, Internal Medicine, Rheumatology Division, Istanbul, Turkey*; [2]*Istanbul Faculty of Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey*

Background: Psoriatic arthritis (PsA) is a heterogeneous disease and GRAPPA have proposed Minimal disease activity (MDA) as a composite outcome measure and has been validated in PsA.
Objectives: In this study, we aimed to evaluate the characteristics, MDA frequencies, first biological disease modifying antirheumatic drugs (b-DMARD) continuation rate and associated factors in our PsA cohort.
Methods: PsA patients who fulfilled the CASPAR classification criteria and had at least six months of follow-up data were evaluated cross-sectionally for MDA.Clinical data were collected from patient charts with standard forms.b-DMARD treatment was initiated in patients who did not respond to at least one conventional synthetic (cs)

DMARD for at least three months. Only anti-TNFs were used as a first line b-DMARD therefore secukinumab (Secu) was used after first line b-DMARD treatment. Adalimumab, certolizumab, etanercept, golimumab were grouped as subcutaneous (s.c) anti-TNFs. MDA was defined as meeting five out of seven criteria during follow-up [1].
Results: One hundred seventy-two patients (61% female) were included into the analysis. The mean follow-up time was 105.4±76 (6-444) months and the mean age was 50.2±13.3 (16-81) years. Mean age of onset for PsA was 38±11.9 (11-79) years; mean PsA and PsO duration were 140±90.7 (7.9-528) and 253±138 (0-756) months, respectively. Methotrexate was the most commonly used (88 %) cs-DMARD and biological DMARDs were used in 74 patients (43.3%)
Overall, 95 patients (55.2 %) were observed at MDA which was significantly lower in b-DMARD users compared to only cs-DMARD users (45.9 % vs 61.9 %; p=0.038, OR: 4.3). MDA did not differ according to PsA subtypes. The addition of cs-DMARD treatment to b-DMARDs did not affect MDA frequency In univariate analysis; higher MDA frequency was associated with older age (p=0.002), longer PsO duration (p=0.036), late onset of PsA (p=0.007) and continuation of first b-DMARD (OR:13.9 p<0.001). In multivariate analysis, older age (OR:1.3;95 % CI:1.02-1.68), late onset PsA (OR:1.03; 95 % CI:1.01-1.067) and continuation of first b-DMARD (OR:46.8; 95 % CI:1.6-1371) were associated with MDA.
Conclusion: Although frequency of MDA in our cohort was consistent with previous reports, a significant number of patients could not achieve MDA. Frequency of MDA was found to be lower in b-DMARD users compared to cs-DMARD users, possibly resulted from initiation of b-DMARD in patients with higher disease activity. Higher MDA rate was associated with higher continuation rate at first line b-DMARD treatment (TNF-inhibitor) and decreased gradually after b-DMARD switches. Although combined use of cs-DMARD with b-DMARDs did not increase the frequency of MDA, it was associated with higher b-DMARD retention. MDA is a useful outcome measure in daily follow-up of PsA patients and the importance of reaching sustained MDA for prognosis should be investigated further.

POS0143 POST-STRESS ULTRASOUND ASSESSMENT OF THE ACHILLES TENDON IS USEFUL TO DIFFERENCIATE PSORIATIC ARTHRITIS FROM THE PHYSIOLOGICAL ADAPTATION TO EXERCISE

C. Guillén-Astete[1], V. García García2, N. García-Montes[1], Á. Andreu-Suárez[1]. *[1]Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*; *[1]Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: Achilles enthesitis is the most accessible psoriatic arthritis hallmark to assess through ultrasound scan. Recently it has been demonstrated that continuous mechanical stress such as experimented by runners can drive to the development of physiological morphological changes that resembles those observed in psoriatic arthritis. In a subject with the suspicious diagnostic of psoriatic arthritis who practice any sports associated to continuous impact over the heels, the challenge to determine in what extent the morphological changes are linked to the exercise or to the disease, is remarkable.
Objectives: To determine morphological differences between patients with psoriatic arthritis, trained runners and sedentary volunteers through ultrasound scan of the Achilles tendon.
Methods: An ultrasound scan of the Achilles tendon was performed to the following subjects: Patients with diagnosis of psoriatic arthritis with a DAPSA score of low activity in at least six months and with history of heel pain in the past, volunteers runners with not less of 3-year sport activity at least three times a week and sedentary volunteers. In the group of patients, ultrasound scan was performed over the feet with history of heel pain. In the case of volunteers, the ultrasound scan was performed in the dominant feet. The selection of volunteers was not randomly-based in order to match their age and sex to the patients as much as possible. Besides demographic features, a comparison between tendon thickness at the level of the calcaneus bone border and the height of the retrocalcaneus bursae in the longitudinal axis were performed through ANOVA test. Power Doppler signal was scaned in all subjects before and after a controlled mechanical stress of the Achilles tendon by climbing stairs (100 steps, two times).
Results: Female/male distribution of the group of patients, runners and sedentary people were: 12/10, 18/18 and 20/18, respectively. Achilles tendon mean thickness ± standard deviation was 6.61 ± 1.05, 5.91 ± 1.44 and 4.61 ± 2.1mm, respectively (*P*=0.01). Retrocalcaneus bursae height was 3.42 ± 0.21, 3.22 ± 0.27 and 2.21 ± 0.31 (*P*=0.01). Basal PD signal was present into the enthesis of 2/22, 1/36 and 0/38, respectively (P not significant). After exercise, PD signal was present in 8/22, 5/36 and 0/38, respectively (P<0.001).
Conclusion: Power Doppler signal after exercise was identified as the most relevant ultrasound hallmark to distinguish a patient with psoriatic arthritis from a trained runner, even when psoriatic arthritis were considered as low activity. Post exercise ultrasound scan should be considered as a diagnosis tool in sportsmen with suspicious of psoriatic arthritis, until further studies confirm our findings.

POS0144 NOVEL APPLICATION OF OPTICAL COHERENCE TOMOGRAPHY ANGIOGRAPHY AND NAILFOLD CAPILLAROSCOPY IN PSORIATIC ARTHRITIS - DIAGNOSTIC AND PROGNOSTIC ACCURACY IN RELATION TO PSORIASIS AND HAND OSTEOARTHRITIS

J. Guldberg-Møller[1,2], T. Schjødt Jørgensen[1], M. Henriksen[1], K. Ellegaard[1], M. Mogensen[3], L. E. Kristensen[1]. *[1]The Parker Institute, University Hospitals of Copenhagen, Bispebjerg and Frederiksberg, Copenhagen F, Denmark*; *[2]Slagelse Sygehus, Zealand University Hospitals, Slagelse, Denmark*; *[3]University Hospitals of Copenhagen, Bispebjerg and Frederiksberg, Department of Dermatology, Copenhagen F, Denmark*

Background: Nailfold video capillaroscopy (NVC) and angiographic optical coherence tomography (OCTA) have potential in diagnosing psoriatic arthritis (PsA) and differentiating it from psoriasis vulgaris (PsO) and hand osteoarthritis (OA).
Objectives: To assess the diagnostic properties of NVC and OCTA in patients with PsA compared to patients with PsO and hand OA based on nailfold capillary patterns.
Methods: Patients with distal interphalangeal-joint PsA and nail involvement (n=50), PsO with nail involvement (n=12); and OA (n=13) were included in this cross-sectional study. Capillaries were evaluated semi-quantitatively and qualitatively. Differences in capillary findings between groups were assessed using

mixed linear models. Binary logistic regression analyses were performed to determine the probability for PsA diagnosis based on capillaroscopy findings.

Results: Reduced capillary density and reduced nailfold blood flow in OCTA images distinguished PsA from both PsO (p=0.004 and p=0.052) and OA (p=0.024 and p<0.001). Qualitative analysis revealed that glomerular capillaries were found in only 3% of PsA patients but in 13% of PsO patients (P=0.003). Furthermore, coiled vessels were only seen in 55% of PsA patients and 71% in PsO patients (P=0.043). NVC microhaemorrhage was dominant in PsA patients (13 % and 17 %) and significantly different to OA patients (p=0.05). No capillary pattern was associated with an increased probability of the PsA diagnosis.

Conclusion: A pathognomic pattern for PsA diagnosis was not identified, however we demonstrated characteristics significant capillaroscopy findings for PsA such as decreased capillary density, reduced blood flow, and less coiled vessels in OCTA and presence of NVC microhemorrhages.

Table 1.

	NVC-rating	PsA (n=188)	PsO (n=42)	OA (n=48)	PsA vs PsO	PsA vs OA
NVC ad modum Cutolo	Reduced capillary density	51 %	31 %	51 %	P=0.107	0.770

Background: Up to 30% of Psoriasis (PsO) patients are prone to develop Psoriatic Arthritis (PsA). Agreement on how to identify PsO patients at risk of developing PsA is still lacking (1).

Objectives: To identify predictors of PsA development in PsO patients through a systematic literature review (SLR) and meta-analyses (MA).

Methods: MEDLINE, EMBASE and COCHRANE databases were searched (up to February 22nd, 2020). The PICO framework (population = PsO patients; intervention = clinical, environmental, imaging and genetic features; comparator = not applicable; outcome = PsA development) was used to design searches and define the eligibility of studies for inclusion. The MA focuses on 3 major features as possible predictors: i) PsO skin and nail involvement; ii) musculoskeletal (MSK) complaints; iii) inflammation and structural damage detected by imaging (Table 1). The sample estimates of the relative risk were pooled only when the studies were homogeneous in terms of cohort of patients, follow-up, study design and metrics.

Results: 4698 articles were screened for eligibility, 110 underwent a full reading and 29 were finally included. Figure 1 shows the study flow-chart for article selection. Though pooling was judge not appropriate, 5/7 prospective studies significantly support a predictive value of PsA development in patients with severe PsO (n=174635). While the predictive value of nail involvement is not well defined (n=2202), the pooled estimate from two cohort studies (n=474) supports nail pitting as predictor of PsA (RR=2.14 [1.32; 3.46]). Moving to the MSK complaints, the risk of developing PsA is about two times greater in PsO with than without arthralgia (pooled RR: 2.15 [1.16, 3.99]) within 2 years. Lastly, PsO patients with inflammation or structural damage detected by imaging are nearly four times more likely to develop PsA within 1-2 years (pooled RR from 4 cohort studies (n=247): 3.72 [2.12; 6.51]) (Table 1). The incidence rate of PsA varies from 1.34 to 5.9/100 p-ys in PsO and from 10.9 to 12.5/100 p-ys in PsOAr.

Conclusion: Arthralgia and inflammation and/or structural damage detected by imaging are predictive features, likely prodromal, of PsA development. PsO severity and nail pitting are clinical manifestations related to PsA development.

POS0146 PERIPHERAL NEUROPATHY IN PSORIASIS AND PSORIATIC ARTHRITIS: A SINGLE BLIND, CONTROLLED, ELECTROPHYSIOLOGICAL STUDY

M. Izci[1], S. Kanyılmaz Turgut[1], O. Akan[2], I. Topal[3], O. Kuru[1]. *[1]Prof Dr Cemil Tascioglu City Hospital, Physical Medicine and Rehabilitation Clinic, İstanbul, Turkey*; *[2]Prof Dr Cemil Tascioglu City Hospital, Neurology Clinic, İstanbul,Turkey*; *[3]Prof Dr Cemil Tascioglu City Hospital, Dermatology Clinic, İstanbul,Turkey*

Background: It is well known that both psoriasis (PsO) and psoriatic arthritis (PsA) causes morbidity and disability in patients' lives. Additional pathologies such as peripheral neuropathy (PN) may interfere with disease specific symptoms and may increase the burden of disease. Neuropathic complaints of patients with PsO and PsA are observed during patients' follow-up (1,2). However, the presence of PN in PsO and PsA is not well defined in clinical studies and clinicians might be neglecting this issue.
Objectives: Our aim was to investigate the presence of PN by electrophysiological methods and to examine its relationship with neuropathic pain and with treatments in patients with PsO and PsA.
Methods: 38 patients with PsA, 36 patients with PsO and 37 age&sex-matched healthy volunteers were enrolled into this prospective, single-blind study. Disease activity was assessed with Psoriasis Area Severity Index (PASI) for patients with PsO and with Disease Activity in Psoriatic Arthritis (DAPSA) score for patients with PsA. Leeds Assessment of Neuropathic Symptoms and Signs (LANSS) score was used to evaluate neuropathic pain. All participants were electrophysiologically examined in Electromyography (EMG) Laboratory by an experienced neurologist blinded for study groups.
Results: There were no significant differences on patients age, sex and body mass index among 3 study groups (p>0.05). However, disease duration was significantly longer in PsO group compared to PsA group (median 19.1[1-43] years in PsO vs median 7.5[2-29] years in PsA; p<0.01). PN was detected in 7 patients (19.44%) in the PsO group, 14 patients (34.21%) in the PsA group, and in 1 volunteer (2.7%) in the control group (PsO vs control: p<0.05; PsA vs control: p<0.001, PsO vs PsA: p>0.05) (Table 1). Among patients with PsA, 1 patient had ulnar neuropathy and 1 patient had both carpal tunnel syndrome (CTS) and sensory polyneuropathy. All other PNs detected electrophysiologically were CTS. Neuropathic pain was present in 11 patients (30.56%), 20 patients (52.63%) and in 2 volunteers (5.41%) in PsO, PsA and control groups consecutively (PsO vs control: p<0.05; PsA vs control: p<0.001, PsO vs PsA: p>0.05). PN did not show any significant correlation with disease activity or treatments including biological agents.
Conclusion: To our knowledge, this is the first study to investigate simultaneously the presence of neuropathic pain and PN by electrophysiological methods in patients with PsO and PsA. We observed PN and neuropathic pain high in patients with PsO&PsA and among them CTS appears as the most prominent neuropathy. Clinicians should keep this in mind during routine care of patients with PsO and PsA, which may improve patient-centred care. Large, prospective studies are needed to understand the characteristics of these neuropathies and its prognosis.

POS0147 ANALYSIS OF VENOUS THROMBOEMBOLIC RISK AMONG PSORIATIC ARTHRITIS PATIENTS

T. Gazitt[1], J. Pesachov[2], I. Lavi[3], M. Elias[1], A. Haddad[1], I. Feldhamer[4], A. Cohen[4], W. Saliba[3], D. Zisman[1,5]. *[1]Carmel Hospital, Rheumatology, Haifa, Israel*; *[2]Technion - Israel Institute of Technology, Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel*; *[3]Carmel Hospital, Community Medicine and Epidemiology, Haifa, Israel*; *[4]Clalit Health Organization, Chief Physician's Office, Central Headquarters,Tel Aviv, Israel*; *[2]Technion - Israel Institute of Technology, Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel*

Background: Psoriatic arthritis (PsA) is a chronic, immune-mediated, systemic inflammatory arthritis associated with comorbidities including metabolic syndrome, cardiovascular risk factors and cardiovascular disease (CVD).
Objectives: To evaluate the prevalence of venous thromboembolism (VTE) in a PsA patient cohort using a large health care provider database.
Methods: A large health care provider database serving 4.7 million healthcare subscribers was interrogated for an adult patient cohort who were newly diagnosed with PsA between January 2005 (start date) and 31 December 2018 with date of diagnosis considered the index date. A risk set was employed to randomly select 4 controls without PsA as a comparator group to the PsA cohort matched by age, sex, ethnic group, and index date. Both groups were followed from the index date until the first occurrence of VTE event, death, or end of follow-up 31 December 2019, whichever came first. Marginal model with robust covariant estimate counting for the matching was used to estimate the crude and adjusted hazard ratio (HR) for the association between PsA and VTE. Within the group of PSA patients, Cox proportional hazard regression models was used to calculate the risk of having VTE given demographic variables, SES, smoking, selected comorbidities, and conventional vs biologic disease modifying anti-rheumatic drugs (c/bDMARD). Continuous variables were summarized with mean ± standard deviation, and categorical variables were presented as numbers and proportions. All tests were 2-sided; p values of < = 0.05 were considered statistically significant. All data were analyzed using SPSS, 24 (IBM SPSS Statistics for Windows, version 24.0, 2016, Armonk, NY) and SAS, 9.4 (SAS institute Inc, Cary, NC).

Table 1. Results of peripheral neuropathy and neuropathic pain in control group and patients with PsO and PsA

	Control Group (n=37)	PsO Group (n=36)	PsA Group (n=38)	p^	p+	p&
CTS	1 (%2.70)	7 (%19.44)	13* (%34.21)	0.028[a]	<0.001[a]	0.153[a]
Ulnar Neuropathy	0	0	1 (%2.63)			
Polyneuropathy	0	0	1* (%2.63)			
Total PN	1 (%2.70)	7 (%19.44)	14 (%36.64)	0.028[a]	<0.001[a]	0.097[a]
LANSS Score	5 (0:13)	6.50 (0:16)	13 (3:19)	0.170[b]	<0.001[b]	0.004[b]
According to LANSS likely neuropathic pain	2 (%5.41)	11 (%30.56)	20 (%52.63)	0.005[a]	<0.001[a]	0.054[a]

*: Both polyneuropathy and CTS were detected in one patient in the PsA group; Data are given as n (%) and median (minimum: maximum); a: Chi-Square Test, b: Kruskal Wallis Test; p^ value: control vs PsO, p+ value: control vs PsA, p& value: PsO vs PsA

Results: The PsA cohort consisted of 5,275 patients, 53.2% females with mean age of 51.66 ±15.41. The control group consisted of 21,011 subjects matched for age and sex. In relation to the control group, the PsA cohort had a higher SES (25.1% vs 23.4%, p<0.0001), higher tobacco use (42.2% vs.39.6% p<0.0001) and obesity (33.5% vs 25.8%, p<0.0001). The study group had a statistically significant higher incidence of diabetes (33.8% vs 26.2%, p<0.0001), IHD (10.3% vs 8.6%, p<0.0001), CHF (2.2% vs 1.6%, p=0.004), hypertension (30.1% vs 26.2%, p<0.0001), CVA/TIA (4.6% vs 3.9%, p=0.024) and vascular disease (3.7% vs 3.0%, p=0.005). There were 62 patients (1.2%) diagnosed with VTE in the PsA group as opposed to 176 patients (0.8%) in the control group (p=0.023, HR=1.397, CI 1.05-1.87). The mean age of patients diagnosed with VTE was higher in the PsA group relative to controls (64.90± 13.20 vs 51.54 ± 15.41, respectively, p<0.0001), with higher age, BMI>30, cancer, IHD, vascular disease, and previous VTE found to be associated with VTE in the PsA group relative to controls in both univariate and multivariate analyses. The higher prevalence of VTE in PsA patients relative to controls did not remain statistically significant in multivariate analysis following adjustment for risk factors. Within the PsA group, patients with VTE were more often of older age and with past history of VTE. Both cDMARD and bDMARD were not associated with increased risk of VTE among PsA patients.

Conclusion: The prevalence of VTE was higher in PsA group compared to the general population, but after adjustment for comorbidities and risk factors, it no longer remained statistically significant. Among PsA patients, age and previous history of VTE were associated with increased risk of VTE. Addressing VTE risk in the management of patients with PsA is recommended especially in the era of Janus kinase inhibitors.

POS0148 MATERNAL AND NEONATAL OUTCOMES IN PREGNANT WOMEN WITH PSORIASIS AND PSORIATIC ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

W. Xie[1], H. Huang[1], Z. Zhang[1]. [1]*Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Psoriasis and psoriatic arthritis (PsA) are inflammatory diseases that affect women in their reproductive years. The evidence regarding the pregnancy outcomes in psoriasis and PsA is more limited and conflicting, to a large extent, confusing our knowledge on this topic.

Objectives: We aim to investigate whether maternal psoriasis and PsA are associated with adverse pregnancy outcomes.

Methods: We searched multiple electronic databases from inception to 3 August 2020, and reference lists of selected articles. Observational studies reporting at least one pregnancy outcomes in women with psoriasis or PsA with a comparator of general population or healthy subjects were included. Data were pooled by random-effects models (DerSimonian and Laird method) and expressed as odds ratio (OR) and 95% confidence interval (CI).

Results: Overall, 16 studies were included in the meta-analysis. The pooled analyses showed pregnant women with psoriatic diseases have significantly higher risk of adverse maternal outcomes compared with general population (caesarean delivery: 1.33 (1.17-1.52); preterm birth: 1.32 (1.15-1.52); (pre)eclampsia: 1.28 (1.14-1.43); gestational diabetes: 1.19 (1.10-1.30); gestational hypertension: 1.30 (1.18-1.44) (Figure 1). However, no statistically increased risks of fetal complications were observed in women with psoriatic diseases (small for gestational age: 1.02 (0.93-1.11); low birth weight: 1.15 (0.93-1.42); congenital malformations: 1.03 (0.93-1.14); Apgar score <7: 1.07 (0.81-1.39); neonatal mortality: 1.13 (0.90-1.43); stillbirth: 1.19 (0.95-1.50)). Subgroup analysis found similar results in women with either psoriasis or PsA regarding maternal outcomes, but the magnitude of risk estimates seems to be greater in PsA.

Conclusion: Pregnant women with psoriasis and PsA have excess risk of adverse maternal events, with seemingly higher risk in women with PsA, but not adverse neonatal events. Close monitoring of the mothers' clinical status before and during pregnancy are decidedly required in daily practice.

POS0149 MUSCULOSKELETAL PAIN IN PATIENTS WITH PSORIASIS AND THE INFLUENCE ON HEALTH-RELATED QUALITY OF LIFE: RESULTS FROM A DANISH POPULATION-BASED SURVEY

S. Kamp Felbo[1,2], L. Terslev[1,2], I. J. Sørensen[3], L. Skov[2,4], C. Zachariae[2,4], M. Østergaard[1,2]. [1]*Rigshospitalet, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark*; [2]*University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*; [3]*Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark*; [4]*Herlev and Gentofte Hospitals, Department of Dermatology and Allergy, Gentofte, Denmark*

Background: Psoriasis (PsO) impacts health-related quality of life (HRQoL). The impact of musculoskeletal (MSK) pain in patients without diagnosed psoriatic arthritis (PsA) (1) is poorly understood.

Objectives: To assess the pattern of MSK pain in patients with PsO, and its influence on important patient-reported outcomes.

Methods: A nationwide survey of patients with PsO and PsA, covering skin and MSK symptoms, healthcare contacts, self-assessed disease severity, treatment satisfaction, HRQoL (including Dermatology Life Quality Index (DLQI) and European Quality of life-5 Dimensions (EQ5D)) and disability. Respondents were grouped according to MSK pain as shown in Table 1. 'PsO previous pain' was combined with 'PsO no pain ever' (labeled 'PsO no pain now') for some analyses and with 'PsO pain now' (labeled 'PsO pain ever') for others.

Results: 561 respondents with PsO completed the questionnaire. Population and subgroup demographics, clinical PsA/PsO features and HRQoL measures are shown in Table 1. Patients in 'PsO pain now' had poorer HRQoL (higher DLQI, lower EQ5D) compared to 'PsO no pain now', and similar to patients with PsA. Patients with PsA assessed their PsO severity higher than patients with 'PsO pain ever' and 'PsO no pain ever' (median (interquartile range) 2 (2-3), 2 (1-3) and 2 (1-2) on a five-level scale, respectively). PsO treatment satisfaction (five-level scale) was lower for 'PsO pain ever' (3 (3-4)) than for 'PsO no pain ever' (4 (3-4), p=0.03). Figure 1 shows contacts to dermatologists and rheumatologists, where 72% of patients in 'PsO pain ever' had never been examined by a rheumatologist. Time from symptom debut to diagnosis was 1.5 (1-3) years for PsO and 7.5 (1.5-12.5) for PsA.

Table 1. Population and subgroup characteristics

DEMOGRAPHICS	All	PsO no pain ever	PsO previous pain	PsO pain now	PsA	p-value*		
N	561	178	104	130	108

POS0150 BEING OVERWEIGHT IS ASSOCIATED WITH NOT REACHING LOW DISEASE ACTIVITY IN WOMEN BUT NOT MEN WITH PSORIATIC ARTHRITIS

M. Mulder[1], M. Wenink[1], J. Vriezekolk[1]. [1]*Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands*

Background: Disease manifestations and outcomes of psoriatic arthritis (PsA) seem to differ between sexes. Gaining knowledge about the underlying mechanisms of these differences between men and women is important to optimize treatment strategies, especially given that women seem to less often reach low disease activity (LDA) treatment targets[1,2].

Objectives: To assess sex differences in disease activity parameters and health-related quality of life in PsA, and to assess whether determinants associated with *not* reaching treatment target differed between men and women.

Methods: A cross-sectional study was conducted, using data from a routine practice cohort of 855 patients with PsA, that were all tightly monitored and treated. Gender differences with respect to Psoriatic Arthritis Disease Activity Score (PASDAS), skin/nail disease, SF12-PCS, SF12-MCS, inflammatory backpain (IBP), and demographics were assessed. Multivariate analyses were used to examine determinants associated with *not* reaching PASDAS ≤3.2 (LDA) in men and women.

Results: Women had worse scores for - among others- swollen and tender joints, CRP, enthesitis, and function (all P<0.001). Higher PASDAS scores in women were found than in men, mean 3.5 (SD=1.5) vs 2.7 (SD=1.5), p<0.001. Likewise, women were more often not at PASDAS treatment target (OR = 2.03, P<0.001). Besides being female, also the presence of nail disease and IBP, a higher number of DMARDs used in the past or current number of DMARDs used, and a higher Body Mass Index (BMI) were associated with not reaching the treatment target in the overall sample. No differences in current medication use was found between the sexes. Table 1 shows that for women, but not men, BMI was associated with not reaching PASDAS ≤3.2 (BMI 25-30: OR =3.6, P<0.001; BMI 30-35: OR=2.41, P=0.023; BMI >35: OR=2.45, P=0.002).

Conclusion: Women with PsA in a tightly monitored and treated setting have more severe disease than men. This is demonstrated by worse scores for women in both subjective and objective disease activity measures, in addition to women less often reaching the treatment target. Notably, being overweight is associated with not reaching the treatment target in women, but not men.

POS0151

A PRACTICAL GUIDE FOR THE ASSESSMENT OF PSORIASIS BURDEN IN PATIENTS WITH PSORIATIC ARTHRITIS

F. R. Kasiem[1], A. Pasma[1], I. Tchetverikov[2], J. Luime[1], J. Hazes[1], M. Van Doorn[3], M. R. Kok[4], M. Vis[1]on behalf of CICERO. [1]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*; [2]*Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands*; [3]*Erasmus MC, Dermatology, Rotterdam, Netherlands*; [4]*Maasstad Hospital, Rheumatology & Clinical Immunology, Rotterdam, Netherlands*

Background: Rheumatologists play an important role in the management of patients with Psoriatic Arthritis (PsA). With PsA being a multifaceted disease, it can be challenging to assess the impact of psoriatic skin symptoms, next to the musculoskeletal complaints. We have previously shown that a dermatology-specific Health-related Quality of Life (HRQoL) questionnaire provides insight into the burden of skin symptoms, in contrast to a general HRQoL questionnaire.[1] When treating PsA patients, specific questions on skin symptoms are necessary in order to assess the burden of psoriasis.

Objectives: To create a set of questions that can easily identify PsA patients with a high psoriasis burden in daily rheumatology clinical practice.

Methods: Data from patients receiving usual care were used from the Dutch south west Psoriatic Arthritis (DEPAR) cohort, consisting of newly diagnosed PsA patients included between July 2013 and March 2020. The two dermatology-specific HRQoL questionnaires used were the Skindex-17 and Dermatology Life Quality Index (DLQI), both with a one-week recall period.

First, an exploratory principal component analysis (PCA) with varimax rotation was performed on both questionnaires combined, to identify underlying latent traits. Subsequently, items were dichotomized on their median frequencies. And a 2-parameter logistic (2PL) model was fitted for each latent trait. Item characteristic curves were plotted for each latent trait. Item selection took place based on the discrimination and difficulty of the items. Per latent trait, we selected 2 to 3 items distributed far apart across the latent trait. A flowchart was made with the selected questions.

Results: In total, 413 patients with completed Skindex-17 and DLQI questionnaires at baseline were included. Mean (sd) age was 50.3 (13.4) years and median (IQR) Psoriasis Area and Severity Index (PASI) score 2 (0.5-4.2). The PCA gave the best fit with two underlying clusters of questions, namely psychosocial (n=20) questions and questions regarding physical symptoms (n=7). Three questions were selected to assess psychosocial impact and two for impact of physical symptoms (Figure 1). Questions should be asked in chronological order.

Cluster 1: Psychosocial

The first question is if the patient was embarrassed by their skin condition. If answered with "never", the patient experienced the lowest burden. When answered with "rarely/sometimes" or "often/always", continue to the second question. Ask the patient if they tended to stay at home because of their skin condition. If answered with "never", they experienced a higher burden. If answered with "rarely/sometimes" or "often/always", continue to the last question. Ask the patient if their skin condition has prevented them from working or studying. If not, the patient experienced a higher burden and if answered with "yes", they experienced the highest burden in this domain.

Cluster 2: Physical symptoms

First ask the patient how itchy, sore, painful or stinging their skin was. If they answer with "not at all", they experienced the lowest burden. If answered with "a little/a lot/very much", continue to the second question. Ask if their skin was irritated. If answered with "never/rarely/sometimes", they experienced a higher burden. If answered with "often/always", the patient experienced the highest burden in this domain.

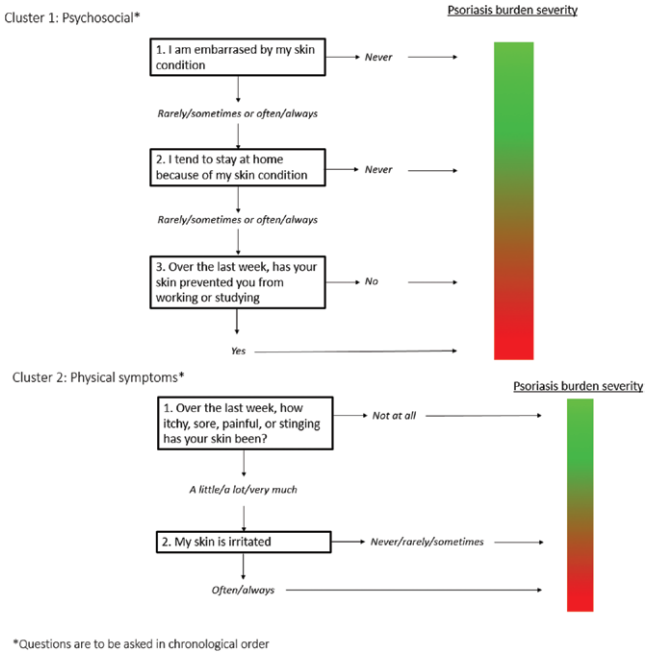

Figure 1. Flowchart of questions assessing psoriasis burden.

Conclusion: We have created a practical guide for rheumatologists to distinguish PsA patients with a high psoriasis burden from those with a lower burden. With a minimum of two and a maximum of five questions, both psychosocial burden of psoriasis and burden of physical symptoms can be easily identified in daily clinical practice.

POS0152-HPR

REMOTE CLINICAL MANAGEMENT: INCORPORATING ELECTRONIC ASSESSMENT OF PATIENTS WITH RHEUMATIC DISEASES INTO STANDARD CLINICAL PATHWAYS DURING THE COVID-19 PANDEMIC: A PILOT STUDY

T. Malley[1], J. Jackman[1], S. Manderson[1], L. Saldana Pena[1], E. Evans[1], J. Barrett[2], A. Soni[2], R. Luqmani[2]. [1]*Nuffield Orthopaedic Centre, Rheumatology, Oxford, United Kingdom*; [2]*The Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Rheumatology, Oxford, United Kingdom*

Background: Many patients with rheumatic disease require immunosuppressive medication putting them at high risk of COVID-19 infection. Reduced staffing in rheumatology due to redeployment to COVID-19 work, limited out patient capacity and patient vulnerability have had a major impact on our ability to review our patients to assess their condition and treatment (by face-to-face, video or telephone consultations). Novel strategies are essential to safely and effectively treat patients with rheumatic disease whilst minimising their risk of exposure to COVID-19 infection.

Objectives: The objective was to develop a digital solution to help deliver safe, efficient and effective care for patients with rheumatic diseases. The aim was to produce a system that allowed us to integrate data recorded directly by patients with information held in our electronic health records to provide a virtual review of care.

Methods: An online questionnaire was used to collect clinical information, including validated disease activity measures, to conduct a remote assessment in 175 patients awaiting follow-up appointments. This assessment was integrated within our electronic health records (EHR). The questionnaire contained measures of disease activity (DAS28 or BASDAI); patient reported outcomes; patient preferences regarding the urgency and type of appointment; any recent problems or changes in medication. This information was imported into a database for clinician review, together with previous clinical records and results of relevant investigations, to inform clinical decisions and to decide on the safest and most appropriate timing for follow-up. Report letters were sent to the patient and their primary care providers.

Results: Of the 175 patients (149 with RA and 26 with AS), 108 patients (89/149 [60%] with RA [mean age=64; female=65%] and 19/26 [73%] with AS [mean age=45; female=54%]) submitted responses over a 6-week period based on which clinical decisions were made. The mean questionnaire completion time was 19 minutes for RA responders and 16 minutes for AS responders. Non responders (67/175 [mean age=61; female=63%]) remained on our list of patients awaiting follow-up arrangements to be made. Sixty-nine responders (64%) had stable disease therefore did not require any changes to their treatment and were offered an appointment within the next 6 months, of whom 12 (11%) requested face-to-face follow-up. Of the remaining 39 – with less stable disease – requiring more rapid follow-up assessment, 22 patients (56%) required a face-to-face consultation to consider treatment change. So far 9 of these patients have had follow-up, of whom 6 necessitated treatment escalation (Methotrexate increase n=2; anti-inflammatory increase n=2; intramuscular steroid n=1; anti-TNF escalation n=1). Thirty-nine patients (36%) provided feedback on the process of completing the questionnaire, 85% of whom used a mobile phone and the remainder used a computer or tablet. The majority (70%) found it "extremely easy" or "somewhat

easy" to complete; remaining responses: "neutral" 20%, "somewhat difficult" 10%, "extremely difficult" 0%.

Conclusion: We have created and tested a system of remote clinical management for patients with RA and AS. Amongst the 108 responders, just 31% required a face-to-face appointment, with treatment changes made accordingly. With a backlog of 3,800 awaiting allocation to follow-up appointments, remote clinical management will allow us to safely and efficiently prioritise patients requiring urgent follow-up for treatment optimisation. We will integrate this system into our standard care pathway beyond the COVID-19 pandemic to streamline our service, deliver effective care and provide evidence to support the use of costly biologic drugs.[1] We plan to investigate the barriers for non-responders.

POS0153-HPR IDENTIFYING TARGETS FOR BEHAVIOURAL INTERVENTIONS IN FIBROMYALGIA: PHYSICAL ACTIVITY BEHAVIOUR

K. Mayana[1], Y. Prior[2]. [1]*University of Salford, School of Health and Society, Manchester, United Kingdom*; [2]*University of Salford, School of Health and Society, Salford, United Kingdom*

Background: There has been much interest in the efficacy of exercise and physical activity interventions in people with Fibromyalgia. This has resulted in guidelines recommending exercise as the first line of management (Macfarlane et al., 2017). Notwithstanding the efficacy of exercises, adherence to structured exercise and interventions aiming to increase physical activities remains a considerable challenge in this population. Exploring behavioural factors that may hinder exercise and physical activity participation in people with Fibromyalgia may help to identify targets for interventions to improve adherence and engagement with physical activities and support self-management.

Objectives: To explore people with Fibromyalgia's perspectives on the personal, social and contextual factors impacting their physical activity behaviour and pain perception.

Methods: Twelve participants with Fibromyalgia were recruited from Social Media, Fibromyalgia charities, organisations and associations across the UK. Semi-structured, one-to-one in-depth telephone interviews were conducted with each participant. Interviews were audio-recorded and transcribed verbatim. Qualitative data analysis was conducted by two researchers independently, using Thematic Analysis. Critical Realism framework was employed to inform the interpretation of the findings.

Results: Four main themes emerged from the data: (i) Lack of guidance on physical activity: most participants expressed increased pain intensity following a vigorous physical activity which, have led to spending more time on sedentary behaviour to recover from pain. (ii) Participants expressed fear of fatigue as a barrier to physical activity participation: This also led to increased sedentary and protective behaviours. (iii) Impact of treatments on physical activity: Participants who received multimodal therapies and patient education reported better coping strategies e.g., pacing physical activities and less pain. (iv): Impact of social support on physical activity participation: Participants felt that a lack of understanding from employers, their family and friends and the wider society has negatively impacted their physical activity behaviours, access to workplace support and psychological wellbeing.

Conclusion: A multimodal approach, incorporating patient education with behavioural components is essential to increase adherence to and engagement with exercise and physical activity interventions to support self-management of Fibromyalgia. There is a need to improve the public perception of this syndrome to increase social and workplace support.

POS0154-HPR FACTORS FACILITATING THE SELF- AND SHARED-MANAGEMENT OF JIA BY CHILDREN, YOUNG PEOPLE, THEIR FAMILIES, AND PROFESSIONALS INVOLVED IN THEIR CARE: A REALIST EVALUATION

S. Stones[1], V. Swallow[2], L. Milnes[1]. [1]*University of Leeds, School of Healthcare, Leeds, United Kingdom*; [2]*Sheffield Hallam University, Department of Nursing & Midwifery, Sheffield, United Kingdom*

Background: Juvenile idiopathic arthritis (JIA) is a long-term condition, often requiring some element of lifelong management. Therefore, it is logical that children and young people are empowered to become competent at self-managing their health and wellbeing, while families are supported in their shared-management role during childhood, relinquishing control at age- and developmentally appropriate periods in their child's development. However, there are limited theoretical foundations underpinning optimal self- and shared-management support for children, young people and families living with JIA.

Objectives: To explain the factors facilitating the self- and shared-management of JIA by children, young people, and their families, with professional support from healthcare professionals, third sector organisations, and education professionals.

Methods: Guided by the Individual and Family Self-management Theory and the Shared Management Model, a three-stage realist evaluation was undertaken: 1) initial JIA self- and shared-management question theories were elicited from a document review, integrative review, and stakeholder insights [1]; 2) seven initial question theories were tested using qualitative research methods with 20 participants (young people, families, healthcare professionals, education professionals, and third sector representatives); 3) analysis of findings using a theory-driven approach to thematic analysis, in order to identify demi-regularities to extend or refute the initial question theories. The analysis drew on deductive, inductive, and retroductive reasoning.

Results: There were six refined JIA self- and shared-management question theories: 1) meaningful and bespoke self-management support across the life course for children and young people with JIA; 2) recognised and valued shared-management support for the families of children and young people with JIA, with autonomy in mind; 3) individual healthcare plans as a shared management communication tool to facilitate optimal management of JIA; 4) consistent recognition, value, and encourage of self- and shared-management support from the paediatric rheumatology multi-disciplinary team and associated professionals; 5) child, young-person, and family-focused paediatric rheumatology care and support services across the lifecourse; and 6) bespoke and inclusive approaches by education providers to enable children and young people with JIA to feel safe, supported, and able to fulfil their potential.

Conclusion: There is an increasing recognition of the importance of self- and shared-management of JIA. However, there is a lack of an overall, cohesive approach to self- and shared-management between healthcare providers, education providers, and the third sector. Findings from this study illuminate the factors facilitating JIA self- and shared-management at individual, interpersonal, institutional and infrastructural levels. Further work is required to empirically test these refined question theories with interventions designed to enhance JIA care, education, and support.

POS0155-HPR DIAPHRAGMATIC BREATHING RELAXATION TECHNIQUE TO DECREASE ANXIETY DURING JOINT INFILTRATION: A RANDOMIZED CONTROLLED TRIAL

R. Ben Aissa[1,1], S. Boussaid[2], H. Tbini[2], H. Sahli[1], S. Jemmali[1], S. Rekik[1], M. El Euch[2]. [1]*Rabta Hospital, Department of Rheumatology, Tunis, Tunisia*; [1]*Rabta Hospital, Department of Rheumatology, Tunis, Tunisia*

Background: Joint infiltration is the injection of therapeutic substances directly into a joint. It may be a stressful experience for patients as imagined different from other usual injections. Several techniques are used to manage anxiety and pain during such a procedure.

Objectives: To evaluate the effectiveness of diaphragmatic breathing relaxation on reducing anxiety and pain during joint infiltration.

Methods: Patients scheduled for a joint infiltration at the rheumatology department's daycare unit were recruited. All infiltrations were performed using steroids without anesthetic therapy except for the hip. Patients were randomized into two groups (cases=38, controls=34). Cases learned from a trained health agent diaphragmatic breathing relaxation technique to perform it immediately before and during the procedure while controls received the usual procedure. We used the Visual Analogue Scale (VAS) to assess self-estimated both anxiety (VAS-Anx) and pain (VAS-Pain) as evaluated on pre and post-joint infiltration. VAS-Pain was evaluated as expected then as experienced respectively on pre and

post-infiltration. We also assessed heart rate and blood pressure on pre and post-procedure.
Results: Seventy-two participants were included with a mean age of 55.48 ± 12.39 years (39-78), treated for an inflammatory rheumatic or degenerative disease (21, 51 respectively), and receiving joint infiltration for the first time among 37. Sites of infiltrations were: wrist=7, elbow=10, shoulder=17, hip=1, knee=22, epidural=6, plantar heel=9. There were no significant differences in pre-procedural
VAS-Anx, VAS-pain, or physiological parameters between cases and controls. Cases had a significant decrease in VAS-Anx from pre to post-infiltration (Mean post-VAS-Anx=23.33/100, p=0,017) but not significant compared with controls (p=0.297). Patients who have performed the breathing technique had no significant decrease in VAS-Pain from pre- to post-infiltration (p=0.083) and compared with controls (p=0.662). Physiological parameters showed a significant decrease in heart rate of cases from pre to post-infiltration (p<0,0001) and compared with controls (p=0,036), but no significant decrease in systolic or diastolic blood pressure from pre to post-infiltration and compared with controls. There were no correlations between all participants' VAS-Anx/VAS-Pain and age, gender, infiltration site or history and joint pain causes.
Conclusion: This study suggests that diaphragmatic breathing relaxation is an effective nonpharmacological intervention that could be used in controlling anxiety and experienced pain during joint infiltration.

POS0156-HPR 'THE RIGHT ADVICE, IN THE RIGHT WAY AND AT THE RIGHT TIME': AN INNOVATIVE MULTIDISCIPLINARY APPROACH TO ADDRESS CLIENT-IDENTIFIED PARTICIPATION NEEDS IN EARLY INFLAMMATORY ARTHRITIS

Y. Codd[1,2], R. Mullan[2], D. Kane[2], A. Coe[2], T. Stapleton[1]. *[1]Trinity College Dublin, Discipline of Occupational Therapy, School of Medicine, Dublin, Ireland*; *[2]Naas General & Tallaght University Hospitals, Rheumatology, Dublin, Ireland*

Background: Inflammatory arthritis (IA) is a complex life-long disease with negative consequences on occupational performance and significant impact on meaningful life roles. International guidelines for the clinical management of IA consistently recommend early intervention and a multidisciplinary (MDT) approach as the optimum method to address the medical, symptom and broader life impacts, however, barriers to timely access to the MDT is a common issue in clinical practice. Limited research has explored how clinical services support broader life impacts and participation restrictions associated with early disease as part of routine healthcare. Four rheumatology services in Ireland have recently reconfigured to provide an MDT-led early arthritis service which operates in parallel to traditional medical clinics. Staffed by nurses, occupational therapists, and physiotherapists this service provides assessment and management to clients with a new diagnosis of IA along a model of care within four to six weeks of diagnosis with mechanisms to follow the client over their first year of diagnosis.
Objectives: To explore how a novel MDT-led early arthritis service addresses client-identified participation restrictions associated with early IA.
Methods: A qualitative description (QD) study was used to explore the perspectives of service providers and service users of this MDT-led early arthritis service. Data were gathered using one-off focus groups with service providers, and individual interviews with service users.
Results: All staff (n=15) currently working in these services participated in the focus groups. Forty-three service users with IA participated in individual interviews (males n=12: females n=31); diagnosis duration ranged from 5 to 24 months. QD principles and thematic analysis were used in data analysis.
Extensive limitations in everyday activity and restriction in participation in meaningful, age-appropriate life roles in early IA were outlined by service users and service providers. Participants described how the MDT-led model provided automatic and immediate access to services focussed on identification and management of occupation-based participation restrictions early in the disease. Participants described how the model used a flexible approach that ensured; ease of early access to a full MDT, prolonged support from the MDT, and a person-centred approach incorporating social prescribing and self-management principles. Service users emphasised the strength of the MDT approach of providing 'the right advice, in the right way and at the right time' as the most influential feature that assisted them to address participation restrictions and support positive health outcomes. This was accomplished by the service providers acting in a coordinated and interdisciplinary manner with a clear remit to address participation restrictions alongside the traditional symptom management approach. Findings highlight the feasibility of the MDT-led early arthritis model as an approach to address participation-based restrictions as part of routine healthcare that delivers on the rheumatology guidelines and was positively regarded by both service users and service providers.
Conclusion: Findings provide important insights into the role of an innovative early MDT intervention approach in addressing client-identified participation needs in early IA. This model maps onto the Irish rheumatology model of care (HSE, 2018), 'right place, right time' approach but importantly includes a 'right way' approach which is identified as influential in the effective delivery of client-focussed and client-centred care.

POS0157-HPR CONSTRUCT VALIDITY OF THE OCTOPUS STRATIFICATION ALGORITHM FOR ALLOCATING PATIENTS WITH KNEE OSTEOARTHRITIS INTO CLINICALLY RELEVANT SUBGROUPS

J. Knoop[1], R. Ostelo[1], M. Van der Esch[2], A. De Zwart[2], K. Bennell[3], M. Van der Leeden[2,4], J. Dekker[4]. *[1]Vrije Universiteit Amsterdam, Health Sciences, Amsterdam, Netherlands*; *[2]Reade, Centre for Rehabilitation and Rheumatology, Amsterdam, Netherlands*; *[3]University of Melbourne, School of Health Sciences, Department of Physiotherapy, Melbourne, Australia*; *[4]Amsterdam UMC (VUmc), Department of Rehabilitation, Amsterdam, Netherlands*

Background: We recently developed a model of stratified exercise therapy [1], consisting of (i) a stratification algorithm allocating patients with knee osteoarthritis (OA) into clinically relevant subgroups, and (ii) subgroup-specific exercise therapy. More specifically, in our model we distinguish the following subgroups with proposed underlying phenotypes: 'high muscle strength subgroup' representing a post-traumatic phenotype, 'low muscle strength subgroup' representing an age-induced phenotype and 'obesity subgroup' representing a metabolic phenotype.
Objectives: In the present study, we aimed to validate the construct of this algorithm, focusing on 3 research questions: (i) are the proportions of patients in each subgroup similar across cohorts?; (ii) are the characteristics of each of the subgroups in line with their proposed underlying phenotypes?; (iii) are the effects of usual exercise therapy in the 3 subgroups in line with the proposed effect sizes?
Methods: Data from five studies (four trials and one cross-sectional cohort) were used to validate the construct of our algorithm by 63 a priori formulated hypotheses regarding the research questions.
Results: Baseline data from a total of 1,211 patients with knee OA were analyzed for the first and second research question, and follow-up data from 584 patients who were part of an exercise arm within a trial for the third research question. In total, the vast majority (73%) of the hypotheses were confirmed. Regarding our first research question, we found similar proportions in each of the three subgroups across cohorts, especially for three cohorts. Regarding our second research question, subgroup characteristics were almost completely in line with the proposed underlying phenotypes. Regarding our third research question, unexpectedly, usual exercise therapy resulted in similar, moderate to large effect sizes for knee pain and physical function for all three subgroups.
Conclusion: This study suggests that our algorithm might be a valid instrument to allocate patients with knee OA into clinically relevant subgroups, as most of our a priori hypotheses could be confirmed. On the other hand, subgroups did not differ substantially in effects of usual exercise therapy, contrary to our expectation. An ongoing trial [1] will assess whether this algorithm accompanied by subgroup-specific exercise therapy improves clinical and economic outcomes.

POS0158-HPR UNDERSTANDING NURSE-LED CARE IN EARLY RA: INTERVIEW STUDY WITH RHEUMATOLOGY NURSE SPECIALISTS

A. M. T. Sweeney[1], J. Robson[1], C. Flurey[1], P. Richards[1], C. Mccabe[1], M. Ndosi[1]. *[1]University of the West of England, Faculty of Health and Applied Sciences, Bristol, United Kingdom*

Background: Nurse-led care in early RA is not well defined in the literature and the current recommendations.
Objectives: This study aimed to develop an understanding of what comprises nurse-led care in early RA from the perspective of rheumatology nurse specialists.
Methods: This was a qualitative study using semi-structured telephone interviews with rheumatology nurse specialists in England (Summer 2020). Interviews were audio-recorded, transcribed verbatim and analysed using inductive thematic analysis.[1]
Results: Sixteen nurses were recruited and interviews lasted between 30 to 60 minutes. Seven themes were identified.
Early disease management
Care was characterised by evidence-based RA management provided by experienced nurse specialists with a high degree of autonomy, in the context of a rheumatology multidisciplinary team. The aims of care were to: start treatment, keep in treatment, educate and support.
'So treat to target...escalating treatment as necessary, and addressing any concerns that the patients might have' (CNS14)
Addressing psychosocial needs
Patients with early RA experience shock, fear, anger, grief and denial while feeling unwell with pain and fatigue. Nurses use a holistic, person-centred and empathetic approach to address psychosocial needs, building a working relationship, listening and creating trust.
'Because it all relates, and if they're stressed because they're not coping at work, then their arthritis isn't going to be so good. So everything relates to one another really' (CNS06)
Monitoring treatment, disease impact and patient outcomes
Nurses monitor disease activity and disease impact using validated outcome measures and by asking questions during the consultation. Good outcomes are disease control, managing disease impact, medication and side effects, wellbeing and keeping in work.
'When you get them stable, when you get them into remission, when they're happy, when they're feeling well, I think there's lots of ways you can measure that'… (CNS13)
Coordinating care, referring and signposting
Nurses coordinate care, refer to other health professionals and signpost patients to relevant services and charities. Lack of access to psychology expertise was highlighted.
'And whilst most of us have got some degree of understanding of…self management, or psychology…we're not psychologists' (CNS02)
Providing a 'lifeline'
Nurse-led telephone advice services provide a 'lifeline' for patients. If patients struggle, they can call and speak with a specialist who knows them and their RA well.
'The advice line has been a lifeline to them, to be able to speak to someone, to be able to get a response quickly to their questions, they feel very well supported, they know that they can always call us' (CNS16)
Service evaluation and auditing
The individual clinics are reviewed regularly. Patients are asked for feedback on their experience of appointments, if their needs were met and about changes to the service.
...'It's really important to ask them initially what they expect to have from the consultation...We've always had really good feedback in general'… (CNS02)
COVID-19 challenges and opportunities
The pandemic caused major disruptions to the services, prohibiting most face-to-face consultations which was an essential aspect of clinical assessments. Despite the challenges imposed by the pandemic, the services adapted fast, using telephone, video clinics and digital solutions, which streamlined procedures and improved documentation and communication.
'I do have to rely on them telling me what's going on, because I can't see it at the moment' (CNS14)
'With Covid we're doing it over the telephone, and we're getting them to watch the video [injection tutorial] before we have the appointment with them' (CNS04)
Conclusion: Nurse-led care in early arthritis is a specialist service, addressing complex needs of patients, using evidence based and person-centred approaches. Innovation and service improvement are seen as part of the role.

POS0159-HPR IMPACT OF SLEEP DISTURBANCES ON ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

M. Sellami[1], O. Hamdi[1], S. Miladi[2], A. Fazaa[2], L. Souabni[2], K. Ouenniche[2], S. Kassab[2], S. Chekili[2], K. Ben Abdelghani[2], A. Laatar[2]. [1]*Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia*; [1]*Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia*

Background: Sleep disturbances have been reported in various rheumatic diseases especially in the elderly. It may be caused by pain and depressive mood. However, reports on the impact of sleep problems in rheumatoid arthritis (RA) activity and functional status were limited.
Objectives: To assess sleep quality in elderly patients with RA and its impact on disease activity and functional status.
Methods: This cross-sectional study included 70 RA patients aged ≥ 65 years fulfilling the ACR/EULAR criteria. Sociodemographic data were collected. RA activity was assessed with the Disease Activity Score (DAS_{28}) and functional status with the Health Assessment Questionnaire (HAQ). Sleep quality was assessed using Arabic translated versions of two indexes: the Insomnia Severity Index (ISI) and the Pittsburg Sleep Quality Index (PSQI). An ISI score of [8-14], [15-21], and [22-28] determined respectively mild, moderate, and severe insomnia. A PSQI score > 5 determined poor sleep quality. ANOVA test was used to assess the relationship between DAS_{28} erythrocyte sedimentation rate (ESR), HAQ, and sleep quality indexes.
Results: This study included 52 females and 18 males with a mean age of 68.3 ± 25 years [65-81]. Seventy percent of patients were married, 27% were widowed and 2% were divorced. Seventy-one percent of patients were illiterate, 18% had primary education and 11% had secondary education. Eighteen percent of patients were employed whereas 34.7% were retired. A history of depression was noted in 16.5% of patients. The mean duration of RA was 17.4 ± 5.2 years. Eighty-five percent of patients were on conventional synthetic DMARD whereas 15% were treated with biologic treatment. The mean patient's global assessment of disease activity was 5.2 ± 1.3. The mean tender joint count and mean swollen joint count were 8 ±1.5 and 5 ±1 respectively. The mean DAS_{28} ESR was 4.7 ±0.9. The mean HAQ was 2.4 ± 0.45. Poor sleep quality was detected in 84% of cases according to the PSQI score. Mild insomnia was detected in 46% of cases, moderate insomnia in 34% of cases, and severe insomnia in 12% of cases. RA activity was higher in patients with poor sleep quality: the mean DAS_{28} ESR was 5.2 in patients with severe insomnia, 4.82 in moderate insomnia, and 4.13 in mild insomnia; p= 0.00 respectively. The mean ESR was 31.5 mm in patients with severe insomnia, 22.1 mm in moderate insomnia, and 10.6 mm in mild insomnia; p= 0.01 respectively. Furthermore, the higher the PSQI was, the higher DAS_{28} ESR is (p =0.01). However, no association was found between poor sleep quality and joint count, swollen joint count, CRP, and HAQ.
Conclusion: Disease activity was a major contributor to poor sleep quality in elderly patients with RA. Functional status however wasn't associated with insomnia. Physicians should include sleep in the clinical assessment of RA patients to improve their quality of life.

POS0160-HPR THE CARE PROCESS OF HIP AND KNEE OSTEOARTHRITIS: GIVING AN ACCOUNT OF PATIENTS' EXPERIENCE

S. Battista[1,2], M. Manoni[1], A. Dell'isola[2], M. Englund[2], A. Palese[3], M. Testa[1]. [1]*University of Genova, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Savona, Italy*; [2]*Lund University, Clinical Epidemiology Unit, Orthopedics, Department of Clinical Sciences, Lund, Sweden*; [3]*University of Udine, School of Nursing, Department of Medical Sciences, Udine, Italy*

Background: The care process is often a complex and intimate process experienced by patients. Osteoarthritis (OA) care is usually characterised by multimodal interventions that consider the broader array of symptoms and functional limitations and often require a high level of patients' compliance. Despite efforts to improve the quality of care of patients suffering from OA, and the publication of state-of-the-art clinical practice guidelines [1], the quality of the care process, as experienced by patients, seems to be suboptimal [2]. Hence, it is essential to investigate how patients experience this process to highlight potential elements that can enhance or spoil it to optimise the care quality.
Objectives: To explore the patients' experience of the received OA care process.
Methods: Qualitative study, 10 semi-structured interviews were performed. The interview guide was created by a pool of healthcare professionals (physiotherapists, psychologists, nurses) and expert patients. It investigated the emotional experience, beliefs, expectations, perceived barriers and facilitators towards conservative treatments perceived by patients suffering from OA. The interviews lasted approximately one hour, were transcribed verbatim and analysed independently by two authors, who labelled their core parts to find categories and subcategories. A theme-based analysis was performed following an ecological paradigm, naturalistic epistemology, philosophy of phenomenological research.
Results: Our analysis revealed 7 main categories with several subcategories (Fig. 1). 1) *Uncertainty* as some patients perceived treatment choice not to be

based on medical evidence "there is an almost religious way of thinking on how to deal with the pathology. It is not an exact science when you choose the physicians you choose the treatment". 2) *Relationship with the self and the others* as some patients did not feel understood or even shameful and hopeless about their condition. 3) *Patients' and Health Professionals' beliefs about the pathology management* where common thoughts were the perceived (ab)use of passive therapies, the movement as something dangerous and that OA is "something that you try to resist to, but (surgery) is your destiny". 4) *facilitators and 5) barriers of the adherence to therapeutic exercise* that revolve around the cost of the therapy, the time needed and the willingness to change life habits. 6) *Patients' attitudes towards pathology* in which the oldest patients perceive OA as "something I have to accept since I am getting old" and the youngest as "Something I have to fight". 7) *Relationship with food* in which diet is seen as something that "you force yourself to follow" which is useful only to lose weight and not to preserve a high health status and where overeating is used "to eat your feelings".

Conclusion: Patients suffering from hip and knee OA seem to experience an uncertain care process. The lack of clear explanations and the attitude towards conservative treatment, which is considered as "a pastime while waiting for surgery," fosters the importance of providing patients with adequate information about the treatment, to shift their beliefs and improve their awareness. This will enhance a patient-centred and shared decision-making treatments.

POS0161-HPR BARRIERS AND FACILITATORS RELATED TO SELF-MANAGEMENT OF SHOULDER PAIN: A SYSTEMATIC REVIEW AND QUALITATIVE SYNTHESIS

A. O'shea[1], J. Drennan[2], C. Littlewood[3], H. Slater[4], J. Sim[5], J. Mcveigh[1].
[1]*University College Cork, Discipline of Physiotherapy, College of Medicine and Health, Cork, Ireland*; [2]*University College Cork, School of Nursing and Midwifery, College of Medicine and Health, Cork, Ireland*; [3]*Manchester Metropolitan University, Department of Health Professions, Faculty of Health, Psychology & Social Care, Manchester, United Kingdom*; [4]*Curtin University, School of Physiotherapy and Exercise Science, Perth, Australia*; [5]*Keele University, School of Medicine, Faculty of Medicine and Health Sciences, Keele, United Kingdom*

Background: Shoulder pain is a significant cause of pain and disability in the general population.[1] Current research suggests that shoulder pain can be resistant to treatment and is often recurrent.[2] Systematic review-level evidence shows modest short-term benefits for most current treatments.[3] Effective self-management strategies that equip patients with the necessary tools to self-manage their condition are urgently required. However, engagement with self-management is poor, potentially compromising treatment outcomes and contributing to ongoing disability.[4]

Objectives: The objectives of this review were to:

• Systematically identify and appraise relevant qualitative evidence on barriers and facilitators relating to self-management from the perspectives of people with shoulder pain and healthcare professionals.

• Collate and synthesise this evidence, to gain an understanding of factors that influence self-management of shoulder pain.

• Develop evidence-based recommendations to inform the implementation and delivery of self-management programmes for shoulder pain.

Methods: A meta-aggregative approach to the synthesis of qualitative evidence was used. Twelve databases were searched, from inception to 13 July 2020, to identify studies exploring barriers and facilitators related to self-management of shoulder pain from the perspectives of people with shoulder pain and clinicians involved in the care of such patients. Two independent reviewers identified eligible articles, extracted the data and conducted critical appraisal. Two reviewers independently identified and developed categories, with validation by two further researchers. Categories were discussed among the wider research team and a comprehensive set of synthesized findings was derived.

Results: Sixteen studies were included in the review, exploring several shoulder conditions: shoulder instability; rotator cuff-related pain; dysfunction post rotator cuff surgery; and degenerative rotator cuff tears. From the perspective of patients, three synthesized findings were identified that influenced self-management: (1) support for self-management, including subthemes related to patient-centred support, knowledge, time, access to equipment, and patient digital literacy; (2) personal factors, including patient beliefs, patient expectations, patient motivation, pain, and therapeutic response; and (3) external factors, including influence of the clinician and therapeutic approach. From the perspective of clinicians, two synthesized findings were identified that influenced adherence to self-management: (1) support for self-management, including education, patient-centred support, patient empowerment, time, and clinician digital literacy; and (2) preferred management approach, including clinician beliefs, expectations, motivation, therapeutic approach, and therapeutic response.

Conclusion: Patients and clinicians identified several barriers and facilitators that influenced self-management of shoulder pain. Clinicians' awareness of these factors could positively influence patient management, enhance patients' ability to self-manage, and improve treatment outcomes.

POS0162 PREDICTIVE FACTORS OF A NEW FRAGILITY FRACTURE AFTER WRIST FRAGILITY FRACTURE

S. Azevedo[1], H. Parente[1], D. Esperança Almeida[2], F. Guimarães[1], J. Rodrigues[1], D. Faria[1], D. Peixoto[1], J. Tavares-Costa[1], C. Afonso[1], F. Teixeira[1].
[1]*Unidade Local de Saúde do Alto Minho, Rheumatology Department, Ponte de Lima, Portugal*; [2]*Hospital de Braga, Rheumatology Department, Braga, Portugal*

Background: Fragility fractures (FF) are fractures that result from mechanical forces that would not ordinarily result in fracture, known as low-level (or 'low energy') trauma.[1] Studies have shown that history of wrist fracture increases the risk for subsequent FF.[2]

Objectives: To assess predictive factors of FF occurring after a wrist fracture.

Methods: Retrospective monocentric study that included patients with a wrist FF observed at the emergency department (ED) in a tertiary center, between 1st January 2017 and 31st December 2018. Wrist fractures were identified through the 10th International Classification of Diseases and FF were identified after revision of the clinical record. Patients with relevant missing data were excluded. Seven hundred thirty-three wrist FF were identified. After calculating a representative sample (90% confidence interval), 188 patients were included. Their clinical records until 31th December 2020 (2 to 3 years after FF) were reviewed. SPSS was used for statistical analysis and significance level was defined as 2-sided $p<0.05$. In multivariate analysis we included variables with a significant association in univariate analysis and those with clinical relevance (reported in others studies).

Results: Wrist fractures represented 44.3% of the FF observed at the ED.

Most patients were woman (83.5%) with a mean age of 70.7 (SD=11.2) years-old at the time of their wrist fracture. A previous FF was seen in 22.9% of patients and 13.3% had a new FF during the follow-up period.
We found an association between the occurrence of a new FF and the number of comorbidities (p=0.012), number of visits to the ED due to falls (p<0.001), previous diagnosis of chronic pulmonary disease (p=0.029) and hematologic pathologies (p=0.047), and the need for hospitalization at time of the wrist FF (p=0.018). No associations were found between the age at the wrist fracture time, number of drugs taken daily nor its type (anxiolytics, antiepileptics, corticoids), previous fractures (and localization), overweight/obesity and other cardiovascular risk factors, endocrinopathies, psychiatric or neurologic disease or other comorbidities.
After adjustment for age, gender, anti-osteoporotic treatment and comorbidities, the main predictors of a new FF were visits to the ED for falls (p=0.005), chronic pulmonary disease (p=0.040), hematologic pathologies (p=0.004) and need for hospitalization (p=0.040) (table 1).

Table 1. Multivariate analyses: linear multiple regression for predictive factors of new fragility fracture.

Determinants	Unstandardized Coefficients B	Standardized Coefficients Beta	95.0% CI	p-value
Age	-0.025	0.975	0.924 – 1.030	NS
Gender	2.065	7.889	0.757 – 82.165	NS
Number of comorbidities	0.186	1.204	0.846 – 1.713	NS
Visits to the emergency service for falls	-2.136	0.118	0.026 – 0.529	0.005
Chronic pulmonary disease	-1.326	0.266	0.075 – 0.940	0.040
Hematologic pathologies	-4.296	0.014	0.001 – 0.255	0.004
Need for hospitalization	-2.764	0.063	0.004 – 0.887	0.040
Anti-osteoporotic treatment	0.157	1.170	0.227 – 6.017	NS

CI: Confidence Interval; NS: non-significant;

Conclusion: Certain comorbidities seem to be associated with new FF. Patients with visits to the emergency service after falls and those who needed hospitalization due to the wrist fracture were more prone to have a new FF. There might be a substantial missed opportunity for intervention in these patients.

POS0163 INCIDENT FRACTURE RISK PREDICTION USING THE FRAGILITY SCORE CALCULATED BY LUMBAR SPINE RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) SCANS

D. Ciardo[1], P. Pisani[2], F. A. Lombardi[2], R. Franchini[2], F. Conversano[2], S. Casciaro[2]. *[1]National Research Council, Institute of Clinical Physiology, Lecce, Italy*; *[1]National Research Council, Institute of Clinical Physiology, Lecce, Italy*

Background: The main consequence of osteoporosis is the occurrence of fractures due to bone fragility, with important sequelae in terms of disability and mortality. It has been already demonstrated that the information about bone mass density (BMD) alone is not sufficient to predict the risk of fragility fractures, since several fractures occur in patients with normal BMD [1].
The Fragility Score is a parameter that allows to estimate skeletal fragility thanks to a trans-abdominal ultrasound scan performed with Radiofrequency Echographic Multi Spectrometry (REMS) technology. It is calculated by comparing the results of the spectral analysis of the patient's raw ultrasound signals with reference models representative of fragile and non-fragile bones [2]. It is a dimensionless parameter, which can vary from 0 to 100, in proportion to the degree of fragility, independently from BMD.
Objectives: This study aims to evaluate the effectiveness of Fragility Score, measured during a bone densitometry exam performed with REMS technology at lumbar spine, in identifying patients at risk of incident osteoporotic fractures at a follow-up period of 5 years.
Methods: Caucasian women with age between 30 and 90 were scanned with spinal REMS and DXA. The incidence of osteoporotic fractures was assessed during a follow-up period of 5 years. The ability of the Fragility Score to discriminate between patients with and without incident fragility fractures was subsequently evaluated and compared with the discriminatory ability of the T-score calculated with DXA and with REMS.
Results: Overall, 533 women (median age: 60 years; interquartile range [IQR]: 54-66 years) completed the follow-up (median 42 months; IQR: 35-56 months), during which 73 patients had sustained an incident fracture.
Both median REMS and DXA measured T-score values were significantly lower in fractured patients than for non-fractured ones, conversely, REMS Fragility Score was significantly higher (Table 1).

Table 1. Analysis of T-score values calculated with REMS and DXA and Fragility Score calculated with REMS. Median values and interquartile ranges (IQR) are reported. The p-value is derived from the Mann-Whitney test.

	Patients without incident fragility fracture	Patients with incident fragility fracture	p-value
T-score DXA [median (IQR)]	-1.9 (-2.7 to -1.0)	-2.6 (-3.3 to -1.7)	0.0001
T-score REMS [median (IQR)]	-2.0 (-2.8 to -1.1)	-2.7 (-3.5 to -1.9)	<0.0001
Fragility Score [median (IQR)]	29.9 (25.7 to 36.2)	53.0 (34.2 to 62.5)	<0.0001

By evaluating the capability to discriminate patients with/without fragility fractures, the Fragility Score obtained a value of the ROC area under the curve (AUC) of 0.80, higher than the AUC of the REMS T-score (0.66) and of the T-score DXA (0.64), and the difference was statistically significant (Figure 1).

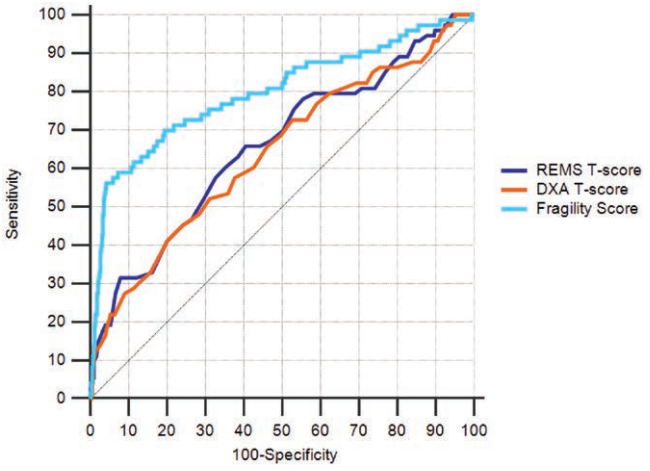

Figure 1. ROC curve comparison of Fragility Score, REMS and DXA T-score values in the classification of patients with incident fragility fractures.

Furthermore, the correlation between the Fragility Score and the T-score values was low, with Pearson correlation coefficient *r*=-0.19 between Fragility Score and DXA T-score and -0.18 between the Fragility Score and the REMS T-score.
Conclusion: The Fragility Score was found to be an effective tool for the prediction of fracture risk in a population of Caucasian women, with performances superior to those of the T-score values. Therefore, this tool presents a high potential as an effective diagnostic tool for the early identification and subsequent early treatment of bone fragility.

POS0164 THE NEED FOR ANTI-OSTEOPOROTIC INTERVENTION IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS BASED ON THE FRACTURE RISK ASSESSMENT

O. Dobrovolskaya[1], A. Feklistov[1], O. Nikitinskaya[1], A. Efremova[1], N. Toroptsova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation*

Background: Rheumatoid arthritis (RA) is a chronic disabling disease that is associated with bone loss. Previous studies estimated that approximately

one-third of the RA patients had osteoporosis (OP). However, most fragility fractures occur in patients not suffering from OP, that can be partly explained by impaired quality of bone, which is not measured with DXA. Therefore, only the measurement of bone mineral density is not sufficient to determine the indication for OP treatment. Another tool for assessing the need for anti-osteoporotic therapy is to calculate the 10-year probability of a major fracture using the fracture risk assessment tool (FRAX).

Objectives: To assess the need for anti-osteoporotic therapy in women with rheumatoid arthritis (RA) based on the identification of individuals with fragility fractures and high risk of fracture according to FRAX.

Methods: 295 postmenopausal women with RA were included in the study. The average age was 63±7 years, the duration of RA was 11 [4;16] years, the duration of postmenopausal period was 13 [6; 20] years. 121 (41%) patients took glucocorticoids (cumulative dose 9025 [3650; 20720] mg in prednisolone equivalent). A survey was conducted to identify patients with risk factors and a history of fragility fractures. The 10-year probability of a major osteoporotic fracture was assessed using the FRAX tool. In patients treated with glucocorticoids at a dose >7.5 mg in prednisolone equivalent the estimates of probabilities of a major osteoporotic fracture were adjusted in accordance with the recommendations [1]. Dual-energy X-ray absorptiometry (DXA) of the proximal femur was performed in patients with a moderate risk (probabilities between the upper and lower assessment age-dependent intervention threshold) and the risk of fracture was recalculated with including femoral neck BMD.

Results: 83 (28.1%) patients had a prior fragility fracture: 44 (14,9%) – 1, 20 (6,8%) – 2 and 19 (6.4%) – 3 or more. Vertebral fractures were the most common, they accounted for 62,1% of all fractures, distal forearm was the second frequent fractures localization (18.2%). Only 2 (0.7%) women had hip fracture. The average 10-year probability of a major osteoporotic fracture was 17 % [11; 28] in RA women. 92 (31.2%) persons were at high risk, 28 (9.5%) patients - at low risk, and 175 (59.3%) - at moderate risk. After recalculation of fracture risk with including femoral neck BMD in people at moderate risk 48 (16.3 %) patients became at high risk, 9 (3.1%) – at very high risk, and 118 (40.0%) - at low risk.

Thus, 149 (50.5%) RA patients were at very high or high risk and 146 (49,5%) – at low risk of major osteoporotic fracture according to FRAX, among the last – only 3 persons had a history of fragility fracture after age of 40 years.

Conclusion: Our study demonstrated that a half of postmenopausal women with RA had indications for anti-osteoporotic treatment based on the results of a 10-year probability of major fragility fractures using FRAX tool.

POS0165 STUDY OF VERTEBRAL AND FEMUR FRACTURE PREVALENCE AND SCANOGRAPHIC BONE ATTENUATION COEFFICIENT OF THE FIRST LUMBAR VERTEBRA IN AN ACADEMIC HOSPITAL SETTING

Z. Vaghaiwalla[1], P. Wasserman[2], G. Kaeley[1]. [1]*University of Florida College of Medicine- Jacksonville, Rheumatology, Jacksonville, United States of America*; [2]*University of Florida College of Medicine- Jacksonville, Radiology, Jacksonville, United States of America*

Background: Patients with osteoporosis are prone to suffer fragility fractures leading to an increased risk of future fractures. Detection of osteoporosis has been led by dual energy-ray absorptiometry (DEXA) as the gold standard. However, in acute fracture incidents, DEXA imaging is typically unavailable, and treatment is often delayed. In recent years scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1) on incidental computed tomography (CT) scans of the lumbar spine has been utilized as an alternative assessment of bone density. In particular, SBAC-L1 ≤ 145 HU correlates with osteoporotic bone density on DEXA imaging.[2]

Objectives: This study aims to assess the SBAC-L1 in HU of incidental CT scans in patients presenting with vertebra or femur fragility fractures in an academic hospital as it relates to osteoporosis.

Methods: We conducted a retrospective chart review of patients aged ≥ 45 admitted to an academic hospital for active vertebral or femur fracture between 1/1/2017- 1/31/2019, excluding traumatic and pathological fractures. Measurement of SBAC-L1 in HU was obtained on incidental CT scan imaging.

Sex, race, prior and post diagnoses of osteoporosis, prior and post DEXA scan orders, use of calcium, vitamin D, and steroids were abstracted.

Results: There were 297 patients with vertebral or femur fractures from 1/1/2017-1/31/2019. Of 297 patients, 85 deemed appropriate after excluding pathological, traumatic fractures, and lack of CT scan on the admission for fracture.

Average SBAC-L1 for all patients was 100.4 ± standard deviation (SD) of 46.5 HU. 82% of all patients had SBAC-L1 ≤ 145 HU. Caucasian patients had a lower average SBAC-L1 [99.4 HU] than African American (AA) patients [122.1 HU]. More Caucasian [n=15] had prior diagnoses of osteoporosis than AA [n=2]. Caucasian patients were prescribed Calcium and Vitamin D more often [n=39] than AA [n=3]. DEXA scan orders were placed more often in Caucasian patients [n=4] than AA patients [n=1]. Osteoporosis medications were prescribed more often in Caucasian patients [n=8] than AA patients [n=0].

Male average SBAC-L1 was 97.4 HU compared to females at 106.3 HU. Females were prescribed calcium and vitamin D more often [n=38] than males [n=8]. DEXA scan orders were placed more frequently in females [n=5] than males [n=2]. Osteoporosis medications were prescribed more often in females [n=9] than male patients [n=0].

Table 1. Study Characteristics

	Total Patients [n=85]	Caucasian Patients [n=67]	AA Patients [n=16]	Male Patients [n=31]	Female Patients [n=54]
SBAC- L1 Average ± SD (HU)	100.4 ± 46.5	99.4 ± 44.1	122.1 ± 49.9	97.4 ± 44.3	106.3 ± 47.2
Patients with SBAC- L1 ≤ 145 HU	70	58	10	26	44
Patients with SBAC- L1 > 145 HU	15	9	6	5	10
Vertebral Fractures	57	47	8	19	38
Femur Fractures	28	20	8	12	16
Age Average	71.7	72	70.9	74	70.4
Prior diagnosis of osteoporosis	16	15	1	2	14
Post diagnosis of osteoporosis	6	2	2	2	4
Calcium	20	16	2	2	18
Vitamin D	26	23	1	6	20
Osteoporosis medication	9	8	0	0	9
Steroid use	5	4	1	2	3
DEXA prior	13	12	1	0	13
DEXA after	7	4	1	2	5

Conclusion: 70 of 85 patients with incidental fragility fractures exhibited SBAC-L1 ≤ 145 HU. This is consistent with osteoporotic bone density on DEXA imaging supporting the use of SBAC-L1 measurement to corroborate the diagnosis osteoporosis. SBAC-L1 ≤ 145 HU can be utilized to increase inpatient diagnostic confidence of osteoporosis in the setting of acute fragility fractures to allow initiation of treatment prior to awaiting outpatient DEXA imaging.

The results here also highlight health disparities present among African Americans and males of all races when considering bone health.

POS0166 ASSOCIATION OF TRABECULAR BONE SCORE AND FAT DISTRIBUTION IN MOROCCAN RHEUMATOID ARTHRITIS PATIENTS

H. Azzouzi[1], O. Lamkhanat[1], I. Linda[1]. [1]*Mohammed VI University Hospital, Mohammed I University, Faculty of Medicine, Rheumatology, Oujda, Morocco*

Background: The association between body composition and bone microarchitecture reflected by trabecular bone score (TBS) has been studied lately (1). In rheumatoid arthritis (RA), this association, especially with fat mass, needs further confirmation.

Objectives: The purpose of the present work was to study the association of TBS with fat distribution in RA.

Methods: We designed a cross-sectional study of patients with RA diagnosis according to ACR-EULAR 2010 classification recruited from first January 2021. Those with prior cancer, hyperparathyroidism, hyperthyroidism, diabetes, chronic kidney disease, cirrhosis, and a body mass index (BMI) of more than 36kg/m^2 were excluded. TBS, total body fat mass (BFM), and its distribution (gynoid (GFM), android (AFM), visceral (VFM), limbs (LFM), trunk (TFM)) were measured with Dual-energy X-ray absorptiometry (Hologic). Clinical data and laboratory tests of the same day of the DXA scan were analyzed. The associations between TBS, BFM, and its distribution were studied by correlations and multiple linear regressions using SPSS 20.

Results: Sixty-nine patients were included. Their mean age was 49.86 ± 14.33 years, mean DAS28CRP was 2.56 ± 1.27, and mean disease duration was 14.84 ± 10.99 years. Sixty-two (89.9%) were women, with 30 (48.4%) had menopause. The mean BMI was 26.46 ± 5.26 kg/m^2, and 41 patients were obese (59.4%).

In the Pearson correlation analysis, TBS was associated with BFM (p = 0.04), AFM (p = 0.001), TFM (p = 0.007), and VFM (p < 0.0001). However, there was no correlation with LFM (p = 0.262), and GFM (p = 0.469). At multivariate analysis, only VFM (p = 0.005, β = - 0.355, 95%IC [- 0.0002; - 0.00004]), and AFM (p = 0.02, β = - 0.395, 95%IC [- 0.00007; - 0.000006]) were associated with TBS, when adjusted on age, menopause, disease duration, disease duration under treatment, lumbar BMD, BMI, HAQ, CRP, and triglycerides level.

Conclusion: In RA patients, TBS was negatively associated with visceral and android fat mass. This result may explain the intriguing coexistence of high BMD and vertebral fractures in RA obese patients.

POS0167 SECONDARY PREVENTION OF VERTEBRAL FRACTURES IN REAL PRACTICE

J. E. Oller Rodríguez[1], E. Grau García[1], S. Leal Rodriguez[1], M. E. Acosta[2], C. Riesco Barcena[1], A. V. Huaylla Quispe[1], C. Pávez Perales[1], M. De la Rubia Navarro[1], I. Martínez Cordellat[1], C. Nájera Herranz[1], R. Negueroles Albuixech[1], F. M. Ortiz Sanjuan[1], E. Vicens Bernabeu[1], C. Alcañiz Escandell[1], I. Cánovas Olmos[1], I. Chalmeta Verdejo[1], J. J. Fragío Gil[1], L. Gonzalez Puig[1], J. Ivorra Cortés[1], J. A. Román Ivorra[1]. *[1]HUP La Fe, Rheumatology Department, Valencia, Spain*; *[2]Complejo Asistencial Universitario de Salamanca, Rheumatology Department, Salamanca, Spain*

Background: Vertebral fractures increases the risk of new fractures and deaths. There are different antiresorptive medications to prevent a secondary fracture, as bisphosphonates, teriparatide or denosumab, but little is known about the effects of secondary fracture appearance in real life.

Objectives: To evaluate the appearance of new vertebral fractures depending on the treatment used for secondary prevention.

Methods: We conducted a prospective descriptive study of patients with a first diagnosis of vertebral fracture from 2010 to 2017 and assessed the subsequent finding of new fractures. We selected patients with at least 3 years of secondary prevention with antiresorptive drugs or with sequential treatment (anabolic followed by, at least, 1 year with antiresorptive drugs), and excluded those who experienced new fractures within the first 6 months of treatment.

Results: A total of 400 patients were selected from an initial base of 1018 patients. The average age of onset of the first fracture was 69.7 years, 84% of female patients and 16% of female patients. 38.5% suffered dorsal fractures, 33.75% lumbar fractures and 27.75% dorsolumbar fractures. We classified the secondary prevention strategies according to the different therapeutic options, as we can see in Table 1.

We analysed the association between the appearance of new vertebral fracture corrected by sex with the age of the initial fracture its location. No association was found.

We also performed a multivariate Bayesian model of logistic regression, in order to analyze the association between the appearance of new vertebral fracture and factors as the age of the initial fracture, its sex and the pharmacologic option used as secondary prevention. No statistically significant differences were observed between the different antiresorptive treatments and their efficacy as a secondary prevention of vertebral fractures. However, there was a tendency for a smaller occurrence of new fractures in patients undergoing sequential treatment. On the other hand, similar results were observed between denosumab and oral bisphosphonates, observing somewhat worse data with zoledronate (figure 1), probably due to patients under zoledronate treatment showed high osteoporotic risk and worse prognosis.

Pharmacologic option	Patients (%)	New fractures (%)
Denosumab	192 (48%)	10 (5.21%)
Teriparatide (up to 2 years) + Denosumab (at least 1 year)	86 (21.5%)	0 (0%)
Oral bisphosphonate (alendronate, risedronate or ibandronate)	58 (14.5%)	3 (5.17%)
Zoledronate	33 (8.25%)	4 (12.12%)
Teriparatide (up to 2 years) + oral bisphosphonate (at least 1 year)	28 (7%)	2 (7.14%)
Teriparatide (up to 2 years) + Zoledronate (at least 1 year)	3 (0,75%)	0 (0%).

Conclusion: No differences between the different secondary prevention options in terms of the appearance of new fractures were observed.

POS0168 BONE MINERAL DENSITY IN PATIENTS WITH MULTIPLE SCLEROSIS. A DESCRIPTIVE STUDY FROM A UNIQUE CENTER FROM THE EAST OF SPAIN

E. Flores-Fernández[1], C. Valera-Ribera[1], I. Vázquez-Gómez[1], A. V. Orenes Vera[1], À. Martínez-Ferrer[1], L. Landete[2], E. Valls-Pascual[1], D. Ybáñez-García[1], J. J. Alegre-Sancho[1]. *[1]Doctor Peset University Hospital, Rheumatology, València, Spain*; *[2]Doctor Peset University Hospital, Neurology, València, Spain*

Background: Several studies have suggested that multiple sclerosis (MS) patients have low bone mineral density (LBMD) compared to healthy adults of same age. This fact, combined with the functional impairment of the disease, increases the risk of fractures. However, information about the prevalence and the risk factors of LBMD in Spanish patients with MS is still quite limited[1–3].

Objectives: To evaluate the prevalence of LBMD and low vitamin D in patients with MS from a unique center from the east of Spain, describing the clinical features of these patients.

Methods: Type of study: observational, cross-sectional, descriptive. Patients with MS from a local cohort have been consecutively recruited for this study since Apr-2020. A cross-sectional visit which included a clinical interview, analytic test (blood and urine) and a dual-energy X-ray absorptiometry (DXA) was performed. We defined LBMD as T score ≤-1SD in postmenopausal women and men over 50 years and a Z score ≤-2SD in premenopausal women and men under 50 years. Low levels of vitamin D were defined as < 20ng/mL. A descriptive and associative analysis of these data was carried out using the SPSS software.

Results: From a cohort of 288 MS patients, due to the COVID-19 pandemia, we have only been able to assess 60 patients, and only 48 out of them have undergone all the tests required. These were 30 women and 18 men, with a mean age of 49 (SD 11,6) years. The main type of MS was relapsing-remiting (77,1%) and 25% of them were not taking any maintenance treatment. Some of the classical factors related to a LBMD are shown in table a1. A 43,8% of the patients had a LBMD and 40,5% had low levels of vitamin D. Despite these results, as far as 89% of patients had never received any specific treatment, not even calcium and/or vitamin D supplementation. Furthermore, 13 patients (27,1%) must have received specific treatment, according to latest guidelines[4], and only 4 of them (8,5%) were being adequately treated.

Table 1.

Women/Men (n)	30/18
Mean age; SD (years)	49; 11,6
Non smokers/Smokers (%)	58,4/41,7
Alcohol abuse (%)	8,3
Personal history of fracture (%)	10,4
Personal history of nephrolithiasis (%)	14,6
Normal/Reduced mobility (%)	77,1/22,9
Sedentary lifestyle (%)	66,7

Conclusion: These preliminary results show that almost half of the MS patients have LBMD and a low vitamin D, most of them without taking any specific treatment. Taking this in mind, it is necessary to integrate the early diagnosis of LBMD

in MS patients, working together with neurologists, to prevent the appearance of fractures and protect the quality of life of these patients. An analysis of our whole cohort of MS patients will help us in correctly assessing the magnitude of this problem.

POS0169 FETUIN-A AS A MARKER OF OSTEOPOROSIS AND OSTEOPOROTIC FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Akhverdyan[1], E. Papichev[1], B. Zavodovsky[1], L. Seewordova[1], J. Polyakova[1]. [1]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology Named After A.B. Zborovsky», Joint Diseases Treatment and Prevention Laboratory, Volgograd, Russian Federation*

Background: The main mechanism of the effect of fetuin-A (FeA) on bone metabolism is its ability to bind calcium and proteins of the TGF-β family. It has been proven that the optimal concentration of TGF-β is necessary for the differentiation of bone tissue, and a high concentration inhibits bone mineralization. Thus, adequate osteogenesis is based on a complex balance between FeA and TGF-β levels. It can be assumed that the determination of the FeA level in the blood of patients with rheumatoid arthritis (RA) will help to optimize the diagnosis and predict the severity of osteoporosis (OP).

Objectives: to study the possibility of predicting the development of osteoporosis and osteoporetic fractures in patients with RA, depending on the level of FeA in blood serum.

Methods: We examined two groups of patients (52 patients with RA complicated by OP, 58 patients with RA without OP) and 30 apparently healthy individuals. The age of the surveyed ranged from 18 to 72 years, the average duration of the disease was 7.53±0.89 years. In both groups, the FeA level was determined by an indirect enzyme-linked immunosorbent assay using a commercial test. Bone mineral density (BMD) was also measured in both groups (Lunar DPX-NT GE).

Results: The average FeA level in the group of RA patients was lower than in the group of conventionally healthy individuals (731.21±109.9 μg/ml and 812.9±76.2 μg/ml, respectively; F=13.34; p=0,0004). The normal FeA level was calculated using the formula M±2σ in the group of apparently healthy individuals and ranged from 653.55 μg/ml to 972.19 μg/ml.

A decreased level of FeA was found in 20 patients (86.96%) in the group of patients with OP and only in 3 (13.04%) patients with RA who did not suffer from OP (p<0.001). It can be concluded that patients with RA and a low concentration of FeA in the blood serum have a higher risk of developing OP.

In the group of patients with normal FeA level, osteoporetic fractures were observed in 12 (13.79%) patients and were absent in 75 (86.21%) patients (p<0.001). Thus, RA patients with normal serum FeA levels have a lower risk of osteoporetic fractures.

We also found a positive significant correlation between the level of FeA and BMD in the femoral neck area. In the group of patients with a reduced FeA level (23 people), the mean BMD values were 0.732±0.022 g/cm2, and in the group of patients with a normal FeA level (87 patients) - 0.890±0.014 g/cm2 (p<0.001, F=27.663). The obtained values are in agreement with the literature data on the effect of the serum FeA concentration on the BMD values.

Conclusion: We consider it expedient to determine the serum FeA concentration in patients with RA. At a FeA level of 653.55 μg/ml and below, a higher risk of developing OP and osteoporetic fractures can be predicted. In this case, the patient is shown a standard examination for osteoporosis. At values of 653.55 μg/ml and above, a more expectant management of the patient is allowed. Thus, by determining the serum concentration of FeA, it is possible to implement an integrated approach to the patient and to optimize the schemes for the diagnosis of OP in patients with RA.

POS0170 IMPROVING MANAGEMENT OF GLUCOCORTICOID INDUCED OSTEOPOROSIS IN RHEUMATOLOGY

A. Bankole[1], S. Pachigolla[2]. [1]*Virginia Tech Carilion School of Medicine, Medicine, Roanoke, United States of America*; [2]*Carilion Roanoke Memorial Hospital, Internal Medicine, Roanoke, United States of America*

Background: Glucocorticoids (GC) are used in the treatment of various inflammatory conditions and it is estimated that about 1% of US population is treated with long term steroids. High doses of GC particularly those used by rheumatologists have adverse effects on bone health and is associated with rapid bone loss resulting in Glucocorticoid induced Osteoporosis(GIO) and an increased risk of fractures. The risk of bone loss relates to high daily dose and the high cumulative dose of the GC.

Despite the availability of effective preventative and treatment options, GIO is often under treated with many patients treated only after a fracture has occurred.

Objectives: The purpose of this study was to examine if providing education to care providers lead to an improvement in the identification, evaluation, and treatment of GIO.

Methods: This is a single center, prospective study that was performed at a university based tertiary referral center. Patients over 40 years, receiving a total cumulative dose of GC of >5 grams and/or a single dose of >30 mg of prednisone or equivalent was enrolled. A patient list was generated by our technology group. All providers received intervention in the form of an academic Journal Club, at which the current ACR guidelines regarding GIO was reviewed. Monthly reminders were shared with all providers within our monthly communications.

All the pre and post interventional data was analyzed. The continuous variables were analyzed using T-test or Mann-Whitney U test. Categorical variables were analyzed using Chi-square Tests or Fisher's exact tests. Statistical analysis was performed using SAS9.4, and p value <0.05 was considered statistically significant.

Results: Post education, there was a statistically significant increase in vitamin D replacement and the use of bisphosphonates as well as a reduction in the use of bone mineral density (BMD) tests within the at risk group while on GC.

Table 1. Glucocorticoid induced Osteoporosis (GIO)

	Pre-treatment (N=72)	Post-treatment (N=54)	p-value
Demographics			
Age (years)	58.9 ± 19.2	64.2 ± 16.7	0.11
Body Mass Index	29.0 ± 6.7	29.4 ± 8.4	0.77
Gender (Female)	73.6%	74.1%	0.95
Race			
White	83.3%	77.8%	0.43
Hispanic	1.4%	5.6%	0.31
Insurance			
ANTHEM BCBS	16.9%	26.9%	
Commercial	11.3%	11.5%	
Medicaid	12.7%	9.6%	
Medicare	59.2%	51.9%	
			0.58
Medical History			
Osteoporosis	68.1%	64.8%	0.70
Osteoporotic Fracture	15.3%	11.1%	0.50
Vasculitis	26.4%	22.2%	0.59
Systemic Lupus Erythematosus	18.1%	13.0%	0.44
Rheumatoid Arthritis	12.5%	25.9%	0.05
Polymyalgia Rheumatica	6.9%	11.1%	0.41
Inflammatory Muscle Disease	18.1%	20.4%	0.74
Spondyloarthritis	1.4%	1.9%	0.99
Lab Results			
Serum Vitamin D (Normal)	41.3% (19/46)	52.8% (19/36)	0.3
GIO Prevention Measures			
Calcium	2.8%	13.0%	0.04
Vitamin D	18.1%	61.1%	<0.01
Bisphosphonates	9.7%	35.2%	<0.01
RANKL inhibitors	4.2%	11.1%	0.17
Bone Mineral Density	43.5% (10/23)	10.5% (2/19)	0.02

Conclusion: There was a significant improvement between the GIO pre and post-educational data, with increasing use of GIO preventive measures. Importantly, there was also a reduction in BMD testing of patients while still on GC. This research show the importance of provider education as a means of disseminating information and improving the quality of patient care.

POS0171 UNDERESTIMATION OF THE FRACTURE RISK BY THE FRAX FORMULA IN CHRONIC GLUCOCORTICOID USERS: A 10-YEAR LONGITUDINAL VALIDATION STUDY

C. C. Mok[1], L. Y. Ho[1], S. M. Tse[1], K. L. Chan[1]. [1]*Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR)*

Background:

Objectives: To compare the actual fracture incidence over 10 years in a longitudinal cohort of patients using glucocorticoids (GCs) with the risk prediction from FRAX (fracture risk assessment tool).

Methods: Patients who attended our out-patient rheumatology clinics were included according to the following criteria: (1) adult patients ≥18 years; (2) underlying rheumatic diseases requiring prednisolone treatment (≥5mg/day); and (3) have had a DXA scan (baseline) performed between years 2007-2009. The predicted rates of major osteoporotic and hip fractures were estimated using FRAX (China database) based on the clinical data at the time of DXA, with adjustment when daily dose of prednisolone ≥7.5mg (multiply by 1.15 for major osteoporotic and 1.20 for hip fracture). The actual observed incidence of symptomatic vertebral and non-vertebral fractures at 10 years (in years 2017-2019) follow-up was retrieved by medical record review and compared with the estimated rates by FRAX. Factors associated with symptomatic clinical fractures at 10 years were studied by logistic regression.

Results: 89 patients were studied (age 49.3±8.8 years at DXA examination; 98% women). The underlying rheumatic diseases were systemic lupus erythematosus (69%), rheumatoid arthritis (17%) and others (14%). The mean daily dose of prednisolone at baseline was 7.7±6.5mg (38% patients had daily dose ≥7.5mg). History of personal fracture was present in 4(4.5%) patients and 22% of female patients had menopause before the age of 45 years. The mean body mass index (BMI) was 23.5±3.3kg/m^2 (4.5% ≤18kg/m^2). Osteoporosis (bone mineral density [BMD] T score ≤-2.5) of the hip, femoral neck and lumbar spine occurred at a frequency of 11.2%, 13.5% and 25.8%, respectively at baseline (32% at any of the 3 sites). 30(34%) patients received anti-osteoporotic treatment (oral bisphosphonates in 25, raloxifene in 3 and denosumab in 2 patients). The estimated mean 10-year risk of major osteoporotic and hip fractures using the BMD data and other risk factors in the FRAX formula, adjusted for prednisolone dose, was 4.3% and 1.0%, respectively. After a follow-up of 10 years, one patient had a hip fracture, 3 patients had humerus fractures and 9 patients had symptomatic vertebral fractures. The actual observed major osteoporotic and hip fracture incidence was 14.6% and 1.1%, respectively (0.146 and 0.011 per 10 patient-years). The observed major clinical fracture rate was significantly higher than that estimated by FRAX (14.6% vs 4.3%; p=0.04). Logistic regression revealed that the only factor independently associated with major clinical fracture at 10 years was BMD T score ≤-2.5 at spine, hip or femoral neck at baseline (OR7.11[1.73-29.2]; p=0.007). Age, prednisolone daily dose, BMI, history of fracture, chronic smoking, having underlying SLE vs not and early menopause were not significantly associated with new clinical fractures.

Conclusion: Despite adjustment for prednisolone dosage, the FRAX formula underestimates the major clinical fracture risk in patients using long-term GCs. The deleterious effect of GCs on bone quality, high proportion of SLE patients, disease activity and use of additional doses of GCs and other immunosuppressive drugs during follow-up are among the contributing factors for this underestimation.

Molecular profiles in connective tissue disease outcome

POS0172 THROMBIN GENERATION ASSAY AND LUPUS ANTICOAGULANT IDENTIFY DIFFERENT POPULATIONS OF PATIENTS WITH ANTIPHOSPHOLIPID ANTIBODIES

M. Radin[1], A. Barinotti[1], I. Cecchi[1], S. G. Foddai[1], E. Rubini[1], D. Roccatello[1], E. Menegatti[1], S. Sciascia[1]. [1]*University of Turin, Clinical and Biological Sciences, Turin, Italy*

Background: Risk stratification in patients with antiphospholipid antibodies (aPL) remains a clinical challenge [1].

Objectives: We aimed to evaluate the role of Thrombin Generation Assay (TGA) in distinguishing various populations of aPL positive patients (with and without lupus anticoagulant - LA) and its association with β2GPI-dependent and anti-phosphatidyl-serine/prothrombin(aPS/PT) antibodies.

Methods: One-hundred-and-eight patients were tested with TGA and divided as follows: 21 patients with aPS/PT IgG/IgM (**Group 1**), 29 with aβ2GPI IgG/IgM (**Group 2**), 31 with aPS/PT and aβ2GPI IgG/IgM (**Group 3**), 27 with aPS/PT and/or aβ2GPI IgM low-titers (**Group 4**). Table 1 resumes the clinical characteristics of the APS patients (excluding aPL asymptomatic). Thirty-one healthy donors (HDs) and 24 controls treated with VKA were also included.

Results: The most deranged TGA and LA profile was observed in patients with both aPS/PT and aβ2GPI when compared to those with an isolated positivity for aPS/PT or aβ2GPI and patients with aPS/PT and/or aβ2GPI IgM at low titres (Figure 1). Similarly, patients with aPS/PT and/or aβ2GPI at medium/high titres presented with the higher rate of clinical manifestations.

When comparing the TGA curves of APS patients, asymptomatic aPL positive (aPL+) subjects, HDs and controls treated with VKA, we observed that aPL+ patients (particularly those with a confirmed diagnosis of APS) showed a characteristic profile.

Differences among groups were confirmed also when comparing APS clinical manifestations. When comparing Group 1 and Group 4 we found significant differences with respect to the number of thrombotic events (21vs.15,p<0.05), the number of venous events (9vs.3,p<0.05), the recurrence of thrombosis (19%vs.0%,p<0.05). Group 2 and Group 4 showed differences in the occurrence of venous thromboses (50vs.20,p<0.05), and in the occurrence of DVT (8vs.2,p<0.05). Group 3 and Group 4, had higher number of thrombotic events (36vs15, p<0.05), the occurrence and the number of venous events (46%-15vs20%-3,p<0.05), the occurrence of TIA and DVT (4-11vs0-2,p<0.05).

When analysing the cumulative frequency of extra-criteria APS manifestations, Group 1,2 and 3 were comparable, while comparing Group 3 and those positive for aβ2GPI and/or aPS/PT IgM at low titres (Group 4) we found a statistically significant difference (71%vs13%,p<0.05).

Conclusion: TGA seems a valuable approach to stratify aPL+ patients according to their risk profile. The differences among groups and different populations of autoantibodies specificities obtained from this test can be considered a translational validation of the increased thrombotic risk of patients with triple or tetra aPL positivity.

POS0173 **METABOLOMIC PROFILING AND SYMPTOM BURDEN IN BLACK WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

L. P. Kimble[1], A. Khosroshahi[2], R. C. Eldridge[1], G. S. Brewster[1], N. S. Carlson[1], E. J. Corwin[3]. [1]*Emory University, School of Nursing, Atlanta, United States of America*; [2]*Emory University, School of Medicine, Rheumatology Division, Atlanta, United States of America*; [3]*Columbia University, School of Nursing, New York, United States of America*

Background: Black individuals with systemic lupus erythematosus (SLE), who are predominantly women, have disproportionately poorer health outcomes across the trajectory of their disease including increased mortality, higher symptom burden, and poor quality of life than non-Hispanic Whites. The heterogeneity of immunopathology and biochemical complexity of SLE create major knowledge gaps around the mechanisms of disease and differences in SLE symptom expression. Metabolomics may reveal biochemical dysregulation that underlies SLE symptoms and provide novel metabolic targets for precision symptom interventions.

Objectives: We conducted untargeted metabolomic plasma profiling of Black females with SLE and Black female non-SLE controls to gain insight into metabolic disturbances associated with SLE.

Methods: We analyzed blood specimens collected from 23 Black female patients with diagnosis of SLE during a routine outpatient rheumatology visit and from 21 Black female non-SLE controls whose data were collected as part of another study of obese caregivers. Data collection for both cases and controls was completed with harmonized protocols. Clinical data for cases were obtained via chart review and both cases and controls completed identical, reliable and valid measures of fatigue, depression, anxiety, and sleep disturbance. A commercial metabolomics analysis company within the US conducted untargeted metabolomics on the 44 plasma samples using ultrahigh performance liquid chromatography/tandem mass spectrometry along with metabolite identification and quantification to examine differences between SLE/non-SLE groups.

Results: All SLE subjects met 2019 EULAR/ACR criteria (Aringer et al., 2019). SLE subjects were significantly ($p < .05$) younger (42.5 ± 12.2 vs. 63.2 ± 6.4), had a lower BMI (30.3 ± 9.4 vs. 34.9 ± 4.1), and greater co-morbidities (2.3 ± 1.3 vs. 1.1 ± 1.3) than non-SLE controls. SLE subjects reported higher symptoms than controls across all measures, but differences were not statistically significant. Metabolomics analysis revealed 290 biochemicals that were statistically significant ($p \leq .05$) between SLE and non-SLE groups. Random Forest analysis had a predictive accuracy of 91% in differing between the two groups using out-of-bag sampling. Significant metabolic differences between groups were noted in biochemicals associated with glycolysis, the TCA cycle (see Table 1), fatty acid metabolism, branched chain amino acids, sterol levels, heme catabolism, and potential markers of renal impairment. Overall, the differences would suggest reduced energy production among SLE patients compared to controls.

Table 1- Comparison SLE (n= 23)and No SLE Subjects (n=21) on Biochemicals in the TCA Cycle

Pathway	Metabolite	SLE/ No SLE log_2 fold change	p-value	FDR q-value
TCA Cycle	citrate	0.82	0.0005	0.008
	aconitate [cis or trans]	0.65	< 0.0001	0.001
	alpha-ketoglutarate	0.74	0.0017	0.017
	succinylcarnitine (C4-DC)	0.94	0.3558	0.362
	succinate	0.75	0.0001	0.003
	fumarate	0.64	0.0002	0.004
	malate	0.73	0.0149	0.057
	citraconate/glutaconate	1.46	0.6843	0.507

Note: SLE= systemic lupus erythematosus. Welch's Two sample t-test used to compare groups. FDR= False discovery rate. Green color indicates value for SLE group significantly lower than non-SLE controls.

Conclusion: Black women with SLE had biochemical profiles consistent with reduced energy production which has implications for the high burden of fatigue and other symptoms in this population. Future work with larger sample sizes should involve integrating symptom and metabolomics data to identify potential biomarkers of symptom burden.

POS0174 IMMUNOPHENOTYPE OF SJÖGREN´S SYNDROME AND SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS IDENTIFIED TWO ENDOTYPES WITH POTENTIAL THERAPEUTIC IMPLICATIONS

L. Martin-Gutierrez[1,2], J. Peng[1,2], G. Robinson[1,2], M. Naja[2,3], H. Peckham[2], W. Wu[2], D. Isenberg[1,3], E. Jury[1], C. Ciurtin[2,3]. [1]*Centre for Rheumatology Research, Department of Medicine, London, United Kingdom*; [2]*Centre for Adolescent Rheumatology Versus Arthritis, Department of Medicine, London, United Kingdom*; [3]*University College London Hospitals, Department of Rheumatology, London, United Kingdom*

Background: Primary Sjögren's syndrome (pSS) and systemic lupus erythematosus (SLE) are chronic autoimmune rheumatic diseases (ARDs) that share a strong female gender bias, as well as genetic, clinical and serological characteristics.Although significant progress has been made in improving treatment and patient related outcomes in pSS and SLE, there is a need for improved early diagnosis, adequate therapy monitoring, treatment of refractory manifestations and strategies to address co-morbidities. However, the results of many clinical trials are disappointing, and nobiologic treatments are licensedin pSS, while few are available for SLE patients with refractory disease.
Objectives: Identifying shared immunological features between patients with pSS and SLE that could lead to better treatment selection using a stratification approach.
Methods: Immune-phenotyping of 29 immune-cell subsets in peripheral blood from patients with pSS (n=45), SLE (n=29) and secondary SS associated with SLE (SLE/SS) (n=14) with low disease activity or in clinical remission, and sex-matched healthy controls (n=31), was performed using flow cytometry. Data were analysed using logistic regression and multiple t-tests andsupervised machine learning (balanced random forest-BRF, sparse partial least squares discriminant analysis-sPLS-DA). Patients were stratified by k-means clustering. Clinical trajectories were analysed over 5 year follow-up.
Results: Comparing the immune profile of pSS and SLE patients using a variety of statistical and machine learning (ML) approaches, identified very few statistically significant differences between the two cohorts despite patients having a different clinical presentation and diagnosis. Thus, we hypothesised that immune-based subtypes could be shared between pSS, SLE and SLE/SS patients. Unsupervised k-means clustering was applied to the immunological features of the combined patient cohorts and two distinct patient endotypes, were identified: Group-1 (n=49; pSS=24, SLE=19, SLE/SS=6) and Group-2 (n=39; pSS=21, SLE=10, SLE/SS=8). Significant differences in immune-cell phenotypes across B-cell and T-cell subsets were identified by logistic regression, BRF (AUC=0.9942, assessed by 10-fold cross-validation) and sPLS-DA analysis. Comparison of the multiple analysis approaches identified eight common immune-cell subsets, including total and memory CD4+ and CD8+ T-cell subsets but no B-cell subsets. Using this common immune-signature the stratification between the groups was maintained and slightly improved (AUC=0.9979 and accuracy 96.16%). Interestingly, patients in Group-2 had elevated disease activity measures at baseline and over a 5-year trajectory compared to Group-1. Finally, correlation analysis identifed correlations between disease activity markers and the top ranked immune features from the ML models.
Conclusion: The identified immune-cell signatures could reflect the underlying disease pathogenesis that spans diagnositc criteria and could be used to select patients for targeted therapeutic approaches.

POS0175 ASSOCIATION BETWEEN BIOMARKERS AND THERAPEUTIC PATHWAY IN PATIENTS WITH SLE

S. U. Hassan[1,2], K. Mahmoud[1,2], Z. Wigston[1], A. Burska[1], M. Y. MD Yusof[1,2], E. Vital[1,2]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, Rheumatology, Leeds, United Kingdom*; [2]*NIHR Leeds Musculoskeletal Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: SLE is heterogeneous in clinical presentation, underlying immunology, and response to therapy. Patients with severe or resistant disease receive cyclophosphamide or rituximab. Although effective, late use of these therapies entails cumulative damage.
Emerging predictors of response to rituximab include demographics, IFN-Scores and autoantibodies. For such predictors to change treatment strategy we need to understand their association with the effectiveness of other therapeutic options at earlier decision points.
Prospective studies of treatment pathways are difficult to perform, requiring large populations followed for many years. We therefore investigated this question by analysing retrospective treatment pathways since diagnosis in patients whose biomarker status is subsequently known.
Objectives: To use interferon scores and other markers to;

[1] identify SLE patients more likely to need escalation of therapy to either rituximab or cyclophosphamide, and
[2] determine if this occurred sooner than in others.

Methods: In patients with established SLE, attending Leeds SLE clinic, we collected demographics, clinical characteristics and blood at a single timepoint. Two previously validated IFN-Scores[1,2] (IFN-Score A and IFN-Score B) were measured using Taqman. Autoantibodies were measured using immunoprecipitation. Treatment history covering all antimalarials, oral and intravenous immunosuppressants (agent, start and stop dates and reasons) since diagnosis was collected. Univariable and multivariable Cox proportional hazards models were used to test variables as predictors of the primary endpoint: time to cyclophosphamide/rituximab.
Results: 124 patients were included. Follow up since diagnosis was Median (IQR) 37.5 (27.4-52.3) years, total therapies per patient was 3 (1-4), therapies per year was 0.2 (0.1-0.3). 54/124 (44%) patients required cyclophosphamide/rituximab.
Results of Cox regression are shown in the table 1. There was a significant association between high expression of IFN-Score B and requirement for cyclophosphamide/rituximab as well as trends for age in the first quartile (<28 years), IFN-Score A and anti-Sm/U1RNP antibodies. Both age <28 and IFN-Score B retained trends as independent predictors in a multivariable model.

Table 1.

Characteristic	CYC/ RTX=Yes n(%)	CYC/ RTX = No n(%)	Univariable Hazard ratio (95% CI)	Univariable p value	Multivariable Hazard Ratio (95% CI)	Multivariable p value
Age						
-Q1: under 28	22 (71%)	9 (29%)	2.25 (0.99,5.12)	0.054	1.74 (0.95,3.18)	0.074
-Q2: 28 – 38	12 (39%)	19 (61%)	1.03 (0.41,2.56)	0.949	Not included	Not included
-Q3: 38 – 52	12 (39%)	19 (61%)	1.52 (0.62,3.72)	0.360	Not included	Not included
-Q4: over 52	8 (26%)	23 (74%)	reference	reference	Not included	Not included
Ethnicity						
-Caucasian	42 (48%)	46 (52%)	1.17 (0.58,2.35)	0.660	Not included	Not included
-AfroCaribbean, South Asian, East Asian, Other	10 (36%)	18 (64%)	reference	reference		
IFN Score A, mean (SD)	−2.59 (−2.67)	−3.84 (−2.71)	1.10 (0.98,1.24)	0.113	Not included	Not included
IFN Score B, mean (SD)	−2.61 (−1.16)	−3.53 (−1.76)	1.31 (1.05,1.64)	0.017	1.23 (0.98,1.55)	0.079
Anti-Sm/U1RNP Ab positive	17 (61%)	11 (39%)	1.50 (0.84,2.67)	0.171	Not included	Not included
Anti-Ro(60) Ab positive	14 (45%)	17 (55%)	0.88 (0.47,1.65)	0.686	Not included	Not included

Conclusion: Patients developing SLE before age 28 with raised interferon scores may be forecast to develop severe disease, fail oral therapies, and require rituximab. While this retrospective analysis may be confounded by a survivorship bias, our findings are consistent with other literature on these variables as predictors of severe disease. Future work will analyse more biomarkers in a larger and more varied patient population.

POS0176 COMBINING CXCL5 WITH CONVENTIONAL THERAPY PROVIDES DURABLE IMMUNOSUPPRESSION IN MURINE LUPUS NEPHRITIS

X. Fan[1,2], D. Guo[1], F. Lim[1], J. Thumboo[3], W. Hwang[4,5], C. T. Ng[3], A. Low[3]. *[1]Singapore General Hospital, Department of Clinical Translational Research, Singapore, Singapore*; *[2]Duke-NUS Medical School, SingHealth Duke-NUS Medicine Academic Clinical Programme, Singapore, Singapore*; *[3]Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore*; *[4]National Cancer Centre, -, Singapore, Singapore*; *[5]Singapore General Hospital, Department of Haematology, Singapore, Singapore*

Background: Lupus nephritis (LN) is a condition arising from abnormal immune responses to internal organs. Patients with LN suffer from severe morbidity and mortality[1, 2]. Despite the aggressive regimen, 20-40% of patients do not respond to current conventional therapy. CXCL5, as a potent chemoattractant and activator of neutrophils[3], demonstrates strong immunosuppression in the pre-clinical mouse model of graft versus host disease (GvHD)[4] and lupus nephritis (LN) by intravenous administration.

Objectives: In this study, we aim to evaluate whether the therapeutic effect of conventional therapy could be further improved by combination therapy with CXCL5.

Methods: Ten doses of exogenous CXCL5 (3ug/kg, biweekly) together with conventional therapy (methylprednisolone (MP, intravenous (IV) injection with 8.3mg/kg/day at day-1, day-2 and day-3) + cyclophosphamide (CP, IV injection with 0.5g/BSA at day-4, monthly for 5 doses)) were administered to 8-week-old Fas^{lpr} mice by IV injection. Mice were monitored for 64 weeks. Splenic immune profile at 3 weeks post treatment (PT) was measured by flow cytometry. Circulating cytokine profile were detected by Luminex technology. Renal function was evaluated by urinary spot albumin creatinine ratio. In situ renal immune cell infiltration and complement 3 deposition were detected by Haematoxylin and Eosin (H&E) and immunohistochemistry staining.

Results: Comparing to control mice (dPBS: 0% at 28 weeks PT), mice survival was improved to 100% at 40 weeks PT and 55.6% at 64 weeks PT by combination therapy of CXCL5 and conventional therapy (MP + CP) (p<0.0001). The accumulation of autoantibody (anti-dsDNA) and proteinuria were reduced 61.2-fold at 32 weeks PT (p=0.004) and 83.5-fold at 28 weeks PT (p=0.03) respectively. Both autoantibody and proteinuria were maintained at low level for 64 weeks. The classification of LN was significantly reduced at 10 weeks PT and equivalent to the classes we observed in pre-onset mice (p=0.004). Although combination therapy was not able to promote Tregs, it reduced both innate (neutrophils and macrophages) and adaptive (T_H1, T_H2 and T_H17 cells and B cells) immunities significantly. Concomitantly, the serum level of endogenous CXCL5 was boosted up by exogenous administration from 74.2 +/- 53.9 pg/ml to 254.1 +/- 147.1 pg/ml at 8 weeks PT (p=0.05) and this relative high concentration was maintained for 48 weeks.

Conclusion: Combining CXCL5 with conventional therapy provides effective and durable immunosuppression in murine LN and it may provide a new option for LN therapy.

POS0177 POTENTIAL INVOLVEMENT OF IL-40 AND IL-40-PRODUCING CELLS IN PRIMARY SJOGREN'S SYNDROME (PSS) AND PSS-ASSOCIATED LYMPHOMA

C. Rizzo[1], M. Lo Pizzo[2], L. Mohammadnezhad[2], V. L. Lentini[3], D. Di Liberto[2], G. Grasso[1], P. Ruscitti[4], R. Giacomelli[5], F. Ciccia[6], G. Guggino[1]. *[1]"P. Background: The pathogenesis of pSS relies on a complex interplay between both innate and adaptive immune responses in which B cells play a pivotal role. Their chronic aberrant hyperactivation may drive clonal escape and consequent lymphomagenesis [1]. In the last few years, B cells have emerged as potential effector cells, able to release a wide range of cytokines that actively contribute to shape the microenvironment they act in. Recently, IL-40, a novel B cell associated cytokine encoded by an uncharacterized gene (C17orf99; chromosome 17 open reading frame 99) was described. Naïve B cells can express IL-40 at both tissue and peripheral level and the stimulation of B cells with IL-4 and TGF-β significantly increases IL-40 release. In addition, human B cells lymphomas are able to constitutively produce IL-40 [2]. Taking into account this emerging evidence and considering the well-known role of IL-4 and TGF-β in pSS pathogenesis, as well as the association with lymphomas, we decided to focus our attention on IL-40 in pSS patients.

Objectives: The aim of the present study was to investigate IL-40 expression in the salivary glands of patients affected by pSS and pSS-associated non-Hodgkin's lymphoma (NHL).

Methods: Minor salivary gland biopsies were obtained from 22 patients with pSS and 12 patients with non-specific chronic sialoadenitis (nSCS), included as controls. Paraffine-embedded samples of parotid glands from patients with a previous diagnosis of pSS-associated NHL (n=10) were selected from the biopsy bank of the Pathology Unit of the Ospedale Cervello (Palermo, Italy). Quantitative gene expression analysis by TaqMan real-time PCR and immunohistochemistry (IHC) for IL-40, IL-4, TGF-β1 was performed on salivary glands from patients and controls. The cellular sources of IL-40 among infiltrating inflammatory cells were determined by fluorescence-activated cell sorting (FACS) analysis and immunofluorescence (IF). Serum IL-40 levels were measured by ELISA in both patients (n=10) and controls (n=9).

Results: IL-40 was significantly increased at both protein and mRNA level in the inflamed salivary glands of patients with pSS where a positive strong correlation between the IL-40 mRNA levels and the focus score (FS) was evidenced. The expression of IL-40 in parotid glands of pSS-associated NHL was also markedly increased (Figure 1). IL-40 expression correlated with the presence of IL-4 and TGF-β; both cytokines were significantly increased in pSS at mRNA and protein level. Among infiltrating immune cells, $CD19^+$ B cells resulted the major source of IL-40. However, we identified $CD4^+$, $CD8^+$ T cells and $CD68^+$ macrophages as additional producers of IL-40 in both FACS and IF analysis. The ELISA test also showed a significant increase of serum IL-40 concentration in pSS patients (p value = 0.0190), compared to controls.

Conclusion: Our preliminary results suggest that IL-40 may play a role in the pathogenesis of pSS and pSS-associated NHL. To the best of our knowledge, this is the first demonstration of the overexpression of this cytokine in salivary gland tissue and sera in pSS. Moreover, we demonstrated that IL-40 is produced by several cellular types, such as T cells and macrophages, and is not exclusively released by B cells. Further studies are necessary to clarify IL-40 pathways and functions in order to unravel IL-40 possible role in pSS development.

POS0178 GENE SIGNATURE FINGERPRINTS DIVIDE SLE PATIENTS IN SUBGROUPS WITH COMPARABLE BIOLOGICAL DISEASE PROFILES: A MULTICENTRE LONGITUDINAL STUDY

M. J. Wahadat[1,2], C. G. Van Helden-Meeuwsen[1], S. Van Tilburg[1], E. Schatorjé[3,4], E. Hoppenreijs[3,4], P. C. E. Hissink Muller[5], J. M. Van den Berg[6], D. Schonenberg-Meinema[6], S. Kamphuis[2], M. Versnel[1]. [1]*Erasmus University Medical Center, Department of Immunology, Rotterdam, Netherlands*; [2]*Sophia Children's Hospital, Erasmus University Medical Center, Department of Pediatric Rheumatology, Rotterdam, Netherlands*; [3]*Amalia Children's Hospital, Radboudumc, Paediatric Rheumatology, Nijmegen, Netherlands*; [4]*St. Maartenskliniek, Paediatric Rheumatology, Nijmegen, Netherlands*; [5]*Leiden University Medical Center, Department of Paediatrics/Paediatric Rheumatology, Leiden, Netherlands*; [6]*Emma Children's Hospital AMC, University of Amsterdam, Department of Paediatric Immunology, Rheumatology and Infectious Diseases, Amsterdam, Netherlands*

Background: Even in the hands of experienced clinicians, clinical phenotyping and predicting treatment responses in Systemic Lupus Erythematosus (SLE) patients remains challenging. Therefore, the identification of biomarkers that can help physicians to divide patients into subgroups based upon aberrantly activated pathways is relevant and might guide future treatment strategies. Extensive blood transcriptional profiling has identified various gene modules that seem promising for stratification of SLE patients into subgroups (1). However, the feasibility to implement these complicated and expensive tests for use in the daily practice of routine clinical laboratories is challenging if not impossible.
Objectives: The aim of this study was to develop gene signatures that stratify patients into groups with comparable disease profiles and are feasible to perform in routine clinical laboratories.
Methods: To identify coordinated expression of a set of genes and reduce data complexity, genes from 4 previously described modules (Interferon M1.2, Interferon M5.12, Neutrophil- and Plasmablast (PB)(1)) were measured using real-time quantitative PCR expression on whole blood RNA samples. Subsequently, a principle component analysis was used to select 2-5 indicator genes, that represent a specific signature. Expression levels of these genes were measured in healthy donors (n=42) and samples from two independent childhood-onset SLE cohorts (n=51 and n=20). Scores higher than the mean + 2 S.D. score of healthy controls were defined as high gene signature scores. Based on their expression levels, gene signatures were divided over 14 clusters. Associated clusters were subsequently grouped into three gene fingerprints termed 1) all-signatures-low, 2) only high IFN (M1.2 and/or M5.12) and 3) high PB and/or Neutrophil. Disease activity was measured by the SELENA-SLEDAI score.
Results: All four gene signatures were higher expressed in patients compared to healthy controls and showed a significant correlation with the SLEDAI. The PB signature showed the highest association with disease activity (r= 0.6512, P<0.0001). In longitudinally collected samples, the PB signature was reduced in patients who were on treatment and showed a significant trend with the SLEDAI. When patients were divided into the described gene fingerprints, the highest SLEDAI scores (median score=8) were observed in the high PB-Neutrophil group. The lowest disease activity (median score =2) was observed in the all-signatures-low group. The same distribution was seen when samples from a second time point were divided based on this stratification method and this was also reproduced in samples from an independent SLE cohort (figure 1).
Conclusion: Various gene signatures are associated with disease activity, which underlines the involvement of different pathophysiological mechanisms in SLE. Combining these signatures into gene fingerprints can help to stratify patients into comparable groups and guide individualized treatment choices for patients in the future.

POS0179 EXPLORING THE EFFECTS OF A TWO-SCORE INTERFERON SIGNATURE AND RESPONSES TO INTERFERON STIMULUS

Z. Wigston[1], A. Burska[1], M. Wittmann[1], E. Vital[1,2]. [1]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [2]*NIHR, Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: IFN Scores are increasingly important as biomarkers to stratify RMDs and select patients for interferon targeted therapies. Several studies have previously demonstrated that different sets of interferon stimulated genes (ISGs) have different clinical associations. We validated a 2-score system of ISGs expression consisting of Score A (a set of ISGs included in most interferon signature assays) and Score B (a set of less commonly

measured ISGs). Score B consistently demonstrated stronger clinical associations in studies of diagnosis, prediction of progression to SLE in At-Risk individuals, response to rituximab and imaging-proven synovitis. Previous literature suggested that subsets of ISGs were explained by different interferon subtypes.

Objectives: To understand the determinants of IFN Score A and IFN Score B.

Methods: PBMCs and whole blood Tempus from 4 different healthy donors were stimulated with various cytokines and IFNs at 6- and 24-hour time points. RNA from both sample types were extracted and the expression of 26 interferon stimulated genes were measured using TaqMan and normalised to house-keeping gene PPIA. IFN Scores A and B were calculated as previously described [1]. To compare relative increase in expression with each condition, we calculated delta Ct fold change relative to non-stimulated. To represent greater expression as numerically higher positive values, relative expression was calculated as (fold change*-100) +100. Independent T-test calculated the significant differences between each condition compared to IFN α stimulation.

Results: Table 1 shows differences between each condition compared with IFN α at the 6-hour time point. In both sample types, all conditions excluding IFN β stimulation were shown to induce significantly lower expression of both scores compared to IFN α ($p < 0.01$). At 6 and 24 hours, IFN α and IFN β showed a strong induction of IFN score A and B. At 6 hours, IFN γ, κ, and λ induced IFN score A and B but weaker than IFN α and β which was shown in both sample types. We did not observe a difference between the expression of these two scores according to interferon subtype. Other cytokines (TNF, IL-1 and IL-6) weakly induced expression of Score A and B. For IL-10 there was a possible discordant effect with increase in expression of Score B, but decreased expression of Score A, however these changes were small in magnitude.

Table 1.

Condition	IFN Score A		IFN Score B	
	Mean relative expression vs. non-stimulated	P value (vs IFN α)	Mean relative expression vs. non-stimulated	P value (vs IFN α)
PBMC				
IFN α	103.4	-	71.8	-
IFN β	97.1	0.373	64.7	0.352
IFN γ	37.5	<0.001	29.5	0.002
IFN κ	16.6	<0.001	3.1	<0.001
IFN λ	24.8	<0.001	11.1	<0.001
IL-1	9.7	<0.001	4.4	<0.001
IL-6	4.5	<0.001	4.1	<0.001
IL-10	-15.2	<0.001	8.0	<0.001
TNF α	9.6	<0.001	1.2	<0.001
Whole Blood				
IFN α	116.7	-	74.1	-
IFN β	116.6	0.997	73.2	0.894
IFN κ	23.0	0.001	7.9	0.003
IFN λ	23.0	0.001	7.6	<0.001

Conclusion: We found a difference in the induction of ISG expression between subtypes of Type I interferon, as well as other interferons and cytokines. However, the relative expression of IFN Score A and IFN Score B is not easily explained by the subtypes of interferon. We have also previously shown that these scores are both similarly expressed comparing different cell subsets. The explanation for the coordinated expression of these ISGs is therefore unclear and future work will explore the scores with a combination of conditions.

TYPE I INTERFERON DEPENDENT HSA-MIR-145-5P DOWNREGULATION MODULATES MUC1 AND TLR4 OVEREXPRESSION IN SALIVARY GLANDS FROM PRIMARY SJÖGREN'S SYNDROME PATIENTS

D. Jara[1], S. Aguilera[2], P. Carvajal[1], I. Castro[3], M. J. Barrera[4], S. González[5], C. Molina[4], M. J. González[1]. [1]*Instituto de Ciencias Biomédicas, Facultad de Medicina, Universidad de Chile, Programa de Biología Celular y Molecular, Santiago, Chile*; [2]*Clínica INDISA, Rheumatology, Santiago, Chile*; [3]*Facultad de Medicina, Universidad de Chile, Departamento de Tecnología Médica, Santiago, Chile*; [4]*Universidad San Sebastián, Facultad de Odontología, Santiago, Chile*; [5]*Facultad de Ciencias, Universidad Mayor, Escuela de Odontología, Santiago, Chile*

Background: Primary Sjögren's syndrome (pSS) is an autoimmune and inflammatory disease that mainly affects the salivary glands (SG) and is characterized by an overactivation of the type I interferon pathway (IFNs I). IFNs I are known to regulate the levels of microRNAs (miRNAs), non-coding RNAs whose levels are altered in pSS. IFNs I can decrease the levels of miR-145-5p, a miRNA with anti-inflammatory roles that has been reported downregulated in SG of from pSS patients [1]. This miRNA has TLR4 and MUC1 transcripts as predicted targets. MUC1 and TLR4 are two proteins overexpressed in SG of pSS patients that contribute, through various mechanisms, to the inflammatory state and glandular dysfunction [2-3]. Thus, we propose that IFNs I may contribute to a self-perpetuating inflammation loop through a hsa-miR-145-5p dependent MUC1 and TLR4 overexpression in the SG of pSS patients.

Objectives: to evaluate whether mRNA levels of MUC1 and TLR4 are modulated by hsa-miR-145-5p in a IFNs I dependent manner.

Methods: 13 pSS patients and 9 controls SG biopsies were analyzed. hsa-miR-145-5p levels were determined by TaqMan assays and MUC1, TLR4, IFN-α and IFN-β mRNA levels by RT-qPCR. Additionally, in vitro assays using type I IFNs and chemically synthesized hsa-miR-145-5p mimics and inhibitors were performed to study its effect on MUC1 and TLR4 expression. JAK1 and STAT1 mRNA levels were also measured.

Results: By Taqman assays we validated the decreased hsa-miR-145-5p levels ($p=0.0001$) in SG of pSS patients compared to controls. The decreased hsa-miR-145-5p levels correlated inversely with the increased mRNA levels of IFN-β ($p=0.0192$) in SG of pSS-patients. The hsa-miR-145-5p downregulation also correlated inversely with the overexpression of its predicted targets MUC1 ($p=0.010$) and TLR4 ($p=0.0004$). In vitro assays showed that IFN-β induces the overexpression of JAK1 ($<p=0.0001$) and STAT1 ($p=<0.0001$) leading to the downregulation of hsa-mir-145-5p ($p=<0.0001$) and increased MUC1 ($p=<0.0001$) and TLR4 mRNA levels ($p=<0.0001$). Functional assays suggest a regulation of hsa-miR-145-5p on MUC1 and TLR4 expression as MUC1 and TLR4 mRNA levels were decreased in HSG cells transfected with hsa-miR-513c-3p mimic and increased in HSG cells transfected with the miRNA inhibitor.

Conclusion: Our findings suggest that IFNs I could induce the downregulation of hsa-miR-145-5p leading to the overexpression of MUC1 and TLR4 in SG from pSS patients. TLR4 is activated by ectopic mucins in the SG extracellular matrix from pSS patients which induces pro-inflammatory cytokines secretion [3]. Furthermore, the high levels of the MUC1-SEC and MUC1-Y isoforms observed in SG from pSS patients may favor cytokine synthesis through the immuno-enhancing peptide of MUC1-SEC or through the formation of a MUC1-SEC/MUC1-Y complex [4]. Therefore, IFNs I may contribute to the development of SS through amplification and perpetuation of inflammation due to a hsa-miR-145-5p dependent MUC1 and TLR4 overexpression.

POS0181 HOW FIT ARE THE SOCIAL SUPPORT INSTRUMENTS USED IN RMDS: A SYSTEMATIC REVIEW OF VALIDATION STUDIES

D. De Cock[1], D. Benavent[2], L. Falzon[3], S. Ramiro[4,5], L. Carmona[6]. [1]*KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium*; [2]*Hospital Universitario la Paz-IdiPaz, Rheumatology Service, Madrid, Spain*; [3]*Northwell Health, Center for Personalized Health, New York, United States of America*; [4]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [5]*Zuyderland Medical Center, Rheumatology, Heerlen, Netherlands*; [6]*Instituto de Salud Musculoesquelética (InMusc), Rheumatology, Madrid, Spain*

Background: Rheumatic and musculoskeletal diseases (RMDs) diminish psychosocial well-being. Social support (SS) is considered to improve this psychosocial wellbeing. Therefore, SS is an important construct to measure in RMDs.
Objectives: To systematically review and summarize the psychometric properties of SS instruments developed or validated in RMDs.
Methods: A comprehensive search in Medline, Embase, PsycINFO, CINAHL and Epistemonikos was performed from inception to June 8, 2020, with the aid of an experienced librarian (LF). Two researchers (DDC and DB) independently screened articles on title+abstract and next on full text. Reference lists of included studies were reviewed for additional references. Articles were included if covering psychometric properties (detailed in the Table 1) of SS instruments used in RMDs. Studies on questionnaires lacking an English version, unpublished material, case reports, editorials, letters, or reviews were excluded. Risk of bias of studies and instruments was assessed via the COSMIN checklist.
Results: From 4986 articles captured, 30 met the predefined inclusion criteria. These articles included 21 SS instruments used in 8 RMDs, mainly rheumatoid arthritis and osteoarthritis.
Table 1 shows the psychometric properties per instrument. Construct validity, structural validity, and internal consistency were assessed for most instruments, while measurement invariance, measurement error, criterion validity and responsiveness in ≤3 instruments each. Development and content validity of the instruments gave consistently high risk of bias by the COSMIN checklist.
The most widely validated instruments were the Arthritis Impact Measurement Scales (AIMS) and the Osteoarthritis Knee and Hip Quality of Life (OAKHQOL), with their respective derived instruments (AIMS2, AIMS2-SF, mini-OAKHQOL and e-OAKHQOL). For the AIMS SS scale, internal consistency ranged between 0.33-0.69 (Cronbach's α) and test-retest reliability was estimated 0.92 (Guttman reproducibility coefficient). For the OAKHQOL SS scale, internal consistency ranged between 0.78-0.81 (Cronbach's α) and test-retest reliability ranged between 0.5-0.85 (ICC). Responsiveness was only investigated in AIMS and the Sickness Impact Profile (SIP) instrument. Relative efficiency for SS for the SIP was considerably higher than for AIMS (0.74 vs 0.18).
Conclusion: This review gives a summary of the psychometric properties of SS instruments in RMDs. Most instruments show sufficient structural validity internal consistency and reliability, but some psychometric properties such as criterion validity, measurement error and invariance, need to be investigated before choosing an optimal SS instruments.

POS0182 MINIMAL CLINICALLY IMPORTANT IMPROVEMENT (MCII) AND PATIENT ACCEPTABLE SYMPTOM STATE (PASS) FOR PAIN AND FUNCTION INSTRUMENTS IN HAND OSTEOARTHRITIS (OA)

F. Kroon[1,2], L. Van de Stadt[1], D. Van der Heijde[1], M. Kloppenburg[1,3]. [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [2]*Zuyderland Medical Center, Rheumatology, Heerlen, Netherlands*; [3]*Leiden University Medical Center, Clinical Epidemiology, Leiden, Netherlands*

Background: Australian/Canadian Hand OA Index (AUSCAN), Michigan Hand Outcomes Questionnaire (MHQ), Functional Index of Hand OA (FIHOA) and visual analogue scale (VAS) are frequently used instruments to measure pain and function in hand OA research. MCII and PASS are useful to interpret results of patient reported outcomes.
Objectives: To estimate MCII and PASS for these instruments using anchor-based methods.
Methods: Hand OA patients participating in a six-week randomised placebo-controlled trial with prednisolone (RCT; NTR5263) and those attending the two-year follow-up visit of the observational Hand OSTeoArthritiS cohort completed AUSCAN subscales pain and function, MHQ subscales pain, activities of daily living (ADL) and overall function, FIHOA and 100mm VAS pain. RCT participants were asked to indicate whether they changed compared to baseline (improved/no change/worse) and to rate the importance of improvement (very much/moderately/slightly/not at all). MCII was defined as the minimal improvement in symptoms achieved by 75% of participants who stated a slight/moderate improvement during the RCT, calculated as the 75th percentile of the distribution of change scores from baseline in this group. Absolute and relative percentage change were evaluated. For MCII direction of effect was unified, so positive values indicate worse symptoms and vice versa. Participants from both studies rated satisfaction with their state of health (acceptable/unacceptable). PASS was defined as the minimal score considered acceptable for 75% of participants, calculated as the 75th percentile of the distribution of scores in participants who rated their health 'acceptable'.
Results: Demographics of the RCT (n=92, mean age 63.9, 79% women) and cohort (n=383, 60.9 years, 84% women) participants were typical for hand OA. RCT participants were more symptomatic (e.g. mean [SD] VAS pain 54.0 [20.5] versus 35.2 [19.1]). Of the function instruments, only AUSCAN had a credible MCII (relative percentage improvement 9.8%), while the (positive) MCII values for FIHOA and MHQ subscales would indicate that worsening was rated as functional improvement (table 1). MCII was negative (corresponding to improvement) for all pain instruments, with relative percentage change around 25% for VAS and MHQ, compared to only 2% for AUSCAN. PASS values of all instruments were comparable in the two populations. Most instruments had a PASS around 50% of the possible maximum score, except for MHQ ADL, in which higher is better and a relatively high PASS is thus indicative of a floor effect (table 1).

Table 1. MCII and PASS of pain and function instruments in hand OA patients in two settings.

	MCII (95% CI) in RCT†			PASS (95% CI)	
Instrument	Absolute units	Percentage	[n]	RCT (n=68)	Cohort (n=126)
MHQ					
Overall function, 0-100*	3.4 (-2.7;9.5)	3.6 (-9.1;16.3)	[23]	55.6 (52.6;58.5)	48.1 (45.7;50.4)
ADL, 0-100*	1.6 (-4.4;7.6)	2.8 (-9.6;15.3)	[23]	71.7 (68.2;75.1)	62.9 (59.8;66.0)
Pain, 0-100	-12.2 (-17.2;-7.1)	-23.1 (-35.4;-10.8)	[16]	47.0 (40.5;53.5)	55.7 (52.0;59.5)
AUSCAN					
Function, 0-36	-3.3 (-5.7;-0.9)	-9.8 (-23.9;4.2)	[23]	17.1 (15.3;19.0)	20.9 (19.4;22.3)
Pain, 0-20	-1.1 (-2.6;0.4)	-1.8 (-18.5;14.9)	[27]	9.0 (8.2;9.9)	11.1 (10.3;11.8)
FIHOA, 0-30	0.1 (-1.6;1.7)	22.7 (-0.7;46.0)	[23]	12.4 (11.1;13.7)	13.9 (12.8;15.0)
VAS pain, 0-100	-11.5 (-18.2;-4.7)	-24.4 (-36.1;-12.8)	[27]	47.7 (42.2;53.3)	48.8 (44.6;53.0)

Direction of effect of all instruments is higher is worse, except those with *.†For all MCII direction of effect was unified, so positive values indicate worse symptoms and negative values values indicate improved symptoms.

Conclusion: The only function instrument with an acceptable threshold for MCII was AUSCAN function, while for pain MHQ and VAS performed better than AUSCAN. PASS values show a relatively high level of tolerance of 50% of the maximum of the scale.

POS0183 SIGLEC1 AS A TYPE I INTERFERON BIOMARKER IN IDIOPATHIC INFLAMMATORY MYOPATHIES

M. Graf[1], A. S. L. Von Stuckrad[2], A. Uruha[3,4], J. Klotsche[5], L. Zorn-Pauly[1], N. Unterwalder[6], T. Buttgereit[7], M. Krusche[1], C. Meisel[6], G. R. Burmester[1], F. Hiepe[1], R. Biesen[1], T. Kallinich[2], W. Stenzel[4], U. Schneider[1], T. Rose[1].
[1]Charité – Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany; *[2]Charité – Universitätsmedizin Berlin, Pediatric Pneumology, Immunology and Critical Care Medicine and SPZ (Center for Chronically Sick Children), Berlin, Germany*; *[3]Tokyo Metropolitan Neurological Hospital, Neurology, Tokyo, Japan*; *[4]Charité – Universitätsmedizin Berlin, Neuropathology, Berlin, Germany*; *[5]Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), DRFZ, Berlin, Germany*; *[6]Labor Berlin - Charité Vivantes GmbH, Immunology, Berlin, Germany*; *[7]Charité – Universitätsmedizin Berlin, Dermatology and Allergy, Dermatological Allergology, Berlin, Germany*

Background: Idiopathic inflammatory myopathies (IIM) are autoimmune diseases that mainly affect skeletal muscle, lung, skin and joints. IIM can be separated into dermatomyositis (DM), inclusion body myositis (IBM), antisynthetase syndrome (AS) and immune-mediated necrotizing myopathy (IMNM). Type I interferons (IFN) are known to play a crucial role in the etiopathogenesis of some of these entities such as DM.[1] Sialic acid binding Ig-like lectin 1 (SIGLEC1, CD169) is part of the type I IFN signature found in SLE and DM and is expressed on the cell surface of monocytes. Thus, analysis of SIGLEC1 expression by flow cytometry enables a straightforward assessment of the type I IFN signature. Its utility has been shown for juvenile and adult SLE and other rheumatic diseases but not in IIM.[2,3] The assessment of the type I IFN system in clinical practice is an unmet need and, in this context, SIGLEC1 might be useful.
Objectives: To assess SIGLEC1 expression on monocytes by flow cytometry as a type I IFN biomarker in IIM
Methods: Pediatric and adult patients with a clinical diagnosis of DM, AS, IMNM and IBM and at least one measurement of SIGLEC1 who have been treated at the Department of Rheumatology, Charité - Universitätsmedizin Berlin between 2015 and 2020 were included in this retrospective study. Control groups of healthy individuals (n=19) and SLE patients (n=30) were included. Disease activity was assessed by Physician Global Assessment (PGA) and Childhood Myositis Assessment Scale (CMAS). SIGLEC1 expression on monocytes was analyzed by flow cytometry. Cross-sectional analyses (n=74) were performed using Mann Whitney-U test (MWU) and two-level mixed-effects linear regression model was used for longitudinal analyses (n=26, 110 visits). This study was approved by the local ethics committee of the Charité - Universitätsmedizin Berlin.
Results: 74 patients (adult/juvenile DM: n=21/n=17; AS: n=19; IMNM: n=8; IBM: n=9) were included. In cross-sectional analysis, SIGLEC1 expression was significantly upregulated in adult and juvenile DM patients with moderate to severe disease activity (PGA≥5) compared with adult/juvenile DM patients with no to moderate disease activity (PGA<5) (both p<0.001). In longitudinal analyses, SIGLEC1 correlated with disease activity in juvenile DM (SIGLEC1 vs. CMAS: betaST=-0.65; p<0.001) and adult DM (SIGLEC1 vs. PGA: betaST=0.52; p<0.001), better than Creatine Kinase (CK) (juvenile DM, CK vs. CMAS: betaST=-0.50; p<0.001; adult DM, CK vs PGA: betaST=0.17; p=0.149). In AS 42,1% of the patients showed elevated SIGLEC1 expression, while it was not upregulated in IMNM and only in two patients with IBM, who were concurrently positive for autoantibodies that affect the type I IFN system (see Figure 1).
Conclusion: SIGLEC1 is a useful biomarker to identify an activated type I IFN system in IIM. Flow cytometry is used widely in laboratory medicine, which could facilitate the implementation of SIGLEC1 into clinical routine.

POS0184 URINE-GALECTINE 3 BINDING PROTEIN (U-GAL3BP) IS A SENSITIVE MARKER OF KIDNEY INFLAMMATION AND RESPONSE TO TREATMENT IN LUPUS

F. Faustini[1,2], H. Idborg[2], E. Svenungsson[1,2], S. Poetzsch[3], S. Okitsu[4], A. Larsson[5], I. Gunnarsson[1,2]. *[1]Karolinska University Hospital, Rheumatology, Stockholm, Sweden*; *[2]Karolinska Institutet, Department of Medicine, Division of Rheumatology, Stockholm, Sweden*; *[3]Merck Healthcare KGaA, Merck Healthcare KGaA, Darmstadt, Germany*; *[4]EMD Serono Research and Development Institute, EMD Serono Research and Development Institute, Billerica, MA, United States of America*; *[5]Uppsala University, Department of Medical Sciences/Clinical Chemistry, Uppsala, Sweden*

Background: Lupus nephritis (LN) represents a serious manifestation of systemic lupus erythematosus (SLE) which requires timely diagnosis, treatment and monitoring. Kidney biopsy is the gold standard of diagnosis and is instrumental to treatment decisions, however it is not generally performed for monitoring and evaluation of response to treatment. To such purposes, accessible biomarkers, for instance urinary, might be highly advantageous.
Objectives: To evaluate urine-Galectin 3 binding protein (uGAL3BP) as a novel biomarker in biopsy-proven active lupus nephritis (A-LN) in comparison to active non-renal SLE (ANR-SLE), inactive SLE (I-SLE), and in population-based controls (HC). Furthermore, we compared uGAL3BP with known markers of renal pathology including neutrophil gelatinase-associated lipocalin (NGAL), osteopontin (OPN), kidney injury molecule 1 (KIM-1), and galectin 3 (GAL3).
Methods: Urine samples from A-LN (n=86), ANR-SLE (n=63), I-SLE (n=73) and HC (n=48) were included. uGAL3BP was measured using a commercial ELISA kit and values, adjusted for u-creatinine levels, were expressed as ng/mmol. Other markers analyzed according to clinical routine at the Department of Clinical Chemistry at Uppsala University Hospital were also adjusted for u-creatinine levels. Renal biopsies were graded according to the ISN/RPS classification(1) and evaluated for activity and chronicity index. Ten A-LN patients were evaluated before and after induction treatment.
Results: In the A-LN group, median (IQR) levels of u-GAL3BP were 15.8 (6.8-24.6) ng/mmol, while in ANR-SLE, I-SLE, HC were significantly lower 4.4 (2.0-9.0), 2.8 (1.7-4.7), 2.0 (0.9-4.8) respectively (Kruskal-Wallis p<0.0001). Similarly, u-NGAL was found at higher levels in A-LN patients, 3.3 (2.0-5.7) µg/mmol, with respect to the ANR-SLE 2.0 (0.9-4.5), I-SLE 1.6 (0.8-3.2), and HC 2.4 (1.2-5.3), (p=0.008). The highest levels of OPN were found in the group of I-SLE (190.6 (85.1-299.9) µg/mmol, compared to A-LN 72.98 (37.6-118.1), ANR-SLE 92.3 (58.5-129.7) and HC 76.5 (58.2-120.3), (p<0.0001). KIM-1 levels differed among groups with higher levels in the A-LN group (188.9 (113.7-309.7) ng/mmol), in comparison to ANR-SLE 131.4 (92.2-186.1), I-SLE 123.8 (70.3-200.2), and HC 78.2 (68.8-115.1), (p<0.0001). GAL3 showed comparable levels across groups.
When exploring the biomarkers across histologic subgroups of LN, u-GAL3BP could discriminate between proliferative and mesangial forms (17.7(9.6-32.5) vs 6.7(5.1-16.1) ng/mmol, p=0.027), while it did not discriminate against membranous LN. U-NGAL was higher in proliferative LN 3.7(2.4-5.8) µg/mmol with respect to membranous 2.4 (1.1-3.8) (p=0.01), while mesangial LN showed comparable levels. OPN, KIM-1 and GAL3 were comparable across groups.
In the ten patients with available samples after induction therapy (mycophenolate mofetil (MMF) in 4, rituximab (RTX) in one, cyclophosphamide in 5 (one combined with MMF and one with RTX), u-GAL3BP showed a significant decrease of median levels from 218.8 to 41.5 ng/mmol (Wilcoxon p=0.03). u-GAL3BP associated with renal activity in class III/IV LN (R=0.42, p=0.004).
Conclusion: Among the tested markers, high uGal3BP adjusted for creatinine was found to be a promising marker of renal involvement in SLE patients and associated with renal activity in patients with proliferative forms (class III/IV) of LN. A decrease was further seen following therapy, suggesting that u GAL3-BP could be used to monitor renal activity.

POS0185

IDENTIFICATION AND VALIDATION OF TWO NOVEL SERUM BIOMARKERS ASSOCIATED WITH THE SEROLOGICAL STATUS OF RHEUMATOID ARTHRITIS PATIENTS.

V. Calamia[1], L. Lourido[1], P. Fernández Puente[1,2], A. Illiano[3], R. Paz González[1], B. Rocha Loureda[1], L. Collado Rodríguez[1], E. Perez-Pampín[4], C. Ruiz-Romero[1], A. Gonzalez[4], F. J. Blanco[1]. *[1]Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas, Universidade da Coruña (UDC), Unidad de Proteómica, Grupo de Investigación de Reumatología (GIR), A Coruña, Spain*; *[2]Universidad de A Coruña (UDC), Centro de Investigaciones Científicas Avanzadas (CICA), A Coruña, Spain*; *[3]University of Naples Federico II, Department of Chemical Sciences, Naples, Italy*; *[4]Instituto de Investigación Sanitaria (IDIS). Hospital Clínico Universitario de Santiago (CHUS), Experimental and Observational Rheumatology and Rheumatology Unit, Santiago de Compostela, Spain*

Background: Despite the diagnostic value of Rheumatoid Factor (RF) and Anti-Citrullinated Protein Antibodies (ACPA), more serological markers are needed in order to improve early diagnosis and treatment response of the Rheumatoid Arthritis (RA) patients. Increased knowledge about how these two major autoreactivities arise is crucial for understanding how RA develops and what mechanisms drive pathogenesis.
Objectives: We aimed to investigate, using a proteomic strategy, novel protein biomarkers associated with RF and/or ACPA that might be useful to stratify seropositive and seronegative RA patients.
Methods: A shotgun proteomic analysis was performed on 80 sera from the RA cohort of the Rheumatology Unit of the University Hospital of Santiago de Compostela (CHUS). Sera were classified as seropositive or seronegative according to their RF and ACPA values, and were then analyzed employing the iTRAQ labelling technique (Sciex) followed by LC-MALDI-MS/MS analysis (MALDI-TOF). A Multiple Reaction Monitoring (MRM) method was subsequently developed using the Skyline Software for the simultaneous quantification of 26 peptides belonging to ten putative protein biomarkers. The quantitative targeted analysis was performed using peptides with isotope labelled amino acids as internal standards. Serum levels of orosomucoid 1 (ORM1) and haptoglobin (HPT) were measured using commercially available ELISA Kits in the whole RA cohort (n=260) from the Rheumatology Unit of the University Hospital of A Coruña (HUAC).
Results: For the initial screening, eighty sera were grouped according to the ACPA/RF status in 4 pools (20 patients/pool). Using an iTRAQ technology-based quantitative proteomic approach, the abundance of eleven proteins was altered in the sera from $ACPA^{pos}/RF^{pos}$, 13 proteins in $ACPA^{neg}/RF^{pos}$ and 12 proteins in $ACPA^{pos}/RF^{neg}$, compared to $ACPA^{neg}/RF^{neg}$. Vitamin D binding protein (VTDB) was the unique protein that resulted increased in all the comparisons. For the biomarker verification phase, all the samples from the CHUS cohort were analyzed individually (n=80). Using the MRM technology, 26 peptides belonging to ten putative protein biomarkers associated with double positivity were simultaneously quantified. The statistical analysis showed a significant modulation of 9 peptides (belonging to 4 different proteins) in $ACPA^{pos}/RF^{pos}$, 7 peptides (5 proteins) in $ACPA^{neg}/RF^{pos}$, and 9 peptides (6 proteins) in $ACPA^{pos}/RF^{neg}$ compared to $ACPA^{neg}/RF^{neg}$ ($p<0.05$). Two acute phase reactants (ORM1 and HPT) displayed the same modulation in both screening and verification phases, thus confirming their association with the double positivity. Finally, in the biomarker validation phase, a total of 260 patients from CHUAC were included (Table 1). RA patients were classified as follows: (1) 112 patients (43.1%) were $ACPA^{pos}/RF^{pos}$; (2) 73 patients (28.1%) were $ACPA^{neg}/RF^{neg}$; (3) 51 patients (19.6%) were $ACPA^{neg}/RF^{pos}$; and (4) 24 patients (9.2%) were $ACPA^{pos}/RF^{neg}$. Serum levels of ORM1 and HPT (Figure 1), measured by commercial immunoassays, confirmed their increased values in double seropositive patients (p=0,0053 ORM1; p=0,0026 HPT). Finally, the increased level of ORM1 resulted associated with RF rather than ACPA status (p=0,0008 $ACPA^{neg}/RF^{pos}$); whereas HPT was associated with ACPA rather than RF status (p=0,0112 $ACPA^{pos}/RF^{neg}$).

Table 1. The different phases of RA biomarker development followed in this study.

	DISCOVERY PHASE		VERIFICATION PHASE		VALIDATION PHASE	
Source center	CHUS		CHUS		CHUAC	
Nº of samples	*n*= 4		*n*= 80		*n*= 260	
	ACPA+RF+	Pool 1	ACPA+RF+	20	ACPA+RF+	112
	ACPA-RF-	Pool 2	ACPA-RF-	20	ACPA-RF-	73
	ACPA-RF+	Pool 3	ACPA-RF+	20	ACPA-RF+	51
	ACPA+RF-	Pool 4	ACPA+RF-	20	ACPA+RF-	24
Nº of biomarkers	ORM1, ORM2, HPT, A2GL, AACT, RBP4, PLMN, IC1, VDBP, APOB		ORM1, HPT, A2GL, AACT		ORM1, HPT	

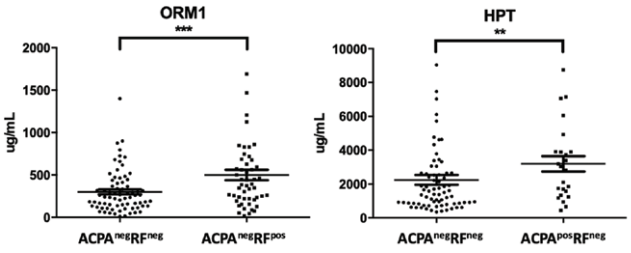

Figure 1: ORM1 levels are increased in RA patients seropositive for RF (499±437 ug/mL in $ACPA^{neg}RF^{pos}$ vs 300±248 ug/mL in $ACPA^{neg}RF^{neg}$). HPT levels are statistically significant increased in RA patients seropositive for ACPA (3193±2233 ug/mL in $ACPA^{pos}RF^{neg}$ vs 2046±1795 ug/mL in $ACPA^{neg}RF^{neg}$).

Figure 1.

Conclusion: The determination of ORM1 and HPT in sera provides novel information useful for patient stratification, which might improve diagnostic and prognostic approaches and facilitate the development of personalized medicine strategies in RA.

POS0186 METABOLOMIC SIGNATURES FOR KNEE CARTILAGE VOLUME LOSS OVER 10 YEARS

Z. Xie[1,2], D. Aitken[3], M. Liu[1], G. Lei[2], G. Jones[3], G. Zhai[1]. [1]*Memorial University of Newfoundland, Division of Biomedical Sciences (Genetics), Faculty of Medicine, St. John's, Canada*; [2]*Central South University, Xiangya Hospital, Changsha, China*; [3]*University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*

Background: Osteoarthritis (OA) is the most common form of arthritis, and its impact is increasing year by year due to an aging population and lack of effective treatments. One of the main structural pathological changes of OA is the loss of articular cartilage. Tools that can predict cartilage loss would help identify people at high risk, thus preventing OA development.

Objectives: Using a metabolomics approach, the current study aimed to identify serum metabolomic signatures for predicting the loss of knee cartilage volume over 10 years in a well-established community-based cohort - the Tasmania Older Adult Cohort (TASOAC).

Methods: TASOAC is an on-going, prospective, population-based study of older adults who were randomly selected from the roll of electors in Southern Tasmania, Australia. Participants had a right knee magnetic resonance imaging (MRI) scan at baseline and a 10-year follow-up. Cartilage volume was measured in the medial, lateral, and patellar compartments and change in cartilage volume over 10 years was calculated as percentage change per year. Fasting serum samples collected at 2.6-year follow-up were metabolomically profiled using the TMIC Prime Metabolomics Profiling Assay which measures a total of 143 metabolites. 129 metabolite concentrations passed the quality control and the pairwise ratios of them as the proxies of enzymatic reaction were calculated. Linear regression models were used to test the association between each of the metabolite ratios and change in cartilage volume in each of the knee compartments with adjustment for age, sex, and body mass index (BMI). The significance was defined at $a=3.0\times10^{-6}$ to control multiple testing of 16,512 ratios with Bonferroni method.

Results: A total of 344 participants (51% females) were included. The mean baseline age was 62.83±6.13 years and the mean BMI was 27.48±4.41 kg/m^2. The average follow-up time was 10.84±0.66 years. Cartilage volume reduced by 1.34±0.72%, 1.06±0.58%, and 0.98±0.46% per year in the medial, lateral, and patellar compartments, respectively. Our data showed that an increased ratio of hexadecenoylcarnitine (C16:1) to tetradecanoylcarnitine (C14) was associated with a 0.12±0.02% per year reduction in patellar cartilage volume ($p = 8.80\times10^{-7}$). An increased ratio of hexadecenoylcarnitine (C16:1) to dodecanoylcarnitine (C12) was also associated with a 0.12±0.02% per year reduction in patellar cartilage volume ($p = 2.66\times10^{-6}$). While there were several metabolite ratios associated with cartilage volume loss in the medial and lateral compartments, none of them reached the predefined significance level.

Conclusion: Our data suggested that alteration of fatty acid β-oxidation is involved in knee cartilage loss, especially in the patellar compartment, and the serum ratio of C16:1 to C14 and to C12 could be used to predict long-term patellar cartilage loss.

POS0187 THE PROGNOSTIC FACTORS IN PREDICTING RELAPSE FOR IGG4-RELATED DISEASE: A LONG-TERM STUDY BASED ON THE CLINICAL AND PATHOLOGICAL CHARACTERISTICS OF THE PATIENTS

Z. Ji[1], L. Chen[2], L. Ma[1], L. Zhang[1], H. Chen[1], L. Ma[1], L. Jiang[1]. [1]*Shanghai Zhongshan hospital, Fudan University, Rheumatology, Shanghai, China*; [2]*Shanghai Zhongshan hospital, Fudan University, Pathology, Shanghai, China*

Background: The relationship between the pathological findings and disease relapse has not been well established.

Objectives: We aim to investigate the clinical and pathological manifestations in relation with disease relapse in IgG4-RD, as well as identify prognostic factors in predicting relapsed disease.

Methods: This study enrolled 71 patients newly diagnosed with IgG4-RD between Jan 2011 and April 2020, all of whom had received pathological examinations. Their pathological manifestations and clinical data were collected. Multivariate Cox regression and AUC (area under curve) were used to identify predictors for relapsed disease and assess the predictive value of these predictors, respectively.

Results: During a follow-up period of 26 (range, 6-123) months, 4.2% (3/71) patients died. The remaining 68 patients were all treated with glucocorticoids with or without immunosuppressor continuously. By the end of follow-up, 47 (69.1%) patients sustained clinical remission, and 21 (30.9%) patients suffered relapsed disease with a median relapse time at 10 (6-30) months. We found that IgG4 ≥ 6.5g/L (OR 1.52-11.06), IgG ≥ 20.8g/L (OR 1.11-7.23), IgG4-RD responder index (RI) ≥ 9 (OR 1.28-11.37), and more $IgG4^+$ plasma cell infiltration (≥ 60 / HPF in visceral organs, or ≥ 200 / HPF in head and neck organs) (OR 1.79-22.41) were all independent predictive factors for disease relapse. A prognostic score was explored for predicting recurrence in IgG4-RD, including three predictive factors (IgG ≥ 20.8g/L, IgG4-RD RI ≥9, and more $IgG4^+$ plasma cell infiltration). The three-year relapse rate for the patients with no, one, two, and three risk factors were 0%, 27.3%, 66.7%, and 100%, respectively.

Conclusion: Patients' earlier IgG4 ≥ 6.5g/L, IgG ≥ 20.8g/L, IgG4-RD RI ≥9, and more $IgG4^+$ plasma cell infiltration independently predicted disease relapse. We explored a prognostic score for predicting recurrence in IgG4-RD include three predictive factors (IgG ≥ 20.8g/L, IgG4-RD RI ≥9, and more $IgG4^+$ plasma cell infiltration), which might be used to evaluate the risk of recurrence in IgG4-RD.

POS0188 DISEASE ACTIVITY OUTCOME MEASURES ARE ONLY AVAILABLE IN HALF OF THE ELECTRONIC MEDICAL FILES OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS FOLLOWED IN AN OUTPATIENT CLINIC: THE RESULTS OF AN AUDIT OF A TERTIARY-CARE RHEUMATOLOGY DEPARTMENT.

E. Portier[1], M. Dougados[1], C. Roux[1], A. Moltó[1]. [1]*Cochin Hospital, Rheumatology, Paris, France*

Background: Current recommendations for management of patients with axial Spondylarthritis (axSpA) include regular collection of validated disease activity outcomes.

Objectives: This study aimed at evaluating the proportion of patients for whom the elements allowing the calculation of the validated outcome measures were available on the visits reported on the electronic medical records (EMR) and the factors associated with the presence of such information on the EMR.

Methods: This was a cross-sectional and monocentric observational study conducted in a tertiary-care rheumatology department, EULAR center of excellence and ASAS center. We performed a systematic electronic search among all patients with a SpA diagnosis code who attended an outpatient visit between February 1st, 2018 and February 28th, 2019. Thereafter, a manual search was performed in order to check whether disease activity outcome measures (or the elements allowing its calculation): BASDAI individual questions, Disease activity Global, CRP, BASDAI and ASDAS) were reported on EMR. Patient's and physician's demographics disease characteristics (including treatment) and whether the patient had participated in a systematic review were also collected. A descriptive analysis of the percentage of EMR with available outcomes was performed, and the characteristics of patients in whom these measures were available/were not available evaluated by univariable and multivariable analysis (including only variables with p < 0,10 on the univariate)

Results: 320 EMR of axSpA patients seen in the outpatient clinic were screened and selected. Among them, 178 (55.6%) had at least one disease activity outcome measure reported, while 144(45%) and 123 (38.4%) had a BASDAI and an ASDAS reported, respectively. The most frequently reported disease activity items were duration of morning stiffness (n=230, 72%) and CRP (n=224, 70%). Only previous participation on an educational program for self-assessment was found to be independently associated with a reported disease activity outcome: among the patients participating in such program, 93.1% (n=27/29) had a disease activity measure available, compared to 51.9% (n=151/291) in those who did not participate in such program (p<0.001) (Table 1)

Conclusion: Implementation of recommendations with regard to regularly collecting disease activity outcome measures is not optimal. The participation in educational programs including self-assessment educational programs might be one of the keys to improve such implementation.

POS0189 SERUM IFNA CONCENTRATIONS MEASURED WITH SINGLE-MOLECULE ARRAY TECHNOLOGY IN SJÖGREN'S SYNDROME REFLECT BLOOD INTERFERON-STIMULATED GENE EXPRESSION

E. Huijser[1], J. Göpfert[2], Z. Brkic[3], C. G. Van Helden-Meeuwsen[1], S. Jansen[1], T. Mandl[4], P. Olsson[4], B. Schrijver[1], M. W. Schreurs[1], P. L. Van Daele[1,3], W. A. Dik[1], M. Versnel[1]. [1]*Erasmus MC, University Medical Center Rotterdam, Immunology, Rotterdam, Netherlands*; [2]*NMI Natural and Medical Sciences Institute at the University of Tübingen, Biochemistry, Reutlingen, Germany*; [3]*Erasmus MC, University Medical Center Rotterdam, Internal Medicine, Division of Clinical Immunology, Rotterdam, Netherlands*; [4]*Lund University, Internal Medicine - Epidemiology, Lund, Sweden*

Background: Type I interferon (IFN-I) activation is a prominent feature of several Rheumatic and Musculoskeletal Diseases (RMDs) including primary Sjögren's syndrome (pSS), systemic lupus erythematosus (SLE) and systemic sclerosis (SSc). Ultrasensitive single-molecule array (SiMoA) technology has facilitated the measurement of subfemtomolar concentrations of IFNs [1-3].

Objectives: Here, we tested the performance of a commercially available SiMoA kit for detection of IFNα in serum from pSS, SLE, and SSc and correlated serum IFNα to whole blood IFN-stimulated gene (ISG) expression.

Methods: Serum IFNα2 was measured in healthy controls (HC; n=68) and patients with pSS (n=85, n=110), SLE (n=24) and SSc (n=23) using a ready-to-use IFNα SiMoA kit on a HD-X Analyzer. IFN-I activation was additionally determined from paired samples of whole blood IFN-stimulated gene (ISG) expression of IFI44, IFI44L, IFIT1, IFIT3, and MxA by RT-PCR or MxA-ELISA.

Results: Serum IFNα2 levels were elevated in pSS (median = 61.3 fg/mL) compared to HC (median < 5fg/mL) and SSc (median = 11.6 fg/mL), lower compared to SLE (median = 313.5 fg/mL), and positively correlated to whole blood ISG expression (rs=0.71-0.76, p<0.001). Comparable to MxA-ELISA (AUC=0.93), IFNα2 SiMoA identified pSS with high ISG expression (AUC=0.90) with 80-93% specificity and 71-84% sensitivity. Blinded validation in an independent pSS cohort yielded a comparable accuracy of 89%. Multiple linear regression indicated independent associations of autoantibodies, IgG, and use of hydroxychloroquine with serum IFNα2 concentrations in pSS. Confirming the literature [4], serum IFNα2 levels were lower in SLE patients in remission (DORIS classification) compared to patients not in remission.

Conclusion: Thus, SiMoA serum IFNα2 reflects blood ISG expression in pSS, SLE and SSc. In light of IFN-targeting treatments, SiMoA could potentially be applied for patient stratification or high-throughput retrospective analysis of stored clinical trial material.

POS0190 ASSOCIATION BETWEEN OSTEOARTHRITIS-RELATED SERUM BIOCHEMICAL MARKERS OVER 11 YEARS AND KNEE SYMPTOMS IN MIDDLE-AGED ADULTS

A. Singh[1], L. Blizzard[2], A. Venn[1], G. Jones[1], J. Burgess[1,3], V. Parameswaran[1,3], C. Ding[1,4,5], B. Antony[1]. [1]*Menzies Institute for Medical Research, Musculoskeletal Health and Disease, Hobart, Australia*; [2]*Menzies Institute for Medical Research, Statistics, Hobart, Australia*; [3]*Royal Hobart Hospital, Department of Endocrinology, Hobart, Australia*; [4]*Monash University, Department of Epidemiology and Preventive Medicine, Clayton, Australia*; [5]*Southern Medical University, Clinical Research Centre, Zhujiang Hospital, Guangzhou Shi, China*

Background: Serum levels of cartilage and joint-specific biochemical markers such as cartilage oligomeric matrix protein (COMP), matrix metalloproteinase (MMP)-3, and hyaluronan (HA) are associated with cartilage degradation, joint tissue degradation, and synovitis in patients with OA. Change in these biomarkers may precede the morphological and clinical manifestations of OA and therefore have been explored as predictive markers in OA. However, few studies have evaluated the association of OA-related biomarkers with knee symptoms in general population-based middle-aged adults
Objectives: To describe the associations between OA-related biomarkers and knee symptoms in middle-aged adults followed up over 10-13 years
Methods: Blood samples were collected during the Childhood Determinants of Adult Health (CDAH)-1 study at baseline (year: 2004-06, age: 26–36 years) and 10-13 year follow-up (CDAH-3; year: 2014–2019, age: 36–49 years). Serum samples from baseline (n=156) and follow-up (n= 167) were analyzed for three OA-related biomarkers – namely COMP, MMP-3, and HA– using ELISA. Knee symptoms (pain, stiffness, and dysfunction) were assessed using the WOMAC scale during the CDAH-3 phase. Univariable and multivariable (adjusted for age, sex, and body mass index (BMI)) zero-inflated Poisson regression models with random effects were used to describe the above associations
Results: The prevalence of knee pain was 46%. In the multivariable model, adjusted for age, sex, and BMI, there was a significant positive association between COMP (ɞ=1.156, 95%CI: 0.989,1.324; p=0.04), MMP-3 (ɞ=1.013, 95%CI: 1.001,1.025; p=0.02), and HA (ɞ=1.008, 95%CI: 1.002,1.015, p=0.01) with knee pain and WOMAC-total score (Table 1) in middle-aged adults. The increase in knee pain per ng/ml increase in COMP, MMP-3, and HA was 15.7%, 1.3%, and 0.8%, respectively. The overall mean biomarker levels decreased over 10-13 years; however, the mean WOMAC-total scores were higher in participants whose COMP and HA levels increased (COMP: 24 (27.31), HA: 14.20 (22.60)) compared to those in whom it decreased or remained stable (COMP: 9.84 (16.83), and HA: 8.28 (13.22)) during this period. There was a significant positive association between COMP (ɞ=1.026, 95%CI: 1.002,1.050, p=0.03) and MMP-3 (ɞ=1.020, 95%CI: 1.009,1.030, p<0.01) measured at baseline and knee pain assessed after 10-13 year in the middle-aged adults (Table 1)
Conclusion: OA-related biochemical markers such as COMP and MMP-3 were positively associated with knee pain in population-based middle-aged adults. These results suggest biochemical markers measured in middle-aged adults may be used as a marker of joint pain

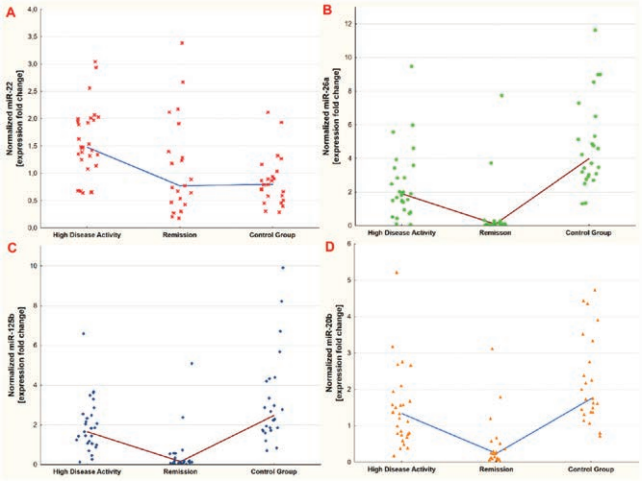
POS0191 THE VALUE OF MIR-20B, MIR-22, MIR-26A, MIR-125B AND MIR-221 IN RHEUMATOID ARTHRITIS

M. Ciesla[1], B. Kolarz[1], M. Majdan[2], M. Dryglewska[2]. [1]*University of Rzeszow, College of Medical Sciences, Rzeszow, Poland*; [2]*Medical University of Lublin, Department of Rheumatology and Connective Tissue Diseases, Lublin, Poland*

Background: Micro-RNAs (miRNAs) are an endogenous small, single-stranded, non-coding RNAs with a 18-25 nucleotide long and have been reported as a potential extracellular biomarkers of various diseases. They mainly decrease the gene expression by inhibiting the translation or cause mRNA destabilization.
Objectives: The aim of the study was to identify miRNAs whose plasma expression level is associated with RA prevalence and/or activity.
Methods: A total of 74 unrelated individuals, 50 with RA and 24 in a control group were enrolled to the study. Real-time PCR was used to evaluate the plasma expression levels of 5 miRNAs: miR-20b, miR-22 miR-26a, miR-125b, miR-221.
Results: We found the differences in four out of five evaluated miRs between RA and HC group – miR-26a, $p<0.0001$; miR-125b, $p<0.0001$; miR-20b $p<0.0001$; miR-22, p=0.005. Graphical presentation of the results is shown in Figure 1. The logistic regression results showed that miR-22 (p=0.0003) and miR-26a (p=0.049) are the most important molecules distinguishing RA patients and healthy controls in the study. MiR-22 was positively correlated with ESR (r_s=0.41), CRP (r_s=0.49) and DAS28 (r_s=0.33) and miR-26a was positively correlated with ESR (r_s=0.49), CRP (r_s=0.41), number of swelling joints (r_s=0.43), number of painful joints (r_s=0.74) and DAS28 (r_s=0.63). Moreover, miR-22 expression was different between rheumatoid factor (RF) positive and RF negative patients (p=0.04).
Conclusion: The results showed that miR-22 (p=0.0003) and miR-26a (p=0.049) may be the most useful in evaluated panel of miRs distinguishing RA



patients and HCs. In this study we demonstrated for the first time that plasma concentration of miR-22 may be considered as a potential molecular marker of RA exacerbation.

PsA treatment: what is new?

POS0192

PROGNOSTIC FACTORS ASSOCIATED WITH ACHIEVING MINIMAL DISEASE ACTIVITY IN EARLY PSORIATIC ARTHRITIS PATIENTS

E. Loginova[1], T. Korotaeva[1], E. Gubar[1], S. Glukhova[2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and psoriatic arthritis, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Medical and Social Problems in Rheumatology, Moscow, Russian Federation*

Background: The goal of treat to target strategy (T2T) in psoriatic arthritis (PsA) is attaining remission or minimal disease activity (MDA). The benefits of T2T have been seen recently [1]. But prognostic factors for MDA achievement in PsA patients (pts) at an early-stage hasn't been studied yet.

Objectives: to determine the prognostic factors associated with MDA achievement within 12 months (mos.) of treatment according to T2T strategy in early PsA pts.

Methods: 77 pts (M/F=36/41) with early active PsA fulfilling the CASPAR criteria were included. Mean age 36.9±10.45 years (yrs.), PsA duration 11.1±10.0 mos., Psoriasis (PsO) duration 82.8±92.1 mos. At baseline (BL) and at 12 mos. of therapy PsA activity by tender joint count (TJC)/68, swelling joint count (SJC)/66, Pain (VAS), Patient global assessment disease activity (PtGA, VAS), CRP mg/l, dactylitis, enthesitis by LEI and plantar fascia, BSA (%), HAQ and fatigue by FACIT (Functional Assessment of Chronic Illness Therapy) Fatigue Scale (Version 4) were evaluated. A score FACIT <30 indicates severe fatigue and > 30 – less fatigue. All pts was given therapy with Methotrexate (MTX) s/c. After 3-9 mos. of ineffectiveness of MTX treatment 29 pts were given biologic DMARDs. By 12 mos. of therapy, the proportion of pts who had reached MDA (5/7) were calculated. Pts were split into 2 groups: MDA + (n=45) and MDA - (n=32). The one-factor model of logistic regression was used to identify a group of features that are associated with MDA achievement. M±SD, Me [Q25; Q75], Min-Max, %, t-test, Pierson-χ2, Manna-Whitney tests, ORs with 95% CI were performed. All p<0.05, were considered to indicate statistical significance.

Results: Comparative analysis in both groups and one-factor model of logistic regression showed the following features at BL were associated with MDA achievement: TJC/SJC < 3 (p<0.001), PGA ≤ 20 mm (p<0.001), Pain (VAS) ≤ 15 mm (p<0.001), CRP ≤ 5 mg/l (p< 0.03), HAQ ≤ 0.5 (p< 0.001), FACIT > 30 (p< 0.021), absent of entesitis (p< 0.003), dactylitis (p< 0.029) and nail damage (p< 0.012). Early PsA pts with combination of these features at first visit have more chance to achieve MDA within 12 mos in comparison to PsA pts without them, OR=9.684 [CI 95% 4.6-20.4]. (Figure 1).

Conclusion: It is a combination of features at first visit to clinic – TJC, SJC < 3, PGA ≤ 20 mm, pain ≤ 15 mm, CRP ≤ 5 mg/l, HAQ ≤ 0.5, FACIT > 30 points, absent of entesitis, dactylitis and nail PsO - that constitutes a clinical prognostic factors for MDA achievement within 12 mos of T2T strategy in early PsA pts.

DAS28-CRP GUIDED TREAT-TO-TARGET TAPERING OF TUMOR NECROSIS FACTOR INHIBITORS IN PSORIATIC ARTHRITIS: A RETROSPECTIVE COHORT STUDY.

C. Michielsens[1,2], N. Den Broeder[1,2], M. Mulder[1,2], M. Wenink[1], F. Van den Hoogen[1,2], L. M. Verhoef[1], A. Den Broeder[1,2]. [1]*Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands*; [2]*Radboud university medical center, Radboud Institute for Health Sciences, Nijmegen, Netherlands*

Background: Tumor Necrosis Factor inhibitors (TNFi) have proven to be safe and effective in the treatment of psoriatic arthritis (PsA) [1]. However, they carry disadvantages, such as adverse effects, patient burden, and costs, which could be reduced by treat-to-target (T2T) tapering. Although there is lack of high level evidence, guidelines suggest that T2T tapering and discontinuation might be considered, but no studies comparing this strategy to continuation in PsA were published [2].

Objectives: To assess the effect of T2T TNFi tapering on disease activity and TNFi dosage in PsA patients with low disease activity (LDA).

Methods: PsA patients using TNFi who visited the clinic between April 2012 and October 2018 were included if eligible for tapering, according to local protocol: ≥ 6 months of TNFi treatment and ≥ 6 months of at least LDA (DAS28-CRP < 2.4 (or 2.9 in patients with disease duration > 3 years) or by judgement of physician and patient). Patients with concomitant inflammatory disease preventing tapering were excluded. Three different time periods were defined: i) full-dose TNFi continuation; ii) TNFi tapering; iii) stable TNFi dosage after tapering. A mixed-model analysis was used to estimate mean DAS28-CRP during these three time periods. This model included: age, gender, disease duration, and the following time-varying components: current dose reduction status (three time periods mentioned above), time since eligibility for tapering and use of concomitant conventional synthetic Disease-Modifying Antirheumatic Drugs (csDMARDs), and a random intercept to account for inter-patient variability. Furthermore, a mean percentage of the Daily Defined Dose (%DDD) was calculated as secondary outcome.

Results: 152 patients were included, with a mean of 6.5 DAS28-CRP measurements, of whom 125 attempted dose reduction during follow-up. Median follow-up duration was 41 months (Inter Quartile Range (IQR) 24-59) for patients who never attempted dose reduction and 43 months (IQR 28-58) for those who did (table 1). The mixed model showed no significant difference in DAS28-CRP between the three time periods. Adjusted for gender, age, disease duration at baseline, time since follow-up and csDMARD use, the mean DAS28-CRP was 1.91 in the continuation period (95% Confidence Interval (CI) [1.76-2.05]) and 2.0 in both the TNFi tapering (95%CI [1.90-2.12], difference with continuation: 0.11, p=0.19) and stable TNFi dosage after tapering (95%CI 1.88-2.11], difference with continuation: 0.09, p=0.31) period. The mean percentage of the DDD for the three time periods was 107% for the continuation period; 62% in the TNFi tapering period and 79% in the stable TNFi dosage period.

Conclusion: T2T tapering of TNFi appears to have no negative effects on disease activity in PsA patients compared with full dose continuation, and reduces

drug exposure. DAS28-CRP might however not capture the full disease spectrum in PsA. Trials using PsA specific endpoints are needed to investigate tapering in a prospective and randomized manner.

Background: Enthesitis is a key musculoskeletal manifestation of psoriatic arthritis (PsA). EULAR guidelines recommend biologics for patients with enthesitis and an inadequate response to or intolerance of nonsteroidal anti-inflammatory drugs, although no guidance on specific biologics is offered. In the EXCEED head-to-head, double-blind study (NCT02745080), secukinumab (SEC) and adalimumab (ADA) showed a similar efficacy in joints and in resolution of enthesitis at Week 52 for patients with PsA,[1] although a detailed analysis of enthesitis was not conducted.

Objectives: To explore detailed enthesitis treatment response, including temporal and additional enthesitis assessment data, in patients with PsA treated with SEC or ADA over 52 weeks.

Methods: In this post hoc analysis, patient data from EXCEED were grouped by presence or absence of baseline enthesitis based on the Leeds Enthesitis Index (LEI) and the Spondyloarthritis Research Consortium of Canada Enthesitis Index (SPARCC). Baseline characteristics of these groups were summarized. Median time to resolution of LEI/SPARCC enthesitis score in patients receiving SEC or ADA was assessed using Kaplan-Meier analysis. Efficacy was further assessed among the enthesitis subset by LEI and SPARCC change from baseline, resolution of enthesitis (LEI/SPARCC) at Weeks 24 and 52, and resolution of enthesitis at Week 52 by baseline enthesitis severity. Relapse of enthesitis after a first resolution was evaluated at Weeks 24 and 52. Missing data were imputed by nonresponder imputation.

Results: Baseline demographics were well balanced in the LEI/SPARCC enthesitis subsets, although a higher proportion of all patients with enthesitis were women vs those with no enthesitis (LEI: 54.6% vs 40.5%; SPARCC: 53.2% vs 36.2%). Patients with baseline enthesitis had higher disease activity vs patients without enthesitis (LEI/SPARCC enthesitis vs no LEI/SPARCC enthesitis: tender joint count of 78 joints [22.8/22.1 vs 15.8/13.8], Health Assessment Questionnaire-Disability Index [1.3/1.3 vs 1.1/1.1], and mean Psoriasis Area and Severity Index [6.4/6.1 vs 5.1/5.3]). Median time to resolution of LEI and SPARCC enthesitis was similar between patients receiving either SEC or ADA (Table 1). Both treatment groups experienced a similar mean change from baseline in LEI and SPARCC enthesitis counts and a similar resolution of LEI and SPARCC at Weeks 24 and 52 (Table 1). Achievement of enthesitis resolution was similar between treatment groups irrespective of disease severity (Figure 1). The proportion of patients who experienced relapse after achieving resolution was low across both treatments (Table 1).

Conclusion: In EXCEED, patients with baseline enthesitis presented with higher disease burden, consistent with the FUTURE trials.[2] SEC and ADA showed similar kinetics of response and efficacy on enthesitis, irrespective of baseline enthesitis severity.

POS0195 GUSELKUMAB TREATMENT MODULATES CORE PSORIATIC ARTHRITIS GENE EXPRESSION IN TWO PHASE 3 CLINICAL TRIALS (DISCOVER-1 AND -2)

S. Siebert[1], K. Sweet[2], C. T. Ritchlin[3], E. C. Hsia[2,4], A. Kollmeier[5], X. L. Xu[5], Q. Song[2], M. Miron[2]. *[1]University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom*; *[2]Janssen Research & Development, LLC, Immunology, Spring House, United States of America*; *[3]University of Rochester Medical Center, Department of Medicine, Allergy/Immunology and Rheumatology (SMD), Rochester, United States of America*; *[4]University of Pennsylvania Medical Center, Rheumatology, Philadelphia, United States of America*; *[5]Janssen Research & Development, LLC, Immunology, San Diego, United States of America*

Background: Guselkumab (GUS), an interleukin-23 p19-subunit monoclonal antibody, demonstrated efficacy compared with placebo (PBO) in reducing signs and symptoms of psoriatic arthritis (PsA) in the phase 3 DISCOVER-1 & 2 studies.[1,2]

Objectives: To evaluate gene expression in the blood of PsA patients (pts) in the DISCOVER-1 & -2 studies and the impact of GUS on the expression of these genes.

Methods: Pts were treated with GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or matching PBO. Whole transcriptome profiling by RNA-sequencing was performed using the Novaseq platform on blood samples obtained from a subset of 673 pts with PsA at baseline across the 2 DISCOVER studies, as well as from 21 demographically (age, sex, and ethnicity) matched healthy controls procured independently of the clinical program. A subgroup (N=227) also had serial blood samples (W0/W4/W24) evaluated; the subgroup pts were selected based on having baseline characteristics (demographics, disease activity, medication use) representative of the overall cross-study PsA population. Significance of differentially expressed genes (DEGs) between PsA and healthy controls was defined by a false discovery rate (FDR) <0.05 based on a log-linear model using edgeR. Top genes were defined by significance and |logFC| >1. For cell type analysis, genes that changed with GUS treatment were tested for enrichment using Cibersort. Gene enrichment scores were calculated using Gene Set Variation Analysis (GSVA).

Results: To define disease genes, we compared genes at baseline in pts with active PsA vs. healthy control whole blood transcriptomes and detected 355 upregulated and 314 downregulated (top genes shown in Table 1), defined here as core disease genes. Upregulated genes were largely related to neutrophils, monocytes, macrophages, and extracellular matrix, whereas downregulated genes were related to T cells. The upregulated disease genes were significantly decreased and the downregulated disease genes were significantly increased by GUS treatment vs. PBO at W4 and W24 (Fig 1). Upon stratification by Psoriasis Area and Severity Index 75% response and American College of Rheumatology 20% response, changes in core disease gene expression from W0 were statistically significant among responders, but not in non-responders, at W4 and W24 (data not shown). We then performed the second differential expression analysis comparing baseline to W4 and W24 for both PBO and GUS treatment arms to define genes that change with treatment arm over time. At W4 and W24 we found many DEGs from baseline with GUS treatment and none with PBO. These included genes related to B-, T-, NK-, and plasma cells (increased by GUS) and neutrophils, monocytes, eosinophils, and macrophages (decreased by GUS), suggestive of a partial normalization of immune cell composition in whole blood.

Conclusion: Using whole transcriptome profiling, we detected DEGs in blood samples obtained from PsA pts vs. healthy controls, suggesting a dysregulation of immune cell profiles in PsA. The majority of these disease-associated genes were modulated by GUS, with directionality toward a normalization of whole blood transcriptomic signatures.

POS0196 UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS REFRACTORY TO BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS: 56-WEEK DATA FROM THE PHASE 3 SELECT-PSA 2 STUDY

P. J. Mease[1], A. Lertratanakul[2], K. Papp[3], F. Van den Bosch[4], S. Tsuji[5], E. Dokoupilova[6], M. Keiserman[7], X. Bu[2], L. Chen[2], R. Mccaskill[2], P. Zueger[2], E. Mcdearmon-Blondell[2], A. Pangan[2], W. Tillett[8]. *[1]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology,*

Seattle, United States of America; [2]*AbbVie Inc, Immunology, North Chicago, United States of America*; [3]*Papp Clinical Research and Probity Medical Research, Dermatology, Waterloo, Canada*; [4]*Ghent University, VIB Center for Inflammation Research, Internal Medicine and Pediatrics, Ghent, Belgium*; [5]*National Hospital Organization, Osaka Minami Medical Center, Orthopaedics/ Rheumatology, Osaka, Japan*; [6]*Medical Plus, s.r.o., Uherske Hradiste, Masaryk University, Pharmaceutical Technology, Brno, Czech Republic*; [7]*Pontificial Catholic University, School of Medicine, Porto Alegre, Brazil*; [8]*Royal National Hospital For Rheumatic Diseases, Rheumatology, Bath, United Kingdom*

Background: Upadacitinib (UPA) is an oral Janus kinase inhibitor currently under evaluation for the treatment of psoriatic arthritis (PsA). Previous 24-week results from the SELECT-PsA 2 study in patients with PsA and prior inadequate response to ≥1 biologic disease-modifying antirheumatic drug (bDMARD) demonstrated UPA efficacy with a safety profile consistent with that observed in rheumatoid arthritis.[1]

Objectives: To evaluate the 56-week efficacy and safety of UPA in the SELECT-PsA 2 study.

Methods: Patients were randomized to 56 weeks of blinded treatment with UPA 15 or 30 mg once daily (QD), or placebo (PBO) switched to UPA 15 or 30 mg QD at Week 24. Efficacy endpoints included proportions of patients achieving 20/50/70% improvement in American College of Rheumatology (ACR) criteria (ACR20/50/70), 75/90/100% improvement in the Psoriasis Area and Severity Index (PASI75/90/100), resolution of dactylitis and enthesitis, and minimal disease activity (MDA). Non-responder imputation was used for missing data. Treatment-emergent adverse events (TEAEs) were summarized for events occurring while on UPA and ≤30 days after last dose (for those who discontinued).

Results: Of 641 patients who received ≥1 dose of study drug, 74.7% completed 56 weeks of treatment. Clinical improvements based on the proportion of patients achieving ACR20/50/70 and MDA (Figure 1), PASI75/90/100, and resolution of dactylitis and enthesitis were generally maintained through 56 weeks of UPA treatment. Week 56 results for patients who switched from PBO to UPA at Week 24 had a similar trajectory to those for patients originally randomized to UPA. Overall, improvements observed with UPA 15 mg were similar to or approached those with UPA 30 mg over 56 weeks. Dose-dependent increases were observed for exposure-adjusted event rates (EAERs) of serious infections, herpes zoster (HZ), hepatic disorders, hematologic lab-related adverse events, and creatine phosphokinase (CPK) elevations, but not for exposure-adjusted incidence rates (EAIRs) of major adverse cardiovascular events (MACE), venous thromboembolic events (VTEs), or malignancies (Table 1). Generally, rates of TEAEs were lower with UPA 15 mg versus 30 mg.

Conclusion: In patients with PsA and prior inadequate response to ≥1 bDMARD, UPA efficacy was maintained over 56 weeks with no new safety signals.

Background: Power Doppler ultrasonography is a sensitive imaging tool to assess synovitis in psoriatic arthritis (PsA).[1,2] ULTIMATE (NCT02662985) is the first large, randomised, double-blind placebo-controlled phase IIIb study in PsA, using ultrasound to evaluate early response to secukinumab on synovitis. The use of the standardised and reliable global EULAR-OMERACT composite ultrasound synovitis score at patient level (GLOESS) as the primary endpoint showed the early and significant benefit of secukinumab vs. placebo on synovitis at week 12.[3]

Objectives: To investigate the responsiveness and discriminative validity of GLOESS compared to clinical outcomes on joints at week 12 and report ultrasound and clinical efficacy data up to week 24.

Methods: This is a 52-week study with a 12-week double-blind, placebo-controlled period followed by 12-week open-label (OL) and 6-month OL extension. All placebo patients were switched to secukinumab (300 or 150 mg) at week 12.[3] Discriminative validity of GLOESS was analysed post-hoc: within-group responsiveness was assessed by comparing its standardised response mean (SRM) to that of core set of ACR response in the initial secukinumab group over 12 and 24 weeks. Mean change from baseline up to week 12 of GLOESS was determined with mixed-effect model repeated measures analysis (MMRM) and from week 12-24 as observed. 24 week efficacy outcomes included ACR responses, HAQ-DI, PASI response and resolution of dactylitis. These outcomes were exploratory and reported either according to non-responder imputation (ACR response), or as observed (HAQ-DI, PASI response and resolution of dactylitis).

Results: Of 166 patients enrolled, a total of 155 patients (93%) completed 24 weeks of treatment (secukinumab, 79 patients 95%; placebo, 76 patients 92%). Mean change from baseline to week 24 in GLOESS was similar in the initial secukinumab and placebo-secukinumab groups. A continued improvement in GLOESS was observed in the secukinumab group, with catch-up improvement in the placebo group after switch to active therapy (Figure 1). Both SRM of GLOESS and ACR core components over 12 and 24 weeks were high (Table 1). Similar clinical response rates were reported for clinical joint count, skin, dactylitis and function at week 24 in secukinumab and placebo switchers groups (Table 1).

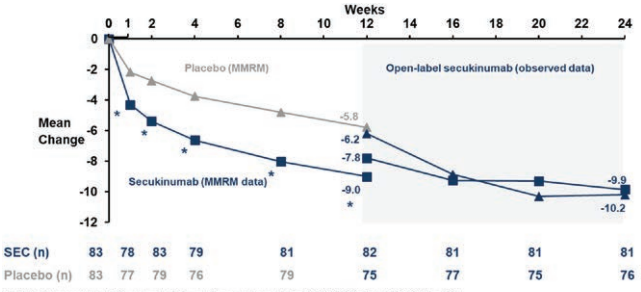

Figure 1. Mean change from baseline in GLOESS by treatment through Week 24

Conclusion: These analyses highlight the responsiveness and high discriminative validity of GLOESS in PsA, resembling that of key clinical PsA manifestations and physical function.

Princeton, United States of America; [9]*Bristol Myers Squibb, Rheumatology and Dermatology, Princeton, United States of America*

Background: Tyrosine kinase 2 (TYK2) is an intracellular kinase that mediates signaling by key cytokines involved in psoriatic arthritis (PsA) and plaque psoriasis (PsO) pathogenesis. Deucravacitinib is a novel oral agent that selectively inhibits TYK2 via an allosteric mechanism by binding to the nonconserved regulatory domain of the kinase. A previous Phase 2 trial in PsO had demonstrated that deucravacitinib was efficacious and well tolerated, with no laboratory abnormalities observed.

Objectives: To evaluate the efficacy and safety of deucravacitinib in active PsA.

Methods: This is an ongoing, 1-year, randomized, double-blind, placebo (PBO)-controlled (initial 16 weeks), multiregional, Phase 2 trial (NCT03881059). Eligible patients had a PsA diagnosis for ≥6 months, met CASPAR criteria, and had active disease with ≥3 tender and ≥3 swollen joints, C-reactive protein ≥3 mg/L (ULN, 5 mg/L), and ≥1 psoriatic lesion (≥2 cm). Patients had failed or were intolerant to ≥1 nonsteroidal anti-inflammatory drug, corticosteroid, conventional synthetic disease-modifying antirheumatic drug (csDMARD), and/or 1 TNF inhibitor (TNFi; ≤30%). Patients were randomized 1:1:1 to deucravacitinib 6 mg once daily (QD) or 12 mg QD, or PBO. The primary endpoint was achievement of ACR 20 response at Week 16. Additional endpoints included the proportion of patients achieving ACR 50/70 response, Health Assessment Questionnaire-Disability Index (HAQ-DI) response (≥0.35 improvement from baseline), enthesitis resolution (Leeds Index score of 0), minimal disease activity, change from baseline in SF-36 physical component score (SF-36 PCS) and mental component score (SF-36 MCS), Psoriasis Area and Severity Index (PASI) 75 response, adverse events (AEs), and laboratory parameters.

Results: Of 203 patients randomized, 180 (89%) completed 16 weeks of treatment (deucravacitinib 6 mg QD, 63/70 [90%]; deucravacitinib 12 mg QD, 59/67 [88%]; PBO, 58/66 [88%]). Demographic and baseline disease characteristics were similar across groups. Mean age was 49.8 years, 51% of patients were female, median PsA duration was 4.5 years, 66% of patients used csDMARDs at baseline and throughout the study, and 15% had used a TNFi. This study met its primary endpoint, with deucravacitinib 6 mg and 12 mg QD demonstrating significantly higher ACR 20 responses versus PBO at Week 16 (Figure 1). Additional endpoints were also met with deucravacitinib versus PBO (Figure 1). Adjusted mean changes from baseline in SF-36 PCS and SF-36 MCS at Week 16, respectively, were significantly higher in the deucravacitinib 6 mg QD group (5.6 vs 2.3, P=0.0062; 3.6 vs 0.7, P=0.0211) and 12 mg QD group (5.8 vs 2.3, P=0.0042; 3.5 vs 0.7, P=0.0263) compared with PBO. PASI 75 responses were also significantly higher in the deucravacitinib groups (P≤0.0136 vs PBO). The most common AEs in the deucravacitinib 6 mg/12 mg/PBO groups, respectively, during the 16-week treatment period were nasopharyngitis (5.7%/17.9%/7.6%), sinusitis (0%/7.5%/0%), headache (7.1%/1.5%/4.5%), and rash (4.3%/6.0%/0%). No serious AEs, herpes zoster infections, opportunistic infections, or thrombotic events were reported in deucravacitinib-treated patients during this period. Additionally, no significant changes from baseline in hematologic parameters (lymphocytes, neutrophils, platelets, and hemoglobin) or serum lipids were observed with deucravacitinib treatment.

Conclusion: Deucravacitinib was efficacious versus PBO over 16 weeks in patients with active PsA. Treatment was generally well tolerated and the safety and laboratory parameter profile of deucravacitinib was consistent with that observed in an earlier Phase 2 PsO trial.

POS0199 TIME-SERIES ANALYSIS IN MODERATE TO SEVERE PLAQUE PSORIASIS UNDER DIFFERENT BIOLOGICS TREATMENTS

Y. Zhang[1,2,3], S. X. Zhang[1,2,3], J. Qiao[1,2,3], R. Zhao[1,2,3], S. Song[1,2,3], Y. Li[1,2,3], M. J. Chang[1,2,3], G. Y. Liu[1], P. F. He[4], X. Li[1,2,3]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*Shanxi Li Xiaofeng Medical Groups, Department of Rheumatology, Taiyuan, China*; [3]*Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; [4]*Shanxi Medical University, Medical Data Sciences, Taiyuan, China*

Background: Moderate to Severe Plaque Psoriasis is an inflammatory skin disease that is associated with multiple comorbidities and substantially diminishes patients' quality of life. As one of the most significant therapeutic advancements in the field of dermatology, Biologics such as TNF inhibitors, IL-12/23 inhibitor, IL-17 inhibitors, and IL-23 inhibitors, have higher efficacy compared with oral medications or phototherapy[1]. However, the previous studies did not focus on the simultaneous comparison of molecular changes in different classes of biologics. The identification of time-series genes (TSGs) could help to uncover the mechanisms underlying transcriptional regulation[2].

Objectives: In this study, we aimed to compare the differences in expression patterns and functions of time-series genes in Moderate to Severe Plaque Psoriasis under different biologics treatments.

Methods: The transcription profile of GSE117239 and GSE51440 were obtained from the Gene Expression Omnibus database (GEO). The GSE117239 included 19 samples treated with Etanercept (TNF inhibitors) and 16 samples treated with Ustekinumab (IL-12/23 inhibitor). The GSE51440 included 4 samples treated with Guselkumab (IL-23 inhibitors). Skin biopsy samples (LS: lesion, NL: non-lesion) were collected at baseline, weeks 1 and 12, respectively. After background adjustment and other pre-procession, differentially expressed genes (DEGs) were extracted from LS skin biopsy and untreated NL skin biopsy at different times after three different biologics treatments, respectively. The Short Time-series Expression Miner (STEM) software was used to cluster and compare average DEGs with coherent changes. Afterward, the different expression patterns of TSGs under the three treatment groups were compared. GO analysis and KEGG pathway enrichment analysis of TSGs were performed by Metascape.

Results: Different DEGs varied in LS skin compared with those of NL skin biopsy: 976 genes in Ustekinumab group, 996 genes in Etanercept group, and 601 genes in Guselkumab group detailly (P < 0.05 and [log FC] > 1). Gene landscapes suggested the signatures of LS gradually changed during the treatment process, and gradually converge to NL signatures (Fig.1a, 2a,3a). Time-series genes in the three treatment groups had different expression patterns and functions. In the Ustekinumab group, a total of 448 TSGs in profile 3 showed a stable-stable-decreasing expression trend and significantly

associated with mitotic nuclear division and defense response to other organism, whereas in profile 4 represented a stable-stable-increasing expression trend and significantly associated with positive regulation of cellular response to organic 9 compound (Fig.1). With the treatment of Etanercept, 22 TSGs had a stable-increasing-increasing expression tendency and closely associated with fatty acid metabolism and steroid metabolic process (Fig.2). After Guselkumab treatment, 13 TSGs also represented a stable-increasing-increasing expression tendency that mainly characterized by defense response to other organism and epidermis development (Fig.3). Interestingly, both Ustekinumab and Guselkumab treatment dramatically influenced defense response to other organism-related genes, while Etanercept mainly affected genes involved in fatty acid metabolism and steroid metabolic process.

Conclusion: Biologics effectively reconstituted the gene signatures of psoriasis in different aspects. TSG features could be one of indicator for precise intervention for psoriasis.

Background: Psoriatic arthritis (PsA), a chronic inflammatory disease characterized by peripheral arthritis, axial inflammation, dactylitis, enthesitis & skin/nail psoriasis, causes impaired physical function, disability & loss of work productivity.
Objectives: Evaluate associations between PsA clinical characteristics & outcomes including fatigue & work productivity using Work Productivity & Activity Impairment Questionnaire: PsA (WPAI-PsA).
Methods: The Phase 3 DISCOVER-2 trial assessed guselkumab (GUS), an anti-IL-23p19 subunit monoclonal antibody, in bio-naïve adults with active PsA (swollen joint count [SJC] ≥5 & tender joint count [TJC] ≥5, C-reactive protein [CRP] ≥0.6 mg/dL) despite standard therapies.[1] Patients (Pts) were randomized 1:1:1 to GUS 100 mg Q4W; GUS 100 mg at W0, W4, then Q8W; or placebo (PBO). WPAI-PsA assesses PsA-related work time missed (absenteeism), impairment while working (presenteeism), productivity loss (absenteeism+presenteeism), & daily activity during the previous week. Spearman correlation testing evaluated relationships between pt demographics & disease characteristics of PsA & WPAI domain scores based on observed values at baseline. Univariate linear regression assessed associations between WPAI & these variables based on observed data at W0 & at W24. Variables with p<0.10 were included in a multivariate analysis employing a mixed-effects model for repeated measures, controlling for all other variables; resulting p-values <0.05 were considered statistically significant.
Results: As reported elsewhere,[2] least-squares mean % changes from baseline at W24 were -3.8/-19.5/-20.0/-20.5 for GUS Q4W, -3.1/-19.4/-19.7/-21.5 for GUS Q8W, & -3.5/-10.2/-10.9/-10.3 for PBO for absenteeism, presenteeism, absenteeism+presenteeism, & daily activity impairment, respectively. Among 738 pts, WPAI domain scores were moderately to strongly correlated (ie, ≥0.4) with pt-reported pain (0-10 visual analog scale), physical function (Health Assessment Questionnaire Disability Index [HAQ-DI]), fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-F] scale) & 36-Item Short Form Health Survey (SF-36) Physical Component Summary (PCS) score, but weakly correlated with other variables (Figure 1). Based on univariate analyses & evaluation of collinearity between variables, attributes included in multivariate models were age, body mass index (BMI), gender, CRP, FACIT-F, pain, Psoriasis Area Severity Index (PASI), TJC, SJC, enthesitis & dactylitis. In final model, CRP, FACIT-F, & pain were statistically significantly associated with all WPAI domains (Table 1). Presence of enthesitis & higher PASI score were significantly associated with higher loss of work productivity & activity outside work.
Conclusion: In PsA pts, extra-articular symptoms, fatigue, pain & elevated CRP were significantly associated with WPAI-assessed work & activity impairment. Treating all major clinical manifestations of PsA is needed to help pts improve work & activity impairment. GUS effectively treats all major clinical manifestations[1] & improves work & activity impairment in PsA.[2]

POS0201

RISK OF MAJOR ADVERSE CARDIOVASCULAR EVENTS IN PATIENTS INITIATING BIOLOGICS/APREMILAST FOR PSORIATIC ARTHRITIS: A NATIONWIDE POPULATION-BASED STUDY USING THE FRENCH HEALTH INSURANCE DATABASE

L. Pina Vegas[1,2], P. Le Corvoisier[3,4], L. Penso[1,5], M. Paul[1,6], E. Sbidian[1,4,7], P. Claudepierre[1,2]. [1]*Université Paris Est-Créteil, EpiDermE, Créteil, France*; [2]*Hôpital Henri Mondor, Rhumatologie, Créteil, France*; [3]*Inserm, Université Paris Est-Créteil, Ecole Nationale Vétérinaire d'Alfort, U955-IMRB, Équipe 03, Créteil, France*; [4]*Inserm, Hôpital Henri Mondor, Centre D'investigation Clinique 1430, Créteil, France*; [5]*French National Agency for the Safety of Medicines and Health Products and French National Health Insurance, EPI-PHARE Scientific Interest Group in Epidemiology of Health Products, Saint-Denis, France*; [6]*Hôpital Henri Mondor, Pharmacie, Créteil, France*; [7]*Hôpital Henri Mondor, Dermatologie, Créteil, France*

Background: Psoriatic arthritis (PsA) is associated with other diseases of the spectrum of spondyloarthritis but also appears to be linked to an increased prevalence of numerous comorbidities and more specifically cardiovascular risk factors and events. Several biological disease-modifying anti-rheumatic drugs (bDMARDs) have demonstrated anti-inflammatory effects in PsA. However, their comparative cardiovascular safety profiles remain unknown.
Objectives: Our objective was to assess the relative comparative risk of major adverse cardiovascular events (MACEs) of different classes of bDMARDs or apremilast for PsA.
Methods: This nationwide cohort study involved the administrative healthcare database of the French health insurance scheme covering approximately 67 million individuals linked to the hospital discharge database. All adults with PsA who were new users of bDMARDs/apremilast (neither in the year before the index date) during 2015-2019 were included. Patients with previous cardiovascular diseases were excluded. End of follow-up was December 31, 2019. The primary end point was an occurrence of MACE (acute myocardial infarction and ischaemic stroke) in a time-to-event analysis with propensity score-weighted Cox and Fine-Gray models (including age, sex, inflammatory diseases associated, cardiovascular risk biomarkers and other comorbidities). To assess the sensitivity of the estimated weighted hazard ratio (HRw) with respect to several possible models, we performed a per-protocol analysis, a conventional multivariate Cox model, an analysis using a larger definition of MACE, an analysis modifying the new-user definition (as those who had not filled a prescription for a bDMARDs or apremilast for 5 years before the index date) and an analysis modifying the treatment discontinuation definition.
Results: Between 2015 and 2019, we included 9,510 bDMARD new users (mean age 48.5±12.7 years; 42% men), including 7,289 starting a TNF inhibitor, 1,058 an IL12/23 inhibitor and 1,163 an IL17 inhibitor, with 1,885 apremilast new users (mean age 54.0±12.5 years; 44% men). MACEs occurred in 51 (0.4%) patients (Figure 1). After propensity score weighting, the risk of MACEs was significantly greater with IL12/23 (HRw 2.0, 95%CI 1.3-3.0) and IL17 (HRw 1.9, 95%CI 1.2-3.0) inhibitors than TNF inhibitors, with no significant increased risk with apremilast (HRw 1.3, 95%CI 0.8-2.2). Similar results were observed with the Fine-Gray competing-risks survival model. The sensitivity analyses results were consistent with those of the main analysis.
Conclusion: Analysis of a large national database revealed an overall small number of MACEs. Using robust methodology from the causal inference field, the risk of MACEs was greater for PsA new users of IL12/23 and IL17 versus TNF inhibitors. The risk of MACEs did not significantly differ between new users of apremilast and new users of TNF inhibitors.

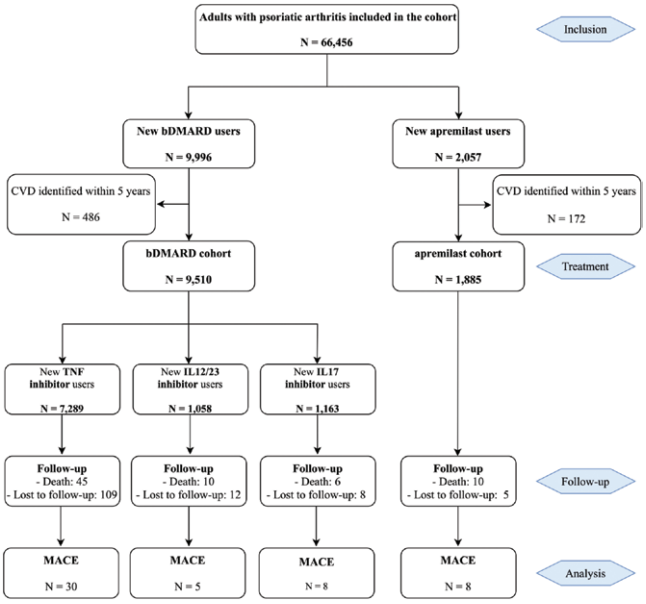

Figure 1. Flowchart for analytic approachData are n. bDMARD: biological disease-modifying antirheumatic drugs; CVD: cardiovascular disease; TNF: tumor necrosis factor; IL: interleukin; MACE: major adverse cardiac events.

ANALYZING CORD BLOOD LEVELS OF TNF INHIBITORS TO VALIDATE THE EULAR POINTS-TO-CONSIDER FOR TNF INHIBITOR USE DURING PREGNANCY

E. Kemper[1,2], N. Ghalandari[1,2], H. J. M. J. Crijns[2], H. T. Smeele[1], R. Dolhain[1]. [1]*Erasmus MC, Department of Rheumatology, Rotterdam, Netherlands*; [2]*Medicines Evaluation Board, FT group 1, Utrecht, Netherlands*

Table 1. TNF inhibitor use during pregnancy and TNF inhibitor concentrations in mother's blood and cord blood.

	Certolizumab pegol (n = 68)	Etanercept (n = 28)	Adalimumab (n = 24)	Infliximab (n = 13)
Stop time point as recommended by EULAR	N/A	GA 30-32	GA 20	GA 20
Gestational age at time of stopping TNFi, median±IQR	37.29 (32.79 – 38.29)	25.43 (18.71 – 28.36)	18.79 (8.93 – 19.86)	18.86 (14.57 – 20.00)
Measurable TNFi in cord blood, n (%)	4 (5.9%)	0 (0%)	12 (50.0%)	8 (61.5%)
Maternal concentration of TNFi in the 1st trimester, median±IQR (µg/ml)	24.55 (19 – 31)	2.1 (0.8 – 2.5)	8.2 (1.5 – 10)	14 (7.98 – 21)
Maternal concentration of TNFi in the 2nd trimester, median±IQR (µg/ml)	22.52 (13 – 30.72)	1.4 (0.89 – 2.7)	6 (4.5 – 7.5)	6.37 (4.2 – 20)
Maternal concentration of TNFi in the 3rd trimester, median±IQR (µg/ml)	20.5 (13 – 29.58)	0.2 (0.2 – 0.67)	0.85 (0.1 – 1.4)	1.4 (0.09 – 1.9)
Concentration of TNFi in the cord blood if measurable, median±IQR (µg/ml)	0.25 (0.15 – 1.3)	-	0.45 (0.15 – 0.65)	0.4 (0.12 – 1.15)

Background: Increasing evidence suggests that TNF inhibitors (TNFi) are safe to use during pregnancy[1]. A drawback of TNFi use during pregnancy is active transport across the placenta, which is affected by the structure of the TNFi[1]. The European League Against Rheumatism (EULAR) defined points to consider (PtC) on the use of TNFi during pregnancy[2]: to prevent placental transfer, etanercept should be discontinued at gestational age (GA) 30-32 weeks, and both adalimumab and infliximab should be discontinued at GA 20 weeks. Certolizumab pegol can be conditionally continued throughout pregnancy.

Objectives: The aim of this research is to validate the EULAR PtC by measuring the level of TNFi in cord blood.

Methods: Patients were derived from the PreCARA study, an ongoing prospective cohort study on inflammatory rheumatic diseases and pregnancy in the Netherlands. Patients were treated according to a treat-to-target approach, which included the use of TNFi. TNFi were, if possible, discontinued at recommended stop time points. Maternal blood samples were collected in each trimester. Cord blood was analyzed for the presence of certolizumab pegol, etanercept, adalimumab and infliximab. Levels of TNFi in the cord blood were compared between patients that stopped at the advised GA and patients who did not.

Results: Data from 111 patients with inflammatory rheumatic diseases were used for the current analysis. Most patients stopped treatment before the recommended GA (table 1). Certolizumab pegol (n = 68) was measured in a low number of cord blood samples (5.9%) and in low concentrations (median, (IQR): 0.25 µg/ml (0.15 – 1.3)). Etanercept was not detected in any cord blood samples (n = 28). Adalimumab (n = 24) and infliximab (n = 13) were measured more often in cord blood (in 50.0% and 61.5% of patients, respectively), this also was observed in patients that stopped before the recommended GA (in 47.7% for adalimumab and 60.0% for infliximab). However, the observed concentrations were low: the maximum observed concentrations in cord blood were 2.1 µg/ml (stopped at GA 19.4 weeks) for adalimumab and 4.5 µg/ml (stopped at GA 21.1 weeks) for infliximab.

Conclusion: Stopping TNFi around the GA recommended by the EULAR PtC resulted in no measurable levels or low concentrations of TNF inhibitor in the cord blood in a majority of patients.

POS0204 AUTOANTIBODIES AND SYSTEMIC LUPUS ERYTHEMATOSUS INDUCED BY ANTI-TUMOUR NECROSIS FACTOR ALPHA THERAPY IN RHEUMATOID ARTHRITIS

D. Santos Oliveira[1,2], A. Martins[1], F. R. Martins[3], F. Oliveira Pinheiro[1], M. Rato[1], D. Fonseca[4], B. M. Fernandes[1], S. Garcia[1], C. Vaz[1,2,5], M. Bernardes[1,5], L. Costa[1]. [1]*Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal*; [2]*Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; [3]*Centro Hospitalar Universitário do Algarve, Rheumatology Department, Faro, Portugal*; [4]*Centro Hospitalar Vila Nova de Gaia / Espinho, Rheumatology Department, Vila Nova de Gaia, Portugal*; [5]*Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal*

Background: Anti-tumour necrosis factor alpha (anti-TNF-α) therapy is commonly used to treat inflammatory conditions such as rheumatoid arthritis (RA). Autoantibodies namely antinuclear antibodies (ANA) induced by these treatments are well established. However, anti-TNF-α-induced systemic lupus erythematosus (SLE) is rarely described and its incidence is yet unknown.

Objectives: This study aimed to determine the prevalence of ANA seroconversion and to characterize the development of SLE induced by anti-TNF-α therapy in patients with RA over time.

Methods: An observational retrospective cohort study was conducted with at least one year of follow-up. Patients with diagnosis of RA, according to American College of Rheumatology criteria (ACR), and registered on Rheumatic Diseases Portuguese Register (Reuma.pt) who started their first anti-TNFα between 2003 and 2019 were included. Patients with positive ANA (titer ≥100) and/or positive double-strand DNA (dsDNA) antibodies and/or with a diagnosis of SLE at their first visit were excluded. Demographic, clinical and laboratory data were obtained by consulting Reuma.pt. As there are no recognized criteria for drug-induced SLE, the diagnosis of SLE induced by anti-TNF-α was considered if there is a temporal relationship between clinical manifestations and anti-TNF-α-therapy, the presence of at least 1 serologic ACR criteria (ANA or anti-dsDNA) and at least 1 nonserologic ACR criteria (arthritis, serositis, hematologic disorder or malar rash) [1]. Continuous variables are presented with mean, standard deviation, median, quartile 1 and quartile 3. Categorical variables are presented with absolute and relative frequencies.

Results: A total of 211 patients (mean age of 49.9±10.9 years old; 84.4% female) were included with a median follow-up time of 6 [3-14] years. We found a seroconversion rate for ANA of 75.4% (n=159) with median treatment duration of 31 [8.5-70.5] months. The most common titre was 1/100 with diffuse and speckled patterns. ANA seroconversion was higher for etanercept (47.8%, n=76) than with adalimumab (23.9%, n=38), infliximab (13.8%, n=22), golimumab (12.6%, n=20) or certolizumab (1.9%, n=3). SLE induced by anti-TNF-α occurred in two patients (0.9%) with erosive and seropositive (rheumatoid factor and anti-citrullinated protein antibodies) RA previously treated with two conventional synthetic disease-modifying antirheumatic drugs, including methotrexate. The first patient, a female with 66 years old and 17 years of disease duration, developed SLE after 16 months of infliximab, with constitutional symptoms, abrupt worsening of polyarthritis, ANA titer of 1/320 diffuse pattern and positive dsDNA (248 UI/mL) antibodies. The second patient, a woman with 43 years old and 11 years of disease duration, developed SLE after 41 months of adalimumab with malar rash and ANA titer of 1/320 diffuse pattern, positive dsDNA (285 UI/mL), positive anti-histone antibodies and hypocomplementemia. In these two cases, anti-TNF-α therapy was stopped and recovery was spontaneous without treatment. The first patient switched to adalimumab and the second switched to golimumab without recurrence of SLE for more than ten years.

Conclusion: We found a high rate of ANA seroconversion induced by anti-TNFα therapy in patients with RA. However, similar to previous literature, only 0.9% of patients developed SLE with mild manifestations without major organ involvement. Although the drug with the highest ANA seroconversion rate was etanercept, those responsible for induced SLE were infliximab and adalimumab. Patients improved after discontinuation of therapy and tolerated an alternative anti-TNF-α drug without recurrence of induced SLE over time. Therefore, ANA and SLE induced by anti-TNF-α should be considered and reported in the follow-up of RA patients. Further research is needed to explore the impact of this adverse event on the outcomes of treatment over time.

POS0205 AMELIORATION OF ENDOTHELIAL DYSFUNCTION WITH JAK INHIBITION IN RHEUMATOID ARTHRITIS: JAK CV-RISK REDUCTION STUDY

A. Syngle[1], N. Garg[2], K. Chauhan[3]. [1]*Healing Touch City Clinic, Chandigarh & Fortis Multispecialty Hospital, Mohali, Cardio-Rheuma Division; Internal Medicine & Rheumatology, Chandigarh, India*; [2]*Chitkara College of Pharmacy,*

Chitkara University, Department of Pharmacy Practice, Patiala, India; [3]*Healing Touch City Clinic, Department of Rheumatology, Chandigarh, India*

Background: Cardiovascular (CV) disease is the leading cause of premature mortality and sudden death in Rheumatoid Arthritis (RA). Conventional CV risk factors and disease specific risk factors are responsible for endothelial dysfunction (ED) in RA. ED is the barometer of CV health and key initial event in atherosclerosis. Tofacitinib, a JAK inhibitor, is in clinical use since 2012 and has had the most extensive development program in RA, but its impact on ED has not yet been explored in humans.

Objectives: To investigate the impact of tofacitinib on endothelial dysfunction in RA

Methods: 40 RA patients fulfilling the 2010 Rheumatoid Arthritis classification criteria with active disease (DAS28>3.2) were randomized to receive 24 weeks of treatment with Tofacitinib (5mg bd, n=20) and placebo (n=20) as an adjunct to existing stable antirheumatic drugs. Primary endpoints included endothelial dysfunction assessed by FMD using Angiodefender and lipids were estimated at baseline and after 12 weeks of treatment. The secondary end points included: DAS28, ESR, CRP, HAQ-DI and cardiovascular risk using SCORE chart assessed at week 0 and 12.

Results: At baseline, endothelial function was impaired and levels of inflammatory measures were elevated in both groups. CV risk SCORE was high and HAQ-DI was impaired at baseline. After treatment, FMD improved significantly in the tofacitinib group from (8.16±1.38% to 10.98±2.33%, p≤0.05) as compared to placebo (7.12±0.25% to 8.04±0.30%, p=0.35) (Fig. 1A). DAS28 (Fig. 1B), ESR and CRP (Fig. 1C) levels improved significantly in tofacitinib group as compared to placebo (p≤0.05). Tofacitinib significantly decreased HAQ-DI and SCORE (Fig. 1D) values as compared to placebo. There was significant increase in HDL (p≤0.05) after treatment with tofacitinib as compared to placebo. After 12 weeks of treatment, FMD and HDL increased by 34.55% and 13.58% respectively where as DAS28, ESR and CRP decreased by 37.40%, 36.10% and 76.59% respectively in the tofacitinib group. Significant negative correlation was observed between FMD and DAS28 (r= -0.50, p≤0.05) and CRP (r= -52, p≤0.05) after treatment with tofacitinib where as no such correlation was found in placebo group.

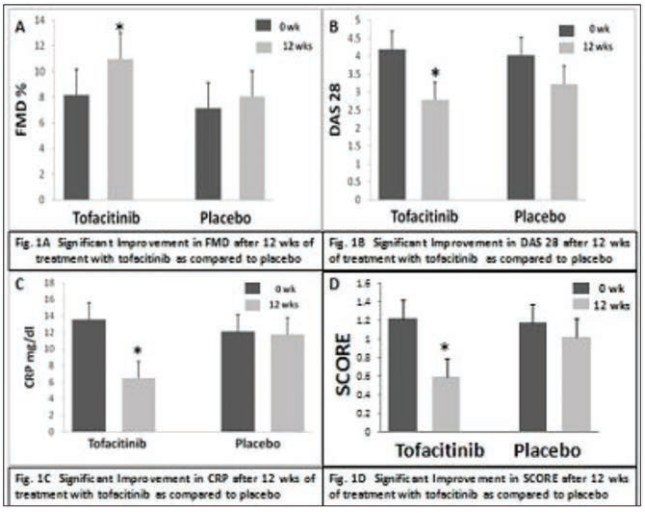

Figure 1. Impact of Tofacitinib on FMD, DAS 28, CRP & SCORE

Conclusion: First study to show that tofacitinib, apart from its anti inflammatory activity, improves endothelial dysfunction and cardiovascular risk in RA. Thus, JAK inhibition with tofacitinib has vasculoprotective and cardioprotective effect mediated through anti-inflammatory and probably other mechanisms. This study would stimulate further research in exploring the vasculoprotective and cardioprotective potential of tofacitinib in RA.

POS0206

DESIGN AND CHARACTERISATION OF A THERAPEUTIC BISPECIFIC TANDEM SCFV-FC FUSION PROTEIN WITH ANTI-TNF AND SYNOVIUM-TARGETING SPECIFICITY FOR THE TREATMENT OF RHEUMATOID ARTHRITIS

S. Pagani[1], F. Colombo[1], C. Pitzalis[1]. [1]*William Harvey Research Institute, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, Centre for Experimental Medicine & Rheumatology, London, United Kingdom*

Background: Rheumatoid Arthritis (RA) is a systemic autoimmune disease with a prevalence of 0.5-1% worldwide[1]. Anti-cytokine antibodies, especially anti-Tumor Necrosis Factor (TNF) antibodies are considered the gold standard for RA therapy. However, there are some concerns regarding their lack of therapeutic efficacy in a significant proportion of patients[2] and their potential systemic implications such as the risk of serious infections[3]. Developing novel agents with synovial targeting specificity might help to increase the therapeutic index while reducing systemic side effects of RA therapeutics.

Objectives: Our work aims to develop a novel bispecific tandem single-chain variable fragment (scFv)-Fc fusion protein combining synovium specificity with anti-TNFα activity. The potential advantage of this construct is a reduced systemic TNF-binding activity and increase delivery and activation of the TNF-neutralising capacity at the inflamed joints.

Methods: The therapeutic tandem scFv-Fc fusion protein comprises two external arms with synovium specific targeting ability linked through a metalloproteinase (MMP) cleavable linker to the anti-TNFα variable fragments of Adalimumab fused to the CH2 and CH3 domains of IgG1 (Figure 1). The external scFv regions with synovium specificity were previously identified by *in vivo* phage display using a SCID mouse model transplanted with human synovium[4]. The construct was tested for its ability to bind and neutralize *in vitro* and *ex vivo* targets.

Results: The fusion protein was tested by immunohistochemistry staining on RA synovium biopsies and an array of non-inflamed human tissues showing specific targeting of synovial microvasculature without no reactivity to the non-inflamed tissues. The TNFα binding and blocking capacity of the fusion protein was measured respectively by ELISA and cell assays measuring NF-κB activation, and it showed a two-fold decreased activity compared to the control antibody Adalimumab prior to detachment of the cleavable targeting fragment shielding the active anti-TNF fragment. Human synovial fluid and recombinant human MMP-1 efficiently cleaved the external arms of the antibody, releasing the anti-TNF scFv-Fc. The cleaved construct, detached from the synovium targeting arms, showed the same binding and anti-TNF inhibitory capacity/potency as Adalimumab.

Conclusion: The novel bispecific tandem scFv-Fc demonstrated specific synovium targeting ability and intended reduced anti-TNF activity in its intact form prior to reaching the joint. Following MMPs-induced cleavage present in RA synovial fluid the therapeutic activity was restored to the same level as Adalimumab. Overall, this construct has the potential of decreasing the anti-TNF off-site activity and consequently, reduce systemic toxicity while maintaining high on-site activity. Also, the presence of a synovium targeting domain has the advantage of increasing the delivery and retention within the inflamed synovium and possibly increase the therapeutic index of this anti-TNF therapeutics.

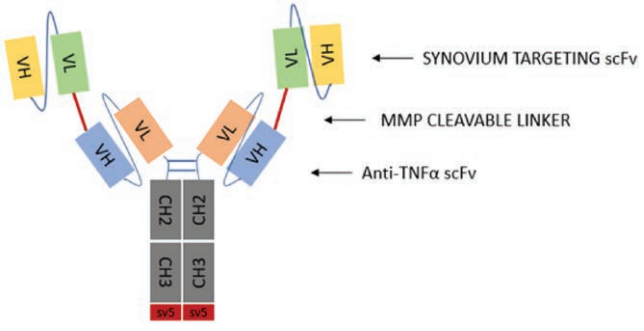

Figure 1. Schematic diagram of the bispecific tandem scFv-Fc fusion protein.

POS0207 REAL-WORLD RETENTION OF JAK INHIBITORS IS LONGER THAN BDMARDS IN RHEUMATOID ARTHRITIS

K. Machlab[1], S. M. Iskandar[1], T. Nevskaya[1], L. Vanderhoek[1], J. Bylsma[1], S. Hewitt[1], J. Pope[1]. [1]*University of Western Ontario, Schulich School of Medicine & Dentistry, London, Canada*

Background: Biological disease modifying anti-rheumatic drugs (bDMARDs) and Janus Kinase inhibitors (JAKi) are both recommended post conventional synthetic disease modifying anti-rheumatic drug (csDMARD) therapy failure in active rheumatoid arthritis (RA), but the data on long-term durability are limited.
Objectives: The objective of this study is to analyze a database of patients at the Western University, Rheumatology Center who initiated a bDMARD or JAKi and compare the proportion and characteristics of patients associated with retention of a drug class.
Methods: This was a single-center study of 215 adult RA patients (82.76 % females, age 59.8 ± 12.0 years, disease duration 15.5 ± 10.0 years; table 1) failing multiple csDMARDs prior to initiating either bDMARDs (TNF inhibitors, abatacept, rituximab, tocilizumab) or JAKi, between June 2014 (when tofacitinib was approved in Canada) and April 2020. All patients enrolled had failed traditional DMARDs, including methotrexate, hydroxychloroquine, sulfasalazine and/or leflunomide. Durability and predictors of discontinuation were analyzed by Kaplan-Meier and Cox regression analyses for all treatment trials, and for patients receiving bDMARDs/JAKi as a first line after csDMARDs failure.
Results: In 215 patients, there were 320 treatment events (148 bDMARDs, 172 JAKi) and 142 discontinuations (53.5% bDMARDs, 46.5% JAKi). Figure 1 represents the Kaplan-Meier survival curve for time to therapy discontinuation in 215 patients receiving bDMARDs vs JAKi. The Cox proportional hazards model was significant with better retention for JAKi, with a hazard ratio (HR) for treatment discontinuation of JAKi compared with bDMARDs of 0.676 (95% CI 0.47-0.97, p=0.034), adjusted for gender, age, disease duration, and line of therapy (Table 1). Moreover, the analysis revealed better retention for both groups as first line advanced therapy compared to later lines of therapy; 57.6% of JAKi and 31.1% of bDMARDs were used as first line advanced therapy. HR for treatment discontinuation for first line vs later lines of therapy was 0.593 (95% CI 0.40-0.88, p=0.01), adjusted for drug class, gender, age, and disease duration (Table 1). The most common reasons for discontinuations were inefficacy (60%), side effects (22%), or other reasons (18%). Inefficacy (58% vs 62%, p=0.8) and side-effects (16% vs 27%, p=0.4) were equally common for bDMARDs and JAKi. Sex, age at treatment onset, and RA duration did not predict discontinuation by Cox regression analyses, and after sub-grouping into bDMARDs and JAKi.
Conclusion: EULAR guidelines have placed bDMARDs equal to JAKi as post csDMARD failure therapy in active RA. However, this study demonstrates that JAKi has a greater durability than biologics regardless of gender, age, disease duration, and line of therapy. Therefore, JAKi may be considered as a preferable method of treatment post csDMARD failure in active RA.

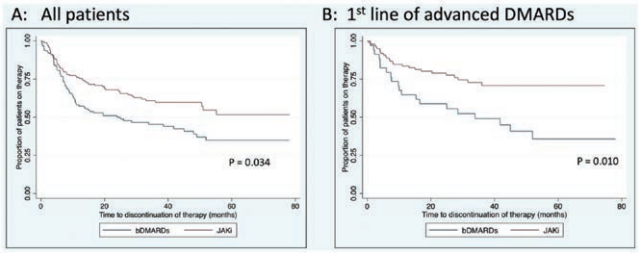

Figure 1. Kaplan-Meier survival curves for (A) time to discontinuation of therapy in all RA patients receiving bDMARDs versus JAKi; P-value represents Cox regression adjusted for gender, age, disease duration, and line of therapy (B) time to discontinuation of therapy in patients using bDMARDs/JAKi as first line of advanced therapy; P-value represents Cox regression adjusted for drug class, gender, age, and disease duration

Table 1. Patient demographics and hazard ratios for discontinuation of bDMARDs versus JAKi by Cox regression model

Characteristic	JAKi (N=172)	bDMARD (N=148)	Mean
Age (years)	60.9	58.5	59.8
Sex (% F)	77.8	88.5	82.8
Disease duration (years)	15.3	15.8	15.5
Line of advanced therapy (% first line)	57.6	31.1	45.3
Drug used (%)	Tofacitinib: 93.5	Rituximab: 26.4 Etanercept: 19.6 Adalimumab: 17.6	
Predictors of Drug Discontinuation		**HR (95% CIs)**	**P values**
Crude Model	JAKi vs bDMARDs	0.60 (0.43, 0.84)	0.003
Adjusted model	JAKi vs bDMARDs	0.68 (0.47, 0.97)	0.034
	Male vs female	0.77 (0.46, 1.31)	0.342
	Age	1.01 (0.99, 1.03)	0.123
	RA duration	0.99 (0.97, 1.01)	0.500
	Treatment line 1 vs >1	0.59 (0.40, 0.88)	0.010

POS0208 GENDER DIFFERENCES IN RESPONSE TO BIOLOGICALS. WOMEN FARE WORSE ACROSS INFLAMMATORY ARTHRITIS DISEASES - DATA FROM THE BIOREG

E. Loibner[1], V. Ritschl[2], B. Leeb[3,4], P. Spellitz[5,6], G. Eichbauer-Sturm[5], J. Zwerina[5,7,8], M. Herold[5,9], M. Stetter[5], R. Puchner[5], F. Singer[5], R. Fritsch-Stork[1,7,8]. [1]*Sigmund Freud Private University, Medical Faculty, Vienna, Austria*; [2]*Medical University of Vienna, Center for Medical Statistics, Informatics and Intelligent Systems; Section for Outcomes Research, Vienna, Austria*; [3]*BioReg, BioReg, Vienna, Austria*; [4]*Karl Landsteiner Private University of Health Science, Rheumatology, Krems, Austria*; [5]*BioReg, BioReg, Vienna, Austria*; [6]*Rheumazentrum Wien Oberlaa, rheumatology, Vienna, Austria*; [7]*Ludwig Boltzmann Institute of Osteology, Hanusch Hospital of Oesterreichische Gesundheitskassa and Allgemeine Unfallversicherungsanstalt, Vienna, Austria*; [8]*Hanusch Hospital, 1st Internal Medicine, wien, Austria*; [9]*Medical University- Innsbruck, Autoimmune Laboratory, Innsbruck, Austria*

Background: Gender differences in prevalence and disease course are known in various rheumatic diseases; however, investigations of gender difference concerning therapeutical response have yielded variable results.

Objectives: The aim of this retrospective study was to investigate, whether a gender difference in response rate to biological disease-modifying antirheumatic drugs (bDMARDs) and apremilast in bDMARD-naïve patients could be observed across the three most prevalent inflammatory arthritis diseases: rheumatoid arthritis (RA), spondylarthritis (SpA) and psoriatic arthritis (PsA). Additionally, a response to individual TNF blockers was investigated in this respect.

Methods: Data from bDMARD-naïve RA-, SpA- and PsA-patients from Bioreg, the Austrian registry for biological DMARDs in rheumatic diseases, were used. Patients with a baseline (Visit 1=V1) and follow-up visits at 6 months (Visit 2=V2) and 12 months (Visit 3=V3) were included and response to therapy with TNF-inhibitors (TNFi), furthermore to therapy with rituximab, tocilizumab and apremilast was analyzed according to gender. The remaining bDMARDs were not analyzed due to small numbers. Key response-parameter for RA was disease activity score (DAS28), whereas for PsoA the Stockerau Activity Score for Psoriatic Arthritis (SASPA) and for SpA the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) were employed; in addition, the Health assessment Questionnaire

(HAQ) was used. Data were analyzed in R Statistic stratified by gender using Kruskal-Wallis and Wilcoxon tests.

Results: 354 women and 123 men with RA (n=477), 81 women and 69 men with PsA (n=150), 121 women and 191 men with SpA (n=312) were included. No significant differences in biometrics was seen between female and male patients at baseline in all diseases.

In RA patients overall DAS28 decreased from baseline (V1) to V2 and V3 (DAS28: V1: male: 4.38 [3.66, 5.11], female: 4.30 [3.68, 5.03], p(m/f) = 0.905; V2: male: 2.66 [1.73, 3.63], female: 3.10 [2.17, 3.98], p(m/f) = 0.015; V3: male: 2.25 [1.39, 3.36], female: 3.01 [1.87, 3.87], p(m/f) = 0.002). For TNF inhibitors (n=311), there was a significant difference between genders at V2 (Fig.1a). Patients receiving Rituximab (n=41) displayed a significantly higher DAS28 at baseline in females, which diminished in the follow up: V1: (p(m/f) p=0.002; V2: p=0.019; V3: p=0.13); response to tocilizumab (n=63) did not show any gender differences.
In PsA patients overall SASPA decreased from baseline (V1) to V2 and V3 (SASPA: V1: male: 4.00 [2.80, 5.20], female: 4.40 [2.80, 5.80], p(m/f) = 0.399; V2: male: 2.20 [1.20, 3.50], female: 3.40 [2.00, 5.00], p(m/f) = 0.071; V3: male: 1.80 [0.80, 2.70], female: 3.01 [2.35, 4.80], p(m/f) = 0.001). For TNF inhibitors (n=79), there was a significant difference between genders at V3 (Fig 1a). For Apremilast (n=39), there was a significant difference between genders at V2 (Fig.1c).
In SpA patients overall BASDAI decreased from baseline (V1) to V2 and V3 (BASDAI: V1: male: 4.70 [2.88, 6.18], female: 4.80 [3.30, 6.20], p(m/f) = 0.463; V2: male: 3.05 [2.00, 4.60], female: 3.64 [2.62, 5.41], p(m/f) = 0.039; V3: male: 3.02 [1.67, 4.20], female: 3.65 [2.18, 5.47], p(m/f) = 0.016). In V3 a differential BASDAI in response to TNFi (n=299) was observed (Fig.1a).
Possible differences of response to individual TNFi (etanercept, infliximab, other TNFi) measured by HAQ were investigated in all diseases together. The difference between male and females was significant at baseline for all 3 TNFi; whereas with the use of ETA the significant difference was carried through to V2 and V3, it was lost with the use of IFX and was variable with the other TNFi (Fig.1b)

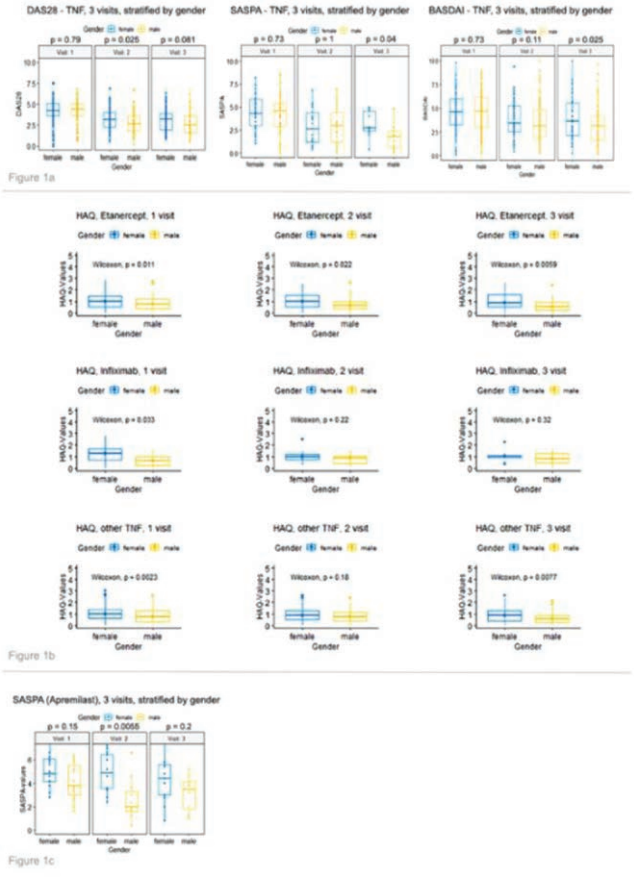

Figure 1.

Conclusion: Female patients showed a statistically lower response to TNFi in all three disease entities (RA, SpA and PsoA) to a variable degree in our homogenous central european population. Interestingly, the difference was not uniform across individual TNFi when measured by HAQ. Gender differences were also seen in response to Apremilast.

POS0209

ASSOCIATION OF FIRST, SECOND, AND THIRD-LINE BDMARDS AND TSDMARD WITH DRUG SURVIVAL AMONG RHEUMATOID ARTHRITIS PATIENTS: A COHORT STUDY

B. Ghang[1], S. Choi[2], E. Y. Lee[3]. *[1]1Division of Rheumatology, Department of Internal Medicine, Jeju National University School of Medicine, Jeju National University Hospital, Rheumatology, Seoul, Korea, Rep. of (South Korea)*; *[2]Seoul National University Graduate School, Biomedical Science, Seoul, Korea, Rep. of (South Korea)*; *[3]Seoul National University College of Medicine, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Since tofacitnib is a tsDMARD with a different mechanism of action compared to bDMARDs, along with the fact that recent releases of bDMARDs or tsDMARDs have led to numerous possible switching patterns, there is a need for comparative studies of bDMARDs and tofacitinib with subsequent drug survival among RA patients.

Objectives: To determine the association of first, second, and third-line biologic disease- modifying antirheumatic drugs (bDMARDs) and tofacitinib with drug survival among rheumatoid arthritis (RA) patients.

Methods: The study population was composed of 8,018 seropositive RA patients who were prescribed bDMARDs or tofacitinib between January 2014 and January 2019 from the Korean Health Insurance Review and Assessment Service database. First, second, and third-line choice of tumor necrosis factor inhibitors (TNFi) including etanercept, infliximab, adalimumab, and golimumab, as well as non-TNFi including tocilizumab, rituximab, tofacitinib, and abatacept were assessed. Multivariate Cox proportional hazards regression was used to determine the adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs) for drug failure according to bDMARD or tofacitinib choice starting from the initial prescription date.

Results: Compared to first etanercept users, patients with first tocilizumab (aHR 0.56, 95% CI 0.46-0.68), tofacitinib (aHR 0.27, 95% CI 0.18-0.42), or abatacept (aHR 0.83, 95% CI 0.69- 0.99) had lower risk of drug failure. Second choice of tocilizumab (aHR 0.38, 95% CI 0.25- 0.55), tofacitinib (aHR 0.23, 95% CI 0.15-0.37), or abatacept (aHR 0.54, 95% CI 0.35-0.84) was associated with lower drug failure risk compared to second etanercept users. Finally, third choice of tocilizumab (aHR 0.32, 95% CI 0.16-0.62) or tofacitinib (aHR 0.35, 95% CI 0.19- 0.63) was associated with lower drug failure risk compared to third TNFi users.

Conclusion: First and second-line tocilizumab, tofacitinib, or abatacept may lead to improved drug survival. Third choices of tocilizumab or tofacitinib may be beneficiary in reducing drug failure risk among RA patients.

Rheumatoid Arthritis - comorbidity and clinical aspects - Part 1

POS0210 **THE INCIDENCE AND RISK FACTORS OF RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE**

B. Samhouri[1], R. Vassallo[1], S. Achenbach[2], V. Kronzer[3], J. M. Davis III[3], E. Myasoedova[3], C. S. Crowson[2]. [1]*Mayo Clinic, Division of Pulmonary and Critical Care Medicine, Rochester, MN, United States of America*; [2]*Mayo Clinic, Department of Quantitative Health Sciences, Rochester, MN, United States of America*; [3]*Mayo Clinic, Division of Rheumatology, Rochester, MN, United States of America*

Background: Rheumatoid arthritis (RA) is a systemic inflammatory disease of the joints and other organs, including the lungs.[1] Interstitial lung disease (ILD) is a lung injury pattern associated with significant symptom burden and poor outcomes in RA.[2] Better understanding of its risk factors could help with disease prevention and treatment.

Objectives: Using a population-based cohort, we sought to ascertain the incidence and risk factors of RA-associated ILD (RA-ILD) in recent years.

Methods: The study included adult residents of Olmsted County, Minnesota with incident RA between 1999 and 2014 based on the 1987 ACR classification criteria.[3] Study subjects were followed until death, migration, or 4/30/2019. ILD was defined by the presence of bilateral interstitial fibrotic changes (excluding biapical scarring) on chest computed tomography (CT). In the absence of chest CT imaging, a physician's diagnosis of ILD in conjunction with chest X-ray findings suggestive of ILD and a restrictive pattern on pulmonary function testing (defined as a total lung capacity less than the lower limit of normal) was considered diagnostic of ILD. Evaluated risk factors included age, sex, calendar year, smoking status, body mass index (BMI) and presence/absence of rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA). Cumulative incidence of ILD was adjusted for the competing risk of death. Cox models were used to assess the association between potential risk factors and the development of RA-ILD.

Results: In Olmsted County, 645 residents were diagnosed with RA between 1999 and 2014. Seventy percent of patients were females, and 30% were males; median age at RA diagnosis was 55.3 [IQR 44.1-66.6] years, and most patients (89%) were white. Fifty-three percent of patients were never-smokers, and 64% had seropositive RA. Forty percent were obese (i.e., BMI ≥30 kg/m^2); median BMI was 28.3 [IQR 24.3-33.0] kg/m^2.

In the cohort, ILD was identified in 73 patients. The ILD diagnosis predated RA diagnosis in 22 patients (3.4%) who were excluded from subsequent analyses. Final analyses included the remaining 623 patients with no ILD preceding, or at the time of RA diagnosis. Over a median follow-up interval of 10.2 [IQR 6.5-14.3] years, 51 patients developed ILD. Cumulative incidence of ILD, adjusted for the competing risk of death, was 4.3% at 5 years; 7.8% at 10 years; 9.4% at 15 years; and 12.3% at 20 years after RA diagnosis (Figure 1).

Age, and history of smoking at RA diagnosis correlated with the incidence of ILD; adjusted hazard ratios (HRs) were 1.89 per 10-year increase in age (95% confidence interval 1.52-2.34) and 1.94 (95% confidence interval 1.10-3.42), respectively. On the other hand, sex (HR: 1.21; 95% CI: 0.68-2.17), BMI (HR: 0.99; 95% CI: 0.95-1.04), obesity (HR: 0.89; 95% CI: 0.50-1.58), and seropositivity (HR: 1.15; 95% CI: 0.65-2.03) did not demonstrate significant associations with ILD.

Conclusion: This study provides a contemporary estimate of the occurrence of ILD in a well-characterized population-based cohort of patients with RA. Our findings of a lack of association between sex, obesity and seropositivity with ILD may indicate a change in established risk factors for ILD and warrant further investigation.

Objectives: To analyze the effect of disease-modifying antirheumatic drugs (DMARDs) and identify risk factors associated with disease progression and mortality in patients with rheumatoid arthritis associated with interstitial lung disease (RA-ILD).
Methods: We performed a multicenter, prospective, observational study of patients with RA-ILD receiving DMARDs between 2015 and 2020. The patients were assessed using high-resolution computed tomography and pulmonary function tests at baseline and at 60 months. The main outcome measure at 60 months was worsening of FVC >10% or DLCO >15% and radiological progression or death. We recorded demographic and clinical characteristics, lung function, and the incidence of adverse events. A Cox regression analysis was performed to identify factors associated with worsening of ILD.
Results: After 60 months, lung disease had stabilized in 66 patients (56.9%), improved in 9 (7.8%), and worsened in 23 (19.8%). Eighteen patients (15.5%) died, with a mean survival of 71.8 (1.9) months. Baseline characteristics of 116 with RA-ILD treated with DMARDs is in table 1.The Cox multivariate analysis revealed the independent predictors of worsening of RA-ILD to be usual interstitial pneumonia (HR, 2.6 [95%CI, 1.0-6.7]), forced vital capacity (%) (HR, 3.8 [95%CI, 1.5-6.7]), anticitrullinated protein antibody titers (HR, 2.8 [95%CI, 1.1-6.8]), smoking (HR, 2.5 [95%CI, 1.1-6.2]), and treatment with abatacept, tocilizumab, or rituximab (HR, 0.4 [95%CI, 0.2-0.8]). During follow-up, 79 patients (68%) experienced an adverse event, mostly infection (61%).
Conclusion: Lung function is stable in most patients with RA-ILD receiving treatment with DMARDs, although one third of patients die. Identifying factors of worsening in RA-ILD is important for clinical management.

POS0212 COMPARISON OF PATIENT CHARACTERISTICS AND TREATMENT PATTERNS ACROSS BODY MASS INDEX CATEGORIES IN PATIENTS WITH PSORIATIC ARTHRITIS AND RHEUMATOID ARTHRITIS

E. Vallejo-Yagüe[1], T. Burkard[1], B. Moeller[2], A. Finckh[3], A. M. Burden[1]. [1]*ETH Zurich, Department of Chemistry and Applied Biosciences, Institute of Pharmaceutical Sciences, Zurich, Switzerland*; [2]*Inselspital, University Hospital of Bern, Rheumatology, Immunology and Allergy, Bern, Switzerland*; [3]*University Hospitals Geneva, Division of Rheumatology, Geneva, Switzerland*

Background: Higher prevalence of obesity has been observed in psoriatic arthritis (PsA) and rheumatoid arthritis (RA) versus the general population, and abnormal body mass index has been associated with worse rheumatic markers.
Objectives: To describe PsA and RA patients in Switzerland, stratified by body mass index (BMI) category.
Methods: We performed a descriptive cohort study in PsA and RA patients registered in the Swiss Clinical Quality Management in Rheumatic Diseases (SCQM) database. Two distinct cohorts were generated based on patient diagnosis (PsA or RA) and analysed separately but using similar approaches. In both cohorts, we included patients treated for the first time with biologics or targeted synthetic disease-modifying anti-rheumatic drugs (tsDMARDs), and considered the treatment start as index date. Patients without baseline BMI were excluded. Patients were stratified by BMI category at the start of biologic/tsDMARD treatment, defined as underweight (BMI<18.5), normal weight (BMI 18.5-24.9), overweight (BMI 25.0-29.9), and obese (BMI≥30). In the PsA cohort, underweight and normal weight groups were merged due to low numbers. The proportion of patients categorized as overweight or underweight were compared to national statistics from the Swiss Federal Statistical Office. Information on patient demographics (e.g., age, sex, BMI, life-habits), disease-specific characteristics (e.g., disease activity scores, health questionnaires, biomarkers), co-medications and comorbidities were summarized at the start of the first biologic/tsDMARD treatment. Patient characteristics across BMI categories were compared, using the normal weight category as reference group. Additionally, we summarized the frequency and reasons for recorded treatment stop/switch at ≤6 months, 6 to 12 months, and >12months from treatment start, and illustrated the prescription patterns for first and second biologic/tsDMARD treatment, stratifying by BMI.
Results: We identified 819 PsA [39.7% normal weight, 36.5% overweight, 23.8% obese] and 3217 RA patients [4.4% underweight, 46.8% normal weight, 31.8% overweight, 17.0% obese]. Figure 1 illustrates the prevalence of overweight and obesity in each cohort stratified by sex, compared to the national average. When comparing obese patients to those with normal weight, both PsA and RA obese patients had significantly higher C-reactive protein, worse disease activity score, lower quality of life (QoL) measures, and more frequent cardiovascular disease and diabetes. Among PsA patients, the overweight and obese had worse physician-assessed skin manifestation and patient-reported pain compared to the normal weight group. While in RA, the obese patients had higher erythrocyte sedimentation rate, smaller prevalence of seropositive patients, lower frequency of fractures/surgeries, and higher tender joint counts, but similar swollen joint counts, when compared to the normal weight group. Adalimumab and etanercept, were the most commonly prescribed drugs as first biologic/tsDMARD treatment in both PsA and RA cohorts and among every BMI category. Overall, 55% PsA and 56% RA patients had recorded treatment stop/switch. Among RA patients, significantly fewer obese patients reported treatment stop/switch at >12 months from treatment start, compared to the normal weight group. Adalimumab and etanercept were also the most commonly prescribed second biologic/tsDMARD treatment, but for the obese group among PsA patients (adalimumab, golimumab) and the obese group in the RA cohort (adalimumab, rituximab).
Conclusion: In this national wide study, we observed that the prevalence of obesity in RA and PsA was higher than that of the general Swiss population. Obese PsA/RA patients starting first biologic/tsDMARD treatment presented worse disease activity and poorer QoL than normal weight patients. Results suggest to take BMI into consideration when treating PsA and RA patients.

POS0213 20 YEAR FOLLOW-UP OF CARDIOVASCULAR EVENT RISK IN RHEUMATOID ARTHRITIS COMPARED TO DIABETES

R. Raadsen[1], R. Agca[1,2], A. Voskuyl[2], M. Boers[3], W. Lems[1,2], M. Nurmohamed[1,2]. [1]*Amsterdam Rheumatology and Immunology Center, location Reade, Rheumatology, Amsterdam, Netherlands*; [2]*Amsterdam Rheumatology and Immunology Center, location VU University Medical Center, Rheumatology, Amsterdam, Netherlands*; [3]*Amsterdam University Medical Center, Location VU University Medical Center, Biostatistics and Epidemiology, Amsterdam, Netherlands*

Background: Patients with rheumatoid arthritis have an increased risk for developing cardiovascular diseases (CVD) compared to the general population, similar to the CVD risk in patients with diabetes mellitus. However, there are no controlled studies investigating the incidence of cardiovascular (CV) events in RA patients with follow up of more than 20 years.
Objectives: The objectives of the current study were to investigate the incidence rates of CV events in a long-term follow up cohort of RA patients, and to compare these to a similar cohort representing the general population, ie. The Hoorn study.
Methods: The CARRÉ study is an ongoing prospective cohort study, which started in 2001, investigating CV mortality and morbidity in 353 randomly selected patients with RA. Primary endpoints, i.e. verified medical history of coronary, cerebral or peripheral arterial disease, were determined at baseline, and after three, ten, fifteen and twenty years of follow up. Patients were censored at the date of an experienced CV event or their death. Incidence density rates per 100 patient years were calculated. Data were compared to results from the Hoorn study, a Dutch cohort study of glucose metabolism and other CV risk factors that began in 1989. All 2,484 participants were subject to an extensive and repeated CV screening program similar to that used in the CARRÉ study.
Results: After 20 years of follow up 118 patients (33%) developed at least one CV event in the Carré group. Mean (SD) follow up time was 11 (6) years with a total of 3,500 years at risk and an incidence rate of 3.4 per 100 patient-years; this is slightly up from the figure reported at 15 years, i.e. 3.2 per 100 patient-years. A CV event-free survival curve is shown in figure 1. After 30 years of follow up, 295 participants of the Hoorn study had developed a CV event, during a mean follow up time 20 (8) years. Total time at risk was 50,000 years, with an incidence rate of 0.6 CV events per 100 patient years.
Conclusion: In our cohort the incidence rate of CV events in RA patients has remained consistently high when compared with the general population, despite better control of RA inflammation in recent years. This again confirms the need for timely CVD-risk screening and management.

Background: Rheumatoid arthritis (RA) is associated with an increased risk of atherosclerotic cardiovascular disease (CVD). The Expanded Cardiovascular Risk Prediction Score for Rheumatoid Arthritis (ERS-RA) estimates the 10-year risk of myocardial infarction, stroke or CVD-related death based on conventional and RA-specific (clinical disease activity index, CDAI, disease duration, glucocorticoid use) risk factors (1).
Objectives: We evaluated the associations between ERS-RA 10-year risk of CVD, high-sensitivity C-reactive protein (hs-CRP) concentrations, and pharmacological treatment in 1,251 RA patients collected by the "Cardiovascular Obesity and Rheumatic Disease Study (CORDIS)" group of the Italian Society of Rheumatology (SIR).
Methods: We assessed independent associations between ERS-RA risk score and each relevant variable using multivariate regression (ENTER approach; listwise deletion analysis). Given the relatively high number of missing hs-CRP data (n=385), regression analysis was also performed using multiple imputation (10 sets, Stata 16.1). Regression models were not adjusted for independent variables included in the ERS-RA score.
Results: Among 1,251 RA patients [mean (SD) age 60.4(9.3), range (40-80) years; 78% female; mean (SD) disease duration, 11.6(8) years; mean (SD) CDAI, 9(9); mean (SD) HAQ, 0.77(0.7); mean (SD) hs-CRP, 6.8(12) mg/L] the estimated 10-year CVD risk was 11.6(0.9) % [mean (SD)]. Regarding treatment, 539(43%) received glucocorticoids, 676(54%) a biological or targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARD) (n missing=1), and 885(81%) at least one conventional synthetic DMARD (csDMARD). Ninety-three (7.4%) patients did not receive any treatment. After adjusting for the use of b/tsDMARD and csDMARD, hs-CRP concentrations were significantly associated with 10-year risk of CVD both in standard multiple regression (n=865; coefficient=0.005 for each 10 mg/L hs-CRP increment, 95% confidence interval (0.000-0.100), p=0.043) and after multiple imputation (n=1,251; coefficient=0.005 for each 10 mg/L hs-CRP increment, 95% confidence interval (0.000-0.114), p=0.035) (Table 1). This corresponds to an increase of 10-year CV risk of 1% for every 20 mg/L increase in hs-CRP concentrations.
Conclusion: In a large cohort of RA patients, we observed a significant, positive, and independent association between hs-CRP concentrations and 10-year CV risk estimated by ERS-RA. The cross-sectional design of the study did not allow to establish a cause-effect relationship between hs-CRP and CV risk. Given that conventional CV risk factors and inflammation-related variables are accounted for in the ERS-RA risk score, other, unexplored, mechanisms may underlie the observed association between hs-CRP and CV risk.

POS0215

DIRECT AND CONDITIONAL EFFECTS OF EPICARDIAL ADIPOSE TISSUE VOLUME ON CORONARY PLAQUE PROGRESSION IN RHEUMATOID ARTHRITIS

G. Karpouzas[1], S. Ormseth[1], E. Hernandez[1], M. Budoff[2]. [1]*The Lundquist Institute, Rheumatology, Torrance, United States of America*; [2]*The Lundquist Institute, Cardiology, Torrance, United States of America*

Background: Epicardial adipose tissue volume (EATv) predicts coronary atherosclerosis presence, progression and cardiovascular event risk in general patients[1,2]. Our group recently reported that EATv associated with greater subclinical coronary plaque burden, non-calcified plaque presence and vulnerable plaque characteristics in patients with rheumatoid arthritis (RA). The relationship was stronger in RA patients with lower disease duration, no traditional cardiac risk factors, and who were not obese.
Objectives: To evaluate the predictive value of EATv on long-term coronary atherosclerosis development, and moderators of the association between EATv and plaque formation.
Methods: This single-center observational cohort study included 100 patients without symptoms or diagnosis of cardiovascular disease who underwent computed tomography angiography for evaluation of EATv and coronary atherosclerosis at baseline and repeat assessments 6.9±0.3 years later to evaluate plaque progression. New plaque formation in segments without plaque at baseline was the main outcome. Robust multivariable logistic regression evaluated the effect of high versus low EATv (based on median) on likelihood of new plaque formation, accounting for clustering of segments within patients. Potential moderator effects of prespecified predictors were also assessed.
Results: High EATv (>107 cm^3) predicted new plaque formation in segments without baseline plaque (OR 2.77 [95% CI 1.43-5.37], p= 0.003); however, significance was lost in the multivariable model. Importantly, high EATv associated with formation of higher-risk non- and partially calcified plaque after adjusting for Framingham D'Agostino risk score, obesity, segment location, time-averaged CRP, duration of bDMARD and statin treatment and cumulative prednisone dose (adjusted OR 2.57 [95% CI 1.02-6.48], p= 0.045). RA duration (<10 versus >10 years), cardiac risk factor burden (≤1 versus >1), presence of mixed/calcified plaque in other coronary segments at baseline, and statin exposure (≤1 versus >1 year, based on median) moderated the effect of EATv on all new plaque formation (all p for interaction ≤ 0.021). Specifically, high EATv predicted new plaque formation in patients with RA duration <10 years (adjusted OR 5.75 [95% CI 1.77-18.67]), those with ≤1 cardiac risk factors (adjusted OR 3.40 [95% CI 1.46-7.90]), those without calcification at baseline (adjusted OR 2.65 [95% CI 1.11-6.31]) and those with statin treatment <1 year (adjusted OR 3.33 [95% CI 1.13-9.77]). This was not the case for patients with RA >10 years, ≥ 2 cardiac risk factors, calcification at baseline and statin treatment >1 year (figure 1).
Conclusion: High baseline EATv independently predicted future higher-risk non-calcified and mixed coronary plaque in RA. Moreover, it conditionally promoted new plaque formation overall in patients with earlier disease, low cardiac risk factor burden, who had little or no atherosclerosis at baseline and who had limited exposure to statin therapy. These findings indicate the need for a larger prospective evaluation of the role of EATv as a biomarker of coronary atherosclerosis development in RA.

POS0216

GREATER HIGH-DENSITY LIPOPROTEIN LEVELS OVER TIME ARE LINKED TO DECREASED CORONARY PLAQUE FORMATION AND REGRESSION AND STABILIZATION OF HIGH-RISK LESIONS IN RHEUMATOID ARTHRITIS

G. Karpouzas[1,2], S. Ormseth[1], E. Hernandez[1], M. Budoff[3]. [1]*The Lundquist Institute, Rheumatology, Torrance, United States of America*; [2]*Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America*; [3]*The Lundquist Institute, Cardiology, Torrance, United States of America*

Background: The relationship between serum lipoproteins and cardiovascular disease risk in rheumatoid arthritis (RA) is complex[1]. Their levels and function may vary based on disease activity and medication use. Beneficial effects on high-density lipoprotein (HDL-C) levels, structure and behavior, in response to treatment have been described. However, the impact of HDL-C levels over time on coronary atherosclerosis progression in RA is unknown.
Objectives: We here evaluated the influence of HDL-C levels over time on long-term coronary plaque formation and progression in patients with RA.
Methods: One hundred one RA patients without symptoms or history of cardiovascular disease who participated in a computed tomography angiography study of coronary atherosclerosis had repeat assessments after 6.9±0.3 years to evaluate plaque progression. Clinical, laboratory and medication data were recorded at baseline and regular outpatient follow-up visits thereafter. Time-averaged HDL-C was calculated for each patient using available consecutive HDL measurements between baseline and follow-up. Robust logistic regression assessed the association between time-averaged HDL-C and likelihood of new plaque formation in segments without plaque at baseline, and transition of prevalent mixed plaque to calcified plaque. Robust multinomial logistic regression evaluated the effect of time-averaged HDL-C on likelihood of new non-calcified, mixed or calcified plaque formation in segments without plaque (compared to remaining without plaque), and non-calcified plaque regression or transition to mixed or calcified plaque at follow-up (compared to remaining non-calcified). All models accounted for clustering of coronary segments within patients and adjusted for Framingham D'Agostino risk score, proximal segment location, time-averaged CRP, cumulative prednisone dose, bDMARD duration, statin duration, waist-to-height ratio, and time-averaged triglycerides.
Results: Participants were mostly female (n=87, 86.1%), with a mean ± standard deviation (SD) age of 51.5±10.3 years and time-averaged HDL-C of 51.7±13.9. Ninety-seven new plaques formed in segments without plaque at baseline; 20 were noncalcified, 21 were mixed, and 56 were calcified. Time-averaged HDL-C

had no effect on new total plaque formation (adjusted odds ratio-OR 0.88 [95% CI 0.64-1.21]). However, each 1-SD increase in time-averaged HDL-C associated with a 44% reduced likelihood of new non-calcified plaque formation at follow-up (adjusted OR 0.56 [95% CI 0.35-0.92], Figure 1). In contrast, there was no effect of time-averaged HDL-C on new mixed or calcified plaque formation. Of 98 non-calcified plaques at baseline, 42 did not change at follow-up, 32 regressed (disappeared), 16 transitioned to mixed and 8 to calcified plaques. Each SD increase in time-averaged HDL-C yielded a 2.2-fold greater likelihood of non-calcified plaque regression (adjusted OR 2.21 [95% CI 1.02-4.83]). Sixteen of 52 mixed plaques present at baseline transitioned to more stable calcified lesions, and time-averaged HDL-C (per 1-SD increment) predicted a 3.5-fold increased likelihood of transition of mixed to fully calcified plaque (adjusted OR 3.56 [95% CI 1.25-10.17]).

Conclusion: Higher HDL-C over time predicted regression of existing and decreased formation of new higher-risk non-calcified plaque. It also associated with transition of vulnerable mixed plaque to more stable fully calcified plaque. These effects were independent of RA treatment duration, prednisone dose and statin exposure.

POS0217 PULSE WAVE VELOCITY ELEVATION ABOVE INDIVIDUAL REFERENCE VALUES AND AORTIC-BRACHIAL STIFFNESS MISMATCH AS EARLY MARKERS OF ARTERIAL STIFFNESS INCREASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Troitskaya[1], S. Velmakin[1], R. Osipyants[1], A. Arbuzova[1], V. R. Espinoza[2], Z. Kobalava[1]. *[1]Peoples' Friendship University of Russia (RUDN University), Internal diseases, Moscow, Russian Federation*; *[2]Peoples' Friendship University of Russia (RUDN University), Int, Moscow, Russian Federation*

Background: Arterial stiffness (AS) is a known predictor of cardiovascular (CV) disease. The measurement of pulse wave velocity (PWV) is considered to be a gold standard of AS assessment but the recommended threshold of 10 m/s[1] may not take into account multiple factors influencing PWV. Use of the proposed individual reference values may help to identify patients with AS increase despite PWV level below this threshold[2]. The impact of AS on CV outcomes may be mediated by the reversal of the aortic-brachial stiffness (AS gradient)[3]. One small study in patients with type 2 diabetes has shown that the aortic-brachial stiffness mismatch (hereafter AS mismatch) was an earlier marker of AS than PWV elevation[4]. Patients with rheumatoid arthritis (RA) have high CV risk and may benefit from early detection of AS increase. Both approaches have not been studied in RA previously

Objectives: To evaluate the incidence of PWV elevation above individual reference values and the frequency of AS mismatch in RA

Methods: Study group included 85 patients (pts) with RA (females 77.6%, aged 59.7±14.3 years, HTN 65%, mean DAS-28(CRP) 3.7±1.1) and control group (40 pts matched by gender, age and risk factors). Parameters of AS were measured by applanation tonometry. Individual PWV reference values were assessed[2]. The AS gradient was calculated as carotid-femoral (cf)PWV/carotid-radial (cr)PWV ratio and its elevation ≥1 was considered as AS mismatch. p<0,05 was considered significant

Results: In pts with RA with and without history of HTN mean cfPWV was 10.3±3.1 and 7.3±1.5 m/s, respectively, mean AS gradient – 1.4±0.4 and 1.1±0.1 (p<0.001 for trend); in controls – 9.6±1.9 and 6.7±1.4 m/s and 1.3±0.3 and 0.99±0.2, respectively (p<0.001 for trend). cfPWV elevation ≥10 m/s was observed in 34.1% pts with RA and 32.5% of controls: 6.7 and 6.3% of normotensives and 49.1 and 50% of hypertensives, respectively (p>0.05). cfPWV elevation above individual reference values was observed in 41.2% RA pts and 27.5% of controls (p=0.03): in 40% and 6.3% of normotensives (p=0.02) and 41.8% and 41.7% of hypertensives, respectively. After adjustment by age, gender and systolic BP cfPWV elevation above individual reference values in normotensive RA pts was independently associated with BMI (beta=0.39, p=0.02) and dyslipidemia (beta=0.48, p=0.01). The frequency of AS mismatch in RA was significantly higher compared to the controls in both normotensive and hypertensive subgroups: 76.7% vs 43.8% (p=0.03) and 94.5% vs 79.2% (p=0.04), respectively. The same trend was observed in a subgroup with normal cfPWV: AS mismatch was present in RA and controls in 82.1% vs 51.9% (p=0.004) in pts with PWV ≤ 10 m/s and in 82% and 51.7% (p=0.04), respectively in pts with PWV below individual reference values.

Conclusion: Patients with RA are characterized by higher frequency of cfPWV elevation above individual reference values compared to controls irrespectively of history of HTN. This method may be more appropriate for AS evaluation than use of standard criteria in this population. AS mismatch in RA pts is highly prevalent and may be considered as an earlier marker of AS than cfPWV elevation. These findings may be used for early detection of vascular ageing in patients with RA.

POS0218 TUMOR-NECROSIS FACTOR INHIBITORS IMPROVE AORTIC STIFFNESS IN PATIENTS WITH LONGSTANDING RHEUMATOID ARTHRITIS

A. Giollo[1], G. Cioffi[1], G. Orsolini[1], F. Ognibeni[1], A. Dalbeni[2], R. Bixio[1], G. Adami[1], A. Fassio[1], L. Idolazzi[1], D. Gatti[1], M. Rossini[1], O. Viapiana[1]. *[1]University of Verona, Rheumatology Section, Department of Medicine, Verona, Italy*; *[2]University of Verona, Internal Medicine and Hypertension Unit, Department of Medicine, Verona, Italy*

Background: Major cardiovascular disease (CVD) benefits of disease-modifying anti-rheumatic drugs (DMARDs) therapy occur in early RA patients with treat-to-target strategy. However, it is unknown whether long-term DMARDs treatment in established RA could be useful to improve CVD risk profile.

Objectives: The aim of this study was to comparatively describe aortic stiffness progression in patients with longstanding and established RA treated with tumor necrosis factor inhibitors (TNFi) or conventional synthetic DMARDs (csDMARDs).

Methods: Ultrasound aortic stiffness index (AoSI) has to be considered a proxy outcome measure in established RA patients. We measured AoSI in a group of RA patients on long-term treatment with TNFi or csDMARDs. Eligible participants were assessed at baseline and after 12 months; changes in serum lipids, glucose and arterial blood pressure were assessed. All patients were on stable medications during the entire follow-up.

Results: We included 107 (64 TNFi and 43 csDMARDs) RA patients. Most patients (74%) were in remission or low disease activity and had some CVD risk factors (45.8% hypertension, 59.8% dyslipidemia, 45.3% smoking; table 1). The two groups did not differ significantly for baseline AoSI (5.95±3.73% vs 6.08±4.20%, p=0.867). Follow-up AoSI was significantly increased from baseline in the csDMARDs group (+1.00%; p<0.0001) but not in the TNFi group (+0.15%, p=0.477). Patients on TNFi had significantly lower follow-up AoSI from baseline than the csDMARDs group (-1.02%, p<0.001; ANCOVA corrected for baseline AoSI, age and systolic blood pressure). Furthermore, follow-up AoSI was significantly lower in TNFi users with 1-2 or >2 CVD risk factors than in those without (figure 1).

Conclusion: Long-term treatment with TNFi was associated with reduced aortic stiffness in patients with established RA and several CVD risk factors.

Baseline characteristics of the study population.	csDMARDs (n=43)	TNFi (n=64)	P value
Age, median years (IQR)	58.6 (53.0, 66.0)	58.1 (49.3, 67.0)	0.839

POS0219

EFFECT OF LOW-DOSE METHOTREXATE ON ESTIMATED GLOMERULAR FILTRATION RATE AND KIDNEY ADVERSE EVENTS IN THE CARDIOVASCULAR INFLAMMATION REDUCTION TRIAL

J. Sparks[1], K. Vanni[1], M. Sparks[2], C. Xu[1], L. Santacroce[1], R. Glynn[3], P. Ridker[4], D. Solomon[1]. *[1]Brigham and Women's Hospital, Division of Rheumatology, Boston, United States of America; [2]Duke University School of Medicine, Division of Nephrology, Durham, United States of America; [3]Brigham and Women's Hospital, Divisions of Cardiovascular and Preventative Medicine, Boston, United States of America; [4]Brigham and Women's Hospital, Division of Preventative Medicine, Boston, United States of America*

Background: Low-dose methotrexate (LD-MTX) is a common first-line treatment for systemic rheumatic diseases, and its use is contraindicated in advanced chronic kidney disease (CKD) because it is primarily excreted by the kidneys. Among patients with preserved kidney function, the safety of LD-MTX on estimated glomerular filtration rate (eGFR) and kidney adverse events (AEs) has not been established.

Objectives: To investigate the effect of LD-MTX on eGFR and kidney AEs using data from a randomized clinical trial.

Methods: We performed a secondary analysis for eGFR and kidney AEs using the randomized double-blind, placebo-controlled Cardiovascular Inflammation Reduction Trial. Adults with known cardiovascular disease and diabetes and/or metabolic syndrome were randomly allocated to oral LD-MTX (target dose 15-20 mg/week) or placebo. All participants took folic acid 1 mg six days/week. Exclusion criteria included systemic inflammatory disease and creatinine clearance <40 mL/min (by Cockcroft-Gault). eGFR was calculated using the CKD-EPI formula. Clinical kidney AEs were blindly adjudicated. The least-squares mean change of eGFR from baseline was calculated at each study visit; the difference in eGFR slopes between LD-MTX and placebo was compared using a modified intention-to-treat approach. We also compared rates of kidney AEs for LD-MTX versus placebo using Cox proportional hazards models.

Results: A total of 2,391 subjects were randomized to LD-MTX and 2,395 to placebo. At baseline, mean age was 66 years, 19% were female, mean eGFR was 80.0 mL/min/1.73m^2, and 18% had stage 3 CKD or worse. Median follow-up duration was 23 months, and median LD-MTX dose was 16 mg/week. Those randomized to LD-MTX had less decline in eGFR over the entire follow-up compared to placebo (slope difference 1.12, 95%CI 0.59-1.65, p<0.001, Figure 1). Those with CKD stage 3 or worse on LD-MTX saw less eGFR decline than those with CKD stage 2 or better (slope difference among CKD stage 3 or worse: 2.46, 95%CI 1.10-3.82, p<0.001; p for interaction 0.02). The LD-MTX group had higher eGFR than placebo over the first 24 months of study follow-up (p<0.05 at each visit). On safety laboratory monitoring, there were 159 acute kidney injury AEs in the LD-MTX group and 187 in the placebo group (HR 0.83, 95%CI 0.67-1.02, Table 1). There were 37 clinical kidney AEs in the LD-MTX group and 42 in the placebo group (0.87, 95%CI 0.56-1.36). One subject began dialysis in the LD-MTX group compared to 3 in the placebo group.

Conclusion: These results demonstrate the kidney safety of LD-MTX among patients without advanced CKD at baseline. We observed a possible beneficial effect of LD-MTX on preserving kidney function, suggesting that inflammation may be involved in the pathogenesis of CKD in this population.

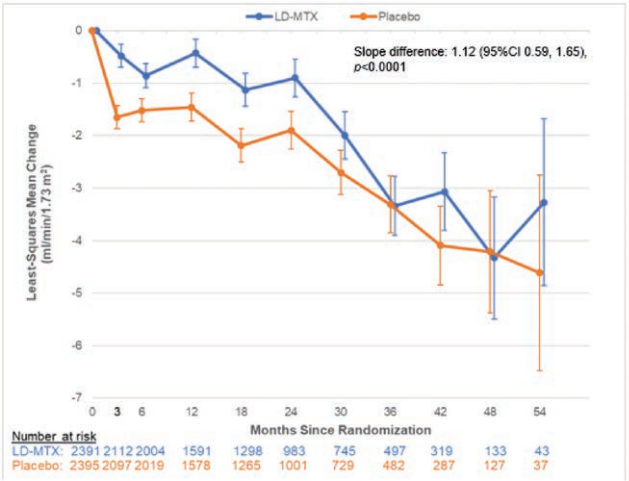

Figure. Least-squares mean change of estimated glomerular filtration rate (eGFR) from baseline to each follow-up visit according to random assignment of low-dose methotrexate (LD-MTX) or placebo in the Cardiovascular Inflammatory Reduction Trial (n=4,786). eGFR was calculated using the CKD-EPI equation. A slope difference significantly above 0 denotes less decline in eGFR for the LD-MTX group.

Background: The safety and efficacy of the oral Janus kinase inhibitor upadacitinib (UPA) has been evaluated across a spectrum of patients with rheumatoid arthritis (RA) in the phase 3 SELECT clinical program.[1–6]
Objectives: To describe the long-term integrated safety profile of UPA relative to active comparators (cutoff date: June 30, 2020) in patients with RA treated in the SELECT clinical program.
Methods: This analysis included updated data from 6 randomized controlled UPA RA trials.[1–6] Treatment-emergent adverse events (TEAEs; onset after first dose and ≤30 days after last dose of study drug or ≤70 days for adalimumab [ADA]) including AEs of special interest were summarized as follows: pooled UPA 15 mg once daily (QD; UPA15, 6 trials); pooled UPA 30 mg QD (UPA30, 4 trials); methotrexate (MTX, 1 trial), and ADA (1 trial). TEAEs were reported as exposure-adjusted adverse event rates (EAERs; events/100 patient-years [E/100 PY]), which included both incident and recurrent events.
Results: 4413 patients (UPA15, n=3209; UPA30, n=1204) received ≥1 dose of UPA, providing 10,115.4 PY of exposure. EAERs for AEs, serious AEs (SAEs), and AEs leading to discontinuation were similar for UPA15, MTX, and ADA; rates for UPA30 were numerically higher than UPA15 (Table 1). The most common AEs were upper respiratory tract infection, nasopharyngitis, and urinary tract infection for both UPA doses, and for UPA30 only, increased creatine phosphokinase (CPK). Pneumonia was the most common SAE for both UPA15 and UPA30. Serious infection rates were similar for UPA15, MTX, and ADA but higher for UPA30 (Figure 1). Rates of herpes zoster (HZ) were higher for both UPA groups (dose-dependent) vs MTX and ADA. Most HZ cases with UPA were non-serious (94%) and involved a single dermatome (74%). CPK elevations, which were mostly asymptomatic, were more common for both UPA groups (dose-dependent) vs MTX and ADA. EAERs of adjudicated gastrointestinal perforations were <0.1 and 0.2 E/100 PY for UPA15 and UPA30, respectively. Rates of non-melanoma skin cancer (due in part to more recurrent events with UPA30), anemia, and neutropenia were higher with UPA30 vs other treatment groups. Events of anemia and neutropenia were generally mild/moderate and treatment discontinuation due to these events was uncommon (<0.4%). Rates of other AEs of special interest, including major adverse cardiovascular and venous thromboembolic events, were broadly similar across treatment groups. The rate of deaths in UPA-treated patients with RA was not higher than expected for the general population (standardized mortality ratio [95% confidence interval (CI)]: UPA15, 0.43 [0.29, 0.63]; UPA30, 0.68 [0.40, 1.08]).
Conclusion: The updated safety profile of UPA with up to 4.5 years of exposure in patients with RA was comparable to previous analyses,[7] with no new safety signals reported. With the exception of HZ and elevated CPK, the safety profile of UPA15, the approved dose for RA, was similar to that observed for ADA.

POS0221 COMPARISON OF TOFACITINIB AND BARICITINIB BY INVERSE PROBABILITY OF TREATMENT WEIGHTING ANALYSES BASED ON PROPENSITY SCORE IN PATIENTS WITH RHEUMATOID ARTHRITIS IN REAL CLINICAL PRACTICE

Y. Miyazaki[1], S. Nakayamada[1], K. Nakano[1], S. Kubo[1], Y. Inoue[1], Y. Fujino[2], Y. Tanaka[1]. *[1]Hospital of University of Occupational and Environmental Health, The First Department of Internal Medicine, Kitakyushu, Japan*; *[2]Hospital of University of Occupational and Environmental Health, Department of Environmental Epidemiology, Institute of Industrial Ecological Sciences, Kitakyushu, Japan*

Background: Tofacitinib (TOFA) and baricitinib (BARI) have been widely used in many regions for treatment of rheumatoid arthritis (RA). The selection of JAK inhibitor for RA treatment based on patient type remains a major concern.
Objectives: The differences of efficacy between each Janus kinase (JAK) inhibitors have not been clarified in the patients with RA in clinical practice. Here, we compared the efficacy between TOFA and BARI in clinical practice.
Methods: A retrospective observational study. The efficacy of TOFA (n=156) in patients with RA was compared with BARI (n=138). Selection bias was reduced to a minimum using propensity score-based inverse probability of treatment weighting (IPTW). We analyzed the trajectories of changes in disease activity in patients receiving TOFA or BARI using growth mixture modeling (GMM). Multivariable logistic regression analysis was performed to identify factors contributing to belonging to treatment-resistance group defined by GMM. The observation period of the study was 24 weeks.
Results: No significant difference was observed in patient characteristics between the TOFA and BARI groups in after adjustment by propensity score-based IPTW. The retention rates over 24 weeks did not differ between the TOFA and BARI groups. No difference was observed in the incidence of adverse events in the TOFA and BARI groups. Clinical disease activity index (CDAI) at week 24 after the introduction of JAK inhibitors was 8.0 ± 8.9 and 6.2 ± 7.2 in the TOFA and BARI group, respectively. The rates of CDAI-remission at week 24 in the TOFA and BARI groups were 43/153 (28.3%) and 57/141 (40.4%), respectively. Compared to the TOFA group, the BARI group showed a significantly lower CDAI (⊿CDAI=-1.9, 95% confidence interval: -3.7 to -0.3, p=0.02) and a significantly higher rate of CDAI-remission (odds ratio: 1.7, 95% CI: 1.1–2.7, p=0.04) at week 24. Similarly, at week 24, SDAI was significantly lower in the BARI group (TOFA vs. BARI = 10.1 ± 9.9 vs. 7.3 ± 7.5, ⊿SDAI=-2.2, 95% CI: -4.2 to -0.2, p=0.04), and the rates of SDAI-remission (OR: 1.6, 95% CI: 1.0–2.6, p=0.04).
The patients were divided into two groups: patients with MDA to HDA at baseline (Group 1) and patients with HDA at baseline than Group 1 (Groups 2 and 3) based on the analysis of the trajectories of CDAI using GMM, In Groups 1 and 2, disease activity was improved immediately after the introduction of JAK inhibitors. In Group 3, disease activity was partially improved, and LDA was not achieved at week 24 after the introduction of JAK inhibitors. The patients in Group 3 were resistant to treatment (Group 3: treatment-resistance group).
When multivariable logistic regression analysis was performed for all patients receiving JAK inhibitors, the factors contributing to belonging to treatment-resistance group were: high baseline HAQ-DI score (OR: 1.76, 95% CI: 1.09–2.84, p=0.02) and high number of biological disease-modifying anti-rheumatic drugs (bDMARDs) used before JAK inhibitors (OR: 1.51, 95% CI: 1.16–1.95, p=0.002) and TOFA use (OR: 2.13, 95% CI: 1.05–4.30, p=0.03).
Next, multivariable logistic regression analysis was separately performed for each treatment group. The patients receiving more bDMARDs before the JAK inhibitor were more likely to belong to treatment-resistance group in the TOFA group (OR: 1.76, 95% CI: 1.24–4.06). Among patients with RA who received TOFA, those who had received ≥4 bDMARDs before the introduction of TOFA were more likely to be classified into the treatment-resistant group.
In the BARI group, multivariable logistic regression analysis did not identify any factors associated with belonging to treatment-resistance group.
Conclusion: TOFA may be partially effective in patients resistant to many bDMARDs. Consequently, efficacy may differ between TOFA and BARI. Because TOFA was less effective in RA patients resistant to ≥4 bDMARDs, the present study suggests that BARI may be more appropriate for RA patients resistant to many bDMARDs.

POS0222 PREDICTORS OF RESPONSE: BASELINE CHARACTERISTICS AND EARLY TREATMENT RESPONSES ASSOCIATED WITH ACHIEVEMENT OF REMISSION AND LOW DISEASE ACTIVITY AMONG UPADACITINIB-TREATED PATIENTS WITH RHEUMATOID ARTHRITIS

A. Kavanaugh[1], Z. Szekanecz[2], E. C. Keystone[3], A. Rubbert-Roth[4], S. Hall[5], R. Xavier[6], J. Polido-Pereira[7], I. H. Song[8], N. Martin[9], Y. Song[8], S. Anyanwu[8], P. Nash[10]. *[1]University of California San Diego, Division of Rheumatology, Allergy and Immunology, Department of Medicine, San Diego, California, United States of America*; *[2]University of Debrecen, Division of Rheumatology, Faculty of Medicine, Debrecen, Hungary*; *[3]MaRS Center, Rheumatology, Toronto, Ontario, Canada*; *[4]Kantonsspital St. Gallen, Rheumatology, St. Gallen, Switzerland*; *[5]Emeritus Research and Monash University, Rheumatology, Melbourne, Victoria, Australia*; *[6]Hospital de Clínicas de Porto Alegre, Serviço de Reumatologia, Porto Alegre, Brazil*; *[7]Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte and Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon Academic Medical Centre, Lisbon, Portugal*; *[8]AbbVie Inc., Immunology, North Chicago, Illinois, United States of America*; *[9]AbbVie Inc., Immunology, Saint Laurent, Quebec, Canada*; *[10]University of Queensland, Rheumatology, Brisbane, Queensland, Australia*

Background: Upadacitinib (UPA) 15 mg once daily (QD) has demonstrated efficacy in phase 3 studies of patients with rheumatoid arthritis (RA).1–4 Early prediction of response to treatment with UPA could help to optimize therapy.
Objectives: To identify baseline (BL) characteristics or Week (Wk) 12 disease activity measures that may predict the achievement of remission (REM) or low disease activity (LDA) at 6 months in patients with RA receiving UPA 15 mg.
Methods: This ad hoc analysis included patients who were randomized to UPA 15 mg QD, as monotherapy in methotrexate (MTX)-naïve patients (SELECT-EARLY) or in combination with conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs), in patients with an inadequate response (IR) to MTX (SELECT-COMPARE) or ≥1 tumor necrosis factor inhibitors (TNFis) (SELECT-BEYOND and SELECT-CHOICE). The association of BL characteristics (including age, disease duration, prior/concomitant treatments, C-reactive protein [CRP], seropositivity, and disease activity) and Wk 12 disease activity parameters with the achievement of Clinical Disease Activity Index (CDAI) REM (≤2.8) or LDA (≤10) at Wk 24 (or Wk 26 in SELECT-COMPARE) was assessed by concordance statistics (C-statistics), or area under the

receiver operator characteristic curve. C-index values and 95% confidence intervals were calculated by fitting a univariate logistic regression model for: demographic and BL characteristics, Wk 12 disease activity measures, and change from BL at Wk 12 in disease activity measures. A multivariate logistic regression with stepwise model selection was also performed. The proportion of patients achieving Wk 24/26 CDAI REM/LDA was stratified by ≥50% improvement from BL in swollen and/or tender joint count in 66/68 joints (SJC66/TJC68).

Results: A total of 1377 patients were included in the analysis. Across the 4 studies, CDAI REM and LDA were achieved in 11.0–28.4% and 50.0–58.6% of patients, respectively (Table 1). BL demographics and disease characteristics were weakly predictive (C-index <0.70) of Wk 24/26 CDAI REM (C-index 0.49–0.69) or LDA (C-index 0.47–0.65), with the exception of BL Health Assessment Questionnaire-Disability Index in SELECT-BEYOND, which was moderately predictive of CDAI REM (C-index 0.73). Changes from BL in disease activity measures at Wk 12 were weakly or moderately predictive of Wk 24/26 CDAI REM (Figure 1) or LDA. CDAI value at Wk 12 was strongly predictive (C-index >0.80) of Wk 24/26 CDAI REM or LDA. Disease Activity Score in 28 joints using CRP and pain at Wk 12 were strongly predictive of Wk 24/26 CDAI REM (except in SELECT-CHOICE). Physician's global assessment at Wk 12 was the only common predictor in the multivariate regression models for CDAI REM/LDA at Wk 24/26 across the 4 studies. A greater proportion of patients achieving ≥50% improvement in SJC66 and TJC68 at Wk 12 achieved CDAI REM (16.5–37.8% vs 0–9.4%) or LDA (66.0–72.8% vs 20.9–35.7%) at Wk 24/26 than those who did not.

Conclusion: BL characteristics did not strongly predict response to UPA, but composite disease activity scores at Wk 12 predicted Wk 24/26 REM/LDA with UPA 15 mg QD across MTX-naïve, MTX-IR, and TNFi-IR patients. ≥50% improvement in SJC/TJC at Wk 12 was also associated with Wk 24/26 REM/LDA.

POS0223 PATTERNS OF JANUS KINASE INHIBITOR CYCLING FOR THE MANAGEMENT OF RHEUMATOID ARTHRITIS IN REAL-WORLD CLINICAL PRACTICE: AN ANALYSIS OF THE OPAL DATASET

S. Ciciriello[1,2], T. Smith[1], C. Osullivan[1], K. Tymms[1,3], P. Youssef[1,4], D. Mathers[1,5], C. Deakin[1], H. Griffiths[1,6], G. Littlejohn[1,7]. [1]*OPAL Rheumatology, Ltd., Sydney, Australia*; [2]*Dept. Rheumatology, Royal Melbourne Hospital, Melbourne, Australia*; [3]*Canberra Rheumatology, Canberra, Australia*; [4]*Dept. Rheumatology, Royal Prince Alfred Hospital, Camperdown, Australia*; [5]*Georgetown Arthritis, Georgetown, Australia*; [6]*Barwon Rheumatology, Services, Geelong, Australia*; [7]*Dept. of Medicine, Monash University, Clayton, Australia*

Background: There are currently eleven biologic and targeted synthetic (b/ts) DMARDs acting via five different modes of action available for the treatment of RA in Australia. The cost of b/tsDMARDs is subsidized by government for patients that have active RA despite six months of combination csDMARD therapy. Once a patient is eligible, the clinician can prescribe the b/tsDMARD they deem to be the most clinically appropriate for the patient. In Oct 2015 the first JAK inhibitor (JAKi) became available in Australia (tofacitinib, TOF), baricitinib (BARI) became available in Sept 2018, and upadacitinib (UPA) in May 2020. Each of these oral tsDMARDs possess different selectivity profiles towards different members of the JAK family (JAK1–3 and Tyk2).

Objectives: The aim of this analysis was to determine the patterns of JAKi cycling in real-world practice in Australia.

Methods: Deidentified clinical data were sourced from the OPAL dataset, which is collected in a custom-built electronic medical record during the routine consultation[1]. Data from patients >18 years with RA who commenced a b/tsDMARD between Jan-2007 and Dec-2020 were included in the analysis. A visual analytics software program was used to display data on medication initiation and cessation dates, and reasons for stopping tsDMARDs, which is recorded in the medical record at the time of the decision.

Results: At Dec 2020, 28% of the 52,190 patients with RA in the OPAL dataset were prescribed b/tsDMARDs. Of these patients, 3,850 (26.3%) were currently prescribed a JAKi with 51.4% receiving TOF, 29.2% BARI and 19.4% UPA. In 2020, JAKi initiations accounted for 48.8% of all initiations and 30.7% of 1st line initiations; an increase of 6.1% and 3.5% from 2019, respectively. The percentage of patients switching from a first line JAKi to a second line JAKi rather than an agent with another mode of action increased from 33.1% in 2019 to 42.6% in 2020. This is despite 26.2% in 2019 and 45.8% in 2020 of the patients switching to another JAKi citing lack of efficacy as the reason for JAKi discontinuation. In the period between May 2020, when a third JAKi (UPA) become available, and Dec 2020, the majority of patients switching from first line TOF or BARI to another JAKI switched to UPA (69.4% and 83.9%, respectively), whilst 30.6% of first line TOF patients switched to BARI (30.6%), and 16.1% of first line BARI patients switched to TOF in second line. The majority of patients switching from second line TOF or BARI to a third line JAKi switched to UPA (73% and 96%, respectively), with 27% of second line TOF patients switching to BARI and a very low number moving from second line BARI to TOF (4%). JAKi choice after a third line TOF or BARI was almost exclusively UPA (86.2% and 95.5%, respectively).

Conclusion: There has been significant and sustained uptake of JAKi for the management of RA in Australia and JAKi cycling is increasingly common in routine clinical care. Clinical outcomes and persistence following JAKi cycling requires further investigation.

POS0224 SELECTIVITY OF CLINICAL JAK INHIBITORS AND THE IMPACT ON NATURAL KILLER (NK) CELL FUNCTIONAL RESPONSES

P. Gonzalez-Traves[1], L. Simpson[1], B. Murray[2], A. Meng[3], J. A. Di Paolo[4], E. Grant[1], G. Min-Oo[1]. *[1]Gilead Sciences, Inflammation Biology, Foster City, United States of America*; *[2]Gilead Sciences, Drug Metabolism, Foster City, United States of America*; *[3]Gilead Sciences, Clinical Pharmacology, Foster City, United States of America*; *[4]Gilead Sciences, External Innovation, Foster City, United States of America*

Background: Janus kinase (JAK) inhibitors (JAKinibs) show similar efficacy in rheumatoid arthritis (RA). However, in vitro studies have shown differences in JAK selectivity profiles for baricitinib (BARI), tofacitinib (TOFA), upadacitinib (UPA) and filgotinib (FIL).[1,2] These lead to distinct pharmacologic profiles in cellular signaling assays that may impact clinical efficacy or safety[1]. NK cells are innate lymphocytes important in anti-pathogen responses and immune surveillance, which function via production of cytokines and cell killing[3]. NK cell proliferation and IFNγ production are JAK-dependent pathways and may be modulated by JAKinibs. Clinical findings show transient decreases in NK cell numbers in patients treated with JAKinibs, but the link to safety is unclear[4]
Objectives: To extend upon findings in proximal cell signaling assays, we compared the selectivity and potency of clinical JAKinibs on NK cell function by assessing proliferation mediated by IL-15 (JAK1/3) and IFN-γ production driven by IL-12 (JAK2/TYK2)+IL-18.
Methods: NK cells were isolated from healthy donor PBMC, incubated in vitro with 8 concentrations of each evaluated JAKinib (TOFA, BARI, FIL, FIL metabolite, UPA) and stimulated with IL-15 for proliferation or IL-12/18 for IFNγ production. Proliferation was assessed by Cell Trace dye dilution after 6 days and IFNγ production by intracellular flow cytometry 4hrs post-stimulation. Half maximal inhibitory concentration (IC_{50}) values were calculated for $CD56^{bright}$, $CD56^{dim}$, and total NK cells. Steady-state pharmacologic profile over a clinical dosing interval was modeled using concentration-time profiles from JAKinib population pharmacokinetic data in RA subjects under the therapeutic dose[5-7]. For each JAKinib, the time above IC_{50} and average daily inhibition of IFNγ or proliferation were calculated for each NK cell population in each donor.
Results: Cellular assays in purified NK cells showed dose-dependent inhibition of IL-15-induced proliferation by all JAKinibs with TOFA showing the highest average inhibition and time above IC_{50} (35-60% inhibition for 8-15 hrs; TOFA>UPA>BARI≈FIL). The differences between JAKinibs are in line with differences in pSTAT inhibition downstream of IL-15[1]. Interestingly, IL-12/18-induced production of IFNγ, which is mediated via JAK2/TYK2 (IL-12) and non-JAK dependent pathways (IL-18), showed weaker inhibition for all compounds. Moreover, all JAKinibs showed <25% average inhibition of IFNγ production over 24hrs and did not show any time above IC_{50} for IFNγ production or pSTAT4 inhibition at clinical doses. $CD56^{dim}$ and $CD56^{bright}$ sub-populations of NK cells are proposed to have distinct functions and unique expression of surface receptors. Analysis of the IC_{50} for pSTAT4 and IFNγ production showed ~2-10-fold weaker inhibition by JAKinibs in $CD56^{bright}$ NK cells, suggesting less dependence on JAK-dependent signals in $CD56^{bright}$ NK cells than $CD56^{dim}$ NK cells.
Conclusion: NK cell proliferation depends on JAK1 and JAK3-mediated signaling and is differentially inhibited at clinical doses of distinct JAKinibs. In contrast, functional responses downstream of JAK2/TYK2-dependent IL-12/18 were not substantially inhibited by any of the JAKinibs studied. Inhibition of functional and proliferative responses in purified NK cells aligned well with proximal pSTAT inhibition. JAKinib modulation of NK cell proliferation, but not response to IL-12, reflects unique pharmacologic profiles of the drugs studied and could be one component underlying clinical safety observations, including increased risk of viral infections or malignancy[4].

POS0225 RISK OF MAJOR CARDIOVASCULAR EVENT ACROSS JAK INHIBITOR TREATED PATIENTS: ANALYSIS OF A NATIONAL CLAIM DATABASE

A. Gouverneur[1,2], J. Avouac[3], C. Prati[4], J. L. Cracowski[5], T. Schaeverbeke[6], A. Pariente[1,2], M. E. Truchetet[6]. *[1]University of Bordeaux, Inserm, Bordeaux Population Health Research Center, Pharmacoepidemiology Team, UMR 1219, Bordeaux, France*; *[2]CHU of Bordeaux, Pôle de Santé Publique, Service de Pharmacologie, Bordeaux, France*; *[3]Université de Paris, Service de Rhumatologie, Hôpital Cochin, AP-HP.CUP, Paris, France*; *[4]University Hospital - CHU Minjoz, Rheumatology Unit, Besancon, France*; *[5]Université Grenoble Alpes, INSERM, HP2, Grenoble, France*; *[6]CHU de Bordeaux, Hôpital Pellegrin, Department of Rheumatology, National Reference Center for Systemic Autoimmune Rare Diseases, Bordeaux, France*

Background: Inhibiting a specific JAK may impede more than one pathway, explaining both the efficacy and adverse effects observed with JAK inhibitors (JAKi). Among those, there have been recent concerns about potential thromboembolic risks with these drugs. As patients enrolled are not representative of all patients who may receive JAKi, data from trials are unlikely to provide definitive answers. Real impact of JAKi in real life on major cardiovascular events is not known.
Objectives: To evaluate the risk of venous and arterial thromboembolic events with the use of JAKi in a real-world setting.
Methods: A self-controlled case series analysis (method in which individuals act as their own control) was performed using data from the French national healthcare insurance system SNDS ("Système National des Données de Santé"), which included all anonymized individual level data about sociodemographic data, outpatient healthcare dispensed, hospital discharge summaries, and registration status for a list of 30 long term diseases. All patients treated by JAKi (baricitinib or tofacitinib) for rheumatoid arthritis, psoriasis arthritis and/or inflammatory bowel disease, and with at least one thromboembolic event (venous (VTE): deep vein thrombosis (DVT), pulmonary embolism (PE), arterial (ATE): acute coronary syndrome (ACS), myocardial infarction (MI), transient ischemic attack (TIA) and stroke) between 2017/11/01 and 2019/06/30 were included in the study. Associations were evaluated by incidence rate ratios (IRR), which compare the rate of events during exposed periods with rate of event during all other observed time periods. Exposed periods were defined as i) exposure to JAKi, ii) the month following exposure (post-exposure 1-30 days), and iii) long-term post-exposure (31 to 60 days). A pre-exposure period of 7 days was individualized to identify event-dependent probabilities of exposure and potential reverse causality bias, and all other periods were considered as non-exposed periods.
Results: Among the 5,870 patients treated with JAKi between 2017/11/01 and 2019/06/30, 94 presented an incident thromboembolic event and were included. Almost two thirds were female (n=61, 64.9%), and median age was 65.4 [IQR: 55.5; 75.8] years. Most of patients have a rheumatoid arthritis (n=91, 96.8%), 62 (66.0%) were treated by baricitinib, and 32 (34.0%) by tofacitinib. Almost half (n=42, 44.7%) presented a venous thromboembolism, mainly DVT (n=31, 33.0%), and 52 (55.3%) presented an arterial thromboembolism, mainly MI (n=16, 17.0%) and stroke (n=14, 14.9%). Eleven patients (11.7%) died during the study period. The median time of occurrence of VTE was 4.3 [IQR: 2.5; 8.9] months, and 6.1 [IQR: 3.3; 9.2] months for ATE.

The median duration of exposure was 6.0 [IQR: 3.3; 10.1] months for VTE, and 12.0 [IQR: 4.8; 15.3] months for ATE. The IRR for VTE and ATE were increased during exposure, and during the 30 days following exposure (Table 1). The IRR for VTE was only increased during exposure and in the early post-exposure phase contrary to the IRR for ATE that was also increased in the pre-exposure 7-Day period. Analysis conducted on survival patients confirmed results.

Conclusion: The present study found an increased risk of VTE and ATE for baricitinib and tofacitinib. The risk persists in the month following the discontinuation of treatment but disappears after day 30 post-exposure.

BIMEKIZUMAB LONG-TERM SAFETY AND EFFICACY IN PATIENTS WITH ANKYLOSING SPONDYLITIS: 3-YEAR RESULTS FROM A PHASE 2B STUDY

D. Van der Heijde[1], A. Deodhar[2], L. S. Gensler[3], D. Poddubnyy[4], A. Kivitz[5], M. Dougados[6], N. De Peyrecave[7], M. Oortgiesen[8], T. Vaux[9], C. Fleurinck[7], X. Baraliakos[10]. *[1]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*; *[2]Oregon Health & Science University, Division of Arthritis and Rheumatic Diseases, Portland, United States of America*; *[3]University of California San Francisco, Department of Rheumatology, San Francisco, United States of America*; *[4]Charité – Universitätsmedizin Berlin, Department of Rheumatology, Berlin, Germany*; *[5]Altoona Center for Clinical Research, Altoona Arthritis & Osteoporosis Center, Duncansville, United States of America*; *[6]Hôpital Cochin, Department of Rheumatology, Paris, France*; *[7]UCB Pharma, N/A, Brussels, Belgium*; *[8]UCB Pharma, N/A, Raleigh, United States of America*; *[9]UCB Pharma, N/A, Slough, United Kingdom*; *[10]Ruhr-University Bochum, Rheumazentrum Ruhrgebiet Herne, Herne, Germany*

Background: Bimekizumab (BKZ), a monoclonal antibody that selectively inhibits interleukin (IL)-17A and IL-17F, has demonstrated clinical efficacy and safety in patients with ankylosing spondylitis (AS) treated over a period up to 96 weeks.[1,2]

Objectives: To report 3-year interim safety and efficacy of BKZ in patients with active AS from a phase 2b dose-ranging study (BE AGILE; NCT02963506) and its ongoing open-label extension (OLE; NCT03355573).

Methods: BE AGILE study design has been described previously.[1] Patients treated with BKZ 160 mg or 320 mg every 4 weeks (Q4W) at Week 48 in BE AGILE were eligible for OLE entry. All OLE patients received BKZ 160 mg Q4W. Treatment-emergent adverse events (TEAEs) are reported for the BE AGILE safety set (patients who received ≥1 dose of BKZ on study entry) for total exposure to BKZ across BE AGILE and the OLE. Efficacy outcomes are reported for the OLE full analysis set (patients who entered the OLE and had ≥1 dose of BKZ and ≥1 valid efficacy variable measurement in the OLE), and include: ASAS40, ASAS20, ASAS PR, ASDAS, ASDAS-CII, ASDAS-MI, ASDAS-ID (<1.3) and ASDAS <2.1. Data are reported as imputed (multiple imputation [MI] based on the missing at random assumption, or non-responder imputation [NRI]) and as observed case (OC).

Results: 262/303 (86%) patients randomised at BE AGILE study baseline completed Week 48 on BKZ 160 mg or 320 mg. At Week 48, 255/262 (97%) patients entered the OLE (full analysis set: 254); 219 patients had an efficacy assessment at Week 156. Over the 156 weeks, the exposure-adjusted incidence rate (EAIR) per 100 patient-years (PY) of TEAEs was 143.5, with an EAIR of 5.8 for serious TEAEs, 1.3 for serious infections, and 3.8 for *Candida* infections (Table 1). All *Candida* infections were mild or moderate; none were systemic or led to study discontinuation. Over 156 weeks, the EAIR of inflammatory bowel disease (1.2), anterior uveitis (0.8), and injection site reactions (0.5) remained low. Efficacy demonstrated at Week 48 in BE AGILE was maintained or improved up to Week 156 (Figure 1). Mean ASDAS improved from 3.9 at BE AGILE baseline to 2.0 and 1.8 at Weeks 48 and 156 respectively (by MI). At Week 156 in the NRI analyses, ASAS40 and ASAS PR were achieved by 62.6% (OC: 72.6%) and 32.7% (OC: 37.9%) patients respectively. ASDAS-ID and ASDAS <2.1 responder rates (NRI) were maintained or continued to increase from Week 48, and by Week 156, responses were achieved by 28.0% (OC: 33.0%) and 57.1% (OC: 67.4%) patients respectively. ASDAS-MI responder rates (NRI) continued to increase from 44.9% at Week 48 to 46.5% at Week 156 (OC: 52.9%).

Conclusion: The safety profile of BKZ in patients with AS was in line with previous observations.[1,2] Patients treated with BKZ demonstrated sustained and consistent efficacy over 156 weeks.

Table 1. Safety for total exposure to BKZ across BE AGILE and the OLE

	BE AGILE Weeks 0–48			BE AGILE + OLE Weeks 0–156
n (%) [EAIR/100 PY]	BKZ 160 mg (n=149; 114.2 PY)	BKZ 320 mg (n=150; 119.6 PY)	All BKZ (N=303; 261.3 PY)	All BKZ (N=303; 781.0 PY)
Any TEAE	103 (69.1) [168.7]	122 (81.3) [221.1]	235 (77.6) [186.2]	280 (92.4) [143.5]
Serious TEAEs	5 (3.4) [4.4]	6 (4.0) [5.1]	13 (4.3) [5.1]	43 (14.2) [5.8]
Key TEAEs of special monitoring				
Serious infections	3 (2.0) [2.7]	1 (0.7) [0.8]	4 (1.3) [1.5]	10 (3.3) [1.3]
Candida infections	10 (6.7) [9.1]	9 (6.0) [7.9]	19 (6.3) [7.5]	28 (9.2) [3.8]
Inflammatory bowel disease	1 (0.7) [0.9]	2 (1.3) [1.7]	4 (1.3) [1.5]	9 (3.0) [1.2]
Anterior uveitis	1 (0.7) [0.9]	1 (0.7) [0.8]	2 (0.7) [0.8]	6 (2.0) [0.8]
Study discontinuations due to TEAEs	7 (4.7)	10 (6.7)	20 (6.6)	38 (12.5)
Drug-related TEAEs	48 (32.2)	54 (36.0)	110 (36.3)	149 (49.2)
Deaths	1 (0.7)	0	1 (0.3)	2 (0.7)

TEAEs are reported for the BE AGILE safety set for total exposure to BKZ across BE AGILE and the OLE. There was one death in BE AGILE (cardiac arrest) and one in the OLE (road traffic accident); neither was considered treatment-related.

POS0227 SHOULD ALL PATIENTS TRIAL SUBCUTANEOUS METHOTREXATE PRIOR TO COMMENCING BIOLOGIC THERAPY – A REAL WORLD STUDY

A. Mirza[1], M. K. Nisar[1]. [1]*Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom*

Background: Methotrexate (MTX) is the bed rock of inflammatory arthritis management. However intolerance is a major limiting factor for drug optimisation and retention. There is data to suggest that subcutaneous (SC) MTX is tolerated better and is now being recommended in several guidelines including ACR's. It is less clear though whether this strategy is effective in those where oral preparation is inefficacious and its potential to avoid escalation to biologic therapy.

Objectives: Our aim was to analyse the reasons for switching to SC formulation in a real world setting, clinical outcomes achieved and proportion requiring biologic prescription.

Methods: We undertook a retrospective survey of all patients prescribed SC MTX in a large university teaching hospital between 1983 and Apr 2019. We had access to full patient records including details on co-morbidities, drugs and disease management. We analysed demographics, reasons for SC MTX initiation, clinical outcomes and impact on biologic prescription.

Results: 352 patients were identified during the study period. The mean age of the cohort was 54 yrs (3-87). 192 (70%) were women. 260 (74%) were Caucasian, 64 (18%) Asian, 21 (6%) Afro-Caribbean and remaining of other ethnicity. Two most common diagnoses were RA [n=243 (69%)] and pSpA [n=66 (18%)]. Average disease duration was 74 months (11-324) with mean of three comorbidities (0-11).

284 (80%) had switched from oral to SC MTX. 137 (49%) stopped oral MTX due to side effects. Mean duration of oral MTX prior to switching was 26 months (0.25-167). Follow up period for SC MTX ranged from two to 132 months (mean 29) until the data cut-off date of Apr 2019. 103 (29%) patients progressed to biologic therapy.

Amongst RA patients, DAS28 improved from mean 4.16 (0.63-8.06) to 2.83 (0.14-7.32) following the switch. pSpA cohort's mean TJC and SJC improved from mean seven (0-42) and two (0-26) to two (0-25) and one (0-6) respectively.

Conclusion: Our study confirms that SC MTX is an effective solution irrespective of whether oral MTX is inefficacious or intolerable. This applies to people with both RA and pSpA. In accordance with prior published data, our findings support the utility of SC MTX for those intolerant of enteral option. Additionally, it shows that even in instances where oral MTX was ineffective, a switch to SC formulation achieved low disease activity despite multi-morbidity, long disease course and protracted oral MTX exposure. This intervention also prevented over two-thirds of patients progressing to biologic therapy with significant financial savings. SC MTX therefore remains a durable strategy with excellent disease outcomes and confers substantial economic benefits to healthcare.

POS0228 BASELINE CHARACTERISTICS AND TREATMENT RESPONSE TO IXEKIZUMAB CATEGORISED BY SEX IN RADIOGRAPHIC AND NON-RADIOGRAPHIC AXIAL SPONDYLARTHRITIS PATIENTS THROUGH 52 WEEKS: DATA FROM 3 PHASE III, RANDOMIZED, CONTROLLED TRIALS

I. Van der Horst-Bruinsma[1], R. Bolce[2], T. Hunter[2], D. Sandoval[2], D. Zhu[2], V. J. Geneus[2], J. Lisse[2], S. Liu Leage[2], M. Magrey[3]. [1]*Amsterdam UMC, locatie VUmc, Department of Rheumatology, Amsterdam, Netherlands*; [2]*Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America*; [3]*MetroHealth, Rhematology Department, Cleveland, United States of America*

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease of the axial skeleton comprising two subtypes within the same spectrum: radiographic (r-axSpA) and non-radiographic (nr-axSpA). Previous studies have shown that clinical presentation and treatment response of males and females may differ[1] despite similar disease burden.[2] Ixekizumab (IXE), a high-affinity monoclonal antibody that selectively targets interleukin-17A, has demonstrated superior efficacy to placebo in the treatment of patients with r-axSpA (COAST-V/W [bDMARD- naïve/TNFi-experienced]) and nr-axSpA (COAST-X [bDMARD-naïve]).[3]

Objectives: Assess baseline characteristics and treatment response to IXE categorised by sex in patients with r-axSpA and nr-axSpA for up to 52 weeks.

Methods: Patients fulfilled the ASAS classification criteria for r-axSpA or nr-axSpA. Patients were randomized to receive 80 mg subcutaneous IXE every 2 weeks (Q2W) or 4 weeks (Q4W), or to placebo (PBO) [16 weeks COAST-V/W; 52 weeks COAST-X]. Baseline characteristics and treatment outcomes were assessed. Patients were categorised by sex, missing data was controlled for using non-responder imputation (NRI) and modified baseline observation carried forward (mBOCF) analysis was conducted on continuous efficacy variables.

Results: At baseline, females were older, with significantly higher pain and fatigue scores and peripheral joint symptoms (table 1). ASAS40 response rate with IXEQ4W was achieved in 39% of males with r-axSpA by week 16, and 44% by week 52. Females achieved 16.7% at week 16, and 33.3% at week 52. In nr-axSpA, 46% of IXEQ4W males achieved ASAS40 at week 16 and 30% at week 52. 23.9% of females achieved ASAS40 at week 16, increasing to 30.4% at week 52.

Conclusion: This analysis demonstrates that for the axSpA disease spectrum, females present with higher disease burden as reflected by higher scores in fatigue/tiredness, and spinal pain at night. Our findings indicate that males and females respond to IXE; however, females experience this benefit later in their treatment course, with a more prolonged attainment of peak response.

POS0229

DISEASE ACTIVITY AND INFLAMMATION FOLLOWING WITHDRAWAL OF CERTOLIZUMAB PEGOL TREATMENT IN AXIAL SPONDYLOARTHRITIS PATIENTS WHO DID NOT EXPERIENCE FLARES DURING THE C-OPTIMISE STUDY

L. S. Gensler[1], X. Baraliakos[2], L. Bauer[3], B. Hoepken[3], T. Kumke[3], M. Kim[4], R. B. M. Landewé[5,6]. [1]*University of California San Francisco, Department of Rheumatology, San Francisco, United States of America*; [2]*Ruhr-University Bochum, Rheumazentrum Ruhrgebiet Herne, Herne, Germany*; [3]*UCB Pharma, N/A, Monheim am Rhein, Germany*; [4]*UCB Pharma, N/A, Smyrna, United States of America*; [5]*Amsterdam University Medical Center, Department of Rheumatology & Clinical Immunology, Amsterdam, Netherlands*; [6]*Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands*

Background: C-OPTIMISE was a phase 3b clinical trial investigating certolizumab pegol (CZP) maintenance dose continuation, reduction or withdrawal following achievement of sustained remission in patients with axial spondyloarthritis (axSpA). During the C-OPTIMISE maintenance period, the majority of patients randomised to CZP, either the full or reduced maintenance dose, did not experience disease flares. Conversely, in those who had CZP withdrawn, only a minority of patients remained flare-free.[1]
Objectives: This post-hoc analysis evaluates disease activity and clinical markers of inflammation in patients who did not experience a disease flare following randomisation to CZP full maintenance dose, CZP reduced maintenance dose or placebo (PBO) during the maintenance period (Weeks 48–96) of C-OPTIMISE.
Methods: C-OPTIMISE (NCT02505542) was a multicentre, double-blind, parallel-group, randomised phase 3b study with a 48-week open-label run-in period.[1] Adult patients with early (<5 years' symptom duration) active axSpA received open-label CZP 200 mg every 2 weeks (Q2W) for the first 48 weeks; from Week 48, patients who achieved sustained remission (Ankylosing Spondylitis Disease Activity Score [ASDAS] <1.3 at Week 32 or 36 and Week 48) were randomised 1:1:1 to double-blind CZP 200 mg Q2W (full maintenance dose), CZP 200 mg Q4W (reduced maintenance dose) or PBO for a further 48 weeks (maintenance period). A flare was defined as ASDAS ≥2.1 at two consecutive visits or ASDAS >3.5 at any visit. We report ASDAS, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and C-reactive protein (CRP) and fecal calprotectin levels during Weeks 48–96 in CZP- and PBO-randomised patients who did not experience a flare (i.e. completed Week 96 on randomised treatment). Missing data were imputed using last observation carried forward.
Results: Of 313 patients entering the maintenance period at Week 48, 197 (62.9%) completed Week 96 on randomised treatment without experiencing a flare; of these, 89 (85.6%) and 84 (80.0%) patients were in the CZP 200 mg Q2W and CZP 200 mg Q4W arm, respectively, with only 24 (23.1%) patients randomised to PBO not experiencing a flare. Baseline characteristics of these patients are shown in the Table 1. During Weeks 48–96, disease activity (ASDAS, BASDAI) and CRP levels were comparable between the CZP full and reduced maintenance dose group, and lower in both CZP arms than in PBO (Figure 1 A–C). From Week 60 up to Week 96, PBO patients who did not flare had consistently higher mean ASDAS, BASDAI and CRP levels compared with CZP-randomised patients (Figure 1 A–C). Similarly, there was a greater increase in fecal calprotectin levels between Weeks 48 and 96 in the PBO arm compared with both CZP arms (Figure 1 D).
Conclusion: Despite not meeting the threshold for a flare, consistently higher disease activity and increases in serologic and inflammatory biomarkers were observed in PBO-randomised patients who did not experience a flare during the C-OPTIMISE study compared to those who remained on CZP. These findings confirm that patients with axSpA who achieve sustained remission benefit from continued CZP treatment, either with the full or reduced maintenance dose, over treatment withdrawal.

Background: the close relationship between joints and gut inflammation has long been known and several data suggest that the dysbiosis could represents the link between Spondyloarthritis (SpA) and Inflammatory Bowel Diseases (IBD). To date, the manipulation of the intestinal microbiota is considered the key to the cure or control of the natural history of several pathologies sustained or favored by dysbiosis. The introduction of biologic drugs, in particular Tumor Necrosis Factor inhibitors (TNFi), revolutionized the management of both these diseases, thanks to the strong inhibition of inflammation and partially indirectly with mechanisms not yet fully clarified. While the impact of conventional drugs on gut microbiota is well known poor data are available about TNFi.
Objectives: to investigate the impact of TNFi on gut microbiota.
Methods: we included CD or UC patients fulfilling criteria for axial or peripheral SpA (ASAS 2009) on a typical Mediterranean diet, naïve to biologics needing TNFi. Clinical history, physical examination, instrumental examinations, biochemical examination including C-reactive protein (CRP), erhytrocyte sedimentation rate (ESR), HLA-B27 and fecal calprotectin at the baseline and after 6 months were performed. TNFi included infliximab and adalimumab. Fecal samples were collected by patients themselves by 24 hours before the start of the therapy. The processing was performed through metagenomic NGS (next generation sequencing) including the amplification of the V3 and V4 regions of the 16S (V3 and V4) and sequencing on the Illumina MiSeq platform. All patients received the treatment at least until week 24. Clinical disease indices included Visual Analogue Scale (VAS)-pain and Visual Analgue Scale(VAS)-disease activity for all patients, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) for axial involvement, clinical disease activity index (CDAI) and Health Assessment Questionnaire-Disability Index (HAQ-DI) for peripheral involvement, Harvey-Bradshaw Index for CD (HBI), or partial Mayo (pMAYO) score for UC, were assessed at baseline and at the end of the study. The study was approved by the ethics committee (approval code 0056924).
Results: we evaluated 20 patients affected by enteropatic arthritis, naïve for biologic drugs, treated with TNFi. After six months of therapy we observed a significant increase in Lachnospiracae family (Δ +10.3, p 0.04) and in Coprococcus genus (Δ +2.8, p 0.003). We also observed a decrease trend in Proteobacteria (Δ -8.0 p 0.095) and Gammaproteobacteria (Δ -9, p 0.093) and an increase trend in Clostridia (Δ +8.2 p 0.083). We didn't find differences between TNFi responders (SpA improvement or IBD remission achieved) and not responders in terms of alpha and beta-diversity.
Conclusion: the decrease of Proteobacteria and the increase of Lachnospiraceae and Coprococcus is consistent with the hypothesis that TNFi therapy, by decreasing inflammation, tends to restore the intestinal eubiosis. However further studies on larger cohort incuding the evaluation of gut virota and micobiota will be necessary to definitively clarify the effects of TNFi on the composition and function of the gut microbiota.

POS0231 IMPACT OF GENDER AND COMORBIDITIES IN ENTEROPHATIC SPONDYLOARTHRITIS: A CROSS-SECTIONAL STUDY

A. D'antonio[1], M. S. Chimenti[1], P. Conigliaro[1], P. Triggianese[1], S. Ferrigno[1], M. Ferraioli[1], B. Neri[2], L. Biancone[2], R. Perricone[1]. [1]*University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Rome, Italy*; [2]*University of Rome Tor Vergata, GI Unit, Rome, Italy*

Background: Enteropathic Spondyloarthritis (ESpA) belongs to the group of Spondyloarthritis (SpA) typically associated with inflammatory bowel disease (IBD). SpA are divided into axial (ax) or peripheral disease. Ax-SpA are classified as

ankylosing spondylitis (AS) and non-radiographic (nr-) axSpA based on the presence or absence of definite structural changes in conventional radiographs (CR).
Objectives: Aim of this study was to determine whether comorbidities and gender could lead to a different response rate to TNF-inhibitors (TNFi) in ESpA patients.
Methods: ESpA patients treated with TNFi [adalimumab (ADA) or infliximab (IFX)] were retrospectively evaluated between November 2018 and October 2020 and divided in two cohort according to gender. In addition, TNFi treatments line/s, effectiveness and reasons of discontinuations, as inefficacy, intolerance, acute adverse reaction, development of infections and other causes, were evaluated at baseline (T0), at 6 (T6), 12 (T12), and 24 (T24) months of therapy. Patients who were failure to at least two TNFi were considered as "multifailure". Statistical analyses were performed using chi square/Fisher tests and variance analysis (SPSS software).
Results: 120 ESpA patients (M 40.52%; F 40.18%) treated with TNFi were evaluated. Clinical and laboratory baseline (T0) characteristics are summarized in Table 1. AS subtype was more common in men (39.5%) than in woman (14.3%) (p=0.03). Concerning comorbidities, hypertension and anemia were more prevalent in men than women (25% vs 9%, p=0.01; 11.6% vs 1.3%, p=0.02, respectively), while thyreopathy and psychiatric disorders were more common in female than male (11.7% vs 0%, p=0.02; 16.9% vs 4.6%, p=0.04, respectively). No difference was observed between genders in distribution of BMI, smokers, disease duration, HLAB27 positivity and presence of extra-articular manifestations. 202 TNFi treatments (50.9% ADA and 24.3% IFX) were evaluated in 120 patients [74 treatments (36.6%) in 43 men; 128 treatments (63.4%) in 77 women]. Considering treatment effectiveness, higher prevalence of failure was observed in woman that in men (67.2% vs 39.2%, p=0.0005). Moreover, women with psychiatric disorders undergone more lines treatment that men (16.8% vs 4.6%, p=0.01, OR=4). On the other hand, men with hypertension, were more multifailure compared with women (25.6% vs 16.3%, p=0.001, OR=3). No other differences according to gender were found.
At T6, 7.5% of patients (n=9) had acute adverse reaction (n=1 with ADA; n=8 with IFX); at T12, 14.2% of patients (n=17) had IBD inefficacy. At T24, secondary inefficacy on IBD and/or SpA was the main cause of TNFi discontinuation compared with other causes (58.4% vs 41.6%; p=0.04), mostly in female cohort (40% *vs* 20% in woman; p=0.04). Analyzing TNFi effectiveness, CRP and HAQ improvement was noted at T6 (p=0.024 and 0.036, respectively), as ASDAS-CRP and BASDAI (p=0.02 and p=0.013, respectively) and maintained in the following evaluations at T12 and T24. At T24, men shown higher PCR and BASDAI improvement compared with women (p=0.036 and p=0.04, respectively).
Conclusion: Data suggest that gender and comorbidities could influenced TNFi response in ESpA patients, advising differences among woman and men. Knowledge of these variable represents a major challenge for a personalized treatment management.

Table 1. Clinical and laboratory baseline (T0) characteristics of ESpA patients treated with TNFi.

	Women N= 77	Men N=43

POS0232

CLINICAL EFFECTIVENESS OF ADALIMUMAB VERSUS NON-BIOLOGIC THERAPY IN THE MANAGEMENT OF EXTRA-ARTICULAR MANIFESTATIONS IN ANKYLOSING SPONDYLITIS PATIENTS OVER 24 MONTHS – RESULTS OF THE COMPLETE-AS CANADIAN OBSERVATIONAL STUDY

L. Bessette[1], B. Haraoui[2], B. Florica[3], M. C. Laliberté[4], M. Khraishi[5].
[1]Laval University, Centre Hospitalier de l'Université Laval, Laval University, Centre Hospitalier de l'Université Laval, Quebec City, Canada; *[2]Institut de rhumatologie de Montréal, Institut de rhumatologie de Montréal, Montreal, Canada*; *[3]University of Toronto, Toronto, University of Toronto, Toronto, Toronto, Canada*; *[4]AbbVie Corporation, AbbVie Corporation, Montreal, Canada*; *[5]Memorial University of Newfoundland, Memorial University of Newfoundland, St. John's, Canada*

Background: COMPLETE-AS was a Canadian observational study among biologic-naïve adults with active ankylosing spondylitis (AS) initiated on either adalimumab (ADA) or subsequent non-biologic disease-modifying anti-rheumatic drugs and/or non-steroidal anti-inflammatory drugs (nbDMARD/NSAID) after a switch from initial treatment due to inadequate response or intolerance, as per the judgement of the treating physician.
Objectives: The aim of this analysis was to assess the 24-month effectiveness of ADA compared to nbDMARD/NSAID in the management of heel enthesitis and extra-articular manifestations (EAMs).
Methods: Patients were enrolled between July 2011 and December 2017, and followed for up to 24 months. Patients were treated as per routine care and all analyses were performed using the intent-to-treat (ITT) approach. The disease outcomes assessed in this study included enthesitis (of the heel) and EAMs [inflammatory bowel disease (IBD), uveitis, and psoriasis (PsO)]. The rate ratio (RR) for first occurrence or flare-up/exacerbation of disease outcomes was ascertained with multivariate models. The time to first occurrence of EAMs and enthesitis was ascertained with Cox proportional hazard models, generating a hazard ratio (HR).
Results: A total of 452 patients treated with ADA and 187 patients receiving a subsequent nbDMARD/NSAID were enrolled in the study. Baseline characteristics were overall comparable between treatment groups: patients had a mean (SD) age of 42.7 (13.4) years, 55.6% were male, and 85.8% were Caucasian. The mean (SD) duration of AS since diagnosis was 5.6 (9.3) years. A total of 17.7%, 12.4%, 18.5%, and 16.3% of patients had experienced enthesitis, IBD, uveitis, and PsO, respectively at baseline. Disease severity (mean [SD] BASDAI) was however higher among ADA- vs. nbDMARD/NSAID-treated patients (6.4 [1.8] vs. 5.0 [1.8]; p<0.001).
In terms of the rates of first occurrence or flare-up/exacerbation of enthesitis and EAMs, statistically significant between-group differences were found, whereby ADA-treated patients had a 60% reduced rate of both uveitis [RR (95% CI): 0.4 (0.2-0.6)] and enthesitis [0.4 (0.3-0.7)] compared to nbDMARD/NSAID-treated patients. The rates of first occurrence or flare-up/exacerbation for IBD [1.1 (0.7-1.7)] and PsO [3.3 (0.9-12.7)]were statistically comparable between treatment groups.
The time to first occurrence of both enthesitis and uveitis was also statistically significant (p<0.05) between groups. ADA-treated patients had a 50% lower risk of enthesitis as a first occurrence compared to nbDMARD/NSAID-treated patients [HR (95% CI): 0.5 (0.3-0.9)], and an 80% lower risk of uveitis [0.2 (0.0-0.8)]. The time to first occurrence of IBD [0.7 (0.2-2.1)] and PsO [1.9 (0.8-4.6)], were statistically comparable between treatment groups.
Conclusion: Despite a comparable proportion of patients reporting baseline EAMs and enthesitis, patients treated with ADA were less likely to experience a first occurrence or flare-up/exacerbation, of both enthesitis and uveitis compared to patients treated with nbDMARD/NSAID. The results of this real-world Canadian study suggest that treatment with ADA among AS patients is more effective at preventing the first occurrence / exacerbation of select EAMs and heel enthesitis.

POS0233 THE EFFICIENCY OF TREATMENT OF COXITIS IN AXIAL SPONDYLOARTHRITIS: EXPERIENCE OF REAL CLINICAL PRACTICE

E. Agafonova[1], S. Erdes[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation*

Background: Standard therapy for axial spondyloarthritis (axSpA) is effective in inflammatory lesions of the axial skeleton and peripheral arthritis, but its effect on coxitis has not been studied.
Objectives: To assess the effectiveness of anti-TNF therapy for coxitis in patients with axSpA.
Methods: An open observational study was conducted. There were 56 patients with axSPA and coxitis for 2 years who received NSAIDs or NSAIDs+anti-TNF therapy in real clinical practice. The study included only those patients who completed a 2-year follow-up period. All patients regardless of complaints underwent X-ray examination of the pelvis, ultrasound and magnetic resonance imaging (MRI) of the hip joints. An increase in the cervical-capsular distance (CCD) of more than 7 mm and the presence of asymmetry between the joints of more than 1.5 mm were taken for coxitis on ultrasound of the hip joint. The presence of synovitis and/or osteitis was taken for coxitis on MRI. The average age was 31.1±7.0 years, with an average duration of the disease 74.5±100.1 months. HLA-B27 positive were 52 (92%) patients.
Results: A comparative analysis of clinical, laboratory and other parameters of the disease was carried out against the background of 2-year follow-up of patients who were constantly taking only NSAIDs or their combination with anti-TNF therapies (Table 1).

Table 1.

Parametrs	Group NSAIDs+ anti-TNF n=27 baseline	Group NSAIDs+ anti-TNF n=27 after 2 y	p	Group NSAIDs n=29 baseline	Group NSAIDs n=29 after 2 y	p
BASRI hip ≥2; n %	10 (37%)	18 (67%)	>0,05	6 (21%)	14 (48%)	<0,05
MRI coxitis; n %	27 (100%)	19 (70%)	<0,05	28 (97%)	24 (83%)	>0,05
CCDmm;Me, [25 ‰;75‰]	7,9 [7,0;8,2]	7,2 [6,1;8,3]	<0,05	7,2 [6,2;7,8]	6,2[5,6;7,8]	>0,05
CRP,mg/L; Me, [25 ‰; 75‰]	23,7[8,4;56]	6,0 [1,0;17,3]	<0,05	10,3 [2,9;18,6]	8,4[2,9;18,5]	>0,05
ESR; Me, [25 ‰; 75‰]	25 [15;38]	15,0 [5;35,2]	<0,05	13 [7,8;25,5]	13 [6;26,3]	>0,05
ASDAS CRP; Me, [25 ‰; 75‰]	3,5 [2,4;4,7]	2,0 [1,0;2,4]	<0,05	2,6 [1,3;3,6]	2,0[1,1;2,3]	>0,05
BASDAI; Me, [25‰; 75‰]	4,7[4,2;6,9]	2,2 [2,0;3,7]	<0,05	4,2 [2,4;5,8]	2,2[1,4;4,2]	>0,05
BASFI; Me,[25‰;75‰]	4,0 [2,0;6,5]	1,9 [0,9;2,9]	<0,05	1,2 [0,3;2,5]	0,9[0,4;2,8]	>0,05

Conclusion:
1. Anti-TNF+NSAIDs therapy with 2 years of use effectively controls the activity of axSpA.
2. Two-year therapy with NSAIDs in combination with anti-TNF, reduces the inflammation of hip joints in some patients according to ultrasound and MRI data.
3. The present study did not conclusively confirm that 2-year anti-TNF therapy with NSAIDs effectively prevents the progression of X-ray bursitis in axSpA.
4. Further studies are needed to improve the effectiveness of treatment of coxitis in axSpA.

POS0234 SECUKINUMAB RETENTION AND SAFETY IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS OR ANKYLOSING SPONDYLITIS: 2 YEAR INTERIM RESULTS OF THE OBSERVATIONAL SERENA STUDY

U. Kiltz[1,2], P. Sfikakis[3], N. Gullick[4], A. Theodoridou[5], J. Brandt-Juergens[6], E. Lespessailles[7], R. Rashkov[8], J. Fang[9], E. Pournara[10], B. Schulz[10], P. Jagiello[10], K. Gaffney[11]on behalf of The study was sponsored by Novartis Pharma AG, Basel, Switzerland.. *[1]Rheumazentrum Ruhrgebiet, Claudiusstraße, Herne, Germany*; *[2]Ruhr-Universität Bochum, Universitätsstraße, Bochum, Germany*; *[3]National and Kapodistrian University of Athens, Medical School, Athens, Greece*; *[4]University Hospital Coventry & Warwickshire, Clifford Bridge Road, Coventry, United Kingdom*; *[5]Euromedica Geniki Kliniki, General Hospital, Thessaloniki, Greece*; *[6]Rheumatologische Schwerpunktpraxis, Seelbergstraße, Stuttgart, Germany*; *[7]Regional Hospital and, University of Orleans, Orléans, France*; *[8]Medical University - Sofia, булевард,"Академик Иван Евстратиев Гешов", София, Bulgaria*; *[9]Novartis Pharmaceuticals Corp., Immunology, Hepatology and Dermatology, East Hanover, United States of America*; *[10]Novartis Pharma AG, Immunology, Hepatology and Dermatology, Basel, Switzerland*; *[11]Norfolk and Norwich University Hospital, NHS Foundation Trust, Norfolk, United Kingdom*

Background: SERENA is an ongoing, prospective, non-interventional study evaluating retention, effectiveness, safety/tolerability and quality of life in more than 2900 patients (pts) with moderate to severe plaque psoriasis, active psoriatic arthritis (PsA) or active ankylosing spondylitis (AS) treated with secukinumab (SEC) at 438 sites across Europe for a period of up to 5 years[1].
Objectives: We present interim results reporting SEC treatment retention and safety data through 2 years in the PsA and AS pts enrolled in the study.
Methods: This interim analysis presents data from 534 PsA and 470 AS pts who were enrolled (target population fulfilling all eligibility criteria) in the study and were followed up for at least 2 years. Pts (aged ≥18 years) with active PsA or AS should have received at least 16 weeks SEC treatment before enrolment in the study[1]. Retention rate was defined as the percentage of pts who have not discontinued SEC treatment. A treatment break was defined as interruption of therapy for at least 3 months after last injection.
Results: The mean treatment duration prior to enrolment in the study was 1.0 year and 0.91 year for PsA and AS, respectively. The retention rates for SEC after 1 year since enrolment and since initiation of treatment were: PsA, 85.2% [n=519, CI: 82.01–88.32] and 96.8% [n=528, CI: 95.18–98.38]; AS, 85.8% [n=452, CI: 82.52–89.17] and 94.2% [n=464, CI: 91.94–96.42], respectively. After 2 years since enrolment and since initiation of treatment, the retention rates were: PsA, 74.9% [n=498, CI: 70.99–78.81] and 87.0% [n=515, CI: 83.99–89.99]; AS, 78.9% [n=437, CI: 75.01–82.88] and 84.8% [n=454, CI: 81.39–88.21], respectively. Survival probabilities for individual indications are presented in Figure 1. At baseline, the majority of PsA (79.5%; n/N=423/532) pts were receiving SEC 300 mg, while 97.0% (n/N=456/470) of AS pts were receiving SEC 150 mg. The majority of pts continued their initial SEC dose; "no dose change" in SEC treatment was reported after 1 and 2 years in the study (Year 1: PsA, 93.4% [n=499] and AS, 92.6% [n=435]; Year 2: PsA, 89.7% [n=479] and AS, 87.9% [n=413]). SEC treatment break was recorded for 31 PsA pts [median (min, max) treatment break duration in days: 125.0 (61, 461)] and for 42 AS [118.0 (61, 813)] pts mainly due to adverse events reported in 58.1% (n=18) and 45.2% (n=19) of pts, respectively. The retreatment started with monthly dosing in most of the cases: PsA, 80.6% (n/N=25/31) and AS, 76.2% (n/N=32/42). No new or unexpected safety signals were reported (Table 1).
Conclusion: Secukinumab retention rates in a real world setting after more than 2 years since initiation of treatment and after 2 years since enrolment in the study indicate high persistence rates. Safety data collected prospectively for up to 2 years confirm the favorable safety profile of secukinumab.

Background: Axial, peripheral, and other disease manifestations often overlap between psoriatic arthritis (PsA) and ankylosing spondylitis (AS). Upadacitinib (UPA) is an oral Janus kinase inhibitor under evaluation for the treatment of PsA and AS.
Objectives: To describe and compare baseline characteristics and UPA efficacy across 4 subgroups of patients (pts) from clinical trials: active PsA (with/without axial involvement) and active AS (with/without peripheral involvement).
Methods: Baseline characteristics and efficacy of UPA in reducing axial and peripheral signs and symptoms were assessed via an integrated analysis across the 4 pt subgroups from the SELECT-PsA 1,[1] SELECT-PsA 2,[2] and SELECT-AXIS[3] studies. Analyses of baseline characteristics included pts in the UPA 15 mg once daily (QD), UPA 30 mg QD, and placebo (PBO) groups; efficacy analyses included pts in the UPA 15 mg QD group only. Axial involvement in PsA (axial PsA) was determined by investigator assessment. Peripheral involvement in AS was defined based on presence of tender or swollen joints (TJC68 >0 or SJC66 >0), or presence of enthesitis at baseline (Maastricht Ankylosing Spondylitis Enthesitis Score >0).
Results: 2102 pts (UPA 15 mg; UPA 30 mg; PBO) were evaluated across the 4 subgroups (PsA [with/without axial involvement]: 626/1289; AS [with/without peripheral involvement]: 135/52). 33% of pts with PsA had axial PsA; 72% of pts with AS had peripheral symptoms. Pts with axial PsA had higher peripheral joint (TJC68 and SJC66) and skin (psoriasis) burden than pts with AS with peripheral involvement (p<0.0001). Pts with AS with peripheral involvement had significantly greater overall pain (pt's assessment of pain; p=0.0002) and back pain (BASDAI Q2; p<0.0001) scores, and higher total BASDAI (p=0.0076) and ASDAS (p=0.0351) scores than pts with axial PsA; physician's global assessment of disease activity, and peripheral pain and tenderness (BASDAI Q3 and Q4) were numerically similar for these 2 subgroups (Table 1). The efficacy of UPA 15 mg (measured using ASDAS and BASDAI) was generally consistent across the 4 pt subgroups regardless of peripheral or axial involvement (Figure 1).
Conclusion: Pts with PsA with axial involvement and pts with active AS showed some differences in baseline characteristics but similar improvements versus placebo with UPA 15 mg QD.

Clinical aspects of spondyloarthritis

POS0236 COMPARISON OF WORK PRODUCTIVITY OUTCOMES BETWEEN CHRONIC BACK PAIN PATIENTS WITH AND WITHOUT A DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS AFTER 2-YEAR PROTOCOLISED FOLLOW-UP: DATA FROM THE SPONDYLOARTHRITIS CAUGHT EARLY COHORT

A. Boel[1], M. Van Lunteren[1], K. M. Fagerli[2], R. Ramonda[3], S. Exarchou[4], M. Van de Sande[5], F. A. Van Gaalen[1], D. Van der Heijde[1]. [1]*Leiden University Medical Centre, Rheumatology, Leiden, Netherlands*; [2]*Diakonhjemmet Hospital, Rheumatology, Oslo, Norway*; [3]*University of Padova, Rheumatology Unit, Padova, Italy*; [4]*Lund University, Clinical Sciences, Section of Rheumatology, Malmö, Sweden*; [5]*Amsterdam University Medical Center, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*

Background:

Objectives: To compare work-productivity and activity impairment outcomes between chronic back pain (CBP) patients with and without an axSpA diagnosis after two years of protocollised follow-up.

Methods: Work productivity was assessed using the Work Productivity and Activity Impairment (WPAI) general health version 1.0 questionnaire. Presenteeism was defined as a reduction in performance due to disease while at work; absenteeism was time missed from work due to disease; work productivity loss (WPL) was a combined measure of presenteeism and absenteeism; and activity impairment was impairment due to disease in all non-work related activities. All WPAI outcomes were presented as percentages; higher scores implying greater impairment. Additionally, the proportion of patients with any (>0%) absenteeism, presenteeism, WPL and activity impairment were given.

This study used data from the SPACE cohort, which consists of patients with CBP (≥ 3 months <2 years) suspected of axSpA. Analyses were restricted to patients with a diagnosis axSpA or no axSpA (CBP group) with a level of confidence ≥7 (on a 0-10 scale) after locally read imaging. Additionally, data had to be available on the WPAI questionnaire at both timepoints. Assessment of presenteeism, absenteeism and WPL was restricted to the working population, defined as having paid work at baseline and 2-year follow-up. Activity impairment was assessed for the entire study population.

Regression models were used to test the difference between groups at two-year follow-up for all WPAI variables. Baseline WPAI values and NSAID-use over time were tested as confounders.

Results: Patients with a diagnosis of axSpA were more frequently male (56% vs 30%) and HLA-B27 positive (73% vs 31%) and had more SpA features at baseline compared to the patients with CBP [mean (SD) 5(2) vs 3(1)]. Age, symptom duration, NSAID-use and the percentage of patients with paid work at baseline were similar between groups.

The population having paid work at baseline and 2 years consisted of 124 patients (69%) in the axSpA group and 52 patients (70%) in the CBP group. In both groups the proportion of patients with any as well as the mean WPL reduces. This reduction was apparent in both presenteeism and absenteeism. Nevertheless, presenteeism, WPL and activity impairment were significantly higher at two-year follow-up in the group with CBP (Table 1). In these regression models with baseline values and NSAID-use over time as covariates, axSpA was an independent predictor of lower presenteeism, WPL and activity impairment at two-year follow-up.

Table 1. Work-productivity outcomes at baseline and two-year follow-up for the group with a diagnosis of axSpA and the group without a diagnosis.

	Diagnosis axSpA		CBP		p-values
	Baseline	2 years	Baseline	2 years	between groups at 2yrs
Working population	N=124		N=52		
Presenteeism, mean (SD) %	31 (28)	18 (24)†	40 (29)	30 (30)†	p=0.003*
Presenteeism present, %	73	52	87	67	
Absenteeism, mean (SD) %	7 (18)	4 (14)†	12 (25)	6 (21)†	p=0.334
Absenteeism present, %	22	7	27	12	
Overall work impairment, mean (SD) %	33 (29)	22 (27)†	43 (30)	35 (33)	p=0.005*
Overall work impairment present, %	72	46	87	65	
Total population	N=181		N=74		
Activity impairment, mean (SD) %	38 (28)	22 (24)†	50 (29)	33 (29)†	p=0.001*
Activity impairment, n(%)	86	64	93	70	

* Significant difference between groups at two years; after correction for baseline values and NSAID use over time† Significant improvement within group over time

Conclusion: Despite significant improvements in both groups, patients with axSpA have significantly better work-related outcomes after two years of protocolised follow-up compared to those without axSpA.

Disclosure of Interests: None declared

POS0237 GUT DYSBIOSIS LINKED TO WORSE DISEASE STATUS IN AXIAL SPONDYLOARTHRITIS

J. Sagard[1,2], T. Olofsson[1,2], E. Mogard[1,2], J. Marsal[3,4], K. Andréasson[1,2], M. Geijer[5,6,7], L. E. Kristensen[1,8], E. Lindqvist[1,2], J. K. Wallman[1,2]. [1]*Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden*; [2]*Skåne University Hospital, Department of Rheumatology, Lund, Sweden*; [3]*Lund University, Department of Immunology, EMV, Lund, Sweden*; [4]*Skåne University Hospital, Department of Gastroenterology, Lund, Sweden*; [5]*University of Gothenburg, Sahlgrenska Academy, Institute of Clinical Sciences, Department of Radiology, Gothenburg, Sweden*; [6]*Sahlgrenska University Hospital, Department of Radiology, Gothenburg, Sweden*; [7]*Lund University, Department of Clinical Sciences, Lund, Sweden*; [8]*Copenhagen University Hospital, Frederiksberg and Bispebjerg, Parker Institute, Department of Rheumatology, Copenhagen, Denmark*

Background: Based on clinical and genetic associations, axial spondyloarthritis (axSpA) and inflammatory bowel disease (IBD) are suspected to have a linked pathogenesis. Gut dysbiosis, intrinsic to IBD, has also been observed in axSpA. It is, however, not established to what degree gut dysbiosis is associated with axSpA disease severity.

Objectives: To compare presence and degree of gut dysbiosis between axSpA patients and controls, and to explore whether gut dysbiosis is associated with axSpA disease activity, function and pain.

Methods: The GA-map Dysbiosis Test (Genetic Analysis, Oslo, Norway) was used to identify and grade gut dysbiosis based on faecal samples from 44 non-radiographic axSpA (nr-axSpA; ASAS criteria) and 88 ankylosing spondylitis (AS; modified New York criteria) patients without IBD, consecutively enrolled in a population-based cohort study, and from 46 controls without rheumatic disease or IBD (frequency-matched to the patients for age/sex). The GA-map Dysbiosis Test is a validated method grading microbiota aberration on a 1-5 scale (Dysbiosis Index, DI), where ≥3 denotes dysbiosis. Analysis of covariance (ANCOVA) was used to compare DI between axSpA patients (nr-axSpA and AS combined) and controls, adjusted for age, sex, body mass index (BMI) and smoking. Within the axSpA group, disease activity (ASDAS-CRP; BASDAI), function (BASFI) and pain (VAS pain) were compared between patients with various DI levels by One-way analysis of variance (ANOVA) or Kruskal-Wallis test, as appropriate. Finally, axSpA patients were subdivided by presence of dysbiosis (DI ≥3 vs. <3) followed by comparison of ASDAS-CRP, BASDAI, BASFI, VAS pain and Evaluator´s global assessment of disease activity (EvalGlobal; 0-4: remission-maximal) by ANCOVA. Analyses were conducted unadjusted and adjusted for age, sex, BMI, smoking, axSpA subtype, gut inflammation (faecal calprotectin ≥50 mg/kg), irritable bowel syndrome symptoms (ROME III criteria), ASAS 3-month NSAID score and cs/bDMARD treatment.

Results: Characteristics of the patients/controls are shown in the Table 1. Gut dysbiosis (DI≥3) was observed in 33% of axSpA patients and 17% of controls. DI was significantly higher among the patients (β-estimate [bootstrapped 95%CI] for the between-group difference: 0.34 [0.04-0.65]; p=0.027). In the axSpA group, higher DI was associated with worse scores in all assessed outcomes (Figure 1, panel A). Moreover, presence of dysbiosis (DI≥3) was associated with worse ASDAS-CRP, BASDAI, BASFI, VAS pain and EvalGlobal (Figure 1, panel B; EvalGlobal not shown in the Figure: unadjusted β [bootstrapped 95%CI]: 0.32 [0.09-0.55], adjusted: 0.28 [0.03-0.52] for patients with DI ≥3 vs. <3), with between-group differences remaining significant after adjustment, except for ASDAS-CRP (p=0.079) and VAS pain (p=0.064).

Conclusion: Gut dysbiosis, present to a higher degree in axSpA patients than controls, is associated with worse axSpA disease activity and function. These

associations appear independent of gut inflammation and both NSAID and immunomodulatory treatment. This provides further evidence for an important link between disturbances in gastrointestinal homeostasis and axSpA manifestations, and implies that gut dysbiosis may be a novel biomarker for severe disease.

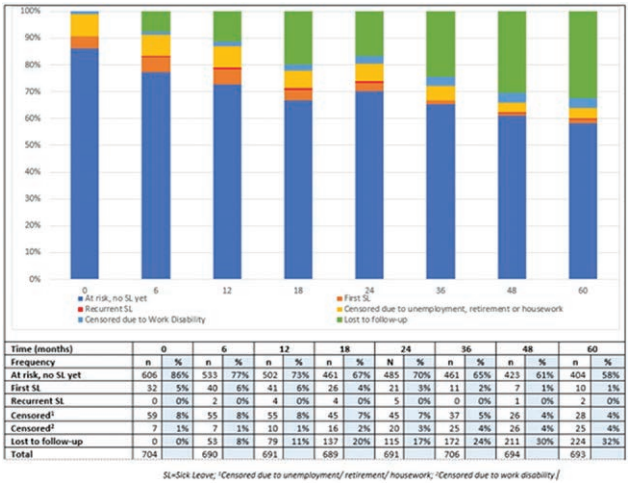
Background: Sick leave (SL) represents an often poorly studied adverse work outcome especially in early axSpA, with speculation around the potential role of clinical and socioeconomic (SE) factors.

Objectives: To investigate the occurrence of SL and the impact of clinical and SE factors on SL in early axSpA.

Methods: Patients with a clinical diagnosis of axSpA from the DESIR cohort up to 5 years of follow-up (6-month visits in the first 2 years, followed by annual visits) were studied. Time to SL and potential baseline and time-varying predictors were explored, with a focus on SE variables: age, gender, smoking status since last visit, ethnicity (Caucasian vs other), job type based on 'collar' (blue vs white), educational status (low vs high -university), marital status (married vs not) and parental status (number of children); and clinical factors including disease activity (ASDAS/BASDAI), function (BASFI), mobility (BASMI), at each time point. The incidence of SL was calculated as the number of SL events over the total number of person-days under observation. Univariable analyses, followed by collinearity and interaction tests, guided subsequent multivariable Cox survival model building.

Results: In total, 704 axSpA patients with work-related data were included in this study: mean (SD) age 33.8 (8.6); 46% male. At baseline, 80% of patients were employed; of these, 5.7% reported being on SL, with people shifting in and out of different work states over time. The distribution of first and recurrent SL episodes over time is shown in the figure 1. The incidence of SL amongst those at risk (n=620, 88%) and across the five years of DESIR was 0.05 (95% CI 0.03, 0.06) per 1000 days calculated in a total of 913,559 observed person-days. In survival analyses, 7% (n=43) of those at risk developed SL at some point. Mean (SD) time to SL was 806 (595) days (min 175, max 2021 days). In people who developed SL, 25% did so at 364 days; 50% and 75% at 545 and 1172 days, respectively. Significant differences were seen between baseline socio-demographic, clinical variables and treatment in patients who developed SL at any point, compared to those who did not. In multivariable models (Table 1) older age, higher disease activity, smoking and use of TNFi, the latter likely a proxy to worse disease, were all significantly associated with more SL. Male gender and higher education were associated with less SL. There were no relevant interactions between SE factors and clinical variables.



Time (months)	0		6		12		18		24		36		48		60

SL=Sick Leave; [1]Censored due to unemployment/ retirement/ housework; [2]Censored due to work disability.

Figure 1. Distribution of first and recurrent sick leave episodes over time in the study population at risk.

Table 1. Univariable and multivariable model analyses with Sick Leave as outcome.

Type of analysis	Univariable analysis HR (95% CI)	Multivariable model HR (95% CI) (N = 614)
Explanatory variables		
Age	1.04 (1.01, 1.08)	1.05 (1.01, 1.09)
Male gender	0.37 (0.19, 0.74)	0.41 (0.20, 0.86)
High education	0.33 (0.17, 0.61)	0.48 (0.24, 0.95)
Marital status	2.44 (1.12, 5.27)	NS
ASDAS (CRP)	1.83 (1.34, 2.50)	1.49 (1.04, 2.13)
BASFI, 0-10	1.24 (1.09, 1.40)	*
BASMI, 0-10	1.76 (1.31, 2.38)	*
Comorbidity count	1.77 (1.22, 2.57)	NS
HLA-B27 positive	0.51 (0.28, 0.93)	NS
Smoking (current vs not)	2.40 (1.31, 4.37)	2.55 (1.32, 4.91)
NSAID score last week, 0-400	1.01 (1.00, 1.01)	NS
Oral Corticosteroid use (vs no)	3.90 (1.80, 8.46)	NS
TNF use	2.86 (1.55, 5.28)	2.41 (1.27, 4.58)

*Variables tested in models separate from ASDAS. NS=Not significant in multivariable model.

Conclusion: In this early axSpA cohort of young, working-age individuals, older age and worse disease activity were associated with more SL, whereas male gender and higher education were associated with less SL. The findings suggest a role of SE factors such as gender and level of education in adverse work outcomes, alongside active disease.

Background: In patients with spondyloarthritis (SpA), root joint diseases (RJD), i.e. hip or shoulder involvement, may be associated with a distinct disease phenotype compared to those with other affected joints. The ASAS-PerSpA study (PERipheral involvement in SPondyloArthritis) [1], offers a unique opportunity to study the phenotypes of patients with RJD in a global cohort.
Objectives: Primary objective was to compare the clinical characteristics of SpA patients with and without RJD. Secondary objectives were to compare the prevalence of RJD across the different SpA subtypes and the different regions of the world, compare the severity of axial disease as well as the disease burden in SpA patients with and without RJD.
Methods: This is a post-hoc analysis of the ASAS-PerSpA study, which included 4,465 patients with any subtype of SpA (axial SpA (axSpA), peripheral SpA (pSpA), psoriatic arthritis (PsA), inflammatory bowel disease associated SpA (IBD-SpA), reactive arthritis (ReA) and Juvenile SpA (Juv-SpA)) according to the rheumatologist's diagnosis. RJD was defined as a positive answer by the investigator to the following question: "Do you consider that the patient has ever suffered from RJD (e.g. hip, shoulder) related to SpA?" In case of a positive answer, a potential specific treatment (e.g. Total Articular Replacement) was investigated. The patient's characteristics were compared between those with and without RJD involvement, using Chi-2 or Fisher exact test for the categorical variables and t-test for the continuous variables. Two separate multivariable stepwise binary logistic regression analyses were conducted to identify factors associated with the dependent variables "hip involvement" and "shoulder involvement".
Results: RJD occurred in 1,503 patients (33.7%), with more prevalent hip (24.2%) than shoulder (13.2%) involvement. The prevalence of RJD as a group was the highest in Juv-SpA (52.7%), followed by pSpA (44.3%) and axSpA (33.9%). The highest prevalence of RJD was found in Asia and the lowest in Europe and North America. Among patients with hip involvement, 6.0% had a history of hip replacement (highest in the Middle East and North Africa and Latin America); among patients with shoulder involvement, 0.8% had a history of shoulder replacement. Hip had a distinct pattern of associations compared to shoulder involvement (Figure 1). Hip involvement was significantly associated with the SpA main diagnosis (highest in pSpA, lowest in PsA), younger age at first SpA symptom, lower prevalence of family history of psoriasis, positive HLA-B27, occiput-to-wall distance>0, and treatment with cs-DMARDs and b-DMARDs. Shoulder involvement was associated with the SpA main diagnosis (highest in Juv-SpA and pSpA, lowest in axSpA), older age at first SpA symptom, higher prevalence of enthesitis, dactylitis, tender joints count, IBD, occiput-to-wall distance>0, EQ5D score and treatment with cs-DMARDs.
Conclusion: Hip involvement was more prevalent than shoulder involvement in patients with SpA, and had a distinct phenotype resembling axial disease whereas shoulder involvement was mostly associated with features of peripheral disease. Hip and shoulder involvement should be analyzed separately in future studies rather than under the RJD entity.

POS0240

GEOGRAPHICAL PREVALENCE OF A FAMILY HISTORY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AND ITS ASSOCIATION WITH HLA-B27: DATA FROM THE WORLDWIDE ASAS-PERSPA STUDY

M. Van Lunteren[1], A. Boel[1], C. López-Medina[2], J. Sieper[3,4], D. Van der Heijde[1], F. A. Van Gaalen[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Cochin Hospital, Rheumatology, Paris, France*; [3]*Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Rheumatology, Berlin, Germany*; [4]*German Rheumatism Research Centre, Rheumatology, Berlin, Germany*

Background: Research has shown that in axial spondyloarthritis (axSpA) patients, the most common form of spondyloarthritis (SpA) in a family history is axSpA. Moreover, the association between a positive family history of spondyloarthritis (PFH) and HLA-B27 carriership is driven by a PFH of axSpA and possibly acute anterior uveitis (AAU), but not by other forms of SpA. However, this research was limited to mostly Western European patients.
Objectives: To investigate the impact of geographical region on family history and its association between HLA-B27 carriership in patients with axSpA around the world.
Methods: Data from the Assessment in SpondyloArthritis international Society (ASAS) peripheral involvement in Spondyloarthritis (ASAS-perSpA) study was used. Analyses were restricted to patients with an axSpA diagnosis who had information available on HLA-B27 status and family history. The frequencies of any PFH, as well as a PFH for axSpA, psoriasis, AAU, inflammatory bowel disease (IBD) and reactive arthritis (ReA), were determined per geographical region. Logistic regression models were built to assess the effect of HLA-B27 status on the occurrence of any PFH and each disease in a PFH in the total population and also stratified per geographical region.
Results: In total, 2,048 patients were included from 4 regions: Asia (n=545), Europe & North America (n=840), Latin America (n=202), and Middle East & North Africa (n=461). Patients had a median age (IQR) of 40 (31-50) years, 31% were female, and had a disease duration of 11 (5-20) years.
A PFH of axSpA was the most common in all geographical regions, regardless of HLA-B27 carriership. A PFH of psoriasis and IBD appeared to be more common in HLA-B27 negative patients, and a PFH of ReA was rare in all patients (figure 1). Univariable logistic regression models showed an association between a PFH and HLA-B27 carriership in the Asian population, but this association does not seem apparent in the other geographical regions (table 1). Contrary, a PFH of axSpA was associated with HLA-B27 carriership in all geographical regions except the Middle East & North Africa (table 1). An association between HLA-B27 carriership and a PFH of psoriasis was solely present in Middle East & North Africa (OR=0.4, 95% CI 0.2-0.7), and an association with a PFH of IBD was solely present in Europe & North America (OR=0.5, 95% CI 0.3-0.9). No associations were found for HLA-B27 carriership and a PFH of AAU and ReA in any geographical region. There was also no effect modification of geographical region (p=0.43) on the association between HLA-B27 status and a PFH.

Table 1. Univariable associations between HLA-B27 carriership and a positive family history of axSpA patients in the perSpA cohort stratified per geographical region

axSpA, axial spondyloarthritis; **CI,** confidence interval; **HLA-B27,** human leucocyte antigen B27; **OR,** odds ratio

Conclusion: Throughout the world, axSpA was the most common form of SpA in a family history. In all regions except Middle East & North Africa, a PFH of axSpA was associated with HLA-B27 carriership in axSpA patients. These results suggest that the current expert definition of a PFH of SpA should be revaluated.

POS0241

VALIDATION OF THE ANKYLOSING SPONDYLITIS DISEASE ACTIVITY SCORE WITH A QUICK QUANTITATIVE C-REACTIVE PROTEIN ASSAY (ASDAS-QCRP) IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS (AXSPA): A PROSPECTIVE, NATIONAL, MULTICENTER STUDY

F. Proft[1], J. Schally[1], H. C. Brandt[2], J. Brandt-Juergens[3], G. R. Burmester[4], H. Haibel[1], H. Käding[1], K. Karberg[2], S. Lüders[1], B. Muche[1], M. Protopopov[1], J. Rademacher[1], V. Rios Rodriguez[1], M. Torgutalp[1], M. Verba[1], S. Zinke[5], D. Poddubnyy[1]. [1]*Charité - Universitätsmedizin Berlin, Division of Gastroenterology, Infectiology and Rheumatology, Campus Benjamin Franklin, Berlin, Germany*; [2]*Praxis für Rheumatologie und Innere Medizin, Praxis für Rheumatologie und Innere Medizin, Berlin, Germany*; [3]*Rheumatologische Schwerpunktpraxis, Rheumatologische Schwerpunktpraxis, Berlin, Germany*; [4]*Charité - Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; [5]*Rheumapraxis Berlin, Rheumapraxis Berlin, Berlin, Germany*

Background: According to international recommendations, the Ankylosing Spondylitis Disease Activity Score (ASDAS) is the preferred score for assessing disease activity in axial spondyloarthritis (axSpA) [1]. However, routine determination of C-reactive protein (CRP) to calculate ASDAS values takes hours to days. This limits the use of ASDAS in clinical routine and clinical trials and hinders the implementation of treat-to-target approaches in axSpA. Whereas quick quantitative CRP (qCRP) tests allow CRP assessment within a few minutes. In a pilot project the performance of qCRP-based ASDAS assessment (ASDAS-qCRP) was already investigated in a single center study of 50 newly diagnosed, bDMARD-naïve axSpA patients with promising results [2].
Objectives: To validate the ASDAS-qCRP in a prospective, multicenter study of axSpA patients in a typical axSpA cohort with an appropriate sample size.
Methods: The study was conducted in five centers in Germany. Consecutive adult (≥ 18 years) axSpA patients were included. In addition to a rheumatological assessment, including patient reported outcomes (PROs), routine CRP and erythrocyte sedimentation rate (ESR) were measured in the local labs. Additionally, a qCRP testing with the „QuikRead go instrument" (Aidian Oy, Finland) was performed at the study center (measurement range 0.5 - 200 mg/l for hematocrit concentrations of 40 – 45%). Statistical analysis included descriptive statistics, cross tabulation and weighted Cohen´s kappa comparing disease activity categories, Bland-Altman plots and intraclass correlation coefficient (ICC) for ASDAS-CRP and ASDAS-qCRP.
Results: In this study 251 axSpA patients were included between January and September 2020 (mean age: 38.4 years; mean disease duration: 6.2 years, 159 patients (63.3%) were male, 211 (84.1%) HLA-B27 positive and 195 (77.7%) were classified as radiographic axSpA). 143 patients (57.0%) were treated with bDMARDs. CRP and qCRP showed mean values of 2.12 and 2.17 mg/l, respectively. With the ASDAS-qCRP, 242 patients (96.4%) were assigned to the same disease activity category as compared to the ASDAS based on the conventional lab CRP measurement (Table 1). Weighted Cohen´s kappa was 0.966 (95%CI: 0.943; 0.988). ICC for ASDAS-CRP- and ASDAS-qCRP-values was 0.997 (95%CI: 0.994; 0.999). The agreement of ASDAS-qCRP and ASDAS-CRP is shown in a Bland-Altman plot (Figure 1).
Conclusion: The ASDAS-qCRP and ASDAS-CRP showed an almost perfect agreement on the assignment to disease activity categories (96%) with the important advantage of time. With ASDAS-qCRP, rheumatologists could base their clinical decision-making on a disease activity measurement by using a composite score immediately. ASDAS-qCRP, therefore, can be integrated in clinical routine and clinical trials in the future and may facilitate implementation of the treat-to-target concept in axial SpA.

ROLE OF HLA-B27 CARRIERSHIP IN PERIPHERAL SPONDYLOARTHRITIS: DATA FROM ASAS PERSPA STUDY

M. Arévalo[1], C. López-Medina[2], V. Navarro-Compán[3], M. Moreno[1], M. Llop Vilaltella[1], J. Calvet[1], J. Gratacos-Masmitja[1], M. Dougados[4]on behalf of ASAS group. [1]*Hospital Parc Taulí I3PT, Rheumatology, Sabadell, Spain*; [2]*Hospital Universitario Reina Sofía/IMIBIC/Universidad de Córdoba, Rheumatology, Cordoba, Spain*; [3]*Hospital Universitario la Paz, IdiPaz, Rheumatology, Madrid, Spain*; [4]*Hôpital Cochin, Rheumatology, Paris, France*

Background: HLA-B27 is well known for its role in conferring susceptibility to spondyloarthritis (SpA), and several studies evaluating its association to axial SpA phenotype have been published. However, there is few evidence about its influence in patients affected with peripheral SpA (pSpA). In this sense we find ASAS perSpA registry suitable for this purpose.
Objectives: To identify phenotypical differences in pSpA patients regarding HLA-B27 status.
Methods: Data from all patients fulfilling ASAS pSpA criteria with HLA-B27-testing result available included in the ASAS perSpA study were used for this analysis. Socio-demographic and disease characteristics were collected. A descriptive and comparative analysis was performed between HLA-B27 positive and negative patients, using a simple logistic regression for all variables to assess their association to HLA-B27 positivity. Results were considered significant when $p < 0.05$. A multivariate model was also performed including significant ($p < 0.1$) and the most relevant clinical variables in agreement of medical criteria.
Results: Among the 4465 patients included in the registry, 555 fulfilled ASAS pSpA criteria and of them 286 had the HLA-B27 typing available. HLA-B27 was positive in 118 (41.3%) and negative in 168 (58.7%). Results are listed in Table 1. No differences were observed for gender distribution (males 55.1% in HLA-B27 positive vs 49.4% in HLA-B27 negatives). HLA-B27 positive patients were significantly younger, presented a younger disease onset, had significantly higher prior axial involvement, radiographic sacroiliitis and higher root joint involvement. On the other hand, HLA-B27 negative patients showed longer disease duration with a higher diagnosis delay. Around half of the patients in both groups showed a mono or oligoarticular pattern without differences regarding HLA-B27 status, however, psoriatic arthritis (PsA) and peripheral joint damage was significantly higher in HLA-B27 negative patients. Also psoriasis and inflammatory bowel disease (IBD) were more frequent in HLA-B27 negative patients compared to positive ones, and acute anterior uveitis (AAU) was significantly more frequent in HLA-B27 positive patients without differences in number of AAU episodes lifelong. Finally, obesity and concomitant fibromyalgia were both more common in HLA-B27 negatives. No significant differences were found for the rest of variables evaluated.
In the multivariate analysis, age at disease onset (OR 0.96, CI95% 0.94-0.98), disease duration (OR 0.96, CI95% 0.92-0.99), PsA (OR 0.28, CI95% 0.09-0.85), presence of psoriasis (OR 0.22, CI95% 0.07-0.64), IBD related arthritis (OR 0.03, CI95% 0.01-0.19), AAU (OR 3.63, CI95% 1.22-11.9) and tarsitis (OR 2.61, CI95% 1.01-6.98) were the most important variables independently associated to HLA-B27 status.

Conclusion: Presence of HLA-B27 in pSpA patients was associated to a higher axial and root joint involvement, an earlier disease onset and presence of AAU, but not to PsA, psoriasis and IBD that were higher in HLA-B27 negative patients.

Table 1.

	HLA-B27+ (N = 118)		HLA-B27- (N = 168)

WHAT DOES REMISSION IN AXIAL SPONDYLOARTHRITIS MEAN FOR CLINICIANS? AN EXPLORATORY STUDY OF 200 FRENCH RHEUMATOLOGISTS BASED ON A VIGNETTE EXERCISE INCLUDING 36 CASES AND PRIORITY RATINGS

K. Aouad[1], D. Wendling[2], A. Baglin[3], M. Breban[4], S. Dadoun[5,6], C. Hudry7, A. Moltó[8,9], E. Pertuiset[10], L. Gossec[1]. [1]*Sorbonne University; AP-HP, Pitié Salpêtrière Hospital, Rheumatology Department, Paris, France*; [2]*Besançon University Hospital, Rheumatology Department, Besançon, France*; [3]*Novartis, Pharmaceutical, Ile de France, France*; [4]*APHP, Ambroise Paré Hospital, Rheumatology Department, Boulogne, France*; [5]*Private practice, Rheumatology, Paris, France*; [6]*CeSOA, MGEN action sociale, Rheumatology, Paris, France*; [6]*CeSOA, MGEN action sociale, Rheumatology, Paris, France*; [8]*Cochin Hospital, APHP, Rheumatology Department, Paris, France*; [9]*INSERM U-1153 (ECAMO), CRESS, Université de Paris, Rheumatology, Paris, France*; [10]*Rene Dubos Hospital, Rheumatology Department, Pontoise, France*

Background: Treat-to-target in axial spondyloarthritis (axSpA) aims to achieve and maintain clinical remission/inactive disease or alternatively, low disease activity [1]. However, there is no consensual definition of remission in axSpA: the T2T international task force has proposed Ankylosing Spondylitis Disease Activity Score (ASDAS) inactive disease, but this definition is not widely accepted [1, 2].

Objectives: To explore rheumatologists' perception of remission in axSpA, using vignette cases and a priority exercise.

Methods: A steering group of 7 rheumatologists designed a national cross-sectional survey during two face-to-face meetings in 2019-2020. The survey comprised 36 vignette cases: fixed elements included the clinical picture (34 year-old-male with confirmed axSpA, normal C-reactive protein (CRP), without synovitis, enthesitis, dactylitis or extra-articular manifestations) and there were 3 varying parameters (axial pain (0-10) [ranging 2 to 5], fatigue (0-10) [2 to 8], and morning stiffness [<15 minutes, 30 minutes or 1 hour]. For each vignette, the rheumatologist answered binarily: "do you consider this patient in remission: yes/no". The second part of the survey comprised a priority rating (0-10 priority and 4 top items) of elements important to consider for remission, from a list of 12 items (BASDAI, ASDAS, elements of BASDAI and ASDAS including CRP, NSAIDs use, extra-articular manifestations, and other explanations for the symptoms e.g., fibromyalgia). The analysis was descriptive.

Results: Overall, 200 French rheumatologists participated between June and September 2020. Out of 2,400 vignette evaluations (mean of 66 evaluations per vignette), 463 (19%) were classified as remission by rheumatologists. Six vignette cases constituted 56% of all remission cases (Figure 1): these comprised a short duration of morning stiffness (<15 minutes), a low VAS axial pain (2 or 3) but with varying levels of VAS fatigue. When the duration of morning stiffness increased from 15 to 30 minutes and VAS axial pain increased from 2-3 to 4-5 independently, classification as remission decreased from 42% to 12% and from 28-33% to 5-11%, respectively. However, when VAS fatigue increased, it impacted less remission.

In priority ratings, 4 items were selected as important by 68-75% of rheumatologists: morning stiffness and axial pain (both included in the vignettes), as well as extra-articular manifestations and NSAID use, whereas only 18% selected fatigue. BASDAI was cited as the 1st priority criteria by 24% of rheumatologists and ASDAS as the 2nd by 16% of rheumatologists.

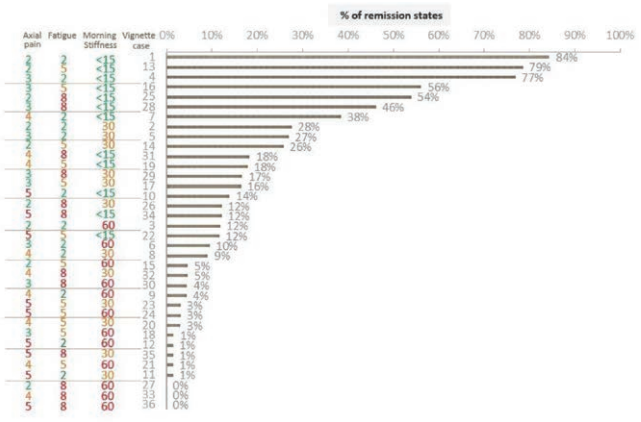

Figure 1. Frequencies of the declared remission states by rheumatologists for each of the 36 vignette cases

Conclusion: Morning stiffness, axial pain, NSAIDs use, and extra-articular manifestations seem to impact the physicians' perception of remission in axSpA, whereas fatigue has less impact on remission for rheumatologists. Consensus is needed on remission in axSpA.

PATIENT JOURNEY WITH AXIAL SPONDYLOARTHRITIS: CRITICAL ISSUES FROM THE PATIENT PERSPECTIVE. RESULTS FROM THE EUROPEAN MAP OF AXIAL SPONDYLOARTHRITIS (EMAS)

M. Garrido-Cumbrera[1], D. Poddubnyy[2], C. Bundy[3], L. Christen[4], R. Mahapatra[5], S. Makri[6], C. J. Delgado-Domínguez[1], S. Sanz-Gómez[1], P. Plazuelo-Ramos[7], V. Navarro-Compán[8]on behalf of IMAS working group. [1]*Universidad de Sevilla, Health & Territory Research (HTR), Seville, Spain*; [2]*Charité - Universitätsmedizin Berlin, Rheumatology Department, Berlin, Germany*; [3]*Cardiff University, School of Healthcare Sciences, Cardiff, United Kingdom*; [4]*Novartis Pharma AG, Patient Engagement, Basel, Switzerland*; [5]*Axial Spondyloarthritis International Federation (ASIF), Patient Advocacy, London, United Kingdom*; [6]*Cyprus League Against Rheumatism (CYPLAR), Patient Advocacy, Nicosia, Cyprus*; [7]*Spanish Federation of Spondyloarthritis Associations (CEADE), Presidency, Madrid, Spain*; [8]*Hospital Universitario La Paz, IdiPaz, Madrid, Spain*

Background: The journey of axial spondyloarthritis (axSpA) for most patients is slow and arduous.
Objectives: The goal of this analysis is to describe the journey to diagnosis and further management in axSpA patients.
Methods: 2,846 unselected patients participated in EMAS, a cross-sectional study (2017-2018) across 13 European countries. Descriptive analysis of socio-demographic factors, insurance scheme, diagnostic journey and post diagnosis healthcare utilization was performed. Mann-Whitey test was used to analyse possible differences between BASDAI (>4 v ≤4) and the number of visits to healthcare professionals and follow-up tests undertaken.
Results: Mean age was 43.9 years, 61.3% were female, 48.1% university educated, 67.9% married, 53.9% employed and 81.7% had public health insurance. Mean age at symptoms onset was 26.6 (11.1), while mean age at diagnosis was 33.7 (11.5) and mean diagnostic delay was 7.4 years. Over 50% had a diagnostic delay of ≥4 years. Prior to receiving a diagnosis, patients visited on average 2.6 specialists. The most commonly performed diagnostic tests were x-rays (72.3%), HLA B27 tests (65.4%) and MRIs (64.3%). 78.4% were diagnosed by a rheumatologist while 14.9% received their diagnosis by a GP. Patients who experienced a diagnostic delay of more than a year (n= 2,208) undertook a considerable number of visits to specialists and medical tests in the year prior to participating in EMAS, which increased with disease activity. Patients with active disease (BASDAI >4) reported a higher number of visits to rheumatologists (3.7±3.5 vs 2.9±2.6), general practitioners (6.6±10.0 vs 3.5±4.1), physiotherapists (19.3±25.0 vs 11.7±17.0), and psychologists/psychiatrists (3.4±10.7 vs 1.9±7.7). Patients with active disease also undertook more x-rays (1.8±2.8 vs. 1.3±1.9), MRI scans (0.9±1.2 vs. 0.6±1.1), and blood tests (4.7±4.4 vs 3.6±3.2). However, one in five patients visited the rheumatologist only once in the year prior to EMAS (21.1%).
Conclusion: Diagnostic delay continues to be a key challenge in the axSpA patient journey, with patients waiting an average of 7.4 years and visiting multiple doctors prior to diagnosis. Once diagnosed, disease management presents a further challenge, as patients with higher disease activity reported more healthcare professional visits as well as medical tests. Safeguarding health and controlling healthcare utilization requires effective disease management, greater education for non-specialists, rapid referral routes for diagnosis and collaborative care between specialists and non-specialists.

POS0245 PERFORMANCE OF STANDARDIZED SCORES FOR DISEASE ASSESSMENT AND PAIN IN PATIENTS WITH SPONDYLOARTHRITIS AND FIBROMYALGIA

X. Baraliakos[1], S. Tsiami[1], P. Dukatz[1], M. C. Gkelaki[1], U. Kiltz[1], J. Braun[1]. [1]*Ruhr-University Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany*

Background: The pathogenesis of spondyloarthritis (SpA) including axial SpA (axSpA) and psoriatic arthritis (PsA) differs from fibromyalgia (FM). However, symptoms partially overlap and both patient groups suffer from pain and stiffness. In addition, SpA patients may also develop a secondary form of FM. Classification criteria for SpA and diagnostic criteria for FM are used to differentiate between these subsets. Patient reported outcomes (PRO) often generated by questionnaires are used to assess severity and other disease features.
Objectives: To study whether PROs developed for axSpA, PsA, and related physician-based information behave in a similar way in patients diagnosed with FM without an additional chronic inflammatory rheumatic disease (CIRD) as in patients with a primary diagnosis of SpA without or with secondary FM.
Methods: Patients were consecutively recruited. The main inclusion criterion was a clinical diagnosis of FM (without CIRD), axSpA or PsA (without or with secondary FM) and the indication for a treatment adaptation (escalation or change within the same class) for any reason, based on the judgement of experienced rheumatologists. Standardized assessment tools and lab parameters (BASDAI, ASDAS-CRP, DAPSA, patient´s and global assessment (NRS), CRP, BASFI, Fibromyalgia Impact questionnaire (FIQ), Leeds Enthesitis Index (LEI), Maastricht Ankylosing Spondylitis (MASES) and SpA Research Consortium of Canada (SPARCC) Enthesitis Score were assessed and compared between subgroups.
Results: The baseline demographics of 300 recruited patients (100 FM. 100 axSpA and 100 PsA) are shown in Table 1. All patients with FM (primary or secondary to SpA) showed the highest scores in almost all assessments, and this was independent of the main diagnosis (Table 2). In comparison, patients with axSpA or PsA without secondary FM showed significantly lower scores in all PROs as compared to those with primary and secondary FM, with exception of (i) scores of ASDAS-CRP and (ii) duration of morning stiffness (Question 6 of BASDAI), which were not affected by the presence of secondary FM (Table 2).
Conclusion: Secondary FM is leading to significantly higher levels of SpA-specific scores. ASDAS-CRP was the only score that was not influenced by the presence of secondary FM in patients with axSpA even though it was also increased in patients with primary FM, while similar results were found for the duration but not the level of morning stiffness. On the other hand, FM-specific questionnaires also showed high scores in patients with axSpA and PsA with concomitant FM but not in those without.

Clinical vasculitis

POS0246 THE WORLDWIDE INCIDENCE AND PREVALENCE OF ANCA VASCULITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF EPIDEMIOLOGICAL STUDIES

R. Redondo Rodriguez[1], N. Mena-Vázquez[1], A. M. Cabezas-Lucena[1], F. Godoy-Navarrete[1], M. Morales-Águila[1], S. Manrique Arija[1]. [1]*Instituto de Investigación*

Biomédica de Málaga. Hospital Regional Universitario de Málaga, Reumatología, Málaga, Spain

Objectives: To evaluate the worldwide incidence and prevalence of ANCA vasculitis through a systematic review of the literature and meta-analysis.
Methods: A systematic search of MEDLINE and EMBASE search engines was carried out for studies that analyzed the incidence and prevalence of ANCA vasculitis in different geographical areas. Inclusion criteria: patients diagnosed with ANCA vasculitis according to ACR criteria/ Chapel Hill Consensus and adult patients (> 16 years). All ANCA vasculitis (microscopic polyangiitis, granulomatosis with polyangiitis, eosinophilic granulomatosis with polyangiitis) were considered. Exclusion criteria: editorials, conference abstracts, case or cases series reports and narrative reviews; insufficient description of the methods; lack of data to compute incidence or prevalence; and duplicate studies.Variables: Main variable: the pooled prevalence measured by the number of prevalent cases per million / person-year (95% CI) and the pooled incidence measured as the number of incident cases per million / person-year (95% CI). Secondary variables: the prevalence and incidence of each vasculitis ANCA and according geographic area. A meta-analysis was undertaken to estimate the pooled incidence and the pooled prevalence per million / person-years. The 95% CI and I2 for heterogeneity were calculated.
Results: Twenty four studies were included. The pooled incidence (95% CI) was 12.2 per million / person-year (8.4-16.5) and the pooled prevalence (95% CI) was 130 per million / person-year (67.5-213). The individual incidence for each vasculitis was: GPA (6.7), MPA (5.9) and EGPA (1.6). The individual prevalence for each vasculitis was: GPA (69.3), MPA (21.9) and EGPA (13.5).
In the analysis by continents, the pooled incidence for GPA vasculitis was higher in Europe (7.5), while the pooled incidence for MPA vasculitis was higher in America (6.9) and for EGPA vasculitis it was higher in Asia (1.8). The pooled prevalence for GPA and MPA vasculitis was higher in Europe (83.9,24.4 respectively) than in America (14.2, 12.8 respectively).
Conclusion: The pooled incidence and the pooled prevalence are higher in the case of GPA vasculitis compared to the rest of ANCA vasculitis. In general there is a predominance of incidence and prevalence of all ANCA vasculitis in the northern hemisphere compared to the south.

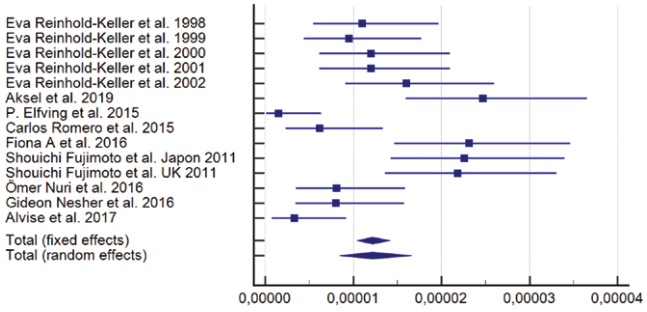

Figure 1. The pooled incidence ANCA vasculitis.

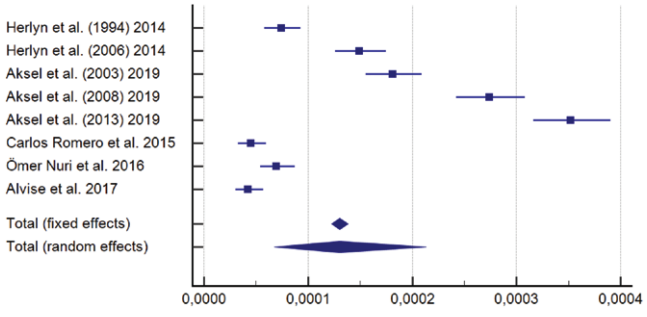

Figure 2. The pooled prevalence ANCA vasculitis

POS0247 INTERSTITIAL ANCA-ASSOCIATED VASCULITIS ASSOCIATES WITH SEVERE KIDNEY INJURY INDEPENDENT OF GLOMERULONEPHRITIS

S. Hakroush[1], B. Tampe[2]. [1]*University Medical Center Göttingen, Institute of Pathology, Göttingen, Germany*; [2]*University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany*

Background: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a small vessel vasculitis affecting multiple organ systems, including the kidney. Small vessels in the kidney include small-sized arteries (interlobular artery, afferent and efferent arteriole), capillaries (glomerular and peritubular capillary) and venules.
Objectives: Although crescentic ANCA glomerulonephritis (GN) is a common histological finding reflecting glomerular small vessel vasculitis, it is reasonable that manifestation of AAV could also contribute to interstitial small vessel vasculitis. Therefore, we here aimed to expand our current knowledge focusing on interstitial vasculitis in ANCA GN by systematic histological scoring of vascular lesions analogous to Banff.
Methods: A total number of 49 kidney biopsies with confirmed renal involvement of AAV at the University Medical Center Göttingen were retrospectively included between 2015 till 2020. A renal pathologist (SH) evaluated all biopsies and was blinded to clinical data collection and analysis. A detailed methological section is provided in the Supplementary material and methods section.
Results: Since previous studies established that crescentic ANCA GN associates with severe kidney injury and acute deterioration of kidney function in AAV, we first systematically scored interstitial vasculitis in association with requirement of renal replacement therapy (RRT). Among all active and chronic tubulointerstitial lesions analogous to the Banff scoring system, the only association between severe kidney injury requiring RRT was observed for interstitial vasculitis in AAV reflected by peritubular capillaritis (ptc, p=0.0002) and arteritis (v, p=0.0069), affecting 5/49 (10.2%) and 11/49 (22.4%) of renal biopsies, respectively. Since it is known that severe deterioration of kidney function also correlates with crescentic ANCA GN, we next directly compared glomerular and tubulointerstitial lesions. The fraction of normal glomeruli was inversely associated with interstitial fibrosis (ci), total (ti) and inflammation in IFTA (i-IFTA), whereas glomerular crescents were associated with interstitial inflammation (i), tubulitis (t) and total inflammation (ti). In contrast, global glomerular sclerosis associated with less interstitial inflammation (i) but correlated with interstitial fibrosis (ci) and tubular atrophy (ct), confirming established mechansim that chronic glomerular injury leads to tubular atrophy and interstitial fibrosis. Interestingly, no association between interstitial vasculitis (ptc and v correlating with severe kidney injury) and any glomerular lesion in ANCA GN (also correlating with severe kidney injury) was observed, thereby confirming that interstitial vasculitis contributes to severe kidney injury independent of ANCA GN. By contrast, short-term renal recovery from RRT was equal in both groups, suggesting a distinct association with acute decline of kidney function at disease onset.
Conclusion: Taken together, by using the Banff scoring system we here expand our current knowledge of renal interstitial lesions in AAV revealing peritubular capillaritis and arteritis as important histological alterations associated with severe kidney injury in a considerable subset of AAV. Furthermore, our findings that interstitial vasculitis did not correlate with crescentic ANCA GN implicate that the characteristics of each vasculitis manifestation are independent and could further improve our understanding of mechanisms contributing to renal injury. These observations suggest that interstitial vasculitis in AAV may also affect long-term prognosis requiring further investigation.

POS0248 PSYCHOMETRIC PROPERTIES OF OUTCOME MEASUREMENT INSTRUMENTS FOR ANCA-ASSOCIATED VASCULITIS: A SYSTEMATIC LITERATURE REVIEW

A. Berti[1,2], G. Boleto[3], P. A. Merkel[4], G. Tomasson[5], S. Monti[6], K. A. Quinn[7], L. Carmona[8], S. Ramiro[9,10]on behalf of OMERACT Vasculitis Working Group. [1]*Hospital of Trento, University of Trento, Rheumatology, Trento, Italy*; [2]*Mayo Clinic, Thoracic Disease Research Unit, Rochester, United States of America*; [3]*Cochin Hospital, Rheumatology, Paris, France*; [4]*Penn Medicine, University of Pennsylvania Health System, Rheumatology, Philadelphia, United States of America*; [5]*Landspítali The National University Hospital of Iceland, Rheumatology, Reykjavik, Iceland*; [6]*University of Pavia, Rheumatology, Pavia, Italy*; [7]*National institute of arthritis and musculoskeletal and skin diseases, Rheumatology, Bethesda, United States of America*; [8]*Instituto de Salud Musculoesquelética (INMUSC), Rheumatology, Madrid, Spain*; [9]*Department of Rheumatology, Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [10]*Department of Rheumatology, Zuyderland Medical Center, Rheumatology, Heerlen, Netherlands*

Background: The OMERACT Vasculitis Working Group has defined a Core Domain Set of outcome measures for ANCA-associated vasculitis (AAV). However, the psychometric properties of available outcome measurement instruments in AAV, an essential consideration when choosing among instruments, have not been summarized.
Objectives: To systematically review and summarize the psychometric properties of outcome measurement instruments used in AAV.

Methods: A comprehensive search of several databases (Medline, EMBASE, Cochrane, Scopus, among others) from inception to July 14, 2020 and without language limitations was conducted. Articles were included if they covered psychometric properties of instruments used in AAV (granulomatosis with polyangiitis, GPA; microscopic polyangiitis, MPA; eosinophilic granulomatosis with polyangiitis, EGPA); articles encompassing other systemic vasculitides and not presenting the data for AAV separately were excluded. Following the COSMIN and OMERACT frameworks, different psychometric properties (validity, inter- and intra-observer reliability, sensitivity to change, and feasibility) of outcome measurement instruments used in AAV were assessed. Risk of bias was assessed according to the COSMIN checklist.

Results: From 2505 articles identified, 20 met the predefined criteria. Three were identified as development studies, 14 were validation studies, and 3 pursued both objectives.

These studies provided information on 16 instruments: 8 assessing disease activity, 1 assessing disease damage, 3 assessing patient-reported outcome, 4 assessing function (Figure 1). Overall, a few psychometric properties have been considered in each study, ranging from one to five. Most of the instruments were tested in GPA only (n=7), followed by AAV as a group (GPA, MPA and EGPA; n=5), MPA and GPA (n=3), and EGPA only (n=1). Sample sizes of the studies ranged between 27 and 626 patients. The studies with a higher risk of bias, according to COSMIN definitions, were those assessing RAPID3, MVIA, ENT/GPA DAS, and ODSS.

There was a wide heterogeneity of the psychometric proprieties assessed for each instrument. Validity was the most frequently assessed domain in 88% of the instruments, and few properties other than construct validity were reported (Figure 1).

Within each domain, BVAS/WG for activity, VDI for damage, AAV-PRO for patient-reported outcomes, and ODSS for function were the instruments with more psychometric features assessed. For the disease activity domain, BVAS/WG showed a good validity having the highest correlation with physician global assessment (r=0.90), a good reliability (intra-observer ICC=0.62; inter-observer ICC=0.97), and good feasibility and responsiveness. For disease damage, VDI showed moderate validity (correlations with BVAS/WG at 5-year with r=0.20 and BVAS/WG at 1-year with r=0.40) and good feasibility. Among patient-reported outcomes, AAV-PRO had the best performance in terms of validity (construct validity: correlations of the 6 disease domains and EQ-5D-5L, with r ranging between -0.78 and -0.55; discriminating validity between active disease versus remission of the 6 disease domains, p<0.0001 for all comparisons). The performance of instruments assessing function domain was low-to-moderate.

Psychometric properties of outcome measures used in the study of ANCA-associated vasculitis

MFI-20=Multidimensional Fatigue Inventory-20

* Only the physical fatigue domain of the score was assessed (not the overall score)

Conclusion: Sixteen instruments covering the OMERACT domains of disease activity, damage, patient-reported outcome, and function had their psychometric properties assessed in the study of AAV. The majority were developed or validated for GPA only or AAV as a group. Overall, validity was the domain most frequently assessed. BVAS/WG, VDI, AAV-PRO, and ODSS were the instruments with more psychometric features assessed. More rigorous studies aimed at estimating a wider range of psychometric properties in larger numbers of patients with AAV are warranted.

POS0249 THE EFFECT OF NASAL STAPHYLOCOCCUS AUREUS COLONIZATION ON DISEASE ACTIVITY AND THE EFFECT OF ANTIBIOTIC TREATMENT IN PATIENTS WITH ANCA ASSOCIATED VASCULITIS; A RETROSPECTIVE COHORT STUDY

C. Schaap[1], R. Krol[1,2], H. H. F. Remmelts[2], R. Klaasen[3], E. Hagen[2], J. Spierings[1], M. W. Heijstek[1]. [1]*University Medical Center Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands*; [2]*Meander Medical Center, Department of Internal Medicine, Amersfoort, Netherlands*; [3]*Meander Medical Center, Department of Rheumatology, Amersfoort, Netherlands*

Background: Antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) is a necrotizing vasculitis, predominantly affecting small or medium vessels with few or no immune deposits. Ear, nose and throat (ENT) involvement in AAV is frequently present. AAV has a relapsing-remitting disease course. A factor that has been associated with induction of relapses is nasal Staphylococcus aureus (S. aureus) colonization. This alleged association between nasal colonization and induction of relapses has resulted in the use of antibiotics. However, the effect of antibiotic treatment on disease activity remains controversial. Some studies showed a beneficial effect of antibiotic treatment whereas other studies found no effect of antibiotic treatment on disease activity.

Objectives: The aim of this study was to identify the role of nasal S. aureus colonization and the effect of systemic or local antibiotic treatment on disease activity in patients with AAV.

Methods: Clinical, laboratory and histological data from all AAV patients with ENT involvement, diagnosed in two medical centers between 1981 and 2020, were retrospectively collected. Nasal S. aureus colonization was defined as at least one positive nasal swab during follow-up. Data on systemic (cotrimoxazole and azithromycin) and local antibiotics (mupirocin) use was collected. Disease activity was divided into systemic and local disease activity. Systemic disease activity consisted of history of relapses, relapse number per patient years and Birmingham vasculitis activity score version 3 (BVAS3) at last visit. Local disease activity included history of ENT relapses, development of saddle nose deformity or subglottic stenosis during follow-up.

Results: Two-hundred and thirteen patients were included in the analysis. Median follow-up time was 8 (IQR 3 -17) years. S. aureus colonization was tested in 100 (46.9%) cases of which 44 patients tested positive. Only one patient developed a subglottic stenosis, and 13 patients developed a saddle nose deformity during follow-up. Systemic and local disease activity at baseline and at last visit were comparable between patients with and without and S. aureus colonization. Regression analysis showed no difference in relapse number per patient year between AAV patients colonized with S. aureus versus non-colonized patients (RR 2.03; 95%CI, 0.97 – 4.26, p=0.06). This also accounted for local ENT relapses (OR 0.134; 95%CI 0.06-1.47, p=0.14) and saddle nose deformity (OR 0.61; 95%CI 0.04-10.68, p=0.74). Twenty-eight (13.1%) S. aureus positive patients received antibiotics aimed at eradication of S. aureus. Twenty-two (10.3%) received cotrimoxazole, 2 (0.9%) received azithromycin and 17 (8.0%) patients received mupirocin ointment. No significant difference was found between the treated versus non-treated group with regard to systemic and local disease activity.

Conclusion: Nasal S. aureus colonization does not influence systemic or local disease activity. Antibiotic eradication treatment did not modify disease activity in this study.

Table 1. Effect of AB treatment on disease activity of 40 AAV patients with ENT involvement and S. aureus colonization

Disease activity	Antibiotic treatment		
	Yes (n=28)	No (n=12)	P-value
Systemic symptoms			
History of one or more relapses, n (%)	18 (47.4%)	4 (10.5%)	0.635
Relapse number per patient years, median (IQR) *	0.11 (0-0.18)	0.17 (0.02 – 0.26)	0.346
BVAS3 last visit, median (IQR)	1 (0-4)	1 (0-4)	0.932
Local symptoms			
History of one or more ENT relapses, n(%) *	9 (33.3%)	3 (11.1%)	0.438
Development of saddle nose deformity during follow-up, n (%) *	4 (12.1%)	0 (0%)	0.367

*Values are median (interquartile range IQR) or n (%). BVAS3: Birmingham Vasculitis Activity Score version 3; ANCA: Anti-Neutrophilic Cytoplasmic Autoantibody; AAV: ANCA associated vasculitis; ENT: ear, nose and throat. * More than 10% missings in analysis. For an overview of the number of included patients per analysis, see supplementary table B.*

POS0250 SIGNIFICANT DAMAGE OCCURS EARLY IN THE COURSE OF EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS AND IS MAINLY DUE TO DISEASE-RELATED SEQUELAE

P. Delvino[1,2], A. Milanesi[1], F. Brandolino[1], S. Monti[1,2], C. Montecucco[1]. [1]*IRCCS Policlinico S. Matteo Foundation, University of Pavia, Rheumatology, Pavia, Italy*; [2]*University of Pavia, PhD in Experimental Medicine, Pavia, Italy*

Background: Following the introduction of effective immunosuppressive treatments, ANCA-associated vasculitides (AAV) have become chronic diseases with a remitting-relapsing course. Therefore, preventing chronic damage accrual during follow-up is critical, as relapses, treatment-related side effects, and comorbidities may significantly affect the long-term outcomes of AAV patients. At present, no study specifically evaluated the burden of damage in patients with eosinophilic granulomatosis with polyangiitis (EGPA).
Objectives: To describe short-term (6 months) and long-term (5 years) damage accrual in patients with newly diagnosed EGPA.
Methods: Patients diagnosed with EGPA, according to ACR criteria and/or Chapel Hill definitions and regularly followed-up in our vasculitis center for ≥5 years were included. Damage accrual was assessed with the Vasculitis Damage Index (VDI). Short-term and long-term damage accrual was defined by VDI at 6 months and at 5 years, respectively, and categorized as related to vasculitis or its treatment.
Results: VDI data at 6 months were available for 45 EGPA patients: 24 (53.3%) female, mean age at diagnosis 51.6±13.0 years. ANCA were positive in 17 patients (37.8%), with MPO being the only detected enzyme immunoassay (EIA)-specificity. At 6 months mean VDI was 2.8±1.3; 25/45 (55.6%) and 6/45 patients (13.3%) presented ≥3 and ≥5 items, respectively, whilst only 1 patient (2.2%) showed no items of damage. VDI data at 5 years were available for 32/45 EGPA patients (71.1%): 16 (50%) female, mean age at diagnosis 51.5±13.1 years. MPO-ANCA were positive in 13 patients (40.6%). At 5 years mean VDI was 3.5±1.3, with 26/32 (81.3%) and 7/32 patients (21.9%) presenting ≥3 and ≥5 items, respectively; notably, no patients presented a VDI=0 at 5 years.
The most frequent disease-related VDI items at 6 months and at 5 years were asthma, chronic sinusitis, peripheral neuropathy, cardiomyopathy, pulmonary function tests abnormalities and nasal blockage (Figure 1). Osteoporotic fractures, diabetes and systemic hypertension were the most commonly reported treatment-related items at 6 months and at 5 years (Figure 1). Damage accrual progressively rose during the 5-year follow-up (P=0.023), mainly due to disease-related items rather than treatment-related items both at 6 months (disease related VDI 2.6±1.2, treatment-related VDI 0.3±0.6) and at 5 years (disease related VDI 2.9±1.2, treatment-related VDI 0.6±0,7). No significant difference in terms of damage accrual was observed between ANCA-positive and ANCA-negative patients (P >0.5).
Conclusion: In our cohort of EGPA patients damage accrual occurs early, with more than half of the patients displaying ≥3 VDI items already at 6 months. Poor control of previous disease activity, particularly ENT and respiratory manifestations, contributes to progressive damage accrual more than treatment side effects.

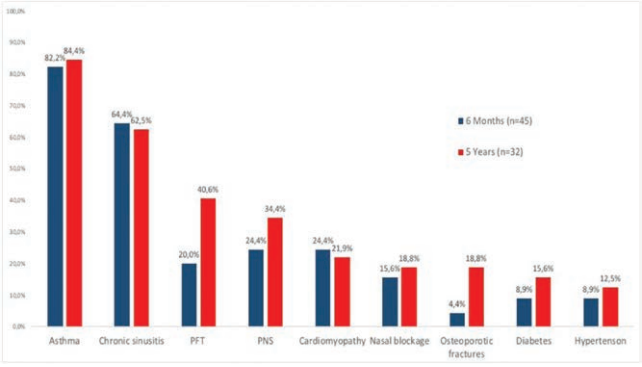

Figure 1. Disease-related and treatment-related VDI items at 6 months and at 5 years in patients with EGPA.

POS0251 ARE CLINICAL FEATURES AND OUTCOMES OF ANCA (+) EGPA PATIENTS DIFFERENT FROM ANCA NEGATIVE ONES?

E. Duran[1], E. Bilgin[1], E. Erkantarcı Levent[2], Ö. Can Bostan[3], L. Kılıç[1], E. Damadoğlu[3], S. Kiraz[1], O. Karadag[1,4]. [1]*Hacettepe University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; [2]*Hacettepe University School of Medicine, Department of Internal Medicine, Ankara, Turkey*; [3]*Hacettepe University School of Medicine, Department of Chest Disease, Division of Allergy and Clinical Immunology, Ankara, Turkey*; [4]*Hacettepe University School of Medicine, Vasculitis Research Centre, Ankara, Turkey*

Background: Recent reports describe EGPA as having two subgroups as ANCA positive and ANCA negative. Furthermore, there could be differences in terms of clinical features and outcomes (1).
Objectives: The aim of this study was to compare the clinical characteristics and outcomes of ANCA positive EGPA patients with those of ANCA negative ones.
Methods: This retrospective, descriptive study included 50 EGPA patients (male/female:13/27) from our prospective vasculitis database from October 2014 (2). The patients had fulfilled the ACR 1990 or DCVAS criteria for EGPA. In addition to clinical features (activity index) and treatment regimens, outcomes of patients (relapse and damage) were also reviewed. For relapse-free survival analysis, time to first relapse was compared according to ANCA phenotype by Kaplan-Meier survival analysis.
Results: Of the patients, 17 (34%) were in ANCA (+) group, 33 (66%) were in ANCA (-) group. Renal involvement and peripheral neuropathy were more frequent in ANCA (+) patients whereas ANCA (-) patients were significantly younger at the time of diagnosis and they had more nasal polyposis. The median BVAS at the EGPA diagnosis was significantly high in ANCA (+) group. All 3 of patients with cardiac involvement were in the ANCA (-) group but difference was found in terms of FFS and VDI between ANA (+) and (-) groups. However, pulse steroid and cyclophosphamide treatments were more commonly used in ANCA (+) group while mepolizumab were used in ¼ of ANCA (-) patients (Table 1). During median 47 (IQR 69.9) months follow up, about 40% of patients had at least one relapse but there was no difference for relapse-free survival rate according to the ANCA status (Figure 1).
Conclusion: Not only clinical features and disease activity but also treatments received were significantly different between ANCA (+) and (-) patients. These results could partially define two distinct subgroups of EGPA. However, these groups were similar regarding damage and relapse.

POS0252 IMPACT OF ANCA-ASSOCIATED VASCULITIS ON CLINICAL OUTCOMES AND RESOURCE UTILIZATION IN ELECTIVE PCI

K. Mathias[1], L. Mathias[2], A. Mantha[3], D. Arkfeld[2]. [1]*University of Chicago, Internal Medicine, Chicago, United States of America*; [2]*USC Keck School of Medicine, Rheumatology, Los Angeles, United States of America*; [3]*USC Keck School of Medicine, Internal Medicine, Los Angeles, United States of America*

Background: Anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitides (AV) can increase risk of atherosclerosis. [1] Patients with autoimmune disease have increased rates of coronary events that are not fully explained by classic risk factors. [2] A prior study has shown that autoimmune vasculitides –including polyarteritis nodosa, hypersensitivity granulomatosis with polyangiitis, giant cell arteritis, thrombotic angiitis, Takayasu arteritis, Goodpasture syndrome, and Kawasaki disease –are associated with increased cost of care and increased 30-day readmission after percutaneous coronary intervention (PCI). [3] It is important to distinguish the cardiovascular outcomes of small–vessel ANCA-associated vasculitides from the other vasculitides included in this prior study because coronary arteritis is typically a complication of medium to large vessel vasculitis.
Objectives: To investigate the impact of comorbid ANCA-associated small vessel vasculitis (AV) on outcomes of PCI in a nationally representative cohort.
Methods: Patients undergoing PCI in the 2016-2018 National Inpatient Sample were selected and those with ANCA-associated vasculitis were identified using the ICD-10 classification system. The NIS is an all-payer, survey-weighted, inpatient database estimating 37 million annual U.S. hospitalizations managed by the Healthcare Cost and Utilization Project (HCUP). Primary study outcomes were prevalence of comorbid vasculitis, mortality, complications, and cost of care.
Results: Of 1,351,670 patients undergoing PCI were identified, 410 (0.03%) had diagnosis of ANCA-vasculitis. AV patients were similar to non-AV patients in distribution of gender, race, and median household income. AV patients were older (70.9 vs 65.2 years, P<0.001) and more likely to utilize Medicare (78% vs 53%, P<0.005). AV patients were more likely to present with non-ST segment myocardial infarction (NSTEMI) (57.3% vs 41.5%, P<0.005) and less likely to present with ST-elevation myocardial infarction (NSTEMI) (18.3% vs 31.3%, P<0.05). AV patients had similar adjusted mortality (6.1% vs 2.6%, aOR: 2.1, P=0.8), cost of care ($32,985 vs $25,767, β = 0.02, P=0.7), and length of hospitalization (6.0 vs 3.9, IRR: 1.2, P=0.13).
Conclusion: The presence of ANCA-associated vasculitis did not appear to negatively impact inpatient clinical outcomes or utilization of care among patients undergoing PCI in the United States. Cost of care was not increased, in contrast to an increase cost of care when small, medium, and large vasculitides are grouped together. The greater proportion of NSTEMI patients among those with AAV corresponds with a growing body of literature implicating inflammatory processes in the pathogenesis of certain forms of myocardial infarction meriting further investigation.

POS0253 RITUXIMAB-BIOSIMILAR FOR ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODIES-ASSOCIATED VASCULITIS: EXPERIENCE OF A SINGLE ITALIAN CENTER

S. Sartorelli[1], A. Cariddi[1], L. Moroni[1,2], E. Baldissera[1], E. Bozzolo[1], L. Dagna[1,2]. [1]*IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*; [2]*Vita-Salute San Raffaele University, School of Medicine, Milan, Italy*

Background: Rituximab (RTX), an anti-CD20 monoclonal antibody, represents a valuable treatment for anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV). RTX biosimilar CT-P10 (RTX-B) has been approved in Europe in all indications held by RTX originator (RTX-O). As stated by recent international consensus-based recommendations, [1] there is evidence regarding safety and efficacy of biosimilars in the context of rheumatic diseases, but it is encouraged to gather additional data. [2,3]
Objectives: To report the experience of a single Italian center with RTX-B in AAV in terms of safety and efficacy.
Methods: We retrospectively reviewed the charts of all AAV patients followed up in our Small Vessel Vasculitis Clinic and we selected those who received RTX-B between October 2017 and May 2020, both naïve to RTX (RTX-Bn) or already treated with ≥1 course of RTX-O and switched to RTX-B (RTX-Bs). Baseline features, disease outcome, concomitant therapy and adverse events 6 (T6), 12 (T12) and 24 (T24) months after RTX-B introduction, when available, were collected. Non-parametric statistic tests were used.
Results: Fifty-six AAV patients (44 [78.6%] granulomatosis with polyangiitis (GPA), 12 [21.4%)] microscopic polyangiitis (MPA)) received RTX-B with a median follow up of 20 (IQR 10-24) months. ANCA were positive in 49 (87.5%) patients. Ten (17.9%) patients were newly diagnosed with AAV, while 23 (41.1%) had refractory disease and another 23 had relapsing disease.
Thirty-three (58.9%) patients were RTX-Bs, whereas 23 (41.1%) RTX-Bn. In 29 (51.8%) patients RTX was decided because of remission induction, while in 27 (48.2%) as maintenance regimen. Median cumulative RTX-B dose was 2.5 (2-3.875) grams with 3 (IQR 2-4) median courses. AAV activity, adverse events and concomitant therapy at T6, T12 and T24 are shown in Table 1. One GPA patient died of severe infection 3 months after a single infusion of RTX-B 500 mg as maintenance therapy.
Considering the 52 (92.6%) patients who reached a 6 months-follow up, we marked a significant decrease of number of patients on steroid therapy (39 [75%] vs 27 [51.9%]; p=0.003), of median prednisone daily dose (5 [IQR 5-25] vs 2.5 [IQR 1.25-5 mg; p=0.001) and of number of patient on concomitant bDMARDs (10 [19.2%] vs 5 [9.6%]; p=0.003).
Analysing the 40 (71.4%) patients who reached a 12 months-follow up, we confirmed the tendency with a decrease of number of patients on steroid therapy (29 [72.5%] vs 13 [32.5%]; p=0.007), of median prednisone daily dose (5 [IQR 5-12.5] vs 3.75 [IQR 2.75-7.5]; p=0.008) and of number of patient on concomitant bDMARDs (9 [22.5%] vs 3 [7.5%]; p=0.009).
No statistically significant difference was found for the same variables comparing T0 versus T24.

Table 1. AAV activity, concomitant therapy and adverse events at T0, T6, T12 and T24.

	T0	T6	T12	T24
n (%)	56 (100)	52 (92.6)	40 (71.4)	18 (32.1)
Dose RTX-B, median (IQR) grams	1.75 (0.5-2)	0.5 (0.5-1)	0.5 (0.5-1)	0.5 (0.5-1)
Concomitant prednisone therapy, n (%)	42 (75)	27 (48.2)	13 (32.5)	4 (22.2)
Dose prednisone, median (IQR) milligrams/day	5 (5-15.625)	2.5 (2.5-5)	3.75 (2.75-7.5)	2.75 (1.56-4.5)
Concomitant bDMARDs, n (%)	10 (17.9)	5 (9.6)	3 (7.5)	1 (5.6)
Refractoriness	NA	4 (7.7)	2 (5)	1 (5.6)
Relapse	NA	0 (0)	3 (7.5)	2 (11.1)
Remission	NA	48 (92.3)	35 (87.5)	15 (83.3)
Suspension	NA	10 (19.2)	9 (22.5)	4 (22.2)
Infusion reaction, n (%)	1 (1.8)	1 (1.9)	0 (0)	0 (0)
Infectious adverse events, n (%)	NA	10 (19.2)	6 (15)	3 (16.7)
Severe infectious adverse events, n (%)	NA	2 (3.8)	1 (2.5)	0 (0)

Conclusion: Our experience with RTX-B is limited; however, it represents an extensive report about the use of RTX-B in AAV patients and confirmed that it may be a well-tolerated and effective therapy in AAV setting, in agreement with previous evidence on RTX-O. Prospective and larger studies are needed to confirm this preliminary evidence.

POS0254 EFFICACY OF APREMILAST IN THE TREATMENT OF ORAL ULCERS OF BEHÇET'S SYNDROME: RESULTS FROM THE EUROPEAN SUBGROUP OF RELIEF

A. Mahr[1], G. Hatemi[2], M. Takeno[3], D. Kim[4], M. Melikoglu[1], D. Saadoun[5], C. C. Zouboulis[6], S. Cheng[7], S. Richter[8], S. Jardon[8], M. Paris[8], M. Chen[8], Y. Yazici[9]. *[1]Cantonal Hospital St. Gallen, Department of Rheumatology, St. Gallen, Switzerland*; *[2]Istanbul University - Cerrahpasa, Department of Internal Medicine, Istanbul, Turkey*; *[3]Nippon Medical School, Musashi Kosugi Hospital, Department of Allergy and Rheumatology, Kawasaki, Japan*; *[4]Yonsei University College of Medicine and Severance Hospital, Associate Professor, Hepotolgy, Seoul, Korea, Rep. of (South Korea)*; *[5]Pitié-Salpêtrière Hospital, Department of Internal Medicine and Clinical Immunology, Paris, France*; *[6]6Dessau Medical Center, Brandenburg Medical School Theodor Fontane, Director of the Departments of Dermatology, Venereology, Allergology and Immunology, Dessau, Germany*; *[7]Amgen, Inc., Global Medical Affairs, Director Biostats, Thousand Oaks, CA, United States of America*; *[8]Amgen, Inc., Global Medical Affairs, Thousand Oaks, CA, United States of America*; *[9]New York University School of Medicine, Department of Rheumatology, New York, NY, United States of America*

Background: Behçet's syndrome, a chronic, multi-system variable vessel vasculitis, is often characterized by painful oral ulcers (OU) affecting quality of life (QoL). Apremilast (APR), an oral PDE4 inhibitor, demonstrated efficacy in OU treatment in the phase 3 multinational RELIEF study.

Objectives: To evaluate APR efficacy in OU treatment in patients with active Behçet's syndrome in a prespecified subgroup of patients enrolled in 13 European RELIEF sites (France, Germany, Greece, and Italy).

Methods: patients were adults with active Behçet's syndrome and ≥3 OU at randomization or ≥2 OU at screening and randomization, without active major organ involvement. Patients were randomized (1:1) to APR 30 mg BID or PBO during a 12-week double-blind phase. The primary endpoint was area under the curve for the number of OU through Week 12 (AUC_{Wk0-12}). Other outcomes were OU pain visual analog scale (VAS); achievement of OU complete response (ie, OU-free) and maintenance of OU complete response (ie, complete response at Week 6 and remaining OU-free for ≥6 additional weeks); OU partial response (ie, OU reduction ≥50%); disease activity (Behçet's Syndrome Activity Score [BSAS]; Behçet's Disease Current Activity Form [BDCAF], including Behçet's Disease Current Activity Index [BDCAI], and Patient's and Clinician's Perception of Disease Activity); and QoL (BDQoL; Short Form Health Survey version 2 [SF-36v2], including Physical Functioning [PF] scale and Physical and Mental Component Summary [PCS, MCS]).

Results: Of 207 patients randomized and treated in RELIEF, 52 were in the European subgroup. Mean (±SD) age in the subgroup was 39 (±12) years; 54% were women. Baseline disease characteristics were similar between treatment groups (Table 1). Patients receiving APR achieved lower AUC_{Wk0-12} for OU vs PBO (Figure 1) and greater reduction in pain. A greater proportion of patients receiving APR achieved complete, maintained, or partial OU responses at Week 12 vs those receiving PBO (Table 1). Consistent treatment effects favoring APR vs PBO were observed in disease activity, as shown by BSAS and BDCAF component scores at Week 12 (Table 1). Greater improvement in SF-36v2 MCS was observed favoring APR vs PBO at Week 12, and moderate treatment differences were seen for other QoL measures (BDQoL, SF-36v2 PF, and SF-36v2 PCS).

Conclusion: In the European subgroup of patients with Behçet's syndrome and OU in RELIEF, APR resulted in greater reduction in OU count, OU pain, and disease activity as well as favorable treatment effect on QoL measures than PBO. These results are consistent with the efficacy of APR treatment in the overall RELIEF population.

POS0255

IMPACT OF PLASMA EXCHANGE (PLEX) IN SEVERE ANCA-ASSOCIATED VASCULITIS (AAV): A REAL-LIFE DATA FROM A PROSPECTIVE COHORT

E. Bilgin[1], E. Duran[1], E. Erkantarcı Levent[2], T. Yıldırım[3], M. Arıcı[3], A. İ. Ertenli[1], O. Karadag[1]. *[1]Hacettepe University, Internal Medicine, Rheumatology, Ankara, Turkey*; *[2]Hacettepe University, Internal Medicine, Ankara, Turkey*; *[3]Hacettepe University, Internal Medicine, Nephrology, Ankara, Turkey*

Background: PEXIVAS was the largest clinical trial conducted on severe AAV patients and failed to demonstrate the contribution of PLEX on the prognosis of severe AAV. This data needs to be tested with real life experiences.
Objectives: The aim of this study was to explore the effects of PLEX on the prognosis of severe AAV in a real-life cohort.
Methods: Hacettepe University Vasculitis Research Center (HUVAC) prospective database was established in October 2014 by registering past and newly diagnosed patients. Baseline disease characteristics, treatments and survival status were recorded. For this study, patients with granulomatosis polyangiitis (GPA) and microscopic polyangiitis (MPA) who met the inclusion criteria of PEXIVAS trial [briefly; ANCA positive MPA or GPA patients with either severe renal involvement (necrotizing glomerulonephritis or active urinary sediment, and eGFR <50 ml/min) and/or severe pulmonary involvement (pulmonary hemorrhage due to active vasculitis)] at the disease onset were included. Patients were grouped whether they had PLEX or not. Demographic and disease-specific data and immunosuppressive agents used in induction phase were compared. Primary outcome was accepted as composite index of mortality or end-stage renal disease (ESRD) at the first year and at the final visit.
Results: Of 145 GPA and MPA patients, 49 patients had inclusion criteria and distribution of patients were as GPA (n=38), MPA (n=8) or renal-limited (n=3). 16 (32.6%) patients had PLEX. Median number of plasma exchange cycles was 6.5 (min-max; 2-12). Although severe pulmonary [10 (62.5%) vs. 5 (15.2%), p=0.001] and combined severe renal+pulmonary involvements were more prevalent [9 (56.3%) vs. 4 (12.1%), p=0.001] and baseline creatinine levels were higher in PLEX (+) group, BVAS and FFS scores were similar (Table 1). Induction immunosuppressive regimens were comparable.
At first year evaluation, primary composite outcome was observed in 11 patients (3 deceased, 8 ESRD) of PLEX (+) group whereas in 12 patients (2 deceased, 10 ESRD) of PLEX (-) group (p = 0.03, log-rank). In multivariate analysis: **combined renal+pulmonary involvements** (aOR: 6.5 [1.1-37.9]) and **serum creatinine** (for 1 mg/dl increment) (aOR: 1.3 [1.1-1.7]) were associated with primary outcome. In this model, having plasma exchange was not associated with a favorable outcome.
At the end of median follow-up [40.7 (1.2-170.3) months], outcome was observed in 12 patients (9 deceased, 3 ESRD) of PLEX (+) group and in 13 patients (6 deceased, 7 ESRD) of PLEX (-) group (p < 0.001, log-rank). In multivariate analysis: **having plasma exchange** (HR: 3.5 [1.4-8.5]) and **combined renal+pulmonary involvements** (HR: 2.4 [1.05-5.8]) were found as the predictors of primary composite outcome. In the figure 1, comparison of primary outcome according to FFS and plasma exchange status was given.
Conclusion: In real-life plasma exchange did not have a positive impact on the composite index of mortality and ESRD, similar to PEXIVAS trial. Presence of combined severe renal and pulmonary involvement was the predictor of worse outcome at 1-year and overall follow-up.

Background: A nailfold capillaroscopy procedure is a non-invasive, low-cost, and well-established examination that can be used to diagnose several rheumatic autoimmune diseases and support the necessary follow-up of patients. There are two main elements to nailfold capillaroscopy: image acquisition and image interpretation. Both of these can present challenges: we need to ensure that the best possible images are captured, and we need to define the enlarged capillaries, capillary loss and pericapillary hemorrhages objectively. We introduce Capillary.io, an automatic image reading system able to recognize capillaries in images obtained with any microscope, generate automatic measurements of each capillary and take advantage of this information to report capillary morphology. Together it allows a comprehensive analysis that is capable of producing detailed reports for each patient.
Objectives: The primary outcome was general sensitivity and specificity, using images assessed by expert capillaroscopists as the gold standard.
Methods: 6500 images previously analyzed by capillaroscopists from GREC were compared with Capillary.io. Capillary morphology (enlarged capillaries, tortuosities, ramifications, megacapillaries, hemorrhages) of each of the capillaries contained in each of the images was analyzed manually by at least one expert capillaroscopist. Subsequently, the automatic image interpretation system was used to fully automatically analyze each of the capillaries contained in each image and the results obtained were compared.
Results: Overall, a total of 78.347 capillaries were compared, of which 47.734 were normal capillaries, 21.991 enlarged capillaries, 2672 megacapillaries, 8512 tortuosities, 1322 ramifications and 5149 hemorrhages. Capillary.io was able to detect 38.101 normal capillaries, 19.126 enlarged capillaries, 2389 megacapillaries, 5698 tortuosities, 718 ramifications and 3706 hemorraghes.

Capillary.io presented a sensitivity (S) of 79.82% and a specificity (E) of 82% in the recognition of normal capillaries. The automatized system was able to recognize enlarged capillaries with a sensitivity of 86.97% and a specificity of 81.38%. Megacapillaries were detected with 89.41% sensitivity and 78.75% specificity. Similarly, the system was able to detect tortuosities (S 66.94%; E 67.71%), ramifications (S 54.34%; E 58.61%) and hemorrhages (S 71.36; E 73.97%).

Conclusion: Capillary.io is a simple, easy-learning web-based system to get interpretation of nailfold capillaroscopic images. It may be a very useful tool to standardize the interpretation of capillaroscopic pictures and could provide great research in that field.

POS0257 TOWARDS A SIMPLIFIED FLUID-SENSITIVE MRI-PROTOCOL IN SMALL JOINTS OF THE HAND IN EARLY ARTHRITIS PATIENTS: RELIABILITY BETWEEN MDIXON AND REGULAR FSE FAT SATURATION MRI-SEQUENCES

E. Niemantsverdriet[1], M. Verstappen[1], F. Wouters[1], M. Reijnierse[2], H. Bloem[2], A. Van der Helm - van Mil[1]. *[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; *[2]Leiden University Medical Center, Radiology, Leiden, Netherlands*

Background: MRI facilitates early recognition of rheumatoid arthritis (RA) by depicting inflammation. Contrast-enhanced T1-weighted and T2-weighted fat-suppressed sequences have been sensitive and thus recommended, but are hampered by invasiveness, costs and long scan time. Therefore we introduced a modified Dixon-sequence (mDixon) which is more patient-friendly, reduces cost, and scan times by 83%. However, it is not known if this mDixon-sequence is reliable in relation to regular MRI-sequences with and without contrast (T1- and T2-weighted, respectively).

Objectives: We determined the reliability between regular MRI-sequences with and without contrast (T1- and T2-weighted, respectively) and mDixon-MRI in early arthritis patients.

Methods: 29 early arthritis patients underwent regular fat-suppressed-MRI (T1- and T2-weighted) and mDixon-sequences, of metacarpophalangeal-2-5 and wrist-joints. Two readers scored erosions, osteitis, synovitis and tenosynovitis. Intraclass correlation coefficients (ICCs) between readers, and comparing the two sequences, were studied. Spearman correlations were determined.

Results: Performance between the two readers with the regular-MRI sequences, was good to excellent (ICCs all ≥0.88). The between reader ICC was also good to excellent for the mDixon-MRI (ICCs all ≥0.76). Next, ICCs between the two sequences was investigated to determine the reliability of mDixon. ICCs were good to excellent for total RAMRIS score 0.87 (95%CI 0.74-0.94), for erosions 0.88 (95%CI 0.69-0.95), and total inflammation score 0.84 (95%CI 0.69-0.82). The individual MRI-inflammation scores, had ICCs for osteitis 0.97 (95%CI 0.93-0.98), for tenosynovitis 0.78 (95%CI 0.58-0.89), and for synovitis 0.57 (95%CI 0.26-0.77). In addition, scores were highly correlated for total RAMRIS, erosions, and total MRI-inflammation score (ρ=0.82, ρ=0.81, ρ=0.80, respectively).

Conclusion: Regular-MRI sequences and mDixon-MRI perform equally well, this suggests that mDixon-sequence is reliable to detect joint inflammation. Thus, this is the first step towards an simplified and abridged MRI-protocol in small hand-joints in early arthritis patients. The ultimate goal will be implementation of this mDixon-MRI sequence. Validation in larger studies is warranted.

POS0258 REAL-TIME VERSUS STATIC SCORING IN MUSCULOSKELETAL ULTRASONOGRAPHY IN PATIENTS WITH INFLAMMATORY HAND OSTEOARTHRITIS

L. Van de Stadt[1], F. Kroon[1], M. Reijnierse[2], D. Van der Heijde[1], F. Rosendaal[3], N. Riyazi[4], R. De Slegte[5], J. Van Zeben[6], C. Allaart[1], M. Kloppenburg[1], M. Kortekaas[1]. *[1]Leiden University Medical Center (LUMC), Reumatology, Leiden, Netherlands*; *[2]Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands*; *[3]Leiden University Medical Center (LUMC), Clinical Epidemiology, Leiden, Netherlands*; *[4]Haga Hospital, Reumatology, The Hague, Netherlands*; *[5]Reade, Radiology, Amsterdam, Netherlands*; *[6]Sint Franciscus Vlietland Groep, Reumatology, Rotterdam, Netherlands*

Background: Ultrasound (US) is used in rheumatic musculoskeletal diseases (RMDs) such as hand osteoarthritis (OA) as outcome measure. Traditionally scoring is performed real-time, but central reading of static US images could avoid issues of inter-rater reliability. However, agreement between real-time and static assessment has not been studied

Objectives: To study the agreement between real-time and static scoring of US in inflammatory hand OA.

Methods: Ultrasound was performed of 30 joints obtained in 75 patients with hand osteoarthritis, treated with prednisolone or placebo in a randomized double-blind trial. Hand joints were assessed for synovial thickening, effusion, Doppler signal and osteophytes by ultrasound (score 0-3 per joint) at baseline and after treatment. Two ultrasonographers blinded for clinical data scored the live images together (simultaneously) in real-time. A consensus score for each joint was recorded. Representative images stored during scanning were scored by one ultrasonographer minimally 6 months after real-time scoring. For each patient, images of each visit were scored paired, with known chronological order. Agreement between scoring methods was studied at joint level with quadratic weighted kappa. At patient level, intra-class correlations (ICC; mixed effect model, absolute agreement, with clustering taken into account) were calculated at both timepoints. ICCs were also calculated for the delta of sum scores. Responsiveness of scoring methods was analyzed with generalized estimating equations (GEE) with treatment as independent and ultrasonography findings as dependent variable.

Results: Thirty-nine patients (52%) were treated with prednisolone and 36 (48%) were treated with placebo. Patient characteristics were well-balanced between treatment groups.

All patients had signs of synovial thickening and osteophytes as assessed by real-time ultrasonography, and almost all signs of effusion (99%) or a positive Doppler signal (95%) in at least one joint. Total ultrasonography sum score for osteophytes was high (mean 45 ±SD 12), whereas sum score was low for positive Doppler signal (mean 5.9 ±SD 4.4), with intermediate sum scores for synovial thickening and effusion (mean 16 ±SD 6.3 and 11 ±SD 6.0 respectively). Static sum scores were overall slightly higher (osteophytes mean 48 ±SD 10; Doppler mean 6.9 S±D 5.0; synovial thickening mean 20 ±SD 7.0 and effusion 13 ±SD 6.5)

Agreement at baseline was good to excellent at joint level (kappa 0.72-0.88) and moderate to excellent at patient level (ICC 0.59-0.86). Agreement for delta sum scores was poor to fair for synovial thickening and effusion (ICC 0.18 and 0.34 respectively), but excellent for Doppler signal (ICC 0.80) (Table 1).

Real-time ultrasonography showed responsiveness to prednisolone with a mean between-group difference of synovial thickening sum score of -2.5 (CI:-4.7 to-0.3). Static ultrasonography did not show a decrease in synovial thickening (Figure 1). No difference in ultrasonography scores was seen for the other ultrasonography features, neither with real-time nor static scoring.

Conclusion: While cross-sectional agreement between real-time and static ultrasonography was good, agreement of delta sum scores was not and paired static ultrasonography measurement of synovial thickening did not show responsiveness to prednisone therapy where real-time ultrasonography did. Therefore, when using ultrasonography in clinical trials, real-time dynamic scoring should remain the standard.

Table 1. Agreement on patient level

	Baseline	Week 6	Delta W6-BL
	ICC (95% CI)	ICC (95% CI)	ICC (95% CI)
Synovitis	0.59 (0.26-0.76)	0.58 (0.24-0.77)	0.18 (0 - 0.40)
Effusion	0.84 (0.66-0.92)	0.84 (0.75-0.89)	0.34 (0.12-0.53)
Osteophytes	0.82 (0.50-0.92)	0.78 (0.56-0.88)	ND
Doppler	0.86 (0.75-0.92)	0.91 (0.85-0.94)	0.80 (0.70 -0.87)

ICC: intra-class correlation coefficient linear mixed model (random patient, fixed rating), absolute agreement. ND: Not Dertermined

POS0259 ULTRASOUND AS AN IMAGING BIOMARKER OF EARLY RESPONSE TO TOCILIZUMAB AND METHOTREXATE IN VERY EARLY RHEUMATOID ARTHRITIS, TOVERA – A LONGITUDINAL STUDY

M. Stoenoiu[1,2], M. Maruseac[1], M. Messaoudi[1], A. Nzeusseu Toukap[1,2], E. Naredo[3]. *[1]Cliniques Universitaires Saint-Luc, Department of Rheumatology, Brussels, Belgium*; *[2]Institut de recherche expérimentale et cliniques (IREC), Department of Rheumatology, Brussels, Belgium*; *[3]Joint and Bone Research Unit. Hospital Universitario Fundación Jiménez Díaz, IIS Fundación Jiménez Díaz and Universidad Autónoma de Madrid., Department of Rheumatology, Madrid, Spain*

Background: The combination of methotrexate (MTX) and tocilizumab (TCZ) has been proven to be superior to MTX alone in early rheumatoid arthritis (RA)[1] and was able to prevent radiographic progression. Ultrasound (US) has become a valid imaging modality in managing RA. Together with clinical examination, US may allow a comprehensive monitoring of response to therapy. So far, few data are available concerning the early response to TCZ plus MTX in very early RA (VERA).

Objectives: In this study we aimed to assess the early US response to TCZ plus MTX in VERA, DMARD-naïve patients.

Methods: In this open-label, single-arm study, VERA patients received TCZ (162 mg/week, subcutaneously) and MTX (15-20 mg/week, *per os*) for 24 weeks as induction therapy, followed by MTX as maintenance therapy. RA was diagnosed according to the 2010 ACR/European league against rheumatism (EULAR) criteria. All patients who fulfilled the inclusion criteria (ClinicalTrials.gov: NCT02837146) underwent blood tests, clinical and ultrasound examinations at the predefined time-points: 0,2,4,8,12,24,32,48,54 weeks (w). Ultrasound examination of 34 joints (elbows, wrists, MCP [1-5, bilateral], PIP ([2-5, bilateral], knees, ankles and MTP [2-5, bilateral]) was performed blindly to clinical data. Gray-scale (GS), power-Doppler (PD) scores, and the global *OMERACT*-EULAR synovitis score (*GLOESS*) were assessed in each joint. The sum of individual scores was calculated for 17-joint score (JS) (whole joint set), 10-JS (wrists, MCP, ankles and MTP joints), 12-JS[2], and 7-JS[3].

Results: Forty-four patients (77% women), aged 46.7 ± 12.4 years, completed the 24-week period. Two-thirds (72.7%) were positive for anti-citrullinated protein antibody (ACPA) and 18.2% had bone erosions. At baseline, the mean 28 swollen joints count (28-SJC) was 7.55± 4.5, mean disease activity score (DAS28)-CRP score was 5.2 ± 0.15, mean simplified clinical activity score (SDAI) was 31.4 ± 1.9, mean clinical activity score (CDAI) was 29.1 ± 1.8 and mean health assessments questionnaire (HAQ) score was 1.3 ± 0.1. The C-reactive protein (CRP) decreased significantly at 2w ($p<0.05$) and, accordingly DAS28-CRP score decreased significantly at 4w ($p<0.05$). The 28-SJC and CDAI scores decreased significantly at 8w ($p<0.05$). The HAQ and visual analogue scale (VAS) disease activity reported by patients decreased significantly at 8w ($p<0.05$) and VAS fatigue at 12w ($p<0.05$).

The GLOESS and GS scores allowed us detecting the earliest significant treatment response at 2w and PD scores at 4w ($p<0.05$). Among US joint subsets, 17-JS ($p<0.01$), 12-JS ($p<0.05$) and 10-JS ($p<0.05$) were able to detect the earliest treatment response at 2w. The 7-joint score detected the earliest response at 4w, both in GS and PD ($p<0.05$).

Conclusion: US scores were able to detect therapeutic response to TCZ plus MTX earlier than clinical scores and may therefore be a promising imaging biomarker.

POS0260 ULTRASOUND ASSESSMENT OF HANDS AND FEET FOR SYNOVITIS PRIOR TO FIRST CLINICAL VISIT MARKEDLY REDUCES TIME TO DIAGNOSIS - EXPERIENCE FROM ROUTINE CARE

M. Ammitzbøll Danielsen[1], U. Møller Døhn[1], V. Fana[1], T. Møller[1], S. N. Ng[1,2], A. E. Secher[1], J. J. Lykkegaard[1], L. Terslev[1]. *[1]Rigshospitalet, Center for Rheumatology and Spine Diseases, Glostrup, Denmark*; *[2]Private Practise, Rheumatology, Hong Kong, China*

Background: All patients referred to our Rheumatology department suspected of having arthritis are scheduled for a visit in the out-patient fast track clinic (FTC) for arthritis. Routine blood samples including C-reactive protein (CRP), anti-CCP, IgM RF, and x-ray of hands and feet are available at the first clinical visit where the medical history and clinical examination is obtained by rheumatologists or rheumatologists-in-training under supervision. The role of ultrasound (US) in routine care for diagnosing arthritis is not fully elucidated but US is more sensitive than clinical joint examination for detecting synovitis. Therefore, US may facilitate diagnosis of arthritis.

Objectives: To assess whether US examinations of hands and feet in relation to the first clinical visit impact the time to diagnosis and number of clinical visits needed.

Methods: From Oct. 2017 to June 2018, US examination of hands and feet (wrist, metacarpophalangeal and proximal interphalangeal joints, ankle, and metatarsophalangeal joints) were performed prior to the first clinical visit by ultrasound-experienced rheumatologists. Using the OMERACT scoring system for grey-scale (GS) and Doppler, synovitis was defined as GS score >1 with or without Doppler score ≥1. Examination time was 20 minutes.

Time from the first clinical visit to the final clinical diagnosis and the number of clinical visits needed in the FTC was assessed and compared to a similar patient cohort the previous year (Nov. 2016 to June 2017) where ultrasound was performed ad hoc. Number of revised diagnoses and the number of patients re-referred after 12 months was noted. Local ethics committee ruled that approval was not needed.

Results: From 2017- 2018, 163 referred patients had US prior to first clinical visit. 76(47%) were diagnosed with inflammatory arthritis (IA), 12(7%) with crystal-related arthritis, 39(24%) with other Rheumatic Diseases (RMDs) and 36(22%) with no RMD diagnosis. The comparative cohort comprised of 109 patients of whom 29(27%) were diagnosed with IA, 16 (15%) with crystal-related arthritis, 31(28%) with other RMDs and 33 (30%) with no RMD diagnosis. Adding US to the first clinical visit reduced the time to diagnosis from mean 31 (standard deviation(SD) ±32.2) days to mean 12 (±17.3) days. The number of clinical visits needed was reduced from mean 2.8(±1.1) to 2.1 (±1.3) corresponding to a reduction of 114 visits in the period from 2017–2018. The mean number of all US examinations in the FTC was 1.1 (±0.3) in the US cohort versus 0.8(±0.7) in the comparative cohort. In the US cohort vs. comparative cohort 8 (4.9%) vs. 17

(15.7%) patients had a revised diagnosis at 1 year-follow-up, and 7 (4%) vs. 12 (11%) were re-referred, respectively. For demographics, clinical, US, and laboratory characteristics see Table 1 where median values and inter-quartile range (IQR) for all parameters.

Conclusion: Adding routine US examination to the first clinical visit reduces time to diagnosis markedly, lowers the number of clinical visits needed thereby reducing the time patients spent away from work, and freeing time for visits in the FTC to be used for other patients

Table 1.

		Comparative cohort		US cohort		P

POS0261 DIAGNOSTIC PERFORMANCE AND CLINICAL UTILITY OF TWO REFERRAL RULES FOR INFLAMMATORY ARTHRITIS

E. Van Delft[1], D. Lopes Barreto[1], A. Van der Helm - van Mil[2,3], C. Alves[4], J. Hazes[3], M. Kuijper[1], A. Weel[1,5]. *[1]Maasstad Hospital, Rheumatology, Rotterdam, Netherlands*; *[2]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[3]Erasmus MC, Rheumatology, Rotterdam, Netherlands*; *[4]ZGT Almelo, Rheumatology, Almelo, Netherlands*; *[5]Erasmus University Rotterdam, Health Technology Assessment, Rotterdam, Netherlands*

Background: The Rotterdam Early Arthritis Cohort (REACH) rule [1] and Clinical Arthritis RulE (CARE) [2] are both evidence-based and easy-to-use methods developed to identify the presence of inflammatory arthritis (IA) in patients suspected by their general practitioner (GP). However, the clinical utility of both models in daily clinical practice in an independent primary care setting has not yet been established. While developed for recognizing IA, we believe that it is also important that the broader spectrum of inflammatory rheumatic diseases (IRDs) is correctly classified from primary care, to facilitate appropriate referral towards outpatient rheumatology clinics.

Objectives: The primary objective was to determine the diagnostic performance and clinical utility of the REACH and CARE referral rules in identifying IA in an independent population of unselected suspected patients from primary care. Secondly we will assess the diagnostic performance and clinical utility of both models in identifying IRDs.

Methods: This prospective observational diagnostic study consisted of adults newly suspected by their GP for the need of referral to the rheumatology outpatient clinic of the Maasstad Hospital in Rotterdam. Primary outcome was IA, consisting of rheumatoid arthritis, axial spondylitis and psoriatic arthritis. Secondary outcome was IRD, defined as IA plus arthritis in systemic disorders such as systemic lupus erythematosus, systemic sclerosis and morbus sjögren. Rheumatologist diagnosis was used as gold standard. To evaluate the clinical performance of the REACH and CARE referral rules in this population, diagnostic accuracy measures were investigated using the Youden index (J) [3]. Moreover, a net benefit approach [4] was used to determine clinical utility of both rules when compared to usual care.

Results: This study consisted of 250 patients (22.8% male) with a mean age of 50.8 years (SD 13.9 years). In total 42 (17%) patients were diagnosed with IA and 55 (22%) with an IRD. Figure 1 presents the diagnostic performance in IA (Figure 1A) and in IRD (Figure 1B). For the primary outcome, the REACH model shows an AUC of 0.72 (95% CI 0.64-0.80) and the optimal cut-off point is indicated (J). The CARE model shows an AUC of 0.82 (95% CI 0.75-0.88) and at J there is a somewhat higher sensitivity and specificity. When taking the broader spectrum of IRDs as outcome, the AUC was 0.66 (95% CI 0.58-0.74) for the REACH and 0.76 (95% CI 0.69-0.83) for the CARE model. The net benefit analysis with either IA or IRD as outcome showed that the CARE was of the highest clinical value when compared to usual care.

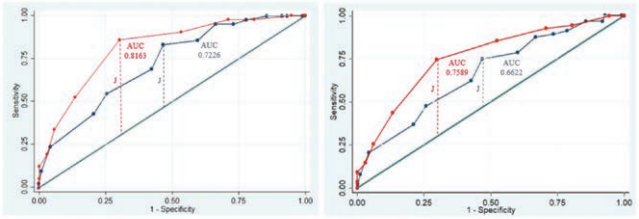

Figure 1: ROC curves; blue lines indicating the REACH model and red lines indicating the CARE model

Conclusion: Both the REACH and CARE model showed a good diagnostic performance for detecting IA in an independent population of unselected suspected patients from primary care. Although not specifically developed to recognize the entire spectrum of IRDs, the CARE shows a good performance in doing so. When evaluating clinical utility, we see that both rules have a net benefit in recognizing IA as well as IRDs compared to usual care, however the CARE shows superiority over the REACH. By using the CARE, over half of all suspected patients can be withheld from expensive outpatient rheumatology care, implied by the high specificity of 70%. These results support the idea that incorporating these easy-to-use methods into primary care could lead to providing patients the right care at the right place and improving value based health care.

POS0262 IDENTIFYING EROSIVE DISEASE FROM RADIOLOGY REPORTS OF VETERANS WITH INFLAMMATORY ARTHRITIS USING NATURAL LANGUAGE PROCESSING

G. Penmetsa[1], S. Pei[1], B. Sauer[1,1], J. A. Walsh[1], B. Feng[2], J. Walker[3], K. Douglas[3], J. Clewell[3]. *[1]1Salt Lake City Veterans Affairs & University of Utah Health., Internal Medicine, Salt Lake City, United States of America*; *[2]University of utah, Dermatology, Salt Lake City, United States of America*; *[3]Abbvie, pharmacy, Salt Lake City, United States of America*

Background: The presence of erosive disease influences diagnosis, management, and prognosis in inflammatory arthritis (IA).Research of IA in large datasets is limited by a lack of methods for identifying erosions.

Objectives: To develop methods for identifying articular erosions in radiology reports from veterans with IA.

Methods: Included veterans had ≥2 ICD codes for ankylosing spondylitis (AS), psoriatic arthritis (PsA), or rheumatoid arthritis (RA) between 2005- 2019, in Veterans Affairs Corporate Data Warehouse. Chart review & annotation of radiology notes produced the reference standard, & identified erosion terms that informed classification rule development. A rule-based natural language processing (NLP) model was created & revised in training snippets. The NLP method was validated in an independent reference sample of IA patients at the snippet & patient levels

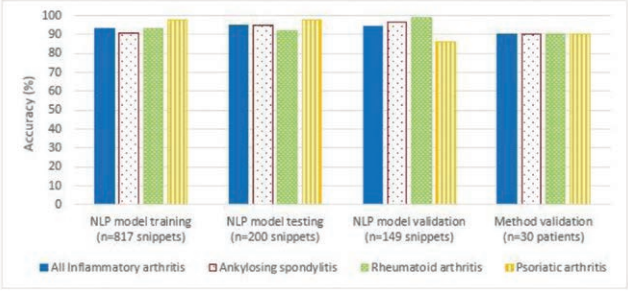
Method development

Step	Description	Number & example
1 Radiology notes		
	a.Select note titles potentially relevant to IA	a. 35,141 notes titles
	b.Extract notes with titles potentially related to IA	b. 2,926,113 radiology notes
2 Possible meaningful terms		
	a.Compile list of root terms that may indicate erosion	a. 11 root terms (i.e. ero*, pencil*cup, irreg*)
	b.Query radiology notes for root term variations	b. 1178 variations (i.e. erosion, erotic, erode)
	c.Select possible meaningful terms	c. 179 possible terms (i.e. erosion, erode)
3 Annotation		
	a.Extract snippets^ containing possible meaningful terms	a.5000 snippets from radiology notes
	b.Classify snippets according to: 1) Meaningful term, 2) Relevance to joint, 3) Attribution to IA, 4) Affirmation	b.4068 classifications with 1017 snippets (in rounds of 50-417 snippets for NLP training & testing)
4 Rule development		
	a.Identify meaningful terms representing erosion	a. 6 terms (pencil * cup, erosion, erosive, etc.)
	b.Exclude erosive processes irrelevant to joint(s)	b. 28 irrelevant processes (i.e. gastric erosion)
	c. Exclude articular erosive processes not attributed to IA	c. 5 non-IA processes IA (i.e. infection)
	d. Classify as affirmed/negated (erosion present/absent)	d. 83 affirmation/negation rules
5 NLP training	Design & revise NLP model until accuracy ≥90%	6 rounds, 817 snippets (AS 417, RA 200, PsA 200)
6 NLP testing	Test NLP model	200 snippets (AS 100, RA 50, PsA 50)
7 Pt classification		
	a. Develop rules for classifying pts with discordant snippets	a. 5 rules developed in 368 pts
	b. Build reference sample (pts classified as erosive or non-erosive via chart review)	b. 30 IA pts (10 AS, 10 RA, 10 PsA)
8 NLP validation	Validate NLP model in reference sample at snippet level	149 snippets (29 AS, 76 RA, 44 PsA)
9 Method validation	Validate methods (NLP+pt classification) at pt level	30 IA pts (reference sample)

pt= patient. ^Snippets include text containing 30 words before & after meaningful terms

Results: In 168,667 veterans with IA, the mean age was 63.1 & 90.3% were male. Method development involved radiology note & erosion term selection, rule development, NLP model building, & method validation. The NLP model accuracy was 94.6% at the snippet level & 90.0% at the patient level, for all IA patients.

Accuracy of methods.



Conclusion: The methods accurately identify erosions from radiology reports of veterans with IA. They may facilitate a broad range of research involving cohort identification & disease severity stratification

POS0263 CLINICAL RELEVANCE OF DFS70 ANTIBODIES – A MULTICENTRE STUDY

A. S. Pinto[1], J. P. Vilas[2], F. Cunha Santos[1,3], M. Cunha[4], B. Samões[5], A. Eduarda Porto Raposo[6], P. Abreu[7], E. Costa[8], N. Madeira[9], J. F. Ferreira[1,10], C. Vaz[1,10]. *[1]Unidade Local de Saúde da Guarda, Serviço de Reumatologia, Guarda, Portugal*; *[2]Baixo Vouga Hospital Centre, Rheumatology Department, Aveiro, Portugal*; *[3]University Hospital Centre of Coimbra, Rheumatology Department, Coimbra, Portugal*; *[4]Garcia de Orta Hospital, Rheumatology Department, Almada, Portugal*; *[5]Vila Nova de Gaia/Espinho Hospital Centre, Rheumatology Department, Vila Nova de Gaia, Portugal*; *[6]Trás-Os-Montes e Alto Douro Hospital Centre, Rheumatology Department, Vila Real, Portugal*; *[7]Local Health Unit of Castelo Branco, Rheumatology Department, Castelo Branco, Portugal*; *[8]Hospital of Braga, Rheumatology Department, Braga, Portugal*; *[9]Portuguese Institute of Rheumatology, Rheumatology Department, Lisboa, Portugal*; *[10]Beira Interior University, Faculty of Health Sciences, Covilhã, Portugal*

Background: Anti-Dense Fine Speckled 70 (DFS70), also known as lens epithelium-derived growth factor (LEDGF) is a common finding when ANA are positive (1.7% in the whole population and 4.6% in the ANA-positive samples). DFS70 antibodies are rare in SARD, especially in the absence of clinical evidence or concomitant anti-extractable nuclear antigen (ENA) antibodies.

Objectives: Our study aimed to understand the meaning of anti-DFS70 antibodies and characterize the clinical and serological features of patients with anti-DFS70 positivity.

Methods: We performed a retrospective observational study of consecutive patients followed up at 9 Portuguese Rheumatology Centres observed from January 2018 until April of 2020 with anti-DFS70 antibodies positivity. Descriptive statistics were presented as mean ± standard deviation if normally distributed or as median and interquartile range if non-normally distributed (continuous variables) or as absolute and relative frequencies (categorical variables). Sensibility and specificity were calculated. Positive and negative predictive values were calculated between patients with and without SARD-specific autoantibodies. Associations between DFS70 with other disease-specific antibody and clinical manifestations were tested using Chi-Square or Fischer's Exact Test, as appropriate.

Results: 120 patients were included, 99 (82.5%) were female with a mean age of 47.8 ± 18.2 years. 96.7% of the patients had ANA titers ≥1:160 (32.5% 1:160; 38.3% 1:320; 16.7% 1:640; 7.5% 1:1280 and 1.7% 1:2560) and 3.3% ANA <1:160.

The main clinical reasons for ANA determination was arthralgia (44.2%), arthritis (11.6%) and Raynaud Phenomenon (RP) (10%). The main analytical reason (7.5%) was an elevation of inflammatory parameters (C-Reactive Protein (CRP) or Erythrocyte Sedimentation Rate (ESR), leukopenia (3.3%) and anaemia (2.5%). Concerning the immunology: 58.3% of patients didn´t have an associated antibody, 9.2% had a positive rheumatoid factor, 5.8% positive ds-DNA, 4.2% histone and 3.3% SS-A. 26 patients had more than one associated antibody.

30 (25%) patients were healthy; 43 (35.8%) patients had Systemic Autoimmune Rheumatic Diseases (SARD) and 47 patients (39.2%) had other diseases (non-SARD). Among patients with a SARD, 16 patients presented an isolated positive anti-DFS70 and 27 patients had other antibodies associated. There was found a positive association with non-SARD and arthralgia (p=0.001) and SARD with arthritis (p<0.001). There was an association with SARD and raised inflammatory parameters (p=0.045), but no association was found with anaemia (p=1.000) or leukopenia (p=0.131). Comparative analysis is described in Table 1, with chi-square or Fischer tests, as appropriated.

The sensitivity of isolated DFS70 was 70.1% and specificity was 62.8%. The positive predictive value was 77.1% and the negative predictive value was 54.0%.

Table 1. Comparative analysis using chi-square or Fischer test

	SARD	Non-SARD	p-value
Arthralgia, n	10	43	0.001
Arthritis, n	14	0	<0.001
Raynaud Phenomenon, n	7	5	0.114
Raised Inflammation parameters, n	6	3	0.045
Anaemia, n	1	2	1.000
Leukopenia, n	3	1	0.131

Conclusion: We concluded that 64.2% of patients with positive DFS70 did not present a SARD and if we only consider patients with isolated anti-DFS70, 77.1% didn´t present a SARD. Therefore, in our study, 22.9% of the patients presented a SARD, which was associated with some clinical features like arthritis or raised inflammatory parameters (p<0.05). Although isolated anti-DFS70 are not specific of a particular condition, our study supports that it can be used as a negative predictor of SARD, if a correlation with clinical and laboratory features is made.

POS0264 THE EMERGING ROLE OF MAGNETIC RESONANCE IMAGING IN INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS: EVIDENCE FOR ULTRA SHORT TE AND COMPRESSED SENSING VIBE ACQUISITIONS AS PROMISING TOOLS FOR THE EVALUATION OF PARENCHYMAL ALTERATIONS

N. Landini[1], M. Orlandi[2], M. Occhipinti[3], C. Nardi[3], L. Tofani[2], S. Bellando-Randone[2], C. Bruni[2], M. Matucci-Cerinic[2], G. Morana[1], S. Colagrande[3]. *[1]Ca' Foncello General Hospital, Department of Radiology, Treviso, Italy*; *[2]University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy*; *[3]University of Florence-Azienda Ospedaliero-Universitaria Careggi, Department of Experimental and Clinical Biomedical Sciences, Florence, Italy*

Background: Interstitial lung disease (ILD) is a frequent complication and the major cause of death in Systemic sclerosis (SSc). Computed tomography (CT) is the gold standard imaging technique to assess ILD but is burdened by exposure to ionizing radiations that limits its use for the follow-up. MRI sequences with Ultra Short Echo Time (UTE) are promising for ILD.

Objectives: We tested two MRI sequences, UTE Spiral VIBE and Compressing Sensing (CS) VIBE, in SSc-ILD, in comparison to chest CT.

Methods: SSc patients with suspected-ascertained ILD were evaluated for undergoing CT-MRI examinations in the same day. Two radiologists visually scored the extent of ground glass opacities (GGO), reticulations, honeycombing and consolidations on CT-MRI. The sum of alteration was assumed as ILD extent. A quantitative texture analysis (qCT) was also performed on CT. Cohen's k was adopted for interreader concordance in ILD detection. MRI sensitivity and specificity in ILD detection were evaluated. Lin's concordance was adopted to compare extent analysis between readers and between CT (visual and qCT analysis) and MRI sequences.

Results: 54 patients performed both CT and MRI. MRI interreader concordance was moderate in ILD detection, while ILD and GGO extent analysis showed good or very good concordance. UTE Spiral VIBE had a sensitivity and specificity in ILD detection of 95.8% and 77.8%, while alterations extent analysis obtained a very good concordance with CT for ILD and GGO. CS VIBE showed a sensitivity and specificity in ILD detection of 46.7% and 95.0%, but a slight or fair concordance with CT in all alterations' extent analysis.

Conclusion: MRI UTE Spiral VIBE sequences are helpful in the evaluation of SSc-ILD. Larger cohorts of patients will be needed to confirm that MRI may be useful in clinical practice, reducing the radiological load of chest CT

POS0265 CLINICAL AND ULTRASONOGRAPHIC ENTHESITIS IN INFLAMMATORY BOWEL DISEASE WITH AND WITHOUT PSORIASIS

G. Citriniti[1], A. Soriano[2], E. Bertolini[2], G. Sandri[3], A. Bertani[4], I. Tinazzi[5], F. Martinis[1], N. Girolimetto[1], C. Salvarani[1,3], M. Beltrami[2], P. Macchioni[1]. *[1]AUSL-IRCCS Reggio Emilia, Rheumatology Department, Reggio Emilia, Italy*; *[2]AUSL-IRCCS Reggio Emilia, Medicine department, IBD Unit, Reggio Emilia, Italy*; *[3]Rheumatology Unit, University of Modena & Reggio Emilia, Rheumatology Department, Modena, Italy*; *[4]University of Modena & Reggio Emilia, Gastroenterology Department, IBD Unit, Modena, Italy*; *[5]Sacro Cuore Don Calabria Hospital, Negrar, Verona, Italy, Rheumatology Unit, Negrar, Italy*

Background: Previous studies have reported an association between psoriasis (PsO) and inflammatory bowel disease (IBD). Coexistence of IBD and PsO has been associated with significant higher prevalence of enthesitis and dactylitis[1].

Objectives: To compare the prevalence of clinical and ultrasonographic peripheral enthesis abnormalities in a consecutive series of patients with IBD and psoriasis (PsO) as compared to a group of IBD patients without psoriasis (IBD).

Methods: One-hundred seventy-four IBD consecutive patients [36 PsO and 138 IBD, M/F 91/83, mean age 42.6±14.7 years, mean disease duration 110 ±12.3 months] entered the study. A complete clinical examination, including rheumatological history, 66/68 peripheral joint count, MASES and LEI scores, BASDAI, and dactylitis count, was performed at study entry. Laboratory test (ESR, CRP, Hb, fecal calprotectin) were collected. Axial or peripheral SpA diagnosis was made using ASAS criteria [2].

US examination was executed by a rheumatologist blind to clinical data, using an Esaote MyLabClass, 18-6MHz linear multifrequence transducer both in B-mode and PD-mode. The following sites were examined bilaterally: lateral epicondyle of the humerus, distal quadriceps femoris insertion into the patella, inferior pole of the patella, tibial distal insertion of the patellar tendon, calcaneal insertion of the Achilles tendon, and plantar aponeurosis insertion. Knee and ankle joints were evaluated for synovial hypertrophy, PD signal and fluid effusion. Enthesitis was defined according to OMERACT [3] and scored as 0-36 for GUESS and 0-136 for MASEI.

Results: PsO patients had later IBD onset (mean age 39±14.7 vs 33 ± 13.2 in IBD group, p=0.02). There weren't observed any significant differences in IBD duration and Crohn/UC prevalence.

No significant difference between the two groups in rheumatological history and clinical examination was detected, except for familiar history of psoriasis (PsO 44% vs IBD 16%, p <0.001). Prevalence of SpA was 33,3% in PsO group and 37% in IBD group (p = 0.687).

146 patients (83.4%) showed structural damage at ≥ 1 enthesis, 44 patients (25%) had at least 1 active enthesitis, with no significant difference between the two groups. PsO group showcased a significantly increased prevalence of patients having ≥ 1 thickened enthesis (86.1% vs 63.9%, p=0.009) and of PD signal at knee examination (11.1% vs 2.2%, p= 0.034). Higher values of GUESS score were observed in PsO (8.1±5.1 vs 5.8±3.9, p=0.017). Enthesis hypoechogenicity was more prevalent in IBD group (27.5% vs 11.1%, p=0.049).

Enthesis thickness was significantly increased in PsO, in every examined site. Enthesophyte length was significantly increased in PsO group at quadriceps tendon, patellar distal insertion and Achilles tendon.

Conclusion: No differences in clinical manifestation and rheumatological history between IBD and PsO patients were observed. Subclinical (US) abnormalities were significantly increased in IBD patients with associated PsO, as compared to patients affected by IBD.

HPR - Understanding and measuring: expanding the toolbox

POS0266-HPR PATIENT-PERCEIVED ASPECTS OF RA FLARE EVOLVE OVER TIME, AS REFLECTED BY THE FLARE-RA QUESTIONNAIRE: POST-HOC ANALYSIS OF TAPERA

M. Doumen[1,2], S. Pazmino[1], D. Bertrand[1], D. De Cock[1], J. Joly[2], R. Westhovens[1,2], P. Verschueren[1,2]on behalf of the TapERA study group. *[1]KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium*; *[2]University Hospital Leuven, Rheumatology, Leuven, Belgium*

Background: Flares are common in rheumatoid arthritis (RA). While flares negatively impact clinical and patient-reported outcomes, different aspects of disease activity may constitute a flare to patients. Flare Assessment in RA (FLARE-RA) is a patient-reported questionnaire aiming to detect active or recent RA flares (1). During its validation, arthritis and general health subscales were identified and the instrument was adapted from 13 questions (1-6 Likert scale) to 11 questions (0-10).

Objectives: To investigate which patient-perceived aspects of flare are assessed by FLARE-RA in the context of a TNFi-tapering trial, using exploratory factor analysis (EFA).

Methods: Patients with RA in DAS28CRP/ESR-remission (≥6 months) and treated with etanercept 50 mg weekly (≥1 year) were included in the 12-month TapERA (Tapering Etanercept in Rheumatoid Arthritis) trial between 2012 and 2014. Participants completed 3-monthly FLARE-RA questionnaires.

The first and final follow-up visits (M3 & M12) were analyzed. Missing data were imputed with multiple imputation (n = 10). Sampling adequacy was assessed by Kaiser-Meyer-Olkin (KMO) and correlations between variables were evaluated with Bartlett's sphericity test. Spearman correlation matrices were constructed in each of the 10 imputed datasets. The pooled matrix was then analyzed by EFA with principal component extraction and promax-rotation. EFA aims to identify clusters of questions that elicit similar responses because of association with the same underlying latent (not observable) constructs/factors.

Results: Sixty-six patients (68% female) with a mean age of 55 years (SD 13) and a mean disease duration of 14.8 years (SD 9) completed a total of 330 FLARE-RA questionnaires. Sampling adequacy was acceptable (KMO = 0.94) and correlation between items was sufficient for factor analysis ($p < 0.001$).

Table 1 shows the results of EFA in TapERA compared to the validation study (1). Factor loadings indicate how strongly each item correlates with its underlying factor. EFA of the full 13-item FLARE-RA at M3 revealed 3 factors: Arthritis, General health and a Medication factor relating to management of flare. The Arthritis factor explained the largest proportion of variance (31%). EFA at M12 showed the same underlying factors, but a less robust factor structure (cross-loadings >0.3) and a larger proportion of variance explained by the General health factor (33%).

Conclusion: FLARE-RA assessed similar patient-perceived aspects of RA flare within the context of a TNFi-tapering trial when compared to the validation study, including a Medication factor reflecting use of both glucocorticoids and analgesics. This underlines the usefulness of FLARE-RA in providing a multi-faceted view of patients' conceptions of RA flare. However, these aspects and their relative importance do seem to evolve over time. Further research is needed to assess if this is due to the influence of time or specific to the studied population/tapering setting.

POS0267-HPR IDENTIFYING MEANINGFUL AND DETECTABLE CHANGE FROM THE PATIENT PERSPECTIVE ACROSS COMMON FATIGUE MEASURES IN RHEUMATOID ARTHRITIS

S. J. Bartlett[1,2], U. Haque3, V. Bykerk[4], J. R. Curtis[5], M. Jones[3], C. Bingham[3]. *[1]McGill University, Clinical Epidemiology & Rheumatology, Montreal, Canada*; *[2]Johns Hopkins Medicine, Rheumatology, Baltimore, United States of America*; *[2]Johns Hopkins Medicine, Rheumatology, Baltimore, United States of America*; *[4]Hospital for Special Surgery, Rheumatology, New York, United States of America*; *[5]University of Alabama at Birmingham, Rheumatology, Birmingham, United States of America*

Background: Different tools are commonly used to assess fatigue in RA including single items (visual analogue (VAS), numeric rating (NRS), and Likert scales), SF-36 Vitality, and PROMIS. Evidence is needed to identify scores that reflect meaningful change to patients to interpret fatigue results in trials and for clinical care.

Objectives: To use symptom-specific and RA change anchors to estimate meaningful and detectable change scores from the patient perspective across several fatigue measures.

Methods: Stable RA patients (ACR/EULAR 2010 criteria) were recruited from 3 academic clinical practices across the Southern, Mid-Atlantic, and Northeastern United States. Scales were administered at 2 consecutive visits to capture PROs including fatigue. We also asked a fatigue-specific change question (*How would*

you rate your fatigue since the last visit?). Response options were a lot better, *a little better, the same, a little worse, and a lot worse*. An RA disease activity change question followed a similar format. We compared mean change between visits across fatigue and RA change categories for the Fatigue NRS, Fatigue 5-point Likert (none to very severe), SF36 Vitality, and PROMIS Fatigue 4a, 7a, and 8a.

Results: The sample included 282 patients with stable RA who completed questionnaires 4.6 (SD 2.4) months apart. Patients were mostly white (78%) women (82%) with RA duration of 13 (11) years. At V1, most were in CDAI LDA (57%) or MDA (30%) with 5% in REM and 8% in HDA states. Using the Fatigue change anchor, 6% were *a lot better*, with mean change ranging from |1-11|points across scales (Table 1); among 13% *a little better*, smaller changes |0.4 to 5|were reported. Across all measures score changes for meaningful and minimal improvement were numerically larger for improvement than worsening.

	Fatigue Change Categories														
	Lot Better 6%			Little Better 13%			Same 49%			Little Worse 22%			Lot Worse 10%		
	N	Mean	SD	N	Mean	SD	N	Mean	SD	N	Mean	SD	N	Mean	SD
Fatigue 11 point NRS	19	-2.2	2.4	37	-0.7	2.3	137	-0.5	1.9	61	0.4	1.9	26	1.3	2.1
Fatigue 5-point Likert	19	-0.8	1.2	36	-0.4	1.2	137	0.0	0.9	60	0.2	0.9	27	0.6	1.2
SF36 Vitality (0-100)	19	11.2	16.1	36	4.9	13.7	137	0.3	10.6	59	-3.2	15.3	26	-11.4	16.6
PROMIS Fatigue 7a	19	-5.9	8.5	37	-2.6	7.5	138	0.0	6.4	62	-0.3	6.5	27	4.3	8.3
PROMIS Fatigue 8a	19	-6.1	10.2	37	-2.7	7.1	138	-0.3	7.1	62	1.3	6.9	27	5.6	11.0
PROMIS Fatigue 4a	19	-6.8	9.9	37	-3.3	8.2	138	-0.4	7.4	60	1.2	7.2	27	5.2	11.5

Using the RA change categories, more people rated their RA as at least *a little better* compared with fatigue (28% vs. 19%, respectively) at the second visit (Table 2). Similar patterns were evident across RA change categories, though score changes associated with improvement and worsening were about half those observed using fatigue change anchors.

	RA Disease Activity Change Categories														
	Lot Better 13%			Little Better 15%			Same 42%			Little Worse 21%			Lot Worse 9%		
	N	Mean	SD	N	Mean	SD	N	Mean	SD	N	Mean	SD	N	Mean	SD
Fatigue 11 point NRS	36	-0.8	2.3	43	-0.6	2.7	117	-0.2	1.9	58	-0.2	1.9	26	0.7	2.2
Fatigue 5-point Likert	35	-0.3	1.2	42	-0.3	1.1	118	0.1	1.0	58	0.1	0.8	26	0.3	1.3
SF36 Vitality (0-100)	35	6.4	17.4	43	3.8	13.0	117	-0.6	12.9	57	-3.7	11.3	25	-6.0	17.0
PROMIS Fatigue 7a	37	-1.6	9.5	43	-1.5	7.4	118	-0.3	7.0	59	0.5	5.6	26	1.3	7.5
PROMIS Fatigue 8a	37	-2.1	9.5	43	-1.7	9.0	118	0.1	7.6	59	0.7	4.8	26	3.0	11.4
PROMIS Fatigue 4a	36	-2.7	9.6	43	-2.3	9.0	118	0.1	8.1	59	0.4	5.6	25	2.6	12.0

Conclusion: The score change associated with meaningful improvement and worsening between visits on commonly used fatigue scales was much larger with fatigue vs. RA change categories. More people rated their RA improved as compared with fatigue at the 2nd visit. Symptom-specific anchors are likely to offer more relevant change scores associated with meaningful improvement and worsening than RA change anchors. These estimates offer new information about meaningful and detectable improvement and worsening on common measures for trialists, researchers, and clinicians monitoring fatigue in people with RA.

POS0268-HPR PATIENT-REPORTED ACTIVITY LIMITATIONS IN HIP AND KNEE OSTEOARTHRITIS IN PRIMARY CARE

T. Moseng[1], H. Solveig Dagfinrud[1], B. Natvig[2], N. Osteras[1]. [1]*Diakonhjemmet Hospital, National Advisory Unit on Rehabilitation in Rheumatology, Department of Rheumatology, Oslo, Norway*; [2]*University of Oslo, Institute of Health and Society, Department of General Practice, Oslo, Norway*

Background: To ensure delivery of high-quality osteoarthritis (OA) care, structured care models incorporating patient education and exercise are increasingly implemented in primary care [1]. A goal is to improve patients' physical function and coping with daily life demands and activities. Yet, there is limited knowledge regarding the type and severity of activity limitations experienced by people with hip and knee OA.

Objectives: 1) To map activity limitations reported by patients with hip and knee OA participating in a research study implementing an OA care model in primary care. 2) To investigate potential changes in self-reported difficulty performing these activities from baseline to 12-weeks follow-up.

Methods: A structured OA care model was implemented in six Norwegian municipalities between January 2015 and October 2017, using a stepped-wedge cluster-randomized controlled design. Implementation was facilitated by interactive workshops for general practitioners and physiotherapists (PTs). The PTs provided a 3-hour, group-based patient education program followed by individually tailored 8-12 weeks exercise with twice weekly 1-hour supervised group sessions. Patients with clinically or radiologically verified symptomatic hip or knee OA ≥45 years were eligible. Patients who received the new model of care completed the Patient-Specific Functional Scale (PSFS) at baseline by identifying between one and three "important activities that you are unable to do or are having difficulty with because of your hip or knee OA". The patients rated their performance of the reported activities on an 11-point numeric rating scale (NRS) ranging from 0 (unable to perform activity) to 10 (perform activity with no problems). After 12 weeks the patients re-rated their previously identified activities. The reported activities were linked to the International Classification of Functioning, Disability and Health (ICF) at Chapter and Domain (second and third) level. Absolute change in scores from baseline to follow-up was calculated as the mean score of the reported activities. Change from baseline to follow-up was investigated using paired samples t-test. P-value was set to <0.05. Clinically important change was regarded 2 points on the 0-10 scale.

Results: A total of 284 patients received the new model of care. The mean age was 63 (SD 10) years, and 211 (74%) were female. The main affected OA joint was the knee for 174 (61%), the hip for 100 (35%) and other joints (e.g. hand) for 9 (3%). The PSFS was completed by 152 (53%) patients, of which 13 reported one, 42 reported two and 97 reported three activities. A total of 382 activities were linked with ICF. Of these, 362 (95%) were linked to the Activities and Participation chapter (D). On second-level, 318 (83%) activities were linked to the Mobility domain (D4). On the third-level, the majority of activities were linked to the domains Changing body positions (d410) (26%), Walking (d450) (23%) and Moving around (d455) (25%). The patients reported significantly less difficulty performing their self-reported activities at 12 week follow-up (4.1 (SD 1.7) versus 6.3 (SD 1.8), mean change 2.1 (95% CI 1.8, 2.5), p<0.001).

Conclusion: The majority of activity limitations reported by patients receiving a structured OA care model in primary care were within the ICF Mobility domain. The most common third-level ICF domains were Changing body positions, Walking and Moving around. After participating in OA patient education and structured 8-12 weeks of exercise, the patients reported a statistically significant and clinically important improvement in the difficulty of performing their individual activities.

POS0269-HPR CONTENT VALIDITY OF A MULTIPLE LANGUAGES QUESTIONNAIRE FOR MEASURING FLARE IN KNEE AND HIP OA: DEVELOPMENT OF THE FLARE-OA

F. Guillemin[1], A. Barcenilla-Wong[2], M. Vitaloni[3], L. Adarmouch[4], M. T. Duruöz[5], J. Epstein[6], M. Sebbani[4], Y. Traore[6], C. Rutherford[7], M. Cross[2], B. Fautrel[8], T. Buttel[9], G. A. Hawker[10], L. March[2], D. Hunter[2], E. Spitz[1]on behalf of OMERACT Flares in OA. *[1]Université de lorraine, EA 4360 APEMAC, Metz, France*; *[2]North Shore Private Hospital, Rheumatology, St Leonards, Australia*; *[3]OAFI Foundation (Osteoarthritis Foundation International), General, Barcelona, Spain*; *[4]Université de Marrakech, Public Health, Marrakech, Morocco*; *[5]Marmara University, Rheumatology, Istambul, Turkey*; *[6]Université de Lorraine, School of Public Health, Nancy, France*; *[7]University of Sydney, Faculty of Science, School of Psychology, Sydney, Australia*; *[8]Assistance Publique – Hôpitaux de Paris, Rheumatology, Paris, France*; *[9]OMERACT, Rheumatology, Sydney, Australia*; *[10]University of Toronto - St. George Campus, Rheumatology, Toronto, Canada*

Background: Flare in osteoarthritis (OA) of the knee and hip (KHOA) is an important outcome for patients' daily life and clinical research. A definition of a flare was set, and a core set of domains was recently endorsed by OMERACT/OARSI. No patient reported outcome (PRO) yet focusses on flare in OA specifically.

Objectives: To develop a self-reporting instrument measuring flare in 5 languages, using qualitative methods and international Delphi consensus.

Methods: We generated items using a dual-language (English and French) approach involving patients with OA from Australia, France and the United States and health care professionals (HCP) from international societies (OARSI, SFR, OMERACT). Item generation relied on semi-structured individual interviews conducted with OA patients and HCP and one focus group with patients. Content analysis allowed for identifying verbatim statements that were meaningful for patients and HCP. A Delphi consensus method was used to select the most relevant items, according to core domains set (OMERACT). A cross-cultural approach using current guidelines (1) was applied to produce Spanish (in Spain), Turkish and classical Arabic (in Morocco) versions using independent translation and expert committee to preserve its content validity.

Results: From semi-structured interviews with 29 patients and 16 HCPs and one focus group with 10 patients, 180 statements in French (106) and English (77) were generated. Based on similarity or redundancy, 50 items with equivalent meaning in both languages were retained by an expert committee. After two Delphi rounds involving 50 patients and 116 HCPs from 17 countries on four continents, it was reduced to 33 items (response 0=not at all, to 10=absolutely) in five domains (pain, swelling, stiffness, consequences of symptoms and psychological aspects). This questionnaire was cross-culturally adapted into Spanish, Turkish and classical Arabic. The Spanish version uncovered one inappropriate item in the original questionnaire that was amended accordingly in all 5 languages.

Conclusion: Flare is more than just an exacerbation of pain. The Flare-OA questionnaire includes all OMERACT recommended core domains. High content validity was seen in 2 original and 3 cross-culturally adapted languages. The Flare-OA should be considered as fit for purpose and evaluation of responsiveness in clinical studies in 5 languages.

POS0270-HPR FLARE-OA QUESTIONNAIRE TO MEASURE FLARES IN OSTEOARTHRITIS OF THE KNEE AND HIP: ASSESSMENT OF ITS PSYCHOMETRIC PROPERTIES

Y. Traore[1], J. Epstein[1,2], E. Spitz[2], L. March[3,4], J. F. Maillefert[5], C. Rutherford[6,7], C. Ricatte[2], C. Alleyrat[1], M. Cross[3,4], L. King[8], L. Callahan[9], B. Fautrel[10,11], T. Buttel[3], G. A. Hawker[8], D. Hunter[3,4], F. Guillemin[1,2]. *[1]CHRU Nancy, CIC 1433 EC, Nancy, France*; *[2]Université de Lorraine, EA 4360 APEMAC, Nancy, France*; *[3]University of Sydney, Institute of Bone and Joint Research, Kolling Institute, Sydney, Australia*; *[4]Royal North Shore Hospital, Rheumatology Department, Sydney, Australia*; *[5]Dijon University Hospital, Department of Rheumatology, Dijon, France*; *[6]University of Sydney, Faculty of Science, School of Psychology, Sydney, Australia*; *[7]University of Sydney, Faculty of Medicine and Health, Sydney Nursing School, Sydney, Australia*; *[8]University of Toronto, Department of Medicine, Toronto, Canada*; *[9]University of North Carolina, Thurston Arthritis Research Center, Chapel Hill, United States of America*; *[10]Sorbonne Université – Assistance Publique Hôpitaux de Paris, Rheumatology Department Pitié-Salpêtrière Hospital, Paris, France*; *[11]Institut Pierre Louis d'Epidémiologie et Santé Publique, INSERM UMR-S 1136, Paris, France*

Background: Hip and knee OA is characterised by disease flares – understanding the determinants and consequences of OA flares has been hampered by lack of a standardized flare measure beyond the pain aspect. The patients point of view on the different aspect of their flares is essential.

Objectives: The objective was to assess the psychometric properties of a new questionnaire for measuring the multidimensional aspect of flares in OA.

Methods: Using a bilingual version of the questionnaire (33 items, response on a numeric scale, from 0 to 10), a multicentre survey (Australia, France and United States) was conducted on line with patients diagnosed with OA of the hip and/or the knee. Based on an international OMERACT/OARSI endorsed definition of the five core domains (pain, swelling, stiffness, consequences of symptoms and psychological aspects) composing a flare in OA [1], a confirmatory factorial analysis linked to the content analysis has been used to reduce the number of items and to determine the validity of the structure. The Flare-OA questionnaire (score from 0 to 100) has been tested in French and English for its internal consistency, its convergent validity with HOOS/KOOS and Mini-OAKHQOL questionnaires, and its discriminant validity.

Results: Out of 398 patients (mean age 64 years old) who completed the questionnaire, 70.4% were female and 86.7% had knee OA. The confirmatory factorial analysis retained a model with 19 items (RMSEA =0.06; SRMR =0.04; CFI =0.96 and TLI = 0.94). The Cronbach Alpha was > 0.9 for the 5 domains and for the whole questionnaire. The correlations between the Flare-OA and the other instruments were in line with that hypothesis flare is related but different from other concepts usually measured. The discriminant validity was evidenced by a significant score difference (31.8; p<0,0001) between patients with and without flare, i.e. over twice the standard measurement error.

Conclusion: The optimized Flare-OA questionnaire (19 items) is a reliable and valid instrument freely available from the authors for measuring the frequency and severity of flare in knee and hip OA in clinical research.

Background: Patient-reported outcomes (PROs) on adverse drug reactions (ADRs) are increasingly used in cohort event monitoring (CEM) to obtain a better understanding of patient's real-world experience with drugs. Despite the leading role for patients, little is known about their perspectives on these monitoring systems.

Objectives: To obtain more insight in patients' perspectives on the perceived usefulness, ease of use and attitude toward using the Dutch Biologic Monitor (DBM), and their preferred design for a national drug safety monitoring system for immune-mediated inflammatory diseases (IMIDs).

Methods: We developed a cross-sectional open survey following the rationale of the Technology Acceptance Model to obtain insight in patients' perspectives on the DBM. The DBM is a pilot for a PRO-based drug safety monitoring system focused on ADRs attributed to biologics that are prescribed for IMIDs. This survey consisted of 20 categorical and 1 open-ended question. Seven categorical questions contained a text field for additional comments. Five-point Likert-type scales or multiple-choice questions were used to identify patients' preferences and perspectives. Patients were eligible for the survey if they were still enrolled in the DBM at the time of the survey opening and if they had completed at least one questionnaire of the DBM. Categorical questions were descriptively analyzed, whereas text fields were analyzed using theoretical thematic analysis.

Results: At the start of the survey a total of 1,225 patients had participated in the DBM. Approximately 70% had an inflammatory rheumatic disease. The survey was completed by 292 eligible respondents (response rate 44.8%). The respondents generally agreed that it was useful to participate in the DBM and would recommend it to their peers (Figure 1). The response burden of the bimonthly questionnaires was scored as 'low', irrespective of the presence of ADRs or education level (Table 1). A number of respondents suggested that the questionnaire frequency should be synchronized with the regular hospital visits or the administration schedule of the biologic. Moreover, questionnaires should be offered less frequent and preferably shortened in case of an unaltered situation or absence of ADRs. Half (49.0%) of the respondents was interested in sharing their questionnaires with a medical specialist, whereas a third (34.2%) advocated sharing the questionnaires with their pharmacist (Figure 1).

Table 1. Perceived response burden of the Dutch Biologic Monitor questionnaires. The average burden is calculated using a five-point Likert-type scale. Data is represented as the number of respondents (n).

			ADRs reported						Education level[a]			
	Overall (n = 292)		Yes (n = 225)		No (n = 54)		Do not know (n = 13)		Lower (n = 149)		Higher (n = 139)	
Burden	n	(%)	n	(%)	n	(%)	n	(%)	n	(%)	n	(%)
1: No burden	224	(76.7)	169	(75.1)	46	(85.2)	9	(69.2)	106	(71.1)	115	(82.7)
2: Low burden	58	(19.9)	48	(21.3)	7	(13.0)	3	(23.1)	36	(24.2)	22	(15.8)
3: Moderate burden	6	(2.1)	6	(2.7)	0	(0.0)	0	(0.0)	4	(2.7)	2	(1.4)

Average burden	1.2		1.3		1.1		1.2		1.3		1.2	

[a]Missing: 4 respondents.

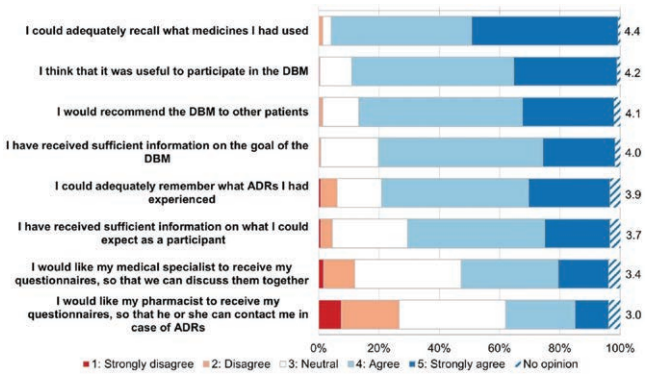

Figure 1. Stacked bar graph of user perspectives. Agreement scores were measured using a five-point Likert-type scale. The average agreement score per statement is indicated on the far right. The percentages represent the share of respondents. DBM: Dutch Biologic Monitor; ADRs: adverse drug reactions.

Conclusion: This study provides valuable insights in the patient perspective on a PRO-based drug safety monitoring system for inflammatory rheumatic diseases and other IMIDs, and provides several useful starting points to further stimulate and improve PRO-based CEM systems. Altogether, it appears feasible to establish a PRO-based drug safety monitoring system that monitors IMID patients' real-world experience with ADRs that has a low burden for the participants.

POS0272-HPR

POOR RESPONSE TO TKA: THE PERSPECTIVE OF PATIENTS AND KNEE SPECIALISTS

M. Te Molder[1], J. Vriezekolk2, J. M. H. Smolders[3], S. Van Onsem[4,5], P. Heesterbeek[2], C. Van den Ende[2]. *[1]Sint Maartenskliniek, Research Department, Nijmegen, Netherlands*; *[1]Sint Maartenskliniek, Research Department, Nijmegen, Netherlands*; *[3]Sint Maartenskliniek, Department of Orthopedics, Nijmegen, Netherlands*; *[4]AZ Alma, Department of Orthopaedics*

and Traumatology, Eeklo, Belgium; [5]*Ghent University, Department of Human Structure and Repair, Ghent, Belgium*

Background: Although most of the patients after total knee replacement (TKA) report very satisfied outcome scores, there is still a significant proportion of patients that experience persistent knee pain, functional disability or dissatisfaction after TKA because of osteoarthritis (OA). It is difficult to quantify the proportion of patients with poor response to TKA, as different definitions on failure are being used (1). Additionally, patients and surgeons only agree in 36% on failure of total joint replacement (TJR) (2). This may be caused by different perceptions about concepts underlying poor response to TKA.
Objectives: To explore if patients and knee specialists have different views about relevant concepts reflecting poor response to primary TKA.
Methods: A qualitative, multicentre study was performed using semi-structured interviews in Belgium and in the Netherlands. Purposive sampling was used to enrich data variation. Twenty-five patients with knee OA without surgical indications (N=2), pre- and postoperative patients (N=11 and N=12, respectively) and fifteen knee specialists (orthopedic surgeons (N=9), physician assistants (N=1), nurse practitioners (N=1) and specialized physiotherapists (N=4)) were interviewed individually. Conversations were audiotaped, transcribed verbatim, and analysed using a thematic analysis.
Results: Concepts underlying poor response to TKA were: persistent pain, limited knee function, limitations in physical functioning, complications, unmet expectations, unexpected sequelae and dissatisfaction (Figure 1). The concepts persistent pain, limited knee functioning, complications and limited physical functioning were found to underly expectations and/or unexpected sequelae after TKA. Dissatisfaction was considered a overarching concept resulting from unmet expectations and/or unexpected sequelae after TKA (e.g. long-term use of pain medication, continuous awareness of the prosthesis). All seven concepts were identified by both patients and knee specialists although poor knee function was more often described by patients in terms of prosthesis awareness, whereas knee specialists described poor knee function in terms of instability.
Conclusion: Patients and knee specialists identified similar concepts as relevant concepts reflecting poor response to TKA. These results will be used to formulate a uniform definition of poor response to TKA.

POS0273-HPR PHARMACIST'S IMPACT ON SELF-MANAGEMENT FOR PATIENTS WITH CHRONIC INFLAMMATORY ARTHRITIS TREATED WITH BIOLOGICAL DMARDS

C. Bottois[1], C. López-Medina[2], S. Dumas[1], H. Julien[1], B. Sephora[1], C. Roux[2], A. Moltó[2], O. Conort[1], M. Dougados[2]. [1]*Hôpitaux Universitaire Paris Centre - Site Cochin, Clinical Pharmacy, Paris, France*; [2]*Hôpitaux Universitaire Paris Centre - Site Cochin, Rheumatology, Paris, France*

Background: Knowledge about chronic inflammatory rheumatisc diseases and skills to administer and manage subcutaneous (subcut) biological DMARDs (bDMARDs) are key aspects to optimize patient's self-management. Intervention of several successive health professionals (e.g comprehensive multidisciplinary team) has proven to be an effective method to improve patient's self-management of their disease and treatment.
Objectives: To assess the pharmacist's impact on patient's knowledge and skills during a multidisciplinary annual review. The secondary objectives were to assess this impact on therapeutic adherence and patient's satisfaction as well as to determine the factors associated with the level of knowledge at baseline.
Methods: Study type: prospective, monocentric, 6 months-follow-up, non-controlled study approved by Local Ethical Committee. Inclusion criteria: patient with either rheumatoid arthritis (RA) or spondyloarthritis (SpA), and treated with subcut bDMARDs. Intervention: The visit with a pharmacist evaluating and discussing patient's knowledge and treatment adherence. At baseline (M0): date of the visit and, 3 (M3) and 6 months (M6) later, knowledge and adherence were assessed using self-administered questionnaires: Biosecure and CQR-5 respectively. A questionnaire was sent at M3 in order to evaluate the patient satisfaction. Endpoints: Primary: Changes in Biosecure score Secondary: Percentage of patients with high level of knowledge (score > 84) and percentage of patients with high adherence at M3 and M6; patient's satisfaction; identification of patient's factors (socio-demographics, rheumatisc disease treatments) associated with different levels of knowledge at baseline.
Statistical analysis: repeated measures ANOVA, Bonferroni and Generalized Estimating Equation, univariate and multivariate linear regression.
Results: The study was conducted from October 2019 to July 2020; 79 patients were included (age (years) = 50±15; sex ratio = 1.1; RA=25, SpA=54). The Biosecure scores changed from 71±18 to 82±15 (M3) and to 84±14 (M6) ($p<0.001$). At M0, M3 and M6, the rate of patients with a high level of knowledge was 24.1%, 59.5% and 63.3% respectively ($p<0.001$). No difference was observed for the change in the 92% of patients considered as high adherent (92% versus 95% at M0 and M6 respectively; $p=0.077$). Patient's satisfaction regarding the pharmaceutical intervention was 25±3 (max = 28).
Factors associated with a better Biosecure score in the multivariate analysis were the following, lifestyle as a couple ($p<0.001$), information given by a nurse ($p=0.033$), information searched for on patient associations ($p=0.013$) and a low Charlson score ($p=0.001$)
Conclusion: Pharmacist's intervention in the comprehensive multidisciplinary annual review resulted in a beneficial impact on patients' knowledge and skills to manage their bDMARDs with a high level of satisfaction from a patient perspective.
Disclosure of Interests: None declared

POS0274-HPR BARRIERS TO PHYSICAL ACTIVITY COLLECTED BY THE IFAB QUESTIONNAIRE CORRELATE WITH LEVELS OF PHYSICAL ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS OR SPONDYLOARTHRITIS: A CROSS-SECTIONAL STUDY OF 150 PATIENTS

T. Davergne[1], R. Tekaya[2], C. Deprouw[3], J. Sellam[3], A. Tournadre[4], S. Mitrovic[5], A. Ruyssen-Witrand[6], C. Hudry[7], S. Dadoun[8], J. Avouac[9], B. Fautrel[10], L. Gossec[10]. [1]*Sorbonne Université, INSERM, Institut Pierre Louis d'Épidémiologie et de Santé Publique, PEPITES, Paris, France*; [2]*Hôpital Charles Nicolle, University of Tunis El Manar, Rheumatology Department, Tunis, Tunisia*; [3]*Saint-Antoine hospital, Rheumatology Department, Paris, France*; [4]*Clermont Ferrand hospital, University of Clermont, Rheumatology Department, Clermont Ferrand, France*; [5]*Institut Mutualiste Montsouris, Internal Medicine Department, Paris, France*; [6]*Purpan hospital, Rheumatology Department, Toulouse, France*; [7]*CeSOA, MGEN, Paris, France*; [8]*Clinique Geoffroy Saint Hilaire, Ramsay, Paris, France*; [9]*Université de Paris, Cochin hospital, Rheumatology Department, Paris, France*; [10]*Pitié Salpêtrière hospital, APHP, Rheumatology Department, Paris, France*

Background: Physical activity is important for patients with inflammatory arthritis (IA), such as spondyloarthritis (axSpA), rheumatoid arthritis (RA) or psoriatic arthritis (PsA). They are more prone to physical inactivity but derive specific benefits from regular physical activity (1,2). It is not easy to modify physical activity level (3). Barriers and facilitators to physical activity can be assessed through questionnaires (4), however, it is important to demonstrate a link between these explanatory elements and physical activity levels.
Objectives: To measure the correlation between barriers and facilitators to physical activity, assessed through a simple questionnaire, and self-reported physical activity levels.

Methods: This was an international, multicentric, cross-sectional study performed between October 2019 and June 2020 (ClinicalTrial NCT04426747). Consecutive patients were included if they had definite axSpA, RA or PsA, were aged above 18 and able to walk. Barriers and facilitators to physical activity were measured using the 10-item Inflammatory arthritis Facilitators and barriers questionnaire (IFAB) (5). The IFAB ranges -70 to 70 with lower scores indicating more barriers; scores below -5 correspond to significant barriers. Physical activity was measured by the IPAQ-S questionnaire (6). Exploratory analyses used steps per day collected by smartphone, and psychological readiness to change by stages of behavior change. Statistical analysis used Spearman correlation (rho, p<0.05), Student T test or multivariate analysis using R version 3.5.1. There was no imputation of missing data.
Results: Of 245 patients included, 150 had analysable data (69 (46%) axSpA, 63 (42%) RA, 18 (12%) PsA). Mean age was 48.6 years (SD 17.1), mean disease duration 11.7 (10.1) years and 60% were women. The mean score of barriers and facilitators to physical activity was 6.0 (SD 19.2, median 4) (Figure 1). A total of 39 (26%) patients scored less than -5, which could justify a targeted intervention. The mean physical activity was 2837 (SD 2668, median 1784) Metabolic Equivalent of Task min per week. Physical activity was correlated with score of barriers and facilitators to physical activity in linear regression (rho 0.28, p<0.001), as well as the stage of behavior change regarding active lifestyle (rho 0.35, p<0.001). No correlation was observed with steps per day (Table 1)
Conclusion: Perceived barriers and facilitators to physical activity are correlated with physical activity. Targeting patients with high barriers and low facilitators to physical activity could be an effective option to improve physical activity levels.

Background: Managing patients with chronic rheumatic diseases is increasingly relying on the collaboration of a multidisciplinary team, including the rheumatology nurse who can aid assessment of disease activity among other healthcare tasks.
However, this practice, although common in Europe and North America, is still poorly implemented in the Middle eastern Arab countries (MEAC).
Objectives: To evaluate the concordance between the physician's and the nurse's assessment of disease activity in patients with rheumatoid arthritis (RA) in the MEAC.
Methods: During a routine patient visit to one of 9 rheumatology clinics located in 7 Middle Eastern Arab countries, the physician and the rheumatology nurse (who was already working in the clinic) performed the disease activity score 28 (DAS), Clinical Disease Activity Index (CDAI) and Simple Disease Activity Index (SDAI) in a blinded manner. The concordance regarding the 3 continuous scores was calculated using paired t-test. The agreement between physician- and nurse-DAS categories (remission, low, moderate and high disease activity) was calculated using weighted kappa for category comparison. Predictive factors of positive concordance between physician- and nurse-DAS were identified using binary logistic regression.
Results: The study included 373 patients' measurements over a period of two years (2018 to 2019). The mean age of the patients was 49.6 years (±28.2), 82.6% were females, and the mean disease duration was 11.3 years (±7.5).
The mean physician-DAS was slightly higher (3.97 (±1.52)) than the nurse-DAS (3.90 (±1.54)) (p=0.002), with a mean difference of +0.08 [95%CI 0.03; 0.12] (Table 1). The difference in the DAS individual items, the CDAI and the SDAI were not statistically significant.
When analyzing DAS as a categorical 4-items variable, the agreement between the physician and the nurse was present in 79.36% of the cases (weighted kappa was 0.77 [95%CI 0.73;0.83] which is considered as excellent, and was higher in patients with high disease activity (Figure 1).
A positive concordance between the physician- and the nurse-DAS was associated with the country (higher in Egypt, p<0.001) and the status of higher disease activity (p<0.001).
Conclusion: The agreement between the DAS-28 performed by the physician and by the nurse was excellent and was associated with the country and a higher disease activity. The present study confirms that the support of a trained nurse for evaluating disease activity in RA is feasible in the Arab countries and may save some valuable time in the clinic, whilst maintaining the quality of care for patients with RA.

Table 1. Comparison of the disease activity measures reported by the physician and by the nurse.

	Physician	Nurse	p-value
Total Joint Count	4.87 (2.26)	5.02 (6.20)	0.152
Swollen Joint Count	2.13 (3.88)	2.15 (3.83)	0.790
Global Assessment	3.30 (2.41)	3.32 (2.43)	0.702
DAS-28	3.97 (1.52)	3.90 (1.54)	0.002
CDAI	14.26 (12.53)	14.38 (12.59)	0.515
SDAI	21.51 (23.57)	21.61 (21.66)	0.527

POS0276

EFFICACY OF KRILL OIL IN THE TREATMENT OF KNEE OSTEOARTHRITIS: A 24-WEEK MULTICENTRE RANDOMISED DOUBLE-BLIND CONTROLLED TRIAL

L. Laslett[1], L. Scheepers[1], B. Antony[1], A. Wluka[2], C. Hill[3,4], L. March[5,6], H. Keen[7], P. Otahal[1], F. Cicuttini[2], G. Jones[1]. [1]*University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*; [2]*Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia*; [3]*Rheumatology Unit, The Queen Elizabeth Hospital, Adelaide, Adelaide, Australia*; [4]*The University of Adelaide, -, Adelaide, Australia*; [5]*Royal North Shore Hospital, Department of Rheumatology, Sydney, Australia*; [6]*University of Sydney, Kolling Inst., Inst. of Bone and Joint Res., Sydney, Australia*; [7]*Fiona Stanley Hospital, School of Medicine and Pharmacology, Perth, Australia*

Background: Elevated levels of systemic inflammation are common in people with osteoarthritis and predict both pain and structural outcomes. Krill oil has anti-inflammatory properties and reduces severity of inflammatory arthritis in mice by 50% compared to controls.[1] In humans, krill oil reduced knee pain and function in two short, moderate quality randomised controlled trials (RCTs) in people with osteoarthritis. However, evidence from longer trials with imaging data is lacking.
Objectives: The aim of this study was to compare the efficacy of krill oil (2g / day) vs. placebo for treating knee pain in patient with clinical knee osteoarthritis who have significant knee pain and effusion-synovitis.
Methods: KARAOKE was a 24-week multicentre, randomised, double-blind, placebo-controlled trial conducted at five Australian sites. Participants aged ≥40 years with symptomatic knee OA (according to ACR criteria), significant knee pain (pain score ≥40mm on a 100mm visual analogue scale [VAS]), and effusion-synovitis present on MRI (grade ≥1 according to modified Whole-Organ Magnetic Resonance Imaging Score (WORMS) scoring) were eligible. The study protocol has been published previously.[2]
Participants were randomised to receive 2g/day of krill oil, (350 mg/g omega-3 content, 12 mg/g total omega-6 content) or inert placebo (vegetable oil, no EPA or DHA, <5 mg/g (0.05%) other omega-3s).
The primary outcome was absolute change in knee pain assessed using a VAS [0-100mm] after 24 weeks. Secondary outcomes were: change in knee pain and function assessed using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) score [0-500mm]), change in back and hand pain assessed using a VAS [0-100mm], change in lower limb leg strength assessed using a dynamometer, and change in blood parameters (including CRP, triglycerides, fasting glucose and total, HDL, LDL cholesterol), after 24 weeks.
Linear mixed-models were used, using patient identification as random intercepts and trial centre and treatment month as random effect to adjust for correlated data within trial centres and repeated measures and to allow different treatment effects among patients over time, respectively.
Results: 262 participants were randomised (mean age 61.5 years, 53% females) to receive krill oil (n=130) or placebo (n=132). A total of 85% completed the trial. Knee pain improved in both groups over 24 weeks, but with no between-group difference (krill oil, -20.1mm; placebo, -19.3mm, p=0.81). Secondary outcomes: knee pain and function score improved in both groups, but with no between-group difference (WOMAC pain: krill oil, -86.7; placebo, -82.5mm, p=0.81; WOMAC function: krill oil, -245.3; placebo, -184.3, p=0.14 at 24 weeks). The same applies for hand pain and back pain. No significant changes were seen in leg strength or any of the blood parameters at 24 weeks). Incidence of one or more adverse events was 50% in the krill oil group (n=66) and 55% in the placebo group (n=71). There were 8 serious adverse events in the krill oil group 6 in the placebo group, all considered unrelated to treatment.
Conclusion: Krill oil was safe and well tolerated, but did not significantly reduce knee pain in patients with clinical knee osteoarthritis, significant knee pain and effusion-synovitis after 24 weeks compared to placebo. These findings do not support use of krill oil for alleviating knee pain in clinical knee osteoarthritis.

POS0277 ANABOLIC EFFECT OF LNA043, A NOVEL DISEASE-MODIFYING OSTEOARTHRITIS DRUG CANDIDATE: RESULTS FROM AN IMAGING-BASED PROOF-OF-CONCEPT TRIAL IN PATIENTS WITH FOCAL ARTICULAR CARTILAGE LESIONS

S. Trattnig[1], C. Scotti[2], D. Laurent[2], V. Juras[1], S. Hacker[3], B. Cole[4], L. Pasa[5], R. Lehovec[6], P. Szomolanyi[1], E. Raithel[7], F. Saxer[2], J. Praestgaard[8], F. La Gamba[9], J. L. Jiménez[9], D. S. Ramos[2], R. Roubenoff[2], M. Schieker[2]. [1]*High Field MR Centre, Medical University of Vienna, Department of Biomedical Imaging and Image-Guided Therapy, Vienna, Austria*; [2]*Novartis Institutes for Biomedical Research, Translational Medicine, Basel, Switzerland*; [3]*Horizon Clinical Research, Grossmont Orthopedic Medical Group, San Diego, United States of America*; [4]*Rush University Medical Center, Department of Orthopedics, Chicago, United States of America*; [5]*Trauma Hospital, Trauma Department, Brno, Czech Republic*; [6]*Dr. Pirek's clinic, Orthopaedic surgery, Mladá Boleslav, Czech Republic*; [7]*Siemens Healthcare GmbH, SHS DI MR DL, Erlangen, Germany*; [8]*Novartis Institutes for Biomedical Research, Early Development Biostatistics, East Hanover, United States of America*; [9]*Novartis Institutes for Biomedical Research, Early Development Analytics, Basel, Switzerland*

Background: LNA043 is a modified, recombinant version of the human angiopoietin-like 3 (ANGPTL3) protein acting directly on cartilage-resident cells to transmit its cartilage anabolic effect. A first-in-human study previously demonstrated the favourable safety profile and the modulation of several pathways involved in cartilage homeostasis and osteoarthritis (OA)[1]. A previous proof-of-mechanism imaging study used high field (7 Tesla) magnetic resonance imaging (MRI) to show formation of hyaline-like tissue after a single injection of 20 mg LNA043 (unpublished data).

Objectives: To evaluate non-invasively the chondro-regenerative capacity of multiple intra-articular (i.a.) injections of LNA043 in patients with articular cartilage lesions in the knee (NCT03275064).

Methods: This was a randomised, double-blind, placebo (PBO)-controlled, proof-of-concept study in patients with a partial thickness cartilage lesion. In total, 58 patients (43 [20 mg LNA043]; 15 [PBO]), stratified by lesion type (condylar or patellar) were treated with 4 weekly i.a. injections. The primary endpoint was T2 relaxation time measurement as a marker of collagen fiber network, and cartilage lesion-volume was a secondary endpoint, both using 3-Tesla MRI. Assessments were performed at baseline, weeks (wks) 8, 16, 28 and 52 (the latter in 23/58 patients). While lesion-volume for the secondary endpoint was determined from manually segmented images, the cartilage volume of 21 sub-regions spanning the entire knee was also measured from 3D isotropic MR images employing an automated segmentation prototype software (MR Chondral Health 2.1 [MRCH], Siemens Healthcare)[2]. An exploratory analysis evaluated the treatment effect for the additive volume of the 3 subregions in the weight-bearing area of the medial femur.

Results: No change in T2 relaxation time was detected between treatment and PBO groups. Manual segmentation showed continuous filling of the cartilage lesions up to wk 28 in LNA043-treated patients with femoral lesions (p=0.08, vs PBO) while no effect was detected for patients with patellar lesions. Given the limitations of measuring small, irregularly shaped lesions with manual image-analysis, the MRCH approach was used (Figure 1). In the medial femoral weight-bearing region, refilling was detected over time (Δ=123 mm^3 at wk 28, N= 37, p= 0.05). No overgrowth was detected in the lateral femoral condyles without cartilage damage. The overall safety profile was favourable; only mild/moderate local reactions were reported, including a higher incidence of joint swelling (9.3% vs 0%) and arthralgia (11.6% vs 6.7%) for LNA043 vs PBO resolving spontaneously or with paracetamol/NSAIDs. No anti-drug antibodies were detected.

Conclusion: Treatment with 4 weekly i.a. injections of 20 mg LNA043 resulted in regeneration of damaged cartilage in patients with femoral articular cartilage lesions. Automated measurement of cartilage volume in the femoral index region was able to detect a relevant treatment effect and was found to be more sensitive than the manual segmentation method. No sign of cartilage overgrowth was observed in healthy femoral regions. A Phase 2b study in patients with mild to moderate knee OA is in preparation.

POS0278 A MULTICENTER, OBSERVATIONAL, EXTENSION STUDY EVALUATING THE SAFETY, TOLERABILITY, AND EFFICACY OF A SINGLE LORECIVIVINT INJECTION IN KNEE OA SUBJECTS

I. Simsek[1], C. Swearingen[2], H. Ghandehari[2], S. Kennedy[3], J. Tambiah[3], Y. Yazici[4], N. Skrepnik[5]. [1]*Samumed, LLC, Clinical Development, San Diego, United States of America*; [2]*Samumed, LLC, Biostatistics, San Diego, United States of America*; [3]*Samumed, LLC, Medical Affairs, San Diego, United States of America*; [4]*Samumed, LLC, Chief Medical Officer, San Diego, United States of America*; [5]*Tucson Orthopaedic Institute, Research, Tucson, United States of America*

Background: Lorecivivint (LOR), a novel intra-articular (IA) CLK2/DYRK1A inhibitor that modulates the Wnt pathway, is in development as a knee osteoarthritis (OA) treatment.

Objectives: Subjects from two consecutive Phase 2 trials were followed up in a 5-year, pooled, observational study that evaluated the safety and exploratory efficacy of a single LOR injection that was previously administered into the target knee joint of subjects with moderate to severe knee OA. The study was terminated in its third year, as relevant long-term safety information became limited in the absence of repeated LOR administration. The primary objective evaluated the incidence of serious adverse events (SAEs). Safety data for all doses and a post hoc efficacy analysis for the pivotal dose (0.07 mg LOR) are reported.

Methods: This was a Phase 3, multicenter, observational, extension study of completer subjects (OA-05; NCT02951026) from two Phase 2 trials of LOR: a 12-month Phase 2a trial (OA-02; NCT02536833)[1] and a 6-month Phase 2b trial (OA-04; NCT03122860)[2]. Subjects received a single LOR or control (placebo or vehicle) injection at their parent-study baseline visit (OA-02 or OA-04 Visit 0 in this analysis). Pooled data from clinic visits at 6, 12, 24, and 36 months contributed to the extension-study (OA-05) analysis. SAEs, knee-related adverse events (AEs), and AEs of newly diagnosed conditions requiring treatment were collected as safety outcomes. Efficacy was assessed by target knee WOMAC Pain and Function subscores and radiographic medial joint space width (mJSW). A post hoc analysis was performed for 0.07 mg LOR versus control to assess responses in a subject subgroup (unilateral symptoms, no widespread pain, 18-month post-injection radiograph at study termination). Baseline-adjusted ANCOVA was performed using data from both the current and parent studies at 0, 3, 6, 12, and 18 months.

Results: Of 703 subjects, 119 (17%) subjects discontinued prior to study termination. Subjects had a mean age of 60.7 years and mean BMI of 29.1 kg/m2, and 61% were female. The majority of subjects had KL 3 (61.2%) OA. The safety analysis set included 495 LOR-treated subjects and 208 control subjects.

There were 169 AEs reported by 110 [15.6%] subjects. Four AEs were considered to be related to study drug and were reported by 3 (0.6%) subjects across LOR groups; no subjects withdrew from the study due to a treatment-related AE. The most common AEs were osteoarthritis (28 [4.0%] subjects) and arthralgia (25 [3.6%] subjects); incidence was similar between LOR and control groups. During the study, 68 SAEs were reported by 38 (5.4%) subjects, and no SAEs were considered to be related to treatment by investigator. One death occurred in the control group. Post hoc efficacy analyses demonstrated that subjects in the 0.07 mg LOR group (n=59) showed greater improvements from baseline in both WOMAC Pain and Function at 6 and 12 months versus subjects in the control group (n=70) (Figure 1; Day 0):
6 months:Pain: -8.16, 95% CI [-15.60, -0.71], *P*=0.032
Function: -9.47, 95% CI [-17.09, -1.84], *P*=0.015
12 months:Pain: -8.51, 95% CI [-15.17, -1.85], *P*=0.013
Function: -9.62, 95% CI [-16.83, -2.42], *P*=0.009
No mJSW progression was observed in any group over 18 months.
Limitations to this analysis include 1) subjects from LOR and control groups were "completers," therefore, more likely to be responders, and 2) subjects could have been on any medication or treatment in the extension study.
Conclusion: From these data, LOR appeared to be safe and well tolerated. A post hoc-analyzed subset of completer subjects treated with a single 0.07 mg LOR injection reported durable symptom improvements in WOMAC Pain and Function for up to at least 12 months versus control subjects.

POS0279

WEARABLE TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION DEMONSTRATED BETTER EFFICACY AND SAFETY THAN WEAK OPIOIDS IN THE TREATMENT OF MODERATE TO SEVERE, CHRONIC NOCICEPTIVE PAIN IN KNEE OSTEOARTHRITIS. A RANDOMIZED, CONTROLLED, NON-INFERIORITY TRIAL

E. Maheu[1], S. Soriot-Thomas[2], E. Noel[3], E. Lespessailles[4], B. Cortet[5]on behalf of arthroTENS. [1]*Hospital Saint-Antoine Ap-Hp, Rheumatology, Paris, France*; [2]*Chu D'amiens-Picardie Site Sud, Clinical Research Center,Amiens, France*; [3]*Santy Orthopedic Center, Rheumatology, Lyon, France*; [4]*Hospital Center Régional D'orléans Hospital La Source, Rheumatology, Orléans, France*; [5]*Chu lille, Rheumatology, Lille, France*

Background: In knee osteoarthritis (KOA) recommendations, the first pharmacological analgesic line is paracetamol. However, its low efficacy, frequently leads to the use of weak opioids (WO) despite their poor tolerance, especially in elderly patients.
Objectives: The primary objective was to compare analgesic efficacy and safety of a new wearable transcutaneous electrical nerve stimulation (W-TENS) to those of WO in the treatment of moderate to severe, nociceptive, chronic pain in KOA patients.
Methods: ArthroTENS study was a phase 3, non-inferiority, multicentric, prospective, randomized, single-blinded for primary efficacy outcome, controlled, in 2-parallel groups, clinical study comparing W-TENS versus WO on two periods: a 3-month controlled period and an additional, optional, non-controlled, 3-month follow-up for patients in W-TENS group.
Eligible participants were KOA patients, ≥55 years old, at Kellgren-Lawrence radiographic grade ≥2, with moderate to severe nociceptive chronic (≥3 months) mean 8-day pain ≥4 on a 11-point numerical rating scale, and in treatment failure with non-opioid analgesics, including NSAIDs. Patients with neuropathic pain were excluded.
Co-primary endpoints were, for efficacy, mean pain intensity (PI), assessed at M3 and, for safety, the number of adverse events (AE) during the 3-month follow-up period.
In W-TENS group, an advanced, mobile app enabled, wearable TENS was used. High (100 Hz) and low (2 Hz) frequency stimulations were delivered via electrodes with standardized positioning (Figure 1).

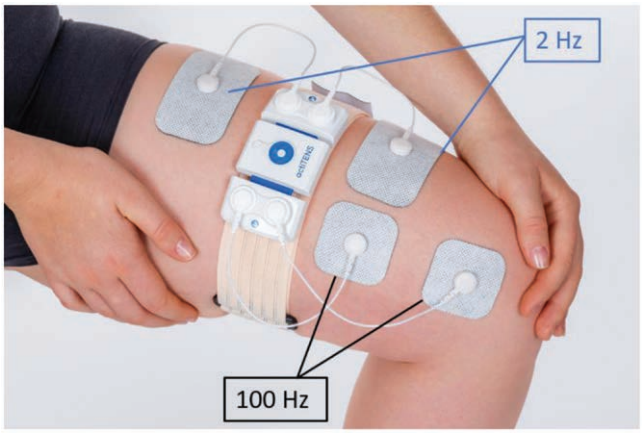

Figure 1. Electrode's positioning

In WO group, investigators chose, for each patient, the best suitable WO and its daily dose, and could switch to another WO, and/or adapt its daily dose if necessary.
A non-inferiority analysis was performed on the primary efficacy endpoint using a pre-defined non-inferiority margin (0.825 point) on PI, below the minimal clinically significant improvement.
Results: Demographic and baseline characteristics were balanced across both groups.
110 patients (55/group) were randomized and 48/55 (87.3%) and 44/55 (80.0%) patients completed the 3-month follow-up in W-TENS and WO groups, respectively. WO's prescriptions were balanced between codeine, opium-powder, tramadol and WO-paracetamol combinations.
Non-inferiority of W-TENS was demonstrated in the PP and ITT populations (Table 1). Since the 95% confidence interval (CI) of the between-treatments difference was below 0 in the ITT population, a planned superiority analysis was performed showing that W-TENS was significantly superior to WO at M3 (p=0.0124) on PI. Additionally, the number of AEs was significantly lower (p<0.001) in W-TENS (n=7) group than in WO (n=36) group. In WO group, AEs were systemic AEs usually reported with WO while AEs in W-TENS group were local, related to the technique used, such as local cutaneous reaction (erythema).

Table 1. Non-inferiority analyses on pain intensity at M3. ITT and PP populations. Least squares means for each study group and study group difference estimate and corresponding 95% CI

Group Population	Within-group change				Between-group difference	
	W-TENS		WO		W-TENS - WO	
ITT Population (n)	55		55			
Non inferiority						
Mean (SD)	3.83 (0.28)	<0.001	4.74 (0.28)	<0.001	-0.92 (0.40)	Non inferiority‡
95% CI	[3.27, 4.40]		[4.18, 5.30]		[-1.71, -0.12]	demonstrated
PP Population (n)	52		47			
Mean (SD)	3.87 (0.30)	<0.001	4.66 (0.32)	<0.001	-0.79 (0.44)	Non inferiority‡
95% CI	[3.28, 4.46]		[4.03, 5.28]		[-1.65, 0.08]	demonstrated

‡ Noninferiority was demonstrated when 95% CI < 0.825

Thirty-nine (70.9%) patients wished to extend W-TENS treatment for 3 additional months. Only one patient discontinued this additional period and results obtained at M3 remained stable at M6.

Conclusion: In this study, W-TENS was more effective and better tolerated than WO in the treatment of nociceptive KOA chronic pain and should represent an interesting non-pharmacological alternative to WO.

POS0280 ASSOCIATION OF COMPLEMENTARY AND ALTERNATIVE MEDICINE USE WITH KNEE SYMPTOMS AND KNEE STRUCTURAL CHANGES OVER 2.6 YEARS: A POPULATION-BASED COHORT STUDY OF TASMANIAN OLDER ADULTS

Z. Wang[1], G. Jones[1], D. Aitken[1], S. Balogun[2], Z. Zhou[1], L. Blizzard[1], F. Cicuttini[3], B. Antony[1]on behalf of Musculoskeletal group. *[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia*; *[2]College of Health & Medicine, Australian National University, Canberra, Australia*; *[3]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia*

Background: There is increasing use of complementary and alternative medicines (CAMs) alone or as an adjuvant therapy to conventional palliative medicines.[1] However, there remains clinical uncertainty about the benefit of CAMs in the management of osteoarthritis in older population.

Objectives: To describe the association between CAM use (alone or in combination with conventional analgesics) with knee symptoms and structural changes amongst a representative sample of Tasmanian older adults.

Methods: A total of 1,099 participants were selected from the Tasmania Older Adult Cohort Study (TASOAC), an ongoing prospective population-based study. Exposure to CAM and conventional medications was classified into four categories according to the national drug code directory: [2] CAM only, conventional analgesics only, both CAM and conventional analgesics, and neither CAMs nor conventional analgesics. Knee pain was assessed using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), and a 1.5-T MRI of the right knee was performed at baseline and follow-up (around 2.6 years). Longitudinal associations were assessed using mixed effect linear models.

Results: At baseline, participants‘ mean age was 63, 86.5% (n=951) reported any medication use. The prevalence of CAM use was 35.0% and of conventional analgesics was 58.6%. Over follow-up, the analgesic only group had a significant increase in WOMAC pain, function, and stiffness scores compared to those who took neither CAMs nor conventional analgesics. There was a statistically significant femoral cartilage volume loss across all four groups, and no statistical difference was found between participants who takes both CAMs and analgesics group and the reference group, but participant in the CAM only or the analgesics only groups loss statistically significant more femoral cartilage volume than the reference group (Table 1).

Conclusion: CAM use alone or in combination with conventional analgesics may associate with slower progression of knee pain. Conclusive evidence on the longitudinal benefits of CAM in the management of osteoarthritis among older adults warrants more studies.

POS0281 RUBUS IDAEUS LEAF EXTRACT IMPROVES SYMPTOMS IN KNEE OSTEOARTHRITIS PATIENTS: RESULTS FROM A DOUBLE BLIND RANDOMIZED CLINICAL STUDY

Y. Henrotin[1], R. Le Cozannet[2], P. Franca-Berthon[2], R. Truillet[3], M. Cohen Solal[4]. *[1]University of Liège, Musculoskeletal Innovative Research Lab, Liège, Belgium*; *[2]Naturex SA, Taste & Wellbeing, Avignon, France*; *[3]Atlanstat, Biostatistics, Rezé, France*; *[4]Université de Paris, Rheumatology, Paris, France*

Background: Osteoarthritis (OA) is the most common cause of disability in older adults. Currently, the aim of the patient management is to reduce symptoms and to improve quality of life using therapeutic modalities with no adverse effects (1). Unfortunately, the first line treatments of OA symptoms remain nonsteroidal anti-inflammatory drugs (NSAIDS) and paracetamol which if long-term administration are associated with severe adverse effects. Therefore, we need of save alternative to manage chronic OA symptoms. One candidate is Rubus idaeus (raspberry) leaf extract rich in flavonoids and phenols known to inhibit inflammatory responses.

Objectives: The aim of this study was to investigate the effects of a 12-weeks intervention with an ethanolic extract from Rubus idaeus leaf on symptoms of knee OA.

Methods: The study was a randomized, double-blind, placebo-controlled, monocentric trial of 198 subjects with femoro-tibial OA. Subjects were randomized equally to receive one daily treatment during 3 months either of 1 cap of Rubus idaeus leaf extract 400 mg, or 200 mg or placebo (maltodextrine). The main objective of this first exploratory study was to assess pain reduction over time. Pain was measured using different scales from the Western Ontario McMaster osteoarthritis index (WOMAC) to the knee pain VAS.

Results: In the ITT population, Rubus idaeus leaf extract 400 mg and 200 mg after 12 weeks of treatment reduced pain measured by the VAS respectively of -10.93 (1.95) mm and -8.51 (1.92) mm compared to baseline, while placebo group had a -3.84 (1.89) mm reduction. The mean pain decrease induced by Rubus ideaus leaf extract was over – 7 mm which is clinically relevant, and reached clinically statistical difference compared to placebo with the highest dose (p=0.017; 95% CI, -13.11 to -1.07). Interestingly, subgroup analysis on the participants with a BMI>25, highlighted clinically relevant pain reduction for the 400 and 200 mg doses compared to baseline of respectively -13.36 (2.26) mm and -11.25 (2.14) mm (placebo = -0.37

(2.16) mm). The reduction was statistically different versus placebo for both doses (400 mg p<0.0001; 95% CI, (-19.95 to -6.04) and 200 mg p=0.0008; 95% CI, (-17.64 to -4.12). There was no effect on the WOMAC subscale of pain.

Conclusion: Rubus idaeus leaf extract, even at the low dose of 200 mg, was effective to relieve pain at short-term in-patient with knee OA. As Rubus idaeus leaf extract is well tolerated, it could be an alternative to nonsteroidal anti-inflammatory drugs and paracetamol to relieve knee joint pain in OA patients.

POS0282 EVALUATION OF A NEW HYALURONATE FORMULATION ONE YEAR AFTER SINGLE INJECTION TO PATIENTS WITH SYMPTOMATIC KNEE OSTEOARTHRITIS (SOYA STUDY)

C. Gavín[1], F. Moreno[1], F. J. Blanco[2], J. L. Pablos[3], M. A. Caracuel-Ruiz[4], J. Rosas[5], P. Hernández-Esteban[6], F. Navarro[7], P. Coronel[8], M. Gimeno[9]on behalf of SOYA study group. *[1]H.U. International, Alcalá de Henares (Madrid), Spain*; *[9]Meiji Pharma Spain, Clinical Development, Alcala de Henares, Spain*

Background: Osteoarthritis (OA) is a leading cause of chronic pain and disability, and its prevalence is expected to increase worldwide (1) being the knee the most affected joint, especially in older adults. Intra-articular hyaluronic acid (HA) could be of particular benefit in OA patients with co-morbidities, and in case of inadequate response to other pharmacological treatments (2). HA has been generally administered in cycles of 3-5 injections, however, due to the pressure on public health systems, the trend is to reduce the number of injections maintaining the duration of effects as longer as possible.

Objectives: To assess the effectiveness and safety of a new formulation of HA, up to one year after one single injection to patients in the SOYA (Symptomatic Osteoarthritis one Year Assessment) study.

Methods: Patients with Kellgren-Lawrence (KL) grade 2-3 and Visual Analogue Scale (VAS) pain >=40-<80mm were prospectively included to receive a single injection of MPS-HA2%. At 6m a second injection could be offered to selected patients. Primary outcome was reduction of VAS pain in the target knee. VAS for joint pain and WOMAC were recorded at 6 and 12m; Minimally Clinical Important Improvement MCII (>=20% relative change for VAS pain) and patient and investigator assessments (PGA, IGA) (Likert scale 0-4 points) were also estimated. Adverse events were recorded for safety assessment.

Results: One hundred and one patients (mean age 68 years, 74% female and 78% with overweight) were included. Mean pain at baseline in the target knee was 63.57mm and 57% were grade 3 KL with a mean evolution of 7.5 years. Table 1 shows the improvement in VAS and WOMAC scores at 6 and 12 months in the mITT population. Similar results were obtained in PP population.

Table 1. Changes in VAS and WOMAC scores, expressed as mean values

SCORE	Baseline	6 months		12 months	
	value	value	% variation (95% CI)	value	% variation (95% CI)
VAS pain	63.57	37.59	-39.74* (-49.23; -30.25)	38.37	-37.67* (-47.82; -27.52)
WOMAC					
total	50.19	31.88	-37.96* (-46.83; -29.09)	31.65	-36.47* (-46.20; -26.73)
pain	49.37	32.01	-32.92* (-43.37; -22.46)	31.08	-32.07* (-43.19; -20.95)
stiffness	49.12	28.35	-35.24** (-53.22; -17.23)	28.71	-34.08* (-49.30; 18.86)
function	52.07	35.30	-33.95* (-43.49; -24.40)	35.15	-32.71* (-42.80; -22.62)

*p-value: 0.0001; **p-value: 0.0002. Student test

The MCII was achieved by 66.3% of patients at 6m and 62.2% at 12m. Regarding PGA mean score was 2.44 at baseline, 1.35 at 6m and 1.46 at 12m (Wilcoxon, p-value <0.05). As for the IGA mean score was 2.29 at baseline, 1.06 at 6m and 1.48 at 12m (Wilcoxon, p-value <0.05).

Fourteen patients received a second injection at 6m and 50% of them achieved at 12m a significant and clinically relevant improvement compared to baseline, above the 20% established for the MCII.

In total, 12 adverse events (8 patients) were reported, all of them local, non-serious, and of mild-moderate intensity.

Conclusion: Viscosupplementation with a single intra-articular injection of MPS-HA2% has proven to be effective and well tolerated up to 12 months after treatment. The re-infiltration of the joint in appropriate cases has proven to be effective in a significant number of patients. The acceptability of the treatment by the patient was optimal.

POS0283 TREATMENT PATTERNS AND CLINICAL CHARACTERISTICS OF PATIENTS WITH OSTEOARTHRITIS OF THE HIP AND/OR KNEE TREATED WITH TRADITIONAL NSAIDS VS COX-2S: A REAL-WORLD STUDY OF COMMERCIALLY-INSURED PATIENTS

S. Silverman[1,2], P. Schepman[3], J. B. Rice[4], C. Beck[3], A. White[4], S. Thakkar[3], M. Johnson[4], R. Robinson[5], B. Emir[3]. *[1]Cedars Sinai Medical Center, Los Angeles, United States of America*; *[2]David Geffen School of Medicine at UCLA, Los Angeles, United States of America*; *[3]Pfizer, New York, United States of America*; *[4]Analysis Group, HEOR, Boston, United States of America*; *[5]Eli Lilly and Company, Indianapolis, United States of America*

Background: The 2019 American College of Rheumatology (ACR) guidelines strongly recommend oral nonsteroidal anti-inflammatory drugs (NSAIDs) for management of hip and knee osteoarthritis (OA) and strongly recommend topical NSAIDs for knee OA. There are, however, important safety considerations with NSAIDs in terms of increased rates of gastrointestinal, cardiovascular, and renal events. Given these risks, it is important to understand the characteristics and drug utilization of the patients who start treatment on these different treatments (i.e., traditional NSAIDs [tNSAIDs] and cyclooxygenase-2 inhibitors [COX-2s]).

Objectives: The goal of this research was to describe and compare baseline characteristics of commercially-insured patients diagnosed with OA of the hip and/or knee who started treatment on different types of NSAIDs (i.e., oral tNSAIDs, topical tNSAIDs, and COX-2s).

Methods: The Optum Healthcare Solutions, Inc. claims database (1/2012-3/2017) was used to identify patients ≥18 years old, with ≥2 diagnoses of hip and/or knee OA, and ≥90 days supply of oral tNSAIDs, topical tNSAIDs, or COX-2s during the one-year follow up period. The index date was defined as the first prescription after the first OA diagnosis. Patients were assigned to cohorts based on the type of NSAID prescribed on index date. Patients were required to be continuously-enrolled six months before (baseline period) and 36 months after (follow-up period) the index date. Demographic and clinical characteristics including age, sex, comorbidities, and healthcare resource use (HRU) were summarized during baseline. Drug utilization characteristics including days supply and number of prescriptions for the different NSAIDs types were summarized during follow-up period.

Results: Data for 23,796 patients were analyzed: 18,100 patients received oral tNSAIDs, 4,825 received COX-2s, and 871 topical tNSAIDs. Patients who initiated treatment on oral tNSAIDs were the youngest (mean age of 60.6 vs. 64.6 for COX-2s and 65.0 for topical tNSAIDs) and topical tNSAIDs had the highest proportion of female patients (71% vs. 62% for oral tNSAIDs and 63% for COX-2s). The topical tNSAIDs cohort had the highest presence of chronic kidney disease (2.6% vs. 1.0% and 1.5% for oral tNSAIDs and COX-2s, respectively) and congestive heart failure (2.5% vs. 0.8% and 1.7% for oral tNSAIDs and COX-2s, respectively) at baseline. In terms of HRU during baseline, topical

tNSAIDs had the most patients with emergency department visits (20.8% vs. 16.7% in both COX-2s and oral tNSAIDs), and COX-2 had the most patients with inpatient visits (18.1% vs. 15.4% for topical tNSAIDs and 11.8% for oral tNSAIDs). Oral tNSAIDs had the lowest total all-cause cost ($6,504), and the topical tNSAIDs cohort had the highest costs ($8,455), but fairly comparable with COX-2s ($8,289). During follow-up, oral tNSAIDs patients stayed mostly on oral tNSAIDs as less than 15% of oral tNSAIDs patients later had a prescription for COX-2s or topical tNSAIDs. 37% of COX-2 patients and 56% of topical tNSAIDs patients later took oral tNSAIDs. Topical tNSAIDs patients had an average of 184.4 days of supply for topical tNSAIDs yet also extensively used oral NSAIDs during follow-up (average days of supply for oral tNSAIDs was 315.5 days and for COX-2s was 383.5 days).

Conclusion: This study suggests that patients with more complex comorbidity profiles, including higher rates of adverse effects, often start pharmacological treatment with topical tNSAIDs. However, patients who start treatment with topical tNSAIDs switch to other types of NSAIDs; oral tNSAIDs were the most frequently prescribed treatment across the cohorts. Thus, despite the safety concerns with oral tNSAIDs and COX-2s, patients are still placed on these treatments to manage their OA pain. There is a need for new innovative treatments as there is currently a lack of other options.

POS0284 CLINICAL AND MRI COMPARISON OF ECCENTRIC VERSUS CONCENTRIC REHABILITATION IN SYMPTOMATIC KNEE OSTEOARTHRITIS: A PROSPECTIVE RANDOMIZED STUDY

M. C. Trojani[1], D. Bendahan[2], F. Chorin[3], P. Gerus[4], V. Breuil[5], S. Guis[6], C. Roux[7]. [1]*Université cote d'azur, Rheumatology, Nice, France*; [2]*Aix Marseille University, CNRS, Centre de Résonance Magnétique Biologique et Médicale (CRMBM), UMR 7339, Marseille, France*; [3]*Université Cote d'Azur, LAMHESS laboratory, NICE, France*; [4]*Université Cote d'Azur, LAMHESS laboratory, Nice, France*; [5]*Université Cote d'Azur, Rheumatology, Nice, France*; [6] *Aix-Marseille University, 13009, Marseille, France, CRMBM UMR CNRS 7339, Marseille, France*; [7]*Université cote d'azur, Rheumatology, Nice, France*

Background: Rehabilitation is at the center of the non-medical management of knee osteoarthritis. Concentric muscle strengthening is often preferred, while eccentric contractions play an important role in controlling knee flexion and knee stability and allow the development of a high level of strength with a low energy cost. But few studies have focused on these two technique

Objectives: To explore the effect of a 6-week-exercise program on function, pain and performance level in symptomatic knee osteoarthritis patients

Methods: An analysis was performed of the data from 60 individuals with symptomatic knee osteoarthritis who were included in the EXART study. The EXART study was a prospective, randomized controlled trial which included patients aged 40 to 85 with KL 2 or 3 responding to the American College of Rheumatology criteria. The first group benefitted from a 6 week eccentric rehabilitation program and the second group from a standard 6 week concentric rehabilitation program. The endpoints were the changes from baseline to week 6 in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), pain, and performance measured with quadriceps power (PMax) and contraction strength (MMax). MRI muscle analysis was performed before and after physical activity.

Results: Among 80 patients screened, 60 were included in the study and randomized. 25/30 subjects finished the program in the concentric group and 28/30 in the eccentric group. The mean population age was 74 (+/-8), mean IMC 27.2 (+/-4). The baseline total WOMAC mean was 49.2 (+/-19), VAS pain 5.3 (+/-2). At 6 weeks, both groups showed a significant improvement compared to baseline for the WOMAC without any difference between the two groups (mean difference evolution concentric = 7.5 ± 11.9 (p= p<0.0001); mean difference evolution eccentric = 4.5 ± 1.9 (p<0.0001); intergroup analysis p=0.7). Similar significant results were found in the WOMAC function subscale. No difference between the groups appeared in VAS pain evolution (p= 0.7). The eccentric group showed a significant improvement in PMax and high speed MMax evolution (p=0.001 and p=0.002). This improvement was not found for the concentric group (p= 0.52 and p=0.27). MRI showed a vastus medialis hypertrophy only in the eccentric group (p=0.002). We did not observe any change in the fatty infiltration of the quadriceps on MRI.

Conclusion: Rehabilitation, whether eccentric or concentric, has a beneficial action on function and pain in symptomatic knee osteoarthritis whatever the methods. A gain in muscle performance and vastus medialis volume was found only with the eccentric rehabilitation. This study confirms the importance of any type of rehabilitation in knee osteoarthritis and raises the question of the relation between muscle gain/performance and function or pain

POS0285 ARE RACIAL DISPARITIES IN REVISION TKA OUTCOMES ASSOCIATED WITH HOSPITAL OR SURGEON VOLUME?

S. Mirza[1], S. Goodman[2,3], Y. Zhang[2], H. Do[2], B. Mehta[2,3], S. Lyman[2], L. A. Mandl[2,3], M. Figgie[4], M. Parks[4], L. Russell[2,3], A. Bass[2,3]. [1]*Touro College of Osteopathic Medicine, Medical School, New York, United States of America*; [2]*Hospital for Special Surgery, Medicine, New York, United States of America*; [3]*Weill Cornell Medical Center, Medicine, New York, United States of America*; [4]*Hospital for Special Surgery, Orthopedic Surgery, New York, United States of America*

Background: Total knee arthroplasty (TKA) outcomes are linked to surgical volume,[1] despite the increase in TKA utilization, racial disparities in TKA outcomes persist. Blacks in the US are at a higher risk of aseptic revision of TKA (R-TKA) when compared to Whites, yet the reasons for this are not understood.

Objectives: The objective of this study is to examine the relationship between hospital and surgeon annual TKA volume and R-TKA outcomes by race.

Methods: This is an observational cohort study. New York Statewide Planning and Research Cooperative System data for 2004 – 2013 was used to identify patients who underwent primary TKA. Data through 2015 was used to identify R-TKA within 2 years of the index TKA. Hospital characteristics were obtained from the AHA Annual Survey. Surgeon data was collected from New York State Education Department and New York State Physician Profile. Surgeon annual TKA volume was categorized based on cutoffs established by Wilson et al[1] as </=12, 13-59, 60-145 or >/= 146, and hospital TKA volume as </=89, 90-235, 236-644 and >/=645. We calculated the odds of R-TKA in Whites and Blacks separately and generated crude odds ratios (OR) comparing Blacks to Whites to examine trends across volume categories. A multivariable logistic regression model adjusted for known R-TKA risk factors was also performed.

Results: A total of 163,576 patients were included. Mean (SD) age was 66.4 (10.4) years, 107,233 (65.6%) were female, 124,277 (76.6%) were White and 15,990 (9.8%) were Black. 2925 patients underwent aseptic R-TKA. In logistic regression analysis, Blacks had a higher risk of R-TKA (OR 1.42, 95%CI 1.26-1.6) (**Table 1).** Risk of R-TKA was also higher when surgeon annual volume was </=12 (OR 1.5, 95%CI 1.25-1.8) or 13-59 (OR 1.16, 95%CI 1.04-1.29) TKA compared to the highest volume surgeons (>/=146). Patients who had surgery at a hospital with annual volume of 236-634 TKA were less likely to undergo R-TKA compared to the highest volume hospitals (>/=645) (OR 0.88, 95%CI 0.79-0.98). Other risk factors for R-TKA were younger age and worker's compensation, while patients with inflammatory arthritis had a lower risk. Figures 1A and 1B show the odds of R-TKA in Whites and Blacks, respectively, by hospital and surgeon volume. Figure 1C shows the crude OR for Blacks to Whites for each category pair. The OR ranged from 0.9 to 2.5, with the largest disparity found in patients who have TKA performed by surgeons with 60-145 annual TKA volume at the highest volume hospitals (>/=645).

Conclusion: Patients having TKA by a surgeon performing <60 TKA per year have higher risk of R-TKA. Racial disparities in R-TKA risk are highest for TKA by surgeons performing 60-145 TKA per year at hospitals performing >/=645 TKA per year. Future studies should examine factors, such as whether trainees are involved the surgery, that may vary based on social determines of health, such as patient race and payor.

POS0286

INCIDENCE OF MALIGNANCIES IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM A LARGE JAPANESE NATIONAL REGISTRY

T. Matsui[1], N. Sugiyama[2], S. Toyoizumi[3], F. Matsuyama[4], T. Murata[4], Y. Urata[5], K. Kawahata[6], S. Tohma[7]. [1]*National Hospital Organization Sagamihara National Hospital, Department of Rheumatology, Clinical Research Center for Allergy and Rheumatology, Kanagawa, Japan*; [2]*Pfizer Japan Inc, Inflammation and Immunology, Tokyo, Japan*; [3]*Pfizer R&D Japan, Biometrics and Data Management, Tokyo, Japan*; [4]*CRECON Medical Assessment Inc, Tokyo, Japan*; [5]*Tsugaru General Hospital, Department of Rheumatology, Aomori, Japan*; [6]*St. Marianna University School of Medicine, Division of Rheumatology and Allergology, Department of Internal Medicine, Kanagawa, Japan*; [7]*National Hospital Organization Tokyo National Hospital, Department of Rheumatology, Tokyo, Japan*

Background: Patients (pts) with rheumatoid arthritis (RA) have an increased risk of some malignancies vs the general population, and this can vary by region/ race.[1,2] Data on the epidemiology and impact of biological (b)DMARDs and targeted synthetic (ts)DMARDs, such as Janus kinase (JAK) inhibitors, on the incidence of malignancies in Japanese pts with RA are limited. The National Database of Rheumatic Diseases in Japan (NinJa) is one of the largest RA registries in Japan.
Objectives: To evaluate the incidence of malignancies in Japanese pts with RA using NinJa registry data.
Methods: This retrospective observational study analysed NinJa registry data for Japanese pts with RA aged ≥18 years with ≥1 data entry between 2013 (first JAK inhibitor approval for RA in Japan) and 2018. The overall cohort included all pts with RA, and two sub-cohorts were analysed: pts exposed and unexposed to bDMARDs (exposure defined as ≥1 bDMARD reported in database). Crude incidence rates (IRs) for malignancies (including non-melanoma skin cancer) were calculated as the number of events per 100 pt-years of follow-up (time between start of follow-up or the date of first bDMARD exposure [for bDMARD-exposed pts] and end of observation period, or withdrawal from database). The most recent data for incidence of malignancy in the Japanese general population (2013–2017 data from the National Cancer Center, Japan) were used to calculate standardised incidence ratios (SIRs) and age- and sex-adjusted standardised rates (ASRs) for malignancies. Cross-sectional (per calendar year) and cumulative analyses were performed for the overall cohort. Cumulative rates were calculated for sub-cohorts, and all cumulative analyses were repeated excluding pts exposed to JAK inhibitors (ie ≥1 JAK inhibitor reported in database).
Results: Data were collected for 26 607 Japanese pts with RA from 2013–2018. In the cross-sectional analysis (Table 1), the SIR and ASR for malignancies in all pts with RA were generally consistent from 2013–2018. In the cumulative analysis, the SIR (95% CI) for malignancies from 2013–2018 was 0.97 (0.91, 1.03) in all pts with RA, and 0.93 (0.82, 1.04) and 0.99 (0.92, 1.07) in pts exposed and unexposed to bDMARDs, respectively (Figure 1). Adjusting for age/sex, the cumulative ASR (95% CI) for malignancies from 2013–2018 was 0.83 (0.76, 0.90) in all pts with RA, and 0.82 (0.69, 0.95) and 0.86 (0.77, 0.96) in pts exposed and unexposed to bDMARDs, respectively (Figure 1). In all cohorts, the cumulative SIR and ASR were similar when pts exposed to JAK inhibitors were excluded (Figure 1).

Table 1. Cross-sectional analysis of the incidence of malignancies in Japanese pts with RA from 2013–2018

	All RA					
	2013 (N=13 423)	2014 (N=15 584)	2015 (N=15 751)	2016 (N=16 107)	2017 (N=15 994)	2018 (N=15 003)
Total follow-up, PY	13 353	14 866	14 829	14 970	14 748	14 898
Pts with events, n	140	164	174	168	161	211
Crude IR[a]	1.05	1.10	1.17	1.12	1.09	1.42
(95% CI)	(0.89, 1.24)	(0.95, 1.29)	(1.01, 1.36)	(0.97, 1.31)	(0.94, 1.27)	(1.24, 1.62)
ASR[a,b]	0.76	0.76	0.90	0.88	0.80	0.88
(95% CI)	(0.60, 0.93)	(0.62, 0.90)	(0.68, 1.11)	(0.68, 1.07)	(0.62, 0.98)	(0.74, 1.01)
SIR[b]	0.97	1.01	1.02	0.88	0.86	1.10
(95% CI)	(0.82, 1.14)	(0.86, 1.17)	(0.87, 1.18)	(0.75, 1.02)	(0.73, 1.00)	(0.95, 1.25)

[a]IR/ASR were calculated as number of events per 100 PY of follow-up[b]Data from a Japanese general population database of malignancy incidence from 2013–2017, provided by the Center for Cancer Control and Information Services, National Cancer Center, JapanPY, pt-years

Conclusion: The incidence of malignancies in Japanese pts with RA, registered in the NinJa database from 2013–2018, was similar to that in the Japanese general population. The SIR and ASR for malignancies were comparable in pts exposed and unexposed to bDMARDs. In all cohorts, rates did not increase when pts exposed to JAK inhibitors were included.

POS0287 USE OF BIOLOGIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS IN RELATION TO THE RISK OF LYMPHOMA: A COHORT STUDY OF US VETERANS WITH RHEUMATOID ARTHRITIS

N. Singh[1], A. Peterson[2], A. Baraff[2], A. Korpak[2], M. Vaughan-Sarrazin[3], N. Smith[2], J. Curtis[4], N. Weiss[5]. *[1]1959 NE Pacific St, Internal Medicine, Seattle, United States of America*; *[2]1660 S Columbian Way, Epidemiologic Research and Information Center, Seattle, United States of America*; *[3]UI Hospitals and Clinics, 200 Hawkins Dr, Internal Medicine, Iowa City, United States of America*; *[4]University of Alabama at Birmingham, Internal Medicine, Birmingham, United States of America*; *[5]University of Washington School of Public Health, Epidemiology, Seattle, United States of America*

Background: Epidemiologic studies suggest that disease duration and degree of inflammatory activity of rheumatoid arthritis (RA) contribute to lymphoma development. However, the association of the use of biologic disease modifying anti-rheumatic drugs (bDMARDs) in patients with RA on lymphoma risk needs further evaluation.
Objectives: Examine the effect of administration of bDMARDS on the incidence of lymphoma in an inception cohort of RA.
Methods: We identified patients diagnosed with RA in any US Veterans Affairs (VA) facility from 1/1/2002 and 12/31/2018 using the Veteran's Health Administration (VHA) databases. To be included, each patient was required to meet the following criteria: 1) 2+ RA diagnostic codes at least 7 days apart but no more than 365 days apart 2) a prescription for a conventional synthetic DMARD (csDMARD) within 90 days of the first RA diagnosis 3) One inpatient or outpatient visit 30 days to 2 years preceding first RA diagnosis (indicating they are a regular user of the VHA). We excluded patients for any of the following if they preceded the first RA diagnosis: 1) a prior single RA diagnostic code 2) a prescription for any DMARD medication 3) a concomitant diagnosis of another inflammatory arthritis (e.g. psoriatic arthropathy) 4) a diagnosis of lymphoma. Index date for the study is the date of the first qualifying RA diagnosis. Lymphoma diagnoses were identified through VHA records using the International Classification of Diseases-Oncology codes.
Results: We identified 27,536 veterans with RA in the study period meeting the inclusion and exclusion criteria. Of these, 53% (n=14,705) were in the age range 60 to 80 years. The cohort was 89% male, 75.5% White, 13.7% African American. Over the study period, 1.2% (n=332) of the study population developed a lymphoma.
Conclusion: Using the nationwide VHA we have identified a large inception cohort of patients with RA of whom 1.2% developed lymphoma over study follow-up. This data will be used in future analyses to produce estimates of the effect of biologic medications on lymphoma risk, adjusting for confounding by indication and other variables.

Table 1. Baseline characteristics of the cohort based on bDMARD exposure status

Characteristic	bDMARD-naive (n= 19,095)	bDMARD-exposed (n=8,441)
Overall Lymphomas		
Age (years)	171	161
18-40	4	6
40-60	63	78
60-80	100	74
>80	4	3
Males	17,206 (90%)	7,270 (86%)
Race		
White	14,150 (74%)	6,627 (76%)
Black	2,674 (14%)	1,090 (13%)
Asian	96 (0.5%)	46 (0.5%)
Native American or Pacific Islander	371 (2%)	187 (2.2%)
Missing	1,804 (9%)	491 (6%)

POS0288 A KEY TIF1Γ EPITOPE MAY FACILITATE THE IDENTIFICATION OF PATIENTS AT HIGHEST RISK OF CANCER ASSOCIATED MYOSITIS

V. Riddell[1], F. Mcmorrow[2], A. Oldroyd[3], C. Deakin[4], J. Lamb[3], H. Chinoy[3,5], L. Wedderburn[4,6], S. Bagby[1], N. Mchugh[2], S. Tansley[2,7]. *[1]University of Bath, Biology and Biochemistry, Bath, United Kingdom*; *[2]University of Bath, Pharmacy and Pharmacology, Bath, United Kingdom*; *[3]University of Manchester, NIHR Manchester Musculoskeletal Biomedical Research Centre, Manchester, United Kingdom*; *[4]University College London, GOS Institute of Child Health, London, United Kingdom*; *[5]Salford Royal NHS Foundation Trust, Rheumatology, Manchester, United Kingdom*; *[6]Great Ormond Street Hospital, Rheumatology, London, United Kingdom*; *[7]Royal United Hospitals Bath NHS Foundation Trust, Rheumatology, Bath, United Kingdom*

Background: The myositis specific autoantibody anti-TIF1γ targets TRIM33, a TRIM family proetin with a PHDBromo domain at the C terminal end. Anti-TIF1γ is strongly associated with malignancy in adult patients with idiopathic inflammatory myopathies (IIM). Intriguingly, anti-TIF1γ is also the most common autoantibody in juvenile-onset IIM but younger patients with anti-TIF1γ do not have an increased risk of cancer (1-3). Genetic studies have consistently shown human leukocyte antigen (HLA) to be the strongest risk factor for IIM. Adult and juvenile-onset patients with anti-TIF1γ have recently been shown to have different associations at the *HLA-DQB1* locus (4). This could be due to differences in the key TIF1γ epitopes and may relate to differences in aetiology, such as malignancy in adults versus other environmental factors in juvenile onset disease.
Objectives: To identify key epitopes targeted by anti-TIF1γ antibody in patients with IIM and establish if different TIF1γ epitopes are targeted in patients with and without malignancy.
Methods: Patient plasma/serum samples were obtained from UK Juvenile Dermatomyositis Cohort and Biomarker and UKMyoNet studies. Autoantibody status had previously been determined by immunoprecipitation. Cancer data was collated from the UK Health and Social Care Information Centre and cancer associated IIM (CAM) defined as that occurring within 3 years of IIM diagnosis. An in house ELISA was developed using a purified TIF1γ fragment comprising residues 882-1090, produced in *E.coli,* corresponding to the PHDBromo protein domain. An ELISA cut-off of 5SD above the mean of 38 healthy control samples was used.
Results: 38 healthy controls, and 117 anti-TIF1γ IIM patient sera (60 juvenile onset) were analysed for reactivity to the TIF1γ PHDbromo domain.
No healthy controls were positive. Anti-TIF1γPHDbromo was more common in JDM: 18 (30%) juvenile patients and 6 (10.5%) adult patients were positive, p=0.01. Additional data was available for 39 adult patients (82% female, median age 52 (IQR 38-64)). Anti-TIF1γPHDbromo was only found in CAM patients plus one young adult non-CAM patient aged 27 years at disease onset, p =0.07 (p=0.02 for patients >30 years at disease onset), see Table 1. No juvenile patients had a history of malignancy.

Table 1. Anti-TIF1γPHDbromo in 39 adult patients with cancer data available

	anti-TIF1γPHDbromo positive	anti-TIF1γPHDbromo negative
Cancer associated myositis n(%)	5[a] (83)	12(36)
Myositis not associated with cancer n(%)	1[b](17)	21(64)
Total	6	33

a. Median age 64 yearsb. Age 27 years

Conclusion: The TIF1γ PHDBromo domain is an important epitope and autoantibody reactivity is more common in patients with juvenile-onset disease and adults with CAM. The distinction between adult and juvenile-onset IIM is arbitrary and it is relevant that the only adult with anti-TIF1γPHDbromo not to have malignancy was just 27 years old. Our numbers are small and further work is needed to establish if anti-TIF1γPHDbromo, and indeed other TIF1γ epitopes, could help identify patients at highest risk of malignancy, and how this relates to our understanding of IIM aetiopathogenesis. Our findings may add weight to the theory that the development of IIM in younger patients occurs after immune-mediated resolution of a pre-cancer event.

POS0289 CANCER RISK IN IMMUNOSUPPRESSED SCLERODERMA PATIENTS: A PROPENSITY SCORE MATCHING ANALYSIS

L. Verardi[1], E. De Lorenzis[1], G. Natalello[1], L. Gigante[1], M. A. D'agostino[1], S. L. Bosello[1]. [1]*Fondazione Policlinico Universitario A. Gemelli IRCCS - Catholic University of the Sacred Heart, Rheumatology Unit, Rome, Italy*

Background: An increased incidence of cancer in patients with systemic sclerosis (SSc) is well-established[1]. Current knowledge about the onco-transforming power of immunosuppressive treatments in both non-rheumatological and rheumatological pathologies, suggests an increased incidence of hematological and solid neoplasms[2]. Evidences on the possible role of the immunosuppressants in the onset of cancer during SSc are lacking.
Objectives: To evaluate the incidence of malignancies in SSc patients exposed to immunosuppressive therapy.
Methods: The incidence of neoplasia in a cohort of 600 patients with SSc was evaluated retrospectively. Patients diagnosed with malignancy within 36 months from SSc onset were excluded from the analysis since suspected for paraneoplastic form. Patients exposed to methotrexate, cyclophosphamide, azathioprine and mycophenolate were confronted with a group comparable for age at onset, sex, disease variant, autoantibodies and exposure to other disease-specific therapies, using propensity score matching analysis. The considered follow-up was between the clinical onset and the diagnosis of cancer or the last available visit or the twenty-fifth year of illness.
Results: The analysis was carried out on 526 patients observed for an average period of 12.1 ± 6.0 years (males 9.5%, age at onset 49.0 ± 15.3 years); 24.9% had diffuse cutaneous variant of the disease and 39.0% and 34.8% were respectively positive for anti-centromere and anti-Scl70 antibodies. During the follow-up, 19.0% of patients were exposed to cyclophosphamide, 15.3% to azathioprine, 14.4% to methotrexate and 11.6% to mycophenolate mofetil. Sixty-five cancer diagnoses were made after the 36th month from onset (incidence 1.02: 100 patients/year), comprising 16 mammary cancers, 12 cancers of the gastro-intestinal tract, 11 cancers of the head-neck area, 10 cancers of the lungs, 9 cases of skin-cancer, 5 haematological malignancies and 1 brain tumour. The incidence of cancers did not differ in relation to treatment with cyclophosphamide (X^2 = 0.001, p = 0.961), azathioprine (X^2 = 2.141, p = 0.143), mycophenolate mofetil (X^2 = 0.001, p = 0.993) or methotrexate (X^2 = 0.920, p = 0.337) (Figure 1).
Conclusion: Our data are consistent with an increased incidence of neoplasms in the course of SSc, with a rate that appears almost doubled compared to the general Italian population with similar sex and age distribution (0.55: 100 patients/year; Italian Association of Tumor Registries data[3]). In our SSc cohort this risk is independent of exposure to immunosuppressive drugs commonly used for the treatment of scleroderma disease.

POS0290 PREDICTING RISK FACTORS OF MALT LYMPHOMA IN SJÖGREN'S SYNDROME

L. Chatzis[1], V. Pezoulas[2], A. Goules[1], I. Stergiou[1], C. Mavragani[3], H. M. Moutsopoulos[4], M. Voulgarelis[1], D. Fotiadis[2], A. Tzioufas[1]. [1]*School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Ag thoma 15, Greece*; [2]*University of Ioannina, Unit of Medical Technology and Intelligent Information Systems, Ioannina, Greece*; [3]*School of Medicine, National and Kapodistrian University of Athens, Physiology, Athens, Greece*; [4]*Academy of Athens, Chair Medical Sciences/Immunology, Greece, Athens, Greece*

Background: Primary Sjögren Syndrome (SS) is a slowly progressive systemic autoimmune disease complicated by lymphoma, with mucosa associated lymphoid tissue (MALT) type being the most common lymphoma form. Several predictors related to pSS associated lymphomas have been described, but there are no studies focusing on specific risk factors for the MALT histologic subtype.
Objectives: To identify predictors at SS diagnosis for MALT lymphoma development in pSS patients using simple clinical features.
Methods: From 815 SS patients of a single center fulfilling the 2016 ACR/EULAR criteria, those with subsequent development of MALT lymphoma according to the 2016 WHO classification were identified and matched in 1:2 ratio, with non-lymphoma SS control patients according to age, disease duration from SS diagnosis and gender. Lymphoma patients diagnosed within a year from SS diagnosis were excluded from the current study. Clinical, laboratory, histologic data as well as the ESSDAI scores at the time of SS diagnosis were recorded and compared between lymphoma and non-lymphoma patients. Independent lymphoma predictors were identified by a data driven Fast Correlation Based Feature selection (FCBF)/Logistic Regression (LR) algorithm.
Results: A unified dataset of 57 MALT lymphoma patients and 114 non lymphoma controls along with 39 features/variables was generated. The median age of SS diagnosis and the disease duration from SS diagnosis to lymphoma diagnosis (lymphoma group) or last follow up (control group) was 50,5 years old (range 25-77) and 7 years (range 0- 30) for the control group and 50 years old (range 24-70) and 8 years (range 1 -30) for the lymphoma group, respectively. MALT lymphoma patients presented more frequently with palpable purpura (23,2% vs 5,3% p=0,001), cryoglobulinemia (30,2% vs 1,6% p<0,0001), low C4 serum levels (62,9% vs 32,1% p=0,0003), rheumatoid factor (76,9% vs 56,1% p=0,01), anti La/SSB antibodies (33,9% vs 50,8% p=0,049) and higher median ESSDAI score (5 vs 2, p<0,0001). In contrast, autoimmune thyroiditis was more prevalent in controls (48,2% vs 18,6%, p=0,004). The FCBF/LR model revealed cryoglobulinemia (p=0,03) and ESSDAI at SS Diagnosis (p<0,001) as the only independent lymphoma predictors.
Conclusion: MALT is the predominant pSS related lymphoproliferative histologic type, associated with systemic disease activity and vasculitic manifestations at SS diagnosis. Cryoglobulinemia and ESSDAI score were proven independent risk factors for MALT lymphoma development.

Table 1. An FCBF-based multivariable logistic regression analysis results for investigating risk factors for MALT lymphoma development

Prominent feature	Regression coefficient	Odds ratio	p-value	CI low	CI upper
Cryoglobulinemia	1.67	5.342	0.033*	1.18	24.327
Total ESSDAI at diagnosis	0.28	1.318	<0.001*	1.208	1.439
Kidney involvement	0.07	1.069	0.5	0.101	0.351

•< 0.05 (95% confidence interval). The rest of the features that participated in the analysis include the following: Palpable purpura, Low C4, Salivary gland enlargement, Lacrimal gland enlargement, ANA Titers, RF, Focus score at Sjögren diagnosis, PNS involvement, Anti-La, Disease duration from SS onset to SS diagnosis, Neutrophils<1500, Autoimmune thyroiditis, Lung involvement – interstitial disease Type, Lymphocytes<1000, Lymphadenopathy fixed, Arthralgias, Dry eyes, Raynaud, Gender, Age at Sjögren diagnosis, Dry mouth, Aca, Hb<12.5 g/dL, ANA, Disease duration from SS Diagnosis to Lymphoma diagnosis or last follow up, Anti-Ro, Arthritis, WBC<4000/μL, Lung involvement bronchocentric disease, Interstitial renal disease, PLTs<100.000/μL, Liver involvement-PBC, Liver involvement–autoimmune hepatitis, CNS involvement.•AUC=0.78

POS0291 THE IMPACT OF DRUG INDUCED AND OTHER RHEUMATIC MUSCULOSKELETAL DISORDERS (MD) ON THE QUALITY OF LIFE (QOL) OF CANCER PATIENTS RECEIVED ANTICANCER DRUG TREATMENT

A. Koltakova[1], A. Lila[2], L. P. Ananyeva[1], A. Fedenko[3]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Adminisrtation, Moscow, Russian Federation*; [3]*National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Department of Drug Treatment of Cancer, Moscow, Russian Federation*

Background: Pts with cancer may have MD that can be caused by neoplastic/ paraneoplastic disease, rheumatic diseases or be induced by anticancer drug treatment. There is no data about MD influence on the QoL of cancer patients. The EORTC QoL questionnaire (QLQ)-C30 is a valid questionnaire designed to assess different aspects (Global health (GH), Functional (FS) and symptoms (SS) scales) that define the QoL of cancer patients [1].
Objectives: The objective of the study was to assess the impact of drug induced and other types of MD on the QoL of cancer patients that received anticancer drug treatment by using of EORTC QLQ-C30 v3.0.
Methods: The sampling of 123 pts (M/F – 40/83; mean age 54.4±12.8) with breast (32,5%), gastrointestinal (17%), ovary (8%), lung (7%) and other cancer was observed by rheumatologist in the oncology outpatient clinic. All pts received anticancer drug treatment: chemotherapy (104 pts), target therapy (16 pts) checkpoint-inhibitors (14 pts), hormone therapy (13 pts) in different combinations. 102(82.9%) of 123pts had MD include arthritis (12 pts), synovitis (5 pts), arthralgia (66 pts), periarthritis (34 pts), osteodynia (13 pts). There were 58 pts (group 1; M/F – 14/44; mean age 52.5±12.2) with anticancer drug treatment induced MD and 44 pts (group 2; M/F – 16/27; mean age 57.6±13.5) with other type of MD include 26 pts with skeletal metastasis. The were 21 pts (group 3; M/F – 10/11; mean age 52.9±11.1) without MD. All pts fulfilled EORTC QLQ-C30 v3.0 (tab.1).

Table 1. The median [Q1;Q3] of results of GH, SS and SS of EORTC QLQ-C30

Scale	Subscale	Group1	Group2	Group3
GH		58.3[50;58]	58.3[41.7;83.3]	50[50;66.7]
FS*	Physical functioning	73.3[60;86.7]	73.3[66.7;86.7]	86.7[80;93]
	Role functioning	66.7[66.7;100]	83.3[50;100]	100[83;100]
	Emotional functioning	83.3[66.7;100]	75[66.7;91.7]	91.6[83.3;100]
	Social functioning	83.3[66.7;100]	83.3[50;100]	100[83.3;100]
SS*	Pain	33.3[0;50]	16.7[0;33.3]	0[0;16.7]

*There are only the scores that had got a statistical difference between the groups.

Kruskal-Wallis H and post-hoc (Dwass-Steel-Critchlow-Fligner (DSCF) pairwise comparisons) tests for data analysis were performed.
Results: A Kruskal-Wallis H test has shown a statistically significant difference in physical ($\chi2(2)=7.54$; p=0.023), role ($\chi2(2)=9.87$; p=0.007), emotion ($\chi2(2)=7.69$; p=0.021) functioning and pain ($\chi2(2)=8.44$; p=0.015) scores between the different groups. A post-hoc test with DSCF pairwise comparisons of median has shown a statistically significant difference between 1 and 3 groups (W=3.904; p=0.016) for physical functioning, between 2 and 3 groups (W=3.35; p=0.004) for role functioning, between 2 and 3 groups (W=4.03; p=0.012) for emotional functioning, between 1 and 3 groups (W=-3.97; p=0.014) for pain scale.
Conclusion: The study has shown that MD associated with anticancer drug treatment adversely affected the QoL of cancer patients received anticancer drug treatment by reducing a physical functioning and by increasing pain scores. Presence of other types of MD adversely affect the QoL by reducing emotional and role functioning.

POS0292 OSTEOPOROSIS IN BREAST CANCER PATIENTS ON AROMATASE INHIBITORS THERAPY: ABOUT 200 CASES

R. Assadi[1], K. Nassar[1], S. Janani[1]. [1]*CHU ibn rochd, Rheumatology, Casablanca, Morocco*

Background: Breast cancer is the most common cancer affecting women both before and after the menopause. Aromatase inhibitors (AIs) used as adjuvant therapy cause bone loss and increase the risk of osteoporosis (OP) (1).
Objectives: To assess the bone status and the frequency of OP in breast cancer patients using AIs.
Methods: We conducted a retrospective study in the rheumatology department, over 5 years (2016-2020).
Inclusion criteria: patients followed for breast neoplasm in oncology department on AIs therapy and referred to rheumatology department for bone evaluation.
All of these patients underwent an evaluation of bone mineral density (BMD) and phosphocalcic assessment.
Exclusion criteria: patients treated by another type of hormone therapy and having other risk factors for OP.
Results: 200 breast cancer women were enrolled for the study, 92 patients (46%) were treated with AIs, the average age was 58.22 years (41 - 75 years) with an average age of discovery of the breast cancer of 46.75 years and the average time between the start of AIs therapy and the diagnosis of OP was 21.6 months. the characteristics of the patients are summed up in Table 1.
97% of patients were postmenopausal and 38% of them had menopause secondary to treatment.
In AIs users, 85 patients (92.3%) were osteoporotic, and 11% had bone fractures. In regard to osteodensitometry measurement, lumbar spine was the most affected site (88%) with mean T score of -2.98 and mean BMD of 0.854, followed by femoral neck (17%) with mean T score of - 2.8 and mean BMD of 0.740 and total hip (14%) with mean T score of -3.10 and mean BMD of 0.497.
The cancer was metastatic in 15.18% patients, 75% of the group had bone metastasis and 25% had visceral metastasis.
The phosphocalcic status of the osteoporotic patients was: mean calcemia: 92.83 mg / l, mean calciuria: 131.8 mg / 24h, mean phosphatemia: 48.09 mg / l, mean 25 OH Vit D level: 19.78 ng / ml, mean PTH: 79 pg / ml.
Osteoporotic patients were treated with bisphosphonates, 60% women had received Alendronate, 17% Risedronate and 12% Zoledronate in addition to dietary measures and correction of calcium and vitamin D deficiency.
Conclusion: AIs are correlated with a high risk of OP and fractures in 30% of patients (2), the frequency of OP in our series is estimated at 42.5%.
Assessment of bone status and OP clinical risk factors should be systematic in all breast cancer patients receiving adjuvant AIs therapy.
Bisphosphonates appear to be beneficial in treating secondary OP, in preventing bone fractures, and in reducing the incidence of breast cancer bone metastases.

POS0293

TRHEUMA REGISTRY PROVIDES FIRST EVIDENCE OF DIFFERENT COURSE OF RHEUMATIC IMMUNE-RELATED ADVERSE EVENTS AND TUMOUR RESPONSE RATES DEPENDING ON THE TUMOUR ENTITY

L. Diekmann[1], L. Daniello[2], J. Kunz[2], J. Leipe[3], H. M. Lorenz[1], J. Hassel[4], K. Jordan[1], P. Christopoulos[2], K. Benesova[1]. [1]*University Hospital Heidelberg, Department of Medicine V, Hematology, Oncology and Rheumatology, Heidelberg, Germany*; [2]*Thoraxklinik Heidelberg, Department of Thoracic Oncology, Heidelberg, Germany*; [3]*University Hospital Mannheim, Division of Rheumatology, Department of Medicine V, Mannheim, Germany*; [4]*University Hospital Heidelberg, Department of Dermatology and National Center for Tumor Diseases, Heidelberg, Germany*

Background: Rheumatic immune-related adverse events (irAE) are associated with a better tumour response to immune checkpoint inhibitors (ICI). In contrast to other irAEs, their potentially chronic course may require long-term immunosuppressive treatment.
Objectives: Our registry-based study analyses real-world data on the characteristics and outcome of rheumatic irAEs and underlying malignancy. Herein, we present first evidence that these parameters and the optimal clinical management may differ depending on the tumour entity.
Methods: The TRheuMa registry is a prospective long-term observational study of a patient cohort suffering from rheumatic side effects of cancer therapies with focus on ICI. It is part of the MalheuR project initiated in July 2018 at the University Hospital Heidelberg to explore interrelations of malignancies and RMDs.
Results: 64 patients were recruited due to a rheumatic irAE under ICI treatment (nivolumab n=30, pembrolizumab n=33, ipilimumab n=12, PD-L1i n=5, ipi/nivo n=10) with a follow-up of up to 30 months. Of these, 47% had NSCLC and 41% melanoma. In local cohorts of patients receiving ICI, 4% of NSCLC (n total=888) and 13% of melanoma (n total=195) developed a rheumatic irAE. 7% of NSCLC and 23% of melanoma patients experienced a flare of a pre-existing RMD. De novo irAE mostly resembled phenotypes of spondyloarthritis both in NSCLC (43%) as well as in melanoma patients (33%). CRP levels were increased in 83% of NSCLC and 71% of melanoma patients. Almost all irAE patients showed autoantibody negativity and signs of inflammation in ultrasound examination (96%). Comparison of best responses to treatment in patients with and without rheumatic irAE in melanoma and without any irAE in NSCLC patients were as following: Complete remission (CR) in 48% vs. 4% of melanoma patients and partial remission (PR) in 68% vs. 41% of NSCLC patients. In accordance with our severity-based treatment algorithm, 25% of the melanoma patients in CR and 16% of the NSCLC patients in PR needed add-on DMARDs for sufficient irAE-treatment. ICI-treatment was discontinued in 7 cases (17% NSCLC, 8% melanoma)
Conclusion: Prospective real-world data from the TRheuMa-registry provide first evidence that rheumatic irAE have distinct characteristics depending on the underlying malignancy. Oncological outcome was better with rheumatic irAE than in their absence and this effect was more pronounced in melanoma patients despite a larger use of immunosuppressants for irAE-treatment.

POS0294

PROFILE OF SPINAL TUMORS IN RHEUMATOLOGY DEPARTMENTS

B. A. Hiba[1], H. Sahli[2], S. Boussaid[3], S. Nouicer[3], S. Jemmali[3], S. Rekik[2], M. Eleuch[1]. [1]*La Rabta, Rheumatology, Tunis, Tunisia*; [2]*La Rabta, Rheumatology, Tunis, Tunisia*; [3]*La Rabta, Rheumatology, Tunis, Tunisia*

Background: Spine tumors remain a hot topic because of their associated morbidity by affecting motor and sensory function. Contrary to metastatic spine disease (MSD), extremely prevalent, rise within or surrounding the spinal cord and/or vertebral column, primary spinal tumors are rare, 5% of all primary skeletal tumors and frequently benign (20%). The diagnostic delay of these tumors, even when benign, is associated with a poor prognosis. Establishing the correct diagnosis is heavily reliant on magnetic resonance imaging and histological confirmation.
Objectives: to provide an overview of the epidemiology, radiological and histopathological of spinal tumors diagnosed in a rheumatology department.
Methods: A retrospective study consisting of clinical characteristics analysis, laboratory and x-ray examinations, was performed on 40 patients who were hospitalised for a spinal tumor, in a rheumatology department, over 5-year period from 2015 to 2020.
Results: A total of 40 patients with a mean age of 66 ± 13.5 years [18-93] and a sex-ratio of 1.1, were included. The most common initial complaints were inflammatory back pain (67.5%) and fatigue (52.5%), with a median duration of 5 months. Physical examination abnormalities included lumbar stiffness (32.5%), radicular signs (18.7%), hepatomegaly (12.5%), and lymphadenopathy (17.5%). Neurological deficit was found in only 3 patients (7.5%). Hypercalcemia (corrected serum calcium > 105 mg/l), and anemia (hemoglobin (Hb) < 100 g/l in female, Hb <110g/l in male) were present initially in respectively 47.5% and 46.3% patients, while biological inflammatory syndrome was present in 89.7% patients (median C-reactive protein of 44.7). Tumor markers were performed in 12 patients and they were positive in 9 of them.
Plain radiographs findings were vertebral compression fractures (43.6%), osteolytic lesions (30.8%) and osteoblastic lesions (12.5%). Lumbar spine was the most affected (57.5%), followed by the dorsal spine (45%). Magnetic resonance imaging (MRI) was performed in 55%, and the most common lesion was low signal intensity on T1-weighted sequences and high signal intensity on T2-weighted sequences (68.1%).
In our study, only one patient was diagnosed for a myxopapillary ependymoma, a benign primary spinal tumor characterised by a metastatic dissemination risk. For the rest (39 patients), the diagnosis of bone metastasis, multiple myeloma (57.7%), and of solid tumor cancers (40%), were established. Primary cancers were mainly prostate cancer (37.5%), lung cancer (18.7%) and kidney cancer (18.7%). By a median follow-up time of 25 months, overall survival rate was 30%.
Conclusion: Extradural lesions are the most common, and are typically metastatic. Special attention should be pain to the patient's medical history and laboratory abnormalities. In fact, an early diagnosis requires a high index of clinical suspicion.

POS0295

NO CAUSAL EFFECTS OF GENETICALLY DETERMINED SERUM URATE LEVELS ON THE RISK OF ALL-CAUSE AND SITE-SPECIFIC CANCER: A MENDELIAN RANDOMIZATION STUDY

T. Fatima[1], Y. Borné[2], M. Dehlin[3], S. Burgess[4], A. Mason[5], L. T. H. Jacobsson[6], M. C. Kapetanovic[7]. [1]*University of Gothenburg, Department of Rheumatology and Inflammation Research, Göteborg, Sweden*; [2]*University of Lund, Department of Clinical Sciences, Malmö, Sweden*; [3]*University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; [4]*University of Cambridge, MRC Biostatistics Unit, School of Clinical Medicine, Cambridge, United Kingdom*; [5]*University of Cambridge, Cardiovascular Epidemiology Unit, School of Clinical Medicine, Cambridge, United Kingdom*; [3]*University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; [7]*University of Lund, Department of Clinical Sciences, Lund, Sweden*

Background: Positive associations between urate levels and gout and the risk of some cancer types (urogenital, prostate, gastrointestinal and lung) have been reported in a number of observational studies; however, whether the relationship is causal remains uncertain.
Objectives: The study aim was to evaluate a causal effect of genetically determined serum urate (SU) concentrations on cancer risks (overall and major cancer types) in individuals with European ancestry using Mendelian randomization (MR) analyses design.
Methods: We used the individual-level data from two population-based Swedish cohorts including middle-aged subjects (mean follow-up = 21.2 years), Malmö Diet Cancer and Malmö Preventive Project (MDC/MPP), for one-sample MR setting. Data from a total of 17,597 individuals (n = 17,597 for SU at baseline, diagnoses during follow-up: 5659 for all-cause, 516 for bladder, 545 for lung, 791 for bowel, 1521 for prostate and 729 for breast cancer) was included. For two-sample MR, summary-statistic data for SU was obtained from Global Urate Genetic Consortium (GUGC: n = 110,347), while UK-Biobank data was employed for several major cancer outcomes (n = 36,815 for all-cause, 2,245 for

bladder, 2,590 for lung, 4,488 for bowel, 6,474 for prostate and 10,274 for breast cancer). The definitions for cancer endpoints were matched for ICD9 and 10 codes between MDC/MPP and UK-Biobank cohorts. For both MR settings, a set of 26 urate-associated single nucleotide variants was selected to build-up the SU instrument (*SU-instr*) to test for a causal effect of SU on cancer outcomes. Statistical analysis, adjusted for age and sex, was done using multiple conventional MR methodologies and MR package in R (v4.0.2). A $p < 0.05$ was designated as statistically significant.

Results: We found no causal effect of our *SU-instr* on neither all-cause nor site-specific cancer across all MR analyses (all $p > 0.05$). In MDC/MPP, *SU-instr* did not show a causal effect on the risk of all-cause [OR = 1.06, $p = 0.32$], bladder [OR = 0.96, $p = 0.84$], lung [OR = 1.26, $p = 0.17$], bowel [OR = 0.96, $p = 0.81$], prostate [OR = 1.05, $p = 0.62$], and breast [OR = 0.99, $p = 0.98$] cancer. Similar findings were made in the two-sample settings. Detailed results are provided in Table 1.

Conclusion: Our MR study, using a series of causal inference approaches, does not support a causal effect of genetically determined SU for major cancer outcomes. There is no evidence to support changing SU levels by lifestyle or pharmacological intervention to attenuate the risk of major cancer types.

POS0296 DOSING OF BDMARDS IN AXSPA AND PSA IN A REAL WORLD SETTING

A. Regierer[1], A. Weiß[1], D. Poddubnyy[1,2], H. Kellner[3], F. Behrens[4], G. Schett[5], J. Braun[6], J. Sieper[2], A. Strangfeld[1]. [1]*German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany*; [2]*Charité University Medicine Berlin, Rheumatology, CBF, Berlin, Germany*; [3]*Rheumatology Practice, Rheumatology, Munich, Germany*; [4]*Goethe University, Rheumatology and Fraunhofer Project Group Translational Medicine and Pharmacology, Frankfurt, Germany*; [5]*Friedrich Alexander University Erlangen-Nuremberg and Universitatsklinikum Erlangen, Department of Internal Medicine 3, Erlangen, Germany*; [6]*Ruhr-University, Rheumazentrum Ruhrgebiet Herne, Bochum, Germany*

Background: The treatment of patients with axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA) has been revolutionised by the introduction of biologic DMARDs targeting TNF, IL17, and IL23 inhibitors (i). In Germany, about 30-50% of axSpA and PsA patients receive treatment with bDMARDs. Although many patients benefit from these drugs, in some patients effectiveness of the standard dose may be insufficient and higher doses are used.

Objectives: To describe dosing of TNFi and non-TNFi bDMARDs over a 2 year period in a real world cohort of patients with axSpA and PsA managed by rheumatologists.

Methods: RABBIT-SpA is a prospective longitudinal cohort study including axSpA and PsA patients enrolled at the start of a new conventional treatment (including NSAID) or b/tsDMARD treatment. Description of dosing of TNFi (adalimumab bio-original (bo), adalimumab bio-similar (bs), etanercept bo, etanercept bs, golimumab, certolizumab) in comparison to nonTNFi-bDMARDs (secukinumab, ustekinumab, ixekizumab, guselkumab) in axSpA and PsA. Standard dosing was defined according to the current labels for axSpA and PsA.

Results: 1628 patients (axSpA: n=903, PsA: n=725) were included in this analysis. At inclusion mean age was 44 years in axSpA and 51 years in PsA. 44% of patients with axSpA and 58% of those with PsA were female. The mean disease duration of axSpA was 7.6 years, of PsA 6.4 years.

Standard doses of TNFi were used during a 2 year period in > 90% of patients with axSpA and PsA (Figure 1). In contrast, standard doses of non-TNFi-bDMARDs were only used in 70-80% of patients. The percentage of documented higher doses in patients with axSpA ranged from 20-30% at different time points. In PsA, this percentage increased from 27% at baseline to 44% at 2 years. On the other hand, TNFi were used in lower doses than the label in up to 9% and 7 % of patients with axSpA and PsA, respectively, after 2 years.

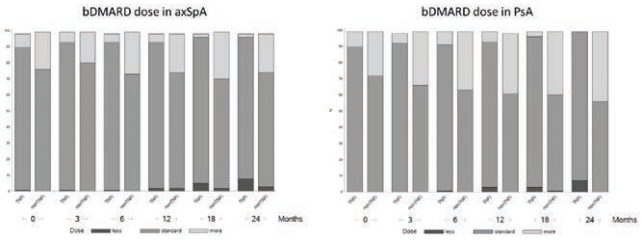

Figure 1. Percentages of patients with axSpA or PsA who received less than, equal to, or more than the approved doses of bDMARDs at baseline and at 5 follow-up visits.

Conclusion: While TNFi are used in licensed doses in most patients, non-TNFi-bDMARDs were often used in higher doses, which corresponds to higher doses approved in other indications like psoriasis. The effectiveness of this treatment strategy in axSpA and PsA needs to be analysed further.

POS0297 HOSPITAL ADMISSIONS FOR PATIENTS WITH RHEUMATOID ARTHRITIS IN WESTERN AUSTRALIA HOSPITALS HAVE DECLINED OVER TIME

K. Almutairi[1], J. Nossent[1], D. Preen[2], H. Keen[1], C. Inderjeeth[1]. [1]*The University of Western Australia, School of Medicine, Perth, Australia*; [2]*The University of Western Australia, School of Population and Global Health, Perth, Australia*

Background: Rheumatoid arthritis (RA) represents a substantial burden on patients and society in terms of morbidity, enduring disability, and medical expenses (1). RA prevalence is poorly described in Australia, and linked health datasets can provide a more meaningful picture for RA epidemiology in the Australian population.

Objectives: To describe the period prevalence rate of RA patients per 1000 hospital separations coded as RA primary or secondary diagnosis in Western Australia (WA) hospitals between 1995 and 2014.

Methods: We extracted data on all patients identified in the WA Hospital Morbidity Data Collection between 1995 and 2014, with the International Classification of Diseases (ICD) codes for RA (ICD 10 M05.00–M06.99, and the corresponding ICD 9 codes). We estimated period prevalence rates per 1000 hospital separations and annual average percentage changes, with the total number of hospital separations each year.

Results: A total of 17,125 patients were admitted to WA hospitals with a diagnostic code for RA over the study period (1995-2014). The total number of hospital separations for RA patients was 50,353, indicating an average of three hospital separations per patient over twenty years. The RA prevalence was 3.4 per 1000 separations over the study period, with a -2.89% annual average decrease since 1995.

Conclusion: These data demonstrate that hospitalisation for RA has decreased considerably in WA over the last two decades. As this decrease roughly coincides with the introduction of biological drug treatment for RA, the reduced need for hospital admission is likely due to improvements in RA management.

POS0298 UNDERSERVED POPULATIONS IDENTIFY BARRIERS AND PROPOSE SOLUTIONS FOR SELF-MANAGING ARTHRITIS AND CHRONIC CONDITIONS

S. Mills[1], K. Khehra[2], P. Ghuman[2], D. Au[3], C. L. Koehn[4], R. Maynard[5], N. Clark[6,7], C. Davis[8], A. Cui[9], C. B. Hamilton[2,10], D. Lacaille[2,10]. *[1]University of British Columbia, Deparment of Medicine, School of Population and Public Health, Vancouver, Canada*; *[2]University of British Columbia, Department of Medicine, Faculty of Medicine, Vancouver, Canada*; *[3]MOSAIC (Multi-lingual Orientation Service Association for Immigrant Communities), Vancouver, Canada*; *[4]Arthritis Consumer Experts, Vancouver, Canada*; *[5]Portland Hotel Society Community Services Society, Vancouver, Canada*; *[6]University of Victoria, School of Nursing, Victoria, Canada*; *[7]University of British Columbia, Centre for Migration Studies, Vancouver, Canada*; *[8]Centre for Collaboration, Motivation and Innovation, Vernon, Canada*; *[9]University of British Columbia, Vancouver, Canada*; *[10]Arthritis Research Canada, Vancouver, Canada*

Background: Underserved populations, such as ethnic minorities, low-income adults, and Indigenous people living with arthritis are more likely to have lower health literacy, higher rates of multi-morbidity, and face challenges in accessing care[1-3]. Self-management support (SMS) can help to mitigate the impacts of living with arthritis[4]. However, we require a more in-depth understanding of the daily barriers underserved communities face in living with arthritis in order to develop effective SMS that can meaningfully improve well-being and quality of life.

Objectives: The study objective was to bring together underserved people living with arthritis to identify common barriers they face in taking care of their conditions in daily life, and to identify their solutions to the identified challenges.

Methods: A team of researchers from several universities, nurse practitioners, physicians, policy makers, an arthritis consumer-patient leader and our community partners (Multi-lingual Orientation Service Association for Immigrant Communities and the Portland Hotel Society Community Services Society) engaged in a Community-based Participatory and Concept Mapping (CM) study[5-7] where participants from underserved communities identified major barriers they face in managing arthritis, agreed on key themes that emerged, and determined priorities for actions. This involved three key CM activities: 1) brainstorming ideas; 2) sorting and rating ideas; and 3) analyzing and interpreting concept maps[8]. Data was collected through face-to-face interviews and prioritized and interpreted in workshop settings.

Results: Sixty-three individuals who were ethnic minorities, immigrants, refugees, low-income, over 65, and/or housing insecure and living with arthritis identified 35 common barriers and made recommendations in the areas of financial difficulties, social services, access to health services, quality of health services, lack of knowledge, and mental health. Additional funding has been sought through Community-University Engagement Support Funding to enable our community partners to prioritize the recommendations in their communities, and to develop mechanisms for implementation using already existing community structures, processes, and services.

Conclusion: Persons living with arthritis in diverse underserved communities face significant health and social inequities, including lack of access to basic life necessities such as food, housing, employment, and safety, which creates barriers to self-managing arthritis and other chronic conditions in daily life. SMS for these communities needs to address these social and environmental barriers shaping capacity for self-management, and ultimately, quality of life and well-being.

Background: Health literacy is increasingly recognised as a critical determinant of health. While care should be tailored to the health literacy needs of each patient [1], research in primary care shows that physicians often under- or overestimate their patients' health literacy, with socioeconomic factors playing a role [2]. Evidence in a rheumatology setting is scarce.

Objectives: -To investigate discordance between health literacy of patients with rheumatic and musculoskeletal diseases (RMDs) and assessment by their treating health professional, across the nine domains of the Health Literacy Questionnaire (HLQ).
-To explore whether discordance is associated with the patient's socioeconomic background.
Methods: Patients with rheumatoid arthritis (RA), spondyloarthritis (SpA), or gout from three Dutch outpatient rheumatology clinics completed the HLQ [3]. The treating health professional (rheumatologist, physician assistant, nurse (practitioner) or resident) assessed their patient's level for each HLQ domain, or answered "I don't know". Discordance per domain was calculated as the patient's score subtracted from the professional's score (both on a 0-10 scale). Discordance was defined as a ≥2-point difference in either direction. Adjusted multilevel multinomial regression models (ref. = no discordance) with patients clustered by health professionals were computed to test the role of socioeconomic factors (age, gender, education level, immigration background, living alone and employment status) in negative (i.e. professional scored lower) and positive (i.e. professional scored higher) discordance.
Results: Of 778 patients included, 41% had RA, 34% had SpA, and 25% had gout. We observed considerable discordance across all HLQ domains (Table 1). Professionals answered "I don't know" most often for "Having social support for health" (19.4%, domain 4). Most discordance occurred for "Critically appraising information" (42.1%, domain 5). For all HLQ domains except "Having social support for health" (domain 4), discordance was associated with socioeconomic factors. In patients with a non-Western immigration background, professionals were likely to assign lower scores than patients' HLQ scores in six domains. Education level was an important driver of discordance in seven domains, with the direction of the association being domain-dependent. Other factors associated with discordance in multiple domains were type of rheumatic disease, comorbidities, mastery, how well the professional knew the patient, type of professional, and disease impact.

Table 1. Discordance per HLQ domain (n=778)

HLQ domain	Professional scored lower	No discordance	Professional scored higher	Professional did not know
	n (%)			
1. Healthcare provider support	128 (16)	514 (66)	126 (16)	10 (1)
2. Having sufficient information	100 (13)	528 (68)	143 (18)	7 (1)
3. Actively managing health	95 (12)	461 (59)	208 (27)	14 (2)
4. Having social support for health	55 (7)	397 (51)	175 (22)	151 (19)
5. Critically appraising information	78 (10)	448 (58)	250 (32)	2 (0)
6. Actively engaging with providers	205 (26)	500 (64)	70 (9)	3 (0)
7. Navigating the health system	115 (15)	544 (70)	107 (14)	12 (2)
8. Finding health information	163 (21)	492 (63)	98 (13)	25 (3)
9. Understanding health information	145 (19)	511 (66)	110 (14)	12 (2)

Conclusion: Considerable discordance between patients' health literacy and their treating health professionals' assessment exists across health literacy domains. In eight out of nine domains, discordance was associated with the patient's socioeconomic background, particularly education and immigration background. Understanding and addressing the reasons for discordance between patient-reported and professional-perceived health literacy has potential to improve responsiveness to patients' needs, promote better communication and ultimately improve care outcomes.

POS0300 DOES COGNITIVE BEHAVIORAL THERAPY IMPROVE PSYCHOSOCIAL OUTCOME IN RHEUMATOID ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

A. Van Breda[1], D. De Cock[1], C. Vervloesem[1], M. Doumen[1,2], D. Bertrand[1], S. Pazmino[1], R. Westhovens[1,2], P. Verschueren[1,2]. *[1]KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium*; *[2]University Hospitals Leuven, Rheumatology, Leuven, Belgium*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory auto-immune disease impacting both physical and mental wellbeing of patients. Cognitive behavioral therapy (CBT), a psycho-social intervention aiming to revert maladaptive thinking and dysfunctional behavior, could improve psychosocial wellbeing in patients with RA. However, it is unclear which CBT components are most successful in improving wellbeing and if certain subpopulations might be more sensitive to CBT therapy.
Objectives: To summarize in a systematic literature review, the effect of CBT on psychosocial outcomes in RA, focussing on most successful components and which patient subgroups benefit most from CBT.
Methods: A search was conducted with the support of a health sciences librarian at the KU Leuven Biomedical Library from inception until 28.06.2020 in 5 electronic databases: PubMed, EMBASE, Web of Science Core Collection, Cochrane Library and Cumulated Index to Nursing and Allied Health Literature (CINAHL). We included studies in English and Dutch involving patients >18 years old with RA, using cognitive behavioral approaches as intervention, with outcomes related to psychosocial variables. Two reviewers (CV&AVB) independently screened first the titles and abstracts of the studies, and later the full texts for eligibility. A third reviewer (DDC) was consulted if no consensus was found. Quality was assessed by the Critical Appraisals Skills Programme (CASP) RCT checklist.
Results: In total, 18 of 1114 retrieved articles could be included (Table 1). Mean age of the participants ranged between 48-63 years with a mean disease duration between 13-16 years. The most used CBT techniques included relaxation training, attention diversion strategies, problem solving skills, goal setting, communication, and social skills training. CBT resulted in ameliorated psychosocial wellbeing related to more active coping styles, improved self-efficacy and reduced perception of disease stressors. Six/18 studies focused on a Ra patient subgroup with an increased psychosocial risk profile, such as high levels of depression. There was limited evidence for an improved treatment effect in these patients because of the elevated levels of psychological distress, but internal motivation seemed key for success.

Table 1. Included studies

First Author	Year	Country	Population	Mean age	Outcomes assessed
O`Leary	1988	USA	N=30	49y	Self-efficacy, Depression, Loneliness, perceived stress
Radojevic	1992	USA	N=59	54y	Depression, Anxiety, Pain coping
Germond	1993	SA	N=24	49y	Coping, Health Control, Stress, Mood, Impact
Parker	1995	USA	N=141	60y	Life stress, Daily stressors, helplessness, depression, anxiety, self-efficacy, impact
Kraaimaat	1995	NL	N=43	57y	Anxiety, Depression, Social Support, Pain Coping
Sharpe	2001	UK	N=55	56y	Anxiety, Depression, Coping
Evers	2002	NL	N=64	54y	Anxiety, Negative mood, Social functioning, Illness cognitions, coping, pain, compliance
Parker	2003	USA	N=54	56y	Depression, Stressors, Stress, Anxiety, Helplessness, Self-efficacy
Van Lankveld	2004	NL	N=58	50y	Depression, Anxiety, Stressors, Coping, Social Support
Zautra	2008	USA	N=142	52y	Affect, Depression, Coping, Pain, Catastrophizing
Hammond	2008	UK	N=167	55y	Self-efficacy, distress, Control, Self-Management
Barsky	2010	USA	N=168	53y	Distress
Hewlett	2011	UK	N=117	60y	Anxiety, Depression, Fatigue
Sharpe	2012	AU	N=104	56y	Anxiety, Depression
Garnefski	2013	NL, BE	N=82	48y	Depression, Anxiety, Self-efficacy
Lumley	2014	USA	N=266	55y	Anxiety, Depression
Vermaak	2015	AU	N=113	54y	Depression, Anxiety, Self-Efficacy, Distress, QoL
Hewlett	2019	UK	N=319	63y	Fatigue, Mood, QoL, Self-Efficacy, Helplessness

Conclusion: Adding CBT to standard care induces modest improvements in psychosocial outcomes for patients with RA. CBT seems more successful if patients are motivated to reflect on their cognitions and behaviours. However, more research with large-scale studies, focusing also on the critical early disease phase, is needed to investigate the long-term benefits of CBT.

POS0301 NO MAJOR DIFFERENCES BETWEEN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASE WHO UNDERWENT MONO- OR MULTISWITCHING OF BIOSIMILARS IN ROUTINE CARE (PERCEPTION STUDY)

S. Gall[1], U. Kiltz[1], T. Kobylinski[1], I. Andreica[1], K. Vaupel[1], X. Baraliakos[1], J. Braun[1]. [1]*Rheumazentrum Ruhrgebiet at Ruhr-University Bochum, Rheumatology, Herne, Germany*

Background: The increasing availability of biosimilars (bsDMARDs) has created a financial incentive to encourage switching to cheaper products ("non-medical switch") leading to different switching scenarios. While the clinical efficacy and safety of multiswitching seems to be established (1), limited data on patients' knowledge about bsDMARDs and satisfaction with care are available.

Objectives: The aim of our study was to learn more about the outcome of mono- and multiswitching scenarios in routine care with respect to patients' attitudes towards bsDMARDs in chronic inflammatory rheumatic diseases (CIRD) such as rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA).

Methods: Consecutive patients with CIRD who were planned to switch treatment of one adalimumab biosimilar (ADA-bsDMARD) to another ADA-bsDMARD were recruited. The number of previous ADA-bsDMARD categorized the patients into: monoswitch = 1 and multiswitch = >1. Demographics and standard assessments using validated outcome parameters for disease activity, physical function, and patient satisfaction with care (Leeds Satisfaction Questionnaire (LSQ) were documented. LSQ contains items on five subscales (provision of information; empathy with the patient; attitude to the patient; access to and continuity with the care giver; and technical competence) and a general satisfaction scale. Knowledge about bsDMARDs was recorded using a structured questionnaire.

Results: Out of 90 patients in total, there were 42 with a monoswitch and 48 with a multiswitch scenario (Table 1). Patients were satisfied with care irrespective of the switching scenario. However, the knowledge about bsDMARDs was generally rather low (Figure 1). Less than one third of patients was able to identify correct answers about manufacturing, efficacy/safety issues, approval status and costs of bsDMARDs. However, when comparing the two switch scenarios, no differences in disease characteristics nor in satisfaction with care were found. Also the number of switches had not increased the knowledge about bsDMARDs.

Conclusion: This study shows that multiswitching did not lead to reduced satisfaction with care in patients on treatment with bsDMARDs. Especially, the number of switches did have no negative impact on patients satisfaction. The observation that patients who underwent multiple switches had no more knowledge about bsDMARDs than patients who just had one switch may just be explained by the positive experience most patients had with switching.

POS0302 BURNOUT IN RHEUMATOLOGISTS IN LATIN AMERICA

M. Intriago[1], G. Maldonado[2], R. Guerrero[1], E. Soriano[3], L. Moreno[4], C. Rios[1,4]. [1]*Universidad Espiritu Santo, Rheumatology, Samborondon, Ecuador*; [2]*Loyola MacNeal Hospital, Internal Medicine, Berwyn, United States of America*; [3]*Hospital Italiano, Rheumatology, Buenos Aires, Argentina*; [4]*Centro de Reumatología y Rehabilitación, Rheumatology, Guayaquil, Ecuador*

Background: Rheumatology is considered a low-risk specialty, but studies have shown a prevalence of burnout between 42% to 51%[1,2]. Factors associated with it include the use of electronic medical records, administrative tasks and prolonged working hours. This has several repercussions such as higher prevalence of depression/anxiety and less productivity.

Objectives: To determine the prevalence of burnout in rheumatologists in Latin America and the factors associated with it.

Methods: Cross-sectional study based on a survey completed through Google Forms platform that was sent by the national rheumatology associations of Latin America. Burnout was assessed with the Maslach Burnout Inventory (MBI) with cut off values of ≥27 for emotional exhaustion (EE), ≥10 for depersonalization (DP), and ≤33 for personal accomplishment (PA). Other variables were studied such as demographics, working conditions, satisfaction, comorbidities, depression using PHQ-9 and happiness using the Subjective Happiness Scale. Data was analyzed using the statistical program SPSS v.22.

Results: 297 rheumatologists from 15 countries were included, mainly Argentina (28.3%), Brazil (26.3%) and Mexico (12.8%). The majority were women 62%, 42.4% worked in public hospitals with an average of 40.1 ± 14.2 hours per week. 31.3% did research, 13.1% clinical trials, 56.6% teaching, and 42.8% administrative work. 36% received an annual income less than 25K.

56.6% had burnout in at least 1 dimension. According to the dimensions, 35.7% had burnout in EE, 25.6% in PA and 26.6% in DP. 32.3% had burnout in only 1 dimension, 17.2% in two and 7.1% in all three dimensions. Only 20.2% thought they had burnout, 9.1% were currently with professional help and 15.8% had sought help in the past. 72.1% said they were willing to participate in a program to reduce burnout.

The rheumatologists with burnout were younger than those without burnout (46.5 vs 49.9 years, p = 0.015), mentioned more frequently that they would like to decrease the number of working hours (56.5% vs 36.4%, p = 0.002) and had lower practice satisfaction (5.2 vs 6.2, p <0.001) and income satisfaction (3.4 vs 4.6, p <0.001). Those with burnout were less happy than those without burnout (5.1 vs 5.9, p <0.001) and had higher PHQ-9 (7.7 vs 2.5, p <0.001). In the burnout group, there was a higher percentage with an income less than $ 25K/year (45.7% vs 25.4%, p=0.008), presence of comorbidities (53.6% vs 40.3%, p=0.023), anxiety (11.9 % vs. 2.3%, p=0.002), use of SSRIs/SNRIs (19% vs 8.5%, p=0.011), suicidal thoughts (13.6% vs 1.6%, p <0.001) and low self-esteem (12.5% vs 3.1%, p <0.001). There was a higher percentage of rheumatologists involved in teaching in the group without burnout (66.7% vs 48.8%, p = 0.002). No statistically significant associations were found between burnout and sex, exercise, alcohol consumption, duration of career, main workplace, type of clinical practice, duration of vacation, clinical research, clinical trials and administrative work.

Conclusion: Burnout affects near half of rheumatologists in Latin America and was associated to younger age, long working hours, low satisfaction, less happiness, higher PHQ-9, suicidal thoughts, anxiety, income, presence of comorbidities and low self-esteem. Most of the rheumatologists were willing to participate in programs to reduce burnout which represents an opportunity for interventions to reduce this syndrome.

POS0303 PREVENTION OF CHRONIC DISEASES DUE TO INFLAMMATION IN INFLAMMATORY ARTHRITIS: RESULTS OF A DELPHI PROCESS TO SELECT CARE RECOMMENDATIONS FOR AN ELECTRONIC MEDICAL RECORD (EMR) INTERVENTION

I. Sheriff[1], A. Lima[2], O. Tseng[3], A. Aviña[2,4], M. Dawes5, C. E. H. Barber[6], J. Esdaile[2,7], K. Shojania[2,7], C. L. Koehn[8], A. Hoens[2,9], S. Mcquitty[10], S. Singh5, J. Yap[3,11], D. Page[12], J. Kur7, B. Hobson[3,13], M. Price[3], D. Lacaille[2,7]. *[1]Arthritis Research Canada, Summer Student Research, Vancouver, Canada*; *[2]Arthritis Research Canada, Research, Vancouver, Canada*; *[3]The University of British Columbia, Department of Family Practice, Vancouver, Canada*; *[4]The University of British Columbia, Department of Medicine, Division of Rheumatology, Vancouver, Canada*; *[3]The University of British Columbia, Department of Family Practice, Vancouver, Canada*; *[6]University of Calgary, Departments of Medicine and Community Health Sciences, Calgary, Canada*; *[4]The University of British Columbia, Department of Medicine, Division of Rheumatology, Vancouver, Canada*; *[8]Arthritis Consumer Experts, President, Vancouver, Canada*; *[9]The University of British Columbia, Department of Physical Therapy, Vancouver, Canada*; *[10]Arthritis Research Canada, Arthritis Patient Advisory Board, Vancouver, Canada*; *[11]New Westminster Family Practice, Family Physician, New Westminster, Canada*; *[12]The University of British Columbia, UBC Family Practice Residency Program, Vancouver, Canada*; *[13] Doctors of BC (previously BC Medical Association) Shared Care Committee and Practice Support Program for Family Physicians, Family Physician, Vancouver, Canada*

Background: Inflammatory arthritis (IA) predisposes patients to several chronic conditions including cardiovascular diseases (CVD), diabetes (DM), osteoporosis (OP) and infections, likely due to systemic effects of inflammation. Studies have found that patients with IA often receive suboptimal care for screening and managing these conditions.
Objectives: This is the first phase of a study which will develop and pilot test automated EMR reminders for family physicians. The reminders will prompt family physicians to screen for and address risk factors for these conditions. We conducted a Delphi process to select care recommendations to be addressed by the EMR reminders.
Methods: We conducted a review of current BC, Canadian and international guidelines for screening and addressing risk factors for CVD, DM, OP and infection. A list of 22 care recommendations, including their level of evidence and risks/benefits of implementation, was reviewed by a panel of six family physicians, three rheumatologists and three IA patients, in a three-round online modified Delphi process. Panelists rated each care recommendation, using 9-point scales, on 1) their clinical importance, 2) their likelihood of improving outcomes, and 3) implementation feasibility. Results were discussed in an online forum. Panelists then rated slightly revised care recommendations, modified based on feedback from the discussion. Care recommendations were retained if the median rating was ≥7 with no disagreement as defined by the RAND/UCLA Method handbook.
Results: A list of 15 care recommendations was selected by the Delphi process for EMR integration, including recommendations that address CVD risk assessment (1), hypertension screening (1), DM screening (2), fracture risk assessment (1), BMD testing (1), osteoporosis prevention (1) and treatment (1) with bisphosphonates, preventing infections through immunization (2), minimizing steroids (1) and hepatitis screening (1), screening for hydroxychloroquine retinal toxicity (1), and counselling for lifestyle modifications (2). We excluded 7 recommendations which addressed lipid testing (1), BMD testing in steroid users (1), immunizations (2), weight management (1), and DMARD laboratory test monitoring (2). Recommendations were excluded on the basis of importance (1) or feasibility (6).
Conclusion: The results of the Delphi process will inform the development of reminders, integrated in EMRs, that will support family physicians in their efforts to engage IA patients in addressing risk factors for chronic diseases related to inflammation. We hope to improve the prevention of these diseases, which represent an important cause of morbidity and mortality for people with inflammatory arthritis.

POS0304 EPIDEMIOLOGY AND ECONOMIC BURDEN ASSOCIATED WITH MENTAL HEALTH COMORBIDITIES IN SYSTEMIC LUPUS ERYTHEMATOSUS AND LUPUS NEPHRITIS PATIENTS

M. A. Petri[1], D. Naessens[2], A. Ogbomo[3], A. Ratiu[3], C. Gutierrez[3], C. Karyekar[4]. *[1]John Hopkins University School of Medicine, Division of Rheumatology, Baltimore, United States of America*; *[2]Janssen Pharmaceutica NV, Director Global Market Access Immunology, Beerse, Belgium*; *[3]STATinMED Research, HEOR, Ann Arbor, United States of America*; *[4]Janssen Global Commercial Strategic Organization, Compound Development Team, Horsham, United States of America*

Background: Systemic lupus erythematosus (SLE), a multisystem autoimmune disease, is associated with mental health (MH) disorders. There is scarce information on the epidemiology and economic burden associated with MH comorbidities and the impact on SLE as well as the subpopulation with lupus nephritis (LN).
Objectives: Examined the incidence and prevalence rate of MH, healthcare resource utilization (HCRU), and costs associated with MH comorbidities in SLE/LN patients.
Methods: Adult SLE and LN patients with ≥1 inpatient or ≥2 outpatient diagnosis claims for SLE/LN (ICD-9 code: 710.0; and ICD-10 codes M32.10-19, M32.8, M32.9) were identified between 01JAN2013-30JUN2019 from two large US commercial databases. Inclusion required continuous enrollment benefits 12 months pre-/post-index date. Patients were divided into two groups: those with (WMH) vs. those without (NMH). WMH was defined as a MH diagnosis of depression, anxiety, bipolar disorder, or psychosis. Index date for the WMH group was first MH diagnosis claim. For the NMH group, a random index date was assigned between 01JAN2014-30JUN2018. The groups were then matched with a 1:1 ratio based on age, sex, and region within their respective databases. Incidence and prevalence rate of MH in the SLE/LN population were determined. All-cause healthcare costs and HCRU per patients per year (PPPY) were examined with generalized linear models.
Results: A total of 7,760 SLE and 336 LN patients were identified. The majority of patients were female (SLE=93.5%; LN=95.2%) with a mean age of 55.1 years (SLE) and 44.5 years (LN). The prevalence rate of MH was 35.7% for SLE and 28.8% for LN patients and the incidence rate was 18.5% and 15.3%, respectively. Anxiety and depression were the most common MH comorbidities (Figure 1). WMH inpatient stays averaged an additional 2.6 and 7.2 days longer than NMH for SLE and LN, respectively. In addition, WMH patients averaged 10.4 (SLE) and 18.4 (LN) significantly more outpatient visits PPPY than NMH. Overall healthcare cost PPPY was significantly higher for WMH patient in both SLE ($49,553 vs $26,064), and LN ($112,169 vs $39,529). Inpatient costs were approximately 3 – 5 times greater in the WMH group (Table 1).
Conclusion: This real-world study shows that MH comorbidities have a high incidence and prevalence rate in SLE and LN patients. Health care costs and utilization for SLE and LN patients with MH comorbidities were significantly higher than patients without MH comorbidities. This study highlights not just the high prevalence of MH comorbidity but its large contribution to SLE healthcare costs.

	SLE		LN	
	Prevalence rate	Incidence rate	Prevalence rate	Incidence rate

Background: The principles of treat to target (T2T) include defining an appropriate treatment target, assessed at pre-defined intervals, with a commitment to changing therapeutic approach if the target is not met (1). T2T is recommended as a key strategy for the treatment of rheumatoid arthritis (RA).

Objectives: To explore attitudes towards T2T, its implementation and stated treatment goals among physicians and their patients with RA.

Methods: The Adelphi RA Disease Specific Programme™ was a large, quantitative, point-in-time survey conducted amongst rheumatologists (n=296) and their consulting patients with RA (n=3042) in Europe (France, Germany, Italy, Spain, UK) between Q4 2019–Q3 2020. Physicians were recruited via publicly available lists, completing an online survey and medical record extraction for their next 10–12 consecutive patients. The same patients were invited to voluntarily complete a self-report questionnaire (n=1098, 36% response), collecting data on attitudes towards T2T and treatment goals.

Results: Physicians reported that 76% of patients were in remission (DAS28: <2.6) or had low disease activity (DAS28: 2.6 – 3.2), and 24% had moderate-high disease activity (DAS28: >3.2). Patient mean age was 53.0 years (SD 14.0), mean time since diagnosis was 7.2 years (SD 7.2). The proportion of patients currently receiving an advanced therapy (AT; defined as biologic or targeted synthetic DMARD) was 68%, of whom 70% were on a first line AT. No difference was observed between disease activity groups.

In the physician survey, 86% of physicians stated they followed T2T principals in at least some of their RA patients, and would utilize a T2T approach in RA patients with moderate-high disease activity (61%), the most uncontrolled patients (37%) and those who do not respond well to initial therapy (34%). In this sample of real-world RA patients, 66% were reported by physicians to be on a T2T plan at the time of data collection. The most common physician-reported targets were remission (DAS28: <2.6) (75%), improvement of quality of life (QoL) (41%) and reduction of pain (31%), with 85% of physicians perceiving these treatment goals were fully or partially met. The most stated reasons for not implementing T2T was physician preference not to adjust current treatment (34%), patient preference not to adjust current treatment (23%), and there are no achievable goals for this patient (16%).

Overall, 29% of patients reported they were involved in setting their T2T goals, while 34% stated their T2T goals were set by their physicians only, and 29% perceived no T2T goal had been set (n=620). The most common overall T2T goals from the patient perspective were remission (61%), controlling symptoms (41%), and reducing impact on QoL (34%). Of those patients who acknowledged a T2T goal had been set (n=407), 77% reported their T2T goal was fully or partially achieved.

Of 719 patients who had moderate-high disease activity, 57% were on a T2T plan, with 46% of physicians perceiving these treatment goals were fully or partially met. The most common physician-stated reason for not implementing T2T was a lack of achievable targets (29%).

Conclusion: Rheumatologists in this study reported a strong belief in T2T. The most common physician-set T2T goals were remission, improvement of QoL and reduction of pain, corresponding with T2T goals as reported by patients. However, a third of patients in this cohort were not aware of a defined T2T objective in their management, which may be a result of a perceived lack of achievable goals by physicians. It may be desirable to promote more patient involvement in defining achievable targets amongst those with moderate-high disease activity who despite best efforts may not reach a clinical state of remission. Further research is needed to identify and understand goals important to RA patients.

POS0306 IMPACT OF MULTIMORBIDITY ON DISEASE MODIFYING ANTI-RHEUMATIC DRUG THERAPY IN EARLY RHEUMATOID ARTHRITIS: DATA FROM THE ESPOIR COHORT

A. Beltai[1], B. Combe[1], A. Coffy[2], C. Gaujoux-Viala[3], C. Lukas[1], A. Saraux[4], M. Dougados[5], J. P. Daures[2], C. Hua[3]. [1]*CHU Montpellier, Rheumatology, Montpellier, France*; [2]*University Institute of Clinical Research, AESIO santé, Statistiques, Montpellier, France*; [3]*CHU Nîmes, Rheumatology, Nîmes, France*; [4]*CHU Brest, Rheumatology, Brest, France*; [5]*CHU Cochin, Rheumatology, Paris, France*

Background: Multimorbidity is frequent in rheumatoid arthritis (RA) and could interfere with the therapeutic response.
Objectives: The aim of this study was to evaluate multimorbidity in the French cohort of early arthritis (ESPOIR cohort) and its possible impact on the therapeutic response.
Methods: We included patients fulfilling 2010 ACR/EULAR criteria for RA. An adapted MultiMorbidity Index (aMMI) was developed [1]. Each patient was assigned scores of binary aMMI (0= no comorbidity, 1= at least 1 comorbidity) and counted and weighted aMMI. The primary endpoint was achievement of Clinical Disease Activity Index (CDAI) low disease activity after initiation of a first disease-modifying anti-rheumatic drug (DMARD) according to the aMMI. Secondary endpoints were other disease activity scores and response criteria. We collected data from the visit preceding the first DMARD initiation (baseline visit) and the visit after at least 3 months of treatment (follow-up visit). The impact of aMMI on therapeutic maintenance at 1, 3, 5 and 10 years was evaluated.
Results: Analyses involved 472 patients: 302 (64%) had at least 1 comorbidity. Overall, 45.3% and 44.7% with binary aMMI= 0 or 1, respectively (p= 0.9), achieved CDAI low disease activity (Table 1). Similar results were found with counted and weighted aMMI. Use of other disease activity scores or response criteria did not show a significant impact of multimorbidity on the therapeutic response. Therapeutic maintenance was significantly better with binary aMMI = 1 than binary aMMI = 0. Increased counted aMMI was associated with increased probability of still being on the first initiated DMARD at each time point (Table 2).
Conclusion: In the ESPOIR cohort, therapeutic response to a first DMARD was not affected by multimorbidity but therapeutic maintenance was better in multimorbid patients.

POS0307 FATIGUE IN RHEUMATOID ARTHRITIS PATIENTS IS ASSOCIATED TO SUBJECTIVE BUT NOT OBJECTIVE ASSESSMENTS OF DISEASE ACTIVITY DURING TREATMENT WITH TOCILIZUMAB

H. B. Hammer[1], B. Agular[2], L. Terslev[3]. [1]*Diakonhjemmet Hospital, Rheumatology, Oslo, Norway*; [2]*Roche, Rheumatology, Copenhagen, Denmark*; [3]*Rigshospitalet Glostrup, Rheumatology, Copenhagen, Denmark*

Background: Fatigue is common in patients with rheumatoid arthritis (RA), and its association with inflammatory activity is not fully understood.
Objectives: To explore the associations between fatigue and inflammation by clinical, laboratory and ultrasound examinations during follow-up of RA patients on biological treatment.

Methods: A Nordic (Denmark, Finland, Norway, Sweden) open-label, single-arm study (part of the umbrella program – TOZURA (1)), enrolled patients with inadequate response to conventional synthetic (cs) DMARDs. Patients received tocilizumab 162 mg sc weekly for 24 weeks as monotherapy or in combination with a csDMARD. Stable oral NSAIDs and corticosteroids (≤10 mg/day prednisone or equivalent), were allowed. Patients were assessed at baseline, 4, 12 and 24 weeks for fatigue (FACIT-F questionnaire (total sum scores)), patient reported outcome measures ((PROMs) including joint pain and patient's global visual analogue scale (VAS) as well as HAQ-DI), clinical assessments (tender and swollen joints, assessor's global VAS), laboratory examinations (ESR, CRP) and ultrasound assessments (36 joints and 4 tendons, scored according to the Norwegian US atlas (2)). Spearman correlations, performed both at baseline and for changes from baseline of variables during follow-up, explored associations between fatigue and PROMs, clinical, laboratory as well as ultrasound variables. Predictive value of fatigue was investigated by linear regression.
Results: 110 patients were included (83% female, mean (SD) age 55.6 (12.1) years and RA duration 8.7 (9.5) years, 81% anti-CCP positive). All PROMs, clinical, laboratory and ultrasound variables decreased significantly, already after 4 weeks (p<0.001). Both for baseline assessments as well as for changes during follow-up, fatigue was associated with PROMs (Table 1 (baseline) and Table 2 (follow-up)). However, there were no or low associations between fatigue and clinical, laboratory and ultrasound assessments at baseline or during follow-up. In addition, baseline fatigue was predictive of joint pain, patient's global VAS and HAQ-DI during follow-up (p<0.05-0.001), but not for the clinical, laboratory or ultrasound assessments.
Conclusion: Fatigue assessed by an established questionnaire did not show any associations with several assessments of inflammatory activity in RA patients, neither at baseline nor during effective treatment. Thus, the present study adds to the increasing number of papers finding fatigue to reflect other aspects of RA disease activity than inflammation.

POS0308 TRAJECTORIES OF FATIGUE IN EARLY RA OVER 10 YEARS: RESULTS FROM THE ESPOIR COHORT

S. Rodriguez-Muguruza[1], B. Combe[2], F. Guillemin[3], A. Olive[4], O. Valero[5], R. Fontova Garrofe[6], S. Marsal[7], F. Bruno[8], C. Lukas[2]. [1]*Hospital Joan XXIII, Rheumatology Department,Tarragona, Spain*; [2]*Hospital Lapeyronie, Rheumatology Department, Montpellier, France*; [3]*Université de Lorraine, Nancy, France, INSERM CIC 1433, CHRU, Nancy, France*; [4]*Hospital Germans Trias i Pujol, Rheumatology Department, Barcelona, Spain*; [5]*Autonomous University of Barcelona, Department of Statistics, Barcelona, Spain*; [6]*Hospital Joan XXIII, Rheumatology Department,Tarragona, Spain*; [7]*Vall d'Hebrón University Hospital, Department of Rheumatology, Barcelona, Spain*; [8]*Pitié-Salpêtrière Hospital, Department of Rheumatology, Paris, France*

Background: Fatigue is one of the most prevalent symptom reported by persons with RA. RA-related fatigue is a complex concept with biological, psychological and social interactions.
Objectives: In a cohort of early RA patients, to determine and characterize fatigue trajectories over 10 years of follow-up and identify predictors of trajectory membership.
Methods: Patients fulfilling the 2010 ACR/EULAR criteria for RA included in the ESPOIR cohort. We used a cluster analysis to obtain fatigue (assessed by fatigue visual analogue scale) trajectories over the course of 10 years from enrolment. Chi-square tests or ANOVA were performed to evaluate differences of baseline variables between fatigue trajectories. Using a multinomial logistic regression we could identify predictors of trajectory membership.
Results: We analysed 598 patients with mean disease duration at enrolment of 26.2 ± 40.9 days. Cluster analysis revealed 3 trajectories: high (18%), moderate (52%) and low fatigue (30%). Compared to patients with moderate or low fatigue trajectory, patients with high fatigue trajectory were predominantly women and reported significantly higher duration and intensity of morning stiffness, HAQ score, number of tender joints, levels of pain, number of awakenings due to arthritis, levels of physician and patient global assessment and more frequent sleep problems, and increased psychological distress. Female patients with pain, psychological distress and presence of sicca symptoms had higher risk of being in high trajectory group.
Conclusion: These findings suggest that levels of fatigue are rather stable over time in each trajectory. Baseline clinical measures and baseline patient-reported measures of functional status better distinguished the three fatigue trajectories. We did not find differences between trajectories in baseline laboratory measures. Inflammatory activity was not a predictor of being in high trajectory fatigue group.

POS0309 SEROPOSITIVITY INCREASES RISK OF INCIDENT DEMENTIA IN INDIVIDUALS WITH RHEUMATOID ARTHRITIS: A POPULATION-BASED COHORT STUDY

V. Kronzer[1], T. Gunderson[2], C. S. Crowson[2], J. M. Davis III[1], M. Vassilaki[2], M. Mielke[2], E. Myasoedova[1]. [1]*Mayo Clinic, Rheumatology, Rochester, United*

States of America; [2]*Mayo Clinic, Health Sciences Research, Rochester, United States of America*

Background: Several studies show increased risk of dementia among individuals with rheumatoid arthritis (RA), while others show no association. One reason for this discrepancy might be differential association by serostatus. No prior studies have investigated the association between RA and dementia by serostatus.
Objectives: We aimed to evaluate the risk of incident dementia among individuals with RA, stratified by serostatus.
Methods: This population-based cohort study included all cases of incident RA within Olmsted County, Minnesota with index date of RA onset between 1 January 1999 and 31 December 2013. We matched RA cases to non-RA comparators 1:1 on age and sex. All RA cases met 1987 ACR criteria for RA. We defined seropositivity as positive rheumatoid factor or anti-cyclic citrullinated peptide antibodies. We defined incident dementia as having two ICD-9/10 codes for dementia at least 30 days apart, with the date of the second code representing the time of dementia onset. We **e**xcluded individuals with dementia prior to index date. We estimated the cumulative incidence of dementia adjusting for the competing risk of death. For the main analysis, cox proportional hazard models estimated adjusted hazard ratios (aHR) with 95% confidence intervals (CI) for incident dementia, adjusting for age, sex, index year, body mass index, and smoking status (never, former, current). These models compared the incidence of dementia for RA versus non-RA, seropositive and seronegative RA versus their matches, and seropositive versus seronegative RA. To validate these results, we also performed sensitivity analyses using groups matched via inverse probability weighting on age, sex, index year, obesity, smoking status, and race.
Results: We identified 597 RA cases (mean age 56, 70% female), and 594 non-RA comparators. Of the RA cases, 388 (65%) were seropositive, and 209 (35%) were seronegative. The ten-year cumulative incidence of dementia in patients with RA was 3.3 (95%CI 2.0,5.5) per 100,000 compared to 2.4 (95%CI 1.3,4.2) in non-RA comparators, for aHR of 1.26 (95%CI 0.7,2.3). When stratifying by serostatus, the ten-year incidence of dementia for seropositive RA cases was 3.6 (95%CI 2.0,6.5), corresponding to aHR of 1.45 (95%CI 0.73,2.9) compared to matched non-RA cases. In contrast, the incidence of dementia in seronegative RA cases was 2.6 (95%CI 1.0,7.0), for an aHR of 1.0 (95%CI 0.29,3.5). Overall, the incidence of dementia in seropositive RA cases was significantly higher than seronegative cases (aHR 3.2, 95%CI 1.2,8.5). Indeed, sensitivity analysis using inverse probability weighting confirmed that among participants aged 50 and older, dementia incidence was higher for seropositive than seronegative RA (aHR 2.9, 95%CI1.1,7.8) (Figure 1).
Conclusion: Individuals with seropositive RA have an increased risk for incident dementia than those with seronegative RA. Future studies should replicate these findings and investigate the mechanism for this association.

Figure 1. Cumulative incidence of dementia for individuals with seropositive versus seronegative RA aged 50 and older, balanced by inverse probability weighting

POS0310

EXPOSURE TO MAJOR PSYCHOLOGICAL TRAUMA OR STRESS IN THE PRECEDING ONE YEAR SIGNIFICANTLY CONTRIBUTES TO POOR DISEASE CONTROL IN PATIENTS WITH RHEUMATOID ARTHRITIS: SINGLE CENTRE RESULTS FROM THE PRIME REGISTRY COHORT

M. Haroon[1], S. Asif[1], S. Batool[1], F. Hashmi[1], S. Ullah[1], A. Ashraf[2], H. J. Shaheen[1]. [1]*Fatima Memorial Hospital & FMH College of Medicine and Dentistry, Department of Rheumatology, Lahore, Pakistan*; [2]*CMH Lahore Medical College & Institute of Dentistry, Medicine, Lahore, Pakistan*

Background: Stress response is considered to involve the activation of both the hypothalamus-pituitary-adrenal axis and the autonomic nervous system, along with its communication with the immune system. Because many rheumatic diseases are characterized by immune-mediated joint inflammation, stressful events might contribute to the aetiology, maintenance and exacerbation of rheumatic diseases.
Objectives: We aimed to examine whether real-life major stressful events lead to poor disease control among patients with Rheumatoid arthritis (RA). We addressed this question using real-world data from the PRIME registry.
Methods: This was a cross-sectional study conducted using data collected at the time of patient enrolment in the PRIME registry. The PRIME Registry is a large, independent, prospective, observational cohort initiated in October 2019 that comprises patients diagnosed with RA, SLE, PsA or AS by a rheumatologist, and is being actively followed up. IRB approval and informed consent was obtained. We assessed the registry data for RA patients. The clinical variables studied were gender, age, smoking habits, body mass index, education status, marital status, disease duration, comorbidities (using Charlson Comorbidity Index). Education status was stratified by whether participants completed secondary (high) school education. Evaluation of disease activity and severity was made as per internationally agreed definitions, such as: swollen joint counts (SJC), tender joint counts (TJC), deformed joint counts, and DAS-28. Major psychological trauma or stress was defined if the patient has experienced any of the following in the past year: a) major personal injury or illness; b) death/major illness of a close relative; c) marital separation/divorce; d) loss of job; e) major financial loss; f) mass casualty incident loss.
Results: The data of consecutive 507 RA patients (mean age 42.3±12.6 years, 73.6% female, disease duration of 80±22 months) was reviewed. Thirty-six percent of the cohort reported to have major psychological stress and trauma in the preceding one year. No statistical association of age, gender, and marital status was noted, but statistical association of low education status (p=0.042), longer disease duration (p=0.044), higher DAS-28 values (p<0.001) and other markers of RA disease activity (SJC, TJC, ESR, patient global health) was found. On multiple logistic regression analysis, a significant association of major psychological stress and trauma in the preceding one year was noted with active disease (DAS-28; OR 1.67, CI 1.17-2.4, p=0.005). Following variables were included in the full regression model, disease duration, gender, age, marital status, education status, and DAS-28 value (also used models with SJC, TJC, deformed joint counts, ESR, patient global health, but the results remained unchanged).
Conclusion: Major psychological stress and trauma in the preceding one year is associated with high disease activity among patients with RA. Therapies that focus on stress management may be important adjuncts to traditional pharmacotherapy in the treatment of inflammatory rheumatic diseases.

POS0311

NEUROIMAGING BIOMARKERS IN INDIVIDUALS WITH AND WITHOUT RHEUMATOID ARTHRITIS: RESULTS FROM THE MAYO CLINIC STUDY OF AGING

M. Vassilaki[1], C. S. Crowson[1], J. M. Davis III[2], S. Duong[1], D. Jones[3], M. Mielke[1,4], P. Vemuri[3], E. Myasoedova[1,2]. [1]*Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America*; [2]*Mayo Clinic, Division of Rheumatology, Rochester, United States of America*; [3]*Mayo Clinic, Department of Radiology, Rochester, United States of America*; [4]*Mayo Clinic, Department of Neurology, Rochester, United States of America*

Background: Age-related increase in the burden of systemic inflammation is an established key player and potential treatment target in Alzheimer's disease (AD) and other age-related dementias. (Dregan, Chowienczyk et al. 2015) Although rheumatoid arthritis (RA) is an autoimmune hyper-inflammatory disease, studies on RA and dementia or vascular neuroimaging biomarkers are lacking.
Objectives: To examine the associations between RA and dementia/vascular neuroimaging biomarkers in the Mayo Clinic Study of Aging (MCSA).

Methods: The study consisted of 35 RA cases in MCSA and 104 MCSA participants without RA matched 1:3 for age, sex, education, cognitive status (≥50 years old) at baseline and the availability of at least one magnetic resonance imaging (MRI). The primary outcome measures were well established dementia-related neuroimaging biomarkers, including global beta-amyloid (Aβ) using PiB-positron-emission tomography (PET; n=47); neurodegeneration (hypometabolism via FDG-PET (n=45), hippocampal volume (n=139), and cortical thickness via structural MRI [n=138], and cerebrovascular pathology via FLAIR-MRI (white matter hyperintensity [WMH; n=49] burden, subcortical, and cortical infarctions (n=55)). Elevated ^{11}C-PiB-PET was defined as standardized uptake value ratio ≥1.48 in an Alzheimer's disease (AD)-related region of interest and reduced AD signature cortical thickness as ≤2.68mm (neurodegeneration; N+). Kruskal-Wallis rank sum and Pearson's chi-squared tests were used to compare the neuroimaging measures between participants with and without RA.

Results: Participants with vs. without-RA did not differ in age, sex, years of education, major comorbidities, Aβ burden, hippocampal volume, and neurodegeneration measures (Table 1). Although the sample size was small, we observed that RA participants (vs. without-RA) had greater mean WMH volume (relative to the total intracranial volume (TIV) (mean (SD) %: 1.12 (0.57) % vs 0.76 (0.69) % of TIV, p=0.011), were more likely to have cortical infarctions (4 vs.1; p=0.013) and had a higher mean number of cortical infarctions (mean (SD): 0.24 (0.44) vs. 0.05 (0.32), p=0.017).

Conclusion: Our preliminary data suggest significant differences in cerebrovascular biomarker measures by RA status. Further studies would add valuable information to our understanding and insight into the development of interventions for the prevention of cerebrovascular pathology in RA patients.

Background: Depression is present in up to half of patients with Rheumatoid Arthritis (RA). The association between this mood disorder and disease activity scores, including DAS28, SDAI and CDAI, has previously been described by various authors.

Objectives: The aim of our study was assessed the effect of depression on the components of different disease activity scores.

Methods: We performed a cross-sectional study of consecutive adults with RA, according to ACR/EULAR 2010 criteria. Sociodemographic data, comorbidities and current treatment were recorded. Disease activity was evaluated using DAS28-ESR, DAS28-CRP, SDAI and CDAI. Depression was assessed using PHQ-9 questionnaire. The PHQ-9 values were categorized in 4 groups as follows: 5 to 9, 10 to 14, 15 to 19, 20 or greater, represents mild, moderate, moderate/severe, and severe depression, respectively. A cutoff value of 10 or greater was set to define major depression. *Statistical analysis:* Student´s T, ANOVA and Chi^2 tests. Multiple logistic regression.

Results: Two hundred fifty eight patients were included, with a median (*m*) disease duration of 9 years (IQR 3.6-16.7). The *m* PHQ-9 score was 6 (IQR 2-12.3) and the prevalence of major depression was 33.7%. Patients with major depression had more tender and swollen joint count (TJC and SJC) (mean 4.9±4.3 vs 2.3±3.7, p<0.0001 and 2.9±3.3 vs 1.7±3.4, p=0.009), more pain (VAS [cm] mean 5.6±2.7 vs 3.3±2.6, p<0.0001), higher patient and physician global assessment (PGA and PhGA) (VAS [cm] mean 5.4±2.9 vs 3.1±2.5, p<0.0001 and 4.4±2.7 vs 2.4±2.4, p<0.0001) and CRP (mean 1.7±3.3 vs 0.7±1.1 mg/dl, p=0.01). ESR values were higher in the group with major depression, but the difference did not reach significance. Disease activity was higher in the depression group by all scores: DAS28-ESR (mean 4.3±1.4 vs 3.3±1.3, p<0.0001), DAS28-CRP (mean 3.9±1.4 vs 2.8±1.7, p<0.0001), SDAI (mean 19.2±12.7 vs 10.3±10.1, p<0.0001) and CDAI (mean 17.6±10.9 vs 9.6±9.9, p<0.0001). While 41 (15.9%) patients had high disease activity according to DAS28-ESR, only 34 (13.2%) had SDAI>26.

In the multivariate analysis, evaluating the association of major depression with the different components of DAS28-ESR, DAS28-CRP, SDAI and CDAI, we observed that the presence of this mood disorder remained significantly associated with higher PGA in all the scores. In addition, a significant association was seen with higher TJC in both DAS28 scores.

Conclusion: Patients with major depression had higher disease activity. It´s presence has a significantly association with the subjective items of the disease activity scores, particularly PGA. CRP value was the only objective component associated with depression.

POS0313 INCIDENCE AND PREVALENCE OF POLYAUTOIMMUNITY IN SEROPOSITIVE COMPARED WITH SERONEGATIVE PATIENTS WITH RHEUMATOID ARTHRITIS: A NATIONWIDE COHORT STUDY

A. Hagelskjær[1], R. Cordtz[1], S. Bliddal[2], A. S. Mortensen[1], S. Kristensen[1,3], C. H. Nielsen[4], U. Feldt-Rasmussen[2,5], C. Torp-Pedersen[6], L. Dreyer[1,3,7]. *[1]Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark*; *[2]Copenhagen University Hospital, Rigshospitalet, Department of Medical Endocrinology and Metabolism, København, Denmark*; *[3]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark*; *[4]Copenhagen University Hospital, Rigshospitalet, Institute of Inflammation Research, København, Denmark*; *[5]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*; *[6]North Zealand Hospital - Hillerød, Department of Cardiology, Hillerød, Denmark*; *[7]DANBIO, Denmark, Nationwide, Denmark*

Background: Rheumatoid arthritis (RA) is categorized as seropositive or seronegative referring to the presence or absence of IgM rheumatoid factor (IgM-RF) and/ or anti-citrullinated protein antibodies (ACPA).
Patients with an autoimmune disease are more likely to develop additional autoimmune conditions than individuals without pre-existing autoimmune disease.
Objectives: The aims of this study were to examine patterns of polyautoimmunity in seropositive compared with seronegative patients with recent-onset RA.
Methods: The study was register-based and used the nationwide DANBIO register (identification of recent-onset (<1 year) seropositive, ICD-10 M05, and seronegative, M06, RA patients) linked to the Danish National Patient Registry and the Danish National Prescription Registry to obtain information on additional autoimmune diseases (see Table 1 for autoimmune conditions). Using age and sex adjusted logistic regression analysis, the odds ratio (OR) of prevalent polyautoimmunity in seropositive compared with seronegative patients at the time of RA diagnosis was calculated.
To estimate the hazard ratio (HR) for developing yet another autoimmune disease in the 5 years after RA diagnosis, adjusted cause-specific Cox regression models were performed. Several sensitivity analyses were carried out including alternative exposure and outcome definitions.
Results: In total, 12,517 patients with recent-onset RA were included. The groups were similar in terms of disease characteristics and DMARD treatment, but seropositive patients were younger and included more women, see Table 1. Patients with seropositive RA had an OR of 0.79 (95% CI 0.71-0.89) for baseline presence of polyautoimmunity compared with seronegative patients, whereas the 5-year HR was 0.86 (95% CI 0.71-1.05) for incident polyautoimmunity. The results remained similar in all sensitivity analyses.
Conclusion: Patients with seropositive RA had a slightly lower prevalence and incidence of polyautoimmunity compared to seropositive patients. The results were somewhat surprising, yet very robust, and thus raises the question if seronegative RA is in fact "more autoimmune" despite the absence of (identified) autoantibodies.

Table 1. Characteristics, prevalence, and incidence of polyautoimmunity in incident RA patients.

	Seropositive	Seronegative
N	7983	4534
Age in years	59.4 (48.6 to 69.1)	63.0 (51.5 to 72.3)
Women	5476 (69 %)	2856 (63 %)
HAQ-DI	0.857 (0.375 to 1.375)	0.875 (0.375 to 1.375)
DAS28-CRP	4.3 (3.3 to 5.2)	4.6 (3.6 to 5.5)
CRP, mg/mL	10 (4 to 23)	10 (3 to 26)
VAS physician, 0-100mm	27 (15 to 45)	30 (16 to 47)
Treated with methotrexate	86 %	84 %
-other csDMARD, %	24 %	24 %
-Biological DMARD, %	5 %	6 %
Smoking status: Current / previous / never / unknown, %	13 / 11 / 17 / 59 %	9 / 9 / 23 / 59 %
Prevalence of polyautoimmunity / diabetes mellitus type 1 / autoimmune thyroid disease / inflammatory bowel disease	549 (10.6 %) / 1.4 % / 6.7 % / 1.4 %	349 (12.8 %) / 1.5 % / 7.8 % / 1.5 %
Age and sex adjusted odds ratio	0.79 (0.71 to 0.89)	1 (ref.)
Incident cases of polyautoimmunity	373 (4.7 %)	242 (5.3 %)
Adjusted hazard ratio	0.86 (0.71 to 1.05)	1 (ref.)

Continuous variables shown as median with interquartile ranges. Autoimmune conditions included:autoimmune thyroid disease (redeemed prescriptions of ATC=H03A); diabetes mellitus type 1 (ICD-10 diagnosis E10 combined with redeemed prescriptions of insulin, ATC=A10A); pernicious anaemia (D51.0); autoimmune haemolytic anaemia (D59.1); idiopathic thrombocytopenic purpura (D69.3); Autoimmune adrenalitis (E27.1B); multiple sclerosis (G35); neuromyelitis optica (G36.0); Guillain-Barré syndrome (G61.0); myasthenia gravis (G70); inflammatory bowel disease (K50-1); primary biliary cirrhosis (K74.3); primary sclerosing cholangitis (K83.0); autoimmune hepatitis (K75.4); celiac disease (K90.0); pemphigus vulgaris (L10.0); bullous pemphigoid (L12.0); dermatitis herpetiformis (L13.0); alopecia areata (L63); vitiligo (L80); lichen sclerosis (L90.0); chronic interstitial cystitis (N30.1).

POS0314

PROSPECTIVE EVALUATION OF A DEDICATED, SERIAL OCCUPATIONAL THERAPY EXERCISE PROGRAM ON HAND FUNCTION IN RHEUMATOID ARTHRITIS (RA)

W. Pietrowski[1], K. Richter-Bastian[2], K. Storck-Müller[2], U. Müller-Ladner[1], U. Lange[1], I. Tarner[1]. [1]*Campus Kerckhoff, Justus-Liebig-University Gießen, Department of Rheumatology, Clinical Immunology, Osteology and Physical Medicine, Bad Nauheim, Germany*; [2]*Rheumazentrum Mittelhessen, Department of Rheumatology, Bad Endbach, Germany*

Background: Rheumatoid arthritis (RA) frequently affects the joints of the hands causing severe pain and significant functional impairment affecting all activities of daily living. At early stages, functional impairment is primarily caused by reversible joint and tendon sheath effusions while at later stages synovial thickening, muscular atrophy and irreversible damage to cartilge, bone, tendons and ligaments cause a reduced range of motion and deformities. Occupational therapy aims to maintain and improve joint mobility and function. However, there is limited data on the effectiveness of serial exercise programs specifically aiming at maintaining and improving hand function in RA.
Objectives: To prospectively evaluate the effects of a dedicated exercise program on hand function, grip strength, joint mobility and pain compared with conventional outpatient physiotherapy not specifically targeting hand function.
Methods: A total of 51 RA patients receiving outpatient physiotherapy once a week were enrolled and randomized to either continue their usual therapy (control group) or to participate in a dedicated hand function training (HFT) twice a week in addition to their usual therapy (HFT group). The HFT program was supervised by an occupational therapist who conducted once weekly HFT sessions and instructed the participants to perform an additional self-administered HFT session at home once a week. Study duration was six months with an option to continue HFT for additional 6 months. Study participants were evaluated at baseline and every 3 months.
The primary outcomes hand function and grip strength were assessed using standardized questionnaires (Cochin hand function scale (CHFS), Australian/ Canadian Osteoarthritis Hand Index (AUSCAN), Michigan Hand Outcomes Questionnaire (MHOQ)) and dynamometer/pinch gauge readings for different types of grip (cylindrical grasp, spherical grasp, hook grasp, tip to tip pinch and key pinch), respectively. The secondary outcomes joint mobility and pain were assessed using a digital goniometer and visual analogue scales (VAS), respectively. Statistical analysis used the Wilcoxon test for evaluating changes of parameters over time within the groups and the Kruskal Wallis test for group comparisons and Bonferroni-Holm correction.
Results: 41 of the 51 patients (HFT group: n = 20, mean age 60.3 ± 8.4 years; control group: n = 21, mean age 60.5 ± 11.5 years) completed the 6-month study period, 14 patients extended their HFT to 12 months. Within the 6-month study period there were no significant improvements of the primary outcome parameters and of pain within the groups vs. baseline and no significant differences between the groups. Only the CHFS improved significantly in the HFT group as of month 9. A significant improvement of the range of motion vs. baseline was achieved by HFT as early as 3 months after baseline which persisted up to month 12. As some improvement was also seen in the control group, there was no significant difference between the groups. Hand mobility improved particularly in the subgroup of patients >60 years of age. There was no influence by pain intensity at baseline (VAS ≤50 mm vs. VAS >50 mm).
Conclusion: Serial dedicated HFT for 6 months resulted in improved joint mobility but did not improve global hand function, grip strength and pain in RA patients. A longer treatment duration (≥12 months), a higher treatment frequency (>2 times/week) and a larger cohort of patients may be required.

Scleroderma, myositis and related syndromes

POS0315

LONG-TERM SAFETY AND EFFICACY OF LENABASUM DURING 3 YEARS IN AN OPEN-LABEL EXTENSION (OLE) OF A PHASE 2 STUDY OF LENABASUM IN REFRACTORY SKIN DISEASE IN DERMATOMYOSITIS (DM)

V Werth.[1], J. Concha[1], J. Burroughs[1], J. Okawa[1], R. Feng[1], A. Jobanputra[1], R. Borucki[1], K. Hally[2], E. Hejazi[1], M. Tillinger[2], S. Constantine[2], N. Dgetluck[2], B. White[2]. [1]*University of Pennsylvania, Dermatology, Philadelphia, United States of America*; [2]*Corbus Pharmaceuticals, Clinical, Norwood, United States of America*

Background: Lenabasum is a synthetic, non-immunosuppressive, selective cannabinoid receptor type 2 agonist that activates resolution of inflammation. Lenabasum had acceptable safety and tolerability and improved efficacy outcomes in the initial 16-week double-blinded, randomized, placebo-controlled Part A of Phase 2 trial JBT101-DM-001 (NCT02466243) in DM subjects with refractory skin involvement. In that study, lenabasum or placebo was added to stable background treatment, with immunosuppressive therapies allowed.
Objectives: To assess long-term safety and efficacy in DM subjects in this study.
Methods: Subjects who completed Part A of the Phase 2 study (n = 22) were eligible to receive oral lenabasum 20 mg BID in an open-label extension (OLE) that assessed safety and efficacy at 4 weeks, then every 8 weeks.

Results: 20/22 (91%) eligible subjects enrolled in the OLE, following a mean interval of 31 weeks from the end of Part A, during which they continued to receive standard-of care treatments, to the start of the OLE during which lenabasum 20mg BID was added. 17/20 (85%) subjects were on stable baseline immunosuppressive drugs. At the time of this data cut-off, 17 subjects were still enrolled, 17 had completed 140 months (2.7 years), and 15 had completed 156 months (3 years) of OLE dosing.

All OLE subjects experienced at least 1 adverse event (AE), with 118 AEs during the OLE through Dec 2020. Most AEs were mild (n = 111, 94%), with 2 severe AEs (fatigue and metastatic prostate cancer) considered unrelated to lenabasum. AEs occurring in ≥ 3/20 OLE subjects were: URI (n = 5); fatigue (n = 4); nausea (n = 3); common cold (n = 3); UTI (n = 3); and DM flare (n = 3). No serious AEs related to lenabasum have been reported in this OLE to date. No subject discontinued the OLE because of an AE related to lenabasum.

Improvement was seen in multiple physician- and patient-reported efficacy outcomes. CDASI activity score improved through the first 15 months of lenabasum treatment in the OLE and remained stable thereafter, with an improvement of ~20 points from the beginning of the study maintained from Month 15 through Year 3 in the OLE. CDASI damage score increased through the first year of the OLE, even though skin activity was decreasing, but lessened thereafter, returning after 3 years to about the same level it was at the beginning of the OLE. Other outcomes shown in Figure 1 followed the same general pattern as CDASI activity score, with improvement through the first 12-16 months of the OLE, then stability thereafter. Of note, 2 subjects had disease flares shortly after stopping lenabasum for conclusion of the OLE.

Conclusion: Lenabasum continues to have a favorable safety and tolerability profile in the OLE of the Phase 2 trial JBT101-DM-001 with no serious AEs or study discontinuations related to lenabasum. The CDASI activity score and multiple other physician and patient-reported outcomes improved and have remained stable, showing durability of improvement in these patients with refractory skin disease. Skin damage was reversible and began to improve once skin activity stabilized. The limitations of attributing this improvement to lenabasum in the setting of open-label dosing is acknowledged. These data support further testing of lenabasum for the treatment of DM, and a Phase 3 study of lenabasum in DM is ongoing.

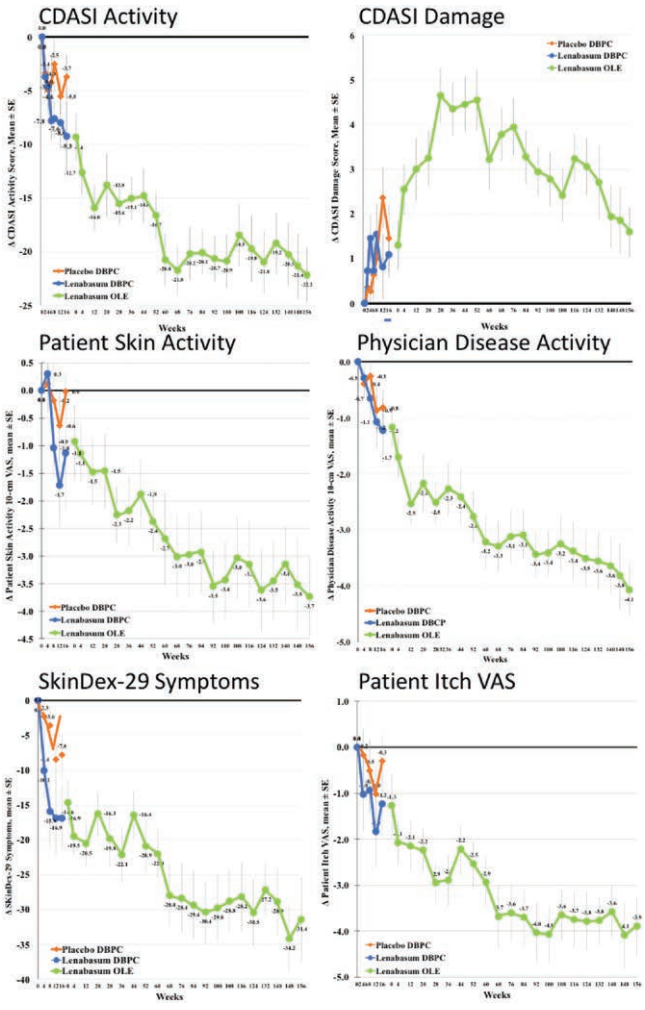

Figure 1. Change from Baseline in Selected Efficacy Outcomes in OLE of Phase 2 Trial JBT101-DM-001

Background: Nintedanib has shown to slow FVC decline by 41ml over 52 weeks in systemic sclerosis-associated interstitial lung disease (SSc-ILD). However, the long-term effect of nintedanib treatment on ILD progression and mortality in SSc patients is so far unknown.

Objectives: Here, the 52-week treatment efficacy of nintedanib was modeled and extrapolated on the long-term FVC course and survival in SSc-ILD patients from the European Scleroderma Trial and Research (EUSTAR) database.

Methods: SSc patients from the EUSTAR database fulfilling the inclusion criteria of the SENSCIS trial (SSc classification criteria, ILD confirmed by imaging, disease duration of <7 years, FVC≥40%pred, diffusion capacity of the lung for carbon monoxide (DLCO) 30-89%pred); and matched for baseline characteristics as well as matched for the 52-week FVC change of SENSCIS patients were included (n=236). Linear mixed models including time, risk factors at baseline (sex, age, dyspnea class, DLCO%, CRP, modified Rodnan skin score, SSc subtype, SSc auto-antibodies, disease duration, synovitis and muscle weakness) were used to estimate the natural FVC course over time. On this natural course of FVC, the observed effect from the SENSCIS trial representing the absolute 52-week difference of FVC decline between the nintedanib and the placebo group was applied as continuous annual effect (SENSCIS effect model). Survival was estimated for both the natural course as well as the SENSCIS effect model using Cox regression.

Results: Of the 236 included patients, 75% were females, 65% had diffuse cutaneous SSc. Mean age was 50.6 years, mean FVC 78.2%pred and DLCO 56.3%pred at time of inclusion. Mean FVC change after 12±3 months was -2.3 ±6.9%pred. These parameters were largely similar to the characteristics of the SENSCIS population.

In the longitudinal follow up of this population, the natural course of FVC showed a total FVC decline of -16.3%pred over 5 years. With assumed SENSCIS effects (effects of nintedanib treatment reported in SENSCIS), the 5-year FVC decline was reduced to -10.3%pred (Figure 1).

The reduced FVC progression translated into an improved survival. The natural 5-year survival of this SSc-ILD population was 88.2%. When extrapolating also a severe FVC decline early in the course, frequently terminated by early mortality of SSc patients excluding them from long-term outcome assessment, the estimated 5-year survival was reduced to 81.6%. When the SENSCIS effects on

FVC were considered, the 5-year extrapolated survival was increased to 86.3% (Figure 2).

Conclusion: Long-term experience of nintedanib treatment in SSc-ILD patients is lacking so far, therefore we modeled and extrapolated the 52-week treatment efficacy of nintedanib on the long-term FVC course and survival in SSc-ILD patients from the EUSTAR database. We could demonstrate a significant reduction of FVC decline by extrapolating the annual treatment effects of nintedanib from the SENSCIS trial from 1 to 5 years in EUSTAR. Translating these reductions of FVC decline into survival, the 5-year mortality rate was reduced from 18% to 13%.

Background: In SSc, ILD is a major cause of morbidity and mortality. High resolution computed tomography (HRCT) is the gold standard for the diagnosis. Predictors of ILD onset are eagerly awaited to improve SSc-ILD management. Pulmonary function test (PFTs) are routinely performed to measure lung function changes.

Objectives: Our aim was to investigate the performance of DLCO (diffusing capacity of lung carbon monoxide) and FVC (forced vital capacity) in predicting the development of SSc-ILD.

Methods: The longitudinal data of DLCO, FVC and ILD on HRCT of SSc patients from the EUSTAR database were evaluated at baseline (t_0), after 12 (±4) (t_1) and 24 (±4) (t_2) months. Patients with negative HRCT for any sign of ILD both at t_0 and t_1 were included. Patients who presented or developed pulmonary hypertension during the study period were excluded. At baseline, demographic data, disease duration from Raynaud's onset, disease subsets, autoantibodies and other laboratory and instrumental data were recorded.

Results: 474/17805 patients were eligible for the study (403 females, 71 males): 26.0% dcSSc, 58.3% lcSSc, 220 (48.0%) patients with positive anticentromere antibodies (ACA) and 117 (25.4%) with positive antitopoisomerase I antibodies (Topo-I abs). Among all enrolled patients, 46 (9.7%) developed HRCT signs of ILD at t_2. Patients with Topo-I abs showed an association with ILD development at t_2 (16.7% vs 7.8%, p=0.0031), contrarily ACA positive patients were negatively associated with ILD appearance after 2 years of follow-up (4.4% vs 14.4%, p=0.0001). Positive t_2 HRCT patients had a significant lower value of DLCO and FVC at all three assessments when compared to patients with a negative HRCT at t_2 (Table 1) and both t_0 DLCO and FVC values negatively correlated with ILD development (Table 1). The mean t_0 to t_1 change (Δ) of DLCO in patients with negative t_2 HRTC and positive t_2 HRCT were -0.5 (±12.6) and -1.0 (±15.1), respectively. The mean t_0 to t_1 ΔFVC in patients with negative t_2 HRTC and positive t_2 HRCT were -0.2 (±10.6) and 0.1 (±11.5), respectively. None of them predicted the appearance of ILD at t_2 (ΔDLCO: OR (IC) 0.997 (0.97-1.02), p=0.8024; ΔFVC OR (IC) 1.002 (0.97-1.03), p=0.8664). The data showed an association between t_0 DLCO value<80% and ILD appearance after 2 years of follow-up [OR(IC): 3.09(1.49-6.40), p=0.0023]. Such association was not observed for t_0 FVC value<80% [OR(IC): 1.95(0.81-4.68), p=0.1329]. The predictive capability of t_0 DLCO<80% was moderate but stronger than FVC<80% [AU ROC: 0.62 (0.56-0.69), 0.53 (0.48-0.59) respectively, p=0.0205].

Conclusion: Our data suggest that an impaired baseline DLCO (<80%) may have a predictive value for the development of ILD on HRCT after 2 years of follow-up. Further rigorous prospective studies are warranted to understand the role of DLCO evaluation in the course of SSc.

Table 1. DLCO and FVC values at t_0, t_1 and t_2 values in patients with positive or negative HRCT for ILD at t_2 and their statistical differences.

	Patients without ILD at t2 (mean±SD)	Patients with ILD at t2 (mean±SD)	OR (95%CL)	p-value
DLCO at t_0	79.0 ± 16.6	69.9 ± 17.4	0.97 (0.95 - 0.99)	0.0006
DLCO at t_1	78.4 ± 16.8	68.9 ± 18.6	0.97 (0.95 - 0.98)	0.0005
DLCO at t_2	78.0 ± 17.0	65.1 ± 19.1	0.95 (0.93 - 0.97)	<0.0001
FVC at t_0	102.2 ± 17.3	94.6 ± 16.2	0.97 (0.96 - 0.99)	0.0052
FVC at t_1	101.9 ± 17.9	94.7 ± 16.5	0.98 (0.96 - 0.99)	0.0092
FVC at t_2	101.6 ± 17.6	94.5 ± 20.0	0.98 (0.96 - 1)	0.0126

Background: There is renewed interest in the role of autoantibodies to predict outcomes in systemic sclerosis (SSc). Among the newly identified subsets, patients with limited cutaneous form (lcSSc) but anti-topoisomerase I antibodies (Scl70) positivity draw particular attention, and namely, assessing the risk of developing interstitial lung disease (ILD) —the main cause of death in SSc—to improve the management of Scl70-lcSSc patients.

Objectives: We aimed to characterize patients with Scl70-lcSSc in the large multicenter European Scleroderma Trial and Research (EUSTAR) cohort.

Methods: The EUSTAR database was locked in July 2019. We included all patients fulfilling 1980 ACR and/or 2013 ACR/EULAR criteria for SSc, with disease duration at database entry ≤3 yrs and known and stable skin form during the first 3 yrs. Patients with lcSSc were compared: Scl70-lcSSc (target group) vs. ACA-lcSSc and ANA-lcSSc (Step 1); and Scl70-lcSSc vs. Scl70-dcSSc (Step 2). In the ANA subgroup we included ANA+ patients with negative SSc-specific antibodies (Scl70, ACA, RNA polymerase III). In each step, we performed 5 generalized mixed models (GMM) for the risk of the new onset of ILD (defined by imaging), primary myocardial involvement (PMI), pulmonary hypertension (PH), "any severe" (ILD+PMI+PH+scleroderma renal crisis) and all-cause-mortality. An additional GMM assessed the risk of forced vital capacity (FVC) decline ≥10% vs. FVC value at ILD onset. Each GMM was adjusted for age, sex and confounders.

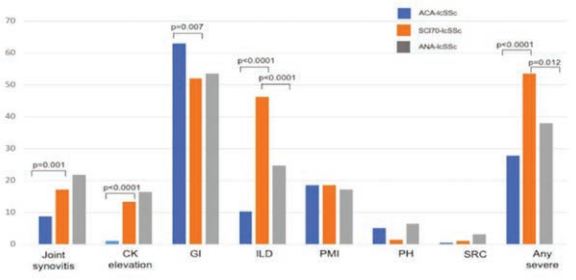
Results: Overall, 1285 SSc patients were included: 1068 (83%) females, 860 (67%) lcSSc and 425 (33%) dcSSc. Among patients with lcSSc, 537 (62%) had ACA+, 194 (23%) Scl70+ and 129 (15%) ANA+; 425 patients had dcSSc and Scl70+. Median follow-up was similar in all 4 groups: 7.2 to 8.1 yrs.

Step 1: At baseline, Scl70-lcSSc patients had significantly shorter time from Raynaud's phenomenon (RP) to SSc onset, higher mRSS (5.8±4.8 vs. 4.3±4, p=0.001), and higher rate of articular and muscular involvement vs. ACA-lcSSc patients (Figure 1). No differences were found between Scl70-lcSSc and ANA-lcSSc comparing the aforementioned variables. ILD was more frequent in Scl70-lcSSc (46%) than in ACA-lcSSc (10%) and ANA-lcSSc (25%), as well as restrictive lung disease. GMM showed that Scl70-lcSSc carries a higher risk of ILD than both ACA-lcSSc (HR 4.55, 95%CI 3.23-6.67) and ANA-lcSSc (HR 2.17, 95%CI 1.39-3.45), with a rate of FVC decline ≥10% over time similar to the other limited forms. In Scl70-lcSSc patients the risk of "any severe" organ involvement was similar to ANA-lcSSc and higher than ACA-lcSSc (HR 1.89, 95%CI 1.40-2.50). In particular, Scl70-lcSSc shows a risk of PMI similar to ANA-lcSSc and lower than ACA-lcSSc; no differences regarding PH risk. The mortality risk in patients with Scl70-lcSSc was similar to the other limited forms'.

Step 2: At baseline, time from RP to SSc onset was longer in patients with Scl70-lcSSc, with less frequent joint synovitis and tendon friction rubs vs. patients with Scl70-dcSSc. Conversely, the frequency of muscular, cardiac and pulmonary involvement was similar. The risk of ILD in Scl70-lcSSc patients was similar to Scl70-dcSSc, with a lower risk of FVC decline ≥10% over time. The risk of "any severe" involvement (HR 0.66, 95%CI 0.49-0.83), PMI and PH was lower and the mortality risk tended to be lower (HR 0.57, 95%CI 0.33-1.01, p=0.053) vs. Scl70-dcSSc.

Conclusion: In our large multicenter EUSTAR cohort one quarter of lcSSc patients were Scl70+. We show a ranking for major organ involvement within lcSSc: Scl70 the most severe, ANA+ intermediate and ACA the milder form. Scl70-dcSSc patients present the most severe phenotype, and Scl70 positivity, more than the cutaneous subset, is strongly predictive of ILD, whereas other variables may influence progression. These results may provide new insight to improve the management of Scl70-lcSSc patients.

Figure 1. Baseline clinical features and organ involvement in the 3 groups of patients with limited cutaneous systemic sclerosis (lcSSc) (step 1)



ACA, anticentromere antibodies; ANA, antinuclear antibodies; CK, creatine kinase; GI, gastrointestinal involvement; ILD, interstitial lung disease; PMI, primary myocardial involvement; PH, pulmonary hypertension; Scl70, anti-topoisomerase I; SRC, scleroderma renal crisis.

POS0319 PERFORMANCE OF PATIENT REPORTED OUTCOMES (PROS) IN SCLERODERMA PATIENTS WITH REDUCED LUNG FUNCTION IN AN OBSERVATIONAL COHORT

M. G. Lazzaroni[1], G. Abignano[2,3], M. Wilson[2], V. Kakkar[2], F. Del Galdo[2]. *[1]ASST Spedali Civili of Brescia, University of Brescia, Rheumatology and Clinical Immunology, Brescia, Italy*; *[2]University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine and NIHR Biomedical Research Centre, Leeds, United Kingdom*; *[3]Azienda Ospedaliera San Carlo, Rheumatology, Potenza, Italy*

Background: Patient Reported Outcomes (PROs) are used to capture disease impact on patients' Health Related Quality of Life (HRQoL) and they have been increasingly used as endpoints in clinical trials for Systemic Sclerosis (SSc). The DeSScipher project within the EUSTAR group highlighted dyspnea as one of the factors more strongly related with the highest SHAQ scores (1). Nevertheless, the SENSCIS trial in SSc-ILD (2) showed the efficacy of Nintedanib in reducing the annual rate of FVC loss, as compared to placebo, without significant changes in the PROs used as secondary endpoints (St. George's Respiratory Questionnaire and the FACIT-Dyspnoea questionnaire). Since patient's perspective is a crucial determinant to define the overall relevance of an intervention, the performance of PROs in reflecting different lung functional stages is a relevant issue in SSc.
Objectives: To analyse in a prospective SSc cohort the inference of reduced lung function as measured by FVC on median PRO scores and the correlation among distinct commonly used PROs.
Methods: A cross-sectional study was performed on data exported from the STRIKE database regarding SSc patients followed in Leeds Scleroderma Programme for SSc. Data included records of periodical visits with scores of different PROs commonly used in SSc (Scleroderma-Health Assessment Questionnaire (SHAQ), Cochin Hand Function Scale (CHFS) and Borg dyspnoea scale) and FVC%-predicted (%pFVC) and DLCO%-predicted (%pDLCO). SHAQ score was calculated as the mean value of HAQ (0-3) with the average of the 7-VAS scores divided by 3.33. The 7-VAS (score 1-10) were 1: pain, 2: general function, 3: arthritis, 4: gastro-intestinal, 5: dyspnoea, 6: Raynaud Phenomena; 7: digital ulcers. The correlation of FVC with distinct PROs, and the inter-PRO correlation, were analysed through the non-parametric Spearman test.
Results: Complete data were available from 182 visits of 87 SSc patients (41 with diffuse and 46 with limited cutaneous involvement). Mean %pFVC was 95.16 ±24.93 (median 95) and mean %pDLCO was 59.31±16.51 (median 59). Overall, FVC and DLCO showed a moderate correlation with SHAQ (r=-0.36, p<0.001 and r=-0.24, p:0.001 respectively), while Borg score showed a stronger negative correlation with FVC and DLCO (r:-0.42 and r-0.38, p<0.001 for both). In a sub-analysis of patients grouped by FVC, patients with FVC 50-70% showed a significant correlation of FVC with SHAQ (r =-0.47, p:0.012), which was not present in patients with FVC 70-90% (r:-0.23, p:0.13). VAS-5 dyspnoea and Borg were not associated with FVC in these two subgroups of patients.
Inter PROs analysis showed that CHFS score had a stronger correlation with SHAQ than Borg dyspnoea score in the overall population (r:0.86 vs. r:0.57, both p<0.001).
Conclusion: The analysis of a single centre prospective cohort of SSc patients, suggests a small inference of lung function in the overall SHAQ. The stronger correlation of SHAQ with CHFS, than with Borg score, suggests a higher weight of hand function on SHAQ in this population with relatively conserved lung function. In patients with %pFVC <70%, the correlation with SHAQ was stronger than in patients with %pFVC >70%, suggesting that mild reductions in FVC might not be perceived by the patients, or at least they might not modify HrQoL as measured by SHAQ.

POS0320 POOR PROGNOSIS PREDICTION IN ANTI-MDA5 POSITIVE DERMATOMYOSITIS ASSOCIATED WITH INTERSTITIAL LUNG DISEASE: THE CROSS-CAR DECISION TREE MODEL

L. Wang[1], C. Lv[1], F. Yuan[2], J. Li[3], M. Wu[4], Z. Da[5], H. Wei[6], L. Zhou[7], S. Yin[8], J. Wu[9], W. Tan[1]. *[1]The First Affiliated Hospital of Nanjing Medical University, Department of Rheumatology, Nanjing, China*; *[2]The Affiliated Wuxi People's Hospital of Nanjing Medical University, Department of Rheumatology, Wuxi, China*; *[3]Huai'an First People's Hospital, Department of Rheumatology, Huai'an, China*; *[4]The Third Affiliated Hospital of Soochow University, Department of Rheumatology, Changzhou, China*; *[5]Affiliated Hospital of Nantong University, Department of Rheumatology, Nantong, China*; *[6]Northern Jiangsu People's Hospital, Department of Rheumatology, Yangzhou, China*; *[7]Changzhou Second People's Hospital Affiliated to Nanjing Medical University, Department of Rheumatology, Changzhou, China*; *[8]Affiliated Hospital of Xuzhou Medical University, Department of Rheumatology, Xuzhou, China*; *[9]The First Affiliated Hospital of Soochow University, Department of Rheumatology, Suzhou, China*

Background: The prognosis of anti-melanoma differentiation-associated gene 5 positive dermatomyositis (anti-MDA5+ DM) – associated interstitial lung disease (ILD) is poor and heterogeneity.
Objectives: The aim of this study was to evaluate prognostic factors and to develop a simple and generally applicable bedside decision tree model for predicting outcomes in patients with anti-MDA5+ DM and to guide treatment.
Methods: We analyzed data for 246 anti-MDA5+ DM patients from Myositis Study Group-Jiangsu, a multicenter cohort across eighteen tertiary hospitals in Jiangsu province, from March 2019 to October 2020. The primary end point was all-cause death, and the secondary end point was occurring of rapidly progressive-ILD (rp-ILD). We used a multivariable Cox proportional hazards model to identify the independent prognostic risk factors of death and rp-ILD respectively. A decision-tree prediction model was developed by using data from 10 hospital of southern region (n=163), with validation by using contemporaneous data from northern region (n=83).
Results: To assess the risk of rp-ILD, we developed a combined risk score, the CROSS score, that included the following values and scores: C-reactive protein (≤8mg/L, 0; >8mg/L, 3), anti-Ro52 antibody (negative, 0; positive, 4), Sex (Female, 0; Male, 2) and Short course of disease (More than 3 months, 0; Less than 3 months, 2). The mortality risk was identified by the CAR score, including C-reactive protein (≤8mg/L, 0; >8mg/L, 1), Alanine Transaminase (≤50units/L, 0; >50units/L, 1) and rp-ILD (non-rpILD, 0; rp-ILD, 3). We divided patients into three risk groups according to the CROSS score: low, 0 to 3; medium, 4 to 7; and high 8-11. And then Use of a simple decision tree prediction model permitted stratification into three different outcome prediction groups. High-risk patients had significantly higher mortality rates than low- and medium-risk patients in both discovery and validation cohorts (p < 0.0001).
Conclusion: The CROSS-CAR decision tree model is easy to evaluate the poor prognostic risk in MDA5+ DM patients during any follow-up period. Unnecessary lung examination, such as chest CT scan and arterial blood gas analysis was avoided in low- and medium- rpILD risk patients. The special ambulance, with red cross sign tagged on car in China, may help to screen the high risk patients and to guide further treatment.

Background: Hydroxychloroquine (HCQ) is a well-tolerated drug that contributes to downregulating the immune response against autoantigens and it has been used in several autoimmune diseases. In systemic sclerosis (SSc) it is used to treat inflammatory arthritis without proof of efficacy.
Objectives: Our aim was to evaluate the use of HCQ and its impact on Health Assessment Questionnaire disability index (HAQ-DI) and the Cochin Hand Function Status (CHFS). in a large SSc cohort compared to a propensity matched group of SSc patients not using HCQ.
Methods: SSc patients from the European Scleroderma Trials and Research (EUSTAR) data base treated with HCQ for at least 6 months were evaluated. Demographic and clinical data, concomitant drugs, duration of HCQ treatment and reasons for its discontinuation, HAQ-DI and CHFS (at least 2 evaluation) were recorded and were the outcome variables of interest. Statistical analysis was performed using propensity score matching for age, gender, disease duration, corticosteroids, immunosuppressives, vasoactive drugs, DMARDs in a 3:1 control:HCQ ratio. Standard descriptive statistics and Student's t-test and Chi-square test were used to assess the propensity-matched groups.
Results: 1,636 of 17,805 SSc patients (9.2%) were treated with HCQ for at least 6 months; out of these 3% (50/1636). had at least a baseline and follow-up HAQ-DI evaluation, (and 44/1636 (2.7%) had at least a baseline and follow-up CHFS evaluation. Propensity matching assured that pts were matched for demographic variables such as gender (mean on HCQ vs no HCQ:femals:92.0 vs 85.3), age(49.8 vs 49.97yrs) disease duration(8.3 vs 9.1 yrs), limited disease(55.3 vs 62.6%) as well as background medications (P>0.1-0.9). We did not find any significant changes in HAQ or CHFS (difference in slope) over 365 days of treatment, comparing the HCQ-treated group to the non-HCQ treated patients (p=0.240 for both (Figure 1).
Conclusion: Results from the EUSTAR registry showed that HCQ was used by 9.2% of SSc patients. HCQ use did not improve the HAQ or CHFS, comparing HCQ users to non-HCQ users.

Figure 1. HAQ trend and CHFS trend over the time

POS0322 CORRELATION BETWEEN QUANTITATIVE COMPUTED TOMOGRAPHY AND DISEASE ACTIVITY IN SYSTEMIC SCLEROSIS

D. Sambataro[1,2], M. Orlandi[3], M. Colaci[1,1], L. Malatino[1], G. Sambataro[1,2], A. Ariani[4]. [1]*University of Catania, Department of Clinical and Experimental Medicine, Catania, Italy*; [2]*Artroreuma srl, Outpatient of Rheumatology associated to Italian National Health System, Mascalucia, Italy*; [3]*University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy*; [4]*Azienda Ospedaliero Universitaria di Parma, Department of Medicine, Parma, Italy*

Background: High Resolution Computed Tomography (HRCT) is the gold standard to evaluate Interstitial Lung Diseases (ILDs) extent and severity. Quantitative Computed Tomography (QCT) is a promising tool as it provides an operator-independent assessment of ILD extent. Even if there are emerging data on QCT in Systemic Sclerosis (SSc), its correlation with disease activity (DA) has not been yet studied.
Objectives: To evaluate the correlation between QCT score and DA in an Italian cohort of SSc patients.
Methods: A multicentric, observational study was conducted in three Italian rheumatological centers.
Adult SSc patients classified according to the ACR/EULAR 2013 criteria [1] were assessed with pulmonary function tests, HRCT and for DA. CT images were analyzed quantitatively with the densitometric radiomic data obtained through a free open software – Mean lung attenuation (MLA), Standard Deviation (SD), Kurtosis, Skewness and Lung volume. DA assessment was conducted according to EUSTAR index [2]: a score ≥2.5 was considered indicative of high disease activity.
Age below 18 and pregnancy were considered exclusion criteria. We used Student's T test to evaluate the means of the parameters, Pearson's r test for correlations, receiver operating characteristics curve to define the cutoff values of the significant details, and linear regression with collinearity test to define the role of the details. P value <0.05 was considered statistically significant.
Results: Sixty patients were enrolled (male 8, female 52), with mean age 53.2 years (SD 15.6) and mean disease duration 5.3 years (SD 4.2). QCT indexes distribution was different in high DA vs low DA SSc patients. In particular mean lung attenuation (MLA, -834.7 vs -812.1, p =0.03), standard deviation (95.9 vs 102, p =0.03), skewness (2.2 vs 1.7, P =0.006) and kurtosis (5.5 vs 3.3, p =0.009) of the parenchymal lung and skewness (3.1 vs 2.8, p =0.03) of the whole lung were statistically different. DA correlates with MLA (r =0.28, p =0.003), standard deviation (r =0.21, p =0.02), skewness (r =-0.32, p =0.001) and kurtosis (r =-0.29, p =0.001) of the parenchymal lung and MLA (r =0.25, p =0.006), skewness (R =-0.27, p =0.003), kurtosis (r =-0.21, P =0.02) of the whole lung. The skewness of the parenchymal lung was the QCT index with the best performance in identifying high DA SSc patients (cutoff value ≤1.85; area under the curve 0.74, p =0.005; sensitivity 79.5%, specificity 68.7% accuracy 76.6%).
Conclusion: To our knowledge, this is the first study which correlate the QCT score with DA in SSc patients. Our results suggest that QCT can identify SSc patients with high DA score. This could open a scenario of new applications as an operator-independent contribution in DA scores with a potential role in clinical practice. Further studies are needed to confirm the data and to better identify the most suitable parameters for the purpose.

Background: Autoantibodies permit to classify and subgroup connective tissue diseases (CTD) in homogeneous groups of patients in terms of phenotype and prognosis. Anti PM-Scl antibodies have been associated with different CTD categories such as: idiopathic inflammatory myositis (IIM), systemic sclerosis (SSc), Sjögren's syndrome (SjS), systemic lupus erythematosus (SLE), mixed connective tissue disease (MCTD) or undifferentiated connective tissue disease (UCTD).
Objectives: To determine clinical spectrum of anti-PM-Scl associated disease and if it an homogenous condition.
Methods: This multicentric (four hospitals) observational and retrospective study included all consecutive patients with positive testing for anti PM-Scl antibodies on immunoblot assay and connective tissue disease (2011 -2020). Epidemiological, biological, clinical and radiological data were collected in standard form as well as patient's outcome.
Results: One hundred twenty height patients (female n=96;75%) were included. Median [quartiles] age at diagnosis was 50 [18;84] (IQR) and follow-up duration of 7 [3.75-12] years. Seventy-six (59.3%) patients were simple anti-Pm-Scl positive, and 40.7% were associated with other antibodies: anti-SSA/Ro52 (n=13; 10.92%), SSc associated antibodies (n=21; 16.4%), anti-dsDNA for (n=9; 7%), anti-RNP (n=6; 4.7%) and anti-CCP antibodies (n=6; 4.7%). Most patients had cutaneous involvement (n=106; 83%) with skin thickening (n=47; 36%), mechanics hands (n= 28; 22%), calcinosis (n=26; 20.3%) and subcutaneous edema (n=20; 15.62%). Vascular involvement was frequent with Raynaud phenomenon (n= 89; 69%), telangiectasia (n=36; 28%), skin ulcers (n=27; 21%), pulmonary hypertension (n=8/120; 6.7%) and scleroderma renal crisis (n=2; 1.5%). A majority of patients also displayed an interstitial lung disease (ILD) (n=83; 65.8%); nonspecific interstitial pneumonia (92.7%) and/or organizing pneumonia (25.3%). ILD was characterized by a subacute onset in 37/81 (45.7%); median [quartiles] forced vital capacity (FVC) and total lung capacity (TLC) at diagnosis of 88% [73-105] and 79.5% [68.5-101] respectively. Sixty patients (47%) had muscular sign including myalgia (47%), elevated CPK (n=51; 40%) and muscular weakness (Medical Research Council score <4) (n=19/124;15%). Finally, fifty-three (41.7%) had gastroesophageal reflux. Thirty-nine patients (30.4%) experienced at least one muscular or ILD relapse and 6 (4.84%) died during follow-up (2 breast cancer, 1 pneumonia, 3 unknown etiology). Concerning patients' prognosis, relapses were associated with skeletal (n=29, 74.4% vs n=32, 35.96%, p < 0.001) or cardiac muscle involvement (n=7, 18.4% vs n=2, 2.5%, p=0.007), and subacute ILD (n=19, 65.5% vs n=18, 34.62%, p= 0.05) with organized pneumonia pattern (n=11, 32.3% vs n=10, 13.9%, p=0.05). Strikingly, ILD occurred mainly in men (90.6% vs 57.2%, p < 0.001) and was associated with anti-Scl-70 positivity (n=14, 16.67% vs 0%, p= 0.01). Muscle involvement was associated arthralgia (n=46, 76.67% vs n=34, 50.75%, p=0.005), respiratory signs at diagnosis: dyspnea NYHA ≥3 (n=46, 75.41% vs n=30, 44.78%, p < 0.001), sub-acute ILD (n=24, 61.54% vs n=13, 30.95%, p=0.0111) with lower FVC (73% [64;88] vs 98 [76;105], p < 0.001). Ulcers were associated with Anti-Scl70 positivity (n=9, 33.33% vs n=5, 4.95%, p < 0.001), Raynaud phenomenon (n=27, 100% vs n=62, 61.39%, p < 0.001), digestive involvement (n=20, 74.07% vs n=34, 33.66%, p < 0.001), ILD with chronic onset (n=15, 78.95% vs n=29, 46.77%, p=0.027) and increased incidence of deaths (n=4, 16% vs n=2, 2.02%, p= 0.01).
Conclusion: Conducted on the largest cohort of Anti-PM-Scl patients, this study highlights two main phenotypes that determine different outcome and prognosis. One was associated with muscular disease and subacute onset ILD with more frequent relapses. The second with a vascular phenotype associated with chronic ILD, digestive involvement, chronic evolution and increased incidence of death. This could lead to a reclassification of PM-Scl associated auto immune diseases.

POS0324 SMOKING HISTORY AND SCLERODERMA CLINICAL TRIALS CONSORTIUM DAMAGE INDEX (SCTC-DI) AS INDEPENDENT PREDICTORS OF MORTALITY IN SYSTEMIC SCLEROSIS IN A SINGLE-CENTRE ITALIAN COHORT

M. Breda[1], M. G. Lazzaroni[1], F. Franceschini[1], P. Airò[1]. [1]*ASST Spedali Civili of Brescia, University of Brescia, Rheumatology and Clinical Immunology, Department of Clinical and Experimental Sciences, Brescia, Italy*

Background: Systemic Sclerosis (SSc) is characterized by increased mortality and organ damage accrual. A composite SSc Damage Index was recently developed by the Scleroderma Clinical Trials Consortium (SCTC-DI) and was demonstrated as a predictor of mortality both in the Australian derivation cohort and in the Canadian validation cohort (1). Several independent predictors of mortality in SSc have been reported, but only limited data are available on the role of smoking.
Objectives: To evaluate smoking history and SCTC-DI as independent predictors of mortality in SSc in a single centre Italian cohort.
Methods: A retrospective analysis was performed on patients prospectively followed in our centre from 1989 to 2019, with at least 2 evaluations and/or cause of death available. Organ damage was evaluated through the SCTC-DI (0-55 scale; severe damage>12), while comorbidities through the Charlson Comorbidity Index (CCI). Survival analysis was performed with Kaplan-Meier curves and with Log-rank test to compare different subsets. Cox-regression analysis was performed to identify baseline independent predictors of mortality.
Results: 648 SSc patients were 99% Caucasian, 90% female and had a median age at diagnosis of 55.5 years (IQR: 45.0-65.6); 19% had diffuse cutaneous involvement. ACA was positive in 52%; anti-TopoI in 22% and anti-RNA Polymerase III in 5%.
Median SCTC-DI at diagnosis was 2 (0-4) (n=560); ever smokers were 27%. During the follow-up 240 patients died after a median period of 10.2 years (4.9-16.8). The cause of death was related to SSc in 41% (n=65; most frequent causes pulmonary arterial hypertension (n=35) and interstitial lung disease (n=30)) and to other diseases in 40% (n=95; most frequent cause cancer (n=40)), while was indeterminate in 19%.
Overall survival at 5, 10, 15, 20 years was 87.8% (SE 1.3%), 75.6% (1.9), 63.8% (2.3), 47.7% (2.8), respectively and was higher in females vs. males (p<0.0001) and in ACA+ vs ACA- (p=0.005), but did not differ between cutaneous subsets. 111 patients were lost at follow-up (17%).
In the Cox-regression analysis smoking history and severe organ damage at diagnosis (score>12) were identified as independent predictors of death, while age at diagnosis, female gender, diffuse cutaneous subsets, ACA positivity and CCI were not (Table 1).
Conclusion: Smoking history and severe organ damage were independent predictors of death in a large Italian single centre SSc cohort. SCTC-DI was confirmed as a useful tool to predict mortality at every timepoint

POS0325 RADIOMIC BIOMARKER OF PULMONARY VASCULAR RELATED STRUCTURES PREDICTS MORTALITY IN SYSTEMIC SCLEROSIS

A. Hinze[1], Y. Radwan[1,2], M. Elnagar[1], R. Kurmann[3,4], S. Amin[1], R. Vassallo[5], C. S. Crowson[1,6], B. Bartholmai[7]. [1]*Mayo Clinic, Department of Medicine, Division of Rheumatology, Rochester, United States of America*; [2]*Michigan State University, Department of Medicine, East Lansing, United States of America*; [3]*Mayo Clinic, Department of Cardiology, Rochester, United States of America*; [4]*Heart Center Kantonsspital Luzern, Department of Cardiology, Lucerne, Switzerland*; [5]*Mayo Clinic, Department of Medicine, Division of Pulmonary and Critical Care Medicine, Rochester, United States of America*; [6]*Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America*; [7]*Mayo Clinic, Department of Radiology, Rochester, United States of America*

Background: Quantitative computed tomography (QCT) extracts features from high-resolution CT scans and quantifies lung parenchymal and vascular abnormalities which may not be discernable by qualitative review. The threshold values

of individual parenchymal abnormalities and vascular features measured by QCT methods which associate with mortality in systemic sclerosis (SSc) are currently unknown.

Objectives: To determine whether QCT measures, specifically pulmonary parenchymal abnormalities and pulmonary vascular related structures (PVRS), can predict mortality in SSc and to determine the optimal quantitative thresholds for those parameters.

Methods: A total of 133 subjects (76% women) meeting 2013 ACR/EULAR classification criteria for SSc with a baseline CT within 3 years of diagnosis were retrospectively identified for inclusion. CALIPER (Computer-Aided Lung Informatics for Pathology Evaluation and Rating) was used to quantitatively measure volume of ground glass opacities (GGO), reticular densities, and honeycombing (HC). Total interstitial lung disease (ILD) was the summation of these features. PVRS was also quantified using CALIPER. Values for each feature were expressed as a percentage of total lung volume. Cox models evaluated the hazard ratio (HR) for mortality for each parameter adjusting for age at SSc diagnosis, sex, diffuse SSc subtype, and history of smoking. The optimal thresholds for mortality prediction for each parameter were determined using consensus between 4 methods: Contal and O'Quigley Method, Cox Model Hazard Ratio, Cox Model Wald P-value, and False Discovery Rate. The c-statistic was used to assess each models' ability to predict mortality.

Results: Mean ±SD for age at SSc diagnosis was 61 ± 13 years and length of follow-up was 4.7 ± 3.0 years. There were 32 deaths (24%). A Cox model including age (HR 1.05, 95% CI: 1.01-1.09), female sex (HR 0.49, 95% CI: 0.22-1.08), diffuse SSc subtype (HR 1.50, 95% CI: 0.69-3.30), and history of smoking (HR 2.09, 95% CI: 0.97-4.53) (Model 1) significantly predicted mortality (C-statistic 0.72, 95% CI: 0.63-0.81). Adjusting for Model 1, reticular densities% (HR 1.19, 95% CI: 1.05-1.35), total ILD% (HR 1.02, 95% CI: 1.00-1.03), and PVRS% (HR 1.19, 95% CI: 1.05-1.35) were associated with mortality on univariable analyses; GGO% (HR 1.01, 95% CI: 0.98-1.04) was not significantly associated with mortality. The optimal thresholds for mortality prediction were then determined and were as follows: GGO=20%, reticular densities=8%, total ILD=20%, and PVRS=5%. While the risk of mortality was significantly increased in subjects with GGO ≥20% (HR 2.70, 95% CI: 1.21-6.05), reticular densities ≥8% (HR 4.64, 95% CI: 1.68-12.81), and total ILD ≥20% (2.59, 95% CI: 1.12-5.99), these baseline thresholds did not improve upon mortality prediction when added individually to Model 1 (C-statistic 0.73 for each). PVRS ≥5%, which had an over six-fold increase in mortality (HR 6.42, 95% CI: 2.60-15.88), did improve mortality prediction when added to Model 1 (C-statistic 0.78, 95% CI: 0.70-0.86).

Conclusion: PVRS strongly associates with early mortality in patients with SSc and represents a novel radiomic biomarker that provides prognostic information on mortality beyond pulmonary parenchymal abnormalities. CALIPER derived PVRS quantifies CT data through a function that defines connected tubular branching structures. This extracts pulmonary arteries and veins from the adjacent parenchyma but could potentially also include regions of adjoining of fibrosis.[1] Larger studies examining the association between PVRS and progression of cardiopulmonary disease are warranted.

ROLE OF THE IL-25 / IL-17RB AXIS IN TH9 POLARIZATION IN PATIENTS WITH PROGRESSIVE SYSTEMIC SCLEROSIS

L. La Barbera[1], M. Lo Pizzo[2], D. DI Liberto[2], C. Schinocca[1], P. Ruscitti[3], R. Giacomelli[4], F. Dieli[2], F. Ciccia[5], G. Guggino[1]. [1]*P. Background: Systemic sclerosis (SSc) is an inflammatory connective tissue disease leading to chronic and progressive fibrosis, typically affecting the skin and internal organs. The alteration of both innate and adaptive immune responses plays a pivotal role in SSc pathophysiology, although it has not yet been fully elucidated [1].

Recent findings have demonstrated interleukin (IL)-9 overexpression and significant group 2 innate lymphoid cells (ILC2) expansion in patients with SSc. Th9-ILC2-mast cells axis seems to be involved in SSc tissue damage and in the induction of fibrosis [2]. Activation and production of IL-9 by Th9 cells are promoted by transforming growth factor (TGF)-β, thymic stromal lymphopoietin (TSLP), IL-25 and IL-33. Thus, the IL-25 / IL-17RB pathway would act as a key player in SSc.

Objectives: The purpose of this study was to evaluate the role of the IL-25 / IL-17RB axis as a driver in Th9 polarization and ILC2 expansion and polarization in SSc patients.

Methods: 26 patients were enrolled in this study. Peripheral blood and skin biopsy specimens were obtained from SSc patients. PBMCs were isolated and incubated with and without recombinant (r)IL-25 for 24-48-72 hours and the frequencies of Th9 cells, Th17 cells and ILC2 were assessed by flow cytometry analysis. Moreover, the *ex vivo* expression of IL-17RB in ILC2 was also assessed. Immunofluorescence analysis was performed on biopsy skin samples to evaluate IL-17RB expression in ILC2.

Results: In SSc samples, Th9 cells frequency progressively increased after stimulation with rIL-25, compared to healthy controls in which IL-9 frequency decreased over time regardless of rIL-25.

Simultaneously, we evaluated the role of the IL-25 / IL-17RB axis in Th17 cells.

In the SSc pool, the initially low rate of IL-17 increased at 72 hours after stimulation with rIL-25. In unstimulated SSc samples, the initially higher IL-17 rate decreased at 72 hours; conversely, it was consistently low in healthy controls, at both baseline and stimulated conditions.

Our results confirmed the presence of IL-25-dependent clonal ILC2 expansion, suggesting a greater and progressive expansion over time in patients with SSc, compared to controls.

Interestingly, increased IL-17RB expression was found in circulating ILC2 from SSc patients supporting the characterization of ILC2 inflammatory phenotype.

Consistently, immunofluorescence on the skin of SSc patients showed a marked infiltrate of $CD3^{-}GATA3^{+}$ $IL\text{-}17RB^{+}$ cells, confirming the presence of the activated inflammatory phenotype ILC2, absent in skin biopsies of healthy controls (Figure 1).

Conclusion: These preliminary data suggest an active role of the IL-25/IL-17RB axis in SSc. It results in Th9 polarization and Th17 clonal expansion, inducing the production of IL-9 and, to a lesser extent, IL-17. Moreover, in addition to promoting Th9-mediated ILC2 differentiation, IL-25 directs the polarization of ILC2 towards the inflammatory phenotype.

POS0327 INACTIVATION OF ALDEHYDE DEHYDROGENASE 3A2 INHIBITS FIBROBLAST ACTIVATION AND TISSUE FIBROSIS

X. Xu[1], Y. N. Li[1], C. W. Chen[1], T. Trinh-Minh[1], G. Schett[1], J. H. W. Distler[1].
[1]Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany

Background: The aldehyde dehydrogenase (ALDH) superfamily composes a group of 20 enzymes that catalyze aldehyde oxidation. Within this enzyme family, ALDH3A2 stands out for its central role in the oxidation of long-chain aldehydes. Of particular interest, the substrates of ALDH3A2 include also profibrotic lipid mediators such as sphingosine 1-phosphate or leukotrienes, which have been reported to be deregulated in the context of SSc.
Objectives: We aimed to investigate the role of ALDH3A2 in fibrotic tissue remodeling in SSc.
Methods: Fibroblast-to-myofibroblast transition was analyzed by quantification of *ACTA2*/αSMA, by assessment of stress fiber formation and mRNA and protein levels of type I collagens. *ALDH3A2*/*Aldh3a2* siRNAs were employed to specifically knockdown ALDH3A2 in dermal fibroblasts both *in vitro* and *in vivo*. Overexpression of ALDH3A2 was achieved by *ALDH3A2*-pcDNA transfection. The role of ALDH3A2 was investigated in three different mouse models: Bleomycin- and cGvHD-induced dermal fibrosis as well as fibrosis induced by overexpression of a constitutively active TGFβ receptor I (TBRI^{CA}). Target genes of *ALDH3A2* in fibroblasts were identified by RNA sequencing.
Results: The expression of ALDH3A2 was modestly reduced in dermal fibroblasts of SSc skin as compared to matched healthy controls. This reduction in ALDH3A2 expression was phenocopied by activation of TGFβ signaling, whereas selective inhibition of TGFβ signaling prevented the downregulation of ALDH3A2 in experimental fibrosis. ALDH3A2 overexpression promoted fibroblast-to-myofibroblast transition with increased levels of αSMA, enhanced formation of stress fibers and reduced collagen release. In contrast, knockdown of ALDH3A2 in dermal fibroblasts inhibited fibroblast activation and collagen release. Moreover, in vivo knockdown of ALDH3A2 in the skin of mice ameliorated dermal thickening, myofibroblast differentiation and collagen deposition in three different murine models of skin fibrosis: Bleomycin-induced skin fibrosis and scleroderma-tous GvHD-as models of inflammatory stages of SSc and TBRI^{CA}-induced fibrosis as an inflammation-independent model of SSc. RNA sequencing of ALDH3A2-knockdown fibroblasts demonstrated that ALDH3A2 regulates the activity of a network of profibrotic developmental pathways including TGFβ, Wnt, Notch, and Hedgehog signaling.
Conclusion: We demonstrate that ALDH3A2 regulates a network of profibrotic pathways to control fibroblast activation and tissue fibrosis. ALDH3A2 is modestly downregulated in SSc fibroblasts as result of an endogenous, TGFβ-driven feedback loop. Although this modest downregulation is not sufficient to counterbalance the aberrant fibroblast activation in SSc, augmentation of this endogenous regulation by knockdown of ALDH3A2 demonstrates potent antifibrotic potential in experimental dermal fibrosis, thereby providing first evidence for ALDH3A2 as a target for antifibrotic therapies.

POS0328 ENGRAILED 1 COORDINATES CYTOSKELETAL ORGANIZATION TO PROMOTE MYOFIBROBLAST DIFFERENTIATION AND FIBROTIC TISSUE REMODELING

A. H. Györfi[1,2], A. E. Matei[1,2], M. Fuchs[3], A. Rius Rigau[1], X. Hong[1], Z. Honglin[4], M. Luber[1], C. Bergmann[1,2], C. Dees[1], I. Ludolph[5], R. Horch[5], O. Distler[6], G. Schett[1,2], M. Kunz[3], J. H. W. Distler[1,2]. *[1]Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany*; *[2]FAU Erlangen-Nürnberg and University Hospital Erlangen, Deutsches Zentrum für Immuntherapie (DZI), Erlangen, Germany*; *[3]Friedrich-Alexander University (FAU) of Erlangen-Nürnberg, Chair of Medical Informatics, Erlangen, Germany*; *[4]Xiangya Hospital, Central South University, Department of Rheumatology, Changsha, Hunan, China*; *[5]Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Department of Plastic and Hand Surgery, Erlangen, Germany*; *[6]Center of Experimental Rheumatology, University Hospital of Zurich, Department of Rheumatology, Zurich, Germany*

Background: Engrailed 1 (EN1) is a homeodomain-containing transcription factor with essential roles in embryonic development. In most cell types, the expression of EN1 is restricted to embryonic development. However, under pathological conditions, EN1 can be re-expressed to promote phenotypical adaptation. En1 is transiently expressed in the developing dermis of murine embryos in a distinct fibroblast lineage and silenced before birth (1). Former EN1-expressing cells give rise to a subpopulation of fibroblasts that has a high capacity for extracellular matrix production in adult murine skin. The role of EN1 in systemic sclerosis (SSc) was previously not explored.
Objectives: To study the role of EN1 in the pathological activation of fibroblasts in tissue fibrosis.
Methods: Bulk RNA-Seq and EN1 or SP1 ChIP-Seq were performed from cultured human dermal fibroblasts. The expression of EN1 was inhibited by siRNA. Cytoskeletal drugs paclitaxel, vinblastin and ROCK inhibitor (Y27632) were used to modulate the cytoskeleton in EN1 knockdown or overexpressing dermal fibroblasts. The role of EN1 in fibroblast activation was evaluated by functional experiments with EN1 knockdown or overexpression in standard 2D culture systems as well as in 3D skin equivalent models. The role of EN1 in skin fibrosis was further studied in En1$^{fl/fl}$ X Col6Cre mice, with fibroblast-specific knockout of En1 in three complementary mouse models: overexpression of a constitutively active TGFß-receptor I (TBRI^{CA}), bleomycin-induced skin fibrosis and TSK1 mice.
Results: Pathologically activated dermal fibroblasts from SSc patients express higher levels of EN1 compared with age and sex matched healthy individuals in the skin and *in vitro*. TGFβ induces EN1 expression in fibroblasts in a SMAD3-dependent manner both in cultured fibroblasts and in murine skin. Knockdown of EN1 prevents TGFβ-induced fibroblast activation, whereas overexpression of EN1 fosters the pro-fibrotic effects of TGFβ with increased expression of αSMA, stress fibers and collagen. RNA sequencing demonstrates that EN1 induces a pro-fibrotic gene expression profile functionally related to cytoskeleton organization and ROCK activation. *In silico* analyses of the promoters of En1 target genes coupled with siRNA-mediated knockdown demonstrated that EN1 regulates these pro-fibrotic target genes by modulating the activity of regulatory modules that contain transcription factors of the specificity protein (SP) family. Functional experiments with selective modulators of ROCK and of microtubule polymerization confirm the coordinating role of EN1 on ROCK activity and the re-organization of cytoskeleton during myofibroblast differentiation in both conventional culture systems and 3D skin equivalents. Consistently, mice with fibroblast-specific knockout of En1 demonstrate impaired fibroblast-to-myofibroblast transition, reduced dermal thickening and impaired collagen deposition in the TBRI^{CA}, bleomycin-induced and TSK1 models.
Conclusion: We characterize the homeodomain transcription factor EN1 as a molecular amplifier of TGFβ signaling in myofibroblast differentiation that coordinates cytoskeletal organization in a SP-dependent manner. EN1 might thus be a novel candidate for molecular targeted therapies to interfere with myofibroblast differentiation in fibrotic diseases.

GASTROINTESTINAL INVOLVEMENT IN SYSTEMIC SCLEROSIS: PATHOGENETIC ROLE OF GUT MICROBIOME, CYTOKINES AND ADIPOKINES

E. Pigatto[1], M. Schiesaro2, M. Caputo[3], M. Beggio[3], P. Galozzi[4], F. Cozzi2, P. Sfriso[4]. [1]*Fondazione Villa Salus, Medicine Unit, Venice, Italy*; [1]*Fondazione Villa Salus, Medicine Unit, Venice, Italy*; [3]*Fondazione Villa Salus, Laboratory Unit of clinical chemistry and microbiology, Venice, Italy*; [4]*Azienda Ospedaliera di Padova, Rheumatology Unit, Padua, Italy*

Background: Gastrointestinal (GI) involvement is very common in patients with Systemic Sclerosis (SSc). The pathophysiology of GI manifestations has not yet been defined. Cell-mediated immunological reactions appear to lead to endothelial damage resulting in fibrosis. The risk of developing malnutrition reinforces the need to better understand GI pathophysiology in these patients.
Objectives: The study aimed to evaluate GI symptoms (GIT 2.0) and malnutrition status (MUST) and to determine specific bacterial changes in gut microbiome by investigating the possible presence of positive hot spots in bacterial species in SSc patients and their potential role in the disease progression. We also evaluated serum levels of adipokines and cytokines involved in the pathogenesis of SSc and their role, in addition to gut microbiome, in predicting the onset of GI involvement and malnutrition in SSc patients.
Methods: We enrolled 25 scleroderma patients (EULAR/ACR 2013 criteria). UCLA-SCTC GIT 2.0 questionnaire to evaluate GI symptoms and MUST to investigate the risk of malnutrition were used. Gut microbiome was analyzed and the samples were subjected to extraction for the 16S rRNA gene (Earth Microbiome Project and the NIH-Human Microbiome Project). The microbiome was investigated at phenotypic and genotypic level. Serum levels of cytokines and adipokines (adiponectin and leptin) were evaluated by ELISA.
Results: 79.9% of patients had GERD and 63.5% abdominal distension at GIT 2.0 questionnaires. 48% of patients had moderate risk of malnutrition (MUST=2) and 12% had high risk (MUST=3). Gut microbioma: 19 patients (76%) had low similarity and 11 (44%) low diversity compared to the healthy population. The prevailing enterotypes of gut microbiome was Bacteroides (80%) and Prevotella (20%). The genotypic evaluation showed a reduced concentration of: gluten-digesting (Lactobacillus); lactose-digesting (Faecalibacterium); vitamin K-producing (Enterococcus, Desulfovibrio and Veillonella); acetaldehyde-degrading bacteria. 24 patients (96%) showed a reduction in bacteria devoted to maintaining weight control (Bifidobacterium and Ruminococcus). The patients had an altered intestinal permeability with less mucolytic bacteria (Bacteroides) and reduced production of LPS (Enterobacter and Escherichia). Low levels of butyrate (Eubacterium and Clostridium), acetate and propionate were found for SCFA-producing bacteria. Potentially pathogenic bacteria were also investigated: Salmonella was found in 14 (56%), Klebsiella in 9 (36%) and Enterococcus Faecalis in 3 (12%) patients. 11 (44%) patients had elevated serum levels of IL10 and IL12; 4 (16%) had high value of leptin. Correlation was found in patients who had a reduced concentration of gluten-digesting bacteria and MUST. Elevated MUST was correlated with serological increase in IL17A and IFN-α. Serum levels of IL12 and IL10 were found to correlate with specific bacteria alterations: high concentration of acetaldehyde-producing bacteria and low levels of acetaldehyde-degrade bacteria (also correlated with high serum levels of IL6), mucolytic bacteria and producers of hydrogen sulphide, acetate and propionate. Finally, reduced levels of mucolytic bacteria and acetate producing bacteria correlated with high serum leptin levels.
Conclusion: The relationship between the gut microbiome and SSc seems to be multifactorial. In our study genotypic changes of gut microbioma might play a role in damaging the permeability of the mucosa and increasing risk of malnutrition. The evaluation of gut microbiome and cytokine profile is probably going to be of value in the follow-up of SSc. However, further studies are needed to clarify the impact of GI dysbiosis on the immune system in SSc.

NINTEDANIB (TYROSINE KINASE INHIBITOR) DOWNREGULATES THE TRANSITION OF CULTURED SYSTEMIC SCLEROSIS FIBROCYTES INTO MYOFIBROBLASTS AND THEIR PRO-FIBROTIC ACTIVITY

S. Soldano[1], P. Montagna[1], E. Gotelli[1], S. Tardito[1], S. Paolino[1], C. Corallo[2], C. Pizzorni[1], A. Sulli[1], C. Schenone[1], G. Pacini[1], V. Smith[3,4,5], M. Cutolo[1]. [1]*University of Genova, IRCCS San Martino Polyclinic Hospital, 1Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Dept. Internal Medicine, Genoa, Italy*; [2]*University of Siena, 2Scleroderma Unit, Department of Medicine, Surgery and Neurosciences, Siena, Italy*; [3]*Ghent University Hospital, Ghent, Department of Rheumatology, Ghent, Belgium*; [4]*Ghent University, Department of Internal Medicine, Ghent, Belgium*; [5]*VIB Inflammation Research Center (IRC), Unit for Molecular Immunology and Inflammation, Ghent, Belgium*

Background: Fibroblast-to-myofibroblast transition is one of the fundamental steps involved in the fibrotic process that characterise systemic sclerosis (SSc) [1]. Myofibroblasts are α-smooth muscle actin (αSMA) positive cells that contribute to fibrosis through the excessive synthesis and deposition of extracellular matrix (ECM) proteins, primarily fibronectin (FN) and type I collagen (COL1) [2]. Among the cells involved in the fibrotic process of SSc, circulating fibrocytes seem to have an emerging role as an important source of fibroblasts and myofibroblasts [3].
Nintedanib is a tyrosine kinase inhibitor approved for the treatment of idiopathic pulmonary fibrosis that interferes with the signalling pathways involved in the pathogenesis of fibrosis (4). Nintedanib was recently demonstrated to have a beneficial effect in patients with interstitial lung disease (ILD) associated with SSc (5).
Objectives: To investigate nintedanib effect in inhibiting the *in vitro* transition of circulating SSc fibrocytes into myofibroblasts and their pro-fibrotic activity.
Methods: Circulating fibrocytes were obtained from 14 SSc patients (mean age 64±14 years), who fulfilled the 2013 ACR/EULAR criteria for SSc and that underwent complete disease staging in a day-hospital setting at the Rheumatology Division of Genoa University. Five age-matched healthy subjects (HSs) were also analysed. All SSc patients and HSs signed the informed consent and the local EC approved the study. Peripheral blood mononuclear cells were isolated by density gradient centrifugation and plated on FN-coated dishes. After overnight culture, non-adherent cells were removed, and adherent cells were maintained in growth medium for 8 days (T8) to obtain fibrocytes [6]. T8-cultured SSc fibrocytes were maintained in growth medium (untreated cells) or treated with nintedanib 0.1μM and 1μM for 3 and 24 hours. Fibroblast specific protein-1 (S100A4) and αSMA, as markers of fibroblast/myofibroblast phenotype, together with COL1 and FN, were investigated by qRT-PCR and Western blotting. Non-parametric Mann-Whitney and Wilcoxon tests were used for the statistical analysis.
Results: Significantly elevated gene and protein expressions of αSMA, S100A4, COL1 and FN were observed in SSc fibrocytes compared to HS fibrocytes (gene: αSMA $p<0.001$; others $p<0.0001$; protein: all $p<0.05$). In accordance with the antibody positivity for Scl70 and the presence or absence of ILD at CT scan, SSc patients were grouped as either Scl70 positive patients with ILD ($Scl70^+ILD^+$) or Scl70 negative patients without ILD ($Scl70^-ILD^-$). Significant αSMA, S100A4, COL1 and FN gene expressions were found in fibrocytes from $Scl70^+ILD^+$ compared to HS fibrocytes (αSMA $p<0.001$; others $p<0.0001$). Moreover, fibrocytes from $Scl70^+ILD^+$patients showed a more significant gene expression of fibroblasts/myofibroblasts markers compared to $Scl70^-ILD^-$patients ($p<0.01$ for S100A4), whereas no differences were observed for ECM gene expression.
Nintedanib reduced the gene and protein expression of αSMA, COL1 and FN in SSc fibrocytes compared to untreated ones with different statistical significance. Noteworthy, nintedanib significantly downregulated αSMA, S100A4, COL1 and FN gene expression (all $p<0.05$) in $Scl70^+ILD^+$fibrocytes, whereas only that of S100A4 and FN was significantly downregulated ($p<0.05$) in $Scl70^-ILD^-$ fibrocytes compared to untreated cells.
Conclusion: Nintedanib seems to downregulate *in vitro* the transition of fibrocytes into myofibroblasts and their pro-fibrotic activity, particularly in cells isolated from $Scl70^+ILD^+$SSc patients.

Background: Interstitial lung disease (ILD), the main cause of mortality in scleroderma (SSc) patients (1), has no treatment (2). P-selectin glycoprotein ligand 1 (PSGL-1), the main ligand for P-Selectin, is expressed on leukocytes and responsible for the initial steps of extravasation (3). The absence of PSGL-1 in mice spontaneously develops an autoimmune syndrome similar to human SSc with fibrosis, vascular damage, autoantibodies and pulmonary arterial hypertension in females, and almost 60% of animals older than 12 months develop ILD with aging (4). In this work, the therapeutic action of everolimus-loaded nanomedicine given by local administration as a treatment for ILD was evaluated. The intratracheal administration of everolimus loaded into in liposomes decorated with hyaluronic acid (HA) is studied as an administration strategy to reach the inflammatory and fibrotic cells, targeting these cells and avoiding systemic effects and possible toxicity on epithelial cells

Objectives: 1) To study the effect of everolimus on bronchoalveolar lavage (BAL) cell populations and in lung pathology in SSc-ILD PSGL-1 KO mice

2) To analyze the intratracheal application of everolimus included in empty liposomes (Lip+Ev) *vs*. liposomes decorated with hyaluronic acid (Lip-HA+Ev) as an administration strategy to decrease drug toxicity and increase drug effectivity

Methods: In an observational study, *PSGL-1*$^{-/-}$ C57BL/6 males older than 12 months (n=4) were treated intratracheally with 4 doses of Lip or Lip-HA (with or without everolimus included), once a week (Lip+Ev 295.67µg/mL; Lip+Ev 82.73µg/mL; Lip-HA+Ev 82.73µg/mL). Then, animals were euthanatized and BAL and lungs were obtained. BAL cells were stained for flow cytometry analysis. Lungs were embedded in paraffin blocks for blind histological analysis by a pathologist and evaluated for interstitial inflammation and fibrosis degree. Lip-HA was selected as the treatment of choice for a second experiment (n=8) following the same experimental design (86.22µg/mL)

Results: The observational study showed an increase in CD45$^+$, alveolar macrophages (AM), eosinophils (Eos), granulocytes (Gr1$^+$) and T cells in the BAL of untreated *PSGL-1*$^{-/-}$ mice compared with WT mice. Everolimus reduced these populations to WT levels in all cases

Lip-HA+Ev administration was chosen for further experiments because a lower dose of the drug gave a better result than the high dose in undecorated liposomes. Reduction of CD45$^+$, AM, eosinophils, and CD45$^-$ cells populations by Lip-HA+Ev was confirmed. Lip-HA treatment increased the number of neutrophils and T cells, but this effect is controlled by the everolimus administration

Histological lung analysis showed an increase in interstitial inflammation and fibrosis in untreated PSGL-1$^{-/-}$ and empty Lip-HA experimental groups. Treatment with everolimus included in Lip-HA reduced the fibrotic and inflammatory interstitial lung lesions, reaching values similar to those observed in WT mice

Conclusion: PSGL-1 KO mice present ILD associated with scleroderma (SSc-ILD) with an increase of CD45$^+$, Gr1$^+$, Eos, T cells and AM populations in the BAL. Intratracheal treatment with everolimus included in liposomes decorated with hyaluronic acid reduces immune cell infiltration and fibrosis once SSc-ILD is established

POS0332

ENDOTHELIAL ACTIVATION IN SYSTEMIC SCLEROSIS VASCULOPATHY: ROLE OF LONG NON-CODING RNA H19X

F. Tirelli[1,2], E. Pachera[1], R. Lafyatis[3], M. Huang[2], F. Zulian[2], G. Kania[1], O. Distler[1]. [1]*Department of Rheumatology, Center of Experimental Rheumatology, University Hospital Zurich, University of Zurich, Zurich, Switzerland*; [2]*Rheumatology Unit, Department of Woman's and Child's Health, University of Padova, Padova, Italy*; [3]*Division of Rheumatology and Clinical Immunology, Department of Medicine, University of Pittsburgh, Pittsburgh, Pennsylvania, United States of America*

Background: Long non-coding RNAs (lncRNA) are a class of non-coding transcripts which modulate many biological processes. Our previous studies showed that lncRNA H19X is pivotal in the regulation of TGFβ driven fibrosis in systemic sclerosis (SSc)[1].

Objectives: We aimed to investigate whether H19X plays a functional role in the regulation of endothelial cell (EC) activation, which is crucial in SSc vasculopathy[2].

Methods: Single-cell RNA sequencing (scRNA-seq) data from 27 dcSSc and 10 healthy control (HC) skin biopsies, following 10X Genomics partitioning and cDNA preparation, were analyzed for H19X expression in skin ECs, using Seurat package in R. A total of 4,981 ECs, of which 1,583 cells originated from HC and 3,398 cells originated from SSc patients, ranging from 59 to 342 ECs per subject, characterized by enrichment of EC markers of *CLDN5*, *VWF* and *PECAM1*.

Expression of H19X in Human Dermal Microvascular ECs (HDMEC) was analyzed by qPCR. HDMEC were stimulated with different proinflammatory cytokines including IFNα, IFNβ, IFNγ, TGFβ, TNFα, IL-6, IL-1β and IL-4 at biologically relevant concentrations. In order to ascertain its effect in ECs, H19X was silenced in HDMECs using locked nucleic acid antisense oligonucleotides (LNA GapmeRs). qPCR and Western Blot (WB) were used to analyze the effects of H19X down-regulation on EC activation biomarkers.

Results: scRNA-seq data showed that H19X was significantly upregulated in SSc compared to healthy ECs (p=0.0095). Based on the differentially expressed gene profiles among subclusters, EC were further annotated as arterial (*SEMA3G, HEY1*), capillary (*CA4, RGCC*), venous (*ACKR1, VCAM1*), lymphatic (*PROX1, LYVE1*) ECs, as well as two aberrant clusters, proliferating (*TOP2A*, *MKI67)* and injured (*HSGP2,APLNR)* ECs, which were dominated by the SSc ECs. Specifically, the highest expression of H19X was found in injured SSc ECs and capillary SSc ECs. Overall, 1.5% SSc EC, about 51 cells, expressed detectable levels of H19X.

In HDMEC (n=3), H19X was consistently induced by IFNα, IFNβ and IFNγ. Time curve analysis demonstrated that the strongest induction was observed at 48H (1.5±0.2, 1.6±0.4 and 2.1±0.3 – fold increase respectively). The combination of different IFNs determined stronger H19X induction after 48H stimulation, with a 2.4±0.1 increase with the combination of all IFNs and a 2.4±0.1 increase after the combination of IFNα+γ.

Importantly, H19X knockdown lead to consistent and significant decrease of mRNAs of several adhesion molecules, including VCAM1, E- Selectin and P-Selectin, both in untreated HDMEC and after IFN stimulation. A decrease of VCAM and P-Selectin could be also demonstrated with WB analysis. No change was seen in other EC activation markers, including endothelin-1 and angiogenesis markers including VEGF, VEGFRA, Tie2 and thrombospondin.

Conclusion: This is the first report analyzing a potential role of lncRNA H19X in SSc vasculopathy. Our results suggest that lncRNA H19X could act as a regulator of adhesion molecules expression in EC, possibly mediated by IFNs, and be therefore involved in EC activation.

POS0333 ALTERED MACROPHAGE POLARIZATION PHENOTYPES IN SYSTEMIC SCLEROSIS

A. Hukara[1], M. Rudnik[1], C. B. Rufer[1], O. Distler[1], P. Blyszczuk[1], G. Kania[1].
[1]*University Hospital Zurich, University of Zurich, Department of Rheumatology, Center of Experimental Rheumatology, Zurich, Switzerland*

Background: Fos-like 2 (Fosl-2) is a transcription factor of the AP-1 family and has a broad range in inducing cellular changes affecting fibrosis and inflammatory responses. Pathological effects of Fosl-2 have been associated with systemic sclerosis (SSc). In addition, increased expression of Fosl-2 has been detected in human SSc monocyte-derived macrophages [1]. Monocytes and macrophages play a central role in activating and propagating acute inflammation followed by pathological fibrosis and organ dysfunction. The classification of the macrophage polarization phenotype can be assigned based on the stimulus, for example into classically-activated M(LPS), and alternatively-activated M(IL-4) macrophages [2]. However, the role of the Fosl-2 transcription factor in macrophage polarization remains elusive.
Objectives: To investigate the role of Fosl-2 in macrophage polarization in SSc using Fosl-2 overexpressing transgenic (Fosl-2 tg) mice and human blood-derived macrophages from SSc patients.
Methods: Thiogylcolate-elicited peritoneal macrophages were isolated from wild-type (wt) and Fosl-2 tg mice. Human peripheral $CD14^+$ blood-derived monocytes were isolated and differentiated to macrophages (hMDM) from healthy controls and SSc patients. Murine and human macrophages were polarized with LPS (10ng/ml), LPS + recombinant mouse IFN-γ (10ng/ml), recombinant mouse, resp. human IL-4 (10ng/ml) or remained untreated. Macrophage surface marker expression was assessed by flow cytometry using a mouse (F4/80, CD11b, CD86, CD80, CD38, MHCII, CD206, PD-L1, PD-L2, CD36) or human (CD38, CD40, CD86, PD-L2, PD-L1, CD163, CD206) designed polarization panel. Phagocytic activity was detected with pHrodo Red *E.coli* particles by flow cytometry. Gene expression and secretion of pro- and anti-inflammatory markers were measured by RT-qPCR, standard ELISAs and Griess Assay for nitric oxide production.
Results: After LPS stimulation, mRNA levels of IL-1β ($p<0.01$, n=11-12), TNF-α ($p=0.05$, n=11-12) and IFN-γ ($p<0.05$, n=7) were reduced, whereas expression of IL-10 ($p<0.05$, n=11-12) was enhanced in Fosl-2 tg peritoneal macrophages in comparison to wt cells. Secretion of TNF-α ($p<0.01$, n=9-11) and nitric oxide ($p<0.01$, n=9) was impaired in Fosl-2 tg peritoneal macrophages compared to wt cells after LPS stimulation. Peritoneal macrophages were analyzed directly after isolation for macrophage polarization cell surface marker expression. Fosl-2 tg peritoneal macrophages showed an increase in the $F4/80^+CD11b^+PD\text{-}L2^+CD36^+$ cell population ($p<0.01$, n=3-6) compared to peritoneal macrophages from wt mice. The expression of cell surface markers of non-polarized and IL-4 stimulated SSc hMDM (n=17) showed an increased percentage of $CD40^+CD86^+CD206^+PD\text{-}L2^+CD163^+$ cells ($p<0.05$) compared to healthy control hMDM (n=7). Phagocytic activity was enhanced in SSc hMDM (n=7) compared to healthy untreated ($p<0.05$), LPS ($p=0.05$) and IL-4 ($p<0.05$) hMDM (n=5).
Conclusion: Our animal data indicates a role of Fosl-2 in regulating macrophage polarization with a shift from a classically-activated to an alternatively-activated phenotype. Similarly, SSc hMDM resemble a functional M(IL-4) alternative macrophage phenotype. Thus, maintaining a balanced proportion of classically- and alternatively-activated macrophage phenotypes may be an effective tool to control macrophage function in SSc.

POS0334 INTERSTITIAL LUNG INFLAMMATION WITH ALVEOLAR HEMORRHAGE IN AUTOIMMUNE MRL/MP-LPR/LPR MICE

S. Sato[1]. [1]*Saitama Children's Medical Center, Division of Infectious Diseases and Immunology and Allergy, Saitama, Japan*

Background: Anti-melanoma differentiation-associated gene 5 (MDA5) antibody is associated with interstitial lung disease (ILD) in patients with juvenile dermatomyositis (JDM). Although the mechanisms leading to pulmonary involvements remain uncertain, both inflammatory cytokines and autoimmune response between MDA5 and anti-MDA5 antibody could been inferred. The present study examined the roles of MDA5 in an inducible form of lung involvement that develops in autoimmune mice treated with the pristane.
Objectives: MRL/Mp-lpr/lpr mice and wild type controls (+/+) at 5 weeks of age. They received 0.5ml of pristane or an equal volume of PBS IP at the age 7 week (day 1). And 1.2μg of recombinant human MDA5 protein (rMDA5) was instilled IP or PBS at day2 and Day9. The mice were sacrificed on 8 weeks after the intraperitoneal injection. Lung tissue was harvested for histological assessment.
Methods: MRL/Mp-lpr/lpr mice and wild type controls (+/+) at 5 weeks of age. They received 0.5ml of pristane or an equal volume of PBS IP at the age 7 week (day 1). And 1.2μg of recombinant human MDA5 protein (rMDA5) was instilled IP or PBS at day2 and Day9. The mice were sacrificed on 8 weeks after the intraperitoneal injection. Lung tissue was harvested for histological assessment.
Results: Lung involvements did not develop in PBS-treated MRL/*lpr* mice and WT mice. And Lung involvements did not develop in rMDA5 protein-treated WT mice. H&E staining of lung tissue from MRL/*lpr* mice and WT mouse with pristane that showed induced bland alveolar hemorrhage. H&E staining of lung from WT mouse compared with lung from a MRL/*lpr* mouse treated with pristane + rMDA5 protein showing mild thickening of the alveolar septa despite the alveolar hemorrhage. And perivascular lymphocytes infiltrate in a MRL/*lpr* mouse rather than a WT mouse treated with pristane + rMDA5 protein. CD163 staining of alveolar macrophages were present in the alveolar spaces was more intense in mouse treated with pristane + rMDA5 protein than in mouuse treated with only pristane. The Lymphocyte infiltrations around alveolar macrophages was more prominent in MRL/*lpr* mouse treated with pristane + rMDA5 protein than other mouse.
Conclusion: These results suggest that lung involvements such as the alveolar hemorrhage, are caused by pristeine and rMDA5 prtotein in the pathogenesis of interstitial pneumonia. MRL/*lpr* mouse treated with pristane + rMDA5 protein showed more alveolar macrophages that had lymphocyte infiltrations. After the alveolar hemorrhage by pritane, the antigen exposure of MDA5 might induce continuously inflammatory response to lymphocytes and macrophages in the alveolar lesions.

POS0335 **THE POTENTIAL ROLE OF IL13 IN VASCULOPATHY IN SYSTEMIC SCLEROSIS PATIENTS**

A. Schumann[1], H. Grasshoff[1], S. Comduehr[1], G. Riemekasten[1]. *[1]University Hospital Schleswig-Holstein, Rheumatology and Clinical Immunology, Lübeck, Germany*

Background: Systemic sclerosis (SSc) is a heterogeneous disease characterized by fibrosis, vasculopathy and autoimmunity. Dysfunctions causing disease pathology are characterized by the activation and recruitment of immune cells, as well as the formation of autoantibodies and cytokines. Profibrotic cytokines, such as interleukin-(IL)13, IL4 or IL6 play a crucial role in collagen production and fibrosis development [1]. Preliminary data reveal IL13 as a main driver for obliterative vasculopathy characterized by severe Raynaud phenomenon, acral ulcers and pulmonary arterial hypertension (PAH). Particularly acral ulcerations lead to a severe impairment in functional capacity in everyday life. In addition, pulmonary arterial hypertension is one of the main causes of the high mortality rate in SSc [2].
Objectives: To prove the impact of IL13 in the pathogenesis of systemic sclerosis and thus provide the rationale for the identification of a potential new therapeutic target, we investigated IL13 expression in CD4 and CD8 T cells in patients suffering from systemic sclerosis compared to healthy controls.
Methods: Peripheral blood mononuclear cells (PBMC) obtained from systemic sclerosis (SSc, n=31) patients and healthy controls (HC, n=13) were cultured without or in the presence of phorbol myristate acetate and ionomycin to activate T cells for cytokine production. Brefeldin A was used as an inhibitor of cytokine secretion. The intracellular IL13 and IL4 expression of CD4 and CD8 positive T cells were measured by flow cytometry and were compared between the investigated subgroups.
To identify a disease phenotype mediated by IL13, the expression levels in the SSc group were correlated to clinical, laboratory and apparative parameters assessing organ dysfunction.
Results: While there were no significant differences in IL4 expression between healthy and diseased individuals, analyses of IL13 positive CD4 and CD8 T cells showed significant differences compared to HC (CD8+IL13 p=0.048; CD4+IL13 p=0.0046) revealing the functional differences though high structural homology of the two interleukins. The increased expression of IL13 in T cells from patients with systemic sclerosis further supports the assumption of an interleukin mediated pathomechanism. Considering the IL13-mediated clinical phenotype, high levels were detected in patients showing signs for vasculopathy, correlation with sPAP (CD8+IL13 p=0.0392), NTproBNP (CD4+IL13 p=0.0461), creatinine (CD4+IL13 p=0.0227), angiotensin II receptor type I and endothelin receptor type A antibodies (CD4+IL13 p=0.0105, p=0.0042) was demonstrated. In addition, patients in the fourth quartile of CD4+IL13 expression showed a higher incidence of acral ulcers and pits than patients with low interleukin levels. Moreover, this group of patients had an increased cardiovascular comorbidity including atherosclerosis, coronary heart disease and arterial hypertension.
Conclusion: Increased IL13 levels could be detected in patients with SSc, especially in patients with the phenotype of an obliterative vasculopathy. This indicates preliminary evidence for the use of IL13 blockers as a new therapeutic approach in systemic sclerosis.

Background: Giant cell arteritis (GCA) is characterized by cranial symptoms and large-vessel lesions (LVL) in the aorta or its branches. We retrospectively analyzed the Japanese patients newly diagnosed as GCA between 2007 and 2014, and subsequently treated with glucocorticoid (GC). The imaging studies revealed that LVLs were observed in approximately half of the GCA patients, and the LVLs were significantly associated with the increased probability of poor treatment outcomes (1).
Objectives: The objective of this study is to evaluate whether the distribution of LVLs of GCA was associated with poor treatment response.
Methods: In a retrospective, multi-centric, nationwide registry of GCA patients treated with GCs between 2007 and 2014, 68 newly-diagnosed GCA with LVLs by imaging were detected. All investigators were members of Japan Research Committee of the Ministry of Health, Labour, and Welfare for Intractable Vasculitis (JPVAS). Poor treatment outcomes (non-achievement of clinical remission by week 24 or relapse during 104 weeks) were primarily evaluated. Cumulative rates and median time to the first event were analyzed by the Kaplan-Meier method and the log-rank test. Associated factors with the outcomes were analyzed by using the Cox proportional hazard model.
Results: The mean age was 70.5 years, and 70.6% were women. Twenty-seven (39.7%) of the 68 patients were diagnosed as having GCA by both positive temporal artery biopsy and positive imaging, and 41 (60.3%) by positive imaging. Aortic lesions were detected in 72.1% (group 2, n=49) of the 68 GCA patients with LVLs. Patients without aortic lesions were categorized into two phenotypes: large-vessel GCA with subclavian lesions (group 1, n=9) and atypical large-vessel GCA without subclavian lesions (group 3, n=10). Cranial lesions were observed in 66.7%, 55.1%, and 80.0% in the group 1, 2, and 3, respectively. The initial mean dose (SD) of prednisolone was 0.74 (0.26) mg/kg/day, and 20.6 % received methotrexate for remission induction therapy. Baseline dose of GCs and mean time to achievement of low-dose GCs (prednisolone ≤ 5 mg/day) was not significantly different among the three groups.
Overall, 35 (51.5%) of the 68 patients had the event of poor treatment outcomes. Eleven patients were not able to achieve clinical remission by week 24. Relapse after achievement of clinical remission was reported in total of 24 patients; 9 between week 0 and 24, 12 between week 24 and 52, 3 between week 52 and 104. The cumulative rate of events of poor treatment outcomes over the two years was 11.1% in patients with group 1, 55.3% in those with group 2, and 88.0% in those with group 3. Mean time to events was significantly different among the three groups. Multivariable analysis showed the risk of poor treatment outcomes was likely to decrease in the group 1 (hazard ratio 0.14 [95% CI 0.02-1.03], p=0.054), while it increased in the group 3 (hazard ratio 2.22 [95% CI 1.06-4.68], p=0.035).
Conclusion: The distribution of LVLs were associated with poorer treatment outcomes. A half of the patients with aortic lesions had poor treatment outcomes while subclavian arteritis without aortic lesions had better clinical outcomes. Atypical large vessel-GCA without the aortic and subclavian artery involvement

was the worst prognostic phenotype of LV-GCA. Extent of LVLs by imaging should be considered when determining the treatment strategy for GCA.

POS0337

SOUTHEND PRE-TEST PROBABILITY SCORE AND HALO SCORE AS MARKERS FOR DIAGNOSIS AND MONITORING OF GCA: EARLY RESULTS FROM THE PROSPECTIVE HAS-GCA STUDY

A. Sebastian[1,2], A. Tomelleri[3], A. Kayani[1], M. Tariq[1], D. Prieto-Peña[4], S. Inness[2], J. Jackson[2], K. Van der Geest[5], B. Dasgupta[1,2]. *[1]Mid and South Essex University Hospital Groups, Southend University Hospital, Rheumatology, Westcliff-on-sea, United Kingdom*; *[2]University of Essex, School of Sport, Rehabilitation and Exercise science, Colchester, United Kingdom*; *[3]IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*; *[4]Marques de Valdecilla University Hospital, Rheumatology, Santander, Spain*; *[5]University of Groningen, University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: EULAR recommends doppler ultrasound (US) as the first line imaging in patients with Giant Cell Arteritis (GCA) suspect. Traditionally, US non-compressive halo sign has been used for diagnosis but prospective studies on response and disease monitoring are lacking

Objectives: The HAS GCA study has the objective of prospectively assessing role of US in diagnosis, prognosis and monitoring in newly diagnosed GCA. We report early baseline and up to month 3 data on our current recruitment in a study that has suffered disruption from the pandemic

Methods: HAS GCA (IRAS#264294) is an ongoing, prospective, multicentre study recruiting from referrals of suspected GCA to fast track clinics. The objective is to recruit 270 patients, including 68 GCA patients. Based on the Southend GCA clinical pre-test probability score (SPTPS)[1], patients were stratified in to low, intermediate and high risk categories[2]. Temporal and axillary US Halo Scores were calculated from the halo thickness and extent in bilateral temporal arteries, parietal and frontal branches and axillary arteries. These individual scores were summed (TA Halo Score x1 plus; AA Halo Score x3) to generate a Total Halo Score (THS)[3].

Mann Whitney U test and Fisher's exact test were used to compare baseline features between GCA and controls. Wilcoxon signed rank test was used to evaluate disease features at baseline and at 3 months in GCA patients. Sensitivity (Sn) and Specificity (Sp) were calculated, where applicable. P value <0.05 is statistically significant

Results: Ninety-three patients (29 GCA, 64 controls) have been recruited thus far: 18 completed 3-month follow up assessment; 4 were lost to follow up (2 died, 2 withdrew consent due to pandemic). Demographics, clinical features, and US results are shown (Table 1).

Table 1. Baseline features of GCA patients and controls.

	GCA (n=29)	Controls (n=64)	P-value
Age, median (IQR)	75 (71-80)	67 (61.25 – 75.0)	0.001
Female, n (%)	15 (42)	50 (78)	0.01
SPTPS category, n (%)			
Low risk	0 (0)	31 (48)	<0.001
Intermediate risk	7 (24)	25 (39)	0.24
High risk	22 (76)	8 (13)	<0.001
Halo score (HS), median (range)			
Temporal artery HS	10 (1-21)	1 (0-9)	<0.001
Axillary artery HS	12 (0-18)	6 (0-18)	<0.001
Total HS	21 (2-38)	6 (0-19)	<0.001
Clinical features, n (%)			
Temporal headache	21 (72)	40 (63)	0.48
Scalp tenderness	17 (59)	31 (48)	0.38
Jaw claudication	19 (66)	4 (6)	<0.001
PMR symptoms	16 (55)	6 (9)	<0.001
Constitutional symptoms	17 (59)	18 (28)	0.006
Visual disturbance	18 (62)	38 (59)	1
Vision loss	7 (24)	4 (6)	0.03

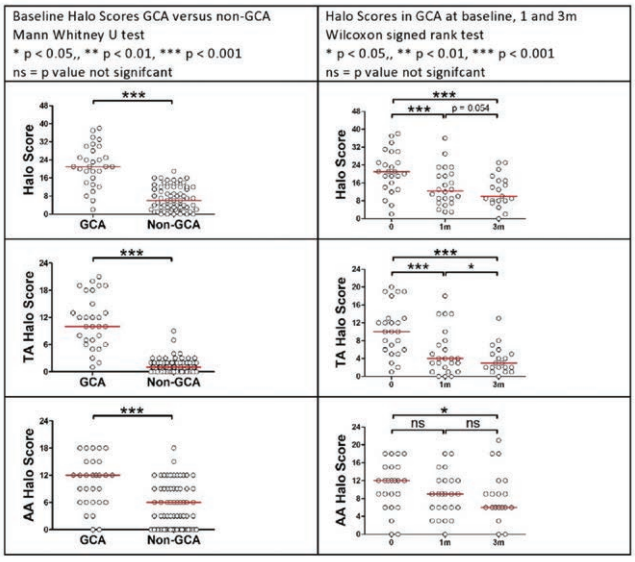
Among GCA patients, 23 had cranial, 2 large-vessel and 4 mixed phenotypes (cranial plus large vessel) disease.

Jaw claudication (66%) and polymyalgic symptoms (55%) were the dominant features in GCA patients. Median age 75 years in GCA (42% females) and 67 years in controls (78% females). GCA and controls were stratified by SPTPS to Low risk (0% vs 48%; Sn-undefined, Sp-97), Intermediate risk (24% vs 39%; Sn-100, Sp-100) and High risk (76% vs 13%; Sn-95, Sp-88). Optimal SPTPS cut-off point was ≥12 (Sn-93, Sp-86); ≥10 (Sn-100 & Sp-69).

Median THS was 21 in GCA and 6 in controls. Optimal cut-off Halo Score in diagnosis was TAHS ≥5 (Sn-90, Sp-98), AAHS ≥11 (Sn-55, Sp-80), THS ≥18 (Sn-72%, Sp-98%). Among the 18 patients who completed 3-months follow up,

median TAHS, AAHS and THS reduced from 10 to 2.5, 12 to 6 and 21 to 10, respectively (Figure 1).

Figure: HS comparing GCA vs non GCA and baseline Halo Score vs 1 and 3 months follow up



AA, Axillary artery; GCA, Giant cell arteritis; TA, Temporal artery

Conclusion: Along with SPTPS, Halo Score successfully discriminates GCA from non GCA mimics. HS is effective in showing 3-month response and may be a useful marker to monitor GCA disease activity.

POS0338 STEROID-SPARING EFFECT OF ANAKINRA IN GIANT-CELL ARTERITIS: A CASE SERIES WITH CLINICAL, BIOLOGICAL AND ICONOGRAPHIC LONG-TERM ASSESSMENTS

S. Deshayes[1], K. Ly[2], V. Rieu[3], G. Maigné[1], N. M. Silva[1], A. Manrique[4], J. Monteil[5], H. De Boysson[1], A. Aouba[4]on behalf of the French Study Group for Large Vessel Vasculitis (GEFA). [1]*CHU de Caen Normandie, Internal Medicine, Caen, France*; [2]*CHU Dupuytren, Internal Medicine, Limoges, France*; [3]*CHU Estaing, Internal Medicine, Clermont-Ferrand, France*; [4]*CHU de Caen Normandie, Nuclear Medicine, Caen, France*; [5]*CHU Dupuytren, Nuclear Medicine, Limoges, France*

Background: The treatment of giant cell arteritis (GCA) relies on corticosteroids but is burdened by a high rate of relapses and adverse effects. Anti-interleukin-6 treatments show a clear benefit with a significant steroid-sparing effect, but late relapses occur after treatment discontinuation. In addition to interleukin-6, interleukin-1 also appears to play a significant role in GCA pathophysiology.

Objectives: We report herein the efficacy of anakinra, an interleukin-1 receptor antagonist, in 6 GCA patients exhibiting corticosteroid dependence or resistance, specifically analyzing the outcome of aortitis in 4 of them, and including the long-term follow-up of 2 previously described patients (1).

Methods: This retrospective study analyzed the cases of all GCA patients treated with anakinra from the French Study Group for Large Vessel Vasculitis. Patients had to satisfy the following two criteria to be enrolled in this retrospective study. First, their diagnosis of GCA should be based on the fulfillment of at least 3 criteria of the American College of Rheumatology (ACR) for GCA or on the satisfaction of 2 of these criteria along with the demonstration of LVI on imaging. Second, patients should have received anakinra because of corticosteroid dependence or resistance. Corticosteroid dependence was defined as ≥2 relapses or the combination of 2 of the following criteria: a daily dose of oral prednisone >20 mg/day (or 0.3 mg/kg) at 6 months; a daily dose of oral prednisone >10 mg/day (or 0.2 mg/kg) at 12 months; and/or a treatment maintained >24 months because of a relapsing disease course. Corticosteroid resistance was defined as persistent increased inflammatory parameters at month 3 despite a steroid dosage over 0.5 mg/kg.

Results: After a median duration of anakinra therapy of 19 [18–32] months, all 6 patients exhibited complete clinical and biological remission. Among the 4 patients with large-vessel involvement, 2 had a disappearance of aortitis under anakinra, and 2 showed a decrease in vascular uptake. After a median follow-up of 56 [48–63] months, corticosteroids were discontinued in 4 patients, and corticosteroid dosage could be decreased to 5 mg/day in 2 patients. One patient relapsed 13 months after anakinra introduction in the context of increasing the daily anakinra injection interval to every 48 hours. Three patients experienced transient injection-site reactions, and 1 patient had pneumonia.

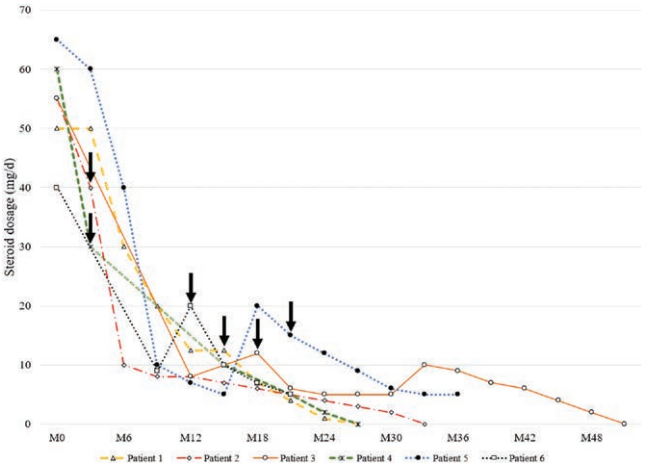

Figure 1. Steroid dosages before and after the introduction of anakinra in 6 patients with giant-cell arteritis and corticosteroid dependence or resistance. The black arrow indicates the time of anakinra introduction.

Conclusion: In this short series, anakinra appears to be an efficient and safe steroid-sparing agent in refractory GCA, with a possible beneficial effect on large-vessel involvement.

POS0339 PREDICTORS OF DEATH IN PATIENTS DIAGNOSED WITH GIANT CELL ARTERITIS IN WESTERN NORWAY 1972-2012

L. K. Brekke[1], B. T. Svanes Fevang[2], J. Assmus[3]. [1]*Hospital for Rheumatic Diseases, Rheumatology, Haugesund, Norway*; [2]*Haukeland University Hospital, Rheumatology, Bergen, Norway*; [3]*Haukeland University Hospital, Centre for Clinical Research, Bergen, Norway*

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis in adults, and the number of incident cases worldwide is projected to increase [1]. Evidence as to whether or not GCA confers a mortality risk is conflicting, and many studies have been limited by inadequate or lacking adjustment for confounders.

Objectives: To investigate possible predictors of death in a large and well characterized Norwegian cohort of GCA-patients.

Methods: This is a hospital-based retrospective cohort study including patients diagnosed with GCA during 1972-2012. Patients were identified through computerized hospital records using the International Classification of Diseases coding system. Clinical information was extracted from patients' medical journals. Further details about the inclusion process have been published previously [2]. Information on time of death was obtained from the Norwegian Cause of Death Registry. We investigated predicting factors using Cox regression. Selected variables were first analyzed in univariate and block regression models (block 1:

clinical features including histology, block 2: laboratory and treatment factors, block 3: demographic and traditional risk factors). Variables included in the final multivariate model were selected on the following basis: P-value <0.1 in univariate or block regression or otherwise deemed clinically significant.

Results: 881 patients were included of which 626 (71.1%) were females. Mean age was 73 years (SD 9). 490 patients (55.6%) died during the study period (1 January 1972 – 31 December 2012). Characteristics and mortality for the GCA-cohort compared to matched controls have been published previously [3]. Within the GCA-cohort we found that presenting with visual disturbance (any) or scalp necrosis was associated with increased risk of death in univariate analysis (Figure 1). However, in multivariate analysis the traditional risk factors (age, smoking, hypertension and previous cardiovascular disease) were more strongly associated with risk of death. Among laboratory parameters only Hemoglobin (Hb) levels were significantly associated with risk of death with increasing Hb-levels indicating decreased risk. Neither temporal artery biopsy result nor initial or maximal (before first tapering) Prednisolone dose were found to be associated with risk of death. Results from univariate and the final multivariate models are presented in Figure 1.

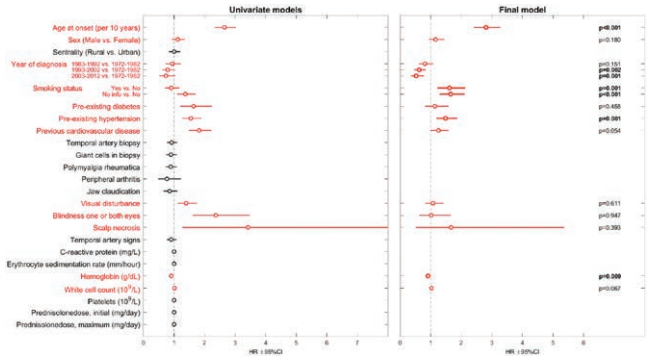

Figure 1.

Conclusion: In our large cohort of GCA-patients the risk of death was found to be predominantly predicted by age (HR 2.81) and traditional risk factors (smoking (HR 1.61), hypertension (HR 1.48) and previous cardiovascular disease (HR 1.26)). Visual disturbance (HR 1.40), visual loss in particular (HR 2.37), and scalp necrosis (HR 3.42) were found to be the clinical features most associated with risk of death. However, we note that our material lacked information about extra-cranial (large vessel) vasculitis, which may also carry increased risk of death.

POS0340 VASCULAR IMAGING IN PATIENTS WITH REFRACTORY TAKAYASU ARTERITIS TREATED WITH TOCILIZUMAB: ANALYSIS FROM A RANDOMIZED CONTROLLED TRIAL

Y. Nakaoka[1,2], M. Yanagawa[3], A. Hata[4], K. Yamashita[5], N. Okada[6], S. Yamakido[7], H. Hayashi[8], D. Jayne[9]. *[1]National Cerebral and Cardiovascular Center Research Institute, Department of Vascular Physiology, Suita, Japan*; *[2]Osaka University Graduate School of Medicine, Department of Cardiovascular Medicine, Osaka, Japan*; *[3]Osaka University Graduate School of Medicine, Department of Diagnostic and Interventional Radiology, Osaka, Japan*; *[4]Osaka University Graduate School of Medicine, Department of Future Diagnostic Radiology, Osaka, Japan*; *[5]Chugai Pharmaceutical Co., Ltd., Medical Science Department, Medical Affairs Division, Tokyo, Japan*; *[6]Chugai Pharmaceutical Co., Ltd., Biometrics Department, Clinical Development Division, Tokyo, Japan*; *[7]Chugai Pharmaceutical Co., Ltd., Primary Clinical Development, Clinical Development Division, Tokyo, Japan*; *[8]Nippon Medical School, Department of Radiology, Tokyo, Japan*; *[9]University of Cambridge, Department of Medicine, Cambridge, United Kingdom*

Background: In the TAKT study, a randomized controlled trial of tocilizumab (TCZ) in patients with refractory Takayasu arteritis (TAK) in Japan, the primary end point of time to relapse after induction of remission with glucocorticoid (GC) treatment showed a trend favoring TCZ over placebo (hazard ratio 0.41 [95.41% confidence interval, 0.15-1.10; p=0.0596]),[1] but the double-blind period was too short for imaging evaluation.

Objectives: To independently evaluate vascular imaging in a post hoc analysis of radiographs from the TAKT study.

Methods: Computed tomography images from patients in the TAKT study were evaluated by three independent radiologists who were not involved in the original trial. Patients who received TCZ and had computed tomography images available (n=28) were included. Assessments were made in 22 arteries for the change from baseline in wall thickness (primary end point), dilatation/aneurysm, stenosis/occlusion, or wall enhancement for at least 96 weeks after the start of tocilizumab treatment. Patient-level assessments were also conducted.

Results: Among 28 patients who received at least one dose of TCZ and for whom images were available, 86.7% of 22 arteries had improved/stable (no progression) wall thickness at week 96. The proportions of patients with no progressed, partially progressed, or newly progressed lesions were 57.1%, 10.7%, and 28.6% for wall thickness, and the proportions without progressed lesions were 92.9% for dilatation/aneurysm and 85.7% for stenosis/occlusion (Figure 1). Patients with newly progressed lesions, reflecting more refractory disease, were receiving glucocorticoid doses that could not be reduced below 0.1 mg/kg/day at week 96.

Conclusion: Approximately 60% of patients with TAK treated with tocilizumab did not experience progression in wall thickness. Few patients experienced progressive dilatation/aneurysm or stenosis/occlusion. Wall thickness progression likely resulted from refractory TAK. Patients who experience this should be monitored regularly by imaging, and additional glucocorticoid or immunosuppressive treatment should be considered to avoid vascular progression.

POS0341 SVCAM-1 EXPRESSION IN TAKAYASU ARTERITIS TREATED WITH TOCILIZUMAB: A PROSPECTIVE PILOT STUDY

S. Ackermann[1], P. Villiger[2], A. Gloor[3], K. K. Eriksson[2], M. Seidel[1]. *[1]Hospital Biel, Rhumatology, Biel, Switzerland*; *[2]Inselspital, Rhumatology, Bern, Switzerland*; *[3]Stanford University, Immunoloy and Rhumatology, Stanford, United States of America*

Background: Takayasu arteritis (TA) is a rare disease, its diagnosis is often delayed by years. Biomarkers might be helpful for earlier diagnosis and for monitoring treatment. We have described serum soluble vascular cell adhesion molecule-1 (sVCAM-1) as a marker of inflammation in a variety of rheumatic diseases, including vasculitis (1). Tocilizumab (TCZ) is a monoclonal antibody against the interleukin-6 receptor with established benefits in TA (2). It may spare oral glucocorticoids (GC) and Disease-Modifying Agents (DMARDs). So far, sVCAM-1 has never been examined as diagnostic marker or to monitor disease activity in TA patients treated with TCZ.

Objectives: To analyze sVCAM-1 in TA patients treated with TCZ in a prospective clinical trial and compare these results to age-matched healthy controls (HC) as well as DMARDs. In addition, MRI analyses of aortic wall thickening and enhancement might serve as a morphologic correlate of serologic disease activity.
Methods: 29 TA patients were prospectively followed between 2016 and 2019 (27 females, mean ± SD: 39.2±13.9 years) at the Department of Rheumatology of the University Hospital of Bern, Switzerland. At baseline, patients were without treatment (n=8) or treated with TCZ (n=13), GC (n=4), GC + methotrexate (MTX) (n=1), infliximab (IFX) + MTX (n=1), GC + IFX (n=1), MTX (n=1). Three follow-ups were performed after an average of 12, 24, 34 ± 3 months. sVCAM-1 was measured in serum using a commercially available ELISA kit (R&D Systems, Germany). Results were compared to 29 sera of matched HC (27 females, 40.8±15.1 years). MRI of aortic changes were scored on a scale of 0 (no thickening and vessel wall enhancement) to 3 (maximal thickening and vessel wall enhancement). Cumulated sVCAM-1 concentrations from each MRI scoring group (0-3) were compared to HC in order to determine if sVCAM-1 from high aortic MRI inflammation was significantly elevated.
Results: At baseline, significantly increased serum concentrations of sVCAM-1 (ng/ml) were observed in TA patients without treatment (n=8, 537.3±130.1, p=0.002) vs. HC (336.0±76.1). A smaller difference was found between patients under treatment and HC (n=21, 468.2±105.3 vs. 405.1±82.5, p=0.04). Follow-ups in the TCZ group showed 518.9±138.9 vs. 417.5±46, p=0.12 (n=6) after 12 months, 436.6±77.3 vs. 399.6±113.1, p=0.46 (n=8) after 24 months and 407.1±27.1 vs. 381.8±60.4, p=0.47 (n=4) after 36 months. In contrast, patients under DMARD therapy showed values of 505.8±126.4 vs. 395.6±60.2 p=0.04 (n=8) after 12 months, 437.8±76.2 vs. 396.4±91.9, p=0.24 (n=12) after 24 months and 440±43.3 vs. 323±50 p=0.03 (n=8) after 36 months. MRI analyses showed that group 0 (no inflammation, n=7) had significant increased values compared to HC (474.7±106.8 vs. 356.9±48.8, p=0.02), and group 3 (maximal inflammation, n=11) was also elevated (461.8±98.4 vs. 379.3±88.9, p=0.05).
Conclusion: The results suggest that sVCAM-1 is a biomarker of disease activity in patients with TA. The results at follow-up show that sVCAM-1 decreased more rapidly under treatment with TCZ compared to treatment with DMARDs. Remarkably, sVCAM-1 concentrations did not correlate with disease activity as assessed with MRI.

POS0342 DISCRIMINANT VALUE OF ULTRASOUND OF THE WALL OF LARGE VESSELS IN THE DIAGNOSIS OF GIANT CELL ARTERITIS

I. González-Mazón[1], E. Fernández-Fernández[2], I. Monjo[3], E. De Miguel[3].
[1]Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain; *[2]La Paz University Hospital, Rheumatology, Madrid, Spain*; *[2]La Paz University Hospital, Rheumatology, Madrid, Spain*

Background: The EULAR recommendations for the use of imaging in large vessel vasculitis in clinical practice suggest the performance of diagnostic imaging tests in all patients with suspected GCA and ultrasound is the recommended first-line test in patients with suspected cranial GCA (c-GCA)[1]. However, a priority imaging modality has not been established in cases of suspected GCA involving large vessels (LV-GCA). Since patients with LV-GCA often undergo extensive screening programs for suspected infection or malignancy before the diagnosis of GCA is established, our knowledge in this field needs to be improved.
Objectives: The aim of this study is to investigate the wall affectation of vasculitis of the proximal arm and neck arteries in patients with suspected GCA, polymyalgia rheumatica (PMR), atherosclerosis and non-GCA patients.
Methods: Retrospective available ultrasound examination from all the patients referred to our GCA fast-track clinic in the last three years were collected. All patients had ultrasound of cranial and large vessel examination (axillary, subclavian and carotid arteries). GCA diagnosis was confirmed by the doctor after a follow-up between six months to three years. Every patient had videos and pictures of every referred vessel. Examination was performed by two rheumatologists with long experience in GCA ultrasound from the same Rheumatology Department with a Esaote Mylab Twice with probe of 13 MHz (2017-2019) and a Esaote Mylab X8plus with a probe of 15 MHz (2019-2020). IMT and hypoechoic halo measures were taken.
Results: We analyzed 300 examinations and selected 196 baseline cases of four different pathologies (29 PMR, 40 atherosclerosis, 71 GCA of which 14 LV-GCA without cranial involvement and 56 non-GCA non-PMR controls). Intima-media thickness (IMT) with the statistical significance between different diseases and controls are showed in the Table 1.

Table 1. Ultrasound IMT and halo measures in large vessels of different diseases and controls

	Non-GCA n=56	GCA n=71	Atherosclerosis n=40	PMR n=29	LV-GCA n=14
Axillary right # *	0.67±.19	0.95±0.30	0.70±0.18	0.65±0.13	1.03±0.33
Axillary left # **	0.61±0.12	0.92±0.29	0.72±0.19	0.66±0.13	0.99±0.25
Subclavian right # *	0.70±0.15	1.00±0.31	0.86±0.29	0.70±0.20	1.09±0.36
Subclavian left # *	0.62±0.14	0.95±0.27	0.70±0.14	0.64±0.18	1.05±0.25
CCD right #	0.79±0.22	0.97±0.26	1.01±0.30	0.81±0.10	0.91±0.29
CCD left #	0.81±0.16	0.99±0.22	0.98±0.32	0.82±0.20	0.97±0.17

GCA= Giant cell arteritis (cranial, large vessel and mixed forms); Non-GCA = Patients suspected but not confirmed as GCA; Atherosclerosis = patients with high arteriosclerosis risk without suspected GCA; PMR = Patients with polymyalgia rheumatica without GCA; LV-GCA= Large vessel vasculitis GCA without cranial involvement.# p<0.01 GCA vs non-GCA and GCA vs PMR* p<0.01 GCA vs Atherosclerosis; ** p<0.05 GCA vs Atherosclerosis

Conclusion: GCA ultrasound of large vessels shows significant differences with other diseases. The differences seem to support the use of ultrasound in the fast-track clinic of GCA not only in c-GCA but also in LV-GCA.

POS0343 RITUXIMAB IS SUPERIOR TO PLACEBO IN POLYMYALGIA RHEUMATICA

D. Marsman[1], N. Den Broeder[2], F. Van den Hoogen[3], A. Den Broeder[3], A. Van der Maas[3]. *[1]Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands*; *[2]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands*; *[1]Sint Maartenskliniek, Rheumatology, Nijmegen, Netherlands*

Background: Corticosteroids remain the cornerstone of polymyalgia rheumatica treatment, but their use has several disadvantages such as long treatment duration and glucocorticoid-related adverse events.[1,2] Data on evidence based effective glucocorticoid-sparing agents are negative or absent.[2]
Objectives: Because B-cells may be involved in the pathogenesis of polymyalgia rheumatica, we evaluated the efficacy of rituximab in polymyalgia rheumatica.
Methods: In a 21-week double-blind placebo controlled exploratory study, 47 polymyalgia rheumatica patients (recently diagnosed n=38 / relapsing on prednisolone ≥7.5mg/day n=9) fulfilling the 2012 EULAR/ACR criteria, were randomized 1:1 to intravenous rituximab 1 x 1000 mg (n=23) or placebo (n=24), with a 17-week long glucocorticoid co-treatment. Primary outcome was glucocorticoid-free remission at week 21. Secondary outcomes were glucocorticoid ≤5mg/day and adverse events. Several post-hoc analyses were done for robustness of results.
Results: Glucocorticoid-free remission was achieved in 48% (rituximab) versus 21% (placebo), one-sided 95%-CI 4% to 100%; p=0.049, and glucocorticoid ≤5mg/day in 100% versus 54% (one sided 95%-CI 20% to 100%; p=0.005). Post-hoc analysis showed efficacy mainly in recently diagnosed patients: glucocorticoid-free remission in 58% versus 21% (one-sided 95%-CI 10% to 100%; p=0.02); glucocorticoid ≤5mg/day in 100% versus 47% (one-sided 95%-CI 29 to 100%; p<0.001). No significant differences were observed regarding other outcomes (Table 1), except for less morning stiffness after rituximab.

Table 1. ***Outcomes at week 21****

	Rituximab (n=23)	Placebo (n=24)	Difference, one sided 95%-CI	One sided p-value

			Rate ratio rituximab versus placebo (95% CI)	
Any adverse event §	136	148	0.9 (0.8 to ∞)	
Serious adverse event(s) ††	1	0		
Infections ‡ ‡	17	14	1.2 (0.7 to ∞)	
Infusion related complaints ¶	10	3	3.3 (1.2 to ∞)	

*Values are means, SD, unless specified otherwise. Numbers of observations is indicated between brackets []. No correction for type I error.

† Judged by research physician.

‡Wilcoxon rank sum (Mann-Whitney) test

§ All adverse events that occurred during the study period were included in the analyses. Adverse events numbers are number of events, not number of patients with events. Safety outcomes were compared by chi-squared test (cumulative incidences). No correction for type I error was performed. All adverse events were graded according to Common Terminology Criteria for Adverse Events version 5.0, grade range 0–5;higher scores indicate worse events.

†† was A pulmonary embolism occurred in one patient

‡ ‡ Labelled by the research physician. No serious infections ≥ grade 3 occurred.

¶ Labelled by research physician. No serious infusion related complaints ≥ grade 3 occurred.CRP denotes C-reactive protein, IQR interquartile range, ESR erythrocyte sedimentation rate, CI confidence interval

Conclusion: Rituximab is superior to placebo in combination with 17-week glucocorticoid-treatment to achieve glucocorticoid free remission in polymyalgia rheumatica. The largest effect was seen in recently diagnosed polymyalgia rheumatica patients (funding: Sint Maartenskliniek; Dutch trial number NL7414).

POS0344 RISK OF ACPA POSITIVITY BY MOTIF-BASED CLASSIFICATION OF HLA-DRB1 SHARED EPITOPE ALLELES IN RA

K. Wipfler[1], X. Han[2], S. S. H. Park[2], K. Wittstock[2], K. Michaud[1,3]. [1]*FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, United States of America*; [2]*Bristol Myers Squibb, Health Economics & Outcomes Research, Princeton, NJ, United States of America*; [3]*University of Nebraska Medical Center, Division of Rheumatology and Immunology, Omaha, NE, United States of America*

Background: The shared epitope (SE) is the strongest known genetic risk factor for rheumatoid arthritis (RA) and is associated with an amino acid motif at positions 70-74 in HLA-DRB1. It is linked to anti-citrullinated protein antibody (ACPA) positivity, a specific serological marker for RA. In 2005, a new classification of HLA-DRB1 alleles was proposed, in which each allele is sorted into one of five classes (S1, S2, S3P, S3D, or X).[1] The method was subsequently validated for predicting risk of developing RA[2] and was described as "a major advance and a template for future studies."[3] However, there have been relatively few studies utilizing this classification.

Objectives: To characterize the prevalence of each SE genotype from the 2005 classification and their association with ACPA positivity in a cohort of individuals with RA.

Methods: Participants in FORWARD, The National Databank for Rheumatic Diseases, with RA and donated serum (collected 2010-2019) were analyzed to obtain ACPA status and high-resolution HLA-DRB1 type. Alleles were classified based on the presence (S2, S3P) or absence (S1, S3D, X; collectively L) of the SE motif, and individuals were classified by allele pair. Logistic regression models (adjusted for age, sex, and race/ethnicity) to determine risk of ACPA positivity by class were generated using L/L as the reference.

Results: Characteristics of the 855 participants at the time of sample collection are presented in Table 1. Overall, 67% of participants were SE positive and 51% were ACPA positive. Of the 1,710 total alleles, X was the most common (29%) followed by S3P (24%), S1 (18%), S2 (18%), and S3D (9%). Adjusted models showed that the risk of ACPA positivity was highest among those with the genotype S2/S3P, followed by S2/S2, S2/S3D, S2/X, S3P/S3D, S1/S2, S3P/S3P, S3P/X, and S1/S3P (Figure 1).

Table 1. Characteristics of study population by SE status and allele count (mean [SD] or n [%]). Significance was assessed by Student's t-test or X^2 test, as appropriate.

	SE negative	SE positive			
	0 alleles	All	1 allele	2 alleles	P (SE- vs SE+)

Patient global severity, 0-10	4.0 (2.5)	3.3 (2.5)	3.4 (2.4)	3.1 (2.6)	<0.001
HAQ-II, 0-3	1.0 (0.7)	0.8 (0.6)	0.8 (0.6)	0.8 (0.6)	<0.001
csDMARD use	204 (71.3)	433 (76.1)	302 (74.2)	131 (80.9)	0.13
bDMARD use	165 (57.7)	351 (61.7)	244 (59.95)	107 (66.0)	0.26
Corticosteroid use	98 (34.3)	165 (29.0)	121 (29.7)	44 (27.2)	0.12

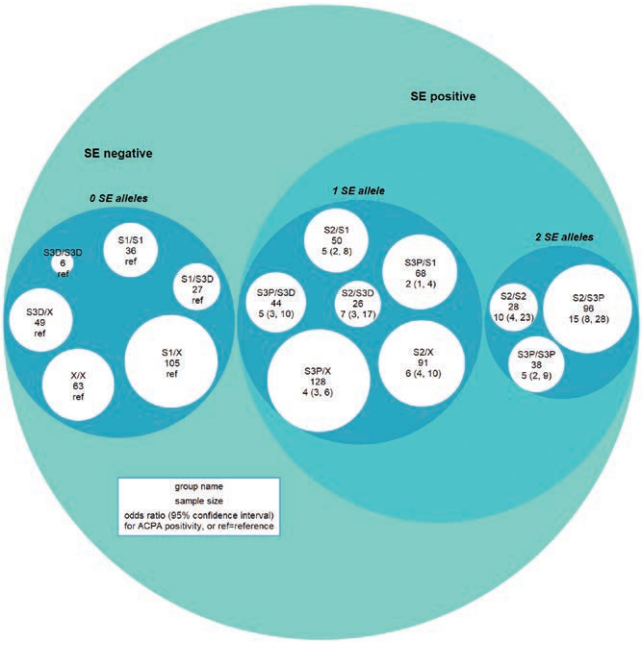

Figure 1. Risk of ACPA positivity by the motif-based classification and prevalence of SE by binary status, allele count, and class. The area within each circle is proportionate to the sample size of that group.

Conclusion: The ranking by risk of ACPA positivity among this RA cohort is similar to the order of risk for developing RA, as determined in the 2006 validation paper for this classification method. A notable trend among the classes with one SE positive allele is the consistent ranking of S3D as higher risk, X in the middle, and S1 as the lowest, suggesting a potential protective effect from S1 alleles. Future work should examine clinical associations with these allele classes, including disease progression and treatment effects.

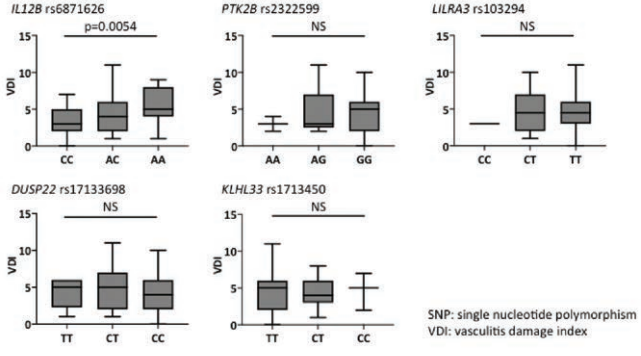
Background: We have previously identified single nucleotide polymorphism (SNP) rs6871626 in *IL12B*, rs103294 in *LILRA3*, rs17133698 in *DUSP22*, rs2322599 in *PTK2B*, and rs1713450 in *KLHL33* as non-HLA susceptibility loci in Takayasu arteritis (TAK) [1, 2]. However, the association of these SNPs with clinical features has scarcely investigated.
Objectives: In this study, we aimed to examine how these SNPs contribute to clinical features and vascular damage in TAK.
Methods: We enrolled 99 TAK patients who were enrolled in our previous genome-wide association study (GWAS) [2]. To assess vascular damage, Takayasu Arteritis Damage Score (TADS) and Vasculitis Damage Index (VDI) were measured at the last visit before November 2020. As for organ damages, the presence or absence of aortic regurgitation (AR), hypertension, ischemic heart disease, cerebrovascular event, visual loss, end-stage renal failure, and inflammatory bowel disease were evaluated. Treatment profiles including immunosuppressive drugs and vascular interventions were also reviewed.
Results: The incidence of AR was positively associated with the risk allele of *IL12B* rs6871626 (p=0.0052; odds ratio (OR) 2.45, 95% confidence interval (CI) 1.27-4.73), and so was the proportion of patients who underwent aortic valve replacement (p=0.023; OR 3.64, 95% CI 1.08-12.24) (table 1). The incidence of hypertension was associated with the risk allele of *IL12B* rs6871626 (p=0.049; OR 1.82, 95% CI 0.99-3.36) and *PTK2B* rs2322599 (p=0.044; OR 2.52, 95% CI 0.97-6.54) (table 1). The proportion of biologic users tended to be higher in the risk genotypes of *IL12B* rs6871626 (p=0.15; OR1.80, 95% CI 0.79-3.99). Regarding vascular damage, there was positive correlation between TADS and the risk allele of *IL12B* rs6871626 (p=0.0035; β= 1.35) (Figure 1). Moreover, VDI was also positively correlated with the allele (p=0.0054; β= 0.96) (Figure 1). No other clinicogenetic associations were observed between five SNPs and vasculitis-associated damages.

Table 1. The association of the five SNPs with aortic regurgitation and hypertension

	Aortic regurgitation		Hypertension	
	OR (95% CI)	p value	OR (95% CI)	p value
IL12B rs6871626	2.45 (1.27-4.73)	0.0052*	1.82 (0.99-3.36)	0.049*
PTK2B rs2322599	1.21 (0.51-2.86)	0.67	2.51 (0.97-6.54)	0.044*
LILRA3 rs103294	1.16 (0.52-2.61)	0.71	1.20 (0.55-1.64)	0.64
DUSP22 rs17133698	0.56 (0.28-1.13)	0.090	0.87 (0.46-1.63)	0.66
KLHL33 rs1713450	0.89 (0.42-1.91)	0.77	1.48 (0.68-3.22)	0.31

SNP, single nucleotide polymorphism; OR, odds ratio; CI, confidence interval

Figure. The association of the five SNPs with VDI



Conclusion: In the present study, *IL12B* rs6871626 was closely correlated with vascular damage. We also found association between *PTK2B* rs2322599 and hypertension. There was no significant relevance between vascular damage and *LILRA3* rs103294, *DUSP22* rs17133698, or *KLHL33* rs1713450.

POS0346 THE THERAPEUTIC EFFECTS OF OMEGA-6 PUFA (PINOLENIC ACID) ON THE TRANSCRIPTOMIC PROFILE OF ACTIVATED PERIPHERAL BLOOD MONONUCLEAR CELLS ISOLATED FROM HEALTHY CONTROLS AND RHEUMATOID ARTHRITIS PATIENTS

R. Takala[1,2], D. Ramji[2], R. Andrews[1], Y. Zhou[1], J. Burston[1], E. Choy[1,3]. [1]*Cardiff University, Division of Infection and Immunity, School of Medicine, Cardiff, United Kingdom*; [2]*Cardiff University, School of Biosciences, Sir Martin Evans Building, Cardiff, United Kingdom*; [3]*Cardiff University, CREATE Centre, Section of Rheumatology, School of Medicine, Cardiff, United Kingdom*

Background: Globally, Rheumatoid arthritis (RA) is the most common chronic inflammatory arthritis. EULAR recommends patient education and disease modifying anti-rheumatic drugs including advanced targeted therapies for management[1 2]. Many patients seek advice on a dietary intervention that may improve symptoms. Foods high in omega-3 polyunsaturated fatty acids (PUFAs) is one of the most common recommended based on their anti-inflammatory properties[3 4]. Previously we showed pinolenic acid (PNLA), an omega-6 (PUFAs) found in pine nuts, reduced lipid uptake, endocytosis and migration of monocyte *in vitro*. PNLA also reduced IL-6, TNF-α, IL-1β and PGE2 produced by lipopolysaccharide (LPS) activated PBMCs from patients with RA and healthy controls (HCs).
Objectives: We hypothesis that PNLA inhibits key inflammatory processes in synovities as in diagram.1. We investigated the transcriptomic profile of PNLA treatment on LPS activated PBMCs isolated from HCs and RA patients.
Methods: Adult RA patients (n=6) were recruited from the Rheumatology Department of University Hospital of Wales together with 6 HCs. Blood was collected after taking signed informed consent. PBMCs were isolated by Ficoll gradient centrifugation and pre-treated with 25 μM PNLA or vehicle and then activated with 100 ng/ml LPS. RNA was extracted followed by library construction and sequencing for whole genomic transcriptome. DEGs were analysed using DESeq2 and pathway analysis was performed using Ingenuity pathway analysis. The study was approved by the Research Ethics Committee for Wales (reference no. 12/WA/0045).
Results: DEGs were selected with at least differential genes using at least 1.2* fold changes and adjusted p-value of <0.05. PNLA significantly upregulates the expression of PDK4, PAI-1 (SERPINE1), FBP1, and NDRG2. These genes have important roles in metabolic pathways. Pathway analysis predicted upstream activation of nuclear receptors peroxisome proliferator-activated receptor (PPARs) involved in the anti-inflammatory process, and inhibition of NF-κB and STAT1, the major transcription factors of the pro-inflammatory cytokines TNF-α, IL-1, IL-6 and IFN-γ.
Conclusion: PNLA has significant effects on the regulation of metabolic and inflammatory pathways in PBMCs from RA patients and HCs. Based on these results we demonstrate that PNLA may have beneficial anti-inflammatory effects in patients with RA

Background: The early identification of patients with rapid progressive osteoarthritis (RPOA) could allow the implementation of prevention strategies and their inclusion in clinical trials. Polymorphisms in nuclear and mitochondrial DNA (mtDNA) have been associated with OA. Preliminary analyses by our group showed nuclear single nucleotide polymorphism (nSNP) rs12107036 of TP63 as a potential risk factor for RPOA of the knee.

Objectives: i) To analyze interactions between mtDNA haplogroups and rs12107036 ii) To apply Next Generation Sequencing (NGS) to discover novel mitochondrial variants to construct predictive models of RPOA of the knee.

Methods: 1102 Caucasian subjects from the OAI were classified as follows: i) Rapid progressors (N=255), baseline KL grade 0-1 or 2 in at least one knee, that increases up to KL≥ 3 or 4 respectively during 48-month follow-up. ii) Non-rapid progressors (N=847), with the same baseline characteristics as rapid progressors, but with slower or no evolution over time.

mtDNA haplogroups and rs12107036 were assigned by mini-sequencing techniques. Novel mtDNA variants were studied by NGS. Statistical analyses included chi-square tests and generalized estimating equations. Relative excess risk due to interaction (RERI) and attributable proportion (AP) were evaluated for the additive interaction between mtDNA clusters and nSNP rs12107036. A nomogram for the estimation of the risk of RPOA was also developed. Analyses were performed using SPSS Statistics v24 and epi.R package included in R software v3.6.3.

Results: Chi-square analyses revealed an increased risk of RPOA in patients with the allele G of rs12107036 and mtDNA cluster UK (OR 2,013; p=0,001). An excess of 70,3% of RERI between nSNP rs12107036 and mtDNA clusters was detected, indicating that 47,1% (AP) of the risk is attributable to this interaction, therefore harboring both genetic factors increase the risk of RPOA up to 4,7 times compared to harboring just one. mtDNA sequencing revealed the variant mt16519 overrepresented in rapid-progressors (OR 1,620; p=0,002).

Table 1 shows the predictive model for the risk of RPOA. The interaction between the allele G of rs12107036 and mtDNA cluster KU (OR 1,727; p=0,036), in addition to the variant mt16519C (OR 1,690; p=0,003), showed a significant association with the RPOA phenotype regardless of age, BMI, contralateral knee OA, previous injury and WOMAC pain. Image 1 displays the nomogram for predicting risk of RPOA; as an example, a 70 year old male, with a BMI of 28, WOMAC pain score of 10, contralateral OA and presence of both mito-nuclear interaction and mt16519C, has a risk of RPOA of 0,7.

Conclusion: mtDNA genetic variants are useful, not only as modulators of the influence of specific nuclear polymorphisms on the risk of developing RPOA, but also as candidate genetic biomarkers of this phenotype.

Background: Patients who achieve remission promptly could have a specific genetic risk profile that supports regaining immune tolerance. The identification of these genes could provide novel drug targets.
Objectives: To test the association between RA genetic risk variants with achieving remission at 6 months.
Methods: We computed genetic risk scores (GRS) comprising of the RA susceptibility variants[1] and HLA-SE status separately in 4425 patients across eight datasets from inception cohorts. Remission was defined as DAS28CRP<2.6 at 6 months. Missing DAS28CRP values in patients were imputed using predictive mean matching by MICE. We first tested whether baseline DAS28CRP changed with increasing GRS using linear regression. Next, we calculated odds ratios for GRS and HLA-SE on remission using logistic regression. Heterogeneity of the outcome between datasets was mitigated by running inverse variance meta-analysis.
Results: Evaluation of the complete dataset, baseline clinical variables did not differ between patients achieving remission and those who did not (Table 1). Distribution of GRS was consistent between datasets. Neither GRS nor HLA-SE was associated with baseline DAS2DAS (OR1.01; 95% CI 0.99-1.04). A fixed effect meta-analysis (Figure 1.) showed no significant effect of the GRS (OR 0.99; 95% CI 0.94-1.03) or HLA-SE (OR 0.8CRP87; 95% CI 0.75-1.01) on remission at 6 months.

Table 1. Summary of the data separated by disease activity after 6 months.

	all	Remission at 6 months	No remission at 6 months
N	4425*	1558	2430
Age, *mean (sd)*	55.38 (13.87)	5517 (14.09)	55.62 (13.59)
Female %	68.98%	65.43%	70.73%
ACPA+ %	61.94%	63.53%	61.67%
Baseline DAS28, *mean (sd)*	4.76 (1.22)	4.47 (1.23)	5.1 (1.15)

**not all patients had 6 months data*

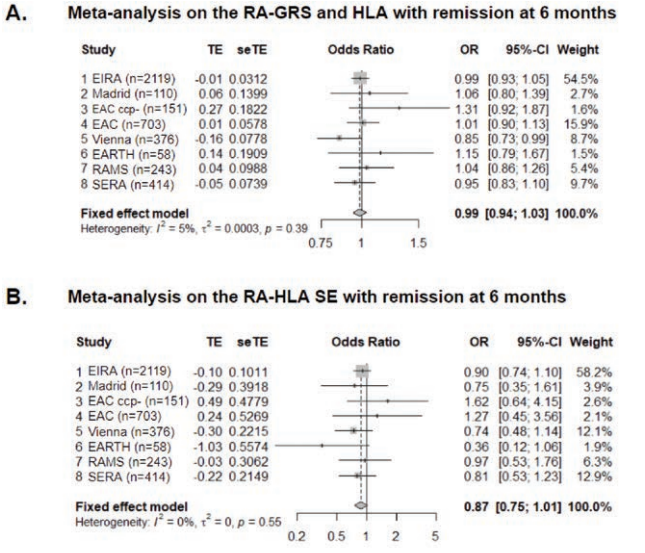

Figure 1. A. Inverse weighted meta-analysis of (**A**) the GRS + HLA and (**B**) the HLA SE. Includes the dataset name (Study), test estimate (TE), the standard error of treatment estimate (seTE), odds ratio (OR), 95% confidence intervals (95%-CI) and the weights of the fixed effect model. I^2 percentage of variation across studies due to heterogeneity. τ^2 states the variance of the true effect size.

Conclusion: In these combined cohorts, RA genetics risk variants are not associated with early disease remission. At baseline there was no difference in genetic risk between patients achieving remission or not. Studies encompassing other genetic variants are needed to elucidate the genetics of RA remission.

POS0349 SEQUENCE COMPLEMENTARITY BETWEEN SARS-CoV-2 GENOME AND HUMAN NONCODING RNAS ASSOCIATED WITH IMMUNOLOGICAL DISORDERS: AN IN SILICO PIVOTAL STUDY

R. Talotta[1], S. Bahrami[2], M. J. Laska[2]. [1]*University of Messina, Clinical and Experimental Medicine, Messina, Italy*; [2]*Aarhus University, Clinical Medicine, Aarhus, Denmark*

Background: Recent evidence shows that human cells may produce several noncoding (nc)RNAs in response to viral infections. Among them, a central role has been attributed to long noncoding (lnc)RNAs, more than 200 nucleotides in length, which are also crucially involved in cancer and autoimmunity. LncRNAs epigenetically control the transcription of genes presiding over cell proliferation, differentiation, migration and apoptosis, by directly or indirectly binding cellular or foreign nucleic acids, including viral genomes.
Objectives: The objectives of this study were to evaluate *in silico* the presence of a nucleotide sequence complementarity between the RNA genome of Severe Acute Respiratory Syndrome CoronaVirus-2 (SARS-CoV-2) and human ncRNA genes and to analyze any associations between SARS-CoV-2 gene-matching ncRNAs and human diseases.
Methods: The FASTA sequence of each of the 11 SARS-CoV-2 isolate Wuhan-Hu-1 genes (ORF1ab, ORF3a, ORF6, ORF7a, ORF7b, ORF8, ORF10, S, E, M, N) was retrieved from NCBI.nlm.nih.gov/gene (reference sequence NC_045512.2). The ensembl.org library for human ncRNA genes was interrogated for any base-pair match and detected human ncRNAs analyzed for their functional activity. Finally, the associations between ncRNAs and human diseases were searched on GWAS databases (https://www.ebi.ac.uk/gwas and https://www.genecards.org).
Results: A total of 252 matches between SARS-CoV-2 genes and human ncRNAs were recorded (ORF1ab: 28; ORF3a: 9; ORF6: 50; ORF7a: 31; ORF7b: 16; ORF8: 23; ORF10: 5; S: 24; E: 17; M: 32; N: 17). With the exception of two small nuclear RNAs (RNVU1-4 and RNU4-74P corresponding to ORF6 and ORF10, respectively), all of them were lncRNAs, mostly expressed in testis and central nervous system under physiological conditions. Percentage of alignment ranged from 91.30% to 100%, with a mean nucleotide alignment length of 17.5±2.4. Polymorphic variants of these transcripts have mostly been reported in patients with neuropsychiatric disorders, cancer and dysmetabolism. Of note, we found 13 and 15 complementarities with lncRNAs associated with immune-mediated diseases Table 1. and immunological pathways (IL-2, IL-6, IL-12, IL-12R, IL-13, IL-17, M-CSF, CXCL-10, TRAIL-R2 and IgG glycosylation), respectively.
Conclusion: This pivotal study shows that SARS-CoV-2 genes contain complementary sequences to human ncRNAs in turn associated with several diseases, including autoimmunity. The biological effects of this interaction remain to be elucidated.

EPIONE APPLICATION: AN INTEGRATED GENOTYPE ANALYSIS WEB SERVER FOR CLINICAL GENOMICS IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

L. Papageorgiou[1], H. Alkenaris[1], M. Zervou[2], D. Vlachakis[1], G. Goulielmos[2], E. Eliopoulos[1]. [1]*Agricultural University of Athens, Laboratory of Genetics, Department of Biotechnology, Athens, Greece*; [2]*University of Crete, Section of Molecular Pathology and Human Genetics, Department of Internal Medicine, School of Medicine, Heraklion, Greece*

Background: Genome wide association studies (GWAS) have successfully identified novel autoimmune disease-associated loci, with many of them shared by multiple disease-associated pathways but much of the genetics and pathophysiological mechanisms remain still obscure [1-3]. SLE is a chronic, highly heterogeneous autoimmune disease, characterized by differences in autoantibody profile, serum cytokines, and a multi-system involvement [4]. Epione Application is an integrated bioinformatics web-tool designed to assist medical experts and researchers in the process of diagnosing SLE [5].

Objectives: To identify the most credible gene variants and single nucleotide polymorphisms (SNPs), causing SLE using the genomic data provided for the patient and aid the medical expert in SLE diagnosis [5].

Methods: In the present study, we have analyzed more than 70.000 SLE-related publications using data mining and semantic techniques towards extracting the SLE -related genes and SNPs [6]. The extracted knowledge has been filtered, evaluated, annotated, classified, and stored in the Epione Application Database (EAD) (Figure 1). Moreover, an updated gene regulatory network with the genes implements in SLE has been estimated [7]. This was followed by the design and development of the Epione application, in which the generated datasets and results were included. The application has been tested and presented here with WES data from several related patients with SLE [8].

Results: SLE-related SNPs and variants identified in genome-wide association studies (GWAS), whole-genome (WGS), whole-exome (WES), or targeted sequencing information are classified, annotated, and analyzed in an integrated patient profile with clinical significance information. Probable genes associated with the patient's genomic profile are visualized with several graphs, including chromosome ideograms, statistic bars, and regulatory networks through data mining studies with relative publications, to obtain a representative number of the most credible candidate genes and biological pathways associated with the SLE. An evaluation study was performed on 7 patients from a three-generation family with SLE [9]. All the recognized gene variants that were previously considered SLE-associated were properly identified in the output profile per patient, and by comparing the results, new findings have emerged.

Conclusion: The Epione application was designed to assist medical doctor diagnosis from the early stages by using the patients' genomic data [5, 8, 10]. Its diagnosis-oriented output presents the patient profile through which the user is provided with a structured set of results in various categories, which are generated based on the list of the most predictable candidate gene variants related to SLE. This novel and accessible webserver tool of SLE to assist medical experts in the clinical genomics and precision medicine procedure is available at http://143.233.188.162/epione/.

POS0351 A DEEP LEARNING METHOD UNCOVERS NOVEL PATHWAY ASSOCIATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS

E. F. Morand[1], T. Dörner[2], B. Jia[3], Y. Liu[3], S. de Bono[3], D. Fantini[3], M. Silk[3], N. Bello Vega[3], P. Fischer[3], M. A. Petri[4]. Background: While there have been recent improvements in therapy for systemic lupus erythematosus (SLE), unmet need remains for novel, efficacious treatments. Artificial intelligence can facilitate drug discovery by identifying potential target molecules and pathways.
Objectives: To devise a Deep Learning method that ranks genes and pathways differentially expressed in SLE by an integrated metric of expression and interactivity.
Methods: HT2A array expression data (17,799 transcripts) were obtained from whole blood samples taken at baseline (N=1,760) from patients with SLE enrolled in two phase 3 trials (NCT01196091 and NCT01205438). We applied a Deep learning algorithm[1] to create a disease-specific gene network for SLE from the Decagon and MetaCore molecular interaction databases[2,3]. A meta-analysis was conducted for each candidate gene by calculating its distance from other genes in the disease-specific network (interactivity analyses). The distance was then multiplied by each gene's utility score, a measure of the gene's relevance to SLE disease activity derived from public datasets[4,5]. The final output was the fractional rank (0–1) of utilities[5] for each gene against prespecified outcomes of SLEDAI-2K and IFN gene signatures, analyzed as a continuous variable combining 34 IFN-related genes. Selected JAK-STAT, cytokine, and IFN genes are presented. Pathways enriched in the top 250 genes from the input data and Deep Learning output were analyzed by hypergeometric tests.
Results: The highest-ranked gene for SLEDAI-2K and IFN signature status was IFNγ, followed, as expected, by the IFNα gene family (Table 1). Application of the Deep Learning method markedly affected pathway analysis outcomes, revealing strong associations in pathways including those related to CD4+ T cell differentiation as well as macrophage and dendritic cells, which were not apparent in conventional analysis (Figure 1).

Table 1.

Gene	SLEDAI-2K fractional rank	IFN signature fractional rank
IFNγ	0.9999	0.9999
IFNα†	0.999*	0.999*
STAT1	0.9991	0.9991
IL10	0.9990	0.9987
IFNB1	0.9990	0.9989
STAT6	0.9981	0.9966
IL6	0.9974	0.9973

POS0352 ALLELIC VARIANTS IN THE ABCG2 GENE CAN LEAD TO HYPERURICEMIA AND GOUT

K. Pavelcova[1,2], J. Bohata[1,2], B. Stiburkova[1,3]. [1]*Institute of Rheumatology, Prague, Czech Republic*; [2]*First Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic*; [3]*First Faculty of Medicine, Charles University and General University Hospital in Prague, Department of Pediatrics and Inherited Metabolic Disorders, Prague, Czech Republic*

Background: The level of uric acid is largely determined by the functions of urate transporters, which are located in the kidney and intestine. The ABCG2 protein is the major excretor of uric acid and its dysfunction may lead to the development of hyperuricemia and gout.
Objectives: The aim of our study was to detect the occurrence and frequency of allelic variants in the ABCG2 gene that can lead to impaired function of the ABCG2 protein and to the development of hyperuricemia and gout.
Methods: We examined allelic variants of *ABCG2* using PCR amplification and Sanger sequencing of all coding regions and exon-intron boundaries in 359 patients with primary hyperuricemia and gout.
Results: We found a rare in-frame deletion p.K360del and 15 missense variants, two of which were common (p.V12M, p.Q141K) and 13 were very rare (p.M71V, p.G74D, p.M131I, p.R147W, p.T153M, p.I242T, p.R236X, p.F373C, p.T421A, p.T434M, p.S476P, p.S572R, p.D620N). The p.R236X variant leads to a premature stop codon. The p.V12M variant probably has a protective effect against gout (minor allele frequency – MAF – in our cohort = 0,025 / MAF in the European population = 0,061), while the p.Q141K variant increases the risk of gout (MAF in our cohort = 0,213 / MAF in the European population = 0,094) (1). As for the rare variants, the p.R147W, p.T153M, p.F373C, p.T434M, p.S476P and p.S572R

according to functional analyzes reduce the function of the ABCG2 protein (2). Based on *in silico* prediction, the impact on reduced function is expected for variants p.M71V, p.G74D, p.M131I, p.R147W, p.I242T, p.F373C, p.T434M, p.S476P and p.S572R.

Conclusion: Our data suggest that the common variant p.Q141K and most of the rare variants in the *ABCG2* gene affect the function of the ABCG2 urate transporter and are a genetic risk factor for hyperuricemia and gout.

POS0353 DEEP PHENOTYPING OF PSORIASIS BASED ON LIPID METABOLISM RELATED GENES BY INTEGRATIVE SYSTEMS ANALYSIS

J. Shi[1,2,3], S. X. Zhang[1,2,3], J. Qiao[1,2,3], S. Song[1,2,3], R. Zhao[1,2,3], P. Zhao[4], G. Y. Liu[1,2,3], J. Luo[1,2,3], P. F. He[5], X. Li[1,2,3]. Background: Psoriasis is an immune-mediated inflammatory, genetic disease with numerous concomitant metabolic disorders[1]. Patients with psoriasis experience substantial morbidity and increased rates of cardiometabolic diseases[2]. Among the metabolic disorders, lipid disturbances are recognized as a very important part in the pathogenesis of psoriasis and psoriasis-associated cardiometabolic diseases[3 4].

Objectives: To characterize the molecular features of psoriasis by the development of a classification system that was based on the gene expression profile of lipid metabolism related genes.

Methods: We performed molecular subtyping and association analysis of psoriasis from Gene Expression Omnibus (GEO). The training sets includes GSE13355 cohort (N = 58), GSE14905 (N = 28) cohort and GSE30999 cohort (N = 81), while the GSE54456 (N = 92) was selected as the validation set. Energy metabolism-related genes were collected from MSigDB (version 7.0; http://software.broadinstitute.org/gsea/msigdb/). Based on these psoriasis lipid metabolism-related genes, we conducted consensus molecular subtyping with nonnegative matrix factorization (NMF). Finally, Gene set variation analysis (GSVA) was used to score individual subtypes against the metabolism-related gene sets, and each group got a GSVA index.

Results: Total 104 lipid metabolism-related genes were clustered into three subgroups (Figure 1A). GSVA revealed the lipid metabolism with the correlation in subtypes. There was no statistical difference was identified between the subtype 1 and subtype 2($P > 0.05$, Figure 1B), so we merged the two types as a new Sub1, another subtype was named as the new Sub2 (Figure 1C). We finally identified 2 distinct subtypes of psoriasis in GEO cohort that were characterized by significantly different lipid metabolic gene score. Sub1 was featured by higher metabolic gene score compared with that of Sub2($P < 0.001$; Figure 1D). The lipid metabolic subtype classification was successfully validated in another independent patient cohorts (GSE54456).

Conclusion: This study established a new classification based on the gene expression profiles of lipid metabolic genes, thereby furthering the understanding of the pathogenesis and psoriasis-associated diseases.

POS0354 DETECTION OF ABCG2 VARIANTS IN ENCODING OF URATE TRANSPORTERS ASSOCIATED WITH THE HYPERURICEMIA IN HAEMODIALYSIS PATIENTS

H. Ciferska[1,2], K. Pavelcova[1,2], J. Vachek[3,4], B. Stiburkova[5,6]. [1]*Institute of Rheumatology, Institute of Rheumatology, Prague, Czech Republic*; [2]*First Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic*; [3]*General University Hospital, Prague and the First Medical Faculty, Charles University, Department of Nephrology, Prague, Czech Republic*; [4]*Klatovska Hospital, Dialysis Ward, Klatovy, Czech Republic*; [1]*Institute of Rheumatology, Institute of Rheumatology, Prague, Czech Republic*; [6]*First Faculty of Medicine, Charles University and General University Hospital in Prague, Department of Pediatrics and Adolescent Medicine, Prague, Czech Republic*

Background: Hyperuricemia is associated with gout, hypertension, cardiovascular diseases and renal disease. The presence of chronic kidney disease (CKD) is associated with low excretion of the uric acid as the homeostasis in maintaining of serum levels of uric acid is impaired. Progression of CKD is connected to hyperuricemia and lowering levels of the uric acid is one of the most important goals in clinical treatment. Dysfunctional variants of ATP-binding cassette transporter subfamily G member 2 (ABCG2), a major urate transporter in the kidney and intestine, are the major causes of hyperuricemia and gout.

A recent studies found that ABCG2 is also a major transporter of uremic toxins and ABCG2 dysfunctional variants are risk genetics factors for mortality in hemodialysis patients.

Objectives: The aim of the present study was to investigate the frequencies of ABCG2 variants in cohort of hemodialysis patients.

Methods: In this retrospective one centre study 167 patients (age=79,8±11,03;female=74) with end-stage CKD (pre-dialysis n=86; dialysis n=79) were collected. Peak urate levels were 456,3±113,6 µmol/l in pre-dialysis and 572,93±114,56 µmol/l in dialysis. ABCG2 coding regions were analyzed from genomic DNA, as we described previously (1). The reference sequence was defined as version ENST00000237612.7, the reference protein sequence was defined as Q9UNQ0. The chi-square goodness-of-fit test was used to compare minor allele frequencies (MAF), and the log-rank test was used to compare empirical distribution functions.

Results: In the CKD cohort, 15 intronic and seven non-synonymous allelic exonic variants were detected: two common (rs2231137/p.V12M; rs2231142/p.Q141K), five ultra rare and/or rare (rs142634180/p.R45Q, rs759726272/p.M131I, rs140207606/p.R236X, rs138606116/p.G354R, rs138892154/p.A607V), and one novel (p.E344D). Common variant p.V12M, previously reported as protective

allele, was detected in 12 heterozygous patients with. The p.Q141K variant, detected in the homozygous stage in three patients and in 31 patients as heterozygous variant. Heterozygous rare variants p.R45Q, p. G354R, p.A607V, and novel variant p.E344D were detected in one heterozygous patient each; heterozygous p.M131I and p.R236X in two patients.

Conclusion: In this study, significantly higher frequency of dysfunctional ABCG2 variants, common and rare, in comparison with common European population, were identified. On the other hand, the frequency of probably protective allele variant p.V12M was significantly lower in CKD cohort (MAF in our cohort = 0,036/ MAF in the European population = 0,061). Further analysis of ABCG2 association with CKD events *via* ABCG2 inflammation role is necessary. In conclusions, our finding of one novel, five rare and two common non-synonymous ABCG2 allelic variants in a sample of 167 CKD patients suggests that the ABCG2 variants should be considered a risk factor for CKD.

POS0355 ASSOCIATIONS BETWEEN HLA-DRB1 SHARED EPITOPES ALLELES AND ANTI-RA33 ANTIBODIES IN DIFFERENT SUBSETS OF RHEUMATOID ARTHRITIS IN MALAYSIAN POPULATION

Background: The mechanisms affecting anti-RA33 antibody's involvement in RA pathogenesis is still unclear. Refining our understanding of anti-RA33's role in RA in relation to known RA-associated genes and serological elements is needed.

Objectives: We investigated the relationship between RA-associated HLA-DRB1 epitope (SE) allele and presence of anti-RA33 antibodies in different serological subsets of rheumatoid arthritis in a Malaysian population.

Methods: Serum samples from 550 RA cases comprising seronegative (negative for anti-CCP2, IgG and IgM, n=250), seropositive (triple-autoantibody positive, n=150), singular anti-CCP2 positive (n=100), and double RF positive RA (n=50) were chosen from the Malaysian Epidemiological Investigations of RA (MyEIRA) case-control study. Three hundred MyEIRA population controls were used for comparison. All serum samples were assayed using a commercial anti-RA33 ELISA kit. All genetic samples were genotyped for four-digit HLA-DRB1 alleles using the PCR-SSO method on Luminex platform.

Results: The proportions of anti-RA33 positive was 20.9% in all RA cases (i.e. 34% in RF only positive RA; 25% in seropositive RA; 18% in seronegative RA and 18% in anti-CCP2 only positive RA). The HLA-DRB1 shared epitope alleles were significantly associated with anti-RA33 positive in the seropositive RA subgroup (OR=6.9, 95% CI 1.4-34.8; p=0.02). We observed significant association between anti-RA33 negative and HLA-DRB1 SE alleles among the seropositive RA patients (OR=4.5, 95% CI 2.8-7.2; p<0.001) and among CCP only positive RA (OR=4.4; 95% CI 2.6-7.4; p<0.01). No association was observed between anti-RA33 status and HLA-DRB1 SE alleles in seronegative RA and RF only positive RA.

Conclusion: The HLA-DRB1 SE alleles increased the risk of seropositive and CCP only positive RA independent of anti-RA33 positivity.

POS0356 THE RELATIONSHIP OF GENETICS AND CLINICALLY SUSPECT ARTHRALGIA IN RA DEVELOPMENT ASSESSED USING HC, CSA AND RA PATIENTS

M. Maurits[1], F. Wouters[1], E. Niemantsverdriet[1], T. Huizinga[1], A. van der Helm - van Mil[1], R. Knevel[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: The identification of a pre-RA stage of patients with clinically suspect arthralgia (CSA) has proven to be beneficial in the early detection of Rheumatoid disease. Similarly, genetic susceptibility studies have identified important genetic risk factors for the development of (CCP positive) RA.[1] The question that arises is whether these findings represent independent etiological pathways and could therefore be complimentary in the early diagnosis of RA.

Objectives: To corroborate the knowledge of genetic differences between HC and RA patients and extend it to include the CSA stage of disease.

Methods: We used three datasets sampled from the same region in the Netherlands: 1,085 healthy controls (HC), 530 CSA and 1,277 RA patients. CSA patients were monitored for a median of 2 years for conversion into clinically apparent inflammatory arthritis (CSAc) or not (CSAnc).[2] We assessed the association between HLA SE and disease stage using logistic regression. The analysis was repeated in the CCP positive and CCP negative strata of both the CSA and the RA populations.

Results: Consistent with previous studies, HLA SE was significantly enriched in RA patients compared to HC (OR 2.28) (Figure 1). HLA SE also differentiated HC vs CSAc (OR 1.69), CSAnc vs CSAc (OR 1.74), and CSAnc vs RA (0R 2.35). No difference was found in HC vs CSAnc and CSAc vs RA.

Conclusion: HLA SE is more prevalent in patients who developed (rheumatoid) arthritis than in both healthy controls and CSA patients who do not progress to arthritis. The results presented here seem to indicate a clear distinction between CSA patients who develop arthritis and those who do not. We therefore believe that known RA genetics play a role in the development of arthritis rather than the CSA symptoms. While this relationship varies by CCP status, an independent effect remains. Studies into the broader role of genetics beyond HLA SE are currently underway.

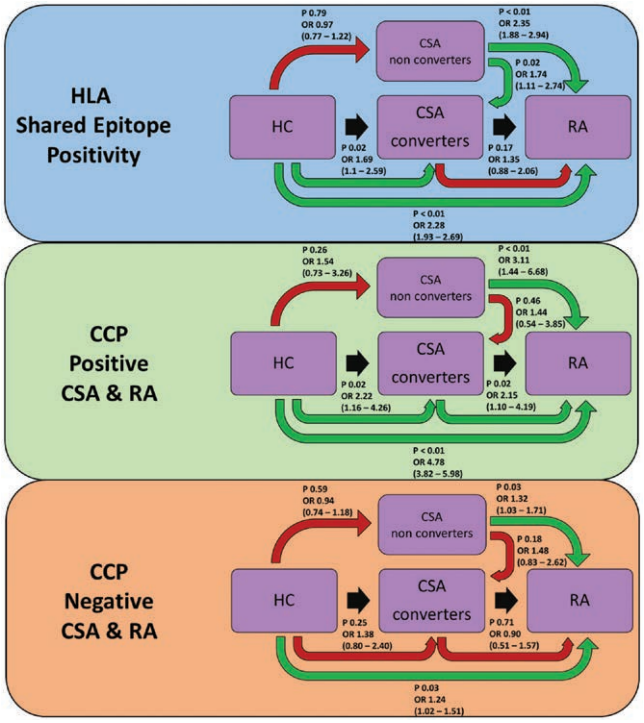

Figure 1. Distinguishing ability of HLA SE across HC, CSAc, CSAnc and RA in the full populations as well as in the CCP positive and negative stratifications. The arrowhead indicates the "case" status in each logistic regression. OR's (95% CI) derived from regression coefficients indicate the change in odds ratio attributable to HLA SE positivity.

Barton[1,2,3]. *[1]Manchester Royal Infirmary, Manchester University NHS Foundation Trust,The Kellgren Centre for Rheumatology, Manchester, United Kingdom*; *[2]The University of Manchester, NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester, United Kingdom*; *[3]The University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom*; *[4]Leeds Teaching Hospitals NHS Trust,Yorkshire and North East Genomic Laboratory Hub, Leeds, United Kingdom*; *[5]FIRALIS S.A., CSO (Molecular Diagnostics), Huningue, France*; *[6]FIRALIS S.A., CEO and CSO (Management Team), Huningue, France*; *[7]The University of Manchester,Arthritis Research UK, Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester Academic Health Sciences Centre, Manchester, United Kingdom*; *[8]University of Leeds, Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom*; *[9]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*; *[10]University College Dublin, UCD School of Medicine and Medical Science, Conway Institute, Dublin, Ireland*; *[11]Newcastle University, Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom*; *[12]Newcastle upon Tyne Hospitals NHS Foundation Trust, Musculoskeletal Unit, Newcastle upon Tyne, United Kingdom*

Background: Tumour necrosis factor inhibitors (TNFi) although effective in the treatment of rheumatoid arthritis (RA), show a variable response rate. Therefore, there is a need to identify treatment response predictors to inform therapy selection in order to practise precision medicine. MicroRNAs (miRNAs) are endogenous, single-stranded, non-coding RNAs that can alter gene expression by regulating messenger RNA translation. There is evidence for miRNA involvement in RA pathogenesis and they may serve as a useful biomarker of treatment response.
Objectives: To identify miRNAs associated with response to TNFi in RA.
Methods: Biologic naïve patients were selected from the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS), a prospective multi-center UK study investigating treatment response biomarkers to TNFi with a primary outcome measure of change in DAS28 scores. Patients were stratified into European League Against Rheumatism (EULAR) good or non-responders based on their 3 or 6-month DAS28-CRP score.
Pre-treatment and 3-month post-treatment serum samples were substrates for miRNA profiling, which was conducted by FIRALIS using the HTG EdgeSeq miRNA whole transcriptome V2 targeted sequencing assay. Linear modelling using R package limma compared miRNA expression at (i) pre-treatment and at three-months, in EULAR good-responders and non-responders (ii) longitudinal change in expression from pre-treatment to three-months in EULAR good and non-responders.
A literature search was conducted to identify miRNAs associated with RA as a diagnostic and/or treatment response predictor. Data on these miRNAs were extracted from the miRNAs identified in the serum samples. A correction for multiple testing was applied to statistical tests.
Results: A total of 54 patients were analysed; of these, 35 (65%) were female, median disease duration [inter-quartile range] was 6 years [2 – 14] (n=51), and 44/51 (86%) patients were on a concomitant disease modifying anti-rheumatic drug. Of the 54 patients, 39 (72%) were classified as EULAR good-responders and 15 (28%) as non-responders. 1880 miRNAs were detected in the serum samples. 64 miRNAs were identified to be associated with RA from the literature, of which, 26 were identified in the serum samples tested.
No difference in pre-treatment or three-month miRNA levels was seen comparing EULAR good-responders and non-responders **(FDR p<0.05)**. There was a significant differential expression of four miRNAs at 3-months in good-responders compared with pre-treatment levels; miR-125a-3p (downregulated, p-value 0.002), miR-149-3p (upregulated, p-value 0.004), miR-766-3p (downregulated, p-value 0.008), miR-146b-5p (upregulated, p-value 0.006). No significant differences were observed between 3-months and baseline in non-responders.
Conclusion: Although no pre-treatment miRNAs were associated with TNFi response, changes in the levels of four miRNAs were detected at 3-months compared to baseline in EULAR good-responders. Future work involves validation of these samples in a larger patient cohort and analysing miRNA levels at 6 and 12 months. Replication and validation of these results in larger studies are required to analyse the role of miRNAs in stratifying EULAR good-responders from non-responders at three-months, and as treatment response predictors to TNFi in RA.

POS0358 EVALUATION OF THE EFFECT OF mTOR EXPRESSION ON THE CLINICAL MANIFESTATIONS OF KNEE OSTEOARTHRITIS IN OBESE AND NORMAL WEIGHT PATIENTS

E. Strebkova[1], E. Tchetina[2], L. Alekseeva[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Osteoarthritis, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*

Background: Currently, a large number of molecular biological and genetic markers are known to be involved in the development of osteoarthritis (OA). The mammalian target of rapamycin (mTOR) signaling pathway is responsible for chondrocyte proliferation, cartilage matrix production, and cell growth. OA is characterized by increased mTOR synthesis, which is accompanied by an increase in proliferative activity and destruction of chondrocytes. Obesity is an important factor in the progression of knee OA. The study of mTOR expression in patients with OA and obesity is an urgent task in the development of personalized OA therapy.
Objectives: To determine the expression of mTOR in patients with knee OA in combination with obesity and normal body weight. To evaluate the effect of mTOR on the clinical manifestations of OA in patients with different body mass index (BMI).
Methods: The study included 73 female patients aged 45-65 y.o. with Kellgren-Lawrence stage II-III knee OA. The patients were divided into 2 groups: group 1 (n=50) with obesity (BMI > 30 kg / cm2) and group 2 (n=23) with normal or increased body weight (BMI < 30 kg/cm2). The average age of patients with obesity is 56.5 ± 5.87 years, without obesity - 58.7 ± 5.43 years. Clinical manifestations were evaluated by a WOMAC. RNA was isolated from the patients ' blood samples, which was used to determine the expression of mTOR.
Results: Patients with knee OA with and without obesity did not differ in age. OA develops at an earlier age in obese patients, than in non-obese patients (p < 0.001). Patients from 1 group had a high BMI > 30 kg/m2 at the onset of OA. Obese patients had more severe knee OA is significantly more often detected: Kellgren-Lawrence stage III was determined in 10% of obese patients and in 4.35% - without obesity (p < 0.001). Significantly higher values of the WOMAC index pain, stiffness, joint functional failure, and total WOMAC were observed in obese patients (p = 0.006, p = 0.039, p = 0.037, and p = 0.014, respectively). Obese patients had higher VAS pain scores (p < 0.05) compared to patients with a lower BMI. Obese patients had a higher mTOR expression (p < 0.05) of 8.02±8.62, compared to non-obese patients. High mTOR expression was associated with VAS knee pain (r=0.78; p < 0.05) and WOMAC pain (r=0.89; p<0.05) in obese patients (Table 1).

Table 1. Correlation of m-TOR

Parameters	mTOR (1 group, n=50)	mTOR (2 group, n=23)
Body weight	p > 0,05	p > 0,05
Pain (VAS)	r=0,78; p<0,05	p = 0,07; r = 0,45
Pain (WOMAC)	r=0,89; p<0,05	p > 0,05
Total WOMAC	p > 0,05	p > 0,05

Conclusion: Our study showed that patients with obesity and knee OA have higher rates of mTOR expression, compared to patients with normal body weight. High mTOR expression correlates with the severity of knee pain in obese patients. Thus, the evaluation of mTOR expression in obese patients and knee OA plays an important role in predicting the severity of clinical manifestations of OA, and may influence the choice of personalized therapy tactics for such patients.

Background: The response to treatment in spondylarthropaties is heterogeneous, due to factors yet to be better described. For that reason, it is important to find tools that might help clinicians to decide what is the best available therapeutic option for each patient.
Objectives: The goal of this study is to use comprehensive molecular profiling to characterize clinical response to therapy in a real-world setting. Specifically, to identify molecular biomarkers differentiating good responders and non-responders to TNF inhibitors (TNFi) treatment, using adalimumab, in radiographic axial spondyloarthritis | ankylosing spondylitis (r-axSpA|AS) patients context.
Methods: Whole-blood mRNA and plasma proteins were measured in a cohort of biologic naïve r-axSpA|AS patients (n = 35) from the Bioefficacy study (Biomarkers identification of anti-TNF alpha agent efficacy in AS patients using RNA sequencing and mass spectrometry), pre and post (14 weeks) TNFi treatment using adalimumab. Response to treatment was categorized according to ASAS20. Results of differential expression analysis were used to identify the most enriched pathways and in predictive models to distinguish responses to TNFi.
Results: A treatment-related signature, independent of the type of response, suggests a reduction in inflammatory disease activity. We found genes and proteins robustly differentially expressed between baseline and week 14 in responders, including the GWAS AS-associated genes *TNFRSF1A, FCGR2A, TYK2, TBKBP1, IL1R1, IL6R, ICOSLG, IL7R, HHAT and LTBR*. Moreover, CRP and HP proteins showed strong and early decrease in the plasma of AS patients, while a cluster of apolipoproteins (APO1, APO2, APO3) showed an increased expression at week 14. Good responders to TNFi treatment tend to have higher expression of innate immunity genes at baseline, and lower expression of markers associated with adaptive immunity, particularly B-cells. A logistic regression model incorporating ASDAS-CRP, gender and *Gene x*, the top differentially expressed gene at baseline between responders and non-responders, enabled an accurate prediction of response to adalimumab in our cohort (AUC=0.97).
Conclusion: Differences in disease activity and/or innate/adaptive immune cell type composition at baseline may be a major contributor to response to adalimumab in r-axSpA|AS. Alternatively, a model including clinical and gene expression variables could be considered, particularly in patients with mild disease activity.

POS0360 COMPLEX LANDSCAPE OF BIRC5/SURVIVIN GENOME BINDING IN HUMAN CD4+ T CELLS

N. Oparina[1], M. Erlandsson[1], V. Chandrasekaran[1], K. M. Andersson[2], A. Damdimopoulos[3], S. Töyrä Silfverswärd[4], G. Katona[5], M. I. Bokarewa[1]. *[1]University of Gothenburg, Department of Rheumatology and Inflammation Research, Institute of Medicine, Gothenburg, Sweden*; *[1]University of Gothenburg, Department of Rheumatology and Inflammation Research, Institute of Medicine, Gothenburg, Sweden*; *[3]Karolinska Institutet, Department of Bioscience and Nutrition, Huddinge, Sweden*; *[4]Sahlgrenska University Hospital, Rheumatology Clinic, Gothenburg, Sweden*; *[5]University of Gothenburg, Department of Chemistry and Molecular Biology, Gothenburg, Sweden*

Background: Survivin, coded by BIRC5 gene, is a multitasking protein essential for cell renewal and homeostasis. In autoimmune conditions as rheumatoid and psoriasis arthritis, survivin was associated with inflammation severity and joint damage. Importantly, inhibition of survivin alleviated experimental arthritis in mice. We have recently shown survivin to be essential for T cell differentiation and microRNA processing. The known anti-apoptotic and proliferation facilitating functions of survivin does not explain the nuclear localization of survivin in interphase.
Objectives: We aimed to uncover nuclear functions of BIRC5/survivin in CD4 cell of RA patients and healthy.
Methods: CD4 T cells were isolated from the peripheral blood using positive selection on magnetic beads (EasySep) and activated for 48h with ConA+LPS. Chromatin immunoprecipitation (ChIP) with polyclonal anti-survivin antibodies was done in four independent samples of healthy donors (n=5), healthy smokers (n=3), rheumatoid arthritis (n=3) and breast cancer (n=2). Pooled libraries were constructed for each group and ChIPseq was carried out (Illumina). For comparative RNAseq analysis, activated CD4 T cells were incubated with or without survivin inhibitor (YM155) for 24h. State-of-the-art bioinformatics pipelines were applied for NGS data and the survivin-binding peaks were used for comparison with genes, chromatin state annotation and functional gene- and regulatory regions-based functional analysis. Co-localization of peaks in the whole genome and in vicinity of the differentially expressed genes (DEG) was done using ReMap integrated ChIPseq datasets for all human cells and tissues.
Results: We identified 13 thousands non-overlapping survivin ChIP-peaks (>3000 peaks were present in at least 3 samples). Survivin-bound regions were enriched near the genes and promoters (p=e-30 and p=e-8), which implied that survivin role in transcription could be mediated by known transcription factors. Thus, we analyzed survivin peaks vs binding regions of 1135 transcription regulators (TR) available in ReMap. Potential partner proteins of survivin were selected based on the enrichment of the overlapping peaks in the whole genome and in CD4-active regulatory areas. Both, strict overlaps and location within 10 and 100kb survivin peak vicinity were analyzed. This approach allowed us to select >150 TRs enriched in all tests. The enriched TRs were involved in immunity and RA-relevant pathways including cytokine response and production, JAK-STAT signaling, etc. Among the TRs co-localized with survivin were CHD8, MAX, EP300, BRD2, CTCF and RAD21, all responsible for chromatin architecture. Several TRs were massively enriched in the vicinity of DEGs after survivin depletion including MAX, AR, CTCF, MYC and IRF1. Search for TR binding motifs in survivin peaks supported over-representation of binding sites for IRFs (p=e-5) and several proteins of the bZIP-family (p=e-5).
Conclusion: Analysis of the survivin bound DNA in CD4 cells demonstrated the nonrandom distribution with specific enrichment within the regulatory elements of the genes and co-localizeation with protein partners to regulate their transcription.

POS0361 DNA METHYLATION SIGNATURES CHARACTERIZE PSORIASIS AND PSORIATIC ARTHRITIS IN MONOZYGOTIC TWINS DISCORDANT FOR THE DISEASE

M. Vecellio[1,2], A. Ceribelli[2], E. Paraboschi[3], N. Isailovic[2], F. Motta[2], M. De Santis[2], R. Asselta[3], S. Duga[3], C. Selmi[2]. *[1]University of Oxford, NDORMS, Oxford, United Kingdom*; *[2]Humanitas Research Hospital, Rheumatology and Clinical Immunology, Rozzano, Italy*; *[3]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Italy*

Background: Psoriatic disease is a chronic inflammatory disorder spanning from skin disease (psoriasis) to psoriatic arthritis (PsA). The genetic background is insufficient to explain disease onset as illustrated by not very informative Genome Wide Association Studies and monozygotic (MZ) twin studies recently performed. It is strongly assumed that epigenetics may contribute to disease susceptibility modulating gene expression. DNA methylation has been found involved in several autoimmune inflammatory rheumatic diseases. Here we have analysed the DNA methylation profile of a selected cohort of MZ twins discordant for psoriasis/PsA.
Objectives: To identify the methylome associated with psoriasis and PsA in the peripheral blood of MZ twins discordant for these conditions.
Methods: Peripheral blood from 7 couples of MZ twins discordant for psoriatic disease was collected and DNA extracted for a genome-wide evaluation of the DNA methylation profile, with the Infinium MethylationEPIC BeadChip. *Minfi* and the packages of the Bioconductor were used to analyse the data obtained. Quality control and exclusion criteria were applied to the raw data having a final number of 762.451 probes, which accounts for 88% of the total.
Results: The approach first identified 2564 differentially methylated positions (DMPs; *p<0.005) with 19 genes potentially affected (with at least two DMPs within 1 kb of distance), including SMAD3 and SMARCA4/BRG1 involved in the Interferon and TGFβ pathways. Gene Ontology (GO) analysis of DMP-associated genes showed a significative enrichment (*p<0.005) in transcription factor binding, transcription corepressor and transcription coactivator activity, SMAD binding and histone -lysine-N-methyltransferase activity. To further validate the results, 5'-methylcytosine immunoprecipitation (MedIP) followed by Real Time PCR was performed to assess the methylation level of SMAD3 and SMARCA4/BRG1 promoters in the same cohort of MZ twins. We found significantly DNA methylation enrichment in SMARCA4/BRG1 promoter in psoriatic disease twins (p<0.05). SMAD3 and SMARCA4/BRG1 mRNA expression was also assessed to evaluate any inverse correlation with promoter methylation level, on the MZ cohort used for the EPIC array (n=4) and on a cohort of PsA/Ps patients (n=8) and appropriate healthy controls (n=3). Reduced mRNA expression (p<0.05) was demonstrated for SMARCA4/BRG1 (n=4). Conversely, no changes were found for SMAD3.
Conclusion: We report the first DNA methylation approach in MZ twins discordant for psoriatic disease. We believe that the observed changes in SMAD3

and SMARCA/BRG1 genes may suggest an epigenetic imbalance of chromatin remodelling factors involved in inflammation pathways with a potential role in PsA/psoriasis immunopathogenesis.

POS0362 **INVESTIGATING THE ANKYLOSING SPONDYLITIS-ASSOCIATED REGULATORY SNPS AT THE RUNX3 LOCUS WITH A FUNCTIONAL GENOMICS APPROACH**

M. Vecellio[1], P. B. Wordsworth[1], C. J. Cohen[1]. [1]*University of Oxford, NDORMS, Oxford, United Kingdom*

Background: Of the >100 genetic associations with ankylosing spondylitis (AS), RUNX3 transcription factor (TF) involved in diverse immunological processes, is robustly (10^{-15}) associated.[1] The biggest challenge is to understand the mechanism behind this association. We demonstrated the association between AS and the single nucleotide polymorphism (SNP) *rs4648889* located in a 2kb regulatory locus upstream of the *RUNX3* promoter can be explained by allele-specific effects on TF recruitment that alter gene expression, specifically in CD8+ T-cells.[2] We recently dissected the full plethora of TFs affected by *rs4648889* AS-associated allele showing the NuRD complex and IRF5 differentially bound and having a crucial role in CD8+ T-cells function[3]. Nevertheless, other post-GWAS approaches are needed to elucidate the function of *RUNX3* AS-associated SNPs (i.e. the lead SNP *rs6600247*).
Objectives: The purpose of this work is to define the functional effect of *rs6622047* in CD8+ T-cells and monocytes. In specific, we expect to define the impact of AS-associated allele to TF binding and to evaluate chromosome looping between *rs6600247* and the RUNX3 promoter.
Methods: The epigenetic landscape of SNP *rs6600247* was defined using Roadmap database. *In vitro* functional studies were performed to characterize the effects of this SNP on TFs binding. Chromosome conformation capture (3C) provided critical functional evidence for looping among AS-associated SNPs and the *RUNX3* promoter.
Results: (1) *In silico* data revealed a c-MYC ChIP-seq peak in GM12878 lymphoblastoid cells overlapping *rs6600247*; (2) Mobility shift assays (EMSAs) and WB-EMSAs showed reduced DNA/protein binding in the presence of the AS-risk allele in CD14+ monocytes. C-MYC binding-site is disrupted and binding abolished in the presence of the AS-risk allele; (3) 3C experiments indicate low interaction frequency between SNP *rs6600247* and RUNX3 promoter.
Conclusion: The enhancer upstream the *RUNX3* gene has a plausible functional role in AS, probably by regulating gene transcription and DNA looping. These observations are critically important in defining dysregulated pathways and potential therapeutic drug targets.

Background: Psoriatic arthritis (PsA) is an inflammatory musculoskeletal disease associated with cutaneous psoriasis[1]. Heterogeneity of clinical manifestation often makes differential diagnosis difficult [2]. Thus, the underlying molecular pathogenesis of PsA need to be further studied to diagnose early and ensure optimal management of arthritis and key comorbidities.
Objectives: This research was conducted to identify molecular phenotypes and immune infiltration in the skin tissues of psoriatic arthritis patients according to bioinformatics analysis.
Methods: The mRNA expression profiles of GSE13355 (116 samples), GSE14905 (56 samples) and GSE30999 (162 samples) were obtained from the publicly GEO databases. Non-negative matrix factorization (NMF), functional enrichment and cibersort algorithm were applied to illustrate the conditions of PsA patients' skin tissues for classification after screening the differentially expressed genes (DEGs) between lesion biopsy and non-lesion biopsy.
Results: Two subsets (Sub1 and Sub2) were identified and validated by NMF typing of 612 detected DEGs (Figure 1a). A total of 54 signature genes (18 in Sub1 and 36 in Sub2) were obtained (Figure 1b). GO and KEGG enrichment analysis showed the signature genes in Sub1 were mainly involved in proliferation and differentiation of immune cells, whereas genes in Sub2 were related to humoral immune response mediated by antimicrobial peptide (Figure 1c.1d). Further, immune cell infiltration results revealed Sub2 had higher levels of resting NK cells (P<0.001), macrophages M1(P<0.001), resting mast cells (P<0.001) and regulatory T cells (P<0.001) but lower concentrations of activated $CD4^+$ memory T cells (P<0.001), activated NK cells (P<0.05), activated dendritic cells(P<0.001), eosinophils (P<0.05) and neutrophil (P<0.001) (Figure 1e).
Conclusion: The pathogenesis of psoriatic arthritis is related to both cellular immunity and humoral immunity. It is indispensable to adjust the treatment strategies according to patient's immune status.

Innate immunity in rheumatic diseases

POS0364

EFFECT OF BIOLOGIC DMARDS TREATMENT ON GENE EXPRESSION AND ACTIVITY OF NATURAL KILLER CELLS IN RHEUMATOID ARTHRITIS

N. M. Elemam[1], M. Hachim[2], S. Hannawi[3], A. A. Maghazachi[1]on behalf of Immuno-Oncology Group. [1]*Sharjah Institute for Medical Research, University of Sharjah, College of Medicine, Sharjah, United Arab Emirates*; [2]*Mohammed Bin Rashid University of Medicine and Health Sciences, College of Medicine, Dubai, United Arab Emirates*; [3]*Ministry of Health and Prevention, Department of Rheumatology, Dubai, United Arab Emirates*

Background: Rheumatoid arthritis (RA) is the most common inflammatory type of arthritis, with various immune players implicated in its pathogenesis. Natural killer (NK) cells are innate lymphocytes that showed controversial roles in RA, whether pathogenic or protective (Shegarfi, H. et al. 2012, Yap, H.-Y. et al. 2018). Previously, we were able to identify a gene signature in NK cells of RA patients that can aid in understanding the state of NK cells in RA disease and identify RA patients from healthy controls (Elemam, N.M. et al. 2019, Elemam, N.M. et al. 2020). Furthermore, this signature might facilitate the selection of biomarkers that can be used for early detection of RA and prediction of effectiveness of RA treatment.

Objectives: In this study we aimed at exploring the effect of several RA therapeutic agents such as tocilizumab, rituximab and anti-TNFα (adalimumab, etanercept and golimumab) on the previously identified gene signature in NK cells of RA patients.

Methods: Whole blood transcriptomic data from publicly available dataset (GSE93272) was used to predict the percentage of activated NK cells in the blood of RA patients using the software CIBERSORT. Then, a correlation analysis was done between the percentage of NK cells and number of days of receiving tocilizumab treatment. Whole blood samples were collected from the recruited 17 RA patients (satisfying the 2010 ACR/EULAR classification criteria for RA). NK cells were isolated using RosetteSep negative selection method and RNA was extracted and gene expression was assessed using qRT-PCR. RA patients taking tocilizumab, rituximab, or anti-TNFα (adalimumab, etanercept or golimumab but none of the patients received infliximab) were compared to those not receiving any biological DMARDs. Statistical analysis was done using Student's t-test.

Results: In silico analysis has shown that the percentage of activated NK cells is positively correlated with the number of days of tocilizumab therapy in RA patients, suggesting a direct enhancing effect of tocilizumab on NK cell activity. Then, it was crucial to investigate the effect of different biological DMARDs on NK gene expression in RA patients. All the investigated chemokines (CCL2, CXCL10, CXCL16, CXCR1, CXCR2, CXCR6 and CCR4) in the identified gene signature showed a significant change in RA patients receiving tocilizumab, rituximab, or anti-TNFα therapies. Furthermore, the other genes including RELA, ICAM, IL1RN, TLR3 and TLR10 were significantly changed in NK cells of RA patients receiving biological DMARDs in comparison to patients not receiving the treatments. However, some of the genes including CD56, BTK, IBTK, ITGB7, IL1B, PECAM-1, IL12RB2, IFNG and CKLF did not show a significant change upon receipt of biological DMARDs.

Conclusion: In conclusion, NK cell activity and gene expression could be affected by the type of biological DMARDs received by RA patients. Therefore, this identified gene signature of NK cells could be used as a diagnostic tool to identify RA patients and a target for biological DMARDs in RA.

ANTI-TNF GLUCOCORTICOID RECEPTOR MODULATOR ANTIBODY DRUG CONJUGATE FOR THE TREATMENT OF AUTOIMMUNE DISEASES

B. Stoffel[1], M. McPherson[2], A. Hernandez[2], C. Goess[1], S. Mathieu[1], W. Waegell[1], S. Bryant[1], A. Hobson[2], M. Ruzek[1], Y. Pang[3], H. Kupper[4], R. D'Cunha[3], J. Parmentier[5], T. Radstake[6]. [1]*AbbVie Bioresearch Center, Immunology Discovery, Worcester, United States of America*; [2]*AbbVie Bioresearch Center, Biologics Discovery, Worcester, United States of America*; [3]*AbbVie, Clinical Pharmacology, North Chicago, United States of America*; [4]*AbbVie, Clinical Development, Ludwigshafen, Germany*; [5]*AbbVie Bioresearch Center, Precision Medicine, Worcester, United States of America*; [6]*AbbVie, Clinical Development, North Chicago, United States of America*

Background: Glucocorticoids (GC) are potent drugs used for treating many inflammatory diseases. While GCs are effective in many immune diseases, dose and duration of administration is limited due to significant side effects. Resting immune cells have very little TNF expression on the cell surface and it is only in an activated state that TNF expression is upregulated. Upon immune cell stimulation, TNF is upregulated and although a significant amount of TNF is cleaved from an activated cell, a portion remains on the cell surface. We have observed that anti-TNF antibodies bind to transmembrane TNF (tmTNF) and undergo endocytosis to the lysosome (1). We have developed a stable antibody drug conjugate (ADC), ABBV-3373, that has a proprietary, highly potent, glucocorticoid receptor modulator (GRM) payload linked to an anti-TNF monoclonal antibody (mAb) that is able to deliver the GC payload to activated immune cells.

Objectives: We hypothesized that a TNF ADC with a GRM payload would be able to deliver increased efficacy through both TNF inhibition and targeted GRM payload delivery to activated immune cells while sparing systemic glucocorticoid side effects.

Methods: A mouse surrogate TNF GRM ADC was characterized in an acute *in vivo* contact hypersensitivity model of inflammation (CHS) and in a mouse model of collagen induced arthritis (mCIA). Additionally, the human anti-TNF GRM ADC, ABBV-3373 has been characterized in healthy volunteers.

Results: In the CHS model the anti-TNF GRM ADC significantly inhibited the inflammatory response with minimal effect on systemic GC biomarkers. In mCIA a single dose of an anti-TNF GRM ADC, administered at disease onset, was able to completely inhibit arthritis for greater than 30 days while an anti-TNF mAb only partially inhibited disease. ABBV-3373, a human anti-TNF GRM ADC with a GC payload, was evaluated in a Phase 1 study in healthy volunteers. ABBV-3373 demonstrated antibody-like PK profile and ABBV-3373 did not impact cortisol levels at predicted efficacious doses while control subjects that received a single oral dose of 10 mg prednisone demonstrated expected decreases in cortisol levels.

Conclusion: These data suggest that an anti-TNF ADC delivering a GRM payload into activated immune cells may provide improved efficacy in immune mediated diseases, while minimizing systemic side effects associated with standard GC treatment.

POS0366 PRO-INFLAMMATORY EFFECTS OF HUMAN APATITE CRYSTALS EXTRACTED FROM PATIENTS SUFFERING FROM CALCIFIC TENDINOPATHY

J. Herman[1,2], B. Le Goff[1,2], J. De Lima[2], R. Brion[2], C. Chevalier[2], F. Blanchard[2], C. Darrieutort-Laffite[1,2]. [1]*Nantes University Hospital, Rheumatology, NANTES, France*; [2]*INSERM-UMR1238, Phy-Os Laboratory, Nantes, France*

Background: Calcific tendonitis of the rotator cuff is due to carbonated apatite deposits in the shoulder tendons. During the evolution of the disease, an acute inflammatory episode may occur leading to the disappearance of the calcification. Although hydroxyapatite crystals-induced inflammation has been previously studied with synthetic crystals, no data are available with calcifications extracted from patients suffering from calcific tendinopathy. The objective of the study was to explore the inflammatory properties of human calcifications and the pathways involved.
Objectives: The objective of the study was to explore the inflammatory properties of human calcifications and the pathways involved.
Methods: Human calcifications were obtained from patients treated for their shoulder pain related to a calcific tendinopathy of the rotator cuff. Calcifications were extracted by ultrasound-guided lavage and aspiration as previously described [1]. Human calcifications and synthetic hydroxyapatite (sHA) were used *in vitro* to stimulate human monocytes and macrophages, the human myeloid cell line THP-1 and human tenocytes. The release of IL-1β, IL-6 and IL-8 by cells was quantified by ELISA. Gene expression of pro- and anti-inflammatory cytokines was evaluated by quantitative PCR. NF-kB activation and NLRP3 involvement was assessed in THP-1 cells using a NF-kB inhibitor and a Caspase 1 inhibitor. The inflammatory properties were then assessed *in vivo* using a mouse air pouch model. The membrane thickness and infiltrate were assessed 6 and 24 hours after the injection of human calcifications or synthetic hydroxyapatite using hematoxylin and eosin staining. Macrophages, neutrophils and lymphocytes infiltrates were assessed by immunohistochemistry. Total RNA was extracted from the membranes and expression of IL-1β, IL-6 and TNFβ was quantified by PCR.
Results: Human calcifications were able to induce a significant release of IL-1β when incubated with monocytes, macrophages and THP-1 only if they were first primed with LPS (lipopolysaccharide) for monocytes and macrophages or PMA (Phorbol 12-myristate 13-acetate) for THP-1. No IL-1β was detected in tenocytes' supernatants. Stimulation of THP-1 by human calcifications led to similar levels of IL-1β when compared to synthetic hydroxyapatite although these levels were significantly inferior in monocytes and macrophages. IL-6 and IL-8 levels were not increased in the supernatants after crystal stimulation. Patient's crystals enhanced mRNA expression of pro-IL-1β, as well as IL-18, NF-kB and TGFβ when IL-6 and TNFα expression were not. IL-1β production was reduced by the inhibition NF-kB as well as Caspase 1 indicating the role of NLRP3 inflammasome. In vivo, injection of human calcifications or synthetic hydroxyapatite in air pouch led to significant increase in membrane thickness with an infiltrate mainly composed of macrophages. Significant overexpression of IL-1β was only observed in the synthetic hydroxyapatite group.
Conclusion: As synthetic hydroxyapatite, human calcifications were able to induce an inflammatory response resulting in the production of IL-1β after NF-kB activation and through NLRP3 inflammasome. In some experiments, IL-1β induction was lower with human calcifications compared to synthetic apatite. Differences in size, shape and protein content may explain this observation.

Background: Rheumatoid arthritis (RA) is an autoimmune disorder in which Th17 cells, B cells and inflammatory cytokines (1-3) contribute to joint tissue damage, however the role of specific myeloid populations to immunopathogenesis of RA remains unclear.
Objectives: To address this question, we studied transcriptional, phenotypical and functional characteristics of monocytes (Mo), CD1c$^+$ and CD141$^+$ conventional dendritic cells (cDC) from RA patients.
Methods: Frequencies and maturation patterns of Lin-CD14-HLADR+ plasmacytoid (CD11c-), CD1c+ and CD141+ cDC (CD11c+) subsets and CD14+ Mo from n=25 RA patients at baseline were analyzed by multicolor flow cytometry. In addition, longitudinal studies on the evolution of these populations after treatment initiation were conducted on a smaller group of RA patients. Moreover, CD1c+ and CD141+ cDC subsets and total Mo were sorted from the peripheral blood from n=4 untreated RA and healthy individuals and the synovial fluid from n=3 RA and chondrocalcinosis patients. Differential transcriptional patterns within each population were analyzed by RNAseq. Functional validation of targets were performed in vitro with cDC subsets isolated form the synoviual fluid of RA patients. Finally, silencing of expression of NLRC4 and NLRP3 on CD1c+cDCs was performed with specific siRNAs.
Results: Both CD1c$^+$ (p=0.0001) and CD141$^+$ (p=0.0008) cDCs were significantly depleted from the blood and enriched in the synovial fluid from untreated RA patients, but proportions of CD1c+ cDCs were more significantly recovered after treatment initiation and associated with improved clinical parameters. In addition, specific increased expression levels of the IgG-Fc receptor CD64 on CD1c$^+$ cDC was associated with higher DAS28 (p=0.0002). Moreover, differential transcriptional patterns of circulating CD1c$^+$cDCs from RA patients were characterized by genes linked to toll-like receptor, Fc-receptor, inflammasome pathways and elevated CCR2 expression (p=0.016), while CD141$^+$cDCs transcribed interferon-related genes. Importantly, CCR2$^+$ CD64^{Hi} CD1c$^+$cDCs from the synovial fluid from RA patients transcribed proinflammatory cytokines such as IL1-β, CCL3 and IL-8, actively expressed the inflammasome mediator caspase 1 and were more effective activating pathogenic IFNγ$^+$IL-17$^+$ CD4$^+$ T cells *in vitro* than CD141$^+$ cDC (p=0.0019). These functional profiles could be artificially induced stimulating CD1c$^+$ cDCs with dsDNA in the presence of IgGs and was dependent on caspase 1 and the NLRC4 inflammasome.
Conclusion: Our data provides novel insights about specific activation and functional patterns on CD1c$^+$cDC contributing to RA pathogenesis and identifies new sensors that could represent novel therapeutic target to treat RA.

POS0368 CITRULLINATION INDUCES EPIGENETIC MEMORY OF THE INNATE IMMUNE SYSTEM

K. Laskari[1], S. Sabu[1], O. Distler[1], M. Neidhart[1], E. Karouzakis[1,2]. [1]*University Hospital Zurich, University of Zurich, Department of Rheumatology, Center of Experimental Rheumatology, Zurich, Switzerland*; [2]*Galapagos, Translational Medicine, Basel, Switzerland*

Background: During trained immunity, monocytes and macrophages undergo a functional and transcriptional reprogramming toward activation, which is induced by a priming stimulus and results in enhanced responsiveness to subsequent triggers. Monocytes from patients with rheumatoid arthritis (RA) display features consistent with a trained immunity phenotype. Citrullinated proteins as citrullinated vimentin (c-vimentin), which function as damage-associated patterns in RA, may be implicated in the process of trained immunity.
Objectives: We aimed to investigate if c-vimentin induces trained immunity in vitro in healthy individuals.
Methods: Monocytes were isolated from the peripheral blood (EDTA blood, n=22; buffy coats, n=6) from healthy donors by Ficoll-paque centrifugation and negative selection using CD3/CD19/CD56 magnetic beads. The cells were stimulated with c-vimentin (0.1 µg/ml) for 24h and re-stimulated 5 days later with the lipopolysaccharide of *E.coli* (LPS) (10 ng/ml). Protein as well as lactate release were estimated in cell culture supernatants at day 6 by ELISA. RT-PCR and/or Western Blotting were applied to measure mRNA and/or protein expression. The Ligand-receptor glycocapture technology LRC-TRiCEPS was used to identify candidate cell surface targets of c-vimentin. The methylation of histone H3 at lysine 4 (H3K4) was examined by chromatin immunoprecipitation.
Results: Priming with citrullinated vimentin induced training in human monocytes, as suggested by the significantly increased levels of secreted interleukin-6 (IL-6), upon restimulation with LPS (1.29-fold increase, n=22, p<0.001). Likewise, the release of chemokines CXCL1 and CCL20/Macrophage Inflammatory Protein 3a was significantly increased (1.81-fold and 2.32-fold increase, respectively, n=14, both p<0.001). LRC-TRiCEPS enabled the identification of STING cell surface receptor for the ligand c-vimentin. Indeed, c-vimentin induced activation of TBK1, which is implicated in the STING signaling pathway, by phosphorylation, while STING inhibition with the covalent small molecule H151 (2µM) abolished this effect. Besides, H151 inhibited trained immunity by decreasing IL-6 release and expression (1.61-fold and 1.93-fold decrease, respectively, n=5). Trained monocytes also displayed high lactate production (primed vs. unprimed cells, n=9, p=0.004), reflecting a shift in metabolism with an increase in glycolysis. By inhibiting the metabolic pathway of glycolysis by 2-deoxyglucose (11mM), the induction of trained immunity could be counteracted (5.32-fold decrease in IL-6 release, n=7, p=0.016). Finally, c-vimentin induced H3K4 methylation with increased levels of this mark in the promoter of the IL-6 gene. By modulating the function of epigenetic enzymes with methylthioadenosine (1mM), which specifically inhibits histone methyltransferase, trained immunity was reversed (8.43-fold decrease in IL-6 release, n=6, p=0.031).
Conclusion: Citrullinated vimentin induces epigenetic modifications and metabolic changes in monocytes, probably through a STING and TBK1-dependent activation, resulting in enhanced cytokine and chemokine production upon restimulation. Inhibition of the STING signaling pathway may be a novel therapeutic target for myeloid activation in RA.

POS0369 ELEVATED EXPRESSION OF TIM-3 ON NEUTROPHILS CORRELATES WITH DISEASE ACTIVITY AND SEVERITY OF ANKYLOSING SPONDYLITIS

X. Huang[1], T. W. Li[1], J. Chen[1], Z. Huang[1], S. Chen[1], X. Guo[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Ankylosing spondylitis (AS) is a type of common, chronic inflammatory disease that compromises the axial skeleton and sacroiliac joints, causing inflammatory low back pain and progressive spinal stiffness, over time some patients develop spinal immobility and ankylosis which can lead to a decrease in quality of life. The last few decades, evidence has clearly indicated that neutrophil also plays key roles in the progression of AS. However, the immunomodulatory roles and mechanisms of neutrophils in AS are poorly understood. T-cell immunoglobulin and mucin domain-containing protein 3 (Tim-3) has been reported as an important regulatory molecule, expressed and regulated on different innate immune cells, plays a pivotal role in several autoimmunity diseases. Recent study indicates that Tim3 is also expressed on neutrophils. However, the frequency and roles of Tim3-expressing neutrophils in AS was not clear.
Objectives: In this study, we investigated the expression of Tim3 on neutrophils in AS patients and explored the correlation between the level of Tim3-expressing neutrophils and the disease activity and severity of AS.
Methods: Patients with AS were recruited from Guangdong Second Provincial General Hospital (n=62). Age/sex-matched volunteers as Healthy controls (HC) (n=39). The medical history, clinical manifestations, physical examination, laboratory measurements were recorded. The expression of costimulatory molecules including programmed death 1 (PD-1), Tim-3 on neutrophils were determined by flow cytometry. The mRNA expression of PD-1 and Tim-3 was determined by real-time PCR. The levels of Tim3-expressing neutrophils in AS patients were further analyzed for their correlation with the markers of inflammation such as ESR,CRP,WBC and neutrophil count(NE), as well as disease activity and severity of AS. The expression of Tim3 on neutrophils was monitored during the course of treatment (4 weeks).
Results: The expression of Tim3 on neutrophils in patients with AS was increased compared to the HC (Figure 1A). However, significant difference was observed in the frequency of PD-1-expressing neutrophils between AS patients and HC (Figure 1B). The expression analysis of Tim-3 mRNA, but not PD-1, confirmed the results obtained from flow cytometry (Figure 1C). The level of Tim3-expressing neutrophils in patients with AS showed an positive correlation with ESR, CRP and ASAS-endorsed disease activity score (ASDAS) (Figure 1D). Moreover, the frequency of Tim3-expressing neutrophils in active patients(ASDAS≥1.3) was increased as compare with the inactive patients (ASDAS<1.3) (Figure 1E). As shown in Figure 1F, the frequency of Tim3-expressing neutrophils decreased after the treatment.

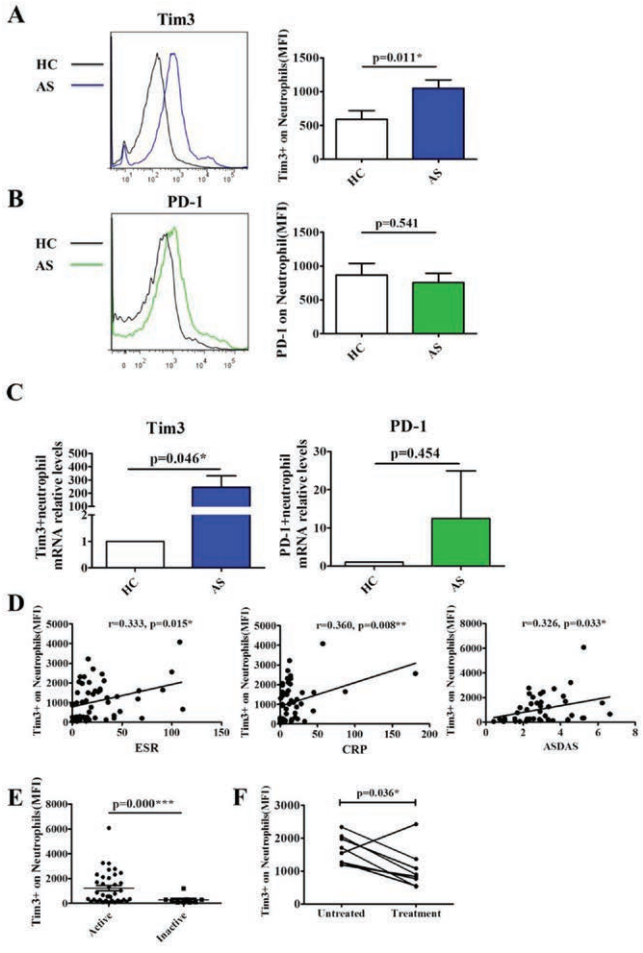

Figure 1. (A,B) The expression of Tim3 and PD-1 on neutrophils in AS and HC were determined by flow cytometry.**(C)** The expression of Tim3 and PD-1 on neutrophils in AS and HC were determined by RT-PCR.**(D)**The correction between Tim3-expressing neutrophils and ESR,CRP,ASDAS.**(E)** The expression of Tim3 on neutrophils in active and inactive patients.**(F)** Influence of treatment on the frequency of Tim3-expressing neutrophils.

Conclusion: Increased Tim-3 expression on neutrophils may be a novel indicator to assess disease activity and severity in AS, which may serves as a negative feedback mechanism preventing potential tissue damage caused by excessive inflammatory responses in AS patients.

Background: The interferon (IFN) pathway is a complex system with multiple proteins and diverse downstream effects on gene and protein expression. IFNs have been implicated in multiple RMDs. Despite significant potential, IFN assays have not progressed into clinical practice.

Objectives: To perform a SLR on IFN assays in RMDs and propose a consensus terminology.

Methods: OvidMedline, Embase and Web of Science were searched for reports of IFN and RMDs up to October 2019. Information about the properties of assays measuring type I IFN and measures of truth were extracted and summarised. Terminology was agreed through an interactive consensus process with reference to the existing evidence.

Results: 10037 abstracts were identified. 275 fulfilled eligibility criteria, and were used for data extraction. Some used more than one technique to measure IFN-I pathway activation. Hence, 275 papers generated data on 393 methods. There was great heterogeneity in the methods used and presentation of results. IFN-I pathway activation was measured using: qPCR (n=121), immunoassays (n=101), microarray (n=69), reporter cell assay (n=38), DNA methylation (n=14), flow cytometry (n=14), cytopathic effect assay (n=11), RNA sequencing (n=9), Plaque reduction assay (n=8), Nanostring (n=5), bisulphite sequencing (n=3). All papers fulfilled Face Validity. Due to lack of gold standard for IFN-I pathway activation, evidence of criterion validity was variable. Concurrent validity was presented for n=150 assays. The terminology used to describe aspects of type I IFN pathway activation was not consistent, so a consensus terminology for IFN research (Table 1) was proposed by the taskforce.

Table 1. Consensus terminology

Term	Abbreviation	Definition
Interferon	IFN	Proteins with anti-viral activity; IFNs are mediators of an anti-viral response. They belong to the Type I, Type II and Type III IFN families.
Type I interferon	IFN-I	The IFNs alpha, beta, omega, kappa, epsilon, secreted by any nucleated cell, and binding to the IFNAR, which is expressed on any nucleated cell.
Type II interferon	IFN-II	IFN gamma, mostly secreted by T cells, binding to the IFNGR, which is expressed on most leucocytes.
Type III interferon	IFN-III	IFN lambda, which are structurally more similar to IL-10 but share downstream signalling and gene expression with IFN-I.
Interferon-stimulated genes	ISGs	Genes whose expression is known to be upregulated by any kind of IFN. Individual ISGs may not exclusively represent Type I IFN pathway activation.
Type I Interferon pathway activation		Any evidence for function of the components of the Type I IFN pathway. This includes: secretion of a Type I IFN protein, binding to the IFNAR, initiation of JAK/STAT signalling pathways, expression of IFN-stimulated genes, expression of IFN-stimulated proteins.
Type I interferon pathway assay		An assay measuring one or more components of the Type I IFN pathway at a molecular or functional level.
Interferon stimulated gene expression signature		A qualitative description of coordinated expression of a set of ISGs that is indicative of Type I IFN pathway activation.
Interferon stimulated gene expression score		A quantitative variable derived from expression of a defined set of ISGs that is indicative of Type I IFN pathway activation.
Interferon stimulated protein score		A variable derived from expression of a defined set of soluble biomarkers known to be upregulated by IFN, although not specific for Type I IFN.
Interferonopathy		Monogenic diseases in which there is constitutive Type I IFN pathway activation with a causal role in pathology. The clinical picture may resemble rheumatic musculoskeletal diseases. However, most diseases with IFN pathway activation are not Interferonopathies.

Conclusion: Diverse methods have been reported as IFN assays and these differ in what elements of type IFN-I pathway activation they measure. The taskforce consensus terminology on type I IFN reporting should be considered for research and clinical applications.

Osteo arthritis, aetiology, pathology and animal models

POS0371 BIOLOGICAL REPRODUCIBILITY OF TARGETED LIPIDOME ANALYSES IN PLASMA AND ERYTHROCYTES OVER A 6-WEEK PERIOD

M. Loef[1], J. von Hegedus[1], M. Ghorasaini[2], F. Kroon[1], M. Giera[2], A. Ioan-Facsinay[1], M. Kloppenburg[1,3]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Leiden University Medical Center, Center for Proteomics and Metabolomics, Leiden, Netherlands*; [3]*Leiden University Medical Center, Clinical Epidemiology, Leiden, Netherlands*

Background: Lipidomics analysis has become a valuable technology for understanding patho-physiological mechanisms and the identification of candidate biomarkers in rheumatic musculoskeletal disorders. Variability in within-subject repeated measurements may lead to bias towards the null when estimating the association between biomarkers and a disease or treatment. Hence, information regarding the stability of the metabolite levels over time is essential.
Objectives: We aimed to assess the lipid composition and biological reproducibility of lipid measurements in plasma and erythrocytes.
Methods: Plasma and erythrocyte samples from 42 osteoarthritis patients (77% women, mean age 65 years, mean BMI 27 kg/m2), obtained non-fasted at baseline and six weeks, were used for the quantitative measurement of up to 1000 lipid species across 13 lipid classes with the LipidyzerTM platform in nmol/mL. Data was processed based on the relative standard deviation of quality controls, taking batch effects into account. Intraclass correlation coefficients (ICCs) and corresponding 95% confidence intervals (CI) were calculated to investigate the variability of the lipid concentrations between timepoints. The ICC distribution of lipid metabolites in plasma and erythrocytes were compared using two-sided paired Wilcoxon tests.
Results: We measured 778 lipids in plasma, compared to 916 lipids in erythrocytes. After data processing, the analyses included 630 lipids in plasma, and 286 in erythrocytes. From these, 243 lipids overlapped between sample types. Major differences were observed between the sample types in the number of lipids per lipid class and the total concentration of the lipids within a class. Triacylglycerols (TAG) and cholesteryl esters (CE) were more abundant in plasma. Conversely, phosphatidylethanolamines (PE), sphingomyelins (SM) and ceramides (CER) were less abundant in plasma compared to erythrocytes (table 1). In plasma 78% of lipid measurements were good to excellently reproduced, with an overall median ICC 0.69. Compared to plasma, a considerably lower amount (35%) of lipids were well reproduced in erythrocytes. Median reproducibility of lipids in erythrocytes was 0.51. Figure 1 shows the ICC score distribution in plasma with erythrocytes, with a significantly better reproducibility in plasma (p-value<0.001). However, while overall reproducibility was better in plasma, this was not observed for all lipid classes. At class-level, reproducibility in plasma was superior for TAGs and CEs, while CERs, DAGs, (L)PEs and SMs showed better reproducibility in erythrocytes.
Conclusion: In plasma biological reproducibility was good for most lipid measurements. Although overall reproducibility was better in plasma compared to erythrocytes, notable differences were observed at individual- and lipid class-level that may favour the use of a particular sample type.

Table 1. Number of individual lipids per class and class concentrations in plasma and erythrocytes

	Plasma		Erythrocytes	
	Number of lipid species	Class concentration (nmol/mL)	Number of lipid species	Class concentration (nmol/mL)
Triacylglycerols	482	1579.4 (1064.9-3195.2)	134	6.5 (5.6-9.4)
Diacylglycerols	9	13.3 (8.4-22.2)	10	5.8 (4.7-6.2)
Free fatty acids	20	745.3 (552.0-1202.9)	20	486.9 (379.2-669.2)
Cholesteryl esters	24	4571.6 (4065.1-5521.3)	5	1.2 (0.9-1.7)
Phosphatidylcholines	31	4013.7 (3203.1-4661.6)	42	3899.2 (3723.0-4296.6)
Phosphatidylethanolamines	26	156.2 (120.9-180.3)	42	3954.6 (3721.9-4323.3)
Lysophosphatidylcholines	9	385.9 (335.6-442.9)	7	119.8 (109.7-168.9)
Lysophosphatidylethanolamines	2	4.2 (3.5-4.9)	4	8.6 (6.8-9.7)
Sphingomyelins	12	1204.6 (1037.0-1351.9)	8	2695.8 (2434.8-2815.6)
Ceramides	6	14.1 (11.9-17.4)	7	163.0 (133.3-186.4)
Dihydroceramides	2	1.0 (0.8-1.3)	1	1.8 (1.4-2.1)
Hexosylceramides	5	5.1 (4.7-5.9)	4	5.6 (5.0-7.4)
Lactosylceramides	2	3.4 (2.7-3.8)	2	23.8 (20.6-33.5)

Numbers represent median (interquartile range) unless otherwise specified. Data represents baseline measurements.

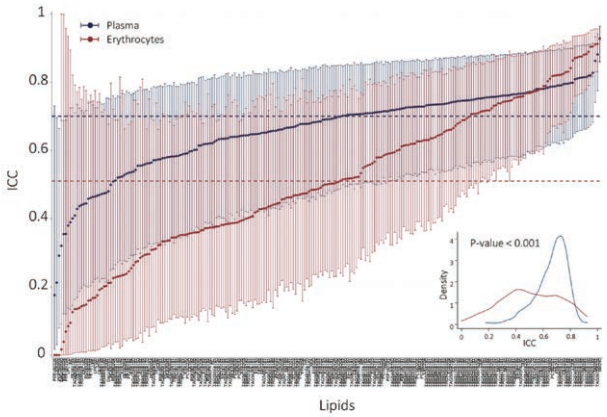

Figure 1. The ICC score distribution of lipids measured in plasma and erythrocytes.
Lipids are ranked ascending by plasma samples. A density plot of the ICC score distributions from plasma and erythrocyte samples is inserted in the lower right corner; the p-value represents the result from the Wilcoxon signed-rank test used to compare the distributions. The dashed lines correspond to the median ICC scores of lipids in plasma (blue) and erythrocytes (red).

POS0372 LORECIVIVINT (SM04690), AN INTRA-ARTICULAR, SMALL-MOLECULE CLK2/DYRK1A INHIBITOR THAT MODULATES THE WNT PATHWAY, AS A POTENTIAL TREATMENT FOR MENISCAL INJURIES

T. Seo[1], V. Deshmukh[1], Y. Yazici[2]. [1]*Samumed, LLC, Biology, San Diego, United States of America*; [2]*Samumed, LLC, Chief Medical Officer, San Diego, United States of America*

Background: Meniscal injuries are the most common pathology of the knee and are associated with pain, stiffness, and localized swelling. Meniscal damage is a frequent finding on MRI images of knee osteoarthritis (OA).[1] Efforts to repair meniscal damage have been largely unsuccessful and do not prevent the progression of degenerative changes that lead to knee OA.[2] The Wnt signaling pathway has been shown to be regulated during meniscal development,[3] suggesting that manipulation of this pathway may influence the regenerative capacity of the meniscus. Lorecivivint (LOR; SM04690) is an intra-articular (IA), small-molecule CLK2/DYRK1A inhibitor that modulates the Wnt pathway.[4]
Objectives: LOR was evaluated in preclinical studies to determine its protective and anabolic effects in ex vivo explants and in a rat model of chemically induced inflammatory meniscal degeneration.
Methods: Effects of LOR (30 nM) on matrix metalloproteinase (MMP) expression in cultured rat menisci treated with IL-1B were measured by qRT-PCR. In vivo, LOR activity was evaluated in a rat model of monosodium iodoacetate (MIA) injection-induced inflammatory meniscal degeneration. A single IA injection of MIA was immediately followed by a single IA injection of LOR (0.3 ug) or vehicle. Knees were harvested on Days 1, 4, and 11 and menisci were isolated. Anti-inflammatory effects were evaluated by qRT-PCR for *TNFA* and *IL6* expression. Meniscal protection was evaluated by qRT-PCR for MMPs and aggrecanase. Anabolic effects were evaluated by qRT-PCR for collagens.
Results: In ex vivo meniscal explants, LOR inhibited expression of *MMP1*, *MMP3*, and *MMP13* compared with DMSO (P<0.01). In vivo, LOR significantly decreased expression of MMPs and aggrecanase (P<0.05) and reduced expression of inflammatory cytokines *TNFA* and *IL6* compared with vehicle in the rat model of inflammatory meniscal degeneration at Day 4 after MIA injection. Additionally, LOR increased expression of collagen types I, II, and III at Day 11 after MIA injection (Figure 1).
Conclusion: LOR exhibited protective effects in the meniscus ex vivo and in vivo by reducing catabolic enzyme expression compared with control. Anti-inflammatory effects of LOR were demonstrated by inhibition of inflammatory cytokine expression. Compared with vehicle, LOR increased collagen expression in vivo, indicating potential meniscal anabolic effects. These data support further investigation of LOR as a potential structure-modifying treatment for meniscal injuries.

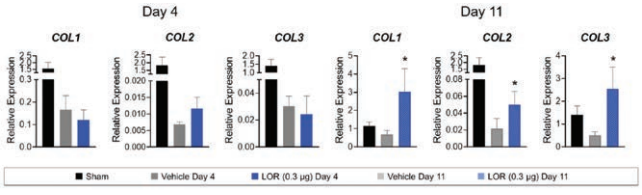

Figure 1. LOR increased collagen gene expression in vivo. A single IA injection of monosodium iodoacetate (MIA; 3 mg) was immediately followed by a single IA injection of LOR (0.3 µg) or vehicle at 10 weeks of age. Knees were harvested on Days 1, 4, and 11 after injection and menisci were isolated. Gene expression was measured by qRT-PCR. N=3, Mean ± SEM, *P<0.05, one-way ANOVA

POS0373 LIRAGLUTIDE HAS POTENT ANTI-INFLAMMATORY AND ANTI-CATABOLIC IN VITRO ACTIVITIES IN OSTEOARTHRITIS

F. Berenbaum[1], C. Meurot[2], L. Sudre[2], K. Bismuth[2], R. Rattenbach[2], P. Denefle[2], C. Martin[2], C. Jacques[3]. [1]*APHP, Sorbonne University, INSERM UMRS_938, CDR St-Antoine, Rheumatology Department, Paris, France*; [2]*4P-Pharma, R&D, Lille, France*; [3]*Sorbonne University, INSERM UMRS_938, CDR St-Antoine, Paris, France*

Background: Osteoarthritis (OA) is an age-related joint disease which provokes chronic pain and limits mobility. The disease progression is associated with inflammatory responses and cartilage degradation. Both chondrocytes, the only cell type present in cartilage, and macrophages from the synovium, play a major role in OA pathophysiology. Liraglutide is a Glucagon-Like Peptide-1 Receptor (GLP-1R) agonist widely prescribed for the treatment of type 2 diabetes. Interestingly, anti-inflammatory properties of the GLP-1 pathway have been reported in various diseases outside diabetes.
Objectives: We evaluated the anti-inflammatory and anti-catabolic effects of Liraglutide in two *in vitro* models relevant to OA by evaluating surrogate markers of inflammation, cartilage matrix proteolysis and differentiation.
Methods: Lipopolysaccharide (LPS)-stimulated murine Raw 264.7 macrophages were treated with 10 concentrations (6.6nM-3.4µM) of Liraglutide for 24h. Anti-inflammatory activity was evaluated by the production of nitric oxide (NO) and prostaglandin E_2 (PGE_2) using Griess reaction and ELISA, respectively. Interleukin 1β (IL-1β)-stimulated mouse articular chondrocytes were treated with Liraglutide (6.6nM-3.4µM) for 24h. Production of IL-6, matrix metalloproteinase-3 (MMP-3) and glycosaminoglycans (GAG) was measured by ELISA and GAG assay, respectively. RTqPCR analyses were performed with three selected concentrations of Liraglutide (13.3nM, 53.1nM and 1.7µM) on both cell types to assess the expression of a panel of genes related to inflammation (IL-6, TNF, iNOS), M1/M2 macrophage phenotype (MCP-1, CD38, ERG-2), catabolism (MMP-13, ADAMTS-5) and differentiation (Sox9, Col2a1, Acan).
Results: Liraglutide induced a dose-dependent inhibition of the LPS-induced production of NO (IC_{50}=45nM) and PGE_2 (IC_{50}=54nM) in macrophages. Moreover, IL-6 and TNF gene expressions were significantly and dose-dependently decreased in Raw 264.7 cells treated with Liraglutide compared to LPS alone. Interestingly, there was a significant dose-dependent reduction of MCP-1 and CD38 (M1 marker) gene expression in cells treated with the 3 doses of Liraglutide compared to LPS alone while we observed a dose-dependent increase of ERG-2 (M2 marker) gene expression induced by Liraglutide. Liraglutide significantly dose-dependently reduced the IL-1β-induced release of IL-6 (IC_{50}=38nM), MMP-3 (IC_{50}=56nM) and GAG (IC_{50}=47nM) in chondrocytes. Additionally, Liraglutide treatment dose-dependently decreased the IL-1β-induced gene expression of iNOS, MMP-13 and ADAMTS-5. Finally, IL-1β decreased gene expression of Sox9, Col2a1 and Acan differentiation markers, which was rescued in a dose-dependent manner by Liraglutide (Table 1).
Conclusion: A shift in M1/M2 macrophage phenotype and the inhibition of chondrocyte expression of several mediators involved in inflammation and cartilage degradation explain, at least in part, our previous results from rodent osteoarthritis models that showed an analgesic, anti-inflammatory and anti-degradative effect of Liraglutide. The fact that Liraglutide is already safely prescribed in another indication allows us to foresee a first trial in humans in the short term.

Table 1. Gene expression results (fold change) in Raw 264.7 murine macrophages or mouse primary articular chondrocytes

Cell type	Markers	Vehicle	Vehicle	Liraglutide (nM)

POS0374 SENESCENCE DID NOT ALTER THE CHONDROPROTECTIVE EFFECT OF EXTRACELLULAR VESICLES FROM MESENCHYMAL STROMAL CELLS

J. Boulestreau[1], M. Maumus[1], P. Rozier[1], C. Jorgensen[1], D. Noel[1]. [1]*Inserm, u1183, Montpellier, France*

Background: Age is the most important risk factor in degenerative osteoarthritis (OA) and is associated with the accumulation of senescent cells that contribute to functional decline of joint. We previously demonstrated that extracellular vesicles (EVs) from mesenchymal stromal cells (MSCs) largely mediate the therapeutic effect of parental cells in OA.
Objectives: Here, we assessed the impact of senescence on the characteristics of EVs from adipose tissue-derived MSCs (ASC-EVs) and their properties in an in vitro model of OA
Methods: ASCs were induced to senescence using 25µM etoposide for 24 hours. Senescence was assessed by quantifying proliferation rate, SA-βGal activity, nuclear γH2AX foci number, phalloidin staining and expression of cyclin dependent kinase inhibitors (CDKI) (RT-qPCR). ASC-EVs were isolated by differential ultracentrifugation and characterized by size, concentration, total protein content, structure (cryo-TEM) and immunophenotype. In vitro OA model used chondrocytes isolated from OA patients, which were stimulated with IL1β for 48h before culture with ASCs or ASC-EVs for 7 days. Expression of chondrocytic and inflammatory markers was quantified by RT-qPCR and SASP factors were quantified by ELISA in supernatants.
Results: Senescence-induced ASCs experienced growth arrest and increase of SA-βGal staining, of p21 CDKI expression, of nuclear γH2AX foci, of stress fibers and of several SASP factors (IL6, IL8, MMP3) confirming the expression of main senescence features. Senescent ASCs produced 4-fold more EVs than healthy ASCs and senescent ASC-EVs were larger. In vitro, both healthy and senescent ASCs decreased fibrotic markers (*type III COLLAGEN*), catabolic and hypertrophic markers (*MMP3, MMP13, AP*) and increased *COX2* expression in OA chondrocytes. By contrast, healthy ASCs decreased the expression of *IL6* while senescent ASCs highly increased *IL6*. Looking at the role of ASC-EVs on OA chondrocytes, we found out that both healthy and senescent ASC-EVs were able to increase the expression of *AGG* and *type II COLLAGEN* while they decreased the expression of *MMP13, AP, type X COLLAGEN, HMOX1* and *IL6*. Finally, healthy and senescent ASC-EVs decreased the number of SA-βGal positive chondrocytes but did not impact the expression of p21 in IL1β-induced chondrocytes.
Conclusion: Our results indicated a chondroprotective effect of ASC-EVs, independently of the senescent state of parental cells and suggested that EVs might act through different mechanisms than ASCs, which warrants further investigation

POS0375 CHAPERONE-MEDIATED AUTOPHAGY IS A HALLMARK OF JOINT DISEASE IN OSTEOARTHRITIC PATIENTS

I. Lorenzo[1], U. Nogueira-Recalde[1], N. Oreiro[2], J. A. Pinto Tasende[2], M. Lotz[3], F. J. Blanco[1,2], B. Carames[1]. [1]*Instituto de Investigación Biomédica de A Coruña (INIBIC), Unidad de Biología del Cartílago, Grupo de Investigación en Reumatología, A Coruña, Spain*; [2]*Complejo Hospitalario Universitario A Coruña, Grupo de Reumatología Clínica, A Coruña, Spain*; [3]*Scripps Research, Department of Molecular Medicine, La Jolla, United States of America*

Background: In Osteoarthritis (OA), defects in macroautophagy (autophagy) are evident and precede joint damage. Indeed, pharmacological activation of autophagy protects against joint damage.
Objectives: Therefore, identifying hallmarks associated with specific autophagy subtypes could shed light to fundamental mechanisms of joint disease.
Methods: A comparative analysis of 35 autophagy genes was performed from blood from the Prospective OA Cohort of A Coruña (PROCOAC). Non-OA subjects (Age:61,44±1,16 years; BMI:25,25±0,52; Females, n=18) and Knee OA subjects (Age:65,50±1,05 years; BMI:29,55±0,67; Females, n=18, OA grade III-IV) were profiled using an autophagy gene expression array by SYBR green qPCR. Confirmatory studies were performed in blood from Non-OA subjects (Age:60,13±1,12 years; BMI:24,85±0,59; Females; n=30) and Knee-OA subjects (Age:68,4±1,11 years; BMI:29,65±0,55; Females; n=30, OA grade III-IV) by Taqman qPCR. The candidate gene was evaluated in human knee joint tissues (cartilage, meniscus, ligaments, synovium) with different KL grades (Age: KL0=28,3±4,50; KL2=77±6,08; KL4=62,3±3,05, n=3) and in both spontaneous aging (2, 6, 12, 18, and 30 months old, n=3) and surgically-induced OA (10 weeks after surgery, n=4) in mice by IHC. The functional consequences were studied in T/C28a2 and primary human OA chondrocytes. Autophagy, FOXO, Chaperone-mediated autophagy (CMA), inflammation, and cellular senescence were analyzing by gene and protein expression. Moreover, oxidative stress and cell death were evaluated by FACS. The contribution of CMA to chondrocyte homeostasis was evaluated by studying the capacity of CMA to restore proteostasis upon autophagy deficiency by siATG5.
Results: 15 autophagy-related genes were significantly downregulated in blood from knee OA patients compared to non-OA patients. No significant upregulation was found for any studied gene, although a trend towards upregulation was found in genes involved in the mTOR pathway. Four key autophagy-related genes, including ATG16L2, ATG12, ATG4B and MAP1LC3B were found downregulated in knee OA patients. Interestingly, HSP90AA1 and HSPA8, CMA markers involved in stress response and protein folding, were downregulated. Confirmatory studies showed a significant downregulation of MAP1LC3B and HSP90AA1 in blood from knee OA patients. Remarkably, HSP90A was found reduced in femoral cartilage (medial and lateral), meniscus and ACL. Moreover, this reduction was higher in medial cartilage compared to lateral cartilage and meniscus, while in synovial membrane, HSP90A expression was found increased. This expression signature was dependent on OA grade severity. In addition, we observed a decrease of HSP90A with aging and OA in mice. The functional consequences of HSP90AA1 gene silencing are related to an increase in NFκB, MMP13, and p16 expression. Interestingly, LAMP2A, a key CMA mediator, HSPA8, MAP1LC3B and FoxO1 expression were upregulated in chondrocytes with HSP90AA1 deficiency, which might indicate an early response to maintain homeostasis. On the other hand, LAMP2A protein is decreased upon HSP90AA1 deficiency, while LC3II and p62 were increased, indicating a failure in the autophagy flux that leads to impaired lysosomal degradation.
Moreover, p21, p16 and prbS6 were increased upon HSP90AA1 deficiency, besides increasing mitochondrial ROS production and apoptosis. ATG5 silencing blocks autophagy by reducing LC3II and increasing prbs6, p62, p16 and p21. Interestingly, LAMP2A and HSP90A were found increased, indicating a possible compensative activation of CMA in response to autophagy defects. These results support that HSP90A has an important role in chondrocyte homeostasis by participating in the cross-talk between CMA and autophagy.
Conclusion: Taking together, we identified HSP90A, a CMA regulator, as critical in chondrocyte homeostasis. These disease mechanisms are relevant in OA and constitute hallmarks potentially useful to prevent OA progression.

POS0376 MONOMERIC C REACTIVE PROTEIN (mCRP) REGULATES INFLAMMATORY RESPONSES IN HUMAN AND MOUSE CHONDROCYTES

C. Ruiz-Fernández[1], M. González-Rodríguez[1], V. Francisco[1], I. M. Rajab[2], R. Gómez Bahamonde[3], J. Conde Aranda[1], F. Lago[4], J. Pino[1], A. Mobasheri[5], M. A. González-Gay[6], A. Mera Varela[7], L. A. Potempa[2], O. Gualillo[1]. [1]*Health Research Institute of Santiago de Compostela (IDIS), NeuroEndocrine Interactions in Rheumatic and Inflammatory Diseases Group, Santiago de Compostela, Spain*; [2]*Roosevelt University, College of Pharmacy, Schaumburg, United States of America*; [3]*Health Research Institute of Santiago de Compostela (IDIS), Musculoskeletal Pathology Laboratory, Santiago de Compostela, Spain*; [4]*Health Research Institute of Santiago de Compostela (IDIS), Molecular and Cellular Cardiology Group, Santiago de Compostela, Spain*; [5]*University of Oulu, Research Unit of Medical Imaging, Physics, and Technology, Faculty of Medicine, Oulu, Finland*; [6]*Hospital Universitario Marqués de Valdecilla, IDIVAL, University of Cantabria, Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Santander, Spain*; [7]*Santiago University Clinical Hospital, Division of Rheumatology, Santiago de Compostela, Spain*

Background: C-reactive protein (CRP) is an acute-phase protein that is used as an established biomarker to follow disease severity and progression in a plethora of inflammatory diseases. However, its pathophysiologic mechanisms of action are still poorly defined and remain elusive. CRP, in its pentameric form, exhibits weak anti-inflammatory activity. On the contrary, the monomeric isoform (mCRP) exhibits potent pro-inflammatory properties in endothelial cells, leukocytes, and platelets. So far, no data exists regarding mCRP effects in human or mouse chondrocytes
Objectives: This work aimed to verify the pathophysiological relevance of mCRP in the etiology and/or progression of osteoarthritis (OA)
Methods: We investigated the effects of mCRP in cultured human primary chondrocytes and in the chondrogenic ATDC5 mouse cell line. We determined mRNA and protein levels of relevant factors involved in inflammatory responses and the modulation of nitric oxide synthase type II (NOS2), an early inflammatory molecular target.
Results: We demonstrate, for the first time, that monomeric C reactive protein increases NOS2, COX2, MMP13, VCAM1, IL-6, IL-8, and LCN2 expression in human and murine chondrocytes. We also demonstrated that NF-kB is a key factor in the intracellular signaling of mCRP-driven induction of pro-inflammatory and catabolic mediators in chondrocytes.
Conclusion: mCRP exerts a sustained catabolic effect on human and murine chondrocytes, increasing the expression of inflammatory mediators and proteolytic enzymes, which can promote extracellular matrix (ECM) breakdown in healthy and OA cartilage. In addition, our results implicate the NF-kB signaling pathway in catabolic effects mediated by mCRP.

FIBROCYTES IN EARLY AND LONGSTANDING RHEUMATOID ARTHRITIS: A 6-MONTH TRIAL WITH REPEATED SYNOVIAL BIOPSY, IMAGING, AND LUNG FUNCTION TEST

S. A. Just[1,2], C. Nielsen[3], J. Werlinrud[4], P. V. Larsen[5], E. K. Hejbøl[6], H. Tenstad[1], H. D. Schrøder[6], T. Barington[3], T. Torfing[7], F. Humby[8], H. M. Lindegaard[2]. *[1]Svendborg Hospital - Odense University Hospital, Department of Medicine, Svendborg, Denmark; [2]Odense University Hospital, Department of Rheumatology, Odense, Denmark; [3]Odense University Hospital, Department of Clinical Immunology, Odense, Denmark; [4]Odense University Hospital, Department of Orthopaedics, Odense, Denmark; [5]Region of Southern Denmark, Mental Health Services, Odense, Denmark; [6]Odense University Hospital, Department of Pathology, Odense, Denmark; [7]Odense University Hospital, Department of Radiology, Odense, Denmark; [8]Experimental Medicine and Rheumatology, William Harvey Research Institute, Queen Mary University of London, London, United Kingdom*

Background: Fibrocytes are bone marrow-derived cells, that express both hematopoietic and stromal markers. In murine collagen-induced arthritis models circulating fibrocytes have been found to home to inflamed joints and enhance arthritis activity. The cell has, therefore, been proposed to be precursor cells for the fibroblast-like synoviocytes (FLS), which are central in the Rheumatoid Arthritis (RA) pathogenesis. Fibrocytes levels are further correlated with disease progression and mortality in interstitial lung disease (ILD) and identified as a new treatment target. ILD is also an extra-articular manifestation of RA (RA-ILD), leading to a reduced lung diffusion capacity and increased mortality.
Objectives: To correlate the level of fibrocytes in peripheral blood, synovial tissue, and *in vitro* culture in RA to changes in disease activity, imaging, and pulmonary function.
Methods: Twenty patients with early RA (ERA) and 20 patients with longstanding RA (LRA) were enrolled in a six months prospective study. Sixteen patients undergoing wrist arthroscopy were healthy controls. RA patients underwent pulmonary function tests, ultrasound, and synovial ultrasound-guided needle biopsy of the same wrist, at baseline and six months. Wrist magnetic resonance imaging was performed at baseline (all) and six months (ERA). Circulating fibrocytes were measured by flow cytometry, *in vitro* by the number of monocytes that were differentiated to fibrocytes, and in synovial biopsies by counting in histological sections.
Results: Fibrocyte levels did not decline during the trial despite effective RA treatment. Fibrocytes were primarily located around vessels and in the subintimal area in the synovium (Figure 1A and 1B, fibrocytes marked with arrows). In the ERA group, increased synovitis assessed by ultrasound was moderate and strongly correlated to respectively increase in circulating and synovial fibrocyte levels. Increased synovitis assessed by MRI during the trial in the ERA group, was moderately correlated to both increased numbers of circulating and cultured fibrocytes. Absolute diffusion capacity level was overall weakly negatively correlated to the level of circulating and synovial fibrocytes. The decline in forced ventilatory capacity and diffusion capacity during the trial was moderately correlated to increased levels of synovial fibrocytes (Figure 1C and 1D).
Conclusion: Our findings point to fibrocytes as key mediators of RA pathogenesis, and as a possible pathogenic link between the disease process in the synovium and RA lung affection. Studies are needed to investigate if the new therapies targeting fibrocyte differentiation/migration could be a path forward in RA/RA-ILD treatment.

POS0378

CCN1: AN ANGIOGENIC ACTOR IMPLICATED IN THE STRUCTURAL DAMAGES OF RHEUMATOID ARTHRITIS

J. Avouac[1], A. Steelandt[2], O. Amiar[2], A. Leblond[2], A. Cauvet[2], V. Gonzalez[2], Y. Allanore[1]. *[1]Cochin Hospital, Rheumatology, Paris, France; [2]Cochin Institute, INSERM U1016, Paris, France*

Background: We have previously shown that decreased expression of the deacetylase sirtuin-1 (SIRT1) contributes to the proliferative, activated and proangiogenic profile of endothelial cells (EC) in rheumatoid arthritis (RA) (1). The matricellular protein CCN1, characterized by proangiogenic and immunomodulatory properties, may be directly implicated in these processes, since its expression is negatively regulated by SIRT1 (1).
Objectives: To study the implication of CCN1 in RA pathogenesis.
Methods: CCN1 expression was assessed in ECs (25 RA and 10 controls) by quantitative RT-PCR, western blot and ELISA, in the synovial tissue (5 RA and 5 controls) by immunohistochemistry and immunofluorescence, and in the serum (205 RA and 20 controls) by ELISA. Invalidation of CCN1 in RA ECs was achieved through the use of shRNA and neutralizing monoclonal antibodies. The functional consequences of CCN1 invalidation in RA ECs were studied i) *in vitro* by the analysis of proliferation (cell impedance), tube formation in Matrigel and migration in Boyden chambers; and ii) *in vivo* in the murine model of tumor neoangiogenesis.
Results: CCN1 mRNA and protein expression were increased by 1.72- ($p = 0.012$) and 7.2-fold ($p=0.008$) in RA ECs compared to controls, respectively. CCN1 concentrations were significantly increased in RA EC culture supernatants (930±153 vs. 359±199 pg/mL, $p=0.007$). CCN1 was overexpressed in the synovial tissue of RA patients (Figure 1A) and confocal microscopy analyses revealed a prominent CCN1 expression in the vascular endothelium (CD31 +) and T cells (CD3 +) (Figure 1B).
In vitro, recombinant TNF-α and IL-17 induced the mRNA and protein expression of CCN1 in RA ECs. CCN1 invalidation was associated with reduced proliferative capacities, delayed capillary tube formation and decreased migration of RA ECs (Figure 1E). *In vivo*, subcutaneous transplantation of CT26 tumor cells combined with RA ECs transfected with CCN1 shRNA to CB17 SCID mice was associated with a 51% reduction in tumor volume ($p=0.008$) and a 27% reduction in tumoral vascular density ($p=0.032$) compared with mice transplanted with MOCK transfected RA-ECs (Figure 1F).
Serum concentrations of CCN1 were significantly reduced in the serum of RA patients compared to controls (233±118 vs. 279±75 pg/mL, $p=0.045$) (Figure 1C). However, serum CCN1 concentrations were significantly higher in the presence of bone erosions (253±139 vs. 202±7 pg/mL, $p=0.002$) (Figure 1D) and correlated with radiographic Larsen score ($r=0.3$, $p=0.001$) and HAQ ($r=0.25$, $p=0.012$).
Conclusion: CCN1 is overexpressed in ECs and the synovial tissue of patients with RA. CCN1 also regulate the functional properties of RA ECs and their angiogenic potential *in vivo*. CCN1 could represent a new therapeutic target, which is being evaluated in experimental models of erosive arthritis.
CCN1 may be a reliable biomarker of structural damages given the association between its serum concentrations and the extent of radiographic lesions. The performance of CCN1 serum levels to predict structural progression is under investigation.

DETERMINING IN WHICH PRECLINICAL STAGE HLA-SHARED EPITOPE ALLELES AND SMOKING EXERT THEIR EFFECT IN THE DEVELOPMENT OF RHEUMATOID ARTHRITIS

F. Wouters[1], M. Maurits[2], L. van Boheemen[3], M. Verstappen[2], X. Matthijssen[2], E. Niemantsverdriet[2], R. Knevel[2], D. van Schaardenburg[3], R. Toes[2], A. van der Helm - van Mil[2,4]. *[1]Leiden University Medical Centre, Department of Rheumatology, Leiden, Netherlands*; *[1]Leiden University Medical Centre, Department of Rheumatology, Leiden, Netherlands*; *[3]Amsterdam Rheumatology and Immunology Centre, Reade, Department of Rheumatology, Amsterdam, Netherlands*; *[4]Erasmus University Medical Centre, Department of Rheumatology, Rotterdam, Netherlands*

Background: The HLA shared epitope (SE) and smoking are the best known genetic and environmental risk factors for rheumatoid arthritis (RA) development; however, at which pre-RA stage they exert their effect is unknown. The following stages are discerned: an asymptomatic stage in which autoimmune responses can develop, a symptomatic stage (clinically suspect arthralgia (CSA)), and development of clinically apparent inflammatory arthritis (IA). Studies in the general asymptomatic population revealed contrasting results on the associations between SE-alleles and smoking and the presence of anti-citrullinated protein antibodies (ACPA). Furthermore, studies on these risk factors in the symptomatic pre-RA phase are scarce and these data might teach us whether SE-alleles and smoking are involved in symptom development and/or progression to clinical arthritis.
Objectives: We aimed to determine at which pre-RA stage SE and smoking exert their effect. In this respect, the analyses were focused on the presence of ACPA, but associations for other anti-modified protein antibodies (anti-carbamylated and anti-acetylated protein antibodies (anti-CarP and AAPA, respectively)) were also studied.
Methods: Results from the literature on the association of SE and smoking with ACPA in the asymptomatic population were summarized in inverse-variance weighted meta-analyses. In addition 577 CSA-patients were studied. Associations of SE and smoking with IgG ACPA were studied at baseline (CSA-onset), to assess an effect on symptom development. Additionally, patients were monitored for the development of clinically apparent inflammatory arthritis (IA) for median 2 years and associations of SE, smoking and auto-antibodies with progression to IA were determined. Analyses were stratified for ACPA-status and associations in ACPA-positive patients were validated in meta-analyses with other arthralgia-cohorts. Finally analyses were repeated for anti-CarP and AAPA.
Results: Meta-analyses showed that SE is not associated with ACPA-positivity in the asymptomatic population (OR 1.06 (95%CI 0.69-1.64)), whereas smoking was associated (OR 1.37 (1.15-1.63)). At CSA-onset, both SE and smoking associated with ACPA-positivity (OR 2.08 (1.24-3.49) and OR 2.41 (1.31-4.43), respectively). During follow-up of CSA-patients SE associated with IA-development (HR 1.86 (1.23-2.82)), in contrast to smoking. SE conferred risk for IA-development in ACPA-negative CSA-patients (HR 1.71 (0.99-2.96)) and in ACPA-positive patients (CSA-cohort HR 1.29 (0.67-2.47); meta-analysis three arthralgia-cohorts HR 1.52 (1.08-2.15)). Investigating the other autoantibodies revealed that SE and smoking were not associated with anti-CarP or AAPA-positivity at CSA-onset; longitudinally AAPA associated with progression to IA independent from ACPA and RF (HR 1.79 (1.02-3.16)), whilst anti-Carp did not.
Conclusion: SE and smoking act in partly different pre-RA stages. Although SE does not associate with ACPA in the general population, it does mediate symptom-development and further progression to clinical arthritis. Smoking confers risk to development of ACPA and/or joint symptoms, but is not further involved in IA-development. The time-specific biologic pathways that are underlying need further exploration. These data enhance the understanding of the timing of key genetic and environmental risk factors in the trajectory of RA development.

Background: Overweight in patients with rheumatic diseases is a condition that prolongs chronic inflammation and promotes synthesis and secretion of pro-inflammatory factors by adipose tissue, such as classical cytokines, tumor necrosis factor-α (TNF-α), adipokines (leptin, adiponektin, resistin) and other newly identified proinflammatory factors (fetuin A, nesfatin, hemerin, lipokain, serum amyloid protein 3) [1,2,3,4].
Objectives: We investigated the relationship the effect of weight loss over 5 kg on the clinical manifestations of arthritis and hormones of adipose tissue serum levels in patients with rheumatoid arthritis (RA).
Methods: We observed 80 female patients with RA (EULAR/ARA 2010 criteria) ranged in age from 39 to 69 years (mean age 51,72 ± 5,83 years) and the control group (60 healthy persons) with no complaints of pain in the joints over a lifetime, and without clinical signs of RA. Fetuin A, nesfatin, hemerin, leptin, adiponektin, resistin, visfatin level in serum was determined by ELISA-test using a commercial test systems.
Results: As overweight patients were recruited in the study, hypocaloric diet low in animal fats and physiotherapy has been recommended to all participants. The positive dynamics in body weight loss over 5kg within 3 months has been achieved by 34 patients (27,2%). In RA patients with weight loss, a significant decrease in the serum level of pro-inflammatory cytokines (fetuin A, nesfatin, hemerin, leptin, adiponektin, resistin, visfatin ($p<0.01$)) and an increase in the quality of life according to the EQ-5D-5L ($p<0.001$) index were observed. This fact is probably explained by the decreased activity of inflammatory process after RA therapy and weight reduction.
Conclusion: Thus, as a result of our study patients with RA with weight loss of more than 5 kg had more obvious pain relief than patients with the original weight. These findings suggest that there is a possible role of tissue pro-inflammatory cytokines in the pathogenesis of rheumatoid arthritis. All patients with RA with a BMI over 25 kg / m ^{2} are recommended to lower their weight to decrease the mechanical stress on the joints, and also to reduce the severity of inflammation and metabolic disorders.

POS0381

PATIENTS AT RISK FOR RA SHOW THE SAME AMOUNT OF ACUTE SOLUBLE CARTILAGE DEGRADATION MARKERS AFTER PHYSICAL ACTIVITY COMPARED TO PATIENTS WITH ESTABLISHED RA

L. Bleckwedel-Rolack[1], K. Tascilar[1], V. Nees[1], J. Hühne[1], A. Hueber[2], J. Rech[1], G. Schett[1], A. Kleyer[1], A. M. Liphardt[1]. *[1]Friedrich-Alexander-University Erlangen-Nürnberg & University Hospital Erlangen, Internal Medicine 3 - Rheumatology & Immunology, Erlangen, Germany*; *[2]Sozialstiftung Bamberg - Klinikum am Bruderwald, Rheumatology, Bamberg, Germany*

Background: Serum concentration of cartilage oligomeric matrix protein (COMP) is related to the degree of cartilage destruction in patients with rheumatoid arthritis (RA) and shows a mechanosensitive response to ambulatory loads. We showed previously, that individuals with positive for anti-citrullinated protein antibody (ACPA+) status already show bone loss. It is unclear if these individuals experience cartilage deterioration and how this is related to physical activity.
Objectives: To test whether soluble COMP levels in ACPA+ display the same response as RA patients after a walking exercise and explore the association between overall serum COMP levels and physical activity.
Methods: RA patients and ACPA+ individuals (IRACE cohort: Individuals at Risk for Arthritis Cohort Erlangen; Ethics approval 334_16B) were enrolled in the study after written informed consent. Inclusion criteria were age between 18 and 69 years, RA (by 2010 ACR/EULAR criteria) or ACPA+ (without clinical manifestation of RA and prior treatment with glucocorticoids, DMARDs and biologics). The study comprised three visits (baseline (Visit 1), 6 (Visit 2), and 12 months (Visit 3). During each visit, serum samples were collected after 30 minutes rest (pre) and at 0, 30, 60, and 120 minutes after a 30-minute walking exercise. Serum COMP concentration was analyzed by commercial ELISA. Physical activity duration (hours) was measured using an activity monitor for 7 consecutive days, and physical activity level (metabolic equivalent of the task (MET)) was quantified using the International Physical Activity Questionnaire (IPAQ). The reponse of COMP levels to the walking exercise was modelled using linear mixed-effects regression models. The association between physical activity and overall serum

COMP concentrations was analyzed using a mixed-effects regression model (Random effects: individuals, visits and COMP measurement time points).

Results: 28 RA and 22 ACPA+ patients participated in this prospective study. Table 1 summarizes patient demographics and outcome measures. Serum COMP levels increased in response to the walking exercise in both groups but the acute response was not different in RA patients compared to ACPA+ individuals. Higher physical activity level by IPAQ was associated with higher overall COMP concentration. Doubling of total physical activity is associated with an increase in serum concentration of 0.32 U/L (95%CI 0.09 to 0.54, p=0.006). ACPA+ individuals but not RA patients show an association between serum COMP concentration and physical activity duration (Figure 1).

Table 1. Summary of subject characteristics and outcome measures.

Descriptives						
Measure	**ACPA+**	**RA**				
individuals, number (%)	22 (44.0)	28 (56.0)				
Age, years (mean (SD))	47.6 (12.8)	57.0 (9.1)				
Female, number (%)	14 (28.0)	19 (38.0)				
BMI, kg/m^2, mean (SD)	25.1 (5.6)	27.2 (5.8)				
Anti-CCP positive (N)	17	14				
DAS28-score, mean (SD)	2.5 (1.2)	2.7 (1.4)				
Cartilage Oligomeric Matrix Protein (U/l)						
	Visit 1		**Visit 2**		**Visit 3**	
	ACPA+	**RA**	**ACPA+**	**RA**	**ACPA+**	**RA**
pre-walking exercise	9.4 (2.8)	9.7 (3.8)	10.8 (2.2)	11.3 (4.5)	10.2 (2.5)	10.5 (3.9)
0	9.5 (2.6)	10.4 (3.9)	11.8 (1.8)	12.2 (4.0)	10.1 (2.0)	11.1 (4.6)
30	9.2 (2.2)	9.9 (3.6)	10.8 (1.9)	11.4 (4.4)	9.2 (2.2)	10.6 (4.2)
60	9.2 (2.0)	9.4 (4.0)	10.4 (2.1)	10.9 (4.5)	8.6 (2.9)	10.0 (4.0)
120	9.2 (2.1)	9.5 (4.0)	9.6 (1.8)	10.9 (4.4)	8.0 (2.4)	9.9 (3.9)

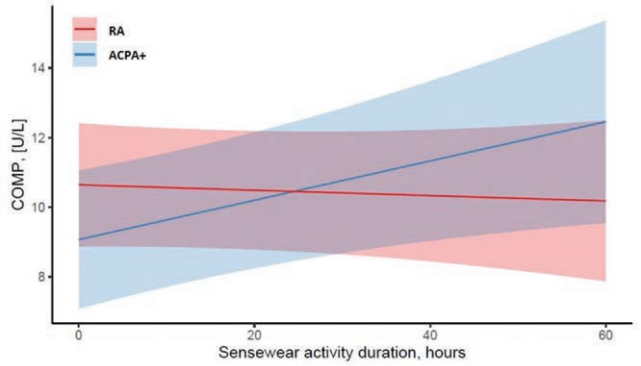

Figure 1. Estimated marginal mean COMP by physical activity duration for RA and ACPA+.

Conclusion: Pre-exercise serum COMP concentration is similar in ACPA+ and RA and shows a similar increase in response to walking in both groups. Physical activity duration appears to influence serum COMP concentration in ACPA+. Given that acute COMP release was not different between ACPA+ and RA while overall COMP values are associated with physical activity level, the discrepancy between ACPA+ and RA for this association can be explained by reduced vigor or qualitative differences in physical activity.

POS0382 EXPANSION OF CD4+/CD8+ DOUBLE-POSITIVE T CELLS IS ASSOCIATED WITH A SEVERE DISEASE COURSE IN RHEUMATOID ARTHRITIS

P. Nguyen[1], K. Rothe[1], M. Melzer[1], M. Krasselt[1], M. Pierer[1], U. Wagner[1].
[1]Leipzig University Hospital, Rheumatology, Leipzig, Germany

Background: CD4$^+$/CD8$^+$ double-positive T (dpT) cells are a set of pathologic T cells, representing about 1% of peripheral blood T cells and increasing with age in healthy individuals. Patients with rheumatoid arthritis (RA) more frequently have expanded dpT cells compared to age-matched controls, up to a frequency of 8% [1]. However, whether dpT cell expansion harbors clinical significance in RA is not known.

Objectives: The goal of the study was to assess possible associations of DPT expansion with clinical features of patients with RA.

Methods: In this cross-sectional study, dpT cells were measured in RA patients (n=70) via fluorescence-activated flow cytometry. Clinical data including age, sex, disease duration, treatment history, disease activity parameters, and radiographic structural damage was collected. Radiographs of hands and feet were used to determine the modified Sharp/van der Heijde (SvdH) score. Expansion of dpT cells was defined as a frequency of >2% of the total T cell pool, based on reference ranges determined in a large cohort of healthy individuals [2]. Mann-Whitney-U test was used to compare groups and X^2 test was used for contingency tables. Statistical analyses were conducted using GraphPad Prism v8 (GraphPad Software, San Diego, USA).

Results: DpT cells were expanded in more than a quarter of our cohort (n=19, 27.1%). Patients with expanded dpT cells more often used biologics or targeted synthetic DMARDs than patients with low dpT cells (68.4% vs. 38%, p=0.02). Radiographic damage was also significantly worse in patients with DPT expansion, as shown in their higher SvdH score (median 24.5 vs. 6, p=0.008) and its component scores for erosion (median 19 vs. 0, p=0.004) and joint space narrowing (median 8 vs. 2, p=0.017) (figure 1A). There was no difference regarding sex, age, disease duration, seropositivity and disease activity between the groups (figure 1B).

Conclusion: DpT cell expansion is associated with higher scores of radiographic structural damage despite more frequent use of highly effective therapeutics. An expansion of dpT cells is not uncommon in RA, and affected patients represent a subset at high risk for a more severe disease course.

POS0383 EFFECTS OF TOFACITINIB THERAPY ON ARGININE AND METHIONINE METABOLITES IN ASSOCIATION WITH VASCULAR PATHOPHYSIOLOGY IN RHEUMATOID ARTHRITIS: A METABOLOMIC APPROACH

B. Soós[1], A. Hamar[1], A. Pusztai[1], M. Czókolyová[1], E. Végh[1], S. Szamosi[1], Z. Pethő[1], K. Gulyás[1], G. Kerekes[2], É. Szekanecz[3], S. Szántó[1], G. Szücs[1], U. Christians[4], J. Klawitter[4], T. Seres[4], Z. Szekanecz[1]. *[1]University of Debrecen, Rheumatology, Debrecen, Hungary*; *[2]University of Debrecen, Medicine, Debrecen, Hungary*; *[3]University of Debrecen, Oncology, Debrecen, Hungary*; *[4]University of Colorado Anschutz Medical Campus, Anesthesiology, Aurora, CO, United States of America*

Background: Rheumatoid arthritis (RA) has been associated with increased cardiovascular (CV) risk and metabolic changes.
Objectives: We wished to determine how the Janus kinase (JAK) inhibitor tofacitinib influences vascular pathophysiology and metabolites of the arginine and methionine-homocysteine pathways.
Methods: Thirty RA patients with active disease were treated with either 5 mg bid or 10 mg bid tofacitinib and evaluated at baseline and after 6 and 12 months. We determined DAS28, CRP, IgM rheumatoid factor (RF) and anti-cyclic citrullinated peptide (aCCP) levels. We assessed brachial artery flow-mediated vasodilation (FMD), carotid intima-media thickness (IMT) and pulse-wave velocity (PWV) by ultrasound. We also determined plasma L-arginine, L-citrulline, L-ornithine, inducible nitric oxide synthase (iNOS), asymmetric (ADMA) and symmetric dimethylarginine (SDMA), L-N-monomethyl-arginine (L-NMMA), cysteine, homocysteine, and methionine levels.
Results: Twenty-six patients completed the study. Tofacitinib treatment maintained FMD and PWV. Ten mg bid tofacitinib significantly increased L-arginine, L-ornithine, iNOS and methionine levels after 12 months. Tofacitinib transiently increased L-citrulline and L-NMMA and decreased homocysteine levels after 12 months. Based on L-citrulline, L-ornithine, ADMA and SDMA levels, L-arginine remained highly available for endothelial NO production. Multivariate analysis indicated variable correlations of L-arginine, L-citrulline, ADMA, L-NMMA, homocysteine and methionine with DAS28, CRP, ESR and RF but not with aCCP. Regarding vascular pathophysiology, only PWV and methionine correlated with each other after 12 months.
Conclusion: Tofacitinib suppressed systemic inflammation in RA yielding stabilization of vascular function. It may exert CV protective effects in RA, at least in part, by shifting L-arginine metabolism to high arginine availability and decreasing homocysteine levels.

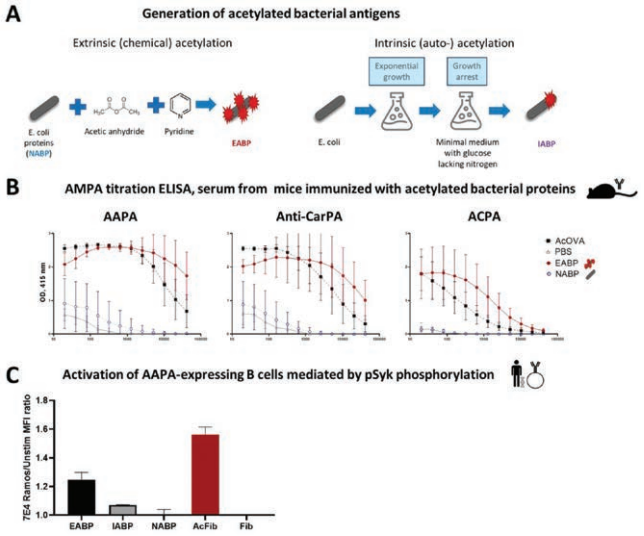
POS0384 A NOVEL MECHANISM LINKING MUCOSAL BACTERIA WITH AUTOANTIBODY RESPONSES IN RA: ACETYLATED BACTERIAL LYSATE AS A MODEL ANTIGEN

M. Volkov[1], A. S. B. Kampstra[1], K. van Schie[1], J. Kwekkeboom[2], T. Huizinga[2], R. Toes[1], D. van der Woude[1]. [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [2]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*

Background: Rheumatoid arthritis (RA) is characterized by autoantibodies against post-translationally modified proteins (AMPA) such as citrullinated, carbamylated and acetylated proteins. Importantly, these antibodies are highly multireactive, as they often recognize more than one of these post-translational modifications. Despite extensive research, the antigens inducing the breach of tolerance remain unknown, although microbial antigens are often suspected. Various bacteria are known to be capable of acetylation, therefore, it is intriguing to know what mechanisms can underlie the breach of tolerance towards acetylated proteins and development of anti-acetylated protein antibodies (AAPA).
Objectives: To investigate whether acetylated proteins of bacterial origin (1) are recognized by human derived AMPA and AMPA expressing B cells; and (2) can induce AMPA development when used to immunize mice.
Methods: Acetylated E. coli proteins were acquired with two separate methods (Figure 1A): by culturing E. coli in a condition promoting auto-acetylation (intrinsically acetylated bacterial proteins, IABP), or by directly acetylating lysate-derived proteins via a chemical reaction (extrinsically acetylated BP, EABP). Acetylated ovalbumin (AcOVA) served as positive control for AAPA induction in mice, non-acetylated BP (NABP) and phosphate buffer saline (PBS) served as negative control. Mice were immunized with these proteins and the resulting antibody response was studied by ELISA. Furthermore, EABP/IABP/NABP were investigated for recognition by human-derived AAPA with ELISA and AAPA-expressing B cells with spleen tyrosine kinase (Syk) phosphorylation assay; acetylated human fibrinogen and native fibrinogen served as positive and negative control.
Results: Repetitive immunization of mice with EABP resulted in an AMPA response recognizing acetylated, carbamylated and citrullinated proteins. AMPA titers in these mice exceeded the titers in the positive control mice immunized with AcOVA and were substantially higher than in the NABP-immunized mice (Figure 1B). Human-derived monoclonal AAPA recognized EABP and IABP (not shown). B cell activation (measured by Syk phosphorylation) assay indicated that AAPA expressing B cells recognized EABP and (to a lesser extent) IABP, but not NABP (Figure 1C).
Conclusion: Acetylated bacterial proteins are potent antigens that can induce cross-reactive AMPA responses in mice and they are recognized by human AAPA. This suggests that acetylated bacterial proteins could possibly be involved in the breach of tolerance in RA.



Acknowledgements: We thank Dr. Can Araman and Prof. Chunaram Choudhary for their advice regarding optimization of bacterial auto-acetylation.

POS0385 DURING DEVELOPMENT OF RHEUMATOID ARTHRITIS, INTERMETATARSAL BURSITIS MAY OCCUR BEFORE CLINICAL JOINT SWELLING: A LARGE MRI STUDY IN PATIENTS WITH CLINICALLY SUSPECT ARTHRALGIA

B. van Dijk[1], F. Wouters[1], E. van Mulligen[1,2], M. Reijnierse[1], A. van der Helm - van Mil[1,2]. [1]*Leiden University Medical Centre (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Erasmus Medical Centre (EMC), Rheumatology, Rotterdam, Netherlands*

Background: Inflammation of the synovial lining is a hallmark of rheumatoid arthritis (RA). A synovial lining is not only present at synovial joints and tendon sheaths but also at bursae. Inflammation of the synovium-lined intermetatarsal bursae in the forefoot, intermetatarsal bursitis (IMB), was recently identified with MRI. It is specific for early RA and present in the majority of RA patients at diagnosis. During development of RA, MRI-detectable subclinical synovitis and tenosynovitis often occur before clinical arthritis presents. Whether IMB is also present in a pre-arthritis stage is unknown.
Objectives: To assess the occurrence of IMB in patients with clinically suspect arthralgia (CSA) and its association with progression to clinical arthritis in a large MRI-study.
Methods: We studied 524 consecutive patients presenting with CSA. CSA was defined as recent-onset arthralgia of small joints that is likely to progress to RA based on the clinical expertise of the rheumatologist. Participants underwent unilateral contrast-enhanced 1.5T MRI of the forefoot, metacarpophalangeal (MCP) joints and wrist at baseline. Thereafter patients were followed for detection of clinical arthritis, as identified at physical joint examination by the rheumatologist. Baseline MRIs were evaluated for IMB at all 4 intermetatarsal spaces. Also synovitis, tenosynovitis and osteitis were

assessed in line with the RA MRI scoring system (summed as RAMRIS-inflammation). Both IMB and RAMRIS-inflammation were dichotomised into positive/negative using data from age-matched symptom-free controls as a reference. Cox regression analysed the association of IMB with progression to clinical arthritis; multivariable analyses were used to adjust for RAMRIS-inflammation which is known to associate with progression to clinical arthritis. Analyses were repeated stratified for ACPA-status, since ACPA-positive and ACPA-negative RA are considered separate entities with differences in pathophysiology.

Results: The baseline MRIs showed ≥1 IMB in 35% of CSA-patients. Patients with IMB were more likely to also have synovitis (OR 2.5 (95%CI 1.2–4.9)) and tenosynovitis (8.9 (3.4–22.9)) on forefoot MRI, but not osteitis (0.9 (0.5–1.8)). Patients were followed for median 25 months (IQR 19–27). IMB-positive patients developed clinical arthritis more often than IMB-negative patients (HR 3.0 (1.9-4.8)). This association was independent of RAMRIS-inflammation (adjusted HR 2.2 (1.4–3.6)). In stratified analyses, IMB was more frequent in ACPA-positive than in ACPA-negative CSA (68% vs. 30%, p<0.001). Moreover IMB predicted clinical arthritis development in ACPA-positive CSA (HR 2.5 (1.1–5.7)) but not in ACPA-negative CSA patients (1.0 (0.5–2.2)).

Conclusion: One-third of CSA patients have IMB. IMB is frequently present in conjunction with subclinical synovitis and tenosynovitis. It precedes the development of clinical arthritis, and in particular the development of ACPA-positive RA. These results reinforce the notion that not only intra- but also juxta-articular synovial inflammation is involved in the development of RA.

POS0386 EVOLUTION OF ANTI-MODIFIED PROTEIN ANTIBODY RESPONSES CAN BE DRIVEN BY CONSECUTIVE EXPOSURE TO DIFFERENT POST-TRANSLATIONAL MODIFICATIONS

M. Volkov[1], A. S. B. Kampstra[1], K. van Schie[1], A. Kawakami[2], M. Tamai[2], S. Y. Kawashiri[3], T. Maeda[4], T. Huizinga[1], R. Toes[1], D. van der Woude[1]. *[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; *[2]Nagasaki University Graduate School of Biomedical Sciences, Immunology and Rheumatology, Nagasaki, Japan*; *[3]Nagasaki University Graduate School of Biomedical Sciences, Community Medicine, Nagasaki, Japan*; *[4]Nagasaki University Graduate School of Biomedical Sciences, General Medicine, Nagasaki, Japan*

Background: Besides anti-citrullinated protein antibodies (ACPA), rheumatoid arthritis patients (RA) often display autoantibody reactivities against other post-translationally modified (PTM) proteins, more specifically carbamylated and acetylated proteins. Immunizing mice with one PTM results in an anti-modified protein antibody (AMPA) response recognizing multiple PTMs. Furthermore, human AMPA, isolated based on their reactivity to one PTM, cross-react with other PTMs at the monoclonal and polyclonal level. However, it is unclear whether the AMPA reactivity profile is "fixed" in time, or whether consecutive exposure to different PTMs can shape the evolving AMPA-response.

Objectives: To investigate the evolution of the AMPA response in mice with controlled exposure to PTMs as well as in AMPA-positive humans.

Methods: Mice were immunized with acetylated (or carbamylated) protein (ovalbumin) twice or cross-immunized with an acetylated and then a carbamylated protein (or vice versa) and their serum was analyzed for AMPA responses with ELISA using a different backbone protein (fibrinogen) bearing the same modifications. Longitudinally collected serum samples of human individuals at risk of RA and with early RA were tested to investigate the evolution of the AMPA responses in humans.

Results: Mice immunized twice with either solely acetylated or solely carbamylated ovalbumin (AcOVA or CaOVA) developed reactivity against both acetylated and carbamylated antigens. Irrespective of the PTM used for the first immunization, a booster immunization with the other PTM resulted in increased titers to the second/booster PTM (Figure 1A), suggesting that immunization with a defined PTM-antigen leads to the generation of anti-PTM memory B cells able to cross-recognize other PTMs. Furthermore, immunizing with CaOVA and boosting with AcOVA (or vice versa) skewed the overall AMPA-response profile towards a relatively higher reactivity against the "booster" PTM (Figure 1B). Human data also illustrated dynamic changes in AMPA reactivity profiles in both individuals at risk of RA and in early RA patients (not shown).

Conclusion: The relationship between different reactivities within the AMPA response is dynamic. The initial exposure to a PTM antigen induces cross-reactive response that can be boosted by the same or other PTMs. The overall reactivity pattern can be skewed by subsequent exposure to other PTMs. These data might explain temporal changes in the reactivity profile of the AMPA response and point to the possibility that the PTM responsible for the initiation of the AMPA response may differ from the PTM predominantly recognized later in time.

Cross-boosting and skewing of AMPA responses in immunized mice

POS0387 ACPA STATUS CORRELATES WITH DIFFERENTIAL IMMUNE PROFILE OF RHEUMATOID ARTHRITIS PATIENTS

A. Floudas[1], M. Canavan[1], T. McGarry[1], V. Krishna[2], S. Nagpal[2], D. Veale[3], U. Fearon[1]. *[1]Trinity Biomedical Sciences Institute, Molecular Rheumatology, DUBLIN, IRELAND, Ireland*; *[2]Janssen Research & Development, Immunology, Spring House, United States of America*; *[3] St Vincent's University Hospital, UCD, EULAR Centre of Excellence, Centre for Arthritis and Rheumatic Diseases, Dublin, Ireland*

Background: Rheumatoid arthritis (RA) is a progressive erosive autoimmune disease that affects 1% of the world population. Anti-citrullinated protein autoantibodies (ACPA) are routinely used for the diagnosis of RA, however 20-30% of patients are ACPA negative. ACPA status is a delineator of RA disease endotypes with similar clinical manifestation but potentially different pathophysiology. Elucidating the underlying mechanisms of disease pathogenesis could inform a treat to target approach for both ACPA-positive and ACPA-negative RA patients.

Objectives: To identify peripheral blood and synovial tissue immune population differences that associate with RA disease endotype.

To identify unique RA patient synovial tissue gene signatures and enriched pathways that correlate with ACPA status.

Methods: Detailed high dimensionality flow cytometric analysis with supervised and unsupervised algorithm analysis of ACPApos and ACPAneg RA patient peripheral blood and synovial tissue single cell suspensions. *Ex vivo* peripheral blood and synovial tissue T cell stimulation and cytokine production characterisation. RNAseq analysis with specific pathway enrichment analysis of APCApos and ACPAneg RA patient synovial tissue biopsies.

Results: Detailed profiling based on high dimensionality flow cytometric analysis of key peripheral blood and synovial tissue immune populations including B cells, T follicular helper (Tfh) cells, T peripheral helper cells (Tph) and CD4 T cell proinflammatory cytokine responses with supervised and unsupervised algorithm analysis revealed unique RA patient peripheral blood B cell and Tfh cell profiles. ACPApos RA patients were characterised by significantly (*P=0.03) increased frequency of Tfh ($CXCR5^+CD4^+$) cells and distinct clustering influenced by increased switched (IgD^-CD27^+) and DN (IgD^-CD27^-) memory B cells compared to APCAneg RA patients. Surprisingly synovial tissue B cell subpopulation distribution was similar between ACPAneg and ACPApos RA patients, with significant accumulation of switched and double negative memory B cells, highlighting a key role for specific B cell subsets in both disease endotypes. Interestingly, synovial tissue CD4 T cell

proinflammatory cytokine (TNF-α, IFN-γ, IL-2, GM-CSF, IL-17A, IL-22, IL-4) production was markedly different between ACPAneg and APCApos RA patients with hierarchical clustering and PCA analysis revealing endotype specific cytokine profiles with ACPAneg RA patient synovial T cells showing increased TNF-α (P=0.01) expression. RNAseq analysis of RA patient synovial tissue revealed significant disease endotype specific gene signatures with specific enrichment for B cell receptor signalling and T cell specific pathways in ACPApos compared to ACPAneg RA patients. Additionally, significantly different chemokine receptor expression based on RA patient ACPA status was observed with increased CXCR3 (P<0.001), CCR7 (P=0.002), and CCR2 (P=0.004) but decreased CXCR7 (P=0.007) expression in APCApos compared to ACPAneg RA patient synovial biopsies.

Conclusion: ACPA status associates with unique synovial tissue immune cell and gene profile signatures highlighting differences in the underlying immunological mechanisms involved, therefore reinforcing the need for a treat to target approach for both endotypes of RA.

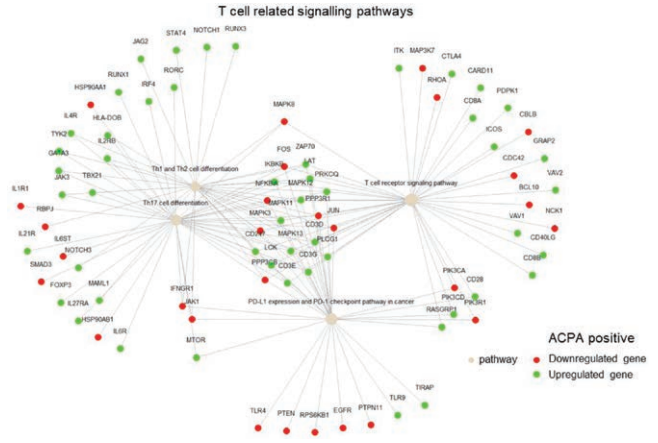

Figure 1. RNAseq analysis of synovial tissue biopsies revealed specific T cell related pathway enrichment in ACPA positive compared to ACPA negative RA patients (n=50, analysis performed with the *DESq2* and *pathfindeR* pipelines in *R*).

POS0388 INTERLEUKIN 40 (IL-40) IS UP-REGULATED IN RHEUMATOID ARTHRITIS (RA) AND ASSOCIATED WITH DISEASE ACTIVITY, LEVELS OF AUTOANTIBODIES AND CHEMOKINES

A. Navrátilová[1,2], L. Andres Cerezo[1,2], H. Hulejova[1], V. Becvar[1], D. Tegzová[1,2], M. Olejárova[1,2], D. Veigl[3], K. Pavelka[1,2], J. Vencovský[1,2], L. Šenolt[1,2]. [1]*Institute of Rheumatology, Department of Experimental Rheumatology, Prague, Czech Republic*; [2]*First Faculty of Medicine Charles University, Department of Rheumatology, Prague, Czech Republic*; [3]*First Faculty of Medicine Charles University, First Orthopaedic Clinic, Prague, Czech Republic*

Background: Interleukin 40 (IL-40) is newly identified B cell - associated cytokine implicated in humoral immune responses and in B cell development. As B cells play a pivotal role in autoimmunity, we aimed to investigate the function of IL-40 in rheumatoid arthritis (RA).

Objectives: The aim of our study was to determine the function of IL-40 in RA.

Methods: IL-40 expression in the synovial tissue was determined by immunohistochemistry and immunofluorescence (n=4-5). IL-40 was analysed in the serum/synovial fluid of patients with RA (n=69), systemic lupus erythematosus (SLE; n=69), osteoarthritis (OA; n=44), and in healthy controls (HC; n=25). Given the association of IL-40 with B cells, we analysed the effect of rituximab therapy on the serum IL-40 in 19 patients with RA after 16 and 24 weeks of the therapy. The clinical activity of patients with RA was assessed according to the 28 joint count Disease Activity Score (DAS28). Levels of C-reactive protein (CRP) and autoantibodies were measured by routine laboratory techniques. *In vitro* experiments were performed in RA synovial fibroblasts (n=9). Levels of cytokines and inflammatory mediators were determined in serum, synovial fluid and supernatants using ELISA or multiplex immunoassay.

Results: IL-40 was overexpressed in RA synovial tissue compared to OA, particularly by synovial fibroblasts and immune cells such as B and T lymphocytes, macrophages and neutrophils. The levels of IL-40 were significantly higher in the synovial fluid of RA patients compared to OA (33.2 (6.6-68.9) vs. 0.7 (0.1-2.4) ng/ml; p<0.0001). In addition, IL-40 was increased in the serum of RA patients compared to SLE, OA or HC (4.8 (1.7-24.9) vs. 1.4 (1.0-1.9), 1.6 (0.6-3.1) or 1.5 (0.7-2.7) ng/ml; p<0.0001 for all) and decreased after 16 (p<0.01) and 24 weeks (p<0.001) in a subgroup of rituximab treated patients with RA. IL-40 levels in RA patients correlated with autoantibodies rheumatoid factor (IgM) and anti-citrullinated protein antibody (ACPA) in the serum (p<0.0001 and p<0.01) as well as in the synovial fluid (p<0.0001 and p<0.001). IL-40 in RA synovial fluid was also significantly associated with DAS28 (p<0.05), synovial fluid leukocyte count (p<0.01), number of swollen joints (p<0.05) and neutrophil attractants IL-8 (p<0.01) and MIP-1α (p<0.01). RA synovial fibroblasts exposed to recombinant IL-40 increased secretion of IL-8 (p<0.01), MCP-1 (p<0.05) and MMP-13 (p<0.01) compared to unstimulated cells in *in vitro* conditions.

Conclusion: Our results show for the first time that IL-40 is elevated in RA and decreases following B-cell depletion therapy. The association of IL-40 with autoantibodies and chemokines may imply its potential involvement in RA development. Moreover, IL-40 up-regulates the secretion of chemokines and MMP-13 by synovial fibroblasts, indicating its role in the regulation of inflammation and tissue destruction in RA.

POS0389 NEUTROPHIL AND MONOCYTE EXTRACELLULAR TRAPS IN RHEUMATOID ARTHRITIS: POTENTIAL SOURCE OF DIAGNOSTIC BIOMARKERS

A. Trofimenko[1], S. Bedina[1], M. Mamus[1], E. Mozgovaya[1], S. Spitsina[1]. [1]*Research Institute of Clinical and Experimental Rheumatology Named After A.B. Zborovsky, Clinical Biochemistry Lab, Volgograd, Russian Federation*

Background: Up-to date quite high rheumatoid arthritis (RA) prevalence has also a trend towards steady increase for several decades. Earliest possible diagnosis and personalized treatment of RA are commonly believed to be principal way to prevent or diminish joint destruction. Emerging biomarkers retrieval has therefore critical importance for improvement of RA treatment outcomes, especially for its biological treatment. One of upcoming sources of new biomarkers is newly discovered phenomenon of neutrophil extracellular traps (NET) and monocyte extracellular traps (MET) formation, specifically in RA.

Objectives: Evaluation of peripheral blood neutrophils and monocytes ability to generate NET and MET spontaneously and after induction in vitro in RA.

Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles. 30 patients with verified RA according to the ACR/EULAR 2010 criteria were included in the study. 30 healthy volunteers were enrolled as a reference group. RA disease activity was assessed using DAS28 score did not exceeded 2.6 in every patient at the inclusion timepoint. Neutrophils and monocytes were isolated with one-step centrifugation procedure using three-layer ficoll-amidotrizoate density gradient with density of upper, intermediate and lower layers 1068 kg/m^3, 1080 kg/m^3, and 1090 kg/m^3, respectively. The cell types in the resulting fractions were identified histochemically, and the extent of cell activation was assessed using common nitro-blue tetrazolium test. Generation of NETs was stimulated by phorbol-12-myristate-13-acetate (PMA). Generation of METs was stimulated using bacterial LPS. The shape and size of NETs and ETs were assessed using fluorescence microscopy with SYBR green.

Results: Mean contamination fraction of neutrophils and monocytes in the reference group did not exceeded 3% and 2%, respectively. Mean purity of neutrophil fraction in RA group was 93.1±6.1%, and cell viability in every sample was above 95.4±5.1%. Mean purity of monocyte fraction in RA group was 98.4±6.4%, cell viability in every sample was above 93.4±4.8%. Spontaneous NET and MET formation was observed in neutrophils and monocytes isolated from both RA patients and, significantly less, in healthy controls. Neutrophils from ACPA-positive RA patients were found to reveal increased spontaneous and induced NETs formation compared to ACPA- negative RA patients. Monocytes did not demonstrate any difference between these subgroups.

Conclusion: NETs could probably be considered as a candidate source of citrulline autoantigen participating in autoantibody production, whereas METs may play less important role in this phenomenon. NETs and ETs can be considered as potential diagnostic biomarkers of RA. Further studies of NETosis and ETosis in RA patients can promote emerging researches for targeted therapy of RA.

POS0390 SIMULTANEOUS ASSESSMENT OF JOINT AND VASCULAR INFLAMMATION BY PET-CT IN TOFACITINIB-TREATED PATIENTS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE STUDY

A. Hamar[1], Z. Hascsi[2], A. Pusztai[1], M. Czókolyová[1], E. Végh[1], Z. Pethö[1], K. Gulyás[1], B. Soós[1], G. Kerekes[3], É. Szekanecz[4], K. Hodosi[1], S. Szántó[1], G. Szücs[1], T. Seres[5], Z. Szekanecz[1], S. Szamosi[1]. *[1]University of Debrecen, Rheumatology, Debrecen, Hungary*; *[2]Scanomed Ltd., PET/CT, Debrecen, Hungary*; *[3]University of Debrecen, Medicine, Debrecen, Hungary*; *[4]University of Debrecen, Oncology, Debrecen, Hungary*; *[5]University of Colorado Anschutz Medical Campus, Anesthesiology, Aurora, Co, United States of America*

Background: Rheumatoid arthritis (RA) has bene associated with atherosclerosis and cardiovascular (CV) disease. 18F-fluorodeoxyglucose positron emission tomography/computed tomography (^{18}FDG-PET/CT) is suitable to detect synovial and vascular inflammation. Tofacitinib has been used to effectively treat RA.
Objectives: We wished to assess the effects of tofacitinib treatment on synovitis and vascular inflammation simultaneously by ^{18}FDG-PET/CT.
Methods: Thirty RA patients with active disease were treated with either 5 mg bid or 10 mg bid tofacitinib and evaluated at baseline and after 6 and 12 months. We determined DAS28, CRP, IgM rheumatoid factor (RF) and anti-cyclic citrullinated peptide (aCCP) levels. All patients underwent 18F-fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) in order to determine vascular and synovial inflammation in five aortic segments and five articular regions, respectively. In the joints, mean (SUV_{mean}) and maximum standard uptake values (SUV_{max}), while in the aorta, mean (TBR_{mean}) and maximum target-to-background ratios (TBR_{max}) were determined. Carotid intima-media thickness (IMT), arterial stiffness (PWV) and endothelial dysfunction (FMD) were determined by ultrasound.
Results: One-year tofacitinib treatment significantly attenuated vascular and synovial inflammation as visualized by PET/CT. Articular SUV_{mean} (p=0.010), SUV_{max} (p=0.001), as well as aorta TBR_{max} (p<0.001) significantly decreased over time. Synovial inflammation as determined by PET/CT variably and positively associated with aCCP, RF, CRP, ApoB, lipoprotein A (LpA), IMT and PWV. Vascular inflammation (TBR_{max}) inversely correlated with HAQ and positively with ESR, ApoA, and PWV. Uni- and multivariable analyses suggested that articular SUV values were independently associated with CRP, ApoB, LpA, IMT and PWV, while aortic TBR_{max} was determined by HAQ and PWV.
Conclusion: ^{18}F-PET/CT is suitable to simultaneously assess synovial and vascular inflammation in RA. One-year tofacitinib treatment dampened inflammation. PET/CT changes were associated with markers of systemic inflammation, atherogenic lipids, carotid atherosclerosis and arterial stiffness.

POS0391 ASSESSING SENESCENT HUMAN LYMPH NODE STROMAL CELLS DURING RHEUMATOID ARTHRITIS DEVELOPMENT

T. de Jong[1,2], J. W. Bolt[1,2], J. F. Semmelink[1,2], L. van Baarsen[1,2]. *[1]Amsterdam UMC, University of Amsterdam, Department of Rheumatology & Clinical Immunology and Department of Experimental Immunology, Amsterdam, Netherlands*; *[2]Amsterdam UMC, Amsterdam Rheumatology & Immunology Center (ARC), Amsterdam, Netherlands*

Background: Cellular senescence is a state of proliferation arrest of cells. The persistence and accumulation of senescent cells has been implicated in the pathogenesis of age-related diseases like rheumatoid arthritis (RA). Clinical disease is preceded by loss of immune tolerance and autoimmunity. Lymph node stromal cells (LNSC) are important regulators of this tolerance. Therefore, senescent LNSC may affect tolerance and the development of systemic autoimmunity.
Objectives: To determine the extent of cellular senescence of LNSC during early phases of systemic autoimmunity.
Methods: We included individuals with arthralgia without any evidence of arthritis who were positive for IgM rheumatoid factor (IgM-RF) and/or anti-citrullinated protein antibodies (ACPA; RA-risk group), early arthritis patients (ACR/EULAR 2010 criteria; disease duration < 1 year) and seronegative healthy controls. All study subjects underwent ultrasound-guided inguinal lymph node biopsy. LNSC were isolated and cultured from freshly collected lymph node needle biopsies and passages 0-9 were used for experiments. Cellular senescence was assessed by measuring cell size, granularity, autofluorescence, senescence-associated gene expression levels, DNA damage and senescence-associated β-galactosidase (SA β-gal) activity.
Results: Preliminary flow cytometry data shows that the cell size and autofluorescence of LNSC from RA patients (n=11) and RA-risk individuals (n=7) is increased compared with healthy LNSC (n=7), while granularity was specifically increased in LNSC from RA patients (n=9). Initial stainings indicate higher SA β-gal activity and more DNA damage in LNSC from RA-risk (n=3) and RA patients (n=4) compared with healthy controls (n=3). Expression levels of senescence-associated genes such as p21 and p53 were significantly higher in LNSC from RA patients compared with healthy controls (n=6 per group).
Conclusion: These preliminary findings suggest senescence already in early RA and provide a rationale for investigating the consequence of senescent LNSC on immune cell responses

POS0392 PRESENCE OF FOUR SERUM AUTOANTIBODIES ASSOCIATES WITH THE ACPA STATUS IN EARLY RHEUMATOID ARTHRITIS

L. Lourido[1], C. Ruiz-Romero[1,2], L. Collado[1], M. Hansson[3], L. Klareskog[3], R. Sjöberg[4], E. Pin[4], P. Nilsson[4], F. J. Blanco[1,5]. *[1]Unidad de Proteómica. Grupo de Investigación de Reumatología (GIR)., Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC)., A Coruña, Spain*; *[2]Centro de Investigación Biomédica en Red de Bioingeniería, Biomateriales y Nanomedicina, (CIBER-BBN), Madrid, Spain*; *[3]Karolinska Institutet, Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden*; *[4]KTH Royal Institute of Technology & SciLifeLab, Division of Affinity Proteomics, Department of Protein Science, Stockholm, Sweden*; *[5]Universidade da Coruña (UDC), Grupo de Investigación de Reumatología y Salud (GIR-S)., Departamento de Fisioterapia, Medicina y Ciencias Biomédicas, Facultad de Fisioterapia, A Coruña, Spain*

Background: The presence of anti-citrullinated protein antibodies (ACPAs) is a hallmark of rheumatoid arthritis (RA) that precede the development of the disease by years and is used for its clinical diagnosis. However, there are RA subjects that test negative for ACPA and thus the early diagnosis on these patients may be delayed. Furthermore, the presence or absence of ACPA in RA supports the hypothesis that on these two subsets of patients underlie different pathogenesis and clinical outcomes.
Objectives: In this work, we searched for serum autoantibodies useful to assist the early diagnosis of ACPA-seronegative RA and its management.
Methods: We profiled the serum autoantibody repertoire of 80 ACPA-seronegative and 80 ACPA-seropositive RA subjects from the Swedish population-based Epidemiological Investigation of RA (EIRA) cohort. A suspension bead array platform built on protein fragments within Human Protein Atlas and selected from an initial untargeted screening using arrays containing 2660 total antigens was employed to identify IgG and IgA serum autoantibodies. A validation phase on antigen suspension bead arrays was carried out on another set of samples from EIRA containing 386 ACPA-seropositive, 358 ACPA-seronegative and 372 randomly selected control subjects of the same age and sex. A sample-specific threshold based on 20 times the median absolute deviation plus the median of all signals was selected to determine the reactivity of samples. The Wilcoxon rank sum test and Fisher's test were applied for the comparison of autoantibody levels and reactivity frequencies between the groups.
Results: Our data revealed four antigens associated with the ACPA status (Table 1). Testis-specific Y-encoded-like protein 4 (TSPYL4) showed significantly higher IgG reactivity frequency in ACPA-seronegative subjects compared to ACPA-seropositive (8% vs. 3%; P<0.05). Significant differences at IgG autoantibody levels (P<0.05) were also observed between ACPA-seronegative subjects and controls for this specific antigen. Significantly higher

IgG autoantibody levels (P<0.05) towards another antigen, dual specificity mitogen-activated protein kinase kinase 6 (MAP2K6), were also observed in ACPA-seronegative subjects compared to ACPA-seropositive and controls. In contrast, we found significantly higher IgG autoantibody levels (P<0.05) in ACPA-seropositive individuals compared to ACPA-seronegative and controls towards two antigens, anosmin-1 (ANOS-1) and muscle related coiled-coil protein (MURC). ANOS-1 shows also significantly higher IgG reactivity frequency in ACPA-seropositive individuals compared to ACPA-seronegative and controls (22%, 9% and 6% respectively; P<0.05). Interestingly, three out of the four antigens discovered to be associated with the ACPA status in early RA are highly expressed in lungs and heart, two of the main extraarticular sites affected in RA. No significant differences were observed at IgA levels for any of the antigens analyzed.

Table 1. Scheme of the different phases of the study, the features within each phase and the results. The reactivity to four antigens allows to distinguish ACPA-seronegative (ACPA-), ACPA seropositive (ACPA+) and controls.

Phases	Untargeted discovery	Targeted discovery	Targeted validation
Number of samples	80 ACPA- 80 ACPA+	80 ACPA- 80 ACPA+	358 ACPA-372 Controls 386 ACPA+
Antigen array platform	Planar arrays	Suspension bead array 1	Suspension bead array 2
Number of antigens	2660	62	27
Number of candidate biomarkers	62	27	4 (TSPYL4,MAP2K6, ANOS1,MURC)

Conclusion: Upon further validation in other early RA sample cohorts, our data suggest the measurement of these four autoantibodies may be useful for the early diagnosis of ACPA-seronegative RA and give insight into the pathogenesis of the different RA subsets.

POS0393 FIBRIN DEPOSITION IS AN ACTIVE TRIGGER OF CARTILAGE DEGENERATION IN RHEUMATOID ARTHRITIS

T. Hügle[1], S. Nasi[1], D. Ehirchiou[1], P. Omoumi[2], A. So[1], N. Busso[1]. [1]*Lausanne University Hospital, CHUV, Department of Rheumatology, Lausanne, Switzerland*; [2]*Lausanne University Hospital, CHUV, Radiology, Lausanne, Switzerland*

Background: Fibrin(ogen) maintains inflammation in various disorders but has never been linked to cartilage damage in rheumatoid arthritis (RA) or other forms of inflammatory arthritis.
Objectives: To investigate the role of fibrin deposition on cartilage integrity in arthritis.
Methods: Fibrin deposition on knee cartilage was analyzed by immunohistochemistry in RA patients and in murine adjuvant-induced arthritis (AIA). In chondrocytes, fibrinogen expression (*Fgα, Fgβ, Fgγ*) and procoagulant activity were evaluated by qRT-PCR and turbidimetry respectively. Fibrin-induced catabolic genes were assessed by qRT-PCR in chondrocytes. Fibrin-mediated chondro-synovial adhesion (CSA) with subsequent cartilage tears was studied in co-cultures of human RA cartilage with autologous synoviocytes, in the AIA model, and by MRI. The link between fibrin and calcification was examined in human RA cartilage stained for calcific deposits and *in vitro* in fibrinogen-stimulated chondrocytes.
Results: Fibrin deposition on cartilage correlated with the severity of cartilage damage in human RA explants and in AIA wildtype (WT) mice, while fibrinogen deficient ($Fg^{-/-}$) mice were protected. Accordingly, fibrin upregulated catabolic enzymes (*Adamts5* and *Mmp13*) in chondrocytes. Secondly, CSA was present in fibrin-rich and damaged cartilage in AIA WT but not in $Fg^{-/-}$ mice. In line, autologous human synoviocytes, cultured on RA cartilage explants, adhered exclusively to fibrin-positive degraded areas. Gadolinium-enhanced MRI of human joints showed contrast-enhancement along cartilage surface in RA patients but not in controls. Finally, fibrin co-localized with calcification in human RA cartilage and triggered chondrocyte mineralization inducing pro-calcification genes (*Anx5, Pit1, Pc1*) and cytokine (IL-6). Although at a much lesser extent, we observed similar fibrin-mediated mechanisms in osteoarthritis (OA).
Conclusion: Fibrin deposition directly impacts on cartilage integrity via induction of catabolism, mechanical stress, and calcification. Potentially, fibrin is a key factor of cartilage damage occurring in RA as a secondary consequence of inflammation.

POS0394 NAD+ BOOSTERS REESTABLISH THE ALTERED NAD+ METABOLISM OF LEUKOCYTES FROM RHEUMATOID ARTHRITIS PATIENTS IMPROVING THEIR OXIDATIVE, APOPTOTIC AND INFLAMMATORY STATUS

C. Perez-Sanchez[1], L. M. Sánchez-Mendoza[2], M. D. C. Abalos-Aguilera[1], N. Barbarroja Puerto[1], M. Luque-Tévar[1], A. M. Patiño-Trives[1], I. Arias de la Rosa[1], J. A. Moreno[2], M. I. Burón[2], J. A. González-Reyes[2], E. Collantes Estevez[1], A. Escudero Contreras[3], C. Lopez-Pedrera[1], J. M. Villalba[2]. Background: NAD^+ is an important cofactor and second messenger for multiple cellular processes that exhibits antioxidant, anti-apoptotic and anti-inflammatory properties. Pre-clinical studies in animal models of Rheumatoid Arthritis (RA) have demonstrated the therapeutic potential of NAD^+ boosters in the control of the disease activity. However, to date no studies have been set up to evaluate the NAD+ metabolism and the therapeutic effects of NAD^+ boosters in RA patients.
Objectives: 1- To study the NAD^+ metabolism in RA patients and its association with key clinical features. 2- To evaluate the effect of anti-TNF therapy in the NAD+ metabolism.
3- To analyze the beneficial effects of NAD^+ boosters in leukocytes from active RA patients.
Methods: Plasma and PBMCs were purified from 100 RA patients and 50 healthy donors (HDs). Moreover, an additional cohort of 50 RA patients treated with Anti-TNF therapy was analyzed before and after 6 months of treatment. NAD^+ levels were determined by using the NAD/NADH-Glo Assay. NAD^+-consuming genes expression were analyzed by RT-PCR. In parallel, PBMCs from eight HDs and eight active RA patients were treated *ex vivo* with 1 mM of NAD^+ boosters including nicotinamide (NAM), nicotinamide riboside (NR), and nicotinamide mononucleotide (NMN). After 24 hours, intracellular reactive oxygen species (ROS) levels (DFCHDA) and the percentage of apoptotic PBMCs (annnexin V/PI) were assessed by flow cytometry. Lastly, a panel of key pro-inflammatory genes were evaluated by RT-PCR.
Results: NAD^+ and NADH levels were significantly reduced in plasma and PBMCs of RA patients compared with HDs and directly related to disease activity (DAS28, CDAI, SDAI). Accordingly, the expression levels of genes involved in the consumption of NAD^+ such as SIRT-1, CD38 and PARP-1 were found up-regulated in PBMCs from RA patients. Anti-TNF therapy for 6 months restored the altered NAD+ levels towards those showed by HDs. Furthermore, the clinical response promoted by Anti-TNF therapy (changes in DAS28) correlated with changes in NAD+ levels. The *in vitro* treatments of PBMCs isolated from active RA patients with NAD^+ boosters significantly increased the NAD^+ levels and promoted a deep reduction of intracellular ROS levels, the percentage of apoptotic cells and the expression levels of key inflammatory mediators, such as IL-6, IL-8, IL-1ß, TNF-α, CCL2, IL-23, and STAT-3.
Conclusion: 1. NAD^+ metabolism is altered and associated with the disease activity of RA patients, involving both, reduced NAD^+ levels and increased expression of NAD^+-consuming genes. 2. Anti-TNF therapy restored NAD+ levels, which were directly linked to the clinical effectiveness. 3. NAD^+ boosters reduced the oxidative, apoptotic and inflammatory profiles of RA leukocytes through the parallel increase of intracellular NAD^+ levels. Thus, NAD^+ boosters might be considered novel therapeutic tools for RA patients.

POS0395 ANTI-ACETYLATED PROTEIN ANTIBODIES IN RHEUMATOID ARTHRITIS (RA): CLUES FOR THE STARTING POINT OF AUTOANTIBODY RESPONSES IN RA

T. J. van Wesemael[1], A. L. Dorjée[1], T. Huizinga[1], A. van der Helm - van Mil[1], R. Toes[1], D. van der Woude[1]. [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*

Background: Rheumatoid arthritis (RA) is characterized by autoantibodies such as rheumatoid factor (RF) and anti-modified protein autoantibodies (AMPAs) like anti-citrullinated protein antibodies (ACPA) and anti-carbamylated protein

antibodies (anti-CarP). Recently, another AMPA: anti-acetylated protein antibodies (AAPA) have been found in RA patients [1]. The prevalence of AAPA antibodies and their isotypes have yet to be determined. Since isotype profiles reflect the breadth of an immune response, the prevalence of AAPA isotypes in arthritis patients with and without RA can help to understand the relevance of this autoantibody response in RA.

Objectives: To describe the prevalence of AAPA isotypes in arthritis patients with and without RA.

Methods: In 650 RA patients fulfilling the 1987 RA criteria and 555 non-RA arthritis patients from the Leiden Early Arthritis Cohort, baseline serum samples were screened by ELISA for IgG, IgM and IgA to an acetylated- and control peptide that was based upon the CCP-2 backbone. The cutoff for positivity was based on 80 controls (mean + 2SD). A sample was considered positive if it was above the cutoff and was 0.1 optical density higher on the acetylated peptide than on the control peptide.

Results: AAPA IgG was found in 36% of RA patients versus 6.7% of non-RA arthritis patients (figure 1a). Within RA patients, AAPA IgG antibodies were mostly present in the ACPA-(CCP-2) positive group (64% in ACPA-positive, compared to 5% in ACPA-negative). Levels of AAPA IgG and IgA were higher in RA patients than in healthy controls and non-RA arthritis patients (figure 1b), however, surprisingly, no difference in levels was found for IgM.

When isotype profiles in AAPA- positive arthritis patients were compared, patients with RA were more often positive for two or more isotypes then patients without RA, and thus displayed considerably more overlap in AAPA isotypes compared to non-RA patients (table 1). Intriguingly, IgM AAPA was the most prevalent isotype in non-RA patients, versus IgG in RA patients.

Table 1. Anti-acetylated protein antibody (AAPA) isotype overlap in AAPA positive patients.

AAPA isotype	RA patients (=310) n (%)	Non-RA arthritis patients (n=106) n (%)
IgG+IgM-IgA-	115 (37.1)	28 (5.1)
IgG-IgM+IgA-	52 (16.8)	48 (8.7)
IgG-IgM-IgA+	14 (4.5)	13 (2.3)
IgG+IgM+IgA-	24 (7.7)	3 (0.5)
IgG+IgM-IgA+	37 (11.9)	4 (0.7)
IgG-IgM+IgA+	9 (2.9)	8 (1.4)
IgG+IgM+IgA+	59 (19.0)	2 (0.4)

AAPA: anti-acetylated protein antibodies, RA: rheumatoid arthritis

Conclusion: AAPA are detected in one third of RA patients, and mainly in the ACPA-positive subgroup. The predominance of IgM AAPA in non-RA arthritis patients and healthy controls suggests that healthy persons can develop AAPA IgM without the development of RA. These results also suggest that in healthy individuals, AAPA responses can occur, but do not mature past the IgM-stage, while in RA patients, the AAPA-response does mature and might form a "starting point" for development of other AMPA leading to the concurrent present of several AMPA in disease.

POS0396

THE LEVEL OF PERIPHERAL REGULATORY T CELLS IS ASSOCIATED WITH THE CHANGES OF INTESTINAL MICROBIOTA IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. Wu[1], J. An[1], T. Ding[1], H. Xue[1], X. F. Li[1], C. Wang[1]. [1]*The Second Hospital of Shanxi Medical University,The Department of Rheumatology,Taiyuan, China*

Background: Rheumatoid arthritis (RA) is a systemic autoimmunity inflammation disease characterized with chronic aggressive arthritis and the presence of abnormal antibodies. Several observations showed that the breakdown of immune tolerance caused by many complex interactions was involved in the development of RA[1]. However, the pathogenesis of RA remained unclear. It has been confirmed that the imbalance of Th17 and Treg cells play a crucial role in destroying immune tolerance [2]. Besides, researches showed that intestinal microbiota can influence host immunity by acting on the immune cells to play pro-inflammatory or anti-inflammatory effect, and in turn immune system can also regulate the microbiota[3, 4]. Thus, a frontier point of view in the field of rheumatism, immune microecology, was proposed, which is a novel concept for the breakdown of immune tolerance. Studies have confirmed that there was an imbalance of intestinal microbiota in patients with RA [4]. But the relationship between the CD4+T subsets cells and intestinal microbiota in RA is unknown.

Objectives: We detected and compared the absolute number of CD4+T cells subsets in the peripheral blood and the proportion or abundance of intestinal microbiota in patients with RA and healthy adults, and then analyzed the relationship between them to explore the role of CD4+T cells subsets and intestinal microbiota in the pathogenesis of RA.

Methods: We collected the sample of stool and blood from 15 patients with RA hospitalized at the Second Hospital of Shanxi Medical University and 8 age and gender-matched healthy controls(HC). The absolute number of CD4+T cells subsets including Th1, Th2, Th17 and Treg cells were detected by flow cytometry. The 16S rRNA in the stool specimens were sequenced by the Roche/45 high-throughput sequencing platform. We analyzed whether there was correlarion between CD4+T subsets cells and intestinal microbiota.

Results: Patients with RA had a higher level of *Christensenellaceae* and a lower level of *Pseudomonadaceae* as compared with those of HCs at the family level ($p<0.05$). And at the genus level, the patients with RA had higher levels of *Ruminococcus torques*, *Christensenellaceae R-7*, *Ruminiclostridium 9* and *Ruminococcus 1* compared with those of HCs ($p<0.05$) (Figure 1).And the *Ruminococcus torques* at the genus level was negative correlated with the absolute number of Treg cells ($p<0.001$) (Figure 2).

Conclusion: The results here suggested that there were different proportion or abundance of intestinal microbiota between the patients with RA andHCs. And the changes of intestinal microbiota such as *Ruminococcus torques* were associated with Treg cells, further indicating that the imbalance of intestinal microbiota in RA can destory the immune tolerance. The above results uncovered that the intestinal microbiota had immunomodulatory function, which may be the upstream mechanism participated in the pathogenesis of RA.

POS0397 AGGREGATED SURVIVIN BINDING AROUND HISTONE H3 EPIGENETIC MODIFICATIONS IN RISK LOCI ASSOCIATED WITH RHEUMATOID ARTHRITIS

V. Chandrasekaran[1], G. Katona[2], M. I. Bokarewa[1], K. M. Andersson[1], M. C. Erlandsson[1], M. Jensen[2], N. Oparina[1], A. Damdimopoulos[3]. [1]*Gothenburg University, Department of Rheumatology, Gothenburg, Sweden*; [2]*Gothenburg University, Department of Chemistry and Molecular Biology, Gothenburg, Sweden*; [3]*Karolinska Institute, Department of Bioscience and Nutrition, Huddinge, Sweden*

Background: Survivin is an integral part of the Chromosomal Passenger Complex (CPC) which plays a vital role in mitosis. Experiments have demonstrated that survivin can physically bind to DNA. Crystallographic studies show that survivin binds to Threonine-3 of histone H3. In patients with autoimmune diseases, increased survivin expression contributes to an aggravated disease phenotype. Thus, functional, and mechanistic data point to a potential chromatin regulatory role for survivin, possibly in combination with the established gene regulatory function carried out by histone epigenetic modifications (EM).
Objectives: The objective of the study was to analyse the co-localization of chromatin bound survivin with three histone H3 epigenetic modifications – acetylated lysine 27 (K27ac) and trimethylated lysine 4 (K4me3) and lysine-27 (K27me3). The second objective was to analyse if survivin-bound DNA sequences overlapped with sequences in the vicinity of 106 GWAS SNPs that are associated with a risk of developing rheumatoid arthritis (RA).
Methods: Chromatin from CD4 T cells of 14 female subjects was immunoprecipitated with survivin antibodies and each of the histone H3 antibodies, and coupled with sequencing (ChIPseq, Hiseq2000, Illumina). After mapping the annotations of sequenced regions to the human reference genome hg38, enriched peaks were identified through Homer software. The identified survivin ChIP peaks were analysed for colocalization with peaks of the three histone H3 EMs and with RA risk loci, using the Bioconductor package 'ChIPPeakAnno' through RStudio.
Results: Among the total of ~13,000 individual survivin ChIP-peaks, 33% colocalized with histone H3 EM peaks. The overlapping peaks show a linear increase in average peak size compared with the peaks showing no colocalization with any H3 EM peak. A maximum of 5.5-fold increase in average peak size was observed when survivin bound peaks overlap with peaks of all three H3 EMs. A major proportion (86%) of top RA risk SNPs was associated with either binding of survivin or H3 EMs. In this subset, 63% of RA risk SNPs were found within an area of 100 kilobases from survivin ChIP-peaks, with preferential enrichment of high-scoring peaks when survivin colocalizes with all 3 H3 EMs. Survivin was bound to risk SNPs annotated to, among others, the major immunological genes CD83, IRF4, CD28, ICOS and IL2RA
Conclusion: This study presents experimental evidence that survivin binding to DNA preferentially occurred in regions with high density of histone EMs. The increased aggregation of survivin around histone H3 EMs point to its potential regulatory function in gene transcription. Since regions around RA risk SNPs overlap with survivin peaks, survivin's nuclear function could have immunologically important effects in mechanisms of autoimmune diseases.

POS0398 ADIPONECTIN INDUCES SYNOVIAL ANGIOGENESIS IN RHEUMATOID ARTHRITIS THROUGH METABOLIC REMODELING

L. Wang[1], W. Tan[1], F. Wang[2], M. Zhang[1]. [1]*The First Affiliated Hospital of Nanjing Medical University, Department of Rheumatology, Nanjing, China*; [2]*The First Affiliated Hospital of Nanjing Medical University, Department of Cardiology, Nanjing, China*

Background: Our team have previously reported that Adiponectin correlates well with synovial inflammation and progressive bone erosion in rheumatoid arthritis (RA). Angiogenesis is another important part, which plays a critical role in the pathogenesis of RA.
Objectives: We hypothesized that adiponectin induces synovial angiogenesis in RA.
Methods: Single-cell RNA sequencing (scRNA-Seq) was used to screen cellular changes in local knee joint of collagen-induced arthritis (CIA) after intraarticularly injected of adiponectin. Chimera models of synovium-cartilage-NOD/SCID mice, matrigel plug assay and rat aortic ring assay were performed to demonstrate the pro-angiogenesis role of adiponectin. Cellular experiment, including proliferation, migration, apoptosis, tube formation and angiogenesis related gene expression profile, were detected with Human Umbilical Vein Endothelial Cells (HUVEC) and Mice Lung Microvessel Endothelial Cell (MLMEC) after adiponectin stimulation. Seahorse was performed to clear the influence of adiponectin to cell metabolism.
Results: The synovium and pannus hyperplasia worse in CIA model after intraarticularly injected of adiponectin, along with more serious synovitis and bone erosion. ScRNA-Seq of synovial tissues separated from CIA reminded that endothelial cell barbarically grows via metabolic remodeling after stimulated with adiponectin. Synovial chimera, matrigel plug and rat aortic ring shows adiponectin accelerates angiogenesis significantly in different background conditions. In vitro, endothelial cell proliferation detecting by RCTA and CCK8, migration by wound healing and transwell, apoptosis by FACS, tube formation and angiogenesis related gene expression profile by PCR-ARRAY were promoted by adiponectin in both HUVEC and MLMEC. Seahorse showed HUVEC made more use of glycolysis after co-cultured with adiponectin, a method of cell energy supply that tumor cells possess called warburg effect, that drives endothelial cell hyperplasia in severe environment.
Conclusion: As a classic metabolic regulator, adiponectin exacerbates CIA by promoting angiogenesis through metabolic remodeling. The findings not only provide a novel insight into the pathogenic role of adiponectin, but also reveals a potential therapeutical strategy to attenuate revascularization in RA.

POS0399 TMT-BASED QUANTITATIVE PROTEOMICS ANALYSIS OF SYNOVIAL FLUID-DERIVED EXOSOMES IN RHEUMATOID ARTHRITIS, AXIAL SPONDYLOARTHRITIS, GOUT AND OSTEOARTHRITIS

Y. Liu[1,2], Y. Huang[1], Q. Huang[1], Z. Huang[1], Z. Li[1], T. W. Li[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China*; [2]*University of South China, Guangdong Second Provincial General Hospital, Guangzhou, China*

Background: The pathogeneses of the joint diseases rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), gout, and osteoarthritis (OA) are still not fully elucidated. Exosomes in synovial fluid (SF) has a critical role in the pathogenesis of arthritis. None of study has compared the proteomics of SF-derived exosomes in RA, axSpA, gout and OA.

Objectives: To compare the proteomics of SF-derived exosomes in RA, axSpA, gout and OA based on tandem mass tags (TMT) labeled quantitative proteomics technique.
Methods: SF-derived exosomes was isolated from RA, axSpA, gout and OA patients by the Exoquick kit combined ultracentrifugation method. TMT labeled quantitative proteomics technique was used to compare the proteomics of SF-derived exosomes. Volcano plot, hierarchical cluster, Gene Ontologies (GO), Encyclopedia of Genes and Genomes (KEGG) pathway analysis were conducted.
Results: A total of 1678 credible proteins were detected. With the cut off criteria of |log2 (fold-change)| ≥1.2 and p-value <0.05, 267 (140 up-regulated and 127 down-regulated)differential proteins were found in OA vs gout, 291 (179 and 112) in axSpA vs OA, 515 (109 and 406) in RA vs axSpA, 298 (191 and 107) in axSpA vs gout, 462 (160 and 302) in RA vs gout, 536 (170 and 366) in RA vs OA. GO analysis showed that the biological progress of differential proteins were mainly enriched in the "immune response". Regarding the molecular function, the differential proteins mainly mediated "antigen binding". GO analysis of the cellular components indicated that most proteins were annotated as "extracellular exosomes". KEGG pathway analysis demonstrated differential proteins were significantly enriched in "complement and coagulation cascades". The hierarchical cluster analysis of the differential proteins in the four groups showed that Lysozyme C and Keratin were more abundant in gout, Hemoglobin and Actin-related protein 2/3 complex subunit 3 in OA, Sodium/potassium-transporting ATPase subunit alpha-1 and Immunoglobulin heavy constant delta in axSpA, Pregnancy zone protein and Stromelysin-1 in RA.
Conclusion: The protein profiles of SF-derived exosomes in RA, axSpA, gout and OA patients were different. The differential proteins were the potential biomarkers of RA, axSpA, gout and OA.

POS0400 **METABOLIC CHANGES INDUCED BY ANTI-MALONDIALDEHYDE/MALINDIALDEHYDE-ACETALDEHYDE ANTIBODIES PROMOTE OSTEOCLAST DEVELOPMENT**

K. Sakuraba[1], A. Krishnamurthy[2], A. Circiumaru[2], V. Joshua[2], H. Wähämaa[2], M. Engström[2], M. Sun[2], X. Zheng[3], C. Xu[3], K. Amara[2], V. Malmström[2], S. B. Catrina[3], C. Grönwall[2], B. Réthi[2], A. Catrina[2]. [1]*National Hospital Organization Kyushu Medical Center, Department of Rheumatology, Fukuoka, Japan*; [2]*Karolinska Institutet & Karolinska University Hospital, Department of Medicine, Solna, Stockholm, Sweden*; [3]*Karolinska Institutet & Karolinska University Hospital, Molecular Medicine and Surgery, Stockholm, Sweden*

Background: Malondialdehyde (MDA) is a highly reactive compound generated during lipid-peroxidation in conditions associated with oxidative stress. MDA can irreversibly modify proteins (e.g. lysine, arginine and histidine residues). In addition, acetaldehyde can further react with MDA adducts to form malondialdehyde-acetaldehyde (MAA) modification. Such protein modifications can lead to immunogenic neo-epitopes that are recognized by autoantibodies. In fact, anti-MDA/MAA IgG antibodies are significantly increased in the serum of patients with autoimmune diseases, such as rheumatoid arthritis (RA) (1). Interestingly, anti-MDA/MAA antibodies have been shown to promote osteoclast (OC) differentiation *in vitro* suggesting a potential role for these autoantibodies in bone damage associated with RA (1).
Objectives: Little is known about the molecular mechanisms activated by autoantibodies in RA. Here, we elucidate the pathways specifically triggered by anti-MDA/MAA autoantibodies in developing osteoclasts.
Methods: Recombinant human monoclonal anti-MDA/MAA antibodies, which were previously cloned from single synovial B cells of RA patients, were added to different OC assays. OCs were generated from monocyte-derived macrophages in the presence of the cytokines RANK-L and M-CSF. OC development was monitored by light microscopy following tartrate-resistant acid phosphatase staining and by erosion assays using calcium phosphate-coated plates. Bone morphometrics were studied in anti-MDA/MAA-injected mice using X-ray microscopy. Cellular metabolism was analyzed by mass spectrometry, Seahorse XF Analyzer and a colorimetric L-Lactate assay.
Results: Anti-MDA/MAA antibodies induced a robust OC differentiation *in vitro* and bone loss *in vivo*. The anti-MDA/MAA antibodies acted on developing OCs by increasing glycolysis via an Fcγ receptor I-mediated pathway and the upregulation of the transcription factors HIF-1α, Myc and CHREBP. Such regulation of cellular metabolism was exclusively observed in the presence of the osteoclastogenic anti-MDA/MAA clones, whereas other RA-associated autoantibodies (anti-MDA/MAA or anti-citrullinated protein antibodies) had no effect on metabolism. The anti-MDA/MAA treatment induced a shift in the tricarboxylic acid (TCA) cycle activity in developing OCs, leading to the accumulation of citrate and aconitate.
Conclusion: We described a novel type of autoantibody-induced pathway in RA, which might contribute to increased OC activation and a consequent bone loss. Anti-MDA/MAA antibodies promoted osteoclast development by increasing glycolysis and by modulating the TCA cycle through a signaling pathway that included Fcγ receptor I and a network of transcription factors acting on glycolysis. A TCA cycle bias towards citrate production suggests that the anti-MDA/MAA antibodies might stimulate OCs via increasing lipid biosynthesis in the cells.

POS0401

THE APPLICATION OF MTX-LOADING DNA TETRAHEDRON IN TREATING COLLAGEN-INDUCED ARTHRITIS MICE VIA REGULATING MACROPHAGE

X. Ge[1], Y. Jin[1], Z. Mao[2], Y. Guo[2], Z. Gu[1]. [1]*Affiliated Hospital of Nantong University, Department of Rheumatology, Nantong, China*; [2]*Affiliated Hospital of Nantong University, Research Center of Clinical Medicine, Nantong, China*

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease which mainly affect joints. [1]. Macrophages often infiltrate in the inflammatory joints. Activated macrophages release TNF-α, IL-1β to accelerate tissue damage, is one of the most important targets for RA intervention. The traditional drugs currently used commonly have some disadvantages cannot be bypassed[2], while DNA nanostructure is a new type of drugs have precise design, and likewise takes biological effect together[3]. We synthesized a DNA tetrahedron loaded with MTX and conjugated with HA which targeted to macrophage.

Objectives: To verify whether MTX-loading DNA tetrahedron can regulate the apoptosis and polarization of macrophage and finally improve the condition of CIA model mice by while decrease the side effect of MTX.

Methods: DNA TET was synthesized by mixing signal strand DNA in TM buffer and heated to 95 °C for 10 min, then cooling to 4 °C. Electrophoresis was applied to confirm the formation of TET. The absorbance of MTX solution was detected by microplate reader to analyze the loading efficiency of MTX into TET. Fluorescence microscope was used to observe the intake of TET into cells. CCK8 experiment was applied to measure the vitality of cells. Flow cytometry was used to detect the apoptosis and polarization. CIA model was established based on DBA/1 mice. Mice were randomly divided into five groups: normal group injected with NS; after established CIA model, CIA group injected with NS, MTX group injected with MTX solution, MTX-TET group injected with MTX-TET NP.

Results: We synthesized DNA tetrahedron(A) and used 8% PAGE electrophoresis to confirmed the successfully synthesis(B). Then We found that when TET concentration fixed, the loading MTX concentration gradually increased and saturated at 190μM(C). While completely loading needed at least 4 hours(D). Fluorescence showed that single DNA strand cannot be taken by RAW, while TET can be easily taken by RAW(E). CCK8 showed that empty TET had no obvious effect on cells, while MTX and MTX-TET with equivalent concentration can obviously suppress the vitality(F). Similarly, the apoptosis trial showed that TET can slightly decrease the apoptosis of RAW, MTX and MTX-TET can significantly promote the apoptosis(G). Flow cytometry showed that the MTX-TET can decrease the expression of M1 marker CD80 (H).

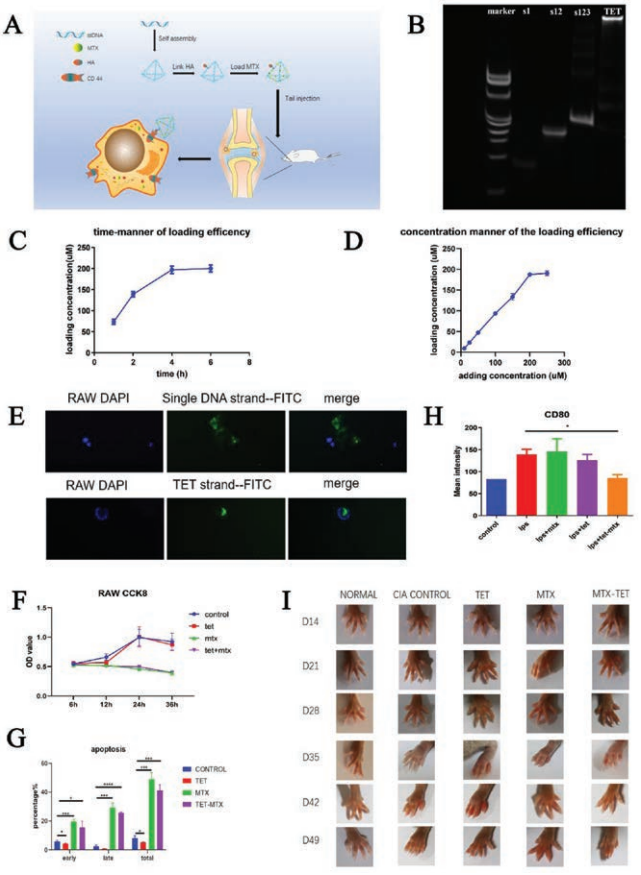

Figure 1.

At last, we treat mice with NS, TET, MTX and MTX-TET once a week after CIA model established, and found that TET have no significantly effect on mice, while MTX and MTX-TET can alleviate the inflammation symptom of paws(I).

Conclusion: Conclusions: We synthesized MTX-loading DNA tetrahedron conjugated with HA, and found that the MTX-TET NP have the excellent ability of promote RAW apoptosis and relieve proinflammatory M1 polarization. while also can alleviate the symptom of CIA mice.

POS0402

IDENTIFYING MECHANISMS UNDERLYING THE ASSOCIATION BETWEEN RHEUMATOID ARTHRITIS AND PERIODONTITIS USING IN SILICO ANALYSIS OF CANONICAL PATHWAYS

K. S. K. Ma[1], L. T. Wang[2]. [1]*National Taiwan University, Taipei, Taiwan, ROC, Department of Life Science, Taipei, Taiwan, Republic of China*; [2] *National Taiwan University Hospital, Department of Obstetrics & Gynecology, Taipei, Taiwan, Republic of China*

Background: Periodontal pathogens such as *Porphyromonas gingivalis (P.g.)* has been proposed too involve in rheumatoid arthritis (RA) progression via citrullinating and producing exogenously citrullinated human and bacterial epitopes.

Objectives: We identified pathways downstream to periodontitis onset that involved in RA progression with RNA-sequencing data.

Methods: Canonical pathway analysis was conducted by comparing mRNA expression data from whole-transcriptome expression profiling using z-score and p-value visualization to identify underlying mechanisms among patients with RA (n=7) and periodontitis (n=9). Collected biopsies included human blood samples for RA and human gingival tissues for periodontitis. RNA-seq data with -$\log_{10}$(P) values larger than 1.3 were considered significant, and positive z-scores indicated up-regulation. The statistical software was Ingenuity Pathway Analysis (QIAGEN).

Results: Among all significantly enriched (-log10(P) > 1.3) periodontitis-associated pathways underlying RA progression identified from the recruited cases, the production of nitric oxide and reactive oxygen species in macrophages, B cell receptor signaling, osteoarthritis pathway, HOTAIR regulatory pathway, IL-8 signaling, LPS/IL-1 mediated inhibition of RXR function, leukocyte extravasation signaling, and neuroinflammation signaling pathway, were up-regulated in RA patients and patients with periodontitis, when compared with patients without either disease. The z-scores of production of nitric oxide and reactive oxygen species in macrophages were 2.45 for RA (-log10(P) = 1.41), 3.89 for periodontitis (-log10(P) = 4.25); the z-scores of B cell receptor signaling were 2.44 for RA (-log10(P) = 1.93), 2.65 for periodontitis (-log10(P) = 6.97); the z-scores of osteoarthritis pathway were 1.89 for RA (-log10(P) = 3.28), 2.33 for periodontitis (-log10(P) = 4.31); the z-scores of HOTAIR regulatory pathway were 1.63 for RA (-log10(P) = 1.71), 3.40 for periodontitis (-log10(P) = 3.68); the z-scores of IL-8 signaling were 1.34 for RA (-log10(P) = 1.30), 4.43 for periodontitis (-log10(P) = 6.05); the z-scores of LPS/IL-1 mediated inhibition of RXR function were 1.33 for RA (-log10(P) = 2.00), 1.27 for periodontitis (-log10(P) = 3.44); and the z-scores of leukocyte extravasation signaling were 1.13 for RA (-log10(P) = 1.80), 3.68 for periodontitis (-log10(P) = 18.14).

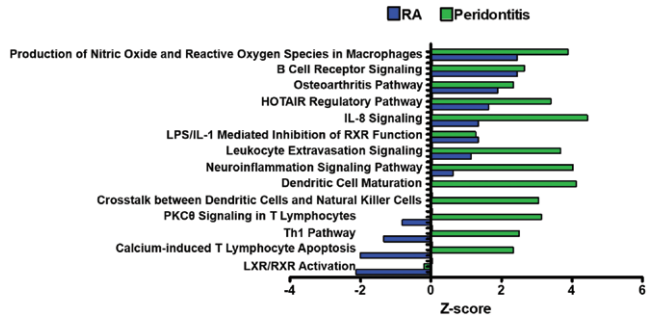

Figure 1. Canonical pathway analysis on transcriptome of blood samples for patients with RA and gingival tissues for periodontitis.

Conclusion: Our findings suggest that infection-driven activation of macrophages and B cells is involved in RA pathogenesis. This occurs primarily

through upregulating cellular activities involving iNOS-presenting macrophages and B cell receptor signaling, which may be associated with the pathogenesis of *P.g.*-triggered RA.

POS0403 **RISK FACTORS FOR PROGRESSION OF RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE: REASSURING IMPACT OF METHOTREXATE**

C. Lucas[1], A. Tremblay[1], S. Jouneau[2], A. Perdriger[1]. [1]*CHU, Rheumatology, Rennes, France*; [2]*CHU, Pneumology, Rennes, France*

Background: Factors associated with rheumatoid arthritis-associated interstitial lung disease (RA-ILD) progression and prognosis are not well identified, especially the impact of methotrexate.

Objectives: Identify risk factors of ILD progression in RA-ILD patients in a longitudinal study.

Methods: RA patients with ILD confirmed in 2 high resolution computed tomography (HRCT) chest scans spaced at least 6 months apart (T0: date of the first HRCT chest scan describing ILD; Tx: date of the last HRCT chest scan available) were consecutively included in this retrospective multi-centric study from 2010 to 2020. HRCT chest scans were analyzed for each patient at T0 and Tx by 2 independent radiologists to determinate ILD pattern (definite UIP, probable UIP, indeterminate UIP, non-UIP) and progression during the follow-up including variation of the fibrosis score (aggravated or non-aggravated). Characteristics of patients (demographic-clinical-biological findings, respiratory function tests, and treatments exposure) at ILD diagnosis and during the follow-up (T0-Tx) were analyzed as potential determinants of ILD progression through multivariable logistic regression analysis. Overall survival was analyzed using Kaplan-Meier method.

Results: 74 RA-ILD patients were included. During a mean duration between T0-Tx of 2.8 years ± 2.4, 26 patients (35%) had ILD progression. Thirty-three patients (45%) were treated by methotrexate at ILD diagnosis (T0) and 29 of them (39%) continued methotrexate during T0-Tx. Logistic regression in multivariate analysis revealed that a treatment by methotrexate at ILD diagnosis was protective against ILD progression (OR=0.14 [0.04-0.52]; p=0.0031). Non-UIP pattern at ILD diagnosis was also protective against ILD progression (OR=0.09 [0.02-0.36]; p=0.0005). The follow-up for survival analysis was 5.1 years ± 2.9. Thirty-three patients (31%) died, and the 3-year survival rate was 80%. Survival was better for non-aggravated ILD patients (HR=3.5 [1.46-8.4]; p=0.004) and for patients treated by methotrexate during T0-Tx (HR= 0.36 [0.15-0.84]; p=0.018) and worse for definite UIP patterns (HR=2.570 [1.078-6.128]; p=0.0332).

Conclusion: In RA-ILD patients, non-UIP pattern and methotrexate treatment are associated with better ILD evolution and prognosis.

Spondyloarthritis - aetiology, pathogenesis and animal models

POS0404 **VOLUNTARY WHEEL RUNNING MODEL IN MICE TO MECHANICALLY STIMULATE THE ENTHESIS OF THE ACHILLES TENDON**

A. Briolay[1], S. Delplace[2], F. Duboeuf[3], O. Peyruchaud[3], D. Magne[1], L. Brizuela[1], C. Bougault[1]. [1]*Université Claude Bernard Lyon 1, CNRS UMR 5246, Lyon, France*; [2]*Université du Littoral-Côte d'Opale, ULR 4490, Boulogne/Mer, France*; [3]*Faculté de Médecine Lyon Est, INSERM U1033, Lyon, France*

Background: Excessive bone formation in the entheses is one of the features of peripheral spondyloarthritis. Biomechanical stress is proposed to occupy a central place in spondyloarthritis pathophysiology, but the precise molecular and cellular mechanisms underlying the pathological response of the enthesis are still largely unknown [1]. Besides, physical therapy and exercise are recommended as non-pharmacologic therapies for patients. We focused on the effect of exercising on enthesis ossification.

Objectives: We aimed to develop and characterize an *in vivo* model in mice to study the impact of mechanical stimulation on the enthesis of the Achilles tendon.

Methods: DBA/1 mice were subjected to voluntary running exercise by the use of activity wheels for two weeks, and compared to mice housed in standard conditions (n=17 per group). The running performances were recorded.

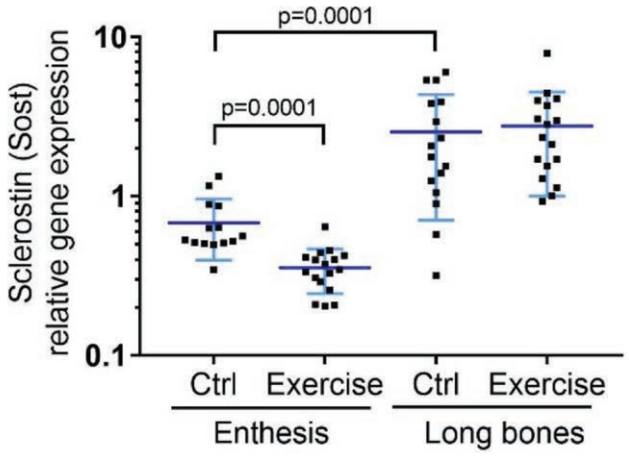

Figure 1. Expression level of the mechanosensitive gene Sclerostin (Sost). It dropped in response to exercise in entheseal tissues, but not in long bones, revealing a tissue-specific response to mechanical stimulation.

mRNAs were extracted from the long bones (flushed tibia and femur) and the ankles' entheses for real-time PCR analysis. µCT was performed on the femurs. Alkaline phosphatase activity was detected by histology on the anchorage of the Achilles tendon to the calcaneum, and by enzymatic assay in serum samples. Luminex analysis was also conducted on serum samples for Il-6 and Il-8/Kc detection.

Results: Free access to the activity wheel resulted in a running exercise of 5.5±0.8 km/day (approximately 80 km in total) at 14.5±0.5 m/min. No effect was detected on the femur architecture by µCT. Sclerostin (*Sost*) gene expression was monitored as a mechanosensitive marker. Its expression was expectedly reduced by half in entheseal tissues, but no modulation was observed in long bones (Figure 1). Similarly, exercise-induced regulation of *Osterix* and *Runx2* expressions was observed only in enthesis samples. This tissue-specific pattern was also verified for key genes of the sphingosine-1 phosphate metabolic pathway, which we recently implicated in spondyloarthritis pathophysiology [2]. The *in situ* staining of alkaline phosphatase activity suggested the presence of more positive cells in the anchorage of Achilles tendon of running mice, compared to control ones. However, alkaline phosphatase activity in serum samples and its gene expression in rough tissue extracts were unchanged. No inflammatory response was detected as Il-8/Kc serum levels were similar in the control and the exercising group (59±14 vs 57±14 pg/mL). In addition, Il-6 was not detected in the serum and its expression was very faint and constant in the tissue extracts.

Conclusion: This work is still in progress for a more complete characterization of the model. We believe that this experimental design will be useful to study the role of mechanical stimulation specifically in the enthesis and that it can help to better understand the spondyloarthritis pathophysiology.

POS0405 **GENETIC VARIANTS WITHIN PSORIATIC ARTHRITIS (PsA)-WEIGHTED GENES FBXL19 AND HLA-B*39 MAY SERVE AS A POTENTIAL LINK BETWEEN PsA AND OBESITY**

C. Welsh[1], T. Burry[1], Q. Li[1], A. Dohey[1], D. Codner[1], V. Chandran[2,3,4], D. D. Gladman[3,4], D. O'Rielly[1], P. Rahman[2]. [1]*Memorial University, Genetics, St. John's, Canada*; [2]*Memorial University, Medicine, St. John's, Canada*; [3]*Krembil Research Institute, UHN, Toronto, Canada*; [4]*University of Toronto, Rheumatology, Toronto, Canada*

Background: PsA patients have been observed to have a higher body mass index (BMI) compared to individuals with a similar disease (e.g., rheumatoid arthritis) or healthy controls[1]. Approximately 45% of PsA patients are considered obese with BMI's exceeding 30 kg/m^2, and these patients have more severe articular disease and lower response to therapy[2]. A recent mendelian randomization study noted that higher BMI leads to higher risk of psoriasis when using genetic variants as instrumental variables for BMI[3].

Objectives: To determine if known PsA-weighted genetic variants are overrepresented in an obese population.

Methods: 696 samples were identified from a previous genetic study in obesity where each patient was systematically examined with BMI and other related anthropometric measures were recorded. No patients had psoriasis, inflammatory arthritis or any extra-articular manifestations of spondyloarthritis. Samples were genotyped using a PsA-weighted single nucleotide polymorphism (SNP) panel, representing genetic variants associated with PsA. The cohort consisted of 73% female with an average age of 49 years ± 15. The average BMI of the group was 35± 8 kg/m^2, ranging from 17 to 67 kg/m^2. The PsA SNP panel consists of 42 SNPs associated with PsA including *IL23R, 5q31, PTPN22, TNFAIP3, HLA-C, TNFRSF9, LCE3A, ADAMTS9-MAGI1, HLA-B, IL13, MICA, IL12B, ZNF8816A, TRAF3IP2, KIR2DS2, FBXL19, REL, IL23R, IL23A, TNIP1,* and *TYK2.* DNA (10ng/uL) was used to prepare a PCR, followed by SAP, and extension reaction with Agena iPLEX Pro kit using Agena MassARRAY. Quantitative trait analysis was performed to obtain the association between BMI and genotype of the 42 SNPs using a linear regression model. Bonferroni correction was used to adjust for multiple comparisons. The factors of age, gender, smoking and height also have been adjusted in the analysis (Table 1).

Table 1. Regression analysis between BMI and 2 significant SNPs

SNP	CHR	Allele 1	Allele 2	BETA	SE	T	P (Genotype Only)	P (adjusted with factors)*
rs3131382	6	T	C	2.227	0.7207	3.17	0.001596	5.40E-05
rs10782001	16	G	A	1.584	0.4347	3.644	0.00029	0.0007524
Genotypes of *FBXL19* and *HLA-B*3905* SNPs with mean BMI								
SNP	rs3131382					rs10782001		
Genotypes	TT	TC		CC		GG	GA	AA
Sample Counts	6	99		575		75	324	246
Genotype Frequency	0.0088	0.15		0.84		0.11	0.50	0.38
Mean BMI	47.17	36.73		35.46		37.29	36.36	34.43
SD	16.07	6.64		7.12		7.68	7.40	6.83

*Adjusted for age, sex, height, and smoking

Results: Linear regression analysis with and without clinical factors for the two significant SNPs are presented in Table 1. Genotypes of two SNPs (rs10782001 and rs3131382) showed a difference with BMI (Table 1). The rs10782001 variant is within *FBXL19* and the average BMI in the presence of GG genotype was 37.2 vs 34.3 for the AA genotype (p=0.0007). The rs3131382 variant is within *HLA-B*39:05* and the average BMI with TT genotype was 47.1 vs 35.4 for the CC genotype (p=0.00005). Both SNPs maintained significance after correction for multiple testing (p<0.001).

Conclusion: Homozygotes for the minor allele of SNPs within *HLA-B*39* and *FBXL19* have shown to have an increased BMI, suggesting a potential genetic link between these genes and PsA and obesity. Interestingly, it has been recently noted that miR-26 suppresses adipocyte progenitor differentiation and fat production by targeting FBXL19, leading to possible biologic possibility regarding the link between PsA-weighted genetic variants and obesity[4].

POS0406

miRNAs DEREGULATED IN RESPONSE TO IL17A INHIBITORS IN PSORIATIC ARTHRITIS REGULATE GENE PRODUCTS IN Rho-GTPase PATHWAYS

P. Rahman[1], Q. Li[2], D. Codner[2], D. O'Rielly[2], A. Dohey[2], K. Jenkins[1], D. D. Gladman[3], V. Chandran[1,3,4], I. Jurisica[5]. [1]*Memorial University, Medicine, St. John's, Canada*; [2]*Memorial University, Genetics, St. John's, Canada*; [3]*University of Toronto, Rheumatology, Toronto, Canada*; [4]*Krembil Research Institute, UHN, Toronto, Canada*; [5]*Krembil Research Institute, Medical Biophysics, Toronto, Canada*

Background: Using transcriptomic data at initiation of therapy, we recently identified differentially expressed genes (DEGs) that separated IL-17Ai response from non-response[1]. Integration of cell-type-specific DEGs with protein-protein interactions (PPIs) and further comprehensive pathway enrichment analysis revealed Rho GTPase signaling pathway exhibited a strong signal specific to IL-17Ai response and particularly the genes, *RAC1* and *ROCK*s.

Objectives: To characterize microRNA (miR) profiles among IL-17Ai responders and non-responders, as it relates to RHO GTPase pathway.

Methods: We interrogated 20 psoriatic arthritis (PsA) patients initiating IL-17Ai. Patients achieving at least low disease activity according to the Disease Activity Index for PsA (DAPSA) at three months were classified as responders. There were seven responders (35%) and thirteen non-responders (65%) in the IL-17Ai group, with biologic treatment naïve (bio-naïve) and previously-exposed (bio-exposed) patients exhibiting a 50% (4/8) and a 25% (3/12) response rate, respectively. For the miR analysis, CD4 positive T cells were isolated from peripheral blood mononuclear cells using Dynabeads^{TM} CD4 beads (ThermoFisher). Total RNA was extracted from the CD4$^+$ T cells using Lexogen's Split RNA Extraction Kit (D-Mark Biosciences). Libraries were prepared from 200ng total RNA with the NEXTFLEX Small RNA-Seq Kit v3 with UDIs (Bioo Scientific) and sequenced on the Illumina NovaSeq 6000. Raw sequencing fastq data assessed the quality using FastQC. The miRDeep2 was used to trim the adapter, align and quantify human mature miRs from miRbase (Release 22). The abundance of miRs was converted to read counts per million, normalized and limma R package was used to identify pre- and post-differentially expressed miRs.

Results: We obtained 2,889 miRs. After removing miRs with low reads in >90% of samples, 1902 high quality miRs remained for further analysis. Using mirDIP v4.1 we identified gene targets for differential miRs, and focused on recently identified DEGs related to RHO GTPase pathway. The miRs on the left of the figure 1 are those deregulated in pre-treatment, and the miRs on the right of the figure 1

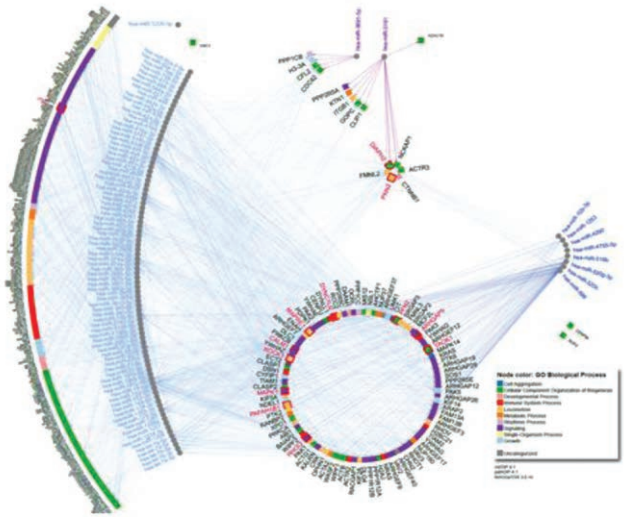

Figure 1.

show the post-treatment deregulated miRs. hsa-miR-3691-5p and hsa-miR-3161 represent the miRs that were deregulated in both conditions. The red highlighted nodes represent the most connected miRs and genes; thus, representing miRs that are the most RHO-pathway centric regulators (hsa-miR-495-3p, 16-5p, 129-5p, 520h, 520g-3p), and genes representing the most strongly regulated RHO-pathway gene products (ROCK1, RHOQ, PFN2, TAOK1, DYNC1L12, MAPRE1, PAFAH1B1, ARHGAP5, MAPK1, CALM1, DIAPH2, PKN2, ITSN1).

Conclusion: Pre- and post-treatment differential miRs related to IL-17Ai response regulate multiple genes from RHO GTPase pathway.

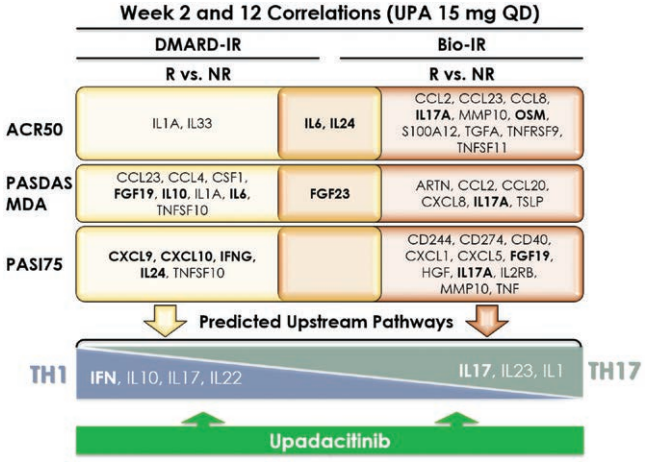
POS0407 PROTEOMICS ANALYSIS COMPARING THE MODE OF ACTION OF UPADACITINIB BETWEEN NON-BIOLOGIC-DMARD-IR AND BIOLOGIC-DMARD-IR PsA PATIENTS IDENTIFIES DISTINCT PATHOGENIC PATHWAYS IN THE SELECT-PsA 1 AND SELECT-PsA 2 PHASE 3 STUDIES

T. Sornasse[1], J. Anderson[2], K. Kato[2], A. Lertratanakul[2], I. McInnes[3], C. T. Ritchlin[4]. [1]*AbbVie, Precision Medicine Immunology, Redwood City, United States of America*; [2]*AbbVie, Immunology Clinical Development, North Chicago, United States of America*; [3]*University of Glasgow, College of Medical, Veterinary and Life Sciences, Glasgow, United Kingdom*; [4]*University of Rochester, Allergy/Immunology and Rheumatology, Rochester, United States of America*

Background: Treatment of non-biologic-DMARD-IR[1] (DMARD-IR) and biologic-DMARD-IR[2] (bio-IR) PsA patients with upadacitinib (UPA) at 15 mg QD, an oral JAK1 selective inhibitor, resulted in significant improvement in signs and symptoms compared to placebo.
Objectives: Using a pre-defined set of inflammation-related plasma protein biomarkers (pBM), to explore immunological pathway modulation by UPA 15 mg QD in PsA patients with active disease despite treatment with non-biologic or biologic DMARDs in the context of clinical response vs. non-response to treatment.
Methods: Patients from the SELECT-PsA 1 (DMARD-IR) and the SELECT-PsA 2 (bio-IR) studies were randomly selected (PBO, n=100; UPA 15 mg QD, n=100 for each study). The levels of 92 inflammation related protein biomarkers (pBM) were analyzed using a multiplexed Proximity Extension Assay platform in plasma samples collected at baseline, week 2, and 12; change from baseline in protein levels was expressed as Log_2 Fold Change; a Repeated Measure Mixed Linear Model was used to identify pBM modulated by UPA compared to Baseline, and those differentially modulated between responders (R) and non-responders (NR) according to ACR50, PASDAS Minimal Disease Activity, and PASI75 at week 12. Correlation of disease activity measures with relative levels of pBM were derived using Pearson's correlation; PASI score was transformed as Log_{10} (x+1) prior to the analysis. Functional pathway prediction was performed in silico with a commercial distributed software.



Results: At baseline, the relative levels of 37 pBM correlated with at least one baseline disease activity measure, with a marked positive correlation of IL6 with musculoskeletal end points (PASDAS and DAS28CRP), and a strong positive correlation of IL20, IL17A, IL17C, and TGFA with baseline PASI.
At the single pBM-level, treatment with UPA 15 mg QD resulted in a down modulation of pBM associated with T cells, myeloid cells, and IFN-, IL6-, and TNF-related pathways in both DMARD-IR and bio-IR PsA patients. Overall effects of UPA on single pBMs were broadly similar between DMARD-IR and bio-IR patients. However, analysis of pBMs differentially modulated by UPA in R vs NR indicated that favorable clinical response (achievement of ACR50, PASDAS MDA, and PASI75) in DMARD-IR patients was associated with the down modulation of pBMs predicted to be linked to IFN, IL10, IL17, IL22, and IL27 pathways; while favorable clinical response in bio-IR patients was associated with the down modulation of multiple pBM predicted to be linked to the IL17, IL23, and IL1 pathways.
Conclusion: UPA effects in both DMARD-IR and bio-IR PsA patients likely stem from the direct and indirect inhibition of multiple biological pathways belonging to the adaptive and innate immune systems. Responder/Non-Responder analysis suggests a possible shift from a TH1 biased biology in DMARD-IR PsA patients to a more TH17 biased biology in bio-IR PsA patients. This apparent change in the disease biology of PsA patients after inadequate response to prior therapy could be attributed to the actual alteration of the disease biology, treatment outcome-based patient selection, or both. Considering the clinical efficacy of UPA in both DMARD-IR and bio-IR PsA patients, this observation highlights the importance of targeting multiple pathways with drugs such as UPA for the treatment of a broad range of PsA patients.

POS0408 INVESTIGATING THE ANTI-INFLAMMATORY POTENTIAL OF A NOVEL MK2 INHIBITOR IN A VITRO MODEL OF ENTHESITIS

C. Bridgewood[1], C. Wong[1], R. Gaur[2], F. Ramirez-Valle[2], D. McGonagle[1]. [1]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRMM), Leeds, United Kingdom*; [2]*Bristol Myers Squibb, Immunology, Cardiovascular and Fibrosis Thematic Research Center, Cambridge, United States of America*

Background: Enthesitis or inflammation of tendon/ligament anchorage points is the cardinal lesion in spondyloarthritis (SpA). Through the use of cytokine targeting biologics and also murine models, several key mediators have been shown to have a role in enthesitis, such as IL-23/17 axis and TNF[1]. We have previously shown that the human enthesis contains myeloid cells capable of IL-23 and TNF production and range of T-cells capable of IL-17A/F secretion[2,3]. Attempted inhibition of p38 MAPK for inflammatory disease in the past has yielded toxicity issues. The MAPK-associated protein kinase 2 (MK2) is situated downstream of p38 MAPK, relaying the phosphorylation signal to the nucleus, and is thus a promising target.
Objectives: To determine if a novel MK2 inhibitor (MK2i) could supress innate and adaptive immune responses in an in vitro human enthesis model.
Methods: Normal spinous process enthesis was obtained from patients undergoing spinal decompression or surgery for scoliosis correction. Following enzymatic digestion, entheseal cells (n=5) were harvested and stimulated either with LPS/IFNγ (Entheseal myeloid cell activator) or anti-CD3 (Entheseal T-cell activator) with and without MK2i (1, 0.1 and 0.01μM) for 24 hr. Supernatant was harvested and protein detected using multiplexing for panels relating to inflammation (IL-1β, IFN-α2, IFN-γ, TNF, CCL2, IL-6, IL-8, IL-10, IL-12p70, IL-17A, IL-18, IL-23, and IL-33) or T-cell activation (IL-2, IL-4, IL-5, IL-6, IL-9, IL-10, IL-13, IL-17A, IL-17F, IL-22, IFN-γ and TNF).
Results: Following LPS/IFNγ stimulation of entheseal cells, 1μM MK2i significantly attenuated secretion of TNF, IFNα, IL-6, IL-10, IL-8 and CCL2.

Several other targets did not reach statistical significance, but trended downwards with inhibition such as IL-1β, IL-12 IL-18 and IL-33. Following Entheseal T-cell activation by anti-CD3 stimulation, 1μM MK2i supressed TNF and IL-17A.

Conclusion: MK2i suppressed LPS driven production of several disease relevant mediators such as TNF. MK2i also supressed anti-CD3 induced T-cell derived mediators such as TNF and IL-17A. MK2 inhibition is a promising novel therapeutic target in the treatment of Spondyloarthritis.

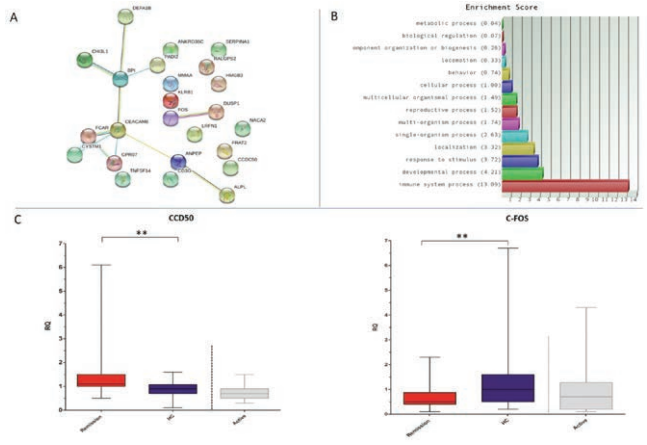
POS0409 MOLECULAR PROFILING OF THE REMISSION STATE IN PSORIATIC ARTHRITIS: IS THE FIRE EXTINGUISHED?

M. M. Angioni[1], I. Cangemi[1], A. Floris[1], M. Congia[1], E. Chessa[1], M. Piga[1], A. Cauli[1]. *[1] AOU and University of Cagliari, Rheumatology Unit, Department of Medical Sciences and Public Health, Monserrato, Italy*

Background: The most important goal of therapy in psoriatic arthritis (PsA) is to reach the remission state of disease. Nowadays, data on molecular players of clinical remission and effective disease inactivation are scarce: gene expression analysis could highlight markers characteristic of PsA remission state.

Objectives: Our aim was to analyze the gene expression profile of patients with clinically inactive (drug-induced remission) PsA versus healthy controls and PsA active state.

Methods: From a cohort of 300 patients affected by PsA according to CASPAR criteria, we selected 40 patients (peripheral arthritis subset) with >1-year remission by TNFα antagonism assessed by DAPSA ≤ 4 (R) and 40 PsA with active disease state by DAPSA > 14 score (no bDMARDs ongoing) (A), and 40 healthy controls (HC) matching for mean age and gender ratio. Both PsA groups were not on corticosteroid treatment. Each condition has been profiled first using pooled RNAs from peripheral blood (biological duplicates) by Affymetrix Human GeneChip HTA 2.0. To identify a transcript as differentially expressed in both duplicates, a fold change (FC) 1.5 and *p-value* 0.05 has been set. Then, from the comparative list of differential expressed genes (DEGs) in R vs HC state, coding mRNAs were selected and interactions analyzed by STRING software, biological functions and annotations by Gene Onthology (GO). From these analysis, 12 genes were validated in the whole PsA cohort (R+A) and HCs, by quantitative real-time PCR (RT-qPCR) in triplicate (TaqMan chemistry, GAPDH housekeeping, $2^{-\Delta\Delta Ct}$ for relative quantification, FC cutoff ±1.5 for differential analysis).



Results: The transcriptomic analysis generated 3 comparative lists of mRNAs (R vs HC= 125; R vs A= 1184; A vs HC= 378 transcripts). Then, we focused on remission state analyzing the mRNAs list R vs HC. Filtering data for coding DEGs, was made a list of 24 genes further analyzed for functions and interactions: STRING analysis created one interactions network and GO highlighted in which biological processes these DEGs are involved (Fig panels 1A, 1B). Validation analysis by rt-qPCR in the PsA cohort (R+A) and HCs confirmed the downregulation of c-FOS and the upregulation of CCDC50 (alias YMER) genes in the R vs HC conditions (*pvalue*= 0.004). The dysregulation of further genes in other comparisons was measured, as shown in Tab and Fig panel 1C.

Conclusion: Observing the amount of DEGs, is evident that the drug-induced remission state is more similar to healthy condition, however this trend of "similarity" does not mean "identical". The bioinformatic analysis showed that DEGs in the R vs HC conditions are primarily involved in biological processes related to immune system as well as correlates in an interactions network. Our molecular characterization of clinical remission revealed that effective disease inactivation appears to be molecularly-driven by two key genes, c-FOS and CCD50 (YMER), both involved in the NF-κB signalling pathway modulation.

Coding DEGs mis-regulated in the remission state. Differentially expressed genes (DEGs) in the Remission (R) state vs Healthy Controls (HC) analyzed for multiple-proteins interaction by STRING software V10.5 (panel A) and biological functions by Gene Set Enrichment Analysis (panel B). DEGs validations by RT-qPCR, confirmed the CCD50 and c-FOS dysregulation in the R state (panel C, RQ= Relative Quantification, t test RvsHC *pvalue*=0,004).

GENE SYMBOL	Gene chip Array R vs HC	Remission vs HC	Active vs HC	Remission vs Active

POS0410 BIOMARKERS REFLECTING DISTURBED GUT BARRIER DIFFER IN PATIENTS WITH SPONDYLOARTHRITIS, CROHN'S DISEASE AND ACUTE ANTERIOR UVEITIS

J. Rademacher[1,2], C. Hempel[1], V. Rios Rodriguez[1], F. Proft[1], M. Protopopov[1], M. Torgutalp[1], H. Haibel[1], U. Pleyer[3], B. Siegmund[1], D. Poddubnyy[1]. *[1]Charité Universitätsmedizin Berlin, Campus Benjamin Franklin, Department of Gastroenterology, Infectiology and Rheumatology, Berlin, Germany*; *[2]Berlin Institute of Health, BIH, Berlin, Germany*; *[3]Charité Universitätsmedizin Berlin, Ophthalmology, Berlin, Germany*

Background: Spondyloarthritides (SpA) are characterized by frequent extra-musculoskeletal manifestations (EMM) among them acute anterior uveitis (AAU) and Crohn's disease (CD). Vice versa, about 50% of AAU and 20% of CD patients have concomitant SpA. SpA patients show gut dysbiosis together with frequent subclinical gut inflammation. Biomarkers reflecting disturbed gut barrier (intestinal-fatty acid binding protein (iFABP), lipopolysaccharide binding protein (LBP) and zonulin) were previously found to be elevated in patients with radiographic axial SpA (r-axSpA) (1).

Objectives: To evaluate whether biomarkers reflecting leaky gut are altered in patients with AAU, CD and SpA compared to healthy controls and whether they differ between patients with EMM with and without concomitant SpA.

Methods: A total of 100 patients from the German Spondyloarthritis Inception Cohort (GESPIC) were included – among them 20 patients with r-axSpA without EMM, 40 patients with CD and 40 patients with non-infectious AAU – out of which 19 and 20 patients, respectively, had concomitant SpA (11/8 and 20/0 axial/peripheral SpA, respectively). The GESPIC patients were compared to 20 age- and

sex-matched healthy donors (HD). The following five serum biomarkers were analyzed with ELISA: calprotectin, iFABP, LBP, soluble CD14 (sCD14) and zonulin.
Results: Patient characteristics are shown in Table 1. Serum levels of calprotectin, LBP, sCD14 and zonulin differed significantly between patients with r-axSpA, AAU and CD with and without concomitant SpA and HD (Figure 1). When comparing patients with EMM with and without underlying SpA, calprotectin serum levels were significantly elevated in CD patients with SpA (8.6µg/ml (SD 5.5µg/ml)) compared to CD patients without SpA (5.7µg/ml (SD 4.1µg/ml); Mann-Whitney U Test, p=0.031). Serum levels of the analyzed biomarkers did not differ between AAU patients with and without axSpA. Spearman rank correlation revealed a significant association between CRP and calprotectin (correlation coefficient r=0.230; p=0.012), LBP (r=0.596; p<0.0001), sCD14 (r=0.428; p<0.0001) and zonulin (r=0.221; p=0.016), respectively. Furthermore, LBP and zonulin serum levels correlated positively (r=0.208; p=0.023); as well as LBP and sCD14 levels (r=0.418; p<0.0001).

Table 1. Patient characteristics. Mean values (standard deviation) or absolute numbers are shown.

	CD + SpA	CD	r-axSpA	AAU + axSpA	AAU	HD
N	19	21	20	20	20	20
Age	39.1 (11.3)	38.7 (14.4)	38.4 (10.3)	39.6 (12.0)	39.2 (12.5)	38.6 (12.9)
Male (%)	9 (47%)	9 (43%)	9 (45%)	9 (45%)	9 (45%)	9 (45%)
HLA-B27 positive (%)	5 (26%)	3 (14%)	17 (85%)	17 (85%)	13 (65%)	2 (10%)
CRP in mg/l	14.3 (25.6)	18.0 (41.8)	9.1 (11.3)	6.7 (9.9)	2.3 (3.4)	0.6 (0.7)
ASDAS	2.8 (1.1)		3.2 (0.6)	2.2 (1.0)		
BASDAI	4.1 (2.2)		5.4 (1.2)	3.2 (2.4)		

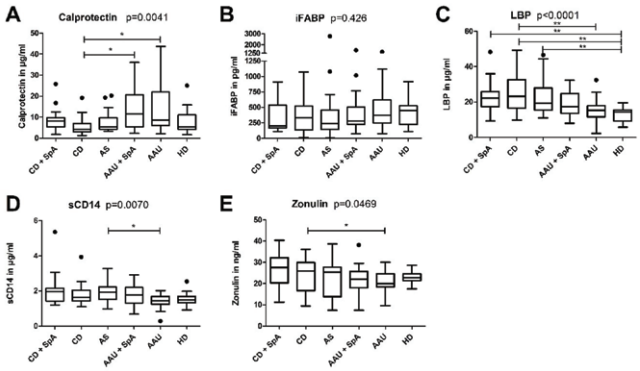

Figure 1. Biomarkers reflecting disturbed gut barrier show distinct signatures in patients with acute anterior uveitis, Crohn's disease and axial Spondyloarthritis. Kruskal Wallis Test; p values shown. Dunn-Bonferroni Post-Hoc analyses, significant pairwise differences are marked; * p<0.05; **p<0.01; ***p<0.0001Conclusion:

We found substantial differences in biomarkers reflecting disturbed gut barrier between with SpA, CD, AAU and healthy controls. The presence of SpA was associated with higher calprotectin serum levels in CD as compared to CD without SpA.

POS0411 TARGETING JAK-STAT SIGNALLING ALTERS THE PHENOTYPIC CHARACTERISTICS OF PsA SYNOVIAL FIBROBLASTS IN RESPONSE TO THE JAK/STAT ACTIVATOR ONCOSTATIN M

A. O' Brien[1], M. Hanlon[1], V. Marzaioli[1], K. Flynn[2], S. Wade[1], D. Veale[2], U. Fearon[1]. [1]*Trinity College Dublin, Molecular Rheumatology, Dublin, Ireland*; [2]*Centre for Arthritis and Rheumatic Diseases, St Vincent's Hospital, Dublin, Ireland*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with psoriasis. The JAK/STAT pathway has been linked to the pathogenesis of PsA. Recently, JAK/STAT inhibitors (JAKi) have emerged as an encouraging class of drugs for the treatment of PsA. Only a few of these inhibitors have been approved for use in PsA patients with others currently in clinical trials.
Objectives: The aim of this study was to examine the effect of JAKi on primary PsA synovial fibroblasts (FLS) function.
Methods: Primary PsA FLS were isolated and cultured with JAKi (Peficitinib, Filgotinib, Baricitinib and Upadacitinib) in the presence of the pro-inflammatory JAK/STAT activator - Oncostatin M (OSM). The effect of JAKi on these cells was determined by Migration and Invasion Assays, ELISA and rtPCR. PsA FLS bioenergetics was assessed using an XF24 analyser, which simultaneously quantifies two energetic pathways- glycolysis (ECAR) and Oxidative phosphorylation (OCR).
Results: OSM-induced Migration and Invasion was supressed by all JAKi with Peficitinib, Filgotinib and Baracitinib showing the greatest effect. Analysis by ELISA and rtPCR showed reduction in MCP-1 and IL-6 expression in response to JAKi, in contrast, an increase in IL-8 was observed. These functional effects were accompanied by a change in the cellular bioenergetic profile of PsA FLS, where OSM significantly increased the ECAR:OCR ratio in favour of glycolysis where PsA FLS displayed a hypermetabolic phenotype. This effect was reversed in the presence of JAKi, which specifically targeted the glycolytic pathway with PsA FLS returning to a more quiescent phenotype.
Conclusion: This study demonstrates that JAK/STAT signalling mediates the complex interplay between inflammation and cellular metabolism in PsA pathogenesis, inhibition of which shows effective suppression of the pathogenic phenotype of PsA FLS that drives joint destruction.

POS0412 CD21-/LOW B-CELLS ARE INCREASED IN PATIENTS WITH ANKYLOSING SPONDYLITIS

R. Wilbrink[1], A. Spoorenberg[1], S. Arends[1], F. G. M. Kroese[1], G. M. Verstappen[1]. [1]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: Ankylosing spondylitis (AS) is a chronic immune mediated inflammatory rheumatic disease, in which primarily the sacroiliac joints and the spine are affected. Extra-skeletal manifestations (ESM) include uveitis, psoriasis, inflammatory bowel disease and peripheral arthritis. In studies into the pathogenesis of AS, B-cells have received little attention most likely due to the lack of auto-antibodies[1]. A B-cell subset that has been particularly associated with autoreactivity is characterized by low expression of CD21. These CD21$^{-/low}$ B-cells are increased in systemic autoimmune diseases, including rheumatoid arthritis, systemic lupus erythematosus and primary Sjögren syndrome (pSS)[2]. At least part of the CD21$^{-/low}$ B-cells are considered to represent anergic, autoreactive B-cells, that fail to become activated through conventional B-cell receptor and CD40 signaling[2].
Objectives: To phenotypically study the peripheral B-cell compartment in in the blood of AS patients compared to pSS patients, a typical B-cell-associated autoimmune disease, and healthy controls (HC). Special emphasis was given to the CD21$^{-/low}$ compartment.
Methods: The proportions and phenotype of peripheral B-cells were assessed in cryopreserved peripheral blood mononuclear cells of 45 AS patients (62% male, mean age 49.2±13.2 years, mean ASDAS 2.5±1.0), 20 age-matched patients with pSS (20% male, mean age 50.6±12.0, median (IQR) ESSDAI 3±6.25) and 30 age- and sex-matched HCs, using 15-color flow-cytometry analysis. Differences between groups were tested using the Independent Samples t-test or Mann-Whitney U test depending on the distribution of variables. Associations between CD21$^{-/low}$ B-cells and clinical parameters were explored using the Pearson or Spearman correlation coefficient.
Results: The percentage of total B-cells in AS patients did not differ from pSS patients and HCs. In AS patients, percentages of CD27^{+} memory B-cells and CD27^{-}IgD^{+} naïve B-cells were also similar to HCs, whereas CD27^{+}IgD^{-} memory B-cells were significantly reduced in pSS patients, as expected. The proportions of CD27^{-}CD38^{low}CD21$^{-/low}$ B-cells among total B-cells were significantly increased in both AS (median 6.4%, p<0.0001) and pSS patients (median 7.8%, p<0.0001) compared to HCs (median 4.9%). Interestingly, only in AS patients, expression of chemokine receptors CXCR3 and CXCR5 was significantly elevated on CD27^{-}CD38^{low}CD21$^{-/low}$ B-cells compared to HCs (p<0.001 and p<0.01, respectively). In comparison to HCs the expression of the immune markers T-bet and CD11c by CD27^{-}CD38^{low}CD21$^{-/low}$ B-cells was significantly lower in AS patients (p<0.01 and p<0.01, respectively). The distribution of IgM and IgD expression within the CD27^{-}CD38^{low}CD21$^{-/low}$ B-cell population was similar between all three study groups. Regarding the association between CD27^{-}CD38^{low}CD21$^{-/low}$ B-cells and clinical parameters in AS patients, we observed a positive correlation with age (r=0.347, p=0.02) and erythrocyte sedimentation rate (ρ=0.386, p=0.01). Furthermore, AS patients with ESM showed increased proportions of CD27^{-}CD38^{low}CD21$^{-/low}$ B-cells compared to patients without ESM (p<0.05).
Conclusion: In this cross-sectional study, we observed an increased proportion of circulating CD27^{-}CD38^{low}CD21$^{-/low}$ B-cells in AS patients, similar as in patients

with pSS, a typical B-cell-mediated autoimmune disease. The elevated expression of CXCR3 on $CD27^{-}CD38^{low}CD21^{-/low}$ B-cells in AS patients is suggestive for active involvement in the inflammatory response. These findings are indicative of B-cell involvement in the pathogenesis of AS, against current dogma.

POS0413 COMPREHENSIVE IMMUNE PROFILING OF PERIPHERAL BLOOD IN PSORIATIC ARTHRITIS (PsA) PATIENTS: EXPANSION OF INTERMEDIATE MONOCYTES AND DECREASED T REG AND CD8 T CELLS

A. Grivas[1], M. Grigoriou[1], P. Katsimpri[2], P. Verginis[3,4], D. Boumpas[1,2]. *[1]Biomedical Research Foundation of the Academy of Athens (BRFAA), Laboratory of Immune Regulation and Tolerance Autoimmunity and Inflammation, Athens, Greece*; *[2]National and Kapodistrian University of Athens, 4th Department of Internal Medicine, Athens, Greece*; *[3]Institute of Molecular Biology and Biotechnology, Foundation for Research and Technology, Institute of Molecular Biology and Biotechnology, Foundation for Research and Technology, Heraklion, Greece*; *[4]University of Crete Medical School, Laboratory of Immune Regulation and Tolerance, Division of Basic Sciences, Heraklion, Greece*

Background: Psoriatic arthritis (PsA) is a heterogeneous inflammatory arthritis that develops in a subset of patients with psoriasis. According to the current paradigm, cells of the innate and adaptive immunity interact with resident tissue fibroblasts mounting an inflammatory response via complex cytokine networks in the skin and joints in which type 1 and type 17 T cells play a dominant role. The abundance and relative contribution of other peripheral blood immune cells to disease pathogenesis as well the molecular signature of peripheral blood mononuclear cells and tissue fibroblasts remain ill defined.
Objectives: To comprehensively characterize immune cell subsets driving inflammation in the peripheral blood of patients with active PsA and their impact on psoriatic skin fibroblasts.
Methods: Peripheral blood was collected from PsA patients (n=31) and age-/sex-matched healthy individuals (HI) (n=9), after informed consent. Psoriatic skin biopsies were acquired from a subset of 5 patients and 3 HI. All patients fulfilled the CASPAR criteria for the diagnosis and displayed peripheral polyarthritis of moderate- to high-disease activity. Patients' demographic and clinical data were recorded at time of sampling. Disease activity was assessed using the Disease Activity Index for Psoriatic arthritis (DAPSA) score. Skin psoriasis activity indices, enthesitis and dactylitis were also recorded. Peripheral blood mononuclear cells (PBMCs) were isolated by ficoll density gradient centrifugation. Flow cytometry was performed using a BD FACS-Aria-III and analyzed using FlowJo software. The antibody staining panel utilized aimed at the identification of the following immune cell subsets: Monocyte subsets (HLA-DR+ CD14+/- CD16+/-), Plasmacytoid dendritic cells (HLA- DR+ CD123+), T helper (CD4+), cytotoxic T (CD8+), regulatory T (CD4+ CD25+ CD127-) and B cells (CD19+). Statistical analyses were performed using GraphPad Prism software. Differences between groups were compared using unpaired T test for parametric data; Mann-Whitney and Kruskal Wallis tests for non-parametric data. The level of significance was set at $P<0.05$.
Results: 9 males and 22 females PsA patients are included (mean age 50 years and the mean disease duration 19.2 years for skin disease and 5.9 years for arthritis). The mean DAPSA score was 43.4, suggestive of high disease activity, while 8 (26%) patients displayed clinical enthesitis at time of sampling. Flow cytometry analysis revealed aberrancies in peripheral blood immune cell populations. More specifically, PsA patients displayed a significant increase in intermediate monocyte subset (HLA-DR+ CD14+ CD16+) compared to HI with patients with clinical enthesitis demonstrating a more exaggerated expansion of intermediate monocytes compared to patients without enthesitis. A trend towards increased patrolling monocytes (HLA-DR+ CD14- CD16+) was also noted although this did not reach statistical significance. In contrast, both regulatory T cells and cytotoxic CD8+ T cells were significantly decreased probably due to their selective migration at the sites of inflammation. RNA-seq from whole blood and skin fibroblasts from affected skin are in progress.
Conclusion: These data demonstrate significant expansion of intermediate monocytes -more pronounced in the enthesitis affected individuals- and decrease in T regulatory cells and T cytotoxic cells in PsA peripheral blood. Increased antigen presentation and co-stimulation mediated via intermediate monocytes in combination with their proangiogenic properties may contribute to disease pathogenesis

POS0414 INCREASED BDNF LEVELS AS A PREDICTOR OF CENTRAL SENSITIZATION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

I. Shapoval[1], K. Zaichko[1], M. Stanislavchuk[1]. *[1]National Pirogov Memorial Medical University, Vinnytsya, Ukraine, Chair of Internal Medicine #1, Vinnytsya, Ukraine*

Background: Ankylosing spondylitis (AS) is a chronic rheumatic disease that manifests itself in a range of inflammatory changes, severe pain and rapid progression with the development of osteoproliferation and the formation of ankylosis. Prerequisites are created for the emergence of signs of central sensitization. Scientists are growing interested in the role of the phenomenon of central sensitization. Central sensitization is present in almost half of patients with chronic pain (45% SpA, 41% RA, 62% OA and 94% of FM patients) [1]. Brain neurotrophic factor (BDNF) is involved in pain regulation mechanisms and the occurrence of central sensitization, but its role in patients with AS is poorly understood.
Objectives: Our study aimed to determine levels of plasma BDNF in patients with AS and evaluate their role as central sensitization predictors in patients with ankylosing spondylitis.
Methods: We examined 143 patients with AS according to modified New York criteria (26 women and 117 men) with mean age 42.1±11.3 years (M±σ) and 35 persons of the control group, representative by age, sex. The content of plasma BDNF was determined at 8:00 and 20:00 by ELISA and calculated the daily average and morning/evening ratio - 8:00/20:00 BDNF index. All patients completed self-administered questionnaire Fibromyalgia Rapid Screening Tool (FiRST) to detect FM. FM was defined by a score = > 5/6 by the FiRST. The study was conducted in compliance with bioethical standards. All data were analyzed using IBM Statistics SPSS 22.
Results: Among 143 patients with AS, there were 51 persons with FiRST ≥ 5, indicating central sensitization and probable FM. In the group with AS mean scores (M±σ) of plasma BDNF levels were 962.5±357.2 pg/ml at 8:00 and 834.7±510.0 pg/ml at 20:00 compared to control group (785.2±109.7 pg/ml and 450.6±358.9 pg/ml; $p< 0.001$). 36% AS patients were with + FiRST and had higher daily average and evening BDNF levels and a decreased 8:00/20:00 BDNF index. According to 8:00/20:00 BDNF index, we divide AS patients into 4 groups: 1st quartile (Q1) included people with BDNF index <0.83; 2nd quartile (Q2) - 0.83 - 1.15; 3rd quartile (Q3) - 1.16 - 2.49; 4th quartile (Q4) - > 2.49. Table 1 shows detailed information about FM's quantitative characteristics in patients with AS (n = 143) depending on the 8:00/20:00 BDNF index.
In patients with AS and + FiRST was registered an inadequate decrease in plasma BDNF levels in the evening, as evidenced by a decrease in the 8:00/20:00 BDNF index, which was combined with increased disease activity and poorer of the functional status.
The ROC analysis results showed that the 8:00/20:00 BDNF index at the cut-off point of 0.95 confirms the presence of central sensitization in patients with AS with a sensitivity of 86.2% and a specificity of 79.6%. The AUC is 0.878, which indicates a good quality of the model. Patients with the 8:00/20:00 BDNF index <0.95 are many times more likely to detect features of central sensitization (OR = 20.9; 95% CI: 8.66-50.39, $p < 0.001$).
Conclusion: Our results showed high diagnostic value to determine plasma levels of BDNF and to calculate 8:00/20:00 BDNF index as central sensitization marker in patients with AS with a sensitivity of 86.2% and a specificity of 79.6%.

Table 1. Quantitative characteristics of FM in patients with AS (n = 143) depending on the 8:00/20:00 BDNF index.

Parameters	BDNF «8:00 / 20:00»			
	< 0.83	0,83 – 1.15	1,16 – 2.49	> 2.49
	Q1 (n=37)	Q2 (n=35)	Q3 (n=35)	Q4 (n=36)
FiRST (M±σ)	4.49±1,46	4.23±1.42	3.03±1.44 ***#	2.81±1.04 ***#
FiRST≥ 5, n (%)	24 (64,9 %)	17 (48.6 %)	9 (25.7 %) ***#	1 (2.78 %) ***#

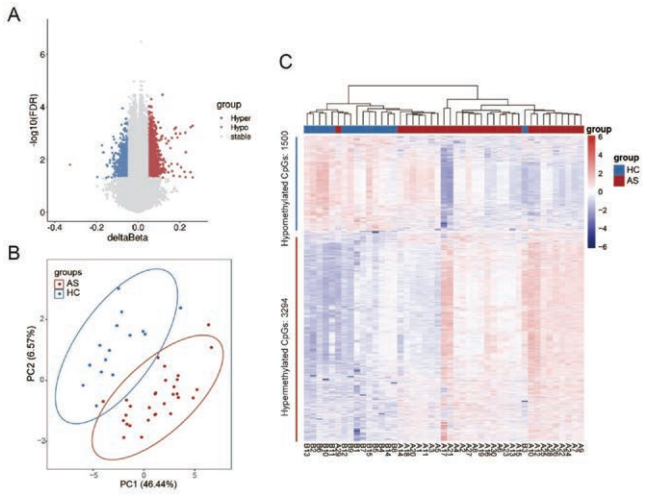
POS0415

BLOOD-DERIVED DNA METHYLATION EPI-SIGNATURES ASSOCIATED WITH ANKYLOSING SPONDYLITIS

M. Xiao[1], J. Gu[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Most (~90%) of the ankylosing spondylitis (AS) susceptibility loci are undefined and located in non-coding regions. Epigenetic changes may alter the expression of genes involved in AS and explain part of the missing heritability. [1]
Objectives: To identify novel DNA methylation sites significant for AS and comprehensively understand the underlying pathological mechanism.
Methods: Genome-wide DNA methylation of blood samples from 30 AS patients and 15 health controls was measured on the Infinium® MethylationEPIC BeadChip microarray. Methylome data were analyzed with ChAMP package in R.
Results: The epigenome-wide association analysis identified 4,794 differentially methylated positions (DMPs) (FDR <0.05 and delta β >0.05), including 3,294 (68.7%) hypermethylated and 1,500 (31.3%) hypomethylated positions in AS patients (Figure 1A). The identified DMPs allowed clear distinction of most AS cases from controls in the PCA (Figure 1B) and unsupervised hierarchical clustering (Figure 1C). KEGG pathway analysis of AS associated DMPs enriched in T cell receptor signaling pathway, Th1 and Th2 cell differentiation. Besides, a total of 1,048 differentially variable positions (DVPs) were identified, the majority of which (974, 92.9%) were hypervariable in AS, while only 74 DVPs were hypovariable. The increased DNA methylation variability in disease were in line with the previous observation in other diseases, indicating the intrinsic heterogeneity in AS patients, which might be influenced by diverse factors, such as disease activity and treatment.
Figure 1.



Conclusion: Peripheral blood mononuclear cells from AS patients display aberrant DNA methylome and increased DNA methylation variability. The results enhanced our understanding of the important role of DNA methylation in pathology of AS and offered the possibility of identifying new targets for intervention.

POS0416

NOVEL LONG NON-CODING RNA EXPRESSION PROFILE OF PERIPHERAL BLOOD MONOUCLEAR CELL REVEALED POTENTIAL BIOMARKERS AND REGULATORY MECHANISM IN SYSTEMIC LUPUS ERYTHEMATOSUS

Q. Cheng[1], M. Chen[1], X. Chen[1], X. Chen[1], H. Wu[1], Y. Du[1]. [1]*the Second Affiliated Hospital of Zhejiang University School of Medicine, Rheumatology, Hangzhou, China*

Background: Systemic lupus erythematosus (SLE) is a complex and heterogeneous autoimmune disease, usually involving multiple systems of the whole body (1). A variety of factors can affect SLE, such as genetic, environmental, immunoregulatory, hormonal and epigenetic (2). Long non-coding RNA is a type of RNA greater than 200 nucleotides that does not encode proteins. With the development of research, lncRNA gradually becomes the key regulator of gene expression in the immune system (3). Studies have shown that several lncRNAs, such as NEAT1 and GAS5 are dysregulated in SLE and are involved in the pathogenesis of SLE (4,5). These results suggest that lncRNA can be used as a potential biomarker for disease diagnosis and treatment. However, our current understanding of SLE related lncRNAS is still limited.
Objectives: The purpose of this study was to find new lncRNAs in peripheral blood monouclear cells of SLE patients by transcriptome sequencing and explore their potential as biomarkers and their correlation with clinical features.
Methods: Transcriptome sequencing was used to screen differentially expressed lncRNAs (DELs) and mRNAs (DEMs). DAVID and WebGestalt were used to perform enrichment analysis. Cytoscape was used to constructed protein-protein network, co-expression network and competitive endogenous RNA network to reveal the regulatory mechanism of lncRNAs in transcriptome level. The expression of these selected lncRNAs in SLE patients and healthy controls were verified by qPCR.
Results: A toal of 1737 DELs and 4078 DEMs were identified between 5 SLE patients and 5 healthy controls. Most of upregulated genes were enriched in defense and immune response, while downregulated genes were mainly enriched in SLE related pathways. Topology network analysis reveal the regulatory mechanism of lncRNAs in transcriptome level including directly acting on mRNA or indirectly affecting gene expression after acting on miRNA. Ten lncRNAs and eight genes was verified by qPCR in bigger samples including 77 SLE patients and 25 healthy controls. LncRNA NONHSAT101022.2 was significantly downregulated in SLE patients (*p=0.001*) and the expression of NONHSAT101022.2 showed a significant negative correlation with SLE disease activity index (SLEDAI, *r=-0.3592, p=0.0013*).
Conclusion: In this work, we identified a large number of mRNAs and novel lncRNAs by transcriptome sequence. The function and regulatory mechanism of these lncRNAs were analyzed by bioinformatics methods. LncRNA NONHSAT101022.2 is significantly downregulated in SLE patients and significantly related to the activity and severity of disease. Additionally, we put forward that NONHSAT101022.2 may enhance the signal transduction of β2-AR by cis-regulating its target gene, LMBRD2, which induces NK cells to produce high levels of IFN-γ, thereby exacerbating SLE.

Background: Systemic lupus erythematosus (SLE) is a multi-organ autoimmune disease that is potentially fatal. There is an unmet need to improve current therapies. In patients with SLE, we observed that serum CXCL5 levels were significantly lower than healthy control subjects and negatively correlated with disease activity[1-9].
Objectives: The aim of this study is to elucidate the effect of supplemental serum CXCL5 in abrogating the pathological processes of SLE.
Methods: Ten doses of exogenous CXCL5 (3μg/kg) was administered to 16-week-old Fas^{lpr} mice weekly by intravenous injection. Mice were monitored for 10 weeks. Splenic immune profile was measured by flow cytometry. Circulating cytokine and immunoglobulin profile were detected by Luminex technology. Renal function was evaluated by urinary spot albumin creatinine ratio. In situ renal immune cell infiltration and complement 3 deposition were detected by Haematoxylin and Eosin (H&E) and immunohistochemistry staining. The molecular pathways involved were examined by RNA sequencing.
Results: In Fas^{lpr} mice, intravenous administration of exogenous CXCL5 significantly improved mouse survival with concomitant reduction of autoantibody secretion, proteinuria, complement 3 deposition, neutrophil infiltration and lupus nephritis classes. Through evaluating the changes of immune profile, cytokine profile and molecular pathways, we found that intravenous CXCL5 reduced inflammation via an orchestral effect of regulating neutrophil trafficking and modulating helper T cell-mediated immune response. Pharmacokinetic and real-time Polymerase Chain Reaction studies further demonstrated that this orchestration was triggered by a cascade reaction - restoring vascular under-expressed CXCL5 by an exogenous stimulation, re-establishing the normal serum levels of endogenous CXCL5 and reverting the CXCL5 chemokine gradient between inflamed tissues and blood circulation.
Conclusion: Managing the dysregulation of CXCL5 by exogenous supplement may provide a new option for SLE therapy.

POS0418 SPLENIC EXTRAMEDULLARY HEMATOPOIESIS IS OMNIPRESENT AND CORRELATES WITH DISEASE SEVERITY IN THE LUPUS NZB/W F1 MURINE MODEL

S. Doumas[1,2], M. Grigoriou[1], A. Banos[1,3], C. Giakopoulou[4], I. Mitroulis[5], P. Verginis[6], D. Boumpas[1,2,7]. Background: Extramedullary hematopoiesis (EMH) is increasingly recognized as an integral component of systemic inflammatory diseases; compared to their bone marrow counterparts, hematopoietic progenitors of EMH have an enhanced role in target organ damage[1,2]. We have found that β-glucan -a non-specific inducer of reprograming of innate immunity- results in dramatic EMH with marked increase in Long-Term (LT)-HSCs, massive splenomegaly and worsening of nephritis in the NZB/W F1 lupus murine model (unpublished data).
Objectives: To investigate EMH's time course and contribution to inflammatory target-organ damage (kidney) in the NZB/W F1 lupus murine model.
Methods: Spleens and kidneys were isolated from female NZB/W F1, at pre-nephritic stage (3-month-old) and nephritic stage (>6-month-old), and age/sex matched C57BL/6 (WT controls). Single-cell suspensions of spleens were analyzed by flow cytometry for Hematopoietic Stem and progenitor cells (HSPCs) phenotyping. Formalin-fixed and paraffin-embedded sections of spleens and kidneys were stained with conventional histological stains (H&E, Silver, Trichrome Masson). Spleens were histologically assessed for the presence of EMH and kidneys were assessed for activity and chronicity through the NIH Lupus nephritis scoring system.
Results: Histological analysis revealed that NZW/B F1 mice at the nephritic stage display massive splenomegaly with concomitant expansion of the red pulp, increased presence of megakaryocytes and disorganized splenic architecture. This is further corroborated by the flow cytometry analysis which demonstrated a significant increase of all HSPCs subsets (Long-term/Short-term Hematopoietic Stem Cells and Multipotent progenitors) compared to the C57BL/6 WT controls at nephritic stage. The degree of HSPC expansion and splenic architecture disorganization correlates strongly with the activity of lupus nephritis as quantified by the NIH scoring system. Of note, evidence of splenic EMH were present even in 3-month-old animals before overt nephritis ensues.
Conclusion: Extramedullary hematopoiesis is present before overt nephritis and is dramatically expanded at the nephritic stage of the NZW/B F1 mouse model. The degree of EMH positively correlates with the severity of lupus nephritis. These data support a pathogenic role of EMH, and spleen derived HSPCs, in driving lupus nephritis.

POS0419 ABERRANT SPLICEOSOME AND ALTERED EXPRESSION OF IFN-RESPONSE RELATED GENES ARE HALLMARKS OF MONOCYTES FROM LUPUS PATIENTS WITH RENAL DISEASE

A. M. Patiño-Trives[1], C. Perez-Sanchez[1], A. Ibañez-Costa[2], M. Luque-Tévar[1], M. D. C. Abalos-Aguilera[1], I. Arias de la Rosa[1], D. Ruiz[1], P. Seguí Azpilcueta[1], M. Espinosa[1], N. Barbarroja Puerto[1], J. P. Castaño[2], R. M. Luque Huertas[2], M. A. Aguirre[1], C. Lopez-Pedrera[3]. Background: To date, novel mechanisms such as the involvement of splicing machinery components in lupus nephropathy and its interplay with the transcriptome in innate immune cells have not been evaluated.
Objectives: 1- To identify altered transcriptomic signatures associated with the immune response of monocytes from SLE patients and its association with clinical features. 2- To evaluate the role of the spliceosome linked to the transcriptomic profile of SLE monocytes. 3- To analyze mechanistically the impact of

anti-dsDNA antibodies (Ab) and the modulation of the spliceosome in the SLE monocytes activity.

Methods: Sixty SLE patients and forty healthy donors (HD) were included in the study. Infiltration rate of myeloid cells and its association with clinical features were analyzed in kidney biopsies by Immunohistochemistry. In parallel, circulating monocytes were purified from peripheral blood by immune-magnetic selection. The expression of a set of 770 genes related to autoimmune/inflammatory diseases was evaluated using NanoString Technologies. The levels of the main 45 components of the splicing machinery were further analyzed in these samples using a microfluidic qPCR array (Fluidigm). An extensive clinical/serological evaluation was also performed, comprising disease activity, renal involvement parameters, autoAb profile, and the systemic inflammatory status (27-plex Assay). Finally, *in vitro* studies involving anti-dsDNA-IgG Ab treatment and over/down-expression of splicing machinery components were carried out to analyze their effects in the monocyte activity.

Results: Infiltration of CD68 expressing cells was confirmed in kidney biopsies and associated with parameters of kidney failure (C3/C4, chronic index), highlighting the key role of the myeloid compartment in lupus nephropathy. Gene expression profiling recognized 156 genes differentially expressed in SLE monocytes compared with HDs, including 87 genes up-regulated and 69 down-regulated. Functional analysis showed that most dysregulated genes were associated with the IFN response (i.e. IFIT1, IFI44, IFI44L, RSAD2). In parallel, the altered expression of 27 spliceosome components was demonstrated in SLE monocytes compared with HD, including 3 up-regulated and 24 down-regulated. Correlation studies demonstrated that the aberrant expression of splicing machinery components was linked to the altered interferon signature and the plasma inflammatory profile. This aberrant profile at molecular level was associated with the disease activity status, anti-dsDNA positivity and C3/C4 levels. Interestingly, SLE patients with renal disease displayed a simultaneous alteration of both, the IFN and the spliceosome signatures in monocytes, along with an enlarged pro-inflammatory profile in plasma. Logistic regression models that integrated the concomitant alteration of some splicing machinery components and IFNs genes identified lupus nephritis patients with high accuracy. Mechanistic studies showed that *in vitro* treatment of monocytes from HDs with anti-dsDNA promoted a concomitant deregulation of the IFN signature and the expression of several spliceosome components (i.e. PTB, RBM17, RNU6ATAC). Finally, the over/down-expression of selected spliceosome components (PTB and RBM17) in monocytes from SLE patients reduced the active release of inflammatory cytokines and their adhesion capacity.

Conclusion: 1) Monocytes from SLE patients with renal involvement exhibit a remarkable alteration of genes associated with the IFN response, further linked with the aberrant expression of several splicing machinery components. 2) Anti-dsDNA promoted the dysregulation in monocytes of both the IFN and spliceosome signatures, along with an active release of pro-inflammatory mediators. 3) The modulation of key splicing components in monocytes from SLE patients reduce their pro-inflammatory status and migration capacity. Ongoing studies may provide novel biomarkers and therapeutic tools to treat lupus nephropathy.

POS0420 DYSREGULATED CD38 EXPRESSION ON PERIPHERAL BLOOD IMMUNE CELL SUBSETS IN SLE

M. Burns[1], L. Ostendorf[2,3], A. Grützkau[1], F. Hiepe[2,3], T. Alexander[2,3], H. Mei[1]. *[1]Deutsches Rheuma-Forschungszentrum (DRFZ Berlin) – a Leibniz Institute, Immune Monitoring & Mass Cytometry, Berlin, Germany*; *[2]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[3]Deutsches Rheuma-Forschungszentrum (DRFZ Berlin) – a Leibniz Institute, Autoimmunology, Berlin, Germany*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by pathogenic antinuclear autoantibodies, which are secreted by autoreactive plasma cells. Among novel plasma cell-depleting strategies, CD38 has been identified as promising target. The monoclonal anti-CD38 antibody daratumumab is approved for treatment of multiple myeloma and provided a therapeutically relevant depletion of plasma cells in patients with SLE[1].

Objectives: Beyond plasma cells, CD38 is widely expressed across innate and adaptive immune cells and additional cellular targets of anti-CD38 treatment, especially in patients with SLE, are largely unknown. Therefore, this study aimed to systematically characterize the expression of CD38 in peripheral blood leukocytes to identify potential target cells of CD38-directed therapies that may contribute to or limit therapeutic benefits in SLE.

Methods: We analyzed the expression of CD38 on peripheral blood leukocytes in two different cohorts, comprising a total of 56 SLE patients and 39 healthy controls, by flow and mass cytometry. CD38 expression levels across major immune cells were analyzed for changes between controls and SLE, as well as for correlation across immune cell lineages, and with clinical and serological disease parameters.

Results: We detected increased CD38 expression levels on circulating NK cells, plasmacytoid dendritic cells, $CD4^+$ and $CD8^+$ memory T cells, as well as IgD^-CD27^- and marginal zone-like B cells in SLE compared to healthy controls. In myeloid and NK cells, CD38 expression was associated with an activated cellular phenotype, reflected by co-expression of molecules such as HLA-DR, CD11c or Syk. In the B cell compartment, IgA^- plasmablasts and plasma cells expressed more CD38 than their IgA^+ counterparts. Also, HLA-DR^{high} plasmablasts showed higher CD38 expression compared to HLA-DR^{low} plasma cells. The strongest differences in CD38 expression between controls and SLE were found in $CD8^+$ central and effector memory T cells. Additionally, we detected an expansion in $CD38^{high}$ and $CD38^{int}$ cells in the T cell memory compartment, with some patients showing distinctly increased expression values. We observed a high intra-individual correlation of CD38 expression across immune cell lineages, yet without correlation of CD38 expression levels with clinical activity (SLEDAI-2K), serological markers of SLE or the type I interferon surrogate marker CD169 (SIGLEC-1).

Conclusion: Our data indicate that not only pathogenic plasma cells are potential target cells of CD38-targeting antibodies. The highly dysregulated CD38 expression across innate and adaptive immune cells in SLE could be of pathophysiological importance with respect to the potential efficacy and side effects of such therapies. Since CD38 expression did not correlate with disease activity, it may be assumed that it is not a response protein solely induced and modulated by type I interferons. Nevertheless, our comprehensive characterization of CD38 expression in the immune system might have important implications for personalized approaches with emerging CD38-directed therapeutics.

Background: Metabolic pathways are important regulators of immune differentiation and activation in kidneys. Kidneys directly impact systemic metabolism, circulating metabolite levels, and express intrinsic metabolic activity. The integration of renal metabolomic and transcriptomic profiles may unravel unique gene-metabolite pairs of biological significance in lupus nephritis (LN).

Objectives: To decipher gene-metabolite signatures at both pre-nephritic and nephritic stages of lupus.

Methods: Kidneys were isolated and snap-frozen after perfusion from female NZB/NZW-F1 lupus mice at the pre-nephritic (3-month-old) and nephritic (6-month-old exhibiting ≥100 ng/dL of urine protein) stage of lupus (n=6/group). Age-matched female C57BL/6 mice were used as healthy controls. Sample extracts were used for RNA sequencing and ^{1}H-NMR spectroscopy metabolic profiling. DESeq2 was used to identify differentially expressed genes. Univariate analysis was used to reveal metabolic differences characteristic for nephritis.

Results: Comparative transcriptomic analyses uncovered multiple transcripts related to metabolic pathways: In pre-nephritic kidneys, lipid metabolism, cellular respiration, TCA cycle, amino acid metabolism processes were overrepresented in the upregulated genes while in nephritic kidneys, amino acid metabolism processes were overrepresented among the downregulated genes (Figure 1). ^{1}H-NMR analysis revealed a total of 49 metabolites. Comparison of the metabolic levels of nephritic and pre-nephritic animals revealed that ADP, ATP, NAD+, Taurine and Myo-inositol decreased, while Thr increased significantly. The comparison to corresponding control animals, demonstrated that only myo-inositol increased significantly. Integration of kidney metabolomics and transcriptomics indicated the involvement of processes related to glutathione metabolism, leukocyte trans-endothelial migration and antigen presentation during the established renal disease stage.

Conclusion: The combined transcriptomics and metabolomics analysis revealed metabolic derangements in lupus-affected kidneys both during subclinical and overt LN. Deregulated tissue-levels of taurine and myo-inositol at the subclinical stage of the disease suggest aberrant renal biochemistry preceding the development of overt LN that may directly impact systemic metabolism and circulating metabolite levels.

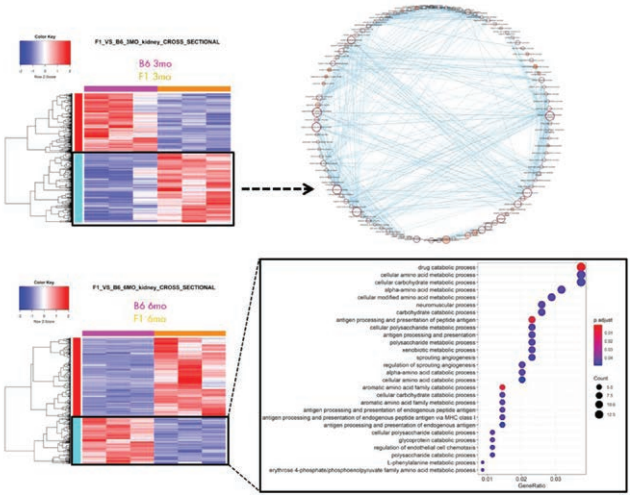

Figure 1. Pathways linked to cell metabolism were overrepresented among 3-month upregulated and 6-month lupus mice (F1) downregulated DEGS (*differentially expressed genes*) compared to controls (C57BL/6).

Nasonova Research Institute of Rheumatology, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: ASIA syndrome or Schonfeld syndrome is an autoimmune/inflammatory condition induced by adjuvants in genetically susceptible individuals with the development of rheumatic diseases (RD), multiple sclerosis, sarcoidosis, and others.
Objectives: to characterize the symptoms of panniculitis (Pn) associated with ASIA-syndrome
Methods: Within 7 years, ASIA syndrome was diagnosed in 12 women, average age 37.2±7.4, with a referral diagnosis of "Erythema Nodosum" or "Panniculitis". The duration of the disease was 16.7±3.9 months. In addition to general clinical study, the serum concentration of α-1 antitrypsin, amylase, lipase, ferritin, creatine phosphokinase (CPK), immunological parameters (ANP-Hep2, dsDNA, C3 and C4, CRP, ANCA, Scl-70, antibodies to cardiolipins G and M), computed tomography of the chest organs, pathomorphological and immunohistochemical examination of a biopsy specimen of skin with subcutaneous fat tissue (SFA) from the affected areas.
Results: The development of ASIA syndrome was preceded by gluteoplasty using propantriol-1,2,3 (in 4 patients), liposuction (2), biorevitalization with hyaluronic acid (2) and endoprosthetics with breast implants (2), bone metal construction (1) and mesh hernioplasty (1). The clinical picture of Pn was characterized by generalized red-purple painful (VAS pain 55.8±17.3 mm) subcutaneous indurations on the upper limbs and trunk (in 100% of cases), face (16.6%) and lower limbs (33.3%), with ulceration and oily fluid leakage (58.6%). The saucer symptom was recorded in 83.3% of the observed patients. In 66.6% of cases, fever and articular syndrome were observed, in 41.6% – myasthenic syndrome and lymphadenopathy, in 8.3% – xerophthalmia, keratoconjunctivitis dry, xerostomia and recurrent parotitis. In blood tests, leukopenia (up to 2.0x109/l) was identified in 33.3% of patients, a significant increase in the level of creatinine phosphakinase – in 16,6%, a two or more times increase in ESR and CRP – in 100%. All patients demonstrated immunological changes. The morphological picture of the skin and SFA in 75% of cases resembled lobular Pn, in 8.3% – tumor lymphocytes with the immunophenotype of cytotoxic T-lymphocytes: CD3+, CD8+ were detected. The results obtained allowed confirming RD in 8 patients: systemic lupus erythematosus and idiopathic lobular panniculitis in 2 patients (respectively) and 1 in dermatomyositis, systemic scleroderma of Sjogren's disease, mixed connective tissue disease. One case was diagnosed with sarcoidosis and T-cell lymphoma. In 2 patients after the liposuction procedure the course of Pn was reversible.
Conclusion: Diagnosis of Pn associated with ASIA syndrome is a complex task that requires a multidisciplinary approach to verify the diagnosis and treatment tactics.

POS0423 NCOA3 AMPLIFIES PROFIBROTIC TRANSCRIPTIONAL PROGRAMS IN SYSTEMIC SCLEROSIS

C. Dees[1], S. Poetter[1], M. Fuchs[2], C. Bergmann[1], A. E. Matei[1], A. H. Györfi[1], A. Soare[1], A. Ramming[1], P. Ceppi[3], G. Schett[1], M. Kunz[2], J. H. W. Distler[1]. [1]*Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany*; [2]*Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Chair of Medical Informatics, Erlangen, Germany*; [3]*Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Interdisciplinary Center for Clinical Research - Junior Research Group 1, Erlangen, Germany*

Background: Excessive activation of fibroblasts with a TGFβ-biased gene signature and deposition of extracellular matrix are key features of fibrotic diseases. The mechanisms underlying these transcriptional changes remain poorly understood. Deregulation, mutations and malfunctions of transcriptional co-regulators, which can interact with multiple transcription factors and enable a broad-spectrum regulation of transcriptional networks, have been implicated as driving factors in a large number of diseases and pathologies.
Objectives: In the present study, we aimed to analyze the role of the co-regulator Nuclear Receptor Co-Activator 3 (NCOA3) in fibroblast activation and tissue fibrosis, and to evaluate a potential interaction of NCOA3 with fibrosis-relevant transcription factors.
Methods: NCOA3 was inhibited genetically by siRNA transfection and pharmacologically by the SRC3 inhibitor-2 (SI-2). We performed bulk RNASeq of human dermal fibroblasts and *in silico* transcription factor binding site screening of differentially expressed genes (DEGs). The interaction of NCOA3 and TGFβ-SMAD signaling was analyzed by reporter and CoIP assays.
Results: The expression of NCOA3 in skin biopsies of SSc patients compared to normal controls demonstrated that SSc fibroblasts express modestly, but significantly reduced levels of NCOA3, which persisted in cultured SSc fibroblasts. Stimulation of normal fibroblasts with chronically high levels of TGFβ as they also occur in fibrotic tissue remodeling strongly decreased NCOA3 expression to a similar extent as in SSc fibroblasts. Furthermore, NCOA3 expression is also deregulated in different murine models of skin fibrosis. To investigate the functional effects of decreased NCOA3 levels, we targeted the expression of NCOA3 in normal fibroblasts. SiRNA-mediated knockdown of NCOA3 ameliorated TGFβ-induced gene expression, collagen release, myofibroblast differentiation and cell proliferation. In contrast, knockdown of NCOA3 had no effects on collagen release, expression of contractile proteins or gene expression in unstimulated fibroblasts, suggesting that NCOA3 is not required for cellular homeostasis. To characterize the molecular mechanisms, we performed RNASeq upon NCOA3 knockdown. We identified 343 significant differentially expressed genes (220 downregulated and 123 upregulated with a Benjamini-Hochberg false discovery rate FDR < 0.25 and fold change > 1.5) between TGFβ-stimulated fibroblasts with and without NCOA3 knockdown (NCOA3-DEGs) including the fibrosis-relevant genes *EDNRB, COL5A3, HES1, IL11* or *IL33*. Functional analysis of the NCOA3-DEGs showed enrichment of pathway terms such as collagen binding and extracellular matrix organization. *In silico* screening of the promoters of the NCOA3-DEGs for potential transcription factor binding motifs revealed binding motifs of core transcription factors of fibroblast activation and tissue fibrosis such as SMAD2/3/4, RBPJ, ZEB1, TCF4, REL, and SNAIL2 amongst the downregulated NCOA3-DEGs. Experimental validation of our biostatistical results using SMAD3 as example demonstrated a higher percentage of NCOA3-pSMAD3 double-positive fibroblasts in skin sections of SSc patients compared to healthy controls. In addition, knockdown of NCOA3 reduced TGFβ-induced SMAD-reporter activity. Furthermore, stimulation with TGFβ increased the interaction of NCOA3 with SMAD3 as analyzed by co-immunoprecipitation. Simultaneous knockdown of NCOA3 and SMAD3 showed no additional reductions compared to the single knockdowns, suggesting that NCOA3 controls SMAD3-dependent gene transcription under fibrotic conditions. Finally, inhibition of NCOA3 showed anti-fibrotic effects in different murine models of experimental skin and lung fibrosis.
Conclusion: Our findings characterize NCOA3 as regulator of multiple pro-fibrotic transcription programs. Pharmaceutical inhibition of NCOA3 might be a strategy to interfere simultaneously with several core pro-fibrotic mediators in fibrotic diseases such as SSc.

POS0424 DETERMINING CIRCULATING ENDOTHELIAL CELLS USING CELLSEARCH SYSTEM IN SYSTEMIC SCLEROSIS PATIENTS

F. Pignataro[1], L. Zorzino[2], W. Maglione[1], A. Minniti[1], G. Clericuzio[2], M. Picozzi[2], C. Simonelli[3], F. Picardo[3], R. Caporali[1,4], N. Del Papa[1]. [1]*ASST Gaetano Pini-CTO, Clinical Rheumatology, Milan, Italy*; [2]*IEO, Division of Laboratory Medicine, Milan, Italy*; [3]*Menarini Silicon Biosystems, Medical Affairs, Bologna, Italy*; [4]*University of Milan, Clinical Science and Community Health, Milano, Italy*

Background: Endothelial damage and fibroproliferative vasculopathy of small vessels are pathological hallmarks of Systemic Sclerosis (SSc). Detection and analysis of circulating endothelial cells (CECs) detached from affected blood vessels may be an informative tool to study vascular dysfunction and could be considered a novel biomarker of scleroderma vasculopathy. Our group first showed the presence of CECs in SSc by fluorescence-activated cell sorting (FACS), demonstrating that a raised counts of active CECs may represent direct evidence of active vascular disease in SSc. Despite these interesting data, issues related to difficulties in CEC counting through FACS analysis, due their very low concentration in peripheral blood, prevented further investigations in this field. Recently, a specific kit for the detection of CECs has been developed through the CellSearch System (CS), a semi-automated device for the standardized analysis of rare cells, such as CECs, in peripheral blood.
Objectives: To assess the counts of CECs determined by the CS in SSc patients and to evaluate their clinical implication and potential as vascular biomarker in SSc.
Methods: 10mL of blood samples were collected from 29 subjects (19 SSc patients and 10 healthy donors - HDs) and stored in tubes containing a specific preservative, to allow the analysis of 4mL of blood within 72 hours, according to manufacturer instructions. Out of 19 SSc patients, 18 were female, 10 had the limited form and 9 the diffuse cutaneous variant of SSc. CS uses a proprietary kit containing a ferrofluid-based reagent, that target CD146 to magnetically capture CECs, and the immunofluorescent reagents to stain the CECs, defined as CD146+, CD105-PE+, DAPI+ and CD45-APC-. Clinical, laboratoristic and demographic data were also collected.
Results: The mean number of CECs in patients with SSc was significantly higher in comparison to HDs (554/4mL vs. 53.5/4 mL, p=0.0042). When analyzed according to disease subset, both lcSSc and dcSSc showed significantly increased levels of CECs in comparison with HDs (p=0.003 and p=0.005, respectively). No statistical difference was observed in the mean number of CECs in patients with lcSSc compared to those with dcSSc. Regarding vascular involvement, the CECs counts strictly correlated with the presence of digital ulcers (DUs) (p=0.0001) showing a median of 863cells/4mL for the SSc patients with DUs versus a median of 276.2/4mL for the SSc patients without DUs. No statistical correlation was found between CECs and serological autoantibody pattern, skin parameters, or joint and muscle involvement. Patients with active disease, according to the EUSTAR Activity Index, showed a higher CECs value than those with inactive disease (p=0.0012).
Conclusion: The amount of CECs detectable in peripheral blood has been recently proposed as a marker of endothelial damage in different vascular diseases, including SSc. However, currently no standardized method is available to determine CEC counts, which makes reported data on CECs reliable and suitable. The CS system is a commercially available semi-automated system that enables standardized determination of CECs. Thus, we examined clinical utility of CECs count by this system in SSc patients. Our results confirm that baseline CEC counts, evaluated by a new standardized method, may represent direct evidence of endothelial damage in SSc and could be a promising tool for monitoring active disease and evaluating therapeutic responses to vascular and immunosuppressive treatments.

POS0425 INCREASED KERATIN 9 EXPRESSION IN SYSTEMIC SCLEROSIS SKIN IS DRIVEN BY THE LNCRNA HOTAIR FROM FIBROBLAST DERIVED EXOSOMES

C. Wasson[1], R. Ross[1], J. Bryon[1], F. Del Galdo[1]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, School of Medicine, Leeds, United Kingdom*

Background: Skin fibrosis is the hallmark fibrotic manifestation of systemic sclerosis (SSc). Despite a key role of tissue fibroblasts, skin changes extend to the keratinocyte layer, which contribute to the loss of skin function. RNA seq. analysis of SSc patient forearm skin showed that palmoplantar specific Keratin 9 (CK9) was highly expressed (1). SSc affected skin shares several features with palmoplantar skin including increased keratinocyte layer thickness and lack of hair. Seminal work of last decade has shown that long noncoding RNA in the HOX loci play a crucial role in skin keratinocyte differentiation (2), with the lncRNA HOTAIR being one of the HOX lncRNA mostly expressed in the palmoplantar region.
Objectives: Following recent data suggesting a role of HOTAIR in the profibrotic phenotype of dermal fibroblasts in SSc (3), here we set out to determine if HOTAIR expressed in SSc dermal fibroblasts was a contributing factor to the high levels of CK9 found in SSc patient skin
Methods: Full-thickness skin biopsies were surgically obtained from the forearms of patients with SSc of recent onset. Fibroblasts were isolated and cultured in monolayers. HOX transcript antisense RNA (HOTAIR) was expressed in healthy dermal fibroblasts by lentiviral induction employing a vector containing the specific sequence. Exosomes were isolated from dermal fibroblast media using the Total exosome isolation reagent (Thermo Fisher). Enhancer of zeste 2 (EZH2) was blocked with GSK126 inhibitor. Skin equivalents were created using scramble and HOTAIR expressing fibroblasts with primary keratinocytes
Results: Media from both SSc patient fibroblasts and HOTAIR expressing fibroblasts induced CK9 expression in healthy keratinocytes *in vitro*. In addition, HOTAIR expressing fibroblasts induces CK9 expression in keratinocytes in 3D skin equivalent models. Media fractionation studies indicated that HOTAIR was present in fibroblasts exosomes and found at a higher concentration (2.7 fold p=0.01) in exosomes from SSc fibroblasts. Importantly, transfection of Exosomal RNAs from SSc fibroblasts could reproduce the increase in CK9 in keratinocytes. Mechanistically, CK9 induction was mediated by changes to the histone methylation profile in the keratinocytes through EZH2.
Conclusion: Pro-fibrotic dermal fibroblasts in systemic sclerosis contribute to the overall skin loss of function by inducing CK9 in adjacent keratinocytes through transfer of the long non-coding RNA HOTAIR. Unraveling the crosstalk of activated fibroblasts with adjacent cells may lead to identify therapeutic targets to re-establish tissue homeostasis and function during fibrosis.

POS0426 CIRCULATING MICRORNA PROFILING IN PATIENTS WITH ANTI-SYNTHETASE SYNDROME AND INTERSTITIAL LUNG DISEASE

G. Zanframundo[1,2], S. Bozzini[3], V. Codullo[2], V. Frangipane[3], L. Pandolfi[3], B. Atienza-Mateo[4], S. Remuzgo Martinez[4], C. Montecucco[1,2], M. A. González-Gay[4], F. Meloni[1,3], L. Cavagna[1,2]. [1]*University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy*; [2]*IRCCS Policlinico San Matteo Foundation, Department of Rheumatology, Pavia, Italy*; [3]*IRCCS Policlinico San Matteo Foundation, Department of Respiratory Diseases, Pavia, Italy*; [4]*Hospital Universitario Marqués de Valdecilla, IDIVAL, Rheumatology Division, Santander, Spain*

Background: Anti-synthetase syndrome (ASSD) is an autoimmune disease characterized by autoantibodies against one of many aminoacyl transfer RNA (tRNA) synthetases. Interstitial Lung Disease (ILD) in ASSD patients is frequent, often severe and rapidly progressive, causing much of the increased morbidity and mortality associated with ASSD as compared to other idiopathic inflammatory myopathies [1].

Objectives: In this study, we hypothesized that immune-related miRNAs may be associated with presence/absence of lung involvement in patients with ASSD and help predict disease course.
Methods: A total of 15 ASSD patients were enrolled: 11 with ILD and 4 without ILD. Differentially expressed miRNAs were identified in plasma derived-exosome, using miRNA PCR array (MIHS-111ZG, Qiagen) including 84 miRNAs involved in activation and differentiation of T and B cells.
Results: Among all miRNAs analyzed we found that miR-15b-5p, miR-23a-3p, miR-25-3p, miR-30a-5p and miR29c-3p were up-regulated in ASSD-ILD patients ($p<0.05$) as compared to patients without lung involvement (Figure 1). To evaluate the effectiveness of the five miRNAs for predicting ILD among ASSD patients, ROC curves were constructed. The AUCs of miR-15b-5p, miR-25-3p, miR-30a-5p and miR29c-3p were 0.83, 0.87, 0.86 and 0.89, respectively ($p= 0.05$ for miR-25-3p and $p<0.05$ for all other curves). The prediction of the biologic targets and pathways as well as cellular processes by DIANA-mirPath analysis showed that all miRNAs associated with ILD presence are involved in PI3K-Akt signaling pathway.
Conclusion: Our study shows that, in ASSD patients with ILD, miR-15b-5p, miR-23a-3p, miR-25-3p, miR-30a-5p and miR29c-3p were up-regulated compared to patients without evidence of ILD. A clear involvement in immune and inflammatory diseases was documented for the miRNAs identified [2] and, for many of these, studies in the literature indicate a possible role in pulmonary fibrosis [3]. It is notable that these miRNAs were related to PI3K-Akt signaling pathway that regulate cell proliferation, differentiation and apoptosis [4]. It has also been demonstrated that in lung fibroblast the PI3K–Akt signals can be aberrantly activated [5]. The identification of markers could be important in the early identification of the disease and for its treatment.

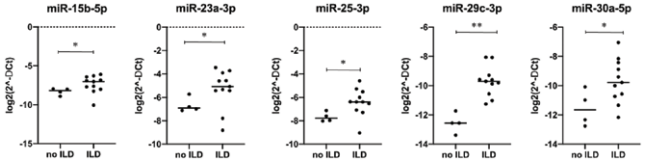

Figure 1. Comparison of relative levels of five miRNAs among patients with and without lung involvement were expressed as $\log_2$ transformed values. $^{*}p<0.05$; $^{**}p<0.01$

POS0427 CLINICAL CHARACTERISTICS OF PATIENTS WITH SYSTEMIC SCLEROSIS AND GASTRIC ANTRAL VASCULAR ECTASIA (GAVE)

C. Codina[1], A. Guillén-del-Castillo[1], E. Callejas-Moraga[2], J. Perurena-Prieto[3], M. Roca-Herrera[2], I. Sanz-Pérez[1], A. Gil-Vila[1], A. Selva-O'Callaghan[1], V. Fonollosa-Pla[1], C. P. Simeón-Aznar[1]. Background: Gastric antral vascular ectasia (GAVE) is one of the gastrointestinal (GI) manifestations related to systemic sclerosis (SSc). It can be presented as iron deficiency anemia or even upper gastrointestinal bleeding. GAVE is diagnosed by endoscopy observing an image of confluent vascular ectasias that is oriented longitudinally on the folds of the antrum in the appearance of "watermelon". The definitive treatment for this manifestation consists in endoscopy guided fulguration when the clinical situation allows it.
Objectives: The objective was to study a cohort of SSc patients at their first endoscopy. The clinical characteristics, laboratory tests and treatments received from SSc patients with GAVE were compared to those without this GI manifestation.
Methods: From the cohort of patients with SSc in Hospital Universitari Vall d'Hebron, a total of 269 patients who had undergone at least one endoscopy during follow-up were selected. Twenty seven were diagnosed with GAVE. We compared the clinical, analytical and treatment characteristics of these patients with the remaining 242 who did not present GAVE. The statistical study was carried out using the SPSS 20.0 package (Chicago, IL), a $p<0.05$ was considered as statistical significance.
Results: The prevalence of GAVE in SSc patients was 10.0%. Patients with GAVE had a higher median age SSc onset taking into account the first non-Raynaud's phenomenon (RP) symptom attributable to the disease (56.6 vs 48.0 years, $p = 0.001$). The median age at first endoscopy was 56.5 years in GAVE group compared with 61.7 in the group without GAVE.
Compared with SSc patients without GAVE, patients with GAVE had a higher prevalence of Barrett's esophagus (14.8% vs. 3.7%, $p = 0.011$), intestinal involvement (37% vs. 18.6%, $p = 0.024$) and a trend towards a lower prevalence of interstitial lung disease (25.9% vs 45.0%, $p = 0.057$).
No difference was identified in the prevalence of scleroderma renal crisis. Patients with GAVE presented a higher frequency of early or active Cutolo capillaroscopy pattern with a predominance of enlarged capillaries or megacapillaries (84.6% vs 62.4%, $p = 0.025$), greater frequency of anti-centromere antibodies (63.0% vs. 42.1%, $p = 0.039$) and a trend towards a lower proportion of anti-topoisomerase I (3.7% vs. 18.6%, $p = 0.052$). No difference was found in prevalence of anti-RNA polymerase III antibodies between groups. Patients with GAVE were treated less frequently with non-glucocorticoid immunosuppressants prior to diagnostic endoscopy (0% vs 20.2%, $p = 0.010$). The 33.3% of patients with GAVE were treated with endoscopic fulguration, and 66.7% of them received supplementary treatment with oral iron.
Conclusion: SSc patients with GAVE had higher age at SSc onset, more frequency of Barrett's esophagus and intestinal involvement, prevalence of anti-centromere antibodies, early or active Cutolo scleroderma pattern and lower prior non-glucocorticoids treatment.

POS0428 REGULATION OF IFN SIGNATURE BY HDAC CLASS IIA-CD52 AXIS IN SYSTEMIC SCLEROSIS

M. Rudnik[1], A. Hukara[1], P. Blyszczuk[1], O. Distler[1], G. Kania[1]. [1]*University Hospital Zurich, University of Zurich, Department of Rheumatology, Center of Experimental Rheumatology, Zurich, Switzerland*

Background: Systemic sclerosis (SSc) is associated with an interferon (IFN) signature, which is defined by a higher expression of IFN-stimulated genes (mainly in response to IFNα). Histone deacetylases (HDACs) are a family of epigenetic modifiers mediating immune function. HDACs function via diverse molecular mechanisms, including direct inhibition of gene transcription or indirectly through modulation of nuclear transcription factors such as NF-κB and STATs. CD52 protein regulates T cell receptor and NF-κB signalling. Previously, we showed downregulation of CD52 in SSc monocytes, however, the influence of CD52 on IFN signalling has not been studied yet.
Objectives: We investigated the role of CD52 in the regulation of IFN response in monocytes. Moreover, we explored the regulatory mechanisms of CD52 expression to identify the involvement of HDACs in that process.
Methods: RNAseq of $CD14^+$ monocytes isolated from peripheral blood of lcSSc (n=5, age=54.4±6.7), dcSSc patients (n=5, age=51.8±7.2) and age- and sex-matched healthy controls (HC) (n=5, age=50.8±9.7) was performed using Illumina HiSeq 4000 platform. Differentially expressed genes were computed using DeSEQ2 algorithm. Gene ontology and pathway analysis were performed using Metacore software and ShinyApp. CD52 activity in monocytes was blocked by monoclonal antibody Alemtuzumab [10ug/ml] and IFN signature genes expression was assessed upon IFNα stimulation [1ng/ml] by qPCR and ELISA. HDAC-dependent regulation of CD52 expression in $CD14^+$ monocytes from HC was analysed on mRNA and protein levels after treatment with pan-HDAC inhibitor valproic acid and HDAC class IIa inhibitor TMP269 [both 2.5μM].
Results: Pathway analysis revealed significant alterations in interferon signalling in SSc monocytes. Monocytes treated with Alemtuzumab and IFNα showed induced expression of *STAT1* (p=0.023, N=4), *CXCL9* (p=0.062, N=4) and *CXCL10* (p=0.005, N=4). RNAseq revealed a specific HDAC expression pattern in SSc monocytes with induced expression of HDAC4, 6, 10, 11 ($p<0.05$) and reduced HDAC1, 3 and 8 ($p<0.05$). *CD52* mRNA was significantly decreased after IFNα stimulation (p=0.001, N=3). Treatment with valproic acid and HDAC class IIa inhibitor TMP269 resulted in decreased phosphorylation of STAT1 ($p<0.01$, N=4) followed by a declined level of CXCL10 ($p<0.01$, N=4) and restored level of *CD52* mRNA ($p<0.001$, N=4).
Conclusion: Our findings demonstrated a new aspect of pro-inflammatory type I IFN signalling in SSc. We described a novel regulation feedback loop in monocytes, in which CD52 suppresses IFN signature, while its expression is inhibited by IFN-induced HDAC activity (mainly HDAC class IIa). Therefore, targeting the CD52-IFN-HDAC axis might serve as a novel therapeutic strategy in SSc.

POS0429 INTERLEUKIN-4 ACTIVATES EOSINOPHILS AND CCR3-POSITIVE T HELPER CELLS MIGRATION TO FASCIA AND PROMOTES FIBROSIS IN EOSINOPHILIC FASCIITIS

M. Hosonuma[1,2,3,4], T. Isozaki[2], H. Furuya[2], Y. Yamazaki[5], Y. Ikari[2], S. Nishimi[2], A. Maeoka[2], S. Ishii[2], T. Tokunaga[2], K. Wakabayashi[2], N. Konishi[2], S. Fukuse[2], K. Ishikawa[6], N. Sakai[7], K. Inagaki[6], T. Kasama[2]. *[1]Clinical Research Institute for Clinical Pharmacology & Therapeutics, Showa University, Department of Clinical Immuno Oncology, Tokyo, Japan*; *[2]Showa University, Division of Rheumatology, Department of Medicine, Tokyo, Japan*; *[3]Showa University, Division of Medical Oncology, Department of Medicine, Tokyo, Japan*; *[4]Showa University, Department of Pharmacology, School of Medicine, Tokyo, Japan*; *[5]Showa University School of Pharmacy, Division of Toxicology, Department of Pharmacology, Toxicology and Therapeutics, Tokyo, Japan*; *[6]Showa University School of Medicine, Department of Orthopaedic Surgery, Tokyo, Japan*; *[7]Showa University School of Dentistry, Department of Pharmacology, Tokyo, Japan*

Background: Eosinophilic fasciitis (EF) is a rare disease that causes inflammation and fibrosis mainly in the fascia of the extremities with eosinophilia. It has been reported that the hypertrophied fascia in EF shows inflammatory cell infiltration by the lymphocytes and eosinophils and increased expression of fibrosis-related cytokines genes in fibroblast [1]. However, its pathophysiology in the fascia remains unresolved.
Objectives: Therefore, we focused on fascial fibroblasts and aimed to determine the role of interleukin-4 (IL-4) in eosinophil and helper T cell infiltration and fibrosis in fascial fibroblast in EF.
Methods: Fascial fibroblasts were obtained from fascia biopsy of a patient with EF, and were stimulated with pre- and post-treatment serum of a patient with EF and healthy control, followed by microarray to analyze gene expression. Fascial fibroblasts were stimulated with IL-4 10 ng/mL, and gene expression of IL-4 receptor and CCR3 ligands, CCL7 and CCL11 were measured by qPCR. Transforming growth factor (TGF) -β and periostin in the pre- and post-treatment serum of a patient with EF and conditioned medium of fascial fibroblasts stimulated with IL-4 were measured by ELISA. To examine the role of IL-4 in proliferation, we performed in proliferation assays using fascial fibroblasts treated with IL-4. CCR3-positive T cells in the fascial tissue of EF, dermatomyositis, and polymyositis patients were evaluated by immunostaining.
Results: By microarray analysis, CCL7 and CCL11 expression of fascial fibroblasts stimulated with pre-treatment EF serum was higher than that in post-treatment EF serum and control serum. CCL7 and CCL11 mRNA in IL-4 stimulated facial fibroblasts were increased by 5.1-fold and 7.3-fold, respectively. TGF-β and periostin in IL-4 stimulated facial fibroblast conditioned medium were also increased. In addition, TGF-β and periostin in EF serum were gradually decreased by treatment for 4 and 10 weeks, compared to before treatment. Finally, fascial fibroblast proliferation was significantly increased by stimulation with IL-4. Furthermore, infiltration of CCR3-positive T cells was specific to the fascial tissue of EF.
Conclusion: In EF, IL-4 enhances the production of CCR3 ligands, TGF-β, and periostin from fascial fibroblasts. As a result, it promotes the migration of eosinophils and CCR3-positive T helper cells to the fascia and fibrosis. These results suggest that inhibition of IL-4 pathway could be a novel strategy for eosinophilic fasciitis.

POS0430 EXPRESSION AND CLINICAL SIGNIFICANCE OF AUTOPHAGY-RELATED GENES IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF SYSTEMIC SCLEROSIS

Y. F. Qing[1], J. Zheng[1], S. B. Wang[1], F. Dai[1], Y. Jiang[1], Y. X. He[1], Q. B. Zhang[2]. *[1]Institute of Rheumatology and Immunology, Department of Rheumatology and Immunology, Nanchong, China*; *[2]Institute of Rheumatology and Immunology, Department of Geriatrics, Affiliated Hospital of North Sichuan Medical College, Nanchong, China*

Background: Growing evidences have demonstrated that autophagy is a powerful regulators in the pathogenesis of fibrosis and autoimmune diseases. Autophagy abnormalities in SSc involve abnormal autophagy-related protein and autophagy-related gene polymorphism[1-2], however there is a few reports on the expression and clinical significance of autophagy-related genes.
Objectives: To investigate the expression and clinical significance of autophagy-related genes LC-3 mRNA, Becline-1 mRNA, Agt-3 mRNA, Agt-5 mRNA, Agt-12 mRNA and Agt-16L1 mRNA in peripheral blood mononuclear cells (PBMC) of systemic sclerosis (SSc).
Methods: 51 cases of SSc and 60 cases of normal control were received from the Affiliated Hospital of North Sichuan Medical College, and autophagy-related genes were detected by RT-PCR. SPSS19.0 statistical software was used to compare the expression of autophagy-related genes between groups and analyze the relationship between autophagy-related genes and clinical data, $P<0.05$ was considered statistically significant
Results: LC-3, Becline-1, and Agt-3 were highly expressed in SSc compared with normal control [LC-3: 0.78(0.60) $\times10^{-3}$ vs. 0.52(0.54) $\times10^{-3}$; Beclin-1: 6.68(3.56)$\times10^{-3}$ vs. 5.22(3.54)$\times10^{-3}$; Agt-3: 17.58(12.33)$\times10^{-3}$ vs. 11.00(4.56)$\times10^{-3}$, $P<0.05$], however Agt-5, Agt-12 and Agt-16L1 of autophagy-related genes were not statistically significant [AGT-5: 6.67(3.58) $\times10^{-3}$ vs. 6.67(2.64) $\times10^{-3}$; AGT-12: 8.64(5.56)$\times10^{-3}$ vs. 8.57(4.66)$\times10^{-3}$; Agt-16L1: 2.69(2.19)$\times10^{-3}$ vs. 2.52(2.26)$\times10^{-3}$] (Figure 1). Beclin-1 and Agt-5 high expressed in SSc with the positive of anti-SSA/Ro antibody. LC-3 was positively correlated with Age($r=0.662$) and ESR($r=0.355$) (all $P<0.05$).
Conclusion: Autophagy-related genes were increased in PBMC of SSc, and were correlated with Age, ESR and autoantibody, suggested that autophagy is a key feature in the pathogenesis of systemic sclerosis.

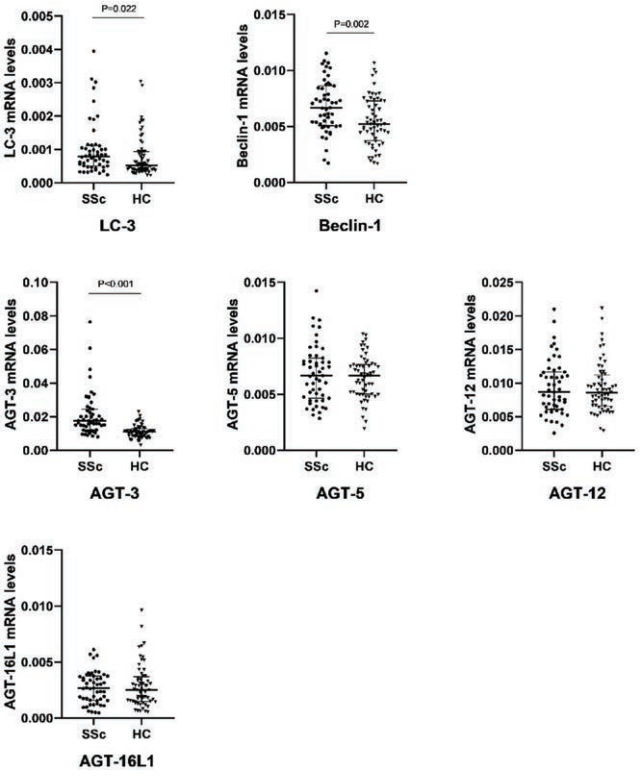

Figure 1. The relative expression of autophagy-related genes

POS0431

FIBROBLASTS ARE NOT JUST FIBROBLASTS - CLEAR DIFFERENCES IN ECM PRODUCTION BETWEEN DERMAL AND LUNG FIBROBLASTS IN RESPONSE TO GROWTH FACTORS

S. F. Madsen[1,2], A. S. Siebuhr[2], H. Jessen[3], J. M. B. Sand[3], M. Karsdal[4], A. C. Bay-Jensen[2]. [1]*University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark*; [2]*Nordic Bioscience, ImmunoScience, Biomarkers and Research, Herlev, Denmark*; [3]*Nordic Bioscience, Respiratory Research, Biomarkers and Research, Herlev, Denmark*; [4]*Nordic Bioscience, Biomarkers and Research, Herlev, Denmark*

Background: Many systemic sclerosis (SSc) patients develop lung fibrosis, which contribute significantly to increased mortality[1]. Activated and proliferating fibroblasts are responsible for the excessive extracellular matrix (ECM) formation and stiffening of the connective tissue leading to skin and lung fibrosis. There is currently no effective treatment for the fibrosis in SSc and there is therefore a medical need for further understanding the pathogenesis of fibrosis. Fibrosis is associated with different growth factors, including tumor growth factor beta 1 (TGF-β1) and platelet derived growth factor-ab (PDGF-ab)[2].

Objectives: We investigated how stimulation with TGF-β1 and PDGF-ab affected the migration capacity and the ECM production using translational biomarkers of type I, III and VI collagens in healthy human dermal and lung fibroblasts.

Methods: The fibroblasts were grown in DMEM media containing 0.4% fetal calf serum, ficoll (to produce a crowded environment) and ascorbic acid for up to 12 days. The cells were stimulated with TGF-β1 [0.04-1 nM] or PDGF-ab [3 nM] at treatment initiation and changed twice a week. Non-stimulated fibroblasts (w/o) were used as control. A wound was induced by scratching the cells at day 1 after treatment initiation and the migration was followed for 2 days. Type I, III and VI collagen formation (PRO-C1, PRO-C3 and PRO-C6, respectively) were evaluated by validated ELISAs (Nordic Bioscience) in supernatant from day 0, 4, 8 and 12. Statistical analysis included 2-way ANOVA and Dunnett's test.

Results: The PDGF-ab stimulated dermal fibroblasts migrated significantly more than the non-stimulated ($p<0.0001$) and TGF-β1 stimulated ($p<0.001$) dermal fibroblasts 48 hours after the scratch (migration app. 70%, 30% and 30% respectively). There was no difference between the migration of the non-stimulated, TGF-β1 and PDGF-ab stimulated lung fibroblasts after 48 hours, as all migrated to approximately 70%.

TGF-β1 stimulation led to a significant increase in type I collagen formation (PRO-C1) in both dermal and lung fibroblasts from day 4 and onwards compared to w/o ($p<0.0001$). TGF-β1 also lead to a significant increase in type III collagen formation (PRO-C3) from day 8 in lung fibroblasts compared to w/o ($p<0.0001$). PDGF-ab stimulation led to a significant increase in type III collagen formation in dermal fibroblasts from day 8 compared to w/o ($p<0.0001$). PDGF-ab stimulation led to a significant increase in type VI collagen formation (PRO-C6) in both dermal and lung fibroblasts from day 4 and onwards compared to w/o ($p<0.0001$).

Conclusion: PDGF-ab increased the migration activity of the dermal fibroblasts, where the lung fibroblasts had a general high migration activity. The dermal and lung fibroblasts showcase the same ECM production within both type I and type VI collagen formation. The two fibroblasts types did however react opposite each other regarding the type III collagen formation: the dermal fibroblasts responded to PDGF-ab stimulation, where the lung fibroblasts responded to the TGF-β1 stimulation. The clear differences in the ECM production between the dermal and lung fibroblasts can be important in the search for an effective treatment for fibrosis in SSc and related lung fibrosis.

POST-IMMUNIZATION WITH COLLAGEN V CONFERS A DISADVANTAGEOUS IMMUNE MATRICES MICROENVIRONMENT FOR EARLY LUNG FIBROSIS IN A SSc MOUSE MODEL

V. Elias[1], Z. Queiroz[1], S. Catanozi[2], A. Santos Filho[1], S. Fernezlian[3], A. P. Velosa[1], P. D. Sampaio-Barros[1], V. Capelozzi[3], W. Teodoro[1]. [1]*University of São Paulo, Division of Rheumatology, São Paulo, Brazil*; [2]*University of São Paulo, Division of Endocrinology, São Paulo, Brazil*; [3]*University of São Paulo, Department of Pathology, São Paulo, Brazil*

Background: The autoimmunity and inflammation phenomena observed in systemic sclerosis (SSc) lead to the dysregulation of type V collagen (Col V) and extracellular matrix (ECM) deposition of Col V, collagen I (Col I) and collagen III (Col III) fibers, characteristic of pulmonary fibroproliferative disease. T cells are the predominant inflammatory infiltrate in the lungs and are believed to produce cytokines that drive the synthesis of matrix proteins by fibroblasts, resulting in excessive fibrosis. Although most studies to date have focused on CD4+ T and CD20+ B immune cells in some SSc subsets, cytotoxic CD8+ T cells are also involved in the pathogenesis of SSc. We previously reported that reactivity to the ColV-self antigen predicts late SSc lung fibrosis in mice immunized with Col V after 120 days; however, the profile of underlying immune matrices in early SSc lung fibrosis remains unclear.

Objectives: To quantify T and B-cells and collagen fibers in the days following immunization with Col V in a mouse model mimicking human lung involvement in SSc.

Methods: Female C57BL/6 mice (n=18) were immunized subcutaneously with human Col V (150 µg) in complete Freund´s adjuvant, followed by two intramuscular boosters (IM-COLV). The control group (n=18) did not receive Col V. Three groups of animals (n=6 each) were euthanized on days 15, 30 and 45 after immunization. The lung sections were fixed in 10% buffered formalin, embedded in paraffin, and sectioned at 4 µm. Immunohistochemistry, immunofluorescence and histomorphometry were performed to phenotype and quantify CD4 and CD8 T-cells, CD20 B-cells, and Col I, III and V, respectively.

Results: We found that T-cells ($CD4^+$), cytotoxic T cells ($CD8^+$), and B-cells ($CD20^+$) were present in high densities in the lungs of IM-COLV mice, with variation in the absolute abundance of each of these immune cell lineages at 15, 30 and 45 days after immunization with Col V. In fact, a significantly higher density of $CD4^+$, $CD8^+$, and $CD20^+$ was detected early along the connective matrix of alveolar septa at 15 days after Col V immunization. In addition, higher density of Col I, III and V fibers were also observed early (Table 1). Although early SSc-lung fibrosis is generally considered to be linked to inflammatory cytokines, we also infer that cytotoxic T-cells may induce alveolar cells apoptosis by triggering kinases on macrophages and then accelerate fibrotic scar.

Conclusion: Our study quantitatively establishes that the densities of CD4+ CD8+ and CD20+, as well as Col I, Col III and Col V can be characterized as markers of early lung fibrosis in SSc. These findings suggest that cytotoxic T cells may induce apoptosis and secrete profibrotic cytokines to induce the deposition of collagen fibers in the lungs, inferring that early B cell depletion may improve early lung fibrosis in SSc.

POS0433

CAN INTERLEUKIN 33 (IL-33) BE CONSIDERED A VALUABLE BIOMARKER IN THE EARLY STAGES OF SYSTEMIC SCLEROSIS? ANALYSIS OF A MONOCENTRIC COHORT

C. Angelelli[1], K. Stefanantoni[1], M. Cadar[1], G. Pellegrino[1], F. Conti[1], V. Riccieri[1]. [1]*Sapienza University of Rome, Scienze cliniche internistiche, anestesiologiche e cardiovascolari, Roma, Italy*

Background: The ScS approach has changed considerably in recent years especially concerning the very early diagnosis of the disease (VEDOSS) at the time when the patient is still in an undifferentiated form (UCTD) at risk of developing SSc (1, 2). Of great value are different clinical, instrumental and laboratory findings, such as specific autoantibodies and Nailfold VideoCapillaroscopy (NVC), able to identify those cases progressing into overt SSc. IL-33 cytokine is known to exert pro-fibrotic effects through its membrane receptor ST2 on immune cells and myofibroblasts and recent studies suggest that it can be released following endothelial cell activation at the onset of SSc (3, 4).
Objectives: Our aim has been to evaluate IL-33 serum levels in a monocentric cohort of VEDOSS patients, looking for the possible association with clinical phenotype and disease progression, focusing on the microvascular capillaroscopic changes.
Methods: Fourty-seven VEDOSS patients underwent a complete clinical, instrumental and laboratory evaluation, including NVC and specific SSc autoantibodies. At baseline serum IL-33 levels were measured using an ELISA assay. In 32 of them we also had a second serum sample at a follow-up time of at least 24 months (range 24 to 96 months).
Results: During the follow-up time, 17 patients were subsequently reclassified as having ScS whereas 30 remained VEDOSS. The "progressor" subjects positively correlated with the presence of anti-Topoisomerase I antibodies (p>0,004). IL-33 concentrations had a median value of 427.2 pg/ml (IQR 967.9 pg/ml) at baseline and of 130.4 pg/ml (IQR 399 pg/ml) at the follow up, showing a statistically significant difference independently from the progression of the disease (p=0.03). Besides significantly higher levels were detected in those patients with more severe NVC changes, defined as "active" pattern (p<0.05). Among the 47 VEDOSS patients, 12 started some kind of vascular therapy. In these patients serum IL-33 concentrations significantly lowered during the follow-up respect to those without any treatment (p<0.03)
Conclusion: The analysis of our data confirms previous report (5) on higher IL-33 serum levels in the very early stages of UCTD patients at risk for SSc, regardless of their progression in established SSc, although related to more severe microvascular NVC involvement. The lowering of IL-33 serum levels that we detected in the follow up of our patients, may be linked to the well-known endothelial changes during the progression of the SSc and seems also to be partially affected by treatments. Investigation on a greater number of patients are needed to better understand our findings.

CLINICAL UTILITY OF SCREENING TOOLS IN REFERRAL OF PATIENTS WITH HAND ARTHRALGIA TO RHEUMATOLOGISTS

G. Figueroa-Parra[1], D. Vega-Morales[1], P. Herrera-Sandate[1], J. A. Esquivel Valerio[1], B. R. Vázquez Fuentes[1], M. A. Garza Elizondo[1], Y. G. Ordoñez Azuara[2], R. F. Gutierrez-Herrera[2], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology Service, Monterrey, Mexico;* [2]*Hospital Universitario Dr. José Eleuterio González, Family Medicine Department, Monterrey, Mexico*

Background: Clinically Suspect Arthralgia (CSA) was defined by European League Against Rheumatism to identify a combination of clinical features that best characterise patients with arthralgia who are at risk of progression to rheumatoid arthritis (RA) (1). A specificity >90% is obtained with the presence of ≥4 parameters. Another clinical feature useful to identify patients at risk is the squeeze test (ST). Recently, we have identified the necessary strength to screen the patient with arthralgia through ST, with a median squeeze force of 3 kg and 2.78 kg to evoke pain in the right and left hand of the RA patient, respectively (2). Primary care physicians (PCP), the first contact of patients at risk, could benefit from these screening tools, prompting early referral, diagnosis, and treatment of these individuals.
Objectives: To identify the clinical utility of CSA and ST in the referral of patients with hand arthralgia from PCP to rheumatologists.
Methods: We conducted a cohort study from October 2018 to December 2020 in 110 patients who attended a Family Medicine clinic at University Hospital "Dr. Jose Eleuterio Gonzalez" in Monterrey, Mexico. We recruited patients with hand arthralgia with no history of previous trauma or autoimmune rheumatic diseases. A questionnaire assessing CSA criteria was employed, and an ST maneuver was performed through an automated compressor with quantitative measures of applied force. Patients were grouped based on referral to Rheumatology consultation and variables categorized according to clinically relevant thresholds. Chi square test was performed in categorical variables, t-student test was performed in normal, continuous variables and Spearman's rho correlation was utilized between CSA number of criteria and quantitative ST force using SPSS v25.
Results: Out of 110 patients, 49 (44.5%) were referred to a rheumatologist. A non-significant association was found across assessed variables in referred and non-referred patients as seen in Table 1. Spearman's rho found a moderate correlation between the number of CSA criteria and quantitative force in right (r=-.445) and left (r=-.382) hand as seen in Figure 1. Evaluation of CSA cutoffs other than ≥4 did not yield a significant association in referral of patients to the rheumatologist (data not shown).
Conclusion: The clinical utility of CSA criteria and ST in referral of patients with hand arthralgia from PCP to rheumatologists is currently limited. More research is needed to elucidate the clinical utility of these screening tools.

Rheumatoid arthritis - prognosis, predictors and outcome

POS0435 CHARACTERISTICS AND 6-MONTH OUTCOMES AMONG REAL-WORLD PATIENTS WITH RHEUMATOID ARTHRITIS INITIATING UPADACITINIB: ANALYSIS FROM THE CORRONA REGISTRY

J. M. Kremer[1,2], N. Tundia[3], R. McLean[1], T. Blachley[1], A. Maniccia[3], D. A. Pappas[1,4]. [1]*Corrona, LLC, Waltham, United States of America*; [2]*Albany Medical College,The Center for Rheumatology,Albany, United States of America*; [3]*AbbVie Inc., North Chicago, United States of America*; [4]*Columbia University, New York, United States of America*

Background: Upadacitinib (UPA) has demonstrated efficacy in randomized controlled trials[1-3]; however, few data are available from patients with rheumatoid arthritis (RA) who have been treated with UPA in real-world clinical practice.
Objectives: Describe the characteristics and 6-month outcomes in patients with RA initiating UPA in a real-world setting.
Methods: We identified adults with RA enrolled in the Corrona RA Registry through October 31, 2020 who initiated UPA during or after August 2019 and had a follow-up visit 6 (±3) months after initiation of UPA. Descriptive statistics were used to summarize characteristics in all patients initiating UPA who had a 6-month follow-up visit. Outcomes (CDAI, modified HAQ-DI, pain, and fatigue) were described at the 6-month visit for all UPA initiators regardless of UPA use at 6 months and for the subset of patients who continued UPA through the 6-month visit. Patients who discontinued UPA before the 6-month visit were considered non-responders for dichotomous variables and were assigned the value at the time of discontinuation for continuous variables. Mean change from baseline in continuous variables was analyzed with one-sample *t* tests or one-sample Wilcoxon rank sum tests. Minimum clinically important difference (MCID) in HAQ-DI is defined as an improvement of 0.22 units or more. MCID in CDAI is an improvement of at least 2, 7, and 13 units for patients in low, moderate and severe disease at initiation, respectively. MCID for 100-point VAS is an improvement of ≥10 points. Percentages of patients achieving MCID thresholds were calculated.
Results: We identified 181 patients who initiated UPA and had a 6-month follow-up visit. Mean±SD age was 58.6±12.1 years, 81% were female. Patients had RA for a mean of 11.5±9.8 years. At UPA initiation, 45% of patients were on monotherapy. Prior use of one or more TNFi and JAKi was 79% and 52%, respectively. Seventy-two percent of patients (n=130) initiated UPA as the third or higher line of therapy. Mean CDAI was 18.7±11.6 and mean HAQ-DI was 1.1±0.8 at initiation. Based on CDAI (n=155), 29%, 52%, and 15% of patients had high, moderate, and low disease activity, respectively; 4.5% were in remission at initiation. At 6 months (n=158), 22%, 39%, and 28% had high, moderate, and low disease activity, respectively; 11% were in remission. Among 138 initiators with valid CDAI measures at initiation and 6 months, mean change in CDAI was –4.8±11.8, $P<0.01$. At 6 months, 46% (63/138) maintained and 39% (54/138) achieved improvement in any CDAI category. Improvements in other outcomes were significantly different from zero. Improvements >=MCID in CDAI, HAQ-DI, pain, and fatigue were achieved in 36–44% of UPA initiators. Improvements were similar, but larger in the subset of patients (n=122) who continued UPA through the 6-month visit (Table 1).
Conclusion: Among patients in the Corrona RA Registry, UPA is frequently started in those who failed multiple previous therapies. UPA initiators responded to therapy in the first 6 months with improvements in several disease activity measures including CDAI and HAQ-DI, as well as patient-reported pain and fatigue.

POS0436 PATIENT CHARACTERISTICS AND OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH UPADACITINIB: THE OM1 RA REGISTRY

M. Bergman[1], N. Tundia[2], A. Bryant[3], I. Topuria[3], T. Brecht[3], K. Dunlap[2], A. Gibofsky[4]. [1]*Drexel University College of Medicine, Philadelphia, United States of America*; [2]*AbbVie Inc, North Chicago, United States of America*; [3]*OM1, Boston, United States of America*; [4]*Weill Cornell Medicine, Hospital for Special Surgery, New York, United States of America*

Background: Upadacitinib (UPA) has demonstrated efficacy in the treatment of rheumatoid arthritis (RA) in randomized controlled trials,[1-6] but there are limited data available on its real-world use and effectiveness in patients with RA.
Objectives: To describe the characteristics and clinical outcomes at 3 months among real-world patients with RA initiating UPA.
Methods: The data source for this study was the OM1 RA Registry, a subset of the OM1 Real-World Data Cloud (OM1, Inc, Boston, MA, US), a large, linked clinical and administrative dataset derived from medical and pharmacy claims, electronic medical record data, and death data. This analysis includes data collected in patients who initiated UPA during or after August 2019. Patients had ≥1 prescription for UPA (index date was first UPA prescription), were ≥18 years of age at index date, had ≥6 months of available data in the OM1 RA Registry prior to index date (ie, baseline period), ≥1 baseline disease activity measure, and ≥1 follow-up disease activity measure (3 or 6 months post-index). Disease activity was based on RAPID3 or CDAI. Multivariate analyses were conducted using a mixed-effects linear model adjusting for age, sex, and baseline scores. Outcomes were also assessed by therapy status (monotherapy or combination therapy) and targeted immunomodulator (TIM) use (naïve vs experienced).
Results: Inclusion criteria were met by 1,102 patients, of whom 620 were on monotherapy and 482 were on combination therapy at index. Mean age was 57.7 years, 83% were female, 75% had prior treatment with a biologic, and 47% had prior treatment with a Janus kinase inhibitor. Of 651 patients with known disease activity category, 113 (17%) were in low disease activity (LDA)/remission. At baseline, overall mean±SD scores were 19.9±12.3 for CDAI, 4.5±2.4 for RAPID3, 5.7±2.8 for pain, 5.2±3.0 for fatigue, 3.1±2.7 for MDHAQ Physician Global Assessment (PGA), 5.2±2.8 for MDHAQ Patient Global Assessment (PtGA), and 3.1±2.3 for MDHAQ Functional Index. At 3 months post-UPA initiation, mean (95% CI) change in CDAI was –5.1 (–7.5

to –2.7) in the monotherapy group and –5.9 (–8.7 to –3.0) in the combination group. At 3 months, 29% (109/374) of patients were in LDA/remission and 32% (120/374) of patients showed improvement in disease activity. Of 94 patients with moderate disease at baseline, 34 (36%) were in LDA/remission at 3 months. Of 215 patients with high disease at baseline, 30 (14%) were in LDA/remission and 49 (23%) had moderate disease at 3 months. RAPID3 and other outcomes also improved at 3 months in the monotherapy and combination therapy groups (Figure 1). Improvements in disease activity were observed at 3 months and maintained at 6 months post-UPA initiation. Of 1,102 patients, 16% were TIM naïve and 84% TIM experienced. Both TIM-naïve and TIM-experienced patients achieved significant mean changes in CDAI (–5.7 [–10.8 to –0.6] and–5.0 [–7.0 to –3.0], respectively) and RAPID3 (–1.0 [–1.6 to –0.4] and –0.5 [–0.8 to –0.1]) at 3 months (Table 1). Improvements in clinical outcomes were maintained at 6 months in both TIM-naïve and TIM-experienced patients.

Conclusion: Significant improvements in disease activity were consistently observed at 3 months and maintained at 6 months post-UPA initiation regardless of monotherapy, combination therapy, or prior TIM use.

IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH GOLIMUMAB: SUB-ANALYSIS OF ASIAN PATIENTS ENROLLED IN PHASE-3 CLINICAL TRIALS

W. C. Tsai[1], R. Mu[2], C. H. Suh[3], D. Furtner[4], K. H. Lo[5], Y. Zhou[5], E. C. Hsia[6,7].
[1]Kaohsiung Medical University, Division of Allergy, Immunology, and Rheumatology, Kaohsiung, Taiwan, Republic of China; *[2]Peking University People's Hospital, Department of Rheumatology and Immunology, Beijing, China*; *[3]Ajou University School of Medicine, Department of Rheumatology, Suwon, Korea, Rep. of (South Korea)*; *[4]Janssen, a division of Jonson & Johnson Pte Ltd., Regional Medical Affairs, Singapore, Singapore*; *[5]Janssen Research & Development, LLC, Clinical Biostats, Spring House, Pennsylvania, United States of America*; *[6]Janssen Research & Development, LLC, Immunology, Spring House, Pennsylvania, United States of America*; *[7]University of Pennsylvania Medical Center, Perelman Center for Advanced Medicine, Pennsylvania, United States of America*

Background: Clinical efficacy and safety of Tumour Necrosis Factor-alpha inhibitor golimumab (GLM) for patients with rheumatoid arthritis (RA) and inadequate response to methotrexate (MTX) were studied in phase-3 clinical trials. A greater proportion of patients treated with GLM 50 mg every 4 weeks (q4w) achieved improvement in clinical signs and symptoms, measured by American College of Rheumatology 20% improvement (ACR20) response and patient-reported outcomes (PROs) when compared with placebo (PBO) at Weeks 14 and 24.

Objectives: To assess PROs in RA patients from Asia treated with GLM in phase-3 trials.

Methods: Post-hoc PRO (Health Assessment Questionnaire [HAQ], Short-Form 36 [SF-36] physical component score [PCS] and mental component score [MCS], pain, and work productivity) sub-analysis of RA patients from China (including Taiwan region) and South Korea with inadequate response to MTX randomized to subcutaneous GLM 50 mg + MTX or PBO + MTX from 2 clinical trials (GO-FORWARD, NCT01248780).

Clinically meaningful improvement was defined as improvement of ≥0.25 point in HAQ or ≥5 points in SF-36 PCS and MCS. Nominal p-values were used for descriptive and exploratory purposes.

Results: At Week 24, MTX-experienced patients from Asia treated with GLM + MTX demonstrated improvements versus PBO + MTX in all PROs analyzed. Pooled patients from Asia on GLM + MTX had greater improvements at Week 24 in all measures of PROs than patients with PBO + MTX, and the improvements are comparable to all other regions (Table 1). Greater proportions of RA patients from Asia in GLM group than PBO achieved clinically meaningful improvement in HAQ, SF-36 PCS, and SF-36 MCS (Figure 1).

Conclusion: MTX-experienced RA patients from Asia treated with GLM demonstrated improved PROs after 24 weeks. The pooled results were comparable with patients enrolled from all other regions and demonstrated clinical meaningful improvements in HAQ, SF-36 PCS, and SF-36 MCS.

POS0438 IS IMAGING DETECTED JOINT INFLAMMATION HELPFUL IN EXPLAINING FATIGUE IN RHEUMATOID ARTHRITIS AT DIAGNOSIS AND DURING THE DISEASE COURSE? – A LARGE MRI STUDY

X. Matthijssen[1], F. Wouters[1], N. Sidhu[1], A. van der Helm - van Mil[1,2]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*

Background: Fatigue in rheumatoid arthritis (RA) is hypothesized to be caused by inflammation. Still ~50% of fatigue in RA cannot be explained by the disease activity score (DAS), nor by generic or psychological factors.
Objectives: Since MRI can detect joint inflammation more sensitively than DAS, we hypothesized that residual inflammation detected by MRI could aid in explaining fatigue in RA at diagnosis and during follow-up.
Methods: 526 consecutive RA-patients were followed longitudinally. Fatigue was assessed yearly on a numerical rating scale. Hand and foot MRIs were performed at inclusion, after 12 and 24-months in 199 patients and were scored for inflammation (synovitis, tenosynovitis and osteitis combined). We studied whether RA-patients with more MRI-inflammation were more fatigued at diagnosis (linear regression), whether the 2-year course of MRI-inflammation associated with the course of fatigue (linear mixed models) and whether decrease in MRI-inflammation in year-1 associated with subsequent improvement in fatigue in year-2 (cross-lagged models). Similar analyses were done with DAS as inflammation measure.
Results: At diagnosis, higher DAS-scores were associated with more severe fatigue (p<0.001). However, patients with more MRI-inflammation were not more fatigued (p=0.94). During 2-year follow-up, DAS decrease associated with improvement in fatigue (p<0.001), but MRI-inflammation decrease did not (p=0.96). DAS decrease in year-1 associated with fatigue improvement in year-2 (p=0.012), as did MRI-inflammation decrease (p=0.039), with similar effect strength.
Conclusion: Sensitive measurements of joint inflammation did not aid in explaining fatigue in RA at diagnosis and follow-up. This supports the concept that fatigue in RA is partly uncoupled from inflammation.

POS0439 THE INFLUENCE OF ESCALATED PGA SCORE ON DISEASE ACTIVITY, DAILY ACTIVITY, AND QUALITY OF LIFE, AND SOLUTION FOR OPTIMAL PGA LEVEL THAT DESERVES CLINICAL REMISSION IN PATIENT WITH RHEUMATOID ARTHRITIS

I. Yoshii[1]. [1]*Yoshii Hospital, Rheumatology and Musculoskeletal Medicine, Shimanto City, Japan*

Background: Patient's global assessment (PGA) is one most difficult component as a part of disease activity index for treatment of rheumatoid arthritis (RA), that often causes an obstacle to attaining clinical remission. Moreover, PGA level affects activities in daily living.
Objectives: The influence of escalated PGA score on disease activity, daily activity, and quality of life for patient with RA was investigated., and the optimal PGA level for both disease activity and daily activities was investigated from real world data.
Methods: A total of 24,075 times of monitoring for RA was performed in the institute. Monitored items included TJC, SJC, PGA, EGA, CRP, and calculated values of DAS28, CDAI, SDAI, composite index of Boolean evaluation (Boolean), pain score with visual analog scale (PS-VAS), Health Assessment Questionnaire Disability Index (HAQ-DI), and quality of life score (QOLS) calculated from Euro-QOL questionnaire with 5th dimensions. Each measured item was calculated as mean value according to the PGA score, which was measured at the same time. The PGA score was classified by one increment from zero to ten. The mean values of DAS28, CDAI, SDAI, remission rate of these indices and Boolean remission rate, and mean values of PS-VAS, HAQ-DI, and QOLS were statistically evaluated.
HAQ-DI below 0.5 was determined as remission (HAQ remission). Sensitivity and specificity regarding attaining HAQ remission according to each level of PGA score were calculated, and cutoff index (COI) was determined with receiver operating characteristic (ROC) curve. For PS-VAS, sensitivity and specificity of Boolean remission regarding each level of PS-VAS after classification divided by one increment was calculated, and comparable level (PS-VAS remission) was determined with reference of the curve. ROC was performed according to PGA level, and COI was determined with a same manner.
Results: Number of measures counted 10428, 3099, 3110, 2346, 998, 1773, 751, 703, 655, 139, and 73 for each PGA level. PGA level from 3 to 5, and 5 to 10 were put together for number adjusting.
Mean DAS28, CDAI, and SDAI demonstrated significant increase as PGA level increased, and remission rate of the all indices including Boolean demonstrated significant decrease as PGA level increases (p<0.01%). Boolean remission rate demonstrated zero percent from two, and CDAI and SDAI remission rate demonstrated zero from five, whereas DAS remission rate showed gradual decrease then zero percent was not shown in any level. Mean value of PS-VAS and HAQ-DI score demonstrated also significant decrease as PGA level increases, and QOLS demonstrated significant decrease as PGA level increases (p<0.01%). Increase of HAQ-DI score and decline of QOLS demonstrated more steep from PGA level 3, whereas no significant difference demonstrated from zero to one.
HAQ remission counted 15,703, whereas no HAQ remission counted 8,335. Using ROC, COI of the PGA level was 2.0, whereas sensitivity and specificity were 63.4% and 66.3%, respectively. The estimated PS-VAS remission level was 10mm. Optimal PGA level for PS-VAS remission was set as 1.0, and sensitivity and specificity regarding PS-VAS remission were 87.1% and 71.3%, respectively.
Conclusion: Increase of PGA affects daily activities and quality of life. The evident level that increases deterioration risk significantly was supposed to be from 3. Optimal level of PGA score for attaining the PS-VAS remission was 1.0, whereas the optimal PGA level for HAQ-DI remission is 1.0, despite sensitivity and specificity for the HAQ remission were lower than these for the PS-VAS remission.

POS0440 REDUCTION IN MONOCYTE COUNT PREDICTS SUSTAINED REMISSION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ANTI-TNF THERAPY

R. Amarnani[1], M. Mainuddin[2], M. Shipa[3], S. A. Yeoh[3], M. Ehrenstein[1,3]. [1]*University College Hospital, Rheumatology, London, United Kingdom*; [2]*North Middlesex University Hospital, Rheumatology, London, United Kingdom*; [3]*University College London, Centre for Rheumatology, Division of Medicine, London, United Kingdom*

Background: Sustained remission is the ultimate goal in the management of rheumatoid arthritis (RA) but is infrequently achieved. After conventional therapy, TNFi (tumour necrosis factor inhibitor) has a strong track record for achieving remission. Existing studies suggest variable effect of RA and TNFi on various cellular components of the full blood count (FBC), but their relationship with loss of remission (LOR) is unclear.
Objectives: To investigate whether cellular changes in the FBC can predict LOR (remission defined as DAS28-ESR≤2.6) in patients with RA receiving TNFi, adjusted using key clinical factors.
Methods: Real-world clinical and routine laboratory data were analysed from two independent cohorts of adult RA patients, who were started on their first TNFi (from 2009 to December 2019), and went into remission. Data was extracted in October 2020. A linear mixed model was used to investigate longitudinal changes of different components of FBC and CRP, stratified by LOR, and grouped by

years of follow-up. Pairwise post-hoc comparisons were performed by Bonferroni correction. Area Under the Receiver Operating Characteristics (AUROC) of cellular changes in FBC components to predict LOR at different time points were calculated. Latent class mixed models were used to investigate trajectories of change in cellular components of the FBC from baseline to one year. Further survival analysis to predict LOR of TNFi was done by using the latent class model and adjusted by clinical parameters, demographics and concomitant treatment.

Results: 92 and 43 biologic-naïve RA patients who attained remission were included from cohorts 1 and 2 respectively. 73 (54%) were treated with adalimumab and 62 (46%) with etanercept. 87 (64%) of patients lost remission over a 10-year period with median time to LOR of 3.3 years (95% CI 2.6-3.7).

Among the cellular components of FBC, monocyte count changes in the first year after initiation of TNFi fell significantly in those who maintained remission over the five years of follow-up, compared to those who lost remission [p<0.001 for all years evaluated] (Figure 1). AUROC of monocyte count change at 6 months and 12 months, to predict LOR from year 1 to year 5 (after TNFi initiation) and after 5 years, ranged between 0.70-0.90. Three latent classes were identified based on monocyte count changes over time: 1-decrease (N=41), 2-increase (N=7) and 3- no change (N=87). Among these latent classes, patients in class 1, sustained remission for longer (unadjusted log-rank *p*=0.001) compared to the other 2 classes. Monocyte latent classes as a predictor of LOR was further tested by cox-regression, where variables (anti-citrullinated protein antibody/ACPA, concomitant methotrexate, baseline DAS28-ESR) were selected by elastic net regularisation and further adjusted by use of steroid, age and gender. Class 2 and Class 3 monocyte latent classes showed a hazard ratio (HR) of 3.15 (95% CI 1.02-9.74, *p* = 0.046, n. of event = 6/7) and 5.48 (95% CI 2.6-11.57, *p* <0.001, n. of event = 73/87) respectively compared to Class 1. ACPA positivity also increased the risk of LOR with HR of 2.13 and 95% CI 1.04-4.37, *p* = 0.04 (n. of event = 78/117) compared to seronegative patients (n. of event = 9/18).

Conclusion: In seropositive RA patients treated with TNFi, a reduction of total monocyte count in the first year was associated with maintenance of remission in subsequent years. Further studies are required to determine whether these effects are specific to TNFi or reflect sustained remission in RA irrespective of therapy.

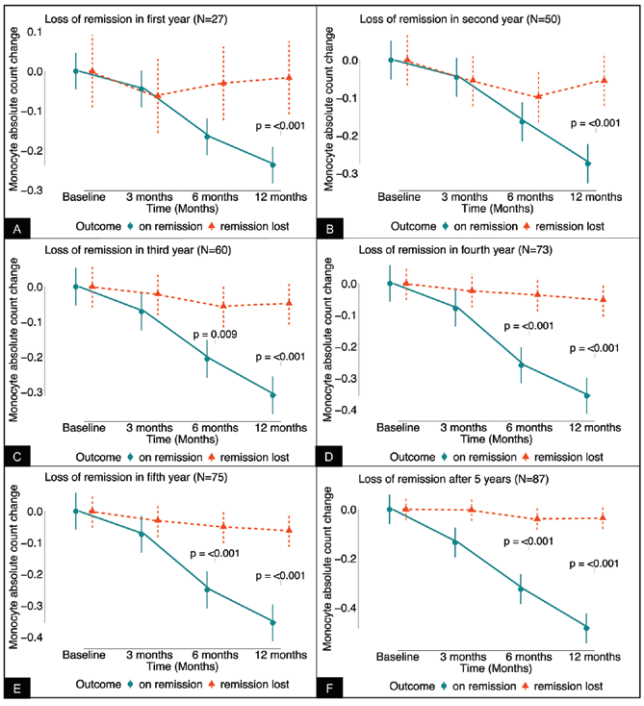

Figure 1 (A-F). Mean change (with 95% confidence interval) in absolute count of monocyte after initiation of tumour necrosis factor inhibitor grouped by years of follow-up and stratified by loss of remission. N = number indicate cumulative number of patients who lost remission by the end of each year.

POS0441 DEVELOPMENT OF RHEUMATOID ARTHRITIS AMONG ANTI-CITRULLINATED PROTEIN ANTIBODIES POSITIVE ASYMPTOMATIC INDIVIDUALS: A PROSPECTIVE OBSERVATIONAL STUDY

S. Mizuki[1], K. Horie[1], K. Imabayashi[1], K. Mishima[2], K. Oryoji[1]. [1]*Matsuyama Red Cross Hospital,The Center for Rheumatic Diseases, Matsuyama, Japan*; [1]*Matsuyama Red Cross Hospital,The Center for Rheumatic Diseases, Matsuyama, Japan*

Background: In the idividuals with genetic and enviromental risk factors, immune events at mucosal surfaces occur and may precede systemic autoimmunity. Anti-citrullinated protein antibodies (ACPA) are present in the serum for an average of 3-5 years prior to the onset of rheumatoid arthritis (RA) during an asymptomatic period. In ACPA-positivite individuals, the additional presence of RA-related risk factors appears to add significant power for the development of RA. To date, there have been few reports in which clinical courses of ACPA-positive asymptomatic individuals were investigated prospectively.

Objectives: To observe the clinical time course of ACPA-positive healthy population for the development of RA.

Methods: Healthy volunteers without joint pain or stiffness, who attended the comprehensive health screening of our hospital, were enrolled in this prospective observational study. The serum ACPA levels were quantified by Ig-G anti-cyclic citrullinated peptide enzyme-linked immunosorbent assay with levels > 4.4 U/mL considered positive. ACPA-positive subjects were followed by rheumatologists of our department clinically or a questionnaire sent by mail for screening to detect arthritis.

Results: 5,971 healthy individuals without joint symptons were included. Ninty-two (1.5%) were positive for ACPA. Of these, 19 (20.7%) developed RA and two were suspected as RA by mail questionnaire. Their average age were 58-years, and women were 68%. The average duration between the date of serum sampling and diagnosis was 10.7 months. ACPA-positive individuals who developed to RA had higher serum ACPA and Ig-M rheumatoid factor levels than ACPA-positive individuals who did not (P value by Mann-Whitney U test: 0.002, 0.005, respectively).

Conclusion: Among ACPA-positive asymptomatic individuals, 20% developed RA. The higher titer of ACPA and Ig-M rheumatoid factor levels are risk factors for devoloping RA.

POS0442 RELATIONSHIP BETWEEN PARAOXONASE-1 GENOTYPE, ACTIVITY AND MAJOR ADVERSE CARDIOVASCULAR EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TOFACITINIB

C. Charles-Schoeman[1], C. Hyde[2], S. Guan[3], N. Parikh[1], J. Wang[1], A. Shahbazian[1], L. Stockert[4], J. Andrews[4]. [1]*University of California, Department of Medicine, Los Angeles, CA, United States of America*; [2]*Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America*; [3]*Pfizer Inc, Inflammation and Immunology, Cambridge, MA, United States of America*; [4]*Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America*

Background: Paraoxonase-1 (PON1) is a high-density lipoprotein (HDL)-associated enzyme with paraoxonase, lactonase and arylesterase activities.[1] PON1 contributes to the antioxidant properties of HDL, and is being investigated for its atheroprotective properties.[1] Patients (pts) with rheumatoid arthritis (RA) who are homozygous for the RR genotype of the Q192R gene polymorphism on PON1 (rs662) have increased paraoxonase activity, and lower risk of carotid plaques, vs those with QQ or QR genotypes.[2] Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA.

Objectives: To investigate the relationship between PON1 genotype/activity and risk of major adverse cardiovascular events (MACE) in the tofacitinib RA clinical programme.

Methods: In this post hoc analysis, data were pooled from pts enrolled in nine Phase 2/3 studies of tofacitinib in RA. Enzyme activities in pt plasma samples were measured at individual study baseline (BL) and at follow-up visits using three substrates: paraoxon (paraoxonase activity), dihydrocoumarin (lactonase activity) and phenylacetate (arylesterase activity). The effect of the PON1 Q192R genotype (QQ, QR or RR) on BL paraoxonase/lactonase/arylesterase activity was assessed using linear regression for each study, with age and sex as covariates, and then fixed-effect meta-analysis assessed effects across studies. The risk of MACE by enzyme activity was determined using Cox proportional hazards regression stratified by clinical studies. Univariate regression against BL enzyme activity and other risk factors, as well as both minimally and fully adjusted multivariable regressions against time-varying enzyme activity, are presented.

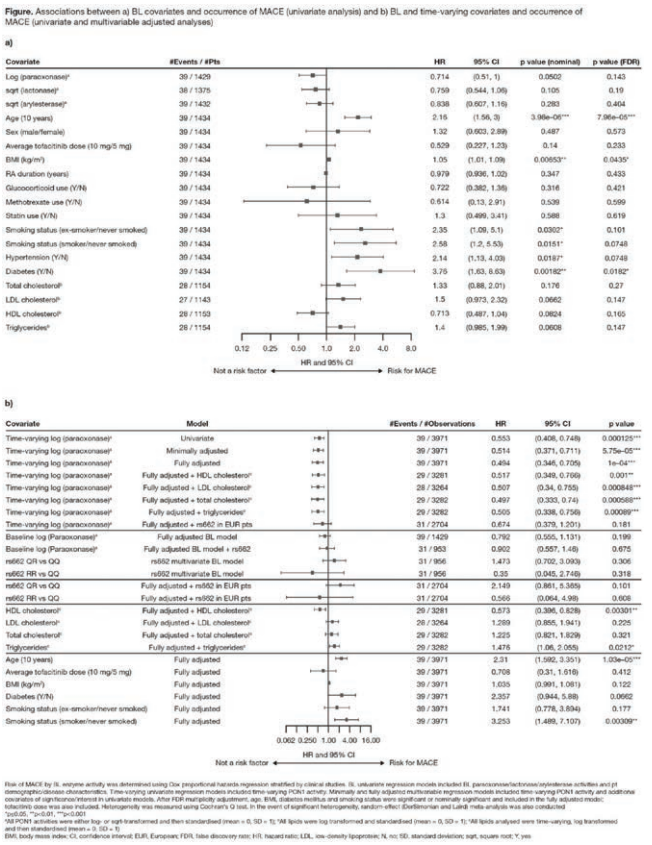
Results: The analysis included 1969 pts with RA who received ≥1 dose of tofacitinib and had PON1 activity measures available at BL; 39 pts had ≥1

MACE event. Compared with the QQ genotype, the RR genotype had a highly significant positive association with BL paraoxonase activity, and a highly significant negative association with BL lactonase and arylesterase activity (Table 1). A univariate analysis identified several BL covariates significantly associated with risk of MACE (Figure 1a). Time-varying models found a highly significant association of increased paraoxonase activity over time with lower risk of future MACE, even after controlling for low-density lipoprotein or HDL cholesterol levels, and other traditional cardiovascular (CV) risk factors identified in univariate analysis (Figure 1b), with similar findings for lactonase and arylesterase (data not shown).

Table 1. Effect of PON1 genotype (RR vs QQ) on BL enzyme activity

	n	Estimate	95% CI	p value	Cochran's Q test
Paraoxonase	1229	1.035	0.93, 1.141	<0.0001	0.209
Lactonase	1188	-0.375	-0.505, -0.246	<0.0001	0.025
Arylesterase	1231	-1.016	-1.382, -0.649	<0.0001	0.251

Fixed-effects model; estimate >0 favours RR genotype and <0 favours QQ genotypeBL, baseline; CI, confidence interval



Conclusion: Higher activity of the HDL-associated protein PON1 over time was associated with a significantly reduced risk of future MACE in pts with RA receiving tofacitinib, after controlling for traditional CV risk factors and cholesterol levels. Further investigation of PON1 as a novel functional lipid biomarker to assess CV risk in pts with RA is warranted.

POS0443 EXPLORING NOVEL TENOSYNOVITIS AND COMBINED INFLAMMATION IMAGING OUTCOMES: RESULTS FROM A RANDOMISED CONTROLLED TRIAL IN EARLY RHEUMATOID ARTHRITIS

P. G. Conaghan[1,2], M. Østergaard[3,4], O. Troum[5], Z. Xie[6], A. Brett[7], M. Snyder[8], A. Ebrahim[8], D. Chapman[9], G. Sawyerr[9], J. Andrews[8]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[2]National Institute for Health Research Leeds Biomedical Research Centre, Leeds, United Kingdom*; *[3]Rigshospitalet, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark*; *[4]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*; *[5]University of Southern California Keck School of Medicine, Division of Rheumatology, Santa Monica, CA, United States of America*; *[6]Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America*; *[7]Imorphics Ltd, Clinical Trials Group, Manchester, United Kingdom*; *[8]Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America*; *[9]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*

Background: Magnetic resonance imaging (MRI) trial outcomes have largely focused on synovitis, bone marrow oedema (BME) and erosions. Tenosynovitis is a common manifestation of rheumatoid arthritis (RA), but is relatively understudied; a combined inflammation score (CIS) summing synovitis, BME and tenosynovitis may be a highly responsive measure. We previously showed the responsiveness of the Outcome Measures in Rheumatology (OMERACT) RA MRI scoring system (RAMRIS) and a machine-learning derived automated tool (RAMRIQ) in a randomised controlled trial (RCT) of tofacitinib and methotrexate (MTX) in MTX-naïve patients (pts) with early RA.[1]

Objectives: This post hoc analysis assessed the impact of tofacitinib ± MTX on MRI tenosynovitis and CIS in pts with early RA using semiquantitative and quantitative MRI outcomes.

Methods: Study A3921068 (NCT01164579), a 1-year, exploratory, Phase 2, RCT, compared tofacitinib 10 mg twice daily (BID) ± MTX, and MTX monotherapy, in MTX-naïve pts with early RA.[1] MRI of unilateral wrist and metacarpophalangeal joints was performed at screening/baseline (BL) and Months (M)1/3/6/12. MRI tenosynovitis and CIS were assessed using RAMRIS and RAMRIQ. Changes from BL (Δ) in RAMRIS and RAMRIQ tenosynovitis and CIS were evaluated at M1/3/6/12. Data were assessed using a mixed-effect model for repeated measures, with treatment arms as factors and BL values as covariates. Using data pooled across treatment arms, Spearman's rank correlation coefficients were calculated for associations between BL RAMRIS and BL RAMRIQ tenosynovitis and CIS vs BL Disease Activity Score in 28 joints, C-reactive protein (DAS28-4[CRP]), and ΔRAMRIS and ΔRAMRIQ tenosynovitis and CIS at M12 vs ΔDAS28-4(CRP) at M12.

Results: In total, 109 pts were randomised and treated. ΔRAMRIS and ΔRAMRIQ tenosynovitis and CIS were generally significantly greater at M3/6/12 in pts receiving tofacitinib ± MTX vs MTX, while ΔRAMRIQ CIS was also significantly greater at M1 (Figure 1). Compared with RAMRIS, RAMRIQ outcomes were generally more responsive to treatment with tofacitinib ± MTX. Significant correlations were seen between BL RAMRIS and BL RAMRIQ tenosynovitis and BL RAMRIS CIS vs BL DAS28-4(CRP), and between ΔRAMRIS and ΔRAMRIQ tenosynovitis and CIS at M12 vs ΔDAS28-4(CRP) at M12 (Table 1). In general, stronger correlations were seen between BL DAS28-4(CRP) and BL RAMRIS vs BL RAMRIQ parameters, while correlations were similar between ΔDAS28-4(CRP) at M12 and ΔRAMRIS and ΔRAMRIQ parameters at M12.

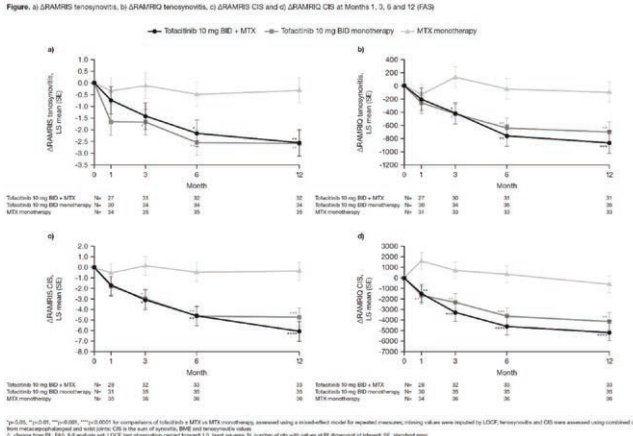

Table 1. Correlations between a) BL RAMRIS and BL RAMRIQ tenosynovitis and CIS vs BL DAS28-4(CRP) (N=109) and b) ΔRAMRIS and ΔRAMRIQ tenosynovitis and CIS at M12 vs ΔDAS28-4(CRP) at M12 (N=73) across treatment arms[a]

a)	BL DAS28-4(CRP)		b)	ΔDAS28-4(CRP)	
BL imaging feature	Correlation	p value	ΔImaging feature	Correlation	p value
RAMRIS tenosynovitis	0.366	0.0001	RAMRIS tenosynovitis	0.531	<0.0001
RAMRIS CIS	0.399	<0.0001	RAMRIS CIS	0.554	<0.0001
RAMRIQ tenosynovitis	0.205	0.037	RAMRIQ tenosynovitis	0.543	<0.0001
RAMRIQ CIS	0.180	0.062	RAMRIQ CIS	0.564	<0.0001

[a]Data were pooled across the tofacitinib 10 mg BID ± MTX and MTX monotherapy armsSpearman's rank correlation coefficients and p values were calculated for associations between RAMRIS and RAMRIQ parameters and DAS28-4(CRP); tenosynovitis and CIS were assessed using combined data from metacarpophalangeal and wrist joints; CIS is the sum of synovitis, BME and tenosynovitis valuesΔ, change from BL; N, number of pts with values at BL/timepoint of interest

Conclusion: Responsiveness of RAMRIS and RAMRIQ tenosynovitis and CIS was demonstrated with significant improvements through M12 in pts receiving tofacitinib 10 mg BID ± MTX vs MTX. Construct validity for RAMRIS and RAMRIQ tenosynovitis and CIS was evident from correlations with DAS28-4(CRP). Further work is needed to validate these novel imaging biomarkers in terms of relative responsiveness and prediction of later structural progression.

DIAGNOSTIC VALUE OF HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY COMPARED TO CONVENTIONAL RADIOGRAPHY FOR DETECTING EROSIVE DISEASE IN RHEUMATOID ARTHRITIS

R. Klose-Jensen[1,2], J. Therkildsen[1,2], A. B. Blavnsfeldt[1], B. Langdahl[3], K. K. Keller[2], E. M. Hauge[1,2]. [1]*Aarhus University Hospital, Department of Rheumatology, Aarhus N, Denmark*; [2]*Aarhus University, Department of Clinical Medicine, Aarhus N, Denmark*; [3]*Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus N, Denmark*

Background: Conventional radiography (CR) of the hands, wrists and feet is currently the gold standard for assessing erosive damage in patients with rheumatoid arthritis (RA). However, CR is prone to relatively low resolution and projection superimposition due to 2-dimensional imaging. Therefore, CR might not detect erosive disease in RA patients. High-resolution peripheral quantitative computed tomography (HR-pQCT) is an imaging modality with superior resolution (82µm^3) to all other imaging modalities in vivo. However, HR-pQCT imaging is limited by a smaller field of view. Therefore, it needs to be illuminated, whether the higher resolution of HR-pQCT imaging is sufficient for diagnosing erosive disease in patients with RA despite the limited field of view.

Objectives: The objective was to investigate whether High-Resolution peripheral Quantitative Computed Tomography (HR-pQCT) of just two metacarpophalangeal (MCP) joints can diagnose more patients having erosive RA than conventional radiography (CR) of 44 joints in the hands, wrist and feet.

Methods: In this single-centre cross-sectional study. Patients with established RA (disease duration ≥ 5 years) were investigated by HR-pQCT and CR. The second and third MCP joints of the dominant hand were assessed for erosions by HR-pQCT. CR in the hands, wrist and feet were scored according to the Sharp/van der Heijde (SHS) method.

Results: Three hundred fifty-four patients were included. By CR, 67 (18.9%) patients were classified with non-erosive RA, and 287 (81.1%) with erosive RA. In the 67 patients with non-erosive RA, 47 patients (70.1%) had erosions in the second and third MCP joints by HR-pQCT (Figure 1). We found an agreement between CR and HR-pQCT for 274 (77.4%) of the patients. The sensitivity and specificity (95%CI) of HR-pQCT for diagnosing erosive RA when CR of hands, wrist and feet were used as the reference was 89% (84 – 92) % and 30% (19 – 42) %, respectively. Using HR-pQCT for two MCP joints as the reference, the sensitivity and specificity of CR of hands, wrist and feet for diagnosing erosive RA were 84% (80 – 88) % and 38% (25 – 52) %, respectively. The McNemar's χ^2 test for diagnosing patients having erosive RA between the two modalities was 2.45, p = 0.146.

Conclusion: HR-pQCT imaging identifies erosions which are not seen by CR. Using HR-pQCT at of the second and third MCP joint reclassified a substantial number of patients as having erosive RA compared to their non-erosive state determined by CR. The sensitivity and specificity of diagnosing patients having erosive RA using HR-pQCT from only two fingers were not statistically different from CR of 44 joints, in the hands, wrist and feet.

POS0445 PHYSICIAN AND PATIENT REPORTED EFFECTIVENESS OUTCOMES ARE SIMILAR IN TOFACITINIB AND TNF INHIBITORS IN RHEUMATOID ARTHRITIS PATIENTS: DATA FROM A RHEUMATOID ARTHRITIS REGISTRY IN CANADA

M. Movahedi[1], A. Cesta[1], X. Li[1], E. Keystone[2], C. Bombardier[1]on behalf of OBRI investigators. *[1] UHN, Toronto General Hospital Research Institute, Toronto, Canada*; *[2]University of Toronto, Medicine, Toronto, Canada*

Background: Tofacitinib (TOFA) is an oral, small molecule drug used for rheumatoid arthritis (RA) treatment as an alternative option to biologic disease modifying antirheumatic drugs (bDMARDs) including tumor necrosis factor inhibitors (TNFi).

Objectives: We aimed to evaluate physician and patient reported effectivness outcomes in TNFi compared to TOFA, using real-world data from the Ontario Best Practices Research Initiative (OBRI).

Methods: RA patients enrolled in the OBRI initiating their TOFA or TNFi (Adalimumab, Certolizumab, Etanercept, Golimumab, Infliximab, and Biosimilars) between 1st June 2014 (TOFA approval date in Canada) and 31st Dec 2019 were included. Patients were required to have physician and patient reported effectivness outcomes data available at treatment initiation and 6-month (± 2 months) follow-up. These included clinical disease activity index (CDAI), rheumatoid arthritis disease activity index (RADAI), HAQ-DI, sleep problem, and anxiety/depression scores. Multiple imputation (Imputation Chained Equation, N=20) was used to deal with missing data for covaraites at treatment initiation. To deal with confounding by indication, we estimated propensity scores for covariates with an absolute standard difference greater than 0.1 between the two treatment groups.

Results: A total of 419 patients were included. Of those, 226 were initiating a TNFi and 193 TOFA, and had a mean (SD) disease duration of 8.0 (8.7) and 12.6 (9.6) years, respectively. In the TNFi group, 81.9% were female and mean age (SD) at treatment initiation was 56.6 (13.4) years. In the TOFA group, 85% were female and mean (SD) age at treatment initiation was 60.3 (11.2) years. The TNFi group was less likely to have prior biologic use (21.7%) compared to the TOFA group (67.9%). At treatment initiation, physical function measured by HAQ-DI was significantly lower in TNFi compared to the TOFA group (1.2 vs.1.4).

The rate of CDAI LDA/remission at 6 months was 36.7% and 33.2% in TNFi and TOFA group, respectively. The generalized linear mixed models (GLMM) adjusting for propensity score quantile, showed that there was no significant difference in CDAI LDA/remission (ORs: 0.85, 95% CI: 0.51, 1.43), RADAI (coefficient: 0.48, 95% CI: -0.18, 1.14), HAQ-DI (coefficient: -0.01, 95% CI: -0.18, 0.16), sleep problems (coefficient: -0.25, 95% CI: -0.95, 0.45), and anxiety/depression scores (coefficient: 0.12, 95% CI: -0.35, 0.58) between the two treatment groups (TOFA used as reference).

Conclusion: In this real-world data study, we found that, physician and patient reported effectivness outcomes are similar in the TNFi and TOFA groups 6 months after treatment initiation in patients with RA.

POS0446 FILGOTINIB-TREATED RHEUMATOID ARTHRITIS PATIENTS WITH HIGH BASELINE NEUTROPHIL-TO-LYMPHOCYTE RATIO SHOW BETTER CLINICAL RESPONSE RATES AND PATIENT-REPORTED OUTCOMES

P. C. Taylor[1], B. Downie[2], S. Kim[2], R. Hawtin[2], R. Moots[3], T. Takeuchi[4]. *[1]University of Oxford, Botnar Research Centre, Nuffield Dept Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; *[2]Gilead Sciences, Inc., Foster City, United States of America*; *[3]Edge Hill University, Faculty of Health, Social Care and Medicine, Ormskirk, United Kingdom*; *[4]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Rheumatoid arthritis (RA) is a systemic inflammatory disease which includes increased innate and myeloid immune cell activation. Filgotinib (FIL), an oral JAK1 inhibitor, has shown safety and efficacy in three phase 3 studies (FINCH1-3) in adults with moderately-to-severely active RA. The baseline (BL) neutrophil-to-lymphocyte ratio (NLR) in RA has been associated with a positive response to anti-tumor necrosis factor (TNF) therapy[1] and a negative response to DMARD triple therapy[2]. We previously reported a BL signature of clinical response in the FINCH2 (bDMARD-IR) population which included a neutrophil component[3].

Objectives: We conducted a post-hoc analysis to explore whether the BL NLR was associated with response to treatment in the FINCH studies.

Methods: Clinical data of 3273 RA patients (pts) enrolled in the FINCH clinical trials (FINCH3, methotrexate (MTX)-naïve: NCT02886728; FINCH1, MTX-Inadequate Responder (IR): NCT02889796; FINCH2, bDMARD-IR: NCT02873936) were retrospectively analyzed for a relationship between the BL NLR and composite clinical endpoints (ACR-N, DAS28CRP, or CDAI) or PROs (Pain VAS, FACIT Fatigue, HAQ-DI) through week 24. Pts were classified as High or Low BL NLR using a cutpoint (2.7) identified as an independent predictor of treatment failure in a published RA study[2]. Adjusted clinical outcomes were estimated based on mixed effects linear regression models including geographic region and demographics covariates.

Results: 57% of pts enrolled in the FINCH trials were classified as BL NLR-High (Table 1) and FINCH3 NLR-High pts showed higher BL DAS28(CRP). FINCH1 and FINCH3 FIL+MTX-arm NLR-High pts demonstrated significantly better DAS28(CRP) response compared to NLR-Low pts (Figure 1). DAS28(CRP) differences between NLR-High and NLR-Low were detectable as early as Week 2 for FIL200mg + MTX and were sustained through Week 24. FINCH1 and FINCH3 FIL200mg + MTX NLR-High pts also demonstrated sustained clinical and PRO improvements over NLR-Low, including CDAI, ACR-N, Pain VAS, FACIT Fatigue, and HAQ-DI. The strength of these associations was dose-dependent; pts that received FIL100mg + MTX demonstrated weaker but directionally consistent trends in both populations. No significant association between NLR subgroup and clinical efficacy was observed in FINCH2 FIL+MTX-arm pts, FIL-monotherapy (FINCH3) pts, or adalimumab+MTX (FINCH1) pts.

Conclusion: In FINCH1 (MTX-IR) and FINCH3 (MTX-naïve), FIL200mg + MTX -arm NLR-High pts demonstrate better sustained clinical response and PRO scores compared to NLR-Low pts. These data are the first to report an association between the BL NLR and therapeutic response in large randomized RA clinical trials. Future studies on pathobiologies reflected by the NLR biomarker may clarify its potential to guide RA disease management.

Background: RA is characterised by the production of autoantibodies, including RF and anti-citrullinated protein antibodies (ACPAs).[1] Seropositive disease is associated with poorer prognosis in patients with RA,[2] and response to different treatments has been shown to vary based on ACPA status.[3] ASCORE (Abatacept SubCutaneOus in Routine Clinical PracticE; NCT02090556) was a 2-year, observational, prospective, multicentre study of SC abatacept for the treatment of RA.[4]
Objectives: This *post hoc* analysis of the ASCORE study evaluated patient-reported outcomes, assessed using HAQ-DI, by RF/ACPA serostatus and treatment line over 24 months of treatment with abatacept.
Methods: Eligible patients, aged ≥18 years, with active moderate-to-severe RA (ACR/EULAR 2010 criteria) who were IV abatacept-naive and initiated SC abatacept 125 mg once weekly, were enrolled into two cohorts: biologic (b)DMARD-naive patients and those with ≥1 prior bDMARD treatment failure. This *post hoc* analysis assessed mean change from baseline in HAQ-DI score at 6, 12, 18 and 24 months in response to treatment with abatacept stratified by baseline serostatus (RF/ACPA double positive [+/+]; RF/ACPA single positive [+/–; RF+/ACPA– or RF–/ACPA+] or RF/ACPA double negative [–/–]) and by line of therapy (all patients, patients receiving abatacept as a first-line bDMARD or as a ≥ second-line bDMARD [data not shown], and those receiving abatacept following 1 [data not shown] or ≥2 prior bDMARDs). Estimates of mean difference with 95% CIs between patients with different serostatus were calculated using a *t*-test for all patients and within different lines of therapy.
Results: Among 2892 eligible patients in ASCORE, 1748 patients with RF/ACPA status available at baseline were included in this analysis (1079 +/+, 326 +/– and 343 –/–). Of these, 791 patients received abatacept as a first-line bDMARD therapy and 957 as a ≥ second-line bDMARD therapy (505 patients had received ≥2 prior bDMARDs). Among all patients, mean change from baseline in HAQ-DI score at 6 months was greater for patients with +/+ RA (mean difference [95% CI]: –0.2 [–0.3, –0.0]; p=0.0068) or +/– RA (mean difference [95% CI]: –0.2 [–0.3, –0.0]; p=0.0315) versus those with –/– RA at baseline (Figure 1). Similarly, mean change (95% CI) in HAQ-DI score at 6 months was greater for patients with +/+ RA versus –/– RA among those receiving abatacept as first-line therapy (–0.2 [–0.4, –0.0]; p=0.0407) or following treatment with ≥2 bDMARDs (–0.3 [–0.5, –0.0]; p=0.0265) (Figure 1). Among patients treated with abatacept following ≥2 prior bDMARDs, mean change in HAQ-DI score was higher among patients with +/– RA versus –/– RA at 18 months (data not shown) and 24 months (Figure 1). No other significant differences were observed by serostatus or line of therapy at any other time points.
Conclusion: Patients with RA who were RF+/ACPA+ at baseline showed an enhanced initial response to abatacept compared with those who were RF–/ACPA–. Over 24 months of treatment in this real-world setting, abatacept was equally effective as a first- or ≥ second-line therapy.

POS0448 DISCONTINUATION RATE OF TOFACITINIB AS MONOTHERAPY IS SIMILAR COMPARED TO COMBINATION THERAPY WITH METHOTREXATE IN RHEUMATOID ARTHRITIS PATIENTS: POOLED DATA FROM TWO RHEUMATOID ARTHRITIS REGISTRIES IN CANADA

M. Movahedi[1], D. Choquette[2], L. Coupal[2], A. Cesta[1], X. Li[1], E. Keystone[3], C. Bombardier[1]on behalf of OBRI and RHUMADATA Investigators. [1]*UHN, Toronto General Hospital Research Institute,Toronto, Canada*; [2]*Institut de Rhumatologie de Montréal, RHUMADATA, Montreal, Canada*; [3]*University of Toronto, Medicine,Toronto, Canada*

Background: Tofacitinib (TOFA) is an oral, small molecule drug used for rheumatoid arthritis (RA) treatment and is prescribed alone or with methotrexate (MTX). We previously reported the similarity in retention between TOFA monotherapy and TOFA with MTX using data from two different registries separately; the Ontario Best Practices Research Initiative (OBRI) and the Quebec registry RHUMADATA.
Objectives: To increase the study power, we propose to evaluate the discontinuation rate (due to any reason) of TOFA with and without MTX, using pooled data from these two registries.
Methods: RA patients enrolled in the OBRI and RHUMADATA initiating their TOFA between 1st June 2014 (TOFA approval date in Canada) and 31st Dec 2019 were included. Concurrent MTX use was defined as MTX use for more than 75% of the time while using TOFA. Multiple imputation (Imputation Chained Equation method, N=20) was used to deal with missing data for covariates at treatment initiation.
Time to discontinuation was assessed using Cox regression models. To deal with confounding by indication, we estimated propensity scores for selected covariates with an absolute standard difference greater than 0.1. We then adjusted Cox regression models for propensity quantile to compare the discontinuation of TOFA with MTX versus TOFA without MTX.
Results: A total of 493 patients were included. Of those, 244 (49.5%) and 249 (51.5%) were treated with MTX and without MTX, respectively. Compared to TOFA monotherapy, the TOFA with MTX group had a significantly lower mean HAQ-DI, fatigue score, and the number of prior biologic use at the time of TOFA initiation. A lower proportion of positive ACPA (59% vs. 66%), prevalence of hypertension (31% vs 37%), and concomitant use of Leflunomide (11% vs. 23%) were also observed for patients using TOFA with MTX.
Over a mean follow-up of 19.0 months, discontinuation was reported in 182 (36.9%) of all TOFA patients. After adjusting for propensity score quantile across 20 imputed datasets, there was no significant difference in discontinuation between treatment groups (adjusted HRs: 1.12, 95% CI: 0.83-1.51; p=0.49).
Conclusion: In this pooled real-world data study, we found that in patients with RA, the retention of TOFA is similar if it is used as monotherapy or in combination with MTX.

POS0449 BIOLOGICS INITIATION IN MODERATE VS SEVERE RHEUMATOID ARTHRITIS PATIENTS: PROSPECTIVE OBSERVATIONAL STUDY FROM A CANADIAN REGISTRY

N. Guo[1], X. Li[2], M. Movahedi[2], A. Cesta[2], C. Bombardier[2]on behalf of OBRI Investigators. [1]*Kingstone Health Sciences Centre, Health Science, Kingstone, Canada*; [2]*UHN,Toronto General Hospital Research Institute,Toronto, Canada*

Background: Prior studies have shown that in the real-world setting, rheumatoid arthritis (RA) patients have lower disease activity than those studied in clinical trials. However, randomized controlled trials for biologics continue to mainly recruit patients with severe disease.
Objectives: To assess the implications of this practice, our study investigates the proportion of patients achieving remission (DAS28-ESR ≤ 2.6), in RA patients with moderate disease activity and severe disease activity, at 12 months post starting their first biologic, and identifies baseline predictors of biologic response.
Methods: This study included RA patients who have never been treated with a biologic and initiated their first biologic while enrolled in the Ontario Best Practices Research Initiative (OBRI) registry, between 2008 and 2019. Patients selected had either moderate RA (DAS28 ≥ 3.2 to ≤ 5.1) or severe RA (DAS28 > 5.1). Comparisons were made between the moderate and severe disease groups using the student's t-test for continuous variables, and the chi-square test for categorical variables. Multivariable logistic regression was used to test potential predictors of remission. Backward stepwise model selection was applied to select variables with *p*-value ≤0.10. Multiple imputation (MCMC method; n=20) was used to impute missing data.
Results: Overall, 641 patients initiated their first biologic, 483 had follow up data at 12 months (moderate disease activity=264; severe disease activity=219). In the moderate group, the mean age (SD) was 55.7 (13.1) and 80% were female. In the severe group, mean age (SD) was 58.4 (12.3) and 81% were female. At time of biologic initiation, the mean DAS28 for the moderate group was 4.1 (0.5), and 6.0 (0.6) for the severe group. After 12 months of starting a biologic, the proportion of patients achieving remission was 50% in the moderate group, and 23% in the severe group ($p<0.0001$). In contrast, the proportion of patients achieving significant clinical change from baseline (improvement in DAS28 ≥ 1.2) was 78% in the severe group, compared to 66% in the moderate group ($p=0.0049$). More specifically, the absolute improvement in DAS28 after 12 months was higher in the severe group at 2.2 (1.5), compared to a change of 1.4 (1.3) in the moderate group ($p<0.0001$). Negative predictors of remission include female gender (odds ratio (OR), 0.57, 95% confidence interval (CI), 0.33-0.97; $p=0.039$), and higher HAQ-DI score (OR 0.49, 95% CI 0.36-0.68; $p<0.001$). In turn, moderate disease at time of biologic initiation (OR 2.38, 95% CI 1.50-3.79; $p=0.0390$) was identified as a positive predictor of remission.
Conclusion: This prospective cohort study found RA patients with moderate disease activity are more likely to reach targeted states (remission and low disease activity), whereas severe patients have greater absolute improvements in DAS28 and HAQ-DI but are less likely to achieve remission. Moderate disease is a positive predictor for remission, whereas female gender and a higher HAQ-DI score are negative predictors.

Table 1. Outcomes at 12 months among patients with RA who initiated the first biologic

	Moderate-RA (n=264)	Severe-RA (n=219)	*P*-Value
Remission, *n* (%)	111 (50)	45 (23)	<0.0001
Low disease activity, *n* (%)	151 (59)	74 (35)	<0.0001
Change in DAS from baseline ≥ 1.2, *n* (%)	168 (66)	164 (78)	0.0049
HAQ-DI change >0.22, *n* (%)	98 (53)	83 (52)	0.7974
Change in DAS28 from baseline, mean (SD)	-1.4 (1.3)	-2.2 (1.5)	<0.0001
Change in HAQ-DI from baseline, mean (SD)	-0.29 (0.57)	-0.30 (0.66)	<0.0001
Change in fatigue from baseline, mean (SD)	-0.98 (3.2)	-1.11 (3.2)	<0.0001
Change in sleep from baseline, mean (SD)	-0.85 (3.6)	-1.05 (3.9)	0.0004

POS0450 INCIDENCE RATES OF DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS IN REAL-WORLD CLINICAL PRACTICE

Y. Hirano[1], J. Hasegawa[1], H. Kosugiyama[2], D. Kihira[2], K. Hattori[2]. [1]*Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan*; [2]*Nagoya University Graduate School of Medicine, Orthopaedic Surgery and Rheumatology, Nagoya, Japan*

Background: A definition of difficult-to-treat rheumatoid arthritis (D2T RA) was recently proposed by the European League Against Rheumatism (EULAR) [1]. However, information on the incidence rates of D2T RA in real-world clinical practice is lacking.
Objectives: The aim of this retrospective cross-sectional study was to evaluate the incidence rates of D2T RA in clinical practice in Japan.
Methods: Data from the Toyohashi RA database (TRAD) was used. The TRAD is a collection of single-center retrospective data. Patients with RA who fulfilled the following three requirements were included in this study: (1) had been treated with >1 biological or targeted synthetic disease-modifying antirheumatic drug (b/tsDMARD); (2) >1 year had passed since b/tsDMARD treatment was initiated; and (3) regularly visited our institute at the time of investigation. The number of targeted patients was 363. The criteria of D2T RA used in this study were modified from the EULAR definition for simplification of the investigation as follows: (a) ≥2 b/t DMARDs with different mechanisms of action had been administered; (b) at least moderate disease activity (DAS28-ESR > 3.2 or clinical disease activity index [CDAI] > 10) at the time of investigation; and (c) 7.5-mg/day of prednisolone (PSL) or more was administered at the time of investigation. In this study, D2T RA was defined as criteria (a) + (b) or (a) + (c) or (a) + (b) + (c). The 363 patients were categorized into four groups as follows: group A, DT2 RA; group B, patients with RA who had been treated with ≥2 b/tsDMARDs and did not fulfill the D2T RA definition; group C, RA patients who had been treated with one kind of b/tsDMARD with the same mechanism of action (e.g., two kinds of tumor necrosis factor inhibitors) and fulfilled either or both criteria (b) and (c); and group D, patients with RA who had been treated with one kind of b/tsDMARD with the same mechanism of action (e.g., a tumor necrosis factor inhibitors or two interleukin 6 inhibitors) and did not fulfill either or both criteria (b) and (c). The incidence rates of D2T RA were calculated, and the patients' characteristics at the time of initiation of the b/tsDMARD treatment were compared between the groups.
Results: The number of patients in groups A, B, C, and D were 34, 53, 94, and 182, respectively. Of all the patients included in this study, 9.4% were categorized into group A, those with D2T RA, and 39.1% were treated with ≥2 b/tsDMARDs and categorized into group A (Fig 1). The patients' characteristics were as follows (group A/B/C/D): mean age (57.1/54.3/61.4/56.2 years), RA duration (10.0/6.7/13.8/8.2 years), %Steinbrocker stage III+IV (%; 84.0/60.0/77.3/54.3), %Steinbrocker class 3+4 (%; 68.0/33.3/43.4/23.0), methotrexate (MTX) concomitant rate (%; 79.4/92.5/74.5/91.8), PSL concomitant rate (%; 91.2/52.8/55.3/43.4), DAS28-ESR score (5.5/5.0/5.5/4.7), and CDAI score (12.3/13.7/22.7/16.9). There were statistically significant differences in RA duration, %stage III+IV, %class 3+4 and PSL concomitant rate between group A and B.
Conclusion: D2T RA occurred in 9.4% of patients treated with b/tsDMARDs. Incidence rate was increased to 39.1% after the treatment with ≥2 b/tsDMARDs. The patients with D2T RA tended to be older, have a long RA duration, be treated without concomitant MTX, be treated with concomitant PSL, and have higher disease activity at the time of starting the b/tsDMARD treatment. The baseline patient characteristics in group C were similar to those in group A. In the future, we suggest that patients with D2T RA be included in group C.

POS0451 SERUM FETUIN-A AND VISFATIN LEVELS IN WOMEN WITH RHEUMATOID ARTHRITIS DEPENDING ON DISEASE ACTIVITY

Y. Akhverdyan[1], B. Zavodovsky[1], E. Papichev[1], J. Polyakova[1], L. Seewordova[1]. [1]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Joint Diseases Treatment and Prevention Laboratory, Volgograd, Russian Federation*

Background: In recent years, the systemic effects of a number of cytokines have been actively studied, in particular, fetuin-A is considered a negative protein of the acute phase response, and visfatin, on the contrary, affects the activation of the cytokine cascade and has a pro-inflammatory effect. Taking into account that women suffer from rheumatoid arthritis (RA) more often, we investigated the levels of fetuin-A and visfatin in the blood serum of females in comparison with a group of healthy individuals and depending on the activity of the disease.
Objectives: to study the levels of fetuin-A and visfatin in the blood serum of women suffering from RA, depending on the activity of the disease
Methods: The study included 110 women with RA and 30 apparently healthy individuals. The inclusion criteria were: a diagnosis of RA verified based on the criteria of the American College of Rheumatology/European Anti-Rheumatic League (ACR/EULAR) 2010. The patients' age ranged from 18 to 90 years. The control group included 30 conventionally healthy individuals. Serum fetuin-A and visfatin levels were determined by indirect enzyme-linked immunosorbent assay using commercial kits. RA activity was determined by the DAS28-CRP index. Activity 0-I was in 33 (30%) patients, grade II in 67 (60.9%), grade III in 10 (9.09%) patients.
Results: The normal level of fetuin-A was calculated using the formula M±2σ in the group of conventionally healthy individuals and ranged from 653.55 to 972.19 μg/ml. In patients with grade 0-I RA activity according to DAS28, the mean serum fetuin-A level was 843.92±130.73 μg/ml, in patients with grade II activity - 742.37±98.85 μg / ml, with III the degree of activity - 663.9±123.7 μg/ml ($p<0.001$).
The average level of visfatin in the blood serum in healthy individuals was 2.43±0.17 ng/ml. The level of normal values of visfatin in healthy individuals, defined as M±2σ, ranged from 0 to 5.07 ng/ml. The average level of visfatin in patients with RA was 6.27±0.18 ng/ml, which is significantly higher than in healthy individuals ($p<0.001$).
In patients with 0-I degree of RA activity according to DAS28, the average level of visfatin in blood serum was 4.94±0.02 ng/ml, in patients with degree II activity - 5.08±0.02 ng/ml, with III degree of activity - 6.82±0.23 ng/ml ($p<0.001$).

Conclusion: Thus, the level of fetuin-A in the blood serum of patients with RA is significantly lower in the case of a high degree of disease activity. The level of visfatin in the blood serum in women with RA is significantly higher in patients with a higher degree of disease activity. Therefore, the concentration values of fetuin-A and visfatin in the blood serum of patients with RA can be used in an integrated assessment of the prognosis of disease activity.

POS0452 SYNOVIAL MYELOID-STROMAL PATHOTYPE PREDICTS ONE-YEAR RADIOGRAPHIC PROGRESSION IN ACTIVE RHEUMATOID ARTHRITIS

X. Zhang[1], J. D. Ma[1], D. H. Zheng[1], C. Chen[1], T. Wu[1], J. Lin[1], J. Jing[1], Y. Mo[1], Y. Y. Zou[1], L. Dai[1]. *[1]Sun Yat-Sen University Sun Yat-Sen Memorial Hospital, Rheumatology, GuangZhou, China*

Background: Rheumatoid arthritis (RA) is a heterogeneous disease with variable prognosis. The cellular composition in synovium is the driving force of joint destruction in RA, and the predictive values of histopathological assessments on the clinical outcomes of RA have been identified. However, current synovial histopathological assessments mainly focus on the infiltrated immunocytes to distinguish RA synovium into different synovial pathotypes. Whether addition of stromal cells improve the accuracy of histopathological assessments remains unknow.

Objectives: To distinguish synovial pathotypes of RA based on intercellular connection and explore their predictive value on one-year radiographic progression.

Methods: Active RA patients who underwent needle synovial biopsy at baseline were recruited from a real-world prospective cohort. Clinical data were evaluated at baseline and 1, 3, 6, 12 months. Histopathologic assessments included Krenn synovitis score and semiquantitative score of immunohistochemical staining for CD20, CD38, CD4, CD8, CD68, CD31 and CD90. Cluster analysis was used to distinguish synovial pathotypes. The primary outcome was one-year radiographic progression defined as a change in total Sharp/van der Heijde modified score≥0.5 units.
