Methods: REUMAVID is an international collaboration led by the Health & Territory Research group at the University of Seville, together with a multidisciplinary team including patient organisations and rheumatologists. This cross-sectional study consisting of an online survey gathering data from 1,800 patients with a diagnosis of 15 RMDs recruited by patient organisations in Cyprus, France, Greece, Italy, Portugal, Spain and, the United Kingdom. Data are collected in two phases, the first phase between April and July 2020, the second in 2021. Participants rated a series of fears (infection, medication consequences, lack of medication, impact on healthcare, job loss, civil disorder) on a Likert scale from zero ("no concern at all") to five ("extremely concerned") and their hopes (treatment/vaccine availability, going outside, travel, economic situation, treatment continuation, health status) on a Likert scale from zero ("not hopeful at all") to five ("extremely hopeful"). The Mann-Whitney and Kruskal-Wallis tests were used to analyse the different fears and hopes according to socio-demographics characteristics, disease and health status.

Results: 1,800 patients participated in the first phase of REUMAVID. The most frequent RMDs group was inflammatory arthritis (75.4%), the mean age was 52.6 years and 80.1% were female. The most important fear for patients was the impact of the COVID-19 pandemic on healthcare (3.1 out of 5), particularly for those younger in age (3.0 vs 3.2, p=0.004), female gender (3.2 vs 2. 9 of men, p=0.003), experiencing greater pain (3.1 vs 2.8, p=0.007), with higher risk of anxiety (3.3 vs 2.9 of without anxiety, p<0.001) and depression (3.3 vs 2.9 without depression, p<0.001). The possible impact of anti-rheumatic medication and the development of severe disease if they became infected with COVID-19,was mostly feared (2.8 out of 5), by those receiving biological therapy (3.1 vs 2.5 not biological therapy, p<0.001) or those with underlying anxiety (2.9 vs 2.6 without anxiety, p=0.007). The risk of contracting COVID-19 due to their condition (2.8 out of 5), was especially feared by those with vasculitis (3.2 out of 5), who were female (2.9 vs 2.5, p<0.001), using biologics (2. 9 vs 2.7 of no use, p=0.003), in greater pain (2.8 vs 2.4, p<0.001), with a risk of anxiety (3.0 vs 2.6 without anxiety, p=0.004), and risk of depression (3.0 vs 2.6 without depression, p<0.001). The major hopes were to be able to continue with their treatment as usual (3.7 out of 5), particularly for those taking biologics (3.8 vs 3.6 not taking, p=0.026), those with a better well-being (3.8 vs 3.6 with worse well-being, p=0.021), without anxiety (3.8 vs 3.6 at risk, p=0.004) and without depression (3.8 vs 3.6 at risk,

p=0.007). Hoping not to become infected with COVID-19 and to maintain the same health status, were especially those who were older (3.6 vs 3.4 p=0.018) without anxiety (3.4 vs 3.6 at risk, p=0.005), and without depression (3.6 vs 3.4 at risk, p=0.006). Another important hope was the availability of a treatment or vaccine for COVID-19, which was important for patients experiencing better well-being (3.3 vs 3.0 with worse well-being, p<0.001; Figure 1).

Conclusion: The outstanding COVID-19-related fear expressed by European patients with RMDs was its impact on healthcare, while the greatest hope was to be able to continue treatment. Younger patients reported more fears while older patients were more hopeful. Those receiving biologics had greater fears and hopes associated with their treatment. In addition, patients at risk of mental disorders presented greater fears and less hopes.

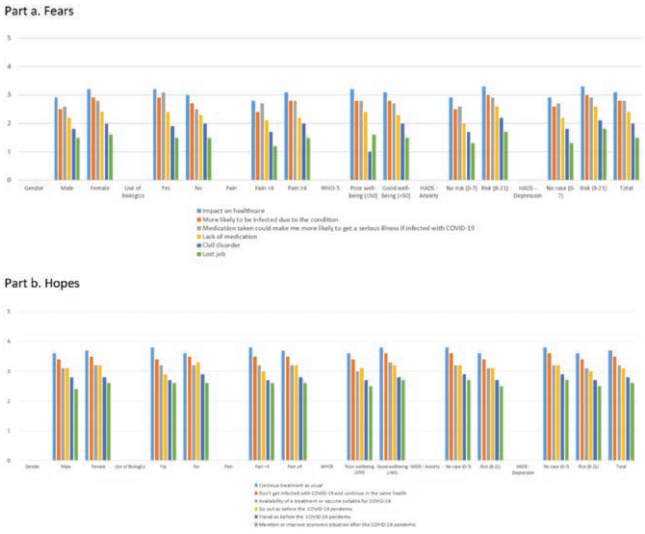

Figure 1. Fears and Hopes of REUMAVID participants

Background: The COVID-19 pandemic has impacted health, lifestyle, treatment and healthcare of European patients with rheumatic and musculoskeletal diseases (RMDs).

Objectives: The aim is to evaluate gender differences on the impact of the first wave of the COVID-19 pandemic in the wellbeing, life habits, treatment, and healthcare access of European patients with RMDs.

Methods: REUMAVID is an international collaboration led by the Health & Territory Research at the University of Seville, together with a multidisciplinary team including patient organisations and rheumatologists. This cross-sectional study consisting of an online survey gathering data from 1,800 patients with a diagnosis of 15 RMDs, recruited by patient organisations in Cyprus, France, Greece, Italy, Portugal, Spain, and the United Kingdom during the first phase of the pandemic (April-July 2020). Mann-Whitney and χ^2 tests were used to analyse differences between gender regarding sociodemographic characteristics, life style, treatment, healthcare, and patient-reported outcomes.

Results: 1,797 patients were included in this analysis. 80.2% were female and a mean age of 52.6 years. The most common diagnosis was inflammatory

Table 1. Bivariate analysis by gender (N= 1,797 unless specify)

		Mean ± SD or n (%)		P- value
		Male (N= 355)	**Female** (N= 1,442)	
Sociodemographic characteristics				
Disease	Inflammatory arthritis[1]	290 (81.7)	1,064 (73.8)

[1]Including: Axial Spondyloarthritis, Rheumatoid Arthritis, Psoriatic Arthritis, Juvenile Idiopathic Arthritis, Gout and Peripheral Spondyloarthritis; [2]Including: Systemic Lupus Erythematosus, Sjögren's Syndrome, Systemic Sclerosis and Myositis; [3]Including: Polymyalgia Rheumatic and Vasculitis or Arteritis.

arthritis (81.7% male vs 73.8% female). There was a higher prevalence of fibromyalgia among females (20% vs 7.0% male). Overall, females reported worse self-perceived health (67.0% vs 51.4%, p<0.001), higher risk of anxiety (59.5% vs 48.1%, p<0.001), and depression (48.0% vs 37.2%, p<0.001). Females reported a greater increase in smoking (26.5% vs 17.5%, p=0.001), although they were less likely to drink alcohol (34.5% vs 25.4%, p=0.013), and also engaged less in physical activity (53.0% vs 60.3%, p=0.045). Overall, females were more likely to keep their scheduled rheumatology appointment (43.3% vs 34.1% of males (p=0.049; Table 1) with a higher proportion of females having their rheumatic treatment changed (17.0% vs 10.7%, p=0.005).

Conclusion: The first wave of the COVID-19 pandemic and the containment measures have worsened self-perceived health status of patients with RMDs, affecting genders differently. Females reported worse psychological health and life habits such as increased smoking and reduced physical activity, while males increased their alcohol consumption and were less likely to attend their rheumatology appointments.

AB0678 RATES OF SURGICAL PROCEDURES OF THE KNEE AND HIP DURING THE "FIRST WAVE" OF COVID 19 IN SWEDEN

A. Dell'isola[1], A. Kiadaliri[1], A. Turkiewicz[1], V. Hughes[1], K. Magnusson[1,2], J. Runhaar[3], S. M. A. Bierma-Zeinstra[3], M. Englund[1]. [1]*Lund University, Clinical Epidemiology Unit, Orthopedics, Department of Clinical Sciences Lund, Lund, Sweden*; [2]*Norwegian Institute of Public Health, Cluster for Health Services Research, Oslo, Norway*; [3]*Erasmus MC, University Medical Center, Department of General Practice, Rotterdam, Netherlands*

Background: Many countries imposed lockdowns in March 2020, in anticipation of the "first wave" of COVID-19 and the massive healthcare resources required to meet its acute medical needs. Sweden adopted a different strategy to contain the epidemic, opting for non-binding recommendations. Nonetheless, elective and acute surgical procedures in health care may have been affected.

Objectives: To investigate the effect of the "first-wave" of COVID-19 and the government's response in Sweden on the rates of total joint replacements (TJR), arthroscopies, and fracture surgeries of the knee and hip.

Methods: We used register data for the entire population of Skåne, the southernmost region in Sweden with 1.3 million inhabitants (13% of the total Swedish population). We identified all residents aged ≥18 years who between 1st January 2015 and 31st November 2020 underwent any of the following surgical procedures of the knee or hip: TJR (TJR due to fracture excluded), arthroscopy, and surgery due to fracture (including TJR). To demarcate pre-event and post-event periods, we established a differentiation point corresponding to mid-March 2020, the timepoint at which the the Swedish Public Health Agency began recommending social distancing, working from home, distance learning for secondary schools and universities,. At the aggregate level, we modelled the number of surgeries per 10,000 adults from January 2015 up to September 2020. We did an interrupted time-series (ITSA) analysis using segmented ordinary least-squares regression to estimate changes in the levels and trends of surgical procedures compared to pre-COVID-19 levels, adjusting for seasonal variations. The month of March was treated as a "phase-in" period to give time for the new recommendations to be implemented. In addition, we estimated the absolute and relative difference (with its 95% confidence interval [CI]) between the predicted and the counterfactual scenario in the monthly number of surgeries from April 2020, where the counterfactual is the rate of surgery that would have been expected if COVID-19 had not happened. To account for the possibility that other co-occurring events may be responsible for the observed changes, we assessed changes in the number of surgeries due to fractures, which are normally treated as emergencies that cannot be cancelled or rescheduled, and thus should be less affected, at least by policies at the hospital level.

Results: We identified a total of 20,831 TJRs, 12,156 arthroscopies and 15,041 fracture surgeries of the knee or hip over the study period. The monthly rate of surgeries and ITSAs are presented in Figure 1, with the pre-COVID period starting from February 2019 for readability (Figure 1). The results suggest that in April 2020, there was a decrease of 2.08 (95%CI 1.81; 2.35) TJRs per 10,000 adults which corresponds to a decrease of 74% (95%CI 65%; 85%) when compared to the counterfactual scenario. This was followed by a positive trend signifying a monthly increase of 0.36 (95%CI 0.31; 0.40) TJRs per 10,000 adults. The rate of arthroscopies followed a similar pattern with a decrease of 0.55 (95%CI 0.39; 0.71) arthroscopies per 10,000 adults in April, which corresponds to a 49% decrease (95%CI 28%; 63%) followed by a positive trend signifying a monthly increase of 0.11 (95%CI 0.07; 0.15) arthroscopies per 10,000 adults. The rate of surgery due to knee or hip fractures showed no decrease in April and was followed by a negative trend signifying a monthly decrease of 0.03 (95%CI 0.002; 0.04) surgeries per 10,000 adults.

Conclusion: In Sweden, we observed a marked decrease in the number of typical elective knee and hip surgeries such as TJRs and arthroscopies, following the government's response to Covid-19. We then observed a slow but steady recovery that brought the rates of procedures towards expected levels by Fall 2020, before the "second wave" hit the country. The number of acute fracture surgeries showed no sharp drop, instead showing a steady and slow decline potentially due to reduction in commuting and in physical activities linked to recommendations of social

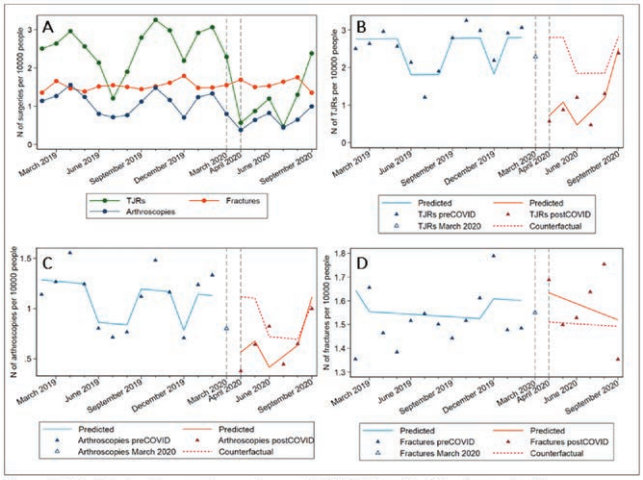

Figure 1: Monthly incidence of surgeries per 10,000 Skåne inhabitants aged > 18
A: Monthly incidence for TJR, arthroscopies and fracture-related surgeries. Interrupted time series for **B:** TJR, **C:** arthroscopies, and **D:** fracture-related surgeries. Pre-COVID data is presented from February 2019 onwards for readability.

AB0679 NAILFOLD VIDEOCAPILLAROSCOPY RESULTS IN COVID-19 PATIENTS RECOVERED FROM DIFFERENT DISEASE SEVERITY

E. Gotelli[1], P. F. Bica[1], T. Aloe'[2], A. Sulli[1], M. Grosso[2], C. Pizzorni[1], F. Cattelan[1], S. Paolino[1], E. Barisione[2], V. Smith[3], M. Cutolo[1]. [1]*Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties, University of Genova, IRCCS San Martino Polyclinic, Genova, Italy*; [2]*Interventional Pneumology Unit, IRCCS San Martino Polyclinic, Genoa, Italy*; [3]*Department of Rheumatology – Department of Internal Medicine – Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Ghent University Hospital, Ghent, Belgium*

Background: COVID-19 is a multifaceted condition with a wide range of clinical manifestations, including microvascular/endothelial dysfunction, that starts in the early phase of the disease and may become dramatically harmful in the late stage, causing a massive pro-thrombotic state. Nailfold videocapillaroscopy (NVC) is the most used tool to identify microvascular status in a large spectrum

of diseases [1]. Recently, non-specific NVC abnormalities have been described in a cohort of COVID-19 patients (no controls used) [2].
Objectives: To assess microvascular damage in recovered COVID-19 patients (range of 40-270 days from recovery) by considering the previous severity of the disease, and, as mandatory, the comparison with matched individuals suffering from primary Raynaud's phenomenon (PRP) and healthy volunteers (HV).
Methods: NVC investigations were performed during standard clinical assessments in forty-four recovered COVID-19 patients (mean age 58±14 years, mean days from disease onset 129±54, mean days from disease recovery 106±52), twenty-two patients with PRP (mean age 60±15 years, mean years from disease onset 11±10) and twenty-two HV (mean age 60±14 years). COVID-19 patients were divided into two subgroups, according to the need of oxygen supplementation: twenty-two patients with severe lung involvement (need of Continuous Positive Airways Pressure and/or mechanical ventilation, mean age 57±12 years) vs twenty-two patients with mild-moderate lung involvement (need of Venturi mask or no need of oxygen supplementation, mean age 59±15 years). Clinical and demographic data of all the enrolled subjects were collected, during NVC examination. The following capillaroscopic parameters were evaluated: capillary number, dilated capillaries, giant capillaries, microhemorrhages, angiogenesis, disorganization of the microvascular array. A validated semiquantitative scoring (0-3) was adopted for NVC abnormalities [3-5]. Statistical analysis was carried out by non-parametric tests.
Results: After COVID-19 recovery, no statistically significant difference was observed between COVID-19 patients and control groups of subjects concerning the score for the following NVC parameters: dilated capillaries, giant capillaries, disorganization of the microvascular array, angiogenesis. However, the capillary number per linear millimeter was significantly lower in COVID-19 patients (8.3±0.9) than in PRP (8.8±0.7, p=0.05) and HV (9.3±0.6, p<0.0001). Surprisingly, recovered COVID-19 patients showed significantly less microhemorrhages (score 0.4±0.3) than subjects of the other groups (PRP 0.6±0.5, p=0.01; HV 0.6±0.6, p=0.05). In particular, recovered patients who had more severe COVID-19 showed less microhemorrhages than patients with mild/moderate disease (score 0.18±0.4 vs 0.36±0.5), but this didn't reach the statistical significance (p=0.18). On the other hand, patients recovered from severe SARS-CoV-2 infection also showed higher rate of angiogenesis (0.18±0.4) than patients with mild/moderate disease (no case, p=0.04).
Conclusion: COVID-19 doesn't seem to significantly induce, in short-term, specific alterations in peripheral microvascular array as evaluated by NVC, despite the severity of the disease, except for a significant reduction of the absolute number of nailfold capillaries. The topic needs longer time of evaluation and larger number of COVID-19 recovered cases to also assess the role of concomitant therapies.

AB0680 SARCOPENIA RATE IN COVID-19 SURVIVORS

D. Levy[1], M. Giannini[1,2], W. Oulehri[3], M. Riou[1], C. Marcot[4], A. Meyer[1,2,5], B. Geny[1,2]. *[1]Hôpitaux Universitaires de Strasbourg, Physiology, Strasbourg, France*; *[2]Université de Strasbourg, Fédération de Médecine Translationnelle de Strasbourg (FMTS), Faculté de Médecine, EA 3072 « Mitochondrie, Stress oxydant et Protection Musculaire », Strasbourg, France*; *[3]Hôpitaux Universitaires de Strasbourg, Service de Réanimation Chirurgicale, Strasbourg, France*; *[4]Hôpitaux Universitaires de Strasbourg, Service de Pneumologie, Strasbourg, France*; *[5]Hôpitaux Universitaires de Strasbourg, Service de Rhumatologie, Strasbourg, France*

Background: COVID-19 survivors may have high risks of developing sarcopenia, which is associated to handicap, poor quality of life, higher healthcare costs, increased risk of falls, increased mortality (1).
Objectives: To assess sarcopenia rate (which has not been described yet) following COVID-19 hospitalization and to highlights features associated with sarcopenic vs. non-sarcopenic patients.
Methods: Major confirmed COVID-19 patients undergoing intensive care unit (ICU) or Pneumology Department admission in Strasbourg University Hospital between March and June 2020 were prospectively included. Muscle and cardio-respiratory evaluations were performed 3 months after discharge. Sarcopenic patients were compared to non-sarcopenic ones. A second muscle assessment 6 months after discharge was performed in patients with pathologic muscle tests.
Results: 127 patients were included, 39 (30.7%) not requiring ICU care, 88 (69.3%) requiring ICU care. The cohort consisted of 71% male patients, with a median age of 63 years [28-82]. Forty-one-percent were obese (BMI>30 kg/m^2). Most individuals had preexisting comorbidities (82 patients, 70%), mainly hypertension and diabetes mellitus. The median total hospital stay duration was 22 days and up to 89 days. At the 3 months assessment, 17/127 (13%) patients were diagnosed with sarcopenia which comprised 6/17 (35%) severe sarcopenia (4.7% of the total cohort). At the 6 months assessment, only 4/15 (27%) of the initial sarcopenic patients remained sarcopenic (3% of the total cohort) and 3 of these 4 patients had severe sarcopenia. BMI (26,3 vs. 29,3, p=0.03), COPD (20% vs. 3%, p=0.03), comorbidities (93% vs. 67%, p=0.04), total hospital stay duration (33 vs. 20 days, p=0.03) and ICU stay duration (33 vs. 13 days, p=0.01) were significantly associated with sarcopenic vs. no sarcopenic patients. However, there was no significant difference concerning cardio-pulmonary evaluations between these two groups.
Conclusion: We here highlighted a sarcopenia prevalence at 3 and 6 months following a hospitalization for COVID-19 of 13% and 3% respectively, occurring mainly in patients with comorbidities. Sarcopenia was not associated to worse cardio-pulmonary results in comparison with non-sarcopenic patients.

Background: People with rheumatic diseases may be at increased risk of contracting COVID-19 due to their rheumatic disease or immunosuppressive treatments. It is currently unclear what the COVID-19 disease burden is for these people and whether any of their personal or disease characteristics are associated with contracting COVID-19.
Objectives: To explore the proportion of, and characteristics associated with, contracting COVID-19 in children and young people (CYP) with rheumatic diseases and adults with rheumatic diseases from March 2020 to December 2020 during the COVID-19 pandemic.
Methods: CYP and adults recruited to the international COVID-19 European Patient Registry, a parent-led, online, self-referred prospective cohort recruiting participants from around the globe, were included in current study if enrolled between 20th March 2020 and 30th December 2020. Demographic information was collected at enrolment and rheumatic disease, diagnoses of COVID-19 and lifestyle factors were collected at weekly intervals.
The proportion of CYP and adults diagnosed with COVID-19 were assessed separately. Associations between contraction of COVID-19 at any point over follow-up and participant demographics, rheumatic disease and lifestyle factors at enrolment were assessed descriptively and via Mann-Whitney U-tests, Chi-squared tests and Fisher's exact tests.
Results: Within 642 CYP and 3646 adults, the majority were female (67%, 89%) and most commonly from the UK (43%, 82%), respectively. The most frequent diagnoses were polyarticular JIA (37%) in the CYP cohort and RA in the adults (63%). Comorbidities were common (45%, 61%) and the majority were taking one or more immunosuppressive therapies (88%, 92%), respectively. At the time of enrolment, 51% and 54% were practising social distancing, respectively.
In both cohorts ~3% contracted COVID-19 at some point during follow-up (n=18 (2.8%) in CYP and n=103 (2.8%) in the adult cohort).
In CYP, those who contracted COVID-19 were older (no COVID, median: 10, IQR: 7, 13, vs COVID, median: 14, IQR: 12, 16, p<0.001) and less often had oligoarticular JIA (no COVID: 31%, COVID: 22%) or polyarticular JIA (No COVID: 38%, COVID: 11%). Systemic JIA (no COVID: 7%, COVID: 11%) and enthesitis-related JIA (no COVID: 5%, COVID: 22%) were more common in those who contracted COVID. No other differences between those with and without COVID-19 were observed with respect to country of residence (p=0.335), gender (p=0.624), control of rheumatic disease (p=0.459), comorbidities (p=0.752), immunosuppressive medication (p=0.713) or social distancing (p=0.729).

In the adult cohort, those contracting COVID-19 were more commonly from Russia (no COVID: 2%, COVID: 14%) and less commonly from the UK (no COVID: 82%, COVID: 71%, p<0.001). There was greater female representation in those that contracted COVID-19 (no COVID: 88%, COVID: 93%, p=0.022). Although there were no differences in overall presence of comorbidity (p=0.923), kidney disease was overrepresented in those that had contracted COVID-19 (no COVID: 2%, COVID: 8%, p<0.001). Finally, there were lower levels of social distancing in those who contracted COVID (no COVID: 54%, COVID: 44%, p=0.047). There were no significant differences in age (p=0.203), BMI (p=0.617), smoking status (p=0.120), rheumatic disease (p=0.181) and its control (p=0.218) or immunosuppressive use (p=0.208) between those who did and did not contract COVID-19 in the adult cohort.

Conclusion: A low proportion of CYP and adults with rheumatic diseases contracted COVID-19 in the 9 months since March 2020. However, given the self-reported nature of the survey and limited testing available across many countries, this study may underestimate the true burden of COVID-19 in the rheumatic disease community. Factors associated with COVID-19 differ between CYP and adults, with age and type of rheumatic disease associated in CYP and gender, kidney comorbidity and social distancing associated in adults.

Acknowledgements: The authors thank all of the participants and families involved in the international COVID-19 European Patient Registry, as well as administrators. We also thank the team of volunteers who helped translate the surveys. We also thank ENCA, PRES and representatives from the international rheumatology community for their expertise and support.

AB0682 RHEUMATOLOGY TEACHING IN TIMES OF COVID-19

Y. Chang[1], J. Nicholls[1]on behalf of Medical Education team of George Eliot Hospital NHS Trust. [1]*George Eliot Hospital NHS Trust, Medical Education, Nuneaton, United Kingdom*

Background: The COVID-19 pandemic has affected the delivery of face-to-face teaching especially bedside teaching for medical students in the hospitals. Rheumatology outpatient clinics have mostly become virtual or telephone consultation clinics which prevent medical students from seeing patients in person. Students are deprived of the opportunities to take rheumatology history, examining patients and seeing signs of rheumatologic diseases. New adaptations have to be made to ensure equitability and that students still receive the relevant teaching in line with their learning curriculum and to help them prepare for their examinations.

Objectives: Our aims are:

1)To adapt bedside teaching in the wards to simulated teaching in the classroom using trained simulated 'patients'; and

2)To create simulation teaching of patient journeys in Objective Structured Clinical Examination (OSCE) format known as Clinically Observed Medical Education Tutorials (COMET) (Nair et al., 2001).

Methods: 1)For simulated teaching in the classroom, we have trained our teaching colleagues as simulated or standardized patients (SPs). We write up fictitious patient histories which simulate common presentations at rheumatology clinics. We train the SPs to give as accurate a history as possible and to simulate pains in different joints (e.g. pain at the metacarpophalangeal joints and proximal interphalangeal joints in rheumatoid arthritis) on clinical examinations. For clinical presentations that are not easily simulated, we use photographs of the relevant signs. This method is used not only as formative assessments but also as end-of-placement summative assessments.

2)COMET comprises 3 OSCE-style stations with a tutor each where the students perform different tasks based on a patient's clinical problem (e.g. acute hot swollen joint). The first station is initial A-to-E assessment of the patient (using a simulator), followed by investigations and interpretations of lab results and imaging (station 2) and lastly, management (including prescribing medications) and communication skills (e.g. explain arthrocentesis to the patient).

Results: The overall feedback from students is very positive. We use Likert scale to assess confidence level before and after the teaching session, and pre-session and post-session multiple choice questions to assess learning and knowledge gained.

Conclusion: While simulated teaching cannot replace encounters with real patients, students do enjoy these sessions as they get to 'experience' a large variety of rheumatologic cases and practice their clinical skills which at times are limited with real patients due to reluctance and pain of the patients.

AB0683 OSTEOARTHRITIS PAIN AND COVID-19 PANDEMIC: THE LOCKDOWN IMPACT

F. Orsini[1], O. De Lucia[1], F. Ingegnoli[1], G. Cincinelli[1], G. Armentaro[1], R. DI Taranto[1], R. Caporali[1]. [1]*Istituto Ortopedico Gaetano Pini, Rheumatology, Milano, Italy*

Background: Both peripheral and central nervous system processes are involved in osteoarthritis (OA) pain. Several aspects such as environmental, psychological and constitutional factors contribute to OA pain and they were enhanced during and after lockdown, for COVID-19 pandemic.

Objectives: The purpose of this study is to assess the impact of the modified lifestyle forced by lockdown on joint pain using Visual Analogic Scale (VAS) scale. the variation of VAS pain, the reduction of physical activity, the variation of body weight, the stress values defined by Perceived Stress Scale (PSS) and the use of anxiolytics and antidepressant drugs were measured in OA patiens during the lockdown period.

Methods: 74 adult patients affected by primary or secondary OA were included. The median age was 69.8 years old and 55/74 (74%) of the patients were female. Sex, age, comorbidities, pharmacological therapy, variation rate of VAS pain referred to OA symptoms (0-100) during lockdown, weight variation, degree of physical activity (defined as: absent 0 h, low 1-5 h, moderate 6-10 h, high > 10 h) were recorded. Perceived stress using PSS was recorded and patients were divided into two classes: low (0-13) or moderate-high (14-40) stress scale. This observational retrospective real-life study was conducted in May 2020. A linear regression model was used to analyze the different patients groups separately. Overall variables were expressed on analogic scales. To assess the impact on VAS pain, regression models were estimated with VAS pain as dependent variable, and weight increase, physical activity and perceived stress as independent variable.

Results: Patients enrolled with a pre lockdown VAS pain < 40 were 30, whereas 44 patients referred a pre lockdown VAS pain > 40. Patients taking anxiolytics, antidepressant, anxiolytics or antidepressant drugs were 14/74 (19%), 7/74 (9%), 19/74 (26%) respectively. PSS score Low (score 0-13), Med (score 14-26), High (score 27-40) was recorded in 34/74 (46%), 36/74 (49%), 4/74 (5%) patients respectively. Patients were divided in two different groups on the basis of baseline pre lockdown VAS pain: low VAS pain (< 40) (n=30) and moderate-high (≥ 40) (n=44). In the low-VAS group there was an average increase of pain by 1,36 points, an average increase of weight by 0.63 kg, and an average decrease of weekly physical activity by 6.4 hours that was statistically relevant (p< 0.0001). In moderate-high VAS group an average increase of pain and weight, by 2.62 points and 0.35 kg respectively, and a significant decrease of physical activity by 3.15 h weekly (p< 0.0001) has been recorded

	MODERATE PAIN (VAS<40) (n=30)		HIGH PAIN (VAS≥40) (n=44)	
	Before LD	During LD	Before LD	During LD
Gender, Female: n (%)	17 (56.7%)		38 (86.4%)	
Age (years) : median (Q1, Q3)	63 (57,73)		73 (66, 79)	
Weight (Kg) : median (Q1, Q3)	66.5 (57.0,76.5)	67.5 (58.0, 77.7)	64.0 (57.7, 74.2)	67.0 (57.7, 75.0)
Physical activity (h/week) : n (%)				
0	0 (0.0%)	11 (36.7%)	10 (22.7%)	26 (59.0%)
1-5	4 (13.3%)	10 (33.3%)	10 (22.7%)	12 (27.3%)
6-10	14 (46.7%)	6 (20.0%)	18 (41.0%)	5 (11.4%)
>10	12 (40.0%)	3 (10.0%)	6 (13.6%)	1 (2.3%)
Perceived Stress:n (%)				
LOW		13 (43.3%)		21 (47.7%)
MED		15 (50.0%)		21 (47.7%)
HIGH		2 (6.7%)		2 (4.5%)
VAS PAIN (score) : mean (sd)	18.7 (10.4)	28.7 (22.1)	54.1 (10.0)	56.2 (16.3)

In low VAS group, 43% of the patients perceived low stress values vs 57% moderate-high. In VAS > 40 group 47% of the patients perceived low stress value vs 53% high-moderate. 80% of low- VAS <group did not take anxiolytics and antidepressant drugs and for this cluster of patients was not recorded a VAS increase regardless of PSS. 16.7% of patients (5/30) with VAS < 40, taking anxiolytics / antidepressant medications and with a moderate-high PSS displayed an average increase of VAS pain by 20 mm. In the VAS > 40 group a VAS variation was not recorded, regardless of taking anxiolytics / antidepressant medications and PSS.
Conclusion: Lockdown impact on OA pain has been higher in the cluster of patients who were taking anxiolytics / antidepressant drugs with a moderate-high PSS. VAS pain increase in this cluster of patients exceeds minimal clinically relevant difference reported in literature [1]. A relevant physical activity decrease which might negatively impact on OA course has also been recorded.

AB0684 LESS THAN 20% OF PATIENTS WITH A CHRONIC INFLAMMATORY RHEUMATIC DISEASE CHANGED THEIR IMMUNOSUPPRESSIVE MEDICATION BECAUSE OF THE COVID 19 PANDEMIC

I. Andreica[1], R. Jast[1], G. Rezniczek[2], U. Kiltz[1], D. Kiefer[1], B. Buehring[1], X. Baraliakos[1], J. Braun[1]. [1]*Rheumazentrum Ruhrgebiet, Ruhr-Universität Bochum, Rheumatology, Herne, Germany*; [2]*Marien Hospital Herne, Hospital of the Ruhr-University Bochum, Department of Obstretics and Gynecology, Research Lab, Herne, Germany*

Background: The best treatment options of patients with chronic inflammatory rheumatic diseases (CIRD) in the pandemic have not been completely clear, especially in the beginning of the lockdown. Whether and to which degree pandemic-related therapy changes have occurred, has not been studied in detail.
Objectives: To study the behaviour of patients with CIRD initially facing the COVID 19 pandemic related to their disease status and medication.
Methods: Patients with CIRD were contacted by telephone to assess their health status and ask for changes in medication. Standardized assessment tools were used to assess disease activity, depression and anxiety. High disease activity was assumed if RADAI-5 ≥ 3.2 and BASDAI ≥ 4. Anxiety (HADS-A) and depression (HADS-D) of patients were assessed using HADS. A score < 8 was taken as indication of no major problem in this regard.
Results: A total of 886 patients was interviewed between April 15 and June 15 of 2020. Here we report on 550 patients with complete information on standard assessments (62%). About 60% were female, mean age 54.4±13.7, mean disease duration 12.2±10.5 years. Most had spondyloarthritis (SpA, n=287) including axial SpA (axSpA, n=172) and psoriatic arthritis (PsA, n=116), in total 52.2%, while 40.2% had rheumatoid arthritis (RA, n=221), and 7.6% connective tissue diseases (CTD, n=42). Most RA patients were on methotrexate (48.8%), while 43.8% took glucocorticoids. In addition, 61.0% of patients were on bDMARDs, mostly on TNF inhibitors (59.6%). More SpA than RA patients were on bDMARDs: 71.0% vs 49.7% respectively. A recent change in medication was reported by 182 patients (33.1%): 89 with RA (40.2%), 88 with SpA (30.6%) and 5 with CTD (11.9%). Half of those who changed (n=92; 50.5%) admitted that the change was mainly made due to fear of the pandemic (16.7% of all patients). Altogether, significantly more patients changed bDMARDs (68.5%) than csDMARDs (57.3%). The data of patients who changed vs patients who didn't change is shown in the Table 1, including subgroup analyses. The median HADS scores were < 8.
Conclusion: Two thirds of patients did not change medication but one third changed. A relatively high number of patients did so due to fear of the pandemic, mostly those on biologics. There were no major differences between RA and SpA. Anxiety and depression do not seem to play an important role for the decision to change medication (Table 1 below).

AB0685 IMPACT OF COVID-19 ON PATIENTS WITH RHEUMATIC DISEASES: EXPERIENCE OF THE DEPARTMENT OF RHEUMATOLOGY OF THE UNIVERSITY HOSPITAL OF IBN ROCHD OF CASABLANCA

H. El Moutaouakil[1], Z. El Ouali[1], K. Nassar[1], S. Janani[1]. [1]*University Hospital of Ibn Rochd, Department of Rheumatology, Casablanca, Morocco*

Background: The COVID-19 outbreak has been a source of major concern for the management of rheumatic patients, particularly those under immunosuppressants. It is generally admitted that patients followed for autoimmune diseases have an increased risk of infectious complications compared to the general population (1). However, to date, there is no established relationship between autoimmune diseases and an increased risk of infection with SARS-CoV-2 (2).
Objectives: The primary objective was to assess the severity of COVID-19 in patients followed in our department. The secondary objective was to assess the subgroup of patients on immunosuppressants.
Methods: We conducted a descriptive retrospective study of patients followed in the Department of Rheumatology of the University Hospital of Ibn Rochd, Casablanca. The patients who presented with COVID-19 between 08/2020 and 12/2020 were included. Epidemiological, clinical, therapeutic, and evolutionary data were collected and analyzed.
Results: Our series included 30 patients, with a sex ratio M/F of 0.3. The mean age of the patients was 46.4 years (±16.3), with a mean follow-up time of 8.1 years. 7 patients had a metabolic syndrome. Patients were followed for rheumatoid arthritis (n = 4), spondyloarthritis (n = 10), systemic lupus erythematosus (n = 5), scleroderma (n = 2), polymyalgia rheumatica (n = 1), adult onset Still's

Table 1. RA and SpA patients who changed and who did not change their medication

Group (N) / Reason	N	Active disease (%)	HADS-D ≥ 8 (%)	HADS-A ≥ 8 (%)	bDMARD therapy (%)
Rheumatoid arthritis	221	134 (60.6)	76 (35.0) [4]	94 (43.3) [4]	110 (50.9) [5]

Data are presented as numbers (percentage proportions; across rows except for column N) or medians (interquartile ranges). Missing values are in square brackets.[a] P values calculated using χ^2 test or Mann-Whitney rank sum test.[b] Self-reported claim of disease activity.

disease (n = 1), polyosteoarthritis (n = 6), benign osteopathy (n = 1). 17 patients were in low disease activity when they presented the COVID-19. 8 patients presented moderate to high activity, of which 2 (25%) developed a form requiring hospitalization. 7 patients were under NSAIDs, 13 under corticosteroids, 19 under csDMARD, 7 under bDMARD. The COVID-19 disease was symptomatic in 83% of cases, with fatigue (68%), cough (52%), back pain (48%), anosmia (48%), ageusia (44%), arthritis (44%), fever (36%). The diagnosis was made with polymerase chain reaction (83%), serology (10%), CT scan (23%). The CT lung lesions reached 25-50% in 2 lupus patients with a moderate disease activity, under corticosteroids and hydroxychloroquine. The involvement was > 75% in 2 patients, who admitted to intensive care: one was followed for polyarthrosis and was hypertensive and poorly balanced diabetic, and the other was followed for Horton's disease. The treatment was administered on an outpatient basis in 77.4% of cases, in an intensive care unit in 16% of cases. 30 patients fully recovered from infection, one patient died secondary to pulmonary embolism. The subgroup of patients on immunosuppressants consisted of 23 patients (76%), of whom 5 (22%) developed a moderate to severe form of COVID-19 requiring hospitalization. Among these hospitalized patients, 2 (40%) had moderate to high disease activity of their rheumatism.

Conclusion: Most of the patients in our series presented a mild form of COVID-19, including those under immunosuppressants. Patients who were under hydroxychloroquine were not spared from COVID-19, but developed a mild form. The disease activity of the chronic rheumatism did not appear to influence the severity of the COVID-19.

AB0686 IMPACT OF COVID19 IN SPONDYLOARTHRITIS (SPA) PATIENTS IN A TERTIARY HOSPITAL

C. L. Garcia Gomez[1], D. Montero[1], L. Vega[1], O. Ibarguengoitia[2], I. Calvo[2], C. E. Perez[1], J. M. Blanco[1], E. Galindez[1], A. R. Inchaurbe[1], M. E. Ruiz[1], I. Torre[1], E. Cuande[1], I. Gorostiza[3], M. R. Exposito-Molinero[1], M. L. García Vivar[1].
[1]Universitary Hospital of Basurto, Rheumatology, Bilbao, Spain; *[2]Hospital of Galdakao, Rheumatology, Galdakao, Spain*; *[3]Universitary Hospital of Basurto, Investigation, Bilbao, Spain*

Background: This tertiary hospital is the referall centre of 360.000 inhabitants, population with a Covid seroprevalence of 8,4% at final 2020.

Since march, we have had a special concern for rheumatologic patients with systemic diseases and under inmunosupressive agents, including disease modifying antirheumatic drugs (DMARDs) and biological therapy (BT). This is why a special protocol for this population was set. It included performance of serology (CLIA test) for patients under BT and PCR and CLIA testing prior to new treatments. PCR testing was also generally performed: if symptomatology consistent with Covid; before hospitalisation; to tight contacts of infected people; and before procedures.

Objectives: To evaluate the impact of COVID-19 in our SpA patients in terms of severity of viral infection and its effect on SpA.

Methods: Data of 665 SpA patients and confirmed Covid infection seen in our center from March 15th to December 15th was crossed. 3 miscoded patients with rheumatoid arthritis and 2 with non definite CLIA positivity were excluded. Finally 49 patients' clinical records were reviewed. Data regarding epidemiologic features, SpA characteristics, comorbidities, therapy received, clinical activity before and after Covid, and severity of the infection was collected. IBM SPSS v23 was used for statistical analysis.

Results: Among 49 SpA patients, 59% were male, mean aged 56,63 years (range 23-79). 62,2% presented at least 1 comorbidity. 65% were psoriatic arthritis. They mostly had longstanding disease (median 10,5 years -range- 1-35). Previously 63% had received DMARDs, mainly methotrexate, and 32 % BT.

When Covid was diagnosed 37,2% were under DMARDs and 53% under BT (69,2% TNF inhibitors, 26,9% anti-Il 17, 3,9% ustekinumab). At this point, disease activity was controlled in 82% of patients (39% in remission, and 43% in low disease activity state). Only 18% showed moderate activity.

Within the 49 patients, 34 were diagnosed by PCR and 15 by CLIA tests. 9 required hospitalisation, of whom 4 developed more severe disease (3 received glucocorticoid pulses and 2 tocilizumab). A woman with PsA under secukinumab presented pneumonia and PE. None required mechanical ventilation. There were no exitus.

Due to Covid infection 9 patients (50%) stopped DMARDs treatment, (5 of them hospitalised). 9 patients withdrew BT after Covid diagnosis; 60% of the BT-hospitalised, and 28.5% of the BT- non-hospitalised. 1 suffered a flow with severe disease activity after withdrawal of Il-17 inhibitor.

Conclusion: Prevalence of SARS cov 2 infection in SpA patients was not greater than in general population. Most were asymptomatic or suffered mild disease. Only 9 were hospitalised. Factors related to hospitalisation seem similar to those of general population, even if statistical significance was not found due to the small sample. BT does not seem to relate to hospitalisation in SpA and we had no deaths to date in them.

More studies should be made to throw out conclusions.

Baseline characteristics of SpA patients with confirmed Covid19	Hospitalised (N 9)	Non-hospitalised (N 40)	Total (N 49)
Mean age (range) – yr	62,56 (43-74)	55,3 (23-79)	56,63 (23-79)
Male sex - no. (%)	6 (66,6)	23 (57,5)	29 (59,1)
Smoking habit (active, ex-smokers) - no. (%)	2 (22,2)	23 (57,5)	25 (51)
Non comorbidities - no. (%)	2 (22,2)	17 (42,5)	19 (38,8)

AB0687 EFFECT OF COVID-19 ON PATIENTS ATTENDING AMBULATORY DEEP VENOUS THROMBOSIS OUT-PATIENT CLINIC: A RETROSPECTIVE, COHORT ANALYSIS[KI1] [KI1]101 CHARACTERS

T. Hill[1], K. P. Iyengar[1], A. Nune[2]. *[1]Southport & Ormskirk Hospital NHS Trust, Trauma and Orthopaedics, Southport, United Kingdom*; *[2]Southport & Ormskirk Hospital NHS Trust, Rheumatology, Southport, United Kingdom*

Background: COVID-19 has been acknowledged as an procoagulant disorder with increased risk of venous thromboembolism (VTE) [1]. High rates of VTE in patients admitted to intensive care unit have been reported [2]. However effect of COVID-19 on ambulatory patients attending out-patient clinics has not been described.

Objectives: This retrospective, observational cohort study analyses the impact of COVID-19 on incidence of Deep Venous Thrombosis (DVT) in patients referred to Ambulatory Deep Venous Thrombosis Out-patient Clinic (ADOC). A comparative analysis of patients attending ADOC during a similar period in 2019 is undertaken.

Methods: Patients who attended the ADOC with suspected DVT during the 'first wave' of the COVID-19 pandemic between 01 February and 30 June 2020 at Southport and Ormskirk NHS Trust were studied and compared to a similar period in 2019. Patients characteristics, comorbidities, risk factors, incidence of DVT and relationship with COVID-19 with the evaluation of haematological parameters including D-dimer and two- tier Wells score. Additionally we examined patients outcomes including morbidity, mortality and hospital admissions.

Results: Overall, there was a decrease in the number of patients attending the ADOC from 290 in 2019 to 233 in 2020. However, a total of 38 patients tested positive for DVT, a rate of 16.3%, which is compared to an incidence of 7.9% in 2019. Due to evolving protocols, the COVID-19 status of all patients attending the ADOC could not be ascertained. However, 5/233 of the 2020 cohort patients either had a positive test result (n=4) or were symptomatic of COVID-19 (n=1).

Conclusion: There has been a 129% increase in the incidence of DVT in patients presenting to ADOC at our trust during the 'first wave' of the COVID-19

pandemic. Furthermore, despite fewer patients presenting with DVT symptoms to the ADOC, there appears to be a higher incidence of confirmed DVTs in ambulatory patients during COVID-19.

Although there is a strong association inferred between COVID-19 and VTE [3], lack of access to SARS-CoV-2 nasal swab testing of patients attending ADOC for VTE assessment was a limiting factor to establish an association in this study. Because of this, we cannot extrapolate a definite association in patients with mild to moderate COVID-19 illness in the community and DVT.

What we postulate is perhaps the higher incidence in the 2020 cohort could be a marker for a mild case of asymptomatic COVID-19 in these patients. Currently there is no guidance as to whether point of care testing should be available in ADOC. We wonder whether a point of care COVID-19 testing of these patients would have positive impact on the rate at which COVID-19 is identified in the community. Furthermore patients have been avoiding hospitals during the pandemic, greater testing should help to reassure and encourage them to seek help earlier during their illness, minimising potential complications such as PE, hospital admission and death.

AB0688 SEVERITY OF COVID-19 INFECTION IN RHEUMATIC IMMUNE-MEDIATEDINFLAMMATORY DISEASES. STUDY IN A SINGLE UNIVERSITY HOSPITAL

D. Martínez-López[1], D. Prieto-Peña[1], L. Sanchez-Bilbao[1], A. Herrero-Morant[1], C. Álvarez-Reguera[1], M. Trigueros-Vazquez[1], M. A. González-Gay[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*

Background: Immune-mediated inflammatory diseases (IMID) may have a global increased risk of infections due to the disease itself, and/or immunosuppressive therapy. The severity and characteristics of COVID-19 in patients with rheumatic IMID (R-IMID) remain unknown.

Objectives: To analyze the severity of COVID-19 infection in R-IMID.

Methods: Cross-sectional study in a single University Hospital. We included all consecutive patients with a diagnosis of a R-IMID and a positive test for COVID-19 up to November 6th, 2020. Confirmed infection was defined if the patient had a positive nasopharyngeal swab for SARS-CoV-2.

Medical records of 11,199 patients with COVID-19 in our region, and 6891 with R-IMID from our hospital were reviewed.

COVID-19 case severity was divided into mild, moderate, severe and critical according to the United States National Institute of Health (NIH) COVID-19 guidelines **(1)**. Mild/moderate COVID19 was compared with critical.

Results: We included 147 patients (96 women/51 men), mean age 60±18 years. Most cases were mild to moderate (n=123, 83.7%), 30 of them (20.4%) were asymptomatic. The remaining patients presented severe (n=5, 3.4%) or critical (n=19, 12.9%) disease (Table 1). Fatal outcome occurred in 12 patients (8.2%).

More frequent underlying R-IMID were Rheumatoid Arthritis (n=36; 24.5%), Psoriatic Arthritis (n=30; 20.4%), axial spondyloarthritis (n=24; 16.3%), conectivopathies (n=19; 12.9%), polymyalgia rheumatica (n=16; 10.9%) and vasculitis (n=9; 6.1%) (Figure 1).

Main comorbidities were hypertension (n=65, 44.2%), dyslipidemia (n=64, 43.5%), age higher than 65 years old (n=55, 37.4%), obesity (n=35, 23.8%), coronary vascular disease (CVD) (n=27, 18.4%) and diabetes mellitus (n=22, 15%).

Comorbidities and R-IMID associated with critical disease (p<0.05) were hypertension, age higher than 65 years,CVD and Polymyalgia Rheumatica. Critical compared with mild/moderate disease showed significantly higher levels of creatinine and D-dimer, and lower level of lymphocytes and platelets (Table 1) and received more frequently systemic glucocorticoids. Tocilizumab and Anakinra were used only in critical patients, 2 cases each.

Conclusion: Although most cases are mild, COVID-19 can be a severe life threatening disease in patients with R-IMID. Hypertension, older age, CVD and polymyalgia rheumatica were associated with critical disease.

Background: There are limited data worldwide on the behavior of SARSCOV2 in patients with Spondyloarthritis (SpA).
Objectives: To describe the incidence and severity of COVID-19 disease in patients with SpA in Argentina.
Methods: Patients with axial spondyloarthritis (AxSpA) radiological (EA) and non-radiological (AxSpA-nr) and peripheral spondyloarthritis (according to ASAS criteria) and psoriatic arthritis (PsA) (according to CASPAR criteria) were included. Sociodemographic data, comorbidities, disease activity and treatments were collected at baseline. The patients were followed up by phone or in person monthly. Data were collected from 1/4/2020 to 9/20/2020. Descriptive statistics were performed with mean and standard deviation (SD) and median and quartile 25-75 according to distribution, and the cumulative incidence (AI) of the disease was calculated.
Results: 320 patients were included, of which 55% were male, with a mean age of 50 SD 13, 21.6% had a diagnosis of AS, 6.9% SpAax-nr, 6.9% SpAp, and 64.7% PsA, BASDAI 3.65 (3), BASFI 3 (1.5-9), PASI 0.3 (0-7), BSA 0.2 (0-6). Fourteen patients with a diagnosis of COVID-19 (4.4%) were reported, of which 10 diagnoses were by positive PCR and 4 by positive symptoms and close contact. 93% (13) of the cases were patients from the Province of Buenos and CABA and 1 patient from Santiago del Estero. The total IA for the country was 0.04. Of the 14 patients with COVID-19, 7 (50%) were men, 4 had a diagnosis of AS, 1 of SpAax-nr, 9 (64.3%) PsA. 100% live in urban areas, 2 (14%) have hypertension, 1 (7%) DBT, 1 (7%) COPD, 2 (14%) depression or anxiety, 11(97%) had received influenza vaccine 2020, 13 (93%), Antineumoccic 23, 14 (100%) Antineumoccic 13. Regarding the treatments: 4 (28.6%) were in treatment with anti TNF (3 with Adalimumab, 1 with certolizumab pegol), 4 (28.6%) with Anti IL17 (3 with Secukinumab, 1 with Ixekizumab), 8 (57%) with methotrexate and 2 (14%) with Leflunomide. Place of follow-up of the disease: 10 (71.4%) at home, 3 (21.4%) in the common room and 1 (7) in the intensive care unit. Treatments received for COVID-19: 1 (7%) antiretroviral, 1 (7%) antibiotic and 1 (7%) steroids. None of the patients died from COVID-19.
Conclusion: An incidence of 4.4% of COVID-19 was found in this population with SpA and most of the patiend had mild symptoms and no deaths were reported.

AB0690 HOW DID COVID-19 AFFECT PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES TREATED WITH DMARDS – EXPERIENCE FROM A ROMANIAN RHEUMATOLOGY HOSPITAL

A. Trandafir[1], I. Saulescu[1,2], A. Balanescu[1,2], D. Opris-Belinski[1,2], V. Bojinca[1,2], F. Berghea[1,2], D. Mazilu[1,2], S. Daia-Iliescu[1,2], D. Predeteanu[1,2], A. Borangiu[1,2], L. Groseanu[1,2], M. M. Negru[1,2], C. L. Constantinescu[1,2], M. Abobului[1,2], V. Violeta[1,2], R. Ionescu[1,2]. *[1]Saint Mary Hospital, Internal Medicine and Rheumatology, București, Romania*; *[2]Carol Davila University of Medicine and Pharmacy, Internal Medicine and Rheumatology, București, Romania*

Background: Certainly, the year 2020 changed the healthcare system due to SARS-CoV2 pandemic that affected globally, more than 100 million people, causing more than 2 million of deaths worldwide. The evidence of how this infection impact patients with rheumatic and musculoskeletal diseases treated with disease modifying anti-rheumatic drugs is still an unmet need.
Objectives: The main focus of this study is to evaluate the influence of DMARDs therapy on the evolution of COVID-19 disease in patients with RMDs. The second objective is to study and find correlations between the severity of infection in patients with rheumatic diseases.
Methods: A retrospective observational study was conducted between June 2020 and January 2021, enrolling 81 patients with rheumatic diseases that went through SARS-CoV2 infection. The data was collected using patients' clinical documents and through telemedicine, in accordance with EULAR COVID-19 Rheumatological Database.
Results: Among the 81 patients, 53 (65,43%) were females and 28 (34,56%) were males. The mean age was 47,9 years old (49,49 years old for females and 45,25 years old for males). The majority lives in urban areas – 62 patients (76,54%).
The temporal trends of COVID-19 observed in this cohort was in consonance with the evolution of the pandemic in Romania: one third of cases were recorded between June and October 2020 and two-thirds between November 2020 and January 2021, when the number of COVID-19 cases tripled in the general population.
Surprisingly, more than 27% of patients in this study were asymptomatic at the time of COVID-19 diagnosis. They were tested according to the protocol before admission to the hospital. 9,8% of patients also asymptomatic, were tested positive as a screening before leaving the country. The majority (45,6%) were symptomatic or contact with someone infected with SARS-CoV2-and tested positive with RT-PCR.
We divided the cohort in 3 groups: patients with mild infection that required no hospitalization (22 patients counting for 27,16%), moderate infection – hospitalization but not in the Intensive Care Unit (52 patients – 64,19%) and severe infection – admission to the ICU/deaths (7 patients in the ICU, 4 deaths – 4,9%).
Mild and moderate COVID 19 disease was identified in patients with axial spondyloarthtis (56,7%), with remission or with low disease activity, with a few or no comorbidities, with a mean age of 47,56 years old and also in patients in treatment with MTX (14,86%) or TNF alfa inhibitors (35,13%). 51% of patients stopped the therapy during COVID19 diseases.
Factors correlated with severe infection and death were age (the mean age was 62,14), high and moderate disease activity RA, overlap syndromes (RA with SLE or Sjogren Syndrome) and important cardiovascular comorbidities. Two of the deceased patients were in treatment with MTX and RTX (the last infusion was more than 6 months).
Conclusion: The data in our study suggests that the use of cs DMARDs (MTX) and TNF alfa inhibitors is associated with better outcomes for patients with RMDs and COVID-19. These results are in accordance with the data found in literature [1,2,3]. The limitation of this study is the little number of patients and the fact that the real number of COVID-19 cases might be higher in reality due to asymptomatic or pauci-symptomatic patients.

ANALYSIS OF SARS-COV-2 ANTIBODIES IN NON-COVID-19 PATIENTS: COMPARISON BETWEEN SYSTEMIC SCLEROSIS PATIENTS AND HEALTHY CONTROLS

L. Giardullo[1], C. Rotondo[1], A. Corrado[1], N. Maruotti[1], R. Colia[1], A. Altomare[1], E. Sanpaolo[1], D. Cici[1], F. P. Cantatore[1]. [1]*University of Foggia "Policlinico Riuniti", Medical and Surgical Sciences, Rheumatology Clinic "Mario Carrozzo", Foggia, Italy*

Background: Previous study evidenced a cross-reactivity between Sars-Cov-2 antibodies and autoimmune tissue antigen involved in connective tissue diseases, as nuclear antigen (NA), extractable nuclear antigen (ENA), histone and collagen (1). No study has been published about the titer of Sars-Cov-2 antibodies in non-infected patients with autoimmune disease.

Objectives: To evaluate the titer of SARS-CoV-2 antibodies in non-COVID-19 patients and compare it between systemic sclerosis (SSc) patients and healthy controls (HC).

Methods: A total of 58 patients with SSc (who fulfilled ACR/EULAR 2013 SSc classification criteria) and 18 HC were enrolled. Sera of all participants were collected, and SARS-CoV-2 antibodies (IgG and IgM) were evaluated by means ELISA. In all participants swabs for SARS-CoV-2 by real-time reverse-transcriptase-polymerase-chain-reaction assay were reported negative. Demographic, clinical, and autoimmune serological characteristics of SSc patients were recorded. The normal distribution was assessed using the Shapiro–Wilk's test. Exclusion criteria was previous or actual Sars-Cov-2 infection. Comparisons between study groups of patients were evaluated by the Student's t-test or Mann – Whitney U-test as appropriate. The differences between categorial variables were assessed by Pearson chi-square or Fisher's exact test, as opportune. Statistical significance was set at $p \leq 0.05$.

Results: We observed significant differences between SSc patients and HC in serum levels of Sars-Cov-2 antibodies (IgG: 1,4±2,1 AU/ml vs 0,36±0,19 AU/ml respectively (p=0,001); and IgM: 2,5±3,1 AU/ml vs 0,8±0,7 AU/ml (p=0,022)). In 5 SSc patients was found titer of Sars-Cov-2 antibodies (IgG) exceeding the cut-off, but the control of swabs for SARS-CoV-2 by real-time reverse-transcriptase-polymerase-chain-reaction assay were negative. No significative differences in Sars-Cov-2 autoantibodies titer were found in subgroup of SSc patients with or without ILD or PAH, limited or diffuse skin subset, and different autoantibodies profile. Furthermore, antibodies titer was not associated with different drugs (steroid, methotrexate, mofetil-mycophenolate and bosentan) in use.

Conclusion: A cross mimicking between Sars-Cov-2 antibodies and antinuclear antibodies or anti ENA could be hypothesized. Further studies are necessary to unravel the reliability of Sars-Cov-2 antibodies detection in autoimmune disease.

REACTIVE ARTHRITIS ASSOCIATED WITH COVID-19 INFECTION: A REVIEW

F. Alkindi[1], K. Alseiari[2], K. Al Naqbi[3]. [1]*Tawam Hospital, Internal Medicine, Al Ain, United Arab Emirates*; [2]*Tawam Hospital, Internal Medicine, AlAin, United Arab Emirates*; [3]*Tawam Hospital, Rheumatology Department, AlAin, United Arab Emirates*

Background: The incidence of COVID-19 infection is increasing globally with high mortality rate. Cytokine release syndrome might contribute to extra-pulmonary manifestations such as acute kidney injury, venous thrombosis, neurological complications, hepatic and myocardial injury. Reactive arthritis is an emerging musculoskeletal (MSK) manifestation post COVID-19 infection. Reactive arthritis manifests as asymmetrical, oligoarthritis mainly involving peripheral or axial joints of lower extremities and associated with extra-articular manifestations.

Objectives: review the clinical presentation and management outcomes of COVID-19 associated reactive arthritis.

Methods: A literature research was conducted using PubMed and Google scholar for published abstracts, case reports, and studies from January 2020 to January 2021. We used search keywords" reactive arthritis", "COVID-19 pneumonia", " SARS CoV2 infection", and "Musculoskeletal". Descriptive analysis was used due to small sample size.

Results: COVID-19 associated reactive arthritis is rarely reported. In review of literature, 10 cases were identified and we included our case of hip arthritis and avascular necrosis post COVID-19 infection. The mean age of cases (n=11) was of 42.8 years and 54.5 % of patients were males. (Table 1) The median duration of reactive arthritis diagnosis from COVID-19 infection ranged from 1 to 8 weeks. The severity of COVID-19 infection varied from mild (n= 6) to severe disease (n=2) per description in each reported case. Majority of the patients had oligoarticular involvement (2 to 4 joints) 45.5%, followed by monoarticular 36.4%, and polyarticular (> 4 joints) in 18%. Extra-articular manifestations were identified in 54.5% of patients including skin rash (erythematous itchy rash), urticarial rash, wrist tendinitis, Achilles enthesitis /tendonitis and balanitis. HLA-B27 testing was done in five patients and only one patient had a positive result. Plain radiographs were normal. Therapy provided of such cases were NSAIDS (n=4), steroids (oral, intra-articular) (n=1) or combination of steroids and NSAIDS (n=3) with favorable outcomes. The median reported follow up period ranged from 1.5 to 8 weeks.

Table 1. Characteristics of the reported reactive arthritis cases post COVID-19 infection

Clinical data of patients (n=11)	**Results (n=11)**
Age (mean)	42.8 Years old
Sex %	Female (n= 5 [45.5%])
	Male (n= 6 [54.5%])
Severity of COVID-19 infection	Mild (n=6 [54.5%])
	Moderate (n=3 [27.3%])
	Severe (n= 2 [18%])
Prior history of rheumatologic disease	(n=0)
Time to onset of reactive arthritis (median)	1 to 8 weeks
Number of joints involved at time of diagnosis	Monoarticular (n= 4[36.4%])
	Oligoarticular (n= 5[45.5%])
	Polyarticular (n= 2[18%])
Location of involved joints (upper vs. lower limbs)	Upper joints (18%)
	Lower joints (54.5%)
	Both (27.3%)
Enthesitis	(n= 1[9%]) Achilles
Tendonitis	(n= 2[18%]) (wrist / Achilles tendonitis)
Extra-articular involvement (eyes, skin, GI, GU, others)	- Skin rash (n=2 [18%]) (erythematous itchy rash, urticarial rash)
	- GU: balanitis (n=1 [9%])
Inflammatory back pain	(n=0)
Avascular necrosis of bone	(n= 1[9%])
HLA-B27	(n= 1[9%]), (n = 5 tested)
Autoimmune workup	Negative
Treatment of reactive arthritis:	DMARDs (n=0)
	NSAIDs (n=4 [36.4%])
	Steroids (n=1 [9%])
	NSAIDs and steroids (n= 3[27.3%])
	Not provided (n=2), others (n=1)
Outcomes of MSK symptoms	Improvement (n=11 [100%])
Follow up period (Median, weeks)	1.5 to 8 weeks

Gastrointestinal (GI), genitourinary (GU), NSAIDs: non-steroidal anti-inflammatory drug

Conclusion: Reactive arthritis is a rare MSK manifestations post COVID-19 infection. HLA-B27 positive testing might indicate severe and delayed form of arthritis with risk of recurrence. Larger studies are required to delineate the potential risk factors and long-term management outcomes for reactive arthritis associated with COVID-19 infection.

AB0693

NON-STEROIDAL ANTI-INFLAMMATORY DRUGS DURING CORONAVIRUS 19 PANDEMIC: WHAT DO TUNISIAN RHEUMATOLOGISTS THINK?

H. Ferjani[1], H. Boussaa[1], K. Maatallah[1], H. Khalfalli[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rheumatology, La Manouba, Tunisia*

Background: Concerns over the safety of non-steroidal anti-inflammatory drugs (NSAIDs) use during severe acute respiratory syndrome associated with coronavirus 19 disease (covid-19) have raised. NSAIDs are one of the most commonly prescribed and used pain medications for acute and chronic rheumatic diseases such as spondyloarthritis (SpA) and osteoarthritis.

Objectives: This study aimed to assess the impact of covid-19 pandemic on NSAIDs prescription.

Methods: A cross-sectional web survey was disseminated to all Tunisian rheumatologists through a mailing system and social media. The French version was accessible on Google form. It included close-ended questions about the prescription of NSAIDs during covid-19 pandemic. Participation was anonymous. Data collection and analysis was performed between January the first and January 30, 2021.

Results: Among one hundred and thirty Tunisian rheumatologists, thirty responded to the online questionnaire. Ninety percent of participants were women. The mean age of rheumatologists was 34 years [25-57]. The duration of

practice was inferior to 5 years in 59.3%, between 5 and 10 years in 18.5%, and superior to 10 years in 22.2% of cases. Sixty-three percent of rheumatologists reported that their activity decreased during covid-19 pandemic. NSAIDs prescription was avoided as much as possible in 40.7% of cases.
The participants indicated NSAIDs less frequently in 33.3% of cases, and as much as before the pandemic in one-quarter of cases.
Rheumatologists believed that NSAIDs worsen the respiratory symptoms (67%), delay recovery (55%), and increase mortality (48%), hospitalization in intensive care (44%), and infectious complications (33%).
The participants suggested that the most incriminated NSAIDs were: Ibuprofen (7.4%), indomethacin (7.4%), celecoxib (7.4%), and diclofenac (3.4%). The majority of rheumatologists (74%) believed that all NSAIDs had a similar risk.
For patients with osteoarthritis, rheumatologists replaced NSAIDs with paracetamol and corticoids in 78% and 11% of cases, respectively. If mandatory, reducing NSAIDs doses or duration was an option in 22% and 74% of cases.
For patients with SpA, half of rheumatologists did not change the treatment. However, the participants limited the use of NSAIDs or discontinued the treatment in patients with comorbidities. More than 60% of rheumatologists didn't know the effect of NSAIDs in the post-covid-19 syndrome.
Conclusion: Covid-19 pandemic has affected rheumatologists' practice. Rheumatic disease management during this pandemic may be challenging. More evidence is mandatory to standardize treatment prescription, especially with NSAIDs.

AB0694 COVID-19 İNFECTION IN PATIENTS WITH RHEUMATIC DISEASES: TWO CENTERS EXPERIENCE

A. Şahin[1], M. A. Gedikli[2], M. E. Derin[3], B. Karakaş[1], B. Karataş[1], N. Çabuk Çelik[1], İ. Yalçın[1]. [1]*Sivas Cumhuriyet University, Internal Medicine – Rheumatology, Sivas, Turkey*; [2]*Sivas Cumhuriyet University, Internal Medicine, Sivas, Turkey*; [3]*Sivas Numune Hospital, Internal Medicine – Rheumatology, Sivas, Turkey*

Background: Coronavirus disease 2019 (COVID-19) is a new viral infection characterized by dry cough, fever, shortness of breath, fatigue and lymphopenia. It may be complicated by interstitial pneumonia leading to severe acute respiratory distress syndrome(1). The COVID-19 outbreak has increased concerns in those with rheumatological diseases(2).
Objectives: To present the clinical course of COVID-19 infection in patients with rheumatological disease and comorbid conditions of patients and drug use.
Methods: 70 COVID-19 patients with autoimmune and autoinflammatory rheumatic diseases over the age of 18 who were followed up in the internal diseases-rheumatology department of Sivas Cumhuriyet University Hospital and Sivas Numune Hospital between April 2020 and January 2021 were included in this study. An application was made to the ethics committee of Sivas Cumhuriyet University Hospital and approval was obtained. Demographic data, comorbidities, smoking, treatments for their diseases, symptoms and hospitalization status of the patients were evaluated.
Results: The median age of the women patients was 48 years (min: 20-max: 73), 41 years in men (min: 21-max: 78). 15 patients (21.4%) were male, 55 patients (78.6%) were female. The most common rheumatic disease was rheumatoid arthritis (RA, 21, 30%) followed by ankylosing spondylitis (19, 27.1%), familial Mediterranean fever (13, 18.6%), Behçet's disease (12, 17.1%). 22 (31.4%) patients hydroxychloroquine sulfate, 14 (20%) leflunomide, 7 (10%) patients methotrexate, 6 (8.6%) patients sulfasalazine, 10 (14.3%) patients azathioprine/mycophenolate mofetil, 22 (31.4%) patients were using colchicine. As a biological medicine; 20 (28.6%) patients were using infliximab, 5 (7.1%) patients were using adalimumab, 6 (8.6%) patients were using rituximab, and 4 (5.7%) patients were using tocilizumab. Other are summarized in Table 1. The most common comorbidities were hypertension (25.7%) and diabetes mellitus (DM 17.1%). While 56 patients (80%) had symptoms of COVID-19, 14 patients (20%) were asymptomatic. The most common symptoms was fever (32, 45.7%) followed by cough (29, 41.4%), dyspnea (28, 40%), myalgia (25, 35.7%), loss of taste and smell (18, 25.7%). 21 pneumonia cases were diagnosed. 22 (31.4%) patients were hospitalized. Mortality rate was 2/70, 2.9%. Two RA patients who just treated with rituximab and tocilizumab were died. 10 cases were using >10 mg/day prednisolone, 2 died, 8 cases were hospitalized and had severe disease. They had hypertension and DM. Characteristics of the patients are summarized in Table 2.
Conclusion: The course of COVID-19 in rheumatic diseases is not clearly. Meta-analysis has shown that the frequency of COVID-19 is increased in autoimmune diseases. However, this increase was mostly associated with the use of> 10mg/day prednisolone. It has been stated that the use of biological drugs and Dmard causes the SARS-CoV 2 process with a milder course and therefore their use is safe (3). Similar results have been obtained in global registry registers (4). In our data, there was no increase in the mortality rate compared to the normal population. However, especially the use of rituximab may increase the rate of severe disease and mortality, so its use should be careful. There is a need for more comprehensive studies.

AB0695 PATTERN OF COVID-19 IN PATIENTS WITH RHEUMATIC DISEASES UNDERGOING BIOLOGICAL THERAPY: A COHORT EXPERIENCE

C. Ancuta[1,2], C. Pomirleanu[1,2], G. Strugariu[2], L. Petrariu[2], E. Ancuta[3], C. Bran[4,5], R. Chirieac[6], C. Mihailov[7,8]. [1]*University of Medicine and Pharmacy "GRIGORE T. Background: Despite emerging vaccines, the world is in the midst of a coronavirus disease 2019 (COVID-19) pandemic. Outcomes of SARS-CoV2 infection remain a major concern in patients with rheumatic and musculoskeletal diseases, especially for those with uncontrolled disease.
Objectives: We aimed to investigate trends and outcomes of COVID-19 occurring in patients with chronic inflammatory rheumatic conditions treated with biologics and targeted synthetic disease modifying antirheumatic drugs (bDMARDs, tsDMARDs).
Methods: We included all confirmed cases of COVID-19 regardless of severity in patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) undergoing bDMARDs or tsDMARDs treatment registered in our local COVID-19 reporting database. We collected relevant information about comorbidities, rheumatologic-related clinical activity (RAPID5, SDAI, BASDAI, DAPSA), type of DMARD and glucocorticoid use, as well as COVID-19 related data as severity (ranging from asymptomatic to life-threatening forms), medication, hospitalization, intensive care unit admission, invasive mechanical ventilation and death.
We did a subgroup analysis among patients with a specific rheumatologic diagnosis, among different class of medication, patients who were or not hospitalized with COVID-19 looking how age, comorbidities, type of rheumatic condition and treatments impact COVID outcomes.
Results: 40 COVID-19 cases (positive PCR for SARS-CoV2) (4.67%) were identified during the 6-month study period among 855 patients registered in our database of patients under biologic treatment, including 20 RA, 18 SpA, 2 PsA patients. The majority were in either low disease activity or remission, only two patients had active uncontrolled disease at the onset of coronavirus infection.
16 cases (40%) were asymptomatic and were tested RT-PCR-positive during routine follow-ups for their disease, 13 cases (32.5%) had mild and 8 cases (20%) moderate illness; severe pneumonia and critical disease with acute respiratory distress syndrome were reported in only 3 cases, 2 recovered after; the only patients who died was 69 years old, had cardiac disease, hypertension and diabetes, had undertaken regular rituximab perfusion one month before coronavirus infection and developed pulmonary embolism followed by septic shock.
Extreme fatigue was the dominant COVID-19 associated symptom apart from the classical ones including fever, cough, shortness of breath, sore throat, nasal congestion, headache, anosmia and ageusia myalgias and anorexia.
No specific pattern for patients requiring intensive care unit admission.
Conclusion: The COVID-16 infection rate in patients with inflammatory rheumatic disorders receiving biologics and tsDMARDs is pretty low; although immunosuppressed, these patients seem not to be at risk for severe COVID-19 illness and outcomes. These findings might reflect a potential protective role of certain biologics and/or JAK inhibitors for development and severity of COVID-19 in patients.

AB0696 ANTI-PHOSPHOLIPID AUTOANTIBODIES IN COVID-19 PATIENTS

M. Jordhani[1], D. Ruci[1], V. Ruci[2]. [1]*UHC Mother Teresa, Tirana, Albania, Internal Medicine, Tirana, Albania*; [2]*University Trauma Hospital Tirana, Orthopaedics, Tirana, Albania*

Background: Because of the inflammation boosting cytokines, Coronavirus disease 2019 (COVID-19) has demonstrated thrombotic consequences that have increased its morbidity and mortality. There is evidence that mechanisms that contribute in thrombosis in COVID-19 patients are similar to those in anti-phospholipid syndrome (aPS). In fact, there is a possibility that anti-phospholipid autoantibodies (aPLs) might impulse thrombosis in patients with COVID-19, as literature suggests[2].

Objectives: The aim of our study was to evaluate the anti-phospholipid autoantibody titre in patients with COVID-19 during and after the infection.

Methods: This is an observational study which included 71 patients with a recent COVID-19 up to 4 weeks after. Every patient was completed with aPL titre about IgG and IgM anti-cardiolipine (ACA) and lupus anticoagulant (LAC) autoantibodies. According to titre results, the patients were divided into groups in order to better show the immunologic results.

Results: After gathering and analysing the data, it was estimated that 21 patients (29.6%) were positive for at least one type of aPL antibody: 12 patients were found positive for lupus anticoagulant autoantibodies (57.1%), 6 patients were double positive for LAC and ACA (28.6%), and 3 patients were positive for anti-cardiolipin antibodies (14.3%). Seven patients were IgM positive for any aPL (33.3%), 6 patients were found to have positive IgM and IgG (28.6%) and 8 patients had only IgG antibodies (38.1%).

Conclusion: From this study it was observed that a significant proportion of patients with recent COVID-19 infection had positive anti-phospholipid antibodies, compared to the general population prevalence. This suggests that the impact of aPLs in COVID-19 might be of great importance. It should be carefully evaluated in order to better understand the mechanisms of thrombotic complications.

AB0697 ANTI-SARS-COV-2 ANTIBODIES AND AUTOANTIBODIES IN COVID-19 PATIENTS SURVIVED AFTER ICU ADMISSION, 6 MONTHS LATER

K. Bitzogli[1], E. Magira[2], L. Chatzis[1], E. Jahaj[2], H. Alexopoulos[1], M. Dalakas[1], A. Kotanidou[2], A. Tzioufas[1], P. Vlachoyiannopoulos[1]. [1]*School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece*; [2]*School of Medicine, National and Kapodistrian University of Athens, 1st Department of Intensive Care Medicine, Athens, Greece*

Background: We[1] and others[2] have previously shown that ICU admitted patients with COVID-19 developed high titers of anti-SARS-CoV-2 antibodies, but also autoantibodies, some of which are pathogenic. We re-evaluated 8 patients of those survived after admission to the ICU of Evangelismos Hospital of Athens -1st Department of Internal Medicine, Medical School, NKUA[3] 6 months later. We did not know whether these autoantibodies still exist, are associated with COVID-19 or with ARDS as described after septic shock[4].

Objectives: To investigate the presence and titers of anti-SARS-CoV-2 antibodies and autoantibodies in patients survived after COVID-19 ICU stay, in the ICU and 6 months later.

Methods: Case series to evaluate titers of anti-SARS-CoV-2 antibodies, specificities of autoantibodies as well as clinical features in ICU admitted COVID-19 patients, initially and 6 months after their discharge. Evaluation of current clinical status included evaluation of lung, heart, kidney, central and peripheral nervous system and mental status using standardized methods. Methods for detection of anti-SARS-CoV-2 antibodies and autoantibodies were described in our previous report[1].

Results: We had initially evaluated[1] 29 ICU admitted COVID-19 patients' files and sera, of which 4 had been already died during serum evaluation. Six more patients died thereafter. Out of 19 having been discharged, 8 were willing to be re-evaluated. On second evaluation 6 months later, serum anti-SARS-CoV-2 antibodies were highly positive, although at lower titers compared to the titers at disease onset (median [range]) 8.705 (range: 7.95-9.56) vs 6.640 (range: 6.29-6.76), p=0.0002, Mann-Whitney test. Initially 3 out of 8 patients expressed antinuclear antibodies (ANA) at titers 1/160, 1/320 and 1/320 with a fine speckled pattern with the second patient also expressing at a titer of 1/160, antimitochondrial (AMA) antibodies. Six months later the same patients and not anyone else expressed ANA of the same pattern at titers 1/640, 1/160 and 1/160 respectively. Two patients with 1/20 p-ANCA and 1/640 c-ANCA initially, lost their respective autoantibodies after 6 months. One patient initially negative for IgM anti-β2GPI became positive at low titer and an initially positive became negative. One patient initially positive for anti-Ro60 antibody continued to be positive 6 months later. One patient initially negative developed anti-Tg antibodies and 3 patients initially positive for anti-TPO antibodies remained positive 6 months later.

Conclusion: Patients with COVID-19 survived after ICU admission still retain high titers of anti-SARS-CoV-2 antibodies but significantly lower that at disease onset, but they tend to lose autoantibodies with pathogenic potential.

AB0698 CORONAVIRUS 19 DISEASE VACCINE: PERCEPTIONS AND INTENTIONS OF TUNISIAN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Ben Abdelghani[1], H. Boussaa[1], S. Miladi[1], M. Sellami[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], A. Fazaa[1], A. Laatar[1]. [1]*Mongi Slim University Hospital, Rheumatology, La Marsa, Tunisia*

Background: Coronavirus disease 2019 (covid-19) has now spread to millions of persons worldwide to become a global pandemic. Covid-19 is asymptomatic for some individuals and for others it can cause symptoms ranging from flu-like to acute respiratory distress syndrome, pneumonia and death. Several vaccine candidates are now available, and patients with chronic inflammatory disease such as rheumatoid arthritis (RA) are encouraged to get vaccinated.

Objectives: The aim of this study was to determine perceptions of RA patients about the covid-19 vaccine.

Methods: We conducted a cross-sectional study including Tunisian patients with RA (ACR/EULAR 2010). Demographic and disease parameters were collected: age, gender, educational status, disease duration, erythrocyte sedimentation rate (ESR), disease activity score (DAS28), and treatments being used. All patients responded to a questionnaire on their perceptions and concerns about the covid-19 vaccine, and whether they intended to get vaccinated or not. A *p* value inferior to 0.05 was considered significant.

Results: We included 54 patients (45 women and nine men) with a mean age of 55±11 years old [23-69]. Thirty-one percent of patients were illiterate. The mean disease duration was 9.9±5.9 years [0-20]. The mean DAS28 ESR was 4.68±1.35 [1.50-7.16].

NSAIDs were used in 13% of patients, corticosteroids in 63% of patients at a mean daily dose of 8mg [2.5-20] of prednisone equivalent, methotrexate in 63% of patients, sulphasalazine in 13% of patients, leflunomide in 3.7%, and biologics in 22.2% of patients.

None of these patients had contracted the covid-19. Seventeen percent of patients had been in close contact with someone positive for the disease. All the patients reported that they respected the preventive measures. Fifteen percent of patients had stopped their treatment because they were afraid of the covid-19: Methotrexate (n=4), sulphasalazine (n=1), tocilizumab (n=2), and rituximab (n=1).

More than half of patients (67.7%) reported that they didn't want to get vaccinated against covid-19. The reasons given by these patients were: presumed adverse events (100%), religious beliefs (86.7%). presumed inefficiency (83.3%), no recommendation from their doctor (80%), fear that the vaccine would interact with their treatment (76.7%), lack of trust in the pharmaceutical laboratories (76.7%), fear from vaccines in general (53.3%), fear that the vaccine would make RA worse (50%), and presumed overprice of the vaccine (30%).

A significant association was noted between educational status and, religious beliefs (p=0.001), lack of trust in the pharmaceutical laboratories (p=0.007), fear that the vaccine would make RA worse (p=0.008) or interact with other treatments (p=0.022), and presumed overprice of vaccine (p<0.001).
Conclusion: Most of RA patients expressed their unwillingness to get vaccinated against covid-19. Doubts about the vaccine's efficiency and security and religious beliefs were the main reasons for this choice.

AB0699 RETROSPECTIVE ANALYSIS OF 52 SARS-COV2 POSITIVE PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASE: A SINGLE CENTER EXPERIENCE

Y. Karabulut[1]. [1]*Private Yıldırım Doruk Hospital, Division of Rheumatology, Bursa, Turkey*

Background: It is a generally accepted opinion that autoimmune and inflammatory rheumatic diseases or drugs used in the treatment of these conditions increase the risk of infection. During the pandemic period, the follow-up and treatment of patients who were diagnosed with rheumatic disease and used corticosteroid, immunosuppressive, biological or synthetic DMARDs and disease management during sars-cov2 infection still remain a problem.
Objectives: In this study, it was aimed to share the demographic data of 52 patients with inflammatory rheumatic disease diagnosed with SARS-COV2 who were followed up and treated in the Rheumatology Department of Private Doruk Hospital during the SARS-COV2 pandemic. Additionally, it is aimed to examine the primary rheumatological diseases of the patients, their biological and conventional DMARD treatments, their comorbidities and the course of SARS-COV2.
Methods: Fifty-two patients who were diagnosed with SARS-COV2 by PCR method while being followed up and treated in the rheumatology center between May 2020 and November 2020 and get COVID treatment in the same center were included in the study. All patients diagnosed with SARS-COV2 and required hospitalization were hospitalized in the same center and followed up and treated. The files and electronic records of the patients were retrospectively recorded by the rheumatologist who followed the patients.
Results: In this retrospective study conducted from a single center, 52 patients whose diagnosis of SARS-COV2 was confirmed by PCR were included. Distribution of primary rheumatic diseases of the patients; 19 rheumatoid arthritis (RA), 14 Ankylosing spondylitis (AS), 4 Psoriatic Arthritis (PsA), 4 Systemic lupus erythematosus (SLE), 5 Behcet's Disease (BD), 4 Familial Mediterranean Fever (FMF), 2 Sjögren's syndrome. 76.8% of the patients were female, 22.2% male, their mean age was 47 ± 18. Biological drug use rate of 37 patients in RA, AS and PsA groups was 83.7% (monotherapy or combination 31/37).
Moreover, 16.2% (6/37) of the patients were using synthetic DMARD combination (MTX+SLZ +HCQ) and 40.5% (15/37) of the patients were using a combination of biological and synthetic DMARDs. While 73% (38/52) of 52 patients had a mild course, 27% (14/52) had severe SARS-COV2 requiring hospitalization. 14 patients who had severe SARS-COV2 infection and required hospitalization, 10 were followed up with the diagnosis of RA, 2 with AS and 2 with SLE. Hospitalization of patients using monotherapy biological drugs (TNF inhibitor, Tocilizumab, IL 17-A) due to severe SARS-COV2 was found to be lower than the group using combined synthetic DMARDs with steroids (MTX+SSZ+HCQ) (p <0.05). The corticosteroid dose of the RA patients was in the range of 5-10 mg/day. The rate of having severe SARS-COV2 was found to be higher in the combination group using biological or synthetic DMARD and low dose corticosteroids compared to group using monotherapy biologicals (p <0.05). The rate of having severe SARS-COV2 was found to be significantly higher in the group using 10/mg or more at the time of diagnosis (p <0.05). Two patients with SLE multiple organ involvement had severe SARS-COV2 while using rituximab, and hospitalization was required. In terms of comorbidities, hypertension was the most common comorbidity with 64.2% (9/14) in the group with severe SARS-COV2, followed by obesity with 21.4% (3/14).
Conclusion: In patients with inflammatory rheumatic disease, SARS-COV-2 infection and the drugs used for the treatment of primary disease are still considered to be a difficult situation in terms of prognosis. In our study with limited cases, data suggesting that there is no increased risk of SARS-COV2 requiring hospitalization in patients using TNF inhibitors, tocilizumab and IL17-A blockers. It was thought that there might be a drug-induced increased risk due to the severe SARS-COV2 infection that developed in our two patients who used rituximab, but the disease-related risk increase was not ignored because the patients were SLE patients with active multi-organ involvement.

AB0700 TOCILIZUMAB DID NOT REDUCE MORTALITY IN SEVERE COVID-19 PATIENTS BUT CAUSED THROMBOCYTOSIS

Z. Öztürk[1], S. M. Türk[1], D. Karataş[1], Ü. Erkorkmaz[2], K. Özmen Süner[3], H. Dheir[4], E. Güçlü[5], E. Gönüllü[1], O. Karabay[5]. [1]*Sakarya University Training and Research Hospital, Rheumatoloji, Adapazarı, Turkey*; [2]*Sakarya University Training and Research Hospital, Biostatistics, Adapazarı, Turkey*; [3]*Sakarya University Training and Research Hospital, Anesthesia, Adapazarı, Turkey*; [4]*Sakarya University Training and Research Hospital, Nephrology, Adapazarı, Turkey*; [5]*Sakarya University Training and Research Hospital, Infectious Diseases and Microbiology, Adapazarı, Turkey*

Background: TCZ is a monoclonal antibody against Interleukin-6 receptor (IL-6R) which is used for relieving inflammation and reducing mortality in COVID-19 patients. Safety and efficacy of Tocilizumab (TCZ) in Covid-19 pneumonia is uncertain yet. In this study, we aimed to determine clinical outcomes in patients treated with TCZ.
Objectives: In this study we aimed to share our retrospective results which we had obtained from patients with COVID-19 diagnosis received TCZ.
Methods: We performed a retrospective case control study between May and August 2020 in Turkey. We compared outcomes in patients who received TCZ with those who did not. Death in hospital and intensive care unit (ICU) requirements were evaluated as endpoints. Demographic data, comorbidities, additional treatment, treatment side effects, laboratory and clinical results were retrospectively assessed. There are no significant differences between groups according to age, gender and Charlson Comorbidity Index (CCI).
Results: 12 (27.3%) patients died in standard group and eight (18.6%) patients died in TCZ group (p=0.150).Days of staying in the hospital were eight days in standard treatment group and 12 days in TCZ group (p=0.03). 10 of 43 patients in TCZ group were admitted to ICU. MV support was needed in 8 of these patients. 18 of 44 patients (40.9%) within the standard group were admitted to ICU and 12 patients (27.3%) were intubated (p=0.125,p=0.480). Significant IL-6 decrease was not observed post treatment in TCZ group according to pre-treatment period (p=0.60). Significant decreases were examined in CRP and ferritin values through TCZ treatment. However, D-dimer and thrombocyte values increased.
Conclusion: TCZ may not be an effective treatment for reducing ICU requirement, to prevent intubation or death, for shortening period for staying in hospital. The patients should be followed up closely for possible thrombosis because of increased D-dimer and thrombocytes with TCZ treatment.

ANTIBODY RAPID TEST POSITIVE HEALTH CARE WORKERS AT A GERMAN UNIVERSITY HOSPITAL: FIRST WAVE CHARACTERISTICS

M. Beck[1,2], A. Nieters[2], M. Rizzi[1], U. Salzer[1], J. Thiel[1], N. Venhoff[1], N. Peter[1], H. Eibel[1], R. Voll[1], S. Finzel[1]. [1]*Faculty of Medicine, University of Freiburg, Department of Rheumatology and Clinical Immunology, University Medical Centre, Freiburg im Breisgau, Germany*; [2]*Institute of Immunodeficiency, Centre for Chronic Immunodeficiency, Freiburg im Breisgau, Germany*

Background: Freiburg was among the most heavily affected German cities during the first wave of Sars-Cov-2 infections in spring 2020. Consequently, the University Medical Center Freiburg was one of the first hospitals in Germany to treat Covid19 patients.
Objectives: To assess the proportion and characteristics of health care workers (HCW) that have been infected during that first wave SARS-CoV-2 serum IgG and IgM antibodies were measured.
Methods: HCW (n=902, mean age: 40.7 years) participated in this study, and filled out an epidemiological questionnaire. Serum samples were analysed for SARS-Cov-2 IgG/IgM antibodies via rapid diagnostic test (RT) and via ELISA. Statistical analyses were performed using STATA 14.2. An exposure prevention score was developed to quantify the adherence to preventive measures in everyday life.
Results: 902 HCW were tested by RT, and 499 by ELISA. In total, 11.5% of recruited HCW were antibody-positive in the RT, 12.2% in the ELISA. 87.5% of RT positives, 98% of ELISA-positives reported symptoms, compared to 74.6% and 78% of negatives, respectively. Symptoms such as cough (57%/46%), loss of smell and taste (34%/5.2%), fatigue (68%/45%), fever (48%/24%), body aches (45%/22%), and headaches (58%/46%) were reported by significantly more RT positives compared to negatives. The respective differences were even more pronounced ($p<0.001$) among ELISA-positives compared to negatives with >50% of those positive reported impaired smell or taste compared to less than 7% among the group of ELISA-negatives ($p<0.00001$).
In logistic regression models, shift work and belonging to the lowest quartile of the exposure prevention score were significantly associated with seropositivity in both tests. Exposure towards children was inversely associated with seropositivity, however, in the finally adjusted model only significant for those that were RT-positive, but not ELISA-positive, reflecting the lower specificity of the former.
Conclusion: The endemic infection rate in HCW was high. HCW adhering to preventive measures in everyday life had lower infection rates.

AB0702

PITFALLS IN THE DIAGNOSIS OF COVID-19 – EXPERIENCES FROM A RHEUMATOLOGY OUTPATIENT CLINIC

S. G. Werner[1], H. E. Langer[1], P. Höhenrieder[2], R. Chatelain[2,3]. [1]*RHIO (Rheumatology, Immunology, Osteology) Düsseldorf, RHIO Research Institute Düsseldorf, Düsseldorf, Germany*; [2] *University of Witten-Herdecke, Faculty of Health, Witten, Germany*; [3]*Evangelical Hospital Düsseldorf, Departement of Dermatology, Düsseldorf, Germany*

Background: PCR (Polymerase Chain Reaction) is generally considered the gold standard for confirming the diagnosis in the early stages of SARS-CoV-2 (severe acute respiratory syndrome coronavirus 2) infection. However, in our rheumatology outpatient clinic we observed a significant discrepancy between clinical evidence of COVID-19 and PCR results.
Objectives: Aim of this retrospective study was to analyze the significance of PCR and serologic tests in the diagnosis of COVID-19 (Corona Virus Disease 2019) in a cohort of patients with rheumatic diseases.
Methods: Between March 2020 and January 2021, 35 patients with a history of established COVID-19 or typical signs and symptoms were identified on the occasion of a routine rheumatology follow-up examination in our institution. Previous diagnostic work-up in external facilities (results of PCR or antibody testing, imaging) was documented. Antibody ELISA-tests (IgG, IgA, IgM, Euroimmun) were performed in patients reporting typical signs and symptoms of COVID-19 in the past.
Results: PCR diagnostics had been performed in 15/35 patients (43%), in 13/35 (39%) at the onset of the first symptoms, in 2 subjects only 2 months later. PCR was positive in 7/13 (54%) of those tested early, but negative in the two patients tested later. In 29/35 patients (83%) SARS-CoV-2-ELISA tests were performed on the occasion of the routine rheumatologic examination (interval between first symptoms and testing on average 98 days, median86, range 4-283 days). In two of the initially negative individuals the second PCR was positive. ELISA tests were positive in all patients. SARS-CoV-2 IgM antibodies were positive in only two patients (however 55 and 71 days after disease onset), n=8/29 (28%) IgG only, n=9/29 (31%) IgG and IgA, n=12/29 (41%) IgA only. In these subjects, IgG antibodies did not develop even in the further course. Antibody titers were in part very high, but in part also very low (only just above the normal value), so even low titers were diagnostic obviously. In all patients with negative PCR, ELISA was positive and retrospectively led to confirmation of the diagnosis. Only in 13/35 patients (37%) diagnosis had been made with the onset of the first symptoms or in the course of clinically manifest disease and had led to appropriate quarantine measures and contact tracing by the health authorities. In contrast, in the majority of patients (63%), the diagnosis of COVID-19 infection was only made retrospectively on the occasion of a routine rheumatologic follow-up. However, 5 of these 22 patients (23%) had quarantined themselves during the symptomatic phase. Titer histories were available from 12 patients. The titer became negative in 7 patients, after a mean of 188 days (median 202, min 51, max 296 days), and remained positive in 5 individuals (mean 190 days, median 191, min 122, max 260 days). The change of the titer was independent of disease severity or antirheumatic therapy.
Conclusion: The results suggest that the importance of PCR in the diagnosis of COVID-19 may be overestimated. Therefore, antibody testing for SARS-CoV-2 should be performed in cases of clinical suspicion and negative PCR. In antibody diagnostics, special features were observed compared to other viruses, in particular, in some patients only low antibody titers or the absence of seroconversion with lack of development of IgG antibodies. Normalization of antibody titers in some patients supports the recommendation to vaccinate even after expired COVID-19 disease.

AB0703

THE COURSE OF COVID-19 INFECTION IN PATIENTS WITH ARTHRITIS RECEIVING TARGETED DMARDS

E. Koltsova[1,2], G. Lukina[2], E. Shmidt[3], K. Lytkina[4], E. Rozochkina[2], E. Zhilyaev[5,6]on behalf of MUAR. [1]*Research Institute of the Organization of Health and Healthcare Management, Rheumatology, Moscow, Russian Federation*; [2]*Moscow Clinical Scientific Center, Rheumatology, Moscow, Russian Federation*; [3]*City Clinical Hospital 1 named after N.I. Pirogov, Rheumatology, Moscow, Russian Federation*; [4]*City Clinical Hospital#4, Rheumatology, Moscow, Russian Federation*; [5]*Russian Medical Academy of Continuing Professional Education, Rheumatology, Moscow, Russian Federation*; [6]*CJSC European Medical Center, Rheumatology, Moscow, Russian Federation*

Background: WHO declared the COVID-19 outbreak as a pandemic on March 12th, 2020. Assessing the risk of severe course in patients with rheumatic diseases, especially those who receive targeted immunosuppressive treatment, is an urgent problem for rheumatologists.
Objectives: determine the relationship between used targeted biologic and synthetic DMARDs (tDMARDs) and the severity of course of COVID-19 infection.
Methods: The analysis included the data of patients with chronic arthritis and COVID-19, used tDMARDs. COVID-19 infection was confirm by serology tests or immune system molecules (immunoglobulins/antibodies). The presence of symptoms, the need for hospitalization, and the need for oxygen therapy were considered as indicators of the severity of the infection. We also analyzed the spread of the lung involvement according to CT data, symptoms during the disease (fever, cough, anosmia, diarrhea).
Results: Analyses included 78 patients, among them 32 patients has ankylosing spondylitis, 31 patients - rheumatoid arthritis, 12 patients has psoriatic arthritis, 3 patients - juvenile arthritis. The average age of the included patients was 51,8 ± 11,69. Most of patients used TNF inhibitors - 43 (Adalimumab -10, Golimumab -4, Infliximab – 4, Certolizumab pegol -3, Etanercept – 22), JAK inhibitor tofacitinib used 13 patients, 5 patients each was treated with Abatacept and Tocilizumab, 3 patients used Rituximab and 2 patients each used Netakimab and Ustekinumab (Table 1). None of the patients included in the analysis required treatment in the ICU and/or mechanical ventilation. The course of the disease in patients treated with tDMARDs did not seem to be more severe than in 5 patients with arthritis who stopped treatment with tDMARDs before the onset of the pandemic. There was a direct correlation between the severity of the infection and the age of the patients ($p=0.007$). There were no significant differences in the severity of the infection depending on the drug, including when adjusting for age.

Conclusion: COVID-19 does not look extremely dangerous in patients with rheumatic diseases, used target DMARDs. Used of tsDMARDs doesn't reliably increase the risk of COVID-19 severity. There is reliable correlation between age and COVID-19 severity.

Table 1. Cohort characteristics

Drugs	Mean age	Number of patients	Patients with symptoms	Hospitalized patients	Asymptomatic course
Adalimumab	41,0±11,4	10	9	2	1
Golimumab	51,0±11,03	4	4	0	0
Infliximab	42,7±11,8	4	0	0	4
Certolizumab	41,6±11,7	3	3	0	0
Etanercept	50,7±11,4	22	20	6	2
Tofacitinib	56,8±10,4	13	12	2	1
Abatacept	57,4±10,9	5	4	1	1
Tocilizumab	48,8±10.9	5	3	1	2
Rituximab	55,6±10,7	3	3	1	0

AB0704 TELEMEDICINE AT THE TIME OF COVID-19: THE EXPERIENCE WITH RA PATIENTS TREATED WITH JAK-INHIBITORS

C. Garufi[1], F. R. Spinelli[1], S. Mancuso[1], F. Ceccarelli[1], F. Conti[1]. [1]*Sapienza University of Rome, Reumatologia, Dipartimento di Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Roma, Italy*

Background: The spread of COVID-19, the lockdown, the limited access to care reevaluated the role of tele-consultation and self-assessment.
Objectives: Our aim was to evaluate in a cohort of Rheumatoid Arthritis (RA) patients treated with JAK-inhibitors (JAKi): the self-assessed disease activity during lockdown, the lockdown impact on fatigue, anxiety, depression and the prevalence of Covid-19.
Methods: We enrolled RA patients treated with baricitinib or tofacitinib. At baseline (BL) and follow-up we collected: patients' demographic data, composite disease activity indices (CDAI, $DAS28_{CRP}$), global assessment (PGA), pain visual analogue scale (VAS), FACIT (functional assessment of chronic illness therapy) and a self-rating scale for disease impact on anxiety and depression (Zung-A/D). Patients were instructed on how to perform self-assessment through video-material and fulfilled the online form of "Rheumatoid Arthritis Impact of Disease" (RAID)[1] and "RA Disease Activity Index" (RADAI). To capture the pandemic effect, we compared patients in different status (remission, low, moderate and high-disease activity) at the last in-person visit (preCoV) through the $DAS28_{CRP}$ and CDAI, to the tele-health visit (THV), measured by the RAID. BL and pre-CoV ZUNG-A, ZUNG-D, FACIT questionnaires were compared with the online results during the pandemic. Exposure, tests and symptoms of Covid-19 were recorded. Data were expressed as mean±standard deviation or median(IQR) according to distribution.
Results: Twenty patients (median age 58.2±11.9 and mean disease duration 153.5 ± 112.7 months) were treated with tofacitinib and 27 with baricitinib. The median time-lapse between the pre-CoV visit and the THV was 12 (IQR 4) weeks. DAS28CRP and CDAI significantly decreased from BL to pre-CoV visit. During the last in-person visit, 21 patients (48.83%) were in remission, 9 (20.93%) in low disease activity; according to the RAID, 15 (31.91%) and 7 (14.89%) patients were respectively in remission and low disease activity during the THV (Table A). PGA and pain significantly decreased from BL to pre-Cov visit but worsened during the lockdown (Table A). FACIT remaining stable during THV. At THV, we detected a significant improvement of anxiety from BL (Zung-A) and a tendency to lower depression scores compared to BL (Table A). JAKi showed a good safety profile considering Covid-19 symptoms, none of the patients was diagnosed with SarsCoV2 infection.
Conclusion: This is the first study on virtual assessment in RA patients treated with JAKi. The unique social experiment of the pandemic impaired the clinical response already achieved before the lockdown, without a collateral worseling of FACIT, anxiety and depression.

AB0705 SHORT-TERM OUTCOMES OF COVID-19 IN PATIENTS WITH RHEUMATIC DISEASES WHO ARE TREATED BY BIOLOGICAL AND TARGETED SYNTHETIC DMARDS: OBSERVATIONAL SINGLE-CENTER STUDY

E. Luchikhina[1], D. Karateev[1], O. Semenova[1], O. Matveychuk[1], T. Kuznetsova[1]. [1]*Moscow Regional Research and Clinical Institute n.a. M.F. Vladimirsky (MONIKI), Moscow Regional Rheumatology Center and Department of Rheumatology, Moscow, Russian Federation*

Background: The course of new coronavirus infection in patients with rheumatic diseases (RD) undergoing treatment with biological and targeted drugs is still poorly understood.
Objectives: To study outcomes of COVID-19 in patients with RD receiving treatment biological and targeted synthetic DMARDs.
Methods: We studied cases of COVID-19 in patients with RD, included in "Moscow regional registry of patients with rheumatic diseases receiving treatment with biological and targeted synthetic drugs" – observational cohort, started in 2018. A total number of patients, included in the registry, is 1048 at December 2020.
Results: By January 2021, 44 known cases of COVID-19 were registered among patients included in the registry (4,2%). This group included 29 (65,9%) females, 15 (34,1%) males, with mean age 45,09±12,7 (median 47,0 [34,0; 57,0]) y.o. The vast majority of patients had rheumatoid arthritis (19, 43,2%) and ankylosing spondylitis (19, 43,2%), there were 3 (6,8%) patients with psoriatic arthritis, and one patient each (2,3%) with systemic lupus erythematosus, systemic sclerosis, and ANCA-vasculitis. Before COVID-19, 20 (45,5%) patients received TNF inhibitors (adalimumab, infliximab, etanercept, certolizumab, golimumab), 7 (15,9%) – IL-6 receptor inhibitors (tocilizumab, sarilumab), 7 (15,9%) – rituximab (period between last infusion and COVID-19 was 1-4 months), 5 (11,4%) – sekukinumab, 2 (4,5%) – tofacitinib, and one patient each (2,3%) received abatacept and ustekinumab. Also, 22 (50%) received methotrexate, 4 (9,1%) – leflunomide, 3 (6,8%) - mycophenolate mofetil, 1 (2,3%) – sulfasalazine; 12 (27,3%) took oral steroids. COVID-19 presented as mild disease in 23 (52,3%) patients, and 21 (47,7%) had viral interstitial pneumonia verified by computed tomography. 16 (36,4%) patients were hospitalized, only one patient underwent artificial lung ventilation. We found no significant associations between particular diagnosis and treatment on the one hand, and hospitalization for COVID-19 on the other hand. For treatment of COVID-19, two (4,5%) patients did not receive any medications, and the rest of patients received antiviral and antibacterial therapy according to standardized protocol. In addition, corticosteroids were administered for COVID-19 in 15 (34,1%) patients, mainly (12 cases) in hospital, and two (4,5%) patients in hospital were treated by tocilizumab. The outcome in all cases was favorable, all patients successfully recovered from the new coronavirus infection.

Conclusion: In this observational study, we found no association between biologic and targeted therapy for rheumatic diseases and severe course of new coronavirus infection, as well as with the need for hospitalization for COVID-19. The outcome of COVID-19 was favorable in all patients receiving treatment with biological and targeted synthetic drugs for rheumatic diseases.

AB0706 ASSOCIATED RISK FACTORS AND OUTCOMES IN HOSPITALISED COVID-19 PATIENTS WITH BIOLOGICS AND JAK-INHIBITORS: A REPORT FROM A CENTER SPECIALISED IN IMMUNE-MEDIATED DISEASES

A. M. Anzola Alfaro[1,2,3], L. R. Caballero Motta[1,2,3], J. C. Nieto González[1,2,3], L. Menchen Viso[4,5], O. Baniandrés[4,6], C. Lobo Rodríguez[5], I. Monteagudo[1,2,3], J. M. Alvaro Gracia[1,2,3], C. Gonzalez[3,7,8]. [1]*Gregorio Marañón Hospital, Rheumatology, Madrid, Spain*; [2]*Centro de Enfermedades Inflamatorias Mediadas por la Inmunidad (CEIMI), Rheumatology, Madrid, Spain*; [3]*Fundación Investigación Biomedica Hospital Gregorio Marañón, Rheumatology, Madrid, Spain*; [4]*Gregorio Marañón Hospital, Gastroenterology, Madrid, Spain*; [5]*Centro de Enfermedades Inflamatorias Mediadas por la Inmunidad (CEIMI), Nurse Supervisor, Madrid, Spain*; [6]*Centro de Enfermedades Inflamatorias Mediadas por la Inmunidad (CEIMI), Gastroenterology, Madrid, Spain*; [7]*Centro de Enfermedades Inflamatorias Mediadas por la Inmunidad (CEIMI), Dermatology, Madrid, Spain*; [8]*Gregorio Marañón Hospital, Dermatology, Madrid, Spain*

Background: There's little data of patients with immune diseases (ID) treated with biologic and JAK-inhibitors and COVID19. Current consensus is to keep treatment, however more studies are needed to ascertain the risk in these patients.
Objectives: To describe the associated risk factors and outcomes in hospitalized patients with ID treated with biologics and JAK-inhibitors of a tertiary center.
Methods: Observational retrospective study of patients with COVID19 from March 1st 2020 to January 31st 2021. Out of all the patients receiving subcutaneous (SC) or intravenous (IV) biologics and oral (PO) JAK-inhibitors, we selected those requiring hospitalization due to pneumonia for analysis. We collected demographic data, comorbidities, seasonal flu vaccination, smoking history and the outcome (discharge/admission in an intensive care unit (ICU)/death). We used a composite index (Charlston's index) for comorbidities.
Results: Of 153 patients, 29 (18.9%) were hospitalized. 18 (62%) were women with a median age of 61 (IQ 52-69). 14 (48.2%) had rheumatoid arthritis, 5 (17%) had axial spondylarthritis and 4 (13.7%) had Chron's disease. The main IV was Rituximab in 3 (50%), and abatacept, infliximab and vedolizumab had one each. Of the SC, tocilizumab and adalimumab had 5 (22.7%) each, etanecept and golimumab had 3 (13.6%) each and secukinumab, ustekinumab and abatacept had 2 (9%) each. The PO was tofacitinib. There were no outcome differences for each treatment.
24 (82.7%) patients had at least 1 comorbidity with significative difference between patients (Table 1). There were 6 (20.6%) deaths, 3 (50%) in the ICU, 2 (33%) did not meet the ICU criteria, and 1 (16%) before ICU admission. None them had the same ID.

Table 1. Baseline data.

Variables, (%)	Total 29 (100)	Deaths 6 (20.6)	Discharged 23 (79.3)	P
Women (%)	18 (62)	4 (66.6)	14 (61)	0.79

Previous or current smokers (%)	9 (31)	3 (50)	6 (26)	0.26

Conclusion: The rate of COVID19 hospitalization in our patients was comparable to the general population's (between 19-24% from 60 years plus) and the risk of in-patient death is also similar, around 24%[1]. Our study suggests that neither their ID nor their treatment influences their risk of a worse outcome.
COPD, DM and previous heart disease were associated with worse outcome; however it seems that the main prognostic factor was the overall impact of comorbidities associated; as measured by the Charlston's index, being significantly higher in the patients with a fatal outcome.
A fatal outcome was more likely in IV biologics, however it could be explained by indication bias probably due to higher comorbidity and disability in these patients rather than an independent prognostic variable.

AB0707 RHEUMATOLOGY PATIENT CARE IN THE COVID-19 PANDEMIC: TELEMEDICINE, DELEGATION, PATIENT SATISFACTION AND VACCINATION BEHAVIOUR

T. Thiele[1], S. Beider[1], H. Kühl[1], G. Miehlke[1], A. Cossmann[1], A. Holz[2], C. Happle[3], K. Hoeper[1], T. Witte[1], A. Jabonka[1], D. Ernst[1]. [1]*Medizinische Hochschule Hannover, Clinic for Rheumatology and Immunology, Hannover, Germany*; [2]*Rheumatologische Facharztpraxis, Rheumatologie, Hildesheim, Germany*; [3]*medizinische Hochschule Hannover, Clinic for Pediatric Pneumology, Allergology and Neonatology, Hannover, Germany*

Background: Use of telemedicine in Germany has increased due to the COVID-19 lockdown. Between March and May 2020, government restrictions led to cancellation of routine outpatient appointments to limit viral spread and optimize resources.
Objectives: This study assesses patient satisfaction of follow-up telemedicine appointments among patients known to be in disease remission, attending either secondary or tertiary care Rheumatology clinics. Appointments were conducted either by a rheumatologist or a qualified medical assistant for rheumatology (RFA). Additional data regarding perceived concerns arising from the COVID-19 pandemic as well as attitudes to vaccination were collected.
Methods: Methods: Patients not requiring adjustment of their DMARDs at the two previous attendances were considered stable. At cancellation of the planned attendance, patients were offered participation in the study and provided verbal informed consent. Participants were randomized to a telemedicine appointment by either a physician or RFA. Telemedicine appointments consisted of a standardized patient interview, including assessment of disease activity (modified CDAI score), attitudes to vaccination as well as current vaccine status and concerns about COVID-19. Following participation, all patients received a pseudonymized postal questionnaire to evaluate appointment satisfaction (FAPI-Score).
Results: In total 112/116 (96%) patients that were offered appointments, participated in the study (RA 50%, axSpA 30%, PsA 20%). Of these 88/112 (79%) returned their postal questionnaires. Overall patient satisfaction was excellent (mean 4.3/5 modified FAPI score) and did not differ between care setting or clinical status of the interviewer. RFAs conducted 19/112 (17%) of appointments, 6 (32%) of which required additional physician intervention. Change of DMARDs occurred in 19/112 (17%) appointments. Patients reporting a pain score ≥7 (VAS 1-10) were most dissatisfied with the telemedicine appointment (p=0.036). Concerns about COVID-19 correlated with disease activity: high disease activity (p = 0.031), presence of tender joints (p=0.001), high pain levels (p=0.009) correlated with concern of contracting COVID-19 or experiencing severe disease course. Only 38% of the patients had been vaccinated against pneumococci in the past 5 years and 54% had been vaccinated against influenza in 2019/2020.
Conclusion: Telemedicine can contribute to patient care in stable patients. RFAs can also contribute to patient care especially for follow-up appointment when patients are in remission. Vaccination rates and motivation needs to be improved as influenza and pneumococcal vaccination is recommended to all patients with rheumatic diseases without contraindications.

AB0708

HIGH DRUG RETENTION RATES DESPITE B/TSDMARD INTERRUPTIONS IN COVID-19 PANDEMIC CHAOS

S. Gulle[1], Y. Erez[1], A. Karakas[1], T. Yüce İnel[1], S. B. Kocaer[2], T. Demirci Yıldırım[1], G. Can[1], İ. Sari[1], M. Birlik[1], F. Onen[1]. *[1]Dokuz Eylul University Faculty of Medicine, Rheumatology, Izmir, Turkey*; *[2]Kastamonu Research and Training Hospital, Rheumatology, Kastamonu, Turkey*

Background: A significant increased risk of COVID-19 related adverse outcomes of the biological or target-directed synthetic DMARDs (b/tsDMARDs) has not yet been reported. For this reason, it is recommended to continue b/tsDMARD treatments with maximum compliance with pandemic measures.
Objectives: The aim of this study was to evaluate the effects of patients using b/tsDMARDs on drug survival and rheumatic disease control during pandemic.
Methods: In this study, patients diagnosed with rheumatic disease using b/tsDMARDs and who were followed up during the 12-month period (January 2020-2021) including the onset of the Covid-19 pandemic at Dokuz Eylul University Faculty of Medicine Rheumatology Clinic were evaluated. In the first 3 months of the pandemic (March-June 2020), the patients skipped at least 2 cycles of treatment with the fear of Covid-19 infection except for infection / surgical reasons was considered as a disruption of the drug. The drug retention rates of the patients on b/tsDMARDs treatments during the pandemic process and the factors affecting this situation were evaluated.
Results: The rate of disrupting their b/tsDMARDs was higher in patients> 65 years of age, with a diagnosis of RA and who needed to come to the hospital for bDMARD treatment (p=0.007, p=0.015 and p=0.004, respectively).
The overall 1-year b/tsDMARD retention rates was found 91%. It was determined that a history of interruption in b/tsDMARD treatments in the first 3 months of the pandemic [OR: 1.28 (CI: 1.042-8.71), p=0.014] and the need to come to the hospital to receive bDMARD [OR: 0.59 (CI: 0.64-13.11), p=0.041] caused unresponsiveness to return to the same bDMARD treatment and a significant increase in the risk of discontinuation of the biologic treatment.
Conclusion: We conclude that it is important for patients to continue taking b/tsDMARD treatments without interruption in the days past abnormal periods such as pandemic conditions and to make sufficient effort for minimum dose of CS and low disease activity by determining patient-based risk.

CHARACTERIZATION OF NAILFOLD CAPILLAROSCOPY IN COVID-19: A CASE CONTROL STUDY

P. E. Bermudez Bermejo[1], R. Jimenez-Soto[2], A. Sanchez Rodríguez[1], A. Turrent[1], D. Mercado Velasco[2], I. Bravo-Lee[2], M. B. Colli-Cortés[3], E. Alvarez Hernandez[4], M. D. C. Amigo Castañeda[1]. *[1]ABC Medical Center, Rheumatology, Mexico City, Mexico*; *[2]ABC Medical Center, Internal Medicine, Mexico City, Mexico*; *[3]Regional Hospital "General Ignacio Zaragoza" ISSSTE, Rheumatology, Mexico City, Mexico*; *[4]Hospital General de Mexico, Rheumatology, Mexico City, Mexico*

Background: Nailfold capillaroscopy is a relatively easy-to-access, low-cost clinical tool that could help identify early coagulopathy in subjects with SARS-CoV-2, but specific findings vs. controls and its possible prognostic role has not been studied.
Objectives: To describe capillaroscopic findings and their usefulness in patients with COVID-19 compared to healthy controls.
Methods: We designed a cross-sectional study, carried out in a single care center for critical patients with SARS-CoV-2 pneumonia at the ABC Medical Center, Mexico City, which included patients from an intensive care unit (ICU) and internal medicine ward from March to April 2020. Demographic, biochemical and clinical features were collected. All patients signed the informed consent and the study was approved by the hospital ethics committee. All patients underwent nail capillary imaging of the 3 central fingers of each hand with a portable microscope with 60-100x magnification coupled to a smartphone with 7 megapixel images in an immersion medium. Capillaroscopy was performed in patients who did not have fever or hypothermia, or need vasopressors at the time of evaluation. Control subjects are healthy subjects matched on age and sex from a database of healthy controls without rheumatic diseases. Image evaluation of COVID-19 patients was performed in a blinded way for their characteristics. Prior to the analysis of the images, a pilot test was obtained with 4 rheumatologists in random cases, obtaining an acceptable global agreement in the visualization of capillaries and specific alterations of the nail bed. (Kappa = 0.58, p = 0.0019). Obtained data from capillaroscopies were used to be compared between severe and moderate cases of SARS-CoV-2 pneumonia. Additionally, we compared the findings against a healthy population in order to establish a reference.
Results: We included data from 27 patients and 32 controls with similar demographic features. Patients with COVID-19 patients had a mean age of 43 +/- 13.8 years, 63% female. Comorbidities were present in 44.4% with: type II Diabetes Mellitus 18.5%, systemic arterial hypertension 18.5%, and rheumatoid arthritis 3.7%. The mean length of stay time was 13 +/- 7.1 days, 48.1% were admitted to the ICU, and 40.7% required invasive mechanical ventilation. In the capillaroscopic review remarkable findings of patients vs. controls were hemosiderin deposits (33 vs 12.5%, p=0.05), less frequently observable capillaries (77 vs 100%, p=0.005), any abnormality in capillaries (25.9 vs. 6.3%, p=0.03). Of notice, specific findings in COVID-19 patients were capillary tortuosities in 19%, dilatation in 9.5%, serpentine pattern in 4.8%, bush pattern in 9.5% and decreased density in only 4.8% of the cases. No avascular areas or capillaries of neoformation were observed. Finally, the presence of hemosiderin was associated with worse presentation and risk factors for severe COVID-19: Male sex 66.7 vs. 27.8%, (p = 0.024); Admission to ICU 77% vs 33% (p = 0.029); BMI > 30 kg/m2 66.7 vs. 27.8% (p = 0.053). And risk for ICU admission OR = 7.0 (95% CI 1.098 - 44.6). No significant associations were found for abnormalities in capillary morphology.
Conclusion: We present one of the first reports of nailfold capillaroscopic findings in patients with COVID-19 and the first to compare to healthy controls. Previous data on this regard suggests the presence of endothelial dysfunction and microvascular complications such as micro hemorrhage or micro thrombosis. Further studies may confirm these findings and prognostic value for worse outcomes in COVID-19 patients.

AB0710 ANISOCYTOSIS INDEX AS AN EARLY PREDICATOR OF HOSPITAL MORTALITY IN PATIENTS WITH COVID-19 PNEUMONIA FROM A LEVEL III HOSPITAL. LIMA PERU

J. Ravelo[1]. [1]*San Juan Bautista Clinic, Lima, San Juan de Lurigancho, Peru*

Background: RDW has been analyzed in recent decades as a poor prognostic factor, associated with an increased risk of mortality from all causes: heart disease, lung disease, sepsis, influenza, cancer, complications associated with heart failure, coronary disease, viral hepatitis, COPD, development of DM2, stroke and anemia, which makes it a nonspecific marker of disease with the potential to provide a stratified quantification of risk in a new disease.
Objectives: To determine if laboratory tests predict mortality in patients with COVID-19 pneumonia upon admission to hospital. Secondary outcome: evaluate if any laboratory parameter predicts longer hospitalization in patients with COVID-19 pneumonia.
Methods: Case control retrospective study of COVID-19 pneumonia patients, admitted to the Peruvian Air Force Hospital from April 6th to June 27th, 2020. Patients were divided in two groups: recovered and deceased and their laboratory parameters entered the statistical analysis. Cox regression was performed (95% CI, p value <0.05, as statistically significant). Bivariate analysis to compare the RDW means of recovered vs. deceased and multivariate analysis with binary logistic regression to evaluate the predictive value of RDW in relation to hospital mortality in our cohort. The statistical package Stata version 14.2 was used.
Results: 186 patients were included. The mean age of the recovered patients was 53.6 ± 16.4 years vs 75.9 ± 13.9 years in the deceased group (p <0.0001). The mean value of RDW was 13.14% in recovered vs. 13.96% of deaths (p< 0.0005), associated with an Odds Ratio (OR) of 1.66 (CI: 1.58-1.74) adjusted for the model.
Conclusion: The finding of a RDW ≥ 13% in patients with COVID-19 pneumonia was associated with higher mortality.

AB0711 FOLLOW-UP OF PATIENTS UNDER BIOLOGICS IN THE ERA OF LOCKDOWN

V. F. Boussougou[1], K. Nassar[1], S. Janani[1]. [1]*University Hospital of Ibn Rochd, Department of Rheumatology, Casablanca, Morocco*

Background: The management of patients with inflammatory rheumatic diseases under biologics has raised many questions about the global management of patients in the time of COVID-19 pandemic. This period could have been particularly painful for the patients due to the virus itself, and to the difficulty to access to healthcare facilities due to the lockdown.
Objectives: To assess the impact of the lockdown in patients under biologics.
Methods: This is a descriptive study, conducted between 03/01/2021 and 07/31/2021 in the Department of Rheumatology of the University Hospital of Ibn Rochd in Casablanca. Inclusion criteria were all patients on biologics during the lockdown period. The number of painful, swollen joints, pain visual analogue scale, and disease activity were collected before and during the lockdown.
Results: Thirty-one patients under biologics were included. The average age was 43.4 years. There were 17 males and 14 females (sex ratio M/F 1,21). Cormibidities were hypertension and type 2 diabetes (9.7%), hypertension and dyslipidemia (6.5%), arrhythmia (6.5%), smoking (9.7%), hypertension and dysthyroidism (3.2%). All the patients were under biologics with an average duration of 2 years distributed as follows: 3 patients on etanercept (9.67%), 8 patients on tocilizumab (28.8%), 10 patients on infliximab (32.25%), 5 patients on adalimumab (16.12%)), 4 patients under golimumab (12.90%), 1 under secukinumab (3.22%). Biologics were associated with conventional synthetic disease-modifying antirheumatic drugs in 38.7% (methotrexate 12.9%, salosopyrine25, 8%), corticosteroids in 25.7%, non-steroidal anti-inflammatory drugs in 16.1%. The disease activity before COVID-19 of the patients was: 48.39% weak activity, 35.4% remission, 16.13% moderate activity. No patient reported a flare of the disease. During lockdown, 5 patients reported a flare of their disease (16.12%) They were followed for: 2 spondyloarthritis, 1 rheumatoid arthritis, 1 psoriatic arthritis, 1 adult onset Still's disease. All the patients have temporarily stopped their drugs because they couldn't come to their appointments because of the lockdown.
Conclusion: Our study notes that the patients who kept their follow-up during lockdown have maintained a control of their disease activity. Our results are consistent with the observations of a French study on the impact of lockdown on the activity of rheumatoid arthritis. However, those who couldn't come to their control appointment due to the lockdown had a flare of their disease. This study remains limited due to the monocentric nature and the small size of our sample.

AB0712 THE INCIDENCE OF SARS-COV-2 INFECTION IN PATIENTS WITH RHEUMATIC DISEASES ON THERAPY BIOLOGICAL DISEASE MODIFYING ANTIRHEUMATIC DRUGS

A. Dadalova[1], E. Vasilenko[1], R. Samigullina[1], V. Mazurov[1]. [1]*North-Western State Medical University named after I.I. Mechnikov, Department of Therapy,*

Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E.Eichwald, St. Petersburg, Russian Federation

Background: At the moment, a highly relevant issue is the course of SARS-CoV-2 infection in patients with rheumatic pathology, especially, those receiving therapy with biological disease modifying antirheumatic drugs.
Objectives: of the current study to assess the prevalence and course of SARS-CoV-2 infection in patients receiving various biological disease modifying antirheumatic drugs.
Methods: to assess the severity of the course of SARS-CoV-2, discharged epicrisis from hospitals or the conclusion of computed tomography were used. The average age of the patients ranged from 41.4 + 11.6 years. In the evaluated sample, 47 patients (49.47%) were males. Among the infected of SARS-CoV-2 were patients with rheumatoid arthritis - 45 (47.4%), spondyloarthritis - 39 (41.1%), systemic connective tissue diseases - 11 (11.5%).
Results: Since March 2020, among the 1319 patients with rheumatic diseases observed at the St. Petersburg Center of therapy biological disease modifying antirheumatic drugs, 95 patients (7,2%) had SARS-CoV-2 infection. In 57,9% (55 patients) there was a mild course of infection, in 35,8% of cases (34 patients) - a moderate course, in 6,3% (6 patients) - a severe course. Inpatient treatment was received by 29,5% (28 patients). A favorable outcome was noted in 95.8%, and a lethal outcome in 4,2%. The use of interleukin-6 inhibitors was required in 2,1% of patients (2) due to the development of a cytokine storm. The structure of the received biological therapy in the severity of the course is shown in Table 1.

Table 1. The structure of the received biological therapy in the severity of the course SARS-CoV-2 infection

	Mild course	CT-1 (<25%)	CT-2 (25-50%)	CT-3 (50-75%)	CT-4 (>75%)
TNF-α inhibitors, n (%)	30 (31,6)	11 (11,6)	7 (7,3)	3 (3,2)	0 (0,0)
anti B-cell therapy (rituximab), n (%)	2 (2,1)	1 (1,1)	2 (2,1)	1 (1,1)	2 (2,1)
Abatacept, n (%)	3 (3.2)	0 (0,0)	2 (2,1)	0 (0,0)	0 (0,0)
Janus kinase inhibitors, n (%)	5 (5,3)	1 (1,1)	1 (1,1)	0 (0,0)	0 (0,0)
Interleukin-6 inhibitors, n (%)	6 (6,3)	0 (0,0)	0 (0,0)	0 (0,0)	0 (0,0)
Interleukin-17 inhibitors, n (%)	8 (8,4)	2 (2,1)	2 (2,1)	0 (0,0)	0 (0,0)
Other, n (%)	1 (1,1)	4 (4,2)	1 (1,1)	0 (0,0)	0 (0,0)

Among 95 infected patients, who were observed in the center, 51 received therapy with TNF-α inhibitors (8.5% of the total number of patients receiving therapy), 8 - rituximab therapy (2.7%), 5 - abatacept (6.3%), 7 - Janus kinase inhibitors (0.9%), 6 – interleukin-6 inhibitors (9.2), 12 - interleukin -17 inhibitors (14.1%), 6 patients treated with other drugs (10%).

Conclusion: Taking into account the SARS-CoV-2 pandemic, further study of the course of infection in patients with rheumatic diseases, including those receiving biological therapy, is required. More information is also needed on the safety and efficacy of vaccination in this patient population.

Pain in rheumatic diseases, including fibromyalgia

AB0713 EVALUATION OF THE EFFECTIVENESS OF LASER THERAPY IN THE TREATMENT OF RHEUMATOID ARTHRITIS

N. Zhuravleva[1], L. Karzakova2, S. Kudryashov3, E. Petrova[4]. [1]*Federal State Budgetary Educational Institution of Higher Education "The Chuvash State University named after I.N. Ulyanov", Department of Internal Medicine, Cheboksary, Russian Federation*; [1]*Federal State Budgetary Educational Institution of Higher Education "The Chuvash State University named after I.N. Ulyanov", Department of Internal Medicine, Cheboksary, Russian Federation*; [1]*Federal State Budgetary Educational Institution of Higher Education "The Chuvash State University named after I.N. Ulyanov", Department of Internal Medicine, Cheboksary, Russian Federation*; [4]*Federal State Budgetary Educational Institution of Higher Education "The Chuvash State University named after I.N. Ulyanov", Department of Instrumental Diagnostics, Cheboksary, Russian Federation*

Background: Despite the fact that the introduction of biological disease-modifying antirheumatic medicines (bDMARDs) and the early start of treatment for rheumatoid arthritis (RA) can effectively stop the inflammatory process in RA, a fairly large number of patients continue to experience joint pain [1]. It is assumed that in some cases, joint pain in patients with RA is not associated with the inflammation, so it requires consideration of the possibility of using alternative strategies for the treatment of RA.
Objectives: The aim of the research is to study the effectiveness of laser therapy in the treatment of RA.
Methods: 114 patients with RA aged from 32 to 53 years have been monitored for 6 months. There were 82 women (71.9 %) and 32 men (28.1%) among them. The patients were randomly divided into 2 groups. The first group of patients (57 people) received basic medical therapy with methotrexate 15 mg intramuscularly once a week and nonsteroidal anti-inflammatory medicines (NSAIDs) on demand. The dose of methotrexate was selected taking into account the disease activity index DAS 28. The second group of patients (57 people) received basic medical therapy with methotrexate 15 mg intramuscularly once a week and NSAIDs on demand. In addition, the cutaneous low-intensity laser irradiation of the joints was added along the projection of the joint gap in a pulse mode with a wavelength of 0.89 microns. The pulse frequency is 80-1500 Hz, the pulse power is 5 W, the exposure time in the field is 1-2 minutes and the total radiation time per session is no more than 10 minutes [2]. The course of treatment consisted of 10 procedures (the device "Milta F-8 RD", Russia, Moscow). The course of laser therapy was repeated after 4 weeks. To assess clinical indicators, patients were examined using the SF-36 questionnaire before treatment and 6 months after the start of treatment.
Results: The survey after 6 months revealed the significant decrease in the severity of pain on the VAS from the initial average indicator 4.5±0.2 to 3.69±0.2 points ($p<0.01$) and morning stiffness from 60±5 to 40.8±4 minutes ($p<0.01$). In the first group, the dynamics of clinical indicators were not statistically significant: the intensity of pain decreased from 4.6±0.2 to 4.2±0.3 points ($p>0.05$) and the duration of morning stiffness reduced from 62±7 to 58.6±6 minutes ($p>0.05$). In the second group the decrease in the need for NSAIDs was observed in 21 patients, while in the first group the same was observed only in 10 patients ($p_{x2} = 0.020$).
Conclusion: Laser therapy in the treatment of patients with RA enabled to decrease the frequency of the need for NSAIDs and reduce morning stiffness. We recommend using laser therapy in patients with RA at the second radiological stage as an addition to basic therapy.

AB0714 COMPARISON OF THE EFFECT OF SUBACROMIAL ADMINISTRATION OF HYALURONIC ACID AND PLATELET RICH PLASMA IN CASES OF DAMAGE TO THE TENDONS OF THE ROTATORS OF THE SHOULDER IN INDIVIDUALS OF DIFFERENT AGE GROUPS

V. Nesterenko[1,1], A. Karateev[1], E. Bialik[1], M. Makarov[1], S. Makarov[1], V. Bialik[1], M. Nurmukhametov[1], A. Chernikova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: Everyone has had shoulder pain at least once in their life. From 70 to 80% of chronic pain in the shoulder joint is associated with subacromial impingement syndrome. The use of non-steroidal anti-inflammatory drugs (NSAIDs) and glucocorticoids does not always meet the needs of patients and have a number of adverse reactions. Local administration of PRP and HA preparations is widely used for chronic shoulder pain. However, the question of the effectiveness of these drugs in patients of different ages has been insufficiently studied.
Objectives: To compare the efficacy of GLA and PRP in patients with chronic shoulder pain by age.
Methods: The study group included 100 patients, 46% women and 54% men, aged 51.5 ± 15.1, with chronic shoulder pain (≥3 months) caused by damage to the tendons of the muscles of the shoulder rotators. Patients <45 years old accounted for 34%, patients ≥45 years old - 66%. All patients were randomly divided into 2 groups. Patients in group 1 received 2 consecutive subacromial injections of GLK, groups 2 - 3 consecutive subacromial injections of PRP. Pain dynamics were assessed using a 100-mm visual analogue scale (VAS),

functional impairments according to ASS (American Shoulder and Elbow Surgeons Assessment) and CS (Constant Score), and a decrease in the need for NSAID use after 6 months. after the course of treatment.

Results: The dynamics of pain and functional disorders in the treatment of GLC and PRP did not differ. The pain decreased from 57.6 ± 17.8 to 30.2 ± 26.3 and 56.0 ± 14.6 to 31.8 ± 26.3 (p = 0.768), ASS from 54.7 ± 15.1 to 77.3 ± 22.5 and 54.8 ± 13.8 to 74.6 ± 22.4 (p = 0.552), CS from 47.8 ± 16.9 to 65.6 ± 19.3 and 59.2 ± 14.4 to 66.9 ± 17.4 (p = 0.245). In general, with the treatment of GLA and PRP, the dynamics of pain and functional disorders was significantly better in patients <45 years old than in patients ≥45 years old. So, pain according to VAS after 6 months. was 22.4 ± 26.3 and 35.5 ± 26.2 (p = 0.022), ASS 83.3 ± 20.9 and 72.1 ± 22.6 (p = 0.017), CS 76.2 ± 16, 1 and 63.2 ± 18.2 (p = 0.001). There was no need to take NSAIDs in 82.4% and 65.2% of patients (p = 0.103). No serious adverse reactions have been reported with the treatment of GLC and PRP.

Conclusion: The efficacy of GLA and PRP in chronic shoulder pain caused by damage to the tendons of the muscles of the rotator of the shoulder does not differ. The clinical response to both drugs was significantly higher in those under 45 years of age.

AB0715 THE PREVALENCE OF FIBROMIYALGIA IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER AND THE RELATIONSHIP BETWEEN FATIGUE AND QUALITY OF LIFE

S. Ugurlu[1], T. Civi Karaaslan[2], Z. Toker Dincer[1], E. Tarakci[2]. *[1]Cerrahpasa Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; *[2]Faculty of Health Sciences, Physiotherapy and Rehabilitation, Istanbul, Turkey*

Background: Familial Mediterranean Fever (FMF) can cause various muscle diseases. Because it is a chronic auto inflammatory disease, painful trigger points may be encountered in the examination due to a decrease in the pain threshold (1-3).

Objectives: The aim of this study was to determine the prevalence of Fibromiyalgia in patients with FMF, at the same time to identify the relationship between fatigue and quality of life.

Methods: Sixtyseven patients (38 female, 29 male) with FMF were enrolled in the study. They were diagnosed with FMF based on the Livneh diagnostic criteria (4). Fibromyalgia involvement of the patients was evaluated according to the Fibromyalgia Impact Questionnaire (FIQ). Patients with diagnose with other chronic disease were excluded. Fatigue Severity Scale (FSS) was used to evaluate fatigue. Quality of life was evaluated with Short Form-36 (SF-36).

Results: Respectively, the mean age, disease duration and body mass index were 34.46±12.69 years, 12.66±7.86 years and 24.96±5.42 kg/m^2. In addition, 65% of the patients had no rheumatic disease in their family history. The mean of scores of FIQ was 38.66±25.14, the mean of FSS was 38.07±17.56, the mean of SF-36-PCS was 45.55±10.54 and SF36-MCS was 30.93±17.39. Patients were categorized as mild (n=28), moderate (n=24) and severe (n=15) affected according to their FİQ score. The relationships of scores of FIQ, FSS and SF-36 were demonstrated Table 1.

Table 1. The correlations of FIQ, FSS and SF-36 scores.

		FSS	SF-36 PCS	SF-36 MCS
FIQ-mild	mean±sd	23.78±14.88	53.34±7.01	40.98±13.73
	r	0.595**	-0.014	-0.551**
	p	0.001	0.944	0.002
FIQ-moderate	mean±sd	45.75±10.83	41.09±8.89	38.13±9.19
	r	0.053	-0.379	-0.145
	p	0.806	0.068	0.498
FIQ-severe	mean±sd	52.46±10.11	38.13±9.19	20.32±15.68
	r	0.622*	-0.548*	-0.268
	p	0.013	0.035	0.333

-Pearson Correlation

Conclusion: Fibromyalgia symptoms can be seen in FMF. According to our results, it has been shown that patients with moderate and severe symptoms have increased fatigue levels and decreased quality of life. In the light of these results, we can say that also the fibromyalgia symptom of patients with FMF should be considered in the treatment.

Background: Fibromyalgia syndrome (FM) is characterised by a complex symptom spectrum, dominated by the presence of chronic widespread pain, fatigue and unrefreshing sleep. FM affects between 2 and 3% of the general population. It is a condition that mainly involves middle-aged women, although it is increasingly being diagnosed in younger people. The severity of symptoms can vary greatly between individual patients, and is influenced by many factors (e.g. sex,

body mass index) [1]. To date, there is little information about changes in severity in accordance with patient age.

Objectives: The aim of this study was to investigate variations in symptom severity in FM patients according to age categories.

Methods: A cross-sectional study of adult FM patients diagnosed according to the American College of Rheumatology 2010/2011 criteria was performed. The case series was included from an Italian national registry [2]. Patients were grouped according to five age categories: 18-40 years, 41-50 years, 51-60 years, 61-70 years, over 71 years. Symptom severity was assessed through the revised Fibromyalgia Impact Questionnaire (FIQR) and domains, including FIQR physical function (items 1-9), FIQR health status (items 10-11), and FIQR symptoms (items 12-21). Between-group characteristics were analysed using one-way analysis of variance (ANOVA).

Results: This study included a total of 2889 patients, 403 aged 18-40 years, 756 aged 40-50 years, 1035 aged 50-60 years, 528 aged 60-70 years, and 167 over 70 years, respectively. The mean (standard deviation [SD]) score of the total FIQR was 52.68 (11.82). Total FIQR and individual domains all showed a normal distribution. Analysing the data by age category, there were statistically significant differences between the categories for the total FIQR (p = 0.030). The age categories with the highest disease severity were those above 71 years (FIQR 62.14, SD 22.45), and between 51-60 years (FIQR 60.31, SD 22.89) (Table 1). Significant differences between age categories were also found for the domains physical function (p = 0.006) and health status (p = 0.012), but not for the domain symptoms (p = 0.164).

Table 1. Mean values of FIQR total score and domains according to age categories.

FIQR and domains	18-40 years	41-50 years	51-60 years	61-70 years	≥71 years	p*
FIQR total, mean (SD)	57.90 (21.76)	59.25 (23.30)	60.31 (22.89)	57.13 (23.59)	62.14 (22.45)	0.030
FIQR physical function, mean (SD)	15.51 (7.56)	16.44 (7.77)	16.77 (7.51)	15.96 (7.82)	17.68 (7.26)	0.006
FIQR health status, mean (SD)	11.19 (5.85)	11.24 (5.99)	11.49 (5.93)	10.57 (6.11)	12.21 (5.97)	0.012
FIQR symptoms, mean (SD)	31.32 (10.48)	31.56 (11.32)	32.10 (11.01)	30.68 (11.47)	32.24 (11.34)	0.164

Abbreviations and legend. FIQR = revised Fibromyalgia Impact Questionnaire; SD = standard deviation; * = one-way analysis of variance (ANOVA).

Conclusion: Distinguishing the disease severity in FM patients according to age categories, a bimodal distribution emerges, with the disease severity being greatest in patients over 71 years and in the 51-60 years decade. The main differences in severity, according to what can be detected through the FIQR, are attributable to the domains physical function and health status, which show higher scores in the two classes with higher severity.

AB0717 PREVALENCE OF MIGRAINE AND NEUROPATHIC PAIN AMONG PATIENTS WITH RHEUMATIC DISEASES

S. Miladi[1], M. Yasmine[1], A. Fazaa[1], S. Mariem[1], K. Ouenniche[1], L. Souebni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Pain in rheumatic diseases (RD) is primarily due to mechanical or inflammatory mechanism, but neuropathic pain (NP) component is yet to be fully evaluated and described, with a particular attention to the distinction with nociceptive pain [1].

Objectives: The aim of our study was to assess the prevalence of migraine and neuropathic pain in patients with RD and to explore factors associated with NP.

Methods: Prospective study including patients with rheumatoid arthritis (RA) and spondylarthritis (SpA) were invited to complete a validated self-assessment questionnaires. Sociodemographic data as well as disease related characteristics were recorded. Migraine was diagnosed according to the IHS migraine diagnostic criteria. NP was evaluated using DN4 (Douleur Neuropathique 4 Questions) and Pain DETECT questionnaire (PDQ). Neuropathic pain was retained in case of a total score of 4 or more at DN4-interview questionnaire or a score ≥19 with the PDQ.

Results: A total of 60 patients with RD were included (42 RA/18 SpA). Females outnumbered males (sex-ratio=1.7). The mean age was 51.3 ± 13.1 years [18-75] and the mean disease duration was 11.9 ±5.6 [1-23] years. The prevalence of migraine was 15%. This latter was higher among women than men and among RA patients than SpA (18% vs 9%, 16.6% vs 11.2%) with no statistically significant correlation (p=0,329, 0,581 respectively). Parameters associated with a higher prevalence of migraine were an older age (p=0,042). However, there was no correlation between the presence of migraine and the type of the RD, disease duration or the level of anxiety (p=0,059, p=0,459 respectively). Chronic pain with neuropathic characteristics was found in 21.7% with the DECT score and 16.7% with DN4 questionnaire. NP was most prevalent among patients with comorbidities (28.5% vs 6%, p=0.021) and with higher body mass index (p=0.01). Prevalence was significantly higher in the RA group (19%) than in the SpA group (11%) without a statistically significant correlation (p=0.45). Similarly, NP was not associated with Salazopyrine intake (p=0.9).

Conclusion: We found a high prevalence of migraine and NP in our sample of patients with RD. It seems therefore important to check the presence of migraine or NP especially in patients with comorbidities and older ones.

AB0718 ASSESSMENT OF SEXUAL DYSFUNCTION IN WOMEN AND MEN WITH FIBROMYALGIA SYNDROME

G. Mouna[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Rhumatology Departement of CHU Fattouma Bourguiba, Rhumatology Departement of CHU Fattouma Bourguiba, Monastir, Tunisia*

Background: Fibromyalgia syndrome is a chronic musculoskeletal disease, which compromises physical, mental, and sexual health. Although concerns related to sexuality are commonly reported, the literature on sexual functioning in patient with fibromyalgia is limited to female patients.

Objectives: The aim of our study is to identify sexual dysfunction in women and men with fibromyalgia syndrome compared with patients with rheumatoid arthritis.

Methods: This is a cross-sectional comparative study: '34 patients with fibromyalgia syndrome compared to 100 patients with rheumatoid arthritis' conducted in the rheumatology department of CHU Fattouma Bourguiba de Monastir over a period from February to November 2017. We used the Female Sexual Function Index (FSFI) and the Sexual Health Inventory for Men (SHIM).

Results: Our sample comprised 34 patients with fibromyalgia (31 females and 3 males) and 100 patients with rheumatoid arthritis (58 females and 15 males). Sexual dysfunction was present in 100% of female patients with fibromyalgia syndrome compared to 60% of female patients with rheumatoid arthritis. Female patients with fibromyalgia syndrome had a decreased FSFI score: 10,3±8,74 versus 16,86±8,87 in the rheumatoid arthitis group with p=0.001. While among the male patients, we found no significant difference between the two groups.

Conclusion: Fibromyalgia syndrome had negative side effect on the sexual life of female patients. Recognition of this dysfunction and its inclusion in the multidisciplinary management of fibromyalgia must be part of the treatment.

ASSOCIATION BETWEEN FIBROMYALGIA AND CHRONIC AUTOIMMUNE THYROIDITIS. RETROSPECTIVE OBSERVATIONAL DATA FROM A MONOCENTRIC ENDOCRINOLOGIST-RHEUMATOLOGIST COLLABORATIVE ANALYSIS

F. Fischetti[1], S. Bernardi2, S. Lovriha2, F. Bozzao2, P. Tomietto[3], B. Fabris2. *[1]University of Trieste, Department of Medical, Surgery and Health Sciences, Trieste, Italy*; *[1]University of Trieste, Department of Medical, Surgery and Health Sciences,Trieste, Italy*; *[3]Azienda Sanitaria Universitaria Giuliano Isontina; Cattinara Hospital, Department of Medicine,Trieste, Italy*

Background: Endocrine and metabolic imbalance conditions can affect the development of subjective abnormal perceptions within fibromyalgia (FMR). In the case of autoimmune thyroid disease (ATD), prolonged, clinically active states of impaired glandular function may be associated with an FMR-type condition. Less clear is the association between subclinical or rapidly well-controlled states of thyroid disease and the presence of FMR, since this assessment, although analysed in some previous studies, was usually performed on cohorts of subjects where the absence of any other confusing factors was not well defined.
Objectives: To evaluate the prevalence of subclinical autoimmune thyroid disease, or functionally controlled autoimmune thyroid disease, in a retrospective cohort of consecutively diagnosed patients suffering from fibromyalgia condition.
Methods: Over a 2 years period of time (2018-2019) a monocentric joint evaluation was activated with the endocrinology section of our healthcare area in order to consecutively monitor the subjects belonging to both specialist clinics. Patients with ATD were not unfrequently firstly evaluated in the rheumatology ambulatory. Diagnosis of FMR was defined according to the American College of Rheumatology 2010/2011 criteria. At the same time, at the rheumatology clinics, all cases addressed with diagnosis of fatigue or chronic pain of no defined origin were analysed in order to carefully identify any associated, comorbidity problems. The diagnosis of ATD was confirmed according to recognized international criteria. The following results will focus on subjects with chronic Hashimoto type Thyroiditis (HT).
Results: Among the HT patients, 98% were women, aged between 28 and 64. Over the 2 years considered period of time, 65 subjects suffering from HT, showing no active disease or unstable endocrine function were addressed to the rheumatology clinics owing to FMR related symptoms. Among them, 55 (84.6%) had a confirmed diagnosis of FMR. Within this time, we recognized 239 consecutive diagnoses of FMR in subjects aging 22-76 years, with a number of 114 found to be devoid of factors (other than ATD) able to be responsible for chronic pain, except for a modest component of situational anxiety, or mild mood depression, not requiring any specific drug intervention. Among the 114, so called "primary" FMR, 35.6% showed to suffer from TCH, under confirmed clinical/hormonal remission, or in a preclinical, early stage of onset. Within the 125 subjects, carrying a FMR condition related to previous or associated fostering pathology, 26.8% were positive for current or previous thyroid problems. The prevalence of TCH, in the "secondary" FMR conditions differed significantly ($p<0.01$) from that of other FMR promoting diseases (eg connective tissue diseases, such as Sjogren Syndrome), except for moderate-severe mood disorders and/or anxiety, and the most severe chronic osteoarthritis conditions, showing a confirmed secondary neuropathy.
Conclusion: Although limited in number, the here reported data confirm the hypothesis of a significant association between ATD and FMR, even in subjects who were considered to be in a subclinical condition or in full clinical remission by the endocrinology colleagues. The physiopathology of this association needs further appropriate insights.

HIP INVOLVEMENT IN A COHORT OF EGYPTIAN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS

A. Radwan[1], H. Alzahrani[2], Y. Alzahrani[2], A. Elsaman[3]. *[1]Sohag University Hospital, Rheumatology and Rehabilitation, Sohag,*; *[2]Armed Forces Specialized Center for Health Rehabilitation, Altaif, Kingdom of Saudi Arabia, Rehabilitation Depatment,Taif, Saudi Arabia*; *[3]Sohag University Hospital, Rheumatology and Rehabilitation, Sohag, Egypt*

Background: The hip joint is frequently involved in Juvenile Idiopathic Arthritis (JIA). It is more common with polyarticular, systemic and enthesitis-related forms and with severe uncontrolled disease. Chronic hip arthritis leads to irreversible joint damage with marked impairment of quality of life and functional limitation [1]. Unilateral or bilateral hip arthritis occurs in 30- 50% of children with JIA [2].
Objectives: The aim of this study is to assess the pattern of hip involvement in a cohort of Egyptian JIA patients in terms of epidemiological aspects, JIA pattern, bilateralism, associated extra-articular manifestations, radiological features, treatment and prognosis.
Methods: We included 179 patients who fulfilled the International league against rheumatism criteria for JIA. Epidemiological, clinical, radiological, and therapeutic parameters were assembled and analyzed. Hip involvement was assessed using a semi-quantitative score of pain and tenderness for the hip, CARSH radiographic score of the hip, and Harris functional hip score. JADAS-27 was used for assessment of disease activity.
Results: We included 113 girls and 66 boys; with a female: male ratio of nearly 2:1. The age at onset mean was 8.8±3 years (8.9±2.9 for females and 8.6±3.1 for males). The mean age at the study time was 13.3±4.1 years. The disease duration mean was 4.5±2.9 years.
Clinically; 20.1% of the cases had hip involvement (12.8% unilateral and 7.3% bilateral), while by imaging, around 30.7% of the cases have hip involvement (19.6% unilateral and 11.2% bilateral). The mean age for cases with hip involvement was 14.1±4.3, compared to 12.9±4 among those with no hip involvement. The mean disease duration for those with hip arthritis (either clinical or by imaging) was 5.5±2.9 years, compared to 4.1±2.9 among those with no hip involvement (Figure 1).

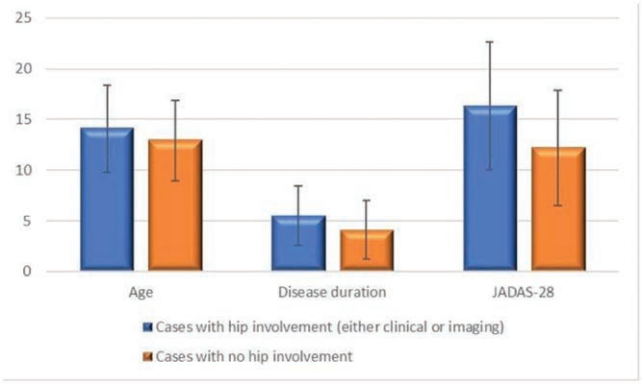

Figure 1. Difference between JIA cases with and without hip involvement.

The Mean JADAS-27 was 13.5±6.2 and for those with hip involvement was 16.3±6.3. The commonest pattern of JIA with hip arthritis was polyarticular followed by enthesitis-related arthritis. There was a strong significant correlation between JADAS-27 and hip involvement at one hand and Harris score, semi-quantitative score for pain and tenderness at the other hand. Further, disease duration was significantly correlated with hip involvement as well. Among cases with hip involvement, 25% demonstrated destructive changes and 30% showed growth abnormalities.
Conclusion: Hip arthritis in JIA is related to polyarticular and enthesitis-related pattern. Longer disease duration, seropositive polyarticular pattern were related to poor prognosis for hip arthritis.

CLINICAL AND LABORATORY CHARACTERISTICS, GENETIC FEATURES OF MACROPHAGE ACTIVATION SYNDROME IN CHILDREN WITH SYSTEMIC-ONSET JUVENILE IDIOPATHIC ARTHRITIS: A SINGLE CENTER EXPERIENCE

I. Kriulin[1,2], E. Alexeeva[1,2], T. Dvoryakovskaya[1,2], K. Savostyanov[3], A. Pushkov[3], K. Isaeva[1], R. Denisova[1], O. Lomakina[1], A. Mamutova[1], A. Chomakhidze[1], A. Fetisova[1], M. Gautier[1], E. Krekhova[1,2], I. Tsulukiya[1], A. Gromov[2]. [1]*National Medical Research Center of Children's Health, Rheumatology, Moscow, Russian Federation*; [2]*Sechenov First Moscow State Medical University, Pediatric, Moscow, Russian Federation*; [3]*National Medical Research Center of Children's Health, Genetic, Moscow, Russian Federation*

Background: Macrophage activation syndrome (MAS) is a life-threatening complication of systemic-onset juvenile idiopathic arthritis (sJIA) characterized by fever, hepatosplenomegaly, lymphadenopathy, coagulopathy, and rapid development of multiple organ failure. MAS is triggered by viral and bacterial infections, most often Epstein-Barr viruses, cytomegalovirus, influenza and parainfluenza viruses, parvavirus B19, yersiniosis, salmonellosis, sepsis.

Despite modern diagnostic and treatment technologies, MAS still remains a formidable complication of sJIA, it is characterized by an aggressive course, a heterogeneous clinical presentation, especially in conditions of treatment with genetically engineered biological drugs, an ambiguous response to pathogenetic therapy and is accompanied by mortality in 5-10% of patients.

Objectives: To analyze the clinical and laboratory features of MAS in children with sJIA and to study the genetic predisposition of this syndrome.

Methods: The study included 24 patients with MAS who are being followed up in the rheumatology department of the National Medical Research Center of Children's Health, Moscow. The clinical presentation and laboratory manifestations were assessed in 24, and genetic features were described in 7 patients using a new generation sequencing with further biostatistical processing of the obtained genetic data.

Results: Of 24 patients, 23 (98%) had fever, 16 (68%) patients had rash, 17 (72%) - organomegaly, 4 (16%) - polyserositis, 2 (7%) - myalgia and myopathy. All 24 (100%) patients had an increase in ferritin level of more than 684 ng/ml, 98% of them had a high level of lactate dehydrogenase (LDH) and 97% - a high level of triglycerides. In CBC, cytopenia was found in 80% of children: in 54% - erythrocytopenia, in 74% - leukopenia, in 88% - thrombocytopenia, in 15% - sharp decrease in erythrocyte sedimentation rate. In a coagulogram of 24 patients, 90% had an increase in D-dimer, 85% had a decrease in fibrinogen. Hyponatremia presented in 95% of patients. Thus, 85% of patients met the diagnostic criteria of the HLH-2004 protocol, adapted for children with sJIA. Genetic characteristics were analyzed in 7 children out of 94 patients with MAS. They are presented in Table 1. These patients have rare and frequent variants, as well as genes polymorphisms that are associated with macrophage activation syndrome.

Table 1. The number of genetic variants in children with MAS (n=7).

Gene	Patient № 1	Patient №2	Patient № 3	Patient № 4	Patient №5	Patient №6	Patient №7
LYST	0	24	7	3	4	6	4
NLRC4	4	4	4	4	4	6	3
NLRP12	5	10	6	4	4	12	4
NLRP3	1	8	5	5	5	7	5
TNFAIP3	2	2	2	0	2	2	2
UNC13D	18	2	5	10	18	26	18
XIAP	1	1	0	0	1	3	1

Conclusion: The macrophage activation syndrome has a typical clinical presentation, there are clinical and laboratory manifestations: fever, hyperferritinemia, cytopenia, hyponatremia, increased levels of LDH and triglycerides, based on which, a diagnosis can be made. Patients with MAS at our center also had genetic characteristics that predisposed to the development of this condition.

TREATMENT RESPONSE TO METHOTREXATE MONOTHERAPY IN ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS: DATA FROM THE NOR-DMARD STUDY

I. Bardan[1], K. M. Fagerli[2], J. Sexton[2], G. Bakland[3], P. Mielnik[4], L. M. Paucar Loli[5], T. K. Kvien[1,2], E. Kristianslund[2], A. B. Aga[2,6]. [1]*University of Oslo, Faculty of Medicine, Oslo, Norway*; [2]*Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*; [3]*University Hospital Northern Norway, Department of Rheumatology, Tromsø, Norway*; [4]*Helse Førde, Section for Rheumatology, Department for Neurology, Rheumatology and Physical Medicine, Førde, Norway*; [5]*Lillehammer Hospital for Rheumatic Diseases, Department of Rheumatology, Oslo, Norway*; [6]*Oslo University Hospital, Department of Rheumatology, Oslo, Norway*

Background: Juvenile idiopathic arthritis (JIA) can cause considerable pain and disability in childhood and adulthood. The number of studies exploring the efficacy of medications in adult JIA patients is limited. Methotrexate (MTX) is a commonly used medication for this patient group.

Objectives: To explore the effects of MTX monotherapy (mono) on disease activity in adult patients diagnosed with JIA, compared to a weighted rheumatoid arthritis (RA) cohort.

Methods: Data from NOR-DMARD, a longitudinal observational study enrolling patients > 18 years starting or switching DMARD treatment for inflammatory joint disease, was used [1]. Patients starting MTX mono treatment, and with a clinical diagnosis of JIA or other inflammatory arthropathies diagnosed before the age of 16 years, were identified from the study population. RA patients starting the same treatment regimen were included for comparative purposes.

Disease activity measurements and remission rates were collected at baseline, 3 and 6 months. Changes in disease activity and absolute remission rates after 3 and 6 months were calculated. Remission rates and change in disease activity from baseline were compared between JIA patients and a weighted RA cohort with weights based on age and gender, using linear and logistic regression for continuous and categorical variables, respectively.

Results: 2201 patients were included in the analyses, 101 JIA patients (80.2% female, mean (SD) age 35.6 (13.0) years, mean (SD) diagnosis duration 24.8 (12.9) years), and 2100 RA patients (69.4% female, mean (SD) age 56.6 (13.6) years, mean (SD) diagnosis duration 4.1 (8.1) years) were included in the analyses. Age, gender distribution and disease duration differed significantly between cohorts.

Both the JIA and RA group improved significantly across all disease activity measures from baseline to 3 and 6 months (Table 1). Both groups had a progressive increase in remission rates from baseline to 6 months (Table 1, Figure 1). The RA group had a significantly greater improvement in ESR after 3 months, SJC28 after 6 months and TJC28, DAS28, SDAI and MHAQ after 3 and 6 months. There were no significant group differences in remission rates.

Table 1.

	Baseline			Change to 3 months			Change to 6 months		
	JIA*	RA*	Diff.§	JIA*	RA*	Diff.§	JIA*	RA*	Diff.§
ESR, mm/h	20.4 (18.2)	28.7 (22.2)	3.7 (-0.6 to 8.1)	-3.1 (15.8)	-9.6 (18.7)	-5.7 (-10.1 to -1.4)	-3.0 (17.5)	-11.3 (19.8)	-5.4 (-10.8 to 0.03)
SJC28	3.9 (4.8)	6.9 (5.7)	2.0 (0.9 to 3.2)	-1.8 (3.3)	-3.5 (5.5)	-0.9 (-1.9 to 0.02)	-1.8 (3.3)	-4.2 (5.6)	-1.5 (-2.6 to -0.5)
TJC 28	4.5 (4.9)	8.0 (7.1)	3.1 (1.9 to 4.2)	-0.8 (4.2)	-3.5 (7.4)	-1.9 (-3.1 to -0.7)	-1.4 (3.8)	-4.0 (6.8)	-2.3 (-3.4 to -1.1)
DAS28	4.0 (1.3)	4.9 (1.3)	0.6 (0.2 to 0.9)	-0.6 (1.2)	-1.2 (1.5)	-0.5 (-0.9 to -0.2)	-0.7 (1.2)	-1.4 (1.5)	-0.6 (-1.0 to -0.2)
SDAI	18.3 (11.3)	26.0 (13.6)	5.6 (2.7 to 8.4)	-6.0 (9.7)	-11.0 (14.0)	-3.1 (-5.9 to -0.2)	-6.3 (8.2)	-12.8 (14.2)	-5.1 (-7.8 to -2.2)
PGA	51.0 (24.6)	48.3 (24.3)	-4.5 (-10.0 to 1.1)	-13.2 (25.3)	-14.7 (26.5)	-1.0 (-7.4 to 5.3)	-11.3 (23.8)	-14.3 (26.7)	-4.6 (-11.9 to 2.7)
MHAQ	0.5 (0.5)	0.7 (0.5)	0.1 (-0.05 to 0.2)	-0.2 (0.3)	-0.2 (0.5)	-0.1 (-0.2 to -0.0)	-0.1 (0.3)	-0.2 (0.5)	-0.16 (-0.3 to -0.1)

*Mean (SD) § Weighted group difference, RA coefficient (95 % confidence interval)

Conclusion: Adult JIA patients had significant improvement across all the presented disease activity measures 3 and 6 months after treatment initiation with MTX mono. The magnitude of improvement was smaller than in the RA group, but JIA patients obtained remission at similar rates as RA patients.

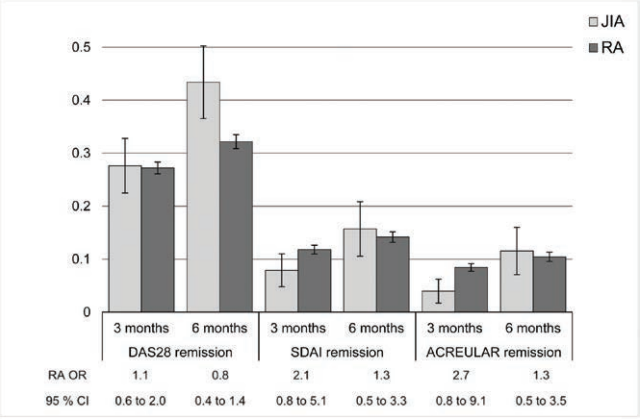

Figure 1. Mean 3- and 6-month remission rates with error bars (SE)

AB0723 JUVENILE BEHCET'S DISEASE: WHICH PARTICULARITIES?

O. Jomaa[1], O. Berriche[1], S. Arfa[1], A. Fraj[1], W. Romdhane[1], R. Makhloufi[1], M. Hermassi[1], M. Belkhiri[1]. *[1]University Hospital Tahar Sfar Mahdia, Tunisia, Internal Medicine Department, Mahdia, Tunisia*

Background: Behcet's disease (BD) is a systemic vasculitis that affects young adults aged between 20 and 30 years old. It is rare in childhood.

Objectives: This work aims to analyze the clinical features of this form by comparing it with adult BD.

Methods: Through a retrospective study including 192 cases with BD seen in The Internal Medicine Department at Tahar Sfar Hospital Mahdia TUNISA, we report 8 cases of juvenile BD (4.2%) that occurred under the age of 16 years.

Results: There were 8 male. The average age of BD onset was 14 years [11, 16 years]. Genital aphthosis was noted in 5 patients. Ophthalmologic damage was observed in 4 patients, dominated by uveitis (75% of cases). No cases of blindness were observed. Joint damage was seen in 5 patients and vascular and neurological damage in 2 patients respectively. All patients received colchicine in addition to a platelet aggregation inhibitors at the moment of BD diagnosis. When comparing juvenile BD group with that of adults, we have noticied, the frequency of cutaneo-mucous and articular manifestations, the rarity of neurological damage and the absence of cardiac and digestive damage in the juvenile BD group.

Conclusion: Juvenile BD is a rare form, with a male predominance. The younger age is not a poor prognostic factor. Early diagnosis and treatment can reduce the disease's complications.

AB0724 CANDIDATE PREDICTIVE BIOMARKERS OF POOR TREATMENT RESPONSE IN OLIGOARTICULAR ONSET JUVENILE ARTHRITIS TO EARLY STEROID INJECTIONS

A. Kozhevnikov[1,2], N. Pozdeeva[1], O. Maricheva[3], M. Nikitin[1], S. Bogdanova[4], G. Novik[2]. *[1]H.Turner National Medical Research Center for Children's Orthopedics and Trauma Surgery, Trauma Sequelae and Rheumatoid Arthritis Clinic, Saint-Petersburg, Russian Federation*; *[2]St.Petersburg State Pediatric Medical University, Department of Children's Diseases named after Professor I. M. Vorontsov, Saint-Petersburg, Russian Federation*; *[3]H.Turner National Medical Research Center for Children's Orthopedics and Trauma Surgery, Diagnostic Radiology, Saint-Petersburg, Russian Federation*; *[4]H.Turner National Medical Research Center for Children's Orthopedics and Trauma Surgery, Laboratory Diagnostics, Saint-Petersburg, Russian Federation*

Background: Intra-articular corticosteroid injections are the first-line antirheumatic drugs of oligoarticular onset juvenile arthritis. Despite significant advances in treatment (anti-TNF, block IL6) this choice of pediatric chronic joint disease still remains relevant. Pediatric rheumatologists and to this day there are no consensus on the best modality for treatment.

Objectives: The aim of this study was to search of biomarkers ineffective of early intra-articular steroid injections of oligoarticular onset juvenile arthritis.

Methods: Clinical, imaging, laboratory data (blood and synovial fluid), and effect of early isolated intra-articular injections (is-IAI) of triamcinolone acetonide 92 children (89% girls) aged median (IQR) 4,2 (1,6 – 7,6) years with oligoarticular onset juvenile arthritis without extra-articular manifestations (oligo-JA) were collected retrospectively and analyzed. All children were met ILAR criteria. Triamcinolone acetonide (TA) was administered intra-articular at a dose of 20-40 mg with an injection interval of 3-6-12 months which was depended on the activity of the disease. All children were divided into two groups: active / inactive arthritis based on the effectiveness of local corticosteroid treatment. The average follow-up was 48 [38; 62] months.

Results: 32 children (35%; all girls) were achieved remission oligo-JA after is-IAI of TA with mean of 2 [1,75; 2] injection per joint (inactive arthritis > 24 months). The mean interval between two consecutive is-IAI was 7 [5,25; 10] months. Other children did not achieve inactive oligo-JA after is-IAI of TA with mean of 3 [2; 4] injection per joint. The mean interval between first two consecutive injection was 5,5 [4,25; 7] months and other injections - 2 [2; 3] months. All children who did not achieve remission oligo-JA for is-IAI were treated by DMARDs. Statistical analyses were performed to determine the relationships between clinical, instrumental, laboratory signs and efficacy is-IAI of TA. Measures included the number of swollen or tender joints [active joint counts]; biological inflammatory markers [erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), serum and synovial fluid level of interleukin 6 (IL6) and tumor necrosis factor alfa (TNF-α)]; autoimmunity [titer of antinuclear factor (ANF)] and physicians' assessment of JIA disease activity [clinical Juvenile Arthritis Disease Activity Score including maximal 10 joints (cJADAS10)]. Efficacy is-IAI of TA was no associated significantly with number of active joint of onset oligo-JA, cJADAS10, serum level of CRP mg/ml, ESR mm/h, IL6 pg/ml and TNF-α pg/ml, titer of ANF. The mean inflamed synovial fluid of IL6 levels 2208 [710; 4564] / 3234 [1265; 16902] pg/ml and TNF-α levels 3,3 [2,5; 3,8] / 1,1 [0,6; 3,7] pg/ml at onset of inactive and active oligo-JA were not significantly differ. The analysis revealed a correlation between a short phase of beneficial effect after is-IAI of TA and risk of activity disease (with an inactive phase of arthritis less than 3 months, the risk activity was OR = 2.09, p <0.001; with an inactive phase less than 2 months - OR = 8.9, p <0.001).

Conclusion: TA is an effective and safe treatment in children with oligo-JA. Research was revealed that about a third of children with oligo-JA achieved inactive arthritis of average after two intra-articular injections of TA (all girls). There are no biomarkers for prediction of poor treatment response in oligo-JA to early steroid injections. But a short phase of beneficial effect after is-IAI of TA may be sign of risk activity disease. In addition boys with oligoarticular onset juvenile arthritis may be considered like potentially ineffective for local steroid therapy.

AB0725 MACROPHAGE ACTIVATION SYNDROME IN CHILDREN WITH RHEUMATIC DISEASES: ANALYSIS OF CASE SERIES

M. Kaleda[1], I. Nikishina[1], V. Matkava[1], A. Shapovalenko[1], E. Fedorov[1], S. Salugina[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*

Background: Macrophage activation syndrome (MAS) is a rare, but severe life-threatening complication of chronic rheumatic disease (RD) in children, which associated with high risks of the multiple organ failure and mortality.

Objectives: To analyze demographic, clinical and laboratory parameters, timing of MAS and disease outcome in patients (pts) with MAS and RD.

Methods: The study included all pts of single center with RD, who developed the MAS. The diagnosis was recognized according to Classification criteria for MAS in sJIA [1].

Results: We observed 52 pts with RD and MAS: 31 (59.6%) with sJIA, 19 (36.5%) – SLE, 1(1.9%) – juvenile dermatomyositis (JDM), 1 (1.9%) – overlap syndrome (JIA+JDM). Pts with MAS accounted of 26% of all pts with sJIA, 7.6% of all pts with SLE. The mean age of pts at onset of sJIA was 2.6 y [1.5; 5.75], at onset of SLE – 11.8 y [8.6; 13.95]. The patient with JDM was 6.5 years old, pts with overlap syndrome – 3.5 years old. Male to female ratio was 1:1,7. A total of 63 episodes of MAS was recorded (41 – in sJIA, 20 – SLE, 1 – JDM, 1 - overlap syndrome). 23 pts (44.2%) had MAS at onset, 26 pts (50%) – "classic" MAS (during the course of disease), 3 pts (5.8%) – recurrent MAS. The clinical manifestations of MAS included fever (90.4%), hepatomegaly (50%), pericarditis (46.2%), hemorrhagic rash (32.7%), neurologic involvement (42.3%), lung involvement (34.6%). We found hyperferritinemia in 98%, thrombocytopenia in 78.8%, increased transaminases in 88.5%, hypofibrinogenemia in 40.4%, hypertriglyceridemia in 42.3 % of pts. Most severe course of MAS was established in pts with ferritin levels >1500 ng/ml and with hypertriglyceridemia more than 6.0 mmol/l at an early stage. Bone marrow investigation was performed in 21 pts, and the evidence of haemophagocytosis was confirmed in 8 pts (38%). First features of MAS were fever, sleepiness, lower platelet counts, high TA. Lesions of the skin and mucous were mainly represented by point hemorrhages at an early stage in pts with SLE and MAS, the development of a bright rash with itching was typical for pts with sJIA and MAS. There are no principal differences between course of MAS in sJIA and other RD in children, but mild "subclinical" cases of MAS were observed only in pts with sJIA on biologics. For treatment of MAS all pts were administered high dose of glucocorticoids (per os+iv). Pts with SLE received: cyclophosphamide iv - 5 (26.3%), cyclosporine per os 1 (5.2%), IVIGs - 6 (31.6%), rituximab - 2 pts (10.5%). Pts with sJIA received: cyclosporine per os - 20 (64.5%), IVIGs - 25 (80.6%), 1 etoposide - (3.2%). Patient with overlap syndrome received cyclosporine per os. 8 pts (15.4%) died from MAS (3 with sJIA, 5 – with SLE).

Conclusion: MAS can develop in various children's RD, but more often in pts with sJIA. In our observation more pts had MAS during the course of disease, not at onset. Rapid recognition of MAS can improve treatment outcomes and prognosis.

AB0726 BIOLOGICS IN CHILDREN WITH IDIOPATHIC INFLAMMATORY MYOPATHIES: AN EXPERIENCE OF SINGLE CENTER

M. Kaleda[1], I. Nikishina[1], V. Matkava[1], Z. Kolkhidova[1], S. Arsenyeva[1], A. Shapovalenko[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*

Background: Juvenile dermatomyositis (JDM) is the most common idiopathic inflammatory myopathy (IIM) of childhood, but the involvement of muscle also can be complication of systemic lupus erythematosus (SLE), mixed connective tissue disease (MCTD) and different overlap syndromes. The presence of myopathy can significantly affect the prognosis of the disease and the quality of life. Despite of the absence of official indication for biological therapy fo IIM, it`s may be needed in severe course of disease.

Objectives: To analyze in retrospective study the efficacy and safety of Biologics (B) in patients (pts) with IIM in our pediatric rheumatology center.

Methods: The study included all pts with rheumatic diseases (RD), who had IIM and received B during past 10 years.

Results: A total of 17 pts (10 females) were identified: 23.5% with JDM, 11.8% - SLE, 35.3% - MCTD, 29.4% - overlap syndromes. The median age at the onset of RD was 9.75 years [interquartile range (IQR) 6.9; 13.5]. The median disease duration at the onset of myopathy was 7.0 months [3.0; 10.0], in all pts with JDM – at onset. All pts had myopathic syndrome. The rash tipical for JDM was in 8 pts (47%). The lung involvement observed in 6 pts (35.3%). Levels of serum muscle enzymes (CK, ALT, AST and lactate dehydrogenase [LDH]) were elevated in 88.2% of pts: CK in 52.9% (mean ± std 624.35±1007.2 U/L), ALT – 82.4% (mean ± std 142.18±148.16U/L), AST – 82.4% (mean ± std 159.6±201.1 U/L), LDH – 88.2% (mean ± std 492.5±229.2 U/L). Abnormal EMG findings were in 10 pts (59.4%). Nailfold capillaroscopic changes tipical for IIM had 10 pts (59.4%). Before B 94.1% of pts received corticosteroids (CS), 58.8% - methotrexate, 29.4% - hydroxychloroquine, 17.6% - cyclophosphamide, 11.8% - cyclosporine, 5.9% - mycophenolate mofetil, 5.9% - azathioprine, 47% - IVIG. B therapy was started due to insufficient efficacy of previous therapy. The median age at start of B was 12.3 years [IQR 9.5; 15.0]. The median disease duration prior to treatment with B was 2.25 years [IQR 0,8; 3.6]. 58.8% of pts received rituximab (RTX), 41.2% - abatacept (ABA). The median time between each course of RTX was 182 days [IQR 156–315]. 80% of pts underwent more than one course of RTM therapy, with a maximum of 5 courses. The median duration of ABA therapy was 2.8 years [IQR 1.6; 5.0]. Discontinuation of B due to serious AE was observed in 1 patient with overlap syndrome (5.9%) – macrophage activation syndrome (MAS) 8 day after RTX infusion (5th course, 1st infusion). One patient (female, 12.3 yo) died from MAS (at onset of SLE, developed before B), the others achieved remission. B therapy allowed to reduce the dose of CS to maintenance in all pts, decrease of calcinosis in 2 pts and improve the quality of life.

Conclusion: Our study demonstrated that B is highly effective in children with IIM and have the acceptable safety. Early diagnosis and initiation of intensive therapy are important in reducing symptoms of myopathy in RD. It seems that the development of IIM in other RDs, not JDM, indicates the need for B and its good efficacy. The further extended studies are needed.

AB0727 STUDY OF MEFV GENE MUTATIONS IN A COHORT OF CHILDREN: A SINGLE CENTER

T. Kriulina[1,2], E. Alexeeva[1,2], T. Dvoryakovskaya[1,2], I. Kriulin[1,2], K. Isaeva[1], R. Denisova[1], O. Lomakina[1], A. Mamutova[1], A. Chomakhidze[1], A. Fetisova[1], M. Gautier[1], E. Krekhova[1,2], I. Tsulukiya[1], A. Gromov[2]. *[1]National Medical Research Center of Children's Health, Rheumatology, Moscow, Russian Federation*; *[2]Sechenov First Moscow State Medical University, Pediatric, Moscow, Russian Federation*

Background: Familial Mediterranean fever (FMF) is a monogenic autoinflammatory hereditary disease characterized by recurrent episodes of fever with sterile peritonitis, pleural inflammation, arthritis, and/or erysipelas-like rash. Among all variants of the MEFV gene, according to the literature, five pathogenic ones have been identified, which in 75% of cases lead to the development of a typical clinical presentation: V726A, M694V, M694I, M680I, and E148Q. Among them, the M694V variant is the most common and occurs in patients with FMF in 20-65% of cases. At the same time, approximately 10 to 20% of patients meeting the diagnostic criteria for FMF do not have pathogenic variants in the MEFV gene. Despite the fact that the molecular genetic, pathogenetic and clinical features of the disease have been studied detailed, the diagnosis remains difficult due to the lack of a clear correlation between the patient's clinical and genetic data.

Objectives: To analyze the obtained genetic data of patients with pathogenic variants in the MEFV gene.

Methods: The study included 103 patients who are mainly observed at the rheumatology department of the National Medical Research Center of Children's Health of Ministry of Health of the Russian Federation in Moscow. All patients underwent analysis of the MEFV gene using Sanger sequencing with further statistical processing of the data obtained.

Results: Of 103 patients, the pathogenic variant of the MEFV gene was found in 93 patients (90.3%), in 10 patients (9.7%) - the pathogenicity of the revealed variant was contradictory. Of 93 patients with the pathogenic variant of MEFV, the clinical presentation of the disease fits to FMF in 37 patients (39.6%). 11 (29.7%) of them had a mutation in M694V. Out of 37 children who met the criteria for FMF diagnosis, 15 (40.5%) children had a homozygous pathogenic variant of MEVF, and 22 (59.5%) children had two mutations in a heterozygous state. 57 patients who do not have a typical clinical presentation, which is specifical for FMF are observed at the departments of rheumatology, cardiology and nephrology, 13 patients are on an outpatient observation, and 6 patients at the time of the study are over 18 years old. 8 (14%) of them had a mutation in M694V. Among 57 patients with pathogenic heterozygous variants in a, 22 patients (38.6%) are observed in the rheumatology department, among them:

- Enthesitis-related arthritis - 2 patients (9%);
- Systemic juvenile arthritis - 13 patients (59%);
- Oligoarthritis - 5 patients (23%);
- Polyarthritis- 2 patients (9%).

Conclusion: Analysis of the obtained data showed that FMF is characterized by a combination of the clinical presentation and the pathogenic variant in the MEFV gene. However, the disease manifests itself not only in the homozygous pathogenic variant, but also in the combination of two mutations in heterozygous. The presence of one heterozygous mutation, generally, does not lead to the development of FMF.

AB0728 OSTEOGENESIS IMPERFECTA: ABOUT 12 CASES

O. Jomaa[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. *[1]University Hospital Fattouma Bourguiba Monastir,Tunisia, Rheumatology Department, Monastir,Tunisia*

Background: Osteogenesis imperfecta (OI), is a rare hereditary disease characterized by bone fragility and low bone mass. The clinical presenatation is various with varying severity skeletal signs and inconstant extra-skeletal signs. Type 1 is the most common form (60% of cases).
Objectives: Our objective is to describe the various clinical features observed over a period of 15 years.
Methods: This is a retrospective descriptive study including 12 patients followed for OI, hospitalized in the Rheumatology Department at Fattouma Bourguiba Hospital Monastir TUNISIA between 2006 and 2019. Files were collected and analyzed.
Results: They are 9 boys and 3 girls with an average age of 14.9 ± 8.6 years. Consanguinity was reported in 25% of cases. The reason leading to consultation was, recurrent fractures (75%), blue sclera (16.7), and bone deformity (8.3%). The number of previous fractures was on average of 5, all of which were caused by a low energy trauma. Similar family cases were noted in 41.6%. The mean age of the first fracture was 4.41 ± 3.2 years. The most frequent fracture sites were respectively: femur (7/12), leg (6/12), tibia (3/12), humerus (4/12), ankle (2/12), and forearm (2/12). A deformity was noted in 58.3% of the cases: lumbar kyphosis (2), exaggerated dorsal kyphosis (2), femurs in parenthesis (2), and an anarchic deformity of 2 lower limbs (1). Imperfect dentinogenesis was found in 8.3% of cases, while ENT examination revealed conductive and sensorineural hearing loss in 2 patients each. The main radiological abnormalities were diffuse bone demineralization (9 patients), cortical thinning (5 patients), vertebral compression (3 patients), and fracture (2 patients). The bone densitometry showed a mean Z score of 3.49±1.4 in the lumbar spine. The average serum calcium level was 2.38±1.15, alkaline phosphatases were elevated in all cases with an average of 756±624.9. The vitamin D level was deficient in all cases with an average of 22.75±5.3. All patients received in addition to the vitamin-calcium supplementation, pamidronate intravenously at a dose of 9mg/kg/year with a mean number of 6 cures. The main side effects observed during the infusion were abdominal pain, polyarthralgia and asthenia (1 patient), chest pain (1 patient) and fever and chills (1 patient). The control bone densitometry showed a mean Z score of 1.81±1.2 in the lumbar spine.
Conclusion: Despite advances in the OI diagnosis and treatment, more research is needed. Bisphosphonate treatment decreases long-bone fracture rates, but such fractures are still frequent. New antiresorptive and anabolic agents are being investigated but efficacy and safety of these drugs, especially in children, need to be better established before they can be used in clinical practice.

AB0729 CLINICO-EPIDEMIOLOGICAL PROFILE OF JUVENILE IDIOPATHIC ARTHRITIS (JIA) PATIENTS IN KENYA; DATA FROM THE KENYA PEDIATRIC RHEUMATOLOGY (KAPRI) REGISTRY

A. Migowa[1], R. Odhiambo[2], J. Orwa[3], J. Shah[4]. *[1]Aga Khan University Hospital-Westlands, Pediatrics and Child Healh, Nairobi, Kenya*; *[2]Aga Khan University Hospital-Westlands, Institute of Human Development, Nairobi, Kenya*; *[3]Aga Khan University Hospital-Westlands, Population Health, Nairobi, Kenya*; *[4]Aga Khan University Hospital-Westlands, Internal Medicine, Nairobi, Kenya*

Background: Pediatric rheumatic diseases are chronic illnesses that impart a significant disease burden upon societies (1-3). Determination of the burden and clinical characteristics of these diseases is a critical first step to improving access to care and optimizing use of existing health systems for the well-being of these patients (4-6). A pediatric rheumatology registry is critical in defining the spectrum, clinical characteristics, outcomes and responses of various interventions for pediatric rheumatic diseases. Given that none exists in Kenya, the Kenya Pediatric Rheumatology Registry (KAPRI) registry offers a platform to generate this much needed data in sub-Sahara Africa.
Objectives: Our objective was to determine the baseline patient characteristics, clinical features and outcomes of the Juvenile Idiopathic Arthritis (JIA) patients assessed at the Aga Khan University Medical College East Africa who were enrolled into the KAPRI registry from inception in March 2019 to December 2020.
Methods: All patients with an ICD 10 M code diagnosis of Juvenile Arthritis were selected from the KAPRI registry database. Age, gender, laboratory and clinical features at diagnosis and treatment options offered were extracted from the database. A further detailed chart review was undertaken to determine the proportion of patients who achieved remission or minimally active diseases.
Results: Among the 207 patients enrolled thus far, 16 (7.7%) were diagnosed to have JIA. Majority of the patients were females (75%; n=12) with a mean age of 7 years and 3 months (Range:1 year – 13 years 7 months).
All patients had joint pain and swelling as the initial presenting complaints. Majority of the patients had polyarticular JIA (75%, n=12). The other 4 patients were oligoarticular (n=2) and systemic JIA (n=2). Among the polyarticular JIA patients (n=12), only 3 (25%) were rheumatoid factor (RF) positive and 1 was antinuclear antibody (ANA) positive. The oligoarticular and systemic JIA patients were all negative for antinuclear antibody, rheumatoid factor and cyclic citrullinated peptide antibodies (anti-ccp). Seven patients (43.8%) required biological therapies; tocilizumab (n=2: systemic JIA), adalimumab (n=2: polyarticular JIA), etanercept (n=2: polyarticular JIA) and tofacitnib (n=1: polyarticular JIA). One patient with systemic JIA on tocilizumab developed herpes simplex which was successfully managed with oral acyclovir. All the other patients did not develop any infections, allergic reactions or any other untoward events as adverse outcomes following the use of biological therapies. Five patients have attained remission as illustrated in the Table 1 below. Two patients have been lost to follow up.
Conclusion: Seronegative polyarticular JIA was the predominant form of JIA observed with a predilection to affect more girls and boys. Over a period of 2 years, remission has been attained among 31.25% of the patients (5 of 16) with use of synthetic disease modifying anti-rheumatic drugs and biological therapies.

AB0730 HIP INVOLVEMENT IN JUVENILE IDIOPATHIC ARTHRITIS

S. Bouden[1], N. Ben Chekaya[1], A. Ben Tekaya[1], O. Saidane[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. *[1]Charles Nicolle Hospital, Rheumatology,Tunis, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is a heterogeneous group of diseases that have in common an onset before the age of 16 years, more than 6-month duration, and the presence of arthritis for at least 6 weeks with no identifiable cause. Hips are the commonly affected joints in severe destructive JIA. Hip disease develops in 20% to 50% of children with JIA.
Objectives: We aimed to analyze the epidemiological, clinical, and radiological aspects of hip involvement in Tunisian JIA.
Methods: A retrospective study including 35 patients was conducted between 2010 and 2019. The patients enrolled met the ILAR criteria for the diagnosis of JIA. Clinical, biological and radiological parameters relating to the hip involvement were collected.
Results: Thirty-five patients were enrolled. The mean age of the disease onset was 9 years [3-15]. The mean age of the patients at the time of the study was 37.8 years [17-69]. The mean duration of the disease was 27 years [2- 56]. These patients were assigned to discrete JIA categories: rheumatoid factor positive polyarthritis (43.5%), rheumatoid factor negative polyarthritis (21.7%), enthesitis-related arthritis (17.4%), oligoarthritis (13%) and psoriatic arthritis (4.4%). A biological inflammatory syndrome was noted in 52% of patients. Hip involvement was noted in 43.5% of patients. Coxitis occurred on average 15 years after the JIA onset [[4-37]. Thirty four percent of the patients had bilateral hip involvement. The mean Lequesne index was 14. Joint space narrowing and erosions were noted in respectively 68% and 34% of cases. The majority of patients (82.6%) received medical treatment combining nonsteroidal anti-inflammatory drugs (NSAID) and rehabilitation. In the other cases, a total hip replacement was necessary. Coxitis was significantly correlated with rheumatoid factor positive polyarthritis subtype (p=0.02) and with the presence of biological inflammatory syndrome (p=0.03).

Conclusion: Hip involvement is a major and highly prevalent issue in our JIA patients.
Disclosure of Interests: None declared
DOI: 10.1136/annrheumdis-2021-eular.2619

AB0731 CERVICAL SPINE INVOLVEMENT IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

S. Bouden[1], N. Ben Chekaya[1], A. Ben Tekaya[1], O. Saidane[1], R. Tekaya[1], I. Mahmoud[1,1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in children. In contrast to adult rheumatoid arthritis, where numerous studies have shown a high prevalence of involvement of the cervical spine, few studies have been published examining this entity in JIA.
Objectives: We aimed to analyze clinical and radiological findings of cervical spine involvement in patients with JIA.
Methods: A retrospective study including 35 patients was conducted between 2010 and 2019. The patients enrolled met the ILAR criteria for the diagnosis of JIA. Clinical, biological, and radiological data were collected. Patients had a radiological evaluation that included cervical spine x-rays in antero-posterior, lateral and lateral views with flexion.
Results: Thirty-five patients were enrolled. The mean age of the disease onset was 9 years [3-15]. The mean age of the patients at the time of the study was 37.8 years [17-69]. The mean duration of the disease was 27 years [2-56]. These patients were assigned to discrete JIA categories: rheumatoid factor positive polyarthritis (43.5%), rheumatoid factor negative polyarthritis (21.7%), enthesitis-related arthritis (17.4%), oligoarthritis (13%) and psoriatic arthritis (4.4%). Sixteen patients (45%) reported neck pain. Cervical spine involvement occurred on average 7 years [0-13] after the JIA onset. Cervical spine radiographs showed anterior atlantoaxial subluxation (> 5mm) in 8 patients. Magnetic-resonance imagining was performed in 9 patients that had abnormal neurological examination showing a pannus formation of C1-C2 junction (3 cases), a basilar invagination (4 cases) and erosions of the odontoid process (2 cases). A cervical collar has been used for immobilization in patients with significant cervical spine damage. A C1-C2 arthrodesis was proposed to 4 patients.
Conclusion: These findings suggest that the presence of cervical involvement in JIA patients is frequent. Radiologic assessment of cervical spine should be systematically performed for early detection and to prevent its complications.

AB0732 JUVENILE IDIOPATHIC ARTHRITIS IN ADULTHOOD

N. Ben Chekaya[1], S. Bouden[1], A. Ben Tekaya[1], O. Ben Saidane[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease of unknown aetiology in childhood. Approximately 40- 60% of patients with juvenile idiopathic arthritis (JIA) have continuous or recurrent disease activity extending into adulthood.
Objectives: The aim of this study was to evaluate the clinical, biological and radiological course of JIA in adulthood.
Methods: A retrospective study including 35 patients was conducted between 2010 and 2019. The patients enrolled met the ILAR criteria for the diagnosis of JIA. Patients with JIA older than 20 years were included. Data regarding sociodemographic features, Physical growth, disease activity, biological and radiological parameters were analysed.
Results: Thirty one patients were recruited. The sex ratio was 0.53. The mean age at the time of the study was 38.9 years [20-69]. The mean age of the disease onset was 9 years [3-16]. These patients were assigned to discrete JIA categories: rheumatoid factor positive polyarthritis (47.7%), rheumatoid factor negative polyarthritis (23.9%), oligoarthritis (14.2%), enthesitis-related arthritis (9.5%), and psoriatic arthritis (4.7%).A failure to thrive was seen in 33.3% of patients. Overweight and obesity were found in 38% and 19% of patients, respectively. Biological inflammatory syndrome was noted in 52% of patients, and 65.2% had active disease. Hip involvement was noted in 43.5% of patients and 17.4% of them had a total hip replacement. Sixteen patients had neck pain and the imagining showed an atloid-axoid dislocation in 50% of them. Radiographs showed a joint destruction in 60.9% of patients and a wrist arthritis was the most frequent involvement.
Conclusion: Most of our included patients maintain active disease and have functional impairment in adulthood.
Disclosure of Interests: None declared

AB0733 DADA2 VASCULITIS PRESENTING AS POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME (PRES): AN ATYPICAL PRESENTATION

M. Mamadapur[1], S. Mahadevan[1], A. Singh[1], R. Chakravarthy C H2, R. S2, T. T N2. [1]*Madras Medical College, Clinical Immunology and Rheumatology, Chennai, India*; [1]*Madras Medical College, Clinical Immunology and Rheumatology, Chennai, India*

Background: Deficiency of Adenosine Aminase deficiency 2 is monogenic disease presenting with multisystem involvement of vasculitis,Stroke[1],hematological manifestations. We hereby present a young child who presented with PRES initially and later diagnosed as DADA2.Only one case of DADA2 presenting as PRES is reported so far[2].This case highlights the atypical presentation of DADA2.
Objectives: A case report to highlight the rare presentation of DADA2 vasculits.
Methods: 8 year old developmentally normal male child,born out of consanguineous marriage presented with with fever,abdominal pain, seizures 1 year back. Ultrasound of abdomen revelaed mesenteric lymphadenitis and MRI Brain was suggestive of Meningoencephalitis.He was managed with antivirals and antibiotics then.
6 months later,he had fever,skin rash,pain abdomen,status epilepticus,hypertension followed by gangrene of fingers and toes.APLA,ANA,ANCA workup was negative. Complete Hemogram was normal. CRP was 130mg/dl. CT Abdomen was normal and no evidence of aneurysms. Renal Doppler Ultrasound was normal.CT upper limb showed left radial and ulnar artery significant narrowing with patchy occlusion. MRI Brain showed bilateral fronto parietal,occipital,putamen,left insula and subcortical and cortical T2W FLAIR hyperintensity without diffusion restriction suggestive of PRES. He was diagnosed as Childhood Polyarteritis Nodosa and treated with cyclophosphamide. Genetic Analysis of ADA2(CECR1) gene mutation by Sanger Sequencing of exons 2 to 10 showed a known variant (rs202134424) in ADA2 gene.

Figure 1. Gangrene of left 1-5th digits and right 4th and 5th digit resorption

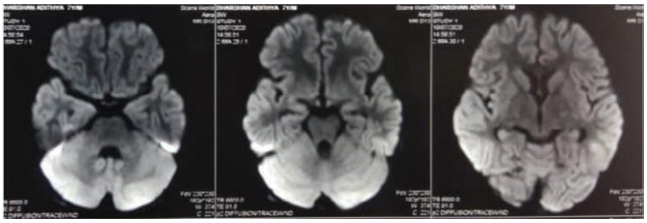

Figure 2. T2W FLAIR image showing bilateral fronto parietal,occipital,putamen,left insula and subcortical and cortical hyperintensity without diffusion restriction suggestive of PRES.

Results: He was started on Infliximab and is on follow up. No further events noted so far.Rehabilitation of left upper hand was done.
Conclusion: DADA2 can present with varied CNS manifestations like infarct,hemorrhage,aneurysms and PRES.High index of suspicion and early recognition can help in maintaining vascular integrity.

AB0734 REMISSION IN JUVENILE IDIOPATHIC ARTHRITIS AFTER WITHDRAWAL OF SYSTEMIC TREATMENT

L. C. Charca Benavente[1], L. Trives Folguera[2], L. R. Caballero Motta[2], A. M. Anzola Alfaro[2], K. López Gloria[2], J. M. Alvaro Gracia[2], I. Monteagudo[2], J. C. Nieto González[2]. [1]*Hospital Universitario Central de Asturias, Rheumatology, Oviedo, Spain*; [2]*Gregorio Marañón Hospital, Pediatric Rheumatology, Madrid, Spain*

Background: Juvenile idiopathic arthritis (JIA) requires frequent systemic treatments, the ideal goal being to achieve remission. Questions remain as to when treatment can be stopped and how to balance the risks and benefits of continuing medications against the possibility of a flare after discontinuation. There is currently little conclusive evidence on the management of JIA in remission.
Objectives: To determine the time to remission and frequency of flares in patients with JIA after withdrawal of systemic treatment in a single-centre cohort.
Methods: Patients with JIA visited in the last 15 years were included. A retrospective cross-sectional study was performed. Demographic data such as sex, age at diagnosis, current age, subcategories of JIA were collected. Systemic treatment was also collected (date of discontinuation, date of flare after discontinuation, time in remission, time of treatment until discontinuation, discontinuation of biologic therapy while maintaining methotrexate). For the analysis of qualitative variables, absolute and relative frequencies were used; for quantitative variables, median and IR; for comparative analysis, Chi-square and Mann-Whitney U test.
Results: We included 146 patients with JIA. Demographic data are shown in Table 1. 134 (90.4%) patients required systemic treatment (synthetic and/or biological DMARDs), of which 61 (45.5%) discontinued treatment completely at some point. Of the total number of patients who discontinued all systemic treatment, 19 (31.1%) had a flare with a median time in remission of 4.1 years (IR 1.3-9.1). 17 of the 134 patients (12.7%) with systemic treatment discontinued biologic therapy while maintaining methotrexate, of which 12 (70.6%) patients had a flare with a median time in remission of 0.9 years (IR 0.6-1.2). The differences between the frequency of flares and median time in remission between both treatment discontinuation groups (all systemic treatment versus discontinuation of biologic while maintaining methotrexate) were statistically significant (p<0.001). The median time from systemic treatment to complete withdrawal was 3.2 years (IR 1.9-4.8).

Table 1. Demographic characteristics of patients with JIA

Variables	N 146
Sex: Women n (%)	89 (60.3)
Age at onset (years, median (IR))	4.6 (2.5-9.2)
Current age (years, median (IR))	16.7 (11.1-20.9)
Types of JIA:	
Persistent oligoarticular n (%)	66 (45.2)
Extended oligoarticular n (%)	11 (7.5)
Polyarticular RF - n (%)	29 (19.9)
Polyarticular RF + n (%)	3 (2.1)
Enthesitis-related n (%)	12 (8.2)
Psoriatic n (%)	9 (6.2)
Systemic n (%)	16 (11.0)

Conclusion: One third of the patients in whom all systemic treatment was withdrawn had a flare (70% remain in remission without medication) with a median time in remission of 4 years. On the other hand, two-thirds of patients in whom biologic therapy was withdrawn while maintaining methotrexate had a flare, with a shorter time in remission. The differences between both groups with withdrawal of systemic treatment are statistically significant (p<0.001).

AB0735 POLYMORPHISMS OF GENES CD14, C-REACTIVE PROTEIN, FIBRINOGEN BETA CHAIN, ASSOCIATED WITH THE DEVELOPMENT OF KAWASAKI DISEASE AND CORONARY ARTERY ANEURYSMS IN CHILDREN FROM CENTRAL RUSSIA

M. Kantemirova[1], S. Kurbanova[1], Y. Novikova[1], A. Glazyrina[1], M. Azova[2], E. Zheludova[2], E. Tarasenko[2], D. Ovsyannikov[1]. [1]*RUDN University, Department of Pediatrics, Moscow, Russian Federation*; [2]*RUDN University, Department of Biology and General Genetics, Moscow, Russian Federation*

Background: Kawasaki disease (KD) is a multifactorial disease with a genetic predisposition, systemic vasculitis complicated by the formation of coronary artery aneurysms (CAA). Its pathogenesis is based on immune inflammation with an increase in the concentration of pro-inflammatory cytokines, the level of C-reactive protein (CRP), and coagulation disorder.
Objectives: to search for polymorphisms of genes cluster of differentiation CD14, CRP, fibrinogen beta chain (FGB), associated with the KD development and a predisposition to the CAA formation among patients with KD living in Moscow and the Moscow region.
Methods: genotyping for gene polymorphisms CD14 –159 C>T (rs2569190), CRP 3872 C>T (rs1205), FGB – 455 G>A (rs1800790) by PCR in 31 children 1 month – 10 years old (median age 19 months [9,0; 38,5]) with KD, among them, in 10 patients the disease was complicated by CAA formation according to echocardiography, and 30 children of the control group.
Results: Three out of six investigated SNPs showed statistically significant difference in genotype and allele distribution: CRP C3872T, CD14 C159T and FGB G455A. CRP gene polymorphism: in patients with KD significantly less frequent is homozygous type TT (RR 0,22, 95% CI: 0,05–0,91, p=0,0168).
CD14 gene polymorphism: in control group heterozygous genotype CT is predominant, (RR 0,58, 95% CI: 0,4–0,83, p=0,0017) among patients with KD homozygous genotypes CC and TT are predominant. (RR 3,61, 95% CI: 1,14–11,49, p=0,0057).
FGB gene polymorphism: genotype GA is predominant in control group (RR 0,48, 95% CI: 0,26–0,9, p=0,0149). In patients with KD significantly less frequent is homozygous type GG (RR 1,69, 95% CI: 1,03–2,8, p=0,0297).
We didn't find any significant difference in genotype and allele distribution in KD patients with and without CA lesions.
Conclusion: statistically significant differences (p<0,05) were revealed in the distribution of genotypes for polymorphisms of the CD14 –159 C>T, CRP 3872 C>T and FGB –455 G>A genes among patients with KD and children of the control group; when comparing the results of KD patients with CAA and the control group, statistically significant differences (p<0,05) were revealed only in the polymorphism CD14 –159 C>T. It can be assumed that these polymorphisms are associated with the development of KD and CAA in these patients.

AB0736 JUVENILE IDIOPATHIC ARTHRITIS IN ADULTHOOD: TRENDS OF THE DISEASE AND SOCIO-PROFESSIONAL FUTURE

S. Miladi[1], M. Yasmine[1], S. Mariem[1], A. Fazaa[1], K. Ouenniche[1], L. Souebni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is the most common arthropathy of childhood that may lead to physical disability and reduced quality of life, thus hindering the ability of the patients to achieve a meaningful adult life.
Objectives: The aim of this study was to assess the trends of the disease and socio-professional future.
Methods: We conducted a retrospective study including adult patients aged > 18 years with a history of JIA according to the International League of Associations for Rheumatology (ILAR). Collected data included age, sex, the

characteristics of the disease (subtype of JIA, disease duration). The level of education, marital status as well as the profession were recorded.
Results: The study included 32 patients with a female perdominance: sex ratio was 1,5. The mean age was 29,5 years old [18-64]. The mean age of onset of the disease was 6 years and 2 months [2-17]. The frequency of each JIA subset was at follows: polyarticular with rheumatoid factor (n= 14), polyarticular without rheumatoid factor (n=9), systemic (n= 2), enthesitis-related arthritis (n=7), oligoarthritis (n= 5). Four patients suffered from bilateral cataract due to corticosteroid intake. Polyarticular RF+ and RF- progressed into an authentic seropositive and seronegative RA in 71.4% and 66.7% respectively. Among oligoarticular subtype, an extension of the disease to a polyarticular FR+ form (n=1) and to a seronegative rheumatoid arthritis (n=1) was noted. Systemic JIA forms remained in remission with an articular involvement. All the patients with ERA developed spondylarthritis. Although forty–two percent of the patients were married, only half of them had children. Ten percent of patients stopped attending school because of disease flares and deformation. A university level was found in 16% of cases. Only Thirty patients had a profession. Of the patients, 74.4% had received disease-modifying anti-rheumatic drugs (DMARDs) and 36.3% of them were still taking a DMARD. Ten patients were on biologics. Severe disability was found in 20% of patients and concerned mainly the hip (57,2%), the wrist (28,5%) and the elbows (14,3%). Prosthetic joint replacement was found in 2% of cases with a revision of the latter in one patient.
Conclusion: Adults with JIA often have significant levels of disability, usually related to severe joint complications. There is a clear requirement for a better transition to adulthood and a socio-professional rehabilitation.

AB0737 THE NAIL FOLD CAPILLAROSCOPIC FINDINGS OF ADOLESCENTS WITH ANOREXIA NERVOSA AND BULIMIA NERVOSA

M. Kasap-Cuceoglu[1], M. Pehlivanturk-Kizilkan[2], E. Sag[1], S. Sener[1], Z. Balik[1], S. Akgul[2], O. Derman[2], Y. Bilginer[1], N. Kanbur[2], S. Özen[1]. [1]*Hacettepe University Faculty of Medicine, Pediatric Rheumatology, Ankara, Turkey*; [2]*Hacettepe University, Department of Pediatrics Division of Adolescent Medicine, Ankara, Turkey*

Background: The nail fold video capillaroscopy (NVC) is usually performed on patients with microcirculation problems, such as Raynaud's phenomenon. It is also used to distinguish between primary and secondary Raynaud's Phenomenon and identify the scleroderma pattern.
Objectives: To describe the acute phase nail fold capillaroscopic findings of adolescents with anorexia nervosa (AN) and bulimia nervosa (BN) and to compare these findings with adolescents diagnosed with primary Reynaud's phenomenon (RP).
Methods: We included 17 AN, 2 BN patients and 6 adolescents with primary RP as a control group. The nail fold video capillaroscopy (NVC) data of three study groups were compared. AN and BN patients were classified according to DSM-5. The participants in these two groups were assessed for the presence of Reynaud's phenomenon/acrocyanosis and the weight loss history (amount and duration), daily calorie intake, vital signs, hydration status, amenorrhea presence and time, the presence and frequency of compensatory behaviors, and drug usage were recorded. Adolescents with primary RP were diagnosed according to 'International consensus criteria for the diagnosis of RP. The initial NVC was performed at the acute phase of AN and BN. For AN acute phase is defined as the period where the nutritional rehabilitation has not yet taken place. The NVC analysis was be performed with a digital USB microscopy by an expert blinded to the participant's clinical status and diagnosis. Eight fingers were evaluated for each patient and average of all fingers' scores were used as quantitative measures.
Results: Among adolescents with AN, 14 of them had enlarged capillaries (capillary diameter 20-50 µm) and 6 of them had mild tortuosity (<50%) which were considered as minor capillaroscopic changes. 5 patients had at least one giant capillary (>50µm), 3 of them had microhemorrhages, 4 of them had capillary ramifications, and 1 of them had capillary disorganization which were considered as major capillaroscopic changes. Two adolescents had capillary loss (6 capillaries/mm). None of them had active or late phase scleroderma findings. In the primary RP group, there were minor findings as five adolescents had mild capillary dilation (capillary diameter 20-50 µm), and 5 had mild tortuosity (<50%). However, none had scleroderma (early-active-late phase) findings. Microangiopathy assessment scores revealed no difference between the AN patients with and without RP and primary RP patients.(Table 1) A positive correlation was found between capillary ramification scores and initial daily calorie intake (r: -0.47; p=0.04).

Table 1. Measurements of capileroscopy findings according to patient groups

	AN+RP+ n=4	AN+RP- n=13	BN n=2	Primer RP kontrol n=6	p
Microangiopathy score	0.84 (IQR 0.98)	0.92 (IQR 0.96)	0.71	0.65 (IQR0.23)	0.62
• **Capillary loss score**	0.22 (IQR 0.62)	0.06 (IQR 0.41)	0.15	0.0 (IQR 0.26)	0.58
• **Capillary ramification score**	0.18 (IQR 0.25)	0.13 (IQR 0.25)	0.09	0.09 (IQR 0.18)	0.88
• **Disorganized capillaries score**	0.38 (IQR 0.48)	0.56 (IQR 0.68)	0.46	0.43 (0.32)	0.98
Enlarged capillaries score (20-50 µm)	0.56 (IQR 0.78)	0.31 (IQR 0.72)	0.73	0.58 (IQR 0.42)	0.60
Giant capillaries score (>50 µm)	0.06 (IQR 0.22)	0.00 (IQR 0.03)	0.18	0.03 (0.14)	0.14
Microhaemorrhage score	0.00	0.00	0.00	0.01	0.67

Conclusion: Preliminary results of our study suggest that adolescents with AN are at risk for vasculopathy especially during the acute phase of the disease.

AB0738 JUVENILE IDIOPATHIC ARTHRITIS AND SCHOOLING

H. Tantaoui[1], K. Nassar[1], S. Janani[1]. [1]*Faculty of Medicine and Pharmacy, Hassan II University, Ibn Rochd University Hospital Center, Rheumatology, Casablanca, Morocco*

Background: Juvenile idiopathic arthritis (JIA) refers to all chronic inflammatory rheumatism in children without a recognized cause, onset before the age of 16. JIA is associated with significant short- and long-term disability, which influences the education and socio-professional integration of patients who suffers from it.
Objectives: Evaluate the impact of JIA on the education and professional integration of affected patients.
Methods: This is a retrospective, descriptive and cross-sectional study carried out in the rheumatology department.
We included all patient followed in our JIA training.
The following information was collected from a questionnaire survey: Educational attainment, main problems experienced during studies, cause of dropping school, and professional data.
Results: Forty-two patients were included. The average age was 27.15 years old [18 - 61 years old]. Sex-Ratio (M / F) was 0.9. The forms of JIA were dominated by spondyloarthropathy (48.64%) and the seropositive polyarticular form (18.91%). The mean age of onset of JIA was 10.8 years [6 months - 16 years]. The mean duration of JIA progression was 14.4 years [4 - 27 years].
Regarding education, 2.94% were illiterate, 23.52% had a primary level, 55.87% a secondary level and 17.64% a higher level. The majority of patients (85%) experienced several problems during their studies: joint pain and stiffness (73.52%), absenteeism (50%), limitation in activities (26.47%), problem with adaptation and social integration (11.76%) and fatigue (5.88%). Only 2.94% of patients benefited from an individualized reception protocol apart from a sports exemption which represents 38.23%. 73.52% of patients received encouragement to continue their studies by those around them (parents, teachers and attending physicians).
Discontinuation of schooling was observed in 70.58% of patients with 8.82% of patients dropping school before the onset of JIA and 61.76% of patients related to JIA. School studies were still ongoing in 23.52% of patients.
Regarding the professional side, unemployment affects 52.94% of these patients and workers represent 23.52%.
Conclusion: In our series, the level of education of JIA patients does not exceed secondary level in 80% of cases. The implementation of an individualized reception protocol is strongly recommended to facilitate the education of these patients and to fight against the main problems experienced. The professional integration of patients with JIA should also be adopted.

AB0739

MULTISYSTEM INFLAMMATORY SYNDROME ASSOCIATED WITH SARS-COV-2 INFECTION AND E.COLI SEPSIS: THE POTENTIAL ROLE OF PROCALCITONINE AS A RAPID DIAGNOSTIC BIOMARKER TO DISTINGUISH TWO DIFFERENT PHASES OF SYSTEMIC INFLAMMATORY RESPONSE SYNDROME

M. Gilio[1], S. B. Morella[1], F. Picaro[1], C. Acierno[1], D. Palazzo[1], A. Erezanu[1], M. Frontuto[1], G. Mastroberti[1], G. De Stefano[1]. [1]*San Carlo Hospital, Infectious Diseases, Potenza, Italy*

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection is typically very mild and often asymptomatic in children. A complication is the rare multisystem inflammatory syndrome in children (MIS-C) associated with COVID-19, presenting 4-6 weeks after infection as high fever, organ dysfunction, and strongly elevated markers of inflammation. The pathogenesis is unclear but has overlapping features with Kawasaki disease suggestive of vasculitis and a likely autoimmune etiology.
Objectives: We report a case of multisystem inflammatory syndrome in children (MIS-C) in patient with SARS-CoV-2 infection and Enteropathogenic Escherichia coli (EPEC) sepsis due to acute enteritis, observed at end of December 2020 to a tertiary-care center (San Carlo Hospital), in Basilicata region (Italy).
Methods: This healthy 12-year- old male patient was tested positive for severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection. Clinical presentations was characterized by fever, abdominal pain, gastrointestinal complaints and evanescent rash. Laboratory values were remarkable for high levels of procalcitonin, C-reactive protein (CRP), D-dimers, B-type natriuretic peptide (BNP), and troponin. He also had low albumin levels. Autoantibodies tests were negative. Chest tomography showed ground-glass opacities in less than 25% of the lungs, small bilateral pleural effusion and increased cardiac area; abdominal tomography showed enlargement of the lymphnodes and ascites. Evaluation for other infectious etiologies showed molecular test positivity on fecal samples for EPEC E. coli. He received broad spectrum intravenous antibiotics (macrolids and quinolones and then carbapenems). On the seventh day the enteritis resolved and procalcitonin normalized, however he continued to have lymphopenia, thrombocytopenia, hypoalbuminemia, elevated levels of CRP, D-dimers, ferritin, troponin, and increased BNP. On the ninth day he was feverish again and developed severe cardiac and respiratory failure requiring advanced respiratory support and admission to the intensive care unit. He received IVIG (intravenous immunoglobulin at 2 g/Kg, glucocorticoids (Methylprednisolone 1mg/kg) and enoxaparin.
Results: The patient was discharged asymptomatic at home after 28 days of hospital stay.
Conclusion: We observed multisystem inflammatory syndrome in children (MIS-C) in a previously healthy patient with SARS-CoV-2 infection and E.coli sepsis, who became critically ill with multisystem involvement. In this case viral and bacterial infections could be considered as a double hit for the etiopathogenesis of MIS-C. The trend of procalcitonin was better than C-reactive protein for differentiating bacterial from non-bacterial phase of systemic inflammatory response syndrome (SIRS) in this critically ill child. Although the accuracy of both tests is moderate. Diagnostic accuracy could be enhanced by combining these tests with bedside clinical judgment.

IMPACT OF DIAGNOSIS DELAY ON DISEASE PARAMETERS DURING JUVENILE IDIOPATHIC ARTHRITIS

H. Bettaieb[1], H. Ferjani[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is the most common type of arthritis in childhood (1). Prompt diagnosis is mandatory to avoid joint destruction and growth abnormalities. However, it's often misdiagnosed by pediatricians and general practitioners leading to longer diagnosis delay (2).
Objectives: The aim of this study was to evaluate the lag time between JIA symptoms onset and diagnosis and its impact on disease activity and bone loss.
Methods: A retrospective monocentric study was carried out on JIA patients (ILAR criteria). Diagnosis delay was collected from the patient's medical files. Disease activity at JIA diagnosis was evaluated by JADAS10 (Juvenile Arthritis Disease Activity Score) in poly and oligoarticular subtypes and by BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) in arthritis related enthesitis form. The data were analyzed using the SPSS statistical package. A p value < 0.05 was considered significant.
Results: We enrolled 48 JIA (31 male and 17 female) with a mean age at disease onset of 11.2 ± 3.8 years. The median disease duration was 84 months [2-408]. The median JIA diagnosis delay was 8 months [1-108]. The JIA subgroups were in decreasing order of frequency: Enthesitis-related Arthritis (n=32), Polyarticular RF- (n=4), Polyarticular RF+ (n=2), Oligoarticular (n=6), Systemic (n=2), Psoriatic Arthritis (n=1) and Undifferentiated (n=1).
At diagnosis, median ESR and CRP were 44 mm/hour [2-100] and 24 mg/l [2-86] respectively. Median JADAS10 score was 4 [0-21]. Median BASDAI score was 6.2 [2-9.4].
At follow-up, five patients (10.4%) had atlantoaxial subluxation and 17 had coxitis (43.8%).
At bone densitometry, 45% of patients had osteroposis and 27.5% had osteopenia.
An agreement was assessed between a long diagnosis delay and the following parameters: male gender (p=0.04) and osteoporosis (p=0.018). A Significant positive correlation was found between delay in JIA diagnosis and BASDAI score (p=0.047, r=0.63). No association was found between JIA diagnosis delay and JADAS score (p=0.56). Neither ESR (p=0.19) nor CRP (p=0.42) was associated with JIA diagnosis delay.
Finally, no link was observed with the occurrence of hip arthritis (p=0.281) or atlantoaxial subluxation (p=0.137).
Conclusion: In this study, delay in diagnosis was associated with higher disease activity scores and bone loss. Our results suggest that early identification and treatment of JIA leads to improved outcomes as well as bone mass.

AB0741

PREVALENCE AND ASSOCIATED FACTORS OF ATLANTO-AXIAL INSTABILITY IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

H. Bettaieb[1], H. Ferjani[1], K. Maatallah[1], H. Boussaa[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia*

Background: Atlanto-axial instability (AAI) is a serious complication during Juvenile Idiopathic Arthritis (JIA). It can lead to severe neurological morbidity or mortality if left untreated (1).
Objectives: To determine the prevalence of AAI in patients with JIA and to identify factors associated with an increased risk of its occurrence.
Methods: A retrospective monocentric study was carried out on JIA patients (ILAR criteria). Data, including age at disease onset, JIA type, disease activity at AAI diagnosis and treatment were collected. Disease activity at JIA diagnosis was evaluated by JADAS10 (Juvenile Arthritis Disease Activity Score) in poly and oligoarticular subtypes and by BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) in arthritis related enthesitis form. Standard radiographs of the cervical spine were analyzed. The data were analyzed using the SPSS statistical package. A p value < 0.05 was considered significant.
Results: We enrolled 48 JIA (31 male and 17 female) with a mean age at disease onset of 11.2 ± 3.8 years. The median disease duration was 84 months [2-408]. The median JIA diagnosis delay was 8 months [1-108]. The JIA subgroups were in decreasing order of frequency: Enthesitis-related Arthritis (n=32), Polyarticular RF- (n=4), Polyarticular RF+ (n=2), Oligoarticular (n=6), Systemic (n=2), Psoriatic Arthritis (n=1) and Undifferentiated (n=1).

At diagnosis, median ESR and CRP were 44 mm/hour [2-100] and 24 mg/l [2-86] respectively. Median JADAS10 score was 4 [0-21]. Median BASDAI score was 6.2 [2-9.4].
At follow-up, five patients (10.4%) had atlantoaxial subluxation and 17 had coxitis (43.8%).
At bone densitometry, 45% of patients had osteroposis and 27.5% had osteopenia.
An agreement was assessed between a long diagnosis delay and the following parameters: male gender (p=0.04) and osteoporosis (p=0.018). A Significant positive correlation was found between delay in JIA diagnosis and BASDAI score (p=0.047, r=0.63). No association was found between JIA diagnosis delay and JADAS score (p=0.56). Neither ESR (p=0.19) nor CRP (p=0.42) was associated with JIA diagnosis delay.
Finally, no link was observed with the occurrence of hip arthritis (p=0.281) or atlantoaxial subluxation (p=0.137).
Conclusion: In our study, the prevalence of AAI was 10.4%. Prolonged corticosteroid use and elevated inflammatory markers were the major factors associated with an increased risk of upper cervical spine involvement. Hence, targeted treatments are required to prevent cervical spine instability.

AB0742 PREVALENCE AND RISK FACTORS OF OSTEOPOROSIS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

H. Bettaieb[1], H. Ferjani[1], K. Maatallah[1], H. Boussaa[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia*

Background: Childhood rheumatic diseases are associated with reduced Bone mass and increased risk of fractures (1). Several factors may interact to determine osteoporosis other than direct bone detrimental effects of the disease or its treatment.
Objectives: In this work, we aimed to investigate the prevalence of bone loss in patients with JIA and to determine the relative factors associated with osteoporosis during this chronic disease.
Methods: A retrospective monocentric study was carried out on JIA patients (ILAR criteria).Dual-energy x-ray absorptiometry (DEXA) was used to determine bone status. Disease activity was evaluated by JADAS10 (Juvenile Arthritis Disease Activity Score) in poly and oligoarticular subtypes and by BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) in arthritis related enthesitis form. Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were noted. The data were analyzed using the SPSS statistical package. A p value < 0.05 was considered significant.
Results: The sample included 40 JIA (25 male and 15 female) with a mean age at disease onset of 11.3 ± 3.6 years. The median disease duration was 90 months [7-408].The median JIA diagnosis delay was 8 months [1-108]. The JIA subgroups were in decreasing order of frequency: Enthesitis-related Arthritis (n=27), Polyarticular RF- (n=4), Polyarticular RF+ (n=1), Oligoarticular (n=4), Systemic (n=2), Psoriatic Arthritis (n=1) and Undifferentiated (n=1). Median ESR and CRP were 29 mm/hour [2-98] and 14.5 mg/l [0-70] respectively. Median BASDAI score was 4.3 [1-9.7]. Median JADAS10 score was 1[1-21].
Overall, 45% of patients had osteoporosis, 27.5% had osteopenia, and 27.5 % had normal bone densitometry. None of the patients had a history of vertebral or peripheral fractures.
Thirty per cent of patients (n=12) were on long term corticosteroid therapy with a mean dose of 6.6 ± 2.8 mg/day. Only 12.5% (n=5) of them had a regular physical activity.
Osteoporosis was associated with age at JIA onset (p=0.005), disease duration (p=0.001), ESR (p=0.08), CRP (p=0.04), BASDAI score (p=0.017) and sedentarily (p=0.026). Osteopenia was only associated with corticosteroid therapy (p=0.01). Neither osteoporosis (p=0.37) nor Osteopenia (p=0.25) was associated with disease activity score.
Conclusion: In our study, osteoporosis was a common feature during JIA. A long term corticosteroid therapy and sedentarily seem to be correlated with more impaired bone abnormalities. Hence, targeted interventions are urgently required to preserve bone health during JIA.

AB0743 SINGLE CENTER EXPERIENCE OF BIOLOGICAL THERAPY IN PATIENTS WITH JUVENILE SYSTEMIC SCLERODERMA

D. Alexseev[1], I. Nikishina[1], L. Ananieva[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Pediatric, Moscow, Russian Federation*

Background: Juvenile systemic scleroderma (jSSC) is a rare multisystem disease with a poor prognosis. The current therapy is imperfect. Biologics, as a modern efficient option for treatment of rheumatic diseases don`t have official indication for jSSC, but it seems to be useful in severe cases, especially lung and heart damage.
Objectives: To analyze the existing experience of Biologics therapy in children with jSSC in single center in order to improve the understanding of the indications for use and the results of using these drugs.
Methods: The retrospective study include 9 patients with jSSC with severe course of disease, 7 of them were girls.
Results: Among this group of patients the age at disease onset was 9.1 years (min-max 1.1-15.1). Clinical manifestations: Raynaud's syndrome (n = 9), ulcers (n = 3), skin changes (n = 9), joints (n = 8), muscles (n = 4), interstitial lungs disease (n = 6), heart (n = 3), esophagus (n = 5), calcification (n = 3). The main therapy prior to the use of biological agents: glucocorticoids (GC) (n = 9), cyclophosphamide (CF) (n = 2), hydroxychloroquine (HC) (n = 5), therapy for the microcirculation improvement. Biologics were prescribed in the case of insufficient effectiveness of previously conducted therapy, primarily in relation to lung damage (interstitial disease) and heart (with reduced contractility, arrhythmia), as well as changes in the skin and musculoskeletal system. In addition, the possibility to reduce the dose of GC (n=6), withdrawal of CF (n=2) was taken into account. Our experience consist of follows: rituximab (RTM) (n=7) at a dose of 375 mg/m2 interval 3-6 months, abatacept i.v.(ABT) (n=2) 10 mg/kg every 4 weeks, tocilizumab i.v.(TCZ) (n=2) 8 mg/kg. In all cases Biologics was prescribed not earlier than 1.5 year after disease onset (4.6 years in average). By present most patients continued to use biological therapy; of them - RTM was used for 2.2 (0.5-6.0) years, in 1 patient – was canceled after 6 years due to the loss of efficasy; ABT is used in 2 children for 0.5 and 3.6 years, TCZ - in 2 children for 0.3 (withdrawal) and 2.0 years (continues to use)., TCZ was prescribed in 1 patient after 6 years of RTM use. In 1 patient TCZ was withdrawal due to an infusion reaction, and ABT was prescribed. As a result of the therapy, it has been found to improve habitus, quality of life and well-being, reduce skin tightening, improve joint function; no progression of changes in the lungs according to CT and functional tests (FVC, DLCO), improvement in cardiac lesions. It seems that disease improvement became notable at least 3-6 months after the Biologics start. In most patients there were no serious adverse events (AE). No significant infections have been reported. But we met an unexpected case of substantial increasing of neutrophil's count just after each TCZ infusions up to 21,000 and reversed by following infusions for a one year of treatment from 2 years of total duration of using.
Conclusion: Our data shown that Biologics could be efficient and well-tolerated option for severe and resistant to «traditional» therapy course of jSSC. Because this kind of condition is extremely rare further multicenter study is needed.

AB0744 HOW JUVENILE IDIOPATHIC ARTHRITIS PATIENTS PERCEIVE THEIR ILLNESS?

K. Maatallah[1], M. Yasmine[1], H. Ferjani[1], W. Triki[1], D. Ben Ncib[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) represents the most common inflammatory rheumatism of childhood. Because of a prolonged course of active disease, many patients experience physical and psychosocial limitations. Illness perceptions involve the personal beliefs that patients have about their illness and may influence health behaviors considerably.
Objectives: The present study aimed to investigate the illness perception of patients with JIA.
Methods: We conducted a cross-sectional study including children with JIA (according to the International League of Associations for Rheumatology (ILAR)). We recorded sociodemographic data and the subtype of the JIA. To assess a child's perception of how arthritis affects their life, the Brief Illness Perception Questionnaire (IPQ) was completed by the parent (child age ≤10 years) or by

the child (age ≥11 years). The Brief IPQ is a nine-item questionnaire rated using a 0-to10 response scale that assesses cognitive illness representations: consequences (Item 1), timeline (Item 2), personal control (Item 3), treatment control (Item 4), and identity (Item 5). Two of the items assess emotional representations: concern (Item 6) and emotions (Item 8). One item assesses illness comprehensibility (Item 7).

Results: The study included 22 patients. The mean age was 15 ± 7 years [4-35], and the mean age at diagnosis was 9 ±3 years [3-14]. There was a female predominance (sex ratio= 2.1). The frequency of each JIA subset was at follows: polyarticular with rheumatoid factor (n= 1), polyarticular without rheumatoid factor (n=3), systemic (n= 2), enthesitis-related arthritis (n=9), oligoarthritis (n= 7), undifferentiated (n=1). Non-steroidal anti-inflammatory drugs were prescribed in 72% of cases, and Cs-DMARDs in 59% of patients. The most-reported causal factor in their illness was a history of traumatism (22%). Perceiving symptoms (identity) were significantly related to being affected by the disease (emotional response) *(p= 0.01)*. Conversely, patients who had personal and treatment control expressed less emotional response (r = –0.7, r=-0.2 respectively). Moreover, those who were concerned about the disease perceived more the consequences of their illness (*p=0.09*) and understood it more (p=0.029). We also noted significant correlations between personal control and treatment control (p = 0.033). A positive correlation was found between identity as well as consequences and timeline (p=0.011, p=0.024), showing that the perception of chronicity was associated with pain and the burden of the disease.

Conclusion: Our study highlighted the importance of assessing illness perception in JIA patients. Patient education programs should be implemented since diagnosis for better disease management.

AB0745 BONE STATUS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA) ON T2T THERAPY

N. Shevchenko[1,2], Y. Khadzhynova[1,2], L. Bohmat[1,2]. [1]*V.N. Karazin Kharkiv National University, Department of Pediatrics No 2, Kharkiv, Ukraine*; [2]*SI Institute for Children and Adolescents Health Care of NAMS of Ukraine, Department of Cardiorheumatology, Kharkiv, Ukraine*

Background: In recent years approaches to both the diagnosis and treatment of JIA have changed. Among it key positions for bone health are reducing the time to make a diagnosis and initiation of basic therapy, as well as reducing the timing and doses of corticosteroids. The interdependence of osteopenia in children with JIA with established impairment of vitamin D status, the prevalence of which remains very high in this cohort of patients, has also not been definitively elucidated.

Objectives: To study the condition of bone tissue in children with JIA in modern disease management and to identify adverse factors for the development of osteopenia among the clinical manifestations signs.

Methods: The study included 35 children with JIA aged 7 to 17 years, mostly female (77.1%), with oligo - (25.7)%, poly - (60.0%) and undifferentiated (14.3 %) arthritis, 53.4% have not yet received basic therapy. No corticosteroid therapy was available. The study of bone tissue was performed by two-energy X-ray absorptiometry (Explorer QD W-Hologic). All patients were tested for serum parathyroid hormone (PTH), the level of 25-hydroxyvitamin D [25(OH) D], the total and ionized calcium and blood phosphorus. The control group consisted of 12 healthy children of the same age with a normal level of 25 (OH) D.

Results: The average level of 25(OH)D was 20.41±1.35 ng/ml, which is considered insufficient and was lower than in the control group (30.03±2.53 ng/ml, $p<0.05$). Studies of calcium and phosphorus in the blood showed that children with JIA have no deviations from the normative values. The majority of examined patients (98.37%) had normal values of PTH, in average was 30.43±0.90 pg/ml. The PTH was significantly different in children with different variants of JIA, the highest content was recorded in non-differential arthritis (34.33±1.80 pg/ml), the lowest - in the oligoarticular variant (28.36±1.43, p<0,05). PTH had a negative correlation with 25(OH)D status (r = -0.41; p <0.05) and did not depend on the sex and disease activity.

The incidence of osteopenia was 28.57%, its prevalence was almost the same in different variants of arthritis and did not depend on the sex and age of patients, positivity for RF. Osteopenia was more common in ANA-positive than in ANA-negative variant (46.15% vs. 18.18%; $p_{\varphi}<0.05$). In 30.0% patients with osteopenia decreased BMD reached the values of osteoporosis (more than 2.5σ). This group consisted of girls with predominantly polyarticular and undifferentiated JIA, with RF-negative and ANA-positive variant.

Deviations from the age normative values of BMD (Z-score) were associated with BMI (r=0.33; p <0.05), JADAS scale results (r=0.35; p<0.04), the number of active joints (r=0.34; p<0.05), ANA (r=-0.34; p<0.05). In children with osteopenia it was correlated with the duration of the disease (r=-0.67; p<0.05), the number of active joints (r=-0.62; p<0.05), blood phosphorus level (r=0.74; p<0.05) and JADAS scale results (r=0.59; p<0.05). In children with preserved BMD correlations was supplemented by 25(OH)D status (r=-0.33; p<0.05) and BMI (r=-0.40; p<0.05). Analysis of the interdependence of the formation of osteopenia and clinical manifestations signs established the total significance of the main parameters of the disease with the highest coefficient of determination in the polyarticular variant: -112.65 + 0.09(patient's age, mo)+4.33 (patient's sex)-3.74 (ANA, units)-1.80 (RF, units)+0.01 (age of onset, months)-0.34 (number of affected joints)-0.18 (number of active joints)-0.18 (ESR, mm/h)+71.58 (ionized calcium, mmol/l)+5.19 (phosphorus, mmol/l)-0.01 (PTH, ng/ml)+0.18 (25(OH)D, ng/ml)(R^2=99.99%; p<0.001).

Conclusion: With modern JIA management a quarter of children have osteopenia. The state of the bone tissue is more associated with the prevalence, immunological and inflammatory activity of the disease against the background of preserved calcium-phosphorus homeostasis and vitamin D deficiency, and is not associated with the present therapy.

AB0746 THE ASSOCIATION BETWEEN PRESARCOPENIA AND BONE MINERAL DENSITY IN ADULT PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

M. Dzhus[1], M. Kulyk[1]. [1]*Bogomolets National Medical University, Internal Medicine Department №2, Kyiv, Ukraine*

Background: The importance of presarcopenia (low lean mass) in clinical practice is accompanied by a high risk of adverse effects such as early disability, reduced quality of life, and increased mortality.

Objectives: The aim of the study was to assess the link between bone mineral density (BMD) and the state of the muscular system in adult patients with juvenile idiopathic arthritis (JIA).

Methods: The study was performed in Oleksandrivska Clinical Hospital of Kyiv, Ukraine, where adult patients were transferred from pediatric rheumatologists. Inclusion criteria: patients aged 18-44 years at the time of signing the informed consent; diagnosis of JIA in childhood, verified according to ILAR criteria, duration of JIA >3 years. According to the European Working Group on Sarcopenia in the Elderly (EWGSOP) 2019, patients with a decrease in muscle mass alone were diagnosed with presarcopenia. The BMD and muscle tissue were determined in standard localizations using dual X-ray absorptiometry (DXA).

Results: The study included 26 adult patients with JIA, including 10 male patients and 16 female patients. The mean age at the time of examination was 22.3 ± 8.15 years; the mean age at the onset of the disease was 9.04 ± 4.9 years. According to the ILAR classification, patients had the following variants of JIA: 3 patients with RF-negative polyarticular variant, 8 patients with persistent oligoarthritis, 4 patients with extended oligoarthritis, 6 patients with RF-positive polyarthritis variant, and 5 patients with systemic JIA. According to the EWGSOP, 2019 reduced muscle mass was calculated by skeletal muscle index (SMI); the cut-off points were considered by SMI <7 kg/m2 for male, <6 kg/m2 for female. Patients were divided into two groups depending on the presence or absence of presarcopenia. The first group (1-st group) included 16 patients with reduced muscle mass (SMI – 5,22± 0,72 kg/m2), and the second group (2-nd group) included 10 patients without reduced muscle mass (SMI – 8,05± 0,94 kg/m2). It was found that the height and weight of patients in the group of presarcopenia was lower than in the group without a low lean mass (height 1,6±0,07 m vs 1,7±0,09 m, t=-2,53; p=0,01; weight 55,06±8,3 kg, 70,0±10,8 kg, t=-3,9; p=0,0007, respectively). The age of patients (25,3±10,1 and 21,3±5,9 years for 1-st and 2-nd groups respectively) and the duration of the disease (17,1±9,5 and 10,3±6,1 for 1-st and 2-nd groups respectively) did not differ statistically between the groups. The age of the onset of JIA in both groups also did not differ (7,8±4,5 and 11,5±4,1 for the 1-st and 2-nd group respectively). The following data were obtained by DXA. The patients of 1-st group had statistically reduced BMD in the region of femoral neck - 0,927±0,15 g/cm2 vs 1,179±0,13 g/cm2, t=-3,18; p=0,006; total hip - 0,977±0,16 g/cm2 vs 1,184±0,05 g/cm2, t=-3,05, p=0,0080; total body - 1,080±0,1 g/cm2 vs 1,193±0,15 g/cm2, t=-2,19; p=0,03; and ultra-distal radius - 0,286±0,06 g/cm2 vs 0,482±0,11 g/cm2, t=-3,60; p=0,007. The BMD in the region of lumbar spine did not differ in two groups - 1,152±0,16 g/cm2 vs 1,137±0,17 g/cm2, t=0,21; p=0,8. In the group of presarcopenia there was a visible decrease in the level of the metabolite of vitamin 25(OH)D3, but not statistically significant: 15,5±7,3 nmol/l vs 19,7±8,6 nmol/l, t =1,0; p=0,3. The study has strengths such as first described presarcopenia in young adults with JIA and potential limitations such as mono-center study and a small number of patients.

Conclusion: The BMD in the region of total hip, femoral neck, ultra-distal radius, and total body in patients with decreased muscle mass was significantly lower than in patients without low lean mass.

AB0747 MATERNAL AND FETAL OUTCOMES IN PREGNANT WOMEN WITH JUVENILE IDIOPATHIC ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

R. Pinheiro Torres[1,2], M. H. Fernandes Lourenco[1,2], A. Neto[1,2,3], F. Pimentel Dos Santos[1,2,4], I. Silva[1,4], A. F. Mourão[1,2,4], H. Donato[5], M. Costa[1], J. Branco[1,2,4]. *[1]Hospital Egas Moniz, Rheumatology, Lisboa, Portugal*; *[2]CEDOC, Rheumatology, Lisboa, Portugal*; *[3]Hospital Central Funchal, Rheumatology, Funchal, Portugal*; *[4]Nova Medical School, Rheumatology, Lisboa, Portugal*; *[5]Centro Hospitalar e Universitário de Coimbra, 5. Serviço de Documentação e Informação Científica, Coimbra, Portugal*

Background: Juvenile idiopathic arthritis (JIA), one of the most common chronic diseases in children, can be classified in seven different categories according to its onset presentation. Concerns about pregnancy outcomes play a secondary role in disease approach. However, recent data showed an increased risk of pre-term birth in women with JIA instead the small patient samples analysed.

Objectives: In this review, our aim is to describe the current available knowledge on JIA adverse, maternal and fetal, outcomes.

Methods: A systematic literature review was conducted since January of 2000 until December 2020, by searching the PubMed and Embase bibliographic databases. The search was limited to articles in English language, presenting a comparator group (healthy individuals or patients without known auto-immune rheumatic diseases) and at least one clinical outcome of interest. Two independent reviewers screened the titles and abstracts followed by a full-text review to assess papers regarding their eligibility.

Results: Ten observational studies out of 1560 references, fulfilled the inclusion criteria, of which, 9 were retrospective and 1 prospective. A total of 6.214 women with JIA (with 6.811 pregnancies) and 18.659.513 healthy controls (with 21.339.194 pregnancies) were included in this review.

Concerning maternal outcomes, delivery by caesarian section (CS) was more frequent among JIA women (in 4 out of 6 studies). Pre-eclampsia was referred in 3 out of 6 studies and a higher risk of vaginal bleeding and placenta previa in one additional study. No study found an increased risk for gestational diabetes or hypertension in pregnant women with JIA.

Regarding fetal outcomes, 8 studies revealed significantly increased of pre-term birth (only in first births in one study) but one study didn't show any increased risk. Two studies showed a higher risk of small gestational age (SGA) and in another 2, increased risk for low birth weight (LBW). No evidence of increased risk of major congenital malformations.

Conclusion: This systematic review suggests an increased risk for pre-eclampsia, preterm birth, delivery by CS, SGA and LBW, among pregnant women with JIA. Conclusions should be carefully interpreted, giving the heterogeneity of studied populations regarding demography, disease type, disease activity, and prescribed medication.

AB0748 ARE ANY DIFFERENCES BETWEEN JIA - ASSOCIATED UVEITIS, DEVELOPED BEFORE AND AFTER JOINT MANIFESTATION

M. Chakhalian[1], E. Gaidar[2], T. Nikitina[3], E. Isupova[4], I. Chikova[2], M. Dubko[2], V. Masalova[2], T. Likhacheva[2], L. Snegireva[2], M. Kaneva[2], O. Kalashnikova[2], V. Chasnyk[2], M. Kostik[2]. *[1]Saint-Petersburg State Pediatric Medical University, Department of Hospital Pediatrics, Pediatric Rheumatology (Department of Pediatrics #3); Hospital Pediatry, Saint-Petersburg, Russian Federation*; *[2]Saint-Petersburg State Pediatric Medical University, Saint-Petersburg State Pediatric Medical University; Pediatric Rheumatology, Saint-Petersburg, Russian Federation*; *[3]Saint-Petersburg State Pediatric Medical University, Saint-Petersburg State Pediatric Medical University; Ophthalmologist, Hospital Pediatry, Saint-Petersburg, Russian Federation*; *[4]Saint-Petersburg State Pediatric Medical University, Department of Hospital Pediatrics, Pediatric Rheumatology, Saint-Petersburg, Russian Federation*

Background: Uveitis is the most common extra-articular manifestation of juvenile idiopathic arthritis (JIA). Usually uveitis developed during first two years after arthritis occurred [1]. In the previous studies was shown the shorter time interval between arthritis and uveitis the severe uveitis course was observed [2]. Information about course of uveitis developed before arthritis is scarce.

Objectives: We aimed to evaluate the clinical features and therapy of JIA-associated uveitis, which developed before and after joint manifestation.

Methods: In the retrospective study 191 pediatric autoimmune uveitis included. The onset age ranged from 1 to 17 years. We evaluated differences in clinical, laboratorial and treatment differences between groups, i) where uveitis developed before (n=58) and ii) after (n=133) arthritis. Chronic autoimmune uveitis without joint manifestations was excluded.

Results: Uveitits before arthritis developed in 58 (30.4%) cases. Patients whom uveitis developed before arthritis had were elder and characterized equal gender involvement, rare ANA positivity, and rare use of immunosupression, e.g. corticosteroids, biologics and methotrexate, due to treatment by ophthalmologist predominantly. Patients developed uveitis before arthritis received biologics earlier due to severity of uveitis (LogRank test, p=0.016, HR=1.97 (95%CI: 1.3; 3.1, p=0.004). Data are in the Table 1 and Figure 1.

Conclusion: Patients with JIA associated uveitis with initial ocular presentation demonstrated more severe course and delayed diagnostics and treatment due to lack of contacts with pediatric rheumatologist. Cooperation between ophthalmologist and pediatric rheumatologist is strictly required in all cases with chronic anterior uveitis.

Table 1.

Parameter	Uveitis before arthritis (n=58)	Uveitis after arthritis (n=133)	p
Sex, female	32 (55,2)	97 (72,9)	0.016

AB0749

LABORATORY MARKERS OF INFLAMMATORY ACTIVITY IN PATIENTS WITH MONOGENIC AND POLYGENIC AUTOINFLAMMATORY DISEASES

E. Fedorov[1], S. Salugina[1], M. Cherkasova[2], A. Gerasimenko[1], M. Kaleda[1]. *[1]V.A.Nassonova Research Institute of Rheumatology, Pediatrics, Moscow, Russian Federation*; *[2]V.A.Nassonova Research Institute of Rheumatology, Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*

Background: Auto-inflammatory diseases (AIDs) – a group of diseases of monogenic and polygenic nature, manifested by recurrent attacks of systemic inflammation in the form of fever, accompanied by multi-system symptoms, which are based on the pathology of natural immunity in the absence of autoantibodies and markers of infection.
Objectives: to evaluate the serum levels of markers of systemic inflammation in patients(pts) with monogenic AIDs (FMF, CAPS, TRAPS) and polygenic AID-systemic Juvenile Arthritis (sJA).
Methods: In 85 pts (68 children and 17 adults) with monogenic AIDs and sJA, the concentrations of C-reactive protein (CRP), serum amyloid A(SAA) and ferritin in the blood serum were detected. SRP and SAA were determined by the nephelometric method using Siemens reagents on a BN Prospect Siemens analyzer. Normal CRP values are 0-5 mg/L, normal SAA values are 0-5 mg/L. Ferritin was determined by ELISA using kits manufactured by Orgentec Diagnostica GmbH(normal values of 7-142 μg/l). During statistical processing of the material, the median(Me), lower and upper quartiles(LQ and UQ), minimum and maximum values were evaluated, and the reliability of differences between the groups was evaluated using the Mann-Whitney U criterion. The correlation between the values of CRP and SAA, CRP and ferritin was estimated by the Pearson criterion.
Results: The study included 30 with systemic JIA, FMF-17 pts, CAPS 25- pts and TRAPS- 17 pts. The results of the detection of CRP, SAA, and ferritin are presented in Table 1.

Table 1. CRP, SAA, and ferritin values in patients with sJA, FMF, CAPS and TRAPS.

Value	sJA	FMF	CAPS	TRAPS
	CRP (N=0-5 mg/L)			
Me (LQ - UQ)	6,95(0,5- 51,7)	30,8(9,41-47,4)	4,61(0,36-20,4)	5,41(2,77-14,7)
Min	0,15	0,48	0,15	0,15
Max	229,0	109,0	80,3	90,1
SAA(N=0-5 mg/L)				
Me (LQ - UQ)	19,05(3,05-257,0)	85,2(38,4-276,0)	7,83(2,25-122,0)	10,6(5,7-72,7)
Min	0,88	1,58	0,88	0,88
Max	962,0	923,0	346,0	516,0
Ferritin (N=7-142 μg/l)				
Me (LQ - UQ)	61,09(22,03-385,76)	57,22(21,36-133,51)	20,49(8,13-28,88)	16,52(5,42-67,27)
Min	0,73	3,36	0,98	2,42
Max	1500,0	174,22	183,57	930,1

Serum concentrations of CRP that exceeded the reference values were observed in 15(50%) pts with sJA, 11(65%) pts with FMF, 17(65%) pts with CAPS, and 5 (29%) pts with TRAPS. An increase in SAA was observed in 23(77%) pts with sJA, 12(71%) pts with FMF, 17(68%) pts with CAPS, and 8 (47%) pts with TRAPS. An increase in ferritin was observed in 9(30%) pts with sJA, 1(6%) pts with FMF, 1(4%) pts with CAPS, and 1 (6%) pts with TRAPS.

A statistically significant difference in the Mann-Whitney U test for SAA concentration was found only between the CAPS and FMF groups (P=0.03), and in the CRP concentration also only between the CAPS and FMF groups(P=0.009). The strongest statistically significant correlation according to the Pearson criterion in the whole study group was noted for CRP and SAA: r= 0.74(p=0.0000), which corresponds to the average correlation strength, a slightly weaker correlation was noted for the pair of CRP/ferritin values: r=0.53 (p=0.0000), which also corresponds to the average correlation strength. For the SAA/ferritin pair as a whole, the lowest correlation was observed in the studied group: r=0.36(p=0.0008). The maximum correlation of studied parameters was observed in the group of patients with TRAPS: for the CRP/SAA pair, it was r= 0.9(p=0.00003), for the SAA/ferritin pair it was r= 0.7(p=0.0072), and for the CRP/ferritin pair, r= 0.59(p=0.0345). For FMF, there was a strong correlation in the SRP/SAA pair r=0.89(p=0.0000).

Conclusion: In the study group, all AIDs, both monogenic(FMF, TRAPS, CAPS) and sJA, were characterized by an increase in the levels of CRP and SAA, but to the greatest extent these indicators were increased in sJA and FMF, and to the least in CAPS. CRP and SAA correlate well with each other, especially with TRAPS and FMF. The maximum values of ferritin and the highest frequency of its increase were noted in the sJA group. Ferritin in the majority of pts with monogenic AIDs were normal.

AB0750

FUNCTIONAL CONDITION OF KIDNEYS IN THE LONG-TERM COURSE OF SLE IN ADOLESCENTS

L. Bohmat[1,2], N. Shevchenko[1,2], I. Bessonova[1,3]. *[1]SI Institute for Children and Adolescents Health Care of NAMS of Ukraine, Department of Cardiorheumatology, Kharkiv, Ukraine*; *[2]V.N. Karazin Kharkiv National University, Department of Pediatrics No 2, Kharkiv, Ukraine*; *[3]V.N. Karazin Kharkiv National University, Department of Pediatrics, Kharkiv, Ukraine*

Background: Lupus nephritis is the most severe and adverse systemic lupus erythematosus (SLE) syndrome. According to modern recommendations, the clinical manifestations of active nephritis should be taken under medical control in 6 months after the start of the disease's treatment[1].
Objectives: The aim of this study was to examine the functional status of the kidneys in children with SLE in the course of the disease for more than one year.
Methods: The analysis included case histories of 43 patients with SLE, mostly females (41), aged 7 to 18 years (mean age 14.4 years) with disease duration of 4.75 ± 0.58 years of whom 22 were less than three years, 21 - more than three years. All children received corticosteroid therapy, at the time of the examination the average dose was 13.85 ± 1.86 mg per day in terms of prednisolone. The second component of therapy was azathioprine (average dose 97.61 ± 2.11 mg). All children received hydroxychloroquine (5 mg/kg per day).
To determine the functional state of the kidneys a clinical analysis of urine, a study of the scope of specific gravity of urine during the day (Zymnytsky test), the content of creatinine and urea in serum to determine the glomerular filtration rate (GFR), the level of microalbuminuria per day were evaluated.
Results: Renal involvement in the developed SLE occurred in 73.08% of patients. Among them, therapy during the first 6 months was considered quite effective in 58.06% of patients. It was found that in children with disease duration from one to three years proteinuria was registered in 68.18%, a decrease in GFR in 4.45% and hyperfiltration in 9.09%. In the group of children with duration of SLE more than three years revealed deeper changes in renal function; there was proteinuria in 90.47%, the frequency of GFR decreased was in 19.04%, a decrease of renal concentration function was in 14.28% of cases.
Indicators of renal function in children with SLE depending on the duration of the disease (M ± m)

Indicator	Duration of the disease	
	from 1 year to 3 years n = 22	over 3 years n = 21
Creatinine, mmol/l	0,080 ± 0,014	0,090 ± 0,018
Мочевина, mmol/l	5,66 ± 1,42	5,63 ± 1,61
GFR, ml/min	117,05 ± 19,68	100,20 ± 18,98 *
Microalbuminuria, mg/day	24,41 ± 13,13	34,73 ± 24,76
Density min	1,007 ± 0,005	1,006 ± 0,005
Density max	1,024 ± 0,005	1,019 ± 0,005 **

*p<0,03;**p<0,01 the probability of differences when comparing between groups

Conclusion: Long-term follow-up of children with SLE over one year reveals a prolongation of renal dysfunction, which worsens after three years, and is the basis for the development of irreversible renal impairment.

AB0751 JUVENILE UVEİTİS: THE 3RD LEVEL EXPERIENCE

S. N. Tigrak[1], Ş. Çekiç[1], O. Yalcinbayir[2], S. S. Kilic[3]. [1]*Uludağ Üniversitesi Tıp Fakültesi Hastanesi, Pediatrics, Bursa, Turkey*; [2]*Uludağ Üniversitesi Tıp Fakültesi Hastanesi, Ophtalmology, Bursa, Turkey*; [3]*Uludağ Üniversitesi Tıp Fakültesi Hastanesi, Pediatric Immunology -Rheumatology, Bursa, Turkey*

Background: Uveitis is the inflammation of the uveal components of the eye (iris, choroid and retina) and is the third leading cause of blindness in the world. It is less common in children than adults. Young children are usually diagnosed late, as they cannot express their complaints.
Objectives: With this work; We aimed to contribute to the literature by determining the underlying primary diagnosis and evaluating the treatment response in patients who were followed up in our clinic with a diagnosis of non-infectious uveitis, mostly juvenile idiopathic arthritis.
Methods: 93 patients under 18 years of age who were followed up with a diagnosis of non-infectious uveitis were included in the study. The data of the patients were scanned retrospectively. According to the last biomicroscopic examinations, the patients were classified as remission, inactive period and active disease. Clinical characteristics, laboratory findings, family history, drugs used during the disease and duration of treatment were examined.
Results: The male to female ratio was 1,06 (48/45). The mean age at diagnosis of childhood uveitis was found to be 10±4.02. 49 Patients (52.6%) were diagnosed with idiopathic uveitis, 33 (33.5%)with juvenile idiopathic arthritis, 11 (11.7%) with Behçet's, 2 (2.2%) with FMF. Juvenile idiopathic arthritis was the most common systemic disease in the patient group. The mean age of patients with uveitis to be diagnosed with rheumatological disease was 10.1±5.32. ANA test was positive in 30 (32.2%) patients. 23 (69.7%) of juvenile idiopathic arthritis patients were oligoartricular type. Anterior uveitis was present in 37 (39.8%) of the patients. Anterior uveitis was most common in the juvenile idiopathic arthritis cases. Of the patients with uveitis, 24 (25.8%) were intermediate, 11 (11.8%) were posterior, 21 (22.6%) were panuveitis. Anti-TNFα agents were administered to patients with unresponsiveness to immunosuppressive therapy and high risk of vision loss. Most used anti-TNFα agents were infliximab and adalimumab. Glaucoma, cataract, and posterior synechiae were common complications in the patients during follow-up.
Conclusion: The most common systemic disease that cause noninfectious uveitis in children is juvenile idiopathic arthritis. In juvenile idiopathic arthritis, the most common involvement of the eye was the anterior segment, and it was thought that the location of the eye involvement could be useful in determining the underlying systemic disease. It is important to ensure regular eye examination in patients with rheumatologic symptoms.

AB0752 CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS: A SINGLE-CENTER CASE SERIES

G. Dallagiacoma[1], T. Buzzegoli[2], M. Karner[2], P. Matzneller[3], B. Raffeiner[4], C. Dejaco[1]. [1]*Hospital of Bruneck, Rheumatology, Bruneck, Italy*; [2]*Hospital of Bruneck, Radiology, Bruneck, Italy*; [3]*Hospital of Schlanders, Rheumatology, Schlanders, Italy*; [4]*Hospital of Bolzano, Rheumatology, Bolzano, Italy*

Background: Chronic recurrent multifocal osteomyelitis (CRMO) is a chronic autoinflammatory disease that primarily affects the skeleton of children and adolescents in the absence of an infectious etiology[1]. CRMO lesions presentation varies widely ranging from episodic bone pain to growth disturbance; lytic and sclerotic bone lesions can be found on X-ray, however magnetic resonance imaging is very useful for evaluating the extent of disease and follow-up [2].
Objectives: To report demographic, clinical and laboratory characteristics and response to therapy in a single center Italian cohort of CRMO patients.
Methods: We reviewed retrospectively the clinical records of seven patients affected by CRMO diagnosed between 2008 and 2019 at rheumatologic service of South Tyrol region in Italy.
Results: We identified 7 patients with CRMO, 4 were female patients, median age of onset of symptoms was seven years. Median delay in diagnosis was seven months; all patients had bone pain as initial symptom and 6 patients presented joint swelling. Median number of lesions was two; all patients had a recurrent pattern, 4 patient had multifocal distribution and 5 had appendicular skeleton involvement. None of our patients had antinuclear antibodies or HLA-B27 positivity. Mean erythrocyte sedimentation rate was 52 mm/h and C-reactive protein 1,96 mg/dL. Regarding other organs involvement one patient presented palmoplantar pustulosis, one psoriatic arthritis and one psoriasis guttata; three patient referred familiarity for psoriasis. Histopathological diagnosis was confirmed in 3 patients. NSAIDs were used in six patients, methotrexate in two patients and bisphosphonates in 6 patients. Among biological DMARDs Adalimumab was used in two patients, one patient was treated subsequently with Secukinumab and Ustekinumab. 3 patients achieved remission (Table 1).

Table 1. Demographic, clinical and laboratory characteristics of patients with chronic recurrent multifocal osteomyelitis.

	Total (n=7)
Demographics	
Female (%)	4 (57)
Age at disease onset, years, median (range)	7 (6-24)
Delay in diagnosis, months, median (range)	7 (2-14)
Follow-up, months, median (range)	69 (11-151)
Initial symptoms	
Bone pain, n (%)	7 (100)
Swelling, n (%)	5 (71)
Limp, n (%)	3 (43)
Fever, n (%)	1 (14)
Clinical features	
Number of lesions, median (range)	2 (1-10)
Axial skeleton involvement, n (%)	2 (29)
Appendicular skeleton involvement, n (%)	5 (71)
Distribution of involvement	
Femur, n (%)	3 (43)
Radius/ulna, n (%)	2 (29)
Humerus, n (%)	1 (14)
Tibia/fibula, n (%)	5 (5)
Tarsal bones, n (%)	1 (14)
Others, n (%)	3 (43)
Laboratory tests	
Hemoglobin, g/dL, mean ± SD	13.1±0.6
Leukocytes $\times 10^3/mm^3$, mean ± SD	8.48 ±1.7
Platelets $\times 10^3/mm^3$, mean ± SD	384±130
Erythrocyte sedimentation rate mm/h, mean ± SD	52±37
C-reactive protein, mg/dL, mean ± SD	1.96±2.35
Positive antinuclear antibodies, n (%)	0 (100)
HLA-B27 positive, n (%)	0 (100)
Comorbidities	
Any type of autoimmunity, n (%)	2 (29)
Others, n (%)	3 (43)
Histological confirmation, n (%)	3 (43)
Treatment	
NSAIDs, n (%)	6 (86)
Glucocorticoids, n (%)	0 (0)
Bisphosphonates, n (%)	6 (86)
TNF blocking agents, n (%)	2 (29)
Biological DMARDs, n (%)	1 (4)
Methotrexate, n (%)	2 (29)
Antibiotics, n (%)	3 (43)
Reached remission, n (%)	3 (43)

Conclusion: CRMO remains a rare diagnosis. From our experience most of the patients had delay in diagnosis, laboratory tests showed mild elevation of inflammatory parameters, was found association with psoriatic arthritis and psoriasis, remission was achieved with combination of bisphosphonate and immunosuppressive therapy in less than half of the cohort

AB0753 ASSESSMENT OF SLEEP PROBLEMS IN PATIENTS WITH KAWASAKI DISEASE: A SURVEY-BASED STUDY

S. Tharwat[1]. [1]*Mansoura University, Internal Medicine, Rheumatology & Immunology, Mansoura, Egypt*

Background: Kawasaki disease (KD) is a type of vasculitis that affects mainly medium and small arteries,especially the coronary arteries (1).It mainly affects children under the age of five (2).Sleep disturbances are more prevalent among medically ill children and adults and may have a negative impact on their health related quality of life (3, 4).To the best of our knowledge,sleep problems have not previously studied in KD patients.
Objectives: This study aimed to investigate sleep problems, sleep disturbances and the relation between sleep problems and clinical manifestations among patients with KD.
Methods: A cross-sectional study was performed using a written survey. Participants were invited through social media groups including patients and parents of children with KD. The survey included questions about demographic data, KD manifestations, disease duration and treatment received for management of the disease. Children's Sleep Habits Questionnaire (33-item version) was also included in the survey (5).

Results: There was a total of 262 survey participants (130 KD and 132 age- and sex matched healthy controls). There was no significant difference in the frequency of clinically significant sleep disturbance between patients with KD and healthy controls. However, the total sleep score was significantly higher in KD patients than health controls (p<.001).Total sleep duration was significantly higher in patients with KD (4.94±1.88 vs 3.74 ±1.14 hr, p<.001).Additionally KD patients had significantly higher scores regarding sleep onset delay (p=.001),night wakings (p<.001),parasomnias (p<.001) and sleep disordered breathing (p<.001) when compared to healthy controls.KD Patients who manifested with chronic heart disease or lethargy had significantly higher sleep score than patients without (p=.015,.039 respectively).

Conclusion: This study showed that patients with KD had more sleep disturbance than their healthy peers. The presence of either chronic heart disease or lethargy is associated with poor sleep quality.This study highlights the need for assessment of sleep disorders in KD patients.

AB0754 THE INFLUENCE OF PHYSICAL ACTIVITY ON BODY COMPOSITION AND SELF-ESTEEM IN ADULTS WITH JUVENIL IDIOPATHIC ARTHRITIS

R. De Oliveira[1], P. Julio[1], P. Fernandes[2], R. Marini[3], S. Appenzeller[4]. *[1]UNICAMP, Child and Adolescent Graduate Program, Campinas, Brazil*; *[2]UNICAMP, Sport Sciences, Campinas, Brazil*; *[3]UNICAMP, Pediatrics, Campinas, Brazil*; *[4]UNICAMP, Orthopedics, Rheumatology and Traumatology, Campinas, Brazil*

Background: With improvement of treatment, long-term factors influencing quality of life have to be addressed in the care of juvenile idiopathic arthritis (JIA) patients.

Objectives: To compare body composition, level of physical activity and self-esteem of adult patients with JIA with control group (CG).

Methods: The levels of physical activity were analyzed using the International Physical Activity Questionnaire (IPAQ) short version. The body composition data were collected using the Omrom HBF 514 C vertical electric bioimpedance device. The Rosenberg Self-Esteem Scale was used to assess positive and negative attitude and feelings about themselves, where the lower the score, the higher the individual's self-esteem. For the statistical analysis of the data, the IBM SPSS software was used with a significance index of p <0.05.

Results: We included 81 individuals >18 years, 38 with JIA and 43 healthy people. The female sex was the largest participant in this research, being. There was no significant difference regarding sex [female =28 (73.7%) in JIA and 26 (60.5%) in CG] and age of the groups (29.39 ± 7.6 vs. 31.1 ± 3.1, p = 0.18). The CG showed greater height and body weight (163.5 ± 9.8 vs. 169.6 ± 8.0, p<0.001; 63.07 ± 16.65 vs. 69.33 ± 6.88, p = 0.003, respectively), but no difference in Body Mass Index (BMI) was observed (24.32 ± 4.9 vs. 24.12 ± 2.09, p = 0.8). JIA had a higher percentage of total fat mass (31.65 ± 10.20 vs. 28.47 ± 4.9, p = 0.07), while the CG had a higher percentage of total muscle mass (29.7 ± 6.5 vs. 35.86 ± 6.05, p<0.001). The self-esteem of JIA patients was lower than in the CG (21 ± 3.9 vs. 16.26 ± 4.3, p<0.001). In the IPAQ classifications, JIA patients were classified as less physically active than the CG (2.63% vs. 20.93%, p = 0.022), less irregularly active (5.26% vs. 23.25, p = 0.023) and a higher level of sedentary lifestyle (65.78% vs. 25.58%, p<0.001). A higher percentage of muscle mass was associated with greater self-esteem (r=-0.3; p=0.01).

Conclusion: The low practice of physical activities by patients with JIA seems to directly influence both, their body composition and their self-esteem. These patients should be encouraged to increase physical activity from an early age by a multiprofessional healthcare team to seek improvement their quality of life.

AB0755 THE FIRST CASE OF AN AUTOLOGOUS STEM CELL TRANSPLANTATION FOR AN EXTREMELY REFRACTORY PROGRESSIVE SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS PATIENT IN BRASÍLIA, BRAZIL

M. Rodrigues Pereira Almeida[1], S. Veloso[1], A. Siqueira Afonso[1]. *[1]Hospital da Criança de Brasília José Alencar, Pediatric Rheumatology, Brasilia, Brazil*

Background: Systemic juvenile idiopathic arthritis (sJIA) is one of the most perplexing diseases of childhood, with a wide range of presentation features and severity. Advances in treatment have improved the outcome, such as the use of modulators of proinflammatory cytokines and their receptors, but in a considerable number of children, especially in polyarticular or sJIA, refractoriness tends to be progressive. As of late, extreme cases have required Autologous Stem Cell Transplantation (ASCT) as a last resort.

Objectives: To describe an extremely refractory clinical evolution in a sAIJ patient, the first one to be submitted to an ASCT for an autoinflammatory condition in Brasília, Brazil's capital.

Methods: Case Report

The patient was classified according to the Pediatric International League of Associations for Rheumatology for sJIA.

I.T.S.M, female, 15-years-old, was diagnosed with sJIA at 6 with the onset of polyarthritis, daily fever for 6 weeks, rash and enlargement of liver and spleen. In the initial investigation infectious and neoplastic causes were ruled out.

The use of prednisone and methotrexate lead to a preliminary effective clinical control, however after an year, there was clinical deterioration and etanercept was associated, leading to a short term improvement. At that time, in addition to anti-tumour necrosis factor medications, no other biological drugs were available in Brazil.

Despite some brief periods of clinical improvement, after different regimes, the patient manifested recurrent flares. Since the diagnosis she has already been treated with:

[1] Methotrexate (2011 to 2014*, 2016 to 2020). *In 2015, it was replaced by Leflunomide (up to May 2016, discontinued due to intolerance);
[2] Etanercept (2012);
[3] Cyclosporine (August to December 2012);
[4] Adalimumab (2013);
[5] Tocilizumab (May 2014 to January 2015);
[6] Canaquinumab (March 2015 to April 2016);
[7] Mycophenolate Mofetil (February 2016, discontinued in May 2017 due to start of Cyclophosphamide);
[8] Rituximab (May 2016 to April 2017);
[9] Cyclophosphamide at a dose of 2 grams /m2 as well as Filgrastim for mobilization and collection of stem cells (May 2017, in a attempt of ASCT), but the parents were unable to reach a mutual agreement to consent to the continuation of this therapy;
[10] Cyclophosphamide (500mg /m^2) in a mensal scheme application for nine consecutive months since June 2017, once was observed a clinical improvement after the intensive immunosuppression previous to ASCT attempt;
[11] Several courses of methylprednisolone and human immunoglobulin since the initial diagnosis;
[12] Abatacept (November 2019 to October 2020);
[13] ASCT was suggested again in 2020, this time with the consent of all family members.

Results: An intensive immunosuppression [Cyclophosphamide and anti-thymocyte globulin (ATG)] followed by ASCT (October 2020) resulted in apparent sustained remission. The patient's evolution since the transplant has been optimistic. She is currently on a low dose prednisone prescription. To ensure a less profound depletion of T cells, a better control of systemic disease and antimicrobial and antiviral prophylaxis after transplantation, slow tapering of corticosteroids were performed.

Conclusion: The goal of hematopoietic stem cell transplantation in patients with autoimmune disease is to reprogram the immune system with the eradication of autoreactive cells, renew the population of regulatory T cells and restore the diversity of T cell receptor function.

ASCT has been used in some refractory children with sJIA as well as hematologic malignancy and some progressive autoimmune diseases. However it is associated with significant morbidity and mortality, due to prolonged and severe depression of T cell immunity.

AB0756 IMMUNE-MEDIATED BASIS FOR A PHASE 2A CLINICAL STUDY COMPARING RILZABRUTINIB VS GLUCOCORTICOIDS IN RITUXIMAB-REFRACTORY PATIENTS WITH IGG4-RELATED DISEASE

L. Long[1], M. Baker[2], M. Carruthers[3], A. Meysami[4], R. Spiera[5], M. Reddy[1], M. Kavanagh[1], M. Francesco[1], C. Langrish[1], A. Neale[1], P. Arora[1], J. H. Stone[6]. [1]*Principia Biopharma Inc, a Sanofi Company, Clinical Development, South San Francisco, United States of America*; [2]*Stanford University, Department of Medicine, Division of Immunology and Rheumatology, Stanford, United States of America*; [3]*Division of Rheumatology, University of British Columbia, Rheumatology, Vancouver, Canada*; [4]*Division of Rheumatology, Henry Ford Health System, Rheumatology, Detroit, United States of America*; [5]*Hospital for Special Surgery, Rheumatology, New York, United States of America*; [6]*Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Rheumatology, Boston, United States of America*

Background: IgG4-related disease (IgG4-RD) is an immune-mediated disorder causing fibro-inflammatory lesions. Although the cause remains unknown, it may be driven by interactions between B lymphocytes and CD4+ cytotoxic and regulatory T cells and is characterized by an increase in short-lived plasmablasts, circulating antibodies, and macrophages. Standard therapy mainly includes glucocorticoids (GC), limited by toxicity with long-term use (> 6 mo), and to a lesser extent, immunosuppressives (eg, rituximab). Bruton tyrosine kinase (BTK) plays an important role in the activation of multiple immune effector cells such as B cells, mast cells, eosinophils, basophils, monocytes/macrophages, and neutrophils. Dysregulation of the activation of these immune cells results in autoimmune inflammation, tissue damage, and development of fibrosis. Rilzabrutinib is a highly selective oral BTK inhibitor that targets multiple pathways of innate and adaptive immunity (with direct effects on B-cell and FcR pathways) and has the potential to inhibit antigen presentation to autoreactive T cells.
Objectives: To provide the biological rationale for rilzabrutinib in IgG4-RD.
Methods: Rilzabrutinib has been evaluated in biochemical, *in vitro* studies, and *in vivo* models of inflammatory diseases. Additional support is provided by the phase 2 trial for oral rilzabrutinib in patients with pemphigus vulgaris and the phase 2 trial for oral rilzabrutinib in patients with immune thrombocytopenia (ITP).
Results: Rilzabrutinib inhibited the activity of BTK and B-cell receptor in B cells (IC_{50} 5-123 nM) and Fc gamma receptor in IgG/Fc gamma receptor-stimulated monocytes (IC_{50} 56 nM) and blocked IgG- and IgM-mediated antibody production in enriched B cells when stimulated in T-cell dependent (anti-CD40+IL-21) and T-cell independent (TLR-9/CpG and TNP-LPS) pathways. The impact of rilzabrutinib on innate cell pathways was further confirmed by significant dose-dependent inhibition of macrophage and neutrophil-driven passive rat Arthus reaction ($P < 0.01$ vs vehicle) and antibody-induced murine ITP ($P < 0.05$ vs vehicle). In a 12-week phase 2 pemphigus vulgaris trial, 54% of patients achieved the primary endpoint, control of disease activity (CDA) on low-dose corticosteroids by week 4, and 73% achieved it by week 12. In the phase 2 trial of ITP patients (median 6 prior therapies), rilzabrutinib 400 mg bid showed rapid and sustained improvement in platelet counts and only grade 1/2-related adverse events[1]. In responders, platelet counts increased as early as day 8, potentially due to innate immune mechanisms. Collectively, results in both B and innate immune cells provide an initial basis for evaluating rilzabrutinib in IgG4-RD. The ongoing phase 2a study (NCT04520451) is investigating rilzabrutinib 400 mg bid (+tapered GC) vs GC control (3:1) for 12 weeks in IgG4-RD patients refractory to rituximab. The primary objective is to evaluate the safety and ability of rilzabrutinib to induce GC-free remission at week 12. Coupled with known preclinical/clinical findings, mechanistic analyses in this ongoing IgG4-RD study will profile B and other immune cell effects pre-/post-rilzabrutinib dosing to enhance the clinical understanding of rilzabrutinib in IgG4-RD.
Conclusion: Studies of rilzabrutinib that show beneficial effects on both B-cell and innate cell pathways provide support for its therapeutic role in immune-mediated diseases and for targeting the underlying pathophysiological effects of IgG4-RD. Effective and safe therapies that rapidly induce and maintain clinical responses, while minimizing the need for continuous GC treatment, remain an unmet need for patients with IgG4-RD.

AB0757 ON THE ISSUE OF DIFFERENTIAL DIAGNOSIS OF PANNICULITIS

O. Egorova[1], V. Gorodetskiy[1], B. Belov[1], A. Potapova[2], S. Radenska-Lopovok[3], N. Probatova[4]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory for the Study of Comorbid Infections and Monitoring the Safety of Drug Therapy, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*; [3]*FSBEI HE "I.M. Sechenov First Moscow State Medical University", Department of Pathological Anatomy, Moscow, Russian Federation*; [4]*Federal State Budgetary Scientific Institution "N.N. Blokhin Russian Cancer Research Center", Department of Morphological and Molecular Genetic Diagnostics of Tumors, Moscow, Russian Federation*

Background: Diagnosis of panniculitis (Pn) is associated with significant difficulties due to the variety of etiological factors, which include panniculitis-like T-cell lymphoma (PLTCL) – a rare variant of non-Hodgkin lymphoma.
Objectives: to study clinical and laboratory features of PLTCL in rheumatology.
Methods: Over 8 years PLTCL was diagnosed in 10 patients (9 women and 1 man, average age 37.2 ± 7.4) who were referred to V.A. Nasonova Research Institute of Rheumatology with a diagnosis of erythema nodosum or panniculitis. In addition to general clinical study, serum concentrations of α-1 antitrypsin, amylase, lipase, ferritin, creatine phosphokinase, immunological parameters (ANF-Hep2, dsDNA, C3 and C4 complements, CRP, ANCA, Scl-70, antibodies to cardiolipins G and M) were determined, and positron emission tomography combined with computed tomography (PET-CT), histological and immunohistochemical examination (IHC) of the biopsy sample of skin with subcutaneous fat from the affected areas were performed.
Results: The clinical picture of PLTCL was characterized by generalized red-crimson moderately painful (VAS pain intensity 45mm) subcutaneous nodes on the upper limbs and trunk (100%), face (60%) and lower extremities (75%), without ulceration and oily fluid leakage. A "trembling saucer" symptom was evident in 75% of the observed cases. All patients had febrile fever. No enlargement of the lymph nodes of the liver and spleen was observed. The blood test revealed leukopenia (up to 2.0·x 10^9 /l) in 50% of cases, an increase in ESR and CRP by three or more times in 100% of cases. The biochemical blood test demonstrated an increase in LDH activity by two or more times in all patients. PET-CT in 100% of cases revealed an intense accumulation of 18F-FDG in the nodes which correlated with a high proliferative activity index. The morphological picture resembled lobular panniculitis without vasculitis. Tumor lymphocytes had an immunophenotype of cytotoxic T-lymphocytes: CD3+, CD8+, granzyme B+. To confirm the tumor nature of the infiltrate the rearrangements of the T-cell receptor genes were studied. Glucocorticoid therapy (23.5±9.6 mg/day) was ineffective which required polychemotherapy in most patients.
Conclusion: PLTCL presents a complex diagnostic task that requires a multidisciplinary approach to verify the diagnosis and treatment tactics.

AB0758 CLINICAL PROFILES DIFFER IN IGG4-RELATED DISEASE WITH AND WITHOUT ATOPY: A LARGE CASE-CONTROL STUDY IN CHINA

Z. Zhao[1], Y. Liu[1], Y. Su[1]. [1]*Peking University People's Hospital, Rheumatology and Immunology, Beijing, China*

Background: IgG4-related ophthalmic disease (IgG4-ROD) is one of the phenotypes of IgG4-related disease (IgG4-RD), and its lesions are mainly located in the ocular. Currently, there are few studies on IgG4-ROD and no study has compared the phenotypic differences between IgG4-ROD and non IgG4-ROD (nIgG4-ROD). Thus, it is difficult to establish the optimal treatment strategy for IgG4-ROD.
Objectives: The aim of this study was to identify the disparities between the two groups and to clarify the risk factors for IgG4-ROD relapse.
Methods: The IgG4-RD patients diagnosed at Peking University People's Hospital between January 2009 and January 2020 were recruited in this study. Patients were divided into IgG4-ROD and nIgG4-ROD group according to the ophthalmic involvement. Demographic, clinical and laboratory data of two groups were collected and compared. Cox regression analysis was used to identify the independent risk factors for IgG4-ROD relapse.

Results: Two hundred and fifty-five cases of IgG4-ROD were identified in 434 IgG4-RD patients in this study. IgG4-ROD group had almost equal sex ratio (male to female 0.96:1 vs 2.14:1, *P*<0.001), younger age of disease onset (51.1±13.2 vs 55.5±13.5, *P*<0.001) and diagnosis (54.4±12.6 vs 56.9±13.4, *P*=0.054) comparing with nIgG4-ROD patients. As compared to nIgG4-ROD group, higher percentage of IgG4-ROD patients met the 2019 American College of Rheumatology/European League Against Rheumatism classification criteria (AECC) for IgG4-RD (89.4% vs 64.8%, *P*<0.001), moreover, IgG4-ROD patients had higher AECC scores (37.0±12.9 vs 27.2±14.0, *P*<0.001) and IgG4-RD responder index (11.4±6.0 vs 10.2±6.3, *P*=0.045). Allergic diseases (65.5% vs 26.3%, *P*<0.001) and multiorgan involvement [6(4-7) vs 3(2-5), *P*<0.001] were more common in IgG4-ROD group. IgG4-ROD was frequently associated with salivary gland (92.5% vs 45.3%, *P*<0.01), paranasal sinuses (38.8% vs 12.8%, *P*<0.01), lung (47.8% vs 32.4%, *P*<0.01) and lymph node (64.3% vs 46.4%, *P*<0.01) involvement, while retroperitoneal fibrosis (7.1% vs 21.2%, *P*<0.01) and biliary system lesions (25.1% vs 35.2%, *P*<0.05) were more common in nIgG4-ROD. IgG4-ROD patients had higher serum IgG4 levels [983(409-1838) vs 523(225-1370), *P*<0.001], IgG4/IgG ratio [0.529(0.272-0.879) vs 0.294(0.143-0.629), *P*<0.001], IgE levels [339.7(160.8-847.6) vs 259.4(83.1-653.3), *P*=0.022] and lower CRP levels [2.24(1.00-4.70) vs 3.05(1.26-12.45), *P*=0.004]. The initial glucocorticoid plus immunosuppressant was a protective factor for IgG4-ROD relapse (HR 0.279, 95%CI 0.165-0.470, P<0.001), and IgG4-ROD patients treated with initial glucocorticoid plus immunosuppressant had longer relapse-free survival time than patients treated with initial glucocorticoid monotherapy (43 vs 17, P<0.001).
Conclusion: IgG4-ROD patients had distinctive clinical features compared with nIgG4-ROD patients. The initial glucocorticoid plus immunosuppressant was a protective factor for IgG4-ROD relapse, which could prolong the relapse-free survival time of IgG4-ROD patients. These findings may have important implications for understanding and management of IgG4-ROD.

AB0759 INDEX OF COMORBIDITY IN PATIENTS WITH LOBULAR PANNICULITIS-LIPODERMATOSCLEROSIS

O. Egorova[1], B. Belov[1], A. Potapova[2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory for the Study of Comorbid Infections and Monitoring the Safety of Drug Therapy, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Early diagnosis of comorbid burden and treatment of rheumatological patients, especially panniculitis (Pn), is a complex problem, the solution of which lies in an interdisciplinary approach and the development of a general algorithm for managing patients.
Objectives: To study the structure and frequency of comorbid conditions in patients with Pn-lipodermatosclerosis (LDS).
Methods: We examined 53 patients (3 men and 50 women aged 18 to 80) with verified LDS, who were observed at the V.A. Nasonova Research Institute of Rheumatology for ten years on average. The duration of the disease varied from 2 weeks to 20 years. Clinical, laboratory and instrumental examination of patients was carried out twice a year. Clinical examination was carried out to determine localization, prevalence, color and number of the affected areas of skin and subcutaneous fat (SCF), as well as pain intensity according to the Visual Analogue Scale (VAS). Laboratory and instrumental research included standard blood and urine tests, as well as computed tomography of the chest and Doppler ultrasound of the lower extremities. To assess the relationship between the presence of comorbid pathology and the course of LDS the patients were analyzed with the CIRS and Charlson indices.
Results: Most patients were overweigh women (60.3%) with average weight of 91.5±21.8 kg. Based on the duration of the disease we identified the main variants of the course of the disease: acute (up to 3 months), subacute (from 3 to 6 months), and chronic (more than 6 months). Skin lesions were associated with polyarthralgias (n=18) and/or myalgias (n=12), mainly in the area of the affected limb. In 16 patients an increase in the erythrocyte sedimentation rate was recorded on average up to 23.8 ±7.8 mm/h. The level of C-reactive protein (CRP) was more than 3 times higher than normal in 7 patients, 4 of them had an acute course of LDS. In the study group 17 patients did not have comorbid diseases, 64.7% of them were under 50 years old with an acute course of LDS (p=0.02). Concomitant pathology was detected in 68% of patients mainly with chronic LDS. In 67.9% of cases it was presented by chronic venous insufficiency (CVI), in 60.3% – by exogenous constitutional obesity, in 45.2% – by rheumatic diseases (75% of these patients had osteoarthritis, 17% – rheumatoid arthritis, 8% – antiphospholipid syndrome) and in 39.6% – arterial hypertension. Most patients had one concomitant disease, almost a fifth of patients had two concomitant diseases. The proportion of patients with three comorbid diseases was 11.1%, four comorbid diseases – 8.3% and five comorbid diseases – 5.5%. When assessing the Charlson index, 10-year survival rates over 90% (index values from 0 to 2 points) were registered in 66% of patients, from 53 to 77% (index values of 3-4) – in 26.4% and less than 21% (≥5 points) – in 7.5%. The comorbidity index correlated with the age of patients (r = 0.8; p<0.05). There was no correlation between the Charlson index and the duration of LDS (r=0.3; p=0.2). In patients older than 61 one or more comorbid conditions were recorded. The CIRS index for this group averaged 4.2 ± 0.3 points (range 0-10), in most patients (45.2%) the CIRS index did not exceed 5 points. An analysis of the relationship between the Charlson and the CIRS scales confirmed their significant correlation at the level of r=0.5, p=0.0000001.
Conclusion: In patients with LDS a high incidence of comorbid pathology was detected. The treatment of this variant of panniculitis requires an interdisciplinary approach and interaction between doctors of different specialties.

AB0760 HIGH SERUM IGA LEVELS HAVE LIMITED CLINICAL SIGNIFICANCE IN PATIENTS WITH IGG4-RELATED DISEASE DIAGNOSED BY EXPERTS

S. Tsuge[1], I. Mizushima[1], S. Shin[1], T. Yoshinobu[1], R. Hoshiba[1], R. Nishioka[1], T. Zoshima[1], S. Hara[1], Y. Suzuki[1], K. Ito[1], M. Kawano[1]. [1]*Kanazawa University Hospital, Department of Rheumatology, Kanazawa, Japan*

Background: While the diagnostic and classification criteria for IgG4-related disease (IgG4-RD) have been recently developed [1-3], it is known that, without appropriate exclusions, some non-IgG4-RDs may meet these criteria. In particular, hyper IL-6 syndromes, including Castleman disease, can be misdiagnosed as IgG4-RD. Some clinical findings, including elevated serum levels of C-reactive protein (CRP) or IgA, have been suggested to be useful for differentiating hyper IL-6 syndromes from IgG4-RD [4]. However, since few clinical studies have focused on IgG4-RD with high serum IgA levels, its clinical significance has not been well known.
Objectives: This study aimed to clarify the clinical significance of high serum IgA levels in patients with IgG4-RD.
Methods: We retrospectively investigated the clinical features of 170 patients with IgG4-RD on the basis of the presence or absence of elevated serum IgA levels (>410 mg/dL) at the time of diagnosis. The diagnosis of IgG4-RD was made by experts on the basis of the fulfillment of the comprehensive diagnostic criteria and/or each organ-specific diagnostic criteria.
Results: Elevated serum IgA levels were observed in 18 patients (10.6%). In the patients with elevated serum IgA levels, serum CRP levels were higher (1.14 ± 1.18 vs. 0.31 ± 0.63 mg/dL, p=0.003) and the prevalence of relapse during the clinical course was lower (5.6% vs. 27.6%, p=0.046) than in those without elevated serum IgA levels. However, there were no significant differences in the other clinical features including the number of involved organs (2.4 ± 1.3 vs. 2.8 ± 1.6, p=0.443) and inclusion scores of the ACR/EULAR classification criteria (32 ± 14 vs. 36 ± 17, p=0.374). To evaluate the influence of serum IgA elevation on relapse, we performed Cox regression analysis, which showed that the elevated serum IgA levels had no significant association with lower incidence of relapse but a tendency of it (hazard ratio 0.997, 95% confidence interval 0.994-1.000, p=0.055) during the clinical course. In addition, a prompt improvement in the IgG4-RD responder index [5] during the clinical course was seen in the patients with serum IgA elevation, suggesting a similar good response to glucocorticoids as in those without it.
Conclusion: The findings of the present study suggest that IgG4-RD patients with high serum IgA levels can be diagnosed and treated in the same way as those without it, although they may be characterized by mild serum CRP elevation.

HISTOPATHOLOGY OF CHECKPOINT INHIBITORS INDUCED ARTHRITIS: RETROSPECTIVE ANALYSIS OF 3 CASES

M. D. B. Laurent[1,2], A. Sandrone[3], D. R. Silvana[2], C. Frank[4], P. Renaud[5], C. Galant[6], B. Lauwerys[7], P. Durez[7]. [1]*Cliniques Universitaires Saint-Luc, Rheumatology, Brussels, Belgium*; [2]*CHU Saint-Pierre, Rheumatology, Brussels, Belgium*; [3]*UZ Brussel, Oncology, Brussels, Belgium*; [4]*Cliniques Universitaires Saint-Luc, Oncology, Brussels, Belgium*; [5]*Clinique Saint-Pierre, Oncology, Ottignies, Belgium*; [6]*Cliniques Universitaires Saint-Luc, Pathology, Brussels, Belgium*; [7]*Cliniques Universitaires Saint-Luc, Rhumatologie & Institut de Recherche Expérimentale et Clinique, Brussels, Belgium*

Background: Induced arthritis (IA) is a rare immune related adverse event occurring in 0.5 to 2% of patients exposed to Immune (irAEs) Checkpoint Inhibitors (CPI). In some patients, this condition may be severe and long lasting even after CPI cessation. Cross-reactivity between tumor- and self-antigens was considered in the etiology of several cases of irAEs but disease mechanisms in IA remain elusive.

We systematically collect synovial tissue of patients with IA (Ethical Committee B403201942386).

Objectives: Here, we report the histopathological findings from ultrasound guided (USG) synovial biopsies from the 3 first patients of our cohort. The immune cell infiltration in CPI IA patients is compared to the histopathological findings in rheumatoid arthritis.

Methods: Patients were referred through their oncologist after the onset of an arthritis in the context of a CPI therapy. The diagnostic of arthritis was confirmed by a rheumatologist and by ultrasound assessment. USG biopsies were performed before initiation of specific therapies.

Pathological and immunohistochemical analyses include semi quantitative scoring of the following: synovial hyperplasia, fibrinoid necrosis, chorion cellular infiltrate, vascular hyperplasia, CD3-, CD20-, CD68- and CD138-positive cells.

All patients gave written informed consent.

Results: Three patients went through the USG biopsy procedure: 2 males and 1 female. No adverse events were recorded.

All patients had metastatic neoplasms and time-to-arthritis was on average 6.7 months after CPI initiation. The USG biopsies were performed from 1 week after the onset of the IA to 16 months. The target joints displayed strong synovial thickening on ultrasound. Histological and immunohistochemistry studies showed light to moderate synovial hyperplasia and inflammatory cell infiltration of the sublining by macrophages and T cells, but no or little B cells (Table 1).

Table 1. Clinical Characteristics and histopathological analyses on synovial biopsies.

	Patient 1	Patient 2	Patient 3
Cancer	uterus	bladder	lungs
Biopsied joint	first metatarsophalangial joint	wrist	knee
Time-to-synovial biopsy	1 week	2 months	16 months
Grey scale on ultrasound	3/3	3/3	3/3
Hematoxylin-eosin staining:			
synovial hyperplasia	+	+	++
fibrinoid necrosis	0	+	++
chorion cellular infiltrate	+	++	+
vascular hyperplasia	0	0/+	++
Immunochemistry staining:			
CD3	+	++	+
CD20	0	0	0/+
CD68	++	0/+	++
CD138	0	0	0/+

Conclusion: USG synovial biopsies have been safely performed and the histopathological analysis have confirmed the synovitis with mainly a macrophage infiltrate (myeloid pattern). IA synovitis is characterized by synovial hyperplasia and macrophage and T cell infiltration of the sublining. Increased collaboration between oncologists and rheumatologists is needed to create opportunities for referral of patients between the two specialties and optimize treatment. Further analyses (such as global or single-cell RNA sequencing) are needed to learn more about IA physiopathology.

THE CHARACTERISTICS OF PERIPHERAL LYMPHOCYTE SUBSETS IN PATIENTS WITH IGG4-RELATED DISEASE

Y. Y. Wang[1], X. Yu[1], R. Su[1], X. LI[1], C. Wang[1]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatic Immunology, Taiyuan, China*

Background: Immunoglobulin G4-related disease (IgG4-RD) is an autoimmune disease with chronic systemic inflammation and fibrosis. The main feature of the disease was diffuse swell of the affected organs, and the serum IgG4 level was increased. Histopathology of the lesions showed infiltration of IgG4+ plasma cells. However, the pathogenesis of IgG4-RD is still unclear[1].

Objectives: To explore the clinical characteristic of lymphocyte subsets of IgG4-related disease patients, and make comparisons with healthy controls.

Methods: A total of 31 patients with IgG4-RD who were admitted to the Rheumatic Immunology Department of the Second Hospital of Shanxi Medical University from January 2016 to June 2020 were included. We collected their Clinical and laboratory data, and selected 30 age and sex matched healthy people as the control group. Flow cytometry was used to detect the percentage and absolute number of lymphocyte subsets (T, B, NK, CD4+T, CD8+T) and CD4+T subsets (Th1, Th2, Th17, CD4+CD25+Foxp3+Treg) in peripheral blood of IgG4-RD patients and healthy controls.

Results: (1)The percentage of CD4+T cells in peripheral blood of IgG4-RD patients was higher than that of healthy controls [45.00(33.97-51.48) vs. 39.36(33.78-43.30), P<0.05]. (2)The percentage and absolute number of Th17 cells was increased in IgG4-RD patients [1.13(0.70-1.55) vs. 0.77(0.43-1.07), P<0.05; 7.90(5.20-12.23) vs. 5.60(3.12-8.47), P<0.05], while the percentage of Treg cells was decreased [3.37(2.82-5.65) vs. 4.96(4.18-6.34), P<0.01]. But Treg cells number showed no difference between the two groups. (3) Th17/Treg ratio was significantly increased in IgG4-RD patients [0.29(0.16-0.46) vs. 0.15(0.08-0.23), P<0.01], and it was positively correlated with IgG4-RD response index score(r=0.491, P<0.01). (Table 1).

Table 1. Comparation of absolute number and percentage of peripheral blood lymphocyte subsets between IgG4-RD patients(n=31) and healthy controls (n=30).

cell subsets	IgG4-RD (n=31)	HC(n=30)	*P* value
B	150.59(120.14-212.38)	203.27(152.90-244.27)	0.089
B%	8.74(6.46-11.45)	10.03(8.26-13.21)	0.059
NK	261.98(178.82-303.08)	290.83(179.93-451.45)	0.175
NK%	13.14(9.92-18.10)	16.50(11.24-21.75)	0.105
CD3+T	1357.44(992.00-1844.82)	1305.81(978.24-1597.94)	0.708
CD3+T%	72.62(69.32-76.96)	71.62(64.97-75.25)	0.135
CD8+T	436.40(342.71-596.86)	513.50(359.73-620.53)	0.665
CD8+T%	24.26(19.48-31.27)	26.50(20.67-32.90)	0.535
CD4+T	741.00(562.78-1095.52)	664.50(585.52-789.97)	0.428
CD4+T%	45.00(33.97-51.48)	39.36(33.78-43.30)	**0.032**
Th1	162.32(108.11-216.61)	144.27(81.52-161.66)	0.094
Th1%	19.00(15.24-25.54)	18.46(14.86-24.27)	0.644
Th2	7.82(5.35-11.78)	8.25(5.32-10.87)	0.817
Th2%	1.00(0.76-1.27)	1.24(0.89-1.64)	0.399
Th17	7.90(5.20-12.23)	5.60(3.12-8.47)	**0.010**
Th17%	1.13(0.70-1.55)	0.77(0.43-1.07)	**0.026**
Treg	24.45(19.76-44.79)	34.55(27.29-46.57)	0.076
Treg%	3.37(2.82-5.65)	4.96(4.18-6.34)	**0.003**
Th1/Th2	20.00(13.78-36.36)	14.97(10.31-21.58)	0.135
Th1/Treg	5.72(2.92-8.86)	3.68(2.53-4.77)	**0.021**
Th2/Treg	0.27(0.16-0.52)	0.22(0.15-0.32)	0.199
Th17/Treg	0.29(0.16-0.46)	0.15(0.08-0.23)	**0.002**

Conclusion: Th17/Treg immune disorder exists in IgG4-RD patients, and it is related to the disease activity, indicating that Th17/Treg imbalance may be an important pathogenesis of IgG4-RD.

IGG4-RELATED CORONARY PERIARTERITIS: SYSTEMATIC LITERATURE REVIEW WITH OUR CASE SERIES

T. Ito[1,2], S. Fukui[1], T. Kanie[3], T. Nakai[1], G. Kidoguchi[1], H. Ozawa[1], S. Kawaai[1], Y. Ikeda[1], A. Koido[1], Y. Haji[2], A. Nomura[1], H. Tamaki[1], K. Yamaguchi[1],

M. Okada[1]. [1]*St. Luke's International Hospital, Immuno-Rheumatology Center, Tokyo, Japan*; [2]*Daido Hospital, Rheumatology Department, Nagoya, Japan*; [3]*St. Luke's International Hospital, Cardiology Department, Tokyo, Japan*

Background: Coronary periarteritis is one of the clinical manifestations of IgG4-related disease. It can cause serious conditions such as angina and ruptured aneurysms. Therefore, it is important to recognize the clinical and radiological characteristics, which was little known.
Objectives: We report four patients with IgG4-related coronary periarteritis with a systematic literature review.
Methods: We identified four patients with IgG4-related coronary periarteritis at the St. Luke's International Hospital in Tokyo, Japan from 2014 to 2020. A systematic literature review was conducted for English articles on IgG4-related coronary periarteritis cases with a full text or abstract available. We summarized patient demographics, IgG and IgG4 titers, the site and morphological type of coronary lesion, and other organ involvements.
Results: Our 4 cases and 38 cases identified by the literature review were assessed. Coronary artery lesions were detected by a coronary CT in all but two cases. Wall thickening was the most common type of the lesion. Moreover, there were 32 (76.1%) patients with other organ involvements. The commonest other lesion was peri-aortitis in 21 (50.0%) patients. In cases with peri-aortitis, IgG and IgG4 titers were significantly higher than those without peri-aortitis (IgG4; 1540 [705.0, 2570.0] vs 246.0 [160.0, 536.3]; p = 0.001, IgG; 3596.5 [2838.3, 4260.0] vs 1779.0 [1288.3, 1992.8]; p =0.040). In addition, 15 (71.4%) patients of them had three or more IgG4 related organ involvements.
Conclusion: Coronary CT was a useful imaging modality for the diagnosis of IgG4-related coronary periarteritis, and wall thickening was the most common lesion. Moreover, about half cases coexisted with peri-aortitis. Peri-aortitis and other organ involvements should be screened in those with higher IgG and IgG4.

Table 1. Characteristics of our cases and the literature review cases.

Table 1. Characteristics of our cases and the literature review cases.

	All cases (n=42)				Total number of coronary lesions (n=126)
Age (years)	64.0 [58.0, 69.8]	The number of organ involvements		Lesion distribution	
Male (%)	35 (83.3)	≥ three (%)	20 (47.6)	RCA (%)	45 (35.7)
IgG4 (mg/dL)	625.0 [214.0, 2090.0]	two (%)	12 (28.6)	LAD (%)	48 (38.1)
IgG (mg/dL)	2841.5 [1672.3, 4138.8]	one (%)	10 (23.8)	LCx (%)	33 (26.2)
Diagnosis criteria		With other organ involvements		Lesion type	
possible (%)	10 (23.8)	all cases (%)	32 (76.1)	stenosis (%)	28 (22.2)
probable (%)	9 (21.4)	peri-aortitis (%)	21 (50.0)	wall thickening (%)	70 (55.6)
definite (%)	23 (54.8)	gland (%)	12 (28.6)	aneurysm (%)	28 (22.2)
		pancreas (%)	9 (21.4)		
		lymph (%)	6 (14.3)		
		kidney (%)	4 (9.5)		
		retroperitoneal (%)	4 (9.5)		
		pulmonary (%)	2 (4.8)		
		colon (%)	1 (2.4)		
		Coronary branch lesion counts			
		mono (%)	14 (33.3)

AB0764 MANIFESTATIONS OF BEHCET'S DISEASE

R. Goloeva[1], Z. Alekberova2. [1]*V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Disease, Москва, Russian Federation*; [1]*V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Disease, Москва, Russian Federation*

Background: Behcet's disease (BD) is a systemic vasculitis of unknown etiology, characterized by recurrent oral and genital erosions and ulcerations, as well as involvement of joints, ocular, vascular, gastrointestinal (GI), and central nervous system (CNS).
Objectives: To study the influence of such factors as patient's gender, age at the disease onset and initial manifestations of the disease on the severity of BD.
Methods: 95 patients with confirmed BB were examined. The majority of patients were males (70 men, 25 women) with the 2.8:1 M:W ratio. Patients' mean age (median [interquartile range]) was 29 years [22; 34], from 16 to 51 years, the average age at disease onset was 20 years [14; 24]; and mean disease duration was 8 years [4; 15].
Results: The following clinical manifestations of BD were documented at disease onset (%): recurrent aphthous stomatitis – 63.1; skin lesions – 12.6; genital ulcers – 4.2; ocular lesions – 6.3; joint syndrome -7.4; CNS lesions -2.1; gastrointestinal tract involvement -2.1; thrombosis -1; epididymitis -1. 11.6% of all patients had signs of organ system involvement by the time of establishing BD diagnosis. Recurrent aphthous stomatitis was more common in female patients at BD onset– 76% vs. 58.6%, p=0.01, while organ system involvement was more common in males-14% vs. 4% in females, p=0.02.
Progression from initial symptoms to the mature BD phenotype allowing to verify the diagnosis occurred within 4.3 years on average [1; 6], although 30.5% of patients progressed to a full-blown disease within 1 year.
Analysis of potential predisposing or precipitating factors prior to BD onset identified such in only 12 patients, including frequent episodes of tonsilitis in 3 patients, cold exposure with hypothermia in 2, dental procedures in 2, stressful events - in 2, and one case of each - herpes labialis, frontal sinus puncture and appendectomy. Other patients could not recall any potential precipitator of BD.
Mean age at BD onset was 20 years [14; 24], including 30.5% of patients with disease onset before 16 years, 22.1% aged from 16 to 21 years, 36.8% aged from 21 to 30 years at disease onset, and in remaining 10.5% the disease manifested after 30 years of age. BD onset in men and women was documented at approximately the same time. There were no signs or correlations indicating that patient's age at disease onset could be associated with specific clinical symptoms in males or females. However, analysis of gender-associated differences in disease severity based on Krause's Clinical Severity Scoring yielded the following results: mild BD was found in 15.7% men and 44% women (p=0.009), moderate disease - in 7.1% men and 16% women, (p>0.05), and severe BD - in 77% men and 40% women, respectively, (p=0.001). The risk of developing severe BD was 5-fold higher in men vs women [OR = 5.06, 95% CI 1.7-15.1].
Conclusion: First BD symptoms manifested in the majority of patients before the age of 30 years, with only 10% of patients with BD onset at the age of > 30 years. In more than 50% of all patients aphthous stomatitis was the first manifestation of the disease, and was more common in women. Prognostically unfavorable BD signs were found in 11.6% of patients already at the initial stages of the disease in men. No correlation was found between the age at BD onset and clinical symptoms of the disease in both males and females.

AB0765 PHENOTYPES OF BEHCET'S DISEASE IN DIFFERENT ETHNIC GROUPS

R. Goloeva[1], Z. Alekberova2. [1]*V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Disease, Москва, Russian Federation*; [1]*V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Disease, Москва, Russian Federation*

Background: Early diagnosis and identification of predominant organ system involvement in Behcet's disease (BD) is crucial for identifying most optimal treatment. The study evaluates 6 described phenotypes of BD - cutaneous-mucous, articular, ophthalmic, vascular, neurological and intestinal in different ethnic groups.
Objectives: To assess the occurrence of Behcet's disease (BD) phenotypes in different ethnic groups.
Methods: The study included 202 patients with BD from the 5 most common ethnic groups.
The male-female ratio was 2.4:1. Patients' mean age was 31 years [24;37], mean age at the disease onset was 21 years [15;28]; and mean disease duration was 7 years [3;14]. The severity of BD (mild, moderate and severe) was assessed based on the I. Krause's Clinical Severity Scoring for BD.
Results: Severe BD was more often diagnosed in Azerbaijanis and indigenous residents of Dagestan compared to Russians (75 and 70.4% vs. 36.2%), in Armenians - 50% and Chechens - 54.5% out of all BD cases.
Russians were significantly more likely to have a neurological phenotype (15.5% vs. 0-9.4% in all other ethnic groups) and intestinal phenotype (36.2% vs. 13.8-22.7 in all other ethnic groups). Azerbaijanis demonstrated higher prevalence of ocular involvement (68.7% versus 36.2% in Russians, 50% - in Chechens and Armenians, and 57% - in Dagestanis). Dagestanis were more likely to have a vascular phenotype (40.7% versus 15.6% in Azerbaijanis and 18.9% in Russians). The male/female ratio among Russian patients was 1:1, among Dagestanis 4.4:1, Azerbaijanis 3.5:1, Chechens and Armenians 2.6: 1.
Conclusion: BD phenotypes vary and demonstrate significant association with the patient's ethnic affiliation therefore, ethnicity should be viewed as the prognostic marker of specific organ-system involvement in case of a disease.

AB0766 SUCCESSFUL TEATMENT OF ANKYLOSING SPONDILITIS ASSOCIATED AA AMYLOIDOSIS WITH SECUKINUMAB: A CASE SERIES WITH THREE PATIENTS

M. Bektaş[1], N. Koca[1], E. Oguz[1], C. Cetin[1], B. Ince[1], Y. Yalçınkaya[1], B. Artim-Esen[1], M. L. Ocal[1], M. Inanc[1], A. Gül[1]. [1]*Istanbul Faculty of Medicine, Internal Medicine, Rheumatology Division, Istanbul, Turkey*

Background: Systemic AA amyloidosis is a serious and life-threatening complication of chronic inflammatory diseases such as rheumatoid arthritis, spondyloarthritis (SpA), and periodic fever syndromes. While most common cause of AA amyloidosis is Familial Mediterranean Fever; Ankylosing Spondylitis (AS) is another frequent cause of AA amyloidosis in Turkey.
Objectives: We aimed to evaluate the response of secukinumab (SEC) treatment in three patients with AS and AA amyloidosis (AS-AA) in our tertiary referral centre.
Methods: We retrospectively evaluated three AA amyloidosis patients who fulfilled Modified New York Criteria for diagnosis of AS in our AA amyloidosis cohort with 163 patients. Diagnosis of AA amyloidosis was confirmed by Congo red stain and by monoclonal AA-specific antibodies.
Results: *Patient 1:* 61-year-old male patient with inflammatory back pain (IBP) and peripheral arthritis for 14 years was evaluated in our clinic. After methotrexate (MTX) failure, he used adalimumab (ADA), etanercept (ETA) and certolizumab (CZP). Nephrotic range proteinuria was detected when he was on CZP, and rectum biopsy documented AA amyloidosis 3 years ago. After the diagnosis, CZP treatment was switched to infliximab (IFX). IFX was ineffective in controlling inflammatory findings. SEC was started 15 months ago and he responded partially. The dose of SEC was increased to 300 mg monthly, which resulted in a sustained improvement in clinical and laboratory findings.
Patient 2: 69-year-old woman was admitted to our clinic with peripheral arthritis in addition to the history of IBP for 19 years in 2005. MTX, NSAID and prednisolone were started. Because of inefficacy to conventional treatments and development of nephrotic range proteinuria, ETA was added to treatment. The patient responded to ETA and was followed-up for 13 years without symptoms of AS and proteinuria. ETA was switched to IFX due to secondary inefficacy two years ago. On the third month of IFX treatment, she developed demyelinating polyneuropathy. IFX treatment was switched to SEC and she is still being followed-up on SEC without any findings of AS and proteinuria.
Patient 3: 49-year-old woman who was on sulphasalasine for 24 years for treatment of ulcerative colitis (UC) was evaluated for recent onset IBP and peripheral arthritis in 2007. After failure of MTX, she started to receive IFX. She did not respond to first IFX and then ADA and CZP, and she developed nephrotic range proteinuria when she was on anti-TNF. Her serum creatinine increased progressively, and haemodialysis (H/D) was started six months later. Due to ongoing IBP and elevated acute phase response with CZP treatment, SEC was started. Significant improvement was observed in both clinical and laboratory findings with no worsening of UC.

Table 1. Clinical characteristics, laboratory findings and treatment responses of patients

	Patient 1	Patient 2	Patient 3
Age (year)	61	69	49
Sex	Male	Female	Female
Age of AS onset (year)	47	35	25
Age of amyloidosis diagnosis (year)	57	50	46
Amyloidosis duration (months)	42	168	30
Family history	No	AS and amyloidosis in siblings	No
HLA-B 27 status	Positive	Positive	Not available
MEFV status	Negative	Negative	M694V heterozygous
Organ involvement of amyloidosis	GIS and kidney	Kidney, liver, heart, bone marrow	GIS, kidney
Secukinumab duration (months)	15	18	24
CRP (mg/L)			
Before	27	15	23
After	2.4	4.5	2.8
Creatinine (mg/dl)			
Before	0.5	1.6	H/D
After	0.5	1.3	H/D
Proteinuria (g/day)			
Before	4.2	5.5	H/D
After	2.4	0.9	H/D
Albumin (g/dL)			
Before	2.7	2.5	3.1
After	3.1	4.3	4.2
ASDAS			
Before	4.1	1.6	4.6
After	1.8	1.1	1.7

GIS: Gastrointestinal System, ASDAS: Ankylosing Spondylitis Disease Activity Score

Conclusion: AA amyloidosis is a rare complication of SpA, and SEC treatment was found to be safe and effective in our three patients with AS-AA. Although anti-TNF agents have previously used successfully in treatment of AS-AA, SEC may be a new option especially in patients who are resistant or intolerant to anti-TNFs.

AB0767 SEVERE BREAST ULCERATION IN BEHÇET'S DISEASE TREATED WITH CYCLOPHOSPHAMIDE: A CASE REPORT

E. Ball[1], D. Okane[2], C. Mccourt[2], M. Mccarron[1], C. Riddell[1]. [1]*Belfast City Hospital, Rheumatology, Belfast, United Kingdom*; [2]*Belfast City Hospital, Dermatology, Belfast, United Kingdom*

Background: Behcet's disease is a systemic autoimmune vasculitis that typically involves mucocutaneous surfaces, the eyes and the skin with varying manifestations. Skin ulceration often secondary to pathergy is a common feature.
Objectives: To raise awareness of breast ulceration as a clinical manifestation in Behcet's disease.
Methods: We report a case of complex Bechet's disease associated with severe refractory breast ulceration successfully treated with cyclophosphamide.
Results: A 27 year old female patient presented to the rheumatology department with a non-healing lesion on her face secondary to a cat scratch. She reported previous episodes of ulceration usually as a result of minor trauma such as IV cannulation, as well as a two year history of severe oral and genital ulceration. She had also been diagnosed with 'colitis' requiring iliocaecal resection two years prior to presentation. Previous treatments for her bowel included azathioprine, infliximab, adalimumab and vedolizumab. Over the next three years she developed recurrent eye involvement in the form of scleritis with ongoing oral and genital ulceration. Further treatment under our care included ustekinumab, entanercept, benepali, certolizumab and tacrolimus with background prednisolone. She then developed a small area of broken skin on her left breast which continued to extend and ulcerate despite treatment with IV steroids. Tissue biopsy showed deep focal vasculitis with intravascular thrombi. Anticoagulation was commenced and she was treated with tocilizumab IV for 3 months with no clinical improvement. Involvement extended to include 80 percent of the breast surface and the nipple self-amputated. Due to the severity and extent of the ulceration which was extremely painful and distressing, she was given 3 months of IV cyclophosphamide at a dose of 15mg/kg every 2-3 weeks. The ulceration showed rapid clinical improvement (see Figure 1).

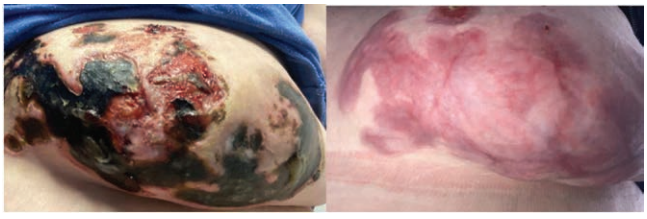

Figure 1. Breast ulceration before and after 3 months of cyclophosphamide treatment

Conclusion: Involvement of the breast in systemic vasculitides (such as GPA or PAN) has been reported, although usually manifesting as a palpable mass with diagnosis on biopsy [1]. Similar presentations in Behcet's disease have been recognised [2], although much less commonly. Our case demonstrates that severe breast ulceration can be a clinical manifestation of this condition and can be refractory to usual therapies.

AB0768 NEUROLOGICAL MANIFESTATIONS IN GRANULOMATOSIS WITH POLYANGIITIS: ABOUT 11 CASES

O. Jomaa[1], O. Berriche[1], S. Arfa[1], A. Fraj[1], M. Belkhiri[1], R. Makhloufi[1], W. Romdhane[1], M. Hermassi[1]. [1]*University Hospital Tahar Sfar Mahdia, Tunisia, Internal Medicine Department, Mahdia, Tunisia*

Background: Granulomatosis with polyangiitis (GPA) is a rare systemic vasculitis, affecting mainly the superior airways, lungs and kidneys. Neurological impairment is frequent, described in 22 to 54% of cases, and rarely inaugurates the disease.

Objectives: The objective of our work was to evaluate its prevalence and its different aspects.
Methods: A retrospective study including 11 files of GPA patients followed over a period of 10 years in The Internal Medecine Department at Tahar Sfar Hospital Mahdia TUNISIA.
Results: Neurological manifestations were reported in 5 patients: a pyramidal syndrome was noted in 3 patients with a normal cerebral MRI, a disabled headache was described in one patient with a normal cerebral MRI. Peripheral neuropathy in 2 cases, and the Electroneuromyogram objectified a mononeuropathy affecting the ulnar nerve, peroneal nerve, and musculocutaneous nerve in one patient and a distal sensitivomotor poly neuropathy in one patient. Cranial nerves damage was noted in two cases, one VII (1 case) and one V (1 case).
Conclusion: Our study results, show the importance of timely diagnosis of these neurological manifestations, as their evolution will depend on the early GPA treatment.

AB0769 EROSIVE SYNOVITIS, DACTYLITIS, HYPERCALCAEMIA, LYMPHADENOPATHY, ELEVATED SERUM ACE & HYPOTHYROIDISM – AN UNUSUAL PRESENTATION OF IGG4-RELATED DISEASE

E. Tranah[1], A. Khan2, N. Bhadauria[1], D. Mukerjee[1]. *[1]North Middlesex University Hospital, Rheumatology, London, United Kingdom*; *[1]North Middlesex University Hospital, Rheumatology, London, United Kingdom*

Background: IgG4-related disease (IgG4-RD) is a fibroinflammatory disorder which can affect almost any tissue in the body. We describe a challenging case of IgG4-RD which reflects the great heterogeneity of this disease.
Objectives: A 49-year-old Mauritanian gentleman was referred to Rheumatology with chronic progressive symmetrical synovitis affecting the upper and lower limbs. He had no features suggestive of a spondyloarthropathy or connective tissue disease. Blood tests revealed a raised C-reactive peptide (CRP) of 194 mg/L and erythrocyte sedimentation rate (ESR) of 46 mm/hr. His rheumatoid factor and anti-cyclic citrullinated peptide antibodies were negative. Anti-nuclear antibody was weakly positive at 1:80 with a speckled pattern, but extractable nuclear antigen antibodies, anti-double-strand DNA-antibodies and anti-neutrophil cytoplasm antibodies were negative. Complement proteins and creatine kinase were normal. Radiographs of the hands and feet demonstrated widespread erosive changes worst at the metacarpophalangeal, metatarsophalangeal and first tarsometatarsal joints, as well as swan-neck deformities of the fifth phalanges in both hands. Chest radiograph and serological virology screen were both unremarkable. He was subsequently diagnosed with a seronegative inflammatory arthritis and treated with intramuscular methylprednisolone. He was awaiting subcutaneous methotrexate.
Methods: He was hospitalised shortly after with worsening polyarthritis and hypercalcaemia (3.34 mmol/L). Examination demonstrated synovitis, new lymphadenopathy and dactylitis. Other investigations revealed a normocytic anaemia (Hb 80 g/dL, MCV 80 fL), neutrophilia (20 x 10^9/L), eosinophilia (4 x 10^9/L), thrombocythaemia (500 x 10^9/L), hypoalbuminaemia (25 g/L), CRP 200 mg/L and ESR 60 mm/hr. All immunoglobulins were raised with IgG 30.5 g/L. IgG4 subset was 3.0 g/L. Parathyroid hormone was low (< 0.7 pmol/L) and vitamin D was 125 nmol/L. Thyroid function, myeloma screen and blood tumour markers were unremarkable. Blood film revealed no blasts. Serum angiotensin-converting enzyme (ACE) was elevated at 171.9 U/L. A CT-chest-abdomen-pelvis revealed an enlarged thyroid with retrosternal extension and widespread lymphadenopathy above the diaphragm.
Results: Biopsies of the thyroid gland and submandibular lymph node demonstrated lymphoplasmacytic fibroinflammatory changes and > 40% of IgG4 cells. Neither biopsy showed evidence of sarcoidosis, tuberculosis or malignancy. He was treated with a weaning regimen of high-dose oral corticosteroids resulting in normalisation of haematological, inflammatory and biochemical parameters. His musculoskeletal pain, swelling and early morning stiffness significantly improved too. Subcutaneous methotrexate was commenced and titrated upwards to 20 mg. Two months later, his arthritis relapsed upon reduction of corticosteroids. Again, there was a marked inflammatory response with raised CRP and ESR. He had also developed a new hypothyroidism (TSH > 100 mU/L, T4 0.5 µg/dL, positive TPO-antibody). Repeat hand and feet radiographs revealed severe erosive progressive disease (Figure 1). He awaits commencement of rituximab.

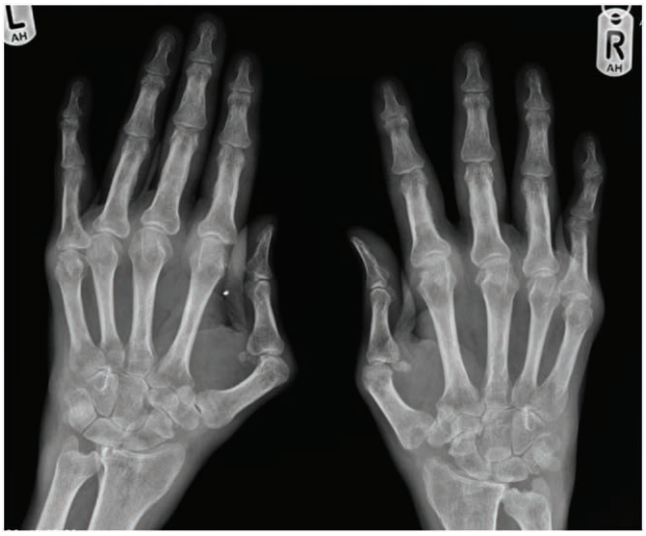

Figure 1. Plain hand radiograph demonstrating extensive erosive arthritis.

Conclusion: This is a unique presentation for a rare disease. There are few case reports of IgG4-RD causing erosive synovitis with rheumatoid-like swan-neck deformities or hypercalcaemia. Furthermore, this is the first case report as far as we know, of the disease associated with dactylitis or a raised serum ACE. Prior to biopsy, our main working diagnoses were sarcoidosis or a lymphoproliferative malignancy. The peculiar presentation necessitated a second opinion via the national IgG4-RD MDT who confirmed the histological diagnosis of IgG4-RD. We hope that this interesting case highlights the importance of histology in diagnosis of complex cases. In addition, the case presentation adds to the multitude of clinical manifestations of IgG4-RD.

AB0770 A RARE CASE OF SYNOVIAL METASTASIS REVEALED BY KNEE PAIN

M. Yasmine[1], S. Miladi[1], A. Fazaa[1], S. Mariem[1], K. Ouenniche[1], L. Souebni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. *[1]Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Intra-articular masses are not frequently encountered in clinical practice. However, the differential diagnosis can be broad. Synovial metastasis is a rare presentation that carries a poor prognosis with a poor survival rate.
Objectives: Here by a case of synovial metastasis of the knee joint in a patient diagnosed with an adenocarcinoma of the lung.
Methods: A 60-year-old man with no remarkable past medical history presented to our department of rheumatology with right knee pain. He described a dull ache and swelling in his right knee with a dragging sensation, waking him up at night on a regular basis. The symptoms lasted from 6 months and were partially improved by analgesics and anti-inflammatory drugs. On examination, temperature was normal. The knee was edematous, erythematous, and warm with a range of motion of <90°. Laboratory investigations showed high acute phase reactants, the erythrocyte sedimentation rate was 75 mm. A plain radiograph of the left knee demonstrated a lytic lesion of the upper tibia. A magnetic resonance imaging of the right knee showed diffuse enlargement of the joint space due to a tissue infiltration within the synovium. These structures demonstrated heterogeneously increased T2 signal and intermediate T1 intensity characteristics. Most of the joint space was replaced by hyper enhancing synovium. At that time, differential considerations included severe inflammatory arthritis and synovial chondromatosis rather than unusual metastasis.
Results: Biopsy concluded to synovial metastasis from primary adenocarcinoma. Further investigations were necessary. Chest tomography showed a tumor process of left lower lobe associated with mediastinal lymphadenopathy. The patient was treated with palliative external radiotherapy to the right knee. The evolution was marked by the appearance of *multiple tracheobronchial fistulas*. The patient died 3 months later due to the progression of the disease.

Conclusion: We report a rare case of synovial metastasis concomitant to a lung adenocarcinoma. It is important to make a rapid diagnosis as early recognition of malignant infiltration into joints ensure appropriate multidisciplinary management decisions.

Background: Rapid and effective remission-inducing therapy is mandatory in uveitis to avoid irreversible structural and functional damage. In some severe cases biological agents might be required **(1-6).**
High-dose intravenous methylprednisolone (IVMP) may achieve prompt control of inflammation in most immune mediated inflammatory diseases (IMID), including non-infectious uveitis (NIU).
Objectives: To evaluate the efficacy and safety of IVMP pulse therapy in NIU of different IMID.
Methods: Multicentre study of 71 patients with severe uveitis who received IVMP. The underlying diseases were: Vogt Koyanagy Harada disease (VKHD) (n=24), Behçet disease (BD) (19), Sarcoidosis (5) and idiopathic NIU (23). The main outcome variable was Best-Corrected Visual Acuity (BCVA) estimated using the Snellen chart. BCVA that was assessed at 0 (basal), 2-5, 7, 15 and 30 days after IVMP.
The results are expressed as mean ±SD in normally distributed variables, or as median [IQR] when are not. Comparison of continuous variables was performed using the Wilcoxon test.
Results: We studied 46♀/ 25♂ patients. The main features are shown in Table 1. IVMP dose ranged from 250 to 1000 mg/day administered for 3-5 consecutive days, the dose was established according to the presence or not of other systemic manifestations apart from uveitis. All of them had active intraocular inflammation at the moment of the study. BCVA values improved considerably after 1 month (Figure 1**).** No major side effects were observed.

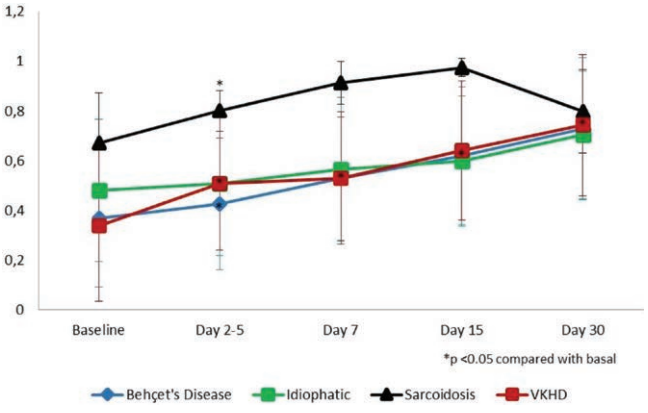

Figure 1. Improvement of best corrected visual acuity (BCVA).

Conclusion: High-dose IVMP pulse therapy is useful and safe for a prompt control of BCVA regardless of the underlying IMID.

AB0772 JAK INHIBITORS IN REFRACTORY ADULT AND CHILDHOOD ONSET STILL'S DISEASE

L. Gillard[1], S. Mitrovic[1,2], H. Reumaux[3], M. Michaud[4], F. Cohen[1,2], J. Pouchot[5], B. Fautrel[1,2,6]. *[1]Pitié-Salpêtrière, AP-HP, Rheumatology Department, Paris, France*; *[2]Sorbonne Université, Rheumatology Department, Paris, France*; *[3]Jeanne de Flandre Hospital, Rheumatology, Lille, France*; *[4]Hospital Joseph Ducuing, Medecine Interne, Toulouse, France*; *[5]European Hospital Georges Pompidou, Medecine Interne, Paris, France*; *[6]Pierre Louis Institute of Epidemiology and Public Health, INSERM UMR 1136, Paris, France*

Background: Excessive and inappropriate production of pro-inflammatory cytokines such as interleukin (IL)-1, IL-6 or IL-18, is a pathogenic cornerstone in adult and childhood onset Still's disease. Beyond therapies targeting IL-1 or IL-6, Janus kinases (JAK) inhibitors have been proposed for adult-onset Still's disease (AOSD) patients refractory to or intolerant of treatment with biologicals. Recently, it has been suggested that JAK inhibitors might be efficient in refractory AOSD patients[1].
Objectives: To assess the efficacy and safety of JAK inhibitors in the treatment of refractory systemic juvenile idiopathic arthritis (sJIA) or AOSD.
Methods: This retrospective study was based on a national survey of the departments of rheumatology, paediatric rheumatology and internal medicine in all French hospitals from an online call of the "Club Rhumatismes et Inflammation" (www.cri-net.com). The data were collected using a standardized questionnaire, and analyzed at different time points (treatment initiation, M1, M3, M6 and end of the follow-up). The response to JAK inhibitors was categorized as: complete remission (resolution of all clinical and biologic signs), partial remission (clinical improvement with persistence of a few symptoms) or failure (lack of clinical or biological improvement).
Results: 6 patients (5 adults and 1 child) were recruited (Table 1). Mean age at treatment start was 39.6 years for the AOSD patient and 6 years for the sJIA patient, and mean disease duration was 5.3 years. The clinical expression was predominantly systemic in 5 five patients and chronic articular in one. Response to corticosteroids, conventional synthetic or biological Disease Modifying Anti-Rheumatic Drugs had been considered inadequate in all patients. Baricitinib was used in 3 patients, ruxolitinib in 2, and tofacitinib in 1. Steroids were concurrently used in all patients, anakinra in one, methotrexate and anakinra in one. At a mean (SD) follow-up of 9.5 months, partial response was observed in 4 (66.7%) cases (patients with ruxolitinib, tofacitinib

Table 1. Characteristics of the AOSD patient

No.	Sex	Age (year)	Main symptoms	Treatments before JAKi onset	JAK inhibitors	Steroids at onset (mg/day)	Concomitant treatment	Response at last F-U	Steroids at the end of F-U (mg/day)	F-U (months)
1	F	6	Fever, polyarthritis, rash	AINS, ANAKI, TOCI, CANAKI, ADA, THALI, INFLIX	RUXOLITINIB 5mgx2/day	3	0	P	1	23
2	M	28	Fever, polyarthritis, rash	ANAKI	BARICITINIB 4mg/day	80	0	**N**	10	1
3	M	32	Fever, polyarthritis, rash	TOCI+MTX, ANAKI+MTX, CANAKI+MTX, ADA, CICLO, IgIV	BARICITINIB 4mg/day	16	MTX 20 mg/week ANAKINRA 100mg/day	P	12	19
4	F	40	Fever, polyarthritis, rash	MTX, IMUREL, CICLO, ETANERCEPT, ANAKI+MTX, TOCI+MTX, IgIV	RUXOLITINIB 15mgx2/day	60	ANAKI 200mg/day	P	30	4
5	F	48	Fever, polyarthritis, rash	TOCI, ANAKI, CICLO, CANAKI, IMUREL	TOFACITINIB 5mgx2/day	50	0	P	7.5	9
6	F	50	Fever, polyarthralgia, rash	ANAKI	BARICITINIB 4mg/day	60	0	**N**	40	1

***F-U**: Follow-up**N**: No response**P**: Partial response*

or baricitinib) and failure in 2 (33.3%) (patients with baricitinib). No patient achieved complete remission. At the last visit, steroids could be decreased but not stopped in all patients. Patients with partial response had an average decrease of 72,8% (90% for tofacitinib, 70% for baricitinib, 58.5% for ruxolitinib between the start and the follow-up end date) and non-responder patients were yet able to reduce steroids by 60,5% (Table 1). Tolerance of JAK inhibitors was excellent, however patient 4 experienced an episode of infectious pulmonary disease.

Conclusion: JAK inhibitors therapy may be helpful for some patients with refractory Still's disease. However, no complete response was observed in this short series of cases. There might be a difference of response between the molecules, although the number of patients is too low to draw conclusions. Additional information is thus needed to evaluate more precisely the risk-benefit ratio of this treatment, and a possible difference in efficacy among the different groups of JAK inhibitors.

AB0773 PATTERN OF MACROPHAGE ACTIVATION SYNDROME IN RHEUMATIC DISEASES

R. Maheshwari[1], R. Sankaralingam2, R. R2, S. Chinnadurai2, B. Chilukuri2, M. Mani2, J. Antony2. *[1]Sri Ramachandra Institute of Higher Education and Research, Clinical Immunology and Rheumatology, Chennai, India*; *[1]Sri Ramachandra Institute of Higher Education and Research, Clinical Immunology and Rheumatology, Chennai, India*

Background: Macrophage activation syndrome (MAS) is a rare, potentially fatal condition complicating autoimmune diseases, as their initial manifestation or during its course.

Objectives: To describe the pattern of MAS and its salient features in patients with rheumatic diseases.

Methods: A retrospective observational study was conducted in 16 patients diagnosed with MAS, due to rheumatic diseases in Department of Rheumatology, SRIHER, Chennai from January 2018-December 2020.

Results: The primary diseases were Systemic Lupus Erythematosus(SLE) in 75%(n=12),Adult Onset Still Disease(AOSD) in18.7%(n=3) and Kikuchi Disease in 6.25%(n=1). 50%(n=8) presented with MAS as the initial manifestation.Others had a known rheumatic disease with an average duration of 6.5 years.Occult MAS was seen in 25%(n=4). The most frequent clinical features were unremitting fever(n=15) and splenomegaly(n=15).All had hyperferritinemia-mean of 2971.10 ng/mL(531-12536).Sub group analysis showed significant hypofibrinogenemia(129.8 vs 200.62 mg/dl) in patients presenting with MAS as their initial manifestation.Transaminitis(666/252.5 vs 243/217.62 U/L), hypertriglyceridemia(316 vs 275.8 mg/dl), high LDH(2490 vs 938.75) were more severe in this group, but not significant.All with SLE had increased disease activity, with 50%(n=8) having SLEDAI 2K of ≥15. Bone marrow aspiration showed haemophagocytes in 81.25%(n=13).H score of >169 was seen in 93.75%(n=15). Infection was the commonest trigger for MAS(n=9)-bacterial(n=5), viral(n=4), fungal(n=1) and mycobacterial(n=2),-followed by parturition(n=1).All patients were managed with pulse steroids followed by intravenous cyclophosphamide(n=8), rituximab(n=2), mycophenolate mofetil(n=2) in SLE, tocilizumab(n=2) and etoposide(n=1) in AOSD. Mortality rate was 18.75%(n=3).

Conclusion: Spectrum of MAS in rheumatic diseases could be occult, associated with infection,high disease activity,or lead to mortality. High index of clinical suspicion is required, due to overlap of features like fever, cytopenias and organomegaly in MAS & SLE.Hyperferritinemia, high LDH, & transaminitis could aid in differentiating & early diagnosis. New criteria for rheumatic diseases,including these parameters are needed, especially in resource-limited settings where sIL-2Rα & NK cell activity tests are not feasible.

AB0774 TREATMENT WITH IL-1 INHIBITORS IN PATIENTS WITH SCHNITZLER'S SYNDROME: A 5-YEAR CLINICAL EXPERIENCE

S. Salugina[1], V. Gorodetskiy[2], E. Fedorov[1], V. Rameev[3], E. Borzova[4,5], N. Lopatina[6]. [1]*V.A.Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*; [2]*V.A.Nasonova Research Institute of Rheumatology, Laboratory of Intensive Therapy Methods, Moscow, Russian Federation*; [3]*Sechenov's First Moscow State Medical University, E. M.Tareev Clinic of Rheumatology, Neurology and Occupational Pathology, Moscow, Russian Federation*; [4]*Sechenov's First Moscow State Medical University, Department of Dermatology and Venereology, Moscow, Russian Federation*; [5]*Research and Clinical Institute of Pediatrics n.a.Yuri Veltischev, Department of Clinical Genetics, Moscow, Russian Federation*; [6]*V.A.Nasonova Research Institute of Rheumatology, 5th Rheumatology Department with Hematology Beds, Moscow, Russian Federation*

Background: Schnitzler's syndrome (SchS) is a rare non-monogenic auto-inflammatory disease (AID) which manifests in adults and is characterized by recurrent urticarial lesions, monoclonal gammopathy, and other manifestations of a systemic inflammatory response (fever, muscle / joint / bone pains, leukocytosis, increased ESR, CRP). Off-label treatment with IL-1 inhibitors (anakinra, canakinumab) was shown to be highly effective and well tolerated in pts with SchS based on a few multicenter studies and practical experience.
Objectives: To analyze a real-life experience of the treatment with IL-1 inhibitors in pts with SchS in the rheumatology tertiary care settings.
Methods: The study included 7 pts (3 women, 4 men) with treated with IL-1 inhibitors (anakinra, canakinumab). A median age at the diagnosis was 44 years old (25 – 68). Age at the disease onset ranged from 22 to 66. All pts met the Strasbourg diagnostic criteria. 7 pts received canakinumab, while 3 pts were first treated with anakinra followed by a switch to canakinumab. Anakinra was administered subcutaneously 100 mg per day. Canakinumab was given subcutaneously at a dosage of 150 mg every 8 weeks. The treatment duration with anakinra ranged from 1 week to 2.5 months with further switching to canakinumab. The duration of canakinumab treatment by the time of analysis ranged from 2 months to 5.5 years.
Results: All pts at the inclusion into the study suffered from urticarial rash, pains in bones and joints, fatigue, fever (6), increased acute phase marker levels (ESR, CRP), monoclonal gammopathy, mainly IgMk (4.7 – 9 g/l). An average period between the disease onset and the treatment initiation was 3 years (2 to 4). In all pts lymphoproliferative diseases and monogenic AIDs (CAPS, TRAPS) were excluded. Before the treatment with IL-1 inhibitors, all pts had received NSAIDs and/or GCs, methotrexate - 2, plaquenil-2. During the treatment with IL-1 inhibitors, 6 out of 7 pts had a complete response as demonstrated by a symptom resolution within several days and a rapid decrease in ESR and CRP levels. In 3 pts, who responded anakinra, the treatment was switched to canakinumab. In one patient with a partial response to anakinra, there was a loss of the effect upon switching to canakinumab, In one patient, the interval between canakinumab injections was increased up to 5 months without a symptom relapse. This patient fathered a healthy child whilst on treatment with canakinumab. The therapy was well tolerated in all pts, no SAE were noted.

Table 1. Clinical and demographic characteristics of patients with SchS

Patients	1	2	3	4	5	6	7
Sex	M	F	M	F	F	M	M
Age (y)	44	32	56	68	25	51	49
Age of disease onset (y)	40	29	53	66	22	39	47
Urticarial rash	+	+	+	+	+	+	+
Fever	+	-	+	+	+	+	+
Fatigue	+	+	+	+	+	+	+
Bone pain	+	+	+	+	+	+	+
Arthralgia/arthritis	+	+	+	+	+	+	+
ESR(normal <15mm/h)	31	140	100	49	81	53	56
CRP (normal <5mg/n)	107	44	192	96	369	76	41,82
IgM kappa (g/l)	7,1-5,2	4,7-7,8	7,6	-	-	5,2	9
IgM lambda(g/l)	-	-	1,36	-	-	-	-
IgG kappa (g/l)	-	-	-	5,1	-	-	-
IgG lambda (g/l)	-	-	-	-	10,7	-	-

Conclusion: SchS is a rare disease that occurs in the practice of a rheumatologist. Short and long acting IL-1 inhibitors are highly efficient and safe treatment options for pts with SchS. A switching from short to long acting IL-1 inhibitors can be effective in SchS pts.

AB0775 MANY RARE AND SERIOUS LOCALIZATIONS IN ONE CASE WITH HEREDITARY EXOSTOSES

R. Sarraj[1], M. Ghali[1], R. Ben Chehida[1], G. Mouna[1], I. Bejia[1], J. Mahbouba[1], S. Zrour[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, Rheumatology, Monastir,Tunisia*

Background: Multiple hereditary exostoses (MHE) is an inherited disorder of bone growth. People who have MHE grow exostoses or boney bumps on their bones that vary in size, location and number. Some localizations are rare but potentially serious such as ribs, spine or pelvis due to proximity to important structures.
Objectives: The aim of this case report was to illustrate the clinical and radiographic features of some rare localizations of MHE.
Methods: We are reporting a rare case of a thirty one-year-old male with severe localizations of MHE.
Results: A thirty one-year-old male affected by hereditary multiple exostoses., not followed up, came to our consultation complaining about chest pain. On examination, he walks with a limp because of the unequalness of his limbs.The osteoarticular examination revealed numerous palpable osseous masses at the distal and proximal end of the 2 arms, 2 forearms, 2 thighs and 2 legs and at the right iliac wing. Neurological examination revealed vivid deep tendon reflexes, bilateral positive Hoffmann'sign and Babinski reflex associated with right hemiparesis. The pulmonary exam was normal. Medullary MRI showed medullary compression with spinal cord atrophy and sign of myelopathy of c1 c2 segment. The ct –scan revealed multiple exostosis, the two largest lesions were located in the second rib measuring 45mm * 35mm axially and 52mm in height compromising blood vessels, and in the right iliac bone with a retroperitoneal growing mass measuring 126 * 94 mm axially and 100 mm in height leading to a serious entrapment of the axial skeleton and the abdominal organs. It also confirmed thickening of the cartilage cap of the right iliac bone suggestive of malignant chondrosarcomatous transformation.
Conclusion: Exostoses are the most common benign bone tumors. Its complications are rare but can cause a functional disability or even a vital risk.

AB0776 MULTIPLE AUTOIMMUNE SYNDROME

A. Fraj[1], S. Arfa[1], O. Jomaa[1], F. Boubaker[1], I. Bannour[2], O. Berriche[1], H. Sfar[1]. *[1]University Hospital Tahar Sfar Mahdia,Tunisia, Internal Medicine and Endocrinology Department, Mahdia,Tunisia*; *[2]University Hospital Fattouma Bourguiba Monastir,TUNISIA, 2-Immunology Department, Monastir,Tunisia*

Background: Multiple autoimmune syndrome (MAS) is a rare entity, defined by the association of three autoimmune diseases in the same patient. MAS can be classified into three groups.
Objectives: The objective of this work was to describe the autoimmune diseases profile in MAS in An Internal Medicine Department.
Methods: We report a retrospective analysis including 14 cases of MAS seen in The Internal Medicine Department at Taher Sfar Hospital, Mahdia, TUNISIA over a period of 10 years.
Results: We followed 14 patients with MAS. They were 14 women. The mean age of patients was 52 years. SAM was type 3 in 12 patients (85%), type 2 in one patient (7.1%) and one patient satisfied both type 2 and type 3 MAS criteria (7.1%). No cases of MAS type 1 had been reported. We found 13 patients with 3 associated autoimmune diseases and one patient with 4 associated autoimmune diseases. The autoimmune diseases were: Sjögren's syndrome in 14 patients (100%), Hashimoto's thyroiditis in 11 cases (78%), systemic lupus erythematosus in 7 cases (50%), Addison's disease in 4 cases (28, 5%), scleroderma, thymoma, vitiligo, Biermer and primary biliary cholangitis each in one case (7.1%).
Conclusion: Multiple autoimmune syndrome remains a rare but probably under-diagnosed entity. Thus, in patients with autoimmune disease, initial investigation and follow-up of clinical signs and biological stigmas of other autoimmune diseases should be cautious.

AB0777 A RARE CASE OF A SOLITARY PLASMOCYTOMA OF A LUMBAR VERTEBRA

D. Khalifa[1], H. Hachfi[1], N. Ben Chekaya[1], M. Brahem[1], M. Younes[1]. *[1]Taher Sfar Hospital, Rheumatology, Mahdia,Tunisia*

Background: Solitary plasmocytoma is a rare tumour that represents around 2 to 5% of all plasma cell dyscrasias. It normally affects soft tissu but rarely the bone. Diagnosis is based on histology, the absence of bone marrow involvement.
Objectives: To drag attention to think of solitary plasmocytoma of bone when dealing with a vertebral fracture in the absence of the CRAB criteria of multiple myeloma.
Methods: We report a rare case of a vertebral fracture of the 4th lumbar vertebra (L4) revealing a solitary plasmocytoma of bone.
Results: A 67-year-old female patient presented to our rheumatology department with back and left radicular pain of brutal onset, 15 days prior to her visit. Pain was severe and awakened her at nights. On examination, mobilities of the spine were unchanged but on palpation she had exquisite pain of L4. Laboratory tests showed a normal sedimentation rate of 15mm the first hour, a negative c-reactive protein, normal calcemia and kidney tests. X-rays of lumbar spine showed a vertebral fracture with a destruction over 50% of the vertebral size and cortical rupture. MRI of the spine showed the absence of other lytic lesions or other fractures or spinal cord compression and showed the total destruction oft he anterior vertebral body of L4 (Figure 1). Protein electrophoresis was in normal range and 24h urinary proteinuria was negative. Other tests rules out gynecological, thyroid, and renal neoplasms. Sternal puncture showed a rich bone marrow of normal cells without further infiltration. Bone biopsy of the detected lesion showed tumour cells made of mature plasmocytes confirming the diagnosis of solitary plasmocytoma of the bone. The patient was treated with radiation therapy. The evolution after 24 months showed a stabalised lesion and the absence of progression to multiple myeloma.

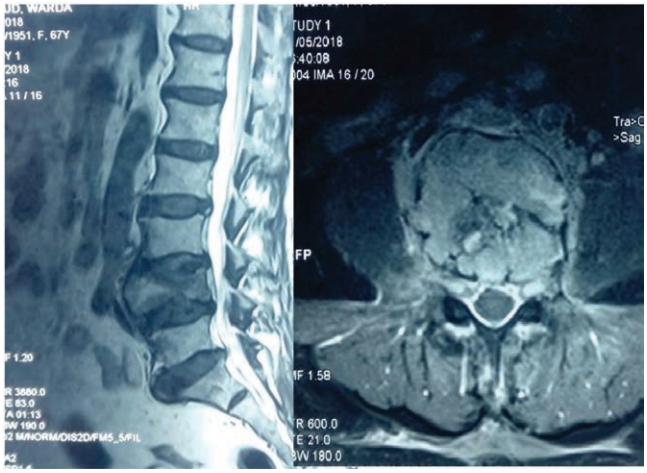

Figure 1. T2 weighted MRI showing the vertebral fracture of L4

Conclusion: It is important to keep in mind the diagnosis of solitary plasmocytoma of bone when facing a solitary lesion or vertebral fracture despite relatively non agressive radiological signs. It is also important to note the possible evolution to multiple myeloma and keep a hawk-eyed guard.

AB0778 VENOUS THROMBOSIS IN UNUSUAL SITES

A. Fraj[1], O. Berriche[1], S. Arfa[1], O. Jomaa[1], W. Romdhane[1], H. Sfar[1]. *[1]University Hospital Tahar Sfar Mahdia,Tunisia, Internal Medicine and Endocrinology Department, Mahdia,Tunisia*

Background: Unusual site venous thrombosis (USVT), which includes venous thromboses of the upper limbs, digestive tract, cellar and brain, are rarely observed compared to those of the lower limbs and require both an etiological approach and a rigorous management.
Objectives: Our objective is to identify the epidemiological, clinical, therapeutic and evolutionary characteristics of USVT.
Methods: Retrospective study including 33 patients files with USVT followed in The Internal Medicine Departments at Tahar Sfar University Hospital Mahdia TUNISIA over a period of 10 years.
Results: They were 21 females (63.6 %) and 12 males (36.4%) with an average age of 45.2 ± 18 years. Cerebral venous thrombosis was the most frequent localization identified in 10 patients (30.3%), followed by gastrointestinal thrombosis in 9 cases (27.3%), vena cava thrombosis in 9 cases (27.3%) and upper limb thrombosis in 5 cases (15.2%). The risk factors were respectively: age (42.4%), obesity (42.4%), smoking (30%), prolonged downtime (24.2%), surgical interventions (6.1%) and pregnancy (3%). An etiology was identified in 21 patients (66.6%), dominated by constitutional thrombophilia (27.3%), followed by BVL (15.1%) and Behçet's disease (16.4%). Rare causes were neoplasia in one case (3%), scleroderma in one case (3%) and inflammatory bowel disease in one case (3%). The etiological investigation was negative in 36.3% of cases. Treatment was based on heparin therapy followed by vitamin K therapy. Progression was favourable without accident or recurrence in 25 patients (75.5%). Complications were dominated by recurrence in 12.1% of cases, post-thrombotic disease in 6% of cases and pulmonary embolism in 3% of cases. We reported one death related to a hemorrhagic event.
Conclusion: USVT is a multifactorial pathology that involves both acquired and constitutional risk factors. Heparin therapy with an early relay by antivitamin K remains the treatment of choice today. The duration of treatment depend on the etiology, the recurrence of venous thrombosis and the risk of hemorrhagic complications.

AB0779 CAN INFLAMMATION COEXIST IN PATIENTS WITH PROGRESSIVE PSEUDORHEUMATOID DYSPLASIA?

S. Mahadevan[1], B. Navaneethan[1], N. Gopalakrishnapillai Syamala[1], M. Mamadapur[1], R. S[1], T. Tn[1]. *[1]Madras Medical College, Rheumatology, Chennai, India*

Background: Progressive pseudorheumatoid dysplasia(PPRD) is considered as a degenerative genetic bone disorder. It is caused by loss of function mutation in WNT-1 inducible signaling pathway protein-3(WISP-3)[1]. WISP-3 gene function is required for the normal function of cartilage and skeletal development. The patients are normal at birth and start developing symptoms around 3-6 years of age[2]. The disease is characterised by stiffness, pain, deformity due to enlargement of the ends of short and long bones. Often, such patients are misdiagnosed as Juvenile idiopathic arthritis(JIA). In general, PPRD being considered as non-inflammatory disease, immunosuppressants or disease modifying anti rheumatic drugs(DMARDS) like methotrexate treatment are not used for treatment.
Objectives: We report a patient with characteristic findings of PPRD but with coexisting clinical and imaging evidence of inflammation.
Methods: 16 year old male boy born of third degree consanguineous asymptomatic parents presented with progressive swelling, deformity of bilateral small and large joints of upper and lower limbs. He also had pain in both hip and knee for past two years. Pain is associated with difficulty in walking and squatting. On examination he had bony enlargement around bilateral elbow, wrist, proximal and distal interphalangeal joints(Figure 1A). He also had restriction of bilateral hip movements and swelling of bilateral knee with effusion. He had exaggerated lumbar lordosis and flexion deformity of bilateral hip, knee. His blood counts, ESR, CRP were normal. Analysis of Knee joint synovial fluid showed cell count of 200/mm3 with no crystals and sterile culture. USG knee showed evidence of synovial thickening with increased power Doppler signals. Skeletal survey showed typical findings of PPRD with enlargement of epiphysis and osteoarthritis

changes(Figure 1B). MRI hip showed minimal effusion, synovial thickening, edema with STIR hyperintensity and enlargement of bilateral femoral epiphysis. MRI knee showed minimal effusion, marrow edema in patella(Figure 1C, arrow head), femoral condyle, diffuse synovial thickening with contrast enhancement(-Figure 1D, arrow) and deformed patellar contour. Immunological tests showed negative RF, ACPA and positive ANA(Hep2) speckled 4+. Immunoblot for ENA was negative. His ophthalmological evaluation showed no evidence of uveitis.

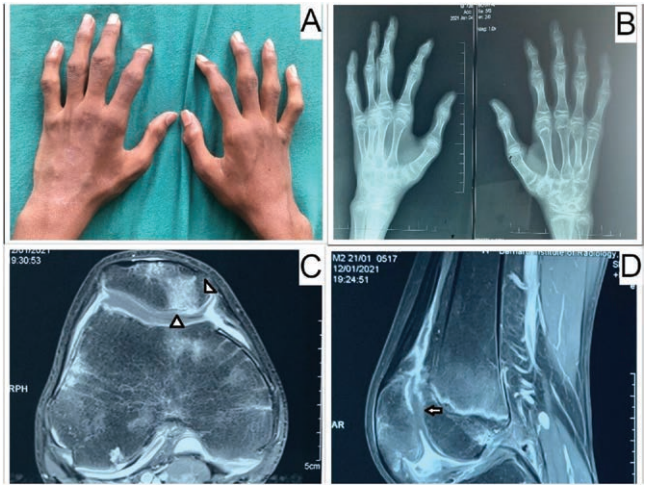

Figure 1. Clinical picture showing typical hand deformity and swelling at bone ends(A), hand radiograph showing epiphyseal enlargement(B), MRI knee T2 STIR showing bone marrow edema(arrow head) in patella(C) and synovial thickening(arrow) with contrast enhancement in fat saturated T1 MRI with contrast.

Results: Patient tested positive for homozygous mutation in WISP-3 gene. He was treated with ibuprofen and supportive measures. Orthopedic consultation obtained and planned for hip, knee replacement during follow up. Follow up imaging and acute phase response was advised after three months.
Conclusion: Although PPRD was classically described as a degenerative disease, the findings presented in our case show coexisting inflammation. Bone marrow edema in weight bearing areas, synovial effusion may be explained as part of cartilage degeneration like in osteoarthritis but synovial hypertrophy with contrast enhancement, power Doppler signals in ultrasound, ANA positivity may be signs of coexisting inflammatory or autoimmune phenomenon.

AB0780 GENDER FEATURES OF VERIFICATION OF DIAGNOSIS UNDIFFERENTIATED ARTHRITIS

O. Malyshenko[1], M. Koroleva[1], M. Letaeva[1], J. Averkieva[1], T. Raskina[1].
[1]*Kemerovo State Medical University, Department of Propedeutics of Internal Medicine, Kemerovo, Russian Federation*

Background: Undifferentiated arthritis (UDA) is an inflammatory arthritis that does not meet the criteria for any rheumatologic disease. Early verification of UDA is currently one of the main goals of modern rheumatology, since a diagnosis established at an early date allows determining a therapeutic strategy. The high social significance of arthritis lies in the predominant lesion of people of working age, the steady progression of the disease, early disability and a reduction in life expectancy.
Objectives: To study the gender characteristics of verification of the diagnosis of undifferentiated arthritis.
Methods: A retrospective analysis of 74 case histories of patients diagnosed with UDA was carried out. The study group consisted of 26 men and 48 women, mean age 50.6 ± 4.3 years. All patients underwent a comprehensive laboratory and instrumental examination according to the standard of an articular syndrome of unclear genesis.
Results: According to the data obtained, the duration of the articular syndrome averaged 2.53 ± 1.2 years. In 29 patients (21.6% of women and 17.6% of men), on average, after 1.72 ± 0.9 years, the diagnosis of NDA was clarified. Taking into account modern diagnostic criteria, the following diseases were verified: rheumatoid arthritis in 13.5% (12.2% in women and 1.3% in men), ankylosing spondylitis in 10.8% (2.7% in women and 8.1% in men). Osteoarthritis, psoriatic arthritis and APS were diagnosed in 5.4%, 1.4% and 1.4% of women, and gouty arthritis, bone tuberculosis and HIV in 4.1%, 1.4% and 1.4% of men respectively. In 60.8% (43.2% in women and 17.6% in men), the etiology of arthritis was not verified.
Conclusion: In a third of patients with UDA, diagnosis verification takes about 2 years on average. In more than half of patients, the diagnosis remains the same. According to the data obtained, rheumatoid arthritis was more often verified in women, while ankylosing spondylitis in men, which is consistent with statistical data.

AB0781 ONE, NONE, MANY: REFLECTIONS ON A RARE CASE

G. Sandri[1], L. Belletti[1], M. Cavedoni[2], C. Galluzzo[1], S. Bruni[3], M. T. Mascia[1].
[1]*Rheumatology Institute, Department of Clinic and Medical Specialties, Modena, Italy*; [2]*General Practitioner, Department of General Medicine, Modena, Italy*; [3]*Genzyme, Orchard Therapeutics, Modena, Italy*

Background: Rare diseases are all those diseases that present, in the European Union, a prevalence of less than 5 cases per 10,000 people. The number of rare diseases is estimated at roughly 7,000 but there are also longstanding medical conditions that elude diagnosis and could be identified as rare.
Objectives: Demonstrate the importance of international research in orphan diseases.
Methods: We report a case of 44 y/o female patient who arrived to our observation in 2006. Short stature, early puberty, ligament laxity, BMI <17. From the age of 29: recurrent diarrhea, pain in the spine, osteolytic lesions in spine and endosteal thickening in long bones, muscle contractures, strength deficit, muscular hypotrophy and hypotonia, cardiac conduction and blood pressure disorders, demyelinating MS-lesions, hyperprolactinaemia, slow wound healing, sicca syndrome, osteoporosis. No familiarity for bone lesions. In 2007 her first son (21y/o) began to complain pain at limbs. The young man presented the same bone lesions as the mother and shortening of the PR, prolactinoma, recurrent diarrhea, short stature, early puberty. Over the years numerous pathologies have been first hypothesized and then excluded: multiple sclerosis, bone metastases, Paget's disease, celiac disease, McCune Albright, Camurati-Engelmann syndrome, mitochondrial disease. No conclusive diagnosis despite the thousands of kilometers traveled, the numerous experts heard and the countless examinations carried out by the patients.
Results: In September 2009, the patients had been investigated at the NIH (Washington D.C.) during the "Undiagnosed Diseases Program" but without results until 2013 when the patients were informed of the detection of an ATP6V1H gene mutation never described before in humans. The gene encodes a vacuolar ATPase, a multimeric enzyme that plays several roles: is involved in endocytosis, intracellular trafficking, and protein degradation and energy production, appears to be a risk factor in the development of dyslipidemias and type II diabetes, has a bone resorption function. Also in the patient's father were founded the same mutation and asymptomatic bone lesions. In 2016 and 2017 studies have reported mouse models of osteoporosis that were generated by knocking out the ATP6V1H gene.
Conclusion: from this case it is possible to understand the difficulty of diagnosing a rare disease, the need of an international collaboration in research. From these studies it can be deduced moreover that the ATP6V1H gene could be an important target for therapeutic interventions aimed at preventing bone resorption and treating osteoporosis; evidence to support exploration of MMP9 and MMP13 as therapeutic targets for patients with ATP6V1H deficiency.This mutation seems to affect only one family, but it is possible that the penetrance of the disease-causing mutation is variable. In literature is reported an enhanced expression of MMP-9 in a variety of autoimmune diseases and neurological pathologies (2) therefore the mutation can be at the basis of other much more common pathologies.

AB0782 MONOARTHRITIS: PROBABLE OUTCOMES

M. Osipyan[1], M. Efraimidou[1], V. Vardanyan[2], K. Ginosyan[1]. [1]*1st University Hospital Complex after M. Heratsi, Rheumatology, Yerevan, Armenia*; [2]*Mikaelyan Institute of Surgery, Rheumatology, Yerevan, Armenia*

Background: Numerous joint disorders initially produce swelling in a single joint and new onset monoartritis will probably further lead to the involvement of other joint groups and development of extraarticular manifestations. It is essential to take a proper diagnostic approach for organizing appropriate treatment and lowering possibility of disease progression.
Objectives: The aim of this study was to investigate joint distribution, determine rheumatological diseases of patients with acute monoarthritis and reveal the development of further systemic manifestations.
Methods: 100 patients (age 18-75 years) with clinically apparent monoarthritis of less than 6 weeks duration were included in the study. Criteria of exclusion were infection, trauma and crystal induced arthritis. Joint distribution, presence of systemic manifestations and development of chronic inflammatory rheumatic disease were evaluated. Presence of arthritis was proved with help of ultrasound examination. Complete blood count, ESR, CRP, RF, anti-CCP; HLAB27; MEFV mutations and X-ray of swollen joint were performed for all patients. Temperature was also measured.
Results: Mean age of patients with acute monoarthritis was 46±13 years. Female predominance was noted (61%). 71% of patients had elevated ESR, 69%- CRP. In 24% of cases homozygous or heterozygous mutations of MEFV gene were revealed. 21% of patients had positive RF and 18% - anti-CCP. 11% patients carried HLA-B27 antigen. 28% of examined patients had subfebril fever. Hepatosplenomegaly was determined in 16%, uveitis in 5%, psoriatic plaque in 4%, interstitial pneumonia in 2% of cases
At the baseline 82 patients were diagnosed with rheumatologically disease. Baseline data is shown in the Table 1 bellow.

Table 1. Baseline data

Diagnosis	Number of patients
FMF	23
Osteoarthritis (reactive synovitis)	16
Rheumatoid arthritis	15
Reactive arthritis	10
Ankylosing spondylitis	6
Psoriatic arthritis	4
SLE	3
Schonleyn-Henoch purpura	2
Sarcoidosis	2
Behcet diseases	1

Conclusion: In this study monoarhtritis in majority of cases underlies FMF. Though FMF is not considered as a frequent cause of acute monoarthritis, more attention should be paid on this pathology in focus of monoarthritis, especially in specific for FMF region. Further follow up of acute monoarthritis progression is needed.

AB0783 "RICE AND SARDINES": AN UNUSUAL CAUSE OF RASH AND JOINT SWELLING

V. Thanopoulou[1], S. A. O. Jafery[2], B. Ramabhadran[1]. [1]*Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom*; [2]*Leicester General Hospital, Endocrinology, Leicester, United Kingdom*

Background: Systemic vasculitis presents with numerous widespread manifestations. Various diseases can masquerade as systemic vasculitis (1). It is crucial to carefully evaluate patients with unusual presentations to look for vasculitis mimics. Scurvy, a disease caused by severe and prolonged vitamin C deficiency, still occurs in industrialized countries (2). Ascorbic acid is involved in various biologic processes including the synthesis of mature collagen. Lack of ascorbic acid especially affects blood vessel integrity leading to haemorrhagic manifestations characteristic of scurvy (3).
Objectives: Case report highlighting that scurvy is still prevalent in the west and may present with features resembling vasculitis.
Methods: Information was obtained from the patient's medical records.
Results: A 61 year old Caucasian female presented with a 3 weeks' history of bilateral lower limb pain, rash and swelling. She was referred to acute medicine to exclude deep vein thrombosis suspected by her general practitioner. She was previously fit and well apart from diagnosis of coeliac disease and various food intolerances. She believed her symptoms started following a recent course of Metronidazole for suspected dental infection which manifested with gum bleeding.She was found to have purpuric spots and ecchymosis bilaterally in her legs, from the toes to the groin. The left knee was swollen with evidence of hematoma around the joint.She denied fever, weight loss, night sweats, arthralgia, myalgia, rash, Raynaud's, alopecia, mouth or genital ulcers, ear-nose-throat manifestations. She denied chest pain, difficulty in breathing or symptoms of peripheral neuropathy. There was no history of asthma, inflammatory bowel disease or uveitis. She reported occasional alcohol intake, she did not smoke cigarettes nor use recreational drugs. Examination otherwise revealed no other major abnormalities with normal vital signs.Initial differential diagnosis included platelet or coagulation disorders or vasculitis. Initial blood tests revealed normal full blood count, coagulation screen, ESR, CRP, liver and renal biochemistry.Urine dip was positive for blood but not for protein. Knee aspiration was attempted but no fluid could be aspirated. Knee x-ray was unremarkable. ANA, ANCA and anti-GBM antibody tests were negative.On further review and enquiry into her symptoms and lifestyle she admitted having a diet exclusively of "rice and sardines" for nearly 2 years. This information along with clinical features led to the suspicion of Vitamin C deficiency that was subsequently confirmed. Ascorbic acid levels were <2.8micromol/l (normal range 26.1-84.6.micromol/l).Replenishment of vitamin C was followed by a rapid and sustained recovery. Detailed investigation for additional macro and micronutrient deficiencies were undertaken with referral to a dietician and to gastroenterology.
Conclusion: This case illustrates scurvy can present in previously "well" individuals and should be considered as a possible differential diagnosis of vasculitic lesions in the appropriate clinical context. Detailed dietary history is invaluable.

AB0784 SPINAL HYDATID CYST DISEASE: WHAT FEATURES IN SURGICAL DEPARTMENTS?

A. Dghaies[1], R. Dhahri[1], M. Slouma[1], L. Metoui[1], I. Gharsallah[1], R. Ayari[2], Y. Mallat[2], K. Amri[2], M. Aloui[3], Y. Arous[3]. [1]*The Military Hospital of Tunis, Rheumatology, Tunis, Tunisia*; [2]*The Military Hospital of Tunis, Traumatology-Orthopedic Department, Tunis, Tunisia*; [3]*The Military Hospital of Tunis, Radiology, Tunis, Tunisia*

Background: Cystic echinococcosis (CE) is a zoonosis caused by the larve of Echinococcus granulosus. Cysts can develop in any part of the body, although the liver and lungs are most frequently involved. Bone echinococcosis is one of the rarest forms of the disease, accounting for 0.5 to 4.0% of all echinococcosis. Spinal cysts are disabling causing destruction similar to malignant bone lesions, with high risk of neurological deficit.
Objectives: To increase awareness of this disease, the clinical data of eight patients with spinal CE were analyzed retrospectively.
Methods: Clinical data of eight patients with spinal CE were analyzed retrospectively, collected over ten years on the department of orthopedics in the Military hospital of Tunis.
Results: The mean age of the patients was 49 years. The median disease duration was five years. All patients presented with back pain and paresthesia without neurological deficit. Radicular pain was reported by two patients. The diagnosis of spinal CE was made after the diagnosis of visceral CE in two patients. Former X rays showed nonspecific abnormalities and patients were treated initially by symptomatic treatments based on paracetamol and non-steroidal antiinflammatory drugs without any improvement. All of the patients needed Magnetic resonance imaging (MRI) to explore chronic back pain with paresthesia, revealing spinal CE. The typical MRI appearance is a multilocular cyst. Six patients had cervical and thoracic spinal cysts, one patient had a lumbar spinal cyst and one patient had cervical, thoracic and lumbar cysts. Further examinations with Computed tomography scans (CTscans) were needed before surgery for better examination bone destruction. All patients underwent surgery.

Cysts were removed with spinal fixation. All the patients showed relapses and needed at least three surgical interventions.
Conclusion: Bone echinococcosis is rare and often misdiagnosed. Radiographic and CT images lack disease-specific characteristics whereas MRI images offers a greater chance of direct diagnosis. Treatment of spinal hydatid disease is entirely surgical with high risk of relapses.

AB0785 TREATING IDIOPATHIC RECURRENT PERICARDITIS WITH INTERLEUKIN-1 INHIBITORS - A SINGLE CENTER EXPERIENCE

P. Andel[1,2,3], S. Brådland[3], G. Haugeberg[3,4]. [1]*Østfold Hospital Trust, Department of Cardiology, Sarpsborg, Norway*; [2]*University of Oslo, Department of Clinical Medicine, Oslo, Norway*; [3]*Hospital of Southern Norway, Department of Rheumatology, Kristiansand, Norway*; [4]*Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Trondheim, Norway*

Background: Pericarditis is a common disease with significant morbidity (1). Idiopathic pericarditis, where an underlying cause cannot be identified, makes up for 80% of cases in the Western World (1). Up to 30% of these patients experience recurrence despite optimal treatment (2). Idiopathic recurrent pericarditis (IRP) is thought to represent an auto-inflammatory process rather than a reinfection (3). 2015 European Society of Cardiology (ESC) guidelines have outlined treatment of acute episodes and first recurrence with nonsteroidal anti-inflammatory drugs (NSAID), acetyl salicylic acid (ASS) and Colchicine as first line and Glucocorticoids (GC) as second line treatment (3). However GC treatment increases the risk of relapse, dependence and toxicity (2). Interleukin-1 (IL-1) inhibitors have been proposed as possible treatments in IRP (3, 4).
Objectives: The aim of this case study is to outline our first experiences treating IRP with the IL-1 inhibitor anakinra in our Rheumatologic clinic.
Methods: All patients referred to our department in 2018/2019 with pericarditis were physically seen in our outpatient clinic. All patients were screened for malignancy, infection or rheumatologic disease as possible cause by clinical measures. Following ESC guideline, patients who suffered either the third recurrence under optimal treatment or significant side effects or dependency from GC were considered for anakinra treatment. Daily injection of anakinra (100mg) were given continuously over at least three months with gradual tapering over at least three months afterwards. Physical emergency department contacts, days hospitalized, colchicine- and GC use, the year prior to Anakinra treatment was recorded retrospectively. During follow up the same data was prospectively recorded.
Results: Over the course of two years 20 patients were referred to our clinic. All fulfilled ESC diagnostic criteria for pericarditis at index episode. In none of the patients could a rheumatologic, infectious or malignant cause be identified. 16 patients could be treated according to 2015 ESC guidelines with first or second line agents. Four patients were aligned to anakinra-treatment. Prior to referral, duration of symptoms was 5 - 120 months (mean 61 months). Further relevant patient- characteristics are outlined in Table 1.
After initiation of anakinra patients were afterwards regularly followed up in scheduled visits every 3 months.

Table 1. Characteristics of the four patients aligned to anakinra prior to anakinra-initiation.

Patient	Number of recurrences	Number emergency hospital contacts related to IRP the year prior to nakinra	Days hospitalized related to IRP the year prior to anakinra	GC dose prior to anakinra	other
I	2	2	3	7.5 mg	steroidglaucoma
II	7	2	4	10 mg	
III	4	7	22	20 mg	
IV	7	3	12	20 mg	

Follow-up after start of anakinra was 6-15 months (mean 11.5 months). No patient was admitted to hospital or emergency department in that period. All four patients could taper and stop GC without recurrence. One patient experienced a mild relapse after discontinuing anakinra and was restarted on a low dose with complete remission. No patient had elevated CRP values at the end of follow-up and no patient experienced tamponade or clinical signs of constriction. No significant side effects were noted, no patient had to stop anakinra-treatment during follow up.
Conclusion: Implementation of anakinra treatment in cases of complicated IRP was both secure and successful in our rheumatologic outpatient department. In our small sample we could confirm findings from bigger trials regarding effect- and side effect rates of anakinra treating IRP.

AB0786 HUGHES–STOVIN SYNDROME: A PECULIAR AUTOIMMUNE ORIGIN OF PULMONARY ANEURYSMS

P. Triggianese[1], A. D'antonio[1], B. Kroegler[1], A. Ascoli Marchetti[2], L. Belvivere[2], D. Morosetti[3], F. Sabuzi[3], A. Ippoliti[2], R. Argiro[3], R. Perricone[1]. [1]*Rheumatology, Allergology and Clinical Immunology, Department of "Medicina dei Sistemi", University of Rome Tor Vergata, Rome, Italy*; [2]*Vascular Surgery Unit, Biomedicine and Prevention Department, University of Rome Tor Vergata, Rome, Italy*; [3]*Diagnostic Imaging and Interventional Radiology, University Hospital of Rome Tor Vergata, Rome, Italy*

Background: Hughes-Stovin Syndrome (HSS) is a rare potentially fatal vasculitis supposedly belonging to the spectrum of Behçet disease without ocular involvement. HSS tends to play by a temporal pattern, starting with thrombosis and followed by formation of pulmonary aneurysms. Since its mortality can reach 25% of cases, the early recognition and the appropriate therapy represent the major challenges.
Objectives: In this report, we aimed at describing a rare case of HSS successfully treated in accordance with a prompt combined management with endovascular approach and immunosuppressive treatments.
Methods: We described a Caucasian 33-year-old man presented to the Emergency Room of our Hospital with hemoptysis associated with dyspnea and chest pain, without fever and hypotension, with a 2-year history of painful genital and oral ulcers. Blood test revealed anemia, elevated white cell count with increased C-reactive protein (77 mg/L) and D-dimer (2740 ng/mL). Doppler ultrasonography of legs showed thrombosis of the left femoral vein, while CT-angiography reported multiple aneurysms of the pulmonary arteries. An early and extensive work-up for infections and autoimmunity did not document relevant abnormalities. An appropriate genetic assessment revealed the HLA-B51 positivity. The patient immediately underwent endovascular embolization with coils and plugs of the largest pulmonary aneurysm, and inferior vena cava filter placement. Then, he started methylprednisolone (1 mg/kg/day) IV for three days in association with LMWH (6000 IU/day). Prednisone (1 mg/kg/day) in combination with cyclophosphamide (100 mg daily) were started orally, with tapering of steroids within a month. At the tight follow up (1 month and 3 months later), no genital and oral ulcers nor vascular thrombosis occurred, and acute phase reactants were in normal range. The 3-month-CT angiography showed a complete resolution of the aneurysms and no new changes.
Results: The peculiar diagnosis of HLAB51 positive HSS with multiple pulmonary aneurysms was made. The appropriate imaging followed by a prompt endovascular embolization of aneurysms with LMWH treatment were successfully performed. Interestingly, the oral combination therapy with corticosteroid and cyclophosphamide showed a rapid efficacy with a relevant safety profile. At the tight follow up, the young man improved significantly with clinical signs and pulmonary changes (Figure 1 next page).
Conclusion: This case is of interest because of the early recognition of such a rare disease that allowed an adequate combined radiological, vascular, and rheumatologic approach. In our case, LMWH resulted useful in preventing the pulmonary embolism, despite the use of anticoagulants is still debated in HSS. Moreover, the endovascular embolization let a less invasive approach to surgery without the need for multiple surgical procedures. For the first time, we documented that oral cyclophosphamide showed an early efficacy as a first line therapy of a HLA-B51 HSS.

RECEIVER OPERATING CHARACTERISTIC ANALYSIS OF JOINT INFLAMMATION IN RELATION TO DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS ASSESSED USING A NOVEL COMBINED THERMAL AND ULTRASOUND IMAGING

Y. K. Tan[1], C. Hong[1], H. LI[2], J. C. Allen Jr[3], J. Thumboo[1]. [1]*Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore*; [2]*Singapore General Hospital, Health Services Research Unit, Singapore, Singapore*; [3]*Duke-NUS Medical School, Centre for Quantitative Medicine, Singapore, Singapore*

Background: A novel combined thermal and ultrasound (CTUS) imaging approach in rheumatoid arthritis (RA) was recently shown to be superior to either imaging modality alone in terms of correlation with the 28-joint disease activity score (DAS28).
Objectives: To determine the performance of CTUS imaging in identifying RA patients with at least moderate disease activity (DAS28 > 3.2).
Methods: Bilateral hand (22 joints) thermal and ultrasound (US) imaging was performed. Thermal imaging provides the surface temperature readings at the joints with MAX, AVG and MIN derived per patient by summing the temperature differences with a control temperature, for the respective maximum (Tmax), average (Tavg) and minimum (Tmin) temperatures at each joint. US imaging assesses joint inflammation by summing up the power Doppler (PD) and grey-scale (GS) joint inflammation scores (graded 0-3 at each joint recess) at each joint to obtain the respective total PD and total GS scores per patient. CTUS imaging utilizes data from both thermal and US imaging to derive the MAX (PD), AVG (PD) and MIN (PD) by multiplying MAX, AVG and MIN by a factor of 2 when a patient's Total PD > median score, which otherwise remained the same as the MAX, AVG and MIN. The results of the imaging parameters were compared between patients with DAS28 ≤ 3.2 and those with DAS28 > 3.2. Sensitivity (Sn), specificity (Sp) and receiver operating characteristic (ROC) curve analysis was performed to determine if the use of CTUS imaging can help identify patients with DAS28 > 3.2.
Results: In this cross-sectional study, 814 joints from 37 RA patients (75.7% female; 75.7% Chinese; baseline mean disease duration, 30.9 months; baseline mean DAS28, 4.43) were imaged. The mean (SD) values for the CTUS—but not single modality—imaging parameters (Table 1) were all significantly greater among patients with DAS28 > 3.2 versus those with DAS28 ≤ 3.2 (P-values were all <0.01). Based on cut-off levels of (a) MAX (PD) ≥ 94.5, (b) MIN (PD) ≥ 42.3 and (c) AVG (PD) ≥ 64.6 in identifying patients with DAS28 > 3.2, the respective area under the ROC curves (AUCs) (95%CIs) were (a) 0.731 (0.541, 0.921) with Sn = 58.1%; Sp = 100.0%; negative predictive value (NPV) = 31.6%; positive predictive value (PPV) = 100.0%; accuracy = 64.9%, (b) 0.758 (0.591, 0.925) with Sn = 61.3%; Sp = 100.0%; NPV = 33.3%; PPV = 100.0%; accuracy = 67.6% and (c) 0.763 (0.596, 0.931) with Sn = 61.3%; Sp = 100.0%; NPV = 33.3%; PPV = 100.0%; accuracy = 67.6%.
Conclusion: The severity of joint inflammation as detected by CTUS—but not single modality—imaging parameters were significantly greater among patients with DAS28 > 3.2 versus those with DAS28 ≤ 3.2. For the first time ever, by applying ROC analysis, this has helped to determine cut-off MAX (PD), MIN (PD) and AVG (PD) levels for identifying patients with DAS28 > 3.2; the usefulness of these cut-off levels will require further validation in independent RA cohorts.

Table 1. Comparison of imaging parameters between patient groups.

Imaging Parameter	DAS28			
	Mean (95% CI)		Difference (95% CI)	P-value
	DAS28 ≤ 3.2	DAS28 > 3.2		
MAX (PD)	75.25 (58.8, 91.7)	119.5 (101.12, 137.87)	-44.25 (-70.49, -18.01)	**0.0022****
MIN (PD)	33.72 (25.82, 41.61)	57.51 (47.63, 67.39)	-23.79 (-37.13, -10.45)	**0.0012****
AVG (PD)	50.72 (39.45, 61.98)	85.39 (71.89, 98.88)	-34.67 (-53.27, -16.07)	**0.0008*****
MAX	67.38 (50.75, 84.02)	82.23 (74.71, 89.75)	-14.85 (-34.11, 4.42)	0.1268
MIN	30.27 (22.06, 38.47)	40.02 (35.02, 45.03)	-9.75 (-22.18, 2.66)	0.1198
AVG	45.45 (33.94, 56.96)	59.11 (52.99, 65.23)	-13.66 (-29.04, 1.72)	0.0801
Total PD	2.83 (-0.23, 5.9)	3.65 (2.71, 4.58)	-0.82 (-3.39, 1.77)	0.5269

MARKER OF CARTILAGE TISSUE LESION IMMUNOPATHOGENESIS OF RHEUMATOID ARTHRITIS

O. Rusanova[1], A. Trofimenko[2], N. Emelyanov[2], O. Emelyanova[1]. [1]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», 1, Волгоград, Russian Federation*; [2]*Federal State Budgetary Educational Institution of Higher Education «Volgoorad State Medical University» of the Ministry of Healthcare of the Russian Federation, 2, Волгоград, Russian Federation*

Background: Collagen type 2 is the basic protein of cartilaginous tissue composing over 80% of its mass. Finding excessive antibodies to collagen type 2 and immune complexes is a diagnostic and prognostic criterion of immune lesion of articular cartilage.
Objectives: To study production of antibodies to collagen type 2 in patients with rheumatoid arthritis using immobilized magnetically controlled forms.
Methods: The antigen was represented by commercial formulation of collagen type 2 produced by Serva (Sweden). Antibodies to collagen type 2 were determined in the patients' blood serum by way of a technique of immunoenzyme assay (ELISA test) using immobilized magnetic sorbents. Magnetic sorbents were polyacrylamide granules from 10 to 100 micron in size containing magnetic material and collagen type 2. We studied 30 apparently healthy donor individuals and 92 patients with a confirmed diagnosis of rheumatoid arthritis.
Results: A study of sera from rheumatoid arthritis patients revealed antibodies to collagen type 2 in 63 patients (68.48%). The correlation coefficient between anti-collagen type 2 antibodies, and IgA / IgM amounted to 0.28 and 0.36, correspondingly. At stage 1 and 2 of disease activity the level of antibodies was higher than in donors (p<0.001). The highest level of antibodies to collagen type 2 was seen in patients with stage 3 of disease activity (0.55±0.02). The amount of antibodies to collagen type 2 in patients with visceral manifestations of rheumatoid arthritis was no different from that in patients without any additional organ involvement, which is hardly surprising since collagen type 2 is mostly localized in articular cartilage and is practically absent from the connective tissue of other organs and systems.
Conclusion: Thus the presence of antibodies to collagen type 2 correlates with the disease activity and is an important marker of articular cartilage lesion in patients with rheumatoid arthritis.

APPLICATIONS OF LOW-FIELD MAGNETIC RESONANCE IMAGING IN A RHEUMATOLOGY DEPARTMENT

I. M. Fernández-Maeztu Palacín[1], D. Ruiz-Montesinos[1], P. Muñoz Reinoso[1], G. Jurado Quijano[1], J. J. Pérez Venegas[1], L. Fernández de la Fuente Bursón[1]. [1]*Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain*

Background: Low-field MRI (LF-MRI) is a useful Imaging technique for the diagnosis and in the follow-up of high-impact rheumatologic pathology[1]. However, the use of the Low-field MRI is not widespread due to the high cost and the use of other techniques such as Musculoskeletal sonography[2]. The Rheumatology Unit of the HUVM owns a Musculoskeletal Imaging Unit (ECO /MRI) and a standardized protocol for LF-MRI[3], which is performed by a rheumatologist applied in a routine clinical practice. We describe the patterns of use of LF-MRI by general rheumatologists in their routine clinical practice.

Objectives: Perform an analysis of the use of LF-MRI in a Rheumatology department to the assessment of joint inflammatory activity. Correlate the results of the analyses in patients without diagnosis or patients with unclear diagnosis.

Methods: Retrospective analysis using the medical records of the patients referred to the Musculoskeletal Imaging Unit from January to June 2018. The main variables collected were reason for referral as well as previous and final diagnosis after LR-MRI. An evaluation on the usefulness of MRI is made twelve months later to establish the diagnosis.

Results: The global population studied of 114 patients were referred to for LF-MRI. 81 females (71%). The 80% of the patients with previous diagnostic 40% Rheumatoid Arthritis (RA), 24% Psoriatic Arthritis (PAs), 16% other rheumatic diseases, and the remaining 20% with an unclear diagnosis. The most frequent reasons for referral were: 1) A total of patients (female and male) was referred to assessment of inflammatory activity prior to the change of treatment and 2) assessment of subclinical activity in patients with optimized treatment. A total of 23 patients (16 female; 7 male), were referred for diagnostic evaluation or differential diagnosis: 7 arthralgias, 6 suspected psoriatic arthritis, 6 with undiagnosed joint inflammation, 2 for differential diagnosis, 1 suspected of juvenile idiopathic arthritis (JIA), and 1 tendinitis. (Table 1)

Table 1. Undiagnosed patients. Post-imaging diagnosis.

	TENO SYNO-VITIS	NO DIAG	AR	MONO ART-HRITIS	OA	CARPAL TUNNEL	RULE OUT PAs	GOUT	SpA	PLAN-TAR FASCII-TIS	JIA	PAs	OS TRI-GO-NUM
ARTHRALGIAS	1	1	1	0	0	1	0	2	0	1	0	0	0
SWOLLEN JOINT WITHOUT DIAGNOSIS	0	1	1	1	2	0	0	0	0	0	0	0	1
DIFFERENTIAL DIAGNOSIS	0	0	1	0	1	0	0	0	0	0	0	0	0
SUSPECTED PAs	0	2	1	0	0	0	1	0	1	0	0	1	0
SUSPECTED JIA	0	0	0	0	0	0	0	0	0	0	1	0	0
TENDINITIS WITHOUT DIAGNOSIS	1	0	0	0	0	0	0	0	0	0	0	0	0
Total	**2**	**4**	**4**	**1**	**3**	**1**	**1**	**2**	**1**	**1**	**1**	**1**	**1**

Conclusion: The results of our study shown that the addition of the LF-MRI into clinical practice and performed by a rheumatologist is a useful tool in the diagnosis and evaluation of the degree of disease activity in patients with joint inflammatory pathology. The main test-indication of these techniques is to assess the degree of activity of the disease. In a 20% of the cases, the LF-MRI was requested for diagnostic evaluation in patients without a clear diagnosis. The long-term follow-up studies that correlate symptoms with structural damage are necessary to define remission more accurately and evaluate the efficiency of different treatment options.

ULTRASOUND-GUIDED VERSUS ANATOMICAL LANDMARK INJECTION OF THE SHOULDER JOINT; A RETROSPECTIVE STUDY

A. Radwan[1], A. Elsaman[1]. [1]*Sohag University Hospital, Rheumatology and Rehabilitation, Sohag, Egypt*

Background: Ultrasound is a widely used tool for diagnostic and interventional purposes for a myriad of musculoskeletal conditions. The question about the value of ultrasound-guided injection over blind injection is debatable [1, 2].

Objectives: To test the value of ultrasound-guided injection versus blind subacromial-subdeltoid bursitis, subcoracoid bursitis, long head of biceps synovial sheath, and intra-articular shoulder injection.

Methods: We included 168 participants (66 subacromial-subdeltoid bursitis, 52 subcoracoid, 10 with long head of biceps tenosynovitis 38 had adhesive capsulitis and performed intra-articular shoulder injection) half of them were injected by blind technique and the other half were injected under ultrasound guidance. All of them were diagnosed by ultrasound. All were injected with methylprednisolone acetate 40 mg (Solumedrol, Pfizer) + lidocaine hydrochloride 1% (Xylocaine Astra Zeneca), 2 ml. SPADI score and range of motion were performed before injection and immediately after the injection, after 2 weeks, and after 4 weeks. Further, complications were recorded immediately after the injection, after 2 weeks, and after 4 weeks.

Results: The mean age of the study group was around 35.5 years, with no significant difference between the two groups, with slightly male predominance (60.7%). The mean SPADI score was similar between the groups before injection, but the improvement was higher among ultrasound-guided group compared to anatomical landmark-guided group, as showed by the significant difference between the two groups regarding SPADI scores at 2 and 4 weeks post-injection. Regarding the improvement of the range of motion, the ultrasound-guided group showed significantly better improvement compared to the anatomical landmark-guided one all over the 4-week course of follow up. The complication rate was slightly higher among the landmark-guided group, but with non-significant difference (Table 1). The difference between the two groups was highest among adhesive capsulitis cases with intra-articular injection.

Conclusion: Ultrasound-guided injections showed better outcomes for all the 4 injections, especially for intra-articular injection, in addition, it showed a significantly less complications than blind injection.

AB0791 THE DIAGNOSIS VALUE OF SYNOVIAL FLUID LYMPHOCYTE IN GOUT PATIENTS

Q. Huang[1], Y. Huang[1], Y. Liu[1], Z. Zhong[1], W. Deng[1], T. W. LI[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Synovial fluid cell counts have long been recognised to have utility in the diagnosis and management of arthritis. Few studies have explained the diagnosis value of synovial fluid cell counts in gout patients.
Objectives: The study aims to investigate the diagnosis value of synovial fluid cell counts in gout patients.
Methods: A total of 185 gout, 64 rheumatoid arthritis(RA), 26 axial spondyloarthritis(axSpA) and 24 osteoarthritis(OA) patients were included into the study. According to serum uric acid(sUA) level on attack, gout patients were divided into normal sUA gout patients and high sUA gout patients. The laboratory data was recorded and ROC curve was performed.
Results: The synovial fluid WBC, PBMC, monocyte, PMN and neutrophil in gout patients were higher than OA patients (P<0.05). The synovial fluid PBMC and lymphocyte in gout patients were lower than RA and axSpA patients (P<0.05). Compared with RA, axSpA and OA patients, ROC curve showed that the AUC value of lymphocyte and sUA for gout were 0.728 and 0.881, which were higher than other variables. The optimal cut off value of lymphocyte for gout was 1.362, with sensitivity of 83.3% and specificity of 60.6%. The AUC value of lymphocyte and sUA for normal sUA gout patients were 0.694 and 0.643, which were higher than other variables. The optimal cut off value of lymphocyte for normal sUA gout patients was 1.362, with sensitivity of 81.6% and specificity of 60.6%.
Conclusion: Synovial fluid cell counts of gout patients were different from RA, axSpA, and OA patients. Synovial fluid lymphocyte had a higher diagnosis value for gout.

AB0792 IMAGING METHODS IN PREDICTING A RADIOLOGIC PROGRESSION IN RA

O. Alekseeva[1], D. Kudinsky2, A. Smirnov2, A. Volkov2, E. Nasonov[3]. [1]*V.A. Nasonova Research Institute of Rheumatology, Diagnostic Department, Moscow, Russian Federation*; [1]*V.A. Nasonova Research Institute of Rheumatology, Diagnostic Department, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Chief Researcher, Moscow, Russian Federation*

Background: Rheumatoid arthritis (RA) is the chronic inflammatory joint disease, and it is responsible for structural damage. Several studies have shown that ACPA + patients were more likely than ACPA– patients to develop erosive changes on radiography. Ultrasound (US) is a well-established method of diagnosis and follow-up in RA, which at the moment may have a prognostic value in assessing the outcomes of the disease.
Objectives: to identify the prognostic role of US in radiologic progression in RA patients.
Methods: 85 RA pts, mean age 53,0 [44,0; 61,0] yrs, mean disease duration 8 [4; 24] months were treated with MTX and biologics according to Treat-To-Target concept. Among them 56 patients with early RA, mean age 53,5 [45,5; 61,0], disease duration 5 [3; 7,5] months. Hands and feet ultrasound (US) with gray scale (GS), power Doppler (PD) and destructive changes (erosion), according to the criteria of OMERACT, were analyzed before initiation of treatment and in 3, 6, 9 and 12 months after. A binary scoring system (presence/absence of erosions) of the joints examined was used. Radiographs were obtained at baseline and 4 years, radiographic changes were assessed using Sharp/van der Heijde modified scoring method. Radiographic progression was documented based on Sharp/Van der Heijde modified score changes during the follow up.
Results: 71 ACPA+ (84%) and 14 ACPA– (16%) patients presented among the 85 patients with RA, among them 49 ACPA+ (87%) and 7 ACPA– (13%) with early RA. RA progression by 4 years the follow-up period was identified in 39% of pts.
During the follow-up period 33 of 85 patients had radiographic progression: the count of erosion increased from 0 [0; 3] to 2 [0; 6]. At the same time, on the background of therapy, a decrease in ultrasound signs of inflammation was determined according to the GS and PD: from 6 [4; 9] to 1 [0; 2] p = 0.000 and from 2 [1; 6] to 0 [0; 1] p = 0.000, respectively, and increase in the number of joints with erosions (from 1 [0; 2] to 2 [0; 4], p = 0.000).
In the group with early RA, the changes were similar.
In ACPA+ general group the count of erosion at 4 years was significantly higher than in ACPA– general group (3 [0; 7] and 0 [0; 1], respectively, p=0.0026).
In ACPA+ early RA group the number of joints with erosions by US at baseline was significantly higher than in ACPA– early RA group (1 [0; 1] and 0 [0; 0], respectively, p=0.017). In ACPA+ early RA group the count of erosion at 4 years was significantly higher than in ACPA– early RA group (2 [0; 4] and 0 [0; 0], respectively, p=0.009) (Table 1)

Table 1. Characteristic of the groups (general group)

at baseline	**ACPA+(71 pts)**	**ACPA- (14 pts)**	**p**
The number of joints with erosions by US	1 [0; 2]	0 [0; 1]	0,36
The number of erosions by X-ray	1 [0; 4]	0 [0; 1]	0,06
after 4 years follow up			
The number of joints with erosions by US	2 [0; 4]	1 [0; 2]	0,16
The number of erosions by X-ray	3 [0; 7]	0 [0; 1]	**0,0026**
Characteristic of the groups (early RA group)			
at baseline	**ACPA+(49 pts)**	**ACPA- (7 pts)**	**p**
The number of joints with erosions by US	1 [0; 1]	0 [0; 0]	**0,017**
The number of erosions by X-ray	0 [0; 2]	0 [0; 0]	0,11
after 4 years follow up			
The number of joints with erosions by US	2 [0; 3]	1 [0; 1]	0,22
The number of erosions by X-ray	2 [0; 4]	0 [0; 0]	**0,009**

Conclusion: Thus, in early RA is advisable to perform an US of the hands and feet to select a group of patients with potentially rapid radiological progression. US evaluation of patients with non-early stage RA is not very important for assessing the prognosis.

AB0793 CONTRIBUTION OF INVESTIGATIONS FOR THE QUEST OF PRIMITIVE CANCER IN FRONT OF BONE METASTASIS

S. Boussaid[1], S. Rekik[1], S. Mechergui[1], S. Jemmali[1], E. Cheour[1], H. Sahli[1], M. Elleuch[1]. [1]*Rabta Hospital, Rheumatology Department, Tunis, Tunisia*

Background: Bone metastases (OM) or secondary cancers bones are bony locations of tumor cells, away from a primary malignant tumor. The Bone metastases are the most common metastases. They can be revealing in 20 to 30% cases or complicate the course of a known cancer. The bone metastases are a pejorative prognostic factor.
Objectives: The aim of this study was to identify the Contribution of diagnostic methods for the quest of primitive cancer in presence of bone metastasis.
Methods: We conduct a retrospective study of 35 files of patients who were hospitalized in the rheumatology department. All patients underwent a questionnaire and a clinical examination. Additional radiological assessment, bone biopsies, biopsies of other sites, bone scintigraphy and tumor markers were carried out on a case-by-case basis.
Results: Thirty-five cases (25 men and 10 women) were analysed. The average age was 61 years [45-85]. Seven patients had a known history of neoplasia. One or more bone biopsies were performed in 8 cases. The vertebrae were the most biopsied bone site (6 cases). The bone biopsies were in favour of carcinoma (3 cases), adenocarcinoma (2 cases), squamous cell carcinoma (1 case) and inconclusive (2 cases). Non bony biopsies (2 pulmonary, 2 prostatic, 1 mammary) concluded to an adenocarcinoma (3 cases) and a carcinoma (2 cases). Bone scintigraphy was carried out in 7 cases and showed in all cases diffuse or localized hyperfixation. The localized value of tumor markers appeared relatively low except for Prostate Specific Antigen (PSA). Other metastatic localisations were identified: hepatic (6 cases) and pulmonary (1 case). The primary cancer identified was pulmonary for 11 patients, prostatic for 7, gynaecological for 4 and digestive for 3. One patient had Otorhinolaryngological cancer and another had bone cancer. Bone biopsy allowed the diagnosis in 6 cases (17%). The primary cancer was discovered by a biopsy of other non-bone sites in 5 cases (14%). Neoplastic antecedents and clinical context were considered sufficient in 16 cases (45%). Primary cancer remained undetermined in 8 cases (22%).
Conclusion: Bone biopsy, as well as non-bone biopsy, remains an essential tool in the etiological diagnosis of bone metastases. They are very contributive in the same proportions. PSA is a major diagnostic asset in the search for primary cancer.

AB0794 CONTRIBUTION OF LABIAL SALIVARY GLAND BIOPSY: EXPERIENCE OF THE DEPARTMENT OF RHEUMATOLOGY OF THE UNIVERSITY HOSPITAL OF IBN ROCHD (ABOUT 57 CASES)

Z. El Ouali[1], A. Elkebir[2], K. Nassar[1], M. Karkouri[2], S. Janani[1]. [1]*University Hospital of Ibn Rochd, Department of Rheumatology, Casablanca, Morocco*; [2]*University Hospital of Ibn Rochd, Department of Anatomical Pathology, Casablanca, Morocco*

Background: Labial salivary gland biopsy (LSGB) is a histological examination indicated for the diagnostic workup of systemic diseases such as Sjogren's syndrome, amyloidosis, or sarcoidosis.
Objectives: To study the contribution of LSGB to the diagnosis of Sjogren's syndrome, amyloidosis, and sarcoidosis.
Methods: We conducted a retrospective study of LSGB histopathological reports and clinical data of patient medical records collected in the Department of Rheumatology of the University Hospital of Ibn Rochd, Casablanca, between January 2019 and June 2020. Histology assessed Chisholm and Masson's sialadenitis score, looked for amyloidosis, and sarcoidotic granulomas.
Results: A total of 57 LSGBs were performed, of which 2 were excluded from our study because of lack of clinical data. The sex-ratio M/F was 0.1, and the median age was 53 (22 – 85). The indications were subjective eyes and mouth dryness in 40% of cases, the search for sarcoidosis and amyloidosis in 23.6% of cases, the assessment of a dryness syndrome in the context of chronic inflammatory rheumatism in 18.2% of cases, isolated dryness of the mouth in 14.5% of cases, and the search for amyloidosis in the context of a known primary Sjögren syndrome in 3.6% of cases. The stages of Chisholm and Masson for sialadenitis found were: stage I at 56.6%, stage II at 24.5%, stage III at 11.3%, and stage IV at 7.5%. Among the LSGBs performed for dryness syndrome, stages III and IV were found in 18.2% of cases among subjective eyes and mouth dryness, in 12.5% of cases among isolated mouth dryness, and in 20% of cases among chronic inflammatory rheumatisms. Three cases of AA amyloidosis (5.5%) were diagnosed. No sarcoidosis granulomas were found.
Conclusion: LSGB is a simple and frequent investigation. The Chisholm stage most often found in our series was stage I, followed by stages II, III, and IV respectively. This is consistent with the results of the study of Baeteman et al (1). In addition, amyloidosis was only found in our series in 5.5% of cases, also matching with the results of Baeteman et al. (4.2%). Their study showed that LSGB has a great diagnostic interest in these two pathologies, with a sensitivity of 52-75% and a specificity of 90-100% for Sjogren's syndrome, and a sensitivity of 48-80% and a specificity of 93-100% for amyloidosis (2). LSGB remains a simple investigation test, contributing to the diagnosis of Sjogren's syndrome, amyloidosis, and sarcoidosis.

AB0795 DYNAMIC CHANGES IN QUANTITATIVE INDICES OF BODY COMPOSITION BY DUAL-ENERGY X-RAY ABSORPTIOMETRY IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS ON DIFFERENT THERAPEUTIC REGIMENS

Y. Gorbunova[1], T. Popkova[1], T. Panafidina[1], N. Demin[2], E. Nasonov[3], A. Lila[3]. [1]*VA Nasonova Research Institute of Rheumatology, Department of Systemic Rheumatic Diseases, Moskva, Russian Federation*; [2]*VA Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moskva, Russian Federation*; [3]*VA Nasonova Research Institute of Rheumatology, Scientific Department, Moskva, Russian Federation*

Background: A redistribution of body fat (abdominal obesity) is quite common in RA patients. Such parameters as body mass index (BMI) and waist circumference do not distinguish or quantify fat and lean (muscle) mass. For that purpose, dual-energy X-ray absorptiometry (DXA) is usually used.
Objectives: to compare quantitative body composition in patients with early RA at baseline and after 24 weeks of therapy with different regimens.
Methods: The study included 37pts (31 women /6 men) with early RA (ACR/EULAR criteria, 2010), 57 [46.5, 62,0] years old, naïve to treatment with glucocorticoids and disease-modifying anti-rheumatics (DMARDs). Pts were seropositive for IgM RF (76%) and anti-CCP (92%), with highly active RA (DAS28 5,5 [5,1; 6,0]; SDAI 32,4 [22,4; 42], CDAI 29,0 [19,7; 39,5]) scores, and median disease duration of 6.0 [5,5;15.5] months. Methotrexate (MTX) 10 [10-15] mg/week subcutaneously was initiated in all included patients as first line therapy for 12 weeks. By this time point therapy was reviewed in 19 patients (51%) due to MTX inefficacy and adalimumab (ADA) at 40mg once every 2 weeks was added on top of MTX. DXA scan (HOLOGIC, USA) was used to measure body composition at baseline and after 6mths of treatment with the protocol assessing total body, body fat and lean muscle mass.
Results: Based on therapeutic regimens at week 24 all study subjects were divided into 2 groups: Group I (n=18) receiving MTX monotherapy, Group II (n=19) – the combination of MTX and ADA (Table 1). Group I patients had lower body weight, lean and fat mass vs patients from Group II (62 kg vs. 73.7 kg; 40.6 kg vs. 49.7 kg; 21.0 kg vs. 25.8 kg, respectively (p<0.05 in all cases) at baseline. 24 weeks of combination therapy eventuated in body weight gain (73.7 kg vs. 75.8 kg), accumulation of fat (25.8 kg vs. 28.1 kg) and unchanged lean tissue mass. In contrast, patients on MTX monotherapy managed to increase their lean mass (40.6 kg vs. 41.6 kg) without gaining in total fat mass.

Table 1.

Indices	I group (*n*=18), monotherapy MT			II group (*n*=19), combination therapy (MTX, ADA)		
	baseline	24 weeks	Δ,%	baseline	24 weeks	Δ,%
Body fat mass, kg	21,0 [17,2;26,2]**	23,4 [17,5;29,7]	+11	25,8 [18,4;35,0]	28,1 [21,4;37,9]*	+9
Lean mass, kg	40,6 [37,3;44,7]**	41,6 [38,2;46,4]***/*	+2,5	49,7 [39,0;56,1]	49,9 [41,0;57,6]	0,4
Total mass, kg	62,0 [57,7;77,6]**	64,1 [59,5;81,6]***	+3,4	73,7 [64,5;97,9]	75,8 [66,8;102,1]*	+2,8

*p<0,05 reliability of differences in parameters before treatment and after 6mth (Wilcoxon); **p<0.05 differences in baseline values in groups I and II (Mann-Whitney test);***p<0.05 difference in the indices between the groups by the 6mth of therapy; Δ,% difference in indices between the groups by the 6mth of therapy.

Conclusion: In general, RA patients on treatment tend to gain weight by week 24. Patients who failed on MTX monotherapy by week 24 and were switched to combination therapy had higher fat mass at baseline. Mediations used for RA treatment produce multidirectional effects on quantitative parameters of body composition: MTX monotherapy triggers some increase of lean mass, while combination of MTX and bDMARD results in weight gain and increase of total and fat mass. These data need to be confirmed in large-scale studies with longer follow-up period.

AB0796 THE EVALUATION OF LUNG DIAGNOSTIC PROCEDURE AT THE ONSET OF INFLAMMATORY RHEUMATIC DISEASES WITH INTERSTITIAL LUNG DISEASE

T. Hoffmann[1], P. Oelzner[1], F. Marcus[2], M. Förster[2], J. Böttcher[3], G. Wolf[1], A. Pfeil[1]. [1]*Jena University Hospital – Friedrich Schiller University Jena, Department of Internal Medicine III, Jena, Germany*; [2]*Jena University Hospital – Friedrich Schiller University Jena, Department of Internal Medicine I, Jena, Germany*; [3]*Jena University Hospital – Friedrich Schiller University Jena, Institute of Diagnostic and Interventional Radiology, Jena, Germany*

Background: Interstitial lung disease (ILD) in inflammatory rheumatic diseases (IRD) is associated with increased mortality. Moreover, the lung is one of the most effected organs on IRD. Consequently, screening methods were required to the detect ILD in IRD.
Objectives: The objective of the following study is to evaluate the diagnostic value of lung function test, chest x-ray and HR-CT of the lung in the detection of ILD at the onset of IRD.
Methods: The study is designed as a case-control study and includes 126 patients with a newly diagnosed IRD. It was matched by gender, age and the performance of lung function test and chest x-ray. The sensitivity and specificity were verified by crosstabs and receiver operating characteristic (ROC) curve analysis. The study cohort was divided in two groups (ILD group: n = 63 and control group: n = 63). If possible, all patients received a lung function test and optional a chest x-ray. Patients with pathological findings in the screening tests (chest x-ray or reduced diffusing capacity for carbon monoxide (DLCO) < 80 %) maintained a high-resolution computer tomography (HR-CT) of the lung. Additionally, an immunological bronchioalveolar lavage was performed in the ILD group as gold standard for the detection of ILD.
Results: The DLCO (< 80 %) revealed a sensitivity of 83.6 % and specificity of 45.8 % for the detection of ILD. Other examined parameter of lung function test showed no sufficient sensitivity as screening test (FVC = Forced Vital Capacity, FEV1 = Forced Expiratory Volume in 1 second, TLC = Total Lung Capacity, TLCO = Transfer factor of the Lung for carbon monoxide). Also, a combination of different parameter did not increase the sensitivity. The sensitivity and specificity of chest x-ray for the verification of ILD was 64.2 % versus 73.6 %. The combination of DLCO (< 80 %) and chest x-ray showed a sensitivity with 95.2 % and specificity with 38.7 %. The highest sensitivity (95.2 %) and specificity (77.4 %) was observed for the combination of DLCO (< 80 %) and HR-CT of the lung.

Conclusion: The study highlighted that a reduced DLCO in lung function test is associated with a lung involvement in IRD. DLCO represented a potential screening parameter for lung manifestation in IRD. Especially patients with suspected vasculitis should receive an additional chest x-ray. Based on the high sensitivity of DLCO in combination with chest x-ray or HR-CT for the detection of ILD in IRD, all patients with a reduced DLCO (< 80%) should obtained an imaging of the lung.

AB0797 THE ROLE OF ULTRASOUND CRITERIA IN ASSESSING PAIN SYNDROME IN THE KNEE JOINT IN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS

N. Aleksandrova[1], A. Aleksandrov[1,2]. [1]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Department of Functional Research Method, Volgograd, Russian Federation*; [2]*Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation*

Background: Pain syndrome and pathological changes in the synovium detected by ultrasound can be early signs of various diseases of the joints [1].
Objectives: the use of ultrasound criteria for changes in the synovial membrane of the joint cavity to assess the severity of pain in patients with rheumatoid arthritis (RA) and osteoarthritis (OA).
Methods: The study included 36 patients with RA (32 women and 4 men aged 22 to 55 years old) and 38 patients with OA (30 women and 8 men aged 30 to 50 years old) with lesions of the knee joints. A visual analogue scale (VAS) was used to determine the severity of pain. The severity of pain in the knee when walking was at least 40 mm according to the VAS in all examined patients. Joint ultrasound examination was carried out according to the standard technique using a linear transducer with a frequency of 5–12 MHz on an Accuvix V10 ultrasound diagnostic system (Samsung Medison, South Korea). The evaluation of ultrasound changes in the upper inversion of a knee joint was carried out according to the following criteria: the severity of intra-articular effusion (1), synovial proliferation (2), local vascularization of the synovial membrane using power Doppler (3) (Table 1).

Table 1. Parameters of ultrasound criteria for assessing changes in the synovial membrane of the joint cavity

Normal indicators	1 - width of the suprapatellar turn is 6 mm
	2 - thickness of the synovial membrane is 3 mm (from the anterior approach)
	3 - lack of vascularization loci
Minimum changes	1 - delamination of the suprapatellar curl leaves from 7 to 9 mm
	2 - thickness of the synovial membrane 3.1–4.5 mm
	3 - appearance of single loci of vascularization (1-2 in the Doppler field)
Moderate changes	1 - delamination of the leaves of the suprapatellar twist 10-14 mm
	2 - thickness of the synovial membrane is 4.6–6.4 mm
	3 - appearance of moderate (> 5) vascularization loci
Severe changes	1 - delamination of suprapatellar folds of more than 15 mm
	2 - thickness of the synovial membrane is more than 6.5 mm
	3 - multiple foci of vascularization (> 5, merging in places)

Results: Correlations of various severity were found between pain indices according to VAS and the thickness of the synovial membrane of the knee joint ($r = 0.33$, $p = 0.019$) and the number of vascularization foci ($r_S = 0.29$, $p = 0.04$) in RA patients, as well as between pain according to VAS and the severity of intra-articular effusion ($r = 0.28$, $p < 0.002$) in patients with OA.
The patients were divided into three groups according to the severity of pain in the knee joint: group I - 41-59 mm (12 patients with OA and 9 patients with RA), group II - 60-79 mm (16 patients with OA and 12 patients with RA), group III - 80–100 mm on the VAS scale (10 patients with OA and 15 patients with RA). Group I was dominated by OA patients with minimal changes in intra-articular effusion and local vascularization of the synovial membrane, with moderate synovial proliferation (28.6% of the total number of patients in the group). In group II patients with OA with moderate severity of intra-articular effusion and local vascularization (21.4%) and patients with RA with moderate changes in the thickness of the synovium and local vascularization (25%) were equally common. Group III was dominated by RA patients with severe synovial proliferation and moderate local vascularization (28%), as well as patients with OA with moderate intra-articular effusion (20%).
Significant differences in the thickness of the synovium in patients with RA in the first and third groups were noted (H-test = 5.9, $p = 0.025$).
Conclusion: The additional use of ultrasound criteria for changes observed in the synovial membrane of the joint cavity in patients with RA and OA can help predict pain in the knee joint. The manifestation of pain syndrome in patients with OA is most associated with the severity of synovitis in the joint, and in patients with RA - with the severity of synovial proliferation.

AB0798 IS THERE A REPRODUCIBILITY OF THE HISTOGRAM AND GRAY SCALE IN ECOEXTRUCTURAL DAMAGES IN RHEUMATOTOLOGICAL DISEASES?

J. A. Mendonça[1], I. Siste de Almeida Aoki[1], C. C. Cavuto[2], V. A. Leandro-Merhi[3], J. L. B. D. Aquino[3]on behalf of Postgraduate Program in Health Sciences, Pontifical Catholic University of Campinas.. [1]*Pontifical Catholic University of Campinas, Rheumatology/Postgraduate Program in Health Sciences, Campinas, Brazil*; [2]*Pontifical Catholic University of Campinas, Rheumatology/ Scientific Initiation Program, Campinas, Brazil*; [3]*Pontifical Catholic University of Campinas, Postgraduate Program in Health Sciences, Campinas, Brazil*

Background: The gray scale (GS) in high resolution ultrasound is already well validated for use in rheumatological diseases, but the color map or the histogram, can be considered a new proposal, to better define and complement the echotextural damages detection[1].
Objectives: To calculate the lesions area measures reproducibility index in arthropathies, between 3 blind evaluators and correlate these measures using the GS and the histogram.
Methods: Observational and retrospective study approved by the ethics committee of the Pontifical Catholic University of Campinas, with the opinion number: 1.526.307. A total of 29 patients have been assessed (31% males and 69% females) on period 2014 to 2019 in Rheumatology service. A MyLab 50 -Esaote equipment was used with frequency transducer that ranged between 6.0 and 18.0 MHz, 10 different area measures were performed from each recorded images previously, by the GS and the histogram. Statistical analysis: Spearman's correlation coefficients, Lin's concordance coefficient (CCC) and the intraclass correlation coefficient (ICC) and their respective 95% confidence intervals, with the SPSS software package for Windows v. 17.0 (SPSS Inc., Chicago, IL, USA).
Results: Average age 43.5 ± 21.5 years of age; with disease duration that varied between ≤ 1 month (48.3%) and ≥36 months (24.1%); with the following diseases: juvenile idiopathic arthritis (17.24%); osteoarthritis (13.79%); psoriatic arthritis (13.79%); undifferentiated spondyloarthritis (3.44%); gout (20.68%); rheumatoid arthritis (27.58%) and reactive arthritis (3.44%). A total of 840 measures of exudative (27.58%), proliferative (27.58%) and snowstorm appearance (6.89%) synovitis were performed; femoral-condyle cartilage (3.44%); synovial cyst (3.44%); paratendinitis (6.89%); calcification (3.44%); nail enthesitis (3.44%); tenosynovitis (6.89%) and tophi (10.34%) (Figure 1). The concordance correlation coefficient showed values closer to 1; $p < 0.001$, the intraclass correlation coefficients with excellent reproducibility (ICC ≥ 0.75); $p < 0.001$, always in relation to the three evaluators (Table 1) and the Spearman correlation between the GS and the histogram ranged from rs = 0.665 to rs = 1,000; $p < 0.001$.
Conclusion: The histogram can be considered an image method to better identify echotextural damages.

AB0799 DO WE OVERDIAGNOSE SERONEGATIVE RHEUMATOID ARTHRITIS? – THE ROLE OF MUSCULOSKELETAL ULTRASOUND IN CLARIFYING SERONEGATIVE INFLAMMATORY ARTHRITIS

D. Esperança Almeida[1], E. Costa[1], F. Guimarães[2], A. S. Pinto[3], H. Parente[2], S. Azevedo[2], J. Rodrigues[2], J. Tavares-Costa[2], C. Afonso[2], D. Faria[2], M. Cerqueira[1], F. Teixeira[2]. *[1]Hospital de Braga, Serviço de Reumatologia, Braga, Portugal*; *[2]Unidade Local de Saúde do Alto Minho, Serviço de Reumatologia, Ponte de Lima, Portugal*; *[3]Unidade Local de Saúde da Guarda, Serviço de Reumatologia, Guarda, Portugal*

Background: Several data indicate that seronegative rheumatoid arthritis (RA-) and seropositive RA (RA+) may have different mechanisms and prognosis, being well established that rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) have diagnostic and prognostic value. Several conditions, like peripheral spondyloarthritis (SpA), psoriatic arthritis or crystal-related arthropathies may mimic the presentation of RA. Mechanisms and treatment of each of these conditions differ significantly. The authors speculate that RA- may be overdiagnosed in the setting of seronegative chronic inflammatory arthritis and that musculoskeletal ultrasound (US) may help us to better classify these patients through the identification of characteristic lesions of the mentioned diseases.
Objectives: To compare the frequency of US lesions found in joints and entheses between RA- and RA+ patients.
Methods: Cross-sectional study: systematic US evaluation of ten joints, twelve entheses and both flexor and extensor tendons of four fingers (Table 1) in consecutive RA- patients. RA+ patients matched for sex and age were recruited. RA- patients included met every of the following criteria: history of chronic polyarthritis, RF and ACPA negativity, no extra-articular features of SpA or RA nor family history of SpA, no suspected crystal-related arthritis.
Results: Twenty-one RA- patients were included and twenty RA+ patients were recruited as controls. No differences between groups were found in sex, age, body mass index, time of disease evolution or use of biological therapy.
RA- patients had a significantly higher number of entheseal structural and/or inflammatory lesions than RA+ patients (median 2.0 vs. 0.5, U 111.5, p=.008**), with triceps enthesitis being significantly more frequent in RA- patients (p=.036*). In total, 18.7% of RA- entheses had enthesitis lesions vs. only 8.3% of RA+ entheses. One RA- patient had ultrasonographic features of dactylitis which was not clinically evident.
As expected, considering the role of RF and ACPA in erosive RA, RA- patients had a significantly lower number of joints with erosions compared to RA+ patients (median 0.0 vs. 3.0, U 64.5, p<.001***), with significant differences in every considered joint. Erosions were found in 6.7% of RA- joints vs. 32.0% RA+ joints.
Additionally, two RA- patients had hyperechogenic foci in knee cartilage or carpal fibrocartilage suggestive of calcium pyrophosphate deposition.

Table 1. Comparative frequency of ultrasound lesions found in joints and entheses of RA- and RA+ patients.

	RA- (n=21)	RA+ (n=20)	*p*-value
Mdn number of ENTHESES with any lesion per patient ± IQR	2.0 ± 3.0	0.5 ± 2.0	.008**
Triceps – n (%)	8 (38.1%)	2 (10.0%)	.036*
Quadriceps – n (%)	9 (42.9%)	6 (30.0%)	.393
Superior patellar – n (%)	4 (19.0%)	1 (5.0%)	.169
Inferior patellar – n (%)	-	-	-
Achilles – n (%)	9 (42.8%)	4 (20.0%)	.116
Plantar fascia – n (%)	5 (23.8%)	1 (5.0%)	.089
DACTYLITIS – 2^{nd} + 5^{th} finger – n (%)	1 (4.8%)	-	-
Mdn number of joints with EROSIONS per patient ± IQR	0.0 ± 1.0	3.0 ± 3.0	<.001***
Ulnar styloid process – n (%)	5 (23.8%)	11 (55.0%)	.041*
Metacarpophalangeal 2 – n (%)	3 (14.3%)	11 (55.0%)	.006**
Metacarpophalangeal 5 – n (%)	1 (4.8%)	10 (50.0%)	.001**
Metatarsophalangeal 1 – n (%)	-	3 (15.0%)	-
Metatarsophalangeal 5 – n (%)	3 (14.3%)	11 (55.0%)	.006**
CHONDROCALCINOSIS – triangular fibrocartilage + knee – n (%)	2 (9.5%)	-	-
DOUBLE CONTOUR – any joint – n (%)	-	-	-

RA- – seronegative rheumatoid arthritis; RA+ – seropositive rheumatoid arthritis Mdn – median; IQR – interquartile range; n (%) – absolute number (percentage) of patients with the indicated lesion.

Conclusion: We found that some patients diagnosed with RA- had, in fact, ultrasonographic features of different diseases, namely enthesitis/dactylitis and crystal deposition. These data suggest that RA- may be overdiagnosed in clinical practice. Systematic US evaluation of joints and entheses may provide valuable diagnostic information in patients with chronic inflammatory seronegative arthritis and improve patient care.

AB0800 HEMATOLOGICAL MARKERS OF SYSTEMIC INFLAMMATION IN PATIENTS RHEUMATOID ARTHRITIS (RA) AND SPONDYLOARTHRITIS (SPA)

B. Targonska-Stepniak[1], K. Grzechnik[2], M. Majdan[1]. *[1]Medical University of Lublin, Rheumatology and Connective Tissue Diseases, Lublin, Poland*; *[2]Samodzielny Publiczny Szpital Kliniczny nr 4, Rheumatology and Connective Tissue Diseases, Lublin, Poland*

Background: An appropriate assessment of disease activity is essential in the management of patients with chronic inflammatory joint diseases, rheumatoid arthritis (RA) and spondyloarthritis (SpA). Hematological parameters [Neutrophil-To-Lymphocyte (NLR), Platelet-To-Lymphocyte (PLR) and Monocyte-To-Lymphocyte (MLR) ratios] have been demonstrated to be good, promising indicators of systemic inflammation status in different diseases, additionally to conventional inflammatory markers [erythrocyte sedimentation rate (ESR), C-reactive protein (CRP)]. However results remain conflicting in rheumatic patients.
Objectives: The goal of the study was to determine the role of NLR, PLR, MLR in assessing inflammatory disease activity and to compare the biomarkers in RA and SpA patients.
Methods: An observational study was conducted in patients with RA and SpA (ankylosing spondylitis and psoriatic arthritis) treated in the Department of Rheumatology and Connective Tissue Diseases, Medical University of Lublin, Poland. Demographic and clinical information was obtained through structured interview, review of medical records and laboratory tests. The following disease activity and functional scores were registered: CRP and ESR levels, swollen and tender joints counts (SJC, TJC), DAS28 (ESR), HAQ, BASDAI, BASFI, patient global assessment (PtGA) and physician global assessment (PGA) rated on a visual analogue scale (VAS).
The study group consisted of 95 patients (58 women, 37 men), with the mean (SD) age 45.4 (9.9), disease duration 10.0 (8.4) years. There were 58 (61.1%) patients with RA (44 women, 14 men) and 37 (38.9%) patients with SpA. The mean age and disease duration were statistically not different in both patients' groups. The mean (SD) DAS28 was 4.21 (1.8) in RA patients; in SpA patients BASDAI 4.9 (2.6) and BASFI 5.0 (2.8).
Results: In the whole group (95 patients) and in the SpA group, we found positive correlations between the PLR value and the following parameters CRP, ESR; between NLR and CRP, ESR; between MLR and CRP. In the RA group positive correlations were observed between PLR and CRP, ESR; NLR and CRP; MLR did not correlate with CRP and ESR.
In RA patients, there were statistically significant correlations between values of PLR and DAS28 (r=0.356, p=0.006), TJC (r=0.308, p=0.02), SJC (r=0.318, p=0.016), PtGA (r=0.372, p=0.008). No significant correlation was found between NLR, MLR and other disease activity scores.
In SpA patients, we found a significant correlation between NLR and PtGA (r=0.488, p=0.04). No significant correlations were found between NLR, PLR, MLR and BASDAI, BASFI.
The group of RA patients as compared with SpA, was characterized by significantly higher value of PLR [respectively 207.8 (94.0) vs 169.9 (77.7), p=0.04]. In turn, SpA patients compared with RA, were characterized by unfavorable metabolic parameters: higher atherogenic index [respectively 4.03 (0.8) vs 3.57 (1.1), p=0.03], lower HDL-cholesterol [47.4 (10.7) vs 56.1 (16.4) mg/dl (p=0.006); higher serum uric acid [5.6 (1.2) vs 4.5 (1.4) mg/dl (p=0.0001)], higher waist measurement [96.1 (14.2) vs 85.9 (11.5) cm (p=0.0003).
Conclusion: In our study we found, that in patients with RA, PLR was associated with both clinical and inflammatory markers of disease activity; in SpA patients NLR, PLR and MLR were associated with conventional inflammatory markers (CRP, ESR). Hematological inflammatory biomarkers may reflect disease activity and could represent potential parameters to evaluate disease activity not only in RA, but also in SpA.

AB0801

TIME FOR REFERRAL AND DEFINITIVE DIAGNOSIS IN PATIENTS WITH HAND ARTHRALGIA

P. Herrera-Sandate[1], G. Figueroa-Parra[1], D. Vega-Morales[1], J. A. Esquivel Valerio[1], B. R. Vázquez Fuentes[1], M. A. Garza Elizondo[1], Y. G. Ordoñez Azuara[2], R. F. Gutierrez-Herrera[2], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology Service, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Family Medicine Department, Monterrey, Mexico*

Background: Early referral of patients with suspicion of progression to rheumatoid arthritis (RA) is of paramount importance in disease prognosis. We had previously described a time delay of 28 months between symptom onset and evaluation by a rheumatologist, and a mean wait time of 9.5 weeks for referral to a secondary-level public hospital (1). The availability of specialized interdisciplinary evaluation of patients in a third-level of care raises the possibility of shortening this time gap, as well as describing patient and physician decisions amidst the referral to a Rheumatology center.

Objectives: Describe the diagnosis profile of patients with hand arthralgia and time of referral to Rheumatology in a Family Medicine clinic.

Methods: A cohort study was conducted in 110 patients from October 2018 to December 2020 in a Family Medicine clinic within the tertiary-care University Hospital "Dr. Jose Eleuterio Gonzalez" in Monterrey, Mexico. Patients with hand arthralgia as their chief complaint were recruited. An observational, descriptive compilation of patient history was retrieved prospectively through medical records. Variables included time of inclusion, number of medical visits until referral and definitive diagnosis. Descriptive statistics, Kaplan-Meier curves and log-rank tests were used to test the association between time of diagnosis and clinical variables of interest.

Results: Assessed variables are shown in Table 1. Out of 110 patients with hand arthralgia, a quarter received a final diagnosis within 3 medical visits. Less than half of patients were referred, and only a third attended the referral indication. It takes 39.3 days from the first medical visit to be referred, and 69 days and 2.89 consultations to receive a definitive diagnosis. Around half of patients will have a definitive diagnosis, osteoarthritis being the most common. The log-rank test for categoric variables including a positive squeeze test or ≥4 criteria of clinically suspect arthralgia did not show a significant association for time of referral and definitive diagnosis (data not shown).

Table 1. Diagnostic and referral characteristics of patients with hand arthralgia attending a Family medicine clinic

Patients recruited in a Family Medicine clinic	n = 110
Female, n (%)	90 (81.8)
Age in years, mean ± SD	49.69 ± 14.90
RF, ACPA, or hand radiography request, n (%)	100 (90.9)
Diagnosis in Family Medicine	
Diagnosed patients after 1 medical visit, cumulative n (%)	5 (4.6)
Diagnosed patients after 2 medical visits, cumulative n (%)	22 (20.0)
Diagnosed patients after 3 medical visits, cumulative n (%)	26 (23.6)
Referral to Rheumatology for diagnostic doubt or clinical follow-up	
Patients referred to a Rheumatology clinic, n (%)	49 (44.5)
Patients attending Rheumatology referral, n (%)	34 (30.9)
Time for referral, days ± SD	39.37 ± 38.64
Global definitive diagnosis	
Patients with a definitive diagnosis, n (%)	51 (46.4)
Osteoarthritis diagnosis, n (%)	23 (20.9)
Rheumatoid arthritis diagnosis, n (%)	13 (11.8)
Overlap syndrome diagnosis, n (%)	5 (4.5)
Time for definitive diagnosis, days ± SD	68.96 ± 106.57
Number of consultations for definitive diagnosis, mean ± SD	2.86 ± 1.05

RF, rheumatoid factor; ACPA, anticitrullinated protein antibodies; SD, standard deviation.

Conclusion: Patients with hand arthralgia evaluated in a tertiary-care Rheumatology center receive a timely referral in one month and a definitive diagnosis after 3 medical visits in around two months.

AB0802

THE CORRELATION BETWEEN N-MID OSTEOCALCIN SERUM VALUES AND BONE MINERAL DENSITY VALUES IN FEMALE SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WHO RECEIVED ORAL METHYLPREDNISOLONE THERAPY BASED ON CUMULATIVE DOSES

S. Hidayatulloh[1], Z. A. Adnan[2,3], A. Nurudhin[2,3], Y. Werdiningsih[2,3], N. A. Prabowo[2,4]. [1]*Faculty of Medicine, Sebelas Maret University, Internal Medicine, Surakarta, Indonesia*; [2]*Faculty of Medicine, Sebelas Maret University, Internal Medicine, Rheumatology Division, Surakarta, Indonesia*; [3]*Dr. Moewardi General Hospital, Internal Medicine, Rheumatology Division, Surakarta, Indonesia*; [4]*Universitas Sebelas Maret Hospital, Internal Medicine, Sukoharjo, Indonesia*

Background: Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease and involves many organ systems in the body. Glucocorticoids are potent anti-inflammatory and immunosuppressive agents used in patients with SLE. The cumulative dose of steroids is a major risk factor for bone loss. A sensitive indicator that reflects bone remodeling activity is a bone turnover marker (BTM), one of which is N-MID Osteocalcin. Bone Mineral Density (BMD) with DXA can be used to assess osteoporosis. DXA is thus not feasible for screening because of its high cost and lack of machine availability. N-MID Osteocalcin is cheaper and more accessible than DXA. The majority of SLE patients at Moewardi Hospital, Surakarta, received the main therapy for methylprednisolone.

Objectives: This study aims to prove the correlation between serum N-MID Osteocalcin values and BMD values in female SLE patients who received oral methylprednisolone therapy based on cumulative doses.

Methods: This is a cross-sectional study with random sampling techniques at Rheumatology Clinic Moewardi Hospital, Surakarta. The 38 samples that met the inclusion criteria were measured BMD by DXA and examined for N-MID Osteocalcin by using the Elecsys N-Mid Osteocalcin Kit with the ECLIA method. The cumulative dose of methylprednisolone is calculated in grams. Data analysis used the Shapiro Wilk test, 2 mean difference test (t-test and Mann Whitney test), Chi-Square test, bivariate correlation analysis and, Moderated Regression Analysis.

Results: There were 38 samples, 34 (89.47%) normal BMD and, 4 (10.53%) Osteoporosis. The N-MID Osteocalcin has a positive and significant correlation both with the BMD Total L1-L4 as well as the BMD NLF ($p < 0.05$). The cumulative dose of MP has a negative and significant correlation both with the BMD Total L1-L4 also with the BMD NLF ($p < 0.05$). MP cumulative dose can significantly function as a moderation of the effect of N-MID Osteocalcin both on the BMD Total L1-L4 or the BMD NLF. The effect of the N-MID Osteocalcin on the total BMD of L1-L4 or the BMD NLF at the Cumulative Dose MP ≥ 8 g was weaker than that of the MP Cumulative Dose <8 g, and the moderating effect of the correlation between N-MID Osteocalcin and BMD was larger on the total BMD of L1-L4.

Conclusion: There is a positive correlation between serum N-MID Osteocalcin values and BMD values in SLE female patients receiving oral methylprednisolone therapy and the cumulative dose of Methylprednisolone affects the correlation between N-MID Osteocalcin values and BMD values in SLE female patients receiving oral methylprednisolone therapy.

AB0803 EXPERIENCES OF SCREENING AND DIAGNOSIS FROM THE PERSPECTIVE OF PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS (PSA)

C. Silverthorne[1,2], J. Lord[2], C. Bowen[3], W. Tillett[3,4], N. Mchugh[3,4], E. Dures[1,2]. [1]*University of the West of England, Faculty of Health and Applied Sciences, Bristol, United Kingdom*; [2]*University Hospitals Bristol and Weston NHS Foundation Trust, Academic Rheumatology, Bristol, United Kingdom*; [3]*Royal United Hospitals Bath NHS Foundation Trust, Rheumatology, Bath, United Kingdom*; [4]*University of Bath, Pharmacy and Pharmacology, Bath, United Kingdom*

Background: Psoriatic arthritis (PsA) is an inflammatory arthritis characterised by pain, swelling and stiffness in the joints and affects approximately 0.3 to 1.02% of the UK population [1]. PsA may result in limited physical function and reduced quality of life [2] and is associated with work disability and unemployment [3]. Patients who have the inflammatory skin condition, psoriasis, are at greater risk of developing PsA than those without.
Objectives: There is no definitive test for PsA. It is usually diagnosed by rheumatologists in secondary care, after referral from primary care. Evidence suggests a delay in diagnosis results in worse outcomes for patients. This study is nested within a randomised controlled trial (RCT) of a new clinical care pathway. The RCT is testing whether screening primary care patients with psoriasis for symptoms of PsA leads to earlier diagnosis and improved outcomes, compared to usual care. This qualitative study explored the acceptability and impact of screening.
Methods: Telephone interviews were conducted with patients with psoriasis from two secondary UK care centres taking part in the RCT. The semi-structured interviews explored patients' thoughts and feelings around screening, the impact of the screening outcome and any changes they made as a result. The semi-structured format allowed flexibility to ask questions that probed more deeply and develop new lines of enquiry based on patients' responses. Patients who did and did not receive a diagnosis of PsA were interviewed.
Results: Twenty-four patients participated in the study (15 women / 9 men) ranging in age from 35 to 73 years old. The length of time patients had psoriasis ranged from 6 to 60 years. Eleven patients were diagnosed with PsA. A Framework Analysis Approach was used to analyse the data. This allowed for an exploration of the predefined areas (the screening process) as well as remaining open to capturing other related experiences and views of patients. Four main themes represent the data (Table 1).

Table 1.

Main theme	Sub-themes
1. Living with psoriasis and psoriatic arthritis:	1. Understanding of psoriasis – causes, symptoms, treatments
'It's [psoriasis] socially debilitating…makes you look a real mess'	2. Effects of psoriasis on self, personal and working life
'It's almost as if the world's on your shoulders'	3. Awareness of PsA
2. Experience of screening:	1. Thoughts and feelings prior to screening
'I was able to talk and be listened to'	2. Valuing 'high quality' care
'It's a lightbulb moment…explained why things were a bit stiff and achy'	3. Impact of screening outcome
3. Gaining control:	1. Increased awareness and knowledge of psoriasis and PsA
'element of surprise that this arthritis should be connected to it [psoriasis]'	2. Improved self-management
'You've got to learn to listen to your body'	3. Early diagnosis of PsA
4. Future screening programs:	1. Changes to questionnaires
'there weren't really any questions about were you in pain'	2. Use of case studies, sign-posting
'support groups…peer support is crucial with long-term conditions'	3. Removing barriers to screening

Conclusion: This study indicates screening was viewed as a positive and reassuring experience. Patients valued the fact that screening appointments were not rushed and felt they were being listened to. Patients valued learning about psoriasis and PsA and referred to making changes beneficial to their health. Screening enabled patients to get the help they needed if diagnosed, provided relief if not diagnosed, and sometimes led to the diagnosis of a different condition.

AB0804 ONE YEAR FOLLOW-UP SAFETY AND EFFICACY RESULTS OF VACCINATION PROTOCOL FROM A RHEUMATOLOGY CLINIC

S. Jeria Navarro[1], S. P. Fernandez-Sanchez[1], V. Pomar[2], D. Lobo Prat[1], L. Sainz Comas[1], H. Park[1], A. García-Guillén[1], A. M. Millán Arciniegas[1], C. Díaz-Torné[1], P. Moya[1], B. Magallares[1], I. Castellví[1], A. Laiz[1], H. Corominas[1]. [1]*Hospital Universitari de la Santa Creu i Sant Pau & Dos de Maig, Rheumatology Unit, Barcelona, Spain*; [2]*Hospital Universitari de la Santa Creu i Sant Pau, Internal Medicine, Barcelona, Spain*

Background: Patients with autoimmune inflammatory rheumatic diseases (AIIRD) have a higher burden of infectious diseases compared to the general population. This could be explained by the disturbances in their immune system response, comorbidities and immunosuppressive treatment. Vaccination is the most effective measure to prevent infections.
Objectives: To describe a cohort of patients with AIIRD referred to the infectious disease´s unit according to the vaccination protocol.
Methods: Restrospective and descriptive study of a cohort of 286 patients with AIIRD who were evaluated in the rheumatology service of a tertiary hospital in Barcelona and referred to the infectious disease´s unit according to the vaccination protocol among 1 year,between January 1rst December 31st, 2019. The vaccination protocol included serologies of human immunodeficiency virus,hepatitis A,B and C, varicella zoster,tuberculosis,measles,mumps and rubella virus.The recommended vaccines were *H.influenzae b,S.pneumonia,*influenza,hepatitis A and B(immunity absence),*meningococcus c*,tetanus – diphtheria (low antigenic load),poliomyelitis and human papillomavirus (not vaccinated).The patients included were diagnosed with a rheumatologic condition under immunosuppressive therapy. Demographic variables,diagnosis,treatment,vaccines administered,infections and adverse effects were collected.
Results: Of 286 patients reviewed the mean age was 61, 4 (±14.4) years. The characteristics of the cohort are shown in Table 1. Most of the patients used csDMARDs 149 (52.1%), 77(26.9%) patients used combined treatment. Measles and rubella are part of the triple virus vaccines included in the systematic Spanish vaccination schedule, in our cohort 20 (7%) patients had negative serologies for measles and 26 (9%) for rubella. 57 (20%) patients had latent TB with positive Quantiferon.Forty-one (14.3%) were vaccinated before receiving immunosuppressive treatment. The less administered vaccine was influenza with 44.9% (vaccination rate in Spain in healthy population, in 2019-2020 was 51.2%).No serious adverse effects were reported in relation to the vaccination. The infectious complications during the follow-up period were bronchopneumonia in a patient with RA treated with certolizumab (1), herpes zoster infection in RA on adalimumab(1), recurrent otitis in RA on adalimumab(1), mycobacterium *avium* infection in RA on etanercept(1), TB reactivation in RA with GCs and csDMARDs(1) and Papilloma virus infection in SpA on ustekinumab (1).

Table 1. CHARACTERISTICS OF COHORT OF PATIENTS

Sex n % (women/men)	193/93 (67,5/32,5)
Age, years ± DE	61.4 ± 14.4
Diagnoses AIIRD, n (%)	
Rheumatoid arthritis n (%)	164 (57.3)
Systemic lupus erythematosus n (%)	6 (2.1)
Sjögren´s syndrome n (%)	9 (3.1)
Systemic sclerosis n (%)	1 (0.35)
Inflammatory myopathie n (%)	5 (1.7)
Vasculitis n (%)	36 (12.6)
Polymyalgia rheumatica n (%)	4 (1.4)
Spondyloarthropathy n (%)	46 (16.1)
Others n (%)	15 (5.2)
Treatment AIIRD	
GCs n (%)	116 (40.7)
csDMARDs n (%)	149 (52.1)
bDMARDs n (%)	80 (27.8)
tsDMARDs n (%)	7 (2.4)
Others[1] n (%)	12 (4.2)
GCs + csDMARDs n (%)	59 (21)
GCs + bDMARDs n (%)	14 (4.9)
GCs + csDMARDs + bDMARDs n (%)	4 (1.4)
Vaccines	
PCV 13 n (%)	283 (99)
PPSV23 n (%)	265 (93)
HiB n (%)	265 (93)
NM n (%)	247 (86.7)
Influenza n (%)	128 (44.9)
HBV n (%)	121 (42.3)
Vaccination before IS n (%)	41 (14.3)
Vaccination with IS n (%)	244 (85.3)

Other: Behcet,Adult Stills,Relapsing polychondritis,IGg4 related disease,SarcoidosisOthers[1]: Mycophenolic acid,cyclosporine and tacrolimus

Conclusion: In our cohort, the vaccination protocol proved to be a good tool to improve the vaccination rate of rheumatological patients, despite this, the vaccination of Hepatitis B and specially of influenza, continues to have a lower prevalence to general population.The vaccines were effective since none of the preventable infections occurred during follow up, despite the use of an immunosuppressant. Vaccination showed a good safety profile, without reported serious adverse effects or worsening of the underlying disease.

AB0805 A SURVEY OF RHEUMATOLOGY PATIENTS' SATISFACTION TO SWITCHING FROM ORIGINATOR TO BIOSIMILAR AGENTS

C. R. Ng[1], S. Samec[1], P. Kavanagh[1], G. Mccarthy[1], S. Donnelly[1], A. G. Wilson[1]. [1]*The Mater Misericordiae University Hospital, Department of Rheumatology, Dublin, Ireland*

Background: The recent widespread switching of patients with inflammatory rheumatic conditions from originators to biosimilars has largely been driven by costs. The views of patients on switching are also important in the successful long term switching to biosimilars. We conducted a survey of patients views on patients satisfaction with the switch to biosimilar therapy.
Objectives: To assess satisfaction and response after switching from originator (Humira or Enbrel) to biosimilar (Amgevita or Benepali respectively), and to describe efficacy, side effects and reactions to biosimilar.
Methods: All patients diagnosed with an inflammatory arthritis and switched to biosimilar were identified using the Irish national HighTech electronic prescriptions system. Participants had been administered the biosimilar for > 3 months and were invited to take part via a telephone survey. This consisted of 4 questions (Question 1: satisfaction with the response to the new medication [Using 5 point Likert scale = 0: very dissatisfied; 1: dissatisfied; 2: neutral; 3 satisfied;4: very satisfied]; Question 2: overall satisfaction with biosimilar compared to originator if originator was 10 [satisfaction rating from 1 – 10 scale: 1,2: very dissatisfied; 3,4: dissatisfied; 5: neutral; 6,7,8: satisfied; 9,10: very satisfied]]; Question 3: adverse effects with biosimilars; Question 4: opinion on usage of new device [0: very difficult; 1: difficult; 2: same as previous device; 3: improvement compare to previous device).
Results: Baseline characteristics of biosimilar switch patients with disease category were:

Category	(n)
Gender	Male (39), Female (56)
Mean age (years)	56
Rheumatoid arthritis	58
Psoriatic arthritis	18
Ankylosing spondylitis	16
Reactive arthritis	1
Enteropathic arthritis	1
Juvenile idiopathic arthritis	1

48 switched from Humira to Amgevita.

The majority of the patients had positive view towards the effectiveness of the biosimilar: 36% very satisfied; 28% satisfied; 13% neutral; 10% dissatisfied; 13% very dissatisfied.
45% of the patients gave score of 9 and 10 in the survey of overall satisfaction to biosimilar if originator was given a score of 10, followed by 32% of them gave a score from 6 to 8, 4% of the patients gave a score of 5 and 7% of them gave a score of 3 and 4. The rest of them gave a score of 1 and 2.
12 participants switched back to originator (Humira, n=5; Enbrel, n=7) for the reasons of unable to use the device, anxiety, hemoptysis, nose bleeding, tongue swelling, neck pain, lethargy and generalized itchiness.
The most common complaints were (12 patients) systemic side effects (tiredness, headache, nausea, skin rashes, hair loss, muscle ache, tongue swelling, mood swing, dizzy, nose bleed, erectile dysfunction, hypertension, hemoptysis and red sclera).
17% of the patients find the biosimilars device easier to use compare to originator and 55% of the patients find both device are similar. 24% and 4% of them find the new device is difficult to very difficult to use respectively.
Conclusion: 69% of patients from Amgevita group and 60% of patients from Benepali group were satisfied with the change. Only 28% of the patients found the new device difficult to use. Overall conclusion from the study showed less than one quarter of the participants showed dissatifaction towards biosimilar and less than 12 % experienced systemic side effects and whether biosimilar could be a next cost effective biologic therapy to replace originator in future requires a longer duration of study.

AB0806 THE JOURNEY OF AXIAL SPONDYLOARTHRITIS IN SPAIN: FROM THE GENERAL PRACTITIONER TO THE RHEUMATOLOGIST

E. Flores-Fernández[1], C. Valera-Ribera[1], I. Vázquez-Gómez[1], A. V. Orenes Vera[1], E. Valls-Pascual[1], À. Martínez-Ferrer[1], D. Ybáñez-García[1], A. Sendra-García[2], J. J. Alegre-Sancho[1]. [1]*Doctor Peset University Hospital, Rheumatology, València, Spain*; [2]*Doctor Peset University Hospital, Hospital Pharmacy, València, Spain*

Background: The delay in the diagnosis of axial spondyloarthropathies (AxSp), with the morbidity and economic burden that this entails, is well known[1,2]. According to the 2017 Atlas of axial spondyloarthritis in Spain[3], the mean diagnostic delay was 8,5 years, with an average total cost per patient of 659,8€ including medical consultations and complementary tests until diagnosis. However, nowadays there are still many patients who are incorrectly referred from the general practitioner (GP) despite showing typical features of AxSp.
Objectives: To describe the AxSp journey until diagnosis and treatment. To analyze additional costs of either a wrong or a delayed referral of the patients with AxSp to rheumatologists.
Methods: Type of study: observational, retrospective, descriptive. We included all the patients who were referred to our Department of Rheumatology from Jan-2019 to Dec-2020 and whose final diagnosis was AxSp. All the data since the first contact to the GP until the final diagnosis and initiation of treatment in Rheumatology were collected, including consultations to our emergency department (EmD) and other specialists. The number of consultations, complementary tests (analytical and imaging), as well as the direct costs of all of them were also collected4. A descriptive and associative analysis of these data was carried out using the SPSS software. We used median and interquartile range (IQR) for descriptive analysis and a significant p value < 0,05.
Results: From Jan-2019 to Dec-2020, 15 patients with AxSp and a median age of 43 (Interquartile range (IQR) 34-51) years were diagnosed, 10 women and 5 men. The main reason for referral was inflammatory low back pain (66.7%). The 60% of the patients were referred from the GP, followed by the EmD (20%). Despite typical symptoms, 4 patients (26,7%) were initially referred to Traumatology, and 3 out of them returned to the GP without the right diagnosis.
The median delay for referral from the GP to the rheumatologist was 47 (IQR 20-173) days. A wrong referral of the patient was associated with a delayed diagnosis (p 0,018) and higher direct costs of management (p 0,034). The average cost (including medical consultation and complementary tests) of the patient referred directly to Rheumatology was 267,71 (IQR 193,7-462,3) €, while the average cost of patients referred to other specialists was 578,83 (IQR 368,32-898,7) €. The extra cost of a wrong referral of a patient with AxSp was 311€ on average per patient in our sample (Table 1).

Table 1.

Women/men	10/5
Median age (years; IQR)	43; 34-51
Median diagnostic delay (days; IQR)	45; 20-173
Median cost of patient referred initially to Rheumatology (€; IQR)	267,71; 193,7-462,3
Median cost of patient referred initially to another specialist (€; IQR)	578,83; 368,32-898,7
Extra cost of wrong referral per patient(€)	311

Conclusion: AxSp is still a disease with a not negligible diagnostic delay, but it seems to be lower than previously reported. A wrong referral of the patient to other specialists, mainly Traumatology, is associated with this delay and can double the cost of managing these patients. This demonstrates the still unmet need of improving the management and referral of the patients with AxSp from the GP to the rheumatologist, ensuring an early diagnosis and treatment at the lowest cost for the system. Our study has limitations due to its small sample size, but preliminary results indicate that a larger-scale study would be necessary to correctly assess the magnitude of this problem.

AB0807 TOAST-STUDY: TREATMENT AND OSTEOARTHRITIS, WHAT ARE PEOPLE SAYING ON TWITTER?

A. Mouamnia[1], A. Desvages[2]. [1]*Valenciennes Hospital, Rheumatology, Valenciennes, France*; [2]*Lille University Hospital, Rheumatology, Lille, France*

Background: Osteoarthritis is a very common chronic disease. The information needs of patients vary depending on the health issue. Social media sites represent a novel source of health information and advice for patients with chronic diseases, such as osteoarthritis. Almost half of them use the internet to look for health related information **[1]**. No study has assessed the impact of social media on osteoarthritis and its treatment.
Objectives: The purpose of this study was to evaluate frequently discussed osteoarthritis treatments on the social media Twitter.
Methods: We retrospectively analyzed tweets, published between 1st and 31st January 2020, containing the keywords "osteoarthritis". Only English language tweets were included. Tweets referred to veterinary medicine were excluded.
Results: 3587 tweets were analyzed. We identified 1737 tweets related to osteoarthritis treatment between 1st and 31st January 2020 (49.8%) (Figure 1). Dietary interventions were the most discussed treatment (18.3%, n=318/1737), including fruits, vegetables and plants (n=101), dietary supplements and vitamins (n=80), and spices (n=19). Physical medicine and rehabilitation (17.6%, n=305/1737) including sport (n=151), physiotherapy (n=70) and rehabilitation (n=57), were commonly discussed. Local therapies for osteoarthritis were also discussed by Twitter users (15.8%, n=274/1737). These included topical treatments such as anti-inflammatory gels and creams (n=23), and more invasive local treatments including intra-articular joint injections with corticosteroid (n=56), hyaluronans (n=29), stem cells (n=97), and Platelet-Rich Plasma (n=52). The frequently used systemic drugs were analgesia and non-steroidal anti-inflammatory drugs (n=113). Surgery and interventional radiology (genicular artery embolization) were also discussed (11.5%, n=199/1737). 5.6% tweets (n=97/1737) were related to alternative therapies. Predominant themes were related to marijuana (n=23), acupuncture treatment (n=17), homeopathy (n=10). Last but not least, 356 tweets (20.5%) referred to other websites including health programs.
Conclusion: Our results demonstrate that osteoarthritis treatment is frequently discussed in published tweets. Thereby, social media could have an impact on behaviors and adherence on medication, and it seems interesting that learned societies, involved in osteoarthritis treatment, communicate more using social media.

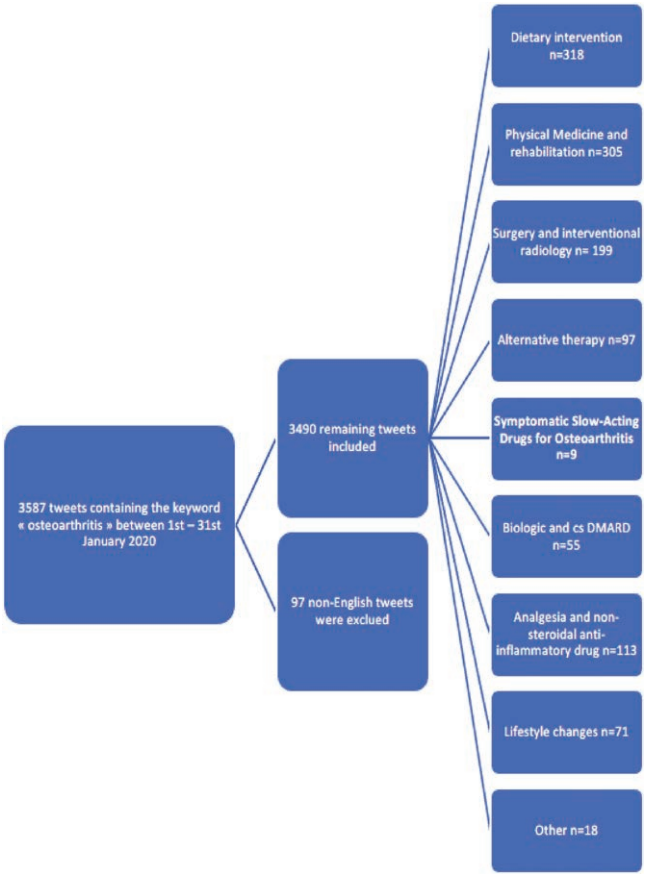

Figure 1. Osteoarthritis treatment discussed in published tweets

A SYSTEMATIC REVIEW ON SYNDEMICS IN RHEUMATIC AND MUSCULOESKELETAL DISEASES (RMDS)

M. F. Ramirez-Flores[1], C. Cadena-Trejo[2], D. Alpizar-Rodriguez[3], V. Fernandez-Garcia[4], A. Gastelum-Strozzi[5], A. Hernandez-Garduno[6], I. Peláez-Ballestas[7]on behalf of Mexican Syndemic Study Group.
[1]Universidad Nacional Autónoma de México, Plan of Combined Studies in Medicine (PECEM-MD/PhD), Mexico City, Mexico; *[2] Universidad Nacional Autónoma de México, Escuela Nacional de Enfermetía y Obstetricia, Mexico City, Mexico*; *[3]Colegio Mexicano de Reumatología, Research Unit, Mexico City, Mexico*; *[4]Escuela Nacional de Enfermería y Obstetricia, Universidad Nacional Autónoma De México, Research Unit, Mexico City, Mexico*; *[5]Instituto de Ciencias Aplicadas y Tecnología, Universidad Nacional Autónoma de México, Scientific and Industrial Instrumentation, Mexico City, Mexico*; *[6]Private Practice, Private Researcher, Mexico City, Mexico*; *[7]Hospital General de México "Dr. Eduardo Liceaga", Rheumatology, Mexico City, Mexico*

Background: Syndemics comprises the interaction of two or more biological diseases in different socio-cultural situations and in the context of varying healthcare standards that exacerbates their deleterious effects on the health of individuals, communities, and societies (1). There is increasing interest in using syndemics in the study of RMDs.
Objectives: To identify quantitative and qualitative RMDs studies focused on syndemics through a systematic review and synthesize the available evidence.
Methods: Inclusion criteria were using a syndemic framework in methods in RMDs studies. A systematic search of studies published from 2003 up to January 2021 was conducted in two electronic databases (SCOPUS and Web of Science). The systematic search was implemented (Figure 1): 1) the word syndemic(s) was searched using the advanced query string search, in the title, abstract, keywords, and text, to identify the relevant studies; 2) the publications were screened by three peer review groups; 3) the group evaluated each title and abstract and reviewed full-text articles to identify those relevant for review; 4) synthesis focused on identifying the variables of each study and integrating findings.
Results: The initial search yielded 658 unique articles, from which ten studies were identified as syndemics in RMDs. After full-text review, six studies were excluded due to not inclusion of a syndemic framework. Four studies were included (Figure 1). The first quantitative study was on eight Latin-American (LatAm) indigenous communities (n=6,155). RMD´s were highly prevalent in the indigenous people (34.5%), RA prevalence was 2.4% in the Qom group of Argentina, and low back pain (LBP) being the most prevalent RMD (13.3%). RMDs were strongly associated with other comorbidities, unhealthy habits, low education levels, rural areas, socioeconomic conditions, and health inequality. The network analysis was the analytical approach using the Syndemic and Syndemogenesis Elements Modeler (SSEM). The second quantitative study focused on six urban/rural LatAm countries (n=55,724). LBP was significantly associated with comorbidities, unhealthy habits, low educational level, rural areas, and indigenous status. SSEM and cluster analysis showed a significant association between LBP prevalence and social variables. One qualitative study in fisher rural families (n=7) with three fisher rural generations from the Netherlands. A case study using life course theory. The first two generation reported syndemic vulnerability (psychological distress, cardiometabolic conditions, or musculoskeletal pain), and the third generation report less syndemic vulnerability, including musculoskeletal pain. A mixed study was identified focused on osteoarthritis with multimorbidities (cardiovascular, hypertension, diabetes mellitus) in an African American population (n=110) in the USA. The methodology was a descriptive secondary analysis and qualitative interviews. The study found that patients with hypertension (80.9%) reported greater chronic pain than those without. The lack of education added to the incorrect use of nonsteroidal anti-inflammatory drugs might contribute to the worst outcomes in this population, a significant burden of cardiovascular disease.
Conclusion: There is growing interest and urge for integrating syndemics in the study of RMDs. This review has demonstrated that there are only a few publications to date. The statistical power and the analytical approach (SSEM-Syndemic and Syndemogenesis Elements Modeler) in the two quantitative studies are relevant. The qualitative study demonstrated less syndemic vulnerability with better health conditions linked to better socioeconomic advantages. The mixed qualitative study did not show a syndemic framework. It is necessary to carry out studies in RMDs from the syndemic perspective to document the complexity of the clinical and social determinants related to these diseases.

AB0809

PADUA PREDICTION SCORE COMBINED WITH SERUM ALBUMIN FOR THE IDENTIFICATION OF VENOUS THROMBOEMBOLISM OF HOSPITALIZED PATIENTS IN THE DEPARTMENT OF RHEUMATOLOGY

Q. Peng[1], L. Long[1], J. Liu[1]. [1]*Sichuan Provincial People's Hospital, Zunyi Medical University, Department of Rheumatology, Chengdu, China*

Background: Venous thromboembolism (VTE) includes thrombotic disease of venous system, but primarily includes lower extremity deep vein thrombosis (DVT) and pulmonary embolism (PE). Population-based epidemiological studies have shown an association between systemic autoimmune diseases and VTE[1]. The Padua prediction score(PPS) is a new 20-point risk assessment model proposed by Professor Barbar et al[2] in 2010. A large number of researches have shown that low serum albumin concentration is associated with an increased risk of VTE [3],but there is a lack of studies on serum albumin in VTE, and there are no reports on PPS in rheumatology inpatients.
Objectives: To investigate the status of VTE in patients in the department of rheumatology, and to explore the value of PPS combined with serum albumin in the identification of VTE in this patient population.
Methods: Baseline data of inpatients in rheumatology department were collected at Sichuan Provincial People's Hospital from September 2018 to September 2020. Occurrence of VTE was compared between high and low risk groups. PPSs were analyzed in VTE and non-VTE patients. Multivariate logistic regression was used to analyze the independent risk factors of VTE. The receiver operating characteristic curve was used to evaluate the probablity of value of rheumatic inpatients with VTE assessed by PPS,serum albumin and PPS with serum albumin. P<0.05 indicates that the difference was statistically significant.
Results: A total of 2282 patients were included in this study, and 50(2.2%) had symptomatic VTE. Among the symptomatic VTE cases,38(1.6%) had DVT only,8(0.4%) had PE only, and 4(0.2%) were diagnosed with DVT and PE. PPSs in VTE and non-VTE groups were 3.00(2.00~6.00) and2.00(1.00~2.00) respectively (P< 0.05). One hundred and eighty-eight cases was divided into high-risk group of VTE (PPS≥4), while 2094 cases (PPS<4) were in the low-risk group. Logistic regression analysis showed that known thrombophilic condition, history of VTE, reduced mobility, and D-dimer were independent risk factors of VTE in rheumatology patients, the odd ration(OR) values were 161.90, 26.08, 8.73,and1.04. Serum albumin was the independent protection factor [OR= 0.92(95%CI:0.87~0.98)]. The AUC of PPS model, serum albumin model and the combined predictive model were 0.77, 0.75, 0.84, respectively. The difference between the combined prediction model and PPS model was statistically significant (Z=3.813, P<0.05). The optimal sensitivity of PPS and serum albumin models is 60%, 82%, respectively, and the optimal specificity of is 82.5%,58.6%, respectively. The combination model corresponds to a sensitivity of 62% and a specificity of 90.4%.
Conclusion: The incidence of symptomatic VTE was relatively higher in hospitalized patients in rheumatology department. Serum albumin was the protective factor. The combination of albumin and PPS can improve the accuracy of screening for VTE in rheumatology in-patients.

AB0810

COST-EFFECTIVENESS ANALYSIS OF THE CLINICAL APPROACH FOR RA PATIENTS IN THE EARLY PHASE VERSUS THOSE IN THE ESTABLISHED PHASE FROM A FOURTH-LEVEL HEALTH SERVICE PROVIDER INSTITUTION IN COLOMBIA

C. Sarmiento Peña[1], G. Quintana Lopez[2,3,4], J. A. Díaz[1]. [1]*Universidad Nacional de Colombia, Farmacia, Bogotá, Colombia*; [2]*School of Medicine - National University of Colombia, Reumavance Research Group. Internal Medicine Department, Bogotá, Colombia*; [3]*Fundacion Santa Fe de Bogota University Hospital, Reumavance Research Group, Internal Medicine Department, Bogotá, Colombia*; [4] *School of Medicine - Universidad de Los Andes, Reumavance Research Group, Internal Medicine Department, Bogota, Colombia*

Background: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease that without treatment causes disability, pain, quality of life impairment, and premature mortality. It causes significant economic repercussions on patients, their families, and the health system. The costs of RA for Sanitary Systems are described in terms of medications and hospitalization. Also, the cost of treatment for patients whose disease was not adequately controlled from an early stage may involve joint replacement surgery and prolonged hospitalizations.
Objectives: To determine and analyze the cost-effectiveness of the clinical approach to rheumatoid arthritis in a cohort of patients in the early phase *versus* a cohort of patients in the established phase from a fourth-level Health Service Provider Institution in Colombia, from the perspective of the third-party payer with a time horizon of six-months.
Methods: An economic evaluation of the cost-effectiveness of the clinical approach was carried out in the early phase *versus* the established phase in a cohort of patients from May 2013 until December 2018, with rheumatoid arthritis from a fourth-level Health Service Provider Institution in Colombia, from the perspective of the third-party payer with a time horizon of six-months. The costs and effectiveness of each of the phases were estimated. A decision tree model was created, and the incremental cost-effectiveness ratio was calculated. The deterministic and probabilistic sensitivity analysis was performed.
Results: The early phase clinical approach for patients with rheumatoid arthritis represents savings of approximately 600 USD per patient in remission or low disease activity level in the first 6 months of follow-up from the perspective of the third-party payer.
Conclusion: The clinical approach to rheumatoid arthritis in the early phase is a less costly and more effective alternative *versus* established phase and generates savings for the third-party payer with a time horizon of six-months.

Objectives: The aim of this study was to calculate direct costs amount in rheumatoid arthritis (R.A) patients in the Moroccan register of biologicals RBSMR registry.
Methods: Patients in the Moroccan register of biologicals RBSMR registry with available 1-year data were included. Variables related to socio-economic status, disease and biological therapy were collected. Direct costs included prices of biologics, costs of infusions, and subcutaneous injections. Biologic use and costs were compared.
Results: 197 patients data (female sex (86,8%), mean age (52,3± 11 years), illiteraty (45,7%)) were analyzed. The median annual direct costs per patient were €1,665 [€1,472 - €9,879]. For all patients, the mean annual direct costs per treated patient for each biological agent is presented in Figure 1.
The total annual direct costs of biological agents in the RBSMR registry were 978 494 €. Rituximab was given to 67% of patients and constituted 25.7% of the total annual budget. TNF-blockers and Tocilizumab were prescribed in 14.2% and 18.8% of cases and represented respectively 27.3% and 47% of this overall budget.

Conclusion: This study presents a global overview of the direct costs of biological therapy associated with RA patients, taking as a source the Moroccan registry of biological therapies in rheumatic diseases. Those results show that overall cost of biological agents according to the Moroccan register is very high. There is a real need for development of strategies for better governance of those costs.

BIOMARKERS FOR CONNECTIVE TISSUE DISEASE-ASSOCIATED INTERSTITIAL LUNG DISEASE: A PILOT STUDY

Y. H. Chiu[1,2], M. Voortman[3], E. M. Delemarre[4], S. Nierkens[4], P. De Jong[5], F. Mohamed Hoesein[5], J. M. Van Laar[1], J. Spierings[1]. [1]*University Medical Centre Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands*; [2]*National Defense Medical Center, Division of Rheumatology/Immunology/Allergy, Taipei, Taiwan, Republic of China*; [3]*University Medical Centre Utrecht, Department of Heart and Lung, Utrecht, Netherlands*; [4]*University Medical Centre Utrecht, Center for Translational Immunology, Utrecht, Netherlands*; [5]*University Medical Centre Utrecht, Department of Radiology, Utrecht, Netherlands*

Background: Connective tissue disease (CTD)-associated interstitial lung disease (ILD) has high morbidity and increased mortality risk. Biomarkers that can predict prognosis and response to therapy have been studied in recent years, including cytokines, chemokines, adhesion molecules, growth factors, extracellular remodelling molecules and pneumocyte associated proteins. However, there is still a knowledge gap for interpreting biomarkers in the context of imaging and response.
Objectives: The aim of our study was to identify biomarkers that are associated with inflammatory and fibrotic changes over time on high-resolution computed tomography (HRCT) and response to treatment in CTD-ILD.
Methods: An exploratory set of 38 biomarkers were measured in serum of patients with CTD-ILD using a multiplex immunoassay, chemiluminescence enzyme immunoassay and enzyme-linked immunosorbent assay. Samples were taken at baseline and one year of follow-up. Clinical data was extracted from electronic medical patients records. Two experienced chest radiologists independently and blindly reviewed the HRCTs. A third expert reviewed the scan in case of discrepancies. They classified ILD patterns according to the classification for idiopathic interstitial pneumonia and categorised into fibrotic or inflammatory. Association between biomarkers at baseline and pulmonary function test (PFT) and HRCT changes in response to treatment were analysed by logistic regression. Responsiveness of biomarkers to treatment was determined using the paired Wilcoxon sign rank test. Correlations between the variation of biomarkers and PFT after one year of treatment were examined using Spearman's rank correlation coefficient.
Results: Sixteen patients were included (12 females (75.0%), median age 51 years (IQR 45–62). Underlying CTDs were systemic sclerosis (n=5), Sjogren's syndrome (n=1), inflammatory myopathies (n=6), rheumatoid arthritis (n=1), systemic lupus erythematosus (n=1), mixed connective tissue disease (n=1), and undifferentiated connective tissue disease (n=1). There were three patients with a fibrotic HRCT pattern and 13 patients with an inflammatory HRCT pattern.
Biomarkers attenuation in CXCL11, CTGF, and KL-6 were associated with inflammatory HRCT patterns as well as less HRCT progression and fewer FVC decline. Furthermore, a decrease in CTGF was observed in patients treated with MMF and corticoids, while a reduction in CXCL11 and SPD were seen in patients treated with hydroxychloroquine. (Table 1) Additionally, an increase in levels of galectin-3 at one-year follow-up was associated with improved predicted FVC (Rho 0.5, p=0.048). (Figure 1)

Table 1. Biomarker responses to clinical treatment

Treatment	Biomarkers	Baseline, Median (IQR)	Follow up, Median (IQR)	Variation percentage	p
MMF	CTGF (pg/ml)	110.69 (63.21–158.06)	4.73 (4.73–45.3)	-95.73	0.036
(n=7)	sVCAM (pg/ml)	2061300 (1939200–3042250)	1767600 (1707100–1986350)	-14.25	0.031
HCQ	CXCL11 (pg/ml)	699.30 (392.50–764.50)	333.39 (223.1–487.92)	-52.33	0.031
(n=6)	SPD (ng/ml)	18.70 (13.40–28.73)	16.80 (11.70–22.80)	-10.16	0.031
Steroid	CTGF (pg/ml)	81.93 (20.80–158.06)	12.76 (4.73–56.74)	-84.43	0.044
(n=11)	MMP-7 (pg/ml)	3146.3 (1779.7–3997.0)	4563.3 (2951.9–7625.8)	45.04	0.005

IQR, interquartile range; MMF, mycophenolate mofetil; HCQ, hydroxychloroquine; CTGF, connective tissue growth factor; sVCAM, soluble vascular cell adhesion molecule-1; SPD, surfactant protein D; MMP-7, matrix metalloproteinase 7.

Conclusion: In this pilot study, CXCL11, CTGF, and KL-6 reduction were associated with inflammatory HRCT patterns and better pulmonary outcome. In contrast to previous research in severe ILD, there was a positive correlation between changes of Galectin-3 and FVC in our study. Further research in a larger group and focusing on combining biomarkers to predict outcome and prognosis are needed.

AB0813 DEVELOPING SARCOPENIA IS A RISK FACTOR FOR FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS: 4-YEAR DATA FROM THE CHIKARA STUDY

Y. Yamada[1], M. Tada[2], K. Mandai[3], N. Hidaka[2], H. Nakamura[1]. *[1]Osaka City University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka City, Japan*; *[2]Osaka City General Hospital, Department of Orthopedic Surgery, Osaka City, Japan*; *[3] Saiseikai Nakatsu Hospital, Department of Orthopedic Surgery, Osaka City, Japan*

Background: Patients with rheumatoid arthritis (RA) tend to have sarcopenia due to decreased muscle mass and function. We previously reported that 13.2% of RA patients without sarcopenia at baseline developed sarcopenia over a year using data from the prospective, observational CHIKARA study1.

Table 1. Characteristics of 77 RA patients by sarcopenia status at baseline and at 4-year follow-up.

fracture, %	14.6	83.3	20.0	23.1	0.002

Data are shown as mean ± standard deviation (SD) or median (25th, 75th percentile).GC: glucocorticoids, BMI: body mass index, SMI: skeletal muscle mass index, BMR: body metabolization rate.

Objectives: The aim was to investigate sarcopenia status and the characteristics of RA patients longitudinally.
Methods: Body composition, laboratory data, disease activity, physical function, treatment, and history of falls and fractures were investigated in 100 RA patients who participated in the CHIKARA study at baseline and at 4 years. The patients were divided into 4 groups depending on their sarcopenia status: no sarcopenia development (N group), sarcopenia development (S group), cured (C group), and persisted (P group).
Results: Of the 77 RA patients who completed the survey, 48 were in the N group; their body mass index, skeletal muscle mass index, fat percentage, estimated bone mass, and body metabolization rate at baseline were significantly elevated. On the other hand, 6 patients were in the S group; 83.3% of them experienced fractures during the 4 years, significantly more than in the other groups. Ten patients were in the P group, and their baseline MMP-3 was significantly higher than in the other groups. Thirteen patients were in the C group. There were no differences among the 4 groups in disease activity and physical function (Table 1).

Conclusion: Overall, 7.8% of RA patients developed sarcopenia during the 4-year follow-up period, and they developed fractures more frequently. Evaluation of sarcopenia is important for risk assessment of fractures.

AB0814 PREGNANCY COURSE ASSESSMENT IN PATIENTS WITH RHEUMATIC DISEASES COMPARED TO CONTROLS

O. Hamdi[1], M. Sellami[1], M. Yasmine[1], A. Fazaa[1], S. Miladi[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. *[1]Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia*

Background: Rheumatic diseases such as rheumatoid arthritis (RA) and spondyloarthritis (SA) may occur among women of childbearing age. Adverse events during pregnancy including disease flare, preterm delivery, and neonatal or fetal death have been reported.
Objectives: Our aim was to assess the impact of rheumatic diseases on the course of pregnancy.
Methods: We conducted a cross-sectional study involving patients with RA (2010 ACR/EULAR criteria) and SA (2009 ASAS criteria) (study group) as well as healthy controls (control group) matched by age and gender. All women included had at least one pregnancy. Data were collected through telephonic interviews. We used the Student t test to compare the study group and the control group.
Results: We enrolled 57 patients (30 RA and 27 SA) and 57 controls. The mean age in the study and the control groups were respectively 43.2 ± 8.2 years [26-48] and 37.5 ± 6 years. The mean chronic inflammatory rheumatisms duration was 13.81 ± 6.2 years. A history of primary sterility was found in 3 patients (1 RA and 2 SA) and none in the control group. The mean age during the first pregnancy was significantly higher in the study group (28 ± 6.2 years versus 24 ± 7 years in the control group) (p=0.01). Eight patients (5 RA and 3 SA) had a history of spontaneous miscarriage. A terminated pregnancy was noted in 3 patients (1 RA and 2 SA). Complications during pregnancy in the study group were gestational diabetes (0.3%), premature delivery (0.3), premature rupture of membranes (0.3%), abortion threat (0.3%) and pre-eclampsia (6%). Pregnancy was more associated with complications in the study group (p=0.05). Cesarean section was more used in the study group (28 patients versus 9 in the control group; p= 0.00). The main indications of cesarean section in the study group were macrosomia (11 patients), scar uterus (6 patients), sacroiliitis (4 SA patients), twin pregnancy (2 patients), and undetermined reasons (6 patients). Fetal presentation in the study group was the seat presentation (3%), top presentation (4%), face (2%), and forehead presentation (0.3%) with no significant difference with the control group. Complications of childbirth in the study group were hemorrhage of delivery (10.3%), cord widening (6.6%), perinatal asphyxia (4.9%), and dystocia (1.9%). However, no statistically significant differences were found between the two groups in the prevalence of complications of childbirth. During pregnancy, 5 patients were on salazopyrine, 2 on corticosteroids and, 1 on non-steroidal anti-inflammatories.
Conclusion: Our study showed that pregnancies with rheumatic diseases were at increased risk of having maternal complications and adverse neonatal outcomes.

AB0815 FIRST DEGREE RELATIVES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS - CLINICAL, SEROLOGICAL AND IMMUNOLOGICAL CORRELATIONS

B. Penev[1], G. Vasilev[2], D. Kyurkchiev[3], S. Monov[4]. [1]*St Anna University Hospital, Internal Medicine, Sofia, Bulgaria*; [2]*St. Ivan Rilski University Hospital, Laboratory of Clinical Immunology, Sofia, Bulgaria*; [3]*St. Ivan Rilski University Hospital, Laboratory of Clinical Immunology, Sofia, Bulgaria*; [4]*St. Ivan Rilski University Hospital, Rheumatology Clinic, Sofia, Bulgaria*

Background: Antinuclear antibodies (ANA) have been unequivocally recognized as essential for diagnosis and play both pathogenic and diagnostic roles in systemic lupus erythematosus (SLE). SLE and ANA have also been found to be more often among relatives of SLE patients. ANA and other immunological changes are known to appear prior to the clinical onset of the disease and thus can be used as predictors. Studies have reported that relatives of SLE patients who later transitioned to SLE displayed more lupus-associated autoantibody specificities and had early clinical signs. They also displayed elevated baseline plasma levels of inflammatory mediators, including B-lymphocyte stimulator (BLyS) and interferon-associated chemokines, with concurrent decreases in levels of regulatory mediators, e.g. tumor growth factor (TGF)-β. Commonly recognized risk factors for SLE are signs of past Epstein-Barr (EBV) infection, use of estrogen drugs and current smoking. It seems that ANA, immunologic changes and risk factors have not been investigated together in relatives of SLE patients.
Objectives: The aim of the study was to determine the relative prevalence of clinical signs of SLE or connective tissue disease (CTD), smoking, use of estrogen drugs and levels of circulating ANA, BLyS, IFN-α, TGF-β, anti-EBV viral capsid antigen (VCA) IgM and IgG antibodies among sera of FDR, non-FDR healthy individuals and SLE patients.
Methods: Forty three FDRs of SLE patients were studied along with 15 SLE patients and 15 clinically healthy subjects as control groups. The FDRs and the healthy answered a questionnaire about early clinical signs of CTD, smoking and estrogen use history. The questionnaire was developed based on the existing Screening Questionnaire for Connective Tissue Diseases and current knowledge of most early signs of CTD. Blood samples were obtained and tested for ANA, both by indirect immunofluorescence and immunoblot, anti-dsDNA by ELISA. ELISA was also performed to measure levels of BLys, IFN-α, TGF-β, anti-EBV IgM and IgG.
Results: More than half of the FDRs displayed ANA in titer 1:160 or more, with predominately AC-4 type of fluorescence according to International Classification on ANA Patterns (ICAP) compared to only AC-1 and AC-0 among patients and controls respectively. A correlation between the ANA titer and the number of complaints was found. This was particularly valid or reported skin complaints and oral ulcers which appeared more frequently when ANA was 1:320 or above (p=0,018 and 0,038 respectively). Furthermore, oral ulcerations showed positive correlation with the presence of anti-Ro60. No associations were found in the healthy group between reported complaints and ANA titers. Smoking and estrogen use did not differ across the three groups. Patients showed significant differences in levels of BLys (p=0,027), TGF-β (p=0,019) and anti-EBV IgG (p=0.041) compared to both FDRs and controls. Without reaching statistical significance, levels of TGF-β tend to split the FDR group into "healthy-like" and "SLE-like".
Conclusion: Our results show that FDR ANA levels are between those of SLE patients and healthy subject groups. This is consistent with previous studies. The data also suggest that ANA positivity correlates with reported complaints, some of which could be interpreted as very early clinical signs of SLE. Of note, anti-Ro60 is known to be among the earliest ANA that appear in "future" SLE patients and in this study they are related to oral complaints that could be caused by early sicca phenomena. Immunologically, our data support previous findings [1] that the FDRs are a heterogenic group with different "lupus-developing" potential.

AB0816 PREDICTORS OF RESPONSE TO THE FIRST BDMARD IN BIOLOGIC-NAÏVE PATIENTS WITH SPONDYLOARTHRITIS: A COHORT STUDY

B. M. Fernandes[1], S. Garcia[1], F. Oliveira Pinheiro[1], M. Rato[1], D. Fonseca[2], D. Santos Oliveira[1,3], A. Martins[1], F. R. Martins[4], M. Bernardes[1,5], L. Costa[1]. [1]*Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal*; [2]*Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal*; [3]*Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; [4]*Centro Hospitalar Universitário do Algarve, Rheumatology, Faro, Portugal*; [5]*Faculty of Medicine, University of Porto, Departamento de Medicina, Porto, Portugal*

Background: Several markers of response to biologic disease-modifying antirheumatic drugs (bDMARDs) have been identified in Rheumatoid Arthritis. However, data on predictors of response in Spondyloarthritis (SpA) are more limited.
Objectives: To identify predictors of response to bDMARDs in a SpA population.
Methods: Monocentric retrospective study including all the SpA patients (ASAS classification criteria) followed at our Rheumatology Department, registered in the national database and treated with bDMARD between July 2001 and August 2020. Demographic, clinical and laboratorial data at baseline and disease activity measures at 6 and 12 months of bDMARD were collected. Mann-Whitney U test and chi-square tests were used to the comparison analysis between groups (continuous and categorical variables, respectively) and univariate logistic regression was used in the prediction analysis.
Results: A total of 325 patients were included, 178 (54.8%) males, 76 (23.4%) smokers and 164 (50.5%) HLA-B27 positive. Concerning SpA subtypes: 236 (72.6%) had Ankylosing Spondylitis, 31 (9.5%) had Inflammatory Bowel Disease Associated SpA and 58 (17.9%) had Undifferentiated SpA. The mean age at the start of the first bDMARD was 41.7 years (±12.2) and the median disease duration was 12.1 years (0.5-52.7). The mean ASDAS-CPR (Ankylosing Spondylitis Disease Activity Score with C-reactive protein) was 4.0 (±0.8) and most patients (57.2%) exhibited very high disease activity at baseline as evaluated by ASDAS-CRP. Ninety-five (29.2%) patients were taking NSAIDs (nonsteroidal anti-inflammatory drugs) and 131 (40.3%) were under csDMARDs (conventional synthetic disease-modifying antirheumatic drugs), being sulfasalazine the most frequent (28.3%). All patients started iTNF (tumor necrosis factor inhibitors): adalimumab (30.2%) and golimumab (24.6%) were the most frequently started bDMARDs.
At 6 and 12 months of bDMARD, 63.5% and 65.7% of the patients had ASDAS response (clinically important improvement or major improvement). Variables that showed statistically significant differences at baseline between those different groups are presented at Table 1.

Table 1. Baseline characteristics that showed statistically significant differences at baseline between groups of patients with vs without ASDAS responses at 6 and 12 months of bDMARD. (bDMARD: biologic disease-modifying antirheumatic drug; BMI: body mass index; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate).

	ASDAS response at 6 months			ASDAS response at 12 months		
	yes	no	p-value	yes	no	p-value
Age at start of bDMARD (mean±SD)	39.6±12.2 years	44.2±10.7 years	p=0.012	40.7±12.8 years	44.2±10.9 years	p=0.035
Age at SpA diagnosis (mean±SD)	32.2±11.1 years	35.8±11.9 years	p=0.023	31.3±10.7 years	35.4±11.2 years	p=0.010
BMI (mean±SD)	25.7±4.3 kg/m^2	28.7±6.0 kg/m^2	p=0.045	25.6±4.3 kg/m^2	28.5±5.7 kg/m^2	p=0.005
CRP (mean±SD)	3.2±3.5 mg/dL	1.1±1.2 mg/dL	p<0.001	3.4±3.5 mg/dL	1.4±1.6 mg/dL	p<0.001
ESR (mean±SD)	36±22	25±20	p<0.001	38±24	27±17	p=0.001
ASDAS-CRP (mean±SD)	4.1±0.8	3.5±0.4	p<0.001	4.2±0.8	3.6±0.8	p<0.001
HLA-B27+	61.5%	26%	p=0.006	60.1%	44.4%	p=0.033
Males	62.3%	35.7%	p=0.004	62.3%	37.5%	p=0.001

Body mass index (BMI) (OR 0.89 [0.80-0.99], 95% CI) and ASDAS-CRP at baseline (OR 2.8 [1.2-6.6], 95% CI) predicted ASDAS response at 6 months; moreover, only BMI (OR 0.91 [0.83-0.99], 95% CI) predicted ASDAS response at 12 months of bDMARD.

Conclusion: Our results demonstrate that a higher baseline disease activity predicts the response to bDMARDs in SpA. Interestingly, BMI at baseline also predicts ASAS response at 6 and 12 monthes of treatment with bDMARD, in line with some data that suggest an association between BMI and disease activity in SpA.

AB0817 CAN RHEUMATIC CONDITIONS ASSOCIATED INTERSTITIAL LUNG DISEASES BE MANAGED IN A DISTRICT GENERAL HOSPITAL – RESULTS FROM A LONGITUDINAL OUTCOMES SURVEY

A. Francioni[1], J. Gnanapragasam[1], N. Ramsundar[1], V. Joshi[1], M. K. Nisar[1]. [1]*Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom*

Background: Interstitial lung disease is a well described extra-articular manifestation in a range of rheumatic diseases. It carries significant morbidity and mortality. Management of rheumatic diseases associated ILD (r-ILD) requires expertise as the needs of such patients are complex and treatment options limited. Historically, such complex ILD has been managed in tertiary referral centres. We set up a combined service incorporating both rheumatology and respiratory domains in a district general hospital (DGH) to help patients avoid long journeys and improve their experience whilst focusing on an integrated care pathway.
Objectives: We evaluated the outcomes of all patients managed over three years in this pilot service model.
Methods: Referrals were accepted from any hospital specialist involved in the management r-ILD. They were triaged by lead ILD pulmonologist to monthly ILD MDT comprising a rheumatologist, respiratory physician, a radiologist and ILD specialist nurse. Appropriate patients were booked into combined clinic, run by the respective rheumatology and chest specialists with ILD interest, attracting a multi-speciality tariff. All the data was recorded electronically with full access to demographics, disease parameters, investigations and drug management.
Results: 111 consecutive patients were included in this evaluation. Mean age was 66.4 yrs (19-92 yrs) and 36% (n=40) were male. 34 (30%) had RA, 31 (28%) had CTD, 20 (18%) had IPAF and 26 others. Most predominant HRCT pattern was NSIP (n=40,36%) followed by UIP (n=31, 28%). Mean FVC was 2.59 L/min (1.93-4.13) with DLCOc of 52.7% (28.9-90.1%) predicted. Only two patients had all antibodies negative whilst 109 had at least one antibody positive with ANA being the most common (n=38).
Most (83%) patients were treated with immunomodulators including 11 with rituximab. 49 (44.1%) patients had significant improvement in clinical, imaging and pulmonary parameters with DLCOc improving to 56.57% and FVC to 2.70 L/min. There were similar improvements in six minute walk test. 21 patients died and 23 patients required long term oxygen therapy.
Conclusion: This pilot real world study confirms the utility of a combined specialist service in a district general hospital. Nearly half of this complex and resource intensive patient cohort had good clinical outcomes and derived benefit from the expertise in one room. Feedback from both patients and referrers was unanimously positive. No patient required tertiary centre referral and all could be managed adequately in the clinical setting.
Our report confirms that r-ILD can be managed in a DGH setting with a stream-lined service offering clear benefits to patients. We would argue that r-ILD service, congruent to satellite pulmonary hypertension clinics in secondary care with hub-and-spoke model liaison with tertiary centre, can be established on similar principles and could help over-stretched tertiary care with repatriation of services whilst helping develop local expertise in the management of chronic ILD.

AB0818 ADVERSE EVENTS UNDER B-CELL DIRECTED THERAPIES IN A LARGE SINGLE-CENTER COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS, SYSTEMIC LUPUS ERYTHEMATOSUS, ANCA-ASSOCIATED VASCULITIS AND RENAL DISEASES

J. G. Rademacher[1], V. Korendovych[1], P. Korsten[1]. [1]*Universitätsmedizin Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany*

Background: The anti-CD20 antibody rituximab (RTX) is approved for the treatment of rheumatoid arthritis (RA) and ANCA-associated vasculitis (AAV). In addition, RTX is used in a wide range of autoimmune diseases. Belimumab (BEL) is an anti-BAFF antibody approved for the treatment of non-renal systemic lupus erythematosus (SLE) in Europe. These agents are generally well-tolerated but severe adverse events (AEs) can occur. The frequency of and factors associated with AEs are currently unknown.
Objectives: To identify adverse events with the use of B-cell directed therapies in a large population of RA, AAV, and SLE.
Methods: This is a single-center retrospective cohort study using routine clinical data over a ten-year period (2010-2020). We recorded epidemiological and clinical data of patients receiving either BEL or RTX. Data included age, gender, type of disease, number and efficacy of infusions, patient-years and concomitant treatment. Patient records were screened for AEs, such as infections, anaphylaxis, occurrence of malignant disease, laboratory abnormalities and immunoglobulin (Ig) deficiency. Between group comparisons were performed.
Results: Database screening yielded 445 patients treated with RTX and 23 with BEL. After exclusion of patients with incomplete data, 425 RTX and 23 BEL patients were analyzed.
Our preliminary analysis of a sample of 60 of these 448 patients (184 patient-years) resulted in 43 patients (72%) with RA, 8 patients with AAV (13%), 5 patients with a renal disease, and 4 patients with mixed connective tissue disease, as well 23 SLE patients. 46 (77%) were female. In RA, a median of 13 treatments of 1000 mg were administered, corresponding to 3.37 patient-years per patient. Primary non-response occurred in 2 patients, secondary non-response in 13 patients. For AAV, a median of 8.4 treatments were given (3.3 patient-years), no treatment failure was detected. SLE patients received a median of 15 treatments.
15 patients had infectious complications during treatment, 11 needed treatment. Herpes zoster infection occurred in 3 patients with RA. Three of the 8 patients with AAV had an infection requiring treatment. In SLE patients, only 2 developed infectious complications, and no Ig-deficiency occurred.
Lymphopenia was the most common laboratory abnormality detected in 25 patients with RTX, 19 of whom had RA. Ig deficiency was common in RA, affecting 30% of patients. Deficiency of IgM and IgG was recognized in 5 patients each; 1 patient had low levels IgA.
Neither the maintenance prednisolone dosage nor Ig deficiency were associated with risk for infection. However, lymphopenia appeared to be associated with risk for infection.
Conclusion: Our preliminary data observe a 184 patient-year period. RTX and BEL were generally associated with few AEs. RA patients frequently had laboratory abnormalities (lymphopenia, Ig-deficiency) which did not necessarily translate to clinical events. Infections were more common in AAV, BEL was the best tolerated B-cell directed agent. Overall, our data are reassuring, but we suggest a more careful vigilance in AAV patients.

AB0819 PROFILE OF RHEUMATOLOGIC EMERGENCIES IN THE DEPARTMENT OF RHEUMATOLOGY OF THE UNIVERSITY HOSPITAL OF IBN ROCHD IN 2019

Z. El Ouali[1], S. Lahrichi[1], R. Assadi[1], K. Nassar[1], S. Janani[1]. [1]*University Hospital of Ibn Rochd, Department of Rheumatology, Casablanca, Morocco*

Background: Rheumatology is a medical field often referred to as "cool" because of the low frequency of life-threatening pathologies in common practice (1). However, rheumatologists may be solicited to manage situations that are often depicted as urgent from the point of view of the patient.
Objectives: To profile the consultations received in the emergency unit of the Department of Rheumatology of the University Hospital of Ibn Rochd in Casablanca.
Methods: We conducted a retrospective study on the 2019 emergency consultations register of the Department of Rheumatology of the University Hospital of Ibn Rochd, Casablanca. We collected epidemiological, clinical, and therapeutic data.
Results: 407 emergency consultations were carried out in 2019. The average age of the patients was 50.7 (range 14 - 88). 20% of the consultants were 65 years old or older. The sex ratio M/F was 0.4. 95.6% of the patients were from the Casablanca-Settat region. 86.4% of the patients came from the emergency department of the hospital, 10.6% came from other intra-hospital services, and 3% were referred directly to our department. The most represented socio-professional categories were respectively people without professional activity other than retirees (67.6%), followed by intermediate professions (9.7%), executives and higher intellectual professions (5.8%), and retirees (5.3%). Regarding social insurance, 49.4% of the consultants benefited from a public health assistance scheme, 30% had a public health insurance, 14.4% had no health insurance, and 9.9% had a private health insurance. The most frequent reasons for consultation were polyarthralgia (26.8%), oligoarthralgia (18.9%), low back pain (22.6%), lumbar radiculalgia (16.7%), monoarthralgia (11,8%), neck pain (8.1%), cervicobrachial neuralgia (6.4%), monoarthritis (5.4%), polyarthritis (3.4%), and oligoarthritis (2,7%). The general condition of the patients was good in 83% of cases, 5.2% had asthenia, 4.4% had a fever above 38°C, and 3.7% had anorexia. Extra-articular signs were present in 24.7% of cases. At the end of the consultation, a diagnosis could be made in 57.2% of cases. The diagnoses comprised degenerative (51%), inflammatory rheumatic (8.6%), infectious (7.3%), metabolic (6.7%), and tumor (2.1%) pathologies. The main treatments prescribed were level 1 analgesics in 65.6% of cases, non-steroidal anti-inflammatory drugs in 45% of cases, local treatment in 28.9% of cases, symptomatic slow-acting drugs in 21.9% of cases, muscle relaxants in 17% of cases, rest in 12.5% of cases, and supportive orthotics in 11.6% of cases. Regarding the outcomes of the consultants, 75.4% were referred to a conventional hospital

consultation for rheumatology follow-up, 13.6% of patients were referred to other specialized departments, 9.1% of patients were lost to follow-up, and 3.9% were hospitalized in our department.

Conclusion: The polyarthralgia and the low back pain were the most frequent reasons for consultation in our rheumatology emergency unit. Degenerative pathology is in the lead of the etiologies. Level I analgesics and non-steroidal anti-inflammatory drugs play an important role in symptomatic emergency treatments.

Background: ANCA associated vasculitides (AAV) are a heterogeneous group of rare diseases with unknown etiology and the broad clinical spectrum ranging from life-threatening systemic disease, through single organ involvement to minor isolated skin changes. Unfortunately the clinical classification, ANCA specificity or genetic characteristics alone is not able to categorize AAV patients in a satisfactory manner. As a consequence advanced statistical techniques were used to identify and stratify AAV subphenotypes [1, 2]. Here we have analyzed influence of the ANCA type on clinical manifestations and demographic characteristics in various types of AAV, based on data from the POLVAS registry

Objectives: We decided to retrospectively analyze a large cohort of Polish AAV patients deriving from several referral centers – members of the Scientific Consortium of the Polish Vasculitis Registry (POLVAS) – and concentrate on demographic and clinical characteristics of anti-PR3 and anti-MPO positive patients regardless of their clinical diagnosis.

Methods: We conducted a systematic multicenter retrospective study of adult patients diagnosed with AAV between Jan 1990 and Dec 2016. Patients were enrolled by 9 referral centers. We analyzed dichotomous variables: gender; ANCA status – anti-PR3+ or anti-MPO+, ANCA negative; organ involvement - skin, eye, ENT, respiratory, heart, GI, renal, urinary, CNS, peripheral nerves and polytomous variable (number of relapses), supported by quantitative covariates (e.g., age at diagnosis, CRP at diagnosis, maximal serum creatinine concentration ever)[3].

Results: MPO-positive patients (both GPA and EGPA phenotype) were older at the time of diagnosis with a substantial percentage diagnosed > 65 years of age, and with high rate of renal involvement. Interestingly, while in the whole group of patients diagnosed with EGPA male to female ratio was 1:2, the MPO+ EGPA patients showed M:F ratio of 1:1.

The analysis of ANCA negative AAV reveled significant differences in GPA, ANCA negative group is characterized with significantly lower frequency of renal involvement compared to rest GPA (11,5% vs 63,7%) p<0,05 what should be emphasized ANCA negative AAV never lead to ESRD (end stage renal disease) or even transient dialysis.

Conclusion: ANCA specificity is indispensable as a separate variable in any clinically relevant analysis of AAV subcategories. MPO+ group is characterized by older age at time of diagnosis, male to female ration 1:1, kidney involvement, and shows more homogenous clinical phenotype than PR3+ AAV patients. In our group ANCA negative AAV never lead to ESRD (end stage renal disease) or even transient dialysis.

AB0821 PSYCHOMETRIC PROFILE OF PATIENTS WITH CHRONIC INFLAMMATORY ARTHRITIS

G. L. Fonti[1], M. S. Chimenti[1], P. Conigliaro[1], P. Triggianese[1], E. Bianciardi[2], G. Tarantino[2], M. Coviello[2], G. Lombardozzi[2], C. Niolu[2], A. Siracusano[2], R. Perricone[1]. *[1]University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Department of Systems Medicine, University of Rome Tor Vergata, Rome, Italy, Rome, Italy*; *[2]University of Rome Tor Vergata, Psychiatric Chair, Department of Systems Medicine, Rome, Italy*

Background: Psoriatic Arthritis (PsA) is a chronic inflammatory disease characterized by a condition of inflammation of joint and periarticular tissues with progressive destruction of bone and cartilage tissues and consequent disability. Numerous studies suggest that the systemic inflammation that characterizes this disease is the basis of the onset of numerous comorbidities, including anxiety and depression.

Objectives: This prospective study aims to examine the psychometric profile of patients with chronic inflammatory arthritis to investigate possible correlations with psychiatric comorbidities and disease status.

Methods: from October 2018 to March 2019, consecutive out-patients with PsA (according to CASPAR criteria) referred to the Rheumatology Unit of the University of Rome Tor Vergata, were evaluated by a dedicated psychiatrist for attachment style (Relationship Questionnaire - RQ), alexithymia (Toronto Alexithymia Scale - TAS20), perceived stress (Perceived Stress Scale - PSS) and depressive symptoms (Beck Depression Inventory - BDI). These indices were then correlated with clinimetric indices, indices of inflammation and therapy taken by the patient. Statistical analysis was performed using Fisher's exact test and Pearson's correlation coefficient.

Results: 33 patients affected by PsA and 40 healthy individuals as control group were enrolled. The RQ test showed that in patients an insecure "avoidant" attachment style prevails (51.5%) compared to the control group (10%) (p<0.0008) [Figure 1]. This result correlates with the presence of alexithymia and with the duration of illness, showing that patients with an "insecure" profile at the RQ test are those who have higher scores on the TAS-20 scale (p=0.035) and a longer duration of illness (p<0.0001). Regarding the perception of stress, at the PSS test women have mean values (18.12±7.31) statistically superior to the values of the male population (11.69±7.79)(p=0.0015). PSS values of the overall study population were directly proportional to RQ values (p<0.0068) and TAS-20 values (p<0.0001). The correlation between PSS and TAS-20 was further confirmed in the analysis of the individual subgroups "patients" (p<0.0001) and control group (p<0.0001)[Figure 2]. No correlation was shown with phlogosis and clinimetric indices.

Conclusion: This study suggests how PsA patients are a more vulnerable subtype of patient from the psychological point of view, with an avoidant attachment style, characterized by the difficulty to express emotions and to rely on others in times of need. These characteristics can influence the adherence to pharmacological therapies and the doctor-patient relationship. This profile is manifested more frequently in female patients, with long duration of illness, high perception of stress. The state of disease activity does not influence these elements, suggesting that the insecure attachment style is not related to the single inflammatory flare, but is the result of years of illness and long-standing disease. Our results support the relevance of early diagnosis in PsA.

BREASTFEEDING AMONG WOMEN WITH RHEUMATIC DISEASES: ANALYSIS OF DATA FROM THE P-RHEUM. IT STUDY

S. Panaro[1], M. C. Gerardi[1], M. Filippini[1], F. Crisafulli[1], M. Fredi[1], R. Gorla[1], M. G. Lazzaroni[1], D. Lini[1], C. Nalli[1], L. Moschetti[1], F. Regola[1], M. Taglietti[1], A. Bortoluzzi[2], A. Zanetti[3], A. Lojacono[4], S. Zatti[4], C. A. Scirè[2], G. Carrara[3], F. Ramazzotto[4], L. Andreoli[1], F. Franceschini[1], A. Tincani[1]on behalf of SIR. [1]*University of Brescia, Spedali Civili of Brescia, Rheumatology Unit, Brescia, Italy*; [2]*UIniversity of Ferrara, Rheumatology Unit, Ferrara, Italy*; [3]*Italian Society for Rheumatology, Epidemiology Unit, MIlan, Italy*; [4]*Spedali Civili of Brescia, Obsterics and Gynceology Unit, Brescia, Italy*

Background: The World Health Organization recommends that infants should be exclusively breastfed until the age of 6 months. The aim of this study was to assess the ratio of breastfeeding patients with Rheumatic Diseases (RD) and to identify possible causes of its discontinuation.
Objectives: The aim of this study was to assess the ratio of breastfeeding patients with Rheumatic Diseases (RD) and to identify possible causes of its discontinuation.
Methods: This study was embedded in the P-RHEUM.it register, as a nationwide prospective cohort study collecting data of pregnancies in inflammatory RD. Pregnancies, enrolled until the 20th week of pregnancy, are followed from pregnancy until 6 months postpartum. At baseline, sociodemographic parameters, obstetric history, comorbidities are reported. During pregnancy, the course of maternal disease, development of foetus and complications are reported. After delivery, the pregnancy outcome, data on lactation and child development are collected.
Results: From May 2018 to May 2020 data of 349 patients were available. Data on lactation were available in 44 pregnancies. Two months after delivery 37 were continuing breastfeeding (n=26) or mixed feeding (n=11), while 7 were using formula feeding. Among patients using formula feeding 2 had a diagnosis of rheumatoid arthritis (RA), 1 of juvenile idiopathic arthritis, 1 of undifferentiated arthritis (UA), 1 of anti-phospholipid syndrome (APS), 1 of vasculitis and 1 of systemic lupus erythematosus. The reasons of formula feeding were the following: 2 for agalactia, 2 for personal preferences, 3 for drug-related concerns (1 for physician's decision in a patient with APS; 2 for maternal concerns about drugs in patients with RA and UA treated respectively with Adalimumab and Tocilizumab). At 6 months 30 continued breastfeeding (n=23) or mixed feeding (n=7) and 14 formula feeding. The reasons of formula feeding were available in 9 patients: 3 for agalactia, 2 for personal preferences, 2 for physician's decision in a patient with APS and in a patient positive for anti-phospholipid antibodies; 2 for maternal concerns about drugs.
Conclusion: Preliminary data of this prospective study demonstrate a high percentage of breastfeeding/mixed feeding after delivery and after 6 months among women with RD. Drug related concerns are the main reason of discontinuation of breastfeeding, although medication results compatible with lactation. Using our results, strategies supporting patients with RD whishing to breastfeed may be developed.

AB0823

TREATMENT WITH ADALIMUMAB IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES: A STUDY OF TREATMENT TRAJECTORIES ON A PATIENT LEVEL IN CLINICAL PRACTICE

I. Redeker[1], S. Moustakis[2], S. Tsiami[2], X. Baraliakos[2], I. Andreica[2], B. Buehring[2], J. Braun[2], U. Kiltz[2]. [1]*Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), Epidemiology, Berlin, Germany*; [2]*Rheumazentrum Ruhrgebiet at Ruhr-University Bochum, Rheumatology, Herne, Germany*

Background: There is evidence that drug retention rates to adalimumab (ADA) in patients (pts.) with chronic inflammatory rheumatic diseases (CIRD) are impaired by loss of efficacy and adverse events, and that about 50% of users had discontinued ADA within 5 years (1). With the introduction of ADA biosimilars in October 2018, non-medical switching from originator to ADA biosimilars is now increasingly part of daily practice in rheumatologic care.
Objectives: The aim was to study treatment trajectories over two years in pts. with CIRD receiving originator ADA.
Methods: Pts. with CIRD on originator ADA who switched to ADA biosimilar from October 2018 onwards were identified and followed until 2020. Disease activity (ASDAS), physical function (HAQ, BASFI), and changes in treatment were documented every 3 months. The four predefined treatment trajectories "continued ADA biosimilar therapy", "back-switch to originator ADA therapy", "switch to other biological (b) disease modifying anti-rheumatic drug (DMARD) therapy", and "stopped bDMARD therapy /death /drop out" were used to compare characteristics of pts. with different trajectories.
Results: A total of 111 CIRD pts. on treatment with originator ADA were switched to ADA biosimilar (Table 1). The majority of pts. 75 continued therapy with ADA biosimilar (Figure 1 next page) while 16% switched back to originator ADA, 7% switched to a different bDMARD, and 9% either stopped treatment (n=9) or died (n=1). Pts. who continued ADA biosimilar were more frequently male, older or with a longer disease duration than those who switched therapy back to originator ADA and those who switched to a different bDMARD (Table 1). The previous duration on originator ADA treatment was increased in patients who continued ADA biosimilar compared to those who switched therapy back to originator ADA and those who switched to a different bDMARD. There was more functional impairment (HAQ, BASFI) and higher disease activity (ASDAS) in pts. who switched compared to those who continued ADA biosimilar therapy (Table 1). Treatment with csDMARDs and glucocorticoids was increased in pts. who continued ADA biosimilar therapy, while pts. who switched therapy had more previous bDMARD therapies (Table 1).

Table 1. Characteristics of patients at baseline for the entire group and stratified by treatment trajectory

		Treatment trajectory			
	Total group N=111 (100%)	continued ADA biosimilar therapy N=75 (67.6%)	back-switch to originator ADA therapy N=18 (16.2%)	switch to different bDMARD therapy N=8 (7.2%)	no bDMARD therapy / death / drop out N=10 (9.0%)
Age, y	51.2 (14.5)	51.5 (13.6)	50.6 (16.8)	43.5 (9.5)	56.4 (19.0)
Women, No. (%)	46 (41.4)	27 (36.0)	9 (50.0)	6 (75.0)	4 (40.0)
RA	23 (20.7)	17 (22.7)	2 (11.1)	1 (12.5)	3 (30.0)
axSpA	68 (61.3)	47 (62.7)	11 (61.1)	6 (75.0)	4 (40.0)
PsA	15 (13.5)	7 (9.3)	4 (22.2)	1 (12.5)	3 (30.0)
Other diagnoses	5 (4.5)	4 (5.3)	1 (5.6)	0 (0.0)	0 (0.0)
Disease duration, median (IQR), y	5.0 (2.0-8.0)	5.0 (2.0-9.0)	3.5 (2.0-6.0)	2.0 (1.0-5.5)	4.5 (2.0-8.0)
Duration previous originator ADA therapy	40.7 (27.7)	45.3 (27.8)	35.0 (25.2)	20.3 (24.7)	32.3 (25.1)
DAS28	3.0 (1.0)	2.9 (1.0)	3.4 (1.0)	-	3.3 (1.2)
CRP, median (IQR), mg/L	0.2 (0.1-0.3)	0.1 (0.1-0.2)	0.2 (0.0-0.5)	0.2 (0.2-1.3)	0.3 (0.2-0.4)
HAQ score	1.3 (0.8)	1.1 (0.7)	1.7 (0.8)	-	1.8 (1.0)
ASDAS	2.2 (1.1)	2.0 (1.0)	3.0 (1.2)	2.7 (0.9)	2.3 (0.2)
BASFI	3.5 (2.6)	3.0 (2.5)	5.4 (2.4)	3.4 (1.6)	5.4 (1.6)

+values are given as mean (SD)

Conclusion: Two thirds of pts. who switched to ADA biosimilar remained on this therapy for 2 years. As many as 16% of pts. switched back to ADA originator. Whether or to what degree this was influenced by nocebo effects needs further

study. The same is true for the effect of functional impairment – it would be interesting to know whether this was due to inflammation or structural damage.

AB0824 ANALYSIS OF GUT MICROBIOTA IN RHEUMATOID ARTHRITIS PATIENTS

Q. Wang[1,2], S. X. Zhang[3,4,5], J. Qiao[3,4,5], G. Shi[1], R. Zhao[3,4,5], S. Song[3,4,5], Y. Zhang[3,4,5], Q. Yu[2,6], X. Li[3,4,5], P. F. He[2]. [1]*Shanxi Medical University, Basic Medical College, Taiyuan, China*; [2]*Shanxi Medical University, Medical Data Sciences, Taiyuan, China*; [3]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [4]*Shanxi Li Xiaofeng Medical Groups, Department of Rheumatology, Taiyuan, China*; [5]*Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; [6]*Shanxi Medical University, School of Management, Taiyuan, China*

Background: Gastrointestinal microbiota, particularly gut microbiota is an indispensable environmental factor in the progression of Rheumatoid Arthritis (RA). Understanding the diversity and function of the intestinal flora in patients with RA is part and parcel to understand the relationship between microbiota and human health.

Objectives: This study aimed to identify the diversity and function of the intestinal flora in patients with RA.

Methods: A total of 166 participants were recruited in this study, comprising 93 RA patients and 73 age and sex-matched healthy controls (HCs). Microbial genome was extracted from approximately 250mg fresh fecal samples from all participants using QIAamp PowerFecal DNA Kit (Qiagen). The V3-V4 variable regions of bacterial 16S rRNA genes were sequenced with the Illumina Miseq PE300 system. Sequence data were compiled and processed using Qiime2. Sequences were grouped into operational taxonomic units (ASVs)[1]. Microbial diversity was estimated by the Simpson index. PICRUSt2 was used to predict KEGG functional pathway differences between RA and HC intestinal flora functions based on ASV Tables[2]. Linear Discriminant Analysis (LDA) Effect Size (LEfSe) analysis was performed using LEfSe software to discovery the different intestinal flora and functions between RA and healthy.

Results: The alpha-diversity index of Simpson the microbiome in RA patients was lower than that of HCs (Figure 1a, P <0.05). Compared with HCs, bacterial Bacilli and Lactobacillales were more abundant in patients with RA (Figure 1b, P <0.05). In contrast, Marinifilaceae, Peptococcaceae, Peptococcales and Phascolarcto bacterium were less abundant in the RA group (Figure 1b, P <0.05). As shown in Figure 1c, propanoate metabolism, taurine and hypotaurine metabolism, ascorbate and aldarate metabolism, biosynthesis of siderophore group nonribosomal peptides and glutathione metabolism were the most significantly altered pathways in RA (P <0.05). Epithelial cell signaling in Helicobacter pylori infection, RNA transport, RNA degradation and plant-pathogen interaction were the most significantly altered pathways in HC (P <0.05). The different KEGG metabolic pathways were mainly concentrated in carbohydrate and amino acid metabolism.

Conclusion: Gut dysbiosis in RA patients mainly characterized by reduced the diversity and impaired abundance of the intestinal flora, which severely influence the metabolism of gastrointestinal microbiota. The discovery of the associated intestinal microbiota of RA may provide a new idea for RA treatment.

AB0825 JAK2 (V617F) MUTATION AND ASSOCIATION TO IMMUNE MEDIATED DISEASES. STUDY OF 130 PATIENTS FROM A SINGLE UNIVERSITY HOSPITAL

C. Álvarez-Reguera[1], L. Sanchez-Bilbao[1], A. Batlle-López[2], S. Fernández López[2], M. Á. González-Gay[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*; [2]*Hospital Universitario Marqués de Valdecilla, Hematology, Santander, Spain*

Background: Janus Kinases (JAK) are tirosin-kinases that can promote cytokine production in immune and hematopoietic cells. The JAK-2 (V617F) mutation is the most frequently detected mutation in myeloproliferative neoplasms (MPN) which include essential thrombocythemia (ET), polycythemia vera (PV), primary myelofibrosis (PMF) and undifferenciated MPN. JAK-2 (V617F) mutation displays a pro-inflammatory phenotype that may be associated to a higher risk of immune mediated diseases (IMID), thromboembolic complications or other cancers **(1-3).**

Objectives: To evaluate the presence of **a)** IMID (rheumatic and non-rheumatic), **b)** cancer and, **c)** Deep vein thrombosis/ Venous thromboembolism (DVT/VTE) events in a cohort of patients with a positive JAK-2 (V617F) mutation.

Methods: We studied all the patients diagnosed with a positive JAK-2 (V16F) mutation in a single University Hospital between January, 2004 and December, 2019.

Results: The study included 130 patients (73 men/57 women; mean age, 70.1±14.5 years). They were diagnosed of ET (n=64, 49.2%), PV 46 (35.4%), undifferentiated MPN (n=12, 9.2%) and PMF (n=8, 6.1%). Of these patients, 54 (41.5 %) (44 non rheumatic and 10 rheumatic) were diagnosed with at least one IMID, 46 (35.4%) with other cancer different of MPN and 36 (27.7%) with DVT/VTE events. (Table 1**/**Figure 1**).**

Conclusion: Due to its prevalence and potential complications, IMID should be taken into consideration when a patient is diagnosed with a positive JAK-2 (V617F) mutation.

AB0826 IMPORTANCE OF PRECONCEPTION CARE AND PLANNING FOR PREGNANCY IN WOMEN OF CHILDBEARING AGE COMPLICATED WITH CONNECTIVE TISSUE DISEASES

H. Shimada[1], R. Wakiya[1], M. Mahmoud Fahmy Mansour[1], S. Nakashima[1], M. Kato[1], T. Miyagi[1], K. Sugihara[1], Y. Ushio[1], T. Kameda[1], H. Dobashi[1].
[1]Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa, Japan

Background: Previous reports showed that connective tissue disease (CTD) have a high risk for adverse pregnancy outcomes (APOs) such as preterm birth, light-for-date, or preeclampsia[1)]. It was revealed that these APOs were associated with high disease activity or treatment agents, particularly in glucocorticoid[2)]. Some patients, who have no or insufficient preconception care and became unplanned pregnant, exacerbate the underlying disease, and lead to disappointing pregnancy outcomes. Therefore, preconception care and planning for pregnancy is very important to control disease activities and manage the appropriate treatment agents, including glucocorticoid, immunosuppressants, biologics, hydroxychloroquine, and anticoagulants[3)].

Objectives: We investigate whether the presence or absence of preconception care before pregnancy affects clinical disease course and pregnancy outcomes.
Methods: We examined 200 CTD women who delivered their newborns in our institution from March 2006 to January 2021. We analyzed the association between preconception care and the clinical course of underlying diseases during pregnancy or pregnancy outcomes.
Results: Of all 200 cases, 133 (55.9%) cases had preconception care in our institution, while the others had no or insufficient preconception care. We showed the comparison of treatment agents and pregnancy outcomes between the cases with and without preconception care in Table 1. There was no significant difference in the rate of glucocorticoid use and the mean prednisolone dose during pregnancy between these two groups. However, the rate of increased dose of glucocorticoid or pulse therapy was significantly higher in the cases without preconception care. As for pregnancy outcomes, there was no significant difference in the live birth rate. On the other hand, the gestational weeks at delivery were significantly shorter, and the rate of preterm birth was higher in the cases without preconception care. In addition, the rate of the hospitalization of neonatal intensive care unit (NICU) was also significantly higher in the cases without preconception care.
Conclusion: We revealed that preconception care before pregnancy reduced the need for intensified treatment such as increasing dose of glucocorticoid or pulse therapy. The rate of preterm birth and NICU hospitalization was also shown to decrease. Therefore, it is important for our rheumatologists to provide an appropriate preconception care for CTD women of childbearing age and to make a plan for pregnancy.

AB0827 SERUM NESPHATIN-1 IN PATHOGENESIS RHEUMATOID ARTHRITIS

T. Kvlividze[1], V. Polyakov[1], B. Zavodovsky[1,2], Y. Polyakova[2], L. Seewordova[2], E. Papichev[2], Y. Akhverdyan[2]. *[1]Volgograd State Medical University, Laboratory Diagnostics, Volgograd, Russian Federation*; *[2]Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Treatment and Prevention of Joint Disease Laboratory, Volgograd, Russian Federation*

Background: Interest in highly specialized tissue cytokines contributed to the discovery of new biologically active molecules. Nesfatin-1 (NF) - discovered in 2006 as an anorexigenic factor. NF-1 is believed to be involved in the regulation of energy homeostasis by regulating appetite and water intake. The role of NF-1 in the pathogenesis of inflammatory diseases is poorly understood. Recently, studies have found a relationship between an increased level of NF-1 and inflammatory markers in various pathologies.
Objectives: Study of the level of nesfatin-1 in the blood serum of healthy people, determination of the correlation between the level of NF-1 with the severity of clinical symptoms and classic markers of inflammation in patients with RA.

Methods: 120 persons were examined: 90 patients with RA and 30 healthy people. All patients underwent a complete clinical and laboratory examination. Plasma NF-1 levels were determined using commercial test systems (RaiBiotech, cat # EIA-NESF) according to the manufacturer's instructions. Patients with various forms of RA were comparable in age to the group of healthy individuals. Statistical processing of clinical examination data was carried out using the "STATISTICA 10.0 for Windows" software package. Quantitative data were processed statistically using the parametric Student's t-test, qualitative data using the non-parametric chi-square test. The significance of differences between groups was determined using analysis of variance. The results were considered statistically significant at $p < 0.05$.

Results: The average level of NF-1 in blood serum in healthy individuals was 31.79 ± 3.21 ng / ml ($M \pm \sigma$). The level of normal NF-1 values in healthy individuals, defined as $M \pm 2\sigma$, ranged from 25.3 to 37.83 ng / ml. There was no significant difference in the levels of circulating NF-1 and BMI in healthy individuals and patients with RA ($p > 0.05$). The inverse relationship of a lower level of NF-1 with an increase in BMI was not significant.

Group 1 (66 patients with RA) with increased serum NF-1 levels (> 37.83 ng / ml), and group 2 (44 patients) with normal values (<37.83 ng / ml). A high level of NF-1 was characteristic for patients with high activity according to DAS28, RF seropositive, ACCP-positive, with extra-articular manifestations, who had been ill for 10 years or more. A reliable relationship between the level of NF-1 in the blood serum and laboratory parameters of RA activity - ESR, CRP, was shown, and secondary synovitis was more common. Our data show a direct correlation between the NF-1 level of the pro-inflammatory markers of RA.

Conclusion: The positive correlation between the level of NF-1 and classical markers of inflammation, such as CRP and ESR, confirms the involvement of NF-1 in the pathophysiology of inflammation in RA. This is also evidenced by the correlation of a high level of NF-1 in the blood serum with a more severe clinical picture of RA. It is known that NF-1 can promote the release of pro-inflammatory cytokines such as interleukin-8 (IL-8), interleukin-6 (IL-6), and macrophage inflammatory protein-1a (MIP-1a) in the chondrocytes of RA patients.

It is necessary to further study the role of NF-1 in the pathogenesis of systemic inflammatory reactions and the possibility of targeting pro-inflammatory cytokines, the possibility of regulating the level of NF-1 by drugs.

AB0828 INFLUENCE OF SEASONAL VARIATIONS ON EMERGENCY RHEUMATOLOGY CONSULTATIONS

Z. El Ouali[1], R. Assadi[1], S. Lahrichi[1], K. Nassar[1], S. Janani[1]. [1]*University Hospital of Ibn Rochd, Department of Rheumatology, Casablanca, Morocco*

Background: The influence of the seasons on the onset of diseases has been demonstrated in epidemiological studies, particularly in infectious pathologies. In rheumatology, recent studies have suggested the role of seasons in the disease activity of rheumatoid arthritis (1,2). However, no epidemiologic data exist on the influence of seasons in urgent rheumatology consultations, all causes combined.

Objectives: To study the influence of seasonal variations on urgent rheumatology consultations received in the Department of Rheumatology of the University Hospital of Ibn Rochd in Casablanca.

Methods: We conducted a retrospective study on the 2019 emergency consultations register of the Department of Rheumatology of the University Hospital of Ibn Rochd, Casablanca. The seasons were divided as follows: winter from December to February, spring from March to May, summer from June to August, and fall from September to November. The studied parameters were age, sex, reasons for consultation, affected joints, and diagnoses.

Results: 407 emergency consultations were carried out, with an average patient age of 50.7 years (range 14 - 88), and a sex ratio M/F of 0.4. The characteristics of the patients throughout the seasons is summed up in Table 1. The distribution of consultations by season was as follows: 29.5% in winter, 26.3% in spring, 25.4% in summer, and 18.8% in fall. The average age of the consultants depending on the season was homogeneous. The most frequent reasons for emergency consultation were respectively back pain (48.6%), polyarthralgia (23.1%), followed by arthritis (12.0%). Back pain slightly predominant in the cold seasons (fall, winter). Polyarthralgias had a winter peak. Arthritis presented a bimodal distribution in seasons of transition (spring, fall). The knees and lumbar spine were the most frequently involved joints throughout the year, with no major differences between the seasons. The most frequent diagnoses over the year were degenerative (51%), inflammatory (8.6%), infectious (7.3%), metabolic (6.7%), and tumor (2.1%) pathologies, respectively. %). Osteoarthritis flares were less frequent in spring and summer. Inflammatory pathologies have not experienced a seasonal peak. Gout flares and infectious pathologies peaked in the spring. Finally, tumor pathologies peaked in the fall.

Conclusion: Seasonal variations seem to have an impact on the distribution of the reasons for consultation as well as the diagnoses made in the context of the rheumatologic emergencies. The cold seasons seemed to favor the onset of back pain and polyarthralgia, while the seasons of transition were conducive to the development of arthritis.

AB0829 WHAT ARE THE DIFFERENCES BETWEEN YOUNG AND ELDERLY SUBJECTS IN URGENT RHEUMATOLOGY CONSULTATIONS?

R. Assadi[1], Z. El Ouali[1], S. Lahrichi[1], K. Nassar[1], S. Janani[1]. [1]*University Hospital of Ibn Rochd, Department of Rheumatology, Casablanca, Morocco*

Background: The pattern of rheumatological diseases shows significant differences depending on age. It is commonly admitted that inflammatory rheumatic diseases is the prerogative of young people (1), while degenerative pathology is more important in older ages (2). In the context of the emergency, little epidemiological data exist about the differences between young and old populations.

Objectives: To study the influence of age on emergency rheumatology consultations received in the Department of Rheumatology of the University Hospital of Ibn Rochd.

Methods: We conducted a retrospective study on the 2019 emergency consultations register of the Department of Rheumatology of the University Hospital of Ibn Rochd, Casablanca. Patients were divided in 2 groups: young subjects included patients aged less than 65 years, and the elderly subjects included people aged 65 and above. The studied parameters were gender, medical coverage, socio-professional category, reasons for consultation, joint involvement, duration of symptoms, diagnoses, and treatments.

Results: 407 emergency consultations were carried out, including 81 in the elderly (19.9%) and 326 in young subjects (80.1%). The characteristics are summed up in Table 1. Although we noted a female predominance in both groups, men were more represented in the elderly group. Radiculalgia was a

more frequent reason for consultation in the elderly population, while arthralgia was more frequent in the young population. Young subjects more frequently had peripheral joints complaints. Degenerative and tumor pathologies were more common in the elderly population, while inflammatory, septic, and tendon pathologies were more prominent in the young population. Regarding treatments, non-steroidal anti-inflammatory drugs were more prescribed in young subjects, while the other treatments had a homogeneous distribution in the two groups.

Conclusion: In our emergency unit, the epidemiological distribution of our patients according to age matches the general epidemiological characteristics of rheumatological pathologies: inflammatory causes are more frequent in young ages, while degenerative pathologies are found at a later age.

ADVERSE PERINATAL OUTCOMES AND CONGENITAL DEFECTS IN MEXICAN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

R. A. Rodriguez Chavez[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], G. A. López-Uriarte[2], E. Barriga-Maldonado[1], G. Figueroa-Parra[1], I. Perez-Onofre[1], A. Elizondo-Plazas[2], L. G. Espinosa Banuelos[1], R. Moyeda Martinez[1], A. Y. Lujano Negrete[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology Service, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Genetics Department, Monterrey, Mexico*

Background: Pregnancy in women with autoimmune rheumatic diseases (ARD) is associated with an increase in the risk of adverse perinatal outcomes and birth defects. Many factors have been attributed to these including medication employed and maternal autoantibodies. The national prevalence of congenital anomalies in newborns in Mexico is estimated to be 73.9 per 10,000 births but the rate of these in Mexican women with ARD is unknown.

Objectives: This study aims to describe the frequency of adverse perinatal outcomes and congenital defects in Mexican women with ARD.

Methods: We performed a descriptive and prospective study that included all pregnant patients with ARDs from the clinic of pregnancy and rheumatic diseases in the University Hospital "Dr. José Eleuterio González" who gave birth between February 2019 to November 2020. Demographic information, pregnancy outcome, and congenital defects were prospectively evaluated. Congenital defects were clinically confirmed by a clinical geneticist.

Results: A total of 40 women were taken in the final analyses. The ARD diagnosis is shown in graphic 1. Rheumatoid arthritis was the most frequent diagnosis that had an adverse perinatal outcome with 4 (40%) and congenital defects in 2 (40%). No complications or birth defects were reported in 25 (62.5%). The adverse perinatal outcome was reported in 10 (25%) women and congenital defects in 5 (12.5%). The most frequent adverse perinatal outcomes were preterm birth 6 (15%) and the second most frequent miscarriage 3 (7.5%) (Table 1 below).

Conclusion: We found a high frequency (12.5%) of adverse perinatal outcomes and congenital defects in Mexican women with ARD. Multidisciplinary groups and clinics are needed to adequately serve this complex population and reduce morbidity and mortality. A multidisciplinary approach before, during, and after pregnancy in patients with ARD may improve morbidity and mortality.

AB0831

FREQUENCY OF RENAL CRISIS IN PATIENTS WITH SYSTEMIC SCLEROSIS: NEW DATA FROM A CHINESE COHORT AND A SYSTEMIC REVIEW WITH META-ANALYSIS

D. Xu[1], J. He[2], T. LI[1], R. Mu[1,1,1]. [1]*Peking University Thrid Hospital, Department of Rheumatology and Immunology, Beijing, China*; [2]*The Third People's Hospital of Datong, Department of Rheumatology and Immunology, Datong, China*

Background: Scleroderma renal crisis (SRC) is a rare but life-threatening complication in SSc, which defined as malignant hypertension and progressive renal failure [1]. Previous reports of the prevalence for scleroderma renal crisis (SRC) show variable outcomes.
Objectives: We aim to find out the prevalence for SRC in Chinese, and conduct a meta-analysis to assess the prevalence of SRC in worldwide and investigate possible factors of variability.
Methods: We evaluated the prevalence for SRC and compared the clinical characteristics in SSc patients with or without SRC. A systematic review on the prevalence of SRC was carried out in PubMed, Embase and Cochrane. Meta-analysis was performed using available data on the prevalence for SRC.
Results: 302 patients were enrolled in PKUPH-SSc cohort and the prevalence of SRC was 4.97%. In our cohort, SRC was found in 3.60% limited cutaneous SSc (lcSSc) and 7.75% diffused cutaneous SSc (dcSSc) patients. Twenty-nine studies including a total population of 22686 SSc patients were analyzed in the meta-analysis. The overall pooled prevalence of SRC was 4.0%, but heterogeneity among the studies was substantial (I^2=86.1%, P <0.00001). Meta-regression revealed that subtype of SSc and geographic factors partially explained this heterogeneity. Sub-group analyses demonstrated that the prevalence of SRC in dcSSc and lcSSc were 9.0% and 2.0%. The SRC prevalence in SSc was 3.0% in Asia, 5.0% in Europe, and 3.0% in North America, respectively.
Conclusion: Data on our new cohort showed the prevalence of SRC was around 5% in China, and meta-analysis confirmed that the prevalence of SRC varies among centers. The marked heterogeneity of SRC prevalence was partially explained by subtype of SSc and geographic origin of patients.

PREVALENCE OF OCULAR DISEASES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE OBSERVATIONAL STUDY IN A TERTIARY HOSPITAL IN TAIWAN

J. H. Kao[1], T. Y. Lan[1], C. H. Lu[1], C. Y. Shen[1], K. J. LI[1], S. C. Hsieh[1]. [1]*National Taiwan University Hospital, Department of Internal Medicine, Division of Allergy, Immunology and Rheumatology, Taipei, Taiwan, Republic of China*

Background: Systemic lupus erythematosus (SLE) could affect multiple parts of the eye. (1,2) Also, there is risk of ocular toxicity associated with treatment, such as hydroxychloroquine.(3) Early diagnosis is essential to avoid major ocular complications. However, complaints of eye discomfort may be vague, and various presentations may pose challenges on rheumatologists. Knowing the real-world prevalence of ocular problems in patients with SLE is important and helpful, yet this has been less common to be reported.
Objectives: To describe the prevalence of various ophthalmologic diagnoses in patients with SLE.
Methods: This is a retrospective observational study conducted in a tertiary hospital in Taipei, Taiwan. Patients diagnosed with SLE in the period between 1st Jan, 2002 and 31th Dec, 2015 and evaluated by ophthalmologists in 2 years before 29th Jan, 2021 were included. Demographic and clinical data, and ophthalmologic diagnoses were recorded by chart review.
Results: A total of 121 patients were included, and 118 (97.5%) were female. Average age was 46.2 years [standard deviation (SD) 11.4 years] upon ophthalmologic evaluation, and average duration suffering from lupus was 11.6 years (SD 3.3 years). Keratoconjunctivitis sicca (n = 48, 39.7%), myopia (n = 39, 32.2%), and cataract (n = 21, 17.4%) were the most common findings. It was also noted that suspicious finding of hydroxychloroquine retinal toxicity was found in 12 patients (9.9% of total patients). Also, two patients had lupus retinopathy, and another two were diagnosed with cytomegalovirus retinitis. In addition, glaucoma was diagnosed in 9 patients (7.4%), which seemed to be higher than the general population.
Conclusion: Higher prevalence of different ocular problems is noted in this cohort of SLE patients. Keratoconjunctivitis sicca was the most common ocular diagnosis, which is consistent with literature. However, high rates of myopia, cataract, glaucoma, and suspicious hydroxychloroquine retinal toxicity were also found. Above result warrants more aggressive ophthalmologic evaluation in SLE patients. More research on the association of lupus and different ocular diseases is needed in the future.

HOSPITAL ADMISSIONS FOR RHEUMATOID ARTHRITIS AND OTHER INFLAMMATORY POLYARTHROPATHIES IN THE BRAZILIAN PUBLIC HEALTH SYSTEM

A. Dal Pra Wendt[1], F. Milene Cardozo[1]. [1]*Feevale University, Institute of Health Sciences, Novo Hamburgo, Brazil*

Background: Rheumatoid arthritis is an idiopathic autoimmune disease that is characterized by symmetrical peripheral polyarthritis. The disease leads to the destruction of joints due to erosion of both bone and cartilage. The other inflammatory polyarthropathies are a group composed of 61 diseases, according to the International Classification of Diseases (ICD-10). Drug treatment is carried out through outpatient follow-up, with no need for hospitalization in mild and / or controlled cases. When surgical treatment is recommended or there are complications from rheumatoid arthritis or other inflammatory polyarthropathies, hospitalization is indicated. In addition, Brazil has a broad public health system, called the Unified Health System (UHS), responsible for most health procedures carried out at the national level, especially with regard to the socioeconomically vulnerable population.
Objectives: To investigate the number of hospital admissions for rheumatoid arthritis and other inflammatory polyarthropathies in UHS during the past three years.
Methods: This is a quantitative and retrospective survey based on the data available on the website of the Department of Informatics of the Brazilian Unified Health System. The data are freely accessible and public domain. Information was collected about the period between December 2017 and November 2020, referring to the number of hospitalizations for rheumatoid arthritis and other inflammatory polyarthropathies in all five regions that make up Brazil.
Results: The number of hospitalizations for rheumatoid arthritis and other inflammatory polyarthropathies fluctuated, between December 2017 and November 2020, from 1083 to 1311 per month, with an average of 1184 and a total of 38228 hospitalizations over the three years analyzed. Throughout the national territory, the region with the least monthly admissions was the central-west (which comprises the states of Mato Grosso, Mato Grosso do Sul, Distrito Federal and Goiás), with 2562 total admissions and an average of 71.1 monthly admissions.

In contrast, the region with the highest number of cases was the southeastern region (where the states of Espírito Santo, Minas Gerais, São Paulo and Rio de Janeiro are located), with a total of 13173 hospitalizations and a monthly average of 365.9, representing 34,4% of hospitalizations in the country. Such data is in line with the Brazilian demography, since the central-west region is the second least inhabited (with 16.09 million inhabitants) and the southeastern region is the most densely inhabited (with 80.35 million inhabitants). The number of monthly hospitalizations, which remained above 1000 from the first month analyzed (December 2017) until February 2020, dropped to 990 in March of the same year and 651 in April, maintaining an average of 678.2 in next seven months.

Conclusion: It is concluded that the number of hospitalizations for rheumatoid arthritis and other inflammatory polyarthropathies in Brazil dropped significantly between March and April 2020, a period that coincides with the beginning of the COVID-19 pandemic in the country, possibly as a result both of the changes in the Brazilian medical care model (in relation to the requirements for hospitalization) and as a result of the lower demand by individuals for hospitals due to fear of contamination by the new coronavirus.

DEVELOPMENT OF A CONCEPTUAL FRAMEWORK FOR A PATIENT REPORTED OUTCOME MEASURE TO CAPTURE PATIENTS' PERCEPTIONS OF GLUCOCORTICOID THERAPY DURING TREATMENT FOR RHEUMATIC DISEASES

S. Bridgewater[1,2], J. Dawson[3], M. Ndosi[1,2], R. J. Black[4,5], J. T. L. Cheah[6], E. Dures[1,2], N. Ghosh[7], E. A. Hoon[8], I. Navarro-Millan[7], D. Pearce-Fisher[7], P. Richards[2], C. Ruediger[8], C. Silverthorne[1,2], J. Tieu[8], S. Mackie[9,10], S. Goodman[7], C. Hill[8], J. Robson[1,11]on behalf of Outcome Measures in Rheumatology (OMERACT) Glucocorticoid Working Group. *[1]University of the West of England - UWE Bristol, Faculty of Health and Applied Sciences, Bristol, United Kingdom*; *[2]University Hospitals Bristol and Weston NHS Foundation Trust, Academic Rheumatology, Bristol, United Kingdom*; *[3]University of Oxford, Nuffield Department of Population Health, Oxford, United Kingdom*; *[4]The University of Adelaide, Discipline of Medicine, Adelaide, Australia*; *[5]Royal Adelaide Hospital, Rheumatology Unit, Adelaide, Australia*; *[6]University of Massachusetts Medical School, Department of Medicine, Division of Rheumatology, Worcester, United States of America*; *[7]Hospital for Special Surgery, Division of Rheumatology, New York, United States of America*; *[8]The Queen Elizabeth Hospital, Department of Rheumatology, Adelaide, Australia*; *[9]Leeds Teaching Hospitals NHS Trust, Leeds Biomedical Research Centre, Leeds, United Kingdom*; *[10]University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[11]University Hospitals Bristol and Weston NHS Foundation Trust, Academic Rheumatology, Bristol, United Kingdom*

Background: Glucocorticoids (GCs) are a key treatment for the autoimmune rheumatic diseases; however, they produce numerous physical and psychological side effects.[1] The Outcome Measures in Rheumatology (OMERACT) Glucocorticoid Working Group have identified that there are no Patient Reported Outcome Measures (PROMs) for assessing the impact of systemic GC therapy across multiple rheumatic diseases from the patient's perspective.[2,3]

Objectives: The aim is to explore the impact of GCs on the symptoms and health-related quality of life of adults with rheumatic inflammatory diseases, to inform items for inclusion in a PROM. Key considerations will include patient perceptions of GC therapy at diagnosis and over the course of treatment, for use in future randomised controlled trials or in clinical practice.

Methods: An international steering committee comprising researchers, rheumatology clinicians, methodologists and patient partners in the UK, Australia and USA developed an initial conceptual framework informed by a review of the literature. Semi-structured interviews were conducted in each country with patients who had an autoimmune rheumatic disease and had received GC therapy. The interviews explored salient aspects of health-related quality of life associated with being treated with GCs.

Results: Interviews have been completed in three continents with patients who had a range of demographic features, rheumatological conditions and duration and dosage of GC therapy. Figure 1 shows the initial conceptual framework for developing the GC PROM (Steroid PRO).

Conclusion: This conceptual framework will act as an evolving guide in the development of a PROM for assessing patients' perspectives of systemic glucocorticoid therapy. Future work will include inductive analysis of qualitative transcripts to inform candidate questionnaire items, cognitive interviewing, linguistic translatability assessment, and an international validation survey to define the final PROM questionnaire and its measurement properties.

AB0835

IS BASELINE VITAMIN D STATUS RELATED WITH THE RESPONSE TO BDMARDS IN SPONDYLOARTHRITIS PATIENTS?

B. M. Fernandes[1], S. Garcia[1], F. Oliveira Pinheiro[1], M. Rato[1], D. Fonseca[2], D. Santos Oliveira[1,3], A. Martins[1], F. R. Martins[4], M. Bernardes[1,5], L. Costa[1]. *[1]Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal*; *[2]Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal*; *[3]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; *[4]Centro Hospitalar Universitário do Algarve, Rheumatology, Faro, Portugal*; *[5]Faculty of Medicine, University of Porto, Departamento de Medicina, Porto, Portugal*

Background: Vitamin D is thought to have an important role in immune regulation and is being subject of research in several autoimmune diseases. Some data suggest that vitamin D deficiency is common in Spondyloarthritis (SpA) and may be associated with disease activity and structural damage.

Objectives: To evaluate if there is a relation between baseline vitamin D status and the response to biologic disease-modifying antirheumatic drugs (bDMARDs) in a SpA monocentric cohort.

Methods: Retrospective study including all the SpA patients (ASAS classification criteria) followed at our Rheumatology Department, registered in the

national database and treated with bDMARD between June 2008 and July 2020. Demographic, clinical and laboratorial data (including 25-hydroxyvitamin D [25-OHvitD]) at baseline and disease activity measures at 6 and 12 months of treatment with the first bDMARD were collected. Correlations between variables were evaluated by Spearman rank test, Mann-Whitney U test was used to the comparison analysis between groups and univariate logistic regression was used in the prediction analysis.

Results: A total of 195 SpA patients were included: 103 (52.8%) females, 47 (24.1%) smokers and 91 (46.7%) HLA-B27 positive; 139 (71.3%) had Ankylosing Spondylitis, 18 (9.2%) had Inflammatory Bowel Disease Associated SpA and 38 (19.5%) had Undifferentiated SpA. At the time of the first bDMARD, the mean age was 43.5 years (±9.6) and the median disease duration was 12.4 years (0.7-52.7). The mean ASDAS-CPR (Ankylosing Spondylitis Disease Activity Score with C-reactive protein) was 3.9 (±0.8) and, in addition, 61 (31.3%) patients had 25-OHvitD levels below 30 ng/mL and 12 (6.2%) had 25-OHvitD levels below 20 ng/mL. Fifty-three patients (27.2%) were taking NSAIDs (nonsteroidal anti-inflammatory drugs), 77 (39.5%) were under csDMARDs (conventional synthetic disease-modifying antirheumatic drugs). Adalimumab (56%) and golimumab (33.3%) were the most frequently initiated bDMARDs in the first line.

There were no statistically significant correlations between baseline 25-OHvitD levels and ASDAS-CRP at 6 (r=0.031; p=0.714) and 12 months (r=0.035; p=0.672) of bDMARD.

In the subgroup analysis: there were no statistically significant differences in the response to bDMARD at 6 and 12 months evaluated by ASDAS response and ASAS 20, 40 and 70 responses according to the baseline 25-OHvitD levels (25-OHvitD <20ng/mL vs ≥20ng/mL; 25-OHvitD <30ng/mL vs ≥30ng/mL); and there were no statistically significant differences in the baseline 25-OHvitD levels at baseline according to the response to bDMARD at 6 and 12 months of bDMARD (ASDAS: no response vs clinically important improvement or major improvement; ASAS 20: no response vs response).

In the line of these previous results, baseline 25-OHvitD levels did not predict the ASDAS response at 6 (OR 0.97 [0.95-1.00], 95% CI) or 12 (OR 0.98 [0.95-1.01], 95% CI) months of bDMARD.

Conclusion: Despite some data that suggest that lower levels of 25-OHvitD may be associated with higher disease activity in SpA, our results failed to demonstrate that the baseline 25-OHvitD levels can be related or predict treatment response after 6 and/or 12 months of therapy with the first bDMARD in real-life SpA patients.

AB0836 DIAGNOSIS VALUE OF INTERLEUKIN 17 IN SPONDYLOARTHRITIS

L. Kharrat[1], M. Slouma[1], A. Tezeghdenti[2], W. Dkhili[2], R. Dhahri[1], E. Ghazouani[2], I. Gharsallah[1], L. Metoui[1], B. Louzir[1]. [1]*Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia*; [2]*Military Hospital of Instruction of Tunis, Immunology, Tunis, Tunisia*

Background: Interleukin 17 (IL-17) is pro-inflammatory cytokine that plays a crucial role in spondyloarthritis via the Th17/IL-17 axis. (1)

Objectives: We aimed to study the diagnosis value of IL-17 serum in spondyloarthritis.

Methods: We conducted a case-control study, including 104 subjects divided into 2 groups:

-G1: 52 patients meeting the Assessment of SpondyloArthritis International Society (ASAS) criteria for spondyloarthritis (SA)

-G2: 52 healthy controls matched for age and sex.

The IL-17 level was measured using Enzyme-linked immunosorbent assay (ELISA).

We performed a ROC analysis and computed the air under the curve (AUC) at IL-17 to assess the ability of IL-17 to diagnose SA.

Statistical analysis was performed using "IBM SPSS Statistics" software version 25.

Results: Eighty per cent of the patients were men (n=41). The mean age was 44.96 ± 13.09 years. The mean age at the onset of the disease was 35.07 ± 12.66 years. The disease duration was 9.25 ± 8.09 years. Axial radiographic spondyloarthritis and peripheral involvement were found in 53.8% (n=28) and 44.2% (n=23) of cases, respectively. Psoriasis was noted in 46% of cases (n=24). The mean ASDAS-CRP was 3.21 ± 1.64.

IL-17 level was significantly higher in patients compared to healthy controls (92.76 ± 71.85 pg/mL and 2.67 ± 9.01 pg/mL, respectively, p<0.0001).

As shown in Figure 1, the AUC value to distinguish between spondyloarthritis and healthy control was 0.987 (p<0.0001). IL-17 cut-off was 13.79 pg/mL (Sensibility= 94.2%, specificity=98.1%).

Conclusion: According to previous studies, our study showed that serum IL-17 level is significantly higher in SA patients compared to healthy controls (2).

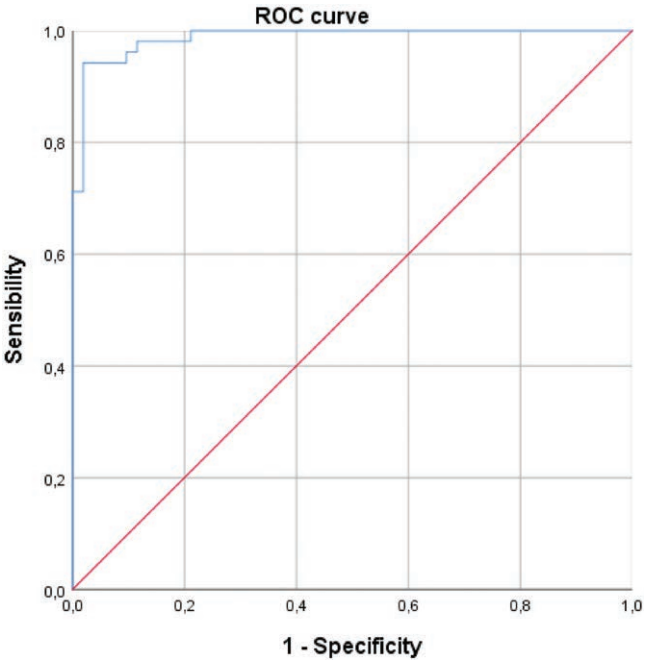

Figure 1. AUC at IL-17 between SA patients and healthy controls 0.987 (p<0.0001)

Interestingly, IL-17 was able to distinguish between SA patients and healthy controls with a cut-off of 13.79 pg/mL. This finding suggests that IL-17 may be useful for the diagnosis of SA.

AB0837 SERUM YKL-40 LEVELS IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: RELATION TO DISEASE ACTIVITY AND JOINT DESTRUCTION

E. Aleksandrova[1], A. Novikov[1], E. Luchikhina[2], D. Karateev[2], G. Lukina[3]. [1]*Moscow Clinical Scientific Center n.a. A.S. Loginov, Clinical Immunology, Moscow, Russian Federation*; [2]*Regional Research and Clinical Institute (MONIKI), Department of Rheumatology, Moscow, Russian Federation*; [3]*Moscow Clinical Scientific Center n.a. A.S. Loginov, Department of Rheumatology, Moscow, Russian Federation*

Background: YKL-40 (chitinase-3-like 1 protein, human cartilage glycoprotein 39) is one of the major proteins secreted locally in the arthritic joint by activated macrophages, chondrocytes, synoviocytes and neutrophils, YKL-40 an important marker for inflammation, cartilage remodelling and synovial hyperplasia is recognized as a possible auto-antigen in rheumatoid arthritis (RA).

Objectives: The aims of the study were to determine the serum level of YKL-40 in early RA and investigate his relationship with biomarkers of disease activity and joint destruction.

Methods: We studied 22 patients with early RA (ACR/EULAR 2010 classification criteria); 4 males, 18 females; median and interquartile range (25th—75th percentile) of age 55,0 (43,0-64,0) years, disease duration 7,0 (5,0-11,0) months, DAS28 4,9 (4,3-5,8); 86% IgM rheumatoid factor (IgM RF) +; 91% anti-cyclic citrullinated peptide antibody (anti-CCP) +. All patients were treated with methotrexate (MTX). Three (14 %) patients received low oral doses of steroids and intra-articular injections. The control group included 22 healthy donors (HC). Radiographs were scored according to the van der Heijde-modified Sharp score. YKL-40, matrix metalloproteinase-3 (MMP-3), anti-CCP were detected using commercially available enzyme-linked immunosorbent assays (ELISA). The serum levels of IgM RF, C-reactive protein (CRP), serum amyloid A (SAA) were measured by immunonephelometry.

Results: RA patients had significantly higher serum level of YKL-40 than HC (92,1; 68,5-153,1 pg/ml vs 54,0; 41,7-83,2 pg/ml, p<0.01). Serum YKL-40 concentration was positively correlated with DAS 28 (r=0,5; p<0,05), erythrocyte sedimentation rate (ESR) (r=0,5; p<0,05), CRP (r=0,8; p<0,05), SAA (r=0,6; p<0,05) and MMP-3 (r = 0,6; p<0,05). We found no relationship between the level of YKL-40 and articular radiographic changes.
Conclusion: Elevated serum concentration of YKL-40 in early RA is associated with clinical and laboratory indicators of disease inflammatory activity and increased level of MMP-3 - an immunological marker of joint destruction.

AB0838 ADHERENCE TO TREATMENT IN PATIENTS WITH RHEUMATIC PROFILE DEPENDING ON THE OPTION OF BASIC THERAPY

O. Malyshenko[1], M. Koroleva[1], M. Letaeva[1], J. Averkieva[1], T. Raskina[1]. *[1]Kemerovo State Medical University, Department of Propedeutics of Internal Medicine, Kemerovo, Russian Federation*

Background: Treatment adherence is an important issue in actual clinical practice. As defined by the WHO, adherence to treatment is seen as the degree to which a patient's actions - taking medications, adhering to diet and other lifestyle interventions - correlate with following the doctor's recommendations. Treatment of patients with rheumatic diseases continues for many years, and often for life. The identification of factors associated with adherence to therapy will justify the implementation of a number of measures in order to increase the effectiveness of treatment of patients. Biological disease modifying antirheumatic drugs (bDMARDs) therapy involves more frequent visits of patients to a doctor with close monitoring of their condition, which may have an impact on adherence to treatment in this group of patients.
Objectives: to assess adherence to treatment of patients with rheumatological profile, depending on the basic therapy option.
Methods: A survey of 84 patients was conducted: 48 (57.1%) women and 36 (42.9%) men, mean age 51 years (36.8; 60.3). Most patients are observed with a diagnosis of rheumatoid arthritis - 48 (57.1%) people, with psoriatic arthritis - 26 (30.9%) and with ankylosing spondyloarthritis - 10 (12.0%) people.
The patients were divided into 2 groups depending on the type of basic therapy: Group 1 (40 people) - patients receiving combined therapy with bDMARDs and methotrexate; Group 2 (44 people) - patients with methotrexate monotherapy.
Patients in group 1 received the following bDMARDs: 18 patients received sarilumab (200 mg sc once every 2 weeks), 22 people received secukinumab (150 mg sc once a month). All patients took methotrexate at an average dose of 17.5 (15.0; 20.0) mg / week and NSAIDs.
Adherence to treatment was assessed using the Morisky-Green scale. Each of the 4 points is evaluated according to the principle of answers to the question "yes-no", while the answer "yes" is estimated at 0 points, and the answer "no" - at 1 point. Patients who score 4 points are considered compliant (adherent); insufficiently committed and those at risk for the development of non-commitment - 3 points; not committed - 2 points or less.
Results: The majority of patients are seen by a doctor monthly - 45.2% (38) and once a quarter - 33.3% (28). Only 7.1% (6) people are observed once every 6 months and 4.8% (4) once a year, and 9.6% (8) are not observed at all.
The frequency of medical observations in the 1st group of patients was higher than in the 2nd: monthly - 60.0% (24) and 40.9% (18), every 3 months - 40.0% (16) and 45.5% (20), respectively (p = 0.072 and p = 0.089), and only patients of the 2nd group were observed once every 6 months (4.5% - 2 people) and once a year (9.1% - 4 people). There were no statistically significant differences in adherence indicators.
When assessing adherence to treatment according to the Morisky-Green scale: only 37.5% (15) of patients in group 1 and 29.6% (13) in group 2 (p = 0.12) adhere to therapy, 30.0% are not adherent enough (12) and 22.7% (10) patients (p = 0.31), not adhering to treatment - 32.5% (13) and 47.7% (21) people, respectively (p = 0.39).
Conclusion: Thus, basic therapy bDMARDs with more frequent medical supervision does not affect adherence to treatment. Only about a third of patients are adherent to bDMARDs therapy.

AB0839 A STUDY OF SERUM COMPLEMENT AND SERUM CALPROTECTIN LEVEL IN SYSTEMIC LUPUS ERYTHEMATOSUS

H. Goswami[1], S. Kakati[1]. *[1]Assam Medical College & Hospital, Dibrugarh, General Medicine, Dibrugarh, India*

Background: Serum calprotectin, also known as MRP8/14 or S100A8/A9, has gained attention in recent years as a candidate biomarker in inflammatory diseases like SLE.[1] Proteins of the complement pathway (serum C3 and C4) are linked to the pathogenesis of SLE and their levels have been measured as a means to assess the disease activity.[2]
Objectives:
[1] To study the relation of serum complement and serum calprotectin levels to disease activity in SLE
[2] To study the relation between serum complement and serum calprotectin level in SLE
Methods: Our study was a hospital based observational study conducted in a tertiary care centre in North-East India during the period of June 2019 to May 2020. A total of 102 patients of SLE were taken up for the study. Disease activity was assessed using SLEDAI-2K scores and serum calprotectin level was measured by ELISA. Serum C3 level was assessed by Nephelometric and C4 level by Turbidimetric immunoassay. The statistical significance was fixed at 5% level of significance (p<0.05) for all analysis.
Results: Our study found a predominantly female population (Female: Male ratio 24.5: 1) with majority of the patients (49.02%) in the 30-39 years age group. Higher calprotectin levels were seen in patients with higher disease activity (SLEDAI) and this relation was statistically significant (r=0.84, p<0.001). There was significant negative correlation between disease activity (SLEDAI) and serum C3 (r=-0.35, p<0.001) and serum C4 (r=-0.4, p<0.001) level. There was a significant negative correlation between complement levels and serum calprotectin levels (r=-0.53, p<0.001).
Conclusion: We found a significant positive correlation between serum calprotectin level and disease activity with a significant negative correlation between complement level and disease activity in SLE patients. There was a significant negative correlation between serum complement and serum calprotectin levels. These findings suggest serum calprotectin levels could be a substantial addition in the existing diagnostic array of tools in assessing lupus disease activity.

AB0840 DIAGNOSIS VALUE OF INTERLEUKIN 23 IN SPONDYLOARTHRITIS

L. Kharrat[1], M. Slouma[1], A. Tezeghdenti[2], W. Dkhili[2], R. Dhahri[1], E. Ghazouani[2], I. Gharsallah[1], L. Metoui[1], B. Louzir[1]. *[1]The Military Hospital of Tunis, Rheumatology, Tunis, Tunisia*; *[2]The Military Hospital of Tunis, Immunology, Tunis, Tunisia*

Background: Interleukin 23 (IL-23) is a pivotal pro-inflammatory cytokine in the Th17/IL-23 axis which became the center of attention in researches during these last decades, especially during spondyloarthritis (1).
Objectives: We aimed to study the diagnosis value of IL-23 serum in spondyloarthritis.
Methods: We conducted a case-control study, including 144 subjects divided into 2 groups:
-G1: 72 patients meeting the Assessment of SpondyloArthritis International Society (ASAS) criteria for spondyloarthritis (SA)
-G2: 72 healthy controls matched for age and sex.
For each SA patient we collected the following parameters: BASDAI (Bath Ankylosing Spondylitis Disease Activity Index), ASDAS (Ankylosing Spondylitis Disease Activity Score), BASFI (Bath Ankylosing Spondylitis Functional Index), and BASRI (Bath Ankylosing Spondylitis Radiology Index).
The IL-23 level was measured using Enzyme-linked immunosorbent assay (ELISA).
Erythrocyte Sedimentation rate (ESR) and C-reactive protein (CRP) were also measured.
We performed a ROC analysis and computed the air under the curve (AUC) at IL-23 to diagnose SA patients.
Statistical analysis was performed using "IBM SPSS Statistics" software version 25.

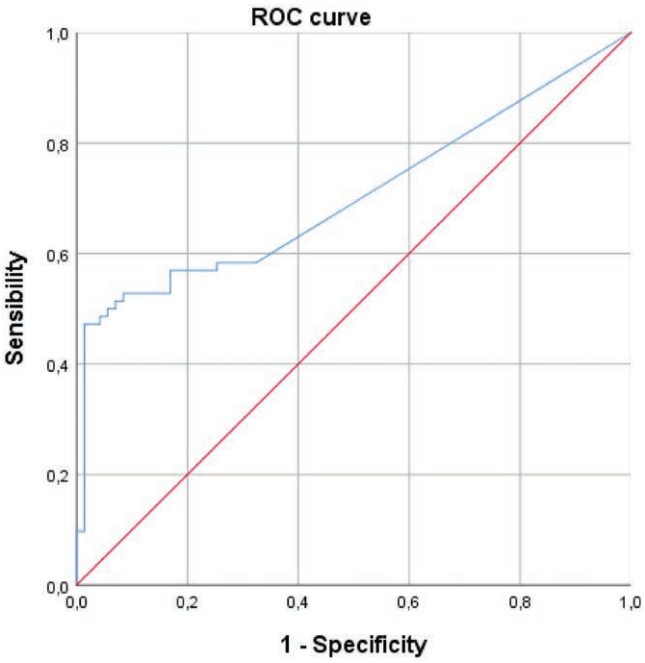

Figure 1. AUC at IL-23 between SA patients 0.705 (p<0.0001)

Nevertheless, no correlation was found between serum IL-23 levels and the following parameters: ESR, CRP, BASDAI, ASDAS-CRP, BASFI and BASRI.

Results: The study included 57 men and 15 women. The mean age was 44.84 ± 13.42 years. The mean age at the onset of the disease was 35.97 ± 12.88 years. The disease duration was 8.54 ± 7.7 years.

Seventy-nine per cent of our patients had axial radiographic spondyloarthritis (n=57). Peripheral involvement was found in 45.8% (n=33). Eighteen patients had both axial and peripheral involvement concomitantly. Psoriasis was found in 36.1% of the cases (n=26).

The mean BASDAI and ASDAS-CRP were 3.21 ± 1.64 and 3.05 ± 1.51, respectively.

The mean was BASFI 3.88 ± 2.69. The mean was BASRI 5.26 ± 4.14.

The mean ESR and CRP were 36.74 ± 29.38 mm/hr and 20.45 ± 25.19 mg/dL, respectively.

IL-23 level was significantly higher in patients compared to healthy controls (23.1 ± 2.72 pg/mL and 5.02 ± 0.59 pg/mL, respectively, p<0.0001).

As shown in Figure 1, the AUC value to distinguish between spondyloarthritis and healthy control was 0.705 (p<0.0001). IL-23 cut-off was 7.96 pg/mL (Sensibility= 69.4%, specificity=98.6%).

Conclusion: As reported to previous studies, our study showed that IL-23 is significantly higher in SA patients (2).

Interestingly, IL-23 was able to distinguish between SA patients and healthy controls with a cut-off of 7.96 pg/mL. This finding suggests that IL-23 may be practical for the diagnosis of SA.

AB0841 ALTERED XANTHINE OXIDASE AND XANTHINE DEHYDROGENASE ACTIVITIES IN RED BLOOD CELLS AS A CONTRIBUTION TO AUTOIMMUNE ANEMIA APPEARANCE IN RHEUMATOID ARTHRITIS

E. Mozgovaya[1], A. Trofimenko[1], S. Bedina[1], S. Spitsina[1], M. Mamus[1], I. Zborovskaya[1]. [1]*Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Clinical Biochemistry Lab, Volgograd, Russian Federation*

Background: Rheumatoid arthritis (RA) is severe autoimmune joint disease, accompanied by a wide variety of extra-articular manifestations. Anemia is one of the most common organ involvements in RA, being diagnosed in 36-65% patients. Iron metabolism alterations, shortened RBC lifespan, and impaired erythropoiesis in bone marrow are believed to play a leading role in RA-related anemia development. These processes in RA can be mediated by increased effect of proinflammatory cytokines, including IFNγ and TNFα, and similar mechanisms could contribute to high xanthine oxidoreductase (XOR) expression. This enzyme makes multiple pathophysiological effects, some of which can be related to the development of anemia in RA. Reactive oxygen species generated by XOR are capable, in particular, of damaging cell membranes, exerting influence on iron mobilization from ferritin in liver, and inducing changes in intestinal iron absorption.

Objectives: Evaluation of changes in XOR interconvertible forms (xanthine oxidase and xanthine dehydrogenase) activities in RBC of RA patients.

Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles. 75 RA patients with verified RA were enrolled in the study. The diagnosis was verified using the ACR/EULAR criteria (2010). The reference group consisted of 35 healthy individuals. Xanthine oxidase (XO, EC 1.17.3.2) and xanthine dehydrogenase (XDG, EC 1.17.1.4) activities were measured in lysed red blood cells by spectrophotometric method as previously described [1]. The enzymatic activities were expressed as nmol/min/ml and normalized to 1×10^9 cells/ml. Statistical comparison tests were selected in according to common guidelines. Central tendencies were expressed as means±SEM. Differences were considered significant when p<0.05.

Results: Mean age of RA patients was 43.9±0.97 years, and mean RA duration was 8.5±0.3 years. Extra-articular manifestations were diagnosed in 32 (42.7%) RA patients and 17 (53.1%) of them had anemia. We revealed substantial changes in XO and XDG activities in lysed RBC of RA patients with anemia. Increased XO activity and decreased XDG activity were observed in comparison with healthy controls (p<0.001 for both enzymes). In parallel with the increase in DAS28 index, significant growth of XOD/XDG coefficient was observed, which was caused by both XOD activity elevation and XDG activity reduction in lysed RBC (p<0.001 for both enzymes). Enzymatic activities depended also on the extra-articular RA manifestations. Mean XO activity was higher and mean XDG activity were lower in patients with extra-articular manifestations (p<0.05 for both enzymes), but the extent of changes was substantially less comparing to anemia.

Conclusion: Autoimmune inflammation in RA is accompanied by changes in enzymatic activities of XOR interconvertible forms and their ratio. Transformation of XDG into KO ultimately leads to significant increase in the generation of reactive oxygen species that have a damaging effect on lipids, proteins and other cellular components, and specifically in RBC. This fact may be one of the reasons for their premature damage and development of anemia in RA.

AB0842 CESAREAN SECTION IN MEXICAN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

A. Y. Lujano Negrete[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], F. Hernández[2], R. A. Rodriguez Chavez[1], L. G. Espinosa Banuelos[1], R. Moyeda Martinez[1], A. Cárdenas[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Reumatología, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Ginecología y Obstetricia, Monterrey, Mexico*

Background: Rheumatic diseases occur among women of childbearing age, adverse events during pregnancy in rheumatic diseases have been frequently reported. Mexico has one of the largest prevalence of cesarean section in women which negatively impacts the product.

Objectives: The objective of this study is to describe the frequency of cesarean section in women with autoimmune rheumatic diseases compared to a control group.

Methods: We conducted a cross-sectional and retrospective study in patients from the pregnancy and rheumatic diseases clinic, and the Obstetrics department form the University Hospital “Dr. José E. González” in Northeast Mexico. Women with autoimmune rheumatic diseases that gave birth between August 2017 to December 2020 were included. All the data, including the way of birth was retrieved from the clinical files.

Results: One hundred and twelve patients were included (56 in the rheumatic disease group and 56 women without rheumatic diseases), two of them suffered miscarriage (one from the rheumatic disease group and 1 from the control group) giving a total of 110 products. The mean age was 29.6 years for the rheumatic patients and 24.6 for the control group. The most frequent rheumatic disease was RA in 22 patients (39.2%), followed by SLE in 13 patients (23.21%).

From the 56 pregnancies on the rheumatic disease group more than half ended by cesarean section (n=33, 58.92%) and there were 22 simple vaginal delivery. Table 1. On the control group there were 24 cesarean section procedures and

31 simple vaginal delivery. The indications for cesarean sections are presented in Figure 1. No statistically significant difference was found on cesarean section prevalence between both groups (p=0.389).

The most common indication for cesarean section in all patients was previous cesarean procedure. (n=12, 36.36%). There were more pathological fetal cardiotocographic changes (PFCC) as an indication for cesarean section on the rheumatic diseases group (n=11, p 0.002) compared with the control group (n=1).

Conclusion: A higher prevalence of cesarean sections was found in women with rheumatic diseases versus women without rheumatic diseases, although this difference was not statistically significant. Studies with a higher sample size are necessary to elucidate the complications and differences between both groups.

AB0843

OBSTETRIC AND PERINATAL OUTCOMES IN MEXICAN WOMEN WITH RHEUMATIC DISEASES

F. Hernández[1], A. Y. Lujano Negrete[2], C. M. Skinner Taylor[2], L. Pérez Barbosa[2], E. Barriga-Maldonado[2], R. A. Rodriguez Chavez[2], L. G. Espinosa Banuelos[2], R. Moyeda Martinez[2], G. Figueroa-Parra[2], D. Á. Galarza-Delgado[2]. [1]*Hospital Universitario Dr. José Eleuterio González, Obstetricia, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Reumatología, Monterrey, Mexico*

Background: Rheumatic diseases (RD) are more frequent among women of childbearing age. Adverse events during pregnancy in RDs have been frequently reported, leading some women to avoid pregnancy. “CEER” is an outpatient clinic in Monterrey, Nuevo Leon, Mexico, that was created for pregnant women with RD.

Objectives: The objective is to describe pregnancy outcomes in patients with RD surveilled at a rheumatology outpatient clinic.

Methods: A single-center retrospective study of women with RD at CEER between 2017 and 2020 was conducted. Clinical features and maternal, fetal and neonatal outcomes were retrospectively collected. The rate of adverse perinatal outcomes (APO) was compared with the tertiary referral center´s general obstetric population (GOP). All data was retrieved from clinical files.

Results: Overall, 62 pregnancies in women with RD were recorded. The median maternal age at conception was significantly higher in pregnancies with RD than GOP (29 [24-35] years old vs 23 [19-28] years old, p<0.001).The odds of preterm delivery were increased among pregnancies with RD (OR 1.85, 95% CI 1.03-3.30, p=0.038). Other APO are summarized in Table 1. Rheumatoid arthritis (RA) was the leading diagnosis followed by systemic erythematosus lupus (SLE) and antiphospholipid syndrome (APS).

Cesarean sections were recorded in 41 pregnancies in RD group, more frequent than in GOP (66.1% vs 50.8%, p=0.016). Figure 1 shows the distribution of indications for cesarean sections, the two leading indications were previous cesarean section (43.9%) and Nonreassuring fetal heart rate pattern (19.5%) Pregnancies with RD appeared to have frequent, emergency cesarean sections and preterm deliveries compared with GOP (12.9% vs 15.9%, p=0.02 and 23.7% vs 12.2%, p=0.006, respectively).

Conclusion: Pregnancies with RD were at increased risk for APO. Women of this population should be made aware of these risks and be closely monitored by a multidisciplinary team as a high-risk pregnancy.

AB0844 HAND GRIP STRENGTH EVALUATION IN RHEUMATOLOGIC DISEASES

A. Caturano[1], P. C. Pafundi[1], R. Galiero[1], M. Tardugno[2], F. C. Sasso[1], G. Cuomo[2]. [1]*University of Campania "Luigi Vanvitelli", Department of Advanced Medical and Surgical Sciences, Naples, Italy*; [2]*University of Campania "Luigi Vanvitelli", Department of Precision Medicine, Naples, Italy*

Background: Handgrip muscle strength test describes the strength of the hand muscles used to grasp or grip. Currently, hand grip evaluation is often used in clinical practice, as a marker of function and disability. In fact, it has already been applied as an outcome measure in arthritis rheumatoid clinical trials, to demonstrate the benefits of several treatments [1]. However, hand disability should also be considered in all other rheumatological diseases.
Objectives: The main aim of this study is to assess the handgrip muscle strength test in a rheumatological cohort of patients as compared to a control group.
Methods: This is a cross-sectional pilot study. We considered eligible 35 rheumatological consecutive female patients followed at our outpatients' clinic of Internal Medicine (I Policlinico of Naples) and 35 healthy control females (HC). Both groups included only right-handed individuals. Rheumatological patients were distributed as follows: 5 rheumatoid arthritis (14,3%), 9 psoriatic arthritis (25,7%), 4 systemic lupus erythematosus (11,4%), 10 systemic sclerosis (28,6%), 4 fibromyalgia (11,4%), 3 juvenile idiopathic arthritis (8,6%). The course of disease was under optimal treatment in all patients.
The type of hand grip used is the power grip, in which an object is held firmly by wrapping the fingers around it, pressing the object against the palm, and using the thumb to apply counter-pressure. We considered as either right or left hand valid measure the mean of three consecutive tests per arm. Between-groups differences were tested both by a uni- and multivariable analysis.
Results: The two subgroups were homogeneously distributed for age (median age 42 yrs. [IQR 33-48] vs. 36 yrs. [IQR 30-52] in HC; p=0.902). At univariate analysis, hand grip strength was significantly lower in the rheumatological patients, both at right hand (right 19.5 kg [IQR 13.6-24.8] vs. 24.5 kg [IQR 20.8-29] in HC; p=0.004) and left hand (18.5 kg [IQR 13.9-22.5] vs. 23.7 kg [IQR 19-27.3] in HC; p=0.002), as compared to HC. This finding was further confirmed at multivariable analysis only as for the left hand (OR 0.919, 95%CI: 0.858-0.984; p=0.016).
Conclusion: Rheumatological diseases are burdened by hand disability, mostly affecting daily activities performance [2,3]. Beyond an optimal disease control, our pilot study shows a decrease in left hand strength as compared to healthy controls. This might be due to a reduced use of the non-dominant hand, which may lead over time to a higher deficit of strength. As such, these patients should be prescribed to a left hand exercise to improve both mobility and strength and, consequently, hand function.

AB0845 THE COMBINATION OF PLASMA FIBRINOGEN CONCENTRATION AND NEUTROPHIL-LYMPHOCYTE RATIO (F-NLR) AS A NOVEL INFLAMMATORY MARKER OF RHEUMATOID ARTHRITIS

M. Liu[1], Z. Huang[1], Y. Huang[1], Z. Huang[1], Q. Huang[1], T. W. LI[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China*

Background: The combined index of fibrinogen and neutrophil-lymphocyte ratio (F-NLR) has recently been reported as a new predictive factor in patients with cancer. However, the fibrinogen and NLR have not been simultaneously evaluated in rheumatoid arthritis (RA).
Objectives: This study aimed to explore the clinical value of F-NLR in RA and its relationship with disease activity.
Methods: This retrospective study collected 143 RA patients and 82 age- and gender-matched healthy controls. Neutrophil, lymphocyte, monocyte, platelet, fibrinogen, NLR, monocyte to lymphocyte ratio (MLR), platelet to lymphocyte ratio (PLR), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), Disease Activity Score of 28 joints-ESR (DAS28-ESR) and other laboratory parameters were recorded. Receiver operating characteristic (ROC) curves were used to defined the optimization cut-off values of fibrinogen and NLR, which were 3.9g/L and 2.42. The F-NLR score was 2 for patients with high fibrinogen (> 3.9g/L) and elevated NLR (> 2.42), while those with one or neither were indexed as 1 or 0. The correlations between F-NLR as well as other inflammatory indexes and DAS28-ESR were measured.
Results: The F-NLR score was higher in RA patients than that in healthy individuals ($P < 0.05$). The proportion of higher F-NLR score increased significantly along with the disease activity ($P < 0.05$). According to the ROC curve which was conducted to discriminate RA patients from healthy subjects, the area under curve (AUC) of F-NLR (0.803, 95% CI: 0.744 - 0.861) was higher than that of fibrinogen (0.735, 95% CI: 0.670 - 0.801), NLR (0.724, 95% CI: 0.655 - 0.794), MLR (0.687, 95% CI: 0.615 - 0.759) and PLR (0.732, 95% CI: 0.664 - 0.800). Furthermore, F-NLR was more strongly associated with DAS28-ESR ($r = 0.572$, $P < 0.001$) when compared with fibrinogen ($r = 0.518$, $P < 0.001$), NLR ($r = 0.365$, $P < 0.001$), MLR ($r = 0.140$, $P = 0.096$), PLR ($r = 0.239$, $P = 0.004$), CRP ($r = 0.539$, $P < 0.001$) and ESR ($r = 0.487$, $P < 0.001$).
Conclusion: The results demonstrated that the F-NLR score was elevated in RA patients. The F-NLR score may be a potential marker to monitor the disease activity of RA patients.

Education

AB0846 CONCEPTION AND FEASIBILITY OF A DIGITAL TELE-GUIDED ABDOMEN, THORAX AND THYROID GLAND ULTRASOUND COURSE FOR MEDICAL STUDENTS

E. Höhne[1], F. Recker[2], E. Schmok[3], P. Brossart[1], T. Raupach[4], V. Schäfer[1]. [1]*University Hospital Bonn, Clinic of Internal Medicine III, Oncology, Hematology, Rheumatology and Clinical Immunology, Bonn, Germany*; [2]*University Hospital Bonn, Department for Obstetrics and Gynecology, Bonn, Germany*; [3]*Amboss GmbH, Institutional Partnerships, Berlin, Germany*; [4]*University Hospital Bonn, Institute for Medical Education, Bonn, Germany*

Background: Over the past few decades, technological advances in both ultrasound (US) and the application of telemedicine have been made [1]. Medical education has shifted to online classes during the COVID-19 pandemic, creating challenges in adequate training of US.

Objectives: In the context of the current COVID-19 pandemic and the discontinuation of traditional classroom teaching, a tele-didactic US course for undergraduate medical students was developed. This study is examining the educational outcome of a new digital US course of the abdomen, thorax and the thyroid gland with the implementation of a modern portable US system.
Methods: A tele-guided US course was established between April 1st and June 20th, 2020, at the University Hospital in Bonn, Germany. Students completed pre- and post-course surveys and underwent six US organ modules. Each module took place in a flipped-classroom concept including a digital learning platform. An objective structured assessment of US skills (OSAUS) [2] was implemented as final exam. Further, US images of the course and exam were rated by the Brightness Mode Quality Ultrasound Imaging Examination Technique (B-QUIET) [3]. Achieved points in image rating were compared to the OSAUS exam and survey results.
Results: A total of 15 medical students were enrolled. There was a significant increase in self-assessed theoretical and practical ability ($p < 0.001$). Students achieved an average score of 154.5 (SD ± 11.72) out of 175 points (88.29%) in OSAUS, which corresponded to the image rating using B-QUIET and self-assessment data obtained in surveys. Interrater analysis of US images showed a favorable agreement with an ICC (2,1) of 0.895 (95% confidence interval $0.858 < ICC < 0.924$).
Conclusion: US training via teleguidance should be considered in medical education. Our pilot study demonstrates the feasibility of this concept that can be used in the future to improve US training of medical students even during a pandemic. The digital implementation with an affordable, portable point-of-care-US device could be an incredible opportunity to expedite US training worldwide.

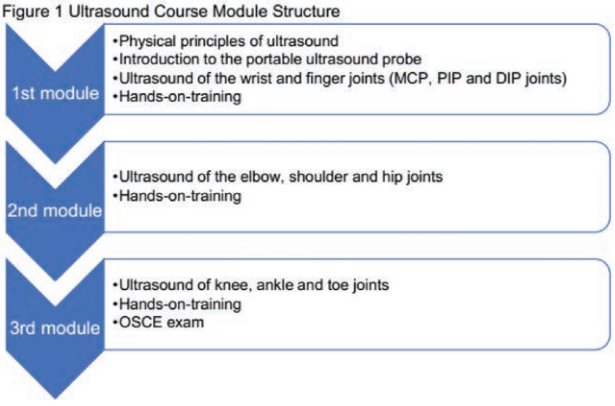
ESTABLISHMENT AND VALIDATION OF A DIDACTIC MUSCULOSKELETAL ULTRASOUND COURSE FOR DERMATOLOGISTS USING AN INNOVATIVE HANDHELD ULTRASOUND SYSTEM – THE MUDE STUDY (MUSCULOSKELETAL ULTRASOUND IN DERMATOLOGY)

J. Grobelski[1], F. Recker[2], D. Wilsmann-Theis[3], W. Hartung[4], P. Karakostas[1], P. Brossart[1], V. Schäfer[1]. [1]*University Hospital Bonn, Clinic of Internal Medicine III, Oncology, Haematology, Rheumatology and Clinical Immunology, Bonn, Germany*; [2]*University Hospital Bonn, Centre for Obstetrics and Gynecology, Bonn, Germany*; [3]*University Hospital Bonn, Clinic and Polyclinic for Dermatology and Allergology, Bonn, Germany*; [4]*Bad Abbach, Rheumatology and Clinical Immunology, Bad Abbach, Germany*

Background: In the early detection of arthritis, such as psoriatic arthritis (PsA), ultrasound (US) of painful joints plays an important role in diagnosis. Pathological findings can be missed during clinical examination, especially if conducted by physicians who are not trained. Furthermore, several publications undermine the importance of early PsA detection in psoriasis patients and the key role of the dermatologists in this process.
Objectives: The objective of this study was to examine a pilot musculoskeletal ultrasound (MSUS) course designed specifically for dermatologists.
Methods: To assess the degree of US expertise of the participants, a questionnaire was conducted before the course. The course concept, based on The German Society for Ultrasound in Medicine (Deutsche Gesellschaft fur Ultraschall in der Medizin, DEGUM) covering only the most important US sections of all joints and focused on the detection of joint effusion and hyperperfusion. The course consisted of three modules and was carried out over 6 months. Figure 1 shows the modular course concept. A portable US device in combination with a tablet was provided to enable practice between the courses. The final teaching evaluation was carried out as an objective structured clinical examination (OSCE) consisting of three stations, each representing the three course modules. According to the following grade scoring system, the performance rating was checked: < 60 % failed, ≥ 60 - < 70 % sufficient, ≥ 70% - < 80 % satisfying, ≥ 80% - < 90 % good, ≥ 90 % very good.

Figure 1 Ultrasound Course Module Structure



MCP: Metacarpophalangeal joint, PIP: Proximal interphalangeal joint, DIP: Distal interphalangeal joint, OSCE: objective structured clinical examination

Results: Twelve dermatologists participated. The mean age of our cohort was 39 years (SD ± 9.99 years) with nine females (75 %). Eight were specialists in dermatology in mean for 11.4 years (SD ± 11 years). Four were assistant physicians practicing dermatology in mean for 3.06 years (SD ± 0.97 years).
The survey revealed no prior knowledge of MSUS. The overall mean score of all participants in the OSCE was 21.86 (SD ± 2.12) (87.44%) out of a total of 25 points resulting in a good grade. There was no statistically significant difference between the assistant physicians and the specialists in dermatology regarding the OSCE results. Table 1 shows the OSCE results.

Table 1. Objective structured clinical examination (OSCE) mean results for all three stations

OSCE stations	Mean absolute	Mean absolute	Standard Deviation	Mean percentage	Standard Deviation	Confidence Interval	Grade
1	18.92	18.92	+/- 3.07	75.67%	+/-12.27%	67.87-83.46%	Sufficient
2	23.83	23.83	+/-0.99	95.33%	+/-3.94%	92.83-97.84%	Very good
3	22.83	22.83	+/-0.37	91.33%	+/-1.49%	90.39-92.28%	Very good
OSCE station 1-3	21.86	21.86	+/-2.12	87.44%	+/-8.49%	66.36-108.53%	Good

Conclusion: The innovative US teaching concept was able to demonstrate, that it is appropriate for the training of dermatologists in MSUS, independently of their age, experience in dermatology and US.

Background: Mental health was widely affected during the new coronavirus pandemic. In addition, some measures adopted by most countries in order to contain the virus spread, such as isolation and social distancing, leading to the interruption of routine activities, including partial or complete interruption of face-to-face classes may be associated with increased stress, depression and anxiety among undergraduate medical students (1). From March to September, 2020, the Brazilian Society of Rheumatology carried out the Mario Pinotti II Project (MPII), a prospective, multicenter, observational cohort study designed to monitor the COVID-19 in patients with rheumatic disease on hydroxychloroquine, using periodic telephone calls performed by undergraduate medical students (2).

Objectives: To compare the mental health status of medical students who were participating from the MPII with theirs colleagues not involved in this project.

Methods: A web-based survey via google forms platform was developed by a panel composed of undergraduate medical students, rheumatologists, medical school professors, and a psychology professor. It included details on demographic and life habits data and domains regarding depression, anxiety and stress, using the DASS-21 (Depression, Anxiety & Stress Scale), Brazilian version. Data collection occurred from July 20th to August 31st, 2020. Statistical analysis was performed using the SPSS version 20.0. Univariate and multivariate linear regression analysis were performed to verify associations with the DASS-21, defined as dependent variable. A p-value < 0.05 was deemed as significant. This study was approved by the Institutional Research Ethics Committee.

Results: A total of 684 undergraduate medical students were included in this study, of whom 228 as MPII volunteers (VG) and 456 as control group (CG). Median age was 23 years (IQ 21-24) and the CG was older than the VG (p<0.03). Most of them were white (68.8%) and women (63%). There were no significant differences regarding comorbidities, ethnicity, smoking status, alcohol intake and physical activity. Older age, male gender, participation of MPII study, absence of a worsening in sleep pattern during the pandemic and a lower number of prior comorbidities were associated with lower DASS21 scores, suggesting a better mental health (Table 1).

Conclusion: Several aspects may be involved with mental health, including increased emotional maturity, gender and sleep pattern. Although with marginal independent association, medical students with participation in the MPII study had better mental health than their student colleagues not engaged with this research. Our data pointed out that voluntary participation in a research project which foresees interaction by telephone contact with rheumatic patients, professors, rheumatologists, and colleagues is associated with better mental health.

AB0849 ONLINE EDUCATION YIELDS SIGNIFICANT GAINS IN RHEUMATOLOGISTS' KNOWLEDGE OF PSORIATIC DISEASE

A. Stan[1], M. Calle[1], P. Schoonheim[1], A. B. Gottlieb[2]. [1]*Medscape, LLC, Education, New York, United States of America*; [2]*Icahn School of Medicine, Mount Sinai, New York, United States of America*

Background: Physicians face challenges staying up-to-date with the latest research and accessing the ever-growing field of knowledge is time-consuming. Online education can make these clinician's tasks more efficient and less time-consuming.

Objectives: As part of a larger curriculum, we developed an online CME activity titled: "Optimizing Treatment in Patients With Moderate to Severe Psoriasis". The goal of this study was to assess whether this online CME accredited video discussion improves physicians' understanding of the prevalence and impact of the various manifestations of psoriatic disease, and how these might impact the choice of treatment in patients with psoriasis and/or psoriatic arthritis.

Methods: Rheumatologists participated in an online CME activity (https://www.medscape.org/viewarticle/931595) consisting of a 30-minute video discussion between 2 experts with synchronized slides. Educational effect was assessed using a 4-question repeated pairs, pre-/post-assessment. A chi-square test determined if a statistically significant improvement (P <.05 significance level) existed in the number of correct responses from the pretest and posttest scores. Cramer's V was used to estimate the level of impact of the education (Modest

[.0]; Extensive [>.26]). The CME activity launched on Jul 6, 2020, and the data were collected through Aug 31, 2020.

Results: A total of 54 rheumatologists completed the pre- and post activity assessments during the study period. Overall the activity had a signficiant impact (*P* =.0002) on rheumatologists' knowledge and competence related to optimisation of treatment in psoriatic disease, with a Cramer's V value of 0.210 indicating a considerable educational impact. The average percentage of correct responses rose from 67% pre-activity to 85% post-activity. A repeated pairs analysis showed that 21% of rheumatologists improved their knowledge and 64% reinforced their knowledge, respectively. The changes in percentage of correct responses from pre- to post-assessment for all questions are shown in Table 1. More than 60% of rheumatologists had a measurable improvement in confidence in their ability to identify patients with psoriatic disease who are candidates for first-line therapy with biologics.

Table 1. Impact of education on rheumatologists' knowledge of psoriatic disease

Question #	Question topic	Aggregated data		Linked Learner Results[a]	
		Average % of correct responses Pre- vs. Post-education	P-value	% Improved[b] learners Pre- vs. Post-education	% Reinforced[c] learners Pre- vs. Post-education
1.	Prevalence of the various manifestations of psoriatic disease	46% vs 80%	.0002	35%	44%
2.	Clinical data with biologic therapies in psoriatic disease	69% vs 78%	NS	17%	61%
3.	Competence related to identification of patients who may benefit from biologic therapy	87% vs 98%	.027	11%	87%

[a]Each individual learner tracked pre and post-education[b]Incorrect answer pre-education, Correct answer post-education[c]Correct answer pre-education, Correct answer post-education

Conclusion: This online CME activity significantly improved rheumatologists' knowledge and competence related to the optimization of treatment in psoriatic disease. However, there is room for further improving physicians' knowledge of clinical trial outcomes with biologics in patients with PsA, since 22% of rheumatologists provided incorrect answers to question 3 post-education. This topic can be addressed in future educational programs.

AB0850 DUTCH RHEUMATOLOGISTS' PERSPECTIVE ON MRI EDUCATION: DO WE NEED TO CHANGE?

M. Cabri[1], C. J. Van der Laken[2], M. Maas[3]. [1]*Amsterdam UMC, Rheumatology, Amsterdam, Netherlands*; [2]*Amsterdam UMC, Rheumatology, 1081HV, Netherlands*; [3]*Amsterdam UMC, Radiology, Amsterdam, Netherlands*

Background: Studies have shown the value of magnetic resonance imaging (MRI) as an objective tool for diagnosis, follow up and detection of complications for a broad spectrum of rheumatology associated diseases [1]. With increasing (potential) clinical applications of MRI, rheumatologists need basic knowledge about the technique and interpretation of the images to get most out of MRI use in clinical practice. Although radiologists will remain the experts of MRI protocols and readings, lack of sufficient rheumatologists training will not yield in optimal interaction between the specialists and will negatively influence the benefit of the MRI contribution to patient care. Despite offered MRI courses within EULAR, in the Netherlands there is currently no structural MRI education for rheumatologists (in training). This while rheumatologists are intrinsically motivated to improve their MRI skills [2,3].

Objectives: By use of a developed questionnaire:

[1] To create an overview of the current communication methods between rheumatologists and radiologists regarding MRI and rheumatologists' perspectives on the efficiency and effectiveness of the imaging requests and radiologists reports.

[2] To make an inventory of current knowledge and interpretation skills of rheumatologists concerning MRI.

[3] To assess the needs of rheumatologists for education to work with MRI requests, reading and reports in routine clinical care by development of a questionnaire to determine the current clinical situation.

Methods: A questionnaire was created.

Results: A total of 109 respondents (28% respons) have filled in the form with a 100% completion rate.

1. Communication:

Communication regarding MRI in rheumatology is done largely per request of the rheumatologist with a high level of satisfaction concerning the quality of the discussion. Most medical centers have no multidisciplinary team meeting with the radiology department, discussions are mostly performed on demand.

2. Interpretation:

Rheumatologist predominantly rely on the conclusion of the radiology report with little understanding of the technical and anatomical characteristics of the images. Only a small percentage (6%) of rheumatologists is able to interpret the images. Half of the responders do not feel competent to teach fellow colleagues about imaging.

3. Educational wishes:

When asked to prioritize the subject of imaging education, most people prefer interpretation skills, followed by instructions on how to provide most optimal clinical information and question(s) on the request form as well as knowledge on anatomy. Least preferred is education concerning the MRI technique itself.

The preferred method of advanced imaging education is a combination of classroom teaching and e-learning.

Conclusion: Dutch rheumatologists express a satisfactory communication with their radiologists, which is mostly not performed structurally. Rheumatologists indicated that education, in particular in MRI imaging reading,will provide a better understanding in the MRI technique and applicability as well as confidence in self-interpretation of the images.

The preferred method of MRI imaging education is blended (e.g., a combination of classroom teaching and e-learning).

The results therefore show that MRI education of rheumatologists is still a need in clinical practice in the Netherlands. MRI education of rheumatologists can contribute to more efficient application of MRI in rheumatology patient care, including a more optimal interaction between radiologists and rheumatologists.

AB0851 CONDUCTING PATIENT SCHOOLS AS A WAY OF MANAGING RHEUMATOLOGIC DISEASES

A. Sarapulova[1], O. Teplyakova[1]. [1]*MA "New Hospital", Center of Clinical Rheumatology, Yekaterinburg, Russian Federation*

Background: 2020 year has become a landmark for the medical care system around the world. A huge number of patients and doctors were involved in the fight against an unknown and rapidly spreading infection, while many patients with chronic diseases or those who were just planning to see a doctor were left without this opportunity. The consequence was the active development of the online format of patient-doctor communication.

Objectives: To determine the value of conducting schools for patients with rheumatologic diseases or related complaints in a pandemic.

Methods: On the basis of the Clinical Rheumatology Center of the Medical Association "New Hospital", online schools were organized for patients with rheumatological diseases and complaints. In just 3 months, 6 schools were held, in which 299 people took part. At the end of each session, patients were asked to answer questions about the level of satisfaction and the value of the information received. The survey was conducted in Google form.

Results: about 80% of the responders lived in the region where the schools were held, 20% were from other regions of Russia or other countries. One third of patients (33.9%) were 31-40 years old, a quarter (25%) were 51-60

years old, and every fifth (19.6) was from 61 to 70 years old. The overwhelming majority (61.1%) learned about the training from employees' announcements or on the website of a medical organization. Interestingly, almost a third of the participants (31.9%) listened to the lecture to "prevent problems in the future" or "for general development," the rest either get sick themselves or have relatives with these problems. The significance and usefulness of the school on a scale from 0 to 10 points was assessed by 75% participants at 10 points, another 21% from 7 to 9 points, and for 1 participant - by 3 and 4 points. When answering the question: "Will something change in the understanding of your disease or further managing after today's lesson?" most of the listeners answered that "they are planning to change their lifestyle" (55.4%), a little less - "understands that you need to come to an in-person appointment" (27.4%), "listened due to problems with relatives" (30.4%) and "understands that it is necessary to adjust the treatment" (23.2%). 87.5% of the responders rated the degree of interest with which the teacher led the school at 10 points; all 100% of participants expressed a desire to attend the following events. When comparing the school with television programs or other similar events, 83.9% of people noted a higher level of information importance and 87.5% of accessibility of its presentation. All responders with a high probability were ready to recommend schools to another people (85.7% for 10 points), trust the doctor conducting such schools (94.6% for 10 points) and would turn to this doctor if possible (87.5% for 10 points). Also, all participants actively answered the question about the desired topic of future schools.

Conclusion: the conducted evaluation of the online format of schools for patients with rheumatic diseases or complaints has confirmed the high satisfaction of patients with this form of communication, the presence of a certain "request" for such format, clarity and accessibility of the transmitted information. The most important result of the training can be considered the readiness of patients to change their lifestyle and the understanding that it is necessary to observe or consult a doctor.

AB0852 BREAKING THE GLASS CEILING IN MEXICAN RHEUMATOLOGY

I. J. Colunga-Pedraza[1], G. Serna-Peña[1], D. Alpizar-Rodriguez[2], N. Guajardo-Jauregui[1], R. Galarza-Molina[3], D. Á. Galarza-Delgado[1], C. F. Pacheco Tena[2], M. A. Reyes Soto[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*; *[2]Colegio Mexicano de Reumatología, Rheumatology, Ciudad de México, Mexico*; *[3]Universidad Auntónoma de Nuevo León, Political Science, Monterrey, Mexico*

Background: The term "glass ceiling" has been used since the late eighties, to designate an invisible barrier that prevents highly qualified women from reaching positions of responsibility in the organizations they work. (1) At first, this concept was used to analyze the career of women who, having a professional career and a high level of competition in their workplaces, encountered an interference when trying to advance in their careers. (2). The so-called "glass ceiling" refers to a last barrier based on prejudice towards women that prevents them from advancing to high-level positions.

Currently, there is almost the same number of men and women affiliated to the Mexican College of Rheumatology (CMR). The position of president is the highest directorial position, we undertook the task of evaluating the percentage of women who have historically held that leadership position.

Objectives: To assess the percentage of woman who have occupied the position of president of the Mexican College of Rheumatology.

Methods: Observational, cross-sectional study. We evaluated the number of man and women who have historically held the position of president of the CMR.

Results: Currently, the CMR has 630 active members, 308 women (48.9%) and 322 men (51.1%). Among rheumatologists younger than 40 years of age, women represent 58% (n=128). We found that historically the CMR has had 48 presidents, of which only 4 (8.3%) are women.

Conclusion: There is a big gender gap between presidents of the CMR. It is important to talk about the gender perspective and recognize the causes that have originated this gap. Incorporating the gender perspective in senior management is a pending issue for our CMR.

AB0853 IGG4-RELATED DISEASE CAUSING OCULAR NERVE PALSIES AND ORBITAL APEX SYNDROME: CASE REPORT AND LITERATURE REVIEW

F. Javed[1], C. Chung[2], H. Fayyaz[1], R. Jeffery[1]. *[1]Northampton General Hospital, Department of Rheumatology, Northampton, United Kingdom*; *[2]Northampton, Department of Ophthalmology, Northampton, United Kingdom*

Background: IgG4-Related Disease (IgG4-RD) is a systemic immune-mediated fibroinflammatory condition. The epidemiology is not well defined: it usually affects adults from middle-age onwards, predominantly male. Both B and T-cells are central in IgG4-RD pathogenesis, as demonstrated by the efficacy of B-cell depletion therapy.IgG4-RD can affect multiple organs including the central and peripheral nervous system, producing a constellation of clinical symptoms and signs, depending on the organ structures involved.

IgG4-related orbital disease is relatively rare can implicate all extra-ocular muscles, structures emerging from the Orbital apex, optic canal, or superior and inferior orbital fissure. Depending on the structures involved, it can produce different or sometimes subtle clinical presentations, posing diagnostic challenge. There were case reports of IgG4-related ophthalmic disease misdiagnosed as intraocular tumour.

Objectives: IgG4-RD is increasingly recognised as an entity affecting the head and neck region. However, it rarely involves skull base and presents with orbital apex syndrome. In this current case report, we describe an interesting case of IgG-related orbital disease presenting with ocular nerve palsies and orbital apex syndrome.

Methods: Case report.

Results: A 36-year-old gentleman with cocaine and alcohol misuse presented with a 2-month history of left sided headache, diplopia, recurrent ear infections, otalgia and hearing loss. Initial imaging suggested left otomastoiditis and intravenous antibiotics were commenced. Contralateral partial third nerve palsy with pupil sparing was elicited. 2 months later, there was worsening right eye ptosis, proptosis, right relative afferent pupillary defect, reduced visual acuity and colour vision as well as a near-complete ophthalmoplegia. Subsequent imaging showed worsening soft tissue swelling centred on the upper left parapharyngeal and masticator space, with multiple perineural enhancement and lateral extension to right orbital apex and orbital fissures. Blood tests only revealed raised IgG4 subclass. Infectious aetiology was excluded. Left nasal mass biopsy performed showed no fungal organism or malignancy. There were lymphoplasmacytic proliferation but no storiform fibrosis or obliterative phlebitis. IgG4 immunostaining on two assessable fields revealed 22 and 17 positive plasma cells respectively, and an IgG4: IgG ratio of <10%, and 50% in the other. Significant improvement was seen clinically and radiologically with antibiotics and a tapering regime of oral Prednisolone. Patient was commenced on Azathioprine as long term immunosuppression.

Conclusion: A high degree of clinical suspicion is necessary to diagnose IgG4-RD when presenting with orbital apex syndrome and ocular nerve palsies,IgG4-RD can mimic mastoiditis of infectious aetiology. Other differentials may include cocaine-induced midline destructive lesions and granulomatosis with polyangiitis. The diagnosis can be supported by elevated serum IgG, elevated IgG index and pathognomonic histopathological findings. . The diagnosis of IgG4-related orbital disease should be deliberated on by a multidisciplinary group, with every effort being made to exclude an infectious aetiology, before embarking on immunosuppressive therapy.Primary treatment is with steroids. However, immunotherapy using azathioprine can be utilised in recurrent disease or patients with steroid intolerance.

AB0854 A CASE REPORT OF BROWN SYNDROME COMPLICATING THE MANAGEMENT OF SCLEROMYOSITIS

P. Arora[1], L. Croot[1]. [1]*Barnsley Hospital NHS Foundation Trust, Rheumatology, Barnsley, United Kingdom*

Background: Brown syndrome is a rare ocular motility disorder which has been reported in JRA, RA and SLE but never in a patient with scleromyositis.
Objectives: To report the first case of Brown syndrome in a patient with scleromyositis and increase awareness of this condition.
Methods: A case report and discussion.
Results: The patient was diagnosed with scleromyositis, at the age of 34, after presenting with arthralgia, sclerodactyly, skin pigmentation, Raynaud's phenomenon, mild muscle weakness and dyspnoea. His labs were CRP 47 mg/L, CK 868 IU/L, ANA strongly positive; anticentromere Ab negative and Anti-PM/Scl-75 and Anti- PM/Scl-100 Ab positive. HRCT chest showed extensive pulmonary fibrosis with lower lobe honeycombing. TLCO was 3.98 (33% of predicted).
He was initially managed with high dose steroids and pulsed IV cyclophosphamide with azathioprine for maintenance therapy. His lung disease stabilised and myositis resolved but he continued to develop calcinosis cutis so was switched to 6 monthly IV rituximab.
6 years later, he developed morning headaches with intermittent diplopia, described as double vision in vertical gaze with one image being above the other. Episodes lasting 10 minutes to 2 hours. Examination showed normal visual acuity and fundoscopy, no peripheral or eye muscle weakness.
Investigations to exclude myasthenia gravis, cerebral vasculitis and atypical infection were organised (MRI, AChR antibody, lumbar puncture, MRA) and were normal.
Because of intermittent nature of his episodes, his eye examination was always normal but he captured images in disconjugate gaze with right eye looking upwards and outwards when trying to look straight (Figure 1). Occasionally this was associated with orbital pain and an audible click. These features are suggestive of Brown syndrome.
He continues to have recurrent episodes despite immunosuppression but prednisolone 20mg daily for 1-2 days at onset of each attack causes rapid resolution of symptoms.

Figure 1. Right eye looking upwards and outwards when trying to look straight

Conclusion: Scleromyositis is an overlap syndrome of scleroderma and dermatomyositis. Muscle involvement is mild and clinical presentation can be variable. The PM/Scl antibodies are highly characteristic of the syndrome. (1)
Brown syndrome is an ocular motility disorder, first described in 1950, characterized by the inability to fully elevate the affected eye in adduction due to pathology of the superior oblique tendon sheath. (2)
It can be congenital or acquired, viz, trauma, surgery or sinusitis and also been described in RA, JIA and SLE. (3)
If superior oblique tendon cannot relax or slide freely through the trochlea then the affected eye cannot depress completely, leading to diplopia on upward gaze. (4) In inflammatory disease it is thought that swelling of the posterior part of the superior oblique tendon or tenosynovitis are likely causes of the tendon sheath abnormality. (4) This is likely to be the case in this patient because his symptoms are recurrent, respond to steroids and tend to occur more towards the end of rituximab cycles.
Recognition of this syndrome is important because invasive investigations can be avoided. Also, intermittent diplopia in a patient with autoimmune disease is suggestive of myasthenia gravis which maybe incorrectly diagnosed.
Finally, this case demonstrates the syndrome can be easily managed with short courses of oral steroids, although patients who are already on immunosuppressant treatment may need this in addition.

AB0855 FIBROUS ARTHROPATHY AS THE KEY FEATURE OF JUVENILE SCLERODERMA - CASE REPORT

D. Dibrov[1], M. Starovoytova[1], O. Desinova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Department of Microcirculation and Inflammation, Moscow, Russian Federation*

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by endothelial dysfunction, immunological disorders, and excessive synthesis of collagen and its deposition in various tissues and organs. The juvenile onset SSc before the age of 16 is very rare, with annual incidence of 0.27-0.5 cases per million children according to English and Finnish authors [1,2].
Objectives: To present a clinical case of juvenile onset SSc, manifesting from the childhood predominantly with fibrous contractures.
Methods: Patient K., 30 yo. Clinical presentation on admission to the Institute of Rheumatology in September 2020: thickening of the trunk and limbs skin (mRSS 10 scores), pronounced induration of subcutaneous tissues and muscles; contractures of the elbow, shoulder, hip and knee joints, short stature (height 142 cm) with proportional shortening of the limbs. ANA (HEp-2) 1/320, a-Scl-70, a-RNP-70 and ACA tests were negative. Ultrasonography revealed left-sided coxitis, esophagogastroduodenoscopy - Barrett's esophagus. Chest CT, echocardiography, electrocardiography and capillaroscopy yielded no specific findings.
The patient has been ill since the age of 3, when SSc manifested with skin thickening, "dry" arthritis and rapid development of contractures of the large joints. Thorough diagnostic elaboration ruled out such potential causes as phenylketonuria, glycogenosis, mucopolysaccharidoses, primary amyloidosis, and porphyria. Histological findings (2007) of a biopsied skin specimen containing subcutaneous fat and muscle tissue included focal vacuolization of keratinocytes, poor perivascular lymphocytic and histiocytic infiltration, fibrosis and hyalinosis of collagen fibers of varying intensity in the in mid- and deep dermis, infiltration of collagen fibers by fibroblasts, skin appendages atrophy – all of them representing a pattern of morphological changes characteristic of SSc. Therapeutic regimens including prednisone at 5-15 mg/day and D-penicillamine were ineffective.
Results: In this case, in view of fibrotic arthropathy, a differential diagnosis was made with deep morphea and stiff skin syndrome. Visceral involvement, immunological disorders and biopsy findings substantiated a diagnosis of juvenile onset SSc. Oral MTX was initiated at 15 mg to target skin lesion and osteoarticular symptoms.
Conclusion: Predominance of fibrotic arthropathy in presented case caused difficulties in establishing SSc diagnosis, as this patient did not have such inherent features as the Raynaud's phenomenon, interstitial lung disease or pulmonary hypertension. Juvenile onset SSc manifesting before the age of 16 has its own clinical features, usually persisting through the adulthood, and therefore, such one-of-a-kind appearances of juvenile onset SSc should not be missed or misinterpreted.

AB0856 CHRONIC INTESTINAL PSEUDO-OBSTRUCTION WITH HYDRONEPHROSIS: A CASE REPORT ON SUCH DISABLING AND RARE COMPLICATION OF LUPUS

C. S. Ng[1], S. L. Kan[1], A. L. Lim[1]. [1]*Hospital Pulau Pinang, Rheumatology Unit, Medical Department, Georgetown, Malaysia*

Background: Chronic intestinal pseudo-obstruction can be a rare complication of systemic lupus erythematosus. It is often late to be identified in contrast to other commoner organs involvement in systemic lupus erythematosus such as nervous system, joint and kidney.
Objectives: To report a case of uncommon gastrointestinal complication of lupus, with associated hydronephrosis at the ureter, with treatment delay.
Methods: We report a case of chronic intestinal pseudo-obstruction.
Results: A 34 year old, with ten-year history of lupus nephritis, presented with recurrent abdominal pain and diarrhoea past nine months. The patient had just been diagnosed as end-stage renal failure a year ago, on regular haemodialysis. For the past ten years, the patient was not able to tolerate immunosuppressant due to the multiple episodes of infections, including shin carbuncle, herpes zoster, breast abscess and catheter-related candida/bacterial infections. However, the patient did not have any other major organs manifestations of lupus for the past ten years. The patient was apyretic. Multiple stool cultures were negative including Clostridium difficile. The abdominal radiography showed dilated small bowel with diffuse thickening of large and small bowels on computed tomography. Bilateral uretero-hydronephrosis was also noted without any evidence of obstructive uropathy on imaging. Ileocolic resection was done for presumed intestinal obstruction and the ileocolic biopsy did not reveal any granuloma, malignancy or vasculitis except for non-specific inflammation of cecum. Cytomegalovirus inclusion body was absent as well. Tuberculosis culture was negative. Oesophagoduodenoscopy and colonoscopy were offered in view of persistent unexplained loose stool and abdominal pain. But unremarkable findings were noted from multiple biopsy specimens of the small and large bowels. Second relook of the initial hemicolectomy specimen with special actin immunostain on the smooth muscle revealed degenerative changes of the muscularis propria. These were evidenced by cytoplasmic vacuolation, atrophy and pyknotic nucleus of the smooth muscle cells with surrounding oedema. Smooth muscle dysmotility could be the underlying pathology of this patient presentation. The patient responded well to intravenous immunoglobulin followed by azathioprine in addition to prednisolone and prokinetic agent.
Conclusion: Prompt recognition is pivotal in this case could have prevented the unnecessary surgical intervention earlier. It is potentially reversible. Long term prognosis of this rare entity is, however, varying.

AB0857 CERTOLIZUMAB PEGOL RELOADING SUCCESSFULLY CONTROLS INFLAMMATORY ARTHRITIS FLARES DURING PREGNANCY – A CASE REPORT

V. Pavlova[1]. [1]*McMaster University, Department of Medicine, Hamilton, Canada*

Background: Approximately 50% of patients with inflammatory arthritis (IA) experience worsening of disease activity during pregnancy.[1,2] Given the evidence that increased disease activity immediately before or during pregnancy is associated with adverse pregnancy outcomes, it is imperative to maintain tighter disease control during this period.[3] Treatment options are limited to steroids or disease-modifying anti-rheumatic drugs (DMARDs) compatible with pregnancy. Certolizumab pegol (CZP) is a humanized TNF-alpha inhibitor with no to minimal transplacental transfer, making it a suitable option during pregnancy.[4] In patients who relapse while on treatment with a biologic, consideration can be given to optimizing the dose of the biologic. Studies in Crohn's disease demonstrated that increasing the CZP dose from 400 mg Q4W to Q2W is a viable strategy for recapturing efficacy.[5] Similar data is not available for the rheumatology population or for pregnancy.
Objectives: To describe the successful control of juvenile inflammatory arthritis (JIA) flares using a reloading strategy with CZP in a pregnant patient with prior failure of multiple conventional systemic (cs)DMARDs and biologics.
Methods: This is a case report of a 31-year old female with JIA who presented with a disease flare in the 1st trimester of her 2ndpregnancy. The patient was treated with multiple csDMARDs and biologics since age 6. She experienced significant gastrointestinal side effects to subcutaneous methotrexate and leflunomide and inadequate response to hydroxychloroquine and sulfasalazine. Subsequently, she initiated and maintained treatment with etanercept for 14 years until she developed secondary loss of efficacy. She had primary non-response to golimumab and abatacept and experienced a severe allergic reaction to infliximab. Since 2017, she has been treated with CZP 200 mg Q2W with good control of disease activity.
Prior to conception, the patient had low disease activity (Table 1). At 11 weeks gestation, the patient noted worsening of disease activity, with pain at 4/10, fatigue at 7/10, morning stiffness for 60 minutes, swollen joint count (SJC) 4/28, and tender joint count (TJC) 19/28. The patient global assessment of disease activity (PtGA) remained at 4/10 while physician global assessment of disease activity (PhGA) and health assessment questionnaire disability index (HAQ-DI) increased to 6/10 and 1.625, respectively (Table 1). She reported that symptoms worsen one week after CZP injection with more joint pain and swelling in hands, wrists, and feet. The patient declined the addition of hydroxychloroquine, sulfasalazine, and steroids due to previous tolerability, lack of efficacy, and concerns about safety during pregnancy. The patient received 3 loading doses of CZP 400 mg Q2W. She then continued treatment with CZP 200 mg Q2W.

Table 1. Disease activity prior to conception and during pregnancy before and after reloading CZP.

Characteristic	Prior to conception	11 weeks gestation	19 weeks gestation after reloading CZP
SJC (28 joints)	2	4	2
TJC (28 joints)	NA	19	NA
PhGA*	4	6	2
PtGA*	4	4	4
HAQ-DI	1.5	1.625	1.5
Pain*	4	4	2
Fatigue*	7	7	5
Morning stiffness (min)	60	60	20-30

*Assessed on a 10-point scale.

Results: On follow-up at 19 weeks gestation the patient reported 80% improvement in joint pain and swelling and reduction in morning stiffness (Table 1). Pain and fatigue were rated as 2/10 and 5/10, respectively. PtGA score was 4/10, PhGA score was 2/10 and HAQ-DI score was 1.5 (Table 1).
Conclusion: Reloading CZP to control increased IA disease activity during pregnancy may be a viable treatment option. To our knowledge, this is the first report of dose optimization in IA and in pregnancy in a patient treated with CZP.

AB0858 SUCCESSFUL TERM PREGNANCY IN A PATIENT WITH GRANULOMATOSIS WITH POLYANGIITIS AFTER UNDERGOING RITUXIMAB THERAPY - CASE REPORT

O. Sirenko[1], O. Kuryata[1], T. Lysunets[2], A. Legkobyt[2], H. Mostova[3]. [1]*Dnipropetrovsk Medical Academy, Internal Medicine 2, Dnipro, Ukraine*; [2]*Dnipropetrovsk Regional Clinical Hospital After Mechnicov, Rheumatology, Dnipro, Ukraine*; [3]*Dnipropetrovsk Regional Clinical Hospital After Mechnicov, Obstetrics and Gynecology, Dnipro, Ukraine*

Background: Granulomatosis with polyangiitis (GWP) is a relatively rare disease with the lack of experience in the management of pregnancy currently. Potentially negative factors of pregnancy prognosis are both disease-related and teratogenic effects of specific vasculitis therapy [1].
Objectives: To describe a clinical case of Successful term pregnancy in a patient with Granulomatosis with polyangiitis after undergoing rituximab therapy.
Methods: 19 years-old woman was admitted to the rheumatology department of Clinical Regional Hospital After Mechnicov in 2013 with the debut of Granulomatosis with polyangiitis. Her disease course included recurrent rhinitis and sinusitis, Granulomatosis of the eye orbits. Positive ANCA titers were present in the disease onset. In the preceding 7 years she had been treated with corticosteroids, cyclophospan (discontinuated in 2017 because of lack of efficiency), than azathioprine. Aseptic necrosis of the both femoral head was estimated on fifth disease year. In 2018 azathioprine therapy had been discontinued owing to the disease progression and biological agents were prescribed – rituximab with positive effect. The disease remission was achived by rituximab therapy, the patient was warned about the need for contraception. The last dose of rituximab was introduced in February 2020. However, in March 2020, the patient reported pregnancy and therapy was discontinued. At the onset of pregnancy she was

treated with 6 mg oral methylprednisolone. Daily and this dose was stable till all pregnancy period. Fetal growth assessment, congenital abnormalities screening test, and laboratory tests for gestational diabetes and preeclampsia were unremarkable during all gestational trimesters. The ANCA titers remained negative and renal function was normal and there was no flare during all pregnancy period.

Results: At 38 weeks' gestation a spontataneous labor started without induction. A 3270-g healthy boy delivered with APGAR score of 9 at 1 minute and 5 minutes. Postpartum the disease remained in remission, and the patient was maintained on corticosteroids. The infant was healthy, with normal development.

Conclusion: Thus, the use of biological agents therapy in patients with GWP shows possible ways to safe reproductive potential with disease remission achievement.

HPR Measuring health (development and measurement properties of PROs, tests, devices)

AB0859-HPR NETWORK OF SUPPORT AND DEPRESSION IN RHEUMATIC DISEASES

L. Cano Garcia[1], S. Manrique Arija[1], F. Godoy-Navarrete[1], F. G. Jiménez-Núñez[1], R. Redondo[1], N. Mena-Vázquez[1]. [1]*Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain*

Objectives: To describe the impact that depression has on the personal support network of patients with rheumatic diseases.

Methods: Design. Cross-sectional observational study of a series of patients with spondyloarthritis (SpA), rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) selected by consecutive sampling of the Rheumatology consultations. Selection criteria: age ≥18 years with AD (ASAS criteria), RA (EULAR / ACR 2010 criteria) and SLE (ACR-EULAR criteria) capable of understanding and willing to take the questionnaires. Protocol: The reference rheumatologist offered to participate in the study to all the patients who attended the consultation between October and December 2019 and met the selection criteria. After their approval and signing the informed consent, they went to the nursing consultation to carry out a battery of questionnaires from the PROMIS platform and collect clinical data. The infirmary was in charge of explaining the questionnaires to the patients. Variables: the main endpoint variable was depression evaluated by PROMIS and the secondary endpoint variables were questionnaires that evaluate the support network in various settings: company, emotional support, instrumental support, support through information. Likewise, data on their disease, comorbidities were collected using Charlson and socio-occupational profile. Statistical analysis: Descriptive analysis, R-Pearson correlation and multivariate linear regression analysis (VD: PROMIS depression).

Results: 151 patients participated: 50 with RA (90% women, mean age 55.12 ± 13.64 years), 51 with AD (51% women, 52.59 ± 12.15 years) and 50 patients with SLE (96 % women, mean age 47.14 ± 11.3 years). The baseline characteristics and comorbidities of the included. The mean (SD) of PROMIS depression in all patients was 16.4 (8.3) and a total of 65 patients (43%) had depression according to the Charlson index. Patients with Charlson depression had a higher mean (SD) of PROMIS depression than those without Charlson depression (24.5 [6.2] vs 10.3 [2.5], p <0.001). An inverse correlation was observed between PROMIS depression with the rest of PROMIS questionnaires: company (r = -0.369, p = <0.001), emotional support (r = -0.533, p = <0.001), information support (r = -0.577, p = <0.001) and instrumental support (r = -0.362, p = <0.001). Likewise, it was observed that patients without depression by Charlson compared with patients with depression had higher mean values (SD) in all questionnaires of the support network compared to those without depression by Charlson: company (17, 8 (2.9) vs 14.7 (4.7), p <0.001), emotional support (37.2 (5.2) vs 29.0 (9.5), p <0.001) and instrumental support (35.7 (7.2) vs 29.4 (8.8), p <0.001).Finally, in the multivariate analysis, the variables that were independently associated with depression by PROMIS were information support (B = -0.390; p <0.001) and emotional support (B = -0.239; p = 0.027). (R2 = 0.340).

Conclusion: Depression in rheumatic diseases negatively influences the support network and the perception of company of these patients. Treating depression is important for social functioning and social relationships in these patients and for any group of chronic patients.

AB0860-HPR IS THERE A RELATIONSHIP BETWEEN PHYSICAL ACTIVITY, SLEEP QUALITY, ANXIETY AND DEPRESSION IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER?

T. Civi Karaaslan[1], S. Ugurlu[2], E. Tarakci[1]. [1]*Faculty of Health Sciences, Physiotherapy and Rehabilitation, Istanbul, Turkey*; [2]*Cerrahpasa Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: Maintenance of regular physical activity is associated with better physical and mental health (1). In addition, sleep disturbances and mood disorders are common in chronic inflammatory diseases (2).

Objectives: The aim of this study was to determine the relationship between physical activity, sleep quality, anxiety and depression in patients with FMF.

Methods: A total of 56 patients (30 female, 26 male) with Familial Mediterranean Fever (FMF) were enrolled in the study. They were diagnosed with FMF based on the Livneh diagnostic criteria (3). International Physical Activity Questionnaire - Short Form (IPAQ) was used to evaluate health-related physical activity. Patient-reported sleep quality was evaluated with the Pittsburgh Sleep Quality Index (PSQI). Hospital Anxiety and Depression Scale (HADS) was used to evaluate anxiety and depression in FMF patients. Patients who were 20-55 years old was included in the study.

Results: The mean age was 32.23±9.87 years. The mean disease duration of the patients was 12.24±7.61 years. The education level of 51.8% (n=29) of the participants was undergraduate and above. The rate of those who did not work was 32.1% (n=18) and 48.2% (n=27) of the participants were married. The mean of scores of IPAQ was 2333.99±2640.29, the mean of PSQI was 6.14±3.66, the mean of HADS-Anxiety was 7.89±5.03 and HADS-Depression was 7.01±4.44. The patients were classified according to physical activity categories as low (25.0%, n=14), moderate (41,1% n=23) and high (33.9%, n=19). Physical activity categories were not found associated with PSQI (p=0.437), HADS-Anxiety (p=0.363) and HADS-Depression (p=0.861). The relationships of scores of IPAQ, PSQI and HADS were demonstrated Table 1.

Conclusion: This study confirmed that patients with FMF suffer from sleep disturbances, anxiety and depression. In addition, sleep disturbances, anxiety and depression were not associated with physical activity category.

MENTAL DISORDERS AND GASTROINTESTINAL SYMPTOMS IN RHEUMATIC DISEASES: A CROSS-SECTIONAL STUDY

F. S. Iaquinta[1], R. Spagnuolo[2], S. Naty[3], P. Doldo[2], R. D. Grembiale[3]. [1]*University "Magna Graecia" of Catanzaro, Rheumatology Research Unit, Department of Health Sciences, Catanzaro, Italy*; [2]*University "Magna Graecia" of Catanzaro - AOU Mater Domini - Gastroenterology Unit, Department of Experimental and Clinical Medicine, Catanzaro, Italy*; [3]*University "Magna Graecia" of Catanzaro, Rheumatology Research Unit, Department of Health Sciences, Catanzaro, Italy*

Background: Several studies agree that patients with chronic diseases are more likely to have mental health problems. Moreover, Rheumatic Diseases (RD) patients may show gastrointestinal symptoms as result of primary inflammation, secondary involvement or as treatment consequences. A better understanding of the potential association among such symptoms can help to improve treatment and quality of life.

Objectives: The aim of this study was to evaluate the impact of gastrointestinal symptoms (GI) on mental and social health in RD patients.

Methods: We performed a cross-sectional study of 69 RD patients with primarily osteoarticular symptoms. Patients completed questionnaires on GI symptoms (belly pain, constipation, diarrhea, disrupted swallowing, gas and bloating, nausea and vomiting, gastroesophageal reflux) and psychosocial changes (anxiety, depression, fatigue, sleep disturbance, pain interference, physical function, satisfaction with participation in social roles), of the Patient-Reported Outcomes Measurement Information System (PROMIS).

Results: Among 69 patients, 34 (49.3%) had a diagnosis of Rheumatoid Arthritis; 35 (50.7%) had axial spondyloarthritis (i.e. Psoriatic arthritis and Ankylosing Spondylitis). Median disease duration was 7,6±4 years and over one-third (36.2%) of patients had active disease. Most patients reported psychosocial changes and GI symptoms, as shown in Table 1. More specifically, figure 1 (A-G) shows that fatigue was associated with belly pain and bloating ($p<0.001$), and with constipation, diarrhea, disrupted swallowing and gastroesophageal reflux ($p<0.01$). Anxiety was related to disrupted swallowing and gastroesophageal reflux ($p<0.01$) whereas depressive symptoms were associated with belly pain ($p<0.001$), bloating and gastroesophageal reflux ($p<0.01$). Moreover, all gastrointestinal symptoms affected sleep quality. Finally, such symptoms significantly affected patients' social domain especially regarding satisfaction with participation in social roles ($p<0.05$ for belly pain and diarrhea, $p<0.01$ for bloating and disrupted swallowing) and physical functions ($p<0.001$ for belly pain, diarrhea, disrupted swallowing; $p<0.01$ for constipation, bloating and nausea and vomiting; $p<0.05$ for gastroesophageal reflux).

Table 1.

N = 69	Yes	Median *t*-Score ± SD
Mental and social Health PROMIS		
Anxiety, *n* (%)	48(69,6)	55,2±10
Depression, *n* (%)	40(58)	51,8±10
Fatigue, *n* (%)	52(75,4)	57,7±10
Sleep Disturbance, *n* (%)	44(63,8)	52±10
Pain interference, *n* (%)	62(89,9)	60,9±8
Physical Function, *n* (%)	64(92,8)	39,4±8
Satisfaction with participation in social roles, *n* (%)	21 (30,4)	45,2±10
GI-PROMIS		
Belly pain, *n* (%)	35(50,7)	50,6±14
Constipation, *n* (%)	36(52,2)	51,2±10
Diarrhea, *n* (%)	20(29)	45,2±8
Disrupted Swallowing, n (%)	31(44,9)	51±10
Gas and Bloating, *n* (%)	54(78,3)	55,5±8
Nausea and Vomiting, *n* (%)	32(46,4)	49,9±8
Gastroesophageal Reflux, *n* (%)	27(39,1)	49,1±11

Continuous variables are expressed as median and standard deviation. Categorical variables are expressed as number and proportion. GI and psychosocial changes scores were dichotomized for the use of categorical variables.

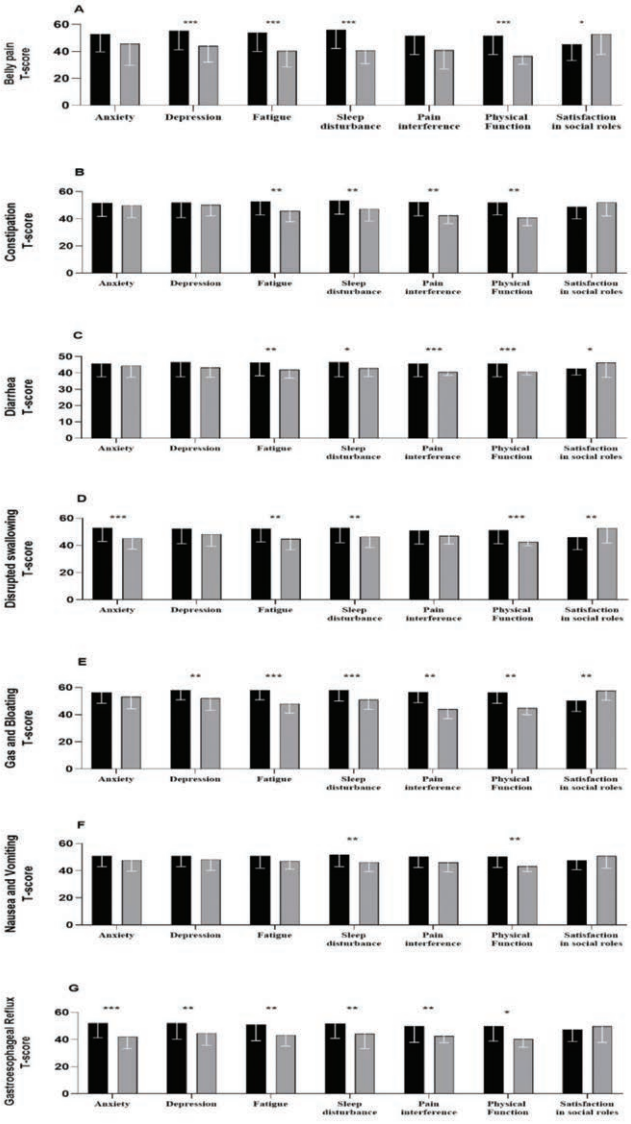

Figure 1. A–G: GI symptoms in RD patients across dichotomized psychosocial symptoms (Yes in Black/No in grey). The overall *p*-value was calculated by the Mann–Whitney non-parametric test for independent samples.

Conclusion: This study highlights the association between GI symptoms and psychosocial changes in RD patients. The use of validated Patients-Reported Outcomes, especially in clinical practice, may help to better define the impact of such symptoms on patients' quality of life and then evaluate patients' needs in a global dimension.

AB0862-HPR

THE RELATIONSHIP BETWEEN ANAEROBIC EXERCISE CAPACITY AND LOWER EXTREMITY FUNCTIONALITY IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

M. E. Acar[1], D. Bayraktar[2], S. Gucenmez[3], D. C. Saraç[2], N. Buker[2], U. Z. Kocak[2], D. Solmaz[4], S. Akar[4]. [1]*Izmir Katip Celebi University, Institute of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey*; [2]*Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey*; [3]*Izmir Katip Celebi University,*

Ataturk Education and Research Hospital, Rheumatology Clinic, Izmir, Turkey; *[4]Izmir Katip Celebi Unviersity, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey*

Background: Familial Mediterranean fever (FMF) is an auto-inflammatory disease commonly affects people from Mediterranean basin. It is characterized by acute self-limiting inflammatory attacks of serous membranes. The disease is commonly associated with musculoskeletal symptoms of lower extremities such as arthritis, exercise induced leg pain, as well as protracted febrile myalgia. The term of anaerobic exercise capacity describes the ability of performing quick and explosive tasks such as stair climbing and brisk walking. It is well known that anaerobic exercise capacity is closely related to functional status.
Objectives: To assess the relationship between anaerobic exercise capacity and lower extremity functionality in patients with FMF.
Methods: Twenty-eight FMF patients (57% female) were included in the study. Median age was 33.5 (IQR 25/75: 23.3/44.3) years, median body mass index was 24.3 (IQR 25/75: 21.0/27.8) kg/m^2 median time since symptom onset was 20.0 (IQR 25/75: 11.5/24.5) years, median time since diagnosis was 10.0 (IQR 25/75: 3.75/17.5) years, and median colchicine dosage was 1.5 (IQR 25/75: 1.0/1.5) mg/day. Anaerobic exercise capacity was measured with Wingate Anaerobic Test by using a cycle ergometer. Peak power (watt/kg) and average power (watt/kg) were calculated. Stair climbing, standing from a chair, and walking were assessed by using 9-step stair climb test, 10-repetition chair stand test, and 6-minute walking distance, respectively. Spearman's rank-order correlation test was used to analyse the relationships between anaerobic exercise capacity and lower extremity functional tests.
Results: The results of the anaerobic exercise capacity and lower extremity functional test scores of patients with FMF were summarized in table 1. Moderate relationships were found between both peak and average anaerobic exercise capacities and lower extremity functional status tests (Table 1, p<0.05). Six-minute walking distance has the strongest association with both peak (rho: .672, p<0.001) and average (rho: .689, p<0.001) anaerobic exercise capacity.

Table 1. Anaerobic exercise capacity scores and lower extremity functionality as well as the relationships between anaerobic capacity and functional tests in patient with familial Mediterranean fever.

Characteristics	Median (IQR 25/75) (n:28)	The correlation results, rho, p values	
		Peak Power (watt/kg)	Average Power (watt/kg)
9-step stair climb test (seconds)	5.7 (5.1/6.4)	**-.590* p:0.001**	**-.648* p: 0.001**
10-repetition chair stand test (seconds)	16.6 (13.7/18.7)	**-.493* p:0.008**	**-.476* p:0.010**
6-minute walking distance (meters)	594.1 (551.1/643.3)	**.672* p<0.001**	**.689* p<0.001**
Peak power (watt/kg)	5.8 (4.1/7.9)		
Average power (watt/kg)	4.6 (3.1/5.9)		

IQR 25/75: Interquartile range between 25th and 75th percentiles; kg: kilograms, *Spearman's rank-order correlation test, p<0.05.

Conclusion: According to our results, anaerobic exercise capacity is related to lower extremity functional status in patients with FMF. Improving anaerobic capacity by using optimal rehabilitation programs including speed and agility exercises may help to improve anaerobic exercise capacity, and consequently lower extremity functionality in those patients.

AB0863-HPR FUNCTIONAL STATUS ASSESSMENT THROUGH SELF-REPORTED QUESTIONNAIRES IN RHEUMATIC DISEASES

P. Herrera-Sandate[1], D. Vega-Morales[1], A. L. De-Leon-Ibarra[1], P. Valdes-Torres[2], L. A. Chavez-Alvarez[1], A. Limon-del Toro[1], I. D. J. Hernandez-Galarza[1], R. Pineda-Sic[1], D. Á. Galarza-Delgado[1]. *[1]Hospital Universitario Dr. José Eleuterio González, Rheumatology Service, Monterrey, Mexico*; *[2]Hospital Universitario Dr. José Eleuterio González, Sports Medicine and Physical Rehabilitation Department, Monterrey, Mexico*

Background: Health and disease status assessment is of paramount importance in rheumatic diseases. Self-report functional status questionnaires provide a cost and time-efficient means of systematic evaluation for physicians. The Health Assessment Questionnaire (HAQ) is one of the most utilized comprehensive measures of outcome, and is divided in 8 sections of activity domains, namely, dressing, arising, eating, walking, hygiene, reach, grip and outside activities. Other disease-specific instruments such as the Western Ontario and McMaster Osteoarthritis Index (WOMAC) share most of the functional domains evaluated by HAQ, whereas Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and WOMAC share domains mostly regarding pain and stiffness. Here, we present the results of the application of self-administered surveys in a third-level reference center in Mexico.
Objectives: Determine the functional status and most affected activity domains of patients with rheumatic diseases measured by generic (HAQ) and disease-specific (WOMAC and BASDAI) questionnaires in a reference center of northeastern Mexico.
Methods: We carried out a cross-sectional study in Rheumatology consultation in University Hospital "Dr. José Eleuterio González" in Monterrey, Mexico from August 2019 to December 2020. Nursery personnel systematically applied self-reported questionnaires HAQ, WOMAC and BASDAI in patients during their medical follow-up. Patient-reported outcomes were categorized by HAQ activity domains and/or pain and stiffness symptoms in WOMAC and BASDAI. Demographical characteristics were retrieved as well.
Results: Demographic characteristics are shown in Table 1. HAQ showed a higher prevalence of difficulty performing daily activities in the Grip domain. WOMAC question regarding heavy domestic duties had the higher degree of difficulty, as well as pain ascending stairs and stiffness after awakening. Fatigue was the most severe symptom in BASDAI, followed by pain in areas tender to touch and pressure and stiffness after awakening.
Conclusion: Disease activity and functional status impact is present on a mild-moderate level in self-reported questionnaires in the Rheumatology consultation of a northeastern center of reference in Mexico. The most affected domain in patients with rheumatic diseases is Grip domain, the most affected daily activities to perform are heavy domestic duties and the most prevalent symptoms are pain ascending stairs and stiffness after awakening as measured by HAQ, WOMAC and BASDAI, respectively.

AB0864-HPR INFLUENCE OF THE TYPE OF PAIN SYNDROME ON THE SEVERITY OF ANXIETY-DEPRESSIVE DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Egorova[1], N. Nikitina2, A. Rebrov[1]. *[1]Saratov State Medical University name of V.I. Razumovsky Ministry of Health of Russia, Hospital Therapy,*

Saratov, Russian Federation; [1]*Saratov State Medical University name of V.I. Razumovsky Ministry of Health of Russia, Hospital Therapy, Saratov, Russian Federation*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease that leads to joint damage and deformation. Pain syndrome, along with functional limitations, causes the emergence of anxiety-depressive disorders. The patient's psycho-emotional characteristics affect the patient's quality of life and the effectiveness of the therapy. The aim: to assess the severity of anxiety and depression in women with rheumatoid arthritis, depending on the type of the pain syndrome.
Objectives: The study included 163 women with RA according to the EULAR / ACR 2010 criteria (age 53,9 ± 10,15 years, RA duration - 10 [4; 14] years, DAS28 – 5,03 [4,35; 5,8]).
Methods: We used the Hospital Depression and Anxiety Scale (HADS) questionnaire: 0-7 points were assessed as the absence of significant symptoms of anxiety and depression, 8-10 points - subclinically expressed anxiety and depression, more than 11 points - clinically expressed anxiety and depression. The severity of pain was determined by the VAS: no pain (0-4 mm), mild pain (5-44 mm), moderate pain (45-74 mm), severe pain (75-100 mm). Assessment of the type of pain (identification of the neuropathic component of pain) was carried out using the DN4 questionnaire: a sum of 4 or more points indicated the presence of a neuropathic component of pain (NCP). Statistical processing was performed using the STATISTICA 10,0 program.
Results: The frequency of occurrence of anxiety-depressive disorders in RA patients was determined: clinically pronounced anxiety was detected in 35 (21,4%) patients, depression - in 34 (20,9%); subclinically expressed anxiety - in 42 (25,8%), depression - in 44 (27%) patients; absence of reliably pronounced symptoms of anxiety - in 86 (52,8%) patients, depression - in 85 (52,1%) patients.
Severe pain according to VAS was noted in 57 (35%) patients, moderate pain - in 75 (46%), in 31 (19%) patients the pain syndrome was mild. In 81 (49,7%) patients a neuropathic component of pain was revealed.
The relationship was established between the presence of NCP and the severity of anxiety ($r = 0,27$, $p < 0,05$), depression ($r = 0,31$, $p < 0,05$). The relationship was revealed between the presence of NCP and the severity of pain according to the VAS ($r = 0.32$, $p < 0.05$).
To explain the relationship between the presence of NCP and anxiety-depressive disorders, the patients were divided into two groups depending on the presence of NCP, comparable in age, the main clinical characteristics of RA, and basic therapy. The level of anxiety in women with NCP (9,5 [7; 13]) was significantly higher than in patients without NCP (6.1 [4; 9]) ($p = 0.01$). The severity of depression in women with NCP was 8,55 [6; 11], in patients without NCP – 5,15 [3; 6] ($p = 0.005$).
Conclusion: Thus, every fifth patient with RA had clinically significance anxiety and depression, subclinical anxiety and depression were found in 26% of RA patients. Most of the patients (81%) had moderate or severe pain, half of the patients had signs of neuropathic pain. The relationship between the severity of anxiety and depression with the intensity of pain and the presence of a neuropathic component was revealed.

AB0865-HPR FREQUENCY OF DEPRESSION IN SYSTEMIC LUPUS ERYTHEMATOSUS

L. Cano Garcia[1], S. Manrique Arija[1], F. Godoy-Navarrete[1], A. M. Cabezas-Lucena[1], G. Diaz-Cordobes[1], N. Mena-Vázquez[1]. [1]*Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain*

Objectives: Cross-sectional observational study of a series of SLE patients selected from the Rheumatology consultations.
Methods: age ≥18 years with SLE (ACR 1997 criteria) capable of understanding and willing to take the questionnaires. Protocol: All patients with SLE undergoing follow-up in the rheumatology clinic are recorded in a database. A telephone call was made to all the patients included in the database and those patients who responded to the call and gave their verbal consent for the collection of data from their clinical history and completed the Goldberg questionnaire were finally included. The nurse was in charge of explaining the questionnaire to the patients. Variables: the main outcome variable was depression assessed by Goldberg (≥2 depression) and other variables were: previous diagnosis of depression, Charlson index, polypharmacy, psychiatric medication, referral to mental health or primary care, SLEDAI and SLICC. Descriptive, bivariate statistical analysis and multivariate logistic regression analysis (VD: Goldberg depression).
Results: 89 patients with SLE were included (95.5% women, mean age 49.44 ± 13.2 years and 18.28 ± 9.19 years of disease). The mean (SD) of the Goldberg scale in all the patients was 3.2 ± 2.9 and a total of 45 patients (50.4%) met criteria of depression according to Goldberg's screening, of which 19 (21.3%) patients had a previous diagnosis of depression. Only 9 patients (10.1%) had had a mental health follow-up and 22 patients (24.7%) were being followed by the family doctor. A total of 87 patients (97.8%) presented polypharmacy: severe polypharmacy 59 (66.3%) and 33 (37.1%) psychiatric medication. The most used psychiatric medication was: 7 (7.8%) bromazepam, 6 (6.7%) citalopram, 5 (5.6%) diazepam. Regarding comorbidities, the Charlson index was 1.82 ± 1.21, also highlighting that 34 (27%) of the sample had Sjögren syndrome. In the multivariate analysis, polypharmacy (OR, 1.8 [95% CI, 1.0-3.1]) and Sjogren's syndrome (OR, 3.8 [95% CI, 1.0-10.7]) were independently associated with depression by Goldberg.
Conclusion: Depression is underdiagnosed and undertreated in patients with SLE. Depression is associated with polypharmacy and the perception of patients with SLE of being ill. It is important to correctly treat depression in the context of SLE comorbidity due to its great impact on quality of life.

HPR Epidemiology and public health (including prevention)

AB0866-HPR INPATIENT RHEUMATOLOGY HEALTHCARE IN A TERTIARY REFERRAL ACADEMIC HOSPITAL

C. M. Gamboa-Alonso[1], G. Figueroa-Parra[1], A. L. De-Leon-Ibarra[1], J. Díaz-Angulo[1], G. Serna-Peña[1], D. Vega-Morales[1], D. Á. Galarza-Delgado[1]. [1]*Universidad Autónoma de Nuevo León, Reumatología e Inmunología Clínica, Monterrey, Mexico*

Background: Diagnosis of autoimmune diseases (AD) has been increasing in recent years, with a prevalence of 3- 5% worldwide. The causes that lead to an inpatient approach in patients with suspicion or a confirmed rheumatic disease (RD) vary widely.
RD are at higher risk of infectious, cardiovascular and other comorbidities due to immunosuppression, a continuous inflammatory state and an altered immune response, increasing morbidity and mortality rates.
Objectives: Describe hospitalized patients who required a rheumatology consultation due to a preexistent or a new RD.
Methods: A descriptive, observational study was performed during a three year follow up (March 2017 -February 2020) in a University Hospital in Mexico. We included patients with definite or suspicion of a RD who received a rheumatologic evaluation. Demographic and clinical characteristics, length of stay and complications such as infection, readmission, use of mechanical ventilation and mortality were registered. Descriptive statistics were used. Binary regression models were applied to find association between clinical factors and infection/mortality in RD hospitalized patients, SPSS v20 was used to perform statistical analysis. A $P < 0.05$ was considered statistically significant.
Results: A total of 642 hospitalized patients received a rheumatologic evaluation. Of the evaluated patients, 315 (49.1%) had a history of a confirmed RD, of these, 237 (75.2%) were hospitalized due to a complication associated to the underlying RD and 78 were hospitalized for other non-rheumatic nor related disorder and were omitted for the rest of the analysis; 327 (50.9 %) patients were evaluated for the first time, 147 (45.0%) of them being diagnosed with a new RD; Systemic Lupus Erythematosus (SLE) 55 (37.4%) was the most frequent diagnosis. Figure 1
Of the 642 evaluated patients, 384 (59.81%) patients with a previous (237) or new (147) rheumatic cause of hospitalization were studied. Table 1A

Factors associated to infection and mortality in the 384 patients are shown in Table 1B.

Conclusion: Inpatient rheumatologic evaluation is a major concern of healthcare due to the severity and prognosis of these diseases. SLE was found to be the most common diagnosis in patients evaluated for the first time. Infection is an important cause of hospitalization and mortality, being the use of steroids and immunosuppression some of the main risk factors of these outcomes.

AB0867-HPR

VIOLENCE IN PREGNANT AND POSTPARTUM MEXICAN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

L. G. Espinosa Banuelos[1], M. E. Corral Trujillo[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], A. Y. Lujano Negrete[1], R. A. Rodriguez Chavez[1], R. Moyeda Martinez[1], A. Cárdenas[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Servicio de Reumatología, Monterrey, Mexico*

Background: Gender violence is a prevalent issue worldwide. In Mexico, four out of ten women suffer any kind of violence. The factors that make women even more vulnerable to domestic violence are pregnancy, socioeconomic status, educational level, and the presence of chronic health problems. Violence represents a major risk factor for depression, anxiety, poor adherence to medical treatment, and obstetric adverse events.

Objectives: The aim of this study is to determine the frequency of domestic violence in pregnant and postpartum women with autoimmune rheumatic diseases (ARD) and to compare with childbearing age women with ARD.

Methods: Pregnant and postpartum women (PPW) with rheumatic disease evaluated at the Pregnancy and Rheumatic Diseases Clinic from the University Hospital "Dr. José E. González" in Monterrey, México from August to October 2020 were invited to participate. To compare, we enrolled childbearing age women with ARD without previous pregnancies. The Spanish validated version of the Hurt, Insulted, Threatened with Harm, Screamed scale (HITS) was applied via telephonic interview. The HITS scale evaluates in 4 questions the presence and frequency of violence by their intimate partners in the last 12 months. A score ≥ 10 points is considered as positive for violence.

Results: A total of 48 women were included, 24 patients each group. The pregnant-postpartum group was divided in 6 (25) pregnant and 18 (75) postpartum women. Most of them were housewives (54.1%) with >10 years of education and with not formalized marital status 41% (common-law marriage). In the childbearing age group, most of them were employees (70.8), with >10 years of education with a current marital status of single (66.6%). The HITS scale was positive in the pregnant-postpartum group in 4 women (16.6%). Two of them had been victims of sexual assault and 2 reported physical/verbal violence. While in childbearing age group only 1 (4.16) reported physical/verbal violence.

Conclusion: The 16% of the pregnant-postpartum group in our sample were suffering from domestic violence by their intimate partners, in contrast to the childbearing age group with only 1 patient reported violence. We found that postpartum and pregnancy women had more prevalence of violence. Screening for domestic violence followed by counseling and early referral are necessary to mitigate the physical and psychological consequences of domestic violence.

AB0868-HPR ADHERENCE TO DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN RHEUMATIC DISEASES DURING COVID-19 PANDEMIC

I. A. Moreno-Arquieta[1], G. G. Sánchez Mendieta[1], D. E. Flores Alvarado[1], J. A. Esquivel Valerio[1], D. Á. Galarza-Delgado[1]. [1]*Dr. José Eleuterio González (Gonzalitos) 235, Rheumatology, Monterrey, Mexico*

Background: The pandemic COVID-19 has set a new challenge in adherence to treatment in patients with rheumatic diseases. Prior studies in Latin America had reported adherence of 16.4% on Rheumatoid Arthritis (RA) and 45.9% in Systemic Lupus Erythematous (SLE). There is evidence that these patients believe their treatment increases the risk and gravity of COVID-19 and therefore, suspending the treatment could reduce this risk. It has been shown that a "Good adherence" is associated to a better survival.
Objectives: Describe the adherence to DMARDs in patients with Rheumatic diseases during COVID-19.
Methods: Descriptive, cross-sectional, self-report study conducted in rheumatology outpatient clinic of University Hospital in Monterrey, México. Consecutive patients with RA, SLE, Inflammatory Myopathies and Systemic Sclerosis, were approached during their routine appointments, March 2020 to December 2020 period during COVID-19 pandemic. They were asked how many days of the month they took the DMARD indicated in the previous appointment, with Based on this, adherence was classified into four categories: Good 100-75% (> 21 days), Regular 74-50% (21-15 days), Bad 49-25% (14-8 days) and Null <25% (<7 days). Data was obtained from our internal electronic patient record registry and analyzed with SPSS V.22.
RESULTS:

	n (DMARDs)	Good	Regular	Bad	Null
		n (%)	n (%)	n (%)	n (%)
Rheumatoid Arthritis	302	255 (84.4)	13 (4.3)	20 (6.6)	14 (4.6)
Systemic Lupus Erithematous	126	111 (88)	3 (2.3)	8 (6.3)	4 (3.1)
Inflammatory Myopathies	11	10 (90.9)	0 (0)	1 (9)	0 (0)
Systemic Sclerosis	30	27 (90)	2 (6.6)	1 (3.3)	0 (0)
TOTAL	469				

Conclusion: Despite what it is believed, patients are not changing therapeutic regimes. The adherence found in this group of patients was good, for the definition used in this study. It should be considered that the self-report method may overestimate adherence, so the data found must be correlated with objective methods in the future.

AB0869-HPR HOW TO IMPROVE THE QUALITY-OF-LIFE IN PATIENTS WITH OSTEOPOROSIS?

A. Lammert[1], S. Lezhenina[1], N. Shuvalova[2], N. Andreeva[1], E. Guryanova[3]. [1]*I.N. Ulianov Chuvash State University, Departament of Healthcare Management and Economics, Cheboksary, Russian Federation*; [2]*I.Ya.Yakovlev Chuvash Pedagogical State University, Department, Cheboksary, Russian Federation*; [3]*I. N. Ulianov Chuvash State University, Department Internal Diseases, Cheboksary, Russian Federation*

Background: This paper is an assessment of quality-of-life for patients living with osteoporosis. It employs special questionnaires and scales to allow for more detailed observation of the patient both during initial treatment and in dynamics. This allows us to establish the effectiveness of the therapy, to assess the need to correct the treatment and rehabilitation program, and to compare the effectiveness of various treatment methods and determine disease prognosis.
Objectives: to assess quality-of-life in patients with osteoporosis for further development of treatment and rehabilitation programs.
Methods: To assess the quality-of-life in patients with osteoporosis, HRQOL and SF-36 scale were used. The study was conducted from January to December 2019, at the Republican Clinical Hospital of the Chuvash Republic. The study involved 70 patients (n = 70) with a diagnosis of osteoporosis with a pathological fracture. Of the 70 patients included in the study, 35 women aged 67 ± 1.2 years and 35 men aged 60 ± 1.2 years. The results were statistically processed using MS Office Excel programs.
Results: According to the analysis carried out by the HRQOL method, more than half of the patients (52.13%) experienced daily back pain, which worsens their mood and well-being. When assessing the degree of pain, almost half of the patients (48.73%) rated their pain by VAS as moderate. Moreover, most of the respondents experienced a "significant" (46.51%) or "moderate" (34.29%) decrease in social activity due to pain syndrome associated with osteoporosis. In connection with this, 44.51% rated their satisfaction with their lives as "average degree of satisfaction".
When analyzing the quality-of-life indicators according to the SF-36 scales, we determined that the mental component of health predominates for women (The Short Form-36: MH=68,6±3,45 (Men: MH=48,5±2,85)). In men, high quantitative values of the scales "physical" and "role physical functioning" (The Short Form-36: PF=62,5±3,33; RP=58,4±3,81) indicate a more pronounced nature of changes in somatic status, which has a significant impact on the quality-of-life. The intensity of pain was perceived to be higher by men (The Short Form-36: BP=75,6±4,06) than by women (The Short Form-36: BP=35,7±1,86). This confirms that osteoporosis and its complications negatively affect the human psyche and can significantly worsen the quality-of-life.
Conclusion: Analysis of quality-of-life indicators using the SF-36, HRQOL method contributes to a more correct choice of effective strategy for specialized medical care and rehabilitation for patients with osteoporosis. This choice should be developed individually, taking into account the age, gender characteristics, the severity of structural and functional disorders and the psychological state of the patient. It must also take into account the presence and severity of concomitant diseases, which will require additional research and discussion at different levels of the organization of medical care.

AB0870-HPR GLOBAL TRENDS IN PRP AND OSTEOARTHRITIS: A BIBLIOMETRIC AND VISUALIZED STUDY

Y. Qiu[1], Y. Zhang[1], L. Wen[1]. [1]*Beijing Hospital, National Center of Gerontology, Deparment of Orthopedic, Beijing, China*

Background: Osteoarthritis (OA) is a serious disease, which is one of the main causes of joint pain and body dysfunction, raising serious economic and social burden. In recent years, there are tremendous articles on the treatment of osteoarthritis, platelet rich plasma (PRP) is one of the new trends in the treatment of osteoarthritis.
Objectives: The purpose of this study is to explore the development trend of PRP related osteoarthritis study and grasp the hot spots and directions in this field.
Methods: Publications focusing on PRP related osteoarthritis research from 2001 to 2020 were retrieved from Web of Science (WoS) and Science Citation Index-Expanded (SCIE) database. The retrieving methods were as follow: (theme = platelet rich plasma arthritis OR theme = platelet rich plasma osteoarthritis OR theme = platelet rich plasma cartilage OR theme = platelet rich plasma knee OR theme = platelet rich plasma orthopedic OR theme = platelet rich plasma orthopaedic OR theme = platelet rich plasma articular OR theme = platelet rich plasma joint OR theme = platelet rich plasma tendon). Publications were analyzed only when type is articles or reviews. The VOS viewer was used for the generation of bibliographic coupling and visualized study.

Results: A total of 2847 publications were retrieved, including 2636 articles and reviews. Before 2000, there were only 15 relevant papers, which were not included in the specific analysis. It is clear that the number of publications on PRP related OA study is increasing every year, a total of 398 articles or reviews were published in 2020. The United States is the leading country in this field, with a number of 932 publications (35.4%), followed by Italy (304 publications, 11.5%) and China (294 publications, 11.2%). The most prevalent areas of PRP related OA research were orthopedics (1013 papers, 38.4%), sports science (651 papers, 24.7%) and surgery (475 papers,18.0%). The top 3 journal that published the most PRP related OA study is American Journal of Sports Medicine (153 papers, 5.8%), Arthroscopy: The Journal of Arthroscopic & Related Surgery (95 papers, 3.6%), Journal of Orthopaedic Research (83 papers, 3.1%). The Harvard University (96 papers, 3.6%), Hospital for Special Surgery (83 papers, 3.1%) and University of London (75 papers, 2.8%) is the top 3 institution that published the most articles or reviews. Filardo G from Italy published the most articles or reviews (52, 2.0%) in this area, followed by Maffulli N from the UK (49 publications, 1.9%) and Kon E from Italy (46, 1.7%). PRP related OA study can be divided into five categories: intra-articular treatment study, clinical trials related study, soft tissue repairment study, gene and molecular biology study, regeneration and implantation study.

Conclusion: Publications on PRP related OA study is increasing according to the analysis on current global trends. The United States is now the leading country in this field, with the largest number and the highest quality of publications. Among the five cluster of PRP related OA studies, "intra-articular treatment study" and "regeneration and implantation study" are considered to be the current research hotspots in the PRP related OA field.

AB0871-HPR

WOMEN IN RHEUMATOLOGY: BARRIERS, LIMITATIONS, AND GENDER INEQUALITY

G. Serna-Peña[1], I. J. Colunga-Pedraza[1], D. Á. Galarza-Delgado[1], N. Guajardo-Jauregui[1], D. Alpizar-Rodriguez[2], C. F. Pacheco Tena[2]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*; *[2]Colegio Mexicano de Reumatología, Rheumatology, Ciudad de México, Mexico*

Background: In the last decades there has been a great progress towards gender equality in medicine, and this can be reflected in the proportion of women in Rheumatology, which has been on the rise recently. However, there continues to be a need for women to be able to succeed on equal opportunities with men (1).

Objectives: The aim of this study was to recognize the professional limitations and barriers that Mexican female rheumatologists must face.

Methods: Female rheumatologists were invited to participate. An online survey was applied anonymously, consisting of questions regarding demographic characteristics, professional, academic and research activities, as well as perceptions of gender discrimination and limitations of their profession.

Results: A total of 127 female rheumatologists voluntarily answered the electronic survey. Most of them were aged between 30 and 35 years (40.9%) and had 1-5 years of professional practice (40.2%) (Table 1); 52% have children and 42.4% of them consider that motherhood has had a negative impact on their professional life; 75.6% of female rheumatologists do not work on research activities and only 20.5% have participated in international congresses in the last 5 years; 80.5% report not participating in medical colleges (as leaders or board members). The three main reasons female rheumatologists refer as limitations on their profession are: having other priorities (34.6%), lack of time (32.3%) and lack of support from their peers/bosses (23.6%). Almost half women (45.7%) consider not being discriminated because of their gender in their profession, while the rest of them consider that they are or may be.

Table 1. Demographic characteristics.

Age, n (%)	
Younger than 35 years	52 (40.9%)
From 35 to 40 years	29 (22.8%)
From 40 to 45 years	16 (12.6%)
From 45 to 50 years	12 (9.4%)
Older than 50 years	18 (14.2%)
Marital status, n (%)	
Married	66 (52%)
Single	38 (29.9%)
Free union	13 (10.2%)
Divorced	8 (6.3%)
Widowed	2 (1.6%)
Years of professional practice, n (%)	
From 1 to 5 years	51 (40.2%)
From 5 to 10 years	31 (24.4%)
From 10 to 15 years	16 (12.6%)
From 15 to 20 years	10 (7.9%)
More than 20 years	19 (15%)

Conclusion: We found that most female rheumatologists are young and with a few years of professional practice, which coincides with the recent increase in the proportion of women in Rheumatology; and perhaps this is the reason why there is low participation in research activities and medical colleges. It is relevant that almost half of them perceive their gender as a reason of discrimination in their professional life. We consider that initiating the conversation of gender equality in Rheumatology, in national and international forums, and to actively search for a strategy to support and encourage our colleagues, are priorities at this moment.

HPR Interventions (educational, physical, social and psychological)

AB0872-HPR

IMPACT OF COVID-19 ON A PHYSICAL ACTIVITY FEASIBILITY PILOT STUDY: THE PIPPRA EXPERIENCE

L. Larkin[1], A. Moses[1], S. Gallagher[2], A. Fraser[3,4], B. A. Esbensen[5,6], J. Green[1], L. Glynn[7], N. Kennedy[1]. *[1]University of Limerick, School of Allied Health and Health Research Institute, Limerick, Ireland*; *[2]University of Limerick, Department of Psychology and Health Research Institute, Limerick, Ireland*; *[3]University of Limerick, School of Medicine, Limerick, Ireland*; *[4]University Hospitals Limerick, Department of Rheumatology, Limerick, Ireland*; *[5]Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark*; *[6]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*; *[7]University of Limerick, School of Medicine and Health Research Institute, Limerick, Ireland*

Background: The PIPPRA (Physiotherapist-led Intervention to Promote Physical Activity in Rheumatoid Arthritis) project is a feasibility project examining the impact of a physical activity behaviour change intervention in people who have rheumatoid arthritis (RA). The PIPPRA study recruitment commenced in October 2019, with participant assessment and intervention commencing in November 2019. In the Republic of Ireland people who have RA are categorised as high risk category for Covid-19, due to immunosuppression [1], although this categorisation contrasts with EULAR's provisional recommendations [2].

Objectives: To examine the impact of the Covid-19 pandemic and public health restrictions on a pilot randomised controlled feasibility study in 2020.

Methods: Participants (aged 18 years+, diagnosis of RA, independently mobile and low levels of physical activity [3]) were recruited from a rheumatology clinic at an urban hospital. Target recruitment was four participants per month for one year (N=48). Assessments were planned at baseline, eight and twenty-four weeks (N=144). Participants were randomised to intervention group or control group. The intervention group received four 1:1 sixty minute sessions with a physiotherapist (N=96). The intervention was delivered over eight weeks. Intervention and control groups received a physical activity information leaflet.

Results: The Covid-19 pandemic and associated public health restrictions forced the study to be formally paused in April 2020 and the study formally resumed

in August 2020. N=48 participants were recruited between October 2019 and March 2020 (six months). N=20 participants have commenced in the study, N=16 are awaiting baseline assessment, N=6 withdrew and N=6 were lost to follow-up prior to baseline. Trial protocol planned for the delivery of N=55 assessments and N=36 intervention sessions for participants who had commenced in the study. N=22 assessments and N=26 intervention sessions were delivered between November 2019 and March 2020. N=5 assessments and N=6 intervention sessions were conducted between August and October 2020. No assessment or intervention delivery occurred in November-December 2020 due to participant hesitancy in attending for assessment and/or intervention with increased public health restrictions. The impact of Covid-19 restrictions resulted in N=33 (60%) deviations from assessment protocol and N=10 (27%) deviations from intervention delivery protocol (Figure 1).

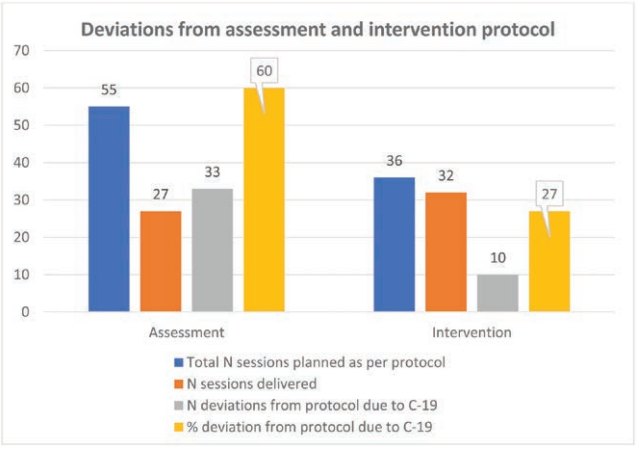

Figure 1. Deviations from assessment and intervention protocol in the PIPPRA study

Conclusion: The Covid-19 pandemic has had a significant impact on the delivery of the PIPPRA study. Feasibility study outcomes, including participant retention rate, and study delivery as per protocol, have been affected due to the Covid-19 pandemic. Participant reluctance to attend face-to-face sessions demonstrates the need to consider alternative methods of delivery, e.g. virtual delivery of interventions, where attending in person is not acceptable to participants [4], in future studies.

AB0873-HPR

EFFECTIVENESS AND COST-EFFECTIVENESS OF LONGSTANDING EXERCISE THERAPY VERSUS USUAL CARE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS OR RHEUMATOID ARTHRITIS: THE PROTOCOLS OF TWO PARALLEL RANDOMIZED CONTROLLED TRIALS

M. A. T. van Wissen[1], M. Teuwen[1], C. Van den Ende[2,3], T. P. M. Vliet Vlieland[1], A. Den Broeder[2,3], W. Van den Hout[4], W. Peter[1], D. Van Schaardenburg[5], A. Van Tubergen[6,7], M. G. J. Gademan[1], S. Van Weely[1]. [1]*Leiden University Medical Center, Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands*; [2]*Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands*; [3]*Sint Maartenskliniek, Departement of Rheumatology, Nijmegen, Netherlands*; [4]*Leiden University Medical Center, Department of Biomedical Data Sciences, Leiden, Netherlands*; [5]*Reade, Center for Rehabilitation and Rheumatology, Amsterdam, Netherlands*; [6]*Maastricht University Medical Center, Department of Rheumatology, Maastricht, Netherlands*; [7]*Maastricht University, The Netherlands and Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands*

Background: Axial SpondyloArthritis (axSpA) and Rheumatoid Arthritis (RA) are chronic rheumatic diseases with an often progressive course, defined by chronic inflammation. With respect to exercise therapy, in axSpA and RA, multiple systematic reviews concluded that supervised exercise therapy is an effective and safe treatment option, resulting in small to modest improvements in pain, disease activity, functional ability and axial mobility. In general, most of the studies included in these reviews concerned programs of a relatively short duration (<12 weeks) and the studies mostly concerned patients with stable disease, without co-morbid conditions and relatively favorable functional ability (1-5). The group of patients with active disease, irreversible joint damage, multiple joint replacements and/or severe comorbidity hampering participation in exercise therapy programs and in need for individualized, longstanding therapy is therefore likely to be underrepresented in research so far. Consequently, cost-effectiveness studies on longstanding physical therapy are also lacking in these specific subgroups.

Objectives: We aim to evaluate the effectiveness and cost-effectiveness of longstanding exercise therapy compared to usual care in the subgroup of patients with axSpA or RA and severe limitations in functioning.

Methods: In two separate, parallel randomized controlled trials, the effectiveness and cost-effectiveness of longstanding, active exercise therapy (52 weeks) compared with usual care (1:1) will be evaluated (Figure 1). The longstanding, active exercise therapy will focus on improving individual limitations in daily activities and participation, and will be given by a trained physical therapist in the vicinity of the participant. For each diagnosis, 215 patients with severe limitations in activities and participation will be included. Assessments are performed at baseline, 12, 26, and 52 weeks. The primary outcome measure of effectiveness is the individual level of functioning (activities and participation), as measured with the Patient-Specific Complaints instrument at 52 weeks. For cost-effectiveness analyses, the EuroQol (EQ-5D-5L) and questionnaires on healthcare use and productivity will be administered. The economic evaluation will be a cost-utility analysis from a societal perspective. After 52 weeks, the patients in the usual care group are offered longstanding, active exercise therapy as well. Follow-up assessments are done at 104, 156 and 208 weeks.

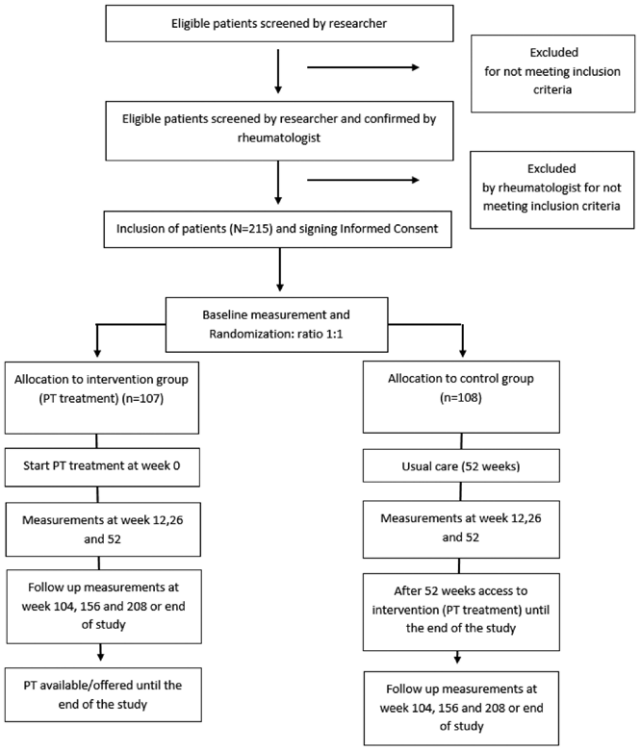

Figure 1. Study flowchart

Results: The results of these studies will provide insights in the effectiveness and cost-effectiveness of longstanding exercise therapy in the subgroup of axSpA and RA patients with severe functional limitations.

AB0874-HPR TELEMEDICINE CONSULTING IN RHEUMATOLOGY: IDENTIFIED PROBLEMS OF NEW TECHNOLOGY

O. Teplyakova[1], A. Sarapulova[1]. [1]*Ural State Medical University, Outpatients Department, Yekaterinburg, Russian Federation*

Background: A feature of healthcare in 2020 was the work in conditions of massive incidence of COVID-19, limited and redistribution of human resources. One of the right decisions in these conditions is to organize schools for patients, which allow simultaneous education and convey the necessary information to a large number of people. The key aspects of the organization of telemedicine schools for patients are presented.
Objectives: To assess the feasibility of telemedicine schools for patients as a technology of modern health care in rheumatology.
Methods: The work was carried out by the method of a one-stage cross-sectional study of the questionnaire survey of participants of education in rheumatology, conducted in an on-line mode. The number of participants in rheumatology schools was 197 people, the results of the questionnaire were received from 36 respondents. The questionnaire based on the Google platform.
Results: 10 key principles of organizing online patient education at the present stage were identified: the use of distance technologies, the interest of a medical institution administration, the team approach, the technical possibilities of implementing schools, adaptation of lecture material for patients, the role of a specialized specialist in the educational process, patient participation, measurement efficiency and timely correction, development and improvement of educational technology for patients, desire for cooperation and exchange of experience.
Conclusion: The emergence of new opportunities related to online health education of the population, including educational activities for patients, opens up new prospects for improving clinical care aimed at promoting health and preventing disease.

AB0875-HPR NON-PHARMACOLOGICAL AND PHARMACOLOGICAL APPROACHES TO THE MANAGEMENT OF PATIENTS WITH OSTEOARTHRITIS AND LIPID METABOLISM DISORDERS

T. Rogatkina[1], O. Korolik[1], V. Polyakov[2], G. Kravtsov[2], Y. Polyakova[3]. [1]*Volgograd State Medical University, Hospital Therapy, Volgograd, Russian Federation*; [2]*Volgograd State Medical University, Therapeutic Physical Education, Volgograd, Russian Federation*; [3]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Treatment and Prevention of Joint Disease Laboratory, Volgograd, Russian Federation*

Background: Attention is drawn to the frequent combination of osteoarthritis (OA) with cardiovascular disease. Non-specific inflammation plays a significant role in the pathogenesis of OA and atherosclerosis. Limiting the physical activity of patients with OA is an additional important factor aggravating the course of cardiovascular disease (CVD). Chronic pain syndrome, causing a neuroendocrine response, is often the cause of the development of complications of atherosclerotic disease. Dyslipidemia is the main cause of atherosclerosis and vascular thrombosis.
Objectives: To study variants of lipid metabolism disorders in female and male patients of different age groups with osteoarthritis.
Methods: Case histories of 90 patients with OA were analyzed. The average age of patients was 63.27 ± 11.31 years. The average body mass index (BMI) is 39.8 ± 3.2. All patients underwent questionnaires, general clinical and biochemical blood tests with lipid profile determination, anthropometry, bioimpedansometry, and the main metabolic rate assessment using indirect calorimetry in dynamics (at the beginning of the study and after 3 months).
Results: Burdened heredity for obesity, arterial hypertension (AH), diabetes mellitus (DM) was revealed. AH was diagnosed in 76 patients (84.4%), type II diabetes in 17 (18.9%), dyslipidemia and hypercholesterolemia in 56 (62.2%). Statins were taken by 43 patients (47.8%) - group I patients, which is associated with low adherence to therapy, group II included patients who did not initially take statins or stopped taking them at least 6 months before inclusion in the study.
Against the background of diet therapy and physiotherapy exercises, BMI (R0.99; p <0.05), fat mass (R0.95; p <0.05) significantly decreased, lipid profile normalization was noted: total cholesterol (R0.66; p <0 .05), LDL (R0.69; p <0.05), HDL (R0.95; p <0.05), TG (R0.57; p <0.05), AST decreased (R0.64; p <0.05) and ALT (R0.76; p <0.05) in both groups of patients, regardless of lipid-lowering therapy. A decrease in fat mass correlated with TG levels (R0.51; p <0.05), an increase in skeletal muscle mass (R0.60; p <0.05), lean mass (R0.72; p <0.05), and active cell mass (R0.59; p <0.05). The lipid profile in the I group of patients was significantly better before and at the end of the study. Long-term effects have not been investigated due to the short duration of the study.
Conclusion: In patients with OA, a high frequency of concomitant diseases of the cardiovascular system, lipid metabolism disorders was found. Non-drug therapy has a positive effect on the lipid profile and the level of transaminases. The decrease in body weight due to loss of fat mass reliably correlates with the level of TG. Timely use of statins contributes to the normalization of the lipid profile, reduces the risk of cardiovascular disease in patients with OA. It is necessary to study lipid profile disorders in patients with OA with recommendations for lifestyle modification (diet, physical activity), and if necessary, prescribe lipid-correcting therapy.

AB0876-HPR NEUROFEEDBACK AND TEMPERATURE BIOFEEDBACK TRAINING IMPROVE MIRCOCIRCULATION IN PATIENTS WITH SYSTEMIC SCLEROSIS

R. Grekhoff[1]. [1]*Zborovsky' Research Institute for Clinical and Experimental Rheumatology, Rehabilitation Department, Volgograd, Russian Federation*

Background: Microcirculatory disorders including Raynaud's phenomenon are one of the most important clinical symptoms of systemic sclerosis (SS).
Objectives: We found it appropriate to evaluate the clinical efficacy of biofeedback (BFB) in the complex therapy of SS patients based on analysis of nailfold capillaroscopy.
Methods: The study included 70 SS patients. 94% of patients we examined were women and 6% were men. The average age of the patients = 38±3,3 years, duration of illness = 14±2,6 years. Raynaud's phenomenon (RP) was observed in all the patients and its severe form was seen in 80% of the patients. The effectiveness of BFB was analyzed by studying the dynamics of the measures from the nailfold capillaroscopy and comparing the data obtained from patients of the main and control groups.
Results: Dynamics of capillaroscopic signs of therapy efficiency in main and control groups are summarized in the table:

Analized signs	Main group (n=40)		Control group (n=30)	
	before the therapy	after the therapy	before the therapy	after the therapy
Skin score, M±SD	22,56±10,24	14,99±9,44*	21,04±12,01	20,01±9,88
Dilation of the capillaries, %	34 (85)	16 (40)*	24 (80)	17 (56,6)
Avascular fields, %	26 (65)	24 (60)	13 (43,3)	17 (56,6)
Morphological capillaries' changes, %	36 (90)	22 (55)*	22 (73,3)	10 (33.3)*
Hemorrhage, %	25 (62,5)	10 (25)*	12 (40)	7 (23.3)

*- p < 0,05

It was found that patients participated in BFB training, showed significant positive dynamics in the following signs of capillaroscopic picture: dilatation of the capillaries (x^2 = 9,643; p = 0,026), morphological changes of the capillaries (x^2 = 4,90; p = 0,027), and hemorrhage (x^2 = 4,514; p = 0,034).

Only one indicator of capillaroscopy showed significant change in the control group of patients, the presence of dilated capillaries (x^2 = 5,833 with p = 0,016).
Conclusion: These findings suggest that treatment results were significantly better in the main study group of SS patients.
We suggest that biofeedback may be a useful adjunctive treatment for Raynaud's syndrome in patients with SS.

DOI: 10.1136/annrheumdis-2021-eular.1701

AB0877-HPR EXERCISE COMPLIANCE AND DISEASE STATUS IN PATIENTS WITH RHEUMATIC DISEASES DURING COVID-19 PANDEMIC

G. G. Pala[1], Z. Tuna[1], N. G. Tore[1], S. Bayram[1], F. Sarİ[1], M. A. Ozturk[2], D. Oskay[1]. [1]*Gazi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey*; [2]*Gazi University, School of Medicine, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey*

Background: The COVID-19 pandemic affects the whole world in many ways. In an effort to slow down the infection, physical distancing and isolation policies have been implemented in Turkey, likewise the rest of the world. Thereby, rheumatic diseases require to obey the self-isolation recommendations strictly due to general vulnerability to infections in those patients. Due to the precautions taken for isolation, the physical inactivity level of the patients which would affect the disease activity has increased (1).
Objectives: The primary purpose of this study was to assess the exercise compliance and clinical status of the patients with rheumatic diseases during the COVID-19 pandemic. The secondary aim of the study was to evaluate the physical activity level and quality of life of the patients during the pandemic.
Methods: The research is a cross-sectional study. Seventy-nine patients with various rheumatic diseases were included in the study. Standard questions were used to evaluate the exercise habits, the level of pain and morning stiffness and severity of exacerbations. Pain and morning stiffness levels and attack severity were scored on a numerical rating scale (NRS) (0-10; with 0 indicating no pain/stiffness and 10 severe pain/stiffness). Attack duration was recorded in number of exacerbated days. Parameters were compared before and after the pandemic with Paired Samples T Test. The International Physical Activity Questionnaire-Short Form (IPAQ) and Nottingham Health Profile (NHP) Questionnaire were filled to assess the physical activity level and quality of life.
Results: Twenty-eight percent of the patients were diagnosed with Familial Mediterranean Fever (FMF), 37% were Ankylosing Spondylitis (AS), 14% were Systemic Sclerosis (ScS) 14% were Systemic Lupus Erythematosus (SLE), 6% were Rheumatoid Arthritis, 1% were Primary Sjogren Syndrome (PSS). Less than half of the patients (46%) did continue exercising regularly during the pandemic and 30 (81%) of them performed only the exercises given by the therapist while 7 (9%) of them tried different exercise types from another source. The reason for discontinuation to exercising expressed by the incompliant patients were mostly "unwillingness" (17 of 37 patients). Pain, morning stiffness and number of attacks were better during the pandemic compared to before however, a statistically significant difference was found only for morning stiffness (p = .036). The results of IPAQ showed that the majority of the patients (n: 48) were physically inactive, while only 2 patients were active during the pandemic. The most deteriorated quality of life subcategory was energy level of the patients according to the NHP scores.
Conclusion: This study results showed that patients with rheumatic diseases stayed physically inactive during the pandemic and the disease status has also been affected negatively. As the duration of the pandemic prolongs, levels of physical inactivity would increase and the progressive physical inactivity is expected to worsen patients' symptoms more. However, as the pandemic appears to continue, face-to-face exercise therapy should still be avoided. For all those reasons above, alternative ways of therapy like tele-rehabilitation would come onto stage to cope with the increasing physical inactivity of the rheumatic patients.

AB0878-HPR EFFECT OF AQUATIC PHYSIOTHERAPY ON PAIN AND QUALITY OF LIFE IN ELDERLY WOMEN WITH FIBROMYALGIA

M. Antunes[1], M. Vertuan[2], A. Miquilin[2], A. Pasqual Marques[1], R. Morales[2]. [1]*University of São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy, São Paulo - SP, Brazil*; [2]*Cesumar University, Physiotherapy Department, Maringá - PR, Brazil*

Background: Fibromyalgia is defined as a chronic non-articular rheumatic disease, characterized by generalized, diffuse bilateral pain and the presence of tender points in specific anatomical regions. Its symptoms are characterized by a very varied picture and the etiology is considered multifactorial. Today, with difficult treatment, fibromyalgia has been a major challenge for healthcare professionals. Aquatic physiotherapy is currently one of the most commonly used forms of intervention in the management of fibromyalgia, and for this reason it has been used in interdisciplinary rehabilitation programs to promote health.
Objectives: To evaluate the effects of aquatic physiotherapy on pain and quality of life in patients with fibromyalgia.
Methods: This is an interventional, quasi-experimental study carried out at the Physiotherapy School Clinic of Universidade Cesumar in the city of Maringá, PR, Brazil. The study was approved by the Human Research Ethics Committee of Unicesumar under opinion No. 1,025,567. Participated in the study, elderly women aged 60 years, with clinical diagnosis of fibromyalgia. To assess the quality of life, the Medical Outcomes Study 36 - Item Short-Form Health Survey (SF-36) instrument was used and to verify the intensity of the pain, the Visual Analogue Scale was used. The aquatic physiotherapy intervention protocol was to perform 10 Watsu sessions, performed twice a week, lasting 40 minutes each. To perform the Watsu method, the following steps of the technique were followed: before starting, opening, delivering the water, dancing the breath in the water, breathing balance and to finish releasing the spine. For data analysis, the Shapiro-Wilk test was initially applied to verify the normality of the variables under study. As the data presented a normal distribution, mean, standard deviation, minimum and maximum were used to characterize the results. To compare the initial and final variables, the dependent student t test was used. The significance adopted was p <0.05.
Results: The study included 17 elderly women with a mean age of 67.5 ± 4.7 years. When comparing the evaluation and the reassessment, a statistically significant improvement was evidenced in the domains of quality of life: functional capacity (p=0.00445), limitation due to physical aspects (p=0.01347), pain (p=0.00861), vitality (p=0.00044), limitation due to emotional aspects (p=0.02019), mental health (p=0.00748). The domains that did not show statistical increase were the general health status (p=0.30663) and the social aspects (p=0.05037). The pain, on the other hand, was statistically less after the intervention (p=0.00059).
Conclusion: Aquatic physical therapy provided benefits in reducing pain and improving the quality of life of elderly women with fibromyalgia. It is important to encourage individuals with fibromyalgia to perform non-pharmacological interventions, such as aquatic physiotherapy, to promote their health and quality of life.

AB0879-HPR MOTIVATION OF HEALTHCARE PROVIDERS DURING COVID19 PANDEMIC OUTBREAK

C. Cobilinschi[1], A. Constantinescu[1], I. Draniceanu[1], A. Balanescu[1], V. Bojinca[1], C. L. Constantinescu[1], L. Groseanu[1], S. Daia-Iliescu[1], I. Saulescu[1], D. Mazilu[1], M. Duna[1], D. Opris-Belinski[1], R. Ionescu[1]. [1]*Sf. Maria Clinical Hospital, Rheumatology and Internal Medicine, Bucharest, Romania*

Background: Since the beginning of 2020, the medical staff caring for patients with rheumatic disorders has been exposed to considerable emotional and physical stress due to the COVID19 pandemic outbreak. Newly-designed circuits were imposed to better manage chronic patient admissions.
Objectives: To assess the level of motivation in healthcare personnel caring for patients with rheumatic disorders and identify determinants that lead to dissatisfaction during the COVID19 spread.
Methods: A 15-item questionnaire was distributed among medical and paramedical staff looking after chronic rheumatic patients. Motivation factors were included in questions having five preset answers, ranging from "not al all", "to a small extent", "moderately", "to a large extent" and "to a very large extent". The final item was an open-type question, favoring personal suggestions and potential changes in local management.

Results: Out of a total of a 124 responders, 82 were doctors with various degrees in training (fellow trainees, specialists in Rheumatology, Head of Department), 37 medical assistants, 3 nurses, a physical therapist, one clinical psychologist. Mean age in the group was 38.3 years old with a strikingly female dominance (87.6%). Within the responders, the financial factor represented by monthly salary or bonuses had no or little impact on work motivation during the pandemic since more than 70% answered with "not al all / to a small extent / moderately". Regarding motivation through working hours, 26.7% responded either "not at all" or "to a small extent", 32.4% were moderately motivated while only 12.4% were more enthusiastic. More than half (53.4%) of the staff stated that motivation was not entirely affected by working conditions in the hospital. Answers were relatively equally divided referring to motivation by safety at their workplace (almost 20% for each statement), and 40.9% suffered some extent of demotivation due to risk of contamination while caring for COVID19 positive patients. 42% of the staff was only moderately motivated by hospital's measure to limit the spread of COVID throughout the personnel. Almost 75% of the healthcare workers were not motivated by news media. Around 54% said that personal motivation was not influenced by a larger work volume and 43% were very much motivated by work relationships with colleagues. 41% of the staff is only moderately satisfied with their work during the COVID outbreak while 18% are not at all satisfied. Finally, the last open-question confirmed that for some the pandemic period was a time to bring healthcare professionals together to a stronger bond. Other responders felt that chronic rheumatic patients were left aside, while caring mostly for COVID19 patients and only limited admissions for life-threatening conditions. Moreover, medical staff suggested that the lack of a more frequent testing throughout the personnel to avoid contamination was demotivating, while still living with families or relatives.

Conclusion: Motivation of the personnel is a process with great economic and social impact. This study challenged the level of healthcare staff in difficult times caused by medical crisis. Results of the enquiry showed that financial benefits had no impact on motivation. Harsher working conditions or larger volume did not negatively impact motivation of staff, but the fear of contamination was considerable. Apparently the media influence was not a motivator for medical staff during the outbreak. Medical teams should find their stamina until the end of pandemia.

AB0880-HPR

FACTORS THAT INFLUENCE PREGNANCY DECISIONS IN WOMEN WITH RHEUMATIC DISEASES

J. E. Compeán-Villegas[1], D. Á. Galarza-Delgado[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], R. Moyeda Martinez[1], R. A. Rodriguez Chavez[1], L. G. Espinosa Banuelos[1], A. Y. Lujano Negrete[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*

Background: The reproductive capacity of women with rheumatic diseases (RD) could be affected by factors such as sexual dysfunction, reduced gonadal function, foetal losses, drugs, and personal choices [1]. Studies have suggested that women with RD may underestimate their reproductive capacity [2], which may be reflected in unplanned pregnancies and/or adverse outcomes. One study found that women with rheumatoid arthritis (RA) have longer time to pregnancy compared to those without RA, suggesting that a reduction in fertility may be involved [3]. Another study found that patients with RA have more subfertility related to medication [4]. Aspects of sexual and reproductive health are not routinely addressed, so they are areas of opportunity to improve quality in care and research.

Objectives: Identify demographic and clinical factors associated with pregnancy decision in women with RD.

Methods: A population study was carried out including women with RD who had their first obstetric event from September 2017 to November 2020. According to the onset of sexual life and the year of conception of the first pregnancy, two groups were formed, who conceived before and after 5 years elapsed. Demographic and clinical data were obtained from medical records. Categorical variables were assessed using χ^2 test and Fisher's exact test where appropriate. Student's t-test was used to assess continuous variables. A p value of 0.05 or less was considered significative.

Results: Data were collected from 28 women, the main diagnosis was rheumatoid arthritis (21, 75%), followed by systemic lupus erythematosus (7, 25%), 14 of them (50%) were pregnant in the first 5 years after starting sex life. There were no differences in age of onset of sex life (p = 0.362), or other clinical characteristic, but women with pregnancies in the first lustrum had lower percentages of marriage union (35% vs 42%), paid-work (21% vs 28%), and use of highly effective contraception (21% vs 28%).

Conclusion: Conclusions: No factors were identified for pregnancies in the first lustrum, but there is a tendency to occur in single women, non-employees, and users of non-highly effective contraceptives methods. Further studies with a larger population are necessary to find modifiable factors and improve outcomes.

Table 1. Clinical characteristics.

	Obstetric event before 5 years	Obstetric event after 5 years	p-value
Total	14	14	
Current average age	24.85 +/- 4.3	29.92 +/- 5.7	0.404
Age at the first obstetric event, years	20.92 +/- 2.9	28.00 +/- 5.9	0.05
Age at the onset of rheumatic disease, years	20.71 +/- 5.5	23.42 +/- 4.0	0.135
Average age of onset of sex life, n (%)	18.64 +/- 2.9	18.07 +/- 2.5	0.362

AB0881-HPR EVALUATION OF NURSING CARE PLANS FOR RHEUMATOID ARTHRITIS PATIENTS: NURSING 2.0 PROJECT

L. Lopez Pedraza[1], M. Rodero[2], G. Candelas[2], C. Lajas[2], T. Mulero López[2], A. M. Perez Saez[1], L. León[1], Z. Rosales[2], B. Fernandez[2], L. Abasolo[1], L. Rodriguez Rodriguez[1]on behalf of Investigación de la Unidad de Gestión Clínica de Reumatología del Hospital Clínico San Carlos. *[1]Hospital Clínico San Carlos, Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IdISSC), Reumatología, Madrid, Spain*; *[2]Hospital Clínico San Carlos, Reumatología, Madrid, Spain*

Background: A better quality of care for chronic patients is only obtainable through multidisciplinary teams. In recent years, rheumatology nurses have been involved in the remote monitoring of aged Rheumatoid Arthritis (RA) patients, as their high levels of multi-morbidity and disability make routine contacts too complex for patients and caregivers. Nursing health care should be evidence-based and organized to optimize the professionals' time.
Objectives: To develop a pilot study of two Nursing Care Plans (NCP) in Rheumatology consultations for Rheumatoid arthritis patients, exploring the satisfaction, disease activity, adherence and quality of life of the patients.
Methods: This is a non-randomised interventional study. All the stablished RA patients attending our clinics were offered one of the care plans, based on clinic characteristics, functional status, social needs, social support, preferences and health literacy. They are focused on three fundamental axes: adaptation, adherence and safety of the patient. We evaluated the two NCP that were created: (1) Elderly established RA face to face/phone visit, (2) Active young established RA face to face/phone visit. The study included a first baseline visit and a second visit at six months. Outcomes were adherence to treatment: using the Morisky Green questionnaire, disease activity; through the erythrocyte sedimentation rate (ESR), patient satisfaction; using the LOPSS questionnaire and quality of life: using the EUROQOL 5D questionnaire, Visual analog scale of the attention received and Visual analog scale of the care received. Final visit were compared to baseline visit in both groups. The paired Wilcoxon or McNemar test were used.
Results: We included 48 patients, 16 from the NCP 1 and 32 from the NCP 2. All patients except one from the NCP 2 were followed-up and ended the study. The mean age of the participants was 56 years. 77.5% were women. 30.6% had an active smoking habit. 46% had universitary studies. 53.1 had an active labor situation. Regarding the main outcomes: a)Disease activity, a slight decrease in activity was observed between baseline and 6 months, but without statistically significant differences. b) Quality of life, we detected some improvement in all care plans in the EQ-index and in the Visual analog scale (VAE) but there were no statistically significant variations. c) Therapeutic adherence, we show the results in the Morinsky Green questionnaire. We obtained statistical significant decrease in the percentage of patients that forgot to take their prescribed medications after 6 months (p=0.04), and we also saw an increase in the percentage of patients taking medications at established times (up to 100% in all groups). d) Patient satisfaction with NCP obtained at the end of study, we used the LOPPS questionnaire. We obtained at six months a punctuation less than 1.5 (ordinal scale that 1 is good 5 is bad). e) Satisfaction of the care received by patients over the phone assessed at the end of study, it was almost 100%, being 75% of the patients scores 9 or over. f) Satisfaction with the care plans assessed at the end of study, the score given by patients was almost 90%, being 75% of the patients scores 8 or over.
Conclusion: After applying the NCP in both groups, we found positive results after 6 months and mainly regarding the therapeutic adherence. The program was well evaluated by the patients in terms of satisfaction of the care provided.

AB0882-HPR ANCA-ASSOCIATED VASCULITIS: A CLINICAL PRACTICE ASSESSMENT

S. Mendly[1], G. Boutsalis[2]. *[1]Medscape Education Global, Medscape Education Global, London, United Kingdom*; *[2]Medscape Education Global, Medscape Education Global, New York, United States of America*

Background: AAV (ANCA-associated vasculitis) is a group of progressive, rare, severe autoimmune diseases[1,2]. AAV can affect blood vessels in different parts of the body resulting in damage to vital organs such as the lungs, kidneys, nervous system, gastrointestinal system, skin, eyes, and heart.[2] There are currently no approved therapies for remission-induction in patients with AAV. The current treatment armamentarium for AAV is comprised of various immunosuppressive therapies in combination with steroid treatment. Understanding clinical practice gaps in the management of AAV, can inform development of tools to improve physician practices.
Objectives: This medical education activity aims to assess physicians' knowledge on the various manifestations of antineutrophil cytoplasmic antibody-associated vasculitis (AAV), current guideline-recommended treatment strategies for remission induction in patients with AAV, as well as recent clinical trial data for combination therapies used for remission induction.
Methods: A 24-question survey consisting of multiple-choice knowledge and case-based questions was made available to nephrologists and rheumatologists without monetary compensation or charge. The questions were designed to evaluate knowledge regarding the various manifestations of AAV and the results from clinical trials that have compared the efficacy of combination therapies used for remission induction in patients with AAV. As well as application of guideline-recommended therapies and clinical trial data for remission induction in patients with AAV within clinical practice. The survey launched online on a website dedicated to continuous professional development. (www.medscape.org/viewarticle/920320) on July 15, 2020. Data were collected until October 1, 2020.
Results: 363 nephrologists and 190 rheumatologists completed the survey. Physicians demonstrated gaps in the following areas:

Topic	Incorrect Responses to Knowledge and Clinical Decision-Making Questions (%)	
	Nephrologists	Rheumatologists
Systemic diseases associated with AAV	59%	45%
How to confirm diagnosis of AAV	42%	25%
Therapy selection to induce remission that would be consistent with guidelines recommendations	71%	51%
Guideline-recommended therapy for patients that do not respond to the induction regimen	32%	34%
Definition of refractory disease	95%	94%
Most effective maintenance strategy for a patient once remission is achieved	80%	64%
Where would an emerging therapy such as a C5a receptor inhibitor fit into the therapeutic armamentarium of AAV?	62%	47%
What are the guideline-recommended therapies to reduce remission in patients without organ-threatening disease?	71%	51%
Most effective maintenance strategy for a patient once remission is achieved	80%	64%
Guideline-recommendations on length of time to continue maintenance therapy	31%	35%

Conclusion: This educational research on assessment of physicians' (nephrologists and rheumatologists) clinical practices yielded important insights into clinical gaps related to understanding of the disease pathophysiology and

progression of AAV, guideline recommendations on diagnosing and managing AAV with guideline-directed medical therapies (GDMTs), strategies for the management of relapsing and refractory disease in AAV and positioning of emerging therapies in the treatment paradigm.

AB0883-HPR CHRONIC RHEUMATIC DISEASE MANAGEMENT AND THE SELF-EFFICACY OF RHEUMATOID ARTHRITIS

Y. H. Xu[1], X. Zhang[1], C. Chen[1], Y. W. Zou[1], K. M. Yang[1], L. Dai[1]. [1]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China*

Background: Rheumatoid arthritis (RA) is a common chronic disabling autoimmune disease, which cannot be cured completely at present, and patients need long-term medication treatment. The overall management of RA disease and patient self-management is important. Therefore, we built up a chronic rheumatic disease management team, formed by rheumatoid clinicians, clinical nurses and case managers, to provide "integrity continuity" disease management for RA by hospital on-site and WeChat APP. To this end, we used the arthritis self-efficacy scale-8 (ASES-8) to investigate the effect of the chronic disease management with RA.
Objectives: To explore the effect of chronic rheumatic disease management and the related factors of self-efficacy of RA patients.
Methods: Consecutive outpatients with RA who had been implemented chronic disease management were recruited from January 2019 to January 2020. A questionnaire survey of ASES-8 and clinical data were collected.
Results: 1. Among the 376 RA patients who have completed the survey, mean follow-up time of chronic disease management was 29 (8, 41) months, 35.4% patients in CDAI remission stage of disease activity, median ASES-8 score was 59(47,70), and 61.2% patients had medium or above medication adherence.
2. Patients with low ASES-8 had higher RA disease activity (including TJC28, SJC28, Pain VAS, PtGA, PrGA, ESR, CRP), more patients with dysfunction and lower medication adherence than those with high ASES-8 (all P<0.05).
3. Patients were divided into CDAI active RA group and in remission group, and those with low ASES-8 in remission group participated in chronic disease management for fewer months than those with high ASES-8 (median 20 vs. 32, P=0.033), and the HAQ-DI score was higher (P < 0.05). Active RA patients with low ASES-8 had higher disease activity, higher HAQ-DI (median 0.25 vs.0), fewer times of participating in patients' exchange meeting (median 0 vs.1), lower medication adherence (10.8% vs. 25.9%), and more anxiety or depression (57.6% vs. 31.8%) than those with high ASES-8 (all P < 0.05, Table 1 below).
Conclusion: The rheumatic chronic disease management team can help RA patients achieve a higher remission rate by continuous chronic disease management through hospital on-site and the Internet, and can help patients with good self-efficacy and medication adherence. In addition to disease control, we should pay attention to functional limitations and problems of back to work with RA patients in remission, while should pay attention to activity participation, medication adherence and emotional problems with active RA in further practice.

HPR Patients' perspectives, functioning and health (descriptive: qualitative or quantitative)

AB0884-HPR PERSONALISED TREATMENT GOALS IN PATIENTS WITH IMMUNE MEDIATED INFLAMMATORY DISEASE

S. Fadaei[1], H. Van Os-Medendorp[1], A. Sloeserwij[1], V. Sigurdsson[2], J. M. Van Laar[1], J. Spierings[1]. [1]*UMC Utrecht, Rheumatology & Clinical Immunology, Utrecht, Netherlands*; [2]*UMC Utrecht, Internal Medicine & Dermatology, Utrecht, Netherlands*

Background: Immune mediated inflammatory diseases (IMIDs) often have a chronic character and large impact on daily life of patients. In order to provide patient-centred care, insight in personal goals is a key issue.
Objectives: The aim of this study was to evaluate treatment goals of patients with IMIDs over time.
Methods: Patients with IMIDs were invited to complete a self-designed questionnaire about lifestyle, personal treatment goals and perceived care at their first visit to our centre and one year after referral. Clinical information was collected through the electronic patient record system.
Results: 41 (30%) patients of the 137 invited, completed both questionnaires. Participants had a mean age of 45.6 years (SD 13.4), N=35 (83%) was female, mean disease duration was 12.7 years (SD 12.7). Patients were diagnosed with connective tissue disease (CTD, n=19; 45%), antiphospholipid syndrome (APS, n=10; 24%), inflammatory arthritis (n=7; 17%) and psoriasis (n=7; 17%). We identified six categories of treatment goals: disease related, daily functioning, lifestyle, emotional wellbeing. Figure 1 shows the reported treatment goals at baseline and follow-up. Most frequently mentioned were goals related to disease, lifestyle and daily functioning. At follow-up we observed a vast increase in reported goals related to psychological wellbeing (from 5% to 16%). At baseline patients with APS chose lifestyle-related goals more often than other patients (RR=3.2; p=0.015). At follow-up patients with CTDs reported disease related-goals less often than other patients (RR=0.4; p=0.002). Patients did not report significant progress in reaching their goals on a Likert scale of 1-10. However, in 90% at first visit and in 83% of patients at follow-up, patients reported that the provided care was addressing issues they personally prioritized.
Conclusion: IMID patients' most frequent treatment goals relate to disease activity, lifestyle and daily functioning. Patients frequently change their treatment goals during the first year of treatment. Better understanding of

personal goals can help physicians providing targeted and personalised medicine.

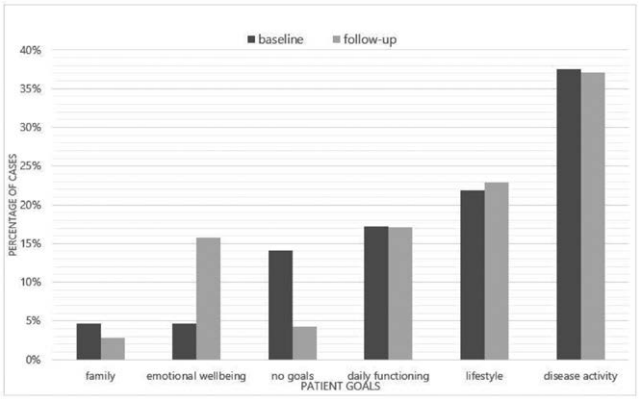

Figure 1. themes of treatment goals at baseline and follow-up

AB0885-HPR SLEEP IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. Andersen[1], K. M. Latocha2, B. A. Esbensen[1]. *[1]Rigshospitalet, Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Glostrup, Denmark*; *[1]Rigshospitalet, Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Glostrup, Denmark*

Background: Many patients with rheumatoid arthritis (RA) live with the consequences of arthritis in everyday life. Sleep disturbances, including insomnia, are highly prevalent and a complex issue that increases existing RA-related symptoms, such as pain, fatigue, and depressed mood. To our knowledge, only two studies have qualitatively investigated the patient perspective and experiences of sleep in people with RA (1-2).
Objectives: To investigate how people with RA and concomitant sleep disturbances describe their sleep and experience everyday life with poor sleep.
Methods: This study is a qualitative phenomenological study. In total, 14 people with RA and sleep disturbance were recruited from an RCT study (3) from the Center for Rheumatology and Spine Diseases at Rigshospitalet in 2012. Semi-structured interviews were performed after the last follow-up in the RCT. The analysis was based on Giorgis' descriptive phenomenological psychological analysis.
Results: For the characteristics of participants, see Table 1. We identified six essences; 1) "*When sleep is put into words*" covered that the participants described their poor sleep experiences simultaneously to their wishes for good sleep still existed. 2) "*The struggle to sleep*" included participants' descriptions of difficulties sleeping and how thoughts and worries could interfere with sleep at night. 3) "*Pain is a companion day and night*" included how pain affected sleep and how participants had problems with pain management. 4) "*To take sleep in their own hands*" described how the participants tried to create their framework for sleeping and how they also strove to reach out for help from, e.g. of professionals. 5) "*Everyday life in the shadow of sleep*" included the overwhelming fatigue, a need to rest during the day, and how social relationships were affected negatively. 6) "*Adapt to the circumstances*," which meant that the participants tried to seek shelter behind a facade, and at the same time tried to learn to live with the consequences of poor sleep in everyday life.
People with RA and sleep disturbances describe several challenges that affect their sleep, e.g., pain, thoughts at night, and many reasons for awakenings. Participants in this qualitative study were not aware of the difference between fatigue and poor sleep, both regarding reasons for occurring and management of the two highly prevalent consequences of RA. At the same time, they believed that health professionals lacked knowledge on sleep disturbances and management hereof in people with RA.
Conclusion: When people with RA and concomitant sleep disturbance describe their sleep, a struggle to sleep was most often described, characterized by pain, thoughts, difficulty falling asleep, and many and early awakenings. Everyday life experience with sleep disturbances was marked by fatigue and sleep deprivation, negative impact on social skills and relationships, and failure when they reached out for help.

AB0886-HPR ASSESSMENT OF SEASONAL VARIATIONS ON CHRONIC INFLAMMATORY RHEUMATISMS ACTIVITY

O. Hamdi[1], M. Sellami[1], S. Miladi[1], A. Fazaa[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. *[1]Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia*

Background: Although rheumatoid arthritis (RA) and spondyloarthritis (SA) activities have been described to vary under the influence of several factors, little is known about the influence of seasonality on the activity of chronic inflammatory rheumatisms.
Objectives: To assess the influence of seasonality on the activity of chronic inflammatory rheumatisms.
Methods: We conducted a cross-sectional study involving patients with RA (2010 ACR/EULAR criteria) and SA (2009 ASAS criteria). Chronic inflammatory rheumatisms activity was assessed during the summer (June-September) and winter (December-February) using clinical parameters including the Patient's Global Assessment of disease activity (PGA), 10-cm Visual Analog Scale (VAS) pain score, morning stiffness, nocturnal awakenings, and joint count for RA (tender joint count (TJC) and swollen joint count (SJC)); biological parameters including erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP); disease activity scores including the SDAI, CDAI and $DAS_{28}$for RA, BASDAI and $ASDAS_{CRP}$ for SA. An analysis of variance (ANOVA) was used to assess the statistical relationship between seasonality and rheumatisms activities.
Results: We enrolled 175 patients (100 RA and 75 SA) with a sex ratio of 0.5 and a mean age of 57.75 ± 10.53 years [23-83]. The mean chronic inflammatory rheumatisms duration was 12.38 ± 4.6 years. RA was erosive in 91% of cases. Rheumatoid factor and anti-citrullinated peptides antibodies were positive respectively in 84% and 85% of cases. Seventy-five percent of RA patients were on corticosteroids with a mean dose of 10.14 mg/day of prednisone equivalent and 79% of SA patients were on non-steroidal anti-inflammatory drugs. Eighty percent of our patients were treated with conventional synthetic DMARD and 44% with biological DMARD. Small joints were more affected than large joints regardless of the season in RA patients (p=0.05). The following parameters were higher in winter than in summer in RA patients: mean PGA 4.73 vs 4.64 (p=0.01); mean morning stiffness 1.6 vs 1.1 (p=0.01); mean SJC 8.7 vs 7.5 (p=0.01); mean DAS_{28} ESR 4.56 vs 3.99 (p= 0.05); mean DAS28 CRP 4.6 vs 3.41 (p= 0.05), mean SDAI 21.8 vs 19.5 (p= 0.05); mean CDAI 20.5 vs 18.75 (p= 0.01) and mean ESR 45.6mm/h vs 38.2 mm/h (p=0.01). As for SA, the following parameters were higher in winter than in summer: mean morning stiffness 2 vs 1.4 (p= 0.01); mean ASDASCRP 3.9 vs 3.1 (p= 0.01) and mean BASDAI 6.2 vs 4.9 (p= 0.05). However, we found no statistically significant

correlation between seasonal changes and VAS pain score, nocturnal awakenings, TJC, and CRP.
Conclusion: Chronic inflammatory rheumatisms activity was higher in winter. Health care professionals should take seasonal changes into account in order to improve therapeutic care.

AB0887-HPR CHARLSON COMORBIDITY INDEX (CCI) IN RHEUMATOID ARTHRITIS: CLASSIFICATION AND CORRELATIONS

C. Flourou[1], S. Psarelis[2], A. Tofarides[3], E. Papanicolaou4, G. Papazisis[5]. *[1]Nicosia General Hospital, Internal Medicine Department, Nicosia, Cyprus*; *[2]Nicosia General Hospital, Rheumatology Department, Nicosia, Cyprus*; *[3]Nicosia General Hospital, Internal Medicine Department, Nicosia, Cyprus*; *[1]Nicosia General Hospital, Internal Medicine Department, Nicosia, Cyprus*; *[5]Aristotle University of Thessaloniki, Clinical Pharmacology, Thessaloniki, Greece*

Background: Charlson Comorbidity Index[1] is a tool including age and chronic diseases assessing the comorbidity burden. The age and the comorbidity burden in RA patients determine the morbidity and mortality.
Objectives: To assess and classification of CCI in RA patients with usage of the health-care system (outpatient clinics) in a real-world setting.
Methods: 327 patients with RA from a large outpatient service of a central hospital were retrospectively reviewed. Demographic characteristics, treatment for RA and comorbidities were recorded. Charlson Comorbidity Index (CCI) was measured and classified as low, intermediate and high score for 1-2, 3-4 and >=5 points, respectively. Its correlation with polypharmacy and necessity of biologic DMARDs was studied. Univariable and multivariable analyses were performed.
Results: Data from 327 RA patients (75,8% females, 24,2%males) with a mean±SD age of 63±11,8 years and disease duration 113±63 months, were recorded.
CCI was 3±1,2 points (mean±SD) and maximum score was observed at 7 points. High score (>=5points) was observed at 9,2% and in the majority the score was intermediate (3-4points) at 55%. All the RA patients with high score fulfilled the criteria of polypharmacy. Patients with high score had 9,7 times more probability of polypharmacy than the patients with low score (p=0.09, 1.4-2.5 95%CI).
70 patients were treated with biologic-DMARDs (21,7%), in the majority with TNFa inhibitors (16,5%). In RA patients receiving biologic-DMARDs was observed low or intermediate score of CCI. The most likely explanation is the severity of the disease that predominated, its complications and the possible overlap with other conditions.
Conclusion: The majority of RA patients had intermediate score of CCI. In patients with high score-meaning more comorbidities- polypharmacy was observed completely. Patients receiving biologic-DMARDs characterized with less comorbidities.

AB0888-HPR EULAR SJOGREN'S SYNDROME PATIENT REPORTED INDEX-FATIGUE SCORE AND HADS-DEPRESSION SCORE MEDIATE IDENTITY SCORE OF ILLNESS PERCEPTION QUESTIONNAIRE IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

A. Kapusuz[1], K. Abacar[2], Y. Yenisoy[1], İ. Tatlı[3], E. N. Çakır[1], F. Türe-Özdemir[3], M. Yay[4], Ü. Karaçaylı[5], H. Direskeneli[2], N. Inanc[2], G. Mumcu[6]. *[1]Marmara University, Institute of Health Sciences, Istanbul, Turkey*; *[2]Marmara University Medical School, Department of Rheumatology, Istanbul, Turkey*; *[3]Marmara University Medical School, Department of Heamatology and Immunology, Istanbul, Turkey*; *[4]Mimar Sinan Fine Arts University, Department of Statistics, Istanbul, Turkey*; *[5]Health Sciences University, Department of Oral and Dental Surgery, Istanbul, Turkey*; *[6]Marmara University, Department of Health Management, Istanbul, Turkey*

Background: Dryness, fatigue, and pain are common clinical manifestations assessed by EULAR Sjogren's Syndrome Patient Reported Index (ESSPRI)-Dryness, -Fatigue, -Pain scores in patients with primary Sjögren's syndrome (pSS). In addition, depression is also seen in these patients owing to the pattern of the chronic disease.
Objectives: The aim of the study was to assess the complex interactions among Depression status, Illness Perception, and prominent clinical manifestations evaluated by the ESSPRI (Dryness, Fatigue, and Pain) in patients with pSS.
Methods: In this cross-sectional study, 111 patients with pSS (M/F: 5/106; mean age: 52.9 ± 12.01 years) were included. The data were collected by clinical examination and a questionnaire regarding patient reported outcome measures (PROMs). Unstimulated (U-WSFR) and stimulated (S-WSFR) whole saliva flow rates of patients were calculated as ml/min. Hospital *Anxiety* and Depression Scale (*HADS*), Illness Perception Questionnaire-R (IPQ-R) and EULAR Sjogren's Syndrome Patient Reported Index were filled by patients. Increases in HADS score and subgroup scores of ESSPRI (Dryness, Fatigue and Pain) and IPQ-R dimensions regarding Identity, Consequences, and Emotional reflected poor conditions for patients. In addition, patients scored their disease activity (0: inactive-100: the worst activity) by using 100-mm visual analogue scale (VAS). After preliminary analysis, a mediation analysis was used to evaluate the relations among these variables.
Results: In the study, ESSPRI-Dryness score (6,27±2,79) was associated with U-WSFR (0,40±0,57) and S-WSFR (1,04±0,86),(r:-0,4 p=0.000; r:-0,3 p=0.004). Moreover, patients reported disease activity score (48,78±26,67) was related to U-WSFR (r: -0,3 p=0.026) as well as Consequence (19,12±5,47) and Emotional (19,54±7,02) scores of IPQ-R questionnaire (r: 0,3 p=0.035; r: 0,3 p=0.014).
In IPQ-R questionnaire, Identity score (8,04±3,1) reflecting number of symptoms that patients experienced due to their illness was correlated with scores of ESSPRI-Fatigue (5,29±2,97), ESSPRI-Pain (5,18±3,01), HADS-Anxiety (11,67±5,55), HADS-Depression (9,2±4,98) in the study (p<0.05).
In the mediation analysis, Identity score was directly mediated by ESSPRI-Fatigue score (p=0.0093) and indirectly mediated by HADS-Depression score (p=0.0011).
A bootstrap analysis with 5000 replications was applied to estimate mediation effect to generate 95% CI. Percentile bootstrap of HADS-Depression was found to be an effective mediator for Identity score based on 5000 bootstrap sample.
Conclusion: Both depression status and fatigue affected Identity score reflecting the number of symptoms poorly. Considering this complex relationship in disease activity assessment may positively affect disease outcomes.

AB0889-HPR PERCEIVED SATISFACTION WITH CHRONIC PAIN CARE IN GERMAN PATIENTS WITH FIBROMYALGIA (FM)

M. Offenbächer[1], L. Toussaint[2], J. Hirsch[3], M. Weigl[4], N. Kohls[5], M. Vallejo[6], J. Rivera[7], F. Sirois[8], J. Dezutter[9]. *[1]Gasteiner Heilstollen, Medical Department, Bad Gastein, Austria*; *[2]Luther College, Psychology, Decorah, United States of America*; *[3]East Tennessee State University, Psychology, Johnson City, United States of America*; *[4]Klinikum Großhadern, Department of Orthopaedics, Physical Medicine and Rehabilitation, München, Germany*; *[5]Coburg University of Applied Sciences, Health Promotion, Coburg, Germany*; *[6]UNED, Psychology, Madrid, Spain*; *[7]Gregorio Marañón Hospital, Rheumatology, Madrid, Spain*; *[8]The University of Sheffield, Psychology, Sheffield, United Kingdom*; *[9]University of Leuven, School Psychology and Development in Context, Leuven, Belgium*

Background: In chronic pain care a multidimensional perspective with attention to patients' cognitions, emotions, and their ability to cope is needed (1). Previous studies are also pointing to the role of experiencing meaningfulness in life in the adjustment to disability.Therefore care should additionally focus on the existential domain of patients' lives to live up to a holistic care approach (2). However, there are only a few studies on how FM patients are satisfied with practitioners' attention to multiple aspects of life with a chronic pain condition.
Objectives: To assess perceived satisfaction with chronic pain care and its associations with health variables in a cohort of patients with FM.
Methods: We invited 18 FM self-help groups in Germany to participate anonymously in our survey and sent them in total 192 paper-and-pencil surveys. Sociodemographics, disease related variables (e.g. pain, general health) and psychological variables [e.g. depression, anxiety, hope, stress] were assessed with standardized instruments, including 5 items (answer format 1=very unsatisfied – 10=very satisfied) assessing subjective satisfaction with medical care in different domains with the following questions: How satisfied are you with the attention of your treatment team/physician at home for physiological aspects of your pain (Physio)/ the consequences of the pain on your physical functioning (Physical)/ on your psychological well-being (Mental)/ on your social life (Social)/ on your meaning in life (Meaning).
Results: In total 162 FM patients participated (=84% response rate). Their mean age was 58 years (SD=10), 84% (N=135) were female. Highest level of education was: Elementary School 29%, Junior High School 35%, High School 15%, College 12%, and other 10%. Duration of chronic pain was

18.2 years (SD=12.0). The satisfaction with care scale showed good internal consistency and measured one factor. The means of the subscale were: Physio 5.7 (SD=2.5)/ Physical 5.5 (SD=2.5)/ Mental 5.5 (SD=2.6)/ Social 5.0 (SD=2.5)/ Meaning 5.3 (SD=2.6). Correlations of the subscales are depicted in Table 1. There were no associations between pain variables and satisfaction with care, but satisfaction with care was associated with mental health, but not physical health, outcomes.

Table 1. Correlations of satisfaction of care with different health variables. Subscales physiological and physical aspects and HADS-anxiety were not significantly correlated. *<.05; **<.01; ns=not significant.

	Physio	Physical	Mental	Social	Meaning
HADS-depression	-.10 (ns)	-.12 (ns)	-.19*	-.16*	-.14 (ns)
General Health	.02 (ns)	.14 (ns)	.13 (ns)	.18*	.12 (ns)
Stress	-.15 (ns)	-.14 (ns)	-.17*	-.17*	-.13 (ns)
Hope	.18 (ns)	.18 (ns)	.26**	.26*	.22*

Conclusion: In this cohort of German FM patients the average satisfaction with care overall, as well as the specific aspects of care, was only moderate. Interestingly we found associations between satisfaction with care in mental, social and meaning in life aspects with psychological well-being pointing to the fact that care for chronic pain patients should also include those aspects in addition to just addressing biomedical aspects.

AB0890-HPR

THE IMPACT OF GENDER ON PHYSICAL FUNCTION, FATIGUE, LONELINESS, DEPRESSION, AND SEXUAL FUNCTIONING IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH A SPECIAL FOCUS ON METHOTREXATE USAGE. A CROSS-SECTIONAL SINGLE-CENTRE STUDY

L. T. Bay[1], D. S. Nielsen[2], C. Flurey[3], A. Giraldi[4], S. Möller[5], C. Graugaard[6], T. Ellingsen[1]. [1]*Odense University Hospital, Rheumatology Research Unit, Department of Rheumatology, Odense, Denmark*; [2]*Odense University Hospital, Migrant Health Clinic & Department of Geriatrics, Odense, Denmark*; [3]*University of the West of England, Faculty of Health and Applied Sciences, Bristol, United Kingdom*; [4]*Copenhagen University, Sexological Clinic, Psychiatric Centre Copenhagen, Copenhagen, Denmark*; [5]*Odense University Hospital & University of Southern Denmark, OPEN, Odense, Denmark*; [6]*Aalborg University, Center for Sexology Research, Aalborg, Denmark*

Background: We lack knowledge of how gender, disease characterization, and measures of various Patient Reported Outcome Measures (PROMS) relate to Methotrexate (MTX) usage in patients with rheumatoid arthritis.

Objectives: To investigate the impact of gender on physical function, fatigue, depression, loneliness, and sexual functioning with a special focus on MTX usage.

Methods: A cross-sectional study design was used to collect data in a rheumatologic outpatient clinic. The following PROMs were applied: Changes in Sexual Functioning Questionnaire, UCLA Loneliness Scale, Beck´s Depression Inventory, Bristol Rheumatoid Arthritis Fatigue-Numeric Rating Scale, and the Health Assessment Questionnaire.

Results: Among 286 patients diagnosed with rheumatoid arthritis (69 men and 217 women), 67.8 % were defined as MTX-users one year after diagnosis.

Comparing women and men we found differences in PROMS, with significantly worse outcomes for women than men in physical functioning at diagnosis and in sexual functioning, depression, fatigue, physical functioning, and patient evaluation of disease burden at enrolment in the study.

There were only significant differences in the HAQ and loneliness score when comparing MTX-users with MTX-non-users in general (Table 1).

Conclusion: The results of this study show that women have more negative outcomes on the selected PROMs compared to men with RA. This difference between genders was also evident when comparing MTX-users with non-MTX-users, again with a poorer outcome on PROMs for women compared to men. This calls for attention in the clinical setting and further research in the used instruments and the importance of gender in the care and treatment of patients with RA.

AB0891-HPR

PATIENTS WITH RHEUMATIC DISEASE WHO WERE 'FEELING STRESSED' DURING THE SECOND WAVE COVID19 INFECTION

H. Baharuddin[1,2], S. L. Lim[2], S. S. Ch'ng[2], M. Mohd Zain[2], A. Rosman[2], H. Mohd Yusoof[2], A. K. B. Authar Singh[2], V. Y. Tay[2]. [1]*Universiti Teknologi MARA, Department of Internal Medicine, Sungai Buloh, Malaysia*; [2]*Selayang Hospital, Department of Medicine, Batu Caves, Malaysia*

Background: COVID-19 pandemic has been devastating not only medically but also socially and economically. Selangor, an urbanised state in Malaysia, has been severely affected by COVID19. There is concern that patients with rheumatic diseases (RD) may have higher risk of infection, with increased mortality[1].
Objectives: To investigate patients' characteristics which are associated with 'feeling stressed' among patients with RD during the second wave of COVID19 infection in Selangor.
Methods: This is a cross-sectional study conducted over 3 weeks during the second wave of COVID19 infection in Malaysia. Patients with RD, scheduled for rheumatology clinic appointment in a rheumatology referral centre were invited to participate in this study.
Personal and clinical data were collected by phone interview and from patients' medical records respectively. Patients were asked to grade their disease activity by giving a score from 0 (not active) to 10 (active). All patients were asked 'are you feeling stressed?' and the answer was recorded as yes or no. Reasons explored for a yes answer, included financial, social disruption, physical illness and future uncertainties. Categorical and continuous data were analysed using chi-squared test and student t-test, respectively. A p-value of <0.05 is considered statistically significant.
Results: Three hundred and sixty-one patients with various RD participated in this study. The mean age of these was 48.2 years (range between 16-80 years). More than half (54.3%) were Malay and other ethnicities were Chinese (25.5%), Indian (18.2%) and others (2%). A quarter of patients (24.7%) were not working (unemployed, retired and students) and a third of patients (32.1%) had unpaid work (mainly housewife). The other patients' characteristics are shown in Table 1.

Table 1. Characteristics of patients who were 'feeling stressed' and not 'feeling stressed' during the second wave of COVID19 infection.

Patients' characteristics		No of patients	Feeling stressed (n=83), no of patients (%)	Not feeling stressed (n=278), p-value no of patients (%)	
Age	<60	272	72 (26.5)	200 (73.5)	**0.006**
	≥60	89	11 (12.4)	78 (87.6)	
Gender	Male	61	16 (26.2)	45 (73.8)	0.510
	Female	300	67 (22.3)	233 (77.7)	
Ethnicity	Malay	196	38 (19.4)	158 (80.6)	0.076
	Others	165	45 (27.3)	120 (72.7)	
Relationship status	Married	275	59 (21.5)	216 (78.5)	0.215
	Unmarried	86	24 (27.9)	62 (72.1)	
Education level	Up to secondary	233	48 (20.6)	185 (79.4)	0.145
	Tertiary	128	35 (27.3)	93 (72.7)	
Work status	No work	89	13 (14.6)	76 (85.4)	**0.002**
	Unpaid work	116	20 (17.2)	96 (82.8)	
	Paid work	156	50 (32.1)	106 (67.9)	
Rheumatic disease	SLE	125	30 (23.8)	96 (76.2)	0.259
	RA	150	30 19.4)	125 (80,6)	
	Others	80	23 (28.8)	57 (71.3)	
Perceived disease activity			3.14 (2.4)	1.87 (2.1)	**<0.001**
Use biologics	Yes	25	7 (28)	18 (72)	0.537
	No	336	76 (22.6)	260 (77.4)	

Eighty-three (23%) admitted to 'feeling stressed' and the stressors identified were physical illness in 34 (40.9%), social disruption in 23 (27.7%), financial problems in 23 (27.7%) and future uncertainties in 19 (22.9%). Patients' characteristics that were significantly different between patients who were 'feeling stressed' and not 'feeling stressed' were age, employment status and perceived disease activity (Table 1).
Conclusion: The COVID19 pandemic has caused mental distress in a significant number of RD patients and associations were found with older age, having paid work and perceived disease activity. Issues that may influence patients' responses, including access to rheumatology care, medication and fear of getting infection were not explored in this study.

PATIENT PERSPECTIVES ON PROVIDER PRACTICES LEADING TO AN AXIAL SPONDYLOARTHRITIS DIAGNOSIS: A QUALITATIVE STUDY

K. Lapane[1], C. Dubé[1], K. Ferrucci[2,3], S. Khan4, K. A. Kuhn[5], A. Ogdie[6], E. Yi[7], J. Kay[8,9], S. H. Liu[8,10]. Background: People with Axial Spondyloarthritis (axSpA) experience a diagnostic delay between 7 to 10 years. (1-5) This delay contributes to increased depression and desperation in searching for an appropriate diagnosis. (6) Consequently, people with axSpA experience impaired physical function, structural damage, and overall worsened quality of life than those who experience a timely diagnosis. (7)
Objectives: To gain knowledge and understand patients' experiences with healthcare providers in diagnosis of axSpA.
Methods: Using qualitative study design, we conducted six focus groups, with a total of 26 participants with a confirmed diagnosis of axSpA by rheumatologists from three different geographic locations: Worcester, MA, Aurora, CO and Philadelphia, PA. Focus groups were audio recorded and approximately 2 hours in duration. The focus groups were transcribed, deidentified, cleaned and stored in a secure location. NVivo software was used to code the data using a coding scheme which emerged from the focus group discussion topics. For intercoder reliability, two researchers coded the data and generated summary reports for data analysis.
Results: Patients described their frustrating journeys to diagnosis and attributed the lengthy diagnosis delays to a multitude of factors. These elements include, lack of definitive diagnostic test, disease characteristics, lack of primary care providers' awareness of axSpA, time, and trust. Patients felt that their physicians dismissed their complaints or would describe their symptoms as psychosomatic. The health care system also contributed to their diagnostic delays, including the lengthy referral process to a rheumatologist and the short clinical appointments. Patients believe that to reduce diagnostic delay, physicians must work with their patients; listening and believing their patients while allotting time for patients to discuss their experiences. In addition, patients believe earlier referral to a rheumatologist, and HLA-B27 genetic testing would decrease the diagnostic delay of axSpA.
Conclusion: In this study, patients desire definitive testing in clinical practice for earlier diagnosis of axSpA. Additionally, more education regarding the guidelines to diagnose axSpA and earlier referral to rheumatologists might be needed. Until this is feasible, patients seek clinicians who will work with them until a diagnosis is made, listening, and believing their experiences and symptoms.

Background: Suboptimal control of RA may lead to severe and progressive articular damage, loss of function, and deterioration of the quality of life (QoL).
Objectives: To assess treatment satisfaction, sociodemographic, clinical, health care resource utilization, and QoL characteristics of patients with sub-optimally controlled RA and treated with conventional synthetic and/or biologic DMARDs.
Methods: This study was an international, multicenter, cross-sectional, non-interventional study. Adult RA patients with moderate to severe disease activity (DAS28>3.2) were enrolled. Patient satisfaction was evaluated with Treatment Satisfaction Questionnaire for Medication (TSQM, version 1.4) with a scale ranging from 0 (indicating poor satisfaction) to 100 (indicating perfect satisfaction). Patients were questioned regarding treatment adherence, patient preferences, and expectations. Workability was evaluated using Work Productivity and Activity Impairment Questionnaire-Rheumatoid Arthritis (WPAI-RA, version 2.0). Short Form 36 (V2) survey were performed to all patients.
Results: One hundred sixty-four patients were included in the study and most (78.0%) were female. The median age was 57.0 years, ranging between 22.0 and 84.0 years. Half of the patients (50.6%) were primary school graduates and 6.1% were unemployed due to RA and seeking work. Median time since RA diagnosis was 8.0 years and mean (±SD) DAS28-CRP score was 4.8 (±1.0). Mean total activity impairment was 54.9% (±27.4). In the past 3 months from enrollment, the mean number of healthcare professional and emergency room visits were 1.8 (±1.1) and 1.8 (±1.3), respectively. Mean number and length of hospitalizations in the previous 3 months were 1.1 (±0.3) times and 8.3 (±7.2) days, respectively. Mean TSQM scores were 53.5 (±21.4) for effectiveness, 86.0 (±26.7) for side effects, 67.8 (±16.5) for convenience, and 57.7 (±22.0) for global satisfaction. The leading expectation was 'lasting relief of RA symptoms' (mean score: 5.8). Preferred time until the effect of onset was 'up to 1 week' for 76.2% of the patients. Most of the patients (57.9%) preferred oral administrations and the most preferred frequency of administration was 'once per day' (46.3%). Mean physical and mental component summary scores for Short Form 36 (V2) survey were 37.9 (±8.3) and 40.1 (±10.7).
Conclusion: Two-thirds of the patients with RA who have suboptimal responses are not satisfied with their treatments. Moreover, oral and once-daily treatment approaches stand out in patient preferences. Finally, suboptimal control leads to deterioration in clinical characteristics, workability, and QoL of patients with RA.
Acknowledgements: The design, study conduct, and financial support for the study were provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of the publication. All authors have received research funding for this study. The authors wish to thank B. Murat Ozdemir of Monitor CRO for medical editing and reviewing services of this manuscript. AB0894-HPR THE JOURNEY OF PATIENTS WITH RHEUMATOID ARTHRITIS

M. Fusama[1], S. Oliver[2], H. Nakahara[3], Y. Van Eijk-Hustings[4], Y. Kuroe[5]. [1]*Takarazuka University, School of Nursing, Osaka, Japan*; [2]*Susan Oliver Associates, Nurse Consultant, Barnstaple, Devon., United Kingdom*; [3]*Osaka Yukioka College of Health Science, Department of Physical Therapy, Ibaragi, Japan*; [4]*Clinical Epidemiology and Medical Technology Assessment (KEMTA), Department of Patient&Care, Amsterdam, Netherlands*; [5]*Gifu College of Nursing, School of Nursing, hashima, Japan*

Background: The course of rheumatoid arthritis (RA) differs from patient to patient, and each patient has a unique story. The disease condition affects psychological and social aspects, greatly affecting the quality of life. The disease course is unpredictable, and each patient's story can be seen as a lifelong journey, full of ups and downs. Therefore, it is crucial to know what kind of support is required during the course of their life.
Objectives: The aim of this study is to examine the life story of patients with RA and clarify a common situation in their stories in order to consider what kind of support is needed.
Methods: This is a qualitative study using life story interview for patients with RA in Japan. Interview included disease history, patients' behaviors, effects on daily life, the patients' perspectives regarding psychological considerations and useful support. Data were analyzed using content analysis. This study was approved by the ethics committee and informed consent was obtained.
Results: Eight patients participated in this study. They were all females and the average age was 57 years old. As a result of the categorization, we extracted the following eight situations: (1) Emergence of symptom; patients thought joint pain would go away, however, the symptom did not improve and began to affect their daily life and work, (2) Choose a hospital to visit; pain and anxiety have continued and decided to visit a hospital, (3) Encounter with their doctors; patients expected their doctor to relieve their pain, while they were afraid of being told that they were suffering from a serious disease. (4) Diagnosis of RA; patients were

shocked when diagnosed and anxious about what would happen and wondered why they had such a disease, (5) Choice of treatment; patients were afraid of the side effects. They wanted to make a decision discussing with their doctor, but they could not understand the explanation about drugs well and, therefore, followed the doctor's opinion. (6) Change of treatment; a biological agent was often recommended. Patients were also worried about side effects and the financial burden. (7) Remission or stable phase; they felt better mentally too, however, they often felt anxiety about disease flare, side effect of drugs and financial burden, and (8) Flare and remission; patients felt shocked and disappointed when RA flared, and then, they noticed that patients with RA had alternating periods of relapse and remission and they had to live with RA.

These interviews revealed repeated worsening and improvement of symptoms and many similar repeated psychological reactions such as anxiety, shock, denial, conflict, acceptance, giving up and relief. To cope with these fluctuating disease and mental conditions, patients were supported by educational and psychological assistance, timely consultations, social life help from nurses and support from their family. The patients considered a trusting relationship with their doctors is necessary. The patients had also realized through their experience the importance of enhancing their own abilities, such as decision-making, prevention of infections and self-management skills. Moreover, they noticed that it is important to have their own goals including hobbies and work.

Conclusion: This study elucidated the common behaviors of patients with RA, the impact of RA on their psychological state and daily and social life, and the required support. The psychological condition and daily and social life also had a great influence on medical behavior. Therefore, psychosocial support and establishment of trust between healthcare professionals and patients are crucial. In addition, improving patients' self-management skills including self-efficacy and empowerment is also necessary. As patients with RA often feel anxious in various situations and expect nurses' support, nurses should listen to patients, pay attention to their concerns and anxieties, and show a solution-oriented attitude. In order for patients to feel at ease in their Patient Journey, nurses should sail with them while maintaining a patient-centered perspective.

AB0895-HPR A MODERATED MEDIATION ANALYSIS FOR POOR ORAL HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH BEHÇET'S DISEASE

E. N. Çakır[1], Y. Yenisoy[1], A. Kapusuz[1], K. Abacar[2], F. Alibaz-Oner[2], M. Yay[3], Ü. Karaçaylı[4], N. Inanc[2], T. Ergun[5], H. Direskeneli[2], G. Mumcu[6]. *[1]Marmara University, Institute of Health Sciences, Istanbul, Turkey*; *[2]Marmara University, Division of Rheumatology, Istanbul, Turkey*; *[3]Mimar Sinan Fine Arts University, Department of Statistics, Istanbul, Turkey*; *[4]Health Sciences University, Department of Oral and Dental Surgery, Ankara, Turkey*; *[5]Marmara University, Department of Dermatology, Istanbul, Turkey*; *[6]Marmara University, Department of Health Management, Istanbul, Turkey*

Background: Since oral ulcer is a common clinical manifestation, oral health-related quality of life (OHRQoL) is affected by the presence of oral ulcer poorly in patients with Behcet's disease (BD).

Objectives: The aim of the study was to examine associated factors for poor OHRQoL status to improve treatment outcomes in patients with BD.

Methods: In this retrospective study, 339 BD patients (F/M: 179/160, mean age: 36,13±9,81 years) included. Data were collected by a structured questionnaire regarding treatment expectation, Oral Health Impact Profile-14 (OHIP-14) questionnaire for OHRQoL, oral ulcer activity, and disease severity score. Treatment expectation was coded by a 5-point Likert type scale (1: symptoms were completely cured vs 5: symptoms were worsened). OHIP-14 score was between "0 point (the best score)" and "56 points (the worst score)". The disease severity score was calculated according to the organ involvement. Then, patients were categorised as mucocutaneous involvement (n=181) and severe organ involvement (n=158). After preliminary analysis, a Moderated Mediation analysis was carried out.

Results: Oral ulcer activity was seen in 63,4% of the group (n=215). OHIP-14 score (22,05±16,47) was correlated with Treatment expectations (2,35±0,98) (r: 0,36 p=0.000) in the group. Poor scores of OHIP-14 and Treatment expectations were found in patients with active oral ulcers (mucocutaneous involvement: 27,56±14,55; 2,68±0,87, vs severe organ involvement: 28,51±17,25; 2,43±0,99) compared to those of inactive patients (mucocutaneous involvement: 13,38±12,23; 1,81±0,73 vs severe organ involvement: 8,79±10,19; 1,85±1,02) (p=0.000 for all). Patients with active oral ulcers were younger (35,09±9,52) than the others (39,57±10,06) in the mucocutaneous involvement group (p=0.0011) whereas a similar relation was not seen in the severe organ involvement (p=0.233).

In the moderated mediation analysis, it was found that OHIP-14 score was increased by the presence of oral ulcer in the direct path (p=0.0000) and the negative Expectation of the treatment as a first mediator (p = 0.0001) in the indirect path. Oral ulcer activity was associated with younger patients (p=0.0039). This effect was seen especially in patients with mucocutaneous involvement that had a moderator effect (p=0.0040). In addition, age was found to be a second mediator for the poor OHIP-14 score (p = 0.0053). Mediators and the moderator were found to effective for OHIP-14 score a bootstrap analysis with 5000 replications.

Conclusion: OHRQoL was affected by oral ulcer activity and poor treatment expectations. Age was also found to be another critical factor for OHRQoL.

AB0896-HPR THE EVALUATION OF TYPE D PERSONALITY AND SELF-ESTEEM IN PATIENTS WITH FIBROMYALGIA

N. Gokcen[1], I. Coskun Benlidayi[2], L. Tamam[3], M. E. Demirkol[3], C. Yesiloglu[3], R. Guzel[2]. *[1]Cukurova University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Division of Rheumatology, Adana, Turkey*; *[2]Cukurova University Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Adana, Turkey*; *[3]Cukurova University Faculty of Medicine, Department of Psychiatry, Adana, Turkey*

Background: Fibromyalgia (FM) is a condition characterized by chronic widespread pain, fatigue, sleep disturbances. Etiopathogenesis remains unclear; however, growing data regarding the effect of psychosocial factors on disease etiopathogenesis have drawn attention. Psychosocial elements such as type D personality and low level of self-esteem might increase disease burden (1). Accordingly, many researchers so far, have examined psychological parameters in FM and a limited number of studies focused on the personality type among patients with FM (2-5).

Objectives: The current study aimed to investigate type D personality and self-esteem in patients with FM.

Methods: Female patients with fibromyalgia and age-matched healthy controls were enrolled in this cross-sectional study. Type D personality was evaluated by using the type D scale (DS-14). The Rosenberg self-esteem scale (RSES) was used to assess self-esteem and psychosomatic symptoms. Psychological status was evaluated by the Beck Depression and Beck Anxiety Inventories. Fibromyalgia Impact Questionnaire (FIQ) was performed to assess functional impairment and health status in patients with FM. The potential confounders of type D personality were evaluated by binary logistic regression analysis.

Results: Seventy patients with FM and 60 controls were included. Type D personality was observed in 58.6% of the patients and in 21.7% of the control group (p<0.001). When compared to patients with non-type D personality, those with type D personality revealed lower self-esteem and poorer health status (p<0.05 for both), higher anxiety and depression scores (p<0.001 for both). According to binary logistic regression analysis, depression (β=1.178, CI 95% 1.055–1.316, p=0.004) and lower education level (β=0.818, CI 95% 0.682–0.982, p=0.031) were significantly related to type D personality in FM (Table 1).

Conclusion: Type D personality is more common in female patients with FM when compared to healthy women. Patients with type D personality have lower level of self-esteem when compared to those with non-type D personality. Depression and lower education level are potential confounders of type D personality in FM.

AB0897-HPR EVALUATION OF ANXIETY AND DEPRESSION IN PATIENTS WITH KNEE OSTEOARTHRITIS USING THE HAD "HOSPITAL ANXIETY AND DEPRESSION SCALE"

M. Brahem[1], S. Abdellatif[1], H. Hachfi[1], A. Ben Salem[1], R. Sarraj[1], R. Ben Tekaya[1], Y. Mohamed[1]. [1]*Taher Sfar Hospital, Rhumatology, Mahdia,Tunisia*

Background: Knee osteoarthritis is considered to be one of the most common causes of functional impairment, which affects the quality of life of patients leading to severe mood disorders. Our goal is to evaluate the frequency of depression and anxiety in patients with knee osteoarthritis.
Objectives: Evaluate the frequency of depression and anxiety in patients with knee osteoarthritis.
Methods: This is a cross-sectional study over a period of 7 months from February to August 2016, including consecutively patients who consulted in the Rheumatology department at Mahdia university hospital for knee osteoarthritis. We evaluated for each patient a validated version of HAD "Hospital Anxiety and Depression scale". This score includes 14 items each one rated from 0 to 3 and two components including depression and anxiety.
Results: We included in our study 66 patients (56 women and 10 men) with an average age of 60.3 years [40-90 years]. Knee osteoarthritis was bilateral in 56.1% of cases. The examination found limited mobility of the knee in 45.5% and flessum in 13.8% of cases. Standard radiography showed stage 1 knee osteoarthritis in 4.5%, stage 2 in 31.8%, stage 3 in 56.1% and stage 4 in 7.6% of cases. All our patients were treated with analgesics, NSAIDs in 95.5%, local corticosteroid infiltrations in 43.9% and hyaluronic acid in 7.6% of cases.The mean visual analog scale(VAS)was 5.84 ±1.7 out of 10 [2-9]. The mean overall WOMAC index was 47.15±15.6 [12-82]. The average Lequesne index was 16.8±13.1, moderate disability was found in 3% of cases, significant disability in 6.1% of cases, very significant disability in 18.2% of cases and extreme disability in 72.7% of cases. The mean depression score was 9.3±2.6 [4-16], with 24.6% of the patients had no depressive symptomatology (score ≤7), 40% had doubtful depressive symptomatology (score between 8 and 10) and 35.4% of them had certain depressive symptomatology (score ≥11).The mean anxiety score was 8.88 ± 4 [0-19], 33.3% of patients had no anxiety symptoms (score ≤ 7), 34.8% had doubtful anxiety (score between 8 and 10) and 31.8% had certain anxiety (score ≥11). The statistical study found a significant correlation between the depression score and WOMAC score, but we did not find an association with age, sex, radiological stage, mobility limitation and VAS. Regarding anxiety, there was a correlation with age, WOMAC score and female gender. On the other hand, there was no correlation with VAS, Lequesne score, radiological stage and limitation of mobility.
Conclusion: Although knee osteoarthritis appears to be a benign pathology, its impact can be severe, including depression and anxiety, which are mainly influenced by the degree of functional disability. Hence psychological care is sometimes necessary in these chronic degenerative diseases.

AB0898-HPR WICH FACTORS ARE RELATED TO PAINFUL EXPERIENCE IN PATIENTS AFFECTED BY CHRONIC INFLAMMATORY RHEUMATIC DISEASE DURING THE COVID-19 PANDEMIC?

T. El Joumani[1], H. Rkain[1,2], T. Fatima Zahrae[1], H. Kenza[3], R. Abouqal[4], N. Laila[5], S. Bahloul[1], E. A. Nada[1], T. Latifa[1], N. Hajjaj-Hassouni[6], F. Allali[1]. [1]*El Ayachi Hospital, Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco, Department of Rheumatology B, Rabat, Morocco*; [2]*Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco, Physiology Laboratory, Rabat, Morocco*; [3] *Université Mohammed VI des Sciences de la Santé - UM6SS, Casablanca, Morocco., Ecole Internationale de Santé Publique, Rabat, Morocco*; [4]*Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco, Laboratory of Biostatistics, Rabat, Morocco*; [5]*Moroccan Association of Patients With Rheumatoid Arthritis and Spondyloarthritis, Rheumatology, Rabat, Morocco*; [6]*International University of Rabat, Rabat, Morocco, Rheumatology, Rabat, Morocco*

Objectives: To evaluate the effect of containment, during the Covid-19 pandemic, on the pain of patients with CIRD, and to analyze the factors associated with the experience of pain.
Methods: A cross-sectional study was conducted among patients with rheumatic diseases using a questionnaire providing information on patients and disease characteristics. Impact of COVID-19 on This is a cross-sectional study that consecutively included
Patients were asked to assess the global pain which they had experienced before and during the containment period, using a single Visual Analogue Scale (VAS) ranging from 0 (no pain) to 10 (greatest pain).
Statistical Analysis System IBM SPSS Statistics V20.0.0 was used to analyze the study data.
We performed univariate then multivariate analysis to search any related factors to pain perception during to quarantines. Qualitative values were analyzed by the chi2 test. Quantitative values were analyzed by the Student test when the measures were normally distributed or by nonparametric test (Mann–Whitney U) when the measures were not normally distributed (Kolmogorov–Smirnov test was used to test normality).
Results: Among the 350 patients who answered to the questionnaire online, rheumatoid arthritis represented 62.3%, spondyloarthropathy 34.3% and undifferentiated CIRD 3.4%.
Pain experience caused by the CIRD during the containment was reported by 79.1% of patients.
The level of pain, using the VAS of Pain increased significantly during the COVID-19 pandemic (4,6 ± 2,8 and 5,4 ± 3 before and during the containment; p<0.001).
In multivariate analysis, the factors implicated in pain were the negative impact of Coronavirus on access to rheumatologic care, discontinuation of therapeutic adherence, the disturbed quality of sleep and the negative psychological impact (table 1).
Table 1: Summarize multivariable analysis of factors associated with painful experience related to CIRD during containement.

Table 1. Multivariable analysis of factors associated with painful experience related to CIRD during containement

	P
Impact on monitoring	0.05
Impact on therapeutic adherence	<0.001
Quality of sleep disturbed	0.001
Negative psychological impact	0.02

Conclusion: This survey showed the that the COVID-19 pandemic have incresed painful experience in CIRD patients. Factors influencing painful experience should be taken into account to help patients to cope with their chronic rheumatism and this global health crisis.

AB0899-HPR THE IMPACT OF CORONAVIRUS (COVID-19) PANDEMIC ON THERAPEUTIC MAINTENANCE IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES

T. El Joumani[1], H. Rkain[1], T. Fatima Zahrae[1], H. Kenza[2], A. Radouan[3], N. Laila[4], S. Bahloul[1], E. A. Nada[1], T. Latifa[1], N. Hajjaj-Hassouni[5], F. Allali[1]. [1]*El Ayachi Hospital, Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco, Department of Rheumatology B, Rabat, Morocco*; [2] *Université Mohammed VI des Sciences de la Santé - UM6SS, Casablanca, Morocco., Ecole Internationale de Santé Publique, Rabat, Morocco*; [3]*Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco, Laboratory of Biostatistics, Rabat, Morocco*; [4]*Moroccan Association of Patients With Rheumatoid Arthritis and Spondyloarthritis, Rheumatology, Rabat, Morocco*; [5]*International University of Rabat, Rabat, Morocco, Rheumatology, Rabat, Morocco*

Background: The Coronavirus pandemic caused many consequences on well being, access to care and therapeutic maintenance in patients with chronic diseases.
Objectives: To assess the impact of COVID-19 on therapeutic maintenance of patients with Chronic Inflammatory Rheumatic Diseases (CIRD) and to identify related factors to difficulties in access to rheumatologist care during the COVID-19 pandemic.
Methods: A cross-sectional study was conducted among patients with rheumatic diseases using a questionnaire providing information on patients and disease characteristics, impact of COVID-19 on access to rheumatologist care and therapeutic maintenance during the confinement. Reasons of therapeutic interruption and of diificulties in access to healthcare were precised.
Results: We received answers from 350 patients (female sex of 68%, mean age of 46,1 ± 14,4 years) suffering from Chronic Inflammatory Rheumatic Diseases (CIRD):rheumatic arthritis (RA) (62.3%), spondyloarthropathies (34.3%), and undifferentiated CIRD (3.4%). The global average disease evolution was 12,1 ± 9,7 years.
The patients were treated with conventional Disease-modifying anti-rheumatic drugs (cDMARDs) and biologic Disease-modifying anti-rheumatic drugs

(bDMARDs) in respectively 67.4% and 30.6% of cases. Corticosteroids and Non-steroidal Anti-Inflammatories (NSAIDs) intake was noted in 39.1 and 33.7% of patients.
Difficulties to access to rheumatologist care appointments were reported in 82.9% of the participants. Reasons of thoses difficulties are summurized in Figure 1.

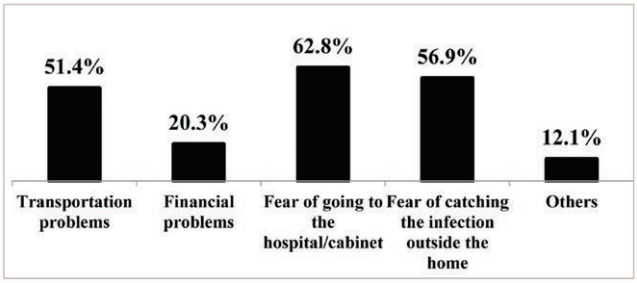

Figure 1. Causes of difficulties of access to Rheumatologist care during COVID-19 pandemic.

Half of patients declared that the pandemic had affected their therapeutic compliance. Discontinued drugs were in decreasing order: Synthetic antimalarials (68.4%), NSAIDs (45.8%), Methotrexate (43.8%), bDMARDs (25.2%), Sulfasalazine (18.2%) and Corticosteroids (10,2%).
Causes of treatments interruption are summarized in Table I.

Table 1. Causes of treatments interuption in patients with CIRD

Drugs	Not found in pharmacies	The pharmacy refuses to give me the treatment without a recent prescription	To avoid the decrease in immunity and therefore to avoid catching Covid-19	I stopped the follow-up, and so I stopped the treatment...	Other reasons
NSAIDS	0	27.8	74.1	44.4	27.8
Corticosteroids	0	14.3	92.9	57.1	50
Methotrexate	70.1	3	10.4	16.4	22.4
Sulfasalazine	0	12.5	25	75	100
Synthetic antimalarial	69.2	0	0	23.1	61.5
Leflunomide	0	0	0	0	0
bDMARDs	0	7.4	40.7	44.4	51.9

Conclusion: The COVID-19 pandemic impacted heavly on therapeutic maintenance in CIRD patients in our country. Patients expressed many difficulties in access to appropiate management. Facing to all thoses consequences, we need to devolopp as soon as possible adequate solutions adapted in such health crisis, especially therapeutic education and telemedecine.

AB0900-HPR THE EXPECTATIONS AND EXPERIENCES OF PATIENTS WITH RHEUMATOID ARTHRITIS AFTER ENROLLING INTO AN EDUCATIONAL PROGRAM. RESULTS FROM A MIXED STUDY APPROACH

R. A. Castiblanco Montañez[1], A. Arevalo Velandia[1], J. D. Garzon Cepeda[1], F. Rodriguez-Florido[2], D. Buitrago-Garcia[1], G. Sánchez[1], P. Santos-Moreno[2]. *[1]Fundación Universitaria de Ciencias de la Salud FUCS. Sede Centro, Bogotá, Bogotá, Colombia*; *[2]Biomab IPS, Bogotá, Bogotá, Colombia*

Background: Rheumatoid arthritis (RA) is a high-cost disease, usually diagnosed at a productive age in life. RA brings significant changes in a patient's life. On an emotional level, the patient perceives a strong impact that generates disorientation, denial, depression, hopelessness, anger and fear due to the uncertainty of the development of the disease and the doubt of the turn that his life will take. However, each patient has different ways of coping with the disease and adapting to it (1,2). These changes require attention from health personnel. In this regard, different studies have reported the effect of educational, support and empowerment programs for patients on reducing the effects of the disease and the benefits are oriented towards improving lifestyles by improving self-care (3,4).
Objectives: To describe the experience of patients with rheumatoid arthritis, their perception and expectations about entering a multicomponent educational program in a specialized center in Bogotá - Colombia.
Methods: For this study a concurrent mixed design was used, in which quantitative and qualitative methods are applied simultaneously, we invited patients with rheumatoid arthritis who attended a specialized center in Bogotá - Colombia who enrolled in an education program called UNIVERSITAR. The quantitative phase included a descriptive analysis and the application of the expectations scale adapted from Borkovec and Nau (5); this scale collects information about the level of expectations and satisfaction of the program. The scale ranges from 0 (not at all) to 10 (very much). Immediately after the application of the scale, the participants were invited to a focus group that allowed the dialogue on the perception and expectations of the participants regarding the program, through a dynamic process in which the participants exchanged their ideas and opinions. A group interview script was used, aimed at identifying the patients' experiences with their diagnosis and their expectations regarding the program. Two focus groups were held with an average duration of one hour; the discussion was recorded on audio and transcribed in its entirely.
Results: We included 31 participants and were distributed in two focus groups. The median age of the participants was 60 years IQR (54-67), 92% were female. 77% of participants reported high scores for the satisfaction regarding the program. In the qualitative phase two categories emerged that speak of the experience of the participants with the disease. They highlighted the appearance of this disease in their lives in an unexpected way, the doubts and uncertainties that were generated from the diagnosis and the implications that this condition causes health in their everyday life. However, in the second category, the expectations and motivations of the participants towards the educational program are highlighted, and the factors that influence their participation and their motivation to train and empower themselves to make decisions and as expert patients, capable of educate, guide and support other patients with the same diagnosis.
Conclusion: The expectations and perceptions of the patients are of great importance, since through these the conditions with which these educational programs provide interventions and a better quality of life to these patients can be improved.

AB0901-HPR SOCIAL AND PSYCHOLOGICAL IMPACT OF THE CONTAINEMENT DURING COVID-19 PANDEMIC ON PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES

T. El Joumani[1], H. Rkain[1], T. Fatima Zahrae[1], H. Kenza[2], A. Radouan[3], N. Laila[4], S. Bahloul[1], E. A. Nada[1], T. Latifa[1], N. Hajjaj-Hassouni[5], F. Allali[1]. *[1]El Ayachi Hospital, Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco, Department of Rheumatology B, Rabat, Morocco*; *[2] Université Mohammed VI des Sciences de la Santé - UM6SS, Casablanca, Morocco., Ecole Internationale de Santé Publique, Rabat, Morocco*; *[3]Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco, Laboratory of Biostatistics, Rabat, Morocco*; *[4]Moroccan Association of Patients With Rheumatoid Arthritis and Spondyloarthritis, Rheumatology, Rabat, Morocco*; *[5]International University of Rabat, Rabat, Morocco, Rheumatology, Rabat, Morocco*

Background: Covid-19 pandemic had a worldwide impact on the population, global economy and health care systems.
Objectives: To evaluate the psychological state and social impact of patients with Chronic Inflammatory Rheumatic Diseases (CIRD) during this pandemic in order to understand how to optimize their quality of life.
Methods: It's a cross-sectional survey, where the data were collected through the online survey tool "google forms". A pilot test were conducted with the study committee members who analyzed the apparent validity of the questionnaire and identified issues that could lead to misunderstandings, and their suggestions were refined by a retest reliability until general agreement.
The social and psychological impacts were evaluated by 14 questions exploring the different effects of the containment on negative feelings, interest in the family, changes in daily activities and plans, quality of sleep, practice of physical activity before and during containment, as well as the impact of the Coronavirus on psychological health. Statistical Analysis System IBM SPSS Statistics V20.0.0 was used to analyze the survey data.
Results: 350 patients had participated in this online survey (mean age of 46,1 ± 14,4, 68% were women, 15.7% were illiterate, 45.7% were unemployed, rural residence in 11.7% of cases).
Patients reported that their mental health has been negatively affected by Coronavirus in 59.1% of cases. Table 1 summarizes the psychological events during the containment.

Table 1. Negative feelings during the containment

Negative feelings (%)	N = 350
Hopelessness	**23.7**
Anxiety	**55.4**
Fear	**29.7**
Frustration	**22.9**
Loneliness	**17.4**
Anger	**22.6**
Powerlessness	**24.3**

Patients reported that they paid more attention to their family in 87.1% during containment. Their daily lives and their life plans had changed because of

Coronavirus(in 89.7% and 81.4%). Sleep during the pandemic has been negatively affected in 72.6% of patients. Physical activity practice had significantly decreased during containment (26.6% vs 51.7%)
Conclusion: This study illustrates the social and psychological impact of COVID-19 pandemic on patients with CIRD. In the light of those results, we have lunched an awareness campaign to reinforce psychologic and social support of patients with CIRD during this global health crisis.

AB0902-HPR **COVID-19 PANDEMIC: KNOWLEDGE, BELIEVES AND FEARS IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES IN A DEVELOPING COUNTRY**

T. El Joumani[1], H. Rkain[1,2], T. Fatima Zahrae[1], H. Kenza[3], A. Radouan[4], N. Laila[5], S. Bahloul[1], E. A. Nada[1], T. Latifa[1], N. Hajjaj-Hassouni[6], F. Allali[1]. *[1]El Ayachi Hospital, Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco, Department of Rheumatology B, Rabat, Morocco*; *[2]Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco, Laboratory of Physiology, Rabat, Morocco*; *[3] Université Mohammed VI des Sciences de la Santé - UM6SS, Casablanca, Morocco., Ecole Internationale de Santé Publique, Rabat, Morocco*; *[4]Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rabat, Morocco, Laboratory of Biostatistics, Rabat, Morocco*; *[5]Moroccan Association of Patients With Rheumatoid Arthritis and Spondyloarthritis, Rheumatology, Rabat, Morocco*; *[6]International University of Rabat, Rabat, Morocco, Rheumatology, Rabat, Morocco*

Objectives: To investigate the knowledge, believes, and fears of patients with Chronic Inflammatory Rheumatic Diseases (CIRD) in Morocco regarding the Covid-19 pandemic.
Methods: COVID-19 related knowledge was evaluated through following items: clinical presentations, age of infection, transmission routes, self-reported preventive behaviors, patient's approach in case of suspicion of being infected by COVID-19 and vaccination. We also investigated the source of the patients' information.
Believes and fears of patients regarding COVID-19 was assessed using 2 items that explored participant's perception of the degree of threat to public health and their individual infection susceptibility compared to the general population.
Results: A cross-sectional study was conducted among patients with rheumatic diseases using a questionnaire providing information on patients and disease characteristics.
350 patients had participated in this online survey (mean age of 46,1 ± 14,4, 68% were women, 15.7% were illiterate, 45.7% were unemployed, rural residence in 11.7% of cases). The correct answer rates of the 6 questions of the knowledge section of the questionnaire were 53.4-100% with an average mean of 90.7%. The mean COVID-19 knowledge score was 5,43/6 (SD:0,48). Most participants (96.6%) correctly identified the age group concerned about Covid-19 infection. Remarkably 92.3% of the participants recognized 3 clinical features when 97.7% and 72.3% of the sample recognized perfectly modes of transmission and disease prevention measures. 87.4% of patients knew the recommended course of action to do if they have fever or cough and have recently been in contact with an infected patient. 64% of the study population thought that there was no vaccine available yet.
The sources of information on COVID-19 were in descending order: rheumatologist (56.6 %), personal research (on the internet or other) (43.4%), video broadcasts on national television channels (28%), other Awareness Video (24.2%).
Regarding the patients believes and fears toward COVID-19, 81.7% of patients believed that the pandemic is a serious threat for the public health and 80.6% thought that their CIRD makes them more exposed to the risk of contamination than general population.
Conclusion: The results of this survey show a high prevalence of patient concern about COVID-19. However, the majority of patients responded correctly on the mode of transmission and the means of protection for the COVID-19 infection. Those results could be explained by enormous awareness-raising efforts carried out by our differents departments of our government.

HPR Service developments, innovation and economics in healthcare

AB0903-HPR **DURATION OF TELEPHONE CONSULTATIONS AMONGST RHEUMATOLOGY PRACTITIONERS IN A DISTRICT GENERAL HOSPITAL - ADAPTING TO REMOTE CONSULTATION IN A COVID-19 PANDEMIC**

L. Parker[1], F. Coldstream[1]. *[1]University Hospitals Dorset NHS Foundation Trust, Rheumatology Department, Christchurch, United Kingdom*

Background: The Covid-19 pandemic has resulted in a rapid adoption of remote consultations in order to limit face to face clinical contact wherever appropriate, as recommended by the British Society for Rheumatology. The same clinic templates which existed for face-to-face encounters have been retrospectively adapted, without consideration of any potential difference in duration of consultations. Rheumatology practitioners from a variety of clinical backgrounds work alongside the rheumatology consultants, providing clinical care to patients with both inflammatory arthritis and connective tissue disease.
Objectives: To record the duration of all scheduled telephone consultations carried out by advances rheumatology practitioners in a 4-week period.
Methods: All scheduled telephone clinic encounters over a 4-week period were timed and the duration recorded in a spreadsheet. Data was collected in real time by all 8 rheumatology advanced practitioners working within the rheumatology department of a district general hospital, following each clinic episode.
Results: Data was recorded from a total of 337 clinic appointments. Of these, 317 (94%) were booked as routine, 3 (0.9%) as urgent, 4 (1.2%) were expedited following an advice line contact, and 13 (3.9%) no data was recorded. 28 (8%) of the patients did not answer when contacted. 80 (24%) clinic appointments lasted 15 minutes or less, 186 (55%) lasted 16 - 30 minutes, 37 (11%) lasted 31 - 45 minutes, and 6 (2%) lasted 46 - 60 minutes. The average duration was 22 minutes.
Conclusion: Within this department, remote consultations appear to have a similar duration when compared against the traditional clinic template for a fully face-to-face clinic, with some encounters lasting significantly longer than the planned duration. This would appear to differ to telephone consultations used in other settings, such as general practice where the duration is reportedly shorter[1]. This may be representative of the additional complexity and co-morbidity of a typical rheumatology patient, or due to the multi-faceted nature of a rheumatology follow-up appointment[2]. Although remote consultations are effective in limiting risk of exposure to Covid-19, they may not offer a quicker or more efficient service compared with the face-to-face model. Further study in this field is required to evaluate this widely adopted new pattern of working.

AB0904-HPR **RHEUMATOLOGY NURSING AND COVID19: FIRST WAVE EXPERIENCES**

L. Cano Garcia[1], S. Garcia Diaz[2], S. P. Fernandez-Sanchez[3], C. Domínguez-Quesada[4], M. D. C. Ordoñez Cañizares[1], J. M. Martín Martín[5]on behalf of GTESER. *[1]Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain*; *[2]Hospital Moises Broggi, Rheumatology, Barcelona, Spain*; *[3]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; *[4]Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain*; *[5]Hospital Universitario Virgen de la Candelaria, Rheumatology,Tenerife, Spain*

Objectives: To know the impact of the first wave of COVID19 (March to June 2020) in the nursing activity in rheumatology and explore improvements in patient care during the pandemic situation.
Methods: 2 surveys were sent to nurses working in the rheumatology area (Both in the Outpatient department and day care unit) during October 2020 in Spain. The first survey had 10 questions about what happened in the rheumatology units in the first wave of the COVID19 pandemic (March to June of 2020) and the second survey had 10 questions about the standards of quality of nursing care in times of pandemic. Google forms were used to collect and analyze data.
Results: 32 nurses completed the survey (30 women (93.8%)) with an average age of 49.6 ± 10.2 years. 93.8% work in the outpatient clinics and 2(6.2%) in day care units. The main results of the effects of the first wave of the pandemic are as follow: 4(12.5%) nurses were transferred to other areas of the hospital, 27(84.4%) showed changes in their care activity; and in 12(37,5%) of the surveyed centers, (slightly less than half of the medical staff) left their usual activity to care for covid-19 patients. In June 2020, at the end of the first wave, 17(53.1%) reported more decompensated patients and 22(68.8%) reported that they had both telephone and face-to-face consultations; 15(46.9%) reported that their clinical activity had increased.
Regarding the standards of quality during the pandemia: 27(84.4%) believed that rheumatology units should be strengthened,31(96.9%) reported the need to carry out COVID educational campaigns in rheumatic patients and 30(100%) stated that nursing education should lead that education; 31(96.7%) believed

that telephone consultation should be on demand and by telephone, 25 (78.1%) considered it necessary to include video calls and the possibility of receiving reports in non-face to face care and photos. Finally, 23(71.9%) centers recorded nursing and medical telephone consultations in their medical records.
Conclusion: The pandemic had a huge impact on nursing care for rheumatic patients, with difficulties associated with extra work load and changes in the dynamics of care. A readjustment of assistance has been necessary and audio-visual aids were necessary to improve telephone (non face to face) service.

AB0905-HPR TELEMEDICINE IN RHEUMATOLOGY AT TIME OF COVID PANDEMIC

G. Cuomo[1], F. Masini[2], K. Gjeloshi[2], D. Lubrano[2], L. E. Adinolfi[2], C. Romano[2]. *[1]University of Campania Studies "Luigi Vanvitelli", Precision of Medicine, Napoli, Italy*; *[2]University of Campania Studies "Luigi Vanvitelli", Department of Medical and Surgical Sciences, Napoli, Italy*

Background: The outbreak of the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic has imposed considerable restrictions on people's mobility in order to limit infection transmission. Before the COVID -19 pandemic tele-rheumatology was proposed to patients living in remote areas. Currently, the use of telemedicine has increased significantly. We report on the implementation of a telemedicine program for the evaluation and treatment of patients with rheumatic diseases (1).
Objectives: The aim of the study is to evaluate telemedicine as a viable approach for routine follow-up and management of rheumatic disease.
Methods: Sixty-six patients were evaluated online by the remote rheumatologist in four weeks. The population of rheumatology patients was evaluated using a IARPLUS platform Information collected included demographic information consisting of age, gender, and primary rheumatologic diagnosis. Results: The average age of patients who were seen was 54 years and 85% of patients were women.
The most common disorders included rheumatoid arthritis (22, 33%), axial spondyloarthropathies (7, 11%), and psoriatic arthritis (15,23%), systemic sclerosis (13, 20%), lupus (6, 9%), UCTD (2,3%), Sjogren and fibromyalgia (1, 1.5%).
Results: All patients were given recommendations on COVID-19 vaccine administration. Therapy was remodeled in 13 patients (in particular in 5 patients with anemia intravenous iron infusion was scheduled; 1 started immunosuppressant therapy for proteinuria, 4 increased methotrexate for disease activity, 2 discontinued Methotrexate for adverse events (hypertransaminasemia), 1 suspended OH-chloroquine due to retinal accumulation; 2 biologic-naive patients, after a three-month of waiting due to inability to come to the hospital, started the biologic drug; 22 patients received a renewal of the therapeutic plan; 25 patients had a regular six-month follow up; 2 ticket exemption for illness; 13 consultations and/or laboratory tests (1 pneumological consultation, 1 ophthalmological consultation, 1 request for sacro-iliac MRI, 3 nailfold videocapillaroscopies, 3 FKT, 1 musculotendinous ultrasound, 1 antibodies for celiac disease, 2 antibodies anti Sars-CoV-2).
Conclusion: Telemedicine is becoming more prevalent. We report the successful use of this service in evaluation and management of rheumatic diseases in a period with limited access to rheumatologic care. We have shown that patients can be seen, evaluated, and successfully treated with a variety of medications, including biologic agents, and evaluated for both chronic inflammatory arthropaties and connective tissue diseases.

AB0906-HPR BENEFIT OF A NURSE-LED PROGRAM OF CARE FOR MANAGEMENT OF PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS: SYSTEMATIC LITERATURE REVIEW

P. Lois[1], L. Lopez Pedraza[1], G. Candelas[2], C. Lajas[2], M. Rodero[2], T. Mulero López[2], L. León[1], B. Fernandez[1], L. Rodriguez Rodriguez[1], L. Abasolo[1]on behalf of Departamento de Investigación de la Unidad de Gestión Clínica de Reumatología del Hospital Clínico San Carlos. *[1]Hospital Clínico San Carlos, Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IdISSC), Reumatología, Madrid, Spain*; *[2]Hospital Clínico San Carlos, Reumatología, Madrid, Spain*

Background: Nowadays, many countries experience an urgent demand for rheumatologists and greater cost-effectiveness. Thus, different alternatives to conventional outpatient physician-led follow-up have been investigated. The alternative of community-based service delivery systems is intended to meet emerging needs, reducing the costs of hospital care and morbidity. In patients with long-term conditions, such as Rheumatoid Arthritis (RA), nurses are seen as essential in the delivery of promotion in self-care and decision-making, favoring the empowerment of patients.
Objectives: To systematically investigate if the nurse led-care management (NLCM) education programs are beneficial in patients with RA.
Methods: This is a systematic literature research publication on the following bibliographic databases: Medline, Embase and the Cochrane Central register of Controlled Trials from the beginning until 2019.
Results: From a yield of 116 studies, 44 were included in the review. After quality assessment and exclusion of the lowest-ranked studies, 19 studies were analyzed. Outcomes were organized into six themes (1) disease activity; (2) adherence; (3)satisfaction; (4)treatment compliance, (5) depression and (6)quality of life. All studies had significant results in at least one of the outcomes.
Conclusion: According to our results, we can conclude that, clinicians could benefit from support conducted by nurse in the management of these patients in tasks such as metrology clinic, participation in enforcement, self-administration, the correct dosage and side effects of treatments, and link the patient and other professionals or entities. It would therefore be advisable to conduct further studies to draw more accurate and reliable conclusions in this context.

AB0907-HPR UNEXPECTED DIFFERENCE IN ACCEPTANCE OF TELECONSULTATION BETWEEN PATIENTS WITH LUPUS AND RHEUMATOID ARTHRITIS WHO UNDERWENT TO A DEVELOPED AND IMPLEMENTED TELEMEDICINE INNOVATIVE PROGRAM AFTER THE DECLARATION OF QUARANTINE DUE TO THE COVID-19 PANDEMIC IN COLOMBIA

S. M. Hernández-Zambrano[1], R. A. Castiblanco-Montañez[1], J. Chavez-Chavez[2], D. P. Rivera-Triana[2], A. Aza[3], L. Villarreal[3], M. Martinez[4], A. Rojas-Villarraga[2], P. Santos-Moreno[5]. *[1]Fundacion Universitaria de Ciencias de la Salud - FUCS, Nurse Department, Bogota, Colombia*; *[2]Fundacion Universitaria de Ciencias de la Salud - FUCS, Research Division, Bogota, Colombia*; *[3]Biomab - Center for Rheumatoid Arthritis, Bogota, Colombia, Administration, Bogota, Colombia*; *[4]Biomab - Center for Rheumatoid Arthritis, Bogota, Colombia, General Medicine, Bogota, Colombia*; *[5]Biomab - Center for Rheumatoid Arthritis, Bogota, Colombia, Rheumatology, Bogota, Colombia*

Background: The Covid-19 pandemic has generated restrictions in the mobility of people, affecting the face-to-face care of patients with chronic diseases, including autoimmune. The health emergency has created the need to establish follow-up alternatives, giving rise to telemedicine.
Objectives: To evaluate the level of attendance to teleconsultation and the face-to-face usual care in patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) who underwent to a developed innovative telemedicine program after the declaration of quarantine due to the Covid-19 pandemic.
Methods: The present cross-sectional descriptive study reports retrospective data collected from patients with RA and SLE from March to June, 2020;. Since the beginning of March 2020 when Covid-19 was declared in Colombia as a health emergency establishing specific standards for outpatient care, our center has made the necessary legal and technical adjustments **to develop an innovative telemedicine service** to prevent the epidemiological risk. To all contacted patients were offered the option of teleconsultation or face-to-face consultation; a standardized protocol was set with clinimetry measures evaluated in both groups. Continuous variables were described using mean and standard deviation, and categorical variables were described using numbers and percentages. We performed chi-square tests of independence to determine differences between teleconsulting and conventional face-to-face consultation.
Results: A total of 5745 RA patients were followed-up, 5292 (92.1%) by teleconsulting and 453 (7.9%) by conventional face-to-face consultation; among the group of SLE patients, a total of 646 were assessed, of which there were 386 (60%) by teleconsultation and 260 (40%) by face-to-face consultation; this highlights an important difference in the level of acceptance of the teleconsultation

between patients with RA and SLE, being much lower in patients with SLE (*p value*< 0.0001). Regarding gender differences, in men, there were 33 (12.7%) SLE and 89 (19.6%) RA face-to-face consultations, while in women there were 227 (87.3%) SLE and 364 (80.4%) RA in a face-to-face consultation. Regarding patients who were attended through telemedicine, 45 (11.7%) SLE and 966 (18.3%) RA were men, while 341 (88.3%) SLE and 4326 (81.7%) RA were women; that means, in the RA cohort, a greater number of men prefer the face-to-face consultation than in the SLE cohort (*p value*< 0.0185). 10 RA patients were diagnosed with the Covid-19 in teleconsultation; in all cases, close contact with infected relatives was verified as the probable cause.

Table 1. Differences by gender in the level of teleconsultation acceptance and face-to-face assistance in patients with SLE and RA

RA Patients					
Gender		Teleconsulting (%[a])		Face-to-face consultation (%[a])	
Male	**1055**	**966**	**91,57%**	**89**	**8,43%**
Female	**4690**	**4326**	**92,23%**	**364**	**7,77%**
SLE Patients					
Gender		**Teleconsulting (%[a])**		**Face-to-face consultation (%[a])**	
Male	**78**	**45**	**57,69%**	**33**	**42,31%**
Female	**568**	**341**	**60,03%**	**227**	**39,97%**

[a] Total percentage of patients by gender. RA: Rheumatoid arthritis; SLE: Systemic lupus erythematosus.

Conclusion: Telemedicine may provide a viable option for the follow-up of patients with rheumatological diseases even beyond the pandemic. But unexpectedly, data showed an important difference in the acceptance of teleconsultation between patients with RA and SLE, being much higher in older and/or male patients with RA compared to patients with SLE; however, further studies are needed to support this conclusion.

AB0908-HPR SIGNED, SEALED, DELIVERED: PHARMACISTS ACHIEVING BETTER CARE CLOSER TO HOME IN RHEUMATOLOGY HIGH COST DRUG MANAGEMENT DURING THE COVID-19 PANDEMIC

S. Gohil[1]. [1]*University Hospitals of Coventry and Warwickshire NHS Trust, Pharmacy, Coventry, United Kingdom*

Background: The Pharmacy High Cost Drug (HCD) and Homecare (HC) team, based at a large acute teaching hospital consists of a range of skilled pharmacists, technicians and administrative staff. The team act as a HCD liaison between the hospital and commissioners, working closely with an expanding variety of specialist clinical teams to manage prescription processing for the following patient groups; HC: 2238; Hospital FP10: 1060; Outsourced Subsidiary Pharmacy Model: 41. HCD management, particularly immunosuppressive biologic therapies for complex rheumatology conditions such as rheumatoid arthritis, has been challenging during the Covid-19 pandemic. The inelasticity in demand for better care closer to home and a functional Integrated Care Records system has intensified, as many patients are now shielding/self-isolating at home.[1] Frugal innovations have been key during this time – achieving value and simplicity in service re-design to deliver better patient care.

Objectives: This review explores the support provided by the Pharmacy HCD and HC team to the rheumatology service since March 2020 to aid in service improvements during the pandemic.

Methods: The Pharmacy HCD and HC team reviewed existing practice to better respond to the service changes required during the pandemic in regard to the following areas; identifying patients for Covid-19 shielding; responding to changes in HC service provision; communication with commissioners; remote staff working; reviewing HCD formulations and administration routes; changes in commissioning arrangements.

Results: i) Rapid development of patient datasets following identification of 1,623 immunosuppressive drug entries in line with BSR Covid-19 guidance (first published in March 2020), thus enabling social distancing/shielding guidance to be issued to patients via letters/virtual platforms.[2] ii) Swift re-routing of urgent new biologic HC registrants to a new hospital pharmacy home delivery provision when certain HC providers temporarily imposed restrictions on intake of new registrants. This hospital initiative was further enhanced to a hub and spoke model enabling patients to have easy access to their medications from their nominated local community pharmacy branch. iii) Providing assurance to commissioners that clinical follow up reviews could continue virtually, blood samples could be taken at an external hub and blueteq documentation would be completed covering NICE technology appraisal (TA) criteria. iv) A successful pilot utilising the lean PDSA (Plan, Do, Study, Act) quality improvement methodology, to enable remote working pharmacists and technicians to process HC prescriptions remotely in the absence of an electronic prescribing and medicines administration system. v) Reviewing potential plans to switch certain hospital day-case intravenous biosimilar infusions such as infliximab to subcutaneous administration via HC. vi) Business contingency development plans to protect fragile medication supply chains. vii) Clarifying implications for changes in contracting and payment arrangements announced by NHS England and NHS Improvement due to the pandemic.[3]

Conclusion: In summary, the role of the HCD Pharmacists during the pandemic in supporting rheumatology patients and the multidisciplinary team has been fundamental; ensuring signed prescriptions are securely processed to safely deliver medication to those in need.

AB0909-HPR COVID 19 CRISIS: RAPID DEVELOPMENT OF REMOTE RHEUMATOLOGY MEDICATION CLINICS

R. Penford[1], E. Wren[1], K. Mackay[1]. [1]*Torbay Hospital, Rheumatology, Torquay, United Kingdom*

Background: We used to initiate DMARD(s) and Biologic therapies via nurse-led shared medical appointments (Group clinics) and could see up to 30 patients per week, with a maximum of 6 patients per group. We did this to start patients on their medications efficiently and safely and to manage the increase in workload.

However, with the onset of the COVID 19 pandemic, we had to stop these clinics immediately, but, we did not have capacity to start everyone on their medications in a timely manner by telephone. Telephoning each individual took > 9 hours per week, whereas previously it took 3-4 haours.

Objectives: We wanted to start patients on their all rheumatology medications safely and efficiently (within 10 days).

Methods: By April 2202, we had organised the filming of 10 short healthcare videos to give patients all the information they required to start a range of DMARDs and biologics.

We developed a new protocol (fig 1); patients are asked to view the relevant video, contact our department to confirm they understand the safety monitoring, risks, potential side effects, dose increases etc. As soon as they confirm by email they are happy to start treatment, a prescription is generated and emailed to the hospital outpatient pharmacy, where it is dispensed and delivered to the patient's home. We send a follow up reminder letter about blood test monitoring etc (copy to GP) and a 'shared care agreement' to GP. They are given the option to have a telephone clinic appointment with a specialist nurse if required.

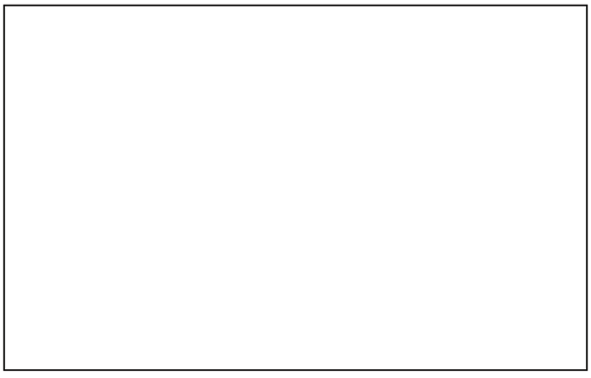

Figure 1.

Results: Of those requiring DMARDs, 62% reviewed the video, completed the checklist and confirmed by email they were happy to start treatment, within 24-hours. 88% had completed within 7 days.

Over half the patients (56%) were starting DMARDs for the first time, of those 8% requested a telephone consultation to discuss treatment further with the Rheumatology nurses. Of the 44% of patients already taking a DMARD and due to start a second medication 24% required a telephone clinic appointment.
As this is a new service, we asked for feedback, receiving replies from 34%, all scoring between 9/10 and 10/10.
We have released > 7 hours of specialist nurse time for telephone/helpline clinics.
Conclusion: The development of digital / remote medication clinics has been a success and we will continue with this approach. We have limited face-to-face appointments, started patients on rheumatology medications more quickly and efficiently than previously (but maintained safety), allowed the nursing staff time to spend more time working in our telephone clinics and have had excellent patient feedback. Although, we are aware, this is at a cost of no peer-to-peer interaction, which has been of value in the past.

HPR Professional education, training and competencies

AB0910-HPR LEVELS OF DEPRESSION AND ANXIETY DURING COVID-19 PANDEMIC: AT WHAT DEGREE ARE HEALTH CARE WORKERS AFFECTED IN TUNISIA?

K. Ben Abdelghani[1], O. Hamdi[1], S. Miladi[1], M. Sellami[1], K. Ouenniche[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], A. Fazaa[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia*

Background: Since December 2019, a novel pneumonia caused by coronavirus-19 (COVID-19) has been spreading internationally. Facing this critical pandemic, health care workers who are involved in treating these patients are at risk of developing psychological distress.
Objectives: To evaluate mental health outcomes among health care workers treating patients exposed to COVID-19.
Methods: This cross-sectional study collected demographic data and mental health measurements from health workers in different hospitals using an online questionnaire. Participants were divided in two groups: G1 included participants working in a COVID-19 unit and G2 included those who worked in a normal ward. Participants were asked to complete the 9-item Patient Health Questionnaire (PHQ-9) and the 7-item Generalized Anxiety Disorder scale (GAD-7). The total scores of these measurement tools were interpreted as follows: PHQ-9 normal (0-4), mild (5-9), moderate (10-14) and severe (15-21) depression; GAD-7 normal (0-4), mild (5-9), moderate (10-14) and severe (15-21) anxiety. We compared the two groups in terms of psychological distress using a Chi-square test.
Results: A total of 155 individuals with a mean age of 31.3 ± 25 years [26-45] and a sex-ratio of 0.3 completed the online questionnaire. Seventy-two participants (46%) worked in a COVID-unit. The mean number of nightshifts per month in the COVID-unit was 9.5 in G1 and 1.3 in G2 respectively. The mean number of work hours per day in the COVID unit was 5 hours in G1, and 0 in G2. G2 participants worked in COVID-units during nightshifts only. An increase in workload compared to the pre-epidemic was noted only in G1. Depression and anxiety scores were higher among participants of G1 compared to G2 (Table 1).

Table 1. Comparison of the participants according to the PHQ-9 and GAD-7 scores:

Score	G1	G2	p
Mild depression	33%	12%	0.001
Moderate depression	14%	9%	0.000
Severe depression	7%	0.9%	0.002
Mild anxiety	29%	17%	0.005
Moderate anxiety	18%	7.3%	0.002
Severe anxiety	8.4%	2.1%	0.001

G: Group

The need for psychological support was more frequent in G1 compared to G2 (38% vs 9%; p=0.005). Participants of G1 were diagnosed with depression (9 cases), anxiety (9 cases) and burn-out (3 cases). In G2, 4 participants were diagnosed with anxiety. The prescribed treatments were: antidepressants (5 cases), anxiolytic (10 cases), and psychotherapy (12 cases).
Conclusion: Individuals experience varying levels of distress during pandemics. In our study, health care workers in the frontline of COVID-units experienced high levels of anxiety and depression. Thus, necessary measures should be attached to psychological support strategies for health care workers.

AB0911-HPR ROLE OF MOBILE APPLICATIONS IN RHEUMATOLOGY CARE: A MULTICENTRIC SURVEY

R. Bixio[1], A. Biglia[2], G. Virelli[1], A. Giollo[1], C. Montecucco[2], M. Rossini[1]. [1]*Università degli studi di Verona, Rheumatology, Verona, Italy*; [2]*Università degli studi di Pavia, Rheumatology, Pavia, Italy*

Background: Although mobile health applications (apps) are becoming increasingly popular across several medical specialties, no data are available in rheumatology. The aim of this study is to investigate whether apps are routinely used by rheumatologists.
Objectives: In our study we aim assess real-life use of mobile applications in rheumatology clinical activity and to evaluate mobile apps role in rheumatology training, in particular for residents, and clinical activity.
Methods: We invited a non-selected sample of rheumatologists (consultants, residents and medical students committed to begin rheumatology residency) to participate in an anonymous web-based survey. This survey investigated mobile application use in rheumatology care and issues and concerns about mobile device use in rheumatology.
Results: Sixty participants completed the survey (40% consultants, 48.3% residents, 11.7% students). 52/60 (86.7%) declared to use mobile apps during their work. More than 50% used apps at least once a day. Apps were mostly used for calculating clinical disease activity scores for chronic inflammatory arthritides. Most rheumatology residents stated that these apps could be a useful tool in medical training. However, using a smartphone during a clinical examination was deemed to be inappropriate by 26/60 (43.3%).
Conclusion: Mobile apps as clinical tools are widespread among rheumatologists.

HPR Interdisciplinary research

AB0912-HPR AMIGOS DE FIBRO (FIBRO FRIENDS): EDUCATIONAL PROGRAM TO PROMOTE THE HEALTH OF PEOPLE WITH FIBROMYALGIA IN BRAZIL

M. Antunes[1], A. Schmitt[1], A. Pasqual Marques[1]. [1]*University of Sao Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy, São Paulo - SP, Brazil*

Background: Health education is pointed out as the front line in non-pharmacological approaches in fibromyalgia.
Objectives: To develop an interdisciplinary educational program to promote the health of individuals with fibromyalgia in Brazil.
Methods: This is a qualitative study, through a focus group, carried out in a Basic Health Unit in the city of São Paulo, SP. The guiding questions were about the needs and demands exposed by patients with fibromyalgia and health professionals who work in primary health care. 12 individuals with fibromyalgia and 10 health professionals participated. The data were analyzed using the content analysis method proposed by Bardin, specifically the thematic content analysis.
Results: Amigos de Fibro (Fibro Friends) should be conducted through lectures, dynamics and conversation circles. The educational program must include 15 meetings with weekly frequency. The meetings are: 1st to present the program and socialization activities. 2nd: Doctor presents the concepts of fibromyalgia. 3rd: Nurse informs about practices and environments that favor self-care. 4th: Social Worker shows the importance of support. 5th: Physiotherapist shows the main body practices and physical activity. 6th: Nutritionist presents an adequate and healthy diet. 7: Psychologist shows mental health practices. 8th: Pharmacist informs about medicines. 9, 11 and 13: participants perform activities at home. 10: Naturologist presents integrative and complementary practices. 12th: Occupational Therapist encourages methods to save energy. Day 14: Speech therapist helps in the quality of sleep. 15: closing activity.
Conclusion: Amigos de Fibro is a program that presents interdisciplinary educational information for individuals with fibromyalgia, being considered a trend of care for the future. The next step is to conduct a clinical trial to verify the effect of this intervention and then implement it in the health service in Brazil. Fibro Friends was created from the conjunct action of patients and healthcare professionals, it can be an effective educational tool to be implemented at primary health attention centers, promoting the self-care, life quality and the promotion of health in individuals with Fibromyalgia. Fibro Friends is an excellent tool for patient education and counseling in Brazil.

Patient information and education

AB0913-PARE METHOTREXATE FOR RHEUMATOID ARTHRITIS: PATIENT PERSPECTIVES ON MONITORING IN PRIMARY CARE

R. de Barros Lopes[1], D. Murphy[1], F. Mclennan Battleday[2]. [1]*Royal Devon and Exeter NHS Foundation Trust, Rheumatology, Exeter, United Kingdom*; [2]*Royal Devon and Exeter NHS Foundation Trust, Medicine, Exeter, United Kingdom*

Background: Monotherapy with methotrexate (MTX) is one first-line option for newly diagnosed Rheumatoid Arthritis (RA)[1]. Although treatment is usually commenced by a specialist, repeat prescribing and monitoring responsibilities often lie with primary care. While inadequate monitoring is a safety concern, unnecessary duplication of monitoring invariably has cost implications for General Practice (GP).
Objectives: To ensure that patients in one South-West GP practice who are taking oral MTX for RA are appropriately monitored in line with current guidance from the British Society of Rheumatology (BSR). Current guidance recommends that once a stable MTX dose is maintained for six weeks, followed by monthly bloods for the next three months, that at least twelve weekly blood monitoring is sufficient from then on[1].
Methods: A randomised sample of 50 patients registered in one South-West GP practice that were taking a stable dose oral MTX for RA; for at least 6 months; was collected. The length of time between the patient's two most recent blood tests was recorded. A random selection of ten patients with more frequent monitoring than BSR guidance suggest were asked a series of questions to determine patient perspectives on reasons for monitoring frequency.
Results: 58% of patients had more frequent monitoring bloods than current BSR guidelines recommend. Within this group, the mode frequency of monitoring was four weeks, in line with the previous National guidance which was superseded in 2017[2].The most common themes in patient's perspectives on monitoring frequency were:
a.Previous abnormal blood results requiring close monitoring
b.Multiple disease modifying anti-rheumatoid drug (DMARD) regimes that included MTX
c.Patient preference
d.Unclear or unknown reason
The purported increased monitoring for multiple DMARD regimes were not in line with current national guidelines[1].
Conclusion: This audit demonstrates that over half of patients taking MTX for RA in one GP practice are having more frequent blood monitoring than BSR guidance suggests is necessary. Furthermore, it demonstrates that patient's understanding of their perceived need for increased monitoring is largely inaccurate or unclear to them. There is a clear deficit in patient education surrounding monitoring frequency which must be addressed in order to empower patients, as well as reducing unnecessary duplication of blood tests. As a result of this audit, patient education on MTX monitoring frequency was formally introduced as part of the RA annual patient review. An information sheet with these monitoring requirements was produced to aid practitioners in the education process.

AB0914-PARE INFORMATION PREFERENCES ABOUT TREATMENT OPTIONS IN DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS: A DELPHI CONSENSUS STUDY

J. Spierings[1,2], H. Nienhuis[3], E. Van Lieshout[1], J. M. Van Laar[1], A. Pieterse[4]. [1]*University Medical Centre Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands*; [2]*Royal Free Hospital and University College London, Centre for Rheumatology and Connective Tissue Diseases and University College Medical School, London, United Kingdom*; [3]*University Medical Centre Utrecht, Department of Internal Medicine, Utrecht, Netherlands*; [4]*Leiden University Medical Centre, Department of Biomedical Data Sciences, Leiden, Netherlands*

Background: Diffuse cutaneous systemic sclerosis (dcSSc) has a high impact on quality of life and is associated with increased mortality. Several treatment options are available in dcSSc, including immunosuppressives, chemotherapy and hematopoietic stem cell transplantation. Shared decision making is key in choosing the appropriate treatment strategy. In earlier studies however, patients reported that the lack of accessible and reliable patient information about treatment options complicates decision making. In order to provide information that meets the needs of patients and addresses relevant benefits and harms, more insight in the preferences of patients is needed.
Objectives: The aim of this study was to identify and prioritize aspects that should be addressed when informing patients with dcSSc about treatment options, from a patient's perspective.
Methods: A three-round Delphi study was conducted with a panel of patients with dcSSc. The first questionnaire was based on a systematic literature search regarding benefits and harms of the four main treatments in dcSSc: methotrexate,

mycophenolate mofetil, cyclophosphamide, and stem cell transplantation. In the first round, patients were asked to indicate which information on the benefits and harms is essential for making a treatment decision; they could also add new items. In the second and third rounds, patients were asked to prioritize the items. After the third round, a live, online panel discussion was held in order to reach consensus. Consensus was defined as ≥75% agreement among panel members.

Results: Of the 36 patients invited, 67% (n=24) completed the first, 69% (n=25) the second and 75% (n=27) the third round. In the third round, median age of participants was 51 years (IQR 18), median disease duration was 4 years (IQR 5), 52% was female. Most patients had completed either an intermediate education level (59%) or high level of education (30%). Patients were or had been treated with mycophenolate mofetil (67%), methotrexate (44%), cyclophosphamide (41%), autologous stem cell transplantation (26%), rituximab (4%). Seven percent of patients were treatment-naïve. After the third round, eight patients joined the online panel discussion to reach final consensus. The panel reached consensus on seven benefits (prolonged progression-free survival, improved quality of life, improved daily functioning, improved pulmonary function, improved skin thickness, improved mobility and reduced fatigue) and four adverse events (treatment-related mortality, viral infections, cardiac damage, increased risk of cancer) as key themes for the decision making process (Table 1).

Conclusion: This study identified essential aspects of the four main treatment options for dcSSc. Our results can be used to develop effective patient information.

Table 1. Agreement on benefits and harms that should be addressed

Benefits	Agreement	Harms	Agreement
Improved pulmonary function	100%	Viral infections	88%
Improved skin thickness	100%	Cardiac damage	88%
Improved mobility	100%	Increased risk of cancer	88%
Prolonged progression-free survival	95%*	Treatment-related mortality	79%*
Improved quality of life	77%*	Flare or relapse of disease	63%
Improved daily functioning	77%*	Temporary increase in fatigue	25%
Reduced fatigue	75%	Temporary negative impact on social activities	25%
Improved hand function	25%	Nausea	25%
Improved mood	25%	Other autoimmune disease	13%
Improved cardiac function	13%	Hormonal imbalance	13%
Improved oesophageal function	7%	Concentration difficulty	13%
		Diarrhea	13%
		Erectile dysfunction	13%
		Depression	13%
		Infertility	13%
		Hair loss	13%

*Items on which consensus was reached in round 3

AB0915-PARE DEVELOPMENT AND USABILITY OF A WEB-BASED PATIENT-TAILORED TOOL TO SUPPORT ADHERENCE TO URATE-LOWERING THERAPY IN GOUT PATIENTS

R. te Kampe[1,2,3], A. Boonen[1,3], T. Jansen[2], J. M. Elling[3,4], M. Flendrie[5], Y. Van Eijk-Hustings[1], M. Janssen[2], C. Van Durme[1], H. De Vries[3,4]. *[1]Maastricht University Medical Center, Internal Medicine, Maastricht, Netherlands*; *[2]VieCuri Medical Center, Rheumatology, Venlo, Netherlands*; *[3]Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands*; *[4]Maastricht University, Health Promotion, Maastricht, Netherlands*; *[5]Radboud University Nijmegen Medical Centre, Rheumatology, Nijmegen, Netherlands*

Background: Adherence to prescribed urate-lowering therapy (ULT) among gout patients is considered to be among the poorest of all chronic conditions. eHealth programs can be a possible opportunity to foster ULT adherence.

Objectives: This study describes the development and usability evaluation of a web-based tool to support ULT adherence among gout patients, specifically designed for a complement to usual care.

Methods: The Integrated Change (I-Change) model was used as theoretical basis for the development. The model combines various socio-cognitive theories and differentiates between three phases: a pre-motivational, a motivational, and a post-motivational phase. In practices, the I-Change gout tool contains three sessions, following the three phases of the I-Change model. Patients receive tailored feedback based on their answers in the form of animated videos and text messages after each session, and are prompted to set specific goals and action plans for their ULT adherence. The content and development of the I-Change gout tool was determined along an iterative process within a steering group of clinicians and researchers, supported by patient interviews and gout specific literature related to key aspects of medication adherence behavior. A cross-sectional mixed methods design was used to test usability of the support tool consisting of a think aloud method and a usability questionnaire.

Results: The steering group decided on the content of the three sessions of the I-Change gout tool. Depending on the intention to change ULT adherence behavior patients were navigated through the I-Change gout tool, patients with a low intention go through all 3 sessions and patients with a high intention go through the pre- and post-motivational session (figure 1). In total, the I-Change gout tool contains three sessions with 80 questions, 66 tailored textual feedback messages, and 40 tailored animated videos.

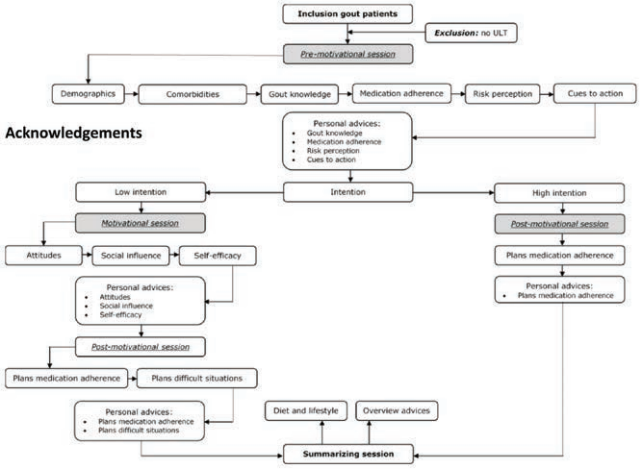

Figure 1. Flowchart of the computer-tailored I-Change gout tool for urate-lowering therapy adherence.

Twenty gout patients and seven healthcare professionals participated in the usability tests. The program end score rating for the gout tool was on average 8.4±0.9 (range 6-10) for patients and 7.7±1.0 (range 6-9) for healthcare professionals. Furthermore, participants reported a high intention to use and/or recommend the program in the future. Yet, participants identified some issues for further improvement of the systems user-friendliness by addressing barriers (e.g. more explicitly navigation) and weaknesses (e.g. technical and health literacy). The I-Change gout tool was updated according suggestions of improvements of the participants.

Conclusion: This study provides initial support for the usability by patients and healthcare professionals of a ULT adherence I-Change gout tool. Further studies need to be conducted to assess its efficacy and (cost-) effectiveness in daily practice.

AB0916-PARE KNOWLEDGE OF DISEASE, DIAGNOSIS, ADHERENCE AND IMPACT OF RESEARCH IN PATIENTS WITH INFLAMMATORY ARTHRITIS

M. Canavan[1,2], V. Marzaioli[1,2], A. Donnelly[3], S. Wade[1,2], A. Fraser[4], T. O'sullivan[3], S. Harney[5], A. Ireland[6], D. Veale[2], U. Fearon[1,2]. *[1]Trinity College Dublin, Molecular Rheumatology, Dublin, Ireland*; *[2]St Vincent's University Hospital, Centre for Arthritis and Rheumatic Diseases, Dublin, Ireland*; *[3]Patient Advocate, Patient Advocate, Dublin, Ireland*; *[4]University of Limerick, UCL, Department of Rheumatology, Limerick, Ireland*; *[5]Cork University Hospital, UCC, Department of Rheumatology, Cork, Ireland*; *[6]Clanwilliam Square, Grand Canal Dock, Dublin, Ireland*

Background: The diagnosis and treatment of inflammatory arthritis has been transformed largely by the development of drugs that target specific molecules of the immune system. However, these changes have increased the complexity of the mechanisms of disease, its treatment and patients understanding. Patient education is needed in this area to facilitate decision making and to facilitate strong patient-partnerships in research.

Objectives: The aim of this study was to examine the level of understanding of inflammatory arthritis patients and the need for strong patient-partnership in research.

Methods: An online anonymous survey addressed questions about diagnosis, routine tests, medications and how they work, medication adherence, disease flare, heredity, pregnancy, and patient involvement in research.

Results: There were 1,873 respondents, 1416 of which had inflammatory arthritis (IA)-RA (65.8%) and PsA (34.2%). They were predominantly female (RA 86%,

PsA 85 %), aged 55±13 and 50±12. Less than 35% of patients had an understanding of diagnostic tests, what was measured and the implication for disease, with 75.5% also concerned about heredity. There was a high level of understanding of how specific medications treat inflammatory arthritis (72.9%). Adherence was also very high (>87%), with the main reasons for stopping medication without the advice of their clinician, 'feeling better' and 'side effects' however a significant proportion of patients (69.9%) reported a disease-flare following cessation of medication. Patients of childbearing age (69%) were also concerned that inflammatory arthritis reduced their chances of getting pregnant, with only 8% believing arthritis medications were safe to take during pregnancy. Finally, only 9% of patients had ever been asked to participate in a research study.

Conclusion: This study demonstrates a need for the development of stronger patient-partnerships with clinicians and researchers in relation to patient education and engagement with research, to create a platform where patients can have meaningful input and involvement in future research studies.

Acknowledgements: We wish to thank all the patients who contributed to this study

AB0917-PARE KNOWLEDGE ON SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND ITS MANAGEMENT AMONG SLE PATIENTS ATTENDING RHEUMATOLOGY CLINIC AT NATIONAL HOSPITAL OF SRI LANKA

H. Perera[1], G. Kasthuriratna2. *[1]National Hospital of Sri Lanka, Rheumatology and Rehabilitation, Colombo, Sri Lanka*; *[1]National Hospital of Sri Lanka, Rheumatology and Rehabilitation, Colombo, Sri Lanka*

Background: Systemic Lupus Erythematosus (SLE) is a chronic relapsing and remitting multi-system involving autoimmune condition mainly affecting females of reproductive years. As any other chronic disease needing long term treatment and follow up, proper patient education and high level of patients' knowledge on their own diagnosis is mandatory for the optimum management. It is proven that poor patient awareness has led to poor compliance and catastrophic relapses. There were no Sri Lankan study to assess patients' knowledge on SLE and its management.

Objectives: To describe the demographic data, any exposure to patient education and to assess knowledge about their own diagnosis and its management among a group of already diagnosed patients with SLE attending rheumatology clinic in National Hospital of Sri Lanka.

Methods: A cross sectional descriptive study was carried out with convenience sampling and data were collected using interviewer administered questionnaire. All already diagnosed patients with Systemic Lupus Erythematosus attending the Rheumatology clinic during the data collection period were invited to participate in the study and total of 45 were enrolled with 100% response rate.

Results: Overall 45 participants were in the study and all were females. The mean age was 37 (±12.53) years and the average disease duration was 62 months. Considering the exposure to patient education 89.87% had at least one type of patient education and 10.1% had none. A significant proportion (84.4%) was aware about their own diagnosis and 82.2% was able to correctly mention their current medication. Overall knowledge about the disease and its management was moderate (68.7%) among this study population according to our scoring system. However, they had a poor knowledge (45%) relating to pregnancy and contraception.

Conclusion: The above study describes important demographic data, exposure to patient education and patients' knowledge about their own disease in population of Systemic Lupus Erythematosus patients attending National Hospital of Sri Lanka. Their overall knowledge regarding SLE, its management and complications were at a moderate level and awareness regarding pregnancy and contraception in a SLE patient was at a lower level. Therefore, clinicians should pay more attention in to patient education when managing conditions like SLE as it directly affect the patients' compliance and overall disease outcome.

AB0918-PARE FAMILY PLANNING AND RMDS: A SURVEY

U. Viora[1], P. Grossi[2], F. Padovani[3], G. Mussi[4], S. Severoni[5], S. Tonolo[6], A. Verducci[7]. *[1]ANMAR Italia, Piemonte, ROMA, Italy*; *[2]ANMAR Italia, Toscana, ROMA, Italy*; *[3]ANMAR Italia, Abruzzo, ROMA, Italy*; *[4]ANMAR Italia, Liguria, ROMA, Italy*; *[5]ANMAR Italia, Lazio, ROMA, Italy*; *[6]ANMAR Italia, Veneto, ROMA, Italy*; *[7]ANMAR Italia, Umbria, ROMA, Italy*

Background: It is well known and universally aknowledged that RMDs are not related to old age, as those who are affected by these illness between 30 and 45 years old are a big number, perhaps the biggest one. Therefore, family planning and pregnancy are topics even more actual and their management is certainly one of the biggest source of distress and troubles in people affected by RMDs and their spouses.

Objectives: to define and deeply understand the problem's dimension, ANMAR made a survey according to the CAPIRE Observatory.

Methods: an pposite questionnaire was given to patients waiting for a rheumatological consultation, during 6 months in 2020.

Results: Over 300 women with an RMD fulfilled the questionnaire:
7 on 10 women are trying to become pregnant
51% of them did not notice it to their Rheumatologist.
57% of them has been already pregnant.

Conclusion: In Italy, women with RMDs are over 3.5 millions and the a lot of them are women of childbearing potential.
As therapies actually used are really effective, but may induce side effects on the reproductive system, it is absolutely needed to inform the Rheumatologist about the intent to procreate and to have suggestions about the correct chice of contracception models.
Communication between patient and Rheumatologist must be improoved, even in this important topic.

AB0919-PARE WHAT DO OLD PEOPLE THINK OF THEIR RHEUMATOID ARTHRITIS TREATMENTS?

D. Khalifa[1], S. Belghali[1], M. Limam[2], N. Elamri[1], K. Baccouche[1], H. Zeglaoui[1], E. Bouajina[1]. *[1]Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*; *[2]Farhat Hached Hospital, Preventive Medicine, Sousse, Tunisia*

Background: Managing chronic diseases such as rheumatoid arthritis (RA) is a challenge on a daily basis for rheumatologists and convincing our patients to properly take their medication may be difficult especially with elderly. First step comes with our patients' education and suppressing misbeliefs and misconceptions.

Objectives: To study beliefs of elderly RA patients on DMARDs and see what they really think of their treatments.

Methods: A cross-sectional study was conducted in a rheumatology clinic over a period of 4 months. Patients over the age of 65 having RA and being treated with conventional DMARDs or biologics were questionned about their medication. The belief about medicines questionnaire (BMQ) was used to assess different beliefs. It is a validated questionnaire of 18 items. Patients responded freely to each item using a Likert scale. The clinician later collected the data and 4 scores were calculated (concern (c), necessity (n), overuse and harm), thus classifying patients on 4 different groups as follows: accepting if n≥ 15 and c<15, ambivalent n≥ 15 and c≥15, indifferent if n< 15 and c <15 and skeptical if n<15 and c≥ 15.

Results: Forty elderly patients joined the study. The median of age was 66 years. They were mostly women (82.5%) with other comorbidities in 55% of the cases. The mean of DAS 28 score was 4.65± 1.77 and the mean of the VAS pain score was 5 out of 10. Only 17.5% of the patients were on remission or low disease activity. Radiological destructions were detected in 87.2% of the patients and deformities in 60% of them. Rheumatoid factor and/or citrullinated peptide antibodies were detected in 81.6% of the cases.95% of the patients were on methotrexate (MTX), 12.5% on Sulfasalazin and 12.5% on biotherapies. Corticosteroids were prescribed in 85% of the patients. Responses to the BMQ specific and general questionnaire are showed in table.1. The mean score of concern was 15.33±3.8, the mean score of harm was 13.44±2.9, the median of the necessity score was 18 and the median of the overuse score was 13.5. Analysing patients' beliefs, the majority of them were ambivalent towards their DMARDs (44.4%), 33.4% were accepting, 11.1% were skeptical and 11.1% were indifferent.

Table 1. BMQ responses

BMQ specific	Do not agree at all %	Do not agree %	Incertain %	Agree %	Agree very much %
My health at present depends on my RA medicines	5.6	22.2%	27.8	44.4	0
Having to take RA medication worries me	5.6	44.4	0	38.9	11.1
My life would be impossible without my RA medication	5.6	16.7	22.2	33.3	22.2
Without my RA medication i would be very ill	11.1	22.2	16.7	38.9	11.1
I sometimes worry about the long-term effects of my RA medication	27.8	11.1	11.1	44.4	5.6
My Ra medication is a mystery to me	5.6	33.3	5.6	50	5.6
My health in the future will depend on my RA medication	5.6	16.7	27.8	50	0
My RA medication disrupts my life	5.6	38.9	5.6	44.4	5.6
I sometimes worry about becoming too dependent to my RA medication	0	38.9	11.1	44.4	5.6
My RA medication protects me from becoming worse	0	16.7	5.6	61.1	16.7
BMQ general					
Doctors use too many medicines	0	16.7	27.8	44.4	11.1
People who take medicines should stop their treatment for a while every now and then	11.1	44.4	22.2	22.2	0
Most medicines are addictive	0	5.6	22.2	61.1	11.1
Natural remedies are safer than medicines	11.1	11.1	27.8	22.2	27.8
Medicines do more harm than good	11.1	27.8	27.8	27.8	5.6
All medicines are poisons	5.6	22.2	27.8	22.2	22.2
Doctors place too much trust on medicines	5.6	16.7	33.3	27.8	16.7
If doctors had more time with patients they would prescribe fewer medicines	0	11.1	22.2	33.3	33.3

Conclusion: Elderly RA patients should me more reassured about the safety of DMARDs and the importance of taking them and try to establish a better patient-doctor relationship.

AB0920-PARE WHAT WE LEARNED DURING COVID-19 PANDEMIC

J. Grygielska[1]. [1]*Polish Rheuma Federation 'REF', National Board, Warsaw, Poland*

Background: When the first official cases of pneumonia of unknown etiology in the city of Wuhan were reported by Chinese authorities to the World Health Organization (WHO) on 31st of December, 2019 nobody couldn't imagine that only month later new disease reached Europe and so fast change lives around the world. The first case of COVID-19 in Poland has been detected on 4th March 2020 and 16 days later Polish government introduced an epidemic state connected with new law regulations and with lockdown.

Objectives: Fast shared new coronavirus was a challenge for all. People with rheumatic and musculoskeletal diseases (RMDs) in very short time lost their sense of security. They received different information about COVID-19. One of the main information was that people with RMDs have higher risk of COVID-19. Providing real information in era of fake-news and giving of possible solutions during pandemic has become the goal of activities of patients organizations.

Methods: Lack of appropriate knowledge about new coronavirus forced different activities among entities acting for the benefit of patients. Our rheumatic patients organizations suspended group exercises and face to face meeting counting that it was only for 1-2 months. In social media from early March 2020 we support action "stay at home" like a warranty of safety. We tried to stay in contact with member organizations and in regional organizations with their members. We participated in action "Patient units us" organized by Minister for Patients Rights – during duty hours we had a chance to inform calling us people about different solutions connected with pandemic. Using our social media we inform people with RMDs about statement of EULAR and Polish Society for Rheumatology. After short break we are continuing works in Council of Patients Organization to the Minister for Patients Rights. Having contacts with RMDs patients we learn from them about their problems met in everyday lives.

Results: COVID-19 pandemic interrupted typical activities of our associations. After summer holidays we could organize group exercises and real meetings only during 2 months to new wave of coronavirus. Many members resigned from participation fear of infection. For the same reason people resigned from medical consultation and examination. Following confirmed information we could share it among our followers using websites and social media. Majority of medical consultations was remotely when physician calls to patient on time of appointed visit.

Conclusion: COVID-19 pandemic accelerated progress of e-health and of using of new technologies. On the one hand it give a challenge for people who didn't use it before to start to do it but on the other hand digital exclusion has deepened among people who never use Internet and stay alone in pandemic times. Virtual activities of associations give a chance to keep a contact with members, increase their knowledge, dispel doubts. Some changes forced by coronavirus infection are good and will stay among us like e-prescription, e-referral, internet patients account, virtual workshops and lectures. We are concerned that teleconsultations can replace medical examination in out-patient center. It can be danger for people with inflammatory arthritis. So long break in face to face meetings in associations can be a reason of lost of members especially older. Fast learning of using of new technology in medicine and in activities of associations give an opportunity for future but nothing can replace personal contact.

AB0921-PARE PRACTICES AND BEHAVIORS DURING THE COVID-19 PANDEMIC IN PATIENTS WHO PARTIALLY ATTEND TO AN EDUCATIONAL PROGRAM ON RHEUMATOID ARTHRITIS. A CROSS-SECTIONAL SURVEY

F. Rodriguez[1], D. Buitrago-Garcia[2], G. Sánchez[3], P. Santos-Moreno[4]. [1]*Biomab - Center for Rheumatoid Arthritis, Bogota, Colombia, Educational Program for RA Patients UniversitAR, Bogota, Colombia*; [2]*Postgraduate Program in Clinical Epidemiology, Fundación Universitaria de Ciencias de la Salud-FUCS. Bogotá, Colombia., Epidemiology, Bogotá, Colombia*; [3]*Postgraduate Program in Clinical Epidemiology, Fundación Universitaria de Ciencias de la Salud-FUCS. Bogotá, Colombia., Epidemiology, Bogota, Colombia*; [4]*Biomab - Center for Rheumatoid Arthritis, Bogota, Colombia, Rheumatology, Bogota, Colombia*

Background: The new coronavirus disease has become a public health emergency that has not been seen for generations. Covid-19 disease leads to an extreme immune activation and cytokine response and constitutes a big risk and a challenge for patients with inflammatory conditions such as rheumatoid arthritis (RA). During the Covid-19 pandemic, rheumatologists and health-care professionals have faced many challenges to provide an adequate follow-up and treatment to RA patients; one of them, has been the establishment of lockdown for populations older than 60 years and the limitation of having face-to-face consultations, moving us to telemedicine activities. On the other hand, in our center an education program for patients with RA had been established in the second semester of 2019, which due to the epidemiological risk control measures, it was necessary to interrupt when we only had 5-6 months of a project that was planned for 2 years; it was mandatory to pause it and implement virtual education alternatives; this educational program for RA patients was also moved to virtual mode later.

Objectives: To describe possible changes in the practices and behaviors of patients with rheumatoid arthritis (RA) during the lockdown that started in March 2020 in Colombia due to the Covid-19 pandemic, who previously partially attended to an educational program on RA.

Methods: We included patients who attended previously a face-to-face educational program, that aims to teach and empower patients in all aspects related to RA. After the lockdown, the educational program had to stop abruptly while an online strategy was developed later; meanwhile the patients did not have any educational activity for 3-4 months. For this study, patients answered to a telephonic survey in July 2020; the survey included questions about their practices related to the Covid-19 pandemic, SARS-Cov-2 symptoms, adherence to rheumatoid arthritis treatment, virtual rheumatology consultations compliance and, the influence of news on their adherence.

Results: A total of 260 patients took part in the survey; mean age of the respondents was 60 years IQR (54-66), 93% were female. In July 2020 88% of patients had accessed a telemedicine-based and 12% a face-to-face rheumatology consultation; only 3.5% of patients reported having been less adherent to pharmacological therapy due to information received through media or social networks. Regarding the prevention measures taken during the pandemic, 98% reported to have stayed in their houses since the lockdown was stablished in Colombia, and have implemented or increased hand washing from one or none to more than three times per day. Also 8% of respondents lived with people who were at bigger risk of having SARS-CoV-2 (i.e. health care professionals, workers at public transportation, and supermarkets among others), the main measurement taken was to be completely separate from the person at risk to avoid contagion and maintaining hygiene measures and physical distancing (Fig 1). Only one patient was positive for SARS-CoV-2, due to a possible contagion from a relative at home and reported only flu-like symptoms without any complications. Patients highlighted the necessity to return to the educational on RA program agreeing to attend to an online modality. Patients highlighted the need for educational sessions focused on the relationship between rheumatoid arthritis, its treatment, and Covid-19.

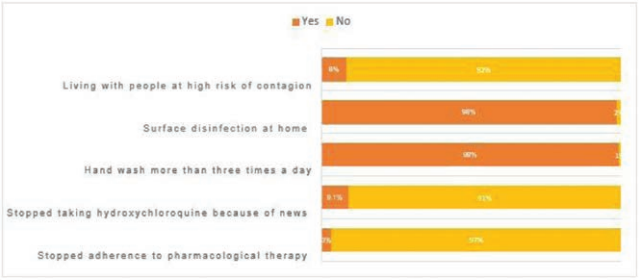

Figure 1. Behaviors, practices, and its changes due to Covid-19 pandemic

Conclusion: An educational on RA program shows to be helpful tool to maintain high adherence rates to the RA treatment despite of the new challenges associated to the pandemic and despite being incomplete due to lack of time; patient-centered education programs should continue to address the patient's concerns and beliefs about their disease and the Covid-19 issues.

DOI: 10.1136/annrheumdis-2021-eular.3434

AB0922-PARE OSTEOPOROSIS AWARENESS LEVEL AS A METHOD FOR IMPROVING PRIMARY PREVENTION

S. Lezhenina[1], A. Lammert2, N. Shuvalova[3], E. Guryanova[4]. *[1]I. N. Ulianova Chuvash State University, Departament of Healthcare Management and Economics, Cheboksary, Russian Federation*; *[1]I. N. Ulianova Chuvash State University, Departament of Healthcare Management and Economics, Cheboksary, Russian Federation*; *[3]I.Ya.Yakovlev Chuvash Pedagogical State University, Department, Cheboksary, Russian Federation*; *[4]I. N. Ulianova Chuvash State University, Department internal diseases, Cheboksary, Russian Federation*

Background: Having complete information about osteoporosis is a prerequisite for preventive behavior, which determines the conscious adherence to the principles of a healthy lifestyle.

Objectives: To assess the level of awareness of osteoporosis among women.

Methods: A survey was conducted of 750 female respondents aged 15 to 55 years in the Chuvash Republic. The survey was conducted from January to December 2019. The questionnaire consisted of 30 questions. One point was awarded for each correct answer. The minimum score for passing the test was 75% correct answers. The questions addressed both general knowledge about osteoporosis and the relationship between disease onset and diet, physical activity, vitamin D, cigarette smoking, excessive alcohol consumption, and being overweight. The respondents were divided into two groups: group A (n = 375) - females from 15 to 35 years old and group B (n = 375) - females from 36 to 55 years old. Survey data was processed in Statistical Analysis Software 15.0. Statistical significance was calculated using Analysis of Variation.

Results: We obtained the following results for the Main Aspects of the survey: 1. Osteoporosis is a rare condition that occurs primarily in women (Awareness level: Group A - 47%; Group B - 67,5%; Analysis of Variation > 0,05). 2. Postmenopausal women are more at risk of osteoporosis (Awareness level: Group A - 73,5%; Group B - 70,4%; Analysis of Variation > 0,05). 3. Prevention of osteoporosis is impossible (Awareness level: Group A - 78,8%; Group B - 89%; Analysis of Variation > 0,05). 4. Vitamin D is synthesized by direct exposure to UV radiation on the skin (Awareness level: Group A - 53,1 %; Group B - 69,1%; Analysis of Variation > 0,05). 5. Effective prevention of osteoporosis are: I. Balanced diet; II. Absence of bad habits; III. Occupation with health-improving physical culture. IV. Reduction of excess body weight (Awareness level: Group A - 69,2%; Group B - 47,1%; Analysis of Variation > 0,05). 6. Increased consumption of table salt, sugar and excessive consumption of protein foods, vegetarianism negatively affects the quality of bone tissue (Awareness level: Group A - 56,7%; Group B - 70,4%; Analysis of Variation > 0,05).

Conclusion: The conducted survey shows that the level of awareness of osteoporosis and its prevention is low among women in different age groups. In some cases, it is even a cause for concern. We believe that respondents' statements that osteoporosis cannot be effectively prevented are the most important findings of our study. Starting from adolescence, women should be well aware of the main risk factors for the development of osteoporosis, the mechanisms of its development and its consequences. This knowledge will help substantiate why it is necessary to lead a healthy lifestyle, which will help to prevent the development of this disease in the future. The concept of prevention of osteoporosis should include the following recommendations for the general population: to maintain a physically active lifestyle and to spend sufficient time under the influence of sunlight, avoid smoking and drinking large amounts of alcohol, ensure that dietary calcium intake is in line with the recommended level in the area, and maintain an appropriate body weight.

Building patient led organisations

AB0923-PARE WHAT IS THE IMPACT ON THE QUALITY OF LIFE (QOL) OF PEOPLE LIVING WITH SPONDYLOARTHRITIS (SPA*)?

S. Patenaude[1], W. Gerhart[2]. *[1]Canadian Spondylitis Association, Intern, Phelpston, Canada*; *[2]Canadian Spondylitis Association, Executive Director, Phelpston, Canada*

Background: SpA describes a group of chronic inflammatory arthritic diseases with common features including inflammation of the spine, eyes, skin and gastrointestinal tract. These conditions can be painful and debilitating for many. Delayed diagnosis and treatment can lead to irreversible damage to the spine and other joints. Diagnosis of these conditions can take, on average, 7 years or more. We don't know what causes SpA and there is no cure. The onset of symptoms can be in early childhood and expands throughout one's lifespan. It affects children, women and men worldwide.

Objectives: To understand how living with SpA impacts QOL (including relationships, work and day-to-day life) and what is important to patients in order to help the CSA** prioritize advocacy focus and resource development.

Methods: The CSA surveyed the community virtually from 11/19/19 to 01/21/20. The results of 838 respondents were analyzed after the survey closed.

Results: 66% of respondents had been diagnosed with Ankylosing Spondylitis and 24% with Psoriatic Arthritis. 22% were diagnosed with more than one form of SpA.

Over 70% reported their day-to-day life was negatively impacted by SpA. Only 7% indicated no impact on their daily life and 22% said it was somewhat impacted. Ability to remain in the workplace was impacted and 16% reported being on long-term disability and 4% on short-term disability. There were 7% who retired early due to their disease.

Sleep loss/interruption was reported by 89% and 74% said they avoid social events. 41% of participants are highly restricted by SpA when it comes to tasks like outdoor yard work. Other highly restricted tasks include exercise (36%) and cleaning (31%). Tasks of medium restriction include preparing meals (31%) and engaging in intimate relations (30%).

Upon diagnosis and disease progression, many reported less frequent participation in exercise, travel, intimate relationships, social outings and family activities. Some even said they stopped participating in these all together.

When asked to rank what was most important regarding QOL, most ranked living with no/reduced pain as most important, followed by improved sleep/no fatigue. The least important were returning to work and going out with friends.

Conclusion: SpA conditions have a negative impact on QOL and are a burden causing patients to constantly assess their situation, worry about tomorrow and adjust different aspects of their lives. Results confirmed every aspect of life is impacted, both physically and mentally, leaving people feeling hopeless and without a purpose. Many can no longer work or do their favorite hobbies which leads to emotional and mental difficulties. People struggle with maintaining social and intimate relationships, intensifying social isolation and low self-confidence. Many indicated that their loved ones have difficulties understanding chronic pain and illness, making patients feel like a burden. This may be attributed to general lack of knowledge about SpA. The unpredictability of the disease impacts QOL leaving patients hesitant to make social plans in advance. Even those who are undergoing successful treatment and have improved QOL worry about the future. QOL can be improved with proper treatment, management and support.

Many expressed frustrations of being limited by their disease and indicated that it is often the chronic pain that causes these limits. It is clear that by living with less pain, patients can improve all aspects of their lives and be happier.

The CSA is committed to educating, supporting and advocating on behalf of Canadians impacted by SpA to improve health outcomes and QOL.

It doesn't have to be visible to be real. Together we are stronger!

Footnotes:

*SpA conditions include: Ankylosing Spondylitis, Psoriatic Arthritis, non-radial SpA, Axial and Peripheral Spondyloarthritis, Enteropathic Arthritis, Reactive Arthritis and Juvenile Onset Arthritis

**The Canadian Spondylitis Association (CSA) is a national non-profit patient association supporting and advocating for those living with SpA.

Arthritis research

AB0924-PARE

EXPERIENCES AND PERCEPTIONS OF PATIENTS WITH PSORIATIC ARTHRITIS PARTICIPATING IN A TRIAL OF FAECAL MICROBIOTA TRANSPLANTATION: A NESTED QUALITATIVE STUDY

M. Skov Kragsnaes[1], S. Theodor Sødergren[1], J. Kjeldsen[2], H. C. Horn[1], H. L. Munk[1], J. K. Pedersen[3], C. Schufri Klinkby[1], M. De Wit[4], N. Gram Ahlmark[5], T. Tjørnhøj-Thomsen[5], T. Ellingsen[1]. *[1]Odense University Hospital, Department of Rheumatology, Odense, Denmark*; *[2]Odense University Hospital, Department of Medical Gastroenterology, Odense, Denmark*; *[3]Svendborg Hospital OUH, Section of Rheumatology, Department of Medicine, Svendborg, Denmark*; *[4]Amsterdam, Patient Research Partner, Amsterdam, Netherlands*; *[5]University of Southern Denmark, National Institute of Public Health, Copenhagen, Denmark*

Background: Patients' first-hand experiences of faecal microbiota transplantation (FMT) performed in a rheumatological care-setting have yet to be elucidated.

Objectives: The objectives were to explore participants' perceptions of being part of an FMT trial thereby identifying potential trial participation effects and enlightening the patient perspective on the outlook for future FMT trials in rheumatic diseases.

Methods: In a qualitative study nested within a double-blind, randomised, placebo-controlled trial (RCT) testing FMT as a potential new anti-rheumatic treatment,[1] semi-structured telephone interviews were conducted following the trial participants' final 26-week visit. The RCT was conducted at a Danish rheumatology university outpatient clinic with nationwide inclusion. The qualitative study included ten patients with psoriatic arthritis (PsA) who completed the final 26-week trial visit and were unaware of their treatment allocation (one gastroscopic-guided FMT or sham transplantation into the duodenum), see table 1. Qualitative researchers, who did not take part in the RCT, performed the interviews and the primary analysis. The experiences explored related to the conduct of the RCT and changes in the participants' everyday life. The analysis was carried out using a thematic approach. There was sufficient repetition of ideas in data to conclude data saturation.

Table 1. Characteristics of the participants.

Characteristic	Total (n = 10)
Female sex, no. (%)	7 (70%)
Age, yr.	53.9 (11.3)
Time since diagnosis, yr.[a]	7.4 (4.2, 12.8)
Rheumatoid factor IgM negative, no. (%)	10 (100%)
Anti-citrullinated peptide antibody negative, no. (%)	10 (100%)
HLA-B27 negative, no. (%)	8 (80%)
C-reactive protein, mg/L	4.5 (3.6)
HAQ-DI[b]	1.09 (0.40)
Swollen joint 66 count	7.4 (3.8)
Tender joint 68 count	22.8 (7.9)
SPARCC enthesitis index[c]	
Score ≥1, no. (%)	10 (100%)
Score in patients with a score ≥1	8.7 (4.0)

Data are mean (SD) or n (%) unless otherwise stated. [a] Time since diagnosis of psoriatic arthritis is presented as median and interquartile range (IQR).[b] Scores on the Health Assessment Questionnaire Disability Index (HAQ-DI) range from 0 to 3, with higher scores indicating greater disability. [c] Spondyloarthritis Research Consortium of Canada (SPAARC) Enthesitis Index range from 0 to 16, with higher scores indicating more severe disease.

Results: Participation in the RCT influenced the patients' understanding of PsA and induced positive changes in their everyday life. Renewed hopes for the future in addition to a feeling of enhanced care contributed to significant trial participation effects.[2] We identified several factors related to the RCT that may have promoted these effects (figure 1). FMT was deemed acceptable and safe, and all participants supported more research into the field of microbiota-targeted interventions in rheumatic diseases.

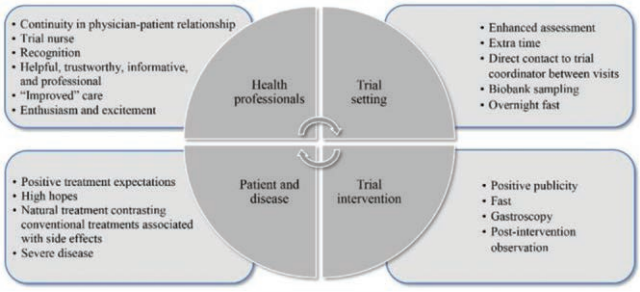

Figure 1. Factors related to the RCT that may have promoted trial participation effects.

Conclusion: Discrepancies between the clinical and the research setting should be considered when discussing the clinical relevance of the results of the RCT. Overall, patients with PsA who have participated in an RCT testing FMT find the treatment acceptable and safe encouraging more research into the field of microbiota-targeted interventions in rheumatic diseases. Further research into the potential beneficial and adverse effects of FMT in addition to exploring the magnitude and mechanisms behind FMT trial participation effects in the rheumatological setting are highly needed.

AB0925-PARE **A NARRATIVE REVIEW ASSESSING THE ROLE OF DIETARY SALT AS AN ENVIRONMENTAL RISK FACTOR FOR THE ONSET AND SEVERITY OF RHEUMATOID ARTHRITIS**

S. Ahmed[1], E. Nikiphorou[2,3], J. Bayliss[4]. [1]*Colchester Hospital, Rheumatology, Colchester, United Kingdom*; [2]*Kings College London, Centre for Rheumatic Diseases, London, United Kingdom*; [3]*Kings College London, Rheumatology Department, London, United Kingdom*; [4]*East Suffolk and North Essex NHS Foundation Trust, Library & Learning Resources, Ipswich, United Kingdom*

Background: The role of dietary salt consumption in the etiopathogenesis of Rheumatoid Arthritis (RA), and autoimmune disease in general, has received renewed interest. This has been fueled by the increased prevalence of autoimmune disease worldwide correlating with western diets and heightened consumption of salt rich foods and also studies at the cellular level demonstrating induction of IL 17 producing T helper cells (Th17) by dietary salt.
Objectives: To conduct a narrative review of observational studies and clinical trials on the role of dietary salt as an environmental risk factor for the onset and development of RA.
Methods: A comprehensive search was done of the literature from 2010 to 2021, using the search terms dietary salt and RA; the native interfaces EBSCO and Ovid were used. Databases searched included Pubmed, Embase, EMCare, Medline and CINAHL using a Population, Exposure and Outcome framework; the MESH terms RA, risk factors, nutrition and salt were used. Data was extracted by an independent reviewer.
Results: Out of the 72 studies initially identified, 50 were included in this review. Studies in murine models have demonstrated that high concentrations of sodium chloride promote the differentiation of T helper lymphocytes, via the serum- and glucocorticoid- inducible kinase 1 (SGK1) mediator towards the proinflammatory Th17 driven immune response. Six studies were carried out in human subjects. Study design ranged from cross sectional observational to nested case control studies. Sodium intake amongst participants characterized as having high intake, or being placed in the higher quartiles, ranged from 4.5-5grams per day. 5 out of 6 studies demonstrated that increased dietary salt consumption is associated with earlier onset RA. One study suggested an association between high salt intake and erosive disease at diagnosis and the development of anti-citrullinated protein antibodies (ACPA), although evidence was weak and from a single study only. Another study found that increased consumption of salt was only associated with risk of RA in smokers, highlighting the need to explore confounding variables further.
Conclusion: This narrative review of the literature provides some evidence that supports a role of excess dietary salt consumption as a risk factor for the onset and severity of RA.

Psychosocial support

AB0926-PARE **IMPACT OF COVID 19 PANDEMIC ON TUNISIAN SPA PATIENTS: PSYCHOLOGICAL STATE AND TREATMENT ADHERENCE**

M. Rachdi[1], A. Feki[2], Z. Gassara[3], S. Ben Jemaa[4], M. Ghali[4], M. Ezzeddine[4], M. H. Kallel[4], H. Fourati[4], R. Akrout[4], S. Baklouti[4]. [1]*Hedi Chaker Hospital Sfax, Rheumatology, Sfax,Tunisia*; [2]*Hedi Chaker Hospital, Rheumatology, Sfax, Tunisia*; [3]*Hedi Chaker Hospital, Rheumatology, Sfax,Tunisia*; [4]*Hedi Chaker Hospital, Rheumatology, Sfax,Tunisia*

Background: The challenge posed by the COVID-19 pandemic may represent an overwhelmingly stressful event for ankylosing spondylitis (SpA) patients and impact their treatment adherence. In response to the COVID-19 pandemic, Tunisia,have adopted community containment to manage the spread of the virus. However, COVID-19 restrictions can alter psychological wellbeing and limit access to treatment for SpA patients.
Objectives: This study aimed to evaluate the impact of COVID-19 pandemic on psychological health and treatment adherence on Tunisian SpA patients.
Methods: This is a cross sectional study including patients with SpA (ASAS criteria). A survey comprising questions about adherence to stay home warnings; the obligation to go outside for work; satisfaction with the medical support or information received for COVID-19; showing up to medical check-ups, proper use of the medications; medications that the patient stopped taking.
Anxious and depressive symptoms were assessed using the Arabic version of Hospital Anxiety and Depression Scale (HADS) questionnaire.
Results: We included thirty patients. the average age was: 39,7 years-old and the sex ratio was: 13,3. 75 % of patients were married. The SpA was axial in 25%, peripheral in 20%, and both in 55 %. Most patients had a moderate activity and the mean activity scores were: BASDAI = 2.60, ASDAScrp:2.65
38% of patients were on biologics, 36 % on sulfasalazine and NSAIDs and 26 % on NSAIDs only.
It seemed that significant number of patients strictly adhered to stay home warnings (>89%) only 11% were obliged to go out for work during general lockdown while only 24 % adhered to it after general lockdown.
Most of the patient 78 % were not satisfied with the medical support or information about COVID 19. 88% of patients requested information from TV while 10 % requested it from social media and 2 % from relatives and friends working in health care field.
After the outbreak, 23% of the patients who had a scheduled chek-up visit attended the appointment as it was before.The remaining either 'did not want to come' (43%), wanted to come but could not contact anyone in the hospital (11%), was advised to postpone their visits (10%), or couldn't find means of transport (13%).A significant number of patients decreased or skipped their dose (69%), while only 13% continued their medications and 16%stopped taking NSAIDs.
Biological DMARDs(anti-TNF agents) were the most frequent drugs which patients decreased their dose, skipped or stopped taking 33%. sulfasalazine and NSAIDs were least likely 17% to be skipped or stopped.
43% of patients Had a HADS anxiety level more than or equal to 11: 87 % women and 13 % men. The highest anxiety scores were found among patients aged less than 45 years old (87%) married with children .32% of patients had a HADS depression level more than or equal to 11: 54 % women and 44 % men. the highest depression scores were found among patients aged less than 45 years old married with children.
No significant relationship was found between anxiety and depression levels regarding biologic treatment.
Conclusion: Our results suggest that patients with SpA were less likely to comply strictly to 'stay home' restrictions, most probably due to the male predominance and relatively younger age. Additionally, we noticed that SpA patients treated with anti-TNF agents were the patients that regular drug use had been considerably disrupted.
COVID 19 pandemic has heightened the need to care for patients with SpA in an increasingly virtual environment.
Additionally, we found that being female, having a lower level of education, having a child, living in a crowded family is correlated to higher levels of anxiety and depression.

Work and rehabilitation

AB0927-PARE **WORK PRODUCTIVITY AND ACTIVITY IMPAIRMENT IN PATIENTS WITH SAPHO SYNDROME**

L. Gong[1], C. Li[2]. [1]*Peking Union Medical College Hospital, Institute of Clinical Medicine, Beijing, China*; [2]*Peking Union Medical College Hospital, Department of Traditional Chinese Medicine, Beijing, China*

Background: Synovitis, acne, pustulosis, hyperostosis, and osteitis (SAPHO) syndrome is a rare disease, characterized by osteoarticular and cutaneous manifestations. Osteitis and hyperostosis are regarded as the core pathophysiological changes of SAPHO syndrome [1], which may lead to bone pain and loss of motor function. The Work Productivity and Activity Impairment (WPAI) questionnaire is an instrument to measure the impact of the disease on work productivity and activity, subsequently adapted for ankylosing spondylitis [2], rheumatoid arthritis [3], irritable bowel syndrome [4], and other chronic diseases [5]. However, no study has investigated the work productivity of patients with SAPHO syndrome.
Objectives: The purpose of this study is to give an overview of work productivity loss in SAPHO patients through the work productivity and activity impairment (WPAI) questionnaire and investigate the relationship between the WPAI and other disease-related indicators.

Methods: Patients for this cross-sectional study were recruited from Peking Union Medical College Hospital (Beijing, China). The questionnaires incorporating the WPAI were administered, along with demographic data, disease-specific measures, and general health variables. The construct validity of WPAI was evaluated by the correlations between WPAI outcomes and other measures. Wilcoxon rank-sum tests and non-parametric Kruskal-Wallis tests were used for comparison of WPAI outcomes between known-groups.

Results: A total of 376 patients were included and 201 patients (53.5%) were employed. The median (interquartile range [IQR]) of absenteeism, presenteeism, work productivity loss and activity impairment were 0% (0-13%), 20% (0-40%), 20% (0-52%) and 30% (0-50%), respectively. All WPAI outcomes showed moderate to strong correlations to other generic and disease-specific measures (|r| =0.43-0.75), except for absenteeism. Increasing disease activity and worse health status are significantly associated with higher impairment of work productivity and activity.

Conclusion: This study highlights the negative effects of SAPHO syndrome on patients' work productivity and activity, indicating a good construct validity and discriminative ability of WPAI. For reducing the economic burden, it is important to improve the patients' work productivity and daily activity with active intervention.
