Guidelines for Authors and Reviewers

Full instructions are available online at http://ard.bmj.com/pages/authors. Articles must be submitted electronically at http://mc.manuscriptcentral.com/ard. Authors retain copyright but are required to grant ARD an exclusive licence to publish. (http://ard.bmj.com/pages/authors/).

Annals of the Rheumatic Diseases publishes original work on all aspects of rheumatology and disorders of connective tissue. Laboratory and clinical studies are equally welcome

Subscription Information

ARD is published monthly; subscribers receive all supplements
ISSN 0003-4967 (print); 1468-2060 (online)

Institutional Rates 2021

Print
£1,121

Online
Site licences are priced on FTE basis and allow access by the whole institution. Details available online at http://journals.bmj.com/content/subscribers or contact the Subscription Manager in the UK (see above right)

Personal Rates 2021

Print (includes online access at no additional cost)
£431

Online only
£241

EULAR congress delegates
Delegates receive a Continuous Professional Development package that includes a 12 month complimentary subscription to *ARD* online

Personal print or online only and institutional print subscriptions may be purchased online at http://journals.bmj.com/content/subscribers (payment by Visa/Mastercard only)

Residents of some EC countries must pay VAT; for details, call us or visit http://journals.bmj.com/content/subscribers

For more information on subscription rates or to subscribe online please visit ard/bmj.com/pages/contact-us/

Scientific Abstracts

Welcome Address
EULAR 2021 Abstracts Reviewers

Oral Presentations

OP0002	New perspectives on therapeutic immune tolerance	1
OP0003–OP0004	Autoimmune diseases by abnormal T cell function	1
OP0005	What the rheumatologist needs to know to interpret studies in 2021	2
OP0006–OP0013	Opening Plenary Abstract session	2
OP0014–OP0021	Genomics, genetic basis of disease and functional genomics	8
OP0022–OP0029	Adaptive immunity (T cells and B cells) in rheumatic diseases and Innate immunity in rheumatic diseases	12
OP0030–OP0037	Of mice and man: insights into pathophysiology of rheumatoid arthritis and spondyloarthritis	16
OP0038–OP0045	Molecular mechanisms in Connective Tissue Disease	20
OP0046–OP0053	Clinical aspects of axial spondyloarthritis – science meets daily practice	24
OP0054–OP0061	Vasculitis - I	28
OP0062–OP0070	Vasculitis - II	33
OP0072–OP0073	New toys in rheumatology: single cell RNA and epigenetic sequencing, the holy grail?	38
OP0074–OP0081	Education	39
OP0083–OP0089	The origins of pain in RMDs	45
OP0090–OP0097	Infection-related rheumatic and orphan diseases	49
OP0098–OP0105	Rheumatoid arthritis - comorbidity and clinical aspects - I	54
OP0106–OP0113	Bone & Joints	59
OP0114–OP0120	Rheumatoid arthritis - biological DMARDs	63
OP0122–OP0128	Rheumatoid arthritis - non biologic treatment and small molecules	68
OP0129–OP0136	SLE, Sjögren's and APS - treatment and SLE, Sjögren's and APS - clinical aspects (other than treatment)	74
OP0137–OP0144	Spondyloarthritis - treatment	80
OP0145–OP0152	Diagnostics and imaging procedures	86
OP0161–OP0168	Advances in Pediatric Rheumatology	97
OP0170–OP0177	Progress in myositis and scleroderma research - I	101
OP0178–OP0185	Rheumatoid arthritis - prognosis, predictors and outcome	106
OP0186–OP0187	Oncorheumatology: the crossroads of cancer and musculoskeletal diseases	112
OP0189–OP0190	Joint Session EULAR ESCMI and EANM (European Association of Nuclear Medicine) – State-of-the-art nuclear imaging in RMDs	114
OP0193	Comorbidities in gout and hyperuricaemia	116
OP0194–OP0195	Immune events with checkpoint inhibitors	117
OP0196–OP0197	The aftermath of metabolic imbalance in OA	118
OP0199–OP0200	Emerging molecular targets in OA	120
OP0201	Origin and role of myeloid cells during homeostasis and inflammation	121
OP0202–OP0209	Crystal diseases	122
OP0210–OP0217	Rheumatoid arthritis - comorbidity and clinical aspects - II	126
OP0218–OP0225	Unrevealing the impact of PsA and comorbidity prevention	130
OP0226–OP0233	Psoriatic arthritis - treatment	136
OP0234–OP0241	Epidemiology and public health	144
OP0242–OP0249	Systemic sclerosis, myositis - etiology, pathogenesis and animal models	148
OP0250–OP0257	Imaging in axial spondyloarthritis – what is new?	152
OP0266–OP0273	Progress in myositis and scleroderma research - II	162
OP0281–OP0288	New Developments in COVID-Research	170
OP0289–OP0297	SLE, Sjörgen's and APS - Clinical Aspects	177
OP0298–OP0299	Difficult to treat RA: definitions and mechanisms	183
OP0300	Quantitative imaging	184
OP0301	Let's consider Biologic Immunogenicity	185
OP0305–OP0306	Controversies on phenotypes in PsA	187
OP0307	Pharmacology and Microbiota	188
OP0308	What can we learn from the tissue	189

OP0309	EULAR Projects in musculoskeletal imaging	189
OP0310–OP0311	What's new: Latest advances in treatment and care in vasculitis and fibromyalgia	190
OP0312	Stress, inflammation & autoimmunity	191
OP0313–OP0314	Hyperinflammation and Covid19	191
OP0315	Metabolic pathways during the regulation of inflammation and immunity	192
OP0316	Let's work. Together.	193
OP0318–OP0319	Deconditioning in rheumatic disease, time to recognise and tackle it	194
OP0320–OP0321	EFIS session: Emerging concepts how B cells drive systemic autoimmunity: from bench to clinic	196

Poster Tours

POS0001–POS0010	Adaptive immunity (T cells and B cells) in rheumatic diseases	203
POS0011–POS0020	Epidemiology and treatment of pain in RMDs	207
POS0021–POS0031	Epidemiology: Big Questions - Big studies	212
POS0032–POS0039	Imaging in axial spondyloarthritis	221
POS0040–POS0046	Molecular and structural changes of bone turnover during inflammatory disease	225
POS0047–POS0056	New Developments in COVID research	228
POS0067–POS0074	Pediatric Rheumatology – Basic and translational science	240
POS0075–POS0085	Pediatric Rheumatology - Clinical	244
POS0086–POS0092	Rheumatoid arthritis - non biologic treatment and small molecules - PART 1	251
POS0093–POS0100	Rheumatoid arthritis - prognosis, predictors and outcome	256
POS0101–POS0111	SLE, Sjögren's and APS - clinical	260
POS0112–POS0121	Translating vasculitis	267
POS0122–POS0131	Central pain and other extra-articular associations to KOA	272
POS0132–POS0141	Crystal arthritis	277
POS0142–POS0151	Fine-tuning strategies (beyond treatments) to reduce the impact of PsA	282
POS0162–POS0171	Metabolic bone disease / Osteoporosis	293
POS0172–POS0180	Molecular profiles in connective tissue disease outcome	298
POS0181–POS0191	PROMs and markers	304
POS0192–POS0201	PsA treatment: what is new?	310
POS0202–POS0209	Rheumatoid arthritis - biological DMARDs	317
POS0210–POS0219	Rheumatoid Arthritis - comorbidity and clinical aspects - Part 1	322
POS0220–POS0225	Rheumatoid arthritis - non biologic treatment and small molecules - PART 2	328
POS0226–POS0235	Spondyloarthritis - treatment	332
POS0236–POS0245	Clinical aspects of spondyloarthritis	339
POS0246–POS0255	Clinical vasculitis	344
POS0256–POS0265	Diagnostics and imaging procedures	350
POS0276–POS0285	New drugs and therapies	362
POS0286–POS0295	Oncorheumatology	368
POS0296–POS0304	Public Health, Health Services and Health Economics	373
POS0305–POS0314	Rheumatoid Arthritis - comorbidity and clinical aspects - Part 2	378
POS0315–POS0325	Scleroderma, myositis and related syndromes	383
POS0326–POS0335	Systemic sclerosis, myositis - etiology, pathogenesis and animal models	390
POS0336–POS0343	Vasculitis - Large vessel vasculitis	395

POSTERS only

POS0344–POS0362	Genomics, genetic basis of disease and functional genomics	401
POS0363	Adaptive immunity (T cells and B cells) in rheumatic diseases	411
POS0364–POS0370	Innate immunity in rheumatic diseases	412
POS0371–POS0376	Osteo arthritis, aetiology, pathology and animal models	416
POS0377–POS0403	Rheumatoid arthritis - aetiology, pathogenesis and animal models	419
POS0404–POS0415	Spondyloarthritis - aetiology, pathogenesis and animal models	431
POS0416–POS0421	SLE, Sjögren's and APS - aetiology, pathogenesis and animal models	437
POS0422–POS0433	Systemic sclerosis, myositis and related syndromes - aetiology, pathogenesis and animal models	440
POS0434	Basic and translational pain science	445
POS0434–POS0504	Rheumatoid arthritis - prognosis, predictors and outcome	446

POS0505–POS0589	Rheumatoid arthritis - comorbidity and clinical aspects	485
POS0590–POS0645	Rheumatoid arthritis - biological DMARDs	527
POS0646–POS0679	Rheumatoid arthritis - non biologic treatment and small molecules	561
POS0680–POS0704	SLE, Sjögren's and APS – treatment	585
POS0705–POS0795	SLE, Sjögren's and APS - clinical aspects (other than treatment)	602
POS0796–POS0821	Vasculitis – large vessel vasculitis	650
POS0822–POS0831	Vasculitis – small vessel vasculitis	664
POS0832-POS0894	Scleroderma, myositis and related syndromes	669
POS0895–POS0941	Spondyloarthritis – treatment	704
POS0942–POS1019	Spondyloarthritis - clinical aspects (other than treatment)	734

New perspectives on therapeutic immune tolerance

OP0002 IMMTOR NANOPARTICLES ENHANCE THE TOLEROGENIC ENVIRONMENT OF THE LIVER IN MICE

P. Ilyinskii[1], C. Roy[1], J. Leprevost[1], K. Kishimoto[1]. [1]*Selecta Biosciences, Biology, Watertown, United States of America*

Background: Tolerogenic ImmTOR biodegradable nanoparticles encapsulating rapamycin have been shown to mitigate the formation of anti-drug antibodies against pegadricase, a pegylated uricase enzyme, which enabled monthly dosing and sustained reduction of serum uric acid levels in a Phase 2 clinical trial of SEL-212, a combination of pegadricase + ImmTOR, in patients with symptomatic gout with hyperuricemia. Prior mechanism of action studies showed selective biodistribution of ImmTOR to the spleen and liver following intravenous (IV) administration in mice. In the spleen, ImmTOR has been demonstrated to induce tolerogenic dendritic cells and antigen-specific regulatory T cells and inhibit antigen-specific B cell activation. Splenectomized mice showed a partial but incomplete abrogation of the tolerogenic immune response mediated by ImmTOR.
Objectives: Here we evaluated the ability of ImmTOR to enhance the tolerogenic environment in the liver.
Results: All the major resident populations of liver cells, including liver sinusoidal endothelial cells (LSECs), Kupffer cells (KC), stellate cells (SC), and hepatocytes, actively took up fluorescent-labeled ImmTOR particles, which resulted in downregulation of MHC class II and co-stimulatory molecules and upregulation of the PD-L1 checkpoint molecule. The LSEC, known to play an important role in hepatic tolerance induction, emerged as a key target cell for ImmTOR. The tolerogenic environment led to a multi-pronged modulation of hepatic T cell populations, resulting in an increase in T cells with a regulatory phenotype, upregulation of PD-1 on $CD4^+$ and $CD8^+$ T cells, and the emergence of a large population of $CD4^-CD8^-$ (double negative) T cell population. Modulation of T cell phenotype was seen to a lesser extent after administration by empty nanoparticles, but not free rapamycin. The upregulation of PD-1, but not the appearance of double negative T cells, was inhibited by antibodies against PD-L1 or CTLA-4.
Conclusion: These results suggest that the liver may contribute to the tolerogenic properties of ImmTOR in mitigating anti-drug antibody responses to biologic therapies, such as pegadricase.

Autoimmune diseases by abnormal T cell function

OP0003 AUTOREACTIVE CD4+ T CELLS AND THEIR TCR REPERTOIRE IN PR3-ANCA ASSOCIATED VASCULITIS

R. Kumar[1], N. Yoosuf[1], A. Bartoletti[2], A. Avik[3], B. Raposo[1], A. Jonasdottir[4], B. Lövström[1], K. Chemin[1], A. Bruchfeld[4], I. Gunnarsson[1], V. Malmström[1]. [1]*Karolinska Institutet, Division of Rheumatology, Department of Medicine, Stockholm, Sweden;* [2]*The University of Pavia, Medicine, Pavia, Italy;* [3]*Danderyds hospital, Rheumatology, Stockholm, Sweden;* [4]*Karolinska University Hospital, CLINTEC, Stockholm, Sweden*

Background: ANCA-associated vasculitis (AAV) with proteinase 3 (PR3) ANCA is genetically associated with HLA-DP [1], is often relapsing in nature, and has a predisposition for kidneys, lungs and ear-nose-throat involvement [2]. Despite the presence of PR3+ANCA, indicating CD4+T-cell help in the disease, the knowledge about autoreactive CD4+T cells is scarce. Activated T cells have been shown at site of inflammation [3] and involvement of proinflammatory cytokines in circulation is also reported [4, 5].
Objectives: Identification of autoreactive T cells may help to identify the drivers of the immune responses and chronicity. We therefore aimed to investigate PR3-specific CD4+T-cell responses in peripheral blood of AAV patients with a focus on both phenotype and T-cell receptor (TCR) repertoires.
Methods: The study included sixty-six patients: 26 with active PR3 autoantibody+ AAV, 21 with inactive but PR3+ AAV and 19 with inactive PR3- AAV. *In-vitro* cultures with PR3 protein were established to assess antigen-specific cytokine responses in a 3-color fluorospot assay. Deep immunophenotyping was performed by flow cytometry. Antigen-responsive CD4+ T cells were isolated and single cell TCR$\alpha\beta$ sequences were generated and analyzed from PR3+ AAV patients (n=5) using a previously published protocol [6].
Results: PBMCs from AAV patients demonstrated an HLA-DP associated cytokine responses to PR3 stimulation including IFN-γ and IL-10, but not IL-17A. This T-cell autoreactivity was found to be confined to a highly differentiated CD4+ T cell population characterized by perforin and GPR56 expression, implicating a cytotoxic feature of the response. Active disease involved a reduction in expression of several markers associated with cytotoxicity amongst the CD4+GPR56+ T cells. Their frequency was also negatively associated with the doses of prednisolone. A similar phenotype was shared with T cells activated by human cytomegalovirus (HCMV) peptides in the same patient cohort. Single cell sequencing of paired alpha beta T-cell receptors (TCRs) revealed different patterns of gene usage between PR3 and HCMV reactive T cells. Moreover, we could identify shared (public) PR3-reactive T-cell clones between different HLA-DPB1*04:01+ patients.
Conclusion: PR3 is an autoantigen which provokes ANCA responses in AAV patients. Our study identified PR3-reactive CD4+ T cells at the level of their phenotype and TCR repertoire. The autoreactive CD4+ T cells, present in both active and inactive disease, implicate chronic antigen exposure and the persistence of long-lived T-cell clones. The presence of public autoreactive clones between HLA-DPB1*04:01+ patients suggests an active role for these cells in pathogenesis of AAV and validates the link with predisposed genotype.

OP0004 AUTOIMMUNE AND INFLAMMATORY MANIFESTATIONS IN COMMON VARIABLE IMMUNODEFICIENCY DISORDERS

K. López-Aldabe[1], L. Hidalgo[2], A. Antolí[2], G. Rocamora[2], X. Corbella[2], X. Solanich[2]. [1]*Bellvitge University Hospital, Bellvitge Biomedical Research Institute-IDIBELL, Internal Medicine, L'Hospitalet de Llobregat, Spain*; [2]*Bellvitge University Hospital, Bellvitge Biomedical Research Institute-IDIBELL, Internal Medicine, Hospitalet de Llobregat, Spain*

Background: Common variable immunodeficiency (CVID) disorders are the second most frequent immunodeficiency worldwide and autoimmune diseases (AD) are present in 20% of such patients, cytopenia being the most frequent manifestation [1]. Defects in central and peripheral tolerance, activation/proliferation of B cells, and hypogammaglobulinemia are key features of the disease, along with a reduction in CD4+T cells, abnormalities in Treg and defective secretion of regulatory cytokines, that could perpetuate autoimmune - autoinflammatory phenomena.
Objectives: To describe immune and inflammatory disorders in our CVID cohort.
Methods: Retrospective analysis of 33 patients who fulfill the European Society for Immunodeficiencies (ESID) Registry – Work criteria for CVID diagnosis [2] treated in the immunodeficiency unit of our tertiary university hospital. After getting an informed consent form, medical records were revised to obtain clinical, analytical and immunological data.
Results: Of the 33 CVID patients analysed, 11 had some autoimmune/inflammatory manifestation. Seven patients presented autoimmune thrombocytopenia (AIT), and one of them also had non-severe neutropenia. Two patients also had seronegative spondyloarthropathy, one patient had cutaneous psoriasis, and

two patients had alopecia. There were no cases of type 1 diabetes, vitiligo or thyroid disorders. Interestingly, four patients had lung involvement, two of them with granulomatous-lymphocytic interstitial lung disease (GLILD), one with organising pneumonia and one with usual interstitial pneumonia. Five of the eleven patients required immunosuppressive treatment, mostly with steroids. One case of AIT required concomitant treatment with azathioprine and the patient with psoriasis was treated with methotrexate. In six patients, autoimmune disorder was the first manifestation.

Conclusion: 33% of the CVID patients had autoimmune or inflammatory manifestations in our cohort; six patients had one immune/inflammatory phenomena, four had two different disorders and one patient presented with three different ones. The most frequent manifestation was AIT, as seen in previous reports. In six cases, the autoimmune-inflammatory manifestation was the first symptom attributable to CVID. In conclusion, AD are common in CVID patients, so clinicians must be aware of possible immunodeficiencies in this type of patients.

What the rheumatologist needs to know to interpret studies in 2021

OP0005 DIETARY HYPERINSULINEMIC POTENTIAL AND RISK OF INCIDENT GOUT: 3 PROSPECTIVE COHORT STUDIES OF US MEN AND WOMEN

N. McCormick[1,2,3,4], C. Yokose[1,3,4], L. Lu[2,5], A. Joshi[3,4,6], H. Choi[1,2,3,4]. *[1]Massachusetts General Hospital, Clinical Epidemiology Program, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America*; *[2]Arthritis Research Canada, -, Richmond, Canada*; *[3]Massachusetts General Hospital, The Mongan Institute, Boston, United States of America*; *[4]Harvard Medical School, Medicine, Boston, United States of America*; *[5]Brigham and Women's Hospital, Channing Division of Network Medicine, Boston, United States of America*; *[6]Massachusetts General Hospital, Clinical & Translational Epidemiology Unit, Boston, United States of America*

Background: Gout and the metabolic (insulin resistance) syndrome frequently coexist. Intravenous insulin has been shown to raise serum urate (SU) levels in physiologic studies and a Mendelian Randomization study also showed a causal role of insulin on the risk of gout. However, it is unknown whether habitual hyperinsulinemic dietary intake confers gout risk.

Objectives: Prospectively examine the relation between two distinct insulin-related dietary indices and risk of incident gout in three large cohorts of US women and men over 30 years.

Methods: We studied 164,090 women from Nurses Health Study I (1986-2016) and II (1989-2017) and 40,598 men from Health Professionals Follow-up Study (1986-2016), who were free of gout at baseline. Dietary intake and covariates were assessed by validated questionnaires every 4 years. Insulinemic potential of diet was evaluated using 1) food-based empirical dietary index for hyperinsulinemia (EDIH) score that was pre-defined based on circulating C-peptide levels[1] and reflects *insulin resistance*;[2] and 2) dietary insulin index (DII), which reflects *transient, postprandial insulin secretion*.[2] We assigned EDIH and DII scores for each participant, adjusted for total energy intake, and prospectively examined the association between scores and incident gout (using ACR survey criteria for gout[3]), adjusting for potential confounders.

Results: We ascertained 2,874 incident gout cases over 5,124,490 person-years of follow-up. In pooled multivariable-adjusted analyses, those in the highest EDIH quintile had 1.76-times (95% CI: 1.56 to 1.99) higher gout risk, compared with the lowest (Table 1). This attenuated with further adjustment for BMI (a likely causal intermediate) but remained positive (RR 1.30, 1.15 to 1.48). DII scores were inversely associated with gout risk (RR 0.66, 0.58 to 0.74) (Table 1).

Conclusion: EDIH scores, reflecting chronic hyperinsulinemia (i.e., greater insulin resistance with reduced clearance), were positively associated with the risk of incident gout, even beyond the pathway through adiposity. Conversely, higher DII scores, which reflect short-term, postprandial elevations in insulin levels (and also greater insulin clearance and sensitivity) conferred a lower risk. This corroborates human physiologic experiments and Mendelian Randomization studies showing insulin resistance can increase SU levels by decreasing renal excretion of urate, and supports lowering insulinemic potential of diet as a strategy to reduce gout risk.

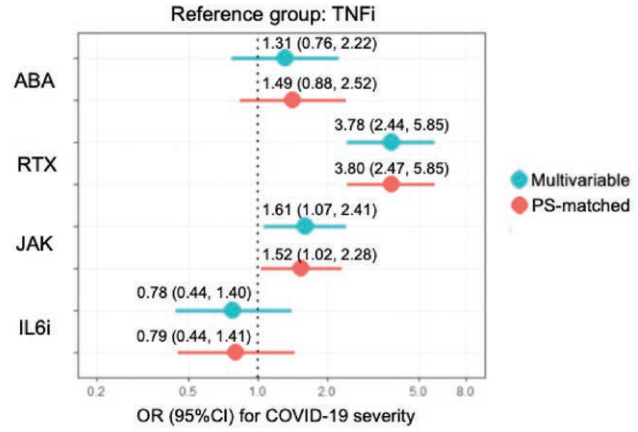
Background: Targeted DMARDs may dampen the inflammatory response in COVID-19, perhaps leading to a less severe clinical course. However, some DMARD targets may impair viral immune defenses. Due to sample size limitations, previous studies of DMARD use and COVID-19 outcomes have combined several heterogeneous rheumatic diseases and medications, investigating a single outcome (e.g., hospitalization).

Objectives: To investigate the associations of baseline use of biologic or targeted synthetic (b/ts) DMARDs with a range of poor COVID-19 outcomes in rheumatoid arthritis (RA).

Methods: We analyzed voluntarily reported cases of COVID-19 in patients with rheumatic diseases in the COVID-19 Global Rheumatology Alliance physician registry (March 12, 2020 - January 6, 2021). We investigated RA treated with b/tsDMARD at the clinical onset of COVID-19 (baseline): abatacept (ABA), rituximab (RTX), Janus kinase inhibitors (JAK), interleukin-6 inhibitors (IL6i), or tumor necrosis factor inhibitors (TNFi). The outcome was an ordinal scale (1-4) for COVID-19 severity: 1) no hospitalization, 2) hospitalization without oxygen need, 3) hospitalization with any oxygen need or ventilation, or 4) death. Baseline covariates including age, sex, smoking, obesity, comorbidities (e.g., cardiovascular disease, cancer, interstitial lung disease [ILD]), concomitant non-biologic DMARD use, glucocorticoid use/dose, RA disease activity, country, and calendar time were used to estimate propensity scores (PS) for b/tsDMARD. The primary analysis used PS matching to compare each drug class to TNFi. Ordinal logistic regression estimated ORs for the COVID-19 severity outcome. In a sensitivity analysis, we used traditional multivariable ordinal logistic regression adjusting for covariates without matching.

Results: Of the 1,673 patients with RA on b/tsDMARDs at the onset of COVID-19, (mean age 56.7 years, 79.6% female) there were n=154 on ABA, n=224 on RTX, n=306 on JAK, n=180 on IL6i, and n=809 on TNFi. Overall, 498 (34.3%) were hospitalized and 112 (6.7%) died. Among all patients, 353 (25.3%) were ever smokers, 197 (11.8%) were obese, 462 (27.6%) were on glucocorticoids, 1,002 (59.8%) were on concomitant DMARDs, and 299 (21.7%) had moderate/high RA disease activity. RTX users were more likely than TNFi users to have ILD (11.6% vs. 1.7%) and history of cancer (7.1% vs. 2.0%); JAK users were more likely than TNFi users to be obese (17.3% vs. 9.0%). After propensity score matching, RTX was strongly associated with greater odds of having a worse outcome compared to TNFi (OR 3.80, 95% CI 2.47, 5.85; Figure). Among RTX users, 42 (18.8%) died compared to 27 (3.3%) of TNFi users (Table). JAK use was also associated with greater odds of having a worse COVID-19 severity (OR 1.52, 95%CI 1.02, 2.28). ABA or IL6i use were not associated with COVID-19 severity compared to TNFi. Results were similar in the sensitivity analysis and after excluding cancer or ILD.

Figure. Odds ratios for the ordinal COVID-19 severity outcome for patients with RA on biologic or targeted synthetic DMARDs (n=1673).



The effect size is the odds of being one level higher on the ordinal scale than the reference group.

n for propensity score (PS)-matched analyses: 98 ABA and 525 TNFi; 127 RTX and 520 TNFi; 198 JAK and 527 TNFi; 107 IL6i and 525 TNFi.

Multivariable covariates and propensity score included age, sex, region, season, smoking, obesity, RA disease activity, interstitial lung disease, cancer, comorbidity count, concomitant non-biologic DMARD use, and glucocorticoid use/dose.

Table 1. Frequencies for the ordinal COVID-19 severity outcome for patients with RA on biologic or targeted synthetic DMARDs (n=1673).

COVID-19 outcomes by severity scale (n,%)	ABA n=154	RTX n=224	JAK n=306	IL6i n=180	TNFi n=809
1)Not hospitalized	113 (73.3%)	121 (54.0%)	220 (71.9%)	150 (83.3%)	666 (82.3%)
2)Hospitalization without oxygenation	10 (6.5%)	14 (6.2%)	11 (3.6%)	9 (5.0%)	53 (6.5%)
3)Hospitalization with any oxygenation or ventilation	16 (10.4%)	47 (21.0%)	52 (17.0%)	16 (8.9%)	63 (7.8%)
4)Death	15 (9.7%)	42 (18.8%)	23 (7.5%)	5 (2.8%)	27 (3.3%)

Conclusion: In this large global registry of patients with RA and COVID-19, baseline use of RTX or JAK was associated with worse severity of COVID-19 compared to TNFi use. The very elevated odds for poor COVID-19 outcomes in RTX users highlights the urgent need for risk-mitigation strategies, such as the optimal timing of vaccination. The novel association of JAK with poor COVID-19 outcomes requires replication.

OP0007

MUC5B PROMOTER VARIANT AND LONG-TERM INCIDENCE OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS: A POPULATION BIOBANK STUDY OF 250,000 INDIVIDUALS

A. Palomäki[1], T. Laitinen[2], J. Koskela[3], A. Palotie[3,4,5], N. Mars[3]on behalf of FinnGen. *[1]Turku University Hospital, Centre for Rheumatology and Clinical Immunology, Turku, Finland*; *[2]Tampere University Hospital, Administration Center, Tampere, Finland*; *[3]University of Helsinki, Institute for Molecular Medicine Finland, FIMM, HiLIFE, Helsinki, Finland*; *[4]Massachusetts General Hospital, Analytic and Translational Genetics Unit, Department of Medicine, Boston, United States of America*; *[5]Broad Institute of MIT and Harvard, Stanley Center for Psychiatric Research, Cambridge, MA, United States of America*

Background: The promoter variant rs35705950 in *MUC5B* is the strongest known genetic risk factor for rheumatoid arthritis-associated interstitial lung disease (RA-ILD) [1]. There is, however, no large-scale data on the impact of *MUC5B* on the long-term incidence of RA-ILD.

Objectives: To describe long term risk of RA-ILD in RA patients carrying *MUC5B* variant compared to non-carriers with RA.

Methods: FinnGen is a collection of epidemiological cohorts and hospital biobank samples, linking genotypes with up to 46 years of follow-up within nationwide registries. Diagnoses of RA and ILD were identified from the Finnish national hospital discharge, medication reimbursement and cause-of-death registries. We estimated lifetime risks of ILD by age 80. *MUC5B* is a common variant and has an allele frequency of 0.1 in the Finnish population.

Results: Out of the 248,400 individuals, 5534 patients have been diagnosed with RA, out of whom 178 (3.2%) developed ILD. *MUC5B* was a strong predictor of ILD in RA patients (HR 2.14, 95%CI 1.56-2.92). In patients with RA, *MUC5B* conferred a lifetime risk of 14.5% (95%CI 10.7-18.1%), compared to 5.2% (4.1-6.2%) in *MUC5B* non-carriers with RA (Figure). In the population, *MUC5B* carriers and *MUC5B* non-carriers had lifetime risks of 3.9% and 1.3%, respectively. The risk difference started to emerge at age 65. The risk was highest in men with RA who are *MUC5B* carriers: 18.5% (11.1-25.2%) developed ILD, compared to 8.5% (6.1-10.9%) of *MUC5B* non-carriers with RA.

Conclusion: We report findings from a large longitudinal study, showing that *MUC5B* confers a considerable lifetime risk of RA-ILD, and contributes to increased morbidity. These findings have clinical implications for improving identification of RA patients at high risk of developing ILD.

Background: Dermatomyositis (DM) is a rare chronic systemic autoimmune disease with characteristic skin rash and progressive proximal muscle weakness. Current therapies encompass corticosteroids and other immunosuppressants and intravenous immunoglobulins (IVIg), however, none of these therapies are proven by randomized controlled phase 3 studies. There have been no large randomized clinical trials supporting the efficacy and safety of IVIg in DM.

Objectives: The ProDERM study aimed to evaluate the efficacy and safety/tolerability of IVIg in DM patients in a double-blind, randomized, placebo-controlled, international multi-center, phase III clinical trial.

Methods: The trial consisted of a double-blind, placebo-controlled First Period (16 weeks), in which adult patients with definite or probable DM (according to Bohan and Peter criteria) were randomized 1:1 to either high dose IVIg (2g/kg every 4 weeks) or placebo. Patients on placebo and patients without clinical worsening while on IVIg treatment entered the open label Extension Period (24 weeks) and received 2g/kg IVIg infusions every 4 weeks. To be included, subjects must have active disease with a manual muscle testing-8 (MMT-8) score < 142/150. Patients who showed clinical worsening (defined according to Oddis et al, 2013 - with slight adaptation) at 2 consecutive visits between week 8 and week 16 were switched to the alternate treatment arm.
Primary endpoint was the proportion of responders in the IVIg vs. placebo arm at week 16, where response was defined per 2016 ACR/EULAR Myositis response criteria of at least minimal improvement [Total Improvement Score (TIS) ≥ 20 points)] and without clinical worsening at 2 consecutive visits up to week 16.
Results: A total of 95 adult DM patients (mean age: 53 years; 75% females; 92% Caucasian) were enrolled, with 47 and 48 randomized to IVIg and placebo, respectively. Baseline clinical characteristics (including medical history and prior DM medication) were balanced between the 2 arms.
The study met the primary endpoint at week 16, with the proportion of responders being significantly higher in the IVIg group (37/47; 78.7%) as compared to the placebo group (21/48; 43.8%; p-value 0.0008; Table 1).

Table 1. Total Improvement Score – Analysis of Proportion of Responders at Week 16 (Full Analysis Set, N=95)

TIS Response	*octagam 10%* N=47	Placebo N=48	Difference *octagam 10%* – placebo
Number (%) of responders	37 (78.72%)	21 (43.75%)	
Difference in response rates [95% CI] p-value[a]			34.97 [16.70, 53.24] 0.0008

[a]Cochran-Mantel-Haenszel TestCI=confidence interval; N=number of patients; TIS=total improvement score

In the analysis of responders per improvement category at Week 16, a 45.2% higher response rate for at least moderate improvement (TIS ≥n40 points; p < 0.0001) and a 23.6% higher response rate for at least major improvement (TIS ≥060 points; p < 0.0062) was observed in the IVIG group as compared to the placebo group.
The mean (SD) TIS was significantly higher in IVIg group [48.4 (24.4)] than in placebo arm [21.6 (20.2)] at week 16 (Fig 1).

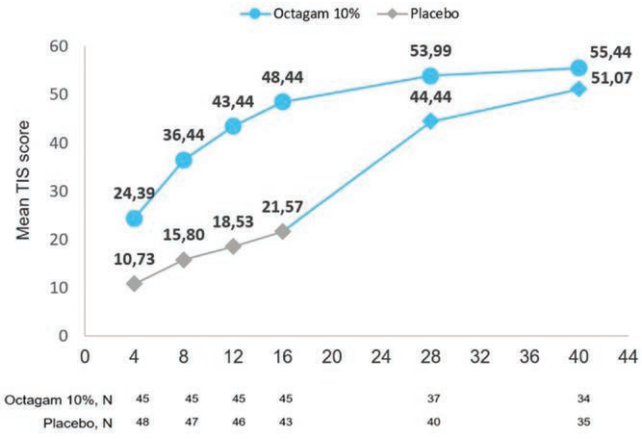

Figure 1.

After switching to IVIG in the Extension Period the placebo group attained a similar response rate at Week 40 as did the IVIg treated patients at Week 16, i.e approx. 70% for minimal improvement.
In line with the overall primary endpoint, secondary end points including all of the sub-components of TIS except muscle enzyme (MMT-8, MD global, Extramuscular global, patient global, HAQ,) as well as CDASI (Cutaneous Dermatomyositis Disease Area and Severity Index), also showed statistically significant improvement under IVIg treatment compared to placebo treatment.
The safety and tolerability profile of IVIg was consistent with previously reported safety outcomes for IVIg administration.
Conclusion: This is the first large international phase III randomized, placebo-controlled trial demonstrating the efficacy and safety of IVIg as a treatment for patients with DM.

SUCCESSFUL PATIENT EDUCATION ON COVID-19 VACCINE SAFETY IN A LARGE RHEUMATOLOGY COHORT USING INTERACTIVE MOBILE-PHONE VIDEO TECHNOLOGY: CONTEXT, RESULTS, AND NEXT STEPS

L. Rajagopala[1], M. Ford[1], M. Jasim[1], D. Mulherin[1], S. Venkatachalam[1], T. Sheeran[1], J. Bateman[1]. [1]*The Rheumatology Centre,Cannock Wolverhampton,The Royal Wolverhampton NHS Trust,UK, Rheumatology, Wolverhampton, United Kingdom*

Background: There are reported concerns of patient misunderstanding of the COVID-19 pandemic and vaccination safety. It is particularly important that these are understood in patients taking complex immunusuppressive therapies. Rapid delivery of targeted and up-to-date video messages from clinicians sent directly to patients could address patient uncertainty, and improve COVID-19 vaccination uptake. Innovative SMS (short message service) based video message has already shown promise in delivering COVID-19 information to patients [1]. We present our experience in creating a tailored vaccine information video sent directly to our large cohort of patients in the UK with a range of rheumatic diseases and report on the learning points going forward.
Objectives: Our three objectives were: (1) educate our patients using an interactive mobile video information resource outlining the safety of the COVID vaccination in these patient groups; (2) better understand our patients' views of the COVID-19 vaccine; (3) evaluate the patient experience of this approach.
Methods: We designed and recorded an 8-minute interactive web-based video delivered education resource designed for mobile phones. This included: aims of the video; details of licenced vaccines; UK vaccination schedule; frequently asked questions; links to national charity resources; our clinician recommendations; a rheumatologist being vaccinated; case studies; and summary data. We produced a simple mobile phone web-based evaluation of the resource, including anonymised patient demographics, their understanding of the safety of the vaccine pre/ post video, and their user experience. Resource and evaluation were piloted by local healthcare professionals, our Patient Participation Group, a national charity, and approved by senior management. We distributed this to our follow-up patient cohort via our hospital SMS provider on 21.12.20, at the start of roll-out of UK vaccines, containing a link to the resource and evaluation.
Results: Of a cohort of 10,981 patients, we had 8886 mobile phone numbers. At Day 14, we recorded 2358 video views (26.3%) and 664/2358 completed evaluations (28.1%). Only one person reported being unable to watch the video. Before watching the video, 348/664 patients (52.4%) were unsure if the vaccine was safe and/or recommended for them, rising to 626/664 (94.3%) post-video. Reasons for uncertainty after the video (38/664) included drug allergy and fertility concerns. Following the video, 509/664 patients (76.6%) reported that they were more likely to have the vaccination. The majority of the patients (614/660, 93.0%)

agreed that the method was a helpful method to share such information.Age distribution of our whole cohort, patients with mobile phones, and responders were similar: Age >50 was 80.4%,76.3%,and 88.6% respectively. A large proportion was treated with immunosuppressive medication (61.3% conventional DMARD, 39.4% biological DMARD and 17.6% corticosteroids). Gender and case mix for responders were similar to published data from our cohort: female 74.0%; rheumatoid arthritis commonest disease (389/664, 58.5%).

Conclusion: To our knowledge, this is the first study to show the potential for SMS linked interactive multimedia message for patient education. The multimedia component allows users to easily navigate to relevant sections, and access a choice of linked resources. We demonstrate this low-cost technology is simple, effective and well placed to assist physicians in educating patients during a time when face-to-face contact is proving to be difficult. We have shown high levels of patient satisfaction, reassurance, and self-reported behaviour change. Such technology has potential utility for national bodies, primary and secondary care groups, and merits further research.

Background: Although causality remains to be established, targeting dysbiosis of the intestinal microbiota by faecal microbiota transplantation (FMT) has been proposed as a novel therapeutic option for treatment of extra-intestinal inflammatory diseases.[1]

Objectives: In this proof-of-concept study, we evaluated efficacy and safety of FMT in psoriatic arthritis (PsA).[2]

Methods: In this double-blind, parallel-group, sham-controlled, superiority trial, we randomly allocated (1:1) adults with active peripheral PsA (≥3 swollen joints) despite ongoing treatment with methotrexate to one gastroscopic-guided FMT or sham transplantation into the duodenum. The transplants (50 g faeces) came from one of four healthy, thoroughly screened, anonymous stool donors.3 The primary efficacy endpoint was the proportion of participants experiencing treatment failure (i.e., needing treatment intensification) through 26 weeks. The first key secondary endpoint was change in Health Assessment Questionnaire Disability Index (HAQ-DI) score from baseline to week 26. Safety was monitored throughout the trial. Trial registration number: NCT03058900, ClinicalTrials.gov.

Results: Of 97 screened, 31 (32%) underwent randomisation (15 allocated to FMT), all received the assigned intervention, and 30 (97%) completed the 26-week clinical evaluation (Table 1). Treatment failure occurred more frequently in the FMT group than in the sham group (9 [60%] vs 3 [19%]; risk ratio, 3.20; 95% CI, 1.06 to 9.62; P=0.018). During the entire 26 weeks of observation, the rate of the treatment failures was significantly higher in the FMT than in the sham group, see figure 1. Improvement in HAQ-DI score differed between groups (0.07 vs 0.30) by 0.23 points (95% CI, 0.02 to 0.44; P=0.031) in favour of sham. No serious adverse events were observed.

Conclusion: In this first interventional randomised controlled trial of FMT in immune-mediated arthritis, FMT was inferior to sham in treating active peripheral PsA. FMT did not appear to result in serious adverse events.

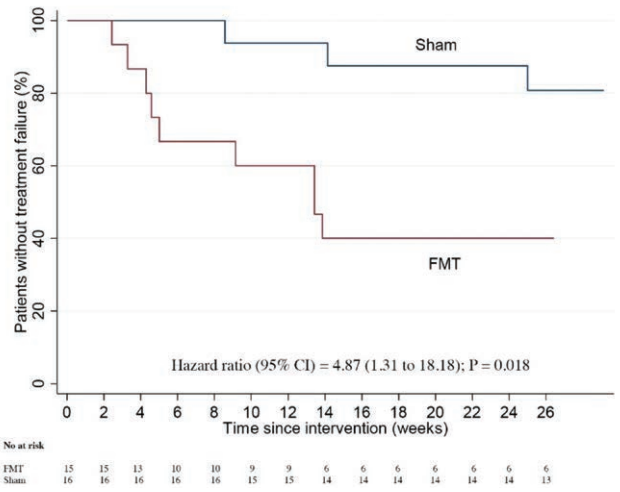

Figure 1. Time-to-event curves by intervention group from baseline to week 26.FMT, faecal microbiota transplantation.

Table 1. Baseline demographics and disease characteristics.

Characteristic	FMT (n=15)	Sham (n=16)
Female sex, no. (%)	8 (53%)	12 (75%)
Age, yr.	48.9 (16.1)	52.4 (11.0)
Height, cm	175.2 (7.0)	169.8 (8.6)
Weight, kg	93.6 (15.4)	92.4 (24.8)
Time since diagnosis, yr.[a]	2.6 (0.3 to 5.8)	5.6 (0.5 to 8.8)
Rheumatoid factor IgM negative, no. (%)[b]	13 (93%)	15 (94%)
Anti-citrullinated peptide antibody negative, no. (%)[b]	14 (100%)	16 (100%)
HLA-B27 negative, no. (%)	15 (100%)	13 (81%)
C-reactive protein, mg/L	4.98 (7.18)	5.54 (5.87)
HAQ-DI	0.89 (0.51)	0.78 (0.50)
Swollen joint 66 count	7.5 (3.0)	6.7 (2.7)
Tender joint 68 count	14.9 (8.9)	17.3 (8.8)
SPARCC enthesitis index		
Score ≥1, no. (%)	13 (87%)	15 (94%)
Score in patients with a score ≥1	8.1 (4.3)	7.2 (3.3)

Data are mean (SD) or n (%) unless otherwise stated.FMT, faecal microbiota transplantation.[a] Time since diagnosis of psoriatic arthritis is presented as median and interquartile range (IQR).[b] Presence of rheumatoid factor (IgM) and anti-citrullinated peptide antibody was not accessed in one patient from the FMT group.

INTEGRATION OF FLOW AND DIGITAL CYTOMETRY IN EARLY TREATMENT-NAÏVE RHEUMATOID ARTHRITIS IDENTIFIES DISTINCT IMMUNOPHENOTYPES IN PERIPHERAL BLOOD AND DISEASE TISSUE

F. Rivellese[1,2], E. Pontarini[1], L. Fossati-Jimack[1], R. A. Moura[3,4], V. C Romão[3,4], J. E. Fonseca[3,4], A. Nerviani[1,2], C. Cubuk[1], K. Goldmann[1], M. Bombardieri[1,2], M. Lewis[1,2], C. Pitzalis[1,2]on behalf of Pathobiology of Early Arthritis Cohort (PEAC) investigators. [1]*William Harvey Research Institute, Centre for Experimental Medicine and Rheumatology, London, United Kingdom*; [2]*Barts Health NHS Trust, Department of Rheumatology, London, United Kingdom*; [3]*Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon Academic Medical Centre, Department of Rheumatology, Lisbon, Portugal*; [4]*Instituto de Medicina Molecular, Faculdade de Medicina, Rheumatology Research Unit, Lisbon, Portugal*

Background: The study of synovial tissue in patients with Rheumatoid Arthritis (RA) has led to the identification of synovial patterns of immune cell infiltration and specific cellular subsets associated that have been disease activity and clinical outcomes(*1–3*). However, the relationship of circulating and synovial immune cell sub-sets with histopathological features and clinical outcomes remains to be defined.

Objectives: To assess the relationship of peripheral blood and synovial immune cells with RA histopathology and clinical outcomes, by performing flow and digital cytometry in matched peripheral blood and synovial samples from patients with early RA.

Methods: 70 patients with early (<12 months) untreated RA (2010 criteria) recruited in the pathobiology of early Arthritis Cohort (PEAC) at the Barts Health NHS Trust were included(*1*). Peripheral blood mononuclear cells (n=70) were analysed by flow cytometry. Matched synovial tissues (n=70) obtained by minimally invasive ultrasound-guided synovial biopsy underwent semi-quantitative scoring (0-4) of immune cell infiltration and classification into lympho-myeloid (LM), diffuse-myeloid (DM) and pauci-immune (PI) pathotypes, as previously described(*1*). 49 synovial and 36 matched peripheral blood samples underwent RNA-sequencing and were analysed by digital cytometry (Xcell) (*4*) and Singular Value Decomposition (SVD).

Results: Circulating B cells and their subsets showed significant inverse correlations with inflammatory markers (ESR, CRP), disease activity (swollen joints, four components and two components(*5*) DAS28) and ultrasound scores (Fig 1A). Among T cell subsets, CXCR5-PD1hiICOS+CD4+ T cells (T peripheral helper cells, Tph) had strong positive correlations with inflammatory markers (ESR and CRP), disease activity (DAS28) and ultrasound scores (Fig 1B). Tph in the peripheral blood also correlated with immune cell infiltration in synovia (Fig 1C) and were significantly higher in patients with a LM pathotype (Fig 1D). Accordingly, circulating Tph were associated with synovial LM pathotype independently of clinical features such as DAS28, ACPA positivity, Body Mass Index (BMI) and age (AUC 0.821). By applying digital cytometry in matched synovial and peripheral blood samples, synovial B and T cells were significantly higher in patients with a LM pathotype, in line with the histological definition of the LM pathotype – rich in B and T cells. On the contrary, circulating B cells and total CD4 and CD8 T cells were significantly lower in patients with a synovial LM pathotype (Fig 1E). The Tph signature in synovia derived by Singular Value Decomposition (SVD) correlated with baseline ESR (R 0.38, p<0.0001) and DAS28 (R 0.35, p <0.0001) and with delta-DAS28 after 6 months of treatment with conventional synthetic DMARDs (R 0.27, p 0.026). Finally, the baseline synovial Tph signature was significantly higher in patients who progressed to the use of biologics and was predictive of future biologic DMARDs use, independently of baseline DAS28, ACPA positivity, BMI and age (AUC 0.703).

Conclusion: By combining conventional flow cytometry in the peripheral blood and digital cytometry on matched synovial and peripheral blood samples, we highlight diverging associations of circulating immune cell subsets with synovial inflammation and pathotypes. Tph cells, in particular, emerge as predictors of lympho-myeloid synovial inflammation and disease progression.

ASSOCIATION BETWEEN PASSIVE SMOKING IN CHILDHOOD AND ADULTHOOD, AND RHEUMATOID ARTHRITIS: RESULTS FROM THE FRENCH E3N-EPIC COHORT STUDY

Y. Nguyen[1,2], C. Salliot[2,3], X. Mariette[4,5], M. C. Boutron-Ruault[2], R. Seror[4,5]. [1]*AP-HP.Nord - Hôpital Beaujon, Department of Internal Medicine, Clichy, France*; [2]*Centre for Research in Epidemiology and Population Health (CESP), Université Paris Sud, INSERM U1018, Villejuif, France*; [3]*Centre Hospitalier Régional D'Orléans, Department of Rheumatology, Orléans, France*; [4]*AP-HP Hôpital Bicêtre, Department of Rheumatology and National Reference Center for Rare Systemic Autoimmune Diseases, Le Kremlin-Bicêtre, France*; [5]*Université Paris Sud - Faculty of Medicine, INSERM UMR1184, Le Kremlin-Bicêtre, France*

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease of multifactorial aetiology, which preferentially affects women. To date, active smoking has been the most reproducibly reported risk factor for anti-citrullinated protein antibodies (ACPA) positive RA, particularly persons who carry the HLA-DRB1-shared epitope (SE) alleles.

Objectives: We aimed to investigate the relationships between passive smoking in childhood (PSc) or in adulthood (PSa), and the risk of incident RA in a large prospective cohort of healthy French women.

Methods: The E3N-EPIC (*Etude Epidémiologique auprès des femmes de la Mutuelle générale de l'Education Nationale*) is a French prospective cohort study that investigates environmental factors associated with chronic diseases. It follows 98,995 healthy French women since 1990 covered by a national health insurance primarily involving teachers. RA cases have been previously identified with specific questionnaires and medication reimbursement database. Women were considered exposed to PSc if they self-declared staying in a smoky room several hours a day during childhood, and to PSa if they self-declared being exposed at least one hour a day to passive smoking while adults. We used Cox multivariable regression models with age as the timescale (model 1), adjusted on smoking status (never, current, or former smoker) and on the two types of passive smoking (model 2), and on educational level, and BMI (model 3). Stratified analyses were conducted depending on the active smoking status (never or ever-smoker).

Results: 79,806 women were included in the study. Mean (± SD) age at cohort entry was 49.0 (± 6.4) years. Among them, 698 incident RA cases were identified, diagnosed after a mean of 11.7 (± 5.8) years after baseline. In the whole cohort, 10,810 (13.5%) women were exposed to PSc, 42,807 (53.6%) to PSa, 6,581 (8.25%) were exposed to both, and 47,036 (58.9%) were exposed to either. In the whole population, PSc was positively associated with the risk of RA in all three models (HR 1.24; 95% CI [1.01 to 1.51] in Model 3). In stratified analyses

on smoking status, PSc was associated with RA among never-smoking women (HR 1.42; 95% CI [1.07 to 1.88]), but not among ever-smoking women (HR 1.10; 95% CI [0.83;1.46]).
In the whole population, PSa was also positively associated with the risk of RA in all three models (HR 1.19; 95% CI [1.02 to 1.40] in Model 3). In stratified analyses on the smoking status, PSa was associated with an increased RA risk only among never-smoking women (HR 1.27; 95% CI [1.02 to 1.57]) and not among ever-smoking women (HR 1.16; 95% CI [0.93;1.44]).
Conclusion: In this large population-based prospective cohort study of French women, we reported that passive exposure to smoking during childhood or adulthood increased the risk of RA. The association was principally observed among never smoking women. These results suggest that smoking by-products, whether actively or passively inhaled absorbed, could generate autoimmunity, at least towards antigens involved in RA pathogenesis.

OP0013 **SEX DIFFERENCES IN AUTOIMMUNE DISEASE SUSCEPTIBILITY; A MULTI-OMIC APPROACH**

G. Robinson[1,2], K. Waddington[2], J. Peng[1], A. Radziszewska[1], H. Peckham[1], D. Isenberg[1,2], Y. Ioannou[2], I. Pineda Torra[3], C. Ciurtin[1], E. Jury[2]. *[1]University College London, Centre for Adolescent Rheumatology Versus Arthritis London, London, United Kingdom*; *[2]University College London, Rheumatology, London, United Kingdom*; *[3]University College London, Centre for Cardiometabolic and Vascular Science, London, United Kingdom*

Background: Males and females have altered immune responses resulting in variation in autoimmune and cardiovascular disease risk (CVR). Recently, these differences have played a role in the inflammatory response to COVID-19. Sex differences exist in the frequency and activity of immune-cell subsets but mechanisms underlying sexual dimorphism remain unknown. Juvenile-onset systemic lupus erythematosus (JSLE) is an autoimmune disorder that commonly emerges during puberty, has a strong female prevalence (female:male ratio, 4.5:1) and results in an increased CVR. JSLE is characterised by chronic inflammation and dyslipidaemia, where cardiovascular disease is a leading cause of mortality for patients. Our previous work identified a link between immune cell function and lipid metabolism in adult-onset SLE. We hypothesised that sex hormones could influence both lipid metabolism and immune cell function and this could determine sex-specific susceptibility to JSLE and associated CVR.
Objectives: We investigated the role of sex hormones in modifying systemic lipid metabolism and inflammation.
Methods: Nuclear magnetic resonance spectroscopy based serum metabolomics measuring over 130 lipoproteins (14-subsets with lipid compositions), flow cytometry measuring immune-cells, and RNA-sequencing were used to assess the metabolic and immune profile in young, pre/post-pubertal males (n=10/17) and females (n=10/23) and in individuals with gender-dysphoria (GD) under cross-hormone treatment (trans-male/female, n=26/25). This analysis was also performed on a cohort of post-pubertal male (n=12) and female (n=23) JSLE patients. Data was analysed by logistic regression, balanced random forest machine learning (BRF-ML), differential gene expression (DEG) and pathway analysis.
Results: Post-pubertal males had significantly reduced cardio-protective high-density lipoprotein (HDL) subsets ($p<0.0001$) and increased cardio-pathogenic very-low-density lipoprotein subsets ($p<0.0001$) compared to females. These differences were not observed pre-puberty and were reversed significantly by cross-hormone treatment in GD individuals, suggesting that sex hormones regulate lipid metabolism *in-vivo*.
BRF-ML (28 immune-cell subsets) identified an increased frequency of anti-inflammatory regulatory T-cells (Tregs) in post-pubertal males compared to females ($p=0.0097$). These Tregs were also more suppressive in males compared to females. Differences in Treg frequency were seen pre-puberty and were not altered by sex hormone treatment in GD individuals. However, Treg DEGs and functional transcriptomic pathways altered between post-pubertal males and females, including those involved in inflammatory signalling, overlapped with those altered by hormones in GD, suggesting hormones may also drive Treg functional changes. In addition, HDL metabolites modified by hormones showed differential associations with Treg phenotypes between post-pubertal males and females.
Strikingly, sex differences in lipoproteins and Tregs were lost in JSLE, suggesting hormone signalling could be dysregulated in the pathogenesis of autoimmunity and could increase CVR for patients.
Conclusion: Sex hormones drive altered lipoprotein metabolism and functional transcriptomic pathways in Tregs. Males have a lipoprotein profile associated with increased CVR, but a more anti-inflammatory immune profile compared to females. Together, this could explain sex differences in inflammatory disease susceptibilities and inform future sex-specific therapeutic strategies for the management of both JSLE and CVR.

Genomics, genetic basis of disease and functional genomics

OP0014 **HLA ASSOCIATIONS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS ASSOCIATED UVEITIS AND CLINICAL SUBTYPES**

M. Tordoff[1], S. Smith[1], E. Lopez Isac[1], A. Morris[1], S. Eyre[1,2], W. Thomson[1,2], J. Bowes[1,2]on behalf of Centre for Genetics and Genomics Versus Arthritis.. *[1]The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom*; *[2]National Institute of Health Research Manchester Biomedical Research Centre, Manchester Academic Health Science Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom*

Background: Juvenile idiopathic arthritis (JIA) is a childhood onset rheumatic disease which is classified into seven different clinical subtypes based upon the ILAR classification criteria. The most common extra articular manifestation of JIA is its associated uveitis (JIAU); particularly chronic anterior uveitis (CAU). Uveitis is a serious complication with the potential to lead to visual impairment and blindness. The rheumatoid factor negative polyarthritis and oligoarthritis ILAR subtypes, often referred to as the "polygo" subgroup, are at a higher risk for developing JIAU, with up to 30% of polygos afflicted by CAU. The HLA region has long been reported as a genetic risk factor for JIA susceptibility, with evidence suggesting that different amino acids of HLA genes infer risk to different JIA subtypes.
Objectives: Investigate the association of amino acids and genetic variants in the HLA region with susceptibility to JIAU and the ILAR clinical subtypes.
Methods: Samples were genotyped using the Illumina Infinium CoreExome and Infinium Onmiexpress arrays. Samples were excluded based on <98% call rate, discrepancy between genetically inferred sex and database records, inferred relatedness (identify-by-descent) and ancestral outliers based on principal component analysis (PCA). SNPs were excluded based on <0.01 minor allele frequency (MAF), and call rate <98%. SNP2HLA was used to impute HLA amino acids, SNPs and alleles. Analysis was then executed on markers with an information score >0.9 and MAF >.01 using logistic regression or an omnibus test for multiallelic markers, including 3 PCs as covariates. Independent associations were identified using forward stepwise logistic regression including previously identified variants as covariates. Comparison of regression models was performed using a likelihood ratio test (LRT).
Results: We analysed 7425 markers within the HLA region in 450 JIAU and 2024 JIA cases without uveitis. The most significant association was to amino acid positions 13 of HLA-DRB1 ($p=2.9\times10^{-30}$). Conditional analysis on DRB1 position 13 revealed an independent signal at DRB1 position 67 ($p=2.4\times10^{-6}$). Conditioning on all DRB1 alleles revealed an independent signal at HLA-DPB1 position 69 ($p=5.3\times10^{-7}$). As expected, ILAR subtype was found to be associated with JIAU ($p=1.58\times10^{-6}$). We used LRT to test if genetics provided further information above ILAR subtype alone and found that including residues at DRB1 position 13 significantly improved the fit of a model based on ILAR subtype alone (LRT $p = 3.6\times10^{-27}$). The reciprocal analysis, adding ILAR subtype to a model based on DRB1 position 13 alone, did not significantly improve the fit of a model (LRT $p=0.83$). Exploring associations in the polygo subgroup (n=1646) we found significant associations to the three previously described amino acids and JIAU (DRB1 position 13 $p=3.4\times10^{-20}$, DRB1 position 67 $p=3.3\times10^{-4}$, DPB1 position 69 $p=2.2\times10^{-6}$).
Conclusion: This is largest analysis of HLA markers in JIAU patients to date and we identify two independent associations to amino acids in HLA-DRB1 and a further independent association to HLA-DPB1. This analysis demonstrates that including data on genetic risk factors adds further information to that captured

by ILAR subtype alone. It also reveals that the previously validated associations at position 13 of HLA-DRB1 are also correlated with JIAU in the polygo subtype suggesting that genetic risk factors will help refine risk within clinical subtypes. Conditioning on DRB1 alleles reveals that the secondary independent DRB1 position 69 association is also strongly associated in the polygo subset of this cohort. Together these results highlight the potential future use of genetics risk factors for risk classification for uveitis in patients with JIA

OP0015 GENOMIC RISK SCORE FOR ADVANCED OSTEOARTHRITIS IN OLDER ADULTS

P. Lacaze[1], G. Polekhina[1], A. Bakshi[1], M. Riaz[1], A. Owen[1], A. Franks[1], Y. Wang[1], J. Abidi[2], J. Tiller[1], S. Orchard[1], J. Mcneil[1], F. Cicuttini[1]. *[1]Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia*; *[2]Alfred Hospital, Department of Medicine, Melbourne, Australia*

Background: Osteoarthritis (OA) is a major cause of disability, with treatment options mostly limited to advanced disease when joint replacement is indicated. Recent genome-wide association analysis more than doubled the number of OA-associated variants identified (1, 2), extending the feasibility of identification of high-risk individuals.

Objectives: Including these variants, we calculated polygenic risk scores (PRSs) and performed validation in a well-characterised population of older individuals.

Methods: We calculated PRSs for knee and hip OA respectively, using joint replacement surgeries as markers of advanced disease in 12,724 older individuals of European descent in the ASPREE trial. We considered in-trial joint replacement (hospitalizations during median 4.7 years follow-up) and pre-trial joint replacement from self-reported medical history. Multivariable models examined the effect of PRS as a continuous variable (per standard deviation [SD]) and categorical variable (low-risk [0-20%], medium-risk [21-80%], high-risk [81-100%] groups), adjusting for age, sex and BMI.

Results: Mean population age at baseline was 75 years and 54.9% of participants were female. In total, 1478 (11.6%) participants had knee replacements and 1324 (10.4%) had hip replacements. Female sex, higher BMI and age were associated with higher risk of knee and hip replacements. PRSs as continuous variables per SD were associated with knee (odds ratio [OR] 1.11, 95% confidence interval [CI] 1.04-1.17) and hip (OR 1.18, 95% CI 1.11-1.25) replacements. We found meaningfully different rates of knee or hip joint replacement occurring between low-, medium- and high-risk PRS groups. Participants in the high-risk PRS group, compared with the low, had a higher risk of knee replacements (OR=1.35, CI 1.12-1.62), and hip replacements (OR 1.66, 95% CI 1.37-2.02). We found no interaction between PRS and sex, and no collinearity between PRS and BMI, suggesting PRS is an independent risk factor for OA.

Conclusion: Joint-specific genomic risk scores predict advanced OA in older adults, independent of age, sex and BMI. Stronger associations are observed for hip versus knee OA. Our study provides some of the first evidence of potential clinical utility of genomic risk prediction for OA, which may help identify individuals who would benefit most from targeted clinical management and preventive intervention.

OP0016 IDENTIFICATION OF FUNCTIONAL VARIANTS IN THE RHEUMATOID ARTHRITIS ASSOCIATED JAZF1 LOCUS IN SYNOVIAL FIBROBLASTS

M. Houtman[1], X. Ge[2], A. Mcgovern[2], K. Klein[1], G. Orozco[2], M. Frank Bertoncelj[1], M. Marks[3], O. Distler[1], P. Martin[2], S. Eyre[2], C. Ospelt[1]. *[1]University Hospital Zurich, University of Zurich, Center of Experimental Rheumatology, Department of Rheumatology, Zurich, Switzerland; [2]The University of Manchester, Versus Arthritis Centre for Genetics and Genomics, School of Biological Sciences, Faculty of Biology, Medicine and Health, Manchester, United Kingdom; [3]Schulthess Klinik, Department of Teaching, Research and Development, Zurich, Switzerland*

Background: Over the past decade, genome wide association studies (GWAS) have identified the *JAZF1* locus as a risk locus for several autoimmune diseases, including rheumatoid arthritis (RA)[1]. However, the exact causal variants in the *JAZF1* locus and their underlying regulatory events contributing to RA are still not known. Here, we focus on the effect of these variants on gene expression in synovial fibroblasts (SF).

Objectives: To characterize the functional consequences of RA-causal variants in the *JAZF1* locus in SF.

Methods: Genetic fine-mapping of RA loci was conducted by computing sets of credible variants driving GWAS signals. These credible variant sets were integrated with DNA architecture (ChIP-seq), 3D chromatin interactions (3C, HiC and capture HiC), DNA accessibility (ATAC-seq) and gene expression (RNA-seq and CAGE-seq) datasets to select putative RA-causal variants in SF. Selected variants in the *JAZF1* locus were tested for regulatory function by luciferase reporter assays and electrophoretic mobility shift assays (EMSA) in the fibrosarcoma cell line HT1080. The JASPAR2020 database was used to identify putative transcription factors (TF) binding to the selected variants. The expression of *HOTTIP* was measured by quantitative PCR in hand SF (n=23). Genotyping was done by pyrosequencing.

Results: Genetic fine mapping revealed 47 variants in the *JAZF1* locus. Integration of these variants with the chromatin datasets prioritized rs2158624, rs57585717 and rs186735625 as the top candidates (posterior probability of causality >0.1) in the *JAZF1* locus. We found that rs2158624 and rs186735625 are located in the vicinity of enhancer elements in SF as determined by ATAC-seq. In addition, the region of rs2158624 exhibited strong chromatin interactions with the genomic region of *HOTTIP* and *HOXA13*. Both these transcripts were previously shown to be specifically expressed in SF isolated from hands and feet[2]. Based on this, we selected rs2158624 as the most promising candidate in the *JAZF1* locus. We found that the rs2158624-C allele (risk) is associated with lower expression of *HOTTIP,* but not *HOXA13*, in hand SF compared to the rs2158624-T allele (non-risk) (p=0.02). Luciferase assays in HT1080 cells demonstrated enhancer activity with both the rs2158624-C allele (p=0.006) and T allele (p=0.04), with no significant difference in enhancer activity between the rs2158624-C and T allele. EMSAs identified stronger specific binding of HT1080-cell nuclear extract for the rs2158624-T allele than for the C allele (risk). Based on the JASPAR2020 database, we identified NFAT5 as a potential TF that can bind to rs2158624 and may regulate the expression of *HOTTIP*.

Conclusion: We were able to substantially narrow down the potential functional variants in the *JAZF1* locus using our data integration approach and functional assays. We suggest that the risk allele of rs2158624 influences the binding of TFs controlling the expression of the long non-coding RNA *HOTTIP* in SF, which might confer specific risk to develop RA in hands.

Background: The interplay between genetics and drug response in rheumatoid arthritis (RA) has shown that response to biologics varies between individuals and that a large proportion of patients show no clinical improvement (Plenge and Bridges, 2011). Despite the disappointing scenario, to date, only a few genetic markers have been consistently identified and we are far from being able to optimize drug dosing or prioritize drug combinations based on genetic findings.
Objectives: With this background, we sought to validate the association of GWAS-identified variants for response to TNF inhibitors (TNFi) in a two-stage case control association study and to shed some light into the functional role of the most interesting markers.
Methods: The discovery population consisted of 1361 RA patients ascertained through the REPAIR consortium and the DANBIO registry. RA patients fulfilled the 1987 revised American College of Rheumatology (ACR) and the ACR/EULAR 2010 classification criteria. The validation cohort included 706 Dutch RA patients from the DREAM registry. The study followed the Declaration of Helsinki and study participants gave their written informed consent to participate in the study, which was approved by the ethical review committee of participant institutions. Twenty-seven single-nucleotide polymorphisms (SNPs) were selected through a literature search of relevant GWAS. Linear regression analysis adjusted for age, sex and country of origin was used to determine the association between GWAS-identified SNPs and changes in DAS28 (ΔDAS28) after 3 or 6 months of treatment. The meta-analysis of both populations was performed using a fixed effect model. Correction for multiple testing was performed using the Bonferroni method but also considering the number of inheritance models tested (P=0.0009). To assess the role of the most interesting markers in modulating immune responses, stimulation experiments in whole blood, peripheral mononuclear cells (PBMCs) and monocyte-derived macrophages using a large number of pathogens and microbiome bacteria were performed in 408 subjects from the Human Functional Genomic Project cohort. We also evaluated the correlation of these SNPs with plasmatic levels of 108 inflammatory proteins, 7 serum steroid hormones and counts of 91 blood-derived immune cell populations.
Results: The meta-analysis of the discovery cohort and DREAM registry including 2067 RA patients treated with TNFi revealed an overall association of the $LINC02549_{rs7767069}$ SNP with a decreased drop in DAS28 that remained significant after correction for multiple testing (per-allele OR_{Meta}=0.83, P_{Meta}=0.000077; P_{Het}=0.61). In addition, the meta-analysis of these large cohorts showed that each copy of the $LARRC55_{rs717117G}$ allele significantly decreased the drop in DAS28 in RF-positive patients (per-allele OR_{Meta}=0.67, P=0.00058; P_{Het}=0.06) whereas an opposite but not significant effect was found in RF-negative subjects (per-allele OR_{Meta}=1.38, P=0.10; $P_{Interaction}$=0.00028; P_{Het}=0.45). Interestingly, the meta-analysis also showed potentially interesting but not statistically significant overall and RF-specific associations for the $MAFB_{rs6071980}$ and $CNTN5_{rs1813443}$ SNPs with ΔDAS28 (per-allele $OR_{Meta_rs6071980}$=0.84, P=0.0059; P_{Het}=0.63 and $OR_{Meta_rs1813443_RF+}$=0.81, P=0.0059; P_{Het}=0.69 and $OR_{Meta_rs1813443_RF-}$=1.00, P=0.99; P_{Het}=0.12; $P_{Interaction}$=0.032). Although analysis of functional data is ongoing, so far, we found that carriers of the $LARRC55_{rs717117G}$ allele showed decreased levels of IL6 after stimulation of PBMCs with *Borrelia burgdorferi* and *Escherichia Coli* bacteria (P=0.00046 and 0.00044), which suggested a reduced IL6-mediated anti-inflammatory effect of this marker to worsen the response to TNFi.
Conclusion: This study confirmed the influence of the *LINC02549* and *LARRC55* loci to determine the response to TNFi in RA patients and a weak effect of the *MAFB* and *CNTN5* loci that needs to be further investigated.

OP0018 PREDICTING RESPONSES TO ANTI-TNF TREATMENTS IN RHEUMATOID ARTHRITIS PATIENTS FROM GENETIC AND CLINICAL DATA USING A MACHINE LEARNING APPROACH

S. Ju[1], M. Hudson[2], I. Colmegna[3], S. Bernatsky[3], Y. LI[1]. *[1]McGill University, School of Computer Science, Montréal, Canada*; *[2]Jewish General Hospital, Rheumatology, Montréal, Canada*; *[3]MUHC Research Institute, Medicine, Montréal, Canada*

Background: Tumor necrosis factor (TNF) inhibitors are key therapies in rheumatoid arthritis (RA). However, a third of patients fail to respond to these agents, and there are no reliable predictors for response. Predictive models, potentially based on clinical and genomic data, are vital to personalizing therapy. The Dialogue for Reverse Engineering Assessments and Methods (DREAM) RA Responder Challenge invited research teams to create models for patient response to anti-TNF therapy. The winning model relied heavily on limited genetic input and was unable to correctly predict responses in a large number of individuals.
Objectives: We compared non-linear and linear analytic methods to predict response and non-response to anti-TNF treatment for RA patients in the DREAM database, using moth clinical variables and a large number of potential genome-wide predictors.
Methods: DREAM data on anti-TNF treated RA patients were accessed through Synapse (synapse.sagebase.org). Analogously to the DREAM challenge, we were provided with the clinical and genomic data of 2706 patients with at least moderate disease activity according to their composite disease activity scores for 28 joints (DAS28). In contrast to the previous analysis that focused on single nucleotide polymorphisms (SNPs) based on existing knowledge of RA, we used the full genome-wide dataset of 2.5 million SNPs. We first reduced this to 284 SNPs by considering the marginal p-value of 0.001 for each SNP based on whether or not it predicted response. Then, we removed SNPs with borderline significant p-values if they were in linkage disequilibrium with the most significant SNPs. Instead of predicting a binary outcome of responder or non-responder, we trained both linear (e.g. least absolute shrinkage and selection operator, or LASSO) and non-linear models (e.g. Random Forest) to predict a continuous outcome, the change in DAS28 from baseline to 3-12 months after initiation of anti-TNF therapy. We split the patients into training (N=2031) and testing (N=675) subsets and used the predicted response scores to evaluate the true binary response labels for the test patients.
Results: The best performing method was Random Forest (RF), a non-linear model that uses decision trees to progressively separate subjects into groups based on the most predictive features. Support Vector Regression (SVR) also out-performed linear methods. Compared to only clinical covariates such as age and sex, adding SNPs improved the prediction from an area under the receiver operating curve (AUROC) of 0.63 to 0.67, i.e., 0.04 improvement. This AUROC of 0.67 was 0.046 greater than the DREAM challenge winner.
Conclusion: Non-linear methods such as RF and SVR gave larger predictive improvements compared to linear methods. This may imply some interaction between SNPs and clinical covariatesas potential predictors of response to anti-TNF therapy in RA. We are further investigating these 284 SNPs and their interactions in this regard.

Background: Systemic Lupus Erythematosus (SLE) is characterized by lack of treatment diversity, largely empirical treatment decisions, and paucity of novel compound development.
Objectives: We sought to stratify SLE patients based on their molecular phenotype and predict personalized therapeutic compounds, tailored to the molecular fingerprint of each subgroup.
Methods: We performed a co-expression analysis using our publicly available whole blood RNA-seq data of 120 SLE patients. Modules of commonly regulated genes were established and used to re-stratify patients through hierarchical clustering, in a data-driven, clinically independent, manner. Next, we established an in silico, subgroup signature-based, drug prediction pipeline. Investigated drugs included both those currently in practice and those who have been tested in SLE clinical trials and are listed in the iLINCS prediction databases. Finally, drug repurposing analysis was performed, to identify novel perturbagens that counteract group-specific SLE signatures.
Results: Molecular taxonomy identified five distinct lupus molecular endotypes, each characterized by a unique gene module enrichment pattern. A group defined by strong neutrophilic signature encompassed almost exclusively patients with active nephritis, while a B-cell expression group included patients with severe lupus phenotype. Metabolic processes enrichment defined a group of patients with disease of moderate severity and serologic activity. Finally, patients with mild lupus features were distributed in two groups, which demonstrated enhanced basic cellular functions, myelopoiesis, and autophagy. The ability of different compounds to reverse the transcriptomic aberrancies observed in each patient group was examined. Bortezomib efficiently reversed disturbances in the "neutrophilic" cluster. Azathioprine and ixazomib might be a reasonable option for patients of the "B-cell" cluster, whereas fostamatinib appeared efficacious for the "Metabolism" patient subgroup.
Conclusion: The clinical spectrum of SLE encompasses distinct molecular endotypes, each defined by unique pathophysiologic aberrancies, which can be utilized to guide personalized care and direct novel compound development.

OP0020 HOMEOBOX D TRANSCRIPTION FACTORS SHAPE DIFFERENTIAL JOINT ENVIRONMENT BETWEEN ANTERIOR FINGER JOINTS AND THUMB

M. Mirrahimi[1], K. Klein[1], M. Houtman[1], M. Maciukiewicz[1], M. Frank Bertoncelj[1], A. Juengel[2], M. Berli[3], M. Marks[4], O. Distler[1], C. Ospelt[1]. [1]*University Hospital of Zürich, Department of Rheumatology, Zürich, Switzerland*; [2]*Universitätsklinik Balgrist, Research Rheumatology, Zürich, Switzerland*; [3]*Universitätsklinik Balgrist, Technical Orthopedics, Zürich, Switzerland*; [4]*Schulthess Klinik, Department of Research and Development, Zürich, Switzerland*

Background: The expression of embryonic Homeobox (HOX) genes is tightly regulated based on anatomic location in human adult dermal and synovial fibroblasts. Previously, we showed that HOX-D10,-D11 and -D13 are higher expressed in synovial fibroblasts from small distal joints from the hands and feet, in particular in digits II-V and wrists compared to thumb and that this expression pattern is epigenetically imprinted[1]. The consequences of the tightly restricted expression of these transcription factors are largely unknown.
Objectives: To elucidate the function of HOXD10, -D11 and -D13 in synovial fibroblasts.
Methods: Synovial tissues were isolated from paws of naïve C57BL/6 mice (n=8), from patients with rheumatoid arthritis (RA), osteoarthritis (OA) and from healthy controls. Synovial fibroblasts were cultured and transfected with GapmeR to silence HOXD10, -D11, and -D13, respectively or with control GapmeR. RNA sequencing was performed on the NovaSeq platform and pathway analysis was done using R packages and web-based tools (GSEA, EnrichR, Cytoscape). HOXD target gene expression was measured by qPCR (n=3-6).
Results: To confirm and further analyze the distinctive expression pattern of HOXD genes, we measured their expression in healthy synovial tissues of different joints of human feet and mouse paws. Similar to what we had found in hands, *HOXD10*, *-D11* and *-D13* were less abundant in the joints of the first digit of human feet compared to digits II-V (n=3-4 in each joint). Measurements in joints of mouse paws showed lower expression of *HoxD10*, *-D11* and *-D13* in distal interphalangeal joints compared to proximal interphalangeal joints and metacarpophalangeal (MCP) joints, respectively. Silencing of HOXD10, -D11 and –D13, affected the expression of 5333, 2217 and 7347 genes, respectively, in cultured RA synovial fibroblasts from human wrists (n=3).
There were more transcripts equally regulated by HOXD10 and -D13 (40% of all HOXD10 and 31% of all HOXD13 regulated transcripts), than by HOXD11 and either -D10 or -D13 (18% of all HOXD10 regulated genes and 16% of all HOXD13 regulated genes), suggesting most redundancy between HOXD10 and -D13 (Figure 1). Among genes differentially expressed in SF isolated from MCP II-V versus thumb joints, 19%, 4% and 33% were regulated by HOXD10, -D11 or –D13, respectively, supporting a role for HOXD13 in particular in shaping the joint specific environment. All three HOXD transcription factors regulated genes involved in cell cycle progression, demonstrating dependence of synovial fibroblasts on these HOX genes for cell division. Other enriched pathways were Toll-like receptor and integrin signaling pathways, regulation of unsaturated fatty acid synthesis and autophagy and extra-cellular matrix protein organization. We could

confirm several targets of HOXD10, -D11, and –D13 by qPCR, e.g. *NR4A1*, *ROR2, LIF, ATF3*.

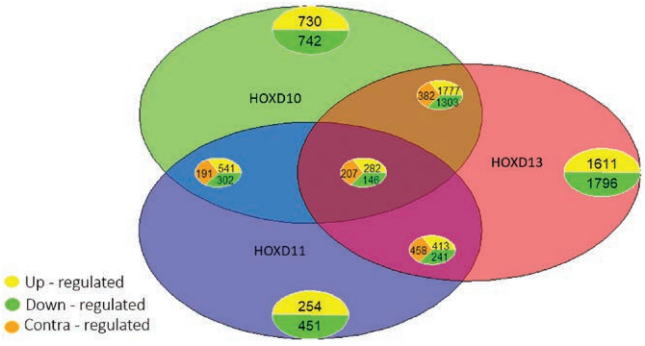

Figure 1. Comparison of the genes which were differentially expressed after HOXD10-11-13 silencing

Conclusion: The expression of HOXD10, -D11 and –D13 in synovial fibroblasts and tissues strikingly overlaps with predilection sites for RA. Silencing experiments suggested that these embryonic HOX transcription factors have a crucial role in regulating fibroblast functions and might shape a joint specific environment that modulates the development and course of RA in specific joints.

OP0021 IDENTIFICATION OF DIFFERENTIALLY EXPRESSED GENES IN EARLY RHEUMATOID ARTHRITIS PATIENTS RESPONDING TO TOCILIZUMAB

I. Muller[1], M. Verhoeven[2], H. Gosselt[1], M. Lin[1], T. De Jong[3], E. Mantel[3], K. Chatzidionysiou[4], G. Jansen[3], L. Padyukov[4], P. Welsing[2], F. Lafeber[2], R. De Jonge[1], C. J. Van der Laken[3]. *[1]Amsterdam UMC, locatie VUmc, Clinical Chemistry, Amsterdam, Netherlands*; *[2]University Medical Center Utrecht, Department of Rheumatology and Clinical Immunology, Utrecht, Netherlands*; *[3]Amsterdam UMC, locatie VUmc, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands*; *[4]Karolinska Institutet and Karolinska University Hospital, Department of Medicine, Stockholm, Sweden*

Background: Tocilizumab (TCZ) is a monoclonal antibody that binds to the interleukin 6 receptor (IL-6R), inhibiting IL-6R signal transduction to downstream inflammatory mediators. TCZ has shown to be effective as monotherapy in early rheumatoid arthritis (RA) patients (1). However, approximately one third of patients inadequately respond to therapy and the biological mechanisms underlying lack of efficacy for TCZ remain elusive (1). Here we report gene expression differences, in both whole blood and peripheral blood mononuclear cells (PBMC) RNA samples between early RA patients, categorized by clinical TCZ response (reaching DAS28 < 3.2 at 6 months). These findings could lead to identification of predictive biomarkers for TCZ response and improve RA treatment strategies.

Objectives: To identify potential baseline gene expression markers for TCZ response in early RA patients using an RNA-sequencing approach.

Methods: Two cohorts of RA patients were included and blood was collected at baseline, before initiating TCZ treatment (8 mg/kg every 4 weeks, intravenously). DAS28-ESR scores were calculated at baseline and clinical response to TCZ was defined as DAS28 < 3.2 at 6 months of treatment. In the first cohort (n=21 patients, previously treated with DMARDs), RNA-sequencing (RNA-seq) was performed on baseline whole blood PAXgene RNA (Illumina TruSeq mRNA Stranded) and differential gene expression (DGE) profiles were measured between responders (n=14) and non-responders (n=7). For external replication, in a second cohort (n=95 therapy-naïve patients receiving TCZ monotherapy), RNA-seq was conducted on baseline PBMC RNA (SMARTer Stranded Total RNA-Seq Kit, Takara Bio) from the 2-year, multicenter, double-blind, placebo-controlled, randomized U-Act-Early trial (ClinicalTrials.gov identifier: NCT01034137) and DGE was analyzed between 84 responders and 11 non-responders.

Results: Whole blood DGE analysis showed two significantly higher expressed genes in TCZ non-responders (False Discovery Rate, FDR < 0.05): urotensin 2 (UTS2) and caveolin-1 (CAV1). Subsequent analysis of U-Act-Early PBMC DGE showed nine differentially expressed genes (FDR < 0.05) of which expression in clinical TCZ non-responders was significantly higher for eight genes (MTCOP12, ZNF774, UTS2, SLC4A1, FECH, IFIT1B, AHSP, and SPTB) and significantly lower for one gene (TND2P28M). Both analyses were corrected for baseline DAS28-ESR, age and gender. Expression of UTS2, with a proposed function in regulatory T-cells (2), was significantly higher in TCZ non-responders in both cohorts. Furthermore, gene ontology enrichment analysis revealed no distinct gene ontology or IL-6 related pathway(s) that were significantly different between TCZ-responders and non-responders.

Conclusion: Several genes are differentially expressed at baseline between responders and non-responders to TCZ therapy at 6 months. Most notably, UTS2 expression is significantly higher in TCZ non-responders in both whole blood as well as PBMC cohorts. UTS2 could be a promising target for further analyses as a potential predictive biomarker for TCZ response in RA patients in combination with clinical parameters (3).

OP0022 RHO EXPRESSION FACILITATES T CELL MIGRATION TO LYMPH NODES IN RESPONSE INFLAMMATION

E. Malmhäll-Bah[1], K. M. Andersson[1], M. C. Erlandsson[1], M. Brisslert[1], O. Khan[2], M. Akula[2], I. M. Jonsson[1], M. Bergö[2,3], M. I. Bokarewa[1,4]. *[1]University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; *[2]University of Gothenburg, Department of Molecular and Clinical Medicine, Gothenburg, Sweden*; *[3]Karolinska Institute, Department of Biosciences and Nutrition, Gothenburg, Sweden*; *[4]Sahlgrenska University Hospital, Rheumatology, Gothenburg, Sweden*

Background: Deficiency in geranylgeranyltransferase type I (GGTase-I) results in accumulation of active Rho family proteins RhoA, Rac1 and Cdc42, responsible for cell communication and migration. We reported that mice with GGTase-I deficient macrophages (GLC mice) develop a spontaneous and age-dependent arthritis, reproducing pathology of RA [1].

Objectives: We study how GGTase-I deficiency in Mø changes T cell phenotype to facilitate their translocation to joints and the development of arthritis.

Methods: GLC mice were developed on a mixed genetic background (129Ola/Hsd-C57BL/6) by Cre-technology using LysM-promotor to knockout the *Pggt1b* gene in Mø[2]. $CD4^+$ cells were isolated from spleen and lymph node (LN) of 16 weeks-old mice (GLC n=7, wt n=5) expected to have high prevalence of arthritis. RNA was extracted to measure expression of the Rho proteins and signature genes to characterize differences in Th-subtypes and migration abilities of $CD4^+$ cells between GLC and wt mice. Furthermore, Illumina RNAseq analyzed the transcriptome of LN $CD4^+$ cells. In a separate experiment we treated GLC mice with CTLA4-FP (n=12) or PBS (n=11) for 20 weeks from the age of 5 weeks. Rationale was to disrupt Mø/T cell contact to prevent arthritis. To study Rho-protein dependent phenotype in human RA, we performed RNAseq of sorted $CD4^+$ cells of RA patients.

Results: RNAseq showed that $CD4^+$ cells in LN of GLC mice had IFN-γ dependent cytotoxic profile and upregulated numerous pro-inflammatory genes including *Eomes*, *Cxcr3*, *Tigit*, *Tnfsf10*, *Il-1rl1*, *Stat1*, *Jak3*, *Irf7*, *Irf5*, *Ptpn13*. Furthermore, the over-represented genes often depended on the IRF family in their transcription.

GLC mice overexpressed *Cdc42* and *Rac1* in spleen $CD4^+$ compared to wt (p=0.005 and p=0.048 resp.). Spleen GLC $CD4^+$ cells had higher levels of $\alpha5\beta1$ and $\alpha2\beta2$ integrins, strongly correlating to *Cdc42* (r= 0.61 p=0.0027 and r=0.50, p=0.018) and arthritis (r=0.64, p=0.0015 and r=0.69, p=0.0004). Importantly, *Cdc42*, *Rac1*, and *RhoA* were higher expressed in LN $CD4^+$ compared to spleen (p=0.016, p=0.031 and p=0.016). In addition, *Itgb1* coding for $\beta1$ integrin, was upregulated in GLC $CD4^+$ cells of both spleen and LN (p=0.003 p=0.03, resp.), suggesting Rho proteins are important for migration of $CD4^+$ cells to the joint draining LN and for arthritis development. $CD4^+$ cells that migrated to the LN had high proportion of $Foxp3^+$ cells. This also correlated to the expression of *Itgb1* (r=0.84, p=0.0012) presenting a plausible mechanism for increased influx of Tregs into joints. Several observations are in favor of this notion. First, GLC mice expressed more *Foxp3* in LN compared to spleen $CD4^+$ cells (p=0.016). Second, transcription of *Foxp3* in LN $CD4^+$ cells was higher in GLC mice compared to wt (p=0.015). Third, this high *Foxp3* coexisted with low transcription of *Lef1* (p=0.03), required for Treg immunosuppression. Last, *Foxp3* correlated negatively to both *Lef1* (r=-0.72, p=0.017), and its cofactor *Tcf1* (r=-0.75, p=0.01).

CTLA4-FP reduced inflammation in GLC mice evident as lower IFN-γ, IL-6 and TNF-α production (p=0.0002, p<0.0001 and p<0.0001 resp.) and the number of $CD25^+CD4^+$cells in spleen (p=0.027). In contrast, we observed increased IL-17A production (p=0.056). However, CTLA4-FP treatment did not affect migration of $CD4^+$ cells enriched with Rho-protein into draining LN nor alleviate arthritis.

Similar to the GLC mice, $CD4^+$ cells of RA patients with high expression of RhoA, Rac1 and Cdc42 demonstrated enrichment for Th1 signature genes including *IFNG*, *TBX21*, *Eomes*, *IL2RA*, *IL2RB*, *IL12RB2*, *TNF*, *IL18RAP* (all, adj. p<0.05).

Conclusion: This study shows that accumulation of Rho-proteins in $CD4^+$ cells results in pro-inflammatory IFN-γ dependent phenotype in mice and human RA. Accumulation of RhoA, Rac1 and Cdc42 proteins trigger the migration of $CD4^+$ cells into joint draining LN and facilitates arthritis. Inhibiting Mø/T cell contact in GLC mice did not suffice to prevent migration of Rho-protein expressing cells and arthritis

OP0023 GENERATION OF PT101, A HIGHLY SELECTIVE IL-2 MUTEIN FOR TREATMENT OF AUTOIMMUNE DISEASES

J. Visweswaraiah[1], E. Sampson[2], P. Petaipimol[1], A. Monsef[3], K. Kis-Toth[4], K. L. Otipoby[2], J. Sundy[3], N. Higginson-Scott[1], J. Viney[5]. *[1]Pandion Therapeutics, Biotherapeutics, Watertown, United States of America*; *[2]Pandion Therapeutics, Immunology, Watertown, United States of America*; *[3]Pandion Therapeutics, Clinical, Watertown, United States of America*; *[4]Pandion Therapeutics, Translational Sciences, Watertown, United States of America*; *[5]Pandion Therapeutics, R&D, Watertown, United States of America*

Background: Regulatory T cells (Tregs) play a critical role in immune homeostasis and are dysfunctional in many autoimmune diseases. Interleukin 2 (IL-2) drives the proliferation and function of Tregs. via the heterotrimeric IL-2 receptor (CD25/CD122/CD132). As a result, CD25 loss-of-function in mice is associated with Treg deficiency and widespread autoimmunity. Low dose IL-2 is being evaluated for treatment of autoimmune diseases and has been shown to expand Tregs, however it has a narrow selectivity window before activating conventional T cells and natural killer cells. To enhance IL-2 selectivity and improve its therapeutic utility for activating and expanding Tregs, mutations can be introduced that reduce CD122/CD132 affinity thus creating a dependency on CD25 binding for signaling through CD122/CD132 upon IL-2 facilitated CD25/CD122/CD132 trimer formation.

Objectives: To generate a highly selective IL-2 mutein that activates and expands Tregs selectively that can be used for treatment of autoimmune diseases

Methods: Using a structure guided approach, we introduced mutations in IL-2 that significantly decreased CD122 binding affinity in addition to other mutations that increased CD25 binding affinity. Finally, we explored additional mutations, format, orientation, and linker lengths to generate the most potent, selective molecule with drug-like manufacturability. These structure activity relationship efforts culminated in the generation of PT101, a mutant IL-2 Fc fusion that is selective in activating and expanding Tregs in vitro and in vivo.

Results: PT101 selectively induced STAT5 phosphorylation in human and cynomolgus monkey Tregs in vitro. In humanized NOD-scid IL-2Rg-null (NSG) mice and cynomolgus monkeys, administration of PT101 dose-dependently and selectively expanded Tregs without significant effects on other immune cell types, and without eliciting proinflammatory cytokine production. The Tregs from PT101-dosed humanized mice have increased expression of FOXP3 and CD25, suggesting enhanced function and stability. In a Phase 1a single ascending dose clinical trial, PT101 was well-tolerated and selectively expanded total Tregs, with a mean maximal increase of up to 3.6-fold over baseline in healthy volunteers. There was no evidence of expansion of natural killer cells nor pro-inflammatory conventional T cells at any of the doses studied.

Conclusion: PT101 selectively activated and expanded Tregs without significant effects on other immune cell types, and without eliciting proinflammatory cytokine production. These Tregs have enhanced function and stability as seen by increase in expression of FOXP3 and CD25 in these cells. PT101 maintained selectivity in Phase 1 a clinical trial with no evidence of expansion of natural killer cells nor pro-inflammatory conventional T at any dose studied. A Phase 1b/2a clinical trial in patients with ulcerative colitis and a Phase 2 clinical trial in patients with systemic lupus erythematosus are planned to further evaluate PT101.

OP0024 DECREASED LEVELS OF T FOLLICULAR HELPER (CD4+CXCR5+) CELLS AND CD27+CD38+ AND CD27+CD38- B CELLS IN ANKYLOSING SPONDYLITIS PATIENTS CORRELATE WITH MARKER OF INFLAMMATION

H. Forsblad-D'elia[1], U. Hellman[2], A. Kumar[2], K. Lejon[3]. *[1]Institute of Medicine, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; *[2]Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden*; *[3]Department of Clinical Microbiology, Infection and Immunology, Umeå University, Umeå, Sweden*

Background: The role of different lymphocyte subsets in ankylosing spondylitis (AS) is still to be elucidated. It has previously been reported contradictory data concerning the levels of T Follicular Helper (TFH) cells and differentiated B cells in peripheral blood of AS patients. In addition, the connection to disease related parameters is still to be fully revealed.

Objectives: The purpose of this study was to investigate the level of CD4+TFH cells and CD27+CD38+/CD38- B cells in patients with AS from northern Sweden and to compare the levels with age and sex-matched controls. We also studied associations between these cell subsets and disease related factors.

Methods: Peripheral blood mononuclear cells (PBMSc) from a cohort of 50 patients with AS from Region Västerbotten (mean age 52±9.1 years, 33 (66 %) men, 50 (100 %) HLAB27 positive) and 50 pair wise matched blood donor controls (mean age 54±8.8 years, 33 (66 %) men) were stained with a combination of antibodies allowing for the detection of CD27, CD38, CD19, CD3, CD4 and CXCR5 markers and analyzed by flow cytometry. In addition, the patient with AS were examined with spinal x-ray for radiographic alterations assessed with mSASSS. CRP and ESR were measured and physical function and disease activity were registered with BASMI and BASFI respectively ASDAS-CRP and BASDAI.

Results: When comparing AS patients and controls pair wise, we observed on average a 50% reduction of TFH (CD3+CD4+CXCR5+) cells among CD45+ lymphocytes in PBMCs from patients (p=0,000008). Furthermore, a 20-30% reduction among memory/plasma cells (CD19+CD27+CD38+ and CD19+CD27+CD38-) among CD45+ lymphocytes in PBMCs from patients (p=0,002 and p=0,007 respectively). For female patients a correlation between TFH and ESR (R_s=-0,551 p=0,022) was observed. Moreover, negative correlations between the two B cell subsets (CD19+CD27+CD38+ and CD19+CD27+CD38-) and ESR were observed for female patients (R_s =–0,476 p=0,053 and R_s =–0,522 p=0,032 respectively).

Conclusion: TFH cells was reduced in AS patients and this reduction correlated with a reduction in differentiated (CD27+CD38+ and CD27+CD38-) B cells. In

addition, the inflammation marker ESR was negatively correlated with TFH as well as with the differentiated B cell subsets in female patients. Our observations indicates a role of the humoral immune response in AS.

OP0025 CD209+/CD14+ DENDRITIC CELLS ARE ENRICHED AND ACTIVATED AT THE SITE OF INFLAMMATION AND ARE MODULATED BY JAK/STAT SIGNALLING

V. Marzaioli[1,2], A. Floudas[1,2], M. Canavan[1,2], S. Wade[1,2], K. Murray[2], R. Mullan[3], D. Veale[1,2], U. Fearon[1,2]. [1]*Trinity Biomedical Sciences Institute, 1Molecular Rheumatology, Dublin, Ireland*; [2]*Centre for Arthritis and Rheumatic Diseases, SVUH, EULAR Centre of Excellence for Rheumatology, Dublin, Ireland*; [3]*Adelaide and Meath Hospital, Department of Rheumatology, Dublin, Ireland*

Background: Dendritic cells (DCs) are a heterogeneous population of professional antigen-presenting cells which are at the interface between innate and adaptive immunity. A specific subset of DCs is known to derive from monocyte and has a key role in inflammation and infection.

Objectives: This study aimed to characterize the phenotype and function of a distinct $CD209^+/CD14^+$ DC subset in the periphery and at the site of inflammation in patients with rheumatoid (RA) and psoriatic arthritic (PsA), in addition to examining the effect Tofacitinib and TNF inhibitor on their development.

Methods: Peripheral blood and synovial fluid mononuclear cells (PBMC and SFMC) were isolated by Ficoll density gradient from healthy subject (HC), and patients with RA and PsA. Single cell synovial tissue suspension (ST) from RA and PsA patients were also established using enzymatic/mechanical digestion. PBMC, SFMC and ST were analysed by flow cytometry to identify the $CD209^+/CD14^+$ DC subset, its frequency and the cell surface expression of chemokines receptors (CCR6, CCR7, CXCR3, CXCR4 and CXCR5) and activation markers (CD40 and CD80). In addition, PBMC were stimulated with different TLR (LPS, CPG, R848, Poly I:C) and intracellular staining for IL12, TNFα, IL1β and IL6 was performed by flow cytometry. Lineage negative cells ($CD3/CD19/CD56^-$) were stimulate with GMCSF/IL4 in the presence or absence of the JAK/STAT inhibitor Tofacitinib or the TNF inhibitor Humira, and the CD209+/CD14+ DC development was evaluated by flow cytometry.

Results: We identified, for the first time, a distinct CD209+/CD14+ DC population in PBMC of patients with RA and PsA, with similar frequency across the groups. However, when PBMC were stimulated with TLRs, an increase of IL12 and TNFα was observed in RA and PsA PBMC when compared to HC. Interestingly, this distinct DC population was significantly enriched at the site of inflammation, in both SFMC and ST, displaying a more mature phenotype, evident by the observed significant increase in CD40 and CD80 expression. SPICE analysis further identified differential expression and co-expression of chemokine receptors at the periphery of RA and PsA patients, when compared to the HC. Furthermore synovial tissue single cell analysis from RA/PsA demonstrated a unique chemokines receptors profile demonstrating increased single expression and co-expression of CXCR3 and CXCR5 compared to periphery. Finally, we have previously observed that JAK/STAT is involved in monocyte-derived dendritic cells population development (1,2), therefore we performed CD3, CD19 and CD56 depletion of RA/PsA PBMC followed by stimulation with GMCSF/IL4, to spike the Mo-DC population, in the presence of Tofacitinib or Humira. Interestingly, we observed that JAK/STAT inhibition, but not TNF inhibitor, reduced the generation and development of CD209+/CD14+ DC.

Conclusion: We identify for the first time a distinct monocyte-derived DC population characterized as $CD209^+/CD14^+$ in the periphery of RA and PsA patients. This population was enriched at the site of inflammation and displayed a unique chemokine receptor profile and activation markers, suggesting that these cells are already activated in the periphery of IA patients, and are recruited and further activated in the inflamed joint. In addition, we showed that the $CD209^+/CD14^+$ DC development is regulated by JAK/STAT signalling, but not TNF inhibition.

OP0026 IGF1R DEPENDENT CELL INTERACTION AND REGULATION OF AUTOANTIBODY PRODUCTION IN RHEUMATOID ARTHRITIS

S. Erdogan[1], M. Erlandsson[1,2], N. Oparina[1], C. Lundquist[1], C. Wasen[1], M. Svensson[1], M. Bemark[3], K. M. Andersson[1], M. I. Bokarewa[1,2]. [1]*Gothenburg University, Rheumatology and Inflammation Research, Göteborg, Sweden*; [2]*Sahlgrenska University Hospital, Rheumatology Clinic, Göteborg, Sweden*; [3]*Göteborg University, Microbiology and Immunology, Göteborg, Sweden*

Background: The insulin-like growth factor 1 receptor (IGF1R) signalling mediates numerous developmental processes acting through downstream adaptor molecules IRS1/2, which activate Akt and inhibit the family of forkhead box class O (FoxO). Inhibition of IGF1R signalling alleviates rheumatoid arthritis (RA) (Erlandsson et al., 2017), however, the role of IGF1R signalling in the regulation of immune function is poorly understood.

Objectives: To investigate the link between IGF1R signalling and antigen presentation in experimental arthritis.

Methods: Arthritis was induced by immunising Balb/c mice with methylated bovine serum albumin (mBSA, n=18) and DBA/1 mice with type II collagen (CII, n=18). The mice were treated with a synthetic IGF1R inhibitor NT157 or with short hairpin RNA targeting IGF1R (shIGF1R) from the day prior to immunisation. Controls were treated with cyclodextrine vehicle/ non-targeting (nt)RNA, respectively. Flow cytometry was used for spleen cell phenotype. Antibody levels were measured by ELISA. Immunohistochemistry (IHC) of spleen was performed for assessment of marginal zone (MZ) and location of pS^{612}IRS1+ and pS^{256}FoxO1+ cells. IHC images were acquired by fluorescent confocal microscopy, and analysed using ZEN2009 and Cell Profiler soft ware.

Results: The inhibition of IGF1R resulted in an 80% increase in MZ area in NT157-treated mice compared to controls (p=0.0001). This was supported by a significant increase of CD21+ (p=0.034) and CD23+ cell populations (p=0.00059), both among the CD19+ B cells and antigen-presenting MHCII+CD19- cells, implying that IGF1R expression regulates the populations of MZ and follicular cells. Additionally, there was a strong positive correlation between the decrease of IGF1R+ and ICOSL+ population on CD21+ cells (r=0.70, p=0.0071), which retained them in the MZ and prolonged communication with macrophages. Insufficient feedback from ICOSL- B cells limited expression of CXCR5 on CD4 cells. The IHC analysis displayed that, IGF1R inhibition led to abundance of inactivate pS^{612}IRS1+ and pS^{256}FoxO1+ cells within the MZ, compared with controls (p=0.0002). Alongside the increase of IgM+ B cell population (p=0.0022), we observed significant increase in number of antigen-presenting F4/80+ cells (p=0.043) and MARCO expression (p=0.043) after IGF1R intervention. Finally, the NT157- treated mice displayed a significant pleiotropic increase in IgM autoantibody production, with anti-CCP IgM (p=0.027), RF-IgM (p=0.0085), anti-DNA IgM (p=0.066) and in total IgM (p=0.027) levels, which correlated positively with $pS^{256}FoxO1^+$ cells (r=0.51, p=0.03). Levels of IgG were not changed.

Conclusion: We show that IGF1R signalling is important for immune cell communication after antigen challenge. IGF1R controls ICOSL dependent trafficking of B cells through the MZ and facilitates interaction with T cells. Retention of B cells in the MZ tips the balance from T cell to macrophage-dependent processes, which permits the formation of autoantibody producing B cells.

Background: Recently a group of T-cell clones with characteristic T-cell receptor (TCR) motif was identified in peripheral blood and synovial fluid of HLA-B*27+ patients with ankylosing spondylitis (AS) [1-2] - a prototypic disease from a wider group of spondyloarthropathies (SpAs). Extraarticular manifestations of AS could involve skin, intestine or eye. Emerging data indicate linkage between intestinal and joint inflammation, including expression of gut-associated integrins on synovial T-cells [3-4]. However, clonal T-cell composition and presence of identical clones in different inflamed sites in SpAs remains poorly studied.
Objectives: To investigate clonal T-cell repertoire and presence of AS-related TCR motif in different sites of inflammation of patients with SpA.
Methods: Samples of synovial fluid (SF) were obtained from HLA-B*27+ and HLA-B*27- patients with ankylosing spondylitis (AS) and psoriatic arthritis (PsA), as well as gut biopsy samples from patients with AS and Crohn's disease (AS/CD) or ulcerative colitis (AS/UC), and conjunctival swabs from patients with uveitis (Uv) and with or without articular manifestations (Table 1). Also SF and gut biopsy samples were obtained from HLA-B*27+ patients with juvenile idiopathic arthritis (JIA). For one patient PsA patient paired samples of SF and gut biopsy were obtained.

Table 1. Detection of the AS-related motif TRBV9_CASS[V/A/L/P][G/A][L/T/V][F/Y]STDTQYF_TRBJ2-3 in bTCR repertoires of samples from different inflamed sites of patients with SpA

Tissue	Diagnosis	B27+	B27-	AS-related TCR motif+ among all samples from B27+ donors
Synovial fluid	AS PsA JIA	20	12	
Intestinal biopsy	AS/CD AS/UC JLA	4	3	3 / 4
Conjunctival swab	Uv	8	0	4 / 8

SF and gut samples were processed to isolate mononuclear cells, while conjunctival swabs were directly lysed in the lysis buffer. CD3+ β7-intergin+ cells were isolated from SF by fluorescence-activated cell sorting. Deep TCR repertoire profiling was carried out using UMI-based cDNA library preparation technology [1].
Results: Identical T-cell clonotypes were detected between paired SF and gut samples of the same patient with psoriatic arthritis and intestinal inflammation. The subpopulation of β7-intergin+ SF T-cells shared significantly more identical clonotypes with gut biopsy repertoire compared to the bulk SF T-cell repertoire. Clonotypes belonging to the AS-related TCR beta motif TRBV9_CASS[V/A/L/P][G/A][L/T/V][F/Y]STDTQYF_TRBJ2-3 were detected in all inflamed tissues tested: synovial fluid, intestinal biopsies and conjunctival swabs of SpA patients (Table 1). Importantly, we observed these clonotypes exclusively in samples from HLA-B*27+ donors (n=26), but not in HLA-B27- context (n=15) with comparable analysis depth, thus confirming strong HLA-B*27-restriction of the clonotypes. The AS-related clonotypes were detected in the subpopulation of β7-intergin+ SF T-cells from HLA-B*27+ patients with PsA.
Conclusion: For the first time we directly report the T-cell clonal sharing between synovial fluid and inflamed gut tissue of SpA patients. In sum our data suggests involvement of identical T-cell clones in inflammation in different anatomical sites in SpA.

OP0028 CD206+CD163+ PATHOGENIC MACROPHAGES ENRICHED IN RHEUMATOID ARTHRITIS SYNOVIAL TISSUE WITH DISTINCT TRANSCRIPTIONAL SIGNATURES

M. Hanlon[1], M. Canavan[1], Q. Song[2], N. Neto[3], P. Gallagher[4], R. Mullan[5], C. Hurson[6], M. Monaghan[3], S. Nagpal[2], D. Veale[4], U. Fearon[1]. *[1]Trinity Biomedical Sciences Institute, Molecular Rheumatology Research Group, Dublin, Ireland*; *[2]Janssen Research and Development Spring House, Immunology & Discovery Sciences, Spring House, United States of America*; *[3]Trinity Biomedical Sciences Institute, Mechanical and Manufacturing Engineering, Dublin, Ireland*; *[4]St. Vincent's University Hospital, Centre for Arthritis & Rheumatic Diseases, Dublin, Ireland*; *[5]Tallaght Hospital, Department of Rheumatology, Dublin, Ireland*; *[6]St. Vincent's University Hospital, Department of Orthopaedics, Dublin, Ireland*

Background: Synovial tissue macrophages are an exquisitely plastic pool of innate cells that play a key role in RA disease progression. However, the precise nature, diversity, and function of macrophage subsets within the inflamed joint remains unexplored.
Objectives: Therefore, the aims of this study are to phenotypically, transcriptionally and functionally characterise synovial tissue macrophages residing within the inflamed joint.
Methods: Rheumatoid Arthritis, Psoriatic Arthritis, Osteoarthritis and healthy control synovial-tissue biopsies and synovial-fluid mononuclear cells were analysed using the following panel (CD40,-CD45,-CD64,-CD68,-CD163,-CD206,-CD253,-CCR4,-CCR7,-CXCR1,-CXCR3). CD206+CD163+ and CD206-CD163- macrophages were sorted from RA synovial-tissue by FACSAria sorter; RNAseq and FLIM analysis, autologous T-cell co-culture and heathy fibroblast experiments performed. Cytokine expression was measured by MSD immunoassay.
Results: RA synovial tissue and fluid macrophages display markers typical of both M1 (CD40+CD253+) and M2 (CD206+CD163+) macrophages with a spectrum of macrophage activation states identified. Within this spectrum, significant enrichment of dominant CD206+CD163+ macrophage-subtype is present in synovial tissue versus fluid ($p<0.05$). CD206+CD163+ synovial tissue macrophages express significantly more CD40 than synovial fluid ($p<0.0003$), positively correlate with disease activity ($r=0.6$, $p<0.01$), with baseline levels predicting response to therapy ($p<0.05$). Moreover, CD206+CD163+CD40+ macrophages are enriched in RA synovial tissue compared to PsA and OA pathotypes ($p<0.05$). While the CD206+CD163+ subset is present in healthy synovial tissue, expression of CD40 is completely absent in healthy synovium ($p<0.05$) with dramatically decreased expression of CX3CR1 on RA macrophages. RNAseq analysis indicates that CD206+CD163+ population is transcriptionally distinct from synovial tissue CD206-CD163-, synovial fluid CD206+CD163+, and RA monocyte-derived M1/M2 macrophages, with unique tissue-resident gene signatures. Moreover, differing metabolic demands between CD206+CD163+ and CD206-CD163- subsets was demonstrated by RNAseq and FLIM analysis. CD206+CD163+ macrophages enhance autologous T-cell responses, spontaneously secrete high levels of pro-inflammatory cytokines and activate healthy fibroblasts towards pro-inflammatory mechanisms thus further contributing to the local inflammatory response. Finally, inhibition of CD40 activity abrogates the expression of pro-inflammatory mediators (TNFa, IL-1B, IL-6, IFNy) and induces IL-10 expression in sorted CD206+CD163+ synovial tissue-macrophages suggesting a key role for CD40 in driving this pathogenic phenotype.
Conclusion: This data identifies for the first-time enrichment of a previously undescribed dysfunctional dominant and transcriptionally distinct macrophage subtype in RA synovial tissue. Taken together, this data provides a greater understanding of the critical role tissue-resident macrophages play in perpetuating inflammation in RA. Further investigation of the molecular patterns and cues that shape specific synovial macrophage subsets may provide opportunities to reinstate RA joint homeostasis.

Background: Giant cell arteritis (GCA) represents the most prevalent form of systemic vasculitis in elderly, characterized by a remarkable heterogeneity in terms of clinical and histological phenotype, the pathogenetic mechanisms and treatment selection (1). An interplay between cells of both innate and adaptive immunity, appear to govern the pathophysiologic mechanisms (2). Among the different cellular populations, neutrophils may hold a central role in GCA pathogenesis, since they are present in abundance in tissue injury (3,4). Most importantly, they are a source of neutrophil extracellular traps (NETs) that may deliver immunocompetent substances, necessary for the perpetuation of the inflammatory response (5). The detection and function of NETs have not been studied in GCA.
Objectives: To explore the presence and clinical significance of NETs in temporal artery biopsies (TABs) of patients with GCA.
Methods: Ten patients with GCA [5 with limited cranial vasculitis (CV) and 5 with associated generalized large vessel vasculitis (LVV), as defined by ^{18}F-fluorodeoxyglucose (FDG) positron-emission tomography with computed tomography (PET/CT)] and 8 patients with polymyalgia rheumatica (PMR) were studied. GCA and PMR patients fulfilled the 1990 ACR and 2012 EULAR/ACR provisional classification criteria, respectively. The presence, location, quantitation and decoration of NETs with IL-6, IL-1β, and IL-17A were assessed in TABs at the time of disease diagnosis by tissue immunofluorescence and confocal microscopy. Quantification of NETs in tissue sections was performed using the Imaris v.9.3 software that counts the total measure volume instead of only the projection area (6). Serum levels of IL-6 and IL-17A around the time of tissue biopsy were also evaluated in all patients.
Results: All temporal artery biopsies from GCA patients had NETs located mainly in the adventitia, adjacent to the vasa vasorum, whereas TABs from PMR patients had no NET structures. LVV was associated with a higher NETs to total tissue volume ratio, compared to CV-GCA [p=0.0317]. NETs decorated with IL-6 were present in TABs of all LVV and 3 of 5 CV-GCA patients, while IL-17A positive NETs were observed in all GCA patients. IL-1β-positive NETs were not detected in any GCA patient. No relation was found between serum IL-6 and IL17A levels and NETs containing IL-6 and/or IL-17A.
Conclusion: NETs bearing IL-6 and IL-17A cytokines are present in inflamed GCA-TABs. IL-6 positive NETs are associated with the LVV phenotype and might be useful as a tissue biomarker for disease severity and extent.

OP0030

TREATMENT OF NON-BIOLOGIC-DMARD-IR PSA PATIENTS WITH UPADACITINIB OR ADALIMUMAB RESULTS IN THE MODULATION OF DISTINCT FUNCTIONAL PATHWAYS: PROTEOMICS ANALYSIS OF THE SELECT-PSA 1 PHASE 3 STUDY

T. Sornasse[1], J. Anderson[2], K. Kato[2], A. Lertratanakul[2], C. T. Ritchlin[3], I. McInnes[4]. [1]*AbbVie, Precision Medicine Immunology, Redwood City, United States of America*; [2]*AbbVie, Immunology Clinical Development, North Chicago, United States of America*; [3]*University of Rochester, Allergy/Immunology and Rheumatology, Rochester, United States of America*; [4]*University of Glasgow, College of Medical, Veterinary and Life Sciences, Glasgow, United Kingdom*

Background: Treatment of non-biologic-DMARD-IR (DMARD-IR) PsA patients with upadacitinib (UPA) at 15 mg QD, an oral JAK1 selective inhibitor, resulted in improvement in musculoskeletal symptoms, psoriasis, physical function, fatigue, quality of life, and inhibited radiographic progression; improvements were observed as early as Week 2 (ACR20 and ACR50). UPA 15 mg QD was non-inferior to adalimumab (ADA) 40 mg EOW for ACR20[1]
Objectives: To determine the relative biological pathway modulation of UPA compared with ADA in patients with PsA via the evaluation of a pre-defined set of plasma proteins associated with inflammation.
Methods: Patients from the SELECT-PsA1 study (DMARD-IR PsA patients) were randomly selected (PBO, n=100; UPA 15 mg QD, n=100; ADA 40 mg EOW, n = 100). The levels of 92 inflammation related protein biomarkers (pBM) were analyzed using a multiplexed Proximity Extension Assay platform in plasma samples collected at baseline, week 2, and 12; change from baseline in protein levels were expressed as Log_2 Fold Change; a Repeated Measure Mixed Linear Model identified proteins modulated by UPA and ADA compared to Baseline. Functional pathway prediction was performed in silico with a commercially distributed software where 52 significantly modulated pBM (mean $|Log_2$ FC$| \geq 0.1$ AND FDR ≤ 0.05) were selected; results were summarized based on 3 core biological groups: 1) adaptive immune system, 2) innate immune system, and 3) non-immune connective and vascular systems.
Results: At the single pBM-level, at the week 2 and 12 time points, treatment with UPA 15 mg QD resulted in distinct down modulation of T cell-associated (CD5, CD8a, IL15Ra, SLAMF1, TRANCE) and myeloid cell-associated pBM (CSF-1, CCL7, CCL13) that was not observed in the ADA treated group. Reciprocally, treatment with ADA 40 mg EOW resulted in a specific down modulation of a subset of neutrophil associated pBM (CCL3, CCL4, and S100A12). Both treatments resulted in the down modulation of IFN-, IL6-, and TNF-related pBM (CXCL9, CXCL10, CXCL11, IL6, TNFRSF19, and TNSF14) suggesting a common node of activity related to these pivotal cytokine-signaling pathways.
Functional pathway prediction based on the pBM data revealed that treatment with UPA is preferentially associated with the inhibition of T cells, but also NK cells and lymphocytes, compared to the predicted effects of treatment with ADA. Treatment with UPA also preferentially inhibited pathways related to bone damage and angiogenesis, as compared to the predicted effect of treatment with ADA. Finally, both treatments were predicted to inhibit multiple pathways associated with the activity of myeloid cells and phagocytes.
Conclusion: Consistent with previous observations in RA[2], UPA is predicted to inhibit multiple functional pathways associated the pathobiology of PsA belonging to the general categories of adaptive and innate immunity but also non-immune vascular and connective tissue biology. In contrast, treatment with ADA appears to affect more specifically functional pathways associated with the innate immune system.

SHARED AND DISTINCT GUT MICROBIOME SIGNATURES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AND ITS RELATED IMMUNE-MEDIATED DISEASES

V. Rios Rodriguez[1], M. Essex[2,3], J. Rademacher[1,4], F. Proft[1], U. Löber[2,3], L. Marko[3,5], U. Pleyer[6], B. Siegmund[1], D. Poddubnyy[1,7], S. Forslund[2,3,5,8]. Background: Immune-mediated diseases such as spondyloarthritis (SpA) consistently coincide with dysbiosis of the gut microbiota and frequently present with additional inflammatory pathologies such as Crohn's disease (CD) and acute anterior uveitis (AAU). Deep profiling of gut microbiota may reveal new pathways of how SpA and its related diseases are initiated and perpetuated.
Objectives: To identify the presence of shared and specific gut microbiota signatures for SpA and its related diseases as a whole, as well as for the individual diseases, relative to healthy controls.
Methods: Patients were recruited with a definite diagnosis of axial SpA, AAU or CD and were compared to controls (patients with back pain and previously ruled out SpA/CD/AAU diagnosis). All patients were naïve to or did not receive treatment with biological disease-modifying antirheumatic drugs for at least 3 months before enrollment of the study. Fecal samples were collected and microbiota composition was determined by 16S rRNA gene sequencing, followed by computational analysis referencing the SILVA138 database. Nonparametric Wilcoxon tests were used to calculate differential abundances between binary groups, and the Spearman correlation was used with continuous covariates. Nested linear models and likelihood ratio tests were used to assess confounding with respect to patient characteristics, HLA-B27 expression, inflammatory markers, and the presence of other immune-mediated diseases.
Results: A total of 300 patients were recruited for the study: 111 axial SpA, 110 AAU, and 79 CD patients and were compared to 63 control individuals. Fifty-three of patients were males with an age (mean±SD) of 39.1±12.3 years. The prevalence of HLA-B27 was 63.0% by patients compared to 7.9% by control individuals. A multivariate PERMANOVA test between the groups was significant ($p<0.001$), revealing a difference in overall composition between the groups.
At the phylum level, patients with axial SpA, AAU and CD contained higher abundances of Proteobacteria, Bacteroidetes and Fusobacteria, and lower abundances of Firmicutes and Actinobacteria compared to the control group. At the genus level, patients (with axial SpA, AAU and CD) displayed a shared gut microbiome signature differing from that of control individuals. Patients samples were strongly depleted in *Blautia* compared to the control group. Many of the differentially abundant taxa also correlated with increased inflammation as measured by C-reactive protein (CRP), including a depletion of *Fusicatenibacter*, *Lachnospiraceae FCS020* and *Roseburia*, as well as an enrichment of *Lactobacillus* and *Veillonella*. By looking at each separate disease phenotype, CD patients differed significantly from the control individuals with respect to many genera. These primarily consisted of depletions in Clostridiales (*Roseburia*, *Coprococcus*, *Ruminococcaceae*), and enrichments of pathogen-harboring genera such as *Escherichia-Shigella* and *Fusobacterium*. Axial SpA patients were uniquely enriched in *Collinsella* and *Holdemanella* and depleted in *Cupriavidus*; the enrichment of *Lactobacillus* and depletion of *Blautia* observed in all patient groups was also associated to the presence of axial SpA, though confounded by CRP. There were strong taxa associations to the presence of HLA-B27, including enrichment of *Asteroleplasma*, *Coprococcus*, *Faecalibacterium*, *Rominococcaceae, Lachnospiraceae NK4A136* and *Rikenellaceae*.
Conclusion: There is a robust shared taxonomic signature among related immune-mediated diseases, in addition to individual disease phenotype signatures. Patients frequently exhibited a strong depletion in *Blautia* and an enrichment in *Lactobacillus* as well as pathogen-harboring genera such as *Escherichia-Shigella* and *Fusobacterium*.

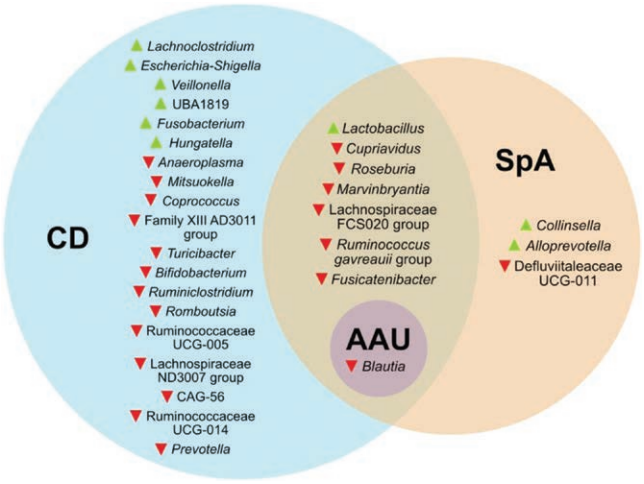

Figure 1. Taxa associations within and between the groups resulting from comparing each with the control group and accounting for disease concomitance and patient characteristics (FDR ≤ 0.05). AAU, anterior acute uveitis; CD, Crohn's disease; SpA, spondyloarthritis.

OP0032

SINGLE CELL ANALYSIS OF SPONDYLOARTHRITIS REGULATORY T CELLS IDENTIFIES DISTINCT SYNOVIAL GENE EXPRESSION PATTERNS AND CLONAL FATES

D. Simone[1,2], F. Penkava[1], A. Ridley[1], S. Sansom[3], H. Al Mossawi[1], P. Bowness[1]. [1]*University of Oxford, NDORMS, Oxford, United Kingdom*; [2]*Università della Campania "Luigi Vanvitelli," Dipartimento Medicina di Precisione, Naples, Italy*; [3]*University of Oxford, Kennedy Institute of Rheumatology, Oxford, United Kingdom*

Background: Regulatory T cells (Tregs) play an important role in controlling inflammation and limiting autoimmunity, but their phenotypes at inflammatory sites in human disease are poorly understood. Whilst the phenotype and transcriptional profile of Tregs have been studied in some immune mediated conditions, they have been little studied (especially at the single cell level) in synovial fluid in the course of inflammatory arthritis. In Spondyloarthritis (SpA), in particular, where pathogenesis and inflammation is driven by dysregulated effector immunity, the role of the regulatory arm of immunity is largely unknown.
Objectives: We aimed to draw an atlas of Tregs in the context of SpA joint inflammation using single cell RNA sequencing of blood and SF Tregs of patients with Ankylosing Spondylitis (AS) and Psoriatic Arthritis (PsA). Functionally distinct specialised Treg subtypes, and specific changes in transcriptional profile occurring in synovial fluid Tregs, providing an insight on Treg adaptation during inflammation. Furthermore, by coupling gene expression analysis with TCR sequencing, we aimed to describe clonally expanded and likely antigen-driven Tregs in the SF.
Methods: Fluorescent activated cell sorting (FACS) was used to isolate 13,400 memory CD3+ CD45RA-ve CD25+127low Tregs from the blood and synovial fluid (SF) of 2 patients with HLA-B27+ AS presenting with active knee arthritis. Single-cell RNA sequencing (scRNA-seq) using 5' V(D)J 10x Genomics technology allowed both transcriptional definition of Tregs, and exploration of their immune TCR repertoire. Findings were compared to >3,000 SF and blood Tregs from 3 patients with olygoarticular PsA [1]. Multicolor flow cytometry and in vitro cell-based assays using patient-derived cells were used to confirm and expand, at protein and functional level, the findings that emerged from the gene expression analysis.
Results: We report a large scRNAseq dataset (approx. 17,000 cells) comparing Tregs from SpA blood and joints. We identify multiple Treg clusters with distinct transcriptomic profiles, including, among others, a regulatory CD8+ subset expressing cytotoxic markers/genes, and a Th17-like *RORC*+ Treg subset characterized by IL-10 and LAG-3 expression. Synovial Tregs show upregulation of interferon signature and TNF receptor superfamily genes, and marked clonal expansion, consistent with tissue adaptation and antigen contact respectively. Individual synovial Treg clones map to different clusters indicating cell fate divergence. Finally, we demonstrate that LAG-3 directly inhibits IL-12/23 and TNF

secretion by patient-derived monocytes, a mechanism with translational potential in SpA.

Conclusion: Our detailed characterization of Tregs at an important inflammatory site illustrates the marked specialization of Treg subpopulations and identifies a broad transcriptional profile upregulated across all synovial regulatory cells. Our TCR analysis provides evidence of Treg clonal expansion, which may be driven by antigen, and confirms functional specialisation of individual clones. We also propose a new insight into a Treg functional mechanism through LAG-3 that suggests a novel therapeutic approach to immune-driven diseases.

OP0033 REGULATORY T CELL CD39 EXPRESSION AS A PREDICTOR OF EARLY REMISSION-INDUCTION WITH METHOTREXATE IN NEW-ONSET RHEUMATOID ARTHRITIS

P. Brown[1,2], A. Anderson[1], B. Hargreaves[1,2], A. Morgan[3,4], J. D. Isaacs[1,2], A. Pratt[1,2]. [1]*Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom*; [2]*Musculoskeletal Unit, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*; [3]*Leeds Institute of Cardiovascular and Metabolic Medicine, Discovery and Translational Science Department, School of Medicine, University of Leeds, Leeds, United Kingdom*; [4]*National Institute for Health Research, Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: The long term outcomes for patients with rheumatoid arthritis (RA) depend on early and effective disease control. Methotrexate remains the key first line disease modifying therapy for the majority of patients, with 40% achieving an ACR50 on monotherapy(1). There are at present no effective biomarkers to predict treatment response, preventing effective personalisation of therapy. A putative mechanism of action of methotrexate, the potentiation of anti-inflammatory adenosine signalling, may inform biomarker discovery. By antagonism of the ATIC enzyme in the purine synthesis pathway, methotrexate has been proposed to increase the release of adenosine moieties from cells, which exert an anti-inflammatory effect through interaction with ADORA2 receptors(2). Lower expression of CD39 (a cell surface 5-'ectonucleotidase required for the first step in the conversion of ATP to adenosine) on circulating regulatory T-Lymphocytes (Tregs) was previously identified in patients already established on methotrexate who were not responding (DAS28 >4.0 vs <3.0)(3). We therefore hypothesised that *pre*-treatment CD39 expression on these cells may have clinical utility as a predictor of early methotrexate efficacy.

Objectives: To characterise CD39 expression in peripheral blood mononuclear cells in RA patients naïve to disease modifying therapy commencing methotrexate, and relate this expression to 4 variable DAS28CRP remission (<2.6) at 6 months.

Methods: 68 treatment naïve early RA patients starting methotrexate were recruited from the Newcastle Early Arthritis Clinic and followed up for 6 months. Serial blood samples were taken before and during methotrexate therapy with peripheral blood mononuclear cells isolated by density centrifugation. Expression of CD39 by major immune subsets (CD4+ and CD8+ T-cells, B-lymphocytes, natural killer cells and monocytes) was determined by flow cytometry. The statistical analysis used was binomial logistic regression with baseline DAS28CRP used as a covariate due to the significant association of baseline disease activity with treatment response.

Results: Higher pre-treatment CD39 expression was observed in circulating CD4+ T-cells of patients who subsequently achieved clinical remission at 6 months versus those who did not (median fluorescence 4854.0 vs 3324.2; p = 0.0108; Figure 1-A). This CD39 expression pattern was primarily accounted for by the CD4+CD25 high sub-population (median fluorescence 9804.7 vs 6455.5; p = 0.0065; Figure 1-B). These CD25 high cells were observed to have higher FoxP3 and lower CD127 expression than their CD39 negative counterparts, indicating a Treg phenotype. No significant associations were observed with any other circulating subset. A ROC curve demonstrates the discriminative utility of differential CD39 expression in the CD4+CD25 high population for the prediction of DAS28CRP remission in this cohort, showing greater specificity than sensitivity for remission prediction(AUC: 0.725; 95% CI: 0.53 - 0.92; Figure 1-C). Longitudinally, no significant induction or suppression of the CD39 marker was observed amongst patients who did or did not achieve remission over the 6 months follow-up period.

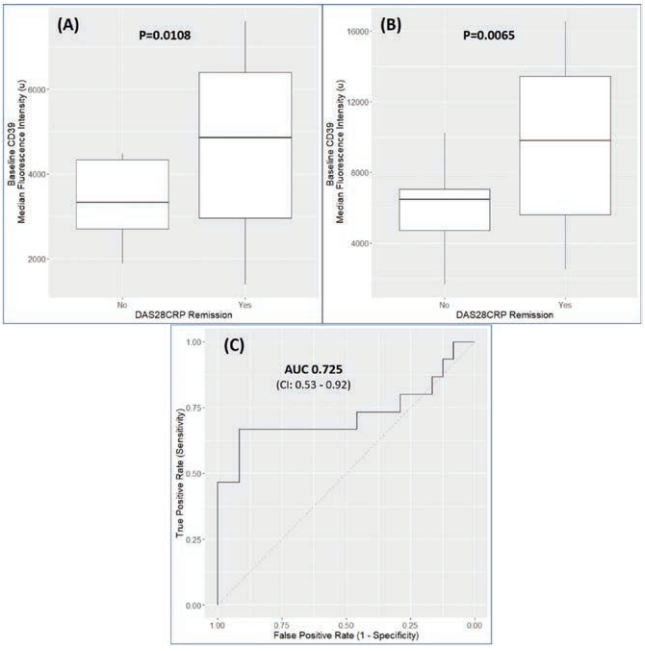

Figure 1. Six month DAS28CRP remission versus pre-treatment median fluorescence of CD39 expression on CD4+ T-cells (A); CD25 High expressing CD4+ T-cells (B); and ROC curve of predictive utility of pre-treatment CD39 expression on CD25 High CD4+ T-cells (C).

Conclusion: These findings support the potential role of CD39 in the mechanism of methotrexate response. Expression of CD39 on circulating Tregs in treatment-naïve RA patients may have particular value in identifying early RA patients likely to respond to methotrexate, and hence add value to evolving multi-parameter discriminatory algorithms.

OP0034 STP938, A NOVEL, POTENT AND SELECTIVE INHIBITOR OF CTP SYNTHASE 1 (CTPS1) DEMONSTRATES EFFICACY IN RODENT MODELS OF INFLAMMATION AND ARTHRITIS

H. Asnagli[1], A. Novak[2], L. Birch[2], R. Lane[2], N. Minet[3], D. Laughton[2], P. George[4], G. De Ribains[5], S. Latour[3], A. Fischer[6], T. Bourne[7], A. Parker[1]. [1]*Step Pharma, Pharmacology, Archamps, France*; [2]*Sygnature Discovery, Discovery Building-Biocity Building, Nottingham, United Kingdom*; [3]*Institut Imagine, Laboratory of Lymphocyte Activation & EBV Susceptibility, INSERM-U1163, Paris, France*; [4]*Independent consultant, Drug Discovery & Development, Paris, France*; [5]*Gamut, Therapeutics, Paris, France*; [6]*INSERM-U1163, AP-HP, Paris, France*; [7]*Milvuswood, Consultancy, High Wycombe, United Kingdom*

Background: The final rate-limiting step in pyrimidine synthesis is the conversion of UTP to CTP which is catalyzed by cytidine triphosphate synthase 1 (CTPS1) or CTPS2. A hypomorphic mutation in the CTPS1 gene has highlighted the essential and non-redundant role of CTPS1 in T and B lymphocyte proliferation[1]. These patients exhibit no effects on non-hematopoietic tissues. Thus, selective inhibition of CTPS1 represents a novel targeted approach to dampen pathological T- and B-cell lympho-proliferation. STP938 is an orally bioavailable, small molecular weight, selective inhibitor of CTPS1 developed by Step Pharma.

Objectives: To demonstrate the in vitro effects of CTPS1 inhibition on T and B cell proliferation and the therapeutic potential of STP938 using in vivo models of disease.

Methods: The *in vitro* anti-proliferative activity of STP938 was investigated using cell lines and primary human PBMCs. STP938 was assessed *in vivo* using the DTH-KLH rat model and the mouse collagen-induced arthritis (CIA) model. For the KLH-DTH model, Lewis rats were immunized with KLH, a week later, challenged locally at the ear with KLH antigen, ear swelling was assessed after 24 hours. Blood samples were collected for detection of KLH-specific IgG levels at day 8. STP938 was given orally one-hour prior to immunization and then b.i.d. for 7 days. For the CIA model, DBA-1 mice were immunized with Collagen type II and complete Freund's adjuvant and received a booster immunization three

weeks later. STP938 was administered to mice developing signs of arthritis from Day 28 to 45 orally daily b.i.d.

Results: STP938 inhibited *in vitro* proliferation of HEK_{wt} but not $HEK\text{-}CTPS1_{KO}$ cells as well as Jurkat and human PBMCs. STP938 demonstrated a significant and dose-dependent inhibition of KLH-specific T and B cell responses *in vivo*. STP938 significantly reduced the disease severity in the CIA model in a dose-dependent manner as determined by clinical and histopathological readouts.

Conclusion: Our preliminary *in vitro* and *in vivo* results indicate that inhibition of CTPS1 specifically blocks proliferation of cells derived from the lymphocyte lineage and reduces the T cell driven inflammatory response. These data highlight the therapeutical potential of STP938 in treating patients with autoimmune diseases such as rheumatoid arthritis.

OP0035 ASSESSMENT OF THE INTESTINAL PERMEABILITY IN PATIENTS WITH RHEUMATOID ARTHRITIS USING COLONIC TISSUES AND SERA

R. Audo[1,2], P. Sanchez[1], J. Mielle[2], L. Macia[3], B. Rivière[4], C. Lukas[1], B. Combe[1], J. Morel[1], C. Daien[1]. [1]*CHU Montpellier, Department of Rheumatology, Montpellier, France*; [2]*UMR5535, IGMM, Montpellier, France*; [3]*University of Sydney, Charles Perkins Center, Montpellier, France*; [4]*CHU Montpellier, Laboratoire d'Anatomie et de Cytologie Pathologiques, Montpellier, France*

Background: Patients with rheumatoid arthritis (RA) have an altered gut microbiota (dysbiosis) (1-3). This microbiota interacts with intestinal epithelium which can lead to an increased intestinal permeability, responsible for the passage of antigens and inflammatory molecules, and can therefore promote systemic inflammation. Gut microbiota tends to normalize with disease control (2), suggesting that systemic inflammation may directly influence the composition of microbiota and the gut barrier. It was shown in many inflammatory diseases that intestinal permeability is impaired, but to date there is very little data in RA.

Objectives: In the present study, we evaluate the intestinal permeability in RA patients by analyzing tight junctions in colonic biopsies and serum markers.

Methods: Colonic biopsies from 20 RA patients who underwent coloscopy for screening with normal histology were compared with those from 20 age and sex matched controls. ZO-1, occludin and claudin 2 junction proteins were evaluated by immunohistochemistry. The staining intensity was assessed by two blinded independent readers. The serum concentrations of LPS-binding protein (LBP), CD14s and zonulin were evaluated by ELISA in 25 patients naive of DMARDs, 41 patients before and after introduction of a DMARDs and 21 controls. Elevated zonulin in serum indicates an increase in intestinal permeability while LBP and CD14s indicate bacterial translocation.

Results: ZO-1 expression was significantly lower in biopsies from patients with RA than controls (mean score ± SD of 1.6 ± 0.56 vs 2.0 ± 0.43; p = 0.01). Age, sex, disease duration and immunological status did not significantly influence the expression of colonic junction proteins. LBP and CD14s were higher in serum from RA patients naive of DMARDs than controls (p = 0.002 and p = 0.003). LBP, CD14s and zonulin levels significantly correlated with DAS28 (r = 0.61, p = 0.005; r = 0.51, p = 0.030 and r = 0.46, p = 0.049, respectively). After treatment, unlike non-responders, LBP and CD14s were significantly reduced in DMARD responders and variations in LBP and CD14s significantly correlated with changes in DAS28 (r = 0.46, p = 0.002 and r = 0, 33 and p = 0.030, respectively).

Conclusion: This work is one of the first to explore intestinal permeability in RA and to show altered tight junction in colonic tissue from RA. This increased intestinal permeability appears to be related to the systemic inflammation. Improving the gut microbiota through food or probiotics could enhance the effect of treatments by limiting this amplification loop of inflammation.

OP0036 IL-6 ACTIVATES YES-ASSOCIATED PROTEIN (YAP) IN FIBROBLASTS AND INDUCES YAP-SNAIL COMPLEX FORMATION TO DRIVE SYNOVIAL LINING PATHOLOGY IN INFLAMMATORY ARTHRITIS

R. Symons[1], F. Colella[1], F. Collins[1], A. Roelofs[1], C. De Bari[1]. [1]*Arthritis and Regenerative Medicine Laboratory, Institute of Medical Sciences, University of Aberdeen, Aberdeen, United Kingdom*

Background: In rheumatoid arthritis (RA), the fibroblast-like synoviocytes (FLS) in synovial lining become invasive and cause joint destruction. The molecular mechanisms underpinning this pathogenic FLS phenotype are incompletely understood. The FLS descend from *Growth differentiation factor 5* (*Gdf5)*-expressing joint interzone cells in the embryo, and we showed that conditional ablation of the transcriptional co-activator Yes associated protein (Yap) in *Gdf5*-lineage cells prevents synovial lining hyperplasia after traumatic cartilage injury in mice [1].

Objectives: Here, we investigated a potential role for Yap in pathogenic FLS in immune-mediated inflammatory arthritis.

Methods: Immunohistochemistry was used to detect Yap in human RA synovium and Yap, Snail and Ctgf in mouse synovium following antigen-induced arthritis (AIA). To determine the effect of Yap knockout (KO) in synovial stromal cells, AIA was induced in *Gdf5-Cre;tdTomato;*$Yap^{fl/fl}$ (*Yap* cKO) and *Gdf5-Cre;tdTomato;*$Yap^{wt/wt}$ (control) mice, or in *Pdgfrα-CreER*;$Yap^{fl/fl}$ (*Yap* ciKO, targeting *Pdgfrα*-expressing fibroblasts) and $Yap^{fl/fl}$ or $Yap^{WT/fl}$ (control) mice after adult tamoxifen induction. Yap KO in both models was confirmed by immunohistochemistry. After nine days, arthritis severity was determined by histological scoring of synovial lining hyperplasia, immune infiltrates, cellular exudate, and marginal erosions. TdTomato+ *Gdf5*-lineage cells in synovium were quantified. *In vitro*, Yap reporter cells were treated with inflammatory cytokines to evaluate their ability to stimulate Yap-induced GFP expression by flow cytometry. Snail overexpression, siRNA-mediated Yap knockdown, and IL-6/sIL-6R stimulation were performed on normal mouse FLS, AIA-FLS or human RA-FLS, and cell invasion through a matrigel-coated transwell was quantified. A proximity ligation assay was utilised to detect Yap/Snail complex formation.

Results: Average expression levels of Yap (p<0.0001), its transcription factor partner Snail (p=0.002), and their downstream target Ctgf (p=0.0003), were increased in mouse synovium after AIA (n=5), and Yap was highly expressed by FLS in human RA synovium. Yap cKO mice (n=24) showed a significantly decreased arthritis severity (p=0.002) after AIA compared to controls (n=22), with significant reductions in synovial lining hyperplasia (p<0.001), synovial immune cell infiltrates (p=0.026) and marginal erosions (p=0.002). Similarly, Yap ciKO mice (n=6) showed a significant decrease in arthritis score (p=0.039) after AIA compared to controls (n=9). However, both control mice (p<0.001) and Yap cKO mice (p<0.001) showed an extensive expansion of tdTomato+ *Gdf5*-lineage synovial cells after AIA, with no significant difference between control and Yap cKO mice. *In vitro*, Yap knockdown prevented IL-6/sIL-6R-induced invasion of normal mouse FLS (p=0.037) and decreased the invasiveness of AIA-FLS (p=0.0057). Using Yap reporter cells, we found that Yap was activated by IL-6/sIL-6R (p=0.016), but not TNFα or IL-1β. Finally, IL-6/sIL-6R treatment of normal mouse FLS (p=0.033) or human RA-FLS (p=0.036) induced Yap-Snail complex formation, and Yap knockdown prevented FLS invasion induced by Snail overexpression (p=0.027).

Conclusion: These data demonstrate that via activation by IL-6, and co-operation with the transcription factor Snail, Yap acts as a key modulator of the invasive and destructive phenotype of FLS in inflammatory arthritis. Therapeutic targeting of Yap could reduce joint destruction in RA.

OP0037

ABATACEPT AND OTHER DMARDS HAVE COMMON TRANSCRIPTOMIC EFFECTS ON RA SYNOVIAL TISSUE

C. Triaille[1,2], T. Gaelle[3], T. Sokolova[1], L. Meric de Bellefon[1,3], C. Galant[4], P. Durez[1,3], B. Lauwerys[1,3], N. Limaye[5]. [1]*Université Catholique de Louvain, Pôle de Pathologies Rhumatismales Systémiques et Inflammatoires, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium*; [2]*Cliniques Universitaires Saint-Luc, Service d'Hématologie, Oncologie et Rhumatologie pédiatrique, Brussels, Belgium*; [3]*Cliniques Universitaires Saint-Luc, Service de Rhumatologie, Brussels, Belgium*; [4]*Cliniques Universitaires Saint-Luc, Service d'Anatomie Pathologique, Brussels, Belgium*; [5]*Université catholique de Louvain, Genetics of Autoimmune Diseases and Cancer, de Duve Institute, Brussels, Belgium*

Background: Modes of action of DMARDs (disease-modifying antirheumatic drugs) in rheumatoid arthritis (RA) are not completely understood at the level of the synovium. Studying treatment-induced modifications in RA synovial tissue can provide unique insights into the pathways modulated downstream of different DMARDs.

Objectives: Our goal was to assess histological and transcriptomic effects of Abatacept (ABA) on RA synovium, and to compare them with previously published data obtained by our group using the same study design on other DMARDs: Tocilizumab (TCZ), Rituximab (RTX), Methotrexate (MTX) and Adalimumab (ADA).

Methods: Synovial tissue was obtained using ultrasound-guided biopsy from affected joints before (W0) and 16 weeks (W16) after treatment with subcutaneous Abatacept 125mg per week on a MTX background. Paraffin-sections were stained for CD3, CD20 and CD68 and scored by a pathologist for T cell, B cell and macrophage infiltration. Transcriptional profiling was performed using GeneChip Human Genome U133 Plus 2.0 arrays (Affymetrix), and analyzed on Genespring GX (Agilent). Pathway analyses were performed on Genespring GX, Metascape (https://metascape.org/) and EnrichR (https://maayanlab.cloud/Enrichr/). Protein-Protein Interaction (PPI) networks were generated on STRING (https://string-db.org/).

Results: 14 RA patients were included (female: 9, ACPA/RF positive: 8, erosive disease: 12, median disease duration in years (± SD): 11.7 (± 8.1), median DAS28CRP (± SD): 4.78 (± 1.11)). Median DAS28CRP significantly decreased between W0 and W16, as did US GS score. Evaluation of histological slides (n=11 pairs of samples) showed no significant effect of Abatacept on T cell, B cell or macrophage infiltration. Gene expression analysis (n=10 pairs of samples) identified 304 transcripts differentially expressed (129 downregulated, 175 upregulated) between W0 and W16 (FC≥1.5 and p<0.05, paired Mann-Whitney). Downregulated genes were significantly enriched for immune processes and included several key T cell regulatory genes (*IL2RA, CD28, IL7, IL7R*), strongly overlapping with data from previous studies on TCZ (n= 12 pairs), RTX (n=12 pairs), MTX (n=8 pairs) and ADA (n=8 pairs). Thus, each treatment shares 31 to 48% of its downregulated genes with the others, with genes downregulated by at least three involved in key RA-associated pathways such as *leukocyte activation*, *NF-kappa B signaling*, *TNF signaling and JAK-STAT signaling*. Given their seemingly overlapping effects, data were pooled across these studies, markedly improving power thanks to their paired-design. This revealed that genes downregulated by DMARDs (n=573, Benjamini-Hochberg corrected p-value<0.05, paired Mann-Whitney) were significantly enriched for both *T cell* and *myeloid leukocyte activation* pathways. Interestingly, DMARDs seem to have a coordinate effect on the two pathways (correlation of mean Log_2FC: r=0.8558, p<0.0001), with a stronger impact ($Log_2FC_{W16\text{-}W0}$) in good responders to therapy (n=17) as compared to moderate (n=20) and to non-responders (n=13) (p<0.0001, Mann-Whitney). Finally, Transcription Factor enrichment and PPI network analyses point to a central role for molecules including JAK/STATs as mediators of all studied therapies.

Conclusion: We provide evidence that the effects of five DMARDs on RA synovium culminate in the same pathways (namely, *T cell* and *myeloid leukocyte activation*). This confirms previous studies suggesting the existence of common mediators downstream of DMARDs, independent of their primary targets, and suggests attractive new therapeutic targets.

Molecular mechanisms in Connective Tissue Disease

OP0038

SPLICEOSOME ALTERATIONS IN LEUCOCYTES FROM APS, SLE AND SLE+APS PATIENTS ARE CLOSELY RELATED TO THEIR MAIN CLINICAL FEATURES

A. M. Patiño-Trives[1], C. Perez-Sanchez[1], A. Ibañez-Costa[2], P. S. Laura[1], M. Luque-Tévar[1], I. Arias de la Rosa[1], M. C. Ábalos-Aguilera[1], D. Ruiz[1], P. Seguí Azpilcueta[1], M. Espinosa[1], N. Barbarroja Puerto[1], E. Collantes Estevez[1], J. P. Castaño[2], R. M. Luque Huertas[2], M. A. Aguirre[1], C. Lopez-Pedrera[1]. [1]*IMIBIC, Reina Sofia Hospital/University of Cordoba, Cordoba, Spain, Córdoba, Spain*; [2]*IMIBIC, Department of Cell Biology, Physiology and Immunology, University of Cordoba, Spain, Córdoba, Spain*

Background: To date, although multiple molecular approaches have illustrated the various aspects of Primary Antiphospholipid Syndrome (APS), systemic lupus erythematosus (SLE) and antiphospholipid syndrome plus lupus (APS plus SLE), no study has so far fully characterized the potential role of posttranscriptional regulatory mechanisms such as the alternative splicing.

Objectives: To identify shared and differential changes in the splicing machinery of immune cells from APS, SLE and APS plus SLE patients, and their involvement in the activity and clinical profile of these autoimmune disorders.

Methods: Monocytes, lymphocytes and neutrophils from 80 patients (22 APS, 35 SLE and 23 APS plus SLE) and 50 healthy donors (HD) were purified by immunomagnetic selection. Then, selected elements of the splicing machinery were evaluated using a microfluidic qPCR array (Fluidigm). In parallel, extensive clinical/serological evaluation was performed, comprising disease activity, thrombosis and renal involvement, along with autoantibodies, acute phase reactants, complement and inflammatory molecules. Molecular clustering analyses and correlation/association studies were developed.

Results: Patients with primary APS, SLE and APS plus SLE displayed significant and specific alterations in the splicing machinery components in comparison with HD, that were further specific for each leukocyte subset. Besides, these alterations were associated with distinctive clinical features.

Hence, in APS, clustering analysis allowed to identify two sets of patients representing different molecular profile groups with respect to the expression levels of splicing machinery components. Principal component analyses confirmed a clear separation between patients. Clinically, cluster 1 characterized patients with higher thrombotic episodes and recurrences than cluster 2 and displayed a higher adjusted global APS score (aGAPSS). Accordingly, these patients showed higher levels of inflammatory mediators than cluster 2.

Similarly, in patients with APS plus SLE, clustering analysis allowed to identify two sets of patients showing differential expression of splicing machinery components. Clinical and laboratory profiles showed that cluster 2 characterized patients that had suffered more thrombotic recurrences, most of them displaying an aGAPSS over 12 points and expressing higher levels of inflammatory mediators than cluster 1. The incidence of lupus nephropathy was similarly represented in both clusters.

Lastly, in SLE patients, molecular clustering analysis identified two sets of patients showing distinctive clinical features. One cluster characterized most of the patients positive for anti-dsDNA antibodies, further suffering lupus nephropathy, and a high proportion of them also presenting atheroma plaques and high levels of inflammatory mediators.

Correlation studies further demonstrated that several deranged splicing machinery components in immune cells (i.e. SF3B1tv1, PTBP1, PRP8 and RBM17) were linked to the autoimmune profile of the three autoimmune diseases, albeit in a specific way on each disorder. Accordingly, *in vitro* treatment of HD lymphocytes with aPL-IgG or anti-dsDNA-IgG changed the expression of spliceosome components also found altered *in vivo* in the three autoimmune diseases. Finally, the induced over/downregulated expression of selected spliceosome components in leukocytes modulated the expression of inflammatory cytokines, changed the procoagulant/adhesion activities of monocytes and regulated NETosis in neutrophils.

Conclusion: 1) The splicing machinery, profoundly altered in leukocytes from APS, APS plus SLE and SLE patients, is closely related to the activity of these diseases, their autoimmune and inflammatory profiles. 2) The analysis of the splicing machinery allows the segregation of APS, APS plus SLE and SLE, with specific components explaining the CV risk and renal involvement in these highly related autoimmune disorders.

OP0039

ALPN-303, AN ENHANCED, POTENT DUAL BAFF/APRIL ANTAGONIST ENGINEERED BY DIRECTED EVOLUTION FOR THE TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND OTHER B CELL-RELATED AUTOIMMUNE DISEASES

S. R. Dillon[1], L. S. Evans[2], K. E. Lewis[1], J. Yang[3], M. W. Rixon[4], J. Kuijper[5], D. Demonte[5], J. Bhandari[4], S. Levin[2], K. Kleist[1], S. Mudri[1], S. Bort[2], D. Ardourel[5], M. A. Seaberg[6], R. Wang[6], C. Gudgeon[1], R. Sanderson[6], M. F. Wolfson[4], J. Hillson[3], S. L. Peng[3]. [1]*Alpine Immune Sciences, Translational Sciences, Seattle, United States of America*; [2]*Alpine Immune Sciences Inc, Immunology, Seattle, United States of America*; [3]*Alpine Immune Sciences Inc, Clinical Development, Seattle, United States of America*; [4]*Alpine Immune Sciences Inc, Protein Therapeutics, Seattle, United States of America*; [5]*Alpine Immune Sciences Inc, Protein Engineering, Seattle, United States of America*; [6]*Alpine Immune Sciences Inc, Bioanalytical Sciences, Seattle, United States of America*

Background: BAFF and APRIL are TNF superfamily members that form homo- and heteromultimers that bind TACI and BCMA on B cells; BAFF also binds BAFF-R. BAFF and APRIL support B cell development, differentiation, and survival, particularly for plasmablasts and plasma cells, and play critical roles in the pathogenesis of B cell-related autoimmune diseases. In nonclinical models, inhibition of either BAFF or APRIL alone mediates relatively modest effects, whereas their co-neutralization dramatically reduces B cell function, including antibody production. Fc fusions of wild-type (WT) TACI (e.g. atacicept and telitacicept) target both BAFF and APRIL and have demonstrated promising clinical potential in e.g. systemic lupus erythematosus (SLE) and IgA nephropathy but have not yet clearly exhibited long-term and/or complete disease remissions.
Objectives: To generate a dual BAFF/APRIL antagonist with inhibitory activity superior to WT TACI and BCMA and with the potential to improve clinical outcomes in B cell-mediated diseases.
Methods: Our directed evolution platform was used to identify a potent variant TNFR domain (vTD) of TACI that exhibits significantly enhanced affinity for BAFF and APRIL as compared to WT TACI; this TACI vTD domain was fused to a human IgG Fc to generate the therapeutic candidate ALPN-303. ALPN-303 was evaluated for functional activity in: 1) human lymphocyte assays, 2) the NOD.*Aec1Aec2* spontaneous model of Sjogren's syndrome (SjS), 3) the bm12-induced mouse model of lupus, 4) the (NZB/NZW)F_1 spontaneous model of lupus, and 5) preclinical rodent and cynomolgus monkey pharmacokinetic/pharmacodynamic studies.
Results: ALPN-303 inhibited BAFF- and APRIL-mediated signaling *in vitro* in human lymphocyte assays, with significantly lower IC_{50} values than WT TACI-Fc and belimumab comparators. In all mouse models evaluated, administration of ALPN-303 rapidly and significantly reduced key lymphocyte subsets including plasma cells, germinal center B cells, and follicular T helper cells. ALPN-303 significantly reduced autoantibodies and sialadenitis in the spontaneous SjS model, inhibited glomerular IgG deposition in the bm12-induced model of lupus, and potently suppressed anti-dsDNA autoAbs, blood urea nitrogen levels, proteinuria, sialadenitis, kidney lesions, and renal immune complex deposition in the NZB/W lupus model. As compared to WT TACI-Fc, ALPN-303 exhibited higher serum exposure and significantly and persistently decreased titers of serum IgM, IgG, and IgA antibodies in mice and cynomolgus monkeys (Figure 1).

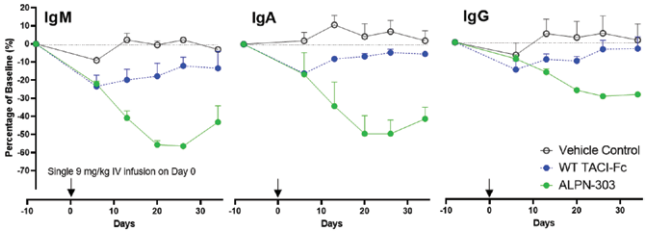

Figure 1. ALPN-303 induces more potent suppression, as compared to WT TACI-Fc, of serum immunoglobulins following a single 9 mg/kg IV infusion (on Day 0; arrows) in female cynomolgus monkeys.

Conclusion: ALPN-303 is a potent BAFF/APRIL antagonist derived from our directed evolution platform that consistently demonstrates encouraging immunomodulatory activity and efficacy *in vitro* and *in vivo*, superior in preclinical studies to anti-BAFF antibody and WT TACI-Fc. This novel Fc fusion molecule demonstrates favorable preliminary developability characteristics, including higher serum exposures and more potent immunosuppressive activities, which may enable lower clinical doses and/or longer dosing intervals than WT TACI-Fc therapeutics. ALPN-303 may thus be an attractive development candidate for the treatment of multiple autoimmune and inflammatory diseases, particularly B cell-related diseases such as SLE, SjS, and other connective tissue diseases. Preclinical development is underway to enable the initiation of clinical trials later this year.

OP0040

HIPPOCAMPAL IMMUNE CELL TRAFFICKING AND A MYELOID PREDOMINANT INFLAMMATORY RESPONSE WITH ENHANCED ANTIGEN PRESENTATION AND DECREASED LEVELS OF NEUROTRANSMITTERS UNDERLY THE NEUROPSYCHIATRIC PHENOTYPE OF THE NZW/NZB MURINE LUPUS MODEL

D. Nikolopoulos[1,2], T. Manolakou[1], A. Filia[1], M. Nakos-Bimpos[1], A. Polissidis[1], D. Boumpas[1,2]. [1]*Biomedical Research Foundation Academy of Athens, Center of Translational Research, Athens, Greece*; [2]*National and Kapodistrian University of Athens, Rheumatology and Clinical Immunology Unit, 4th Department of Medicine, Athens, Greece*

Background: Neuropsychiatric events are common in patients with systemic lupus erythematosus (SLE), yet the underlying pathogenesis remains ill-defined, as the access to brain tissue is limited. We have previously shown that NZW/NZB F1 murine lupus model recapitulates the neuropsychiatric lupus phenotype including depressive-like behavior, increased rates of anxiety, cognitive dysfunction and motor disturbances, both at pre-nephritic and nephritic stages of the disease.
Objectives: To dissect specific regions in the brain, which account for this phenotype and elucidate inflammatory and non-inflammatory mechanisms involved.
Methods: Four distinct brain regions (hippocampus, amygdala, striatum and pre-frontal cortex) were dissected from brains of female C57BL/6 (WT) and NZW/NZB F1 mice at the age of 3 months (pre-nephritic) and 6 months (nephritic stage) (n=5-8/condition/experiment). Since most of the behavioral phenotype corresponds to the hippocampus, we first examined in depth the hippocampal pathology by bulk RNA sequencing, measurements of neurotransmitters levels via high-performance liquid chromatography (HPLC) and by immunophenotyping via flow cytometry analyses. For comparisons, statistical significance was indicated as a two-sided P<0.05.
Results: Transcriptomic analysis revealed aberrant immune mediated response in the hippocampus of 6 month-old lupus mice compared to WT. Specifically, inflammatory pathways including both innate and adaptive immune responses, increased cytokine production, increased antigen presentation and immune cell trafficking, along with increased apoptosis and decreased cell proliferation suggest that immune aberrancies may lead to neuronal damage. These aberrancies were present in mice at 3 month-old, yet were progressed with time being more prominent at 6 month of age in lupus hippocampus. The RNA sequencing date were validated by immunophenotyping on lupus hippocampus demonstrating increased reactive GFAP+ astrocytes both at 3 and 6-month old mice. Activated IBA1+ microglia and CD11b+CD45hi CNS myeloid cells were increased only at 6 months of age. Furthermore, increased immune cell infiltration from the periphery including lymphocytes (CD45+CD11b-) mainly T cells (CD4+/CD8+) and monocytes (CD45+CD11b+Ly6G-Ly6C+), was evident only in 6 month-old lupus hippocampus compared to WT. Importantly, microglia cells in lupus hippocampus at 6 but not at 3 month of age, exhibited increased expression of antigen presenting markers including CD80, CD86 and MHC-II

indicating that microglia cells may carry out the antigen presentation process seen in transcriptomic data. Low levels of serotonin and noradrenaline were observed at both 3 and 6 months of age in lupus mice; these aberrancies were mainly attributed to decreased serotonin synthesis as evidenced by intact serotonin metabolism (no differences were observed at its metabolite: 5-hydroxyindoleacetic acid). Analysis of the remaining regions of the brain combined with studies of metabolic activities of various brain regions by PET-CT scanning is in progress.

Conclusion: Immune cell trafficking from the periphery combined with marked inflammatory response in the hippocampus underlie the neuropsychiatric phenotype in NZW/B murine lupus. Our data indicate increased expression of activated myeloid cells -including microglia- in the hippocampus of lupus mice culminating in increased antigen presentation and decreased neurotransmitter levels.

OP0041 SALIVA AND SERUM LEVELS OF CXCL13: ASSOCIATION WITH THE SEVERITY OF SALIVARY GLAND LESIONS AND LYMPHOMA IN PATIENTS WITH SJÖGREN'S SYNDROME (SS)

L. Chatzis[1], A. Goules[1], A. Tzioufas[1], E. Kapsogeorgou[1]. [1]*School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece*

Background: CXCL13 has been implicated in the formation of ectopic germinal centers (GC) in minor salivary gland (MSG) inflammatory lesions of SS patients. Recent studies suggest that serum CXCL13 levels associate with disease severity and risk for non-Hodgkin's lymphoma (NHL) development.

Objectives: To validate the clinical utility of CXCL13 by investigating potential associations of saliva and serum CXCL13 levels with various histopathologic (including severity of MSG autoimmune infiltrates and GC formation), serologic and clinical features of the disease, as well as NHL.

Methods: CXCL13 levels were measured by a commercially available ELISA (sensitivity: 1 pg/ml; Abcam, Cambridge, UK) in paired serum and saliva specimens from 25 SS patients (9 with NHL; SSL), 9 sicca controls (SC; sicca-complaining individuals with no infiltrates in diagnostic MSG biopsy and negative autoantibody profile) and 6 healthy controls (HC). From the 16 SS patients without evidence of NHL, 5 had mild, 6 intermediate and 5 severe lesions at MSGs, as arbitrarily defined by focus (FS) and Tarpley (TS) biopsy scores (mild: FS:1-1.7, TS:1, intermediate: FS:1.8-2.95, TS:2 and severe: FS: 3.0-11, TS: 3-4). Furthermore, the organization of the MSG infiltrates to GCs has been evaluated in 23 patients revealing 10 with GCs.

Results: Kruskal-Wallis analysis revealed that serum CXCL13 levels were significantly increased in SS patients without or with NHL (median: 94.83 pg/ml and 96.70 pg/ml, respectively), compared to SC and HC (35.44 and 40.92 pg/ml respectively; $p<0.05$), whereas saliva levels were only marginally increased (76.47, 84.10, 55.98 and 65.30 pg/ml in SS, SSL, SC and HC, respectively, $p=0.051$). Among SS patients with distinct MSG lesion severity, only those with severe lesions were found to express significantly higher serum CXCL13 levels (149.3 pg/ml) from SC and HC (p: 0,0051 and 0.0166, respectively). Spearman's Rank correlation analysis showed that both serum and saliva levels correlated with SG biopsy focus score (r: 0.6889, $p=0.0001$ and r: 0.4222, $p=0.01$, respectively). Mann-Whitney test revealed that serum CXCL13 levels were significantly elevated in patients with GCs at MSG lesions (156.1 *vs* 69.64 pg/ml, p:0.0015), rheumatoid factor (105.0 *vs* 53.72 pg/ml, p: 0.015) and marginally with anti-Ro/La antibodies (121.8 *vs* 65.05 pg/ml, p: 0.06) compared to those without. Furthermore, CXCL13 levels were significantly increased in SS patients at high risk to develop NHL compared to low risk (149.3 *vs* 71.54 pg/ml, respectively, p: 0.0275). Saliva levels were not found to associate with the studied features.

Conclusion: Serum and to a lesser extend saliva CXCL13 levels are increased in SS and SSL patients and associate with the degree of MSG infiltration, as assessed by focus score. Serum, but not saliva, CXCL13 associates with various disease features, including GC formation, and may have a clinical utility in identifying SS patients at high risk to develop lymphoma.

OP0042 BLOCKING OF CD103+ TISSUE RESIDENT MEMORY T CELLS (TRM) AS A THERAPEUTIC STRATEGY IN SJOGREN'S SYNDROME

D. Mauro[1], X. Lin[2], G. Guggino[3], D. Chong[2], S. Raimondo[4], D. MA[5], F. Xiao[2], W. Du[2], M. Lo Pizzo[3], L. Zhang[5], A. Rizzo[6], R. Alessandro[4], L. Lu[2], F. Ciccia[1]. Background: Tissue-resident memory T cells (TRM), are a recently identified T cells population featuring tissue localization and expression of markers of tissue homing, CD69 and CD103. Recently, the expansion of CD8+ TRMs and their involvement in the sialadenitis was described in a murine model of SS. However, CD4+ and CD8+ TRM's functional relevance in pSS is still not fully understood, and the TRM therapeutic targeting unexplored.

Objectives: The study aimed to address the role of $CD4^+$ and $CD8^+$ TRMs in the pathogenesis of pSS and to explore the therapeutic targeting of the tissue residency marker of TRM CD103.

Methods: An animal model of experimental (ESS) obtained by immunization of female C57BL/6 mice (n=10) with salivary glands (SG) protein extract and Freund's complete adjuvant used to investigate the dynamic of infiltration of SG by $CD4^+$ and $CD8^+$ TRMs, their frequency, and the impact of CD103 blockade. For the therapeutic intervention, at 10-weeks post-immunization, the salivary gland was cannulated via Wharton's duct, and an anti-CD103 neutralizing antibody or vehicle-injected. The mice's saliva flow rate was assessed, and SGs were analyzed by Flow-cytometry and immunohistochemistry (IHC).

The frequency and localization of TRMs was analyzed in minor SG of sicca syndrome (nSS) and pSS patients (n=39) by flow cytometry and IHC. The expression of genes involved in the tissue retention of TRMs was assessed in SG by RT-PCR.

Results: Upon the ESS progression, a significant progressive increase in $CD45^+CD103+$ cells frequency was observed from 5wk to 20wk post-immunization ($p<0.001$), where the $CD8^+$ were the most abundant, followed by $CD4^+$. Consistently, $CD103^+CD8^+$ T cells were detected within the lymphocytic infiltration of SG from ESS mice. Sorted purified SG $CD10^+CD3^+CD8^+$ T cells showed higher Granzyme B, TNF-alpha expression compared to $CD103^-CD3^+CD8^+$ at both mRNA and protein levels. Notably, ESS mice treated with anti-CD103 showed improvement in salivary function ($p<0.05$) and reduced lymphocytic infiltrations measured as focus score (FS) ($p<0.01$) and area-fraction ($p<0.01$). Consistently, anti-CD103 treatment consistently reduced $CD103^+$ cells and IFN-gamma$^+$, Granzyme B^+, and $TNFa^+$ $CD8^+$ cells. We next performed phenotypic analysis of $CD45^+CD103^+$ immune cells in the SG of pSS patients observing an increase in both with $CD8^+CD103^+CD69^+$ and $CD4^+CD103^+CD69^+$ ($p<0.05$). Finally, IHC showed that the expansion of TRMs in pSS salivary glands was accompanied by a down-regulation of E-cadherin glandular expression and their migration outside the epithelium in the context of inflammatory infiltrates. SG of patients with pSS showed a significant up-regulation of BLIMP1, KFL-2, and S1PR1 and down-regulation of ITGB2. CXCL9 and CXCL10, and IL-15 involved in the tissue recruitment and long-term survival of TRMs were significantly modulated in pSS salivary glands.

Conclusion: TRM are expanded and activated in the SG of pSS and ESS, participating in the organization of tissue inflammation. Although the mechanisms behind this expansion are still not fully understood, CD103 could be a valuable novel therapeutic target to prevent lymphocytic infiltrations and glandular destruction in Sjogren syndrome.

OP0043 INCREASED RISK OF SEVERE INFECTIONS AND MORTALITY IN PATIENTS WITH NEWLY DIAGNOSED SYSTEMIC LUPUS ERYTHEMATOSUS: A POPULATION-BASED STUDY

K. Zhao[1,2], H. Xie[1,2], L. Ll[2,3], A. Aviña[2,3], J. Esdaile[2,3]. [1]*Simon Fraser University, Health Sciences, Burnaby, Canada*; [2]*Arthritis Research Canada, Biostatistics, Richmond, Canada*; [3]*The University of British Columbia, Experimental Medicine, Vancouver, Canada*

Background: Systemic lupus erythematosus (SLE) is a chronic disease with a broad spectrum of autoantibodies and clinical manifestations. As much as 45%

of SLE patients were reported to suffer from severe infections[1,2]. However, due to the high cost of recruiting patients, we still do not have a holistic picture of the SLE-infection association. Administrative data which encompass all provincially funded healthcare service data shows promising opportunities to advance the knowledge and management of the SLE patients which cannot be evaluated by the conventional clinical setting with small sample size and selective samples[3,4,5].

Objectives: To evaluate the risk of severe infection and infection-related mortality among patients with newly diagnosed systemic lupus erythematosus.

Methods: We conducted an age- and gender- matched cohort study of all patients with incident SLE between January 1, 1997 and March 31, 2015 using administrative health data from British Columbia, Canada. Primary outcome was the first severe infection after SLE onset necessitating hospitalization or occurring during hospitalization. Secondary outcomes were total number of severe infections and infection-related mortality.

Results: We identified 5,169 SLE patients and matched them with 25,845 non-SLE individuals from the general population, yielding 955 and 1,986 first severe infections during 48,367 and 260,712 person-years follow-up, respectively. The crude incidence rate ratios for first severe infection and infection-related mortality were 2.59 (95% CI, 2.39-2.80) and 2.20 (95% CI, 1.76-2.73), respectively. The corresponding adjusted hazard ratios were 1.82 (95% CI 1.66-1.99) and 1.61 (95% CI, 1.24-2.08). SLE patients had an increased risk of a greater total number of severe infections with crude rate ratio of 3.24 (95% CI, 3.06-3.43) and adjusted rate ratio of 2.07 (95% CI, 1.82-2.36).

Conclusion: SLE is associated with increased risks of first severe infection (1.8-fold), a greater total number of severe infections (2.1-fold) and infection-related mortality (1.6-fold).

OP0044 ANA POSITIVITY IS ASSOCIATED WITH COMPLEX IMMUNE DISTURBANCE EVEN IN INDIVIDUALS WHO DO NOT DEVELOP CLINICAL AUTOIMMUNE DISEASE

S. U. Hassan[1,2], Z. Wigston[1], A. Burska[1], M. Y. MD Yusof[1,2], E. Vital[1,2]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, Rheumatology, Leeds, United Kingdom*; [2]*NIHR Leeds Musculoskeletal Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Study of pre-clinical autoimmunity can reveal immune changes that initiate or prevent clinical disease. We previously reported an At Risk cohort of ANA positive individuals referred to secondary care, of whom 16% progressed to SLE or Sjogren's syndrome during follow up[1]. Recently, we also reported that even ANA positive individuals who do not develop clinical autoimmunity, have defective pDC function and non-haematopoietic interferon-production[2].

Objectives: To describe the immunophenotype of ANA-positive progressors and non-progressors compared to healthy controls.

Methods: We conducted a prospective observational longitudinal study of At-Risk individuals in Leeds (n=150) over 3 years with annual follow up. Those who met classification criteria for autoimmune connective tissue disease (AI-CTD) during follow up were termed progressors and others; non-progressors. Among the non-progressors, those with no clinical diagnostic criteria at any time point were called absolute non-progressors (ANP).

At baseline we analysed two IFN-stimulated gene expression scores previously described[3] and flow cytometry performed for major circulating subsets. Association between progression group and biomarkers were tested using independent samples t-test.

Results: 3 year follow up data were available in 148/150 patients. Outcomes were: progressors: 30/148 (20%) [SLE=25; pSS=5] and non-progressors: 118/148 (80%). Within the non-progressors, 69/148 (47%) were ANP.

A detailed analysis of baseline biomarkers is included in Table 1. Despite not developing clinically significant disease, non-progressors had significant alterations in several biomarkers. This was also evident in the ANP sub-group.

Table 1.

Biomarker	Healthy Controls Mean (95% CI)	Non-progressors Mean (95% CI)	Difference from healthy controls p	Absolute non-progressors Mean (95% CI)	Difference from healthy controls p	Progressors Mean (95% CI)	Difference from healthy controls p
IFN score A	-6.27 (-6.88, -5.65)	-5.22 (-5.64, -4.80)	0.016	-5.11 (-5.91, -4.32)	0.120	-4.14 (-5.11, -3.18)	0.001
IFN score B	-5.43 (-6.00, -4.85)	-5.30 (-5.62, -4.98)	0.193	-4.96 (-5.45, -4.47)	0.949	-4.27 (-4.90, -3.65)	0.136
% Monocytes	14.80 (10.50, 19.11)	15.46 (12.96, 17.97)	0.187	14.94 (11.42, 18.47)	0.738	10.36 (7.42, 13.30)	0.227
% CD4 T cells	62.90 (57.75, 68.05)	64.89 (60.86, 68.92)	0.001	68.72 (62.97, 74.47)	0.267	60.93 (53.64, 68.21)	0.001
% CD8 T cells	32.18 (27.47, 36.90)	28.60 (25.12, 32.09)	0.135	25.02 (20.28, 29.77)	0.044	31.51 (25.63, 37.40)	0.875
% Naïve B cells	65.59 (56.56, 74.61)	73.74 (70.02, 77.46)	0.001	76.86 (72.21, 81.51)	0.128	68.86 60.62, 75.84)	0.173
% Memory B cells	29.56 (20.42, 38.72)	19.72 (15.84, 23.61)	<0.000	23.13 (16.65, 29.61)	0.054	25.57 (17.18, 33.96)	0.163
% Plasmablasts	1.12 (0.81, 1.43)	0.91 (0.58, 1.24)	0.964	1.01 (0.44, 1.58)	0.457	0.81 (0.53, 1.10)	0.112
% NK cells	13.65 (9.65, 17.65)	12.30 (8.90, 15.71)	0.480	12.35 (6.65, 18.05)	0.781	11.90 (8.65, 15.14)	0.195

Conclusion: Clinically benign ANA positivity is a complex immune state with many features seen in active SLE, including pDC exhaustion, keratinocyte interferon production and strong skin interferon score, increased blood interferon score, and disturbance of B cell subsets. These findings suggest that other factors are necessary for clinical disease, or that regulatory mechanisms stabilise autoimmunity. Further work in this cohort will address these questions.

OP0045 NLRP12 INVOLVES IN THE LUPUS WITH POSITIVE INTERFERON SIGNATURE

Y. P. Tsao[1], F. Y. Tseng[2], C. W. Chao[2], M. H. Chen[1], S. T. Chen[2]. [1]*Taipei Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Medicine, Taipei, Taiwan, Republic of China*; [2]*National Yang-Ming University, Institutes of Clinical Medicine, Taipei, Taiwan, Republic of China*

Background: Systemic lupus erythematous (SLE) is a systemic autoimmune disease with diverse etiological factors. It was recognized that interferon (IFN) signature involved in the progress of SLE. NLRP12 (NOD-like receptor family (NLR) pyrin domain containing 12) is a pyrin containing NLR protein that we had linked its new biological function to the cross-regulation of Toll like receptor (TLRs) and Rig-I like receptor (RIG-I) pathways. NLPR12 acts as an innate immune check-point in regulating type I IFNs expression during TLRs and RIG-I activation. The importance of NLRP12 in lupus disease activity remained to be elucidated.

Objectives: To clarify the role of NLRP12 in regulating the interferon signature.

Methods: Peripheral blood mononuclear cells (PBMCs) were collected from SLE patients and healthy donors for analysis of *NLRP12* and IFN-α gene expression by RT-QPCR. PBMCs were applied for Chromatin immunepreciptation (ChIP) assay and electrical mobility shift assay (EMSA) to determine the putative transcription factor that regulates *NLRP12* expression. An involvement of epigenetic regulation of NLRP12 expression in SLE patients was also analyzed. Bone marrow derived dendritic cells (BMDCs) were collected from wild type mouse and Nlrp12 knocked-out mice. Another CD14+ monocytes were isolated from 10 cases of lupus patients and 8 cases of healthy control, following by stimulating different type of nucleic acids, and IFN-α and IL-6 were measured with ELISA assay. CD14+ monocytes in lupus patients were also pre-treated with IFNAR2 antibody for further nucleic acid stimulation. Two mice models were applied for evaluation the role of Nlrp12: intraperitoneal injection of TMPD (2,6,10,14-tetramethylpentadecane, or pristane) in C57BL/6 mice and Fas^{lpr} mice. Both models were conducted with and without Nlrp12 knockout.

Results: *NLRP12* expression was significantly lower in PBMC isolated from SLE patients compared to healthy donors. The inverse correlation was observed in *NLRP12* and *IFNA* gene expression as well as *NLRP12* expression and amount of double-stranded DNA autoantibody in SLE patients. *NLRP12* expression showed negative correlations with IFN-α treatment, as well as herpes simplex virus-1 (HSV-1) infection. Results from ChIP and EMSA analysis indicated a potential transcription factor 1 (TF-1) regulating NLRP12 promoter activity. TF-1 lead to transcriptional suppression of *NLRP12* in SLE PBMC, and it was gradually induced after IFN treatment. Recruitment of TF-1 to NLRP12 promoter in SLE PBMC compared to the healthy PBMC was detected, and increased when treating with IFN. Human CD14+ monocytes collected from lupus and healthy control stimulating with different type of nucleic acids revealing significant increasing level of *IFN-α* and *IL-6* in lupus patients. Among animal models, both pristine induced mice and Fas^{lpr} mice revealed increasing autoantibodies production and severity of glomerulonephritis in *Nlrp12*-/- group in comparison with *Nlrp12*+/+ ones, indicating the role of NLRP12 in maintaining positive interferon signature as well as disease activity.

Conclusion: Expression level of *NLRP1.2* has been demonstrated to be a biomarker of disease activity in SLE patients. The NLRP12 was involved in the interferon signature, which was also negatively regulated by TF-1. Both clinical samples and animal models revealed NLRP12 in maintaining the positive interferon signature, indicating the possible role of exacerbating factor for lupus disease activity.

Clinical aspects of axial spondyloarthritis – science meets daily practice

OP0046 CAN PATIENTS WITH AXIAL SPONDYLOARTHRITIS INDICATE WHETHER PAIN IS MAINLY RELATED TO INFLAMMATION OR STRUCTURAL DAMAGE?

A. Kampman[1], F. Wink[1,2], M. Carbo[2], F. Maas[2], A. Spoorenberg[2], S. Arends[2].
[1]*Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands*;
[2]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: Patients with axial spondylarthritis (axSpA) mainly rate disease activity on experienced symptoms such as pain (1). Pain is also included in the assessments (ASDAS and BASDAI) used to monitor disease activity in axSpA. However, besides disease activity, also other factors including the presence of structural damage may be related to experienced pain and discomfort.

Objectives: To explore to what extent axSpA patients relate their experienced pain in neck, back and hips to inflammation and/or structural damage.

Methods: Patients from the Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort visiting the out-patient clinic between May 2016 and October 2019 were included in this cross-sectional analysis. Patients filled out two additional questions related to question 2 of the BASDAI: To what extent do you think pain in your neck, back and hips is related to: 1. inflammation caused by axSpA?, 2. damage of spine and joints caused by axSpA? These questions were answered on a NRS from 0 (none) to 10 (very much). A difference of ≥2 points was considered as clinically relevant. Patients who differentiated the cause of their pain were allocated to an inflammation or damage group, in favour of their highest score. Furthermore, patient characteristics and clinical assessments were compared between the inflammation and damage groups.

Results: In total, 688 axSpA patients were included, 62.4% were male, mean age was 47.9 years, median symptom duration was 19 years, 77.9% were HLA-B27+, mean BASDAI was 3.9 and mean $ASDAS_{CRP}$ was 2.3. Respectively 13% and 14% of the patients reported a score of 0 on the additional questions about inflammation or damage.

In total, 517 (75%) patients could not differentiate between inflammation or damage. 102 (15%) patients interpreted experienced pain as mainly related to inflammation and 69 (10%) patients interpreted their pain as mainly related to structural damage.

Patients who interpreted pain as mainly related to inflammation were significantly younger, had shorter symptom duration, were more frequently diagnosed as non-radiographic axSpA and had higher $ASDAS_{CRP}$, which was driven by the patient-reported questions as the objective marker CRP was not significantly different between both groups (Table 1).

Table 1. Patients characteristics and clinical assessments of axSpA patients who related pain mainly to inflammation versus to structural damage.

	Inflammation group (n = 102)	Structural damage group (n = 69)	P-value
Age (years)	39.5 ± 12.4	48.9 ± 12.4	<0.001
Symptom duration (years)	12 (6 – 20)	28 (17 – 35)	<0.001
Diagnosis non-radiographic axSpA	39 (40%)	8 (13%)	<0.001
Male gender	60 (59%)	44 (64%)	0.627
BASDAI	4.2 ± 1.8	3.9 ± 2.0	0.371
BASDAI – Q2	6 (3 – 7)	4 (2 – 6)	0.005
Patient global disease activity	4 (3 – 7)	3 (2 – 5)	<0.001
$ASDAS_{CRP}$	2.6 ± 0.9	2.2 ± 0.8	0.003
CRP	3.0 (2.0 – 8.0)	2.5 (2.0 – 4.4)	0.094
Occiput wall distance (cm)	0.0 (0.0 – 4.0)	4.0 (0.0 – 10.0)	<0.001
Chest expansion (cm)	5.8 (4.0 – 7.0)	4.0 (3.0 – 6.0)	0.006
Modified Schober test (cm)	14.0 ± 1.6	13.5 ± 1.6	0.052
Lateral flexion mean (cm)	15.3 ± 6.5	12 ± 5.9	0.001
Cervical rotation mean (degrees)	80 (70 – 90)	70 (45 - 81)	<0.001
mSASSS *	3.0 (0.0 – 9.0)	8.0 (1.8 – 26.0)	0.061

* only available in a subgroup of patients. Inflammation group (n=31), structural damage group (n=39).

Patients who reported their pain as mainly related to structural damage showed significantly worse spinal mobility on almost all spinal mobility tests. In the subgroup of patients with available mSASSS data, there was also a trend towards more spinal radiographic damage (Table 1).

Conclusion: In our large observational cohort of axSpA patients, the vast majority (75%) could not rate whether experienced pain in neck, back and hips was more related to inflammation or structural damage. However, if patients were able to relate pain to inflammation or damage, it seems in accordance with the outcome of their clinical assessments.

Background: Patients with a diagnosis of Spondyloarthritis (SpA) and Psoriatic Arthritis (PsA) may have predominant axial or peripheral symptoms, and the frequency and distribution of these symptoms may determine the clinical diagnosis by the rheumatologist ("clinical clusters"). Clustering analysis represents an unsupervised exploratory analysis which tries to identify homogeneous groups of cases ("statistical clusters") without prior information about the membership for any of the cases.
Objectives: To identify "statistical clusters" of peripheral involvement according to the specific location of these symptoms in the whole spectrum of SpA and PsA (without prior information about the diagnosis of the patients), and to evaluate whether these "statistical clusters" are in agreement with the "clinical clusters".
Methods: Cross-sectional and multicentre study with 24 participating countries. Consecutive patients considered by their treating rheumatologist as suffering from either PsA, axial SpA (axSpA) or peripheral SpA (pSpA) were enrolled. Four different cluster analyses were conducted: the first one using information about the specific location from all the peripheral musculoskeletal manifestations (i.e., peripheral arthritis, enthesitis and dactylitis), and thereafter a cluster analysis for each peripheral manifestation individually. Multiple correspondence analyses and k-means clustering methods were used. Distribution of peripheral manifestations and clinical characteristics were compared across the different clusters.
Results: 4465 patients were included in the analysis. Two clusters were found with regard to the *location of all the peripheral manifestations* (Fig. 1). Cluster 1 showed a low prevalence of peripheral manifestations in comparison with cluster 2; however, when peripheral involvement appeared in cluster 1, this was mostly represented by arthritis of hip, knee and ankle, as well as enthesitis of the heel. Patients from cluster 1 showed a higher prevalence of males (63% vs 44%), HLA-B27 positivity (69% vs 38%) and axial involvement (80% vs 52%), as well as more frequent diagnosis of axSpA (66% vs 21%) and more frequently fulfilling the ASAS axSpA criteria (69% vs. 41%). Patients from cluster 2 showed a higher prevalence of psoriasis (63% vs 25%), a more frequent diagnosis of PsA (61% vs 19%), and they fulfilled more frequently the peripheral ASAS (26% vs 11%) and the CASPAR criteria (57% vs 19%).

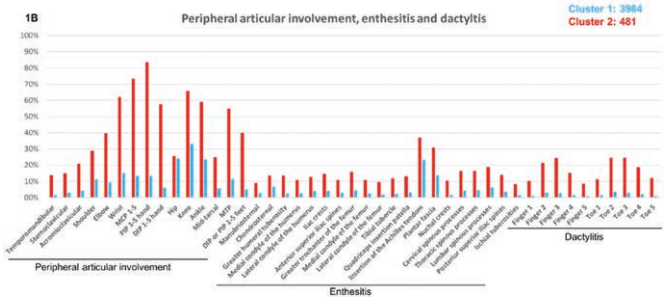

Figure 1. Distribution of the peripheral involvement across clusters

Three clusters were found with regard to the *location of the peripheral arthritis.* Clusters 2 and 3 showed a high prevalence of peripheral joint disease, although this was located more predominantly in the lower limbs in cluster 2, and in the upper limbs in cluster 3. Cluster 1 showed a higher prevalence of males, HLA-B27 positivity, axial involvement, a lower presence of psoriasis, a more frequent diagnosis of axSpA and fulfilling the ASAS axSpA criteria in comparison with clusters 2 and 3, respectively. Clusters 2 and 3 showed a higher prevalence of enthesitis and dactylitis in comparison with cluster 1, a more frequent diagnosis of PsA and fulfillment of the CASPAR criteria. Information about the *location of enthesitis* exhibited three groups: cluster 1 showed a very low prevalence of enthesitis, while cluster 2 and 3 showed a high prevalence of enthesitis, with a predominant involvement of axial enthesis in cluster 2 and peripheral enthesitis in cluster 3.
Finally, the *analysis of dactylitis* also exhibited three clusters that showed a very low prevalence of dactylitis, predominantly toes and predominantly fingers involvement, respectively.
Conclusion: These results suggest the presence of heterogeneous patterns of peripheral involvement in SpA and PsA patients without clearly defined groups, confirming the clear overlap of these peripheral manifestations across the different underlying diagnoses.

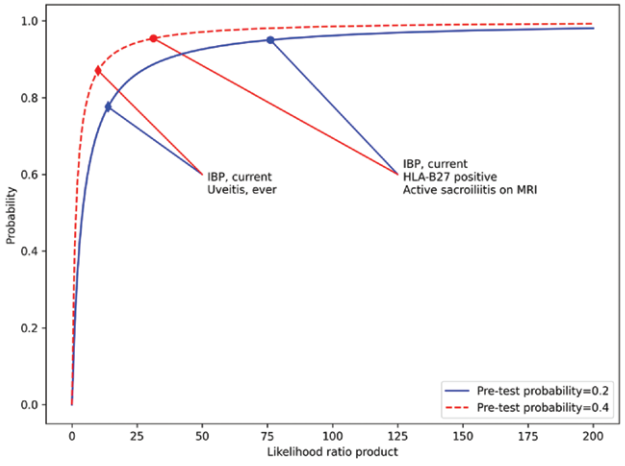
OP0048

DIAGNOSING AXIAL SPONDYLOARTHRITIS: ESTIMATION OF THE DISEASE PROBABILITY IN PATIENTS WITH A PRIORI DIFFERENT LIKELIHOODS OF THE DIAGNOSIS

D. Poddubnyy[1,2], F. Proft[1], L. Spiller[1], M. Protopopov[1], V. Rios Rodriguez[1], B. Muche[1], J. Rademacher[1], M. Torgutalp[1], J. L. Vahldiek[3], J. Sieper[1], I. Redeker[2]. [1]*Charité – Universitätsmedizin Berlin, Division of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*; [2]*Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology Unit, Berlin, Germany*; [3]*Charité – Universitätsmedizin Berlin, Division of Radiology, Berlin, Germany*

Background: The diagnostic approach in axial spondyloarthritis (SpA) relies on a estimation of the post-test disease probability that is based on evaluation of positive and negative results of diagnostic tests in the context of the pre-test disease probability.
Objectives: To evaluate the diagnostic value of SpA parameters and their combination for the diagnosis of axial SpA in patients with an *a priori* different probability of the diagnosis.
Methods: A total of 361 patients with chronic back pain and suspicion of axial SpA (181 referred by primary care physicians or orthopaedists, 180 recruited via an online screening tool) received a structured rheumatologic examination as a part of the OptiRef study [1], which resulted into a diagnosis or exclusion of axial SpA. The prevalence of axial SpA indicating the pre-test probability was 40% in the physician-referred subgroup and 20% in the online screening subgroup. Sensitivities, specificities, and likelihood ratios (LRs) for SpA features were determined in both subgroups and the respective post-test probabilities of axial SpA were calculated.
Results: The relative diagnostic value of single SpA features varied substantially between the groups with different referral pathways – see the online disease probability calculator http://www.axspa.de/calculator.html. It can be seen that the diagnostic values of the SpA parameters vary substantially between the groups. For instance, HLA-B27 positivity increased the probability of the presence of axial SpA by 35% to 55% in online-screened patients and by 22% to 62% in physician-referred patients. Furthermore, the absence of HLA-B27 resulted in a sharp decrease in the probability of the presence of axial SpA in physician-referred patients (from 40% to 6%). This decrease was less sharp in the online screening group (from 20% to 10%). Furthermore, combinations of parameters performed differently in the studied subgroups. Figure 1 illustrates that the observed differences in the diagnostic values of the SpA parameters in different subgroups were only clinically relevant in the presence of a low number of positive test results. For instance, combining IBP with anterior uveitis increased the post-test probability for axial SpA to 78% in the online screening group and to 87% in the physician-referred group, whereas using HLA-B27 positivity and active sacroiliitis on MRI in combination with IBP resulted in a surge in the post-test probability of the presence of axial SpA to around 95% in both groups.

Figure 1. The relationship between the likelihood ratio product and the post-test probability of axial SpA in patients with different pre-test disease probability.



The relationship between the likelihood ratio product and the post-test probability of axial SpA is depicted for patients referred via an online screening tool (pre-test probability of axial SpA = 20%) and in patients referred via a physician-based referral tool (pre-test probability of axial SpA = 40%).

IBP: inflammatory back pain; MRI: magnetic resonance imaging; SpA: spondyloarthritis.

Conclusion: The diagnostic value of a single diagnostic test in the clinical practice is not fixed and a number of factors including the referral pathway can affect it. Fluctuation of the diagnostic values is especially relevant when the number of positive parameters is low (1-2).

OP0049 COMPARISON OF BASELINE DISEASE ACTIVITY AND PATIENT (PT)-REPORTED OUTCOMES (PROS) BETWEEN PTS WITH PSORIATIC ARTHRITIS AND AXIAL INVOLVEMENT (AXIAL PSA) AND AXIAL SPONDYLOARTHRITIS (AXIAL SPA) FROM THE CORRONA PSA/SPA REGISTRY

P. J. Mease[1], M. Marchese[2], R. Mclean[2], T. Blachley[2], L. Anatale-Tardiff[2], C. Saffore[3], E. Lesser[3], A. Ogdie[4]. [1]*Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, United States of America*; [2]*Corrona, LLC, Waltham, United States of America*; [3]*AbbVie Inc., North Chicago, United States of America*; [4]*University of Pennsylvania, Philadelphia, United States of America*

Background: Although pts with axial PsA and axial SpA share some common clinical characteristics, there are also potential differences that may influence disease assessment and treatment response. Identifying differences between the two pt populations is important for assessment of disease characteristics and severity as well as informing treatment decisions. There has been little comparative characterization of these conditions in a US population.

Objectives: To compare characteristics of pts with axial PsA and axial SpA.

Methods: Pts ≥18 years of age diagnosed with axial PsA or axial SpA at enrollment in the prospective, multicenter, observational Corrona PsA/SpA Registry between March 2013 and August 2020 were included. Enrollment visit demographics, clinical characteristics, treatment history, disease activity measures, and PROs were compared between disease groups. Continuous measures were reported using means and standard deviations; means for disease groups were compared using two-sample *t* tests or Wilcoxon rank sum tests. Categorical measures were reported as frequencies and percentages; frequencies in disease groups were compared using chi-square or Fisher exact tests.

Results: A total of 1044 pts (470 with axial PsA and 574 with axial SpA) were identified (Table). Pts with axial PsA were older with a higher percentage being female vs pts with axial SpA. Time since symptom onset and diagnosis were shorter for pts with axial PsA vs axial SpA (12.0 vs 15.6 years [*P*<0.001] and 6.8 vs 8.3 years [*P*=0.01]). Pts with axial PsA were less likely than pts with axial SpA to have current or historical uveitis (4% vs 14% [*P*<0.001]) or inflammatory bowel disease (5% vs 10% [*P*=0.005]). Prior biologic synthetic disease-modifying antirheumatic drug (bDMARD) and conventional synthetic DMARD use was more prevalent in the axial PsA vs axial SpA groups (64% vs 52% [*P*<0.001]/59% vs 32% [*P*<0.001]), while mean dactylitis (measured by Dactylitis Count) and enthesitis (measured by Spondyloarthritis Research Consortium of Canada [SPARCC] Enthesitis Index) counts were higher (0.4 vs 0.1 [*P*<0.001]/1.7 vs 1.2 [*P*<0.001]). Mean pt-reported pain and spinal pain were lower in pts with axial PsA vs axial SpA (49.4 vs 53.9 [*P*=0.015]/40.8 vs 49.7 [*P*<0.001]) (Figure). The proportion of pts with morning stiffness along with mean fatigue and work impairment scores were similar between disease groups.

Table.

Baseline demographics and clinical characteristics	Axial PsA N=470	Axial SpA N=574	*P* value
Age (years), mean ± SD	51.6 ± 13.2	47.7 ± 14.0	<0.001
Female, n (%)	265 (57)	248 (44)	<0.001
White, n (%)	428 (94)	507 (91)	0.089
Years since symptom onset, mean ± SD	12.0 ± 11.6	15.6 ± 12.1	<0.001
Years since diagnosis, mean ± SD	6.8 ± 9.0	8.3 ± 10.5	0.010
HLA-B27 positive status, n/n (%)	52/189 (28)	214/295 (73)	<0.001
Abnormal CRP, n (%)	88 (19)	140 (24)	0.033
Uveitis, n (%)	20 (4)	80 (14)	<0.001
IBD, n (%)	25 (5)	59 (10)	0.005
Dactylitis count, mean ± SD	0.4 ± 1.5	0.1 ± 0.7	<0.001
SPARCC enthesitis count, mean ± SD	1.7 ± 2.9	1.2 ± 2.4	<0.001
Morning stiffness, n (%)	439 (95)	537 (96)	0.923
BASDAI (0–10), mean ± SD	4.8 ± 2.5	4.9 ± 2.4	0.463
BASDAI Q2 (0–10): spinal pain, mean ± SD	5.0 ± 2.9	5.7 ± 2.9	<0.001
BASDAI Q3 (0–10): peripheral pain/swelling, mean ± SD	4.5 ± 2.9	4.0 ± 3.1	0.010
Modified BASDAI (0–10), mean ± SD	5.0 ± 2.5	5.4 ± 2.4	0.013
Prior bDMARDs, n (%)	300 (64)	299 (52)	<0.001
Prior csDMARDs, n (%)	275 (59)	181 (32)	<0.001
Prior prednisone use, n (%)	54 (12)	73 (13)	0.611
Prior NSAID use, n (%)	52 (11)	46 (8)	0.115

Conclusion: Findings from this descriptive real-world analysis suggest there may be meaningful differences between pts with axial SpA and axial PsA but future studies are needed to better understand these differences.

OP0050 TWO-YEAR DIAGNOSTIC CONSISTENCY IN PATIENTS WITH CHRONIC BACK PAIN SUSPECTED OF AXIAL SPONDYLOARTHRITIS IN PROTOCOLISED FOLLOW-UP: DATA FROM THE SPONDYLOARTHRITIS CAUGHT EARLY COHORT

A. Boel[1], M. Van Lunteren[1], K. M. Fagerli[2], U. Lindström[3], R. Ramonda[4], M. G. H. Van de Sande[5], F. A. Van Gaalen[1], D. Van der Heijde[1]. Background: A diagnosis of (early) axial spondyloarthritis (axSpA) is based on pattern recognition, which can be challenging and may change over time.

Objectives: To investigate consistency of diagnosis over two years in patients with chronic back pain (<2 years symptoms) suspected of axSpA.

Methods: In the SPACE cohort, patients over 16 years of age referred to the rheumatology outpatient clinic with chronic back pain (CBP) (≥3 months and <2 years) starting before the age of 45, suspected of axSpA were included. Follow-up was performed only in patients with at least two SpA features or one SpA feature with a positive likelihood ratio ≥6.4[1].

According to protocol, all SpA features as well as MRI and radiographs of the sacroiliac joints were performed at baseline and two years. Physicians were asked to report whether the diagnosis was axSpA or no axSpA at both timepoints, for which they had information available on all SpA features and locally

read imaging. Only patients with complete data on diagnosis and imaging at baseline and 2 years were included.
Patients were labelled with a consistent axSpA diagnosis if they had a diagnosis of axSpA at baseline and at two-year follow-up. Those patients whose diagnosis switched from axSpA to no axSpA; or from no axSpA to axSpA were labelled inconsistent axSpA diagnosis.
Results: Over two years, in 295 patients with CBP the diagnostic consistency rate was 84%, of whom 184 patients (62%) had a diagnosis axSpA and 66 (22%) a diagnosis no axSpA at both timepoints. 26 patients changed from axSpA to no axSpA (9%) and 19 patients from no axSpA to axSpA (7%).
The patients who only had an axSpA diagnosis at baseline were more often male and less often HLA-B27 positive compared to the other two groups (Table). Furthermore, both groups with an inconsistent diagnosis had fewer SpA features and a lower level of confidence of the diagnosis (LoC) compared to the group with a consistent diagnosis of axSpA, especially at baseline.

Table 1. Characteristics at baseline and 2-year follow-up of the group with a consistent axSpA diagnosis over 2 years and the groups whose diagnosis (axSpA/no axSpA) changed

	Consistent diagnosis axSpA AxSpA at baseline and 2yrs *(N=184)*		Inconsistent diagnosis AxSpA at baseline only *(N=26)*		Inconsistent diagnosis AxSpA at 2yrs only *(N=19)*	
	Baseline	2-year	Baseline	2-year	Baseline	2-year
Female	45%		15%		42%	
Inflammatory Back Pain	69%	74%	69%	77%	68%	84%
HLA-B27 positive	75%	75%	27%	27%	68%	68%
Sacroiliitis radiographs*	27%	38%	0%	0%	5%	5%
Sacroiliitis MRI*	69%	81%	23%	27%	5%	21%
Number of SpA features, mean (SD)	5 (2)	7 (2)	3 (1)	5 (2)	3 (1)	5 (1)
LoC diagnosis axSpA/no axSpA, mean (SD)	8.1 (2.0)	8.6 (1.8)	5.8 (1.7)	7.5 (1.9)	5.6 (2.2)	6.1 (2.3)

* Based on local reading axSpA, axial Spondyloarthritis; HLA-B27, Human Leucocyte Antigen B27; LoC, Level of Confidence regarding diagnosis; MRI, Magnetic Resonance Imaging; SpA, Spondyloarthritis.

At two-year follow-up the LoC in the group with an axSpA diagnosis at 2 years only was much lower than in the other two groups. In the group that only had an axSpA diagnosis at baseline, the LoC regarding the diagnosis increased most compared to baseline: physicians were more certain of the diagnosis no axSpA at two-year follow-up than they were of the diagnosis axSpA at baseline.
The number of patients with sacroiliitis on radiographs and MRI was much higher in the group with a consistent diagnosis of axSpA. Although the percentage of patients with sacroiliitis on MRI increased in the group with a diagnosis of axSpA at two-year follow-up only, this was still much lower (21%) compared to the patients with a consistent diagnosis (81%). This was in line with a low LoC in this group.
Conclusion: In a cohort of patients with CBP suspected of axSpA the diagnostic consistency rate was high. Interestingly, in the group that only had a diagnosis axSpA at baseline, rheumatologists were more certain about the absence of axSpA at two years than the presence of axSpA at baseline.

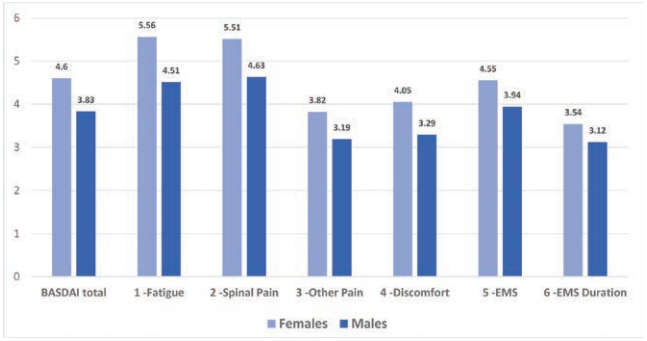
OP0051 LOOKING BEYOND BASDAI TOTAL SCORES: ANALYSIS OF THE BASDAI ON THE BASIS OF SEX

S. Maguire[1,2], P. Gallagher[3], F. B. O'shea[1,2]. [1]*St James' Hospital, Department of Rheumatology, Dublin, Ireland*; [2]*Trinity College Dublin, School of Medicine, Dublin, Ireland*; [3]*St Vincent's Hospital, Department of Rheumatology, Dublin, Ireland*

Background: Females with axial spondyloarthropathy (axSpA) average scores on patient reported outcomes (PROs) than males. However, this does not necessarily correlate to worse clinical findings. The Ankylosing Spondylitis Registry of Ireland (ARSI) is a national registry on patients with axSpA in Ireland and a source of epidemiological data.
Objectives: The purpose of this study was to compare the scores of each sex across the individual components of the BASDAI to understand why females report worse scores than males.
Methods: Analysis of the ASRI was preformed using IBM SPSS version 26. Patients were analyzed on the basis of gender. Comparison of baseline characteristics and mean BASMI, BASFI, HAQ and ASQoL were tested for significance using an independent two tailed t-test and a Mann Whitney U test. Mean total BASDAI score and mean score for each component of the BASDAI were compared and tested for significance with the same statistical tests. A chi-squared test for independence was used to determine significance in variation of HLA-B27 status and radiographic findings.
Results: A total of 857 patients were included in the analysis. Patient population was 24.9% (213) female and 75.1% (644) male with a mean age of 45.9 years and mean disease duration of 19.4 years (means: BASDAI 4.02, BASMI 4, BASFI 3.67, HAQ 0.53, ASQoL 6.48). Females had worse BASDAI(4.6 vs 3.83, p<0.01), HAQ(0.6 vs 0.51, p=0.03) and ASQoL scores (7.62 vs 6.12, p<0.01) than males. BASFI scores were worse in females which did not reach significance (3.89 vs 3.63, p=0.26). However, females had significantly better BASMI scores than males (3.51 vs 4.16, p<0.01). Within the BASDAI, females scored significantly worse than males across all components (Fatigue: 5.56 vs 4.51, p<0.01; Spinal pain: 5.51 vs 4.63, p<0.01; Other pain: 3.82 vs 3.19, p=0.01; Discomfort: 4.05 vs 3.29, p<0.01; EMS: 4.55 vs 3.94, p=0.01), however duration of EMS did not reach significance (3.54 vs 3.12, p=0.07)(graph 1). Within the BASDAI, females recorded highest mean scores for fatigue (5.56), while males recorded highest mean scores for spinal pain(4.63). Lowest mean scores for both genders was for EMS duration (3.54 vs 3.12). Ranking of the BASDAI components by mean scores show similarity in the ranking of discomfort, EMS, other pain and EMS duration(Table 1).



Graph 1. Breakdown of BASDAI scores in Females compared to Males

Table 1. Ranking in order of severity by mean score

	Females	Males
1 -most severe	Fatigue	Spinal pain
2	Spinal Pain	Fatigue
3	EMS	EMS
4	Discomfort	Discomfort
5	Other pain	Other pain
6 -least severe	EMS duration	EMS duration

Conclusion: AxSpA females have consistently worse PROs but have better spinal mobility than males. Despite females recording worse BASDAI scores than males, the pattern of active disease is similar in 4 of the 6 components of the BASDAI. However, fatigue is the most problematic symptom in females with active axSpA while spinal pain is the most problematic symptom for males. This variation by gender should be kept in consideration when evaluating a patient with suspected active axSpA.

Vétérinaire d'Alfort, Inserm, U955-IMRB, Équipe 03, Créteil, France; [9]*Université Paris Est Créteil, INSERM, U955 équipe 03, Créteil, France*; [10]*Université Paris Est Créteil, INSERM, U955 équipe 18, Créteil, France*

Background: The disease course of axial SpA (axSpA) is highly variable and can be characterized by ongoing axial inflammation and radiographic progression associated with restricted mobility of the spine, reduced function and disability leading to impairment in quality of life. Control of disease activity is a primary aim in axSpA management. To assess disease activity the Ankylosing Spondylitis Disease Activity Score-C-reactive protein (ASDAS-CRP) is often considered as a reference tool. The data on remission are spare in axSpA and the identification of long-term remission factors, enabling the patient's management to be adapted, seems necessary but remains unclear.
Objectives: To evaluate the proportion of patients in remission according to ASDAS-CRP at 5 years of follow-up, to describe their characteristics in comparison with patients with active disease at that time, and to identify baseline factors associated with remission at 5 years of follow-up.
Methods: We included all patients from the DESIR (*Devenir des Spondylarthropathies Indifférenciées Récentes*) cohort with available data on ASDAS-CRP at 5-year follow-up and TNFα inhibitors exposure. Patients in remission, defined as an ASDAS-CRP<1.3, and with active disease were compared according to their main demographic, clinical, biological and radiological characteristics. A logistic model stratified on TNFα inhibitors exposure was used in the main analysis. Sensitivity analyses among patients with axSpA diagnosis confirmed by rheumatologist at 5-years were performed.
Results: A total of 614 patients were followed in the DESIR cohort at M60. After excluding those with missing data on ASDAS score (n= 163) and TNFα inhibitors exposure (n= 2), analyzed patients were 449 (73%). Excluded patients had similar baseline characteristics to those included in the analysis. Among patients unexposed to TNFα inhibitors (n=247), 77 (31%) were in remission (37,8±8,3 years; 55% men, 58% NSAID users), 170 (69%) weren't (39,8±8,6 years; 42% men, 81% NSAID users). Among exposed patients (n=202), 34 (17%) were in remission (36,1±8,1 years; 71% men, 29% NSAID users), 168 (83%) weren't (39,5±9,0 years; 41% men, 63% NSAID users) (Figure 1). Overall, patients in remission were more frequently men, HLA-B27+, with high education and lower BMI at 5-year of follow-up. The baseline factors associated with remission at 5 years of follow-up from the multivariate analysis are presented in Table 1.

Table 1. Baseline factors associated with remission at 5-year follow-up (multivariate analysis)

	Baseline factors positively associated with 5-year remission	Baseline factors negatively associated with 5-year remission
Unexposed to TNFα inhibitors	• Past history of **arthritis** (OR_a=2.1, 95%CI 1.2-5.3)	• Low **BASDAI** (OR_a=0.9, 95%CI 0.8-0.9)
Exposed to TNFα inhibitors	• High **education** (OR_a=2.9, 95%CI 1.6-5.1)	• Low **BASDAI** (OR_a=0.9, 95%CI 0.9-0.9) • Low **BMI** (OR_a=0.8, 95%CI 0.7-0.9) • Low **enthesitic index** (OR_a=0.8, IC95% 0.7-0.9)

Conclusion: The overall remission rate at 5 years was 25%, 31% among patients unexposed to TNFα inhibitors and 17% among those exposed. This study reveals the difficulty in achieving 5-year remission in recent axSpA, especially in the most active forms at baseline; socio-educational factors and overweight also appear to be related.

OP0053

IMPACT OF CORRECTING CRP THRESHOLD ACCORDING TO BMI ON DIAGNOSIS, DISEASE ACTIVITY, INDICATION OF BIOLOGICAL TREATMENT AND PREDICTION OF THERAPEUTIC RESPONSE, IN PATIENTS SUSPECTED OF AXIAL SPONDYLOARTHRITIS. RESULTS FROM DESIR COHORT

O. Facorat[1], J. Morel[2], B. Combe[2], P. Richette[3], C. Lukas[2]. [1]*University Hospital of Martinique, Rheumatology, Fort de France, France*; [2]*University Hospital of Montpellier, Rheumatology, Montpellier, France*; [3]*Lariboisière Hospital, Rheumatology, Paris, France*

Background: Acute phase reactants are crucial parameters to consider for management of chronic inflammatory back pain (IBP) patients suspect of axial spondyloarthritis (ax-SpA). Indeed, C-reactive protein (CRP) is part of ASAS classification criteria for SpA, impacts on assessment of disease activity by ASDAS-CRP score, and should be elevated when a bDMARD is discussed in patients without radiological sacroiliac lesions. Moreover, elevated CRP is regarded predictive of favorable therapeutic response. Obesity in otherwise healthy people is associated with high CRP values. An adjusted definition of normal CRP threshold based on gender and BMI has been proposed.
Objectives: The aim of this study was to assess whether correcting CRP threshold with patient's BMI would change classification according to ASAS criteria for ax-SpA, presence of clinically relevant activity according to ASDAS-CRP, indication for TNF inhibitor (TNFi) and, as primary endpoint, improve prediction of therapeutic response to first TNFi.
Methods: The study was conducted in DESIR cohort, which included 708 patients with early IBP suspect of ax-SpA. We included all patients with available data on BMI and CRP. High CRP level was defined either according to usual threshold (5 mg/L) or to the formula using BMI for adjustment. With this formula, CRP could be considered "normal" or due to obesity if: ≤ 1 + (BMI-25)/25 for men and ≤ 1 + (BMI-25)/12.5 for women (with CRP in mg/dL). We reported distribution of CRP levels in patients with high level according to usual threshold but below BMI adjusted threshold, as it is potentially suggestive of false-positive CRP due to overweight/obesity. Among them, we identified those who had no objective sign of disease activity (defined as arthritis, dactylitis, active uveitis or inflammatory bowel disease). To evaluate the impact on classification/diagnosis, we examined HLAB27-positive patients with only 2 ASAS criteria, including high CRP (the second being IBP, since it was mandatory for inclusion in DESIR cohort). Then, we calculated ASDAS-CRP score. We presented proportions of patients with ASDAS-high or very high disease activity but high CRP level possibly due to BMI only, and among those, the number concerned by a change of disease activity level when adjusting ASDAS-CRP score with minimal value for CRP (2mg/l). Among patients treated by TNFi during first 24-month follow-up, we excluded those with sacro-iliitis, and studied in others, CRP levels at last visit before treatment initiation using both thresholds. We compared proportion of ASAS40 responders using logistic regression analysis, with abnormal CRP defined after correction for BMI in patients without any sign of activity, beside other classical predictive factor of therapeutic response (age, gender, sacro-iliitis, HLAB27, psoriasis, arthritis, smoking).
Results: Data were available for 634 patients. 205 had a high CRP level using usual threshold, of which 73 (35.6%) had a high CRP possibly due to BMI alone as they had no objective sign of disease activity. There were no differences in diagnosis as no patient had as only ASAS criteria: HLAB27 associated with high CRP and IBP. ASDAS-CRP score could be calculated in 626 patients. By correcting ASDAS score for patients with high CRP possibly due to BMI, 95.3% remained with same activity level (kappa for the ASDAS levels was 0.93). For impact of CRP on indication of bDMARD, 178 patients were treated by TNFi during first 24 months of follow-up: 61% of patients had an indication of TNFi according to EMA, with usual CRP threshold, and 56% with the adjusted one. Regarding response to TNFi, there were no association between any of the 2 CRP thresholds and ASAS40 response. Only sacro-iliitis on MRI was associated with ASAS40 response.
Conclusion: Adjustment of CRP threshold according to BMI has a very limited impact on diagnosis, evaluation of disease activity of SpA, indication of TNFi initiation and prediction of TNFi response.

NEW ROLE FOR PROTEINASE 3 IN IL-16 BIOACTIVITY CONTROL IN GRANULOMATOSIS WITH POLYANGIITIS

A. Kerstein-Staehle[1], C. Alarcin[1], J. Luo[1], G. Riemekasten[1], P. Lamprecht[1], A. Müller[1]. [1]*University of Luebeck, Department of Rheumatology and Clinical Immunology, Lübeck, Germany*

Background: The immunomodulatory cytokine IL-16 is increased in several inflammatory and autoimmune diseases[1]. IL-16 recruits and activates CD4+ immune cells such as T cells, dendritic cells, or monocytes. IL-16 is produced by various immune and non-immune cells, but synthesis and storage of IL-16 is regulated differentially depending on the cell type and stimulation. For its biological activity, IL-16 cleavage by caspase-3 is required[1]. Necrotizing granulomatous inflammation is a hallmark of granulomatosis with polyangiitis (GPA) with neutrophil dysregulation as a central driver of chronic inflammation and autoimmunity[2]. Earlier studies showed a correlation between increased serum IL-16 and disease parameters in AAV, including GPA[3], but functional evidence for a direct link between IL-16 and neutrophils in granulomatous inflammation is missing so far.
Objectives: In this study we aim to identify a functional link between increased IL-16, neutrophils, and the autoantigen proteinase 3 (PR3) with regard to chronic inflammation and autoimmunity in GPA.
Methods: IL-16 was measured in sera of GPA patients (n = 40) and healthy controls (HC, n = 50) by ELISA and correlated with clinical features, such as disease activity (BVAS), creatinine, GFR, VDI and PR3-ANCA status. IL-16 protein expression was analyzed in peripheral blood mononuclear cells (PBMC) and polymorphonuclear cells (PMN) from GPA patients and HC (n = 5, each) by SDS-PAGE and western blot. Binding affinity of recombinant pro-IL-16 to native human PR3 was assessed by microscale thermophoresis. Cleavage of pro-IL-16 by active human PR3 was performed at various time points at 37°C. Cleavage products were analyzed by SDS-PAGE and western blot.
Results: Circulating IL-16 was significantly increased in GPA patients compared to HC. Elevated IL-16 positively correlated with BVAS, creatinine, VDI and PR3-ANCA status and negatively correlated with GFR. In PMBC and PMN from GPA and HC we identified different expression patters of precursor and active forms of IL-16. In healthy PBMC we found high amounts of precursor (80kD), pro-IL-16 (55kD) and active IL-16 (17kD). In contrast, PBMC from GPA patients had lower amounts of pro-IL-16 and no active IL-16, indicating activation and secretion of IL-16 due to inflammatory stimulation, as shown earlier[5]. In GPA PMN we detected no precursor IL-16, but pro-IL-16 and its active form, in contrast to very low amounts of all IL-16 forms in healthy PMN. Processing and release of IL-16 in neutrophils has been linked to apoptosis and secondary necrosis[5]. By interaction studies we demonstrated direct binding of pro-IL-16 to PR3 with a Kd of 10 nM. In a subsequent cleavage assay we confirmed IL-16 processing by PR3 in a time-dependent manner.
Conclusion: Correlation of serum IL-16 with clinical features of GPA suggests that IL-16 is associated with markers of disease activity, tissue damage and autoreactivity. We showed that PBMC and PMN represent a source of IL-16 in GPA. By the identification of PR3 as an additional IL-16-activating enzyme we could demonstrate a potential link between excessive PR3 expression, cell death and IL-16-dependent mechanisms, contributing to chronic granulomatous inflammation and autoimmunity in GPA.

OP0055 ULTRASOUND HALO SIGN AS A POTENTIAL MONITORING TOOL FOR PATIENTS WITH GIANT CELL ARTERITIS: A PROSPECTIVE ANALYSIS

C. Ponte[1,2], S. Monti[3,4], C. A. Scirè[5,6], P. Delvino[3,4], N. Khmelinskii[1,2], A. Milanesi[3], V. Teixeira[1,7], F. Brandolino[3], F. M. Diamantino Saraiva[1], C. Montecucco[3], J. E. Fonseca[1,2], W. A. Schmidt[8], R. Luqmani[9]. *[1]Hospital de Santa Maria - Centro Hospitalar Universitário Lisboa Norte, Department of Rheumatology, Lisboa, Portugal*; *[2]Instituto de Medicina Molecular (IMM), Reumatology Research Unit, Lisboa, Portugal*; *[3]Fondazione I.R.C.C.S. Policlinico San Matteo, Department of Rheumatology, Pavia, Italy*; *[4]University of Pavia, PhD in Experimental Medicine, Pavia, Italy*; *[5]Italian Society for Rheumatology, Epidemiology Research Unit, Milan, Italy*; *[6]University of Ferrara, Rheumatology Unit, Department of Medical Sciences, Ferrara, Italy*; *[7]Centro Hospitalar Universitário do Algarve, Department of Rheumatology, Faro, Portugal*; *[8]Immanuel Hospital Berlin, Medical Centre for Rheumatology Berlin-Buch, Berlin, Germany*; *[9]University of Oxford, Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: Ultrasound of the temporal ± axillary arteries showing a non-compressible halo sign is recommended for diagnosing patients with giant cell arteritis (GCA); however, its value for monitoring disease activity is still poorly understood.
Objectives: To assess the sensitivity to change of ultrasound halo features and their association with disease activity and glucocorticoid (GC) treatment in patients with newly diagnosed GCA.
Methods: Two centre prospective study of new patients with ultrasound confirmed-GCA who underwent serial ultrasound assessments of the temporal (TA) and axillary (AX) arteries at fixed time-points. The number of arterial segments with halo and the maximum halo intima-media thickness (IMT) per segment was recorded at each visit. Only time-points in which >80% of patients were assessed were considered for analysis. Sensitivity to change of the halo sign was calculated as standardised mean difference (SMD) for each time-point separately. Correlation between ultrasound findings and erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Birmingham Vasculitis Activity Score (BVAS), and GC treatment was performed using Spearman's correlation coefficient. Logistic regression was used to determine the probability of being in remission for each unit increase (standardised) of the halo feature of interest. Remission was defined as the absence of relapse with a prednisolone dose <30 mg/day, and relapse as the recurrence of GCA-related symptoms or rise of CRP/ESR values not otherwise explained and requiring GC increase. Halo features at disease onset and first relapse were compared using Wilcoxon test.
Results: A total of 49 patients (73.5% females) with a mean age of 78.2 ± 7.4 years at baseline were assessed at 354 visits. TA involvement was reported in 47 (95.9%) patients and AX involvement in 11 (22.4%); 220 arterial segments with halo were recorded (201 TA, 19 AX). Halo sensitivity to change was calculated for weeks 1, 3, 6, 12 and 24, and showed a significant SMD between all time-points and baseline for the TA halo features, but only after week 6 for the AX halo features (Table and Figure). The number of TA segments with halo, sum of TA halo IMT and maximum TA halo IMT showed a significant correlation with ESR (0.41; 0.44; 0.48), CRP (0.34; 0.39; 0.41), BVAS (0.29; 0.36; 0.35) and GC cumulative dose (-0.34; -0.37; -0.32). The likelihood of achieving disease remission was lower in patients with a higher number of TA segments with halo (OR 0.39, p<0.05) and increased values of sum and maximum TA halo IMT (OR 0.34, p<0.05). By contrast, AX halo features showed no correlation with disease activity, nor any association with attaining clinical remission. During the study period, 32 relapses were observed (mean time for first relapse of 31.8 weeks ± 18.5 days). Halo sign was present in 16/17 (94.1%) cases of first disease relapse, all showing an increased halo IMT (sum and maximum) in relation to the previous ultrasound assessment performed. When compared to disease onset, a lower mean number of segments with halo and mean sum of halo IMT was reported for patients presenting with their first clinical relapse (2.93 ± 1.59 vs. 4.85 ± 1.51, p=0.0012; 2.01 ± 1.13 vs. 4.49 ± 1.95 mm, p=0.0012).

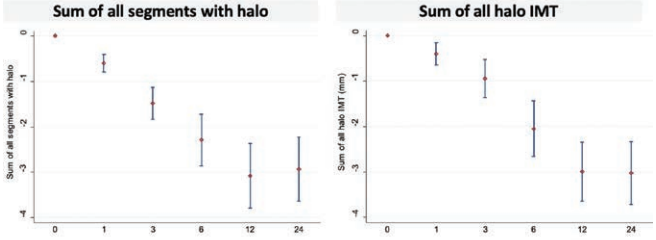
Table 1. SMD of halo features between baseline and different time-points

	Week 1	Week 3	Week 6	Week 12	Week 24
N of arterial segments					
Sum of all segments with halo (n=49)	**-0.51**	**-0.78**	**-1.13**	**-1.69**	**-1.52**
Sum of TA segments with halo (n=47)	**-0.49**	**-0.78**	**-1.18**	**-1.87**	**-1.69**
Sum of AX segments with halo (n=11)	-0.35	-	-0.62	-0.73	-0.91
Halo thickness (mm)					
Sum of all halo IMT (n=49)	**-0.98**	**-1.44**	**-1.37**	**-1.60**	**-1.48**
Sum of TA halo IMT (n=47)	**-1.01**	**-1.55**	**-1.54**	**-1.81**	**-1.69**
Sum of AX halo IMT (n=11)	-0.15	-0.45	**-0.81**	-0.84	-0.98
Max. TA halo IMT (n=47)	**-1.07**	**-1.32**	**-1.47**	**-1.91**	**-2.19**
Max. AX halo IMT (n=11)	-0.04	-0.29	**-0.94**	**-1.13**	-1.01

In bold p<0.05; n=n at baseline

Conclusion: Ultrasound is a reliable imaging tool to assess disease activity and response to treatment in patients with GCA. Future clinical trials in GCA should evaluate direct treatment effect on halo features as an outcome measure of interest.

Figure: Mean variation (not standardised) of halo features at different time-points



Eight arterial segments were evaluated at each time-point: bilateral common superficial temporal arteries, parietal and frontal branches, and bilateral axillary arteries

PLASMA MICROVESICLES AS LIQUID BIOPSIES OF THE ARTERIAL WALL IN LARGE VESSEL VASCULITIS

E. Tombetti[1], K. H. Chun[2], C. Iannone[3], E. M. Baldissera[4], J. Mason[5], A. Manfredi[6]. [1]*Milan University, Biomedical and Clinical Sciences Luigi Sacco, Milan, Italy*; [2]*Vita-Salute San Raffaele University, Milan, Italy*; [3]*Vita-Salute San Raffaele University, Autoimmunity and Vascular Inflammation, Milan, Italy*; [4]*Ospedale San Raffaele, UniRAR, Milan, Italy*; [5]*Hammersmith Hospital, Vascular Sciences and Rheumatology - NHLI, London, United Kingdom*; [6]*Vita-Salute San Raffaele University, Autoimmunity and Vascular Inflammation; UniRAR, Milan, Italy*

Background: Large-vessel vasculitides comprise Takayasu arteritis (TA)and giant cell arteritis (GCA). Arterial stenosis and dilatation directly affect prognosis but the mechanism(s) underlying remodeling of the vessel wall have not been identified. Microvesicles (MVs) are membrane-enclosed extracellular vesicles released upon cellular activation and stress and as a consequence of environmental inflammation. MVs maintain features and constituents of their parental cells. They have been proposed to serve as potential liquid biopsies in oncology.
Objectives: To verify whether arterial wall derived-MVs are recognizable in the blood of TA patients and express bioactive molecules potentially involved in arterial injury, inflammation and remodeling.
Methods: Platelet was obtained from 112 LVV pts (73 TA, 39 GCA), 42 age and age- and sex-matched healthy controls (HC) and 30 pts with severe carotid atherosclerosis requiring vascular surgery. Plasma flow cytometry was performed with anti-CD14, CD16, anti-CD144 (VE-cadherin, an endothelial marker), anti-CD140a/b (PDGF receptor A/B a vascular stromal marker), anti-HMGB1, anti-PTX3, mitotracker green (that identifies mithochondrial moieties) and mitosox (that revels mitochondrial reactive oxygen species). MVs were identified by physical parameters using Gigamix beads. Medium- to large-sized MVs were defined as MVs with >240nm-eq diameter.
Results: Preliminary results are available for 49 LVV (42 TA, 7 GCA), 8 severe carotidatherosclerosis and 14 age- and sex-matched HC. As compared to HC or CA, LVV plasma contains a higher number of MVs and in particular of medium- to large- sized MVs ($p<0.001$ for all comparisons) (Figure, panels A-B). Next, we evaluated the MVs surface expression of markers of leukocytic, endothelial and stromal/vascular stromal lineages. Total counts of CD14+, CD16+, CD66b+, CD140a+, CD140b+, CD144+ MVs were increased in LVV plasma with very high level of significance (Figure, panels C-G) while higher percentage of CD16+ and CD140a+ medium-to large-sized MVs was found in atherosclerosis. Expression of molecules involved in inflammation or repair, PTX3 or HMGB1 mitochondrial antigens and mitochondrial ROS all were consistently higher in LVV (Figure, panels H-M).
Conclusion: MVs, including those expressing arterial stromal biomarkers, are increased in LVV plasma, suggesting a communication between the vessel wall and peripheral blood. MV express signals that may in turn contribute to persisting vascular inflammation in large vessel vascultis Further analysis is required to dissect their potential use as disease biomarkers

OP0057

A PERSONALISED RITUXIMAB RETREATMENT APPROACH BASED ON CLINICAL AND B-CELL BIOMARKERS IN ANCA-ASSOCIATED VASCULITIS

J. Arnold[1], E. Vital[1], S. Dass[1], A. Aslam[1], A. Rawstron[2], S. Savic[1], P. Emery[1], M. Y. MD Yusof[1]. [1]*Chapel Allerton Hospital, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [2]*St James's University Hospital, Haematological Malignancy Diagnostic Service, Leeds, United Kingdom*

Background: Time-to-relapse after rituximab for ANCA-associated vasculitis (AAV) is variable and optimal retreatment strategy has been unclear. We previously showed that repopulation of naïve B-cells at 6 months predicts sustained response [1].
Objectives: In AAV following rituximab induction, to evaluate clinical and B-cell predictors of relapse in order to develop a retreatment algorithm.
Methods: An observational study was conducted in 60 rituximab-treated AAV patients followed for over 10 years. Complete response (CR) was defined as Birmingham Vasculitis Activity Score v3.0 = 0. Retreatment was given on clinical relapse, defined as new features or worsening of persistent disease (not by biomarker status). Peripheral B-cell subsets were measured using highly sensitive flow cytometry. Predictors were tested using multivariable Cox-Regression.
Results: Median times-to-retreatment for rituximab cycles 1-5 were 87, 71, 65, 59 and 86 weeks. Over 417 patient-years follow-up, 137 relapses occurred in 50 patients; 16 (in 14 patients) were major (renal=7, neurological=4, ENT=3 and respiratory=2). The major-relapse rate was 3.8/100 patient-years. In multivariable analysis, concomitant immunosuppressant [HR 0.48 (95% CI 0.24–0.94)], achieving CR [0.24 (0.12–0.50)] and naïve B-cell repopulation at 6 months [0.43 (0.22–0.84)] were associated with longer time-to-relapse. Higher baseline memory B-cells [1.01 (1.00–1.02)] were associated with a shorter time-to-relapse. AUROC for prediction of time-to-relapse was greater if guided by naïve B-cell repopulation than if ANCA and/or CD19+ return at 6 months had been used, 0.82 and 0.52 respectively.
Conclusion: These data suggest that all patients should receive concomitant oral immunosuppressant. Those with incomplete response or with absent naïve B-cells should be retreated at 6 months. Patients with complete response and naïve repopulation at 6 months should not receive fixed retreatment. This algorithm could reduce hypogammaglobulinaemia due to unnecessary retreatment.

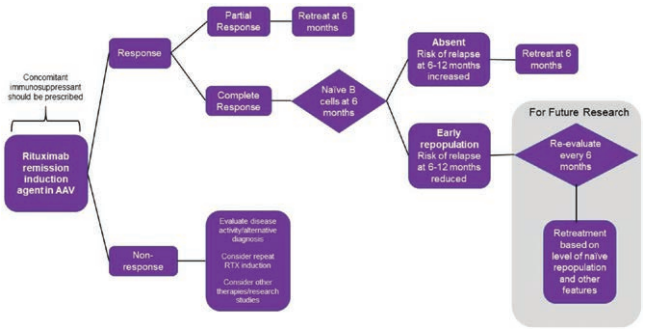

Figure 1. A personalised retreatment algorithm for rituximab in ANCA-associated vasculitis

OP0058

CARDIOVASCULAR AND CEREBROVASCULAR RISK IN PATIENTS WITH SMALL VESSEL VASCULITIDES: A COMPARATIVE ANALYSIS BETWEEN AORTIC STIFFNESS, CAROTID SONOGRAPHY AND SCORE

K. Triantafyllias[1], L. E. Thiele[2], M. De Blasi[1], A. Schwarting[2,3]. [1]*ACURA Clinics, Rheumatology, Bad Kreuznach, Germany*; [2]*Johannes Gutenberg University Medical Center, Internal Medicine I, Department of Rheumatology and Clinical Immunology, Mainz, Germany*; [3]*ACURA Clinics, Rheumatology, 55543, Germany*

Background: Cardiovascular (CV) and cerebrovascular (CVB) risk have not been adequately examined in the setting of patients with small vessel vasculitides. In particular, data on CV/CVB surogate markers are scarce and the diagnostic value of traditional CV risk scores, such as the Systematic COronary Risk Evaluation (SCORE) and ist EULAR modified version (mSCORE) is unknown.
Objectives: Aims of this study were to examine gold standard surrogates of CV risk and subclinical atherosclerosis (1), as well as novel duplex-sonographic markers of CVB risk in a cohort of patients with small vessel vasculitides. Moreover, we sought to evaluate for the first time the diagnostic value of SCORE and mSCORE in identifying patients at high CV and CVB risk.
Methods: SCORE/mSCORE and the gold standard marker of aortic stiffness (carotid-femoral pulse wave velocity; cfPWV) were examined in patients with small vessel vasculitides and healthy controls across 3 Rheumatology Centers. Moreover, sonography of the common- (CCA), internal- (ICA) and external- (ECA) carotid arteries was performed in subsets of both groups, evaluating carotid intima-media-thickness (cIMT), plaque presence and duplex-sonographic indices of CBV risk, such as the resistance- (RI) and pulsatility-index (PI). Disease characteristics, clinical and serological activity markers, as well as traditional CV risk factors were also documented.
Results: We recruited 46 patients with small vessel vasculitides [granulomatosis with polyangiitis (n=33), eosinophilic granulomatosis with polyangiitis (n=6), microscopic polyangiitis (n=4), cryoglobulinemic vasculitis (n=1), urticaria vasculitis (n=2): 76.1% female, median age 61.5 years (52-72.25, IQR)] and 105 healthy controls [76.1% female, median age 61.5 years (52-72.25, IQR)]. cfPWV was significantly higher in the patient group compared to the control group, even after statistical corrections for confounding factors (i.e. age, gender: different in the two groups) (8.4 m/s vs. 6.8 m/s; p_{adj}<0.001). Moreover, carotid sonography revealed higher CVB surrogates in the patient subgroup, compared to controls.
According to SCORE and (EULAR)-mSCORE, 0.9% and 15.8% of the patients had high CV risk (defined as SCORE/mSCORE >5), respectively. However, cfPWV revealed an increased CV risk in 28.2% of the patients. Moreover, carotid sonography showed signs of subclinical carotid arteriosclerosis in 50% (plaques) and 71.7% (cIMT >0.9 mm) of the patients, respectively.
Conclusion: Herein, we could show that patients with small vessel vasculitides had higher aortic stiffness and subclinical carotid atherosclerosis, compared to controls and could thus have higher CV and CVB risk. Moreover, we were able to demonstrate for the first time that SCORE/mSCORE performed poorly in identifying patients at high CV risk and carotid atherosclerosis compared to cfPWV and carotid sonography respectively. Thus, cfPWV and carotid sonography could improve CV and CBV screening in patients with small vessel vasculitides.

MAVRILIMUMAB (ANTI GM-CSF RECEPTOR A MONOCLONAL ANTIBODY) REDUCES RISK OF FLARE AND INCREASES SUSTAINED REMISSION IN A PHASE 2 TRIAL OF PATIENTS WITH GIANT CELL ARTERITIS

M. C. Cid[1], S. Unizony[2], L. Pupim[3], F. Fang[3], J. Pirrello[4], A. Ren[5], M. Samant[3], T. Zhou[3], J. F. Paolini[3]. [1]*Hospital Clínic, University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Vasculitis Research Unit, Department of Autoimmune Diseases, Barcelona, Spain*; [2]*Massachusetts General Hospital, Vasculitis and Glomerulonephritis Center, Department of Rheumatology, Allergy and Immunology, Boston, United States of America*; [3]*Kiniksa Pharmaceuticals Corp., Clinical Development, Lexington, United States of America*; [4]*Kiniksa Pharmaceuticals Corp., Business Development, Lexington, United States of America*; [5]*Kiniksa Pharmaceuticals Corp., Clinical Operations, Lexington, United States of America*

Background: T helper (Th)1 and Th17 lymphocytes play a role in the pathogenesis of giant cell arteritis (GCA). Current treatments primarily target the Th17 axis, possibly leaving residual Th1 activity. Granulocyte macrophage colony stimulating factor (GM-CSF), a mediator of Th1 and Th17 cells, is a pathogenic factor in GCA.
Objectives: To evaluate the efficacy and safety of the GM-CSF inhibitor mavrilimumab in patients with GCA.
Methods: Randomized, double-blind, placebo-controlled phase 2 trial enrolling patients with active, biopsy- or imaging-proven new onset (N/O) or relapsing refractory (R/R) GCA. Active disease: GCA symptoms and erythrocyte sedimentation rate (ESR) (>30 mm/hr) and/or C-reactive protein (CRP) (≥1 mg/dL) elevation within 6 weeks from randomization. Corticosteroid-induced remission (resolution of GCA symptoms and CRP <1 mg/dL or ESR <20 mm/hr) was required by baseline. 3:2 randomization to mavrilimumab 150 mg or placebo subcutaneously every 2 weeks and protocol-defined 26-week prednisone taper starting at 20-60 mg/day.
Primary efficacy endpoint: time to first adjudicated flare (ESR ≥30 mm/hr and/or CRP ≥1 mg/dL and GCA symptoms or new/worsening vasculitis on imaging) by Week 26 in all treated patients. Key secondary endpoint: sustained remission through Week 26. Safety up to Week 38 was assessed.
Results: 70 patients (35 N/O, 35 R/R) were enrolled (mavrilimumab [N=42] or placebo [N=28]). Mean (SD) age was 69.7 (7.48) years and 71.4% were female. Flare by Week 26 occurred in 8 (19%) and 13 (46.4%) patients receiving mavrilimumab and placebo, respectively (27.4 percentage points reduction). Median time to flare by Week 26 could not be estimated in the mavrilimumab group due to too few events (Not Estimable) and was 25.1 weeks [95% CI: (16.0, NE)] in the placebo group (HR [95% CI] 0.38 [0.15, 0.92]; p=0.0263) (Figure). Sustained remission at Week 26 occurred in 83.2% of patients receiving mavrilimumab and 49.9% of those receiving placebo (33.4 percentage points increase; p=0.0038). Results were consistent across disease type subgroups (HR for flare: N/O 0.29 [95% CI: 0.06, 1.31; nominal p= 0.0873]; R/R 0.43 [95% CI: 0.14, 1.30]; nominal p=0.1231), although not powered for significance (Table). Adverse events (AEs), mostly mild to moderate, were comparable between groups. There were 5 serious AEs (mavrilimumab 2 [4.8%], placebo 3 [10.7%]), none drug-related. No deaths or vision loss occurred. No adjudicated cases of pulmonary alveolar proteinosis were observed.

Figure 1. Time to Flare by Week 26 after randomization in All Patients.

	Patients at Risk, n														
Week	0	2	4	6	8	10	12	14	16	18	20	22	24	26	28
Mavrilimumab	42	42	42	40	40	40	40	40	39	35	35	34	34	28	0
Placebo	28	27	27	27	26	26	23	20	19	15	15	14	14	10	0

Conclusion: Mavrilimumab was superior to placebo on the primary and secondary efficacy endpoints of time to flare and sustained remission at week 26 in patients with GCA. Mavrilimumab was well tolerated, and no new safety signals were observed.

Background: Posterior segment involvement is the most serious affection of uveitis in Behçet's disease (BD), with cystoid macular edema (CME) being the leading cause of blindness. Anti-TNF, especially adalimumab (ADA) and infliximab (IFX), have demonstrated efficacy as first-line biologic agents in BD-related uveitis **[1,2]**. Moreover, the anti-IL6R tocilizumab (TCZ) has shown excellent results in highly refractory BD-uveitis and noninfectious uveitic CME **[3-6]**.
Objectives: To compare the efficacy of ADA vs IFX vs TCZ in patients with refractory CME due to BD.
Methods: Observational multicenter study of patients with BD-associated CME refractory to conventional and/or biological immunosuppressive drugs. From a cohort of 177 patients treated with anti-TNF and 14 patients treated with TCZ, we selected those with CME at baseline. CME was defined as macular thickness > 300µm (measured by optic coherence tomography). We analyzed in the 3 groups of treatment (ADA, IFX, TCZ) from baseline up to 4 years the evolution of macular thickness (main outcome) and best-corrected visual acuity (BCVA). Differences between basal and final follow-up were evaluated. Multivariable linear regression was used to assess the differences between the 3 groups.
Results: A total of 49 patients were included. ADA was used in 25 patients (40 eyes with CME), IFX in 15 (21 eyes with CME) and TCZ in 9 (11 eyes with CME). No statistically significant baseline differences were observed between the 3 groups (Table) except for previous anti-TNF therapy, which was used only in patients treated with TCZ (5 patients received ADA, 1 received IFX and 2 received both ADA and IFX, in different times). Most patients from all groups had received several conventional immunosuppressive drugs. Biological therapy was used in monotherapy or combined with azathioprine (n=10, 5 and 1 in ADA, IFX and TCZ group, respectively), cyclosporine A (n=10, 5 and 1) or methotrexate (n=4, 2 and 3). Macular thickness progressively decreased in the 3 groups, with no signs of CME after 1 year of treatment. Similarly, BCVA improvement and inflammatory ocular remission was reached in all groups (Figure).

Table 1. Demographic and clinical characteristics of 49 patients with cystoid macular edema due to Behçet's disease receiving ADA, IFX or TCZ.

OP0061

A PROOF-OF-CONCEPT STUDY TO ASSESS THE EFFICACY OF TOCILIZUMAB MONOTHERAPY AFTER ULTRA-SHORT GLUCOCORTICOID ADMINISTRATION TO TREAT GIANT CELL ARTERITIS - THE GUSTO TRIAL

L. Christ[1], L. Seitz[1], G. Scholz[1], A. C. Sarbu[1], J. Amsler[1], L. Bütikofer[2], C. Tappeiner[3], F. Kollert[1], S. Reichenbach[1], P. Villiger[1]. *[1]Inselspital, Bern University Hospital, Department of Rheumatology, Immunology and Allergology, Bern, Switzerland*; *[2]Inselspital, University of Bern, Clinical Trial Unit (CTU), Bern, Switzerland*; *[3]Inselspital, Bern University Hospital, Department of Ophthalmology, Bern, Switzerland*

Background: Two randomised controlled trials [1, 2] demonstrated a glucocorticoid (GC)-sparing effect of tocilizumab (TCZ) of at least 50%. Long-term GC treatment leads invariably to numerous side effects, particularly in elderly giant cell arteritis (GCA) patients.
Objectives: The GUSTO (GCA treatment with ultra-short GC and TCZ) trial was set up to evaluate the efficacy and safety of TCZ-monotherapy after ultra-short GC treatment in new-onset GCA.
Methods: Eighteen patients with newly diagnosed GCA were enrolled in this investigator-initiated, single-arm, single-center, open-label clinical trial with Simon's two stage design (NCT03745586). Patients received 500 mg methylprednisolone intravenously for 3 consecutive days. Thereafter, GC treatment was discontinued and TCZ (8 mg/kg body-weight) was administered intravenously, followed by weekly subcutaneous TCZ injections (162 mg) from day 10 until week 52. The primary endpoint was defined as the proportion of patients who achieved remission within 31 days and showed no relapse at week 24; the secondary endpoint included the proportion of patients with complete relapse-free remission of disease at week 52. Remission was defined as disappearance of GCA symptoms, whereas partial remission included the presence of mild symptoms (defined as non-ischemic with NRS<5/10, reported as mild, not occurring on most days of the week). An interim analysis of the primary endpoint was performed after the first 12 patients reached the primary endpoint.
Results: At baseline there were 12/18 female patients, and the median age was 71 (range 64-78) years. Overall, 15/18 had cranial symptoms (10/18 had jaw claudication, 6/18 had visual symptoms), 10/18 suffered from polymyalgia rheumatica (PMR)-symptoms, 16/18 had positive cranial ultrasound, and 13/18 had positive histopathology.
At interim analysis, only 25% (3/12) of patients achieved remission within 31 days and stayed relapse-free up to week 24. Thus, the null hypothesis that the proportion of responders would be smaller than 40% (p=0.92) was not rejected. Of the 18 patients recruited at the time of interim analysis, 14 achieved remission within 24 weeks (mean duration 11.1 (95% CI 8.3-13.9) weeks) and 13 showed no relapses up to 52 weeks (72%, 95% CI 47-90%). Overall, 3/18 patients were non-responders (2/3 with persistent cranial symptoms including one new-onset of an anterior ischemic optic neuropathy (AION); 1/3 with persistent PMR symptoms) and started on rescue GC-treatment, and 2/18 discontinued the study due to an adverse event (hepatopathy and diverticulitis, respectively; 1/2 after induction of remission).
Figure 1 demonstrates remission status over time.
Conclusion: After a 3-days pulse of methylprednisolone, ensuing TCZ monotherapy induced and maintained remission until week 52 in 13/18 patients. The data add an important piece of evidence regarding the potency of blocking the interleukin-6 pathway in GCA and suggest that a substantial reduction of concomitant GC treatment in TCZ-treated GCA patients is feasible.

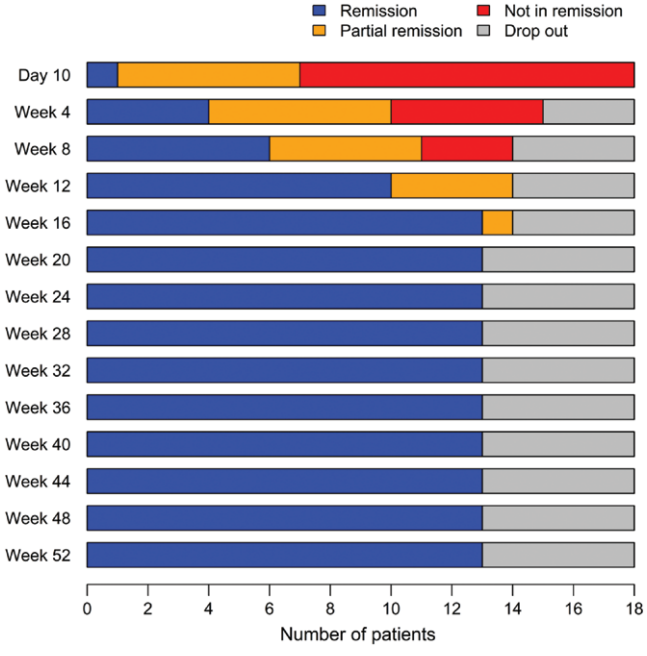

Figure 1. Disease status of patients at each visit (Day 10 - week 52, n=18).

Vasculitis - II

OP0062

CYTOKINE PRODUCING B CELLS SKEW MACROPHAGES TOWARDS A PRO-INFLAMMATORY PHENOTYPE IN GIANT CELL ARTERITIS

J. C. Graver[1], W. F. Jiemy[1], D. Altulea[1], A. Boots[1], P. Heeringa[2], W. Abdulahad[1], E. Brouwer[1], M. Sandovici[1]. *[1]University of Groningen, University Medical Center Groningen, Rheumatology & Clinical Immunology, Groningen, Netherlands*; *[2]University of Groningen, University Medical Center Groningen, Pathology & Medical Biology, Groningen, Netherlands*

Background: Giant cell arteritis (GCA) is the most frequent form of systemic vasculitis affecting the temporal artery (TA) and the aorta. Macrophages and T cells are well recognized players in the pathogenesis of GCA while B cells are often not taken into account. Recently, changes in the circulating B cell compartment were documented in GCA and B cells were found to organize into tertiary lymphoid organs at the site of vascular inflammation (TA and aorta).[1,2] The exact role of B cells in GCA is still unknown as no disease-specific antibodies have been defined. However, beside their role in humoral immunity, B cells can also produce various cytokines. In GCA, peripheral B cells of treated GCA patients, showed an enhanced capacity to produce pro-inflammatory cytokine Interleukin (IL)6[3] which is nowadays an important target of treatment in GCA.[4] We hypothesize that B cells help shape the inflammatory response in GCA by producing effector and regulatory cytokines.
Objectives: We aimed to assess the cytokine profile of circulating and lesional B cells in GCA and studied the effects on macrophage skewing.
Methods: To assess B cells with the capacity to produce cytokines, cryopreserved peripheral blood mononuclear cells of 11 untreated GCA patients and 15 age- and sex-matched healthy controls (HC) were cultured for 3 days in the presence of CpG-ODN 2006. During the last 5 hours phorbol myristate acetate and Calcium Ionophore were added. Thereafter, intracellular effector (IL6, TNFa, IFNy, LTb) and regulatory B cell-related cytokines (IL10) were measured with flow cytometry. To assess potential skewing of macrophages by B cell products, THP-1 cells were differentiated into macrophages and stimulated for 24 hours with supernatant from stimulated B cells (n=6). Expression of IL23, IL6, IL1b, TNFa, MMP9 and YKL40 was assessed on mRNA level with qPCR. To assess local cytokine production, TA (n=11) and aorta tissue samples (n=10) of histologically-proven GCA patients were stained to detect CD20, IL6, TNFa, IFNy, LTb, and IL10 expression. For comparison, 14 aorta tissues samples of patients with an atherosclerosis-related aortic aneurysm were included.
Results: *In vitro* stimulated B cells from untreated GCA patients showed an enhanced percentage of IL6+ B cells (median (IQR); 44 (41-52)) and of IL6+TNFa+ B cells (12 (8-24)) compared to stimulated B cells from HC (IL6+: 28 (23-39), IL6+TNFa+: 6 (4-24)). In addition, soluble factors, secreted by GCA derived and stimulated B cells, skewed macrophages towards a pro-inflammatory phenotype with enhanced expression of IL23, IL6, IL1b, and TNFa. Furthermore, these macrophages also showed higher expression of the tissue remodelling factor MMP9 and the pro-angiogenic factor YKL40. At the site of vascular inflammation, B cells were detected in the regions with clear TNFa, IL6, IFNY, LTb and IL10 expression in both the TA and aorta of GCA patients.

Conclusion: This study demonstrates that circulating B cells of patients with GCA have the capacity to express pro-inflammatory cytokines (IL6 and TNFa) which can influence other cellular players in GCA. Specifically, B cell secreted soluble factors were able to skew macrophages towards a pro-inflammatory phenotype. In addition, this study provides evidence for an active role of B cells in shaping the cytokine milieu at the site of inflammation thereby revealing the B cell as a new target of intervention in GCA.

OP0063 SINGLE CENTRE EXPERIENCE OF THE CLINICAL SPECTRUM, AETIOLOGIES AND MANAGEMENT OF NON-INFECTIOUS AORTITIS

R. S. Andev[1,2], N. Ahmad[2], A. Verdiyeva[2], R. Luqmani[1,2], S. Dubey[2].
[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom; *[2]Oxford University Hospitals NHS Foundation Trust, Department of Rheumatology, Oxford, United Kingdom*

Background: Aortitis, a rare form of large vessel vasculitis, may occur in the context of a primary systemic vasculitis, as a part of systemic autoimmune disease or in isolation. The evidence and guidelines to diagnose, manage and monitor aortitis remain limited. However, PET CT and vascular MRI scans have facilitated our ability to make the diagnosis more readily. The optimal management strategy and complication rates remain uncertain.

Objectives: Our aim was to explore the clinical, laboratory and radiological features of aortitis. We sought to review the management and complications of this illness by collecting detailed information on the outcomes and treatments used, including disease modifying agents (DMARDs) and biologics.

Methods: Patients diagnosed with aortitis since 2006 that had been managed in a single tertiary centre were identified using the Rheumatology Assessment Database Innovation in Oxford (RHADIO). Their medical notes were retrospectively reviewed using a local electronic patient record system and the following information was obtained: demographics, underlying risk factors, imaging and laboratory results (including biopsy reports if available), management and outcome.

Results: We identified 155 patients who met the inclusion criteria. There was a female preponderance of 57.4% (n=89). At the time of diagnosis, the average age was 69 (range 30-92) and the mean symptomatology length prior to diagnosis was 12 months (range 0-120). The majority of patients (60.4%, n=94) had aortitis secondary to giant cell arteritis (GCA), isolated aortitis was identified in 29.7% (n=46) and IgG4-related disease aortitis was uncommon (2.6%, n=4). Those with cranial GCA-like symptoms were diagnosed on average 3.9 months before those who presented differently (10.1 months versus 14.0 months).

Common presentations comprised: systemic inflammatory response syndrome (49.0%, n=76), cranial GCA-like symptoms (26.5%, n=41) and unexplained weight loss (24.5%, n=38). Importantly, 18.7% (n=29) of patients presented with ischaemic symptoms that included angina, TIAs/strokes and claudication. Aortic dissection was the primary presentation for 6.5% (n=10) of patients.

At presentation, the mean CRP was 84 mg/L (range 1-249) and the ESR was 72 mm/hr (range 2-164). Most (73.5%, n=114) had diagnostic PET CT changes. For those patients with GCA, diagnostic ultrasound changes were seen in 27.7% (n=26).

Nearly all were treated with prednisolone (92.3%, n=143) and all but 8 (5.1%) received a DMARD at some point. Methotrexate was the most commonly used DMARD (93.9%, n=138), followed by leflunomide (22.3%, n=35) and azathioprine (19.1%, n=28). Cyclophosphamide was used in 23.8% of patients (n=38) and 15 patients (9.7%) received tocilizumab.

Around a third (34.1% n=53/155) had received at least two DMARDs during their treatment course. On average, patients required 3.46 drugs to manage their aortitis. Those who relapsed (43.2%, n=67) were more likely to have GCA (65.7%, n=44).

Vascular sequelae were present in 37.4% (n=58). The most common complications were ischaemic in nature with stroke/TIA and claudication reported in 16.8% (n=26). Aortic aneurysms were recorded in 11.6% (n=18) of cases and 5.1% (n=8) developed dissections despite being on treatment for their aortitis. One patient developed renal infarcts and ischaemic bowel leading to intestinal failure because of florid vasculitis.

Conclusion: Aortitis has a varied presentation with systemic inflammatory response syndrome being the most common. Delayed diagnosis remains a problem and especially for those with non-GCA related aortitis, which is likely to contribute to the risk of subsequent vascular complications. Vascular events including dissection are common, many of which could be preventable, emphasising the importance of early diagnosis and good disease control.

Background: Giant cell arteritis (GCA) may be divided into cranial, and extracranial GCA. Tocilizumab (TCZ) has shown efficacy and safety in GCA and other large-vessel vasculitis (LVV) (1-5).
Objectives: To compare the efficacy of TCZ in cranial and extracranial GCA.
Methods: Multicenter observational study of 312 patients with GCA treated with TCZ. They were divided into 3 groups a) only cranial (cGCA), b) only extracranial (ecGCA), c) mixed affection (mixGCA). GCA was diagnosed by a) ACR criteria, and/or b) positive temporal artery biopsy, and/or c) LVV by imaging. Remission and sustained remission was defined according to EULAR definitions (1). In ecGCA and mixGCA we also studied the improvement (complete or partial) by imaging techniques.
Results: We studied 312 patients (218 females; mean age, 73.4±9.6 years). TABLE shows the main features of the 3 groups. Remission at month 6 was higher in cGCA, as well as the sustained remission at month12 (FIGURE). At 18 and 24months, were similar in the 3 groups. Improvement by imaging techniques was partial/complete at 6,12,18 and 24 months, in 50%/0%,71%/0%, 61%/15% and 67%/17% respectively, in ecGCA, and in 75%/0%,53%/18%, 64%/12% and 50%/28% in mixGCA.

Table 1. Main features of 312 patients at TCZ onset.

	Cranial GCA	Extracranial GCA	Mixed GCA	Cranial vs Extracranial GCA
	(n=152)	(n=49)	(n=111)	p
Age at TCZ onset, years, mean± SD	76.0±8.2	65.4±12.2	73.5±8.1	**0.000***
Sex, female/male, n (% female)	105/47 (69)	33/16 (67)	80/31 (72)	0.960
Time from diagnosis to TCZ onset (months, median [IQR]	6 [2-21]	7 [2-20]	9 [3-25]	0.765
Biopsy-proven GCA, n (%)	87/128 (68)	0 (0)	50/87 (57)	**0.000***
Systemic manifestations at TCZ onset	109 (72)	32 (65)	84 (76)	0.501
Fever, n (%)	18 (12)	1 (2)	8 (7)	**0.048***
Constitutional syndrome, n (%)	52 (34)	16 (33)	47 (42)	0.933
PmR, n (%)	88 (58)	29 (59)	71 (64)	0.999
Ischemic manifestations at TCZ onset	117 (77)	0 (0)	70 (63)	**0.000***
Visual involvement, n (%)	31 (20)	0 (0)	16 (14)	**0.000***
Headache, n (%)	103 (85)	0 (0)	63 (57)	**0.000***
Jaw claudication, n (%)	39 (26)	0 (0)	21 (19)	**0.000***
Acute phase reactants				
ESR, mm/1st hour, median [IQR]	28 [9-53]	24 [10-43]	28 [15-48]	0.462
CRP, mg/dL, median [IQR]	1.2 [0.3-3.4]	0.7 [0.4-1.8]	1.6 [0.4-3.8]	0.153
Prednisone dose at TCZ onset, mean ± SD	26.2±17.6	15.4±14.2	20.1±14.9	**0.000***
TCZmono/TCZcombo, n (% TCZ mono)	116/36 (76)	26/23 (53)	69/42 (62)	**0.003***
Follow-up (months), mean ± SD	27.3±21.1	32.7±23.3	27.9±22.0	0.143

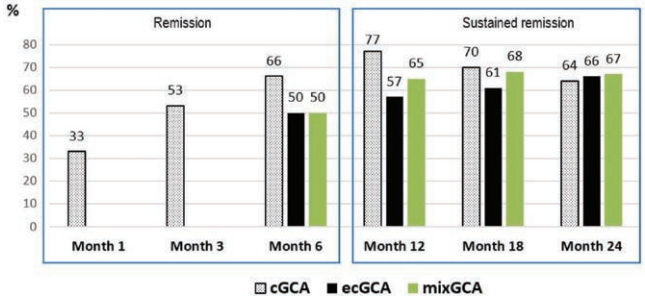

Figure 1. Remission and sustained remission of cGCA, ecGCA and mixGCA according to EULAR **(1).** In the first 3 months we only could assess cGCA because in ecGCA and mixGCA a control imaging was not performed

Conclusion: TCZ seems to be effective in all phenotypes but it is faster in cGCA in reaching remission. However, improvement by imaging techniques was partial and very rarely complete in ecGCA and mixGCA.

Background: Visual involvement is one of the most feared complication of Giant Cell Arteritis (GCA).Tocilizumab (TCZ) has shown efficacy and safety in large-vessel vasculitis (LVV) including GCA **(1-4).**
Objectives: To assess the efficacy of TCZ to: **a)** prevent the appearance of new ocular involvement, and **b)** to improve visual symptoms if present.

Methods: Observational, multicenter study of 312 patients with GCA treated with TCZ. Patients were diagnosed with GCA accordingly to **a)** ACR criteria, and/or **b)** biopsy of temporal artery, and/or **c)** presence of LVV by imaging.
Patients were divided into two subgroups: **a)** with, and **b)** without visual involvement at any time. Visual manifestations were classified as: **a)** Transient visual loss (TVL) (amaurosis fugax), **b)** Permanent visual loss (PVL) (longer than 24 hours) (partial or complete; unilateral or bilateral), **c)** diplopia, and **d)** blurred vision. Accordingly to visual duration up to TCZ onset, we considered: **a)** 1-10 days, **b)** 11-30 days, and **c)** more than 30 days.
Results: We studied 312 (218 women/94 men; mean age73.4±9.6 years). Visual manifestations at any time (before and/or after TCZ) were observed in 78 (25%). In 47 of them visual manifestations were present at TCZ onset, and in the remaining 31 patients had had a complete recovery. Main clinical features of GCA with and without visual involvement are shown in TABLE. Patients with visual involvement were older, with other ischemic complications, and requiring more corticosteroids dose.

Table 1. Main features of 312 patients at TCZ onset.

	Overall N= 312	GCA with visual involvement (n= 78)	GCA without visual involvement (n=234)	p
General features

Time from GCA diagnosis to TCZ onset (months), median [IQR]	8 [3-24]	5 [1-14]	10 [3-24]	**0.040***
Positive TAB, n (%)	137/229 (60)	33/60 (55)	104/169 (61)	0.444
Ischemic manifestations				
Visual involvement, n (%)	47 (15)	47 (60)	0	**0.000***
Headache, n (%)	166 (53)	59 (76)	107 (46)	**0.000***
Jaw claudication	60 (19)	26 (33)	34 (14)	**0.001***
Systemic manifestations				
Fever, n (%)	27 (9)	8 (10)	19 (8)	0.743
Constitutional syndrome, n (%)	115 (37)	30 (38)	85 (36)	0.878
PmR, n (%)	188 (60)	46 (59)	142 (61)	0.830
Acute phase reactants				
ESR, mm/1st hour, median [IQR]	27 [10-50]	34.5 [15.2-58]	26.0 [10.0-48.0]	0.193
CRP (mg/dL), median [IQR]	1.4 [0.4-3.3]	1.5 [0.3-5.5]	1.3 [0.4-2.9]	0.134
Prednisone dose, mg/day, mean±SD	22.3±16.6	27.1±18.6	20.8±15.6	**0.008***
TCZmono/TCZcombo, n (%)	211/101	57/21	154/80	0.295
Follow-up (months), mean±SD	28.4±21.8	25.8±22.4	29.3±21.6	0.119

After TCZ onset, none patient developed new visual involvement. At TCZ onset 47 patients had the following visual manifestations; PVL (n= 28; unilateral/bilateral; 22/6), TVL (n=15; unilateral/bilateral; 9/6), diplopia (n=2) and blurred vision (n=2).
None of the patients with TVL presented new episodes after TCZ onset, while 8 out of 28 patients with PVL experienced partial improvement (FIGURE). The 2 patients with diplopia and 1 of 2 patients with blurred vision improved.

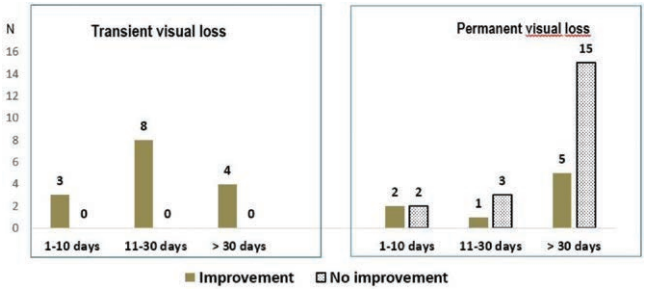

Figure 1. Efficacy of TCZ in 47 patients with GCA and visual involvement at TCZ onset.

Conclusion: TCZ seems to prevent the appearance of new ocular manifestations. When they are present, TCZ may improve totally TVL and partially PVL.

OP0066

METABOLIC PROFILE AND COMORBIDITIES IN GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA PATIENTS BEFORE AND AFTER TREATMENT

I. Esen[1,2], P. Therkildsen[3], B. Dalsgaard Nielsen[4], A. Van 't Ende[1], A. Boots[1,2], P. Heeringa[2,5], E. M. Hauge[4], E. Brouwer[1,2], Y. Van Sleen[1,2]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]University Medical Center Groningen, Vasculitis Expertise Center Groningen, Groningen, Netherlands*; *[3]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark*; *[4]Aarhus University Hospital, Department of Rheumatology and Department of Clinical Medicine, Aarhus, Denmark*; *[5]University Medical Center Groningen, Department of Pathology and Medical Biology, Groningen, Netherlands*

Background: Giant cell arteritis (GCA) is a granulomatous vasculitis that affects the large vessels, occurring in people over 50 years of age. GCA frequently overlaps with polymyalgia rheumatica (PMR), which affects the proximal joints in the shoulders and hips. Both GCA and PMR patients require long-term treatment with glucocorticoids (GCs). Investigation of new treatment options is required because many GCA and PMR patients experience GC-related adverse events. These include hypercholesterolemia, hypertension, diabetes mellitus, cataract, and infections.(1) Previous studies suggest that unhealthy metabolic features and a higher Body Mass Index (BMI) might be protective in the development of GCA (2). However, data are limited.
Objectives: We aimed to elaborate more-in depth on the metabolic features, BMI and prevalence of comorbidities of GCA and PMR patients at the time of diagnosis and during treatment, to characterize patients for improved treatment options.
Methods: This study included two independent cohorts: the GPS (Groningen) cohort, and the Aarhus cohort for validation of baseline data (Table 1). Patients in the GPS cohort were prospectively followed with visits at 3 months, 1, 2, and 5 years. Laboratory measurements, metabolic co-morbidities were assessed at every visit. At baseline, we assessed whether comorbidities and BMI predicted the duration of GC treatment.

Table 1. Baseline characteristics. P-values were calculated with Mann-Whitney U test and Fischer Exact test. Numbers in bold: significance between HC and GCA/PMR patients from GPS cohort. *: significance between GCA and PMR of GPS cohort. [a]: significance between two cohorts.

	GCA GPS cohort (n=50)	*PMR GPS cohort (n=44)*	*HCs GPS cohort (n=65)*	**GCA Aarhus cohort (n=52)**	**PMR Aarhus cohort (n=25)**
Age, median	71	73	70	67	68
Female, %	35	26	43	32	13
Follow-up duration in months, median	42	40	NA	NA	NA
BMI, median	24.3	26.6	25.4	24	26.4
Systolic BP (mmHg), median	140	140	145	135	143
Diastolic BP (mmHg), median	**79.5***	80	80	76.5	83
HbA1c (mmol/mol), median	**43**	**40**	39	43	40
CRP (mg/L), median	**54**	**42**	4	76	53
ESR (mm/h), median	**94***	**57**	9	77	51
Diabetes mellitus, %	12	23	12	15	8
Hypercholesterolemia, %	22	14	17	15	24
Hypertension, %	66[a]	55	60	38	36
Cataract, %	**14**	**16**	34	NA	NA

Results: Frequencies of metabolic features in GCA/PMR patients from the GPS cohort were not significantly different in comparison to healthy controls (HCs). Higher HbA1c levels were detected in GCA patients than in HCs. Data on metabolic features from the Aarhus cohort compared well with the GPS cohort data and thus validated these findings (Table 1). Next, the effect of co-existing co-morbidities on the clinical manifestations was investigated. GCA patients with cataract had reduced CRP and ESR whereas PMR patients with cataract had a higher ESR than

patients without cataract (p=0,034). Analysis of GC treatment effect on co-morbidities revealed a significant increase in prevalence of diabetes (after 3 months) and cataract (after 5 years) compared to baseline. BMI was significantly higher after one year and five years of GC treatment. PMR patients with cataract at baseline required longer treatment with GCs (p=0.023). Presence of other metabolic features at the time of GCA or PMR diagnosis did not affect the treatment duration (Figure 1).
Conclusion: Newly-diagnosed GCA and PMR patients did not appear to have a healthier metabolic profile than HCs. As expected, GC treatment resulted in the development of an unhealthier metabolic profile in GCA patients. In PMR patients, the presence of cataract at baseline was predictive for a prolonged treatment period which could be explained by higher ESR levels in PMR patients with cataract. Together, our findings emphasize the importance of novel GC sparing therapeutic agents and personalized medicine in GCA and PMR.

OP0068 EFFICACY AND SAFETY OF TNF-A ANTAGONISTS AND TOCILIZUMAB IN TAKAYASU ARTERITIS: MULTICENTER WORLDWIDE RETROSPECTIVE STUDY OF 209 PATIENTS

A. Mekinian[1], L. Biard[2], L. Dagna[3], P. Jégo[4], C. Salvarani[5], M. Sergey[6], O. Espitia[1], S. Sciascia[7], P. Hernan[8], P. Cacoub[1], O. Fain[1], D. Saadoun[9]on behalf of TAK FRENCH GROUP. *[1]Saint Antoine, Internal Medicine, Paris, France; [2]Saint Antoine, SDF, Paris, France; [3]Saint Antoine, QF, Paris, Italy; [4]Saint Antoine, SFD, Paris, France; [5]Saint Antoine, Internal Medicine, Itale, Italy; [6]Saint Antoine, Internal Medicine, Moscou, Russian Federation; [7]Saint Antoine, Internal Medicine, Paris, Italy; [8]Saint Antoine, Internal Medicine, Paris, Spain; [9]Pitie, Internal Medicine, Paris, France*

Background: In this large worldwide TAK registry, we report 209 patients treated with TNF-α antagonists and tocilizumab aiming to compare their safety and efficacy, and determine the predictive factors of treatment response and relapse.
Objectives: To assess safety and efficacy of TNF-α antagonists and tocilizumab in patients with Takayasu arteritis (TAK).
Methods: We conducted a retrospective multicenter study in referral centers from France, Italy, Spain, Israel, Japan, Tunisia and Russia about biological-targeted therapies in TAK during the period from January 2017 to September 2019 for the data collection.
Results: Two-hundred nine patients with TAK [median age of 29 years [7-62], and 186 (89%) females] were included. They received either TNF-α antagonists [n=132 (63%) with 172 lines; infliximab (n=109), adalimumab (n=45), golimumab (n=8), certolizumab (n=6) and etanercept (n=5)], or tocilizumab [n=77 (37%) with 121 lines; intravenous and subcutaneous in 95 and 26 cases, respectively]. A complete response at 6 months was evidenced in 101/152 (66%) on TNF-α antagonists and 75/107 (70%) on tocilizumab, respectively. Age ≥ 30 years [OR= 2.09 [1.09; 3.99]] was associated with complete response, whereas vascular signs [0.26 [0.1;0.65]], baseline prednisone ≥ 20 mg/day [0.51 [0.28;0.93]] were negatively associated with the complete response to TNF-α antagonists or tocilizumab. During a median follow-up of 36 months, 103 relapses were noted. Supra-aortic branches and thoracic aorta involvements [HR 2.44 (1.06;5.65) and 3.66 (1.18;11.4), respectively], and systemic signs at baseline [HR 2.01 (1.30;3.11)] were significantly associated with relapse. The cumulative incidence of treatment discontinuation and relapse were similar in TNFα antagonists and tocilizumab. Fifty-eight (20%) adverse effects occurred on biological-targeted therapies of whom 37 (21%) and 21 (17%), (p=0.4) on TNF-α antagonists and tocilizumab, respectively
Conclusion: This large multicenter study shows high efficacy of biological-targeted treatments in refractory TAK. Efficacy, relapse and drug retention rate were equivalent with TNF-α antagonists and tocilizumab.

OP0069 THE ROLE OF POSITRON EMISSION TOMOGRAPHY/ COMPUTED TOMOGRAPHY (PET/CT) IN DISEASE ACTIVITY ASSESSMENT IN PATIENTS WITH LARGE VESSEL VASCULITIS

E. Galli[1], F. Muratore[2], L. Boiardi[2], M. I. Casali[3], A. Versari[3], G. Besutti[4], L. Spaggiari[4], P. Mancuso[5], P. Giorgi Rossi[5], C. Salvarani[1,2]. *[1]University of Modena and Reggio Emilia, Department of Rheumatology, Modena, Italy; [2]Rheumatology Unit, Azienda USL-IRCCS di Reggio Emilia, Department of Specialistic Medicine, Reggio Emilia, Italy; [3]Nuclear Medicine Unit, Azienda USL-IRCCS di Reggio Emilia, Department of Oncology and Advanced Technology, Reggio Emilia, Italy; [4]Radiology Unit, Azienda USL-IRCCS di Reggio Emilia, Department of Imaging and Laboratory Medicine, Reggio Emilia, Italy; [5]Epidemiology Unit, Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Department of Epidemiology Service, Reggio Emilia, Italy*

Background: Assessment of disease activity in large vessel vasculitis (LVV) is still an unmet need. PET Vascular Activity Score (PETVAS) is a new composite score aimed at quantifying the overall inflammatory burden by adding together PET qualitative visual scores (0-3, according to Meller) in nine selected arterial regions (1). In two independent cohorts, PETVAS showed to be effective in discriminating between patients with clinically active and inactive vasculitis.
Objectives: To assess the role of PET/CT and the performance of PETVAS in differentiating between clinically active and inactive vasculitis in a single center cohort of patients with LVV.
Methods: One-hundred patients with radiographic evidence of LVV were enrolled by the Rheumatology Unit of Reggio Emilia Hospital (Italy) between June 2007 and September 2020. All subjects underwent full clinical, laboratory and imaging evaluation (including PET/CT) at baseline, annually and when a relapse was suspected. Medical records of recruited patients were retrospectively reviewed from baseline visit until 30 September 2020, last follow-up or death.
For each PET/CT test, the nuclear medicine physician's interpretation of scans (active/inactive vasculitis) was compared with disease activity clinical judgement (active disease/remission). The latter was based on comprehensive signs/symptoms assessment, laboratory and imaging (excluding PET/CT) data and was considered the reference standard.
For each PET/CT scan, PETVAS score was calculated and its performance in discriminating between patients with active and inactive disease was compared to clinical judgement.
Results: In the study period 100 LVV patients [51 giant cell arteritis (GCA), 49 Takayasu arteritis (TAK)] underwent a total of 474 PET scans. Nuclear medicine physician's interpretation of PET/CT was able to discriminate between patients in clinically active LVV (n 167) and those in clinical remission (n 307) with a sensitivity of 60% (95% CI, 51 to 69%) and a specificity of 80% (95% CI, 75 to 84%). The following sensitivity and specificity values were found in LVV subgroups: 73% (95% CI, 59 to 84%) and 77% (95% CI, 70 to 83%) for TAK, and 51% (95% CI, 38 to 63%) and 82% (95% CI, 76 to 88%) for GCA, respectively.
LVV patients with higher PETVAS scores were more frequently classified as having active disease: age and sex adjusted OR 1.15 (95% CI, 1.11 to 1.19), p<0.0001. Similar results were found in LVV subgroups, [age and sex adjusted OR 1.12 (95% CI, 1.08 to 1.17) for GCA and 1.22 (95% CI, 1.14 to 1.31) for TAK, all p<0.0001].
The area under receiver operating characteristics (ROC) curve (AUC) of PETVAS in differentiating between clinically active and inactive LVV was 0.73 (95% CI, 0.68 to 0.79). Similar results were found in LVV subgroups, [0.70 (95% CI, 0.62 to 0.78) for GCA, and 0.79 (95% CI, 0.71 to 0.87) for TAK]. A PETVAS ≥10 provided 61% sensitivity and 80% specificity in differentiating between clinically active and inactive LVV (52% sensitivity and 82% specificity in GCA subgroup and 73% sensitivity and 78% specificity in TAK subgroup).
Conclusion: In our cohort PET/CT has shown to be useful in monitoring LVV disease activity.
PETVAS seems to be a reliable tool in helping clinicians to discriminate between LVV patients with active disease and those in remission.

OP0070 ONSET TO DIAGNOSIS TIME PREDICTS SURVIVAL RATE IN TAKAYASU ARTERITIS

A. Popov[1], I. Borodina[2], L. Shardina[3]. *[1]Ural State Medical University, Hospital Therapy and Urgent Medical Care Service, Ekaterinburg, Russian Federation; [2]Sverdlovsk Regional Clinical Hospital 1, Therapy, Yekaterinburg, Russian Federation; [3]Ural State Medical University, Higher Medical Nurse and Social Education, Yekaterinburg, Russian Federation*

Background: Takayasu arteritis (TA) is large vessel vasculitis. In spite of relatively high 5 to 15 years survival rate, TA affects young persons and causes major cardiovascular events, disability and preterm deaths [1]. Nowadays, though new

high-resolution visualization and effective treatment options are available, quite a large number of TA patients remain undiagnosed and untreated for years [2].
Objectives: To assess the influence of timely TA diagnosis and treatment initiation on the survival rate and cardiovascular events risk.
Methods: A retrospective cohort study included 183 patients (139 females, 44 males), enrolled during the period from 1979 to 2018 after TA diagnosis verification according to ACR1990 criteria [3]. All subjects have been followed up at the Sverdlovsk Regional Clinical Hospital 1. Cox regression model was used to compare survival rate.
Results: By enrollment, females median age was 35 [25%-75%: 24 - 44] and in males median age was 34 [26 -42]. Median time duration from the first symptoms onset to the diagnosis verification was 3 [1-7] years in females and [1.5 - 8] years in males. The most common affected arteries were subclavian (55%), carotid (53%), and renal (42%). 5-year survival rate was 92%; 10-year survival rate was 90%; 15-year survival rate was 80%. The median term of survival was 34 [20 - 41] years. 31 deaths (18 males and 13 females) occurred during the follow-up period. Median age of death was 36 [32-44] in females, and 50 [40-57]) in males. The average disease course duration at the time of death was 9.25 years, median term being 6.5 [3-16] in females and 5 [3-10] in males. Also a total of 72 cardiovascular events were recorded during the follow-up period: 27 in men and 45 in women. The median duration of AT course by the development of the first ever event was 10 (5 -20). There were 24 cases of ischemic stroke, 3 transient ischemic attacks, 4 cases of hemorrhagic stroke. Median age of the first ever event was 38 (30 - 49.5). Time duration 4 years or more from AT symptoms onset to diagnosis was associated with significantly more frequent cardiovascular events (OR 1.8; 95% CI 1.07 – 3.34); and premature deaths (see table) by the 5^{th} year of follow up (OR 2.9; 1.27- 6.55).
Conclusion: In a retrospective cohort, time duration 4 years or more from TA symptoms onset to diagnosis verification was associated with higher risk of cardiovascular events and lower survival rate.

Like a gearwheel: HPR's research, education, and practice

OP0071-HPR **PILOT IMPLEMENTATION OF ENHANCEMENTS IN SUPERVISED GROUP EXERCISE FOR PEOPLE WITH AXIAL SPONDYLOARTHRITIS (AXSPA) IN THE NETHERLANDS**

B. Hilberdink[1], F. Van der Giesen[2], T. P. M. Vliet Vlieland[1], L. Van Bodegom-Vos[3], S. Van Weely[1]. [1]*Leiden University Medical Center, Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands*; [2]*Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*; [3]*Leiden University Medical Center, Department of Biomedical Data Sciences, section Medical Decision Making, Leiden, Netherlands*

Background: Supervised group exercise (SGE) for people with axSpA is widely available in the Netherlands [1]. Its contents have barely changed over the past 30 years, despite new evidence-based insights to improve the quality of SGE [1,2].
Objectives: To evaluate the process and effect of the implementation of enhancements in SGE for people with axSpA in the Netherlands.
Methods: This implementation study was executed in four regions, organising nine axSpA-specific SGE classes. The implemented enhancements included: 1. Exercise personalisation based on periodic assessments, including the 6-Minute Walk Test (6MWT) and the Ankylosing Spondylitis Performance Index (ASPI; improved/not improved); 2. High intensity aerobic exercise including intensity monitoring (e.g. by heartrate or BORG-scale); 3. Group education on home exercise and physical activity (e.g. promotion of an app). The implementation strategy was executed over a period of one year and consisted of a one-day training for the supervisors and bimonthly telephone support.
To evaluate the implementation effect, a survey was sent to 95 SGE participants, including two questions evaluating changes in the programme and in own functioning, as well as the 'ASAS Health Index' (ASAS HI) and the 'Short Questionnaire to Assess Health-enhancing physical activity' (SQUASH), which were also administered at baseline. In addition, the data from the periodic assessments (6MWT and ASPI) were used. Changes were analysed with the Wilcoxon Signed-Rank Test.
To evaluate the implementation process, apart from specific questions in the patient survey, semi-structured interviews with supervisors from each region were conducted.
Results: The survey was returned by 60/95 (63%) SGE participants (72% male, median age 60 years).
Effects: As shown in Table 1, 33% experienced improved functioning, 37% improved performance on ASPI and the improvements on 6MWT were statistically significant, $p < .05$, whereas there were no significant changes in ASAS HI and SQUASH.

Table 1.

	SGE Participants (n=60)
Effect evaluation	
Self-reported improvements in functioning, n (%)	20/60 (33)
Change in 6MWT score, median (IQR)	10 (-20;62)*
Improved on ASPI, n (%)	20/54 (37)
Change in ASAS HI score, median (IQR)	0 (-1;1.9)
Change in number of days with exercise (SQUASH), median (IQR)	0 (-1;2)
Evaluation of enhancements	
Satisfied with overall programme changes, n (%)	35/60 (58)
Satisfied with amount of exercise personalisation, n (%)	51/58 (88)
Assessment is applied, n (%)	50/58 (86)
Assessment is favourable, n (%)	47/50 (94)
Satisfied with amount of aerobic exercise, n (%)	39/56 (70)
Satisfied with exercise intensity, n (%)	44/57 (77)
Heartrate monitoring is applied, n (%)	29/59 (49)
Heartrate monitoring is favourable, n (%)	27/29 (93)
Familiar with axSpA-specific home exercise app, n (%)	12/56 (21)
Exercises at home using the app, n (%)	1/56 (2)

*$p < .05$

Process: The semi-structured interviews with the SGE supervisors (n=4, 25% male, aged 28-56 years, SGE experience 8-30 years) showed that: 1. exercise personalisation was difficult and periodic assessments were only maintained in two regions; 2. all regions increased focus on high intensity aerobic exercise and three monitored intensity; 3. none provided structural group education on home exercise. Table 1 shows that the majority of participants was satisfied with the overall programme changes, the personalisation, the assessments and the high intensity aerobic exercise and that heartrate monitoring and education on a home exercise app were applied in less than half of the participants.
Conclusion: After a training for SGE supervisors and telephone support, a set of enhancements was only partially implemented. However, the majority of participants was satisfied with applied changes and about a third improved functioning. For a nationwide implementation, a more extensive strategy addressing specific barriers is warranted.

New toys in rheumatology: single cell RNA and epigenetic sequencing, the holy grail?

OP0072 **SINGLE CELL SEQUENCING REVEALS CLONALLY EXPANDED CYTOTOXIC CD4+ T CELLS IN THE JOINTS OF ACPA+ RA PATIENTS**

A. Argyriou[1], M. H. Wadsworth II[2], A. Lendvai[1], S. Christensen[2], A. Hensvold[1,3], C. Gerstner[1], K. Kravarik[2], A. Winkler[2], V. Malmström[1], K. Chemin[1]. [1]*Division of Rheumatology, Center for Molecular Medicine (CMM), Department of Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden*; [2]*Inflammation & Immunology Research Unit, Pfizer Inc., Cambridge, MA, United States of America*; [3]*Center for Rheumatology, Academic Specialist Center, Stockholm Health Region, Stockholm, Sweden*

Background: CD4+ T cells with cytotoxic functions (CD4+ CTL) have gained attention in recent years. Accumulating evidence supports their importance in defense against human viral infections such as CMV[1], EBV[2], dengue[3], HIV[4, 5] and SARS-CoV-2[6]. Moreover, expansion of so called CD28null cytotoxic CD4+ T cells have been reported in the blood of patients with rheumatic diseases such as rheumatoid arthritis (RA)[7], myositis[8] and vasculitis[9] as well as in cardiovascular diseases[10].
Objectives: Here, we aimed to investigate the presence and clonal expansion of CD4+ CTL in the peripheral blood (PB) and synovial fluid (SF) of RA patients using single cell technologies.

Methods: We assessed the expression of cytotoxic effector molecules and transcription factors in CD4+ T cells in synovial fluid (n=21) and paired peripheral blood (n=16) from ACPA- and APCA+ RA patients by multi-parameter flow cytometry. We performed single cell sequencing, in combination with 5´ TCRab sequencing, on purified CD4+ T cells from the peripheral blood (PB) and synovial fluid (SF) of ACPA+ RA patients (n=7).
Results: Flow cytometry experiments show that Granzyme-B+ Perforin-1+ CD4+ CTL are significantly increased in the SF of ACPA+ RA patients as compared to ACPA- RA patients (p=0.0072). The presence of CD4+ CTL could be confirmed by single cell sequencing in SF of each ACPA+ RA patient tested (n=7). Moreover, we found that the adhesion G-protein coupled receptor GPR56 is selectively expressed on the recently described peripheral helper (T_{PH}) T-cell subset[11] and associates with the expression of tissue resident memory markers LAG-3, CXCR6 and CD69. In blood, we confirmed a previous report[12] showing that GPR56 delineates cytotoxic CD4+ T cells. Finally, expanded TCR clones expressing cytotoxic effector molecules were identified in synovial fluid of ACPA+ RA patients and, for some patients, in their corresponding peripheral blood.
Conclusion: We identified GPR56 as a marker of T_{PH} cells in SF of ACPA+ RA patients that associates with tissue residency receptors. The combination of single cell sequencing and multi-parameter flow cytometry highlights the importance of CD4+ CTL in ACPA+ RA and suggests a potential therapeutic target (Figure 1).

SINGLE-CELL TRANSCRIPTOMICS UNCOVERS DEFECTIVE BONE MARROW EARLY B CELL DEVELOPMENT IN A SUBSET OF LUPUS PATIENTS ASSOCIATED WITH AGGRAVATED INFLAMMATION

C. Dong[1], X. Gu[1], J. Ji[1], X. Zhang[2], Z. Gu[1]. [1]*Affiliated Hospital of Nantong University, Department of Rheumatology, Nantong, China*; [2]*Institute Pasteur of Shanghai Chinese Academy of Sciences, Key Laboratory of Molecular Virology & Immunology, Shanghai, China*

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease that occurs when the body's immune system attacks own tissues and organs. B cells play a central role in SLE pathogenesis by producing autoantibodies as well as antibody-independent functions. Peripheral B cell abnormality is well known in lupus patients such as expansions of plasmablasts and atypical memory B cells, which are associated with active diseases. However, little is known about the B cell development in the bone marrow of lupus patients.
Objectives: We conduct this survey to explore the disorder of the B cell development in the bone marrow of lupus patients.
Methods: In this study, we have performed the scRNASeq to profile the bone marrow B cell compartment in lupus patients and healthy donors.
Results: We identified that in a subset of lupus patients, the early B cells (proB and preB cells) were strongly decreased, which were confirmed by flow cytometry in an expanded cohort. Furthermore, bone marrow B cells from these patients showed a strong proinflammatory signature revealed by pathway analysis. Interestingly, BCR repertoire analysis showed that the IGHV-4-34 was highly enriched in these patients, indicating an enhanced B cell tolerance defect. Finally, a panel of proinflammatory cytokines (TNF-a, IL-1a, IL-12p70, IFN-g, et al.) were strongly increased in the bone marrow plasma of these patients compared with early B normal patients and healthy donors, confirming a localized proinflammatory microenvironment.
Conclusion: Altogether, the current study has revealed that a defective early B cell development in lupus patients is associated with a more severe B cell tolerance defect and aggravated inflammation, which may shed new light on developing novel therapies by targeting relevant pathways.

Background: A growing number of professional societies in clinical and medically related disciplines investigate evidence, make recommendations, and take action to advance gender equity. Evidence on women's advancement and leadership in the context of the European Alliance of Associations for Rheumatology, EULAR, is limited [1].
Objectives: The objective of the EULAR Task Force on Gender Equity in Academic Rheumatology was to establish the extent of the unmet need for support of female rheumatologists, health professionals and non-clinical scientists in academic rheumatology and develop a framework to address this through EULAR and Emerging EULAR Network (EMEUNET).
Methods: Potential interventions to accelerate gender-equitable career advancement in academic rheumatology were gathered from a narrative review of the relevant literature, expert opinion of a multi-disciplinary Task Force (comprised of 23 members from 11 countries), data from the surveys of EULAR scientific member society leaders, EULAR and EMEUNET members, and EULAR Executive Committee members. These interventions were rated by Task Force members, who ranked each according to perceived priority on a five-point numeric scale from 1 = very low to 5 = very high.
Results: A framework of 29 potential interventions was formulated, which covers six thematic areas, namely, EULAR policies, advocacy and communication, EULAR Congress and associated symposia, training courses, mentoring/peer support, and EULAR funding (Figure 1).

Theme	Intervention	Level of priority, Mean	SD
EULAR policies	Requirements for EULAR Centres of Excellence to demonstrate commitment to gender equity	4.5	0.8
	Gender-equitable EULAR committees, working groups, and task forces	4.4	0.8
	Gender-equitable grants committees	4.0	0.9
	Gender-equitable editorial boards and peer-review in rheumatology journals	3.9	1.0
Advocacy and communication	Campaigns to increase visibility of female role models and promote women's leadership	4.5	0.7
	Raising awareness of unconscious bias and gender equity issues in rheumatology	4.3	1.0
	Promoting gender-sensitive clinical practice, research and training	4.1	1.0
	Engaging national rheumatology groups to develop country-specific support	3.6	1.2
EULAR Congress and associated symposia	Monitoring gender equity of chairs and invited speakers (invitees and acceptances)	4.6	0.7
	Increasing visibility of female role models	4.4	0.7
	Family- and child-friendly policies	4.1	1.2
	Code of Conduct expressing and enforcing the values of diversity and inclusion	4.1	0.9
	EULAR no male only panel pledge	4.0	1.1
	Collating a register of female experts in field	3.5	1.3
Training courses (open to men and women)	Leadership skills training	4.2	0.7
	Training and support for writing grant applications	4.0	0.8

OP0075

EVALUATION OF A VIRTUAL REALITY TEACHING CONCEPT FOR MEDICAL STUDENTS DURING THE SARS-COV-2 PANDEMIC

A. Pfeil[1], F. Marcus[2], T. Hoffmann[1], P. Klemm[3], P. Oelzner[1], U. Müller-Ladner[3], A. Hueber[4], U. Lange[3], G. Wolf[1], G. Schett[5,6], D. Simon[5,6], A. Kleyer[5,6]. [1]*Jena University Hospital – Friedrich Schiller University Jena, Department of Internal Medicine III, Jena, Germany*; [2]*Jena University Hospital – Friedrich Schiller University Jena, Department of Internal Medicine I, Jena, Germany*; [3]*Campus Kerckhoff, Justus-Liebig University Gießen, Department of Rheumatology, Immunology, Osteology and Physical Medicine, Bad Nauheim, Germany*; [4]*Sozialstiftung Bamberg, Section Rheumatology, Bamberg, Germany*; [5]*University Hospital Erlangen, Department of Internal Medicine 3, Rheumatology and Immunology, Erlangen, Germany*; [6]*University Hospital Erlangen, German Center Immune Therapy, Erlangen, Germany*

Background: The ongoing COVID-19 pandemic has disrupted face-to-face teaching of medical students and forced efforts in finding alternative approaches. In order to help maintain high-quality education, a new virtual reality (VR)-based concept for training medical students in rheumatic and musculoskeletal diseases (RMD) has been developed. This VR training concept is based on the integration of real patient data with two- and three-dimensional visualized pathological joints from X-ray and computed tomography generated images.
Objectives: To evaluate the practicability and acceptance of the VR training application in the digital curricular education of medical students during the COVID-19 pandemic.
Methods: A short refresher lecture on rheumatic diseases (duration 60 minutes) was followed by presenting the VR training concept to the students. The VR training concept included the demonstration of three virtual patients with early rheumatoid arthritis, rheumatoid arthritis psoriatic arthritis regarding the symptoms, current medical problems, disease patterns at the imaging (conventional radiographs and high-resolution computed tomography) and therapy options. The practicability and acceptance of the VR was evaluated by medical students using a survey.
Results: The study encompassed 237 medical students (163 female, 73 male, one diverse, age range 20 to 40 years). 72 % of the participants rated the virtual teaching as good or very good. 87 % presented an expanded knowledge for rheumatoid arthritis and psoriatic arthritis through the VR. Moreover, 91 % reported that the lecture provided a deeper understanding of RMD. Furthermore, 60 % of the students asked for additional courses by VR.
Conclusion: The study highlighted the usefulness of innovative VR tools for teaching medical students digitally about RMD. VR applications can be a complementary educational modality for medical students, especially during the COVID-19 pandemic, to provide students with the best possible clinical experience while ensuring that patient, student, and staff safety is not compromised.

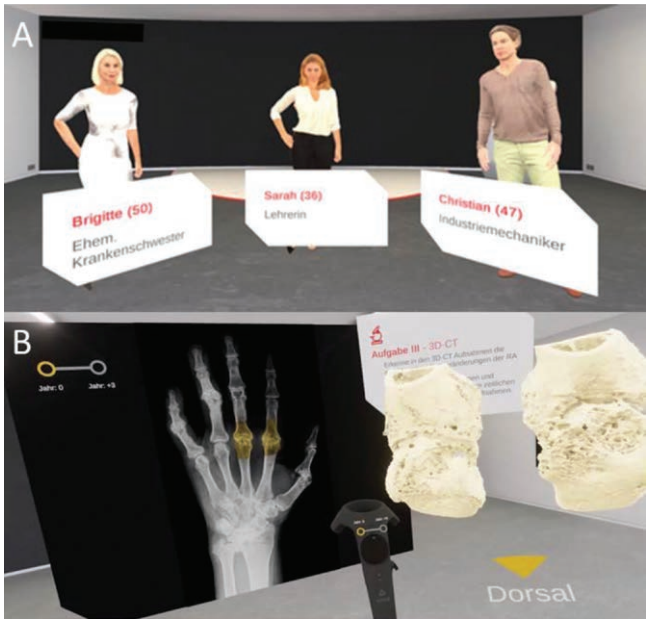

Figure 1. ***A*** Screen view of virtual reality included three virtual patients with early rheumatoid arthritis (RA), RA, and psoriatic arthritis (PsA) and ***B*** demonstration of structural damage in RA and PsA using hand X-ray and high-resolution quantitative computed tomography images.

OP0076

HOW TO SELF-EXAMINE FOR TENDER AND SWOLLEN JOINTS: CO-DEVELOPMENT OF A TRAINING VIDEO FOR PEOPLE WITH RHEUMATOID ARTHRITIS

C. Sharp[1,2], K. Staniland[3], T. Cornell[4], W. Dixon[3,5]. [1]*The University of Manchester, Centre for Epidemiology Versus Arthritis, & Centre for Primary Care and Health Services Research, Manchester, United Kingdom*; [2]*Manchester Royal Infirmary, Kellgren Centre for Rheumatology, Manchester, United Kingdom*; [3]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [4]*Poole Hospital, Rheumatology, Poole, United Kingdom*; [5]*Salford Royal NHS Foundation Trust (Formerly Hope Hospital), Rheumatology, Salford, United Kingdom*

Background: COVID-19 has catalysed the transformation of healthcare services, with outpatient services increasingly dependent upon remote models of care. Healthcare professionals now have to make clinical assessments based on remote patient examinations. The number of tender and swollen joints a patient has drives decision-making in RA, making it particularly important that people with RA and HCPs have a shared understanding of these examinations.
Even before remote consultations became widespread, long gaps between clinic visits create challenges in enabling HCPs to form an accurate picture of disease activity over time. The REMORA (REmote MOnitoring of Rheumatoid Arthritis) app aims to address this issue by asking people with RA to track disease activity, including counting the number of tender or swollen joints, weekly(1). Data are integrated into the electronic patient record for clinicians to access with patients during clinical consultations. As part of the supporting materials for the REMORA app, we planned to develop a video to train people with RA how to examine their own joints. This video may now help meet the need created by the recent expansion in remote consultations.
Objectives: To describe the co-production, implementation and evaluation of a video to train patients how to examine their own joints.
Methods: The need for the video to fill a current gap in patient education was identified by the REMORA patient and public involvement and engagement (PPIE) group. A core working group comprising the PPIE lead, a nurse consultant, rheumatology clinicians, project and communications managers was formed. A storyboard was drafted and feedback gained from the PPIE group and wider REMORA team. Images were sourced from licenced suppliers, or co-developed with the PPIE group where necessary. No ethical approval was required as the PPIE group lead was acting as an equal member of the research term. Written informed consent was gained from video participants. Filming took place between two national lockdowns during the COVID-19 pandemic, providing a challenge to ensure social distancing and requiring the use of masks.
Results: A 15 minute video to train people with RA to self-examine for tender and swollen joints was developed. An introduction outlining the rationale behind self-examination is followed by a nurse consultant coaching an RA patient in individual joint self-examination. Shoulders, elbows, wrists, metacarpophalangeal joints, proximal interphalangeal joints and knees are included, all of which are counted in disease activity scores.
Early feedback from stakeholders has been overwhelmingly positive. The video will be publicly available on YouTube from February 2021. A survey of patients and HCPs aims to obtain more formal feedback on the video, with a view to a further iteration, if required. Leading national organisations in rheumatology will promote the video, as it supports national programmes including the British Society for Rheumatology national early inflammatory arthritis audit and ePROMS (electronic patient report outcome measure) platform, both of which include entry of patient reported tender and swollen joint counts.
Conclusion: This video was co-designed by people with RA, aiming to support self-examination of tender and swollen joint counts. Hits on YouTube and survey responses will help assess its impact. Evaluation to assess whether the video affects patients' ability to self-examine for tender and swollen joints before and after watching is planned. We hope the video will support remote consultations and help people with arthritis to better understand and self-manage their arthritis, and to have shared decision making conversations with their clinicians.

OP0077

THE EMERGING EULAR NETWORK (EMEUNET): AN INTERNATIONAL SURVEY REFLECTING ON A TEN-YEAR JOURNEY

M. de Hooge[1], M. Hanlon[2], A. Alunno[3], A. Sepriano[4], K. Lauper[5], F. Rivellese[6]. [1]*Ghent University Hospital, Rheumatology, Ghent, Belgium*; [2]*Trinity University College, Rheumatology, Dublin, Ireland*; [3]*University of Perugia, Rheumatology, Perugia, Italy*; [4]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [5]*University Hospitals of Geneva, Rheumatology, Geneva, Switzerland*; [6]*Queen Mary University, Rheumatology, London, United Kingdom*

Background: The Emerging EULAR NETwork (EMEUNET), founded in 2009, aims to promote education, foster research collaborations and facilitate the integration of young researchers and rheumatologists within EULAR.
Objectives: After 10 years, we aimed to interview our members to assess how EMEUNET is fulfilling its goals, understand if there are unmet needs and explore new ideas.
Methods: In July 2019 a survey was circulated for 3 months among EMEUNET members via its social media channels. The survey contained 18 closed and 2 open items, in addition to general questions on age, job and country of origin and work.
Results: Out of 124 total respondents, most completed all items (120/124) and only a minority had some missing items (4/124). A little over half of the respondents were female (n=69, 54.8%) and median age was 33y (range 25y-42y). Most respondents were born (n=109, 88.6%) and/or worked in Europe (n=114, 92.7%) (fig. 1), although there was also a representation from extra-European countries, which is in line with the general EMEUNET membership (https://emeunet.eular.org/map.cfm).

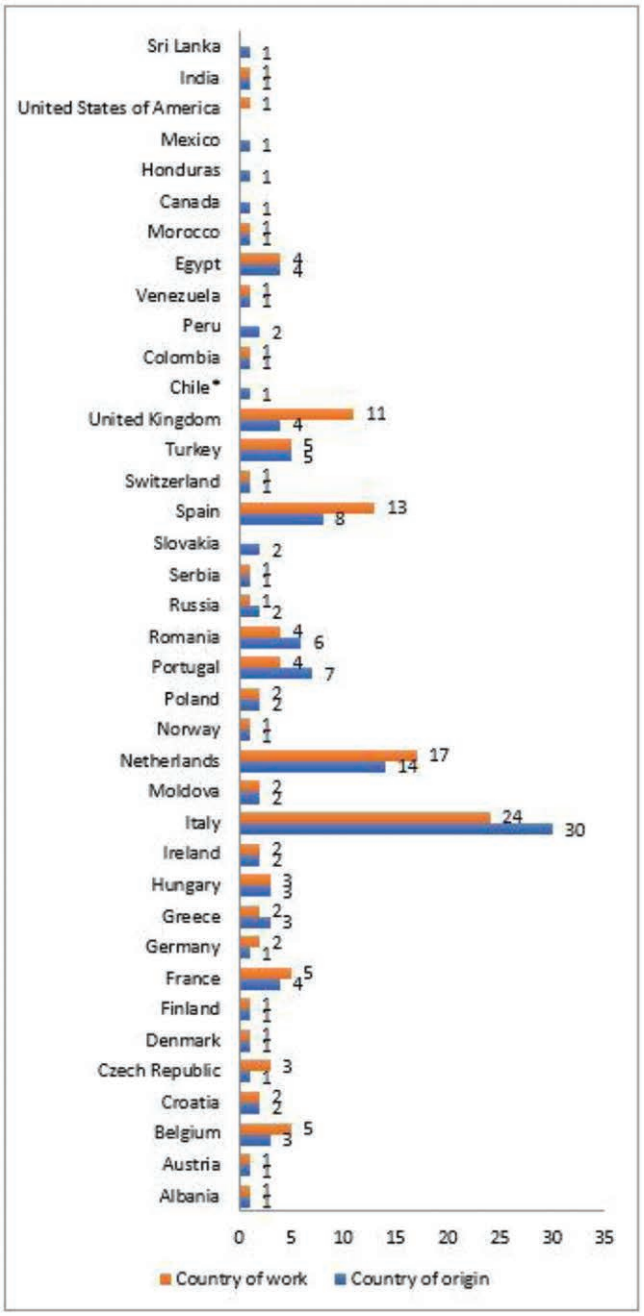

Figure 1. Country of origin and where respondents work at the time of completing the EMEUNET VISE questionnaire.

11 (9.1%) had been EMEUNET members for less than 2 years, 81 (66.9%) for 2-5years and 29 (24.0%) for more than 5 years.
Figure 2 shows a clear link between the respondents' perception of EMEUNET aim(s) and the actual aims of EMEUNET set out in our mission statement (https://emeunet.eular.org/mission_statement.cfm).

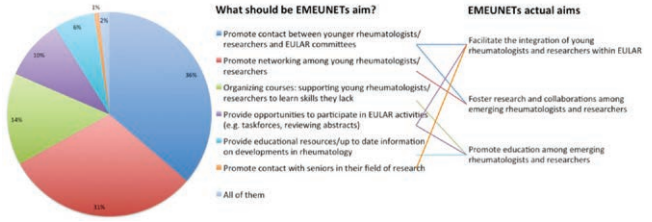

Figure 2. The links between what participants would like to see as EMEUNET aims and the aims of EMEUNET as they are now

Most of the respondents got to know about EMEUNET through a friend/colleague in Rheumatology (n=67, 54.0%), at EULAR/ACR annual conferences (n=32, 25.8%), via social media (n=9, 7.3%), other international meeting (n=6, 4.8%), national Rheumatology meeting (n=6, 4.8%) or via the EMEUNETs country liaisons (n=4, 3.2%).
29 respondents (24%) were part of the EMEUNET working group (WG), 43% (n=53) applied before to be part of the WG, 24% (n=29) never applied and 15% (n=19) did not know what the WG was. Most of the respondents who never applied to the WG thought it to be too time consuming. Only 21 (16.9%) felt there was a subgroup in the WG missing and most of those (n=8, 38.1%) found this should fully focus on research collaborations, which is actually part of the general aims of EMEUNET and a focus of all Working Groups.
Only a relatively small portion of EMEUNET of respondents (<5%) stated to have approached EMEUNET with their ideas. Although 90.2% (n=110) felt that the opportunity to submit new ideas is a good initiative, only 52.5% (n=..) knew that such possibilities exists. This suggests that EMEUNET could do more to make members aware of this possibility. Additionally, while the main reasons for not contacting EMEUNET with an idea were 'not having one' (41.9%) or having 'no time' (34.9%), 20.9% feels their ideas would not be received well, which is another aspect offering room for improvement.
Twice a year, EMEUNET organises networking events (NE) for their members to discuss their work in an informal setting. We found that 56/120 (46.7%) of the respondents prefer a low-budget (<€20) event, including an activity and the possibility to network, accompanied by drinks and bites. This is much in line with EMEUNETs past NE. In addition, past NEs were often mentioned as an example of ideal events.
Conclusion: Awareness on EMEUNET often comes from colleagues and international conferences in rheumatology, which coincides with one of the focuses of EMEUNET to increase visibility in the last 10 years. Expectations about NE are in line with the previously organised NE.
Areas for improvement are dissemination of information on the EMEUNET WG, the possibility to submit ideas -which is open to all members- and the increased focus on research collaboration, an aspect on which we are actively working as EMEUNET is fully engaged with the newly launched EULAR Virtual Research Centre.

OP0078 HIGH MEDIAN NERVE LESION SECONDARY TO SEVERE GIANT CELL ARTERITIS (GCA)

K. Iqbal[1,2], J. Miller[3], M. Lai[4], M. Charnley[2], M. Meraj[2], B. Thompson[1,2].
[1]*Newcastle University, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom*; [2]*Freeman Hospital, Newcastle upon Tyne Hospitals NHS Foundation Trust, Rheumatology, Newcastle upon Tyne, United Kingdom*; [3]*Royal Victoria Infirmary, Newcastle upon Tyne Hospitals NHS Foundation Trust, Neurology, Newcastle upon Tyne, United Kingdom*; [4]*Royal Victoria Infirmary, Newcastle upon Tyne Hospitals NHS Foundation Trust, Neurophysiology, Newcastle upon Tyne, United Kingdom*

Background: Giant cell arteritis (GCA) is a systemic vasculitis affecting large to medium-sized vessels. Cranial nerve lesions are frequently documented secondary to GCA, however peripheral nerves are rarely involved.

Objectives: We present an unusual case of a GCA-associated isolated high median nerve palsy.
Methods: Case report.
Results: A 76 year old white British female presented in Spain with three weeks of frontotemporal headaches, mandibular claudication, photopsia and constitutional symptoms, followed by acute-onset right hand paresis and dysaesthesia. Acute-phase reactants were elevated. COVID-19 PCR was negative. Shortly after admission she developed acute bilateral anterior ischaemic optic neuropathy and tongue necrosis with autoamputation. Temporal artery ultrasound and biopsy confirmed GCA. PET-CT showed no evidence of a diffuse large-vessel vasculitis. She was repatriated to the UK for ongoing inpatient care. Upper limb neurophysiology two months later demonstrated an isolated right high median nerve lesion, with reduced median motor responses and absent sensory responses with denervation in extensor carpi radialis. Imaging excluded a central lesion. The timing of her symptoms suggested the lesion was secondary to GCA. Treatment was with tocilizumab, methotrexate and tapering corticosteroids, alongside PEG feeding and careful multi-disciplinary rehabilitation.
Conclusion: We suggest there are two important learning points from this complex case. Firstly, peripheral nerve lesions can occur in GCA, although they are rare. A literature search identified a modest number of case reports of brachial plexus or lower cervical nerve lesions[1,2]. Neurologic manifestations in GCA are attributed to vasculitis of the vasa nervorum, or extension of inflammation from arteries to contiguous nerves[1,2]. The restriction of clinical involvement to the median nerve alone would appear to favour the former mechanism. Functional recovery of neurological deficits is typically partial at best.
Secondly, this case highlights the difficulty faced by clinicians in recognising GCA and the importance of urgent treatment with glucocorticoids. The patient developed GCA during the ongoing COVID-19 pandemic when Spain was the second-worst affected European country (5% seroprevalence; 95% CI 4.7-5.4)[3]. The partial overlap in symptoms between GCA and COVID-19 (e.g. headache, pyrexia, malaise, elevated acute-phase reactants) can cause diagnostic confusion and treatment delay[4]. GCA should be considered in the differential diagnosis of older patients with suspected COVID-19, or the non-specifically unwell elderly patient.

OP0079 **LIMB GIRDLE MUSCULAR DYSTROPHY TYPE 2B - A RARE MYOSITIS MIMIC**

A. Merriman[1], S. Boyle[1]. *[1]Western General Hospital, Rheumatic Diseases Unit, Edinburgh, United Kingdom*

Background: Proximal muscle weakness with associated raised creatine kinase (CK) commonly leads to referral to Rheumatology for the investigation of Idiopathic Inflammatory Myopathy (IIM). Some genetic myopathies can have a similar presentation with investigations that suggest inflammatory disease, leading to difficulty with accurate diagnosis (Amato & Brown, 2011; Harlan & Mammen, 2019).
Objectives: To describe the case of a patient with Limb Girdle Muscular Dystrophy Type 2B (LGMD2B), whose initial presentation mimicked an inflammatory myopathy.
Methods: Case report.
Results: A 43-year-old patient was reviewed by Rheumatology due to proximal muscle weakness with a raised CK. Muscle biopsy was suggestive of inflammatory myopathy. Therefore, he was started on treatment with corticosteroids. Corticosteroid treatment resulted in no improvement in his weakness or CK. His diagnosis was reviewed, and he was referred to the Neurology and Genetics services. Following molecular genetic analysis, a diagnosis of Limb Girdle Muscular Dystrophy Type 2B was made.
Conclusion: Muscle biopsies can suggest an inflammatory aetiology in some genetic myopathies (Amato & Brown, 2011; Harlan & Mammen, 2019). If a patient with suspected IIM presents with atypical features, or they do not respond as expected to treatment, then consider a genetic myopathy such as LGMD2B as a cause and involve the Neurology and Genetics services in the case.

OP0080 **OSTEOPOIKILOSIS IN PATIENT WITH ANKYLOSING SPONDYLITIS**

V. Omelchenko[1,2], E. Letyagina[1,2], Y. Kurochkina[1], A. Akimova[1], M. Korolev[1,2]. *[1]RICEL - Branch of IC&G SB RAS, Rheumatology Department, Novosibirsk, Russian Federation*; *[2]Novosibirsk State University, Internal Medicine Section, Novosibirsk, Russian Federation*

Background: Osteopoikilosis (OPK) – a rare congenital genetic-mediated benign sclerosing disease of skeleton. OPK is usually clinically asymptomatic and is most often an incidental finding during an X-ray study [1]. The lesions are from 2 to 10 mm and are located in the area of the ischial, pubic bones, metaepiphyseal regions of the tubular bones. The axial skeleton is usually not affected in OPK. As early described, OPK may be associated with inflammatory rheumatic diseases, such as rheumatoid arthritis, spondyloarthritis, reactive arthritis and scleroderma [2–4]. Ankylosing spondylitis is a chronic rheumatic disease from the group of spondyloarthritis with obligatory involvement of the sacroiliac joints and frequent involvement of entheses and peripheral joints. Although a significant mutual influence of OPK and AS has not been proven, their combination can lead to unreasonable over-examination in real clinical practice.
Objectives: To present a clinical case of rare coexisting of osteopoikilosis and ankylosing spondylitis.
Methods: Case report. The patient was treated and examined based on real clinical practice.
Results: A 33-year-old man was admitted to our rheumatology department with a three-year history of inflammation pain in cervical region of spine and hip, knees and shoulder joints and long morning stiffness duration (up to 3 hours). AS was earlier verified based on modified New York criteria (1984) and Nonsteroidal anti-inflammatory drugs were prescribed promptly. On the outpatient basis he also received sulfasalazine and methotrexate due to arthritis and enthesitis. Nevertheless he had high disease activity (ESR 66 mm/h, CRP 77.5 mg/l, BASDAI = 7.5), severely limited range of motion in the cervical, thoracic and lumbar spine, arthritis, enthesitis when he entered in our clinic. He had been treated with secukinumab 150 mg for fourteen months and then he was switched to golimumab 50 mg per month because of lack of efficacy. Low disease activity has now been achieved.
During the assessment of radiographs of the pelvic bones and spine, typical changes of the late stage of ankylosing spondylitis (syndesmophytes, stage 4 sacroiliitis) were revealed at the first visit in our clinic. At the same time, a number of phenomena were discovered that were not related to the course of the AS, which required expanding the differential diagnosis range. The tumor process and endocrine pathologies were excluded. OPK was diagnosed on the basis of characteristic changes in various parts of the skeleton, especially in phalanges, wrists and pelvis bones (fig.1).

Figure 1. OPK spots in phalanges and wrists.

Conclusion: We've reported rare case of AS and OPK coexisting in young patient. The identification of typical radiological phenomena and correct evaluation of clinical data may allow to avoid unnecessary expensive examinations.

OP0081 **A CASE OF ATYPICAL MYCOBACTERIUM INFECTION COMPLICATING EXTRA-NODAL ROSAI-DORFMAN DISEASE IN A PATIENT WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)**

K. Su[1], G. Hagan[2], S. Tosounidou[1], C. Gordon[1,3], J. Reynolds[1,3]. *[1]Sandwell and West Birmingham NHS Trust, Rheumatology, Birmingham, United Kingdom*; *[2]Sandwell and West Birmingham NHS Trust, Respiratory, Birmingham, United Kingdom*; *[3]University of Birmingham, Institute of Inflammation and Aging, Birmingham, United Kingdom*

Background: We present the case of a 28 year old Black-British female with severe SLE requiring treatment with rituximab in 2012 due to persistent low-grade activity and severe episodes of pleuro-pericardial effusions, pancytopaenia, fever and weight loss

Her other background includes beta-thalassaemia trait and excision of calcific fibrotic tissue on bilateral anterolateral orbits in 2015.
In 2018 she reported an 18-month history of non-tender, non-fluctuant, slow growing left thigh mass with USS revealing a well demarcated subcutaneous complex cystic lesion of ~2x4x7cm. There was no preceding trauma or skin infection. Histology from a needle biopsy revealed diffuse histiocytosis with positive immunohistochemistry (ICH) for S100, CD68 and CD31, it was negative for CD1a, consistent with **Extra-nodal Rosai-Dorfman disease (RDD)**.
She developed constitutional symptoms after reporting months of gradual weight loss with gradual ESR, CRP rise and leucocytosis. Her SLE symptoms were stable and given lack of SLE-specific symptoms; PET-CT was used to identify systemic RDD; the thigh mass showed strong FDG avidity along with a small focus of uptake in the small bowel, thought to be RDD related with no other areas of uptake.
She had ongoing ooze from the enlarging thigh lesion (5 x 26 x 15 cm), this was sent for MCS and AAFB; which isolated **Mycobacterium avium**. She was treated with rifampicin, ethambutol and clarithromycin resulting in improved thigh lesion, constitutional symptoms and inflammatory markers.

Objectives:

[1] To describe a rare associated complication of severe SLE and to educate and inform clinicians regarding possible masquerades of disease
[2] To education and inform about the approach to diagnosis of mycobacterium infection.

Methods: Case report and literature review.

Results: Mycobacterium infections rarely complicate RDD; to date, only one case report is published involving an HIV infected patient with RDD confirmed on LN biopsy presenting with splenomegaly and treated with oral corticosteroids (OCS) complicated by *Mycobacterium avium complex* and *Salmonella enterica* confirmed on bone marrow biopsy/culture, similar to our patient, he presented with constitutional symptoms and weight loss[(2)].
Mycobacterium can also mimic RDD, a case report has described a 74 year old with tender lymphadenopathy diagnosed with RDD on LN biopsy. She was treated with IV and OCS, but was unresponsive. A repeat LN biopsy and CT imaging revealed the presence of *mycobacterium kansasii;* her biopsy was positive for CD68/S100 throughout. Of note, she had high levels of anti-interferon autoantibodies and was diagnosed with adult-onset immunodeficiency syndrome[(3)].

Conclusion: This case illustrates the need for a MDT approach for multi-system diseases such as SLE and RDD, and the need to consider atypical infections when blood tests are incongruent with clinical state.

Challenges for Patients and Patients' Organisations in Times of the Pandemic

OP0082-PARE THE EFFECT COVID-19 HAS ON THE MENTAL HEALTH OF PEOPLE LIVING WITH RHEUMATIC DISEASES. FROM DATA TO INTERVENTIONS.

S. Mingolla[1], A. Celano[2], M. Santopietro[3]. [1]*APMARR APS, Communication, Lecce /Puglia, Italy*; [2]*APMARR APS, National Association of People with Rheumatic and Rare Diseases, Lecce, Italy*; [3]*WeResearch, Ricerche di Marketing, Milan, Italy*

Background: Covid-19 has had an important impact on the mental health conditions of over 5 million Italians suffering from one of the over 150 rheumatic diseases. In order to understand the psychological impact of the Covid-19 emergency and the restrictions imposed to counter it, the Italian National Association of People with Rheumatic and Rare Diseases – APMARR APS launched the research "Living with a rheumatic pathology".

Objectives: Gather data directly from Italian patients about the impact of the COVID-19 and consequent restrictions on their mental health and feelings; evaluate the most effective intervention to be implemented to face the pandemic by Patients organization.

Methods: A qualitative-quantitative survey was carried out through a questionnaire administered throughout the national territory to a sample of N = 1,001 people. The people invited to complete the questionnaire were women (55,9%) and men (44,1%), aged 18-85 years (age 18-41=26,7%; age 42-65=64%; age >65=9,3%) with at least one rheumatic pathology. The questionnaire was made up of 39 questions, of which 29 were closed and 10 were open. For the administration of the questionnaires, the CAWI (Computer Aided Web Interview) methodology of on-line survey was used. The 1,001 interviews were carried out from 7 to 14 August 2020.

Results: More than 4 out of 10 people (total sample 44.2%; male 60%, female 35,7%; age 18-41=39,1%; age 42-65=45,9%; age >65 = 50%) declared that the emergency period has somehow caused a worsening of their health condition. People declared that the deterioration of their health is due to the emergency period for the following reasons: 1) Psychological: such as stress and anxiety: "Too much stress and anxiety made the symptoms worse."; "The stress of the quarantine affected my problem"; "Insomnia. Nervousness. General ailments. Depression. Strong stress" 2) Inability to perform physiotherapy and motor activities due to the lockdown 3) Postponement of examinations, visits and checks 4) remote working, in some cases described as harmful for people's mental and physical health: "Due to Covid19 I had to do remote working and I worked even 12 hours a day including holidays to the detriment of my family life".
Furthermore, from January 31, 2020 a significant increase emerged in communication problems with rheumatology specialist compared to the period before the emergency due to Covid-19. The sharp increase may be due to the situation of severe psychological stress to which also the doctors were subjected in the emergency phase: people could not find the comfort of being empathically listened to.

Conclusion: The research shows that the most frequent symptoms among people with rheumatic diseases were depression and high levels of anxiety due to strong emotional stress. Psychological malaise caused direct effects in worsening the symptoms of rheumatic disease as well as other related effects, for example, insomnia. The forced isolation due to the lockdown has made people lack the social support that is fundamental for the psychological well-being especially for those suffering from some chronic pathology. Starting from the data collected, APMARR promptly activated a completely free psychological support service with 6 professional psychologists, two of them specialized in emergency psychology. The service is accessible online and is still going on for all who are not able to overcome the anxiety and fear related to the pandemic and its evolution. Thousands of accesses to the service have been measured to date.

The origins of pain in RMDs

OP0083 INFECTIOUS AND AUTOINFLAMMATORY MODIC TYPE 1 CHANGES HAVE DIFFERENT PATHOMECHANISMS

I. Heggli[1,2], R. Schüpbach[3], N. Herger[1,2], T. A. Schweizer[4], A. Juengel[1,2], N. Farshad-Amacker[5], M. Betz[6], J. M. Spirig[6], F. Wanivenhaus[6], N. H. Ulrich[6], F. Brunner[2], A. S. Zinkernagel[4], M. Farshad[6], O. Distler[1,2], S. Dudli[1,2]. [1]*Center of Experimental Rheumatology, Department of Rheumatology, University Hospital, University of Zurich, Zurich, Switzerland*; [2]*Department of Physical Medicine and Rheumatology, Balgrist University Hospital, University of Zurich, Zurich, Switzerland*; [3]*Unit of Clinical and Applied Research, Balgrist University Hospital, University of Zurich, Zurich, Switzerland*; [4]*Department of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, University of Zurich, Zurich, Switzerland*; [5]*Department of Radiology, Balgrist University Hospital, University of Zurich, Zurich, Switzerland*; [6]*Department of Orthopeadic Surgery, Balgrist University Hospital, University of Zurich, Zurich, Switzerland*

Background: Modic type 1 changes (MC1) are vertebral bone marrow (BM) edema that associate with non-specific low back pain (LBP). Two etiologies have been described. In the infectious etiology the anaerobic aerotolerant *Cutibacterium acnes* (*C. acnes*) invades damaged intervertebral discs (IVDs) resulting in disc infection and endplate damage, which leads to the evocation of an immune response. In the autoinflammatory etiology disc and endplate damage lead to the exposure of immune privileged disc cells and matrix to leukocytes, thereby evoking an immune response in the BM. Different etiologies require different treatment strategies. However, it is unknown if etiology-specific pathological mechanisms exist.

Objectives: The aim of this study was to identify etiology-specific dysregulated pathways of MC1 and to perform in-depth analysis of immune cell populations of the autoinflammatory etiology.

Methods: BM aspirates and biopsies were obtained from LBP patients with MC1 undergoing spinal fusion. Aspirates/biopsies were taken prior screw insertion through the pedicle screw trajectory. From each patient, a MC1 and an intra-patient control aspiration/biopsy from the adjacent vertebral level was taken. If *C. acnes* in IVDs adjacent to MC1 were detected by anaerobic bacterial culture, patients were assigned to the infectious, otherwise to the autoinflammatory etiology.

Total RNA was isolated from aspirates and sequenced (Novaseq) (infectious n=3+3, autoinflammatory n=5+5). Genes were considered as differentially expressed (DEG) if p-value < 0.01 and log2fc > ± 0.5. Gene ontology (GO) enrichment was performed in R (GOseq), gene set enrichment analysis (GSEA) with GSEA software.

Changes in cell populations of the autoinflammatory etiology were analyzed with single cell RNA sequencing (scRNAseq): Control and MC1 biopsies (n=1+1) were digested, $CD45^+CD66b^-$ mononuclear cells isolated with fluorescence activated cell sorting (FACS), and 10000 cells were sequenced (10x Genomics). Seurat R toolkit was used for quality-control, clustering, and differential expression analysis.

Transcriptomic changes (n=5+5) of $CD45^+CD66b^+$ neutrophils isolated with flow cytometry from aspirates were analyzed as for total bulk RNAseq. Neutrophil activation (n=3+3) was measured as $CD66b^+$ expression with flow cytometry. $CD66b^{high}$ and $CD66b^{low}$ fractions in MC1 and control neutrophils were compared with paired t-test.

Results: Comparing MC1 to control in total bulk RNAseq, 204 DEG in the autoinflammatory and 444 DEG in the infectious etiology were identified with only 67 shared genes (Fig. 1a). GO enrichment revealed "T-cell activation" (p = 2.50E-03) in the autoinflammatory and "complement activation, classical pathway" (p=1.1E-25) in the infectious etiology as top enriched upregulated biological processes (BP) (Fig 1b). ScRNAseq of autoinflammatory MC1 showed an overrepresentation of T-cells (p= 1.00E-34, OR=1.54) and myelocytes (neutrophil progenitor cells) (p=4.00E-05, OR=2.27) indicating an increased demand of these cells (Fig. 1c). Bulk RNAseq analysis of neutrophils from the autoinflammatory etiology revealed an activated, pro-inflammatory phenotype (Fig 1d), which was confirmed with more $CD66b^{high}$ neutrophils in MC1 (+11.13 ± 2.71%, p=0.02) (Fig. 1e).

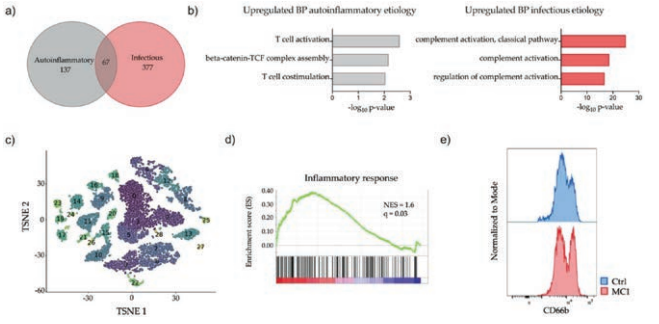

Figure 1. (a) Venn diagram of DEG from total bulk RNAseq (b) Top enriched upregulated BP of autoinflammatory (left) and infectious (right) etiology (c) Cell clustering of autoinflammatory MC1 BM (d) Enrichment of "inflammatory response" gene set in autoinflammatory MC1 neutrophils (e) Representative histogram of $CD66b^+$ expression in MC1 and control neutrophils.

Conclusion: Autoinflammatory and infectious etiologies of MC1 have different pathological mechanisms. T-cell and neutrophil activation seem to be important in the autoinflammatory etiology. This has clinical implication as it could be explored for diagnostic approaches to distinguish the two MC1 etiologies and supports developing targeted treatments for both etiologies.

OP0084 CENTRAL MECHANISMS TRAIT PREDICTS PERSISTENT KNEE OSTEOARTHRITIS PAIN AT 24-MONTHS: DATA FROM THE OSTEOARTHRITIS INITIATIVE

S. Holden[1,2,3], D. Mcwilliams[1,2,3], S. Smith[1,2,3], D. Walsh[1,2,3,4]. [1]*University of Nottingham, Pain Centre Versus Arthritis, Nottingham, United Kingdom*; [2]*University of Nottingham, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom*; [3]*University of Nottingham, Division of Rheumatology, Orthopaedics and Dermatology, Nottingham, United Kingdom*; [4]*Sherwood Forest Hospitals NHS Foundation Trust, Rheumatology, Mansfield, United Kingdom*

Background: In the UK, 10% of men and 18% of women over the age of 60 suffer from symptomatic osteoarthritis (OA), and rising. OA knee pain can worsen without significant radiographic changes and pain remains a major problem for up to 20% of patients after total knee joint replacement. Chronic knee OA pain is

augmented by central pain mechanisms, including central sensitisation. Measures of the level of central involvement in pain could inform clinical decision making. Self-report characteristics of depression, anxiety, cognitive difficulties, catastrophizing, sleep disturbance, fatigue, and widespread pain distribution together contribute to a Central Mechanisms Trait which is associated with central sensitisation and OA knee pain

Objectives: Using self-report questionnaire data from the Osteoarthritis Initiative Cohort Study (OAI) we aimed to evaluate the prognostic performance of baseline CMT for pain at 24-months.

Methods: OAI participants with knee OA or at risk of knee OA with pain in the same knee at both index time point (48-months) and one year prior to that date were included (n=1984). Knee pain was measured using the Western Ontario and McMasters Universities Osteoarthritis Index (WOMAC) pain sub-scale, by reference to the index knee (the knee with the highest WOMAC pain sub-scale score at baseline). Questionnaire items were selected to assess the 7 available characteristics identified by Akin-Akinyosoye et al.[1], from which a single CMT factor was calculated by confirmatory factor analysis. Anxiety, fatigue and cognitive difficulties were assessed by single items, depression and sleep disturbance represented by multiple items, and catastrophising by using the Coping Strategies Questionnaire – Catastrophising sub-scale. Pain distribution was defined as a sum of other painful joints at or below the hip. A CMT factor was derived from the 7 characteristics using confirmatory factor analysis. The association between the CMT factor score and 24-month pain (adjusted for baseline pain, radiographic OA (Kellgren-Lawrence (KL) scale) and demographic confounders) was investigated using generalised linear regression with a negative binomial link function.

Results: At baseline, participants had a mean (SD) age 65(9) years, a BMI 29.6(5.1) kg/m^2, 60% were female, 19.8% were African American, KL score was 1.92(1.35) indicating that the majority of the cohort had radiographic OA. Model diagnostics informed the CMT model, with the final model having an RMSEA of 0.073 (90%CI 0.070-0.076). Data were consistent with a single factor model for CMT. In the multivariable model, higher baseline CMT scores were significantly associated with 24-month WOMAC pain scores, with or without adjustment for baseline pain and other covariates, including KL score (multivariable model; std beta=0.173 (SE=0.027), p=0.004). Association of baseline CMT was of similar strength, and over and above association of KL score with 24-month pain (std beta=0.164 (SE=0.038), p=<0.001). Adjusted regression coefficients and associated p-values are shown in Table 1.

Table 1. Adjusted regression coefficients for analysed variables against WOMAC pain at 24-months

Variables	Std beta (SE)	P
Sex	-0.096 (0.101)	0.344
Age, y	-0.001 (0.006)	0.881
BMI, kg/m^2	0.017 (0.010)	0.088
Index Knee Kellgren-Lawrence Score	**0.164 (0.038)**	**<0.001**
CMT Factor Score	**0.173 (0.060)**	**0.004**
Baseline Pain	**0.857 (0.035)**	**<0.001**

n=1421, rows in bold indicate significant association (p<0.05), associations adjusted for race and ethnicity

Conclusion: CMT predicts worse pain prognosis with a similar magnitude to radiographic OA even after adjustment for other factors. A self-report tool which included items relevant to the characteristics included in the CMT may help to select people with OA knee pain with unfavourable pain prognosis. Poor outcomes related to central pain mechanisms or to joint structural damage might be amenable to treatments addressing central or peripheral pain mechanisms respectively.

OP0085 ALTERED EXPRESSION OF NEUROTROPHINS AND THEIR RECEPTORS IN THE SKIN OF PATIENT WITH COMPLEX REGIONAL PAIN SYNDROME (CRPS)

S. Stroeve[1,2], S. Dudli[1,2], I. Kolm[3], I. Heggli[1,2], N. Herger[1,2], S. Catanzaro[4], A. Schweizer[5], M. Calcagni[6], O. Distler[1,2], F. Brunner[2], A. Juengel[1,2]on behalf of Experimental Rheumatology Balgrist Campus. *[1]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zürich, Switzerland*; *[2]Department of Physical Medicine and Rheumatology, Balgrist University Hospital, University of Zurich, Zurich, Switzerland*; *[3]University Hospital Zurich, Department of Dermatology, Zurich, Switzerland*; *[4]Balgrist University Hospital, University of Zurich, Switzerland, Unit of Clinical and Applied Research, Zurich, Switzerland*; *[5]Balgrist University Hospital, University of Zurich, Switzerland, Department of Hand surgery, Zurich, Switzerland*; *[6]University Hospital Zurich, Department of Plastic Surgery and Hand Surgery, Zurich, Switzerland*

Background: Complex regional pain syndrome (CRPS) is a rare painful condition that usually appears after trauma or surgery of the extremities. Symptoms include pain, sensory, sudomotor and vasomotor disturbances, trophic changes and impaired motor function. The course varies from mild to chronic disease with a high impact on daily functioning and quality of life. In skin tissue, sustained inflammatory, fibrotic processes together with reduced epidermal nerve fibers are reported. Neurotrophins and their receptors are mediators in cell-to-cell communication and key mediators of pain signaling

Objectives: The aim of this study was to identify differential expression of neurotrophins and their receptors in the skin and skin fibroblasts of patients with CRPS

Methods: Healthy controls (HC) and patients with acute CRPS with symptoms for less than 6 months fulfilling the Budapest criteria were recruited. Pain scores were evaluated by numeric rating scale (0=no pain, 100=maximal) and body perception was assessed using the Bath Body Perception Disturbance Scale (BBPDS) (0=no perception disturbance, 57=maximal perception disturbance).

Skin biopsies of the affected and/or non-affected side were taken. Immunohistochemistry on formalin-fixed, paraffin-embedded skin tissue slides was used to show NT3 expression in skin tissues. Blinded analysis was done by an experienced dermato-pathologist determined staining graduated by 0= none, 1= sparse, 2=moderate, 3= dense.

Skin fibroblast were isolated from skin biopsies by outgrowth cultures (CRPS, affected side, n=6 and HC, n=5). Cells (passage 3-6) were starved and subsequently stimulated with TNFα (10 ng/ml) or TGFβ (10 ng/ml) for 24 h to mimic active disease and total RNA was isolated by miRNeasy kit. Gene expression of neurotrophins (NGF, BDNF, and NT3) and neurotrophin receptors (NGFR, TrkA, TrkB and TrkC) was measured by quantitative real time PCR and quantified using the $\Delta\Delta$Cq method with GAPDH as a reference gene. ELISA was used to analyze NT3 protein expression in cell culture supernatants.

Results: In 5 of 9 patients with CRPS immunohistological staining of NT3 showed an higher expression (from low to moderate) in the affected side versus the non-affected side. In 4 of 9 patients the expression of NT3 was high in the non-affected side (moderate/dense) and stayed high in the affected side.

Of interest, the patients with increasing expression of NT3 in the affected side showed increased pain scores (max pain 80+/-10.95, n=5 versus 48.16+/-18.16, n=4, p=0.059 and changed body perception 26.8+/-8.68 n=5 versus 6.5+/-3.91, n=4, p=0.016).

Isolated skin fibroblasts from the affected side of patients with CRPS compared to healthy skin fibroblasts showed higher **basal** gene expression of NT3 ($\log_2$ fold-change= 1.9 +/- 0.4, *p= 0.005*) and NGFR ($\log_2$ fold-change= 3.6 +/- 2.1, *p=0.014*). **TNFα** stimulated CRPS skin fibroblasts showed higher expression for NT3 ($\log_2$ fold-change= 2.1 +/- 1.2, p=0.002) compared to HC. **TGFb** stimulated skin fibroblasts of patients with CRPS showed higher expression of NT3 ($\log_2$ fold-change= 1.4+/-0.8, *p=0.019*), NGFR ($\log_2$ fold-change= 2.6 +/- 1.8, *p=0.036*) and TrkC ($\log_2$ fold-change= 2.3 +/- 1.8, *p=0.032*) compared to HC.

On protein level, NT3 showed a tendency of upregulation in unstimulated fibroblasts from CRPS patients comparing to HC (CRPS mean= 8.0 +/- 2.2 pg/ml, HC

mean= 6.3 +/- 1.8 pg/ml, *p=0.25*). After **TNFα** stimulation, protein level of NT3 was significantly higher in CRPS skin fibroblasts (CRPS mean= 10.6 +/- 2.4 pg/ml, HC mean= 4.8 +/- 1.3 pg/ml, *p=0.004*).

Conclusion: These data indicate a new role of skin fibroblasts in CRPS. Differential basal and stimulated expression of NT3, the receptor for NT3 (TrkC) and NGFR, the common receptor for all neurotrophins, indicates deregulated communication of fibroblasts with the sensory nerve fibers in CRPS. This might contribute to the dysregulated healing process and sustained pain.

OP0086

GENDER INFLUENCE ON CLINICAL MANIFESTATIONS, DEPRESSIVE SYMPTOMS AND BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) SERUM LEVELS IN PATIENTS AFFECTED BY FIBROMYALGIA

C. Gioia[1], B. Lucchino[1], C. Iannuccelli[1], G. Dolcini[1], M. Di Franco[1]. [1]*Sapienza Università di Roma, Reumatologia, Dipartimento di Scienze Cliniche, Internistiche, Anestesiologiche e Cardiovascolari, Sapienza Università di Roma, Roma, Italy*

Background: Fibromyalgia (FM) is a common rheumatic disease characterized by chronic widespread pain, sleep and mood disorders. A higher prevalence of FM in women compared with men is well known, although the specific differences in clinical manifestations related to gender are still poorly defined. Brain-Derived Neurotrophic Factor (BDNF) is an endogenous growth factor that gained attention for its potential as biomarker of several diseases, including FM and depression.

Objectives: The aims of this study were to investigate gender-related difference among males and females affected by FM in clinical manifestations, depressive features and BDNF serum level, evaluating also the diagnostic potential of the latter.

Methods: We consecutively enrolled adult patients affected by FM (ACR 2016) referring to our out-patient clinic. Each subject underwent clinical and answered to questionnaires for the severity of FM symptoms (Revised Fibromyalgia Impact Questionnaire, R-FIQ) and depressive symptoms (Beck Depression Inventory-II, BDI-II). We collected blood samples from a subgroup of patients of both sexes, matched for age, for BDNF serum level dosage through ELISA. BDNF levels were assessed also in a control group, matched for sex and age.

Results: The cohort was composed by 201 FM patients (172 F, 29 M), mean age 49.13. Females showed higher values of R-FIQ total score (p=0,0005) as well the specific items of the R-FIQ for pain (p=0,013), fatigue (p=0,014), memory problems (p=0,007), tenderness to touch (p<0,0001), balance problems (p<0,0001) and sensitivity to environmental stimuli (p=0,012) when compared with males (fig. 1). There was no difference in BDI-II between males and females, but notably male patients reported a significantly higher frequency of coexisting depressive disorder (p=0,038) (fig. 2). Serum BDNF levels were evaluated in 40 FM patients and 40 healthy controls (HC) (F:M 1:1). BDNF levels were significantly lower in FM patients compared with HC (p<0,0001). Among FM patients, BDNF levels were lower in males compared with females (p<0,0001) (fig.3). BDNF did not correlate with any clinical and clinimetric parameter. BDNF showed a good diagnostic performance (AUC=0,89, CI95%=0,82-0,9630, p<0,0001) (fig. 4). At a cut-off value <6,47 ng/dl, BDNF showed a specificity of 75% and a sensibility of 92,31%,(CI 95%=79,68-97.35) for FM identification (LR=3,692).

Conclusion: FM clinical manifestations are strongly dependant from gender. While females present a more severe disease and a higher burden of symptoms, mood disorders tend to be a major characteristic of males with FM. Reduced BDNF serum levels have been reported as typical of depressive disorders. Our findings of lower BDNF levels in male FM patients compared to females support this hypothesis. BDNF have potential as biomarker of the disease and should be validated in larger cohorts.

OP0087

COMORBIDITIES IN HAND OSTEOARTHRITIS PATIENTS: PREVALENCE AND IMPACT ON PAIN AND PAIN SENSITIZATION

E. Mulrooney[1], T. Neogi[2], H. Solveig Dagfinrud[1,3], H. Berner Hammer[1,4], P. Steen Pettersen[1], T. L. Gaarden[5,6], K. Engedal[7,8], T. K. Kvien[1,9], K. Magnusson[10], I. K. Haugen[1]. [1]*Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*; [2]*Boston University School of Medicine, Section of Rheumatology, Boston, United States of America*; [3]*University of Oslo, Department for Interdisciplinary Health Sciences, Oslo, Norway*; [4]*University of Oslo, Department of Orthopaedics, Oslo, Norway*; [5]*Diakonhjemmet sykehus, Alderspsykiatrisk Avdeling, Oslo, Norway*; [6]*University of Oslo, Faculty of Medicine, Oslo, Norway*; [7]*Norwegian Centre of Ageing and Health, Norwegian Centre of Ageing and Health, Oslo, Norway*; [8]*University of Oslo, Department of Geriatric Medicine, Oslo, Norway*; [9]*University of Oslo, Division of Orthopaedic Surgery, Oslo, Norway*; [10]*Lund University, Department of Clinical Sciences, Lund, Sweden*

Background: Pain is a hallmark symptom of hand osteoarthritis (OA). A subset of people with hand OA display centrally driven pain characteristics. Pain is driven by person-related factors, but how comorbidities are related to the hand OA pain experience is undetermined. Changes in pain pathophysiology and pain levels by for instants low-grade inflammation, might explain the link.

Objectives: The purpose of this study was to determine whether the burden of comorbidities or the individual comorbidities were associated with pain and pain sensitization in persons with hand OA.

Methods: These cross-sectional analyses included 282 participants with hand OA from the Nor-Hand study. Comorbidities were assessed by an index (subscales: Disease, Limitation and Treatment, (0-45 scale)) by Sangha et al. The participants completed pain questionnaires; Numeric Rating Scale (NRS) hand pain (0-10) and all joints (0-10), Australian/Canadian (AUSCAN) hand pain subscale (0-20 scale), Western Ontario & McMaster Universities Arthritis Index (WOMAC) pain subscale (0-20) and homunculus (painful joint sites last six weeks, (0-18)). Pressure pain threshold (PPT, handheld algometer, kg/cm^2) at tibialis anterior and trapezius and Temporal summation (TS) at the distal radioulnar joint tapped with weighted probe (x10), assessed central pain sensitization. TS-delta was calculated of the first and peak measure of the fifth or tenth tap. Linear regression was used to examine all relations, while adjusted for age, sex, body mass index and education.

Results: The participants (89% women, median (IQR) age: 61 (57-66)) showed broad range in pain severity. Most frequent comorbidities were back pain (n=170, 60%), hypertension (n= 85, 30%), stomach ulcer/abdominal disease (n=62, 22%) and depression (n=46, 16%). 281 (99.3%) participants reported >1

comorbidity other than OA. Mean (SD) comorbidity index value was 7.73 (4.25). Higher values were statistically significantly associated with greater pain severity by each pain questionnaire, lower PPT trapezium (borderline significant for PPT tibialis anterior), and greater TS (Table). Similar results were found for subscales. Depression, back pain and hypertension associated with most measures of pain. (Table). Included in the same model, results remained similar (not shown). No statistically significant association between individual comorbidities and pain sensitization (Table).

Conclusion: Higher burden of comorbidities was associated with greater pain intensity and central pain sensitization. Hypertension, back pain and depression were associated with most pain measures. The lack of relation between individual comorbidities and pain sensitization suggest the burden of comorbidity is more important.

OP0088 A COHORT STUDY ON THE BIDIRECTIONAL RELATIONSHIP BETWEEN FIBROMYALGIA AND PERIODONTITIS OVER A 15-YEAR FOLLOW-UP

K. S. K. MA[1], T. Van Dyke[2]. [1] *National Taiwan University, Taipei, Taiwan, Department of Life Science, Taipei, Taiwan, Republic of China*; [2]*Forsyth Institute, Cambridge, Center for Clinical and Translational Research, Boston, United States of America*

Background: Fibromyalgia has been proposed to be driven by chronic inflammation and infections that are associated with early rheumatoid arthritis and inflammatory arthritis. Other than the central sensitization model, our knowledge of fibromyalgia pathogenesis has been expanded with an inflammation-dependent theory, which is stimulated by prolonged spinal cord hyperexcitability.

Objectives: To determine the relationship between periodontitis and fibromyalgia.

Methods: In this cohort study, 196,428 periodontitis patients and 196,428 propensity score-matched non-periodontitis controls were enrolled. A Cox proportional hazard model was utilized to estimate the risk of fibromyalgia and survival analysis was adopted to assess the time-dependent effect of periodontitis on fibromyalgia. Subgroup analyses stratified by age, gender, and follow-up years were conducted to identify susceptible populations. A symmetrical cohort was designed to ascertain the relationship between fibromyalgia and the risk of periodontitis.

Results: Patients with history of periodontitis were more likely to develop fibromyalgia than non-periodontitis controls (HR =1.42, 95% CI =1.39–1.44, P < 0.001), which persisted in the survival analysis (log-rank test P < 0.0001). This effect was significant in both genders and all age subgroups, and was particularly evident in males (HR=1.52, 95% CI = 1.48–1.56, P < 0.001) and younger periodontitis patients (HR= 1.55, 95% CI =1.50-1.60, P < 0.001). Fibromyalgia patients who never had periodontitis presented with higher risk for periodontitis over time (HR = 1.43, 95% CI = 1.40 - 1.45, P < 0.001).

Conclusion: This is the first longitudinal study that addresses the bidirectional relationship between fibromyalgia and periodontitis, in which periodontitis may serve as a risk factor or early sign of fibromyalgia. Based on the observed relationship between fibromyalgia and periodontitis, regular follow-ups and patient education are recommended for patients with either disease.

OP0089 DO PAIN CATASTROPHIZING REDUCE THE LIKELIHOOD OF REMISSION IN PATIENTS WITH CHRONIC INFLAMMATORY JOINT DISORDERS?

M. Wilk[1], K. Łosińska[1], A. H. Pripp[2], M. Korkosz[1,3], G. Haugeberg[4,5]. [1]*University Hospital, Division of Rheumatology and Immunology, Cracow, Poland*; [2]*Oslo University Hospital, Oslo Centre of Biostatistics and Epidemiology, Oslo, Norway*; [3]*Jagiellonian University Medical College, Department of Rheumatology, Cracow, Poland*; [4]*Sørlandet Hospital, Department of Rheumatology, Kristiansand, Norway*; [5]*5NTNU, Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Trondheim, Norway*

Background: Rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (ax-SpA) may have a devastating impact on patients' lives, including chronic and relapsing pain. One factor contributing to bio-psycho-social model of pain in these diseases, is pain catastrophizing (PC) defined as tendency to report pain experience in exaggerated terms, to ruminate more or to feel helpless about it. In one RA study PC has been shown to be associated with patient reported outcomes e.g. reduced likelihood of remission using composite measures.[1]

Objectives: Main objective of this study was to explore if pain catastrophizing score is associated with remission rates in the chronic inflammatory joint disorders RA, PsA and ax-SpA.

Methods: Patients were recruited during routine assessment at an outpatient clinic in Norway. Variables collected included demographics, treatment, disease duration, global pain VAS, pain catastrophizing score (PCS), and disease activity scores: DAS28-CRP for RA, BASDAI for ax-SpA and DAPSA for PsA. Cut off definitions of remission was for DAS28 <2.6, for BASDAI <4.0 and for DAPSA ≤4.0. Two questions from Coping Strategies Questionnaire as recommended by Jensen et al [2] were used to describe PC, range PC total score (PCS) 0–6. Patients with PCS ≥ 4 were defined as high pain catastrophizers. Statistics included Chi-Square test and adjusted logistic regression (enter procedure).

Results: For RA (N=580), PsA (N=394) and ax-SpA (N=225) mean age (SD) was 61.5 (13.1), 54.4 (12.9) and 47.5 (12.9) years, mean disease duration 12.6 (10.9), 10.2 (8.4) and 12.2 (10.7) years and percentage of women 66.7%, 47.0% and 38.4%. Mean (SD) DAS28-CRP in RA was 2.3 (1.0), BASDAI for ax-SpA 3.7 (2.3) and DAPSA for PsA 10.8 (8.5). Mean (SD) global pain (VAS 0-100mm) was for RA 32.0 (25.6), for PsA 35.5 (25.4) and for ax-SpA 39.4 (25.4) mm.

Conventional synthetic DMARDs were used by 65.0% of RA patients, 54.8% by PsA and 9.8% in ax-SpA and for biologic DMARDs the corresponding numbers were 36.7%, 43.9%, 65.9%, respectively.

Percentage of patients in remission was significantly lower in high pain catastrophizers compared with low pain catastrophizers in RA (34.1% vs 70.3%, p<0.01) and ax-SpA patients (17.9% vs 64.5%, p<0.01) but not in PsA (10.3% vs 26.7%, p=0.06).

In analysis adjusting for age, gender, disease duration and global pain (Tab. 1), PC was independently associated with lower remission rate in RA (OR 0.79 (95% CI 0.63, 0.99), p=0.04) and in ax-SpA (OR 0.65 (95% CI 0.46, 0.93), p=0.02) but not in PsA (OR 0.83 (95% CI 0.55, 1.25), p=0.37)

Conclusion: Our data indicates that high level of patient's PC may reduce likelihood of achieving remission in RA and ax-SpA. Interestingly, this was not shown in PsA patients. Further studies are needed to reveal the importance of PC and its influence on composite disease activity measures used to define disease status e.g. remission.

Table 1. Variables and their associations with remission rates in RA, PsA, ax-SpA in logistic regression analysis.

	RA remission		PsA remission		ax-SpA remission	
	OR (95%CI)	p	OR (95%CI)	p	OR (95%CI)	p
PCS	0.79 (0.63, 0.99)	0.04	0.83 (0.55, 1.25)	0.37	0.65 (0.46, 0.93)	0.02
Age	0.99 (0.97, 1.01)	0.17	1.00 (0.96, 1.04)	0.85	0.98 (0.94, 1.02)	0.27
Gender	0.87 (0.52, 1.45)	0.59	0.37 (0.15, 0.93)	0.03	0.92 (0.40, 2.14)	0.85
Disease duration	1.03 (1.00, 1.05)	0.03	0.95 (0.90, 1.00)	0.06	1.04 (0.99, 1.09)	0.09
Global pain (VAS)	0.96 (0.95, 0.97)	<0.01	0.85 (0.81, 0.89)	<0.01	0.90 (0.88, 0.92)	<0.01

OP0090 CLASSIFICATION OF PATIENTS WITH RELAPSING POLYCHONDRITIS BASED ON SOMATIC MUTATIONS IN UBA1

M. Ferrada[1], K. Sikora[1], Y. Lou[1], K. Wells[1], B. Patel[2], D. Ospina Cardona[3], E. Rose[1], W. Goodspeed[1], P. Hoffman[4], A. Jones[3], L. Wilson[3], N. Young[2], S. Savic[4], D. Kastner[4], A. Ombrello[4], D. Beck[4], P. Grayson[1]. [1]*NIH, NIAMS, Bethesda, United States of America*; [2] *NIH, NHLBI, Bethesda, United States of America*; [3]*NIH, NHGRI, Bethesda, United States of America*; [4]*NIHR, Leeds Biomedical Research Centre and Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: Somatic mutations in ubiquitin activating enzyme 1 (*UBA1*) cause a newly defined syndrome known as VEXAS. [1] More than fifty percent of patients currently identified with VEXAS meet diagnostic criteria for relapsing polychondritis (RP).

Objectives: To determine the prevalence VEXAS within a cohort of patients with RP, to compare their clinical, laboratory, and immunologic features and to develop a clinical algorithm to inform genetic screening for VEXAS among patients with RP.

Methods: Exome and targeted sequencing of the *UBA1* gene was performed in a prospective observational cohort of patients with RP. Clinical and immunological characteristics of patients with RP were compared based on presence or absence of *UBA1* mutations. Random forest was used to derive a clinical algorithm to identify patients with *UBA1* mutations. Immune populations were quantified by multipanel flow cytometry. Categorical and continuous variables were compared using the chi square or Kruskal-Wallis test. P<0.05 defined statistical significance.

Results: Seven of 92 patients with RP (7.6%) were confirmed to have *UBA1* mutations (VEXAS-RP). Six additional patients with VEXAS-RP from other cohorts were included for subsequent analyses. Patients with VEXAS-RP were all male, older at disease onset, and commonly had fever, ear chondritis, skin involvement, deep vein thrombosis, and pulmonary infiltrates. Patients with RP as compared with VEXAS-RP had a significantly higher prevalence of airway chondritis, costochondritis and tenosynovitis/arthralgias. (Table). Mortality was significantly greater in VEXAS-RP than RP (27% vs 2% p=0.01). Maximum ESR, CRP, and mean corpuscular volume (MCV) values were significantly greater in VEXAS-RP. Absolute monocyte, lymphocyte, and platelet counts were significantly lower in VEXAS-RP. A decision tree based on male sex, MCV>100 fl and Platelet count<200 K/ul classified between VEXAS-RP and RP with 100% sensitivity and 96% specificity.

Conclusion: Mutations in *UBA1* are causal for disease in a subset of patients with RP. These patients are defined by disease onset in the fifth decade of life or later, male sex, ear/nose chondritis and hematologic abnormalities. Early identification is important in VEXAS given the associated high mortality rate.

OP0091

TREATMENT OF OCULAR SARCOIDOSIS. STUDY OF 65 PATIENTS OF A SERIES OF 384 PATIENTS FROM A SINGLE UNIVERSITY HOSPITAL

C. Álvarez-Reguera[1], J. J. Gaitán-Valdizán[2], R. Fernández-Ramón[2], R. Demetrio-Pablo[2], J. L. Martín-Varillas[3], L. Sanchez-Bilbao[1], D. Martínez-López[1], I. González-Mazón[1], M. Á. González-Gay[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*; [2]*Hospital Universitario Marqués de Valdecilla, Ophthalmology, Santander, Spain*; [3]*Hospital de Sierrallana, Rheumatology, Torrelavega, Spain*

Background: Ocular involvement is a relatively frequent and potentially severe complication of sarcoidosis. Oral corticosteroids (OCS) are the first-line treatment. Conventional immunosuppressive agents (cIS) and biological therapy (BT) can be used in refractory cases **(1-5).**

Objectives: To evaluate the treatment and visual outcomes of a cohort of patients diagnosed with ocular sarcoidosis.

Methods: Study of a large cohort (n=384) of all consecutive patients diagnosed with sarcoidosis from January 1, 1999 to December 31, 2019 at a single University Hospital. Finally, 344 patients were included according the ATS/ERS/WASOG criteria *(Eur Respir J. 1999; 14:735-7).* Different ocular manifestations and the following systemic treatments were assessed: **a)** OCS, **b)** cIS), **c)** monoclonal TNF inhibitors, **d)** Etanercept (ETN), **e)** Tocilizumab (TCZ). Best Corrected Visual Acuity (BCVA) according to different systemic treatments was compared at diagnosis and after one year of follow-up (Kruskall Wallis test).

Results: 344 patients were reviewed. From these, 65 (18.9%) presented ocular manifestations as uveitis (83.1%), orbital lesions (7.7%), retinal vasculitis (6.2%), dry eye (6.2%) and scleritis (1.5%). All of them received systemic treatment. BT was particularly used in patients with retinal vasculitis (100%), panuveitis (75%) and orbital lesions (40%). Systemic treatment and BCVA outcome according to ocular manifestations are shown in table. Median BCVA at onset and after one year was 0.6 [interquartile range (IQR) 0.3-0.8] and 0.9 [0.6-1], respectively. No statistically significant differences were observed between systemic treatments in BCVA of patients with uveitis after 1 year of follow-up (Figure**).**

Conclusion: Panuveitis, intermediate uveitis and orbital lesions, require a more aggressive treatment than other manifestations of ocular sarcoidosis. In uveitis, an important improvement in BCVA after 1 year of follow-up was observed regardless of the type of treatment used.

Table 1. Median BCVA at onset and after one year according to ocular manifestations and type of systemic therapy.

Type of ocular affectation	n (%)	Median BCVA at onset [IQR]	Median BCVA after 1 year [IQR]	OCS n (%)	cIS n (%)	monoclonal TNFi n (%)	ETN n (%)	TCZ n (%)

Background: In clinical trials as well as in real-life, the IL-1ß inhibitor canakinumab leads to rapid remission of symptoms in the treatment of CAPS, a monogenic autoinflammatory disease with severe systemic and organ inflammation.

Objectives: The RELIANCE registry is designed to explore long-term safety and effectiveness of canakinumab under routine clinical practice conditions in pediatric (≥2 years) and adult patients with CAPS, including Muckle-Wells syndrome (MWS), familial cold autoinflammatory syndrome (FCAS), and neonatal onset multisystem inflammatory disease (NOMID)/chronic infantile neurological cutaneous and articular syndrome (CINCA).

Methods: This prospective, non-interventional, observational study with a 3-year follow-up enrolls patients with clinically confirmed diagnoses of CAPS routinely receiving canakinumab. In 6-monthly visits, clinical data, physician assessments and patient-reported outcomes are evaluated starting at baseline with last update at 30 months of follow-up in the total cohort including the cohort with severe CAPS subtypes (NOMID/CINCA).

Results: 91 CAPS patients (50% female; 14 [15%] NOMID/CINCA subtypes) were enrolled by December 2020 (Table 1). At baseline, median age was 20.5 years and median duration of prior canakinumab treatment was 6 years. 11 drug related severe adverse events per 100 patient years were reported. 68% of patients

reached disease remission by physicians´ assessment along with rates of 40-61% absent disease activity in PGA. Patients reported stable low level disease activity, fatigue and Auto-Inflammatory Diseases Activity Index scores (AIDAI, figure 1). CAPS was impairing social life in 50% of patients and another 50% reported days off from school/work. Lab parameters were within normal limits.

Table 1. Patient and physician assessment of clinical CAPS disease activity and laboratory markers over time.

	Baseline		12 months		30 months	
	Total cohort	NOMID/ CINCA	Total cohort	NOMID/ CINCA	Total cohort	NOMID/ CINCA

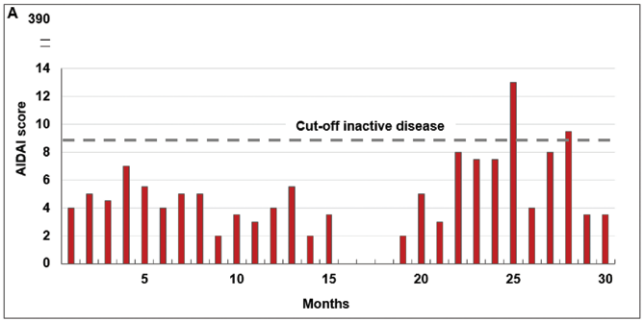
Figure 1: Median AIDAI score (0-390) of the CAPS cohort (N = 91 at baseline) over 30 months



Conclusion: The 30-month interim analysis of the RELIANCE study demonstrates that long-term canakinumab treatment is safe and effective in patients with any subtype of CAPS. However, impairment of social life and days off school/work still exists.

OP0093 RETENTION RATE OF IL-1 INHIBITORS IN PATIENTS WITH SCHNITZLER'S SYNDROME

F. Crisafulli[1], A. Vitale[2], C. Gaggiano[2], L. Dagna[3], G. Cavalli[3], R. Cimaz[4], O. Viapiana[5], F. Iannone[6], G. Lopalco[6], R. Bortolotti[7], M. Abdel Jaber[7], C. Montecucco[8], S. Monti[8], S. Balduzzi[8], G. Emmi[9], P. Airò[1], F. Franceschini[1], L. Cantarini[2], M. Frassi[1]on behalf of Working Group of Autoinflammatory Diseases of Italian Society of Rheumatology (SIR). *[1]ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; [2]University of Siena, Research Center of Systemic Autoinflammatory Diseases and Behçet's Disease Clinic, Department of Medical Sciences, Surgery and Neurosciences, Siena, Italy; [3]Vita-Salute San Raffele University, IRCCS San Raffaele Scientific Institute, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UniRAR), Milano, Italy; [4]Università degli Studi di Milano, ASST Gaetano Pini-CTO Institute, Department of Clinical Sciences and Community Health, Research Center for Adult and Pediatric Rheumatic Diseases, Division of Pediatric Rheumatology, Milano, Italy; [5]University of Verona, Rheumatology Unit, Verona, Italy; [6]University of Bari "Aldo Moro," Department of Emergency and Organ Transplantations, Rheumatology Unit, Bari, Italy; [7]Santa Chiara Hospital, Department of Rheumatology, Trento, Italy; [8]IRCCS Fondazione Policlinico San Matteo, University of Pavia, Department of Rheumatology, Pavia, Italy; [9]University of Florence, Department of Experimental and Clinical Medicine, Firenze, Italy*

Background: Schnitzler's syndrome is an autoinflammatory disease characterized by monoclonal gammopathy and recurrent episodes of urticaria accompanied by clinical and laboratory signs of acute inflammation. Interleukin (IL)-1 inhibitors proved to be useful in the treatment, but data on long-term safety and efficacy of these agents are sparse.
Objectives: To evaluate the retention rate of IL-1 inhibitors in patients with Schnitzler's Syndrome.
Methods: Retrospective analysis of an Italian multicenter cohort (9 Centers). All patients fulfilled Strasbourg diagnostic criteria. Data are expressed as median [IQR].
Results: We identified 15 patients (8 females, 7 males) who received a total of 24 treatment courses with IL-1 inhibitor treatment (16 anakinra and 8 canakinumab) between January 2001 and December 2019, with a median treatment duration of 19 months [8.5-51.3]. Median age at diagnosis was 64.0 years [56.0-72.5] and median follow up was 5.0 years [2.0-8.0]. Before the biological treatment, all patients were treated with corticosteroids and 11 with at least one conventional synthetic disease-modifying antirheumatic drug (csDMARD): methotrexate (5), colchicine (5), cyclosporine (3), azathioprine (1), mycophenolate mofetil (1), cyclophosphamide (1).
Fifteen patients received 16 courses of Anakinra, which was the 1st line biological treatment in 14 patients. Seven patients continued it with benefit, while 7 patients discontinued it: 3 for secondary inefficacy; 3 for adverse events (2 injection site reactions, 1 severe allergic reaction); 1 for secondary inefficacy and leukopenia. Anakinra was used as 2nd line treatment in 1 case (after tocilizumab failure); in 1 patient anakinra was resumed after temporary discontinuation and an attempt with infliximab. One patient died for multiple myeloma progression while on treatment with anakinra. The median duration of the courses with anakinra was 20.0 months [6.0-58.3].
Seven patients received 8 courses of canakinumab (150 mg/8weeks in 5 cases and 150 mg/4weeks in 3). In 5 cases the drug was administered as 2nd line biological treatment (after anakinra failure) and in 2 cases as 3rd line treatment (1 after tocilizumab and anakinra failures and 1 after anakinra and adalimumab failure). In 1 patient, it was resumed after temporary discontinuation and an attempt with etanercept. One patient died while on treatment with canakinumab due to a presumably unrelated adverse event. The median duration of canakinumab treatment courses was 19.0 months [13.5-31.0].
At last follow-up visit, all patients were on treatment with an IL-1 inhibitor: 8 with anakinra (7 at the dosage of 100 mg/day, 1 at the dosage of 200 mg/day) and 7 with canakinumab (2 at the dosage of 150 mg/8 weeks, 4 at the dosage of 150 mg/4 weeks and 1 at the dosage of 300 mg/4 weeks). Notably, in 3 patients the dosage of canakinumab was increased since the start of the treatment.

Among 9 patients who were on treatment with prednisone at the start of the last IL-1 inhibitor, the prednisone median dose was 12.5 mg/day [10.0-18.8] while at the last follow-up visit it was 5.0 mg/day [0-7.5] (p= 0.02).
The retention rate of IL-1 inhibitors was 73.4% [SE 9.4] at 1 year and 63.6% [SE 10.4] at 2 years (Figure 1a). There was no significant difference between the retention rate of anakinra (at 1 year: 67.0% [12.2]; at 2 years: 59.6% [12.9]) and canakinumab (at 1 year: 85.7% [13.2]; at 2 years 71.4% [17.1]) (log-rank test: p=0.41) (Figure 1b).

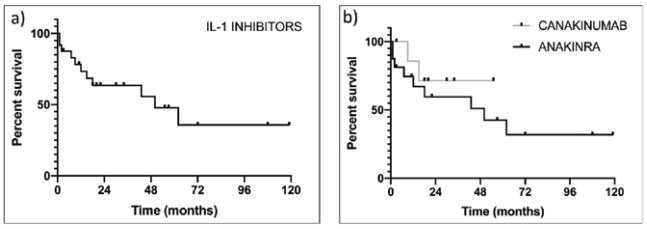

Figure 1. a) Retention rate of IL-1 inhibitors (24 courses); b) Retention rate of canakinumab (8 courses) and anakinra (16 courses).

Conclusion: In this multicentric cohort of patients affected by Schnitzler's syndrome, the treatment with IL-1 inhibitors as 1st, 2nd or 3rd line biological treatment permitted a good disease control and corticosteroid reduction in patients who did not respond to csDMARDs and/or to prior other biological DMARDs. The optimal dosage of these drugs needs to be tailored for every patient.

OP0094 PULMONARY ARTERIAL HYPERTENSION IN ADULT-ONSET STILL'S DISEASE: A CASE SERIES OF 13 PATIENTS

S. Mitrovic[1,2], A. Boucly[3,4], E. Lazaro[5], N. Schleinitz[6], C. Bloch-Queyrat[7], C. Christides[8], J. Pouchot[9], M. Humbert[3,4,10], D. Montani[3], L. Savale[3], X. Jaïs[3], O. Sitbon[3,4], B. Fautrel[11,12,13,14]. *[1]Hôpital Pitié-Salpêtrière, AP-HP, Department of Rheumatology, Paris, France*; *[2]Institut Mutualiste Montsouris, Department of Medicine, Paris, France*; *[3]Hôpital Bicêtre, AP-HP, Service de Pneumologie, Centre de Référence de l'Hypertension Pulmonaire, Paris, France*; *[4]Université Paris-Sud, Université Paris-Saclay, INSERM Unité Mixte de Recherche en Santé S_999, Le Kremlin-Bicêtre, France*; *[5]CHU Bordeaux, Service de Médecine Interne et Maladies Infectieuses, Bordeaux, France*; *[6]Hôpital Timone, AP-HM, Service de Médecine Interne, Marseille, France*; *[7]Hôpital Avicennes, Médecine Interne, Bobigny, France*; *[8]Centre Hospitalier Henri Duffaut, Service de Médecine Interne, Avignon, France*; *[9]Hôpital Européen Georges Pompidou, AP-HP, Service de Médecine Interne, Paris, France*; *[10]Université Paris-Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, France*; *[11] Hôpital Pitié-Salpêtrière, AP-HP, Service de Rhumatologie, Paris, France*; *[12]Centre de Référence des Maladies Auto-Inflammatoires rares et des Amyloses, (CeRéMAIA), Paris, France*; *[13]Pierre Louis Institute of Epidemiology and Public Health, INSERM UMR 1136, Paris, France*; *[14]Sorbonne Université, Department of Rheumatology, Paris, France*

Background: Pulmonary Arterial Hypertension (PAH) is a rare but potentially fatal complication of Adult-Onset Still's Disease (AOSD) (1). To date, only isolated observations have been published.
Objectives: To establish the largest case series of AOSD patients with PAH, and to describe their clinical profile, evolution and response to treatments.
Methods: Cases were retrospectively identified from the French PAH network database and from an online call of the "Club Rhumatismes et Inflammation" (http://www.cri-net.com). To be included, all patients had to fulfil the Yamaguchi or Fautrel's criteria for AOSD and PAH had to be confirmed by right heart catheterization. The data were collected using a standardized questionnaire.
Results: Thirteen patients were identified. All were female, the mean age at PAH diagnosis was 32± 12 years, 2 (15%) patients were Caucasian, 6 (46%) from Sub-Saharan Africa, 1 (8%) from Asia and 4 (31%) from West Indies. Only 2 (15%) patients were smokers. All patients had a systemic onset of AOSD, 12 had a polycyclic and 1 a chronic articular evolution, and the mean delay between AOSD and PAH diagnosis was 2.9 (range 1.7 -5.4) years. At PAH diagnosis, patients were receiving the following treatments: 13 (100%) corticosteroids (median dose 12 mg [interquartile range (IQR) 9-18]), 3 (23%) methotrexate, 8 (61%) interleukin (IL)-1 inhibitors (exposure median duration 6.7 months [IQR 3.6-8.5]), none IL-6 inhibitors, 2 (15%) TNF inhibitors. Six (46%) patients developed PAH during an AOSD flare. PAH was severe at diagnosis: 2 (15%), 7 (54%) and 4 (31%) patients were in NYHA functional class II, III and IV, respectively, with a median 6-minute walk distance of 289 m [IQR 0-448], a mean pulmonary arterial pressure of 41 ± 12 mmHg, a mean pulmonary arterial occlusion pressure of 6 ± 3 mmHg, a mean cardiac output of 3.9 ± 1.2 L/min, a mean cardiac index of 2.5 ± 0.9 L/min/m^2 and a median pulmonary vascular resistance of 7 Wood Units [IQR 6-11]. The treatment prescribed after PAH diagnosis is detailed in the table. The median follow-up was 34 months [IQR 7-42]. Five patients (38.5 %) died. Figure 1 shows the overall survival. The haemodynamic response to PAH treatment seemed to be dissociated from the prognosis since several patients have died while their haemodynamic had improved or almost normalised.
Conclusion: PAH is a rare but potentially severe complication of AOSD, leading to death in 38.5% of our cases series. AOSD remission should be physicians' objective, since PAH seems to occur when the underlying disease is not controlled.

OP0095 NON-GONOCOCCAL PYOGENIC ARTHRITIS OF NATIVE JOINTS IN WESTERN AUSTRALIA. A LONGITUDINAL POPULATION-BASED STUDY OF FREQUENCY, RISK FACTORS AND OUTCOME.

J. Nossent[1], W. Raymond[1], D. Preen[2], H. Keen[1], C. Inderjeeth[1]. *[1]The University of Western Australia, Rheumatology, Crawley, Australia*; *[2]The University of Western Australia, School of Population and Global Health, Crawley, Australia*

Background: The worldwide incidence of PyA is reportedly rising due to a combination of increased longevity, multi- comorbidity, iatrogenic complications and increasing use of immunomodulating therapies, while there is limited data on longterm outcomes of PyA.
Objectives: To describe the recent incidence, risk factors and long-term outcomes in adults hospitalised with non-gonococcal pyogenic arthritis (PyA) of native joints in Western Australia (WA).

Methods: We extracted population-based longitudinally linked administrative health data for patients 16 years or older with a first diagnostic code of 711.xx (ICD9-CM) and M00.xx (ICD10-AM) in WA in the period 1990-2010. Annual incidence rates (IR), risk factors during 14.5 years lookback and outcomes including standardized mortality rates (SMR) during 10.1 years follow-up are reported.
Results: A total of 2,777 patients (67% male, mean age 49.8 ± 20.5) received a first diagnostic code for PyA. The AIR increased from 4.5 to 11.8 /100,000 over time as did age at onset (45.1 to 55.4 years) and proportion of female patients (23 to 36%). There was no seasonal variation in PyA incidence but a higher rate of predisposing comorbidities in female patients. Knees (33.6%) and hands (22%) were most frequently affected with 28.4 % of positive cultures not due to Gr+ cocci. Mean hospital stay was 8 days, 30-day readmittance and mortality rate was 12 .8% and 3.1% respectively. During ten years follow-up serious infections (43%), new diagnosis of osteoarthrosis (20%), joint replacement (10.8%), osteomyelitis (6%), and crystal arthropathy (6.3%) were the most common morbidities. SMR were increased across all age and gender categories (Table) but highest in females aged 16-40 (SMR 25.9).

Table 1. Mortality rates (MR) per 1000 person years in patients with pyogenic arthritis compared with age (at death) and gender matched categories from the general population by standardised mortality rate (SMR)

Gender	Age	Deaths	Person years	MR PyA	MR Gen pop *	SMR
Male						
	16-40	27	4015	6.72	0.892	7.53
	40-59	80	7106	11.25	2.972	3.78
	>60	331	7366	44.93	21.55	2.08
	All	**438**	**18487**	**23.69**	**5.820**	**4.07**
Female						
	16-40	11	1026	10.72	0.41	25.95
	40-59	40	2769	14.44	1.75	8.21
	>60	208	4088	50.88	24.20	2.10
	All	**259**	**7883**	**32.85**	**5.50**	**5.96**

* Based on WA death data from Australian Bureau of statistics in 2011

Conclusion: The incidence of PyA has increased significantly between 1990 and 2010 in WA. PyA associates with a 3% in-hospital mortality rate and significant late bone and joint morbidity including osteomyelitis. PyA associated with excess mortality across age and gender categories, most markedly in younger female patients.

Background: Dengue infection is associated with joints pain mimicking disease onset symptom of rheumatoid arthritis (RA). However, there is lack of epidemiological studies on exposure to dengue infection and risk of future RA.
Objectives: We investigated the relationship between exposure to dengue infection and risk of developing different subsets of RA, defined by the presence of anti-citrullinated peptide antibody (ACPA) in the multi-ethnic Malaysian population.
Methods: Serum samples from 1,235 RA cases (i.e. 516 Malay, 254 Chinese, 405 Indians and 60 others/mixed-ethnicity) and 1,624 epidemiological matched population-based controls (i.e. 1,023 Malay, 208 Chinese, 297 Indians and 96 others/mixed-ethnicity) were assayed for presence of dengue IgG antibody using World Health Organization recommended ELISA kits. Positive results of dengue IgG antibodies indicates previous exposure to dengue infection(s). We performed chi-square and Mann-Whitney U analysis to determine the association of ever-exposed dengue infection with ACPA-positive/ACPA-negative RA and to investigate the antibody frequency and levels among the studied populations.
Results: We observed high occurrence of dengue IgG antibody in the overall RA cases (79.7%) and matched controls (77.3%), with no significant differences detected between the ACPA subsets of RA. Ethnicity stratification analysis revealed a decrease risk of developing ACPA-positive RA in the Indian patients with positive dengue IgG antibody (OR=0.59, 95% CI=0.37-0.94, p=0.03), and in particular patients with elevated level of dengue IgG antibody (OR=0.44, 95% CI=0.25-0.78, p<0.05). On the other hand, the significant decrease mean levels of dengue IgG antibody were observed in the ACPA-positive RA subset for all three major ethnic groups (i.e. Malay, p<0.0001, Chinese, p<0.01 and Indian<0.05) (Figure 1). No association was observed between presence of dengue IgG antibody and ACPA-negative RA subset.

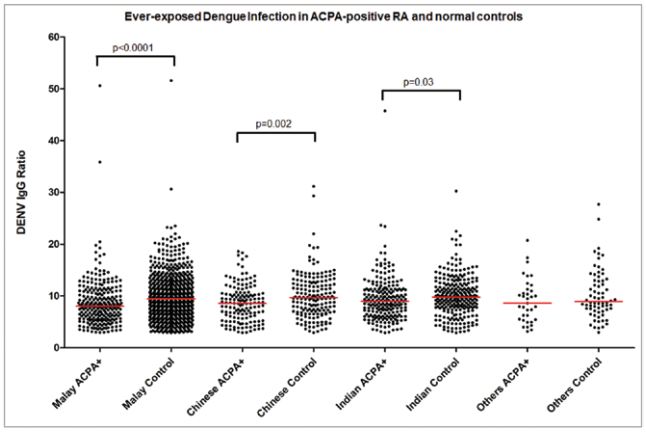

Figure 1. Comparison of mean dengue IgG antibody level between ever-exposed dengue infection RA cases, stratified by ACPA status. Comparison of median dengue IgG antibody level between the ever-exposed dengue infection ACPA-positive RA and normal controls in the four ethnic groups. The red line indicates the mean level of dengue IgG antibody level

Conclusion: Our findings demonstrated that exposure to dengue infection do not increase the risk of developing future RA in the multi-ethnic Malaysian population. The inverse associations observed in the Indian ethnic group are in line with the other studies investigating exposure to viral infection and risk of RA.

OP0097 LISTERIA MONOCYTOGENES. DESCRIPTION AND ANALYSIS OF CASES IN AN IMMUNODEPRESSED POPULATION BY RHEUMATIC DISEASES

M. Lisbona Muñoz[1], P. León[1], G. Lopez Antequera[1], E. Rubio-Romero[1]. *[1]H.U.Virgen del Rocío, Rheumatology, Seville, Spain*

Background: Listeria monocytogenes is a gram-positive bacteria that cause the invasive disease listeriosis. Human clinical syndromes are infrequent, mostly appearing in immunosuppressed individuals, newborns, the elderly, pregnant women, and occasionally healthy patients.

Objectives: We describe and analyze Listeria-related demographics and clinical features to determine the predisposing conditions for severe infections in an immunodepressed population by rheumatic diseases.
Methods: Descriptive Observational Study. A retrospective analysis of 143 patients were performed affected by listeriosis, with positive isolation of Listeria monocytogenes from blood, treated in the H.U. Virgen del Rocío (Seville- Spain) between 2003-2019. Of them 9 were rheumatic patients. The type of clinical manifestation was analyzed, paying special attention to the characteristics associated with patients with neurological complications or unfavorable outcome (death and / or abortion in pregnant women), immunosuppression (associated with cancer or rheumatic disease) was assessed as independent variables, chronic diseases (Hypertension, Diabetes Mellitus, dyslipidemia, COPD, Renal Insufficiency and Ischemic Heart Disease) as well as other baseline characteristics of the patient. (age, sex, pregnancy) and their toxic habits (tobacco and alcohol).
Results: The sample includes a similar proportion of men (70 cases) and women (73 cases), of all ages. Of the total patients, most (85%) required hospital admission, with a duration median (non-parametric data) of 11 days. 78% of the cases admitted showed a favorable evolution. However, 15.4% resulted in death and 5.6% in abortion. This percentage of abortions represented 29% of the total pregnant women admitted Of all the patients admitted, a third (33%) were immunocompromised, including patiets with cancer (79%) and rheumatic diseases (21%). Include lupus (33%), RA (22%), APs (11%), polymyalgia rheumatica (11%), panuveitis (11%) and ANCA vasculitis MPO specificity (11%). All of them required admission although the majority showed a favorable evolution, except one of the patient. which resulted in death, in which case in addition to lupus he presented with prostate cancer. Regarding the baseline treatment of these patients, 7 underwent treatment with synthetic DMARDs and three with biological DMARDs (1 Adalimumab, 1 Infliximab and 1 Rituximab) As a result of the listeria infection, most of them had fever or digestive symptoms and two of they experienced neurological manifestations (meningoencephalitis) None of these last two (with lupus and RA) had biological DMARDs.
Conclusion: Listeriosis is an uncommon but potentially serious infection usually in older people, pregnant women and immunocompromised patients. In our sample, 33% of the patients were immunocompromised. Of the 9 patients. affected by listeria with rheumatic disease we find a death for meningoencephalitis. Given the impact of this infection in immunosuppressed patients should pay attention in our patients with fever and neurological manifestations.

Background: Polypharmacy is steadily increasing in patients with rheumatoid arthritis (RA). They may interfere with treatment response and the occurrence of serious adverse events. Medications taken by a patient may reflect active comorbidities, whereas comorbidity indices usually used include past or current diseases.
Objectives: To evaluate whether polypharmarcy is associated with treatment response and adverse events in an early RA cohort and to establish whether polypharmacy could represent a substitute of comorbidities.
Methods: We used data from the French cohort ESPOIR, including 813 patients with early onset arthritis. Patients included the current study had to start their first disease modifying anti-rheumatic drug (DMARD) within 24 months of inclusion in the cohort. Disease activity data were collected at one, five and ten years from the initiation of the first DMARD. For each patient, treatments were collected at baseline and at five years. Medications count included all specialties other than background RA therapy, analgesics/NSAIDs and topicals. Polypharmacy was defined as a categorical variable based on the median and tertiles of distribution in the cohort. Treatment response was assessed by achieving DAS28 ESR remission (REM) at 1 year, 5 years and 10 years from the initiation of the first DMARD. The occurrence of severe adverse events (SAE) was measured by the occurrence of severe infection, hospitalization, or death during the 10-year follow-up. The association between patient's characteristics and achievement of REM and occurrence of SAE were tested in univariate analysis. A logistic regression model was used to evaluate associations between polypharmacy and REM at 1 year, 5 years and 10 years (we used baseline polypharmacy for the 1-year analysis and five years polypharmacy for the 5- and 10-years analyses). Multivariate adjustment was made for age, sex, BMI, duration of disease, initial DAS28 ESR, initial HAQ, smoking status, rheumatic disease comorbidity index (RDCI).
Results: The proportion of patients who achieved REM one year after the initiation of the first DMARD was 32.1% in the polypharmacy according to the median group (patients taken ≥2 medication) versus 67.9% in the non-polypharmacy group (p=0.07). At 5 years after the first DMARD, the proportion of patients with REM was 45.0% in the polypharmacy group versus 56.3% in the non-polypharmacy group (p=0.03). At 10 years the proportion of patients with REM was 32.5% in the polypharmacy group versus 67.5% (p=0.06). Patients who take greater or equal to 2 medications had a 40% lower probability of achieving REM (OR = 0.60 [0.38-0.94] p = 0.03) at 5 years from the first DMARD (if RDCI index was not included in the model). At 10 years, patients receiving multiple medications had a 43% lower probability of achieving REM (OR = 0.57 [0.34-0.94] p = 0.02). SAE incidence was 61 per 1000 patient-years. For patients who developed SAE all causes 71.4% where in the polypharmacy group versus 57.8% were in the non-polypharmacy group (p = 0.03; univariate analysis). These results are no longer significant after adjustment for comorbidities indices.
Conclusion: In this early RA cohort, polypharmacy is associated with a poorer treatment response and increased risk of adverse events. Polypharmacy may represent a good substitute of comorbidities for epidemiological studies.

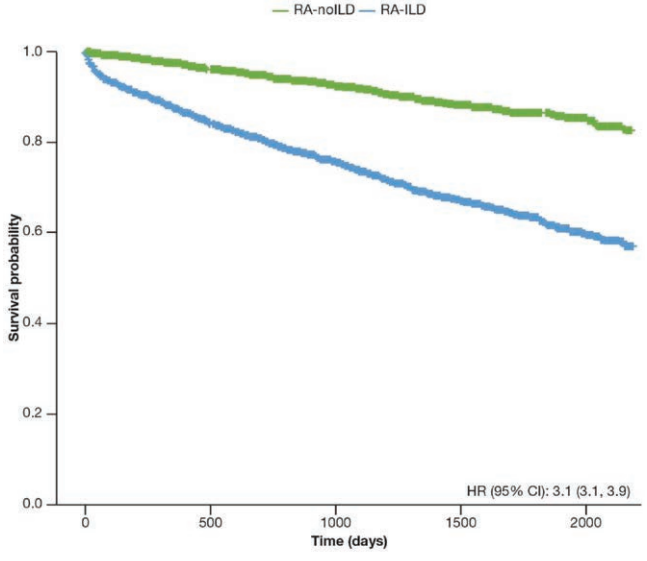
Department of Rheumatology, Paris, France; [4]*Sanoïa, eHealth Services, Aubagne, France*; [5]*Bristol Myers Squibb, Worldwide Health Economics and Outcomes Research, Princeton, United States of America*; [6]*Bristol Myers Squibb, Health Economics and Public Health, Rueil-Malmaison, France*; [7]*Bristol Myers Squibb, Medical Affairs, France, Rueil-Malmaison, France*; [8]*Centre Hospitalier Universitaire de France, Department of Rheumatology, Lille, France*; [9]*Assistance Publique-Hôpitaux de Paris, Hôpital Bichat-Claude-Bernard, Department of Pulmonology, Paris, France*

Background: Interstitial lung disease (ILD) is a common extra-articular manifestation of RA and is associated with increased morbidity and mortality.[1-3] Studies have shown variability in the prevalence and mortality rate of patients with RA-associated ILD (RA-ILD).[4] Further studies are needed to better characterise the epidemiology of RA-ILD.
Objectives: To estimate the prevalence and incidence of clinical RA-ILD in France and to compare mortality rates between patients with RA-ILD and patients with RA without clinical ILD (RA-noILD).
Methods: A historical cohort study was conducted using data from the French national claims database (SNDS) between 1 January 2013 and 31 December 2018. Adults with an RA diagnosis (International Classification of Diseases, Tenth revision [ICD-10] codes M05, M06.0, M06.8 and M06.9) and ≥2 distinct dates of DMARD delivery were included. Onset of RA was defined as the first date of occurrence between RA codes and the first known DMARD reimbursement. ILD diagnosis was defined as having ICD-10 code J84 and ≥1 computed tomography scan after, but within 1 year of, the first date of ILD occurrence. All patients had ≥6 months' reimbursement after RA-ILD onset. The prevalence and incidence (2014–2018) of RA-ILD were estimated. The mortality rate was calculated, comparing patients with RA-ILD and patients with RA-noILD, matched 1:1 for age, sex, age at RA-ILD onset, duration of RA and presence of diabetes, arterial disease, dyslipidaemia and cardiac disease. Mortality was compared between patients with RA with and without clinical ILD in the matched population using Cox proportional hazards regression.
Results: The prevalence of RA-ILD was 6.52 per 100,000 inhabitants (incidence=1.04 per 100,000 person-years). Of the 173,138 patients with RA included in the overall population, 4330 (2.5%) had clinical ILD. Patients with RA-ILD were older at RA diagnosis (mean [SD] age: 63.3 [13.7] vs 56.9 [15.2] years) and were more likely to be male (39.8% vs 27.0%) compared with patients with RA-noILD. Patients with RA-ILD were more likely to have cardiac disease (84.9% vs 63.1%), arterial disease (38.0% vs 19.3%), diabetes (21.4% vs 12.5%) and dyslipidaemia (44.7% vs 32.9%) compared with those with RA-noILD. The mortality rate in patients with clinical RA-ILD was 1.71 per 100,000 inhabitants. The mortality rate increased according to age (0.28 per 100,000 inhabitants for patients aged <65 years, 4.60 per 100,000 inhabitants for patients aged 65–74 years and 11.4 per 100,000 inhabitants for patients aged ≥75 years). After matching, the adjusted mortality risk was three times higher (HR [95% CI]: 3.1 [3.1, 3.9]) in patients with RA-ILD than in those with RA-noILD (Figure 1).
Conclusion: This is the largest epidemiological study of RA-ILD in France. The prevalence of clinical RA-ILD in this population was towards the lower end of previous estimates (1–58%),[3] possibly due to under-reporting of claims data. However, the occurrence of clinical ILD was associated with a strong increase in mortality compared with patients with RA-noILD.

Figure 1. Mortality risk in patients with RA with versus without ILD in the matched population[a]



[a]Patients with RA-ILD and RA-noILD were matched for age, sex, age at RA-ILD onset, duration of RA and presence of diabetes, arterial disease, dyslipidaemia and cardiac disease.
HR=hazard ratio; ILD=interstitial lung disease; RA-ILD=RA-associated interstitial lung disease; RA-noILD=RA without ILD.

OP0100-HPR

THE INFLUENCE OF COMORBIDITY ON MORTALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS 1980-2015: A LONGITUDINAL POPULATION-BASED STUDY IN WESTERN AUSTRALIA

K. Almutairi[1], J. Nossent[1], D. Preen[2], H. Keen[1], C. Inderjeeth[1]. [1]*The University of Western Australia, School of Medicine, Perth, Australia*; [2]*The University of Western Australia, School of Population and Global Health, Perth, Australia*

Background: Rheumatoid arthritis (RA) contributes to excess morbidity and mortality in RA patients compared with the general population (1). In Australia, there is a paucity of published literature on the mortality and morbidity rates in RA patients, despite the significant morbidity and mortality burden on health care costs due to RA. Linked data is the preferred method to estimate morbidity and mortality outcomes as they provide the best case-ascertainment.
Objectives: To describe temporal changes in mortality rates for patients with RA in relation to comorbidity accrual from 1980-2015 in Western Australia (WA).
Methods: Using population-level linked data from WA health administrative datasets (hospital morbidity, emergency department and death data) we followed 17,125 RA patients (ICD-10-AM M05.00–M06.99, ICD-9-CM 714) from 1980-2015. Comorbidity was ascertained using the Charlson Comorbidity Index (CCI). Mortality rate ratios (MRR) were calculated per decade between the RA cohort and the WA general population by direct age standardisation method, while temporal trends of comorbidities and in-hospital mortality were estimated per 1000 hospital separations in three consecutive decades.
Results: During 356,069 patient-years, a total of 8955 (52%) deaths occurred in the RA cohort. The leading causes of deaths were cardiovascular diseases 2386 (26.6%), cancer 1511 (16.8%), rheumatic diseases 519 (5.8%), chronic pulmonary disease 491 (5.5%), dementia 269 (3.0%) and diabetes 235 (2.6%). The highest prevalence of comorbidity (688.6 per 1000 separations) was in the period 1991-2000 following a 1.3% average annual increase since 1980. In-hospital mortality rate was also highest (26.7 deaths per 1000 separations) in the same

Table 1. Mortality rates observed among patients with rheumatoid arthritis, based on Charlson Comorbidity Index, per 1000 hospital separations, Western Australia hospitals (1980-2015).

Time period	1980-1990	1991-2000	2001-2010	2011-2015
Total number of hospital separations	82099	107731	185398	80410
Number of deaths	1620	2875	3183	1277
CCI score				
0	481 (29.7%)	1024 (35.6%)	1197 (37.6%)	565 (44.2%)
1	838 (51.7%)	1271 (44.2%)	1358 (42.6%)	467 (36.6%)
2	273 (16.8%)	518 (18%)	581 (18.3%)	232 (18.2%)
3	1 (0.1%)	4 (0.2%)	2 (0.1%)	0 (0%)
6	27 (1.7%)	58 (2%)	45 (1.4%)	13 (1%)
In-hospital RA mortality per 1000 hospital separation	19.7	26.7	17.2	15.9
Parentage of average annual change per annum in the period	0	3.8	-4.8	-2.6
Parentage of average annual change since 1980	0	1.5	-1.4	-0.2

CCI= Charlson Comorbidity Index.

period. After 2001, both RA comorbidity and mortality rates decreased annually by -0.5% and -4.8%, respectively, with annual changes of -4.4% to -2% and from 2011- 2015, respectively. The overall mortality rate in RA patients after age adjustment was 2.5-times (95%CI: 2.52-2.65) higher than the general population between 1980- 2015 and 1.5-times (95%CI: 1.39-1.81) for the period 2011-2015.
Conclusion: The annual comorbidity prevalence and mortality rates in WA have decreased significantly since 2001 reflecting improvements in the management of RA and comorbidity. Nonetheless, the mortality rate in RA patients in WA remains 1.5-times higher than their community counterparts suggesting that there is room to achieve further improvements.

OP0101 RHEUMATOID ARTHRITIS DISEASE ACTIVITY OVER TIME AND SUBSEQUENT CARDIOVASCULAR RISKS.

K. Yoshida[1], H. Guan[1], S. Stryker[2], E. Karis[2], L. Harrold[3], D. Solomon[1].
[1]Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, United States of America; *[2]Amgen, Inc., Thousand Oaks, United States of America*; *[3]Corrona, LLC., Waltham, MA, United States of America*

Background: Rheumatoid arthritis (RA) patients have an increased risk of cardiovascular (CV) events not fully explained by traditional CV risk factors. The relationship between fluctuating inflammation due to RA disease activity and CV events is of interest.
Objectives: To examine the influence of time-varying disease activity on the subsequent risks of CV disease.
Methods: We followed patients from a large US registry of clinically diagnosed RA patients, starting at their first visit with a Clinical Disease Activity Index (CDAI) through the end of follow-up or first CV event. Exposure of interest was disease activity measured by categorical CDAI (high, moderate, low, and remission) averaged within each 6-month window. The outcome of interest was major adverse CV events (MACE) defined as non-fatal myocardial infarction, non-fatal stroke (excluding transient ischemic attacks), and CV death. For baseline confounders we considered age, gender, race, disease duration, Health Assessment Questionnaire, hypertension, diabetes, hyperlipidemia, family history of premature (age<50) CV events, and RF/ACPA seropositivity. For time-varying variables we considered tumor necrosis factor inhibitor (TNFi), non-TNFi biologic, methotrexate, oral glucocorticoid, non-steroidal anti-inflammatory drugs, statin, and aspirin use. We used the marginal structural model (MSM) framework to examine the impact of CDAI at each 6-month interval on MACE. We estimated time-varying hazard ratios (HRs) comparing high CDAI during follow-up to CDAI remission. Several predicted survival curves were constructed under different hypothetical CDAI scenarios, such as early and late transition to CDAI remission.
Results: 40,721 patients were eligible for our analyses. 77% were female and 84% were Caucasian. The mean age was 58 (SD 13) years with mean disease duration of 8.8 (median 5) years. Mean CDAI at their first registry visit was 14 (SD 13; remission 19%, low 31%, moderate 28%, and high 22%). Other baseline characteristics include: 41% current/former smokers, 31.5% with hypertension, 8.6% with diabetes, 18% with hyperlipidemia, and 52% seropositive. The average follow-up duration after baseline was 4.4 (median 3.3; max. 17.6) years. The crude event count of MACE was 1,050 events / 180,402 person-years.
In the MSM analysis, the average HRs, assuming a constant HR, were 1.31 [0.90, 1.90] for low, 1.46 [1.01, 2.10] for moderate, and 1.43 [0.89, 2.31] for high CDAI disease activity categories during each 6-month interval. When approximating time-varying HR with linear trends, the highest estimates during the first 6 months of follow up were 1.61 [0.93, 2.77] for low CDAI, 1.97 [1.13, 3.43] for moderate CDAI, and 2.11 [1.13, 3.96] for high CDAI. These HRs gradually diminished during the follow up (Table). When we constructed hypothetical survival curves with transition to CDAI remission at different time points, earlier transition to CDAI remission was related to better event-free survival (Figure).

Table 1. Time-varying hazard ratio estimates [95% confidence intervals] by duration in study

	Disease activity measured by CDAI			
Year	Remission	Low	Moderate	High
0.5	1.00 [ref]	1.61 [0.93, 2.77]	1.97 [1.13, 3.43]	2.11 [1.13, 3.96]
1	1.00 [ref]	1.54 [0.97, 2.44]	1.85 [1.17, 2.93]	1.94 [1.13, 3.31]
2	1.00 [ref]	1.42 [1.00, 2.01]	1.63 [1.16, 2.29]	1.62 [1.04, 2.54]
3	1.00 [ref]	1.31 [0.90, 1.90]	1.43 [0.97, 2.11]	1.36 [0.80, 2.31]
4	1.00 [ref]	1.20 [0.72, 2.02]	1.26 [0.72, 2.21]	1.14 [0.55, 2.36]
5	1.00 [ref]	1.11 [0.54, 2.26]	1.11 [0.51, 2.42]	0.96 [0.36, 2.53]

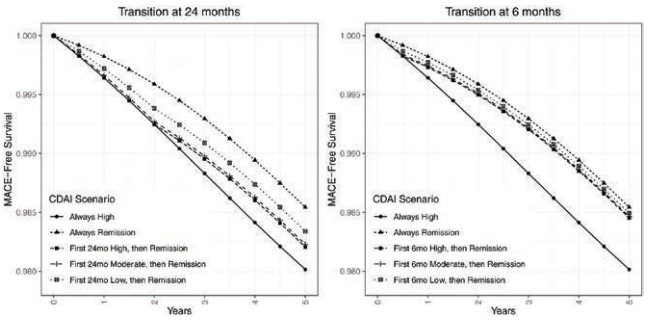

Figure 1. MACE-free survival curves under hypothetical CDAI scenarios

Conclusion: High and moderate CDAI were associated with higher hazard of MACE during the earlier period of follow-up, but the increased hazard diminished over time. In hypothetical senarios, earlier transition to CDAI remission would improve MACE free-survival.

OP0102 DECLINE IN EXCESS RISK OF HEART FAILURE IN PATIENTS WITH RHEUMATOID ARTHRITIS IN RECENT YEARS

E. Myasoedova[1,2], J. M. Davis III[1], S. Achenbach[3], K. Wright[1], R. Kurmann[4,5], R. Mankad[4], V. Roger[4], C. S. Crowson[3]. *[1]Mayo Clinic, Rheumatology, Rochester, MN, United States of America*; *[2]Mayo Clinic, Quantitative Health Sciences, Epidemiology, Rochester, United States of America*; *[3]Mayo Clinic, Quantitative Health Sciences, Biomedical Statistics and Informatics, Rochester, United States of America*; *[4]Mayo Clinic, Cardiovascular Disease, Rochester, United States of America*; *[5]Luzerner Kantonsspital, Department of Cardiology, Heart Center, Lucerne, Switzerland*

Background: Heart failure (HF) is one of the most common cardiovascular conditions in patients with rheumatoid arthritis (RA). Previous studies showed a 2-fold excess risk of HF in RA versus the general population (1). Whether this has changed over time is not known. Longitudinal studies on trends in occurrence of HF in RA patients over time, and studies comparing trends in HF in RA versus the general population are lacking.
Objectives: 1) To assess trends in incidence of HF in patients with incident RA in 1980-2009; and 2) To compare incidence of HF in RA patients and population-based comparators without RA with RA incidence/ index date in 1980-2009.
Methods: The study population comprised Olmsted County, Minnesota residents with incident RA (age ≥18 years, 1987 ACR criteria met in 1980-2009) and non-RA subjects from the same underlying population with similar age, sex and calendar year of index. All subjects were followed until death, migration, or 04/30/2019. Incident HF was defined using Framingham criteria. Patients with HF prior to RA incidence/index date were excluded. Cox proportional hazards models were used

to compare incident HF events by decade, adjusting for age, sex and cardiovascular risk factors: smoking, obesity, diabetes mellitus, hypertension, dyslipidemia. Cumulative incidence of HF adjusted for death was also computed.

Results: The study included 905 patients with RA (mean age 55.9 years; 69% female; median follow-up 13.4 years). The 10-year cumulative incidence of HF in RA cohort in the 1980s was 8.5% (95%CI 5.3-13.6%), 1990s was 10.8% (95%CI 7.7-15.1%), and 2000s was 7.1% (95%CI 4.9-10.3%). There was no difference in incidence of HF in 1990s (hazard ratio [HR] 0.91, 95% Confidence Interval [CI] 0.62-1.35) and 2000s (HR 0.73; 95%CI 0.46-1.18) compared to 1980s. Patients with incident RA were then compared to 903 individuals without RA (mean age 56.0 years; 69% female; median follow-up 13.8 years). The 10-year cumulative incidence of HF in these individuals in the 1980s was 7.4% (95%CI 4.5-12.3%), 1990s was 7.5% (95%CI 4.9-11.3%), and 2000s was 7.3% (95%CI 5.0-10.7%). Similar to RA, there was no statistically significant difference in incidence of HF in 1990s (HR 0.96, 95%CI 0.60-1.51) and 2000s (HR 0.75, 95%CI 0.44-1.30) compared to the 1980s. When comparing the risk of HF in RA and non-RA subjects, patients with RA in 2000s had no excess in HF risk as compared to the general population (HR 1.14, 95%CI 0.73-1.78, Figure 1). This is in contrast to the 2-fold excess risk of HF in patients with RA in 1980s (HR 2.20, 95%CI 1.44-3.34) and ~1.5-fold increase in risk of HF in 1990s (HR 1.54, 95%CI 1.04-2.29).

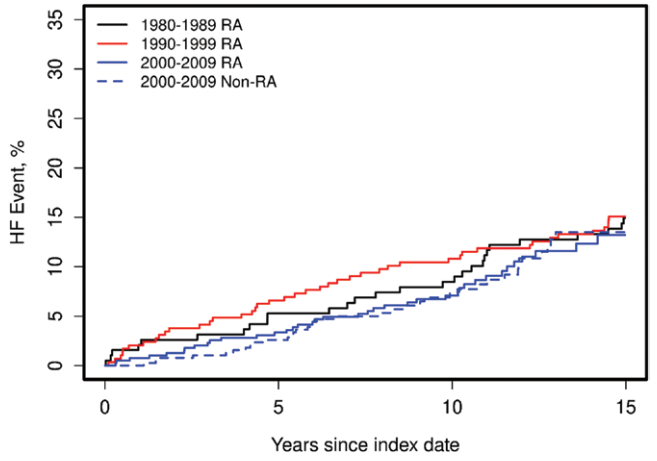

Figure 1. Cumulative incidence of any HF event in RA and non-RA patients by decade of RA incidence/index

Conclusion: We found a reduction in excess HF risk in patients with RA compared to individuals without RA in 2000s compared to 1980s. There were no statistically significant changes in incidence of HF in patients with RA and in individuals without RA over time. More studies are needed to understand the reasons and implications of these trends.

OP0103

5-YEAR CARDIOVASCULAR EVENT RISK IN EARLY RHEUMATOID ARTHRITIS PATIENTS WHO RECEIVED TREAT-TO-TARGET MANAGEMENT: A POPULATION-BASED COHORT STUDY

T. O. Lam[1], L. S. Tam[1]on behalf of The Clinical Rheumatology Systematic Treat-to-target in Asia Leadership (CRYSTAL). [1]*The Chinese University of Hong Kong, Department of Medicine & Therapeutics, The Prince of Wales Hospital, Hong Kong, Hong Kong (SAR)*

Background: Rheumatoid arthritis (RA) is associated with higher cardiovascular disease (CVD) risk due to the underlying inflammation [(1)]. It is uncertain if the excess CV risk could be reduced by effective suppression of inflammation using the treat-to-target (T2T) approach in patients with early RA (ERA).

Objectives: This study compared the 5-year cardiovascular event (CVE) rate among ERA patients managed by a T2T strategy with a CV risk factor-matched non-RA population.

Methods: This was an observational study using the Hong Kong Hospital Authority population-based hospital database known as the Clinical Data Analysis and Reporting System (CDARS) and the Clinical Rheumatology Systematic Treat-to-target in Asia Leadership (CRYSTAL) registry. ERA subjects from the registry with baseline disease duration less than 2 years were recruited between 2012-2016. All patients received a tight control, T2T treatment strategy aiming at remission and had been followed for at least 5 years. Each ERA subject was matched to 3 non-RA controls according to age, gender, smoking status, and the presence of diabetes mellitus (DM), hypertension (HT) and hyperlipidaemia (HL). All subjects on antiplatelet agents, with pre-existing CVD or chronic kidney disease were excluded. All subjects were analysed up to 5 years from baseline. The primary end point was the first occurence of a CVE, namely ischaemic cerebrovascular disease, ischaemic heart disease and heart failure.

Results: The study identified 261 ERA subjects and 783 matched controls. Their characteristics were shown on Table 1. The mean age was 60+/-12 years, 78% were female, 18% were smokers, 8%, 25% and 22% had DM, HT and HL respectively.

Table 1. Characteristics of ERA subjects and the matched controls

	ERA (n=261)	Controls (n=783)	*p-value*
Age (mean +/- SD)	60.2 +/- 12	60.3 +/- 12	*0.99*
Total cholesterol (mean +/- SD)	4.8 +/- 0.94	4.9 +/- 1.00	*0.34*
High density lipoprotein-cholesterol (median, IQR)	1.4 (1.2-1.6)	1.4 (1.2-1.7)	*0.612*
Low density lipoprotein-cholesterol (mean +/- SD)	2.8 +/- 0.8	2.6 +/- 0.8	*0.27*
Triglyceride (median, IQR)	0.96 (0.7-1.3)	1.2 (0.8-1.7)	*0.00*
Atherogenic index# (mean +/- SD)	-0.07 +/-0.29	-0.15 +/- 0.28	*0.48*
RA disease characteristics	**Baseline**	**last visit**	
Seropositivity	89.3%		
Disease duration (median days, IQR)	177 (96-299)	2026 (1818-2126)	
Erythrocyte sedimentation rate (mean +/- SD)	55.7 +/- 34	32.6 +/- 21.3	
C-reactive protein (median, IQR)	7.9 (3.5-22.2)	2.1 (1.0-5.0)	
Swollen joint count (median, IQR)	3 (2-6)	0 (0-1)	
Tender joint count (median, IQR)	6 (3-10)	0 (0-1)	
Patient's global assessment (mean mm +/- SD)	50.7 +/- 26.8	16.0 +/- 18.3	
DAS28-ESR (mean +/- SD)	5.2 +/- 1.3	2.4 +/- 1.8	
DAS28-CRP (mean +/- SD)	4.4 +/- 1.3	1.8 +/- 1.5	
Health assessment questionnaire (mean +/- SD)	0.77 +/- 0.74	0.38 +/- 0.51	

Atherogenic index = $\log_{10}$ (triglyceride/HDL-cholesterol)SD: standard deviation, IQR: interquartile range, DAS28: disease activity score-28

CVEs occurred in 2.3% ERA subjects and in 3.3% controls. The difference was statistically insignificant. The CVE-free survival was shown in Figure 1.

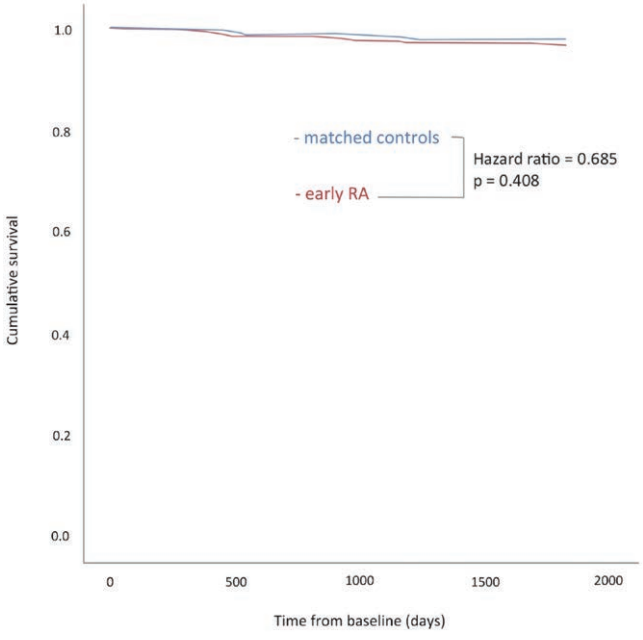

Figure 1. CVE-free survival curves of ERA subjects & matched controls

In the ERA cohort, after adjusting for baseline age and atherogenic index, cox-regression analysis showed that i) a longer DAS28 remission duration was protective for CVE with an adjusted hazard ratio (AHR) of 0.46 (95% CI 0.23-0.93),

while ii) poor baseline function as reflected by a higher health assessment questionnaire (HAQ) score was predictive of CVE with an AHR of 5.2 (95% CI 1.2-23).
Conclusion: ERA patients treated by a T2T strategy did not develop excess CVE compared to CV risk factor-matched controls over 5 years. A longer disease remission duration was protective while a higher baseline HAQ was associated with a higher CVE risk.

OP0104 DIFFERENCES IN LOW-DENSITY LIPOPROTEIN (LDL) PARTICLE COMPOSITION AND OXIDATION MAY UNDERLIE THE PARADOXICAL ASSOCIATION OF LOW LDL WITH HIGHER CORONARY ATHEROSCLEROSIS BURDEN IN RHEUMATOID ARTHRITIS

G. Karpouzas[1,2], S. Ormseth[2], E. Hernandez[2], M. Budoff[3]. [1]*Harbor-UCLA Medical Center, Rheumatology, Torrance, United States of America*; [2]*The Lundquist Institute, Rheumatology, Torrance, United States of America*; [3]*The Lundquist Institute, Cardiology, Torrance, United States of America*

Background: The association between cholesterol and cardiovascular disease (CVD) risk is attenuated in Rheumatoid arthritis (RA). In fact, RA patients in the lowest low-density lipoprotein (LDL) group (<70mg/dl) may experience unexpectedly high CVD risk.
Objectives: We here explored whether patients with LDL<70mg/dl (Group 1) had higher coronary atherosclerosis burden compared to other LDL groups (Group 2: 70≤LDL≤130 and Group 3: LDL>130), as a reason for this risk. We further evaluated whether low LDL in group 1 associated with differences in inflammation, LDL particle composition or oxidation.
Methods: One hundred fifty RA patients without symptoms or history of CVD underwent coronary atherosclerosis evaluation with computed tomography angiography. Coronary artery calcium (CAC), number of segments with plaque (segment involvement score), stenotic severity (segment stenosis score), and extensive (>4 segments with plaque) or obstructive disease (>50% stenosis) were assessed. Lipoprotein classes and subclasses were directly measured. Oxidized LDL (oxLDL) was measured with monoclonal antibody E06. Chemiluminescence Elisa quantified IgG and IgM antibodies to oxLDL (anti-oxLDL) and apoB100 immune complexes (IC). Proinflammatory cytokines were measured with Erenna Immunoassay. Robust linear and logistic regression models-adjusted for Framingham D'Agostino score, obesity, disease activity, bDMARD and statin treatment- evaluated associations between LDL groups and plaque outcomes. Similar models evaluated adjusted differences in LDL subclasses, oxLDL, anti-oxLDL, anti-ApoB100 IC, and cytokines across LDL groups.
Results: Group 1 patients had higher coronary plaque burden (Figure 1A) and 2.8 times greater risk of extensive or obstructive disease (adjusted OR 2.82 [95% CI 1.12-7.17], *P* = 0.031) compared to LDL>70 groups. Among statin naïve patients, those with LDL<70 also had higher oxLDL (log-transformed adjusted mean 2.55 [95% CI 2.34-2.77] versus 2.27 [95% CI 2.19-2.36], *P* = 0.018 for LDL>70). Notably, Group 1 patients also had higher anti-oxLDL IgG and anti-ApoB100 IgG IC levels compared to other groups (Figure 1B). LDL subclass relative content in the LDL particle differed across groups (Figure 1C). Lp(a) was higher in LDL particles in Group 1 (adjusted mean 16.04% [95% CI 11.75-20.33], versus 10.48% [95% CI 8.20-12.75] in Group 2, *P* = 0.026 and 7.41% [95% CI 0.77-14.04] in Group 3, *P* = 0.033). Notably, Lp(a) content strongly associated with oxLDL overall (r = 0.83, *P* < 0.0001). This association was stronger for Group 1 compared to others (*P* < 0.005, Figure 1D). No differences in RA activity, CRP, TNF-α, IL-17A, or IL-17F were seen across groups. However, Group 1 had higher IL-6 (log-transformed adjusted mean 1.98 [95% CI 1.64- 2.32] versus 1.57 [95% CI 1.45-1.70], *P* = 0.028 in Group 2 and 1.32 [95% CI 0.84-1.80], *P* = 0.031 in Group 3). IL-6 associated with both IgG anti-oxLDL (*P* = 0.015) and anti-apoB100 IC (*P* = 0.016). Log-transformed IL-6 further associated with higher log-transformed CAC (adjusted B 0.41 [95% CI 0.01-0.81], *P* = 0.049).
Conclusion: RA patients with LDL<70 mg/dl had higher coronary atherosclerosis burden. Low circulating LDL in that group may reflect higher oxidation; this was mostly linked to the larger Lp(a) relative content of LDL and its significantly higher oxidation potential in that group. OxLDL immune recognition was linked to higher IgG anti-oxLDL Ab and anti-ApoB100 IC levels in the LDL<70 group, which further associated with higher IL-6 elaboration and atherosclerosis burden.

Background: The Observational and Medical Outcomes Partnerships (OMOP) common data model (CDM) provides a framework for standardising health data with a view towards federated analyses, thus maximising the use and power of combining disparate datasets.
Objectives: To assess feasibility and usefulness of mapping biologic registry data from different European countries to the OMOP CDM and present initial descriptive data regarding comorbidities.
Methods: Five biologic registries, as part of a funded FOREUM project, have been mapped to the OMOP CDM: 1) the Czech biologics register (ATTRA), 2) Registro Español de Acontecimientos Adversos de Terapias Biológicas en Enfermedades Reumáticas (BIOBADASER), 3) British Society for Rheumatology Biologics Register for Rheumatoid Arthritis (BSRBR-RA), 4) German biologics register 'Rheumatoid arthritis observation of biologic therapy' (RABBIT), and 5) Swiss register 'Swiss Clinical Quality Management in Rheumatic Diseases' (SCQM). The mapping includes socio-demographic, observation period within the studies, baseline comorbidities, and baseline medications. Only patients with RA were included. Using R, registers received identical scripts to run on their mapped databases to produce an initial description of patient characteristics without the need to share patient-level data.
Results: A total of 54,458 individuals are included the five registries being mapped to the OMOP CDM, see table. Age and gender distribution was similar across registries. All registers reported on cardiovascular system comorbidities, diabetes mellitus, mental disorders, and respiratory system comorbidities. However, it was noted that results of comorbidity mapping relies on what each register collect on each patient at the point of registration.
Whilst the Charlson comorbidity index could be calculated within each registry, due to lack of the specific coding needed, such as "uncomplicated diabetes mellitus" / "end-organ damage diabetes mellitus", it was felt to be an inaccurate

measure. The granularity of the comorbidities was insufficient, as many registers coded, for example, diabetes mellitus without any extra information.

Registry	ATTRA	BIOBADASER	BSRBR-RA	RABBIT	SCQM
Country	Czechia	Spain	United Kingdom	Germany	Switzerland
Number of Participants	2334	3012	25179	13652	10281
Gender					
Female	1808 (77%)	2372 (79%)	18995 (75%)	10191 (75%)	7584 (74%)
Male	526 (23%)	640 (21%)	6184 (25%)	3461 (25%)	2697 (26%)
Age at observation start date	59 (52, 66)	56 (47, 63)	58 (49, 66)	58 (50, 67)	57 (47, 66)
First observation start date	Feb-2002	Oct-1999	Oct-2001	Aug-2006	March-1995
Number of comorbidities	1 (1, 2)	1 (0, 2)	1 (0, 2)	2 (1, 3)	2 (1, 4)
Disorder of cardiovascular system	1609 (69%)	208 (7%)	2239 (9%)	6330 (46%)	3969 (39%)
Diabetes mellitus	331 (14%)	273 (9%)	1770 (7%)	1591 (12%)	792 (8%)
Depressive Disorder	165 (7%)	0	4971 (20%)	1023 (7%)	1337 (13%)
Disorder of respiratory system	215 (9%)	209 (7%)	4125 (16%)	1282 (9%)	1630 (16%)

Conclusion: This is the first analysis of data from the newly mapped OMOP CDM across five European registers. Through mapping the registers into a CDM, and using the same script, the ability to undertake collaborative analysis without sharing patient level data outside of the country can be realised. Due to differences in study design and data capture, there needs to be a focus on harmonising the coding and analysing of the comorbidities and drugs across registries.

THE ASSOCIATIONS BETWEEN BARIATRIC SURGERY AND HIP OR KNEE ARTHROPLASTY, AND HIP OR KNEE OSTEOARTHRITIS: A COHORT STUDY FROM SWEDISH NATIONWIDE HEALTHCARE REGISTRIES

T. Burkard[1], D. Holmberg[2], T. Hügle[3], A. M. Burden[1,4]. *[1]ETH Zurich, Department of Chemistry and Applied Biosciences, Zurich, Switzerland*; *[2]Karolinska University Hospital, Department of Molecular medicine and Surgery, Stockholm, Sweden*; *[3]Lausanne University Hospital (CHUV) and University Lausanne, Department of Rheumatology, Lausanne, Switzerland*; *[4]Maastricht University Medical Center+, Department of Clinical Pharmacy and Toxicology, Maastricht, Netherlands*

Background: Osteoarthritis (OA) is a slowly developing chronic joint disease mainly characterized by joint pain which may lead to physical disability. OA in weight bearing joints, such as the hip and knee, was suggested to be susceptible to high body weight. In end-stage disease, hip and knee OA are often treated with arthroplasty. The impact of weight loss among obese patients on hip and knee arthroplasty has not been assessed to date.

Objectives: To assess the association between bariatric surgery and hip or knee arthroplasty. As a secondary aim, we assessed the association between bariatric surgery and hip or knee OA in a secondary care setting.

Methods: We performed a propensity score (PS)-matched cohort study using data from Swedish nationwide healthcare registries (patient registry [secondary care], causes of death registry, prescribed drug registry). Patients aged 18-79 years who underwent bariatric surgery between 2006 and 2019 were matched to up to 2 obese bariatric surgery free patients (called unexposed patients) based on their PS. PS-matching was carried out in risk set sampling to reduce selection bias, within 4 sequential cohort entry blocks to account for time trend biases. The primary outcome was hip or knee arthroplasty. The secondary outcome was a diagnosis of hip or knee OA in secondary care. We excluded patients with differential indications for arthroplasty or OA (e.g. rheumatoid arthritis, septic arthritis). After a 1-year run-in period, patients were followed in an "as-treated" approach until the outcome or censoring due to onset of an exclusion criterion, change of exposure status, or end of study period. We applied Cox proportional hazard regression to calculate hazard ratios (HR) with 95% confidence intervals (CIs) of hip or knee arthroplasty, and separately of hip or knee OA, among bariatric surgery patients when compared to obese unexposed patients. Additionally, we performed analyses in subgroups of age, sex, joint location, bariatric surgery type, and by duration of follow-up.

Results: A total of 39 392 bariatric surgery patients were PS-matched to 61 085 obese unexposed patients. The study population had a mean age of 42 years, a mean follow-up of 6.5 years, and 72.5% of patients were women. We observed 1138 and 1108 hip or knee arthroplasties among bariatric surgery and obese unexposed patients, respectively. We observed an overall increased risk of hip or knee arthroplasty among bariatric surgery patients (HR of 1.43, 95% CI 1.32-1.55), compared to obese unexposed patients. The risk for knee arthroplasty was higher than that for hip arthroplasty among bariatric surgery patients (HR of 1.58, 95% CI 1.42-1.76, and HR of 1.21, 95% CI 1.06-1.39, respectively). Patients who underwent combined malabsorptive and restrictive bariatric surgery yielded highest risks of hip or knee arthroplasty (HR of 3.58, 95% CI 1.34-9.54). Risks of hip or knee arthroplasty decreased with duration of follow-up (highest risks 1-3 years post-bariatric surgery, HR of 1.79, 95% CI 1.56-2.07). In secondary analyses, risks of secondary care hip or knee OA were decreased among bariatric surgery versus obese unexposed patients (HR of 0.84, 95% CI 0.79-0.90). We observed lower risks for knee OA (HR of 0.82, 95% CI 0.76-0.88) than for hip OA (HR of 0.90, 95% CI 0.79-1.01) and observed lowest risks of hip or knee OA in early follow-up (1-3 years post-bariatric surgery) with a HR of 0.79, 95% CI 0.71-0.88, stable thereafter at a HR of 0.87, 95% CI 0.78-0.97.

Conclusion: Our results suggest that substantial weight loss among obese patients is associated with decreased risks of secondary care hip and knee OA. Increased risks of hip and knee arthroplasty after bariatric surgery are likely the result of increased operability of patients who have lost a substantial amount of excess body weight. Stronger associations for the knee than for the hip in both arthroplasty and OA are consistent with existing literature suggesting a stronger impact of body weight on knee than on hip joints.

OP0107

CLINICAL EFFICACY OF ROMOSOZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS FOR 12 MONTHS

Y. Kanayama[1], R. Sugimoto[2]. *[1]Toyota Kosei Hospital, Orthopedic surgery and Rheumatology, Toyota, Japan*; *[2]Toyota Kosei Hospital, Orthopedic surgery, Toyota, Japan*

Background: Romosozumab (ROMO), a monoclonal antibody that binds sclerostin, increases bone formation and decreases bone resorption. And although it is a novel therapeutic agent for osteoporosis, which has shown high effects of increasing bone density and inhibiting fragile fracture in overseas clinical trials. However the clinical efficacy for rheumatoid arthritis complicated with osteoporosis (RA-OP) is unknown.

Objectives: To evaluate the clinical efficacy of ROMO in patients with RA-OP for 12 months.

Methods: RA patients diagnosed according to the 2010 ACR/EULAR criteria. All patients met at least one of the following criteria were eligible; a bone mineral density T score of -2.5 or less at the lumber spine or total hip and either one or more moderate or severe vertebral fractures or two or more mild vertebral fractures. All patients were initiated ROMO from between March and December, 2019. The total number of patients was 13 cases. The ROMO dose was 210mg at once every 1 months. In all cases native or activated vitamin D has been used. We reviewed the results for 12 months about the increase and decrease of bone mineral density (BMD) of lumbar spine(LS) and total hip(TH) by DEXA and bone turnover markers, intact n-terminal propeptide type I procollagen(PINP) and tartrate-resistant acid phopshatate form 5b(TRACP-5b).

Results: The gender was all female. The mean age was 73.2 ± 7.6; disease duration was 20.5 ± 16.9 years; the body mass index was 19.7 ± 3.0 and the FRAX was 40.5 ± 16.2. Clinical findings related to RA-OP at baseline were as follows; CRP 1.29 ± 1.66; DAS-CRP 3.43 ± 0.96; HAQ 1.59 ± 0.97 and, bone turnover markers and bone mineral density at baseline were as follows; P1NP 58.1 ± 33.5; TRACP-5b 438 ± 216; LS-BMD and T-score 0.81 ± 0.15 g/cm^2 and -2.63 ± 1.05 and TH-BMD 0.54 ± 0.08 g/cm^2 and -3.22 ± 0.64 g/cm^2. The rate of increased P1NP from baseline to 1, 3, 6 and 12 months were each 114.3 ± 90.6% at 1 month, 131.6 ± 134.3% at 3 month, 122.6 ± 174.3% at 6 month and 80.4 ± 181.6% at 12 month and decreased TRAC-5b were -10.7 ± 20.8% at 1 month, 7.9 ± 36.9% at 3 month, 25.5 ± 64.6% at 6 month and 32.5

± 77.0% at 12 month. The rate of increased LS-BMD from baseline to 6 and 12 months were 8.6 ± 8.0%, 12.5 ± 11.1% and TH-BMD were 4.3 ± 5.0%, 6.8 ± 6.9% (Fig. 1, 2).
Conclusion: Clinical efficacy of ROMO for RA-OP was extremely effective and has the high potential to be an important option in the treatment of RA-OP.

OP0108

LORECIVIVINT (SM04690), AN INTRA-ARTICULAR, SMALL-MOLECULE CLK2/DYRK1A INHIBITOR THAT MODULATES THE WNT PATHWAY, PROVIDED CARTILAGE-PROTECTIVE EFFECTS IN AN ANIMAL MODEL OF POST-TRAUMATIC OA

T. Seo[1], V. Deshmukh[1], Y. Yazici[2]. [1]*Samumed, LLC, Biology, San Diego, United States of America*; [2]*Samumed, LLC, Chief Medical Officer, San Diego, United States of America*

Background: Osteoarthritis (OA) is characterized by increased cartilage thinning, bone remodeling, and inflammation. Post-traumatic OA, which develops after acute direct trauma to the joints, accounts for approximately 12% of all OA cases.[1] Current therapeutic options focus on alleviating symptoms and pain rather than disease modification. Lorecivivint (LOR; SM04690), an intra-articular (IA), small-molecule CLK2/DYRK1A inhibitor that modulates the Wnt pathway, has been shown in animal studies to induce chondrogenesis, protect cartilage, and reduce inflammation and, thereby, improve joint health.[2]
Objectives: A single IA LOR injection was evaluated in a rat model of knee instability to determine its protective and regenerative effects when injected at different timepoints after induction of post-traumatic OA.
Methods: Knee instability/post-traumatic OA was surgically induced in rats by combining anterior cruciate ligament transection with partial medial meniscus transection (ACLT+pMMx). LOR (0.3 ug) or vehicle was injected into the IA space of the damaged knee at 2, 3, or 4 weeks after induction of OA. OA-induced (n=10/group) or sham-operated (surgery without ACLT+pMMx; n=5/group) rats were sacrificed at the injection timepoint (baseline) or 12 weeks following LOR/vehicle injection (study conclusion). Histological grades were evaluated using the summed OARSI scores (stage and grade of cartilage damage)[3] of the anterior and posterior medial femoral condyle (MFC) and medial tibial plateau (MTP). Weight distribution analysis was performed using an incapacitance meter at several timepoints. Statistical analysis was performed using one-way ANOVA with Dunnett's multiple comparison test.
Results: ACLT+pMMx surgeries led to increased OARSI scores in rats compared with sham surgeries by 2 weeks. LOR treatment at Weeks 2, 3, and 4 led to significant decreases (P<0.05) in total joint OARSI scores (Table 1) at the end of the study compared with vehicle treatment. Rats treated with LOR for 12 weeks and rats at injection baseline had similar OARSI scores, suggesting that LOR treatment arrested the progression of cartilage damage. Significant improvements (P<0.05) were also observed in the weight distribution of LOR-treated rats in the 3- and 4-week groups at 6 and 12 weeks after their respective IA injections compared with vehicle-treated rats.

Table 1. OARSI scores

Week-2 injection	**Sham-operated**	**Baseline (BL)**	**Vehicle**	**LOR**
	(14 weeks after surgery)	(2 weeks after surgery)	(12 weeks after injection)	(12 weeks after injection)
Total score	5.99	19.17	31.36	19.19

OP0109

CARTILAGE LESIONS OF THE KNEE: GAGCEST IMAGING AT 3 T MRI AND INTRAOPERATIVE VALIDATION

M. Pachowsky[1], S. Söllner[2], A. Kleyer[3], G. Welsch[4], G. Schett[3]. [1]*University Hospital of Erlangen, Erlangen, Germany, Department of Internal Medicine 3 – Rheumatology and Immunology, Department of Trauma and Orthopaedic Surgery and Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Germany, Erlangen, Germany*; [2]*University Hospital of Erlangen, Germany, Department of Trauma and Orthopaedic Surgery, Erlangen, Germany*; [3]*University Hospital of Erlangen, Erlangen, Germany, Department of Internal Medicine 3 – Rheumatology and Immunology, and Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Germany, Erlangen, Germany*; [4]*University Hospital Hamburg-Eppendorf, Hamburg, Germany, UKE Athleticum, Hamburg, Germany*

Background: Morphological Magnetic Resonance Imaging (MRI) has become the accepted diagnostic tool for non-invasive evaluation of cartilage lesions[1]. Emerging

techniques including chemical exchange saturation transfer (CEST) can be used to visualize microstructural and biochemical changes to the cartilage matrix even before morphological damage is visible[2,3]. CEST is a promising technique based on detecting the chemical exchange between bulk water protons and protons bound to solutes. This technique renders the possibility to function as a biomarker for glycosaminoglycan (GAG/gag) content for instance in cartilage of joints.

Objectives: The aim of the study was to compare glycosaminoglycan chemical exchange saturation transfer (gagCEST) of knee cartilage with intraoperative results for the assessment of early osteoarthritis (OA) and to define gagCEST values for the differentiation between healthy and degenerated cartilage.

Methods: Patients with cartilage lesions or moderate OA were preoperatively examined using 3T Magnetic Resonance Imaging (MRI). In this prospective study, regions of interest (ROIs) were examined by a sagittal gagCEST analysis and a morphological high-resolution three-dimensional, fat-saturated proton-density space sequence. Cartilage lesions were identified arthroscopically, graded by the International Cartilage Repair Society (ICRS) score in 42 defined ROIs per patient and consecutively compared with mean gagCEST values using analysis of variance and Spearman's rank correlation test. Receiver operating characteristics (ROC) curves were applied to identify gagCEST threshold values to differentiate between the ICRS grades.a

Results: Twenty-one patients with cartilage lesions or moderate OA were examined. The imaging assessment consisted of a total of 882 ROIs which were examined and graduated in ICRS score 0 (67.3%), 1 (25.2%), 2 (6.2%) and the merged ICRS 3 and 4 (1.0%). gagCEST values decreased with increasing grade of cartilage damage with a negative correlation between gagCEST values and ICRS scores. A gagCEST value threshold of 3.55% was identified to differentiate between ICRS score 0 (normal) and all other grades.

Conclusion: Conclusions. gagCEST reflects the content of glycosaminoglycan and might provide a diagnostic tool for the detection of early knee-joint cartilage damage and for the non-invasive subtle differentiation between ICRS grades by MRI even at early stages in clinical practice.

OP0110 A COHORT STUDY ON THE BIDIRECTIONAL RELATIONSHIP BETWEEN PERIODONTITIS AND OSTEOARTHRITIS OVER A 15-YEAR FOLLOW-UP

K. S. K. MA[1], E. Thota[1], T. Van Dyke[2]. [1]*National Taiwan University, Taipei, Taiwan, ROC, Department of Life Science, Taipei, Taiwan, Republic of China*; [2]*Forsyth Institute, Cambridge, Center for Clinical and Translational Research, Boston, United States of America*

Background: Recently, osteoarthritis has been proposed to be driven by complement-mediated inflammatory cascades. That is, in addition to the conventional degenerative model, our knowledge of osteoarthritis pathogenesis has been expanded with an inflammation-dependent theory.

Objectives: To identify the relationship between osteoarthritis and periodontitis.

Methods: 144,788 periodontitis patients and 144,788 propensity score-matched controls without history of periodontitis were enrolled in this cohort study. A Cox proportional hazard model was used to estimate the risk of osteoarthritis. Survival analysis was utilized to assess the time-dependent effect of periodontitis on osteoarthritis. Age and gender were stratified to identify susceptible subgroups. A symmetrical case-control analysis was designed to determine the relationship between periodontitis and history of osteoarthritis.

Results: Patients with periodontitis had higher risk of osteoarthritis (HR =1.15, 95% CI =1.12–1.17, P < 0.001) and severe osteoarthritis that led to total knee/hip replacement (HR =1.12, 95% CI =1.03–1.21, P < 0.01) than controls, which was time-dependent (log-rank test P < 0.01). The effect of periodontitis on osteoarthritis was significant in both genders and age subgroups over 30 years old (all P < 0.001). Among them, females (HR=1.27, 95% CI = 1.13–1.42, P < 0.001) and patients aged over 51 (HR= 1.21, 95% CI =1.10-1.33, P < 0.001) with periodontitis were predisposed to severe osteoarthritis that led to total knee/hip replacement. In addition, periodontitis patients were more likely to have a history of osteoarthritis (OR = 1.11, 95% CI = 1.06 - 1.17, P < 0.001).

Conclusion: These findings suggest a bidirectional relationship between osteoarthritis and periodontitis. Patients with periodontitis presented with a higher risk of osteoarthritis, including severe osteoarthritis that led to total knee/hip replacement. Likewise, periodontitis was more likely to develop following osteoarthritis.

OP0111 PLASMA PROTEOMICS IDENTIFIES CRTAC1 AS BIOMARKER FOR OSTEOARTHRITIS SEVERITY AND PROGRESSION

I. Szilagyi[1,2], C. Vallerga[3], J. H. Waarsing[4], D. Schiphof[2], S. M. A. Bierma-Zeinstra[2], J. Van Meurs[3]. [1]*Erasmus MC, General Practice, Rotterdam, Netherlands*; [2]*Erasmus University Medical Center, General Practice, Rotterdam, Netherlands*; [3]*Erasmus University Medical Center, Internal Medicine, Rotterdam, Netherlands*; [4]*Erasmus University Medical Center, Orthopedics, Rotterdam, Netherlands*

Background: Accurate biomarkers for diagnosis and prediction of osteoarthritis (OA) are needed. In addition, biomarkers have the potential to serve as a measure of the different pathological processes underlying OA. Here, we report on a proteomics screen targeted at two important pathways thought to underlie the etiology of OA: the inflammation and metabolic pathways.

Objectives: The aim of this study was to identify a robust biomarker for OA severity and progression.

Methods: We used data from the Rotterdam Study, a population based prospective study with participants aged 45 and older. The participants in this study underwent blood measurement at baseline and radiographic measurements at baseline as well as after a mean follow-up time of 5 years. We measured 184 proteins (inflammation and cardiometabolic panel) in plasma from 3,517 participants in the Rotterdam Study using the Olink platform.

We estimated the association for all available proteomic biomarkers with OA in knee, hip and hand in 2 ways: 1) Cross-sectionally in all joints, where we analyzed severity of OA by adding up KL-scores of both joints (knee and hip OA), and all joints of the left and right hand (total amount of joints=30); 2) Longitudinally in Knee and Hip, defining cases of progression of OA as an increase with at least 1 unit in KL-grade per person, excluding progressing from KL0 to KL1. We analyzed the relationship with multivariate regression

Figure 1. Forest plot for significantly associated proteins with severity of Hand OA

models using generalized linear models with binomial link function. In model 1 we adjusted for age, sex and cell counts, in model 2 we additionally adjusted for BMI. We report effect estimate(beta) per standard deviation (SD) change in protein levels with 95% Confidence Interval (CI) and nominal p-value (significance level<0.05) for each protein. All statistical analyses were performed in R version 3.5.2.

Results: We found in total 56 proteins that were significantly associated with one or more OA-outcomes at nominal level. Figure 1 illustrates the 19 significant associations for severity of hand OA ordered by significance level (most significant at top). We observed a very robust association between the level of circulating Cartilage acidic protein 1 (CRTAC1) and severity of OA in the knee (β=0.16, 95%CI 0.09-0.23, p=0.000013, FDR-corrected P:0.0011) hand (β=0.086, 95%CI 0.03-0.14, p=0.00085, FDR-corrected P: 0.0252), while a similar trend was seen in hip (β=0.08, 95%CI -0.02-0.18, p=0.12), although power in hip was limited in our study. The association with CRTAC1was also found for progression in knee (β=0.21, 95%CI 0.03-0.36, p=0.0156, FDR-corrected P>0.2) and hip (β=0.18, 95%CI -0.01-0.38, p=0.0624, FDR-corrected P>0.9). These associations were independent of BMI. Among the findings were several other promising biomarkers, e.g. MMP-10, which we observed to be associated with severity of hand OA (β=-0.09, 95%CI -0.15- -0.04, p=0. 00067, FDR-corrected P:0.0383) and progression of knee OA (β=-0.24, 95%CI -0.42- -0.06, p=0.0073, FDR-corrected P>0.1). Additionally, COMP, a well-known biomarker for OA, was also found significant for OA severity in hand (β=0.10, 95%CI 0.05-0.16, p<0.001, FDR-corrected P:0.0043) and knee (β=0.09, 95%CI 0.02-0.17, p=0.01, FDR-corrected P>0.2).

Conclusion: We identified the CRTAC1 protein as a robust, promising biomarker for osteoarthritis severity and progression. This protein is a glycosylated extracellular matrix protein that is found in the interterritorial matrix of articular deep zone cartilage. This protein can also be used to distinguish chondrocytes from osteoblasts and mesenchymal stem cells in culture. This suggests that CRTAC1-levels reflects a cartilage-specific process in the joint. Such a biomarker might be useful for targeting the right patients for clinical trials and designing novel therapies for OA.

OP0112 FACTORS ASSOCIATED WITH OSTEOPOROSIS CARE OF MEN: A REAL-LIFE STUDY ON A NATION-WIDE DATASET

G. Adami[1], D. Gatti[1], A. Giollo[1], E. Bertoldo[1], O. Viapiana[1], P. Olivi[2], A. Fassio[1], M. Rossini[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*; [2]*University of Verona, Orthopedic Unit, Verona, Italy*

Background: Male osteoporosis is associated with an important clinical and economic burden worldwide. Notwithstanding that, undertreatment of men with osteoporosis is common. Understanding the factors associated with less osteoporosis care utilization might help define future intervention to improve access of men to osteoporosis care.

Objectives: The aim of the study was to describe the factors associated with osteoporosis care in men.

Methods: We conducted a retrospective analysis of a nation-wide cohort (DeFRACalc79 database). DeFRACalc79 is a tool that estimates the fracture risk considering clinical and densitometric risk factors, including the presence of prior hip or vertebral and non-vertebral or non-hip fractures. We compared the clinical characteristics of male individuals with an age matched cohort of women. Propensity score generation with 2:1 matching for female and male patients was performed matching the cohorts for age, generating propensity estimates with a logistic regression model.

Results: We analyzed a sample of 4,902 men at high risk of osteoporosis. We found that the factors associated to osteoporosis care utilization in men were: the presence of comorbidities (OR 1.939, 95% CI 1.799-2.090), adjuvant hormonal therapy for prostate cancer (OR 1.482, 95% CI 1.315-1.670), the presence of vertebral or hip fractures (OR 1.490, 95% CI 1.378-1.611) and glucocorticoid treatment (OR 2.573, 95% CI 2.274-2.832) (Table 1)

Conclusion: We found that men accessed osteoporosis care with more severe osteoporosis and/or with a diagnosis of secondary osteoporosis. Male osteoporosis remains largely underdiagnosed with a dramatic latency in osteoporosis care utilization compared to women.

Background: Previous studies on the link between female reproductive factors and osteoarthritis (OA) have shown conflicting results.

Objectives: This study attempted to explore the association between reproductive factors and joint replacement arthroplasty of knee (TKRA) and hip (THRA) in a large nationwide population-based cohort of postmenopausal women.

Methods: 1,218,257 subjects who participated in national health examination in 2009 were included in the study. The study outcomes is incident THRA or TKRA

due to severe hip or knee OA. The association of reproductive factors and THRA or TKRA was evaluated using a multivariate-adjusted proportional hazards model.
Results: During the mean follow-up duration of 8.2 years, 1,733 incident THRA cases and 65,108 incident TKRA cases were observed. Later age at menarche (aHR 1.12 in 13-14 years; aHR 1.24 in 15-16 years; aHR 1.32 in ≥ 17 years), longer breastfeeding (aHR 1.24 in < 6 months; aHR 1.24 in 6-12 months; aHR 1.50 in ≥ 12 months), HRT (aHR 1.06 in < 2 years; aHR 1.11 in 2-5 years; aHR 1.21 ≥ 5 years) and OC use (aHR 1.11 in < 1 year; aHR 1.17 ≥ 1 year) was associated with increased risk of TKRA for severe knee OA, while later age at menopause (aHR 0.93 in 45-49 years; aHR 0.89 in 50-54 years), longer reproductive span (aHR 0.91 in 30-34 years; aHR 0.87 in 35-39 years; aHR 0.91 in ≥ 40 years) was associated with decreased risk. With regard to THRA for severe hip OA, later menarche (aHR 1.21 ≥ 17 years), longer breastfeeding (aHR 1.39 in < 6 months; aHR 1.31 in ≥ 12 months), and HRT more than 5 years (aHR 1.49) were associated with higher risk. The association between reproductive factors and severe OA was more pronounced in underweight and younger subjects.
Conclusion: Our study found that shorter estrogen exposure was associated with higher risk of joint replacement therapy due to severe OA, and such association was more pronounced in underweight and younger subjects.

Rheumatoid arthritis - biological DMARDs

OP0114

SHORT- AND LONGER-TERM RISKS FOR ACUTE CORONARY SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS STARTING TREATMENT WITH DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS. A COLLABORATIVE OBSERVATIONAL HEAD-TO-HEAD STUDY ACROSS FIVE NORDIC RHEUMATOLOGY REGISTERS

B. Delcoigne[1], L. Ljung[1,2], S. A. Provan[3], B. Glintborg[4,5], K. Lederballe Gron[4,5], M. L. Hetland[4,5], N. Steen Krogh[6], N. Trokovic[7], H. Relas[8], C. Turesson[9], B. Michelsen[3,10], J. Askling[1]on behalf of Nordforsk Rheumatology. *[1]Karolinska Institutet, of Medecine, Division of Clinical Epidemiology, Stockholm, Sweden*; *[2]Umeå University, Department of Public Health and Clinical Medicine/ Rheumatology, Umeå, Sweden*; *[3]Diakonhjemmet Hospital, Department of Rheumatology and Research, Oslo, Norway*; *[4]DANBIO and Copenhagen Center for Arthritis Research, COPECARE, Copenhaguen, Denmark*; *[5]Rigshospitalet, Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Copenhagen, Denmark*; *[6]Zitelab, Zitelab, Frederiksberg, Denmark*; *[7]Helsinki University Hospital, Department of Medicine, Helsinki, Finland*; *[8]Helsinki University Hospital, Division of Rheumatology, Helsinki, Finland*; *[9]Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden*; *[10]Sorlandet Hospital, Division of Rheumatology, Department of Medicine, Kristiansand, Norway*

Background: Rheumatoid Arthritis (RA) is associated with increased cardiovascular co-morbidity including acute coronary syndrome (ACS), partly due to effects of systemic inflammation. Disease-modifying anti-rheumatic drugs (DMARDs) may reduce RA disease activity, but act through several pathways and may themselves have an impact on cardiovascular risks. Whether the risks of ACS associated with biologic (b) and targeted synthetic (ts) DMARDs differ is still unknown.
Objectives: To assess and compare incidences of ACS during treatment of RA with etanercept (ETA), adalimumab (ADA), infliximab (INF), certolizumab pegol (CTZ), golimumab (GOL), rituximab (RIT), abatacept (ABA), tocilizumab (TCZ), baricitinib (BAR) or tofacitinib (TOF).
Methods: We defined and pooled treatment cohorts of patients starting any of the above treatments between 2008 and 2017 from clinical rheumatology registers in Denmark (DK), Finland (FI), Norway (NO), and Sweden (SE). One patient could contribute several treatment episodes. Age, sex, co-medication (methotrexate, prednisolone), number of previous b/tsDMARDs, CRP, comorbidities (cardiovascular (including ACS (defined as ICD-10: I20.0, I21.0-4, I21.9) and cerebrovascular disease, thromboembolic events, diabetes, hospitalized infection, cancer, kidney failure, COPD) and associated drugs were extracted and used as adjustment in Cox regression analyses comparing the incidence of ACS between treatments. We used several follow-up lengths (1, 2, and up to 5 years) and two different risk windows (ACS on drug [ending follow-up on treatment discontinuation] and ACS ever since treatment start [disregarding any treatment discontinuation]). We also stratified by age and number of previous b/tsDMARDs.
Results: We included 40850 treatment courses in 24083 patients (DK 7271, FI 3732, NO 1540, and SE 11540; around 75% women). ETA was the most common treatment (27%) whereas BAR and TOF comprised <1%, and the other DMARDs 6-14% each. The proportions with a history of ACS at treatment start ranged from 1.2% (NO) to 1.8% (DK).

We found 780 incident ACS events during 141 326 person-years (pyrs) in the 5-year follow-up time and "ACS ever since treatment start" risk window, resulting in a crude incidence rate of 5.5 events per 1000 pyrs. No event was recorded for BAR nor TOF, which also had the shortest follow-up. Adjusted hazard ratios (HR) increased slightly with longer follow-up times, but the two risk windows provided similar HRs. For the 5-year follow-up, RIT was associated with an increased risk of ACS compared to ETA (Table), while no association was observed for shorter follow-up times. Stratifying on age did not modify the associations. Separate analyses by number of previous b/tsDMARDs suggested that ABA (HR=1.8, 95% CI 1.0-3.3), INF (HR=2.2, 95% CI 1.0-4.6) and RIT (HR=1.9, 95% CI 1.1-3.4) were associated with increased risks of ACS compared to ETA in the subgroup of patients with two or more previous bDMARDs (Figure), whereas no differences were found among patients starting either drug as 1st/2nd bDMARD.

Table 1. Comparisons of risks for ACS during a 5-year follow-up since start of bDMARD treatment.

Drug	N events	pyrs	Crude incidence rate/ 1000 pyrs	HR (95% CI)[1]
ETA	175	35917	4.9	ref.

Pyrs: person-years; HR: hazards ratio[1] adjustment: see text.

Conclusion: In this cohort including ≥ 24,000 patients followed for up to 5 years, the ACS incidence rate was 5.5/1000 pyrs, with RIT showing an increased risk compared to ETA. In clinical practice, the choice of bDMARD does not seem to influence ACS risk in the short term. In the longer term, differences in ACS risk between bDMARDs may reflect channeling to these, or truly differential effects in subpopulations of patients.

OP0115 EFFICACY AND SAFETY OF ABBV-3373, A NOVEL ANTI-TNF GLUCOCORTICOID RECEPTOR MODULATOR ANTIBODY DRUG CONJUGATE, IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS DESPITE METHOTREXATE THERAPY: A PHASE 2A PROOF OF CONCEPT STUDY

F. Buttgereit[1], J. Aelion[2], B. Rojkovich[3], A. Zubrzycka-Sienkiewicz[4], T. Radstake[5], S. Chen[5], D. Arikan[5], H. Kupper[6], H. Amital[7,8]. [1]*Charité University Medicine, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; [2]*West Tennessee Research Institute, Jackson, United States of America*; [3]*Buda Hospital of the Hospitaller Order of St. John of God, Rheumatology, Budapest, Hungary*; [4]*Reumatika –Centrum Reumatologii, ARS Rheumatica sp.z.o.o, Warsaw, Poland*; [5]*AbbVie, Immunology, North Chicago, United States of America*; [6]*AbbVie Deutschland GmbH & Co. KG, Immunology, Ludwigshafen, Germany*; [7]*Sheba Medical Center, Department of Medicine 'B' and Zabludowicz Center for Autoimmune Diseases, Ramat Gan, Israel*; [8]*Affiliated to Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel*

Background: ABBV-3373 is a novel antibody drug conjugate composed of adalimumab (ADA) linked to a proprietary and highly potent glucocorticoid receptor modulator (the anti-inflammatory payload) currently evaluated for the treatment of rheumatoid arthritis (RA).

Objectives: To assess the efficacy and safety of ABBV-3373 vs ADA in RA patients (pts).

Methods: This was a 24-week (wk) randomized, double-blind, double-dummy, active-controlled Phase 2a study of intravenously (IV)-administered ABBV-3373 100 mg (for 12 wks followed by placebo [PBO] for 12 wks) vs subcutaneous injections of ADA 80 mg every other wk (for 24 wks) in pts on background methotrexate. The primary endpoint was the change from baseline (BL) in DAS28(CRP) at Wk 12. Pre-planned statistical methods incorporating pre-specified historical ADA data both alone (pre-specified success criterion, 2-sided $P \leq 0.1$) and supplemented with in-trial ADA data (pre-specified success criterion, probability >95%) were used to achieve adequate statistical power with a reduced trial size. Assay sensitivity was evaluated through construction of a synthetic PBO arm by propensity score matching, using individual pt-level PBO data from 3 recent sponsor-run trials of similar populations and trial settings. Secondary endpoints at Wk 12 included 1) mean change from BL in CDAI, SDAI, DAS28(ESR), HAQ-DI; 2) proportion of pts achieving DAS28(CRP)≤3.2, ACR20/50/70 responses, HAQ-DI≤-0.22. Continuous and categorical efficacy variables were analyzed using mixed effect model repeated measurements and Cochran-Mantel-Haenszel test, respectively; non-responder imputation was applied to missing categorical data. Treatment-emergent adverse events were summarized through Wk 12.

Results: A total of 48 pts were randomized and treated (ABBV-3373: 31; ADA: 17); 46 pts (96%) completed 12 wks of study treatment. BL demographics and disease characteristics were indicative of established RA and similar among the 2 treatment arms and the synthetic PBO arm. ABBV-3373 demonstrated significant improvement in mean DAS28(CRP) at Wk 12 vs the pre-specified historical ADA (-2.65 vs -2.13; P=0.022) and numerically greater improvement vs the combined in-trial and historical ADA arm (-2.65 vs -2.29; probability 90%; Figure). Comparable improvements in disease activity and targets were observed for ABBV-3373 and in-trial ADA. Assay sensitivity was supported by the fact that both ABBV-3373 and ADA arms were superior to synthetic PBO (P<0.001). For secondary endpoints, greater efficacy was observed with ABBV-3373 vs historical ADA; ABBV-3373 was predicted with 79-99% probability to be better than ADA based on the combined in-trial and historical ADA data. 2 serious infections were reported with ABBV-3373 (pneumonia, upper respiratory tract infection) and none with ADA through Wk 12 (Table). 1 event of anaphylactic shock reaction was reported with ABBV-3373. After increasing the duration of IV administration from 3 min to 15-30 min, no similar events were observed.

Conclusion: These data demonstrate the clinical efficacy of ABBV-3373 and its potential to provide improved outcomes for RA pts compared to ADA. The safety profile of ABBV-3373 was generally similar to ADA.

OP0116 ELDERLY PATIENTS ARE NOT AT INCREASED RISK OF SERIOUS INFECTIONS WHEN RECEIVING BDMARDS OR JAK INHIBITORS COMPARED TO CSDMARD TREATMENT

A. Strangfeld[1], B. Manger[2], M. Worsch[3], T. Schmeiser[4], A. Zink[1], M. Schaefer[1]. [1]*German Rheumatism Research Centre, Epidemiology and Health Care Research, Berlin, Germany*; [2]*University Hospital Erlangen, Faculty of Medicine, Erlangen, Germany*; [3]*Private Practice, Mühlhausen, Germany*; [4]*Private Practice, Cologne, Germany*

Background: Elderly rheumatoid arthritis (RA) patients are generally at increased risk of serious infections (SI). At the same time, treatment with bDMARDs has been associated with a higher SI risk than treatment with csDMARDs (1). However, long-term use of bDMARDs did not increase the risk of SI in a small group of elderly patients over 65 (2). The extent to which elderly patients are exposed to a higher SI risk when treated with JAK inhibitors (JAKi) is an open question.

Objectives: To assess the effects of bDMARDs and specifically JAKi on the risk of SI in elderly patients with RA.

Methods: The German register RABBIT is a prospective, longitudinally followed cohort of RA patients enrolled with a new start of a DMARD after at least one csDMARD failure. This analysis comprises patients over 70 years of age who were enrolled between 01/2007 and 04/2020 and had at least one follow-up.

Results: Of 13,491 patients followed-up in RABBIT, 2274 with an age > 70 years were included in the analysis. 626 SI were observed in 425 of these patients. Baseline characteristics at start of the respective DMARD are shown in Table 1. In most characteristics, patients on JAKi were more comparable to patients under bDMARDs than to those on csDMARDs. JAKi patients received glucocorticoids (GC) less frequently than patients on other treatments. The HR for SI was lower than 1 in patients receiving bDMARDs or JAKi compared to csDMARDs, but without statistical significance (Figure 1). GC use (HR 1.6, 95% CI: 1.2 – 2.2 for ≤ 10 mg/d), higher DAS28-ESR values (HR 1.1, 95% CI: 1.0 – 1.2 per 1 point increase), COPD or pulmonary fibrosis (HR 1. 8, 95% CI: 1.3 – 2.4), chronic kidney disease (HR 1.5, 95% CI: 1.2 – 1.9) and diabetes mellitus (HR 1.3, 95% CI: 1.0 – 1.7) were associated with an increased risk of SI. Better physical capacity was associated with a decreased risk of SI (HR 0.9, 95% CI: 0.88 – 0.98 for a 10 point increase).

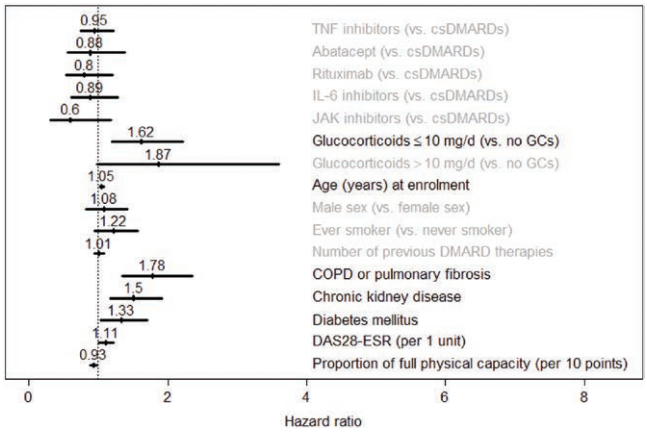

Figure 1. Hazard ratios for serious infections with 95% confidence intervals

Conclusion: Treatment with JAKi as well as treatment with bDMARDs was not associated with an increased risk of SI in elderly patients above 70 years of age. Key comorbidities such as diabetes mellitus, chronic pulmonary and kidney diseases were associated with increased risk, as was concomitant GC use and higher disease activity.

OP0117

REAL-WORLD EFFECTIVENESS OF TNFI VERSUS NON-TNFI BIOLOGICS ON DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM THE ACR'S RISE REGISTRY

M. Gianfrancesco[1], J. LI[1], M. Evans[1], M. Petersen[2], G. Schmajuk[1], J. Yazdany[1]. *[1]University of California, San Francisco, Medicine, San Francisco, United States of America; [2]University of California, Berkeley, Biostatistics, San Francisco, United States of America*

Background: Our understanding of how medications such as biologic disease modifying anti-rheumatic drugs and targeted small molecules (b/tsDMARDs) influence disease activity in RA is based largely on randomized controlled trials (RCTs). However, most U.S. trials in RA are limited by small sample sizes and have often excluded patients who are older, male, and from racial/ethnic minorities. Whether effectiveness of b/tsDMARDs varies in these populations has largely been unexplored.

Objectives: We aimed to examine differences in longitudinal RA disease activity by demographic and clinical characteristics using a novel electronic health record data source of rheumatology providers across the U.S. We simulated various treatment assignments of b/tsDMARDs that have been examined in RCTs: namely, TNF-inhibitors (TNFi) and non-TNFi.

Methods: We included 16,448 individuals from the ACR's RISE registry with ≥ 2 RA diagnoses (ICD-9: 714.0) ≥ 30 days apart, who had at least 2 recorded clinical disease activity index (CDAI) scores and no historical b/tsDMARD use documented in RISE. b/tsDMARD use and CDAI scores were assessed at each quarter; covariates included sex, race (white, Black, Asian, other), ethnicity (Hispanic/non-Hispanic), age, smoking, obesity, area deprivation index, other DMARD use, RF status, anti-CCP status, and practice type. Longitudinal targeted maximum likelihood estimation estimated the average treatment effect (ATE) of cumulative TNFi vs. non-TNFi use over a 12-month period on CDAI score among the entire population and across various subgroups based on demographic and clinical characteristics, accounting for censoring and time-varying confounding.

Results: Approximately 75% of patients were female with a mean age of 65.1 (+/- 13.7) years. Sixty percent of patients were white, 8% black, 2% Asian, and 30% other/mixed or unknown race; 6% were Hispanic. The mean CDAI score at baseline was 11.3 (+/- 10.7). For the overall population, there was no significant difference in disease activity between TNFi and non-TNFi at 12 months (ATE= 0.85, 95% CI -0.26, 1.96; Table 1). Stratified analyses found higher disease activity for TNFi compared to non-TNFi among patients of Black and Asian race, non-Hispanic ethnicity, and female sex. Among Black race patients, TNFi use was associated with a 6.08 point higher CDAI score compared to non-TNFi use (95% CI 1.99, 10.17). In contrast, in Hispanic/Latino ethnicity patients, TNFi use was associated with a lower CDAI score compared to non-TNFi use (ATE= -2.64, 95% CI -3.99, -1.30).

Table 1. Average treatment effect (ATE) of cumulative TNFi vs. non-TNFi use at 12-months on CDAI score in patients with RA

	TNFi	Non-TNFi	ATE (95% CI)
Overall (n=16,448)	8.84	7.99	0.85 (-0.26, 1.96)
Race			
White (n=9,814)	8.24	6.81	1.42 (0.03, 2.81)*
Black (n=1,358)	13.91	7.83	6.08 (1.99, 10.17)*
Asian (n=301)	6.54	2.74	3.80 (2.93, 4.67)*
Ethnicity			
Non-Hispanic (n=14,216)	8.92	7.63	1.29 (0.08, 2.51)*
Hispanic (n=938)	5.69	8.33	-2.64 (-3.99, -1.30)*
Sex			
Female (n=12,527)	8.98	7.47	1.51 (0.31, 2.72)*
Male (n=3,921)	8.57	9.49	-0.92 (-3.42, 1.58)

*$P<0.05$

Conclusion: Results from this RCT simulation study suggest that non-TNFi may have an important role as first-line agents in the treatment of Black and Asian patients, but not Hispanic patients. These novel findings fill gaps where RCTs have not been conducted, highlight the need for inclusion of diverse populations in future trials, and have the potential to lead to a more personalized approach to rheumatologic care.

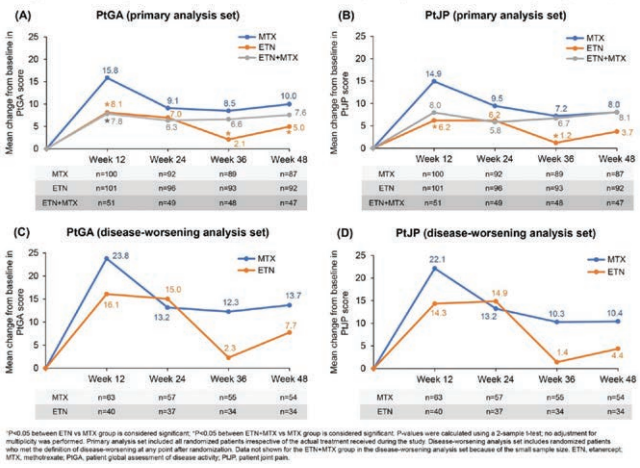
OP0118 EFFECT OF WITHDRAWING ETANERCEPT OR METHOTREXATE ON PATIENT-REPORTED OUTCOMES IN RHEUMATOID ARTHRITIS PATIENTS IN REMISSION ON COMBINATION THERAPY: RESULTS FROM THE SEAM-RA TRIAL

J. Curtis[1], E. Karis[2], V. Bykerk[3], G. Kricorian[4], P. Yen[5], P. Emery[6], P. Haraoui[7], D. Collier[4], B. Stolshek[8]. [1]*University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, United States of America*; [2]*Amgen Inc, Global Development, California, United States of America*; [3]*Hospital for Special Surgery, Department of Rheumatology, New York, United States of America*; [4]*Amgen Inc, Global Medical, California, United States of America*; [5]*Amgen Inc, Global Biostatistical Science, California, United States of America*; [6]*Leeds National Institute for Health Research, Biomedical Research Center at Leeds Teaching Hospitals Trust, LIRMM Leeds University, Division of Rheumatic and Musculoskeletal Disease, Leeds, United Kingdom*; [7]*Rheumatology Institute of Montreal, Department of Medicine, Montreal, Canada*; [8]*Amgen Inc, Global Health Economics, California, United States of America*

Background: Limited studies have assessed the effect of withdrawal of either methotrexate (MTX) or etanercept (ETN) on patient-reported outcomes (PROs) in rheumatoid arthritis (RA).
Objectives: To evaluate the baseline and change in PROs following withdrawal of MTX or ETN in RA patients with sustained remission receiving combination ETN+MTX.
Methods: Adult patients with RA on ETN+MTX and in remission (SDAI ≤3.3) for ≥12 months (including a 24-week, open-label, run-in period) were randomized to a 48-week double-blind period to receive ETN 50 mg weekly (N=101), oral MTX 10-25 mg weekly (N=101) or continue ETN+MTX (N=51). The primary endpoint was maintenance of SDAI remission without disease worsening (DW) at week 48 between ETN and MTX groups. Patients who experienced SDAI >11 at any time after randomization, or SDAI >3.3 and ≤11 during 2 consecutive or on 3 non-consecutive visits were considered to have DW and resumed ETN+MTX. PROs assessed were patient global assessment of disease activity (PtGA, 0-100 mm), patient joint pain (PtJP, 0-100 mm), Health Assessment Questionnaire-Disability Index (HAQ-DI), and the 36-item short-form health survey (SF-36) component and domain scores. A 2-sample t-test was used to compare the treatment differences between groups. A subgroup analysis for patients with DW was also performed (DW analysis set) and compared PROs between ETN vs MTX arms (ETN+MTX not shown given the small sample size).
Results: Of the 253 patients randomized, 121 (47.8%) experienced DW and were included in the DW analysis set. Baseline demographics were generally balanced between the 3 treatment groups. Most patients were women (76.3%), White (87.0%), and with a mean age of 55.6 years. The mean (SD) MTX dose was 16.3 (4.69) mg and the mean (SD) duration of RA was 10.3 (7.8) years. At week 48, a significantly greater proportion of patients on ETN vs MTX monotherapy maintained SDAI remission (49.5% vs 28.7%; P=0.004) after therapy withdrawal. In the overall population, PtGA and PtJP scores were very low at baseline (PtGA–MTX: 4.4, ETN: 4.5, ETN+MTX: 3.5; PtJP–MTX: 4.9, ETN: 5.5, ETN+MTX: 3.5) and showed some worsening over the study period in all treatment groups, with a mean change at week 48 ranging from 5.0 to 10.0 units for PtGA and 3.7 to 8.1 units for PtJP. Patients on ETN had less worsening, with a nominally significant treatment difference observed between ETN and MTX monotherapy groups for PtGA at almost all timepoints, and for PtJP at weeks 12 and 36 (Figure). Mean HAQ-DI (MTX: 0.32; ETN: 0.26; ETN+MTX: 0.28) and SF-36 scores (physical component [PCS]–MTX: 52.1, ETN: 52.7, ETN+MTX: 52.3; mental component [MCS]–MTX: 55.5, ETN: 55.8, ETN+MTX: 57.1) at baseline show that patients had low disability and excellent health-related quality of life compared with normative values for the general non-RA population. HAQ-DI scores were well maintained at weeks 24 and 48 (change from baseline at week 48–MTX: 0.14; ETN: 0.15; ETN+MTX: 0.21). The SF-36 PCS, MCS, and domain scores decreased minimally from baseline with treatment differences that were not nominally significant between groups. Among patients with DW during the study, those on ETN showed less PtGA and PtJP worsening from baseline than those on MTX at weeks 12, 36, and 48 (Figure). Other PROs (HAQ-DI [change from baseline at week 24–ETN: 0.34; MTX: 0.21; at week 48–ETN: 0.15; MTX: 0.15], SF-36 PCS, MCS, and domain scores) showed a similar degree of worsening in both the MTX and ETN arms.
Conclusion: In patients with sustained SDAI remission on ETN+MTX, mental and physical health as measured by SF-36 was comparable with that of the non-RA population. Withdrawal of ETN (MTX monotherapy) resulted in a greater worsening of PtGA and PtJP than withdrawal of MTX (ETN monotherapy), and patients on ETN monotherapy restored these scores close to baseline towards the end of the treatment period. These findings demonstrate that ETN monotherapy has a greater effect on maintaining overall patient assessment of disease and joint pain compared with MTX monotherapy.

Figure. Mean change from baseline in PtGA and PtJP scores (primary and disease-worsening analysis set)



[a]P<0.05 between ETN vs MTX group is considered significant; [b]P<0.05 between ETN+MTX vs MTX group is considered significant. P-values were calculated using a 2-sample t-test; no adjustment for multiplicity was performed. Primary analysis set included all randomized patients irrespective of the actual treatment received during the study. Disease-worsening analysis set includes randomized patients who met the definition of disease-worsening at any point after randomization. Data not shown for the ETN+MTX group in the disease-worsening analysis set because of the small sample size. ETN, etanercept; MTX, methotrexate; PtGA, patient global assessment of disease activity; PtJP, patient joint pain.

OP0119 SHOULD WE USE BIODMARDS IN FIRST INTENTION IN EARLY RHEUMATOID ARTHRITIS?: RESULTS AT 5 YEARS FROM THE ERA LOUVAIN BRUSSELS COHORT

E. Sapart[1], T. Sokolova[1], S. De Montjoye[1], S. Dierckx[2], A. Nzeusseu Toukap[1], A. Avramovska[1], L. Meric de Bellefon[1], P. Durez[1]. [1]*Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCL) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium*; [2]*CHU Mont-Godinne, Rheumatology, Mont-Godinne, Belgium*

Background: Early effective treatment has led to major improvements in patients with rheumatoid arthritis (ERA). Low disease activity and remission are achieved earlier and in higher frequency when the initial treatment in rheumatoid arthritis includes a combination of methotrexate (MTX) with a bDMARD compared to MTX alone.
Objectives: The aim of this study is to retrospectively analyse and compare the benefit of a treatment with methotrexate (MTX) alone or combined with a bDMARD as an induction therapy during 5 years of follow-up in early rheumatoid arthritis (ERA) patients.
Methods: We included ERA patients from the UCLouvain Brussels cohort who met the ACR/EULAR 2010 classification criteria and were naïve to DMARDs. Treatments were initiated based on the decision of a senior rheumatologist. bDMARDs induction therapy was usually limited to 6 or 12 months. We collected patient characteristics at baseline and clinical response was analysed at 6 months, 1 year, 3 years and 5 years.
Results: Data from 470 eligible ERA patients were collected. The average age of the population is 48.9 years; 70.5% of the patients are women; 27.3% are smokers and 68.8% are positive for anti-citrullinated protein antibody (ACPA).

281 patients (59.8 %) initiated MTX as a monotherapy (MTX group) compared to 189 patients (40.2%) who received a bDMARD (Bio group).
At baseline, the disease activity is the main factor that favors the initiation of bDMARDs (DAS28-CRP 5.2 vs 4.5, p<0.001) followed by HAQ (1.32 vs 1.15, p=0.009), ACPA positivity (77.8% vs 62.5%, p=0.0006), rheumatoid factor positivity (71.5% vs 60.2%, p=0.0134). Other parameters such as age, gender, smoking habits or baseline erosion were similar between groups.
391 patients were followed up to 5 years. We then divided each of the two groups into two subgroups according to the last treatment they received at 5 years. Figure 1 shows the percentage of DAS28-CRP remission during time in each of the four groups (MTX->MTX (n=134), MTX->BIO (n=103); BIO->MTX (n=95), BIO->BIO (n=59);

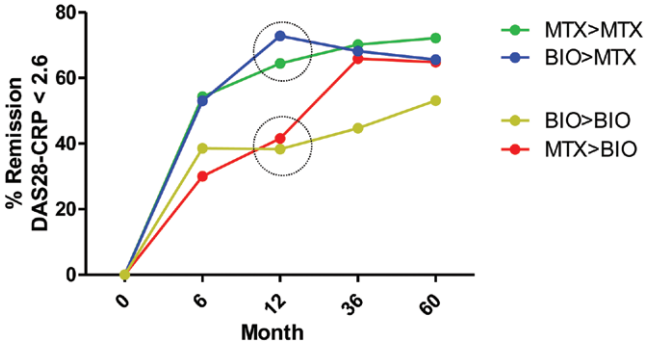

Figure 1. DAS28-CRP remission rate during time in each of the four groups (MTX->MTX (n=134), MTX->BIO (n=103); BIO->MTX (n=95), BIO->BIO (n=59).

At 12 months, DAS28-CRP response rate was statistically significantly higher in MTX>MTX and BIO>MTX groups compared to the two other groups. As expected, the remission rate was rescued in the group MTX->Bio after 12 months.
Interestingly, ERA patients initially treated by a bDMARD followed by a MTX maintenance therapy experienced a stable and sustained rate of remission.
Conclusion: Longterm remission is an achievable goal in ERA followed in daily clinic. Our results suggest that a bDMARD induction therapy followed by MTX maintenance therapy could be a good option in severe case of ERA.

OP0120 DURATION OF CLINICAL EFFICACY FOLLOWING TREATMENT WITH VIB4920 IN SUBJECTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS

O. Ali[1], L. Wang[2], W. Xu[2], D. Falleroni[3], J. Falloon[1], G. Illei[1]. [1]*Viela Bio, Clinical Development, Gaithersburg, United States of America*; [2]*Viela Bio, Biostatistics, Gaithersburg, United States of America*; [3]*Viela Bio, Clinical Operations, Gaithersburg, United States of America*

Background: VIB4920 binds CD40 ligand and functionally neutralizes its engagement with CD40[1]. We reported results through Day 85 of a Phase 1b, randomized, double-blind, placebo-controlled study (NCT02780388) in subjects with moderate to severe rheumatoid arthritis (RA) who had an inadequate response to methotrexate (MTX) or other disease modifying anti-rheumatic drugs (DMARDs) or tumor necrosis factor (TNF)-inhibitors[1]. We showed that at the end of the 12-week treatment period (Day 85), subjects treated with 1000 or 1500 mg VIB4920 (once every 2 weeks) had a clinically meaningful and statistically significant greater reduction in disease activity compared to placebo.
Objectives: To assess the duration of clinical efficacy following the last dose of VIB4920 in subjects with moderate to severe RA.
Methods: Subjects in the Phase 1b study (Ph1b) continued to have monthly safety and efficacy assessments between Days 85 and 169, the end of a 12-week follow-up. To estimate the subsequent duration of meaningful clinical improvement, we conducted an observational one-visit study (OS) (EudraCT 2019-002351-42) with the primary endpoint of time from last dose of VIB4920 to start of a new DMARD or biologic therapy or increase in dose of DMARD that was ongoing at Day 169 (ie, rescue therapy).
Results: At Day 169 of the Ph1b (3 months after the last dose), clinical responses achieved at Day 85 were maintained in the 1000 and 1500 mg cohorts (Figure). Of 24 subjects, 16 (6/12 treated with 1000 mg and 10/12 with 1500 mg) participated in the OS. The median (range) time from Day 169 (last visit) in the Ph1b to the OS was 21.8 (21.2 to 23.1) months in the 1000 mg group and 33.7 (32.3 to 34.8) months in the 1500 mg group. All subjects had taken DMARDs (primarily methotrexate [MTX]) for at least part of this time (Table). Rescue therapy was started in 1/6 (16.7%) subject in the 1000 mg group and 3/10 (30.0%) subjects in the 1500 mg group (Table); median time to rescue could not be estimated due to the limited number of rescues. Two subjects were on no DMARDs at the OS. All subjects, except for 1 in the 1000 mg group, who was rescued with adalimumab, and 2 in the 1500 mg group (no rescue), had active disease (DAS28-CRP ≥ 2.6) at the OS. The median DAS28-CRP at the OS was higher than at Day 169 of the Ph1b but lower than at the Ph1b baseline visit (Table). Two subjects who received 1500 mg and met DAS28-CRP criteria for low disease activity (< 3.2) at Day 169 also met these criteria at the OS without receiving any rescue therapy after a median of nearly 37 months after last treatment. Results from the Patient and Physician Global Assessment VAS showed trends similar to the DAS28-CRP.
Conclusion: Blocking CD40L with VIB4920 led to prolonged clinical benefit in patients with RA when added to stable background DMARD therapy. The exact duration of benefit could not be defined in this study, but most patients did not require rescue therapy during a prolonged follow-up period, and some patients maintained low disease activity or discontinued DMARDs, suggesting a possible long-term benefit of VIB4920. Interpretation of these data is limited because the OS did not include placebo-treated subjects from the Ph1b. The duration of clinical response needs to be confirmed in prospective, double-blind, placebo-controlled studies.

Rheumatoid arthritis - non biologic treatment and small molecules

OP0122 COMPARATIVE EFFECTIVENESS OF JAKI VERSUS BDMARDS; A NATIONWIDE STUDY IN RA

A. Barbulescu[1], J. Askling[1,2], K. Chatzidionysiou[2,3], H. Forsblad-D'elia[4], A. Kastbom[5], U. Lindström[4], C. Turesson[6], T. Frisell[1]on behalf of the ARTIS Study Group. *[1]Karolinska Institute, Department of Medicine Solna, Clinical Epidemiology, Stockholm, Sweden*; *[2]Nya Karolinska, Department of Rheumatology, Stockholm, Sweden*; *[3]Karolinska Institute, Department of Medicine Solna, Stockholm, Sweden*; *[4]Gothenburg University, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; *[5]Linköping University, Department of Biomedical and Clinical Sciences, Linköping, Sweden*; *[6]Lund University, Department of Clinical Sciences, Rheumatology, Malmö, Sweden*

Background: The Janus kinase inhibitors (JAKi) have been increasingly used for the treatment of rheumatoid arthritis (RA) in Sweden, with baricitinib representing ~80% of prescriptions. Evidence regarding the comparative effectiveness of JAKis versus biologics (bDMARDs), and in particular non- tumour-necrosis-factor inhibitor (TNFi) bDMARDs, in real-life is limited.
Objectives: To compare RA patients treated with bDMARDs and JAKi in Sweden, in terms of: (1) patient characteristics at treatment start; (2) proportions of patients remaining on therapy, and response rates, at 12 months.
Methods: RA patients starting treatment in 2017 and 2018 with either a TNFi, rituximab, abatacept, interleukin 6 inhibitors (IL6i) or a JAKi as different lines of treatment were identified in the Swedish Rheumatology Quality Register. One patient could contribute with more than one treatment episode.
Treatment response at 12 months was measured as EULAR good response, HAQ improvement >0.2 units, DAS28 and CDAI remission, and as 0 tender and swollen joint counts (28JC). Patients were classified as non-responders if they stopped treatment before evaluation due to safety or inefficacy. Responses for patients who stopped treatment due to pregnancy or death and patients on treatment but with missing response were imputed using multiple imputation.
Proportions of responders and differences in proportions between treatment groups, adjusted using inverse probability of treatment weighting, were estimated using linear regression with robust standard errors.
Results: JAKi were often used after bDMARDs, and less frequently prescribed in combination with methotrexate. Measured comorbidities were less frequent among JAKi initiators than among non-TNFi biologic initiators, but RA activity was similar (Table).

Table 1. Patient characteristics at treatment initiation

Diabetes*	324 (9.9)	216 (7.7)	456 (9.7)	1479 (6.7)	69 (7.5)

* any diagnosis within 5 years before startAdjusted differences in proportion with each response outcome

In a crude comparison, 65% (61%-68%) of JAKi, 62% (59%-66%) of abatacept, 58% (53%-62%) of IL6i, 80% (77%-83%) of rituximab and 68% (67%-70%) of TNFi initiators remained on treatment at 12 months after start. Also, JAKi showed lower overall responder proportions than TNFi, rituximab and IL6i.

After adjustment for demographic and socio-economic factors, RA disease activity, previous use of ts/bDMARDs, co-medication with glucocorticoids and methotrexate and comorbidities at baseline, no significant differences in responder proportions between JAKi and bDMARDs remained (Figure). Furthermore, the adjusted proportions of patients on treatment were higher for JAKi and rituximab than for the other bDMARDs.
Conclusion: This preliminary analysis of patients treated in clinical practice found no statistically significant difference in effectiveness between JAKi and bDMARDs.

OP0123 SAFETY PROFILE OF JAK-INHIBITORS VERSUS TNF-INHIBITORS IN REAL-WORLD CLINICAL PRACTICE: DATA FROM A MULTICENTER REGISTER

B. Hernández-Cruz[1], C. Sánchez-Piedra[2], M. Freire González[3], N. Busquets[4], J. García-González[5], M. Moreno[6], J. M. Blanco[7], S. Manrique Arija[8], E. Perez-Pampín[9], F. Sánchez-Alonso[2], I. Castrejon[10]on behalf of BIOBADASER. *[1]Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain*; *[2]Fundación Española de Reumatologia, Rheumatology, Madrid, Spain*; *[3]Complejo Hospitalario A Coruña, Rheumatology, A Coruña, Spain*; *[4]Hospital General de Granollers, Rheumatology, Granollers, Spain*; *[5]Hospital 12 De Octubre, Rheumatology, Madrid, Spain*; *[6]Hospital Clínico Universitario Virgen de la Arrixaca, Rheumatology, El Palmar, Spain*; *[7]Hospital Universitario Basurto, Rheumatology, Bilbo, Spain*; *[8]Hospital Regional Universitario de Málaga (Carlos de Haya), Rheumatology, Málaga, Spain*; *[9]Hospital Clínico Universitario de Santiago, Rheumatology, Santiago de Compostela, Spain*; *[10]Hospital Universitario Gregorio Marañón, Rheumatology, Madrid, Spain*

Background: JAK-inhibitors (JAKi) are small molecules emerging as a promising treatment for immune mediated diseases. Data from clinical trials are very promising. But long-term observational studies, with patients with diverse clinical backgrounds are required to confirm safety profile.
Objectives: To compare the safety profile of JAKi versus TNF antagonists (anti-TNF) in a multicenter real world dataset.
Methods: Data of patients enrolled in BIOBADASER 3.0 up to November 2020 with the start of anti-TNF or JAKi were analysed. Adverse events (AE) were classified according to Meddra dictionary (v19.0). For each group, demographic, clinical variables and ncidence rate ratios of AE per 1000 patients-year (PYs) and 95% confidence interval were estimated.
Results: A total of 3,729 patients on anti-TNF (5,306) or JAKi (493) were analyzed. Patients on JAKi were older and with a mean disease duration of 10 years. JAKi were prescribed as first line treatment only in 24% of patients. The main reason of stopping treatment was ineffectiveness (53-59%) followed by adverse events (25-34%) in both groups. Survival during first year was similar between groups.

Table 1. Patient characteristics and adverse events by treatment group

	Anti-TNF	JAKi
Mean age start of treatment (SD), yrs	50.8 (12.6)	57.6 (11.9)
Female, n (%)	3122 (58.8)	392 (79.5)
Disease duration, median (IQR)	7.0 (2.7-13.7)	9.9 (4.9-16.8)
First line biologic, n (%)	2614 (49.3)	117 (23.7)
Rheumatoid Arthritis	1385 (41.1)	339 (95.2)
Ankylsosing Spondylitis	1031 (30.6)	1 (0.3)
Psoriatic Arthritis	957 (28.4)	16 (4.5)
DAS28-ESR	4.3 (1.4)	4.7 (1.4)
Survival first year (IC 95%)	73.3 (71.9-74.6)	69.7 (66.0-73.0)
Charlson Index, mean (SD)	1.9 (1.3)	2.3 (1.6)
Reason to stop therapy (n)*:		
Lack of efficacy	1534 (53.2)	57 (58.8)
Adverse event	723 (25.1)	33 (34.0)
Adverse events (AE)*		
Serious infections	14.2 (12.4-16.2)	33.2 (19.3-57.3)
Herpes zoster	5.7 (4.6-7.1)	12.8 (5.3-30.7)
Tuberculosis	0.7 (0.4-1.3)	0.0 (0.0-0.0)
Malignancy/Neoplasia	10.2 (8.7-11.9)	15.3 (6.9-34.2)
Cardiac events	13.9 (12.2-16.0)	30.7 (17.4-54.0)
GI perforation	1.2 (0.8-1.9)	10.2 (3.8-27.3)
Vascular events	9.8 (8.3-11.5)	25.6 (13.8-47.5)

*Data show the incidence rate ratio per 1000 patient-years (PYs; 95% CI)

Conclusion: Serious infections and herpes zoster tend to be more frequent in patients on JAKi. However patients on JAKi were older, presented higher comorbidity and have a longer disease duration.

OP0124

EFFECTS OF NINTEDANIB IN PATIENTS WITH PROGRESSIVE FIBROSING INTERSTITIAL LUNG DISEASE ASSOCIATED WITH RHEUMATOID ARTHRITIS (RA-ILD) IN THE INBUILD TRIAL

C. Kelly[1], E. Matteson[2], M. Aringer[3], G. R. Burmester[4], H. Mueller[5], L. Moros[6], K. Rohr[6], M. Kolb[7] on behalf of the INBUILD Trial Investigators.. [1]*Newcastle University, Institute of Cellular Medicine, Newcatle upon Tyne, United Kingdom*; [2]*Mayo Clinic College of Medicine and Science, Division of Rheumatology, Rochester, United States of America*; [3]*University Medical Center & Faculty of Medicine, TU Dresden, Rheumatology, Medicine III, Dresden, Germany*; [4]*Charité–University Medicine Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; [5]*Boehringer Ingelheim Pharma GmbH & Co. KG, Biostatistics and Data Sciences, Biberach, Germany*; [6]*Boehringer Ingelheim International GmbH, TA Inflammation Med, Ingelheim am Rhein, Germany*; [7]*McMaster University and St. Joseph's Healthcare, Department of Medicine, Hamilton, Canada*

Background: In the INBUILD trial in subjects with progressive fibrosing ILDs other than idiopathic pulmonary fibrosis (IPF), nintedanib reduced the rate of decline in FVC (mL/year) over 52 weeks by 57% compared with placebo.

Objectives: To assess the rate of decline in FVC in subjects with RA-ILD in the INBUILD trial.

Methods: Subjects in the INBUILD trial had a chronic fibrosing ILD other than IPF, reticular abnormality with traction bronchiectasis (with or without honeycombing) of >10% extent on high-resolution computed tomography (HRCT), forced vital capacity (FVC) ≥45% predicted, diffusing capacity of the lungs for carbon monoxide ≥30%–<80% predicted, and met criteria for progression of ILD within the 24 months before screening, despite management deemed appropriate in clinical practice. Patients taking stable doses of approved medications to treat RA or connective tissue disease could participate, except that the protocol excluded those taking azathioprine, cyclosporine, mycophenolate mofetil, tacrolimus, rituximab, cyclophosphamide, or oral glucocorticoids >20 mg/day. We analysed the rate of decline in FVC (mL/year) over 52 weeks and adverse events in subjects with RA-ILD.

Results: Of 663 subjects who received trial medication, 89 had RA-ILD (42 nintedanib, 47 placebo), of whom 60.7% were male, 64.0% were current or former smokers, 86.5% had a usual interstitial pneumonia (UIP)-like pattern on HRCT; 93.3% had received confirmation of their RA diagnosis from a rheumatologist. At baseline, 21.3% of subjects were taking biologic disease-modifying anti-rheumatic drugs (DMARDs), 53.9% were taking non-biologic DMARDs and 73.0% were taking glucocorticoids (≤20 mg/day prednisone or equivalent). At baseline, mean (SD) age was 66.9 (9.6) years, time since RA diagnosis was 9.9 (9.4) years, time since ILD diagnosis was 3.6 (3.2) years, FVC was 71.5 (16.2) % predicted and C-reactive protein was 13.7 (22.5) mg/L. The adjusted mean (SE) rate of decline in FVC over 52 weeks was -82.6 (41.3) mL/year in the nintedanib group versus -199.3 (36.2) mL/year in the placebo group (difference 116.7 mL/year [95% CI 7.4, 226.1]; nominal p=0.037), consistent with findings in the overall trial population (Figure). As in the overall trial population, the most common adverse event in subjects with RA-ILD was diarrhoea (reported in 54.8% of the nintedanib group and 25.5% of the placebo group). Adverse events led to permanent discontinuation of trial drug in 19.0% of subjects in the nintedanib group and 12.8% of subjects in the placebo group.

Conclusion: In the INBUILD trial, nintedanib slowed the rate of decline in FVC in patients with progressive fibrosing RA-ILD, with adverse events that were manageable for most patients. The efficacy and safety of nintedanib in subjects with RA-ILD were consistent with those observed in the overall trial population.

Figure. Rate of decline in FVC (mL/year) over 52 weeks with nintedanib versus placebo in all subjects and in subjects with RA-ILD in the INBUILD trial.

Background: Beyond the joints, rheumatoid arthritis (RA) may affect lungs. Especially the involvement of the paranchyme, RA-associated interstitial lung disease (RA-ILD), is a major cause of mortality and morbidity. Tofacitinib, an oral JAK 1/3 inhibitor, has been used increasingly in the management of rheumatoid arthritis (RA) in recent years. Recently, a couple of animal and human studies reported promising results (1).

Objectives: To assess the real-life efficacy and safety of tofacitinib in patients with RA-ILD in TReasure registry.

Methods: This is a multicenter, observational study included RA patients with ILD diagnosis based on the HRCT images of the lungs, and were followed in 8 different centers participated in the TReasure database. Demographic data and patients' characteristics regarding RA and RA-ILD at the visit in which tofacitinib was initiated and for the last follow-up visit under tofacitinib were recorded. Using the present study cohort, the RA patients with ILD receiving tofacitinib were compared with those without ILD receiving tofacitinib (controls) in terms of the general and disease-related characteristics and data of concomitant DMARD use. To evaluate retention rates of tofacitinib and reasons for discontinuation, data of the patients with RA-ILD in this study cohort were compared with the data of RA patients without ILD who were followed in Hacettepe University (major contributor of the TReasure registry). This research was funded by Pfizer.

Results: A total of 47 RA patients with RA-ILD and a control group of 387 patients without ILD were included. The RA patients with ILD receiving tofacitinib were mostly male, older, and had higher baseline disease activity as compared with those without ILD (Table). The ILD pattern was known in 44 (93.6%) of 47 RA-ILD: 16 (36.3%) had UIP, 24 (54.5%) had NSIP, and 4 (9.1%) had airway disease. While 15 (31.9%) of the patients was asymptomatic, most common initial symptom was shortness of breath (in 14 (29.7%) patients). 18 patients had pre- and post-treatment FVC% and FEV1% values (with a median of 12 (9-19) months). Mean FEV1%; 82.1 vs. 82.8 (pre and post-treatment, respectively, p=0.079), mean FVC%; 79.8 vs. 82.8 (pre and post-treatment, respectively, p=0.014). To evaluate retention rates and reasons for discontinuation, 47 RA-ILD and 239 RA patients without ILD were analyzed. Retention rates were similar (p=0.21, log-rank) (Figure). Most common cause of tofacitinib discontinuation in RA-ILD group was infections (5 (25%) patients). Follow-up durations under tofacitinib were 15 (7-32) and 11 (4-24) months in ILD + and – groups, respectively. The rate of drug discontinuation due to infection in the RA patients with and without ILD was 6.3 per 100 patient-years and 2.4 per 100 patient-years, respectively.

Table 1. Characteristics of the RA patients with and without ILD under tofacitinib

Variables	RA-ILD(+) n=47	RA-ILD(-) n=387	p
Male sex	20 (42.6)	69 (17.8)	<0.001
Age, years	64 (57-69)	56 (46-64)	<0.001
Disease duration for RA, months	128 (78-212)	110 (64-183)	0.171
Smoking status			
Never smoker	26 (55.3)	211 (56.4)	0.259
Current&Ex-smoker	19 (44.7)	163 (43.6)	
RF (+)	36 (78.3)	249 (68.8)	0.187
Anti-CCP (+)	30 (65.2)	196 (61.6)	0.640
RF positive or CCP (+)	41 (87.2)	242 (76.3)	0.094
Presence of comorbidity	33 (70.2)	203 (52.5)	0.021
DAS-28 before tofacitinib	5.4 (4.6-6.22)	4.36 (3.22-5.58)	<0.001
ESR before tofacitinib, mm/h	38 (19-73)	29 (17-45)	0.029
CRP before tofacitinib	6.75 (1.63-24)	9.95 (4.18-25.1)	0.065
Follow-up duration under tofacitinib	15 (7-32)	7 (3-12)	<0.001

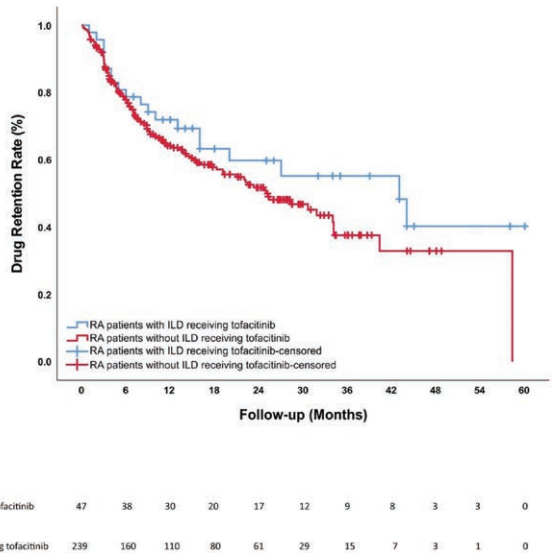

Figure 1. Tofacitinib retention rates in the RA patients with and without ILD

Conclusion: In majority of patients, pulmonary functions remained stable during follow-up. Tofacitinib seems as a promising option for RA-ILD. High rate of discontinuation due infections was observed in RA-ILD patients under tofacitinib; however, it should be kept in mind that RA-ILD patients were older than RA patients without ILD.

OP0126 INFECTIONS AND SERIOUS INFECTIONS IN THE FILGOTINIB RHEUMATOID ARTHRITIS PROGRAM

J. Galloway[1], M. H. Buch[2], K. Yamaoka[3], C. Leatherwood[4], A. Pechonkina[5], I. Tiamiyu[4], D. Jiang[6], L. Ye[6], R. Besuyen[7], D. Aletaha[8], K. Winthrop[9]. [1]*King's College London, Centre for Rheumatic Diseases, School of Immunology and Microbial Sciences, London, United Kingdom*; [2]*University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom*; [3]*Kitasato University School of Medicine, Department of Rheumatology and Infectious Diseases, Kanagawa, Japan*; [4]*Gilead Sciences, Inc., Clinical Research, Foster City, United States of America*; [5]*Gilead Sciences, Inc., Inflammation and Respiratory Therapeutic Area, Foster City, United States of America*; [6]*Gilead Sciences, Inc., Biostatistics, Foster City, United States of America*; [7]*Galapagos BV, Clinical Development, Leiden, Netherlands*; [8]*Medical University of Vienna, Division of Rheumatology, Department of Medicine 3, Vienna, Austria*; [9]*Oregon Health and Science University, Division of Infectious Diseases, Portland, United States of America*

Background: The Janus kinase (JAK)-1 preferential inhibitor filgotinib (FIL) improved rheumatoid arthritis (RA) signs and symptoms in 3 phase (P)3 trials.[1–3] Like other RA therapies, JAK inhibition is associated with increased infection rates.[4]

Objectives: To assess long-term safety across the FIL program regarding infections, including serious infections (SI).

Methods: Patients (pts) meeting 2010 ACR/EULAR RA criteria in pooled analysis of P2 DARWIN 1–2 (D1–2), P3 FINCH 1–3 (F1–3), and long-term extension studies (DARWIN 3, FINCH 4) were included. The placebo (PBO)-controlled as-randomised data set included pts receiving FIL 100 mg (FIL100), FIL 200 mg (FIL200), or PBO up to week (W)12 (D1–2, F1–2). The active-controlled as-randomised data set included pts receiving FIL100, FIL200, adalimumab (ADA), or methotrexate (MTX) up to W52 (F1, F3). The long-term as-treated data set included pts in all 7 studies receiving FIL100 or FIL200; data after rerandomisation were included and contributed to treatment received.

Exposure-adjusted incidence rates (EAIRs) per 100 patient-years exposure (PYE) and differences with 95% confidence intervals (CIs) were calculated using Poisson regression; EAIRs for tuberculosis (TB) in active controlled sets were calculated using an Exact Poisson method. Kaplan-Meier (KM) event probabilities with 95% CIs were provided for SI. If pts had multiple events within the same treatment period, only the first event was counted in EAIR calculation; PYE were calculated up to the last follow-up time or day before next treatment, including after first event. For KM analysis, time to event was calculated until the first event.

Results: Of 2267/1647 pts in as-treated set receiving FIL200/FIL100, 1697 had treatment-emergent infection; 118 were SI. Baseline potential risk factors for pts with SI are in Table.

Table 1. Baseline characteristics of pts with/without treatment emergent SI[a]

Parameter, n (%)	SI N = 92	No SI N = 2491
Medical history

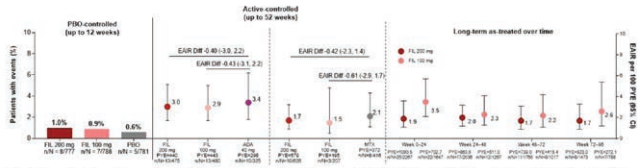
[a]Phase 3 (FINCH 1-4) studies, as randomised.SI, serious infection.

In 12W PBO-controlled period, infection rates were 17.9%/15.6%/13.3% for FIL200/FIL100/PBO. In 52W ADA-controlled period, infection EAIRs (95% CIs)/100 PYE were 46.9 (40.9, 53.7)/43.7 (38.0, 50.4)/43.4 (36.5, 51.5), FIL200/FIL100/ADA; and 38.5 (33.8, 43.9)/39.0 (31.1, 48.8)/42.2 (36.1, 49.3), FIL200/FIL100/MTX in 52W MTX-controlled period; 24.8 (23.1, 26.5)/34.4 (30.4, 38.8), FIL200/FIL100 in long-term analysis. In 12W PBO-controlled period, there was no active TB for FIL200/FIL100/PBO. In 52W ADA-controlled period, active TB EAIRs (95% CIs)/100 PYE were: 0 (0.0, 0.8)/0 (0.0, 0.8)/0.3 (0.0, 1.9), FIL200/FIL100/ADA and 0 (0.0, 0.6)/0 (0.0, 1.9)/0 (0.0, 1.0), FIL200/FIL100/MTX in 52W MTX-controlled period; 0/0.1 (0.0, 0.5), FIL200/FIL100 in long-term analysis.

SI rate or EAIRs are in Figure. Most common infections were upper respiratory tract infection and nasopharyngitis; majority were low grade. Pneumonia was most common SI (<1%). In long-term population, event probability (95% CI) of SI was 2.2% (1.6, 2.9)/2.5% (1.8, 3.4) for FIL200/FIL100 at 52W. In F1–3 (excluding data after rerandomisation), there were no significant changes in mean neutrophil and lymphocyte counts; values remained within normal limits up to W52 for all arms.

Figure. Rate or EAIR of serious infections



ADA, adalimumab; CI, confidence interval; EAIR, exposure-adjusted incidence rate/100 PYE; FIL, filgotinib; MTX, methotrexate; PBO, placebo; PYE, patient-years of exposure.

Conclusion: EAIRs of infections and SI for FIL were similar to PBO, ADA, and MTX. At 52W, incidence rates of SI were comparable for FIL100 and FIL200. Long-term SI EAIR for FIL100 was slightly higher than for FIL200.

OP0127 CONFOUNDING EFFECTS OF CONTINUED METHOTREXATE IN PLACEBO ARMS (PLC) OF RHEUMATOID ARTHRITIS (RA) CLINICAL TRIALS – A POST-HOC ANALYSIS OF TWO RANDOMIZED CONTROLLED TRIALS (RCTS)

A. Kerschbaumer[1], Z. I. Rivai[1], J. S. Smolen[1], D. Aletaha[1]. [1]*Medical University of Vienna, Department of Medicine III / Division of Rheumatology, Vienna, Austria*

Background: Various hypotheses exist for the explanation of PLC response rates in RA clinical trials. Here we hypothesized that PLC-treated patients who continue to take methotrexate (cMTX) when entering the trial compared to those who have no cMTX would have higher response rates, because of increased adherence to MTX in the trial environment.

Objectives: To compare differences in response rates in PLC treated RA patients receiving MTX background therapy to patients receiving PLC without background conventional synthetic (cs)DMARDs in two RCTs.

Methods: To investigate the hypothesis we conducted a post-hoc analysis of two RCTs that allowed inclusion of patients with and without cMTX - the GO-AFTER and the SIRROUND-T trials, investigating golimumab and sirukumab, respectively, compared with PLC in patients who had an insufficient response to biological DMARDs.(1,2)

All PLC randomized patients of both trials were pooled and included in the analyses; we did not analyse the active treatment groups. Subsequently we stratified the pooled PLC group into patients receiving PLC on top of cMTX and patients receiving PLC without any csDMARD as background therapy. We compared American College of Rheumatology (ACR) 20/50/70% response rates and Clinical Disease Activity Index (CDAI) low disease activity (LDA, i.e. CDAI≤10) responses between the two groups using Fisher's exact test.

Similar to the primary analyses of the individual studies, non-responder imputation (NRI) for state outcomes (ACR responses, CDAI LDA) was applied in patients who initiated any csDMARD after randomization, had MTX or glucocorticoid doses increased during the study or discontinued the study. NRI was also applied for early escape patients receiving active therapy after failing to achieve a ≥20% decrease in joint counts at week (wk) 16 in GO-AFTER and at wk 18 in SIRROUND-T.

Results: Of the 398 pooled PLC patients, 285 continued their MTX and 113 had no MTX (or other background csDMARDs). Baseline characteristics were similar (Table 1).

Table 1. Baseline characteristics

	Placebo without background csDMARD	Placebo + continued MTX
n	113	285
Age (years) *	56 (48-64)	56 (45-64)
Female (%)	95 (84.1%)	236 (82.8%)
Disease duration (years)	8.4±5.2	8.8±7.5
ACPA positive (%)	88 (77.9%)	214 (75.1%)
RF positive (%)	90 (79.6%)	211 (74%)
SJC 66 (0-66)	15.9±9.9	16.2±10.8
TJC 68 (0-68)	29.1±16.8	26.7±15.7
PGA (VAS 0-10)	6.8±2.2	6.5±2.1
EGA (VAS 0-10)	6.4±1.8	6.1±1.9
Pain (VAS 0-10)	7.0±1.9	6.6±2.1
HAQ-DI (0-3)	1.6±0.7	1.6±0.6
CRP (mg/dL) *	1.2 (0.5-3.5)	1.0 (0.4-2.6)
CDAI	39.4±13.5	38.5±12.8
Concomitant GC intake (%)	67 (59.3%)	174 (61.1%)
Concomitant MTX (%)	0 (0%)	285 (100%)
MTX dosage ≥12.5mg (%)	0 (0%)	222 (77.9%)
MTX dosage <12.5mg (%)	0 (0%)	63 (22.1%)

Data is shown as mean (± standard deviation) or n (%) unless stated otherwise* median (IQR)

At wk 16, an ACR20 response was achieved by 72/285 (25.3%) of PLC+c-MTX and 14/113 (12.4%) receiving PLC only patients (p=0.005); for ACR50 these numbers were 25/285 (8.4%) vs. 1/113 (0.9%; p=0.003); and for ACR70 they were 8/285 (2.8%) vs. 0/113 (0%; p=0.112). Also, significantly more PLC+cMTX patients achieved a CDAI LDA at wk 16 (25/285, 8.8%) compared to PLC only treated patients (2/113; 1.8%; p=0.013). Results between the two arms were numerically or statistically different already from week 4 (for ACR 20) or week 8 (ACR 50, CDAI LDA) onwards (Figure 1).

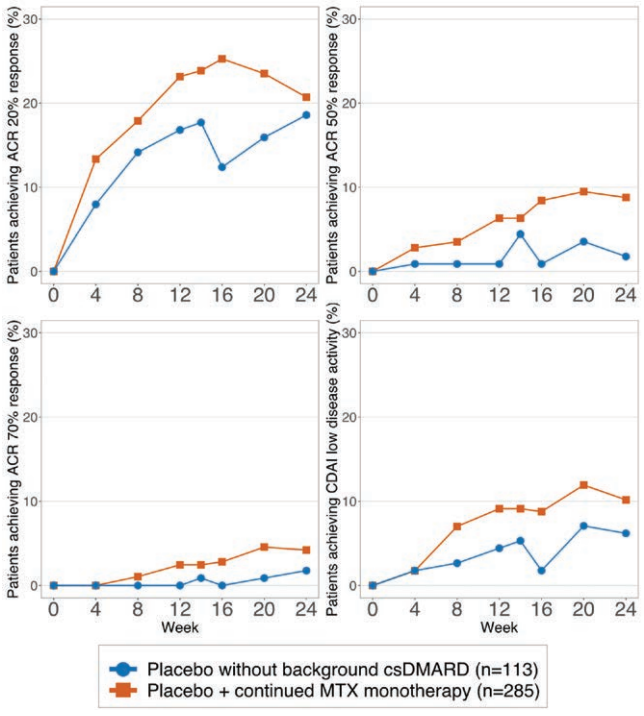

Figure 1. ACR 20/50/70 and CDAI LDA responses of PLC patients with continued MTX vs. PLC patients without csDMARD background therapy.

Conclusion: In patients randomized to placebo therapy, continued MTX background therapy increases clinical responses and achievement of good clinical states. These findings imply that pre-existing and putatively insufficient background therapy should be effectively optimized before enrollment into a clinical trial protocol.

Background: Upadacitinib (UPA) is an oral Janus kinase inhibitor approved for rheumatoid arthritis (RA). The safety and efficacy of UPA has been evaluated across a spectrum of patients (pts) with RA in the phase 3 SELECT clinical program.[1,2]

Objectives: To describe long-term laboratory profiles (cutoff date: June 30, 2020) associated with exposure to UPA, adalimumab (ADA), and methotrexate (MTX) in pts with RA treated in the SELECT trials.

Methods: Data were analyzed from 6 randomized controlled UPA RA trials.[1,2] The proportions of pts experiencing potentially clinically significant laboratory changes at a single time point were summarized for the following groups: pooled UPA 15 mg once daily (QD; UPA15; 6 trials), pooled UPA 30 mg QD (UPA30; 4 trials), ADA 40 mg every other week (EOW; 1 trial), and MTX monotherapy (1 trial). Pts received UPA with/without background conventional synthetic disease-modifying antirheumatic drugs. Treatment-emergent adverse events are reported as exposure-adjusted event rates (events/100 pt-years [E/100 PY]). Toxicity was graded per OMERACT criteria, or NCI CTCAE for creatine phosphokinase (CPK) and creatinine.

Results: 4413 pts received ≥1 dose of UPA (UPA15, n=3209; UPA30, n=1204). Exposures were comparable between treatment groups (Table). Proportions of pts with Grade (Gr) 3 and 4 decreases in hemoglobin were highest with UPA30 and MTX (Table). Rates of anemia, as reported by the investigator, were comparable between UPA15, ADA, and MTX groups (Figure); the frequency of UPA-treated pts who discontinued due to anemia was low in all arms. Gr 3 and 4 decreases in neutrophils and lymphocytes with UPA were dose-dependent and higher vs ADA or MTX. Discontinuations due to neutropenia and lymphopenia were rare (<0.1%). Transaminase elevations were more frequent with UPA and MTX vs ADA; however, the proportion of pts who discontinued due to increases in alanine (ALT) or aspartate aminotransferase (AST) were comparable between UPA15 and ADA, and numerically higher with UPA30 and MTX. CPK elevations were more frequent with UPA (Figure). Most events were asymptomatic, and the 1 case of rhabdomyolysis in the UPA30 group was unrelated to study drug (attributed to influenza).

Table 1. Pts with potentially clinically significant laboratory changes

Conclusion: This long-term analysis of UPA-treated pts with RA showed dose-dependent relationships for several laboratory abnormalities. Incidences of these with UPA15 were typically higher than with ADA but similar to MTX, except for increased CPK elevations. Treatment discontinuations due to laboratory abnormalities were infrequent and similar across all treatment groups.

SLE, Sjögren's and APS - treatment and SLE, Sjögren's and APS - clinical aspects (other than treatment)

OP0129 BELIMUMAB AFTER RITUXIMAB SIGNIFICANTLY REDUCED IGG ANTI-DSDNA ANTIBODY LEVELS AND PROLONGED TIME TO SEVERE FLARE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Shipa[1], A. Embleton-Thirsk[2], M. Parvaz[1], L. Santos Ribeiro[1], P. Muller[2], K. Chowdhury[2], D. Isenberg[1], C. Doré[2], C. Gordon[3], M. Ehrenstein[1]. [1]*University College London, Department of Rheumatology, London, United Kingdom*; [2]*University College London, Comprehensive Clinical Trials Unit, London, United Kingdom*; [3]*University of Birmingham, Rheumatology Research Team - Inflammation and Ageing, Birmingham, United Kingdom*

Background: B cell depletion with rituximab, an anti-CD20 mAb, has shown efficacy for systemic lupus erythematosus (SLE) in open-label studies but failed to meet primary endpoints in two randomised, placebo controlled trials. Rituximab increases BAFF levels which has been associated with subsequent lupus flares. We hypothesised that high BAFF levels after rituximab limit its effectiveness in SLE and that the anti-BAFF monoclonal antibody belimumab given immediately after rituximab could be a valuable therapeutic strategy.

Objectives: To assess the safety and obtain preliminary evidence for efficacy of belimumab following rituximab therapy in patients with SLE.

Methods: BEAT-LUPUS (Belimumab after B cell depletion in SLE) is a 52-week phase IIb, randomised, double-blind, placebo-controlled clinical trial investigating the safety and efficacy of intravenous belimumab after B cell depletion therapy (rituximab). The maximum permissible prednisolone dose throughout the trial was 20mg/day with encouragement to reduce by 50% from baseline by 6 months. The primary outcome measure was log IgG anti-dsDNA antibody serum levels at 52 weeks measured by ELISA. A linear regression ANCOVA model was fitted to evaluate the difference in 52-week anti-dsDNA levels between treatment arms adjusting for anti-dsDNA value at screening (before rituximab) and randomisation (4-8 weeks after the 1st infusion of rituximab), CD19 > or < $0.01x10^9$/l at randomisation, and renal involvement at screen. Secondary outcomes included measures of disease activity and incidence of adverse events. B cell (CD19) counts were measured by flow cytometry. Intention to treat analysis was adopted. Full ethical and regulatory approval was obtained. A comprehensive description of the protocol and statistical analysis plan is available[1,2].

Results: 52 patients with active SLE received rituximab (2 infusions, 2 weeks apart) and then randomised to receive either belimumab (n=26) or placebo (n=26) 4-8 weeks after their 1st dose of rituximab. 32 patients completed trial treatment protocol (belimumab or placebo) through to 52 weeks, withdrawals were equally split between belimumab and placebo. There was a significant reduction in IgG anti-dsDNA antibody levels in patients treated with belimumab compared to placebo at 52 weeks (p<0.001, Figure 1); 43 patients were included in the intention to treat analysis at 52 weeks.

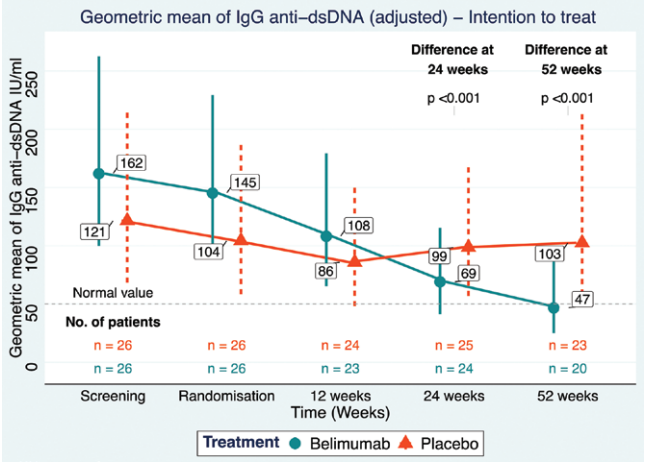

Figure 1. Serum IgG anti-dsDNA antibody levels (geometric means with 95% confidence intervals) in patients treated with rituximab, then randomised to belimumab or placebo at 1st trial infusion. An intention to treat linear regression ANCOVA model was fitted to evaluate the difference in 52-week anti-dsDNA between belimumab or placebo adjusting for baseline values and stratification factors. N= patient numbers who provided serum samples at time indicated.

Kaplan-Meier curves demonstrated that belimumab reduced the risk of severe flare (BILAG A flare) compared to placebo (hazard ratio 0.27, 95% confidence interval 0.07-0.97, unadjusted log-rank p=0.03). There were 10 and 3 severe flares in the placebo and belimumab group respectively. There was no difference in cumulative steroid dose over the course of the trial between belimumab and placebo.

Belimumab did not increase the incidence of infections, serious or total adverse events, nor withdrawals due to adverse events compared to placebo. Belimumab significantly suppressed B cell repopulation at 52 weeks compared to placebo (p=0.001), but not total serum IgG.

Conclusion: This placebo controlled double blind trial met its primary endpoint, a significant reduction in IgG anti-dsDNA antibody levels, and demonstrated that belimumab prolongs the time to severe flare compared to placebo. These results suggest that belimumab after rituximab is a safe and effective treatment for patients with SLE and supports further development of this combination as a novel therapeutic strategy.

Background: Several large randomised controlled trials (RCTs) in primary Sjögren's syndrome (pSS) failed to demonstrate drug efficacy.[1-4] Many of these trials used ESSDAI as primary endpoint, showing large but similar response rates in active treatment and placebo groups.[1,3,4] Given the heterogeneous nature of pSS, there is need for a composite endpoint including multiple clinically relevant parameters.

Objectives: To develop and validate the Composite of Relevant Endpoints in Sjögren's Syndrome (CRESS).

Methods: A multidisciplinary team of pSS experts selected clinically relevant items and measurements to include in the CRESS. Definition of response of CRESS items was based on clinical relevance, previously defined minimal clinically important improvement (MCII) and data of the single-centre ASAP-III (abatacept) trial.[1] CRESS was validated in three independent RCTs: TRACTISS (rituximab) trial[2],

multi-centre abatacept trial[3] and ETAP (tocilizumab) trial[4]. CRESS response rates were assessed at the primary endpoint visit of all four trials.

Results: Five complementary items were selected to form CRESS: systemic disease activity, patient-reported symptoms, tear gland, salivary gland and serological item. Definition of response per item is presented in Table 1. Total CRESS response was defined as response on ≥3 of 5 items. Since not all trials have ocular staining score or salivary gland ultrasonography (SGUS) available, the concise CRESS (cCRESS) was developed simultaneously, leaving Schirmer's test and unstimulated whole saliva flow for the tear and salivary gland items, respectively. In the ASAP-III trial, CRESS response rates were 24/40 (60%) for abatacept vs. 7/39 (18%) for placebo at week 24 (p<0.001).

Table 1. CRESS items and definition of response

Items	*Measurements*	*Definition of response*
Systemic disease activity	ClinESSDAI	Score<5 (low disease activity)
Patient-reported symptoms	ESSPRI	Decrease of ≥1 point or ≥15%
Tear gland*	Schirmer/OSS**	-If abnormal Schirmer (≤5 mm) at baseline: increase of ≥5 mm in Schirmer -Or if abnormal OSS (≥3 points) at baseline: decrease ≥2 points in OSS -Or if both Schirmer/OSS normal scores at baseline: no change to abnormal in both
Salivary gland*	UWS/SGUS	Increase of ≥25% in UWS (or if score is 0 at baseline, any increase) Or decrease of ≥25% in total Hocevar score (SGUS)
Serological	RF/IgG	Decrease of ≥25% in RF Or decrease of ≥10% in IgG
CRESS responder	**Responder on ≥3 of 5 items**	

Ocular Staining Score (OSS), Unstimulated whole salivary flow (UWS), Salivary gland ultrasonography (SGUS), Rheumatoid factor (RF), Immunoglobuline G (IgG)***Concise CRESS (cCRESS):** CRESS without OSS and SGUS, leaving Schirmer and UWS for tear and salivary gland items, respectively**Mean of both eyes

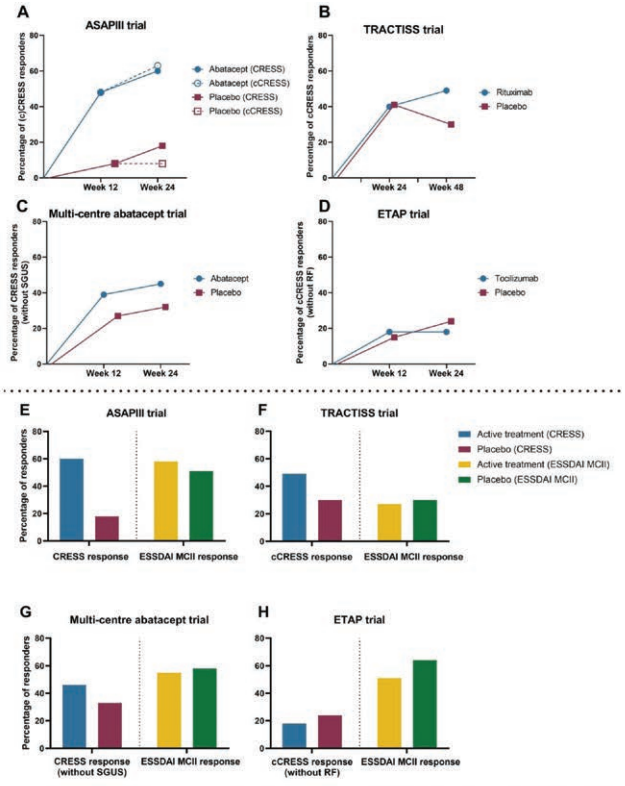

Figure 1 A. CRESS and cCRESS (=CRESS without OSS and SGUS) response rates in ASAP-III trial at week 12 and 24. At week 12, only CRESS without SGUS was available **B.** cCRESS response rates in TRACTISS (rituximab) trial at week 24 and 48 **C.** CRESS without SGUS response rates in multi-centre abatacept trial at week 12 and 24. **D.** cCRESS without rheumatoid factor response rates in ETAP (tocilizumab) trial at week 12 and 24. **E.** CRESS response rates vs. ESSDAI MCII response rates in ASAP-III trial at week 24. Median baseline ESSDAI scores for abatacept were 14.0 (IQR 9.0-16.8), for placebo 13.0 (IQR 8.0-18.0) **F.** cCRESS response rates vs. ESSDAI MCII response rates in TRACTISS trial at week 48. Mean baseline ESSDAI scores for rituximab were 5.3, SD±4.7, for placebo 6.0, SD±4.3 **G.** CRESS without SGUS response rates vs. ESSDAI MCII response rates in multi-centre abatacept trial at week 24. Mean baseline ESSDAI scores for abatacept were 8.7, SD±3.4, for placebo 10.1, SD±5.0 **H.** cCRESS without RF response rates vs. ESSDAI MCII response rates in ETAP trial at week 24. Median baseline ESSDAI scores for tocilizumab were 11.0 (IQR 8.0-13.5), for placebo 10.0 (IQR 8.0-14.8). For all trials, ESSDAI response percentages were calculated imputing missing patients as non-responders.

In the external validation trials, cCRESS response rates for TRACTISS were: 33/67 (49%) rituximab vs. 20/66 (30%) placebo at week 48 (p=0.026). CRESS response rates (without SGUS) for the multi-centre abatacept trial were: 41/92 (45%) abatacept vs. 30/95 (32%) placebo at week 24 (p=0.067). cCRESS response rates (without rheumatoid factor) for ETAP were: 10/55 (18%) tocilizumab vs. 13/55 (24%) placebo at week 24 (p=0.482) (Figure 1A-D). Compared to ESSDAI MCII of ≥3 points decrease, CRESS was able to approximately halve placebo response rates in RCTs with high baseline ESSDAI scores (>5) (Figures 1E-H).

Conclusion: CRESS shows lower placebo response rates compared to ESSDAI MCII, which is crucial for demonstrating treatment efficacy. With the CRESS, higher response rates in abatacept and rituximab treated patients compared to placebo were found in RCTs which previously showed negative primary endpoint results. CRESS confirmed that no differences were found for almost all outcome measures between tocilizumab and placebo,[4] with low response rates. The CRESS is a well-balanced, feasible, composite endpoint for use in clinical trials in pSS patients.

OP0131

ANIFROLUMAB EFFECTS ON RASH AND ARTHRITIS IN PATIENTS WITH SLE AND IMPACT OF INTERFERON SIGNAL IN POOLED DATA FROM PHASE 3 TRIALS

J. T. Merrill[1], V. Werth[2], R. Furie[3], E. F. Morand[4], J. M. Kahlenberg[5], G. Abreu[6], R. Tummala[7]. *[1]Oklahoma Medical Research Foundation, Arthritis & Clinical Immunology Research Program, Oklahoma City, United States of America*; *[2]University of Pennsylvania and Corporal Michael J. Crescenz Veterans Administration Hospital, Dermatology, Philadelphia, United States of America*; *[3]Zucker School of Medicine at Hofstra/Northwell, Division of Rheumatology, Great Neck, United States of America*; *[4]Monash University, Centre for Inflammatory Disease Monash Health, Melbourne, United States of America*; *[5]University of Michigan, Division of Rheumatology, Ann Arbor, United States of America*; *[6]AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden*; *[7]AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, United States of America*

Background: Treatment with the type I interferon (IFN) receptor antibody anifrolumab was associated with clinical improvements in mucocutaneous and musculoskeletal disease activity in patients with systemic lupus erythematosus (SLE) in the phase 2 MUSE trial (NCT01438489) and phase 3 TULIP trials.[1–4] Because rash and arthritis are the most common manifestations of SLE, the effect of anifrolumab on these symptoms can be examined in biomarker-defined subsets, as previously reported for the MUSE trial.[2]

Objectives: To evaluate the effect of anifrolumab on rash and arthritis in patients with SLE, and the impact of IFN gene signature (IFNGS) on treatment response, using disease measures of different stringency in pooled data from the phase 3 TULIP trials.

Methods: TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) were placebo-controlled, 52-week trials of intravenous anifrolumab administered every 4 weeks in patients with moderate to severe SLE.[3,4] In this post hoc analysis, outcomes of rash and arthritis were evaluated using mucocutaneous and musculoskeletal domains of the SLE Disease Activity Index 2000 (SLEDAI-2K) and the

British Isles Lupus Assessment Group (BILAG) index. In addition, the modified Cutaneous Lupus Erythematosus Disease Area and Severity Index (mCLASI) score was used to evaluate rash, and tender and swollen joint counts were used to assess arthritis.

Results: 360 patients received anifrolumab 300 mg (IFNGS test–high, n=298; IFNGS test–low, n=62) and 366 patients were given placebo (IFNGS test–high, n=302; IFNGS test–low, n=64). Change from baseline to Week 52 compared with placebo was measured by outcomes, ordered by their stringency. More anifrolumab-treated patients achieved rash improvement using SLEDAI-2K (complete resolution: difference 13.5%, nominal *P*<0.001), BILAG (at least 1 severity grade lowering: difference 15.5%, nominal *P*<0.001), and mCLASI (≥50% improvement, if baseline score >0: difference 15.6%, nominal *P*<0.001). Results were comparable in the IFNGS test–high subset (SLEDAI-2K: difference 17.0%, nominal *P*<0.001, BILAG: difference 16.1%, nominal *P*<0.001; mCLASI: difference 18.1%, nominal *P*<0.001). There was a trend toward anifrolumab-associated rash improvement in IFNGS test–low patients using BILAG (Figure). More patients receiving anifrolumab had SLEDAI-2K–defined resolution in arthritis (difference 8.2%, nominal *P*=0.029), BILAG severity lessening (difference 11.8%, nominal *P*=0.002), and ≥50% decrease in tender/swollen joint counts, when ≥6 at baseline (difference 12.6%, nominal *P*=0.016). Results were comparable in the IFNGS test–high subset (SLEDAI-2K: difference 11.7%, nominal *P*=0.005; BILAG: difference 12.9%, nominal *P*=0.003; joint counts: difference 11.3%, nominal *P*=0.054). In IFNGS test–low patients, there was a trend toward anifrolumab-associated arthritis improvement when measured using BILAG, and the effect of anifrolumab on the number of swollen/tender joint counts was similar to the IFNGS test–high group, although the IFNGS test–low sample size in this analysis was very small (Figure).

Conclusion: In pooled data from the TULIP trials, anifrolumab treatment was associated with improvements in rash and arthritis using measures of different stringency. The SLEDAI-2K findings were largely driven by the subset of patients who were IFNGS test–high. However, using measures that were more sensitive to change, despite small sample sizes, IFNGS test–low patients may also have benefit.

OP0132 EFFECT OF IBERDOMIDE ON CUTANEOUS MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF A 24-WEEK, PLACEBO-CONTROLLED, PHASE 2 STUDY

V. Werth[1], J. Merrill[2], R. Furie[3], T. Dörner[4], R. Van Vollenhoven[5], P. Lipsky[6], M. Weiswasser[7], S. Korish[7], P. Schafer[8], M. Stern[9], Z. Liu[10], S. Tang[11], N. Delev[7]. [1]*University of Pennsylvania, Michael J. Crescenz VA Medical Center, Philadelphia, United States of America*; [2]*Oklahoma Medical Research Foundation, University of Oklahoma Health Sciences Center, Oklahoma City, United States of America*; [3]*Northwell Health, Rheumatology, Great Neck, United States of America*; [4]*DRFZ and Charité University Hospitals, Rheumatology and Hemostaseology, Berlin, Germany*; [5]*Amsterdam University Medical Centers, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands*; [6]*RILITE Foundation, President, Charlottesville, United States of America*; [7]*Bristol Myers Squibb, Clinical R&D, Princeton, United States of America*; [8]*Bristol Myers Squibb, Translational Medicine, Princeton, United States of America*; [9]*Bristol Myers Squibb, Translational Development & Diagnostics, Princeton, United States of America*; [10]*Bristol Myers Squibb, Biometrics, Princeton, United States of America*; [11]*Bristol Myers Squibb, Translational Bioinformatics, Princeton, United States of America*

Background: Iberdomide is a high-affinity cereblon ligand that promotes proteasomal degradation of Ikaros (*IKZF1*) and Aiolos (*IKZF3*), transcription factors involved in innate and adaptive immune cell development and homeostasis, and linked to the genetic risk for systemic lupus erythematosus (SLE). A phase 2, placebo-controlled study evaluated the efficacy and safety of iberdomide in patients (pts) with moderate to severe SLE.

Objectives: To examine the effect of iberdomide on cutaneous manifestations in SLE pts.

Methods: Adult autoantibody-positive SLE pts with a SLE Disease Activity Index 2000 (SLEDAI 2K) score ≥6 were randomized (2:2:1:2) to oral iberdomide (0.45, 0.3, 0.15 mg) or placebo once daily (QD) for 24 weeks while continuing standard background lupus medications. The Cutaneous Lupus Area and Severity Index Activity score (CLASI-A) was assessed every 4 weeks through week 24. As prespecified, exploratory analyses, change from baseline and the proportion of pts who achieved ≥50% reduction from baseline (CLASI-50) were evaluated for all pts, pts with baseline CLASI-A ≥8, and by cutaneous lupus subtypes (acute [ACLE], subacute [SCLE], chronic [CCLE]). CLASI-A outcomes were also evaluated post hoc for subgroups with high baseline expression of *IKZF3* or the type 1 interferon (IFN) gene signatures in the blood.

Results: Of 288 randomized pts, the mean and median (range) baseline CLASI-A scores were 6.9 and 5.0 (0-49), with 28% of pts having a score ≥8. 56% of pts had ACLE, 29% CCLE, and 16% SCLE. CLASI-50 responses were not significantly different comparing iberdomide to placebo in all pts and pts with baseline CLASI-A ≥8 at week 24, where high placebo response rates were observed (Table). Numerically greater mean improvement from baseline in CLASI-A scores in pts with baseline CLASI-A ≥8 was observed for iberdomide 0.45 mg vs placebo beginning at week 4, with continuous improvement through week 24. For pts with SCLE or CCLE, CLASI-50 response rates were significantly higher with iberdomide 0.45 mg vs placebo (*P*<0.04; Table). SCLE pts had significantly greater mean change and median percent improvement in CLASI-A from baseline with iberdomide 0.45 mg vs placebo at week 24 (*P*<0.03). Treatment differences in CLASI-A between iberdomide 0.45 mg and placebo were larger for SCLE and CCLE subgroups with high baseline *IKZF3* or type 1 IFN gene signatures, with statistical significance achieved for SCLE pts but not CCLE pts (Figure).

Conclusion: Iberdomide showed beneficial effects on skin manifestations in pts with SLE. Efficacy appears to be more pronounced in pts with SCLE and CCLE skin subtypes, and in pts with high *IKZF3* or IFN gene expression signatures.

OP0133

THE PREVALENCE AND RISK FACTORS OF RETINAL TOXICITY ASSOCIATED WITH LONG-TERM HYDROXYCHLOROQUINE USE

S. Do[1], J. H. Du[2], J. X. An[3], J. Wang[4], A. Lin[5]. *[1]Western University of Health Sciences, School of Pharmacy, Pomona, United States of America*; *[2]Kaiser Permanente Fontana Medical Center, Department of Pharmacy, Fontana, United States of America*; *[3]Kaiser Permanente Research & Evaluation, Department of Research and Evaluation, Pasadena, United States of America*; *[4]Kaiser Permanente Fontana Medical Center, Department of Ophthalmology, Fontana, United States of America*; *[5]Kaiser Permanente Southern California, Department of Rheumatology, Fontana, United States of America*

Background: Hydroxychloroquine (HCQ) is commonly used for the treatment of various autoimmune diseases. The medication is generally well-tolerated. However, long-term use after 5 years may increase the risk of retinopathy. One study in 2014 has demonstrated the risk can be as high as 7.5%. Optical Coherence Tomography (OCT) has become a major modality in screening retinopathy.

Objectives: To evaluate the prevalence of retinal toxicity among patients using hydroxychloroquine and to determine various risk factors associated with hydroxychloroquine-associated retinal toxicity.

Methods: We performed a retrospective chart review on a cohort of adult patients with long-term use (≥ 5 years cumulative) of HCQ between January 1st, 2011 to December 31st, 2018 from the Kaiser Permanente San Bernardino County and Riverside medical center areas in Southern California, USA. Patients were excluded if they had previously been diagnosed with retinopathy prior to hydroxychloroquine use, were deceased, or had incomplete OCT exam. Our primary endpoint was the prevalence of patients who developed retinal toxicity detected by OCT, and later confirmed by retinal specialist. Potential risk factors (age, duration of therapy, daily consumption per actual body weight, cumulative dose, confounding diseases and medication) for developing retinopathy were also evaluated. Univariable and multivariable logistic regression analyses were used to determine risk factors associated with retinal toxicity.

Results: Among 676 patients exposed to more than 5 years of HCQ, the overall prevalence of retinal toxicity was 6.8%, and ranged from 2.5% to 22.2% depending on the age, weight-based dosing, duration of use and cumulative dose. Duration of therapy for 10 years or more increased risk of retinopathy by approximately 5 to 19 folds. Similarly, weight-based dose of 7 mg/kg/day or greater was asscciated with increased risk of retinopathy by approximately 5 times. Patients with cumulative dose of 2000 grams or more had greater than 15 times higher risk of developing retinopathy. Duration of use for10 years or more (odd ratio 4.32, 95% CI 1.99 – 12.49), age (odd ratio 1.04; 95% CI 1.01 - 1.08), cumulative dose of more than 1500 g (odd ratio 7.4; 95% CI 1.40 – 39.04) and atherosclerosis of the aorta (odd ratio 2.59; 95% CI, 1.24 – 5.41) correlated with higher risk of retinal toxicity.

Table 2. Hydroxychloroquine Treatment Exposure

	No Retinal Toxicity (N=630)		Retinal Toxicity (N=46)		
	Mean	Std Dev	Mean	Std Dev	p-value
Dose per day (mg)	326.6	96.2	337	92.8	0.479
Dose per kg/day	**4.3**	**1.4**	**4.9**	**1.7**	**0.003**
Duration of use					
Months	**99.3**	**33.4**	**141.5**	**64.5**	**< 0.0001**
Years	**8.3**	**2.8**	**11.8**	**5.4**	**< 0.0001**
Cumulative dose (mg)	**983.2**	**445.2**	**1483.6**	**891.5**	**< 0.0001**

Conclusion: The overall prevalence of retinopathy was 6.8%. Regular OCT screening, especially in patients with hydroxychloroquine use for more than 10 years, daily intake > 7 mg/kg, or cumulative dose > 1500 grams is important in detecting hydroxychloroquine-associated retinal toxicity

OP0134 NOVEL INTERFERON GENE EXPRESSION SCORES PREDICT REFRACTORY SEVERE CUTANEOUS DISEASE FOLLOWING RITUXIMAB THERAPY IN SLE

L. M. Carter[1], A. Alase2, Z. Wigston2, A. Psarras2, A. Burska2, M. Y. MD Yusof2, E. Hensor2, J. Reynolds[3], M. Wittmann2, I. N. Bruce[4], E. Vital2on behalf of The MASTERPLANS Consortium. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[3]University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom*; *[4]University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom*

Background: We developed and validated two continuous interferon-stimulated gene (ISG) expression scores (IFN-Score-A and IFN-Score-B) that predict clinical outcomes in SLE. IFN-Score-A includes ISGs typically present in a global interferon signature while IFN-Score-B includes additional ISGs potentially responsive to multiple IFN subtypes [1].
We have previously shown that these scores associate with treatment response following rituximab (RTX) therapy within the British Isles Lupus Assessment Group (BILAG) Biologics Register (BILAG-BR), a UK wide study of patients treated with RTX for active SLE following cyclophosphamide and/ or mycophenolate mofetil treatment failure. Specifically, multivariable analysis showed higher baseline IFN-Score-B independently predicted BILAG response at 6 months post treatment [2]. We also showed that response of cutaneous lupus to RTX can be poor even when other organs respond well, and that interferons are enriched in the skin of patients with SLE where dysregulated keratinocytes are a source of IFNκ [3]. MASTERPLANS is a consortium aimed at identifying therapeutic biomarkers in SLE.
Objectives: To investigate how IFN-Score-A and -B associated with skin disease and response to RTX.
Methods: Pre-treatment whole blood samples were collected in TEMPUS tubes from subjects undergoing first RTX treatment within BILAG-BR. IFN-Scores were derived using a custom Taqman array as previously described [1]. Clinical response was defined as improvement in BILAG-2004 disease activity, with a maximum of one domain showing persistent BILAG-2004 grade B disease, and no new BILAG grade A or B disease flares at 6 months. The mucocutaneous domain of BILAG was then analysed separately.
Results: 147 patients were studied, of whom 90 had follow up data available. Baseline BILAG-2004 grade A/B disease activity predominantly affected the mucocutaneous domain in 74/147 (50.3%), musculoskeletal in 61 /147 (41.5%) and renal domain 66/147 (37.4%).
At 6 months 59/90 (65.6%) achieved an overall treatment response. Responders showed significantly higher mean IFN-Score-B compared with non-responders (-1.8 vs -2.4, p = 0.04). Among those with active grade A/B BILAG-2004 mucocutaneous disease at baseline, 38/50 (76%) showed improvement within this domain at 6 months. However, among overall non-responders, 7/31 (22.6%) had new or residual BILAG-A mucocutaneous disease at 6 months post RTX, indicating it to be a substantial component of overall treatment failure. In contrast, persistent grade A musculoskeletal disease was seen in 9.7% of non-responders. BILAG-A mucocutaneous disease is characterised by severe manifestations including extensive rashes covering > 18% of body surface area, severe bullous lupus or panniculitis and disabling deep mucosal ulceration. Neither IFN-Score-A nor IFN-Score-B were significantly associated with the severity of mucocutaneous disease at baseline. However, individuals with persistent or new BILAG-A mucocutaneous disease at six months following RTX displayed significantly lower baseline IFN-Score-B than those with improving or residual less severe disease (-3.0 vs -2.1, p = 0.04) after RTX.
Conclusion: Low IFN score-B status identified an endotype of severe mucocutaneous SLE which was resistant to RTX therapy in the BILAG-BR cohort. We previously showed that high IFN-score-B independently predicts overall therapeutic response to rituximab. Further work will aim to refine IFN status as overall and organ specific biomarkers in SLE.

Background: B-lymphocyte stimulator (BLyS) is increased in primary Sjögren's syndrome (pSS) and plays a role in the B-cell hyperactivity thought to contribute to pSS. Belimumab (BEL, anti-BLyS) and rituximab (RTX, anti-CD20) target B cells through distinct and potentially complementary mechanisms.
Objectives: To evaluate the safety and efficacy of subcutaneous (SC) BEL/intravenous (IV) RTX combination (BEL/RTX) in patients with pSS.
Methods: This Phase 2, double-blind study (GSK Study 201842; NCT02631538) randomised 86 adults with active pSS to 4 treatment arms stratified for baseline EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) scores 5-12 or >12: placebo (PBO; N=13), BEL/RTX (N=24; BEL 200 mg SC weekly to Week [Wk] 24 followed by weekly PBO SC to Wk 52 + RTX 1000 mg IV, Wk 8 + 10), BEL monotherapy (N=24; BEL 200 mg SC weekly to Wk 52) or RTX monotherapy (N=25; RTX 1000 mg IV, Wk 8 + 10). Follow-up was at Wk 68. Safety to Wk 68 was the primary endpoint (safety population; patients received ≥1 dose of study treatment). Secondary/other endpoints (completer population; patients completed treatment and follow-up phase) were ESSDAI score, stimulated salivary flow, CD20+ B-cell count within salivary gland biopsies, patient-reported oral dryness, and EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) score.
Results: Baseline demographics and disease characteristics were similar among arms. Adverse events (AEs) were balanced across arms. Serious AEs were infrequent but occurred only in active treatment arms (Table). No unexpected safety issues were identified with BEL/RTX relative to BEL or RTX. Treatment phase and follow-up were completed by 60/86 patients. ESSDAI reductions with BEL/RTX were numerically greater over time than PBO, with greatest difference at Wk 68 (Table), but were not differentiated from monotherapy. Stimulated salivary flow showed a trend favouring BEL/RTX vs PBO over later time points (Table). In contrast with PBO, BEL, and RTX, salivary gland biopsies from BEL/RTX showed almost complete B-cell depletion (Wk 24). There was no clear evidence for a positive effect of BEL/RTX on patient-reported oral dryness or ESSPRI score.

Table 1. Key safety endpoints and selected efficacy endpoints

RITUXIMAB PREVENTS THE PROGRESSION OF B-CELL DRIVEN INFLAMMATORY INFILTRATE IN THE MINOR SALIVARY GLANDS OF PRIMARY SJOGREN'S SYNDROME BY DOWNREGULATING IMMUNOLOGICAL PATHWAYS KEY IN ECTOPIC GERMINAL CENTRE ORGANIZATION: RESULTS FROM THE TRACTISS TRIAL

E. Pontarini[1], F. Chowdhury[1,2], E. Sciacca[1], S. Grigoriadou[1], F. Rivellese[1], D. Lucchesi[1], K. Goldmann[1], L. Fossati-Jimack[1], P. Emery[3], W. F. Ng[4], N. Sutcliffe[5], C. Everett[6], C. Fernandez[6], A. Tappuni[2,5], M. Lewis[1], C. Pitzalis[1], S. J. Bowman[7], M. Bombardieri[1]. *[1]William Harvey Research Institute, Queen Mary University of London, Experimental Medicine and Rheumatology, London, United Kingdom*; *[2]Institute of Dentistry, Queen Mary University of London, Oral Immunobiology and Regenerative Medicine, London, United Kingdom*; *[3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Chapel Allerton Hospital, Leeds, United Kingdom*; *[4]Translational and Clinical Research Institute, Newcastle University, Newcastle-upon-Tyne, Newcastle, United Kingdom*; *[5]Royal London Hospital, Bart's Health NHS Trust, Rheumatology department, London, United Kingdom*; *[6]Leeds Institute for Clinical Trials Research, University of Leeds, Clinical Trials Research Unit, Leeds, United Kingdom*; *[7] University Hospitals Birmingham NHS Foundation Trust, Rheumatology Department, Birmingham, United Kingdom*

Background: The pathogenic role of B-cells in primary Sjögren's Syndrome (pSS) is well established and B cell abnormalities. Because of the substantial role of B-cells, rituximab (RTX), a chimeric anti-CD20 monoclonal antibody, has been considered as a potential biologic disease modifying drug to reduce disease activity in pSS. To date, the TRial for Anti-B-Cell Therapy In patients with pSS (TRACTISS) is the largest multi-centre, placebo-controlled trial with RTX. Despite the unmet primary endpoints (30% reduction in fatigue or oral dryness, measured by visual analogue scale), RTX treated patients showed an improvement in unstimulated whole salivary flow (Bowman et al. Arthritis Rheumatol 2017;69:1440–1450).
Objectives: To provide the first longitudinal transcriptomic and histological analysis at 3 time points over 48 weeks of labial SGs of pSS patients treated with RTX, in comparison to placebo, from the TRACTISS cohort.
Methods: 26 pSS patients randomised to RTX or placebo arm consented for labial SG biopsies at baseline, weeks 16 and 48. Patients received two 1000mg cycles of RTX or placebo at baseline and week 24. SG focus score, inflammatory aggregate area fraction, B-cells (CD20+), T-cells (CD3+), follicular dendritic cells (FDCs) (CD21+) and plasma cells (CD138+) density were assessed by H&E and immunofluorescence staining. The histological analysis was performed by digital imaging using QuPath software. RNA was extracted from matched labial SG lobules and sequenced with Illumina platform. A Principal Component Analysis (PCA) and features driving the PCA were investigated along with the most influential gene loadings. The limma-voom R pipeline was used to extract Differential Expressed Genes (DEGs) between placebo and RTX group at week 48, and gene ontology (GO) enrichment analysis performed through EnrichR to derive GO terms and pathways associated with DEGs.
Results: Placebo-treated labial SGs showed a worsening of inflammation highlighted by the increment of B-cell density, development of new FDC networks, and a higher ectopic GC prevalence at week 48, compared to RTX-treated patients. No difference in total T-cells and plasma cell infiltration was observed. RTX downregulated genes involved in immune cell recruitment and inflammatory aggregate organisation (e.g. CCR7, CCL19, CD52, and PDCD1) and gene signature-based analysis of 64 immune cell types highlighted how RTX preferentially blocked class-switched- and memory-B-cells infiltration in SGs at week 48. Pathway analyses confirmed the downregulation of leukocyte migration, MHC class II antigen presentation, and T-cell co-stimulation immunological pathways, such as the CD40 receptor complex pathway. The analysis of placebo SGs transcriptomic at week 48 showed a higher expression of genes linked to ectopic GC organisation, such as CXCL13, CCL19, LTβ, in female compared to male subjects. Gender was confirmed as a key co-variate responsible for most of the variation in the PCA, together with the SG focus score and the *foci* area fraction.
Conclusion: Treatment with RTX showed beneficial effects on labial SG inflammatory infiltration in pSS, by downregulating genes involved in immune cell recruitment, activation and organisation in ectopic GCs. Class-switched-B-cells, memory-B-cells and FDC network development were primarily affected appearing to be responsible for the lack of progression in SG B cell infiltration in the RTX compared to the placebo arm in which clear worsening of SG immunopathology over 48 weeks was detected in female patients. Although a clear association with the clinical improvement in unstimulated salivary flow observed at week 48 in

RTX-treated patients could not be established given the low number of patients consenting to 3 longitudinal biopsies it is conceivable that RTX is responsible for preserving exocrine function.

Spondyloarthritis - treatment

OP0137 TUMOR NECROSIS FACTOR INHIBITORS SHOW A DELAYED EFFECT ON RADIOGRAPHIC SACROILIITIS PROGRESSION IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS: 10-YEAR RESULTS FROM THE GERMAN SPONDYLOARTHRITIS INCEPTION COHORT

M. Torgutalp[1], V. Rios Rodriguez[1], M. Verba[1], M. Protopopov[1], F. Proft[1], J. Rademacher[1,2], H. Haibel[1], M. Rudwaleit[3], J. Sieper[1], D. Poddubnyy[1,4]. [1]*Charité – Universitätsmedizin Berlin, Division of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*; [2]*Berlin Institute of Health,., Berlin, Germany*; [3]*Klinikum Bielefeld, Department of Internal Medicine and Rheumatology, Bielefeld, Germany*; [4]*Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), Epidemiology Unit, Berlin, Germany*

Background: Observational cohort studies have shown that there is low, but still detectable progression level in radiographic sacroiliitis, which might also have an impact on the function in patients with axial spondyloarthritis (axSpA). Recent data showed that tumor necrosis factor inhibitors (TNFi) might retard spinal progression when initiated earlier and taken longer in patients with axSpA. However, the question of whether they also have such an effect on radiographic progression in sacroiliac joints (SIJs) is still unclear.

Objectives: To investigate the longitudinal association between radiographic sacroiliitis progression and treatment with TNFi in patients with early axial SpA in a long-term inception cohort.

Methods: Based on the availability of at least two sets of SIJ radiographs, 301 patients (166 with nr-axSpA, symptom duration ≤5 years and 135 with r-axSpA, symptom duration ≤10 years) from the German Spondyloarthritis Inception Cohort (GESPIC) were included in this analysis. These patients contributed with a total of 737 2-year radiographic intervals. Two trained and calibrated central readers scored the radiographs according to the modified New York criteria. If both scored an image as definite radiographic sacroiliitis, the patient was classified as having r-axSpA. The sacroiliac sum score was calculated as a mean of both readers. The association between previous as well as current TNFi use and radiographic sacroiliitis progression, which was defined as the change in the sacroiliitis sum score over 2 years, was analysed using longitudinal generalized estimating equations (GEE) analysis.

Results: At baseline, 9 (3.0%) patients were treated with a TNFi, and 87 (28.9%) patients received at least one TNFi during the entire follow-up period. A total of 141 of the radiographic intervals were covered with TNFi of any duration, while 109 of them were covered with a TNFi of at least 12 months. While receiving ≥12 months TNFi in the previous interval was associated with a lower progression of the sacroiliitis sum score compared to not receiving TNFi in the previous interval, this was not the case in patients who received TNFi ≥12 months in the current 2-year interval (Figure 1). The significant association between TNF ≥12 months in the previous interval and progression in the sacroiliitis sum score were confirmed in the adjusted multivariable longitudinal GEE analysis. In addition, a similar trend for the beneficial effects was observed in different models, which included other treatment definitions with TNFi in the previous 2-year interval (Table).

Conclusion: Treatment with TNFi was associated with retardation of radiographic sacroiliitis progression in patients with axSpA. This effect becomes evident between 2 and 4 years after treatment initiation.

Figure. A) Cumulative probability plot of the 2-year progression in the sacroiliitis sum score, stratified by receiving at least 12 months TNFi in the previous and current 2-year radiographic intervals. **B)** The change in sacroiliitis sum scores over two years in patients with axial spondyloarthritis treated vs non-treated with TNFi at least 12 months in the previous and current 2-year radiographic intervals.

OP0138 FEASIBILITY OF PROGRESSIVE ANTI-TNF TAPERING IN AXIAL SPONDYLOARTHRITIS PATIENTS IN LOW DISEASE ACTIVITY: RESULTS FROM THE MULTICENTER NON-INFERIORITY PROSPECTIVE RANDOMIZED CONTROLLED TRIAL SPACING

C. Lukas[1,2], A. Tournadre[3], M. C. Picot[4], E. Nogué[4], E. Dernis[5], P. Goupille[6,7], B. Combe[2], J. Morel[2]. [1]*University Montpellier, IDESP, Montpellier, France*;

Background: Anti-TNF treatments (TNFi) have shown high efficacy in axial spondyloarthritis (ax-SpA) with inadequate response to non-steroidal anti-inflammatory drugs (NSAIDs). However their effect remains predominantly symptomatic, and their long-term tolerance as well as significant societal cost justify investigation about a potential reduction in drug dosage, or –most feasible and comfortable for the patient– increase in intervals between doses.
Objectives: To assess if a progressive and monitored reduction of administered TNFi by increase of intervals between injections results in a comparable proportion of patients remaining after 12 months (m) in low disease activity state despite a decreased cumulative treatment dose received.
Methods: Non-inferiority randomized controlled trial, having included adult patients with ax-SpA fulfilling ASAS criteria, already treated by anti-TNF, and in stable low disease activity for at least 6 m (current and at least 6 m old BASDAI<4/10), who were randomized into 2 groups: either keeping on their usual treatment with stable doses ("unchanged" group), or progressive spacing of injections of their treatment ("spacing" group). Follow-up was done every 3 m during 12 m, with regular monitoring of disease activity and, in patients from the group "spacing", modification of the rhythm of injections according to disease activity and predefined standardized protocol (either increase or decrease (step-back) of intervals between injections). The primary endpoint was the difference of proportions of patients having a low disease activity state (BASDAI<4/10) after 12 m of follow-up between the 2 groups. It was estimated on the ITT population after multiple imputation. The 90% confidence interval associated was calculated using the Farrington-Manning method and the lower bound was compared to the non-inferiority margin of -20%. With an expected proportion of 85% patients remaining in low disease activity in the unchanged group, and α and β risks at respectively 5% and 90%, the required number of patients was calculated at 358, and thus 398 had to be included with a 10% expected proportion of patients with unavailable data.
Results: 398 patients were randomized in 23 French rheumatology units (197 and 201 in the spacing and unchanged groups respectively), and 389 included in analyses (9 did not receive the allocated treatment). Mean (SD) age was 44.3 (12.4) years, 71.2% were males. Mean (SD) BASDAI at inclusion was 1.45 (1.02). TNFi used were etanercept (35.7%), adalimumab (33.9%), infliximab (20.6%), golimumab (9.3%) and certolizumab (0.5%). For the 373 patients with complete follow-up (93.7%), 162/184 (88.0%) had a low disease activity in the "spacing" group vs. 173/189 (91.5%) in the "unchanged" group at 12 m. After multiple imputation for the 16 patients with missing data, the difference of proportion between the two groups was estimated to -4.18% [CI90% -10.0; 1.7], thus confirming the non-inferiority of the "spacing" procedure. In the "spacing" group at 12 m, 134/162 (82.7%) patients in low disease activity were still receiving a lowered TNFi dose.
Conclusion: In ax-SpA patients with BASDAI<4 for at least 6 months under TNFi, it is possible to increase intervals between injections while maintaining a low disease activity by adjusting treatment with quarterly monitoring of SpA activity.

OP0139

A TIME-SHIFTED EFFECT OF TUMOR NECROSIS FACTOR INHIBITORS ON RADIOGRAPHIC SPINAL PROGRESSION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: LONG-TERM RESULTS FROM THE GERMAN SPONDYLOARTHRITIS INCEPTION COHORT

D. Poddubnyy[1,2], V. Rios Rodriguez[1], M. Torgutalp[1], A. Dilbaryan[1], M. Verba[1], F. Proft[1], M. Protopopov[1], J. Rademacher[1], H. Haibel[1], J. Sieper[1], M. Rudwaleit[3]. [1]Charité – Universitätsmedizin Berlin, Division of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany; [2]Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology Unit, Berlin, Germany; [3]Klinikum Bielefeld Rosenhöhe, Department of Internal Medicine and Rheumatology, Bielefeld, Germany

Background: There are inconclusive data on the effect of tumor necrosis factor inhibitors (TNFi) on radiographic spinal progression in axial spondyloarthritis (axSpA). Although inflammation and new bone formation are linked in axSpA, TNFi failed to show inhibition of radiographic spinal progression over two years compared to historical cohorts in pivotal studies in radiographic axSpA. Subsequent observational studies suggested that a longer treatment duration, earlier treatment initiation and effective inflammation suppression might be required to achieve inhibition of radiographic progression.
Objectives: The aim of the current study was to evaluate the effect of TNFi on radiographic spinal progression in patients with early axSpA in a long-term inception cohort.
Methods: A total of 266 patients with early axSpA (with r-axSpA with symptom duration ≤10 years and nr-axSpA with symptom duration ≤5 years) from the German Spondyloarthritis Inception Cohort (GESPIC) with at least two sets of spinal radiographs obtained at least 2 years apart during a 10-year follow-up were included. These patients contributed with a total of 542 2-year radiographic intervals. Spinal radiographs were evaluated by three trained and calibrated readers according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). The final mSASSS was calculated as a mean of three reader scores. The association between the current TNFi, previous TNFi and radiographic spinal progression defined as the absolute mSASSS change score over 2 years was analyzed using longitudinal generalized estimating equations (GEE) analysis.
Results: Only 9 patients were treated with a tumor necrosis factor inhibitor (TNFi) at baseline, and a total of 77 patients received TNFi during the entire follow-up period that gave 103 2-year intervals covered by TNFi of any duration, and 78 intervals covered by TNFi with treatment duration of at least 12 months. Radiographic spinal progression in axSpA patients receiving TNFi in the current 2-year interval was not different from progression in patients not treated with TNFi, while TNFi in the previous 2-year interval was associated with lower progression compared to patients without TNFi in this interval (Figure 1). The latter was also evident for patients who received TNFi in both previous and current 2-year intervals, i.e. patients treated with TNFi over 4 years. The longitudinal GEE analysis confirmed no significant association between current TNFi treatment and radiographic spinal progression but a significant association between TNFi in the previous 2-year interval (especially if this was continued also in the current interval giving 4 years in total) and the progression in the current one (Table 1).

Table 1. The association between the change of the mSASSS over two years and current and/or previous treatment with TNFi in the longitudinal generalized estimation equation analysis.

TNFi treatment definition			
TNFi for ≥12 months in the previous 2-year interval	TNFi for ≥12 months in the current 2-year interval	Reference	β* (95% CI)
	Yes	No TNFi for ≥12 months in the current 2-year interval	-0.19 (-0.56 to 0.18)
Yes		No TNFi for ≥12 months in the previous 2-year interval	**-0.56 (-0.95 to -0.17)**
Yes	Yes	No TNFi for ≥12 months in the current and previous 2-year intervals	**-0.59 (-1.03 to -0.15)**

*Parameter estimates from the multivariable models adjusted for sex, symptom duration at the beginning of the current 2-year interval, time-averaged ASDAS in the current 2-year interval, smoking in the current 2-year interval, classification as non-radiographic or radiographic axSpA, and mSASSS at the beginning of the current 2-year interval.

Conclusion: TNFi treatment exhibits a time-shifted inhibitory effect on radiographic spinal progression in axSpA that becomes evident only in the second 2-year interval after treatment initiation.

Background: In clinical practice, some patients with axial spondyloarthritis (axSpA) fail several consecutive biological treatments (bDMARDs). How this group of "refractory" patients should best be defined, how common they are, and what their characteristics are, is poorly understood.

Objectives: To explore the point prevalence of bDMARD refractory disease in axSpA over time, according to different definitions, and to describe the characteristics of refractory vs. not-refractory patients upon start of their first bDMARD.

Methods: Observational prospective cohort study. Patients with axSpA (ankylosing spondylitis/non-radiographic axial SpA) starting a first bDMARD 2009-2018 were identified in biologic registries in Denmark, Sweden, Finland, Norway and Iceland. Clinical characteristics and treatments were retrieved, and data were pooled for analysis.

Refractory disease was defined based on the number of different bDMARD treatments started in individual patients: mild (≥3 bDMARDs), moderate (≥4), and strict (5 or more). Restart of same bDMARD with another bDMARD in between counted as separate courses whereas switch from originator to corresponding biosimilar was ignored.

Proportions of patients fulfilling each definition of refractory disease at 2 and 5 years after the start of 1st bDMARD were calculated.

Point-prevalence per calendar-year was calculated as the number of patients with refractory disease at the end of each year, divided by the total number of patients ever having starting a first bDMARD before that time-point, and who were still alive and resident in the country.

Results: The point prevalence of refractory axSpA increased with calendar-time (Figure). Among 12,037 included axSpA patients (64% male), the point-prevalence of bDMARD refractory disease in 2018 was 16%/7%/3% according to mild/moderate/strict definitions (Table).

Table 1. Biologic refractory axSpA according to three definitions

		Refractory definition		
	Overall cohort	MILD	MODERATE	STRICT
A. Baseline characteristics upon start 1st bDMARD

2 years, %		5%	1%	0%
5 years, %		13%	4%	1%

Numbers are means (SD) unless otherwise stated

Upon start of their 1st bDMARD, patients later fulfilling the definitions for refractory axSpA were more frequently women, had shorter disease duration, higher C-reactive protein and higher patient reported outcomes.

Overall, 5%/1%/0% had mild/moderate/strict refractory disease 2 years after start of first bDMARD, after 5 years it was 13%/4%/1% (Table).

Conclusion: In this large Nordic observational cohort of axSpA patients treated in routine care, we could demonstrate that a substantial proportion of all patients had used multiple bDMARDs. In 2018, one in six patients had received ≥3 bDMARDs, indicating a bDMARD refractory disease. Multiple switching was more frequent during later years, probably due to more bDMARDs becoming available. The characteristics of refractory axSpA, including sex and disease activity, will have to be further explored, as will the impact of refractory disease on long-term outcomes.

EFFECTS OF FILGOTINIB ON SPINAL LESIONS IN ANKYLOSING SPONDYLITIS: MAGNETIC RESONANCE IMAGING DATA FROM THE TORTUGA TRIAL

X. Baraliakos[1], M. Østergaard[2], R. B. M. Landewé[3], W. Barchuk[4], K. Liu[5], C. Tasset[6], L. Gilles[7], T. Hendrikx[8], R. Besuyen[9], W. P. Maksymowych[10]. [1]*Ruhr-University Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany*; [2]*University of Copenhagen, Copenhagen Center for Arthritis Research, Rigshospitalet, Copenhagen, Denmark*; [3]*Maastricht University Medical Center, Department of Rheumatology, Maastricht, Netherlands*; [4]*Gilead Sciences, Inc., Inflammation Clinical Research, Foster City, United States of America*; [5]*Gilead Sciences, Inc., Biostatistics, Foster City, United States of America*; [6]*Galapagos NV, Late Stage Development, Mechelen, Belgium*; [7]*Galapagos NV, Clinical Research, Mechelen, Belgium*; [8]*Galapagos BV, Medical Affairs, Leiden, Netherlands*; [9]*Galapagos BV, Clinical Research, Leiden, Netherlands*; [10]*University of Alberta, Department of Medicine, Division of Rheumatology, Edmonton, Canada*

Background: The oral Janus kinase 1 preferential inhibitor filgotinib (FIL) significantly improved Spondyloarthritis Research Consortium of Canada (SPARCC) magnetic resonance imaging (MRI) inflammation scores (bone marrow oedema) in the spine and sacroiliac joints vs placebo (PBO) in the Phase 2 TORTUGA trial (NCT03117270) in patients with active ankylosing spondylitis (AS).[1]

Objectives: This post-hoc analysis evaluated the effects of FIL on Canada-Denmark (CANDEN) MRI measures of spinal inflammation and structural lesions in patients from the TORTUGA trial.

Methods: TORTUGA was a PBO-controlled, multicentre, double-blind, randomised trial. Patients with active AS (as per modified New York classification criteria, with sacroiliitis confirmed by central reading) were treated with FIL 200 mg (n=58) or PBO (n=58) once daily for 12 weeks. MRI of the total spine was conducted at baseline and at treatment end. Scans were re-evaluated post-hoc by 2 independent experts (blinded to time point and assigned treatment) using the CANDEN method;[2] inter-reader discrepancies were resolved by an independent adjudicator. Observed changes from baseline were evaluated using analysis of covariance, with factors for treatment, baseline value, and randomisation stratification by prior tumour necrosis factor inhibitor use. Least-squares (LS) mean changes from baseline and between-group differences with 95% confidence intervals (CI) were calculated; P values are nominal.

Results: MRI scans from 88 patients (47 FIL, 41 PBO) with an evaluable scan at baseline and Week 12 (or early termination) were re-evaluated. Baseline characteristics were generally similar between patients with/without an MRI scan. Of those with MRI scans, mean total spine inflammation score (which ranges from 0–614) was higher, and mean ankylosis score (which ranges from 0–460) was lower, in the FIL vs PBO group at baseline. Total spine inflammation scores decreased from baseline with FIL but not with PBO (Figure and Table; P=0.0003 for between-group difference). Cumulative probability plots favoured FIL over PBO for change from baseline in subregion inflammation scores, including posterolateral elements (i.e. sum of lesions in ribs, transverse processes, spinous processes, soft tissue inflammation, and postero-lateral vertebral body), facet joint, and vertebral body. Total spine fat lesion scores numerically increased from baseline in the FIL but not PBO group (P=0.0878 for between-group difference; Table). There were no significant differences between groups for changes in erosion (P=0.1956) or ankylosis (P=0.3888) scores (Table).

Table 1. Change from baseline at Week 12 in CANDEN total spine inflammation, total spine fat, total spine bone erosion, and ankylosis scores

	Treatment group	n	Sample mean (SE)	LS mean (SE)	95% CI of treatment mean	LS mean of group difference (SE)	95% CI of group difference	Between-group P value
Total spine inflammation score	Filgotinib	47	–4.98 (0.96)	–4.40 (1.13)	–6.65, –2.15	–4.49 (1.21)	–6.85, –2.12	0.0003
	Placebo	41	0.29 (0.78)	0.09 (1.13)	–2.17, 2.34			
Total spine fat score	Filgotinib	47	1.01 (0.62)	1.09 (0.66)	–0.22, 2.40	1.18 (0.69)	–0.18, 2.55	0.0878
	Placebo	41	–0.25 (0.19)	–0.09 (0.66)	–1.40, 1.21			
Total spine bone erosion score	Filgotinib	47	0.01 (0.02)	0.07 (0.03)	0.00, 0.14	0.05 (0.04)	–0.02, 0.12	0.1956
	Placebo	41	–0.02 (0.03)	0.02 (0.03)	–0.04, 0.09			
Total ankylosis score	Filgotinib	47	0.30 (0.29)	0.23 (0.31)	–0.40, 0.85	0.28 (0.34)	–0.37, 0.94	0.3888
	Placebo	41	–0.01 (0.08)	–0.06 (0.31)	–0.68, 0.56			

SE, standard error

Conclusion: This is the first PBO-controlled trial to demonstrate a decrease in inflammatory activity with FIL, not only in the spinal vertebrae but also in the postero-lateral elements of the spine and facet joints. As expected in a 12-week study period, no changes in erosion or ankylosis were seen, while fat lesions showed a tendency to increase with FIL. Larger trials are needed to confirm these results.

NETAKIMAB REDUCES ANKYLOSING SPONDYLITIS ACTIVITY IN PATIENTS WITH OR WITHOUT SACROILIITS ON MRI: RESULTS OF SUBANALYSIS OF PHASE 3 ASTERA TRIAL

I. Gaydukova[1,2], V. Mazurov[1], S. Erdes[3], T. Dubinina[4], A. Kundzer[5], N. Soroka[6], A. Eremeeva[7]. *[1]Mechnikov North-Western State Medical University, Department of Therapy and Rheumatology of Temporary Disability and Medical Care Quality Expertise, St-Petersburg, Russian Federation*; *[2]Clinical Rheumatology Hospital No 25, Consultative Outpatient Department, St-Petersburg, Russian Federation*; *[3]Nasonova Research Institute of Rheumatology, Laboratory of Spondyloarthritides, Moscow, Russian Federation*; *[4]Nasonova Research Institute of Rheumatology, Laboratory of Medical and Social Problems of Rheumatology, Moscow, Russian Federation*; *[5]Belarusian Medical Academy of Postgraduate Education, Department of Cardiology and Rheumatology, Minsk, Belarus*; *[6]Belarusian State Medical University, Department of Internal Diseases №2, Minsk, Belarus*; *[7]JSC BIOCAD, Clinical Development Department, St-Petersburg, Russian Federation*

Background: The presence of sacroiliitis in patients (pts) with ankylosing spondylitis (AS) on imaging can be established both by sacroiliac joint (SIJ) X-ray or MRI. Active sacroiliitis on MRI as defined by ASAS is predictor of good treatment response to biological disease modifying anti-rheumatic drugs [1, 2]. Netakimab (NTK) is a humanized anti-interleukin-17A antibody approved for the treatment of AS, psoriatic arthritis, moderate-to-severe plaque psoriasis in Russia and Belarus. The difference in treatment response to NTK in AS pts with and without active sacroiliitis on MRI (MRI+/MRI–) is unclear.

Objectives: To report the changes in AS activity in pts with and without sacroiliitis on MRI at week 16 of NTK treatment.

Methods: ASTERA (NCT03447704) is an ongoing phase 3 placebo (PBO)-controlled clinical study, aimed at evaluating NTK efficacy in AS. All pts fulfilled modified New York criteria. Evaluation of acute inflammation on SIJ MRI was performed at the baseline but was not an inclusion criterion. This analysis includes pts received subcutaneous NTK 120 mg every 2 wks with available baseline SIJ MRI. The presence of sacroiliitis on MRI was defined as SPARCC>2. Efficacy endpoints included ASAS20/40, ASAS partial remission (PR), changes from baseline in BASDAI (Bath Ankylosing Spondylitis Disease Activity Index), ASDAS-CRP (Ankylosing Spondylitis Disease Activity Score).

Results: 67 MRI+ and 46 MRI– pts were included into analysis. Baseline characteristics were balanced across both arms. 42.4% of MRI+ pts and 38.3% of MRI– pts achieved ASAS40 at week 16 ($p \geq 0.05$), ASAS20 was observed in 65.2%/55.3% pts in the same arms respectively ($p \geq 0.05$). ASAS PR was reported for 15.2% MRI+ and 17.0% MRI– pts ($p \geq 0.05$). Improvements in BASDAI and ASDAS-CRP were similar across both arms. At wk 16, mean change from baseline in BASDAI was –2.7 vs –3.0 for MRI+ and MRI– pts respectively, mean change in ASDAS-CRP was –1.7 vs –1.4 in the same arms ($p \geq 0.05$ for all), (figure 1).

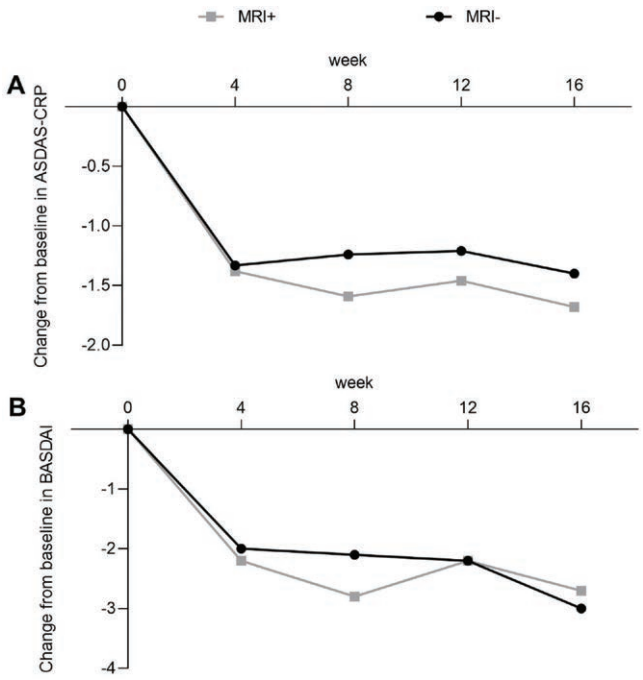

Figure 1. Clinical improvements in AS disease activity. Mean change from baseline is shown for (A) ASDAS-CRP, and (B) BASDAI

Conclusion: NTK leads to decline of disease activity in AS pts irrespectively of sacroiliitis on MRI.

OP0143

IMPACT OF ADALIMUMAB VERSUS NON-BIOLOGIC THERAPY ON DISEASE ACTIVITY AND PATIENT-REPORTED OUTCOMES IN ANKYLOSING SPONDYLITIS OVER 24 MONTHS – RESULTS OF THE COMPLETE-AS CANADIAN OBSERVATIONAL STUDY

L. Bessette[1], A. Chow[2], V. Pavlova[3], M. C. Laliberté[4], M. Khraishi[5]. *[1]Laval University, Centre Hospitalier de l'Université Laval, Laval University, Centre Hospitalier de l'Université Laval, Quebec City, Canada*; *[2]University of Toronto, University of Toronto, Toronto, Canada*; *[3]McMaster University, McMaster University, Hamilton, Canada*; *[4]AbbVie Corporation, AbbVie Corporation, Montreal, Canada*; *[5]Memorial University of Newfoundland, Memorial University of Newfoundland, St. John's, Canada*

Background: COMPLETE-AS was an observational study among Canadian biologic-naïve adults with active ankylosing spondylitis (AS) treated with either adalimumab or subsequent non-biologic disease-modifying anti-rheumatic drugs and/or non-steroidal anti-inflammatory drugs (nbDMARD/NSAID) after having switched from initial treatment with a preceding nbDMARD and/or NSAID due to lack of response or intolerance, as per treating physician judgement.

Objectives: To assess the impact of adalimumab on disease activity and patient-reported outcomes among adalimumab- vs. nbDMARD/NSAID-treated patients over 24 months.
Methods: Patients were enrolled between July 2011 and December 2017 and followed for up to 24 months. Treatment was per routine care and all analyses were perfomed using the intent-to-treat (ITT) approach. Between-group differences for change in patient-reported disease activity (BASDAI), morning stiffness (minutes/day), functional limitation (BASFI), quality of life (QoL: SF-12), depression (BDI-II), and work productivity (WLQ) were assessed with repeated measures models for overall treatment effect; baseline-adjusted estimates (least square means [LSM]) for each visit were produced. Achievement of, and time to the following endpoints were assessed: 50% improvement from baseline in BASDAI (BASDAI50); minimum clinically important improvements (MCIIs) in BASDAI ($\Delta \geq 1.1$); BASFI ($\Delta \geq 0.6$); SF-12 physical component score (PCS; $\Delta \geq 4.4$) and mental component score (MCS; $\Delta \geq 3.1$); and low disease activity for BASDAI (<4) and BASFI (<3.8).
Results: A total of 452 adalimumab-treated patients and 187 nbDMARD/NSAID-treated patients were enrolled in the study and included in the analyses. At baseline, mean (SD) BASDAI [6.4 (1.8) vs. 5.0 (1.8); p<0.001] and BASFI [5.5 (2.4) vs. 3.7 (2.4)] were however significantly (p<0.001) higher among adalimumab-treated patients compared to nbDMARD/NSAID-treated patients, respectively. Over 24 months, adalimumab-treated patients had significantly lower overall BASDAI scores compared to nbDMARD/NSAID-treated patients [estimate (95% CI): -0.7 (-1.2, -0.3); p=0.007]. BASFI scores were also significantly lower among adalimumab-treated patients over the course of the study [estimate (95% CI): -0.4 (-0.8, 0.0); p=0.013]. Both groups had statistically comparable outcomes for morning stiffness, BDI-II, WLQ, and SF-12.
Adalimumab-treated patients were also at significantly higher odds of achieving therapeutic response thresholds, including BASDAI50 [OR (95% CI): 1.7 (1.2-2.3)], BASDAI<4 [1.8 (1.2-2.7)], MCII for BASDAI [1.9 (13.-2.9)], and MCII for BASFI [1.6 (1.1-1.2)]. Time to achievement of each threshold was significantly shorter among adalimumab-treated patients for BASDAI50 [HR (95% CI): 1.8 (1.1-2.8)], BASDAI<4 [1.7 (1.6-3.6)], and MCII for BASDAI [1.5 (1.0-2.3)]. Time to achievement of MCII for BASFI was not statistically different between groups; for BASFI<3.8 and MCII for both SF-12 PCS and MCS, both odds of, and time to achievement, were also statistically comparable.
At month 24, baseline-adjusted BASDAI and BASFI was comparable (p>0.05): LSM (95%CI) 3.5 (3.3, 3.8) vs. 3.6 (3.2-4.0), and 2.9 (2.6-3.1) vs. 3.3 (2.9-3.7), respectively, for adalimumab-treated vs. nbDMARD/NSAID-treated patients.
Conclusion: Among Canadian patients with active AS, adalimumab-treated patients reported a greater overall reduction in disease burden related to both self-reported disease activity and functional capacity compared to nbDMARD/NSAID-treated patients, along with higher odds and shorter time to achieving therapeutic response thresholds. Despite the overall beneficial effects observed with adalimumab, residual disease burden, however, is observed for Canadian AS patients even after 24 months of treatment.

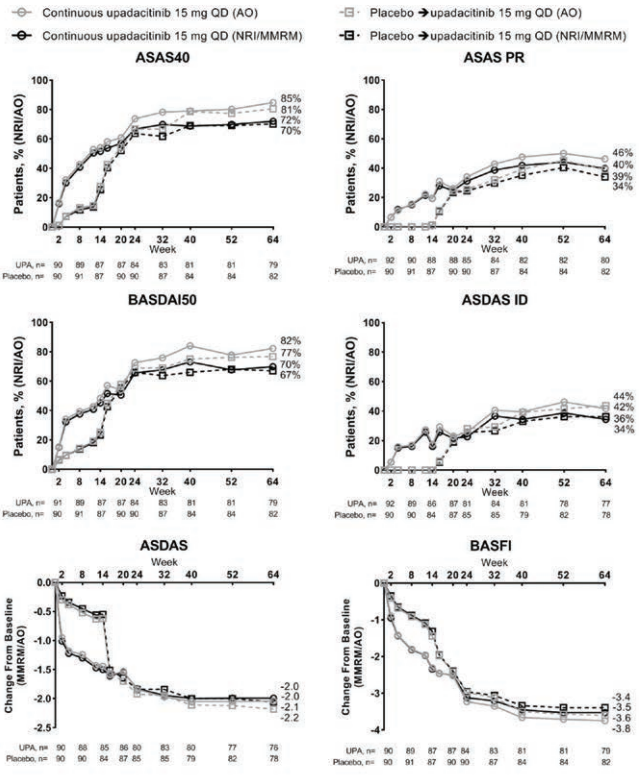
EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: 1-YEAR RESULTS FROM A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY WITH OPEN-LABEL EXTENSION

A. Deodhar[1], D. Van der Heijde[2], J. Sieper[3], F. Van den Bosch[4], W. P. Maksymowych[5], T. H. Kim[6], M. Kishimoto[7], A. Ostor[8], B. Combe[9], Y. Sui[10], X. Wang[10], A. Chu[10], I. H. Song[10]. [1]*Oregon Health, Science University, Portland, United States of America*; [2]*Leiden University, Medical Center, Leiden, Netherlands*; [3]*Charité Universitätsmedizin, Medicine, Berlin, Germany*; [4]*Ghent University Hospital, Rheumatology, Ghent, Belgium*; [5]*University of Alberta, Rheumatology, Edmonton, Canada*; [6]*Hanyang University, Hospital for Rheumatic Diseases, Seoul, Korea, Rep. of (South Korea)*; [7]*Kyorin University, School of Medicine, Tokyo, Japan*; [8]*Cabrini Hospital, Monash University & Emeritus Research, Melbourne, Australia*; [9]*CHU Montpellier, Montpellier University, Montpellier, France*; [10]*AbbVie Inc., Rheumatology, North Chicago, United States of America*

Background: Upadacitinib (UPA) was efficacious and well tolerated vs placebo (PBO) during the first 14 weeks (wks) of the phase 2/3 SELECT-AXIS 1 study in patients (pts) with active ankylosing spondylitis (AS) who had an inadequate response to NSAIDs.[1]
Objectives: To report efficacy and safety of UPA through 1 year in the SELECT-AXIS 1 study.
Methods: In SELECT-AXIS 1 (NCT03178487) pts were randomized 1:1 to UPA 15 mg once daily (QD) or PBO; at wk 14, pts continued in the 90-wk open-label extension and received UPA 15 mg QD; reported here are data up to wk 64. The study enrolled pts (≥18 y) with active AS (defined as BASDAI ≥4 and pt assessment of back pain ≥4 [numeric rating scale, 0–10] at screening and baseline [BL]) who had inadequate response to ≥2 NSAIDs or intolerance to or contraindication for NSAIDs and were biologic DMARD naive. Efficacy assessments included percentage of pts with Assessment of SpondyloArthritis international Society (ASAS) 20/40 response, ASAS partial remission, BASDAI50, AS Disease Activity Score (ASDAS) and change from BL in ASDAS and BASFI. Data are reported as observed and by using non-responder imputation (NRI). Treatment-emergent adverse events (TEAEs) were reported as events per 100 patient-years (PY) up to January 31, 2020.
Results: Of 187 pts, 178 pts (each n=89 for UPA and PBO arms) completed wk 14 on study drug and entered the open-label extension; 160 pts completed wk 64. Efficacy was maintained or continued to improve throughout the study in the continuous UPA group: 85% (95% CI, 77%–93%) of pts achieved ASAS40 at wk 64 in the as-observed analysis and 72% (63%–81%) in the NRI analysis (Figure). Pts who switched from PBO to UPA at wk 14 showed similar speed of onset and magnitude of response vs pts

Figure. Efficacy Endpoints Over Time



AO, as observed; ASAS, Assessment of SpondyloArthritis international Society; ASDAS, Ankylosing Spondylitis Disease Activity Scores; ID, inactive disease; MMRM, mixed-effect model repeated measures; NRI, non-responder imputation; PR, partial remission; QD, once daily; UPA, upadacitinib.
Dashed line: all patients randomized to placebo received open-label UPA starting from week 14.
N's below the graphs are for as observed analysis. N's for NRI analysis were 94 for placebo to upadacitinib and 93 for continuous upadacitinib.
160 patients completed week 64; lack of efficacy (n=10) and adverse events (n=4) were the most common reasons for discontinuation between weeks 14 and 64.

initially randomized to UPA: 81% (95% CI, 72%–89%) in the as-observed analysis and 70% (61%–80%) in the NRI analysis achieved ASAS40 at wk 64 (Figure). Similar results were observed for other efficacy endpoints (Figure). Among all 182 pts receiving UPA, 618 AEs were reported. AEs leading to discontinuation and serious AEs were low (Table). No serious infections, active tuberculosis, venous thromboembolic events, gastrointestinal perforation, major adverse cardiovascular events, renal dysfunction, or deaths were reported.

Diagnostics and imaging procedures

OP0145

DIFFERENTIAL DIAGNOSIS OF RA AND PSA USING NEURAL NETWORKS ON THREE-DIMENSIONAL BONE SHAPE OF FINGER JOINTS

L. Folle[1], C. Liu[1], D. Simon[2], T. Meinderink[2], A. M. Liphardt[2], G. Krönke[2], G. Schett[2], A. Maier[1], A. Kleyer[2]. *[1]Friedrich-Alexander-Universität Erlangen-Nürnberg - Pattern Recognition Laboratory, Department of Computer Science, Erlangen, Germany*; *[2]Friedrich-Alexander; University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany*

Background: Early diagnosis and reliable differentiation between rheumatic diseases (RMDs) are crucial to start an adequate therapy and prevent irreversible damage. Since finger joints are commonly affected in rheumatoid arthritis (RA) and psoriatic arthritis (PsA), imaging of the peripheral skeleton is an essential step of diagnosis at a rheumatologist. High resolution peripheral quantitative computed tomography (HR-pQCT) allows an even more detailed and three-dimensional (3D) illustration of the peripheral bone than conventional radiographs. Segmented scans contain further information, such as the density, microstructure, and shape of the bones, which can be further analyzed by neural networks.
Objectives: We hypothesize that, based on the shape of the second metacarpophalangeal (MCP) joint from HR-pQCT images, a neural network can be trained to differentiate between RA, PsA, and healthy controls and to reveal regions in the bone shape characteristic for the diseases.
Methods: HR-pQCT images of MCP joints from patients with classified CCP positive RA, classified PsA, and healthy controls with low motion artifacts and appropriate scan region were selected as reported previously [3]. Scans were performed as part of the clinical routine and patients gave their informed consent to use pseudonymized data (Ethics approval 334_16B). Based on the assumption that pathognomonic changes develop over time, only images were used, where the period between classification and imaging exceeded one year.
Based on previous work [4], a pixel-wise mask of the second metacarpal bone was generated using a neural network based on the HR-pQCT scans of patients. Supervised auto-encoder [1] networks were used to predict the correct class given the bone mask only. For the neural network experiment, the patient scans were split on a patient-level into training (70%), validation (20%), and testing (10%). Guided backpropagation [2] was used as a method to investigate the regions influencing the class prediction most.
Results: In total, images of 331 patients were included in the experiments. The evaluation of the model on the 33 test cases yielded a high accuracy for the healthy control with 94%, RA patients with 84%, and PsA patients with 89%. An area under the receiver operator curve of 91% could be achieved. The regions of the bone mask influencing the network´s decision most are highlighted exemplary in Figure 1.

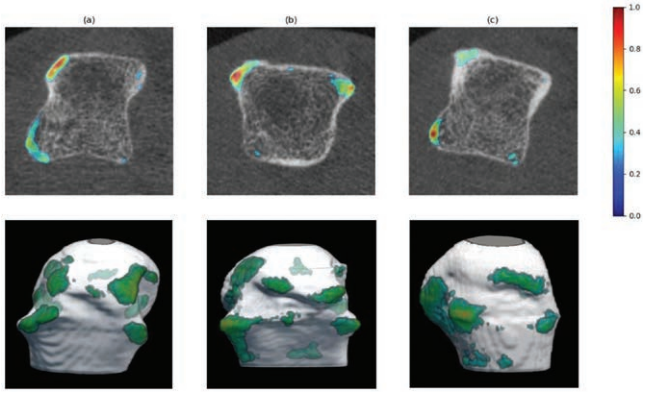

Figure 1. Visualization of the HR-pQCT slices with gradient maps. Higher values (red) represent regions that had a stronger contribution to the classification result. The HR-pQCT images are displayed for reference only. (a) Healthy patient, (b) RA diagnosed patient, and (c) PsA diagnosed patient. The first row shows the single slices with the highest values corresponding to the 3D bone masks in the second row.

Conclusion: For the first time, a neural network-based approach successfully provides a differential diagnosis of RA and PsA based only on the shape of the second MCP in HR-pQCT images. The evaluation of the test set suggests that high curvatures of the bone surface in the joint region significantly influence the prediction of the network, suggesting an in-depth investigation of these regions

for patients affected by RA and PsA. Based on these promising findings, we aim to extend the approach to seronegative RA as well as early RA and PsA.

OP0146 TENOSYNOVITIS, SYNOVIAL HYPERTROPHY AND FEET BURSITIS ARE USEFUL ULTRASOUND BIOMARKERS FOR PREDICTING ARTHRITIS DEVELOPMENT IN A POPULATION AT-RISK FOR RHEUMATOID ARTHRITIS

Y. Kisten[1], A. Circiumaru[1], M. Loberg[1], N. Vivar-Pomiano[1], A. Antovic[2], H. Rezaei[1], E. Af Klint[1], A. Hensvold[1,2], A. Catrina[1,2]. *[1]Karolinska Institute, Department of Medicine, Rheumatology Unit and Early Arthritis Clinic of the Karolinska University Hospital, Stockholm, Sweden*; *[2]Academic Specialist Center, Center for Rheumatology, Stockholm Health Region, Stockholm, Sweden*

Background: Musculoskeletal ultrasound (MSUS) evaluation of individuals at risk for developing rheumatoid arthritis (RA) having Anti-Citrullinated Protein Antibody (ACPA) positivity and musculoskeletal complaints, may play an important role in the very early detection of RA.

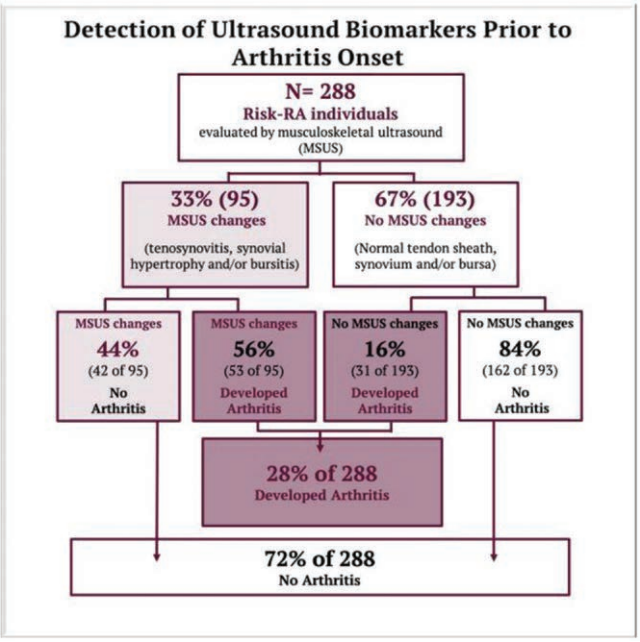
Objectives: We aimed to identify which ultrasound markers could predict arthritis development.

Methods: Individuals with musculoskeletal complaints with a positive anti-CCP2 test were referred to the rheumatology department for a detailed clinical (68 joint count) and MSUS examination of the hands, feet and any symptomatic joints. Only those without clinical and/or MSUS detected arthritis were included in the RISK RA prospective cohort and followed-up over 3 years/ or until arthritis onset. Using EULAR-OMERACT guidelines[1], MSUS markers for synovial hypertrophy (SH) and hyperemia (Doppler activity) were documented for each visit. Finger and wrist tendons were screened for any signs of tenosynovitis (TS), and between metatarsal joints for bursitis. Association of MSUS biomarkers with arthritis development was tested (comparing proportions) using Chi-Squared or Fisher's exact tests.

Results: 288 individuals were included from January 2014 to October 2019 (79% female, 35% RF positive, median age 48 years: IQR: 36-58). Within a median of 38 months (IQR: 1-72) since recruitment, 84 individuals (28%) developed an arthritis diagnosis.

Prior to obtaining any diagnosis (at inclusion and/or follow-up visit), 95 of the 288 individuals (33%) had at least one type of MSUS anatomical modification present (around the tendons, joint synovium and/or within bursal cavities), and 56% (53/95) of these individuals eventually developed arthritis. Of the remaining 193 that did not present with any obvious MSUS changes, 16% progressed towards arthritis development.

The presence of tenosynovitis was detected in 64 of 288 individuals scanned prior to diagnosis and were more frequent in those developing arthritis (44%, 37/84) as compared to those with TS not developing arthritis (13%, 27/204), p<0.0001. The extensor carpi ulnaris wrist tendons were mostly involved. Sonographic changes within the synovium were noted in 11% (32/288) of all individuals, mostly affecting the metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints. There was a higher incidence of synovial hypertrophy detected in those developing arthritis (22%, 18/24), as compared to those that remained arthritis free (7%, 14/204), p<0.0001. The MCP joints with synovial hypertrophy were more prone to arthritis development as compared to the MTP's. Furthermore, we observed a higher frequency of bursitis between the MTP joints in individuals developing arthritis, as compared to individuals having a bursitis who did not develop arthritis (13%, 11/84 versus 7%, 14/204, p=0.009).



Conclusion: Ultrasound biomarkers such as tenosynovitis of the extensor carpi ulnaris, synovial hypertrophy of the MCP joints and feet bursitis have good potential to predict arthritis development in a population at-risk for rheumatoid arthritis.

OP0147 RHEUMATIC? - A DIGITAL DIAGNOSTIC DECISION SUPPORT TOOL FOR INDIVIDUALS SUSPECTING RHEUMATIC DISEASES: A MULTICENTER VALIDATION STUDY

R. Knevel[1], J. Knitza[2,3,4], A. Hensvold[5,6], A. Circiumaru[5,6], T. Bruce[7], S. Evans[8], T. Maarseveen[1], M. Maurits[1], L. Beaart- van de Voorde[1], D. Simon[2,3], A. Kleyer[2,3], M. Johannesson[6], G. Schett[2,3], T. Huizinga[1], S. Svanteson[8], A. Lindfors[7], L. Klareskog[5], A. Catrina[5]. *[1]LUMC, Rheumatology, Leiden, Netherlands*; *[2]Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany*; *[3]FAU Erlangen-Nuremberg and Universitätsklinikum, Deutsches Zentrum fuer Immuntherapie (DZI), Erlangen, Germany*; *[4]Université Grenoble Alpe, AGEIS, Grenoble, France*; *[5]Karolinska Institutet, Karolinska University Hospital, Division of Rheumatology, Department of Medicine, Stockholm, Sweden*; *[6]Academic Specialist Center, Center for Rheumatology, Center for Rheumatology, Stockholm Region, Sweden*; *[7]Ocean Observations, a Design Consultancy, Stockholm, Sweden*; *[8]Elsa Science, A Digital Health Company, Stockholm, Sweden*

Background: Digital diagnostic decision support tools promise to accelerate diagnosis and increase health care efficiency in rheumatology. *Rheumatic?* is an online tool developed by specialists in rheumatology and general medicine together with patients and patient organizations for individuals suspecting a rheumatic disease.[1,2] The tool can be used by people suspicious for rheumatic diseases resulting in individual advise on eventually seeking further health care.

Objectives: We tested *Rheumatic?* for its ability to differentiate symptoms from immune-mediated diseases from other rheumatic and musculoskeletal complaints and disorders in patients visiting rheumatology clinics.

Methods: The performance of *Rheumatic?* was tested using data from 175 patients from three university rheumatology centers covering two different settings: A.Risk-RA phase setting. Here, we tested whether *Rheumatic?* could predict the development of arthritis in 50 at risk-individuals with musculoskeletal complaints and anti-citrullinated protein antibody positivity from the KI (Karolinska Institutet) B.Early arthritis setting. Here, we tested whether *Rheumatic?* could predict the development of an immune-mediated rheumatic disease in i) EUMC (Erlangen) n=52 patients and ii) LUMC (Leiden) n=73 patients.
In each setting, we examined the discriminative power of the total score with the Wilcoxon rank test and the area-under-the-receiver-operating-characteristic curve (AUC-ROC).
Results: In setting A, the total test score clearly differentiated between individuals developing arthritis or not, median 245 versus 163, *P < 0.0001,* AUC-ROC = 75.3 (Figure 1**).** Also within patients with arthritis the *Rheumatic?* total score was significantly higher in patients developing an immune-mediated arthritic disease versus those who did not: median score EUMC 191 versus 107, *P < 0.0001,* AUC-ROC = 79.0, and LUMC 262 versus 212, *P < 0.0001,* AUC-ROC = 53.6.

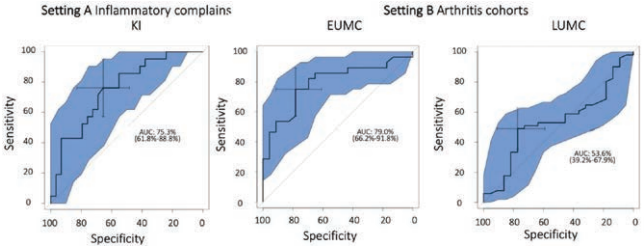

Figure 1. (Area under) the receiver operating curve for the total *Rheumatic?* score

Conclusion: *Rheumatic?* is a web-based patient-centered multilingual diagnostic tool capable of differentiating immune-mediated rheumatic conditions from other musculoskeletal problems. A following subject of research is how the tool performs in a population-wide setting.

OP0148

SPATIOTEMPORAL DYNAMICS OF BONE LOSS BEFORE AND AFTER THE ONSET OF RHEUMATOID ARTHRITIS

K. Tascilar[1], D. Simon[1], A. M. Liphardt[1], T. Meinderink[1], S. Bayat[1], J. Rech[1], A. Hueber[2], G. Krönke[1], G. Schett[1], A. Kleyer[1]. *[1]Friedrich-Alexander; University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, 91054 Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany*; *[2]Solzialstiftung Bamberg, Sektion Rheumatologie, Bamberg, Germany*

Background: Rheumatoid Arthritis (RA) is preceded by a clinically silent pre-phase characterized by autoimmunity against anti-modified protein antibodies including anti-citrullinated protein antibodies (ACPA). At this pre-stage patients already experience significant loss of volumetric peripheral bone mineral density (vBMD) compared to healthy controls measured by high-resolution peripheral quantitative computed tomography (HR-pQCT) (1-2). However, the longitudinal course of vBMD changes during the preclinical phase, after diagnosis, and its association with time to disease onset have not been investigated.

Objectives: To longitudinally characterize the changes of metacarpal and radial vBMD before and after the clinical onset of RA and its association with time to onset of arthritis.
Methods: To explore the development of arthritis, we initiated a RA-at-risk cohort in 2011. (Ethics 334_16B). This prospective cohort includes adults positive for CCP-AB with or without musculoskeletal symptoms, excluding arthritis. Participants are regularly followed with clinical examination and HR-pQCT imaging of the MCP and radial bone to monitor early bone changes. HR-pQCT images with low motion grade artefacts were analyzed to obtain the total (D100), cortical (DComp) and trabecular (DTrab) vBMD (D100) in mg HA cm^3.
We descriptively analyzed the vBMD time course in patients who developed RA by fitting regression curves separately for the pre-clinical and clinical periods and estimated time-conditional marginal mean VBMDs for the 5-year peri-RA period. We analyzed time to diagnosis of clinical RA defined by the 2010 ACR/EULAR classification criteria using Cox regression models. Hazard ratios indicate the relative risk of clinical disease onset associated with 1 standard deviation reduction in bone density.
Results: 130 subjects (mean [SD] age 47.0 [12.2], 89 female [68%]) between 2011 and 2020 were analyzed. Median (IQR) follow-up duration for the cohort was 18.6 (4.6-47.6) months. Participants underwent 233 HR-pQCT scans and 58 (45%) underwent 2 to 6 scans with a median interval of 16.2 (12.2-21.2) months. 49 (38%) patients who developed RA had a pre-diagnosis follow-up of 4.1 (2.5-13.4) months and post-diagnosis follow-up of 22.0 (8.8-38.9) months. The time course of scaled bone mineral densities depicted in Figure 1A suggest that bone

Table 1. Relative risk of RA development in the total cohort; crude and age/sex adjusted hazard ratios for one standard-deviation reduction in vBMD.

	Crude		Adjusted	
	HR (95%CI)	P	HR (95%CI)	P
MCP.D-Comp	1.16 (0.86 to 1.57)	0.336	1.20 (0.89 to 1.63)	0.229
MCP.D-Trab	1.14 (0.83 to 1.57)	0.405	1.17 (0.85 to 1.62)	0.341
MCP.D100	1.16 (0.83 to 1.61)	0.392	1.21 (0.86 to 1.71)	0.265
Rad.D-Comp	1.42 (0.97 to 2.07)	0.071	1.66 (1.07 to 2.55)	0.023
Rad.D-Trab	1.20 (0.87 to 1.66)	0.257	1.23 (0.88 to 1.71)	0.223
Rad.D100	1.43 (0.99 to 2.06)	0.056	1.52 (1.03 to 2.25)	0.033

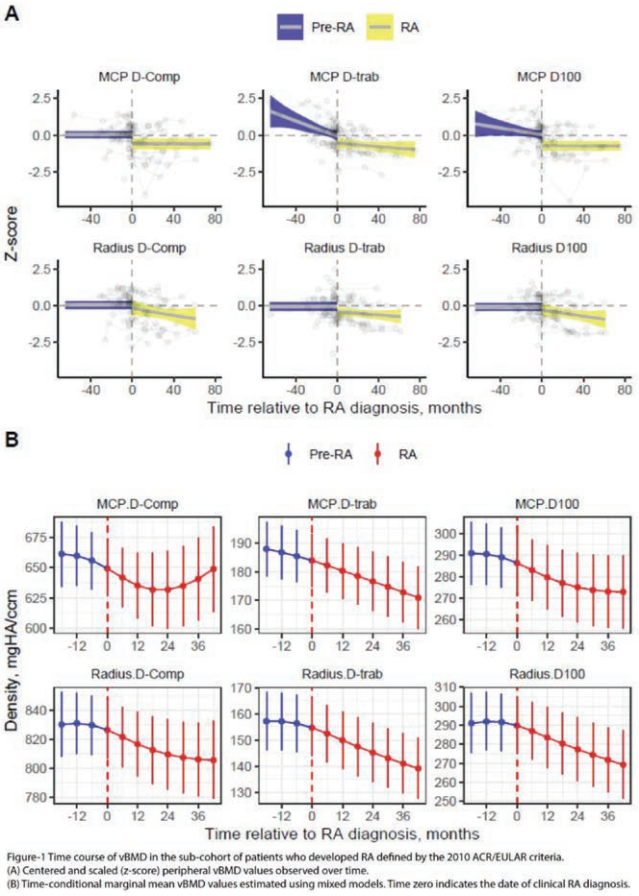

Figure-1 Time course of vBMD in the sub-cohort of patients who developed RA defined by the 2010 ACR/EULAR criteria.
(A) Centered and scaled (z-score) peripheral vBMD values observed over time.
(B) Time-conditional marginal mean vBMD values estimated using mixed models. Time zero indicates the date of clinical RA diagnosis.

density around the MCP joints deteriorate in the preclinical phase of RA, which is mostly prominent in the trabecular bone. Modelling (Figure 1B) suggests that trabecular bone loss around the MCP joints has a constant pace regardless of the clinical status. Whereas the radial bone densities are relatively stable in the preclinical phase and show a reduction after the clinical onset of RA. Age and sex adjusted hazard ratios (95%CI) for the risk of RA clinical onset were 1.52 (1.03 to 2.25) for radius D100 and 1.66 (1.07 to 2.55) for radius DComp (Table-1).
Conclusion: Metacarpal bone showed a constant decline that started already in the pre-phase of RA and continued after its clinical onset. In contrast, bone loss in the radius was not observed in the pre-phase but started at onset of RA. Low radial vBMD in the pre-clinical phase, however, was associated with a higher risk of RA onset. These findings suggest different spatiotemporal dynamics of bone loss before and after RA onset

Background: Inflammation in peripheral joints and entheses is common in spondyloarthritis (SpA). Whole-body magnetic resonance imaging (WB-MRI) allows assessment of the overall inflammatory status of arthritis patients including joints and entheses. The OMERACT MRI Whole-body scoring system for Inflammation in Peripheral joints and Entheses (MRI-WIPE) [1] has been developed and validated for the entire body assessment, including the knee, but not separately validated for the knee joint region. Detailed MRI scoring systems exist for heels, hands and feet, but although knee arthritis is a key cause of functional impairment, no detailed scoring system has been validated for inflammatory arthritides. The Knee Inflammation MRI Scoring System (KIMRISS) [2] was developed and validated in osteoarthritis and demonstrated good reliability.
Objectives: To perform region-based development of whole-body MRI through validation of two knee region scoring systems in SpA.
Methods: Assessment of inflammation was performed in the knee region on sagittal WB-MRIs using 2 scoring systems, MRI-WIPE and KIMRISS (Figure 1), in 4 iterative multi-reader exercises. In the final exercise, images (psoriatic arthritis, axial and peripheral SpA) were obtained before and after TNF-inhibitor.

Figure 1

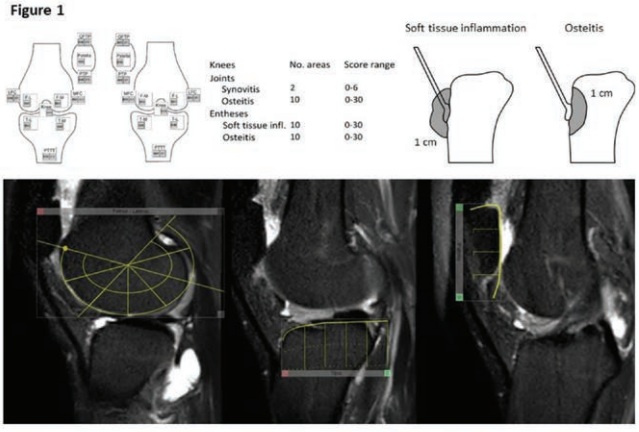

Figure 1. Upper row, left: MRI-WIPE schematic and scoring ranges for the knee-region from Krabbe, et al. [1]; Upper row, right: schematic drawing of the principle of scoring osteitis and soft tissue inflammation illustrated by the tibial insertion of the patellar ligament.
Lower row: Sagittal WB-MRI of a knee with the web-based superimposed interactive overlays used in KIMRISS for osteitis scoring positioned for femur, tibia and patella.

Results: In the final exercise (exercise 4), reliability was mostly good for experienced readers with the overall highest interreader agreement in the previous exercise (exercise 3). Median pairwise single measure intraclass correlation coefficients for osteitis and synovitis/effusion for status/change were 0.71/0.48 (WIPE osteitis), 0.48/0.77 (WIPE synovitis/effusion), 0.59/0.91 (KIMRISS osteitis) and 0.92/0.97 (KIMRISS synovitis/effusion) (Table 1). Wilcoxon signed-rank test showed significant change in synovitis/effusion for both methods and they correlated significantly regarding status in osteitis (0.92, p<0.001) and synovitis/effusion (0.89, p=0.001) and change in synovitis/effusion (0.89, p<0.001). Standardized response mean was 0.74 (WIPE synovitis/effusion) and 0.78 (KIMRISS synovitis/effusion).
Conclusion: MRI-WIPE and KIMRISS may both be useful as part of modular whole-body evaluation in clinical studies.

OP0150

MACHINE LEARNING APPROACHES FOR RISK MODELLING IN INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS USING HIGH DIMENSIONAL IMAGE ANALYSIS

M. Maciukiewicz[1], J. Schniering[1], H. Gabrys[2], M. Brunner[1], C. Blüthgen[3], C. Meier[1], M. Guckenberger[2], H. Fretheim[4], A. M. Hoffmann-Vold[4], O. Distler[1], T. Frauenfelder[3], S. Tanadini-Lang[2], B. Maurer[1,5]. *[1]Center of Experimental Rheumatology, Department of Rheumatology, University of Zurich, Zurich, Switzerland*; *[2]Department of Radiation Oncology, University Hospital Zurich, University of Zurich, Zurich, Switzerland*; *[3]Institute of Diagnostic and Interventional Radiology, University Hospital Zurich, University of Zurich, Zurich, Switzerland*; *[4]Institute of Clinical Medicine, University of Oslo, Rheumatology, Oslo University Hospital, Oslo, Norway*; *[5]Department of Rheumatology and Immunology, University Hospital Bern, Bern, Switzerland*

Background: The interstitial lung disease (ILD) associated with connective tissue diseases including systemic sclerosis (SSc) is heterogenous disease characterized by reduced survival of approximately 3 years (1). “Radiomics” is a field of research which describes the in-depth analysis of tissues by computational retrieval of high-dimensional quantitative features from medical images (2). Our previous study suggested capacity of radiomics features to differentiate between “high” and “low” risk groups for lung function decline in two independent cohorts (3).

Objectives:

- bTo develop robust, machine learning (ML) workflow for “radiomics” data in SSc-ILD to select optimal methods for prediction.
- oTo predict the time to individual lung function decline defined as defined by the time to a relative decline of ≥ 15% in Forced Vital Capacity (FVC)% as previously (3), using workflow.

Methods: We investigated two cohorts of SSc-ILD: 90 patients (76.7% female, median age 57.5 years) from the University Hospital Zurich and 66 patients (75.8% female, median age 61.0 years) from Oslo University Hospital’s. Patients were retrospectively selected if (3): a) diagnosed with early/mild SSc according to the Very Early Diagnosis of Systemic Sclerosis (VEDOSS) criteria, b) presence of ILD on HRCT as determined by a senior radiologist. For every subject, we defined 1,355 robust radiomic features from HRCT images. The follow-up period was defined as the time interval between baseline visit and the last available follow-up visit.

We have developed a systematic computational workflow to build predictive ML models. To reduce the number of redundant radiomic features, we applied correlation thresholds. We applied distinct methods including 1) Lasso Penalized Regression for feature selection, and 2) Random Forest (RF) for modeling using the R package ‘caret’. To select the optimal ML model, we randomly divided derivation cohort into Training (70%) and Holdout (30%) sets and applied fivefold cross-validation (5kCV) for feature and classifier selection on Training set only.

Results: We have investigated various methods to select the optimal set of predictive radiomic features. Since the ML model performance is affected by both, feature, and classifier selection, we assessed these factors first.

Results from feature filtering and selection, suggested that the combination of correlation threshold of 0.9 with Lasso regression proved best. As we perform feature selection in 5k CV workflow, features present in at least 2 sets entered model optimization step.

During model selection, we selected RF classifier. We detected positive correlation between actual and predicted values with Spearman’s rho = 0.313, p = 0.167 and Spearman’s rho = 0.341, p = 0.015 in Oslo and Holdout sets respectively, as shown on Figure 1. The percentage of variance remained modest for both Holdout (Rsq = 0.104) and Oslo (Rsq = 0.126) datasets.

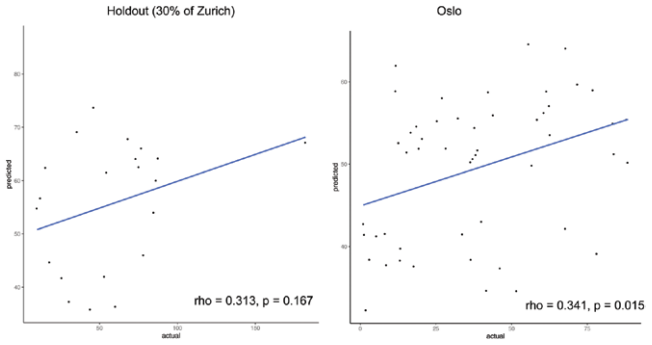

Figure 1. Performance of the best, RF classifier shown as scatterplot between actual and predicted values of individual time to lung decline.

Conclusion: In summary, we: (1) developed ML workflow that allowed to select o optimal methodology for modeling (i.e., feature and classifier selection), and (2) provide models that predicted time to individual lung function decline, characterized by significant correlation between predicted and actual values.

OP0151

AUTOANTIBODIES AGAINST DENSE-FINE-SPECKLED 70 (DFS70) DO NOT ENTIRELY EXCLUDE CONNECTIVE TISSUE DISEASES

L. M. Mockenhaupt[1], R. Dolscheid-Pommerich[2], C. Behning[3], B. Stoffel-Wagner[2], P. Brossart[1], V. Schäfer[1]. *[1]University Hospital Bonn, Clinic of Internal Medicine III, Department of Oncology, Hematology, Rheumatology and Clinical Immunology, Bonn, Germany*; *[2]University Hospital Bonn, Institute of Clinical Chemistry and Clinical Pharmacology, Bonn, Germany*; *[3]University Hospital Bonn, Institute of Medical Biometry, Informatics and Epidemiology, Bonn, Germany*

Background: Antinuclear antibodies (ANA) are serological markers for the presence of rheumatic diseases [1]. In some patients, a pattern can be detected in ANA immunofluorescence that resembles an anti-dense-fine-speckled-70 antibody [2]. This is detected less frequently in patients with connective tissue diseases (CTD) and is therefore often used as an exclusion criteria for a CTD [2]. To date, however, it is not clear how the presence of an anti-DSF70 autoantibody will reliably rule out CTDs.

Objectives: To examine the degree to which CTDs can be excluded from either a positive test and whether there are discrepancies between patients with CTDs and a negative anti-DSF70 test and those with CTDs and a positive anti-DSF70 test.

Methods: We analyzed data of 460 patients who were tested for the presence of the DSF70 antibody at the University Hospital Bonn, Germany. Patients were examined with regard to clinical symptoms and signs, type of disease, type of CTD, fulfillment of the classification criteria for the particular CTD, DSF70 antibodies, other autoantibodies and ANA titer. Gold standard for presence of a CTD was the diagnosis of the treating rheumatologist.

In addition to variations between patients with CTD and positive or negative DSF70 antibodies, specificity, sensitivity and positive predictive value were calculated for different ANA titers.

Results: Of the 460 patients, 79.8% were female and 182 were diagnosed with a CTD. 354 patients (77.0%) were tested negative, 81 (17.6%) positive and 25 (5.4%) had a borderline anti-DSF70 autoantibody result.

We identified 21 patients with a positive test result in the presence of a CTD, which accounts for 25.9% of all anti-DSF70 autoantibody positive tested patients. We found no significant differences in DSF70-positive patients with CTD in regard to age, gender, symptoms, clinical signs and also disease-specific antibodies compared to patients with negative DSF70 status and present CTD.

Of the 21 DSF70-positive patients with CTD, 12 (57.1%) were tested for the presence of disease-specific autoantibodies. Specific autoantibodies could be detected in all of the tested patients with systemic lupus erythematosus, systemic sclerosis, Sjögren's syndrome and mixed connective tissue disease.

DSF70 autoantibodies had a specificity of 86.8%, a sensitivity of 26.9% and a positive predictive value of 68.2% at an ANA titer of ≥1:160, with respect to the absence of a connective tissue disease.

Table 1. Sensitivity, specificity and positive predictive value of anti-DSF70 autoantibody in different ANA titers (borderline patients excluded)

a) ANA-Titer ≥ 1:80		
N=362	*No present CTD*	*Present CTD*
DSF70 positive	52	21
DFS70 negative	145	144
	Sensitivity: 26.4%	Specificity: 87.3%
Positive predictive value= 71.2%		
b) ANA-Titer ≥ 1:160		
N=326	*No present CTD*	*Present CTD*
DSF70 positive	45	21
DSF70 negative	122	138
	Sensitivity: 26.9%	Specificity: 86.8%
Positive predictive value= 68.2%		
c) ANA-Titer ≥ 1:640		
N=167	*No present CTD*	*Present CTD*
DSF70 positive	17	14
DSF70 negative	48	88
	Sensitivity: 26.2%	Specificity: 86.3%
Positive predictive value= 54.8%		

Conclusion: Autoantibodies to DSF70 often occur in CTD patients and are therefore not a valid exclusion criteria for a CTD. We observed no CTD in 68.2% of patients who were tested positive. Thus, in difficult situations, the DSF70 test may be helpful and the additional exclusion of other autoantibodies may render CTD even less probable.

OP0152

COMPARISON OF DIAGNOSTIC CRITERIA IN BEHÇET DISEASE AND SENSITIVITY IN DIAGNOSING SEVERE MANIFESTATIONS.

C. Álvarez-Reguera[1], A. Herrero-Morant[1], L. Sanchez-Bilbao[1], D. Martínez-López[1], J. L. Martín-Varillas[2], G. Suárez Amorín[3], C. Mata-Arnaiz[4], M. Á. González-Gay[1], R. Blanco[1]. *[1]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*; *[2]Hospital de Sierrallana, Rheumatology, Sierrallana, Spain*; *[3]Hospital Universitario Marqués de Valdecilla, Ophthalmology, Santander, Spain*; *[4]Hospital de Laredo, Rheumatology, Laredo, Spain*

Background: Behçet disease (BD) is characterized by painful recurrent oral aphthosis genital ulcers and skin lesions. Nevertheless, the major causes of morbidity result from ocular, vascular and neurological involvement. Diagnosis of BD is usually performed according to the International Study Group (ISG*) (Lancet 1990; 335:1078-80).* Recently, criteria proposed by the International Team for the Revision of the International Criteria for BD (ITR-ICBD) have demonstrated a higher sensitivity *(J Eur Acad Dermatology Venereol 2014;28:338-47).*

Table 1. Main clinical features according to different diagnostic criteria. Patients characteristics, data are in n (%)

	Expert rheumatologists (N=120)	ISG criteria (N=59)	ICBD criteria (N=96)
Age, mean years / (SD)	38 (13.8)	35.6 (13)	37 (13)
Gender, men/women, N (%)	62/58 (52.1/47.9)	29/30 (49.1/50.8)	48/48 (50/50)
Oral aphthosis, N (%)	113 (94.2)	59 (100)	94 (97.9)
Genital aphthosis, N (%)	71 (78.5)	46 (78)	71 (74)
Skin manifestations N (%)	76 (63.3)	52 (88.1)	64 (71.6)
Ocular lesions, N (%)	54 (45)	31 (52.5)	50 (52.1)
Joint manifestations, N (%)	78 (65)	38 (64.4)	62 (64.6)
Neurological manifestations, N (%)	23 (19.2)	9 (15.2)	20 (21.1)
Vascular manifestations, N (%)	14 (11.6)	7 (11.9)	14 (14.6)
Gastrointestinal features, N (%)	8 (6.6)	3 (5.1)	5 (5.3)

Objectives: To assess **a)** the concordance and differences between ISG and ICDB criteria **b)** sensitivity in diagnosing severe manifestations (ocular, vascular and neurological).

Methods: The study included 120 patients diagnosed with definitive or possible BD by expert rheumatologists. They were diagnosed at a well-defined population in Northern Spain between January 1980 and December 2019. The ISG and ICBD diagnostic criteria for BD were applied to all patients and compared among them.

Results: 120 patients (62 men/ 58 women) were studied. Mean age at diagnosis was 37.6±13.8 years. 59 (49.2%) patients fulfilled ISG criteria and 96 (80%) ICBD criteria. Concordance between both criteria was moderate (Kappa 0.41). ICBD criteria diagnosed more patients with neurological (χ^2=49.1, p<0.01), vascular (χ^2= 56.7, p<0.01) and ocular manifestations (χ^2=84.4 p<0.01) (Figure**).**

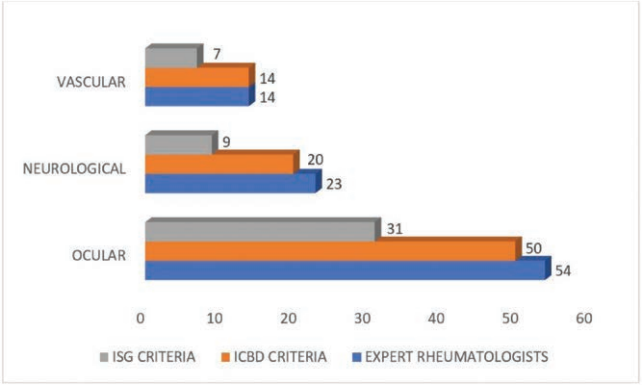

Figure 1. Number of patients with vascular, neurological or ocular manifestations diagnosed with BD by different criteria. **Abbreviations: ITRC-ICBD:** International Team for the Revision of the International Criteria for BD; **ISG:** International Study Group for Behçet Disease.

Conclusion: ICBD criteria are more likely to diagnose BD and classify more patients with severe manifestations of the disease.

Background: Previous research show that patients with rheumatic and musculoskeletal diseases (RMDs) benefit from rehabilitation, but the health effects are small and decline over time. Later reports reveal that the quality of rehabilitation services varies largely, with lack of coordination and continuity across levels of care. This may weaken the effect on patients' long-lasting health, ability to self-manage their conditions and achieve their goals. We therefore developed a new, evidence-based rehabilitation program to strengthen the quality and bridge the gaps in rehabilitation services for this patient group.

Objectives: To evaluate if a new rehabilitation program (the BRIDGE program) designed to improve the quality and continuity of rehabilitation across levels of care, was more effective than traditional rehabilitation in improving goal achievement, function, self-assessed health and health related quality of life (HR-QoL) in patients with RMDs.

Methods: In a stepped wedge cluster randomised controlled trial 8 rehabilitation centres organised in secondary health care and located across all health regions of Norway recruited a total of 374 patients with rheumatic and musculoskeletal diseases. These patients received either traditional rehabilitation (control) (n=206), or traditional rehabilitation extended with an individually adapted complex intervention consisting of structured goal setting, plans for self-management, motivational interviewing, self-monitored digital feedback, and tailored follow-up support after discharge according to patients' needs and available resources in primary healthcare (the BRIDGE program) (n=168). Patient-reported data were collected electronically on admission and discharge from rehabilitation, and after 2, 7, and 12 months. The primary outcome measure was patients' goal achievement measured by the Patient Specific Functional Scale (PSFS) (0-10, 10=best) seven months after rehabilitation stay. Secondary outcome measures were function measured by the 30-seconds Sit-To-Stand Test (30secSTS), self-assessed health and HR-QoL measured by the EuroQol instruments EQ-5D-5L-VAS (0-100, 100=best) and EQ 5D-5L-index (-1 to 1, 1=best). The main comparative analysis was performed on the intention to treat population, using all available data, by linear mixed models adjusted for the baseline scores and for the potentially confounding effects of calendar time and data clustering. Sensitivity analyses were performed on data provided by the per protocol population according to predefined criteria, in addition to centerwise comparisons of the control and intervention groups.

Results: No significant treatment effects of the BRIDGE-program were demonstrated either for patients' goal achievement (mean difference 0.1 [95% CI: -0.5, 0.8], p=0.70) (Figure 1), function (mean difference 0.9 [95% CI: - 0.4, 2.2], p=0.18), self-assessed health (mean difference -0.1 [95% CI: -4.1, 3.9], p=0.98), or HR-QoL (mean difference 0.0 [95% CI: -0.0, 0.0], p=0.99) seven months after rehabilitation. Sensitivity analyses confirmed the findings from the primary analysis. A significant proportion of missing data for the primary outcome measure (29% in the control and 41% in the intervention group), caused by errors in the digital data collection system, may impair the reliability of the results.

Conclusion: The BRIDGE program was not shown to be more effective than traditional rehabilitation in terms of improving goal achievement, function, self-assessed health and HR-QoL in patients with RMDs. There is still a need for more knowledge about factors that can improve the quality, continuity and long-term health effects of rehabilitation for this patient group.

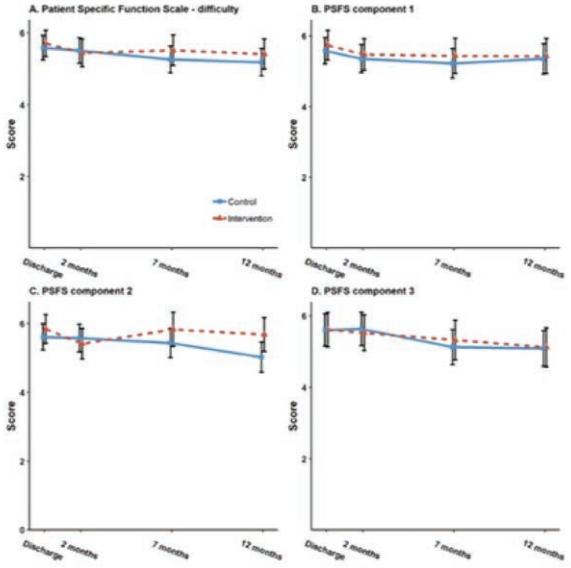

Figure 1. Goal achievement measured with PSFS (0-10, 10 best) indicated by difficulty to perform goal at 4 time-points: discharge from rehabilitation (baseline for this particular outcome) and after 2, 7 and 12 months. Vertical lines indicate the estimated mean values (center) with 95% confidence interval. Horizontal lines show the fluctuating mean PSFS values from baseline to 12 months after discharge. Graph A shows the average of the first three goals set by the patients, measured over time, while the graphs B, C and D show the results separately for the first, second and third goal, respectively.

OP0154-HPR FEASIBILITY OF A WEB-BASED, PEER-SUPPORTED EXERCISE PROGRAM FOR PEOPLE WITH HIP OR KNEE OSTEOARTHRITIS

K. L. Joseph[1,2], H. Solveig Dagfinrud[1], K. B. Hagen[3], K. Røren Nordén[1], C. Fongen[1], O. M. Wold[4], A. T. Tveter[1]. *[1]Diakonhjemmet Hospital, National Advisory Unit on Rehabilitation in Rheumatology,The division of Rheumatology and Research, Oslo, Norway*; *[2]University of Oslo, Faculty of Medicine, Institute of Health and Society, Oslo, Norway*; *[3]Norwegian Institute of Public health, Division of Health Service, Oslo, Norway*; *[4]Norwegian Association for Rheumatic diseases, Norwegian Association for Rheumatic diseases, Oslo, Norway*

Background: Long-term physical activity (PA) and exercise is recommended as a cornerstone in the treatment of people with osteoarthritis (OA) (1), yet adherence to exercise is challenging (2). The treatment needs for this large group of patients cannot be fully managed within the health-care system, thus developing innovative and effective follow-up strategies is urgently needed.

Objectives: To explore the feasibility and preliminary efficacy of a web-based, peer-supported exercise program for people with hip or knee OA.
Methods: This study was a single-group, pre-post feasibility study. Patients aged 40-80 years with hip or knee OA who were not candidates for surgery were eligible. The 12-week intervention was delivered through a patient-organizations (The Norwegian Association for Rheumatic Diseases) web-based platforms, and included weekly exercise programs, weekly motivational messages, an OA and exercise website and assigned peer-supporters. Feasibility was evaluated by calculating the proportion of eligible patients who were enrolled and retained at follow-up, as well as time resources used on delivery of the intervention. Acceptability was evaluated by calculating proportion of patients who had valid baseline accelerometer data and completed the maximal cardiorespiratory exercise test according to protocol. Primary efficacy measures were change in PA assessed by accelerometers and change in exercise capacity (VO2peak) assessed by indirect maximal cardiorespiratory exercise test. Secondary efficacy measures were change in patient reported outcomes assessed by HOOS and KOOS (www.koos.nu) (a 10-point change in normalized scores was considered a minimally important change). Data was analysed using paired sample t-test, given as mean change (95% confidence interval) and p-values.
Results: We identified 49 eligible patients of which 35 (71%) consented and were enrolled. Among those who consented, 22 (63%) were retained. Time resources used on delivery of the exercise programs and motivational messages were mean (SD) 7.3±1.1 min per week/patient. Compliance with wearing the accelerometer was mean (SD) 6.1±1.0 valid days (mean (SD) 13.8±1.3 hours/day). Twenty (67%) out of 30 patients who attended baseline testing performed the maximal cardiorespiratory exercise test, of which 18 completed according to protocol. Due to Covid-19 restrictions, follow-up testing of primary efficacy measures included only eight patients. For these patients there was a significant increase from baseline to follow-up on moderate-to-vigorous PA (mean change 16.4 minutes/day; 95% CI 6.9, 25.9, p=0.005) and VO2peak (mean change 1.83 ml/kg/min; 95% CI 0.29, 3.36, p=0.026). Across all secondary efficacy measures 30-52% of the patients (n=21) improved from baseline to follow-up (Figure 1).

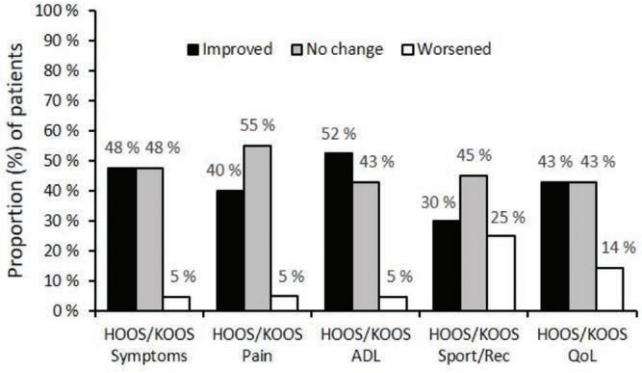

Figure 1. Proportion (%) of patients with Minimally Important Change (from baseline to follow-up) in normalized scores in subdomains of Hip disability and Osteoarthritis Outcome Score (HOOS) / Knee injury and Osteoarthritis Outcome Score (KOOS).

Conclusion: Overall, the examined study processes were considered to be feasible and acceptable. Some minor amendments should be applied to improve the recruitment and retention rate before it can be carried out in a larger trial. The efficacy results should be interpreted with caution due the small sample size. However, if the positive results in this study are confirmed in a power-calculated randomised controlled trial, our novel follow-up strategy may be implemented and recommended for long-term management of hip and knee OA.

OP0155-HPR

REMOTE MANAGEMENT OF RHEUMATOID ARTHRITIS VS ROUTINE OUTPATIENT FOLLOW-UP: A PROSPECTIVE, LONGITUDINAL REAL-WORLD STUDY

M. Ndosi[1], S. Kingsbury[2], P. G. Conaghan[2]. [1]*University of the West of England, Faculty of Health and Applied Sciences, Bristol, United Kingdom*; [2]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: Remote management of rheumatoid arthritis (RA) using patient self-assessment of disease and patient-reported outcomes has potential to inform timely clinical decisions on disease management, reduce burden on busy rheumatology services and promote effective self-management. However, it is unclear how patients' self-reporting relates to treatment decisions.
Objectives: To determine the agreement between remote treatment decisions based on patient self-assessment questionnaire assessed blindly by a health professional and treatment decisions based on routine outpatient monitoring appointments.
Methods: This was a prospective real-world study including patients (who gave informed consent) enrolled in an observational study of RA patients starting a new biologic therapy.
Enrolled patients continued with their usual care and usual clinic monitoring. In addition, they completed at home, self-assessment questionnaires at monthly intervals, including: two self-reported components which are collected as part of routine clinical practice (joint stiffness and flare), visual analogue scales for pain, global health and fatigue; and HAQ-DI and self-efficacy scales (Arthritis Self-Efficacy Pain and Other Symptoms subscales) at inclusion visits, 12 and 24 months. Remote treatment decisions were made by an independent (blinded) health professional, based on the self-assessment questionnaires and information collected in the study: medical history, ongoing therapies for RA, clinical outcomes, adverse events and toxicity. In this analysis, the independent blinded clinician did not have the same information as the routine hospital visit clinician (blood results and joints assessment).
The remote decisions were matched with the hospital visit decisions (within 2 weeks) and the measure of agreement between the 2 raters (independent blinded health professional and clinician at outpatient appointment) were evaluated using kappa coefficient: <0.2, 0.21-0.40, 0.41-0.60, 0.61-0.80 and 0.81-0.99 representing poor, fair, moderate, substantial and almost perfect agreement respectively.
Results: A total of 72 RA patients were recruited into the sub-study: mean (SD) age 57.8 (11.6), disease duration 11.7 (10.3) and 52 (87%) were female. The pre-categorised remote decisions were: no change to biologic, stop biologic, add concomitant DMARD, reduction/removal of a concomitant DMARD and bring in for review. There were 57 matched decisions between the independent health professional and the outpatient clinicians. The outpatient clinician made 7 changes to biologic and 18 non-biologic therapy changes, while the remote health professional made 1 change to biologic and 17 changes to a non-biologic DMARD including bringing in for review. The self-assessment questionnaires reported 34 RA flares of which 21 had resolved. In the matched decisions, there was only one adverse event that needed stopping treatment, identified by both the remote and the outpatient treatment. The independent health professional and the outpatient clinician had a 'fair' agreement on changes to biologic therapy (Kappa = 0.226, p = 0.007) and overall changes to RA therapy (Kappa = 0.24, p = 0.07).
Conclusion: Remote RA monitoring using patient self-assessment and outcome measures was feasible with fair agreement on treatment decisions. Further work is required on understanding the importance of adding blood test monitoring to remote decision-making.

OP0156-HPR

THE EFFECT OF A PERSON-CENTERED SMOKING CESSATION PROGRAM IN RHEUMATOID ARTHRITIS PATIENTS IN A RHEUMATOLOGY OUTPATIENT CLINIC SETTING – RESULTS OF AN INTERVENTIONAL FEASIBILITY STUDY

M. L. Karlsson[1,2], K. Hertzberg-Nyquist[3], S. Saevarsdottir[2], I. E. Lundberg[1,2], I. Demmelmaie[4], S. Pettersson[1], K. Chatzidionysiou[2,5]. [1]*Karolinska University Hospital, Department of Gastroentorogy, Dematology and Rheumatology, Stockholm, Sweden*; [2]*Karolinska Institute, Department of medicine Solna, Stockholm, Sweden*; [3]*Centre of Rheumatology, Rehumatology, Stockholm, Sweden*; [4]*Uppsala University, Department of Public health and Caring Science, Uppsala, Sweden*; [1]*Karolinska University Hospital, Department of Gastroentorogy, Dematology and Rheumatology, Stockholm, Sweden*

Background: Smoking is associated with worse treatment response[1] and higher mortality[2] in rheumatoid arthritis (RA).

Objectives: To assess the effect of a smoking cessation intervention in a rheumatology setting.
Methods: We designed a smoking cessation interventional feasibility study. RA patients who were active smokers were asked to participate. A nurse-delivered program consisting of behavioural changes techniques and voluntary pharmacotherapy was executed. The intervention was at baseline and at several time points during a 24 month period, based on the individual patient's needs. Smoking status was collected at baseline, 6, 12, 18 and 24 months. Smoking cessation was verified by 7-days abstinence and carbon monoxide in expiratory air. The main outcome was the proportion of patients who quit smoking (QS) at 24 months.
Results: A total of 99 patients were included in the study between 2011-2020. Median (IQR) age of patients was 58 (50 - 64), 69 % were female and 82% were RF and/or ACPA positive. 59% of patients had a newly diagnosed RA, (included from the early RA-track), with a median (IQR) symptom duration of 5 (2-9,5) months. Patients with established RA 41% (included from regular rheumatology department) had a median disease duration of 4 (2-8) years. After 24 months 21% quit smoking (QS) (Table 1). At months 6, 12, 18 and 24 the proportion of QS patients was 12, 13, 15 and 21, respectively. The proportion of QS patients at month 12 and continued being in the QS group throughout the study period was 10%. In the subgroup of patients who continued smoking (CS) the median number of cigarettes per day was significantly reduced at all follow-up time points (Table 1). No significant differences were observed at baseline between CS at 24 months and QS, apart from the proportion of patients who reported anxiety (extracted from EQ-5D and defined as absent or present), which was significantly fewer in the QS group (Table). In the QS group at month 24, the proportion of females was numerically lower compared to CS (52% vs. 73%, p=0.07).

Table 1. Baseline demographical, clinical characteristics and number of cigarettes at specific time-points for patients who were non-smokers (QS) and smokers (CS) at month 24.

	QS N=21 (21%)	CS N=78 (79%)	Difference between QS and CS (p-value)
Age*(median, IQR)	60 (53-62)	57 (50-64)	0.94
Symptom duration in early RA patients (months) (median, IQR)	6 (2-12)	4.5 (2-8.5)	0.49
Disease duration of patients with established RA (years) (median, IQR)	8 (3.5-16.5)	3 (2-6)	0.12
% females	52	73	0.07
% RF and/or ACPA positive	85	81	0.70
DAS28* (median, IQR)	4.24 (3.13-5.72)	4.11 (2.88-5.36)	0.69
HAQ* (median, IQR)	0.75 (0.25 -1.38)	0.88 (0.38-1.25)	0.74
VAS pain* (median, IQR)	46.0 (11-60)	34.5 (12-70)	0.90
% of patients with reported anxiety* (part of EQ5D)	28	58	0.02
Smoking duration (years) (median, IQR)	40 (30-50)	40 (34-49)	0.92
Median number of cigarettes per day			
-at baseline	10 (7-15)	12 (10-20)	0.22
-at 6 months	0 (0-3)	6 (3-10)	0.006
-at 12 months	0 (0-5)	6 (3-10)	0.0003
-at 18 months	0 (0-0)	6 (2-10)	0.00
-at 24 months	0 (0-0)	6 (3-10)	0.00

*=measured at baseline

Conclusion: Smoking cessation intervention in a rheumatology clinic setting may facilitate reduced smoking or complete cessation in patients with RA. Patient who did not report anxiety were more likely to quit smoking.

CHANGES IN PAIN AND HAND FUNCTION AFTER MULTIMODAL OCCUPATIONAL THERAPY AND/OR SURGERY IN PATIENTS WITH CARPOMETACARPAL OSTEOARTHRITIS

A. T. Tveter[1], N. Osteras[1], R. Nossum[2], R. E. Mehl Eide[3], Å. Klokkeide[4], K. Hoegh Matre[3], M. Olsen[4], I. Kjeken[1]. *[1]Diakonhjemmet Hospital, Department of Rheumatology, National advisory unit on rehabilitation in rheumatology, Oslo, Norway*; *[2]Trondheim University Hospital, St.Olavs Hospital, Clinic for Clinical Service functions, Trondheim, Norway*; *[3]Haukeland University Hospital, Department of Rheumatology, Bergen, Norway*; *[4]Haugesund Rheumatism Hospital AS, Department of Rheumatology, Haugesund, Norway*

Background: Carpometacarpal osteoarthritis (CMC1 OA) is a subset of hand OA, often leading to pain and functional limitations. The EULAR recommends conservative treatment as first-line management, and a recent study showed significant short-term effect of multimodal occupational therapy on pain and hand function in patients referred to surgical consultation[1]. However, long-term results are lacking.
Objectives: To explore the long-term effect of multimodal occupational therapy on pain and hand function in patients with CMC1 OA, and to assess the differences between those undergoing surgery or not in the two groups.
Methods: This project presents secondary analyses of a multicentre RCT. Patients referred by their general practitioner to surgical consultation due to CMC1 OA at three Norwegian hospitals from 2013-2015 were eligible. During the waiting period between referral and surgical consultation, 180 patients were randomized to usual care (information, n=90) or a 3-month multimodal occupational therapy intervention (patient education, hand exercises, orthoses and assistive devices, n=90). Patients were assessed at baseline, and 4 (before surgical consultation), 18 and 24 months. Pain at rest was assessed using a 11-point numeric rating scale, and hand function was self-reported with the MAP-Hand (1-4, 1=no problem). The long-term within- and between-group differences on pain and hand function were assessed using repeated measure ANOVA. Sub-analyses were done among those undergoing surgery or not in the two groups. P-value <0.05.
Results: 163 patients (63 (8) years, 81% women) were included in the analyses. Both groups showed a significant reduction in pain and improvement in hand function over time (p<0.001), with a significant between-group difference for pain (F (1, 161) = 8.56, p = 0.004), in favour of the intervention group, but not hand function.
After 2 years, 22 patients had undergone surgery in the intervention group vs 29 in the control group. No significant difference over time were found in pain or hand function between those undergoing surgery or not in the two groups. However, at the time of the surgical consultation, significantly higher pain (Figure 1) and poorer hand function were reported among those later undergoing surgery in the control group (p≤0.001). Surgery did not lead to further improvement in pain and hand function in the intervention group.

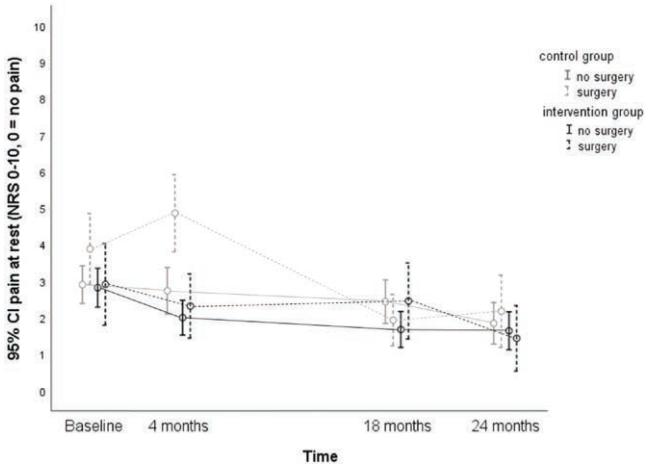

Figure 1. Between-group difference on pain over a 2-year period. The control group is marked in light grey and the intervention group in black. Those who underwent surgery are marked with dotted lines, while those who did not are marked with solid lines (n=163)

Conclusion: The results showed that the positive effect of multimodal occupational therapy on pain and hand function persisted over the 2-year period, however, no significant between-groups difference over time was found. No significant between-group differences were found when dividing into sub-groups, however, those later undergoing surgery in the control group scored significantly worse on pain and hand function at the time of surgical consultation. The results may imply that patients who would benefit from surgery were identified, and that surgery does not give an additional benefit in patients who have received multimodal occupational therapy. This needs to be further investigated.

OP0158-HPR THE FALL PREVENTION PROGRAMME 'SICHER DURCH DEN ALLTAG' IS EFFECTIVE AND COST-EFFECTIVE

K. Niedermann Schneider[1], A. Meichtry[1], B. Zindel[2], B. Brunner[3], M. Ernst[1], V. Krafft[2], R. Mattli[3], I. Nast[1], M. Wirz[1], S. Wieser[3]. *[1]Zurich University of Applied Sciences, Institute of Physiotherapy, Winterthur, Switzerland*; *[2]Swiss League Against Rheumatism, Swiss League Against Rheumatism, Zurich, Switzerland*; *[3]Zurich University of Applied Sciences, Winterthur Institute of Health Economics, Winterthur, Switzerland*

Background: Falls in older people are frequent and have often severe health consequences. Reinforced by population ageing, they represent a substantial challenge for health care systems. Falls are often due to a combination of intrinsic and extrinsic risk factors. For these reasons, the Swiss League Against Rheumatism (SLAR) developed the multidimensional, home-based fall prevention programme 'Sicher durch den Alltag' ('Safely Through Everyday Life'). The programme has been implemented nationwide since 2013 and is financed by selected health insurance companies. Trained physiotherapists (PTs) or occupational therapists (OTs) visit the senior at home for a 60-90 minutes session. They perform a detailed assessment of the senior's individual risk of falling and subsequently eliminate identified environmental risk factors and provide tailored exercises. After 4 weeks, the PT/OT calls the senior to discuss further needs. The cost of the intervention is at 500 Swiss Francs (approximately 460 Euro) per senior.

Objectives: Assess the effectiveness and cost-effectiveness of this fall prevention programme.

Methods: A prospective, longitudinal observational study was performed. Baseline study data was assessed at the home visit, including the self-reported number of falls during a) the year and b) the month before the visit. The participants of the programme were monitored for one year after the home visit by bi-monthly telephone calls. Participants were asked to report the falls that they continuously documented in a diary. Questionnaires administered orally included the Falls Efficacy Scale-International (FES-I), a Quality of Life Questionnaire (EQ-5D-5L), and the amount of moderately intensive physical activity (PA).To compare the falls during the years before and after the home visit, the mean number of falls before the visit was calculated based on reported falls during a) the year and b) the month (multiplied by 12) before the visit. A 2:1 weighted mean from a) and b) was calculated, considering that retrospective reporting over one year or over one month may underestimate or overestimate, respectively, the number of falls. Statistical analysis fitted a GEE-Poisson-Modell (Generalized Estimating Equations) to the data for number of falls and a Linear Mixed Model (LMM) for fear of falling, quality of life and PA. Falls related health care spending in the years before and after the intervention were compared based on health insurance claims data.

Results: Overall, 639 person-years of observation time were available for analysis. Participants were mainly female (59%) and had a mean age of 81.8+/- 5.2 years. On average, rate of falling decreased from 1.35 to 1.02 per person year (-23.9%), fear of falling decreased by -1.27 (95%CI -1.50, -1.05), quality of life improved by -0.88 (95%CI -1.09, -0.68), PA increased by 9.87 minutes per day (95%CI 5.65, 14.09). Health insurance claims data showed a 48.0% reduction (95%CI 30.5%, 61.0%) of medically treated falls. The average cost per prevented medically treated fall was estimated at 1317 Swiss Francs (approximately 1200 Euro) and the probability of the intervention being cost-saving at 47%.

Conclusion: This low-threshold fall prevention programme was found to be very effective and cost-effective. Home visits by trained PTs or OTs contribute substantially to reduce falls in the elderly. The high cost-effectiveness is explained by a substantial reduction of severe falls.

OP0159-HPR IMPACT OF NON-PHARMACOLOGICAL INTERVENTIONS TARGETING SLEEP DISTURBANCES OR DISORDERS IN PATIENTS WITH INFLAMMATORY ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMISED TRIALS

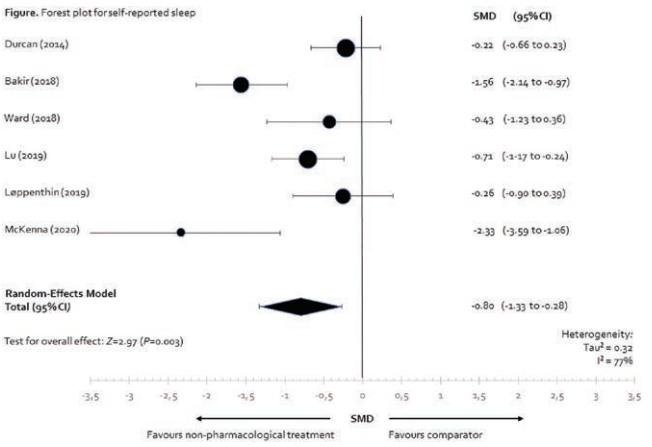
K. M. Latocha[1], K. Løppenthin[2,3], S. Al-Bazy[1], T. Albrechtsen[1], H. Jensen[1], M. Østergaard[1,3], P. Jennum[3,4], B. A. Esbensen[1,3], R. Christensen[5,6]. *[1]Rigshospitalet, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Glostrup, Denmark*; *[2]Rigshospitalet, Research Unit for Cancer Late Effect, Department of Oncology, Copenhagen, Denmark*; *[3]Copenhagen University, Department of Clinical Medicine, Faculty of Health and Medical Sciences, København, Denmark*; *[4]Rigshospitalet, Danish Center for Sleep Medicine, Department of Clinical Neurophysiology, Glostrup, Denmark*; *[5]The Parker Institute, Musculoskeletal Statistics Unit, Copenhagen, Denmark*; *[6]University of Southern Denmark, Department of Clinical Research, Faculty of Health Sciences, Odense, Denmark*

Background: Patients with inflammatory arthritis (IA) often present limitations in daily life due to unpredictability, severity and chronicity of the disease, reduced functional ability and health-related quality of life. Moreover, sleep disturbances or disorders have been reported in up to 40-90% of patients with IA [1-3]. Sleep disturbances are further associated with pain, fatigue, mental well-being and disease activity [4]. As chronic us of hypnotic drugs are associated with tolerance and side effects, there is growing interest in non-pharmacological management to improve sleep.

Objectives: With a systematic review and meta-analysis, our primary objective was to evaluate the evidence of non-pharmacological interventions targeting sleep in patients with IA. Primary outcome was sleep domains, while secondary objectives were based on the core outcome domains for IA trials and harms.

Methods: Following protocol closure, a systematic search was undertaken in MEDLINE, CENTRAL, PsycINFO, CINAHL, ClinicalTrials.gov, ACR and EULAR in September 2020. Eligible studies were randomised trials with adults with IA and concomitant sleep disturbances or disorders, comparing a non-pharmacological intervention targeting sleep disturbances or disorders to another non-pharmacological intervention, a pharmacological intervention or standard care. Screening of titles, abstracts, and subsequent full text assessment were conducted independently by two reviewers using the Covidence tool. Randomisation, blinding, and adequacy of analyses was assessed using the Cochrane's RoB tool and the overall quality of evidence was rated using GRADE methodology. Disagreements were resolved at consensus meetings with last authors. Effect sizes for continuous outcomes were based on the standardised mean difference (SMD), combined using standard random-effects meta-analysis (all with 95% CIs).

Results: Six trials (308 patients) were included in the quantitative synthesis. Two trials included patients with the sleep disorder insomnia and the remaining four trials included patients with sleep disturbances. Sleep domains were measured with Pittsburgh Sleep Quality Index (PSQI) or Insomnia Severity index (ISI). Three trials reported improvement on sleep following foot reflexology, auricular plaster therapy, and exercise. The overall meta-analysis presented in the figure of forest plot for self-reported sleep suggests that non-pharmacological interventions have a potentially large effect size of -0.80 (95% CI, -1.33 to -0.28) on sleep. However, the quality of the evidence was assessed as corresponding to low, given that the body of the evidence was rated down twice, due to serious study limitations and inconsistency.



Conclusion: Although the effect of non-pharmacological interventions targeting sleep disturbances or the sleep disorder insomnia was statistically highly significant, the implication for clinical practice is questionable because of the overall quality evidence. None of the core outcomes used in contemporary IA trials have indicated clinical benefit in favour of non-pharmacological interventions targeting sleep disturbances or disorders.

In conclusion, more rigorous research on non-pharmacological management of sleep disturbances and disorders is urgently needed, also aimed at specific sleep disorders, in order to fully reveal the clinical utility of these novel treatment options. At this point, non-pharmacological treatment of sleep disturbances or disorders is promising and potentially highly effective, and may have the potential to persistently decrease the symptom burden and increase the quality of life of patients with IA.

OP0160-HPR

PREFERENCES FOR TREATMENTS TO PREVENT RHEUMATOID ARTHRITIS: DISCRETE CHOICE SURVEY OF GENERAL POPULATIONS IN UNITED KINGDOM, GERMANY, AND ROMANIA

G. Simons[1], J. Veldwijk[2], R. DI Santostefano[3], M. Englbrecht[4], C. Radawski[5], L. Valor[6], K. Raza[7], M. Falahee[7]. [1]*University of Birmingham, Rheumatology Research Group, Institute of Inflammation and Ageing, Birmingham, United Kingdom*; [2]*Erasmus University Rotterdam, Erasmus School of Health Policy and Management, Rotterdam, Netherlands*; [3]*Janssen R&D, Janssen R&D, NJ, United States of America*; [4]*Freelance data scientist, Freelance data scientist, Eckental, Germany*; [5]*Eli Lilly & Company, Eli Lilly & Company, Indianapolis, United States of America*; [6]*Friedrich-Alexander-University Erlangen, Department of Internal Medicine, Erlangen, Germany*; [7]*University of Birmingham, Rheumatology Research Group, Institute of Inflammation and Ageing, Birmingham, United Kingdom*

Background: There is increasing research focus on intervention for rheumatoid arthritis (RA) at the earliest stages of disease development, including treatment to prevent RA in at-risk groups. Novel cellular therapies are in development, and the effectiveness of existing immunomodulatory agents to prevent RA in those at risk is under investigation. Quantitative evidence of likely uptake of preventive treatments, and preferences for benefits and risks of such treatments is limited.

Objectives: To quantify preferences for preventive therapies for RA.

Methods: A web-based survey (n = 2959) was administered to an age- and gender- stratified sample of adults in the general population from online survey panels in the UK, Germany, and Romania. After receiving information about RA, questions to check comprehension of background information, an introduction to the survey tasks and warm-up questions, participants were asked to imagine that they were experiencing arthralgia (without swelling) and had positive autoantibody tests indicating a 60% chance of developing RA in the next two years. Using a discrete choice experiment with a Bayesian D-efficient design, participants were offered a series of 15 choices between no treatment and two unlabeled hypothetical treatments to lower risk of RA development. Treatments were defined by six attributes with varying levels including benefits, risks, and frequency/route of administration (Table 1). One choice task with fixed levels described treatments representative of those under investigation for RA prevention (abatacept, hydroxychloroquine, atorvastatin and tolerogenic cell-based therapy). Attribute selection and presentation was informed by previous qualitative research, ranking surveys, systematic literature review, and expert opinion. Survey design was informed by patient research partners. The survey was pretested during qualitative interviews and revised. A pilot of the final survey with 100 respondents was conducted to obtain priors for the final experimental design. Random parameters logit (RPL) models were used to estimate relative importance of treatment attributes and likely treatment uptake rates in each country.

Table 1. Treatment attributes and levels

Attribute	Levels
Chance of developing RA reduced from 60% to	10%; 20%; 30%; 40%
How the treatment is taken	A shallow injection under the skin A drip into the vein One or two tablets
How often the medication has to be taken	Daily Weekly Monthly Every 6 months
Chance of mild side effects	2%; 5%; 10%
Chance of a serious infection due to treatment	0%; 1%; 5%
Chance of a serious side effect that is potentially irreversible	1 in 100,000 people 20 in 100,000 people 100 in 100,000 people

Results: Across all three countries, effectiveness was the treatment attribute that had most impact on treatment choice (Figure 1). Method of administration was second most important for respondents from the UK and Romania but less important for German respondents. Risks of serious infection and serious side effects were more important determinants of treatment choice for respondents in Romania than they were in the UK and Germany. Percentage choice of fixed profiles reflecting abatacept, atorvastatin, hydroxychloroquine, tolerogenic cell-based therapy and no treatment differed across countries (χ^2=78.90; p<0.001): 28.3%, 20.6%, 22.2% 18.5% and 10.4% respectively in the UK; 31.3%, 18.8%, 11.2%, 23.4% and 15.3% in Germany; and 27.6%, 20.5%, 15.8%, 21.7% and 14.4% in Romania.

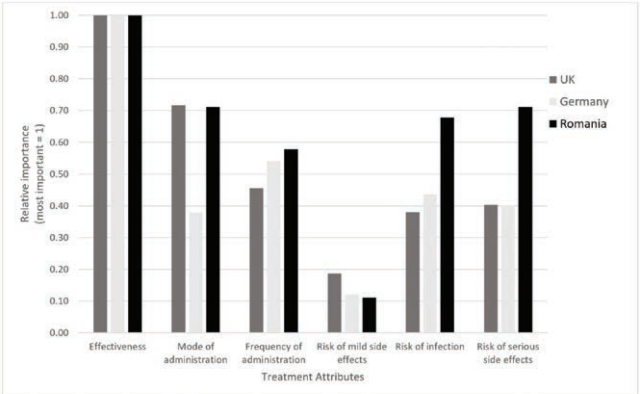

Figure 1: Relative importance of treatment attributes stratified by country; UK (N=982), Germany (N =984) and Romania (N =993). Separate RPL models were used for each country.

Conclusion: This study suggests that effective preventive treatments for RA are acceptable to members of the general population told to assume up a 60% chance of developing RA. The relative importance of treatment attributes and likely uptake of fixed treatment profiles differed across countries. These findings are informative for the design of prevention trials, and the development of informational resources and efficient preventive strategies for those at risk of developing RA.

Advances in Pediatric Rheumatology

OP0161 PREDICTIVE VALUE OF MUSCULOSKELETAL ULTRASOUND IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS IN CLINICAL REMISSION

M. Mazzoni[1], S. Merlo[1,2], C. Morreale[1,2], A. Pistorio[3], S. Viola[2], S. Ancona[1,2], F. Magnaguagno[4], A. Consolaro[1,2], A. Ravelli[1,2], C. Malattia[1,2]. *[1]Università degli Studi di Genova, Dipartimento di Neuroscienze, Riabilitazione, Oftalmologia, Genetica e Scienze Materno-Infantili, Genoa, Italy*; *[2]IRCCS Istituto Giannina Gaslini, Clinica Pediatrica e Reumatologia, Genoa, Italy*; *[3]IRCCS Istituto Giannina Gaslini, Epidemiologia e Biostatistica, Genoa, Italy*; *[4]IRCCS Istituto Giannina Gaslini, UOC Radiologia, Genoa, Italy*

Background: The accurate assessment of remission status in JIA patients is of utmost relevance to taper medications and prevent side effects from their long-term administration. In RA patients in clinical remission (CR), musculoskeletal ultrasound (MSUS) allows to detect persistent joint inflammation (subclinical synovitis), which predicts disease flare and structural damage progression. Although subclinical synovitis has been reported in a substantial proportion of JIA patients with inactive disease, its prognostic value is still being defined.
Objectives: 1) to investigate the prevalence of MSUS-detected subclinical synovitis in JIA patients in CR; 2) to establish which and how many joints should be scanned to reliably assess remission; 3) to evaluate the persistence of subclinical synovitis over the time; 4) to investigate whether subclinical synovitis entails a risk of disease flare and whether it should affect the therapeutic strategy.
Methods: 135 consecutive JIA patients who met the Wallace criteria for CR were included in this 3-years prospective study. All patients underwent MSUS assessment of 56 joints at study entry and at 6 months follow-up visit. Joints were scanned for synovial hyperplasia, joint effusion and Power Doppler (PD) signal by two independent ultrasonographers. Patients were followed clinically for 3 years. A flare of synovitis was defined as a recurrence of clinically active arthritis. The association between clinical and MSUS variables with flare, was evaluated by adjusted logistic regression models.
Results: 135 patients (78.5% F; median age 11.3 y; median disease duration 5.7 y; median CR duration 1.4 y) were included. Fifty-seven/135 (42.2%) patients had persistent oligoarthiritis; 41/135 (30.4%) extended oligoarthiritis; 32/135 (23.7%) polyarthiritis; 5/135 (3.7%) systemic arthritis. Seventy-eight/135 (57.7%) patients were in CR on medication. Subclinical synovitis was detected in 32/135 (23.7%) patients and in 53/7560 (0.7%) joints. Subclinical tenosynovitis was present in 20/135 (14.8%) patients. Subclinical synovitis was found more frequently in the ankle and wrist joints. 58.6% of patients showed persistent subclinical synovitis at 6 month follow up MSUS examination. During the 3-year follow up 45/135 (33.3%) patients experienced a disease flare (median survival time 2.2 y). PD positivity in tendons was the stronger independent risk factor of flare on multivariable regression analysis (HR: 4.8; P=0.04). Other predictors of flare were the JIA subtype (oligo-extended form: HR: 2.3; P=0.031) and the status of CR on medication (HR: 3.7; P=0.002).
Conclusion: our results confirm that MSUS is more sensitive than clinical evaluation in the assessment of persistent synovial inflammation in JIA patients. Subclinical tenosynovitis was the best predictor of disease flare. To date, the role of tenosynovitis in the diagnosis and prognosis of JIA has been poorly investigated. Our results further support the role of MSUS, especially of the wrist and the ankle, in monitoring JIA patients in clinical remission and to predict disease flare.

OP0162 ETANERCEPT RESPONSE CLUSTERS IN JUVENILE IDIOPATHIC ARTHRITIS

S. Shoop-Worrall[1,2], K. Hyrich[1,3], L. Wedderburn[4,5,6], W. Thomson[3,7], N. Geifman[2]on behalf of BSPAR-ETN Study, BCRD Study, CAPS, CHARMS, CLUSTER. *[1]The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; *[2]The University of Manchester, Centre for Health Informatics, Manchester, United Kingdom*; *[3]Manchester University NHS FT, Manchester Academic Health Science Centre, NIHR Manchester BRC, Manchester, United Kingdom*; *[4]UCL Great Ormond Street Institute of Child Health, Centre for Adolescent Rheumatology Versus Arthritis, London, United Kingdom*; *[5]Great Ormond Street Hospital NHS Foundation Trust, Paediatric Rheumatology, London, United Kingdom*; *[6]Great Ormond Street Biomedical Research Centre, NIHR, London, United Kingdom*; *[7]The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom*

Background: In children and young people (CYP) with JIA, we have previously identified clusters with different patterns of disease impact following methotrexate (MTX) initiation. It is unclear whether clusters of treatment response following etanercept (ETN) therapy exist and whether, in a group of CYP who have responded inadequately to or had adverse events on methotrexate, similar treatment response patterns exist. Novel response patterns would aid stratified treatment approaches through better understanding and potential forecasting of more specific response patterns across multiple domains of disease.
Objectives: To identify and characterise trajectories of juvenile arthritis disease activity score (JADAS) components following ETN initiation for JIA.
Methods: ETN-naïve CYP with non-systemic JIA were selected if enrolled prior to January 2019 in at least one of four CLUSTER consortium studies: BSPAR-ETN, BCRD, CAPS and CHARMS, at point of starting ETN as their first biological therapy. JADAS components (active joint count, physician's global assessment (0-10cm), parental global evaluation (0-10cm) and standardised ESR (0-10) were collected at ETN initiation and during the following year.
Multivariate group-based trajectory models, that identify clusters of CYP with similar patterns of change over time, were used to explore ETN response clusters across the different JADAS components. Censored-normal (global scores, ESR) and zero-inflated Poisson (active joint count) models were used, adjusting for year of ETN initiation. Optimal models were selected based on a combination of model fit (BIC), parsimony, and clinical plausibility.
Results: Of the 1003 CYP included, the majority were female (70%) and of white ethnicity (90%), with rheumatoid factor-negative JIA the most common disease category (39%).
The optimal model identified five trajectory clusters of disease activity following initiation of ETN (Figure 1). Clusters following ETN were similar and covered similar proportions of CYP to those previously identified following MTX: Fast (Group 1: 13%) and Slow (Group 2: 10%) response, active joint count improves but either physician (Group 3: 6%) or parent global scores (Group 4: 34%) remain persistently raised and a group with persistent raised scores across all JADAS components (Group 5: 36%). Compared to the persistent disease cluster, those with greater improvement had lower age and higher functional ability at ETN initiation and those with persistent raised parent global scores had lower ESR levels and were less likely to be RF-positive at ETN initiation.

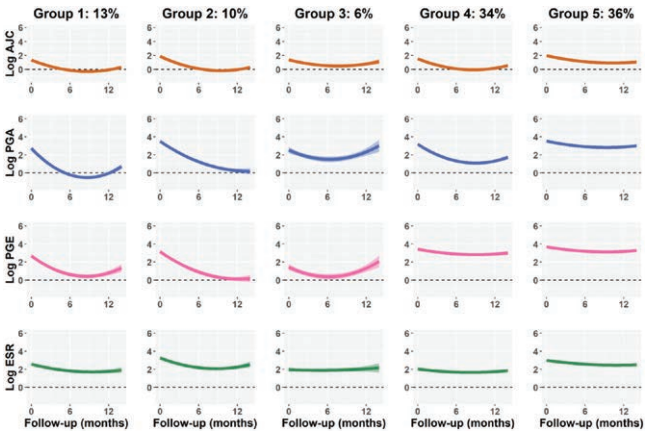

Figure 1. Clusters identified following ETN initiation in children and young people recruited to the UK BSPAR-ETN, BCRD, CAPS and CHARMS studies.

Conclusion: This study has identified that within CYP initiating ETN, similar response clusters are evident to those previously identified following MTX. This commonality suggests a new framework for understanding treatment response, beyond a simple responder/non-responder analysis at a set point, which applies across multiple drugs despite different mechanisms of action and previous unfavourable treatment outcomes. Understanding both clinical factors associated with, and biological mechanisms underpinning, these clusters would aid stratified medicine in JIA.

OP0163 COMPARATIVE ANALYSIS OF ETANERCEPT BIOSIMILAR AND ORIGINATOR USE IN CLINICAL PRACTICE: DATA FROM THE GERMAN BIKER-REGISTRY

G. Horneff[1], D. Windschall[2], T. Hospach[3], S. Mrusek[4], M. Rühlmann[5], A. Klein[1]on behalf of BIKER-Registry collaborative group. [1]*Sankt Augustin, Paediatrics, Sankt Augustin, Germany*; [2]*Sendenhorst, Paediatric Rheumatology, Sendenhorst, Germany*; [3]*Klinikum Stuttgart - Olga Hospital / Women's Hospital, Paediatrics, Stuttgart, Germany*; [4]*Baden-Baden, Paediatric rheumatology, Baden-Baden, Germany*; [5]*Göttingen, Paediatrics, Göttingen, Germany*

Background: In 2017, 2 Etanercept biosimilars became approved. Comparative studies performed in adult patients with rheumatoid arthritis, ankylosing spondylitis or psoriasis by extrapolation led to approval for juvenile idiopathic arthritis (JIA).

Objectives: So far there is limited experience with Etanercept biosimilars in JIA: The large national data base of the BIKER-registry was used to describe experience with Etanercept biosimilars in clinical practice.

Methods: In this retrospective analysis patients exposed to ETA were identified in the German BIKER-registry and grouped into cohorts according to initiation of treatment after 2017, use of the originator and of biosimilars. The course of JADAS10, Physician global assessment VAS 0–100-mm, Parent/patient global assessment VAS 0–100-cm, Active joint count 0-71, truncated at 10, ESR and CHAQ-DI was analyzed. Descriptive statistics was used for demographic, clinical data, drug exposure, adverse events (AEs) and events of special interest (ESI).

Results: Until 31.10.2020, 2917 JIA patients were reported to have received Etanercept. Since January 1 2017, in 39 centres treatment with Etanercept was started in 439 patients (377 (85.9%) started with the originator and 62 (14.1%) started a Biosimilar). Biosimilars were prescribed n 17 centres (44%). In 12 centres (31%), Etanercept biosimilars were used first line in 62 patients. In 17 centres (44%), 63 patients switched for the originator to a biosimilar. 3 patients reswitched from the biosimilar to the originator. 4 patient switched from a biosimilar to the originator). 22 centres (56%) had not prescribed a biosimilars so far.

In not a single centre, initiation of a biosimilar was more frequent than of the originator.

The patients' characteristics and disease activity parameters were widely comparable. Patients receiving biosimilar first line were slightly older at disease onset and had a longer disease duration. Patients receiving biosimilar first line had more often rheumatoid factor (RF) negative polyarthritis while extended oligoarthritis was more frequent in the originator cohort. In the switching cohort, more patients had extended oligoarthritis and fewer had RF negative polyarthritis and ERA JIA.

No difference in disease activity parameters was noted, neither at baseline, during the course of treatment nor at last observation upon treatment. A decrease of the JADAS10 indicates improvement in both groups (Figure 1). At the time of switching, 68% had JADAS minimal disease activity (MDA) and 43% were in JASDAS remission. At month 6 and 12 these numbers increased to 74%/65% and 62%/50%.

In total, 66 adverse events (AE) were reported in 45 patients upon biosimilar treatment.

33 patients had 1, 5 patients 2, 5 patients had 3 and 2 reported 4 events. Adverse event of special interest were hypersensitivity n=1, injection site reaction n=1, new onset of psoriasis n=1, celiac disease n=1, Crohn's diesease n=1, elevated transaminases n=2, depression n=1 and disease deterioration (arthritis flare) in n=21. In 20 patients, the etanercept biosimilar was discontinued.

Conclusion: This analysis is the first attempt to present a large data sample on JIA patients exposed to Etanercept biosimilars. Biosimilar were used in a minority of patients and by a minority of centers although no difference in efficacy or safety was noted from our analysis. Until today, the use of the originator is by far exceeding the use of biosimilars. The prescription of a biosimilar either first line or by switching from the originator is limited to a part of centres. Differences in efficacy between first line biosimilar users and originator users could not be observed. Also, after switching, no loss of efficacy was observed.

Background: Systemic juvenile idiopathic arthritis (SJIA) is characterized by extra-articular manifestations, as fever and rash, and rarely associated by a potentially lethal complication as macrophage activation syndrome (MAS). Anakinra is a recombinant human interleukin (IL)-1 receptor antagonist whose efficacy and safety profile has been studied for patients with SJIA.

Objectives: To evaluate the long-term safety profile of anakinra in patients with SJIA.

Methods: Data from patients with SJIA enrolled in the Pharmachild registry before 30 September 2018 and treated with anakinra were analyzed. The study

endpoints were the occurrence of non-serious adverse events (AEs) of at least moderate severity and serious AEs (SAEs), including macrophage activation syndrome (MAS), and the duration of anakinra treatment with reasons for discontinuation. All endpoints were analyzed overall, by 6 month-time windows and in different treatment sets represented by those patients continuously treated with anakinra for at least 12, 18 and 24 months (set-12, -18, -24, respectively).
Results: 306 patients were enrolled. 46%, 34% and 28% of them had been treated for at least 12, 18 and 24 months, respectively. 201 AEs, mostly represented by infections, were reported for 509.3 patient-years (py) with an overall incidence rate (IR) of 39.5/100 py. Among 56 SAEs (IR 11.0/100 py), (Table 1) 23.2% were infections and 19.6% MAS episodes. The IR of AEs was higher during the first 6 months of anakinra, followed by decreasing IR in the different long-term treatment sets. Treatment discontinuation occurred in 76% of patients, most in the first 6 months, due to inefficacy (43%), remission (31%) or AEs/intolerance (15%). No deaths or malignancies occurred during anakinra treatment.

Table 1. Number of SAEs and incidence rates (95% CI) by overall PT decreasing order and time window in the complete set (events with a frequency >1 by overall SOC and >1 by overall PT were reported) Only time windows <13 months were reported in the present table.

	Time window	1-6 months		7-12 months		Overall	
	N	306		194		306	
	Patient-time (years)	117.3		80.2		509.3	
SOC	PT	n	Rate (95% CI)	n	Rate (95% CI)	n	Rate (95% CI)
All	All	33	28.1 (19.1-41.5)	4	5.0 (1.9-13.2)	56	11.0 (7.9-15.2)
Infections and infestations	All	7	6.0 (2.9- 12.4)	1	1.2 (0.2- 8.8)	13	2.6 (1.4- 4.8)

OP0165 RISK FOR UVEITIS EVENTS AFTER WITHDRAWAL OF DISEASE MODIFYING ANTIRHEUMATIC DRUGS IN THE TREATMENT OF PATIENTS WITH EXTENDED OLIGOARTHRITIS OR RHEUMATOID FACTOR NEGATIVE POLYARTHRITIS

J. Klotsche[1], A. Klein[2], M. Niewerth[1], T. Kallinich[3], D. Windschall[4], J. P. Haas[5], F. Weller-Heinemann[6], T. Hospach[7], F. Dressler[8], K. Minden[1], G. Horneff[2]. *[1]German Rheumatism Research Centre Berlin, a Leibniz Institute, Epidemiology unit, Berlin, Germany*; *[2]Asklepios Kinderklinik Sankt Augustin, Department of General Pediatrics, Sankt Augustin, Germany*; *[3]Charité - Universitätsmedizin Berlin, Pediatric Pneumology and Immunology, Berlin, Germany*; *[4]St Josef-Stift Sendenhorst, Kinder- und Jugendrheumatologie, Sendenhorst, Germany*; *[5]Deutsches Zentrum für Kinder- und Jugendrheumatologie, Kinder- und Jugendrheumatologie, Garmisch-Partenkirchen, Germany*; *[6]Klinikum Bremen-Mitte gGmbH, Prof.-Hess-Kinderklinik, Bremen, Germany*; *[7]Olgahospital Stuttgart, Department of Paediatric Rheumatology, Stuttgart, Germany*; *[8]Medizinische Hochschule Hannover, Kinderklinik, Hannover, Germany*

Background: Juvenile idiopathic arthritis (JIA) associated uveitis is an extra-articular manifestation of the JIA disease that may cause vision-threatening complications and an uncontrolled uveitis may even lead to blindness. Uveitis occurs in up to 20% of patients with JIA, depending on the JIA category. The majority of patients develop uveitis within the first two years after JIA symptom onset, but uveitis can continue into adulthood.
Objectives: The main objective of this study was to analyze the risk for uveitis events after discontinuing disease-modifying antirheumatic drugs (DMARD) in patients with extended oligoarthritis and rheumatoid factor (RF)-negative polyarthritis.
Methods: Data of the two ongoing multicenter biologic registers: German Biologics in Pediatric Rheumatology (BiKeR) and the Juvenile arthritis Methotrexate/Biologics long-term Observation (JuMBO) were used to analyze the adverse-event (AE) and events of special interest (ESI) reports about uveitis events during treatment and after discontinuation of DMARDs. Biker started recruitment of children and adolescent patients with JIA exposed to biological (b) or conventional (cs) DMARD's in 2001. The patients were further followed in JuMBO after reaching the age of 18 or transitioning to an adult rheumatologist. Disease characteristics, treatment data, AE's and ESI's were reported by the pediatric or adults rheumatologist, respectively.
Results: A total of 2,041 patients with RF-negative polyarthritis (n=1,280) or extended oligoarthritis (n=761) were included into the analyses. The mean follow-up of this study was 7.6 years (SD 5.3). About half of the patients were enrolled in BiKeR with start of etanercept (1,137, 55.7%), followed by 635 (31.1%) patients with start of methotrexate (MTX) monotherapy or adalimumab (ADA, n=198, 9.7%). A history of uveitis was reported for 238 (11.7%) patients

at enrolment in BiKeR. More patients with a history of uveitis treated with ADA were included in BiKeR initiating ADA (n=98 of 238, 41.2%). Patients with uveitis had a lower age at JIA onset in comparison to patients without uveitis (mean 3.6 (SD 3.0) versus 7.0 (SD 4.5) years). A total of 142 recurrent (84% of 169) uveitis events were reported in 93 patients and for 27 patients (1.3% of 2,041) was an incident uveitis reported during follow-up. More than one uveitis event was reported for 32 patients with a maximum number of 4 uveitis flares in 3 patients. Nineteen uveitis flares (11.2% of 169) were reported for patients after the age of 18. The longer the time since DMARD discontinuation the fewer uveitis events occurred. Uveitis events were significantly more often reported in the first 24 months after MTX discontinuation (<6 months: OR=3.19, 95%CI: 1.70 to 5.96; 6 to <12 months: OR=2.06, 95%CI: 1.01 to 4.66; 12 to <24 months: OR=2.20, 95%CI: 1.14 to 4.25) and in the first three months after biological DMARD discontinuation (OR=5.4, 95%CI: 1.56 to 18.33). Patients with a MTX dose of ≤ 10 mg/m^2 at last MTX intake had a higher likelihood for uveitis events (OR=1.40, 95%CI: 1.02 to 1.92).

Conclusion: This is the first study that analyzed the risk of uveitis after DMARD withdrawal. Uveitis relapses are common. Patients who discontinued DMARD therapy were at high risk for uveitis within the first 3 to 24 months after discontinuation. Rheumatologists and ophthalmologists should be aware about this risk which should lead to a regular uveitis screening after DMARD withdrawal.

OP0166 DISEASE ACTIVITY IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS AFTER SIMULTANEOUS PCV13 AND HIB VACCINATION: A COHORT STUDY

O. Lomakina[1], E. Alexeeva[1,2], T. Dvoryakovskaya[1], K. Isaeva[1], A. Chomakhidze[1], R. Denisova[1], A. Mamutova[1], A. Fetisova[1], M. Gautier[1], K. Chibisova[1], D. Vankova[1], E. Krekhova[1,2], M. Shingarova[2], I. Kriulin[1,2], I. Tsulukiya[1], I. Zybkova[1], N. Tkachenko[1]. *[1]National Medical Research Center of Children's Health, Department of Rheumatology, Moscow, Russian Federation*; *[2]Sechenov First Moscow State Medical University (Sechenov University), Pediatrics and pediatric rheumatology, Moscow, Russian Federation*

Background: The safety of vaccination of children with rheumatic diseases is determined not only by the risk of adverse events but also by the risk of exacerbation of the disease. The simultaneous administration of several vaccines can increase the likelihood of these events.

Objectives: To evaluate the clinical and laboratory signs of disease activity in children with juvenile idiopathic arthritis (JIA) after simultaneous vaccination against pneumococcal and Haemophilus influenzae type b (Hib) infections.

Methods: We included hospitalized patients with JIA ages 2 through 18 without serious comorbidity, immunized with polysaccharide conjugate vaccines against pneumococcal (PCV13) and Hib infections. Vaccines were administered (0.5 ml each) concurrently subcutaneously into the deltoid area. In all children before and 3 weeks after vaccination, clinical (joints with active arthritis, uveitis activity) and laboratory signs (increased ESR, concentrations of highly sensitive C-reactive protein – hsCRP, and calprotectin) of JIA activity were assessed. Serum hsCRP and calprotectin were quantified by ELISA. The upper limit of the reference interval for hsCRP was considered (according to the manufacturer's instructions) a value of 8.2 mg/L, for calprotectin – 2.9 µg/ml, and for ESR – > 10 mm/h.

Results: The study included 430 patients with JIA (girls 60.9%), median (IQR) age – 11.1 years (7.3 to 14.4), onset of JIA – 4.7 years (2.4 to 8.6). Patients with persistent oligoarticular JIA numbered 149 (34.7%), polyarticular RF-negative – 148 (34.4%), systemic – 101 (23.4%), enthesitis-related – 20 (4.7%), and polyarticular RF-positive JIA – 12 (2.8%). Biologic disease-modifying antirheumatic drugs (DMARDs) were administered to 278 (64.7%), non-biologic DMARDs (mostly methotrexate) – 282 (65.6%), corticosteroids – 45 (10.5%), and NSAIDs – 18 (4.2%) patients. Three weeks after vaccination, out of 100 (23.3%) patients with initially active joints, signs of active arthritis remained in 96 patients, of which 16 patients had a decrease in the median (IQR) number of active joints by 4 (2 to 8). Among patients without active joints at baseline, signs of active arthritis were not subsequently detected. Before vaccination, 9 patients had uveitis in the exacerbation phase, 7 - in the subactive phase, and 41 - in the remission phase. After vaccination, exacerbation of uveitis persisted in 4 patients. There were no new cases of uveitis or its exacerbation. The dynamics of laboratory signs of JIA activity are presented in Table 1. Initially, the high concentration of calprotectin was found in 191 (44.4%) patients, and after vaccination – in 220 (51.2%) patients; the difference was 6.7% (95% CI 1.0 - 12.5); hsCRP - in 34 (7.9%) and 51 (11.9%) patients; the difference was 4.0% (95% CI 0.6 - 7.3); high ESR – in 76 (17.7%) and 41 (9.5%) patients; the difference was -8.1% (95% CI -11.6 to -4.7), respectively. An independent predictor of new cases of high concentration of hsCRP (n = 36), but not new cases of high concentration of calprotectin (n = 94), was the initial number of joints with active arthritis – odds ratio 2.37 (95% CI 1.14 - 4.93).

Table 1. Laboratory signs of JIA activity after simultaneous administration of vaccines against pneumococcal (PCV13) and Hib-infections

	Baseline	After 3 weeks		
Variables	Geometric mean (95% CI)		**Ratio***	**p****
Calprotectin, µg/ml	2.93 (2.70 – 3.17)	3.15 (2.92 – 3.40)	1.08 (0.99 – 1.17)	0.087
hsCRP, mg/L	0.69 (0.60 – 0.78)	0.79 (0.69 – 0.90)	1.15 (0.99 – 1.33)	0.073
ESR, mm/h	4.4 (4.0 – 4.8)	3.7 (3.4 – 4.0)	0.84 (0.78 – 0.90)	0.001

Note. CI – confidence interval. * Ratios of paired observations (95% CI). ** P-value calculated in paired samples t-test.

Conclusion: Simultaneous vaccination against pneumococcal (PCV13) and Hib-infections in children with JIA produced no negative dynamics of the traditional indicators of disease activity (joint activity, uveitis, high ESR). At the same time, 3 weeks after vaccination, an increase in the concentration of calprotectin and hsCRP was found in a small number of patients (<10%).

OP0167 THE ROLE OF LUNG ULTRASOUND IN THE DIAGNOSIS OF INTERSTITIAL LUNG DISEASE IN CHILDREN WITH DERMATOMYOSISTIS

R. Dertkgil[1], C. Cappello[1], S. Dertkigil[1], R. Marini[2], S. Appenzeller[3]. *[1]UNICAMP, Radiology, Campinas, Brazil*; *[2]UNICAMP, Pediatrics, Campinas, Brazil*; *[3]UNICAMP, Orthopedics, Rheumatology and Traumatology, Campinas, Brazil*

Background: Dermatomyositis is a multi organ autoimmune disease wich is commonly complicated with interstitial lung disease. Chest high-resolution computed tomography (HRCT) is still considered the diagnostic gold standard for interstitial lung disease and is quantification, however he increasing use of lung ultrasound may play an important role in the future.

Objectives: The aim of our study was to determine the diagnostic value of lung ultrasound in the detection and progression of interstitial pulmonary disease in patients with dermatomyositis.

Methods: Twenty two subjects with dermatomyositis diagnosed according to the American College of Rheumatology criteria were enrolled (6 males, 16 females; mean age: 15,8 ± 8.8 years; range: 6 to 29 years). All subjects underwent high resolution computed tomography followed by transthoracic ultrasound for comet tail sign detection and pleural irregularity in order to predict the degree of interstitial lung disease. The modified transthoracic ultrasound assessment was performed at 06 thoracic regions each side. The Warrick score was calculated according standard high-resolution chest computed tomography images that were evaluated independently from each other by two thoracics radiologists.

Results: A significantly positive correlation between transthoracic ultrasound and the severity of pulmonary involvement, as seen by the number of B lines (Spearman 's correlation coefficient = 0.80, p < 0.001), and the number of positive areas (regions wih more than 3 B lines) (Spearman 's correlation coefficient = 0.75, p < 0.001) were found. When compared with high-resolution chest computed tomography as the gold standard method, the sensitivity, specificity, of transthoracic ultrasound was 96.4%, 83,3% respectively. Addicionally the number of B lines (sum of 35 or more B lines) and a number of B lines positive areas (7 or more regions with at least 3 B lines) cut of allowed to discriminate the inflamatory pattern (ground glass) to those with structural pattern (honeycomb and pulmonary cysts).

Conclusion: Our study showed that transthoracic ultrasound comet tails scoring system could be useful in the assessment of the pulmonary involvement in patients with dermatomyositis, and should be considered as a primary screening exam to exclude lung involvement, rather than routine chest CT scans in assimptomatic patients.

OP0168 THE ROLE OF VASCULAR INFLAMMATION MARKERS IN DEFICIENCY OF ADENOSINE DEAMINASE 2

U. Kaya Akca[1], E. Sag2, Ş. Ünal[3], M. Kasap-Cuceoglu2, Y. Bilginer2, S. Özen2. *[1]Hacettepe University School of Medicine, Pediatric Rheumatology, Ankara, Turkey*; *[1]Hacettepe University School of Medicine, Pediatric Rheumatology, Ankara, Turkey*; *[3]Hacettepe University School of Medicine, Pediatric Hematology, Ankara, Turkey*

Background: Deficiency of adenosine deaminase 2 (DADA2) is a monogenic autoinflammatory disease whose pathogenesis has not been clearly elucidated.
Objectives: To investigate the role of vascular inflammatory factors in the pathogenesis of DADA2, to compare the vascular inflammation profiles of DADA2 patients with different phenotypes, and to compare DADA2 patients with classic polyarteritis nodosa (PAN).
Methods: The study included eighteen DADA2 patients, ten PAN patients, and eight healthy controls. Plasma levels of sST2, sRAGE, Tie-2, sCD40L, Tie-1, sFlt-1, LIGHT, TNF-α, PlGF, IL-6, IL-18, IL-10, MCP-1 were studied by cytometric bead-based multiplex assay panel.
Results: Among the DADA2 patients, five had hematological manifestations, 13 had vasculitic findings, and accompanying immunological findings were present in seven patients. Nine patients had neurological findings, five of whom had neuropathy. Hematological findings were Diamond-Blackfan anemia-like phenotype in four patients and bicytopenia (anemia and thrombocytopenia) in one patient. Disease characteristics of DADA2 and PAN patients revealed that neurological involvement and livedo reticularis were more frequent in DADA2 patients (p=0.034 and p=0.009, respectively), while myalgia was more common in PAN patients (p:0.001).
Plasma levels of Tie-1 and sFlt-1 were higher in the overall DADA2 patients compared to healthy controls and PAN patients (p<0.001 and p=0.004, respectively). DADA2 patients with PAN-like features had higher sRAGE, Tie-2, and TNF-α levels compared to PAN patients (p=0.013, p=0.003, and p=0.001, respectively). There was no significant difference in the levels of vascular inflammation markers between DADA2 patients with vasculitis and hematological involvement except IL-18. The plasma IL-18 levels were higher in the DADA2 patients with hematological findings compared to vasculitic phenotype (p=0.001). Finally DADA2 patients with neuropathy had higher sRAGE concentrations than patients without neuropathy and healthy controls (p=0.03 and p=0.008, respectively).
Conclusion: We suggest that the high plasma IL-18 levels may be associated with an activated IFN pathway, the pathogenesis of hematologic manifestations, and unresponsive to anti-TNF treatment. Higher concentrations of Tie-1, Tie-2, sFlt-1, sRAGE, and TNF-α distinguished DADA2 patients with PAN-like features from PAN patients. We identified sRAGE as a potential biomarker of neuropathy in DADA2 patients.

Challenges for working people with RMDs in pandemic times

OP0169-PARE **DEVELOPMENT OF POINTS TO CONSIDER WHEN SUPPORTING PERSONS WITH REUMATIC AND MUSCULOSKELETAL DISEASES TO PARTICIPATE IN HEALTHY AND SUSTAINABLE PAID WORK**

A. Boonen[1], S. Verstappen[2], M. Butink[1], C. Webers[1], N. Betteridge[3], T. Stamm[4], D. Wiek[5], A. Woolf[6], G. R. Burmester[7], H. Bijlsma[8]. [1]*Academic Hospital Maastricht, Rheumatology, Maastricht, Netherlands*; [2]*University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom*; [3]*University of Liverpool, Public Health, Liverpool, United Kingdom*; [4]*Medical University of Vienna, Section of Outcome Research; Center for Medical Statistics, InformaticsArticial Intelligence, Vienna, Austria*; [5]*EULAR, PARE, Zurich, Switzerland*; [6]*Royal Cornwall Hospital, Bone and Joint Resreach Group, Truro, United Kingdom*; [7]*Charité – Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany*; [8]*UMC Utrecht, Rheumatology, Utrecht, Netherlands*

Background: Despite earlier diagnosis and improved management of rheumatic and musculoskeletal diseases (RMDs), a work participation gap remains when compared to the general population. To bridge this work participation gap, EULAR's current strategy states that *'by 2023, EULAR's activities and related advocacy will have increased participation in work by people with RMDs'*. To achieve this goal, guidance is needed how to support people with RMDs to remain in paid work or (re)-enter the labour force.
Objectives: To develop Points to Consider (PtC) when supporting people with RMD to participate in healthy and sustainable paid work.
Methods: An international expert group, established by Eular in 2019, convened twice to agree on a protocol for the development of PtC. EULAR's standard operating procedures were followed. The group (a) defined the target audience, (b) identified areas from which knowledge should be derived to enable formulation of the PtC, (c) agreed on a strategy to collect evidence, (d) established an international taskforce to formulate and agree on the PtC, and (e) proposed an implementation plan.
Results: The target audience are professionals involved in clinical care for patients with RMDs as well as their organisations, persons with RMDs and their organisations, and administrators responsible for healthcare and work policies. Six knowledge areas are identified (Table). Depending on the specific knowledge area, strategies for collecting evidence comprise synthesis of published and grey literature, surveys among various organisations and collection of case studies from employers. Whenever evidence in RMDs is limited, evidence from other chronic diseases will be sought. The international taskforce includes experts from different disciplines in rheumatology (one in other chronic diseases), EU policy makers, and representatives of PARE, HCP, EULAR Public Affairs and EMEUNET. As part of the implementation, close cooperation with national professional and patients societies is planned. Additionally, results will be included in EULAR's activities at the EU policy level.

Table 1. Knowledge areas and strategy to retrieve evidence

	In persons with RMDs:	Sources of evidence
1	Is work relevant for the clinical outcome of disease	LR; Review of managament recommendations and Care Standards
2	What are barriers and facilitators to enter or stay in the labor force	SLR
3	What is the effectiveness of interventions to enter or stay in the labor force	SLR; Survey among professional and patient organisations
4	Which social security systems are more effective when entering or staying in the labor force	LR
5	How does disease influence the cycle of work	SLR; Grey literature
6	What (not) to do by employers to let patients enter or stay in the work force	SLR; Survey among large companies; case studies

LR: Literature review; SLR: Systematic literature review

Conclusion: The proposed initiative to develop PtC should ultimately result in improvement of healthy and sustainable labor force participation of people with RMDs.

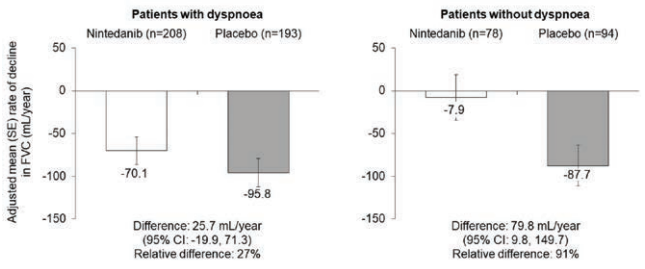
Background: Some patients with SSc-ILD develop dyspnoea secondary to parenchymal lung disease, while others do not report dyspnoea even when their

lung function is impaired. It is unclear whether the presence of dyspnoea is associated with a worse course of SSc-ILD or with response to therapy.
Objectives: To investigate the rate of decline in FVC in patients with SSc-ILD in the SENSCIS trial in subgroups by patient-reported dyspnoea at baseline.
Methods: The SENSCIS trial enrolled patients with SSc-ILD with first non-Raynaud symptom within ≤7 years before screening, extent of fibrotic ILD ≥10% on HRCT and FVC ≥40% predicted. Patients were randomised to receive nintedanib or placebo until the last patient reached week 52. In post-hoc analyses, we analysed the rate of decline in FVC (mL/year) over 52 weeks in patients with and without dyspnoea at baseline based on the question about dyspnoea in the St. George's Respiratory Questionnaire (SGRQ). Patients who reported having shortness of breath "most days a week", "several days a week" or "a few days a month" (rather than "only with chest infection" or "not at all") over the last month were considered to have dyspnoea at baseline. A random slope and intercept model was used to assess the rate of decline in FVC (mL/year) and an interaction test was applied to assess potential heterogeneity in the treatment effect of nintedanib between the subgroups.
Results: Of 576 patients, 69.8% had dyspnoea at baseline. At baseline, in patients with and without dyspnoea, respectively, mean (SD) extent of fibrotic ILD on HRCT was 37.7 (21.7)% and 31.6 (19.4)%; mean (SD) FVC was 71.0 (16.3) and 76.5 (16.8) % predicted; 50.7% and 44.8% were taking mycophenolate; 53.5% and 41.9% were taking corticosteroids. In the placebo group, the rate of decline in FVC (mL/year) was similar in patients with and without dyspnoea at baseline (Figure). The effect of nintedanib versus placebo on reducing the rate of decline in FVC (mL/year) was numerically more pronounced in patients without dyspnoea (difference: 79.8 [95% CI: 9.8, 149.7]) than with dyspnoea (difference: 25.7 [-19.9, 71.3]), but the exploratory interaction p-value did not indicate heterogeneity in the treatment effect between subgroups (p=0.20).
Conclusion: In the SENSCIS trial, patients with SSc-ILD who had dyspnoea at baseline had a numerically greater extent of fibrotic ILD on HRCT and numerically lower FVC % predicted at baseline. The rate of decline in FVC in the placebo group was similar in patients with and without dyspnoea. Nintedanib had a numerically greater treatment effect in patients without dyspnoea. These data suggest that the presence of dyspnoea should not be used as a criterion for starting nintedanib in patients with SSc-ILD.

Figure. Rate of decline in FVC (mL/year) over 52 weeks in subgroups by dyspnoea at baseline in the SENSCIS trial.



Treatment-by-time-by-subgroup interaction p=0.20.
The presence of dyspnoea was based on this question from the St George's Respiratory Questionnaire: "Over the last month, I have had shortness of breath:". Patients who ticked boxes for "most days a week", "several days a week" or "a few days a month" were considered to have dyspnoea.

Background: Lenabasum is an oral CB2 agonist that attenuates inflammation and fibrosis in SSc animal models and showed clinical benefit with acceptable safety in a Phase 2 trial in dcSSc.
Objectives: Test efficacy and safety of lenabasum in a Phase 3 trial in dcSSc.
Methods: Subjects ≥18 years old with disease duration ≤ 6 years were randomized 1:1:1 to lenabasum 5 mg, 20 mg, or placebo (PBO), all BID, with stable background immunosuppressant therapy (IST) allowed. The primary efficacy endpoint was ACR CRISS score, and secondary endpoints were ΔmRSS, ΔHAQ-DI, and ΔFVC, all at Week 52 for lenabasum 20 mg vs PBO.
Results: 363 adults were dosed; 37 (10%) stopped study drug early, with only 1 subject (PBO cohort) stopping due to adverse event (AE). Baseline demographics were similar among groups. Disease duration was ≤ 3 years in 60% and 66%, mean mRSS score was 22.0 and 23.3, and background IST was used by 89% and 84% of lenabasum 20 mg and PBO groups, respectively.
Safety results showed serious AEs and severe AEs occurred in 9.2% and 5.8% vs 14.6% and 13.0%, respectively, of lenabasum 20 mg and PBO groups.
Efficacy results (Table) demonstrated:

- No significant differences were seen in primary and secondary efficacy endpoints. Primary MMRM analyses with treatment-by-time-by-subgroup interactions showed that background mycophenolate (MMF) significantly influenced the outcome
- oSubjects on no IST with disease duration ≤3 years were only 7% of PBO subjects and showed little improvement on PBO, in line with other dcSSc trials in which IST was restricted. Post-hoc subgroup analyses of these subjects on no IST suggested improvement in ΔmRSS and ΔHAQ-DI, for lenabasum 20 mg vs PBO
- uUnexpectedly high improvement occurred in PBO subjects receiving IST, notably those on MMF started within 2 years of baseline
- nPost-hoc analyses of subjects on established IST (MMF or, if no MMF, ≥ 1 non-MMF IST started > 2 years before baseline)

Table 1. Primary and secondary efficacy endpoints and post-hoc analyses, Week 52

Group, by IST treatment	Cohort	N	ΔmRSS, mean (SD)	ΔFVC% mean (SD)	ΔFVC, mL mean (SD)	ΔHAQ-DI mean (SD)	ACR CRISS median

[2] P = 0.0386 two-sample t-test; [3] P = 0.0481 two-sample t-test; other comparisons were not significant

suggested improvement in ΔFVC% (nominal P = 0.0386) and ΔFVC mL (nominal P = 0.0481) for lenabasum 20 mg vs PBO. Improvement in FVC was also seen in subjects on established IST who had ILD at baseline, lenabasum 20 mg vs PBO

- mACR CRISS score demonstrated a ceiling effect and correlated most highly with ΔmRSS (r = -0.739) and moderately with MDGA (-0.432), HAQ-DI (-0.362), FVC% (0.366), and PtGA (-0.288)

Conclusion: Lenabasum was safely used in this study. Unexpectedly high improvement on background IST, especially MMF, has not been previously reported at this level. The primary endpoint was not met. Post-hoc analyses showed greater improvement in lenabasum- vs PBO-treated subjects who were not on background IST and those on established IST, including subjects with ILD.

OP0172

BRENTUXIMAB VEDONTIN FOR SKIN INVOLVEMENT IN REFRACTORY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS, INTERIM RESULTS OF A PHASE IIB OPEN-LABEL TRIAL

A. Fernandez-Codina[1,2,3], T. Nevskaya[1], J. Pope[1]. *[1]Western University, Medicine, Rheumatology division, London, Canada*; *[2]Windsor Regional Hospital - Ouellette Campus, Medicine, Windsor, Canada*; *[3]Hospital Clínic de Barcelona, Systemic Autoimmune Diseases, Barcelona, Spain*

Background: Systemic sclerosis (SSc) is an autoimmune disease affecting multiple organs causing morbidity and mortality. Treatments targeting SSc skin often have limited success. The presence of CD30+ lymphocytes in skin biopsies and increased levels of serum CD30 have been reported in SSc patients[1]. This could constitute a new therapeutic target.

Objectives: To explore the efficacy and safety of brentuximab vedotin, a chimeric anti-CD30 antibody drug conjugate, in patients with severe active diffuse cutaneous SSc who failed multiple treatments.

Methods: This Phase IIb, single center, open-label, investigator-initiated trial will recruit 10 patients. Brentuximab vedotin 0.6 mg/Kg was infused intravenously every 3 weeks for 48 weeks. Inclusion criteria were age ≥18 years, meeting the 2013 ACR/EULAR SSc classification criteria, modified Rodnan skin score (mRSS) ≥15 with <5 years since the first non-Raynaud's symptom and/or skin worsening despite immunosuppression. Patients were allowed to continue their standard of care medications for SSc except for rituximab. Patients with severe cardiac or pulmonary SSc involvement, severe infections, significant peripheral neuropathy, or active malignancy were excluded. The primary objective was a decrease in mRSS of ≥8 at 48 weeks. The main secondary endpoint was MRSS at 24 weeks. Differences were assessed by paired t tests. Data were compared to 16 age, disease duration, mRSS and past/present use of immunosuppressors-matched controls (ratio 2-3:1) from the Canadian Scleroderma Research Group (CSRG) registry.

Results: Eight of 10 patients have been recruited to date; two are in the first 8 weeks and one was withdrawn at her request after developing influenza at week 12. Five subjects (60% female) have reached week 24, and 3 have completed 48 weeks. The mRSS is shown in Table 1. The ΔMRSS for patients treated with brentuximab between weeks 0 and 24 was 8.2 ([CI 95% 2.8, 13.6], p = 0.013) and from 0 to 48 was 15.3 ([CI 95% 8.2, 22.5], p = 0.012). Whereas, the ΔMRSS for the CSRG controls was 3.1 ([CI 95% -2, 8.2], p = 0.211) at 48 weeks. Assuming that mRSS would at least be the same from week 24 to 48 in the 2 cases who are between 24 and 48 weeks with brentuximab, we compared the 5 cases vs controls (Figure 1). ΔMRSS for Brentuximab was 12.2 ([CI 95% 5.9, 18.5], p = 0.006. No cases have developed a peripheral neuropathy and only one SAE (influenza).

Table 1.

N (SD)	N	Age	Disease duration	mRSS week 0	mRSS week 24	mRSS week 48	mRSS week 48**
Case	5	60.2 (9.3)	4.5 (2.1)	33 (5.2)	24.8 (6)	15.7 (3)	20.8 (8.3)
Control	16	58.5 (8.3)	4.9 (2.1)	31.3 (5.9)	N/D	28.1 (7.5)	28.1 (7.5)
p		0.731	0.775	0.559	N/D	0.013	0.079

mRSS = modified Rodnan skin score, N/D = no data, ** = comparisons including 5 cases, assuming stability in MRSS from week 24 to 48 in cases 5 and 6

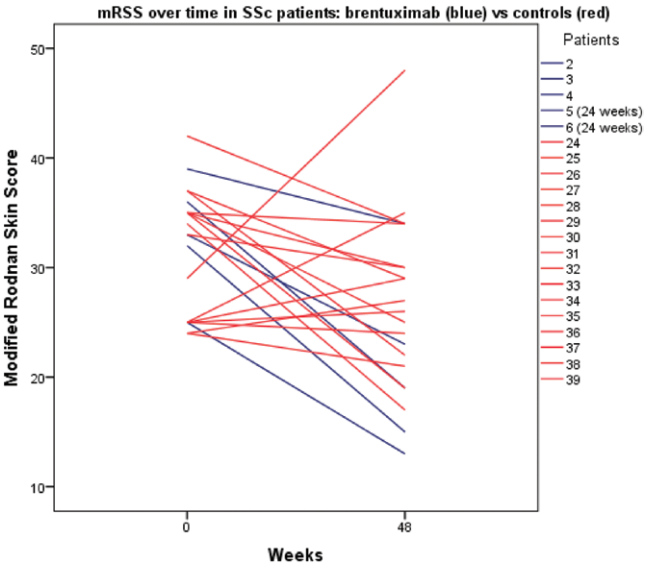

Figure 1.

Conclusion: Brentuximab vedontin already achieved the primary endpoint at 24 weeks, after half of the intended recruitment sample reached this landmark. A comparison with CSRG controls showed that mRSS only decreased significantly in patients treated with brentuximab. This interim report suggests that brentuximab vedontin might effectively improve skin involvement in patients with diffuse SSc and severe skin involvement.

OP0173 REDUCTION OF SKIN FIBROSIS IN SYSTEMIC SCLEROSIS ON RITUXIMAB TREATMENT. LONG-TERM FOLLOW-UP

L. Garzanova[1], L. Ananyeva[1], O. Koneva[1], O. Ovsyannikova[1], O. Desinova[1], M. Starovoytova[1], R. Shayakhmetova[1]. [1]*V A Nasonova Research Institute of Rheumatology, Laboratory of microcirculation and inflammation, Moscow, Russian Federation*

Background: A sound experience has been accumulated up to date with the use of rituximab (RTX) for treatment of systemic sclerosis (SSc). Some studies reported improvement of skin fibrosis following treatment with RTX, but long-term follow-ups are really few.

Objectives: to evaluate the effect of RTX on the manifestations of skin fibrosis in patients (pts) with SSc in the long-term follow-up.

Methods: This prospective study included 71 pts aged 46 years (17-66) on average, 59 (83%) pts were females, mean disease duration was 5,6±4,4 years, and mean follow-up - 42 months (12-72) (mo). Diffuse SSc was established in 42 (59%) pts. All pts received glucocorticoids in low doses. 45% of pts were receiving immunosuppressants at study entry. The following parameters were evaluated: Rodnan skin score (mRSS), interdigital space(IDS) (the distance between the tips of 1 and 5 fingers at maximum extension), oral aperture (OAp) and activity index (EScSG-AI) over the periods: 12-18 mo, 24-30 mo, 36-42 mo, 48-54 mo and 60-72 mo after initiation of RTX therapy. The results are presented as: mean values, delta (Δ), median, upper and lower quartiles.

Results: RTX therapy resulted in significant decrease of disease activity index, which statistically significantly correlated with decrease of mRSS - the main indicator of the severity of skin fibrosis (r=0,39;p=0,001). Changes in parameters by follow-up periods are presented in the Table 1.

Table 1. Changes in clinical and instrumental parameters at RTX treatment (delta; median; lower quartile; upper quartile).

Parameters	12-18 mo (n=71)	24-30 mo (n=55)	36-42 mo (n=36)	48-54 mo (n=24)	60-72 mo (n=17)
ΔmRSS	3,32 [3.3; 0; 8] p=0,001	5,4 [3; 0; 10] p=0,001	5,1 [3,5; 0; 9] p=0,001	5,3 [3; 0; 10] p=0,001	7,3 [5; 1; 14] p=0,001
ΔOAp, cm	0,24 [0,1; 0; 0,5] p=0,0009	0,26 [0,1; 0; 0,6] p=0,0006	0,39 [0,2; 0; 0,8] p=0,004	0,31 [0.3; 0; 0,7] p=0,006	0,36 [0,2; 0; 0,8] p=0,009
ΔActivity index (EScSG-AI)	1,49 [1,5; 0; 2,5] p=0,001	1,64 [1,5; 0; 2,5] p=0,001	1,11 [1; 0; 2] p=0,0001	2 [2; 1; 3] p=0,0001	2,17 [2; 1,5; 2] p=0,0001
Cumulative dose of RTX, g	1,43±0,6	2,97±0,8	3,45±1,3	3,96±1,1	5,15±1,7

Decreasing of mRSS statistically significantly correlated with increasing cumulative dose of RTX (r=0,29;p=0,01). Decreasing disease activity index correlated with increasing cumulative dose of RTX (r=-0,37; p=0,01). IDS improvement was documented at all assessment time periods, although statistically insignificant.

Conclusion: The results of this study confirm reported positive effect of RTX on the reduction of skin fibrosis in SSc. Long-term follow-up demonstrated steadily decreasing skin fibrosis and improvement of microstomia with increasing oral aperture in parallel with a decrease of the disease activity index and increasing cumulative dose of RTX.

OP0174 SUBCLINICAL INTERSTITIAL LUNG DISEASE IS FREQUENT AND PROGRESSES ACROSS DIFFERENT CONNECTIVE TISSUE DISEASES

A. M. Hoffmann-Vold[1], H. Andersson[1], S. Reiseter[2], H. Fretheim[1], I. Barua[1], T. Garen[1], Ø. Midtvedt[1], R. Gunnarsson[1], M. Durheim[3], T. M. Aaløkken[4], Ø. Molberg[1]. [1]*Oslo University Hospital, Rheumatology, Oslo, Norway*; [2]*Akershus University Hospital, Internal Medicine, Oslo, Norway*; [3]*Oslo University Hospital, Respiratory Medicine, Oslo, Norway*; [4]*Oslo University Hospital, Radiology, Oslo, Norway*

Background: Based on the argument that symptoms define disease, physicians commonly apply the terms “preclinical” or “subclinical” disease to describe patients with disease-related findings but no accompanying symptoms for connective tissue disease associated interstitial lung disease (CTD-ILD). The term subclinical frequently applies to patients with mild ILD changes on high resolution chest tomography (HRCT), normal forced vital capacity (FVC), and without respiratory symptoms. Previous work in systemic sclerosis (SSc)-ILD did show that patients with even minor extent of ILD at baseline often progressed and had increased mortality risk, suggesting that it is not appropriate to define these patients as “subclinical.”

Objectives: To identify the prevalence of subclinical ILD across CTD diagnoses, and assess the rate of progression of lung fibrosis compared to CTD without ILD and with clinical ILD.

Methods: All CTD patients, including SSc, anti-synthetase syndrome (ASS) and mixed connective tissue disease (MCTD) from the Oslo University Hospital diagnosed before 2015 and assessed for the presence of ILD by HRCT were included. The year 2015 was chosen to secure an observation time of at least five years from ILD diagnosis to study end on 01.01.2021 or time of death. All patients fulfilled the respective CTD classification criteria. Subclinical ILD was defined as an ILD extent <5% by semi-quantitative assessment of baseline HRCT, preserved lung function with FVC >80% predicted and without respiratory symptoms. Clinical ILD was defined as >5% extent of ILD or <5% extent of ILD on HRCT with respiratory symtoms or FVC<80%. The outcome was ILD progression, defined as increasing extent of ILD from basline to follow-up HRCT by semi-quantitative assessment. Vital status was available in all patients and mortality was evaluated. Descriptive statistical analyses were conducted and time to ILD progression determined by Kaplan-Meier estimates.

Results: We identified 525 CTD patients, including 296 with SSc, 135 with MCTD and 94 with ASS who had conducted a baseline HRCT. Of these, 227 (43%) had no ILD, 67 (13%) subclinical and 231 (44%) clinical ILD (Table). Of the 67 subclinical ILD patients, 45 (15%) had SSc, 13 (10%) MCTD and 9 (10%) ASS of thespecific cohorts. Over a median time of 4.5 years between baseline and follow-up HRCT, 95/395 (24%) showed progression of ILD, including 72 (26%) SSc and 23 (19%) MCTD patients. Disease progression frequently occurred in both subclinical ILD (38%) and clinical ILD (51%) patients (Figure). Age, gender, underlying CTD, and baseline lung function were not predictive for the progression of lung fibrosis. Progression was too infrequent to allow for meaningful multivariable regression analyses. After a median observation period of 12 years, 153 (29%) of the patients died. The 1-, 5- and 10-year survival rates in those without ILD, subclinical and clinical ILD were 97%/97%/99%, 88%/91%/82%, and 82%/85%/68% (p<0.001), respectively.

Table 1. Clinical characteristics, demographics and outcome

	No ILD (n=227)	Subclinical ILD (n=67)	Clinical ILD (n=231)
Age, y (SD)	50 (15.4)	51 (14.4)	52 (15.3)
Male sex, n (%)	89 (39)	22 (33)	111 (48)
Deceased, n (%)	50 (22)	12 (18)	91 (39)
Observation period, y median (range)	13.7 (18.6)	13.9 (17.9)	11.5 (17.1)
FVC% (SD)	97 (18.6)	99 (17.9)	81 (20.9)
FVC decline% (SD)	-0.70 (11.1)	-0.81 (16.5)	-1.61 (15.9)
DLCO% (SD)	73 (19.4)	73 (16.9)	55 (17.4)
Extent of ILD% (SD)	0 (0)	2.3 (1.5)	19.3 (16.8)
ILD progression% (SD)	0.08 (1.0)	3.1 (6.2)	3.6 (9.9)
ILD progressors, n (%)	3 (2)	20 (38)	72 (51)

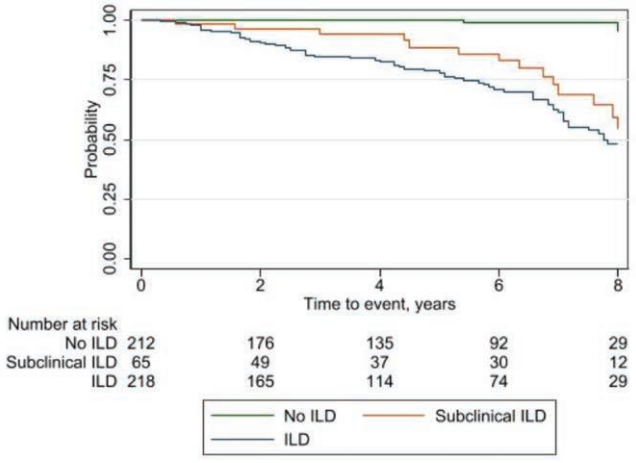

Figure 1. Time to ILD progression in CTD without ILD, with subclinical and clinical ILD

Conclusion: Subclinical ILD is frequently present across CTDs and progresses over time in a substantial subgroup of patients, comparable to patients with clinical ILD. Our findings question the terms sub- and preclinical ILD, which may potentially lead to a suboptimal "watchful waiting management strategy". Monitoring all CTD patients with any ILD is of high importance to identify disease progression early.

OP0175 INTERNATIONAL MULTICENTRIC PROSPECTIVE STUDY ON PREGNANCY IN SYSTEMIC SCLEROSIS (IMPRESS-2)

E. Tombetti[1], V. Ramoni[2], M. Betelli[3], Y. Allanore[4], M. Matucci Cerinic[5], A. Tincani[6], A. Brucato[7] on behalf of the IMPRESS-2 Working group. *[1]Milan University, Biomedical and Clinical Sciences Luigi Sacco, Milan, Italy*; *[2]ASST Lodi, Medicina Generale, Lodi, Italy*; *[3]Ospedale Papa Giovanni XXIII, Medicina, BErgamo, Italy*; *[4]Cochin Institute, Rheumatology, Paris, France*; *[5]Università Di Firenze, Rheumatology, Firenze, Italy*; *[6]Università di Brescia, Rheumatology, Brescia, Italy*; *[7]Milan University, Medicine, Milan, Italy*

Background: Data about the obstetric outcomes of pregnant women with Systemic Sclerosis (SSc) mainly derive from retrospective studies. Moreover, little evidence is available to define if pregnancy impacts on SSc course and if children of SSc mothers have a normal post-natal development.

Objectives: To assessed the obstetric, pediatric and rheumatologic outcomes of SSc pregnancies in a prospective controlled study

Methods: Prospective recruitment of three cohorts.

1) 110 pregnant women with SSc.

2) 218 control pregnancies without systemic autoimmune diseases

3) 78 non-pregnant control SSc with a matching subject in cohort-1.

SSc was characterized for disease activity, severity, cutaneous/organ involvement and therapy. Women and their offspring were followed until 21 months after enrollment (ie, 12 months after expected delivery).

Results: Gestational and neonatal outcomes

Miscarriages and fetal death occurred in 7% and 5% of SSc pregnancies. Compared to control pregnancies, SSc pregnancies had higher rates of gestational hypertension (12% Vs 4%, p=0.004), pre-eclampsia (9% Vs 1%, p=0.002), fetal growth-restriction (13% Vs 4%, p=0.004), prematurity (26% Vs 7%, p<0.001) and cesarean section (52% Vs 4%, p=0.002). Newborns from SSc mothers weighted less (2773 Vs 3243g, p<0.001), were more frequently small for gestational age (SGA, 18% Vs 12%, p=0.05) and required neonatal-intensive care unit (ICU) more frequently (12% Vs 1%, p<0.001). Rates of newborn malformation/death, and one year-pediatric outcomes were similar.

Univariate and multivariate analyses were performed for relevant outcomes. For example, pre-eclampsia positively associated with baseline skin score and its evolution during pregnancy (p=0.015 and 0.013), immunosuppressive agents, bosentan and iloprost at baseline (p=0.001, 0.041 and 0.007), and twin pregnancy(p=0.006). Multivariate logistic regression for pre-eclampsia in SSc identified baseline arterial hypertension, immunosuppressive agents or of iloprost, twin pregnancy and assisted conception as risk factors (p=0.000, 0.002, 0.0025, 0.000 and 0.027), and baseline calcium channel blockers as protective factors (p=0.001).

SSc course during pregnancy

As compared to matched non-pregnant SSc, SSc pregnant women had lower Medsger disease severity index (0.6 +/-0.9 Vs 1.0 +/-1.1, p=0.022), health assessment questionnaire (HAQ, 0.21 +/-0.38 Vs 0.40 +/-0.55, p=0.026), and lower rate of iv iloprost (21% Vs 42%, p=0.006). Pregnant and non-pregnant SSc women had a similar disease course during the 21 months of follow-up, despite a lower use of immunosuppressive agents (17% Vs 36%, p=0.014). Two scleroderma-renal-crises (SRC) occurred during pregnancy (one was a relapse of a previous SRC; the other occurred at week 33, and resolved after premature delivery of a SGA newborn and ACE-inhibitors, preventing differentiation from pre-eclampsia).

Conclusion: SSc pregnancies have generally a favorable obstetric/pediatric outcome, albeit at a higher risk of gestational hypertension, pre-eclampsia, fetal growth restriction, prematurity, delivery of SGA newborn and requirement of neonatal-ICU. Pregnancy does not impact on SSc course, although SRC during late pregnancy and pre-eclampsia might be hardly discriminated.

OP0176 ULTRASOUND (US) EVALUATION OF BOWEL VASCULOPATHY IN SYSTEMIC SCLEROSIS (SSC)

L. Cometi[1], G. Bandini[2], K. El Aoufy[1], A. Domanico[3], L. Tofani[1], C. Bruni[1], S. Bellando Randone[1], S. Guiducci[1], A. Moggi Pignone[2], E. Accogli[3], M. Matucci-Cerinic[1]. *[1]University of Florence & Division of Rheumatology, Azienda Ospedaliero Universitaria Careggi, Florence, Italy*; *[2]University of Florence & Division of Internal Medicine Unit III, Azienda Ospedaliero Universitaria Careggi, Florence, Italy*; *[3]Department of Internal Medicine, Centre of Research and Learning in Ultrasound, Maggiore Hospital, Bologna, Italy*

Background: Gastrointestinal involvement is one of the most frequent features of SSc, affecting nearly 90% of patients, with a great impact on quality of life and morbidity. One of the key pathological factors of SSc bowel involvement is vasculopathy (1), although little is known about its pathophysiology and no treatments are currently available.

Objectives: to assess with abdominal US the superior mesenteric artery (SMA) and the inferior mesenteric artery (IMA) vessel characteristics and blood flow in SSc, compared to healthy controls (HC).

Methods: we performed fasting abdominal US in SSc patients fulfilling the ACR/EULAR 2013 classification criteria and HC. Patients with a history of peripheral / coronary arterial disease were excluded. For both SMA and IMA, caliber (mm), Peak Systolic Velocity – PSV (cm/sec), Reverse Velocity – RV (cm/sec), End-Diastolic Velocity – EDV (cm/sec), Mean Velocity – mV (cm/sec), Blood-flow (cm/sec), Resistive Index – RI and Pulsatility Index – PI were measured.

Results: 28 SSc patients [25 females (89.3%), mean age 48.75 ± 12.39 years; 6 (22.22%) anti-centromere and 19 (70.37%) positive for anti-topoisomerase I antibodies] and 28 HC [18 females (64.3%), mean age 36.25 ± 12.08 years] were evaluated. In SSc, the SMA caliber was significantly smaller than in HC (5.75 ± 0.62 vs. 6.45 ± 0.60 mm, p<0.0001), while IMA dimensions did not differ.

The SMA study revealed SSc patients had a significant reduction of RV (7.25 ± 6.37 vs. 18.52 ± 6.16 cm/sec, p<0.0001) and PI (3.33 ± 0.75 vs. 4.53 ± 1.03, p<0.0001) when compared to HC. In addition, in SSc the mV of SMA was significantly lower than in HC (38.03 ± 13.90 vs. 28.32 ±9.25 cm/sec, p=0.0035), as well as the RI (0.88 ± 0.04 vs. 0.91 ± 0.03, p=0.0034); EDV was significantly increased (16.34 ± 7.03 vs. 12.64 ± 5.46 cm/sec, p=0.0321). Similarly to SMA, also in IMA RV and PI were significantly lower that controls (RV: 2.69 ± 6.10 vs. 17.06 ± 5.75 cm/sec, p<0.0001; PI: 3.54 ± 0.95 vs. 6.08 ± 1.53, p<0.0001). Moreover SSc patients presented a significant reduction of PSV and RI of IMA (PSV: 72.27 ± 27.23 vs. 93.81 ± 25.73 cm/sec, p=0.0084; RI: 0.88 ± 0.04 vs. 0.91 ± 0.03, p=0.0132) when compared to HC. Although the HC group was significantly younger than the SSc group (p=0.0003), all the results were confirmed after adjustment for age (Table 1).

Table 1. comparison of the characteristics of SMA and IMA between SSc patients and HC.

SMA=superior mesentheric artery, IMA=inferior mesentheric artery, PSV=Peak Systolic Velocity, RV=Reverse Velocity, EDV=End-Diastolic Velocity, mV=Mean Velocity, PI=Pulsatility Index, RI=Resistive Index.

Conclusion: this preliminary study shows, for the first time, the presence of a significant reduction of RV, PI and RI in the intestinal arteries of SSc patients when compared to HC. These data show an increased stiffness of the gastrointestinal arterial wall, in agreement with the typical SSc vasculopathy. A larger cohort is needed to confirm the results and explore the possible relationship with other clinical features of the disease.

OP0177 PRESENCE AND SEVERITY OF DIGITAL OCCLUSIVE ARTERIAL DISEASE PREDICTS DIGITAL ISCHEMIC COMPLICATIONS IN SYSTEMIC SCLEROSIS

Y. Radwan[1,2], T. Gunderson[3], C. S. Crowson[2,3], D. Liedl[4], K. J. Warrington[2], P. Wennberg[4], A. Makol[2]. *[1]Michigan State University, Department of Internal Medicine, Lansing, United States of America*; *[2]Mayo Clinic, Division of Rheumatology, Rochester, United States of America*; *[3]Mayo Clinic, Health Sciences Research, Rochester, United States of America*; *[4]Mayo Clinic, Department of Cardiovascular Disease, Rochester, United States of America*

Background: Vasculopathy is a key feature of systemic sclerosis (SSc), manifesting clinically as Raynaud's phenomenon (RP) with or without digital ischemia. Laser doppler flowmetry (LDF) with thermal challenge is a safe, noninvasive and reproducible technique to detect digital occlusive arterial disease (DOAD) with a high sensitivity and specificity of >90% (1).

Objectives: To study the prevalence and clinical correlates of DOAD assessed by LDF in patients with SSc referred for evaluation of RP at a tertiary referral center.

Methods: Medical records of all patients with SSc meeting ACR/EULAR 2013 classification criteria that underwent LDF between Jan 2001-Dec 2018 at our institution were retrospectively reviewed to abstract the presence or absence of DOAD. The presence of DOAD on LDF was confirmed if pre- and post-warming skin blood flow was ≤206 arbitrary units. Severity of DOAD was assessed based on number of digits involved. Risk factors associated with presence of DOAD in SSc, and correlation between presence and severity of DOAD with digital ischemic complications were studied.

Results: 304 patients with SSc (mean age 57.1 ± 3.3 y, 81% females, 93% Caucasians) underwent LDF during the study period. Median time between SSc diagnosis and performing LDF was 12.9 months. Majority of patients with SSc had limited cutaneous SSc (lcSSc) (79.6%) and 64.1% had a positive SSc specific antibody.

On LDF with thermal challenge, presence of DOAD was noted in 243 (79.9%) patients, of whom 78.6% had lcSSc, 42.4% had a centromere antibody (Ab), 17.3% had a Scl-70 Ab, 53.5% had interstitial lung disease, 36.6% had pulmonary arterial hypertension, and 73.3% had gastrointestinal dysmotility (GID). Of 159 patients with DOAD who also had a nailfold capillaroscopy, 70.4% had abnormalities. Large vessel occlusive disease was significantly higher in patients with DOAD in comparison to those without DOAD (29.2% vs 16.4%; p: 0.04). After adjusting for age and sex, GID (OR: 2.73 [95%CI 1.52-4.92]) and telangiectasia (OR: 2.83 [95%CI 1.23-6.40]) were significantly associated with DOAD.

Digital ischemic complications among patients with SSc with DOAD were significantly higher than among those without DOAD (79.8% vs 41.0% had digital ulcers, 53.9% vs 26.2% had pitting/scars, 31.3% vs 8.2% had gangrene/amputation; p <0.001). (Figure 1) Increasing severity of DOAD was associated with a statistically significantly higher incidence of digital ischemic complications as presented in Table 1.

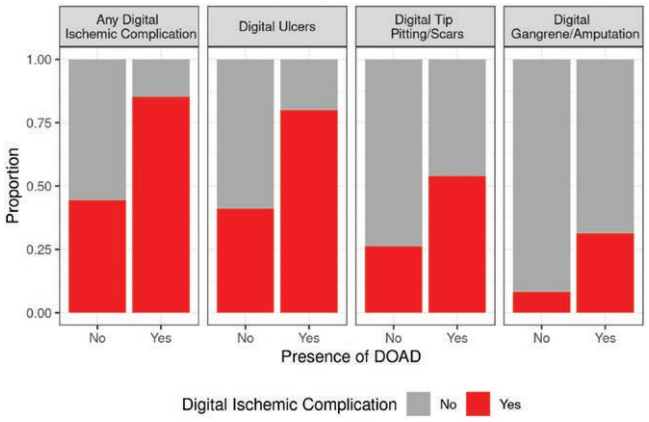

Figure 1. Correlation between the presence of digital occlusive arterial disease (DOAD) and digital ischemic complications in systemic sclerosis

Table 1. Logistic regression models for association of digital ischemic complications and severity of digital occlusive arterial disease

Digital Involvement	Odds Ratio (OR)		
Complication	**Reflects "digits vs. 0"**	**OR**	**CI 95%**
Digital Ulcer	**Unit Increase**	1.28	1.19-1.39
	1-2	2.11	0.927-4.92
	3-7	5.57	2.84-11.2
	8-10	10.9	4.98-25.4
Digital Tip Pitting/Scars	**Unit Increase**	1.17	1.10-1.26
	1-2	1.92	0.803-4.61
	3-7	2.62	1.35-5.28
	8-10	5.45	2.72-11.4
Digital Gangrene/Amputation	**Unit Increase**	1.26	1.16-1.37
	1-2	1.36	0.317-5.48
	3-7	4.10	1.62-12.6
	8-10	9.05	3.60-27.7
Any Digital Involvement	**Unit Increase**	1.35	1.24-1.49
	1-2	2.98	1.27-7.30
	3-7	6.16	3.08-12.7
	8-10	18.5	7.46-53.2

Conclusion: This is the largest single center study to describe the prevalence and predictors of DOAD on LDF in a well-defined cohort of patients with SSc. The high prevalence of DOAD on LDF noted in SSc-RP make it a valuable tool not only for evaluation of vasculopathy in SSc but also to distinguish it from Primary RP. The presence and severity of DOAD strongly correlates with digital ischemic complications and can be used as a guide to counsel patients and determine the aggressiveness of therapeutic interventions. Our study underscores the significance of LDF as a reliable non-invasive modality to detect DOAD and a prognostic tool to identify patients at highest risk of digital ischemic complications.

Rheumatoid arthritis - prognosis, predictors and outcome

OP0178 ASSOCIATION BETWEEN ENVIRONMENTAL AIR POLLUTION AND RHEUMATOID ARTHRITIS FLARES

G. Adami[1], A. Fassio[1], O. Viapiana[1], G. Orsolini[1], E. Bertoldo[1], A. Giollo[1], D. Gatti[1], M. Rossini[1]. *[1]University of Verona, Rheumatology Unit, Verona, Italy*

Background: Environmental air pollution has been linked to the pathogenesis of Rheumatoid Arthritis (RA). Nevertheless, evidence linking higher concentrations of air pollutants with the risk of RA reactivations is missing.

Objectives: The objective of the present study was to determine the association between RA flares and air pollution.

Methods: We collected longitudinal data of patients affected by RA and of the daily concentration of air pollutants in the Verona area. We designed a case-crossover study. In case-crossover studies, instead of obtaining information from two groups (cases and controls), the exposure information is obtained comparing two different periods of time in the same group of patients followed longitudinally. We compared the exposure to pollutants in the 30-day and 60-day periods preceding an arthritic flare referent to the 30-day and 60-day preceding a low-disease activity visit. Flare was defined as an increase in DAS28-CRP of >1.2 points with current DAS28-CRP ≥3.2 (OMERACT definition).

Results: 888 patients with RA with 3,396 follow-up visits were included in the study. 13,636 daily air pollution records were retrieved. We found an exposure-response relationship between the concentration of air pollutants and the risk of having abnormal CRP levels (Figure 1). Patients exposed to greater concentrations of air pollutants were at higher risk of having CRP levels ≥5 mg/L. Patients exposed to PM10 concentrations ≥50 µg/m3 had a 70% higher risk of having CRP levels ≥5 mg/L (OR 1.696 95% CI, 1.245-2.311). Among RA patients, 440 patients (49.5%) had at least 2 follow-up visits with a difference in DAS28-CRP of more than 1.2 points (with current DAS28-CRP ≥3.2), serving as our sample for the case-crossover study. Concentrations of CO, NO, NO2, NOx, PM10, PM2.5 and O3 were higher in the 60-day period preceding a flare (Table 1). Sensitivity analyses considering geometric mean and cumulative concentrations yielded similar results (data not shown). Remarkably, we found that the cumulative exposure to NO2 in the 60 days preceding a flare was approximately 500 µg/m3 higher than the low disease activity visit, an exposure that equates to approximately to 200 passively smoked cigarettes (3.5 cigarettes per day on a 60-day period).

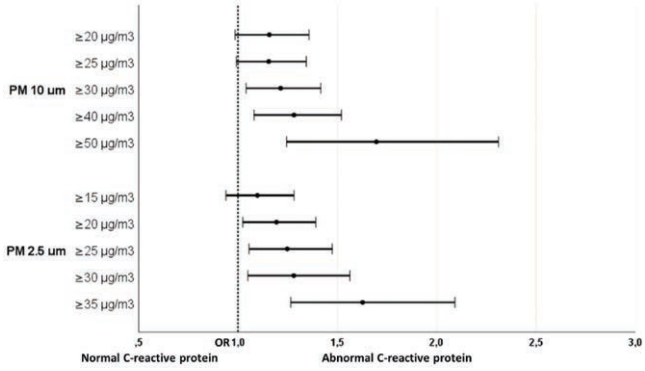

Figure 1. Odds of having abnormal CRP serum levels (≥5 mg/L) at different exposures of PM10 and PM2.5 (mean concentration in the 60 days before assessment)

Table 1. Case-crossover study. Mean concentrations (mean and Area Under the Curve) of air pollutants in the 60 days before low-disease activity visit and flare visit (DAS28-CRP difference >1.2)

Pollutant		Control period (low disease activity, n=440)	Hazard period (flare, n=440)	p value
CO µg/m^3	Mean	0.38	0.42	0.001
	AUC	22.00	24.53	0.001
NO µg/m^3	Mean	19.23	24.11	0.002
	AUC	1,120.53	1,403.88	0.002
NO_2 µg/m^3	Mean	30.91	32.44	0.042
	AUC	1,800.96	1,892.05	0.040
NO_x µg/m^3	Mean	60.34	69.35	0.004
	AUC	3,515.77	4,041.06	0.004
PM10 µg/m^3	Mean	31.21	33.65	0.011
	AUC	1,789.22	1,942.52	0.005
O_3 µg/m^3	Mean	31.08	33.79	0.002
	AUC	1,776.37	1,934.35	0.001
PM2.5 µg/m^3	Mean	23.08	24.74	0.018
	AUC	1,272.61	1,403.60	<0.001

Conclusion: We found a striking association between air pollution and RA disease severity and reactivations in a cohort of patients followed over a 5-year period. The exposure to high levels of air pollutants was associated with increased CRP levels and a higher risk of experiencing a flare of arthritis. This excessive risk was evident at very low levels of exposure, even below the proposed threshold for the protection of human health. Our study has important and direct consequences. In order to reduce the burden of RA, public and environmental health policy makers should aim to diminish gaseous and PM emissions to a larger extent as currently recommended.

OP0179

DISCONTINUATION RATE OF TOFACITINIB IS SIMILAR WHEN COMPARED TO TNF INHIBITORS IN RHEUMATOID ARTHRITIS PATIENTS: POOLED DATA FROM TWO RHEUMATOID ARTHRITIS REGISTRIES IN CANADA

M. Movahedi[1], D. Choquette[2], L. Coupal[2], A. Cesta[1], X. LI[1], E. Keystone[3], C. Bombardier[1]on behalf of OBRI and RHUMADATA Investigators. *[1]UHN, Toronto General Hospital Research Institute, Toronto, Canada*; *[2]Institut de Rhumatologie de Montréal, RHUMADATA, Montreal, Canada*; *[3]University of Toronto, Medicine, Toronto, Canada*

Background: Tofacitinib (TOFA) is an oral, small molecule drug used for rheumatoid arthritis (RA) treatment as the first or an alternative option to biologic disease- modifying antirheumatic drugs (bDMARDs), including tumor necrosis factor inhibitors (TNFi). The similarity in retention of TNFi and TOFA was previously reported separately by the Ontario Best Practices Research Initiative (OBRI) and the Quebec cohort RHUMADATA®.
Objectives: To increase the study power, we propose to evaluate the discontinuation rate (due to any reason) of TNFi compared to TOFA, using pooled data from both these registries.
Methods: RA patients enrolled in the OBRI and RHUMADATA initiating their TOFA or TNFi between 1st June 2014 (TOFA approval date in Canada) and 31st Dec 2019 were included. Time to discontinuation was assessed using adjusted Kaplan-Meier (KM) survival and Cox regression models. To deal with confounding by indication, we estimated propensity scores for covariates with a standard difference greater than 0.1. Models were then adjusted using stratification and inverse probability of treatment weight (IPTW) methods. Multiple imputation (Imputation by Chained Equation method, N=20) was used to deal with missing data for covariates at treatment initiation.
Results: A total of 1318 patients initiated TNFi (n=825) or TOFA (n=493) with mean (SD) disease duration of 8.9 (9.3) and 13.0 (10.1) years, respectively. In the TNFi group, 78.8% were female and mean age (SD) at treatment initiation was 57.6 (12.6) years. In the TOFA group, 84.6% were female and mean (SD) age at treatment initiation was 59.5 (11.5) years. The TNFi group was less likely to have prior biologic use (33.9%) than the TOFA group (66.9%). At treatment initiation, the mean (SD) CDAI was significantly ($p<0.05$) lower in the TNFi group [20.0 (11.7)] compared to the TOFA group [22.1(12.4)]. Physical function measured by HAQ-DI was also significantly lower ($p<0.05$) in the TNFi compared to the TOFA group (1.2 vs.1.3).
Over a mean follow-up of 23.2 months, discontinuation was reported in 309 (37.5%) and 182 (36.9%) of all TNFi and TOFA patients, respectively. After adjusting for propensity score deciles across 20 imputed datasets, there was no significant difference in discontinuation between treatment groups (adjusted HRs: 0.96, 95% CI: 0.78-1.18; p=0.69). The results were similar for two propensity adjustment methods. Figure 1 shows IPTW adjusted KM survival curves comparing discontinuation rates in patients treated with TNFi and TOFA.

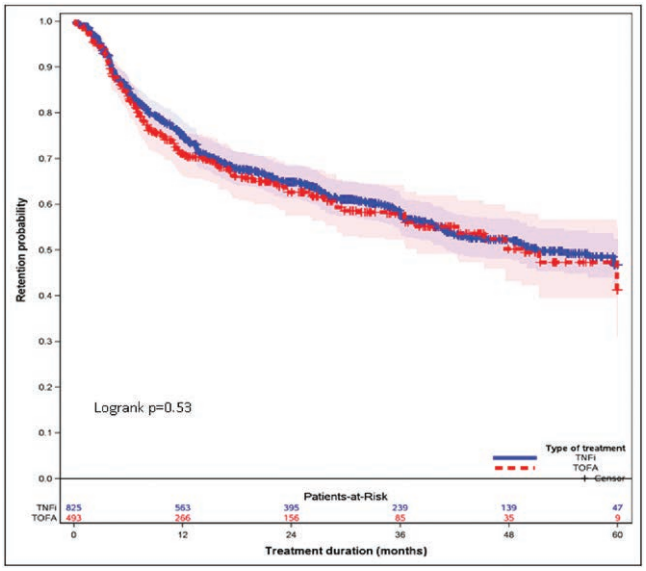

Figure 1. Note: Propensity Score Weighted (IPTW) Survival Curves was performed using one imputed dataset

Conclusion: In this pooled real -world data study, we found that TNFi and TOFA retention is similar in patients with RA. In the next step we will analysis the data for specific reasons of dicontinutaion. We will also repeat analysis comparing discontinuation in the first users versus those after one or more biologic failure.

Background: Up to 50% of patients with RA discontinue DMARD treatment within 18 months.[1] However, up to 20% of patients who fail multiple treatments may have a good treatment response to another therapy.[1] Predictive biomarkers, such as RF and anti-citrullinated protein antibodies (ACPAs), may be useful to stratify patients with RA to the most appropriate treatment.[1] ASCORE (Abatacept SubCutaneOus in Routine Clinical PracticE; NCT02090556) was a 2-year, observational, prospective, multicentre study of SC abatacept for the treatment of RA in routine clinical practice.[2]
Objectives: To determine if RF/ACPA serostatus and treatment line impact abatacept retention in patients with RA in a *post hoc* analysis of ASCORE.
Methods: Eligible patients, aged ≥18 years, with active moderate-to-severe RA (ACR/EULAR 2010 criteria) who were IV abatacept-naive and initiated SC abatacept 125 mg once weekly, were enrolled into two cohorts: biologic (b) DMARD-naive patients and those with ≥1 prior bDMARD treatment failure. This *post hoc* analysis assessed abatacept retention rate at 2 years in a subset of patients with RF/ACPA serostatus data (n=1748) from the ASCORE study (N=2892; as observed). Baseline (BL) serostatus groups examined by treatment line were: RF/ACPA double positive (+/+) RA, RF/ACPA single positive (RF+/ACPA– or RF–/ACPA+) RA (data not shown) and RF/ACPA double negative (–/–) RA. Last observation carried forward (LOCF) analyses were used to assess change from BL and measures of disease remission (DAS28 [CRP] <2.6, CDAI ≤2.8, and SDAI ≤3.3) in patients with +/+ RA versus –/– RA.
Results: BL demographic and disease characteristics were similar across serostatus groups and treatment lines (Table 1). Mean age was 57.1 and 57.8 years for +/+ RA and –/– RA, respectively. Mean DAS28 (CRP) was 4.7 and 4.8 for +/+ RA and –/– RA, respectively. In patients with +/+ RA, abatacept retention was greater when given as first-line treatment (57% vs 48% when given as ≥ second-line) (Figure 1). Retention was similar in patients with –/– RA regardless of treatment line. After 2 years, mean (SE) change from BL (LOCF) in DAS28 (CRP) was –1.41 (0.06) and –0.97 (0.09) for patients with +/+ and –/– RA, respectively. For patients with +/+ RA, mean (SE) change from BL in DAS28 (CRP) was –1.62 (0.08) for those in whom abatacept was first-line and –1.19 (0.08) for those in whom abatacept was ≥ second-line. For patients with –/– RA, mean (SE) change from BL in DAS28 (CRP) was –1.03 (0.13) for those in whom abatacept was first-line and –0.93 (0.12) for those in whom abatacept was ≥ second-line. Remission rates (LOCF) were significantly (p<0.0001) higher in patients with +/+ RA vs –/– RA respectively: DAS28 (CRP) 38.4% (n=393) versus 19.3% (n=62); CDAI 50.6% (n=513) versus 33.0% (n=107); and SDAI 49.5% (n=497) versus 32.5% (n=102).
Conclusion: In this real-world analysis, patients with +/+ RA treated with first-line abatacept had higher retention than patients receiving abatacept as a ≥ second-line therapy. Remission rates on abatacept were higher in patients with +/+ RA versus –/– RA. These results support early treatment with abatacept and highlight the importance of further evaluating precision medicine approaches in RA.

Table 1. BL demographics and disease characteristics by RF/ACPA status

	+/+ RA (n=1079)		–/– RA (n=343)	
	First-line (n=511)	≥ second-line (n=568)	First-line (n=140)	≥ second-line (n=203)
Age	57.1 (13.4)	57.1 (12.2)	59.5 (14.7)	56.6 (13.2)
DAS28 (CRP)	4.7 (1.2)	4.7 (1.2)	4.8 (1.1)	4.8 (1.2)
CDAI	26.6 (12.5)	26.6 (12.4)	27.7 (12.5)	28.6 (13.8)
SDAI	28.1 (13.1)	28.1 (12.9)	29.1 (12.9)	30.2 (14.7)

Data are mean (SD). Patients with missing data for BL RF/ACPA status are excluded. ACPA=anti-citrullinated protein antibody; BL=baseline.

Schaeverbeke[9], J. Sibilia[10], O. Vittecoq[11], J. P. Daures[2]on behalf of ESPOIR Cohort. *[1]Montpellier, Rhumatologie, Montpellier, France*; *[2]Montpellier, INSERM, Montpellier, France*; *[3]Paris, RHUMATOLOGIE, Paris, France*; *[4]Limoges, RHUMATOLOGIE, Limoges, France*; *[5]CHU, Rheumatology, Toulouse, France*; *[6]Lille, RHUMATOLOGIE, Lille, France*; *[7]Tours, RHUMATOLOGIE, Tours, France*; *[8]Brest, RHUMATOLOGIE, Brest, France*; *[9]Bordeaux, RHUMATOLOGIE, Bordeaux, France*; *[10]Strasbourg, RHUMATOLOGIE, Strasbourg, France*; *[11]Rouen, RHUMATOLOGIE, Rouen, France*

Background: ESPOIR is a longitudinal prospective cohort of adults with possible early RA (ClinicalTrials.gov: NCT03666091). Patients were referred by rheumatologists and general practitioners to one of the 14 regional centers in France. The objective and design of the cohort are described elsewhere (1). Patients received standard of care by their rheumatologists and were followed without predefined therapeutic strategies

Objectives: To report the current 10-year outcome of patients with early rheumatoid arthritis (RA) in the ESPOIR cohort, and predictors of outcome.

Methods: From 2003 to 2005, 813 patients were included if they had early arthritis (< 6 months) with a high probability of RA developing and had never been prescribed disease modifying anti-rheumatic drugs (DMARDs). Multivariate logistic regression analysis was used to evaluate predictors of outcome.

Results: In total, 521 (64.1%) RA patients were followed up for 10 years and 35 (4.3%) died, which appears similar to the French general population. Overall, 480 (92.1%) patients received a DMARD; 174/521 (33.4%) received at least one biologic DMARD, 13.6 and 23.4% within 2 and 5 years. At year 10 (Table), mean DAS28 ESR was 2.5 ± 1.3; 273 (52.4%) patients were in DAS28 remission, 39.7% in CDAI remission, 40.1% in DAS28 sustained remission, and 14.1% in drug-free remission. Disability was well controlled overtime (Figure) and half of the patients achieved a HAQ Disability Index < 0.5; the SF-36 physical component and pain were well controlled. Structural progression was weak, with a mean change from baseline in modified Sharp score of 11.0 ± 17.9. A total of 82 (16.5%) patients required joint surgery including arthroplasty or arthrodesis in only 6.5% of the cases. A substantial number of patients showed new comorbidities, mainly cardiovascular or metabolic diseases over 10 years. Finally, positivity for anti-citrullinated protein antibodies was confirmed as a robust predictor of long-term outcome in patients with early RA.

Table 1. Outcome in ESPOIR cohort and 1993 cohort at 10 years

	ESPOIR cohort n=521	1993 cohort n=112
DAS28 ESR	2.5 ± 1.3

Conclusion: We report a very mild 10-year outcome of a large inception cohort of patients with early RA diagnosed in the early 2000s, which was much better than results for a previous cohort of early RA patients who were recruited in 1993. This current favourable outcome may be related to more intensive care for real-life patients than previously.

OP0182 IN RA PATIENTS IN REMISSION, WHICH BIOMARKERS PREDICT SUCCESSFUL TAPERING OF CSDMARDS?

H. Gul[1], F. Ponchel[1], P. Emery[1]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, Rheumatology, Leeds, United Kingdom*

Background: Recommendations for the management of patients with RA who achieve stable clinical remission ≥6 months with conventional synthetic (cs) disease-modifying anti-rheumatic drugs (DMARDs) are to taper (with the aim of potentially stopping), although there are currently no validated biomarkers permitting prediction of sustained remission.

Objectives: To assess the rate of sustained remission over 12 months In RA patients in remission, who received either (i) structured tapering of csDMARDs or (ii) continuation of current therapy, focusing on the value of imaging and immunological biomarkers as well as patient-reported outcome measures (PROs).

Methods: RA patients (n=200) prospectively attending a remission clinic, fulfilling DAS28(3v)CRP<2.6 for ≥6 months on stable csDMARD therapy (mono or combination therapy & no corticosteroids) were included. Patients were offered the choice of structured cs-DMARD tapering according to a pre-defined protocol (Table 1) or remaining on stable therapy. Clinical, ultrasound (US), immunological (T-cell subsets) and PRO data were collected at inclusion. Loss of remission was defined as increase of DAS28(3v)CRP >2.6. Mann-Whitney-U and Chi-square tests were used to compare outcomes. After imputing missing data, regressions for predicting sustained remission were performed. AUROCs were used to compare models.

Results: The decision to taper treatment was associated with male gender, longer remission duration, normal CRP and lower grey scale scores (p<0.05). Of those who tapered 64% (75/117) remained in clinical remission at 12 months, compared to 80% (66/83, p=0.018) of patients who remained on stable treatment. At 15 months 11/117 (10%) had successfully stopped therapy.

In the tapering group, higher CRP, TJC and IRC were consistently associated with inability to sustain remission, as well as higher scores for several PROs (p<0.05) with a trend for total PD (P=0.066). Predicting sustained remission was modelled and retained RAQoL, total PD and a T-cell subset (Figure 1, 85% accuracy, AUROC 0.872).

In the non-tapering group, higher CRP/ESR, SJC and shorter disease duration (p<0.05) were associated with flare. No parameter was able to predict sustained remission.

Conclusion: In patients who chose to taper, the combination of clinical, PRO, US and T-cell parameters demonstrated added value for predicting sustained remission (85% accuracy) compared to clinical parameters alone. Different biomarkers were associated with sustained remission on continued therapy. These data may assist with informed tapering of csDMARDs.

OP0183 IDENTIFICATION OF A SUBGROUP OF PEOPLE WITH RHEUMATOID ARTHRITIS CHARACTERISED BY HIGH DISABILITY OVER 10 YEARS, DESPITE LOW INFLAMMATION: RESULTS FROM TWO EUROPEAN PROSPECTIVE COHORT STUDIES

J. Gwinnutt[1], S. Norton[2,3], K. Hyrich[1,4], M. Lunt[1], B. Combe[5], N. Rincheval[6], A. Ruyssen-Witrand[7], B. Fautrel[8,9], J. Chipping[10,11], A. Macgregor[10,11], S. Verstappen[1,4]. Background: Long-term studies in rheumatoid arthritis (RA) have reported low inflammation yet high disability over time. It is important to determine which factors are driving this disparity, so appropriate interventions can be used to reduce this gap.

Objectives: To identify a subgroup of people with RA with low inflammation yet high disability over 10 years, and describe their characteristics.

Methods: Data came from two cohorts of inflammatory arthritis with regular assessments over 10 years: the Norfolk Arthritis Register (NOAR, inclusion: ≥2 swollen joints for ≥4 weeks) from the UK and the *Etude et Suivi des Polyarthrites Indifférenciées Récentes* study (ESPOIR, inclusion: early RA) from France. Participants provided demographic data and completed patient reported outcomes (PROs, including the Health Assessment Questionnaire [HAQ]). The 2-component Disease Activity Score (DAS28-2C)[1], a measure of inflammation, was

Table 1. csDMARD tapering schedule

Drug	Baseline Dose	Taper 1	Taper 2	Taper 3	Taper 4	Taper 5
Hydroxychloroquine	200mg bd	200mg od	Stop	-	-	-
Hydroxychloroquine	200mg od	Stop	-	-	-	-
Sulfasalazine	1.5g bd	1g bd	1.5g od	500mg bd	500mg od	Stop
Sulfasalazine	1g bd	1.5g od	500mg bd	500mg od	Stop	-
Sulfasalazine	500mg bd	500mg od	Stop	-	-	-
Sulfasalazine	500mg od	Stop	-	-	-	-
Methotrexate	25mg/week	15mg/week	7.5mg/week	No change	Stop	-
Methotrexate	15mg/week	7.5mg/week	No change	Stop	-	-
Methotrexate	7.5mg/week	No change	Stop	-	-	-

NB: Patients were seen 3-monthly. If they remained in remission following tapering, they proceeded to the next taper unless there is a significant clinical reason not to taper at the time of assessment (as per standard care). Order of cs-DMARD tapering applies to patients on dual/triple therapy. All but 5 (112) were on methotrexate.

calculated from swollen joint counts and C-reactive protein level. Inclusion criteria for this analyis: <2 years baseline symptom duration; HAQ and DAS28-2C at baseline and one other follow-up; recruited after 1/1/2000. HAQ and DAS28-2C were modelled simultaneously using a multivariate group-based trajectory model, to identify groups of participants with similar trajectories of HAQ and DAS28-2C over 10 years. Baseline demographics and PROs were compared between the trajectory groups using logistic regression. Analyses performed separately in NOAR and ESPOIR.

Results: 1001 NOAR and 767 ESPOIR participants were included. In both cohorts, a four group trajectory model had the best fit (Figure). Two subgroups were identified in each cohort that demonstrated the hypothesised relationship: similar DAS28-2C but differing HAQ scores (red trajectories in Figure), titled "High HAQ" and "Low HAQ" (mean difference in HAQ over follow-up [95% confidence interval (CI)]: NOAR 0.76 [0.73, 0.80]; ESPOIR 0.89 [0.82, 0.96]). At baseline, the High HAQ groups in both NOAR and ESPOIR were older, had a higher proportion of women, and had higher levels of fatigue (NOAR: odds ratio [OR] 1.16 [95% CI 1.06, 1.28]; ESPOIR: OR 1.20 [95% CI 1.05, 1.36] [Table]) and pain (NOAR only).

Conclusion: There is a group of people with RA with high levels of disability, despite low inflammation. These results underline the potential need for pain and fatigue management in people with RA, even when inflammation is low.

OP0184

PHENOTYPING OF MOLECULAR SIGNATURES IN THE SYNOVIAL TISSUE OF RHEUMATOID ARTHRITIS BY INTEGRATIVE SYSTEMS ANALYSIS

J. Qiao[1,2,3], S. X. Zhang[1,2,3], H. Wang[1,2,3], J. Q. Zhang[1,2,3], M. T. Qiu[1,2,3], M. J. Chang[1,2,3], R. Zhao[1,2,3], S. Song[1,2,3], G. Y. Liu[1], P. F. He[4], X. LI[1,2,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; *[2]Shanxi Li Xiaofeng Medical Groups, Department of Rheumatology, Taiyuan, China*; *[3]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; *[4]Shanxi Medical University, Medical Data Sciences, Taiyuan, China*

Background: Rheumatoid arthritis (RA) is an aggressive immune-mediated joint disease characterized by synovial proliferation and inflammation, cartilage destruction, and joint destruction[1]. Despite efforts to characterize the disease subsets and to predict the differential prognosis in RA patients, disease heterogeneity is not adequately translated into the current clinical subclassification[2].

Objectives: To develop and validate an integrative system approach for stratifying patients with RA according to disease status and whole-genome gene expression data.

Methods: An RNA sequencing dataset of synovial tissues from 124 RA patients (including 57 patients with early RA, 95 with established RA) and 15 healthy controls (HC) was imported from the Gene Expression Omnibus (GEO) database (GSE89408) by software package R (version 4.0.3). After filtrating of differentially expressed genes (DEGs) between RA and HC, non-negative matrix factorization, functional enrichment, and immune cell infiltration were applied to illustrate the landscapes of these patients for classification. Clinical features (age, gender, and auto-antibodies) were also compared to discover the signatures of these classifications.

Results: A matrix of 576 DEGs from RA samples was classified into 5 subtypes (early/C1–C3, established/C4-C5) with distinct molecular and cellular signatures and two sub-groups (S1 and S2) (Figure 1A-1D). New-onset patients (early C2) and established C4 patients were named as S1, they shared similar gene signatures mainly characterized by prominent immune cells and proinflammatory signatures, and enriched in the chemokine-mediated signaling pathway, lymphocyte activation, response to bacterium and Primary immunodeficiency. S2(C1, C3 and C5) were more occupied by synovial fibroblasts of destructive phenotype. They were mainly enriched in the response to external factors and PPAR signaling pathway (Figure 1E-1H). Interestingly, combined with clinical information, S1 and S2 had no significance in age and gender ($P > 0.05$). But patients in S1 had a stronger association with the presence of anti-citrullinated protein antibodies (ACPA) ($P < 0.05$) (Figure 1I-1J).

Conclusion: We successfully deconvoluted RA synovial tissues into pathobiological discrete subsets using an unsupervised machine learning method and described their distinct molecular and cellular characteristics. These results

provide important insights into divergent and shared mechanistic features of RA and serve as a template for future studies to guide drug tar-get discovery by synovial molecular signatures and de-sign stratified approaches for patients with RA.

OP0185

RADIOGRAPHIC PROGRESSION DESPITE PERSISTENT LDA OR REMISSION IS INFLUENCED BY CURRENT SMOKING RATHER THAN THE RESPECTIVE DAS 28 LEVEL, RESULTS OF THE SWISS RHEUMATOID ARTHRITIS REGISTER (SCQM)

L. Brandt[1,2], H. Schulze-Koops[3], T. Hügle[4], M. J. Nissen[5], H. Paul[6], R. Muller[6]. *[1]Division of Rheumatology, Medical University Department, Kantonsspital Aarau, Aarau, Switzerland*; *[2]Ludwig-Maximilians-University Munich, Division of Rheumatology and Clinical Immunology, Department of Internal Medicine IV, Munich, Germany*; *[3]Ludwig-Maximilians-University Munich, Division of Rheumatology and Clinical Immunology, Department of Internal Medicine IV, Munich, Germany*; *[4]University Lausanne, Division of Rheumatology, University Hospital Lausanne (CHUV), Lausanne, Switzerland*; *[5]Geneva university hospital, Rheumatology, Geneva, Switzerland*; *[6]Kantonsspital Aarau, Division of Rheumatology, Medical University Department, Aarau, Switzerland*

Background: The therapeutic aim for rheumatoid arthritis (RA) is to control disease activity and prevent radiographic progression. Various clinical scores are utilized to describe disease activity in RA patients. The DAS28 score can define states of low disease activity (LDA) and remission. Despite achieving LDA or remission, radiographic progression may nevertheless occur. However, the rates and frequency of this occurrence have not been analyzed in detail.

Objectives: To describe the frequency and rate of radiographic progression in patients with persistent LDA or remission.

Methods: Analysis of RA patients from the SCQM cohort. Persistent LDA or remission were defined as DAS 28 ≤3.2 or <2.6 respectively, at two subsequent follow up time points in the database. We included patients with at least two sets of radiographs within these intervals of LDA and/or remission. Radiographic progression was measured with the Ratingen-score (range 0-190), which describes joint erosions numerically. Repair was defined as an improvement in the Ratingen score >5 points/year and progression as >2 or >5 points change in the Ratingen score within one year.

Results: Among 10'141 RA patients, 4'342 episodes of remission occurred in 3'927 patients with 1'776 sets of X rays available within these episodes. Similarly, 8'136 episodes of LDA in 6'765 patients and 2'358 sets of X rays were present within these intervals. For patients in LDA or remission, rates of repair were 5.5% and 4.8%, respectively, while for radiographic progression >5 points in the Ratingen score/year were 10.3% in both groups and for >2 points change of Ratingen score/year were 27.7 and 25.4%, respectively).

No differences for demographic factors or measures of disease activity, rheumatoid factor or ACPA were found comparing patients with radiographic progression or non-progression despite LDA or remission at the beginning of the episode of LDA and/or remission.

Interestingly, 42.9% of patients in LDA with progression of >5 points in the Ratingen score/year were current smokers vs 29.4% among the non-progressors (X^2 = 6.55, p = 0.01). This significant difference vanished when the cut-off for radiographic progression was set at >2 points yearly change in Ratingen score or in patients in remission.

Conclusion: Radiographic progression despite LDA or remission are more frequent than expected. No differences in radiographic progression were found comparing LDA and remission suggesting that the goal of LDA is appropriate. Smoking seems to be an independent risk factor for radiographic progression despite LDA. Why the effect of smoking could was not demonstrated in patients in remission, remains unclear.

OP0186

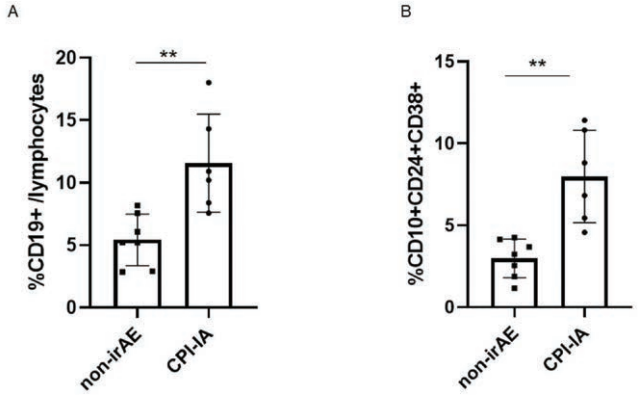
CHANGES IN CIRCULATING B CELL LEVELS AND IMMUNOPHENOTYPE ARE ASSOCIATED WITH DEVELOPMENT OF ARTHRITIS FOLLOWING TREATMENT WITH CHECKPOINT INHIBITORS

M. Gatto[1,2,2], S. Bjursten[3,4], C. Jonell[1], C. Jonsson[1], S. Mcgrath[1], A. Rudin[1], M. Levin[3,4,5], I. Gjertsson[1]. *[1]University of Gothenburg, Rheumatology and Inflammation Research, GOTHENBURG, Sweden*; *[2]University of Padova, Unit of Rheumatology, Padova, Italy*; *[3]University of Gothenburg, Oncology, Sahlgrenska University Hospital, GOTHENBURG, Sweden*; *[4]University of Gothenburg, Oncology, Institute of Clinical Sciences, Sahlgrenska Academy, GOTHENBURG,*

Sweden; [5]*University of Gothenburg, Wallenberg Laboratory for Cardiovascular Research, Department of Molecular and Clinical Medicine, Sahlgrenska Academy, GOTHENBURG, Sweden*

Background: Inflammatory arthritis (IA) is frequent among rheumatic side effects induced by checkpoint inhibitor (CPI) therapy for metastatic malignancies[1]. While T cells are likely to sustain the inflammatory process[2], fewer data are available concerning the role of B cells[3].
Objectives: To investigate the phenotype of circulating B cells in patients who develop CPI-induced IA (CPI-IA) and to compare it with features of B cells in patients not developing immune-related adverse events (irAE) upon CPI treatment.
Methods: B cell subsets at baseline (before CPI initiation) and during CPI treatment were analyzed in CPI-IA patients and in patients receiving CPI but who did not develop irAE (non-irAE). Peripheral blood mononuclear cells (PBMC) were analyzed by flow cytometry and B cells were identified as $CD19^+$ and divided into naïve ($CD27^-IgD^+$), memory ($CD27^+IgD^{+/-}$), double negative ($CD27^-IgD^-$) and transitional ($CD10^+CD24^+CD38^{+/hi}$) B cells. Levels of CD21, an activation marker on transitional B cells, were also analyzed. Non-parametric tests were used for analysis of differences between groups.
Results: Six CPI-IA and 7 non-irAE patients matched for age, gender and CPI treatment were included, who had received CPI treatment due to metastatic melanoma. Flow cytometry revealed a significant increase of circulating B cells (p=0.002) (Figure 1A) and especially of transitional B cells in CPI-IA patients vs. non-irAE (median %, range: 7.8 (4.5-11.4) vs. 3.2 (1.6-4.3),p=0.007) (Figure 1B), while no remarkable changes were seen across other subsets. Transitional B cell levels significantly decreased from active to quiescent CPI-IA in all patients (p=0.008). In two CPI-IA patients for whom baseline sampling was available, the increase of transitional levels occurred early after CPI treatment and before CPI-IA onset. Levels of expression of CD21 on transitional B cells were increased in CPI-IA vs. non-irAE (p=0.01).

Figure 1. B cells (CD19+) and transitionals are significantly increased in CPI-IA patients
Mann-whitney U test, **<0.01



Conclusion: Transitional B cells are expanded in CPI-IA patients and seem to increase early after start of CPI therapy. Monitoring this B cell subset might lead to closer follow-up and earlier diagnosis of CPI-IA.

OP0187 INCIDENCE OF MALIGNANCY IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM THE JAPANESE IORRA PATIENT REGISTRY

M. Harigai[1], N. Sugitani[1], R. Sakai[1], E. Inoue[1,2], M. Mochizuki[3], S. Toyoizumi[4], N. Yoshii[3], N. Sugiyama[3], E. Tanaka[1], H. Yamanaka[1,5]. [1]*Tokyo Women's Medical University School of Medicine, Department of Rheumatology, Tokyo, Japan*; [2]*Showa University, Showa University Research Administration Center, Tokyo, Japan*; [3]*Pfizer Japan Inc, Inflammation and Immunology, Tokyo, Japan*; [4]*Pfizer R&D Japan, Biometrics and Data Management, Tokyo, Japan*; [5]*Sanno Medical Center, Tokyo, Japan*

Background: The risk of some types of malignancy is increased in patients (pts) with rheumatoid arthritis (RA), compared with the general population. We have previously reported the incidence of malignancy in Japanese pts with RA.[1-4]
Objectives: This analysis further evaluated the incidence of malignancy in Japanese pts with RA using recent data from the large prospective observational study, IORRA.
Methods: This analysis included all pts with RA aged ≥18 years who were enrolled in IORRA from April 2013 to October 2018, with follow-up through October 2019, and participated in ≥2 surveys. Index was defined as the date of the first entry in the IORRA database, with baseline defined as the 6-month period prior to the index date. Malignancies were identified in pt reports of biannual IORRA surveys and confirmed using medical records. Age- and sex-standardised incidence ratios (SIRs) and 95% confidence intervals (CIs) were calculated.
Results: In total, 8020 pts were included. At baseline, the majority (85.0%) of pts were female; mean disease duration was 12.8 years, 5.8% and 4.8% of pts had a past history of malignancy or comorbid malignancy at baseline, respectively, and the majority (75.9%) of pts were receiving methotrexate (Table). The SIR (95% CI) was 0.90 (0.80, 1.01). SIRs (95% CI) of site-specific malignancies were: breast cancer, 0.91 (0.69, 1.18); lung cancer, 0.67 (0.44, 0.97); colon cancer, 0.93 (0.62, 1.32); stomach cancer, 0.82 (0.56, 1.14); and lymphoma, 3.74 (2.73, 4.96).

Table 1. Patient demographics and baseline disease characteristics

	Patients with RA (N=8020)
Age (years), mean (SD)	59.3 (13.8)
Female, n (%)	6816 (85.0)
Duration of RA (years), mean (SD)	12.8 (10.3)
Never smoked, n (%)	5086 (66.2)
DAS28, mean (SD)	2.8 (1.1)
J-HAQ, mean (SD)	0.60 (0.72)
Malignancy status, n (%)	
Past history of malignancy	467 (5.8)
Comorbid malignancy at baseline	386 (4.8)
Medication use, n (%)	
MTX	6088 (75.9)
Tacrolimus	787 (9.8)
Corticosteroids	2641 (32.9)
bDMARD use	1508 (18.8)
TNFi	1163 (14.5)
Tocilizumab	311 (3.9)
Abatacept	106 (1.3)
JAK inhibitors	4 (0.05)

bDMARD, biological disease-modifying antirheumatic drug; DAS28, Disease Activity Score in 28 joints; JAK, Janus kinase; J-HAQ, Japanese Health Assessment Questionnaire; MTX, methotrexate; N, the number of patients included in the analysis, the number of patients assessed for each characteristic may be fewer than N; n, the number of patients with each characteristic; SD, standard deviation; TNFi, tumour necrosis factor inhibitor

Conclusion: Overall risk of malignancy was similar to that in the general Japanese population, although a significantly higher risk of lymphoma was identified.

Joint Session EULAR ESCMI and EANM (European Association of Nuclear Medicine) – State-of-the-art nuclear imaging in RMDs

OP0189 MACROPHAGE PET/CT IMAGING OF THE FEET CAN CONTRIBUTE TO EARLY PREDICTION OF THERAPY OUTCOME IN RHEUMATOID ARTHRITIS

N. J. F. Verweij[1], M. Ter Wee[1,2], J. De Jongh[1], G. C. J. Zwezerijnen[3], M. Yaqub[3], D. Van Schaardenburg[1], A. Voskuyl[1], W. Lems[1], A. A. Lammertsma[3], M. Boers[1,2], C. J. Van der Laken[1]. [1]*Amsterdam Rheumatology and Immunology Center, Amsterdam UMC - Location VUmc, Department of Rheumatology, Amsterdam, Netherlands*; [2]*Amsterdam Public Health, Amsterdam UMC – location VUmc, Department of Epidemiology and Biostatistics, Amsterdam, Netherlands*; [3]*Amsterdam UMC - Location VUmc, Department of Radiology & Nuclear Medicine, Amsterdam, Netherlands*

Background: Treat-to-target strategies for rheumatoid arthritis (RA) have shown significant improvements in therapy outcomes. Nevertheless, it usually takes a minimum of 12 weeks before clinical assessment of treatment response can be made. Quantitative positron emission tomography (PET) has shown potential to predict clinical response at a very early stage in the treatment in RA patients.(1) In particular, macrophage imaging by [^{11}C]-(*R*)-PK11195 PET allows for highly sensitive and specific imaging of RA disease activity.(2,3)

Objectives: To determine whether quantitative assessment using [^{11}C]-(R)-PK11195 PET/CT imaging at 0-2 weeks is associated with subsequent clinical response to therapy with methotrexate and step-down prednisolone (COBRA-light) therapy in therapy-naive RA patients.

Methods: Whole body [11C]-(R)-PK11195 PET/CT scans were performed at baseline and after two weeks of treatment in thirty-five clinically active and therapy-naive RA patients and at least two clinically inflamed joints. All patients were DMARD-naïve and received medication according to the COBRA-light schedule. (4) Clinical follow up with DAS44 assessment was performed at 0, 2 and 13 weeks of treatment. PET/CT scans were visually assessed by two experienced readers blinded to clinical data and quantitatively analyzed using in-house software. Regions of interest (ROIs) with a fixed size per joint (on both visual PET positive and negative joints) were placed on shoulders, elbows, hips, knees and hand and feet joints, with the CT-scan as anatomical reference. Standardized uptake values (SUVs) normalized for body weight were calculated in these ROIs to determine the amount of tracer uptake per joint. SPSS version 22.0 was used to perform regression analyses. The sum of visually positive joints and the average SUV in hand joints, feet joints and all joints in the body were compared with DAS44 scores.

Results: Included patients were mostly male (51%) and aged 54 ± 12. Baseline DAS44 was 3.2 ± 1.0; all but one of the thirty-five patients demonstrated visually enhanced tracer uptake in one or more joints on PET/CT. A total of 171 (out of 1470) joints (12%) were visually PET positive at baseline. Over 90% of PET positive sites were located either in the wrists (15%), small hand joints (37%), or small feet joints (40%; Figure 1A). After 2 weeks, the number of PET positive joints had decreased to 100, with the highest decrease in quantitative uptake in feet joints (Figure 1B). Notably, both visual and quantitative PET data at baseline and differences between baseline and 2 weeks did not correlate with DAS44 at 13 weeks (DAS44-13wks). However, at 2 weeks, the average SUV in the feet (SUVfeet-2wks) – but not average SUVhands-2wks or average SUVtotalbody-2wks – was significantly correlated with DAS44-13wks (R^2 = 0.14, p = 0.04). DAS44-2wks and SUVfeet-2wks both contributed independent information to the prediction DAS44-13wks (combined R^2 = 0.297, p < 0.01).

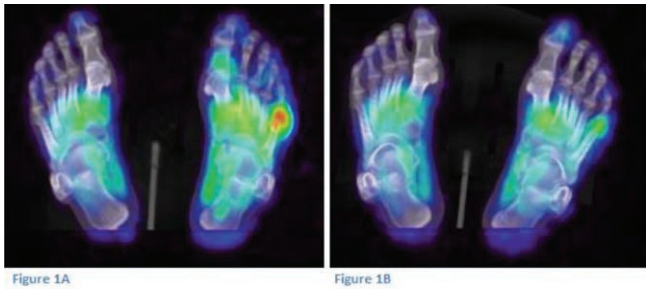

Figure 1. Changes in [^{11}C]-(R)-PK11195 uptake in MTP joints of a RA patient, before (A) and 2 weeks after initiation of COBRA light treatment (B).

Conclusion: Quantitative macrophage PET assessment in feet joints after 2 weeks of COBRA light treatment in early RA patients correlates with clinical response after 3 months of treatment. This correlation further increases when combined with the DAS44 score at 2 weeks. Therefore, quantitative, non-invasive macrophage PET/CT, especially when combined with early clinical assessment, may be useful for early assessment of response to treatment. Further studies will help optimize timing and focus of the PET examination in prediction of treatment response.

OP0190 USEFULNESS OF 18F-FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY IN DIAGNOSING POLYMYALGIA RHEUMATICA AND LARGE-VESSEL VASCULITIS: A CASE-CONTROL STUDY

A. Desvages[1], F. Hives[2], X. Deprez[3], A. Pierache[4], R. M. Flipo[1], J. Paccou[1]. [1]*Lille University Hospital, Rheumatology, Lille, France*; [2]*Lille University Hospital, Nuclear Medicine, Lille, France*; [3]*Valenciennes Hospital, Rheumatology, Valenciennes, France*; [4]*Lille University Hospital, Biostatistics, Lille, France*

Background: Polymyalgia rheumatica (PMR) is a relatively common disease among the elderly. None of the most common imaging techniques provides diagnostic certainty of PMR. 18F-fluoro-dexoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) may be a useful candidate as it can be used to visualize articular and periarticular FDG uptake at different locations, as well as associated large-vessel vasculitis (LVV), but its usefulness needs to be evaluated in the absence of large-scale case-control studies.

Objectives: The purpose of this study was to determine the usefulness of FDG-PET/CT in diagnosing PMR and LVV.

Methods: We analysed FDG-PET/CT scans performed between January 2015 and December 2019 on patients diagnosed with PMR. For comparisons, patients with PMR were matched 1:1 to controls according to age and sex. FDG-PET/CT scans had been performed on controls over the same period for diagnosis of cancer-associated stroke. FDG uptake was scored visually using a semi-quantitative analysis (score 0-3) for 17 articular or periarticular sites, as described by Sondag *et* al. **[1]**, and for 13 vascular sites, as described by Slart *et* al. **[2]**. The case and control groups were compared using generalized linear mixed models (binomial distribution, logit function) for binary outcomes, and linear mixed models for continuous outcomes, with matched sets as a random effect. The optimal threshold for the number of sites with significant hyperfixation (score ≥ 2) was determined by maximizing the Youden index.

Results: 81 patients with a diagnosis of PMR and 81 controls were included (mean (SD) age 70.7 (9.8) years; 44.4% women). We found significant differences between the PMR and control groups at all articular or periarticular sites for: 1) FDG uptake score (p<0.0001); 2) number of patients per site with significant FDG uptake (score ≥ 2) (p<0.0001); 3) global FDG articular uptake scores (score 0-51) (31 [IQR, 21 to 37] versus 6 [IQR, 3 to 10], p<0.001); and 4) number of sites with significant FDG uptake (score ≥ 2) (score 0-17) (11 [IQR, 7 to 13] versus 1 [IQR, 0 to 2], p<0.001). Using ROC curve analysis (Figure 1), we found that the presence of 6 or more sites with significant FDG uptake (≥ 2) was associated with the diagnosis of PMR with a sensitivity of 84% and a specificity of 96% (AUC 0.96 [95% CI 0.93-0.99]). No significant differences in global FDG vascular uptake scores (score 0-39) or in number of patients with at least 1 significant uptake vascular site (score ≥ 2) were found between the PMR and control groups (1 [IQR, 0 to 4] versus 4 [0 to 6], p=0.06 and 8 (11.3%) versus 10 (14.1%), p=0.62 respectively).

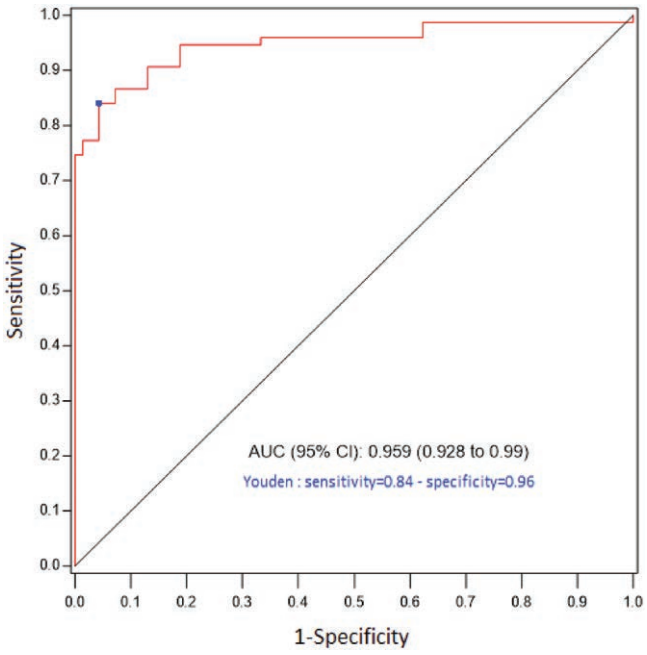

Figure 1. ROC curve analyzing performance of FDG-PET/CT for the diagnosis of PMR according to the number of sites with significant FDG uptake (≥ 2)

Conclusion: Our results demonstrate that the FDG uptake score and the number of sites with significant FDG uptake could be relevant criteria for the diagnosis of PMR. However, unlike other authors, we found no evidence suggesting that FDG-PET/CT may be useful in diagnosing silent underlying LVV in patients with isolated PMR.

Improving collaborative research and patients' participation in health decision-making

OP0191-PARE

DEVELOPMENT OF A PUBLIC AND PATIENT INVOLVEMENT (PPI) RESEARCH NETWORK FOR PEOPLE WHO HAVE RHEUMATIC CONDITIONS

L. Larkin[1], A. Moses[1], T. Raad[1], A. Tierney[1], N. Kennedy[1], W. Costello[2].
[1]*University of Limerick, School of Allied Health and Health Research Institute, Limerick, Ireland*; [2]*iCAN, Irish Children's Arthritis Network, Tipperary, Ireland*

Background: Public and patient involvement (PPI) improves quality and relevance of research (1). PPI is advocated by policy makers and funding bodies and is supported by EULAR (2). Arthritis Research Limerick (ARL) is a partnership between researchers at the University of Limerick and clinicians at University Hospitals Limerick. PPI representatives have been involved in ARL projects, however no formal PPI network had been established prior to 2020. The need for a formal PPI network to collaborate with ARL was identified by both ARL and patient representatives. This need arose from a joint ambition to promote meaningful involvement of the public and patients in ARL projects and to develop a platform through which researchers and PPI representatives could collaboratively set research priorities.

Objectives: The aim of this project was to create a formal PPI network to engage with people living with rheumatic and musculoskeletal diseases (RMDs) and their families and to identify collaborative research opportunities between ARL and PPI representatives.

Methods: A face-to-face PPI seminar was planned for October 2020. The seminar consisted of speakers from ARL providing an overview of research projects and a World Café research ideas session. Funding was obtained through a competitive, peer-review funding call from the PPI Ignite group at the University of Limerick to support the PPI seminar. The funding application was a joint application between ARL members and a PPI partner (iCAN - Irish Children's Arthritis Network). The seminar was advertised through national patient organisations (iCAN and Arthritis Ireland), social media and ARL research networks.

Results: Due to Covid-19 public health restrictions the PPI seminar was held virtually. The ARL PPI inaugural seminar was attended by N=19 researchers and people living with RMDs. The seminar speakers included ARL researchers and a PPI representative. The World Café event was modified to adapt to the virtual seminar delivery. Research ideas were noted by the seminar organiser and summarised for attendees at the end of the research ideas and priorities session. An ARL PPI mailing list was set-up post seminar as a means of communicating with seminar attendees and will serve as a formal PPI network for ARL. Research updates and opportunities will be communicated via this formal network to people living with RMDs and researchers alike.

Conclusion: This was the first PPI seminar organised by ARL in collaboration with a PPI seminar, and has led to the creation of a formal PPI network. Delivery mode of the PPI seminar was changed due to Covid-19 public health restrictions. This change may also have impacted engagement and attendance at the PPI seminar, given that virtual events are not accessible to all of the RMD population. Future PPI seminars will consider a hybrid approach of face-to-face and virtual attendance, to enhance accessibility. A formal PPI communication network has been established. Future work will focus future collaborative opportunities between the PPI panel and the ARL group, including project development, co-led research funding applications and joint research dissemination.

Comorbidities in gout and hyperuricaemia

OP0192

INCIDENT GOUT AND RISK OF FIRST-TIME ACUTE CORONARY SYNDROME: A PROSPECTIVE, POPULATION-BASED, COHORT STUDY IN SWEDEN

P. Drivelegka[1], L. T. H. Jacobsson[1], U. Lindström[1], K. Bengtsson[1], M. Dehlin[1].
[1]*Institute of Medicine, The Sahlgrenska Academy at University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*

Background: Gout is associated with an increased risk of cardiovascular disease (CVD), but it is not clear whether this risk is intrinsic to gout itself or to underlying comorbidities. Although the impact of gout on CVD has been studied previously, the results have been conflicting and studies from European countries are scarce.

Objectives: To investigate the risk of first-time acute coronary syndrome (ACS) in patients with incident gout in western Sweden, compared to the general population.

Methods: Using data from the population-based health care database VEGA, we identified all patients with incident gout diagnosis at either primary or specialized health care units in western Sweden, in the period 2007– 2017 (20,287 cases; mean age, 65.6 years; 67.4% males). Cases regarded as incident, if they did not have any recorded diagnosis of gout in the previous seven years. For each case, up to five controls matched on age, sex, and county at the date of first gout diagnosis were identified from the census register (84,240 controls). Cases and controls with prior history of ischemic heart disease were

excluded. The follow-up began at the first diagnosis of gout, and ended at the earliest of an ACS event, emigration, death, or 31 December 2017. To estimate the risk of first-time ACS, we used incident rate (IR) and univariable and multivariable Cox regression analysis with adjustments for the following cardiovascular risk factors: the diagnoses of hypertension, diabetes, hyperlipidemia, obesity, renal disease, heart failure, cardiomyopathy, psoriasis, chronic obstructive pulmonary disease, alcoholism, cancer, cerebrovascular, and atherosclerotic disease, as well as for the dispensed prescriptions of statins, anticoagulants, anti-hypertensive, anti-diabetic, anti-hyperlipidemic, anti-obesity, and vasodilator drugs.

Results: The IR of first-time ACS was 9.0 events per 1,000 person-years in the gout cohort, compared to 6.3 in the control cohort. The IRs were lower for women than men, both in the gout (IR, 8.2 vs 9.4) and in the control cohort (IR, 5.0 vs 7.0). Univariable analysis showed that patients with gout have a higher risk of first-time ACS, as compared to the general population (Figure 1, Table 1), but the increased risk is largely diminished after adjustments for cardiovascular risk factors (Table 1).

Table 1. Risk of first-time ACS in patients with incident gout, as compared to the general population.

	Unadjusted HR	95% CI	p-value	Adjusted HR	95% CI	p-value
ACS						
Overall	1.43	1.32-1.55	<.0001	1.15	1.05-1.24	0.0013
Men	1.35	1.23-1.48	<.0001	1.12	1.02-1.23	0.0230
Women	1.63	1.41-1.89	<.0001	1.21	1.03-1.41	0.0207

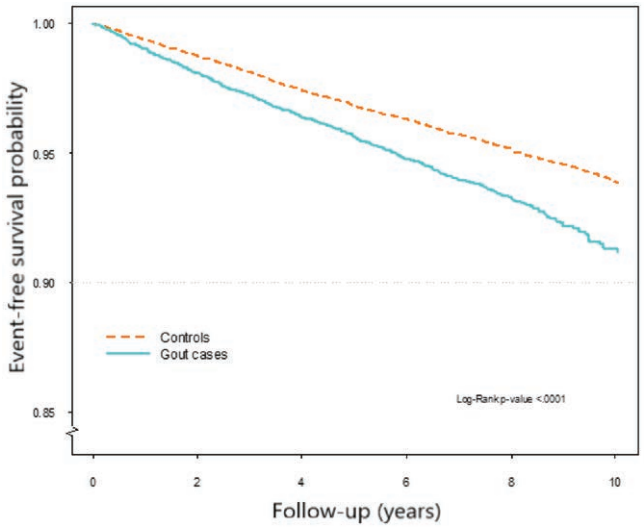

Figure 1. Event-free survival curve for patients with gout and controls during the follow-up, where event is first-time acute coronary syndrome.

Conclusion: Patients with incident gout have a 43% higher risk of first-time ACS, as compared to the general population. This increased risk is largely explained by the increased occurrence of comorbidities in gout, but there is still a modestly increased risk that may be due to gout related factors. Our results underline the importance of cardiovascular risk assessment and the need for appropriate management of the underlying cardiovascular risk factors in patients with gout.

OP0193

EVALUATION OF THE CAUSAL EFFECTS BETWEEN GOUT AND HYPERTENSION: A MENDELIAN RANDOMIZATION STUDY

Y. J. Chang[1], L. C. Wang[2], C. K. Chen[1], C. I. Hsieh[2], C. F. Kuo[1,2]. *[1]Chang Gung Memorial Hospital, Center for Artificial Intelligence in Medicine, Taoyuan, Taiwan, Republic of China*; *[2]Chang Gung Memorial Hospital, Rheumatology, Allergy and Immunology, Taoyuan, Taiwan, Republic of China*

Background: Gout is the most common inflammatory arthritis worldwide associated with comorbidities that may impair well-being and reduce longevity. Epidemiological evidence generally supports that gout patients are at high risk of hypertension. However, the causality between gout and hypertension is uncertain since confounding and other types of bias are difficult to contain in the observational study.

Objectives: To test the causal link between gout and hypertension using a Mendelian Randomization (MR) analysis.

Methods: A mendelian randomization analysis was conducted using individual patient data from the Taiwan Biobank featured 2452 individuals with gout and 66527 controls. We selected 12 SNPs as instrumental variables (IVs) with p-values $< 5 \times 10^{-8}$ and the linkage disequilibrium (LD) R^2 value less than 0.8. We conducted traditional MR analysis using the inversed weighted variance (IVW) and median methods with different settings as the primary analysis. Further IV assumption-free methods, the MR-Egger methods [1], Causal Analysis Using Summary Effect Estimates (CAUSE) model [2], and structural equation modeling (SEM) [3,4] were also performed as a sensitivity analysis.

Results: The prevalence of hypertension was 0.15% (n = 9549) in the cohort. Table 1 shows causal effect estimates between gout and hypertension using different methods. The average causal effect β is estimated at 0.09 and the corresponding odds ratio (OR) at 1.09 using traditional methods across different settings. Similar estimates were observed in the MR-Egger method, SEM model, and the CAUSE model, demonstrating the robustness of the causal association between gout and hypertension considering pleiotropic effects (Table 1). Furthermore, the model fit of the hypothesized SEM model is excellent with a comparative fit index of 0.978 and Tucker-Lewis index of 0.968. The SEM model explains at least 32.70% variance of hypertension and 32.6% variance of gout (Figure 1).

Table 1. Estimate the causal effect of MR analysis and sensitivity analysis

Method	Causal effect estimate β	95% lower bound	95% upper bound	p-value
Primary analysis				
IVW with fixed effect, first order	0.0900	0.0656[a]	0.1145[a]	$<10^{-5}$
IVW with fixed effect, second order	0.0895	0.0647[a]	0.1143[a]	$<10^{-5}$
IVW with random effect, first order	0.0900	0.0656[a]	0.1145[a]	$<10^{-5}$
IVW with random effect, second order	0.0895	0.0647[a]	0.1143[a]	$<10^{-5}$
Median method, simple	0.0989	0.0645[a]	0.1332[a]	$<10^{-5}$
Median method, weighted	0.0902	0.0583[a]	0.1220[a]	$<10^{-5}$
Median method, penalized	0.0902	0.0583[a]	0.1220[a]	$<10^{-5}$
Sensitivity analysis				
MR-Egger	0.0786	0.0132[a]	0.1440[a]	0.0183
SEM	0.0519	0.0481[a]	0.0697[a]	$<10^{-5}$
CAUSE model	0.0764	0.0176[b]	0.1349[b]	$<10^{-5}$

* [a] represents the 95% confidence interval; [b] represents the 95% credible interval.

** For the random effect model, if the estimated residual standard error is less than 1, then the *MendelianRandomization* package will automatically set the value of residual standard error into 1.

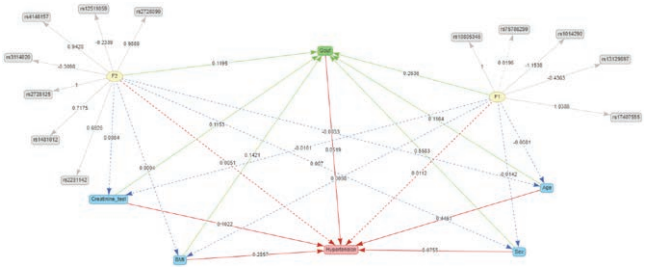

Figure 1. Pathway analysis for SEM study assessing the relationships between gout and hypertension.

Conclusion: These results strongly suggest that the association between gout and hypertension has a causal basis.

Immune events with checkpoint inhibitors

OP0194 GENERALIZED IMMUNE ACTIVATION IN STRUCTURES RELATED TO PMR OR GCA ON PET/CT ASSESSMENT DOES NOT OCCUR IN IMMUNE CHECKPOINT INHIBITOR-TREATED PATIENTS WHO DO NOT GO ON TO DEVELOP RHEUMATIC IMMUNE-RELATED ADVERSE EVENTS

D. Liew[1,2,3], A. Poon[4], C. Mcmaster[1,2,3], C. Owen[1,3], J. Leung[1,3], A. Frauman[2,3], J. Cebon[5,6,7], A. Scott[3,4,5], R. Buchanan[1,3]. *[1]Austin Hospital, Rheumatology, Heidelberg, Australia*; *[2]Austin Hospital, Clinical Pharmacology and Therapeutics, Heidelberg, Australia*; *[3]University of Melbourne, Medicine, Parkville, Australia*; *[4]Austin Hospital, Molecular Imaging and Therapy, Heidelberg, Australia*; *[5]Olivia Newton-John Cancer Wellness & Research Centre, Medical Oncology, Heidelberg, Australia*; *[6]La Trobe University, Melbourne Campus, Tumour Immunology Laboratory, Bundoora, Australia*; *[7]La Trobe University, Melbourne Campus, School of Cancer Medicine, Bundoora, Australia*

Background: The pathogenesis of rheumatic immune-related adverse events (irAEs) from checkpoint inhibitor cancer immunotherapy directed against programmed cell death protein 1 (PD-1) and programmed death ligand 1 (PD-L1) remains unknown, even though they are a consequence of pharmacologic inhibition of a specific immune mechanism. Given that some irAEs resemble polymyalgia rheumatica (PMR) or giant cell arteritis (GCA), a disease whose pathogenesis is poorly understood, observations regarding the pathogenesis of PMR-like or GCA-like irAEs are of significant interest. One proposed pathogenic mechanism involves generalized immune activation leading to a spectrum of subclinical disease. Interrogation of this hypothesis may be aided by PET/CT, which is frequently utilized for oncological staging purposes but is also useful in classical PMR or GCA diagnosis. If PMR or GCA irAEs merely represent a spectrum of generalized immune activation, low-grade subclinical PMR or GCA-related changes on PET/CT might be expected to be seen in patients who receive immunotherapy, irrespective of whether they develop clinically evident rheumatic irAEs.
Objectives: This study investigated whether such changes occurred in patients receiving immunotherapy who did not develop clinically evident rheumatic irAEs.
Methods: Consecutive patients exposed to PD-1 or PD-L1 inhibitor immunotherapy at a single center had scintigraphic uptake calculated by a nuclear medicine physician experienced in assessment of vasculitis. Patients were included if they had had 18F-fluorodeoxyglucose (18F-FDG) PET/CT imaging both within the two weeks prior to immunotherapy initiation and after at least eleven weeks of immunotherapy. Patients who went on to develop a rheumatic irAE were excluded, as were patients with scintigraphic evidence of liver metastases owing to their potential influence on scoring of uptake. Quantification of 18F-FDG uptake by maximum standardized uptake values (maximum standard unit value, SUVmax) was performed at sites relevant to PMR or GCA (17 sites relevant to PMR, 17 sites relevant to GCA) in paired scans, and the difference calculated.
Results: Twenty-four patients receiving nivolumab, pembrolizumab or avelumab met the inclusion criteria, primarily for melanoma, non-small cell lung cancer, or lymphoma. The mean age was 67 at the time of the first scan, 71% were male, and 66% had a complete or partial oncological response at best response. No statistically or clinically significant difference in SUVmax was noted at any PMR or GCA-relevant anatomical site interrogated. Latent class analysis did not reveal clusters identifiable by cancer type, best response, or presence of combination therapy.
Conclusion: Patients treated with PD-1/PD-L1 inhibitors without clinically evident rheumatic irAEs do not develop subclinical PMR or GCA-like changes on PET/CT. This supports the proposition that PMR-like and GCA-like irAEs are a distinct entity with stochastic onset, and do not simply represent generalized immune activation induced by immunotherapy.

OP0195 PLASMA CHECKPOINT PROTEIN LEVELS AND GALECTIN-9 IN JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS

E. Sag[1,2], K. Yüksel[1], S. Demir[1], S. Ozdel[3], U. Kaya Akca[1], E. Atalay[1], M. Kasap-Cuceoglu[1], R. Topaloglu[4], Y. Bilginer[1,2], S. Özen[1,2]. *[1]Hacettepe University Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey*; *[2]Hacettepe University Faculty of Medicine, Translational Medicine Laboratories, Pediatric Rheumatology Unit, Ankara, Turkey*; *[3]Dr Sami Ulus Maternity and Child Health and Diseases Training and Research Hospital, Department of Pediatric Rheumatology, Ankara, Turkey*; *[4]Hacettepe University Faculty of Medicine, Department of Pediatric Nephrology, Ankara, Turkey*

Background: Systemic Lupus Erythematosus (SLE) is the prototype for a systemic autoimmune disease. SLE is a disease of the adaptive immune system where T lymphocyte dysfunction has an important role as well. Checkpoint proteins have become an important topic in the study of Tcell. The balance of T cell co-stimulatory and co-inhibitory receptors is important for the regulation of the adaptive immune system response.
Objectives: In this study we aimed to assess the checkpoint proteins in childhood SLE patients
Methods: Fourty-nine jSLE patients together with 15 age- and gender-matched controls were included. Clinical features, disease activity scores and laboratory parameters were recorded both retrospectively and at the time of samplimg. Patient samples were collected at their last visit, Plasma CD25 (IL-2Rα), 4-1BB, B7.2 (CD86), TGF-β1, CTLA-4, PD-L1, PD-1, Tim-3, LAG- 3, Galectin-9 levels were studied by the cytometric bead-based multiplex assay panel according to manufacturer's instruction (LEGENDplex HU Immune Checkpoint Panel 1 (10-plex); catalogue number 740962, Biolegend) and analysed by Novocyte 3005 flow cytometer. Two-step cluster analysis procedure was conducted over the chosen 7 symptom status and 3 clusters were chosen for the final analysis
Results: A total of 49 patients (71.4% female) diagnosed with SLE according to the SLICC criteria and 15 healthy controls (73.3% female) were included in the study. The mean age of the patients was 17.7 ± 2.6 years and the controls was 13.3±1.4 years. The median disease duration was 5.7 years. At the time of sampling fifteen of the patients had a SLEDAI score of zero (no activity), 21 of them had between 1-5 (mild activity), 7 of them had between 6-10 (moderate activity), 5 of them had between 11-19 (high activity), 1 of them had >20 (very high activity).
Galectin-9 and PD-L1 were significantly higher in SLE patients. Other checkpoint proteins and IL-2Rα were also higher but did not reach statistical significance. There were significant correlations between SLEDAI and IL-2Rα, Galectin-9 and PDL1. (Figure 1) There were three clinical clusters: Cluster 1 included patients with no major organ involvement, cluster 2 had predominantly haematological involvement (n=16) and cluster 3 (n=11) had predominantly renal involvement. Checkpoint proteins were not different among these three clusters.

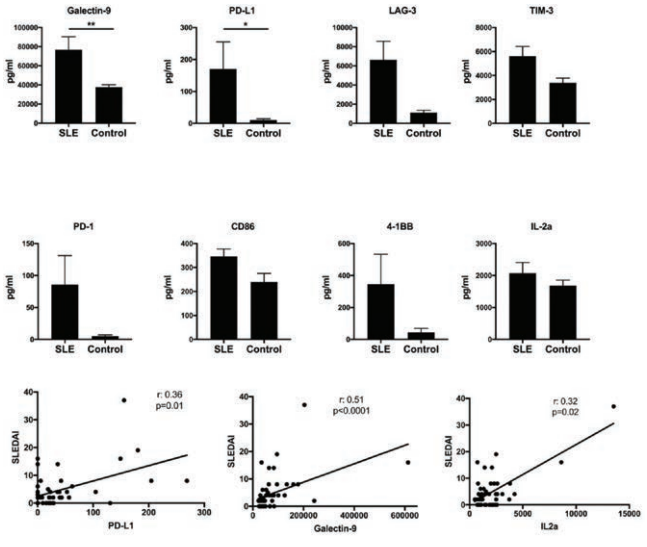

Figure 1.

Table 1. Demographic, Clinical and Laboratory Features of Patients (n=49)

Female gender, n (%)	35 (%71.4)
Mean age at diagnosis, years (mean±SD)	12.5±3.3
Mean age at the time of inclusion, years (mean±SD)	17.7±2.6
Duration of illness, years (median/IQR)	5.7 (3.0-7.0) years
Active system involvement at study,	n (%)
Renal	14 (28.5)
Skin	11 (22.4)
Musculoskeletal	9 (18.3)
Hematologic	9 (18.3)
Neurologic	1 (2.0)
Serositis	1 (2.0)
Laboratory findings (median/minimum-maximum)	
Hemoglobin, gr/dl	12.7 (7.3-18.3)
WBC, /mm^3	6.900 (2.600-26.200)
Platelet, /mm^3	252.000 (39.000-529.000)
Erythrocyte sedimentation rate, mm/hour	10 (1-71)
C-reactive protein, mg/dl	0.1 (0-21.1)
Complement 3, mg/dl	87.6 (25.4-186.0)
Complement 4, mg/dl	15.3 (0-45.8)
Anti-ds DNA, IU/ml	12.8 (0-741.7)
SLEDAI score (mean±SD)	4.69±6.69

Conclusion: Our data supports that Galectin 9 and IL-2Rα are good markers for disease activity in childhood SLE. We need larger series to evaluate differences between disease clusters in SLE. We failed to show a significant correlation with checkpoint proteins and SLEDAI except for PDL1.

The aftermath of metabolic imbalance in OA

OP0196 CIRCULATING LEVEL OF IL-6 IS ASSOCIATED WITH 10.7-YEAR KNEE CARTILAGE VOLUME LOSS AND WORSE PAIN TRAJECTORY

F. Pan[1], J. Tian[1], F. Cicuttini[2], G. Jones[1]. [1]*University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*; [2]*Monash University Medical School, Department of Epidemiology and Preventive Medicine, Melbourne, Australia*

Background: There is growing evidence that inflammation plays a critical role in osteoarthritis (OA) progression and its symptoms evolution. OA pain is heterogeneous and there are distinct subgroups within OA pain patients. Recently, we identified three homogeneous subgroups following distinct pain trajectories in which metabolic mechanism may be involved. Whether circulating inflammatory markers are associated with long-term knee structural changes on MRI, and whether the association between inflammatory markers and the trajectories we identified differs remain to be clarified.

Objectives: To examine whether inflammatory markers are associated with 10.7-year knee structural changes including knee cartilage volume (CV) and bone marrow lesions (BMLs), and to assess the associations between inflammatory markers and different pain trajectories.

Methods: This study was conducted as part of a population-based older adult (mean age 63 years, 51% of females) cohort study with 1,099, 875, 768 and 563 participants attending at baseline, and 2.6-, 5.1- and 10.7-year follow-ups. Circulating levels of interleukin (IL)-6, tumour necrosis factor alpha (TNF-α) and high sensitivity C-reactive protein (CRP) were measured at baseline in 193 randomly selected participants. T1-weighted or T2-weighted MRI of the right knee was performed to measure CV and BMLs at baseline and 10.7-year. X-ray was performed to assess radiographic knee osteoarthritis (ROA). The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain questionnaire was used to measure knee pain at all four visits. Data on demographic, psychological, lifestyle and comorbidities were also collected. Pain trajectories was previously identified using the group-based trajectory modelling. Linear, log-binomial and multi-nominal logistic regression modellings were used for the analyses.

Results: IL-6 was associated with both medial and lateral tibial CV loss (Medial: β=-0.51% per log pg/ml, 95%CI -0.88 to -0.15; Lateral: β=-0.34% per log pg/ml, 95%CI -0.64 to -0.04) after adjusting for age, sex, body mass index, physical activity, comorbidities, and ROA. TNF-α was not associated with either medial or lateral CV loss, but CRP was positively associated with medial tibial CV loss (Medial: β=0.27% per log mg/L, 95%CI 0.04 to 0.49), not lateral CV loss. No inflammatory markers were found to associate with medial and lateral BML size increase. Of 169 participants who had complete data at baseline, 54%, 35% and 11% of participants fell into 'Minimal pain', 'Mild pain' and 'Moderate pain' trajectory group, respectively. In multivariable analysis, IL-6 was associated with an increased risk of being a 'Moderate pain' trajectory (relative risk ratio [RRR]: 4.03, 95%CI 1.34 to 12.13) in comparison with 'Minimal pain' trajectory group. There was no significant association of TNF-α and CRP with trajectory groups.

Conclusion: IL-6 was associated with both medial and lateral tibial CV loss (Medial: β=-0.51% per log ml/pg, 95%CI -0.88 to -0.15; Lateral: β=-0.34% per log ml/pg, 95%CI -0.64 to -0.04) after adjusting for age, sex, body mass index, physical activity, comorbidities, and ROA. TNF-α was not associated with either medial or lateral CV loss, but CRP was positively associated with medial tibial CV loss (Medial: β=0.27% per log ml/pg, 95%CI 0.04 to 0.49), not lateral CV loss. No inflammatory markers were found to associate with medial and lateral BML size increase. Of 169 participants who had complete data at baseline, 54%, 35% and 11% of participants fell into 'Minimal pain', 'Mild pain' and 'Moderate pain' trajectory group, respectively. In multivariable analysis, IL-6 was associated with an increased risk of being a 'Moderate pain' trajectory (relative risk ratio [RRR]: 4.03, 95%CI 1.34 to 12.13) in comparison with 'Minimal pain' trajectory group. There was no significant association of TNF-α and CRP with trajectory groups.

OP0197 EVALUATION OF THE RELATIONSHIP OF LEPTIN WITH THE METABOLIC PHENOTYPE OF KNEE OSTEOARTHRITIS IN THE CONTEXT OF OBESITY THERAPY

E. Strebkova[1], L. Alekseeva[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Osteoarthritis, Moscow, Russian Federation*

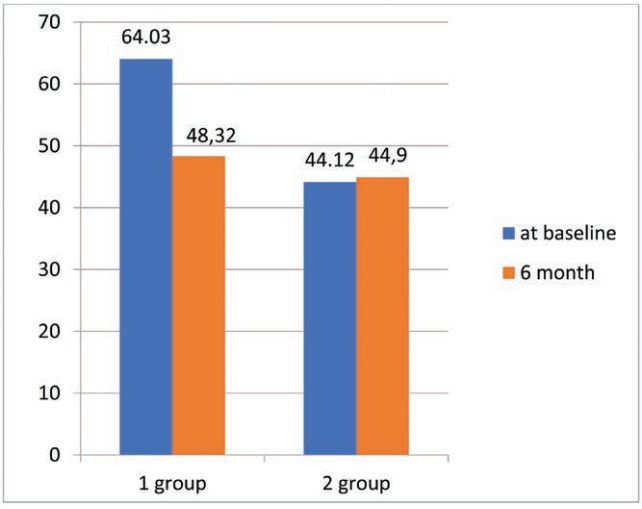
Background: Obesity and components of the metabolic syndrome (MS) play a key role in the pathogenesis of the metabolic phenotype of osteoarthritis (OA). Obesity is a process meta inflammation due to the synthesis of proinflammatory mediators (adipokines and adipocytokines). The severity of OA depends on the presence of obesity, adipokine activity, comorbidity, and the presence of MS. The problem of treatment of metabolic OA and obesity is very relevant, in connection with the obesity pandemic.

Objectives: To evaluate the relationship of leptin with the clinical manifestations of OA and various components of MS in the context of obesity therapy.

Methods: The study included 50 female patients aged 45-65 y.o. with Kellgren-Lawrence stage II-III knee OA and obesity (body mass index (BMI)>30kg/m^2). The average age of the patients was 56.5 ± 5.86 years, the average duration of the disease was 7.43 ± 3.93 years. 62% of patients were diagnosed MS. Patients were randomly divided into 2 groups for the treatment of obesity.

Patients from group 1 (n=25) took orlistat 120mg 3 times a day in combination with a hypocaloric diet and exercise for 6 months. Patients from group 2 (n=25) were on a hypocaloric diet in combination with exercise for 6 months. The groups were comparable in clinical parameters. The clinical course of OA was determined by the WOMAC and VAS. Anthropometric data (height, weight) were determined. All patients underwent a laboratory examination at 2 points (initially and after 6 months): a biochemical blood test, leptin was determined by PCR in peripheral blood.

Results: 8% of patients had 1 MS component, 34% - 2 MS components, 34% - 3 MS components, 22% - 4 MS components, and 2% - 5 MS components at the beginning of the study. High leptin levels (p=0.001) were determined in patients with more than 3 MS components. The correlation analysis showed direct correlations of high leptin levels with the severity of knee WOMAC pain (r=0.36, p=0.02) and VAS pain (r=0.51, p=0.01). A positive correlation was determined between high leptin levels and body weight (r=0.56, p<0.01) and waist circumference (r=0.38, p<0.01). Patients from group 1 had a significant decrease of body weight by 10.07% (p<0.05), the indicators of the WOMAC index improved: pain decreased by 52.5% (p<0.05), stiffness by 47.98% (p<0.05), joint functional failure by 51.55% (p<0.05) after 6 months of drug therapy for obesity. Patients of group 2 had a not significant decrease of body weight by 0.84% (p>0.05), and they were worse indicators of clinical manifestations of OA according to WOMAC compared to group 1 (p<0.05). 24% of patients from group 1 showed a decrease in the number of MS components. 12% of patients from group 2 had a decrease in the number of MS components and 12% patients increase in MS components. Patients from 1 group with a significant decrease in body weight, there was a decrease in the level of leptin (p = 0.05) (graphic 1), in contrast to patients without weight loss on the background of non-drug therapy (p = 0.64). We found direct correlations between a decrease in leptin levels and a decrease in the WOMAC index (pain, stiffness, joint functional failure, total WOMAC) (r=0.5, p=0.01; r=0.4, p=0.04; r=0.4, p=0.03; r=0.5, p=0.01, respectively). Patients with a decrease in the number of MS components had a significantly lower leptin levels (p=0.01).



Graphic 1. Dynamic of leptin.

Conclusion: Leptin is a predictor of a worse course of the metabolic phenotype of OA associated with MS and obesity. High levels of leptin were observed with more MS components, and were associated with the severity of knee pain and body weight. We observed a decrease in the level of leptin, a decrease in the number of MS components, and an improvement in the clinical manifestations of OA against the background of a significant decrease in body weight. Thus, the treatment of obesity in patients with the metabolic phenotype of OA and other interventions aimed at reducing the level of leptin may contribute to reducing the progression of knee OA.

[1]Diakonhjemmet Hospital, National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway; *[2]University of Oslo, Department Health Management and Health Economics, Oslo, Norway*; *[3]Leiden University Medical Center, Dep. of Biomedical Data Sciences, Leiden, Netherlands*; *[4]Keele University, Primary Care Centre Versus Arthritis, Keele, United Kingdom*; *[5]University of Oslo, Department General Practice, Oslo, Norway*; *[6]Akershus University Hospital, Department of Orthopaedic Surgery, Lørenskog, Norway*; *[7]Leiden University Medical Center, Department of Orthopaedics, Leiden, Norway*; *[8]Norwegian Institute of Public Health, Health Services, Oslo, Norway*

Background: To improve quality of care for patients with hip and knee osteoarthritis (OA), a structured model for integrated OA care was developed based on international treatment recommendations. A previous analysis of a cluster RCT (cRCT) showed that compared to usual care, the intervention group reported higher quality of care and greater satisfaction with care. Also, more patients were treated according to international guidelines and fulfilled recommendations for physical activity at the 6-month follow-up.

Objectives: To assess the cost-utility of a structured model for hip or knee OA care.

Methods: A cRCT with stepped-wedge cohort design was conducted in 6 Norwegian municipalities (clusters) in 2015-17. The OA care model was implemented in one cluster at the time by switching from "usual care" to the structured model. The implementation of the model was facilitated by interactive workshops for general practitioners (GPs) and physiotherapists (PTs) with an update on OA treatment recommendations. The GPs explained the OA diagnosis and treatment alternatives, provided pharmacological treatment when appropriate, and suggested referral to physiotherapy. The PT-led patient OA education programme was group-based and lasted 3 hours followed by an 8–12-week individually tailored resistance exercise programme with twice weekly 1-hour supervised group sessions (5–10 patients per PT). An optional 10-hours Healthy Eating Program was available. Participants were ≥45 years with symptomatic hip or knee OA.
Costs were measured from the healthcare perspective and collected from several sources. Patients self-reported visits in primary healthcare at 3, 6, 9 and 12 months. Secondary healthcare visits and joint surgery data were extracted from the Norwegian Patient Register. The health outcome, quality-adjusted life-year (QALY), was estimated based on the EQ-5D-5L scores at baseline, 3, 6, 9 and 12 months. The result of the cost-utility analysis was reported using the incremental cost-effectiveness ratio (ICER), defined as the incremental costs relative to incremental QALYs (QALYs gained). Based on Norwegian guidelines, the threshold is €27500. Sensitivity analyses were performed using bootstrapping to assess the robustness of reported results and presented in a cost-effectiveness plane (Figure 1).

Results: The 393 patients' mean age was 63 years (SD 9.6) and 74% were women. 109 patients were recruited during control periods (control group), and 284 patients were recruited during interventions periods (intervention group). Only the intervention group had a significant increase in EQ-5D-5L utility scores from baseline to 12 months follow-up (mean change 0.03; 95% CI 0.01, 0.05) with QALYs gained: 0.02 (95% CI -0.08, 0.12). The structured OA model cost approx. €301 p.p. with an additional €50 for the Healthy Eating Program. Total 12 months healthcare cost p.p. was €1281 in the intervention and €3147 in the control group, resulting in an incremental cost of -€1866 (95% CI -3147, -584) p.p. Costs related to surgical procedures had the largest impact on total healthcare costs in both groups. During the 12-months follow-up period, 5% (n=14) in the intervention compared to 12% (n=13) in the control group underwent joint surgery; resulting in a mean surgical procedure cost of €553 p.p. in the intervention as compared to €1624 p.p. in the control group. The ICER was -€93300, indicating that the OA care model resulted in QALYs gained and cost-savings. At a threshold of €27500, it is 99% likely that the OA care model is a cost-effective alternative.

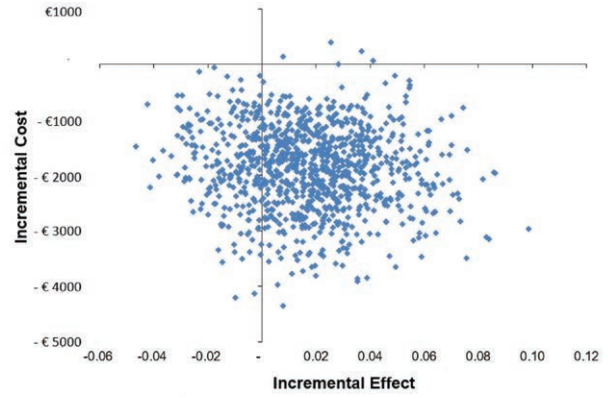

Figure 1 Cost-effectiveness plane for the comparison of implementation of a structured model for OA care (intervention group) and usual care (control group)

Conclusion: The results of the cost-utility analysis show that implementing a structured model for OA care in primary healthcare based on international guidelines is highly likely a cost-effective alternative compared to usual care for people with hip and knee OA. More studies are needed to confirm this finding, but this study results indicate that implementing structured OA care models in primary healthcare may be beneficial for the individual as well as for the society.

Emerging molecular targets in OA

OP0199 EX VIVO BIOMARKER PROFILING IDENTIFIES ONCOSTATIN-M AS SPINE OSTEOARTHRITIS-SPECIFIC OSTEOIMMUNOLOGICAL TARGET

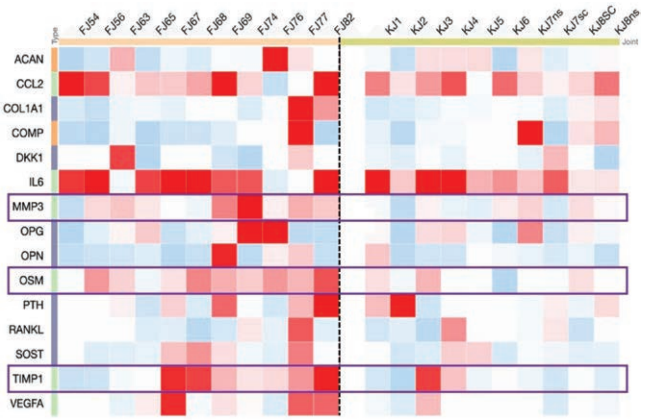
O. Roessinger[1], M. Blanchard[1], M. Briki[1], D. Jurić[2], C. Netzer[3], T. Hügle[1], T. Ecker[4], J. Geurts[1]. [1]*Lausanne University Hospital, Rheumatology, Lausanne, Switzerland*; [2]*University Hospital Basel, Orthopaedics & Traumatology, Basel, Switzerland*; [3]*Lausanne University Hospital, Spine Surgery, Basel, Switzerland*; [4]*Lausanne University Hospital, Spine Surgery, Lausanne, Switzerland*

Background: Disease heterogeneity, both clinically and molecularly, has been a major hurdle in the development of efficacious disease-modifying osteoarthritis drugs (DMOADs). Biomechanical, inflammatory, osteoporotic and metabolic OA have been proposed as clinically relevant subtypes for stratification of knee OA patients, yet this remains to be included in clinical trial design. Disease heterogeneity does not only occur within, but also between joint types. However, robust data on joint-specific pathomechanisms of OA are still lacking.

Objectives: In this study, we performed ex vivo biomarker profiling of human osteochondral tissue of knee and spine OA to identify joint-specific pathomechanisms and DMOAD treatment responses.

Methods: Facet joint and tibial plateaus were obtained from patients undergoing lumbar spinal fusion (n=11, mean age 72.8) and total joint arthroplasty (n=8, mean age 73.0) respectively. Osteochondral specimens were cut in equal-sized samples (100-300 mg wet weight) and randomly assigned to treatment groups: control (DMSO), inflammation (1 µg/mL LPS) or inflammation + DMOAD (TGF-beta type I receptor inhibitor,10 µM SB-505124). Explant culture was conducted for one week and biomarkers of bone metabolism (Pro-Col-Ia, SOST, OPG, SPP1), inflammation (MCP-1, IL-6, MMP3, OSM, TIMP1, VEGFA) and cartilage metabolism (ACAN, COMP) were determined by ELISA. Normalized biomarker secretion was analysed using clusteranalyses and ANOVA. Cartilage proteoglycans were assessed by whole mount Alcian blue staining. Expression of Oncostatin-M (OSM) and its receptors OSMR and LIFR in joint tissues was assessed by RT-PCR and immunohistochemistry.

Results: Clusteranalyses revealed that LPS stimulation increased IL-6 and MCP-1 secretion by both facet joint (FJ) and knee joint (KJ) tissues. Interestingly, Oncostatin-M (OSM) and its downstream mediators MMP3 and TIMP1 were increased in the majority of FJ, but not KJ specimens. Statistical analyses corroborated increased OSM, MMP3 and TIMP1 levels in a spine-specific fashion (Figure).



Whole mount Alcian blue staining revealed heterogeneous effects of LPS treatment on cartilage proteoglycans, which was negatively correlated with OSM (r=-0.54) and TIMP1 levels (r=-0.45) – yet poorly associated with ACAN (r=0.19). Inhibition of TGF-beta type I receptor signalling in osteochondral tissues led to a drastic reduction of Pro-Collagen-Ia and IL-6 secretion in both spine and knee OA specimens. Interestingly, DMOAD treatment significantly reduced OSM, TIMP1 and MMP3 levels in FJ specimens only. Vice versa, KJ tissues revealed a specific upregulation of monocyte chemoattractant protein-1 (MCP-1) and osteopontin (SPP1) upon inhibition of TGF-beta signalling. OSM was exclusively expressed in subchondral bone marrow macrophages. Isolated chondrocytes and osteoblasts expressed both LIFR and OSMR, yet intact cartilage only showed OSMR expression, while OSMR and LIFR was expressed in marrow tissue

Conclusion: Oncostatin-M expression and signalling was uncovered as specific pathomechanism of spine OA. DMOAD treatment effects suggested interplay of OSM and TGF-beta signalling pathways in facet joint osteoarthritis. Known to be predominantly expressed by macrophages and immune cells, OSM may be an important osteoimmunological mediator of tissue damage and remodelling in spine, but not knee OA. This study also highlights the value of *ex vivo* human tissue models for OA phenotyping and preclinical evaluation of DMOADs.

OP0200 BLOCKING ROR2 IMPROVES CARTILAGE INTEGRITY AND PROVIDES PAIN RELIEF IN OSTEOARTHRITIS

A. S. Thorup[1], D. Strachan[1], S. Caxaria[1], B. Poulet[2], B. Thomas[1], S. Eldridge[1], G. Nalesso[3], J. Whiteford[4], C. Pitzalis[1], T. Aigner[5], R. Corder[6], J. Bertrand[7], F. Dell'accio[1]. Background: Osteoarthritis (OA) is the leading cause of chronic disability worldwide, affecting 12% of the population, and yet we still do not have a disease-modifying treatment. Cartilage breakdown is the hallmark of OA, and patients suffer from pain and loss of joint function/independence, severely affecting quality of life. Therefore, there is a huge unmet clinical need.

Receptor tyrosine kinase–like orphan receptor 2 (ROR2) is a non-canonical WNT receptor that regulates the planar cell polarity pathway, controlling limb outgrowth during development. During skeletal development, chondrocytes require ROR2 to undergo hypertrophy throughout the process of endochondral bone formation[1]. Loss of function mutations in humans causes Recessive Robinow Syndrome, leading to limb shortening and brachydactyly[2,3].

Although absent from healthy adult articular cartilage, our initial studies identified high expression levels of ROR2 in chondrocytes from patients with OA, suggesting a role in the disease process

Objectives: To test the potential of ROR2 blockade as a disease-modifying treatment for OA.

Methods: Human cartilage organoid model in nude mice, menisco-ligament injury (MLI) model of OA in mice, behavioural studies, *in vitro* studies in cells.

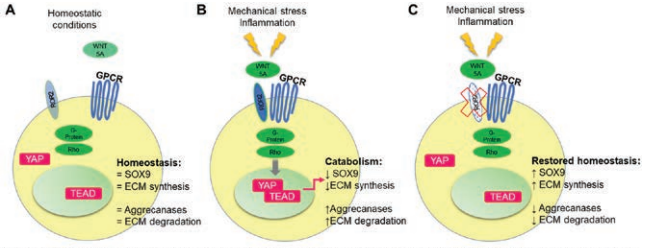
Results: ROR2/WNT5A signaling was increased in osteoarthritic cartilage. Blocking ROR2 was sufficient to induce articular chondrogenesis and suppress expression of aggrecanases in a mesenchymal stem cell line, and to support cartilage formation in a human cartilage organoid model in nude mice using primary chondrocytes from patients with OA.

In the MLI model of OA, blocking ROR2 in therapeutic regime using atelocollagen-conjugated siRNA resulted in reduced cartilage destruction and in rapid and sustained pain relief. Due to the limited expression pattern of ROR2 in adulthood, no systemic or local toxicity were expected, nor were any observed[4].

With the current technology, ROR2 blockade requires intra-articular (IA) injections of siRNA conjugated to atelocollagen every 5 days. Preliminary efficacy data of potentially longer-acting ROR2 blockers are promising.

The mechanism of action of ROR2 blockade was independent of modulation of canonical WNT signaling.

ROR2/WNT5A promoted nuclear localization of YAP, which required both Rho and G-proteins. YAP signaling downstream of ROR2 also required Rho, but not G-proteins. YAP and TEAD inhibition was required, but not sufficient, for the chondrogenic effect of blocking ROR2. Therefore, additional, yet unknown mechanisms must be involved downstream of ROR2.



(**A**) ROR2 and WNT5A are expressed in low amounts in the cartilage in adulthood, under physiological conditions. (**B**) Upon cartilage injury, ROR2 and WNTs, including WNT5A, are upregulated. WNT5A activates ROR2 signaling, and through G-proteins and Rho induces nuclear localization of YAP, and interaction with TEAD transcription factors; and activates catabolic signaling. (**C**) Blocking ROR2 prevents nuclear localization of YAP and restores homeostasis through downregulation of catabolic enzymes and increased proteoglycan production. In the menisco-ligament injury model of osteoarthritis, this ameliorates pain and protects the cartilage from damage.

Conclusion: ROR2 blockade has potential as a disease-modifying treatment for OA, resulting in cartilage protection and rapid and sustained pain relief in a murine model. This will be crucial for clinical success of any treatment for OA and promote patient compliance.

Our current siRNA-atelocollagen based technology requires IA injections too frequently to be acceptable for patients. We are developing ROR2 blockade which can be administered systemically or IA not more often than every 3 months - work funded by FOREUM.

Origin and role of myeloid cells during homeostasis and inflammation

OP0201

DYNAMIC CHANGES IN O-GLCNACYLATION REGULATE OSTEOCLAST DIFFERENTIATION AND BONE LOSS IN ARTHRITIS

C. W. Chen[1], Y. N. Li[1], T. Trinh-Minh[1], Z. Honglin[2], A. E. Matei[1], X. Ding[1], C. Tran Manh[1], X. Xu[1], C. Liebel[1], R. Liang[1], M. C. Huang[3], N. Y. Lin[3], A. Ramming[1], G. Background: Bone remodeling is a constant process maintained by the balance between osteoclast-triggered bone resorption and osteoblast-mediated bone formation. In inflammatory arthritis, such as rheumatoid arthritis (RA), the pro-inflammatory environment favors osteoclast differentiation and skews the balance towards resorption, leading to progressive bone erosion and bone loss. O-GlcNAcylation is a post-translational modification, which transfers a single N-acetylglucosamine molecule to the serine or threonine of the target protein. The modification is accomplished by a single pair of enzymes, O-GlcNAc transferase (OGT) and O-GlcNAcase (OGA). Unlike other glycosylation, O-GlcNAcylation occurs in multiple cellular compartments, including the nucleus. Although O-GlcNAcylation is one of the most common modifications, its role in bone homeostasis is still poorly understood.

Objectives: We aimed to investigate the role of O-GlcNAcylation in osteoclastogenesis under pro-inflammatory milieus. We also focused on dissecting the signaling pathways affected by O-GlcNAcylation during osteoclast differentiation.

Methods: We examined the levels of O-GlcNAc during in vitro osteoclastogenesis by western blotting. The levels of O-GlcNAc in tissue from RA patients and experimental arthritis were detected by immunofluorescence. Pharmacological inhibition and genetic knockout were used to manipulate O-GlcNAcylaiton during osteoclastogenesis. RNA sequencing was performed to study O-GlcNAc-mediated pathways.

Results: We demonstrate the dynamic changes in O-GlcNAcylation during osteoclastogenesis. The elevated O-GlcNAcylation was found in the early differentiation stages, whereas its downregulation was detected in the maturation process. TNFα elaborates the dynamic changes in O-GlcNAcylation, which further intensifies osteoclast differentiation.

Targeting OGT by selective inhibitor and genetic knockout restrain O-GlcNAcylation and hinder the expression of the early differentiation marker *Nfatc1*. Inhibition of OGA, which forces high levels of O-GlcNAcylation throughout the differentiation, reduces the formation of multinucleated mature osteoclasts. Consistent with our *in vitro* data, suppressing OGT and OGA both ameliorate bone loss in experimental arthritis. We detected a reduced number of TRAP-expressing precursors and mature osteoclasts in the mice subjected to OGT inhibition. While inhibiting OGA only lowers the number of $TRAP^+F4/80^-$ mature osteoclasts without affecting the number of $TRAP^+F4/80^+$ precursors.

Transcriptome profiling reveals that O-GlcNAcylation regulates several biological processes. Increased O-GlcNAcylation promotes cytokine signaling and oxidative phosphorylation. The downregulation of O-GlcNAcylation is essential for cytoskeleton organization and cell fusion.

Conclusion: We demonstrate that the dynamic changes of O-GlcNAcylation are essential for osteoclast differentiation. These findings reveal the therapeutic potential of targeting O-GlcNAcylation in pathologic bone resorption.

OP0202 DOES EXCESS WEIGHT AFFECT GOUT RISK DIFFERENTLY AMONG GENETICALLY PREDISPOSED INDIVIDUALS? – SEX-SPECIFIC PROSPECTIVE COHORT FINDINGS OVER >26 YEARS

C. Yokose[1,2], N. McCormick[1,2], L. Lu[3], A. Joshi[4], H. Choi[1,2]. [1]*Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America*; [2]*Massachusetts General Hospital, Clinical Epidemiology Program, Mongan Institute, Department of Medicine, Boston, United States of America*; [3]*Arthritis Research Canada, n/a, Richmond, Canada*; [4]*Massachusetts General Hospital, Clinical and Translational Epidemiology Unit, Boston, United States of America*

Background: Global burden of gout has increased substantially, particularly among women.[1,2] Addressing obesity, a major modifiable risk factor for gout, may alleviate this burden; however, there is also a significant genetic contribution to gout risk according to the genome-wide association studies (GWAS).[3,4] Genetic predisposition may modify the excess weight effect on gout risk.

Objectives: To investigate the potential role of genetic predisposition on the association between excess weight (i.e., BMI ≥ 25 kg/m^2) and gout risk in two US prospective longitudinal cohorts over >26 years, stratified by sex.

Methods: We examined the association between excess weight and risk of incident gout meeting the ACR survey criteria,[5] according to genetic risk, in 18,512 women from the Nurses' Health Study (NHS) over 32 years, and 10,917 men from Health Professionals Follow-Up Study (HPFS) over 26 years. We derived a genetic risk score (GRS) using 114 serum urate single nucleotide polymorphisms from the latest GWAS.[3] We also calculated the population attributable risk (PAR) for excess weight according to GRS stratum.

Results: We ascertained 530 incident gout cases in NHS and 983 in HPFS. While the relative risks (RRs) due to excess weight (overweight or obesity) appeared larger among women above the mean than below the mean, the RRs among men appeared similar according to genetic predisposition (Table 1). The RRs among women for excess weight compared to normal were 1.66 (95% CI, 1.17 to 2.37) and 2.55 (1.95 to 3.34) below and above the mean GRS, respectively (P for multiplicative interaction = 0.06), whereas corresponding RRs among men were 1.68 (95% CI, 1.31 to 2.16) and 1.76 (1.47 to 2.10) (P for multiplicative interaction = 0.8). The risk differences (RD) among women for excess weight were 0.69 and 2.38 with GRS below and above the mean, respectively, resulting in the relative excess risk due to interaction (RERI) of 1.69 (95% CI, 1.03 to 2.35, P for additive interaction = 5.4x10^{-}7); for men, the corresponding RDs were 0.70 and 1.46, with RERI = 0.76 (0.26, 1.25; P for additive interaction = 2.6x10^{-}3). Excess weight accounted for a larger proportion of incident gout cases among women with GRS above the mean (PAR, 48.5% [95% CI, 38.8 to 55.9]) compared to those with GRS below the mean (PAR, 29.0% [95% CI, 10.5 to 42.1]), whereas the PARs among men were similar (31.6% vs 29.7%, respectively).

Conclusion: These large scale longitudinal prospective cohorts suggest maintaining healthy weight is an important gout prevention strategy, regardless of underlying genetic risk. In genetically predisposed individuals, addressing excess weight may prevent a large proportion of gout cases, especially among women.

OP0203 GENE-DIET INTERACTION ON THE RISK OF INCIDENT GOUT AMONG WOMEN – PROSPECTIVE COHORT STUDY OVER 32 YEARS

C. Yokose[1,2], N. McCormick[1,2], L. Lu[3], A. Joshi[4], H. Choi[1,2]. [1]*Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America*; [2]*Massachusetts General Hospital, Clinical Epidemiology Program, Mongan Institute, Department of Medicine, Boston, United States of America*; [3]*Arthritis Research Canada, n/a, Richmond, Canada*; [4]*Massachusetts General Hospital, Clinical and Translational Epidemiology Unit, Boston, United States of America*

Background: Although gout is conventionally known as a male condition, the recent Global Burden of Disease (GBD) Study found disproportionate worsening among women.[1] We have found Dietary Approaches to Stop Hypertension (DASH) diet is independently associated with a lower risk of incident gout, while Western diet is associated with increased risk.[2] Whether these risks vary according to genetic risk remains unknown.

Objectives: To investigate the influence of genetic predisposition on the relation between diets (one protective and another hazardous) and gout risk in a large prospective US cohort of women over 32 years.

Methods: We examined the role of genes on the association between two dietary patterns (DASH and Western) on the risk of incident gout in 18,512 women from the Nurses' Health Study. Using validated food frequency questionnaires, for each participant we derived: 1) DASH score emphasizing fruits, vegetables, nuts, legumes, whole grains, low-fat dairy, and reduced intake of saturated fat and sugar-sweetened beverages (SSBs) and 2) Western diet score characterized by high intake of red and processed meats, SSBs, desserts, French fries, and refined grains. A genetic risk score (GRS) was derived using 114 serum urate single nucleotide polymorphisms from the latest GWAS consortium.[3]

Results: There were 523 incident gout cases meeting ACR survey criteria[4] (170 vs. 353 in GRS below and above the mean, respectively) (Table 1). Among women with GRS below and above the mean, the multivariable relative risks (RRs) of gout were 1.0, 1.56. 1.32, 0.89, and 0.61 (0.34 to 1.09) and 1.0, 1.0, 0.85, 0.51, and 0.68 (0.49 to 0.96), for quintiles (Q) 1 through 5 of DASH score, respectively (p for interaction = 0.69) (Table 1). For the Western diet, RRs for Q1 through 5 were 1, 1.34, 1.07, 1.33, and 1.63 (0.91 to 2.93) for those with GRS below the mean and 1.0, 1.17, 0.93, 1.27, and 1.77 (1.19 to 2.61) among those with GRS above the mean, respectively (p for multiplicative interaction = 0.64).

Conclusion: In this prospective female cohort that ascertained gout with standardized criteria over 32 years, regardless of genetic predisposition, DASH diet was similarly associated with lower risk of incident gout while Western diet was associated with a higher risk. The anticipated absolute impact of diet among

OP0204 URATE CRYSTAL DEPOSITIONS ARE ASSOCIATED WITH INFLAMMATORY MARKERS AND CAROTID PLAQUES INDICATING SUBCLINICAL INFLAMMATION IN GOUT; BASELINE RESULTS FROM THE NOR-GOUT STUDY

H. B. Hammer[1,2], S. Rollefstad3, G. Jensen3, L. Karoliussen3, L. Terslev[4], E. A. Haavardsholm[2,3], T. K. Kvien[2,3], A. G. Semb3, T. Uhlig[2,3]. [1]*Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway*; [2]*University of Oslo, Faculty of Medicine, Oslo, Norway*; [1]*Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway*; [4]*Rigshospitalet Glostrup, Centre for Rheumatology and Spinal Diseases, Copenhagen, Denmark*

Background: In gout patients the extent of monosodium urate (MSU) crystal depositions can be quantitated by use of ultrasound. Gout may be associated with atherosclerotic disease which might be related to low-grade inflammation. Calprotectin is a major granulocyte protein reflecting the level of systemic inflammation.
Objectives: To explore whether the extent of MSU crystal depositions is associated with low grade systemic inflammation as assessed by calprotectin/C-reactive protein (CRP) and with carotid pathologies in asymptomatic gout patients.
Methods: The baseline data from NOR-GOUT, a prospective study of patients with crystal-proven gout with increased serum urate levels (>360 µmol/L), were used. All patients were assessed by ultrasound (GE Logiq E9 machine) to assess MSU depositions (OMERACT definitions; double contour (DC), tophi and aggregates) with bilateral assessment of wrist, MCP2, knee, ankle, MTP1 and insertions of triceps, quadriceps, proximal/distal patellar and Achilles tendons, all scored semi-quantitatively 0-3. Bilateral B-mode ultrasound assessments of the carotid arteries examined carotid intima-media thickness (cIMT; increased thickness >0.9mm). Atherosclerotic plaques were identified as protrusions of ≥1.5 mm or ≥ 2 times the adjacent IMT. Sum scores of each of the ultrasound elementary lesions for MSU depositions were calculated and the associations with calprotectin (plasma assessed by ELISA (Calpro), normal levels <910 µg/L), CRP (routine assessment, normal levels <4mg/L) as well as cIMT and presence of carotid plaque were explored. Correlations were performed by use of Spearman and differences between group was investigated by Mann-Whitney test.
Results: A total of 202 gout patients without flare were included (95.5% men, mean (SD) age of 56.5 (13.8) years, 7.9 (7.7) years since first flare). The mean (SD) sum sore of DC was 4.4 (3.5), tophi 6.6 (6.6), aggregates 9.3 (5.6), calprotectin 801 (525) µg/L, CRP 7 (14) mg/L and serum urate (SUA) 499 (77) µmol/L. Carotid examinations were performed in 122 (60.4%) of the patients. Significant correlations were found between the MSU depositions and the inflammatory markers as well as cIMT. The 27% patients with increased calprotectin had the highest levels of each of the three elementary lesions (p=0.001) (Figure), and the 39% with elevated CRP levels had the highest levels of tophi and aggregates (p<0.05). The 18% with increased thickness of cIMT and the 53% of patients with carotid plaque had the highest levels of aggregates (p=0.003 and p=0.037, respectively).
Conclusion: In asymptomatic gout patients, higher load of MSU crystal depositions was associated with increased levels of inflammatory markers, cIMT and presence of atherosclerotic plaques in the carotid arteries. This may indicate that crystal depositions cause subclinical inflammation with subsequent systemic implications, but future longitudinal studies are needed to confirm such causal relationships.

OP0205 ULTRASOUND-DETECTED CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION: WHICH SITES SHOULD BE SCANNED?

E. Cipolletta[1], J. DI Battista[1], W. Grassi[1], E. Filippucci[1]. [1]*Polytechnic University of Marche, Department of Clinical and Molecular Sciences, Ancona, Italy*

Background: In recent years, ultrasonography (US) has emerged as an accurate and reliable tool for the diagnosis of calcium pyrophosphate (CPP) deposition disease (CPPD) in daily practice. Previous studies analyzed the diagnostic value of US findings in different tissues and joints. However, no studies have investigated the optimal US scanning protocol in the diagnosis of CPPD at patient level.
Objectives: To assess the diagnostic value of the combinations of OMERACT-defined US findings of CPPD in the upper and lower limbs and to select the best minimal combination of anatomic structures to be scanned for diagnosing CPPD in inter-critical periods.

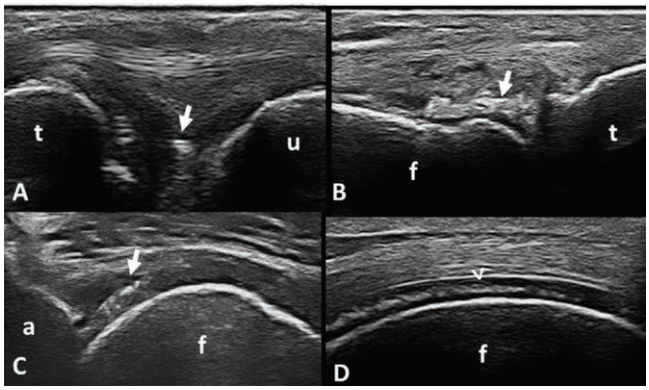
Methods: Patients with a crystal-proven diagnosis of CPPD and age- and sex-matched disease-controls were prospectively enrolled in this cross-sectional, monocentric, case-control study. All subjects underwent a bilateral US examination of 9 hyaline cartilages (HC), 6 fibrocartilages (FC), 5 tendons, 1 joint recess and 1 ligament as follows: shoulder (glenoid FC, humeral HC and acromioclavicular FC), elbow (humeral HC and triceps tendon), wrist (triangular FC, scapho-lunate ligament, volar recess of the radio-lunate joint), hand (HC of the metacarpophalangeal joints from 2nd to 5th finger), hip (acetabular FC and femoral HC), knee (femoral condyles' HC, meniscal FC, patellar and quadriceps tendons), ankle (talar HC, Achilles tendon and plantar fascia). US assessment was carried-out by a rheumatologist blinded to clinical data. CPP deposits were identified as presence/absence, according to the OMERACT definitions [1].
Results: Ninety-five patients were enrolled: 45 CPPD patients (age: 72±10.6 years, disease duration: 5.6±7.8 years, female/male ratio: 1.3) and 50 age- and sex-matched disease-controls (18 with rheumatoid arthritis, 13 with osteoarthritis, 10 with psoriatic arthritis and 9 with gout).
The FC of the medial and lateral meniscus were the most frequently involved targets of CPP deposits in cases (81.8% and 77.3% of patients, respectively), followed by the triangular FC of the wrist (68.2%), the HC of the femoral condyles (54.5%), the scapho-lunate ligament (52.3%) and the acetabular FC (50.0%). In all these anatomical targets, US findings indicative of CPP deposits were detected in a significantly higher percentage of cases than controls ($p<0.01$).
The US scanning protocols that showed the best balance between sensitivity and specificity, the most sensitive and the most specific were shown in Table 1.

Table 1. Diagnostic performances of different US scanning protocols

Anatomical targets	SE	SP	LH+	LH-
Knee meniscal FC and wrist triangular FC	0.86 (0.76-0.96)	0.86 (0.73-0.94)	6.35 (3.17-12.72)	0.13 (0.06-0.30)
Knee meniscal FC, wrist triangular FC and hip acetabular FC	0.93 (0.82-0.99)	0.82 (0.69-0.91)	5.19 (2.85-9.42)	0.08 (0.03-0.24)
Hip acetabular FC, knee femoral condyles' HC and wrist scapho-lunate ligament	0.67 (0.51-0.80)	0.96 (0.86-0.99)	16.67 (4.22-65.82)	0.35 (0.23-0.53)

LH: likelihood ratio, **SE**: sensitivity, **SP**: specificity, **US**: ultrasonography.
In all US scanning protocols, each anatomical target was assessed bilaterally.

Figure 1 includes representative pictures showing CPP crystal deposits in different anatomical targets.



A: Wrist, longitudinal scan of the triangular FC complex.
B: Knee, longitudinal scan of the lateral meniscus.
C: Hip, longitudinal scan of the acetabular labrum FC,
D: Knee, longitudinal scan of the medial femoral condyle's HC.
Arrows: CPP crystal deposits at FC, arrowhead: CPP crystal deposits at HC.
Conclusion: Our results suggest that bilateral US assessment of knee, wrist and hip provided acceptable sensitivity and specificity for diagnosing CPPD.

OP0206 ASSOCIATION BETWEEN FEMALE REPRODUCTIVE FACTORS AND GOUT: NATIONWIDE POPULATION-BASED COHORT STUDY OF 1 MILLION POSTMENOPAUSAL WOMEN

Y. Eun[1], I. Y. Kim[2], K. D. Han[3], K. Lee[3], S. Y. Kang[1], S. Lee[1], H. S. Cha[1], E. M. Koh[1], J. Lee[1], H. Kim[4]. *[1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, c of (South Korea)*; *[2]National Police Hospital, Department of Medicine, Seoul, Korea, Republic of (South Korea)*; *[3]Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Republic of (South Korea)*; *[4]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medical Humanities, Seoul, Korea, Republic of (South Korea)*

Background: Previous studies have shown that the incidence of gout differs according to gender, and its risk factors also differ according to gender. However, little research has been done on the association between reproductive factors and gout.
Objectives: Our study attempted to determine whether there is an association between reproductive factors and the incidence of gout in a large nationwide population-based cohort of postmenopausal women.
Methods: Postmenopausal women aged 40-69 who participated in national health screenings in 2009 were included in the study. Subjects who had been diagnosed with gout prior to medical examination were excluded from the study, and a total of 1,076,378 women were included in the study. Outcome was the occurrence of gout which was defined as a case of two outpatient visit or one hospitalization for gout using the ICD-10 code of gout (M10) in the claim database. The Cox proportional hazard model was used for the analysis, and stratified analysis according to the body mass index (BMI) and chronic kidney disease (CKD) was performed.
Results: Mean follow-up duration was 8.1 years, and incident cases of gout were 64,052. Later menarche (adjusted HR 1.10, 95% CI 1.02-1.19 in >16 years, compared with ≤12 years), earlier menopause (adjusted HR 1.12 in <40 years, 1.06 in 40-45 years, 1.03 in 45-50 years, compared with 50-55 years), and shorter reproductive span (adjusted HR 1.10 in <30 years, 1.06 in 30-35 years, compared with ≥40 years) were associated with a high risk of gout. No association between parity and gout incidence was observed. Use of oral contraceptives (OC; adjusted HR 1.03 in <1 year, 1.05 ≥1 year, compared with non-user) and hormone replacement therapy (HRT; adjusted HR 1.16 in <2 years, 1.16 in 2-5 years, 1.18 in ≥5 years, compared with non-user) were associated with an increased risk of gout. The association between reproductive factors and gout remained in the trend without statistical significance in the low BMI group, but not in the high BMI group. The effects of use OC and HRT on gout were not significant in the CKD group.
Conclusion: Shorter exposure to endogenous estrogen was associated with a high risk of gout. Conversely, exposure to exogenous estrogen such as OC and HRT was associated with an increase in gout risk. This association was not significant in subjects with high BMI or CKD.

OP0207 ASSOCIATION BETWEEN DEMENTIA AND GOUT: A NATIONWIDE POPULATION-BASED STUDY

J. Kim[1], H. M. P. Park[2], D. H. Yim[3], I. A. Choi[4], S. Y. Eom[5]. *[1]Chungbuk National University Hospital, Internal Medicine, Division of Rheumatology, Cheongju-si, Chungcheongbuk-do, Korea, Republic of (South Korea)*; *[2]Chungbuk National University Hospital, Psychiatry, Cheongju, Korea, Republic of (South Korea)*; *[3]Chungbuk National University, Center for Environmental Medicine, Cheongju, Korea, Republic of (South Korea)*; *[4]Chungbuk National University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Cheongju, Korea, Republic of (South Korea)*; *[5]College of Medicine, Chungbuk National University, Department of Preventive Medicine, Cheongju, Korea, Republic of (South Korea)*

Background: Dementia is a common mental illness associated with aging. Alzheimer's disease (AD) and Vascular dementia (VaD) are the most common causes of dementia in the elderly. In previous studies, hyperuricemia was suggested to have anti-oxidant effects and possible neuroprotective effects [1,2].
Objectives: Hyperuricemia is the most important factor in the pathogenesis of gout. This study aims to investigate association between gout and dementia.
Methods: We conducted a nationwide population-based study using the NHIS-NSC database of the Korean populations consisted of 1 million individuals between 2002 and 2013. Gout patients were defined by International Classification of Diseases (ICD)-10 code for gout (M10) and prescriptions for urate lowering therapy including allopurinol, febuxostat and benzbromarone at least 30days. Dementia was also defined by ICD-10 codes for dementia; Alzheimer's disease (AD; F00), vascular dementia (VaD; F01).

Results: Excluded 40 patients with previous diagnosed dementia, total 5,496 gout patients were compared to 27,480 age- and sex-matched control group. The analysis results showed that gout patients had a lower risk of overall dementia [odds ratio (OR): 0.79; 95% confidence interval (CI): 0.63-0.99; p < 0.05] after adjusted for age, sex, household income, comorbidities. The risk of VaD (OR: 0.77; 95% CI: 0.32-1.9; p=0.68) and AD (OR; 0.8; 95% CI: 0.53-1.19; p=0.06) tended to be lower in gout group but these were not significant.

Conclusion: Gout patients had a lower risk of dementia. This result tended to exist for both AD and VaD type of dementia.

OP0208 INCIDENT GOUT: RISK OF DEATH AND CAUSE-SPECIFIC MORTALITY IN WESTERN SWEDEN – A NESTED CASE CONTROL STUDY

M. Dehlin[1], T. Zverkova Sandström[1], L. T. H. Jacobsson[1]. [1]*Institute of Medicine, Sahlgrenska Academy, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*

Background: Excess mortality in gout has been attributed to it's positive association with many comorbidities. Lately, a negative association with dementia has been suggested in some cohort studies. Data is limited on how this reflects in cause-specific mortality of gout patients.

Objectives: Our aims were to determine the relative risks in incident gout patients compared to general population 1) for overall death 2) for cause-specific mortality.

Methods: All incident cases of gout (definition: 1≥ ICD-10 code for gout (M10/M14.0) in the population based health care database VEGA; no gout diagnosis ≥5 years previously) between 2006-2015 in western Sweden were identified. Five population controls per case matched on age, sex and place of residence were identified. Comorbidities, defined by ICD-10 codes, (alcohol related disorders, hypertension, ischemic heart disease, heart failure, cerebrovascular disease, diabetes, dyslipidemia, obesity, renal disease, dementia, lung diseases and cancer) were identified for 5 years preceding index date for cases and controls in VEGA. Patients were followed until the earliest of death, migration or study end 31 of December 2017. Cause of death was identified through the national cause of death register and grouped as death due to: CVD, renal disease, dementia, infections, diabetes, diseases of the digestive system, lung diseases, cancer and other. COX regression analyses, adjusted for baseline demographics and comorbidities, were used to compare mortality in cases and controls, taking competing cause of death into account by the Fine and Gray method.

Results: From the total adult population of western Sweden between 2006 and 2015 (yearly average of 1264150 individuals), we identified 24320 cases of incident gout and 119781 controls, who were followed on average 5.3 and 5.6 years respectively. At baseline mean age was (SD) 67.3 years (15.3) and 67.6% were men. At baseline, income and level of education was significantly lower in gout cases compared to controls, whereas all comorbidities were significantly more common among gout cases (data not shown) except for dementia which was significantly more common in controls, 4.2% versus 2.5% in cases, p<.0001. The HR for overall death was increased in gout patients (HR: 1.08 (95% CL: 1.05-1.11) (Table 1). Gout cases had significantly increased risk for death by CVD, renal disease, infections, diseases of the digestive system and significantly decreased risk for death by dementia and cancer (Table 1). Point estimates were similar in men and women (data not shown).

Table 1. Causes of death by exposure status and cause-specific mortality overall, gout cases compared to controls, adjusted hazard ratios by the Fine and Gray method, 95% confidence intervals

Causes of death	Cause of death, n (%)		Hazard ratios (95% CI)	
	Gout cases, n = 24320	Controls, n= 119781	Model 1	Model 2
Cardiovascular disease	3527 (14.5)	11369 (9.5)	1.61 (1.55-1.67)	1.20 (1.16-1.26)
Renal disease	140 (0.6)	239 (0.2)	2.79 (2.26-3.44)	1.68 (1.31-2.16)
Dementia	287 (1.2)	2922 (2.4)	0.45 (0.40-0.51)	0.68 (0.60-0.77)
Infections	437 (1.8)	1631 (1.4)	1.27 (1.14-1.41)	1.15 (1.03-1.28)
Diabetes	250 (1.0)	665 (0.6)	1.80 (1.55-2.08)	1.02 (0.87-1.20)
Diseases digestive system	226 (0.9)	725 (0.6)	1.49 (1.29-1.74)	1.36 (1.16-1.59)
Lung diseases	306 (1.3)	1216 (1.0)	1.20 (1.06-1.36)	0.89 (0.78-1.01)
Cancer	1179 (4.9)	6067 (5.1)	0.92 (0.87-0.98)	0.94 (0.88-0.99)
Other	655 (2.7)	2899 (2.4)	1.08 (0.99-1.17)	1.09 (0.99-1.19)
All-cause mortality	7007 (28.8)	27733 (23.2)	1.32 (1.29-1.36)	1.08 (1.05-1.11)

Model 1: adjusted for age and sex

Model 2: adjusted for baseline values for: age, sex, marital status, income, education, born outside of Sweden, alcohol related disorders, hypertension, ischemic heart disease, heart failure, cerebrovascular disease, diabetes, dyslipidemia, obesity, renal disease, dementia, lung diseases and cancer

Conclusion: This study demonstrates a modest increase in overall mortality in gout patients and a decreased risk of death from dementia reflecting it's inverse relation to gout.

OP0209 SONOGRAPHIC ESTIMATION OF MONOSODIUM URATE BURDEN PREDICTS THE FULFILMENT OF THE 2016 REMISSION CRITERIA FOR GOUT: A 12-MONTH STUDY

E. Cipolletta[1], A. DI Matteo[1], W. Grassi[1], E. Filippucci[1]. [1]*Polytechnic University of Marche, Department of Clinical and Molecular Sciences, Ancona, Italy*

Background: Preliminary remission criteria for gout include the following five domains: serum uric acid (SUA) levels <360 µmol/l, absence of subcutaneous tophi, absence of gouty flares, pain (due to gout) <2/10 and patient global assessment of disease activity <2/10 [1]. To achieve remission, all criteria must be fulfilled at least twice in a 12-month period [1]. Although imaging techniques allow to visualise monosodium urate (MSU) deposits and to estimate their burden, an imaging domain was not included.

Objectives: To investigate whether baseline MSU burden estimated by ultrasonography (US) predicts the achievement of remission according to these criteria [1] over 12 months.

Methods: In this 12-month prospective, observational and monocentric study, patients with gout according to the 2015 ACR/EULAR criteria and on urate-lowering therapy for at least the preceding 6 months were consecutively recruited. After the baseline clinical assessment, only patients fulfilling all domains of the remission criteria [1] (and therefore amenable to achieve the remission at 12 months) were followed up at 6-month intervals for one year.

The US findings indicative of MSU deposits were identified according to the OMERACT definitions. The following joints were included in the US scanning protocol: elbows, wrists, 2nd metacarpophalangeal joints, knees, ankles and 1st metatarsophalangeal joints. Sum scores of aggregates, double contour (DC) signs, and tophi were calculated separately, and a total score resulting from the sum of all elementary US findings was recorded.

Results: Seventy patients with gout were recruited; of these, 20 (28.6%) were excluded at baseline because 13 (18.6%) did not satisfy the SUA domain, 11 (15.7%) tophus domain, 7 (10.0%) pain domain and 5 (7.1%) disease activity domain.

In the enrolled patients (Age: 59.9±14.8 years, female/male ratio: 1/49, disease duration: 6.5±6.6 years), remission criteria were fulfilled in 21 (42.0%) of 50 patients over 12 months.

No significant difference was found between patients fulfilling and not fulfilling the remission criteria at 12 months in all clinical and laboratory data except for the gout flare prophylaxis (7, 33.3% vs 20, 69.0%; p=0.02).

The baseline US MSU burden was significantly lower (total score 1.9±1.8) in patients in remission than in those not in remission at 12 months (total score 5.1±3.1) (p<0.01). The fulfilment of the remission criteria at 12 months was recorded in 87.5% of the patients without baseline US evidence of MSU deposits and in only 33.0% of those with at least one US finding indicating MSU deposits (p<0.01).

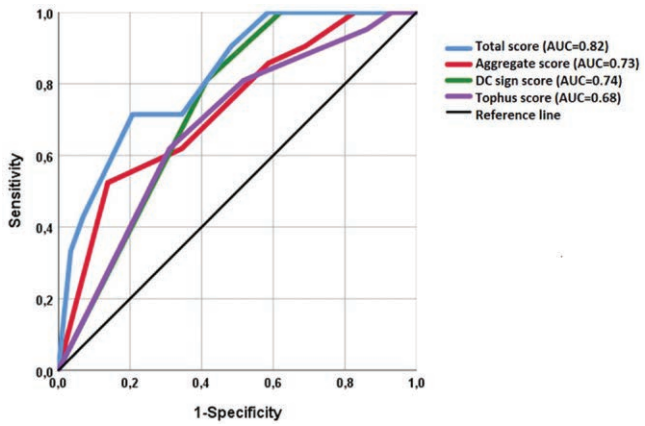
US scores and gout flare prophylaxis were the only significant predictors of remission in the univariate analyses (Table 1).

Table 1. Predictive values of baseline data for the remission at 12 months.

	OR (95%CI)	P value
Ongoing flare prophylaxis	0.23 (0.07-0.75)	**0.02**
Total score=0	10.83 (1.14-102.59)	**0.04**
Aggregate score=0	5.53 (1.34-22.76)	**<0.01**
DC sign score=0	7.33 (1.71-31.44)	**<0.01**
Tophus score=0	3.88 (1.08-13.92)	**0.02**

95%CI: 95% confidence interval; **OR:** odds ratio.

The risk of not fulfilling the remission criteria increased with the US burden of MSU deposits. For each 1-point increase in total score, aggregate score, DC sign score and tophus score, the risk increased by 1.81- (95%CI: 1.27-2.60), 1.73- (95%CI: 1.14-2.64), 4.16- (95%CI: 1.55-11.3) and 1.95-fold (95%CI: 1.07-3.56), respectively (Figure 1).



Conclusion: Baseline US estimation of MSU burden is an independent predictor of gout clinical remission at 12 months. The absence of US MSU deposits was the most significant predictor of remission, whereas the US detection of DC sign in at least one joint of not achieving remission. Thus, performing an US examination in patients amenable to fulfil the remission criteria after 12 months may improve risk-stratification and inform management of these patients.

PREGNANCY OUTCOMES IN RELATION TO DISEASE ACTIVITY AND ANTI-RHEUMATIC TREATMENT STRATEGIES IN WOMEN WITH RHEUMATOID ARTHRITIS – A MATCHED COHORT STUDY FROM SWEDEN AND DENMARK

K. Hellgren[1,2], A. E. Secher[3], B. Glintborg[3], A. Lilleoere Rom[4], B. Gudbjornsson[5], B. Michelsen[6], F. Granath[1], M. L. Hetland[3]. [1]*Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden*; [2]*Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockkholm, Sweden*; [3]*DANBIO and COPECARE, Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Rigshospitalet, Copenhagen, Denmark*; [4]*Rigshospitalet, Department of Obstetrics and Research Unit Women's and Children's Health, Copenhagen, Denmark*; [5] *Landspitali University Hospital and University of Iceland, Centre for Rheumatology Research and Faculty of Medicine, Reykjavik, Iceland*; [6]*Diakonhjemmet Hospital, Department of Rheumatology, Oslo, Norway*

Background: Women with rheumatoid arthritis (RA) are at increased risks of adverse pregnancy outcomes, especially preterm birth (PTB) and small for gestational age (SGA). However, the link between RA disease activity, type and timing of anti-rheumatic treatment, and the risk of these outcomes remains unclear.
Objectives: To explore the associations between maternal RA and PTB/SGA in relation to disease activity and use of anti-rheumatic treatment before and during pregnancy.
Methods: By linking national medical birth registers to prospective clinical rheumatology registers (CRRs) in Sweden (SRQ) and Denmark (DANBIO), we identified 1739 RA-pregnancies and 17390 control-pregnancies (matched 1:10 on maternal age, birth year, and parity) with delivery 2006-2018. From CRRs and prescribed drug registers, we collected information on RA disease activity (DAS28, CRP and HAQ-score) and anti-rheumatic drugs (biologics, conventional synthetic (cs)DMARDs and oral steroids) nine months before and during pregnancy. Using logistic regression, we estimated adjusted odds ratios (ORs) with 95% confidence intervals (CI) for PTB and SGA in RA-pregnancies vs. control-pregnancies overall, and stratified by disease activity and type of anti-rheumatic treatment before and during pregnancy. Apart from the matching variables we adjusted for body mass index, smoking, educational level and country.
Results: Overall, RA-pregnancies were associated with increased ORs of PTB (1.92, 95% CI 1.56-2.35) and SGA (1.93, 95% CI 1.45-2.57). High maternal disease activity during pregnancy strengthened the associations with both PTB and SGA, whereas the ORs approached 1 for low disease activity (control-pregnancies constituting the reference), Table 1. Among RA-pregnancies with available information on DAS28-CRP (n=686, 39%), OR was 2.69 (95% CI 1.37-5.26) for PTB, and 3.39 (95% CI 1.43-8.06) for SGA, comparing DAS28-CRP >=3.2 vs.<3.2 during pregnancy. Stratifying on type of anti-rheumatic treatment did not substantially change the results. Combination therapy with biologics together with oral steroids and/or csDMARDs in the nine months before pregnancy was associated with PTB (ORs spanning 2.57-3.45) and SGA (ORs spanning 2.40-3.81).
Conclusion: During pregnancy, disease activity rather than treatment, appears to be the most important risk factor for PTB and SGA in RA. The findings highlight the importance of monitoring RA during pregnancy, especially in women receiving extensive anti-rheumatic treatment or with residual disease activity.

PATERNAL INFLAMMATORY ARTHRITIS IS ASSOCIATED WITH A HIGHER RISK OF MISCARRIAGES: RESULTS OF A LARGE MULTICENTER STUDY (IFAME-FERTILITY)

L. F. Perez-Garcia[1], E. Röder[1], R. Goekoop[2], M. R. Kok[3], P. Kok[4], H. T. Smeele[1], I. Tchetverikov[5], A. Van der Helm - van Mil[1,6], J. H. Van der Kaap[1,7], B. Krijthe[1,8], R. Dolhain[1]. *[1]Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands*; *[2]Haga Hospital (Leyweg), Rheumatology, Den Haag, Netherlands*; *[3]Maasstad Hospital, Rheumatology, Rotterdam, Netherlands*; *[4]Reinier de Graaf Gasthuis, Rheumatology, Delft, Netherlands*; *[5]Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands*; *[6]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[7]Adrz Medical Center, Rheumatology, Goes, Netherlands*; *[8]Franciscus Gasthuis & Vlietland, Rheumatology, Rotterdam, Netherlands*

Background: The effect of inflammatory arthritis (IA) on pregnancy outcomes has been studied mainly in women. Paternal older age, sperm DNA integrity and certain genetic defects have been associated with worse pregnancy outcomes (1). However, pregnancy outcomes of partners of men with IA have never been studied.

Objectives: To describe the pregnancy characteristics and outcomes of partners of men diagnosed with IA.

Methods: We performed a multicenter cross-sectional retrospective study conducted in eight Dutch hospitals. Men with IA (Rheumatoid Arthritis (RA), Juvenile Idiopathic Arthritis (JIA) and Spondyloarthritis (SpA)) who were over 40 years old and indicated that their family size was complete were invited to participate. Participants completed a digital questionnaire that included pregnancy-related questions and questions regarding their demographic and clinical information. To analyze the impact of IA on pregnancy outcomes, pregnancies were classified into two groups; pregnancies that occurred after diagnosis of IA and before the diagnosis of IA.

Results: In total 628 male participants diagnosed with IA were included. 408 men reported 897 singleton pregnancies that resulted in 794 live births. Regarding pregnancy characteristics, pregnancies conceived after diagnosis of IA had a higher mean paternal and maternal age at conception and a lower rate of spontaneous pregnancies (90.91 vs 96.60%, p=<0.005) (See Table 1). With regards to pregnancy outcomes, pregnancies conceived after receiving the diagnosis of IA had a lower rate of live births (86.36% and 89.22%, p=0.053) and a significant higher rate of miscarriages (12.27 vs 7.53%, p=<0.05). After correcting for maternal age and year of pregnancy, pregnancies conceived after the diagnosis of IA had a higher risk of miscarriages (OR 1.71 [CI 1.04-2.81], p<0.05). No statistically significant differences between the two groups were reported for the rates of abortions, preterm births and pregnancy complications.

Table 1. Pregnancy characteristics and outcomes.

	All pregnancies	Pregnancy after diagnosis of IA	Pregnancy before diagnosis of IA	P value
Pregnancy characteristics				
Total number of pregnancies	897	220	677	
Maternal age at conception, mean (SD)	29.00 (5.00)	30.69 (5.16)	28.45 (4.83)	**p<0.005**
Paternal age at conception, mean (SD)	31.31 (5.72)	34.27 (6.08)	30.49 (5.34)	**p<0.005**
Spontaneous pregnancy, n (%)	854 (95.21)	200 (90.91)	654 (96.60)	**p<0.005**
Pregnancy duration-months, median (IQR)	39 (38-40)	39 (38-40)	39 (38-40)	p=0.928
Pregnancy outcomes				
Live births, n (%)	794 (88.52)	190 (86.36)	604 (89.22)	p=0.053
Miscarriage, n (%)	78 (8.70)	27 (12.27)	51 (7.53)	**p<0.05**
Abortion, n (%)	25 (2.78)	3 (1.36)	22 (3.25)	p=0.128
*Medical indication	5 (20.00)	0 (0)	5 (22.73)	
*Personal reasons	20 (80.00)	3 (100.00)	17 (77.27)	
Pre-term birth	149 (16.61)	31 (14.09)	118 (17.43)	p=0.248
Pregnancy complications				
No complications during pregnancy, n (%)	754 (84.34)	184 (83.64)	570 (84.57)	p=0.741
Hypertensive disorders (hypertension, pre/eclampsia), n (%)	41 (4.57)	8 (3.64)	33 (4.87)	p=0.445
Gestational Diabetes Mellitus	11 (1.28)	2 (0.94)	9 (1.38)	p=0.619
Growth restriction	12 (1.34)	1 (0.45)	11 (1.65)	p=0.193

Conclusion: This is the largest study to describe the pregnancy characteristics and outcomes of partners of men diagnosed with IA and the first to demonstrate that paternal IA is associated with a higher risk of miscarriage. Prospective studies are needed to corroborate these findings.

OP0212

MEN DIAGNOSED WITH INFLAMMATORY ARTHRITIS BEFORE THE AGE OF 40 YEARS HAVE A LOWER FERTILITY RATE THAN THOSE DIAGNOSED AFTER THE AGE OF 40 YEARS: RESULTS OF A LARGE MULTICENTER STUDY (IFAME-FERTILITY)

L. F. Perez-Garcia[1], E. Röder[1], R. Goekoop[2], J. Hazes[1], M. R. Kok[3], P. Kok[4], H. T. Smeele[1], I. Tchetverikov[5], J. H. Van der Kaap[1,6], A. Van der Helm - van Mil[1,7], B. Krijthe[1,8], R. Dolhain[1]. *[1]Erasmus University Medical Centrum, Rheumatology, Rotterdam, Netherlands*; *[2]Haga Hospital, Rheumatology, Den Haag, Netherlands*; *[3]Maasstad Hospital, Rheumatology, Rotterdam, Netherlands*; *[4]Reinier de Graaf Gasthuis, Rheumatology, Delft, Netherlands*; *[5]Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands*; *[6]Adrz Medical Center, Rheumatology, Goes, Netherlands*; *[7]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[8]Franciscus Gasthuis & Vlietland, Rheumatology, Rotterdam, Netherlands*

Background: The effect of inflammatory arthritis (IA) on fertility has been mainly studied in women. Multiple factors associated with lower fertility rate in women can also be present in male patients with IA (1). The fertility rate in men with IA, however, has never been studied.

Objectives: To describe the fertility rate (number of biological children per individual) of men with IA.

Methods: We performed a multicenter cross-sectional retrospective study conducted in eight Dutch hospitals. Men with IA (Rheumatoid Arthritis (RA), Juvenile Idiopathic Arthritis (JIA) and Spondyloarthritis (SpA)) who were over 40 years old and indicated that their family size was complete were invited to participate. Men who were still planning on having biological children were excluded. Participants completed a digital questionnaire that included fertility-related questions and questions regarding their demographic and clinical information. To analyze the impact of IA on male fertility rate, patients were divided into groups according to the age at the time of their diagnosis: age<30 years, age 31-40 years and age>41 years.

Results: In total 628 participants diagnosed with IA were included. The response rate 34.87%. Information regarding their age, age at diagnosis, clinical diagnosis and number of children is presented per group in Table 1. Regarding the total number of children per man, there was a statistically significant difference between the three groups (p=<0.005). The mean total number of children was significantly lower in men diagnosed at age<30 years (1.39 {SD 1.41}) and at age 31-40 years (1.60 {SD 1.35}) compared to those diagnosed after at age>41 years (1.88 {SD 1.14}). Compared to men from the general population of the Netherlands, the total number of children of men diagnosed at age>41 years was not statistically different (1.88 vs 1.80, respectively).

Table 1. Participants' basic demographic and clinical characteristics, including the number of biological children per men.

	All patients	IA diagnosed at age <30 years	IA diagnosed at age 31-40 years	IA diagnosed at age >41 years
Total, n (%)	628	137 (21.82)	149 (23.73)	342 (54.46)
Age, mean (SD)	57.17 (9.98)	53.01 (9.96)	52.76 (7.35)	61.06 (9.47)
Diagnosis, n (%)				
• iRA	297 (47.29)	42 (30.66)	67 (44.97)	188 (55.32)
• AJIA	10 (1.59)	10 (6.25)	0 (0)	0 (0)
• ISpA (incl. PsA)	320 (50.96)	90 (65.69)	83 (55.70)	147 (42.98)
Age at diagnosis, mean (SD)	41.29 (13.08)	26.27 (9.15)	36.99 (5.66)	49.98 (9.70)
Disease duration, mean (SD)	15.89 (11.88)	26.48 (12.57)	15.70 (8.52)	11.30 (9.87)
Number of biological children, mean (95% CI)	1.71 (1.60-1.81)	**1.39 (1.15-1.63)**[a,b]	**1.60 (1.38-1.82)**[a]	1.88 (1.75 -2.01)

[a] p< 0.05 compared to those diagnosed age >41 years[b] p< 0.05 compared to those diagnosed age >31-40 years

Conclusion: This is the largest study ever conducted to evaluate the impact of IA on male fertility. We demonstrated that men diagnosed with IA before and during their reproductive years have a lower fertility rate than those men diagnosed with IA after their reproductive years. Multiple mechanisms (biological and non-biological) can be responsible for this association. More research is needed to identify the causes of these lower fertility rates in men with IA.

OP0213 SEX DIFFERENCES IN MULTIMORBIDITY BETWEEN PATIENTS WITH RHEUMATOID ARTHRITIS AND COMPARATORS IN A LARGE NATIONWIDE US STUDY

H. J. Dykhoff[1], E. Myasoedova[2,3], M. Peterson[2], J. M. Davis III[2], V. Kronzer[2], C. Coffey[2], T. Gunderson[3], C. S. Crowson[2,3]. *[1]Mayo Clinic, Robert D. and Patricia E. Kern Center for the Science of Health Care Delivery, Rochester, United States of America*; *[2]Mayo Clinic, Division of Rheumatology, Rochester, United States of America*; *[3]Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America*

Background: Patients with rheumatoid arthritis (RA) have an increased burden of multimorbidity. Although many comorbidities vary by sex, sex differences in multimorbidity among individuals with RA have not been examined.

Objectives: We aimed to compare multimorbidity between women and men with RA and comparators without RA.

Methods: We used a large longitudinal, real-world data warehouse with de-identified administrative claims for commercial and Medicare Advantage enrollees, to identify cases of RA and matched controls. Cases were defined as patients aged ≥18 years with ≥2 diagnoses of RA in January 1, 2010 - June 30, 2019 and ≥1 prescription fill for methotrexate in the year after the first RA diagnosis. Controls were persons without RA matched 1:1 to RA cases on age, sex, census region, calendar year of index date (corresponding to the date of second diagnosis code for RA), and length of prior medical/pharmacy coverage. Race was classified as non-Hispanic White (White), non-Hispanic Black (Black), Asian, Hispanic, or other/unknown, based on self-report or derived rule sets. Multimorbidity (2 or more comorbidities) was defined using 25 chronic comorbidities from a combination of the Charlson and Elixhauser Comorbidity Indices assessed during the year prior to index date. Rheumatic comorbidities were not included. Logistic regression models were used to estimate odds ratios (OR) with 95% confidence intervals (CI).

Results: The study included 16,363 cases with RA and 16,363 matched non-RA comparators (mean age 58.2 years, 70.7% female for both cohorts). In both cohorts, women were slightly younger (mean age 57.5 vs. 59.8 years). Among RA patients, women were more racially/ethnically diverse than men, with 72% of women (78% men) being White, 12% (10%) Hispanic, 11% (7%) Black, 3% (3%) Asian, and 3% (3%) other/unknown. Racial/ethnic diversity was similar among non-RA women and men with 74% women (75% men) being White, 9% (9%) Hispanic, 10% (8%) Black, 4% (4%) Asian, and 3% (4%) other/unknown. Patients with RA had more multimorbidity than non-RA subjects (51.3% vs 44.8%). Observed rates of multimorbidity were similar in women and men with RA (51.6% vs 50.5%, p=0.18), but among non-RA patients, women had lower observed rates of multimorbidity than men (43.7% vs 47.4%, p<0.0001). However, following adjustment for age, race/ethnicity, and geographic region, multimorbidity among RA patients was greater in women versus men (OR: 1.19; 95% CI: 1.11-1.28) and similar among non-RA women and men (OR: 0.97 for females; 95% CI: 0.90-1.05). Examination of individual comorbidities showed that women with RA had more depression, hypothyroidism, diabetes mellitus, and chronic pulmonary disease compared to men with RA and women without RA.

Conclusion: This large nationwide study showed increased occurrence of multimorbidity in women with RA compared to men with RA, while women and men without RA had similar levels of multimorbidity following adjustment for age, race/ethnicity, and geographic region. The underlying mechanisms for these sex differences require further investigation.

OP0214 IMPACT OF A MULTI-MORBIDITY SCREENING AND PREVENTION PROGRAM IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES ON THE ONE-YEAR HOSPITALIZATION RATE BASED ON AN ANALYSIS OF THE FRENCH NATIONAL HEALTH DATABASE

G. Decarriere[1], J. Pastor[2], D. Demoulin[2], G. Mouterde[1], C. Lukas[1], B. Combe[1], G. Mercier[2], J. Morel[1], C. Daien[1]. *[1]CHU, Rheumatology, Montpellier, France*; *[2]CHU, Medical Information, Montpellier, France*

Background: A screening program for multimorbidities started in 2014 at the Montpellier University Hospital for primary prevention in patients with chronic inflammatory rheumatic diseases (IRD).

Objectives: The objective of this work was to assess the impact of this program on morbidity by comparing the hospitalization rate of those patients in the year following the screening to the one of patients with IRD who did not benefit from this program.

Methods: Patients with IRD who benefit from the screening program in 2015, 2016 and 2017 were identified in the French national health database PMSI and matched to 3 controls living in the same area on age, sex, type of IRD, use of intravenous (IV) biologic (b) DMARDs and index date. The exclusion criteria were subjects in secondary prevention identified as history of myocardial infarction in the previous 5 years or use of antiplatelet therapy. The primary outcome was the rate of all-cause hospitalization in the following year. The secondary endpoints were hospitalizations for another reason than IRD ("non-IRD") including those for cardiovascular [CV] events and major fractures. Hospitalization rates were compared between the two groups in the year after screening (or index date) and also between the year preceding screening and the year after for each group. Univariate and multivariate odds ratios (CI95%) were calculated, taking into account the medical history (hypertension, diabetes, heart failure, CV disease, COPD, major fractures in the 5 years preceding the index date) and hospitalizations in the previous year.

Results: 486 patients were identified and matched with 1458 controls. 67.08% had rheumatoid arthritis and 21.81% spondyloarthritis; 7% of them had IV bDMARDs. Unscreened patients had more hypertension (19% vs 10.1%), diabetes (9% vs 4.9%), heart failure (2.3% vs 0.4%) and "non-IRD" hospitalizations (78.5% vs 72.2%) in the 5 years preceding the index date. In the year following the index date, the percentages of "all causes" and "non-IRD" hospitalizations were significantly higher in non-screened than in screened patients (n = 1944, 64.8% versus 51%, Chi2 test, p <0.001; and 47.1% versus 37.9%, p <0.001 respectively). 17 (1.17%) cardiovascular events occurred in non-screened versus 2 (0.41%) in screened patients (n = 1944, Chi2 test, p = 0.14). There was no difference in the occurrence of CV events or major fractures between the 2 groups. In multivariate analysis, screening was associated with a 49% (0.51 [0.41-0.64]) reduction in "all causes" hospitalization and a 27% (0, 73 [0.58-0.91]) decrease in "non-IRD" hospitalization, with no difference for CV or fracture cardiological events. The risk factors associated with "non-IRD" hospitalization were: history of "non-IRD" hospitalization in the previous year (2.26 [1.63-3.13]), IV bDMARDs (1.69 [1, 14-2.53]) and age> 70 years (1.44 [1.02-2.03] vs <50 years). Hospitalization in the previous year for "all causes" or "non-IRD" was associated with

rehospitalization in the following year in the non-screened group (p <0.001), but not in the screened group (p = 0.750 and p = 0.066 respectively).
Conclusion: Our screening and prevention program was associated with a reduction in hospitalizations in the following year and a decrease in the risk of re-hospitalization compared to unscreened patients with IRD. This suggests a positive impact of performing systematic screening for multi-morbidities in IRD patients.

OP0215 MENTAL HEALTH, SLEEP AND COGNITION CHARACTERISTICS IN RHEUMATOID ARTHRITIS AND ASSOCIATIONS WITH RHEUMATOID FACTOR STATUS IN THE UK BIOBANK

I. Stanciu[1], S. Siebert[2], D. Mackay[1], D. Lyall[1]. [1]*University of Glasgow, Public Health, Glasgow, United Kingdom*; [2]*University of Glasgow, Infection Immunity & Inflammation, Glasgow, United Kingdom*

Background: There are significant gaps in the literature regarding sleep, mental health, and cognition for people with rheumatoid arthritis (RA) despite being important aspects of patients' overall quality of life. Similarly, there is a lack of understanding about the role of rheumatoid factor (RF) on these domains.
Objectives: The aim of the current study was to characterize mental health, cognition, and sleep variables in people with RA and to compare these associations in people with positive RF (RF+) and negative RF (RF-) in a large population cohort.
Methods: This cross-sectional study used baseline data from the UK Biobank cohort (n= 502,506) to compare people with and without RA and people that are RF+ versus RF- on a variety of sociodemographic, lifestyle, illness-related factors and depression, neuroticism, performance on cognitive tests and sleep-related factors. Logistic regression analyses were also performed to determine whether RF seropositivity was associated with mental health, cognition, and sleep variables. We adjusted for the covariates of age, sex, ethnicity, deprivation index, smoking status, BMI and alcohol intake.
Results: In this sample 5,907 people self-reported having RA (1.17%), of which 74% were RF- and 26% were RF+. There were significant differences ($p < 0.05$) between people with and without RA for depression, neuroticism, nap during the day, getting up in the morning, insomnia, reaction time, fluid intelligence and prospective memory. There were significant differences ($p < 0.05$) between RF+ and RF- people for depression, neuroticism, sleep duration, nap during the day, getting up in the morning, insomnia, and reaction time. In the unadjusted regression analyses neuroticism (B=-0.06, SE= 0.01, $p < 0.001$), sleep duration (B=0.02, SE= 0.005, $p < 0.001$), nap during the day (OR=1.28, 95% CI: 1.02-1.65, $p < 0.05$) and reaction time (B=4.55, SE=0.53, $p< 0.001$) were significantly associated with RF status. After adjusting for covariates, only sleep duration (B=0.01, SE=0.005, $p< 0.01$) remained significant.
Conclusion: The current study suggests that RA diagnosis and RF status are associated with differences in mental health, sleep, and cognition, highlighting the importance of addressing these aspects in clinical settings and future research.

OP0216 TRENDS IN OCCURRENCE OF DEMENTIA IN PATIENTS WITH RHEUMATOID ARTHRITIS: A POPULATION-BASED COHORT STUDY, 1980-2009

V. Kronzer[1], C. S. Crowson[1], J. M. Davis III[1], M. Vassilaki[2], M. Mielke[2], E. Myasoedova[1]. [1]*Mayo Clinic, Rheumatology, Rochester, United States of America*; [2]*Mayo Clinic, Health Sciences Research, Rochester, United States of America*

Background: Some cross-sectional studies show increased odds of cognitive impairment and dementia in patients with rheumatoid arthritis (RA) compared to the general population, while others show the reverse. Furthermore, existing studies have not evaluated trends in incidence of dementia on a longitudinal basis.
Objectives: We aimed to assess the incidence of dementia over time in patients with incident RA and to compare it to those of population-based comparators.
Methods: This population-based, retrospective cohort study included Olmsted County residents with incident RA and non-RA individuals matched on age, sex, and calendar year. All RA cases met 1987 ACR criteria for RA between 1980 and 2009. Index date was the date of RA criteria fulfillment or a corresponding date for referents. All individuals were followed until death, migration, or 12/31/2019. For sensitivity analyses, follow-up of each decade was truncated at eleven years to make the length of follow-up comparable (e.g., the 1980–89 cohort was truncated at 12/31/1999). Incident dementia was defined as an ICD-9/10 code for dementia. Patients with dementia prior to RA incidence/index date were excluded. Cox proportional hazards models calculated hazard ratios (HR) with 95% confidence intervals (CI) for incident dementia by decade, adjusting for age and sex. The cumulative incidence of dementia was assessed, adjusting for the competing risk of death.
Results: The study included 895 persons with RA (mean age 55.3 years; 69% female) followed up for a median of 15.2 years. The 10-year cumulative incidence of dementia in these individuals during the 1980s was 12.7% (95%CI 7.9-15.7%), 1990s was 7.2% (95%CI 3.7-9.4%), and 2000s was 6.2% (95%CI 3.6-7.8%) Patients with incident RA in 2000-09 had markedly lower cumulative incidence of dementia than patients diagnosed in the 1980s (HR 0.57; 95%CI 0.33-0.98). Patients with incident RA were then compared to population-based comparators without RA (N=880, mean age 55.2 years; 68% female) followed up for a median of 16.4 years. The 10-year cumulative incidence of dementia in these individuals in the 1980s was 9.3% (95%CI 4.6-11.9%), in the 1990s was 5.0% (95%CI 2.2-6.3%) and in the 2000s was 7.1% (95%CI 4.3-8.9%). Overall, the risk of dementia in RA patients was significantly higher than in the non-RA persons (HR 1.38; 95%CI 1.04-1.83). When subdivided by decade, the risk of dementia in patients diagnosed with RA was higher than non-RA comparators in the 1980s and 1990s but not 2000s (Figure 1). Sensitivity analysis with truncated follow-up yielded similar results.

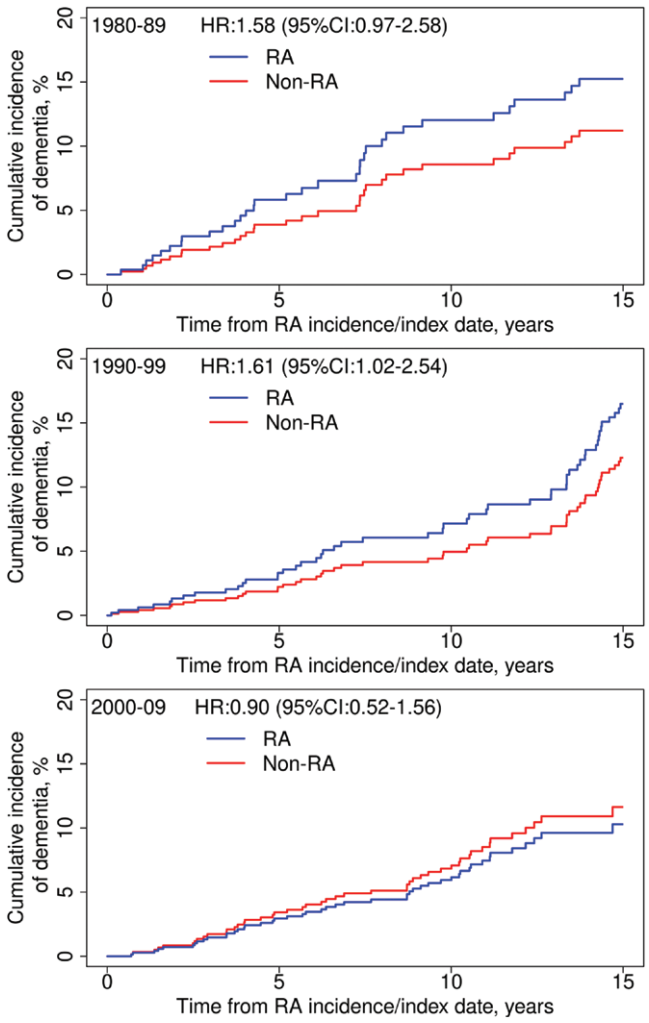

Figure 1. Cumulative incidence of dementia (based on ICD 9/10 codes) versus age-and sex-matched non-RA comparators by decade of RA incidence/index.

Conclusion: Our findings show substantial decline in risk of dementia in patients with RA onset in the 2000s as compared to 1980s, including when compared to the general population comparators. This decline coincides with the advent of novel biologic treatments for RA. Further studies should investigate this association using manual verification rather than billing codes for dementia, and should also elucidate the role of inflammation, autoimmunity, and anti-rheumatic treatments in risk of dementia.

OP0217 IS METACARPOPHALANGEAL-JOINT PAIN AS AN EARLY SYMPTOM OF PATIENTS AT RISK FOR PROGRESSION TO INFLAMMATORY ARTHRITIS EXPLAINED BY MRI-DETECTED SUBCLINICAL INFLAMMATION? – A LARGE OBSERVATIONAL STUDY

Q. Dumoulin[1], X. Matthijssen[1], F. Wouters[1], A. Van der Helm - van Mil[1,2], E. Niemantsverdriet[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*

Background: Pain in metacarpophalangeal (MCP)-joints in patients presenting with clinically suspect arthralgia (CSA) is one of the clinical features by which patients are considered at risk for progression to inflammatory arthritis (IA). As such this symptom is characteristic for CSA and therefore part of a list of clinical parameters determined by an EULAR-taskforce to identify a more homogeneous group of patients within CSA (the EULAR definition of arthralgia suspicious for progression to RA). MRI-detected subclinical inflammation is known to be present in patients with CSA. In general, arthralgia in CSA can be explained by this subclinical inflammation, however to date, the association of subclinical inflammation with pain in MCP-joints specifically is not clear. Subsequently, it is unknown whether this association differs pertinently when investigated with self-reported pain, or with pain in the form of tenderness at physical examination.
Objectives: This study will investigate whether MCP-pain and MCP-joint tenderness are associated with MRI-detected subclinical inflammation in patients with CSA, and more specifically those who have progressed to IA.
Methods: Between April 2012- February 2019, 602 patients were consecutively included in the Leiden clinically suspect arthralgia (CSA)-cohort. Follow-up ended when patients developed clinically apparent IA (determined at physical examination), or else after 2-years (median follow-up time 25 months). MCP-joints were assessed for self-reported joint pain by the patient using a mannequin and subsequently for joint tenderness by physical examination. Baseline unilateral MRIs of the MCP (2-5)-joints were scored by two readers, blinded for clinical data, on subclinical inflammation (synovitis, tenosynovitis, osteitis). Associations between MCP-pain or MCP-joint tenderness and MRI-detected subclinical inflammation were studied at patient level by logistic regression analyses, entering the mentioned MRI-detected features separately (univariable) and together (multivariable).
Results: 33% of 227 patients with self-reported MCP-pain had MRI-detected subclinical inflammation and 38% of 226 patients with MCP-joint tenderness had MRI-detected subclinical inflammation. Self-reported MCP-joint pain was univariable associated with subclinical inflammation and synovitis in particular (OR 2.00, 95% CI: 1.21-3.30, OR 2.87, 95% CI: 1.29-6.39). In multivariable analysis this MCP-pain was associated with synovitis (OR 2.54, 95% CI: 1.12-5.77). MCP-joint tenderness was univariable associated with subclinical inflammation, and synovitis and tenosynovitis in particular (OR 1.84, 95% CI: 1.29-2.63, OR 1.76, 95% CI: 1.10-2.81, OR 1.69, 95% CI: 1.12-2.55, respectively). In multivariable analysis, tenosynovitis remained significant (OR 1.54, 95% CI: 1.00-2.36). Of all patients with self-reported MCP-joint pain who developed IA, 50% had MRI-detected subclinical inflammation. For MCP-joint tenderness this was 61%. Patients with MCP-joint tenderness without subclinical inflammation who developed IA, developed clinical arthritis at a joint that was not scanned (85%), hence they may have had subclinical inflammation that was not imaged. The other 15% did develop arthritis in an MCP-joint, suggesting that subclinical inflammation developed after CSA-onset.
Conclusion: Arthralgia in the MCP-joints is associated with subclinical inflammation in CSA, in particular with synovitis and tenosynovitis. The prevalence of subclinical inflammation is highest for tender joints at physical examination; this can be acknowledged when applying the EULAR definition of arthralgia suspicious for progression to RA.

Unrevealing the impact of PsA and comorbidity prevention

OP0218 MORTALITY IN PATIENTS WITH PSORIATIC ARTHRITIS IN SWEDEN

S. Exarchou[1], D. DI Giuseppe[2], G. M. Alenius[3], E. Klingberg[4,5], V. Sigurdardottir[6,7], S. Wedrén[2,8], U. Lindström[5], C. Turesson[1], L. T. H. Jacobsson[5], J. Askling[2], J. K. Wallman[9,10]. [1]*Lund University, Department of Clinical Sciences Malmö, Rheumatology, Lund, Sweden*; [2]*Karolinska Institutet, Department of Medicine Solna, Clinical Epidemiology Division, Stockholm, Sweden*; [3]*Umeå University, Department of Public Health and Clinical Medicine/Rheumatology, Umeå, Sweden*; [4]*Sahlgrenska University Hospital, Department of Rheumatology, Gothenburg, Sweden*; [5]*Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; [6]*Falun Hospital, Department of Rheumatology, Falun, Sweden*; [7]*Uppsala University, Centre for Clinical Research Dalarna, Uppsala, Sweden*; [8]*Karolinska University Hospital, Department of Rheumatology, Stockholm, Sweden*; [9]*Skåne University Hospital, Department of Rheumatology, Lund, Sweden*; [10]*Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden*

Background: In contrast to the increased mortality reported in other inflammatory diseases such as rheumatoid arthritis and psoriasis, prior mortality studies in psoriatic arthritis (PsA) have shown inconsistent results.
Objectives: To compare all-cause mortality between PsA patients in Sweden and matched general population controls, and to describe cause of death distributions in the two groups.
Methods: All individuals in Sweden with ≥1 main diagnosis of PsA (ICD-10: L40.5/M07.0-M07.3) from outpatient visits to rheumatology or internal medicine clinics at age ≥18 years (y) 2001-2017 were identified from the Swedish National Patient Register. Each case was matched to 5 general population controls based on sex, county and age in the year of the first registered arthritis diagnosis for the case. Cases and controls were followed from 1 Jan, 2007, or from first PsA diagnosis thereafter for index cases, until first occurrence of death (data from the Swedish Cause of Death Register), emigration or 31 Dec, 2018. Mortality was assessed overall, as well as stratified by sex (45% males) and disease duration (PsA diagnosis prior to 2007 [38% of cases] vs. 2007-2017), using matched Cox proportional hazard regression, or – in case the Cox assumption regarding proportionality did not hold – matched Breslow test. To account for potential PsA misclassification (in a previous validation study, 86% of 400 cases fulfilled PsA classification criteria), a sensitivity analysis was performed by randomly replacing 20% of cases with one of their own controls. Moreover, incidence rate ratios (IRR) of death were calculated overall and stratified by sex, disease duration and age. Finally, causes of death (from the Cause of Death Register) were described for PsA cases and controls.
Results: Over the 12y follow-up, 3 121 deaths occurred among 33 036 PsA cases (268 402 person-years at risk) and 12 884 deaths among 161 144 controls (1 302 250 person-years), resulting in an increased mortality among the PsA cases (HR 1.11 [95%CI 1.07-1.16], p<0.001, Figure and Table; sensitivity analysis HR 1.09 [1.05-1.14]). The increased mortality was seen mainly among female PsA cases and among cases with longer disease duration (Figure; Table). IRR:s of death were significantly increased for all ages except <40y, with the numerically highest point-estimates for ages 40-49y and 50-59y (Table). Cause of death frequencies among the PsA cases/controls: cardiovascular disease 29/27%; diabetes mellitus 2.1/2.5%; chronic kidney disease 0.4/0.3%; infection 5.7/4.5%; chronic pulmonary disease 5.1/4.1%; malignancy 29/34%; suicide 2.3/2.0%; other 27/26%.
Conclusion: In this nationwide 12y assessment, the mortality risk among PsA patients in Sweden was increased by around 10% as compared to the general population, mainly driven by increased risks among females and patients with longer disease duration. Cause of death distributions were numerically similar between PsA cases and controls.

OP0219 THE ASSOCIATION OF PSORIATIC ARTHRITIS WITH ALL-CAUSE MORTALITY AND LEADING CAUSES OF DEATH IN PSORIATIC ARTHRITIS

A. Haddad[1], W. Saliba[2,3], I. Lavi[3], A. Batheesh[4], S. Kasem[2,4], T. Gazitt[1], I. Feldhamer[5], A. Cohen[5,6], D. Zisman[1,2]. *[1]Carmel Medical Center, Rheumatology, Haifa, Israel*; *[2]Technion, Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel*; *[3]Clalit Health Services, Department of Epidemiology, Haifa, Israel*; *[4]Carmel Medical Center, Internal Medicine, Haifa, Israel*; *[5]Clalit Health Services, Department of Epidemiology, Telaviv, Israel*; *[6]Ben Gurion University of the Negev, Dermatology, Bear-Sheva, Israel*

Background: Data on the association between PsA and mortality remains conflicting as it has been hampered by small sample size with few events and the potential for confounders of selection and severity biases from clinic-based studies.
Objectives: To examine the association between PsA and all-cause mortality in a cohort of PsA patients and matched controls, using data from a population-based large medical record database.
Methods: Patients with newly diagnosis of PsA between January 1st, 2003 and December 31st, 2018 from the Clalit Health database were identified. 4 controls without PsA were selected and matched to cases of PsA by age (within 1 year), sex, ethnicity (Jewish *vs.* non-Jewish), and index date. The two groups were followed from the index date until the first occurrence of death from any cause or end of follow-up (June 30, 2019). Data on mortality and on the immediate cause of death was based on the Notification of Death form legally required by the Israeli Ministry of the Interior for every deceased person in the country. Demographic data including age, sex, ethnicity (Jewish or Arab), and socioeconomic status (SES) at inception were retrieved from the CHS database. Data regarding tobacco use (ever), obesity, body mass index, diabetes mellitus, hyperlipidemia, hypertension, ischemic heart disease, prior cerebrovascular accident, congestive heart failure, chronic renal failure, chronic obstructive pulmonary disease, cirrhosis, prior malignancy, psoriasis, and the concomitant use of glucocorticosteroids, conventional and biologic disease-modifying anti-rheumatic drugs (cDMARDs and bDMARDs, respectively) were extracted from the database.
We estimated the attributable fraction of the various causes of death in PsA patients and compared it to the proportionate mortality rate (PMR) of the leading causes of death in Israel during 2014-2016 based on a recently published report by the Central Bureau of Statistics. Cox proportional hazard regression models were used to estimate the crude and the multivariate adjusted hazard ratio (HR) for the association between PsA and all-cause mortality, as well as for factors associated with mortality within the PsA group.
Results: A total of 5275 PsA patients were identified between 2003 and 2018 and where matched to 21,011 controls based on age, sex, and ethnicity. The mean age was 51.7 ± 15.4 years of whom 53% were females. More individuals in the PsA group were smokers, obese, with diabetes, hypertension, and dyslipidemia, as well as with a history of ischemic heart disease, cerebrovascular disease, congestive heart failure, chronic obstructive pulmonary disease, chronic renal failure and cirrhosis than patients in the control group, and 38.2% of PsA patients were on b-DMARDS. Overall 471 (8.9%) patients died in the PsA group compared to 1,668 (7.9%) in the control group during a mean follow-up of 7.2 ± 4.4 years. The crude HR for the association of PsA and all-cause mortality was 1.16 (95% CI, 1.042-1.29). However, the association was not significant on multivariate analysis with HR of 1.096 (95% CI, 0.977-1.229).
In PsA patients, malignancy was the leading cause of death, constituting 26% of all deaths, followed by ischemic heart disease 15.8%, diabetes 6.2%, cerebrovascular diseases 5.5% and septicemia 5.5%, in keeping with the order of the leading causes of death in the general population of Israel during 2014-2016 as recently reported by the Central Bureau of Statistics.
On multivariate model Cox regression analysis, male sex, increased body mass index, increased Charlson comorbidity index scores and history of hospitalization in a year prior to death were associated with higher mortality, whereas treatment bDMARDs and cDMARDs were associated with a lower relative risk of death.
Conclusion: No clinically relevant increase in mortality rate was observed in PsA patients from the period 2003-2018. The most common causes of specific proportionate mortality rates in our cohort were similar to those in the general population.

Gr, Group; c/L, crude/LUNDEX.

Background: Knowledge of changes over time in baseline characteristics and tumor necrosis factor inhibitor (TNFi) response in bionaïve psoriatic arthritis (PsA) patients treated in routine care is limited.

Objectives: To investigate secular trends in baseline characteristics and retention, remission and response rates in PsA patients initiating a first TNFi.

Methods: Prospectively collected data on bionaïve PsA patients starting TNFi in routine care from 15 European countries were pooled. According to year of TNFi initiation, three groups were defined a priori based on bDMARD availability: Group A (1999–2008), Group B (2009–2014) and Group C (2015–2018).

Retention rates (Kaplan-Meier), crude and LUNDEX adjusted[1] remission (Disease Activity Score (DAS28) <2.6, 28-joint Disease Activity index for PsA (DAPSA28) ≤4, Clinical Disease Activity Index (CDAI) ≤2.8) and ACR50 response rates were assessed at 6, 12 and 24 months. No statistical comparisons were made.

Results: A total of 17453 PsA patients were included (4069, 7551 and 5833 in groups A, B and C).

Patients in group A were older and had longer disease duration compared to B and C. Retention rates at 6, 12 and 24 months were highest in group A (88%/77%/64%) but differed little between B (83%/69%/55%) and C (84%/70%/56%).

Baseline disease activity was higher in group A than in B and C (DAS28: 4.6/4.3/4.0, DAPSA28: 29.9/25.7/24.0, CDAI: 21.8/20.0/18.6), and this persisted at 6 and 12 months. Crude and LUNDEX adjusted remission rates at 6 and 12 months tended to be lowest in group A, although crude/LUNDEX adjusted ACR50 response rates at all time points were highest in group A. At 24 months, disease activity and remission rates were similar in the three groups (Table).

Conclusion: Over the past 20 years, patient age, disease duration and disease activity level at the start of the first TNFi in PsA patients have decreased. Furthermore, TNFi retention rates have decreased while remission rates have increased, especially remission rates within the first year of treatment. These findings may reflect a greater awareness of early diagnosis in PsA patients, a lowered threshold for initiating TNFi and the possibility for earlier switching in patients with inadequate treatment response.

Eder[1,9]. *[1]Women's College Hospital, Women's College Research Institute, Toronto, Canada*; *[2]University Health Network, Krembil Research Institute, Toronto, Canada*; *[3]University of Toronto, Institute of Medical Science, Toronto, Canada*; *[4]University of Waterloo, Statistics and Actuarial Science, Waterloo, Canada*; *[5]Women's College Hospital, Cardiology, Toronto, Canada*; *[6]Rambam Health Care Campus, Neurology, Haifa, Israel*; *[7]University of Glasgow, Institute of Cardiovascular & Medical Sciences, Glasgow, United Kingdom*; *[8]University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom*; *[9]University of Toronto, Medicine, Toronto, Canada*; *[10]Toronto Western Hospital, Centre for Prognosis Studies in the Rheumatic Diseases, Toronto, Canada*

Background: Psoriatic arthritis and psoriasis, collectively termed psoriatic disease (PsD), are associated with increased cardiovascular (CV) risk. Metabolites comprise biomarkers that may add predictive value over traditional CV risk factors.

Objectives: We aimed to identify metabolites associated with CV events (CVEs) and to determine whether they could improve CV risk prediction beyond traditional CV risk factors.

Methods: Patients from a longitudinal PsD cohort without a prior history of CVEs were included. In the first available serum sample, a targeted nuclear magnetic resonance (NMR) metabolomics platform was used to quantify 64 metabolite measures comprised of lipoprotein subclasses, fatty acids, glycolysis precursors, ketone bodies and amino acids. The study outcome included any of the following CVEs occurring within the first 10 years of biomarker assessment: angina, myocardial infarction, congestive heart failure, transient ischemic attack, cerebrovascular accident, revascularization procedures and CV death. The association of each metabolite with incident CVEs were analyzed separately using Cox proportional hazards regression models first adjusted for age and sex, and subsequently for traditional CV risk factors. Variable selection was performed using penalization with boosting after adjusting for age and sex. The added predictive value of the selected metabolites to improve risk prediction beyond traditional CV risk factors was assessed using the area under the receiver operator characteristic curve (AUC).

Results: A total of 977 patients with PsD, followed between 2002 and 2019, were analyzed (mean age 49.1 ± 12.6 years, 45.1% female). During a mean follow-up of 7.1 years, 70 (7.2%) patients developed incident CVEs. In Cox regression models adjusted for CV risk factors, alanine, tyrosine, total high-density lipoprotein (HDL) cholesterol, medium and large HDL particles, and the degree of unsaturation of fatty acids were significantly associated with decreased CV risk. Glycoprotein acetyls, apolipoprotein B, remnant cholesterol, very low-density lipoprotein (VLDL) cholesterol, and very small VLDL particles were associated with an increased CV risk. In proportional sub-distribution hazards regression models adjusted for age and sex, 13 metabolites were selected (Table 1). The age- and sex-adjusted expanded model (base model + 13 metabolites) significantly improved prediction of CVEs beyond the base model (only age and sex) with an AUC of 79.9 vs. 72.6, respectively (p=0.019) (Figure 1).

Table 1. Regression coefficients of the selected metabolites in a model adjusted for age and sex.

Category	Metabolite	Model adjusted for Age and Sex
Amino Acids	Alanine	-0.1179
	Glycine	-0.0339
	Tyrosine	-0.1010
Fatty acid ratios, relative to total fatty acids	Docosahexaenoic acid	-0.0862
	Unsaturation degree, double bonds per fatty acid	-0.1265
Fluid Balance	Albumin	+0.0685
Glycerides	Triglycerides in IDL cholesterol	+0.1546
Glycolysis precursors	Glucose	+0.1391
Inflammation	Glycoprotein acetyls	+0.1478
Ketone bodies	Acetoacetate	+0.0464
Lipoprotein subclasses	HDL_3 Cholesterol	-0.0211
	Medium HDL	-0.0296
	Large HDL	-0.0309

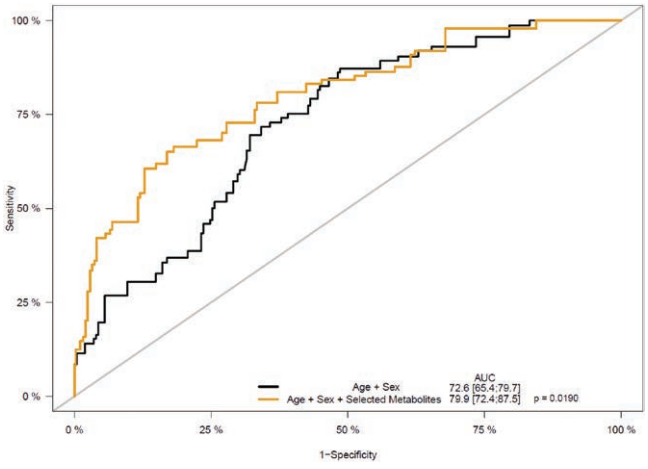

Figure 1. Predictive performance of a model with age and sex alone is compared to a model with age and sex plus selected metabolites.

Conclusion: Using NMR metabolomics profiling, we identified a variety of metabolites associated with a lower and higher risk of developing CVEs in patients with PsD. Further study of their underlying association with CVEs is needed to clarify the clinical utility of these biomarkers to guide CV risk assessment in this population.

Background: Interstitial lung disease (ILD) is an established extra-articular manifestation of rheumatoid arthritis (RA). Few studies have investigated the prevalence of ILD in patients with psoriatic arthritis (PsA). Methotrexate (MTX) is frequently used in the treatment of both RA and PsA and has been suggested to be a risk factor for the development of ILD. It is of interest to understand the interaction between disease and treatment in the development of ILD.

Objectives: To compare the incidence of ILD between patient with PsA and RA treated with biologic disease modifying antirheumatic drugs (bDMARDS), with or without MTX as a co-medication.

Methods: Cohorts of patients with RA and PsA starting bDMARD were identified in Nordic registers (Danish nationwide clinical register for patients with RA (DANBIO), Register on antirheumatic and biological therapy in Finland (ROB-FIN), Icelandic nationwide database of biologic therapy (ICEBIO), Norwegian Antirheumatic Drug Register (*NOR-DMARD*), and the Swedish Rheumatology Quality Register (SRQ)). Linkages to the National Patient Registers and to the Cause of Death Registers were performed in each country to identify cases of ILD. Each individual patient could contribute several treatment courses. ILD was identified as hospital or death certificate ICD10 codes of ILD (J84.1, J84.8, J84.9, J70.2, J70.3, J70.4, J99.0, J99.1, J99.8) given during the follow-up period which was defined as the treatment course duration, plus a 30-day wash-out period added to the end of treatment course period. MTX co-medication was specified as use of MTX at the start of bDMARD. Incidence rates (IR) for any ILD were calculated per 1000 person years at risk (PYR) for each country. The five cohorts were pooled and incidence rate ratios (IRR) for PsA vs. RA were calculated. Hazard ratios (HR) for any ILD in PsA vs. RA were estimated in Cox regression models adjusted for age, gender and repeated observations, and stratified for the use of MTX co-medication.

Results: Overall 47 987 individual patients representing 89 239 bDMARD treatment courses and contributing 201 279 PYR were included in the study (Table 1). Methotrexate was reported as comedication in 29 916 (33.5 %) of the treatment courses (PsA vs. RA, 30.4 % vs 34.5 %). 970 cases of ILD were identified during the follow-up period. The risk of ILD was consistently lower in patients with PsA compared to patients with RA in all countries. In models stratified for co-medication the HR for ILD in PsA vs. RA was 0.34 (0.21-0.57) in patients treated with MTX and 0.26 (0.18-0.36) in patients not treated with MTX.

Table 1. Interstitial lung disease in PsA vs. RA in five Nordic biologic registers

	DENMARK		FINLAND		ICELAND		NORWAY		SWEDEN

Age baseline (SD)	57.3 (13.1)	49.0 (12.6)	53.8 (13.4)	48.8 (11.4)	53.9 (14.2)	50.1 (13.3)	53.8 (13.7)	48.7 (12.0)	57.1 (13.7)	50.6 (12.8)
Female n (%)	12 963 (76)	3929 (59)	6571 (76)	933 (51)	969 (76)	551 (65)	1815 (77)	818 (57)	29 635 (77)	6162 (57)
Number of PYR	40235	13986	21798	4910	4517	2799	4556	2653	120334	27412
ILD-events within PYR	218	22	132	8	7	2	32	6	680	28
IR pr 1000 PYR	5.4	1.6	6.1	1.6	1.5	0.7	7.0	2.3	5.7	1.0
IRR PsA vs RA crude	0.29 (0.18-0.45)		0.27 (0.11-0.55)		0.46 (0.05-2.42)		0.32 (0.11-0.78)		0.18 (0.12-0.26)	
HR PsA vs RA	0.31 (0.17-0.56)		0.46 (0.22-0.96)		0.62 (0.12-3.14)		0.19 (0.06-0.54)		0.25 (0.17-0.37)	

PYR: Patient years at risk, IR: Incidence rates, IRR: Incidence rate ratios, HR: Hazard Ratios

Conclusion: In these preliminary analyses, the incidence of ILD is lower in bDMARD treated PsA vs. RA patients, irrespective of co-medication with MTX. This indicates that the clinician should consider the rheumatological diagnosis when assessing the risk for future ILD in patients treated with bDMARDs and MTX.

Background: The UPSTREAM (NCT03330769) is a 24-month multi-center prospective cohort study that primarily aims to evaluate the additional value of musculoskeletal ultrasound (msk-US) over clinical examination in predicting 6-month minimal disease activity in Psoriatic Arthritis (PsA). (1)

Objectives: To develop and preliminarily validate an activity msk-US score and a damage msk-US score for PsA using the UPSTREAM database.

Methods: Patients classified with PsA according to CASPAR criteria and starting a new course of therapy for clinically active peripheral joint disease were eligible. The information regarding objectives, study design, clinical and US assessment has already been published (1). The msk-US examination was performed in 42 joints, 36 tendons, 12 entheses and 2 bursae defined through a web-based exercise (2). The sonographic elementary lesions were allocated to disease activity [i.e. synovitis (sy), tenosynovitis (ts), peritendinitis (pt), bursitis (bs) all evaluated both in Grey Scale (GS) and Power Doppler (PD) and active enthesitis (en)] and to damage (i.e. joint erosion, bone proliferation, tendon tear, enthesophyte, calcification and irregular enthesis bone profile). Hands and feet X-ray were assessed using the modified Sharp-Van der Heijde (mSVH) score. A principal component (PC) analysis (PCA) was performed for each score and the number of PCs was defined by means of parallel analysis using baseline data. Each PC was normalized (n) taking into account the proportion between the observed value (e.g. sy-GS count) and the maximum expected value (e.g. 42 for sy-GS). Spearman' correlation was used to investigate the construct and discrimination validity of the new scores.

Results: Between February 2017 and May 2020, 312 PsA patients (155 men), with a mean (SD) age of 52.8 13.4, were enrolled from 19 centers; 22 expert sonographers were involved with substantial agreement for US lesions evaluated (k ≥0.7). The median [IQR] disease duration was 1.3 [0.1-6.1] years and the median [IQR] tender joint and swollen joint counts were 6 [3-13] and 2 [1-5], respectively. The weight derived from PCA for each sonographic lesions and the final equation for calculating the scores are reported in Figure 1 (1A activity and 1B damage). The final msk-US activity score **[n(ts-GS + ts-PD)*2.87] + [n(bs-GS + bs-PD)*1.76] + [n(pt-GS + pt-PD)*1.43] + [n(active en)*1.00] + [n(sy-GS)*0.83] + [n(sy-PD)*0.45]** has the best construct and discrimination validities according to a significant correlation with all clinical variables usually related to clinical activity (Table 1). The msk-US damage score correlated with mSVH score, HAQ and other clinical variables (Table 1).

Table 1.

	Msk-US activity score		Msk-US damage score	
Variables	*Spearman correlation*	*P-value*	*Spearman correlation*	*P-value*
ESR	0.196	0.002	0.075	0.235
CRP	0.209	<0.001	0.068	0.254
TJC	0.338	<0.001	0.286	<0.001
SJC	0.338	<0.001	0.072	0.221

OP0224 CONTINUOUS COMPOSITE MEASURES FOR ROUTINE CARE IN PSORIATIC ARTHRITIS: THRESHOLDS OF MEANING AND CLINICALLY IMPORTANT DIFFERENCE ESTIMATES FOR THE 3 AND 4 VAS SCALES FROM A UK MULTICENTRE STUDY

W. Tillett[1,2], J. Day[1], N. Mchugh[2], O. Fitzgerald[3], L. C. Coates[4], P. Helliwell[5]. *[1]Royal National Hospital for Rheumatic Diseases, Rheumatology, Bath, United Kingdom*; *[2]University of Bath, Pharmacy and Pharmacology, Bath, United Kingdom*; *[3]University College Dublin, Conway Institute for Biomolecular Research, Dublin, Ireland*; *[4]University of Oxford, Nuffield Department of Orthopaedics, Oxford, United Kingdom*; *[5]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: There is a recognised need for a continuous composite measure of disease activity for the assessment of Psoriatic Arthritis (PsA) in routine clinical settings to allow objective assessment of response and implementation of treat to target.[1] Longer multidimensional measures are considered less feasible in routine care and a number of shorter measures have been proposed including, the Disease Activity Score for Psoriatic Arthritis (DAPSA), Disease Activity Score 28 (DAS28), the 3 Visual Analogue Scale (VAS) (comprising physician global VAS, patient global VAS and patient skin VAS) or 4 VAS (comprising physician global VAS, patient pain VAS, joint VAS and patient skin VAS). Testing of these measures in clinical trial datasets has been suggested but thresholds of meaning have not been established.[2]

Objectives: To estimate clinically relevant thresholds of disease activity and improvement for composite measures for routine clinical practice in PsA.

Methods: Clinical and patient reported outcome measures were assessed in patients fulfilling CASPAR criteria for PsA at three consecutive follow up visits in a UK multicentre observational study. Participants underwent clinical assessment and completed patient reported measures including health anchor questions. Estimates for Minimal Detectible Change (MDC) were derived using 1.96*2*Standard Error of the Mean (SEM). Minimal Clinically Important Difference (MCID) for improvement were derived using the health anchor method and two distribution methods (Table 1). Thresholds for low, moderate and high disease activity were triangulated from established cut-off values for the patient global VAS, PASDAS and DAPSA.

Table 1. Minimal Clinically Important Difference (MCID) and Minimal detectable change (MDC)

	ANCHOR (MEDIAN)	DISTRIBUTION#1	DISTRIBUTION #2	MDC
CPDAI	0.5	1.49	1.5	4.16
GRACE	0.26	0.6	0.77	2.18
PASDAS	1.22	0.64	0.76	1.58
DAS28	0.2	0.85	0.62	1.46
3VAS	1.13	1.16	0.91	3.12
4VAS	1.11	0.96	0.94	2.45
DAPSA	7.25	9.09	10.40	35.63

Disease Activity Score for Psoriatic Arthritis (DAPSA); Psoriatic Arthritis Disease Activity Score (PASDAS); Composite Psoriatic Arthritis Disease Activity Index (CPDAI); Disease Activity Score 28 (DAS28).Distribution #1: Baseline standard deviation (sd) * √ 1 – Cronbach's alphaDistribution #2: 0.5 * baseline sdMinimal detectable change (MDC): 1.96*2*SEM where SEM = baseline sd √1 - ICC

Results: 139 subjects were recruited (59 male, 80 female, mean (range) age (years) 52.7 (19 – 83), mean (range) duration of psoriasis (years) 21.9 (2 – 71), mean (range) duration of psoriatic arthritis (years) 6.1 (0 – 41). Cut-off values for low, moderate and high disease activity were 1.3, 2.4, and 4.8 for the 3 Vas and 1.6, 2.8 and 5.0 for the 4 VAS (Figure 1). Estimates for the MCID and MDC for the continuous composite measures and are reported in Table 1.

Conclusion: We report estimates of clinically relevant improvements for continuous composite measures in PsA and estimates of low, moderate and high disease activity for the 3 and 4 VAS scales. The thresholds of meaning can now be tested in independent observational and clinical trial datasets.

OP0225 DEPRESSIVE SYMPTOMS IN PSA: A CROSS-SECTIONAL ANALYSIS FROM THE NATIONAL GERMAN RABBIT-SPA REGISTRY

A. Regierer[1], A. Weiß[1], M. Bohl-Buehler[2], X. Baraliakos[3], F. Behrens[4], G. Schett[5], A. Strangfeld[1]. *[1]German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany*; *[2]Rheumatology Practice, Rheumatology, Potsdam, Germany*; *[3]Rheumazentrum Ruhrgebiet Herne, Ruhr-University, Bochum, Germany*; *[4]Goethe University, Rheumatology and Fraunhofer Institute Translational Medicine and Pharmacology ITMP, Frankfurt, Germany*; *[5]Friedrich Alexander University Erlangen-Nuremberg and Universitatsklinikum Erlangen, Department of Internal Medicine 3, Erlangen, Germany*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease affecting the musculoskeletal system as well as skin and nails. The prevalence of depression in psoriasis and PsA is high and ranges from 7-40% [1]. Persistent depressive mood may influence disease activity outcome in PsA, especially patient-reported outcomes.

Objectives: To assess the correlation of depressive symptoms with PsA-specific outcome parameters.

Methods: RABBIT-SpA is a prospective longitudinal cohort study including PsA patients enrolled at start of a new conventional treatment or b/tsDMARD treatment. In regularly provided follow-up questionnaires, physician- and patient-reported information on the disease course including the depression screening tool WHO-5 to assess mental health is collected. For the current analysis, the WHO-5 score was categorised into 4 groups using validated cut-offs: severe depressive symptoms <13, moderate depressive symptoms 13-28, mild depressive symptoms 29-50, well-being >50. Spearman correlation coefficient was calculated to analyse the relationship between the WHO-5 score and various PsA related outcome parameters.

Results: 936 PsA patients were included. Baseline characteristics are shown in Table 1. In 411 patients (43.9%) the WHO-5 score indicated well-being, 249

(26.6%) had mild depressive, 203 (21.7%) moderate depressive and 73 patients (7.8%) severe depressive symptoms. WHO-5 results correlated with patient reported skin involvement (DLQI: -0.25, patient assessment skin: -0.17), and the composite scores DAPSA (-0.33) and DAS28 (-0.28) as well as with patient reported pain (-0.43) and patient global disease assessment (-0.42). The highest correlation was found for physician assessed global health status (-0.51) and PSAID (-0.62). No significant correlation was found with CRP, swollen joint count and physician assessed skin involvement including body surface area (BSA).

Table 1. Baseline characteristics of patients included in the analysis stratified by WHO-5 categories.

Parameter	WHO-5 (<13) severe N=73	WHO-5 (13-28) moderate N=203	WHO-5 (29-50) mild N=249	WHO-5 (>50) well-being N=411	Total N=936
Age, mean (SD)	52.6 (11.4)	51 (11.3)	51.4 (12.5)	52.8 (12.7)	52 (12.2)
Female, n (%)	52 (71.2)	127 (62.6)	157 (63.1)	227 (55.2)	563 (60.1)
Disease duration, years, mean (SD)	8.3 (8.7)	6 (7.9)	6.2 (6.7)	6.4 (7.5)	6.4 (7.5)
Dactylitis, n (%)	14 (19.7)	31 (15.5)	46 (18.5)	77 (18.8)	168 (18.1)
Axial involvement, n (%)	14 (19.7)	54 (26.9)	49 (19.7)	71 (17.3)	188 (20.2)
Nail involvement, n (%)	34 (47.2)	85 (42.3)	106 (42.6)	158 (38.6)	383 (41.1)
BMI>=30, n (%)	37 (51.4)	75 (37.1)	98 (39.5)	125 (30.9)	335 (36.2)
CRP of >=5 mg/L, n (%)	33 (51.6)	84 (45.4)	99 (46.5)	138 (39.1)	354 (43.4)
BSA (0-100), mean (SD)	10.1 (18.3)	9.5 (16.8)	8.5 (14.9)	8.1 (14.6)	8.7 (15.5)
Physician assessed global health (NRS 0-10), mean (SD)	6.3 (1.5)	5.6 (1.8)	5.2 (1.7)	4.9 (1.9)	5.2 (1.9)
TJC68, mean (SD)	9.9 (7.1)	8.6 (7.6)	8.2 (7.6)	7.3 (8.2)	8 (7.8)
SJC66, mean (SD)	6 (5.2)	4.8 (4.9)	4.7 (4.4)	4.3 (3.8)	4.6 (4.4)
DAPSA, mean (SD)	29.3 (11.1)	25.1 (12.9)	23.4 (12.1)	18.9 (12.4)	22.3 (12.8)
DAS28-CRP, mean (SD)	4.1 (1)	3.8 (1.2)	3.7 (1.1)	3.2 (1.1)	3.6 (1.2)
Patient assessed global health (NRS 0-10), mean (SD)	7.9 (2.1)	6.6 (2.1)	5.9 (2)	4.8 (2.3)	5.7 (2.4)
Patient assessed pain (NRS 0-10), mean (SD)	7.8 (1.8)	6.4 (2.1)	5.8 (2)	4.6 (2.4)	5.5 (2.4)
DLQI (0-30), mean (SD)	8.5 (8.2)	7.8 (7.2)	5.4 (5.7)	4.1 (4.9)	5.6 (6.2)
PSAID (0-10), mean (SD)	6.9 (1.8)	5.5 (1.8)	4.4 (1.7)	3 (1.7)	4.2 (2.2)

Conclusion: The impact of depressive symptoms on outcome parameters used in rheumatology is increasingly being recognised. Interestingly, direct measures of inflammatory disease activity of joint and skin disease such as BSA, CRP, and swollen joint count were not correlated with depressive symptoms. The highest correlation was found for broader assessments like global health status and PSAID.

Schett[12]. *[1]Catholic University of Sacred Heart, UOC of Rheumatology, Agostino Gemelli University Polyclinic Foundation IRCCS, Roma, Italy*; *[2]University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[3]Novartis Pharma AG, Global Medical Affairs, Basel, Switzerland*; *[4]Amsterdam Rheumatology and Immunology Centre, Amsterdam UMC, Vrije Universiteit, Department of Epidemiology and Data Science, Amsterdam, Netherlands*; *[5]Hospital Fundación Jiménez Díaz and Autónoma University, Department of Rheumatology and Joint and Bone Research Unit, Madrid, Spain*; *[6] VIB Inflammation Research Centre, Ghent University Hospital, Department of Rheumatology, Ghent, Belgium*; *[7]Charles University, Institute of Rheumatology and Department of Rheumatology, Prague, Czech Republic*; *[8]Instituto de Rehabilitacion Psicofisica, Rheumatology, Buenos Aires, Argentina*; *[9]Salt lake Clinic, Intermountain Healthcare Medical Group, Salt lake city, United States of America*; *[10]Novartis Ireland Limited, CTS Stats Analysis, Dublin, Iceland*; *[11]Novartis Healthcare Pvt Ltd, Clinical Project Management, Hyderabad, India*; *[12]Friedrich Alexander University of Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Erlangen, Germany*

Background: Enthesitis is a key clinical domain and imaging hallmark of psoriatic arthritis (PsA). Ultrasound (US) is a highly sensitive tool for detecting synovitis and enthesitis in PsA. The Outcome Measures in Rheumatology Initiative (OMERACT) has developed an US definition and scoring system of enthesitis for clinical studies.[1] The ULTIMATE study (NCT02662985) is the first large double-blind (DB), placebo-controlled phase IIIb study designed to demonstrate a rapid and significant benefit of subcutaneous secukinumab vs. placebo on US detected synovitis in patients with PsA.[2]

Objectives: To report the enthesitis response to secukinumab over 24 weeks using two novel US composite enthesitis scores.

Methods: This was a 52-week study consisting of a 12-week DB, a 12-week open-label (OL) and a 6-month extension period.[2] Inclusion criteria required ≥1 clinical enthesitis as per SPARCC enthesitis index, but not US-assessed enthesitis.[2] Patients were randomised (1:1) to either weekly secukinumab (300 or 150 mg according to severity of skin psoriasis) or placebo followed by 4-weekly dosing thereafter. All placebo patients switched to OL secukinumab (placebo-secukinumab) at Week 12. Throughout the study, enthesitis was assessed with SPARCC and US. Six anatomical sites were assessed bilaterally with US: insertions of lateral epicondyle tendons, quadriceps, patellar ligaments (distal and proximal insertions), Achilles tendons and plantar fascia. Two exploratory global OMERACT-US enthesitis scores were tested: Definition 1 combining power Doppler (PD; 0–3) and Grey Scale (0–1) inflammation and Definition 2 rating PD only (0–3) across the six anatomical sites. Data were analysed with mixed-effect model repeated measures (MMRM) up to Week 12 and as observed from Week 12 to 24. The comparison of OMERACT-US enthesitis score within treatment groups was tested with paired and between treatment groups with unpaired t-tests.

Results: Of 166 patients enrolled, 93% completed 24 weeks of treatment (secukinumab, 95%; placebo-secukinumab, 92%). The average clinical enthesitis count at baseline was 4. Since the presence of PD was not a mandatory inclusion criterion, a higher proportion of patients met Global OMERACT-US enthesitis score with Definition 1 vs. Definition 2 (81% vs. 33%) at baseline (Table). Mean reduction from baseline to Week 24 in SPARCC enthesitis index was 3 each for initial secukinumab and placebo-secukinumab groups. Resolution of enthesitis (SPARCC) was 46% for initial secukinumab and 54% for placebo-secukinumab groups at Week 24. A comparable decrease in OMERACT-US enthesitis (Definition 1 and 2) score was observed from baseline to Week 24 for initial secukinumab and placebo-secukinumab groups (Figure).

Table 1. Distribution of US detected enthesitis at baseline according to OMERACT enthesitis score Definition 1 and 2

	Secukinumab		Placebo	
	Def 1 >0	Def 2 >0	Def 1 >0	Def 2 >0
N=	73	34	61	20
Anatomical sites, %				
Achilles tendon	49	12	45	2
Lateral epicondyle	49	21	46	21
Patellar ligament distal insertion	34	8	29	4
Patellar ligament proximal insertion	34	10	18	4
Plantar fascia	36	0	28	0
Quadriceps insertion	55	12	40	2

Proportion of patients is irrespective of the enthesitis site left or right side. N, total number of patients

Conclusion: A consistent clinical and US response on enthesitis was shown through 24 weeks across initial secukinumab and placebo switcher groups. While ULTIMATE has demonstrated the responsiveness of these global OMERACT-US enthesitis scores, further work is required to test these scores in PsA cohorts with inclusion criteria for both clinical and US enthesitis.

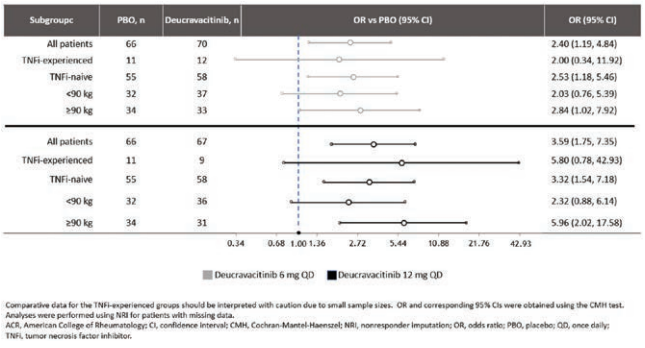
Background: Tyrosine kinase 2 (TYK2) is an intracellular kinase that mediates IL-23, IL-12, and IFNα/β signaling. Deucravacitinib is a novel, oral selective inhibitor of TYK2 acting via the TYK2 regulatory domain. Phase 2 results showed deucravacitinib was efficacious and well tolerated versus placebo (PBO) in patients with active psoriatic arthritis (PsA).

Objectives: This analysis further evaluated improvements in musculoskeletal disease manifestations in patients in the Phase 2 PsA trial.

Methods: The ongoing Phase 2 trial (NCT03881059) enrolled patients who had a PsA diagnosis for ≥6 months, met CASPAR criteria, had active disease (≥3 tender joints, ≥3 swollen joints, C-reactive protein [CRP] ≥3 mg/L), and had at least 1 active skin lesion. Patients either failed or were intolerant to at least 1 nonsteroidal anti-inflammatory drug, corticosteroid, conventional synthetic disease-modifying antirheumatic drug, and/or 1 TNF inhibitor (TNFi; ≤30%). Patients were randomized 1:1:1 to deucravacitinib 6 mg QD or 12 mg QD or PBO, and stratified by TNFi status (experienced vs naive) and body weight (<90 vs ≥90 kg). The primary endpoint, ACR20 response at Week 16, was met and significant improvements in enthesitis vs PBO were observed. The current prespecified subgroup analysis assessed the likelihood of achieving ACR20 response at Week 16 based on study stratification factors. A post hoc analysis evaluated mean change from baseline to Week 16 in ACR components (tender joint count, swollen joint count, Physician's Global Assessment of PsA, Patients' Global Assessment of disease activity, Patients' Global Assessment of pain, high-sensitivity CRP [hCRP], and HAQ-DI score). Analyses were descriptive using data as observed.

Results: Patients treated with deucravacitinib were numerically more likely to achieve ACR20 response at Week 16 compared with PBO-treated patients regardless of TNFi experience or body weight, although some of these groups were small (Figure). Improvements for deucravacitinib 6 mg and 12 mg QD versus PBO were observed in all ACR components, with apparent separation occurring as early as Week 4 on, for example, HAQ-DI (mean change from baseline, -0.2 vs -0.2 vs -0.1, respectively) and hCRP (mean change from baseline, -7.4 vs -5.2 vs 0.3, respectively) and maintained through Week 16 (Table).

Figure. ACR20 subgroup analysis at Week 16



Comparative data for the TNFi-experienced groups should be interpreted with caution due to small sample sizes. OR and corresponding 95% CIs were obtained using the CMH test. Analyses were performed using NRI for patients with missing data.
ACR, American College of Rheumatology; CI, confidence interval; CMH, Cochran-Mantel-Haenszel; NRI, nonresponder imputation; OR, odds ratio; PBO, placebo; QD, once daily; TNFi, tumor necrosis factor inhibitor.

Table 1. Mean (SD) change from baseline for ACR components

	TJC	SJC	PtGA	Pain	PGA	HAQ-DI	hCRP
Baseline[a]							
PBO	16.9 (9.8)	10.5 (7.7)	66.2 (15.8)	64.9 (18.2)	63.8 (14.8)	1.3 (0.6)	20.4 (39.1)
DEUC 6	18.1 (10.3)	11.9 (7.0)	68.2 (16.8)	63.6 (21.7)	68.2 (14.7)	1.3 (0.6)	17.6 (23.6)
DEUC12	19.4 (11.8)	11.3 (9.0)	63.6 (15.6)	63.8 (15.9)	63.3 (16.1)	1.3 (0.6)	16.5 (21.7)
Week 16[b]							
PBO	-4.6 (9.7)	-4.3 (8.0)	-13.4 (23.5)	-13.8 (21.5)	-19.9 (21.8)	-0.1 (0.4)	-3.3 (22.6)
DEUC 6	-9.3 (9.7)	-7.7 (5.8)	-28.7 (23.1)	-25.3 (26.1)	-33.6 (23.0)	-0.4 (0.5)	-14.2 (24.5)
DEUC 12	-12.2 (10.2)	-8.5 (9.1)	-27.6 (25.8)	-27.5 (25.0)	-32.2 (25.0)	-0.4 (0.6)	-10.9 (22.8)

PBO, n/N=58/66; DEUC 6, n/N=63/70; DEUC 12, n/N=59/67; n/N = number of patients who completed treatment/number of patients randomized; the number of patients with data available for individual components at each time point may vary.[a]Mean (SD). [b]Mean (SD) change from baseline.ACR, American College of Rheumatology; DEUC 6, deucravacitinib 6 mg QD; DEUC 12, deucravacitinib 12 mg QD; HAQ-DI, Health Assessment Questionnaire-Disability Index total score; hCRP, high-sensitivity C-reactive protein; PBO, placebo; PGA, Physician's Global Assessment of psoriatic arthritis; PtGA, Patients' Global Assessment of disease activity; QD, once daily; SJC, swollen joint count; TJC, tender joint count.

Conclusion: Analyses confirmed the efficacy of deucravacitinib versus PBO across TNFi and body weight subgroups. With deucravacitinib treatment, improvements were displayed in all ACR components.

OP0228

EFFICACY AND SAFETY OF RISANKIZUMAB FOR ACTIVE PSORIATIC ARTHRITIS, INCLUDING PATIENTS WITH INADEQUATE RESPONSE OR INTOLERANCE TO BIOLOGIC THERAPIES: 24-WEEK RESULTS FROM THE PHASE 3, RANDOMIZED, DOUBLE-BLIND, KEEPSAKE 2 TRIAL

A. Ostor[1], F. Van den Bosch[2], K. Papp[3], C. Asnal[4], R. Blanco[5], J. Aelion[6], G. Alperovich[7], Y. Zhang[8], Z. Wang[8], A. M. Soliman[8], A. Eldred[8], A. Kivitz[9]. *[1]Monash University, Cabrini Hospital, and Emertius Research, Melbourne, Australia*; *[2]Ghent University, Department of Rheumatology, Gent, Belgium*; *[3]Probity Medical Research, K. Papp Clinical Research, Waterloo, Canada*; *[4]Buenos Aires, DOM Centro de Reumatología, Buenos Aires, Argentina*; *[5]Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain*; *[6]West Tennessee Research Institute, Not Applicable, Jackson, United States of America*; *[7]AbbVie, Inc, Not Applicable, Madrid, Spain*; *[8]AbbVie, Inc, Not Applicable, North Chicago, United States of America*; *[9]Altoona Center for Clinical Research, Not Applicable, Duncansville, United States of America*

Background: Risankizumab (RZB) is a humanized immunoglobin G1 monoclonal antibody that specifically inhibits interleukin 23 by binding its p19 subunit. RZB is being investigated as a treatment for adults with psoriatic arthritis (PsA).
Objectives: To compare the efficacy and safety of RZB vs placebo (PBO) for the treatment of active PsA in patients who have had inadequate response or intolerance to 1 or 2 biologic therapies (Bio-IR) or to ≥ 1 conventional synthetic disease modifying antirheumatic drug (csDMARD-IR).
Methods: KEEPsAKE 2 (NCT03671148) enrolled adults with active PsA (≥ 5 swollen joints [SJC] and ≥ 5 tender joints [TJC]) who were Bio-IR or csDMARD-IR. Patients were randomized to receive blinded subcutaneous RZB 150 mg or PBO at weeks 0, 4, and 16. The primary endpoint was the proportion of patients achieving ≥ 20% improvement in American College of Rheumatology score (ACR20) at week 24. Ranked secondary endpoints and other secondary endpoints are shown in the Table. Safety was assessed throughout the study. Results reported here are from the 24-week double-blind period; the open-label period with all patients receiving RZB is ongoing.
Results: A total of 443 patients (RZB, N = 224; PBO, N = 219) were included in the analysis. Demographics and baseline disease characteristics were similar across treatment arms (mean SJC: 13.3; mean TJC: 22.6; mean duration of PsA: 8.2 years; mean body surface area involved with psoriasis [BSA] in patients with BSA ≥ 3%: 12.1%); 206 patients (46.5%) were Bio-IR. Significantly greater proportions of RZB-treated patients vs PBO-treated patients achieved the primary endpoint (51.3% vs 26.5%, respectively; $P < .001$) and all ranked secondary endpoints ($P < .001$ for all except for Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-Fatigue; $P < .009$]; Table). Other secondary outcomes also showed improvement for RZB- vs PBO-treated patients (Table). Serious adverse events were reported for 4.0% and 5.5% of RZB- and PBO-treated patients, respectively; serious infections were reported for 0.9% and 2.3%.
Conclusion: RZB resulted in significantly greater improvements in signs and symptoms of PsA compared with PBO and was well tolerated in patients who were Bio-IR or csDMARD-IR.

Table. Efficacy Results

	RZB 150 mg N = 224	PBO N = 219	Difference (95% CI)	*P* value[a]

Background: Since the 2015 GRAPPA treatment recommendations were published, therapeutic options and management strategies for psoriatic arthritis (PsA) have advanced considerably.

Objectives: The goal of the GRAPPA recommendations update is to develop high quality, evidence-based recommendations for the treatment of PsA, including related conditions and comorbidities.

Methods: GRAPPA rheumatologists, dermatologists and patient research partners (PRPs) updated overarching principles for the management of adults with PsA by consensus. Principles considering use of biosimilars and tapering/discontinuing of therapy were added to this update. Systematic literature searches based on data publicly available from three databases (MEDLINE, EMBASE, and Cochrane CENTRAL) were conducted from the end of the previous recommendations' searches through August 2020. Additional abstract searches were performed for conference presentations in 2017-2020. Searches covered PsA treatments (peripheral arthritis, axial arthritis, enthesitis, dactylitis, skin, and nail disease). Additional searches were performed for related conditions (uveitis and IBD) and comorbidities evaluating their impact on safety and treatment outcomes. Individual groups assessed the risk of bias and applied the GRADE system to generate strong or conditional recommendations for therapies within the domain groups and for the management of comorbidities and related conditions. These recommendations were then incorporated into an overall treatment schema.

Results: Updated, evidence-based treatment recommendations are shown (Table 1). Since 2015, many new medications have been incorporated. Additional results for older medications, such as methotrexate, have been published across PsA domains. Based on the evidence, the treatment recommendations developed by individual groups were incorporated into the overall schema including principles for management of arthritis, spondylitis, enthesitis, dactylitis, skin, and nail disease in PsA, and associated conditions (Figure 1). Choice of therapy for an individual should ideally address all of the domains that impact on that patient, supporting shared decision making with the patient involved. Additional consideration in the recommendations was given to key associated conditions and comorbidities as these often impact on therapy choice.

Conclusion: These GRAPPA treatment recommendations provide up to date, evidence-based guidance to providers who manage and treat adult patients with PsA. These recommendations are based on domain-based strategy for PsA and supplemented by overarching principles developed by consensus of GRAPPA members.

EFFICACY AND SAFETY OF GUSELKUMAB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS WHO DEMONSTRATED INADEQUATE RESPONSE TO TUMOR NECROSIS FACTOR INHIBITION: WEEK 24 RESULTS OF A PHASE 3B, RANDOMIZED, CONTROLLED STUDY

L. C. Coates[1], L. Gossec[2], E. Theander[3], P. Bergmans[4], M. Neuhold[5], C. Karyekar[6], M. Shawi[6], W. Noel[5], G. Schett[7], I. Mcinnes[8]. [1]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; [2]*Sorbonne Université, Professor of Rheumatology, Paris, France*; [3]*Janssen Scientific Affairs, LLC, Immunology, Solna, Sweden*; [4]*Janssen, Biostatistics, Breda, Netherlands*; [5]*Janssen Scientific Affairs, LLC, Immunology, Brussels, Belgium*; [6]*Janssen Global Services, LLC, Immunology, Horsham, United States of America*; [7]*University of Erlangen-Nuremberg, Internal Medicine 3, Erlangen, Germany*; [8]*University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom*

Background: Guselkumab (GUS), a selective monoclonal antibody targeting the interleukin-23p19 subunit, has demonstrated efficacy in 2 pivotal Ph3 psoriatic arthritis (PsA) studies (DISCOVER-1,[1] DISCOVER-2[2]).

Objectives: Evaluate GUS efficacy and safety in PsA patients (pts) with inadequate response (IR) to tumor-necrosis-factor inhibition (TNFi) through Week24 (W24) of the Ph3b COSMOS study.

Methods: In this randomized, double-blind, placebo (PBO)-controlled trial, 285 pts with active PsA (≥3 swollen & ≥3 tender joints) who demonstrated lack of benefit or intolerance to 1-2 TNFi were randomized 2:1 to subcutaneous GUS 100mg (n=189) or PBO (n=96) at W0, W4, then every 8 weeks (Q8W) through W44 (with PBO crossover to GUS at W24). At W16, pts who met early escape (EE) criteria (<5% improvement in both tender & swollen joint counts) also could switch from PBO to GUS. The primary efficacy endpoint was ACR20 response at W24 among randomized, treated pts. Pts missing ACR20 data at W24 or who met treatment failure criteria (including meeting EE criteria at W16) were considered nonresponders (NRs). Subgroup analyses were performed to assess consistency of primary treatment effect based on demographics, disease characteristics, and medication use at baseline. Prespecified sensitivity analyses included 'Per-Protocol' (PP) (excluded pts with major protocol deviations) and 'EE-Correction' (included pts incorrectly routed to EE) analyses. Adverse events (AEs) were summarized by treatment received.

Results: Baseline characteristics were similar across GUS and PBO pts, though a higher proportion of females and more severe joint symptoms were seen in the GUS group. At W24, 44.4% of GUS vs 19.8% of PBO pts achieved ACR20 (p<0.001) (Figure). GUS was superior to PBO for all major secondary endpoints. Efficacy was consistent across subgroups defined by baseline characteristics, including in pts who discontinued prior TNFi use due to inadequate efficacy (84% GUS vs 81% PBO) and safety (16% GUS vs 19% PBO) (Table). 20 pts (12 GUS, 8 PBO) were incorrectly routed to EE. Results of PP (48.8% vs 23.8%) and EE-correction (48.1% vs 19.8%) sensitivity analyses were consistent with the primary analysis (Figure). AEs were similar between GUS- and PBO-treated pts (Table).

Table 1. Baseline characteristics of, and adverse events reported by, randomized and treated COSMOS pts

	GUS 100 mg Q8W (N=189)	PBO (N=96)
Age, y	49	49
Sex, Female	54%	46%
Duration of PsA, y	8.3	8.7
Body mass index, kg/m^2	29	31[a]
Swollen (0-66) / tender (0-68) joint count	10 / 21	9 / 18
Pt pain / Pt global arthritis / Physician global disease, 0-10 cm VAS	6.5 / 6.5 / 6.9	6.0 / 6.2 / 6.4
Health Assessment Questionnaire-Disability Index, 0-3	1.3[b]	1.2
C-reactive protein, mg/dL	1.2[b]	1.2
Methotrexate use at baseline	56%	53%
Psoriatic body surface area, %	17.9	13.4
Number of prior TNFi: 1 / 2	88% / 12%	89% / 11%
Reason for prior TNFi discontinuation: Efficacy / Safety	84% / 16%*	81% / 19%*
Pts with ≥1 AE / SAE	37% / 3%	48% / 3%
Pts with ≥1 infection / serious infection	18% / 0%	20% / 0%
Pts with ≥1 AE leading to study agent discontinuation	2%	2%
Pts with ≥1 malignancy	0.4%	0
Pts with ≥1 injection-site reaction	2%	1%

Data shown are mean or %. [a]N=95; [b]N=188. *Missing for 1 pt. *SAE – serious adverse events*; *VAS – visual analog scale*

Conclusion: In this Ph3b, placebo-controlled study of PsA pts with IR to 1-2 TNFi, GUS 100 mg Q8W elicited a significantly higher ACR20 response rate vs.

PBO at W24; results of prespecified sensitivity and subgroup analyses were consistent. GUS safety in TNF-IR PsA pts through W24 is consistent with the favorable GUS safety profile in psoriasis and biologic-naïve PsA pts.[3]

OP0231

DIFFERENCES IN REAL-WORLD PATIENT CHARACTERISTICS OF 8921 PSORIASIS PATIENTS WITH AND WITHOUT COMORBID PSORIATIC ARTHRITIS USING THE UK BADBIR DATABASE

W. Tillett[1], A. Ogdie[2], P. Gorecki[3], A. Passey[4]. [1]*Royal National Hospital for Rheumatic Diseases, Rheumatology, Bath, United Kingdom*; [2]*University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States of America*; [3]*Janssen, Medical Affairs, High Wycombe, United Kingdom*; [4]*Janssen Real World Evidence, HEMAR EMEA, High Wycombe, United Kingdom*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with psoriasis (PsO) and multiple comorbidities.[1] Approximately one-third of PsO patients develop PsA during the course of their disease.[2] As patient cohorts included in randomised clinical trials are not necessarily representative of the real world, registry data can complement any information gained on patient characteristics and disease outcomes.[3] The British Association of Dermatologists Biologic and Immunomodulators Register (BADBIR) is one such registry for patients with plaque PsO, with PsA being one of the recorded comorbidities at time of patient enrolment into the database.

Objectives: The primary objective of this study was to evaluate baseline characteristics and comorbidities in PsO patients with and without a PsA diagnosis using the BADBIR database. The hypothesis was that patients with both diseases show a higher likelihood of being diagnosed with additional comorbid conditions vs. PsO alone.

Methods: This was a retrospective observational study using two cohorts of BADBIR data (i.e. adult PsO patients either receiving ustekinumab [UST] as their biologic treatment or receiving conventional systemic anti-psoriatic medication [conventional systemic]). Comparisons were made between PsA and PsO alone in each cohort at baseline, additionally stratifying by biologic experience in the UST treatment group. Baseline characteristics of interest were evaluated, including body mass index, smoking and employment status, as well as comorbidities (i.e. diabetes, hypertension, myocardial infarction and depression). Effect sizes and 95% confidence intervals were generated via matching with a two-sided Fisher's exact test.

Results: Cohort patient counts were as follows: 2697 UST treated without PsA; 590 UST treated with PsA; 5105 conventional systemic without PsA; 529 conventional systemic with PsA. PsO patients with a PsA diagnosis had a higher prevalence of diabetes, obesity and hypertension across both conventional systemic and UST cohorts vs. PsO alone (Table 1). Similarly, inability to work was notably higher in PsO patients with PsA vs. PsO alone (Figure 1). Patients with PsO and comorbid PsA who were receiving UST were more likely to have a diagnosis of depression than those receiving conventional systemic treatment (Table 1).

Table 1. Prevalence odds ratio of baseline characteristics of patients with PsO treated with either UST or a conventional systemic agent.

Baseline variable	Treatment cohort	Odds ratio	95% CI
Ability to work	UST	0.27	0.21–0.35
	Conventional systemic	0.49	0.37–0.65
Smoking	UST	0.94	0.76–1.17
	Conventional systemic	0.72	0.58–0.89
Depression	UST	1.54	1.25–1.88
	Conventional systemic	1.14	0.91–1.42
Obesity*	UST	1.34	1.11–1.62
	Conventional systemic	1.21	1.01–1.46
Diabetes	UST	1.45	1.10–1.89
	Conventional systemic	1.51	1.11–2.04
Hypertension	UST	1.54	1.26–1.87
	Conventional systemic	1.30	1.03–1.62
Myocardial infarction	UST	1.67	0.98–2.76
	Conventional systemic	1.17	0.56–2.21

Odds ratios and 95% CIs are shown for the prevalence of each patient baseline characteristic in the PsO with comorbid PsA group vs. the prevalence in the PsO group. *Obesity is defined as a BMI ≥30 kg/m^2. BMI, body mass index; CI, confidence interval; PsA, psoriatic arthritis; PsO, psoriasis; UST, ustekinumab.

Conclusion: These results indicate that PsO patients with PsA had a higher prevalence of obesity, diabetes, hypertension and inability to work vs. PsO alone. Depression also seems to be more prevalent in PsO patients with comorbid PsA receiving biologic treatment vs. those receiving conventional systemics. These results potentially indicate a higher inflammatory and quality-of-life burden in PsO patients with a PsA diagnosis, highlighting the need for adequate patient assessment and follow-up to ensure a best possible holistic patient management approach.

Background: Sex-related differences in biologic treatment of psoriatic arthritis (PsA) have been insufficiently studied in a real-world setting.
Objectives: To evaluate impact of sex on PsA, treatment effectiveness and persistence after 1 year of biologic treatment.
Methods: PsABio (NCT02627768) is a multinational, prospective real-world study in PsA with ustekinumab (UST) or TNF inhibitor (TNFi) as 1st/2nd/3rd-line biologic. Males and females were compared for disease activity and patient-reported outcomes. Descriptive statistics including 95% CI at baseline (BL) and 12 (±3) months (LOCF) follow-up are presented. Intra-sex comparisons between UST and TNFi cohorts were done by logistic regression analysis, with propensity score adjustment for imbalanced BL covariates and non-response imputation for stopping/switching biologic drugs.
Results: Among 494 females and 399 males, age and disease duration were similar. However, differences in disease characteristics at BL were considerable:

Data are % (95% CI) unless indicated otherwise. Bold data are significantly different (non-overlapping 95% CI).

females had worse scores than males for cDAPSA, HAQ-DI, EQ5D VAS, PsAID-12, pain and comorbidities. At 1 year, similar improvements from BL were observed between sexes, but females remained in a worse health state than males (Table). Achievement of composite endpoints MDA (including VLDA) and cDAPSA LDA (including remission) was high overall (38.6% and 61.5%, respectively), but reached by >2-fold and 3-fold more males than females, respectively. HAQ-DI scores remained worse for females at 1 year (0.95) than for males at BL (0.93). Enthesitis resolution was achieved in 46% of females and 75% of males. No significant differences in effectiveness of UST vs TNFi were detected between sexes (Figure). Kaplan–Meier estimated drug persistence was significantly better in males than females (log-rank p=0.0007). There was no intra-sex difference between UST or TNFi in risk of stopping/switching in males or females.

Conclusion: These real-world data from PsABio on sex differences with biologic treatment suggest that females generally start biologics in a worse PsA state than males. Although treatment improvements were similar between sexes, females remained in worse health at 1 year, and stopped/switched biologic earlier. More comprehensive treatment before severe disease manifestations evolve may improve management in females.

OP0233

EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS AND AXIAL INVOLVEMENT

A. Deodhar[1], R. Ranza[2], F. Ganz[3], T. Gao[4], J. Anderson[4], A. Ostor[5].
[1]*Oregon Health & Science University, Rheumatology, Portland, United States of America*; [2]*Universidade Federal de Uberlândia, Rheumatology, Uberlândia, Brazil*; [3]*AbbVie Inc., Rheumatology, Baar, Switzerland*; [4]*AbbVie Inc., Rheumatology, North Chicago, United States of America*; [5]*Cabrini Hospital, Monash University & Emeritus Research, Melbourne, Australia*

Background: Patients (pts) with psoriatic arthritis (PsA) and axial involvment exhibit greater disease activity and quality of life impairments compared with those without axial involvment.
Objectives: To characterize PsA pts with and without axial involvement and compare efficacy of UPA vs placebo (PBO) in PsA pts with axial involvement.
Methods: In SELECT-PsA 1 (NCT03104400; N=1705, non-biologic DMARD IR) and SELECT-PsA 2 (NCT03104374; N=642, biologic DMARD IR), pts with active PsA (≥3 swollen and ≥3 tender joints), active or historical psoriasis, and on ≤2 non-biologic DMARDs were randomized to once daily UPA 15 mg, UPA 30 mg, adalimumab 40 mg every other week (SELECT-PsA 1 only), or PBO. Efficacy was assessed in pts with axial involvement (diagnosed by investigators based on totality of information) pooled from the 2 studies. Assessments included change from BL in BASDAI, BASDAI Q2 (neck/back/hip pain) and Q3 (joint swelling/pain), and the AS Disease Activity Score (ASDAS-CRP), and percentage with BASDAI 50 response, ASDAS inactive disease (ID), ASDAS low disease activity (LDA), ASDAS major improvement (MI), and ASDAS clinically important improvement (CII). Uveitis and inflammatory bowel disease (IBD) adverse events were reviewed. Data on 24-week PBO-controlled period are presented.
Results: Prevalence of axial involvment was 31.3% in SELECT-PsA 1 and 34.2% in SELECT-PsA 2 (Table). Treatment with UPA 15 mg and 30 mg resulted in significantly greater improvements from BL in the BASDAI, BASDAI Q2 (neck/back/hip pain) and Q3 (joint swelling/pain) and ASDAS-CRP at weeks 12 and 24 vs PBO (Figure). Similarly, significantly higher percentages of pts on UPA 15 mg and 30 mg achieved BASDAI 50, ASDAS ID, LDA, MI, and CII at weeks 12 and 24 vs PBO (Figure). One pt on UPA 30 mg had incident uveitis, and no IBD was reported on UPA.
Conclusion: PsA pts with axial involvement had higher BL disease burden compared with those without axial involvement. UPA was efficacious in treating axial symptoms in pts with psoriatic spondylits.

RISK OF ACUTE MYOCARDIAL INFARCTION AMONG NEW USERS OF CHONDROITIN SULPHATE: A NESTED CASE-CONTROL STUDY

R. Mazzucchelli[1], S. Rodriguez-Martin[2], A. García-Vadillo[3], M. Gil[4], A. Rodríguez-Miguel[2], D. Barreira-Hernández[5], A. García-Lledó[6], F. De Abajo[7]. *[1]Hospital Universitario Fundación Alcorcón, Rheumatologu Unit, Alcorcón, Spain*; *[2]Hospital Universitario Príncipe de Asturias, Clinical Pharmacology Unit, Alcalá de Henares, Spain*; *[3]Hospital de La Princesa, Rheumatologu Unit, Madrid, Spain*; *[4]Spanish Agency of Medicines and Medical Devices, Division of Pharmacoepidemiology and Pharmacovigilance, Madrid, Spain*; *[5]Hospital Universitario Príncipe de Asturias, Clinical Pharmacology Unit, Meco, Spain*; *[6]Hospital Universitario Príncipe de Asturias, Department of Cardiology, Alcalá de Henares, Spain*; *[7]Hospital Universitario Príncipe de Asturias, 2 Clinical Pharmacology Unit, Alcalá de Henares, Spain*

Background: There is some evidence from epidemiological studies suggesting that CS and glucosamine could play a role in cardiovascular disease (CVD) prevention (1-4).Studies to date have included prevalent users, therefore a bias that overestimates protection cannot be excluded.
Objectives: To test the hypothesis that chondroitin sulphate (CS) or glucosamine reduce the risk of acute myocardial infarction (AMI).
Methods: Case-control study nested in a primary cohort composed of patients aged 40 to 99 years, with at least one year of follow-up in the BIFAP database during the 2002-2015 study period. From this cohort of patients, we identified incident cases of AMI and randomly selected five controls per case, matched by exact age, gender, and index date. Adjusted odds ratios (AOR) and their corresponding 95% confidence interval (CI)) were calculated through a conditional logistic regression. Only new users of CS or glucosamine were considered.
Results: A total of 23,585 incident cases of AMI and 117,405 controls were included. The mean age was 67.0 (SD 13.4) years and 71.75% were male, in both groups. 558 (2.37%) cases and 3,082 (2.62%) controls used or had used CS. The current use of CS was associated with a lower risk of AMI (AOR 0.57; 95%CI: 0.46–0.72) and disappeared after discontinuation (recent and past users). The reduced risk among current users was observed in both short-term (<365 days AOR 0.58; 95%CI: 0.45-0.75) and long-term users (>364 days AOR 0.56; 95%CI 0.36-0.87), in both sexes (men, AOR=0.52; 95%CI:0.38-0.70; women, AOR=0.65; 95%CI: 0.46-0.91), in individuals over or under 70 years of age (AOR=0.54; 95%CI:0.38-0.77, and AOR=0.61; 95%CI:0.45-0.82, respectively) and in individuals at intermediate (AOR=0.65; 95%CI:0.48-0.91) and high cardiovascular risk (AOR=0.48;95%CI:0.27-0.83), but not in those at low risk (AOR=1.11; 95%CI:0.48-2.56). In contrast, the current use of glucosamine was not associated with either increased or decreased risk of AMI (AOR= 0.86; CI95% 0.66-1.08)
Conclusion: Our results support a cardioprotective effect of CS, while no effect was observed with glucosamine. The highest protection was found among subgroups at higher cardiovascular risk.

OP0235

PRO-INFLAMMATORY DIET AND RISK OF INCIDENT GOUT: 3 PROSPECTIVE COHORT STUDIES OF US MEN AND WOMEN

N. McCormick[1,2,3,4], C. Yokose[1,2,3], L. Lu[4], A. Joshi[2,3,5], H. Choi[1,2,3,4]. *[1]Massachusetts General Hospital, Clinical Epidemiology Program, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America*; *[2]Harvard Medical School, Medicine, Boston, United States of America*; *[3]Massachusetts General Hospital, The Mongan Institute, Boston, United States of America*; *[4]Arthritis Research Canada, Richmond, Canada*; *[5]Massachusetts General Hospital, Clinical & Translational Epidemiology Unit, Boston, United States of America*

Background: Emerging evidence suggests inflammation may drive progression from hyperuricemia to clinical gout, but the role of extrinsic, modifiable sources of chronic inflammation, such as diet, on gout risk is unknown. Notably, greater dietary inflammatory potential has been independently associated with increased risk of incident cardiovascular disease (CVD)[1] and type 2 diabetes (T2D).[2]
Objectives: Prospectively examine the relation between dietary inflammatory potential and risk of gout in three large cohorts of US women and men over 30 years.
Methods: Ascertaining the ACR survey criteria for gout for several decades,[3] we studied gout risk among 164,090 women from Nurses Health Study I (1986-2016) and II (1989-2017) and 40,598 men from Health Professionals Follow-up Study (1986-2016), free of gout at baseline. Dietary intake and covariates were assessed by validated questionnaires every 4 years. Inflammatory potential of diet was evaluated using a food-based empirical dietary index of inflammatory potential score (EDIP) pre-defined based on circulating levels of IL-6, C-reactive protein, adiponectin, and TNFαR2.[4]
We assigned an EDIP score for each participant, adjusted for total energy take, and prospectively examined the association between quintiles of EDIP score and incident gout, adjusting for potential confounders. We also stratified by alcohol intake, as alcohol has anti-inflammatory properties,[4] but is associated with a higher gout risk, particularly beer.[5]
Results: We documented 2,874 incident gout cases over 5,124,940 person-years of follow-up. In pooled multivariable-adjusted analyses, those in the highest EDIP quintile had 59% higher gout risk (multivariable RR 1.59; 95% CI 1.41–1.79), compared with the lowest (Table **1**). This remained positive with further adjustment for BMI, a likely causal intermediate (RR 1.27, 1.12 to 1.42), and was stronger among non-drinkers (RR 2.37, 1.58 to 2.56) than drinkers (RR 1.57, 1.38 to 1.78) (Table 1).

Table 1. Risk Ratio (95% CI) of Gout According to Quintiles of Inflammatory Diet Score, Overall and by Alcohol Use

MV-Adjusted* RR	1.00 (Ref)	1.04 (0.91, 1.19)	1.13 (0.99, 1.29)	1.31 (1.15, 1.50)	1.57 (1.38, 1.78)	<0.001
MV-Adjusted** RR (+ BMI)	1.00 (Ref)	1.00 (0.88, 1.14)	1.05 (0.92, 1.20)	1.17 (1.03, 1.33)	1.28 (1.12, 1.46)	<0.001

*Multivariable (MV) models adjusted for age (month), White race, smoking, menopause (women only), hormone use (women only), physical activity, history of hypertension, and diuretic use. **MV + BMI models additionally adjusted for BMI (a likely causal intermediate)

Conclusion: Habitual pro-inflammatory dietary pattern was independently associated with higher risk of incident gout in these prospective cohorts, even beyond the pathway through adiposity. Our findings support a role for chronic inflammation in development of gout, similar to CVD[1] and T2D.[2] Adhering to a diet with lower inflammatory potential may modulate systemic inflammation, potentially reducing gout risk and these life-threatening comorbidities.

OP0236 THE EFFECT OF UV-B RADIATION EXPOSURE ON THE RISK OF DEVELOPING RHEUMATOID ARTHRITIS

J. Hagman[1], B. Delcoigne[1], L. Klareskog[1], L. Alfredsson[1], J. Askling[1].
[1]*Karolinska Institute, Department of Medicine, Division of Clinical Epidemiology, Stockholm, Sweden*

Background: UV-B radiation has known immunomodulatory properties, but to what extent UV-B radiation exposure might affect the occurrence of rheumatoid arthritis (RA) has been relatively little studied, and with partially contradictory results.

Objectives: To investigate the association between sun- and travel habits, as proxy markers for UV-B radiation exposure, and risk of incident RA, overall and by RA subtype.

Methods: We performed a matched case-control study of 1151 incident cases with new-onset RA and 2374 population controls from the Swedish Epidemiological Investigation of Rheumatoid Arthritis (EIRA) study, recruited between 2006 and 2017. The association between sunbathing frequency, solarium use, and frequency of travels to sunnier countries than Sweden (exposures) and risk of RA (outcome) were assessed as odds ratios (OR) with 95 % confidence intervals (CI) through logistic regression, and adjusted for age, sex, residential region, year of study entry, body mass index, education, income, smoking and alcohol consumption. We further assessed effect modification by self-reported skin type, income and education, and by rheumatoid factor (RF) serostatus.

Results: Overall, the frequency of sunbathing, and solarium use, were similar among RA cases and controls: 'never doing sunbathing' amongst RA cases vs. controls: 22% vs. 21 %, 'sunbathing daily when possible': 10% vs. 12%, and solarium use 13% vs. 12%. The proportion of 'not travelled abroad to a sunnier country than Sweden during the past 5 years' was higher for RA cases than controls: 27% vs. 23%, and 'travelling abroad more than once a year' was less common among RA cases: 15% vs. 20%.

Sunbathing frequency was not linked to risk of RA (OR 0.91, 95% CI 0.69-1.20), nor was solarium use (OR 1.07, 95% CI 0.85-1.35). Stratification by skin type revealed no major effect modification, nor did stratification by RF status. In contrast, frequency of travel to sunnier countries than Sweden was inversely associated with RA risk comparing the most to least frequent travelers (OR 0.68, 95% CI 0.54-0.87). When stratified by educational level, this association was confined to individuals with medium (OR 0.69, 95% CI 0.48-0.98) or high (OR 0.60, 95% CI 0.50-0.91) and absent among subjects with low education (OR 1.10, 95% CI 0.56-1.99). No such interaction was observed between travel habits and income.

Table 1. RA cases and controls with adjusted odds ratios and confidence intervals for overall risk of RA and by RA serostatus.

	N				OR* for RA (95% CI)

OP0237 EXPOSURE TO ENVIRONMENTAL AIR POLLUTANTS AS A RISK FACTOR FOR PRIMARY SJÖGREN'S SYNDROME: A POPULATION-BASED COHORT STUDY

K. S. K. MA[1], L. T. Wang[2]. [1]*National Taiwan University, Taipei, Taiwan, ROC, Department of Life Science, Taipei, Taiwan, Republic of China*; [2]*National Taiwan University Hospital, Department of Obstetrics & Gynecology, Taipei, Taiwan, Republic of China*

Background: Recent studies suggest that air pollution may play a role in autoimmune diseases. However, few of them report the correlation between air pollution and primary Sjögren's syndrome (pSS).

Objectives: We sought to determine whether people exposed to environmental fine particulate of air pollution have a higher risk of developing pSS.

Methods: We performed a retrospective population-based cohort study from the National Health Insurance Research Database (NHIRD) of Taiwan's population, using the international Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) to categorize each disease diagnosis. Air pollution data on Nitric oxide (NO), methane (CH4), and carbon monoxide (CO) were obtained from the Taiwan Air Quality-Monitoring Database (TAQMD), where daily air pollution data from community-based monitoring sites (78 sites since 1993) was available on a real-time basis. We followed up from January 1st, 1998 to the endpoint of SS diagnosis or to December 31, 2011. The daily average air pollutant concentrations were divided into 4 quartile-based groups (Q1-Q4). The incidence rate, hazard ratios (HRs), as well as 95% confidence intervals for pSS, were stratified by the quartiles of air pollutant concentration, and calculated with a Cox proportional regression model. Finally, Ingenuity Systems Pathway Analysis (IPA) was conducted to identify activated pathways among air way epithelial cells exposed to airborne coarse, fine, and ultrafine particles, and parotid gland tissues from pSS patients using Z-score visualization.

Results: A total of 200 patients were diagnosed with SS. The mean age of patients with pSS was 53.1 years. The incidence of pSS was 0.11%. With the increase in exposure concentrations of nitrogen dioxide, methane, and carbon monoxide (from Q1 to Q4), the incidence rate for pSS of per 1000 person-years increased from 0.7 to 1.19, from 0.93 to 2.14, and from 0.57 to 1.06, respectively. Moreover, compared with Q1, the adjusted HR in Q4 after adjusting for age, gender, monthly income and urbanization levels increased to 1.86, 2.21 and 2.04, respectively. IPA analyses suggested that the underlying cellular mechanisms involved up-regulation of chronic inflammatory pathways including fibrosis signaling pathway.

Conclusion: Exposure to air pollutants, specifically NO, CH4, and CO, was associated with SS development, mostly driven by fibrotic signaling cascades occurred during chronic inflammation.

OP0238 DRUG COST FOR BIOLOGIC AND TARGETED SYNTHETIC DMARDS FOR RHEUMATOID ARTHRITIS PATIENTS IN NORWAY FROM 2010 TO 2019 - A COUNTRY WITH A NATIONAL TENDER SYSTEM FOR DRUG PRESCRIPTION

A. Brkic[1], A. Diamantopoulos[2], G. Haugeberg[3,4], on behalf of BioRheuma research project. [1]*Sørlandet Hospital, Kristiansand, Research Department,*

Kristiansand, Norway; [2]*Martina Hansens Hospital, Department of Rheumatology, Bærum, Norway*; [3]*Sørlandet Hospital Kristiansand, Division of Rheumatology, Department of Medicine, Kristiansand, Norway*; [4]*NTNU, Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Trondheim, Norway*

Background: Biologic and Target Synthetic disease-modifying antirheumatic drugs (BTSs) have caused a paradigm shift in the treatment of patients with inflammatory joint disorders, e.g., rheumatoid arthritis (RA), where remission is now attainable [1]. The high cost of BTSs has caused restrictions on use and prescription, contributing to inequality of care worldwide [2]. An annual tender system was introduced in 2008 in Norway to reduce the costs of these drugs [3].
Objectives: Explore changes in drug costs for BTSs for RA patients treated at Norwegian rheumatology outpatient clinics between 2010 and 2019.
Methods: The project BioRheuma (BIOlogic treatment of patients suffering from inflammatory RHEUMAtic disorders in Norway) aimed to monitor patients treated with BTSs while using a designed computer program. Anonymized data files from the ten participating centers were merged and analyzed (EXCEL and SPSS). For each year in the ten-year period, the annual total cost for BTSs and mean BTS cost for treatment of one patient was calculated for all current BTSs users, for all those who started BTSs, and for patients starting naïve to BTSs. The cost was calculated based on price offers given at the annual tender process for the different years.
Results: The number of registered RA patients in the databases increased from 4909 in 2010 to 9335 in 2019. Simultaneously, the number of patients treated with BTSs increased from 1959 (39.9%) in 2010 to 4209 (45.1%) in 2019. The total treatment expenditure of these BTS treated patients was lowest in 2010 with 226 million Norwegian Kroner (NOK), highest in 2014 (350 million NOK) treating 3448 patients, and second-lowest in 2019 (255 million NOK).
The number of BTSs used for each year (Figure 1) is shown for all current users, all who started new BTSs treatment, and those starting BTSs naïve to BTSs. The same figure also reports the average cost of treating one RA patient with BTSs in these three groups. For the current users of BTSs, when the number of treated patients during follow-up doubled, the mean cost to treat one patient with BTSs was reduced by approximately 50% (decreasing from 115497 NOK in 2010 to 60701 NOK in 2019). The number of patients starting on BTSs approximately doubled, while keeping a steady small increase for the naïve patients to BTSs (382 in 2010 to 405 in 2019). The average starting treatment cost decreased from 114549 NOK in 2010 to 37384 NOK in 2019, and from 114987 NOK in 2010 to 28249 NOK in 2019, for patients starting on BTSs and for patients naïve to BTSs, respectively.

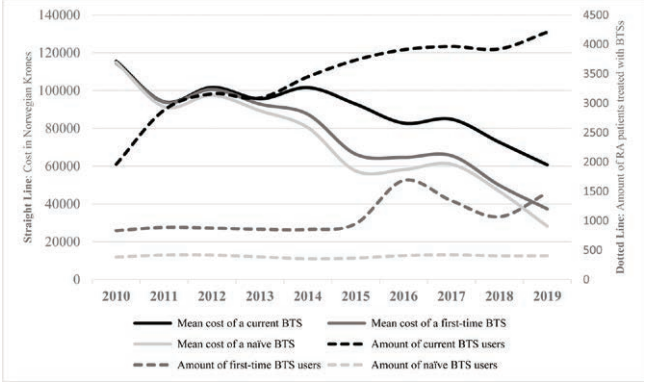

Figure 1. A ten-year overview of treating RA patient with BTSs

Conclusion: Our data shows that the average annual costs of treating a Norwegian RA patient on a current BTS, with a national tender system, were reduced by approximately 50% over the ten years 2010-19. For patients starting on a BTS, the average annual cost was reduced by approximately 75%. The consequence for the payers is that treatment can be offered at a lower price, and thus costly drugs may become more available for patients. We believe that mechanisms like the Norwegian tender system enforced upon the commercial pharmaceutical market improve competition and increase availability and use of costly drugs.

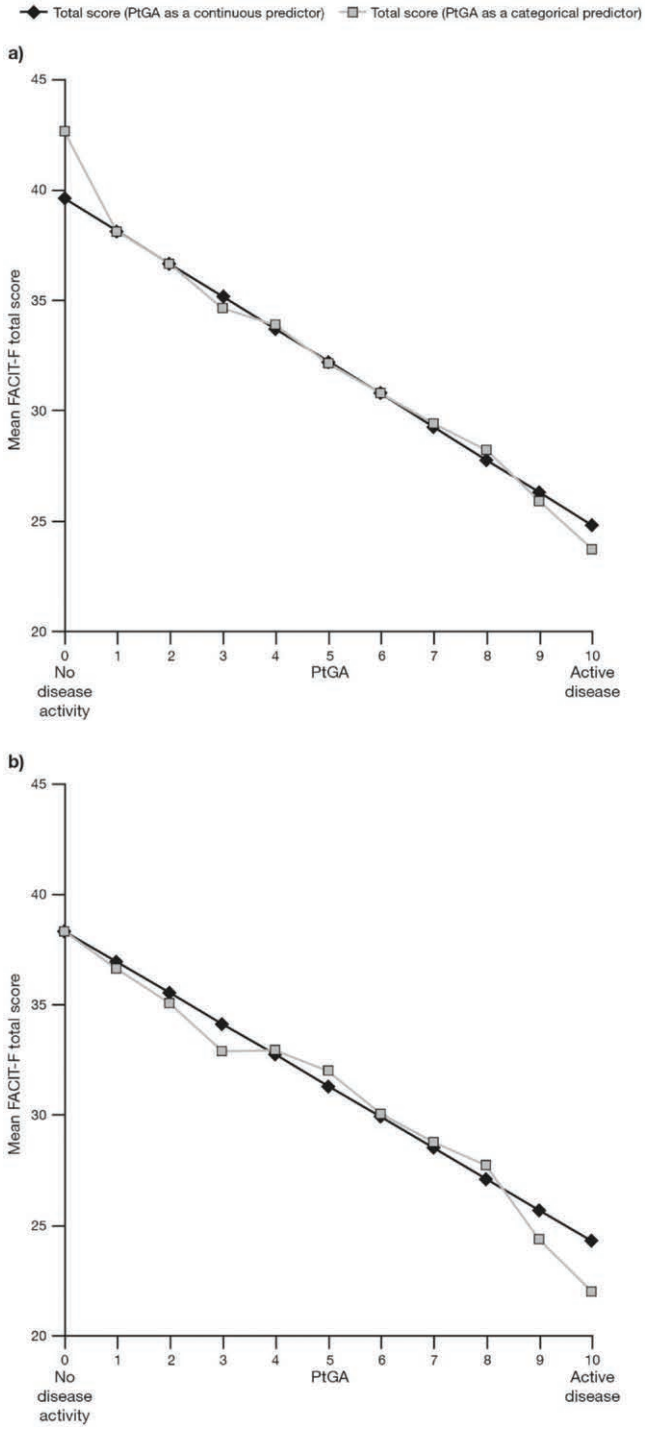
OP0239 PSYCHOMETRIC EVALUATION OF FUNCTIONAL ASSESSMENT OF CHRONIC ILLNESS THERAPY-FATIGUE IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS

D. Cella[1], W. Lenderking[2], P. Chongpinitchai[3], A. G. Bushmakin[4], O. Dina[5], L. Wang[4], J. C. Cappelleri[4], V. Navarro-Compán[6]. [1]*Northwestern University Feinberg School of Medicine, Department of Medical Social Sciences, Chicago, IL, United States of America*; [2]*Evidera, Patient-Centered Research, Waltham, MA, United States of America*; [3]*Evidera, Bethesda, MD, United States of America*; [4]*Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America*; [5]*Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; [6]*University Hospital La Paz, Rheumatology Department, Madrid, Spain*

Background: Due to its impact on their health-related quality of life (QoL), fatigue is considered a core domain of disease assessment in patients (pts) with ankylosing spondylitis (AS). Psychometric data analyses in pts with rheumatoid and psoriatic arthritis have previously demonstrated that the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) is a reliable and valid measure in these pt populations,[1,2] but there are limited data supporting the psychometric validity and reliability of the FACIT-F scale in adult pts with active AS.
Objectives: To further evaluate the psychometric properties of the FACIT-F scale in adult pts with active AS.
Methods: This post hoc analysis used data from the Phase (P)2 (NCT01786668, Study 1) and P3 (NCT03502616, Study 2) studies of tofacitinib in pts with active AS. Second-order confirmatory analysis (CFA) evaluated the measurement model of FACIT-F with two domains (Experience and Impact) and the total score at baseline (BL) and the studies' respective primary analysis time points, Week (W)12 (Study 1) or W16 (Study 2). At the same time points, internal consistency reliability was examined by Cronbach's Coefficient alpha (α), and convergent validity was assessed through correlations of FACIT-F domain and total scores with a set of pt-reported outcomes (PROs): Pt Global Assessment of Disease Activity (PtGA), total back pain/nocturnal spinal pain due to AS, Short Form-36 Health Survey (SF-36v2), Bath AS Functional Index, Bath AS Disease Activity Index and ASQoL. Test-retest reliability was assessed by calculating Intraclass Correlation Coefficients (ICCs). The known-groups validity assessment was derived from an anchor-based repeated measures longitudinal model, with PtGA scores as the anchor (PtGA represented pt state from 'no disease activity' to 'very active disease' [PtGA=0 and 10, respectively]), and FACIT-F domain/total scores as the outcome. Estimations of ability to detect change and meaningful within-pt change (MWPC) were derived from anchor-based repeated measures longitudinal models, with change from BL in PtGA scores as the anchor and change from BL in FACIT-F domain/total scores as the outcome.
Results: The CFA model fit the data well (Bentler's Comparative Index ≥0.92 at BL, W12 [Study 1] and W16 [Study 2]), supporting the measurement model of the FACIT-F scale in pts with AS. Across time points in each study, the FACIT-F domain and total scores demonstrated excellent internal consistency (Cronbach's Coefficient α ≥0.88), and correlations between FACIT-F domain/total scores, and all PROs assessed generally exceeded 0.40. Generally, in both studies, the largest correlations (0.62–0.85) were between FACIT-F domain/total scores and the SF-36v2 vitality domain score and ASQoL. Test-retest reliability was acceptable for all FACIT-F domain/total scores (ICC ranged from 0.75–0.89 in both studies). An approximately linear relationship was observed between FACIT-F total scores and PtGA scores in both studies (Figure), as well as for Experience and Impact domain scores. The differences in FACIT-F domain/total scores were large and statistically significant between 'no disease activity' and 'very active disease' pt groups (standardised effect size ≥1.17), supporting known-groups validity. Ability to detect change was evidenced by an approximately linear relationship between changes in PtGA and FACIT-F domain/total scores in both studies; when pts experienced a change in PtGA, values for FACIT-F domain/total scores changed

accordingly. Conservatively, MWPC was estimated as 6.3 for FACIT-F total score, and 2.8 and 3.6 for FACIT-F Experience and Impact domain scores, respectively.

Figure. Relationship between FACIT-F total score and PtGA in a) Study 1 and b) Study 2



Conclusion: This quantitative analysis of data from two clinical studies of tofacitinib demonstrates the validity and reliability of the FACIT-F scale in adult pts with active AS. Therefore, these findings support the use of FACIT-F in AS studies.

OP0240

EPIDEMIOLOGY, PREDICTORS OF MORTALITY AND ROLE OF PROPHYLAXIS FOR PNEUMOCYSTITIS JIROVECI PNEUMONIA AMONG RHEUMATIC PATIENTS: A TERRITORY-WIDE STUDY

C. W. S. Chan[1], H. Y. Chung[1], W. Y. Yeung[1], C. S. Lau[1], P. H. LI[1]. [1]*The University of Hong Kong, Queen Mary Hospital, Hong Kong, Division of Rheumatology and Clinical Immunology, Department of Medicine, Hong Kong, Hong Kong (SAR)*

Background: *Pneumocystis jiroveci* pneumonia (PJP) is an opportunistic infection affecting immunocompromised individuals. Due to its high mortality, PJP prophylaxis is commonly recommended for many immunocompromising conditions. However, evidence regarding the burden and role of prophylaxis in PJP among rheumatic patients remains limited. There is lack of consensus for when and for whom to initiate prophylaxis. Delineating the epidemiology, predictors of mortality and efficacy of prophylaxis in PJP among rheumatic patients is urgently needed.
Objectives: To delineate the epidemiology of PJP, identify predictors of mortality and evaluate the usefulness of prophylaxis in rheumatology patients.
Methods: We performed a big-data cohort study based on the territory-wide healthcare database of the Hong Kong Hospital Authority. All patients with a diagnosis of anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV), immune-mediated myositis (IMM), rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), systemic sclerosis (SSc), or spondyloarthritis (SpA) between 2015-2019 were included. PJP were identified based on physician diagnosis and/or positive microbiological results from deep respiratory tract specimens. Prophylaxis was defined as prescription of a prophylactic dose of co-trimoxazole for at least 2 weeks and/or inhaled pentamidine. Prevalence of PJP, prophylaxis and mortality among rheumatic patients were calculated. Demographics, blood parameters and immunosuppressants use was also collected for multivariate analysis. Number needed to treat (NNT) analysis was performed based on absolute risk reduction of PJP in patients with and without prior PJP prophylaxis.
Results: A total of 21,587 unique rheumatic patients were analysed (54% RA, 25% SLE, 13% SpA, 5% IMM, 2% AAV and 1% SSc). Between 2015-2019, 1141 (5.3%) patients were prescribed PJP prophylaxis and 48 (0.2%) developed PJP. None of those patients who developed PJP had received prophylaxis prior to infection. The risk of PJP was highest among SSc (1.8%), AAV (1.4%) and IMM (0.7%) patients, with NNT of SSc 36, AAV 48 and IMM 114. Within these disease entities, the majority of PJP occurred at prednisolone dose of 15mg/day (P15) or above (100% in SSc and IIM, 66.7% in AAV). Overall, PJP was associated with a mortality-rate of 39.6%. Glucocorticoid dose (daily prednisolone dose equivalent 29.1±23.5mg vs 11.4±7.2mg, P<0.01) and lymphopenia ($0.44x10^9$/L vs $0.90x10^9$/L, P= 0.04) at PJP diagnosis were associated with PJP mortality in rheumatic patients.
Conclusion: PJP is an uncommon but important infection in rheumatic patients associated with significant mortality. PJP prophylaxis is effective and should be considered in patients with SSc, AAV and IMM, especially in those receiving a steroid dose above P15.

OP0241

SERIOUS INFECTION WITH TOCILIZUMAB COMPARED TO TNF-INHIBITORS AND OTHER BDMARDS IN RHEUMATOID ARTHRITIS PATIENTS: DOES LINE OF THERAPY MATTER?

K. Lauper[1,2,3], L. Kearsley-Fleet[3], R. Davies[3], K. Watson[3], M. Lunt[3], K. Hyrich[3,4]. *[1]Hôpitaux Universitaires de Genève (HUG), Rheumatology, Genève, Switzerland; [2]Faculty of Medicine, University of Geneva, Internal Medicine, Genève, Switzerland; [3]Centre for Musculoskeletal Research, University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; [4]Manchester University NHS Foundation Trust, National Institute of Health Research Manchester Musculoskeletal Biomedical Research Centre, Manchester, United Kingdom*

Background: In the real-world, tocilizumab is prescribed to a population of patients different from those prescribed TNF-inhibitors, often older with longer disease duration, worse functional status and more previous b- or tsDMARDs.
Objectives: The aim of this study was to evaluate if and how the risk of serious infection on tocilizumab and other bDMARDs differs when stratifying by line of therapy in a real-world population of rheumatoid arthritis patients.
Methods: We included patients registered in the BSRBR-RA treated with tocilizumab, etanercept, adalimumab, infliximab, certolizumab, abatacept or rituximab, including biosimilars. Primary outcome was the occurrence of a serious infection (defined as infection requiring hospitalisation, intravenous antibiotics or resulting in death). Primary covariate of interest was line of therapy (from first to fifth line of therapy). Every change to another b- or tsDMARD was considered a new line of therapy, but not a change between a bio-original and a biosimilar. Hazard ratios (HR) of serious infections were estimated using an inverse probability weighted Cox regression, based on a propensity score including baseline patient and disease characteristics, and adjusting for time in study (see Table). The reference group was etanercept, which included the highest number of patients. Treatment exposure was analysed without and with stratification by line of therapy.

Table.

ABA, abatacept; ADA, adalimumab; CERT, certolizumab; ETN, etanercept; HR, hazard ratio; IFX, infliximab; RTX, rituximab; TCZ, tocilizumab*Adjusted using inverse probably weighting (with age, gender, concomitant steroids, concomitant DMARDs, comorbidities, seropositivity, smoking, disease duration, HAQ and DAS28 at baseline in the model) and time since study entry (categorised from 0 to 4, 0 starting just before or at the moment of entering study, 1 starting during the first year, 2 starting during the second year until 4 for the fourth year and more)

Results: A total of 33,916 treatment courses were included (Table) contributing to 62,532 years of follow-up. Compared to etanercept, participants starting abatacept, tocilizumab and rituximab were older, had more previous bDMARDs, longer disease duration and more comorbidities. The crude HR of serious infections were higher with infliximab and adalimumab, lower with certolizumab and rituximab, and not significantly different for abatacept and tocilizumab compared to etanercept. After adjustment, HR of serious infections were higher with tocilizumab, adalimumab and infliximab. However, when stratified by line of therapy, HR were no longer significantly different compared to etanercept for tocilizumab, adalimumab and infliximab for most lines of therapy.
Conclusion: Whilst initially there appears to be a difference in rates of serious infection between biologic therapies, line of therapy may be a confounding factor when comparing the risk of serious infections between bDMARDs.

Systemic sclerosis, myositis - etiology, pathogenesis and animal models

OP0242

EFFECTS OF THE AUTOTAXIN INHIBITOR ZIRITAXESTAT ON SKIN AND LUNG FIBROSIS IN A MURINE GRAFT-VERSUS-HOST DISEASE MODEL OF SYSTEMIC SCLEROSIS

Y. Zhang[1], L. Summa[1], B. Heckmann[2], J. H. W. Distler[1]. *[1]Universitätsklinikum Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany; [2]Galapagos SASU, Drug Innovation, Romainville, France*

Background: There is an unmet medical need for new drugs to treat systemic sclerosis (SSc). Autotaxin (ATX) is a widely expressed enzyme that regulates diverse cellular processes, including proliferation, differentiation and migration, and has been implicated in the pathogenesis of SSc. Targeting ATX is a promising new strategy for treating SSc. The autotaxin inhibitor ziritaxestat (GLPG1690) is a potential first-in-class disease-modifying drug for SSc that has been shown to improve skin score in the Phase 2a NOVESA (NCT03798366) trial in patients with SSc.
Objectives: To investigate the effects of ziritaxestat in a chronic graft-versus-host disease (cGvHD) murine model of SSc.
Methods: Effects of ziritaxestat (10 or 30 mg/kg twice daily [bid]) on disease activity were assessed in a cGvHD murine model of SSc (allogeneic bone marrow transplantation [BMT] with B10.D2 donor and BALB/c recipient; syngeneic mice as controls). Ziritaxestat or nintedanib (60 mg/kg once daily [qd]) as active comparator was administered 21 d after BMT and continued for 35 d. Effects of ziritaxestat were assessed by clinical monitoring, histologic assessment of skin and lungs (dermal thickness, Ashcroft scores and collagen-covered area), immunofluorescence staining with Trichrome and Sirius Red for myofibroblasts, and biochemical analysis of collagen content, as measured by hydroxyproline levels.
Results: Ziritaxestat 30 mg/kg bid for 35 days significantly reduced the clinical cutaneous score in the murine cGvHD model by 57% ($p<0.05$) compared with vehicle, and to a similar extent when compared with nintedanib 60 mg/kg (38%; $p<0.05$). Dermal accumulation of collagen and dermal thickness (Figure) were reduced with ziritaxestat 10 and 30 mg/kg compared with vehicle. At 30 mg/kg, ziritaxestat reversed the increase in the allogeneic model ($p<0.001$), returning dermal thickness to the levels in non-fibrotic control mice. Ziritaxestat also significantly reduced pulmonary fibrosis in the cGvHD model, with reductions in the fibrotic lung area (ziritaxestat 10 and 30 mg/kg; $p<0.001$ for both) and Ashcroft scores (ziritaxestat 30 mg/kg; $p<0.05$). Ziritaxestat was generally well tolerated.
Conclusion: Ziritaxestat improved the histological, biochemical and clinical symptom readouts of dermal and pulmonary fibrosis in a murine model, consistent with a broad and rapid disease-modifying effect in SSc.

Figure. Effect of ziritaxestat on dermal thickness in a murine cGvHD model of SSc

OP0243 AN APPROACH COMBINING TRANSCRIPTOMIC AND TOPOGRAPHIC ANALYSIS REVEALS A POTENTIAL ROLE OF PROTEASOME AND AUTOPHAGY DEREGULATION IN THE PATHOPHYSIOLOGY OF DERMATOMYOSITIS

L. Debrut[1], G. Laverny[2], P. Mertz[3], M. Giannini[4], M. Pizzimenti5, A. Charlot5, C. Keime[6], B. Lannes[7], D. Metzger[2], B. Geny[8], J. Sibilia[4], A. Meyer[4]. *[1]Centre de Recherche en Biomédecine de Strasbourg, UR3072, mitochondrie, stress oxydant et protection musculaire, Strasbourg, France*; *[2]IGBMC, IGBMC, Illkirch, France*; *[3]CHU Strasbourg, Immunology, Strasbourg, France*; *[4]CHU Strasbourg, Rhumatologie, Strasbourg, France*; *[1]Centre de Recherche en Biomédecine de Strasbourg, UR3072, mitochondrie, stress oxydant et protection musculaire, Strasbourg, France*; *[6]IGBMC, Genomeast, Illkirch, France*; *[7]CHU Strasbourg, Anatomopathologie, Strasbourg, France*; *[8]CHU Strasbourg, Explorations fonctionnelles, Strasbourg, France*

Background: Dermatomyositis (DM) is a rare autoimmune muscle disease characterized by an atrophy and a type-I interferon signature in perifascicular fibers. We recently showed that muscle mitochondrial dysfunction is also a characteristic of this disease that participates to both decrease exercise capacity and maintenance of inflammation (1). Pathophysiological mechanisms underlying these characteristics are unknown.

Objectives: The objective of this study is to reveal the mechanisms underlying the modifications of perifascicular fibers during DM, taking advantage of a method combining transcriptomic and topographical information.

Methods: Fourteen patients with recent (<6 months) untreated myositis (DM: n=7, other myositis: n=7) who underwent a biopsy of the deltoid muscle for diagnostic purposes were included. Seven other patients with suspected but not confirmed neuromuscular pathology (normal creatine kinase level, electromyogram and deltoid biopsy) were also included (no myopathy: n=7). Under the control of optical microscopy, perifascicular fibers (about 400 fibers) and endofascicular fibers (about 400 fibers) were microdissected by laser. The transcriptome of endofascicular fibers and perifascicular fibers in all three groups of patients were then obtained by massive sequencing of total messenger RNA. The DAVID database (2) (http://david.abcc.ncifcrf.gov) were used to determine the deregulated molecular pathways in the perifascicular fibers during DM.

Results: 482 transcripts were differently expressed in perifascicular fibers of patients with DM compared to perifascicular fibers of the 2 other groups (348 overexpressed and 134 underexpressed). The most overexpressed transcripts were involved in the type I interferon response while the most underexpressed transcripts were involved in mitochondria and in proteasome functioning. The study of the transcripts differentially expressed in perifasicular versus endofascicular fibers revealed that there is a physiological perifascicular signature: in patients without myopathy, 83 genes were overexpressed and 54 were underexpressed in perifascicular fibers compared to endofascicular fibers. This physiological perifascicular signature was abolished in patient with myositis (DM and other myositis). In the group of patients with DM (but not other myositis), a specific perifascicular signature (18 genes overexpressed and 10 genes underexpressed in perifascicular fibers compared to endofascicular fibers) was identified. The most deregulated transcripts in DM perifascicular fibers were involved in autophagy/mitophagy, mitochondria and proteasome pathways.

Conclusion: In the physiological state, perifascicular fibers are characterized by a different transcriptomic profile from endofascicular fibers. During DM, this physiological perifascicular signature is abolished and replaced by a transcriptomic signature that reveal a potential role of proteasome and autophagy deregulation in the pathophysiology of DM.

OP0244 28 NEW AUTOANTIBODIES AGAINST GPCR, GROWTH FACTORS AND GROWTH FACTOR RECEPTORS ARE ASSOCIATED WITH DISEASE MANIFESTATIONS IN SYSTEMIC SCLEROSIS

K. Sterner[1], C. J. K. Fouodo[2], I. König[2], A. Künstner[3], H. Busch[3], H. Heidecke[4], A. Schumann[5], A. Müller[5], G. Riemekasten[1], S. Schinke[5]. *[1]University of Lübeck, Department of Rheumatology and Clinical Immunology, Lübeck, Germany*; *[2]University of Lübeck, Institute of Medical Biometry and Statistics, Lübeck, Germany*; *[3]University of Lübeck, Lübeck Institute of Experimental Dermatology, Lübeck, Germany*; *[4]CellTrend GmbH, -, Luckenwalde, Germany*; *[5]UKSH Campus Lübeck, Department of Rheumatology and Clinical Immunology, Lübeck, Germany*

Background: The morbidity and mortality of systemic sclerosis (SSc) are largely determined by vascular and fibrotic pathologies. Levels of autoantibodies (ab) against G protein-coupled receptors (GPCR), growth factors (GF) and growth factor receptors (GFR) are altered in SSc compared to healthy controls (HC) [1]. Thus, higher angiotensin II receptor type 1 - (AT1R) and endothelin receptor type A - (ETAR) ab levels are associated with severe disease and SSc-related mortality [2]. CXC motiv chemokine receptor 3 - (CXCR3) and 4 - (CXCR4) ab have predictive value for deterioration of pulmonary fibrosis (PF) [3].

Objectives: We used statistical methods to identify associations between disease manifestations and 28 new ab directed against GPCR, GF and GFR in SSc.

Methods: Ab against the following targets were measured in sera from SSc patients (n = 177) and HC (n = 88): Adrenoceptors alpha-1 (ADRA1), alpha-2 (ADRA2), beta-1 (ADRB1), beta-2 (ADRB2); muscarinoceptors 1-5 (M1R - M5R); AT1R, ETAR, endothelin B receptor (ETBR); CXCR3, CXCR4; complement receptors 3a (C3aR) and 5a (C5aR); protease-activated receptors 1 (PAR1) and 2 (PAR2); vascular endothelial growth factor A (VEGFA) and its receptors 1 (VEGFR1) and 2 (VEGFR2), epithelial growth factor (EGF)/ - receptor (EGFR); hepatocyte growth factor (HGF)/ - receptor (HGFR), platelet-derived growth factor-AA (PDGFAA), placental growth factor (PlGF).

The organ involvement (PF, cardiac involvement, PAH, gastrointestinal tract) and quantitative markers (modified Rodnan skin score, SSc activity score, pulmonary function, cardiac enzymes and echocardiography, routine laboratory, autoimmune diagnostics) as well as demographic data were recorded retrospectively at the time of sample collection. Statistical analysis was performed using the Mann-Whitney U test (MWU), Pearson correlations, ROC analysis, and age-adjusted logistic regression models.

Results: In SSc 20 of 28 measured ab levels are significantly altered compared to HC. According to the Pearson correlation matrix, the ab-levels are highly correlated and build a network that differs between HC and SSc. Furthermore, altered network signatures are formed in the differentiated analysis of several disease manifestations of SSc such as SSc-subtype or PF. Based on ROC analysis, FGF-ab, ADRB1-ab and PlGF-ab are well suited to predict SSc (Figure 1).

In addition, limited cutaneous SSc (lSSc) patients displayed lower levels of most ab than diffuse cutaneous SSc patients, whereas cardiac and pulmonary involvement are associated with higher ab levels. In the logistic regression lSSc is associated with lower levels of ab against M1R, M2R, C5aR, ETAR, AT1R, PAR1, EGFR. Higher levels for ab against M1R, M2R, ETBR, C5aR are associated with PF, higher levels of ab against complement receptors, adrenoreceptors and EGF with NT-proBNP elevation.

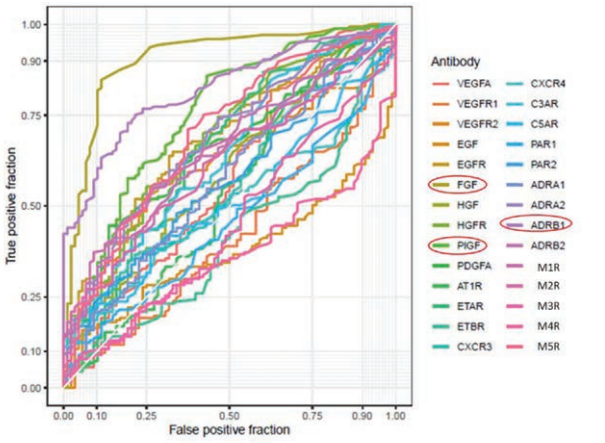

Figure 1: Receiver operating characteristic analyses for 28 new autoantibodies in systemic sclerosis (n =177) compared with healthy controls (n = 88). Ab against FGF, ADRB1 and PlGF may predict SSc.

Conclusion: The newly described antibodies against GPCR, GF and GFR are highly correlated. Associations with morbidity- and mortality-determining organ involvement indicate their possible functional relevance and novel pathophysiological mechanisms. As new biomarkers, some of the ab have prognostic value for SSc; for other manifestations, their value should be evaluated in further studies.

OP0245 ANTI-S100A4 MONOCLONAL ANTIBODY TREATMENT AMELIORATES SKIN FIBROSIS IN INFLAMMATORY AND NON-INFLAMMATORY PRE-CLINICAL MODELS OF SYSTEMIC SCLEROSIS

M. Tomčík[1], T. Trinh-Minh[2], C. T. Manh[2], H. Štorkánová[1], L. Štorkánová[1], L. Šenolt[1], J. Klingelhöfer[3], R. I. Hussain[3], J. Hallén[3], J. H. W. Distler[2]. Background: AX-202 is a monoclonal antibody that inhibits the bioactivity of S100A4. S100A4 is an alarm signal that is released from cells in response to stress or injury and functions as an amplifying mechanism of inflammation and fibrosis in the diseased tissue microenvironment. Previous in vitro studies have found that S100A4 induces fibroblast activation, sensitizes fibroblasts to the effects of TGFβ, drives epithelial-mesenchymal transition, and stimulates monocyte cytokine release (1-3). Moreover, S100A4-/- mice are protected from fibrosis in several animal models (1). In patients with systemic sclerosis (SSc), S100A4 is elevated both in lesional tissue and systemically and correlates with skin involvement, disease activity, and pulmonary function.

Objectives: The aim of this study was to assess the antifibrotic effects of murine AX-202 in two pre-clinical models of SSs reflecting both inflammation-mediated and inflammation non-mediated fibrosis and confirm the in vivo activity of humanized AX-202.

Methods: We first evaluated the effects of murine AX-202 in the bleomycin-induced skin fibrosis model and the tight-skin 1 (Tsk-1) model. In the bleomycin (BLM) model, fibrosis was induced by 3 weeks of BLM s.c. injections followed by 3 weeks of AX-202 treatment in parallel with continued BLM s.c. injections. The control groups included NaCl s.c. injections for 6 weeks, BLM s.c. injections for 6 weeks, or BLM s.c. injections for 3 weeks, followed by NaCl s.c. injections for 3 weeks. Three dosing regimens of AX-202 were tested: 3.75, 7.5, or 12.5 mg/kg i.p. every 3rd day. In the Tsk-1 model, treatment with 7.5 mg/kg i.p. every 3rd day was administered from week 5 until week 10. The control groups included pa mice, Tsk-1 mice, and Tsk-1 mice treated i.p. with isotype IgG. We subsequently evaluated the effects of humanized AX-202 in the model of BLM-induced skin fibrosis in a similar design as used for the murine AX-202 study. Three dosing regimens were tested: 8 mg/kg and 16 mg/kg i.p. every 3rd day and 24 mg/kg i.v. once weekly.

Results: In the BLM model, murine AX-202 (7.5 mg/kg) was effective both in the prevention of progression of pre-established skin fibrosis and in the induction of regression of fibrosis as assessed by the dermal thickness (-55%, p<0.0001 vs BLM for 6 weeks, and -23%, p<0.0001 vs BLM for 3 weeks), myofibroblast count and hydroxyproline content. Murine AX-202 also ameliorated fibrosis in the Tsk-1 model as assessed by the hypodermal thickness (-24%, p=0.01 vs Tsk-1 isotype control), myofibroblast count, and hydroxyproline content. In both models, the antifibrotic effects were associated with a reduction in pSMAD3 expression. Humanized AX-202 was effective in the prevention of progression of pre-established skin fibrosis in all doses tested across all endpoints (dermal thickness, myofibroblast counts, hydroxyproline content). In the two groups treated with 16 mg/kg i.p. and 24 mg/kg i.v., humanized AX-202 also induced regression of fibrosis (-83%, p<0.001, and -61%, p<0.001 vs BLM for 3 weeks, respectively). Both murine and humanized AX-202 were well tolerated in all study groups in both models.

Conclusion: We demonstrate that AX-202 confers potent antifibrotic effects in complementary models of SSc. These results confirm and expand previous data showing that inhibition of S100A4 by AX-202 is a promising potential therapeutic candidate for disease modification in SSc or other fibrotic conditions.

OP0246 PREDICTIVE VALUE OF LABORATORY AND INSTRUMENTAL FINDINGS IN THE VERY EARLY DIAGNOSIS OF SYSTEMIC SCLEROSIS. ROLE FOR CXCL4 CHEMOKINE

M. Cadar[1], C. Angelelli[1], G. Pellegrino[1], K. Stefanantoni[1], R. Palazzo[2], R. Lande[2], L. Frasca[2], V. Riccieri[1]. [1]*Sapienza University of Rome, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Roma, Italy*; [2]*Italian National Institute of Health, National Centre for Pre-Clinical and Clinical Drug Research and Evaluation, Pharmacological Research and Experimental Therapy Unit, Roma, Italy*

Background: Systemic sclerosis (SSc) is a rare and progressive autoimmune disease, whose diagnosis is difficult in the early stages because of the lack of specific signs and symptoms. Criteria for a Very Early Diagnosis of SSc (VEDOSS) have been proposed to identify those patients affected by undifferentiated connective tissue disease (UCTD) at risk to develop SSc [1]. For the diagnosis of SSc a strict clinical and laboratory follow up is mandatory [2]. CXCL4 chemokine recently proved to be higher in early SSc [3][4][5].

Objectives: Aim of our study was to evaluate at baseline the main clinical-demographic and laboratory parameters in a group of VEDOSS patients, comparing these features during the follow-up, to detect any difference between progressors (P) and non-progressors (NP) into SSc. Furthermore, we dosed plasma levels of CXCL4.

Methods: We included 27 VEDOSS patients, defined by EUSTAR 2011 Criteria and not fulfilling the 2013 ACR/EULAR classification criteria of SSc, attending the Rheumatology Unit of Policlinico Umberto I in Rome from 2009 to 2020. Demographic, laboratory and instrumental features were analyzed, and, after a mean follow-up of 5.7±1,7 years, we compared the P to NP patients. Having obtained written informed consent, blood samples were taken at baseline to measure plasma levels of CXCL4 chemokine using an ELISA assay.

Results: At baseline the 27 VEDOSS patients (mean age 53.2±13.5 years, all females) had ANA positivity in 25 (93%) cases and Raynaud's phenomenon in 25 (93%) cases. In a mean follow-up time of 43.5 ± 23.1 weeks from the first clinical examination, 15 (55%) patients were classified as P into SSc. These P patients showed a significant association with SSc specific antibodies such as anti-Centromere, anti-Scl70 and anti-RNAPIII (p=0.014) as well as with a specific "*Scleroderma pattern*" at the nailfold capillaroscopy (p=0.022) respect to those NP into SSc. A group of 6 P patients evolved in less than 24 months (mean 19,6 ± 6,8 weeks) and were defined "*Fast Progressor*". They were also significantly associated with those autoantibodies considered as having a worse prognosis such as anti-Scl70 and anti-RNAPIII (p=0.005), and had a shorter duration of RP (88 vs 189.3 months) and a younger mean age (49.5 vs 55.4 years) respect to "*Slow Progressor*" (SSc evolving in >24 months). At baseline we detected significantly higher median plasma levels of CXCL4 in the 27 VEDOSS patients compared to 10 healthy subjects (9024±10559 pg/ml versus 348,5±684,3 pg/ml; p=0.0047). We also noticed a trend for lower CXCL4 levels in the "*Fast Progressor*" than in

the "*Slow Progressor*" (3303 ± 6065 pg/ml vs 13300 ± 10308 pg/ml; p=0.052) without reaching a significant value, due probably to the low number of cases.
Conclusion: Our study confirms that the presence of specific autoantibodies and capillaroscopic abnormalities correlate to an increased risk of developing SSc in patients with UCTD [6]. Beside we found significantly higher levels of CXCL4 in our 27 VEDOSS patients respect to controls, in agreement with other authors showing the association of this chemokine with early stages and specific organ involvement [4][5][7]. The finding of CXCL4 lower levels in "*fast progressor*" cases is consistent with our recent report of anti-CXCL4 antibodies in patients with early SSc, determining lower levels of this antigen [7]. We need deeper investigations to better evaluate the role of CXCL4 in the different stages of SSc.

OP0247 IN MYOSITIS MUSCLE FIBRE PLAYS A DIRECT AND CRITICAL ROLE IN THERAPEUTIC RESPONSE TO GLUCOCORTICOIDS

M. Giannini[1], G. Laverny[2], D. Duteil[2], D. Rovito[2], A. L. Charles[3], B. Geny[4], D. Metzger[2], A. Meyer[5]. *[1]University of Strasbourg, Service de Physiologie et d'explorations fonctionnelles, Nouvel Hopital Civil, Centre de Référence des Maladies Autoimmunes Rares, Fédération de Médecine Translationnelle, UR3072, Strasbourg, Strasbourg, France*; *[2]University of Strasbourg, CNRS UMR7104, INSERM U1258, IGBMC, F-67400 Illkirch, Illkirch, France*; *[3]University of Strasbourg, Fédération de Médecine translationnelle, UR3072, Strasbourg, Strasbourg, France*; *[4]University of Strasbourg, Service de Physiologie et d'explorations fonctionnelles, Nouvel Hopital Civil, Fédération de Médecine Translationnelle, UR3072, Strasbourg, Strasbourg, France*; *[5]University of Strasbourg, Service de Physiologie et d'explorations fonctionnelles, Nouvel Hopital Civil, Centre de Référence des Maladies Autoimmunes Rares, Fédération de Médecine Translationnelle, UR3072, Strasbourg, Strasbourg, France*

Background: Myositis are rare autoimmune diseases, affecting more women than men, characterized by chronic inflammation of skeletal muscle causing muscle weakness, decreased quality of life and increased mortality.
Glucocorticoids (GC) are potent anti-inflammatory drugs, and are the first line treatment of myositis. They improve muscle strength of myositis patients (therapeutic effect), yet muscle recovery is generally only partial. Moreover, GC have an iatrogenic effect on skeletal muscle fibre leading to steroid myopathy. Thus myositis care has to be improved. Despite the autoimmune terrain of myositis, our team has recently shown that muscle fibres themselves develop immuno-metabolic modifications that participate to muscle weakness and perpetuation of the disease[1]. GC effects are mediated by the glucocorticoid receptor (GR), which is expressed in various cell types including immune cells and myofibres, but the cells mediating therapeutic responses remain to be determined.
Objectives: Unravel the mechanisms underlying the therapeutic effect of GC in myositis, particularly elucidate the role of skeletal muscle fibres.
Methods: Experimental myositis was induced in eight to ten week-old C57BL/6J female mice by a single intradermal injection of part of skeletal muscle fast-type C protein along with Freund's adjuvant and an intraperitoneal (IP) injection of pertussis toxin, as previously described[2]. Prednisone (PDN) was administered 14 days (D) after the immunization at 1 mg/kg/day for 7 days by gavage. Mice were euthanized 21 days after myositis induction. Muscle strength was assessed by grip test at D 0, before the 1st PDN administration (D 14) and the day before sacrifice (D 20). To investigate whether the PDN effects are mediated by myofibre, we generated transgenic mice carrying two LoxP sites within the GR gene in muscle, expressing the tamoxifen-inducible Cre-ERT2 recombinase selectively in skeletal muscle fibre (HSA-CreERT2/GR L2/L2). Tamoxifen (1 mg/day for 5 days by IP injection) was administered 9 days after immunization to induce GR ablation selectively in skeletal muscle fibres (GR(i)skm-/- mice). Similar treatments were applied to GR L2/L2 that do not express Cre-ER(T2), and served as controls.
We compared 4 groups of myositis mice, GR L2/L2 treated by PDN (n=9) or vehicle (n=9) and GR(i)skm$^{-/-}$ treated by PDN (n=10) or vehicle (n=10), by grip test and at the histological level (hematoxylin-eosin (HE) and Gomori trichrome (GT) staining). Moreover, LC3 expression was studied by RTqPCR and western blot.
Results: Muscle strength was decreased in both GR L2/L2 and GR(i)skm$^{-/-}$ myositis mice from D 14 to D 20. GR L2/L2 myositis mice recovered muscle strength after PDN treatment; no significant difference compared to D 0 was detected. In contrast, PDN did not improve muscle strength in GR(i)skm$^{-/-}$ myositis mice (Figure 1).
HE and GT staining did not reveal quantitative differences in inflammatory infiltrate. Necrotic and degenerative fibres were detected in the 4 groups. At RTqPCR, LC3, an autophagy marker, was upregulated in PDN-treated GR L2/L2 myositis mice compared to untreated GR L2/L2 myositis mice; moreover it was 2-fold more expressed in PDN-treated GR L2/L2 myositis mice compared to PDN-treated GR(i)skm$^{-/-}$ mice.
Conclusion: GR in skeletal muscle fibre is crucial to mediate the therapeutic response to GC in a murine model of myositis. Autophagy is one of the candidate pathways controlled by myofibre GR underlying this effect.

OP0248 DEVELOPMENT OF A 3D SKIN MICROTISSUE MODEL FOR FIBROTIC DISEASES

E. Pachera[1], G. Kania[1], A. Juengel[1,2], M. Calcagni[3], O. Distler[1,2]. *[1]Department of Rheumatology, Center of Experimental Rheumatology, University Hospital Zurich, University of Zurich, Zurich, Switzerland*; *[2]Department of Physical Medicine and Rheumatology, Balgrist University Hospital, University of Zurich, Zurich, Switzerland*; *[3]Department of Hand Surgery, Balgrist University Hospital, University of Zurich, Zurich, Switzerland*

Background: Traditional preclinical approaches, such as two-dimensional cell culture and animal models, are often inadequate to mimic the pathophysiological features of complex diseases such as systemic sclerosis (SSc). Human specific targets, such as the recently described pro-fibrotic long non coding RNA (lncRNA) H19X[1], are becoming increasingly relevant in preclinical research, creating the need of new strategies and tools in translational medicine. The employment of novel three-dimensional (3D) culture systems, where multiple cell types are included, is filling an important gap left by the traditional preclinical methods.
Objectives: To develop an easy to produce 3D fibrotic skin microtissues model for translational proof of concept studies.
Methods: Two thousand five hundred dermal fibroblasts isolated from skin of SSc patients were seeded in ultra-low attachment 96-well plates. Fibroblast were let to aggregate into spheres for 48h. Two thousand five hundred primary normal human keratinocytes were added to the culture and let to layer onto the fibroblast spheres for 72h. H19X silencing experiments were used as proof of concept studies. H19X silencing with antisense oligonucleotides or transfections with a scrambled control were performed in fibroblasts prior to the sphere formation for 24h. TGFβ (10 ng/ml) was added to microtissue to exacerbate the fibrotic phenotype. Haematoxylin eosin staining as well as immunohistochemistry staining for vimentin and cytokeratin 10 was performed. Skin microtissues were processed for RNA and protein isolation. Pro-collagen Iα1 and fibronectin were quantified in the supernatants with ELISA.

Results: The microtissues presented a core of SSc fibroblast as revealed by vimentin staining and an external layer of keratinocytes as revealed by cytokeratin 10 staining, mimicking the human skin architecture. Gene expression analysis following TGFβ stimulation displayed induced expression of extracellular matrix gene *COL1A1* (p=0.044) and the myofibroblast marker *ACTA2* (p=0.018), indicating that the microtissues were able to develop a fibrotic response. Microtissues, where H19X was silenced, displayed reduced gene expression of *COL1A1* and *ACTA2* after TGFβ stimulation (*COL1A1* p=0.007, *ACTA2* p=0.045). Additionally, H19X silencing led to lower levels of αSMA protein expression (p=0.009) and pro-collagen1α1 secretion (p=0.039) in the supernatant of the microtissue cultures as revealed by Western Blot and ELISA, respectively. *FN1* expression and fibronectin protein levels were not significantly reduced in the microtissues after H19X silencing.

Conclusion: We were able to produce a 3D microtissue resembling skin architecture that can respond to fibrotic stimuli. Knockdown experiments of pro-fibrotic lncRNA H19X confirmed the potential of the model as screening platform for novel pro-fibrotic effectors. A future aim will be to optimize the model for high-throughput automated screening platforms.

OP0249 SERUM PROTEOMIC BIOMARKERS DEFINE PATIENTS WITH SYSTEMIC SCLEROSIS WITH INTERSTITIAL LUNG DISEASE

M. De Santis[1], N. Isailovic[1], A. Ceribelli[1], F. Motta[1,2], M. Vecellio[2,3], C. Selmi[1,2]. *[1]Humanitas Clinical and Research Center - IRCCS, Rheumatology and Clinical Immunology, Rozzano, Italy*; *[2]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Italy*; *[3]University of Oxford, Botnar Research Center, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: Systemic sclerosis (SSc) is a systemic condition affecting multiple organs and thus being burdened by high morbidity and mortality; disease management is based largely on the early detection of organ involvement, particularly in the case of interstitial lung disease (ILD), ideally through noninvasive biomarkers. Beside serum autoantibodies associated with diffuse SSc, there is currently no reliable serum marker to predict the onset of SSc organ involvement, monitor its progression, and foresee the response to treatments. Proteomic analysis based on aptamer technology is a powerful method with the potential to address this unmet need in SSc.

Objectives: To identify serum biomarkers associated with ILD in SSc.

Methods: Serum samples from 6 women with SSc (3 with ILD at high-resolution pulmonary CT scan) and 7 age-matched female healthy controls (HC) were analyzed using the SOMAscan platform (SomaLogic, Inc., Boulder, CO, USA) to test more than 1300 proteins even at femtomolar concentration. Subsequent validation of candidate proteins was performed using ELISA in an independent cohort of 88 patients with SSc and 48 HC. Statistical analysis included Student's t-test and was assessed using the SomaSuite software (SomaLogic, Boulder, CO, USA).

Results: The proteomic analysis identified 33 proteins with significantly different serum levels in SSc cases compared to HC and 9 proteins differentiating SSc patients according to ILD (Table 1). Compared to HC, SSc sera manifested an altered expression of proteins involved in extracellular matrix formation and cell-cell adhesion (with higher Calpain, EphA5, IDS, MATN2, MMP-12, TNR4, and lower desmoglein-1, SNP25), angiogenesis (with higher anti-angiogenetic factors as angiopoietin-2 and kininogen high molecular weight) lymphocyte recruitment, activation, and signaling (with higher CXCL-1, LAG3 and lower SH21A) with an overall inhibition of neutrophil function (with lower G-CSF-R, CD177, calgranulin B).

Table 1. Significantly altered proteins at serum proteomic analysis of systemic sclerosis (SSc) with or without interstitial lung disease (ILD) and healthy controls (HC)

*significantly increased also at ELISA** significantly increased at ELISA only in SSc with ILD versus HC

The majority of proteins with higher levels in SSc with ILD compared to SSc without ILD were involved in intracellular signaling and cell cycle (FCRL3, PDE11, Stratifin), along with higher MCP-3, a monocyte chemoattractant, and sICAM-5, ligand for the leukocyte adhesion protein LFA-1. Of note, we found that increased IL-22BP, antagonist of IL-22, and decreased BAFF levels characterized SSc with ILD.

Conclusion: Aptamer proteomic analysis allowed to define serum profiles differentiating SSc patients from healthy controls and SSc with ILD from SSc without ILD; the proteins identified are involved in SSc pathogenic pathways and after further investigation on larger cohorts they can be used as reliable biomarkers.

Imaging in axial spondyloarthritis – what is new?

OP0250 MRI VERTEBRAL CORNER INFLAMMATION AND FAT DEPOSITION ARE ASSOCIATED WITH WHOLE SPINE LOW DOSE CT DETECTED SYNDESMOPHYTES: A MULTILEVEL ANALYSIS

R. Stal[1], X. Baraliakos[2], A. Sepriano[1], F. A. Van Gaalen[1], S. Ramiro[1], R. Van den Berg[1], M. Reijnierse[3], J. Braun[2], R. B. M. Landewé[4], D. Van der Heijde[1]. *[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; *[2]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*; *[3]Leiden University Medical Center, Radiology, Leiden, Netherlands*; *[4]Amsterdam University Medical Center, Rheumatology, Amsterdam, Netherlands*

Background: A few studies have shown an association between vertebral corner inflammation (VCI) and vertebral corner fat deposition (VCFD) on MRI and syndesmophyte formation on cervical and lumbar conventional radiography.

Objectives: To investigate whether magnetic resonance imaging (MRI) patterns of VCI, VCFD and a combination of both are associated with the development of new or grown syndesmophytes as detected by whole spine low dose computed tomography (ldCT), thereby studying these associations also in the thoracic spine.

Methods: Patients in the Sensitive Imaging in Ankylosing Spondylitis cohort underwent MRI at baseline, 1 year and 2 years, and ldCT at baseline and 2 years. MRI lesions were scored by 3 central readers, using the SPARCC method for VCI and the CanDen method for VCFD, and coded as absent or present per timepoint and per reader. MRI patterns over time (Table) were based on patterns studied by Machado et al.[1] and deemed present if seen by ≥2 out of 3 readers. The patterns reflect hypothetical associations between presence and absence of VCI and VCFD, independently and combined, on ldCT detected new or grown syndesmophytes. Individual reader change scores were used for ldCT images, scored by 2 central readers with the Computed Tomography Syndesmophyte Score. New (CTSS 0 to 1, 2 or 3) and grown (CTSS 1 to 2 or 3; 2 to 3) syndesmophytes were grouped together to represent bone formation. Corners not at risk

for the outcome due to presence of a bridged syndesmophyte at baseline were excluded. Multilevel generalized estimated equations were used, with separate models per MRI pattern, accounting for correlations within patients and between ldCT readers.

Table 1. Effect of vertebral corner inflammation and vertebral corner fat deposition on syndesmophyte formation

Patterns of lesions over time on MRI	Corners with VCI/ VCFD pattern N(%)	OR (95% CI)
1. VCI at any TP, irrespective of VCFD	691 (15.0%)	**2.37 (1.49-3.78)**
2. VCFD at any TP, irrespective of VCI	1080 (23.5%)	**2.58 (1.97-3.39)**
3. VCI on ≥1 TP and absence of VCFD on all TPs	372 (8.1%)	**1.90 (1.15-3.13)**
4. VCFD on ≥1 TP and absence of VCI on all TPs	754 (16.4%)	**1.87 (1.41-2.48)**
5. VCI precedes VCFD	43 (0.9%)	2.20 (0.83-5.86)
6. VCI precedes or coincides with VCFD. VCFD does not precede VCI	198 (4.3%)	**2.33 (1.47-3.69)**
7. Absence of VCI and VCFD on all TPs	3108 (67.6%)	**0.35 (0.25-0.49)**

VCI, vertebral corner inflammation; VCFD, vertebral corner fat deposition; TP, timepoint.

Results: 50 patients were included, contributing a total of 4600 vertebral corners. Their mean age was 49.3 years (SD 9.8), 86% were male and 78% were HLA-B27+. Presence of VCI and VCFD patterns ranged from 43 (0.9%) to 3108 (67.6%) corners (Table), with the lowest frequency being for VCI preceding VCFD. Protection against syndesmophyte development was seen in case of absence of both VCI and VCFD (OR 0.35) and positive associations with ORs ranging from 1.87-2.58 were observed for various VCI/VCFD patterns. Nevertheless, out of all corners with a new or grown syndesmophyte, 47.3% of corners according to reader 1 and 43.9% according to reader 2 had neither VCI nor VCFD preceding the bone formation.

Conclusion: Presence of VCI or VCFD and combinations of the two, measured yearly on MRI, increased odds of bone formation 2 years later, whereas absence of both VCI and VCFD decreased the odds, showing that VCI and VCFD have some role in the development of syndesmophytes. However, almost half of all bone formation occurred in corners without VCI or VCFD, suggesting the presence of these lesions in yearly MRIs does not fully explain the development of syndesmophytes. This study confirmed that there is an association between VCI and VCFD and bone formation also for the thoracic spine and on ldCT compared to conventional radiography.

Background: The ASAS definition of a positive MRI for inflammation in the spine (ASAS-MRIspine+) is intended for classification of patients as having axSpA but is often misused for diagnostic purposes. This is problematic because bone marrow edema (BME) in the spine may occur in 20-40% of those with mechanical back disorders. The ASAS MRI group has generated updated consensus lesion definitions which have been validated on MRI spine images from the ASAS Classification Cohort.

Objectives: We aimed to identify quantitative cut-offs based on numbers of vertebral corners that define ASAS-MRIspine+, there being two gold standards: A. majority central reader decision as to the presence of spine MRI findings consistent with axSpA B. rheumatologist expert opinion diagnosis of axSpA.

Methods: Eight ASAS-MRI readers recorded MRI lesions in the spine according to recently updated ASAS definitions from 62 cases in an eCRF that comprises global assessment (MRI consistent with axSpA? (yes/no)), and detailed scoring of lesions for all sites in the spine. We calculated sensitivity and specificity for numbers of vertebral corners with BME where a majority of readers (≥5/8) agreed as to the presence of MRI findings consistent with axSpA. We selected cut-offs with ≥95% specificity. These cut-offs were analyzed for their predictive utility for rheumatologist diagnosis of axSpA by calculating positive and negative predictive values (PPV, NPV) and selecting cut-offs with PPV ≥95%. Both criteria were considered requirements for designation of MRI cut-offs defining ASAS-MRIspine+.

Results: MRI findings consistent with axSpA were observed by majority read in 8 (20%) of 40 cases diagnosed with axSpA, and 0 (0%) of 19 cases without axSpA. Cut-offs achieving specificity of ≥95% for MRI findings consistent with axSpA were 4 vertebral corners (sensitivity 75%) for all cases, 3 vertebral corners (sensitivity 37.5%) for cases with ≥1 additional location with inflammation, 1 vertebral corner (sensitivity 62.5%) in cases with ≥2 vertebral corner fat lesions (Table 1). All of the above cut-offs also had very high PPV (≥95%) for diagnosis of axSpA in cases diagnosed by the rheumatologist (Table 2).

Table 1. Majority readers agree MRI findings consistent with axSpA are present is the gold-standard external reference

MRI cut-offs	Sensitivity (95%CI)	Specificity (95%CI)
BME in ≥2 vertebral corners	87.5 (47.3 - 99.7)	87.0 (75.1 - 94.6)
BME in ≥ 3 vertebral corners	87.5 (47.3 - 99.7)	94.4 (84.6 - 98.8)
BME in ≥4 vertebral corners	**75.0 (34.9 - 96.8)**	**98.2 (90.1 - 100.0)**
Cases with ≥1 additional non-corner site inflammatory lesion		
BME in ≥2 vertebral corners	37.5 (8.5 - 75.5)	94.4 (84.6 - 98.8)
BME in ≥3 vertebral corners	**37.5 (8.5 - 75.5)**	**98.2 (90.1-100.0)**
Cases with ≥2 vertebral corner fat lesions		
BME in ≥1 vertebral corner	**62.5 (24.5 - 91.5)**	**100.0 (93.4-100.0)**
BME in ≥2 vertebral corners	62.5 (24.5 - 91.5)	100.0 (93.4-100.0)

Table 2. Predictive values of cut-offs for number of vertebral corners with BME according to the diagnostic ascertainment of the rheumatologist

MRI cut-offs	Sensitivity (95%CI)	Specificity (95%CI)	PPV	NPV
MRI findings consistent with axSpA ≥any 2 readers	52.5 (36.1 - 68.5)	94.7 (74.0 - 99.9)	95.5 (75.3 - 99.3)	48.6 (40.2 - 57.2)
MRI findings consistent with axSpA ≥majority read	20.0 (9.1 - 35.6)	100.0 (82.4 - 100.0)	100.0	37.3 (33.7 - 40.9)
BME in ≥ 4 vertebral corners	**17.5 (7.3 - 32.8**	**100.0 (82.4 - 100.0)**	**100.0**	**36.5 (33.3 - 39.9)**
Cases with ≥1 additional inflammatory lesion				
BME in ≥ 3 vertebral corners	**10.00 (2.8 - 23.7)**	**100.00 (82.4 - 100.0)**	**100.0**	**34.5 (32.2 - 36.9)**
Cases with ≥2 vertebral corner fat lesions				
BME in ≥1 vertebral corner	**12.50 (4.2 - 26.8)**	**100.00 (82.4 - 100.0)**	**100.0**	**35.2 (32.6 - 37.9)**

Conclusion: A cut-off of BME in ≥4 vertebral corners, or ≥3 corners in the setting of additional inflammatory lesions at other locations or corner fat, are primary candidates for defining ASAS-MRIspine+. These cut-offs apply to typical patients referred to a rheumatologist with a high index of suspicion of axSpA and may not be appropriate in other populations.

Background: Whole-body MRI (WB-MRI) allows assessment of the overall inflammation in arthritis patients, including joint and entheses. To enhance the use of WB-MRI in clinical trials, the OMERACT MRI in Arthritis Working Group developed the OMERACT MRI Whole-body score for Inflammation in Peripheral joints and Entheses in inflammatory arthritis (MRI-WIPE) [1]. This has been validated for the entire body, including the hip/pelvis region, but not for each individual region. More detailed scoring systems exist for heels, hands and feet but although hip arthritis is a key cause of functional impairment in spondyloarthritis (SpA), no detailed scoring system has been published for use in SpA. The Hip Inflammation Magnetic Resonance Imaging Scoring System (HIMRISS) was developed and validated in osteoarthritis showing good reliability.

Objectives: To validate reliability, correlation and responsiveness of two WB-MRI scores for the hip/pelvis region in SpA.

Methods: Inflammation in the hip/pelvis region was assessed on coronal WB-MRIs in 4 iterative multi-reader exercises using MRI-WIPE for the hip/pelvis region and HIMRISS (Figure 1). In final exercises, images (axial/peripheral SpA and psoriatic arthritis) were obtained before and after TNF-inhibitor.

Figure 1

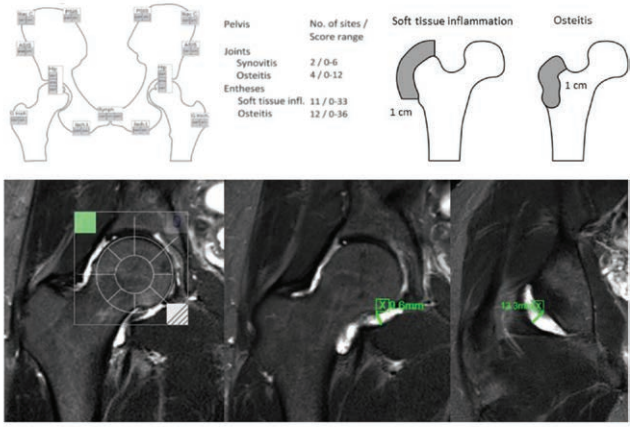

Figure 1. Upper row, left: MRI-WIPE schematic and scoring ranges for the hip and pelvis insertion of the region from Krabbe et al. [1]; Lower row, right: schematic drawing of the principle of scoring osteitis and soft tissue inflammation using MRI-WIPE, illustrated by the greater trochanter.
Lower row: Left coronal STIR whole-body MR image of the hip with the web-based semitransparent overlay used in HIMRISS for osteitis scoring positioned for femoral head and acetabulum; Right two examples of synovitis/effusion measuring according to HIMRISS.

Results: In final exercises reliability was mostly good for the best calibrated readers. Median single-measure intraclass correlation coefficients were 0.58-0.65 (WIPE osteitis), 0.10-0.88 (HIMRISS osteitis), 0.38-0.72/0.52-0.60 (WIPE synovitis/effusion) and 0.68-0.89/0.78-0.85 (HIMRISS synovitis/effusion) (Table 1). The methods correlated significantly for status in osteitis (0.72, p=0.019) and for synovitis/effusion status (0.83, p=0.003) and change (0.73, p=0.017) (Table 1). In exercise 4 Wilcoxon signed-rank test showed significant change in osteitis between timepoints using WIPE hip/pelvis and SRM was large (1.23), while lower for WIPE synovitis/effusion and HIMRISS.

Conclusion: MRI-WIPE and HIMRISS may be useful tools in modular WB-MRI evaluation of hip/pelvis inflammation in clinical trials in SpA.

OP0253

STRUCTURAL DAMAGE IN AXIAL SPONDYLOARTHRITIS: IS THERE A PREFERRED WAY TO ASSESS PROGRESSION OVER TIME?

X. Baraliakos[1], V. Rios Rodriguez[2], M. Torgutalp[2], A. Dilbaryan[2], H. Haibel[2], M. Verba[2], J. Sieper[2], J. Braun[1], M. Rudwaleit[3], D. Poddubnyy[2,4]. [1]*Ruhr-University Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany*; [2]*Charité-Universitätsmedizin, Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*; [3]*Klinikum Rosenhöhe, Universitätsklinikum OWL, Bielefeld, Germany*; [4]*German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany*

Background: Axial spondyloarthritis (axSpA) is characterized by development of structural damage in the spine, assessed by conventional radiographs (CR). The modified Stokes Ankylosing Spondylitis Scoring System (mSASSS) includes all the SpA-relevant CR findings and is the most frequently used scoring system for quantification of spinal structural damage in patients (pts) with axSpA. Radiographic progression over 2 years using mean mSASSS progression, scored by a blinded 'paired' (sets of CRs of the same patient) approach, is considered as a key treatment outcome reflecting structural progression in clinical trials. However, this approach has been accompanied by questions about the influence of pts showing mSASSS 'improvement', indicating possible disappearance of syndesmophytes over time, something 'naturally unexpected'.

Objectives: To investigate the performance of mSASSS in assessing spinal radiographic damage and progression in axSpA pts using different approaches of CR evaluations.

Methods: Complete sets (cervical and lumbar CRs) from the German SpA Inception Cohort (GESPIC) at baseline and after 2 years were blinded to all clinical and demographic characteristics and then scored using the mSASSS by 5 different experienced readers, 2 blinded and 3 unblinded to the timepoint of CR performance. The final mSASSS score was calculated as a mean of 2 (blinded) or 3 (unblinded) readers. Descriptive statistics, cumulative probability plots and shift analyses *(agreement of 2/2 readers in the blinded and 2/3 readers in the unblinded group)* were performed for each reader group.

Results: A total of 210 pts (mean age 37.3y, 51% male, 79% HLA-B27+) with non-radiographic (n=115) and radiographic (n=95) axSpA at baseline were included. The mean mSASSS at baseline was 4.3±8.3 vs. 3.4±7.9, while the mean progression was 0.7±2.3 vs.1.0±1.9 mSASSS units for the blinded vs. the unblinded group, respectively (Figure). On the patient level, progression of ≥2 mSASSS units was found in 30 (14.3%) vs. 37 (17.6%) pts in the blinded vs. the unblinded group, while agreement between groups was seen in 179 (85.2%) pts, 18 (8.9%) pts for progression and 161 (76.7%) for no progression.

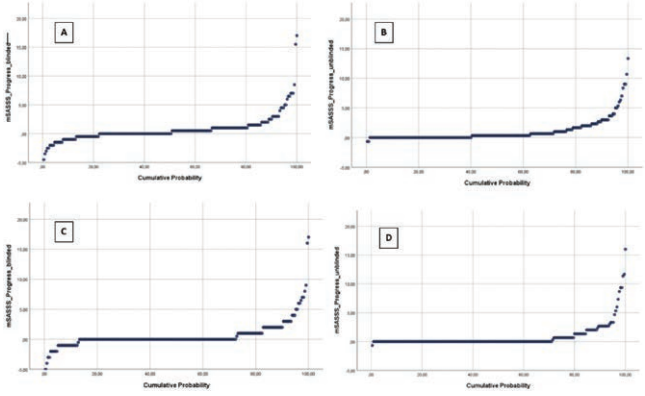

Figure 1. Cumulative probability plot for mean mSASSS scores (all scores) in blinded (A) and unblinded (B) and 'definite' scores in blinded (C) and unblinded (D) scoring approach

In the analysis of 'definite' CR findings (only scores of 2=syndesmophytes or 3=ankylosis), the mean mSASSS score at baseline was 3.3±8.0 vs. 2.6±7.2 and the mean radiographic progression was 0.6±2.4 vs. 0.8±2.1 mSASSS units for the blinded vs. the unblinded group, respectively (Figure). On the patient level, progression was found in 37 (17.6%) vs. 33 (15.7%) pts in the blinded vs. the unblinded group, while agreement between groups was seen in 188 (89.5%) pts, 24 (11.3%) for progression and in 164 (78.1%) pts for no progression.

In the shift analysis, mSASSS worsening was found in 35 (0.8%) and mSASSS 'improvement' in only 4 (0.1%) out of a total of 4.373 vertebral edges (VE) analyzed in the blinded and in 109 (2.2%) and 2 (0.04%), respectively, out of a total of 4.914 VE analyzed in the unblinded group (Table). The majority of progression was found for the development of 'definite' signs of progression in both the blinded (25/35, 71.4%) and the unblinded (61/109, 56%) group, while more VE showing 'minor' (only scores of 1=sclerosis, squaring, erosion) signs of progression were found in the unblinded (48/109, 44%) vs. to the blinded (10/25, 28.6%) group.

Conclusion: Despite lower mean baseline mSASSS, higher mean mSASSS progression was found using the unblinded approach, while in the shift analysis the unblinded approach was also more specific, confirming the absence of 'improvement' of radiographic damage over time. These results were similar in the analysis on the patient's level. The scoring approach and the influence of 'minor' radiographic changes should be taken into account for avoiding the so-called 'background noise' in the evaluation of mSASSS.

OP0254

AN ARTIFICIAL NEURAL NETWORK FOR THE DETECTION OF DEFINITE RADIOGRAPHIC SACROILIITIS WITH HIGH SPECIFICITY IN THE DIAGNOSTIC SETTING

J. L. Vahldiek[1], K. K. Bressem[1], S. Niehues[1], L. Adams[1], L. Spiller[2], M. Protopopov[2], V. Rios Rodriguez[2], B. Muche[2], J. Rademacher[2], H. Haibel[2], M. Torgutalp[2], F. Proft[2], D. Poddubnyy[2,3]. [1]*Charité – Universitätsmedizin Berlin, Division of Radiology, Berlin, Germany*; [2]*Charité – Universitätsmedizin Berlin, Division of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*; [3]*Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology Unit, Berlin, Germany*

Background: Radiographs of the sacroiliac joints are commonly used as the first imaging method for the diagnosis of axial spondyloarthritis (axSpA), but the reliability of sacroiliitis detection is usually low. Recently we developed a deep convolutional neural network (CNN) that can detect radiographic sacroiliitis with expert-like accuracy in patients with axSpA, i.e., classification as radiographic or non-radiographic [1]. There is frequent criticism that many artificial intelligence algorithms for diagnostic analysis of medical images lack robust validation in real-world clinical applications.

Objectives: The aim of this study was to evaluate the performance of our deep CNN in detecting definite radiographic sacroiliitis in the diagnostic setting.

Methods: In this study, we included a total of 361 patients with chronic back pain who presented to a rheumatologist in a specialized SpA center with a suspicion of axSpA within the OptiRef project [2]. All patients received a structured rheumatologic diagnostic work-up that resulted in the final diagnosis of axial SpA/no axial SpA. Radiographs of sacroiliac joints were evaluated by a rheumatologist and radiologist according to the modified New York criteria; the consensus judgement of the presence of definite radiographic sacroiliitis (>=grade 2 bilaterally or >=grade 3 unilaterally) was used as a reference. The predictions of the deep CNN's inference (with a balanced cutoff of 0.724 for the predictions of the model that was derived from the training and validation steps [1]) on all available pelvic radiographs was compared to this reference judgement.

Results: Pelvic radiographs of 340 patients (110 with axSpA including 61 patient with radiographic and 49 with non-radiographic axSpA, and 230 without SpA) were available for the CNN evaluation. The deep CNN achieved a sensitivity of 79% for the diagnosis of radiographic axSpA. The specificity of radiographic sacroiliitis detection was 94% (Table 1). The area under the receiver operating characteristics curve for the prediction of the presence of definite radiographic sacroiliitis was 88%. Figure 1 shows an exemplary class activation map of our CNN.

Table 1. Convolutional neural network predictions of the presence of radiographic sacroiliitis in patients with suspected axSpA according to the final diagnosis by rheumatologist in OptiRef (N=340).

Clinical diagnosis	CNN's prediction on the presence of definite radiographic sacroiliitis	
	Present	**Not present**
Radiographic axial SpA	48/61 (78.7%)	13/61 (21.3%)
Non-radiographic axial SpA	4/49 (8.2%)	45/49 (91.8%)
No SpA (other diagnosis)	14/230 (6.1%)	216/230 (93.9%)

Conclusion: The artificial neural network showed good generalizability and a high specificity with acceptable sensitivity in the detection of radiographic sacroiliitis when applied in the diagnostic setting of patients with chronic back pain and suspicion of axSpA. This algorithm can therefore be used to aid the detection of radiographic sacroiliitis as a part of the diagnostic approach.

OP0255 THE ROLE OF PELVIC MORPHOLOGY IN AXIAL SPONDYLOARTHRITIS

E. Zaccagnino[1], R. Patel[2], L. S. Gensler[3]. [1]*UCSF Medical Center, School of Medicine, San Francisco, United States of America*; [2]*UCSF Medical Center, Radiology & Biomedical Imaging, San Francisco, United States of America*; [3]*UCSF Medical Center, Rheumatology, San Francisco, United States of America*

Background: Axial Spondyloarthritis (axSpA) is a chronic inflammatory disease affecting the axial skeleton. It includes non-radiographic axSpA and radiographic axSpA [Ankylosing Spondylitis (AS)]. Male axSpA patients often have greater damage, while women report a higher disease burden. The role of pelvic morphology in the axSpA phenotype has not been explored. There is anatomic sexual dimorphism between the male and female pelvis. Given the phenotypic gender differences in axSpA, the role of pelvic morphometry is of interest.

Objectives: The purpose of this study is to determine whether an association exists between pelvic dimensions and radiographic damage in patients with axSpA, as well as to compare these measurements in axSpA patients and healthy controls.

Methods: This was a cross-sectional analysis comparing axSpA cases from a prospective cohort and non-axSpA controls from the UCSF radiology databank. Informed consent was obtained from axSpA cohort patients and this study was approved by the institutional IRB. To be included in the analysis, we limited inclusion to age ≤ 50 with an Anterior Posterior (AP) pelvis radiograph in the system. We excluded non-nulliparity, pelvic fracture history, BMI ≥ 30kg/m2, any prosthetic history and avascular necrosis. We measured the pelvic inlet, pelvic outlet, and subpubic angle (based on validated scoring methods) (Figure 1) and assessed its relation to sacroiliac joint (SIJ) damage (average SIJ score, New York criteria) and modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) in cases. AxSpA patients were also compared to age/gender matched controls. Pelvic measurements were performed by 2 blinded independent-trained readers in randomized, blinded image order. Inter-rater reliability was assessed. When examining the relationship between pelvic measurements and damage, linear regression was used to stratify by gender and adjust for potential confounders.

Results: The axSpA cohort included 481 patients, of which 210 men and 89 women were included in this analysis and gender/age matched controls. Rater inter-class correlation was above 0.70 for pelvic outlet and above 0.80 for other measures. Cases and controls were similar (Table 1). The regression analysis showed a significant relationship between the sub-pubic angle and damage in the spine (coeff=-0.342, p=0.003) in men with axSpA. A sensitivity analysis, excluding mSASSS outliers (mSASSS ≥ 16) upheld the relationship (coeff=-1.40, p=0.002).

Conclusion: In men with axSpA, there appears to be a relationship between sub-pubic angle and spinal radiographic damage. This is consistent with our finding that women have larger sub-pubic angles and lower spinal radiographic damage than men. A greater sub-pubic angle may protect against spinal involvement or associate with other protective factors. Further work should be performed to understand the contribution of pelvic anatomy to damage in axSpA.

OP0256 CHOOSE WISELY: IMAGING FOR DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS

T. Diekhoff[1], I. Eshed[2], F. Radny[1], K. Ziegeler[1], F. Proft[3], J. Greese[1], D. Deppe[1], R. Biesen[4], K. G. Hermann[1], D. Poddubnyy[3,5]. [1]*Charité Universitaetsmedizin Berlin, Division of Radiology, Berlin, Germany*; [2]*Chaim Sheba Medical Center, Division of Radiology, Tel Aviv, Israel*; [3]*Charité Universitaetsmedizin Berlin, Divison of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*; [4]*Charité Universitaetsmedizin Berlin, Division of Rheumatology and Clinical Immunology, Berlin, Germany*; [5]*German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany*

Background: To date, the European Alliance of Associations for Rheumatology (EULAR) guidelines recommend X-ray (XR) as first line imaging in axial Spondyloarthritis (axSpA) and magnetic resonance imaging (MR) if the diagnosis cannot be established by XR and clinical features. However, much knowledge has been gained recently strengthening the applicability of MR for the detection of structural lesions and raising the question, whether XR is still necessary. Also, several publications used low-dose computed tomography (CT) as reference standard and imaging test.

Objectives: In light of this complex diagnostic situation, the aim of this study was to compare the three major modalities, XR, MR and CT of SIJ, in their diagnostic performance of axSpA and differential diagnosis in a cohort of patients with low back pain using the final judgment of the rheumatologist as standard of reference.

Methods: 163 patients (89 with axSpA; 74 with degenerative diseases) underwent XR, CT and MR. Three blinded experts categorized the imaging into axSpA, other diseases or normal in 5 separate reading rounds (XR, CT, MR, XR+MR, CT+MR, respectively). The results were compared to the clinical diagnosis. Sensitivity and specificity values for axSpA and interrater reliability were compared.

Results: XR showed lower sensitivity and specificity (66.3%/67.6% respectively) compared to MR (82.0%/86.5%) and CT (77.5%/97.3%). Sensitivity and specificity of XR+MR was similar to MR alone (77.5% / 87.8%). However, CT+MR was

superior to MR alone (75.6% / 97.3%) (see Figure). CT had the best interrater reliability (kappa = 0.875) followed by MR (0.665) and XR (0.517). CR+MR reliability was similar (0.662) compared to MR alone, while CT+MR reliability (0.732) was superior.

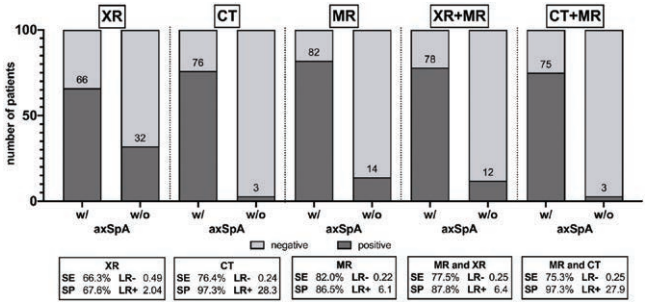

Figure 1. Frequency of positive and negative findings in radiography (XR), computed tomography (CT), magnetic resonance imaging (MR) and combinations and resulting diagnostic accuracy values. SE: Sensitivity, SP: Specificity, LR-/+: negative/positive likelihood ratio.

Conclusion: In conclusion, XR is inferior to cross-sectional imaging and should be replaced by MR or CT for differential diagnosis. While MR is the most sensitive imaging technique, it lacks specificity when compared to CT. CT alone has high diagnostic accuracy, despite being insensitive to bone marrow lesions such as fatty metaplasia or osteitis. Adding CT to MR leads to an increase in specificity at a minor expense of sensitivity.

OP0257

VALUE OF COLOR DOPPLER ULTRASOUND ASSESSMENT OF SACROILIAC JOINTS IN NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS:A COMPARISON WITH ANKYLOSING SPONDYLITIS

N. MA[1], S. Haili[1]. [1]*Lanzhou University Second Hospital, Rheumatology, Lanzhou, China*

Background: Ultrasound (US) is an accessible imaging technique with a possible role to diagnose active sacroiliitis, so this technique is projected as a promising diagnostic tool for the diagnosis of spondyloarthritis(SpA).The diagnostic value of sacroiliac US has been studied in patients with Ankylosing Spondylitis(AS),becoming a useful and practical tool in comparison with MRI.There are scarce data on the utility of US in the evaluation of Non-radiographic Axial Spondyloarthritis (nr-axSpA).

Objectives: The aim of this study is to evaluate the diagnostic utility of color Doppler ultrasound (CDUS) for the detection of sacroiliitis in patients with nr-axSpA and AS.

Methods: Patients with nr-axSpA (n=114) and AS(n=80) were enrolled in the study with standardized clinical criteria.According to the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI),nr-axSpA and AS patients were separately divided into active group(n=47,n=43)and inactive group (n=67,n=37). All patients underwent clinical evaluation,and CDUS of sacroiliac joints (SIJs) within the same week. Vascularization, the resistive index (RI) of the SIJs and the first foraminal ramus of the lateral sacral artery were observed and measured by a sonographer who is blinded to initial clinical and radiological assessments. The associated statistics and graphs was utilized to obtain the relationship,which were reflected by the Co-index receiver operating characteristic(ROC)curve or calculating the area under ROC curve(AUC),between the RI of the SIJs and the RI of the first foraminal ramus of the lateral sacral artery in nr-axSpA and AS by using the Logistic Regressive analysis methods,SPSS24.0 and MedCalc19.6.0 software.With MRI-proven sacroiliitis as the
diagnostic standard,the Kappa test were used to measure the consistency between the RI of the SIJs and MRI.

Results: 1. The RI of the SIJs(AUC=0.855,P<0.001)and Co-index-(AUC=0.886,P<0.001)were similar sufficient (Z=1.331, P=0.183) to distinguish the active and inactive group in nr-axSpA .2.The RI of the SIJs(AUC=0.869,P<0.001)and Co-index(AUC=0.893,P<0.001)were also similar sufficient (Z=1.292, P=0.196) to distinguish the active and inactive group in AS .3.Neither of the RI of the first foraminal ramus of the lateral sacral artery in nr-axSpA(AUC=0.748,P<0.001)and AS(AUC=0.674,P=0.003)was outstanding to distinguish the active and inactive group.4.The RI of the SIJs was similar sufficient (Z=0.267,P=0.790) to detect sacroiliitis in nr-axSpA and AS.5. The Co-index was also similar sufficient (Z=0.146, P=0.884) to detect sacroiliitis in nr-axSpA and AS.6.The RI of the SIJs in nr-axSpA and AS showed moderate consistency with MRI(the Kappa values were 0.534 and 0.609,respectively,P<0.01).

Conclusion: The RI of the SIJs is a possible role to diagnose active sacroiliitis, so CDUS is projected as a promising diagnostic tool for the diagnosis of nr-axSpA and AS in comparison with MRI.

HPR Abstract Session (II)

OP0258-HPR

IS THERE A SUBSET OF PATIENTS WITH SJÖGREN'S SYNDROME WHO ARE MORE AT RISK FOR SEXUAL DYSFUNCTION? RESULTS FROM A SCOPING REVIEW

J. McCready[1], M. Hogg[2], V. Deary[3,4], T. Collins[1], K. Hackett[1,4]. [1]*Northumbria University, Department of Social Work, Education and Community Wellbeing, Newcastle upon Tyne, United Kingdom*; [1]*Northumbria University, Department of Social Work, Education and Community Wellbeing, Newcastle upon Tyne, United Kingdom*; [3]*Northumbria University, Department of Psychology, Newcastle upon Tyne, United Kingdom*; [4]*Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*

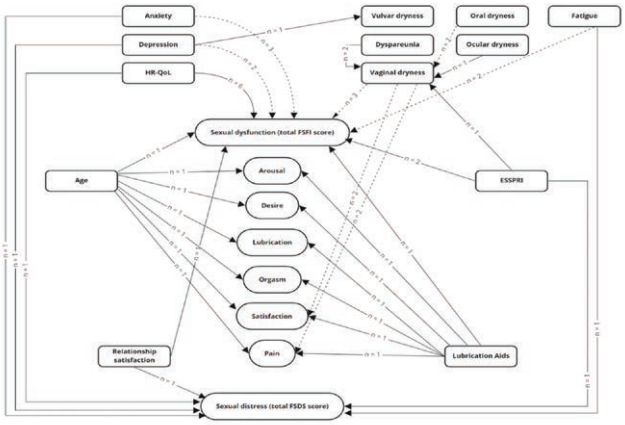
Background: Individuals with Sjögren's syndrome (SS) experience significantly higher levels of sexual dysfunction and sexual distress than healthy controls (van Nimwegen et al., 2015). Identifying associated factors may help to identify a subgroup of patients with SS who may benefit from early intervention to maintain sexual wellbeing and avoid unnecessary sexual disruption.

Objectives: To explore and map the salient symptoms and factors that influence alterations in sexual functioning and intimate relationships for people with SS.

Methods: The protocol for this review was registered with the Open Science Framework prior to commencement of the searches. The peer-reviewed search strings were used to search the following databases from inception to June 2019: Cochrane Library, CINAHL [EBSCO], MEDLINE [ProQuest], PUBMED [MEDLINE], ScienceDirect, Scopus and Web of Science. Grey literature was searched for on academic databases, topic-specific repositories, and Google Scholar. Databases were searched using key terms corresponding to sexual functioning and intimate relationships. Studies were included if their participant sample was comprised of adults aged ≥18 years, with a diagnosis of primary or secondary SS. Studies were not excluded based on source type, methodology or design. To qualify for inclusion, studies needed to have been peer-reviewed and available in English. Retrieved articles were then screened against the inclusion/exclusion criteria by two reviewers. Hand-searching was conducted on the reference lists of included articles, as well as the three most prevalent publishing journals until saturation had been achieved.

Results: The search strategy returned 3527 unique citations. After screening processes were completed, only 19 articles met the inclusion criteria. Studies were predominately conducted in European countries (79%), within the last decade (68%; 2010-2019), and were mainly quantitative (n = 17; 89.5%), case-controlled

(88.3%), and cross-sectional (100%) in nature. In total there were 1281 patients, 47% (n = 605) were patients with primary SS and the remaining 53% (n = 676) were patients with secondary SS. Both patient groups were predominately comprised of females (n = 600; 99% and n = 673; 99.5%, respectively), with a combined mean age of 50.82 years (*M* ranges = 35 – 62.82 years). An amalgamation of results from 17 studies, found that women with SS who score higher on the ESSPRI scale (total score and the subdomains of pain, fatigue and dryness) were more likely to experience significantly greater levels of vaginal dryness, sexual dysfunction and sexual distress. Moreover, women with SS who present with clinical levels of anxiety or depression were also more likely to experience disruptions in their sexual functioning and appraise their sexual life more negatively. Furthermore, patients who report greater severity of oral or ocular dryness, or dyspareunia may experience vaginal dryness, which may have ramifications on sexual functioning. Women of all ages are at risk of experiencing sexual dysfunctions, however, younger women (≤50 years) may experience more burdensome disruptions than older women. Finally, women who do not use lubrication products during sexual activity may be impacted further.



Note. The solid line represents results that were significant across studies. The dotted line represents results where the significance was inconsistent across studies. Relationships that were unanimously non-significant are not shown.

Figure 1. Factors significantly associated with sexual dysfunction and sexual distress for patients with SS.

Conclusion: Younger women (≤50) with SS who present with more severe symptoms of fatigue, pain, and oral or ocular dryness, or with clinical levels of anxiety or depression, may be at increased risk of experiencing sexual dysfunction and sexual distress. Healthcare professionals should be aware of these potential risk factors and initiate conversations around sexuality as and when a potentially 'at risk' individual is identified.

OP0259-HPR THE EFFECT OF OSTEOARTHRITIS ON HEALTHY WORKING LIFE EXPECTANCY AT AGE 50 IN ENGLAND

M. Lynch[1], M. Bucknall[1], C. Jagger[2], R. Wilkie[1]. *[1]Keele University, School of Medicine, Newcastle under Lyme, United Kingdom*; *[2]Newcastle University, Population Health Sciences Institute, Newcastle, United Kingdom*

Background: Retirement ages are rising in many countries due to population ageing and increasing life expectancy. However, poor health, comorbidity and workplace factors are major reasons for work absence and it is unclear if people in later working-age life (age ≥50) are able to work for longer. Osteoarthritis (OA), the most common joint condition in adults, is the fastest increasing major health condition globally and is a leading cause of disability (especially in adults age ≥50).

Objectives: We aimed to estimate healthy working life expectancy (HWLE; defined as the average number of years that adults from age 50 can expect to be healthy and in paid work) for adults with and without osteoarthritis and investigate the role of mental health problems as a comorbidity and the role of workplace factors through examining whether there is a sense of having any control over what happens at work.

Methods: Longitudinal survey data of adults aged ≥50 years were used from six waves (2002-2013) of the English Longitudinal Study of Ageing with linked mortality data from the National Health Service Central Register. HWLE was defined using two self-report variables; health was defined as no long-standing illness or no activity limitation if long-standing illness was present, and work was defined being in employment or self-employment. OA status was identified by self-report of ever receiving a diagnosis from a doctor. Mental health and control of work were measured by self-report. Continuous-time multistate models with three states (healthy and working [state 1], other alive [2], dead [3]) were fitted in R (version 3.6.1) to investigate factors driving transitions out of the healthy and working state. Models included age and combinations of sex, OA, control at work, and mental health problems. Age-adjusted hazards of transitions between states were estimated using the 'msm' R package. HWLE for adults with different factors (OA, control of work, mental health) was estimated with the 'elect' R package using models fitted with 'msm'. Missing data was handled using multiple imputation by predictive mean matching.

Results: There were 11,540 adults with at least two observations (including survey and mortality data) for the study period (5251 males, 6289 females). Life expectancy at age 50 was 29.7 years for men and 33.4 years for women with HWLE being 9.9 years (men) and 8.3 years (women). HWLE at age 50 for adults with osteoarthritis was 7.3 years (men: 8.2, women: 6.8), and for adults without osteoarthritis was higher at 9.9 years (men: 10.6, women: 9.1). After adjusting for age, the instantaneous risk of ceasing to be both healthy and in work (not due to death) for people with OA was 1.5 times that of people without OA (hazard rate ratio 1.5 with 95% CI [1.3, 1.6]). For adults without OA, HWLE at age 50 was 13.2 years if they felt they had control at work and 4.1 years without control at work, whilst for adults with OA, HWLE was 10.4 years if they felt they had control at work and 3.1 years without. The effect of mental health problems as a comorbidity on HWLE was smaller; for adults without OA, HWLE at age 50 was 11.0 years for those without mental health problems and 8.3 years for those with, whilst for adults with OA, HWLE was 8.6 years for those without mental health problems and 6.2 years with.

Conclusion: While the average HWLE for men and women in England is lower than State Pension age, HWLE at age 50 is even lower (by approximately 25%) in adults with OA compared to adults without OA. Poor mental health further reduces HWLE. However, good quality work environments significantly lessen the impact of osteoarthritis (there is a 7.3 year difference in HWLE for those with OA who do and do not experience control at work). These results suggest that interventions and policies that create appropriate job opportunities and supportive workplaces for older workers with health conditions are key to the feasibility and success of extended working life policies.

OP0260-HPR PREDICTORS OF WORK PARTICIPATION IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AFTER 12 MONTHS OF T2T THERAPY INTERVENTION

S. E. Meyer[1,2], J. R. Hoeper[3], T. Witte[1,2], K. Hoeper[1,2], D. Meyer-Olson[1,4]. *[1]Medizinische Hochschule Hannover, Clinic for Rheumatology and Immunology, Hannover, Germany*; *[2]Regionales Kooperatives Rheumazentrum Niedersachsen e.V., Hannover, Germany*; *[3]Leibniz Universität Hannover, Center for Health Economics Research Hannover, Hannover, Germany*; *[4]m&i Fachklinik Bad Pyrmont and Medizinisches Forschungszentrum Weserbergland, Bad Pyrmont, Germany*

Background: Rheumatoid arthritis (RA) is associated with restrictions on work participation (WP) caused mainly by periods of sick leave (absenteeism), reduced productivity at work due to disease (presenteeism) and occupational disability, which account for a significant proportion of indirect costs.

Objectives: We investigate the predictors of WP after 12 months of Treat-to-Target (T2T) intervention.

Methods: Data were analyzed from the multi-center ERFASS study, which included patients with rheumatoid factor and/or APCA positive RA after initiation or escalation of disease modifying anti rheumatic drug (DMARD) therapy following a T2T regimen prospectively over 12 months from 01/2018 to 12/2019. A total of 157 patients of working age (18 to 65 years) were included in this evaluation. Socio-demographic and occupational characteristics (WPAI, self-conducted work questionnaire), clinical parameters including disease activity (DAS28, RADAI), impact of disease (RAID), functional capacity (FFbH), depression (PHQ-9) and fatigue (VAS) were analyzed and logistic regression analysis to detect baseline predictors for unimpaired WP after 12 months was performed.

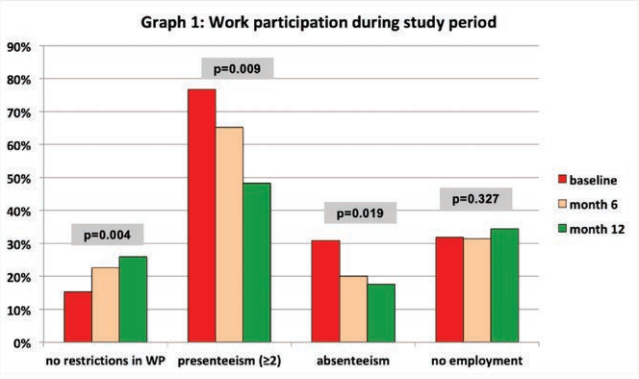
Results: The mean age of the patients was 52.9 years (standard deviation (SD): 8.19) and 117 (74.5%) were female. 51 patients (32.5%) started first line DMARDs and in 106 patients (67.5%) treatment was escalated. T2T resulted in a significant decrease in mean DAS28 from 4.2 (SD 1.10) at baseline to 2.5 (SD 1.11; p<0.001) after 12 months, 64.3% of the patients were in remission (DAS28<2.6) and 12.1% had low disease activity (DAS28 2.6-3.2). The proportion of patients with no impairment of WP increased significantly and presenteeism and absenteeism became significantly less prevalent, but the proportion

of patients with reduced WP at month 12 remained high (74.1%; graph 1). We observed a moderate positive significant correlation between presenteeism and absenteeism (r_{Mo12}=0.446; p<0.001). Patients with no restrictions on WP showed a significantly greater decrease in mean DAS28 from 3.7 (SD 1.15) at baseline to 1.9 (SD 0.61) at month 12 as compared to patients with restrictions (mean DAS28: 4.4 (SD 1.04) at baseline to 2.7 (SD 1.15) at month 12; p<0.001). Results from univariate and logistic regression analyses revealed high functional capacity and low depression score at baseline as major contributing factors for unimpaired WP (Table 1).

Table 1. Baseline predictors of work participation[1] at month 12

Predictors (independent variables)	Univariate analysis[2]: p-values	Multivariate analysis[3]: Odds Ratios, p-values
gender	0.117+	OR: 0.412; p=0.113
age	0.010*+	OR:0.951; p=0.071
school graduation	0.150+	
professional degree	0.739	
duration of complaints	0.127+	
therapy group (starters vs. escalation/ change)	0.004*+	
DAS-28(CRP)	0.001*	
CRP	0.906	
tender joints	0.004*	
swollen joints	0.021*	
disease activity (VAS)	0.003*+	OR: 0.827; p=0.086
subjective disease activity (RADAI)	<0.001*	
disease burden (RAID)	<0.001*	
functional capacity (FFbH)	<0.001*+	OR: 1.477; p=0.031*
fatigue (VAS)	<0.001*+	
depression (PHQ-9)	<0.001*+	OR: 0.876; p=0.035*
working time model (full vs. part-time)	0.498	
physical work load	0.427	

[1] dependant variable: 0=reduced WP (not working/ absenteeism/ presenteeism (≥2)); 1=full WP (working without absenteeism/ presenteeism (≥2))[2] according to applicability chi-square test, t-test for independent variables, Mann-Whitney-U test[3] binary logistic regression analysis, stepwise-backward procedure+ included into logistic regression model* significance level: p<0.05



Conclusion: Despite T2T and high DAS28 remission, we observed persistent limitations in WP. Impaired WP was associated with increased disease activity but logistic regression revealed a significant influence of depression and functional capacity. Our data underscore the multifactorial causes of impaired WP, which should be targeted by vocational rehabilitation.

OP0261-HPR PERCEIVED CHALLENGES AT WORK AND NEED FOR SUPPORT AMONG PEOPLE WITH INFLAMMATORY ARTHRITIS

C. M. T. Madsen[1,2], J. Reffstrup Christensen[3,4], A. Bremander[1,2,5], J. Primdahl[1,2,6]. [1]*Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark*; [2]*Department of Regional Health Research, University of Southern Denmark, Odense, Denmark*; [3]*Research Unit of General Practice, Department of Public Health, University of Southern Denmark, Odense, Denmark*; [4]*Research Unit of User Perspectives, Department of Public Health, University of Southern Denmark, Odense, Denmark*; [5]*Section of Rheumatology, Department of Clinical Sciences Lund, Lund University, Lund, Sweden*; [6]*Hospital of Southern Jutland, University Hospital of Southern Denmark, Aabenraa, Denmark*

Background: People with inflammatory arthritis (IA), i.e. rheumatoid arthritis, psoriatic arthritis and axial spondyloarthritis, often experience low work ability and up to 38% lose their job during the first years after being diagnosed with IA (1). As a result, people with IA have a higher risk of job loss and permanent exclusion from the labor market than people without IA (1, 2). Work-related rehabilitation is complex and encompass a variety of interventions which aim to reduce barriers to maintain work and improve work ability. Unfortunately, positive results from work-related rehabilitation is scarce (3), why a better understanding of the challenges people at risk for job loss experience is needed to develop relevant interventions.

Objectives: To explore perceived challenges and need for support to remain at work among people with IA who are at risk of job loss.

Methods: A qualitative explorative design based on a hermeneutic approach was applied. Outpatients with IA who considered themselves at risk for long-term job loss, were recruited at the Danish Hospital for Rheumatic Diseases. An interview guide was developed based on earlier results from a systematic review and qualitative studies in close cooperation with three patient research partners. Individual semi-structured interviews were performed from December 2019 to May 2020.

Results: Eleven women and four men with IA (aged 36-68 years) were interviewed. The participants were employed full time, part time or on sick leave. From the analysis, a main theme 'Balancing work as a part of everyday life' and four sub-themes emerged: 1) Working despite challenges, 2) Prioritizing energy for work, 3) Fatigue affects everything and 4) Need for support. To be able to work was very important to all participants. In general, they were stretching their limits, had concerns about maintaining their job and they used different strategies to deal with the challenges they met at work. Flexibility at work in every possible way and support from employers and co-workers were the main needs to be able to remain at work.

Conclusion: Overall, patients with IA prioritized to keep working, but experienced challenges with balancing their work and energy in everyday life. They need support and flexibility at work to be able to remain at work.

OP0262-HPR THE NEURO-QOL UPPER EXTREMITY FUNCTION SCALE: NEW OPPORTUNITIES TO MORE RELIABLY AND PRECISELY MEASURE SELF-REPORTED HAND FUNCTION AND SELF-CARE ACTIVITIES IN PEOPLE WITH RA

S. J. Bartlett[1], O. Schieir[2], M. F. Valois[3], G. Boire[4], J. Pope[5], E. Keystone[6], C. Thorne[7], D. Tin[7], C. Hitchon[8], L. Bessette[9], G. Hazlewood[10], V. Bykerk[11]on behalf of CATCH Investigators. [1]*McGill University & McGill University Health Centre, Clinical Epidemiology & Rheumatology, Montreal, Canada*; [2].,., *Montreal, Canada*; [3]*McGill University, Clinical Epidemiology, Montreal, Canada*; [4]*University of Sherbrooke, Rheumatology, Sherbrooke, Canada*; [5]*Western University, Rheumatology, London, Canada*; [6]*University of Toronto, Rheumatology,Toronto, Canada*; [7]*The Arthritis Program, Rheumatology, Newmarket, Canada*; [8]*University of Manitoba, Rheumatology, Winnipeg, Canada*; [9]*Laval University, Rheumatology, Québec, Canada*; [10]*University of Calgary, Rheumatology, Calgary, Canada*; [11]*Hospital for Special Surgery, Rheumatology, New York, Canada*

Background: RA is an inflammatory disease that results in pain and loss of function, especially in the hands and wrists. Brief self-assessment tools that can reliably and precisely quantify hand/wrist function are needed to assess inflammatory activity when a physical exam is not feasible and to capture day-to-day experience of living with RA. Neuro-QoL is part of the PROMIS family of self-report measures created using a patient-centred approach and IRT methodology. The Neuro-Qol Upper Extremity Function (UEF) scale measures ability across fine motor and ADLs involving digital, manual and reach-related function and self-care. Little is known about its performance in RA.

Objectives: To evaluate the validity and responsiveness of the 8-item Neuro-QoL UEF in RA. We hypothesized scores would be strongly (r>.70) associated with MHAQ, MD-HAQ, and PROMIS PF, moderately (r=.4 to .7) to symptoms, disease activity, and QoL indicators, and be responsive to change in disease activity and PF.
Methods: Data were from the 0 and 6-month visits of adults with early RA (sx <1 yr) enrolled in the Canadian Early Arthritis Cohort, a prospective real-world study at 16 sites across Canada. Participants completed the Neuro-QoL UEF, MHAQ, MDHAQ, PROMIS-29, and PT Global at each visit. Rheumatologists recorded joint counts and MD Global. To evaluate content validity, we examined descriptive statistics across CDAI disease activity levels, and Pearson correlations between the Neuro-QOL UEF, legacy measures, CRP & ESR. Responsiveness was assessed by correlating change scores from visits 0-6 between Neuro-QoL UEF, disease activity and legacy PF scores.
Results: The 262 participants were mostly white (83%) women (71%) with a mean (SD) age of 55 (13). Summary statistics at 6-months are shown in Table 1. Neuro-QOL UEF was moderately-strongly correlated with MHAQ, MDHAQ, PROMIS-PF (|r|=.63-.75) and moderately correlated with pain and stiffness, (|r|=.59, -.64), and CDAI, SDAI, PT&MD Global, TJ & SJ (|r|=.39-.58). Neuro-QOL UEF was moderately correlated with PROMIS QoL domains Pain, Fatigue, Anxiety, Depression, Sleep & Participation (|r|=.39-.60).

Table 1. Summary statistics of physical function and RA disease activity indices at 6 months.

	Mean	SD	Mdn	25%	75%	(Min, Max)
Physical Function						
Neuro-Qol UEF	46.5	9.7	53.8	37.5	53.8	(21.8, 53.8)
MHAQ (0-3)	0.29	0.43	0.13	0.00	0.38	(0.00, 2.25)
MD-HAQ (0-10)	1.39	1.64	0.70	0.00	2.00	(0.00, 8.00)
PROMIS-PF	46.4	8.5	46.2	39.5	56.0	(23.3, 56.0)
RA Disease Activity						
CDAI	9.3	9.9	6.0	3.0	13.0	(0.0, 56.0)
SDAI	10.7	10.9	6.8	3.1	15.2	(0.0, 57.0)
Patient Global	3.0	2.5	3	1	5	(0, 10)
MD Global	1.8	2.2	1	0	3	(0, 9)
Swollen Joints (28)	2.1	3.7	0	0	2	(0, 20)
Tender Joints (28)	2.4	3.9	1	0	3	(0, 24)

Neuro-QOL scores decreased in a dose-response manner across worsening CDAI DA states reflecting increasing impairment (Table 2). Persons with HDA reported the highest disability, scoring nearly 0.5 SD lower on the Neuro-QoL UEF than PROMIS PF. Change from baseline to 6 months in Neuro-QoL UEF was moderately correlated with changes in PROMIS PF, MHAQ, PT Global, and CDAI (|r|=.44-.65). The mean change and range from 0-6 months in Neuro-QoL was significantly larger than in PROMIS (8.9 [95% CI 7.5, 10.4] vs. 5.4 [95% CI 4.4, 6.4])(see Figure).

Table 2. Mean scores (95% CI) at 6 months by CDAI level.

	REM	LDA	MDA	HAD
NeuroQol UEF	52.8 (51.8, 53.7)	48.1 (46.6, 49.7)	42.0 (39.4, 44.6)	33.8 (30.5, 37.1)
MHAQ (0-3)	0.05 (0.02, 0.09)	0.19 (0.14, 0.24)	0.45 (0.34, 0.57)	0.90 (0.63, 1.17)
MD-HAQ (0-10)	0.31 (0.17, 0.46)	1.11 (0.90, 1.32)	2.15 (1.71, 2.59)	3.56 (2.56, 4.56)
PROMIS-PF	52.8 (51.4, 54.2)	46.8 (45.3, 48.2)	42.3 (40.4, 44.2)	38.0 (34.4, 41.6)

Conclusion: Clinicians, researchers, and patients benefit from practical self-report tools that reliably and precisely monitor hand function in RA. Results offer initial evidence of validity and responsiveness and support use of Neuro-QoL UEF to self-assess inflammatory activity in the hands and day-to-day experiences of living with RA.

OP0263-HPR THE ROLE OF PHYSICAL EXERCISES IN REDUCING CHRONIC FATIGUE IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Aleksandrov[1,2], M. Nikitin[3], V. Aleksandrov[1,2], N. Aleksandrova[1]. *[1]Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Department of Functional Research Method, Volgograd, Russian Federation*; *[2]Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation*; *[3]FSB Institution "National Medical Research Center for Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Sanatorium-Resort Complex "Vulan" - Scientific and Clinical Branch, Gelendzhik, Russian Federation*

Background: Physical activity is an important non-pharmacological intervention that has a combination of biological, physical and psycho-social benefits and can positively influence chronic fatigue in patients with rheumatoid arthritis (RA) [1, 2, 3].
Objectives: Evaluation of the effectiveness of the use of aerobic exercise (walking) to reduce fatigue in RA patients.
Methods: The study included 111 women with RA (mean age 54.4 ± 11.03 years old, mean duration of illness - 11.9 ± 9.3 years old). The DAS28-ESR indicator in RA patients was 2.84 [2.32; 3.05] points: low disease activity was diagnosed in 61.3% of patients, and remission in 38.7%. The average level of fatigue according to the VAS screening scale was 71.6 ± 8.93 points. Fatigue was assessed using the Bristol Rheumatoid Arthritis Fatigue Numerical Rating Scale (BRAF-NRS V2). To assess the patient's tolerance to physical activity, a 6-minute walking distance (6MWD) test was used. A walking test at 50 meters was used to assess the functional state of patients in dynamics. The rehabilitation program (RP) of patients (for 21 days) included morning hygienic gymnastics, dosed walking (daily, duration 30-60 minutes) and walking in the air up to 3-3.5 hours a day. Vigorous movements "through pain" were contraindicated.
Results: No association was found between the duration of RA and all of the used numerical fatigue scales (p> 0.05), but there was a weak positive relationship between VAS and NRS-overcoming with age (r = 0.21 and r = 0.28). An association between DAS28-ESR and numerical fatigue scales VAS (r = 0.21), NRS effect (r = 0.25) and NRS - overcoming (r = 0.24) was found, despite the fact that this study did not include patients with moderate and high RA activity. There was a significant correlation between the walking time and the number of steps during the 50-meter test (r = 0.6, p <0.001), as well as an association between the fatigue and the walking time (r = 0.33, p = 0.001 for VAS and r = 0.41, p <0.001 for NRS-severity) and the number of steps (r = 0.39, p <0.001 for VAS; r = 0.47, p <0.001 for NRS-severity; r = 0.44, p <0.001 for NRS-bridging).

Table 1. Dynamics of fatigue levels and physical indicators in RA patients

	Before RP	In the end of RP	p
VAS fatigue level	71,2 ± 9,08 (71,5; 64–78)	70,4 ± 9,15 (70; 64–78)	p>0,05
BRAF-NRS: severity	6,83 ± 1,21 (7; 6–8)	6,51 ± 1,18 (7; 6–7)	p<0,01
BRAF-NRS: effect	6,24 ± 1,07 (5; 4–6)	5,95 ± 1,08 (6; 5–7)	p<0,05
BRAF-NRS: overcoming	5,0 ± 1,7 (7; 6–8)	7,76 ± 1,37 (5; 4–5)	p>0,05
50 meter test, number of steps	79,3 ± 8,64 (78; 73–84)	78,91 ± 8,15 (78; 73–83)	p>0,05
50-meter test, walking time, seconds	56,7 ± 8,72 (57; 50–63)	55,9 ± 8,59 (56; 51–60)	p=0,01

* The data are presented as mean ± standard deviation (median; interquartile range)After the completion of RP (Table), RA patients showed a significant reduction in the aspects of fatigue according to the NRS-severity (Z = 2.98, p = 0.003) and NRS-effect (Z = 2.08, p = 0.037) scales. There was also a decrease in the time spent by patients performing the 50 m walking test (t = 2.63, p = 0.01), but the total number of steps did not change (t = 1.44, p = 0.154). Fatigue and pain are important barriers to physical activity, but it is severe fatigue that reduces physical activity in patients with RA [4]. At the same time, physical activity itself can become a factor in reducing fatigue [5], including by reducing the activity of the disease [6].

Conclusion: The severity of fatigue in RA patients can be reduced by actively using non-pharmacological treatment strategies. Walking is a simple and effective solution to increase physical activity and it has a significant effect on fatigue in RA.

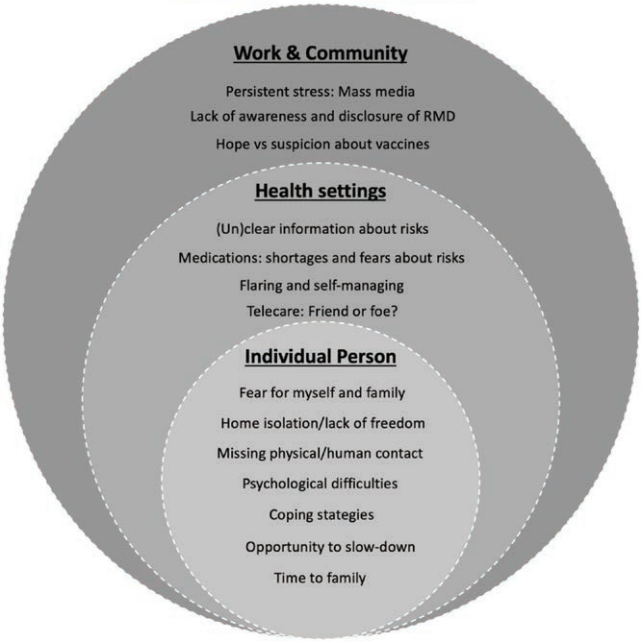
OP0264-HPR "I LITERALLY CONVINCED MYSELF I WAS GOING TO CATCH IT AND DIE": LIVED EXPERIENCES OF THE COVID-19 PANDEMIC BY PEOPLE WITH RHEUMATIC DISEASES FROM FOUR EUROPEAN COUNTRIES

R. J. O. Ferreira[1,2], C. Costa[3], A. Marques[1,2,4], A. J. Barata Cavaleiro[2,4], S. Makri[5], K. Parperis[6], S. Psarelis[7], R. Williams[8], G. E. Fragoulis[9], H. Lempp[8], E. Nikiphorou[8,10]. *[1]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; *[2]Escola Superior de Enfermagem de Coimbra, Health Sciences Research Unit: Nursing (UICISA: E), Coimbra, Portugal*; *[3]Centro Hospitalar e Universitário de Coimbra, Ortophedics, Coimbra, Portugal*; *[4]Escola Superior de Enfermagem de Coimbra, UCP Elderly Nursing, Coimbra, Portugal*; *[5]Cyprus League Against Rheumatism, Board, Nicosia, Cyprus*; *[6]University of Cyprus Medical School, Rheumatology, Nicosia, Cyprus*; *[7]Nicosia General Hospital, Rheumatology, Nicosia, Cyprus*; *[8]King's College London, Centre for Rheumatic Diseases, London, United Kingdom*; *[9]Laiko Hospital, University of Athens, First Department of Internal Medicine, Athens, Greece*; *[10]King's College Hospital, Rheumatology, London, United Kingdom*

Background: The COVID-19 pandemic has resulted in unforeseen challenges for humanity, taking a significant toll, especially the immune-suppressed individuals. In this regard, the health and general well-being of people with rheumatic diseases, the great majority users of immunosuppressives, have been at stake.
Objectives: To explore the impact of the COVID-19 pandemic on people with rheumatic diseases on immunosuppression during the first wave, concerning a) (self-)management of their disease; b) interaction with the health care team; c) emotional well-being and d) overall health.
Methods: A qualitative study was conducted following a phenomenological approach. Adults (>18 years) with a rheumatic disease from four European countries (Cyprus, England, Greece, Portugal). Patients were recruited through patient's associations and social media and were invited to participate in semi-structured, audio-recorded interview or focus groups, between July - August 2020. Following a pilot study the information provided was transcribed verbatim, anonymized and translated into English where necessary. An inductive approach was adopted to carry out a thematic framework analysis with the assistance of ATLAS.ti to identify key themes and subthemes. Data validation strategies were employed, and Ethical approval and informed consent were obtained.
Results: Participants were 24 patients (21 women, age range 33 to 74 years) divided by 7 focus-groups and 1 individual interview. Most frequent diagnoses were rheumatoid arthritis (n=7), lupus (n=4), juvenile idiopathic arthritis (n=3).
Three key themes with 3-7 subthemes were identified within the analytical framework, centred around the impact of the Covid-19 on patients' lives (Figure 1): i) individual person (e.g. fear for myself and family, social isolation and lack of personal freedom, more time with family) ii) health settings (e.g. (un)clear information about risks of contamination, fear or risk of shortages of medication, remote consultations), and iii) work and community (e.g. persistent stress due to mass media exposure, lack of awareness by others about patients' rheumatic disease and its disclosure, hope and suspicion about new vaccine development: "I hear that they will ask vulnerable groups to have the vaccine first (...) Why is that? we will be again the innocent victims"). Findings were similar across countries, except for spirituality (i.e. the pandemic as "the hand of God"), a coping subtheme particular to Portugal. These main themes resonated well with the social ecological model and Walsh's Family Resilience Process [1,2].

Figure 1. **Lived experiences of the Covid-19 pandemic by people with rheumatic diseases**



Conclusion: When experiencing a significant life-event people require some time to process the different lived experiences. This study provides insights on how patients from four countries coped with the new challenges. Such insights are invaluable for health care providers and policy makers, in guiding more meaningful support tailored to individual needs, especially at times of crisis. The study highlights the impact of COVID-19 on the lives of people with rheumatic disease. A follow-up study is currently underway to examine the effect of subsequent waves of the pandemic.

OP0265-HPR IMPACT OF COVID-19 PANDEMIC ON RHEUMATOLOGY PATIENTS IN NORTHERN IRELAND – A WEB BASED CROSS-SECTIONAL SURVEY

P. McKee[1], A. Irvine[1], C. Riddell[1], E. Ball[1]. *[1]Musgrave Park Hospital, Rheumatology, Belfast, United Kingdom*

Background: Concern for the susceptibility of rheumatology patients to severe COVID-19 illness has been raised since the start of the pandemic. Rheumatic disease and their immunosuppressant therapies placed many patients into the 'clinically extremely vulnerable' group when the UK's shielding guidance commenced on 23 March 2020. The impact of DMARDs/glucocorticoids/biologics on COVID-19 remains under investigation [1]. A recent study suggested caution may be required with rituximab and sulfasalazine in COVID-19 patients [2].

Objectives: The objective of this study is to evaluate the impact of the COVID-19 pandemic on rheumatology patients in Northern Ireland by assessing demographics, rheumatic disease, medications, disease progress, shielding advice, access to primary & tertiary care and incidence of COVID-19 infection.
Methods: A web-based cross-sectional survey was completed in Northern Ireland. The study duration was between 23rd November 2020 and 22nd January 2021. The questionnaire included consent, demographic details, medication history, comorbidities, disease course, patient experience, shielding advice, COVID-19 illness and hospitalisation. The survey was publicised by sending 6,032 Belfast Trust NHS patients a link via SMS, posters were displayed in rheumatology departments, and links made available via NHS/Versus Arthritis social media platforms.
Results: There were 2,615 responses and of these 2,539 had been completed and were analysed. Most respondents were aged 45+ (78.27%) and female (N=1819). Rheumatoid arthritis (41%) and psoriatic arthritis (29%) were the most common diagnoses. Just over one third (35.27%, N=896) of patients were on biological drugs. Most patients were taking methotrexate (28.04%) followed by hydroxychloroquine (15.20%) and adalimumab (12.52%). The majority (79.6%) continued treatment during the pandemic. There was evidence of disease 'flaring' in 30.75% of patients who had stopped treatment. Of the respondents surveyed 7.8% (N=198), tested positive for Covid-19 and of these 77.55% reported that they had received adequate shielding advice, primarily from GP or UK government sources. Only 11.11% (N=22) of those who tested positive for Covid-19 required hospital admission and 2 patients required intensive care support. Both patients requiring ICU were not on immunosuppression. Less than one third of patients testing positive for COVID-19 were on biological drugs (30.3%, N=60). Cardiovascular disease was the most prevalent comorbidity. Of the 22 patients hospitalised with COVID-19, 13.64% (N=3) were on solitary sulphasalazine therapy.
Conclusion: The survey showed low levels of COVID-19 hospitalisation despite most patients continuing DMARD/biologic/glucocorticoid therapy. This has been replicated in other studies [1], however data continues to be gathered on the safety of some biologic drugs particularly rituximab [2]. Most of our patients received clear understandable shielding guidance from a variety of sources. Many patients expressed fear of mortality, isolation and mental health issues. The survey findings indicated that stopping medication can have a negative impact on disease control.

Progress in myositis and scleroderma research - II

OP0266 EFFICACY OF NINTEDANIB IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE (SSC-ILD) AND INTERNAL ORGAN INVOLVEMENT: DATA FROM THE SENSCIS TRIAL

Y. Allanore[1], A. M. Hoffmann-Vold[2], M. Mayes[3], M. Vonk[4], C. Miede[5], M. Alves[6], G. Riemekasten[7,8]on behalf of the SENSCIS trial investigators.. [1]*Descartes University,APHP,Cochin Hospital, Department of Rheumatology A, Paris, France*; [2]*Oslo University Hospital, Department of Rheumatology, Oslo, Norway*; [3]*University of Texas McGovern Medical School, Division of Rheumatology and Clinical Immunogenetics, Houston, United States of America*; [4]*Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands*; [5]*Mainanalytics GmbH, Statistics, Sulzbach (Taunus), Germany*; [6]*Boehringer Ingelheim International GmbH,TA Inflammation Med, Ingelheim am Rhein, Germany*; [7]*University Hospital Charité, Rheumatology and Clinical Immunology, Berlin, Germany*; [8]*University Hospital Schleswig-Holstein, Rheumatology, Lübeck, Germany*

Background: SSc is a heterogeneous autoimmune disease characterised by fibrosis of the skin and internal organs. In most patients with SSc-ILD, organs other than the lungs are also affected. In the SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) (mL/year) over 52 weeks by 44% versus placebo.
Objectives: We investigated the extent of organ involvement related to SSc at baseline in patients in the SENSCIS trial and the effect of nintedanib versus placebo on the rate of FVC decline in subgroups by internal organ involvement.
Methods: The SENSCIS trial enrolled patients with SSc-ILD with first non-Raynaud symptom ≤7 years before screening, extent of fibrotic ILD ≥10% on high-resolution computed tomography (HRCT) and FVC ≥40% predicted. Patients with clinically significant pulmonary hypertension were excluded. Patients were randomised to receive nintedanib or placebo until the last patient reached week 52 but for ≤100 weeks. In post-hoc analyses, we analysed the rate of decline in FVC (mL/year) over 52 weeks in subgroups with and without different types of SSc-related internal organ involvement (upper gastrointestinal; lower gastrointestinal; cardiovascular [CV]; peripheral vascular; muscular; joint). These subgroups were defined based on patients' SSc-related medical history as reported in the case report form. A random slope and intercept model was used to assess the rate of decline in FVC (mL/year) and an interaction test applied to assess potential heterogeneity in the treatment effect of nintedanib between the subgroups.
Results: Of 576 patients, 96.9% had peripheral vascular involvement, 75.5% had upper gastrointestinal and 39.8% lower gastrointestinal involvement, 45.7% had CV involvement, 40.6% had joint involvement, and 27.1% had muscular involvement at baseline. In the placebo group, the rate of decline in FVC (mL/year) was numerically greater in patients with than without upper gastrointestinal involvement and in patients without than with joint involvement or muscular involvement (Figure). The exploratory interaction p-values did not indicate heterogeneity in the treatment effect of nintedanib versus placebo on reducing the rate of decline in FVC (mL/year) between the subgroups based on organ involvement (p>0.05 for all treatment-by-time-by-subgroup interactions) (Figure).
Conclusion: Patients in the SENSCIS trial had diverse complications related to SSc. There was no evidence of a differential treatment effect of nintedanib on reducing the rate of decline in FVC based on gastrointestinal, CV, joint, or muscular involvement at baseline.

Figure. Rate of decline in FVC (mL/year) over 52 weeks in subgroups by internal organ involvement at baseline in the SENSCIS trial.

OP0267 SHORT-TERM CHANGES IN THE RADIOGRAPHIC EXTENT OF INTERSTITIAL LUNG DISEASE PREDICT LONG-TERM MORTALITY IN SYSTEMIC SCLEROSIS

E. Volkmann[1], D. Tashkin[1], M. Roth[1], J. Goldin[2], G. Kim[2]. [1]*UCLA, Medicine, Los Angeles, United States of America*; [2]*UCLA, Radiology, Los Angeles, United States of America*

Background: The forced vital capacity (FVC) is often used as the primary endpoint in treatment trials for systemic sclerosis-interstitial lung disease (SSc-ILD), and while trends in FVC have been found to predict mortality in SSc-ILD,[1,2] FVC measurements are also influenced by extra-pulmonary factors, such as cutaneous sclerosis, myopathy, and patient/technician effort. Change in the quantitative extent of ILD (QILD) on HRCT is an emerging endpoint in clinical trials; however, no studies have evaluated whether changes in radiographic extent ILD predict mortality in SSc-ILD.
Objectives: To evaluate the relationship between changes QILD in the whole lung (WL) and long-term survival in patients who participated in the Scleroderma Lung Study (SLS) I[3] and II.[4]

Methods: SLS I randomized 158 SSc-ILD patients to 12 months of cyclophosphamide (CYC) vs. placebo. SLS II randomized 142 SSc-ILD patients to 12 months of CYC, followed by 12 months of placebo vs. 24 months of mycophenolate (MMF). QILD-WL scores were calculated at baseline and 12 months (SLS I) and 24 months (SLS II). Participants were followed for up to 12 (SLS I) and 8 years (SLS II). Using landmark survival analysis, Kaplan Meier curves were generated to compare survival between participants who had worse QILD-WL scores (≥2% increase) and those who had stable/improved QILD-WL scores (<2% increase). Cox proportional hazards models were created to determine whether the change in QILD-WL scores predicted survival after controlling other variables found to affect survival in these cohorts.
Results: Among all the SLS I and II participants, 82 and 90 had follow up HRCT scans, respectively, and were included in these analyses. SLS I participants with an increase in QILD-WL scores of ≥2% at 12 months had significantly worse long-term survival (P= 0.01; Figure). Similarly, SLS II participants with an increase in QILD-WL scores of ≥2% at 24 months had significantly worse long-term survival (P= 0.019; Figure). After adjusting for baseline FVC, age, and modified Rodnan skin score (mRSS), an increase in QILD-WL scores of ≥2% remained associated with worse long-term survival in SLS I (*trend:* P=0.089) and SLS II (P=0.014).
Conclusion: Progression of the radiographic extent of ILD of ≥2% was associated with worse long-term survival in two independent SSc cohorts with extensive long-term follow up. The findings provide compelling evidence that short-term changes in the radiographic extent of ILD may serve as a surrogate endpoint for mortality in patients with SSc.

OP0268 TREATMENT STATUS AFFECTS HOW PULMONARY BIOMARKERS PREDICT PROGRESSION OF SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE

E. Volkmann[1], D. Tashkin[1], M. Leng[1], N. LI[1], G. Kim[2], J. Goldin[2], A. Harui[1], M. Roth[1]. [1]*UCLA, Medicine, Los Angeles, United States of America*; [2]*UCLA, Radiology, Los Angeles, United States of America*

Background: The course of interstitial lung disease (ILD) varies considerably in patients with systemic sclerosis (SSc), and no biomarkers have been found to consistently predict ILD progression in this population. Treatment may affect how a candidate biomarker correlates with improvement/worsening of SSc-ILD. We hypothesized that specific proteins recovered from bronchoalveolar lavage (BAL) would differentially predict progression of SSc-ILD based on whether a patient was receiving ILD therapy.
Objectives: (1) To assess the relationship between 68 unique BAL proteins measured in participants of Scleroderma Lung Study (SLS) I[1] and changes in radiographic extent of SSc-ILD; (2) To determine if treatment affects whether a specific protein predicts improvement or worsening of SSc-ILD.
Methods: Bronchoscopy was performed on 144 of the 158 participants in SLS I (Cyclophosphamide [CYC] vs. placebo) with 103 BAL samples available for analysis. BAL was lyophilized, concentrated 10X and used in a multiplex protein analysis of 68 distinct cytokines, chemokines and growth factors. Quantitative imaging analysis (QIA) was used to calculate the extent of radiographic fibrosis (QLF) in the whole lung using HRCT of the chest at baseline and 12 months. Multivariable linear regression models were created to determine the key BAL proteins associated with change in QLF scores using a backward selection process adjusting for treatment arm and ILD severity. The bootstrap procedure was employed for internal validation.
Results: A number of BAL proteins were significantly associated with change in QLF scores at 12 months; however, the directionality of these associations was often based on the presence/absence of treatment. For example, increased levels of granulocyte-macrophage colony-stimulating factor (GM-CSF), interleukin (IL)-1, monocyte chemoattractant protein (MCP)-3, chemokine ligand (CCL)-5, transforming growth factor (TGF)-β, hepatocyte growth factor (HGF), stem cell factor (SCF), IL-4, TGF-α, were associated with worse QLF scores in patients who received placebo; whereas, increased levels of these same proteins were associated with improved QLF scores in patients who received CYC (Figure). Increased levels of Fractalkine were associated with worse in QLF scores, and increased levels of IL-7 were associated with improved QLF scores, regardless of treatment arm. In the multivariable model adjusting for treatment arm and baseline severity of ILD, IL-1, MCP-3, surfactant protein C, IL-7, and CCL-5 were independently associated with change in QLF scores.

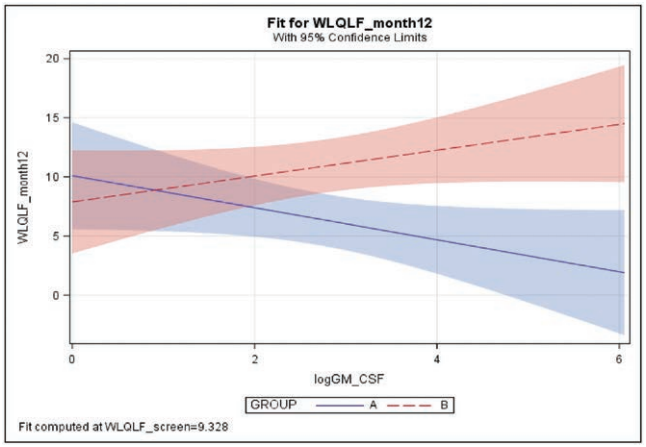

Figure 1. Example of a specific BAL protein (GM-CSF) that predicts worse QLF scores in patients receiving placebo (Group B, Red dotted line) and improved QLF scores in patients receiving CYC (Group A, Blue solid line). Shaded areas represent 95% confidence intervals.

Conclusion: Proteins that mediate both inflammation and fibrosis differentially affected progression of SSc-ILD based on treatment status. Higher levels of certain proteins predicted worsening of ILD in patients receiving placebo, but improvement in patients receiving CYC. Measuring these proteins could help to identify patients who: (1) are at risk for ILD progression, and (2) may preferentially benefit from treatment with immunosuppression.

OP0269 A COMBINED CLINICAL AND BIOMARKER ALGORITHM TO PREDICT FVC DECLINE IN SYSTEMIC SCLEROSIS ASSOCIATED INTERSTITIAL LUNG DISEASE: RESULTS FROM AN INTERNATIONAL MULTICENTRE OBSERVATIONAL COHORT

M. Hutchinson[1], G. Abignano[1], J. Blagojevic[2], S. L. Bosello[3], Y. Allanore[4], C. Denton[5], O. Distler[6], P. Emery[1], M. Matucci-Cerinic[3], F. Del Galdo[1]. [1]*United Kingdom, Institute of Rheumatic and Musculoskeletal Medicine and NIHR Biomedical Research*

Centre, University of Leeds, Leeds, United Kingdom; [2]*Italy, University of FLorence, florence, Italy*; [3]*Universita la Cattolica, Rheumatology, florence, Italy*; [4]*INSERM, Rheumatology, Paris, France*; [5]*University College Lodon, Rheumatology, London, United Kingdom*; [6]*University of Zurich, Rheumatology, Zürich, Switzerland*

Background: Interstitial lung disease (ILD) is the leading cause of mortality in patients with Systemic Sclerosis (SSc). Forced Vital Capacity (FVC) is a major indicator of severity in SSc ILD. The ELF serum test and its constituent biomarkers (HA, PIIINP and TIMP-1) have shown to correlate with FVC in two large, independent multicentre cohorts of 457 patients, but also showed a correlation with age.
Objectives: Here we aimed to investigate the relationship of the ELF biomarkers and age in a large population of healthy controls and to identify a combined clinical and biomarkers model to stratify for risk of ILD progression in a multicentre longitudinal cohort of patients with SSc.
Methods: ELF score was measured in sera from 925 healthy controls in one centre and 869 longitudinal samples from 254 SSc patients from 6 centres across 4 European countries. Clinical data were recorded according to EUSTAR Minimal Essential dataset. FVC% change over time was estimated by Mixed-effects modelling. Patients were then divided in two groups: progressors, with a %FVC drop > 3%/year (according to published MCID) and a group of patients with stable or improving FVC. Lasso penalised regression was carried out with biomarkers and the available clinical and demographic variables at patient's first visit as potential predictors. The resulting linear predictor was used to derive two thresholds, one for optimal sensitivity (rule-out) and one for optimal specificity (rule-in). Patients within thresholds were further selected according to the ratio of TIMP-1: PIIINP (Figure 1).
Results: HA was the only ELF biomarker that correlated significantly with age in the healthy control cohort. Therefore, we defined by linear regression a "residual HA" which accounted for age. TIMP1, PIIINP and residual HA were then considered as distinct biomarkers in the analysis of the SSc cohort. 189 SSc patients with 785 time-points had complete datasets and were included in the analysis. Median follow up was 33 months (IQR 18-48). One-hundred and forty patients (74%) were classified as non progressors, 94 (50%) with no change or improving FVC and 46 (24%) with FVC drop <3% year. 49 patients (26%) were classed as progressors (drop of 3%/year or more in FVC, median slope -4.7%/year). Variable selection via Lasso penalised logistic regression resulted in a model with a c-index of 0.69 (95% CI: 0.60-0.78)) and contained age, disease duration (from first non-Raynaud's symptom), residual HA, anti-centromere antibodies (ACA) status, previous diagnosis of ILD, joint synovitis and history of protein pump inhibitor use. A two-step process was developed using the linear predictor from the model and the ratio of TIMP-1 and PIIINP (Figure 1). The stratification tool increased by nearly two-fold the ability to predict progressors in any 12 months interval (46 to 49% predictive value vs 26% probability) identifying an 82 to 91% negative predictive value for progression.
Conclusion: Building on the face and content validity of the biomarkers included in the ELF score, here we identify an easy to assess combined clinical and biomarker model to stratify patients for their risk of ILD progression. Despite its derivation from a large multicentre cohort, independent validation will determine the clinical value of Scleroscore as a stratification tool for risk of progression of SSc ILD.

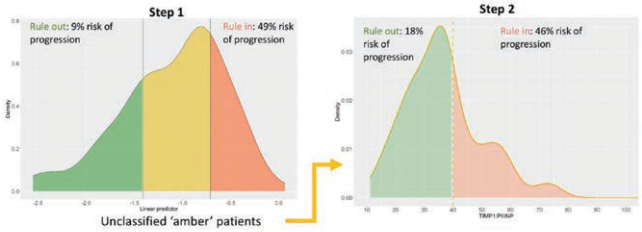

Figure 1: Two-step process to stratify patients for risk of ILD progression
Patients with overall 24% risk of 3% yearly FVC drop are stratified by regression model in patients with 49% (rule in) vs 9% risk (rule out) in (Step 1). Patients in between thresholds of Step 1 are further stratified according to the biomarker ratio (TIMP1/PIIINP) in the same risk categories.

OP0270 LONG-TERM EFFICACY AND SAFETY OF BOSENTAN IN PATIENTS WITH DIGITAL ULCERS RELATED TO SYSTEMIC SCLEROSIS

N. Cristina[1], L. Groseanu[1,2], F. Berghea[1,2], A. Balanescu[1,2], V. Bojinca[1,2], D. Mazilu[1,2], S. Daia[1,2], D. Opris-Belinski[1,2], I. Saulescu[1,2], C. L. Constantinescu[1,2], M. Abobului[1,2], A. Borangiu[1,2], M. M. Negru[1,2], C. Cobilinschi[1,2], D. Predeteanu[1,2], M. Duna[1,2], R. Ionescu[1,2]. [1]*St Mary Clinical Hospital, Department of Internal Medicine and Rheumatology, Bucharest, Romania*; [2]*Carol Davila University of Medicine and Pharmacy, Internal Medicine and Rheumatology, Bucharest, Romania*

Background: Two pivotal studies, RAPIDS-1 and RAPIDS-2 revealed that bosentan reduces the development of new digital ulcers (DUs) in patients with systemic sclerosis (SSc). However data regarding the long-term use of this dual endothelin antagonist receptor in the treatment of DUs is scarce.
Objectives: The aim of the present study was to evaluate long term efficacy and safety profile of bosentan in patients with DUs related to SSc.
Methods: A prospective observational case-control study, conducted between 2014 and 2020 enrolled 65 SSc patients with ≥1 active DUs at baseline, who received bosentan therapy. Demographic and clinical features, including DUs incidence and patients subjective perception of DU pain and/or Raynaud's Phenomenon, were collected. Nailfold videocapillaroscopy was performed in all patients.
Results: The study included 51 females and 14 males, with a mean age of 52.6 years, 30 with diffuse subset, most of them with late scleroderma pattern (46/65). Number of DUs at baseline was 4.55 (±2.8), median duration of treatment was 25.95 (±19.4) months. Microangiopathy evolution score (MES) was 5.1 (2.19), visual analog scale (VAS) for DU was 77.9, VAS for Raynaud was 73.4.
Patients receiving bosentan had clinically significant reduction in the mean number of DU ($p<0.001$). The effect was most powerful for the first 6 months of treatment, but the improvement was sustained until 24 months' follow-up, when the mean DU number reached a plateau that was kept until end of study. 6 month and 24 month evaluations also revealed significant decrease in the VAS for DU ($p<0.05$) and in the VAS for Raynaud ($p<0.01$). Statistically significant difference was noted between bosentan-treated and the control group with respect to the decrease in the mean number of digital ulcers. ($p=0.005$).
There was a clear trend towards an improvement in MES score, between baseline and the next follow-up assessments ($p=0.003$). The difference was statistically significant when compared to control group, but only for the first 18 months of treatment ($p<0.001$).
14 patients (28.75%) discontinued bosentan therapy for administrative reasons. The median time among patients who interrupted the treatment was 6.9 months. An accelerated development of new DU was described 6 months after ($p=0.02$). Following recommencement of bosentan, the mean number of DU has rapidly decreased ($p=0.008$). There was no significant difference between patients who temporarily discontinued bosentan for 6 or 12 months.
Bosentan was stopped due to lack of efficacy in 2 cases and due to side effects in 7 cases: 4 elevated liver enzymes, 1 severe trombocytopenia, 1 dyspneea agravation and low blood pressure.
Conclusion: The present data suggest that treatment with endothelin receptor antagonist bosentan was associated with a significant reduction in the mean number of DU in patients with SSc. The beneficial effect of bosentan persisted throughout the study but was most evident in the first 6 months of treatment. Statistical analysis showed a significant improvement of the microangiopathy evolution score from baseline to end of therapy. 14 patients had a high relapse rate due to potential rebound effect, 6 months after bosentan withdrawal.The drug was reintroduced succesfully for 10 (70%) patients with a significant decrease in the number of DU.

OP0271

JUVENILE LOCALIZED SCLERODERMA: A LARGE RETROSPECTIVE COHORT STUDY FROM A TERTIARY CARE CENTER

B. Egeli[1], J. Dallas[1], E. Anderson[1], M. Min[2], D. Mazori[2], S. Gellis[2], M. B. Son[1], R. Sundel[1], R. Vleugels[2], F. Dedeoglu[1]. *[1]Boston Children's Hospital, Rheumatology, Boston, United States of America*; *[2]Boston Children's Hospital, Dermatology, Boston, United States of America*

Background: Juvenile Localized Scleroderma (jLS) is a rare pediatric inflammatory disease of skin and underlying tissues that may cause significant functional impairment and disfigurement. Management approaches vary and an optimum treatment regimen is lacking. In 2012, a group of jLS researchers of Childhood Arthritis and Rheumatology Research Alliance (CARRA) proposed consensus treatment plans (CTPs), aimed to streamline the approach to care for jLS patients.

Objectives: This study aimed to evaluate a large jLS patient cohort seen over a 21-year period in a single tertiary care pediatric hospital in the USA, in order to examine treatments utilized and determine parameters for systemic therapy initiation.

Methods: This retrospective cohort study included jLS patients with disease onset in childhood (≤18-years of age) who were seen in rheumatology, dermatology, or combined rheumatology-dermatology clinics from 1999-2020, with ≤ 3 years of follow-up. Data on demographics, disease characteristics, therapies prescribed, and treatment trends were analyzed.

Results: Of the 270 jLS patients identified, 101 fulfilled the inclusion criteria. The primary reason for exclusion was <3 years of follow-up. Selected demographic data and disease characteristics of patients are shown in Table 1. There were no statistically significant differences in most patient and disease characteristics between patients who received systemic treatment and those who did not. There were no significant differences in baseline laboratory values. The group treated with systemic therapy did have higher rates of extracutaneous involvement and had a higher proportion of patients with a generalized morphea phenotype.

Table 1. Demographic and Disease Characteristics

	All Patients (n=101)	On Systemic Therapy (n=63)	No Systemic Therapy (n=38)	p value
Age-onset (Y), median (IQR)	7.5 (6.4)	9 (6)	7 (4)	NS
Age-diagnosis(Y), median (IQR)	9 (7.9)	10 (6.7)	9 (3.7)	NS
Diagnostic delay(M), median (IQR)	10 (2.9)	12 (13)	7.5 (17)	NS
Follow-up (M), median (IQR)	74 (69.3)	65 (44.5)	78 (47.7)	NS
Subtype				
Linear	56	39	17	NS
Face	29	20	9	NS
Circumscribed	23	4	19	<0.0001
Mixed	2	2	0	NS
Generalized	20	18	2	0.004
Extracutaneous Involvement	19	18	1	0.001
Clinic type				
Dermatology	29	2	27	<0.0001
Rheumatology	21	19	2	0.003
Combined	51	42	9	<0.0001

The majority of patients who were on systemic immunomodulatory therapy were treated with methotrexate (59/63, 93.6 %) and/or systemic corticosteroids (21/63, 33 %). 5 patients were treated with hydroxychloroquine, 2 of which were also on methotrexate. 6 patients on methotrexate were either switched to or had mycophenolate mofetil added as concomitant therapy. The most common adverse effects observed in methotrexate-treated patients were gastrointestinal complaints (12/61, 19.7%) and fatigue (7/61, 11.5%). The median treatment duration was 50 months (IQR: 33.5). Patients were more likely to receive systemic therapy if they were followed in rheumatology or combined rheumatology-dermatology clinics as compared to dermatology clinics. Finally, 78% of patients with jLS received systemic treatment after 2013 (a year after publication of the CARRA jLS CTP) as compared to 55% of patients prior to 2013 ($p < 0.05$).

Conclusion: This jLS cohort is one of the largest reported from a single center and reflects an increase in the use of systemic therapy since publication of CARRA CTPs in 2012. Further studies on long-term treatment outcomes and therapeutic approaches utilized when first-line treatment failures occur are warranted.

68GA-FAPI-04 PET/CT STUDY EXTENSION FOR THE ASSESSMENT OF FIBROBLAST ACTIVATION AND RISK EVALUATION IN SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE

C. Bergmann[1], J. H. W. Distler[1], C. Treutlein[2], K. Tascilar[1], A. T. Mueller[1], A. Atzinger[3], A. E. Matei[1], J. Knitza[1], A. H. Györfi[1], A. Lueck[1], C. Dees[1], A. Soare[1], A. Ramming[1], V. Schönau[1], O. Distler[4], O. Prante[3], P. Ritt[3], T. I. Goetz[3], M. Koehner[3], M. Cordes[3], T. Baeuerle[2], T. Kuwert[3], G. Schett[1], C. Schmidkonz[3]. *[1]University Hospital Erlangen, Department Internal Medicine 3, Erlangen, Germany*; *[2]University Hospital Erlangen, Department Radiology, Erlangen, Germany*; *[3]University Hospital Erlangen, Department Nuclear Medicine, Erlangen, Germany*; *[4]University Hospital Zuerich, Department Rheumatology, Zuerich, Switzerland*

Background: Interstitial lung disease (ILD) is the most common cause of death in systemic sclerosis (SSc). To date, the progression of SSc-ILD is judged by the accrual of lung damage on computed tomography (CT) and functional decline (forced vital capacity). However, this approach does not directly assess the activity of tissue remodeling. Moreover, prediction of the course of ILD in individual SSc patients remains challenging. Fibroblast Activation Protein (FAP) is a specific, ex vivo validated marker for activated fibroblasts.

Objectives: The aims of this study were: 1. To assess differences in the uptake of ^{68}GA-FAPI 04 in SSc-ILD patients compared to controls, to analyze 2. whether ^{68}GA-FAPI 04 uptake at baseline correlates with other risk factors of disease progression and 3. Whether ^{68}GA-FAPI 04 uptake is associated with the course of SSc-ILD.

Methods: Between September 2018 and April 2020, 21 patients with SSc-ILD confirmed by HRCT and onset of SSc-ILD within ≤ 5 years or signs of progressive ILD and 21 controls without ILD were consecutively enrolled. All participants underwent ^{68}Ga-FAPI-04 PET/CT imaging and standard-of-care procedures including HRCT and lung function testing (PFT) at baseline. Patients with SSc-ILD patients were followed-up for 6 months with HRCT and PFT. Follow-up ^{68}Ga-FAPI-04 PET/CT scans were obtained in a subset of patients treated with nintedanib. We compared baseline ^{68}Ga-FAPI-04 PET/CT uptake to standard diagnostic tools and currently used predictors of ILD progression. The association of ^{68}Ga-FAPI-04 uptake with changes in FVC was analyzed using mixed-effects models.

Results: ^{68}Ga-FAPI-04 accumulated in fibrotic areas of the lungs in SSc-ILD compared to controls with a median (q1-q3 interval) wlSUVmean of 0.8 (0.6 to 2.1) in the SSc-ILD group and 0.5 (0.4 to 0.5) in the control group ($p<0.0001$ with Mann-Whitney test) and a median whole lung maximal standardized uptake value (wlSUVmax) of 4.4 (3.05 to 5.2) in the SSc-ILD group compared to 0.7 (0.65 to 0.7) in the control group ($p<0.0001$). wlFAPI-MAV and wlTL-FAPI were not measurable in control subjects, as no 68Ga-FAPI-04 uptake above background level was observed. In the SSc-ILD group the median wlFAPI-MAV was 254cm^3 (163.4 to 442.3) and the median wlTL-FAPI was 183.6cm^3 (98.04 to 960.7). ^{68}Ga-FAPI-04 uptake was higher in patients with extensive disease, with previous ILD progression or high EUSTAR activity scores. Increased ^{68}Ga-FAPI-04 uptake at baseline was associated with progression of ILD independently of extent of involvement on HRCT scan and the forced vital capacity at baseline. In consecutive ^{68}Ga-FAPI-04-PET/CTs, changes in ^{68}Ga-FAPI-04 uptake was concordant with the observed response to the fibroblast-targeting antifibrotic agent nintedanib.

Conclusion: Our study presents first in human evidence that ^{68}Ga-FAPI-04-fibroblast uptake correlates with fibrotic activity and disease progression in the lungs of SSc-ILD patients and that ^{68}Ga-FAPI-04-PET/CT may be of potential to improve risk assessment of SSc-ILD.

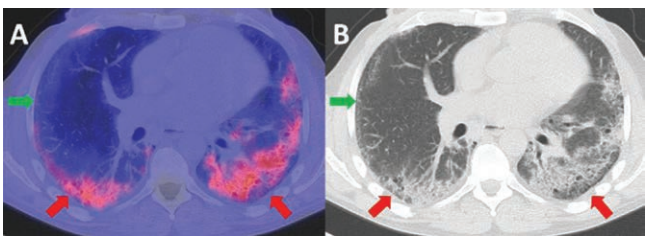

Figure 1. A and B: ^{68}Ga-FAPI-04 PET/CT scan from a patient with SSc-ILD with selective ^{68}Ga-FAPI-04 uptake in fibrotic areas of the left- and right lower lung lobes (red arrows), but not in non-fibrotic areas such as the middle lobe (green arrow). B Corresponding CT component.

OP0273 **THE SCLERODERMA CLINICAL TRIALS CONSORTIUM DAMAGE INDEX (SCTC-DI) IN A SYSTEMIC SCLEROSIS COHORT WITH 10-YEARS FOLLOW-UP**

M. G. Lazzaroni[1], M. Breda[1], F. Franceschini[1], P. Airò[1]. [1]*ASST Spedali Civili of Brescia, University of Brescia, Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, Brescia, Italy*

Background: Systemic Sclerosis (SSc) is characterized by increased mortality and organ damage accrual. A composite SSc Damage Index was recently developed by the Scleroderma Clinical Trials Consortium (SCTC-DI) and was demonstrated as a predictor of mortality both in the Australian derivation cohort and in the Canadian validation cohort.
Objectives: To evaluate in a single centre cohort of SSc patients with 10-years follow-up: (1) the evolution of organ damage over time; (2) factors associated with the development and accrual of organ damage.
Methods: A retrospective analysis was performed on patients prospectively followed in our centre from 1989 to 2019. Organ damage was evaluated with SCTC-DI (0-55 scale; moderate damage >5, severe damage>12) and comorbidities with Charlson Comorbidity Index (CCI, which includes the age of the patient). Patients were included when a follow-up of at least 10 years was available together with SCTC-DI at the diagnosis (baseline, T0), 1 year (T1), 5 years (T5) and 10 years (T10) after the diagnosis. Univariable and multivariable analysis (logistic regression) were performed when appropriated.
Results: 253 SSc patients were included (female 93%; Caucasians: 99%; median age at diagnosis: 52 years (IQR: 43-60); diffuse cutaneous subset: 15%; anti-centromere (ACA)+ 55%; anti-Topoisomerase 1+20%; anti-RNA polymerase III+: 4%; ever smokers: 28%). Median interval between the first SSc symptom other than Raynaud's phenomenon and the diagnosis was 1 year. SCTC-DI progressively increased from diagnosis to T10 (p<0.0001; Kruskal-Wallis test).
Moderate damage (score:6-12) was observed in 22 patients at T0 (8.7%), in 30 at T1 (11.9%), in 45 at T5 (17.7%) and in 73 at T10 (28.9%). None of the patients had severe damage (score:13-55) at T0 and T1, while it was present in 6 at T5 (2.4%) and in 13 at T10 (5.1%).
At T0 no difference in SCTC-DI scores was observed when comparing different subgroups according to gender (female vs. male), disease subsets (diffuse vs. limited) and autoantibodies (ACA- vs. ACA+). At T1, SCTC-DI score was higher in patients with diffuse vs. limited cutaneous subset, and ACA- vs ACA+ (p<0.0001 for both).
Multivariable analysis demonstrated that a moderate or severe organ damage (SCTC-DI score >5) at 5 years was positively associated with diffuse cutaneous involvement (p:0.009, OR 4.55, 1.46-14.1), SCTC-DI at T0 (p:0.015, OR 1.34, 1.06-1.70) and at T1 (p:<0.0001, OR 1.65, 1.30-2.07), and negatively associated with ACA+ (p:0.024, OR 0.32, 0.12-0.86), while CCI and male sex showed no association. At 10 years SCTC-DI>5 was associated with diffuse cutaneous involvement (p:0.013, OR 4.30, 1.36-13.7), SCTC-DI at T5 (p:<0.0001, OR 1.67, 1.38-2.01), while SCTC-DI at T0, CCI, male sex and ACA+ had no association.
Among 253 patients, 90 (36%) died after >10 years of follow-up. In non-survivors, as compared to survivors, SCTC-DI score was significantly higher at the baseline (T0) and during the entire follow-up (p<0.0001 for every timepoint).
Conclusion: At the end of 10-years follow-up (T10), 35% of patients in our cohort had moderate or severe organ damage (SCTC-DI score>5). Diffuse cutaneous involvement was associated with higher SCTC-DI scores at different time points (T5 and T10). Organ damage, quantified by SCTC-DI at different time points, was confirmed as a factor associated with mortality in patients who reached more than 10 years of follow-up.

PARE Abstract session

OP0274-PARE **EVALUATION OF PATIENT SATISFACTION FOR TELEHEALTH (PHONE AND VIDEO) IN RHEUMATOLOGY OUTPATIENTS DURING COVID-19 PANDEMIC**

Y. Oh[1,2], A. Hennessey[1,2], L. Young[1,2], D. Yates[1,2], C. Barrett[1,2]. [1]*Redcliffe Hospital, Rheumatology, Redcliffe, Australia*; [2]*The University of Queensland, Medicine, Saint Lucia, Australia*

Background: Telehealth via phone (TPhone) or video conference (TVideo) in rheumatology has been a topic of interest for many years. Its use was rapidly expanded due to the international public health emergency of coronavirus disease-19 (COVID-19) outbreak in 2020. Australian Medicare Benefits Schedule (MBS) swiftly enabled temporary MBS telehealth items on 13 March 2020, currently extended until 31 March 2021[1]. In the early phase of the COVID-19 pandemic, Antony et al. conducted a single-centre public survey to assess patient perception of rheumatology telehealth. Their results showed that 98.4% of patients consider telehealth acceptable during the pandemic[2]. It is unclear, however, whether this positive perception persists after patients experience a telehealth. In addition, a survey data in 2019 suggested more than half of Australian rheumatologists work in private practice[3]. Therefore, inclusion of private patients will better represent patient perception of telehealth.
Objectives: The aim of this study was to evaluate patient satisfaction with telehealth during the COVID-19 pandemic. This would determine its feasibility to be integrated in future rheumatology outpatient model.
Methods: A questionnaire containing 30 questions was sent to rheumatology patients who attended telehealth appointments at a level 2 public hospital and a local private clinic between April and May 2020. The questionnaires aimed to obtain information on baseline demographics (sex, age, public or private patient, employment status, visual or auditory impairment), appointment details (TPhone or TVideo, usual arrangement for face-to-face (F2F) appointment, cost effectiveness) and appointment satisfaction using a 5-point Likert scale. Descriptive statistical analysis was conducted.
Results: The questionnaire was sent to 1452 patients, of which 494 patients responded (34%). Female predominance (77.1%) and a higher proportion of TPhone (79.1%) was seen in the respondents. A majority of patients were existing patients known to the services (90.9%). More than 70% of responses indicated overall satisfaction in specialist care via telehealth, and 88.7% perceived this suitable during a pandemic. Of all respondents, 21.7% were prescribed new medication, and the majority of these patients were confident in taking the new medication after the telehealth appointment. Future acceptability for TPhone was significantly lower in private patients compared to public patients (p= 0.01). Subgroup analysis revealed that higher telehealth satisfaction was associated with needing to take time off work to attend face-to-face appointment (p= 0.02), perception of cost effectiveness (p<0.001) and TVideo (p=0.03).
Conclusion: This is the first study which included both public and private rheumatology patients to evaluate patient satisfaction for telehealth during the COVID-19 pandemic. Overall high level of satisfaction was seen in telehealth most notably associated with its cost effectiveness. A higher percentage of patients who had TVideo compared to TPhone were receptive to future telehealth via TVideo, supportive of the importance of visual cues. This in turn will have significant administrative and technological burdens to coordinate in comparison to a F2F or TPhone review. This qualitative study provides valuable insight of patient perception of telehealth, which has the potential to compliment the traditional rheumatology outpatient model of care following the pandemic.

OP0275-PARE THE UNACCEPTABLE DELAY TO DIAGNOSIS IN AXIAL SPONDYLOARTHRITIS; DEVELOPING A CALL TO ACTION FOR A GLOBAL HEALTHCARE CHALLENGE

W. Gerhart[1], M. T. Duruöz[2], J. Lowe[3], D. Webb[4], L. Wermskog[5], J. Davies[6], R. Howard[7], M. Mallinson[8], C. L. Koehn[9]. [1]*Canadian Spondylitis Association, Director, Toronto, Canada*; [2]*Marmara University School of Medicine, PMR Department, Istanbul, Turkey*; [3]*Axialspondyloarthritis International Federation, Projects, London, United Kingdom*; [4]*National Axialspondyloarthritis Society, Director, London, United Kingdom*; [5]*Spafo Norge Spondyloartrittforbundet, Director, Oslo, Norway*; [6]*Axialspondyloarthritis International Federation, Executive, London, United Kingdom*; [7]*Spondylitis Association of America, Executive, Los Angeles, United States of America*; [8]*Axialspondyloarthritis International Federation, Volunteering, London, United Kingdom*; [9]*Arthritis Consumer Experts, Director, Vancouver, Canada*

Background: The current delay to diagnosis from symptom onset represents one of the greatest challenges in axial spondyloarthritis (axSpA). Research shows an average global delay of almost 7 years[1] – and as long as 15 years in some cases[2] – during which time the condition can progress considerably and lead to irreversible damage. Data indicates that women wait longer than men for a diagnosis[3], and there has been very limited progress in reducing the time to axSpA diagnosis. The axSpA diagnosis delay has a hugely detrimental impact on an individual's quality of life. Because the disease frequently has early onset[1], individuals are left with untreated or incorrectly-treated symptoms at a formative period in their life course, whilst they await their diagnosis.
Objectives: The Axial Spondyloarthritis International Federation (ASIF) set out to coordinate a comprehensive evidence-based global review of the factors influencing the current axSpA diagnosis delay and to produce a definitive report that shines a light on these barriers, as well as providing a resource that can ultimately empower a range of international stakeholders to reduce this delay.
Methods: A full literature review was carried out to identify relevant available global evidence exploring the axSpA diagnosis delay. In autumn 2020 ASIF held two virtual global forum events, involving patients and patient group representatives, researchers, rheumatologists and other healthcare professionals, to methodically explore key diagnosis challenges across different healthcare systems and the opportunities for addressing these. Break-out discussions were held and participants were asked to identify the personal and societal effects of the diagnostic delay; the reasons it occurs; and initiatives to tackle the challenge. Alongside key stakeholder testimonies, best practices from around the world were also identified. 92 stakeholders participated in the events; they represented patients and healthcare professionals from 23 countries across five continents.
Results: The findings from these activities were incorporated within a new 'Delay to Diagnosis' report, which for the first time definitively sets out the lived realities from a global perspective of the axSpA diagnosis delay. The report identified important commonalities across different countries and healthcare systems contributing to the current average global 7-year diagnosis delay, including:

- Poor awareness of axSpA, particularly in primary care services
- Complexities in diagnosing the disease
- Poorly defined referral pathways
- Insufficient patient access to rheumatologists and appropriate diagnostics

The report also highlights the significant impact this delay has on individuals and wider society, providing a foundation for future advocacy work. A series of recommendations have also been identified, the implementation of which will help to instigate tangible progress in reducing the current delay.
Conclusion: Despite longstanding challenges, there are now clear opportunities for transforming how axSpA is diagnosed around the world. This message needs to be heard and acted upon urgently by all those involved in the management and delivery of axSpA care. The future programme of work for ASIF's Delay to Diagnosis project will respond to these findings and be centred around supporting axSpA patient associations globally to take this call to action forward throughout 2021 and beyond.

OP0276-PARE CREATING POLITICAL LEVERS TO IMPROVE AXIAL SPONDYLOARTHRITIS CARE

J. Hamilton[1], D. Webb[2], S. Whalley[3]. [1]*National Axial Spondyloarthritis Society, Head of Policy & Health Services, London, United Kingdom*; [2]*National Axial Spondyloarthritis Society, CEO, London, United Kingdom*; [3]*M&F Health, Health Communications, London, United Kingdom*

Background: Research carried out in 2016 by NASS showed that the range and quality of axial spondyloarthritis (axial SpA) services generally offered around the UK were variable [1]. The publication by the regulator, the National Institute for Health and Care Excellence (NICE), of a Guideline for Spondyloarthritis (NG65) in 2017 [2] and the corresponding Quality Standard (QS170) in 2018 [3], for the first time provided national guidance and standards of services that should be available for people with axial SpA. National oversight of the implementation of these however was missing.
Objectives: NASS worked with Parliamentarians to establish the All-Party Parliamentary Group for Axial Spondyloarthritis in January 2019. We gave it a very specific objective - to oversee the implementation of NH65 and QS170. The group seeks to improve axial SpA services in England whilst raising awareness of the condition at a parliamentary level, working closely with NASS.
Methods: The group is a unique forum in the UK, bringing together patients, clinicians, researchers, policy makers, national bodies and parliamentarians. The group has met five times covering a range of topics including the delay to diagnosis, the uptake of NG65 and hydrotherapy.
In 2019 the group carried out a national inquiry into the standards of axial SpA services in the UK, developing a ten-question quality framework, based largely on the NICE Guideline recommendations and Quality Standard. In July 2020 a meeting was convened to discuss the impact of COVID-19 on axial SpA services. The meeting presented research carried out by NASS and M&F Health with patients and clinicians respectively.
Results: The results of the national inquiry for England were published in January 2020 [4]. The inquiry found that large discrepancies remain in the provision of axial SpA services. Only 21% of local commissioning bodies have an inflammatory back pain pathway, and less than half of NHS providers have a specialist axial SpA clinic.
The results of COVID survey shows significant impacts on the health of axial SpA patients and on the availability and modality of rheumatology services. The APPG later published a report with a set of recommendations [5], creating minimum service specifications for axial SpA services during crisis periods such as the recent pandemic, as well as service recovery. Comment on this research was also published in The Lancet Rheumatology [6].

In September 2020 the work of the APPG led to a debate in Parliament on delayed diagnosis in axial SpA.
Discussions on the future of hydrotherapy services has resulted in the mobilisation of stakeholders across condition areas.
Conclusion: All All Party Parliamentary Group is already proving to be an effective political lever to improve axial SpA care. It has shown huge variations in the standard of care and provision of services still remain and has brought this to the attention of Parliamentarians, policy makers and clinicians.

OP0277-PARE METABERN, THE EUROPEAN REFERENCE NETWORK FOR RARE HEREDITARY DISEASES: STRUCTURE, OBJECTIVES, METABOLIC RMDS AND THE ROLES OF EUROPEAN PATIENT ADVOCACY GROUPS (EPAGS)

L. Wagner[1], S. Sestini[2], C. Brown[3], A. Finglas[4], R. Francisco[5], S. Bond[6], C. Lampe[7], C. Belettato[6], C. Van Lingen[6], M. Scarpa[6], on behalf of MetabERN collaboration group. [1]*Deutschsprachige Selbsthilfegruppe für Alkaptonurie e.V., DSAKU e.V., Stuttgart, Germany*; [2]*Associazione italiana dei malati di alcaptonuria, AimAKU, Siena, Italy*; [3]*Krabbe UK, Krabbe UK, London, United Kingdom*; [4]*MSD Action Foundation, MSD Action Foundation, Dublin, Ireland*; [5]*Portuguese Association for CDG and Other Rare Metabolic Diseases, APCDG-DMR, Almada, Portugal*; [6]*Udine University Hospital, MetabERN, Regional Coordination Center for Rare Diseases, Udine, Italy*; [7]*Center for Rare Diseases Giessen, ZSEGI, Giessen, Germany*

Background: Inborn metabolic disorders (IMDs) currently encompass more than 1,500 diseases with new ones still to be identified[1]. Each of them is characterised by a genetic defect affecting a metabolic pathway. Only few of them have curative treatments, that target the respective metabolic pathway. Commonly, treatment examples include diet, substrate reduction therapies, enzyme replacement therapies, gene therapy and biologicals, enabling IMD-patient now to survive to adulthood. About 30 % of all IMDs involve the musculoskeletal system and are here referred to as rare metabolic RMDs. Generally, IMDs are very heterogenous with respect to symptoms and severity, often being systemic and affecting more children than adults. Thus, challenges include certified advanced training of adult metabolic experts, standardised transition plans, social support and development of therapies for diseases that do not have any cure yet.
Objectives: Introduction of MetabERN, its structure and objectives, highlighting on the unique features and challenges of metabolic RMDs and describing the involvement of patient representation in MetabERN.
Methods: MetabERN is stratified in 7 subnetworks (SNW) according to the respective metabolic pathways and 9 work packages (WP), including administration, dissemination, guidelines, virtual counselling framework, research/clinical trials, continuity of care, education and patient involvement. The patient board involves a steering committee and single point of contacts for each subnetwork and work package, respectively[2]. Projects include identifying the need of implementing social science to assess the psycho-socio-economic burden of IMDs, webinars on IMDs and their transition as well as surveys on the impact of COVID-19[3] on IMD-patients and health care providers (HCPs), social assistance for IMD-patients and analysing the transition landscape within Europe.
Results: The MetabERN structure enables bundling of expertise, capacity building and knowledge transfer for faster diagnosis and better health care. Rare metabolic RMDs are present in all SNWs that require unique treatments according to their metabolic pathways. Implementation of social science to assess the psycho-socio-economic burden of IMDs is still underused. Involvement of patient representatives is essential for a holistic healthcare not only focusing on clinical care, but also on the quality of life for IMD-patients. Surveys identified unmet needs of patient care, patients having little information on national support systems and structural deficits of healthcare systems to ensure HCP can provide adequate clinical care during transition phases. These results are collected by MetabERN and forwarded to the Directorate-General for Health and Food Safety (DG SANTE) of the European Commission (EC) to be addressed further.
Conclusion: MetabERN offers an infrastructure of virtual healthcare for patients with IMDs. Thus, in collaboration with ERN ReCONNET, MetabERN can assist in identifying rare metabolic disorders of RMDs to shorten the odyssey of diagnosis and advise on their respective therapies. On the other hand, MetabERN can benefit from EULAR's longstanding experience regarding issues affecting the quality of life, all RMD patients are facing, such as pain, stiffness, fatigue, rehabilitation, maintaining work and disability claims.

OP0278-PARE PROVIDING SUPPORT TO FAMILIES OF CHILDREN NEWLY-DIAGNOSED WITH CHILDHOOD ARTHRITIS: A PATIENT AND PARENT-LED PILOT STUDY TO DEVELOP AND ASSESS 'A LITTLE BOX OF HOPE' SUPPORT PACKS

S. Chibnell-Smith[1], A. L. Chibnell-Smith[1], R. Beesley[1]. [1]*Juvenile Arthritis Research, JAR Project, Tonbridge, United Kingdom*

Background: Juvenile Idiopathic Arthritis (JIA) is a heterogenous group of autoimmune disorders characterised by chronic joint inflammation, diagnosed in around 1 in 1,000 children and young people (CYP) under the age of 16. Delays in diagnosis are common [1], awareness is low, and paediatric rheumatological conditions have a considerable impact on young people and their families [2]. A lack of understanding amongst families of newly-diagnosed children leads to uncertainty and anxiety.
Objectives: This patient and parent-led project developed a resource pack for parents of CYP newly-diagnosed with JIA, to provide information and support. Following a pilot, feedback from recipients was collated and analysed to help improve future provision.
Methods: A young person with JIA identified the need for direct family support. Juvenile Arthritis Research (a UK charity) developed a unique pack of support information, containing resources for both children and their families - called *A Little Box Of Hope.* This included information about JIA and support services available for families, as well as Kipo (a children's book about JIA) and accompanying finger puppet. Clinicians at one paediatric rheumatology centre provided information about the packs to newly diagnosed families, who then requested a free box to be posted to them.

Following an initial pilot study, recipients were invited to complete a short online questionnaire and provide feedback to allow refinement of the provision.
Results: Respondents were asked a series of questions, each on a scale of 1-5. Every respondent gave a score of 5 in response to "What do you think of the idea of *A Little Box Of Hope*?"
Every parent of children under ten years old gave a score of 5 for every item when asked "How useful is each item in your *Little Box Of Hope*?"
Respondents also gave free-text comments:
* "It was very well thought out and I felt supported"
* "I know so much more about JIA now than I did before. I cannot thank you enough."
* "It was extremely useful and made me feel supported during a very stressful time and this enabled me to support my son more effectively."
* "It made my daughter feel less alone."
Some parents of older children felt that some information specifically for teens would be useful, and a Teen pack is being developed.
Conclusion: Recipients of *A Little Box Of Hope* have found the information useful and feel supported. Following the pilot study, we have developed *My JIA*, a booklet reviewed by a multi-disciplinary clinical team, with comprehensive information for families affected by JIA. A Teen pack, for children aged around 10 years or older, is being developed to provide targeted support to this group.
The COVID-19 pandemic has adversely affected access to healthcare services, increasing the need for remote parent- and charity-provided support through *A Little Box Of Hope*.
As such, we intend to expedite the roll-out of the project across the country building on the success of the pilot project.

OP0279-PARE CHRONIC RHEUMATIC DISEASE (CRD) AND SPORT

P. Lemesle[1], L. Poulain[2], X. Grapton[3], N. Bouhedja[2]on behalf of CREER.
[1]*Hospital of Courbevoie, Clinic Rives de Seine, Courbevoie, France*; [2]*La Garenne-Colombes, Private practice, La Garenne-Colombes, France*; [3]*Neuilly-sur-Seine, Private practice, Neuilly-sur-Seine, France*

Background: In order to study the state of mind of patients with chronic inflammatory rheumatic disease (CRD) regarding physical/sports activity, excluding household activities despite their quantifiable energy value (MET), the CREER group produces this study.
Objectives: Analyze a population in the Ile-de-France region with CRD practicing a physical activity (their motivations, expectations, nature and rhythm). Determine the place of physical activity in the management of an CRD by the rheumatologist (Rh).
Methods: 207 patients, 53 yo average, 56% between 50 and 70 years, 60% are women; 97% of the CRD, Rheumatoid arthritis (RA): 57%) or Ankylosing Spondylitis (AS): 40%, low or moderate activity (66%).
10 years evolution (RA) and 11.5 years (AS), corticosteroids RA/AS as follows (34/5 %), NSAIDs (15/52 %), conventional DMARDS (84/30%) or biotherapies (21/43%).
Co-morbidities are found for RA/AS in 55% vs 44%, includes high blood pressure 20%, overweight 21%, tobacco 13.5%, other 19%.
Results: 7/10 patients are encouraged to engage in physical activity, regardless of gender, age, RA or AS. The most common activity proposed is walking (53%), followed by swimming and/or aquagym (40%) and gym (19%). The practice is regular in 60% more by women, RA=AS, more before 40 yo and after 60 years old (70%).
The activity actually practiced is: 1- walking 46.4%, 2- aquatic activities 37%, 3- cycling 29%, 4- home sports 19%.
Once/week minimum is good for cycling and swimming, insufficient for walking, very good for sport at home.
50% have been practicing for 3 years. 60% adapt the rhythm to rheumatism. Their motivations are: to maintain one's health, to de-stress.
A discordance exists between Rh/General physician that advise sport 8 times/10 vs 4.5/10. Nevertheless 50% ignore whether he or she is getting worse or better, hence the need for information.
Rh needs to communicate more about the interest of physical activity and the absence of deleterious effect on CRD which one patient over two ignores.
If 60% of patients modify their activity with CRD, many do not participate in sports because no time, no need, no desire RA=AS.
If the activity is supervised, adapted, prescribed is well-known, its application is confidential due to lack of coaches, and of qualified centers.
Conclusion: If the main activity practiced by patients and advocated by Rh is walking, the patients go beyond this framework by mobilizing for cycling, walking, swimming and gym. But the reluctance persists and we must, through therapeutic education convince of the benefits of the activity on CRD and its co-morbidities, unknown to 50% of patients. To map lesions, judge the ability and desires are necessary to set goals for duration and frequency of activity. Using connected tools improves compliance. Finally, walking which does not require neither schedule nor equipment (otherwise a cane) should become a first-line prescription.
Disclosure of Interests: None declared.

OP0280-PARE A MINDFULNESS PROGRAM DOSING STUDY TO EVALUATE IMPROVEMENT IN EMOTIONAL DISTRESS AMONG PEOPLE WITH RHEUMATIC DISEASE

J. Thompson[1], N. Parikh[1], K. Gavigan[1], S. Venkatachalam[1], W. B. Nowell[1].
[1]*Global Healthy Living Foundation, Patient Centered Research, Upper Nyack, United States of America*

Background: Mindfulness-based interventions for chronic pain and emotional distress have increased in popularity as complementary therapies among people living with rheumatic and musculoskeletal disease (RMD).[1,2] Despite growing evidence that mindfulness meditation reduces pain and anxiety associated with RMD, more research is needed to specify the optimal duration of mindfulness training necessary to be effective for short- and long-term benefit.
Objectives: To evaluate and compare the effectiveness of full-length versus brief mindfulness training programs for improving anxiety among people living with RMD.
Methods: Adult US participants (pts) within the ArthritisPower registry were invited to participate in the Healthy Mind Healthy You study comparing the effectiveness of two online mindfulness training programs of different lengths accessed via the MoodNetwork platform. The full-length mindfulness based cognitive therapy program lasted 8 weeks, while the brief evidence-based mindfulness program lasted 3 weeks. Pts were randomized to one of the two programs and completed assessments every two weeks during the program and then every four weeks during the 12-week follow-up period. Assessments included World Health Organization-Five Well-Being Index (WHO-5), Five Facet Mindfulness Questionnaire (FFMQ), Perceived Stress Scale (PSS), and two measures of emotional distress, PROMIS Short Forms for Anxiety and Depression. Analyses compared demographic characteristics and assessment scores by program length.
Results: 324 pts completed assessments at baseline and 70 pts completed them at week 8, an attrition rate of 78% in each of the program arms. The majority of pts were female, White, with 67% between the ages of 45-64 years. No statistically significant differences were observed at baseline between participants randomized to each of the two programs, and in their assessment scores at week 8 (Table 1); PROMIS Anxiety and Depression scores improved from baseline to week 8 for pts in both programs (Figure 1). Overall, mean (SD) PROMIS Depression scores improved from 58.4 (7.7) at baseline to 55.4 (7.2) at week 8 (p=0.018), a meaningfully important difference, among the 70 pts reporting scores at both time points.

Table 1. Assessment Scores at Baseline and Week 8, Mean (SD)

	Baseline				Week 8			
	All (n=324)	8-week course (n=163)	3-week course (n=161)	p-value	All (n=70)	8-week course (n=35)	3-week course (n=35)	p-value
WHO-5 [b]	10.6 (4.9)	10.4 (4.8)	10.9 (5.0)	0.378	12.0 (5.1)	12.5 (5.5)	11.6 (4.7)	0.488
FFMQ [c]	42.7 (6.1)	42.7 (6.1)	42.7 (6.1)	0.932	39.2 (5.7)	38.9 (6.1)	39.4 (5.3)	0.741
PSS [d]	18.7 (7.5)	19.2 (6.8)	18.3 (8.2)	0.304	16.6 (7.3)	15.7 (7.8)	17.6 (6.8)	0.291
PROMIS Depression [e]	56.5 (8.3)	57.3 (8.0)	55.7 (8.6)	0.097	55.1 (8.5)	54.8 (9.3)	55.5 (7.8)	0.735
PROMIS Anxiety [f]	58.7 (8.2)	59.0 (8.2)	58.4 (8.1)	0.470	55.4 (7.2)	54.6 (7.4)	56.1 (7.1)	0.404

[a] denotes use of Fisher's Exact Test [b] Range 0 (worse) to 25 (better), [c] Range 3 (worse) to 15 (better), [d] Range 0 (better) to 40 (worse), [e] Range 24.7 (better) to 63.5 (worse), [f] Range 25.7 (better) to 62.0 (worse)

Conclusion: People living with RMD who are part of a real-world US registry are willing to participate in an online mindfulness training program study, but may require additional support to remain engaged and adherent throughout the program and to participate to study conclusion. Participation in a mindfulness training program, whether full-length or brief, appears to improve symptoms of emotional distress among people with RMD.

New Developments in COVID-Research

OP0281 EXCESS GIANT CELL ARTERITIS CASES ARE ASSOCIATED WITH PEAKS IN COVID-19 PREVALENCE

B. Mulhearn[1,2], J. Ellis[1], S. Skeoch[1], J. Pauling[1,2], S. Tansley[1,2]. [1]*Royal United Hospital, Royal National Hospital For Rheumatic Diseases, Bath, United Kingdom*; [2]*University of Bath, Pharmacy and Pharmacology, Bath, United Kingdom*

Background: Immediately following the first wave of the COVID-19 pandemic, the number of giant cell arteritis (GCA) diagnoses noticeably increased at the Royal National Hospital for Rheumatic Diseases in Bath, UK. Furthermore, there was an increase in the proportion of patients with visual complications [1]. The finding supports the viral hypothesis of GCA aetiopathogenesis as previously described [2]. This not only has ramifications for understanding the underlying disease mechanisms in GCA but also has implications for the provision of local GCA services which may have already be affected by the pandemic.

Objectives: The objective of the study was to estimate the incidence of giant cell arteritis during the COVID-19 pandemic years of 2020 – 2021 and compare it to 2019 data. Given that there have now been two distinct peaks of COVID-19 as reflected by hospital admissions of COVID-19-positive patients this has allowed us to investigate if there is a temporal relationship between the prevalence of COVID-19 and the incidence of GCA.

Methods: The incidence of GCA was calculated by assessing emailed referrals to the GCA service and the hospital electronic medical records to identity positive cases from 2019 to the current date. Local COVID-19 prevalence was estimated by measuring the number of hospital beds taken up by COVID-19 positive patients, available publicly in a UK Government COVID-19 dataset [3].

Results: There were 61 (95% Poisson distribution confidence interval [CI] 47 - 78) probable or definite GCA diagnoses made in 2020 compared to 28 (CI 19 – 40) in 2019 (Figure 1). This is an excess of 33 cases in 2020, or an increase in 118%. Given that 41% of the hospital's catchment population is over 50, this equates to an annual incidence rate of 13.7 per 100,000 in 2019 and 29.8 per 100,000 in 2020. This compares to a previously estimated regional incidence rate of 21.6 per 100,000 for the South West of the UK [4].

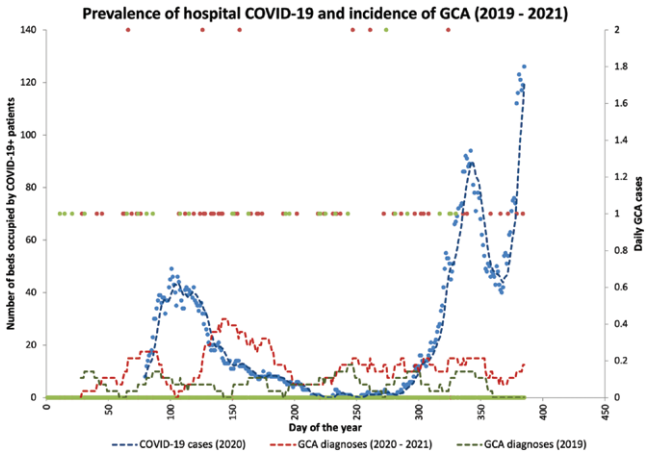

Figure 1. Prevalence of hospital COVID-19 and incidence of GCA (2019 – 2021). Graph showing the number of hospital beds occupied by COVID-19-positive patients in 2020 – 2021 (blue circles), number of daily GCA diagnoses in 2020 – 2021 (red circles), and previous GCA diagnoses in 2019 (green circles). The broken lines represent moving averages with a period of 7 days for COVID-19 cases and 28 days for GCA diagnoses.

A peak in COVID-19-positive inpatients was seen on 10th April 2020 with a corresponding peak of GCA diagnoses on 29th May 2020, giving a lag period of approximately 6 weeks between these peaks (Figure 1).

Conclusion: The incidence of GCA in Bath was significantly increased in 2020 compared to 2019. This may be the result of the widespread infection of the local population with the COVID-19 virus as a precipitating factor. Possible mechanisms include, but are not limited to, endothelial disruption by the virus, immune system priming towards T helper cell type 1 (Th1) cellular immunity and/or activation of the monocyte-macrophage system. More work is currently underway to assess the causal relationship between the two diseases.

There was a lag period of 6 weeks between the peak during the first wave of the pandemic and the rise in GCA cases. We shall be closely monitoring the number of referrals that follow the current wave of the pandemic.

OP0282 RITUXIMAB ASSOCIATED WITH SEVERE COVID-19 AMONG PATIENTS WITH INFLAMMATORY ARTHRITIDES: A 1-YEAR MULTICENTER STUDY IN 1116 SUCCESSIVE PATIENTS RECEIVING BIOLOGIC AGENTS

R. Felten[1], P. M. Duret[2], E. Bauer[3], M. Ardizzone[4], H. J. Djossou[5], J. H. Salmon[6], C. Fabre[7], J. Walther[7], I. Chary Valckenaere[3], M. Geoffroy[6], L. Messer[2], F. Berenbaum[5], M. Soubrier[8], J. Sellam[5], J. E. Gottenberg[1]on behalf of BIOCOV Study Group. [1]*Hôpitaux Universitaires de Strasbourg, Service de Rhumatologie, Centre National de Référence des Maladies Auto-immunes Systémiques Rares Est Sud-Ouest (RESO), Strasbourg, France*; [2]*Hospices Civils de Colmar, Hôpital Pasteur, Service Rhumatologie, Colmar, France*; [3]*Hôpitaux Universitaires de Nancy, Service de Rhumatologie, Nancy, France*; [4]*Hôpital Emile MULLER de Mulhouse, Service de Rhumatologie, Mulhouse,*

France; [5]*Hôpital Saint Antoine, APHP, Service de Rhumatologie, Paris, France*; [6] *Hôpitaux Universitaires Reims, Service de Rhumatologie, Reims, France*; [7]*Hôpitaux Universitaires de Strasbourg, Service de Pharmacie-Stérilisation, Strasbourg, France*; [8]*Hôpitaux Universitaires de Clermont-Ferrand, Service de Rhumatologie, Clermont-Ferrand, France*

Background: At a time when vaccines are being prioritized for individuals most at risk, there is currently no clear evidence that risk of SARS-CoV-2 infection is higher for patients with than without inflammatory arthritides (IA). Biologic use was not associated with worse COVID-19 outcomes for yet but the case of rituximab (RTX) remains an issue, given its immunological long term effect, the role of humoral response against SARS-CoV-2 and its indirect effect on T-cell response. A potential association between rituximab and worse COVID-19 outcomes was raised by case reports and retrospective, declarative studies (with few data on the total number of patients exposed).

Objectives: To address differently the issue of the risk of COVID-19 related to RTX and limit biases, we examined the occurrence of severe COVID-19 in all patients receiving intravenous biologic agents at day-hospitals during the pandemic in France.

Methods: From 1st September 2019 to 1st January 2021, we analyzed patients with IA prospectively treated with intravenous biologic agents (RTX, abatacept, infliximab or tocilizumab) in 7 clinical centers in France. We obtained the list of patients receiving intravenous biologic agents in each center from the pharmacist of the hospitals. Therefore, all consecutive patients receiving 1 of the 4 drugs at the time of the study were included in each center. Patients with no follow-up after September 2020 were systematically contacted by phone. The occurrence of a severe COVID -19 (i.e. resulting in death, hospitalization or increase in length of hospitalization related to COVID-19) was the primary outcome criteria.

Results: In total, 1116 patients receiving intravenous biologic agents were included: 449 with infliximab, 392 RTX, 170 tocilizumab and 105 abatacept. From 1st September 2019, the median follow-up time was 15 months (interquartile range 14-16). In total, 10 cases of severe COVID-19 occurred, 9 treated with RTX and 1 with infliximab (supplementary Table 1). Four deaths occurred in our cohort during follow-up but none was related to COVID-19 (1 patient treated by tocilizumab, 1 by RTX and 2 by infliximab). In univariate analysis, the proportion of severe COVID-19 was significantly higher for patients receiving RTX than other biologic agents (9/392 vs 1/724, p=0.0003, OR [95%CI] 17.0 [2.1-134.6]). To take into account potential confounders, we performed multivariate analysis accounting for baseline parameters that differed between RTX and other biologic groups. RTX remained significantly associated with risk of severe COVID-19 (p=0.019) (Table 1).

Patient characteristics	Rituximab (n= 392)	Other bDMARDs (n= 724)	Univariate analysis, p-value	Multivariate analysis, p-value
Median age (years), — [IQR]	64 [56-71]	57.3 [47.0-67.0]	**< 0.0001**	0.51
Female — n (%)	285 (72.7)	426 (58.8)	**< 0.0001**	0.58
IA diagnosis			**< 0.0001**	0.12
Median follow-up from 1st September to last news	14 [13-15]	15 [14-16]	**< 0.0001**	0.86
Confirmed severe COVID-19 cases —n (%)	9 (2.3)	1 (0.1)	**0.0003**	**0.019**
Comorbidities** (history of) — n (%)				
Cardiovascular disease	60 (15.4)	167 (23.1)	**0.0025**	0.77
Chronic lung disease,	92 (23.5)	84 (11.6)	**0.0001**	0.88
Median BMI (kg/m^2) — [IQR]	25.8 [23.2-29.4]	27.3 [23.4-31.2]	**0.015**	0.80
Treatments — n (%)				
Methotrexate	179 (45.8)	322 (44.5)	0.71	
Leflunomide	41 (10.5)	39 (5.4)	**0.0023**	0.43
Hydroxychloroquine	35 (8.9)	24 (3.3)	**0.0001**	0.15
Glucocorticoids	127 (41.8)	100 (19.4)	**< 0.0001**	0.36
Median dose (mg/day) — [IQR]	1 [0-5]	0 [0-0]	**< 0.0001**	

No significant difference in terms of baseline gammaglobulins (p=0.46) or number of previous RTX infusions (p=0.57) was observed among patients receiving RTX with or without a severe COVID-19.

Conclusion: The present results highly indicate increased risk of severe COVID-19 with RTX. Among patients with inflammatory arthritides, those receiving RTX should be prioritized for vaccination against SARS-CoV-2, sufficiently long before infusion/reinfusion and the immunization checked, or an alternative targeted therapy proposed.

Background: Patients with rheumatic and musculoskeletal diseases (RMD) might have an increased risk for infection due to their immunomodulatory treatment, secondary to their disease and comorbidities. Recent studies suggest a decreased risk of severe COVID-19 in RMD-patients treated with biologics.

Objectives: The aim of this study was to assess courses of RMD patients treated with TNF-inhibitors (TNF-I) included in the German COVID-19 registry.

Methods: In the German physician-reported COVID-19-RMD registry, patients with an RMD and confirmed SARS-CoV-2-infection were documented (data entered between March 30, 2020 and January 30, 2021). We analysed TNF-I treated patients, their course and outcome of the infection. Data were compared to RMD-patients treated with other immunomodulatory drugs (OID) than TNF-I.

Results: A total of 269 patients were treated with a TNF-I (57% female) compared to 874 patients who were treated with OID (68% female). Median age was 52 years (range: 19-87) in the TNF-I-group versus 58 years (range: 18-91) in the OID-group. Rheumatoid arthritis was the most common diagnosis (38% in TNF-I-group vs. 52% in the OID-group), followed by ankylosing spondylitis (32% vs. 6%), psoriatic arthritis (22% vs. 11%) and other RMD (9% vs. 31%). Adalimumab (35%) and etanercept (35%) were the most frequently used TNF-I (tab. 1). Glucocorticoids (GC) were used in 22% of TNF-I-treated patients and in 42% of the OID-group.

Under TNF-I, stable disease was reported prior to the SARS-CoV-2-infection in 53% of the patients (OID-group: 47%), followed by low disease activity in 35% (OID: 34%), moderate disease activity in 6% (OID: 12%) and high disease activity in 4% (OID: 3%). Most frequent comorbidities were arterial hypertension (29% under TNF-I vs. 35% under OID), diabetes (8% vs. 11%) and cardiovascular diseases (7% vs. 12%).

The most common reported COVID-19 symptoms were dry cough (57% vs. 55%), fever (53% vs. 61%) and fatigue (50% vs. 49%). Hospitalization due to SARS-CoV infection was required in only 12% of the TNF-I-treated cases vs. in 29% in the OID-group. Oxygen treatment was necessary in 5% of the patients under TNF-I compared to 22% under OID and invasive ventilation in 2% in the TNF-I-group compared to 6% under OID. Most notably, no fatal courses of COVID-19 were reported among the 269 RMD-patients treated with TNF-I versus 49 deaths in the 874 cases (5.6%) treated with OID. Focussing on the hospitalizated TNF-I patients, the rate of concomitant GC use (p<0.001) and higher disease activity (p=0.005) was significant higher (tab.1).

Conclusion: High or moderate RMD-disease activity is an important factor associated with severity of COVID-19 including mortality. In this large cohort RMD patients treated with TNF-I show a low hospitalisation rate and no fatal course. This is reassuring for patients and treating rheumatologists to use TNF-I to control RMD disease activity. The use of glucocorticoids and high disease activity seem to counteract possible protective effects of TNF-I.

Background: Various observations have suggested that the course of the COVID-19 infection may be less favorable in patients with inflammatory rheumatic and musculoskeletal diseases (iRMD) receiving rituximab (RTX).

Objectives: To investigate whether treatment with RTX is associated with severe infection and death.

Methods: We performed an observational, multicenter, French national cohort study querying the French RMD COVID-19 cohort, including highly suspected/confirmed iRMD-COVID-19 patients. The primary endpoint was to assess the severity rate of COVID-19. Severe disease was defined by hospitalization in intensive care unit or death. The secondary objectives were to analyze death rate and length of hospital stay. Two control groups were considered for comparison with RTX treated patients: a first group including all non-RTX treated iRMD patients and a second consisting on RTX untreated iRMD patients with diseases for which RTX is a recognized therapeutic option. Adjusting on potential confounding factors was performed by using inverse probability of treatment weighting (IPTW) propensity score method.

Results: We collected a total of 1090 records. Patients were mainly females (67.3%, 734/1090) with a mean age of 55.2±16.4 years, and 51.1% (557/1090) were over the age of 55. Almost 70% of the population had at least one comorbidity (756/1090). A total of 63 patients were treated with RTX, mainly for rheumatoid arthritis (RA) (31/63, 49.2%). RTX treated patients were more likely to be males, with older age, higher prevalence of comorbidities and corticosteroid use. The control population consisted on 1027 non-RTX treated iRMD patients, and 495 RTX untreated iRMD patients with diseases for which RTX is a recognized therapeutic option.

Of the 1,090 patients, 137 developed severe disease (12.6%). After adjusting on potential confounding factors (age, sex, arterial hypertension, diabetes, smoking status, body mass index, interstitial lung disease, cardiovascular diseases, cancer, corticosteroid use, chronic renal failure and the underlying disease), severe disease was confirmed to be observed more frequently in patients receiving RTX compared to all RTX untreated iRMD patients (effect size, ES 3.26, 95% confidence interval, CI 1.66 to 6.40, p<0.001) and the subgroup of untreated RTX patients with diseases eligible for RTX therapy (ES 2.62, 95% CI 1.34 to 5.09, p=0.005). Patients who developed a severe disease had a more recent rituximab infusion compared to patients with mild or moderate disease. Indeed, the time between the last infusion of rituximab and the first symptoms of COVID-19 was significantly shorter in patients who developed a severe form of COVID-19 (Figure 1).

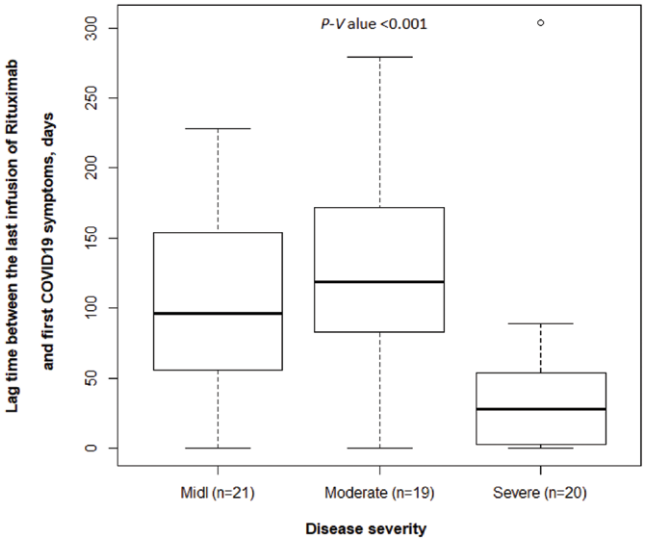

Figure 1. Distribution (Tukey's box plot) of Lag time between last infusion of Rituximab according to disease severity. P-Values for comparison between disease severity with Kruskal Wallis test are reported; P-Value<0.001 for either post-hoc comparison of severe disease group with moderate or mild disease group (calculated using Dunn's test).

Eighty-nine patients in our cohort died, resulting in an overall death rate of 8.2%. Death rate was numerically higher in RTX treated patients (13/63, 20.6%) compared to all RTX untreated iRMDs patients (76/1027, 7.4%) and the subgroup of untreated RTX patients with diseases eligible for RTX therapy (49/495, 9.9%). After considering the previously described confounding factors, the risk of death was not significantly increased in patients treated with RTX compared to all RTX untreated iRMDs patients (ES 1.32, 95% CI 0.55 to 3.19, p=0.53) (Table 2) and the subgroup of untreated RTX patients with diseases eligible for RTX therapy (ES 1.48, 95% CI 0.68 to 3.20, p=0.32). In line with a more severe COVID-19 disease, the length of hospital stay was markedly longer in patients treated with RTX compared to both untreated RTX patient groups.

Conclusion: RTX therapy is associated with a more severe COVID-19 infection. RTX will have to be applied with particular caution in patients with iRMDs.

Acknowledgements: Muriel Herasse played a major role in collecting the missing data of the cohort.

OP0285 COVID-19 HOSPITALIZATIONS, ICU ADMISSION, AND DEATH AMONG PATIENTS WITH IMMUNE MEDIATED INFLAMMATORY DISEASES (IMID) – A POPULATION-BASED STUDY

L. Eder[1,2], R. Croxford[3], A. Drucker[2,4], A. Mendel[5], K. Bindee[4,6], Z. Touma[4,7], R. Cook[8], S. Johnson[4,7], S. Bernatsky[5], N. Haroon[1,7], J. Widdifield[9,10].
[1]University of Toronto, Medicine and Institute of Medical Science, Toronto, Canada; *[2]Women's College Research Institute, Medicine, Toronto, Canada*; *[3]ICES, NA, Toronto, Canada*; *[4]University of Toronto, Medicine and Health Policy Management and Evaluation, Toronto, Canada*; *[5]McGill University, Medicine, Montreal, Canada*; *[6]Sinai Health System, Medicine, Toronto, Canada*; *[7]Toronto Western Hospital, Medicine, Toronto, Canada*; *[8]University of Waterloo, Biostatistics, Waterloo, Canada*; *[9]University of Toronto, Institute of Health Policy Management and Evaluation, Toronto, Canada*; *[10]Sunnybrook Research Institute, Medicine, Toronto, Canada*

Background: It remains unclear whether patients with IMID are at greater risk for severe COVID-19.
Objectives: To investigate the risk of COVID-19 hospitalizations and their outcomes in patients with IMID compared with matched non-IMID patents from the general population.
Methods: A population-based, matched cohort study was conducted in adults living in Ontario, Canada using health administrative data. Ten cohorts of the following IMID were assembled: rheumatoid arthritis, psoriasis, psoriatic arthritis, ankylosing spondylitis, systemic autoimmune rheumatic diseases (SARDs, including systemic lupus, systemic sclerosis, Sjogren's, myositis), multiple sclerosis (MS), iritis, inflammatory bowel disease, polymyalgia rheumatica (PMR), and vasculitis (including giant cell arteritis and other types of vasculitidies). Each patient was matched with 5 non-IMID comparators based on age, sex, area of residence and living in long-term care (LTC). Patients who were admitted to hospital from January 1st to July 31th, 2020 and had ICD-10 COVID-19 diagnosis codes (U07.2 or U07.1) were identified. Among those with COVID-19 hospitalizations, we determined those with admissions to intensive care unit or required mechanical ventilation or died in hospital ('complicated hospitalization'). Age-sex-standardized rates were compared between IMID and non-IMID patients and risk factors for hospitalizations were identified by multivariable logistic regression analysis.
Results: In total, 493,499 IMID (417 hospitalized) and 2,466,946 non-IMID patients (1,519 hospitalized) were assessed. The age-sex-standardized rate of COVID-19 hospitalization was higher in IMID (6.4 per 10,000, 95% confidence interval (CI) 5.8, 7.2) versus non-IMID patients (4.8 per 100,000, 95% CI 4.5, 5). The highest rates of hospitalizations were found in vasculitis (18/10,000), MS (16.7/10,000) and PMR (10.1/10,000). IMID diagnosis was associated with 37% higher risk of being hospitalized for COVID-19 (Odds Ratio (OR) 1.37, 95% CI 1.23, 1.53) (Figure 1). This risk was slightly attenuated after adjusting for sociodemographic factors and comorbidities but remained elevated by 23% compared to non-IMID (OR 1.23, 95% CI 1.10, 1.37). The risk for hospitalizations was increased in RA, vasculitis, SARDs, PsA, MS and iritis (Figure 1). Risk factors for COVID-19 hospitalizations included older age, male sex, lower income, multimorbidity and living in long-term care (Table 1). The risk for complicated COVID-19 hospitalizations was higher by 21% in IMID patients (OR 1.21, 95% CI 1.02, 1.43), however, this association was attenuated after adjustment for demographics and comorbidities (OR 1.08).

Table 1. Risk Factors for COVID-19 Hospitalizations in IMIDs vs. non-IMIDs

Variable	OR	95% CI
IMIDs vs. Non-IMID	1.23	1.10, 1.37
Age (10 yrs)	1.49	1.44, 1.54
Sex: Female	0.68	0.62, 0.75
Long term care resident	8.28	7.32, 9.37
ADG: 5-9 vs. 0-4	1.45	1.22, 1.71
10-14 vs. 0-4	2.26	1.92, 2.67
15+ vs. 0-4	3.23	2.73, 3.82
Income (quintile)		
Quintile 2 vs. 1	0.82	0.73, 0.93
Quintile 3 vs. 1	0.76	0.67, 0.86
Quintile 4 vs. 1	0.56	0.48, 0.64
Quintile 5 vs. 1	0.46	0.40, 0.54
Urban vs. rural	4.33	3.32, 5.67

ADG - Aggregated Diagnosis Groups

Conclusion: Patients with IMID were at higher risk of being hospitalized with COVID-19 and for having complicated hospitalizations. Hospitalization risk was partially independent of their comorbid conditions.

Background: An increased risk of severe COVID-19 outcomes may be seen in patients with autoimmune diseases on moderate to high daily doses of glucocorticoids, as well as in those with comorbidities. However, specific information about COVID-19 outcomes in SLE is scarce.

Objectives: To determine the characteristics associated with severe COVID-19 outcomes in a multi-national cross-sectional registry of COVID-19 patients with SLE.

Methods: SLE adult patients from a physician-reported registry of the COVID-19 GRA were studied. Variables collected at COVID-19 diagnosis included age, sex, race/ethnicity, region, comorbidities, disease activity, time period of COVID-19 diagnosis, glucocorticoid (GC) dose, and immunomodulatory therapy. Immunomodulatory therapy was categorized as: antimalarials only, no SLE therapy, traditional immunosuppressive (IS) drug monotherapy, biologics/targeted synthetic IS drug monotherapy, and biologic and traditional IS drug combination therapy. We used an ordinal COVID-19 severity outcome defined as: not hospitalized/hospitalized without supplementary oxygen; hospitalized with non-invasive ventilation; hospitalized with mechanical ventilation/extracorporeal membrane oxygenation; and death. An ordinal logistic regression model was constructed to assess the association between demographic characteristics, comorbidities, medications, disease activity and COVID-19 severity. This assumed that the relationship between each pair of outcome groups is of the same direction and magnitude.

Results: Of 1069 SLE patients included, 1047 (89.6%) were female, with a mean age of 44.5 (SD: 14.1) years. Patient outcomes included 815 (78.8%) not hospitalized/hospitalized without supplementary oxygen; 116 (11.2) hospitalized with non-invasive ventilation, 25 (2.4%) hospitalized with mechanical ventilation/extracorporeal membrane oxygenation and 78 (7.5%) died. In a multivariate model (n=804), increased age [OR=1.03 (1.01, 1.04)], male sex [OR =1.93 (1.21, 3.08)], COVID-19 diagnosis between June 2020 and January 2021 (OR =1.87 (1.17, 3.00)), no IS drug use [OR =2.29 (1.34, 3.91)], chronic renal disease [OR =2.34 (1.48, 3.70)], cardiovascular disease [OR =1.93 (1.34, 3.91)] and moderate/high disease activity [OR =2.24 (1.46, 3.43)] were associated with more severe COVID-19 outcomes. Compared with no use of GC, patients using GC had a higher odds of poor outcome: 0-5 mg/d, OR =1.98 (1.33, 2.96); 5-10 mg/d, OR =2.88 (1.27, 6.56); >10 mg/d, OR =2.01 (1.26, 3.21) (Table 1).

Table 1. Characteristics associated with more severe COVID-19 outcomes in SLE. (N=804)

	OR (95% CI)
Age, years	1.03 (1.01, 1.04)
Sex, Male	1.93 (1.21, 3.08)
Race/Ethnicity, Non-White vs White	1.47 (0.87, 2.50)
Region	
Europe	Ref.
North America	0.67 (0.29, 1.54)
South America	0.67 (0.29, 1.54)
Other	1.93 (0.85, 4.39)
Season, June 16th 2020-January 8th 2021 vs January-June 15th 2020	1.87 (1.17, 3.00)
Glucocorticoids	
0 mg/day	Ref.
0-5 mg/day	1.98 (1.33, 2.96)
5-10 mg/day	2.88 (1.27, 6.56)
=>10 mg/day	2.01 (1.26, 3.21)
Medication Category	
Antimalarial only	Ref.
No IS drugs	2.29 (1.34, 3.91)
Traditional IS drugs as monotherapy	1.17 (0.77, 1.77)
b/ts IS drugs as monotherapy	1.00 (0.37, 2.71)
Combination of traditional and b/ts IS	1.00 (0.55, 1.82)
Comorbidity Burden	
Number of Comorbidities (excluding renal and cardiovascular disease)	1.39 (0.97, 1.99)
Chronic renal disease	2.34 (1.48, 3.70)
Cardiovascular disease	1.93 (1.34, 3.91)
Disease Activity, Moderate/ high vs Remission/ low	2.24 (1.46, 3.43)

IS: immunosuppressive. b/ts: biologics/targeted synthetics

Conclusion: Increased age, male sex, glucocorticoid use, chronic renal disease, cardiovascular disease and moderate/high disease activity at time of COVID-19 diagnosis were associated with more severe COVID-19 outcomes in SLE. Potential limitations include possible selection bias (physician reporting), the cross-sectional nature of the data, and the assumptions underlying the outcomes modelling.

OP0287 IMMUNOMODULATORY THERAPIES FOR SEVERE FORMS OF COVID-19: A SYSTEMATIC LITERATURE REVIEW TO INFORM EULAR POINTS TO CONSIDER

A. Alunno[1], A. Najm[2], X. Mariette[3], J. Emmel[4], L. Mason[4], G. De Marco[5], D. Mcgonagle[5], P. Machado[6]. [1]*Rheumatology Unit, University of Perugia, Department of Medicine, Perugia, Italy*; [2]*Institute of Infection, Immunity and Inflammation, University of Glasgow, College of Medical Veterinary and Life Sciences, Glasgow, United Kingdom*; [3]*Paris-Saclay University, AP-HP, INSERM, Le Kremlin Bicêtre, France*; [4]*Leeds Teaching Hospitals NHS Trust, Library & Evidence Research Centre, Medical Education, Leeds, United Kingdom*; [5]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [6]*University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom*

Background: The severe acute respiratory syndrome coronavirus 2 (SARS-CoV2) pandemic is a global health problem. Beside the specific pathogenic effect of SARS-CoV-2, a deleterious aberrant non-effective host immune response plays an important role especially in severe forms of COVID-19. There is intense investigation to explore the utility of immunomodulatory drugs commonly used in the Rheumatology arena as agents that may mitigate against COVID-19 to improve disease prognosis. Rheumatologists are used to the utilization of these immune targeted therapies.

Objectives: To summarize the available information on the use of immunomodulatory agents in severe COVID-19.

Methods: As part of a EULAR taskforce, a systematic literature search was conducted from January 2019 up to December 11, 2020. Two reviewers independently identified eligible studies according to the PICO framework P (population): patients with SARS-CoV-2 infection; I (intervention): any immunomodulator agent/strategy; C (comparator): any comparator; O (outcome) any clinical outcome including but not limited to mortality, admission to intensive care unit and clinical improvement. Data on efficacy and safety of immunomodulatory agents utilized therapeutically in SARS-CoV-2 infection at any stage were extracted. The risk of bias was assessed using validated tools.

Results: Of 60372 records, 401 articles were eligible for inclusion. Studies were at variable risk of bias. Randomised controlled trials (RCTs) were available for the following drugs: hydroxychloroquine (N=12), glucocorticoids (N=6), tocilizumab (N= 4), convalescent plasma (N=4), interferon beta (N=2), IVIg (N=2) and N=1 each for anakinra, baricitinib, colchicine, leflunomide, ruxolitinib, interferon kappa, and vilobelimab. For glucocorticoids, dexamethasone reduced mortality only in patients requiring respiratory support; while methylprednisolone reduced mortality in patients aged 60 years or over. Data from RCTs on tocilizumab are conflicting and definite conclusions cannot be drawn at this point in time, but recent studies suggest possible benefit in patients requiring respiratory support. Hydroxychloroquine was not beneficial at any disease stage, one RCT with anakinra was negative, one RCT with baricitinib+remdesivir was positive, and individual trials testing some other compounds provided interesting, albeit preliminary, results.

Conclusion: Although there is emerging evidence about immunomodulatory therapies for the management of COVID-19, conclusive data is scarce with some conflicting data. Since glucocorticoids seem to improve survival in some subsets of patients, RCTs comparing glucocorticoids alone versus glucocorticoids plus anti-cytokine/immunomodulatory treatment are warranted. This SLR informed the initiative to formulate EULAR points to consider on pathophysiology and use of immunomodulatory therapies in COVID-19.

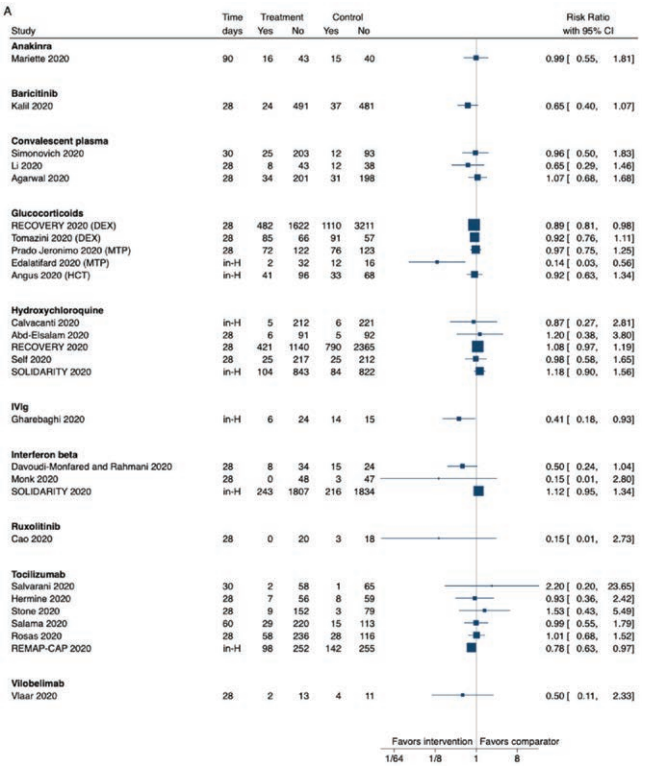

Figure 1. Forest plots showing the risk ratio (RR) and 95% confidence interval for mortality in randomized controlled trials divided by intervention. The latest follow-up available is reported in the timing column.

Background: Acute Respiratory Distress Syndrome (ARDS) is a life-threatening complication of COVID-19 and has been reported in approximately one-third of hospitalized patients with COVID-19[1]. Risk factors associated with the development of ARDS include older age and diabetes[2]. However, little is known about factors associated with ARDS in the setting of COVID-19, in patients with rheumatic disease or those receiving immunosuppressive medications. Prediction algorithms using traditional regression methods perform poorly with rare outcomes, often yielding high specificity but very low sensitivity. Machine learning algorithms optimized for rare events are an alternative approach with potentially improved sensitivity for rare events, such as ARDS in COVID-19 among patients with rheumatic disease.

Objectives: We aimed to develop a prediction model for ARDS in people with COVID-19 and pre-existing rheumatic disease using a series of machine learning algorithms and to identify risk factors associated with ARDS in this population.

Methods: We used data from the COVID-19 Global Rheumatology Alliance (GRA) Registry from March 24 to Nov 1, 2020. ARDS diagnosis was indicated by the reporting clinician. Five machine learning algorithms optimized for rare events predicted ARDS using 42 variables covering patient demographics, rheumatic disease diagnoses, medications used at the time of COVID-19 diagnosis, and comorbidities. Model performance was assessed using accuracy, area under curve, sensitivity, specificity, positive predictive value, and negative predictive value. Adjusted odds ratios corresponding to the 10 most influential predictors from the best performing model were derived using hierarchical multivariate mixed-effects logistic regression that accounted for within-country correlations.

Results: A total of 5,931 COVID-19 cases from 67 countries were included in the analysis. Mean (SD) age was 54.9 (16.0) years, 4,152 (70.0%) were female, and 2,399 (40.5%) were hospitalized. ARDS was reported in 388 (6.5% of total and 15.6% of hospitalized) cases. Statistically significant differences in the risk of ARDS were observed by demographics, diagnoses, medications, and comorbidities using unadjusted univariate comparisons (data not shown). Gradient boosting machine (GBM) had the highest sensitivity (0.81) and was considered the best performing model (Table 1). Hypertension, interstitial lung disease, kidney disease, diabetes, older age, glucocorticoids, and anti-CD20 monoclonal antibodies were associated with the development of ARDS while tumor necrosis factor inhibitors were associated with a protective effect (Figure 1).

Table 1. Performance of machine learning algorithms.

	GBM	SVM	GLMNET	NNET	RF
Accuracy	0.79	0.68	0.66	0.66	0.67
AUC	0.75	0.70	0.74	0.58	0.74
Sensitivity	0.81	0.68	0.65	0.68	0.67
Specificity	0.49	0.60	0.73	0.48	0.68
PPV	0.96	0.96	0.97	0.95	0.97
NPV	0.16	0.12	0.13	0.09	0.13

GBM: Gradient Boosting Machine, SVM: Support vector machines, GLMNET: Lasso and Elastic-Net Regularized Generalized Linear Models, NNET: Neural Networks, RF: Random Forest. AUC: Area Under Curve; PPV: Positive Predictive Value; NPV: Negative Predictive Value.

Conclusion: In this global cohort of patients with rheumatic disease, a machine learning model, GBM, predicted the onset of ARDS with 81% sensitivity using baseline information obtained at the time of COVID-19 diagnosis. These results identify patients who may be at higher risk of severe COVID-19 outcomes. Further studies are necessary to validate the proposed prediction model in external cohorts and to evaluate its clinical utility. Background: Remission, LDA and LDAS have been proposed as treatment goals for SLE. However, the independent impact of these states on damage accrual has not been fully evaluated.

Objectives: To determine the independent impact of remission (both off & on treatment), LDA, and LLDAS on damage accrual.

Methods: We studied a long-term longitudinal multinational SLE cohort, including patients completing at least two annual assessments. Remission off-treatment was defined as a SLEDAI (excluding serology) =0, without prednisone and immunosuppressive (IS) drugs. Remission on-treatment was defined as a SLEDAI (excluding serology) =0, prednisone daily dose<=5 mg/d and maintenance IS drugs. LDA was defined as a SLEDAI (excluding serology) <=2, without prednisone or IS drugs. LLDAS was defined as a SLEDAI <=4 with no activity in major organ systems, with no new features of lupus disease activity compared to the previous assessment, prednisone daily dose<=7.5 mg/d and maintenance IS drugs. Antimalarials were allowed in all groups. Damage accrual was ascertained with the SLICC/ACR damage index (SDI). Univariable and multivariable generalized estimated equation (GEE) negative binomial regression models were used. To create mutually exclusive groups, disease activity was divided into five states: remission off-treatment, remission on-treatment (minus remission off treatment), LDA (minus remission), LLDAS (minus remission and LDA) and not-optimally controlled. The proportion of the time that patients were in the specific state at each visit since cohort entry was determined. Possible effect modifiers and confounders adjusted for included sex, age at diagnosis, race/ethnicity, education, baseline disease duration, follow-up time, the highest-ever glucocorticoid dose prior to cohort entry, antimalarials and SDI. Time-dependent covariates were determined at the same annual visit as disease activity state; the outcome was the increase in the SDI and it was assessed at the subsequent visit.

Results: There were 1,652 patients, 1464 (88.6%) were female, mean age at diagnosis was 34.6 (SD 13.4) years and mean baseline disease duration was 5.5 (SD 4.1) months. Patients had a mean follow-up of 6.5 (SD 4.3) years, 11686 visits were included. 763 patients (46.2%) had an increase in SDI score ≥1 during follow-up. 2483 (21.2%) of the visits were classified as remission off-treatment, 2276 (19.5%) as remission on-treatment, 544 (4.7%) as LDA, 657 (5.6%) as LLDAS and 5726 (49.0%) as not-optimally controlled. Being in remission off-treatment, remission on-treatment, LDA and LLDAS were predictive of a lower probability of damage accrual [remission off-treatment IRR=0.403, 95% CI 0.301-0.541); remission on-treatment IRR=0.313 (95% CI 0.218-0.451) LDA: IRR=0.469 (CI 95% CI 0.272-0.809); LLDAS IRR=0.440 (95% CI 0.241-0.803)]. The multivariable model is summarized in Table 1.

Table 1. Multivariable GEE model of the impact of disease activity states on damage accrual.

	Incidence Rate Ratio	95% CI
Disease activity state		
Remission off treatment	0.403	0.301-0.541
Remission on treatment	0.313	0.218-0.451
LDA	0.469	0.272-0.809
LLDAS	0.440	0.241-0.803
Gender, male	1.274	1.086-1.495
Age at diagnosis	1.024	1.020-1.029
Ethnicity		
Caucasian US	Ref.	
Caucasian other	1.017	0.849-1.217
African	1.467	1.211-1.776
Asian	0.863	0.693-1.075
Hispanic	1.266	1.034-1.550
Other	1.121	0.759-1.656
Educational level, years	0.977	0.957-0.996
Disease duration at baseline	0.960	0.801-1.150
Follow-up time	0.942	0.923-0.960
Antimalarial use	0.786	0.681-0.908
Highest prednisone dose before baseline	1.002	1.001-1.007
SDI before	1.100	1.050-1.1152

LLDAS: Low lupus disease activity state LDA: Low disease activity SDI: SLICC/ACR Damage Index

Conclusion: Remission on- and off-treatment, LDA and LLDAS were associated with less damage accrual, even adjusting for possible confounders and effect modifiers. This highlights the importance of treating to target in SLE.

OP0290 CLINICAL CHARACTERISTICS AND PROGNOSIS OF ANTIPHOSPHOLIPID SYNDROME PATIENTS BASED ON CLUSTER ANALYSIS: A 10-YEAR COHORT STUDY

W. Qi[1], J. L. Zhao[1], X. Tian[1], M. LI[1], X. Zeng[1]. [1]*Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China*

Background: APS is an autoimmune disease characterized by persistent antiphospholipid antibodies (aPLs) positivity, leading to thrombotic events or pregnancy morbidity. High-risk aPLs profiles included positive lupus anticoagulant (LA) and multiple aPLs positivity[1]. Association was also found between aPLs and a variety of manifestations beyond thrombosis, referred to "non-criteria manifestations" (i.e. thrombocytopenia, hemolytic anemia, heart valve disease and aPL-related nephropathy)[2], of which the role in APS risk stratification is poorly understood. The manifestation spectrum of APS is wide, ranging from asymptomatic aPLs positivity to life-threatening catastrophic APS, and patients other than confirmed APS also need proper management. Therefore, a risk stratification integrating demographic data, aPL-related manifestations, aPLs profiles, coexisting cardiovascular risk factors and SLE is needed for management guidance and prognosis assessment.
Objectives: Using cluster analysis, to identify phenotypes among aPL-positive patients and assess the prognosis of each phenotype.
Methods: This is a single-center, prospective cohort study of aPL-positive patients who presented to Peking Union Medical College Hospital from 2004 to 2020. Demographic characteristics, aPL-related manifestations, cardiovascular risk factors, antibodies profile and follow-up data were recorded. The primary end point was defined as a combination of newly onset arterial thrombosis (AT) or deep venous thrombosis (DVT), major bleeding events, non-criteria manifestations and all-cause death. Hierarchical cluster analysis with the Euclidean distance and the Ward method was applied to identify clusters of patients and variables separately. Multiple comparison and Kaplan-Meier survival analysis were performed among clusters.
Results: Four clusters among 383 patients (70.2% female; mean age 37.7 years) were identified (Figure 1A). Cluster 1 (n=138): female patients with SLE, non-criteria manifestations, triple aPLs positivity, high AT rate and moderate DVT rate. Cluster 2 (n=112): male patients with obesity, smoking history, hypertension, hyperhomocysteinemia, triple aPLs positivity and the highest rate of AT and DVT. Cluster 3 (n=83): female patients with the highest pregnancy morbidity rate and the lowest thrombosis rate. Cluster 4 (n=50): 62% male patients with isolated LA positivity, high AT rate and moderate DVT rate. Four clusters of variables were also identified (Figure 1A). From Kaplan-Meier survival analysis, 1-, 5- and 10-year event-free survival rates were 92.6%, 79.8% and 66.8%, respectively. Cluster 3 showed lowest incidence of primary endpoint (Figure 1B), while Cluster 1 and 2 showed higher newly-onset AT risk compared with other clusters (P=0.028 for 2 vs 3 and P=0.049 for 2 vs 4).

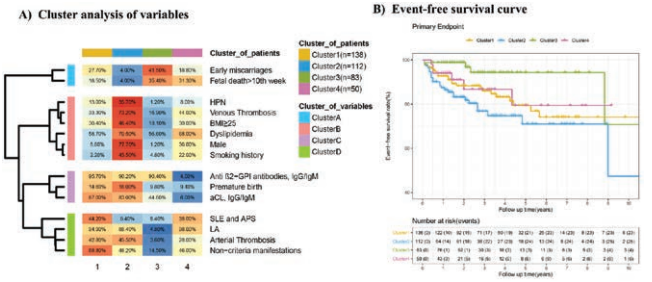

Figure 1.

Conclusion: We identified 4 clinical phenotypes of aPL-positive patients. APS secondary to SLE was always aggregated with non-criteria manifestations. Clinicians should be alert to the possibility of SLE in aPL-positive patients with coexisting non-criteria manifestations, for whom immunosuppressive therapy besides anticoagulation may be necessary. Cluster 4 represented patients with isolated LA positivity and shared similar prognosis with secondary APS and male patients, which confirmed that LA represented a high-risk antibody spectrum. Additionally, cardiovascular risk factors (i.e. male, smoking history and obesity) played an important role in thrombosis events, and led to poor prognosis. Therefore, more attention should be paid to male patients, and the screening and management of cardiovascular risk factors should not be ignored.

OP0291 SEVERITY OF LABIAL MINOR SALIVARY GLAND FOCUS SCORE AND FUTURE LYMPHOMA DEVELOPMENT IN SJÖGREN'S SYNDROME

A. Goules[1], L. Chatzis[1], V. Pezoulas[2], C. Baldini[3], F. Skopouli[4], A. Venetsanopoulou[5], P. Voulgari[5], S. De Vita[6], M. Voulgarelis[1], H. M. Moutsopoulos[7], D. Fotiadis[2], A. Tzioufas[1]. [1]*School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece*; [2]*University of Ioannina, Unit of Medical Technology and Intelligent Information Systems, Athens, Greece*; [3]*University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Athens, Greece*; [4]*Harokopio University of Athens, Department of Nutrition and Clinical Dietetics, Athens, Greece*; [5]*University of Ioannina, Department of Internal Medicine, Athens, Greece*; [6]*University of Udine, Rheumatology Clinic, Department of Medical area, Athens, Greece*; [7]*Academy of Athens, Chair Medical Sciences/Immunology, Greece, Athens, Greece*

Background: The typical histologic picture of focal sialadenitis in the labial minor salivary gland (LMSG) tissues has been incorporated as a parameter in the majority of Sjögren's syndrome (SS) classification criteria, with focus score (FS) being the most widely used (1). In previous studies, higher FS has been associated with the presence of autoantibodies and extra-glandular manifestations including lymphoma, implying that FS can predict severe disease (2,3). However, there are no studies exploring the association of FS with lymphoma development along with the time interval from SS diagnosis to lymphoma diagnosis.
Objectives: To investigate an association of focus score grading with lymphoma development and time to lymphoma occurrence.
Methods: From a total population 1998 consecutive patients fulfilling the 2016 ACR-EULAR criteria for SS who were followed-up in 5 Rheumatology centers from Greece and Italy (Universities of Athens, Pisa, Udine, Harokopio and Ioannina) (UPAHI group), those with positive (LMSG) (FS ≥1) were identified. (1). Patients who had not been subjected to an LMSG biopsy or had a negative biopsy (FS<1) or the biopsy was evaluated using other histologic classifications were excluded from the present study. Lymphoma patients with diagnostic LMSG biopsy performed within a year from lymphoma diagnosis as well as non-lymphoma patients with less than 1 year between SS diagnosis and their last follow up, were also excluded. Cumulative clinical and histologic data attributed to SS as defined by ESSDAI and/or ESSPRI, up to lymphoma diagnosis or last follow up, were recorded. A combined data driven Fast Correlation Based Feature selection (FCBF)/Logistic Regression (LR) model was applied on the unified dataset to identify independent lymphoma associated risk factors. A correlation between FS and time interval until lymphoma diagnosis was performed using the Pearson formula.
Results: A unified dataset of 618 SS patients with FS≥1 and at least one year of disease duration from SS diagnosis to lymphoma diagnosis or last follow up, with 30 clinical, laboratory and histologic features, was constructed. The median age at SS diagnosis was 53 (range: 15 – 80) years old, the female to male ratio was 20:1 and the median disease duration was 6 years (range: 1-35). Half (49%) of the study population had focus score between one and two (1≤FS<2), followed by a declining proportion of patients accounted for every subsequent escalating FS group. No statistically significant difference was found regarding disease duration among the various FS escalating groups (p= 0.1603, Kruskal-Wallis test). Fifty eight patients had lymphoma with no statistically significant difference in disease duration compared to non-lymphoma controls. The data driven FCBF/LR algorithm with lymphoma on the whole dataset revealed that cryoglobulinemia (p=0.021), salivary gland enlargement (p=0.008) and FS (p=0,049) are independent lymphoma associated risk factors. A statistically significant negative correlation was found using a Pearson formula (R=-0.32 and p=0.015) regarding the focus score and the time to lymphoma diagnosis.
Conclusion: This is the largest study of SS patients' histologic analysis exploring the association of LMSG FS grading with lymphoma development and the time interval until its diagnosis. Higher FS values correlate with increased lymphoma risk and early lymphoma occurrence.

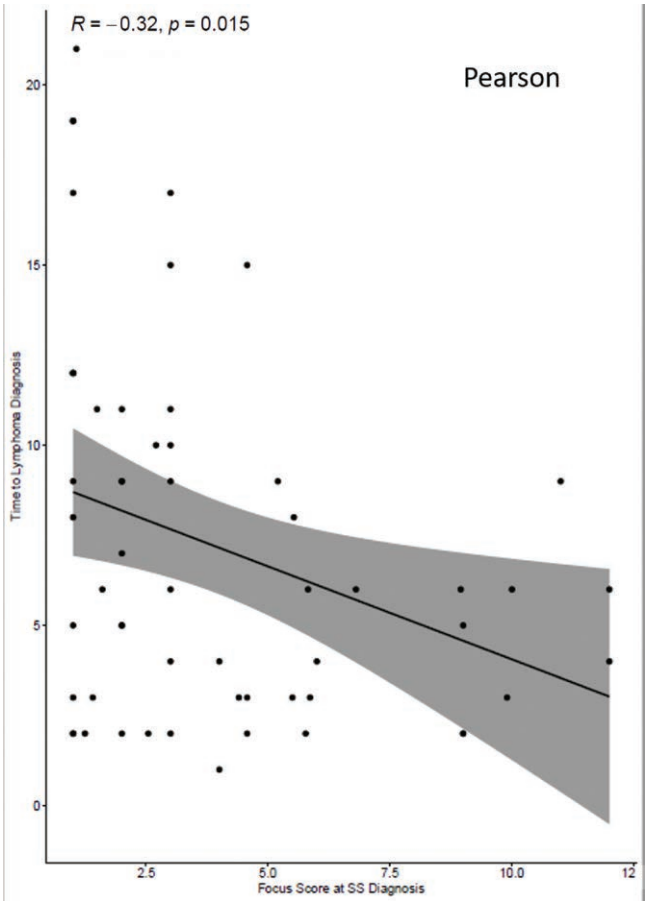

Figure 1. Pearson correlation between FS and time interval until lymphoma diagnosis

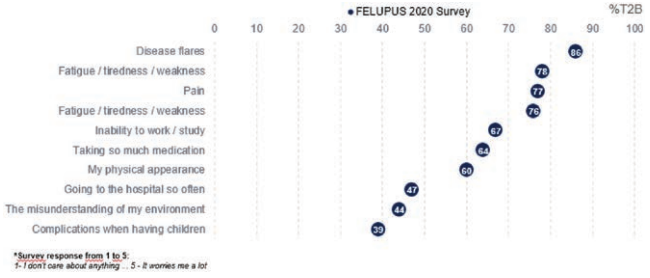
OP0292 SURVEY ON THE PERCEPTIONS AND EXPERIENCES OF SPANISH LUPUS PATIENTS. RESULTS ABOUT KNOWLEDGE OF THE DISEASE AND RELATIONSHIP TO DISEASE-FELUPUS SURVEY

P. Fanlo[1], T. C. Salman Monte[2], J. L. Callejas-Rubio[3], M. Galindo[4], Á. Robles Marhuenda[5], L. Pallares Ferreres[6], M. J. Ángel Torres[7], S. Pérez Ortega[7]on behalf of FELUPUS. *[1]Complejo Hospitalario de Navarra, Internal Medicine, Pamplona, Spain*; *[2]Hospital Universitario del Mar, Rheumatology, Barcelona, Spain*; *[3]Internal Medicine, Hospital Universitario Clínico San Cecilio, Granada, Spain*; *[4]Hospital Universitario 12 de Octubre, Rheumatology, Madrid, Spain*; *[5]Hospital Universitario La Paz, Internal Medicine, Madrid, Spain*; *[6]Hospital Universitario Son Spases, Internal Medicine, Palma de Mallorca, Spain*; *[7]FELUPUS, FELUPUS, Madrid, Spain*

Background: Despite great advances in the diagnosis and treatment of lupus, the scientific community does not know the perception of our patients regarding the knowledge of the disease and the relationship between patients and disease. Fatigue had the greatest impact on activities of daily living, yet the majority reported receiving no support or poor support in managing it[1].
Objectives: Through this initiative, it is intended to investigate about the knowledge of the disease and impact of the disease on quality of life of Lupus patients. Another objective is to give visibility to the current needs of people living with lupus.
Methods: It was performed a national survey with 1,263 interviews with Lupus patients who reside in Spanish territory and belonging to lupus patient associations in Spain. The survey was carried out by the Spanish Lupus Federation (FELUPUS) in collaboration with GSK company.
Online interview lasting approximately 25 minutes. The collection of information was anonymously carried out from May 21 to June 30, 2020.
Results: 1.263 lupus patients were interviewed, 92% diagnosed with SLE and 8% with CLE. Survey sample is representative of the Lupus patient population in Spain [associated sampling error: 2.76%]. Questions about knowledge of the disease showed that 73% of patients considered that there is very little knowledge of the disease by society. Patient awareness of lupus increases as the disease progresses, so at the time of diagnosis, level of knowledge of the patient about Lupus is low in 92% of patients and at the moment of survey, 68% of patient had high knowledge. In terms of the perception of his illness, the affectation of the kidneys and heart (97%), fatigue and skin rashes (97%), are the statements that generate the greatest consensus. The survey about the relationship to disease demonstrated that 3 out of 4 patients have symptoms related to the disease, muscle and joint pain (75%) and fatigue (74%) are the symptoms that cause the greatest discomfort (Graph 1). Remarkable degree of agreement with the fact of not being able to sunbathe (78%), as well as the lack of energy (61%) and weakness in the body (60%). Flare-ups (86%), followed by fatigue (78%) and pain (77%) cause great concern. At diagnosis, 92% of patients have some organic involvement and regarding the diagnosis, at present, a greater number of patients present damage to the CNS (17%) and bones (21%). Many patients do not understand the concept of organ damage, wrongly relating it to fatigue (38%) or joint pain (47%).



Graph 1.

Conclusion: Among the conclusions of the survey, it stands out that society and the general population are unaware of what lupus is, while in the case of lupus patients, knowledge increases as the disease progresses. Citizen awareness campaigns about this disease are necessary, where patient associations together with health authorities have a crucial job. On the other hand, 92% of patients present organ damage at diagnosis. This means that we are arriving late to the diagnosis of many patients, which makes it necessary to promote a close collaboration between Primary Care and Hospitals, to refer patients as soon as they suspect SLE.

OP0293 OPTIMIZING A TOOL TO IDENTIFY LUPUS FLARES IN DAILY CLINICAL PRACTICE: SLE-DAS FLARE VERSUS SELENA FLARE INDEX

L. Saraiva[1], A. R. Cunha[2], D. Jesus[3,4], J. A. P. Da Silva[1,5], A. Doria[6], L. Inês[1,4]. *[1]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; *[2]Centro Hospital do Baixo Vouga, Rheumatology, Aveiro, Portugal*; *[3]Centro Hospitalar de Leiria, Rheumatology, Leiria, Portugal*; *[4]Faculty of Health Sciences, University of Beira Interior, Health Sciences, Covilhã, Portugal*; *[5]Faculty of Medicine, University of Coimbra., Coimbra Institute for Clinical and Biomedical Researh (iCBR), Coimbra, Portugal*; *[6]University of Padova, Rheumatology, Padova, Italy*

Background: In the management of patients with Systemic Lupus Erythematosus (SLE), it is of utmost importance to accurately identify lupus flares. There is a conceptual consensus definition of lupus flares [1]; however, the instruments used to identify flares in clinical trials, such as the SELENA Flare Index (SFI) are too cumbersome to apply in daily clinical practice. The SLE disease activity score (SLE-DAS) is a validated continuous measure of disease activity with higher sensitivity to change and validity in predicting damage accrual when compared

to SLEDAI-2K. SLE-DAS is quickly scored with its online calculator. An increase in SLE-DAS ≥1.72 was validated as a clinically meaningful worsening of SLE disease activity. [2]

Objectives: To compare the performance of SLE-DAS, classic SFI (c-SFI), revised SFI (r-SFI) and SLEDAI-2K in the identification of lupus flares in a real-life clinical setting.

Methods: We included patients with SLE fulfilling classification criteria [ACR (1997) and/or SLICC and/or EULAR/ACR], followed at an academic lupus clinic from January 2017 to June 2020, and presenting with lupus low disease activity score (LLDAS) at baseline.

Flares occurring after baseline were identified as fulfillment of the conceptual definition of flare, as assessed by the senior lupus expert at time of each outpatient visit. For each flare event, we evaluated the fulfillment of flare criteria according to c-SFI, r-SFI, SLEDAI-2K (score increase ≥4 points from baseline), and SLE-DAS (score increase ≥1.72 from baseline). As control visits without flare, we considered the first visit after baseline, where we assessed the four tools, excluding those where a flare was identified by the gold-standard expert evaluation. Sensitivity and specificity of the four flare tools were estimated and McNemar's test applied to assess differences with the gold-standard flare definition. The inter-instrument agreement with the gold-standard was assessed through Cohen's Kappa.

Results: We included 297 patients (female: 86.2%; mean age: 48.9±14.6 years, mean disease duration: 12.5±9.0 years). At baseline, all patients were in LLDAS, receiving ongoing antimalarials, immunosuppressants, and/or glucocorticoids in 91.0%, 43.8% and 33.6%, respectively. During follow-up, 22.2% developed flares. The analysis included 92 flares [musculoskeletal (40.2%); renal (23.9%), mucocutaneous (18.5%), haematological (5.9%), serositis (3.3%); multisystemic (8.7%)], with increase or change of treatment in 80.4% of these episodes, and 292 visits without flare considered as control.

There was no statistically significant difference between either SLE-DAS flare or c-SFI and the gold-standard expert flare definition (p=0.41 and p=0.82, respectively), while r-SFI and SLEDAI-2K flare were different from the gold-standard (Table 1). There was a strong agreement between SLE-DAS flare, c-SFI, r-SFI and the expert definition (Cohen's kappa, Table 1).

Table 1. Performance of the flare tools for the gold-standard flare definition.

	Sensitivity (%)	Specificity (%)	McNemar's[§§]	Kappa[§]
SLE-DAS flare	90.1	95.0	n.s.	0.836
c-SFI flare	91.1	96.5	n.s.	0.869
r-SFI flare	93.4	92.9	p<0.01	0.820
SLEDAI-2K flare	51.6	98.6	p<0.0001	0.590

[§§] McNemar's test: significant difference from gold-standard if p<0.05; [§] Cohen's kappa agreement (0-1) with the gold-standard flare definition; n.s.: non-significant

Conclusion: The c-SFI and SLE-DAS showed the best performance in identifying SLE flares. The SLE-DAS flare definition is easier to apply and hence might be considered as an optimal tool to be used in daily clinical practice.

OP0294

SJÖGREN'S SYNDROME ASSOCIATED LYMPHOMAS: CLINICAL DESCRIPTION AND 10-YEAR SURVIVAL

L. Chatzis[1], V. Pezoulas[2], A. Goules[1], I. Stergiou[1], C. Mavragani[3], G. Tsourouflis[4], D. Fotiadis[2], H. M. Moutsopoulos[5], M. Voulgarelis[1], A. Tzioufas[1].

[1]School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece; [2]University of Ioannina, Unit of Medical Technology and Intelligent Information Systems, Athens, Greece; [3]School of Medicine, National and Kapodistrian University of Athens, Physiology, Athens, Greece; [4]School of Medicine, National and Kapodistrian University of Athens, Second Department of Propaedeutic Surgery, Athens, Greece; [5]Academy of Athens, Chair Medical Sciences/Immunology, Chair Medical Sciences/Immunology, Greece, Athens, Greece

Background: Sjögren's Syndrome (SS) is a chronic systemic autoimmune disease of unknown etiology, carrying the highest lymphoma risk among autoimmune diseases, with significant impact on mortality and morbidity of patients.

Objectives: To describe: i) the clinical phenotype of SS, ii) the histologic type, stage, treatment options regarding lymphomas and iii) the prognosis of patients with SS related lymphoproliferative disorders.

Methods: Eight hundred and fifteen consecutive SS patients' records from a single center fulfilling the 2016 ACR/EULAR were reviewed retrospectively for the purpose of this study. One hundred twenty-one patients with a diagnosis of non-Hodgkin Lymphoma (NHL) were identified and enrolled in the study population. Cumulative clinical, laboratory and histologic data were recorded and overall survival as well as event free survival curves were constructed using the Kaplan-Meier method. An event was defined as a disease progression, lymphoma relapse, treatment failure, histologic transformation, development of a 2nd lymphoma or death from any cause.

Results: From 121 pSS patients with lymphoma the most common histologic type encountered was MALT lymphoma (92/121, 76,0%) followed by DLBCL (11/121, 9.0%) and NMZL (8/119, 6.6%). The remaining 10 patients had various lymphomas of B (follicular, lymphoplasmacytic, chronic lymphocytic leukemia} and T cell origin (peripheral T cell lymphoma not otherwise specified, primary cutaneous T cell lymphoma, angioimmunoblastic t-cell lymphoma). Permanent salivary gland enlargement (66.1%, 80/121), palpable purpura (34,7% 42/121), peripheral nervous involvement (9,9%, 12/121), interstitial lung disease (8,2%, 10/121) presence of serum cryoglobulins (38,7%, 43/111) and C4 hypocomplementemia (69,8% 81/116) present at least 1 year before the development of lymphoma were the main pSS related features. The median age at lymphoma diagnosis was 58 years old (range 29-82) while MALT lymphomas developed earlier compared to DLBCL from pSS diagnosis (8 vs 3 OR= 3.84, 95%CI: 0.29 to 10.46; p=0.0266). The commonest biopsy proven extranodal sites included the labial minor salivary (43,8% patients) and parotid glands (30,5%) while 11% of patients had more than 1 extranodal sites affected. Bone marrow involvement was evident in 24,3% of patients (29/119) while nodal involvement in 35,5% (42/118). The majority of patients (65%) had limited disease (stage I or II). A watch and wait therapeutic policy was chosen in 40 patients while the rest received rituximab with or without chemotherapy. The 10-year survival and event free rates were 79% and 45,5% for MALT lymphomas, 40,9% and 24,2% for DLBCL and 46% and 31% for NMZL respectively (Figure 1). The Mantel-Cox log-rank comparison of the overall survival curves revealed a statistically significant difference (p=0.0016) among lymphoma subtypes.

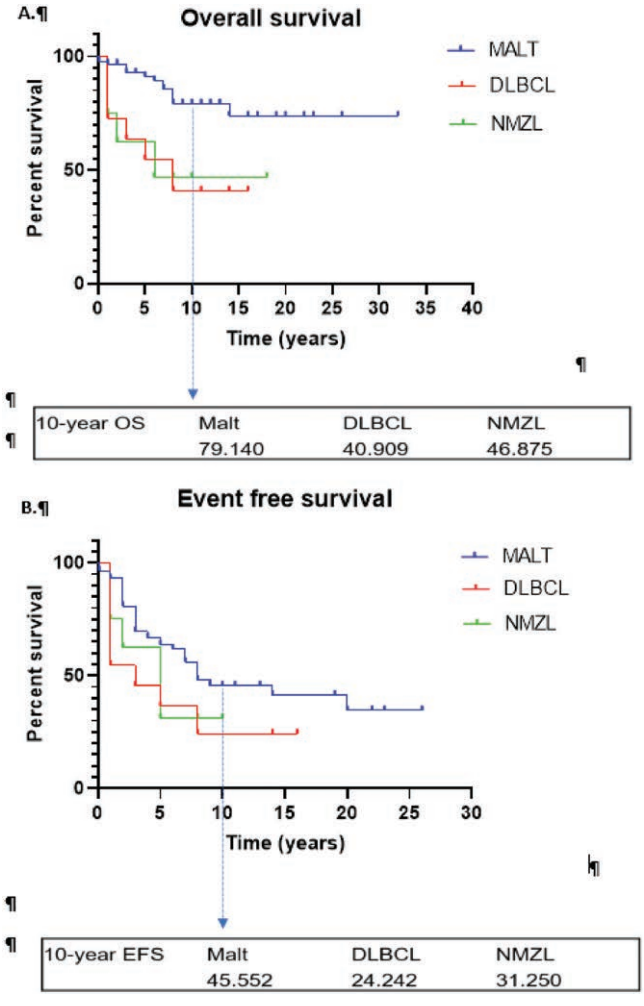

Figure 1. Overall and event free survival of SS-associated lymphoma patients. A. Kaplan-Meier overall survival analysis. B. A Kaplan-Meier event free survival analysis.

Conclusion: This is the largest single center series of SS- associated lymphoma patients, providing a detailed description of SS and lymphoma related features, combined with a 10-year survival and event free curves for the first time in the literature.

Disclosure of Interests: None declared.

OP0295 GR2 MULTICENTRIC PROSPECTIVE FRENCH STUDY'S RESULTS: DAMAGE BUT NOT REMISSION AT FIRST TRIMESTER PREDICTS ADVERSE PREGNANCY OUTCOME IN LUPUS PREGNANCIES

M. Larosa[1,2], V. Le Guern[1], G. Guettrot Imbert[1], E. Lazaro[3], N. Morel[1], N. Abisror Jeannin[4], C. Morati-Hafsaoui[5], P. Orquevaux[6], E. Diot[7], F. Sarrot-Reynauld[8], A. Doria[2], A. Moltó[9], C. Deneux-Tharaux[10], N. Costedoat-Chalumeau[1]on behalf of GR2 Group. *[1]AP-HP, Hôpital Cochin; Centre Référence Maladies Rares, Service de Médecine interne, Paris, France*; *[2]University of Padova, Rheumatology Unit, Department of Medicine-DIMED, Padova, Italy*; *[3]Centre Hospitalier Universitaire de Bordeaux, Service De Médecine Interne et Maladies Infectieuses, Bordeaux, France*; *[4]AP-HP, Hôpital Saint-Antoine, Service de Médecine interne, Paris, France*; *[5]CH Annecy Genevois, Service Infectiologie et médecine interne, Annecy, France*; *[6]CHU de Reims-Robert Debré, Service de Médecine interne, Reims, France*; *[7]CHRU de Tours - Hôpital Bretonneau, Service de Médecine interne, Tours, France*; *[8]CHU Grenoble, Service de Médecine interne, Grenoble, France*; *[9]AP-HP, Hôpital Cochin, Service de Rhumatologie B, Paris, France*; *[10]Epidemiology and Statistics Research Center/CRESS, INSERM, INRA F-75004, Equipe Épope, Paris, France*

Background: Active Systemic Lupus Erythematosus (SLE) during pregnancy is associated with poor obstetrical outcome but it is still not clear if remission, lupus low disease activity state (LLDAS) is the best target to achieve at conception. Besides, the effect of damage on pregnancy outcome has not been studied.

Objectives: Our aim was to determine the 1st trimester risk factors for adverse pregnancy outcome (APO).

Methods: Inclusion criteria were: 1) women≥18 years enrolled in the prospective GR2 study; 2) with SLE (SLICC criteria); 3) and an ongoing singleton pregnancy at 12 weeks (only 1 pregnancy per patient). We used the following definitions: DORIS[1], DORIA[2], clinical SLEDAI-2K=0, LLDAS[3] (for SLE activity), SFI[4] (for flares), and SLICC-damage index[5] (for damage). APO included: foetal death, neonatal death, placental insufficiency with premature delivery<37 weeks, and small for gestational age (SGA:≤3rd percentile).

Results: 238 patients were included. 234 (98.3%) women were on hydroxychloroquine (HCQ) and 206 (86.5%) had a clinical SLEDAI-2K=0. Regarding pregnancy outcome, 230 (96.6%) patients had a live birth (mean term 37.7 weeks). Thirty-four (14.3%) patients developed at least 1 APO: placental insufficiency (n=22), foetal death (n=7), neonatal death (n=1), and SGA (n=5). Two different regression logistic models were assessed, one for DORIA and one for LLDAS. We found that only SLICC-Damage index and lupus anticoagulant (LAC) were associated with APO (p=0.02, OR 1.8, 95% CI: 1.1-2.9; p=0.001, OR 4.2, 95% CI: 1.8-9.7 respectively for DORIA model; p=0.03, OR 1.7, 95% CI:1.1-2.8; p=0.002, OR 3.7, 95% CI: 1.6-8.7 respectively for LLDAS model).

Table 1.

Prednisone (PDN)	119(50.0)	23(67.7)	96(47.1)	**0.03**
PDN (mg/day) median (IQR)	7(5-10)	0(0-6)	5(0-10)	**0.007**
Immunosuppressants	57(24.0)	13(38.2)	44(21.6)	**0.04**
Hydroxychloroquine	234(98.3)	34(100.0)	200(98.0)	1.00
Low dose aspirin	165(69.3)	29(85.3)	136(66.7)	**0.03**
Low molecular weight heparin	61(25.6)	15(44.1)	46(22.6)	**0.01**

Legend: APS: antiphospholipid syndrome; aPL: antiphospholipid; PGA: Physician global assessment. *: DORIA definition of remission = clinical SLEDAI=0 and prednisone ≤5 mg/day; **: DORIS definition of remission = clinical SLEDAI=0, prednisone ≤5 mg/day, and PGA<0.5.

Conclusion: We confirmed that LAC predicts APO. We found for the first time that chronic damage at 1st trimester also predicted APO. No effect of remission/LLDAS was observed in this cohort of patients on HCQ with a stable and well-controlled SLE.

Background: Remission is the stated goal for both patient and care-giver (1), but consensus on a definition of remission has been lacking. Previously, an international task force consisting of patient representatives and medical specialists published a frame-work for such a definition (2), but without making a final recommendation.

Objectives: To achieve consensus around a definition of remission in SLE (DORIS).

Methods: The DORIS task force met annually from 2015 to 2020 and consisted of patient representatives and specialists in rheumatology, nephrology, dermatology, and clinical immunology. Systemic literature reviews of several key topics were done and specific research questions were examined in suitably chosen datasets. The findings were discussed, reformulated as recommendations, and voted upon. Level of evidence (LoE), strength of recommendation (SoR), and agreement were determined in standard fashion. The final recommendation for the DORIS definition of remission was established by electronic vote after finalization of the minutes of the most recent task force meeting.

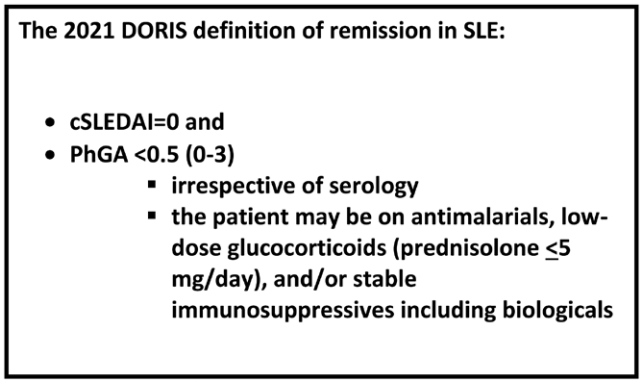
Results: Based on data from the literature and from several SLE-specific data sets, five key recommendations were endorsed (Table 1) that should be seen as additions to those published previously (2). Literature reviews identified strong support for the face-, content-, construct- and criterion validity of the definition based on the clinical SLEDAI (not including anti-DNA and complement) equal to zero plus low physician global assessment and allowing stable medical treatment. Thus, the DORIS Task Force recommended a single definition of remission in SLE, based on clinical SLEDAI = 0, evaluator's global assessment <0.5 (0-3),

prednisone 5 mg/day or less, and stable antimalarials, immunosuppressives and biologics.

Table 1.

	Vote in favor	LoE	SoR	Agreement
1.Inclusion of serology [anti-DNA, complement] in the DORIS definition of remission-on-treatment does not meaningfully alter the construct validity and therefore it is not recommended to include it	90%	2a	B	8.38
2.While the goal of treatment is sustained remission, a definition of remission should be able to be met at any point in time; therefore, duration should not be included in the definition	100%	5	C	9.02
3.To date, the SLEDAI-based definitions of remission have formally been investigated more extensively than BILAG-or ECLAM-based definitions. The SLEDAI-based definitions can therefore more confidently be recommended	91%	2a	B	9.25
4.Remission off treatment, while the ultimate goal for many patients and providers, is achieved very rarely. In clinical research and as an outcome in clinical trials, the definition for remission-on-treatment is recommended	92%	2a	B	9.52
5.In clinical trials, the LLDAS definition for low disease activity and the DORIS definition of remission are both recommended as outcomes	100%	5	C	9.25

The 2021 DORIS definition of remission in SLE:



Conclusion: The 2021 DORIS definition of remission in SLE was established. It is recommended for use as an aspirational treatment target in clinical care, a clear concept in education, and a key outcome in research including clinical trials and observational studies.

OP0297

THE SLE-DAS ENABLES ACCURATE AND USER-FRIENDLY DEFINITIONS OF REMISSION AND CATEGORIES OF LUPUS DISEASE ACTIVITY: DERIVATION AND VALIDATION STUDY IN 1190 SLE PATIENTS

D. Jesus[1,2], M. Larosa[3], C. Henriques[4,5], A. Matos[4,6], M. Zen[3], P. Tomé[4,6], V. Alves[4,6], N. Costa[4], V. Le Guern[7], L. Iaccarino[3], N. Costedoat-Chalumeau[7], A. Doria[3], L. Inês[2,8]. *[1]Centro Hospitalar de Leiria, Rheumatology Department, Leiria, Portugal*; *[2]University of Beira Interior, Faculty of Health Sciences, Covilhã, Portugal*; *[3]University of Padova, Division of Rheumatology, Padova, Italy*; *[4]Institute of Viseu, Technology and Management, Viseu, Portugal*; *[5]University of Coimbra, Centre for Mathematics, Coimbra, Portugal*; *[6]Research Centre in Digital Services, CISeD, Viseu, Portugal*; *[7]Cochin Hospital, Internal Medicine Department, Paris, France*; *[8]Centro Hospitalar e Universitário de Coimbra, CHUC Lupus Clinic, Rheumatology Department, Coimbra, Portugal*

Background: Treatment of systemic lupus erythematosus (SLE) is tailored according to the intensity of SLE disease activity and aims to achieve remission. Current definitions of remission and disease activity categories are mostly based on the SLE Disease Activity Index (SLEDAI), which has important limitations. The SLE Disease Activity Score (SLE-DAS) is a validated continuous disease activity score with higher accuracy in measuring SLE activity and higher sensitivity-to-change as compared to SLEDAI[1]. SLE-DAS is user-friendly with its online calculator.

Objectives: To derive and validate the SLE-DAS cut-off values for defining SLE disease activity categories and SLE clinical remission state.

Methods: Derivation study was conducted at the Padova Lupus Clinic. Validation was performed prospectively in patients from the Cochin Lupus Clinic and by post-hoc analysis of BLISS-76 (NCT00410384) trial. Gold-standard for clinical remission state was fulfillment of Definition Of Remission In SLE (DORIS). In Padova and Cochin Clinics, at time of inclusion, a senior clinician classified each patient as presenting: (i) remission, (ii) mild, or (iii) moderate/severe disease activity. Derivation of the SLE-DAS cut-offs for disease activity categories was performed using ROC curve analysis against this expert clinical classification. Performance of these SLE-DAS categories of disease activity was assessed as compared with: (i) expert classification (in Cochin cohort); (ii) British Isles Lupus Assessment Group (BILAG) index (in BLISS-76). An index-based and a Boolean definition of remission were tested applying decision trees, using CHAID (chi-square automatic interaction detection) algorithm and their performance estimated.

Results: We included 1190 SLE patients (221 in Padova, 150 in Cochin and 819 from BLISS-76 cohorts). In the derivation cohort, best SLE-DAS cut-off values for disease activity categories were: (i) remission, SLE-DAS≤2.08; (ii) mild activity, 2.08<SLE-DAS≤7.10; (iii) moderate/severe activity, SLE-DAS>7.10. Table 1 shows the performance of these SLE-DAS cut-offs. The SLE-DAS Boolean-based definition of remission (all SLE-DAS clinical items scores = 0 and prednisone ≤5mg/day) showed sensitivity and specificity of 100% in the derivation (Padova) and validation (Cochin) clinical cohorts. The SLE-DAS index-based definition of remission (SLE-DAS ≤2.08 and prednisone ≤5mg/day) presented sensitivity =100% and specificity =97.4% in the derivation and validation clinical cohorts. The SLE-DAS definitions of remission were fully substantiated by CHAID.

Table 1. Performance of SLE-DAS cut-offs for remission and disease activity categories compared to physician's classification and BILAG (n =1190).

	Disease activity category	Sensitivity (%)	Specificity (%)	Accuracy (%)
Derivation Padova Cohort	**Remission** (SLE-DAS≤2.08)	99.3	97.1	98.6
	Mild Disease Activity (2.08<SLE-DAS≤7.10)	74.2	98.9	95.5
	Moderate and Severe Disease Activity (SLE-DAS>7.10)	97.4	96.7	96.8
Validation Cochin Cohort	**Remission** (SLE-DAS≤2.08)	99.1	93.9	98.0
	Mild Disease Activity (2.08<SLE-DAS≤7.10)	82.6	99.2	96.7
	Moderate and Severe Disease Activity (SLE-DAS>7.10)	100.0	98.6	98.7
Validation BLISS-76	**Remission and Mild Disease Activity**§ ***vs.*** **Moderate and Severe Disease Activity**§§ (SLE-DAS≤7.10 *vs.* >7.10)	91.4	84.1	90.8

§ Remission/Mild: No BILAG B or A scores§§ Moderate/severe: ≥1 BILAG B or A scores

Conclusion: The SLE-DAS is an accurate and easy to use tool for defining clinical remission state and SLE disease activity categories, validated with both the expert assessment and BILAG.

Background: In psoriatic arthritis (PsA), EULAR recommendations are to aim for remission or low disease activity(1). Many treatments are now available, though some are costly and not widely available in all countries. Country of patient care, and in particular Gross Domestic Product (GDP) may be linked to PsA outcomes(2). Although patients with high disease activity are eligible for targeted therapies such as biologic disease-modifying anti-rheumatic drugs (bDMARDs), they may not be able to get the benefits from these efficacious treatments in all countries equally.

Objectives: The objective was to explore the rate of PsA patients with high to moderate disease activity, not receiving bDMARDs across countries, and to assess the consequences on functional incapacity.

Methods: This was a cross-sectional analysis of an observational study (ReFlap, NCT03119805)(3), which included adult patients with PsA with ≥ 2 years disease duration from 14 countries. One country was excluded from this analysis since only 7 patients were included. We explored the rate of patients with significant disease activity (i.e based on DAPSA > 14) and no ongoing bDMARD prescription. Countries of inclusion were analysed separately, and classified into tertiles by GDP/capita (lowest tertile: Brazil, Turkey, Russia, Romania, Estonia; middle tertile: Spain, Italy, UK, France; highest tertile: Canada, Germany, USA and Singapore). The rate of no bDMARDs - DAPSA > 14 patients was analysed by country and compared between the 3 tertiles of GDP/capita by parametric tests. Functional capacity (HAQ) was compared between no bDMARDs - DAPSA > 14 patients and the other patients (pooling patients with moderate or high disease activity with bDMARD, low disease activity and remission with or without bDMARD). There was no imputation of missing data.

Results: Of the 459 patients, 429 had complete data available and were analysed: mean age 52.3 (SD 12.6) years, mean disease duration 10.2 (SD 8.2) years, 215 (50.1%) males. The rate of no bDMARDs - DAPSA > 14 patients was 18.4% (76/414). The rate ranged from 7.4% (UK and Spain) to 40% (Russia): Figure 1. A link was seen with the country and the tertiles of countries according to GDP/capita, with higher rate of no bDMARDs - DAPSA > 14 patients in the lowest GDP/capita countries (28.8%, 15.3% and 14.3% in the 3 GDP/capita tertiles, respectively, p=0.005; Figure 1). Of note, 40/76 no bDMARDs - DAPSA > 14 patients received a treatment intensification during the visit. Among no bDMARDs - DAPSA > 14 patients, functional incapacity was higher than in the other patients, as expected (mean HAQ 0.96 (SD 0.64) vs 0.57 (SD 0.63), p<0.001).

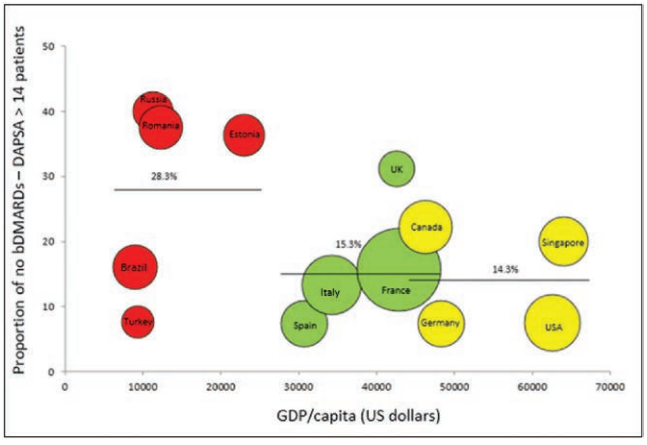

Figure 1. The size of the bubbles represent the number of patients per country (range, 13 to 89).The horizontal lines represent the mean proportion of patients with no bDMARDs – DAPSA > 14 for each tertiles of countries by GDP/capita.

Conclusion: In this exploratory comparison of disease patterns and treatments choices in 13 countries, we observed that more PsA patients with high or moderate disease activity and living in low GDP/capita countries were less likely to be treated with bDMARDs. As a consequence, no bDMARDs – DAPSA > 14 patients had worse functional incapacity. Equitable access to bDMARDs should be aimed for all patients regardless of their country of origin.

OP0299

IN RHEUMATOID ARTHRITIS PATIENTS HIGHER NUMBER OF COMORBIDITIES PREDICTS 6-MONTH INSUFFICIENT RESPONSE TO FIRST BIOLOGIC THERAPY AND EVENTUAL CATEGORIZATION OF THE DISEASE AS DIFFICULT-TO-TREAT

I. Flouri[1], A. Repa[1], N. Avgustidis[1], N. Kougkas[1], A. Eskitzis[1], A. Molla Ismail Sali[1], S. Pitsigavdaki[1], K. Pateromichelaki[1], E. Kalogiannaki[1], M. Terizaki[1], G. Bertsias[1], P. Sidiropoulos[1]. [1]*University Hospital of Heraklion, Crete, Rheumatology Department, Heraklion, Crete, Greece*

Background: Difficult-to-treat rheumatoid arthritis (D2T RA) was recently defined by a EULAR study group (1) and, as a disease category it is largely complicated and under-researched. Patient comorbidities may play a significant role in the response to therapy with biologic disease-modifying antirheumatic drugs (bDMARDs) and in the disease classification as D2T RA.
Objectives: To evaluate the impact of comorbidities [studied as total Comorbidities Count (CC) and rheumatic disease comorbidity index (RDCI)] on 6-month response to therapy with the first bDMARD in real-world clinical practice and on eventual disease designation as D2T RA.
Methods: Prospective study of all RA patients who start any bDMARD in a tertiary centre University Hospital after their consent. All patient comorbidities [among a list of approximately 100 pre-specified major comorbidities] are registered by treating physicians. Response to therapy was defined as achievement of low disease activity or remission (LDA/Rem) according to simplified disease activity index (SDAI) and health assessment questionnaire (HAQ) improvement of ≥ 0.25.
D2T RA patient group was defined according to the EULAR definition of D2T RA and was compared to: a/ all other patients and b/ to a sub-group of patients designated as "well-controlled RA" (follow-up ≥2 years and ≥2 visits in the last year in LDA/Rem).
Logistic regression models were used to adjust for the potential confounding of age, sex, disease duration, seropositivity, number of previous synthetic DMARDs, type of 1st bDMARD initiated (TNF inhibitor vs. non-TNF inhibitor), co-administered methotrexate and corticosteroids (yes/no), baseline SDAI and HAQ and year of therapy start.
Results: Analysis included 501 RA patients who received a total of 1098 bDMARD treatments. At 1st bDMARD treatment start, patients (women: 81%) had a median (IQR) age: 60 (51-68) years, disease duration: 5.4 (3-11) years, SDAI: 36 (28-46), HAQ: 1.0 (0.5-1.5), CC: 3 (2-6) και RDCI: 2 (0-3).
In adjusted analyses, total comorbidity count (CC) ≤1 (vs ≥ 2) was predicting LDA/Rem at 6 months of therapy [OR (95%CI) = 4.1 (1.5-11), p=0.005], while RDCI=0 (vs. ≥ 1) was predicting HAQ improvement ≥ 0.25 [OR (95% CI) = 2.6 (1.2-6.7), p=0.046].
During 2614 patient-years of follow-up, the disease in 98 patients could be classified as "D2T RA", while 127 patients had "well-controlled RA". Baseline independent predictors for D2T RA compared to all other patients were RDCI ≥ 1 (vs. 0) [OR = 3.3 (1.7-9.4), p = 0.024], female sex [OR =3.1 (1.01-9.5)] and age [OR = 0.97 (0.94-0.99)]. Multivariable analyses for predictors of "D2T" compared to "well-controlled" RA yielded similar results.
Conclusion: In RA patients starting the first bDMARD treatment, a higher number of comorbidities at baseline is an independent predictor of lower 6-month response to therapy and final disease classification as "difficult-to-treat" RA.

USE OF THERMOGRAPHY OF HANDS AND MACHINE LEARNING TO QUANTIFY JOINT INFLAMMATION AND ESTIMATE DAS28, CDAI, SDAI IN PATIENTS WITH RHEUMATOID ARTHRITIS

I. Morales-Ivorra[1,2], C. Gómez Vaquero[3], C. Moragues Pastor[3], J. M. Nolla[3], J. Narváez[3], J. A. Narvaez[4], D. Grados Canovas[1], M. A. Marin-López[2]. [1]*Hospital Igualada, Rheumatology, Igualada, Spain*; [2]*Singularity Biomed, R+D, Sant Cugat del Vallès, Spain*; [3]*Hospital Universitari de Bellvitge, Rheumatology, L' Hospitalet de Llobregat, Spain*; [4]*Hospital Universitari de Bellvitge, Radiodiagnosis, L' Hospitalet de Llobregat, Spain*

Background: Disease activity scores such as DAS28, CDAI and SDAI are used in the follow-up of patients with rheumatoid arthritis (RA). These scores include variables obtained on physical examination such as the tender joint count (TJC) and the swollen joint count (SJC). In telematic consultations, it is not possible to determine these variables by physical joint assessment. Therefore, it is necessary to develop new tools that allow detecting joint inflammation in places close to the patient. Thermography is a safe and fast technique that measures heat through infrared imaging. Inflammation of the joints causes an increase in temperature and can therefore be detect by thermography. Machine learning methods are highly accurate in analyzing medical images automatically.
Objectives: To develop an algorithm that, based on thermographic images of hands and machine learning, learn to quantify joint inflammation in patients with RA and estimate the DAS28, CDAI, SDAI by including the patient global health (PGH).
Methods: Multicenter observational study conducted in the rheumatology and radiology service of two hospitals. Patients with RA, psoriatic arthritis (PA), undifferentiated arthritis (UA) and arthritis of hands secondary to other diseases (SA) that attended the follow-up visits were recruited. Companions of patients and healthcare professionals were also recruited as healthy subjects (HS). In all cases, a thermographic image of the hands was taken using a Flir One Pro or a Thermal Expert TE-Q1 camera connected to a smartphone. Ultrasound (US) of both hands was performed in patients with RA, PA, UA and SA. The degree of synovial hypertrophy (SH) and power doppler (PD) was assessed for each joint (score from 0 to 3). Machine learning was used to quantify joint inflammation (SH+PD) from the thermal images using US as ground truth. RA patients whose thermal image was taken with the Thermal Expert TE-Q1 camera were used to evaluate the performance (test dataset). The other participants were used as training dataset. The TJC, SJC, PGH, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were also assessed in the test dataset. A linear regression was used to estimate the DAS28, CDAI and SDAI with the resultant joint inflammation quantification from the thermal images and the PGH. Performance was evaluated by means of Pearson's correlation coefficient. The study was approved by the Clinical Ethics and Research Committee of both centers.
Results: The total number of recruited subjects was 521 (422 for the training and 99 for the testing dataset). In the training dataset, the thermography of 296 patients was taken with the Flir One Pro (163 RA, 17 PA, 22 UA, 12 SA and 82 HS) and 126 with the Thermal Expert TE-Q1 camera (6 RA without clinical data, 20 PA, 7 UA, 23 SA and 70 HS).
We found higher correlations between joint inflammation variables (US and SJC) and thermography (0.48, p<0.01 for US and 0.48, p<0.01 for SJC) than between joint inflammation variables (US and SJC) and the PGH (0.29, p<0.01 for US and 0.35, p<0.01 for SJC). Thermography did not show statistically significant correlation with the PGH (0.14, p=0.164). The linear regression of thermography and the PGH showed strong correlation with the DAS28 (0.73, p<0.01), CDAI (0.84, p<0.01) and SDAI (0.82, p<0.01).
Conclusion: Thermography of hands and machine learning can effectively quantify joint inflammation and can be used in combination with the PGH to estimate disease activity scores. These results open an opportunity to develop tools that facilitate telematic consultations in patients with RA.

Let's consider Biologic Immunogenicity

OP0301 **RISK FACTORS FOR ANTI-INFLIXIMAB ANTIBODY FORMATION: RESULTS FROM THE RANDOMISED CONTROLLED NOR-DRUM A TRIAL**

M. K. Brun[1,2], G. L. Goll[1], K. K. Jørgensen[3], J. Sexton[1], J. E. Gehin[2,4], Ø. Sandanger[5], I. Olsen[6], R. A. Klaasen[4], D. J. Warren[4], C. Mørk[7], T. K. Kvien[1,2], J. Jahnsen[2,3], N. Bolstad[4], E. A. Haavardsholm[1,2], S. W. Syversen[1] on behalf of the NOR-DRUM Study Group. *[1]Diakonhjemmet Hospital, Division of Rheumatology and Research, Norway, Norway*; *[2]University of Oslo, Institute of Clinical Medicine, Oslo, Norway*; *[3]Akershus University Hospital, Department of Gastroenterology, Lørenskog, Norway*; *[4]Norwegian Radium Hospital, Department of Medical Biochemistry, Oslo, Norway*; *[5]Oslo University hospital, Section of Dermatology, Oslo, Norway*; *[6]Oslo University hospital, Department of Research Support for Clinical Trials, Oslo, Norway*; *[7]Akershus dermatologist center, Department of Dermatology, Lørenskog, Norway*

Background: Immunogenicity is related to loss of efficacy and safety to TNFα inhibitors and is frequently observed early in the treatment course. The highest rate of anti-drug antibody (ADAb) formation has been reported for infliximab (IFX). [1] Knowledge about risk factors for immunogenicity might contribute to better handling of this problem in clinical practice.

Objectives: To identify risk factors for ADAb formation during the early phase of IFX treatment.

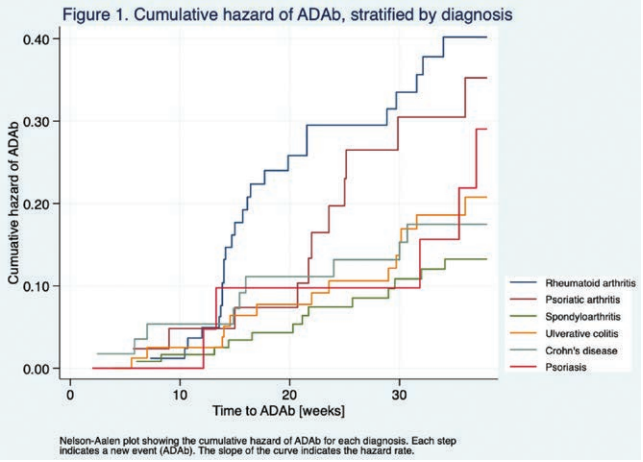
Methods: 411 patients with immune-mediated inflammatory diseases (84 rheumatoid arthritis (RA), 119 spondyloarthritis (SpA), 45 psoriatic arthritis, 83 ulcerative colitis, 58 Crohn's disease and 22 psoriasis) initiating IFX treatment were included in the 38-week NOR-DRUM A trial and randomised 1:1 to therapeutic drug monitoring or standard IFX therapy.[2] The primary endpoint was clinical remission at week 30. Serum (s) IFX levels and ADAb were measured at each infusion by in-house assays; time-resolved fluorometric assay for sIFX and inhibition assay for ADAb.[2] In this sub-study, possible risk factors for ADAb formation including demographic variables, diagnosis, comedication, disease activity, IFX dose, sIFX and drug holidays, were assessed using logistic regression. Variables with a p-value <0.25 in univariate analyses were further examined in multivariate analyses adjusting for potential confounders (diagnosis, disease activity, age and gender).

Results: 410 of 411 patients had at least one measurement of sIFX and were included in the present analyses. 76% of patients were biologic-naive and 45% (18% of RA patients) used IFX as monotherapy. Patients received a mean IFX dose of 3.2-5.9 mg/kg (RA 3.2 mg/kg). ADAb were detected in 78 (19%) patients. The Table 1 shows variables with a significant association to ADAb development. Analyses revealed an increased risk of ADAb development in patients with RA (Odds ratio (OR) 2.1, 95% confidence interval (CI) 1.1-3.9), while SpA had a lower risk (OR 0.5, CI 0.2-0.9) compared to the other diagnoses. These findings were consistent in both univariate- and multivariate analyses (Table 1). Figure 1 shows the cumulative hazard for ADAb development according to diagnosis. Other risk factors for ADAb (Table 1) were smoking (OR 1.8, CI 1.0-3.3) and drug holidays of more than 12 weeks (OR 4.7, CI 1.2-18.3). Additionally, the risk of ADAb increased with higher disease activity (OR 1.5, CI 1.0-2.3) and lower sIFX levels (0.7, 0.6-0.8). Patients co-treated with methotrexate (OR 0.4, CI 0.2-0.9) or thiopurines (OR 0.3, CI 0.1-0.8), or having one or more IFX dose increments (OR 0.4, CI 0.3-0.8), had a reduced risk of immunogenicity.

Table 1. Risk factors for ADAb. Results from logistic regression analyses

	Univariate analyses		Multivariate analyses (Adjusted for diagnosis, disease activity, age and gender)	
	OR	CI	OR	CI
RA	2.2**	[1.3,3.8]	2.1*	[1.1,3.9]
SpA	0.4**	[0.2,0.8]	0.5*	[0.2,0.9]
Methotrexate	1.1	[0.7,1.9]	0.4*	[0.2,0.9]
Thiopurine	0.3*	[0.1,0.9]	0.3*	[0.1,0.8]
Current or former smoking	2.2**	[1.3,3.8]	1.8*	[1.0,3.3]
Mean sIFX	0.7***	[0.6,0.8]	0.7***	[0.6,0.8]
>12 weeks between infusions	4.5*	[1.3,16.0]	4.7*	[1.2,18.3]
IFX dose increment	0.5*	[0.3,0.9]	0.4**	[0.3,0.8]
Mean DAS28 (RA and PsA)	1.5*	[1.0,2.1]	1.5*	[1.0,2.3]
Mean ESR	1.1***	[1.0,1.1]	1.1***	[1.0,1.1]
Mean CRP	1.1**	[1.0,1.1]	1.1**	[1.0,1.1]

* p<0.05, ** p<0.01, *** p<0.001Only variables with a p-value <0.05 are shown. Non-significant variables include other demographic variables and IFX dose.



Conclusion: This study identified smoking, drug holidays, high disease activity, IFX monotherapy and low sIFX levels as risk factors for ADAb development. Of particular interest, we found that RA patients had significantly increased risk of ADAb compared to the other immune-mediated inflammatory diseases. Whether this novel finding reflects different underlying disease mechanisms or the fact that RA patients receive a lower IFX dose, is not known and needs to be further explored.

Context matters: Placebo and nocebo effects for pain management

OP0302-HPR **IDENTIFYING THE CONTEXTUAL FACTORS IN THE PATIENT-PRACTITIONER ENCOUNTER THAT HAVE THERAPEUTIC EFFECT: A SYSTEMATIC REVIEW AND META-ANALYSIS**

A. Ismail[1,2], M. Hall[3,4], K. Yaseen[2,3], M. Doherty[1,4,5], W. Zhang[4,5,6]. *[1]University of Nottingham, Academic Rheumatology Department, Division of Rheumatology, Orthopaedics and Dermatology, School of Medicine, Nottingham, United Kingdom*; *[2]King Abdulaziz University, Faculty of Medical Rehabilitation Sciences, Jeddah, Saudi Arabia*; *[3]University of Nottingham, Division of Physiotherapy School of Health Sciences, Nottingham, United Kingdom*; *[4]University of Nottingham, Arthritis Research UK Pain Centre, Nottingham, United Kingdom*; *[5]National Institute for Health Research, Nottingham Biomedical Research Centre, Nottingham, United Kingdom*; *[6]University of Nottingham, School of Medicine, Division of Rheumatology, Orthopaedics and Dermatology, Nottingham, United Kingdom*

Background: Placebo or contextual effect is an integral part of the treatment effect (1). The factors related to this effect are "contextual factors" (CFs) (2). CFs may be categorised into five groups as factors related to practitioner, patient, practitioner-patient interaction, treatment and therapeutic environment (3). Several CFs have demonstrated their therapeutic effect, whereas others not (4). The majority of musculoskeletal pain relief result from CFs (5). Identifying the key CFs may encourage health practitioners to optimize the contextual aspects of care.

Objectives: To identify the modifiable CFs that can improve clinical outcomes in published randomised controlled trials (RCTs).
Methods: A systematic search was carried out, up until April 18th 2019, on the following databases: MEDLINE via Ovid, EMBASE, AMED, PsycINFO and Cochrane library. RCTs comparing contextual enhanced interventions versus non-enhanced control in adults for any health conditions were searched. The outcomes included both self-reported outcomes and objectively measured outcomes. The effect size and 95%confidence interval were calculated using the standard mean difference. Risk of bias was evaluated using the modified Cochrane tool. The random effects model was used to pool the results.
Results: Of 3900 records generated from the systematic search, 15 trials (4615 participants) met the inclusion criteria, and 13 were included in this meta-analysis (Figure 1). Conditions studied included musculoskeletal [4], cardiovascular [2], irritable bowel syndrome [1], diabetes [1], asthma [1], GP or hospital patients [6]. Three CFs have been identified from these trials, including empathy, patient involvement and positive communication. All were found to be effective for patient experience i.e. satisfaction. Positive communication was also effective for symptoms but not objective outcomes (Table 1).

Table 1. Summary of results.

Outcome	Intervention	Number of studies (Number of participants)	SMD (95% CI)	I^2
Patient experience outcomes, e.g. satisfaction	Empathy	2 (137)	0.45 (0.11, 0.79)	42.2 %
	Patient involvement	4 (1596)	0.31 (0.21, 0.41)	93.0 %
	Positive communication	3 (793)	0.38 (0.24, 0.52)	93.9 %
Symptomatic outcomes, e.g. pain	Empathy	1 (221)	-0.18 (-0.45, 0.08)	0.0 %
	Patient involvement	1 (314)	-0.05 (-0.27, 0.17)	0.0 %
	Positive communication	3 (658)	0.20 (0.05, 0.35)	64.8 %
Objective outcomes, e.g. peak expiratory flow	Positive communication	2 (266)	0.10 (-0.14, 0.34)	66.6 %

Positive SMD favours intervention group. SMD= Standard mean difference, CI= Confidence interval, I^2= heterogeneity.

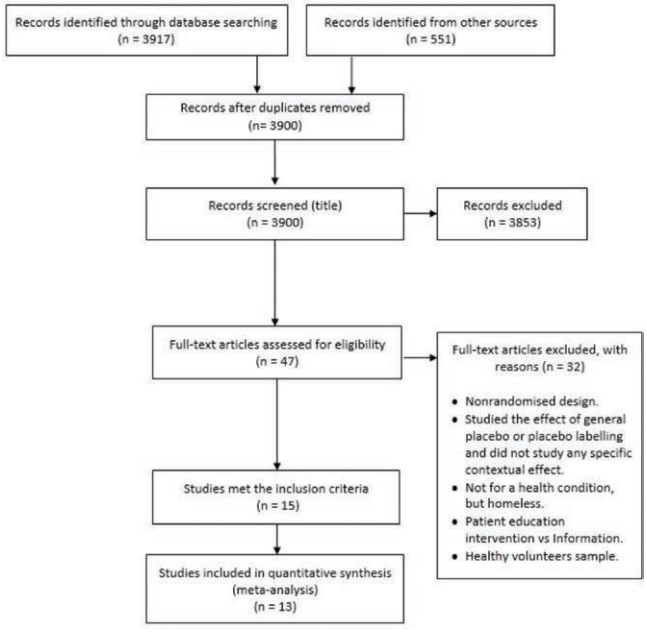

Figure 1. Summary of screening process.

Conclusion: This systematic review has identified three CFs (empathy, patient involvement and positive communication) that have therapeutic effects for different conditions in trials, especially for self-reported outcomes. More research is needed to examine the clinical outcomes of CFs and to understand the influence of health practitioners on disease processes.

Myths and taboos around relationships: strategies for a sexy life

OP0303-HPR

IT IS NOT JUST ABOUT THE SEX: VIEWPOINTS OF DUTCH ADULT MEN WITH INFLAMMATORY ARTHRITIS REGARDING THE IMPACT OF THE DISEASE ON THEIR SEXUAL HEALTH

L. F. Perez-Garcia[1], E. Röder[1], H. Pastoor[2], H. Bolt[2], J. Van Exel[3], R. Dolhain[1].
[1]Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands; *[2]Erasmus University Medical Center, Division of Reproductive Endocrinology and Infertility, Department of Obstetrics and Gynecology, Rotterdam, Netherlands*; *[3]Erasmus University Rotterdam, Erasmus School of Health Policy and Management, Rotterdam, Netherlands*

Background: Sexual health (SH) can be impaired in men with inflammatory arthritis (IA) (1). In addition to biological factors, such as inflammation, subjective factors such as personal beliefs can also impair SH. The Q methodology combines aspects of qualitative and quantitative approaches to systematically study subjectivity, and has been applied successfully in other medical fields.
Objectives: To describe the viewpoints of adult men with IA on the impact of IA on their SH using the Q methodology.
Methods: Men, 18 years and older, diagnosed with RA or JIA were invited by their rheumatologist. Participants ranked 34 opinion statements about potential impacts of IA on their SH on an agreement scale. A by-person factor analysis identified common patterns in the rankings. These patterns represent the different viewpoints among the men. Data from interviews, in which the men explained their ranking, was used to further interpret the viewpoints. A Q-methodology study usually consists of 30-40 participants.
Results: 30 men with IA were included. Their mean age was 43.2 (range 22–77) years. The analysis revealed three viewpoints:
1."I am satisfied with my sex life"
Men with viewpoint 1 experience no significant impact of IA on their SH. However, most men indicated that when their disease was active, IA had a negative impact on their SH.
2."Arthritis has a negative influence on my sex life"
Men with viewpoint 2 experience a dramatic impact, due to pain, fatigue and gloom. Their relationship worsened and they feel guilty towards their partner. Discussing their problems is not difficult.
3."I am keeping up appearances"
Men with viewpoint 3 experience SH impairment mainly as a result of pain. IA impairs them physically, makes them feel less of a man, less attractive and reduces their self-confidence. Due to problems with accepting their disease and communicating their problems, these men tend to hide their problems.
Conclusion: We identified 3 viewpoints on the impact of IA on male SH, 2 of them revealing a negative influence that goes beyond the physical act of sex. IA can also affect relationships, self-confidence and manhood. Future research will focus on identifying men with SH problems in the clinic and the best counseling approach.

OP0304-PARE **DEVELOPMENT OF INTERACTIVE DECISION AID TOOL FOR MOTHERHOOD AND PARENTHOOD AMONG PATIENTS LIVING WITH AUTOIMMUNE RHEUMATIC DISEASES**

Y. El-Miedany[1,2], M. El Gaafary[3], N. El Aroussy[4], S. Bahlas[5], D. Palmer[6]. *[1]Canterbury Christ Church University, Rheumatology, Canterbury, United Kingdom*; *[2]King's College London, Education, London, United Kingdom*; *[3]Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt*; *[4]Faculty of Medicine, Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt*; *[5]King Abdulaziz University, Rheumatology, Jeddah, Saudi Arabia*; *[6]North Middlesex University Hospital, Rheumatology, London, United Kingdom*

Background: There are clear educational pregnancy-related needs for both women and men living with Autoimmune Rheumatic Diseases (ARDs) who seek specific advice from their health care providers. Most of the time those subjects would seek specific information regarding their chances of pregnancy, impact of the disease, as well as safety of their medications during pregnancy and breast feeding. They also require emotional and physical support as well as advice towards practical coping strategies to manage pain and disease flares particularly during the postnatal period.
Objectives: To evaluate the effectiveness of a new interactive pregnancy decision aid (DA) developed for both men and women living with inflammatory arthritis.
Methods: Driven by the Cochrane review of patient decision aids (DA) and the International Patient Decision Aids framework (IPDAS), which identify shared decision making (SDM) instrument as evidence-based tools designed to help people engage in deliberative management-related decision making by providing information on the options and outcomes relevant to health status. This project involved an overall three-phase SDM aid development. It has been set up for both men and women and included information on pregnancy, contraception and breast feeding. The first phase included the development of the decision tool and review by expert faculty composed of: decision experts, patient representatives, policy makers, and patients living with RA, PsA, AS and SLE. The second phase was a pilot testing of the tool in both online and paper format styles. The third phase involved an evaluation of the decision support tool and its impact on the patients. The DA adopted an interactive style with embedded video recordings (this was converted into text in the paper format). All the patient completed these questionnaires: the ReproKnow, Decisional Conflict Scale (DCS), Hospital Anxiety and Depression Scale (HADS), and Arthritis Self-Efficacy Scale (ASES) pre- and post-intervention. A control group of 92 patients (19 men and 71 women) managed according to the standard protocols was also included. Comprehensibility of the video recordings were also assessed using VAS (0-10).
Results: 126 patients shared in this work (101 women and 25 men). The patients who received the DA had an 81% (women) and 83% (men) increase in ReproKnow scores and a 76 % decrease in scores on the decisional conflict (DCS), compared to the control group (10 % and 11 % respectively); p< 0.001. There were no changes in the scores of depression and anxiety symptoms (p= 0.873) indicating no adverse psychological impact detected. There was no significant difference in terms of self-efficacy assessment p=0.481. The patients rated the comprehensibility of the video recording as high (9.4/10)
Conclusion: The DA which was developed to support pregnancy and breast feeding decision-making for patients with ARDs. The interactive SDM aid was found to be a simple, user-friendly tool which can be implemented in standard clinical practice. The interactive style made it more comprehensible to the patients. It is consistent with the IPDAS criteria. Results revealed its effectiveness in improving relevant knowledge and reducing decisional conflict without causing distress to the patients.
Disclosure of Interests: None declared.

Controversies on phenotypes in PsA

OP0305 **VALIDATION OF THE PSORIASIS EPIDEMIOLOGY SCREENING TOOL (PEST) AND THE NEW EARLY ARTHRITIS FOR PSORIATIC PATIENTS (EARP) IN PEDIATRIC POPULATION - PILOT STUDY**

Y. Butbul[1]. *[1]The Ruth and Bruce Rappaport Faculty of Medicine, Technion - Israel Institute of Technology; PEDIATRIC RHEUMATOLOGY UNIT, Haifa, Israel*

Background: Juvenile Psoriatic Arthritis (JPsA) is an inflammatory arthritis associated with irreversible joint damage among the pediatric population, which is associated with psoriasis in most cases.
While there are few validated screening tools for diagnosis of arthritis for adult patients with psoriasis, those screening tools were never evaluated in children.
Objectives: The aims of this study were to evaluate two screening tools among pediatric patients with psoriasis.
Methods: Thirty-nine patients with the diagnosis of psoriasis were administered two screening questionnaires: the new Early Arthritis for Psoriatic Patients (EARP) questionnaire and the Psoriatic Arthritis Screening and Evaluation (PASE) questionnaire.
All patients were evaluated by a rheumatologist for the diagnosis of JPsA, and the accuracy of the two questionnaires compared.
Results: The 4/39 (10.1%) patients diagnosed with JPsA had a PEST questionnaire score of ≥ 3, compared to a median PEST score of the patients without the diagnosis of JPsA of 0 (0-2). Thus both the sensitivity and specificity of the PEST in diagnosing JPsA were 100%.
For the EARP questionnaire, 8/39 patients had a screening questionnaire score of ≥ 3, suggestive of JPsA, four were true positive, and four false positive. Thus, the sensitivity and specificity of EARP in diagnosing JPsA were 100% and 89%, respectively.
Conclusion: Both the PEST and EARP questionnaires were easy to use and had high sensitivity for pediatric population with psoriasis, however the PEST questionnaire had a higher specificity than the EARP.
Disclosure of Interests: None declared.
DOI: 10.1136/annrheumdis-2021-eular.4165

OP0306 **ETANERCEPT AND ADALIMUMAB IN THE TREATMENT OF JUVENILE PSORIATIC ARTHRITIS**

K. Aleksanyan[1], S. Chebysheva[1], O. Sukhovyova[1], E. Zholobova[1]. *[1]I.M. Sechenov First Moscow State Medical University, Clinical Institute of Child Health named after N.F. Filatov, Moscow, Russian Federation*

Background: Juvenile psoriatic arthritis (JPsA) accounts for 4 to 9% of children with juvenile arthritis (1). Biologics, particularly TNF-α inhibitors, have proved to be effective and safe for treatment of psoriatic arthritis in adults (2). However, no comprehensive evidence exists on the comparative effectiveness and safety of TNF-α inhibitors in the treatment of JPsA, which challenges a decision of what biologic should be prescribed to children with JPsA.
Objectives: To study the comparative effectiveness of etanercept and adalimumab in patients with JPsA with respect to both the articular and skin manifestations.
Methods: Our observational (2012-2019), parallel-group, open-label, single-centre cohort clinical study involved 34 patients (2-13 y/o) with JPsA who met Vancouver and I/E criteria and received etanercept SC (0.8 mg/kg QW, max 50 mg per week) or adalimumab SC (max 40 mg Q2W), both in combination with methotrexate (10-15 mg/m^2 QW). Intention-to-treat analysis was used to evaluate treatment efficacy at months 6, 12, and 18 after biologic therapy initiation. To assess articular manifestations of JPsA, we applied ACRpedi criteria; to estimate the surface area of involved skin and severity of psoriasis – the PASI score.
Results: We observed 34 patients with JPsA (2 to 13 y/o), who were initiated by biological therapy (etanercept [n=18 - group 1] and adalimumab [n=16 - group 2]) (Table 1, Figure 1).

Table 1. Clinical and demographic characteristics of patients with JPsA before biologic therapy initiation (n=34)

clinical and demographic indicators	Group 1 (Etanercept) M±δ / Me (Q1-Q3)	Group 2 (Adalimumab) M±δ / Me (Q1-Q3)
Girl/Boy Ratio	12:6 (2:1)	10:6 (1,7:1)
Average age, years	7,58 ± 3,7	5,8 ± 3
Duration of the disease, years	3,0 (1,4-6,6)	3,5 ± 2
Uveitis (n, %)	0	5 (31,3%)
ANA positivity (n, %)	2 (11%)	8 (50%)
RF positivity (%)	0	0
No. active joints	8,0 (5-16,5)	5,5 (3-8,5)
No. joints with LOM	9(5,75-18,25)	6 (3,5-10,5)
PGA of disease activity, mm	70 ± 15	65,9 ± 12,7
Parent's global assessment of the child's pain, VAS	71,5 (65-90)	72,5 ± 14
CHAQ	1,34 (1,1-1,68)	1,25 (0,93-1,44)
Psoriasis BSA, %	7,0 (4-13)	8 (3-13)
PASI score	5,7 (3-8,2)	9 (5-19)
ESR, mm/h	28 (20,75-40)	24,5 (21-32)

ANA - antinuclear antibodies, RF - rheumatoid factor, LOM - limitation of motion, PGA - physician's global assessment; VAS - visual analog scale, CHAQ - Childhood Health Assessment Questionnaire; BSA - body surface area; PASI - Psoriasis Area Severity Index, ESR - erythrocyte sedimentation rate; CRP - C-reactive protein.

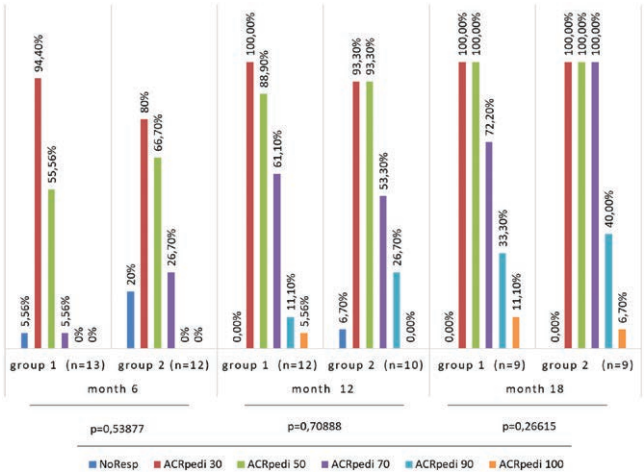

Figure 1. Comparative efficacy of etanercept and adalimumab in children with JPsA, according to the ACRpedi criteria at months 6, 12, and 18 after treatment initiation.No statistically significant difference in the efficacy of etanercept and adalimumab in patients with juvenile psoriatic arthritis was obtained, according to the ACRpedi criteria.The efficacy of biologic treatment on skin manifestations of JPsA was also evaluated (Figure 2).

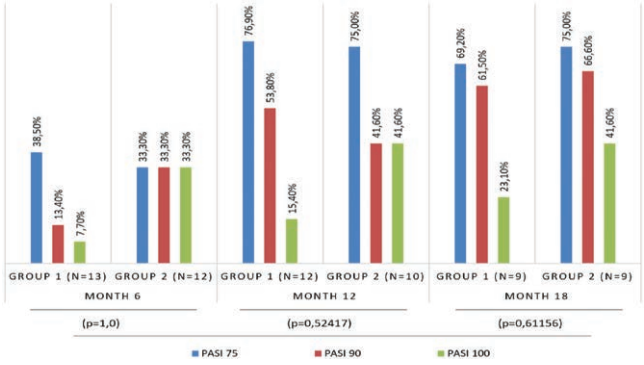

Figure 2. Comparative efficacy of etanercept and adalimumab in children with JPsA by PASI score at months 6, 12, and 18 after treatment initiation.Both TNF-α blockers (etanercept, adalimumab) showed similar efficacy for psoriasis in patients with JPsA, though response rate for psoriasis in adalimumab group was higher than in etanercept group.

Conclusion: Both TNF-α inhibitors (etanercept and adalimumab) proved to be effective in the treatment of arthritis and psoriasis in JPsA. There was no statistically significant difference in the effectiveness of etanercept and adalimumab in the treatment of JPsA in our cohort. Both biological agents can be successfully used to treat JPsA.

Pharmacology and Microbiota

OP0307

GUT MICROBIOTA AND ITS RELEVANCE TO PERIPHERAL LYMPHOCYTE SUBPOPULATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

T. Cheng[1], X. Wang[1], S. X. Zhang[1], J. Yang[2], C. Zhao[3], Y. Wang[1], J. An[1], J. Chen[1]. [1]*The Second Hospital of Shanxi Medical University / Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*The Central Hospital of Xinghualing District, Department of Rheumatology, Taiyuan, China*; [3]*Xi'an International Medical Center Hospital, Department of Rheumatology, Taiyuan, China*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with disturbance of lymphocyte subpopulations[1]. Growing experimental and clinical evidence suggests that chronic inflammatory response induced by gut microbiome critically contribute to the development of SLE[2 3].

Objectives: To investigate the characteristics of gut microbiome and the associations between flora and peripheral lymphocyte subpopulations in SLE patients.

Methods: A total of 19 SLE patients who fulfilled the 2019 American college of Rheumatology (ACR) and European League Against Rheumatism (EULAR) classification criteria and 16 age- and sex- matched healthy controls (HC) were enrolled in this study. The peripheral T lymphocyte subsets of these participants were assessed by flow cytometry and the gut microbiota were investigated via 16s rRNA. Indicators of disease activity such as erythrocyte sedimentation rate (ESR), complement C3 and C4 were recorded at the same time. Mann-Whitney U test was applied to compare T lymphocyte subsets between SLE patients and HC. Spearman analysis was used for calculating correlation between T subsets and highly expressed differential flora as well as their correlation with disease activity indicators. All *P*-values reported herein were two-tailed and *P*-value<0.05 was taken as statistically significant.

Results: SLE patients had higher proportions of Th17 cells (*P*=0.020) and γδT cells (*P*=0.018) but lower levels of Treg cells (*P*=0.001), Tfh cells (*P*=0.018) and Naïve $CD4^+$T cells (*P*=0.004) (Figure 1a-e). The diversity and relative abundance of intestinal flora in patients with SLE were significantly different from those in HCs. Detailly, the α-diversity was decreased in SLE (*P*<0.05) (Figure 2a-c). Compared with HC, 11 species of flora were discovered to be distinctly different(*P*<0.05) (Figure 2d-e). Moreover, there was a significant positive correlation between Treg levels and *Ruminococcus2* (*P*=0.042), Th17 and *Megamonas* (*P*=0.009), γδT and *Streptococcus* (*P*=0.004) as well as *Megamonas* (*P*=0.003), Tfh and *Bacteroides* (*P*=0.040). Whereas Th1 levels and *Bifidobacterium* were negatively correlated in these participants (*P*=0.005). As for clinical disease measures, there were negative correlations not only between ESR and Treg

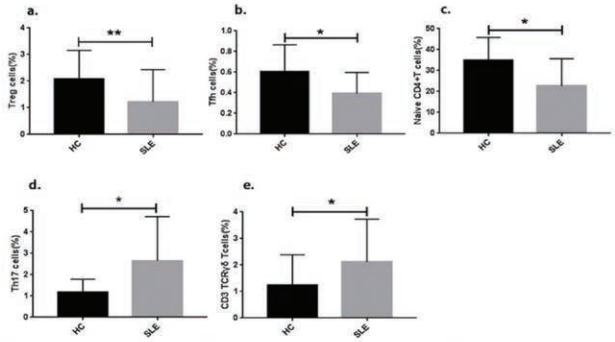

Figure 1(**a-e**) Comparison of T lymphocyte subsets in peripheral blood between healthy controls and SLE patients.

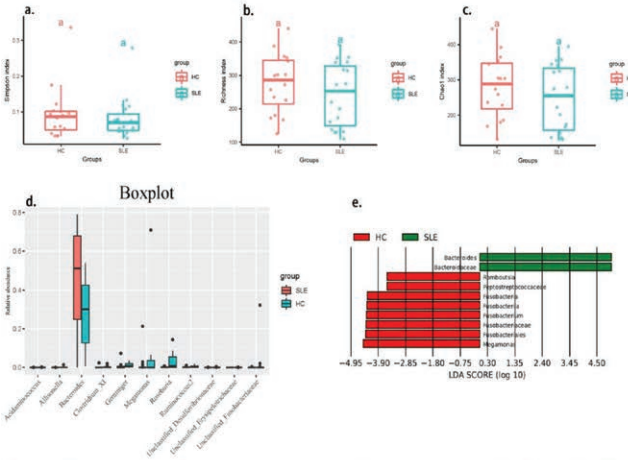

Figure 2(**a-e**) Variation of gut microbiota in SLE patients compared with HC and the LDA score of highly expressed differential flora. *P < 0.05, **P < 0.01, ***P < 0.001.

cells (*P*=0.031) but also C4 and the amount of *Unclassified Ruminococcaceae* (*P*=0.032).

Conclusion: Abnormality of T cell subsets, especially the level of Naïve CD4$^+$T, γδT, Tfh, Treg, and Th17 cells contributes to the occurrence and progression of SLE, which may be related to the disturbance of gut microbiota. Therefore it is necessary to attach importance to the alteration of gut microbiota to prevent the outbreak of inflammation and maybe they can be identified as biomarkers predicting disease activity.

What can we learn from the tissue

OP0308 SENESCENT PROGENITOR CELLS IN THE SKIN OF LUPUS PATIENTS

X. Wang[1], G. Diercks[2], W. Lambers[1], J. Westra[1], H. Bootsma[1], F. G. M. Kroese[1], K. De Leeuw[1], S. A. Pringle[1]. *[1]UMCG, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]UMCG, Department of Pathology, Groningen, Netherlands*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease, which is characterized by skin lesions, amongst other symptoms. These lesions (chronic discoid lupus erythematosus (CDLE) and subacute cutaneous lupus erythematosus (SCLE)) feature lymphocytic infiltration close to basal layer of the epidermis (i.e. the location of the epidermal progenitor cells), namely the epidermal dermal junction (EDJ) area. Epidermal progenitor cells maintain the homeostasis of the skin through their proliferation and differentiation into keratinocytes. In fast turnover tissues, like the skin, a population of 'transient amplifying cells' (TA cells), additionally facilitates generation of enough daughter cells to maintain skin homeostasis. These cells are located in an upper layer (suprabasal layer) of the epidermis, next to the basal layer. Senescence is an irreversible and locally spreading phenomenon that induces permanent cell cycle arrest.

Objectives: To evaluate expression of senescence markers p16 and p21 in the epidermal progenitor and TA niches in patients with SCLE and CDLE. This was compared to a panel of other dermatological conditions with and without infiltration close to EDJ, as disease controls, and to control skin tissue.

Methods: Age-matched skin lesions from patients with SCLE (n=12), CDLE (n=8), other conditions with EDJ infiltration (e.g. lichen planus, n=22), and dermatoses without EDJ infiltration (e.g. eczema, n=27), and non-lesion control biopsies (n=3) from SLE patients were employed. p16 and p21 expression in the progenitor niche (basal layer) and TA cell niche (suprabasal layer), and the whole epidermis of skin lesions biopsies were examined by immunohistochemistry.

Results: In healthy skin biopsies, 0 ± 0 SEM p16$^+$ cells/mm2 in the progenitor niche and 5 ± 4 SEM p21$^+$ cells/mm2 in TA niche were observed. In skin lesions from patients with CDLE and SCLE, significantly more p16$^+$ cells in the progenitor cell niche (45 ± 14 SEM/mm2) and p21$^+$ cells (182 ± 38 SEM/mm2) in TA niches were detected, compared to control biopsies ($p < 0.05$), and compared to those dermatoses without EDJ infiltration (p16$^+$ 11 ± 3 SEM/mm2, p21$^+$ 86 ± 28 SEM/mm2, $p < 0.05$, Figure 1). p16 and p21 expression in CDLE and SCLE lesions did not significantly differ from other dermatoses with EDJ infiltration ($p>0.05$). Across all dermatoses analyzed, the number of p16$^+$ cells was significantly correlated with the number of p21$^+$ cells, both in the progenitor niche ($r=0.45$, $p<0.0001$) and TA niche ($r=0.47$, $p<0.0001$). p16$^+$ cells however were more frequently found in the progenitor cell niche, and p21$^+$ cells conversely in the TA cell niche ($p<0.0001$).

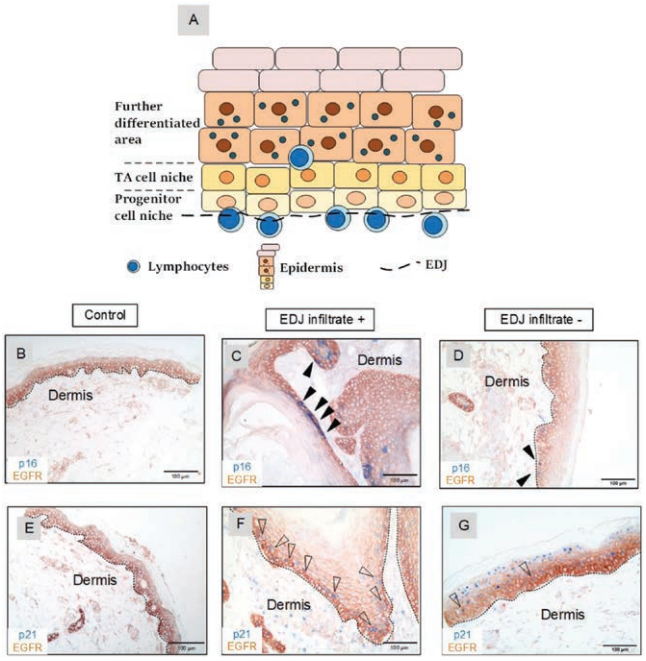

Figure 1. Increased p16$^+$ and p21$^+$ cells in the progenitor and TA niches in dermatoses with EDJ infiltration.A. Graphic illustration for the progenitor cell niche (the basal layer), the transient amplifying (TA, the supra-basal layer) cell niche, and the further differentiated area. B-D. Representative staining of p16 (blue) and epidermal growth factor receptor (EGFR, brown, an epithelial cell marker) in dermatoses with (CDLE) and without (PMLE) epidermal-dermal junction (EDJ) infiltration groups. Black arrowheads point to p16$^+$ progenitor epidermal cells. E-G. Representative staining of p21 (blue) and EGFR (brown) in dermatoses with (CDLE) and without (PMLE) EDJ infiltration groups. Hollow arrowheads point to p21$^+$ TA epidermal cells. The dashed line indicates the EDJ. CDLE: chronic discoid lupus erythematosus, PMLE: polymorphous light eruption.

Conclusion: In CDLE and SCLE, cutaneous manifestations of SLE, more progenitor and TA cells expressing markers of senescence were detected. This was in common with other dermatological conditions where lymphocytic infiltration is in close proximity to the progenitor and TA cell niche, namely in the EDJ. Increased senescence might infer the collapse of homeostasis in target (local) epidermis, which may influence tissue repair in the lesion. Elimination of senescent cells may therefore represent a viable therapeutic option to encourage timely and complete wound healing, in skin lesions of CDLE and SCLE patients.

EULAR Projects in musculoskeletal imaging

OP0309 THE ROLE OF IMAGING TO GUIDE INTERVENTIONAL PROCEDURES IN RHEUMATIC AND MUSCULOSKELETAL DISEASES: A SYSTEMATIC LITERATURE REVIEW TO INFORM EULAR RECOMMENDATIONS

P. Bosch[1], F. Carubbi[2], C. A. Scirè[3], X. Baraliakos[4], L. Falzon[5], C. Dejaco[1,6], P. M. Machado[7]. *[1]Medical University of Graz, Rheumatology and Immunology, Graz, Austria*; *[2]University of L'Aquila, Medicine, Aquila, Italy*; *[3]University of Ferrara, Rheumatology, Ferrara, Italy*; *[4]Ruhr University Bochum, Reumatology, Bochum, Germany*; *[5]Northwell Health, Medical Research, New York, United States of America*; *[6]Hospital of Bruneck, Rheumatology Service, Bruneck, Italy*; *[7]Centre for Rheumatology, University College London, Neuromuscular Diseases, London, United Kingdom*

Background: Imaging guidance gives the opportunity to visualize a needle or other instrument when performing interventions on musculoskeletal sites in patients with rheumatic and musculoskeletal diseases (RMDs). Studies assessing the role of imaging guided procedures have been performed, however, no consensus has been made yet about when and which imaging techniques to use for these interventions.

Objectives: To inform a EULAR taskforce on the current literature on different imaging techniques, procedures and materials to guide interventions on musculoskeletal sites in RMD patients.
Methods: Prospective and retrospective studies published in English and comparing either palpation or imaging guided interventions in patients with RMDs were included. MEDLINE, EMBASE, the Cochrane Library and Epistemonikos were searched through October 2021. Risk of bias (RoB) was assessed using the Cochrane RoB tool for randomized trials version 2 (ROB2), the RoB tool for Non-Randomized Studies of Interventions (ROBINS-I) and the appraisal tool for cross-sectional studies (AXIS).
Results: Sixty-six studies, with moderate to high RoB, consisting of 49 randomized controlled trials, three prospective cohort studies and 14 retrospective studies were included.
Fifty-one studies compared one imaging technique against either another imaging technique, or palpation-guided interventions. Most of the studies were on peripheral joints (47/51), while data on joints of the axial skeleton were scare and heterogeneous (4/51). For peripheral joints, ultrasound (US) was the most studied imaging technique (49/51), followed by fluoroscopy (10/51). Results revealed a higher accuracy and safety (including procedural pain) of US or fluoroscopy compared to palpation- guided interventions. Data on other imaging techniques was scarce (computed tomography: n=3, arthroscopy: n=1) and the results heterogeneous. Results of studies comparing different imaging techniques (12/51) did not favor one imaging method over another.
Three studies comparing different materials used for imaging guided interventions were found (e.g. automatic vs manual syringes), showing little evidence for one material being superior to another one.
Fifteen studies were found comparing different imaging guided procedures (e.g. intraarticular vs periarticular injections). Overall, studies indicated an advantage of targeted vs. not targeted interventions (intraarticular vs periarticular or intraepineurial vs extraepineurial injections) concerning pain levels, while the comparison of different puncture sites to inject (e.g. ulnar vs midline carpal tunnel injection) was inconclusive.
Conclusion: Imaging guidance, especially US, performs favorably for interventions at the peripheral joints compared to palpation-guided interventions, concerning accuracy and safety. Data for the axial skeleton are scarce. Imaging guided targeted interventions may lead to better outcomes than non-targeted interventions.

Background: Fibromyalgia (FM) patients report chronic widespread pain, fatigue, cognitive difficulties and sleep disturbances, often associated with anxiety and/or depression (1). FM syndrome more frequently affects women and many papers describe gender-related differences in the perception, description and expression of pain (2), but up to now, the impact of gender on the clinical severity of FM is still a controversial topic.
Objectives: The aim of this study was to analyse the data from a web-based registry of FM patients in order to detect a relationship between gender and disease severity.
Methods: Adult patients with FM, diagnosed on the basis of the 2010/2011 American College of Rheumatology (ACR) diagnostic criteria (3), were recruited at 19 Italian rheumatology centres between November 2018 and April 2019. Those affected by other conditions that could interfere with the assessment of FM, e.g. psychiatric disorders, were excluded from the study. The severity of the disease was evaluated by validated FM-specific questionnaires: the revised Fibromyalgia Impact Questionnaire (FIQR) (4), the modified Fibromyalgia Assessment Status (ModFAS) questionnaire (5), and the Polysymptomatic Distress Scale (PDS) (6). The data obtained were collected in the Italian Fibromyalgia Registry, an online registry created with the support of the Italian Society of Rheumatology (SIR).
Results: We analyse data from 2.381 patients affected by FM, 2.184 females (91.7%) and 197 males. No significant differences in mean age, disease duration, or BMI between the two genders were reported. The women expressed greater disease burden as indicated by higher scores for each completed test: higher mean ModFAS score (25.23 ± 8.83 Vs 23.37 ± 9.22; p = 0.005), mean FIQR score (58.62 ± 23.22 Vs 51.68 ± 23.06; p <0.001), and mean PDS score (18.77 ± 7.34 Vs 17.19 ± 7.25; p = 0.004). Figure 1 shows the mean scores of each item of the FIQR divided by gender. Women reported significantly higher values on all the items of FIQR except three (feeling overwhelmed, FIQR-11; depression, FIQR-16; and anxiety, FIQR-18). It is interesting to note that men self-reported higher levels of depression (FIQR-16).

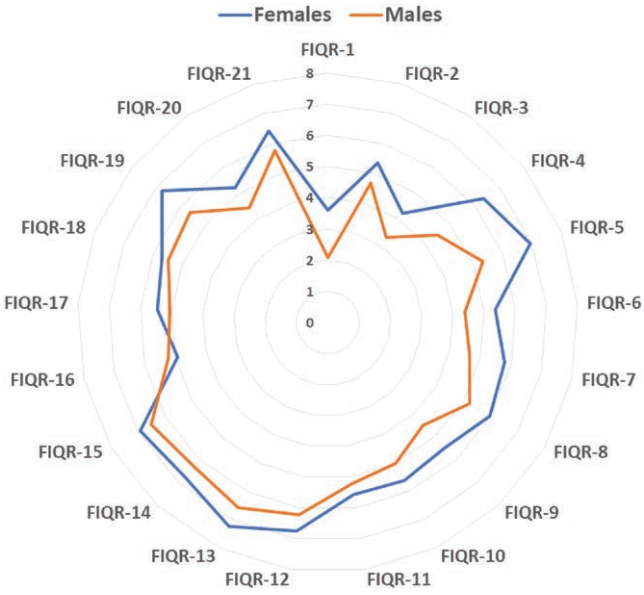

Figure 1. Mean scores for each FIQR item by gender.

Conclusion: Our findings demonstrate that women with FM are globally more impaired than men (even if some psychological aspects of the disease are comparable), thus reinforcing the idea that gender plays a role in symptoms and functional impairments associated with the disease.

OP0311 **THE ROLE OF COMORBID PATHOLOGY IN THE PROGRESSIVE COURSE OF ANCA-ASSOCIATED SYSTEMIC VASCULITIS**

A. Chudinov[1], I. Belyaeva[2], V. Mazurov[2], O. Inamova[1]. [1]*Clinical rheumatological hospital #25, rheumatology, Saint-Peterburg, Russian Federation*; [2]*North-West State Medical University named after I.I. Mechnikov, rheumatology, Saint-Peterburg, Russian Federation*

Background: ANCA-associated systemic vasculitis (AAV) is characterized by a high incidence of complications and high damage index. Comorbid pathology at the onset can significantly worsen the prognosis AAV. The most significant comorbid conditions in patients with AAV are coronary artery disease, hypertension and dyslipidemia.
Objectives: The aim of this study was to determine the role of comorbid pathology in the progressive course in patients with AAV.
Methods: Patients with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) were observed during the first 3 years of the disease and included in this study between 2010 and 2018. At the onset of AAV 75% of patients had significant comorbidities (coronary artery disease, hypertension, dyslipidemia, chronic obstructive pulmonary disease, peptic ulcer, diabetes mellitus, autoimmune thyroiditis and others).
Results: In total 209 (165 [79%] female and mean age 51.8 ± 13.2 years) AAV patients (94 GPA; 46 MPA; and 69 EGPA) were included in the analysis. Formation of chronic kidney disease was significantly more frequent in the group of AAV patients with hypertension at the onset, than in patients without hypertension (respectively 37% and 23.6%, p=0.041). Development of thromboembolic complications was significantly more frequent in the group of AAV patients with coronary artery disease at the onset of AAV, than in patients without coronary artery disease (respectively 34% and 14.8%, p=0.034). Dyslipidemia also was risk factor for cardiovascular complications (OR – 3.81, 95% CI (2.43; 8.2) p=0.009). Presence of diabetes mellitus in the AAV onset was risk factor for infectious complications (OR – 1.77, 95% CI (1.14; 3.45) p=0.038).
Conclusion: Our study has shown that comorbid pathology increase risk of serious complications and can significantly worsen the prognosis AAV. Prevention of development of comorbid conditions and control of lipid levels, hypertension levels are necessary to prevent the formation of irreversible organ damage.

Stress, inflammation & autoimmunity

OP0312 **METABOLIC REPROGRAMMING IN MEMORY CD4+ T CELLS IS ASSOCIATED WITH REACTIVE OXYGEN INDUCED IMMUNE CELL DYSFUNCTION DURING AGING**

Y. Chen[1,2], Y. Ye[3], H. Wu[4], P. L. Krauß[1,2], P. Löwe[1,2], M. Pfeiffenberger[1,2], L. Ehlers[1,2], A. Damerau[1,2], P. Hoff[1], F. Buttgereit[1,2], T. Gaber[1,2]. [1]*Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; [2]*German Rheumatism Research Centre (DRFZ) Berlin, a Leibniz Institute, Berlin, Germany*; [3]*Quanzhou First Hospital Affiliated to Fujian Medical University, Department of Gastroenterology, Quanzhou, China*; [4]*Julius-Maximilians Universität Würzburg, Institut für Systemimmunologie, Würzburg, Germany*

Background: Inflamm-aging is a chronic, sterile, low-grade inflammatory status, characterized by an increase of proinflammatory cytokines which participate in the development of most age-related diseases such as cancer, Alzheimer's disease, type 2 diabetes mellitus, stroke, cardiovascular diseases, and rheumatoid arthritis (RA). As cellular metabolism modulates T cell function, it can be assumed that metabolic changes accompany the differentiation of memory CD4+ T cells into senescent CD4+ T cell and contribute to memory CD4+ T cells dysfunction during aging.
Objectives: Therefore, we hypothesized that metabolic reprograming in memory CD4+ T cells might represent an essential factor promoting immune cell dysfunction during aging, thereby fuelling to the pathogenesis of age-related diseases including RA
Methods: To this end, we analysed memory CD4+ T cells isolated from PBMCs of young donors (20-32 years) and old donors (52-67 years) by using MACS™ technology. *Ex vivo* memory CD4+ T cells were analysed by Seahorse™ Technology to determine proton efflux rate (PER) as a measure of glycolysis (glycPER) and oxygen consumption rate (OCR) as a measure of mitochondrial respiration (mitoOCR). Cytokine expression and secretion was measured by flow cytometry and multiplex assay with and without Mitotempo an inhibitor of reactive oxygen species (ROS). Finally, TCR-stimulated memory CD4+ T cell proliferation was determined using CSFE and Ki-67 after 3 days and 4 days by flow cytometry. ROS and mitochondrial activity were analysed after 24 h using DCF-DA and CellROX Deep Red and Mitotracker by flow cytometry.
Results: In a quiescent state, memory $CD4^+$ T cells from elderly individuals demonstrated a decrease in basal glycolysis and compensatory glycolysis, and an increase in the ratio of basal mitochondrial oxygen consumption rate (mitoOCR) to glycolytic proton efflux rate (glycoPER) while their mitochondrial profile was equivalent to that of young donors while the amount of mitochondria was higher with no increase in steady-state ATP level. In this line and in comparison to the younger reference group, memory $CD4^+$ T cells from aged donors presented a greater spare respiratory capacity after TCR-activation and a marked increase in intracellular ROS production. Interestingly, we did not observe an impact of aging on memory $CD4^+$ T cell proliferation as determined by CFSE and Ki-67. Although the capacity of intracellular cytokine expression did not differ between the compared groups, the levels of secreted IFN-γ, IP-10, IL-6, IL-9, and MCAF were significantly higher in the supernatants of memory $CD4^+$ T cells taken from aged donors but were sensitive to ROS inhibition. .
Conclusion: These findings suggest that metabolic reprogramming in human memory $CD4^+$ T cells during aging results in an increased expression of proinflammatory cytokines as a result of ROS production and mitochondrial dysfunction. This process may culminate in T cell dysfunction and thus contribute to the pathogenesis of inflamm-aging and the development of age-related diseases such as rheumatoid arthritis (RA).

Background: COVID-19 runs a severe disease associated with acute respiratory distress syndrome in a subset of patients, and a hyperinflammatory response developing in the second week contributes to the worse outcome. Inflammatory

features are mostly compatible with macrophage activation syndrome (MAS) observed in other viral infections despite resulting in milder changes. Early detection and treatment of MAS may be associated with a better outcome. However, available criteria for MAS associated with other causes have not been helpful.
Objectives: To identify distinct features of MAS associated with COVID-19 using a large database enabling to assess of dynamic changes.
Methods: PCR-confirmed hospitalized COVID-19 patients followed between March and September 2020 constituted the discovery set. Patients considered to have findings of MAS by experienced physicians and given anakinra or tocilizumab were classified as the MAS group and the remaining patients as the non-MAS group. The MAS group was then re-grouped as the cases with exact-MAS and borderline-MAS cases by the study group. Clinical and laboratory data including the Ct values of the PCR test were obtained from the database, and dynamic changes were evaluated especially for the first 14 days of the hospitalization. The second set of 162 patients followed between September-December 2020 were used as the replication group to test the preliminary criteria. In the second set, hospitalization rules were changed, and all patients required oxygen support and received dexamethasone 6mg/day or equivalent glucocorticoids. Daily changes were calculated for the laboratory items in MAS, borderline, and non-MAS groups to see the days differentiating the groups, and ROC curves and lower and upper limits (10-90%) of the selected parameters were calculated to determine the cutoff values.
Results: A total of 769 PCR-confirmed hospitalized patients were analysed, and 77 of them were classified as MAS and 83 as borderline MAS patients. There was no statistically significant difference in the baseline viral loads of MAS patients compared to the non-MAS group according to the Ct values. Daily dynamic changes in the MAS group differed from the non-MAS group especially around the 6th day of hospitalization, and more than a twofold increase in ferritin and a 1.5-fold increase in D-dimer levels compared to the baseline values help to define the MAS group. Twelve items selected for the criteria are given in Table 1 below. The total score of 45 provided 79.6% sensitivity for the MAS (including borderline cases) and 81.3% specificity around days 5 and 6 in the discovery set, and a score of 60 increased the specificity to 94.9% despite a decrease in sensitivity to 40.8%. The same set provided a similar sensitivity (80.3%) in the replication, but a lower specificity (47.4-66% on days 6 to 9) due to a group of control patients with findings of MAS possibly masked by glucocorticoids.

Table 1. Preliminary Criteria for Macrophage Activation Syndrome Associated with Coronavirus Disease-19

1.Fever (>37.0 °C)
2.Ferritin concentration > 550 ng/mL
3.More than 2 times increase of ferritin concentration within 7 days of disease onset
4.Neutrophil count > 6000 cell/mm^3
5.Lymphopenia < 1000 cell/mm^3
6.Neutrophil/lymphocyte ratio > 6
7.D-dimer concentration > 1000 ng/ml
8.More than 50% increase of D-dimer concentration within 7 days of disease onset
9.CRP concetration > 50 mg/L
10.LDH concentration > 300 U/L
11.ALT or AST concentration > 50 U/L
12.Procalcitonin concentration < 1.2

1 point for each positive item assessed on Days 5-7Score calculation: Total points / 12 x 100Possible MAS ≥45 and Definite MAS ≥60

Conclusion: This study defined a set of preliminary criteria using the most relevant items of MAS according to the dynamic changes in the parameters in a group of COVID-19 patients. A score of 45 would be helpful to define a possible MAS group with reasonable sensitivity and specificity to start necessary treatments as early as possible.

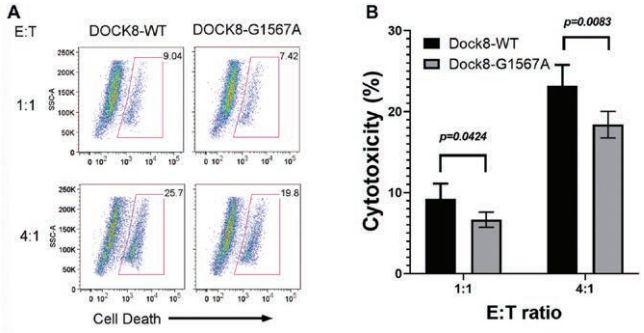
OP0314 **DOCK8 MUTATIONS IN COVID-19 AND MIS-C CYTOKINE STORM SYNDROME**

R. Cron[1], M. Zhang[1], D. Absher[2], J. Bridges[1], A. Schnell[3], P. Bhatraju[4], A. Vagrecha[5], S. Lozinsky[6], S. Acharya[7], C. Levy[7], W. Chatham[3]. [1]*University of Alabama at Birmingham, Pediatrics, Birmingham, United States of America*; [2]*HudsonAlpha Institute for Biotechnology, Genomic Health Research, Huntsville, United States of America*; [3]*University of Alabama at Birmingham, Medicine, Birmingham, United States of America*; [4]*University of Washington, Medicine, Seattle, United States of America*; [5]*Hofstra University, Pediatrics, Hempstead, United States of America*; [6]*Hofstra University, Neurosurgery, Hampstead, United States of America*; [7]*Hofstra University, Pediatrics, Hampstead, United States of America*

Background: We recently identified *DOCK8* as a novel gene associated with cytokine storm syndrome (CSS)[1]. Heterozygous missense mutations in *DOCK8* diminish NK cell lytic function and contribute to increased pro-inflammatory cytokine production (CSS). CSS is a potential complication of COVID-19 with severe consequences[2]. Children are at risk of a SARS-CoV-2 post-infectious CSS, multisystem inflammatory syndrome in children (MIS-C)[3]. Host genetic factors associated with COVID-19 CSS and MIS-C CSS are unknown.
Objectives: The goals are to identify and functionally study rare mutations in *DOCK8* in patients with SARS-CoV-2 COVID-19 and MIS-C.
Methods: To date, 16 adult patients enrolled in a COVID-19 CSS clinical trial at UAB had whole genome sequencing. Four (25%) had rare heterozygous *DOCK8* mutations (3 missense, 1 intronic). A COVID-19 CSS adult patient in Seattle also had a *DOCK8* missense mutation. In addition, *DOCK8* missense mutations were identified in five children (UAB & Northwell) hospitalized with MIS-C. *DOCK8* mutations, or wild-type (WT) sequence controls, were introduced into human NK-92 cells by FOAMY virus transduction. WT and mutant DOCK8-expressing NK-92 cells were incubated with K562 target cells and compared for cytolysis and degranulation (CD107a).
Results: One COVID-19 patient *DOCK8* mutation (Gly523Arg) reduced NK cell degranulation by 30% and cytolysis by 23% (n=3) (Figure 1). Similar studies of 3 MIS-C patients with *DOCK8* missense mutations (Arg899Trp, Ala2Thr, Pro687Leu) revealed up to 31% reduced NK cell degranulation and 48% reduction in cytolysis by 3 distinct mutations (n=3). Two-way ANOVA analysis revealed statistically significant ($p<0.05$) differences in NK cell degranulation and lysis for four unique *DOCK8* mutations.



Conclusion: Heterozygous *DOCK8* missense mutations may contribute to severe COVID-19 and MIS-C CSS by partial dominant-negative effects yielding decreased NK cell cytolysis.

Metabolic pathways during the regulation of inflammation and immunity

OP0315 **EFFECTOR CD4 T CELLS REQUIRE SURVIVIN FOR REGULATION OF GLUCOSE METABOLISM AND IFNG PRODUCTION**

M. Erlandsson[1,2], K. M. Andersson[1], N. Oparina[1], S. Töyrä Silfverswärd[1], M. I. Bokarewa[1,2]. [1]*Gothenburg University, Rheumatology and Inflammation Research, Gothenburg, Sweden*; [2]*Sahlgrenska University Hospital, Rheumatology clinic, Göteborg, Sweden*

Background: Interferon-gamma (IFNg) producing effector T cells play the leading role in triggering and perpetuation of inflammation in rheumatoid arthritis. Inflammation leads to metabolic reprogramming of T cells and high energy consumption supporting proliferation and IFNg production. Being a part of chromosomal passenger complex, oncoprotein survivin is essential for cell proliferation. It has also been identified as a marker of severe therapy-resistant rheumatoid

arthritis. Thus, we aimed to explore the association between survivin and IFNg producing phenotype of CD4 T cells.
Objectives: We study if survivin mediates the glucose dependent mechanism of IFNg production in CD4 T cells.
Methods: CD4 cells were sorted from the peripheral blood of RA patients and healthy controls, activated with aCD3, cultured in presence of survivin inhibitor YM155 and subjected to RNA sequencing (Illumina, Life Science). IFNg levels in supernatants were measured by ELISA. To study glucose uptake in presence of YM155, CD4 cells were treated with IFNg+aCD3 overnight followed by 2NBD-glucose challenge for 30 min. Uptake of fluorescent 2NBD-glucose probe was measured by flow cytometry. Statistical analysis of RNAseq was performed in R-studio using the Bioconductor package DESeq2.
Results: Comparison of the whole-genome transcription profile of CD4 cells different by levels of BIRC5, coding for survivin, demonstrated that the BIRC5hi group expressed significantly higher levels of IFNg (mRNA, $p=10^{-26}$ and protein, $p=10^{-4}$). Also, BIRC5hi CD4 cells had higher expression of glucose transporter GLUT1 (SLC2A1, p=0.0064) and of glycolytic enzymes glucose-6-phosphate dehydrogenase (G6PD, $p=10^{-6}$), pyruvate kinase (PFKP, $p=10^{-6}$), and lactate dehydrogenase (LDHA, $p=10^{-14}$). On the contrary, expression of the key regulator of glycolysis 6-phosphofructo-2-kinase (PFKFB3) was significantly lower in the BIRC5hi group ($p=4.4x10^{-5}$). Notably, expression of glycolytic enzymes G6PD and PFKFB3 correlated strongly to IFNg (r=0.880 and -0.698, respectively), TBX21 (r=0.811 and -0.698) and perforin (r=0.781 and -0.698). To demonstrate functional relevance of the connection between BIRC5 and glucose metabolism, survivin was inhibited in CD4 cell cultures. Survivin inhibition resulted in significant increase of PFKFB3 ($p=7x10^{-6}$) and LDHA (p=0.0089), leading to inhibition of phosphoglycerate mutase PGAM1 and ATF citrate lyase ACLY (p=0.021 and p=0.0074, respectively), which dignify the restoration of aerobic glycolysis. Importantly, inhibition of survivin decreased 2NBD-glucose uptake by CD4 cells (p=0.031) and reduced expression of GLUT1 (p=0.034). These changes in glucose metabolism were followed by decreased IFNg production in supernatants (p=0.037).
Conclusion: The study demonstrates a strong connection between IFNg production and glucose metabolism in CD4 cells. Survivin emerges as an important regulator of glycolysis acting through expression of glycolytic enzymes and glucose transport.
Disclosure of Interests: None declared.

Let's work. Together.

OP0316

ASSOCIATION BETWEEN INDIVIDUAL AND COUNTRY-LEVEL SOCIOECONOMIC FACTORS AND WORK PARTICIPATION IN PERIPHERAL AND AXIAL SPONDYLOARTHRITIS: ANALYSIS OF THE ASAS PERSPA STUDY

S. S. Zhao[1], E. Nikiphorou[2], A. Boonen[3,4], C. López-Medina[5,6], M. Dougados[5,7], S. Ramiro[8,9]. [1]*University of Liverpool, Musculoskeletal Biology, Institute of Life Course and Medical Sciences, Liverpool, United Kingdom*; [2]*King's College London, Department of Rheumatology and Centre for Rheumatic Diseases, London, United Kingdom*; [3]*Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands*; [4]*Academic Hospital Maastricht, Department of Internal Medicine, Division of Rheumatology, Maastricht, Netherlands*; [5]*Cochin Hospital, Université de Paris, Rheumatology Department, Paris, France*; [6]*University of Cordoba, Rheumatology Department, Reina Sofia Hospital, IMIBIC, Córdoba, Spain*; [7]*University of Paris, INSERM (U1153): Clinical Epidemiology and Biostatistics, Paris, France*; [8]*Leiden University Medical Center (LUMC), Department of Rheumatology, Leiden, Netherlands*; [9]*Zuyderland MC, Department of Rheumatology, Heerlen, Netherlands*

Background: Work outcomes in spondyloarthritis (SpA) have mostly been studied in axSpA, less in peripheral SpA (pSpA) or PsA. The ASAS-COMOSPA study showed that lower education, female gender and lower healthcare expenditures (HCE) are associated with lower odds of employment in SpA. However, it is unknown whether country-level factors or SpA phenotype (axSpA/pSpA/PsA) modify the effect of individual-level socioeconomic factors.
Objectives: To examine whether associations between socioeconomic factors and work outcomes differ across SpA phenotype and whether associations for individual-level socioeconomic factors are modified by country-level factors.
Methods: Working age patients (18-65 years) from the ASAS-perSpA (peripheral involvement in SpA) study were included. Associations between individual- (age, gender, education, marital status) and country-level socioeconomic factors (Human Development Index (HDI), HCE) with work outcomes (employment status (binary), absenteeism, presenteeism (tertiles)) were assessed using mixed-effects logistic and ordinal logistic models. Models were adjusted for confounders. Separate models for ASDAS, BASFI and BASDAI were created in turn due to collinearity. Effect modification by SpA phenotype and country-level factors was tested using interaction terms.
Results: A total of 3835 patients (mean age 42 years, 61% males) from 23 countries worldwide were included (66% axSpA, 10% pSpA, 23% PsA). Being employed was associated with gender (male vs female OR 2.5; 95%CI 1.9-3.2), education (university vs primary OR 3.7; 2.9-4.7) and being married (vs single OR 1.3; 1.04-1.6) (Table 1). University (vs primary) education was associated with lower odds of absenteeism (OR 0.7; 0.5-0.7) and presenteeism (OR 0.5; 0.3-0.7). Associations were not statistically different across SpA phenotypes. HCE was significantly associated with all work outcomes: employment (OR 2.5; 1.5-4.1), absenteeism (OR 0.6; 0.4-0.9) and presenteeism (OR 0.6; 0.3-0.9). HDI results were similar. Gender discrepancy in odds of employment was greater in countries with lower socioeconomic development; eg, males had 3.5 higher odds of employment than females in countries with low HCE, whereas the difference was 1.8 fold in high HCE countries.

Table 1. Effect of individual socio-economic factors on work outcomes.

		Employment status	Absenteeism	Presenteeism
		OR (95% CI)	OR (95% CI)	OR (95% CI)
N		3780	2218	2127
Age		1.43 (1.36,1.51)	1.00 (0.99,1.01)	1.00 (0.99,1.01)
Age^2		0.996 (0.995, 0.996)	NS - uni	NS - uni
Male (vs female)		2.48 (1.92,3.21)	1.22 (0.96,1.56)	0.97 (0.78,1.20)
Education	Primary	ref	ref	ref
	Secondary	1.86 (1.48,2.35)	0.69 (0.49,0.99)	0.69 (0.49,0.99)
	University	3.68 (2.87,4.72)	0.67 (0.47,0.96)	0.49 (0.34,0.69)
Marital status	Single	ref	ref	ref
	Married	1.27 (1.04,1.56)	0.95 (0.73,1.22)	0.98 (0.78,1.22)
	Divorced or Widowed	1.39 (0.98,1.97)	1.39 (0.88,2.18)	1.16 (0.74,1.82)
ASDAS		0.78 (0.72,0.84)	1.51 (1.33,1.72)	2.31 (2.04,2.61)
Fatigue		NS - multi	1.14 (1.09,1.21)	1.30 (1.24,1.36)
Depression		0.70 (0.59,0.82)	1.45 (1.15,1.82)	1.95 (1.59,2.39)
Fibromyalgia		NS - multi	1.62 (1.11,2.35)	1.58 (1.03,2.41)
BMI		NS - multi	0.99 (0.97,1.02)	NS - multi
Dactylitis		1.41 (1.12,1.76)	NS - uni	NS - uni
Uveitis		NS - multi	0.62 (0.46,0.84)	NS - uni
NSAIDs		NS - multi	1.53 (1.18,1.99)	1.32 (1.07,1.64)
bDMARDs		NS - multi	NS - uni	1.23 (1.01,1.51)

Models used ASDAS rather than BASDAI/BASFI, which are collinear. NS, not significant in the univariable or multivariable model.

Conclusion: Individual- (lower education) and country-level socioeconomic factors (lower healthcare expenditure) were both associated with (lower) work participation, independently of SpA phenotype. The disadvantageous effect of female gender on employment is particularly strong in countries with lower socioeconomic development. This highlights the need for wider societal interventions, such as improving education and healthcare investment, to improve work outcomes.

Background: EULAR recommendations emphasize the importance of suitable working conditions for people with Rheumatic diseases (RD). Thus, opportunities and choices at work need to be increased for people with rheumatic diseases. Conversely, the COVID-19 pandemic has challenged the working population and particularly those with chronic conditions, such as those with RD. However, there is still a lack of reliable data.
Objectives: To depict contemporary real-life data regarding the work-related burden of disease among Greek patients with RD. To develop a White Paper with proposals to the State in order to facilitate people with rheumatic diseases to rejoin or be retained in the work force.
Methods: A 24-item quantitative questionnaire was uploaded in the website and social media of REUMAZEIN to capture patients' responses in respect to work life. The questionnaire was online accessible for a 45-day period (15/8-30/9/2020).
Results: The responses of 503 adult people with RD (M/F/NA 94/408/1), were available for analysis. Their age was stratified in decades (18-20 0.6%,21-30 5.99%, 31-40 22.36%, 41-50 38.92%, 51-60 22.16% and over 60 9.58%); totally, 83.44% were in the "work-reproductive" period. The predominant RD types were RA 30.3%, SLE 22.8%, AS 20.2% and PsA 20.2%, respectively. Nearly 90% were on medication, namely 40% on biologics, 33% on methotrexate (as a monotherapy or combined therapy), 16.2% on steroids. A minority were either on alternative therapies (2.8%) or off medication (7.5%), respectively. Most of the people were still employed (72.9%) on a full-time schedule (57.7%) and 4.8% on a part-time one, due to their RD. The rest of them (27.1%) were out of work either due to RD (17%) or retirement (1.7%) or for unrelated to the RD reasons (8.4%). The main source of financial income was personal work (52.4%), followed by a family member support (31.1%), while 11% had either a state pension (8%) or a subsidy (3.2%). In respect to the daily house-keeping, half of them (59.3%) had a varying difficulty (mild 36.3%, severe 23%) and 0.8% considered themselves as "unable". The diagnosis was mostly established (81%) prior to the work onset. Post-diagnosis, RD had not affected their working schedule in 47.2%, 17% continued to work with respective adaptations but 30% had quitted or resigned from their work 1-7 years later. RD was notified to the work environment by 85%. As for a compassionate work management, 46% reported no change, 28% an improved policy but 28% a worse one. The development of relative adaptations in the work setting (as chairs, devices, flexible schedule) were considered as favorite factors easing the work by 85%. 17% reported an employer's knowledge on RD related working legislation, 43% the contrary and another 38.7% wished for a future employer's awareness. Most of the participants (58.9%) had no personal information on this field but were eager to get it. The uneventful impact of RD on finding or keeping a job was registered by 77.4% and 66.9%, respectively. During COVID, most of the participants (53%) have not asked for an RD-related leave and only 24.2% chose to telework, a policy that raised mutual satisfaction in 19%. Of note, the working conditions have not mainly been altered (67%) after the end of the 1st quarantine.
Conclusion: This study highlighted that although RD predominate in females, women are more willing to participate in such projects (F 90%). The financial income was mainly based on a personal or a family member work reimbursement (83%), while 11% depended on a state pension or subsidy. The majority has notified the RD to their work environment (85%) while another 85% considered as favorite factors easing the work, several adaptations in the work setting such as chairs, devices, flexible schedule etc. Interestingly, 60% of the participants were unaware of the beneficial legal work rights and nearly 70% of them believe that RD is an obstacle for employment or working maintenance. COVID has not dramatically impaired their work life although the use of teleworking should be strengthened.
Disclosure of Interests: None declared.

Background: Due to better treatment strategies and higher remission rates the management of rheumatoid arthritis (RA) patients in sustained remission is of increasing interest (1). The Rheumatoid Arthritis in Ongoing Remission (RETRO) study investigated the possibility to taper and stop disease modifying anti-rheumatic drugs (DMARDs).
Objectives: To compare one-year remission and relapse rates in rheumatoid arthritis patients randomized to continued treatment, reduced treatment or gradual treatment withdrawal after stable remission under routine care.
Methods: Primary data of the phase III, randomized, controlled RETRO trial in RA patients with stable conventional synthetic and/or biologic DMARD treatment in sustained (>6 months) DAS28-ESR remission (<2.6 units). Patients were randomized 1:1:1 into three strategy arms (continuation of 100% DMARD dose, CONT; tapering to 50% DMARD dose, TAP; 50% tapering followed by withdrawal of DMARDs, STOP). The primary endpoint was the proportion of patients in sustained DAS28-ESR remission after 1 year.
Results: 316 RA patients in sustained remission were included, 303 were randomized (CONT: N=100; TAP: N=102; STOP: N=101) and 282 (93%) had complete data sets after 1 year (CONT:N=93; TAP: N=93; STOP: N=96; Table 1). After 1 year, 81.2%, 58.6%, 43.3% of patients, maintained their remission state over 1 year in the CONT, TAP and STOP arms, respectively (p=0.0004 with log rank test for trend; Figure 1). Hazard ratios for flare were 3.02 (95%CI 1.69 to 5.40) and 4.34 (95%CI 2.48 to 7.60) for the TAP and STOP arms. RA patients who flared were more likely to be female, have longer disease duration, RF/ACPA positivity and higher baseline DAS-28 scores with standardized mean differences >0.2. Serious adverse events were reported in 10.8%, 7.5%, and 13.5% in the CONT, TAP and STOP arms, respectively.

Table 1. Baseline Characteristics

	Group			
	Control	**Reduce**	**Reduce/Stop**	**Overall**
N	93	93	96	282

HAQ, alternative, mean(SD)	0.2 (0.4)	0.1 (0.3)	0.2 (0.3)	0.2 (0.3)
DAS-28, mean(SD)	1.7 (0.7)	1.7 (0.6)	1.7 (0.6)	1.7 (0.6)
SDAI, mean(SD)	1.4 (1.5)	1.4 (1.5)	1.3 (1.3)	1.3 (1.4)
DAS-28 remission, n (%)	91 (97.8)	93 (100.0)	95 (99.0)	279 (98.9)
SDAI remission, n (%)	79 (87.8)	79 (84.9)	88 (92.6)	246 (88.5)
Boolean remission, n (%)	69 (75.8)	71 (76.3)	76 (79.2)	216 (77.1)

Conclusion: This randomized controlled study shows that half of RA patients in sustained remission relapse when tapering/stopping their DMARDs. Presence of autoantibodies, higher baseline DAS28-ESR and female sex are predictors for flares.

OP0319 OSTEOSARCOPENIA INCREASES THE RISK OF FALLS IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS OF A FOUR-YEAR LONGITUDINAL STUDY

M. Tada[1], Y. Yamada[2], K. Mandai[3], N. Hidaka[1]. [1]*Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan*; [2]*Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan*; [3]*Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan*

Background: Osteosarcopenia is defined as osteoporosis combined with sarcopenia. Both osteoporosis and sarcopenia are risk factors for falls and fractures in healthy individuals[1]. The relationships of falls and fractures to osteosarcopenia in rheumatoid arthritis (RA) patients are unknown.

Objectives: The synergistic effect of osteoporosis and sarcopenia and the impact of osteosarcopenia on falls and fractures in RA patients were investigated using four years of data from a longitudinal study.

Methods: The data from a prospective, observational study (CHIKARA study: UMIN000023744) were examined. The patients were divided into four groups according to their baseline status: no sarcopenia and osteoporosis (SP-OP-); only sarcopenia (SP+OP-); only osteoporosis (SP-OP+); and both sarcopenia and osteoporosis (SP+OP+). Sarcopenia was diagnosed by the criteria of the Asia Working Group on Sarcopenia 2014[2]. Patients with osteoporosis were defined as those having a therapeutic intervention for osteoporosis. The survival rate and Cox hazard ratio were analyzed using falls and fractures as endpoints, adjusted by age, sex, and body mass index.

Results: A total of 100 RA patients (female 78%, mean age 66.1 years) were enrolled. The number of SP-OP-, SP+OP-, SP-OP+, and SP+OP+ patients was 45, 17, 27, and 11, respectively. Their baseline characteristics are shown in Table 1. A total of 35 patients had falls, and 19 patients had fractures during the four-year follow-up. The fall-free survival rate in the SP-OP-, SP+OP-, SP-OP+, and SP+OP+ groups was 75.6%, 64.7%, 51.9%, and 36.4%, respectively; that of the SP+OP+ group was significantly lower than that of the other groups (P=0.021) (Figure 1). The fracture-free survival rate in the SP-OP-, SP+OP-, SP-OP+, and SP+OP+ groups was 86.7%, 82.4%, 81.5%, and 54.5%, respectively. That of the SP+OP+ group was relatively lower than that of the other groups (P=0.121). The hazard ratio of falls was significantly increased in the SP+OP+ group by 3.32-fold (95%CI: 1.01-10.9) compared to that in the SP-OP- group, whereas that in the SP+OP- and SP-OP+ groups was 2.58-fold (95%CI: 0.75-8.8) and 2.29-fold (95%CI: 0.94-5.6) higher, respectively. There were no significant differences compared to the SP-OP- group. The hazard ratio of fractures in the SP+OP+ group was increased 2.73-fold (95%CI: 0.61-12.2) compared to that in the SP-OP- group.

Table 1. Baseline characteristics of the four groups

	SA-OP-	SA+OP-	SA-OP+	SA+OP+	P value*
Female, %	73.3	58.8	88.9	100	0.027
Age, years	63 (49, 72)	69 (60, 79)	73 (64, 75)	73 (65, 81)	0.008
Disease duration, years	4.4 (1.0, 8.4)	4.0 (1.3, 8.9)	7.6 (1.5, 14.5)	10.5 (3.2, 26.5)	0.035
DAS28-ESR	3.14 (2.66, 3.70)	3.55 (3.01, 4.65)	3.93 (3.28, 4.63)	3.53 (2.48, 3.89)	0.01
mHAQ	0.25 (0, 0.375)	0.375 (0.125, 0.875)	0.375 (0.125, 0.875)	0.5 (0.125, 0.875)	0.065
MTX, mg/week, rate (%)	8.4 ± 2.9 (86.7)	8.7 ± 3.5 (70.6)	8.3 ± 2.8 (92.6)	6.8 ± 1.0 (90.9)	0.388
Glucocorticoid, mg/day, rate (%)	3.7 ± 1.9 (20.0)	6.3 ± 1.8 (11.8)	4.0 ± 1.7 (44.4)	3.8 ± 1.8 (18.2)	0.400
Body mass index, kg/m^2	23.4 ± 3.8	19.2 ± 2.3	21.7 ± 2.4	19.2 ± 2.0	<0.001

Data are shown as mean ± standard deviation (SD) or median (25th, 75th percentile).*: compared in four groups by Kruskal-Walls test.

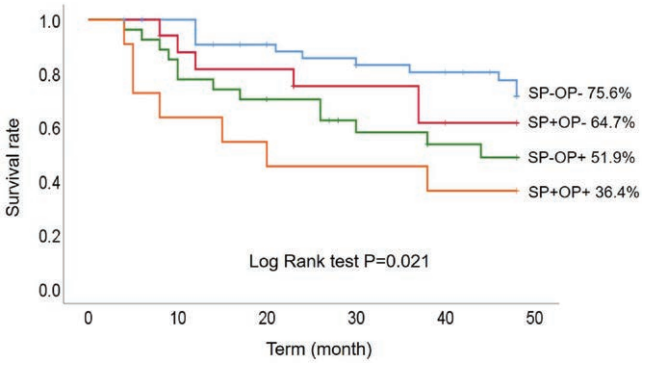

Figure 1. Fall-free survival rates of the four groups.

Conclusion: The survival rates with the endpoints of falls and fractures in RA patients with osteosarcopenia were lower during the four-year follow-up. In particular, the risk of falls increased with the synergistic effect of osteoporosis and sarcopenia in RA patients.

EFIS session: Emerging concepts how B cells drive systemic autoimmunity: from bench to clinic

OP0320 CHARACTERISTICS OF PERIPHERAL BLOOD B-CELL SUBSETS IN PATIENTS WITH SJOGREN SYNDROME

A. Torgashina[1], E. Sokol[1], J. Khvan[1], B. Chalcev[1], D. Tabakov[2], S. Glukhova[3], O. Golovina4. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of intensive care of rheumatic diseases, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Laboratory of immunology and molecular biology, Moscow, Russian Federation*; *[3]V.A. Nasonova Research Institute of Rheumatology, Educational-methodical department, Moscow, Russian Federation*; *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of intensive care of rheumatic diseases, Moscow, Russian Federation*

Background: B-cells play a pivotal role in primary Sjogren's syndrome (SS) pathogenesis. Recent studies have shown disturbances in the peripheral B cell populations in primary SS.
Objectives: To examine B-cell subsets in peripheral blood of SS patients (pts) and to analyze the association between B-cell subsets and SS activity.
Methods: Twenty active SS pts (19F/1M): median age 42 years (range) (32-54); disease duration 3 (2-10) years; ESSDAI score ≥5 in 6 pts, <5 in 14 pts), were included. SS was diagnosed based on the ACR-EULAR 2016 criteria. Twenty healthy donors composed the control group. CD19+B cells, memory B-cells (CD19+CD27+), non-switched memory B-cells (CD19+IgD+CD27+), switched memory B-cells (CD19+IgD-CD27+), naïve (CD19+IgD+CD27-), double negative (CD19+IgD-CD27-), transitional (CD19+IgD+CD10+CD38+) B-cells, plasmablasts (CD19+CD38+++IgD-CD27+), and plasma cells (CD19+CD38+) were analyzed by multicolor flow cytometry using cytometer Navios (Beckman Coulter, USA).
The nonparametric Mann-Whitney test, the unpaired Student's t test for group comparison, and the Pearson`s x2 criterion were used for statistical analysis. Data were shown as median (Me) with an interquartile range of 25 - 75 percentile. The differences were considered statistically significant when p <0.05. Statistica 10 for Windows (StatSoft Inc., USA) package was used for statistical data processing.
Results: The percentages/absolute numbers of plasmablasts, plasma cells and transitional B-cells in SS were significantly higher than in healthy donors, p<0.01 for all cases (Table 1).

Table 1. B-cell subsets in patients with SS, SS and MALT lymphoma and healthy donors.

B-cell subsets	SS		HD		Pt 1		FN
	%	Abs. cells/μl	%	Abs. cells/μl	%	Abs. cells/μl	
B lymphocyte	12,8 (7,9 – 19,7)	151 (95-112)	8,5 (7,2-11,0)	200 (100-200)	4,5	31	**
plasma cells	6,9 (4,2-10)	12 (6-22)	0,1 (0,05-0,1)	0,1 (0-0,2)	5,7	13	*
plasmablasts	0,88 (0.37-1.8)	2 (1-3)	0,1 (0,1-0,2)	0,2 (0,1-0,4)	26,6	12	*/**
transitional B-cells	5.7 (0.9-17)	8 (4-32)	0,1 (0-0,1)	0,1 (0-0,3)	0	0	*
switched cells	9.1 (5.9-20.7)	18 (11-29)	12,8 (9,3-17,0)	20 (10-40)	52	16	**
non-switched memory B-cells	4.13 (2.7-5.4)	7 (3-15)	7,4 (3,7-11,1)	10 (5-20)	16	5	**

SS Sjogren's patients; HD healthy donors, Pt 1 patient with SS and MALT lymphoma* SS and HD groups compared, p<0.01** Pt 1 and SS group compared

One of the patients (Pt 1) was diagnosed with MALT lymphoma of the parotid salivary gland; she had a distinct B-lymphocyte subpopulations distribution, which was different from the rest of the SS group. She had the lowest percentage / absolute B lymphocyte count of all patients with SS, the highest percentage of switched cells and non-switched memory B-cells, and the highest percentages/ absolute numbers of plasmablasts. For this reason, the patient was excluded from the subsequent analysis (Table 1).
Patients with activity of SS by ESSDAI ≥ 5 had a significantly higher percentage of B cells (p=0.007), and significantly higher absolute B lymphocyte count of naïve cells (p=0.04) and plasmablasts (p=0.048).
Conclusion: Immunophenotyping showed disturbed homeostasis of the B-cells subpopulations in our SS cohort. A significant increase in plasmablasts in SS, as well as a positive correlation of the level of plasmablasts with the SS activity and presence of lymphoma could suggest the important role of these cells in the pathogenesis of SS.

OP0321 DELINEATING THE IMMUNOGENIC DOMAINS OF MDA5 USING PATIENT DERIVED AUTOANTIBODIES

E. Van Gompel[1,2,3], C. Cerqueira[2,3,4], E. Wigren[2,3,5], S. Gräslund[2,3,5], K. Chemin[2,3], B. Horuluoglu[2,3], E. De Langhe[1,6], O. Benveniste[7], I. E. Lundberg[2,3]. *[1]KU Leuven, Department of Development and Regeneration, Leuven, Belgium*; *[2]Karolinska Institutet, CMM, Stockholm, Sweden*; *[3]Karolinska University Hospitals, Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden*; *[4]4D Cell, -, Montreuil, France*; *[5]Structural Genomics Consortium, CMM, Stockholm, Sweden*; *[6]UZ Leuven, Reumatologie, Leuven, Belgium*; *[7]Hôpital Pitié-Salpêtrière, UMR 974, UPMC, Internal Medicine and Clinical Immunology, Paris, France*

Background: The presence of myositis specific anti-melanoma differentiation associated protein 5 (MDA5) autoantibodies is associated with mucocutaneous ulcerations, rapidly progressing interstitial lung disease (RPILD), arthritis and mild muscle involvement in patients. RPILD is the major cause of mortality. At present it is unknown which domain of the MDA5 protein is the main elicitor of an immunogenic response.
Objectives: The aim of this study is to delineate the domains in the MDA5 protein that are the target of autoantibodies.
Methods: Anti-MDA5 IgG were isolated from MDA5(+) patient plasma (7 UPMC, 1 KI and 1 KULeuven) by affinity chromatography using an in-house affinity column as described earlier in *Ossipova et al, 2014*[(1)]. 8 constructs covering different regions of the MDA5 protein were recombinantly produced in *E.coli* (Uniprot ID Q9BYX4, Figure 1). An in-house ELISA was developed to identify the domains with the main epitope(s) by measuring the reactivity of the plasma samples and purified autoantibodies against these MDA5 protein constructs, similar to what was reported by *Fernandes-Cerqueira et al, 2018*[(2)]. The biotinylated MDA5 proteins were immobilized on streptavidin coated plates and subsequently incubated with primary antibodies (purified autoantibodies[(2)] or original plasma) and a HRP-conjugated secondary antibody. The ELISA was developed by the addition of TMB substrate and the optical density (OD) was measured at 450 nm.

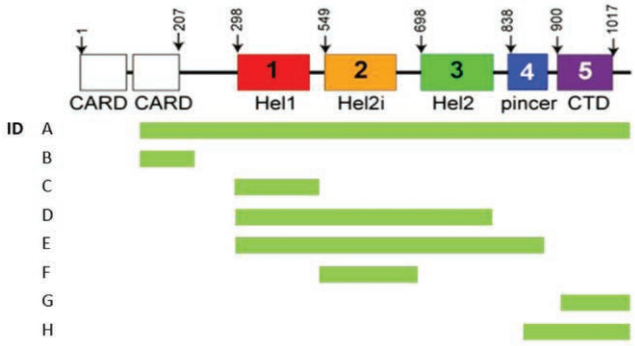

Figure 1. Graphical presentation of the constructs representing different (combinations of) domains of the MDA5 protein.

Results: The preliminary data suggest the main reactivity of the plasma samples and the corresponding purified autoantibodies is directed towards the helicase domains and that there is variability between the patients in the reactivity towards domains located at the end of the protein.

Conclusion: The study aims to resolve the main immunogenic domain of the MDA5 protein, which will lead to more insight in the disease mechanisms. The preliminary results suggest this domain is in the center of the MDA5 protein, but further experiments are necessary. We will use this set up to study differences in reactivity between patients (from different cohorts) and assess if differences in antibody reactivity could be linked to clinical features such as RPILD. Such correlations might be beneficial to predict the disease progression and to apply personal treatment approaches.

[Joint session HPR/ PARE/ ARP] Mastering Self-management: State of art in a New Era

OP0322-HPR

EMPOWERMENT AND ASSOCIATIONS TO DISEASE ACTIVITY AND PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Andersson[1,2], A. Bremander[1,2,3,4], I. Larsson[2,5]on behalf of BARFOT study group. [1]*Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund, Sweden*; [2]*Spenshult Reserach and Development center,., Halmstad, Sweden*; [3]*University of Southern Denmark, Department of Regional Health Research, Odense, Denmark*; [4]*University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark*; [5]*Halmstad University, School of Health and Welfare, Halmstad, Sweden*

Background: The WHO describes empowerment as a process in which patients can take control and make informed decisions about their life and health. Empowerment is important for patients with rheumatoid arthritis (RA) since most of the care is provided by the patients themselves.
Objectives: The aim was to study levels of empowerment and associated variables in individuals with RA and to investigate longitudinal clinical data in patients with low and high empowerment.
Methods: This study involved patients with RA from the BARFOT (Better Anti-Rheumatic PharmacOTherapy) cohort, who were recruited between 1992 and 2006 and included in the study at the time for diagnosis (n = 2,837) [1]. The patients were assessed according to a structured protocol at inclusion and after 3, 6, 12, 24, 60, 96, and 180 months. At each follow-up DAS28-3, HAQ and pain were assessed. In 2017, a postal survey was sent to all still living patients (n=1542), with a response rate of 69% (n = 1,065). The questionnaire included disease characteristics, questions about lifestyle habits and the Swedish Rheumatic Disease Empowerment Scale (SWE-RES-23) [2]. The 844 patients who answered the SWE-RES-23 made up the study cohort. Differences in empowerment between groups (lowest third [LE], SWE-RES-23 ≤3.48 vs. highest third [HE], SWE-RES-23 ≥4.04) were analysed with t-tests. Logistic regression analysis was used to study associations with LE vs. all others. Thirdly, differences between LE and HE were studied with longitudinal data (seven time points) of pain, HAQ and disease activity.

Results: Responders were mean 65 (SD13) years old, disease duration 15.6 (3.9) years, and 74% were women. The LE group (n=282) were older and were more often women, and reported worse overall health compared with the HE group (n=270), Table 1.

Table 1. Descriptives at questionnaire 2017, including all participants and comparisons between highest and lowest third of SWE-RES-23

	All	Low SWERES*	High SWERES*	p-value
	Mean (sd)	Mean (sd)	Mean (sd)	
N	844	282	270	
Sex, women, %	74	78	69	0.015
Age	65 (13)	66 (13)	63 (12)	0.002
Disease duration, year	15.6 (3.9)	15.7 (4.1)	15.6 (3.8)	0.917
TJC28 (0-28)	5 (6)	6 (8)	4 (5)	<0.001
SJC28 (0-28)	3 (5)	3 (4)	3 (4)	0.334
PatGA (0-10)	3 (2)	4 (3)	2 (2)	<0.001
Pain (0-10)	3 (2)	4 (3)	3 (2)	<0.001
Fatigue (0-10)	4 (3)	5 (3)	3 (3)	<0.001
HAQ (0-3)	0.62 (0.61)	0.81 (0.69)	0.42 (0.51)	<0.001
EQ5D (0-1)	0.70 (0.25)	0.62 (0.29)	0.79 (0.19)	<0.001
SWERES	3.8 (0.7)	3.1 (0.3)	4.6 (0.3)	<0.001

*tricotomized data, lowest third vs. highest third

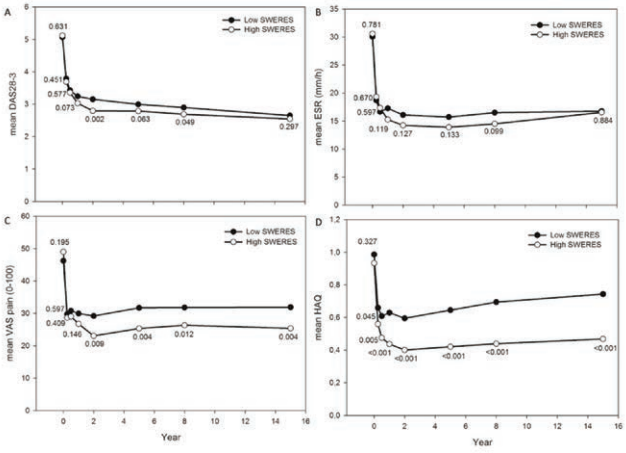

Figure 1. Panel showing mean DAS28-3 (A), ESR (B), VAS pain (C) and HAQ (D) over 15 years in the different groups.

Regarding lifestyle habits, there were no differences between the groups in smoking habits, diets, or drinking habits. Moderate physical activity for ≥150 min/week was reported by 27% in the LE group vs. 41% in the HE group, p<0.001. Vigorous physical activity ≥60 min/week was reported by 22% vs. 37% in the LE and the HE group respectively, p<0.001.
In the logistic regression analysis (n=844), several factors were associated with LE: being a woman (OR 1.40, 95% CI 1.00-1.97), pain-related factors as higher tender joint count (OR 1.04, 95% CI 1.01-1.06), worse patient global assessment (OR 1.19, 95% CI 1.12-1.27), pain (OR 1.14, 95% CI 1.08-1.21), fatigue (OR 1.14, 95% CI 1.09-1.21), HAQ (OR 2.08, 95% CI 1.64-2.64) and EQ-5D (OR 0.16, 95% CI 0.09-0.28). There were also associations between moderate physical activity (<150 min/week) (OR 1.60, 95% CI 1.16-2.19) and vigorous (< 60min/week) (OR 1.50, 95% CI 1.07-2.10) and LE.
Analysing longitudinal data, the LE group reported worse pain and HAQ at all timepoints, a worse DAS28-3 at year 2 and 8, and a worse ESR at 15 years follow-up compared with the HE group (p<0.05).

Conclusion: In patients with RA, low empowerment is associated with worse all over health. Interventions aimed to improve empowerment may include mastering of pain, physical function, and improved physical activity.

Members and Volunteers – Unknown beings? How to explore their interests, establish contacts and support

OP0323-PARE

"CELEBRATING THE 50TH ANNIVERSARY OF OUR ORGANISATION IN TIMES OF PANDEMIC: HOW WE USED DIGITAL TOOLS TO OVERCOME CHALLENGES AND DIFFICULTIES AND CAME INTO CONTACT WITH MORE PARTICIPANTS AND VIEWERS THAN EVER ENVISAGED!"

C. Elling-Audersch[1]. [1]*Deutsche Rheum-Liga Bundesverband, NRW, Solingen, Germany*

Background: The German League against Arthritis (DRL) with about 300.000 members wanted to celebrate its 50th anniversary in 2020. The original idea to perform a large jubilee gala was crossed by the limitation of contact and the precaution for members our organisation in times of pandemic.
Objectives: It was a big challenge to transfer the celebration into a digital form in the pandemic. Our goal was to reach as many people (with RMDs, their family, colleagues, politicians) as possible, not only members of our organisation. We wanted to generate even more awareness for people with RMDs, their needs and difficulties nationwide.
Methods: We decided to focus on digital formats and produced video clips and podcasts that were presented online. Some of the topics of the videos: Voluntary work,

Young people with RMDs, Participation, Doctors and Patients as Partners. Furthermore, in 17 podcasts our member organisations highlighted their activities for people with RMDs. Volunteers vividly described their inside view in the podcasts. In addition, we created a historical timeline for the website. Special highlight was a radio programme based on our videos, summarising our activities that was broadcast by 19 radio stations.
Results: The video clips attracted more viewers than could have been reached with an event in Berlin. For example we generated 35.000 viewers on our YouTube channel by presenting the birthday speech by our president. Altogether we reached successfully approximately 1.5 million people national wide. I will present the numbers of people our activities reached and feedback we received.
Conclusion: We are convinced going on the right track using digital media as one of our priorities not only in times of pandemic but as a valuable enrichment for all RMD patients on national and international level.
These examples of best practise experiences shall encourage other patient organisations to take on the challenge in pandemic times. By using digital tools and formats patient organisations can succeed in reaching more RMD patients and in staying connected with their members.

OP0324-PARE PATIENT INFORMATION IN TIMES OF CRISIS: LESSONS LEARNED FROM COVID-19 COMMUNICATION IN RHEUMATOLOGY

M. M. Bakker[1,2], T. Luttikhuis[1], I. Jansen[1], J. Rademakers[2,3], M. De Wit[4], A. Boonen[1,2], P. Putrik[1,2]. [1]*Maastricht University Medical Centre, Department of Internal Medicine, Rheumatology Division, Maastricht, Netherlands*; [2]*Maastricht University, CAPHRI - Care and Public Health Research Institute, Maastricht, Netherlands*; [3]*Nivel - Netherlands Institute for Health Services Research, -, Utrecht, Netherlands*; [4]*Tools2Use Patient Association, -, Amsterdam, Netherlands*

Background: The rapid global spread of COVID-19 required swift action to provide people with rheumatic and musculoskeletal diseases (RMDs) with reliable information. Important issues included the risk of infection and severe illness, (continued) use of medication, temporary closure of clinics, and organization of (semi-) virtual care. People with limited health literacy are a particularly vulnerable group that might have difficulty accessing, understanding, and applying health information.

Objectives: To evaluate (a) key aspects of crisis communication and (b) explicit consideration of people's health literacy needs in communication to people with RMDs during the first wave of COVID-19 in the Netherlands.

Methods: We conducted an explorative qualitative study including seven interviews in May and June 2020 with representatives of organisations (a mixed regional/academic hospital, the association for RMD professionals and two patient organisations) responsible for information provision to people with RMDs in the Netherlands. Interviewees were asked about preparedness (1) and strategy (2) for crisis communication, and content (3) and reach (4) of communication, considering principles of good crisis communication and health literacy. In addition, through systematic screening of websites, social media and emails, we identified and analysed 13 written communications provided to people with RMDs by these organisations during the first three months of the COVID-19 pandemic. We assessed comprehensibility and applicability with the Dutch adapted version of the Patient Education Materials Assessment tool (PEMAT), the outcome being a percentage of adherence to 24 criteria. We assessed difficulty level using an online assessment application (Figure 1), with Common European Framework of Reference for Languages (CEFR) level B1 being the highest acceptable level.

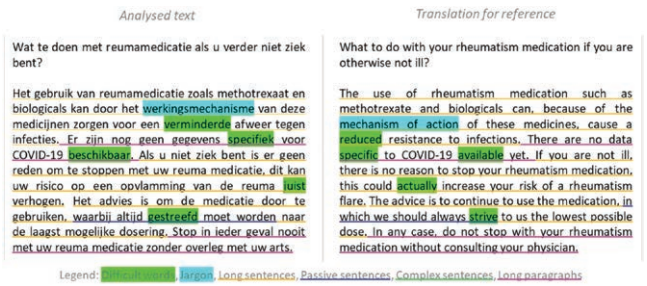

Figure 1. Example of textual assessment using the application. Note: Dutch-language text was used for analysis; the English translation is provided as a reference only and might be of different difficulty.

Results: While admittedly being underprepared, respondents generally perceived their crisis communication as adequate. They quickly adapted to people's needs and changing circumstances and attempted to adapt written and verbal communication to people with limited health literacy. Respondents reported challenges related to the scientific uncertainty, lack of reach, difficulty simplifying information, and being unsure if their communication approach was adequate. Textual assessment showed great variation in applicability (range 60-100%) and comprehensibility (range 58-100%) of these texts, and 69% of communications were more difficult than B1-level. Considering principles of crisis communication and health literacy, we propose several lessons to be learned for future crises (Table 1).

Table 1. Recommendations for improvement of crisis communication

Preparedness:
Use current experience to establish a future crisis communication plan
Train staff and management in crisis communication and health literate communication
Strategy:
Collaborate with relevant organisations to ensure consistency in messages
Inform people early and frequently
Remain transparent about uncertainty
Content:
Adapt information to different people's needs, considering e.g. age, cultural background
Check difficulty level of written information (aim at B1) and adapt accordingly
Ask your audience for feedback
Make sure information is directly applicable in practice
Combat fake news through acknowledgement and counterarguments
Reach:
Use multiple channels
Use diverse outreach strategies to cater to a diverse audience
Overall:
Consider people's health literacy throughout

Conclusion: The rheumatology organisations mostly adhered to principles of crisis communication, and made efforts to adapt information to their audience's needs, including health literacy needs. Nevertheless, important recommendations were drawn which are potentially also relevant for other clinical fields.
Acknowledgements: We thank Mr. Tigran Spaan for providing free access to the online language assessment application.

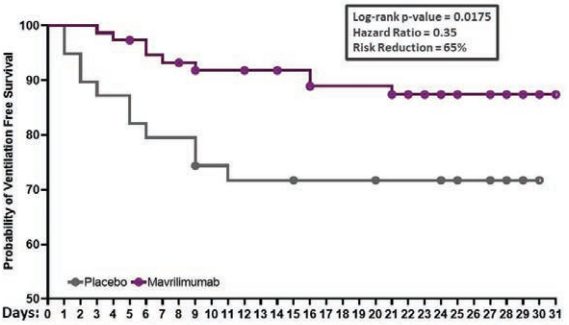
Background: Granulocyte/macrophage-colony stimulating factor (GM-CSF) is a cytokine both vital to lung homeostasis and important in regulating inflammation and autoimmunity[1,2,3] that has been implicated in the pathogenesis of respiratory failure and death in patients with severe COVID-19 pneumonia and systemic hyperinflammation.[4-6] Mavrilimumab is a human anti GM-CSF receptor α monoclonal antibody capable of blocking GM-CSF signaling and downregulating the inflammatory process.
Objectives: To evaluate the effect of mavrilimumab on clinical outcomes in patients hospitalized with severe COVID-19 pneumonia and systemic hyperinflammation.
Methods: This on-going, global, randomized, double-blind, placebo-controlled seamless transition Phase 2/3 trial was designed to evaluate the efficacy and safety of mavrilimumab in adults hospitalized with severe COVID-19 pneumonia and hyperinflammation. The Phase 2 portion comprised two groups: Cohort 1 patients requiring supplemental oxygen therapy without mechanical

ventilation (to maintain SpO_2 ≥92%) and Cohort 2 patients requiring mechanical ventilation, initiated ≤48 hours before randomization. Here, we report results for Phase 2, Cohort 1: 116 patients with severe COVID- 19 pneumonia and hyperinflammation from USA, Brazil, Chile, Peru, and South Africa; randomized 1:1:1 to receive a single intravenous administration of mavrilimumab (10 or 6 mg/kg) or placebo. The primary efficacy endpoint was proportion of patients alive and free of mechanical ventilation at Day 29. Secondary endpoints included [1] time to 2-point clinical improvement (National Institute of Allergy and Infectious Diseases COVID-19 ordinal scale), [2] time to return to room air, and [3] mortality, all measured through Day 29. The prespecified evidentiary standard was a 2-sided α of 0.2 (not adjusted for multiplicity).

Results: Baseline demographics were balanced among the intervention groups; patients were racially diverse (43% non-white), had a mean age of 57 years, and 49% were obese (BMI ≥ 30). All patients received the local standard of care: 96% received corticosteroids (including dexamethasone) and 29% received remdesivir. No differences in outcomes were observed between the 10 mg/kg and 6 mg/kg mavrilimumab arms. Results for these groups are presented together. Mavrilimumab recipients had a reduced requirement for mechanical ventilation and improved survival: at day 29, the proportion of patients alive and free of mechanical ventilation was 12.3 percentage points higher with mavrilimumab (86.7% of patients) than placebo (74.4% of patients) (Primary endpoint; p=0.1224). Mavrilimumab recipients experienced a 65% reduction in the risk of mechanical ventilation or death through Day 29 (Hazard Ratio (HR) = 0.35; p=0.0175). Day 29 mortality was 12.5 percentage points lower in mavrilimumab recipients (8%) compared to placebo (20.5%) (p=0.0718). Mavrilimumab recipients had a 61% reduction in the risk of death through Day 29 (HR= 0.39; p=0.0726). Adverse events occurred less frequently in mavrilimumab recipients compared to placebo, including secondary infections and thrombotic events (known complications of COVID-19). Thrombotic events occurred only in the placebo arm (5/40 [12.5%]).

Mavrilimumab Reduced the Risk of Mechanical Ventilation or Death by 65% Versus Placebo



Mavrilimumab Patients at Risk, n	75	75	75	75	74	73	71	69	68	67	65	65	65	64	64	63	63	59	59	59	59	59	55	52	50	49	47	47	45	38	18	3
Placebo Patients at Risk, n	39	39	37	35	34	34	32	31	31	31	28	28	27	27	27	27	26	26	26	26	26	25	25	25	25	24	22	22	17	14	4	

Conclusion: In a global, diverse population of patients with severe COVID-19 pneumonia and hyperinflammation receiving supplemental oxygen therapy, corticosteroids, and remdesivir, a single infusion of mavrilimumab reduced progression to mechanical ventilation and improved survival. Results indicate mavrilimumab, a potent inhibitor of GM-CSF signaling, may have added clinical benefit on top of the current standard therapy for COVID-19. Of potential importance is that this treatment strategy is mechanistically independent of the specific virus or viral variant.

Background: The consequences of the COVID-19 outbreak are unprecedented and have been felt by everyone around the world, including people with rheumatic and musculoskeletal diseases (RMDs). With the development of vaccines, the future is becoming brighter. Vaccines are a key pillar of public health and have been proven to prevent many serious diseases. However, vaccination also raises questions, especially for patients with inflammatory RMDs and/or treated with drugs that influence their immune system.

Objectives: Our aim was to collect safety data among RMD patients receiving COVID-19 vaccines.

Methods: The EULAR COVID-19 Vaccination (COVAX) Registry is an observational registry launched on 5 February 2021. Data are entered voluntarily by clinicians or associated healthcare staff; patients are eligible for inclusion if they have an RMD and have been vaccinated against SARS-CoV-2. Descriptive statistics are presented.

Results: As of 27 April 2021, 1519 patients were reported to the registry. The majority were female (68%) and above the age of 60 (57%). Mean age was 63 years (SD 16), ranging from 15 to 97 years. A total of 28 countries contributed to the registry, with France (60%) and Italy (13%) as the highest contributors. The majority (91%) had inflammatory RMDs. Inflammatory joint diseases accounted for 51% of cases, connective tissue diseases 19%, vasculitis 16%, other immune mediated inflammatory diseases 4%, and non-inflammatory/mechanical RMDs 9%. The most frequent individual diagnoses were rheumatoid arthritis (30%), axial spondyloarthritis (8%), psoriatic arthritis (8%), systemic lupus erythematosus (SLE, 7%) and polymyalgia rheumatica (6%). At the time of vaccination, 45% were taking conventional synthetic DMARDs, 36% biological DMARDs, 31% systemic glucocorticoids, 6% other immunosuppressants (azathioprine; mycophenolate; cyclosporine; cyclophosphamide; tacrolimus), and 3% targeted synthetic DMARDs. The most frequent individual DMARDs were methotrexate (29%), TNF-inhibitors (18%), antimalarials (10%) and rituximab (6%). The vaccines administered were: 78% Pfizer, 16% AstraZeneca, 5% Moderna and 1% other/unknown; 66% of cases received two doses and 34% one dose. Mean time from 1st and 2nd dose to case report was 41 days (SD 26) and 26 days (SD 23), respectively. COVID-19 diagnosis after vaccination was reported in 1% (18/1519) of cases. Mean time from first vaccination until COVID-19 diagnosis was 24 days (SD 17). Disease flares were reported by 5% (73/1375) of patients with inflammatory RMDs, with 1.2% (17/1375) classified as severe flares. Mean time from closest vaccination date to inflammatory RMD flare was 5 days (SD 5). The most common flare types were arthritis (35/1375=2.5%), arthralgia (29/1375=2.1%), cutaneous flare (11/1375=0.8%) and increase in fatigue (11/1375=0.8%). Potential vaccine side effects were reported by 31% of patients (467/1519). The majority were typical early adverse events within 7 days of vaccination, namely pain at the site of injection (281/1519=19%), fatigue (171/1519=11%) and headache (103/1519=7%). Organ/system adverse events were reported by 2% (33/1519) but only 0.1% (2/1519) reported

severe adverse events, namely a case of hemiparesis in a patient with systemic sclerosis/SLE overlap syndrome (ongoing at the time of reporting), and a case of giant cell arteritis in a patient with osteoarthritis (recovered/resolved without sequelae).

Conclusion: The safety profiles for COVID-19 vaccines in RMD patients was reassuring. Most adverse events were the same as in the general population, they were non-serious and involved short term local and systemic symptoms. The overwhelming majority of patients tolerated their vaccination well with rare reports of inflammatory RMD flare (5%; 1.2% severe) and very rare reports of severe adverse events (0.1%). These initial findings should provide reassurance to rheumatologists and vaccine recipients, and promote confidence in COVID-19 vaccine safety in RMD patients, namely those with inflammatory RMDs and/or taking treatments that influence their immune system.

IMMUNOGENICITY AND SAFETY OF THE BNT162B2 MRNA COVID-19 VACCINE IN ADULT PATIENTS WITH AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES AND GENERAL POPULATION: A MULTICENTER STUDY

V. Furer[1], T. Eviatar[1], D. Zisman[2], H. Peleg[3], D. Paran[1], D. Levartovsky[1], M. Zisapel[1], O. Elalouf[1], I. Kaufman[1], R. Meidan[1], A. Broyde[1], A. Polachek[1], J. Wollman[1], I. Litinsky[1], K. Meridor[1], H. Nochomovitz[1], A. Silberman[1], D. Rosenberg[1], J. Feld[2], A. Haddad[2], T. Gazitt[2], M. Elias[2], N. Higazi[2], F. Kharouf[3], G. Shefer[4], O. Sharon[4], S. Pel[1], S. Nevo[1], O. Elkayam[1]. [1]*Tel Aviv Medical Center, Rheumatology, Tel Aviv, Israel*; [2]*Carmel Medical Center, Rheumatology, Haifa, Israel*; [3]*Hadassah Medical Center, Rheumatology, Jerusalem, Israel*; [4]*Tel Aviv Medical Center, Endocrinology, Tel Aviv, Israel*

Background: Vaccination represents a cornerstone in mastering the COVID-19 pandemic. Data on immunogenicity, efficacy, and safety of the novel BNT162b2 mRNA vaccine in patients with autoimmune inflammatory rheumatic diseases (AIIRD) are limited.

Objectives: To investigate the immunogenicity, efficacy, and safety of the BNT162b2 mRNA vaccine in patients with AIIRD compared to the general population.

Methods: A prospective multicenter study investigated immunogenicity, efficacy, and safety of the two-dose regimen BNT162b2 mRNA vaccine in adult patients with AIIRD including rheumatoid arthritis (RA), psoriatic arthritis (PsA), axial spondyloarthropathy (axSpA), systemic lupus erythematosus (SLE), connective tissues diseases (CTD), systemic vasculitides, and idiopathic inflammatory myositis (IIM), compared to control subjects without rheumatic diseases or immunosuppressive therapies. Serum IgG antibody levels against SARS-CoV-2 spike S1/S2 proteins were measured 2 - 6 weeks after the second vaccine dose. Seropositivity was defined as IgG ≥15 binding antibody units (BAU)/ml. Post-vaccination efficacy defined as post-vaccination COVID-19 infection and safety were assessed. Pre- and post- vaccination disease activity indices were assessed as appropriate for each disease.

Results: A total of 686 AIIRD patients and 121 controls participated into the study. AIIRD patients were significantly older than controls, mean age±SD 56.76±14.88 vs 50.76±14.68, respectively, p<0.0001. A total of 95.2% (n=653) AIIRD patients were treated with immunomodulatory medications.

The seropositivity rate was 86% (n=590) in patients with AIIRD compared to 100% in controls (p <0.0001) The level of the S1/S2 antibodies was significantly reduced in AIIRD patients compared to controls (mean± SD 132.9±91.7 vs 218.6±82.06, P<0.0001). In patients with PsA, AxSpA, SLE, and LVV, the seropositive rate was above 90%. In RA, the seropositive rate was 82.1% and the lowest seropositive rate (<40%) was observed in patients with AAV and IIM.

Anti-CD20 significantly impaired the vaccine's immunogenicity, with the lowest seropositivity rate of 39%. The use of GC, mycophenolate mofetil (MMF), and abatacept was associated with a significantly lower rate of seropositivity (Figure 1). MTX significantly reduced the seropositivity in patients treated with MTX monotherapy and in combinations with other treatments (92% and 84%, respectively), although at a lesser magnitude than anti-CD20, MMF, and abatacept. More than 97% of patients treated with anti-cytokine therapies including TNFi, interleukin-17 and interleukin-6 inhibitors had an appropriate immunogenic response when used as monotherapy. The combination of TNFi with MTX significantly reduced the rate of seropositivity to 93%, p=0.04. Age over 65 years, a diagnosis of RA, IIM, ANCA-associated vascilitis, and treatment with GC, MMF, anti-CD20, and abatacept were associated with a reduced likelihood of seropositivity.

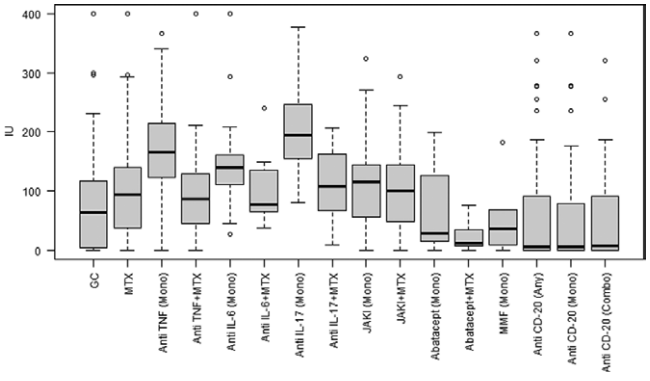

Figure 1. Seropositivity rate by immunosuppressive treatment.

There were no post-vaccination symptomatic cases of COVID-19 among AIIRD patients and one mild case in the control group. Major adverse events in AIIRD patients included death (n=2) several weeks after the second vaccine dose, non-disseminated herpes zoster (n=6), uveitis (n=2), and pericarditis (n=1). Post-vaccination disease activity remained stable in the majority of patients.

Conclusion: Vaccination with the BNTb262 vaccine resulted in an adequate immunogenic response with an acceptable safety profile in the majority of patients with AIIRD. Treatment with GC, rituximab, MMF, and abatacept may impair BNT162b2-induced immunogenicity. Postponing administration

of rituximab, when clinically feasible, seems to be reasonable to improve vaccine-induced immunogenicity. Holding treatment with abatacept and MMF may be considered on an individual basis.

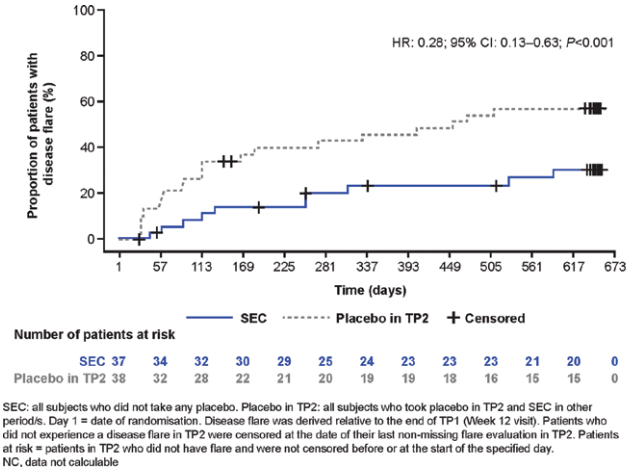
Background: Enthesitis-related arthritis (ERA) and juvenile psoriatic arthritis (JPsA) are two ILAR categories of juvenile idiopathic arthritis (JIA) and represent paediatric correlates of axial spondyloarthritis (axSpA) and adult psoriatic arthritis (PsA), respectively.[1,2] Secukinumab (SEC) has demonstrated efficacy and safety in adult patients (pts) with PsA, ankylosing spondylitis and non-radiographic axSpA.[3-5]

Objectives: Evaluate efficacy and safety of SEC using a flare prevention design in pts with active ERA and JPsA.

Methods: This 2-yr study consisted of an open-label (OL) s.c. SEC (75/150 mg in pts <50/ ≥50 kg) at baseline (BL), and at Weeks (Wk) 1, 2, 3, 4, 8 and 12 in treatment-period (TP) 1. Responder pts who achieved at least JIA ACR 30 response at Wk 12 were randomised into the double-blinded TP2 to continue SEC or placebo (PBO) q4w until a disease flare, or up to Wk 100. Pts (aged 2 to <18 yrs) classified as ERA or JPsA according to ILAR criteria of ≥6 months duration with active disease were included. Primary endpoint was time to flare in TP2 and key secondary endpoints were JIA ACR 30/50/70/90/100, inactive disease, JADAS, enthesitis count and safety. Analysis of time to flare in TP2 included proportion of disease flare, Kaplan-Meier (KM) estimate of median time to flare in days, hazard ratio (95% CI) from Cox model, and *P*-value for the Stratified log-rank test. KM estimates of the probability to disease flare by treatment groups in TP2 were plotted against days. Observed data were used in all analyses. Post-hoc analyses using non-responder imputation (NRI) were performed for JIA ACR 30/50/70/90/100 responses.

Results: 86/97 (89%) pts were enrolled in the OL period TP1 (mean age, 13.1 yrs; female, 33.7%; ERA, n=52; JPsA, n=34). At BL, mean JADAS-27 score was 15.1 and enthesitis count was 2.6. At the end of TP1, 90.4% (75/83) of pts achieved JIA ACR 30 and 69.9% (58/83) achieved JIA ACR 70. There were 21 and 10 flares in TP2, respectively in PBO and SEC treated pts with a significantly longer time to flare and 72% risk of flare reduction in SEC treatment vs PBO (HR: 0.28; 95% CI: 0.13–0.63; *P*<0.001) (Figure 1). JIA ACR responses, disease activity and enthesitis count are reported in Table 1. NRI analyses showed that 87.2%, 83.7%, 67.4%, 38.4% and 24.4% of pts achieved JIA ACR 30/50/70/90/100, respectively. Rates of adverse events (AEs; 91.7% vs 92.1%) and serious AEs (14.6% vs 10.5%) in SEC and PBO groups were comparable in the entire TP. No new safety signals were observed.



SEC: all subjects who did not take any placebo. Placebo in TP2: all subjects who took placebo in TP2 and SEC in other period/s. Day 1 = date of randomisation. Disease flare was derived relative to the end of TP1 (Week 12 visit). Patients who did not experience a disease flare in TP2 were censored at the date of their last non-missing flare evaluation in TP2. Patients at risk = patients in TP2 who did not have flare and were not censored before or at the start of the specified day.
NC, data not calculable

Adaptive immunity (T cells and B cells) in rheumatic diseases

POS0001 PHENOTYPE AND FUNCTIONAL CHARACTERISTICS OF ANTIGEN-SPECIFIC, AUTO-REACTIVE B CELL RESPONSES REVEAL DIFFERENTIAL IMMUNOLOGICAL ACTIVITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

C. Wortel[1], N. Van Leeuwen[1], S. Liem[1], M. Boonstra[1], C. Fehres[1], T. Huizinga[1], R. Toes[1], J. De Vries-Bouwstra[1], H. U. Scherer[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: Systemic Sclerosis (SSc) is a systemic autoimmune disease that carries the highest mortality burden among the rheumatic diseases. Disease risk and course are difficult to predict in individual patients, and anti-inflammatory and B-cell depleting therapies show varying results. >95% of SSc patients harbor autoantibodies. Among those, anti-topoisomerase antibodies (ATA) and anti-centromere antibodies (ACA) are most prevalent, mutually exclusive in individual patients and associate with distinct disease phenotypes. Despite these associations, the clinical value of both ATA and ACA for patient stratification within these phenotypes is limited. Here, we hypothesized that phenotypic and functional characteristics of the underlying autoreactive B cell responses could allow insights in differential 'immunological disease activity' in individual patients, thereby providing indications as to potential drivers of these responses as well as granularity as to which patients may benefit from targeted interventions.
Objectives: To assess phenotypic and functional characteristics of anti-topoisomerase and anticentromere specific B cell responses in individual patients with SSc.
Methods: Peripheral blood mononuclear cells (PBMC) from ATA- and ACA-positive SSc patients were cultured without stimulation or in the presence of CD40L-expressing fibroblasts, IL-21 and BAFF. Following culture, ATA- and ACA-IgG and -IgA were measured in culture supernatants by ELISA. In addition, PBMC were depleted of circulating plasmablasts by fluorescence activated cell sorting (FACS), and isolated plasmablasts were cultured separately. Furthermore, the presence of antigen-specific plasmablasts was confirmed by ELISPOT. Finally, the degree of spontaneous ATA secretion was correlated to the presence or absence of interstitial lung disease (ILD; based on high-resolution computed tomography). Healthy donors and patients with rheumatoid arthritis served as controls.
Results: We observed that individual ATA- and ACA-positive SSc patients harbored circulating B cells that secrete either ATA-IgG or ACA-IgG upon stimulation, depending on their serotype. In addition, we noted spontaneous secretion of ATA-IgG and, more remarkably, extensive secretion of ATA-IgA in ATA-positive patients. This degree of spontaneous, antigen-specific IgA secretion was specific for the ATA response, while spontaneous ACA-IgA secretion was undetectable in patients harboring ACA. FACS experiments and ELISPOT showed that the spontaneous ATA-IgA and -IgG secretion was attributable to circulating plasmablasts. Of note, the degree of spontaneous ATA-IgG secretion was remarkably higher in patients with ILD than in those without.
Conclusion: Our findings demonstrate that individual ATA-positive SSc patients harbor activated ATA-IgG and ATA-IgA B cell responses, as indicated by the spontaneous secretion of both ATA isotypes by circulating plasmablasts. Importantly, by taking the presence of plasmablasts as a proxy for recent B cell activation, our data suggest a link between the activity of the antigen-specific B cell response and the presence of ILD. In contrast, the ACA B cell response was far less active and lacked the active IgA component, which suggests a difference in the triggers driving these autoreactive B cell responses in patients. In fact, the remarkable ATA-IgA secretion points towards a potential mucosal trigger of the ATA response, which may be continuously active in individual patients.

POS0002 PI16 REPRESSES FOXP3 EXPRESSION IN T REGULATORY CELLS AND EXACERBATES AUTOIMMUNE ARTHRITIS VIA INHIBITING THE K48-LINKED POLYUBIQUITIN DEGRADATION OF BMI-1

S. Lin[1], X. Gu[1,2], F. Wang[3], W. Tan[1]. [1]*The First Affiliated Hospital of Nanjing Medical University, China, Department of Rheumatology, Nanjing, China;* [2]*The Affiliated Hospital of Jiangnan University, Department of Cardiology, Wuxi, Jiangsu, China;* [3]*The First Affiliated Hospital of Nanjing Medical University, China, Department of Cardiology, Nanjing, China*

Background: Regulatory T cells (Tregs) play an essential role in maintaining self-tolerance and immune homeostasis. Abnormalities in the quantity or function of Treg cells are believed in RA patients, contributing to the inability to suppress autoimmunity and proinflammatory cytokines. Forkhead box P3 (Foxp3) is a crucial transcription factor for the development and differentiation of Tregs. How Tregs lose Foxp3 expression under inflammatory milieu remains largely unknown. Peptidase inhibitor 16 (PI16) is a member of the CAP (Cysteine-rich secretory proteins, Antigen 5, and Pathogenesis-related 1) protein family and its function are largely poor understood. In a genome-wide expression profiling study for identifying human Foxp3 target genes revealed PI16 was expressed on the cell surface of >80% of resting human $CD25^+$ $Foxp3^+$ Tregs. In the inflamed joint of juvenile idiopathic arthritis revealed a low number of $PI16^+$ Tregs but high number of Th17 cells. However, little is known the function role of PI16 on Tregs or on RA development.
Objectives: To investigate the role of peptidase inhibitor 16 (PI16) on the key T regulatory (Tregs) cells transcription factor Foxp3 expression and on the development of autoimmune arthritis.
Methods: The expression of PI16 in blood, synovial fluid, inflamed joints were examined in Rheumatoid arthritis (RA) patients and in arthritic mice. Arthritis symptom, histological features and Foxp3 expression in PI16 transgenic ($PI16^{Tg}$) arthritic mice were examined. Posttranslational mechanisms on PI16-mediated Foxp3 expression were analyzed. The specific role PI16 on Foxp3 expression was validated in conditional knockout (KO) mice.
Results: The expression of PI16 was significantly increased in PBMC, serum, synovial tissue from RA patients or arthritic mice compared with controls. $PI16^{Tg}$ arthritic mice exhibited obvious inflammation, synovial hyperplasia and articular cartilage destruction in the joints compared with those in wild-type mice (WT) arthritic mice.
Foxp3 is downregulated in splenic T cells and synovial tissue from $PI16^{Tg}$ arthritic mice. Naïve T cells derived from $PI16^{Tg}$ arthritic mice showed the decreased capacity to differentiate into Tregs. Polycomb-group (PcG) proteins complex molecule of Bmi-1 was significant increase in Tregs and joint tissue from $PI16^{Tg}$ arthritic mice. A direct interaction between 1-95AA domains of PI16 and 169 and 436 domains of Bmi-1 in Tregs promoter was observed. The binding of PI16 with Bmi-1 in the Foxp3 promoter inhibit the K48-linked polyubiquitin degradation of Bmi-1 at lysine site 72 and 153 region, which prompts the repressive histone modification of H3K27me3 and H2AK119ub, and inhibits the active histone modification of H3K4me3. Furthermore, conditional knockout of PI16 in Tregs retarded Foxp3 loss and blunted disease progression in experimental arthritis.
Conclusion: PI16 represses Foxp3 expression by mediating histone modification via inhibiting K48-linked polyubiquitin degradation of Bmi-1 in Foxp3 promoter, contributing to disease progression in arthritic mice.

POS0003 RITUXIMAB THERAPY IN SYSTEMIC LUPUS ERYTHEMATOSUS – TRANSIENT EFFECTS ON AGE ASSOCIATED B-CELLS

F. Faustini[1,2], N. Sippl[1], R. Stålesen[1], K. Chemin[1], I. Gunnarsson[1,2], V. Malmström[1]. [1]*Karolinska Institutet, Department of Medicine, Solna, Division of Rheumatology, Centre of Molecular Medicine, Stockholm, Sweden;* [2]*Karolinska University Hospital, Rheumatology, Stockholm, Sweden*

Background: Immune system's abnormalities in SLE involve several subsets of the B-cell compartment, including double negative B-cells (DN) and CD11c+CD21- B cells (also referred to as ABC-age associated B cells), which are expanded in the disease. ABC cells are also known to interact with T helper cells, T follicular and peripheral helper cells (1). Rituximab, a chimeric anti- CD20 antibody, depleting B cells, is commonly used off-label as treatment for SLE patients, especially in lupus nephritis. Little is known on the impact of B-cell depletion on such B-cell subsets and on B-T-cell interactions.
Objectives: to investigate the effects of rituximab (RTX) on the frequencies of double negative B-cell subsets and CD11c+CD21- ABC cells and as well as T follicular helper (T_{FH}, CXCR5+ PD-1+) and T peripheral helper (T_{PH}, PD-1^{high}) CD4+ T-cell subsets.
Methods: 15 SLE patients, starting RTX and followed longitudinally up to two years, were analyzed for lymphocyte subsets using multicolor flow cytometry. Cryopreserved PBMC were thawed and stained at the same time together with one buffy coat. Around 1 x 10^6 PBMC for each panel were labeled and further stained with fluorescent antibodies for B and T-cell markers. For the B-cell panel, PBMC were stained with anti-CD3, CD14, CD16, CD19, IgD, CD27, CD38, CD11c, CD21 and in some samples with anti-CXCR5 antibodies. For the T-cell panel, PBMC were labeled with anti-CD16, CD14, CD19 and CD3, CD4, CD8,

PD-1, CCR7, CXCR5, CD45RA antibodies. All patients fulfilled the ACR 1982 classification criteria for SLE. Cellular changes were analyzed in the context of clinical information.

Results: in the present cohort, the SLE patients were mainly female (86.6%) and of median age of 36.7 (29.8-49.4) with a disease duration of 6.1(1.6-11.8) years, and active disease with SLEDAI-2K at baseline 12.0 (8.0-16.0). The frequency of age-associated B cells (ABCs; CD27-IgD-CD11c+ CD21-) decreased by 13% (p=0.03) in the first two to four months after rituximab start, while globally the DN (IgD-CD27-) B cells transiently increased by around 3% (p=0.15) at the first follow-up. This increase could not be attributed to the DN1 (CXCR5+CD11c-) or DN2 (CXCR5-CD11c+) subsets but to the CD11c-CXCR5- DN (DN3) B cells (increase= 6.7%, p=0.03). In parallel, T effector cells (CCR7- CD45RA+) and TEMRA (CD45RA+ CCR7-) frequencies increased after first follow up in both CD4+ and CD8+ T cells. The frequency of T_{FH} (CXCR5+ PD-1+) cells did not change after rituximab, however a decrease of PD-1^{high} CD4+ cells was observed in most patients, although not significant, after 2-4 month of treatment. In most patients the frequency of PD-1^{high} CD4+ cells either reduce or stay the same after RTX treatment (reduction= 0.53, p=0.28). After 11-15 months of RTX treatment the frequency of PD-1^{high} CD4+ T cell reduces by a -0.5% in comparison to 2-4 months (p=0.039). The SLEDAI at baseline did not correlate with the frequency of PD-1^{high} CD4+ T cells (r=0.03, p=0.9).

Conclusion: the importance of T cell - B cell interactions in SLE pathogenesis was recently strengthened by the identification of the lymphocyte subsets T_{FH}/T_{PH} and ABCs respectively. Here, in the context of rituximab treated SLE, we could detect a reduction in the frequencies of both ABCs and PD-1^{high} T cells after treatment with rituximab, while the DN3 and effector memory T cells frequencies increased. Our data suggests that anti-CD20 mediated B-cell depletion affects both B-cell and T-cell subsets frequencies, and that monitoring these specific cell subsets may be clinically relevant.

POS0004 T-CELL REPERTOIRE OF SYNOVIAL FLUID IN SPONDYLOARTHROPATHIES EXHIBITS HALLMARKS OF HLA-DEPENDENT CLONAL EXPANSIONS AND REMAINS STABLE OVER 1.5 YEARS

E. Komech[1], A. Koltakova[2], E. Shmidt[3], A. Barinova[1,4], M. Salnikova[1], A. Minervina[1], T. Korotaeva[2], Y. Lebedev[1], I. Zvyagin[1,4]. *[1]Shemaykin-Ovchinnikov Institute of Bioorganic Chemistry, Laboratory of Comparative and Functional Genomics, Moscow, Russian Federation; [2]Nasonova Research Institute of Rheumatology, Lab of Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation; [3]Pirogov Russian National Research Medical University, City Clinical Hospital #1, Moscow, Russian Federation; [4]Pirogov Russian National Research Medical University, Institute of Translational Medicine, Moscow, Russian Federation*

Background: Different studies show involvement of T-cells in pathogenesis of spondyloarthropathies (SpAs) - a group of rheumatic diseases strongly associated with presence of several MHC-I alleles (HLA-B*27, -B*38, -B*39, etc). Recently we and others identified a specific T-cell receptor motif in blood and synovial fluid of HLA-B*27+ AS patients that reinforces the “arthritogenic peptide” hypothesis of AS pathogenesis [1-2]. However, common characteristics of clonal T-cell repertoire of synovial fluid in SpAs remain poorly investigated.

Objectives: We aimed to investigate synovial fluid T-cell repertoires of SpA patients with different HLA-genotypes and stability of the clonal composition in recurring flares of the disease.

Methods: Mononuclear cells were isolated from paired peripheral blood (PB) and synovial fluid (SF) samples of SpA patients (ankylosing spondylitis and psoriatic arthritis, n=27). For 3 patients additional SF samples were collected during relapse of the synovitis (after 9-15 months). CD4 and CD8 T-cells were isolated by immunomagnetic separation. Deep sequencing of UMI-tagged TCR beta cDNA libraries was used to accurately reconstruct clonal T-cell repertoires. HLA class I and II were typed for each donor using an in-house NGS-based system.

Results: We observed restricted T-cell clonal composition in synovial fluid: on average only 6% of PB T-cell clonotypes were detected in SF of the same donor. T-cell repertoires of both CD4 and CD8 SF subsets compared to PB were highly oligoclonal (index Gini PB vs SF: CD4 0.36±0.10 vs 0.68±0.08, CD8 0.57±0.17 vs 0.81±0.12) in all patients. Number of identical amino acid CDR3 sequences between two repertoires correlated with the number of identical HLA-alleles for the donors. This trend was exhibited more strikingly in SF compared to PB, suggesting that common antigens may play a role in accumulation of identical T-cell clonotypes in the inflamed joint. Using several bioinformatic approaches we identified groups of highly similar SF clonotypes linked to HLA-B*27 and/or HLA-B*38 genotype.

Total SF repertoires of relapsing synovitis of the same donor showed huge clonal overlap, and the most frequent clonotypes remained almost unchanged (Morisita’s overlap index for total SF repertoires 0.69±0.26; for top 1000 clonotypes 0.79±0.19, n=3).

Conclusion: We report HLA-dependent sharing of identical and similar T-cell clonotypes in SF of patients with ankylosing spondylitis and psoriatic arthritis and high stability of SF repertoire during several flares that support antigen-driven accumulation of T-cells in the site of inflammation.

POS0005 THE EFFECT OF LKB1 INHIBITION IN RA PATHOGENESIS

H. R. Lee[1,2], J. Kim[2], S. J. Yoo[2], J. A. Park[2], S. W. Kang[1,2]. *[1]Chungnam National University School of Medicine, Research Institute for Medical Sciences, Daejeon, Korea, Republic of (South Korea); [2]Chungnam National University Hospital, Department of Internal Medicine, Daejeon, Korea, Republic of (South Korea)*

Background: Liver kinase B1 (LKB1) is known as a tumor suppressor gene and also inhibits reactive oxygen species (ROS) levels. Intracellular ROS are catalyzed by the enzyme complex nicotinamide adenine dinucleotide phosphate (NADPH) oxidase (NOX). We previously reported that NOX4 induced the migration and invasion of fibroblast-like synoviocytes (FLS) in rheumatoid arthritis (RA). Although LKB1 is expected to alleviate synovial inflammation through ROS regulation, the role of LKB1 in RA has not been examined.

Objectives: To explore whether LKB1 affects RA inflammation, we transfected LKB1 siRNA and analyzed related gene expressions in RA FLS.

Methods: Synovial tissues were obtained from RA patients who were undergoing synovectomy or joint replacement. The isolated cells were cultured in Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 10% fetal bovine serum, 100 U/ml penicillin and 100 mg/ml streptomycin and maintained in a 5% CO_2 incubator at 37 °C. FLS were used for experiments after four to six passages. Cells were transfected with lipofectamine transfection reagent and LKB1 siRNA duplex targeting constructs. After incubation for 24 h, downregulation of target expression was evaluated by real-time PCR and western blot analysis.

Results: RA FLS was transfected with LKB1 siRNA and 90% of LKB1 mRNA expression was decreased. LKB1 knock-down also caused the decreased expression of mechanistic target of rapamycin (mTOR; 0.38 fold) and serine/threonine kinase (AKT) 2 (0.40 fold), which are downstream targets of LKB1. NOX4 was significantly increased (4.94 fold) by LKB1 inhibition. On the other side, the down regulated NOX4 induced significantly elevated LKB1 mRNA expression in RA FLS. When the expressions of proinflammatory cytokines were examined, IL-1β, IL-6, TNF-α were highly increased by LKB1 deficiency. FLS migration-related chemokines, IL-8 and MMP-3 were also enhanced compared to control.

Conclusion: There was a negative correlation between NOX4 and LKB1 in RA FLS. As LKB1 deficiency induced the expression of proinflammatory cytokines and migration related chemokines, LKB1 could play a critical role in RA pathogenesis.

POS0006 NX-5948, A SELECTIVE DEGRADER OF BTK, SIGNIFICANTLY REDUCES INFLAMMATION IN A MODEL OF AUTOIMMUNE DISEASE

D. Robbins[1], M. Noviski[2], M. Tan[3], C. Guiducci[2], T. Ingallinera[4], D. Karr[4], A. Kelly[2], Z. Konst[1], A. Tenn-Mcclellan[2], J. Mckinnell[4], L. Perez[2], G. Hansen[5], R. Rountree[2]. *[1]Nurix Therapeutics, Medicinal Chemistry, San Francisco, United States of America; [2]Nurix Therapeutics, Discovery Biology, San Francisco, United States of America; [3]Nurix Therapeutics, Translational Medicine, San Francisco, United States of America; [4]Nurix Therapeutics, Preclinical*

Development, San Francisco, United States of America; [5]Nurix Therapeutics, Nurix Therapeutics, San Francisco, United States of America

Background: Aberrant activation of B cells and autoantibody mediated tissue damage are hallmarks of autoimmune diseases such as systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). Therefore, novel treatments that prevent autoantibody generation or antibody-mediated end organ tissue damage are of high interest. Bruton's tyrosine kinase (BTK) transduces signals downstream of the B cell receptor (BCR), toll-like receptors, and Fc receptors in B cells and myeloid cells [1]. Overexpression of BTK in B cells leads to hyperactive BCR signaling, plasma cell generation, autoantibody secretion, and an SLE-like disease in mice [2]. Conversely, reducing BTK expression in B cells can ameliorate disease in Lyn-deficient mice.[3] BTK inhibitors, such as evobrutinib, have entered clinical studies for the treatment of autoimmune diseases.[4]

Objectives: Small molecule-induced protein degradation offers a unique approach to target BTK; this approach simultaneously eliminates both BTK kinase activity and BTK-mediated scaffolding interactions in the signalosome. Chimeric Targeting Molecules (CTMs) are small molecules that catalyze ubiquitylation and proteasomal degradation of target proteins and are comprised of a ubiquitin ligase binding element ("harness"), a linker, and a target binding element ("hook"). NX-5948 is a CTM that contains a BTK hook linked to a cereblon (CRBN) harness. We examined the activity of NX-5948 in a collagen-induced arthritis model as part of an assessment of its potential as a drug candidate for autoimmune disease.

Methods: Cellular degradation of BTK, Aiolos and Ikaros as well as induction of CD69 and CD86 was determined using flow cytometry. Degradation of BTK in CD-1 mice or cynomolgus monkey was determined using flow cytometry analysis. In a collagen-induced arthritis (CIA) model, mice were vaccinated with type II collagen and treated before the onset of symptoms. Serum cytokine and anti-type II collagen antibody levels were determined using Luminex and ELISA, respectively.

Results: In human PBMCs, NX-5948 degrades BTK at sub-nanomolar concentrations and inhibits BCR signaling as measured by CD69 and CD86 induction in anti-IgM-stimulated B cells with similar potency. Oral administration of NX-5948 in mice leads to BTK degradation to <10% of baseline levels in circulating and splenic B cells. NX-5948 also promotes potent BTK degradation in cynomolgus monkeys, and it can suppress BTK levels to <10% of baseline levels after a single oral dose as low as 10 mg/kg.

Unlike IMiD drugs such as lenalidomide, the CRBN harness of NX-5948 was designed to avoid the degradation of known CRBN neo-substrates Aiolos (IKZF3) and Ikaros (IKZF1). In primary human T cells, NX-5948 induces minimal degradation of Aiolos and Ikaros and does not promote IL-2 secretion suggesting that NX-5948 does not convey IMiD activity associated with agents such as lenalidomide.

We examined the activity of NX-5948 in a mouse CIA model compared to that of the BTK inhibitor ibrutinib or dexamethasone as a positive control. In mice treated with NX-5948, symptoms of arthritis were resolved, and a significant reduction in arthritis clinical score was observed. Treatment with NX-5948 resulted in a reduction in anti-type II collagen titer and serum levels of the pro-inflammatory cytokine IL-6. Treatment with NX-5948 yielded superior anti-inflammatory activity relative to ibrutinib and similar activity to dexamethasone. Treatment with NX-5948 was well-tolerated and, unlike dexamethasone, did not promote body weight loss.

Conclusion: Degradation of BTK by NX-5948 shows robust activity in a CIA model compared to existing agents tested as controls. These findings provide support for further investigation of NX-5948 in additional models of autoimmune disease to inform plans for clinical development.

LOSS OF BALANCE BETWEEN PROTECTIVE AND PRO-INFLAMMATORY SYNOVIAL TISSUE T CELL POLYFUNCTIONALITY PREDATES CLINICAL ONSET OF RHEUMATOID ARTHRITIS

A. Floudas[1], N. Neto[2], M. Canavan[1], T. Mcgarry[1], V. Krishna[3], S. Nagpal[3], M. Monaghan[2], D. Veale[4], U. Fearon[1]. *[1]Trinity Biomedical Sciences Institute, Molecular Rheumatology, Dublin, Ireland; [2]Trinity Biomedical Sciences Institute, Mechanical and Manufacturing Engineering, Dublin, Ireland; [3]Janssen Research & Development, Immunology, Spring House, United States of America; [4]St Vincent's University Hospital, UCD, EULAR Centre of Excellence, Centre for Arthritis and Rheumatic Diseases, Dublin, Ireland*

Background: Effective treatment of Rheumatoid arthritis (RA) patients is achievable within a short window of opportunity following diagnosis. T-cells are early drivers of synovial inflammation of RA, therefore, identification of pathogenic T-cell subsets at the synovial tissue of pre-RA, arthralgia subjects, would greatly improve our understanding of disease pathogenesis. Comparative analysis of healthy control, arthralgia subject and RA-patient derived synovial tissue T-cell responses will lead to the identification of pathogenic as well as protective cytokine milieu, thus enabling the identification of early therapeutic targets to help steer the immune response towards resolution.

Objectives: Characterization of T-cell polyfunctionality in the periphery and synovial tissue of 'at-risk; subjects (Arthralgia) RA-patients and healthy controls (HC).

Identification of specific, pathogenic, synovial tissue T-cell subsets.

Methods: Synovial biopsies from RA, AR and HC were obtained by arthroscopic surgery followed by RNAseq analysis (Guo et al., PLoS One, 2018). Single cell synovial tissue cell suspensions from RA, AR and HC and paired PBMC were stimulated *in vitro* and polyfunctional synovial T-cell subsets examined by flow cytometric analysis, SPICE visualization and FlowSom clustering. Flow-Imaging, was utilised to confirm specific T-cell cluster identification. Fluorescent Lifetime Imaging Microscopy (FLIM) was used to visualise metabolic status of specific T-cell populations.

Results: T-cell associated pro-inflammatory gene pathways were increased in RNAseq analysis of RA-patient and arthralgia subject compared to HC synovial tissue biopsies. Flow cytometric analysis of pro-inflammatory cytokine (TNF-α, IFN-γ, IL-2, GM-CSF, IL-17A, IL-22) production and SPICE analysis of *ex vivo* stimulated T-cells revealed marked polyfunctionality of arthralgia subject synovial T-cells, thus providing evidence for a dysregulated synovial T-cell response that pre-dates clinical onset of disease. Importantly, HC synovial tissue harbours a small, albeit surprisingly polyfunctional, CD4 T-cell population characterised

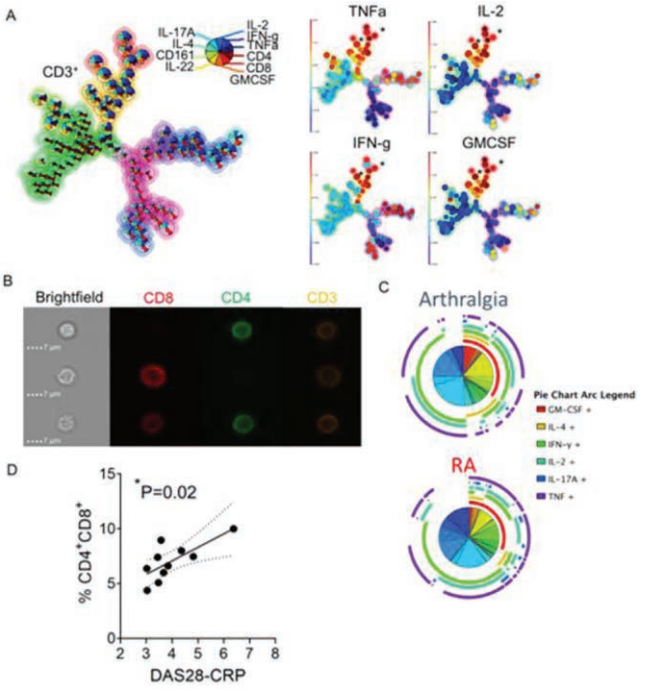

Figure 1. Identification of highly polyfunctional and pro-inflammatory synovial DP T-cells. A. Cluster analysis of RA-patient synovial tissue T-cells (asterisks indicate DP T-cell clusters). B. Flow imaging of $CD4^+$, $CD8^+$ and DP synovial T-cells. C. SPICE flow cytometric data visualization of DP arthralgia subject and RA-patient synovial T-cells. D. Correlation between the frequency of RA-patient synovial DP T-cells and disease severity.

by significantly increased IL-4 and GM-CSF cytokine production compared to arthralgia subject (P<0.001 and P=0.01) and RA-patient (P<0.001 and P=0.004) synovial tissue. However, not all polyfunctional T-cells are equal in their pathogenic potential. Therefore, in order to identify highly pathogenic synovial T-cells, cluster analysis of flow cytometric data using the unsupervised algorithm FlowSom was performed and led to the identification of specific T-cell clusters with unique polyfunctionality characteristics. Specifically a cluster of $CD4^+CD8^+$ double positive (DP) T-cells with high polyfunctionality scores was identified. Hybrid flow cytometry and imaging technique confirmed the co-expression of CD4 and CD8 by a synovial T-cell population. DP T-cells are enriched in RA-patient synovial fluid and synovial tissue and arthralgia subject synovial tissue, but are absent from HC synovial tissue. Importantly, DP T-cell synovial accumulation strongly (P=0.002) correlates with DAS28(CRP) of RA-patients. Initial studies utilising the novel, non-invasive FLIM technique for visualisation of cellular NAD, revealed that DP T-cells have a metabolic profile indicative of activated memory T-cells.

Conclusion: These data highlight a key early loss of balance between protective and pathogenic synovial T-cell polyfunctionality and the emergence of specific, highly polyfunctional and pathogenic T-cell clusters in RA.

POS0008 IDENTIFICATION AND CHARACTERIZATION OF HISRS+ CD4+ T CELLS PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

B. Horuluoglu[1], A. S. Galindo-Feria[1], K. Chemin[1], G. Kozhukh[1,2], A. Dubnovitsky[1,2], V. Malmström[1], I. E. Lundberg[1]. *[1]Karolinska Insitutet, Division of Rheumatology, Center for Molecular Medicine, Department of Medicine, STOCKHOLM, Sweden; [2]Karolinska Insitutet, Science for Life Laboratory, Department of Medicine, Stockholm, Sweden*

Background: Idiopathic inflammatory myopathies (IIM) also known as myositis, are rare chronic autoimmune disorders which are represented by muscle weakness and extra-muscular features such as skin rash, interstitial lung disease (ILD) and arthritis. One of the most common autoantibodies in myositis, with a prevalence of 25-35%, is the anti Jo-1 autoantibodies, targeting the histidyl-transfer RNA synthetase (HisRS). Although the exact mechanism of how these antibodies are developed is unknown, we have previously shown that upon stimulation of both peripheral blood mononuclear cells (PBMC) and bronchoalveolar lavage fluid cells (BALF) with HisRS protein, $CD4^+$ T cells were activated and produced inflammatory cytokines. Hitherto the presence of antigen specific autoreactive T cells has not been established in myositis, however previous studies by our group showed a strong indication of their presence with a reactivity to a specific HisRS peptide.

Objectives: The main aim of this project is to detect and characterize HisRS specific $CD4^+$T cells using HLA Class II tetramers. HLA Class II tetramers allow the detection of rare antigen specific CD4+ T cells and are widely used in studies of immunity, vaccine development, allergy monitoring and in autoimmunity. These cells are of specific interest to understand autoimmunity and to develop new therapies in autoimmune diseases

Methods: HLA-DRB1*03:01 monomers with selected tetanus and HisRS peptides were in-house in *E.coli* system. The peptides of interest were attached to the N-terminus of the HLA b-chain *via* a flexible peptide linker. HLA-tetramers were assembled using a commercial fluorescently labeled streptavidin. The efficacy of the peptide-HLA tetramers was validated by stimulating PBMCs from HLA-matched healthy controls with tetanus peptide. The drequency of tetanus specific $CD4^+$ T cells were detected at different time points (6,13 and 21 days) from the cultures using tetanus peptides bound HLA-DRB1*0301 tetramers. The presence of tetanus specific T cells was confirmed by the secretion of significantly higher IFNg levels upon re-stimulation of cells with tetanus peptide. The same protocol is applied for the HisRS-peptide tetramers. Peripheral blood cells are analysed from anti-Jo1+ and HLA-DRB1*0301 positive patients with IIM.

Results: Applying this method, our preliminary findings demonstrate the presence of $HisRS^+CD4^+$ T cells in peripheral blood from Jo-1+ patients (n=3) using HisRS tetramers following stimulation with the respective peptide. We are now including more patient samples to confirm our findings, and further characterize their phenotype and functionalities by flow cytometry and ELISA/fluorospot assays

Conclusion: Myositis is a rare and chronic autoimmune disorder, with no currently available cure. Previous studies indicate the importance of T cells in this disease. However, the phenotype, functionality and role of these cells in the disease pathogenesis has not been fully established. Characterization of this autoreactive T-cell population will help us enhance our understanding of the disease pathogenesis and thus to develop better treatment options.

POS0009 THE RELATIONSHIP BETWEEN DIFFERENT IGG AND IGA ANTI-MODIFIED PROTEIN AUTOANTIBODIES IN RHEUMATOID ARTHRITIS

C. Grönwall[1], L. Liljefors[1], H. Bang[2], A. Hensvold[1], M. Hansson[1], L. Mathsson-Alm[3], L. Israelsson[1], A. Svärd[4], C. Clavel[5], E. Svenungsson[1], I. Gunnarsson[1], G. Serre[5], S. Saevarsdottir[6], A. Kastbom[4], L. Alfredsson[7], V. Malmström[1], J. Rönnelid[8], A. Catrina[1], K. Lundberg[1], L. Klareskog[1]. *[1]Karolinska Institutet, Department of Medicine, Division of Rheumatology, Stockholm, Sweden; [2]ORGENTEC Diagnostika GmbH, Mainz, Germany; [3]Thermo Fisher Scientific, Uppsala, Sweden; [4]Linköping University, Department of Biomedical and Clinical Sciences, Linköping, Sweden; [5]INSERM - Université de Toulouse, Unité Différenciation Épithéliale et Autoimmunité Rhumatoïde, Toulouse, France; [6]Karolinska Institutet, Department of Medicine Solna, Division of Clinical Epidemiology, Stockholm, Sweden; [7]Karolinska Institutet, Institute of Environmental Medicine, Stockholm, Sweden; [8]Uppsala University, Department of Immunology, Genetics and Pathology, Uppsala, Sweden*

Background: Seropositive rheumatoid arthritis (RA) is characterized by the presence of rheumatoid factor (RF) and anti-citrullinated protein autoantibodies (ACPA) with different fine-specificities. Yet, other serum anti-modified protein autoantibodies (AMPA), e.g. anti-carbamylated (Carb), anti-acetylated (KAc), and anti-malondialdehyde acetaldehyde (MAA) modified protein antibodies, have been described. By using RA patient single-cell derived monoclonal antibodies we have previously shown that individual ACPA clones recognize small distinct citrulline-containing epitopes giving them extensive multireactivity when these epitopes are found in many peptides and proteins. Moreover, certain CCP2+ multireactive ACPA clones bind also to cabamylated and acetylated autoantigens [1].

Objectives: To provide a comprehensive evaluation of serum IgG and IgA autoreactivity to different post-translational modifications in RA.

Methods: We analyzed 30 different IgG and IgA AMPA reactivities to modified antigens by ELISA and autoantigen arrays, in N=1985 newly diagnosed RA patients and population controls. The study utilized both previously established (i.e IgG and IgA CCP2; IgG ACPA fine-specificities; IgG anti-Carb fibrinogen and Carb FCS; IgG and IgA Cit/Carb/KAc/Orn(Ac)-vimentin), and novel assays (e.g. IgG anti-MAA and IgG anti-acetylated histones). Association with patient characteristics such as smoking and disease activity were explored. The newly developed assays were also evaluated in SLE disease controls and CCP2+ RA-risk individuals without arthritis.

Results: Carb and KAc reactivities by different assays were primarily seen in patients also positive for citrulline-reactivity. Modified vimentin (mod-Vim) peptides were used for direct comparison of different AMPA reactivities, revealing that IgA AMPA recognizing mod-Vim was mainly detected in subsets of patients with high IgG anti-Cit-Vim levels and a history of smoking. IgG acetylation reactivity was mainly detected in a subset of patients with Cit and Carb reactivity. Anti-acetylated histone 2B reactivity was RA-specific and associated with high anti-CCP2 IgG levels, multiple ACPA fine-specificities, and smoking. This reactivity was also found to be present in CCP2+ RA-risk individuals without arthritis. Our data further demonstrate that IgG autoreactivity to MAA was increased in RA compared to controls with highest levels in CCP2+ RA, but was not RA-specific, and showed low correlation with other AMPA. Anti-MAA was instead associated with disease activity and was not significantly increased in CCP2+ individuals at risk of RA. Notably, RA patients could be subdivided into four different subsets based on their AMPA IgG and IgA reactivity profiles.

Conclusion: We conclude that autoantibodies exhibiting different patterns of ACPA fine-specificities as well as Carb and KAc reactivity are present in RA and may be derived from multireactive B-cell clones. Anti-Carb and anti-KAc could be considered reactivities within the “Cit-umbrella” similar to ACPA fine-specificities, while MAA is distinctly different.

POS0010 CD38+ MEMORY T CELLS ARE A FUNCTIONALLY DISTINCT SUBSET THAT IS EXPANDED IN SLE AND ASSOCIATED WITH LUPUS NEPHRITIS

L. Ostendorf[1,2,3], P. Garantziotis[1,2], D. L. Wagner[4,5,6], P. Durek[7], F. Heinrich[7], P. Enghard[3], G. R. Burmester[1], A. Radbruch[8], M. F. Mashreghi[7], F. Hiepe[1,2], T. Alexander[1,2]. *[1]Charité Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [2]Deutsches Rheumaforschungszentrum Berlin, Autoimmunology Laboratory, Berlin, Germany; [3]Charité Universitätsmedizin Berlin, Department of Nephrology and Intensive Care Medicine, Berlin, Germany; [4]Charité Universitätsmedizin Berlin, BIH Center for Regenerative Therapies (BCRT), Berlin, Germany; [5]Charité Universitätsmedizin Berlin, Berlin Center for Advanced Therapies (BeCAT), Berlin, Germany; [6]Charité Universitätsmedizin Berlin, Institute of Transfusion Medicine, Berlin, Germany; [7]Deutsches Rheumaforschungszentrum Berlin, Therapeutic Gene Regulation Laboratory, Berlin, Germany; [8]Deutsches Rheumaforschungszentrum Berlin, Cell Biology Laboratory, Berlin, Germany*

Background: We recently reported the beneficial clinical responses of the anti-CD38 monoclonal antibody daratumumab in two patients with systemic lupus erythematosus (SLE) [1]. While the primary rationale for its use was the depletion of autoantibody-producing long-lived plasma cells, daratumumab may promote additional therapeutic effects on CD38-expressing T cells, but their origin, lifestyle and role in lupus pathophysiology remains elusive.

Objectives: To investigate the phenotype, transcriptional program, functional properties and clinical associations of CD4+ and CD8+CD38+ memory T cells in SLE compared to healthy controls (HC).

Methods: CD38-expression on memory T cell subsets was measured by flow cytometry in 65 patients with SLE and 28 healthy controls. We investigated the functional capacity of CD38+ T cells using CFSE staining and intracellular cytokine staining after polyclonal stimulation. Additionally, we performed single-cell transcriptome and T-cell-receptor sequencing of 7 SLE patients and 7 matched healthy controls, including surface protein expression analysis using CITE-seq (RNA-barcoded) antibodies.

Results: Compared to healthy controls, the frequency of CD38-expressing memory T cells in SLE was significantly increased in both CD4+ and CD8+ T cells. SLE patients with a previous or current lupus nephritis had significantly increased levels of CD8+CD38+ memory T cells compared to those without history of renal involvement. CD38+ memory T cells expressed increased levels of Ki-67 and displayed higher proliferative capacity upon polyclonal stimulation than their CD38- counterparts, both in SLE patients and HC, while they showed decreased ability to secrete IFN-γ, IL-2, GM-CSF and TNF-α. Single-cell transcriptome sequencing revealed that CD8+CD38+ memory T cells were enriched within terminally differentiated, cytotoxic CD8 T cells, and had reduced TCR repertoire diversity compared to their CD38- counterparts. CD8+CD38+ memory T cells from SLE patients had significantly higher expression of type I interferon associated genes, both compared to CD38- memory T cells from SLE patients and CD38+ cells from HCs.

Conclusion: CD38+ memory T cells with increased proliferative capacity but altered effector functions are significantly expanded in peripheral blood of SLE and correlate with the lupus nephritis. Although the factors mediating their generation and their precise role in the disease pathophysiology remain to be investigated, CD38-expressing T cells may be useful as a future biomarker for lupus nephritis.

Epidemiology and treatment of pain in RMDs

POS0011 THE ASSOCIATION BETWEEN BARIATRIC SURGERY AND CARPAL TUNNEL SYNDROME: A COHORT STUDY FROM SWEDISH NATIONWIDE HEALTHCARE REGISTRIES

J. Lane[1], D. Holmberg[2], A. M. Burden[3,4], D. Furniss[1], T. Burkard[3]. *[1]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, Oxford, United Kingdom; [2]Karolinska Institutet and Karolinska University Hospital, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [3]ETH Zurich, Department of Chemistry and Applied Biosciences, Zurich, Switzerland; [4]Maastricht University Medical Center+, Department of Clinical Pharmacy and Toxicology, Maastricht, Netherlands*

Background: Carpal tunnel syndrome (CTS) is a chronic compression neuropathy caused by entrapment of the median nerve in the wrist causing pain and sensory loss. Prior observational research suggested that obesity increased the risk of CTS. However, the impact of weight loss among obese patients on CTS has not been assessed to date.

Objectives: To assess the association between bariatric surgery and CTS in a secondary care setting.

Methods: We performed a propensity score (PS)-matched cohort study using data from Swedish nationwide healthcare registries (patient registry [secondary care], causes of death registry, prescribed drug registry). Patients aged 18-79 years who underwent bariatric surgery between 2006 and 2019 were matched to up to 2 obese bariatric surgery-free patients (called unexposed patients) based on their PS. PS-matching was carried out in risk set sampling to reduce selection bias, within 4 sequential cohort entry blocks to account for time trend biases. The outcome CTS was defined as a diagnosis of CTS in secondary care or carpal tunnel decompression surgery. After a 1-year run-in period, patients were followed in an "as-treated" approach. We applied Cox proportional hazard regression to calculate hazard ratios (HR) with 95% confidence intervals (CIs) of CTS among bariatric surgery patients when compared to obese unexposed patients overall, and in subgroups of age, sex, bariatric surgery type, and by duration of follow-up.

Results: A total of 40 619 bariatric surgery patients were PS-matched to 63 540 obese unexposed patients. A total of 72.3% of bariatric surgery patients were women. Bariatric surgery patients had a mean age of 41.7 years and a mean follow-up of 6.8 years. All patient characteristics in obese unexposed patients were highly similar. We observed 1 356 and 1 938 severe CTS cases among bariatric surgery and obese unexposed patients, respectively. Bariatric surgery was not associated overall with CTS (HR of 0.98, 95% CI 0.91-1.05). However, the risk of CTS seemed to decrease with age at bariatric surgery – the lowest CTS risk was observed among bariatric surgery patients aged 18-34 years (HR of 0.87, 95% CI 0.74-1.01), when compared to obese unexposed patients. Sex did not modify the risk of CTS among bariatric surgery patients compared to obese

unexposed patients. Restrictive bariatric surgery yielded lower risks of CTS (HRs of 0.81, 95% CI 0.69-0.88) than did malabsorptive bariatric surgery (HR of 0.95, 95% CI 0.88-1.02) when compared to obese unexposed patients. The risk of CTS increased with duration of follow-up. The lowest risk was observed 1-3 years after bariatric surgery (HR of 0.77, 95% CI 0.68-0.88) and the highest risk 6-13 years after bariatric surgery (HR of 1.20, 95% CI 1.05-1.36) when compared to obese unexposed patients.

Conclusion: Our results suggest that substantial weight loss is not overall associated with severe CTS in an obese patient population. However, bariatric surgery was associated with an initial decreased risk of CTS after bariatric surgery followed by an increased risk in later follow-up. Furthermore, restrictive bariatric surgery but not malapsorptive bariatric surgery was associated with a decreased risk of CTS.

POS0012 EPIDEMIOLOGY OF FIBROMYALGIA HOSPITALIZATIONS IN THE UNITED STATES

K. Mathias[1], A. Mantha[2], L. Mathias[3], D. Arkfeld[3]. *[1]University of Chicago, Internal Medicine, Los Angeles, United States of America; [2]USC Keck School of Medicine, Internal Medicine, Los Angeles, United States of America; [3]USC Keck School of Medicine, Rheumatology, Los Angeles, United States of America*

Background: Fibromyalgia is a chronic pain syndrome that is associated with protean symptoms including musculoskeletal pain, psychiatric symptoms, cognitive dysfunction, memory difficulty, and sleep disturbance. Fibromyalgia can be a primary diagnosis, or it can be associated with other conditions. Fibromyalgia is often seen in conjunction with autoimmune diseases such as systemic lupus erythematosus and rheumatoid arthritis. In 1990, the American College of Rheumatology released classification criteria for fibromyalgia that included symptoms of diffuse pain and physical exam findings of at least 11 of 18 defined tender points. In 2010, the ACR updated these criteria and eliminated the requirement of tender points. In 2011, these criteria were further modified to that they could be self-administered. A previous study used the national inpatient sample to examine hospitalization data for patients with fibromyalgia from 1999-2007. [1] No studies, however, have examined this data since the new ACR criteria were established in 2010.

Objectives: We aim to characterize the epidemiology of hospitalized patients with diagnosis of fibromyalgia.

Methods: Hospitalized patients with a diagnosis of fibromyalgia were identified in the 2016-2018 National Inpatient Sample (NIS) using the International Classification of Diseases 10 system (ICD-10). The NIS is an all-payer inpatient database that estimates over 37 million annual U.S. hospitalizations and is maintained by the Healthcare Cost and Utilization Project. The primary outcomes were prevalence of fibromyalgia and comorbid rheumatologic conditions among hospitalized patients. Secondary outcomes included cause of admission, mortality, length of stay, and cost of care.

Results: Of 1,351,234 patients with fibromyalgia identified, 437,145 were admitted in 2016 increasing to 461,820 in 2018. On average 59.1 years old, more likely female (1,262,735, 93.5%) and white (1,060,845, 81.3%). Patients were most likely to have Medicare (775,420, 57.5%) and were in the bottom quartile of income (402,945, 30.3%). The most common rheumatologic comorbidities were rheumatoid arthritis (142,195, 10.5%), lupus (69,980, 5.2%), and inflammatory bowel disease (38,165, 2.2%). Notably fibromyalgia was commonly associated with depression (500,420, 37.0%), obesity (379,324, 28.1%), hypothyroidism (334,585 24.7%), and congestive heart failure (213,790, 15.8%).The mortality rate was 13,605 (1.0%) patients, the average length of stay was (4.53 days), and the average cost of hospitalization ($12,522). The most common causes of admission were inflammatory syndromes and joint disorders (13.4%) of which OA (4.2%) was most common complaint, digestive complaints (12.1%) of which IBD (4.4%) was most common.

Conclusion: The yearly number of fibromyalgia hospital discharges were greater than previously described. This may be a result of a more sensitive classification criteria. Further investigation into the etiology of this increase in fibromyalgia hospitalization diagnosis is warranted.

POS0013 MUSCULOSKELETAL MANIFESTATIONS IN PATIENTS WITH ENDOCRINE DISEASES IN TERTIARY SERVICE

T. Quereza e Silva Faria[1], S. Ribeiro[1], J. Simão[1], A. Vieira[1], A. P. Narciso Resk Maklouf[1], R. Patrícia Quereza e Silva Faria[1], L. Praciano[1], G. Araújo[1], B. Corrêa[1]on behalf of IMUNOLOGIA DAS DOENÇAS TROPICAIS - IMMUNOLOGY OF TROPICAL DISEASES. *[1]UFAM, Clínca médica, Manaus, Brazil*

Background: Musculoskeletal diseases represent about 50 to 70% of the frequency of chronic diseases according to previous studies (SOUZA, OLIVEIRA, 2015). Chronic pain is often associated with these diseases and is an important cause of care in the health service. Thus, medical professionals are required to adequately manage their patients. Despite the lack of knowledge of some, endocrine diseases are basic diseases linked to musculoskeletal manifestations. Thus, secondary arthropathies of the non-rheumatologic origin or osteoarticular complaints that simulate or show rheumatic diseases can be seen in patients with endocrine diseases during their evolution or in the initial phase along with other systemic symptoms.

Based on this concept, the musculoskeletal manifestations presented by patients with endocrine disorders in tertiary health service were monitored and evaluated.

Objectives: The objective of this study is to characterize the musculoskeletal manifestations in patients with endocrine diseases: type 1 and type 2 diabetes mellitus; hypothyroidism; hyperthyroidism and pituitary diseases and to clinically classify the patients based on physical and imaging findings.

Methods: A cross-sectional and descriptive study, where clinical screening was performed at the endocrinology outpatient clinic, in which patients with musculoskeletal complaints were identified. These patients were referred for evaluation with a rheumatologist with clinical, laboratory and imaging investigation for the diagnosis of rheumatic disease. A questionnaire with epidemiological and clinical data was applied.

Results: In this study, 325 patients with endocrine diseases were interviewed, 53 ± 16.4 years old, 258 (80%) were female and 64 (20%) males. Of the interviewed patients, 236 (72.8%) reported musculoskeletal pain, being that 196 (75.9%) of the women and 33% of the men indicated this type of symptom. Regarding endocrine diseases, the most frequent was Diabetes Mellitus type 2 with 158 patients (48.6%), and 75% of these people have chronic musculoskeletal pain, most 5 to 7 times a week, showing an intrinsic character of this disease with pain complaints from a large part of this population. It was also identified the prevalence of 25% of Hypothyroidism, 12% of Diabetes type 1, 9% of Hyperthyroidism and less expressive amounts of other endocrine diseases such as Acromegaly (2.1%), Gigantism (0.3%) and similar. About 63% of those who have pain are not followed up in the service of rheumatology, 42% of these have already indicated these pains to their endocrinologist, however they have not had their complaint properly flagged. Of these patients, 94 (29%) use Antihypertensives and 25% Oral Antidiabetics. The most notable diagnoses in rheumatology are: Rheumatoid Arthritis (29%); Osteoarthritis (27%); Osteoporosis and Fibromyalgia both with 20.6% of diagnoses and Psoriatic Arthritis and GOUT with 6%. The main regions that are subject to pain are the Hands (52%); Knees (40%); Spine and feet with 30% each.

Conclusion: Although there is a demand of more confirmatory studies, our preliminary results showed the mutuality between endocrine diseases and musculoskeletal manifestations and, therefore, that rheumatological findings are increasingly frequent in this population. The high prevalence of these symptoms secondary to endocrine diseases raises serious questions in order to improve the quality of life of these patients, and also to increase the number of researches in this field, because the pathophysiological mechanisms of this association are not well elucidated and, from this, expand this information to professionals who may not be aware of this relationship.

POS0014 TIME-TRENDS IN COCAINE AND HALLUCINOGEN USE DISORDER HOSPITALIZATIONS IN RHEUMATIC DISEASES: A NATIONAL TIME-TRENDS STUDY

J. Singh[1]. *[1]University of Alabama at Birmingham, Medicine, Birmingham, United States of America*

Background: Cocaine use disorder is a frequent cause of drug use disorders in the U.S. Although hallucinogen use disorder is less common, both are potentially preventable public health issues. To our knowledge, epidemiological studies

estimating burden of cocaine or hallucinogen use disorders in common Musculoskeletal diseases (MSDs) are lacking.
Objectives: To assess national time-trends in cocaine use and hallucinogen use disorders in people with MSDs
Methods: This study used the U.S. National Inpatient Sample (NIS), a de-identified national all-payer inpatient health care database (https://www.hcup-us.ahrq.gov/nisoverview.jsp) from 1998-2014. The NIS is a 20% stratified sample of hospital discharges in the U.S. It is commonly used to derive national estimates of hospitalization and outcomes. Cocaine or hallucinogen use disorder hospitalization was defined in a validated approach as the presence of the following International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) diagnostic codes: cocaine use disorder, 304.2x, or 305.6x; and hallucinogen use disorder, 304.5x or 305.3x; hospitalizations for drug use in remission, drug counseling, rehabilitation or detoxification were excluded, as in previous studies. MSDs were identified based on the respective ICD-9 codes, a validated approach (5-9), in non-primary position: Gout: 274.xx; rheumatoid arthritis (RA): 714.xx; Fibromyalgia: 729.1; osteoarthritis (OA): 715.xx; or low back pain (LBP): 724.
Results: In 1998-2000, the highest frequency of cocaine use hospitalizations was in people with LBP: LBP (n=5,914), followed by OA (n=4,931), gout (n=2,093), RA (n=2,026), and fibromyalgia (n=1,620). In 2013-2014, the order changed slightly with OA (n=22,185), followed by LBP (n=16,810), gout (n=10,570), RA (n=8,975), and fibromyalgia (n=5,680). Respective rates per 1 million U.S. NIS hospitalizations in 2013-2014 and the relative increase from 1998-2000 to 2013-2014 were: Gout, 10.2 (increase, 4.1-fold); OA, 21.4 (3.5-fold); fibromyalgia, 5.48 (2.5-fold); RA, 8.66 (3.4-fold); and LBP, 16.22 (1.8-fold; Figure 1).
In 1998-2000, hallucinogen use disorder hospitalizations were as follows: LBP (n=176), followed by OA (n=63), RA (n=42), fibromyalgia (n=41) and gout (n<10; cells with frequency of 10 of fewer are reported as <10 per NIS guidance). In 2013-2014, the frequency order was the similar, with the highest numbers for LBP (n=525) followed by OA (n=400), RA (n=395), gout (n=135) and fibromyalgia (n=125). Respective rates per 1 million US NIS hospitalizations in 2013-2014 and the relative increase from 1998-2000 to 2013-2014 were: Gout, 0.13 (increase, 25-fold); OA, 0.39 (5.5-fold); fibromyalgia, 0.12 (2-fold); RA, 0.38 (8.5-fold); and LBP, 0.51 (2-fold; Figure 1).
Conclusion: This study confirmed an increasing rate of both, cocaine use and hallucinogen use disorder hospitalizations in people with 5 MSDs over a 17-year period from 1998-2014 in the U.S.

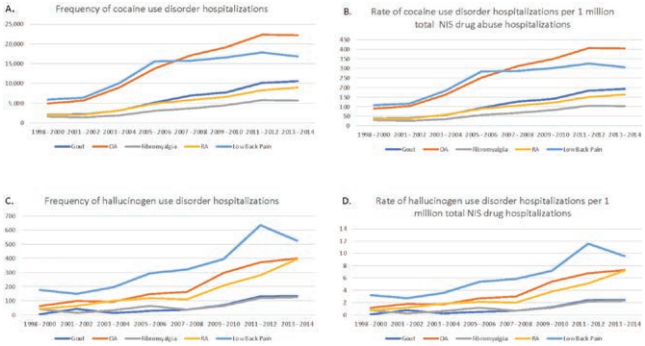

Figure 1. Time-trends in the rates of hospitalization with cocaine use and hallucinogen use disorder (A), non-home discharge (B), and in-hospital mortality (C) per 100,000 NIS hospitalization claims.The x-axis shows rate per 100,000 NIS hospitalization claims and the y-axis the study periods

POS0015 PREVALENCE OF NEUROPATHIES IN RHEUMATIC AND MUSCULOSKELETAL DISEASES

R. Hasseli[1], M. Tschernatsch[2,3], N. Heimann[1], E. Neumann[1], T. Gerriets[2,4], J. Allendörfer[5], T. Ruck[6], A. Schänzer[7], U. Müller-Ladner[1]. [1]*Justus-Liebig-University Giessen, Campus Kerckhoff, Department of Rheumatology and Clinical Immunology, Bad Nauheim, Germany*; [2]*Justus-Liebig-University Giessen, Department of Neurology, Giessen, Germany*; [3]*Gesundheitszentrum Wetterau, Department of Neurology, Bad Nauheim, Germany*; [4]*Gesundheitszentrum Wetterau, Department of Neurology, Friedberg, Germany*; [5]*Asklepios Hospital, Department of Neurology, Bad Salzhausen, Germany*; [6]*Heinrich-Heine-University Duesseldorf, Department of Neurology, Giessen, Germany*; [7]*Justus-Liebig-University Giessen, Institute of Neuropathology, Giessen, Germany*

Background: In rheumatic and musculoskeletal diseases (RMDs), peripheral neurons can be affected, which can result in sensory symptoms like pain, burning, tingling, numbness and motor symptoms like muscle-atrophy or even paresis. More detailed knowledge about the prevalence and the cause of neuropathy (NP) in RMD are urgently needed, especially as RMD patients may develop different subtypes of NP.
Objectives: The aim of this project was to assess the prevalence and the individual types of NP in rheumatoid arthritis (RA), spondyloarthritis (SpA) and systemic sclerosis (SSc) patients, and to elucidate the clinical, neurophysiological and neuropathologic features of associated NP.
Methods: Baseline questionnaires and neurological and physical examination were used to elucidate the presence of neuropathic pain and autonomic dysfunction. Laboratory tests were performed to exclude other causes for NP. Electrophysiological tests were performed to differentiate demyelinating from axonal large fiber (LF)NPs. Additionally, skin biopsies were used to detect an involvement of small fibres (SF).
Results: A total of 31 patients (median age 64 years (range 43-75)) were included. The majority of patients were female (90%). The mean disease duration was 10 years (1-41 years). More than 50% of the patients were diagnosed with RA, 7 with SpA and 6 with SSc. Of 31 patients, 48% (15/31) had clinical signs of NP and of those, neurophysiological examination showed 14 axonal 2, demyelinating and 4 mixed types. A combined LFNP and SFNP was present in 35% (11/31) of the patients. In 4 patients, only a SFNP was detectable, and in only two patients, no NP was detectable.
Conclusion: NP was detectable in 94% (29/31) of the RMD patients, with LFNP predominating. This high proportion of NP in RMD suggests a surprisingly high coincidence of both diseases.

Table 1. Subtypes of NP in RMD

	Number of patients
Axonal NP	14/31 (45%)
Demyelinating NP	2/31 (6%)
Mixed axonal and demyelinating NP	4/31 (12%)
Sensory NP	9/31 (26%)
Sensorimotor NP	5/31 (10%)
Motor NP	1/31 (3%)

Disclosure of Interests: None declared.

POS0016 THE EVALUATION OF FUNCTIONAL ABILITIES OF PATIENTS WITH OSTEOPOROTIC VERTEBRAL FRACTURES AS A BASIS FOR REHABILITATION PROGRAMS DEVELOPING

L. Marchenkova[1], V. Vasileva[1], M. Eryomushkin[1]. [1]*National Medical Research Center for Rehabilitation and Balneology of Ministry of Health of Russian Federation, Rehabilitation Department for Somatic Patients, Moscow, Russian Federation*

Background: Due to the demand for special rehabilitation programs for patients with osteoporotic vertebral fractures (VFs), it is of interest to study the functional abilities of those patients. The scientific hypothesis suggests that osteoporotic VFs would cause muscle weakness, muscle dysfunction and conditional disturbances.
Objectives: to estimate muscle strength, motor function and coordination disorders in patients with VFs in the setting of systemic osteoporosis as a basis for rehabilitation programs developing.
Methods: 120 patients aged 43–80 with primary osteoporosis were enrolled. Study group comprised of 60 subjects (56 women, 4 men) with at least 1 VF confirmed by X-rays. Control group included 60 subjects (56 women, 4 men) with osteoporosis but without any osteoporotic fracture. The examination program included back muscles tenzodynamometry, balance tests and stabilometry.
Results: Muscle strength deficiency was estimated in study group in trunk flexors (TF) — 40.9% and in trunk extensors (TE) — 18.1% with an adequate function of the left lateral flexors (LLF) and in right lateral flexors (RLF). Patients with VFs had the lower muscle strength vs controls of TE (15.64±9.8 vs 27.73±9.9 kg, p=0.00002), TF (14.61±8.98 vs 21.28±8.38 kg, p=0.0006), LLF (13.10±7.2 vs

24.06±8.9 kg, p=0.005) and RLF 13.44±7.43 vs 24.26±7.65 kg, p=0.0003). Patients with VFs lose their balance faster during one-leg-standing test with open eyes (5.0 [1.0; 10.0] vs 7.5 [5.0; 10.5] sec in control group, p=0.03) and with closed eyes (2.0 [0; 3.0] vs 3.5 [3.0; 5.0] sec, p=0.04). Fukuda-Unterberger test showed greater side dislocation in study group — 40º [25; 45] vs controls 30º [10; 45], (p=0.02). According to stabilometry study group was characterized vs control group by lower balance coefficient with open eyes (77.2±7.6 vs 85.7±9.4%, p=0.002) and with closed eyes (67.1±9.8 vs 73.4±9.9%, p=0.03), greater sagittal displacement (6.8 [2.1; 37.7] vs 4.8 [1.8; 10.7] mm, p=0.025) and deviation in the saggital plane (1.2 [-1.07; 1.5] vs -1.2 [-1.5; 1.2] mm, p=0.01), and also less pressure center velocity (9.51±4.4 vs 7.1±2.7 mm/sec, p=0.009).

Conclusion: Osteoporotic VFs are associated with reduction of trunk muscles strength and negatively affect static and dynamic balance function that should be taken into account when developing rehabilitation programs for these patients.

Disclosure of Interests: None declared.

POS0017 IMC-1, A FIXED DOSE COMBINATION OF FAMCICLOVIR AND CELECOXIB, IMPROVES COMMON SYMPTOMS ASSOCIATED WITH FIBROMYALGIA IN ADDITION TO PAIN: POST HOC ANALYSIS OF A PHASE 2A TRIAL

W. Pridgen[1], C. Duffy[2], J. F. Gendreau[3], R. M. Gendreau[4]. [1]*Tuscaloosa Surgical Associates, P.C., LLC, Tuscaloosa, United States of America*; [2]*University of Alabama, Department of Biological Sciences, Tuscaloosa, United States of America*; [3]*Gendreau Consulting, LLC, Poway, United States of America*; [4]*Virios Therapeutics, Alpharetta, United States of America*

Background: Fibromyalgia is a chronic disease characterized by widespread pain and severe fatigue that may be triggered by reactivation of latent herpes simplex virus type 1 (HSV-1). In a Phase 2a proof of concept trial, IMC-1 (a fixed dose combination of famciclovir and celecoxib) demonstrated greater tolerability and statistically significant reduction in pain compared with placebo, as measured by change from baseline to week 16 in 24-hour recall pain intensity on an 11-point Numerical Rating Scale (NRS) and 7-day recall pain intensity on the 11-point pain item on the Revised Fibromyalgia Impact Questionnaire (FIQ-R).

Objectives: In this post hoc analysis, we evaluated the effects of IMC-1 compared with placebo on other fibromyalgia symptoms, including lack of energy, stiffness, problems with sleep, problems with memory, depression, and anxiety.

Methods: In the double-blind, multi-center, placebo-controlled trial, male or female patients 18–70 years of age who met diagnostic criteria for fibromyalgia and had at baseline a 24-hour recall average pain intensity score between 4 and 9 on the NRS were randomized 1:1 to 16 weeks of treatment with IMC-1 or placebo. Mean changes from baseline to week 16 in FIQ-R symptom scores were analyzed using a Mixed-Effect Model Repeated Measure (MMRM) model with treatment as the main effect, and investigative site and baseline FIQ-R symptom scores as covariates.

Results: A total of 143 patients were enrolled and randomized to treatment with IMC-1 (n=69) or placebo (n=74). Baseline demographic and clinical characteristics were comparable between treatment groups; the majority of patients were Caucasian (95.8%) and female (93.7%) with a mean age of ~49 years. Compared with placebo, treatment with IMC-1 resulted in statistically significant improvements in the FIQ-R symptom scores of stiffness (least squares mean change from baseline -0.96 vs. -1.92, P=0.03), sleep quality (-0.76 vs. -1.76, P=0.039), depression (-0.44 vs. -1.33, P=0.016), and anxiety (-0.30 vs. -1.69, P<0.001), but not in energy level (-0.67 vs. -1.29, P=0.115) or memory problems (-0.71 vs. -1.24, P=0.165).

Conclusion: In addition to alleviation of chronic pain, treatment with IMC-1 appears to be effective in improving many of the other symptoms often associated with fibromyalgia. Further clinical trials are warranted.

POS0018 INVESTIGATING VIRTUAL IMMERSIVE EXPERIENCES IN THE MANAGEMENT OF CHRONIC PAIN – THE VIPA STUDY (PRELIMINARY RESULTS)

J. Tsigarides[1], V. Grove[1], D. Sethi[1], J. Chipping[1], S. Miles[1], N. Shenker[2], S. Sami[1], A. Macgregor[1]. [1]*University of East Anglia, Norwich Medical School, Norwich, United Kingdom*; [2]*Addenbrookes University Hospital, Rheumatology, Cambridge, United Kingdom*

Background: Chronic pain is debilitating and prevalent. Current non-pharmacological management of pain conditions such as Fibromyalgia Syndrome (FMS) are labour intensive to implement and poorly available, especially during the pandemic. There is an urgent need to develop widely adoptable, innovative treatment options for pain cohorts.

Virtual reality (VR) provides an innovative therapeutic tool, immersing users within a three-dimensional, interactive virtual environment with use of a head-mounted display (HMD). Beneficial effects of VR have been demonstrated in acute pain[1], with limited studies in chronic pain. Given the variation of available VR technologies, it is vital to investigate the impact of different VR characteristics on acceptability in specific chronic pain cohorts.

Objectives: This feasibility study aims to establish the acceptability of four different VR technologies in patients with FMS whilst undertaking a single interactive VR experience.

Methods: Patients with FMS were recruited through outpatient clinics at the Norfolk and Norwich University Hospital. Baseline questionnaires were used including the McGill pain questionnaire (MPQ-SF), pain visual analogue scale (VAS) and Revised Fibromyalgia Impact Questionnaire (FIQR). Subjective experience questionnaires collected acceptability data with 7-point Likert scale rating questions (strongly disagree to strongly agree). The simulation sickness questionnaire (SSQ) gained side-effect data (total severity score: 0-235). Categorical data were described using frequencies; and continuous data using mean and standard deviation. Likert-scale data were dichotomised (rating ≤3: disagree, rating ≥5: agree).

Four VR systems representing the spectrum of commercially available technologies were used (seen in Figure 1). These possess different characteristics including screen resolution, processor speed, weight, strap and controller type. The VR experience used with each headset was co-developed alongside industry partners (Orbital Global). Participants are immersed within a naturalistic environment, situated on a wooden boat travelling slowly along a calm river surrounded by trees and hills. The interactive element involves the user shooting targets that appear using handheld controllers.

Results: 13 patients with FMS were included (mean age 41.8±15.6, 92.3% female). Most had severe disease (mean FIQR 67.8±14.1) with moderate self-reported pain at baseline (mean MPQ 25.5±8.8, VAS 6.0±1.7). Most had no previous VR exposure (69.2%). 100% of participants agreed that they would be open to using VR for future pain management (mean rating 6.5±0.7) and that they would use VR regularly at home (mean rating 6.5±0.7). VR HMD comfort and enjoyment data are presented in Table 1. Mean ratings of comfort were high across the four HMDs (Gear VR: 4.9±1.7, Oculus Go: 4.5±1.8, Oculus Quest 5.3±1.9, Oculus Rift 6.6±0.5). Mean ratings of enjoyment with each HMD were also high (Gear VR: 5.4±1.6, Oculus Go: 5.4±1.8, Oculus Quest: 5.6±1.9, Oculus Rift S: 6.6±0.5). Low levels of side effects were described with mean SSQ total scores ranging from 20.1±16.8 (Oculus Rift S) to 38.0±23.9 (Gear VR).

Conclusion: Preliminary results indicate that FMS patients find VR acceptable, describing high ratings of comfort and enjoyment across the VR HMD spectrum. Side-effect frequency was low, with most settling after HMD removal. All participants were open to future use of VR for home-based pain management.

POS0019 PREDICTORS OF SUSTAINED 6 MONTHS REMISSION AND FLARE IN PATIENTS WITH POLYMYALGIA RHEUMATICA

C. Perricone[1], E. Fiumicelli[1], G. Cafaro[1], R. Bursi[1], R. Ilenia[1], E. Bartoloni Bocci[1], R. Gerli[1]. [1]*Rheumatology, Department of Medicine and Surgery, Perugia, Italy*

Background: Polymyalgia rheumatica (PMR) is a typical inflammatory disease of the elderly. The mainstay of treatment is usage of oral glucocorticoids (GC) usually leading to a dramatic response. However, long-term treatment is often required. In some instances, remission cannot be achieved and disease flares can occur. To date, few papers investigated the predictive factors of response to GC therapy suggesting a role for weight, elevated plasma viscosity and C-reactive protein (CRP). Moreover, there are no data on predictor factors of disease flares after 6 months of sustained remission.

Objectives: To evaluate the factors predictive of sustained 6 months remission and of flare in patients with PMR.

Methods: We evaluated clinical data from 137 PMR patients treated with GC for more than 6 months between September 2002 and June 2020. Patients were evaluated at baseline, re-evaluated at 1 month and after 3 months and then at least every 3 months. We analyzed the differences between patients who achieved remission within 6 months of diagnosis, who maintained it for at least 6 months, and patients who did not. Remission was defined as 1) the absence of clinical symptoms, 2) <7.5 mg / day of prednisone equivalents and 3) negativity of ESR and CRP. Patients treated with methylprednisolone were excluded from the analysis.

Results: Among the 137 patients (baseline F68: M69, mean age ± SD 74.5±6.6 years, mean ESR ± SD 49.9±27.7 mm/h, mean CRP ± SD 6.1±11.4 mg/dl), 57 achieved remission at 6 months (41.6%), and after this period, another 47 went into remission for a total of 104 patients (75.9%). The months required to achieve remission averaged 6.4 ± 3. No differences were observed between patients who achieved remission and patients who did not regarding age, sex, CRP, starting dose of GC, anti-CCP and rheumatoid factor. The ESR at baseline was higher in patients who did not achieve remission (58.1±33.4 mm/h) than in patients who achieved it (46±24.8 mm/h, p=0.06). ESR at baseline correlated with the time needed to reach normalization of both ESR and CRP (p=0.01, Figure 1). Thirty-six of 104 patients (34.6%) had a disease flare after a mean of 6.1±2.7 months of remission. The mean GC intake at flare was 2.8±3 mg/day. Only 15/36 (41.6%) patients were able to withhold GCs after flare, compared with 48/68 (70.5%) patients who achieved remission and did not experience flare. There were no significant differences in any analyzed parameters between patients who experienced flares and those who did not, including ESR and CRP values at baseline (50.3±26.7 mm/h and 6.8±12.1 mg/dl, respectively). A higher percentage of patients who did not achieve remission experienced flare than patients who went into remission (p=0.009).

Conclusion: Achieving complete remission at 6 months occurs in a consistent percentage of patients with PMR. Despite this, a significant percentage of patients may need prolonged steroid treatment and may experience flare, even after 12 months of follow-up. Remission at 6 months is likely to be a good predictor of remission at 12 months, as already reported in recent studies (1, 2). Elevated ESR at diagnosis appears to be a negative predictor for remission at 6 months. Patients who achieve complete remission are less likely to develop flare. True remission should coincide with the discontinuation of steroid treatment; in fact, the maintenance of steroid therapy, even at low doses, is predictive of the development of flare.

POS0020 EFFICACY AND SAFETY OF SECUKINUMAB IN PATIENTS WITH ROTATOR CUFF TENDINOPATHY: A 24-WEEK, RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PHASE II PROOF-OF-CONCEPT TRIAL

N. L. Millar[1], I. Mcinnes[1], L. Mindeholm[2], A. Seroutou[3], J. Praestgaard[4], U. Schramm[2], R. Levitch[5], E. Weber[6], D. Laurent[7], J. Rosen[8], G. Schett[9], R. Roubenoff[10], M. Schieker[2]. [1]*Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow, United Kingdom*; [2]*Novartis Institutes for BioMedical Research,TM MSD Bone, Joint and Tendon, Basel, Switzerland*; [3]*Novartis Institutes for BioMedical Research, Biostatistics, Basel, Switzerland*; [4]*Novartis Institutes for BioMedical Research, Data Science, Cambridge, United States of America*; [5]*Novartis Institutes for BioMedical Research, Cardio-renal-metabolic, Basel, Switzerland*; [6]*Novartis Institutes for BioMedical Research, MSD LAB WEBER, Basel, Switzerland*; [7]*Novartis Institutes for BioMedical Research, BMD Clincal &Transplant Imaging, Basel, Switzerland*; [8]*New York Presbyterian Queens, Department of Orthopaedics & Rehabilitation, New York, United States of America*; [9]*University of Erlangen-Nuremberg, Department of Internal Medicine 3, Erlangen, Germany*; [10]*Novartis Institutes for BioMedical Research,Translational Medicine, Basel, Switzerland*

Background: Rotator cuff tendinopathy (RC TP) is a multifactorial condition and one of the most common causes of musculoskeletal burden. Current standard of care (SoC) is limited to pain relief with NSAIDs and physiotherapy. Recent evidence indicates that IL-17A-expressing tendon-resident immune cells are present in human overuse tendinopathy, and IL-17A levels are increased in early human tendinopathic tissue samples [1, 2]. Secukinumab (SEC) is a fully human, monoclonal antibody that binds to and neutralises IL-17A.

Objectives: To evaluate the efficacy and safety of SEC in patients with active overuse RC TP refractory to oral NSAIDs/acetaminophen, physiotherapy or corticosteroid injections.

Methods: 96 patients with symptomatic RC TP with no or <50% rupture were randomly assigned to receive seven subcutaneous injections of SEC 300 mg or placebo (PBO) at baseline and Weeks 1, 2 and 3, followed by every 4 weeks starting at Week 4. The primary endpoint was change from baseline in the Western Ontario Rotator Cuff (WORC) index score at Week 14 for SEC vs PBO (two-sided p<0.1). Secondary endpoints included, visual analogue scale (VAS) pain score, Disability of Arm, Shoulder and Hand Questionnaire (QuickDASH) score,

American Shoulder and Elbow Surgeons Shoulder Evaluation Form (ASES), EQ-5D-5L score and patient global assessment (PGA) score. All endpoints were assessed through 24 weeks.

Results: Clinically relevant improvement in both SEC and PBO groups on top of SoC treatment was observed, with no statistically significant difference demonstrated in the full study population on physical symptoms and function (Table 1). Similar results were observed in the secondary endpoints with marked improvement in both groups over time. Exploratory post-hoc analyses in a subpopulation of 39% of the study subjects with non-acute, moderate to severe disease, SEC provided significant and clinically relevant improvements vs PBO through Week 24 in total WORC score (overall treatment difference: 19.2, p <0.01) and pain (VAS, overall treatment difference: 15, p = 0.02) with early effect observed after two weeks (Figure 1). A favourable treatment effect in the more severe subgroup was demonstrated in other patient-reported outcomes. No serious adverse events were reported.

Conclusion: Although SEC did not demonstrate a significant benefit vs PBO in the overall patient population with active overuse RC TP, SEC did provide benefit in the subpopulation with non-acute, moderate to severe disease. Larger clinical trials of SEC in this area are warranted.

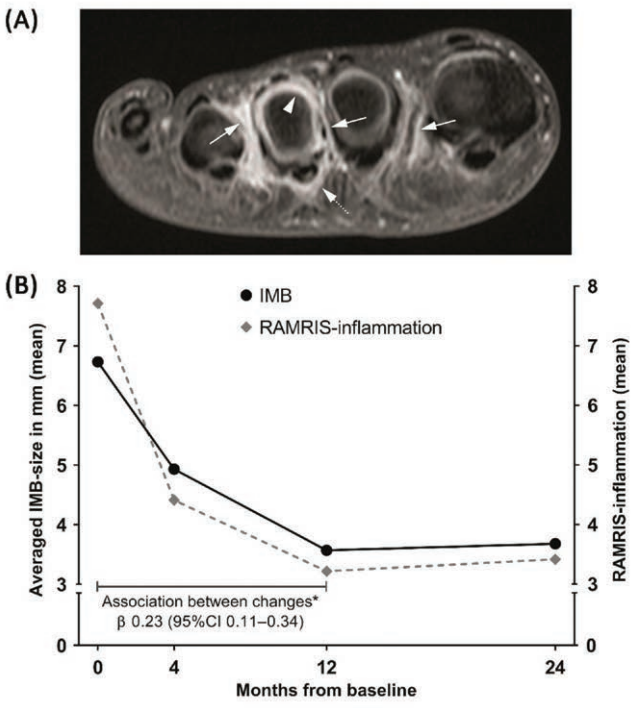
INTERMETATARSAL BURSITIS, A NOVEL FEATURE OF JUXTA-ARTICULAR INFLAMMATION IN EARLY RHEUMATOID ARTHRITIS: RESULTS FROM A LONGITUDINAL MRI-STUDY

B. Van Dijk[1], Y. Dakkak[1], X. Matthijssen[1], E. Niemantsverdriet[1], M. Reijnierse[2], A. Van der Helm-van Mil[1,3]. [1]*Leiden University Medical Centre (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Leiden University Medical Centre (LUMC), Radiology, Leiden, Netherlands*; [3]*Erasmus Medical Centre (EMC), Rheumatology, Rotterdam, Netherlands*

Background: Rheumatoid arthritis (RA) is characterised by inflammation of the synovial lining. In addition to synovitis, the tendon sheaths of small hand and foot joints are also frequently inflamed. This results in tenosynovitis, which is often missed at clinical evaluation in early RA but visible on imaging, such as MRI. A third anatomical structure surrounded by a synovial lining is formed by the intermetatarsal bursae in the forefeet. Inflammation of these bursae (intermetatarsal bursitis; IMB) was recently identified at MRI-studies and shown to be specific for early RA.[1] This suggests that IMB is also a feature of early RA.

Figure. (**A**) Example MR-image of IMB co-occurring with synovitis and flexor tenosynovitis; (**B**) IMB-size and total RAMRIS-inflammation in the forefoot over time



Legend

(A) Full arrows: IMB; Dotted arrow: tenosynovitis; Arrowhead: synovitis.
(B) * β signifies the association of change in averaged IMB-size with change in total RAMRIS-inflammation between 0–12 months, estimated using GEEs. IMB-decrease was statistically significantly associated with total RAMRIS-inflammation decrease at the 0.05 level.

Objectives: We hypothesised that if IMB is indeed an RA-feature, then (1) at diagnosis its presence associates with other measures of local inflammation (synovitis, tenosynovitis and osteitis) and (2) it responds to DMARD therapy similarly as these other local inflammatory measures. These hypotheses were tested in a comprehensive MRI-study.
Methods: 157 consecutive early RA patients underwent unilateral contrast-enhanced 1.5T MRI of the forefoot at diagnosis. MRIs were evaluated for presence of IMB and for synovitis, tenosynovitis and osteitis in line with the RA MRI scoring system (summed as RAMRIS-inflammation). MRIs at 4, 12 and 24 months were evaluated for presence and size of IMB-lesions in patients who had IMB at baseline and received early DMARD-therapy. Logistic regression was used for analyses at patient-level; generalised estimating equations were used for bursa-level analyses. Stratification for ACPA was performed.
Results: 69% of RA patients had ≥1 IMB. In multivariable analyses on bursa-level, presence of IMB was independently associated with local presence of synovitis and tenosynovitis (OR 1.69 (95%CI 1.12–2.57) and 2.83 (1.80–4.44), respectively), but not with osteitis. On patient-level, presence of IMB was most strongly associated with tenosynovitis (OR 2.92 (1.62–5.24)). During treatment with DMARDs, the average size of IMB-lesions decreased (Figure 1). This decrease was associated with decrease in RAMRIS-inflammation scores; most strongly with a decrease in synovitis but not in osteitis. Within ACPA-positive and ACPA-negative RA similar results were obtained.
Conclusion: IMB particularly accompanies inflammation of the synovial lining of joints and tendon-sheaths, both regarding simultaneous occurrence at diagnosis and simultaneous treatment-response. These findings suggest that IMB represents juxta-articular synovial inflammation and indeed is a hallmark of early RA.

POS0022 PHARMACOVIGILANCE PREGNANCY DATA IN A LARGE POPULATION OF PATIENTS WITH CHRONIC INFLAMMATORY DISEASE EXPOSED TO CERTOLIZUMAB PEGOL: PREGNANCY OUTCOMES AND CONFOUNDERS

M. Clowse[1], R. Fischer-Betz[2], C. Nelson-Piercy[3], A. Scheuerle[4], T. Kumke[5], B. Lauwerys[6], R. Kasliwal[7], F. Förger[8]. [1]*Duke University Medical Center, Division of Rheumatology, Durham, United States of America*; [2]*Heinrich Heine University Düsseldorf, Department for Rheumatology, Düsseldorf, Germany*; [3]*Guy's and St Thomas' NHS Foundation Trust, Department of Women and Children's Health, London, United Kingdom*; [4]*UT Southwestern Medical Center, Department of Pediatrics, Division of Genetics and Metabolism, Dallas, United States of America*; [5]*UCB Pharma, N/A, Monheim am Rhein, Germany*; [6]*UCB Pharma, N/A, Brussels, Belgium*; [7]*UCB Pharma, N/A, Slough, United Kingdom*; [8]*Inselspital, University of Bern, University Clinic for Rheumatology, Immunology and Allergology, Bern, Switzerland*

Background: Chronic inflammatory diseases (CID) in women of reproductive age are increasingly being treated with tumour necrosis factor inhibitors (TNFi), in line with recent guidelines.[1] However, data on TNFi-exposed pregnancy outcomes are still limited. Certolizumab pegol (CZP), a PEGylated, Fc-free TNFi, has no/minimal placental transfer from mother to infant during the third trimester.[2]
Objectives: To assess pregnancy outcomes from the UCB Pharmacovigilance safety database from over 1,300 prospectively reported pregnancies with maternal CZP exposure.
Methods: Details of CZP-exposed pregnancies from the UCB Pharmacovigilance safety database were reviewed up to November 1, 2020. Analysis was limited to prospectively reported cases with known pregnancy outcomes to avoid potential reporting bias. Confounders (specific CID, non-biologic medications and maternal infection) were evaluated using a multivariate stepwise regression model; results from the confounders analysis are reported as odds ratios (OR) with 95% confidence intervals (CI). Patients with missing information about presence or absence of confounders were excluded from the model.
Results: 1,392 prospective pregnancies (1,425 fetuses) with maternal CZP exposure and known outcomes were reported (Figure 1). Mean (SD) maternal age was 31.9 (5.1) years. Of these, 1,021/1,392 (73.3%) pregnancies had at least first-trimester CZP exposure and 547/1,392 (39.3%) were exposed during all trimesters. Overall, there were 1,259/1,425 (88.4%) live births, 150/1,425 (10.5%) abortions (miscarriages and terminations), 11/1,425 (0.8%) stillbirths, and 5/1,425 (0.4%) ectopic pregnancies. Congenital malformations were reported in 35/1,425 fetuses (2.5%) and in 30/1,259 live-born infants (2.4%); 26 (2.1%) congenital malformations were major according to the Metropolitan Atlanta Congenital Defects Program criteria. There was no pattern of specific congenital malformations. Preterm births occurred in 124/1,259 (9.8%) live births, and 101/1,259 (8.0%) of infants had low birth weight (<2.5 kg). In the confounders analysis, reported corticosteroid use was independently associated with increased odds of preterm birth (OR [95% CI]: 2.1 [1.3–3.4]; p<0.005) and low birth weight (OR [95% CI]: 1.7 [1.0–2.9]; p<0.05), but decreased odds of abortion (OR [95% CI]: 0.5 [0.3–0.9]; p<0.05). Reported NSAID use was associated with increased odds of abortion (OR [95% CI]: 2.2 [1.2–4.0]; p<0.05), as was methotrexate/leflunomide use (OR [95% CI]: 3.2 [1.7–6.2]; p<0.0005). Maternal infections were associated with increased odds of preterm birth (OR [95% CI]: 1.9 (1.1–3.5; p<0.05). Finally, there was an association between a diagnosis of Crohn's disease and odds of abortion (OR [95% CI]: 2.5 [1.5–4.1]; p=0.0005), and between rheumatoid arthritis and low birth weight (OR [95% CI]: 1.9 [1.1–3.3]; p<0.05).
Conclusion: This prospective analysis, including more than 1,000 pregnancies with CZP exposure in at least the first trimester, represents one of the largest cohorts of pregnancies with known outcomes in patients with CID. Our data confirm the impact of specific CID, concomitant drugs or comorbidities on pregnancy outcomes. In particular, additional use of corticosteroids was highlighted as a risk factor for preterm birth and low birth weight in our cohort of CZP-treated patients. No increase in adverse pregnancy outcomes or specific congenital malformations was observed in CZP-exposed pregnancies, compared to the general population,[3,4] which offers further reassurance for women of childbearing age considering CZP treatment.

POS0023 RACIAL/ETHNIC AND REGIONAL DIFFERENCES IN MULTIMORBIDITY BETWEEN PATIENTS WITH RHEUMATOID ARTHRITIS AND COMPARATORS IN A LARGE NATIONWIDE US STUDY

H. J. Dykhoff[1], E. Myasoedova[2,3], M. Peterson[2], J. M. Davis III[2], V. Kronzer[2], C. Coffey[2], T. Gunderson[3], C. S. Crowson[2,3]. [1]*Mayo Clinic, Robert D. and Patricia E. Kern Center for the Science of Health Care Delivery, Rochester,*

United States of America; [2]*Mayo Clinic, Division of Rheumatology, Rochester, United States of America*; [3]*Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America*

Background: Patients with rheumatoid arthritis (RA) have an increased burden of multimorbidity. Racial/ethnic disparities have also been associated with an increased burden of multimorbidity.
Objectives: We aimed to compare multimorbidity among different racial/ethnic groups and geographic regions of the US in patients with RA and comparators without RA.
Methods: We used a large longitudinal, real-world data warehouse with de-identified administrative claims for commercial and Medicare Advantage enrollees, to identify cases of RA and matched controls. Cases were defined as patients aged ≥18 years with ≥2 diagnoses of RA in January 1, 2010 - June 30, 2019 and ≥1 prescription fill for methotrexate in the year after the first RA diagnosis. Controls were persons without RA matched 1:1 to RA cases on age, sex, census region, calendar year of index date (corresponding to the date of second diagnosis code for RA), and length of prior medical/pharmacy coverage. Race was classified as non-Hispanic White (White), non-Hispanic Black (Black), Asian, Hispanic, or other/unknown, based on self-report or derived rule sets. Multimorbidity (2 or more comorbidities) was defined using 25 chronic comorbidities from a combination of the Charlson and Elixhauser Comorbidity Indices assessed during the year prior to index date. Rheumatic comorbidities were not included. Logistic regression models were used to estimate odds ratios (OR) with 95% confidence intervals (CI).
Results: The study included 16,363 cases with RA and 16,363 matched non-RA comparators (mean age 58.2 years, 70.7% female for both cohorts). Geographic regions were the same in both cohorts: 50% South, 26% Midwest, 13% West, and 11% Northeast. Race/ethnicity was not part of the matching criteria and varied slightly between the cohorts: among RA (non-RA) patients, 74% (74%) were White, 11% (9%) Hispanic, 10% (9%) Black, 3% (4%) Asian, and 3% (4%) other/unknown. Patients with RA had more multimorbidity than non-RA subjects (51.3% vs 44.8%). Multimorbidity comparisons across US geographic regions were similar in both cohorts, with comparable multimorbidity levels for patients in the West and Midwest and higher levels for those in the Northeast and South (Figure 1). Among the non-RA patients, 43.5% of Whites experienced multimorbidity, compared to 33.9% of Asians, 46.1% of Hispanics, and 58.4% of Blacks. These associations remained after adjustment for age, sex, and geographic region, with significantly lower multimorbidity among Asians (OR: 0.81; 95%CI: 0.67-0.99) and significantly higher multimorbidity among Hispanics (OR: 1.21; 95%CI: 1.07-1.37) and Blacks (OR: 1.74; 95%CI: 1.54-1.97), compared to Whites in the non-RA cohort. Among the RA patients, racial/ethnic differences were less pronounced; 50.6% of Whites, 42.8% of Asians, 48.8% of Hispanics, and 58.4% of Blacks experienced multimorbidity. Adjusted analyses revealed no significant differences in multimorbidity for Asians (OR: 0.88; 95%CI: 0.70-1.08) and Hispanics (OR: 1.06; 95%CI: 0.95-1.19) and a less pronounced increase in multimorbidity among Blacks (OR: 1.32; 95%CI: 1.17-1.49) compared to Whites in the RA cohort.
Conclusion: This large nationwide study showed increased occurrence of multimorbidity in RA versus non-RA patients and in both cohorts for residents of the Northeast and South regions of the US. Racial/ethnic disparities in multimorbidity were more pronounced among patients without RA compared to RA patients. This indicates the effects of RA and race/ethnicity on multimorbidity do not aggregate. The underlying mechanisms for these associations require further investigation.

ESTIMATED PREVALENCE, INCIDENCE AND HEALTHCARE COSTS OF SJÖGREN'S SYNDROME IN FRANCE: A NATIONAL CLAIMS-BASED STUDY

R. Seror[1], L. Chiche[2], G. Desjeux[3], J. Zhuo[4], B. Bregman[5], V. Vannier-Moreau[6], V. Devauchelle-Pensec[7]. [1]*Université Paris-Sud, AP-HP, Hôpitaux Universitaires Paris-Sud, N/A, Paris, France*; [2]*Hôpital Européen Marseille, Unité de medicine interne et recherche clinique, Marseille, France*; [3]*Sanoia, eHealth services, Aubagne, France*; [4]*Bristol Myers Squibb, Worldwide Health Economics and Outcomes Research, Princeton, United States of America*; [5]*Bristol Myers Squibb, Health Economics and Public Health, Rueil-Malmaison, France*; [6]*Bristol Myers Squibb, Medical Affairs, France, Rueil-Malmaison, France*; [7]*CHU de Cavale Blanche, Rheumatology Department, Brest, France*

Background: Sjögren's syndrome (SS) is a chronic, systemic autoimmune disorder characterised by oral and ocular dryness related to lymphocytic infiltration of exocrine glands.[1–3] Extra-glandular manifestations may include fatigue, musculoskeletal pain and glomerulonephritis.[1,3] SS can present as primary SS (pSS)

or as SS associated with another autoimmune disorder (SS+AID).[1] Reported prevalence of pSS in the French general population is 1.02–1.52 cases/10,000 people.[3]

Objectives: To estimate prevalence, incidence and healthcare costs of SS in France using national health insurance claims data.

Methods: Claims from 2011–2018 from the Système National des Données de Santé (SNDS), comprised of data from 99% of the French population, were analysed. Patients (pts) with SS were identified using an algorithm.[4] Inclusion criteria: International Classification of Diseases, Tenth Revision code M35.0 (Sicca syndrome [Sjögren]) or M35 (other systemic involvement of connective tissue), and ≥2 drug reimbursements for SS-related treatments. Key exclusion criteria: amyloidosis, sarcoidosis, HIV, and head and neck radiotherapy. Denominators for estimated prevalence rates were derived from French population census data. Healthcare costs were based on Assurance Maladie rates.

Results: 23,152 pts with pSS and 15,462 with SS+AID were identified during the study period. Estimated prevalence of SS (2011–2018) per 100,000 persons ranged from 22–32 (pSS) and 17–22 (SS+AID) and was stable over time; proportion of female pts was 90–91% (pSS) and 92–93% (SS+AID); mean age ranged from 63–66 (pSS) and 58–63 (SS+AID) years. Estimated incidence of SS (2012–2018) per 100,000 persons ranged from 4.1–0.3 (pSS) and 2.1–0.1 (SS+AID); proportion of female pts was 76–87% (pSS) and 74–90% (SS+AID); mean age ranged from 53–64 (pSS) and 50–62 (SS+AID) years. RA was the most frequently associated autoimmune disorder (32%) in pts with SS+AID. In the first year, artificial tears was the most frequently reimbursed drug (66% [pSS], 55% [SS+AID]), followed by hydroxychloroquine (19% [pSS], 35% [SS+AID]). From 2014–2018, ~30% of men and ~22% of women with pSS reported no drug reimbursement; ~20% of men and ~15% of women with SS+AID reported no drug reimbursement during the same time frame. From 2013–2018, ~50% of all pts had consultations with a dentist or an ophthalmologist. Mean healthcare costs increased over the study period: from €5836 to €9618 (pSS) and €8905 to €13,271 (SS+AID). Pt characteristics and healthcare consumption data are presented (Table 1).

Conclusion: Prevalence of pSS in this French claims data study was stable over time and consistent with previous reports.[3] Based on these results, SS may be considered an orphan disease. Overall costs for pts with SS were higher than previously estimated.[5] Results may help inform and optimise specialist care for pts with SS in France.

POS0025

INCIDENCE RATES AND POINT PREVALENCE OF SEROPOSITIVE AND SERONEGATIVE RHEUMATOID ARTHRITIS IN DENMARK: A NATIONWIDE REGISTER-BASED STUDY FROM 1998 TO 2018 USING FOUR DIFFERENT CASE CRITERIA

B. G. Soussi[1], R. L. Cordtz[1], S. Kristensen[1,2], C. S. Bork[3], J. Christensen[2,4], E. B. Schmidt[2,3], D. Prieto-Alhambra[5], L. Dreyer[1,2]. *[1]Aalborg University Hospital, Department of Rheumatology, Aalborg, Denmark*; *[2]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark*; *[3]Aalborg University Hospital, Department of Cardiology, Aalborg, Denmark*; *[4]Aalborg University Hospital, Department of Nephrology, Aalborg, Denmark*; *[5]University of Oxford, CSM-NDORMS, Oxford, United Kingdom*

Background: Few previous studies have investigated the incidence rate (IR) and point prevalence (PP) of seropositive and seronegative rheumatoid arthritis (RA), and further, the estimates remain unknown in the Danish population.

Objectives: To investigate the IR and PP of seropositive and seronegative RA in the adult Danish population from 1998 to 2018 using four register-based case definitions of RA.

Methods: Nationwide register-based cohort study. Using the Danish administrative registers, patients with RA between 1998 and end of 2018 were identified. ICD-10 codes for RA were identified in the Danish National Patient Registry and information on DMARD prescriptions were obtained through the Danish National Prescription Registry using ATC codes. The used case definitions were[1]: Criteria A, first time M05/M06 RA diagnosis and redemption of a DMARD in the following year; Criteria B, two RA diagnoses within 90 days of each other, originating from department of rheumatology or general internal medicine, where the latest registered M05/M06 diagnosis defined the serologic status; Criteria C, a M05/M06 diagnosis recorded at any time preceded or followed by redemption of a DMARD prescription within one year, where the M05/M06 diagnosis recorded determined the serologic status; Criteria D, as Criteria A, but with the additional requirements that cases had no registration for other selected inflammatory diseases.

In calculation of IRs the total Danish population from 1998 to 2018 was used as reference population for standardisation. The PP was calculated for years 2000, 2009, 2011 and 2018.

Results: From 1998 to 2018 the overall IR was 18.0 (95%CI 17.7 to 18.3) per 100,000 person years (PY) for seropositive RA and 16.7 (95%CI 16.4 to 16.9) per 100,000 PY for seronegative RA using Criteria A. A higher IR for seropositive RA than for seronegative RA was found regardless of the case criteria used. Figure 1 shows the temporal IRs of seropositive and seronegative RA.

Regardless of case criteria used, the PP increased from 2000 to 2018 for both seropositive and seronegative RA, and the estimates were higher for seropositive RA than for seronegative RA (Table 1).

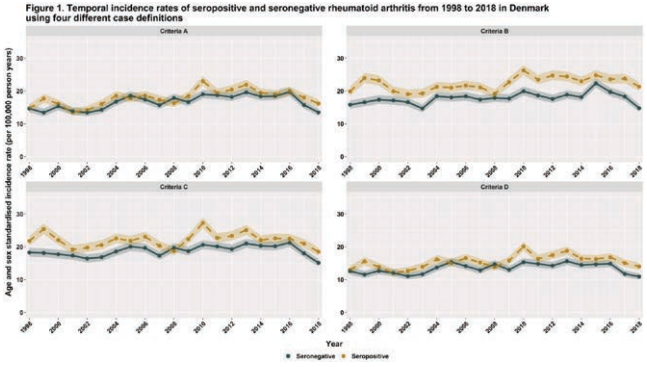

Figure 1. Temporal incidence rates of seropositive and seronegative rheumatoid arthritis from 1998 to 2018 in Denmark using four different case definitions

PP = Point prevalence

Conclusion: In Denmark, the IR and PP estimates were higher for seropositive compared to seronegative RA during the study period. However, when applying stricter case criteria for RA (Criteria A and D) the differences in IR and PP estimates were smaller, than when using less strict criteria (Criteria B and C). The findings of such small differences between seropositive and seronegative IRs warrant further investigation.

ASSOCIATION BETWEEN RA DISEASE ACTIVITY AND TOOTH LOSS: RESULTS OF TWO NATIONAL COHORTS

K. Albrecht[1], P. De Pablo[2], T. Eidner[3], G. Hoese[4], S. Wassenberg[5], A. Zink[1], J. Callhoff[1,6]. [1]*German Rheumatism Research Centre, Epidemiology, Berlin, Germany*; [2]*University of Birmingham, Rheumatology Research Group, Institute of Inflammation & Ageing, College of Medical & Dental Sciences, Birmingham, United Kingdom*; [3]*Jena University Hospital, Department of Internal Medicine III, Division of Rheumatology & Osteology, Jena, Germany*; [4]*Practice of Rheumatology, Stadthagen, Stadthagen, Germany*; [5]*Rheumazentrum Ratingen,, Ratingen, Germany*; [6]*Charité - Universitätsmedizin Berlin, Institute for Social Medicine, Epidemiology and Health Economics, Berlin, Germany*

Background: Cross-sectional studies suggest an association between the presence of tooth loss and/or periodontitis, cytokine levels and disease activity in patients with rheumatoid arthritis (RA) (1).

Objectives: To analyze the association between tooth loss and disease activity/inflammatory activity in patients with early arthritis and established RA.

Methods: Two data sources were used for analysis. Participants of the early arthritis cohort study CAPEA, conducted between 2010 and 2013, reported their number of teeth present at baseline and were followed over 2 years. Tooth loss categories were defined according to the number of teeth present, as follows: 0, 1-19, 19-27, and all 28 teeth. Disease activity/inflammatory activity data, such as disease activity scores (DAS28-ESR) and disease activity parameters, including swollen joint count (SJC) and inflammatory markers, i.e. erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), were collected longitudinally at baseline, 3, 6, 12, 18, and 24 months. We used linear mixed regression models (with negative binomial distribution for SJC) to estimate the association between tooth loss and disease activity scores, SJC and inflammatory markers (ESR, CRP), over time. We also investigated the association between tooth loss and disease activity/inflammatory markers in patients with established RA, using cross-sectional data from the German National database (NDB) collected between 2015 and 2018. All models were adjusted for age, sex, smoking (ever vs. never), rheumatoid factor and education level, defined as years in education. Models with the NDB data were additionally adjusted for disease duration, missing data were imputed using multiple imputation. In all models, number of teeth was entered as a continuous variable.

Results: Of a total of 1,124 CAPEA participants included, those with higher tooth loss were older, more often smokers, had a lower level of education, higher inflammatory markers and higher disease activity scores at baseline (Table 1). Inflammatory markers decreased comparably across all categories of tooth loss over time (Figure 1), in particular CRP. Tooth loss was not significantly associated with CRP or SJC alone. Glucocorticoid use was higher among those with more tooth loss, however dose reduction was similar across tooth loss categories. Among 7,179 NDB participants, adjusted disease activity scores and inflammatory markers were higher across tooth loss categories (DAS28 no teeth: 2.7, all teeth: 2.4; ESR no teeth: 23 mm/h, all teeth: 17 mm/h). SJC was not relevantly associated with tooth loss (no teeth: 1.2, all teeth: 1.2). Mean disease duration in the NDB sample was 13 years.

Table 1. Early arthritis cohort (CAPEA) baseline characteristics, stratified by number of teeth

	Number of teeth present				Total	n
	0	1-19	20-27	All 28		
N	89	315	452	268	1,124	1,124
Female, %	57	65	64	69	65	1,124
Age (years), mean	69	64	54	45	56	1,124
ESR (mm), mean	42	38	28	24	31	1,074
CRP (mg/l), mean	25	24	15	15	19	1,069
SJC, mean	6.1	6.9	5.6	5.2	5.9	1,120
DAS28-ESR, mean	5.5	5.2	4.7	4.5	4.9	983
RF positive, %	63	53	52	54	54	1,124
Education, %						1,020
<=8 years	80	58	35	21	42	
9-10 years	16	30	43	46	38	
11-13 years	4	12	22	33	20	
Smoking (ever), %	73	64	61	56	61	1,102

ESR: erythrocyte sedimentation rate, CRP: C-reactive protein, DAS28: disease activity score, RF: rheumatoid factor, SJC: swollen joint count

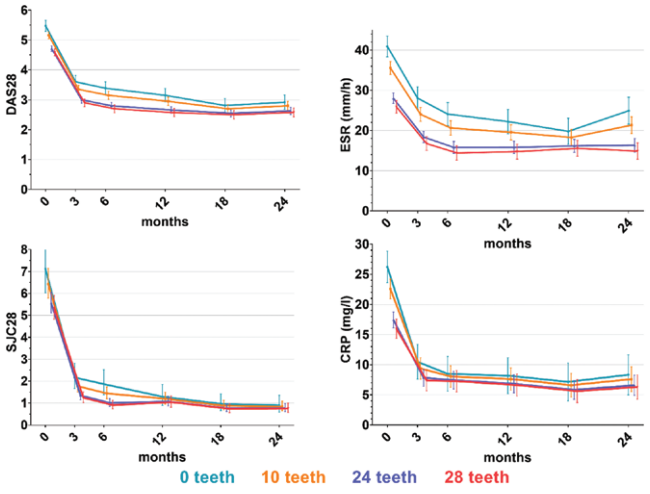

Figure 1. Disease activity parameters during the 24-months follow-up, stratified by the number of teeth at baseline: results from mixed models, adjusted for age, sex, smoking and education level.

Conclusion: While we observed a significant association between tooth loss and disease activity and inflammation markers in both early arthritis and established RA, our longitudinal results suggest that tooth loss has no influence on response to therapy.

Background: Knowledge of changes over time in baseline characteristics and tumor necrosis factor inhibitor (TNFi) response in bio-naïve axial spondyloarthritis (axSpA) patients treated in routine care is limited.

Objectives: To investigate secular trends in baseline characteristics and retention, remission and response rates in axSpA patients initiating a first TNFi.

Methods: Prospectively collected data on bio-naïve axSpA patients starting TNFi in routine care from 15 European countries were pooled. According to year of TNFi initiation, three groups were defined a priori based on bDMARD availability: Group A (1999–2008), Group B (2009–2014) and Group C (2015–2018). Retention rates (Kaplan-Meier), crude and LUNDEX adjusted[1] remission (Ankylosing Spondylitis Disease Activity Score (ASDAS) <1.3, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) <20) and response (ASDAS Major and Clinically Important Improvement (MI/CII), BASDAI 50) rates were assessed at 6, 12 and 24 months. No statistical comparisons were made.

Results: In total, 27189 axSpA patients were included (5945, 11255 and 9989 in groups A, B and C).

At baseline, patients in group A were older, had longer disease duration and a larger proportion of male and HLA-B27 positive patients compared to B and C, whereas disease activity was similar across groups.

Retention rates at 6, 12 and 24 months were highest in group A (88%/81%/71%) but differed little between B (84%/74%/64%) and C (85%/76%/67%).

In all groups, median ASDAS and BASDAI had decreased markedly at 6 months (Table 1). The ASDAS values at 12 and 24 months and BASDAI at 24 months were higher in group A compared with groups B and C. Similarly, crude remission and response rates were lowest in group A. After adjustments for drug retention (LUNDEX), remission and response rates showed less pronounced between-group differences regarding ASDAS measures and no relevant differences regarding BASDAI measures.

Conclusion: Nowadays, axSpA patients initiating TNFi are younger with shorter disease duration and more frequently female and HLA-B27 negative than previously, while baseline disease activity is unchanged. Drug retention rates have decreased, whereas crude remission and response rates have increased. This may indicate expanded indication but also a stable disease activity threshold for TNFi initiation over time, an increased focus on targeting disease remission and more available treatment options.

Table 1. Secular trends in baseline characteristics, treatment retention, remission and response rates in European axSpA patients initiating a 1st TNFi

Background: The recent prospectively validated definition of the lupus low disease activity state (LLDAS) allows characterisation of patients not achieving a treatment goal, providing impetus for an analysis of unmet needs in SLE using formal definitions. Other recently described definitions of high disease burden include disease activity over time, high disease activity status (HDAS) episodes, and the combination of high disease activity, serological activity and glucocorticoid (GC) use (HDAS+SA+GC).
Objectives: To determine the prevalence of formal categories of unmet need, and the association of these with adverse outcomes, in SLE.
Methods: Data from a 13-country longitudinal SLE cohort (ACR/SLICC criteria) were collected between 2013 and 19 using standard templates. Unmet need was defined as (i) patients never attaining LLDAS defined as in Golder *et al.*, 2019 [1], (ii) having persistently active disease (time adjusted mean SLEDAI-2K (AMS) > 4), (iii) ever exhibiting high disease activity status (HDAS; SLEDAI-2K ≥10[2]), or (iv) ever exhibiting all of SLEDAI≥10, serological activity, and glucocorticoid use (HDAS+SA+GC)[3]. Health-related quality of life (HRQoL) was assessed using SF36 (v2) surveys and damage accrual using SLE Damage Index (SDI).
Results: 3,384 SLE patients were followed for 30,313 visits over median [IQR] 2.4 [0.4, 4.3] years. 53% of all visits were not in LLDAS; 813 patients (24%) never achieved LLDAS during observation. Median AMS was 3.0 [1.4, 4.9] and 34% of patients had AMS > 4 throughout the study. 25% of patients had at least one episode of HDAS, representing 8% of visits. 702 patients (21%) had at least one episode of HDAS+SA+GC, representing 8% of visits. Each of never-LLDAS, AMS>4, ever-HDAS, and ever-HDAS+SA+GC were associated with significantly greater number of physician visits, higher mean glucocorticoid dose, lower HRQoL and higher mortality. 31%, 58% and 83% of never-LLDAS, AMS>4, and ever-HDAS patients respectively were also HDAS+SA+GC on at least one occasion.
Conclusion: Data from a multinational longitudinal SLE cohort indicate that unmet need, defined by LLDAS-never, AMS>4, HDAS, or HDAS+SA+GC, is prevalent in SLE, and that these definitions are associated with poor outcomes.

INCIDENCE AND TREATMENT PENETRATION OF RHEUMATOID ARTHRITIS IN NORWAY – A NATIONWIDE REGISTER LINKAGE STUDY

A. Kerola[1,2], J. Sexton[1], G. Wibetoe[1], S. Rollefstad[1], C. S. Crowson[3], E. Haavardsholm[1], T. K. Kvien[1], A. G. Semb[1]. [1]*Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*; [2]*Päijät-Häme Joint Authority for Health and Wellbeing, Rheumatology, Lahti, Finland*; [3]*Mayo Clinic, Department of Quantitative Health Sciences, Rochester, Minnesota, United States of America*

Background: Incidence of rheumatoid arthritis (RA) in Norway has not been evaluated in a nationwide setting.

Objectives: To estimate the incidence of RA and real-life penetration of disease-modifying antirheumatic drug (DMARD) use in Norway.

Methods: The Norwegian Cardio-Rheuma register comprises pseudonymized data from nationwide registries including the total Norwegian population ≥18 years during 2008-2017. Demographic and socioeconomic data were retrieved from the National Population Register and Statistics Norway. Data on public or private somatic specialized care episodes were collected from the Norwegian Patient register (NPR) (ICD-10 codes for diagnoses and medical procedure codes for biologic DMARD infusions). Dispensed DMARD prescriptions were captured from the Norwegian Prescription Database. RA cases were defined as persons with NPR records of all of the following: 1) 1st episode with ICD-10 code M05/M06 as main or contributory diagnosis (index date), 2) 2nd episode with code M05/M06 within 2-year period following index date, 3) M05/M06 recorded in an internal medicine or rheumatology department during the 2-year period. Years 2008-2010 served as a look-back period to identify prevalent RA cases. To estimate person-years (pyrs) at risk, we calculated number of persons aged ≥ 18 living in Norway on the 1st of January of each year 2011-2015 and multiplied it by one year (prevalent RA cases excluded). Standardized estimates were calculated with 5-year age groups using Norwegian adult population 1st of January 2015 as the standard.

Results: Between 2011 and 2015, 9,493 persons fulfilled the RA definition (62.4% seropositive based on ICD-10 codes). Incidence rate was 49/100,000 pyrs (32 in men and 65 in women). A sensitivity analysis excluding cases who had dispensed DMARDs >12 months before index date yielded 8,125 RA cases (incidence 42/100,000 pyrs). Whereas absolute number of incident cases was highest among those aged 60-69 in both sexes, incidence was highest among those aged 70-79 (Figure 1). Both crude and age- and sex-standardized incidences were lower among persons with higher education level (crude/standardized incidence per 100,000 pyrs for those below upper secondary education 60/57; upper secondary or post-secondary non-tertiary education 53/52; higher education 36/39). Of incident cases, 94% received any DMARD treatment or glucocorticoids, 78% methotrexate, and 17% biologic DMARDs within 2 years after index date (Table 1).

Conclusion: Contemporary register-based estimate of RA incidence in Norway is comparable to other Nordic countries.[1,2] In line with treatment recommendations, methotrexate is the most commonly used DMARD in the initial treatment strategy in Norway. One in six patients used a biologic DMARD within 2 years from 1st recorded RA diagnosis.

POS0030 SARCOIDOSIS INCIDENCE IN A NORTHERN SPANISH HEALTH REGION.

C. Álvarez-Reguera[1], R. Fernández-Ramón[2], J. J. Gaitán-Valdizán[2], J. L. Martín-Varillas[3], L. Sanchez-Bilbao[1], D. Martínez-López[3], I. González-Mazón[1], R. Demetrio-Pablo[2], M. Á. González-Gay[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*; [2]*Hospital Universitario Marqués de Valdecilla, Ophthalmology, Santander, Spain*; [3]*Hospital de Sierrallana, Rheumatology,Torrelavega, Spain*

Background: Sarcoidosis is a systemic and potentially severe disease **(1).** Its incidence varies widely worldwide.
Objectives: The aim of this study was to estimate the sarcoidosis incidence in a Northern Spanish population-based cohort.
Methods: All incident cases of sarcoidosis between January 1999 and December 2019 in a tertiary hospital were reviewed. Inclusion criteria were **a)** diagnosis of sarcoidosis according to ATS/ERS/WASOG *(Eur Respir J. 1999; 14:735-7)* and **b)** patients residing in our health region. Incidence between 1999 and 2019 was estimated by sex, age, and year of diagnosis.
Results: From a total of 384 patients diagnosed with sarcoidosis, 234 (129 women/ 105 men) met the inclusion criteria and were finally included in the study. Mean age of the cohort at diagnosis was 48.43±14.83 years (46.95±14.50 in males; 49.63±15.04 in females, p=0.12). Annual incidence during 1999-2019 period was 3.56 per 100,000 population (3.32 per 100,000 in males and 3.72 per 100,000 in females). An upward trend in annual incidence over time was observed with rates ranging from 1.73 per 100,000 inhabitants in 1999 to 6.91 per 100,000 inhabitants in 2016 (Figure 1). Overall, sarcoidosis was predominantly diagnosed during middle adulthood. A bimodal distribution of age-specific incidence rates was observed in both sexes with two peaks in the age groups of 30-39 (4.98 per 100,000) and 60-69 years (5.12 per 100,000) in men, and in 40-49 (6.45 per 100,000) and 60-69 years (5.94 per 100,000) in women.
Comparative studies with other regions are summarize in Table 1.
Conclusion: A progressive increase in incident sarcoidosis is observed. The estimated incidence of sarcoidosis in this study (3.56 per 100,000) was like that of other Mediterranean countries **(2).** No gender predominance was observed. Demographics variations, changes in practice patters or diagnostic test improvements could explain the upward trend in sarcoidosis incidence detected in our study. Consistent with previous studies, male presented an incidence peak 10 years earlier than female **(3-5)**.

POS0031

THE PREVALENCE OF INFLAMMATORY BACK PAIN AND HLA-B27 IN A LARGE POPULATION-BASED COHORT IN THE NETHERLANDS

S. Kieskamp[1], S. Arends[1], E. Brouwer[1], H. Bootsma[1], I. M. Nolte[2], A. Spoorenberg[1]. [1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [2]University Medical Center Groningen, Department of Epidemiology, Groningen, Netherlands

Background: Although chronic low back pain (≥3 months) before the age of 45 and inflammatory back pain (IBP) are regarded as early presenting and key features of axial spondyloarthritis (axSpA), and Magnetic Resonance Imaging (MRI) can be used to demonstrate sacroiliitis, the substantial delay in the diagnosis of axSpA has not improved.(1) Additionally, knowledge on the prevalence of chronic low back pain before the age of 45 and IBP in combination with the axSpA-related genetic risk factor Human Leukocyte Antigen-B27 (HLA-B27) in the general population is scarce.

Objectives: To estimate the prevalence of chronic low back pain before the age of 45 and IBP in combination with the presence of HLA-B27 in a large Dutch population based cohort.

Methods: Participants of the Lifelines cohort, a large population-based cohort of the northern region of the Netherlands, filled out a questionnaire on chronic low back pain and IBP. Chronic low back pain was defined as an affirmative answer to the question 'Did you suffer from low back pain for ≥3 months?'. IBP was questioned based on the validated European Spondyloarthropathy Study Group (ESSG) IBP criteria and was confirmed if at least 4 out of the following 5 criteria were present: (a) onset before age 45, (b) insidious onset, (c) improvement with exercise, (d) associated with morning stiffness, (e) at least 3 months duration. Participants reporting to have been diagnosed with axSpA were identified using variations of the search terms "Bechterew", "spondyloarthritis" and "ankylosing spondylitis". The Illumina global screening array (GSA) beadchip-24 v1.0 was used to genotype genome-wide SNPs in a subset of Lifelines participants. HLA-B haplotypes were imputed using neighboring SNPs with HIBAG, which is an R-package, using published parameter estimates.(2) The predicted HLA-B haplotype was considered valid if the posterior probability was >80%.

Results: In total 94,277 Lifelines participants answered the chronic low back pain question, of which 93,665 (99.4%) completed the ESSG IBP questions. Of these participants, 56,008 (59.8%) were female, mean age was 45.6 ± 12.8 years and 22,192 (23.7%) reported to have been suffering from chronic low back pain. In this chronic low back pain group, the pain began before the age of 45 in 17,122 (77.2%; 18,3% of entire Lifelines population) participants, and 13,514 (60.9%; 14.4% of entire Lifelines population) participants reported to have IBP according to the ESSG criteria.

Of 32,785 participants genetic data were available and in 29,399 (89.7%) the HLA-B haplotype could be determined with high prediction accuracy, of which 2,279 (7.8%) participants were HLA-B27 positive. Of these HLA-B27 positive participants, 1,610 (70.6%) also had available chronic low back pain data, of which 373 (23.2%) reported chronic low back pain. Of these 373 patients with chronic back pain and HLA-B27 positivity, the pain began before the age of 45 in 296 (79.4%), and 237 (64.2%) fulfilled the ESSG IBP criteria of which only 11 (4.6%) participants reported to be diagnosed with axSpA.

Conclusion: In this large population-based cohort, 18.3% of participants reported chronic low back pain that began before the age of 45. 14.4% of the participants reported IBP, which is relatively high in comparison to previous studies. HLA-B27 prevalence (7.8%) was similar to previously published data from the North-Western European population. The vast majority of participants with both IBP and the presence of HLA-B27 did not report an axSpA diagnosis. A next step in the analyses will be to explore associations with other demographic and clinical factors present including additional SpA features.

SCORING MRI STRUCTURAL LESIONS IN SACROILIAC JOINTS OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS: HOW MANY SLICES ARE OPTIMAL?

W. P. Maksymowych[1,2], U. Weber[3], X. Baraliakos[4], P. Machado[5], S. Juhl Pedersen[6,7], J. Sieper[8], S. Wichuk[1], D. Poddubnyy[8], M. Rudwaleit[9], D. Van der Heijde[10], R. B. M. Landewé[11], J. Paschke[2], M. Østergaard[6,7], R. G. Lambert[12]on behalf of ASAS MRImagine. [1]University of Alberta, Medicine, Edmonton, Canada; [2]CARE Arthritis, Rheumatology, Edmonton, Canada; [3]Practice Buchsbaum, Medicine, Schaffhausen, Switzerland; [4]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; [5]University College London, Rheumatology, London, United Kingdom; [6]COPECARE, Rheumatology, Copenhagen, Denmark; [7]Rigshospitalet, Clinical Medicine, Glostrup, Denmark; [8]Charité Universitätsmedizin, Rheumatology, Berlin, Germany; [9]Klinikum Bielefeld, Rheumatology, Bielefeld, Germany; [10]Leiden University Medical Centre, Rheumatology, Leiden, Netherlands; [11]Academic Medical Center, Rheumatology, Amsterdam, Netherlands; [12]University of Alberta, Radiology and Diagnostic Imaging, Edmonton, Canada

Background: There is no international consensus on the optimal number of slices for evaluation of MRI structural lesions in the SIJ. An "all slice" method evaluates lesions from the most anterior slice, defined as the first slice with vertical height of ≥1cm of the SIJ joint cavity, up to the most posterior slice, defined as the most posterior slice where ≥1cm vertical height of the cartilaginous portion is still visible. The SPARCC method scores the transitional slice between cartilaginous and ligamentous compartments as the first slice and then an additional 4 slices anterior to the transitional slice.

Objectives: We aimed to investigate inter-reader reliability, the extent of detection of lesions, and frequency of cases with a positive MRI for structural lesions when using an "all slice" approach versus the SPARCC scoring of 5 central slices.

Methods: MRI T1W images with DICOM series were available from 148 cases who had MRI performed in the ASAS-Classification Cohort. Seven central readers recorded MRI lesions in an eCRF that recorded global assessments of presence/absence of changes suggestive of axSpA and structural lesions typical of axSpA. Structural lesions per the ASAS definitions were also recorded in consecutive semicoronal slices using the "all slice" approach, but also recording the transitional slice, according to their presence/absence in SIJ quadrants (erosion, fat lesion, sclerosis) or halves (backfill, ankylosis). Structural lesion frequencies were assessed descriptively according to majority agreement (≥4/7) of central readers and also any 2 central readers. Reliability for detection of MRI lesions was compared between central and local readers using the ICC.

Results: The mean (SD) (range) number of anterior and posterior slices peripheral to the 5 central slices was 1.0 (1.0) (0-4) and 2.2 (1.8) (0-6) per case, respectively. There were 2 cases (1.4%) where ≥2 readers scored structural lesions in peripheral slices but not in the 5 central slices. The mean percentage of the total structural lesion score that was captured by the 5 central slices was >75% for all types of lesions except ankylosis (59%) (Table 1). Inter-reader reliability was greater for all lesions when assessing the 5 central slices and especially for erosion and backfill (Table 1).

Conclusion: The major component of structural lesion data is captured by assessment of 5 slices, which includes the transitional slice and the subsequent 4 anterior slices. Moreover, reliability for detection of structural lesions is substantially worse in peripheral slices.

Disclosure of Interests: None declared.

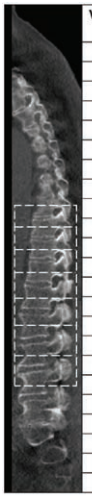
IN RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS, BRIDGING SYNDESMOPHYTES INCREASE RISK OF FACET JOINT ANKYLOSIS ON THE SAME VERTEBRAL LEVEL WHILE FACET JOINT ANKYLOSIS DOES NOT INCREASE RISK OF SAME LEVEL SYNDESMOPHYTES

R. Stal[1], A. Sepriano[1], F. A. Van Gaalen[1], X. Baraliakos[2], R. Van den Berg[1], M. Reijnierse[3], J. Braun[2], R. B. M. Landewé[4], D. Van der Heijde[1]. [1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands; [2]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; [3]Leiden University Medical Center, Radiology, Leiden, Netherlands; [4]Amsterdam University Medical Center, Rheumatology, Amsterdam, Netherlands

Background: In radiographic axial spondyloarthritis (r-axSpA), spinal damage manifests as syndesmophytes and facet joint ankylosis (FJA).
Objectives: Explore whether syndesmophytes and FJA seem to have a preferential order of development.
Methods: Data were used from the Sensitive Imaging in Ankylosing Spondylitis cohort from Leiden and Herne. Patients underwent low-dose Computed Tomography (ldCT) at baseline and two-years. LdCT images were scored independently by two trained readers. Vertebrae were scored according to the Computed Tomography Syndesmophyte Score (CTSS) for presence and size of syndesmophytes; facet joints were scored as not-ankylosed and ankylosed. Analyses were performed on the vertebral unit (VU) level and using individual-reader data (Figure 1). Two hypotheses were tested: 1) presence of bridging syndesmophyte(s) is associated with FJA on the same VU two years later, and 2) presence of FJA is associated with syndesmophyte(s) on the same VU two years later. Generalized Estimating Equations (GEE) models were used to take into account the correlations between VUs from the same patient and adjusting for reader to account for individual reader scores. Two models were tested per hypothesis using different outcomes. Model 1 uses the presence of syndesmophytes or FJA as outcome adjusting for the outcome at baseline. Model 2 uses development of new syndesmophytes or FJA at two years plus an increase in the number of syndesmophytes or FJA.**Results:** In total, 50 patients were included (mean age 49, 84% male, 82% HLA-B27+). At baseline, there was a higher percentage of bridging syndesmophytes (range: 10-60%) than FJA (range: 8-36%) considering all VUs and both readers (Figure 1). In both models, presence of bridging syndesmophytes was associated with development of FJA two years later (OR (95%CI) Model 1: 3.35 (2.18-5.14); Model 2: 2.23 (1.19-4.16)) while presence of FJA at baseline did not have a statistically significant association with development of syndesmophytes two years later (Table 1).
Conclusion: The data showed a higher occurrence of bridging syndesmophytes than FJA at baseline and showed significantly increased odds to develop FJA when bridging syndesmophyte(s) are present on the same VU two years prior. This mechanism did not hold true for the other direction. These results cautiously imply that bridging syndesmophytes precede FJA, rather than FJA preceding syndesmophytes.



VU	Segment	≥1 bridging synd at BL reader 1	≥1 bridging synd at BL reader 2	≥1 FJA at BL reader 1	≥1 FJA at BL reader 2

POS0034

RADIOGRAPHIC ENTHESEAL LESIONS AT HIP AND PELVIC REGION ARE ASSOCIATED WITH LONGER DISEASE DURATION, HIGHER BMI AND MORE SEVERE SPINAL AND HIP RADIOGRAPHIC DAMAGE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

F. Wink[1], T. Diemel[2], S. Arends[2], A. Spoorenberg[2]. [1]Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands; [2]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands

Background: Enthesitis is an important feature of ankylosing spondylitis (AS) and structural and inflammatory entheseal lesions (EL) are frequently present on ultrasound. Plain radiographs also provide good imaging of structural entheseal involvement1. Until now, little is known about the presence of structural EL at the hip and pelvic region and the association with patient characteristics in AS.
Objectives: Our aim was to investigate the prevalence of radiographic EL at the hip and pelvic region in AS patients compared to age and sex matched control subjects and to explore the relation with AS patient characteristics.
Methods: AS patients from the Groningen Leeuwarden Axial SpA (GLAS) cohort, included between November 2004 and December 2010, with available anteroposterior (AP) pelvis radiographs at baseline were included. All patients fulfilled the modified New York criteria for AS. Additionally, 100 randomly selected AP pelvis radiographs from age and sex matched control subjects were obtained from the radiology department of the University Medical Center Groningen. The sacroiliac joints of all radiographs were blinded and radiographs were scored independently by two trained observers unaware of patient characteristics and treatment. The entheseal sites scored were: trochanter major, trochanter minor, os ischium, crista iliaca, both left and right side. The following 3 EL were scored: erosion/cortical irregularity, calcification and enthesophyte. Only lesions with absolute agreement between both observers were used for analyses. Radiographic spinal involvement was scored according to the modified Stoke AS Spine Score (mSASSS; range 0-72) and radiographic hip involvement according to the Bath AS Radiology Index (BASRI)-hip (range 0-4). Independent samples t test, Mann-Whitney U test, Chi-Square test, and Fisher Exact test were used to compare patient characteristics between patients with and without radiographic EL.
Results: Of the 167 included AS patients, 117 (70%) were male, mean age was 43 ± 11 years, 133 (80%) were HLA-B27 positive and median symptom duration was 16 years (range 1-53). 127 (76%) AS patients and 58 (58%) controls showed EL, with 501 lesions in total of which 377 (75%) in AS patients. AS patients showed significantly more lesions than controls at all 5 locations. Os ischii showed the most lesions in both AS patients and controls (66% vs 53%, p<0.05). The most prevalent type of lesion in both groups was erosion/cortical irregularity (72% vs 51%, p<0.005). Enthesophytes were also more often observed in AS patients than in controls (31% vs 21%, p=0.07). Prevalence of calcifications was low in both groups and not significantly different (5% vs 2%, p=0.22). AS patients with EL were significantly older (mean 45.2 vs 35.1 yrs, p<0.005) and had longer symptom duration (median 18 vs 7.5 yrs, p<0.005) than patients without EL. Furthermore, patients with BMI >25 had significantly more often enthesophytes (42% vs 16%, p<0.05) than patients with a normal BMI. Additionally, AS patients with EL had significantly more often radiographic spinal damage than patients without EL with median mSASSS total score 8.7 vs 1.0 (p<0.005) and a trend toward significance for radiographic hip involvement (BASRI-hip score ≥2; p=0.06).
Conclusion: Radiographic EL at hip and pelvic region are significantly more prevalent in AS patients than in age and sex matched controls. AS patients with EL were significantly older, had longer symptom duration and more spinal radiographic damage than patient without EL. Furthermore, BMI >25 was associated with a higher prevalence of enthesophytes. These new findings contribute to the knowledge of entheseal involvement in AS.

ONE IN TWENTY INFLAMMATORY BOWEL DISEASE PATIENTS WHO UNDERWENT ABDOMINOPELVIC COMPUTED TOMOGRAPHY HAVE UNDIAGNOSED AXIAL SPONDYLOARTHRITIS

C. S. E. Lim[1], L. Hamilton[1], S. Low[2], A. Toms[2], A. Macgregor[1], K. Gaffney[1]. [1]Norfolk & Norwich University Hospital, Rheumatology, Norwich, United Kingdom; [2]Norfolk & Norwich University Hospital, Radiology, Norwich, United Kingdom

Background: The diagnosis of axial spondyloarthritis (axSpA) is challenging and hindered by delay. There may be an opportunity to identify sacroiliitis for further rheumatology review in inflammatory bowel disease (IBD) patients who undergo Computed Tomography (CT) for non-musculoskeletal (MSK) indications.
Objectives: To identify what proportion of IBD patients who underwent abdominopelvic CT for non-MSK indications have axSpA and to explore the role of an imaging strategy for identifying axSpA.
Methods: Abdominopelvic CT scans of verified IBD patients were identified retrospectively from eight years of imaging archive. Patients between 18-55 yrs. were selected as having the highest diagnostic yield for axSpA. CT review (using criteria from a validated CT screening tool developed by Chan[1]) was undertaken by a trained radiology team for presence of CT-defined sacroiliitis (CTSI). All CTSI patients were sent a screening questionnaire. Those with self-reported chronic back pain (CBP), duration > 3 months, onset < 45 years were invited for rheumatology review. This included a medical interview, physical examination (joint count, MASES, dactylitis count, BASMI), patient reported outcomes (BASDAI, BASFI, BASGI, Harvey-Bradshaw-Index, Partial-Mayo-Index), relevant laboratory tests (CRP, ESR, HLA-B27), axSpA protocol MRI, and remote review by a panel of experienced rheumatologists with a special interest in axSpA.
Results: CTSI was identified in 60 of 301 patients. Thirty-two (53%) responded to the invitation to participate and 27 (84%) were enrolled. Of these, eight had a pre-existing axSpA diagnosis and five did not report chronic back pain. Fourteen patients underwent rheumatological assessment; three of 14 (21.4% [95% CI: 4.7%, 50.8%]) had undiagnosed axSpA. In total, 11 of 27 (40.7% [95% CI: 22.4%, 61.2%]) patients had a rheumatologist verified diagnosis of axSpA.
Conclusion: One in five patients (60/301) with IBD who underwent abdominopelvic CT for non-MSK indications have CTSI and at least one in five (11/60) have axSpA. Five percent (3/60) were previously undiagnosed. This highlights a hidden disease burden and a potential strategy for identifying new cases.

AN ARTIFICIAL INTELLIGENCE MODEL IN RHEUMATOLOGY: INTERPRETATION OF THE SACROILIAC JOINT GRAPHY IN ANKYLOSING SPONDYLITIS

A. C. Genç[1,2], Z. N. Kaya[3], F. Turkoglu Genc[4], L. Genc Kaya[5], Z. Öztürk[6], D. Karatas[6], S. M. Turk[6], E. Gönüllü[6]. [1]Geyve Government Hospital, Internal Medicine, Sakarya, Turkey; [2]Bahcesehir University, Artificial Intelligence, Istanbul, Turkey; [3]Saratoga High School, SHS AI Club, Saratoga, United States of America; [4]Sakarya University, Internal Medicine, Sakarya, Turkey; [5] Data Scientist, Data Scientist, Santa Clara, United States of America; [6]Sakarya University, Rheumatology, Sakarya, Turkey

Background: There is an average of 8 years delay in the diagnosis of ankylosing spondylitis (AS). The most important danger of late diagnosis is that the disease can cause physical and functional disability (2). There is no specific diagnostic biomarker for AS. Sacroiliac joint (SIJ) radiography is frequently used in the diagnosis and follow-up of AS due to its easy accessibility and low cost. It can be classified as grade 0, 1, 2, 3, 4, and these classes may not be sharply separated from each other (3).
Objectives: Interpretation of the SIJ radiography may differ from physician to physician. In fact, the same physician may interpret it differently at different times (3). We wanted to find a solution to the intraobserver disagreement problem with the artificial intelligence model.
Methods: The SIJ radiography of 590 patients who applied to our center were divided into 3 categories as right and left, separately, grade 0, grade 1-2, grade 3-4, and an educational data set was prepared for the object recognition method. 488 images were augmented through noise from 490 images in the training data. 242 articular objects were trained for grade 0, 278 for grade 1-2, and 1426 for grade 2-3. The model was tested with 100 images for 36 joint objects for grade 0, 29 for grade 1-2, and 135 for grade 3-4 to create a computer vision-artificial intelligence model (image 1).
Results: Training performance is 70% for grade 0, %63 for grade 1-2, %90 for grade 3-4 and test performance is %52 for grade 0, %24 for grade 1-2, %86

intersection over union (I/U:Intersection over Union is a form of measurement used to indicate the accuracy of an object detector.) for grade 3-4. The mean average precision (mAP) score of our object detection model is %65.9 for test data set (image 1). The estimation quality of the model can be affected by the distribution and number of each class.

Conclusion: The experience of the x-ray technician, dose adjustment, and position differences due to patient compliance complicate the standardization of SIJ radiography and this may cause interobserver disagreement (3). Artificial intelligence models to be created with a larger and homogeneous data set in order to ensure objective standardization in the interpretation of the SIJ graph can help physicians.

POS0037 DOES IMAGING OF THE SACROILIAC JOINT DIFFER IN PATIENTS PRESENTING WITH UNDIAGNOSED BACK PAIN AND PSORIASIS, ACUTE ANTERIOR UVEITIS, AND COLITIS: AN INCEPTION COHORT STUDY

W. P. Maksymowych[1,2], U. Weber[3], J. Chan[4], R. Carmona[5], J. Yeung[6], S. Aydin[7], J. Reis[8], L. Martin[9], A. Masetto[10], O. Ziouzina[9], D. Mosher[9], S. Keeling[1], S. Rohekar[11], R. Dadashova[2], J. Paschke[2], A. Carapellucci[2], R. G. Lambert[2,12]on behalf of Screening for Axial Spondyloarthritis in Psoriasis, Iritis, Colitis. [1]University of Alberta, Medicine, Edmonton, Canada; [2]CARE Arthritis, Rheumatology, Edmonton, Canada; [3]Practice Buchsbaum, Rheumatology, Schaffhausen, Switzerland; [4]Artus Health Clinic, Rheumatology, Vancouver, Canada; [5]St. Joseph's Healthcare, Rheumatology, Hamilton, Canada; [6]James Yeung Rheumatology, Rheumatology, Richmond, Canada; [7]Ottawa Hospital, Rheumatology, Ottawa, Canada; [8]Polmed Research, Rheumatology, Saskatoon, Canada; [9]University of Calgary, Medicine, Calgary, Canada; [10]University of Sherbrooke, Medicine, Sherbrooke, Canada; [11]Lawson Health Research Institute, Medicine, London, Canada; [12]University of Alberta, Radiology and Diagnostic Imaging, Edmonton, Canada

Background: Axial spondyloarthritis (axSpA) presents diagnostic challenges incurring a delay of up to a decade and relies considerably on radiographic and MRI evidence of sacroiliitis which has led to the development of classification criteria which also rely on imaging. However, it has been suggested that such criteria may not be appropriate for axSpA patients presenting with other forms of SpA, especially psoriatic, because imaging features may vary in frequency and/or may be atypical. This hypothesis has never been tested in a prospective inception cohort of patients presenting with undiagnosed back pain.

Objectives: We aimed to compare the spectrum of radiographic and MRI abnormalities in the sacroiliac joint (SIJ) of an inception cohort of patients presenting with undiagnosed back pain and psoriasis, iritis, and colitis.

Methods: We used data from the prospective multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study, which is aimed at early detection of axial SpA in patients referred by the respective specialist after first presenting with these disorders. Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, AAU, or colitis undergo routine clinical evaluation by a rheumatologist for axial SpA followed by imaging. In SASPIC I, MRI evaluation of the SIJ was ordered per rheumatologist decision. In SASPIC II, MRI evaluation was ordered for all patients. Radiographs and MRI scans were assessed by two central readers and comparisons of the three groups were based on concordant assessments of imaging features. Evaluation of MRI scans included both global assessment for presence/absence of axSpA with confidence scale (-10 to +10), active and structural lesions typical of axSpA per recent ASAS definitions, and granular assessment of individual lesions according to SIJ quadrants and halves in consecutive semicoronal slices through the SIJ. Groups were compared by ANOVA and the chi-square test.

Results: A total of 240 patients were recruited, 143 from SASPIC I and 97 from SASPIC II, 101 (42.1%) being diagnosed with axSpA (65.3% male, mean age 34.4 years, mean symptom duration 8.7 years, B27 positive 55.4%). Mean age of colitis (N=101), psoriasis (N=61), iritis (N=78) patients were 33.4, 36.6, 34.3 years, respectively, mean symptom duration was 6.8, 7.2, 9.4 years, respectively, and % males were 45.5%, 52.5%, 51.3%, respectively. There were no significant group differences for unilateral versus bilateral radiographic sacroiliitis and no significant differences in the frequencies, type, or distribution of MRI lesions (Table 1).

Conclusion: Data from the SASPIC prospective inception cohort does not support the view that imaging of the SIJ differs in psoriatic axSpA, which appears similar to axSpA associated with iritis or colitis. These data support the umbrella concept of axSpA.

Imaging Feature	Colitis (n=30)	Psoriasis (n=19)	Iritis (n=52)	P value
Unilateral sacroiliitis (grade ≥2), N(%)	1 (3.3%)	0 (0%)	2 (3.8%)	0.69
mNY criteria +, N(%)	5 (16.7%)	6 (31.2%)	15 (28.8%)	0.39

POS0038 THE INFLUENCE OF AGE ON THE PREVALENCE OF INFLAMMATORY AND POST-INFLAMMATORY MRI LESIONS IN THE SACROILIAC JOINTS OF PATIENTS WITH AND WITHOUT AXIAL SPONDYLOARTHRITIS

X. Baraliakos[1], S. Tsiami[1], A. Kühn[1], M. Fruth[2], J. Braun[1]. [1]Ruhr-University Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany; [2]Radiologie blikk, Rheumazentrum Ruhrgebiet, Herne, Germany

Background: Axial spondyloarthritis (axSpA) is clinically characterized by chronic inflammatory back pain and by inflammatory and structural changes in the sacroiliac joint (SIJ) as assessed by magnetic resonance imaging (MRI). Several studies have reported high rates of bone marrow edema (BME) suggestive of inflammatory SIJ changes in up to 20% of individuals in the general population <45 years. An update of the definition of a positive MRI of the SIJ in axSpA for classification purposes, based on the number of slices or quadrants showing BME or structural changes such as erosions or fat lesions (FL), was recently published by ASAS.

Objectives: To compare the influence of age on the prevalence of inflammatory and structural MRI changes in the SIJ of patients with chronic low back pain diagnosed with axSpA or non-SpA.

Methods: MRIs of the SIJ of patients referred for differential diagnosis of back pain who were finally diagnosed with axSpA or not by experienced rheumatologists, were evaluated using semi-coronal STIR and T1-weighted MRI sequences. All images were scored blinded to, age, sex and diagnosis for the occurrence of BME, FL, erosions and ankylosis on the level of SIJ-quadrants (SIJ-Q). Patient groups were built based on decade of age (until 29, 30-39, 40-49 and ≥50 years).

Results: A total of 309 patients (175 axSpA and 134 non-SpA) with complete MRI sets were included in the analysis. The mean age was 38.5±11.4 and 43.4±13.8, 66.9% and 35.8% were male, the mean CRP was 1.6±2.4 and 1.1±2.1mg/dl and the median back pain symptom duration was 48 and 60 months, respectively. The number of SIJ-Q with BME and erosions was significantly higher in axSpA vs. non-SpA independent of the age group (Table 1). In comparison, with exception of the patients in the oldest population (≥50 years), the number of SIJ-Q with FL and the number of patients with at least one FL was not different between subgroups, while the number of erosions and FL but not BME was higher in both groups with increasing age. In the univariate analysis, only female sex was significantly associated with higher occurrence of FL.

Conclusion: Despite a relatively high prevalence in non-SpA patients, BME and erosions were significantly more frequent in axSpA independent of age, while the presence of FL was not different between groups. FL and erosions are increasingly found in older age groups independent of diagnosis. These data are relevant for the interpretation of MRI findings in the SIJ of patients suspicious of axSpA.

Table 1. Comparison of MRI findings between axSpA and non-SpA patients at different age groups

Age subgroup	Diagnosis	Mean number of SIJ quadrants			Proportion of patients with…		
		BME	FL	Erosion	BME	FL	Erosion
until 29 years	axSpA (n=46)	6.0±3.7	6.8±5.7	4.4±3.8	95.7%	80.4%	89.1%
	non-SpA (n=25)	1.4±1.5	5.4±4.4	0.8±1.5	64,0%	76,0%	48,0%
	p-value	*<0.001*	*0.311*	*<0.001*	*<0.001*	*0.664*	*<0.001*
30-39 years	axSpA (n=50)	5.0±4.1	8.7±5.9	4.6±3.7	92,0%	98,0%	82,0%
	non-SpA (n=26)	1.0±1.3	9.5±6.0	1.1±1.3	46.2%	92.3%	53.8%
	p-value	*<0.001*	*0.485*	*<0.001*	*<0.001*	*0.23*	*0.01*
40-49 years	axSpA (n=47)	4.2±3.7	11.3±6.0	4.6±3.7	85.1%	97.9%	87.2%
	non-SpA (n=35)	1.4±2.9	10.3±5.8	1.6±2.4	34.3%	97.1%	62.9%

MRI LESIONS IN SPA: A COMPARISON WITH AGE AND SEX MATCHED PARTICIPANTS WITH NON-INFLAMMATORY BACK PAIN

C. W. S. Chan[1], E. T. F. Chui[1], H. H. L. Tsang[1], C. S. Lau[1], H. Y. Chung[1]. [1]The University of Hong Kong, Queen Mary Hospital, Hong Kong, Division of Rheumatology and Clinical Immunology, Department of Medicine, Hong Kong, Hong Kong (SAR)

Background: Magnetic resonance imaging (MRI) is becoming increasingly important in axial spondyloarthritis (SpA) due to its unique role in early diagnosis, classification, and monitoring of disease (1, 2). It is the only disease assessment tool that has been validated with histological inflammatory cellularity in tissue biopsy of the sacroiliac (SI) joint (3). However, many MRI lesions are not exclusive to axial SpA and may occur in other conditions such as infection, degeneration and malignancy. Further characterization of these lesions may guide more targeted therapies.
Objectives: The objective of this study was to describe, investigate associated factors, and to compare individual MRI lesions with age and sex matched controls.
Methods: This was a cross-sectional observational study of MRI lesions of 431 participants with axial SpA compared with 53 age and sex matched participants with non-inflammatory back pain. Individual lesions identified included: discovertebral lesions (DVL), facet joint lesions, costovertebral joint lesions, corner inflammatory lesions (CIL), and fatty corner lesions (FCL). Associated factors of the lesions were determined by regression analyses.
Results: Compared to the control group, participants with axial SpA had more costovertebral lesions (12.5% vs 1.9%; p=0.02), CIL (46.6% vs 15.1%; p=0.03), and FCL (55.5% vs 39.6%; p=0.03). Multivariate regression showed that age (OR=1.02; p=0.03), regular alcohol use (OR=0.40; p=0.04) and radiographic axial SpA (OR=1.89; p=0.01) were associated with DVL; Chinese ethnicity (OR=0.06; p=0.01) and radiographic axial SpA (OR=3.63; p=0.01) were associated with facet joint lesion; radiographic axial SpA (OR=4.26; p<0.001) was associated with costovertebral joint lesion; male gender (ß=1.10; p=0.01), HLA B27 (ß=1.02; p=0.02), and radiographic axial SpA (ß=1.05; p=0.01) were associated with CIL; age (ß=0.10; p<0.01), male gender (ß=1.96; p=0.01), body weight (ß=0.11; p<0.01), HLA B27 (ß=3.23; p<0.001), and radiographic axial SpA (ß=1.77; p=0.02) were associated with FCL.
Conclusion: The individual MRI lesions more specific to axial SpA when compared to non-inflammatory back pain were costovertebral joint lesions, CIL, and FCL.

Molecular and structural changes of bone turnover during inflammatory disease

POS0040

THE DECREASE IN BONE MINERAL DENSITY DEPENDS ON THE CONCENTRATIONS OF ANGIOPOIETIN-LIKE PROTEIN TYPE 4 IN PATIENTS WITH RHEUMATOID ARTHRITIS

V. Aleksandrov[1,2], L. Shilova[1], A. Aleksandrov[1,2], G. Osmanova[1], N. Aleksandrova[2], I. Zborovskaya[2]. [1]Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation; [2]Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Department of Clinical and Laboratory Diagnostics, Volgograd, Russian Federation

Background: New serological markers that can serve as objective indicators of osteoporotic changes in patients with rheumatoid arthritis (RA) are being currently searched [1, 2, 3, 4, 5].
Objectives: To reveal the connection between the concentrations of serum angiopoietin-like protein type 4 (ANGPTL4) and the decrease in bone mineral density (BMD) in patients with RA.
Methods: 114 patients with reliable RA (90.4% of women, 9.6% of men) aged 21 to 80 years (mean age 55.4 ± 11.2 years old, disease duration - 11.18 ± 9.03 years, positive for rheumatoid factor (RF-IgM) - 63.2%, positive for anti-citrullinated protein antibody (ACPA) - 59.7%) were examined using a bone X-ray densitometer LUNAR DPX (GE, USA). Patients with an advanced clinical stage - 49%, moderate activity according to DAS28 - 58.8%, II-III radiological stage - 85.1% and functional class II - 64.9% prevailed. ANGPTL4 measurement in blood serum was carried out by enzyme immunoassay using a commercial test system "RayBio Human ANGPTL4 ELISA Kit" (RayBiotech, USA). ESR, RF, as well as C-reactive protein (CRP), ACPA, and antibodies to modified vimentin (anti-MCV) in an ELISA test were determined in all RA patients.
Results: ANGPTL4 indices in RA patients correlated with the CRP level (r = 0.34, p = 0.001) and the DAS-28 (r = 0.29, p = 0.002). There was no correlation between the level of ANGPTL4 and the intake of glucocorticoids, both at the time of the study (p = 0.678) and with their long-term (more than 3 months) use (p = 0.097). There was a negative correlation of weak strength between ANGPTL4 and the dose of non-steroidal anti-inflammatory drugs (r = -0.21, p = 0.035). There was no correlation between ACPA, anti-MCV, and ANGPTL4 levels (p> 0.1 and p = 0.084). A direct correlation was found between the level of ANGPTL4 and the presence of osteopenia in RA patients (r = 0.43, p = 0.036), as well as a negative correlation between ANGPTL4 and bone mineral density in the spine (BMD L_{1-4}, r = -0.631, p <0.001), but not in the femur (p> 0.05). Densitometry data also allowed to establish a negative correlation between low values of the T-criterion and increased titers of anti-MCV (r = -0.51, p = 0.029), but not ACPA (p = 0.276). It has previously been noted that anti-MCV are able to activate osteoclasts with a consequent decrease in periarticular BMD.
Conclusion: The absence of a relationship between anti-MCV and the level of ANGPTL4 may indicate different mechanisms of osteoporosis development and localization of osteoporotic changes in groups of anti-MCV or ANGPTL4 positive patients with RA.

POS0041 THE GASOTRANSMITTER HYDROGEN SULFIDE (H2S) IS PROTECTIVE AGAINST CALCIFIC TENDINOPATHY (CT)

I. Bernabei[1], D. Kronenberg[2], R. Stange[2], J. Bertrand[3], T. Hügle[1], A. So[1], N. Busso[1], S. Nasi[1]. [1]Centre Hospitalier Universitaire Vaudois and University of Lausanne, Department of Musculoskeletal Medicine, Service of Rheumatology, Lausanne, Switzerland; [2]Institute of Musculoskeletal Medicine, Westfaelische Wilhelms University Muenster, Department of Regenerative Musculoskeletal Medicine, Münster, Germany; [3]Otto-von-Guericke University, Department of Orthopaedic Surgery, Magdeburg, Germany

Background: Pathological (or heterotopic) calcification is the deposition of calcium-containing crystals in soft tissues that normally do not calcify. The deposition of these crystals in tendons such as the rotator cuff and the Achilles tendon is known as calcific tendinopathy (CT). CT is a painful condition, which increases tendon rupture rate and leads to disability.
Objectives: To understand what inhibits calcification, in order to provide new strategies to treat a condition for which existing therapies are ineffective.
Methods: We investigated the role of the gasotransmitter hydrogen sulfide (H_2S), and in particular of the H_2S-producing enzyme cystathionine γ-lyase (CSE) in CT. *In vitro*, we induced calcification in tenocytes from WT and CSE KO mice or we treated WT tenocytes with different H_2S donors. *In vivo,* calcification was assessed in a surgery-induced murine model of CT (tenotomy of the Achilles tendon) and in a spontaneous model of CT (aging). Samples obtained from patients with rotator cuff or Achilles tendon CT were also analyzed. To investigate the underlying mechanisms of the CSE-H_2S effect, we focused on the bone morphogenic proteins (BMPs) pathway. We additionally explored if altered extracellular matrix (ECM) organization, due to lysyl oxidase (LOX) activity and aberrant collagen-crosslinks, could also be involved in CT. In this context, we studied if H_2S could affect LOX expression and activity.
Results: *In vitro*, tenocyte calcification was inhibited by exogenous H_2S-donors, while it was exacerbated in CSE KO tenocytes. The protective role of CSE-H_2S was confirmed *in vivo.* In aged mice, microtomography analysis revealed exacerbated Achilles tendon calcification in CSE KO mice compared to WT. In the surgery-induced model of CT, an inverse correlation between calcification and CSE expression in operated Achilles tendon was seen over time. Similarly, inversed correlation between calcification and CSE expression was found in human CT samples.
Reduced calcification in tenocytes exposed to H_2S was accompanied by decreased expression of genes coding for BMP2, BMP4 and decreased activation of the BMP signaling pathway (pSMAD1/5/8). On the contrary, BMPs expression and BMPs-pathway activation were exacerbated in CSE KO tenocytes compared to WT tenocytes.
We next investigated whether ECM disorganization could play a role in CT. Tenocytes cultured in calcification media and treated with the pan-inhibitor of lysyl oxidases (LOX, LOXL1-4) β-aminopropionitrile (BAPN) showed decreased calcification. This pointed to a potential beneficial role of LOX inhibition, therefore decreased collagen-crosslinks, in CT. By analysis of LOXs gene expression in WT and CSE KO tenocytes cultured in calcifying condition, we found much higher expression (4-fold) of LOX, LOL2 and LOXL4 in CSE KO tenocytes. Moreover, H_2S-donors inhibited LOX activity. Altogether, these results suggest that decreased H_2S could lead to aberrant LOX expression and activity, excessive collagen cross-links in the ECM, and ultimately calcification. Further experiments are ongoing to prove these hypotheses.
Conclusion: We suggest targeting H_2S production by CSE, or supplying an H_2S-donor, is of therapeutic relevance to pathological calcification in the context of CT and can modify its disease course.
The anti-mineralizing effect of H_2S in tendons could be due to both inhibition of the BMPs pathway and suppression of abnormal LOXs activity.

POS0042 NOTCH 1 INHIBITION INCREASES OSTEOCLAST PROGENITOR ACTIVITY IN THE MOUSE MODEL OF RHEUMATOID ARTHRITIS

M. Filipović[1], A. Šućur[1], D. Flegar[1], Z. Jajić[2], M. Ikić Matijašević[3], N. Lukač[1], N. Kovačić[1], T. Kelava[1], D. Šisl[1], K. Zrinski Petrović[1], V. Katavić[1], D. Grčević[1]. [1]University of Zagreb School of Medicine, Croatian Institute for Brain Research, Laboratory for Molecular Immunology, Zagreb, Croatia; [2]University of Zagreb School of Medicine, Clinical Hospital Center "Sestre Milosrdnice", Department of Rheumatology, Physical Medicine and Rehabilitation, Zagreb, Croatia; [3]University of Zagreb School of Medicine, Clinical Hospital "Sveti Duh", Department of Clinical Immunology and Allergology, Zagreb, Croatia

Background: Osteoclasts mediate periarticular and systemic bone loss in rheumatoid arthritis (RA). Osteoclast progenitor cells (OCPs) derived from the myeloid lineage are susceptible to regulation through Notch signaling. Murine bone marrow and splenic OCPs, identified as $CD45^+Ly6G^-CD3^-B220^-NK1.1^-CD11b^{lo/+}CD115^+CCR2^+$ cells, are specifically increased in arthritis. We previously identified an increased frequency of OCPs expressing Notch receptors in arthritic mice.
Objectives: Several studies suggested that Notch signaling modulation affects the course of experimental arthritis. We aimed to determine the effects of Notch receptor signaling inhibition on OCP activity and arthritis severity in murine collagen-induced arthritis (CIA).
Methods: Male C57/Bl6 and DBA mice were immunized with chicken type II collagen and treated with i.p. injections of anti-Notch 1 neutralizing antibodies (1mg/kg). Notch receptor 1 through 4 expression on OCPs was analyzed by flow cytometry in periarticular bone marrow (PBM) and spleen (SPL). Gene expression of Notch receptors, ligands and transcription targets as well as osteoclast differentiation genes RANK, cFos and cFms was determined by qPCR from tissues and sorted OCPs. FACS sorted OCPs were stimulated by osteoclastogenic factors (M-CSF and RANKL), in control, IgG, Jagged (Jag)1 or Delta-like (DLL)1 coated wells, with or without anti-Notch 1 antibodies. Research was approved by the Ethics Committee.
Results: We confirmed the expression of Notch receptors on OCPs by flow cytometry with Notch 1 and 2 being most abundantly expressed (around 25% and 40% positive OCPs in PBM and 35% and 20% in SPL respectively), with a significant increase of Notch 2 expression in arthritis. Seeding OCPs on DLL1 coated wells significantly increased while seeding on Jag1 coated wells significantly decreased osteoclastogenesis as reflected on the number of TRAP+ osteoclasts and expression of osteoclast differentiation genes. The addition of anti-Notch 1 antibodies to ligand-stimulated OCPs resulted in an increased number of TRAP+ osteoclasts, partially reversing Jag1 inhibition. *In vivo* treatment with anti-Notch 1 antibodies did not affect total OCP frequency, but increased expression of Notch 4 both in PBM and SPL as seen by flow cytometry and qPCR. Additionally, anti-Notch 1 treatment stimulated Notch transcription factors HES and HEY. Both PBM and SPL cultured OCPs from anti-Notch 1 treated mice produced a higher number of large TRAP+ osteoclasts, doubling the area covered with osteoclasts in the latter compared to untreated mice. Increased osteoclastogenesis *in vitro* was further confirmed by an increased expression of osteoclast differentiation genes in the treated group.
Conclusion: Our results confirm that Notch signaling may represent an important therapeutic target for the regulation of osteoclast activity in arthritis. Both *in vitro* and *in vivo* anti-Notch 1 neutralizing antibodies enhanced osteoclastogenesis in CIA model, implying an inhibitory role of Notch 1 signaling in osteoclast differentiation. As Notch 2 expression is increased on OCPs of arthritic mice, we next plan to determine the effects of Notch 2 neutralization on osteoclast activity and arthritis severity.

POS0043 PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY IN THE ASSESSMENT OF BONE MINERAL DENSITY IN ANTI-TNF-TREATED RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS PATIENTS

B. Juhász[1], K. Gulyás[2], Á. Horváth[2], E. Végh[2], A. Pusztai[2], A. Szentpetery[3], Z. Pethő[2], N. Bodnár[2], A. Hamar[2], L. Bodoki[2], H. P. Bhattoa[4], É . Szekanecz[1], K. Hodosi[2], A. Domjan[2], S. Szamosi[2], C. Horváth[5], S. Szántó[2], G. Szücs[2], H. Raterman[6], W. Lems[7], O. Fitzgerald[8], Z. Szekanecz[2]. [1]University of Debrecen, Oncology, Debrecen, Hungary; [2]University of Debrecen, Rheumatology, Debrecen, Hungary; [3]Uppsala University Hospital, Rheumatology, Uppsala, Sweden; [4]University of Debrecen, Laboratory Medicine, Debrecen, Hungary; [5]Semmelweis University, Medicine, Budapest, Hungary; [6]Northwest Clinics, Rheumatology, Alkmaar, Netherlands; [7]University of Amsterdam, Rheumatology, Amsterdam, Netherlands; [8]University College Dublin, Conway Institute for Biomolecular Research, Dublin, Ireland

Background: Rheumatoid arthritis (RA) and ankylosing spondylitis (AS) have been associated with osteoporosis. There have been very few data on the use of peripheral quantitative computed tomography (QCT) in anti-TNF-treated patients.

Objectives: We wished to assess volumetric bone mineral density (BMD) by forearm QCT in conjunction with dual-energy X-ray absorptiometry (DXA) and bone biomarkers in RA and AS.
Methods: Forty RA and AS patients treated with etanercept (ETN) or certolizumab pegol (CZP) were included in a 12-month follow-up study. Peripheral QCT and DXA BMD were determined. Bone biomarkers, such as PTH, osteocalcin, RANKL, 25-hydroxyvitamin D (VITD), P1NP, CTX, sclerostin, DKK-1 and cathepsin K (CATHK) were assessed by ELISA.
Results: There was no further bone loss during anti-TNF treatment. Volumetric and areal BMD showed significant correlations with each other ($p<0.05$). Total QCT BMD after 12 months was inversely determined by disease activity at baseline in the full cohort ($p=0.030$). Cortical BMD was negatively determined by baseline disease activity ($p=0.005$) and CATHK ($p=0.025$). In RA, VITD-0 determined QTRABBMD-12 ($p=0.005$). In the full cohort, the one-year change in QTRABBMD was related to TNF inhibition together with higher VITD-0 ($p=0.031$). Therapy and lower CATHK determined QCORTBMD changes ($p=0.006$). In RA, treatment together with VITD-0 ($p<0.01$) or CATHK-0 ($p=0.002$), while in AS, treatment together with RANKL-0 ($p<0.05$) determined QCT BMD changes.
Conclusion: QCT confirmed that biologics may attenuate bone loss. Disease activity, CATHK, RANKL and VITD may predict the effects of anti-TNF treatment on volumetric BMD changes. There may be differences between RA and AS in this respect.
