Results: The biologics used in RA patients were Etanercept (49.4%), Rituximab (44.8%), and Infliximab (5.7%). The 1- and 5- year remission rates were 8.5% and 23.9%, respectively. Drug survival rates were 33.6% for Etanercept, 40.7% for Rituximab, and 36% for Infliximab at five years. The main reasons for drug discontinuation were disease remission (32.1%), inadequate response (32.1%), and side effects (15.1%). Rituximab had the highest discontinuation rate due to remission (56.4%). There was no predictive factor for biologics discontinuation due to remission.
SpA patients were treated with Etanercept (83.6%) and Infliximab (16.4%). The 1- and 5- year remission rates were 67.4% and 66.7%, respectively. Drug survival rates were 50.3% for Etanercept and 0% for Infliximab at five years. Biologics withdrawal due to side effects occurred in 16%, inadequate response in 10%, and disease remission in 10% of patients. The predictive factor for biologics discontinuation due to remission was disease duration < 5 years (Hazard ratio 6.92, 95%CI 1.10, 43.29)
Conclusion: Biologic therapies are effective in patients with active RA and SpA despite csDMARDs treatment. The highest drug survival rates are Rituximab in RA and Etanercept in SpA. Infliximab has the shortest drug retention rate in SpA. Drug discontinuation due to remission is more successful in RA patients, particularly in the Rituximab group. The best predictor for biologics discontinuation due to remission in SpA is the disease duration of fewer than five years.

Background: Tocilizumab (TCZ) is a human anti-interleukin (IL)-6 receptor antibody approved in Turkey for the treatment of rheumatoid arthritis (RA).
Objectives: In this study our purpose was to describe the disease activity, quality of life (QoL), and retention rate in RA patients who were prescribed TCZ as first-line biologic treatment in a real-world setting.
Methods: Anonymized patient registry of TURKBIO was used based in a national, multicenter, and retrospective context. We conducted a search in the registry between years 2013 and 2020 and included adult RA patients who were prescribed with TCZ as their first-line biologic treatment with a post-TCZ follow-up of at least 6 months. CDAI, DAS28-(ESR), and HAQ-DI scores in 6, 12, and 24 months were obtained. Pairwise comparison was carried out for survey scores across baseline and timepoints. Subgroup analysis for route of TCZ administration was performed. EULAR response criteria were used for response evaluation. Retention of TCZ was evaluated by Kaplan-Meier analysis.
Results: Overall,130 patients with a mean RA duration of14 years were included in the study. 87.7% of the patients were female and mean age was53 (SD; 15.0). Median duration of follow-up was 18.5 months. Majority (90.8%) of patients were given tocilizumab via intravenous route at baseline. Number of patients with ongoing TCZ treatment and follow-up at 6, 12, and 24 months were 121 (93%), 85 (65%), and 46 (35%), respectively. Remission rates at 6, 12, and 24 months per CDAI (<2.8) and DAS28-(ESR) (<2.6) scores were 61.5%, 44.6%, 30%, and 54.6%, 40.8%, 27.7%, respectively. CDAI, DAS28-(ESR) and HAQ-DI survey scores significantly improved at 6, 12 and 26 months, respectively (p<0.001) (Table 1) in both IV and SC TCZ subgroups. At 6, 12 and 24months 74.8%, 82.5% and 86.4% of patients achieved a EULAR good response respectively. Twenty-three patients (17.6%) discontinued TCZ at 24 months. Of these, 19 patients discontinued due to unsatisfactory response. Retention rates of TCZ at 6, 12, and 24 months were 93%, 84.3%, and 72.2%, respectively (Figure 1).
Conclusion: TCZ as a first-line biologic treatment was found to be clinically effective in this real-world study with a high retention rate. These results are in line with the results gathered from previous TCZ controlled and real-life studies in which TCZ was found clinically safe and effective.

AB0230 **OPTIMIZED TREATMENT OF BIOLOGICAL DISEASE MODIFYING DRUGS IN ROUTINE CLINICAL PRACTICE: SURVIVAL STUDY ANDANALYSIS OF PATIENT CHARACTERISTICS**

A. De Diego Sola[1], N. Alcorta Lorenzo[1], C. A. Egües[1], L. M. Lopez Dominguez[1], O. Maiz-Alonso[1], J. J. Cancio Fanlo[1], E. Uriarte Isacelaya[1], M. B. Irastorza Larburu[2], M. A. Aranguren Redondo[2], J. M. Belzunegui Otano[1]. [1]*Hospital Universitario Donostia, Rheumatology Service, San Sebastian, Spain*; [2]*Hospital Universitario Donostia, Pharmacology Service, San Sebastian, Spain*

Background: Biological disease modifying drugs (bDMARD) has allowed a targeted approach to rheumatoid arthritis (RA). Once sustained remission is achieved, the use of bDMARDs at lower doses than indicated in data sheets is considered (optimized treatment, OT). Studies show that 33-64.2% of patients on OT lose remission in the first 6 months. Still, it is a feasible practice in selected patients.

Objectives: We aimed to describe demographic, clinical, analytical and therapeutic characteristics of RA patients on OT in our hospital. Secondly, we wanted to study the survival of OT and to compare patients with survival longer or shorter to one year.

Methods: We did a retrospective review of the medical records of RA patients who began OT between January 2014 and December 2018. We included patients on Abatacept(ABA), anti-TNF drugs and Tocilizumab (TCZ). We defined the end of OT as the restart of the usual dose. Continuous variables are described with mean and standard deviation (SD) and qualitative variables are shown in absolute value and percentage. We divided the sample into patients with OT survival greater than or equal to one year and patients with OT survival less than one year, after which the characteristics of both populations were compared. Categorical variables were analyzed using Pearsons chi and quantitative variables using Student's t-test. Survival analysis was performed using a Kaplan-Meier estimator.

Results: We identified 234 RA patients on bDMARD at our hospital, of which 53 (22.6%) had been optimized between January 2014 and December 2018: 39 (73.6%) with anti-TNF, 7 (13.2) with ABA and 7 (13.2%) with TCZ. Their characteristics are shown in table 1. It is worth mentioning the rate of monotherapy (43.3%)and the low number of bDMARD prior to optimization (median 0.71, SD 0.97). The median survival of OT was 33.8 months and thirty-nine patients (73.6%) maintained OT for at least one year (95%confidence interval, 0.59 to 0.83). When comparing patients with survival greater/equal versus shorter to one year (table 2), the only variable showing significant differences was the presence of erosions at beginning of OT (28 patients in the >1 year group vs 7 in the < 1 year group; p=0.012). Although the difference is not significant (p = 0.07), patients with a survival of less than one year had more time between the debut of disease and the beginning of the first conventional synthetic DMARD (csDMARD).

Table 1. Characteristics of the sample (N=53)

Female	40 (75.47%)
Age at diagnosis (years)	49.54 (11.68)
Active smoker	15 (33.33%)
ACPA positive	36 (67.92%)
mRF positive	44 (83.02%)
Nodules	11 (20.75%)
Extra-articular disease	11 (20.75%)
Erosions*	35 (74.47%)
Monotherapy at optimization	23 (43.4%)
bDMARD* previous to OT	0.71 (0.97)
Optimized bDMARD	
• ETN	20 (37.74%)
• ADA	16 (30.19%)
• ABA	7 (13.21%)
• TCZ	7 (13.21%)
• GOL	2 (3.77%)
• CZB	1 (1.89%)
DAS28 at	
• Diagnosis	4.88 (1.25)
• Beginning – 1st sDMARD	4.62 (1.6)
• Beginning – 1st bDMARD	4.98 (1.06)
• Beginning – opt bDMARD	4.67 (1.17)
• Optimization	1.88 (0.65)
Months from diagnosis to introduction of 1st sDMARD*	19.67 (35.01)
Months from disease debut to low activity*	38.75 (30.34)
Months in low activity until start of OT	23.73 (22.47)

ACPA: anti-citrullinated protein antibodies; mRF: monoclonal rheumatoid factor; Erosions: presence of erosions at Optimization; bDMARD: biological DMARD; ETN: Etanercept; ADA: Adalimumab; ABA:Abatacept; TCZ:Tocilizumab; GOL:Golimumab; CZB:Certolizumab; Opt bDMARD: bDMARD optimized; csDMARD: conventional synthetic DMARD; Low activity: DAS28 < 3.2

Conclusion: OT is a therapeutic option from which some patients could benefit. Maintenance of OT may be related to early start of DMARDs. More studies are needed to define the characteristics of patients who can safely benefit from OT.

AB0231 OUTCOMES IN RHEUMATOID ARTHRITIS PATIENTS UNDER TOCILIZUMAB AS FIRST BDMARD: A REAL-LIFE MONOCENTRIC COHORT STUDY

F. R. Martins[1], A. Martins[2], D. Santos Oliveira[2,3], D. Fonseca[4], M. Rato[2], F. Oliveira Pinheiro[2], S. Garcia[2], B. M. Fernandes[2], L. Costa[2], M. Bernardes[2]. *[1]Centro Hospitalar Universitário do Algarve - Faro, Rheumathology, Faro, Portugal; [2]Centro Hospitalar Universitário São João, Rheumathology, Porto, Portugal; [3]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal; [4]C. H. Vila Nova de Gaia/ Espinho, Rheumathology, Vila Nova de Gaia, Portugal*

Background: Rheumatoid arthritis (RA) is one of the most frequent systemic inflammatory rheumatic diseases, being constantly assessed regarding new disease activity monitoring tools and new therapeutic targets and therapies. Tocilizumab (TCZ) is one of the latest biological disease-modifying antirheumatic drugs (bDMARDs) approved for RA's treatment, usually as a second line agent in daily clinical practice.
Objectives: Evaluate the different disease and patient reported outcomes in patients undergoing treatment with tocilizumab as the first biologic therapy.
Methods: All patients with a definite RA diagnosis who had undergone treatment with TCZ as the first biologic therapy at a tertiary hospital's rheumatology department were included in this analysis. Diverse socio-demographic data, as well as disease and patient related outcomes were assessed at baseline, 6 and 12 months of treatment with TCZ, and posteriorly extracted from the Portuguese register of rheumatic diseases (Reuma.PT). Statistical analysis included non-parametric tests such as Wilcoxon test and univariate analysis using linear and logistic regression models.
Results: Fifty-one patients were included, 88.2% females, with a median age at introduction of TCZ of 53.5 +/- 10.4 years; mainly seropositive for either rheumatoid factor (66%) or anti citrullinated peptide antibody (ACPA; 68%), with an erosive disease (75.6%) and concomitantly treated with a conventional synthetic disease modifying anti-rheumatic drug (csDMARD) (70.5%). During follow-up there was a statistically significant reduction at 6 and 12 months of TCZ treatment regarding DAS28 (4 variables) (4v) and DAS28(4V)-CRP scores ($p < 0.001$), SDAI ($p < 0.001$), CDAI ($p < 0.001$), 68/66 tender and swollen joint counts (TJC/SJC) ($p < 0.001$), ESR and CRP ($p < 0.001$), patient and physician VAS ($p < 0.001$) and HAQ score ($p = 0.01$ at 6 months and $p < 0.001$ at 12 months). Rheumatoid factor and ACPA serum levels weren't statistically different at 6 and 12 months of treatment with TCZ compared to the initial assessment, as well as the ACR responders at the same 6 months versus those at 12 months. A majority of patients showed good EULAR response at 6 (52.6%) and 12 (56.3%) months, as well as moderate to high mean improvement in ACR core set measures at 6 (53.3±22.7) and 12 (54.3±25.2) months. Assessment of subsequent therapeutic maintenance showed that 75% of patients remained under tocilizumab with an average treatment duration of 48.8±37.7 months. Reasons for switch ranged from adverse effects (63.6%) to primary failure (18.2%) and secondary failure (18.2%). There was a significant reduction in DAS28(4V), DAS28(4V)-CRP, CDAI, SDAI, TJC and SJC, ESR, CRP, patient and physician VAS and HAQ scores between 6 and 12 months of therapy ($p < 0,001$). ACR and EULAR responses didn't differ significantly between assessments at 6 and 12 months. In the absence of a representative number of RA patients on TCZ monotherapy, it wasn't possible to draw conclusions about the need to use combined therapy with a csDMARD for better clinically significant response.
A higher degree of ACR response at 6 months was associated with higher serum rheumatoid factor levels (OR 1.13, $p < 0.05$) at baseline, while a lower degree of response was seen with higher TJC ($p = 0.05$) and HAQ score ($p < 0.01$). ACR response at 12 months was lower in patients with erosive disease at baseline ($p < 0.05$). Regarding EULAR response criteria at 6 months, there was a negative association with higher TJC ($p < 0.05$), while at 12 months the negative trend was associated with ESR levels ($p < 0.05$) and HAQ scores ($p < 0.05$) at baseline.
Conclusion: There seems to be evidence of good therapeutic response to TCZ in bDMARD naïve RA patients assessed at 6 months from baseline, without evidence of significant improvement of response measures further down the line. Basal serum rheumatoid factor levels, TJC, HAQ scores and the presence of erosive disease may have some predictive value on the therapeutic response. Further studies comparing TCZ as the first bDMARD in naïve RA patients against TNF inhibitors are needed.

AB0232 PREVALENCE OF INFECTIONS UNDER BIOTHERAPY DURING RHEUMATOID ARTHRITIS

K. Baccouche[1], R. Grassa[1], S. Lataoui[1], O. Jomaa[1], N. El Amri[1], H. Zeglaoui[1], E. Bouajina[1]. *[1]Farhat Hached Hospital, Rheumathology, Sousse, Tunisia*

Background: Biologic therapies are emerging as a significant therapeutic option for many with debilitating inflammatory and autoimmune conditions including rheumatoid arthritis (RA).These biological agents are highly effective in RA. Potential complications are dominated by infections.
Objectives: To evaluate the different infections occurred under biotherapy.
Methods: This is a descriptive retrospective study including patients under biotherapy, hospitalized between 2000-2016 in the Rheumatology Department of Farhat Hached hospital in Sousse,Tunisia. We evaluated for each patient the different infections that have occurred, specifying the different types of biotherapy received.
Results: Sixty one patients are included (54 women and 7 men).The average age is 55.33 years ±11.51 [34-81 years].We found 47 infections in 40 patients (65.57%) with at least one infection under biotherapy: 41 women and 6 men with a mean age at 57.72 years [34-81 years]. Infections occurred under anti IL6 in 46.32%, Infliximab in 31.58%, anti CD20 in 11.58%, Etanercept in 7.37% and under Certolizumab in 3.16%. The infection was bacterial in 68.42%: 28 pulmonary infections, 8 oto rhino laryngology infections, 14 urinary infections, 2 soft tissue abscess, 13 cutaneous infections, 02 ocular infections. A viral origin of the infection was noted in 12.63% of cases. As for mycosis infections they represent 18.75% of the etiologies identified. The treatment was medical in 100% of cases and the evolution was favorable in all patients without resorting to the definitive discontinuation of biotherapy.
Conclusion: The infections reported in our series are much more frequent under anti IL6 treatment and bacteria are the most incriminating pathogenic agents in our patients.

AB0233 REASONS AND RISK FACTOR FOR DISCONTINUATION OF BIOLOGIC AGENTS FOR RHEUMATOID ARTHRITIS PATIENTS IN LONG-TERM OBSERVATION

K. Terabe[1], N. Takahashi[1], S. Asai[1], Y. Hirano[2], Y. Kanayama[3], T. Kojima[1]. *[1]Nagoya University School of Medicie, Orthopedic Surgery, Nagoya, Japan; [2]Toyohashi Municipal Hospital, Rheumatology, Toyohashi, Japan; [3]Toyota Kosei Hospital, Orthopedic Surgery, Toyota, Japan*

Background: Rheumatoid arthritis (RA) patients who failed a first biologic agent due to any reasons have the option of switching to a second one along with the strategy of biologic agent treatment. Patients go over switching to the next one at failing their biologic agent. On the other hand, there are some patients who discontinue any biologic agent treatment due to various reasons such as tolerability concern, complications, economic issue, remission and so on[1 2]. The impact of this concern has been less studied.
Objectives: The objective of this study was to investigate the reasons and the risk factors for discontinuation any biologic agent in RA patients.
Methods: To Include patients who are observed long-term, patients who underwent biologic agent treatment between 2003 and 2007 at Nagoya University Hospital and 12 other institutes (Tsurumai Biologics Communication Study Group) were enrolled. 570 patients who were confirmed continuation or discontinuation of biologic agent treatment were enrolled. The last observation was September 2017. We analyzed the retention rate of biologic agent treatment and the reasons for discontinuation. To identify the risks for discontinuation, baseline demographics were compared between the continuing group and the disc continuing group using cox hazard regression analysis.
Results: In total 570 patients, the average duration of treatment with biologics was 6.6±3.3 (years) and total patient-year was 3739 in this study. 458 patients were administered biologics continuously, 112 patients were withdrawn. Table 1 showed the demographic data in total patients. The retention rate was 96.0% (discontinuation n=23) at least 1 year from starting biologics treatment, 92.6% (n=42) at 3 years, 88.2% (n=67) at 5 years, 84.4% (n=89) at 7 years, 81.1% (n=108) at 10 years. In 112 patients who discontinued, the reasons were adverse events in 74 patients, lack of effectiveness in 11 patients, others in 27 patients. Comparison of incidence for discontinuation using cumulative hazard function, the reason of adverse events was significantly higher than others reasons

(Figure 1). To identify the risks of discontinuation, we analyzed by multivariable Cox proportional hazard modeling in patients who discontinued treatment due to adverse events, the risk factors (hazard ratio: HR, confidence interval: CI) were over 3 of Steinblocker class (HR 1.85 [1.02-2.04]), age (HR:1.07 [1.04-1.10]) and Non-concomitant with methotrexate (HR 1.90 [1.08-3.33]) (Figure 2).

Table 1.

Age (years)	56.1 ± 13.4
Gender	
n (% male)	110 (19%)
n (% female)	460 (81%)
Disease duration (years)	11.1 ± 9.8
stage	
1,2	104 (19%)
3,4	455 (81%)
class	
1,2	336 (60%)
3,4	225 (40%)
Methotrexate use, no (%)	400 (70%)
Glucocorticoid use, no (%)	262 (47%)
Rheumatoid Factor, no (%)	287 (65%)
anti CCP antibody, no (%)	137 (87%)

Conclusion: The most common reason for discontinuation was adverse events in long term observation. The risk factors for discontinuation were class, age, and non-concomitant MTX. These results suggested that comorbidity has a significant impact on continuation rates because there are some reasons of non-concomitant MTX in addition to relate with age and the activities of daily living.

AB0234 SURVIVAL OF ABATACEPT IN RHEUMATOID ARTHRITIS PATIENTS: A REAL-LIFE STUDY

E. Molteni[1], F. Ceccarelli[1], C. Castellani[1], F. Giardina[1], C. Alessandri[2], M. Di Franco[2], V. Riccieri[2], F. R. Spinelli[2], R. Scrivo[2], R. Priori[3,4], F. Conti[2]. [1]*Sapienza University of Rome, Rheumatology, Roma, Italy*; [2]*Sapienza University of Rome, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Roma, Italy*; [3]*Policlinico Umberto I, Rheumatology, Roma, Italy*; [4]*Policlinico Umberto I, Rheumatology Unit, Roma, Italy*

Background: Abatacept (ABA) is a biological drug approved for the treatment of rheumatoid arthritis (RA) patients that, by working on CTLA4, can inhibit T-cell activation. Randomized controlled trials have demonstrated both the efficacy and a good safety profile, characterized by a lower infectious risk in comparison with other biological DMARDs, in RA patients. In a real-life setting, the drug retention rate could be considered as a surrogate of drug effectiveness. Data from the literature reported a retention rate of ABA ranging from 55 to 76% at 12 months and from 54 to 64% at 24 months (1-3).

Objectives: In the present longitudinal analysis, we evaluated the retention rate of ABA in a large monocentric RA cohort.

Methods: We enrolled consecutive RA patients starting treatment with intravenous (IV) or subcutaneous (SC) ABA according to the standard of care. All the patients fulfilled the 2010 ACR/EULAR classification criteria for RA. For each patient, we collected demographic parameters, serological status, previous and concomitant treatments, and disease activity by DAS28 with C reactive protein (DAS28-CRP). All the patients were assessed at baseline, and after 4 and 12 months (T4 and T12, respectively). The reasons for withdrawal of treatment were registered and classified as primary or secondary inefficacy or adverse events (AEs). Kaplan-Meier statistical analysis has been done to evaluate the survival of the treatment in patients with at least 12 months follow-up.

Results: We evaluated 161 patients [M/F 21/140; median age 67 years (IQR 21.7), median disease duration 180 months (IQR 161)]. RF was positive in 70.3% of patients, ACPA in 66.4%. ABA was the first biological DMARD in 66 patients (41%). At baseline, the median DAS28-CRP was 4.3 (IQR 1.6) and ABA was administered in association with MTX in 96 patients (59.6%). One hundred-eleven patients (68.9%) started SC ABA [M/F 16/95; median age 64.5 years (IQR 21.5), median disease duration 156 months (IQR 132)], the remaining 50 IV ABA [M/F 5/45, median age 71 years (IQR 60.2), median disease duration 187 months (IQR 157)]. Median age and disease duration were significantly higher in patients receiving IV in comparison with SC ABA (p=0.008 and p=0.03, respectively). We found a significant reduction of DAS28-CRP values during the follow-up in comparison with baseline [4 months: median 3.5 (IQR 1.9), p<0.0001; 12 months: median 3.2 (IQR 1.4), p<0.0001]. Seven patients were lost to follow-up, in the remaining 154 patients a median treatment duration of 33 months (IQR 49) was registered. Data on drug survival are reported in Figure 1A: at 12 months, 92% of patients persisted on treatment; this percentage decreased to 78.2% at 24 months and to 67.9% at 36 months. Furthermore, we did not find any differences in drug survival either with respect to SC vs IV administration (12 months: 93.7% versus 88.6%; 24 months 78.9% versus 72.6%; 36 months 63.7% versus 72.6%; Figure 1B) or according to the association with MTX. Concerning the withdrawal reasons, 46 patients (29.9%) stopped ABA due to inefficacy (primary in 28, secondary in 18), 11 patients (7.1%) due to AEs, and 7 for inadequate adherence (4.5%). Finally, 10 patients switched from IV to SC administration, due to patient's preference.

Conclusion: In our monocentric RA cohort, we have observed a high retention rate of ABA at both 12 and 24 months, confirming the good profile of this drug in terms of effectiveness and safety, irrespective of the route of administration and association with MTX.

AB0235 RITUXIMAB (BIOSIMILAR) IN RHEUMATOID ARTHRITIS: CLINICAL & IMMUNOLOGICAL RESPONSE TO VARYING DOSES- EXPERIENCES FROM A TERTIARY CARE CENTER IN SOUTH INDIA

J. Antony[1], R. Sankaralingam[1], R. Maheshwari[1], B. Chilukuri[1], S. Chinnadurai[1]. [1]*Sriramachandra Medical College, Rheumatology, Chennai, India*

Background: Rituximab (RTX) is a chimeric monoclonal antibody against CD20. There is a paucity of studies done with RTX biosimilars. This is a Retrospective and Observational study from January 2018 to December 2019 done in the Department of Clinical Immunology & Rheumatology, Sri Ramachandra Institute of Higher Education and Research, Chennai, India.

Objectives: 1.To find the effects of varying doses of RTX in attaining clinical remission in RA.

2.To find if CD19, CD20 & IgG help in identifying impending flare & if these levels help in deciding the timing of the next dose of RTX.

Methods: Rheumatoid arthritis (RA) cases who were given Rituximab from January 2018 were selected. Clinical Response at 6 & 12 months & wherever feasible at 18 & 24 months was assessed by Simplified Disease Activity index (SDAI). RTX initial dose was given at 0 and 14 days followed by fixed dose at six months interval.CD19, CD20 B cell count, IgG levels were tested in patients in whom it was feasible at baseline & 6 months (select patients at 12,18 &24 months). Patients were divided in to 5 groups (DMARD naïve, DMARD resistant & Interstitial Lung disease (ILD) [Lung involvement>20% in Computed Tomography (CT)]) and (500mg & 1g). Patients were divided into three clinical groups, (DMARD naïve, DMARD resistant & Interstitial Lung disease (ILD) [Lung involvement>20% in Computed Tomography (CT)]) and two treatment groups (500mg & 1g) based on clinical indication for RTX and dose of RTX,

respectively. In patients with ILD, CT scan & FVC were compared at baseline & 12 months.

Results: 29 patients (seropositive 28 (RF/Anti CCP/BOTH+VE), seronegative 1) were given RTX for RA over a 2-year period of which 12 had CD19, CD20 & IgG tested. Mean SDAI reduction from baseline to 6 months post treatment was 30%, 32% & 14% while complete remission (SDAI<3.3) was attained in 100%, 18% & 20% in DMARD naïve, DMARD resistant & ILD groups, respectively. CD19, CD20 & IgG reduced from 18.6%, 18.4% & 18.53g/L to 3.7%,3.7% & 9.7g/L respectively FVC improved from 62.4% to 67% at 12. The percentage of patients with lung involvement >20% reduced from 53.3% to 46.7%. Flare was observed in one patient who received 500mg RTX. CD19, CD20 & IgG levels increased from 7.9%, 8% & 9.8g/L to 27%, 25% & 13g/L respectively. 3 patients in the 1g group were followed up at 12,18 & 24 months. In these patients there were no flares or worsening symptoms. 1 patient was double negative for RF & Anti CCP and this patient did not attain clinical remission even after 2 doses of 1g RTX.

Conclusion:

[1] Patients with early arthritis (diagnosis made within 1 year) and who were DMARD naïve had an excellent response to Rituximab.
[2] Complete remission was observed in more patients the 1g compared to 500mg group.
[3] Reduction in CD19 & CD20 was associated with significant reduction in the SDAI score.
[4] There was no significant reduction of CD19 & CD20 with 500mg dose of Rituximab where either a partial remission or mild flare was observed.
[5] There was reduction in the lung involvement to less than 20%(CT) in few patients with 1g dose.
[6] Double negative Rheumatoid arthritis poorly responded to Rituximab.
[7] The positive effects of 1g Rituximab could be noted up to 24 months.
[8] Flare of RA was associated with significant increase in CD19 & CD20.

AB0236 DOWN-TITRATION STRATEGY OF TUMOR NECROSIS FACTOR-INHIBITOR AGENTS FOR RHEUMATOID ARTHRITIS IN TUNISIA

K. Saadaoui[1], H. Sahli[1], S. Boussaid[1], J. Samia[1], R. Sonia[1], C. Elhem[1], E. Mohammed[1]. [1]*La Rabta Hospital, Rheumatology, Tunis, Tunisia*

Background: Tumor necrosis factor (TNF) blocking agents are effective in treating rheumatoid arthritis, but they are associated with several adverse effects and high costs. Some studies have assessed the effectiveness of down-titration compared with continuation of standard dose.

Objectives: The aim of our study is to assess dose tapering in Tunisia.

Methods: A retrospective study including 170 rheumatoid arthritis patients treated by TNF blocker agent and with either low disease activity or remission (ACR/EULAR criteria). Two groups were compared, in the first group (G1) the interval of TNFi administration was extended, in the second group (G2) the standard dose and rhythm of administration were maintained.

Results: The TNFi tapering group (G1) included 96 persons whereas the group having the same drug administration rhythm (G2) included 74 case. The baseline age of the down-dosing drug group was 56.6 ± 12.6 years versus 52.9 ± 11.6 years in the other group (p = 0.046) and the average disease duration were respectively 12.3 ± 7.2 years versus 11.2 ± 6 years (p = 0.346). Women represented 88.5% in G1 versus 93% in G2 (p = 0.298). Rheumatoid Factors and ACPA were positive respectively in (85.5% versus 83.8; p = 0.748) and (76.4% versus 67.8%; p= 0.309). Etanercept, adalimumab, certolizumab pegol and infliximab were respectively used in 84.4%, 9.4%, 4.2% and 2.1% cases (G1), whereas they were used in 48.6%, 16.2%, 27% and 8.1% cases in the second group (G2). In the TNFi down dosing group, methotrexate was associated to TNFi in 74% cases while 71.6% of patient received methotrexate in the standard rhythm of administration group (p = 0.734). Corticosteroids were used by 40.6% of patients in G1 vs. 56.8% of patients in G2 (p = 0.037). The average DAS_{28} at baseline was 5.91 ± 0.81 (G1) versus 5.95 ± 0.80 (G2) (p = 0.759). There was no statistically significant difference between the two groups for rates of TNFi withdrawal (p = 0.798). In fact, TNFi was interrupted due to inefficacy for 17 patients (17.7%) in the down-dosing group versus 12 patients (16.2%) in the other group.

Conclusion: Our study add evidence that TNFi drugs tapering could be equivalent to maintenance strategy. This could be beneficial to decrease the risk of adverse effect or reduce costs. Further studies are needed to confirm those results and identify patients who could benefit of TNFi administration rhythm step-down.

AB0237 INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH RITUXIMAB AND ANTI-TNF INHIBITOR

N. Zehraoui[1], R. Benaziez.Boutaleb[1], H. Hafirassou[1], F. Mechid[1], N. Bahaz[1], C. Makhloufi-Dahou[1]. [1]*Mohamed Lamine Debaghine University Hospital, Rheumatology, Algiers, Algeria*

Background: Biological therapies have significantly improved the management of rheumatoid arthritis (RA). These molecules are very effective, but are known for their specific risks, especially infectious. It depends on several factors including the type of molecule used.

Objectives: The objective of our study is to compare the rate of infection in RA patients treated with rituximab and anti-TNFα.

Methods: Prospective, observational, monocentric study. Were included RA patients (ACR / EULAR 2010 criteria) treated with rituximab and anti-TNFα (adalimumab, infliximab and Etanercept) after inadequate response to DMARDs. Demographic characteristics, comorbidities, association with methotrexate and corticosteroids were collected and compared for each group.

The number, type and severity of the infections in both cases were noted.

SPSS (Statistical Package for Social Science) was used for data analysis.

Results: 40 RA patients treated with rituximab and 31 patients who received anti-TNFα were included.

Patient characteristics and Comparison of rate of infection in RA patients between the two groups are summarized in Table 1

Table 1.

Parameters	Rituximab	Anti-TNFα	*p*
Number of patients	**40**	**31**	
Average age (years)	**56,28**	**46,06**	**0,01**
Sexratio	**0,14**	**0,11**	**0,7**
Average duration of evolution (years)	**15,83**	**13,74**	**0,3**
Patients under corticosteroid (%)	**97,5**	**87,1**	**0,08**
Average corticosteroid dose	**6,41**	**5,48**	**0,3**
patients under methotrexate (%)	**37,5**	**45,2**	**0,5**
Diabetes (%)	**20**	**16,1**	**0,7**
Patients with infection (%)	**32,5**	**51,6**	**0,1**
Number of infections	**18**	**24**	**0,4**
Number of serious infections	**5**	**0**	**0,04**

Conclusion: The rate of infections in patients with RA treated with rituximab or anti-TNF was similar. However, the infections observed were more serious in patients with RA treated with rituximab

AB0238 SECOND BIOLOGICAL DMARD THERAPY IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE COHORT ANALYSIS

K. Saadaoui[1], H. Sahli[1], S. Jemmali[1], S. Boussaid[1], S. Rekik[1], E. Cheour[1], M. Elleuch[1]. [1]*La Rabta Hospital, Rheumatology, Tunis, Tunisia*

Background: The development of biologic disease modifying antirheumatic drugs (bDMARD) has dramatically improved the management of rheumatoid arthritis (RA). However, some patients did not respond or partially respond to biologic agents. Management of first bDMARD failure may involve another biotherapy.

Objectives: The aim of our study is to assess the efficacy of second line biologic as well as survival rates of 2nd line biotherapy in RA.

Methods: This is a retrospective study based on Tunisian data including 374 RA patients treated with biologic agent from 2014 and followed until December 2018.

Results: Tumor necrosis factor inhibitor (TNFi) was the most prescribed class as first-line therapy with 86.4% patients (Etanercept: ETA 54%; adalimumab: ADA 13.6%; certolizumab pegol: CZP 12.8% and infliximab: IFX 5.9%), IL-6 inhibitor (Tociluzimab: TCZ) and anti-CD 20 (Rituximab: RTX) were given respectively to 6.4% and 7.2% cases. The first biotherapy was discontinued for 146 patients (39%). Of these, 79 patients (21.1%) received a second bDMARD (mean age 52.6 ± 11.8; sex ratio = 0.12; ETA 17.7%, ADA 7.6%, CZP 41.8%, IFX 1.3%, TCZ 24.1% and RTX 7.6%). Average DAS_{28} at second line biotherapy initiation was 5.93 ±

0.96. Overall survival rates of 2nd line bDMARD at 12, 24 and 36 months was respectively 91%, 76.4% and 72.1%. Among the patients receiving second biologic agent, 30.4% patients (24 cases) achieved either low disease activity (LDA) or remission. On average 38 weeks [14 – 96] were needed to reach that therapeutic target. In fact, 27.8% of the TNFi vs. 40% of the non TNFi patients achieved LDA (p = 0.277). Second biotherapy was withdrawn in 16.7% of the cases of TNFi group vs. 20% of the non TNFi group (p = 0.718). Moreover, no significant difference has emerged between the TNFi and the non-TNFi patients when comparing time to biotherapy discontinuation (15.8 months vs. 20.9; p = 0.11).

Conclusion: In our study, no significant difference was found between TNFi and non-TNFi switcher in RA. But, treatment strategy after first bDMARD failure is still controversial. Further studies have to be done to get the most beneficial strategy in RA.

AB0239 PERSISTENCE TO BIOLOGICAL DMARDS TNF INHIBITORS VS BIOLOGICAL DMARDS NO TNF INHIBITORS AFTER FAILURE TO SYNTHETIC CONVENTIONAL DMARDS IN RA PATIENTS TREATED IN STANDARD CLINICAL PRACTICE

B. Hernández-Cruz[1], P. Muñoz Reinoso[2], I. García Hernández[3], G. Jurado Quijano[3], L. Fernández de la Fuente Bursón[3], I. M. Fernández-Maeztu Palacín[3], A. Fernández Reboul Fernández[3], D. Ruiz-Montesinos[3], J. J. Pérez Venegas[3]. [1]*Hospital Universitario Virgen Macarena, Rheumatology, Seville, Spain*; [2]*Hospital Universitario Virgen Macarena, Rheumatologyy, Sevilla, Spain*; [3]*Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain*

Background: There are no RA response predictors for our patients. The decision to initiate a first biological depends on multiple factors such as rheumatologist experience, clinical characteristics of the patient and health system. What is clear is that the best strategy is T2T.

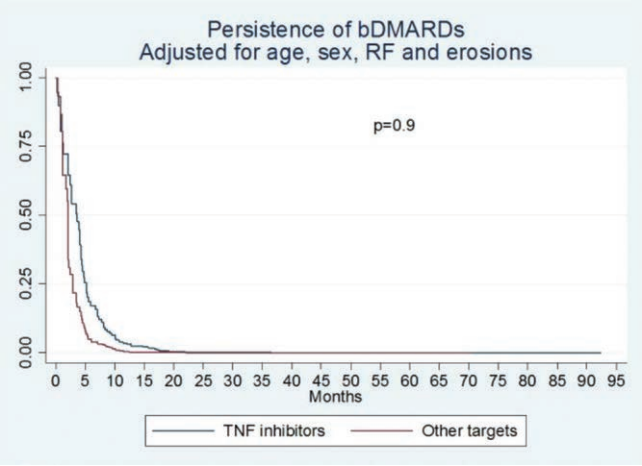
Objectives: To know the clinical characteristics and persistence of the first biological DMARD in patients receiving bDMARDS TNF inhibitors vs DMARDs aimed at other targets.

Methods: A observational cohort of adult RA patients (ACR/EULAR 2010) in a rheumatology department of a third-level university hospital. All patients were treated with a first bDMARD marketed in Spain, from 2010 to December 2020 and prescribed according to product data sheet. Biological drugs were divided into TNF inhibitors drugs (adalimumab, etanercept, infliximab, golimumab, certolizumab) and Other targets (abatacept, rituximab, sarilumab, tocilizumab). Clinical data, duration of treatment and EULAR response were collected from each patient. The data were analyzed with descriptive, bivariate statistics and survival analysis adjusted for age, sex, FR, erosions and duration of the disease.

Results: Data were collected from 332 patients (table 1). Patients treated with other target bDMARDs were mostly female, with higher activity, shorter disease duration, and treated without MTX.b Survival graphs showed that regardless of the target chosen as fist bDMARD, EULAR response rates and persistence to the drug were similar.

Table 1.

Variable	TNF inhibitors n=194	Other targets n = 138	Total n =332	p
	n (%)	n (%)	n (%)	0.02
Female	142 (73)	115 (83)	257 (77)	0.2
FR +	163 (82)	121 (88)	284 (86)	0.6
ACPA +	125 (63)	84 (61)	209 (63)	0.9
Erosions	177 (89)	80 (58)	257 (77)	0.01
Concomitant MTX	153 (77)	62 (47)	215 (65)	0.003
EULAR response				
Good	103 (77)	67 (71)	170 (75)	0.2
Moderate	24 (18)	16 (17)	40 (17)	
No	7 (5)	11 (11)	18 (8)	
	Mean ± SD	Mean ± SD	Mean ± SD	
Age (years)	55.7 ± 13.3	57.6 ± 11.9	56.5 ± 12.7	0.1
Evolution of RA (years)	9.6 ± 10.2	7.5 ± 7.5	8.7 ± 9.2	0.04
Persistence (months)	19.3 ± 20.5	16.07 ± 15.11	17.5 ± 18.5	0.04
DAS28VSG4V basal	5.02 ± 1.5	5.59 ± 1.03	5.25 ± 1.3	0.001
DAS28VSG4V final	2.68 ± 1.1	2.84 ± 1.4	2.7 ± 1.25	0,31



Conclusion: Patients receiving Anti-TNF vs bDMARD with other mechanisms of action have clinical differences. However, the response and persistence to the drug are similar, perhaps due to the implementation of the correct T2T strategy.

AB0240 PREDICTORS OF RESPONSE TO BIOLOGIC AGENTS IN RHEUMATOID ARTHRITIS

K. Saadaoui[1], H. Sahli[1], S. Jemmali[1], S. Boussaid[1], S. Rekik[1], E. Cheour[1], M. Elleuch[1]. [1]*La Rabta Hospital, Rheumatology, Tunis, Tunisia*

Background: In rheumatoid arthritis (RA), the 'treat-to-target' therapeutic approach imposes rigorous control of disease activity. Although biological agents have been shown to be effective, these therapies fail sometimes to achieve therapeutic goals.

Objectives: In this study we tried to determine predictive factors of good therapeutic response to biologic disease-modifying antirheumatic drugs (bDMARD).

Methods: This is a retrospective study including 374 Tunisian patients who received their first biotherapy between 2014 and 2016. Categorical variables were reported in numbers and percentages, while quantitative variables were expressed by mean with standard deviations. The univariate analysis was performed using the student t-test or the Chi2 test. Multivariate analysis was performed by binary logistic regression.

Results: Average age of our cohort was 55 ± 12.5 years with a female predominance of 87.2%. The average duration of RA was 11.7 ± 6.7 years. Rheumatoid factors were positive in 79% and ACPA were positive in 72% of cases. After the introduction of biotherapy, low disease activity (LDA) or remission was achieved in 55% of cases (206 patients).

No statistically significant difference between biotherapy responder and non-responder groups for age (55.7 vs. 54.7 years; p = 0.44), gender (Female: 86.5% vs. 88.7%; p = 0.08) and disease duration (12 years vs. 11.4 years; p = 0.41). A significant difference between the two groups was found for the positivity of rheumatoid factors (76.4% vs. 88.9%; p = 0.004), methotrexate's association (65% vs. 53.4%; p = 0.02) and corticosteroids' use (50% vs. 66.5%; p < 0.001).

Positive predictive factors of remission or LDA by biotherapy were female sex (Odds Ratio = 2.2; p = 0.026), presence of rheumatoid factors (Odds Ratio = 2.64; p = 0.001), association with methotrexate (Odds Ratio = 1.69; p = 0.028). Whereas, corticosteroid use (OR = 0.41; p < 10-3) was a negative predictor of disease control by bDMARDs.

Conclusion: Achieving LDA low level or even remission is currently achievable with biological treatments. Certain factors need to be studied in order to optimize RA treatment and adapt the right bDMARD for each patient.

AB0241 FACTORS THAT DIFFERENTLY ASSOCIATE WITH THE RETENTION ON TARGETED THERAPY OF PATIENTS WITH RHEUMATOID ARTHRITIS

E. Zhilyaev[1,2], G. Lukina[3], E. Koltsova[3,4], K. Lytkina[5], E. Shmidt[6]. [1]*European Medical Center, Medical Derection, Moscow, Russian Federation*; [2]*Russian Medical Academy of Continous Professional Education, Rheumatology, Moscow, Russian Federation*; [3]*A.S.Loginov Moscow Clinical Scientific Center, Rheumatology, Moscow, Russian Federation*; [4]*Research Institute of the Organization of Health and Healthcare Managment, Organizational and Methodological Department of Rheumatology, Moscow, Russian Federation*; [5]*City Clinical Hospital, Rheumatology, Moscow, Russian Federation*; [6]*N.I.Pirogov City Clinical Hospital, Rheumatology, Moscow, Russian Federation*

Background: A personalized approach to prescribing targeted drugs implies the availability of data that can be used to suggest that a particular drug is better suited for a given patient than others. Retention on the treatment can be considered as an integral indicator of the acceptability of the drug in real practice. For the purposes of treatment personalization, the indicators that are associated with better retention on some drugs and with worse retention, or that do not have a clear association with retention on others, are of particular interest.
Objectives: to identify predictors those are differently associated with retention on different targeted drugs for the treatment of rheumatoid arthritis.
Methods: Data of the patients with rheumatoid arthritis (RA) from the Moscow Unified Register of Arthritis (MUAR) were used. The analysis includes episodes of treatment with biological or synthetic targeted drugs (tDMARDs) that continue or end during the patient's follow-up in the registry. Within the framework of the Cox proportional risk regression model, significant independent predictors of tDMARDs cancellation were identified. These indicators were later considered as confounders. Further, in the generated linear regression risk model, all available indicators were tested for the presence of a statistically significant interaction with the factor of used tDMARD.
Results: The study included 944 episodes of tDMARDs treatment (Table 1.) in 832 patients. The average age is 55.3 + 12.4 years. There were 131 males (16.1%). The average duration of the disease is 13.1 + 9.4 years. Smoking, family history of RA, and the nature of RA onset (acute or gradual) were identified as reliable mutually independent predictors of retention on tDMARDs treatment. As a result of the search for indicators that reliably interact with used tDMARD, patient's reports of the association of the onset of arthritis 1) with symptoms of intestinal dyspepsia ($p < 0.001$), 2) with genital inflammatory disease ($p = 0.002$) were revealed. Most strongly associated with factor 1) was retention on abatacept (ABA), rituximab (RIT), and tofacitinib (TOFA). The second indicator was most strongly associated with retention on ABA, adalimumab (ADA) and TOFA (Picture 1).

Table 1. Description of treatment episodes included in the analysis

	ABA	ADA	CER	ETAT	GOL	INF	RIT	TOC	TOFA	Total

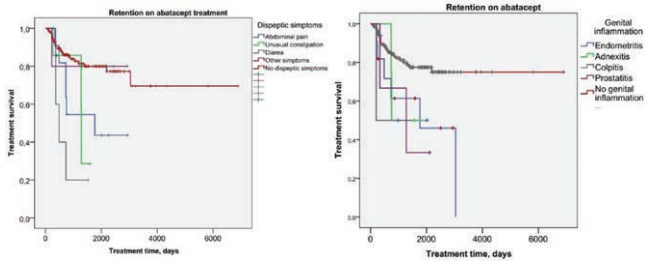
ABA – abatacept, ADA – adalimumab, CER – certolizumab paegol, ETA- etanercept, GOL – golimumab, INF – infliximab, TOC- tocilizumab, TOFA – tofacitinib.

Conclusion: Anamnestic indications of the association of the onset of rheumatoid arthritis with symptoms of intestinal dyspepsia and with preceding genital inflammation are differently associated with retention on different targeted drugs in patients with RA. These indicators can be used to personalize the treatment.



Picture 1. Retention on the abatacept depending on the features of the onset of rheumatoid arthritis

AB0242 CERTOLIZUMAB IN MONOTHERAPY AS EFFECTIVE THAN IN COMBINATION IN RHEUMATOID ARTHRITIS PATIENTS

P. Osorio[1], L. Villarreal[1], W. Rivero[2], L. Ibata[3], S. Martinez[3], A. Rojas-Villarraga[4], P. Santos-Moreno[5]. [1]*Biomab - Center for Rheumatoid Arthritis, Bogota, Colombia, Administration, Bogota, Colombia*; [2]*Biomab - Center for Rheumatoid Arthritis, Bogota, Colombia, Pharmaceutical Chemist, Bogota, Colombia*; [3]*Epithink Health Consulting, Epidemiology, Bogota, Colombia*; [4]*Fundacion Universitaria de Ciencias de la Salud - FUCS, Research Division, Bogota, Colombia*; [5]*Biomab - Center for Rheumatoid Arthritis, Bogota, Colombia, Rheumatology, Bogota, Colombia*

Background: Tumour necrosis factor-a (TNFa) inhibitors are one of the most used biological therapy for rheumatoid arthritis (RA) patients without response to conventional disease-modifying antirheumatic drugs (cDMARDs). There is scarce information about biological DMARDs (bDMARDs) effectiveness as monotherapy in real life.
Objectives: To assess the effectiveness of Certolizumab pegol in real-life clinical practice in a cohort of patients with RA and previous failure to cDMARDs who received certolizumab as monotherapy, combined with Methotrexate (MTX), combined with leflunomide (LFN), or both MTX and LFN.
Methods: A retrospective cohort study was conducted at a specialized center for RA management in Colombia. Patients treated with Certolizumab as monotherapy or in combination with MTX, or LFN, or both MTX plus LFN, (2012 – 2020) were included. The indication of certolizumab was a independent decision based on disease activity. Patients could be taking adjuvant medications for pain and/or corticosteroids. Certolizumab was administered 400 mg SC monthly after three induction doses at weeks 0, 2 y 4, as monotherapy or in combination with MTX (until 25 mg/week), LFN (20 mg/day) or both as a first-line treatment after failure with cDMARDs or as a second-line treatment after failure with one or more bDMARDs. Effectiveness was assessed at three, six, and twelve months according to the change in DAS28. Exploratory comparisons of numeric variable data between groups were done (ANOVA). Chi-square test and Fisher's exact test were used for categorical variables. Multivariate analyses (logistic regressions) were performed to analyse factors related to the response at 6 and 12 months.
Results: Of 181 enrolled patients, 24 received certolizumab as monotherapy, 62 combined with MTX, 47 in combination with LFN and 48 in combination with MTX and LFN. 55.2% of patients were first-line treatment, without significant differences between groups. Mean age of subjects included was 57.87 ± 12.33 with a mean age of around 60 years in patients treated with CERTO+MTX and CERTO+LFN (p=0,014). Women predominated in all groups (84% of the total) (p=0,275). The duration of arthritis on average was 8.27 ± 8.73 years, without significant differences between treatment groups (p=0,871). In terms of disease activity, 78.5% of patients were in moderate or high disease activity, according to DAS28, without significant differences between the groups (p=0,787). Differences in the number of biologicals and corticoid use were observed, patients in the combination groups had used in a higher proportion two or more biological (p=0,046) than in the monotherapy group and had used corticosteroids (p=0,042) more frequently. Overall, there were decreased disease activity, at 3 and 6 months with no significant differences between groups (p=0,08). At 12 months of treatment, there was a higher maintenance in mild activity/remission response in monotherapy group compared to the others (p=0,01). In the multivariate analysis, no differences were observed in the response at 6 and 12 months between the treatment groups. The response at three months was the only variable associated with the 6-month response (OR 5.46; CI 95% 2.08 – 14.32). The response at three months (OR 4.04; CI 95% 1.28-12.69) and positive anti-CCP (OR 3.83; CI 95% 1.11-13.21) were associated with 12-month response.
Conclusion: These exploratory results show a clear trend of Certolizumab being effective as monotherapy in patients previously treated with cDMARDs and even after being treated with one bDMARD. Although results are not statistically different, it seems that certolizumab in monotherapy could be as least as effective as combination therapy. Prospective studies with larger sample size and with a structured follow-up are needed to confirm these findings.

AB0243

CONSIDERING THE COMBINATION OF TWO BIOLOGICS IN CASE OF FAILURE OF THE MONOTHERAPY IN JUVENILE ONSET RHEUMATOID ARTHRITIS

A. Haddouche[1], K. Ait Bellabas[1], W. F. Hamrani[1], S. Sahraoui[1], R. Fatma[1], F. Rahal[2], S. Slimani[3], F. Hanni[1]. *[1]EHS Ben Aknoun, Rheumatology, Algiers, Algeria*; *[2]CHU Beni Messous, Rheumatology, Algiers, Algeria*; *[3]Private Practice Office, Rheumatology, Batna, Algeria*

Background: The management of rheumatoid arthritis refractory to conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) is currently well codified and includes different types of biologics and even targeted sDMARDs. A rotation of biologic therapies is recommended in order to better control the disease.

Methods: We report the case of a 20-year-old patient followed in our hospital for the management of a deforming and erosive seropositive rheumatoid arthritis (FR +, ACPA +) with a juvenile onset at the age of 8 years. The diagnosis of an immunopositive polyarticular form of JIA was retained in 2010 (9 years old); the patient was treated with methotrexate (MTX) at a dose of 10 mg per week and methylprednisolone at doses varying between 4 and 10 mg per day. Following the failure of MTX, etanercept was introduced for 6 months without success, followed by tocilizumab in 2012 at a dose of 8mg/kg/month for a year, without good response. In 2014, a course of rituximab (RTX) at a dose of 2 shots of 500mg, 2 weeks apart was prescribed followed 9 months later by etanercept at a dose of 50 mg a week for 3 years then by adalimumab (40mg/ week) because of the multiple treatment failures.

In 2018, the repetition of RTX at a dose of 1g, renewed 15 days later, improved the patient for only 3 months. Then, a combination of two biologics, namely RTX (2 x 1g, 15 days apart) and adalimumab 1 month later (40mg / week) was received by the patient with a good response at 3 months. The latter was maintained for 7 months even after stopping the adalimumab following confinement for COVID-19. In September 2020, flares occurred and the adalimumab (ADA) has been delivered but without success during 3 months, stopped later for a benign form of COVID-19 (15 months after RTX). In January 2021, the association RTX + ADA was given again and we hope that it will be as effective as the first prescription.

Results: The clinical and biological severity of our patient's rheumatoid arthritis led us to give a combination of two biological treatments. Indeed, we do not have other therapeutic classes to deliver to her, that encouraged us to rotate between all the available biological therapies in our country. The combination of a CD20 inhibitor (RTX) with a TNF blocker (ADA) was safe and made possible, for the first time, the achievement of clinical and biological remission during 7 months, even after stopping the TNF blocker. Greenwald *et al*. reported the safety of the combination of RTX + TNF inhibitors in a randomized clinical trial in 51 patients. Its efficacy, a secondary goal of the study, was suggested at 24 weeks by the percentage of ACR 20 and ACR 50 responses that was greater than in the RTX placebo group.

Conclusion: The combination of RTX with a TNF blocker can be a real alternative therapy in rheumatoid arthritis with failure to a biological monotherapy.

AB0244

INFLUENCE OF BIOLOGICAL DRUGS ON HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Jriri[1], S. Boussaid[1], S. Rekik[1], M. Abbes[1], M. Ben Majdouba[1], S. Jemmali[1], H. Sahli[1], M. Elleuch[1]. *[1]RABTA, Rhuematology, Tunis, Tunisia*

Background: The level of the Health-related quality of life (HRQL) in patients with rheumatoid arthritis (RA) is often negleglected in their medical care. While, theese patients are suffering from a precarious quality of life, resulting from pain, impaired physical function and fatigue. The use of biological agents for treating this disease is then a challenge, leading to the possibility of reducing the consequences of the disease.

Objectives: The main purpose of this study was to compare the level of HRQL in patients with rheumatoid arthritis (RA) during therapy applying disease-modifying antirheumatic drugs (DMARDs) with conventional synthetics (csDMARDs) or with csDMARDs in combination with biological drugs (bDMARDs).

Methods: The study involved 120 patients with RA, divided into two groups: group I –treated using csDMARDs (combination therapy: methotrexate and salazopyrine), group II – using csDMARDs in association with bDMARDs which included TNF inhibitors (etanercept and adalimumab). All the studied patients were surveyed with the use of the following questionnaires: *the short-form health survey (SF-36)* for HRQL that assesses eight domains: functional capacity (ten items), physical aspects (four items), pain (two items), general health (five items), vitality (four items), social aspects (two items), emotional issues (three items) and mental health (five items), in addiction to one item to compare current health status and that of the previous year, *The AIMS2-SF*, and *Health Assessment Questionnaire* (HAQ). The questionnaires were filled out at the consultation after patient's consent.The 28-Joint Disease Activity Score (DAS-28) was calculated.

Results: Group I consisted of 72 persons including 55 women and 17 men with a mean age of 58.4 years. Group II contaned 48 patients where females predominated (sex ratio: 0.3), the mean age was 52.4 years. The majority of patients (53.3%) had been diagnosed with RA for more than five years. Most of the SF-36 domains showed significant improvement in the second group ($p<0.01$), highlighting the social aspects, pain, physical functioning, emotional issues, vitality and physical aspects. The mean score of HAQ II decreased from 1.97 up to 1.23 with biological therapy ($p<0.01$). The highest AIMS scores were comparatively in the two groups (I vs II): in social activity (6.49±1.93 vs 6.23±1.56), pain (4.70±2.04 vs 4.01±2), depression (4.70±2.23 vs 4.66±2.03), and physical activity (4.03±2.10 vs 4.01±2.08). The DAS-28 value, the number of swollen joints, and the duration of morning stiffness were significantly smaller among patients from group II ($P=0.04$). After logistical regression,treatement with biotherapy was isolated as a fundamental independent factor influencing the mentel component of SF-36 scale with an OR of 1.59.

Conclusion: we conclude that the use of biologic therapy in patients with RA proved to be an important pharmacological strategy for improving HRQL and functional capacity as assessed by the HAQ II and SF-36 instruments.The intensity of the activity of RA as well as experiencing pain and the duration of morning stiffness were smaller among patients applying csDMARDs plus bDMARDs compared with patients treated only with csDMARDs.

ANALYSIS OF THE CLINICAL AND ANTIDESTRUCTIVE EFFECTS OF RITUXIMAB DEPENDING ON GENDER IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Kudryavtseva[1], G. Lukina[1], E. Aronova[1], G. Gridneva[1], S. Glukhova[1], A. Smirnov[1]. *[1]V.A.Nasonova Research Institute of Rheumatology, Laboratory for the Study of Comorbid Infections and Monitoring the Safety of Therapy, Moscow, Russian Federation*

Background: Rheumatoid arthritis is a chronic autoimmune disease characterized by inflammation of the synovial tissue and destruction of the underlying cartilage and bones. It was found that RA more often affects women than men, with a sex ratio of 3: 1. And the question of the influence of gender on the outcomes and course of RA remains controversial, there is no consensus on whether RA is worse in women or men. Recent reports indicate that women are less likely to achieve remission than men. Women suffer from RA at an earlier age and have higher markers of disease activity such as DAS28 and HAQ. Rituximab is a chimeric monoclonal antibody that targets the CD20 molecule expressed on the surface of B cells, it has been successfully and widely used for the treatment of rheumatoid arthritis, so it is of interest to assess whether gender influences the therapeutic and radiological effects of RTX.

Objectives: The aim of this study was to analyze the impact of gender on the response to rituximab (RTX) in patients with RA.

Methods: Initially, 221 women(w), 27 men(m), were examined to assess the clinical and X-ray effect (88w/6m), who received RTX treatment (1000 mgx2 or 500 mgx2). Both groups were comparable in terms of the main clinical and laboratory characteristics (age, duration of the disease, the number of preceding DMARDs, in both groups most patients were RF + and ACCP +, a high degree of activity according to DAS 8 - men - 5.6 [4.6-6.7], women - 6.04 [5.2-6.63] Initially, the degree of radiological changes in men is slightly higher than in women ($p> 0.05$). Clinical effect was scored by EULAR criteria, radiographic progression was assessed using Sharp/van der Heijde modified scoring method.

Results: When assessing the clinical effect after 48 weeks in men, a significantly better effect of RTX treatment was noted in comparison with women (Δ DAS28, a significantly better effect was noted in men - Δ DAS28 =3.75[2.8-4.14], and Δ DAS28=1.3[0.37-2.72] in women, ($p=0.04$). Analyzing the X-ray effect after 48 weeks of RTM treatment: the absence of progression in terms of the total score in 83.33% of men and 60.98% of women; there was no progression in narrowing of the joint space in 83.33% of men and 65.85% of women, noteworthy that the account of erosion practically reaches statistical significance - inhibition of destruction in 100% of men and 74.31% of women ($p = 0.06$).

Conclusion: Thus, having analyzed the clinical and antidestructive effects of RTM therapy depending on gender, we can conclude that the effect is significantly

higher in the male group. Also, there is a tendency towards more effective inhibition of radiographic progression in men.

Objectives: The aims of our study are to determine the new comorbidities appearing under biologic therapy, their prevalence, and the factors implicated in their appearance.

Methods: It's a multicentric historical-prospective cohort including 10 rheumatology departments of Moroccan University Hospitals. The data were collected from the national register of patients under biologic therapy supervised by the Moroccan Society of Rheumatology. An electronic follow-up questionnaire is completed every 6 months by the investigator.

Results: The study included 418 patients: 224 with Rheumatoid Arthritis (RA) who represented 53.6% and 194 with spondyloarthropathy (SP) who represented 46.4%.

The prevalence rate of comorbidities appearing after one year of treatment with biologic therapy was 15.7% in RA and 8.4% in SP. The rate of cardiovascular diseases was 12.9% (arterial hypertension, myocardial infarction and/or ischemic stroke), 6.4% was the same value of hypercholesterolemia and depression, diabetes 3.3%, ulcer 3.2%, and osteoporosis 9.7%. The sedentary rate was 54.8% and smoking was about 3.3%.

No patient had developed hypertriglyceridemia or chronic obstructive pulmonary disease.

In the group of patients with RA, the average age of the patients who had developed a new comorbidity was 51,8 ± 11,3 years, women represented 87.5%, the average of Body Mass Index (BMI) was 27,6 ± 5,9 and the average duration of the disease was 14,1 ± 9,2 years. The disease activity score (DAS28) had an average of 3,15 ± 1,47.

59.6% of patients used Rituximab, 23.8% Tociluzimab, 8.1% Etanercept, 5.8% Adalimumab, 0.18% Infliximab, and 0.9% Golimumab.

In the group of patients with SP, the average age of the patients who had developed a new comobidity was 40,2 ± 13,7 years, men represented 63.4%, and the average of BMI was 24,3 ± 4,94.

The activity of the desease, had an average Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) of 2,62 ± 1,79 and ankylosing Spondylitis Disease Activity **Score** (ASDAS) of 1,93 ± 1,09.

Regarding the type of biologic therapy, 33.2% of patients used Etanercept, 30.1% Adalimumab, 24.9% Infliximab, 9.8% Golimumab, 1.6% Secukinumab, and 0.5% Tociluzimab.

Conclusion: Our study showed a high prevalence of cardiovascular disease in patients under biologic therapy. This can be explained by the sedentary lifestyle secondary to rheumatic disease.

Background: A prior post hoc analysis of tofacitinib clinical trial data reported improvements in rheumatoid arthritis (RA) outcomes with tofacitinib vs placebo (PBO) through Month (M)6, regardless of baseline (BL) body mass index (BMI).[1]

Objectives: To assess change from BL (Δ) in BMI, and disease activity by BL BMI status, in patients (pts) with moderate/severe RA receiving tofacitinib through M12.

Methods: This post hoc analysis included data pooled from Phase 3 and 3b/4 studies of pts who were methotrexate-naïve (NCT01039688) or inadequate responders to conventional synthetic (cs) or biologic DMARDs (NCT00960440; NCT00847613; NCT00814307; NCT00856544; NCT00853385; NCT02187055; NCT02831855). Pts received ≥1 dose of tofacitinib 5 or 10 mg twice daily (BID) or 11 mg once daily (QD), ± csDMARDs, or PBO. Least squares (LS) mean ΔBMI (linear mixed model repeated measures; observed cases) was summarised for all treatment groups at M3/6/12 (M3/6 only for tofacitinib 11 mg QD and PBO). Other assessments at M3/6/12 included ΔBMI ± BL concomitant glucocorticoids (GCs) or antidepressants (descriptive statistics), LS mean ΔDAS28-4(ESR) stratified by BL BMI status (<25, ≥25–<30, ≥30), and correlations between LS mean ΔBMI and ΔDAS28-4(ESR).

Results: In total, 2349, 1611, 694 and 681 pts received tofacitinib 5 mg BID, 10 mg BID, 11 mg QD or PBO, respectively. Demographics/baseline characteristics were generally similar across treatments, except for some numerical differences in the tofacitinib 11 mg QD group, eg fewer female pts, more White pts and fewer pts receiving concomitant GCs, compared with other treatment groups. At M3/6, LS mean BMI significantly increased from BL with all tofacitinib doses vs PBO (all p<0.05); LS mean ΔBMI was greatest with 10 mg BID and lowest with 11 mg QD (Figure 1a). LS mean ΔBMI was greater in pts receiving tofacitinib as monotherapy vs combination therapy at M3/6/12 (Figure 1b). ΔBMI was generally similar in pts receiving treatment ± concomitant GCs or antidepressants (data not shown). Improvements in DAS28-4(ESR) were observed in each BL BMI status group at M3/6/12 and were greatest with all tofacitinib doses vs PBO. LS mean ΔDAS28-4(ESR) was generally numerically highest for pts with BMI <25 and numerically lowest for pts with BMI >30, for all tofacitinib doses. LS mean ΔDAS28-4(ESR) was generally greatest with tofacitinib 10 mg BID and 11 mg QD vs 5 mg BID across BL BMI status groups (Figure 1c). Across treatments, model-adjusted associations between LS mean ΔDAS28-4(ESR) and ΔBMI were weak (correlation coefficients all <0.3; Table 1).

Table 1. Correlations between LS mean ΔDAS28-4(ESR) and ΔBMI through M12

	Tofacitinib 5 mg BID		Tofacitinib 10 mg BID		Tofacitinib 11 mg QD		PBO	
	N	Correlation coefficient	N	Correlation coefficient	N	Correlation coefficient	N	Correlation coefficient
M3	2021	0.1169	1348	0.1240	641	0.0907	554	0.0783
M6	1918	0.1305	1270	0.1397	611	0.0438	150	0.1556
M12	1455	0.1213	874	0.1826	-	-	-	-

Slopes for associations between LS mean ΔBMI and ΔDAS28-4(ESR) were significantly different from 0 at M3/6/12 with tofacitinib 5 and 10 mg BID (all p<0.05). Correlations were analysed by a general linear model method, which included BL age, gender, race and RA duration. For pts receiving tofacitinib 11 mg QD in ORAL Shift (NCT02831855), only data to M6 were included. Pts who advanced from PBO to tofacitinib were not analysed post-advancement-DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; N, number of pts analysed

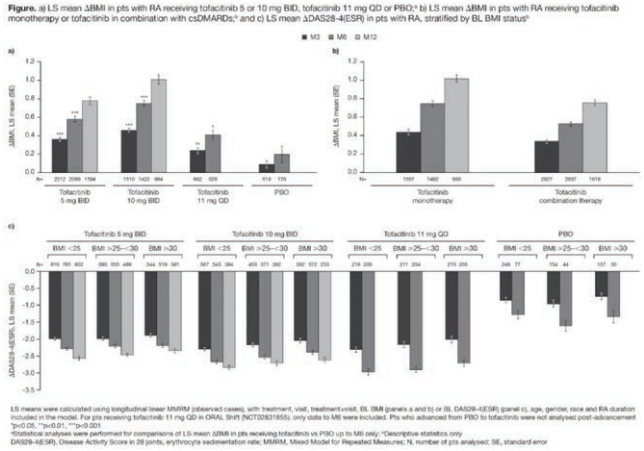

Figure. a) LS mean ΔBMI in pts with RA receiving tofacitinib 5 or 10 mg BID, tofacitinib 11 mg QD or PBO;[a] b) LS mean ΔBMI in pts with RA receiving tofacitinib monotherapy or tofacitinib in combination with csDMARDs;[a] and c) LS mean ΔDAS28-4(ESR) in pts with RA, stratified by BL BMI status[b]

LS means were calculated using longitudinal linear MMRM (observed cases), with treatment, visit, treatment-visit, BL BMI (panels a and b) or BL DAS28–4(ESR) (panel c), age, gender, race and RA duration included in the model. For pts receiving tofacitinib 11 mg QD in ORAL Shift (NCT02831855), only data to M6 were included. Pts who advanced from PBO to tofacitinib were not analysed post-advancement
*p<0.05, **p<0.01, ***p<0.001
[a]Statistical analyses were performed for comparisons of LS mean ΔBMI in pts receiving tofacitinib vs PBO up to M6 only; [b]Descriptive statistics only
DAS28–4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; MMRM, Mixed Model for Repeated Measures; N, number of pts analysed; SE, standard error

Conclusion: LS mean ΔBMI was greater with tofacitinib (all doses) vs PBO at M3/6, and with tofacitinib monotherapy vs combination therapy at M3/6/12. Improvements in DAS28-4(ESR) were seen across all BL BMI status groups. BMI increases with tofacitinib were only weakly associated with DAS28-4(ESR) improvements. The relationship between disease activity and ΔBMI requires further investigation.

AB0248 INFLUENZA ADVERSE EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN THE TOFACITINIB CLINICAL PROGRAMME

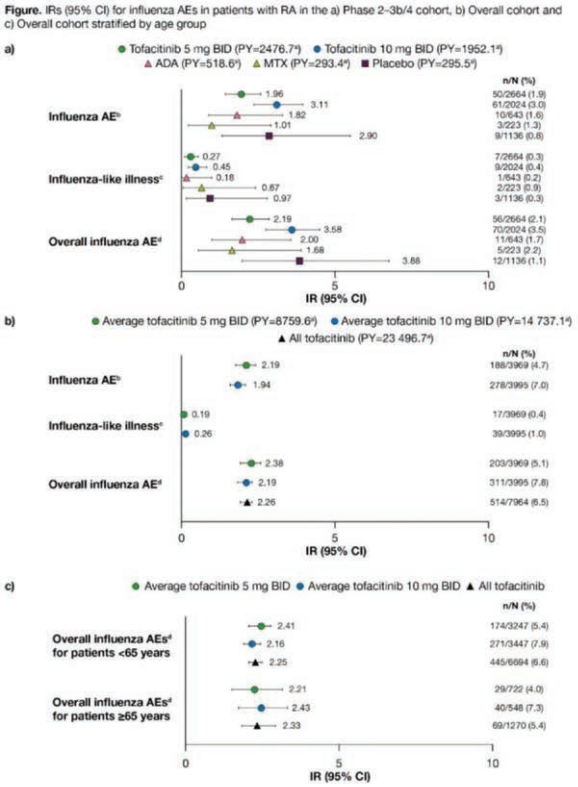
K. Winthrop[1], A. Yndestad[2], D. Henrohn[3], H. Jo[4], S. Marsal[5], M. Galindo-Izquierdo[6], A. Diehl[7], A. Shapiro[8], S. B. Cohen[9]. [1]*Oregon Health & Science University, Portland, OR, United States of America*; [2]*Pfizer Inc, Inflammation and Immunology, Oslo, Norway*; [3]*Pfizer Inc, Inflammation and Immunology, Sollentuna, Sweden*; [4]*Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; [5]*Vall d'Hebron Hospital, Rheumatology Department, Barcelona, Spain*; [6]*Hospital Universitario 12 de Octubre, Rheumatology Unit, Madrid, Spain*; [7]*Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America*; [8]*Pfizer Inc, Inflammation and Immunology, Peapack, NJ, United States of America*; [9]*Metroplex Clinical Research Center, Dallas, TX, United States of America*

Background: Patients (pts) with rheumatoid arthritis (RA) have an increased susceptibility to seasonal influenza and its complications.[1] In light of the COVID-19 pandemic, there is a need to better understand acute respiratory viral RNA infections, such as influenza, in pts with RA.

Objectives: To present a comprehensive summary of data on influenza adverse events (AEs) occurring in the tofacitinib RA clinical programme.

Methods: Influenza AEs were evaluated in pts with RA from 21 Phase (P)1–3b/4 trials and two open-label, long-term extension (LTE) studies from 2005–2019. These were analysed as two cohorts: P2–3b/4 cohort (pts who received tofacitinib 5 or 10 mg twice daily [BID] as monotherapy or with conventional synthetic [cs]DMARDs, adalimumab, methotrexate or placebo, in P2–3b/4 controlled studies) and Overall cohort (pts who received ≥1 tofacitinib dose, as monotherapy or with csDMARDs, in P1–3b/4 and LTE studies; data were summarised by average tofacitinib dose [average tofacitinib 5 or 10 mg BID based on average total daily dose of <15 or ≥15 mg, respectively]). Incidence rates (IRs; unique pts with events/100 pt-years of exposure; censored at day of first event or up to last dose +28 days) were evaluated for influenza AEs, influenza complication AEs, influenza-like illness (all composites of several MedDRA preferred/verbatim terms) and overall influenza AEs (composite of all preferred/verbatim terms included under influenza AEs, influenza complication AEs and influenza-like illness). In the Overall cohort, the incidence of serious non-influenza AEs within 28 days of the start of an overall influenza AE and time taken to resolution of overall influenza AEs by action taken were summarised descriptively.

Results: In total, 7964 pts were included; 517 (6.5%) pts reported overall influenza AEs, three of which occurred outside the risk period. In the P2–3b/4 cohort (N=6690), IRs for influenza AEs, influenza-like illness and overall influenza AEs generally appeared similar across treatment arms (Figure 1a). In the Overall cohort, IRs for influenza AEs and influenza-like illness were similar between tofacitinib doses (Figure 1b), and IRs for overall influenza AEs were similar between tofacitinib doses and pt age groups (Figure 1c). No influenza complication AEs (eg pneumonia/encephalitis influenzal) were reported in either cohort. Among pts with overall influenza AEs, nine (1.7%) had serious overall influenza AEs (average tofacitinib 5 mg BID, n=6; average tofacitinib 10 mg BID, n=3). Of these pts, eight (1.5%) were hospitalised (average tofacitinib 5 mg BID, n=6; average tofacitinib 10 mg BID, n=2) and two (0.4%) died (average tofacitinib 5 mg BID, n=1; average tofacitinib 10 mg BID, n=1). Both deaths occurred in pts with H1N1 Influenza A. Twelve (2.3%) pts had a serious non-influenza AE within 28 days of the start of the overall influenza AE (average tofacitinib 5 mg BID, n=6; average tofacitinib 10 mg BID, n=6). The most common serious non-influenza AEs (one event each in average tofacitinib 5 and 10 mg BID groups) were acute respiratory distress syndrome and pneumonia. In most pts with overall influenza AEs, no change to tofacitinib treatment was made (70.2%, n=363) or treatment was stopped temporarily (28.2%, n=146) for a mean duration of 11.0 days. The mean number of days to resolution of overall influenza AEs was numerically similar, ranging from 10.4–11.8 days across tofacitinib doses, irrespective of these actions.



IRs were calculated as the number of unique pts with events (per 100 PY) during the time between the first and last dose +28 days, divided by the pt time accrued during the first and last dose +28 days, or up to the first event, whichever occurred earlier. 95% CI are based on the Exact Poisson method adjusted for exposure time
[a]Total PY of study drug exposure for all pts in treatment group
[b]Included all PTs under the high-level term 'influenza viral infections', and a collection of VTs for influenza AEs
[c]Included the PT 'influenza-like illness' and a collection of VTs for influenza-like illness
[d]Included all PTs and VTs included under influenza AEs, influenza complication AEs and influenza-like illness; no events of influenza complication AEs were reported
ADA, adalimumab; CI, confidence interval; MTX, methotrexate; PT, preferred term; PY, pt-years; VT, verbatim term

Conclusion: This post hoc analysis of influenza AEs across the tofacitinib RA clinical programme, over 14–15 influenza seasons, showed generally similar rates between treatment groups, and between tofacitinib doses and pt age groups. Limitations include varying exposure across treatment arms in the P2–3b/4 cohort. Most influenza AEs were non-serious (98.3%), and were not associated with changes to tofacitinib treatment.

Background: An all-case post marketing surveillance (PMS) of baricitinib (Bari), that started in Sep 2017, collects safety and effectiveness for the first 24 wks of treatment and continues to collect serious adverse events (SAEs) for 3 yrs.
Objectives: To evaluate Bari safety in RA patients (pt) in clinical practice.
Methods: We report pt baseline demographics and adverse events (AEs) up to 24 wks for pts whose case report files for 24-wk data were completed as of Jun 2020.
Results: Data from 3445 pts were analyzed (females=80%, mean age=64yr, mean RA duration 12yr). Bari dose regimen was as follows: 4mg, 60%, 2mg, 27%, 4mg→2mg, 5%, 2mg→4mg, 5%, and others, 2%. Concomitant use of MTX and glucocorticoid was 65% and 48%, respectively. 74% continued treatment for 24 wks. AE and SAE were recognized in 887 (26%) and 122 pts (4%), respectively. 6 pts died of pneumonia, aspiration pneumonia, bacterial pneumonia, cerebral infarction/ILD/aspiration pneumonia, adenocarcinoma, and colorectal cancer. Major AEs were as follows: herpes zoster=3%, liver dysfunction=3%, serious infection=1%, anemia=1%, hyperlipidemia=1%, malignancy=0.3%, interstitial pneumonia=0.2%, MACE=0.1%, and VTE=0.1%.
Conclusion: Data do not show new safety concerns and encourage guideline-compliant use of Bari.

AB0250 TOFACITINIB SUPPRESSES SEVERAL JAK-STAT PATHWAYS IN RHEUMATOID ARTHRITIS AND BASELINE SIGNALING PROFILE ASSOCIATES WITH TREATMENT RESPONSE

M. Palmroth[1], K. Kuuliala[2], R. Peltomaa[3], A. Virtanen[1], A. Kuuliala[2], A. Kurttila[1], A. Kinnunen[4], M. Leirisalo-Repo[3], O. Silvennoinen[1,5,6], P. Isomäki[1,4]. [1]*Tampere University, Faculty of Medicine and Life Sciences, Tampere, Finland*; [2]*University of Helsinki, Department of Bacteriology and Immunology, Faculty of Medicine, Helsinki, Finland*; [3]*University of Helsinki and Helsinki University Hospital, Faculty of Medicine, Helsinki, Finland*; [4]*Tampere University Hospital, Centre for Rheumatic Diseases, Tampere, Finland*; [5]*Fimlab Laboratories, Pirkanmaa Hospital District, Tampere, Finland*; [6]*University of Helsinki, Institute of Biotechnology, HiLIFE Helsinki Institute of Life Sciences, Helsinki, Finland*

Background: Cytokines are important mediators of inflammation and tissue destruction in rheumatoid arthritis (RA) [1]. Several cytokines involved in RA pathogenesis act through Janus kinase (JAK)-signal transducer and activator of transcription (STAT) pathway [2]. The effects of JAK-inhibitor tofacitinib on cytokine signaling *in vitro* are well established, while *in vivo* evidence in patients remains scarce.
Objectives: To investigate *in vivo* in rheumatoid arthritis patients i) which JAK-STAT pathways are inhibited by tofacitinib and ii) if baseline signaling profile is associated with the treatment response.
Methods: Sixteen patients with active RA, despite treatment with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), received tofacitinib 5 mg twice daily for three months. Levels of basal and cytokine-induced phosphorylated STATs and total STAT1 and STAT3 in peripheral blood monocytes, T cells and B cells were measured by flow cytometry. mRNA expression of JAKs, STATs and suppressors of cytokine signaling (SOCS) were measured from peripheral blood mononuclear cells (PBMCs) by quantitative PCR. Association of baseline signaling profile with treatment response (the change from baseline in disease activity score (DAS28)) was studied by calculating correlation coefficients.
Results: Treatment with tofacitinib and csDMARDs decreased median DAS28 from 4.4 to 2.6 ($p < 0.001$). Tofacitinib significantly decreased cytokine-induced phosphorylation of all JAK-STAT pathways studied. Basal STAT1, STAT3, STAT4 and STAT5 phosphorylation in monocytes and/or T cells was downregulated by tofacitinib. No changes were observed in STAT1 and STAT3 protein

levels, while gene expression of *STAT3*, *STAT4*, *STAT5A*, *JAK1*, *JAK3* and all studied *SOCS*s was significantly suppressed. Baseline STAT phosphorylation levels in T cells and monocytes and *SOCS3* expression in PBMCs correlated with treatment response.

Conclusion: Tofacitinib suppresses multiple JAK-STAT pathways in RA patients *in vivo*. Baseline JAK-STAT signaling profile may be applicable as a prognostic marker for treatment response to tofacitinib.

AB0251 INCREASED ACCUMULATION OF ERYTHROCYTE METHOTREXATE POLYGLUTAMATES DURING EARLY PHASE SUBCUTANEOUS VERSUS ORAL METHOTREXATE TREATMENT OF RHEUMATOID ARTHRITIS PATIENTS

R. Hebing[1,2], I. Muller[3], M. Lin[3], S. Mahmoud[1], S. Heil[4], W. Lems[1,2], M. Nurmohamed[1,2], R. De Jonge[3], G. Jansen[3]. *[1]Reade, Rheumatology, Amsterdam, Netherlands*; *[2]Amsterdam UMC, Location VUmc, Rheumatology, Amsterdam, Netherlands*; *[3]Amsterdam UMC, Location VUmc, Clinical Chemistry, Amsterdam, Netherlands*; *[4]Erasmus MC, Clinical Chemistry, Rotterdam, Netherlands*

Background: Optimal dosing of methotrexate (MTX) for individual rheumatoid arthritis (RA) patients to achieve adequate disease control is an ongoing challenge. Assessment of erythrocyte MTX-polyglutamates (PGs) levels has been employed as a tool to monitor clinical response of RA patients in the first 3-12 months of treatment and MTX-PG_{2-4} and total MTX-PGs were associated with a lower DAS28 over 9 months.[1] However, data from earlier time points, MTX-PG_6 and per route of administration are unavailable.

Objectives: To investigate the pharmacokinetics and -dynamics of erythrocyte MTX-PG accumulation in RA patients receiving oral or subcutaneous MTX in the early phase (1, 2, and 3 months) of MTX treatment initiation.

Methods: In a clinical prospective cohort study (MeMo study (NTR7149)), newly diagnosed RA patients were administered oral (n=24) or subcutaneous (n=22) MTX, mostly according to the COBRA-light schedule (start 10 mg MTX, increased to 25 mg MTX in 8 weeks). At 1, 2, and 3 months after start of therapy, blood was collected and individual MTX-PGs (MTX-PG_1 – MTX-PG_6) were analyzed in erythrocytes at a minimal detection limit of 1 nmol/L, using a validated UHPLC-MS/MS method with labeled internal standards.[1] Dosing, concomitant treatments and DAS28-ESR assessments were in conformity with clinical practice. Adverse events were recorded.

Results: 46 consecutive patients were included in this study; 76% female, mean age: 57.8 years, BMI: 25.8, 20% smokers, mean baseline DAS28-ESR: 3.5. Notwithstanding marked interpatient variability, patients starting subcutaneous MTX had accumulated significantly higher (approximately 2-fold) long chain MTX-PGs (MTX-PG_{4-6}) when compared to patients in the oral MTX group at 1 and 2 months (Figure 1A, Table 1). Similarly, MTX-PG_{1-6} and MTX-PG_3 accumulation were higher in subcutaneous MTX-users at month 1 (p=0.022 and p=0.011) compared to the oral group (median 68.6 nmol/L (IQR:40.5) vs 51.9 (55.6) and 17.4 (11.1) vs 11.2 (15.6), respectively (Figure 1B, Table 1).

Table 1. ***Linear regression of MTX-PG levels and administration route, corrected for age, baseline DAS28, smoking, BMI, eGFR and MTX dose.***

month	ß (P-value) 1	ß (P-value) 2	ß (P-value) 3
MTX-PG_{1-6}	1.65 (0.022)	1.51 (0.073)	1.30 (0.233)
MTX-$PG_{1,2}$	1.13 (0.599)	1.19 (0.470)	1.12 (0.623)
MTX-PG_3	1.75 (0.011)	1.51 (0.071)	1.19 (0.439)
MTX-PG_{4-6}	1.97 (0.036)	2.04 (0.033)	1.55 (0.136)

Mean MTX dose at baseline was 10.5mg (SD 1.5) for both groups, 15.4 (4.4) and 16.8 (1.8) at 1 month and 22.8 (3.9) and 22.4 (5.2) at 2 months for oral and subcutaneous use respectively.

DAS28 decreased with 1.6 in the oral group and 1.1 in the subcutaneous group (p=0.382). With and without corrections for age, baseline DAS28, eGFR, MTX dose (1 month before sampling), smoking and BMI, no significant relation between MTX-PG concentrations and DAS28 was observed during the first 3 months of treatment.

43 patients reported any side effect, mostly headache and dizziness, which was similar in both groups and uncorrelated with MTX-PG levels.

No association was found between MTX-PG_1 levels and number of days between timing of blood withdrawal and last administration.

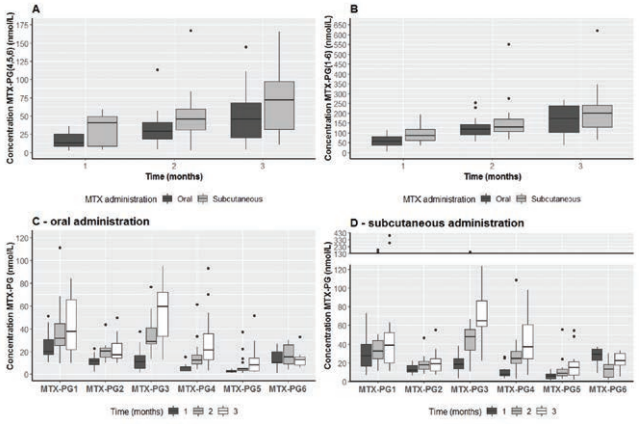

Figure 1. *Erythrocyte long chain MTX-PG (**A**) and total MTX-PG (**B**) accumulation in RA patients of the first 3 months of oral (**C**) or subcutaneous (**D**) MTX administration. At 3 months, 18 patients using oral and 18 patients using subcutaneous MTX were still continuing MTX treatment. Medians and IQR are depicted.*

Conclusion: This study shows the feasibility of measuring erythrocyte MTX-PGs early on in the treatment of RA patients with MTX and demonstrated significantly higher accumulation of MTX-PGs following subcutaneous versus oral MTX administration. Early phase erythrocyte MTX-PG analyses may hold potential for positioning in optimizing individual patient MTX dose scheduling.

AB0252 EFFICACY OF A SECOND JANUS KINASE INHIBITOR THAT WAS SWITCHED FOR DIFFICULT-TO-TREAT RA IN CLINICAL PRACTICE

M. Kamiya[1], D. Togawa[2], S. Mori[2], K. Yamazaki[2]. *[1]Nara Hospital, Kindai University, Orthopedic Surgery and Rheumatology, Ikoma-City, Japan*; *[2]Nara Hospital, Kindai University, Orthopaedic Surgery and Rheumatology, Ikoma-City, Japan*

Background: In clinical practice, when refractory rheumatoid arthritis (RA) is present, of which the definition implies previous use of at least two biologic disease-modifying antirheumatic drugs (bDMARDs) (generally tumour necrosis factor inhibitors (TNFis)), the next treatment choice often made is a bDMARD of another class (non-TNFis) [1]. However, patients who are inadequately responding to bDMARDs need new treatment options because subsequent bDMARDs treatment reduces their response [2]. Janus Kinase inhibitors (JAKis) are the first targeted synthetic DMARDs (tsDMARD) licensed for the treatment of RA with comparable efficacy to bDMARDs. Unlike the single cytokine targeting approach of bDMARDs, JAKis are specifically designed to inhibit intracellular signalling molecules common to the receptors of multiple inflammatory cytokines implicated in RA pathogenesis. The choice of therapeutic agents for refractory RA is increasing, and its efficacy is expected. On the other hand, it is also true that some patients discontinued JAKis at a rate that cannot be overlooked because

of insufficient efficacy. Difficult-to-treat (D2T) RA is defined as refractory to two or more b/ts DMARDs with different mechanisms of action, with active and progressive disease, as published by Eular(3)

Objectives: To evaluate real world efficacy of approved JAKis switching in patients with D2T RA who were unable to control their disease activity due to insufficient efficacy despite the sequential use of multiple bDMARDs and JAKis, focusing on the drug retention rate.

Methods: In our hospital, RA was diagnosed according to the 1987 or 2010 classification criteria, and when two or more bDMARDs (including both TNFis and non-TNFis) were inadequately effective, it was defined as D2T RA. We retrospectively investigated patients who switched to JAKis for D2T RA. The drug retention rate was investigated by the Kaplan-Meier method, and the difference was tested by the Logrank test.

Results: The 1-year retention rate of JAKis for D2T RA was 50.8% in TOF 38 cases [28 women, age average 70.2 years, disease duration average 12.4 years, past bDMARDs use average 3.5 drugs, MTX combination 9 cases, DAS28 ESR average 4.11] and 66.3% in BAR 35 cases [26 cases, 73.0 years old, 14.8 years, 4.17 agents, 9 cases, 3.68], and there was no significant difference (P = 0.30). Among them, there were 17 cases [11 cases, 70.6 years old, 13.5 years, 4.18 drugs, 2 cases, 3.65] of switching between JAKis, all of which were switching from TOF to BAR. The 1-year retention rate was 45.8% [reason for discontinuation: insufficient effect in 3 cases, adverse events in 6 cases], which was not significantly different but tended to be lower than 72.7% [reason for discontinuation: insufficient effect in 1 case, adverse event in 2 cases, patient's convenience in 1 case] in 16 patients [13 cases, 76.3 years old, 17.1 years, 3.19 drugs, 7 cases, 3.69] who received BAR as the first JAKi for D2T RA patients (P = 0.089).

Conclusion: Although the number of cases is small in the retrospective survey, it is suggested that the retention rate of BAR switched to D2T RA may be slightly lower in patients with a history of TOF discontinuation due to insufficient efficacy than in JAKi naive patients. It is expected that the number of new JAKi usage cases will increase in the future, and it is necessary to consider switching between other JAKis in addition to switching from BAR to TOF.

Background: Methotrexate (MTX) is the first-line therapy for rheumatoid arthritis (RA). The concentrations of MTX-polyglutamates (PG) in erythrocytes, an active form of MTX, are useful markers for the optimal usage of MTX in patients with RA. The concentrations of MTX-PG have been reported to be different between Japanese and Caucasians. However, the difference among Asian ethnicity remains unclear.

Objectives: To examine MTX-PG concentrations in association with MTX dose during the first 24 weeks after the initiation of MTX for newly diagnosed RA patients in Japan, Korea and Taiwan.

Methods: MIRACLE study is a multicenter, open-label, randomized, 48 weeks interventional study conducted in Japan, Korea and Taiwan to evaluate non-inferiority of low dose to high dose of MTX as an add-on therapy to adalimumab in 300 patients with RA who do not achieve remission after 24 weeks MTX monotherapy in stipulated dosage. In the first 24 weeks, MTX was started at 6 to 8 mg/week for newly diagnosed RA patients, and promptly escalated to the maximum tolerable dose in 12 weeks in principle. This interim data evaluation was intended to investigate the differences among countries in the relationship between MTX dose, safety and MTX-PG concentrations in erythrocytes during the first 24 weeks. The efficacy of the treatment is not included at this point.

Results: A total of 166 patients (106 in Japan, 35 in Korea, 25 in Taiwan) were included in this interim data. The age at treatment initiation was 57.2 years old on average and female was 79.5%. The time course changes in total and individual MTX-PG levels differed in the three countries. At 24 weeks, whereas the mean total MTX-PG concentrations were comparable (112.9 nmol/L in Japan, 104.4 nmol/L in Korea, and 115.7 nmol/L in Taiwan) with a dose of MTX of 12.3 mg/week, 14.1 mg/week, and 12.2 mg/week, respectively, the individual MTX-PG concentrations were different. The MTX-PG1 and MTX-PG2 concentrations were lower in Korea than Japan and Taiwan whereas MTX-PG3, MTX-PG4 and MTX-PG5 concentrations were the highest in Korea.

Conclusion: The distribution of short-chain and long-chain MTX-PG concentrations were various among Asian countries despite similar dose of MTX administration: NCT03505008.

AB0254 NEUROPSYCHIATRIC ADVERSE DRUG REACTIONS ASSOCIATED WITH LOW DOSE METHOTREXATE IN RHEUMATOID ARTHRITIS PATIENTS

J. Van Lint[1], T. Bakker[1], P. Ten Klooster[2,3], H. Vonkeman[2,4], N. Jessurun[1].
[1]Netherlands Pharmacovigilance Centre Lareb,'s Hertogenbosch, Netherlands; *[2]University of Twente, Psychology, Health & Technology, Enschede, Netherlands*; *[3]Transparency in Healthcare B.V., -, Hengelo, Netherlands*; *[4]Medisch Spectrum Twente, Rheumatology and Clinical Immunology, Enschede, Netherlands*

Background: Neuropsychiatric adverse drug reactions (NPADRs) are well known with high dose methotrexate treatment. However, NPADRs have also been observed with low dose methotrexate (LDMTX) treatment in real world rheumatology data.
Objectives: To evaluate the association between LDMTX and NPADRs, the impact of these NPADRs on further treatment and on health related quality of life (HRQoL) in patients with rheumatoid arthritis (RA) using real world data.
Methods: The nature and frequency of NPADRs associated with LDMTX in the Dutch DREAM-RA registry were described. We assessed the causality of each NPADR with the Naranjo Probability Scale (NPS), the impact of NPADRs on further LDMTX treatment and the impact on patient reported HRQoL. NPADRs were structured using terminology of the Medical Dictionary for Regulatory Activities.
Results: A total of 71 NPADRs (frequency 6.8%) associated with LDMTX were captured in the DREAM-RA registry. NPADRs were registered for 62 (5.9%) out of 1048 patients with 10.9 NPADRs per 1000 patient years (Table 1). The most frequently reported NPADRs were headache, dizziness and depression. The causality was considered probable for 67 NPADRs (94.4%) and definite for 1 NPADR (1.4%). The NPADRs led to LDMTX withdrawal in 34 cases (47.9%) and LDMTX was not restarted in 16 cases (47.1%). Median mental HRQoL was significantly decreased around the occurrence of the NPADR and remained significantly lower after the event. Median physical HRQoL was not significantly affected.

Table 1. Baseline characteristics of DREAM-RA patients using methotrexate with at least one neuropsychiatric adverse drug reaction

Characteristics N=62		N (%)
Female sex		40 (64.5%)
Age in years, mean (± SD), range		59.8 (± 13.1), 25 – 82
Rheumatoid factor	Positive	43 (69.4%)
	Negative	13 (21.0%)
	Unknown	6 (9.7%)
Anti-CCP, n (%)	Positive	34 (54.8%)
	Negative	19 (30.7%)
	Unknown	9 (14.5%)
Methotrexate dosage in mg/week, mean (± SD)		18.7 (± 5.9)
Specific methotrexate dosage	< 15 mg / week	5 (7.0%)
	15 mg/week	28 (39.4%)
	20 mg/week	11 (15.5%)
	25 mg/week	14 (19.7%)
	30 mg/week	5 (7.0%)
	Unknown	8 (11.3%)
Concomitant medication at moment of NPADR	Folic acid	68 (95.8%)
	Prednisolone	20 (28.2%)

Anti-CCP: anti cyclic citrullinated peptides, NPADR: neuropsychiatric adverse drug reaction, SD: Standard Deviation

Conclusion: The association between NPADRs and LDMTX in RA patients was recognised by HCPs and frequently led to LDMTX withdrawal and a decrease in mental HRQoL. Many NPADRs scored 'probable' using the NPS. Knowledge on the nature, frequency and impact of these NPADRs will enhance attention towards potential NPADRs during LDMTX therapy allowing better risk assessment and communication to patients.

AB0255 BASELINE CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH UPADACITINIB IN GERMAN REAL-WORLD PRACTICE: RESULTS FROM THE POST-MARKETING OBSERVATIONAL UPwARDS STUDY

T. Witte[1], U. Kiltz[2,3], F. Haas[4], E. Riechers[1], U. Prothmann[5], D. Adolf[6], C. Holland[7], R. Hecht[7], A. Roessler[7], K. Famulla[7], K. Krueger[8]on behalf of the UPwArds Study Group. *[1]Hannover Medical University, Clinic for Rheumatology and Immunology, Hannover, Germany*; *[2]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*; *[3]Ruhr-Universität Bochum, Rheumatology, Bochum, Germany*; *[4]Internistisch-Rheumatologische Facharztpraxis, Rheumatology, Tübingen, Germany*; *[5]Knappschaftsklinikum Saar, Rheumatology, Puettlingen, Germany*; *[6]StatConsult GmbH, Statistics, Magdeburg, Germany*; *[7]AbbVie Germany GmbH & Co. KG, Immunology, Wiesbaden, Germany*; *[8]Praxiszentrum St. Bonifatius, Rheumatology, Munich, Germany*

Background: The efficacy and safety of upadacitinib (UPA), a selective Janus kinase inhibitor, has been evaluated in the SELECT rheumatoid arthritis (RA) clinical program,[1–6] but its real-world effectiveness remains to be investigated. The UPwArds study will assess the association of C-reactive protein (CRP) level with remission and other efficacy outcomes in patients with RA treated with UPA in German real-world practice.
Objectives: To describe the baseline characteristics of patients enrolled in the UPwArds study.
Methods: The prospective, open-label, multicenter, non-interventional, post-marketing UPwArds study included adult patients with moderate-to-severe RA (swollen joint count [SJC28] ≥3 and inadequate response or intolerance to ≥1 disease-modifying antirheumatic drug [DMARD]). Patients were treated with UPA 15 mg once daily, as monotherapy or in combination with methotrexate (MTX; 50:50 mono:combo enrollment planned), according to the German label. Variables assessed included medical history (disease duration, previous RA therapy, and vaccination status), CRP level, and disease activity (disease activity score [DAS28(CRP)], tender joint count [TJC28], and SJC28). There was no recruitment restriction regarding CRP level. This descriptive interim analysis reports patient baseline characteristics after enrollment was complete. All data were analyzed as observed, with no imputation of missing data.
Results: 533 patients (UPA monotherapy: 257 [48%]; UPA plus MTX: 276 [52%]) were included. Mean patient age was 58 years; mean disease duration was 9 years (Table 1). Despite having active RA, almost half the population (44%; n=237) did not have elevated CRP at the start of UPA treatment. Mean DAS28(CRP) was 4.6; mean TJC28 and SJC28 were 7.7 and 5.6, respectively. Overall, 39% of patients had not been treated with any biologic (b) DMARD or targeted synthetic (ts) DMARD before enrollment; 25% and 36% had previously been treated with 1 or ≥2 bDMARDs or tsDMARDs, respectively (Figure 1). 8.7% of patients had previously received a herpes zoster vaccination (8.1% Shingrix; 0.6% Zostavax).
Conclusion: In German clinical practice, the population of patients with RA in the UPwArds study was predominantly treatment-refractory. Half of these patients had no elevated CRP despite active disease; future analyses will assess the impact of CRP on efficacy outcomes.

AB0256 BARICITINIB (BARI) VERSUS BIOLOGICS IMPACT ON STEROID TAPERING IN RHEUMATOID ARTHRITIS (RA)

L. Cometi[1], C. Bruni[1], L. Tofani[1], G. Tesei[1,2], F. Nacci[1], G. Fiori[1], F. Bartoli[1], M. Matucci-Cerinic[1]. [1]*Careggi University Hospital, Experimental and Clinical Medicine, Division of Rheumatology, Firenze, Italy*; [2]*Ospedale "Infermi" di Rimini, Medicina e Reumatologia, Rimini, Italy*

Background: Biologic and target synthetic disease modifying anti-rheumatic drugs (bDMARDs and tcDMARDs) are recommended to control RA disease activity, pain and steroid use. Following randomized clinical trials (RCTs) and their post-hoc analyses, the Janus Kinase Inhibitor tsDMARDs BARI was superior to reference bDMARD Adalimumab in reducing disease activity, pain and functional disability. In addition, BARI monotherapy also determined more significant pain reduction and functional improvement when compared to Tocilizumab monotherapy (3).

Objectives: to confirm RCT results in a real-life clinical setting, with focus on disease activity, pain, functional disability and steroid tapering, when comparing BARI to bDMARDs for the treatment of active RA.

Methods: RA patients starting BARI or a bDMARD for active RA were retrospectively evaluated from June 2019 to June 2020. Disease activity (DAS28CRP, SDAI, CDAI), pain visual analogic scale (pain_VAS), functional disability (HAQ) assessments and mean prednisone dosage (pred_dose) were collected at baseline (BL), 3 months (3M) and 6 months (6M) after BARI/bDMARD initiation. The changes of the outcome measures were evaluated between BL-3M, 3M-6M and BL-6M, as well as between BARI and bDMARDs groups. Finally, we assessed the variables associated with prednisone tapering in the whole population.

Results: 90 out of 100 RA patients evaluated (baseline: age 57±12 years, disease duration 131±100 months, DAS28PCR 4.8±1.0, pain_VAS 61±23 mm, prednisone dose 5.5±5.3 mg) were eligible for the study; 49 received BARI and 41 bDMARDs (17 abatacept, 12 TNF inhibitors, 11 tocilizumab, 1 rituximab). At BL, the two groups did not differ statistically in terms of age, sex, disease duration, disease activity, pain_VAS, previous bDMARD failure or ts/bDMARD naive, concomitant conventional synthetic DMARDs treatment, pred_dose. Both BARI and bDMARDs determined a significant reduction in activity scales and HAQ when comparing BL-3M and BL-6M, with only pain_VAS and pred_dose showing a significant decrease in the 3M-6M interval. When comparing the two groups, BARI showed a significantly higher reduction of pred_dose (-3.2±5.1 vs -1.7±3.7 mg at BL-3M, and -4.1±5.3 vs -1.9±4.6 mg at BL-6M), which was not significant after adjusting for BL pred_dose. No other difference was seen when the two groups, including the numerically higher reduction of pain_VAS in the BARI group (-29±28 vs -20±27 mm at BL-3M and -35±25 vs -30±28 mm at BL-6M comparison). The analysis of the predictors for steroid tapering (Δmean_pred) in the two intervals, showed that BL DAS28PCR, DAS28PCR BL-3M change and BL pred_dose were associated with BL-3M Δmean_pred, while 3M pain_VAS and 3M pred_dose were associated with 3M-6M Δmean_pred.

Conclusion: Although limited by the small samples and the retrospective nature, our real-life comparison shows similar efficacy of BARI and bDMARDs in terms of disease activity control, functional disability and pain. In addition, the treatment with BARI or bDMARD did not influence the steroid tapering, which was driven mostly by its initial dose, disease activity and pain. Larger real-life multi-center studies are warranted to confirm our results.

AB0257 IMPACT OF CONVENTIONAL ANTIRHEUMATIC TREATMENT ON CARDIOVASCULAR RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. Gerasimova[1], E. Gerasimova[2], T. Popkova[2], A. Melkumyan[1]. [1]*I.M. Sechenov First Moscow State Medical University (Sechenov University), Department of Organization and Economy of Pharmacy, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases Laboratory, Moscow, Russian Federation*

Background: Cardiovascular diseases (CVD) are the most common and socially significant comorbidities and the main cause of premature mortality in rheumatoid arthritis (RA). Appropriate RA therapy should not only suppress RA activity, but also reduce CVD risk.
Objectives: To evaluate CVD risk and analyze its association with the use of conventional therapy in RA patients (pts).
Methods: The study included 100 pts with RA (92 women and 8 men) aged 30 to 60 without established CVD. The median age was 49.5 [44.5;53] years, duration of RA was 144 [60;240] months, DAS28 was 4.4 [3.3;5.3] points. Eighty six RA pts (86%) treated with disease-modifying antirheumatic drugs (DMARDs) (methotrexate, n=55; leflunomide, n=12; hydroxychloroquine, n=8; sulfasalazine, n=11), including 33 pts (33%) in combination with glucocorticoids (GCs). Fourteen pts (14%) received monotherapy with GCs. Pts were divided into three treatment groups: DMARDs group, n=53; GCs group, n=14; DMARDs+GCs group, n=33. CVD risk was calculated with ASSIGN, QRISK3, and ERS-RA scales.
Results: No differences were found between the groups when calculating CVD risk using ASSIGN (table 1). Estimated CVD risk by QRISK3 was lower in DMARDs group (4.9 [3.0; 7.7]) than in DMARDs+GCs group (7.1 [4.1; 13.6], p<0.05). High CVD risk on the ERS-RA scale was determined less frequently (13%) and median CVD risk was lower in DMARDs group (4.2 [2.2; 5.4]) than in GCs group (57%; 8.9 [4.8; 11.7], p<0.01) and DMARDs+GCs group (39%; 6.6 [3; 9.3], p<0.05, respectively). In DMARDs group, significant differences in CVD risk by ERS-RA were found in pts treated with hydroxychloroquine (2 [1.4; 5.8]) and leflunomid (6.2 [2.8; 12.3], p<0.05).
Conclusion: RA pts treated with DMARDs have a reduced risk for CVD than pts treated with GCs or a combination of DMARDs and GCs. GCs significantly increase CVD risk. To clarify the impact of hydroxychloroquine and leflunomid on CVD risk, a study on a larger number of pts is required.

Table 1. The impact of conventional antirheumatic therapy on CVD risk.

Treatment	ASSIGN		QRISK3		ERS-RA	
	High CVD risk, %	median [25-75 percentiles]	High CVD risk,%	median [25-75 percentiles]	High CVD risk,%	median [25-75 percentiles]
DMARDs, n=53	6	11 [6.5;14]	2	4.9 [3;7.7] ˅	13*˅	4.2 [2.2;5.4] *˅
GCs, n=14	7	9.5 [7;13]	7	6.6 [4.4;15.8]	57*	8.9 [4.8;11.7] *
DMARDs+GCs, n=33	15	10 [5;13.5]	9	7.1 [4.1;13.6] ˅	39˅	6.6 [3;9.3] ˅

Note: * - p<0.01 between pts receiving DMARDs and GCs; ˅ - p<0.05 between pts receiving DMARDs and DMARDs+GCs.

AB0258 DMARD-TREATMENT OF UNDIFFERENTIATED ARTHRITIS INTENSIFIED DURING THE LAST DECENNIA, BUT DID NOT RESULT IN IMPROVED LONG TERM OUTCOMES

M. Verstappen[1], X. Matthijssen[1], A. Van der Helm - van Mil[1,2]. [1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [2]*Erasmus University Medical Center, Rheumatology, Rotterdam, Netherlands*

Background: EULAR guidelines stress timely initiation of DMARD-treatment in early arthritis patients also when classification criteria are not yet fulfilled. Consequently, undifferentiated arthritis (UA) patients may be increasingly treated with disease modifying antirheumatic drugs (DMARDs), despite inadequate placebo-controlled evidence for its effectivity. Implementation of this guideline also hampers future placebo-controlled trials in UA. However, historical data, with inclusion period as instrumental variable, can provide insight whether long term outcome is improved with increased DMARD-use, and thus serve to investigate if DMARD-treatment is effective in UA.
Objectives: With 25-years of observational data of newly referred UA-patients, we studied whether enhanced treatment strategies resulted in better long term outcomes for UA.
Methods: Between 1993 and 2019, 1132 consecutive UA-patients, not fulfilling the 1987/2010 criteria for RA or any other distinct diagnosis, were included in the Leiden Early Arthritis Cohort; patients were divided in 5 inclusion periods (1993-1998, 1999-2005, 2006-2010, 2011-2014, 2015-2019). Frequency of DMARD-initiation after diagnosis was compared. We studied the following outcomes: the course of disease activity scores (DAS28-CRP) and Health assessment questionnaires (HAQ), progression to RA after 1-year (according to the 1987 and/or 2010 criteria) and the frequency of prolonged DMARD-free status within 10-years of follow-up (this was defined as either spontaneous remission or sustained remission after discontinuation of DMARD-treatment).
Results: The current population of UA-patients, thus not fulfilling 1987 or 2010 criteria, had rather mild disease: the median SJC was 1, the median TJC 2, 95% was autoantibody-negative and the median HAQ was 0.6. These characteristics were similar in the different inclusion periods. Initiation of DMARD-treatment in UA increased over time: 18%, 35%, 38%, 43% up to 55% in respectively 1993-1998, 1999-2005, 2006-2010, 2011-2014 and 2015-2019, in which methotrexate became more common in the last decade. Frequency of progression to RA after 1-year did not decrease and was 14%, 21%, 26%, 19% and 28% in the respective inclusion periods. Long-term DAS28CRP-scores improved from 2011 onwards (range -0.18, -0.24; p<0.05). However HAQ-score over time did not improve compared to the 1993-1998 period (range -0.00, -0.08; p>0.05). Also the percentages of patients in DMARD-free status after 10-years of follow-up did not significantly improve over time: 57%, 58%, 59% (for 1993-1998, 1999-2005, 2006-2010 respectively, p=0.59).
Conclusion: Intensified DMARD-treatment of patients with UA did not result in improved outcomes. These data may indicate overtreatment of UA-patients. Yet, methods to stratify which UA-patients should be treated remains warranted.

AB0259 EVALUATION OF THE EFFECT OF FILGOTINIB ON THE PHARMACOKINETICS OF ROSUVASTATIN, ATORVASTATIN, AND PRAVASTATIN

K. Anderson[1], C. Nelson[1], Q. Gong[1], M. Alani[1], T. Tarnowski[1], A. A. Othman[1]. [1]*Gilead Sciences, Inc., Foster City, United States of America*

Background: Filgotinib is an orally administered small molecule that preferentially inhibits Janus kinase 1 and is approved for use in Europe and Japan in adult patients with rheumatoid arthritis (RA) who have had an inadequate response to conventional therapies. Patients with RA are at a higher risk of cardiovascular morbidity and mortality relative to the general population[1]. Thus, it is important to understand potential drug-drug interactions of filgotinib with lipid-lowering agents such as statins. Based on in vitro studies, filgotinib is not expected to significantly increase exposure of statins via inhibition of the organic anion transporting peptide (OATP) at clinically relevant exposures. Hence, in Phase 2 and Phase 3 clinical studies, statins were allowed for use with filgotinib. A post-hoc analysis showed no increase in statin-induced AEs such as muscle or liver toxicities when statins were coadministered with filgotinib ("Concomitant Use of Statins in Filgotinib-Treated Patients with Rheumatoid Arthritis: A Post Hoc Analysis," submitted to EULAR 2021).
Objectives: The objectives of this study (NCT04608344) were to evaluate the effect of filgotinib on the pharmacokinetics of atorvastatin, pravastatin, and rosuvastatin, which are sensitive substrates for the OATP-1B1/1B3, and the short-term safety of administering filgotinib with or without statins.
Methods: This was an open-label, randomized, two-way, crossover study in healthy adult volunteers (n = 27). Study participants received a single dose of atorvastatin (ATV 40 mg) and a single dose of a cocktail of pravastatin (PRA 40 mg)/rosuvastatin (ROS 10 mg), on two different occasions with washout in between, alone or in combination with filgotinib (200 mg QD for 11 days). Serial pharmacokinetic sampling was performed and pharmacokinetic parameters for each statin were calculated. Safety was assessed throughout the study. An analysis of variance using a mixed-effects model was applied to the natural logarithmic transformation of pharmacokinetic parameters (C_{max} and AUC_{inf}) for ATV, 2-OH-ATV (active metabolite of ATV), PRA, and ROS. Geometric-least squares means (GLSM) ratios and 90% confidence intervals (90% CI) of pharmacokinetic parameters were estimated for each analyte and were compared against pre-specified lack of pharmacokinetic alteration boundaries of 70 to 143%.
Results: Of the 27 enrolled participants, 25 participants completed all study treatments. Most AEs and laboratory abnormalities were Grade 1 or 2 in severity; 1 participant discontinued due to a Grade 3 increase in creatine kinase and 1 participant discontinued due to difficulty in blood draws. Following coadministration of filgotinib with ATV, relative to ATV alone, ATV AUC_{inf} was unaffected

(GLSM ratio (90% CI): 0.91 (0.84, 0.99)), but ATV C_{max} was slightly reduced (GLSM ratio (90% CI): 0.82 (0.69, 0.98)). 2-OH-ATV exposure (C_{max} and AUC_{inf}) were unaffected (GLSM ratio (90% CI): 0.98 (0.81, 1.18) for C_{max} and 1.12 (1.02, 1.22) for AUC_{inf}), and were within the pre-specified lack-of-effect bounds. Following coadministration with filgotinib, PRA AUC_{inf} was unaffected (GLSM ratio (90% CI): 1.22 (1.06, 1.42)), but PRA C_{max} was slightly higher (1.25 (1.01, 1.54)). ROS exposure (C_{max} and AUC_{inf}) were moderately higher upon coadministration with filgotinib (GLSM ratio (90% CI): 1.68 (1.43, 1.97) for C_{max} and 1.42 (1.30, 1.56) for AUC_{inf}), and these changes in rosuvastatin exposure are not considered to be clinically relevant.

Conclusion: All study treatments were generally well tolerated. Co-administration with filgotinib did not have a clinically meaningful impact on the exposure of ATV, PRA, and ROS. These data support concomitant use of filgotinib with OATP substrates such as statins.

AB0260 LONG-TERM EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS FROM CHINA, BRAZIL, AND SOUTH KOREA WITH RHEUMATOID ARTHRITIS AND AN INADEQUATE RESPONSE TO CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS: RESULTS AT 64 WEEKS

X. Zeng[1,2], D. Zhao[3], S. Radominski[4], M. Keiserman[5], C. K. Lee[6], N. Martin[7], S. Meerwein[8], Y. Sui[9], W. Park[10]. *[1]Peking Union Medical College Hospital (PUMCH), Chinese Academy of Medical Sciences, Beijing, China*; *[2]National Clinical Research Center for Dermatologic and Immunologic Diseases (NCRC-DID), Dermatology and Immunology, Beijing, China*; *[3]Shanghai Changhai Hospital, Rheumatology and Immunology, Shanghai, China*; *[4]Universidade Federal do Paraná, Rheumatology, Curitiba, Brazil*; *[5]Pontifical Catholic University, Rheumatology, Porto Alegre, Brazil*; *[6]Asan Medical Center, Rheumatology, Seoul, Korea, Rep. of (South Korea)*; *[7]AbbVie Inc, Immunology, Quebec, Canada*; *[8]AbbVie Deutschland GmbH & Co. KG, Immunology, Ludwigshafen, Germany*; *[9]AbbVie Inc, Immunology, North Chicago, Illinois, United States of America*; *[10]School of Medicine, Inha University, Rheumatology, Incheon, Korea, Rep. of (South Korea)*

Background: Upadacitinib (UPA), an oral Janus kinase inhibitor, in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), showed significant improvements in clinical and functional measures compared with placebo (PBO) up to 12 weeks (wks), in patients (pts) from China, Brazil, and South Korea with rheumatoid arthritis (RA) and prior inadequate response to csDMARDs (csDMARD-IR).[1]

Objectives: To assess the efficacy and safety of UPA up to 64 wks (long-term extension; LTE) in csDMARD-IR pts with RA from China, Brazil, and South Korea.

Methods: Pts were randomized to 12 wks of blinded treatment with UPA 15 mg once daily (QD) or PBO, in combination with csDMARDs. From Wk 12 onward, pts could continue to receive open-label UPA 15 mg QD. Efficacy endpoints were analyzed by original randomized treatment group sequences over 64 wks and included American College of Rheumatology (ACR) responses, and key remission and low disease activity measures. Non-responder imputation was used to handle missing data for binary endpoints. Treatment-emergent adverse events (TEAEs) per 100 patient-years (PY) were summarized for pts receiving ≥1 dose of UPA from baseline through to Wk 64.

Results: Of 338 randomized pts who received ≥1 dose of study drug, 310 (91.7%) entered the LTE and 275 (81.4%) completed 64 wks of treatment. Among those initially randomized to UPA, the proportion of pts achieving 20%/50%/70% improvement in ACR criteria, and key remission and low disease activity measures increased over 64 wks of treatment (Figure 1). Improvements from baseline in the Health Assessment Questionnaire-Disability Index and pts' assessment of pain were observed over 64 wks of UPA treatment (data not shown). By Wk 64, efficacy results for pts who switched from PBO to UPA at Wk 12 followed a similar trajectory to those originally randomized to UPA.

The observed rate of serious infections was 8.1 events/100 PY. Herpes zoster events were mostly non-serious, involving only 1 or 2 dermatomes. Most cases of hepatic disorders were Grade 1 or 2 hepatic transaminase elevations. There was 1 case of venous thromboembolic event (VTE; concurrent pulmonary embolism and deep vein thrombosis [DVT] in a patient with a history of DVT) and 3 cases of malignancy. Adjudicated major adverse cardiovascular events (Table 1) occurred in 2 pts (1 with non-fatal myocardial infarction and 1 with non-fatal stroke) who had underlying risk factors for cardiovascular disease. There were no deaths, active tuberculosis, or renal dysfunction.

Conclusion: UPA 15 mg was effective in treating the signs and symptoms of RA and in improving physical function over 64 wks with no new safety signals[1] in csDMARD-IR pts with RA from China, Brazil, and South Korea.

AB0261 A MULTINATIONAL, PROSPECTIVE, OBSERVATIONAL STUDY IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING BARICITINIB, TARGETED SYNTHETIC OR BIOLOGIC DISEASE-MODIFYING THERAPIES (RA-BE-REAL) – STUDY DESIGN AND BASELINE CHARACTERISTICS

R. Alten[1], G. R. Burmester[2], M. Matucci-Cerinic[3], J. H. Salmon[4], P. López-Romero[5], W. Fakhouri[5], I. De La Torre[5], A. Gentzel-Jorczyk[5], T. Holzkaemper[5], B. Fautrel[6,7]. [1]*University Medicine Berlin, Department of Internal Medicine and Rheumatology, Berlin, Germany*; [2]*Charité Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; [3]*University of Florence, Division of Rheumatology, Florence, Italy*; [4]*CHU de Reims, Traumatologie-Orthopédie, Reims, France*; [5]*Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America*; [6]*Sorbonne University, Department of Rheumatology, Paris, France*; [7]*Pierre Louis Institute of Epidemiology and Public Health, PEPITES Team, Paris, France*

Background: Baricitinib (BARI) is a JAK1-2 inhibitor approved for the treatment of adults with moderately to severely active rheumatoid arthritis (RA). RA-BE-REAL is a 3-year, prospective, observational study of adult RA patients (pts) evaluating adherence to treatment in clinical practice.
Objectives: To describe pt and disease characteristics of pts enrolling into RA-BE-REAL in 5 European countries.
Methods: The primary endpoint of RA-BE-REAL is time until discontinuation of initial treatment for all causes (excluding sustained clinical response) over a 24-month (M) period. Secondary endpoints include clinical and pt reported outcomes, healthcare resource utilization and treatment patterns over a 36M period. Two pt cohorts are assessed: cohort A, started treatment with BARI (2-mg or 4-mg), and cohort B, any other targeted synthetic (ts)DMARDs or biologic (b) DMARD (Fig. 1). Treatment initiation and changes are at the discretion of the pt and physician. Data is collected at baseline and at routine visits (~3M, 6M, 12M, 18M, 24M and 36M). Summaries are presented with t-test and chi-square test of independence.
Results: Between October 2018 and March 2020, 1074 adult RA pts were enrolled from France, Germany, Italy, Spain, and UK. In cohort A, 88.2% of pts are treated with BARI 4-mg. At time of enrolment pts in cohort A are more likely to commence treatment as a monotherapy as compared to pts in cohort B who are more likely to commence treatment in combination with csDMARDs (p<0.001). Cohort A are more likely to be older (59.2 vs 57.0, mean years p=0.009) and have higher Health Assessment Questionnaire-Disability Index (HAQ-DI) scores (1.4 vs 1.3, p=0.03). A greater percentage of cohort A pts have received prior treatment with either 1 b/tsDMARD (15.3 vs 11.0%), 2 b/tsDMARD (20.2 vs 14.7%) or >2 b/tsDMARD (15.9 vs 12.9%), while cohort B are more likely to be treatment naïve (61.4 vs 48.5%). There are no significant differences in other baseline characteristics shown in Table 1.
Conclusion: There are few but potentially clinically important differences between cohorts. Pts in cohort A are more likely to be older, have a longer disease duration, have received prior b/tsDMARD treatment, and are more likely to receive treatment as a monotherapy as compared to pts in cohort B.

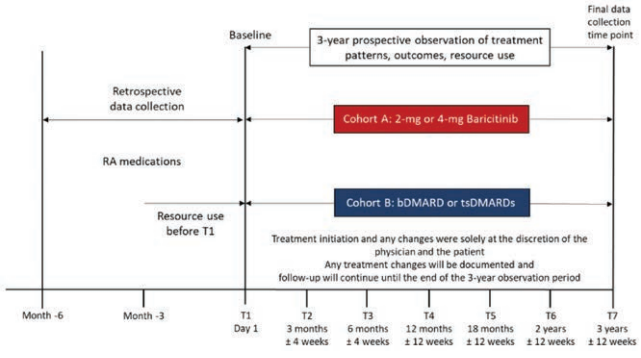

Figure 1. Study Design. Participants entered cohort A or B based on their treatment decision for BARI or another b/tsDMARD, pts in each cohort were with/without concomitant csDMARDs.

Table 1. Patient disposition and baseline characteristics.

	Cohort A Baricitinib (n=509)	Cohort B			Overall (n=1074)

AB0262 CLINICAL EFFICACY OF SWITCHING FROM ORAL TO SUBCUTANEOUS METHOTREXATE IN MANAGEMENT OF RHEUMATOID ARTHRITIS: EXPERIENCE FROM OUT-PATIENT SETTING OF A DISTRICT GENERAL HOSPITAL IN UK

G. Ansari[1], A. Nandagudi[1], A. Bharadwaj[1]. [1]*Basildon Hospital Mid and South Essex NHS Foundation Trust UK, Rheumatology, Essex, United Kingdom*

Background: Methotrexate (MTX) is an anchor drug in the treatment of Rheumatoid arthritis. The literature review has shown that subcutaneous (SC) methotrexate has shown better efficacy, less adverse side effects and better compliance in inflammatory arthritis. Our department modified Inflammatory arthritis pathway in 2018 where all patient with moderate or severe disease are switched from oral to SC Methotrexate injection for improved management.
Objectives: The aim of our study is to review whether switching of oral methotrexate (PO MTX) to subcutaneous methotrexate (SC MTX) helps to improve disease activity in patients with rheumatoid arthritis and avoids the need to introduce biologic therapy.
Methods: We conducted a retrospective audit of patients with rheumatoid arthritis seen between January 2018 to January 2020 recording their age, gender, diagnosis, date of MTX switch and disease activity score 6 months after switching to SC MTX. Significance of change was calculated with test of proportion/chi square test.

Results: Fifty patients were reviewed, thirty eight (76%) were female and twelve (24%) were male with age ranging between 34 - 86 years (median 61.5 years). Switching to MTX injection was done within 2 yrs of diagnosis in 21 (42%) patients, between 2-5 yrs of diagnosis in 11 (22%) patients and more than 5 yrs after diagnosis in 18 (36%) patients. The main reasons of switching were either maximum MTX dose (25mg) or intolerance to oral MTX at any dose.

After switching methotrexate, review at 6 months showed 26 patients (52%) in remission (compared to 6 at baseline) and 3 (6%) patients avoided the need to go on biologic therapy. Five patient commenced on biologic therapy between 3 and 6 months.

Table 1. Disease activity compared at Baseline and at 6 months

Disease Activity	Baseline	At 6 months
Remission <2.6	6	26 (p<0.0001)
Mild (26-3.19)	11	10
Mod (3.2 - 5.09)	25	9 (p<0.01)
Severe (>5.1)	8	5

Conclusion: Switching to SC Methotrexate even in patients with long duration of disease results in significant number of patients achieving remission or lower disease activity (P<0.001). This may obviate the need of biologics therapy

AB0263 THE LEVEL OF 7-HYDROXY METHOTREXATE IN BLOOD CELLS IN PATIENTS WITH RHEUMATOID ARTHRITIS DIRECTLY CORRELATES WITH THE LEVEL OF POLYGLUTAMATES OF METHOTREXATE

G. Gridneva[1], E. Samarkina[1], S. Glukhova[1], Y. Muraviev[1], A. Kudryavtseva[1], E. Aronova[1], N. Baymeeva[2], V. Sygyrta[1]. [1]*V.A.Nasonova Rheumatology Research Institute, Laboratory for the Study of Comorbid Infections and Monitoring the Safety of Drug Therapy, Moscow, Russian Federation*; [2]*Mental Health Center, Pharmacokinetics Laboratory, Moscow, Russian Federation*

Background: 7-hydroxy Methotrexate (7-hydroxy-MTX) is a phase I metabolite of MTX, which is converted by hepatic aldehyde oxidases. It is known that 7-hydroxy MTX can reduce the effectiveness of methotrexate, which is associated with increased excretion of methotrexate due to a decrease in polyglutamation and binding to enzymes [1].

Objectives: To analyze the level of 7-hydroxy-MTX in peripheral blood cells in order to study the correlation of the level of this metabolite with the level of polyglutamates of methotrexate (MTXPGs).

Methods: The prospective study included 65 patients aged 53±11 years, 50 women, 13 men, diagnosed with RA, according to the ACR/EULAR 2020 criteria, methotrexate (MTX) naiive. The duration of the disease was 7,5[4;24] months. All patients were administrated MTX subcutaneously at a dose of 10-15 mg/m2. The visits were carried out at weeks 0, 4, 12, 24 and 36, at all visits samples were taken for the content of MTXPGs with 1,2,3 and 4 glutamate residues and 7-hydroxy MTX separately in red blood cells mass (RBC) and mononuclear cells (MO). The mononuclear fraction was isolated by layering on verografin-ficoll. All patients received folic acid at a standard dose of 5 mg 24 hours after parenteral MTX administration. Samples were collected no earlier than 36 hours after MTX administration. All patients had normal renal function. Disease activity was assessed using the DAS28 index calculated by C-reactive protein.

Results: The average concentration of 7-hydroxy MTX is shown in Table 1.

Table 1. Level of 7-hydroxy MTX in erythrocytes and mononuclear cells, nmol/L, Median [25; 75 quartiles]

7-hydroxy MTX level in:	4 weeks	12 weeks	24 weeks	36 weeks
RBC	18,5[3,1;61,5]	10,2[3,6;50,8]	10,3[1,7;36,8]	7,2[0,1;25,3]
MO	0,8[0,1;15,2]	4,0[0,1;42,2]	3,5[0,1;8,1]	0,4[0,1;8,9]

The level of 7-hydroxy-MTX directly correlated with the level of MTXPGs 1-4, and summary MTXPG in both RBC and MO. Analysis of pairwise correlations according to Pearson showed that: after 4, 12 and 36 weeks, the level of 7-hydroxy-MTX did not correlate with the value of DAS28. After 24 weeks of therapy, the level of 7-hydroxy-MTX in RBC was inversely correlated with DAS28 of the disease (p=0.043).

Conclusion: The preliminary results indicate a positive correlation between the level of 7-hydroxy-MTX and MTXPGs in RBC and MO. In this regard, the concentration of 7-hydroxy-MTX can be used as a prognostic marker for MTX therapy in the absence of opportunities in clinical centers to measure the entire line of MTXPGs in RBC and MO. Since the data obtained are somewhat at odds with the few literary sources, it is necessary to conduct further research on this fact.

AB0264 1-YEAR RESULTS OF A NON-INVASIVE AURICULAR VAGUS NERVE STIMULATION DEVICE IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Marsal[1], H. Corominas[2], J. J. De Agustin[1], C. Perez-Garcia[3], M. Lopez Lasanta[1], H. Borrell Paños[1], D. Reina-Sanz[4], R. Sanmartí[5], J. Narváez[6], C. Franco-Jarava[7], C. Peterfy[8], J. A. Narvaez[9], V. Sharma[10], K. Alataris[11], M. C. Genovese[12], M. Baker[13]. [1]*Hospital Universitari Vall d'Hebron, Rheumatology, Barcelona, Spain*; [2]*Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; [3]*Hospital Universitari Parc Salut Mar, Rheumatology, Barcelona, Spain*; [4]*Hospital Moisès Broggi, Rheumatology, Barcelona, Spain*; [5]*Hospital Clinic de Barcelona, Rheumatology, Barcelona, Spain*; [6]*Hospital Universitari de Bellvitge, Rheumatology, Barcelona, Spain*; [7]*Hospital Universitari Vall d'Hebron, Immunology, Barcelona, Spain*; [8]*Spire Sciences, NA, Boca Raton, United States of America*; [9]*Clinica Diagonal, Imaging, Barcelona, Spain*; [10]*Nēsos Corp, R&D, Redwood City, United States of America*; [11]*Nēsos Corp, NA, Redwood City, United States of America*; [12]*Gilead Sciences, Clinical Development, Inflammation, Foster City, United States of America*; [13]*Stanford University, Division of Immunology and Rheumatology, Stanford, United States of America*

Background: Despite the clinical benefits of current pharmacological treatments for rheumatoid arthritis (RA), there remains an unmet need for alternative treatment approaches. Initial results of a 12-week proof-of-concept study of non-invasive, vagus nerve stimulation (VNS) of the auricular branch of the vagus nerve from a wearable device to treat RA showed the device to be well-tolerated with significant reductions in the DAS28-CRP and RA disease severity[1].

Objectives: This analysis presents data from the 9-month extension of the original proof-of-concept study.

Methods: Following the completion of the 12-week proof-of-concept study, responding patients (defined as achieving a reduction in DAS28-CRP of ≥1.2 from baseline and/or achievement of ACR20) were given the option to enroll in a 9-month extension study. Use of the wearable device continued daily for up to 30 minutes as in the first 12 weeks of the study. Alteration of baseline medication and addition of conventional synthetic disease-modifying antirheumatic drugs (DMARDs) and biologic DMARDs were allowed during the extension phase.

Results: 20/27 patients who completed the initial 12-week study met the enrollment criteria for the extension phase; 19 of those patients consented to participate. 4/19 patients (21%) discontinued the extension study due to lack of efficacy (1 patient after 1 month, 2 patients after 3 months, and 1 patient after 6 months in the extension); 15 patients completed the extension phase. 2/15 patients (13%) added biologic therapy to their treatment regimen. Mean DAS28-CRP reduction from baseline to the end of the extension (12 months total) in all patients completing the extension was 2.23 (95% CI: -1.60, -2.86). For patients who did and did not add biologic therapy, mean DAS28-CRP reduction was 2.98 and 2.11, respectively. Individual DAS28-CRP reductions are shown in the figure 1. Mean HAQ-DI reduction from baseline to the end of the extension in all patients was 0.70. 2 non-device related adverse events were reported in the study extension: one related to cornea transplant and one related to dysesthesia. No serious adverse events were reported during the study extension phase.

Conclusion: Benefits from the use of the wearable device were maintained over longer periods of time from the initial 12-week proof-of-concept study, with few safety concerns as no additional side effects were observed.

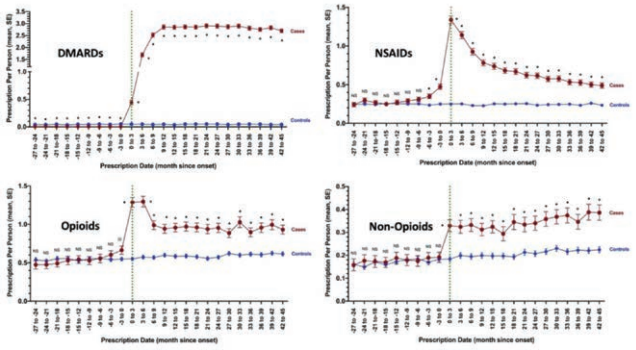
AB0265 OPIOIDS AND ANALGESIC USE IN EARLY RHEUMATOID ARTHRITIS: A LONGITUDINAL ANALYSIS OF LINKED REAL-WORLD PRESCRIPTION DATA

M. H. Derakhshan[1], F. Morton[1], G. E. Fragoulis[2], C. Paterson[1], J. Dale[3], N. Basu[1], I. Mcinnes[1], D. Porter[4], S. Siebert[1]on behalf of Scottish Early Rheumatoid Arthritis (SERA) Investigators. *[1]University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom*; *[2]University of Athens, Laiko General Hospital, Athens, Greece*; *[3]NHS Lanarkshire, University Hospital Hairmyres, Glasgow, United Kingdom*; *[4]NHS Greater Glasgow and Clyde, Gartnavel General Hospital, Glasgow, United Kingdom*

Background: Large numbers of patients with rheumatoid arthritis (RA) receive regular opioids despite significant toxicity and a lack of evidence supporting their use in non-cancer pain. In order to address this situation, we need to understand when opioids are started in early RA where this has not been studied.
Objectives: To examine the temporal trend of opioid prescriptions before and after RA symptom onset and to compare this with DMARD and NSAID prescriptions.
Methods: RA participants (cases) were recruited as part of the Scottish Early Rheumatoid Arthritis (SERA) inception cohort[1]. Controls without RA (five per case), matched for sex, age and post code over the same time period, were obtained through routine data linkage. Prescription data between Jan 2009 to Nov 2019 of cases and matched controls were compared using date of RA symptom onset as reference point. The Prescriptions Per Participant (PPP) for each three-month block was estimated by dividing the number of prescribed drugs in the selected drug classes (assigned using the British National Formulary) in that time block by the number of participants in each group. The differences between mean PPP of the RA cases and controls in each time block were tested by t-test for independent groups and subsequent adjustment for multiple testing.
Results: 1,720,335 prescriptions were available for analysis with 421,961 items for 950 RA cases and 1,299,374 items for 4,558 matched controls. As expected, DMARD prescriptions in the SERA cases increased after the symptom onset period and were then sustained (Figure 1: top left panel). NSAID prescriptions in RA cases peaked during the 3 months after symptom onset and then reduced progressively (top right panel). Opioid analgesic prescriptions for the RA cases increased two-fold during the reference period and then reduced 6-9 months post-symptom onset. However, unlike NSAIDs, after this there was no further significant reduction in opioid prescriptions in the RA cases, which remained stable and significantly higher than in the controls for the remaining study period. The non-opioid analgesic mean PPP increased sharply at the time of symptom onset, with a steady gradual upward trend over time (lower right panel).



Conclusion: Opioid prescriptions increase significantly at the time of RA symptoms onset. Despite rapid introduction of DMARDs and resultant reductions in NSAIDs, analgesic use remains significantly higher than in controls. Further research is required to identify the factors associated with persistent opioid use in early RA with interventions aimed at the first 6 months.

AB0266 METHOTREXATE AND CARDIOVASCULAR RISK IN RHEUMATIC DISEASES:A COMPREHENSIVE REVIEW

F. Verhoeven[1,2], C. Prati[1,2], M. Chouk[1], C. Demougeot[2], D. Wendling[1,3]. *[1]CHRU Besancon, Rheumatology, Besançon, France*; *[2]Université de Bourgogne - Franche Comté, EA 4267 PEPITE, Besançon, France*; *[3]Université de Bourgogne - Franche Comté, EA 4266 EPILAB, Besançon, France*

Background: The management of inflammatory rheumatic disease has evolved in the last decade with the importance of the management of comorbidities. Methotrexate is the cornerstone of inflammatory rheumatic disease management, but its cardiovascular effects are still poorly understood
Objectives: To assess the cardiovascular impact of methotrexate in inflammatory rheumatic disease.
Methods: A systematic review of the literature, following the prisma recommandations, was performed on the PubMed and Embase databases with the following keywords: ("Methotrexate") AND ("cardiovascular"). We included papers written in English and including patients older than 18 years.
Results: 570 references were identified and, 36 articles were kept for analysis.
The mechanism of action of methotrexate lies mainly on the antagonism of purines. It reduces systemic inflammation, oxidative stress.
In Rheumatoid arthritis, the use of methotrexate was associated with a decreased incidence of high blood pressure, an improvement of the lipid profile and of the insulin resistance. Major adverse cardiovascular events were decreased with methotrexate. The effects of methotrexate on the endothelial

function were more controversial and available data did not argue for a direct vascular effect of MTX in RA.
In psoriatic arthritis, evidences were more scarce. A meta-analysis showed that methotrexate was associated with a reduction of cardiovascular events in patients with psoriatic arthtritis. In psoriatic arthritis, methotrexate did not improve the endothelial function.
In plaque psoriasis, available data were rare. The use of methotrexate in this condition was not associated with a reduction of cardiovascular events. Nevertheless, a decrease in circulating VCAM-1 and in E selectin levels was described with the use of methotrexate.
In HIV infection, a model of pro inflammatory state, the use of methotrexate did not change the endothelial function and thus the cardiovascular events.
Finally, in general population, the use of methotrexate did not decrease the occurrence of cardiovascular events after a myocardial infarction.
Conclusion: The cardiovascular effects of methotrexate are poorly understood at this time. Nevertheless, it seems clear that methotrexate can reduce the occurrence of cardiovascular events in inflammatory disease. The mechanisms explaining this good issue are poorly understood, but it seems possible that the essential effect of methotrexate lies in the reduction of the inflammatory syndrome without a direct vascular impact.

AB0267 HOW EFFECTIVE IS PAIN MANAGEMENT IN THE PATIENTS' OPINION? DATA FROM THE COMPAS STUDY

E. Pogozheva[1], A. Karateev[1], V. Amirdzhanova[1]. [1]*V.A. Nasonova Research Institute, Pain Management, Moscow, Russian Federation*

Objectives: to evaluate the effectiveness and satisfaction of pain management in patients with rheumatic diseases (RD) according to a survey in the COMPAS (Quality of Pain Management according to Patients with Arthritis and Back pain) study.
Methods: the survey involved 1040 patients with RD (rheumatoid arthritis-40.6%, osteoarthritis -32.1%, spondyloarthritis-10.6%, connective tissue diseases-8.6% of patients). 76.8% were women, the mean age was 55.8±14.0 years. 35.7% of patients continued to work in their specialty, 31.6% had various degrees of disability. The effectiveness of pain therapy was evaluated by the patient in the last month preceding the survey on a 5-point scale, where 1 - no effect and 5-excellent effect. Patients ' satisfaction with treatment, possible reasons for the lack of effectiveness of pain therapy and the use of additional treatment tools were also evaluated.
Results: as therapy for the underlying disease, 40% of patients received conventional disease modifying antirheumatic drugs, 33.1% - glucocorticoids, 7.2% - biological agents and 15.2% - symptomatic slow-acting drugs in osteoarthritis. At the same time, 68% of patients needed additional analgesic therapy with nonsteroidal anti-inflammatory drugs (NSAIDs). Slightly less than half of the surveyed patients (46.9%) noted a moderate effect of analgesic therapy, 22.7% - a low effect and 5% - no effect, 23.7% rated the effectiveness of therapy as good and only 1.7% - as excellent. At the same time, only 15.6% of patients were completely satisfied with the result of NSAIDs, 64% were partially satisfied with the treatment and 20.4% were completely dissatisfied. As the reason of insufficient effectiveness of NSAIDs, most often (34.3%) patients named fear of adverse events associated with taking drugs, 19.4% - weak drugs, 15.3% - insufficient attention of doctors to complaints, 6.6% - poor diagnosis of the causes of pain. Others found it difficult to answer or were completely satisfied with the treatment. 40% of patients used additional methods, most often chiropractic (12.3%), acupuncture (4.8%), physiotherapy (12.7%) and folk remedies (7.4%).
Conclusion: A significant proportion of patients with RD don't have adequate pain control. Only 25.4% of patients rate the result of treatment as good and excellent, and even fewer patients (15.6%) are completely satisfied with the results of therapy. Thus, a personalized approach to analgesic therapy is necessary, taking into account the expectations of patients regarding the results of treatment.

AB0268 LOW DOSE TACROLIMUS IS AN EFFECTIVE ADD ON THERAPY FOR PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS – A SINGLE CENTRE EXPERIENCE

N. Prabu[1], V. Petciappan[2], G. Anand[1], T. A[3], A. Nijish[3]. [1]*Sakthi Rheumatology Centre Pvt. Ltd, Rheumatology, Coimbatore, India*; [2]*PSG Institute of Medical Sciences & Research, General Medicine, Coimbatore, India*; [3]*PSG College of Pharmacy, Pharmacy Practice, Coimbatore, India*

Background: Rheumatoid arthritis (RA) a chronic inflammatory arthritis requiring tight control of disease activity. While traditional DMARDS have been used effectively, there always remains a need for add on drugs in good number of patients. Tacrolimus since its first approval in 2004 had been used widely as monotherapy and in combination with conventional and biological DMARDS. The primary concern was safety followed by the efficacy for patients with active disease.
Objectives: The main objective was to ascertain the safety and tolerability of patients who were treated with tacrolimus as an add on therapy over and above the standard care in RA.
Methods: A retrospective analysis of patients who were prescribed Tacrolimus from January 2019 to August 2020 was done. Details of patients along with the change in Blood pressure(BP), Serum creatinine, Blood sugar and Clinical disease activity index(CDAI) before and after tacrolimus were analyzed.
Results: A total of 245 patients with active Rheumatoid arthritis received the drug. The mean age was 48.58(1.49) years and the disease duration was 5.9(0.56) years. Of 245 patients, 24 patients were lost to follow up,103 patients stopped the drug for various reasons and 118 patients are still continuing the drug. The mean tacrolimus dose was 1.24 + 0.46 mg in the patients who are continuing. The commonest reason for stopping the drug was adverse events (57%) followed by lack of efficacy(29%), low disease activity (8%)and others(7%). There was no significant change in the mean blood pressure, Blood sugars and Creatinine levels in both the stopped and continuing group. However the CDAI and the steroid dosages reduced significantly in the patients who are still on tacrolimus.The lost to follow up group had high disease activity at baseline and also were on higher doses of steroids.

PARAMETERS	RA – CONTINUING(118)			RA STOPPED(103)			LOST TO FOLLOWUP (24)
	BEFORE TAC	AFTER TAC	p value	BEFORE TAC	AFTER TAC	P value	BEFORE TAC
SBP mm of hg	100.44(9.54)	101.06(9.80)	0.67	103(9.77)	104(9.92)	0.44	127.35(10.05)
DBP mm of hg	66.30(6.26)	67.22(6.37)	0.30	68.44(6.4)	70.43(6.65)	0.07	82.83(5.05)
SUGAR mg	76.43(13.73)	76.67(11.24)	0.95	71.86(10.79)	76.74(14.1)	0.08	89.12(9.7)
S.CR mg	0.55(0.06)	0.56(0.09)	0.80	0.66(0.16)	0.57(0.06)	0.21	0.74(0.06)
STEROID USE mg	2.82(0.41)	1.65(0.54)	**<0.001**	2.12(0.43)	2.43(0.54)	0.36	2.86(1.42)
CDAI	12.28(1.84)	7.42(1.49)	**<0.001**	12.23(2.03)	10.49(2.69)	0.07	16.62(3.88)

Conclusion: Low dose Tacrolimus is an effective add on therapy for patients with high disease activity and did not lead to change in serum creatinine, blood pressure or change in blood sugars in the study subjects.

AB0269 ARE INTERFERON-GAMMA RELEASE ASSAYS RELIABLE TO DETECT TUBERCULOSIS INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH JANUS KINASE INHIBITORS?

C. Castellani[1], E. Molteni[1], A. Altobelli[1], C. Garufi[1], S. Mancuso[1], F. R. Spinelli[1], F. Ceccarelli[1], F. Conti[1], R. Scrivo[1]. [1]*Sapienza University of Rome, UOC Reumatologia - Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Roma, Italy*

Background: The therapeutic armamentarium for patients with rheumatoid arthritis (RA) has recently been enriched with the family of Janus kinase (JAK) inhibitors. Because the risk of reactivation of latent tuberculosis infection (LTBI) following the use of these drugs seems to be similar to that seen with anti-TNF agents, screening for LTBI is recommended in patients with RA before starting

treatment with JAK inhibitors. Interferon(IFN)-gamma release assays (IGRAs) are increasingly used for this purpose. However, JAK inhibitors tend to decrease the levels of IFNs, questioning the reliability of IGRAs during treatment with this novel class of drugs.

Objectives: To compare the performance of the QuantiFERON-TB Gold Plus (QFT-Plus) test with that of QuantiFERON-TB Gold In-tube (QFT-GIT) assay in RA patients before and during treatment with JAK inhibitors.

Methods: A longitudinal, prospective study has been performed in RA patients (ACR/EULAR 2010 criteria) candidates for tofacitinib or baricitinib treatment. All patients underwent QFT-Plus and QFT-GIT at baseline (T0), and after 3 (T3) and 9/12 months (T9/12) of treatment with JAK inhibitors. The agreement of the two tests was calculated at all timepoints. The agreement between IGRAs and tuberculin skin test (TST) or chest radiography at baseline was also determined. Lastly, the variability of QTF-Plus results was assessed during follow-up.

Results: Twenty-nine RA patients (F/M 23/6; median age/IQR 63/15.5 years; median disease duration/IQR 174/216 months) were enrolled: among them, 22 were to start baricitinib (75.9%) and 7 tofacitinib (24.1%). A perfect agreement was found between QFT-Plus and QFT-GIT at all times of observation (κ=1). At baseline, no agreement was recorded between IGRAs and TST (κ=-0.08) and between TST and chest radiography (κ=-0.07), while a low agreement was found between QFT-Plus and chest radiography (κ=0.17). A variation of 33.3% in the results of the QFT-Plus test was recorded at T3 compared to T0, of 29.4% at T9/12 compared to T0, and of 11.8% at T9/12 compared to T3. The median levels of IFN-γ produced by lymphocytes in response to the mitogen of QFT-Plus decreased after 3 months of treatment (1.59/4.72 IU/ml vs 3.08/7.68 IU/ml at baseline), followed by an increase after 9/12 months (2.25/4.61 IU/ml), but these differences were not significant. No significant change in the median number of circulating lymphocytes such as to explain the variation of the QFT-Plus results after 3 months of JAK inhibitor therapy was documented (1815/690/mm^3 vs 2140/750/mm^3 at baseline). At baseline, both QFT-Plus and QFT-GIT showed positive results in 5 patients (17.2%), negative in 19 (65.5%), and indeterminate in 5 (17.2%). Glucocorticoids intake was associated with a higher probability of negative or indeterminate result of IGRAs at baseline (p<0.0001).

Conclusion: Our data show that a response to IGRAs is detectable in the course of treatment with JAK inhibitors. However, similarly to what has been observed during treatment with TNF antagonists, the results of QFT-GIT and QFT-Plus show some variability when longitudinally repeated. These fluctuations occur in the absence of correlation with clinical outcome, thus challenging their interpretation. Since we do not have a sufficiently sensitive test capable of detecting TB infection, an integrated evaluation of risk factors, clinical manifestations and multiple diagnostic tests should be considered for a proper evaluation of the risk of TB infection in immunosuppressed patients.

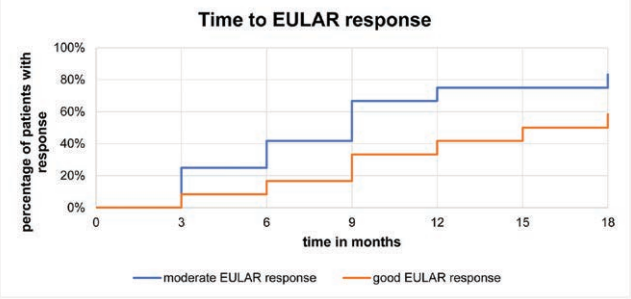
Background: Janus Kinase Inhibitors (JAKi) have recently been approved for the treatment of rheumatoid arthritis (RA) over the last years. JAKi differ in their specificity for the different JAK family members (JAK1, JAK2, JAK3 and TYK2). All three JAKis that are currently approved in Switzerland seem to have comparable efficacy on different disease stages of RA. Whether a JAKi can be effective after discontinuation of another JAKi is one of the open questions of interest according to the EULAR RA guidelines [1].

Objectives: To study the effectiveness of baricitinib in patients with RA after discontinuation of tofacitinib.

Methods: Longitudinal, retrospective chart review conducted between October 2019 and December 2020 of patients with RA at two Swiss centers (Kantonsspital Aarau and Inselspital Bern). Disease activity was assessed by DAS 28.

Results: 12 patients (1 male, 11 female) were treated with 4mg baricitinib/d after tofacitinib was discontinued. Mean age of the patients was 61 years, disease duration 140 months. Patients were previously treated with at least two conventional synthetic DMARDs and 75% with at least one biological DMARD. 58% of patients were positive for ACPA, 42% for rheumatoid factor. 50% of the patients suffered from erosive disease. Tofacitinib was stopped in 92% of the patients because of an insufficient response after a mean of 25.8 months. Moderate EULAR response was achieved in 83.3% of the patients after an average of 8 months treatment with baricitinib, and good EULAR response in 58.3% after an average of 10 months. There were no serious adverse events, neoplasms, opportunistic or serious infections during follow-up.



Conclusion: The first retrospective analysis of real-world data of baricitinib following tofacitinib shows that there is a good clinical response in 70% of cases. Although limited by the number of patients this study therefore supports the notion that baricitinib after discontinuation of tofacitinib in RA patients may be an effective therapeutic option.

COMPARISON OF DOSE REDUCTION METHODS BETWEEN RAPIDLY AND GRADUALLY DE-ESCALATION IN RHEUMATOID ARTHRITIS TREATED WITH BARICITINIB OVER 15 MONTHS

M. Yamasaki[1]. [1]*Shin-Yokohama Arthritis and Rheumatology Clinic, Rheumatology, Yokohama, Japan*

Background: However tsDMARDs and treatment strategies have improved the outcomes of rheumatoid arthritis (RA), it is unknown who can taper or stop tsDMARDs and strategies for de-escalation.
Objectives: We analyze predictors of de-escalation in RA patients treated with baricitinib over 15 months in each group who start baricitinib with 4mg/day and 2mg/day.
This study will assess and compare (1) characteristic of patients who achieve remission (REM) or low disease activity (LDA) as who can taper baricitinib and (2) two de-escalation methods, rapidly and gradually de-escalation in patients who respond first-line therapy.
Methods: Cases were recruited to SHin-yokohama Arthritis REgister (SHARE) between 2015 and 2020 (n=3,961). Patients were diagnosed according to ACR/EULAR 2010 classification criteria and treated with baricitinib started with 4mg/day(n=42) or 2mg/day(n=108) over 15 months. 45 cases fulfilled EULAR definition for difficult-to-treat RA (D2T-RA). In 150 (Male25, Female125 cases, RA duration 12.5+/-5.9years) cases, Clinical Disease Activity Index (CDAI), Health Assessment Questionnaire-Disability Index (HAQ-DI), anti-CCP2 and clinical parameters were analyzed. Two de-escalation methods were compared in this study. In rapidly de-escalation methods, baricitinib were stopped in patients with stable REM/LDA with no swollen joint over 12 weeks. In gradually de-escalation methods, baricitinib were decreased to 50%, 42%, 28%, 14% in order with stable REM/LDA with no swollen joint over 12 weeks.
Results: (1)" Detect predictors who can achieve REM/LDA with no swollen joint as starting de-escalation baricitinib" In patients started with baricitinib 4mg/day group, 17 patients achieved REM/LDA with no swollen joint(40.5%), there were no differences in duration of RA, onset age of RA, biologics and/or JAK inhibitors naïve, anti-CCP2 titer and CDAI at the start baricitinib between REM/LDA and non-achieved cases. In patients started with baricitinib 2mg/day group, 59 patients achieved REM/LDA with no swollen joint (54.6%). In 2mg/day group, biologics and/or JAK inhibitors naïve was predictor for achieving REM/LDA with no swollen joint. In 2mg/day group, D2T-RA patients was negative predictor.
(2)"Comparison of sustained REM and/or LDA rate between rapidly and gradually de-escalation of baricitinib in rheumatoid arthritis" In whole patients, 15 patients were tapered baricitinib with rapidly de-escalation methods and 61 patients were with gradually de-escalation. Gradually de-escalation methods showed less relapse rate compared with rapidly de-escalation after tapered baricitinib (33.3% vs. 93.8%, p<0.0001). Particularly in 2mg/day group, 12 patients were tapered baricitinib with rapidly de-escalation methods and 47 patients were with gradually de-escalation. Gradually de-escalation methods showed less relapse rate compared with rapidly de-escalation after tapered baricitinib for 32.7 months (33.3% vs. 80.9%, p<0.0001). However 2cases in 4mg/day group and 8cases in 2mg/day showed increase of CDAI, all these cases regain LDA after increasing baricitinib.
Conclusion: Tapering baricitinib using gradually de-escalation methods may help to sucseed deduction of baricitinib in RA patients with sustained clinical REM and/or LDA with no swollen joint in each group who start baricitinib with 4mg/day and 2mg/day.

AB0272

CAN NONSTEROIDAL ANTI-INFLAMMATORY DRUGS CONTROL THE SYMPTOMS OF MODERATE RHEUMATOID ARTHRITIS?

E. Pogozheva[1], A. Karateev[1], V. Amirdzhanova[1], E. Filatova[1]. [1]*V.A. Nasonova Research Institute, Pain Management, Moscow, Russian Federation*

Objectives: to evaluate the efficacy of long-term pain therapy with nonsteroidal anti-inflammatory drugs (NSAIDs) in patients with rheumatoid arthritis (RA) with an initially moderate disease activity (DAS 28 <5,1).
Methods: the study included 404 RA patients, disease duration was more than 1 year, mean DAS 28 3.7±1.6, mean age 58.6±10.0 years, 69% women, 76,7% RF "+", 81,5% ACPA "+". 91,2% of the patients received conventional DMARDs (methotrexate), 8,8% - biological agents. All patients received NSAIDs (aceclofenac) to control their symptoms. The follow-up period was 6 months. We evaluated the dynamics of the DAS 28 index, the level of pain and patient global health on a 100- mm visual analog scale (VAS).
Results: the level of pain (VAS) decreased from 63,1 ± 15,4 to 46,3± 8,3 (p=0,001) by 3 months of follow-up and up to 39,5± 11,2 (p= 0,001) by 6 months of follow-up. The patient global health (VAS) also improved from 58,2 ± 13,4 at baseline to 40,3 ± 11,2 (p=0,001) at 3 months and to 35,5 ± 9,7 (p=0,001) at 6 months of follow up. The mean DAS 28 remained within the moderate disease activity and decreased from 3,7±1,5 to 3,4 ±1,1 (p=0,01) after 3 months, and to 3,1± 0,9 (p=0,01) after 6 months.
Conclusion: long-term NSAID therapy allows to control the disease activity in patients with moderate RA. This should be taken into account when planning therapy, including deciding whether to "switch" DMARDs and prescribing biological agents.

HYPERSENSIVITY REACTIONS TO NON STEROID ANTI INFLAMMATORY DRUGS: A BOUT 87 CASES

K. Ksouda[1], R. Sahnoun[1], R. Atheymen[1], I. Bouaziz[1], A. Hanène[1], S. Hammami[1], L. Chtourou[2], Z. Khaled[1]. [1]*Medecine School of Sfax, Pharmacovigilance Department, Sfax, Tunisia*; [2]*Hedi Chaker Hopital, Gastroenterology Department, Sfax, Tunisia*

Background: Non-steroidal anti-inflammatory drugs (NSAIDs) are one of the leading causes of hypersensitivity reactions to drugs. The pathogenesis may be immunological mechanisms (allergic reactions) or non specific immunological reactions often incriminated in cross reactivity independently of chemical structure of these molecules. Understanding of the underlying mechanism is necessary for prevention and choice of safe alternatives [1, 2].
Objectives: Analyze all cases of non-steroidal anti-inflammatory drugs cutaneous eruption reported to sfax pharmacovigilance service since January 2015 to December 2020 and evaluate the possibility of cross-reactions between different molecules in this class.
Methods: We conducted a retrospective study of all cases reported to sfax pharmacovigilance department. An enquiry of pharmacovigilance was performed in patients who presented side effects to AINS. The imputability study was carried out by the French method of Imputability. Medical history specifies if there is a re-administration to assess tolerance and cross-reactivity.
Results: Our study included 87 patients whose average age was 45, 8 years. The sex ratio (F/M) was 1.18. lysine salicylate acetyl is the most incriminated (31%), then mefenamic acid (19.5%), diclofenac (19.5 %), ketoprofen in (9.2%), piroxicam in (6.9 %), ibuprofen in (5.4%), celocoxib in (3.4%), tiaprofenic acid in (1.1%) and naproxen in 1.1% of cases. The most common skin injury was urticaria in 29 cases (33.3%). Fixed drug eruption was observed in 17 cases. Maculopapular rash was observed in 19 cases, anaphylaxis in 5 cases and 4 cases of photosensitivity were observed. In our study we found cross-reactivity between (NSAIDs) in 8 patients.
Conclusion: The diagnostic approach is often based on the controlled administration of the drug to assess tolerance and to identify safe alternatives. In cases of intolerance to COX 1 inhibitors, cross-reactions to selective cox 2 inhibitors are very rare [3].

METHOTREXATE INTOLERANCE IN MOROCCAN RHEUMATOID ARTHRITIS PATIENTS

M. Mahroug[1], H. Azzouzi[1], H. Boutaibi[1], O. Lamkhanat[1], I. Linda[1]. [1]*Mohammed VI University Hospital, Mohammed I University, Faculty of Medicine, Rheumatology, Oujda, Morocco*

Background: Methotrexate intolerance is a principal reason for treatment discontinuation, hence the interest in a more in-depth study.
Objectives: We aimed to study the prevalence of methotrexate gastrointestinal intolerance and determine its associated factors in rheumatoid arthritis (RA) patients.
Methods: We designed a cross-sectional study on our RA patients recruited in January 2021 at our rheumatology department. Methotrexate Intolerance Severity Score (MISS) [1], previously validated in juvenile idiopathic arthritis

patients, was used to determine methotrexate (MTX) intolerance prevalence in RA patients. The MISS consisted of four domains: abdominal pain, nausea, vomiting, and behavioral symptoms, occurring before (anticipatory), after, and when thinking of MTX (associative). MTX intolerance was defined as six or more points on the MISS. Our statistical analysis was based on a descriptive study and logistic regression with SPSS20.

Results: We included 102 RA patients with a mean age of 51.60 ± 14.33 years, Women were predominant (93.1%). The mean disease duration was 14.86 ± 9.78 years, with a mean methotrexate use duration of 7.42 ± 6.44 years. The mean dose of methotrexate was 12.13 ± 9.06 mg per week. The prevalence of methotrexate intolerance was 55.9%, and seventy-six patients (74.5 %) experienced at least one gastrointestinal symptom during MTX treatment. After MTX administration, the most prevalent gastrointestinal symptom was nausea (93% of the intolerant patient), whereas abdominal pain occurred in 73.7% and vomiting in 57.9%. These symptoms were also prevalent before and when thinking of MTX. Anticipatory nausea was reported in 45.6% and associative nausea in 54.5% of the cases, abdominal pain occurred anticipatory in 22.8% and associative in 42.1 %, anticipatory vomiting was the least prevalent, affecting 8.8 %. Behavioral symptoms affected 87.7% of intolerant patients, with restlessness being the most prominent symptom in 71.9% of them. Among the intolerant patients, 45 patients (79%) took parenteral MTX, and 12 (21.1%) took methotrexate orally. In comparison, young patients (49.11 ± 14.95 years) were more intolerant to MTX than old (54.76 ± 13 years, p = 0.048) ones. However, in univariate logistic regression analysis, we did not find any significant association between methotrexate administration route, dose, duration, and digestive intolerance.

Conclusion: Methotrexate intolerance was highly prevalent in our RA population. These results strengthen the idea that early detection of MTX intolerance may avoid effective treatment discontinuation, especially in younger patients.

AB0275 TOFACITINIB EFFECTIVENESS IN PATIENTS WITH RHEUMATOID ARTHRITIS AFTER CONVENTIONAL OR BIOLOGICAL THERAPY - IT REAL ROLE IN DIFFERENT LINES OF TREATMENT

W. Rivero[1], L. Ibata[2], S. Martinez[2], A. Rojas-Villarraga[3], P. Santos-Moreno[4].
[1]Biomab - Center for Rheumatoid Arthritis, Bogota, Colombia, Pharmaceutical chemist, Bogota, Colombia; *[2]Epithink Health Consulting, Epidemiology, Bogota, Colombia*; *[3]Fundacion Universitaria de Ciencias de la Salud - FUCS, Research Division, Bogota, Colombia*; *[4]Biomab - Center for Rheumatoid Arthritis, Bogota, Colombia, Rheumatology, Bogota, Colombia*

Background: rheumatoid arthritis (RA) is a chronic and disabling autoimmune disease, with a high clinical and economic burden. This implies the need to investigate therapies that maximize clinical results. Tofacitinib is recommended as a different alternative to biologic therapy when a patient remains with moderate or high disease activity after conventional DMARDs use, or as an option after failure to biologic therapy.

Objectives: to evaluate the effectiveness of Tofacitinib in RA as first-line (after conventional DMARDs failure) or second-line treatment (after biologic therapy failure) in a real-life cohort of RA patients and its differences.

Methods: this is a descriptive retrospective cohort study conducted at a specialized center for RA in Bogota, Colombia; databases from 2017 to 2019 were used to select and study patients with indication of Tofacitinib, regardless of their previous treatment or disease status. The indication and initiation of Tofacitinib (5 mg BID or 11 mg once daily) was an independent medical decision made as part of the individualized management of every patient. Effectiveness was evaluated in those patients who met the high adherence criteria (at least three visits with a rheumatologist per year), with no change or addition of other conventional DMARDs. Frequencies and proportions in baseline characteristics, differences in disease activity were calculated between the first and second line tofacitinib treatment. Comparisons of continuous variables data between the two patient groups were made using the t-test; the chi-square test and Fisher's exact test were used for statistical analysis of categorical variables. Logistic regressions were performed to analyze related factors with therapeutic response outcomes.

Results: we included 152 RA patients who received tofacitinib: first-line (T1) (n= 85, 55.9%) or second-line (T2) (n= 67, 44.1%). T1 first-line group was younger than the T2 second-line patients (53±12.8 years and 59±11.4 years, p-value 0.01) and they had a shorter disease duration than T2 patients (11.8 vs. 12.8 years, p-value 0.01). Comparative analysis of response to treatment showed a reduction in DAS28 at 3, 6 and 12 months in both study groups. The response in disease activity at 3 months was a major factor related to 6-month response (OR 13.4, 95% CI 4.5-39.4, p value 0.000), while non-response at 3 months were associated with no response at 6 months of follow-up. Baseline DAS28 was significantly associated with response at 12 months (OR 1.9, 95% CI 1.11-3.25, p-value 0.028). At 12 months of treatment, both groups showed disease response and control according to the DAS28 from baseline, but a higher proportion of T1 patients achieved remission (45% vs 23%). A subgroup analysis to evaluate T2 second-line Tofacitinib therapy showed no statistically significant differences in any response criteria according to the number of previously received biologicals.

Table 1. Regression analysis (risk of response of the disease at 6 and 12 months of treatment with Tofacitinib)

Factor	Response at Month 6			Response at Month 12*		
	OR	IC95%	P value	OR	IC95%	P value
Age	1.00	0.97-1.03	0.788	1.02	0.98-1.06	0.211
Male	1.82	0.65-5.08	0.251	0.81	0.27-2.38	0.709
Duration of RA	0.99	0.94-1.04	0.908	1.02	0.96-1.08	0.444
Positive Rheumatoid Factor	0.81	026-2.56	0.730	0.63	0.17-2.26	0.485
Positive Anti-CCP	0.34	0.068-1.6	0.189			
Initial DAS28	1.61	1.04-2.49	0.033	1.9	1.11-3.25	0.018
First line	0.44	0.19-1.01	0.054	1.47	0.56-3.83	0.423
Treatment period	1.12	0.80-1.55	0.492	1.1	0.75-1.61	0.607
Dose: 11 mg.	0.95	0.42-2.13	0.904	0.75	0.258-1.9	0.565
Response at Month 3	13.42	4.57-39.4	0.000	2.32	0.87-6.18	0.091

*Positive Anti-CCP at month 12 was omitted because of collinearity

Conclusion: Tofacitinib is an effective treatment option for patients with RA after conventional DMARDs and in patients after biologic therapy failure, but maybe is better used it as a T1 first-line of treatment. Further studies are required to determine the real role of tofacitinib in different lines of RA treatment.

AB0276 HOW FAST CAN METHOTREXATE BE ESCALATED IN RHEUMATOID ARTHRITIS? A MULTICENTRE, PARALLEL-GROUP RANDOMIZED CONTROLLED TRIAL (MEIRA)

S. Jain[1], V. Dhir[1], A. Aggarwal[2], S. Maurya[2], R. Gupta[3], B. Leishangthem[1], A. Khullar[1], V. Dhawan[4], G. Naidu[1], S. K. Sharma[1], A. Sharma[1], S. Jain[1].
[1]PGIMER, Division of Clinical Immunology and Rheumatology, Department of Internal Medicine, Chandigarh, India; *[2]SGPGIMS, Department of Clinical Immunology and Rheumatology, Lucknow, India*; *[3]AIIMS, Department of Rheumatology, New Delhi, India*; *[4]PGIMER, Department of Experimental Medicine and Biotechnology, Chandigarh, India*

Background: Literature regarding the optimal dose escalation strategy of methotrexate (MTX) in RA is scant and ambiguous (1). Concerns regarding the safety of rapid escalation may lead to delayed attainment of the optimal dose and treatment target.

Objectives: To compare the efficacy, safety and tolerability of fast versus usual dose escalation of oral MTX in RA.

Methods: This multicenter, open-label (assessor blinded) RCT included patients with active RA (SJC≥2 and TJC≥4) aged 18-55 years, not on DMARDs (except HCQ and/or low-dose prednisolone) and with disease duration <5 years. Patients were randomized 1:1 into two groups with the same starting dose of oral MTX (15 mg/week), but escalated either by 5 mg every 2 weeks (fast escalation group) or 5 mg every 4 weeks (usual escalation group), till a maximum of 25 mg/wk. Primary outcome was proportion of EULAR good responders at 16 weeks. Secondary outcomes were change in DAS28-3 and EULAR responders (good or moderate) at 8 and 16 weeks, change in Indian HAQ at 16 weeks, and symptomatic (questionnaire based) and laboratory adverse effects over 16 weeks. RBC MTX polyglutamate-3 levels were measured using HPLC in both groups. There was an open-label extension phase till 24 weeks (use of other DMARDs was permitted beyond 16 weeks if target was not met), and DAS28-3 at 24 weeks was compared.

Trial Reg: CTRI/2018/12/016549

Results: 178 patients (mean age 39.8 (8.6) years, 84% females) with mean disease duration of 1.9 (1.4) years were randomized (89 in each group). Mean DAS28ESR-3 and DAS28CRP-3 at enrollment were 6.3 (0.9) and 5.4 (1.1). At 16 weeks, there was no significant difference in good EULAR response by DAS28ESR-3 (5.6, 7.9%, p=0.9) or DAS28CRP-3 (28.1, 22.5%, p=0.8) between the two groups (Figure 1).

The change in DAS28-ESR-3 at 8, 16 and 24 weeks (or by DASCRP-3, not shown) and improvement in HAQ at 16 weeks were also not significantly different (Table 1). Notably, there was no significant difference in symptomatic GI or CNS adverse effects, incidence of cytopenia, transaminitis or rates of drug discontinuation. RBC MTX polyglutamate-3 levels at 8 and 16 weeks were also similar (Table 1).

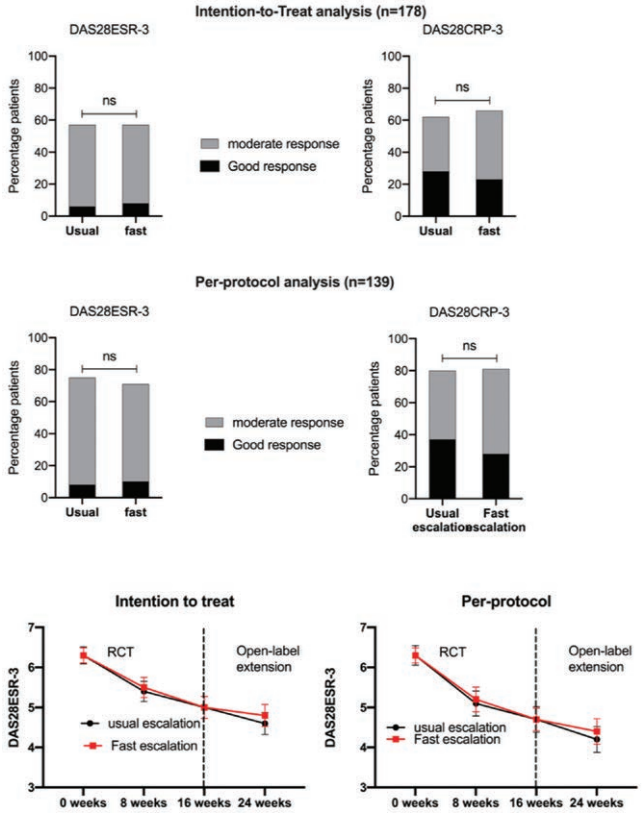

Figure 1. EULAR response and change in DAS28ESR-3 over time

MTX-polyglutamate-3 (nmol/L)			
-8 wk	25.8 ± 10.5	26.9 ± 13.6	0.6
-16 wk	40.7 ± 20.9	40.1 ± 23.4	0.9

*Ever=any time during the studyITT= intention-to-treat, PP=per-protocol, AE=adverse effect

Conclusion: A faster escalation of MTX (5 mg every 2 weeks) reaching 25 mg/week by 4 weeks did not have a significantly higher rate of adverse effects (symptomatic or laboratory) compared to an escalation by 5 mg every 4 weeks. Although not more efficacious, it may shorten the time to recognize MTX failure, and optimize treat-to-target.

ASSOCIATION BETWEEN INTRA-ERYTHROCYTE METHOTREXATE POLYGLUTAMATE CONCENTRATION AND CLINICAL RESPONSE IN RHEUMATOID ARTHRITIS IN PATIENTS TREATED WITH METHOTREXATE INJECTABLE SUBCUTANEOUSLY

M. Poudret[1], M. Norman[2], S. Hodin[3], A. S. Amouzougan[1], K. Boussoualim[1], A. Coassy[1], T. Neel[1], T. Thomas[1,2], X. Delavenne[3], H. Marotte[1,2]. [1]*CHU Saint-Etienne, Rheumatology, Saint-Etienne, France*; [2]*Université de Lyon, SAINBIOSE LBTO, INSERM 1059, Saint-Etienne, France*; [3]*Université de Lyon, SAINBIOSE DVH, INSERM 1059, Saint-Etienne, France*

Background: Methotrexate (MTX) is the first-line treatment for rheumatoid arthritis (RA). Due to its short half-life, blood MTX dosage is not performed in current practice. Erythrocyte MTX-polyglutamate (MTX-PG), which penetrates into the red blood cells, would be correlated with the area under the MTX curve and would be more accessible for dosing. When treatment is initiated, its concentration correlates with efficacy and therapeutic adherence.

Objectives: To determine the interest of erythrocyte MTX-PG dosage in case of failure of 1st line MTX treatment.

Methods: In this single-centre cross-sectional study, RA patients presenting for consultation at the Saint-Etienne University Hospital, with a stable dose of MTX for more than 3 months at least 15 mg/week subcutaneously with either clinical remission (DAS28<2.6) or active disease (DAS28>3.2) were included between July 2nd 2018 and May 28th 2020. In order to assess therapeutic compliance, the patient completed the compliance questionnaire of Rheumatology (CQR) questionnaire. The determination of erythrocytic MTX-PG was performed on a 5 mL blood sample by liquid chromatography method for the determination of the different PG forms.

Results: Sixty patients were included, 34 in the active RA group and 26 in the RA group in remission. One patient withdrew his consent. Only 16% of patients were observed with a CQR score > 80%. Patients in remission were leaner with a longer duration of disease and MTX treatment. The sex ratio, RA status, creatinine clearance and MTX dose was not different in both groups. The CQR was better in the remission group than in the active RA group. However, total MTX-PG was not different in the two groups. The same results were observed for the different forms of MTX-PG 1, 2, 3 or 4. In contrast, in the remission PR group, total MTX-PG or MTX-PG2, 3, 4 and 5 correlated inversely with BMI while MTX-PG3 correlated positively with BMI in the active PR group. In the active PR group, MTX-PG5 correlated with MTX dose.

Conclusion: MTX-PG dosage is not a biomarker of good response to MTX in our study. However, compliance is a key factor to be considered in RA with active disease in adapting patient management.

SLE, Sjögren's and APS – treatment

AB0278 OFF-LABEL RITUXIMAB FOR SYSTEMIC AUTOIMMUNE DISEASES: A CASE SERIES FROM A THIRD LEVEL HOSPITAL DURING A 5 YEAR- PERIOD

C. Sieiro Santos[1], C. Moriano Morales[1], E. Diez Alvarez[1], I. González Fernández[1], A. López Robles[1], T. Pérez Sandoval[1]. [1]*Complejo Asistencial Universitario de León, Rheumatology, León, Spain*

Background: Rituximab (RTX) is a drug composed of chimeric monoclonal antibodies against the CD20 protein that leads to B cell lymphocyte depletion and is currently licensed for rheumatoid arthritis. There is growing evidence of off-label use of rituximab for severe and refractory systemic autoimmune diseases (SAD).
Objectives: Analysing the clinical effectiveness of RTX for SADs such as vasculitis (VS), systemic lupus erythematosus (SLE), systemic sclerosis (SS), primary sjögren syndrome (pSS), necrotizing myopathy (NM) and dermatomyositis (DM) in a rheumatology outpatient clinic in a third level hospital during a 5 year-period (2015 –2020).
Methods: We conducted a retrospective analysis of patients with SAD treated with RTX in the last 5 years. We evaluated demographic and clinical data, indication for RXT, previous treatments, cumulative dose of rituximab and corticosteroids, clinical response, and the presence of adverse events. We considered follow-up period between the first and the last clinical evaluation. Clinical response was considered complete with symptom and analytical remission; incomplete with partial symptom or analytical response and no response if there was no symptom or analytical response.
Results: 35 patients were included (54% women, mean age 60.16 ±17 years). The diagnosis were: pSS (31.4%), SS (17%), SLE (17%), VS (20%), NM (8.8%) and DM (5.8%). Indications for treatment were pulmonary disease in 37% of cases, renal disease in 17%, articular manifestations in 11.4%, haematological manifestations in 14.3%, skin involvement in 8.8%, neurologic manifestations in 5.7% and myopathy in 5.8%. RTX was used after therapeutic failure with previous treatments in 80% (20% of which had receiving treatment with biological disease-modifying antirheumatic drugs) and as first line treatment in only 20% of the cases. After rituximab, 60% of patients had complete response, 17% partial response, and 20% nonresponding. Mean corticosteroid dose post-rituximab was significantly reduced by 60% in pSS (p 0.02), 65% in VS (p 0.03), 50% in SS (p 0.04) and NM (p 0.046). Five patients (14%) had infectious complications, 2 of which needed hospitalization. 7 patients (17%) discontinued therapy, 5 due to ineffectiveness (2 SLE, 1 NM, 1 DM and 1 SS) and 2 patients (14%) due to infectious complications (1 pSS and 1 VS). Patients underwent a median of 2 treatment cycle. The median follow-up after starting RTX was 48.5 (IQR 25.9-74.4) months.

Table 1. Clinical characteristics

	pSS	VS	SLE	SS	NM	DM
%	31.4%	20%	17%	17%	8.8%	5.8%
Age (years)	63.8 (19-73)	63.5 (43-82)	59.2 (43-78)	65.8 (56-78)	58.5 (54-63)	48.5 (26-52)
Female	100%	71%	50%	66%	50%	50 %
Duration of disease (months)	80.5 (24-108)	39 (12-60)	38.4 (36-90)	56.4 (14-96)	69 (48-90)	60 (25-82)
Cumulative RTM dose (g/m2)	2.5 (0.75-6)	3.2 (0.5-8)	1.4 (0.75-5)	2.8 (0.5 – 7)	1.2 (0.5 – 5)	0.56 (0.38-0.75)
Complete clinical response	63%	86%	33%	71%	33%	0%
Incomplete response	18%	14%	33%	14%	0%	50%
No response	18%	0%	33%	14%	66%	50%
Glucocorticoid dose (mg/day) Before RTMX	12.5 (5-20)	21.3 (5-30)	9 (0-15)	9 (5-15)	15 (7.5 – 25)	15 (7.5 – 25)
Glucocorticoid dose (mg/day) After RTX	5 (2.5-15)	7.5 (5-15)	5 (2.5-15)	4.5 (2.5-10)	10 (7.5-25)	12.5 (8 – 20)
Immunosuppressants Before RTX	81%	71%	90%	50%	33%	50%
Immunosuppressants After RTX	54%	28%	57%	66%	67%	50%
Severe infusion-related side effects including need for admission	0%	14%	16%	0%	0%	0%
Other infusion-related side effects	9%	29%	17%	17%	0%	0%

Conclusion: Treatment with RTX was very effective in SADs, particularly in VS, SS and pSS. Further studies are needed to clarify RTX efficacy and safety in SADs, as well as indications and optimal RTX regimens.

AB0279 THE IMPACT OF HYDROXYCHLOROQUINE DAILY DOSE IN THE PREVENTION OF FLARES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN REMISSION

S. Fasano[1], V. Messiniti[1], M. A. Coscia[1], E. Gaggiano[1], M. Iudici[2], F. Ciccia[1]. [1]*University of Campania, Department of Precision Medicine, Rheumatology Unit, Naples, Italy*; [2]*Cochin Institute, National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, Department of Internal Medicine, Paris, France*

Background: The EULAR recommendations for the management of systemic lupus erythematosus (SLE) suggest a hydroxychloroquine (HCQ) dose of ≤5.0 mg/kg/day instead of 6.5 mg/kg/day to reduce the risk of HCQ-induced retinopathy (1). This change in HCQ dose may potentially lead to undertreatment with blood levels below the presumed therapeutic range.
Objectives: The aim of this study was to compare flare rates and HCQ blood levels between the two different oral dosages in patients with SLE in remission.
Methods: Eligible patients were SLE patients in clinical remission according to the preliminary Definitions of Remission in SLE (DORIS) criteria for at least one year and treatment with stable dose of HCQ for at least six months and stable dose of glucocorticoids and/or immunosuppressants (2). Flares were defined by SELENA-SLEDAI Flare Index (3). A venous blood sample was collected on two different occasions from all patients, reflecting actual therapeutic adherence. The biosamples were analyzed in a UPLC-MS/MS system composed of a Nexera chromatograph (Shimadzu) coupled with a Q-trap 6500 spectrometer (AB Sciex). A mean [HCQ] value ([HCQm]) for each patient was then calculated. Predictors of flares were analyzed by Cox regression.
Results: We selected 66 patients who were stratified according to HCQ oral dose in two groups (Table 1). We observed 23 (35%) flares that developed in mean 26,0 (±15,1) months: 8/32 (25%) patients taking HCQ 5 mg/kg/day; 15/34 (44%) in the other group. No statistically significant difference was observed between the two group in number of flares (p=0,106), mean time of occurrence (p=0,904) and median [HCQm] (p=0,983). At regression analysis, older age at baseline was protective against flare occurrence (HR 0,93), while concomitant immunosuppressive therapy showed significant positive association (HR 3,66).
Conclusion: Our study suggests that low dosage of HCQ (5 mg/kg/day) may safely be prescribed in SLE patients in remission, without significant differences in terms of blood concentration and impact on the clinical course of SLE.

THE INFLUENCE OF TARGET THERAPY AS WELL AS GLUCOCORTICOIDS TAPERING ON DISEASE FLARE IN SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM A PROSPECTIVE CHINESE COHORT

Y. Hao[1], L. Ji[1], D. Gao[2], Y. Fan[1], B. Wei[1], Y. Geng[1], X. Zhang[1], G. Li[1], Z. Zhang[1]. *[1]Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*; *[2]Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing,*

Background: Treat-to-target in systemic lupus erythematosus (SLE) has been proposed for 7 years and several recommendations were developed [1]. In these recommendations, prevention of flares should be a realistic target. Meanwhile, 'remission' or 'low disease activity' was recommended as the treatment target and minimizing glucocorticoids (GC) dose or withdrawal if possible was suggested in the maintenance treatment. However, would target therapy and GC tapering/withdrawal influence disease flare?
Objectives: To investigate the frequency and determinants of disease flare, especially the influence of target therapy as well as GC tapering on flare in Chinese lupus patients.
Methods: The baseline and follow-up data of all consecutive patients in a prospective longitudinal lupus cohort from January 2017 to June 2020 were collected. The lupus low disease activity state (LLDAS) was defined as in Golder et al., 2019[2]. The criteria for remission were from DORIS definitions [3]. Flare was assessed using the SELENA-SLEDAI flare index [4].
Results: We enrolled 185 patients with disease duration at recruitment of 2.3 (0.8–7.7) years. During the 26.2 (12.5-34.5) months of follow-up, 73 (39.5%) patients experienced 95 flares, including 70 mild/moderate and 25 severe flares. The incidence of flare per patient-year was 0.27. Kaplan-Meier analyses showed that compared with those who never achieved LLDAS or DORIS, the patients who achieved the target at least once had a higher flare free survival rate; meanwhile, the patients with prednisone withdrawn had significantly lower flare free rate compared with those with small dose of GC maintained (≤7.5mg/d) (Figure 1A), but among the patients with different prednisone maintain doses (7.5~5mg, 5~2.5mg, and ≤2.5mg) there was not significant difference (Figure 1B). Cox regression analysis showed that younger age at disease onset and lower Complement 3 (C3) level at recruitment were independent risk factors for flare and achieving LLDAS or DORIS ≥50% of visits was independent protective factor (Table 1).
Conclusion: In this Chinese prospective SLE cohort, age at disease onset, C3 level at recruitment and therapeutic target achieving influenced disease flare independently and significantly. GC tapering in appropriate patients and with appropriate pace did not increase the flare rate, but prednisone withdrawal may induce more disease exacerbation, which needs to be confirmed by large prospective studies.

MORTALITY PREDICTORS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A SINGLE TERTIARY CENTER REFERRAL EXPERIENCE

C. M. Gamboa-Alonso[1], G. Figueroa-Parra[1], A. L. De-Leon-Ibarra[1], M. Á. Villarreal-Alarcón[1], J. Díaz-Angulo[1], D. Vega-Morales[1], D. Á. Galarza-Delgado[1]. *[1]Universidad Autónoma de Nuevo León, Reumatología e Inmunología Clínica, Monterrey, Mexico*

Background: Systemic Lupus Erythematosus (SLE) is a heterogeneous chronic multisystemic disease that has an increased risk of requiring inpatient management with higher morbidity and mortality rates.
The most frequent causes of mortality are a high disease activity, infections, and cardiovascular diseases.
Objectives: To determine the predictors of mortality in patients diagnosed with SLE.
Methods: A longitudinal, descriptive, observational study was performed from March 2017-March 2020 at the University Hospital of the Autonomous University of Nuevo León, México, including patients with a diagnosis of SLE according to the ACR-EULAR 2012/2019 criteria.
Descriptive statistics were used for demographic variables. Associations between mortality and clinical variables were determined using binary logistic regression analysis; a p <0.05 was considered statistically significant. The SPSS program version 20 was used.
Results: One-hundred and eighty-six patients with SLE diagnosis who fulfilled ACR-EULAR 2012/2019 criteria were included, 161 (86.6%) were women; the mean age was 35.8 (SD 15.41) years. The main chief complaints were dyspnea 31 (16.7%), fever in 28 (15.1%), renal involvement in 21 (11.29%), and arthritis in 19 (10.22%) patients.
Of the 186 patients, 34 (18.3%) had a readmission, 13 (7%) required intensive care unit management, 68 (36.6%) had some type of infection and 22 (11.8%) died. Factors associated with mortality are shown in table 1.
Patients receiving steroids and immunosuppression previous to hospitalization were 73 (39.2%) and 92 (49.5%) respectively.
Conclusion: Infections remain the leading cause of death in SLE patients. Factors that predispose to infections are a chronic use of steroids and immunosuppression as well as high activity of disease.

SAFETY, TOLERABILITY AND SELECTIVE EXPANSION OF REGULATORY T CELLS BY A SINGLE DOSE OF THE NOVEL IL-2 MUTEIN PT101 IN A PHASE 1 STUDY IN HEALTHY VOLUNTEERS

J. S. Sundy[1], K. L. Otipoby[1], N. Higginson-Scott[1], J. Visweswaraiah[1], E. Sampson[1], K. Kis-Toth[1], A. Monsef[1], P. Petaipimol[1], D. Essayan[2], M. E. Cosenza[3], R. Kakkar[1], J. Viney[1]. *[1]Pandion Therapeutics, Watertown, MA, United States of America*; *[2]Oncord, Inc, West Lake Village, CA, United States of America*; *[3]MEC Regulatory Consulting, LLC, Moorpark, CA, United States of America*

Background: Activation and expansion of regulatory T cells (Tregs) has been proposed as a strategy to treat autoimmunity. When administered in low doses, IL-2 expands and activates Tregs leading to clinical response in several autoimmune diseases. However, the narrow therapeutic window of IL-2 results in loss of selectivity for Tregs and concurrent activation of conventional T cells (Tconv) and NK cells, limiting its clinical utility. This loss of selectivity may negate the clinical benefit of Treg activation and lead to dose-limiting side effects. PT101 is a novel engineered variant of IL-2 fused to an Fc protein backbone which in preclinical studies selectively activates Tregs without expanding Tconv or NK cells. PT101 is in clinical development for the treatment of patients with autoimmune diseases.
Objectives: To assess the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of PT101 after a single dose in healthy human volunteers.
Methods: We conducted a randomized, double-blind, single-ascending dose trial of PT101 or placebo (3:1 allocation). Five dose levels from 1 mg to 10 mg were administered by subcutaneous injection. Adverse events, physical examination findings, and clinical laboratory results were assessed for 29 days. Serum PT101 levels and antidrug antibody were assessed. Changes in mononuclear cell populations were measured in peripheral blood by flow cytometry.
Results: 56 subjects were administered PT101 or placebo. All subjects completed the study. There were no deaths, serious adverse events, dose limiting toxicities, or clinically significant changes in vital sign, ECG, or laboratory results. All adverse events were Grade 1 or 2 and self-limited. Injection site reactions were the most common adverse event. Transient increases in eosinophil counts were observed in some subjects, consistent with the known class effect of IL-2. Peak levels of PT101 occurred 11.0 to 14.6 hours after administration, and declined with a mean half-life of 20.4 to 28.3 hours, demonstrating linear exposure through the dose range. No anti-drug antibodies were induced. PT101 caused dose-related expansion of Tregs that plateaued at doses between 3.5 and 10 mg. Mean maximum expansion above baseline was 3.6-fold for total Tregs and 72.5-fold for the CD25bright subset of Tregs. Maximal expansion was observed by Day 8-10 with a return toward baseline by Day 29. Over 80% of subjects achieved a 2-fold or greater expansion of total Tregs (Table 1). No significant expansion of Tconv or NK cells was observed at any dose level.

Table 1. Percent Total Treg Responders

	Placebo	1 mg	3.5 mg	5 mg	7.5 mg	10 mg
Fold Change Total Tregs	(n=14)	(n=6)	(n=12)	(n=12)	(n=6)	(n=6)
≥ 2X	7%	33%	83%	83%	100%	100%
≥ 3X	0%	0%	58%	75%	33%	50%
≥ 4X	0%	0%	24%	42%	33%	17%

Conclusion: PT101 was safe and well tolerated after a single dose in healthy volunteers. Marked expansion of both total Treg and CD25bright Treg cells was observed. High selectivity for Tregs was observed with no significant expansion of pro-inflammatory Tconv and NK cells even at the highest dose studied. These results support the therapeutic potential of PT101 in planned multiple dose studies in systemic lupus erythematosus, ulcerative colitis, and other autoimmune diseases.

CHOREOATHETHOSIS AND LONGITUDINALLY EXTENSIVE TRANSVERSE MYELITIS AS RARE AND SEVERE MANIFESTATIONS OF NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS AND PRIMARY SJÖGREN'S SYNDROME – A TWO-CENTER EXPERIENCE

P. Korsten[1], M. Plüß[1], S. Glaubitz[2], A. Jambus[3], R. Vasko[1], B. M. Göricke[2], S. Piantoni[4]. *[1]Universitätsmedizin Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany*; *[2]Universitätsmedizin Göttingen, Department of Neurology, Göttingen, Germany*; *[3]Universitätsmedizin Göttingen, Department of Neuroradiology, Göttingen, Germany*; *[4]University of Brescia, Department of Rheumatology and Clinical Immunology, Brescia, Italy*

Background: Systemic lupus erythematosus (SLE) can affect almost any organ system. Nevertheless, Lupus nephritis and neuropsychiatric manifestations (NPSLE) are associated with increased mortality (1). Therapeutic options include glucocorticoids, often pulse methylprednisolone (MP), and other immunosuppressive therapies. In refractory cases, therapeutic plasma exchange, rituximab, or intravenous immunoglobulins are often used (2). However, an optimal therapeutic strategy has not been established because NPSLE is an exclusion criterion in most clinical trials. In addition, NPSLE can present with a broad spectrum of manifestations ranging from cognitive dysfunction to severe and life-threatening disease with choreoathetosis or transverse myelitis (TM). In primary Sjögren's syndrome (pSS), neurological manifestations most often include peripheral neuropathies, but TM has also been reported.
Objectives: To analyze the clinical presentation and outcomes after treatment in severe, life-threatening NPSLE.
Methods: We retrospectively analyzed clinical, laboratory, and imaging features in severe NPSLE manifestations in SLE and pSS patients at two tertiary academic centers (University Medical Center Göttingen, Germany, and ASST Spedali Civili Brescia, Italy) with a high volume of SLE patients. Severe NPSLE was defined as either severe movement disorder or extensive tetra- or paraplegia secondary to (longitudinally extensive) transverse myelitis.
Results: Our retrospective chart review resulted in seven patients fulfilling the inclusion criteria (six with SLE and 1 with pSS). Of these, five were females (71.4%). Median age was 26 (16-55) years. Three were of Asian origin, four were of European descent. Median disease duration was 15 (2-228) months. Three patients presented with severe choreoathetosis, all had positive ANA, anti-dsDNA antibodies (abs), and complement consumption. Of note, all three had at least one positive antiphospholipid antibody (APLA). All patients received IV MP 1g x 3 and mycophenolate mofetil and achieved complete remission. Of the four patients with longitudinally extensive TM, all were ANA positive, only two had anti-dsDNA abs. None of them had APLA, and only one tested positive for anti-aquaporine-4 abs. Of all patients, only one had positive ribosomal P-abs. Patients with TM received IV MP 1g x 5 and either RTX (4 cycles with 375 mg/m^2 or IVIg 0.4 g/kg/d x 5). All four TM patients improved; two improved markedly, two only moderately with residual deficits as assessed by EDMUS-grading scale and functional independence measure.
Conclusion: Severe NPSLE, defined as choreoathetosis or TM require intensive treatment. While the former patients achieved complete remission, two of four patients with TM only achieved partial remission. Our data support the use of early

and aggressive immunosuppressive therapy. Nevertheless, therapy for TM in the context remains insufficient and should be assessed in a controlled clinical trial setting.

AB0284 COMBINATION THERAPY WITH RITUXIMAB AND BELIMUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A. Mesnyankina[1], E. Aseeva[1], N. Nikishina[1], A. Torgashina[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Federal State Budgetary Scientific Institution, Moscow, Russian Federation*

Objectives: To assess the efficacy of combined therapy with rituximab (RTM) and belimumab (BLM) in patients with active systemic lupus erythematosus (SLE).

Methods: The study included 12 SLE pts (1M/11F) with severe (SLEDAI2K≥10 – 8pts.) and moderate (SLEDAI2K<10- 4pts.) disease activity; out of them 5 patients had lupus nephritis, vasculitis and 7 had predominantly mucocutaneous and articular manifestations of SLE. The dose of oral GC was: 60 mg in one patient with vasculitis, LN, cerebrovasculitis; in 9 patients from 10 to 5 mg; in 2 patients without oral glucocorticoids. All patients with SLE with kidney damage, CNS, and vasculitis received cytostatics. All patients with vasculitis, LN, etc. received mycophenolate mofetil or cyclophosphamide. Rituximab (RTM) was administered at 500-2000 mg, with subsequent adding of Belimumab (BLM) 1-6 months later at a standard dosing regimen 10 mg/kg once a month a total of 7 infusions. The following parameters were evaluated: the effectiveness of therapy, the concentration of autoantibodies, the dose of oral corticosteroids initially at the time of RTM administration and then every 3 months after the initiation of BLM therapy.

Results: 8 pts demonstrated the decrease in clinical and laboratory SLE activity, starting from 3mo of follow-up. After the start of BLM infusions, a decrease in SLE activity was observed in all patients. Among them, 9 had SLEDAI-2K activity of less than 4 points (SLEDAI-2k Me 12 [9,5;17], after treatment of RTM and BLM 4[2;4]). Only one patient (№4) had a relapse of SLE, due to the omission of the BLM infusion. He was receiving standard GC doses. In dynamics, a decrease anti-double DNA titres (Me 101 [39;250]U/ml vs 19 [9;70] U/ml), C3 (0,44 [0,39;0,59]g/l vs 0,81 [0,72;0,87] g/l), C4 (0,06 [0,031;0,1] g/l vs 0,14 [0,13;0,14] g/l) was registered. The GC dose was reduced in most patients (tab. 1), but the previously prescribed immunosuppressive therapy continued. There were no cases of severe infection.

Conclusion: Combination therapy allows to gain control over disease activity in short time, due to the effect of RTM, while added BLM provides further prolongation of the effect achieved, minimizing the risk of flare. The use of such therapy contributes to a rapid and effective reduction in the activity of the disease, normalization of laboratory markers of SLE (at to ds-DNA, C3, C4), the use of lower doses of oral GCs. This combination may be used as a method of choice in pts with severe SLE involving vital organs, and in persistent cutaneous-articular disease and high immunological activity.

AB0285 EFFECTIVENESS OF IMMUNOSUPPRESSIVE THERAPY FOR CONNECTIVE TISSUE DISEASE–ASSOCIATED PULMONARY ARTERIAL HYPERTENSION

R. Kishikawa[1], M. Hatano[1,2], S. Ishii[1], M. Shimbo[1], A. Saito[1], S. Minatsuki[1], Y. Iwasaki[3], K. Fujio[3], I. Komuro[1]. *[1]Graduate School of Medicine, The University of Tokyo, Department of Cardiovascular Medicine, Tokyo, Japan*; *[2]Graduate School of Medicine, The University of Tokyo., Department of Therapeutic Strategy for Heart Failure, Tokyo, Japan*; *[3]Graduate School of Medicine, The University of Tokyo, Department of Allergy and Rheumatology, Tokyo, Japan*

Background: Connective tissue disease (CTD) associated pulmonary arterial hypertension (PAH) is considered to be an indication for immunosuppressive therapy (IT) except scleroderma associated PAH. However, the response rate defined by improvement of WHO functional class and hemodynamic parameters is reported to be around 50% [1]. Since CTDs are systemic diseases, it may be difficult to evaluate the efficacy of IT by subjective symptoms. Although there are previous studies reporting that the combined use of IT and pulmonary vasodilators significantly improved hemodynamics [2], response to IT without titration of pulmonary vasodilators remains to be elucidated.

Objectives: To examine whether IT is effective for CTD-PAH.

Methods: We retrospectively examined the medical records of consecutive 13 patients with CTD-PAH (female 13, mean age 47 ± 15 years) treated with methylprednisolone (1 mg/kg/day, oral) and intravenous bolus cyclophosphamide (IVCY) (500 mg/m^2) every four weeks for six times. Patient characteristics are described in Table 1. Right heart catheterization (RHC) was done at prior to IT, before adding PAH specific agents, and at the fifth or sixth course of IVCY. In treated cases, the previous vasodilators remained unchanged during the first term of IT.

Results: At the first follow up RHC, decrease of mean pulmonary arterial pressure over 5 mmHg was observed in all patients, and decrease of pulmonary vascular resistance (PVR) was observed in twelve out of 13 patients (Figure 1). Over 20% of PVR reduction was observed more in the patients of pulmonary vasodilator naïve and started IT within one year from symptoms than others (6/7 vs 1/6, p=0.03). Although six-minutes walk distance (6MWD) tended to be prolonged between first and second RHC (298 ± 70 m vs 382 ± 81 m; p=0.054; n = 9), 6MWD was shortened in some cases with good hemodynamic improvement (2/5). All patients were prescribed oral PAH specific agents finally, but no one needed parenteral prostanoids. Two patients (15%) died during maintenance therapy for causes other than PAH. Three-year and five-year survival rates were 91.7% and 81.5%, respectively.

Conclusion: IT without titration of pulmonary vasodilators significantly improved hemodynamic parameters despite of less improvement in 6MWD in CTD-PAH patients. Considering that CTDs itself might affect the exercise tolerance regardless of PAH, these hemodynamic changes may contribute to better prognosis and IT might be considered especially for patients early in clinical courses and treatment naïve.

AB0286 EFFICACY OF MYCOPHENOLATE MOFETIL PLUS RITUXIMAB COMPARED WITH INTRAVENOUS CYCLOPHOSPHAMIDE PLUS RITUXIMAB IN PATIENTS WITH RELAPSING LUPUS NEPHRITIS

L. D. Fajardo Hermosillo[1]. [1]*Centro Médico Nacional de Occidente IMSS, Rheumatology, Guadalajara, Mexico*

Background: Lupus nephritis (LN) remaining as one of the most devastating manifestations of systemic lupus erythematosus (SLE). Only 60% of patients with LN achieve a complete (CR) or partial remission (PR) with mycophenolate mofetil (MMF) or intravenous (iv) cyclophosphamide (CY) plus corticosteroids. Of those nearly one-half will have a relapse following maintenance therapy [1]. Rituximab (RTX) is considered a treatment of relapsing LN [2]. Although potential benefits have been revealed in descriptive studies, efficacy has not been established in randomized trials [3,4].
Objectives: This study compares the efficacy achieving a CR or PR with MMF+RTX versus iv CY+RTX in patients with relapsing LN.
Methods: Mexican SLE patients classified by SLICC 2012 criteria were recruited from 2013 to 2019 with LN diagnosed by renal biopsy who previously having achieved a CR with MMF or iv CY followed by the maintenance therapy with azathioprine (AZA) or MMF and subsequently present relapsing LN consisting of a new active urinary sediment (US), worsening proteinuria and renal function. Demographic, renal clinical and paraclinical variables were examined. All patients received oral prednisone (1 mg/kg/d) accompanying MMF 3 g/d or CY 0.5–1 g/m^2 monthly plus RTX 1 g at 0 and 14 days. The data were evaluated at 0, 6, 12 and 24 month(s) after the start both treatments. CR was defined as normal serum creatinine (SCr), inactive US, plus 24-Hour Urine Protein (24hUP) <500 mg/d and PC was established as 50 percent improvement in renal parameters. Fisher's exact and Student´s-t tests were performed by univariate analysis.
Results: Of nine SLE patients with relapsing LN, seven were women. The mean age [standard deviation (SD)] was 25.1 (6.4) years. The mean time at the onset of SLE (SD) was 3.44 (1.12) years ago. Four and five patients had class IV and IV/V LN respectively. Time of relapsing LN after of CR (SD) was 21.2 (7.17) months. Seven patients used CY followed by AZA and two employed MMF previously of relapsing LN. The mean of basal SLEDAI and SLICC (SD) were 19.11(3.2) and 1.22 (0.44) respectively. The mean of basal 24hUP (SD) was 4.67 (2.6) g/d and sCr (SD) was 2.0 (0.84) mg/dl. Five patients used MMF+RTX and four patients utilized CY+RTX. No statistically significant differences were found for CR, PR, 24hUP, sCr, US, anti-dsDNA and complement between both groups. At 6 months one patient achieved a CR and six reached a PR. At 12 months four patients fulfilled a CR and seven had a PR. Finally, at 24 months seven patients showed a CR and a CP. Only two patients did not achieve a CR or PR at 24 months.
Conclusion: This study suggests that the most of SLE patients with relapsing LN treated with CY or MMF plus RTX achieved CR or PR at 24 months, although were no found differences between both treatments. However, these observations must be confirmed in larger and prospective studies.

AB0287 EFFECTS OF HYDROXYCHLOROQUINE ON PERIPHERAL BLOOD CYTOKINE EXPRESSION ASSOCIATED WITH ATHEROSCLEROSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS

R. Wakiya[1], K. Ueeda[1], H. Shimada[1], S. Nakashima[1], M. Kato[1], M. Mahmoud Fahmy Mansour[1], T. Miyagi[1], K. Sugihara[1], Y. Ushio[1], M. Mizusaki[1], R. Senba[1], T. Kameda[1], H. Dobashi[1]. [1]*Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Kagawa, Japan*

Background: In systemic lupus erythematosus(SLE), a higher frequency of atherosclerotic lesions is associated with a poor life prognosis (1). Hydroxychloroquine (HCQ) has been reported to improve the prognosis of life and dyslipidemia in SLE (2), and the mechanism has been unclear.
Objectives: To determine the effect of HCQ treatment on serum cytokines associated with atherosclerosis in SLE.
Methods: SLE patients who received additional HCQ and maintained low disease activity between January 2016 and September 2020 were included in this study. Disease activity was assessed by SLEDAI, CLASI and LLDAS, and serum complement titers, anti-ds-DNA antibodies, serum insulin and serum cytokines (adiponectin, resistin and leptin) were analyzed before and after HCQ treatment.
Results: Fifty-four patients (3 males, 51 females, mean age 41.9±12.8 years) were included (Table 1). Thirty-two patients achieved LLDAS at baseline. Serum adiponectin and insulin levels were significantly increased after 3 months of HCQ treatment compared to baseline, and serum resistin levels were significantly lower (Figure 1). Patients with a history of renal disease had greater degree of changes in serum adiponectin and resistin levels. Among SLE patients who did not achieve LLDAS at baseline, those who still did not achieve LLDAS after 3 months had significantly lower serum leptin levels before HCQ treatment than those who achieved it after 3 months.
The change of serum resistin levels correlated with those of serum S100A8 levels (r=0.5, p=0.0001).
Conclusion: Additional HCQ treatment in SLE patients improves lipid abnormalities. HCQ may improve prognosis by controlling disease activity in SLE and reducing risk factors for atherosclerosis.

Background: Belimumab (BEL), a recombinant human monoclonal antibody that inhibits B-lymphocyte stimulator (BLyS), is approved for the treatment of systemic lupus erythematosus (SLE). Clinical studies have yielded varying incidence rates of mortality and adverse events of special interest, such as malignancies, thereby necessitating large-scale, long-term assessment following BEL exposure.

Objectives: To assess all-cause mortality and new primary malignancies during post-treatment Year 2 follow-up in adult patients with active, autoantibody-positive SLE who received intravenous (IV) BEL or placebo (PBO), plus standard therapy in the 52-week double-blind treatment period of the ongoing BASE trial.[1]

Methods: This was a post-treatment follow-up of the Phase 4, double-blind study (BASE[1]; GSK Study BEL115467; NCT01705977), which randomised 4019 adults with active SLE and receiving standard therapy to BEL (10 mg/kg IV) or PBO on Days 0, 14, 28, and monthly thereafter until Week 48. All patients (including those who discontinued BEL before the end-of-treatment phase) were contacted by phone annually (+/-30-day time window). Rates of mortality and new primary malignancy are summarised for Year 2 follow-up, presented by the treatment received during the 52-week double-blind treatment period (Year 1).

Results: Baseline patient characteristics and disease activity collected at the start of the study, evaluated in patients with Year 2 follow-up were similar to the overall Year 1 study population. Cumulatively by Year 2 follow-up, 10.7% and 9.5% of patients had been exposed to commercial BEL in the BEL and PBO groups, respectively. Cumulative follow-up adjusted mortality and malignancy rates (per 100 patient years) were lower in the BEL vs PBO Year 1 treatment group (Table 1).

Conclusion: Year 2 follow-up results of BASE, the largest clinical trial of SLE to date,[1] provide continued support for the BEL safety profile. No new BEL safety concerns were identified in patients with active, autoantibody-positive SLE receiving standard therapy.

AB0289 PATIENT REPORTED PHYSICAL HEALTH COMPARED TO CLINICIAN RECORDED BILAG-2004 MUSCULOSKELETAL SYSTEM SCORES – DISCORDANCE BETWEEN PATIENTS AND CLINICIANS

E. Olech[1,2], D. Stull[3], B. Williams[3], S. Bean[3], G. Abreu[4], E. Schwetje[5], R. Tummala[5], S. O'quinn[6]. [1]*IQVIA, Rheumatology Center of Excellence Therapeutic Strategy & Science Unit, San Diego, United States of America*; [2]*IQVIA, Rheumatology Center of Excellence, Las Vegas, United States of America*; [3]*IQVIA, Patient Centered Endpoints, New York, United States of America*; [4]*AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden*; [5]*AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, United States of America*; [6]*AstraZeneca, BioPharmaceuticals Medical: Evidence, Gaithersburg, United States of America*

Background: The musculoskeletal organ system BILAG-2004 (MSK BILAG) assessment is of critical importance in SLE clinical trials. Severe active polyarthritis, MSK BILAG A, by definition includes significant impairment of basic activities of daily living (ADLs), as opposed to MSK BILAG C, D, or E where ability to perform ADLs is expected to be preserved. In clinical trials, BILAG is scored by clinicians without formal review of patient reported outcomes (PROs). The Physical Health domain of the LupusQoL (LQol PH) (range 0 – 100) can be used to assess the patient's physical function and ADLs. LQoL PH score thresholds defining impairment severity have not been established; however, a transformed LQoL PH score ≤50 suggests more impaired function, which would not be expected in MSK BILAG C, D, or E. Conversely, a score >50 implies no major issues with ADLs, which would be contradictory to the definition of MSK BILAG A.

Objectives: To assess correlation of patient reported LQoL PH with MSK BILAG scores recorded by clinicians at various timepoints using data from the phase 3 TULIP studies [1,2] and to investigate the percent of discordance between patients and clinicians.

Methods: Data from TULIP 1 and 2 studies (anifrolumab 300 mg and placebo arms) were pooled to evaluate the relationship between LQoL PH and MSK BILAG scores at baseline, weeks 24 and 52 using Spearman correlations as post-hoc analysis. Mean LQoL PH scores were assessed for each MSK BILAG category at the three timepoints using one-way ANOVA. Percent of patients with MSK BILAG A and LQoL PH scores >50 and patients with MSK BILAG C, D, or E and LQoL PH scores ≤50 was calculated at baseline, week 24 and 52. MSK BILAG B was excluded from the analysis because discordance could not be easily defined for this category compared with the more extreme MSK BILAG categories.

Results: Total of 690 patients were included in the pooled analysis (Table 1). Significant correlations between LQoL PH and MSK BILAG scores were found at each time point (nominal p<0.0001); this relationship became stronger over time. Mean LQoL PH scores were different in each MSK BILAG category, with the highest in MSK BILAG D/E and the lowest in the MSK BILAG A category, thus confirming the discriminatory ability of the LQoL PH (Table 1).

Table 1. Correlation coefficients (CC) between LQoL PH and MSK BILAG scores, and mean LQoL PH scores with standard deviations (SD) per each MSK BILAG category at baseline, weeks 24 and 52.

	Baseline		Week 24		Week 52	
	CC	N	CC	N	CC	N
Total Population	-0.25	690	-0.36	626	-0.41	552
MSK BILAG	Mean LQoL PH Score (SD)		Mean LQoL PH Score (SD)		Mean LQoL PH Score (SD)	
0 (D/E)	69.3 (24.7)	17	74.2 (22.1)	186	74.5 (21.3)	237
1 (C)	62.3 (25.4)	60	64.0 (23.9)	233	60.6 (22.5)	184
8 (B)	56.6 (24.4)	398	55.1 (24.2)	163	51.3 (24.3)	105
12 (A)	44.9 (25.8)	215	43.9 (25.9)	44	44.2 (26.2)	26

At baseline, 40% of patients who were assessed by clinicians as having MSK BILAG A reported minimal impairment in physical function and ADLs (LQoL PH >50) and 24.1% who had MSK BILAG C, D, or E reported difficulties with ADLs (LQoL HP ≤50), suggesting discordance between patients and clinicians. This discordance slightly decreased over time (Figure 1).

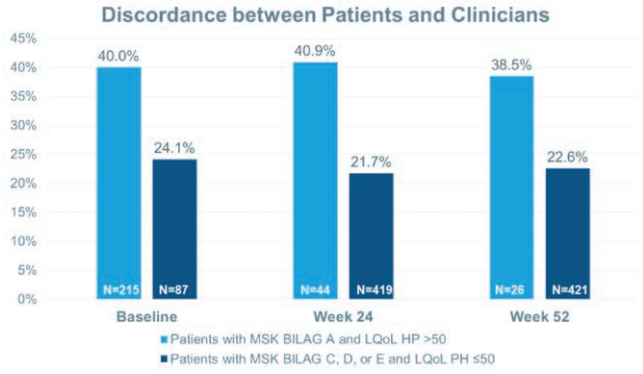

Figure 1. Percent of patients with MSK BILAG A and LQoL PH scores >50 and patients with MSK BILAG C, D, or E and LQoL PH scores ≤50 at baseline, weeks 24 and 52.

Conclusion: Patient reported LQoL PH scores correlated with MSK BILAG scores and showed discriminant validity for MSK BILAG scores. Greater discordance was seen between LQoL PH and MSK BILAG A compared with C, D, or E. These findings suggest a need for further investigation of a role for PROs in MSK BILAG scoring. Formal review of PROs by clinicians during MSK BILAG assessment could be considered in future SLE clinical trials.

AB0290 TREATMENT OF INTERSTITIAL LUNG INVOLVEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS: EXPERIENCE IN A THIRD LEVEL HOSPITAL

I. González Fernández[1], C. Moriano[1], E. Diez Álvarez[1], C. Sieiro Santos[1], C. Álvarez Castro[1], M. Martín Martín[1], M. E. Vallejo Pascual[2], M. T. Perez Sandoval[1]. [1]*Complejo Asistencial Universitario de León, Reumatología, León, Spain*; [2]*Universidad de León, Facultad de CC. EE y Empresariales, León, Spain*

Background: There are few studies[1] on the treatment of diffuse interstitial lung disease (ILD) associated with systemic lupus erythematosus (SLE). Corticosteroids are usually used in cases of mild to moderate decrease in diffusion and the association with immunosuppressants (Cyclophosphamide, Rituximab…) is reserved for cases of more severe affectation.

Objectives: Assess the main treatments used in ILD associated with SLE in a third level hospital and analyze the therapeutic response through improvement in imaging tests and in respiratory function studies.

Methods: Descriptive observational study of patients diagnosed with SLE (SLICC criteria) who developed ILD in our hospital between 1973 and 2020. As variables of response to treatment, HRCT pattern at diagnosis and at two years, respiratory function tests at diagnosis and at one year were analyzed. Likewise, the different treatments used before and after diagnosis were studied such as hydroxychloroquine (HCQ), prednisone, methotrexate (MTX), Rituximab (RTX), belimumab (BLM), Cyclophosphamide (CFM), azathioprine (AZA) and mycophenolate mofetil (MMF).

Results: A total of 455 patients diagnosed with SLE were included, of which 20 had ILD (4.4%). 65% of the analyzed sample were women with a mean age at diagnosis of 63 ± 16.23 years. 30% presented ILD as the first clinical data for the diagnosis of SLE. Only 3 patients died (due to causes other than ILD and SLE). At diagnosis, 90% had symptoms such as dyspnea (75%) and cough (60%).

85% had alterations in the X-ray and 100% in the HRCT, where the predominant pattern was NINE (65%). Spirometry showed an obstructive (25%), restrictive (20%) and normal (55%) pattern; 90% had decreased diffusion, the majority being mild (67%). With the treatment administered, HRCT stability was observed

at two years in 30% of cases and progression in 25%; while, at the functional level, 40% remained stable with worsening in 4 patients per year (20%).
50% of the patients with SLE received treatment with HCQ and MTX before the diagnosis of ILD; and 35% corticosteroids (4 + 7.3 mg / day). With ILD diagnosed, HCQ was administered to 95% of patients and the standard of treatment was based on corticosteroids in monotherapy at a mean dose of 13 ± 10.5 mg / day due to stability both at radiological level and in function tests respiratory. 25% and 15% required treatments such as RTX and BLM as they did not have an adequate response with the previous one.
In our study, we did not find any statistical significance between the variables analyzed, due to the small sample size.
Conclusion: 1)ILD in SLE is a rare manifestation, present in 4.4% of our series. Standard treatment with hydroxychloroquine and corticosteroids appears to be a useful therapeutic option, stabilizing radiological progression in one third of cases early. More studies with a larger sample size are needed to analyze the role of immunosuppressive treatment in this type of lung involvement.

AB0291 PROGNOSTIC VALUE OF LATE GADOLINIUM ENHANCEMENT ON CARDIAC MAGNETIC RESONANCE IMAGING IN SYSTEMIC LUPUS ERYTHEMATOSUS

A. J. Velvet[1], S. Vohra[1], T. David[2], B. Keavney[3], I. Bruce[2], B. Parker[2], K. Bratis[1]. *[1]Manchester University NHS Foundation Trust, Cardiology, Manchester, United Kingdom*; *[2]Manchester University NHS Foundation Trust,The Kellgren Centre for Rheumatology, Manchester, United Kingdom*; *[3]The University of Manchester, NIHR Manchester Musculoskeletal Biomedical Research Centre, Manchester, United Kingdom*

Background: Cardiac Magnetic Resonance Imaging (CMRI) with Late Gadolinium Enhancement (LGE) has an established value in the diagnostic and prognostic assessment of ischaemic and non-ischaemic cardiomyopathies. Although CMRI is widely used for the detection of myocardial involvement in subclinical Systemic Lupus Erythematosus (SLE), its prognostic value has not been determined.
Objectives: To determine the prognostic value of CMRI with LGE for major adverse cardiovascular events (MACE) in patients with SLE, and investigate its correlation with the severity of systemic inflammation.
Methods: A retrospective tertiary single-centre review of patients with SLE who underwent a CMRI study at Manchester Foundation Trust between 2009-2020 was conducted. Patients were categorized into two groups; those who experienced a MACE (cardiac death, myocardial infarction (MI), stroke/TIA or heart failure) and those who did not. We compared cardiovascular (CV) risk factors, CMRI findings, SLE risk scores and biochemistry between the 2 groups.
Results: We identified 20 female patients who underwent a CMRI, with a mean age of 46 years at the time of the scan. Indications for CMRI were assessment for worsening dyspnoea and new onset left ventricular systolic dysfunction. Table 1 demonstrates the clinical, laboratory and CMRI characteristics of the two groups. There were no significant differences in the clinical background and traditional CV risk factors between the 2 groups. 5/20 (25%) patients experienced a MACE. The SLEDAI-2K score was >12 in 2/5 (40%) of patients who suffered a MACE and they presented with a stroke within a year of CMRI study, suggesting that systemic inflammation contributes to poor vascular outcomes. 3/5 (60%) patients who reported a MACE demonstrated LGE on their CMRI study compared to 3/15 (20%) of those who did not (p-0.045). The LGE was predominantly diffuse, mid myocardial in distribution and not ischaemic in pattern, signifying a complex pathophysiological substrate in the development of myocardial pathology in SLE. Additionally, an increase in left ventricular end-diastolic, end-systolic volumes and left atrial diameter was noted in patients who had a MACE (p<0.05). Patients who had a MACE showed a higher incidence of valvular abnormalities and pericardial disease in their CMRI studies. On looking at the medications around the CMRI, the majority of MACE positive patients 4/5 (80%) were on conventional Disease Modifying Anti-Rheumatic Drugs (DMARDs) such as Mycophenolate, Tacrolimus, Cyclophosphamide, Methotrexate or hydroxychloroquine and none on biologics like Rituximab or Belimumab. While 9/15 of the MACE negative patients were on DMARDs and 4/15 were on biologics.

Table 1. clinical, laboratory and CMRI characteristics of SLE patients with and without MACE. LVEDV-left ventricular end-diastolic volume, LVESV-left ventricular end-systolic volume, LA-left atrial, LVEF-Left ventricular ejection fraction, SLEDAI- SLE Disease Activity Index, +ve-positive.

	MACE+ (n = 5)	MACE- (n = 15)
Mean age of SLE diagnosis (years)	35.6	34.4
Mean duration to CMRI (years)	8.8	11.71
Lupus nephritis	20%	20%
Raynaud's	40%	27%
Previous CV involvement	0	2
SLEDAI-2K > 12	2(40%)	11(73%)
Lupus anticoagulant +ve	20%	27%
Anticardiolipin +ve	2(40%)	2(14%)
anti-dsDNA (iu/ml)+ve	3(60%)	6(40%)
Low C3 (g/L)	2(40%)	6(40%)
Mean prednisolone dose	28.33	8.21
Conventional DMARDs	4/5(80%)	9/15(60%)
Biologics	0/5	4/15
Mean LVEF (%)	47.4	56.7
CMR LGE	3(60%)	3(20%)
Valvular abnormalities	2(40%)	4(27%)
Mean LA area (cm^2)	29.6	20.6
Pericardial effusion	40%	27%

Conclusion: In our small SLE cohort, we add to existing knowledge that CMRI with LGE is an indispensable tool to investigate cardiac involvement in SLE and may indeed add important prognostic information. Larger scaled studies are required to confirm the use of CMRI with LGE as a predictor of MACE in patients with SLE.

AB0292 A RETROSPECTIVE STUDY OF PERIOPERATIVE MANAGEMENT OF PATIENTS WITH SLE IN TOTAL HIP ARTHROPLASTY

I. Kushnareva[1], M. Makarov[1], T. Popkova[2], A. Khramov[1], S. Maglevaniy[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Orthopaedic Department, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Systemic Rheumatic Diseases, Moscow, Russian Federation*

Background: Aseptic necrosis (AN) of bones is one of the most serious complications of systemic lupus erythematosus (SLE), which is characterized by multicomponent joint damage mainly in young people. Long-term observations show that two thirds of patients have multiple aseptic necrosis of bones, with the femoral head being most often affected. Obviously, caused by much strain on the hip joint. In this regard, total hip arthroplasty (THA) is an integral part of the treatment of SLE patients. Despite the fact that THA in these patients allows to achieve good functional outcomes, the amount of complications remains high.
Objectives: To retrospectively analyze the outcomes and structure of complications to determine the tactics of perioperative management of patients with SLE.
Methods: The retrospective group included patients over 18 years of age with a reliable diagnosis of SLE, established according to the classification criteria (SLICC, 2012, ACR, 1997). 123 THA were performed in 77 patients. Outcomes and the structure of complications were analyzed for the period from 1998 to 2016 inclusive.
Results: The period of hospital stay of patients was analyzed. Cementless fixation of the components of the endoprosthesis was used and the friction pair was metal-polyethyleneIn all cases. In 23 patients, additional fixation of the acetabular component with screws was performed, which indirectly indicates a poor quality of bone tissue. A more detailed analysis of these patients revealed a long period of glucocorticoid therapy (from 1.5 to 35 years). In 3 patients, during preparation for implantation of the femoral component, a femoral fracture occurred, which required using the cerclages. One patient also had a fracture of the acetabulum, which required the implantation of a Müller anti-protrusio ring. The above-described technical features led to increasing of the total time of surgery, which significantly increased the volume of blood loss. Thus, this required transfusions of blood components: fresh frozen plasma (FFP), erythrocyte suspension, as well as replenishment the circulating blood volume with colloidal solutions.
Prevention of thromboembolism. All patients in the postoperative period underwent common measures of prevention of venous thromboembolism.

The drugs of choice were calcium nadroparin (Fraxiparin) 0.3 or 0.6 ml subcutaneously - depending on body weight, respectively, or Dabigatran etexilate (Pradaxa) 220 mg per day, or rivaroxaban (Xarelto) 10 mg per day.
Prevention of infectious complications. The first injection of antibiotic is carried out immediately before surgery achieve it's maximum concentration in blood plasma just in the time of first incision. In the postoperative period, antibiotic therapy was carried out for at least 5 days. In 1 patient, the course of antibiotic therapy was prolonged and another broad-spectrum antibiotic was added due to a history of tuberculosis infection. Postoperative rehabilitation in patients with SLE met standard protocols: activation in bed and verticalization was carried out on day 1, standing with crutches and walking on day 2.
Conclusion: During the period of hospital stay in the early postoperative period, not a single one thromboembolic event developed, as well as no cases of infectious complication occurred. There was one case of dislocation of the femoral component of the endoprosthesis, which was immediately repaired in the early postoperative period.

AB0293 IDENTIFYING PREDICTORS OF SHORT-TERM RESPONSE TO RITUXIMAB IN PRIMARY SJOGREN'S SYNDROME

S. Pepple[1], J. Arnold[1], E. Vital[2,3], A. Rawstron[4], C. Pease[1], S. Dass[1], P. Emery[1,3], M. Y. MD Yusof[1,3]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[3]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*; *[4]Leeds Teaching Hospitals NHS Trust, Haematological Malignancy Diagnostic Service, Leeds, United Kingdom*

Background: Randomised controlled trials of rituximab (RTX) in primary Sjogren's syndrome (pSS) have aimed to alleviate glandular symptoms and fatigue with only limited data on efficacy/effectiveness of the initial and repeat cycles of RTX on extra-glandular pSS.
Objectives: To assess the effectiveness of RTX on extra-glandular symptoms and identify predictors of short-term response with a view to personalised B-cell depleting therapy in patients with pSS.
Methods: An observational study was conducted in 40 consecutive RTX-treated pSS patients in a single centre for over 15 years. All patients fulfilled the 2002 AEG criteria and were CCP negative. Clinical response at 6 months was defined as ≥3 reduction of ESSDAI from baseline. B-cell subsets were measured using highly sensitive flow cytometry. Predictors of short-term response were analysed using penalised logistic regression.
Results: 38/40 (95%) patients were female, mean (SD) Age 54 (13.7) years, median (IQR) disease duration 5 (2-9) years, 39/40 (98%) had positive ANA, 26/40 (65%) were on concomitant immunosuppressant (IS). Mean (SD) ESSDAI at RTX initiation was 11.5 (6.7); main domains for RTX were articular (73%), skin (23%), PNS (15%) and muscular (15%). 169 RTX cycles were administered with a total follow-up of 165PY. In Cycle 1 (C1) RTX, the proportion of patient achieving ESSDAI response from baseline was 29/40 (73%; 95% CI 58-87). There were significant reductions in ESSDAI, daily prednisolone dose and IgG levels at 6 months (all p<0.05). Of C1 responders, 23/29 received retreatment on clinical relapse; of which 8/23 (35%) lost response [secondary non-depletion non response (2NDNR) associated with anti-RTX antibodies=4 (17%) as we previously observed in SLE[1], side effects=2, ineffective=2]. Of C1 non-responders, 9/11 were retreated but only 2/9 responded in C2. Overall, 13/40 (33%) discontinued RTX within two cycles. In multivariable analysis, concomitant IS and achieving compete B-cell depletion in C1 reduced non-response to RTX (Table 1).
Conclusion: All pSS patients should be prescribed concomitant immunosuppressant with RTX and therapy should aim to achieve complete depletion. About 1 in 6 pSS patients lose response in repeat cycles which is associated with 2NDNR phenomenon. The use of humanised or type 2 anti-CD20mAbs should overcome these issues and improve the clinical response of extra-glandular pSS.

AB0294 PREDICTORS OF CHLOROQUINE AND DERIVATES TREATMENT INVOLVING OCULAR TOXICITY: RESULTS FROM A COHORT

R. Dos-Santos[1], D. Fernández Fernández[1], I. González Fernández[1], M. Sanchez-Wonenburger[1], P. Castro-Santamaria[1], A. Souto Vilas[1], E. Perez-Pampín[1], A. Mera Varela[1]. *[1]Clinical University Hospital in Santiago de Compostela, Rheumatology Department, Santiago de Compostela, Spain*

Background: Chloroquine (CQ) and hydroxychloroquine (HCQ) have been employed in a huge range of indications, from autoimmune diseases (such as rheumatoid arthritis [RA], cutaneous lupus or systemic erythematosus lupus [SLE]) to infectious ones (as malaria or helminthiasis).[1] A newer purpose came upon the new coronavirus disease 2019 (COVID-19), where they seem to be effective modulating immune response. Controversial results have been published from clinical and observational data concerning its effectiveness.[2] Ocular toxicity have been described as a serious adverse event of these antimalarial drugs and screening protocols have been displayed for its prevention.[3]
Objectives: To evaluate CQ/HCQ ocular toxicity and to identify potential predictors of appearance. Also to asses screening protocols compliance.
Methods: Demographic, diagnostic and treatment data were collected from patients under CQ or HCQ treatment in the Clinical University Hospital in Santiago de Compostela (Spain) during the first wave of the COVID-19 pandemic (January to April 2020).
Univariable logistic regression was performed to identify potential predictors of maculopathy. Variables with p<0.20 were selected for multivariable testing.
Stata 15.1 was used to perform statistical analysis.
Results: 503 patients taking CQ/HCQ were identified. 495 were women. Most frequent diagnosis were SLE (48.28%), cutaneous lupus (22.85%) and rheumatoid arthritis (RA, 12.54%). Mean age at diagnosis was 44.99 years (SD 17,88). 93.33% of patients were under treatment with HCQ. Mean age at beginning of CQ/HCQ treatment was 48.10 years (SD 17.79) and mean time between diagnosis and CQ/HCQ onset was 2.03 years (SD 5.50). Mean maximum HCQ dosage per patient was 3.83 mg/kg (SD 1,59; 252.57 mg per day, SD 89.98) and CQ was 3.24 mg/kg (SD 1,91; 219.49 mg per day, SD 103.90). Mean time under CQ/HCQ treatment was 6.39 years (SD 5.63). 20 patients developed maculopathy. Mean time between CQ/HCQ onset and maculopathy appearance was 2.67 years (SD 3.10). Only 25 patients did not complete ophthalmologic exams for maculopathy screening.
After univariable analysis, higher age at diagnosis and age at beginning of CQ/HCQ treatment were identified as potential predictors of maculopathy (p<0.20). After multivariable analysis, both higher age at diagnosis and higher age at CQ/HCQ onset were identified as predictors for suffering maculopathy under treatment with CQ/HCQ (OR 1.06 [CI95% 1.03-1.10] p=0.000 and OR 1.09 [CI95% 1.02-1.16] p=0.008, respectively).

Conclusion: Ocular toxicity remains as one of the most harmful and disabling adverse events in patients under CQ/HCQ treatment. Higher age at diagnosis and higher age at beginning of treatment appear to be risk factors for maculopathy appearance. Screening protocols are well-assumed by patients and seemed to be helpful for preventing and early identifying events. CQ/HCQ usage in COVID-19 patients should be individualized, specially in older patients, and protocols involving ocular toxicity should be implemented in the follow-up of this population.

AB0295 TREATMENT OF HIGH RISK/REFRACTORY OBSTETRIC ANTIPHOSPHOLIPID SYNDROME. A SINGLE CENTRE EXPERIENCE

A. Hoxha[1], P. Marson[2], M. Favaro[3], M. Tonello[3], M. Zen[3], T. Del Ross[3], A. Calligaro[3], A. Ruffatti[4]. [1]*San Bortolo Hospital, Department of Medicine, Vicenza, Italy*; [2]*University-Hospital of Padua, Padua, Italy, Apheresis Unit, Blood Transfusion Service, Padua, Italy*; [3]*University Hospital of Padua, Padua, Italy, Department of Medicine, Rheumatology Unit, Padua, Italy*; [4]*University Hospital of Padua, Padua, Italy, Department of Medicine, Padua, Italy*

Background: The most efficacious strategy to manage pregnant patients with antiphospholipid syndrome (APS) who are at high risk of adverse pregnancy outcomes ± refractory to conventional heparin/low-dose aspirin treatment is currently unknown (1, 2).

Objectives: The purposes of this study were to investigate the efficacy and safety of a second-line treatment protocol administered in addition to twice daily low molecular weight heparin and low-dose aspirin to pregnant patients affected with high-risk ± refractory primary APS.

Methods: Patients were included in the study if satisfying the following criteria were: 1) the presence of triple antiphospholipid antibody positivity (IgG/IgM anticardiolipin + IgG/IgM anti-β2 Glycoprotein I antibodies + lupus anticoagulant), 2) previous thrombosis and/or a history of one or more early and severe pregnancy complications. The second-line treatment protocol included weekly plasmapheresis or immunoadsorption and fortnightly 1g/kg intravenous immunoglobulins.

Results: Twenty-four pregnancies occurring between 2002 and 2019 in 19 primary APS patients, (mean age 35.1 ± 3.5 SD) were monitored. Triple antiphospholipid positivity was detected in all 19 cases (100%). Seven of these women (36.8%) had a history of thrombosis, five (26.3%) one or more previous failed pregnancies associated to severe pregnancy complications and seven (36.8%) both clinical criteria. Twenty-three pregnancies (95.8%) produced live neonates (13 females and 10 males), all born between the 26th and 38th week of gestation (mean 33.6 ± 3.5 SD); birth weight percentile was 35.8 ± 24.1 SD and mean Apgar score at 5min 8.7 ± 1.1 SD. Due to premature birth (24th week) complicated by fetal sepsis, one pregnancy (4.2%) had a negative outcome. During the treated pregnancy there were no episodes of thrombosis; there were five cases (20.8%) of severe maternal complications during pregnancy or puerperium and four of fetal complications (16.6%), all followed by complete recovery after delivery. No side-effects of the treatment were registered.

Conclusion: Given the high live birth rate and the safety associated to it, the second-line treatment protocol described here could be taken into consideration when the treatment of a high-risk APS pregnancy ± refractory to conventional therapy is being evaluated.

AB0296 PASSIVE TRANSFER OF ANTI-SSA, ANTI-Ro52, AND ANTI-MITOCHONDRIAL M2 FROM INTRAVENOUS IMMUNOGLOBULIN PRODUCTS TO PATIENTS WITH RHEUMATIC DISEASES

L. J. Yang[1], H. G. Li[1], A. Q. Zeng[1], Z. M. Ouyang[1], X. N. Wei[1], Q. H. Li[1], D. H. Zheng[1], L. Dai[1], Y. Mo[1]. [1]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China*

Background: Passive transfer of ANA and anti-SSA has been reported in patients with common variable immunodeficiency disorder who received intravenous immunoglobulin (IVIG). IVIG is also recommended to treat some special or life-threatening rheumatic diseases.

Objectives: This study was aimed to explore whether any extractable nuclear antibodies (ENAs) were transferred to these rheumatic patients who received IVIG therapy.

Methods: IVIG products of three batches were tested for ANA by using indirect immunofluorescent assay, and for ENAs by using line immunoassay (LIA) and chemiluminescence immunoassay (CLIA). These IVIG products were administrated to rheumatic patients at a dose of 20g/d×3 days (day1 to day3). Serum samples of these patients before IVIG (day0) and after IVIG (day4, day8, day10, day12, and more than one month) were tested by using LIA and CLIA. Anti-SSA was also detected using ELISA.

Results: In these IVIG products, ANA was positive at a titer of 1:640 (cytoplasmic speckled) and 1:80 (speckled). Among 14 types of ENAs that could be tested using LIA, anti-SSA, anti-Ro52, anti-mitochondrial M2, and anti-centromere B antibodies were clearly detectable in IVIG products (Table 1). Likewise, another assay CLIA also detected the same positive autoantibodies in these products. LIA showed the highest concentration in anti-mitochondrial M2, while CLIA showed the highest concentration in anti-mitochondrial M2 and anti-Ro52. One 31-year-old male patient who was diagnosed as SLE (Figure 1) and one 72-year-old male patients who was diagnosed as necrotizing myositis received these IVIG products. Anti-SSA, anti-Ro52, anti-mitochondrial M2, but not anti-centromere B, were positive in the day4 serum samples, although all of these antibodies were negative at baseline (day0). The concentration of these antibodies decreased gradually as days passed and became undetectable around one month after IVIG.

Table 1. The concentration of autoantibodies in intravenous immunoglobulin products

	anti-SSA	anti-Ro-52	anti-mitochondrial M2	anti-centromere B	Cut-off
LIA(grey value)	20±3	28±3	69±10	19±4	≥11
CLIA (U/ml)	333±107	444±86	434±66	390±89	>20
ELISA (U/ml)	90±13	NA	NA	NA	>20

LIA, line immunoassay; CLIA, chemiluminescence immunoassay; ELISA, enzyme linked immunosorbent assay

Conclusion: This study preliminarily reported transient positivity of anti-SSA, anti-Ro52, and anti-mitochondrial M2 in rheumatic patients maybe because the passive transfer of these antibodies from IVIG products to the patients, although the potential influence of this transfer on the rheumatic diseases remained unknown.

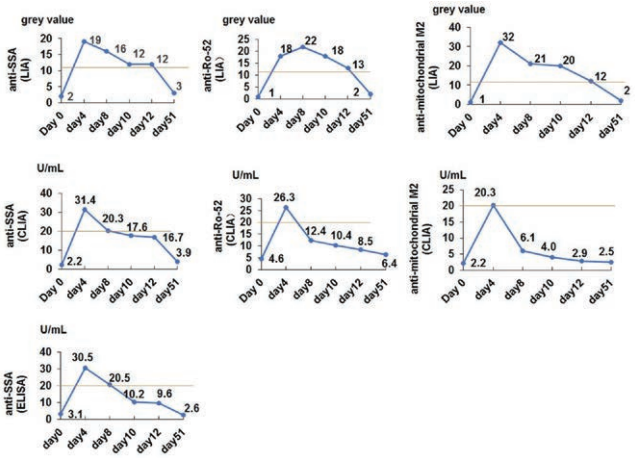

Figure 1. The concentration of autoantibodies in a 31-year-old male SLE patient receiving intravenous immunoglobulin at a dose of 20g/d×3 days (day1 to day3). Serum samples of these patients before IVIG (day0) and after IVIG (day4, day8, day10, day12, and day51) were tested by using line immunoassay (LIA) and chemiluminescence immunoassay (CLIA). Anti-SSA was also detected using ELISA. The horizontal red lines were the corresponding cut-off values of each assay.

SLE, Sjögren's and APS - clinical aspects (other than treatment)

AB0297

MORTALITY AND DISEASE RELATED COMORBIDITIES IN SYSTEMIC LUPUS ERYTHEMATOSUS: DATA FROM AN EGYPTIAN COHORT WITH SYSTEMIC LUPUS ERYTHEMATOSUS-PHASE I

R. Hamdy Abdellatif Mohammed[1], H. Lotfy Fayed[2], N. Emara[2]. [1]*School of Medicine- Cairo University, Rheumatology and Rehabilitation, Gizah, Egypt*; [2]*School of Medicine- Cairo University, Rheumatology and Rehabilitation, Cairo, Egypt*

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune disorder with considerably high mortality.
Objectives: To investigate the survival rates 5, 10, 15 and 20 years and the impact of disease related morbidity and mortality among Egyptians patients afflicted by SLE.
Methods: This is a single center observational study performed in one of the leading medical school governmental hospital for teaching and training in the north African region and middle east sectors Kasr Alainy School of Medicine-Cairo University. Medical records of adult SLE patients ≥ 16 years (classified according to ACR 1997 SLE classification criteria set forth by Hochberg, 1997) who received longitudinal clinical care during the time period from 1999 to 2019 were included. Data analysis: causes of mortality, damage score and survival were determined from the time of SLE diagnosis to the last contact or date of death.
Results: Records of two hundred and two SLE patients were included, 91.1% were females and 8.9% patients were males (ratio is 10:1). The mean age at diagnosis 26.71 ± 7.93 years with a mean follow up between mean: 6.6 ± 4.58 years, 34.15% had damage in at least one of the organ systems by SLICC/ACR-DI in the first 6 months. Considering an outcome label of dead or alive at the end of follow up period, results showed a total of 52 mortalities, 88.5% were females, the mean age at death onset was 30.9±8.8 years. Results identified the following death causalities in the studied SLE patients in order of frequency: Septic shock and disseminated intravascular coagulation in 11.5 %, acute respiratory distress syndrome ARDS in 11.5 %, congestive heart failure in 9.6%, thrombotic microangiopathy 5.7%, cerebritis, acute renal failure 5.7%, intracranial hemorrhage 5.7%, hypertensive encephalopathy in 5.7%. Alveolar hemorrhage, infection, intraoperative deaths each contributed to deaths in 3.8%. Hypovolemic shock, acute liver failure, brain edema, thrombotic thrombocytopenic purpura, end stage kidney disease, pulmonary renal syndrome, suicide and acute hydrocephalus contributed to fatalities in 1.9%. The cause of death was unclearly identified in 26.9%. Results of the Kaplan Meier survival curve in the studied SLE cohort showed an overall cumulative probability of survival at 5, 10, 15 and 20 years after SLE diagnosis was 82.9%, 68.8%,51.4% and 20.4%, respectively. Multivariate regression analysis revealed psychosis, chronic kidney disease and heart failure were independent predictors of survival (HR= 4.3 times, 3.58 times and 3 times respectively, $p < 0.001$), while the use of hydroxychloroquine and AZA showed a protective effect.

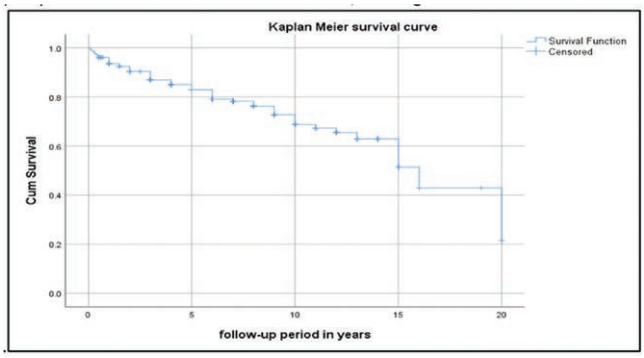

Figure 1. Kaplan-Meier estimated survival function, starting at date of SLE diagnosis.

Conclusion: The cumulative probability of survival at 5, 10, 15 and 20 years after SLE diagnosis was 82.9%, 68.8%,51.4% and 20.4%, respectively. The presence of renal manifestations, neuropsychiatric lupus and heart failure were independent predictors of poor survival in our cohort. The use of hydroxychloroquine and AZA were protective.

PREGNANCY IN RHEUMATIC DISEASE: A REGION WIDE SURVEY OF CURRENT PRACTICE AMONGST CLINICIANS IN THE WESSEX MULTI-DISCIPLINARY CONNECTIVE TISSUE DISEASE NETWORK

L. Parker[1], A. Mason[2], M. Coleman[3], B. Davidson[2]. [1]*University Hospitals Dorset NHS Foundation Trust, Rheumatology Department, Christchurch, United Kingdom*; [2]*University Hospital Southampton NHS Foundation Trust, Rheumatology Department, Southampton, United Kingdom*; [3]*University Hospital Southampton NHS Foundation Trust, Maternal Medicine Department, Southampton, United Kingdom*

Background: Rheumatic diseases frequently affect females of child-bearing age, with implications for foetal and maternal outcomes.
Two-thirds (66%) of the women who died in the 2016-18 MBRRACE report were known to have pre-existing medical problems[1]. The NHS long-term plan supports creation of Maternal Medicine Networks to facilitate access to specialist care and advice in pregnancy.
Guidelines exist for use of disease modifying anti-rheumatic drugs (DMARDs) during pregnancy but other aspects of pregnancy related care in rheumatic disease remain less well defined. The Wessex wide connective tissue disease (CTD) network provides a multi-disciplinary forum to discuss cases, to obtain approval for high cost drugs, to compare practice in multiple hospitals but does not specifically discuss pregnancy related uncertainties.
Objectives: To survey variations in clinical practice relating to rheumatic disease in pregnancy
Methods: Following careful project planning with the tertiary referral centre obstetric lead consultant for maternal medicine, several areas of care were identified which were prone to local and individual variation. An anonymous online survey relating to these specific areas of pregnancy related care was circulated amongst members of the CTD network, including rheumatology consultants, rheumatology practitioners and specialist trainees.
Results: 16 responses were obtained across 7 hospital sites; 56% were from rheumatology consultants. 12/16 (75%) reported routinely offering contraceptive advice when prescribing DMARDs. Only 4/16 (25%) were aware of a specific pre-natal obstetric clinic available in their hospital. There was major variation in planned frequency of clinical review. 10/16 would increase frequency of review during pregnancy if a patient's disease became active or unstable; 6/16 would aim to review patients approximately 3 monthly; 3/16 would not routinely increase frequency of review during pregnancy. Planned post-natal care was equally varied. 3/16 would routinely prescribe aspirin to all lupus women during pregnancy despite this being recommended for all women with SLE for prevention of pre-eclampsia[2]. Prescription of low molecular weight heparin was variable, and several responses were at odds with the current RCOG guidance on the subject[3]. 8/16 (50%) would prescribe corticosteroids judiciously in case of an acute disease flare.
Conclusion: This survey has revealed significant variation in practice relating to rheumatic disease in pregnancy. Integrated care with colleagues from the regional referral centre for maternal medicine is required, in keeping with the recently published NICE guidance on the subject[4]. Adopting a hub and spoke model, with local centres working closely alongside a tertiary centre, will help optimise peri-partum care and outcome for patients with long-term rheumatic conditions.

AB0299 QUANTITATIVE EVALUATION OF PROTEINURIA WITH URINALYSIS TEST AND COMPARING ITS CORRELATION WITH RANDOM SPOT URINE PROTEIN-CREATININE RATIO AND 24 HOUR URINE PROTEIN IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS –A SINGLE CENTRE EXPERIENCE IN MALAYSIA

C. R. Ng[1], Y. L. Loh[1]. [1]*Sultan Ismail Hospital, Rheumatology Unit, Johor Bahru, Malaysia*

Background: Lupus nephritis is an important concern among Systemic Lupus Erythematosus (SLE) patients in Asia and its mortality rate was reported to be 6 times higher compared to the general population [1]. Without prompt treatment it can lead to end stage renal failure and affect quality of life. 24 hour urine protein collection has long been used as the gold standard test to assess proteinuria. However due to its cumbersome process random spot urine protein-creatinine ratio is used as an alternative to replace the former in some centres before subjecting patients to renal biopsy. In a study done by Matar HE et al in 2012, he showed that there was a significant correlation between 24 hour urine protein and urine protein creatinine ratio in his 95 subjects [2].
Urinalysis is a semi-quantitative screening tool for early detection of potential kidney disorders. A survey done by Siedner MJ et al on practice preferences among American Rheumatologists in 2005 reported that 64.6% of them preferred to use urinalysis as the primary tool to screen for proteinuria [3].
Objectives: To assess the correlation of urinalysis test with random spot urine protein-creatinine ratio PCR) compared with 24 hour urine protein.
Methods: This was a retrospective study. The electronic medical records of all SLE patients seen in the rheumatology clinic of Hospital Sultan Ismail from 1/1/2017 to 31/12/2020 were reviewed. Patients who had urinalysis, urine protein creatinine ratio and 24 hour urine protein tests done were identified. Data on demography, urinalysis, random spot urine protein creatinine ratio and 24 hour urine protein were obtained and analysed.
Results: There were a total of 131 patients and 124 were females. The majority were Malays (75/131) followed by the Chinese (45/131),Indians (9/141) and others (2/131). The mean age group for the studied subjects was 34 (13-67). The urinalysis test showed that 34 of them had negative results, 37 of them had urine protein of 1 +, 18 of them had urine protein of 2+ followed by 23 patients with urine protein of 3 + and the rest had urine protein of 4+. The correlation between urinalysis and 24 hour urine protein was strong (r = 0.702), whereas the correlation between urinalysis and urine PCR ratio was stronger (r = 0.797).
Conclusion: We conclude that urinalysis correlates well with both random spot urine protein creatinine ratio and 24 hour urine protein and the correlation is stronger with urine PCR.

AB0300 LUPUS DISEASE ACTIVITY CORRELATES WITH QUALITY OF LIFE BUT NOT WITH HEALTH LITERACY STATUS

E. Eraslan[1], R. Bilici Salman[2], H. Satış[2], A. Avanoglu Guler[2], H. Karadeniz[2], H. Küçük[2], S. Haznedaroglu[2], M. A. Ozturk[2], A. Tufan[2], B. Goker[2]. [1]*Gazi University Faculty of Medicine, Internal Medicine, Ankara, Turkey*; [2]*Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease of unknown etiology that can affect any organ of the body. SLE is associated with adverse effects on both health and non-health-related quality of life (HRQOL and non-HRQOL). Lupus PRO is a patient reported outcome measure that has been validated in many languages. It has 44 items that cover both HRQOL and non-HRQOL (1). Health literacy is defined as the degree to which individuals have the capacity to obtain, process and understand basic health information and services needed to make appropriate health decisions. Multiple studies indicate that people with limited health literacy have worse health status and higher rates of hospitalization (2).
Objectives: We aimed to evaluate the relationship between the LLDAS (Lupus Low Disease Activity State) criteria and the Lupus PRO test, as well as the health literacy status of lupus patients.
Methods: 83 SLE patients (94% women) were included in the study. We performed Lupus PRO and the European Health Literacy Survey tests during the routine follow-up visits of lupus patients to our rheumatology outpatient clinic and admissions to rheumatology inpatient clinic. Available clinical data on medical records were obtained, physician global assessments (PGA) were recorded by the attending physician.
Results: LLDAS criteria strongly and inversely correlated with the total score, as well as the mood subunit of the Lupus PRO. Similarly, it also significantly inversely correlated with the body appearence and goals subunits. Health literacy status of the patients did not correlate with their LLDAS scores, ie their disease activities.
Conclusion: Our results suggest that lupus disease activity, assessed by LLDAS criteria, significantly correlates with measures of quality of life, spesicifically Lupus PRO test, but not with health literacy status. Further studies are needed to evaluate if health literacy is related with damage, hospitalization or mortality associated with lupus.

AB0301 CRITERIA FULLFILLMENT OF PRIMARY SJÖGREN'S SYNDROME ACCORDING TO TIME OF EVOLUTION OF SICCA SYMPTOMS

C. M. Gamboa-Alonso[1], D. Vega-Morales[1], J. C. Riegatorres[1], B. R. Vázquez Fuentes[1], L. Á. Ceseñas-Falcón[1], G. Figueroa-Parra[1], D. Á. Galarza-Delgado[1]. [1]*Universidad Autónoma de Nuevo León, Reumatología e Inmunología Clínica, Monterrey, Mexico*

Background: Primary Sjǒgren´s Syndrome (PSS) is an autoimmune disease characterized by sicca symptoms, autoantibodies and lymphocytic infiltrate in exocrine glands.
Classification and diagnosis of PSS is performed by applying 2002 AECG, 2012 ACR or 2016 ACR-EULAR criteria.
Time of evolution of symptoms has been associated with different clinical, serological and pathology findings.
Objectives: Document sicca profiles and compare findings according to time of evolution of symptoms.
Methods: A descriptive retrospective observational study was performed in 116 patients with sicca symptoms in a Rheumatology center in México.
Patients were separated according to time of evolution of sicca symptoms in ≤1 year, ≤2 years, ≤3 years, and ≥3 years. Clinical, serological, and histopathology features were assessed at each established time.
Time from symptom onset to diagnosis was reported in median and interquartil range (IQR); age at symptom onset and age at diagnosis was expressed in mean and standard deviation (SD).
Patients were classified as PSS if they fullfilled the 2002 AECG or 2016 ACR-EULAR criteria. Serology of Rheumatoid factor (RF), ANA, Anti-Ro, and Anti-La were documented.
Description of MSGB was performed reporting presence of foci, lobules, atrophy, adipose tissue infiltration and ductal dilatation.
Results: One hundred and sixteen sicca patients had a complete profile and 97 (83.62%) fulfilled AECG 2002 SSP criteria. Eighty-two (70.6%) patients with an ocular staining score were able to classify as PSS using the 2016 ACR-EULAR criteria.
Of the sicca cohort, 112 (96.6%) were female. The mean age of symptom onset was 48.4 (SD 13.11) years, and the mean age at diagnosis was 53.33 (SD 12.43) years. The median time from symptom onset to diagnosis was 36 (IQR 12-84) months.
Fullfilment the 2002 AECG PSS classification criteria according to duration of sicca symptoms is described in Table 1.

Table 1. Classification PSS criteria according to time of evolution of sicca symptoms

	<12 months	<24 months	<36 months	>37 months	
Oral symptoms	28%	40%	48%	89%	
Ocular symptoms	26%	39%	47%	93%	
Altered Salivary flow rate test	21%	32%	41%	81%	
Altered Schirmer test	19%	28%	38%	75%	
Positive Anti Ro	13%	19%	26%	47%	
Positive Anti La	3%	6%	10%	16%	
≥1 foci score/4mm2	14%	24%	34%	67%	
2002 AECG Criteria*	22%	34%	44%	84%	
*AECG-American European Consensus Group					
	0%	25%	50%	75%	100%

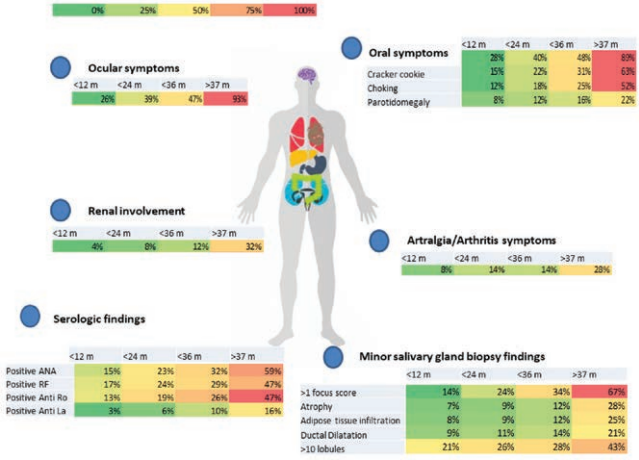

Figure 1. Clinical, serologic and histopathologic findings according to sicca symptom duration

Extra-classification criteria such as severe oral symptoms (choking, cracker cookie) were more common with prolonged symptom duration. Figure 1
Conclusion: The probability and capability of fulfilling PSS criteria is time dependent, this should be taken into consideration when evaluating patients referring sicca symptoms. Longer symptom duration was associated with more severe clinical, serological and histopathology profiles.

AB0302 FACTORS ASSOCIATED WITH GESTATIONAL DIABETES MELLITUS (GDM) IN A MULTI-ETHNIC SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) COHORT

S. S. Shaharir[1], R. Mustafar[2], M. S. Mohamed Said[1], R. Abd Rahman[3]. [1]*Universiti Kebangsaan Malaysia Medical Centre, Rheumatology Unit, Department of Medicine, Cheras, Malaysia*; [2]*Universiti Kebangsaan Malaysia Medical Centre, Nephrology Unit, Department of Medicine, Cheras, Malaysia*; [3]*Universiti Kebangsaan Malaysia Medical Centre, Obstetrics and Gynaecology, Cheras, Malaysia*

Background: The risks of insulin resistance and diabetes mellitus are elevated in systemic lupus erythematosus (SLE) patients. The use of glucocorticoid and anti-double stranded DNA antibodies positive are among the factors reported to be associated with the risk of gestational diabetes mellitus (GDM) in SLE patients. However, the relationship between GDM in Asian SLE patients is still obscure.
Objectives: To determine the prevalence of gestational diabetes mellitus (GDM) in a multi-ethnic SLE cohort in Malaysia and the associated risk factors.
Methods: This was a retrospective study of SLE pregnant women who have completed their antenatal care in Universiti Kebangsaan Malaysia Medical Centre (UKMMC) from 2004 until 2019. Screening and diagnosis of gestational diabetes mellitus (GDM) were as recommended in the guidelines by the Ministry of Health Malaysia. Information on SLE disease activity and treatment at 6 months before pregnancy and during pregnancy were determined from the medical records. Univariate and multi-variable logistic regression analyses were performed to determine the factors associated with GDM in the SLE patients.
Results: A total of 89 patients with 202 pregnancies were included in the study. Malay was the predominant ethnic in this cohort (n=82, 67.2%), followed by Chinese (n=33,27.0%) and Indian (n=7, 5.7%). The most common system involvement of SLE was musculoskeletal (n=91, 74.6%), followed by haematological (n=78, 63.9%), lupus nephritis (54.9%, n=67) and mucocutaneous (n=66, 54.1%). The prevalence of GDM was 8.9% (n=18). More patients with GDM had positive anti-cardiolipin IgG antibody (aCL IgG) and lupus anticoagulant (LA) antibody as compared to the patients with no GDM, (55.6% vs 25.8%, p=0.01) and (50.0% vs 25.4%, p=0.05) respectively. On the other hand, the use of hydroxychloroquine (HCQ) in pregnancy was significantly lower in GDM patients (11.1%) as compared to no GDM group (39.1%), p=0.02. There was no significant difference in the ethnicity, SLE system involvement, disease activity status and immunosupressant use including steroid, azathioprine and cyclosporine A at 6 months before and during pregnancy between the GDM and non-GDM group. A forward logistic regression which include aCL IgG, LA and HCQ use in pregnancy, only the HCQ use remained significantly associated with lower risk of GDM in the model with OR= 0.12, 95% C.I = 0.02-0.94, p=0.04.
Conclusion: Our study demonstrates the potential benefit of hydroxychloroquine in reducing the risk of gestational diabetes mellitus in SLE patients. The prevalence of antiphospholipid antibodies particularly aCL IgG and LA was found to be higher among patients with GDM. Further prospective studies are needed to confirm this association.

Nasonova Research Institute of Rheumatology, Moscow, Russia;, Department of Rheumatology, Moscow, Russian Federation*; [4]*V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia;, Laboratory of Medical and Social Problems of Rheumatology, Moscow, Russian Federation*

Background: Classification criteria for SLE need validation and selection of the most advanced ones for clinical practice
Objectives: To validate Systemic Lupus International Collaborating Clinics (SLICC)-12, American College of Rheumatology (ACR)-97 and 2019 European League against Rheumatism/American College of Rheumatology (EULAR/ACR-2019) for Systemic
Lupus Erythematosus classification criteria on a patient cohort from V.A. Nasonova Scientific Research Institute of Rheumatology (Moscow)
Methods: This prospective study included 252 (n=152 with SLE and n=100 non SLE: 74 – with systemic sclerosis (SC) and 26 – with primary antiphospholipid syndrome (pAPS)) patients who were sequentially admitted to the 4th Rheumatology Department from December 2018 to June 2020. All of the patient records were reevaluated by expert rheumatologist in order to determine if they agree with the diagnosis. For every patient, a check-list of SLE-related features was filled out. The association between clinical diagnosis and diagnosis generated on the basis of ACR-97, SLICC-12 and EULAR/ACR-2019classification criteria was assessed. The overall sensitivity and specificity of ACR-97, SLICC-12 and EULAR/ACR-2019 classifications, as well as the sensitivity and specificity according to disease duration was calculated. The predictive value of every criterion in ACR-97, SLICC-12 and 2019 EULAR/ACR classification was assessed using logistic regression analysis and receiver operating characteristic (ROC) curves.
Results: According to ACR-97 criteria, reliable SLE was diagnosed in 131 (86%), according to SLICC-2012 – in 145 (95.3%) and according to EULAR/ACR-2019 – in 144 (94.7%) of 152 patients, respectively. We identified the criteria that were significantly more represented in the SLE-group. The sensitivity and specificity (Table 1) did not change depending on the ANA titers (1/160 and 1/320) and the duration of the disease.

Table 1. The sensitivity and specificity of SLE criteria in 152 SLE patients and 100 non SLE patients

SLE classification criteria	AUC, 95% CI	Cut point	Sensivity	Specifity
ACR-97	0.654 (0.550-0.758)	4	89.7	36
SLICC-12	0.616 (0.505-0.728)	4	93.1	43
2019 EULAR/ACR	0.609 (0.492-0.727)	10*	97.4	48

Note. ACR-97 – American College of Rheumatology classification from 1997; SIICC-12 – Systemic lupus International Collaboration Clinics classification from 2012; 2019 European League Against Rheumatism/American College of Rheumatology. ANA – anti-nuclear antibody more than 1/320 n=116; ANA < 320 n= 36. AUC – area under the ROC curve; Cut point - reference point for the number of criteria, * number of points ≥ 10.

When excluding patients with SC in a single-factor logistic model of patients with SLE and pAPS, indicating the number of criteria, the sensitivity was for ACR-97 - 86, for SIICC-12 - 95, for 2019 EULAR/ACR - 95, the specificity was 100, 62 and 62, respectively.
Conclusion: Evaluation of the criteria by level ANA revealed the highest sensitivity for 2019 EULAR/ACR and SLICC-12, the specificity was low for all three criteria. In the analysis of patients with SLE and pAPS, the sensitivity was highest for 2019 EULAR/ACR and SLICC-12, the specificity was 100 for ACR-97.

AB0304 LEVELS AND TRENDS IN PREMATURE MORTALITY BURDEN DUE TO SYSTEMIC LUPUS ERYTHEMATOSUS IN CUBA

H. Hernández-Negrín[1]. [1]*Universidad de Ciencias Médicas de Villa Clara, Internal Medicine, Santa Clara, Cuba*

Background: Analysis of the causes of premature mortality is an essential function of public health surveillance. A variety of methods have been used to accurately assess and report the level and trends of premature mortality; however, many have significant limitations, particularly in capturing actual early deaths. Years of life lost (YLL) has been recognized as a robust and comprehensive measure of premature mortality.[1] Systemic lupus erythematosus (SLE) is among the leading causes of premature mortality burden in young women in the United States and premature mortality from SLE is increasing in Latin America.[2, 3] However, the premature mortality burden from SLE has not been fully characterized in Cuba.
Objectives: To identify levels and trends in premature mortality burden due to SLE in Cuba during 2001-2018.
Methods: Data were obtained from the mortality database of the Ministry of Public Health of Cuba (International Classification of Diseases-10, code 32 as underlying cause of death). YLL were calculated using the standard life expectancy of the WHO's global health estimates. Age- and sex-specific YLL rates were calculated using the Cuban mid-year population estimates and the age-standardized YLL rate (ASYR) was estimated by the direct method using the WHO's standard population. The 2001-2018 temporal trends were analyzed using Joinpoint software.
Results: During 2001-2018, 1 475 patients died from SLE. These deaths contributed 66 605 YLL (women= 59 166; men=7 433), with a mean of 45.1 YLL per death (women= 45.2; men= 44.5). The 40-44 age group was the most affected in both sexes with 9 266 YLL (women=8 177; men=1 086). The ASYR was higher in 2018 than in 2001 for both sexes (Figure 1). A significantly increasing trend in ASYR due to SLE was identified throughout the period (average annual percent change [AAPC] =1.9; 95% confidence interval [CI] = 0.9 to 3.0), more pronounced in men (AAPC = 7.0; 95% CI = 3.5 to 10.6) than in women (AAPC = 1.3; 95% CI = 0.3 to 2.3).
Conclusion: The high levels and growing trends in premature mortality burden from SLE in Cuba, demands its recognition as an important health problem and immediate actions that help mitigate it.

AB0305 IS THERE HYPERCOAGULATION IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME AND BEHCET'S DISEASE?

N. Seredavkina[1], T. Reshetnyak[1,2], T. Lisitsyna[1], A. Lila[1,2]. [1]*VA Nasonova Research Institute of Rheumatology, Department of Vascular Rheumatology, Moscow, Russian Federation*; [2]*Federal State Budgetary Educational Institution of Further Professional Education "Russian Medical Academy of Continuous Professional Education" of the Ministry of Healthcare of the Russian Federation, Department of Rheumatology, Moscow, Russian Federation*

Background: Whereas antiphospholipid syndrome (APS) is a non-inflammatory vasculopathy and is associated with thrombosis in 98% of cases, Behcet's disease (BD) is a systemic vasculitis of unknown etiology, characterized by vascular damage of any calibre. Both venous and arterial thromboses occur in 45% of BD patients and are associated not with hypercoagulable disease but with inflammatory changes in the vascular wall mediated by hypersecretion of pro-inflammatory cytokines and endothelial cells dysfunction. Thrombodynamics (TD) is a new global test for diagnosing plasma haemostasis disorders, identifying bleeding and thrombosis risks, and can be used to detect a prothrombotic state and assess the influence of disease activity and course on the hypercoagulation process.
Objectives: comparative assessment of TD in patients with APS and BD before anticoagulant therapy (AC).
Methods: The study included 20 patients (9 APS and 11 BD) and 8 age and sex-matched healthy controls (HC). None of the subjects received AC. Thromboses

in past history were registered in 5/9 (55%) APS patients and 2/11 (18%) BD patients and none of HC. Fetal loss occurred only in women with APS (4/4 (100%) who had pregnancy during the disease). All the patients were hospitalized and underwent fool investigation according to the diagnosis including TD, local coagulation tests and antiphospholipid antibodies profile.

Results: the velocity of clot growth in APS was lower, than in BD and in HC: 23.7 [22.6; 24.7] vs 29.0 [28.2; 34.4] and 31.1 [28.9; 33.5] Um/min, respectively (p=0.001). Clot size at 30 minutes in APS also was lower, than in BD and HC: 972.1 [921.3; 1007.4] vs 1152.7 [1098.3; 1225.4] and 1226.6 [1140.5; 1295.1] Um, respectively (p=0.001). Spontaneous clotting was registered only in 2 BD patients in mean time 2 minutes. Clot density and lag time (Tlag, the delay between the test start and the onset of clot formation) were the same in all three groups. Prolonged APTT was found in APS (33.7 [30.6; 47.1] sec) and normal APTT - in BD (30.9 [29.1; 31.1] sec) and HC (29.7 [28.2; 30.8] sec). Increased soluble fibrin-monomer complexes were revealed in all APS patients (100%), 91% BD patients and 25% HC (p=0.01). After interpretation the TD results were distributed as follows: hypocoagulation was noted in 1 APS patient with a positive lupus anticoagulant, while all other APS patients had normocoagulation. Thrombotic readiness status (TRS) was diagnosed only in 2 BD patients. The frequency of normocoagulation and hypercoagulation did not differ between BD and HC. Local coagulation tests (APTT, thrombin time, prothrombin time) were the same depending on hypo- and hypercoagulation by TD results. Fibrinogen level in BD patients with hypercoagulation was higher, than in BD patients with normocoagulation and TRS: 4.2 [3.6; 4.7] vs 2.8 [2.7; 3.0] and 2.8 [2.7;2.8] g/l respectively, p=0.04. BD activity by Behcet's Disease Current Activity Form correlated with stationary velocity of clot growth (R_s = 0.68, p<0.05).

Conclusion: Thrombodynamics results showed: before anticoagulant therapy there were normocoagulation with a tendency to hypocoagulation in APS and hypercoagulation in BD. In BD hypercoagulation associated with disease activity.

AB0306 OBESITY PHENOTYPES IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

L. Kondrateva[1], T. Panafidina[1], T. Popkova[1], M. Cherkasova[2], A. Lila[3], E. Nasonov[3]. *[1]V.A.Nasonova Research Institute of Rheumatology, Department of Systemic Rheumatic Diseases, Moscow, Russian Federation*; *[2]V.A.Nasonova Research Institute of Rheumatology, Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*; *[3]V.A.Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation*

Background: The so-called "obesity paradox" when cardiovascular risk is lower in overweight compared to lean patients accompanies some chronic conditions. A possible explanation for this phenomenon comes from variability of obesity phenotypes, i.e., "classical" obesity as exemplary perception of obesity is equal to increased body mass index (BMI) and metabolic disorders; but there are also "metabolically healthy" overweight individuals (increased BMI without metabolic disorders), and "latent" obesity phenomenon (when normal weight is associated with metabolic disorders, especially with insulin resistance (IR) and adipocytokines imbalance). Serum leptin concentrations increase has been established in obese, therefore, this adipocytokine synthesized in adipose tissue, can be used as a marker of body fat mass. Higher cardiovascular risks are known even in young patients with systemic lupus erythematosus (SLE), but obesity phenotypes have not been studied.

Objectives: To find out the rate of various obesity phenotypes and to identify factors contributing to "latent" obesity in SLE pts without diabetes mellitus (DM) or hyperglycemia.

Methods: A total of 49 SLE pts (46 women, 3 men, 40 [33;48] years old) without established DM or hyperglycemia were enrolled in the study. The median disease duration was 3,0[0,7;8,0] years, SLEDAI-2K was 5[2;8]. SLE pts were treated with glucocorticoids (GC) (84%) and hydroxychloroquine (78%), immunosuppressive drugs (20%) and biological agents (10%). Insulin levels were measured using electrochemiluminescence assay Elecsys (Roche Diagnostics), serum leptin concentrations were estimated using ELISA (DBS-Diagnostics Biochem Canada Inc.). IR was defined as Homeostasis Model Assessment of Insulin Resistance index (HOMA-IR) ≥2,77. Leptin levels were considered elevated at values ≥11,1 ng/ml for women, ≥5.6 ng/ml for men. The overweight / obesity status was determined by World Health Organization criteria in patients with body mass index (BMI) ≥25kg/m^2.

Results: Overweight / obesity were established in 45% of pts, normal BMI was in 55% of SLE pts. The combination of IR and high leptin levels was found in 32% of overweight / obese pts and 11% of pts with normal BMI (p=0,2), an isolated increased leptin levels - in 64% and 41%, respectively (p=0,1). Metabolic disturbances were absent in 4% of overweight pts and 48% of pts with a normal BMI (p=0,001). Thus, "classical" obesity was found in 43% of cases, "metabolically healthy" obesity - in 2%, and "latent" obesity - in 29% of SLE pts. Leptin levels correlated with BMI (r=0,5, p=0,02), waist circumference (r=0,5, p=0,02) in the overweight / obesity group, and with disease duration (r=0,5, p=0,02), SLEDAI-2K (r=-0,6, p=0,002), anti-dsDNA (r=-0,7, p<0,001), C3 complement (r=0,5, p=0,01), maximum (r=0,7, p<0,001) and current GCs doses (r=0,4, p=0,03) in patients with normal weight. There was a trend to association between leptin levels and duration of GCs therapy in SLE pts with normal BMI (r=0,4, p=0,06).

Conclusion: Metabolic disorders - most often increased leptin levels - were diagnosed in the majority of overweight / obese patients, as well as in about 50% of SLE patients with normal weight. There were only isolated cases of "metabolically healthy" obesity in SLE patients. Metabolically obese normal weight ("latent" obesity) phenotype was strongly associated with GCs therapy and decreased disease activity.

AB0307 IS THERE ANY INFLUENCE OF THE ANTIRHEUMATIC THERAPY ON ECHOCARDIOGRAPHIC FINDINGS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS?

T. Panafidina[1], T. Popkova[1], L. Kondrateva[1], A. Volkov[2], E. Nasonov[3], A. Lila[3]. *[1]V.A.Nasonova Research Institute of Rheumatology, Department of Systemic Rheumatic Diseases, Moscow, Russian Federation*; *[2]V.A.Nasonova Research Institute of Rheumatology, Department of Instrumental Diagnostics, Moscow, Russian Federation*; *[3]V.A.Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation*

Background: Cardiovascular diseases are becoming the leading cause of death among SLE patients due to increasing life-spans. Transthoracic echocardiography (TTE) is a routine and widely available modality in everyday clinical practice useful to identify specific pathological cardiac changes and predictors of heart failure.

Objectives: The goal was to identify potential abnormalities in the TTE findings in SLE patients, with and without antirheumatic therapy.

Methods: This is a prospective cross-sectional study including 91pts (91% females, aged 32[28-41]years (median [interquartile range 25%-75%]) with SLE (SLICC 2012 criteria). All patients were divided into 2 groups: the 1st group was composed of "untreated" patients and the 2nd – of patients receiving antirheumatic therapy. The 1st group included 43pts (93% females) aged 31[27–40]years who were not receiving steroids, immunosuppressants and biological agents at the time of enrollment, 5(12%) of them were on hydroxychloroquine (HCQ) therapy 200 mg/day. The 2nd group is represented by 48pts (89% females) with median age 34[28-45]years. Out of them 47(98%) patients were on prednisone therapy at 10[8-15]mg/day, 10(21%)- on cyclophosphamide, 6(13%)-azathioprine, 4(8%)-mycophenolate mofetil, 4(8%)-methotrexate, 37(71%)–HCQ, and 9(19%)–on biologic (rituximab, belimumab). Both groups were matched by age and gender. Patients receiving antirheumatic therapy (group 2) had longer disease duration (96 vs 18 months, p<0,00001), lower disease activity (SLEDAI-2K 4 vs 11 scores, p<0,001), higher SLICC/DI (1 vs 0 score, p<0,001); lower percentage of them had skin lesions (11 vs 57%, p<0,0001), arthritis (22 vs 52%, p<0,05) and hematological disorders (24 vs 74%, p<0,0001) than "untreated" patients from the 1st group.

Results: Valve insufficiency with varying degree of clinically insignificant regurgitation and pericarditis were the commonest pathology found in "untreated" and "treated" SLE patients based on TTE data. No differences in rates of valve insufficiency (95% and 83%), pericarditis (43% and 47%) (both exudative and adhesive), endocarditis (26% and 33%), median left ventricular (LV) ejection fraction (64[59-68]% and 64[61-69]%), LV end-systolic dimension (30[27-32]mm and 29[25-31]mm), LV end-diastolic dimension (48[45-50]mm and 45[42-49]mm), pulmonary artery systolic pressure (25[22-31]mm Hg and 23[22-30]mm Hg), LV diastolic disfunction (26% and 21%) and LV systolic dysfunction (9% and 6%), LV myocardial hypertrophy (14% and 21%) and left atrium dilatation (9% and 21%) were found between the "untreated" SLE patients and patients receiving antirheumatic therapy (p>0,05 for all cases). Higher rates of mitral and tricuspid valves prolapse was seen more often in "treatment-naïv" SLE patients: 16(47%) vs 10(21%), p<0,01.

Conclusion: Valvular dysfunction (insufficiency with clinically insignificant regurgitation), pericarditis, endocarditis and LVDD were the most common cardiac TTE abnormalities in SLE patients. Antirheumatic therapy seems not to worsen structural and functional cardiac abnormalities based on TTE findings in SLE patients. Only mitral and tricuspid valves prolapse was seen more often in "treatment-naïv" SLE patients.

AB0308 COGNITIVE IMPAIRMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME PATIENTS

A. Borisova[1], T. Lisitsyna[2], D. Veltishchev[1], T. Reshetnyak[2], O. Seravina[1], O. Kovalevskaya[1], F. Cheldieva[2], E. Nasonov[3]. [1]*Moscow Research Institute of Psychiatry, Serbsky NMRC PN MoH, Department of mental Disorders in Somatic Diseases, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Vascular Rheumatology, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Scientific Director of the Institute, Moscow, Russian Federation*

Background: Cognitive impairment (CI) in systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) patients have been poorly described and recognized.
Objectives: to describe the rates and spectrum of CI in primary (PAPS) and secondary to systemic lupus erythematosus (SLE) (SAPS) APS patients
Methods: 113 patients (70 with APS (37 – PAPS, 33 – SAPS) and 43 - SLE without APS), 89 (78,8%) – women, were consecutively enrolled in the study. The mean (M±SD) age was 37,9±11,9 years. SLE activity was measured by SLEDAI scale. Mental disorders (MD) were diagnosed by psychiatrist in accordance with ICI-10 in semi-structured interview. CI were diagnosed with psychology and neuropsychology methods
Results: CI of varying severity were found in 105 (92,9%) patients: 62,9% - mild, 23,8% - moderate and 13,3% - severe. Severe and moderate CI were more associated with APS (48,6% in PAPS and 39,5% in SAPS vs 18,6% in SLE, p=0,004 and p=0,04, accordingly). CI were predominantly organic origin in all patients, but vascular dementia was detected only among patients with APS (10,8% of PAPS and 3,03% of SAPS patients). There was no association of CI with clinical manifestations and SLE activity. In patients with PAPS CI was associated with stroke, livedo reticularis and lupus anticoagulant positivity. In 84 patients (74,3%) CI were also specifically bounded to MD. Current MD were detected in 100 (88,5%) patients: schizotypal disorder was found in 10 (8,85%) patients and was associated with PAPS (13,5% vs 9,09% in SAPS and 4,65% in SLE); anxiety-depressive spectrum disorders (ADDs) - in 95 (84,1%) (chronic and recurrent depression prevailed 37 (32,7%) and 42 (37,2%) resp.); the structure of MDs in accordance with ICI-10 differed slightly between groups, but no statistically significant differences were obtained.
Conclusion: cognitive impairment, mainly of an organic type, are characteristic of most patients with SLE and APS. The significant associations of cognitive impairment with clinical manifestations and activity of SLE were not identified, but patients with cognitive impairments were more likely to have anxiety and depressive disorders, strokes, livedo reticularis and lupus anticoagulant positivity

Nasonova Research Institute of Rheumatology, Vascular Rheumatology Laboratory, Moscow, Russian Federation*; [5]*V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases Laboratory, Moscow, Russian Federation*

Background: Vaccination of patients with autoimmune diseases with pneumococcal vaccines is necessary to prevent severe respiratory infections in this group of patients. The main issue of immunization of patients with systemic lupus erythematosus (SLE) remains the issue of safety.
Objectives: The aim of the study was to study the safety of the 23-valent polysaccharide pneumococcal vaccine (PPV-23) in patients with SLE.
Methods: The study included 73 patients with a reliable diagnosis of SLE, of which women - 64, men - 9, aged 19 - 68 years. 69 patients received glucocorticoids (GC) 5-30 mg/day, 55- hydroxychloroquine (GCH), 37-cytostatics (CS), 27 – biologics (14 – rituximab (RTM), 11 – belimumab (BLM), 2-BLM and RTM). 1 dose (0.5 ml) of PPV23 was administered subcutaneously. 60 patients were examined within 1 year, 13 - within 2-3 months.
Results: Vaccination tolerance was assessed in 73 patients: in 33 (45.2%) - vaccine reactions were absent, in 36 (49.3%) - local reactions of mild and moderate severity were noted (pain, swelling, skin hyperemia at the injection site of the vaccine), lasting from 2 to 7 days, in 1 (1.4%) - general weakness within 1 month, in 2 (2.7%) - mild diarrhea within 1 day. Vaccinal reactions were typical and completely reversible, did not require additional appointments. One patient (1.4%) developed a hyperergic reaction of the Artyus phenomenon type, which was arrested within 7 days by the use of antihistamines and topical GCs. None of the 60 patients, whose follow-up period was 1 year, had no exacerbations of the disease directly related to vaccination (i.e., in the next 2-3 months). Vaccination was carried out both at a low degree of activity (n = 33 (55%)) and remission (n = 6 (10%)), and at an average (n = 12 (20%)) and high (n = 9 (15%))) the degree of SLE activity. The dynamics of the SLE activity index SLEDAI-2k (Me) during the year was as follows: initially - 4 (2; 6), after 2-3 months - 2 (2; 4), after 12 months - 2 (2; 4). During the year, 7 out of 60 patients had a moderate exacerbation of the disease, which was not related to the vaccination in terms of timing: after 3.5-5 months (3), 12 months (4). An exacerbation occurred in 4 - with a decrease in the HA dose, in 1 - after psychological stress, in 1 - against the background of persistently high immunological activity and insufficient therapy, in 1 - without an increase in immunological activity. In 4 out of 7, exacerbation was manifested by skin rashes and articular syndrome, in 1 - by the development of panniculitis, in 2 - by leukopenia. All these symptoms were noted earlier in the period of exacerbation. In all, the exacerbation was quickly stopped by a moderate increase in the HA dose. In 60 patients, the dynamics of immunological markers of SLE was analyzed during the year after vaccination. There was no evidence of a significant increase in the immunological activity of SLE after vaccination with PPV-23. After vaccination, no new autoimmune phenomena have been identified. In the first 3 months. after vaccination, in isolated cases, there was a transient increase / decrease in SLE markers (a-DNA, ANF, C3, C4) with a subsequent return to the initial values, without symptoms of exacerbation of the disease.
Conclusion: 1. During the year of observation, no exacerbations were observed that were reliably associated with vaccination. 2. Vaccination with PPV-23 is safe for SLE patients during periods of low and moderate activity. If necessary, vaccination is possible at high activity without the development of adverse events. 3. The multidirectional dynamics of the main markers of SLE observed during the year reflects the instability of immunological parameters characteristic of SLE.

AB0310 TOLERABILITY AND SAFETY OF 23-VALENT POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME, PRELIMINARY RESULTS

G. Tarasova[1], B. Belov[1], M. Cherkasova[2], E. Aseeva[3], T. Reshetnyak[4], N. Kosheleva[4], T. Popkova[5]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory for the Study of Comorbid Infections and Monitoring the Safety of Drug Therapy, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Intensive Therapy Laboratory, Moscow, Russian Federation*; [4]*V.A. Nasonova Research Institute of Rheumatology, Vascular Rheumatology Laboratory, Moscow, Russian Federation*; [5]*V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases Laboratory, Moscow, Russian Federation*

Background: Antiphospholipid syndrome (APS) is an autoimmune disease often associated with severe, life-threatening vascular complications. The majority of patients (and in case of secondary APS, in 100% of cases) receive immunosuppressive therapy. Immunization with pneumococcal vaccines in patients with both primary APS (PAPS) and APS+SLE or secondary (sAPS) is necessary to prevent severe respiratory infections in these patients.
Objectives: Purpose of the study - to study the tolerance and safety of 23-valent polysaccharide pneumococcal vaccine (PPV-23) in patients with PAPS and sAPS.
Methods: At this stage, the study included 28 patients with APS, of which 10 with PAPS, 18 with sAPS proceeding against the background of systemic lupus erythematosus (SLE), of which 23 women (82%), 5 men (18%). The average age (Me) of patients was 43 (35.5; 53.0) g. 20 patients received glucocorticoids (GC) 5-30 mg/day equivalent to prednisone, 17- hydroxychloroquine, 6- cytostatics (3-cyclophosphamide, 2-azathioprine, 1- mycophenolate mofetil), 8- biologics: 5-rituximab (RTM), 3-belimumab (BLM); 20-received anticoagulants (direct-10, indirect-10).
1 dose (0.5 ml) of PPV-23 was administered subcutaneously. The follow-up time was 1 year in 23 patients and 5-5.5 months in 5-5.5 months. During the visits, standard clinical and laboratory tests were performed, immunological blood test and the level of antibodies to S.pneumoniae
Results: Vaccination was well tolerated in all patients. In 29% of cases, vaccine reactions of mild severity were observed: in 7 (25%) - a local reaction (pain in the arm for 1-3 days-at 7, redness up to 2 cm at the injection site-at 1), in 1 (3,6%), the patient experienced general weakness (moderately pronounced) for 1 month. Vaccinal reactions were completely reversible and did not require additional prescriptions. Post-vaccination complications develop, as a rule, in the first 1-2

months after vaccination. During the observation period, none of the patients had an exacerbation of the disease, reliably associated with the vaccination. There was no recurrence of thrombosis, both in patients receiving anticoagulant therapy and without it. No new autoimmune phenomena, both clinical and laboratory, were identified. The dynamics of the production of anti-streptococcal antibodies during the year was followed in 16 patients. One year after vaccination, 31% of patients showed a significant (more than 2-fold compared to the initial) increase in the concentration of antibodies to polysaccharides of the cell wall of S. pneumoniae ("responders"), 69% of patients were "non-responders" to the vaccine. At the same time, all 5 patients with PAPS were "non-responders", and 45.5% "respondents" with sAPS.

Conclusion: Preliminary results show that patients with APS tolerate PPV-23 vaccination well. In the next post-vaccination period, exacerbations of the disease, thrombosis were not recorded. Attention is drawn to the large number of "non-responders" in PAPS, however, to obtain statistically reliable results, it is necessary to continue the study and recruit more patients.

AB0311 INCREASED LEVELS OF SERUM WISTERIA FLORIBUNDA AGGLUTININPOSITIVE MAC-2 BINDING PROTEIN IN RHEUMATIC DISEASES INCLUDING SLE

T. Yoshikawa[1], K. Azuma[1], T. Furukawa[1], M. Tamura[1], T. Hashimoto[1], M. Morimoto[1], N. Azuma[1], K. Matsui[1]. [1]*Hyogo College of Medicine College Hospital, Division of Allergology and Rheumatology, Department of Internal Medicine, Nishinomiya-City, Japan*

Background: Mac-2 binding protein is a cell-adhesive glycoprotein of the extracellular
matrix secreted as a ligand of galectin-3 (Mac-2). Recently, a Wisteria floribunda agglutinin positive-M2BP (M2BP) assay developed using a lectin-antibody sandwich
immunoassay has shown promise as a new fibrotic marker in liver fibrosis and interstitial
lung disease (ILD) to detect unique fibrosis-related glycoalteration.

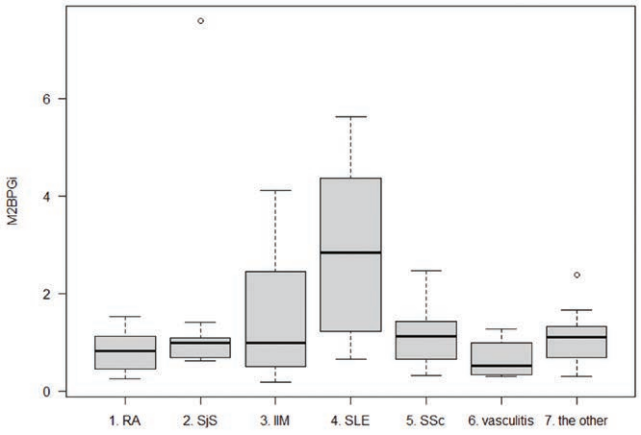
Objectives: The aim of this study is to evaluate the utility of serum Mac-2 binding protein glycosylation isomer (M2BPGi) levels in patients with rheumatic diseases (RD).

Methods: We retrospectively measured serum M2BPGi levels in 68 patients with RD and 16 healthy controls (HC). There were no patients of cirrhosis and active hepatitis. Serum levels of M2BPGi were measured using HISCL M2BP glycosylation isomer Assay Kit. We examined the relationship between serum M2BPGi levels and clinical parameters in patients with RD.

Results: In patients with RD, the median age was 62.0 years and 79.4% of them were female.

Serum M2BPGi levels were significantly higher in patients with RD than in HC (median 0.98 cutoff index [COI], 0.32 COI, respectively; $P < 0.00001$). Patients with SLE tended to have higher serum M2BPGi levels than other rheumatic diseases.

In patients with RD, a significant correlation was not found between serum M2BP levels and inflammation markers such as CRP or ferritin. However, serum M2BPGi levels were significantly correlated with B cell activation markers such as immunoglobulin free light chain and IgG ($r = 0.588$, 0.504) and T cell activation marker such as sIL-2R ($r = 0.408$).



Conclusion: Most of the rheumatic diseases in this study were considered to be type I interferonopathy diseases such as rheumatoid arthritis, Sjogren's syndrome, inflammatory myositis, scleroderma and SLE.

Serum M2BPGi was reported to have a significant correlation with SLE disease activity [SS Ahn et al. Lupus. 2018; 27: 771], and also to have a significant correlation with Gakectin-9, a novel biomarker for IFN signiture [Lucas L van den Hoogen et al. Ann Rheum Dis. 2018; 77: 1810].

So, it was suggested that serum M2BPGi may be a novel biomarker that indirectly indicates how much IFN is activated in rheumatic diseases.

AB0312 INCREASED PREVALENCE OF OBSTRUCTIVE SLEEP APNEA IN INDIVIDUALS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

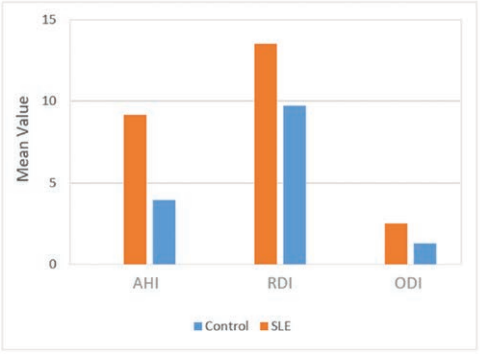
R. Meidan[1,2], D. Paran[2,3], R. Tauman[2,4], V. Furer[2,3], T. Eviatar[2,3], D. Levartovsky[2,3], A. Polachek[2,3], J. Wollman[2,3], H. Padova[2,3], M. Zisapel[2,3], M. Anouk[2,3], E. Seyman[2,5], O. Elkayam[2,3], O. Elalouf[2,3]. [1]*Tel Aviv Sourasky Medical Center, Internal Ward B, Tel Aviv, Israel*; [2]*Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel*; [3]*Tel Aviv Sourasky Medical Center, Rheumatology, Tel Aviv, Israel*; [4]*Tel Aviv Sourasky Medical center, Sleep Medicine Center, Tel Aviv, Israel*; [5]*Tel Aviv Sourasky Medical Center, Neurology, Tel Aviv, Israel*

Background: Sleep disturbances are common in individuals with rheumatological diseases in general and systemic lupus erythematosus (SLE) in particular[1]. Studies suggest that obstructive sleep apnea (OSA) might correlate with SLE disease activity and the presence of additional symptoms such as pain, fatigue, affective symptoms and steroid use[2]. Sleep disturbances symptomatology such as fatigue and increased pain overlap with constitutional inflammatory symptoms of SLE and may mimic or mask disease related relapse[3,4]. Therein lies the importance of diagnosing and treating such disorders in SLE.

Objectives: To determine whether patients with SLE have increased prevalence of OSA as assessed by the apnea hypopnea index (AHI) and to explore possible contributors to OSA including SLE disease activity and accrued damage, medications, secondary fibromyalgia and depression.

Methods: 42 consecutive patients with SLE (38 women, 4 men) and 20 healthy, sex, body mass index (BMI) and age matched controls (15 women, 5 men) were consecutively recruited and underwent an ambulatory sleep study using the WatchPAT device. All participants completed questionnaires including Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), Functional Assessment of Chronic Illness Therapy (FACIT), Widespread Pain Index (WPI), Symptoms Severity Scale (SSS) and Beck Depression Inventory. SLE disease activity and damage were assessed using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and Systemic Lupus International Collaborating Clinics (SLICC) damage index.

Results: The mean AHI was 9.19 ± 6.79 in the SLE group and 3.95 ± 3.47 in the control group ($p=0.004$). Moderate-severe OSA (AHI≥15) was significantly more common in patients with SLE (23.6% vs. 0%, $p=0.04$). Patients with SLE had lower sleep efficiency (83.38 ± 6.15 vs. 87.22 ± 4.24, $p=0.03$), increased sleep arousals (7.72 ± 5.66 vs. 5.13 ± 2.29, $p=0.01$), higher PSQI and FACIT scores SLE (8.14 ± 3.47 vs. 5.10 ± 2.64, $p=0.001$, 16.89 ± 11.19 vs. 7.29 ± 5.93, $p=0.0008$ respectively) and had more fibromyalgia as assessed by WPI and SSS



SLE, Systemic Lupus Erythematosus; RDI, Respiratory Disturbance Index; AHI, Apnea Hypopnea Index; ODI, Oxygen Desaturation Index

(19.5% vs. 0%, p=0.04). BMI and the SLICC score were independent predictors of OSA (p=0.03 and p=0.02 respectively). A correlation between SLEDAI and moderate-severe OSA was found (p=0.03), although an association to medications, secondary fibromyalgia and depression was not found.

Conclusion: Patients with SLE have increased prevalence of OSA with lower sleep quality compared to healthy controls. Our findings suggest a possible correlation between accrued damage as assessed by the SLE damage index and OSA.

AB0313 THE CLINICAL CHARACTERISTICS OF PATIENTS WITH IMMUNE-ASSOCIATED ADVERSE PREGNANCY

W. Su[1,2], Y. Zhuang[1,2], J. Zhu[1,2]. [1]*Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Department of Rheumatology and Immunology, Chengdu, China*; [2]*Chinese Academy of Sciences Sichuan Translational Medicine Research Hospital, Department of Rheumatology and Immunology, Chengdu, China*

Background: Immune-associated adverse pregnancy is the adverse pregnancy outcomes induced by autoimmune factors or autoimmune diseases, including infertility, recurrent spontaneous abortion, failed assisted reproduction, fetal growing restriction. It is helpful to explore the mechanism and improve the management by analyzing the clinical characteristics of patients with immune-associated adverse pregnancy.

Objectives: To find the risk factors of Immune-associated adverse pregnancy by analyzing the clinical characteristics of patients with immune-associated adverse pregnancy.

Methods: The patients involved in this study were from the multi-department clinic of immune-associated adverse pregnancy, during April 2019 and August 2020. They were diagnosed with autoimmune diseases according to relative classification standards or with autoimmune abnormality. Patients with adverse pregnancy due to anatomic, endocrine, infectious and chromosomal factors were excluded.

Results: A total of 107 patients were included. The average age was 29.3 years old. The number of total adverse pregnancy was 115 and the average was 1.07. For the diagnosis, 22 (22.4%) were autoimmune abnormality (with autoantibody but cannot be classified to any autoimmune disease), 30 (28.0%) were antiphospholipid syndrome (APS), 17 (15.9%) were systemic lupus erythematosus (SLE), 13 (12.1%) were mixed connective tissue disease (MCTD), 8 (7.5%) were undifferentiated connective tissue disease, 5 (4.7%) were Sjogren syndrome (SS), other autoimmune disease account for 10 (9.4%). For the antibodies, the positive rate of ANA was 44.8% (48/107), anti-SSA 36.4% (39/107), anti-RNP 15.0% (16/107), anti-dsDNA8.4% (9/107), anti-Sm 9.3% (10/107), anticardiolipin antibody 17.8% (19/107), anti-B2GP1 24.3% (26/107), LA 8.4% (9/107), non-criteria antiphospholipid antibody 3.7% (4/107).

Conclusion: Our data showed that autoimmune abnormality, SLE, APS, MTCD and SS impacted immune-associated adverse pregnancy the most. The most crucial antibodies were ANA, anti-SSA, anti-RNP, anti-dsDNA and antiphospholipid antibodies.

AB0314 SEMAPHORIN 3A LEVELS IN LUPUS WITH AND WITHOUT SECONDARY ANTIPHOSPHOLIPID ANTIBODY SYNDROME AND RENAL INVOLVEMENT

G. S. Kart-Bayram[1], D. Bayram[1], A. Erden[2], S. C. Güven[2], B. Özdemir[2], H. Apaydın[2], A. Omma[2], Ö. Karakaş[2], B. Armagan[2], K. Gok[2], Y. Maraş[2], O. Ateş[3], C. Topçuoğlu[3], O. Küçükşahin[2], S. Erten[2]. [1]*Ankara Şehir Hastanesi, Internal Medicine, Ankara, Turkey*; [2]*Ankara Şehir Hastanesi, Rheumatology, Ankara, Turkey*; [3]*Ankara Şehir Hastanesi, Biochemical, Ankara, Turkey*

Background: In this study, we aimed to evaluate sema3A levels in SLE patients with and without renal involvementor secondary antiphospholipid antibody syndrome (APS), to further elucidate the contribution ofsema3A in etiopathogenesis these conditions

Objectives: Aim of this study is to evaluate sema3A levels in systemic lupus erythematosus patients (SLE) with and without renal involvement and secondary antiphospholipid antibody syndrome (APS).

Methods: SLE patients were grouped according to presence of secondary APS or renal involvement. The control group consisted of age-matched, non-smoker, healthy volunteers. Sema3A levels were compared among groups. All SLE patients were regrouped according to presence of thrombotic events, miscarriages and proteinuria and sema3A levels were investigated. Finally, sema3A levels of all SLE patients as a single group were compared to controls.

Results: The mean sema3A values were 16.16±2.84 ng/dL in the control group, 11.28±5.23 ng/dL in SLE patients without nephritis and APS, 9.05±5.65 ng/dL in SLE with APS group, and 8.53±5.11 ng/dL in lupus nephritis group. When all three patient groups were examined as a single group, mean sema3A value was significantly lower than that of the control group. Sema3A was reduced in SLE patients with thromboembolism and/or miscarriage.

Conclusion: Sema3A levels were lower in all patient groups compared to the control group. Moreover, the reduced sema3A levels in patients with a history of thromboembolism and/or miscarriage suggests that sema3A may play an important role in the pathogenesis of vasculopathy

Table 1. Comparison of sema3A levels between SLE patient groups and control subjects

AB0315 DISEASE DAMAGE ACCRUAL AND LOW BONE MINERAL DENSITY IN FEMALE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Correa Rodríguez[1,2], G. Pocovi-Gerardino[2], J. L. Callejas-Rubio[2,3], R. Ríos Fernández[2,3], S. Delolmo-Romero[1], N. Ortego[2,4], B. Rueda-Medina[1,2]. [1]*University of Granada, Nursing, Granada, Spain*; [2]*Biohealth Research Institute*

in Granada (ibs.GRANADA), Biohealth Research Institute in Granada (ibs.GRANADA), Granada, Spain; [3]*Unidad de Enfermedades Autoinmunes Sistémicas, Servicio de Medicina Interna, Hospital Universitario San Cecilio., Unidad de Enfermedades Autoinmunes Sistémicas, Servicio de Medicina Interna, Hospital Universitario San Cecilio., Granada, Spain*; [4]*University of Granada, Department of Medicine. Faculty of Medicine. University of Granada, Granada, Spain*

Background: Osteoporosis is a common comorbidity in patients with systemic lupus erythematosus (SLE). Available evidence showed that autoimmunity and associated inflammation play main effect in the pathogenesis of negative skeletal effects in SLE patients. However, the potential contribution of disease-associated factors to bone status in SLE is not well known since the reported risk factors from different studies differ greatly.
Objectives: The aim of this study was to examine frequency of reduced bone mass in SLE women, and determine their potential associations with disease activity, damage accrual and SLE-related clinical markers.
Methods: A cross-sectional study including a total 121 Caucasian pre-menopausal and postmenopausal women was conducted (mean age 49.29±12.43 years). The SLE Disease Activity Index (SLEDAI-2K) and the SDI Damage Index were used to asses disease activity and disease-related damage, respectively. Bone mineral density (BMD) of the left femoral neck and lumbar spine (L2–L4) were measured by dual-energy X-ray absorptiometry (Hologic QDR 400).
Results: Ten patients (8.3%) had osteoporosis, 63 (52.1%) patients had osteopenia and 6.8% of women had history of previous fracture. Patients with low bone mass had a significantly higher mean SDI (1.36±1.26 versus 0.70±1.09 p=0.003). T-score at lumbar spine was inversely correlated with SDI score (r=-0.222, p=0.014) and complement C3 level (r=-0.206, p=0.024). Results of bivariate correlations showed that T-score at lumbar spine was inversely correlated with SDI score (r=-0.222, p=0.014) and complement C3 level (r=-0.206, p=0.024). SDI scores were significantly different between patients with osteoporosis, osteopenia and normal BMD after adjusting for age, menstrual status, BMI, time since diagnosis and corticoid use (p=0.004).
Conclusion: There is a high prevalence of low BMD in Caucasian women with SLE and this status of osteopenia/osteoporosis was associated with higher damage accrual scores, supporting that disease damage may itself be a major contributor to the low BMD. SLE women with organ damage require regular bone status monitoring to prevent further musculoskeletal damage. Since diminished BMD is a main comorbidity it is therefore essential to study, monitor and prevent osteoporosis in SLE women to avoid fractures leading to reduced quality of life.

AB0316 ADHERENCE TO THE MEDITERRANEAN DIET AND ITS ASSOCIATION WITH DISEASE ACTIVITY AND DAMAGE ACCRUAL IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Correa Rodríguez[1,2], G. Pocovi-Gerardino[2], J. L. Callejas-Rubio[2,3], R. Ríos-Fernández[2,3], M. Martín Amada[4], M. Cruz-Caparrós[5], B. Rueda-Medina[1,2], N. Ortego[2,6]. Servicio de Medicina Interna. Hospital de Poniente, El Ejido, Spain, Unidad de Enfermedades Autoinmunes Sistémicas, Almería, Spain*; [6]*University of Granada, Department of Medicine. Faculty of Medicine. University of Granada. Avenida de la Investigación, 11, 18016 Granada, Spain., Granada, Spain*

Background: There is limited evidence regarding the impact of the Mediterranean Diet (Med Diet) on autoimmune diseases although it has been proposed that adherence to the Med Diet may decrease the risk of certain autoimmune diseases. However, the potential usefulness of the Med Diet as a high-quality dietary pattern for other autoimmune diseases such as SLE has not yet been investigated.
Objectives: The aim of this study was to evaluate the potential association between the adherence to the Med Diet and disease activity, damage accrual and SLE-related clinical markers in a large cohort of women with SLE.
Methods: In this cross-sectional study, we assessed Med Diet adherence through a 14-item questionnaire in 253 women with SLE (mean age 46.74 ± 12.70 years). The SLE Disease Activity Index (SLEDAI-2K) and the SDI Damage Index were used to asses disease activity and disease-related damage, respectively. Levels of C-reactive protein (CRP; mg/dL), homocysteine (Hcy; mol/L), anti-double stranded DNA antibodies (anti-dsDNA) (IU/mL), complement C3 (mg/dL), and complement C4 (mg/dL) were determined.
Results: The Med Diet adherence score was classified as follows: low adherence (≤ 5 points); medium adherence (6–9 points) and good adherence (≥ 10 points). Only 50.2% of the SLE women had good adherence to the Med Diet. The ANCOVA models showed significant differences between patients with good adherence to the Med Diet and those with medium and low adherence in SLEDAI ($p \leq 0.001$) and SDI ($p \leq 0.001$). Age, medical treatment (immunosuppressors, corticoids, or antimalarials), smoking status, and body mass index (BMI) were included as confounding factors. The odds ratio (OR) for having active SLE (SLEDAI ≥ 5) or the presence of damage (SDI ≥ 1) was lower among patients whose Med Diet score was higher ($p \leq 0.001$).
Conclusion: Adherence to the Med Diet influences disease activity and damage accrual in SLE women. Thus, these patients would benefit from nutritional counselling and education on modification, to help adapt their lifestyles towards the Med Diet pattern. This would help slow the progression of SLE and the damage it causes.

AB0317 ADHERENCE TO MEDITERRANEAN DIET AND NUTRITIONAL STATE IN ITALIAN WOMEN WITH ISOLATED SJÖGREN'S SYNDROME

R. Izzo[1], S. Colafrancesco[1], A. Pinto[2], A. Gattamelata[1], F. Giardina[1], F. Claudia[2], L. M. Donini[2], R. Priori[1]. [1]*Sapienza Università di Roma, Dipartimento di Medicina interna e Specialità Mediche, Roma, Italy*; [2]*Sapienza Università di Roma, Dipartimento di Medicina Sperimentale, Roma, Italy*

Background: The Mediterranean Diet (MD) has anti-inflammatory and immunomodulatory effects[1,2] suggesting a protective role in rheumatic diseases. There is limited knowledge about the eating habits and the nutritional state in patients with isolated Sjögren Syndrome (SS) living within the Mediterranean area.
Objectives: assessment of adherence to the MD and analysis of the nutritional state in women with SS and their correlations with the clinical, laboratory and histological data of the disease.
Methods: patients classified as isolated SS according to AECG criteria 2002[3] who had undergone to minor salivary gland biopsy during the previous twelve months were consecutively enrolled during follow-up visits. The adherence to the MD was assessed by the Med Diet (MDiet)[4] which includes eleven groups of foods; to each group is assigned a value ranging between 0 and 5 based on the frequency of monthly intake. The total score spans from 0 (poor adherence) to 55 (maximum adherence). The level of physical activity was measured by the 6-minutes walking test (6MWT) and by the International Physical Activity Questionnaire (IPAQ). Systemic disease activity was evaluated with the EULAR SS disease activity index (ESSDAI); EULAR SS patient-reported index (ESSPRI) was calculated as well. A subgroup of patients was asked to fill a daily food

diary processed with FOOD CONS software which allows to study in detail their eating habits. Nutritional state, muscle strength and basal metabolic rate were assessed. Alcoholism or drug abuse, diabetes mellitus, specific dietary models, treatment with drugs and/or food supplements with anti-inflammatory and/or antioxidant activity were considered exclusion criteria. Multivariate linear regression was performed with R project for Statistical Computing.

RESULTS:

N= 40	N= 26
Age, median (range)	53 (25-80) 33 (25-71)
BMI, median (range)	21 (19-29.3) 25.1 (19-33.7)
MedDiet score, median (range)	33 (26-43) 33 (23-40)
ESSDAI, median (range)	2 (0-16) 1 (0-16)
ESSPRI, median (range)	6 (0-8.6) 5.3 (1.6-9)
ESSPRI dryness, median (range)	6 (0-10) 6 (2-10)
Focus score, median (range)	2.5 (0-9.6) 1.7 (0.8-6.24)
ASM kg, median (range)	- 16.8 (13.3-21.7)
IPAQ meters, median (range)	- 1386 (99-11865)
6MWT meters, median (range)	- 595 (536-680)

BMI, body mass index; ASM appendicular skeletal mass; IPAQ International Physical Activity Questionnaire; 6MWT, six minute walking test.

MDiet was administered to 40 female SS outpatients. Even if not reaching significativity, patients with a higher focus score in their MSG have a lower value of MDiet score (p = 0.058, r = -1.00). The MDiet score is not associated with ESSDAI (p = 0.85, r 0.02), but only with lower serum levels of C3 (p = 0.004, r = - 0.08).

In 26 patients, daily food questionnaire shows that their diet consists of 43% of carbohydrates while fats represent 40% of total energy intake, the remaining 17% daily energy comes from proteins. Fat consumption is higher compared to the levels of energy and nutrient intake for the Italian population[5]. Six patients had a reduction in muscle mass; sarcopenia is not associated to ESSDAI (p = 0.610). The MDiet score and the amount eaten of polyunsaturated fatty acids (PUFA) were reduced in patients with high value of subscale dryness of ESSPRI (p = 0.057, r -1.21; p =0.610, r -1.00).

Conclusion: This study highlights a lower degree of glandular lymphocytic infiltration (expressed as focus score) in minor salivary glands in patients following MD, so its anti-inflammatory role of seems to be confirmed. SS patients have an unbalanced diet because of a higher intake of fat foods, likely for their lubricating effect. Despite the absence of correlation with objective parameters, the increased dryness in patients with a reduced intake of PUFA arouses our interest in a future study including omega-3 supplementation.

AB0318 RISK FOR CONCOMITANT AUTOIMMUNITY IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME; A SWEDISH COHORT STUDY

N. Karandyszowska[1], J. Oesman[1], H. Alagündüz[1], M. Magnusson[2], E. Svenungsson[1], M. Bruzelius[1], A. Antovic[3]. *[1]Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden*; *[2]Karolinska Institutet, Clinical Chemistry and Blood Coagulation, MMK, Stockholm, Sweden*; *[3]Karolinska Institutet, Department of Medicine Solna, Division of Rheumatology, Stockholm, Sweden*

Background: In patients with the antiphospholipid syndrome (APS), concomitant systemic autoimmune rheumatic diseases (SARD) are common and often associated with more disease associated damage.

Less is known about the prevalence of non-rheumatic autoimmune diseases (NRAID) in patients with APS.

Objectives: To evaluate the incidence and prevalence of concomitant autoimmune diseases (AID) in a cohort of APS patients. The risk of AID was also evaluated with respect to the antiphospholipid antibodies (aPL) profiles.

Methods: This retrospective cohort study comprises consecutive patients identified with APS through review of electronic medical records at Karolinska University Hospital, Sweden between 2014 and 2020. Exclusion criteria were misdiagnosis and age <18. Descriptive statistics was used for baseline data and multivariable Cox proportional hazard regression analysis to investigate the risk factors to develop new onset AID. Ethical approval was obtained from the Swedish Ethical Review Authority (2020-02333).

Results: Of 271 included patients, 66% were women and the median age at diagnosis of APS was 43 years (IQR 31–55). At inclusion, 130 (48%) patients presented with other AID; 101 (37%) of them had a concomitant SARD while 54 (19%) had a NRAID. Systemic lupus erythematosus (SLE) was the most frequent in 30% of patients, followed by autoimmune thyroid disease (ATD) in 10% of patients.

In addition, 35 (13%) APS-patients developed AID during the study period, corresponding to an incidence rate of 28.4 (95% CI; 19.3-40.3) per 1.000 person-years with mean time at risk of 4 (±2) years. Twenty-one (8%) patients developed a SARD and further 14 (5%) were diagnosed with a NRAID.

The cumulative incidence for AID was significantly higher in patients with high titers of IgG aPL. Patients that developed SARD had significantly higher median titers of a-β2GPI IgG isotype, p=0.05. In the NRAID group, median a-β2GPI and aCL IgG isotypes were significantly increased, p=0.02 and p=0.04, respectively. *The hazard ratio to develop diagnosis of AID was significantly increased in patients with high titers of the IgG isotype aPL (HR 2.4 95% CI; 1.1-5.3). Obstetric APS manifestations were associated with a significantly increased hazard ratio of 2.8 (95% CI; 1.1-7.7) to develop SARD, and also trendwise for AID, as a compound variable.*

During the study period, 52 patients had at least one new APS manifestation, as defined by the Sydney criteria (1). In comparison to patients without new manifestations, these patients had significantly higher median titers of aPL of the IgG isotype, and concomitant AID at first visit (p=0.01, p=0.02, respectively).

Conclusion: APS patients are at high risk to develop other AID, and APS patients with concomitant AID had an increased risk to develop new clinical APS manifestations. These findings might be helpful when considering risk stratification and alternate treatment options in this patient group.

AB0319 HEALTH-RELATED QUALITY OF LIFE ASSESSED BY LUPUSQOL IN 1102 LUPUS PATIENTS FROM RUSSIAN FEDERATION (RF), KIRGHIZSTAN AND KAZAKHSTAN (RENAISSANCE COHORT)

E. Aseeva[1], S. Solovyev[1], G. Koilubaeva[2], B. Issayeva[3], M. Saparbayeva[3], N. Nikishina[4], A. Mesnyankina[4], A. Lila[1]. *[1]Rheumatology Federal State Research Institution (FSRI) named after V.A . Nasonova, Intensive Care Department, Moscow, Russian Federation*; *[2]Rheumatology, National Center of Cardiology and Internal Medicine named after Academician M. Mirrahimov (NCCIM), Rheumatology Department, Bishkek, Kyrgyzstan*; *[3]Asfendiyarov National Medical University, City Rheumatology Center, Almaty, Kazakhstan*; *[4]Rheumatology Federal State Research Institution (FSRI) named after V.A. Nasonova, Intensive Care Department, Moscow, Russian Federation*

Background: Health related quality of life (HRQoL) is an aspect that is generally underexplored in the routine clinical practice but it is attracting more and more attention. Lack of concordance between physician derived outcomes of disease activity and patient HRQoL outcomes is commonly found in SLE. This is due to the fact that the former is influenced by the immunologic pathogenic inflammatory mechanisms while the latter may be affected by a variety of psychological, social and co-morbid conditions.

Objectives: The aim of this study was to compare health-related quality of life assessed by LupusQoL in 1102 Lupus patients (pts) from the Russian Federation, Kirghizstan and Kazakhstan (RENAISSANCE cohort).

Methods: 1102 SLE pts who fulfilled SLICC 2012 criteria were enrolled into the study. The SLEDAI 2K index activity, SLICC damage index, and HRQoL using the LupusQoL questionnaire (validated for the Russian-speaking population in 2018) were evaluated. Descriptive statistics, Spearman's correlation coefficients were performed to analyze the data.

Results: 400/600/102 Lupus pts from RF, Kirghizstan and Kazakhstan respectively were studied. The pts were predominantly female (91%/93%/98%) and of indigenous nationality (Russian 83%/ Kirghiz 88%/ Kazakh 76%) with a mean±SD age of 34,2±11,5/35,07±12,2/33,8±10,5 years (p=0,36; p=0,96) respectively. The mean disease duration (Me) in RF/ Kazakhstan was 6 [3;12]/ 5[2;9] years (p=0,15), in Kirgizstan - 2[0,6; 7] years(p≤0,05). Kazakh pts (p=0,00) have higher disease activity (SLEDAI 2K) 17,6±8,8 than Kirghiz pts 15,1±8,3 and Russian pts 9,4±8,1. SLICC damage index 2,39±1,61 in Kazakh pts (p=0,00) was higher than in Russian 1,57±1,54 and Kirghiz 0,79±0,32 pts. 54% pts from RF and 58 % from Kazakhstan had high education. Only 33% pts from Kirgizstan also had high education. 45%/24%/33% pts from RF, Kirgizstan and Kazakhstan respectively had steady employment, 53%/30%/32% pts received disability benefits. HRQoL assessed by LupusQoL was low in all patients with SLE. The mean scores for each of the domains of LupusQoL are shown in Table 1. The statistically significant lowest HRQoL in all 8 domains is obtained among

Kirghiz patients in the comparative analysis of HRQoL in SLE patients of RF and Kazakhstan. The HRQoL was comparable in lupus patients from RF and Kazakhstan. There was a strong correlation between Sum LupusQoL domain and age (r = -0.19), steady employment (r=0,28), high education (r = 0.19), disease duration (r = -0.29), SLEDAI 2K index activity (r = -0.22), SLICC damage index (r = -0.25).

Table 1. HRQoL Assessed by LupusQoL in 1102 Lupus Patients from The Russian Federation, Kirgizstan and Kazakhstan

LupusQoL domains	Russian Federation Mean (SD)	Kazakhstan Mean (SD)	P	Kyrgyztan Mean (SD)	P
Physical health	67,2±23,04	63,1±24,5	0,25	44,6±28,6	0,00
Pain	70,2±24,5	65,2±25,5	0,3	45,9±29,3	0,00
Planning	64,4±28,9	65,9±27,4	0,17	46,5± 31,5	0,00
Intimate	59,3±39,9	58,4±36,7	0,5	57,5±38,5	0,00
relationships					
Burden to others	57,1±27,7	56,6±27,7	0,34	41,1±30,9	0,00
Emotional health	64,9±24,9	65,9±23,4	0,21	48,3±27,9	0,00
Body image	61,4±31,6	62,5±26,5	0,17	57,7±28,6	0,00
Fatigue	63,0±24,8	58,6±26,3	0,16	47,7±28,1	0,00
LupusQoL Sum	63,1±20,4	60,8±20,1	0,25	48,5±23,5	0,00

Conclusion: HRQoL assessed by LupusQoL was low in SLE pts from the RF, Kirgizstan and Kazakhstan. The lowest HRQoL is reported among Kirghiz patients in the comparative analysis of HRQoL with SLE patients in RF and Kazakhstan. The low HRQoL is associated with age, unavailability of work, low education, disease duration, disease activity and damage.

AB0320

CLINICAL FEATURES AND TREATMENT OF 1102 PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN THE RUSSIAN FEDERATION (RF), KIRGIZSTAN AND KAZAKHSTAN IN REAL CLINICAL PRACTICE (RENAISSANCE COHORT)

E. Aseeva[1], S. Solovyev[1], G. Koilubaeva[2], B. Issayeva[3], M. Saparbayeva[3], N. Nikishina[1], A. Mesnyankina[1], A. Lila[1]. [1]*Rheumatology Federal State Research Institution (FSRI) named after V.A . Nasonova, Intensive Care Department, Moscow, Russian Federation*; [2]*Rheumatology, National Center of Cardiology and Internal Medicine named after Academician M. Mirrahimov (NCCIM), Rheumatology Department, Bishkek, Kyrgyzstan*; [3]*Asfendiyarov National Medical University, City Rheumatology Center, Almaty, Kazakhstan*

Background: Clinical features of systemic lupus erythematosus may differ significantly in various regions and are frequently associated with the ethnicity of patients.

Objectives: The aim of this study was to compare clinical features and treatment of patients with systemic lupus erythematosus in the Russian Federation (RF), Kirgizstan and Kazakhstan in real clinical practice.

Methods: 1102 SLE pts who fulfilled SLICC 2012 criteria were enrolled into the study. Disease activity was evaluated by the SLEDAI-2K, and chronic damage by the Systemic Lupus International Collaborating Clinics Damage Index score (SDI).

Results: 400/600/102 Lupus pts from RF, Kirgizstan and Kazakhstan respectively were studied. Pts were predominantly female (91%/93%/98%) with a mean±SD age of 34,2±11,5/35,07±12,2/33,8±10,5 years (p=0,36; p=0,96) respectively. The mean disease duration (Me) in RF/ Kazakhstan was 6 [3;12]/ 5[2;9] years (p=0,15), in Kirgizstan- 2[0,6; 7] years(p≤0,05). Kazakh pts (p=0,00) have higher disease activity (SLEDAI 2K) 17,6±8,8 than Kirghiz pts 15,1±8,3 and Russian pts 9,4±8,1. The higher SLICC damage index 2,39±1,61was in Kazakh pts (p=0,00) as compared to the Russian. Clinical features of 1102 patients with systemic lupus erythematosus in the Russian Federation (RF), Kirgizstan and Kazakhstan are shown in Table 1. Among the Kirghiz, most of the patients were with Neuropsychiatric disorders (33%), vasculitis (27%), serositis (49%) and lupus nephritis (41%). Patients in RF and Kazakhstan were more likely to have arthritis (60%/80%) and mucocutaneus lesions (44%/74%) respectively.

Russian/Kirghiz/ Kazakh pts received corticosteroids per os with duration (Me) 48[18; 106] /24[7,2; 84]/ 37[13; 84] months. The mean±SD dosage was 17,8±12,0/23,2± 19,9/12,33±9,8 mg per day. Among cytostatic drugs, patients in Kirgizstan were prescribed more often cyclophosphamide (64%) and methotrexate (27%). They were prescribed mofetila micofenolate much less frequently (4%) than patients from Russia (20%) and Kazakhstan (46%). Prescription of cyclophosphamide, azathioprine and methotrexate in the Russian and Kazakhstan pts was approximately of the same frequency and ranged from 10 to 23%. Hydroxychloroquine was obtained in 67%/26%/51% Russian/Kirghiz/ Kazakh pts respectively. Disability benefits in RF included payment for biological therapy. Lupus patients in Kirgizstan and Kazakhstan bought biological drugs at their own expense. In RF rituximab was administrated in 34% cases and belimumab -in 10%. In Kirgizstan and Kazakhstan rituximab was administrated in 2% and 6% respectively.

Table 1. Clinical Features of 1102 Patients with Systemic Lupus Erythematosus in the Russian Federation (RF), Kirgizstan and Kazakhstan

Clinical features	Russian Federation n (%)	Kyrgyztan n (%)	Kazakhstan n (%)
Pyrexia	52(13%)	276 (46%)	15 (15%)
Neuropsychiatric	68 (17%)	198 (33%)	34(33%)
Mucocutaneus	176 (44%)	396 (66%)	75 (74%)
Vasculitis	40 (10%)	162 (27%)	4 (4%)
Arthritis	240 (60%)	282 (47%)	81(80%)
Myocarditis	16 (4%)	78 (13%)	-
Serositis	52 (13%)	294 (49%)	12 (12 %)
Lupus nephritis	116 (29%)	246 (41%)	24 (24%)
Leukopenia≤3x10^9	36 (9%)	96 (16%)	6 (6%)
Trombocytopenia ≤ 100X 10 ^{9}	12 (3%)	90(15%)	5(5%)
Anti dsDNA ≥20 Ед\мл	276 (69%)	198 (33%)	80 (80%)
Low complement	200 (50%)	324 (54%)	6 (6%)

Conclusion: Significant differences have been revealed in the Kirghiz patients as compared to those of the RF and Kazakhstan. Disease activity in vital organs was more often revealed in the Kirghiz patients: neuropsychiatric disorders, vasculitis, serositis and lupus nephritis. As a result, they received a higher mean corticosteroids dose and cyclophosphamide was administered more often. Prescription of biological therapy was limited by a high cost of such sort of drugs. In spite of this fact, the highest SLICC damage index was demonstrated by the Kazakh cohort (2,38 score, while the lowest of merely 0,79) was in the Kirghiz cohort.

AB0321

SALIVARY GLANDS ULTRASONOGRAPHY AS A DIAGNOSTIC TOOL IN PRIMARY SJÖGREN'S SYNDROME ON THE RUSSIAN COHORT OF PATIENTS

J. Khvan[1], A. Torgashina[1], B. Chalcev[1], E. Sokol[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Intensive Care of Rheumatic Diseases, Moscow, Russian Federation*

Background: In the international scientific community there has been a long discussion about the role of ultrasound and ultrasound scores for assessing the structure of the salivary glands in Sjögren's syndrome. Stomatological examination according to The American College of Rheumatology (ACR) 2012 classification criteria of primary Sjögren's syndrome (pSS) includes only labial salivary gland biopsy (focus score - FS) and the ACR with European League Against Rheumatism (ACR/EULAR) 2016 criteria include FS and unstimulated saliva flow test (SFT).

Objectives: to compare the diagnostic value of ultrasonography salivary glands (SGUS) with other methods (sialography, stimulated SFT, FS).

Methods: From 2016 to 2020, we examined 94 patients (93 women, 1 man) with the mean age 48.6 ± 14.3 years (minimum 18, maximum 78) with newly diagnosed pSS according to Russian criteria 2001, 86% of patients fulfilled ACR 2012 criteria and 87% - the ACR/EULAR 2016 criteria. All patients underwent classical examination (stomatological, ophthalmological, immunological), and SGUS was performed using GE LOGIQ 9 on the two parotid and two submandibular glands. Ultrasound images were evaluated with the OMERACT SS severity scoring system from grades 0 to 3 (1). Statistical analyses (Spearman coefficient p <0.05) were performed using STATISTICA version 12.

Results: All patients in SGUS had inhomogeneity structure from mild to diffuse with hypoechoic areas from single to multiple. 4 patients had no signs of sialectasia on sialography, however, in ultrasound we found SGUS grade 2. In 5 patients with SGUS grade 0 we determined punctate sialectasia. Detailed characteristics of patients are presented in Table 1.

Table 1.

Parameters	N	%
Oral dryness	78	83,0
Enlargement of parotid salivary glands	32	34,0
Recurrent parotitis	19	20,2
Retention pain	31	33,0
RF positive >2UNL (>30 IU/ml)	51	54,2
anti-SSA (anti-Ro) positive (>25 IU/ml)	81	86,1
anti-SSB (anti-La) positive (>25 IU/ml)	48	51,0
ANA ≥ 1:320	94	100,0
SGUS 0	8	8,5
SGUS 1	1	1,0
SGUS 2	20	21,2
SGUS 3	65	69,1
Stimulated SFT < 2,5ml/5 min	59	62,8
Sialectasia on parotid sialography	90	94,7
Punctate sialectasia	12	12,6
Globular sialectasia	63	66,3
Cavitary sialectasia	10	10,5
Distructive sialectasia	6	6,3
FS ≥ 1foci/4 mm2	83	88,2

Correlation was calculated for each SGUS (0-3) with clinical and classical methods of examination of the salivary glands. Pronounced changes in SGUS 3 correlated with recurrent parotitis r = 0.22 (p = 0.03), enlargement of parotid salivary glands r = 0.23 (p = 0.02) and cavitary sialectasia r = 0.23 (p = 0.02). Histological changes FS ≥ 1 correlated with all grades on ultrasound (SGUS 0 r = -0.24 (p = 0.01), SGUS 1 r = 0.41 (p = 0.000027), SGUS 2 r = - 0.21 (p = 0.03), SGUS 3 r = 0.40 (p = 0.00006)). The punctate sialectasia correlated with SGUS 1 r = -0.28 (p = 0.005) and SGUS 0 r = 0.45 (p = 0.000004). Stimulated SFT didn't correlate with ultrasound changes.

Conclusion: : Probably, in everyday clinical practice, SGUS can be used as an additional method for salivary gland assessment, given the availability and safety of the method. The most convenient system for assessing the salivary glands, at present, is the OMERACT SS severity scoring system, however, now we don't have a score for the complete differentiation in pSS and lymphoproliferative complications.

AB0322 ASSOCIATION OF DEPRESSIVE SYMPTOMS ASSESSED BY BDI II WITH PHYSICAL ACTIVITY IN PATIENTS WITH PRIMARY SJÖGREN´S SYNDROME

S. Beider[1], T. Witte[1], D. Ernst[1]. *[1]Medical School Hanover, Department of Rheumatology and Immunology, Hannover, Germany*

Background: Patients with primary Sjögren´s syndrome (pSS) suffer from pain, oral or ocular dryness and fatigue. Such symptoms can have a detrimental impact on health-related quality of life. The prevalence of mental health disorders in patients with pSS is considerably higher than in the general population [1]. Regular physical activity, such as nordic walking, improves aerobic capacity and may reduce reported fatigue [2]. According to current European League Against Rheumatism (EULAR) recommendations, management of pSS concomitant diseases should be evaluated in patients presenting with fatigue and pain, and severity scored using specific tools [3].

Objectives: This study analyses the frequency and severity of depressive symptoms in patients with pSS and their relationship to fatigue and physical activity.

Methods: In this monocentric, cross-sectional study, patients with pSS attending our Rheumatology clinic between January 2019 and March 2020 completed standardized questionnaires: Beck´s depression inventory second edition (BDI II) and the international physical activity questionnaire short form (IPAQ-SF). Data were analyzed using SPSS 26 (IBM, Armonk, NY, USA). The tests include bivariate and partial correlations and nonparametric Kruskal-Wallis-Test.

Results: In total, 134 patients were included. The majority were female (117/134, 87.3 %), and the patients median age was 57 [21 – 85] years. Median duration of disease-related symptoms at inclusion was 56 months (range 0-388 months). Physical activity was low in 44. 8 % (n = 60), moderate in 32.1 % (n = 43), and high in 23.1 % (n = 31) of patients. Depressive symptoms of varying severity were identified in 76/134 (56.7%) of patients. Severe depression occurred in 10/76 (13.2%) and moderate depression in 14/76 (18.4%) patients. The remaining 52/76 (68.4%) patients had minimal or mild depression. Over two-thirds (67.7%) of patients reporting high physical activity showed no depression and no one with a high level of physical activity had severe depression. There was a clear association between the BDI II depression score and the level of physical activity (p = 0.003) regardless of age and illness duration. However, not all the symptoms assessed by BDI II had the same impact. From 21 items of the BDI II Inventory, symptoms such as loss of energy and fatigue were profoundly relevant, being reported by over 75 % of patients. The main depressive symptoms, which had a strong negative correlation with the level of physical activity were loss of energy (p < 0.001), sadness (p=0.018), inability to make decisions (p=0.007) and loss of pleasure (p=0.004). Somatic symptoms of decreased activation such as fatigue (p=0.026) and concentration difficulty (p=0.013) were also significant. The cognitive, self-negative symptoms were not associated with the level of physical activity.

Conclusion: A negative correlation of physical activity with fatigue and depression in patients with pSS has been demonstrated. The somatic symptoms of decreased activation played a profound role in this association, while the cognitive self-negotiation symptoms were not influenced by physical activity in our patients. Such symptoms as fatigue and loss of energy could potentially be reduced by exercises and functional training and consequently decrease the level of depression. An intervention study in this regard would be recommended.

AB0323 INTIMA-MEDIA THICKNESS IS INDEPENDENTLY ASSOCIATED WITH STROKE IN PRIMARY ANTIPHOSPHOLIPID SYNDROME

L. D. Azoulay[1], A. Mathian[1], F. Cohen[1], J. Haroche[1], M. Pha[1], P. Cherin[1], P. Cluzel[2], Z. Amoura[1]. *[1]Pitié-Salpetrière, Internal Medicine 2, Paris, France*; *[2]Pitié-Salpêtrière, Cardiovascular Imaging and Interventionnal Radiology, Paris, France*

Background: Compared to secondary antiphospholipid syndrome (APS), little is known on intima-media thickness (IMT) in primary APS. Previous reports suggest that intima-media thickness may be associated with anti-cardiolipin antibodies, anti-β2-glycoprotein-1 antibodies, and with stroke in APS[1].

Objectives: To assess clinical significance of intima-media thickness in primary APS.

Methods: We have included 29 patients with primary APS (defined according to international consensus criteria) seen, at least once, in our tertiary center for a cardiovascular risk assessment from April 2014 to November 2018.

Results: 29 patients were included (females 83%). Mean (SD) age at evaluation was 48 years (16.1). Mean APS duration before assessment was 9.1 years (6.2). 27 patients had thrombotic APS (93%), among which 13 (45%) had a history of arterial thrombosis (12 strokes and 1 myocardial infarction) and 16 (55%) of venous thrombosis. Obstetrical APS was present in 7 patients (24%). Positive APL antibodies were: anti-cardiolipin antibodies (aCL) n = 15 (54%), anti-β2-glycoprotein I (anti-β2GP1) n = 10 (36%), lupus-anticoagulant (LAC) n = 11 (39%) and anti-phospholipid antibodies (aPL) n = 19 (68%). Mean IgG levels (GPL) were 52.4 (80.3) UGPL, 52.2 (124) UI, 39.2 (40.5) UGPL for aCL anti-βG2P1, and aPL, respectively. 6 patients (21%) were simple positive, 3 (11%) were double positive, and 10 (36%) were triple positive.

Cardiovascular risk factors were: smoking n = 6 patients (21%), overweight n = 11 (39%), hypercholesterolemia n = 12 (43%), arterial hypertension n = 11 (38%), chronic kidney disease (defined by estimated glomerular filtration rate < 60 mL/mn) n = 5 (17%). No patient had diabetes mellitus. Median risk SCORE was 0.65 (0-2.4). Male sex, obesity, chronic kidney disease and risk SCORE were significantly more frequent in patients with arterial APS compared to patients with venous and/or obstetrical APS (38% vs 0%, P=0.01; 33% vs 0%, P=0.02; 38% vs 0%, P=0.01; 2.3 vs 0.7, P=0.03).

22 patients (76%) underwent an IMT measurement. Mean IMT was 0.57 (0.14) millimeters (mm). Median IMT was significantly higher in APS patient with stroke

than in those without (0.63 IQR (0.55-0.77) mm versus 0.51 (0.44-0.55) mm, P=0.02) (Figure 1A). IMT was neither correlated with duration of APS nor with antibody titers.

Variables associated with IMT were studied on uni- and multivariate analysis (Table 1). On univariate analysis, age, aCL positivity and stroke were significantly associated with IMT and were included in the multivariate analysis. On multivariate analysis, there was a positive, independent and significant association between IMT and stroke (P=0.047) and between IMT and age (P=0.024). aCL positivity was not associated with IMT on multivariate analysis (Figure 1B).

Conclusion: Intima-media thickness is independently associated with stroke in primary antiphospholipid antibody syndrome.

AB0324 ALLERGIC DISORDERS AND DRUG ALLERGIES IN PRIMARY SJÖGREN'S SYNDROME AND RHEUMATOID ARTHRITIS

M. Higashida-Konishi[1], K. Izumi[1,2], S. Hama[1], H. Takei[1], H. Oshima[1], Y. Okano[1]. [1]*National Hospital Organization Tokyo Medical Center, Department of Connective Tissue Diseases, Tokyo, Japan*; [2]*Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Allergic disorders have been reported in a variety of rheumatic diseases. A high prevalence of allergic disorders was found in patients with Sjoegren's syndrome [1]. Nevertheless, it was not clear what is a risk factor for allergic disorders and drug allergies in patients with primary Sjögren's syndrome (pSS). Drug allergies may lead to delayed treatment and unnecessary clinical tests.

Objectives: The primary aim of this study was to compare the prevalence of allergic disorders and drug allergies in patients with pSS and rheumatoid arthritis (RA). The secondary aim was to compare the clinical features with and without drug allergies in patients with pSS.

Methods: We retrospectively examined consecutive patients diagnosed with pSS or RA in our hospital from 2010 to 2020. The patients with SS met the criteria of the 1999 revised Japanese Ministry of Health criteria[2]. We included patients with pSS without RA or other rheumatic diseases. The patients with RA met the EULAR/ACR 2010 criteria. We included patients with RA without other rheumatic diseases.

The first analysis was performed on six types of allergic reactions: (1) food allergy (exanthema, angioedema and anaphylaxis after foods exposure), (2) drug allergy (exanthema, angioedema and anaphylaxis after drug exposure), (3) allergic contact dermatitis such as metals, alcohol swab, and other cosmetics, (4) seasonal allergic rhinitis and/or allergic conjunctivitis, and allergic rhinitis and/or allergic conjunctivitis associated with house dust, (5) asthma, and (6) atopic dermatitis.

The secondary analysis was performed on patient baseline laboratory data at diagnosis of pSS and RA patients with or without drug allergies.

Results: In the first analysis, 292 patients with pSS and 413 patients with RA were enrolled (Table 1). The mean ages (pSS, RA) were 57.3±15.8, 66.0±14.6 years old. Females were 94.2%, 78.2%. The mean observation period was 82.7±70.8, 65.6±37.0 months. 54.8% of pSS patients and 34.9% of RA patients presented at least one type of allergic disorders or drug allergies. These included food allergy, drug allergy, allergic rhinitis/conjunctivitis, asthma, and atopic dermatitis. Allergic disorders and drug allergies were more frequent in patients with pSS.

In the second analysis, 77 patients with drug allergies and 215 patients without drug allergies were enrolled. The mean ages with drug allergies and without drug allergies were 56.0±15.8 and 57.8±15.8 years old, respectively; females were 96.1% and 93.5%; the mean observation period was 90.9±72.4 and 79.8±70.2 months. The pSS patients with drug allergies had higher levels of Immunoglobulin G (IgG) (2028±1409 mg/dL, 1726±587 mg/dL: p = 0.01), higher levels of eosinophils (220±247/μL, 126±112/μL: p<0.019), and higher positivity rate of anti–Sjögren's-syndrome-related antigen A autoantibody (anti-SSA antibody) than those without drug allergies (89.6%, 79.7%: p = 0.06).

Conclusion: Patients with pSS had a higher prevalence of allergic disorders and drug allergies than patients with RA. Among patients with pSS, patients with drug allergies had higher levels of IgG, higher levels of eosinophils, and higher positivity rate of anti-SSA antibody than those without drug allergies.

Table 1. Allergic Disorders and Drug Allergies in pSS and RA

	pSS (n = 292)	RA (n = 413)	P
at least one type of allergy, n (%)	160 (54.8)	144 (34.9)	<0.01
food allergy, n (%)	35 (12.0)	27 (6.7)	0.02
drug allergy, n (%)	76 (26.1)	69 (16.7)	<0.01
allergic contact dermatitis, n (%)	10 (3.4)	19 (4.6)	0.6
allergic rhinitis and/or conjunctivitis, n (%)	99 (33.9)	35 (8.5)	<0.01
asthma, n (%)	29 (9.9)	25 (6.1)	0.06
atopic dermatitis, n (%)	15 (5.1)	0 (0)	<0.01

AB0325 FREQUENCY OF ATHEROMATOUS PLAQUES IN CAROTID ARTERIES BY DOPPLER IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS, SANTO DOMINGO, DOMINICAN REPUBLIC

J. Santana Peralta[1], T. Polanco Mora[2], A. Cornelio[1], Y. Cruz[1], E. Rodriguez Bautista[1], T. Valdez[1], R. Muñoz[1], A. Feriz[1]. [1]*Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic*; [2]*Hospital Docente Padre Billini, Rheumatology, Santo DOMINGO, Dominican Republic*

Background: Systemic lupus erythematosus (SLE) is a multisystemic autoimmune disease. [1] Atherosclerosis is considered an alteration of the arteries by the abnormal deposit of lipids and fibrous tissue. [2] Cardiovascular disease is one of the leading causes of morbidity and mortality, especially due to its precocity, which occurs in women during childbearing age, is associated with a higher prevalence of cardiovascular disease (CVD), due to accelerated atherosclerosis[3,4,5]. Patients with rheumatic diseases have an increased cardiovascular risk due to

systemic inflammation and endothelial dysfunction, which promotes accelerated atherosclerosis[2].

Objectives: Evaluate the frequency of atheromatous plaques in patients with systemic lupus erythematosus.

Methods: Observational, prospective, cross-sectional study. Carotid Doppler was performed on patients with SLE from the external consultation of the rheumatology service from November 2019 to 2020. Inclusion criteria: > 18 years old, diagnosis SLE with the classification criteria ACR 2007, realization of Doppler. Controls: no disease, equated by age and sex. The data was analyzed with SPSS V23.

Results: 116 patients met inclusion criteria, including 116 female controls. Mean sick time was 6.23 years. 14.65% (17) had atheromaus plates, 29.4% calcified plates (5). 34.7% Dyslipidemia (63.1%) (73), obesity 34.7% (33), high blood pressure 23.1% (22), diabetes 3.44% (4), smokers 0% (0). The activity rate using SLEDAI showed 68.96% (80) without activity, 13.79% (16) low, 11.20% (13) moderate, 6.03% (7) high activity. About control group (116), 19.82% (23) showed atheromatous plates, 39.13% (9) calcified plates.

Conclusion: Our study shows that less than a quarter of patients have atheromatous plaques in the carotid Doppler. In relation to LES activity, the vast majority are in low activity. We suggest the realization of Carotid Doppler in patients with low activity SLE for evaluation and monitoring of cardiovascular risk. Our study showed that there is no increased risk of atheroma plaque formation in SLE patients, compared to the general population.

AB0326 USEFULNESS OF THE INTIMA-MEDIA THICKNESS INDEX BY CAROTID DOPPLER IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS OF HOSPITAL DOCENTE PADRE BILLINI, DOMINICAN REPUBLIC

J. Santana Peralta[1], T. Polanco Mora[1], A. Cornelio[1], Y. Cruz[1], E. Rodriguez Bautista[1], T. Valdez[1], R. Muñoz[1], A. Feriz[1]. [1]*Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic*

Background: Systemic lupus erythematosus (SLE) is a multisistemic autoimmune disease. [1]There are studies where the increase in the thickness of the intimate/media average in carotid (IMT) is valued, most have shown increase[2]. Cardiovascular disease is one of the leading causes of morbidity, especially due to its precocity, which occurs in women during the fertile potential, is associated with a higher prevalence of cardiovascular disease (CVD), due to accelerated atherosclerosis[3,4,5]. Patients with rheumatic diseases have an increased cardiovascular risk due to systemic inflammation and endothelial dysfunction, which promotes accelerated atherosclerosis[2]. Values below 0.9mm of IMT are considered normal.

Objectives: Evaluate the thickness of the intimate/media average in carotid in patients with systemic lupus erythematosus.

Methods: Prospective, Observational, cross-sectional study. Carotid Doppler was performed on patients in the outpatient clinic with a diagnosis of SLE from November 2019 to 2020 of the rheumatology service of the Hospital Docente Padre Billini and healthy controls. Inclusion criteria: > 18 years old, SLE diagnosis with ACR 2007 classification criteria, carotid Doppler, measurement of IMT. Controls without disease, matched by sex and age. The data was analyzed with SPSS V23.

Results: 116 patients with SLE. 95 patients met inclusion criteria;95 healthy controls were included. 97.8% female. Average disease of 6.23 years. 71. 57% (68) use glucocorticoids, antimalarials 70.52% (67), 38.94% (37) mofetil mycophenolate, 20% (19) methotrexate, 11. 57% (11) rituximab, 5.26% (5) azathioprine, 1.05% (1) cyclosporine, 1.05% (1) cyclophosphamide and 0.86% (1) tacrolimus. Dyslipidemia (63.1%) (73), obesity 34.7% (33), high blood pressure 23.1% (22), diabetes 3.44% (4), smokers 0% (0). The carotid doppler with SLE showed 17.89% (17) atheromatous plates, 29.4% (5) calcified plates, Carotid Doppler in healthy controls showed 20% (19) atheromatous plates, 36.84% (7) calcified plates. The activity rate using SLEDAI showed 68.96% (80) without activity, 13.79% (16) low, 11.20% (13) moderate, 6.03% (7) high activity. 78% (75) patients with SLE had increased IMT mean (SD) 2.15mm (0.99). About control 71.57% (68) had an increase of IMT, mean (SD) 1.27mm (1.07) (p-0.046).

Conclusion: Our study found that most patients with SLE had IMT increase. The activity ratio of SLE showed that the vast majority of our patients are in low activity. Alterations in IMT were associated with low SLEDAI and glucocorticoid use. There was no significant difference in the intima-media carotid thickness index with respect to the control group. We suggest the realization of Doppler in patients with SLE despite being in low activity for evaluation and monitoring of cardiovascular risk.

AB0327 DRUG-INDUCED LUPUS ERYTHEMATOSUS SECONDARY TO ANTI-TNF-A AGENTS IN PATIENTS WITH SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS

A. Martins[1], D. Santos Oliveira[1,2], F. R. Martins[3], M. Rato[1], F. Oliveira Pinheiro[1], D. Fonseca[4], S. Garcia[1], B. M. Fernandes[1], S. Pimenta[1,5], M. Bernardes[1,5], L. Costa[1]. [1]*Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal*; [2]*Faculdade de Medicina da Universidade do Porto - FMUP, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; [3]*University Hospital Center of Algarve, Rheumatology, Faro, Portugal*; [4]*Centro Hospitalar Vila Nova de Gaia / Espinho - Unit 1, Rheumatology, Vila Nova de Gaia, Portugal*; [5]*Faculdade de Medicina da Universidade do Porto - FMUP, Rheumatology, Porto, Portugal*

Background: Induction of autoantibodies is frequently observed in patients treated with TNF-α antagonist and the possible development of drug-induced lupus erythematosus (DILE) remains a matter of concern. The prevalence of DILE secondary to anti-TNF-α therapy is estimated around 0.5-1% and clinical features include arthritis/arthralgia, rash, serositis, fever, myalgias, cytopenias, among others. According to the literature, DILE secondary to anti-TNF-α agents differs in several ways from the clinical and laboratory findings typically associated with classic DILE.

Objectives: To estimate the incidence of induction of antinuclear antibodies (ANA) and DILE in a monocentric cohort of patients with spondyloarthritis and psoriatic arthritis treated with anti-TNF-α agents. To describe the clinical and laboratorial features and outcomes of patients with DILE.

Methods: We performed a retrospective analysis of patients with spondyloarthritis and psoriatic arthritis treated with anti-TNF-α agents, from our University Hospital, who have been registered on the Portuguese Rheumatic Diseases Register (Reuma.pt) between July 2001 and December 2020. Patients with

positive ANA (titer > 1/100) before the anti-TNF-α therapy were excluded. Because specific criteria for the diagnosis of DILE have not been established, we considered the diagnosis in case of a temporal relationship between clinical manifestations and anti-TNF-α treatment and fulfillment of ACR/EULAR 2019 classification criteria for SLE. In patients with DILE, clinical features, laboratory findings, systemic therapies and outcome after discontinuation of medication were collected from reuma.pt and medical records. For the clinical and demographic predictors, continuous variables were analyzed using a two-sided t-test and categorical variables using a Fisher's exact test. P-value <0.05 was considered statistically significant.

Results: In the spondyloarthritis group, 290 patients were included (44.8% females, mean age at diagnosis of 33.3 ± 11.5 years and mean disease duration of 15.1 ± 10.4 years) and in the psoriatic arthritis group, 116 patients were included (50.0% females, mean age at diagnosis of 40.1 ± 11.0 years and mean disease duration of 13.1 ± 6.8 years). In our study, we observed high serology conversion rates (positive ANA in 67.9% and 58.6% of patients with Spondyloarthritis and Psoriatic Arthritis, respectively), with similar conversion rates between different anti-TNF drugs. Three patients with spondyloarthritis (1.0%) and 1 patient with psoriatic arthritis (0.9%) developed DILE. Etanercept was the causative agent in 2 cases, infliximab and adalimumab in 1 case, each. Peripheral arthritis (new onset or abrupt worsening) occurred in 2 patients, serositis in 1 patient, constitutional symptoms in 2 patients, subnephrotic proteinuria in 1 patient, lymphopenia in 2 patients and hypocomplementemia in 1 patient. Specific treatment was prescribed to the 4 patients (oral corticosteroids) and they achieved complete recovery. After anti–TNF-α treatment interruption, no patient had recurrent disease. We observed that patients with DILE had a significantly longer disease duration (> 8.4 years; p=0.04) and a significantly longer duration of therapy with anti-TNF (> 4.0 years; p=0.04) when compared to patients without DILE.

Conclusion: Despite the frequent induction of autoantibodies, the development of DILE secondary to anti–TNF-α agents is rare. Our study demonstrates an incidence rate similar to other studies reported before. The clinical and laboratorial characteristics of our patients with DILE attributable to anti–TNF-α agents differ significantly from DILE due to more traditional agents, as is described in literature. Overall, patients in this study had mild disease that improved after therapy discontinuation, without recurrence of the disease. It seems that a longer disease duration and a longer period under anti-TNF-α therapy may increase the risk of DILE development.

AB0328 CLINICAL AND SEROLOGICAL DIFFERENCES BETWEEN PRIMARY SJOGREN'S SYNDROME PHENOTYPES

X. E. Larco Rojas[1], E. Diez Alvarez[1], C. Moriano[1], A. López Robles[1], T. Pérez Sandoval[1]. [1]*Complejo Asistencial Universitario de León, Rheumatology, León, Spain*

Background: Primary Sjogren's Syndrome (PSS) is an autoimmune and lymphoproliferative disease with a heterogeneous presentation. It has been postulated that there may be different phenotypes, in some cases presenting a more aggressive disease with systemic manifestations and a higher risk of developing complications. This phenotype has been associated with a higher autoimmune load and an earlier age of presentation. Furthermore, the presence of anti La + has been related to an increased risk of developing Lymphoma.

Objectives: To describe the phenotypic characteristics of seronegative PSS in a sample of patients from our practice. To compare the clinical and laboratory characteristics between patients with Ro + / La + and Ro + / La- antibodies. To Analyze if there are differences in patients diagnosed at an early age, compared to a later age.

Methods: Clinical and serological characteristics of patients with the diagnosis of PSS were collected from the Rheumatology database of León`s Hospital between 2014-2020. All patients who met the ACR / EULAR 2016 criteria were classified as seronegative Sjogren.

In the group of patients with positive autoimmunity, anti-Ro + / La + were compared with the anti-Ro + / La- patients and by age, stratifying them into the following groups: 0-49; 50-69 and> 70 years. The clinical variables analyzed were: glandular inflammation, Raynaud's phenomenon (RP), pulmonary and neurological involvement, presence of Lymphoma and other tumours. The serological variables were: positivity of ANA, Rheumatoid Factor (RF), hypocomplementemia, hypergammaglobulinemia and B2 microglobulin.

Results: 72 patients were analysed, 9 were excluded because didn't meet the criteria. Of the remaining: 90,4% were women, with a mean age of 58,7+/-15,8 years, 12,6% (8) were seronegative. In the seronegative group 25% presented lung involvement (Lymphoid Interstitial Pneumonia), 50% presented with glandular inflammation and only one patient had RP. As complications 1 patient presented Lymphoma and 1 Breast Carcinoma.

58,7% (37) Ro + / La + and 28,5% (18) Ro + / La- patients were identified, no statistically significant differences were found between the two groups when comparing: glandular inflammation (8/37 vs 2/18, p = >0.05) RP (9/37 vs 4/18, p = >0.05), pulmonary involvement (5/37 vs. 6/18, p = >0.05), neurological involvement (2/37 vs. 1/18, p = >0.05), presence of Lymphoma (2/37 vs. 0 / 18, p = >0,05), other tumours (2/37 vs 3/18, p = >0.05), ANA positivity (36/37 vs 16/18, p =>0,05), Hypocomplementemia (4/37 vs 3/18, p =>0.05) and Hypergammaglobulinemia (20/37 vs 10/18, p =>0.05). But a higher frequency of positive RF linked to anti La positivity (29/37 vs 6 / 18p = 0.002) was found.

When comparing by age groups, the association between RF + and La + remained in the group of 50-69 years (15/18 vs 3/18, p = 0.002) while in the other age groups there were no statistically significant differences. We also observed an increasing trend of the levels of B2microglobulin in La+ patients and later age (p=0,04)

Conclusion: The presence of anti La + seems to be associated with other components of autoimmunity such as RF in patients with PSS, although this study did not show a relation with a higher frequency of complications or systemic disease. Also, the presence of La+ at older ages was associated with higher levels of B2 microglobulin. We didn't find differences with the other described markers of B cell reactivation. Findings differ from those found in the literature, which may be largely due to sample size.

AB0329 HIGHER PREVALENCE OF ECHOCARDIOGRAPHIC ABNORMALITIES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

N. Guajardo-Jauregui[1], J. R. Azpiri-López[2], D. Á. Galarza-Delgado[1], I. J. Colunga-Pedraza[1], R. A. Reyna-de la Garza[3], S. Lugo-Perez[2], A. B. Rodriguez-Romero[1], A. Cárdenas[1], H. Azpiri-Diaz[2], O. A. Cepeda-Ayala[2]. [1]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*; [2]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*; [3]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Internal Medicine, Monterrey, Mexico*

Background: Systemic lupus erythematosus (SLE) is a chronic, inflammatory, and autoimmune disease that damages vital organs such as the heart. Patients with SLE have a higher risk of developing a cardiovascular (CV) disease than the general population (1).

Objectives: The aim of this study was to compare the echocardiographic findings in patients with SLE and controls.

Methods: This was a cross-sectional, observational, and comparative study. A total of 38 patients with SLE according to the 2019 EULAR/ACR classification criteria, ≥18 years old and 38 matched controls by age (±5 years) and gender, were recruited for this study. Exclusion criteria were a poor echocardiographic window, patients with a previous CV event, such as myocardial infarction, cerebrovascular event or peripheral arterial disease, and pregnant women. A transthoracic echocardiogram, including speckle tracking technique,

was performed, by two certified echocardiographers, in all study subjects. Distribution was evaluated with Kolmogorov-Smirnov test. Comparisons were done with χ^2 and Fisher´s Exact test for qualitative variables, and Student's t test and Mann-Whitney´s U test for quantitative variables. A p-value <0.05 was considered statistically significant.

Results: When comparing demographic characteristics there were no significant differences in age, gender, and comorbidities between SLE patients and controls. In the echocardiographic findings a significant difference was found in the left ventricular ejection fraction (LVEF), lower in SLE patients compared to controls (57.02% vs 61.89%, p=0.001), in the global longitudinal strain (GLS), reduced in SLE patients (-19.55% vs -22.00%, p=0.001), in the tricuspid annular plane systolic excursion (TAPSE), lower in SLE patients (22.00mm vs 24.00mm, p=0.011), in the left atrial volume index, higher in SLE patients (28.44ml/m^2 vs 22.29ml/m^2, p=0.014) and in the presence of mitral regurgitation, more prevalent in SLE patients (31.6% vs 10.5%, p=0.024) (Table 1).

Conclusion: Patients with SLE have a worse left ventricular function, evaluated by LVEF and GLS, a worse right ventricular systolic function, evaluated by TAPSE, an increased left atrial volume index and a higher prevalence of mitral regurgitation, which are associated with a higher risk of CV death. It is important to consider including a transthoracic echocardiogram as part of the CV evaluation in patients with SLE, which may result in an early detection of CV abnormalities and an opportune treatment.

ANTIPHOSPHOLIPID ANTIBODIES AND ANTICOAGULANT TREATMENT: CAPILLAROSCOPIC FINDINGS

G. Ferrari[1], E. Gotelli[1], G. Pesce[2], L. Nanni[3], B. Colombo[4], S. Paolino[1], C. Pizzorni[1], A. Sulli[1], V. Smith[5], M. Cutolo[1]. [1]*Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genova, Italy*; [2]*Autoimmunity Laboratory, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genova, Italy*; [3]*Medicine Laboratory, IRCCS San Martino Polyclinic Hospital, Genova, Italy*; [4]*Italian Cardiovascular Network, IRCCS San Martino Polyclinic Hospital, Genova, Italy*; [5]*Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Department of Rheumatology, Ghent University Hospital – Department of Internal Medicine, Ghent University, Belgium, Ghent, Belgium*

Background: Antiphospholipid syndrome (APS) is an autoimmune condition characterized by arterial and/or venous thrombosis and/or obstetric morbidity, associated with the presence in the serum of antiphospholipid antibodies (aPL) [1]. Subjects with confirmed positivity of aPL in absence of thrombotic/obstetric manifestations are identified as aPL carriers [2] The microangiopathy detected by nailfold videocapillaroscopy (NVC) in APS and in aPL-carrier patients is poorly investigated, as well as the possible interference of anticoagulant drugs [3].

Objectives: To compare microvascular damage in APS, aPL carriers and a group of patients (CTR) without aPL positivity and on regular warfarin therapy for cardiovascular indications

Methods: NVC investigations were performed as part of standard procedures in APS patients (18, mean age 50.0±12.8 years), aPL carriers (24, mean age 46.4±16.4 years) and CTR without aPL (18, mean age 74±12.5 years) in therapy with oral anticoagulant (warfarin) for non-immunological vascular complications (atrial fibrillation, mechanical heart valve, deep venous thrombosis). Only patients affected by primary APS form were selected from data files (2006 Sapporo classification criteria). The following NVC parameters were availble: dilated capillaries, giant capillaries, microhemorrhages (with particular attention to linear and thin hemosiderin deposits, arranged perpendicularly and parallel to the nailfold bed, "comb-like"), abnormal shape (i.e. brunched "bushy" capillaries) and capillary number reduction. Those parameters were scored according to a semi-quantitative scale [4,5]. Statistical analysis was performed by non-parametric tests. Any p values equal or lower than 0.05 was considered statistically significant.

Results: APS patients showed a higher score for dilated capillaries (p=0.001), more frequent microhemorrhages (p=0.03), in particular "comb-like" microhemorrhages (p=0.007) than simply aPL carriers. Of note, there wasn't a statistically significant difference in the number of microhemorrhages between APS and CTR group (p=0.23), but again the number of "comb-like" hemorrhages, was almost absent in the CTR group (p=0.03). No significant correlation was found between the different aPL subtypes and the NVC parameters.

Conclusion: APS patients showed significantly higher number of non-specific NVC abnormalities than aPL carriers. Anticoagulant treatment could represent a further risk factor for the appearance of microhemorrhages in all the patients, being the NVC "comb-like" pattern mainly associated with the APS. Further investigations with larger cohorts of patients are needed for the definition of a possible APS specific NVC-pattern.

PULMONARY INVOLVEMENT IN A SINGLE CENTER COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

N. Senkal[1], E. Kiyan[2], E. Kocasoy-Orhan[3], A. Demir[4], M. Aydogan[5], Y. Yalçınkaya[6], A. Gul[6], M. Inanc[6], M. L. Ocal[6], B. Artim-Esen[6]. [1]*Istanbul University Istanbul Faculty of Medicine, Internal Medicine, Istanbul, Turkey*; [2]*Istanbul University Istanbul Faculty of Medicine, Chest Diseases, Istanbul, Turkey*; [3]*Istanbul University Istanbul Faculty of Medicine, Neurology, Istanbul, Turkey*; [4]*Fulya Radiologic Imaging Center, Radiology, Istanbul, Turkey*; [5]*Istanbul University Istanbul Faculty of Medicine, Cardiology, Istanbul, Turkey*; [6]*Istanbul University Istanbul Faculty of Medicine, Rheumatology, Istanbul, Turkey*

Background: The prevalence of SLE pulmonary involvement varies depending on several factors, including diagnostic methods [1].
Objectives: We aimed to determine the frequency of involvement with different diagnostic methods in a single center cohort.
Methods: 300 SLE patients were included. Chest x-ray (CXR), lung spirometry, carbonmonoxide diffusion test (DLCOc) and echocardiography were performed. High resolution thorax computed tomography (HRCT) was done for a definite diagnosis of interstitial lung disease (ILD) whilst diagram electromyography (EMG), ultrasonography (USG) and magnetic resonance imaging (MR) were utilized to diagnose shrinking lung syndrome (SLS).
Results: The mean age and follow-up time were 43 and 11,5 years respectively. Of 300 patients, 16% had ILD, 6,7% had pulmonary hypertension (PHT), 3% had SLS, 0,3% had pulmonary infarction. At the start of the study, patients' records showed that 4% had ILD, 5% PHT, 0,3% SLS and 0,3% pulmonary infarction. The median age, mean duration of disease and follow-up time were significantly higher and longer in patients with ILD compared to patients without (p<0.05). Forced expiratory volume (FEV1), forced vital capacity (FVC), DLCOc and total lung capacity (TLC) were significantly lower in patients with ILD and with SLS (p<0,001). Patients with ILD had significantly higher frequency of arthritis, serositis, Raynaud myositis and anti-Scl70 positivity. Avascular necrosis, diabetes and malignancy were significantly more frequent in those patients. All patients with suspected SLS undergone diagram EMG, USG and MR. Out of 10 suspected cases, in 6 EMG, in 5 USG and in 9 MR was compatible with SLS diagnosis. 5 patients had 3 of the diagnostic methods positive to diagnose SLS. Muscle atrophy and weakness, avascular necrosis were more frequent in this group of patients (p<0.05). There were more patients treated with mycophenolate mofetil (MMF) and cyclophosphamide in the SLS group whilst more with MMF in the ILD group. Significantly higher frequency of patients had stopped using hydroxychloroquine (HCQ) in the ILD group (p=0,04).
Conclusion: Interstitial lung disease is common in patients with SLE and considerable number of patients have SLS [2]. Spirometry, DLCOc and CXR are simple but valuable to diagnose pulmonary involvement in SLE patients. Diaphragm MR, USG and EMG are complementary methods for definite diagnosis in SLS [2]. Considering the significant difference of prevalence between the start and the end of the study, one of the possibbilities is the underrecognition of SLE pulmonary disease due to its being part of a multisystemic presentation. Higher usage of immunosuppressives in these patients may support a multisystemic active disease. Although drug effect is another concern, it is hard to establish a causal relationship due to the study's cross-sectional design. HCQ may have a role in ILD prevention.

IS MINOR SALIVARY GLAND HISTOLOGY A GOOD BIOMARKER SCORE TO PREDICT THE EXTRAGLANDULAR INVOLVEMENT IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME?

A. Martins[1], R. Ferreira[1], S. Pimenta[1,2], L. Costa[1]. [1]*Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal*; [2]*Faculdade de Medicina da Universidade do Porto - FMUP, Rheumatology, Porto, Portugal*

Background: The minor salivary gland biopsy (MSGB) is considered the "*gold standard*" for the diagnosis of primary Sjögren's syndrome (pSS). The histological hallmark is focal lymphocytic infiltration with the presence of 50 or more lymphocytes per 4 mm^2 (focus score ≥ 1). Several studies have documented the association between focus score (FS) and extraglandular involvement, suggesting that FS could be used as a histological index of disease severity and a prognostic tool.
Objectives: To investigate the association between the FS and clinical, haematological and serological findings in a cohort of patients with pSS.
Methods: We performed a retrospective analysis of patients with pSS who fulfilled the ACR/EULAR 2016 classification criteria that were submitted to a minor salivary gland biopsy (MSGB). Demographic data, disease duration, extraglandular involvement and histopathologic data were collected and analyzed. The severity of histologic changes was graded according to the Chisholm and Mason scoring system and the FS was determined. Fisher's exact test/Chi-square test and Mann-Whitney U test were used to compare the patients with and without positive biopsy (FS <1 versus FS ≥ 1). Futhermore, to investigate the association between the quantitative value of focus score in groups with and without each extraglandular manifestations the authors used the Mann-Whitney U test. P-value < 0.05 was considered statistically significant.
Results: A total of 59 pSS patients were included. Regarding the histopathologic pattern, 40 of 59 patients had a FS ≥ 1, while 19 patients had a FS <1. Although described as having FS ≥ 1, the pathologists failed to report the absolute value in 11 of 40 (27,5%) patients. Germinal center-like structures were found in 1 (1,7%) patient. The demographic and clinical features in pSS patients with FS <1 and with FS ≥ 1 are presented in table 1. Anti-SSA was strongly associated with FS <1 (p <0,001). No significant difference in demographic and clinical features were found between the two groups.

Table 1. Demographic and clinical features in pSS patients with FS <1 and with FS ≥ 1 (* Fisher's exact/Chi-square test; † T-test; ‡ Mann-Whitney U test).

	FS <1 (n=19)	FS ≥ 1 (n=48)	p-value
Gender (female), n (%)	17 (89,5)	34 (85,0)	0,639 *
Current age (years) (mean ± SD)	60,11+-13,39	54,78 (+-13,48)	0.16 †
Disease duration (years) (median, P25-P75)	3 (2-7)	4 (3-5)	0,507 ‡
Extraglandular involvement			
Arthralgias/Arthritis, n (%)	6 (31,7)	22 (55,0)	0,092 *
Myositis, n (%)	0 (0)	1 (2,5)	-
Pulmonary involvement, n (%)	3 (15,8)	5 (12,5)	0,704 *
PNS involvement, n (%)	0 (0)	1 (2,5)	-
CNS involvement, n (%)	0 (0)	1 (2,5)	-
Cutaneous involvement, n (%)	1 (5,3)	1 (2,5)	0,544 *
Lymphoma, n (%)	0 (0)	2 (5,6)	-
Haematological and serological characteristics			
Leukocytopenia, n (%)			
Hypergammaglobulinaemia, n (%)	10 (52,6)	16 (40,0)	0,361 *
RF positivity, n (%)	5 (26,3)	10 (25,6)	1 *
ANA positivity, n (%)	18 (94,7)	34 (85,0)	0,411*
Anti-SSA positivity, n (%)	19 (100)	21 (52,5)	< 0,001 *
Anti-SSB positivity, n (%)	7 (36,8)	12 (32,5)	0,742 *
ESSDAI score (median, P25-P75)	2 (0-8)	2 (0-7,25)	0,816 ‡

When comparing the quantitative value of FS in groups with and without each extraglandular manifestation, the authors found that patients with articular involvement had a significant higher FS value than patients without articular manifestations (p=0.037). No other significant association was found.
Conclusion: Regarding the clinical manifestations, we didn't find a significant difference between patients with a FS < 1 and those with a FS ≥ 1. Anti-SSA was strongly associated with a FS <1, which corroborates the importance of anti-SSA for the pSS diagnosis in patients with a negative biopsy. We found that a higher FS value was associated with articular involvement. However, this study has limitations such as a small sample and a low incidence of extraglandular manifestations. In conclusion, more studies are needed to clarify the associations found in the literature.

USEFULNESS OF MULTI-PARAMETRIC EVALUATION INCLUDING MINOR SALIVARY GLAND BIOPSY FOR THE DIFFERENTIAL DIAGNOSIS OF SICCA SYNDROME IN A SPANISH SINGLE-CENTER EXPERIENCE

J. Álvarez Troncoso[1], C. M. Oñoro López[1], C. Soto Abánades[1], E. Ruiz Bravo[2], L. Blasco Santana[2], A. Noblejas Mozo[1], E. Martínez Robles[1], Á. Robles Marhuenda[1], L. Ramos Ruperto[1], J. J. Rios[1], F. Arnalich Fernández[1]. [1]*Hospital Universitario La Paz, Internal Medicine, Madrid, Spain*; [2]*Hospital Universitario La Paz, Pathology, Madrid, Spain*

Background: Sjögren's syndrome (SS) is a systemic autoimmune disease characterized by mononuclear cell infiltration of the exocrine glands, which leads to sicca syndrome and systemic manifestations. The minor salivary gland biopsy (MSGB) is undoubtedly important for the classification, diagnosis and prognosis of SS. However, differentiating SS and non-Sjögren's sicca syndrome (NSS) can be challenging.
Objectives: The aim was to evaluate the histological characteristics of MSGB besides focus score (FS) in patients with sicca syndrome and the usefulness of the different clinical, serological and histological parameters to diagnose, classify and describe the prognosis of patients with Sjögren's syndrome.
Methods: Prospective observational single-center study of patients referred for study of sicca syndrome with multi-parametric evaluation from January 2019 to December 2020. A diagnostic protocol based on Schirmer's test, unstimulated whole salivary flow (UWSF) and minimally invasive MSGB was applied. Patients fulfilling 2016 ACR-EULAR classification criteria were classified as SS.
Results: In a cohort of 115 patients with sicca syndrome, 55 (47.8%) were diagnosed with SS. The mean age was 56.9±14.5 years and most of the patients were women (81,7%) with no significant differences between SS and NSS. SS were more likely to present positive Schirmer's test, positive UWSF, anti-Ro+, FS≥1, antinuclear antibodies (ANA+), rheumatoid factor (RF+) and anti-La+ among others.
MSGB was a safe procedure and very effective (only 7% insufficient biopsies) in our cohort. The mean gland size of the MSGB was 5.7±0.37 mm^2. Furthermore, it was the individual parameter that most correlated with SS, even more than anti-Ro+, Schirmer's and UWSF. Seronegative SS (Anti-Ro-) was 47.3%. These patients could not have been diagnosed except by MSGB. Scintigraphy did not help to differentiate SS from NSS, neither patient-referred xerostomia nor xerophthalmia. The most frequent histological diagnosis was focal lymphocytic sialadenitis (FLS) (81.8%) followed by nonspecific chronic sialadenitis (9.1%). However, only FLS had a correlation with SS. There were no MSGBs labeled normal among the SS patients. Mean FS was 2.22±0.2 (16.7% had FS≥3).
The rest of the histological parameters that showed a positive correlation with SS were glandular atrophy (GA), germinal centers (GC), lymphoepithelial lesions (LEL) and lymphoid follicles (LF). FS≥1 is the current histological classification criteria for ACR/EULAR. However, the presence of lymphocytic infiltrates (LI) (although not FS≥1) and FLS were suggestive markers of SS with greater sensitivity (SE) and specificity (SP). FS≥3, GC, LEL and LF were only found in SS and were associated in previous studies with higher risk of lymphoma and systemic disease.

		Prevalence			Test	
		SS	NSS	p value	Sensitivity	Specificity
Classification criteria	Schirmer's test	78.6%	57.6%	p=0.019	0.78	0.42
	UWSF	65.5%	38.3%	p=0.004	0.65	0.62
	Anti-Ro+	52.7%	6.7%	p<0.001	0.53	0.93
	FS≥1	66.7%	25%	p=0,027	0.67	0.75
Non classification criteria	Anti-La+	18.5%	1.8%	p=0.003	0.43	0.87
	ANA+	74.5%	28.3%	p<0.001	0.75	0.72
	RF+	38.2%	10.0%	p=0.001	0.43	0.87
	Scintigraphy	49.1%	38.3%	p=0.245	0.49	0.62
	Xerostomia	76.1%	77.9%	p=0.663	0.76	0.2
	Xerophthalmia	74.5%	83.8%	p=0.302	0.74	0.16
Histological characteristics	LI	92.2%	27.5%	p<0.001	0.9	0.78
	FLS	81.8%	6.7%	p<0.001	0.82	0.93
	GA	75.5%	50.9%	p=0.010	0.76	0.49
	GC	2.0%	-	p=0.310	0.02	1.00
	LEL	12.2%	-	p=0.011	0.11	1.00
	LF	4.1%	-	p=0.153	0.04	1.00

Conclusion: SS is a heterogeneous disease that requires a comprehensive clinical, serological, functional and histological evaluation. MSGB is a simple, safe, repeatable procedure that provides enormous information. It was the single parameter that best correlated with SS and allowed the diagnosis of seronegative SS. In summary, the use of MSGB is essential not only for the differential diagnosis of sicca syndrome but also as a prognostic marker for SS.

THE FIRST 1000 DAYS OF LIFE AND REPRODUCTIVE DISORDERS IN WOMAN WITH RHEUMATIC DISEASE (RDS)

M. Orlandi[1], S. Vannuccini[2], K. El Aoufy[1], M. R. Melis[1], G. Lepri[1], S. Bellando-Randone[1], S. Guiducci[1], M. Matucci-Cerinic[1], F. Petraglia[2]. [1]*University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy*; [2]*Obstetrics and Gynecology, AOU Careggi, Department of Maternity and Infancy, Florence, Italy*

Background: Gynaecological problems are often ignored by rheumatologist and have a negative impact on quality of life of RDs patients.
Objectives: The aim of this study was to describe gynaecological, reproductive and sexual problems in premenopausal woman with RDs.
Methods: A monocentric, cross-sectional observational study was conducted in the Rheumatology Department of Careggi Hospital in Florence. Inclusion criteria: female gender, premenopausal age (and≥18 years old), diagnosis of rheumatic diseases. All patients have been investigated about gynaecological anamnesis and symptoms and subjected to a self-administered validated questionnaire.
Results: From May 4 th to November 30th, 2020, 200 patients were enrolled (mean age 39.1± 8.7 years (M±SD)): 58% arthritis, 40% connective tissue disease and 1.5% systemic vasculitis. In the history, spontaneous, full-term birth in 91% and 93% of patients, respectively, was observed and pre-term birth was reported in 8.1%. 63% of patients were breastfed. In family history, menorrhagia, dysmenorrhea, or chronic pelvic pain were reported in 59%, 55 and 7% of patients, respectively. The first menstruation was at 12.3±2.0 years (M±DS) and mostly woman reported menstrual disorders during adolescence (56% experienced dysmenorrhea and 52% menorrhagia). Menstrual disorders and abnormal bleeding were frequently reported also in adulthood: 71% had dysmenorrhea, 38% heavy menstrual cycles and 9% metrorrhagia. Moreover, 26% of patients referred non- menstrual pelvic pain, 19% urinary pain and 18% pain during defecation. Vaginal symptoms were frequently reported: 36% of patients referred vaginal dryness, 29% burning, 19% recurrent vaginal infections and dyspareunia in 39% of patients. Uterine fibroma was present in 23% and endometriosis in 10% of patients. Fertility problems were reported by 10% of patients in a time frame of 7.5±6.4 years and 30% of patients experienced at least one miscarriage; otherwise, 56% of patients have had at least one full-term pregnancy.
Conclusion: RDs patients show a high prevalence of various gynaecological problems affecting their quality of life. The management of female RDs patients is a challenge for the clinician and should include an accurate evaluation of the gynaecological aspects (menstruation, fertility, maternity, sexuality) as well as a multidisciplinary teamwork (rheumatologist and gynaecologists).

SURVIVAL ASSESSMENT IN PATIENTS WITH SLE AND PULMONARY MANIFESTATIONS IN A COLOMBIAN COHORT WITH 2-YEAR FOLLOW-UP

S. Herrera[1], J. C. Diaz-Coronado[1,2], S. Monsalve[2], S. Guerra-Zarama[2], M. F. Saavedra Chacón[2], J. Barbosa[2], J. D. Serna Giraldo[2], J. D. Lopez[2], J. M. Gutiérrez[2], T. Vega[2], D. Orozco[2], D. Ocampo[2], N. Zuluaga[2], D. Hernandez-Parra[1], D. Rojas-Gualdrón[3], R. Pineda.Tamayo[1]. [1]*Artmedica, Clinical Information Group, Medellín, Colombia*; [2]*CES University, Department of Internal Medicine, Medellín, Colombia*; [3]*CES University, Facultad de medicina, Medellín, Colombia*

Background: Systemic lupus erythematosus (SLE) is a multisystemic autoimmune disease with heterogenous and variable behavior. The frequency of pulmonary involvement ranges from 10-90%, with this variability in occurrence attributed to differences in populations and heterogeneity in detection methods and study designs.
Objectives: To analyze survival in patients with SLE and the presence of pulmonary manifestations according to clinical and demographic characteristics in a cohort of patients in Colombia
Methods: Observational-analytical, retrospective, follow-up study of a cohort of adult patients with SLE. We included 559 adult patients who fulfilled the 2012 SLICC SLE classification criteria and with at least 6 months of disease evolution, treated in a medical center specialized in rheumatology with locations in 6 cities in Colombia between 2015 and 2018. Pregnant patients and those who had incomplete data or visits were excluded. Immunoserological profile was characterized and pulmonary involvement was followed for 1 year. The diagnosis of pulmonary involvement was obtained from the rheumatology report in the clinical chart. The prevalence of pulmonary manifestations and the immunoserological profile were determined and subsequently a logistic regression adjusted for age, sex and level of education was performed to establish the association between pulmonary manifestations and a positive autoantibody profile
Results: Median age was 44.5 ± 14 years, 96.6% were women. In patients with pulmonary compromise 9.7% were smokers, 12.4% had an active alcohol intake, 58.4% had a low socioeconomic status, 38.1% medium and 4.7% high. Pulmonary involvement was present in 20% of patients, the most common manifestations were pleuritis (14.3%), lupus pneumonitis (3.6%), pulmonary hypertension (3.2%), interstitial lung disease (2.3%), pulmonary embolism (2.3%), pulmonary fibrosis (2.14%), alveolar hemorrhage (1.4%), shrinking lung (0.2%). there was no significant difference in the follow up at one year. Immunoserological characteristics shows ANA positivity in 92%, anti-DNA in 53%, ENAS in 97%, with anti-RNP being the most common (41.7%), and low complement levels in 53%. Mortality for pulmonary compromise was 1.4%, and survival at 2 years did not have a statistically significant difference (p=0.155)
Conclusion: Survival was not found to be lower in patients with SLE and pulmonary involvement (p=0.155) when compared to SLE patients without pulmonary involvement after 2-year follow-up. This finding was independent of age, gender, and educational level. Previous large cohorts like GLADEL and RELESSER describe an association between pulmonary involvement and lower survival HR 2,79 (95% CI: 1,80-4,31), p <0,001 and HR 3.13, (95% IC: 1.56– 6.28, P = 0.00 respectively. In the RELESSER cohort pleural involvement and pulmonary embolism was found to have low to minimal impact on survival.
In our cohort pleuritis was the most common finding whereas the other pulmonary manifestations were reported in less than 4% of patients. This difference could explain our differences with other cohorts. Other causes for this difference are a smaller sample size and a short follow-up.
The results of our study do not suggest that there is an association between pulmonary involvement and mortality in Colombian patients with SLE during a 2-year follow-up. We will continue to monitor and report in this regard

AB0336 PULMONARY MANIFESTATIONS IN A COLOMBIAN COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Herrera[1], J. C. Diaz-Coronado[1,2], S. Monsalve[2], S. Guerra-Zarama[2], M. F. Saavedra Chacón[2], J. Barbosa[1], J. D. Serna Giraldo[2], J. D. Lopez[2], J. M. Gutiérrez[2], T. Vega[2], D. Orozco[2], D. Ocampo[2], N. Zuluaga[2], D. Hernandez-Parra[1], D. Rojas-Gualdrón[3], R. Pineda.Tamayo[1]. [1]*Artmedica IPS, Clinical Information Group, Medellín, Colombia*; [2]*CES University, Department of Internal Medicine, Medellín, Colombia*; [3]*CES University, Facultad de medicina, Medellín, Colombia*

Background: Pulmonary manifestations are frequent in systemic lupus erythematosus (SLE) with a frequency of 30-90% that depends on the cohort and the methods used for their identification. The association of this compromise with mortality highlights its importance and the need for biomarkers to adequately predict this complication. We describe the prevalence of pulmonary manifestations, and the clinic and immunoserological characteristics of 551 Colombian patients with SLE
Objectives: We performed an observational and analytic study of a retrospective cohort with adult SLE patients who fulfilled the 2012 SLICC classification criteria and that had a history of at least 6 months of the disease. These patients were treated in a specialized center of rheumatology with presence in six cities of Colombia between 2015 and 2018. We excluded pregnant patients and those with incomplete data for our survey. The first clinic consult occurred between 2015 and 2018, being defined as moment one. The follow up one year later was defined as moment two. We obtained 710 registries that were potentially eligible and analyzed 465 patients at moment two after applying the exclusion criteria
Methods: In 465 eligible patients, 20,5% had pulmonary compromise (93.8% female) with a median age of 42,4 years. The average SLICC Damage Index of 551 patients with SLE was 0,9 in women and 1.05 in men, while the average SDI of patients with pulmonary compromise was 1. The most frequent manifestation was pleural (14.3%), followed by Lupus pneumonitis (3.6%) and pulmonary hypertension (3.2%). Other manifestations and serological characteristics are recorded in Table 1. Of note, ANA homogeneous pattern was the most common (34.5%), anti-RNP positivity was 41.7%, anti-dsDNA positivity was 53.1% and 53.1% had hypocomplementemia.
Results: The prevalence of pulmonary manifestations in our cohort was 20,5%, which is lower that in the previous described GLADEL cohort (28,4%). This could be explained by the regional differences of ethnicities in Latin America and in immune-serological profiles. Anti-RNP positivity was frequent (41.7%) and new pulmonary compromise for one year follow-up was rare. Of not, the mean damage index for our patients with pulmonary manifestations was 1, this could highlight the importance of this organ as a causa of higher damage accrual and mortality, which we will explore in the future
Conclusion: The prevalence of pulmonary manifestations in our cohort was 20,5%, which is lower that in the previous described GLADEL cohort (28,4%). This could be explained by the regional differences of ethnicities in Latin America and in immune-serological profiles. Anti-RNP positivity was frequent (41.7%) and new pulmonary compromise for one year follow-up was rare. AB0337 ASSESSMENT OF HEALTH-RELATED QUALITY OF LIFE IN SYSTEMIC LUPUS ERYTHEMATOSUS USING THE SLEQoL (SYSTEMIC LUPUS ERYTHEMATOSUS-SPECIFICQUALITY OF LIFE QUESTIONNAIRE)

M. Brahem[1], M. Ardhaoui[1], S. Arfa[2], H. Hachfi[1], B. Ben Rejeb[2], R. Sarraj[1], M. Hassayoun[1], S. Abdellatif[1], A. Ben Salem[1], R. Ben Tekaya[1], O. Berriche[2], Y. Mohamed[1]. [1]*Taher Sfar Hospital, Rheumatology, Mahdia, Tunisia*; [2]*Taher Sfar Hospital, Internal Medicine, Mahdia, Tunisia*

Background: Patients withsystemic lupus erythematosus (SLE) have a better survival than decades ago. Nevertheless, they still experience a low health-related quality of life (HRQoL). The Systemic Lupus Erythematosus-Specific Quality of Life Questionnaire (SLEQoL) is one of the most widely used specific tools for measuring HRQoL in SLE.
Objectives: The aim of our study is to assess the impact of the SLE in the HRQoL using the SLEQoL tool.
Methods: This is a cross-sectional study during a period of the year 2020, including patients followed in the departments of Internal Medicine and Rheumatology in Mahdia, Tunisia. All patients were diagnosed with SLE based in ACR 1997/ SLICC2012. The SLEQoL is composed of 40 items scored from 1 to 7, it includes six HRQoL domains: physical functioning (Items 1 to 6), activities (items 7 to 15), symptoms (items 16 to 23), treatment (items 24 to 27), mood (items 28 to 31) and self-image (items 32 to 40) with higher values corresponding to worse HRQoL.
Results: Forty patients were enrolled. The age of the SLE patients (36 females/4 males) ranged from 11 to 87 years. The mean age was 47.75±17.59 years. The mean disease duration was 2.3 ±2.9 years. The mean SLEDAI score was 5.78±4.94. The main target organs involved were cutaneous, musculoskeletal, neurological, pulmonary, cardiovascular and renal in 85%, 82.5%, 32.5%, 17.5%, 15% and 7.5% of cases respectively. The biologic analysis showed the positivity of anti-nuclear antibodies in 97.5% of cases, low serum complement C3 and C4 in 20% and 32.5% of cases respectively. A biological inflammatory syndrome was found in 37.5% of cases and Anemia in 42.5%. 85% of SLE patients were treated by anti-malarial, 62.5% were treated by Glucocorticoids and 5% by Methotrexate. The mean SLEQoL global score was 77.92 ± 34.02 [40-153]. The means of different domains (physical functioning, activities, symptoms, treatment, mood and self-image) were respectively 12.1±6.49 [6-30]; 19.6±10.9 [9-49]; 16.4±8.1 [8-34]; 5.5±2.36 [4-14]; 9.6±5.4 [4-20]; 14.9±7.5 [9-36]. The most severely impacted domains were activities and symptoms. The less affected domains were treatment and mood. The SLEQoL global score was correlated with increased age (p=0.03), longer disease duration (p=0.05), SLEDAI score (p=0.02), visual analog scale of pain (p=0.04), musculoskeletal manifestations (p=0.04), cutaneous manifestations (p=0.05) and pulmonary manifestations (p=0.05). By analyzing biological tests of our patients, we found a correlation between the SLEQoL global score and Erythrocyte sedimentation rate [ESR] (p=0.05), Anemia (p=0.04), low serum complement C3 (p=0.02) and C4 (p=0.003). SLEQoL global score and its six domains were not correlated with gender, educational level nor marital status.
Conclusion: Our study showed that HRQoL is impaired in patients with SLE. The most important predictors of low HRQoL were older age, longer disease duration, some clinical manifestations, biological activity disease indicators (ESR, anemia and low complement level) and the SLEDAI score.

AB0338 PREGNANCY OUTCOMES IN ADOLESCENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

P. Alba[1], Y. Tissera[1], N. Cucchiaro[2], V. Savio[1], R. Serrano Morales[3], M. I. Quaglia[1], J. A. Albiero[1], V. Juarez4, C. A. Gobbi[5], M. Yorio[1], M. E. Crespo Espindola[2]. *[1]Universidad Nacional de Cordoba, Catedra de Semiologia. Servicio de Reumatologia Hospital Cordoba, Cordoba, Argentina*; *[2]Hospital Señor del Milagro, Servicio de Reumatologia, Salta, Argentina*; *[3]Centro de Enfermedades autoinmunes y Reumaticas, Maternidad Oroño, Rosario, Argentina*; *[2]Hospital Señor del Milagro, Servicio de Reumatologia, Salta, Argentina*; *[5]Universidad Nacional de Cordoba, Catedra de Medicina I. Servicio de Reumatologia Hospital Cordoba, Cordoba, Argentina*

Background: Systemic lupus erythematosus (SLE) is a autoimmune disease that affects adolescents and young women of childbearing age. In spite of the improvement in fetal and maternal SLE pregnancy outcome in the last decades, they have increased risk of adverse outcomes including disease flare, abortions, preeclampsia (PE) and premature birth (PB). However, pregnancy outcomes among adolescents with SLE have not been well explored.
Objectives: To evaluate maternal and fetal outcomes in pregnant adolescents with SLE.
Methods: We retrospectively studied all pregnant SLE adolescent patients, who attended to 3 Maternity Hospitals in Argentina in the last 5 years. Demographic, clinical, and laboratory data were collected. The presence of Antiphospholipid Syndrome (APS) and the Antiphospholipid antibodies (AA), and maternal and fetal outcome were evaluated. Adolescent pregnancy was defined it is happened between 10 and 19 years old. Lupus activity was evaluated by SELENA SLEDAI at the conception and each trimester of pregnancy and puerperium.
Results: 32 pregnancies in 21 patients were included. Mean age was 18 years old, 66% was mestizo ethnicity and mean disease duration of 2 years. Renal involvement was found in 19, Mucocutaneous in 21, and hematological in 14 patients. 4 patients had positive Anti-SSA/Ro antibodies, 1 Anti-SSB/La, 2 Lupus anticoagulant, 6 Ig G ACL, 3 Ig M ACL, and 8 patients fulfilled APS criteria. Activity disease was 0 SELENA SLEDAI in 1 ° trimester, 4 in 2°,3° trimester and puerperium. Maternal and fetal outcomes are shown in Table 1. Cesarean section was performed in 58%(n=18) of the patients, 6 had abortions and 1 fetal death.

Table 1.

Maternal outcomes	
Disease Flares	13(41%) 7 renal
(PE)/Hellp	6 (19%)
Gestational Diabetes	1 (3%)
Maternal outcomes Spontaneous Membrane Rupture	1 (3%)
Mortality	0
Fetal outcome	
Live birth	24 (75%)
Gestational age (weeks)	32 (32-38)
Weight (grs)	2805 (2100-3340)
IUGR	5 (16%)
PB	8 (25%)

Conclusion: Maternal and fetal complications were high in adolescent pregnancy with SLE, including disease activity, PE and PB. A tight control of patients should be performed before and after conception. These patients should be managed by a multidisciplinary team, thus allowing an improvement of maternal and fetal prognosis.

AB0339 PREVALENCE AND ASSOCIATED FACTORS OF LOW BONE MINERAL DENSITY IN ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Ardhaoui[1], M. Brahem[1], S. Arfa[2], H. Hachfi[1], B. Ben Rejeb[2], M. Hassayoun[1], R. Sarraj[1], S. Abdellatif[1], A. Ben Salem[1], R. Ben Tekaya[1], O. Berriche[2], Y. Mohamed[1]. *[1]Taher Sfar Hospital, Rheumatology, Mahdia, Tunisia*; *[2]Taher Sfar Hospital, Internal Medicine, Mahdia, Tunisia*

Background: Patients with Systemic Lupus Erythematosus (SLE) are at risk of osteoporosis (OP) and fragility fractures (FFx) because of the disease or its treatments. We assessed the prevalence and risk factors for OP in patients with SLE.
Objectives: Our objective is to determine the prevalence of bone mineral density (BMD) loss and fracture risk factors in SLE patients undergoing dual-energy X-ray absorptiometry (DXA).
Methods: This is a cross sectional study conducted during the year 2020 in the Rheumatology and internal medicine departements in Taher Sfar hospital of Mahdia, Tunisia. We included patients aged ≥18 years with a diagnosis of SLE according to the 1997 ACR or 2012 SLICC criteria. Patients with renal or hepatic osteodystrophy, or receiving bisphosphonates were excluded from the study. The BMD values were measured by DXA. The T-score, Z-scores and BMD of the lumbar spine (LS) and femoral neck (FN) were determined. OP was defined as a value of the T-score less or equal to -2.5 SD for postmenopausal women and men aged more than 50 years old, and Z-scores less or equal to -2 for premenopausal women and men aged less than 50 years old.
Results: Forty-six SLE patients were included. The mean age was 47.19±16.45 years [18-85], with a mean disease duration of 2.52±3.46 years [15days-15years]. The mean SLEDAI score was 5.34±4.82. As regards menstrual history of female patients: 56.5% were premenopausal, 43.5% were post-menopausal and 6% had premature menopause. 13% of our patients gave history of smoking. The mean BMI was 27.6 ± 6 kg/m2 [15-39.8]. FFx were diagnosed in 4 patients (9%) and the mean age of the first fracture was 45years. GCs were used in 65.2% of cases (30 patients). The mean daily dose of GCs was 10 mg/day and the mean cumulative dose was 20g. Calcium and Vitamin D intake was mentioned in 65.2% of cases (30 patients). The association of SLE with other rheumatic diseases was found in 14 of patients. The mean T-score at FN and LS were respectively 0.02±1.17 and -1.32±1.36. The mean Z-score at FN and LS were respectively 0.53±1.14 and -0.6±1.26. It was found that 17 patients (37% of cases) had OP, 12 had osteopenia (26%) and 17 patients (37%) had normal BMD. 37% of patients had OP at LS, 23.9% osteopenia at LS, 6.5% OP at FN and 21.7% osteopenia at

FN. Low BMD was significantly correlated with increased age (p=0.01) and disease duration(p=0.05),post-menopausal status(p=0.04), higher BMI (p=0.004), musculoskeletal involvement (p=0.01), association to other rheumatic diseases (p=0.01), higher disease activity by SLEDAI score (p=0.05), higher Erythrocyte sedimentation Rate (p=0.01) and C-Reactive Protein (p=0.007), low serum complement C3 (p=0.009) and C4 (p=0.04) and cumulative doses of GCs (p=0.01). We found also that BMD at LS was mostly affected by GCs intake, BMI and CRP while BMD at FN was mostly affected by SLEDAI score, C3 and C4 (p<0.001 in all cases). Gender, history of smoking and cardiovascular comorbidities had no significant impact on BMD.

Conclusion: OP is a common but unrecognised complication of SLE with increased frequency of both peripheral and vertebral FFx. Our study suggests a high risk profile for OP and FFx in SLE which seems to be associated with age, disease duration, post-menopausal status, BMI and GCs.

AB0340 PATIENTS WITH LABORATORY CRITERIA OF ANTIPHOSPHOLIPID SYNDROME AND "NON-CRITERIA" MANIFESTATIONS: A MULTICENTER STUDY

G. Pires Da Rosa[1,2], E. Ferreira[2,3], B. Sousa-Pinto[4,5], P. Bettencourt[2,6], R. Cervera[1], G. Espinosa[1]. *[1]Hospital Clínic, Institut d'Investigacions Biomèdiques August Pi I Sunyer (IDIBAPS), University of Barcelona, Department of Autoimmune Diseases, Barcelona, Catalonia, Spain*; *[2]University of Porto, Faculty of Medicine, Porto, Portugal*; *[3]Centro Hospitalar Universitário de São João, Department of Internal Medicine, Porto, Portugal*; *[4]CINTESIS – Center for Health Technology and Services Research, Porto, Portugal*; *[5]Faculty of Medicine, University of Porto, MEDCIDS – Department of Community Medicine, Information and Health Decision Sciences, Porto, Portugal*; *[6]Hospital CUF, Department of Internal Medicine, Porto, Portugal*

Background: Patients with laboratory criteria for antiphospholipid syndrome (APS) and presenting only "non-criteria" clinical manifestations are scarcely described in the literature [1-3].

Objectives: To describe a cohort of these patients, portraying potential associations between "non-criteria" manifestations, antiphospholipid antibodies (aPL) and treatments.

Methods: Retrospective analysis of patients with aPL positivity fulfilling APS criteria assessed in two tertiary European hospitals between 2005 and 2020. Those without criteria clinical manifestations but with the presence of "non-criteria" manifestations were included.

Results: A total of 75 patients were analyzed. The predominant non-obstetric involvements were hematologic (thrombocytopenia, hemolytic anemia) and "mild" neurological (white matter lesions, migraine), with an absence or near absence of cutaneous, cardiac, pulmonary and more severe neurologic manifestations (Table 1). In obstetric morbidity, two spontaneous abortions before 10 weeks and infertility were the more frequent manifestations. LA positivity was positively associated with non-obstetric manifestations (OR=4.2, 95% CI 1.5-11.9; p=0.007) while an aCL profile was associated with obstetric manifestations (OR 7.0, 95% CI 2.3-21.3; p=0.001). A suspicion of progression towards SLE was considered plausible in 13 (19%) of non-SLE individuals. Twelve (40.0%) of patients with thrombocytopenia as their only hematological involvement required corticosteroids. History of infertility (OR 6.1, 95% CI 1.3-28; p=0.02) and IVF recurrent failure (OR 6.5, 95% CI 1.2-36.3; p=0.032) were associated with pregnancy treatment with LMWH/LDA combination. Among patients under anticoagulation, clinical manifestations included brain white matter lesions, APS nephropathy, superficial vein thrombosis, amaurosis fugax, and livedoid vasculopathy. A higher value of GAPSS was observed in patients with non-obstetric (median 9, IQR 5-13) in comparison to those with obstetric manifestations (median 5, IQR 4-5.5).

Conclusion: The present article stresses the clinical relevance of these patients, with an impression that at least some manifestations will contribute in the future to the classification of individuals as definite APS.

AB0341 SLE PREGNANCIES AT HIGH RISK FOR PRE-ECLAMPSIA BENEFIT MOST FROM COMBINATION OF LOW DOSE ASPIRIN AND HYDROXYCHLOROQUINE

I. Haase[1], G. Chehab[1], O. Sander[1], M. Schneider[1], R. Fischer-Betz[1]. *[1]Heinrich-Heine-University Duesseldorf, Policlinic for Rheumatology & Hiller Research Unit for Rheumatology, Duesseldorf, Germany*

Background: Women with SLE face a high risk of preeclampsia (PE). Low dose Aspirin (LDA) is known to protect against PE in non-autoimmune patients and is recommended for SLE patients[1]. Besides, a beneficial effect of hydroxychloroquine (HCQ) on the occurrence of PE has recently been discussed[2].

Objectives: To investigate the influence of LDA and HCQ on the occurrence of PE in SLE patients.

Methods: Pregnancies of women with SLE from an outpatient pregnancy clinic were prospectively evaluated. Clinical characteristics, medication use and pregnancy outcomes were analysed. Association of LDA use (latest from gestational week 16 on) and HCQ use (from 1st trimester on) with PE were analysed using a multiple logistic regression model (adjustment for age, BMI, hypertension, disease activity in 1st trimester, lupus nephritis, nulliparity, history of PE and high-risk aPL profile[3]).

Results: We enrolled 190 lupus pregnancies (148 women, 1995-2019). Additional risk factors for PE were present in 83.7%: 55.8% showed a high-risk profile (HRP) for PE according to ACOG[4] (history of PE, hypertension, lupus nephritis or aPL), another 27.9% had at least one moderate risk factor (nulliparous, BMI>30 or age>35) (see table 1).

Each 20.5% of pregnancies received HCQ only or LDA only, while 22.6% were prescribed both drugs. 36.3% took neither HCQ nor LDA. Women with HRP were more likely to take LDA alone or in combination with HCQ (28.3% and 35.8%, respectively).

PE occurred in 13.2% of pregnancies (7.7% in HCQ only, 15.4% in LDA only, 14.0% in HCQ and LDA, 14.5% in no HCQ or LDA). Most pregnancies affected by PE carried a HRP (88.0%).

Use of LDA was significantly associated with a lower risk for PE [aOR 0.21 (95%-CI 0.05-0.99), p<0.05]. HCQ use also had a moderating effect on the incidence of PE, but this effect did not reach significance [aOR 0.47 (95%-CI 0.15-1.52), p=0.21]. If only pregnancies with HRP were considered, the effect size increased for HCQ (LDA [aOR 0.18 (95%-CI 0.04-0.96), p<0.05], HCQ [aOR 0.28 (95%-CI 0.07-1.14), p=0.075]).

Conclusion: In this prospective real-life cohort, timely LDA medication was associated with a lower risk of PE in SLE pregnancies. In a multiple regression model taking LDA and HCQ into account, the favourable effect on the occurrence of PE was partially explained by HCQ. In particular, SLE patients at high risk

for PE seem to benefit from HCQ during pregnancy. Future research may reveal mechanisms by which HCQ might lower the incidence of PE.

Pons-Estel[1]on behalf of Antiphospholipid Syndrome Study GroupArgentine Society of Rheumatology..
[1]*Argentine Society of Rheumatology,APS Study Group, Buenos Aires, Argentina*

Background: Several studies showed two main clinical phenotypes of antiphospholipid syndrome (APS): thrombotic (TAPS) and obstetric APS (OAPS). Although they have the same autoantibody profile, one of them developed thrombosis and other one obstetric morbidity.
Objectives: To study clinical, demographic and antibody profile in patients with TAPS and OAPS.
Methods: we retrospectively evaluated TAPS and OAPS patients who were included in Argentine Antiphospholipid antibodies registry. We studied clinical, demographic and antibody profile in both groups.
Results: 238 patients were included in the registry. 201 (84.81%) of them were female. 122 (60.69 %) of them fullfilled APS Sydney classification criteria, 47 (38.52%) TAPS and 52 (42.62%) OAPS. 23 (18.85%) patients had both thrombotic and obstetric events so they were excluded in this analysis.
Arterial Hypertension (HBP) and Hyperlipidemia were more frequent in TAPS versus OAPS. Older age was found in TAPS as well as in association with Systemic lupus erythematosus (SLE). There was no difference in antibody profile between the 2 groups, and the Global Antiphospholipid Syndrome Score (aGAPSS) was higher in TAPS than OAPS.
18 (38.3%) of TAPS patients had at least 1 pregnancy. Mean number of pregnancies of TAPS was 2.5 (1.10) and 3.84 (1.86) in OAPS. Thrombotic events were not found in TAPS during pregnancy and puerperium. HBP and gestational diabetes (GD) and other pregnancy related comorbidities were found in TAPS.

AB0343 THE CHARACTERISTICS OF T CELLS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH ANXIETY BASED ON MACHINE LEARNING

X. Gu[1], Y. Jin[1], R. Li[1], D. Zhang[1], C. Dong[1], Q. Zhang[2], Z. Xue[2], Z. Gu[1].
[1]*Affiliated Hospital of Nantong University, Department of Rheumatology, Nantong, China*; [2]*Affiliated Hospital of Nantong University, Research Center of Clinical Medicine, Nantong, China*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease, the immune system of patients to be disordered, especially in T cell subsets[1]. They were prone to mental diseases, anxiety particularly, which lead to suicide[2]. The recent study had reported that $CD4^+$ T cells in the peripheral blood played the key role in like anxiety behavior of mice[3]. Although there showed that the level of serum TNF-α in SLE patients with anxiety was higher than without anxiety[4], finding the important special mediators especially in T cell subsets was still necessary for the prevention of anxiety in SLE patients.
Objectives: In total, 108 SLE patients, which met the diagnostic criteria of the American Society of rheumatology (v1997), were enrolled in this study from Affiliated Hospital of Nantong University, China. Exclusion criteria included other autoimmune diseases and active infection (including hepatitis B or C virus, Epstein-Barr virus, human immunodeficiency virus or Mycobacterium tuberculosis infection).
Methods: We surveyed the abundance of 74 immune cell subpopulations from 108 SLE patients using flow cytometry, and investigated their differences between patients with and without anxiety (24 versus 84). Moreover, machine learning including Lasso regression, Random forest (RF) and Sparsity partial least squares discriminant analysis (sPLS-DA) was employed to build models and futher selected important features for the classification of SLE patients with anxiety.
Results: SLE patients with anxiety showed higher body mass index (BMI) and lower quality of life. In their peripheral blood, the proportion of internal cell subsets composition of Th cell and Treg cells changed. By machine learning, we

finally found that BMI and PD1$^-$CD28$^-$ Treg played important rules to developing lupus anxiety.

Conclusion: In this study, machine learning was applied to build models to select the most important T cell subset in SLE patients with anxiety. These findings suggested that BMI and imbalance of PD1$^-$CD28$^-$ Treg containing effector memory Treg cells and effector Treg cells mostly played important roles in the development of SLE anxiety.

AB0344 PREVALENCE AND RISK FACTORS FOR SEROSITIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A CASE CONTROL STUDY

L. Gimeno-Torres[1], I. Carrión Barberà[1], X. Duran[2], T. C. Salman Monte[1]. *[1]Hospital del Mar, Rheumatology, Barcelona, Spain; [2]IMIM, Statistics, Barcelona, Spain*

Background: Systemic lupus erythematosus (SLE) is an autoimmune multisystemic disease with a wide variety of clinical manifestations, being one of them serositis, which includes pericarditis, pleuritis and peritonitis [1]. Incidence of serositis ranges between 11-54% [2].

Objectives: To determine the prevalence of serositis in patients (pt) with SLE attended at the outpatient Lupus Unit and identify factors that could be used as predictors of this manifestation.

Methods: Retrospective case-control study. 297 medical records of SLE pt were reviewed: 28 pt were diagnosed with serositis (cases) and were age- and sex-matched with 2 controls with SLE without serositis. Differences between cases and controls were analyzed as well as factors associated with serositis.

Results: Patient's characteristics are described in Table 1. The prevalence of serositis in our cohort was 9.42%. The difference between the prevalence of serositis in men and women was statistically higher in men, 30% vs 7.9% (p=0.001, CI 95%: 1.7%-42.4%). Serositis was diagnosed at an age of 41 ±14 years (y) and in 40.7% it was the first symptom. Time from SLE diagnosis to serositis was 4±5.3 y. 10 pt had recurrences: 6 had 2, and 4 had 3. Incidence of pericarditis and pleuritis was 78.6% and 82.1% respectively. 2 pt suffered from pericardial tamponade. Mean prednisone dose received during the serositis was 44.6±26.6mg. At the moment of serositis 100% were ANA+, 85.7% antidsDNA+, 80% CrithidiaDNA+, 57.9% antiRo60+, 52.6% antiRo52+, 15.9% antiLa+, 47.4% antiRNP+, 21.1% antiSm+, and 77.8% had low C3.

When looking for serositis-associated factors we only found association with antidsDNA measured by Crithidia (p=0.016) and different measures of glucocorticosteroids (GC), having cases needed higher doses than controls (Table 1). Those with serositis had significantly received more mycophenolic acid (p=0.021) and marginally, more belimumab (p=0.056).

Table 1. Characteristics of cases and controls. *indicates mean±SD, Bold=statistically significant difference.

VARIABLES	CASES (28)	CONTROLS (54)	p-value
Female	22 (33.3%)	44 (66.7%)	0.775
Male	6 (37.5%)	10 (62.5%)

Leukopenia	17 (34.0%)	33 (66.0%)	1.000
Lymphopenia	25 (33.8%)	49 (66.2%)	1.000
Thrombocytopenia	5 (20.8%)	19 (79.2%)	0.128
Nephritis	8 (50.0%)	8 (50.0%)	0.152
Raynaud's phenomenon	6 (42.9%)	8 (57.1%)	0.263
Haemolytic anaemia	3 (42.9%)	4 (57.1%)	0.686
Antinuclear antibodies	28 (34.6%)	53 (65.4%)	1.000
AntidsDNA	23 (37.7%)	38 (62.3%)	0.295
AntiSm	9 (42.9%)	12 (57.1%)	0.425
AntiRo52	10 (41.7%)	14 (58.3%)	0.444
AntiRo60	13 (37.1%)	22 (62.9%)	0.645
AntiRNP	14 (43.8%)	18 (56.3%)	0.159
CrithidiaDNA	19 (47.5%)	21 (52.5%)	**0.016**
Low C3	21 (39.6%)	32 (60.4%)	0.224
Low C4	13 (38.2%)	21 (61.8%)	0.637
Low CH50	13 (39.4%)	20 (60.6%)	0.480
SLICC*	0.54 (±0.9)	0.49 (±1.1)	0.717
SLEDAI*	3.1 (±3.1)	2.98 (±3.2)	0.844
Corticosteroids			
Ever	27 (38.6%)	43 (61.4%)	**0,051**
Pulses ever	9 (60.0%)	6 (40.0%)	**0.033**
Maximum prednisone dose ever:			
<10mg	18 (85.7%)	3 (14.3%)	**0.003**
10-29mg	14 (87.5%)	2 (12.5%)	
30-60mg	11 (45.8%)	13 (54.2%)	
>60mg	8 (47.1%)	9 (52.9%)	

Conclusion: The prevalence of serositis was 9.42%. Serositis is significantly more frequent in SLE men than in women: almost ⅓ will develop serositis, so we need greater awareness of serositis in SLE men.

CrithidiaDNA+ was identified as an associated factor of serositis. Furthermore, pt with serositis significantly received more pulses of GC and a higher maximum dose throughout the disease, which could imply a more aggressive form of SLE than in those without serositis. No correlation was found between serositis and any other characteristic.

AB0345 TH9 CELLS AND THEIR ASSOCIATED CYTOKINES: THE PROBABLE PLAYERS IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND TYPE 1 DIABETES MELLITUS (T1DM)

N. Mohannad[1], M. Moaaz[2], R. Mohamed Shehata[3]. *[1]Alexandria University Hospitals, Faculty of Medicine, Alexandria University, Internal Medicine Department, Alexandria, Egypt; [2]Medical Research Institute, Alexandria University, Immunology & Allergy, Alexandria, Egypt; [3]Molecular Biology Department, Faculty of Science, Alexandria University*

Background: SLE is an autoimmune disease (AID) of unknown origin. Several factors can contribute to immune dysfunction in SLE.

Interleukin 9 (IL9) is a newly emerging T cell-derived factor preferentially expressed by CD4+T cells: T helper 9 (Th9)

IL9 targets different cell lineages, and can contribute to the development of allergic & AIDs

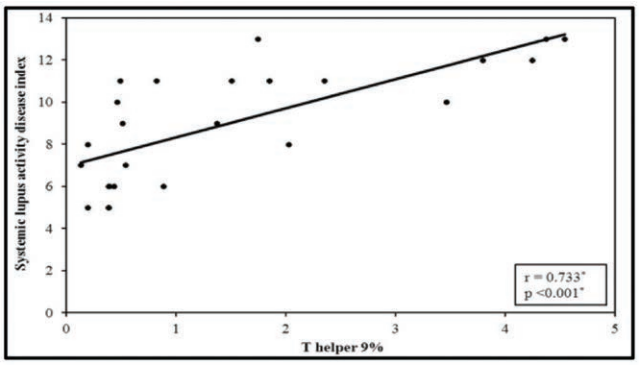
Whether abnormal expression and secretion of IL9 are present in SLE patients (pts) still unidentified. It is also unclear whether IL9 exerts main proinflammatory or anti-inflammatory activities in SLE. T1DM is characterized by inflammation of the pancreatic islets of Langerhans. Insulitis progresses over time and β cells become destroyed then clinical DM is established. T1DM is regarded as a T cell-driven AID

Objectives: Evaluation of the expression of CD4+ IL9+ T cells & the level of IL9 in SLE pts compared to both healthy subjects & pts with another AID: T1DM.Also, to evaluate the correlation of these expressions with clinical features, laboratory parameters and SLE activity

Methods: The study included: **Group I** 25 SLE pts fulfilling SLICC classification criteria divided into 2 subgroups (gps) according to SLE disease activity index (SLEDAI) IA: 20 pts with mild to moderate activity (<12) IB:5 pts with severe activity (>12) recruited from rheumatology clinic or internal medicine ward (Rheumatology unit), Main University Hospital, Alexandria. **Group II** 15 healthy individuals as a first control gp. **Group III** 15 pts with T1DM fulfilling the American Diabetes Association criteria as a second control gp. All pts were subjected to history taking, clinical examination,laboratory investigations: CBC,LFT,KFT,ESR,CRP,ANA,Anti-dsDNA,Th9 cell expression detection by flowcytometry and serum IL9 by ELISA

Results: There was no statistical difference between all gps as regards age & sex but a significant increased ESR in SLE compared to controls & T1DM p< 0.001 p=0.001

Th9 expression was highly increased in SLE pts, range 0.13-4.54% & mean ±SD=1.50 ± 1.47% than both control gps. In healthy controls Th9 ranged between 0.0-1.29% with mean 0.37 ±0.52%, while in T1DM pts ranged between 0.03



to 2.13% with mean of 0.67 ± 0.59%. A high significant difference was found between SLE pts and controls p=0.001, an insignificant rise was seen in SLE pts compared to T1DM pts p=0.157. A high significant increase in Th9 was found in severe SLE: mean of 3.74 ±1.15% than in pts with mild to moderate SLE: mean 0.94±0.88% p=<0.001

IL9 level was highly increased in SLE pts: mean of 42.83± 23.98 pg/ml than both control gps. In healthy controls the mean was 8.54±13.27, while in T1DM with mean of 29.17±16.09 pg/ml. A high significant difference was found between SLE pts and normal controls p<0.001 but an insignificant rise with T1DM p=0.294. A high significant increase in IL9 in pts with severe ds compared to mild to moderate pts p<0.001.A significant direct correlation between Th9 & IL9 and SLEDAI/105 A significant direct correlation between damage index and Th9 p=0.040 but not IL9 p=0.053

In SLE no significant relation between Th9 or IL9 & clinical manifestations or disease duration. A direct correlations between Th9 & ESR p=0.046 and CRP p=0.025,a significant correlation between IL9 and CRP p=0.033, no correlations between Th9&IL9 level and anti-dsDNA p=0.593& 0.4 Significant direct correlation between Th9 and IL9 in T1DM pts, still no correlation with glycemic profile. IL9 levels were significantly increased in SLE with elevated CRP p=0.033 & the % of Th9 cells were increased with elevated ESR and CRP p=0.025, 0.046

Conclusion: In SLE pts; IL9 level and Th9 cells expression were significantly elevated compared to healthy controls. IL9 levels and the percentages of Th9 directly correlated with the SLE disease activity. IL9 levels also were significantly increased in T1DM pts compared to controls,but they were less expressed than in SLE. This suggests an important role of IL9 in the pathogenesis AIDs as SLE

AB0346 RHUPUS SYNDROME: CLINICAL ANALYSIS OF 21 PATIENTS

M. Ben Brahim[1], S. Daada[1], M. Elghali[2], J. Mahbouba[3], N. Bergaoui[3], S. Hammami[1]. [1]*Fattouma Bourguiba University Hospital, Internal Medicine, Monastir,Tunisia*; [2]*Fattouma Bourguiba University Hospital, Immunology, Monastir,Tunisia*; [3]*Fattouma Bourguiba University Hospital, Rhumatology, Monastir,Tunisia*

Background: Rhupus syndrome is a clinical condition characterized by a combination of the clinical and immunologic features of rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) (1). However, this definition did not establish whether Rhupus syndrome is a distinct clinical entity or is an overlap between RA and SLE. To date, fewer than 200 cases of Rhupus have been reported (1).

Objectives: Our purpose was to analyze the clinical and serological characteristics of patients with Rhupus and compare them with patients with SLE.

Methods: We undertook a retrospective study covering 10 years (2009 to 2019) of experience in our University Hospital: Department of Internal Medicine and department of Rheumatology. 238 patients hospitalized were evaluated during this period. The clinical and laboratory parameters of 21 patients with Rhupus syndrome were compared with those of 217 SLE without RA patients

Results: Twenty one patients were included (all fulfilled ACR criteria for SLE as well as for RA).They were 19 female and 2 male. The mean age of patients at the disease onset was 43.5 years. Among these, 9 patients (42.8%) were diagnosed with RA at the onset of disease and then developed SLE over an average period of 6.2 years. Six patients (28.5%) had a diagnosis of SLE prior to the RA diagnosis with an interval of 8.6 years between diagnoses. Six patients (28.5%) were diagnosed with RA and SLE concomitantly. Patients with Rhupus experienced more often arthritis, joint swelling, morning stiffness and joint erosions then patients with SLE alone (p<0.001). Comparison of extra-articular manifestations showed that, renal involvement was less often in patients with Rhupus when compared to patients with SLE-alone. There were no significant differences in the prevalence of malar rash, serositis, neurological and hematological features between the Rhupus and SLE-alone groups. Rheumatoid factor and anticyclic citrullinated peptide (CCP) antibody were significantly more prevalent in the Rhupus group than in the control group. The incidences of increased erythrocyte sediment rate (ESR) and C-reactive protein (CRP) were also significantly higher in Rhupus patients. (Table 1)

Table 1. Comparison of clinical and biological features between Rhupus Syndrome (Rhupus Group) and SLE-alone patients (Control Group).

	Rhupus Group N=21 (%)	Control Group N=217 (%)	p
Malar rash	12 (57.1)	120 (55.3)	0.87
serositis	6 (28.5)	47 (21.7)	0.46
Lupus nephritis	4 (19)	56 (25.8)	0.49
Hemolytic anemia	1 (4.7)	8 (3.6)	1
Leucopenia	8 (38)	90 (41.4)	0.15
Thrombopenia	4 (19)	27 (12.4)	1
Polyarthritis	21 (100)	54 (24.8)	<0.001
Erosion of joint	21 (100)	0	<0.001
Increased ESR	20 (95.2)	155 (71.4)	0.019
Increased CRP	18 (85.7)	88 (40.5)	<0.001
Anti-DNA antibodies	16 (76.1)	134 (61.7)	0.61
Anti-Sm antibodies	6 (28.5)	63 (29)	0.57
Rhumatoide Factor	12 (57.1)	52 (23.9)	0.04
Anti-CCP antibody	6 (28.5)	14 (6.5)	0.027

CRP: C-reactive protein, ESR: erythrocyte sediment rate, Anti-CCP: anticyclic citrullinated peptide antibody.

Conclusion: Patients sharing features of both RA and SLE have been observed infrequently. In fact, the incidence of Rhupus syndrome in SLE patients is estimated at 1.3% **(2)**. In our study, this incidence was 8.8%. The findings of our study are consistent with those of most studies with respect to the frequencies arthritis, lupus related features, and serological disorders **(2,3)**.

AB0347 RENAL BIOPSY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: IS IT ONLY LUPUS NEPHRITIS?

E. Duran[1], T. Yıldırım[2], U. Kalyoncu[1], A. Taghiyeva[3], E. Bilgin[1], E. Arzu Sağlam[4], M. Üner[4], J. Jabrayilov[2], E. C. Bolek[1], C. Önal[2], B. Farisoğulları[1], N. S. Koç[2], G. K. Yardımcı[1], S. Girgin[2], G. Ayan[1], Z. Özsoy[1], G. Sandal Uzun[1], L. Kılıç[1], Ş. R. Yılmaz[2], A. Akdoğan[1], Ş. A. Bilgen[1], O. Karadag[1], S. Kiraz[1], B. Altun[2], Y. Erdem[2], M. Arıcı[2], A. İ. Ertenli[1]. [1]*Hacettepe University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; [2]*Hacettepe University School of Medicine, Department of Internal Medicine, Division of Nephrology, Ankara, Turkey*; [3]*Hacettepe University School of Medicine, Department of Internal Medicine, Ankara, Turkey*; [4]*Hacettepe University School of Medicine, Department of Department of Pathology, Ankara, Turkey*

Background: Renal biopsy is a cornerstone in the diagnosis and management of renal involvement in patients with systemic lupus erythematosus (SLE). However, non-lupus nephritis has been also observed in SLE patients with renal disease (1).

Objectives: The aim of this study was to draw attention to the causes of non-lupus nephritis in SLE patients with kidney biopsy.

Methods: This retrospective, descriptive study included 139 SLE patients who had at least one kidney biopsy between 2001 and 2020. All patients had fulfilled the SLICC or EULAR/ACR criteria for SLE. According to the pathology report results, 116 of the patients were diagnosed with lupus nephritis (LN), 18 patients had non-lupus nephritis, 2 biopsies were normal, and 3 biopsies were insufficient. Demographics, SLE disease duration, and renal biopsy diagnosis were derived from our hospital medical records.

Results: Of the 23 patients (female:18/male:5), the mean age at the SLE diagnosis was 30.5 years and the median SLE disease duration was 8.5 (11.6) years. Pathologic report findings were compatible with focal segmental glomerulosclerosis in 6 patients, membranous nephropathy with no cellular proliferation and inflammation in 4 patients, thrombotic microangiopathy in 3 patients, IgM nephropathy in 2 patients, tubulointerstitial nephritis in 2 patients, and proliferative glomerulonephritis with monoclonal IgG deposits in one patient. There were no different for SLE manifestation in both gropus. LN vs other renal pathologies

laboratory comparing as follow: ANA (+) ≥ 1:320 89 (76.7%) vs 14 (60.9%), APS antibodies 31 (33.7%) vs 8 (57.1), anti-Sm (+) 8 (11.8%) vs 1 (4.3%) were similar for LN and other renal pathologies, but anti-ds-DNA positivity 94 (84.7%) vs 10 (50%), median ds-DNA level 421 (591) vs 150 (340) and low level of C3 and C4 were more frequent in LN (p<0.001; p=0.005; p<0.001, respectively).In addition, the rate of active urinary sediment and renal SLEDAI score were significantly high in LN patients.

Conclusion: Various renal lesions unrelated to lupus nephritis can be observed in SLE patients. Renal biopsy plays a critical role in identifying these lesions, which may have prognostic and therapeutic implications distinctive from those of lupus nephritis. Also, anti ds-DNA positivity/level, low C3 and C4, active urinary sediment and renal SLEDAI scores may give us some clues in terms of renal pathology for SLE patients. Moreover, almost half of the patients without LN in renal biopsy have anti ds-DNA positivity.

ALBUMIN-TO-GLOBULIN RATIO AS A POTENTIAL PREDICTOR OF RENAL REMISSION IN LUPUS NEPHRITIS

T. Knežević[1], I. Padjen[2], S. Bulimbašić[3], M. Ćorić[3], V. Ivković[1], M. Laganović[4], B. Anić[2]. [1]*University Hospital Centre Zagreb, Division of Nephrology, Hypertension, Dialysis and Transplantation, Department of Internal Medicine, ZAGREB, Croatia*; [2]*University Hospital Centre Zagreb and University of Zagreb, School of Medicine, Zagreb, Croatia, Division of Clinical Immunology and Rheumatology, Department of Internal Medicine, ZAGREB, Croatia*; [3]*University Hospital Centre Zagreb and University of Zagreb, School of Medicine, Zagreb, Croatia, Department of Pathology and Cytology, University Hospital Centre Zagreb, Croatia, ZAGREB, Croatia*; [4]*University Hospital Centre Zagreb and University of Zagreb, School of Medicine, Zagreb, Croatia, Division of Nephrology, Hypertension, Dialysis and Transplantation, National Referral Centre for Glomerular and Tubulointerstitial Diseases, Zagreb, Croatia, ZAGREB, Croatia*

Background: Optimal prognostic predictors in lupus nephritis (LN) are still not clearly defined. Studies have recently shown that albumin-to-globulin ratio (A/G) is not only a good predictor of outcomes in malignancy, infection and renal disease, but is also a potential marker of increased immunoglobulin synthesis and LN activity and might be useful as a predictor of the development of LN in SLE patients. Studies on the role of A/G in predicting outcomes in LN are, however, lacking.

Objectives: To assess a potential prognostic value of A/G at renal biopsy in predicting outcomes in LN.

Methods: In this retrospective study we analyzed the demographic, histologic, laboratory and clinical characteristics of patients with biopsy-proven LN diagnosed between 2011 and 2020. All patients met the 1997 revised American College of Rheumatology classification criteria for SLE. Complete remission was defined as proteinuria <0.5 g/day and serum creatinine within 10% from baseline, and partial remission as more than 50% reduction in proteinuria to sub-nephrotic levels and serum creatinine within 10% from baseline.

Results: We have included 55 patients (80% women) with biopsy-proven LN (age at biopsy 38±13 years). On renal histology, one patient was class I LN, two patients were class II, 7 were class III, 5 were class III+V, 23 were class IV, two were class IV+V, 11 class VI and 4 had other features. Median eGFR and proteinuria at biopsy were 69 (IQR: 44, 100) mL/min/1.73 m^2 and 3.5 (2.3, 5.6) g/day, respectively. Baseline mean A/G was 1.12±0.29 and did not differ between LN classes (p=0.91). At one-year follow-up eGFR increased non-significantly (69 vs. 82 mL/min/1.73 m^2, p=0.13) and proteinuria decreased (3.5 vs. 0.6 g/day, p<0.001). Eighteen patients achieved complete remission (CR), 16 partial remission and 21 did not achieve remission. None progressed to ESRD and two patients died, both from sepsis. A/G at the time of biopsy did not differ between group which achieved CR/PR vs. no remission (p>0.05; Figure 1) and was not a significant predictor of remission in a multivariate regression model (OR 5.9, 95% CI 0.6, 63.2).

Conclusion: While being a potential marker for transition of SLE to LN, A/G was not showed to be a predictor of renal remission in LN.

NEUTROPHIL-TO-LYMPHOCYTE RATIO, PLATELET-TO-LYMPHOCYTE RATIO AND MEAN PLATELET VOLUME IN LUPUS NEPHRITIS

T. Knežević[1], I. Padjen[2], S. Bulimbašić[3], M. Ćorić[3], V. Ivković[4], M. Laganović[1], B. Anić[2]. [1]*University Hospital Centre Zagreb and University of Zagreb, School of Medicine, Zagreb, Croatia, Division of Nephrology, Hypertension, Dialysis and Transplantation, Department of Internal Medicine, ZAGREB, Croatia*; [2]*University Hospital Centre Zagreb and University of Zagreb, School of Medicine, Zagreb, Croatia, Division of Clinical Immunology and Rheumatology, Department of Internal Medicine, ZAGREB, Croatia*; [3]*University Hospital Centre Zagreb and University of Zagreb, School of Medicine, Zagreb, Croatia, Department of Pathology and Cytology, University Hospital Centre Zagreb, Croatia, ZAGREB, Croatia*; [4]*University Hospital Centre Zagreb and University of Rijeka, Faculty of Health Studies, Rijeka, Croatia, Division of Nephrology, Hypertension, Dialysis and Transplantation, Department of Internal Medicine, ZAGREB, Croatia*

Background: A number of blood count parameters are associated with inflammatory and autoimmune diseases. There is discordant evidence whether neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR) and mean platelet volume (MPV) might reflect inflammatory response and have prognostic value in SLE patients. However, the studies examining the potential role of these markers in LN are missing.

Objectives: To examine NLR, PLR and MPV at the time of biopsy in patients with LN and evaluate their association with prognosis.

Methods: In this retrospective study we analyzed the demographic, histologic, laboratory and clinical characteristics of patients with biopsy-proven LN diagnosed between 2011 and 2020. All patients met the 1997 revised American College of Rheumatology classification criteria for SLE. Complete remission was defined as proteinuria <0.5 g/day and serum creatinine within 10% from baseline,

and partial remission as more than 50% reduction in proteinuria to sub-nephrotic levels and serum creatinine within 10% from baseline.

Results: We have included 55 patients (80% women) with biopsy-proven LN (age at biopsy 38±13 years). On renal histology, one patient was class I LN, two patients were class II, 7 were class III, 5 were class III+V, 23 were class IV, two were class IV+V, 11 class VI and 4 had other features. Median baseline NLR was 3.64 (IQR: 1.85, 6.93), PLR was 167 (IQR: 116, 300) and MPV was 10.0 (IQR: 9.2, 10.8). There were no differences in any of the three parameters between different classess of LN (all p>0.05). Eighteen patients achieved complete remission (CR), 16 partial remission and 21 did not achieve remission. None progressed to ESRD and two patients died, both from sepsis. There no differences in NLR, PLR and MPV at the time of biopsy between group which achieved CR/PR vs. no remission (all p>0.05; Figure 1). We constructed a thorough multivariate regression model which showed that neither NLR, PLR or MPV are predictors of renal remission in LN.

Conclusion: NLR, PLR and MPV are not useful prognostic markers in predicting renal remission in LN.

AB0350 MATERNAL AND FETAL OUTCOME IN MEXICAN WOMEN WITH PRIMARY ANTIPHOSPHOLIPID SYNDROME, SECONDARY ANTIPHOSPHOLIPID SYNDROME AND SYSTEMIC LUPUS ERYTHEMATOSUS WITH ANTIPHOSPHOLIPID ANTIBODIES

A. A. Sánchez[1], D. Miranda[1], M. A. Saavedra[1], A. Sanchez Gonzalez[1], Z. Castro[1]. [1]*Hospital de Especialidades La Raza, Rheumatology, Ciudad de México, Mexico*

Background: Primary antiphospholipid syndrome (APS) is associated with a higher frequency of maternal-fetal adverse outcomes, with increased risk when APS is associated with systemic lupus erythematosus (SLE).

Objectives: We compared maternal-fetal complications in patients with primary APS, APS associated with SLE and SLE with anti-phospholipid antibodies (aPLs).

Methods: Observational, analytical, retrospective, cross-sectional, comparative study, between 2009-2019. Three groups were compared: primary APS, APS associated with SLE and SLE with anti-phospholipid antibodies (aPLs).

Results: We include 179 pregnant women, 31.8% with primary APS, 35.8% with APS associated with SLE, and 32.4% with SLE and aPLs A history of a higher frequency of abortions was found in APS associated with SLE (62.5%, p <0.001) and thrombosis (61.9%, p <0.001) and aCL IgG + in primary APS (80.7%, p = 0.011). More frequent use during pregnancy of antimalarials is applied in associated APS (81.30%, p <0.001) and aspirin / heparin in primary APS (96.5% / 94.7%, p <0.001). Abortions were observed more frequently in APS associated with SLE (23.80%, p = 0.021) and preeclampsia / HELLP in primary APS (31.6% and 15.8%, p = 0.047) who were also less frequently the use of antimalarial (24% vs. 81.3% vs. 72.4%, p <0.001) compared to the other groups. Table 1

Conclusion: Patients with APS and SLE have an increased risk of miscarriage whereas those with primary APS have an increased risk for preeclampsia / HELLP. The use of antimalarials could reduce the risk of hypertensive disorders of pregnancy.

AB0351 PROGRESSION TO SEVERE LUPUS NEPHRITIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOUS: UPDATE FROM A COLOMBIAN COHORT

S. Herrera[1], J. Marenco Maldonado[1], J. C. Diaz-Coronado[1,2], D. Rojas-Gualdrón[3], D. Hernandez-Parra[1], R. Pineda.Tamayo[1]. [1]*Artmedica IPS, Clinical Information Group, Medellín, Colombia*; [2]*CES University, Department of Internal Medicine, Medellín, Colombia*; [3]*CES University, Facultad de medicina, Medellín, Colombia*

Background: Continuous monitoring of patients with Systemic lupus erythematosus (SLE) provides relevant information

Objectives: To update the analysis of clinical and immunological characteristics associated with time to severe renal involvement in patients with Systemic Lupus Erythematous in a Colombian cohort followed from January 2015 to October 2020

Methods: A retrospective follow-up study based on clinical records. Patients with SLE diagnosis fulfilled either 1987 American College of Rheumatology Classification Criteria for SLE or 2011 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria for SLE. We included patients with the diagnosis of lupus nephritis according to Wallace and Dubois criteria. Patients who did not have at least two follow-up measurements or had a cause of nephritis other than lupus were excluded. The primary outcome was defined as the time from diagnosis to severe renal involvement defined as creatinine clearance ≤50ml/min, 24-hour proteinuria ≥3.5 grams o end-stage renal disease. Updated age and sex-adjusted survival functions and Hazard ratios (HR) with 95% confidence intervals and p-values were estimated using parametric Weibull models for interval-censored data. P values <0.05 were considered statistically significant. Descriptive statistics were previously reported in EULAR 2020 (1)

Results: 548 patients were analyzed: 67 were left-censored as they presented renal involvement at entry, 25 were interval censored as outcome occurred between study visits (19 new events), and 456 were right-censored as involvement was not registered during follow-up. In this cohort update Age and sex-adjusted Hazard Ratios for high blood pressure were HR = 3.1 (95%CI 1.5-6.3; p-value = 0.003) and Anti-RO (per unit increase) HR = 1.003 (95%CI 1.001-1.005; p-value = 0.029). Figure 1 shows the updated age and sex-adjusted survival function

Conclusion: In this cohort update, we found similar clinical and immunological characteristics associated with time to severe renal involvement in SLE patients to those reported in (1). However, continuous follow-up allows us to deepen our understanding of the progression to severe renal involvement in SLE patients

Vasculitis – large vessel vasculitis

AB0352 **ANTICARDIOLIPIN ANTIBODIES AND ACTIVITY OF GIANT CELL ARTERITIS**

A. Hočevar[1,2], R. Jese[1], J. Kramarič[1], S. Cucnik[1], M. Tomsic[1,2], Z. Rotar[1,2]. *[1]University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia*; *[2]Medical Faculty, University of Ljubljana, Internal Medicine, Ljubljana, Slovenia*

Background: Anticardiolipin antibodies (aCL) can be detected in newly diagnosed GCA as reactive antibodies to endothelial lesions. Their prognostic role, as a marker of disease activity, has not been extensively studied in GCA.
Objectives: Our aim was to determine whether aCL IgG might represent laboratory marker of active GCA.
Methods: We included patients with new clinical diagnosis of GCA supported by histology or imaging between September 2011 and July 2019, who completed at least a 48-week follow-up at our secondary/tertiary rheumatology center. Follow up visits with predetermined clinical and laboratory tests, including aCL IgG, were performed 12, 24, 48, and 96 weeks after diagnosis. GCA relapse was defined as worsening or new disease activity after initial remission. Other reasons for the disease-related symptoms, elevated inflammatory markers (C reactive protein or erythrocyte sedimentation rate) had to be excluded. aCL IgG were determined in the patients' sera samples at baseline and at follow up visits, using an in-house solid phase enzyme-linked immunosorbent assay[1]. A value above the 99th percentile of the healthy control population was taken as significant.
Results: During the observation period we identified 288 newly diagnosed GCA patients. Two hundred and twelve GCA patients (66.5% females, median (IQR) age 73.9 (67.0–78.7) years) fulfilled the study inclusion criterion, among them 145 patients completed the 96-week follow up visit. At baseline, 129/212 (60.8%) GCA patients had positive aCL IgG. During in total 781 follow up visits, we recorded 77 (9.9%) episodes of active/relapsing GCA (clinical, laboratory or combined in 4 (5.2%), 48 (62.3%), 25 (32.5%) episodes, respectively). aCL IgG were present at 155/781 (19.8%) measurements (at 24/77 episodes of relapsing/active and 131/573 episodes of quiescent GCA). The correlation between active/relapsing GCA and aCL IgG positivity was only weekly positive (r coefficient=0.094; p= 0.015).
Conclusion: The role of aCL IgG as a biomarker for GCA activity seems to be rather limited.

AB0353 **ADRENAL INSUFFICIENCY AFTER GLUCOCORTICOID TREATMENT OF GIANT CELL ARTERITIS**

A. Hočevar[1,2], R. Jese[1], J. Kramarič[1], M. Tomsic[1,2], Z. Rotar[1,2]. *[1]University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia*; *[2]Medical Faculty, University of Ljubljana, Internal Medicine, Ljubljana, Slovenia*

Background: Adrenal insufficiency is frequently neglected and underappreciated, potentially severe complication of systemic glucocorticoid therapy.
Objectives: We aimed to evaluate the prevalence of glucocorticoid induced adrenal insufficiency in giant cell arteritis (GCA).
Methods: We analysed adrenal function data in a cohort of GCA patients diagnosed between July 2014 and July 2019, in whom discontinuation of methylprednisolone therapy was planned. Adrenal function was tested by Corticotropin stimulation test (CST). To perform the CST, methylprednisolone was substituted with hydrocortisone (20mg qd in three divided doses) for one to four weeks before the test. Adrenal insufficiency was defined as cortisol level <450 nmol/l measured 30 minutes after the corticotropin injection; additionally, the result of the CST was defined as borderline when the cortisol level 30 minutes after corticotropin injection was between 450 nmol/l and 500 nmol/l.
Results: Adrenal function was tested in 74/215 GCA patients before definite methylprednisolone withdrawal (after a median 13.5 (12.9 – 22.4) months of glucocorticoid therapy). The mean (SD) methylprednisolone dose, prior to substitution with hydrocortisone and subsequent CST, was 3.1 (1.6) mg. Adrenal insufficiency was detected in 36/74 patients (48.6%); additionally, 10/74 patients (13.5%) had a borderline CST result. Seventeen patients with either adrenal insufficiency or borderline CST result, had a repeated CST after median (IQR) 11.6 (8.9; 12.6) months. Adrenal insufficiency persisted in 11/17 (64.7%) patients, and 1/17 patients had a borderline CST. A third CST was performed in 4/12 patients with abnormal second CST after median (IQR) 8.3 (6.9; 10.6) months. Adrenal function recovered in one patient, while the adrenal insufficiency persisted in the remaining 3 patients.
Conclusion: Adrenal insufficiency is a common and potentially long-lasting glucocorticoid induced adverse event in GCA patients.

AB0354 **FDG-PET-DETECTED LARGE VESSEL VASCULITIS DOES NOT PREDICT DISEASE OUTCOME IN PATIENTS WITH GIANT CELL ARTERITIS AND POLYMYALGIA RHEUMATICA**

E. Hysa[1], D. Camellino[2], C. Bernini[3], E. Gotelli[4], S. Paolino[1], C. Schenone[4], G. Ferrari[4], A. Sulli[1], M. Cutolo[1], M. A. Cimmino[4]. *[1]Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy*; *[2]Division of Rheumatology, Local Health Trust 3, Musculoskeletal System Department, Genoa, Italy*; *[3]Operational Unit of Internal Medicine 2, Department of Internal Medicine, University of Genoa, Genoa, Italy*; *[4]Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy*

Background: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are tightly associated inflammatory conditions of the elderly [1]. Both disorders can exhibit an increased articular and vascular uptake of 18-fluorodeoxyglucose (18-FDG) at positron emission tomography (PET)/computed tomography (CT) scan [2].
Objectives: This study evaluated if large-vessel vasculitis (LVV) detected by PET/CT in patients with PMR and/or cranial GCA had a negative prognostic value.
Methods: 108 patients (35 men and 73 women) with a median age of 74 years (range 50-92 years) were prospectively enrolled in our centre over 4 years. PMR was diagnosed by Bird et al. criteria and GCA by the ACR criteria. Six patients died shortly after the first visit (V_0) and six were lost at follow-up. Of the remaining 96 patients, 77 were classified as PMR, 6 as GCA and 13 were affected by both diseases.
At V_0, patients underwent a clinical, laboratory and PET/CT evaluation, and were stratified according to the presence or not of LVV. Follow-up visits

were performed every 6 months for a median of 40 months. Disease outcomes were: prednisone (PDN) use and its cumulative dosage, need of methotrexate (MTX), number of relapses, patients' death, and PMR disease activity score (PMR-DAS). The independent variables were age, sex, disease duration, fever, C-reactive protein (CRP) concentration, platelet count (PLT), presence of cranial GCA, degree of joint and vascular uptake of FDG, and presence of LVV. The predictive role of LVV was tested by multiple regression.

Results: LVV was seen in 47 patients (49 %), 31 with PMR, 6 with GCA and 10 with both diseases. Patients with or without LVV did not significantly differ in terms of demographic and laboratory parameters except for a non-significant higher number of PLT in patients with LVV. Clinical and laboratory parameters at V_0, stratified per disease and considered together, did not significantly change between PET+ and PET- patients (table 1). Lastly, none of the independent variables, including LVV, could predict disease outcomes.

Conclusion: The presence of a PET-detected LVV at diagnosis does not seem a negative prognostic factor in PMR and GCA. As a consequence, routine investigation by PET/CT of patients with PMR and GCA is not indicated to predict disease outcome.

AB0355 THE VALUE OF PLATELET-TO-LYMPHOCYTE AND NEUTROPHIL-TO-LYMPHOCYTE RATIOS AS INFLAMMATORY MARKERS IN BIOPSY-PROVEN GIANT CELL ARTERITIS

U. Møller Døhn[1], M. Stormly Hansen[2], Y. Subhi[2], V. Fana[1], M. Radmer Jensen[3], J. Maestri Brittain[4], C. Faber[2], S. Heegaard[2,5], O. N. Klefter[2], A. K. Wiencke[2], S. E. Hamann[2], L. Terslev[1]. [1]*Rigshospitalet, Glostrup; University of Copenhagen, Center for Rheumatology and Spine Diseases, Glostrup, Denmark*; [2]*Rigshospitalet, University of Copenhagen, Department of Ophthalmology, Glostrup, Denmark*; [3]*Bispebjerg & Frederiksberg Hospital, Department of Clinical Physiology and Nuclear Medicine, Copenhagen, Denmark*; [4]*Rigshospitalet, University of Copenhagen, Department of Clinical Physiology, Nuclear Medicine and PET, Copenhagen, Denmark*; [5]*Rigshospitalet, University of Copenhagen, Eye Pathology Section, Department of Pathology, Copenhagen, Denmark*

Background: Platelet-to-lymphocyte ratio (PLR) and neutrophil-to-lymphocyte ratio (NLR) have been shown to correlate with disease activity in various rheumatic diseases. High PLR and elevated platelet count are potentially useful in diagnosing some systemic vasculitides, eg. giant cell arteritis (GCA)[1] and has been suggested predictive for diagnosing GCA, even in the absence of characteristic temporal artery involvement[2].

Objectives: To evaluate the role of PLR and NLR as inflammatory markers in the diagnosis of GCA in patients referred to temporal artery biopsy (TAB).

Methods: During 10 months, all patients referred to TAB at the Department of Ophthalmology (Rigshospitalet, Copenhagen, Denmark) in suspected GCA were included. Immediately prior to TAB, ultrasound of bilateral temporal arteries was performed at the Center for Rheumatology and Spine Disease (Rigshospitalet, Copenhagen, Denmark) by rheumatologists experienced in vascular ultrasound. Ultrasound signs of GCA were a positive Halo sign or compression sign. Patients had C-reactive protein (CRP), erythrocyte sedimentation ratio (ESR), platelets, white blood cells with differential counts, hemoglobin and platelets measured. Final clinical diagnosis, based on rheumatological expert opinion, and fulfilment of ACR1990 classification criteria for temporal arteritis at six months was noted, with clinical diagnosis being the reference standard.

Results: 106 patients were included and had a TAB evaluated. Forty-five (42%) had a clinical diagnosis of GCA at 6 months of which 28 (62%) also were TAB positive. US was performed in 74 (70%), of these 20 (67%) of the GCA patients had a positive ultrasound for GCA (termed US GCA patients). There was no significant difference in mean age or gender distribution between GCA and non-GCA patients. ESR, CRP and platelets were significantly higher in GCA than non-GCA patients ($p<0.001$). PLR was significantly higher in GCA than non-GCA patients ($p<0.007$), while NLR was not ($p=0.076$). For US GCA patients vs. US non-GCA patients, platelets were significantly higher in the US GCA group ($p=0.025$). Both PLR and NLR were significantly higher in the US GCA group compared to the US non-GCA group ($p= 0.003$ and $p=0.007$, respectively).

Conclusion: In this cohort of patients, suspected of GCA and referred to TAB, PLR but not NLR was significantly higher in GCA patients than in non-GCA patients. In patients with US findings of GCA, both PLR and NLR were significantly higher in GCA compared to non-GCA. An elevated PLR could be considered an additional feature in diagnosing GCA.

AB0356 VENOUS INVOLVEMENT IN BEHÇET'S DISEASE

Ö. Özdemir Işık[1], S. Şan[1], A. Yazici[1], A. Cefle[1]. [1]*Kocaeli University School of Medicine, Rheumatology, Kocaeli, Turkey*

Background: Behçet's disease (BD) is a vasculitic multisystem inflammatory disorder. It may also involve the skin, mucosa, eyes, blood vessels, joints, gastrointestinal system, and central nervous system.

Objectives: In this study, we aimed to present venous involvement data in patients followed up with a diagnosis of BD.

Methods: The clinical, demographic, laboratory and medication data of 394 patients who were followed up with a diagnosis of BD in our

rheumatology outpatient clinic between 2000 and 2020 were retrospectively evaluated.

Results: Venous involvement was detected in 17.6% (n:76) patients who were followed up with a diagnosis of BD. 75% of the patients were male, and their mean diagnosis age was 27.1±9.9, disease duration was 14.2±6.3 years. While the thrombosis of lower extremity veins, cervical veins, and vena cava were observed in 85.5% of BD patients, superficial thrombophlebitis was found in 31.6%. Cerebral venous involvement (CVI) was evaluated in cranial involvement. Oral aphthous ulcer was found in 97.4 % of the patients, genital ulcer in 65.8%, pathergy positivity in 44.7%, papulopustular lesion in 34.2%, erythema nodosum in 40.8%. 27.6% of the patients were evaluated for hereditary thrombophilia and 5.3% (n:7) had hereditary thrombophilia. Deep venous thrombosis was found in 85.7% (6/7) of these patients, renal artery occlusion in 14.3%, pulmonary artery thrombosis in 14.3%, and cerebral venous thrombosis in 28.6%. Patients with and without venous involvement were compared in terms of clinical findings. A significant difference was observed in terms of retinal vasculitis, artery occlusion, arterial aneurysm, family history for BD and gender. In logistic regression analysis, a significant relationship was observed between venous involvement and gender, family history, retinal vasculitis, artery occlusion, arterial aneurysm (Table1).

Table 1. Comparison of data of patients with and without venous involvement

	Venous Involvement (+) n:76	Venous Involvement (-) n:318	P	OR* (%95CI)
Gender			***0.000***	2.78
Female	19(25)	153(48.1)		(1.58-4.88)
Male	57(75)	165(51.9)		
Family History	4(5.3)	44(13.8)	***0.049***	0.035 (0.12-0.99)
Oral Aphthous Ulcer	74(97.4)	305(95.9)	0,745	
Genital Ulcer	50(65.8)	206(64.8)	0,894	
Papulopustular lesion	26(34.2)	103(32.4)	0,786	
Erythema Nodosum	31(40.8)	119(37.4)	0,601	
Pathergy	34(44.7)	151(47.5)	0,772	
Uveitis	20(26.3)	118(37.1)	0,083	
Retinal Vasculitis	5(6.6)	6(1.9)	***0.036***	3.66 (1.08-12.33)
Arthritis	13(17.1)	85(26.7)	0,104	
Artery Occlusion	6(7.9)	3(0.9)	***0.002***	8.97 (2.19-36.74)
Arterial Aneurysm	7(9.2)	8(2.5)	***0.013***	3.93 (1.37-11.20)
Gastrointestinal involvement	6(7.9)	11(3.5)	0,111	
Cardiac involvement	3(3.9)	3(0.9)	0,089	
Cranial involvement	7(9.2)	17(5.3)	0,282	

* Significant data in logistic regression analysis were presented

Conclusion: Superficial venous thrombosis and deep vein thrombosis are the most frequent vascular involvements in BD patients. Significant correlations exist between CVI and pulmonary artery involvement (PAI), intracardiac thrombosis and PAI. It should be recalled that lower extremity venous thrombosis is often present in these associations, and even precede them (1).

AB0357 LANDSCAPE REVIEW OF PATIENT-REPORTED OUTCOME MEASURES IN GIANT CELL ARTERITIS

H. H. Colwell[1], S. Mathias2, K. Kato[3], C. E. Najem[4], A. M. Archer[5]. *[1]Health Outcomes Solutions, Outcomes Research, Winter Park, United States of America*; *[1]Health Outcomes Solutions, Outcomes Research, Winter Park, United States of America*; *[3]Janssen Pharmaceutical Companies of Johnson & Johnson, Patient Reported Outcomes, Raritan, United States of America*; *[4]Janssen Pharmaceutical Companies of Johnson & Johnson, Rheumatology Clinical Research, Spring House, United States of America*; *[5]Janssen Pharmaceutical Companies of Johnson & Johnson, Translational Medicine, Spring House, United States of America*

Background: Giant cell arteritis (GCA) is a systemic large vessel vasculitis that results in symptoms (e.g., headaches, jaw claudication, fatigue, pain, etc.) that can have multiple negative impacts on an individual's health-related quality of life.

Objectives: To identify important symptoms and impacts experienced by individuals with GCA, develop a conceptual model, and evaluate available patient reported outcome (PRO) measures for appropriateness for inclusion in GCA clinical studies.

Methods: Published literature on disease experience from databases, conference abstracts, and Guidance/OMERACT documents were reviewed. A GCA conceptual model was developed based on the symptoms and impacts identified from this literature and supplemented with clinical input. A detailed review of selected PROs was then conducted to assess concept coverage and gaps to evaluate appropriateness for a GCA population.

Results: Of 245 identified citations, 24 abstracts and 18 articles were reviewed. Key symptoms affecting GCA patients (e.g., ischemic and constitutional symptoms) and impacts to the lives of GCA patients (e.g., reduced physical, social and emotional functioning) formed the basis for a GCA conceptual model (see Figure 1).

No GCA-specific PROs were identified. Therefore, the PROs that were used most frequently in GCA clinical studies were reviewed and evaluated. These included the SF-36, FACIT-Fatigue, Patient Global Assessment (PtGA), Multidimensional Fatigue Inventory (MFI), EQ-5D, Health Assessment Questionnaire (HAQ), Brief Illness Perception Questionnaire (BIPQ), and Visual Functioning Questionnaire-25 (VFQ-25). These PROs included some key impacts but did not assess most GCA-specific symptoms (e.g., headaches, fever, etc.). No measures were developed with input from GCA patients and there has been limited evaluation of the measurement properties of these PROs in GCA patients.

The FACIT-Fatigue, SF-36, and the PtGA, which were frequently administered in published GCA studies, measure key GCA concepts such as fatigue, functioning, impact on daily activities and disease status. The measurement properties (reliability, validity, sensitivity to change) have been documented in several other rheumatologic diseases (Table 1).

Conclusion: In the absence of a GCA-specific PRO, the SF-36, FACIT-Fatigue, and PtGA are recommended for use in GCA clinical studies for the assessment of key concepts identified in the literature. Qualitative and quantitative research should be conducted with GCA patients to assess the content validity and measurement properties of these PROs in a GCA population.

Figure 1: Conceptual Model

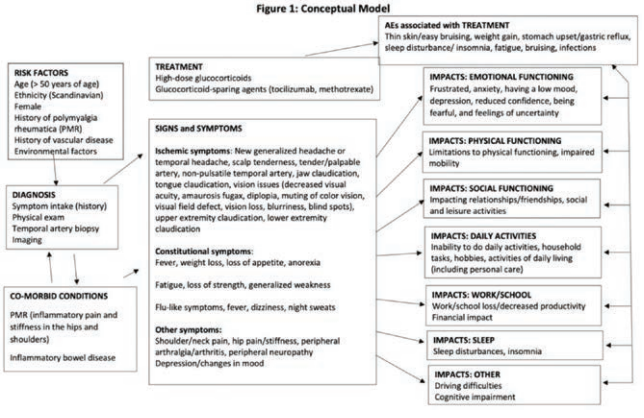

Table 1. Summary of Recommended Measures

Description	SF-36	FACIT-Fatigue	PtGA
Type	Generic, health status measure	Fatigue and impact on function/daily activities	Measure of disease activity
Method of Administration	Self/Interviewer	Self/Interviewer	Self
# of Items	36	13	1
Recall period	Past 4 weeks/past week	Past 7 days	Varies
Scoring	8 domain scores; 2 component summary scores	Total score	Total score
Measurement properties	Measurement properties demonstrated in other rheumatologic diseases (SLE, RA, SpA, and chronic knee pain); construct validity demonstrated in a single study with GCA patients	Measurement properties demonstrated in rheumatologic populations including SLE, PsA, and RA	Select measurement properties have been demonstrated in GCA and other populations (RA, TAK, RP)
Concept coverage	GCA impacts (emotional, physical, and social functioning, and daily activities), bodily pain, fatigue	Fatigue	Overall assessment of disease activity
Administered in recent GCA studies	YES	YES	YES

SLE= systemic lupus erythematosus, SpA = spondyloarthritis, PsA=psoriatic arthritis, RA=rheumatoid arthritis, GCA= giant cell arteritis, TAK=Takayasu's arteritis, RP=relapsing polychondritis

AB0358 ABATACEPT AS A bDMARD IN STEROID-REFRACTORY POLYMYALGIA RHEUMATICA

E. Toussirot[1], M. Michaud[2], D. Wendling[3], V. Devauchelle-Pensec[4]. [1]*CHU de Besançon, INSERM CIC-1431, Besancon, France*; [2]*Hôpital Joseph Ducuing, Centre de Compétence Maladies Lysosomales, Toulouse, France*; [3]*CHU de Besançon, Rhumatologie, Besancon, France*; [4]*CHU de Brest, Rhumatologie, Brest, France*

Background: polymyalgia rheumatica (PMR) is a chronic inflammatory disorder affecting elderly people. Glucocorticoids (GC) are the mainstay of therapy for PMR. Despite this treatment, the disease may relapse or GC dosage cannot be tapered. Methotrexate (MTX) may be helpful in these cases. Blockade of IL-6 has an effective steroid-sparing effect in patients with giant cell arteritis (GCA) and may improve the clinical symptoms of patients with PMR. The pathophysiology of PMR still remains uncertain but there are evidences for a participation of Th1 and Th17 lymphocytes. Recently, blockade of the costimulatory pathway by abatacept (ABA) gave favorable results in GCA.

Objectives: to report our experience (efficacy and safety) of ABA in the treatment of patients with isolated PMR who required longstanding GC and who failed to respond to MTX and/or IL-6 receptor blocking agents.

Methods: a call for observations of all cases of patient with PMR who received at least one dose (SC or IV) of ABA was sent to the members of the French specialist network "Club Rhumatismes & Inflammation" (CRI: www.cri-net.com)(rheumatologist and internal medicine). Patients must satisfy the EULAR/ACR criteria for PMR and have isolated PMR without associated GCA.

Results: 4 cases were declared during a 12 months period: 2 men and 2 women; age (median [range]): 60.7 [50-68] years; disease duration 30 [7-48] months; duration of GC treatment before starting ABA: 60 [10-72] months. They all required prednisolone with a daily dosage of 14.5 mg [10-20]. Before ABA administration, they all received MTX while 2 patients were treated by IL-6R inhibitor (tocilizumab 6 months and sarilumab 3 months, respectively) without improvement. ABA was given as a monthly infusion (10 mg/kg) in one case and subcutaneously (every week) in 3 cases. ABA treatment duration ranged from 3 to 18 months. Two patients responded to the treatment with a progressive decline of DAS-PMR and GC dosage tapering during a 12 month follow-up, while there was no improvement for the 2 others (Table 1). CRP levels also decreased for one responder. The safety was excellent for all. ABA was still maintained in one responder. Among the non-responders, one patient was switched to tocilizumab and the second still received high GC dosage.

Conclusion: ABA may be effective in certain PMR patients who were unable to taper GC, with a good safety profile. A randomized controlled trial is required in order to determine its place in the treatment of PMR and to select the appropriate patients who could potentially benefit from this biological agent.

AB0359 CRANIAL INVOLVEMENT IN BEHÇET'S DISEASE

Ö. Özdemir Işık[1], S. Şan[1], A. Yazici[1], A. Cefle[1]. [1]*Kocaeli University School of Medicine, Rheumatology, Kocaeli, Turkey*

Background: Behçet's disease (BD) is a vasculitic multisystem inflammatory disorder. It may also involve the skin, mucosa, eyes, blood vessels, joints, gastrointestinal system, and central nervous system (CNS).

Objectives: In this study, we aimed to present CNS involvement data in patients followed up with a diagnosis of BD.

Methods: The clinical, demographic, laboratory and medication data of 394 patients who were followed up with a diagnosis of BD in our rheumatology outpatient clinic between 2000 and 2020 were retrospectively evaluated.

Results: CNS involvement was detected in %5.6(24) patients who were followed up with a diagnosis of BD. 66.7% of the patients were male, and their mean diagnosis age was 25.1±8.2 years, mean CNS involvement age was 28.39±9.6 years. Neurological symptoms occurred in an average of 3.3 years after the diagnosis of BD. Parenchymal involvement was present in 54.2% of the patients with CNS involvement, 45.8 % had cerebral venous thrombosis. Oral apthous ulcer was found in 91.7 % of the patients, genital ulcer in 70.8%, pathergy positivity in %45.8 papulopustular lesion in %37.5, erythema nodosum in %45.8. Patients with CNS involvement had headache, vision loss, diplopia, hemiparesis, epilepsy, proptosis, and ataxic gait and walking difficulty in 66.6%, 12.5%, 25%, 12.5%, 8.3%, 8.3% and 12.5%, respectively. Patients with and without CNS involvement were compared in terms of clinical findings and medications. A significant difference was observed in terms of cardiac involvement (Table 1). While one of the 2 patients with cardiac involvement had a thrombus in the right ventricle, the other had pericardial effusion. The patient with cardiac thrombus also had cerebral venous thrombus. Steroid, azathioprine, cyclophosphamide treatments have been used at a higher in patients with CNS involvement. In addition, the patients with parenchymal and cerebral venous involvement were compared in terms of clinical, demographics findings and medications. The presence of papulopustular lesions (9.1% vs 57.1%) and pathergy positivity (18.2% vs 71.4%) were higher in patients with parenchymal involvement (p:0.033, p: 0.020, respectively).

Table 1. Comparison of data of patients with and without CNS involvement

n (%)	CNS Involvement (+) n:24	CNS Involvement (-) n:370	P
Gender			0.396
Female	8(33.3)	164(44.3)	
Male	16(66.7)	206(55.7)	
Oral Aphthous Ulcer	22(91.7)	357(96.5)	0.230
Genital Ulcer	17(70.8)	239(64.6)	0.661
Papulopustular lesion	9(37.5)	120(32.4)	0.655
Erythema Nodosum	11(45.8)	139(37.6)	0.516
Pathergy	11(45.8)	174(47)	0.988
Uveitis	9(37.5)	129(34.9)	0.827
Retinal Vasculitis	1(4.2)	10(2.7)	0.504
Arthritis	3(12.5)	95(25.7)	0.221
Deep Venous Involvement	6(25)	59(15.9)	0.256
Artery Occlusion	1(4.2)	8(2.2)	0.436
Arterial Aneurysm	1(4.2)	14(3.8)	1
GIS involvement	2(8.3)	15(4.1)	0.277
Cardiac involvement	2(8.3)	4(1.1)	***0.046***

Conclusion: It has been reported that neurological symptoms occur in an average of 2.5 to 6.5 years after the diagnosis of BD. On the other hand, it has been stated that neurological complications may be the first involvement in 3-33% of the cases and this situation will cause diagnostic difficulties[1]. These data are consistent with our study.

AB0360

A DECADE OF SUSPECTED GIANT CELL ARTERITIS: CLINICAL FEATURES OF A HIGHLY HETEROGENEOUS DISEASE

A. Castro[1], J. Mathew[2], O. Azzouqah[3], J. Diaz[4], A. Reimold[1,2], K. Shwin[1,2]. *[1]UT Southwestern Medical Center, Rheumatology, Dallas, United States of America*; *[2]Dallas VA Medical Center, Rheumatology, Dallas, United States of America*; *[3]Presbyterian Rust Medical Center, Rheumatology, Rio Rancho, United States of America*; *[4]Universidad de los Andes, Epidemiology, Bogotá, Colombia*

Background: Giant cell arteritis is the most common chronic systemic vasculitis in older adults. Permanent visual loss is the most concerning complication can occur in up to 20% of patients (1). Diagnosis is based on a combination of clinical findings, laboratory evidence of inflammatory markers, and temporal artery biopsy (TAB) confirming histologic evidence of inflammation. There are no definitive markers of the disease when TAB is negative.

Objectives: The objective of this study was to illustrate the clinical features of subjects suspected with GCA evaluated at the Dallas Veterans Affairs Medical Center (VAMC) and identify those features that would differentiate between TAB positive GCA, TAB negative GCA and non-GCA patients.

Methods: This retrospective study searched the Dallas VAMC database for subjects between January of 2010 until December 2019 with ICD-9 and ICD-10 entry code for GCA. Based on the 1990 ACR clinical classification criteria for GCA, suspected patients were classified as TAB positive GCA, TAB negative GCA and non-GCA. Subjects with incomplete data needed for classification were excluded. Group comparisons were performed with Fisher's exact test for categorical variables and the Mann-Whitney test for continuous variables.

Results: One-hundred and sixty-nine subjects had ICD-9/10 entry code for GCA. Ophthalmology was the specialty who did the initial evaluation in 46% of the suspected cases. Seventy-one patients were excluded due to incomplete data. Of the remaining 98 patients, 42 (42.9%) were diagnosed with GCA out of which 10 patients had a positive TAB. Seventy-six percent of patients diagnosed with GCA had negative temporal artery biopsies. In 56 (57.1%) patients GCA was ruled out (Figure 1). New-onset headache was the predominant symptom suggestive of GCA affecting 88.9% TAB positive and 100% of TAB negative cases compared to 56.6% of non-GCA patients (p< 0.001), followed by scalp tenderness in 33.3%, 58.1% and 10.9%, respectively (p< 0.001), jaw claudication in 57.1%, 34.5% and 14.9% (p=0.021), and elevated sedimentation rate in 33%, 65.6% and 33% (p=0.013) (Table 1). Polymyalgia rheumatica was present in 28.6% and 21.7% of patients diagnosed with GCA compared to zero percent in non-GCA cases (p=0.017). More than 30% of patients with GCA had normal acute phase reactants in this cohort.

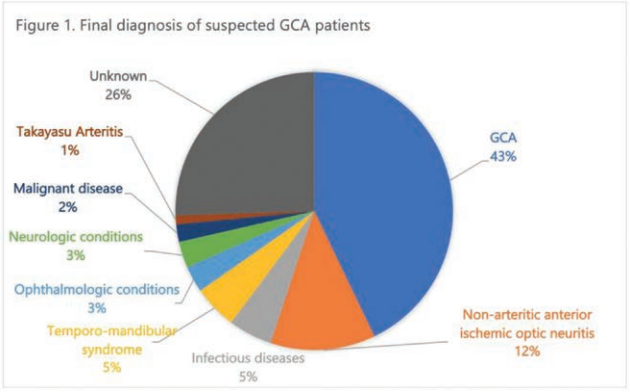

Table 1. Comparison of demographics and clinical features of patients with suspected GCA

	GCA TAB Positive (n=10)		GCA - TAB Negative (n=32)		non-GCA (n=56)		
	n	%	n	%	n	%	p
Age (mean/sd)	71.3 (7.8)		67.3 (8.1)		67.3 (8.9)		0.367
Male	9	90	30/32	93.8	51/56	91.1	0.885
Clinical findings							
New onset headache	8/9	88.9	32/32	100	30/53	56.6	<0.001
Visual symptoms	9/10	90	22/32	68.8	42/54	77.8	0.351
Jaw claudication	4/7	57.1	10/29	34.5	7/47	14.9	0.021
PMR	2/7	28.6	5/23	21.7	0/30	0	0.017
Scalp tenderness	2/6	33.3	18/31	58.1	5/46	10.9	<0.001
Fever	0/5	0	5/23	21.7	2/35	5.7	0.117
ESR > 50	1/3	33.3	21/32	65.6	18/54	33.3	0.013
CRP > 10	1/3	33.3	5/30	16.7	6/54	11.1	0.473
Anemia (hemoglobin < 12 g/ dl)	2/7	28.6	15/32	46.9	21/52	40.4	0.642
Thrombocytosis (platelets >400)	2/7	28.6	3/32	9.4	4/51	7.8	0.228

Conclusion: There is clinical heterogeneity within the patients diagnosed with GCA regardless of TAB. A high index of clinical suspicion needs to be the cornerstone of diagnosis. There is need for new classification criteria to include patients with negative TAB.

AB0361 EFFECTIVENESS AND SAFETY OF INFLIXIMAB DOSE ESCALATION IN PATIENTS WITH REFRACTORY TAKAYASU ARTERITIS: A REAL-LIFE EXPERIENCE FROM A MONOCENTRIC COHORT

A. Tomelleri[1], C. Campochiaro[1], S. Sartorelli[1], F. Baldassi[2], F. Fallanca[2], M. Picchio[2], E. Baldissera[1], L. Dagna[1]. [1]*IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare diseases, Milan, Italy*; [2]*IRCCS San Raffaele Hospital, Unit of Nuclear Medicine, Milan, Italy*

Background: Most published evidence on infliximab (IFX) in Takayasu arteritis (TAK) refers to its use at the standard dose of 5 mg/kg every 6-8 weeks[1]. However, in other diseases such as rheumatoid arthritis or Crohn's disease[2,3], it has been already demonstrated that IFX often requires a dose escalation to maintain its response.
Objectives: To evaluate effectiveness and safety of IFX dose escalation in TAK patients. To identify predictors of refractoriness to standard-dose IFX.
Methods: Medical records of IFX-treated TAK patients from a large single-centre observational cohort were reviewed. Decisions on IFX start, interruption, and dose modification were always made by the same experienced physician (EB). IFX therapy duration and reasons for dose escalation and therapy suspension were evaluated. Occurrence of adverse events was recorded. A comparison between patients who maintained IFX standard-dose and those who needed dose-escalation was performed. Factors predicting standard-dose refractoriness were analyzed.
Results: Forty-one patients were included (38 women; median age at IFX start, 36 [IQR, 28-45] years; median disease duration, 22 [13-60] months). Starting IFX dose was 5 mg/kg 6-weekly; 39 patients (95%) were on concomitant csDMARD and 38 patients (93%) on systemic glucocorticoids (GC). IFX dose escalation was performed in the majority of patients (n=28, 68%) (Figure 1). Persistence/recurrence of clinical symptoms was the most frequent reason for dose escalation (62%). Median IFX therapy duration was 39 (26-61) months in the standard-dose and 68 (38-87) months in the intensified-dose group. Patients in the intensified-dose group had a higher number of relapses (3.4 vs 0.8 events/patient), expression of a more aggressive disease phenotype. Nevertheless, in only 8 patients (29%) from this group IFX was suspended, after a median of 38 (31-71) months. Causes of suspension were loss of response (n=7) or patient's request (n=1). GC were successfully suspended in 4 patients from the standard-dose (36%) and 3 patients from intensified-dose (11%) group. Median daily prednisone dose was reduced from 10 (6-10) to 3 (0-5) mg in the standard-dose group, and from 13 (9-18) to 5 (4-5) mg in the intensified-dose group. Three patients from the intensified-dose group had a serious infection; one patient from the standard-dose group developed paradoxical psoriasis. At univariate analysis, younger age at diagnosis and at IFX start were associated with IFX escalation (Table 1).

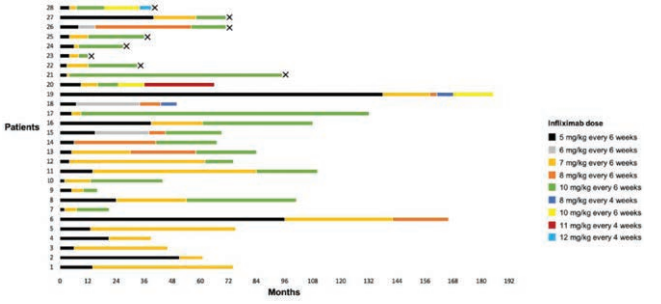

Figure 1. Infliximab dose escalation regimens (the cross (x) indicates treatment suspension)

Table 1. Factors influencing IFX dose escalation in patients with TAK (Cox proportional hazards model)

	Standard-dose IFX	Intensified-dose IFX	*P*-value
Age at diagnosis, years	40 (34-46)	30 (23-40)	**0.031**
Diagnostic delay, months	12 (7-77)	27 (15-50)	0.73
Age at IFX start, years	42 (38-61)	34 (27-44)	**0.040**
Delay before IFX start, months	33 (14-90)	24 (11-53)	0.48
Daily PDN at IFX start, mg	8.75 (5-10)	11.25 (8.5-16.25)	0.051
CRP at IFX start, mg/L	6.5 (2.1-9.3)	10.7 (5.2-20.9)	0.07
Class V Numano, n (%)	3 (30)	16 (57)	0.133
PETVAS score	8 (6-12)	12 (9-16)	0.056

Conclusion: In TAK, dose escalation can be a safe strategy to optimize IFX durability in refractory patients. Younger patients seem to be more refractory to standard dosages.

AB0362 DEMOGRAPHIC AND CLINICAL CHARACTERISTICS OF BEHCET'S DİSEASE PATIENTS

S. Şan[1], Ö. Özdemir Işık[1], A. Yazici[1], A. Cefle[1]. [1]*Kocaeli Üniversitesi Tıp Fakültesi, Rheumatology, Kocaeli, Turkey*

Background: Behcet's Disease (BD) is a systemic variable vessel vasculitis that involves the skin, mucosa, joints, eyes, arteries, veins, nervous system and the gastrointestinal system.
Objectives: In this study we aimed to present variety of involvements in patients who were followed up in our outpatient clinic with a diagnosis of BD.
Methods: Data of 394 patients diagnosed with BD between 2000-2020 were retrospectively reviewed clinical, demographic characteristics and systemic involvements.
Results: In our study 43.7% of BD patients were female, 56.3% were male and the mean age was 40±11years, disease average age of onset 36.5±10.6, disease duration was 12.8±6.8years. It was observed mucocutaneus involvement 98% of the patients, uveitis in 35%, retinal vasculitis in 2.8%, arthritis in 24.9%, arterial occlusion in 2.3%, arterial aneurysm in 3.8%, venous involvement in 19.8%, gastrointestinal (GIS) involvement in 4.3%, cardiac involvement in 1.5%, and cranial involvement 7.1 (Table 1).

Table 1. The Data of Behçet Disease

n (%)	n= 394
Gender	
Female	*172 (43.7)*
Male	*222 (56.3)*

1mg/kg steroid	48 (12.2)
Infliximab	13 (3.3)
Azathioprine	184 (46.7)
Cyclophosphamide	31 (7.9)

When all patients evaluated in terms of renal findings, proteinuria was observed in 5 patients and hematuria was observed in 2 patients. 3 patients had proteinuria over than 500mg/day. Their renal biopsy findings; 2 of them were nonspecific involvements and one of them was minimal mesangioproliferative changes.

Conclusion: As a multi-system disease, general data have been presented, as clinical symptoms involve almost all systems of the body (1).

AB0363 PERIOPERATIVE MANAGEMENT WITH BIOLOGICS ON SEVERE AORTIC VALVE REGURGITATION CAUSED BY BEHÇET'S SYNDROME: THE EXPERIENCE FROM A SINGLE CENTER

L. Sun[1], J. Liu[1], W. Zheng[1]. [1]*Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Cardiovascular involvement in Behçet's syndrome (BS) is associated with poor prognosis and accounts for the leading cause of mortality and morbidity in BS[1, 2]. Perioperative management of severe aortic valve regurgitation (AR) caused by BS is critical while challenging. AR caused by BS is associated with a high incidence of severe postoperative complications, especially paravalvular leakage (PVL) due to the fragilities of aortic lesions and tissue inflammation, leading to a significantly increased risk of re-operation and life-threatening conditions[3-5]. For the perioperative management of patients with AR caused by BS, many patients respond inadequately to the combination therapies of glucocorticoids (GCs) and immunosuppressants. Meanwhile, rapid and efficient control of inflammation is critical in preserving cardiac function and surgical management. However, the application of biologics in the perioperative treatment of AR attributable to BS has not yet been evaluated.

Objectives: To investigate the efficacy and safety of biologics in the perioperative management of severe AR caused by BS.

Methods: We retrospectively analyzed twenty patients with severe AR caused by BS and were treated with biologics during the perioperative cardiac surgeries in our center between February 2016 and October 2020.

Results: Twenty patients with severe AR were enrolled, including 19 males and 1 female, with a mean age of 39.1±8.8 years and median course 8 (IQR, 5.25-10) years. Before biologics administration, 92.9% of the patients who underwent aortic valve replacement surgeries had failed conventional therapy and developed postoperative paravalvular leakage (PVL) at a median interval of 4 months. Biologics was administered during the perioperative period of 22 aortic valve surgeries, including preoperatively with a median interval of 3.5 (IQR, 2.75-4.25) months in 13 cases, or within three-month postoperatively in 9 cases, with background glucocorticoids (GCs) and immunosuppressants. After a median follow-up of 21 (IQR, 15-32) months, 11 out of 13 cases (84.6%) preoperatively and 8 out of 9 cases (88.9%) postoperatively treated with biologics were event-free. The BDCAF score improved significantly (7 vs. 0, median, p<0.0001). Significant decrease of ESR (25.0 (IQR, 11-36.25) mm/h vs. 6.5 (IQR, 4-8.8) mm/h, p<0.001), and CRP (20.77 (IQR, 7.19-29.58) mg/L vs. 1.53 (IQR, 0.94-2.92) mg/L, p=0.001) were achieved rapidly and effectively. The dosage of GCs tapered from 40 (IQR, 30-60) mg/d to 10 (IQR, 5-11.25) mg/d, p<0.0001. Immunosuppressants were tapered in number and dosage in 6 (30%) and 20 patients (100%), respectively. No serious adverse event was observed.

Conclusion: Our study suggests that biologics was effective and well-tolerated for the perioperative management of severe and refractory AR caused by BS, which significantly reduced the occurrence of postoperative PVL and had a favorable GCs- and immunosuppressants- sparing effect.

AB0364 DO PATIENTS PARTICIPATING IN MEETINGS REPRESENT THE ACTUAL PATIENT POPULATION IN BEHÇET SYNDROME?

S. S. Taflan[1,2], S. N. Esatoglu[1,2], Y. Ozguler[1,2], B. Yurttas[1,2], M. Melikoglu[1,2], G. Hatemi[1,2]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; [2]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behcet Disease Center, Istanbul, Turkey*

Background: The importance of patient involvement in healthcare research is increasingly emphasized. Patients participate as research partners in designing studies and development of management recommendations, measurement tools and outcome measures. However, ensuring representation of the general patient population by specific patient groups may be challenging for multisystem diseases with heterogenous phenotype.

Objectives: We aimed to evaluate whether patients with Behcet syndrome (BS) participating in a patient convention represent the actual patient population attending the clinic.

Methods: A questionnaire was applied to 104 BS patients (Meeting group) attending the patient convention which was held during the Cerrahpasa Behcet Disease Symposium in Istanbul in February 2020. Patients had been invited to the convention through posters, advertisement on our website and social media. The questionnaire was conducted with a keypad given to the patients and it consisted of 21 items including age, gender, education level, working status, disease duration, BS manifestations, and treatment. The same questionnaire was filled by 97 consecutive patients (Clinic group) who attended our rheumatology outpatient clinic for their routine controls. Chi-square test was used to compare the groups.

Results: Table 1 shows demographic and disease characteristics of the patient groups. The groups were similar in terms of sex and education level. There were more men in both groups, probably reflecting the more severe disease course among men in BS. There were significantly more patients who were >40 years of age and had a disease duration more than 20 years in the Meeting group. Although there were more patients who had a job in Clinic group, the difference was not significant. Central nervous system involvement, vascular involvement, genital ulcers, erythema nodosum, and arthritis were significantly more common in patients in the Meeting group compared with those in the Clinic group. The frequency of eye involvement, gastrointestinal involvement and papulopustular lesions were similar in the two groups. Cyclophosphamide use was significantly more common in Meeting group compared to the Clinic group.

Table 1. Demographics, clinical characteristics, and treatments

	Meeting Group (n=104) (n/N, %)	Clinic Group (n=97) (n, %)	*P*

AB0365

CLINICAL, LABORATORY AND IMAGING OUTCOMES IN TOCILIZUMAB-TREATED PATIENTS WITH LARGE VESSEL-GIANT CELL ARTERITIS ACCORDING TO EARLY ONSET THERAPY

D. Prieto-Peña[1], I. Martínez-Rodríguez[2], B. Atienza-Mateo[1], O. Cuenca-Vera[2], F. J. Gomez de la Fuente[2], A. Sanchez-Salmón[2], M. A. González-Gay[1], R. Blanco[1]. *[1]Hospital Universitario Marques de Valdecilla, IDIVAL, Rheumatology, Santander, Spain*; *[2]Hospital Universitario Marques de Valdecilla, IDIVAL, Nuclear Medicine, Santander, Spain*

Background: Tocilizumab (TCZ) has shown efficacy in large vessel vasculitis (LVV)-Giant Cell Arteritis (LVV-GCA) **(1-2)**. ^{18}F-fluodeoxyglucose positron emission tomography (^{18}F-FDG PET/CT) is useful to assess LVV disease activity **(3-5)**. It is unknown if early treatment with TCZ may have an influence on clinical, laboratory and imaging outcomes.
Objectives: To assess clinical, laboratory and PET/CT activity improvement in LVV-GCA patients treated with TCZ according to the time from disease diagnosis to TCZ onset.
Methods: Comparative single-center study of 30 LVV-GCA patients treated with TCZ who were divided into 2 groups depending on the time of onset of TCZ: **a)** early onset (≤ 6 months; n=15) and **b)** late onset (> 6 months; n=15). All patients had a baseline and a follow-up PET/CT scan. Complete clinical improvement and normalization of laboratory markers (CRP ≤0.5mg/dL and/or ESR ≤ 20 mm/1st hour) was assessed. For imaging evaluation, normalization of total visual score (TVS) was considered when TVS = 0 and normalization of semiquantitative activity if the target to background ratio (TBR) at the thoracic aorta was <1.34.
Results: 30 patients were included (24 women/6 men); mean age 65.7± 9.8 years. Patients in the TCZ early-onset group were receiving higher doses of prednisone (10.0[5.9-15.0] vs 5.0 [5.0-7.5] mg/day; p< 0.01) and had higher TVS scores (7.0 [4.0-9.0] vs 3.0 [2.0-5.0]; p< 0.01) at baseline (Table 1). Following TCZ initiation, after a mean of 10.8±3.7 months, most patients achieved complete clinical improvement and normalization of ESR and CRP in both groups. Uncoupling with imaging outcomes was observed in both groups. Although non-significant statistical differences were observed, complete TBR normalization (TBR <1.34) and complete TVS normalization (TVS=0) tended to be more frequent in the group of patients who received early-onset TCZ therapy (Figure 1).

Table 1.

	Early-onset TCZ therapy (n= 15)	Late-onset TCZ therapy (n=15)	p
General features			
Age (years), mean ± SD	65.8 ± 9.9	65.5 ± 10.1	0.94
Sex (female), n (%)	11 (73.3)	13 (86.7)	0.65
GCA evolution before TCZ onset, median [IQR]	2.0 [1.0-5.0]	18.0 [9.0-34.0]	**< 0.01**
Laboratory			
ESR (mm/1st hour), mean ± SD	34.7 ± 26.3	30.8 ± 28.7	0.70
CRP (mg/dL), median [IQR]	1.1 [0.6-2.3]	0.8 [1.8 -2.5]	0.28
Prednisone dose (mg/day), mean ± SD	10.0 [5.9-15.0]	5.0 [5.0-7.5]	**0.01**
TCZ therapy			
Intravenous, n (%)	10 (66.7)	11(73.3)	0.99
Combined with MTX, n(%)	6 (40)	8 (53.3)	0.46
PET /CT activity			
TBR at thoracic aorta	1.86 ± 0.69	1.54 ± 0.18	0.09
TVS	7.0 [4.0-9.0]	3.0 [2.0-5.0]	**< 0.01**
Complete clinical improvement, n (%)	13 (86.7)	12 (80)	0.99
Normalization of ESR and CRP, n (%)	15 (100)	15 (100)	0.99
PET/CT improvement			
Complete TBR normalization	6 (40)	3 (20)	0.23
Complete TVS normalization	2 (13.3)	1 (6.7)	0.54

CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; TBR: target-to-background ratio. * Normalization of TBR was considered when TBR < 1.34. ** Normalization of TVS was considered when TVS=0.

Conclusion: TCZ was effective in patients with LVV-GCA regardless the time from disease diagnosis to TCZ onset. However, complete normalization of vascular activity in PET/CT scans tended to occur more likely in patients who receive early-onset TCZ therapy within the first 6 months of the disease.

Background: Tocilizumab (TCZ) has shown to be effective for large vessel vasculitis including Takayasu arteritis (TAK) **(1-3).** Most evidence in TAK comes from Asian patients. However, white patients seem to have different clinical and prognostic features.
Objectives: Our aims were to: **a)** assess the efficacy and safety of TCZ in white patients with refractory TAK, **b)** determine if clinical improvement correlates with imaging outcomes, **c)** compare TCZ in monotherapy (TCZ_{MONO}) vs combined with conventional immunosuppressive drugs (TCZ_{COMBO})
Methods: Multicenter study of white patients with refractory TAK who received TCZ.Outcomes variables were remission, glucocorticoid-sparing effect, improvement in imaging techniques, and adverse events. A comparative study between patients who received TCZ_{MONO} and TCZ_{COMBO} was performed.
Results: 54 patients (46 women/8 men; median age 42.0 [32.5-50.5] years). TCZ was started after 12.0 [3.0-31.5] months since TAK diagnosis. Remission was achieved in 12/54 (22.2%), 19/49 (38.8%), 23/44 (52.3%) and 27/36 (75%)

at 1, 3, 6 and 12 months, respectively. Prednisone dose was reduced from 30.0 [12.5-50.0] to 5.0 [0.0-5.6] mg/day at 12 months (Table 1). 10 (26.3%) of the 38 patients in whom an imaging follow-up test was performed showed no radiographic improvement after a median of 9.0 [6.0-14.0] months. 4 of them were in clinical remission.23 (42.6%) patients were on TCZ_{MONO} and 31 (57.4%) on TCZ_{COMBO}: MTX (n=28), cyclosporine A (n=2), azathioprine (n=1). Patients on TCZ_{COMBO} were younger (38.0 [27.0-46.0] vs 45 [38.0-57.0] years; p= 0.048), with a trend to longer TAK duration (21.0 [6.0-38.0] vs 6.0 [1.0-23.0] months; p= 0.08) and higher C-reactive protein (2.4 [0.7-5.6] vs 1.3 [0.3-3.3] mg/dL; p=0.16). Despite these differences, similar outcomes were observed in both groups (log rank p=0.862) (Figure 1). Relevant adverse events were reported in 6 (11.1%) patients, but only 3 developed severe events that required TCZ withdrawal.

Table 1.

	Baseline n=54	**Month 1** N=54	**Month 3** N=49	**Month 6** N=44	**Month 12** N=36
Clinical remission, n (%)		12 (22.2)	19 (38.8)	23 (52.3)	27 (75.0)
Laboratory improvement					
CRP (*mg/dL*), median [IQR]	1.5 [0.5-3.5]	0.2 [0.1-0.7]*	0.2 [0.5-0.5]*	0.2 [0.1-0.5]*	0.1 [0.0-0.4]*
ESR (*mm/1st hour*), median [IQR]	30.5 [8.7-52.7]	7.0 [3.0-14.0]*	4.5 [2.0-8.0]*	5.0 [2.0-6.0]*	4.0 [2.0-9.5]*
Hemoglobin (*g/dL*), mean ± SD	12.4 ±1.5	13.0 ±1.2*	13.0 ±1.4*	13.2 ±1.5*	12.9 ±1.6*
Prednisone dose, median [IQR]	30.0 [12.5-50.0]	20.0 [10.0-30.0]*	10.0 [5.0-20.0]*	5.0 [5.0-10.5]*	5.0 [0.0-5.6]*

CRP: C-Reactive Protein; **ESR**: Erythrocyte Sedimentation Rate; **IQR:** interquartile range; n: number. *p<0.01 vs baseline (Wilcoxon test).

Conclusion: TCZ is effective and safe in white patients with refractory TAK. A discordance between clinical and imaging activity assessment may exist.

AB0367 DIAGNOSTIC DELAY IN PATIENTS WITH GIANT CELL ARTERITIS

M. Van Nieuwland[1], E. Colin[1], D. Boumans[1], M. Vermeer[2], E. Brouwer[3], C. Alves[1]. *[1]Hospital Group Twente, Rheumatology and Clinical Immunology, Almelo, Netherlands*; *[2]Hospital Group Twente, ZGT Academy, Almelo, Netherlands*; *[3]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis in the elderly which can lead to severe complications when treatment is delayed. Therefore, timely diagnosis and start of treatment is essential. Several forms of delay (consultation, referral and diagnostic delay) can contribute to the total delay towards GCA diagnosis. In the Dutch healthcare system, treatment is not started by a general practitioner (GP). When GCA is suspected, GPs refer to specialists. In our hospital, a fast track clinic (FTC) is used to expedite diagnosis. However, information on factors contributing to delay is scarce.

Objectives: The aim of this study was to describe the different components of delay towards diagnosis in GCA suspected patients in a general hospital, Ziekenhuisgroep Twente (the Netherlands).

Methods: For this descriptive study, a retrospective cohort consisting of patients with suspected GCA between January 1st 2017 and October 1st 2019 was used to analyse components of delay in diagnosis, as suggested by Prior et al. Consultation delay was defined as the time between start of symptoms and a patient's first consultation with a GP. Referral delay was defined as the time between a patient's first consultation with a GP and first visit to the FTC. Diagnostic delay was defined as the time between the first visit to the FTC and treatment initiation. Total delay was defined as the time from symptom onset until start of treatment. Delays were described using the median and interquartile ranges (IQR).

Results: In our cohort, 206 patients were included for analysis of whom 62 had GCA. Controls (n=144) were suspected of but did not have GCA. Comparing GCA patients with controls, 66.1% and 50.7% were female and the mean (SD) age was 74.2 (9.4) and 70.2 (11.0) years, respectively. In our cohort, the majority of patients (n=42, 67.7%) had cranial GCA (C-GCA). Furthermore, 8 (12.9%) had large vessel GCA (LV-GCA) and 12 (19.4%) had a combination of C-GCA and LV-GCA. For GCA patients, median consultation delay was 2.1 (IQR 0.8-5.8) weeks, referral delay 1.4 (IQR 0.4-4.6) weeks and diagnostic delay 0 (IQR 0-0.1) weeks (Figure 1). For delay regarding consultation and referral, results of controls were comparable to GCA patients. The median total delay was 4.4 weeks (IQR 1.57-10.14) for GCA patients.

Conclusion: With a median total delay of 4.4 weeks, delay in our cohort is almost half the delay described in a review by Prior et al. This difference might be due to FTC implementation and subsequent awareness in our hospital and by local GPs. Patients generally received treatment within one day after FTC visit. Nevertheless, contribution of consultation and referral delay is not resolved by introduction of the FTC, as shown in our data. Timely diagnosis is essential as severe complications can develop instantly, which emphasizes the need to tackle consultation and referral delay.

AB0368 CLINICAL CHARACTERISTICS AND RADIOGRAPHIC OUTCOME OF VASCULAR BEHCET'S DISEASE INVOLVING AORTA AND ITS MAJOR BRANCHES

S. Lee[1], S. Y. Kang[1], Y. H. Eun[1], H. Kim[1], J. Lee[1], E. M. Koh[1], H. S. Cha[1]. [1]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Behcet's disease (BD) is an immune-mediated systemic vasculitis affecting any size of blood vessels. Previous studies showed that BD may involve large arterial vessels [1] but the radiographic outcome has not been well known due to its low prevalence.
Objectives: To evaluate the radiographic outcome of vascular BD involving aorta and its major branches and the clinical characteristics of each prognosis group.
Methods: We retrospectively analyzed the medical records of patients who visited a single-center tertiary hospital in Seoul, Korea, across a 19-year period (Jan 2002 to Dec 2020). All patients fulfilled the International Criteria for Behcet's Disease. The patients included in this study had undergone CT angiography (CTA) of the aorta and its major branches at least twice in a 2–5 year interval and showed characteristic vascular involvements (aneurysm, stenosis, occlusion, vessel wall thickening, and thrombosis). Due to lack of the validated definition of radiographic progression of large vessel vasculitis in BD, we defined 20% changes of existing lesions or occurrence of new lesions as a radiographic progression.
Results: 22 patients with BD met the inclusion criteria. 5 patients (22.7%) progressed radiographically between the initial and follow-up CTA despite low acute phase reactant levels (AUC of ESR and CRP were 13.94 mm/h and 0.32 mg/dl, respectively). Aneurysm was the most frequent form of vascular involvement followed by thrombosis (21 [95.5%] and 11 [50.0%] patients, respectively, Table 1). Patients with radiographically progressive disease had longer disease duration (1.63 vs. 6.61 years, p=0.010) at initial CTA evaluation. Other clinical characteristics, including ESR, CRP, medication use, and follow up duration, were not different between two groups (Table 2).

Table 1. Radiographic characteristics of the cohort.

	Overall	Not progressed	Progressed	
n	22	17	5	p
Aneurysm (%)	21 (95.5)	16 (94.1)	5 (100.0)	>0.999
Stenosis (%)	5 (22.7)	4 (23.5)	1 (20.0)	>0.999
Occlusion (%)	5 (22.7)	5 (29.4)	0 (0.0)	0.440
Wall thickening (%)	4 (18.2)	4 (23.5)	0 (0.0)	0.589
Thrombosis (%)	11 (50.0)	9 (52.9)	2 (40.0)	>0.999

Conclusion: A considerable number of vascular BD patients involving aorta and its major branches progressed radiographically despite low disease activity. Radiographically progressed patients had longer disease duration, but other clinical characteristics were not significantly different whether progressed or not.

AB0369 EVALUATION OF BASELINE POSITRON EMISSION TOMOGRAPHY IN THE DIAGNOSIS AND ASSESSMENT OF GIANT CELL ARTERITIS

B. Ince[1], E. G. Işık[2], Z. G. Özkan[2], Y. Yalçınkaya[1], B. Artim-Esen[1], A. Gül[1], M. L. Ocal[1], M. Inanc[1]. [1]*Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; [2]*Istanbul University, Istanbul Faculty of Medicine, Department of Nuclear Medicine, Istanbul, Turkey*

Background: Positron emission tomography (PET/CT) has gained importance in the diagnosis and assessment of large vessel vasculitis (LVV) recently.
Objectives: We aimed to investigate the diagnostic importance and clinical significance of PET/CT findings in giant cell arteritis (GCA).
Methods: Data of the patients who underwent PET/CT to investigate large vessel involvement and who had at least 6 months of follow-up with a clinical diagnosis of GCA were retrospectively evaluated. PET/CT images were assessed by an experienced nuclear medicine specialist, regions of interest were drawn for major vascular territories and standardized maximum uptake values (SUVmax) of these areas were recorded.
Results: Twenty-nine consecutive patients (median age 68 (50-83), mean follow-up time 37.1 ± 48.8 (6-242)) were included into the study. All patients were over 50 years old and had erythrocyte sedimentation rate (ESR) over 50 mm/h at the time of imaging. Twenty patients (68.9%) met the ACR 1990 Classification criteria (ACR (+) group). The number of patients who had hypermetabolism in the aorta and its major branches in favour of LVV in PET/CT was 23 (79.3%) (PET-CT (+) group). Thoracic and abdominal aorta involvement were detected in 22 (75.8%) and 16 (55.2%) patients, respectively. There was positive correlation

between SUVmax in thoracic and abdominal aorta on PET/CT and ESR at diagnosis (r = 0.63 p = 0.002 and r = 0.77 p <0.001, respectively) and SUVmax in thoracic aorta and CRP (r=0.50 p=0.026). PET/CT (-) patients had more frequent disease flares during the follow-up (4/6 vs. 5/23 p = 0.035 OR = 7.2 (1.01- 51)). Three distinct subgroups were defined by implementing both ACR criteria and PET/CT positivity. Among ACR (+) patients (n=20); comparison of PET/CT (+) (n=14) and PET/CT (-) (n=6) patients did not show any difference in age of diagnosis, presence of polymyalgia rheumatica (PMR), flare rate and damage scores. Among PET/CT (+) patients (n=23), the mean age at diagnosis was higher, PMR and bilateral axillary artery involvement was more frequent in ACR (+) group (n=14) (Table 1).

Conclusion: PET/CT is increasingly used in the diagnosis and assessment of GCA in our center. The level of FDG uptake of the vessel wall in PET/CT correlates with the acute phase response. Flare was rarely observed in PET/CT (+) patients at diagnosis. Axillary artery involvement detected on PET/CT may be associated with the classical GCA clinic in ACR(+) patients (1). PET/CT (+) patients who does not met ACR criteria seems to have a diverse clinic features like young age and rare presence of PMR. PET/CT findings may be helpful in recognizing subgroups and predicting prognosis of GCA although prospective studies with follow-up scans are warranted.

Background: No universally accepted definition of flare currently exists in giant cell arteritis (GCA). Although relapses are defined mostly on clinical grounds (recurrence of GCA-related signs/symptoms), C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) help clinicians assess disease activity. In fact, >70% of patients on glucocorticoids (GCs) alone have increased CRP or ESR when the disease is active. In contrast, tocilizumab, given its IL-6-blockade effect in the liver, rapidly reduces CRP and ESR levels, rendering them unreliable for disease activity monitoring. Mavrilimumab – a GM-CSF receptor α inhibitor with demonstrated efficacy in a Phase 2 GCA trial[1] – downregulates inflammation upstream of IL-6. We hypothesized that mavrilimumab would not interfere with the utility of CRP and ESR in monitoring disease activity and in identifying GCA relapse.

Objectives: To analyze the relationship between CRP/ESR and clinical disease activity in GCA patients treated with mavrilimumab.

Methods: New-onset and relapsing GCA patients with active disease were recruited. GC-induced remission (no GCA symptoms and CRP <1 mg/dL or ESR <20 mm/hr) was required by baseline. Patients were randomized 3:2 to mavrilimumab 150 mg or placebo subcutaneously every 2 weeks plus a protocol-defined 26-week prednisone taper. The primary efficacy endpoint was time to relapse by Week 26. Relapse (adjudicated) was defined as recurrent GCA-related signs/symptoms, including new/worsening vasculitis on imaging, concurrent with CRP ≥1 mg/dL and/or ESR ≥30 mm/hr. CRP and ESR were also measured periodically during the trial.

This post hoc analysis assessed the association of recurrent GCA-related signs/symptoms with concurrent CRP or ESR elevation post-randomization by treatment arm. We also assessed the proportion of patients with CRP or ESR elevation without GCA-related signs/symptoms up to Week 26.

Results: Seventy patients were enrolled (mavrilimumab, N=42; placebo, N=28). The association of CRP or ESR elevation with unequivocal GCA-related signs/symptoms post-randomization was consistent regardless of treatment arm: 8/8 in the mavrilimumab group and 13/13 in the placebo group (Table 1). During relapse, median (range) CRP was 1.8 (1.4 – 8.4) mg/dL (mavrilimumab group) and 1.8 (1.1 – 9.0) mg/dL (placebo group). Corresponding ESR values were 39.5 (30 – 102) mm/hr (mavrilimumab group) and 49 (31 – 101) mm/hr (placebo group). Four mavrilimumab recipients had self-limited, equivocal GCA-related signs/symptoms without concurrent CRP or ESR elevation; all 4 completed the prespecified GC taper by Week 26 without need for rescue GCs, so relapse was not confirmed. At least 1 elevated CRP or ESR value in the absence of GCA-related signs/symptoms was observed in 58.8% of mavrilimumab recipients and 93.3% of placebo recipients by Week 26.

Conclusion: The observed association of CRP or ESR elevation with GCA-related signs/symptoms is consistent with the upstream mechanism and supports the utility of the stringent protocol definition of relapse. The frequency and magnitude of CRP and ESR elevations at relapse were similar in both treatment groups, suggesting that CRP and ESR remain useful in assessments of disease activity in mavrilimumab-treated patients. CRP and ESR elevations without GCA-related signs/symptoms occurred more often in placebo recipients.

AB0371 PATIENTS WITH PROLONGED SYMPTOMS BEFORE GCA DIAGNOSIS DO NOT INCUR HIGHER RATES OF VISUAL LOSS

V. Yang[1], C. Mcmaster[1,2], C. Owen[1,2], J. Leung[1,2], R. Buchanan[1,2], D. Liew[1,2]. [1]*Austin Health, Rheumatology, Heidelberg, Australia*; [2]*The University of Melbourne, Medicine, Parkville, Australia*

Background: Giant cell arteritis (GCA), if left untreated, confers the threat of serious cranial ischaemic complications including permanent visual loss. Although achieving a prompt and accurate diagnosis remains challenging, early diagnosis is viewed as being paramount in preventing significant morbidity.[1] This raises the question of whether GCA patients are at greater risk of developing visual sequelae if there is a longer window between symptom onset and presentation.

Objectives: To compare the frequency of lasting visual loss in patients diagnosed with GCA undergoing temporal artery biopsy (TAB) within three months and after three months of symptom onset.

Methods: Patients who underwent TAB from January 2011 to November 2020 were identified from the pathology database of an Australian rheumatology referral centre. The diagnosis of GCA was established for each patient based on either positive TAB or, in the setting of negative TAB, clinical diagnosis by a rheumatologist. Baseline demographics, symptoms and major confounders – including age, sex, history of polymyalgia rheumatica or inflammatory arthritis, headache, jaw pain, fatigue, temporal artery tenderness or diminished pulse, and number of 1990 American College of Rheumatology (ACR) classification criteria for GCA[2] fulfilled – were manually extracted from electronic medical records, as was the duration between onset of GCA symptoms and TAB, and the presence of visual loss before and after TAB. Logistic regression log-likelihood tests were used to examine the two cohorts presenting before and after three months.

Results: There were 167 patients who underwent TAB during the study period with accessible clinical information. Of these, 31 (19%) had a delayed presentation of greater than three months from symptom onset. There were no statistical differences in patient demographics between the two groups (Table 1). No patients with delayed presentation experienced lasting, objective visual loss. In contrast, there were three cases in the cohort of patients who presented more promptly; these included two patients who developed permanent unilateral blindness, and one who experienced unilateral vision loss with some improvement at three months of follow-up.

Table 1. ***Patient characteristics by time from symptom onset to TAB.***

	Presentation <3 months	Presentation ≥3 months	p-value
Age (years)	73.45±10.06	69.84±10.75	0.080
Female	92 (67.65%)	20 (64.52%)	0.738
History of polymyalgia rheumatica	23 (16.91%)	4 (12.90%)	0.586
History of inflammatory arthritis	6 (4.41%)	2 (6.45%)	0.633
Headache	110 (80.88%)	23 (74.19%)	0.406
Jaw pain	37 (27.21%)	5 (16.13%)	0.206
Fatigue	28 (20.59%)	6 (19.35%)	0.878
Temporal artery tenderness or diminished pulse	46 (33.82%)	11 (35.48%)	0.860
ACR classification criteria	2.83±0.99	2.58±0.89	0.199

Conclusion: GCA patients with a lengthier course of symptoms before diagnosis did not experience any enduring visual loss. This may reflect a pattern of more aggressive disease leading to earlier presentation, but further study should explore whether longer symptom duration before diagnosis necessitates a higher degree of clinical concern.

AB0372 TOCILIZUMAB WAS EFFECTIVE IN REFRACTORY ARTERIAL INVOLVEMENT OF BEHCET'S DISEASE: A REAL-LIFE SINGLE- CENTER EXPERIENCE IN CHINA

H. Zhong[1], T. Liu[1], Y. Liu[1], X. Zhang[1], Y. Zhou[1], Y. Su[1]. [1]*Peking University People's Hospital, Department of Rheumatology and Immunology, Beijing, China*

Background: Behcet's disease (BD) is a chronic and relapsing vasculitis, in which major vessel involvement is a main cause of mortality and morbidity. The therapeutic arsenal is mainly composed of classical immunosuppressants. However, when faced with resistance to these drugs, no alternative therapeutic strategy is currently recommended.

Objectives: To assess the efficacy and safety of interleukin 6 receptor inhibitor tocilizumab (TCZ) in refractory arterial involvement of BD in a real-life observational setting.

Methods: 10 patients were enrolled in our center between 2014 and 2019. All patients met the international criteria for BD and had severe arterial involvement evaluated by echocardiography, angio-Computerized Tomography scan and vascular Doppler. The diagnosis of refractory arterio-BD was based on objective vascular symptoms not explained by any other known disease and non-response to conventional immunosuppressants combined with glucocorticoids therapy. All patients underwent TCZ infusions at 8mg/kg every 4 weeks. Concomitant therapy with immunosuppressants and glucocorticoids was continued. Clinical and imaging findings were assessed before and after TCZ therapy. All adverse events were recorded during follow-up.

Results: All the patients were males, with a mean age of 44.3±10.5 years in this study. The mean age at presentation of arterial involvement was 40.8±9.2 years old. The patterns of arterial involvement were aneurysm (n=9), stenosis (n=3) and aortic valve lesion (n=2). After a mean follow-up of 26.8±7.2 months, TCZ yielded rapid and maintained clinical improvement in 9 patients, with complete remission in 6 of them and partial response in 3 of them. Discontinuation of TCZ treatment due to relapse occurred in one case as the enlargement of abdominal aortic aneurysm. The mean glucocorticoid dosage was tapered from 54.5±20.6mg/d to 8.3±3.6mg/d ($p<0.001$). And the use of immunosuppressants was tapered in 4 (40.0%) patients. As for serological improvement, the median ESR and CRP levels decreased from 50 (2-82) mm/h and 32.9 (2.1-62.3) mg/dL to 4 (1-10) mm/h ($p<0.001$) and 2.9 (0.2-12.1) mg/dL ($p<0.001$), respectively. Radiologic improvement of artery lesion was demonstrated in 4(40%) patients. None of the patients had serious adverse events during follow-up.

Conclusion: TCZ was a safe and effective therapeutic option for refractory arterial involvement of BD, with a favorable steroid-sparing effect.

AB0373 PSYCHOMETRIC PROPERTIES OF OUTCOME MEASUREMENT INSTRUMENTS FOR LARGE VESSEL VASCULITIS: A SYSTEMATIC LITERATURE REVIEW

G. Boleto[1], A. Berti[2], P. A. Merkel[3], S. Aydin[4], H. Direskeneli[5], C. Dejaco[6], L. Carmona[7], S. Ramiro[8,9]. *[1]Université de Paris, Hôpital Cochin, Rheumatology, Paris, France*; *[2]Santa Chiara Regional Hospital and Department of Cellular, Computational and Integrative Biology (CIBIO), University of Trento, Rheumatology, Trento, Italy*; *[3]Vasculitis Clinical Research Consortium; Hospital of the University of Pennsylvania, Rheumatology Division, Philadelphia, United States of America*; *[4]University of Ottawa Faculty of Medicine, Rheumatology, Ottawa, Canada*; *[5]Marmara University, Internal medicine, division of Rheumatology, Istanbul, Turkey*; *[6]Medical University of Graz, Rheumatology, Graz, Austria*; *[7]Instituto de Salud Musculoesquelética (InMusc), Rheumatology, Madrid, Spain*; *[8]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[9]Zuyderland Medical Center, Rheumatology, Heerlen, Netherlands*

Background: Giant cell arteritis (GCA) and Takayasu arteritis (TAK) are two forms of chronic progressive large-vessel vasculitis (LVV) of unknown etiology. In 2016, the OMERACT Vasculitis Working Group proposed the development of a Core Domain Set of outcome measures for LVV including organ and arterial function, fatigue, pain, biomarkers, and death (1). Understanding the psychometric properties of outcome measurement instruments is essential when selecting among instruments to use in research; a summary of such properties for measures of LVV has not been developed.

Objectives: To systematically review and summarize the psychometric properties of outcome measurement instruments used to measure the domains of the OMERACT core domain set for LVV.

Methods: A comprehensive search of several databases (Medline, EMBASE, Cochrane, among others) from inception to July 14, 2020 was conducted. Articles were included if they covered psychometric properties of instruments used in LVV. Following the COSMIN and OMERACT frameworks, different psychometric properties (validity, inter- and intra-observer reliability, sensitivity to change, and feasibility) of outcome measurement instruments used in LVV (GCA and TAK) were assessed. Risk of bias was assessed according to the COSMIN checklist.

Results: Among the 3534 articles identified, 15 studies focusing on the development or validation of psychometric properties on LVV met the predefined criteria. Two were development studies and 13 were validation studies. These studies provided information on 13 instruments: 5 instruments specific to TAK, 2 specific to systemic vasculitides, and 6 general, non-disease-specific instruments. No instruments specific to GCA were identified.

Of the main psychometric properties assessed in the included studies, 40% had a low, 47% had moderate, and 13% had high risk of bias. Construct validity was the property most frequently assessed (in 93% of the tools) (Figure 1).

In TAK, the Indian Takayasu Clinical Activity Score 2010 (ITAS2010) showed good consistency (r=0.97), reliability (intra-observer, ICC=0.60; inter-observer, ICC=0.92) and validity (correlation with Physician Global Assessment (PGA) (r=0.73)) for disease activity. Regarding disease damage, the Disease Extent Index-Takayasu (DEI-Tak) showed good validity (correlation with NIH score 94%, k=0.85). Non-specific vasculitis instruments such as the Vasculitis Damage Index (VDI) and the Birmingham Vasculitis Activity Score (BVAS) showed moderate validity in the assessment of disease damage in GCA (cumulative glucocorticoid dose and disease duration, r=0.30 and r=0.29) and TAK (cumulative glucocorticoid dose and disease duration, r=0.29 and r=0.25) in the former and disease activity in GCA in the later (PGA, r=0.50).

Six non-vasculitis-specific patient-reported outcomes (PROs) instruments were identified, all showing low to moderate validity in GCA/TAK.

Psychometric properties among 13 outcomes instruments developed and/or validated for largel-vessel vasculitis

Abbreviations: ITAS2010=Indian Takayasu Activity Score 2010; ITAS A=Indian Takayasu Activity Score A;, DEI Tak=Disease Extent Index Takayasu;, VDI=Vasculitis Damage Index; BVAS=Birmingham Vasculitis Activity Score; TADS=Takayasu Arteritis Damage Score; BIPQ=Brief Illness Perception Questionnaire; ADVS=Activities of Daily Vision Scale; SF-36=Medical Outcomes Study Short-Form 36; VCM1=Vision Core Measurement 1; PtGA: Patient Global assessment; MFI=Multidimensional Fatigue Inventory.

Conclusion: The psychometric properties of 13 outcome measures to study LVV covering the OMERACT domains of disease activity, damage, and patient-reported outcomes were assessed. ITAS2010, DEI-Tak, VDI, and BVAS were the instruments with better psychometric properties for disease activity and/or damage. Disease activity and/or damage instruments specific for GCA, and validated PROs for both GCA and TAK are needed.

AB0374 CHARACTERISTICS OF A GIANT CELL ARTERITIS COHORT IN LATINOAMERICA

T. Urrego Callejas[1,2], D. Álvarez[3], D. Jaramillo Arroyave[4,5], A. L. Vanegas-García[2,6], C. Muñoz[2,3,5]on behalf of Grupo de Reumatología de la Universidad de Antioquia. *[1]Universidad de Antioquia, Facultad de Medicina, Medellín, Colombia*; *[2]Universidad de Antioquia, Grupo de Reumatología Universidad de Antioquia, Medellín, Colombia*; *[3]Hospital San Vicente Fundación, Internal Medicine, Rionegro, Colombia*; *[4]Grupo de Epidemiología, Universidad CES,*

Epidemiología, Medellín, Colombia; [5]*IPS Universitaria Servicios de Salud Universidad de Antioquia, Rheumatology, Medellín, Colombia*; [6]*Hospital San Vicente Fundación, Rheumatology, Medellín, Colombia*

Background: Giant cell arteritis (GCA) is a large vessel vasculitis (LVV) that affects mostly the elderly (1). Temporal artery biopsy (TAB) has been defined as the gold standard, although this has come to question (3). EULAR guidelines recommended non-invasive imaging techniques such as the temporal artery Doppler ultrasound to aid in LVV diagnosis (2). The characterization of GCA in Latin American countries, and specifically in Colombia, is scarce.

Objectives: To perform a clinical, demographical, histopathological, and radiological characterization of
Colombian GCA patients.

Methods: Retrospective data from GCA patients at two teaching hospitals in Medellín, Colombia, was collected. A bioethics committee previously approved the research protocol. Inclusion criteria: diagnosis of GCA, based on clinical characteristics or imaging/biopsy findings. Exclusion criteria: HIV diagnosis, paraneoplastic large vessel vasculitis. Clinical, radiological, and histopathological variables were selected based on the clinicians' expertise and the 2018 EULAR recommendations for a core data set to support observational research and clinical care in giant cell arteritis (3). The data were analyzed in SPSS v22.0 (IBM, USA).

Results: Twenty-two patients were collected. Demographical and clinical characteristics are summarized in Table 1. Most patients were women (68.1%), with a mean age of 71.8 years, mean duration of symptoms of 5.3 months. In the cranial form of the disease, the most common symptoms were headache and jaw claudication (95% and 68%). Six patients experienced visual loss: complete unilateral visual loss in two, partial unilateral in two, complete bilateral in one, and partial bilateral in one patient.

Sixteen patients (72.7%) underwent TAB; the most common finding was mononuclear infiltrate and internal elastic fragmentation in 43.7% of the biopsies. Giant cells were observed in 6 biopsies (37.5%). Doppler ultrasound was performed in 19 patients (86.35%), finding intima-media thickening and the halo sign t in 7 patients (36.8%).

Table 1. Demographical and clinical characteristics

Characteristic	n = 22
Mean age (years SD)	71.8 (10.6)
Female sex n (%)	15 (68.1%)
Mean symptoms duration (months ± SD)	5.3 ± 6.8
Mestizo n (%)	20 (90%)
Headache n (%)	21 (95.4%)
Jaw claudication n (%)	15 (68.1%)
Weight loss n (%)	13 (59%)
Scalp sensitivity n (%)	11 (50%)
Fever n (%)	8 (36.3%)
Presence of polymyalgia rheumatica n (%)	7 (31.8%)
Visual loss n (%)	6 (27.2%)
Amaurosis fugax n (%)	1 (4.5%)
Glucocorticoids n (%)	22 (100%)
Pulse n (%)	8 (36.3%)
Mean dose (mg ± SD)	47.1 ± 16.7
Methotrexate n (%)	17 (77.7%)
Azathioprine n (%)	2 (9%)
Tocilizumab n (%)	1 (4.5%)

Conclusion: In this GCA cohort, the main phenotype was cranial GCA, with 95% of the patients presenting with headache. The most common imaging study performed was Doppler ultrasound of temporal arteries, with intima-media thickening and halo sign being the most common findings. The mainstay of treatment was glucocorticoids with methotrexate as a sparing agent. To our knowledge, this study is the first to perform a specific characterization of GCA patients in the Colombian population, and it can represent the foundation of further research for these patients.

AB0375

EXTERNAL VALIDATION OF THE GIANT CELL ARTERITIS PROBABILITY SCORE IN THE NETHERLANDS

L. M. Neuman[1], M. Van Nieuwland[1], M. Vermeer[2], D. Boumans[1], E. Colin[1], C. Alves[1]. [1]*Hospital Group Twente, Rheumatology and Clinical Immunology, Almelo, Netherlands*; [2]*Hospital Group Twente, ZGT Academy, Almelo, Netherlands*

Background: Severe complications of giant cell arteritis (GCA), such as blindness and ischemic stroke, can be prevented by timely treatment. This requires early and accurate diagnosis. In 2019, Laskou et al. developed a clinical GCA probability score (GCAPS) that allows physicians to assess the probability of GCA at initial assessment. The GCAPS is suitable for easy implementation in daily practice. It has a high sensitivity (95.7%) and specificity (86.7%) at a cut-off value of 9.5 as proposed by Laskou et al.

Objectives: The aim of this study was to externally validate the GCAPS in a general hospital.

Methods: A retrospective cohort of patients with suspected GCA between January 1st 2017 and October 1st 2019 at Ziekenhuisgroep Twente (the Netherlands) was used. As the parameter extra-cranial artery abnormality was not available in our cohort, a modified version of the GCAPS was used (m-GCAPS). The m-GCAPS was compared to clinical diagnosis of a rheumatologist after six months in accordance with Laskou et al. The validity of the m-GCAPS was assessed by plotting a receiver operating characteristic (ROC) curve and assessing sensitivity and specificity for multiple cut-off values. For practical purposes, risk stratifications as proposed by Sebastian et al. (2020) were applied to our data (low-risk <9; intermediate-risk 9-12; high-risk >12).

Results: In our cohort, 40 GCA patients and 95 controls (suspected of GCA) had complete records and were therefore used for analysis. In the patient group, 29 (72.5%) were female and mean (SD) age was 73.3 (1.6). The area under the ROC curve (AUC) was 0.83 (95% CI 0.75 – 0.91). At our optimal cut-off value of 10.5, sensitivity was 80.0% and specificity was 75.8%. In total, 5 patients and 45 controls were stratified as low, 7 patients and 35 controls as intermediate and 28 patients and 15 controls as high-risk.

Conclusion: The m-GCAPS showed good discrimination in our cohort. Risk stratification of patients looks promising, although cut-off values by Sebastian et al. might need optimization based on population and modification to the GCAPS. Colour Doppler ultrasound is recommended by EULAR as the first-choice diagnostic test to confirm GCA in case of high pre-test probability and exclude GCA for low pre-test probability. The (m-)GCAPS may aid in quantification of this pre-test probability.

AB0376

LEVEL OF DIAGNOSTIC AND THERAPEUTIC KNOWLEDGE, SKILLS AND COMPETENCIES IN GIANT CELL ARTERITIS AMONG EMERGENCY MEDICAL STAFF

C. Guillén-Astete[1], I. Perea-Fuentes[2], L. Ayala-Terrados[2], N. García-Montes[3]. *[1]Hospital Ramón y Cajal, Rheumatology, MADRID, Spain*; *[2]CEU San Pablo, Medicine, Madrid, Spain*; *[3]Hospital Ramón y Cajal, Emergency, Madrid, Spain*

Background: Giant cell arteritis (GCA) is the most frequently diagnosed vasculitis in Spain. The highest incidence recorded in the country is 17 new cases per 100,000 inhabitants/year. Its delayed diagnosis exposes the patient to an increased risk of multiple ischaemic complications. Among them, vision loss has been reported in up to 1 in 6 cases. Most of these patients, according to unpublished local observations, presented with headache, visual disturbances or polymyalgic symptoms to an emergency department facility and were not correctly or prompted diagnosed.
Objectives: To determine the level of knowledge, skills and diagnostic and therapeutic competencies of the medical staff of multiple emergency departments in our city in regard to giant cell arteritis.
Methods: We designed an observational study based on a single survey carried out between February and March 2020 to medical staff from 12 emergency departments in the city of Madrid. Four private and eight public emergency departments were deliberately included. The selection of the surveyed staff was randomly selected to reach 50% of the total number of physicians in each department. A total of 229 surveys were distributed by e-mail. A total of 125 physicians responded (final response rate 54.5%). Twenty-two physicians (9.2%) did not respond to the request and the rest declined to participate, although they responded to the demographic section (35.8%).
The survey included the following sections: respondent profile, knowledge of epidemiological aspects, identification of clinical manifestations, diagnostic and therapeutic skills, and educational interest.
Results: Forty respondents (33.6%) worked in a privately managed emergency department and 79 (66.4%) in a public centre.The mean age of respondents was 37.3 SD 5.9 years, and the proportion of women was 62.4%. Mean length of service was 3.4 SD 1.2 years among physicians in private emergency departments and 5.7 SD 2.3 in a public management unit. Sixty-four respondents (53.7%) were specialists in Family and Community Medicine, and 46 (38.6%) in internal medicine. No significant differences in demographic characteristics were identified between respondents who agreed to participate and those who declined.
In regard to epidemiological knowledge, 50.6% of respondents were unable to identify the age group at highest risk of GCA, 32.7% did not recognise its predominance in the female sex, and 26% did not know the approximate incidence of the disease.
In terms of diagnostic suspicion, 46.2% of respondents were able to identify at least five clinical manifestations of the disease. Elevated ESR, CRP and the presence of anaemia were recognised as positive analytical data by 98.3%, 85.7% and 57.7% of respondents, respectively. Ultrasonography of temporal arteries was identified by 97.5% of respondents as a useful diagnostic technique.
One hundred and two respondents (81.6%) indicated that they had not suspected GCA in the last month. In the last year, 34 respondents (27.2%) reported having diagnosed the disease on at least one occasion. Regarding treatment, in cases of absence of ischaemic lesion 85.7% indicated suboptimal corticosteroid therapy guidelines, however, 63.0% of the respondents self-rated their therapeutic skills as very good or excellent.
Finally, 88.2% of respondents expressed interest in participating in training programmes in diagnosis and treatment of GCA.
Conclusion: There are important areas for improvement in knowledge, diagnostic skills and therapeutic competencies among emergency physicians in relation to the suspicion and management of GCA.

AB0377

CLINICAL REVIEW OF 19 CASES WITH IDIOPATHIC AORTITIS – A SINGLE CENTRE STUDY

M. J. Villar[1], S. Sangle[2], D. D'cruz[2]. *[1]Clinica Alemana, Reumatología, Vitacura, Chile*; *[2] Guys and St Thomas' Hospital NHS Foundation Trust, Louise Coote Lupus Unit, London, United Kingdom*

Background: Aortitis is a group of disorders leading to inflammation in the aorta. When aortitis has no clinical evidence of systemic vasculitis, it is called idiopathic aortitis or clinically isolated aortitis (CIA).
There is no consensus on the management of CIA.
Objectives: Our purpose is to describe our cohort of patients with CIA and their response to treatment.
Methods: This is a retrospective analysis of 19 patients with CIA. All records of patients with CIA were analyzed and demographic variables, comorbidities, symptoms, images, histology, treatment
received, outcome and mortality were recorded. The description of quantitative variables was made using the median and the interquartile range (IQR).
Results: Nineteen patients were analyzed. Diagnosis was made by imaging in 18 (94.7%), one patient was diagnosed by histology after aortic root surgery. Patient characteristics are detailed in Table 1.
The median duration of follow- up was 38 months (IQR 43). Seven patients (36.8%) had constitutional symptoms including fever, weight loss, sweats and fatigue. 4 (21.05%) presented with back or abdominal pain for a mean duration of 3 months (SD 0.81) before the diagnosis. In 8 (42.1%) patients the diagnosis was made incidentally.
All patients had negative treponema, hepatitis B, hepatitis C and Human Immunodeficiency Virus (HIV) serology.
All patients had negative autoimmune serology included ANCA. Interestingly 4 (21.05%) had positive lupus anticoagulant without other manifestation of antiphospholipid syndrome.
The type of aortic involvement was aortitis in 10 patients (52.6%), inflammatory aneurysm in 8 (42.1%) and dissection in 1 (5.2%).
Seven (36.8%) patients had thoracic and abdominal aorta involvement, 6 (31.5%) only thoracic aorta and 6 (31.5%) only abdominal aorta.
Aortic histology was obtained in 5 patients, 2 had necrotizing arteritis with giant cell pattern and 2 had lymphoplasmacytic pattern. Temporal artery biopsy was done in one patient and the result was negative for GCA.
All patients received corticosteroids as a remission inducing agent, 12 (63.1%) received methotrexate and 2 (10.5%) mycophenolate. 2 patients died (10.5%).
The median prednisone dose at the beginning was 20 mg (IQR 20) and at remission was 5 mg (IQR 20). 41.6% (5/12) of patients treated with steroids plus methotrexate were able to stop steroids without reactivation over a median follow-up time of 23.5 months (IQR 31). (Table 2.)
Details of treatment, ESR and CRP pre and post treatment is shown in Figure 1.
Seven patients (36.8%) had follow-up imaging, none of them showed active inflammation, new aneurysm, dissection or disease progression.
Conclusion: Treatment of isolated aortitis with steroids and methotrexate was effective resulting in clinical and laboratory improvement and allowed cessation or decrease in steroids to 5 mg or less in 83% of patients. This therapeutic approach may be useful in patients with CIA.

Table 1. Characteristic of the patients.

Nº Patients		19
Female		6 (31.5%)
Male		13 (68.4%)
Age median		64 (IQR18)
Ethnicity	Black	4 (21.05%)
	Caucasian	15 (78.9%)
Comorbidities		
Diabetes mellitus type 2		2 (10.5%)
Hypertension		12 (63.1%)
Obesity		5 (26.3%)
Hypercholesterolemia		9 (47.3%)
Smoker		6 (31.5%)
Nº (%) patients with prednisone ≤ 5 mg at end of follow-up according to treatment received		
Only steroids (5)		1(20%)
Steroids + methotrexate (12)		10 (83.3%)
Steroids + mycophenolate (2)		1 (50%)

AB0378 UTILITY AND ACCURACY OF SOUTHEND PRETEST PROBABILITY SCORE IN GCA FAST-TRACK CLINIC: ANALYSIS IN 261 CONSECUTIVE PATIENTS

J. Ortega[1], I. Monjo[2], E. Fernández-Fernández[2], E. De Miguel[1,2]. *[1]Universidad Autónoma Madrid, Rheumatology, Madrid, Spain*; *[2]Universitary Hospital La Paz, Rheumatology, Madrid, Spain*

Background: Strategies for early diagnosis of Giant Cell Arteritis (GCA) have been implemented in the last decade in order to reduce the occurrence of blindness, ischemic events and other manifestations of the disease. The Southend pretest probability score (SPTPS) [1] seem to be useful in stratifying and select the referral patients sent to the GCA fast-track clinics.

Objectives: The aim of this study was to test the validity and utility of this score in our patients.

Methods: Retrospective available data records of all the patients referred to our GCA fast-track clinic in the last three years were collected. The clinical and laboratory features at referral were evaluated, and the SPTPS was generated. All patients had ultrasound of cranial and large vessel examination (axillary, subclavian and carotid arteries). GCA diagnosis was confirmed by the doctor after at least six months of follow-up. Quartile frequencies, ROC curves and accuracy of the SPTPS was calculated.

Results: 261 patients (180 females) with suspicions of GCA were evaluated in our fast-track clinic. Mean age (±SD) was 76±9.2 years, and C-reactive protein 75.7±68.6 mg/l. The time since the first symptoms was less of 6, 6-12, 12-24 or >24 weeks in 37.5%, 19.9, 12.3 and 15.7 respectively. Mean SPTPS was 11.4±4.4, with values of 9.1±3.2 and 12.9±4.4. The area under the ROC curve was 0.761 (95% confidence interval: 0.703-0.819). PTPS overall showed a 50th percentile score of 11 and a 75th percentile score of 14. We, therefore, classified "Low Risk" (LR) as SPTPS <11, "Intermediate Risk" (IR) 11–14 and "High Risk" (HR) >14. Of 261 referrals, 156 had GCA with cases categorised as LR (119), IR (91) and HR (51). HR score showed a specificity of 96.2% and in IR the specificity ranged between 86.7 and 94.3% (Table 1). Score below 7 appears in 29 cases with only 8 cases of GCA with a probability of GCA < 5%, more of these cases was associated a large vessel vasculitis: 3 cranial arteritis (CA), 4 large vessel vasculitis (LVV) and 1 mixed pattern (MP). LR score included 72 of the 105 (68.6%) non-GCA cases but 47 of 156 (30.1%) GCA patients (20 CA, 11 LVV and 16 MP). IR risk score included 26 (24.8%) of the non-GCA cases and 65 (41.7%) of GCA patients (31 CA, 13 LVV and 21 MP). Finally HR score had only 7 non-GCA cases and 44 (28.2%) patients with GCA (20 CA, 11 LVV and 13 MP). Mean score in cranial forms was 13.1±4.5 and in large vessel vasculitis 12.8±5.0 (p=0.807).

Table 1. Sensitivity and Specificity of SPTPS at different cut-off points

Cut-off point	Sensitivity	1-Specificity
2	1.000	1.000
3.5	0.994	0.971
4.5	0.987	0.943
5.5	0.987	0.876
6.5	0.949	0.790
7.5	0.897	0.676
8.5	0.846	0.476
9.5	0.750	0.362
10.5	0.679	0.248
11.5	0.538	0.133
12.5	0.449	0.086
13.5	0.353	0.057
14.5	0.218	0.038
15.5	0.147	0.019
16.5	0.128	0.019
17.5	0.077	0.010
19	0.038	0,000
20.5	0.032	0,000
21.5	0.019	0,000
22.5	0.013	0,000
24	0.000	0,000

Conclusion: The SPTPS is helpful to stratified patients sent to the fast-track clinic. Scores below of 7 points has a very low probability to have GCA. The diagnostic probability increases directly with the score. There were minor differences without statistical significance between cranial or large vessel vasculitis patterns in the score.

AB0379 BARICITINIB IN POLYMYALGIA RHEUMATICA AND GIANT CELL ARTERITIS: REPORT OF SIX CASES

D. Camellino[1], C. Dejaco[2,3], A. Giusti[1], F. Martini[4], R. Cosso[5], G. Girasole[1], G. Bianchi[1]. *[1]Local Health Trust 3, Genoa, Division of Rheumatology, Department of Medical Specialties, Genoa, Italy*; *[2]Medical University Graz, Department of Rheumatology, Graz, Austria*; *[3]Hospital of Bruneck (ASAA-SABES), Department of Rheumatology, Bruneck, Italy*; *[4]Local Health Trust 1, Medical Department, Sanremo, Italy*; *[5]Local Health Trust, 3, Medical Department, Genoa, Italy*

Background: Glucocorticoids (GC) are the cornerstone of the treatment of polymyalgia rheumatica (PMR) and giant cell arteritis (GCA), but they are associated with several adverse events (AEs). Moreover, a considerable proportion of patients relapse during GC tapering.

Objectives: To describe the efficacy and safety of the JAK-inhibitor baricitinib (BARI) in a group of patients with PMR and/or GCA.

Methods: Case series of patients with PMR and/or GCA with a refractory disease course, despite several lines of therapy, including methotrexate (MTX) and tocilizumab (TCZ), started treatment with BARI. All patients underwent periodic, standardised clinical and laboratory examinations, and also FDG-PET/CT. PMR-activity score (AS) was calculated at each visit except in patients with isolated large vessel vasculitis (LVV) or GCA.

Results: A total of six patients (five females and one male, median age 64 years, range 50-83) were treated with BARI. Two of them had isolated PMR (patients #1 and #6), two had PMR with associated LVV (patients #2 and #5), and one (patient #3) had cranial-GCA. Demographic and clinical characteristics are provided in Table 1. At the time of starting BARI, patients were taking a median prednisone dose of 8.75 mg/day (range 0-25), and the 4 patients with PMR±LVV had a median PMR-activity score (PMR-AS) of 23.3 (indicating high disease activity), which decreased to 1.58 after 6 months of treatment with BARI. Two of them could stop GC and continued BARI monotherapy (in one case, BARI was tapered down to 2 mg/day after 12 months).

After starting BARI, patient #3 (GCA) could gradually taper prednisone from 25 mg/day to 10 mg/day in six months, without reporting fever or headache. After one year of treatment, she feels well while taking prednisone 7.5 mg/day.

Patient #4 (LVV) remained clinically stable during the treatment with BARI, but a follow-up FDG-PET/CT showed LVV, and we decided to stop BARI and restart TCZ. After 4 months of treatment with BARI, patient #5 suffered from pneumonia, while she was also taking prednisone 15 mg/day. BARI was therefore stopped. No other AEs attributable to BARI were detected.

Conclusion: BARI appears as an appealing option for treating patients with PMR and/or GCA. Although these preliminary results should be confirmed by a RCT, BARI lowered rapidly disease activity and exerted a significant steroid-sparing effect, allowing GC withdrawal in 2 out of 6 patients.

Table 1. Demographic and clinical characteristics of patients.

Patient #	Sex	Age	Diagnosis	Previous treatment	Disease duration (months)	PMR-AS
1	F	66	PMR	MTX, HCQ, SSZ	25.5	40.5
2	F	78	PMR+LVV	TCZ, MTX	41.8	28.8
3	F	61	GCA	CYC, MMF, TCZ	119.8	N/A
4	F	60	LVV	TCZ	16.4	N/A
5	F	83	PMR+LVV	MTX, TCZ	24.4	15.2
6	M	50	PMR	MTX	24.6	17.8

CYC: cyclophosphamide, GCA: giant cell arteritis, HCQ: hydroxychloroquine, LVV: large vessel vasculitis, MMF: mycophenolate mofetil, MTX: methotrexate, N/A: not applicable, PMR: polymyalgia rheumatica, PMR-AS: PMR-activity score, SSZ: sulfasalazine, TCZ: tocilizumab.

AB0380

MACHINE LEARNING CAN PREDICT GIANT CELL ARTERITIS RELAPSE AFTER GLUCOCORTICOID TAPERING

V. Venerito[1], G. Emmi[2], L. Cantarini[3], N. Lascaro[4], M. Fornaro[1], O. Angelini[5], L. Coladonato[1], F. Cacciapaglia[1], P. Leccese[4], G. Lopalco[1], F. Iannone[1].
[1]University of Bari Aldo Moro, Department of Emergency and Organ Transplantations - Rheumatology Unit, Bari, Italy; *[2] University of Firenze, Department of Experimental and Clinical Medicine, Firenze, Italy*; *[3]University of Siena, Research Center of Systemic Autoinflammatory Diseases and Behçet's Disease Clinic, Siena, Italy*; *[4] San Carlo Hospital of Potenza and Madonna delle Grazie Hospital of Matera, Rheumatology Institute of Lucania (IRel) and the Rheumatology Department of Lucania, Potenza, Italy*; *[5]Amazon Research Center, Amazon Research Center, Cambridge, United Kingdom*

Background: To date reliable biomarkers and risk factors for relapsing giant cell arteris (GCA) after glucocorticoid (GC) tapering are still lacking.

In an increasing number of social and clinical scenarios, machine learning (ML) is emerging as a promising tool for the implementation of complex multi-parametric decision algorithms. A ML approach allows to handle complex non-linear relationships between patient attributes that are hard to model with traditional statistical methods, merging them to output a forecast or a probability for a given outcome.

Objectives: To assess whether ML algorithms can predict GCA relapse after glucocorticoid tapering.

Methods: GC-naïve GCA patients who presented to 4 tertiary care centers between January 2015 and January 2019, who underwent GC therapy and regular follow up visits for at least 12 months were retrospectively analyzed and used for training and validation (through 10-fold cross-validation) of n.2 ML algorithms, namely Decision Trees (DT) and Random Forest (RF).

Test of the algorithms was carried out GCA patients referred to the same centers from March 2019 to September 2020 whose data was longitudinally recorded during the 12 months after presentation.

Demographic, clinical an laboratory characteristics (Erythrocyte Sedimentation Rate (ESR) and C Reactive Protein (CRP) levels) were gathered.

The outcome of interest was the GCA relapse within 12 months after induction of remission, during GC tapering.

The accuracy of the algorithms in both validation and test phases was assessed.

Results: The training and validation dataset consisted of n.85 GCA patients (59 female, 69.4%) with mean age 73.8 (±8.7) years at presentation. They were treated with 27.1 (±17.4) mg prednisone (PDN) equivalent at first visit. During GC tapering 34 of them (40%) experienced a disease relapse within 12 months. The test dataset consisted of n.22 patients (14 female, 63.4%) with mean age 75.5 (±8.7) years at presentation, who underwent GC induction therapy with a mean dose of 30.3 (±17.3) mg PDN equivalent. Nine of them (40.9%) had a GCA flare during GC tapering, within 12 months. Accuracy of DT and RF in predicting the outcome of interest on the training dataset was 68.3% and 73.4% respectively. On testing datasets DT and RF accuracy was 57.1 and 72.4%, respectively.

As shown in Figure 1, the most important patient attributes for RF forecast were found to be CRP and ESR baseline levels as well as age and symptom duration (months) at first visit.

Conclusion: RF algorithm can predict GCA relapse after glucocorticoid tapering with fairly good accuracy. To date this is one of the most accurate predictive modeling for such outcome. This ML method represents a reproducible tool executable on computers as well as mobile devices and capable of supporting clinicians in GCA patient management.

AB0381 **VALIDATING DRAFT DCVAS CRITERIA IN A SINGLE CENTER GCA COHORT IN SOUTHERN NORWAY**

P. Andel[1,2,3], S. Brådland[3], A. Diamandopoulos[4,5], G. Myklebust[3], G. Haugeberg[3,6]. *[1]Østfold Hospital Trust, Department of Cardiology, Kalnes, Norway*; *[2]University of Oslo, Department of Clinical Medicine, Oslo, Norway*; *[3]Hospital of Southern Norway, Department of Rheumatology, Kristiansand, Norway*; *[4]Akershus University Hospital, Department of Rheumatology, Oslo, Norway*; *[5]Martina Hansens Hospital, Department of Rheumatology, Kristiansand, Norway*; *[6]Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Trondheim, Norway*

Background: Giant cell arteritis (GCA) is the most common medium- and large vessel vasculitis in the elderly population. The diagnostic algorithm has changed in recent years in many institutions from temporal artery biopsy (TAB) to imaging based diagnosis (1). However, classification criteria that relied on TAB remained unchanged since 1990 (2). Reflecting the recent change in practice the Diagnostic and Classification Criteria for Vasculitis Study (DCVAS) group presented a draft classification criteria set for GCA. Endorsement by major scientific societies is currently pending (3).

Objectives: To test the accordance of the GCA cohort of a single center in southern Norway between 2006 and 2018 to the draft DCVAS classification criteria in GCA.

Methods: All patients diagnosed with GCA between 2006 and 2018 in our clinic were identified by international classification of disease (ICD) code for GCA (m31.5/m31.6) in the local electronic database. The draft DCVAS classification criteria were applied to all patients at the time of diagnosis, irrespective of the algorithm used to diagnose GCA. In the draft DCVAS classification criteria a score of 6 would be necessary to classify a patient as having GCA.

Results: A total of 77 patients (55 female) diagnosed with GCA in the defined timespan were identified. Mean age was 69.2 years (57 – 83 years). As all patients were diagnosed with vasculitis and were older than 40 years of age, all patients met the compulsory criteria. The table 1 below shows the absolute number of patients that fulfilled the single criteria.

The number of patients fulfilling the draft DCVAS classification criteria was 75 (97.4%). In the female cohort 96.4% patients finally diagnosed with GCA would be classified as having GCA as would 100% in the male cohort.

Mean score was 12.4 (range 3-25). In 33.3 % of patients imaging was critical for classification. Laboratory findings were critical for classification in 9.3 %, head ache and scalp tenderness in 5.3%, temporal artery biopsy, morning stiffness and jaw claudication in 2.7%. The differentiation in possible and definite vasculitis in TAB did not change the result in any patient. Neither did sight-loss contribute to classify any patient. Five patients (6.5%) were diagnosed on clinical features and laboratory findings alone. Thirteen patients diagnosed with GCA and fulfilling DCVAS criteria had negative biopsies, three patients had an inconclusive TAB. Mean arterial biopsy length was 9 mm.

Table 1.

Draft DCVAS classification criteria		Aboslute number
Age>40 years and vasculitis diagnosis (compulsatory)		77
New temporal headache	+2	48
Scalp tenderness	+2	21
Sudden visual loss	+2	2
Morning stiffness shoulder/neck	+2	34
Jaw claudication	+2	22
ESR > 50 mm/h or CRP > 10 mg/l	+3	72
TAB showing possible vasculitis	+3	8
TAB showing definite vasculitis	+5	16
Halo sign	+5	61
Bilateral axillary involvement	+3	25
PET showing aortitis	+3	4

Conclusion: A high percentage (97.4 %) of the patients diagnosed with GCA in our cohort fulfilled the draft DCVAS classification criteria. The high mean score (12.4) showed that DCVAS criteria did not depend heavily on single criteria. As diagnosis in our cohort was mainly based on ultrasound, imaging was the most critical item. This might be desirable as clinical features and laboratory markers should in general be confirmed by either imaging or TAB to ascertain diagnosis. However, five patients were solely diagnosed on clinical features and laboratory markers. Sight-loss did not contribute to classification in our cohort as most patients were seen in a fast-track clinic (FTC), but might be valuable in cohorts without FTC.

AB0382 **DOES THE ULTRASOUND IMAGE OF THE LARGE VESSEL WALLS DIFFER IN THE SUBTYPES OF GCA AND PMR OR THERE IS A SYSTEMIC SUBCLINICAL COMMON INFLAMMATION?**

E. Fernández-Fernández[1], I. González-Mazón[2], I. Monjo[1], J. M. Mostaza[3], C. Lahoz[3], E. De Miguel[1]. *[1]La Paz University Hospital, Rheumatology, Madrid, Spain*; *[2]Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; *[3]Carlos III Hospital, Internal Medicine, Madrid, Spain*

Background: Several clinical patterns of giant cell arteritis (GCA) have been described including cranial GCA (c-GCA), large vessel GCA (LV-GCA), mixed forms of c-GCA and LV-GCA (mixed-GCA), and even polymyalgia rheumatica (PMR) that has been associated with GCA and some degree of subclinical vascular inflammation could be present in the patients. However, many questions about this disease and its subtypes remain unanswered.

Objectives: To investigate the affectation of the arterial wall of GCA and its subtypes and PMR and to know if there really are different ultrasound patterns that can be determined or if otherwise they present a common subclinical systemic inflammation with only different degrees of involvement of the vascular wall.

Methods: All available ultrasound examinations of patients referred to our fast-track GCA clinic for suspected GCA in the last three years were reviewed and retrospectively collected data. Patients who had undergone ultrasound examination of both cranial and large vessels (axillary, subclavian and carotid arteries) were included. The videos and images of the large vessels of each patient were reviewed and intima-media thickness (IMT) and hypoechoic halo measurements were taken. The data of the following groups, established according to the final diagnosis confirmed by the doctor after a follow-up between six months and three years, were compared: GCA group (within it 3 other groups were included: c-GCA, LV-GCA and mixed-GCA), PMR group and the group without ACG or PMR (non-GCA).

Results: We analyzed the examinations of 300 patients and 161 baseline examinations were included: 76 with GCA (32 c-GCA, 14 LV-GCA and 30 mixed-GCA), 29 with PMR and 56 non-GCA. The mean IMT for each large vessel explored and the statistical significance between the different groups

Table 1. Ultrasound IMT and halo measures in the different subtypes of GCA, PMR and controls

Arteries	Non-GCA n=56	GCA n=76	c-GCA n=32	LV-GCA n=14	Mixed-GCA n=30	PMR n=29	p < 0.05
Right axillary (mean ± SD)	0.67±0.19	0.95±0.30	0.75±0.20	1.03±0.33	1.11±0.27	0.65±0.13	2*, 3*, 4*, 5*, 6, 7*, 8*
Left axillary (mean ± SD)	0.61±0.12	0.92±0.29	0.77±0.19	0.99±0.25	1.03±0.33	0.66±0.13	1*, 2*, 3*, 4, 5*, 6, 7*, 8*
Right subclavian (mean ± SD)	0.70±0.15	1.00±0.31	0.79±0.16	1.09±0.36	1.10±0.29	0.70±0.20	2*,3*, 4*, 5*, 7*, 8*
Left Subclavian (mean ± SD)	0.62±0.14	0.95±0.27	0.76±0.16	1.05±0.25	1.06±0.26	0.64±0.18	1*, 2*, 3*, 4*, 5*, 7*, 8*
Right CCD (mean ± SD)	0.79±0.22	0.97±0.26	0.99±0.22	0.91±0.29	1.05±0.28	0.81±0.10	1*, 3*, 6*, 8*
Left CCD (mean ± SD)	0.81±0.16	0.99±0.22	0.95±0.20	0.97±0.17	1.03±0.27	0.82±0.20	1, 2, 3*, 8

SD: Standard deviation; CCD: common distal carotid artery.1=c-GCA vs non-GCA; 2=LV-GCA vs non-GCA; 3=mixed-GCA vs non-GCA; 4=c-GCA vs LV-GCA; 5=c-GCA vs mixed-GCA; 6=PMR vs c-GCA; 7=PMR vs LV-GCA; 8=PMR vs mixed-GCA; *p < 0.01.

are shown in Table 1. All arteries except the carotid arteries had a significantly higher IMT in the LV-GCA and mixed-GCA groups when compared with both c-GCA and non-GCA groups. There were no differences in IMT between mixed-GCA and LV-GCA. There were also no differences in any explored artery between PMR and non-GCA. There were statistically significant differences in the IMT of the bilateral axillary and subclavian arteries between the PMR group and all the GCA subtypes, being greater in the latter. IMT tended to be higher in the c-GCA group when compared to non-GCA, reaching statistical significance in the left arteries (axillary, subclavian, and distal carotid). Although there was also a tendency for IMT to be higher in mixed-GCA patients than in LV-GCA patients, the differences did not reach statistical significance.

Conclusion: Large vessel ultrasound does not differ between healthy patients and those with PMR without confirmed GCA. Our data suggest that mixed-GCA subtype is not an intermediate form between the cranial and LV-GCA suptypes but could have a higher inflammatory burden.

AB0383 OCULAR MANIFESTATIONS DURING GIANT CELL ARTERITIS

A. Mzabi[1], N. Adaily[1], L. Ines[1], I. Ben Hassine[1], J. Anoun[1], M. Karmani[1], F. Ben Fredj[1], C. Laouani[1]. [1]*University Hospital Center of Sahloul, Internal Medicine, Sousse, Tunisia*

Background: Horton's disease (HD) or giant cell arteritis (GCA) is a segmental and plurifocal giant cell inflammatory panarteritis, predominant in large and medium sized vessels. Ocular damage during giant cell arteritis is frequent and is considered the most serious damage, possibly causing blindness in 15% of cases in recent series (1).
Objectives: Describe the different ophthalmological manifestations during GCA.
Methods: This is a retrospective monocentric descriptive study of 19 files of subjects diagnosed with HD, hospitalized in the internal medicine department of de Sousse between January 2000 and December 2020.
Results: The average age of patients at diagnosis was 70 years, with extremes of 53 and 92 years. There were 14 females (71.4%) and 5 males (28.6%). Ophthalmologic manifestations were present in 13 patients (71%), 6 of whom were female.
Decreased visual acuity was reported in 8 cases (58.33%) with biolateral blindness in one case, visual blur in 9 cases (75%), eye pain in two cases.
Ophthalmological examination was normal in 8 cases (42%). A decrease in visual acuity was objective in 4 cases (21%). One case of nodular episcleritis was noted. The fundus showed anterior ischemic optic neuropathy in 2 cases (10.5%) and left optic atrophy in another case. A visual field was performed in 2 cases showing associated retrobulbar optic neuritis. Therapeutically, Methylprednisolone boli were prescribed in patients with anterior ischemic optic neuropathy, followed by oral corticosteroid therapy at a dose of 1mg/kg/day. A dose of 0.7 mg/kg/day of prednisone was prescribed in the other cases. Blindness was irreversible.
Conclusion: The most common eye diseases in HD are acute anterior ischemic optic neuritis, retinal artery occlusion and posterior ischemic optic neuropathy. Episcleritis is a rare ophthalmologic manifestation of this vasculitis (2). More exceptionally, Horton's disease may cause NORB by affecting the vessels that supply the optic nerve (< 5% of cases)(3,4). In our series of studies, acute anterior ischemic optic neuritis was less observed than in the literature. This is probably due to the reduced number of patients.

AB0384 IMPACT OF TEMPORAL ARTERY ULTRASOUND ON SURVIVAL OF PATIENTS WITH GIANT CELL ARTERITIS

P. Estrada[1], D. Reina[1], V. Navarro[1], O. Camacho[1], D. Cerda[1], D. Roig Vilaseca[1], S. Heredia[1], H. Corominas[2]. [1]*Hospital de Sant Joan Despí Moisès Broggi, Rheumatology, Sant Joan Despí, Spain*; [2]*Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*

Background: Giant cell arteritis (GCA) is the most common primary systemic vasculitis in adults over 50 years of age. Its incidence increases with age, with a peak between 70-80 years and predominates in women, 3:1. It is a medical emergency that, if not diagnosed, can lead to irreversible complications. The delay in time from diagnosis to start of treatment is crucial to avoid possible serious outcomes on short, medium and long term. Survival in GCA is estimated between 60-90% at 5 years and 48-81% at 10 years. Efforts have been made to implement rapid diagnostic circuits to assess patients and initiate treatment without delay with good results both in reducing permanent vision loss and in reducing the costs of these patients due to emergency visits and admissions. The morbidity and mortality of this disease is high, but the use of efficient diagnostic strategies, such as ultrasound of superficial temporal arteries, has proven to be a useful, practical, cost-effective and, above all, quick tool to make the diagnostic approach.
Objectives: Analyze the impact of early temporal artery ultrasound on survival for patients with GCA.
Methods: Survival study of 48 patients with GCA, in two different "stages" in terms of diagnostic approach: Group A (n = 27), patients diagnosed between 2002 - 2011 using only ACR 1990 criteria and Group E (n = 21) diagnosed between 2010-2015 using ACR criteria and TAUS. TAUS was performed by Rheumatologists with extensive experience in ultrasound and within a period of no more than 7 days for these patients. The definitive diagnosis of GCA was based on the clinical criteria of the Rheumatologist within the clinical and analytical context and with the specific complementary examinations for each case (Ultrasound, PET-CT, biopsy). Demographic data, comorbidities, signs and symptoms at debut, analytical data, complementary examinations, treatment and evolution were obtained retrospectively through the electronic medical record of the patient, based on the database of our GCA cohort. A survival analysis was performed considering death as the main outcome. The statistic used was the Kaplan-Meier test. In addition, other complications related to treatment or pathology are collected.
Results: The mean age at diagnosis of our patients was 79 + - 6 years, with a female: male ratio of 3: 1. The follow-up was between 2 and 16 years with a mean of 5.8 + - 3 years, until the last visit collected or until the outcome of death. Group A had a survival at 5 and 10 years of 53.4% and 36.7% respectively, while group E of 79.5% at both cut-off points. (Figure 1).
There is a significant difference between the survival of both groups, p <0.01, this being better in the group in which TAUS was implemented for rapid diagnosis (group E). The main causes of death were cardiovascular

events, 30%, predominantly in group E (75%), and infection, 30%, predominantly in group A. The median from diagnosis to death was 3 years (range 1 - 13).

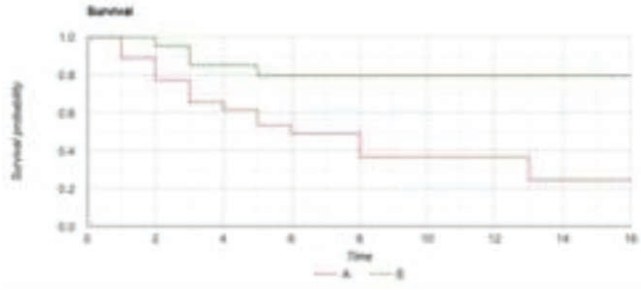

Figure 1. Group A (red line) according to ACG 1990 criteria and Group B (green line) according to ACG criteria and implementing TAUS for rapid diagnosis

Conclusion: The implementation of temporal artery ultrasound (TAUS) is associated with a significant improvement in the survival rate of patients with GCA and a reduction in treatment-related complications in patients who were diagnosed with ultrasound in less than 7 days compared to those diagnosed by the conventional healthcare attention routes.

Vasculitis – small vessel vasculitis

AB0385

THE EFFECTIVENESS OF THE ANTI-TUMOR NECROSIS FACTOR THERAPY INFLIXIMAB IN NEURO-BEHCET'S DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

R. Hamdy Abdellatif Mohammed[1], Y. Woldeamanuel[2]. [1]*Kasr Alainy School of Medicine- Cairo University., Rheumatology and Rehabitation, Cairo, Egypt*; [2]*Stanford University, Stanford Headache Center, Department of Neurology- Center for Innovation in Global Health- Stanford University School of Medicine: Stanford, CA, US., Stanford-CA, United States of America*

Background: The use and benefit of biologic targeted therapy in the treatment of refractory manifestations of behcet's syndrome remain unclearly defined due to the relative paucity of published research. Neuro-behcet's disease represents a challenging clinical presentation. The lack of identified effective strategies in the management of refractory neuro-behcet's adds to the disease burden and contributes to lack of tight control. [1-3]

Objectives: The aim of this systematic review and meta-analysis is to examine the effect of anti-TNF therapy on refractory NBD by performing a systematic review and meta-analysis of the previously published studies assessing the effectiveness of anti-TNF therapy in patients with BD having refractory or recurrent neurological manifestations.

Methods: Authors used the PICO Model (P= population, I= intervention, C= comparator, O= outcome) used for designing the research question. The PRISMA statement was used for developing the study protocol search methodology. Literature searches were done for articles in published in English language only from January 2000 till January 2020 (considering the first till the last available publication that addresses the research question and satisfied eligibility criteria). The study was registered on the Prospero PROSPERO website for systematic reviews and meta-analysis. Random-effects meta-analysis was performed. Inter-study heterogeneity was explored using I2 statistics. Cumulative meta-analysis was conducted to assess temporal trend for accumulating evidence from accruing published studies. Meta-regression was used to analyze possible confounders.

Authors of the current systematic review and meta-analysis worked on a simple score "Hamdy and Woldeamanuel simple response score, 2020", the aim behind the score was to incorporate standard evaluation parameters for assessment of responses driven by the measures used in each study. The authors used numerical values to grade the pattern of response in each parameter considered attempting to standardize the quantification of the responses and minimize tendency towards overestimation. The score included clinical and radiographic points rated on a scale of 5.

Results: Twenty-one studies involving 64 patients were included, 52 male patient and 12 females at a ratio of 4.3:1, with a mean age of 38 .21 years, mean disease duration of 84.76 5 months. Effect size analysis showed that 59 out of 64 patients i.e. 93.7% of the treated patients with neuro-behcet's disease in the analysis were responders to infliximab therapy (CI 88% - 99.3%). There was no significant inter-study heterogeneity (I2 = 0%, p = 0.744). Cumulative analysis showed accumulating evidence favoring increasing effectiveness over the last 20 years. There was no statistically significant confounding of infliximab effect size by age (p = 0.89), sex ratio (p = 0.29), and disease duration (p = 0.67).

Conclusion: In this systematic review and meta-analysis Infliximab showed a strong therapeutic effectiveness in the treatment of refractory neuro-behcet's disease. There is an increasing trend of effectiveness observed in the last two decades which may be due to improved neuro-behcet's diagnostic accuracy.

AB0386

CORONAVIRUS INFECTION AND VASCULITIS: IDENTIFYING ASSOCIATIONS MINING THE BIOMEDICAL LITERATURE

A. Rodriguez-Pla[1], R. Cartin-Ceba[2]. [1]*Mayo Clinic Scottsdale Campus, Rheumatology, Scottsdale, United States of America*; [2]*Mayo Clinic Hospital, Pulmonary, Phoenix, United States of America*

Background: Based on recent publications suggesting an association between COVID-19 and vascular
Inflammation.

Objectives: Our aim was to explore new associations between coronavirus infections and vasculitis utilizing semantic mining of PubMed results.

Methods: The following literature search string: "(vasculitis OR vascular inflammation OR vascular damage) AND (coronavirus OR SARS virus OR

MERS-CoV OR Covid-19)" was used to retrieve abstracts from the whole PubMed database, using Semantic MEDLINE 2. on 6/7/2020. This application represents a network of semantic predications (triples of the form subject-predicate-object, e.g. COVID-19 causes Disease) on a knowledge graph. The system allows for choosing the maximum number of nodes represented, the central topic, and the length of the network. For our network we chose to display all relations, COVID-19 (31 edges) as the central term, 3 lengths, and selecting the most informative nodes. Automatic summarization eliminated the less informative predications.

Results: The search string retrieved 152 citations from PubMed and identified 1,028 predications. The

network (Figure 1), displayed using COVID-19 as the central term, consisted of 72 nodes and 140 edges. The 5 most connected nodes were 'Patients: 19 nodes', COVID-19: 13', 'Inflammation: 13', 'Lung: 11', and 'Disease: 11'. Multiple links have been found between coronavirus and vasculitis. Animal coronaviruses, including the one causing feline infectious peritonitis (FIP), the murine coronavirus mouse hepatitis virus (MHV), the SARS-CoV in transgenic mice and coronavirus in ferrets, are known to cause vasculitis in animals. It is known that coronaviruses that infect animals can evolve and become new human coronaviruses. SARS produces inflammation in blood vessels. In 2005, a link between the coronavirus HCoV-NL63 or New Haven Coronavirus (HCoV-NH) and KD was reported,

although later studies concluded that HCoV-NH did not play a dominant role in the etiology or

pathogenesis of KD. In 2014, serological testing suggested the possible involvement of CoV-229E in the development of KD. There has also been a report of KD patients being infected by coronavirus OC43/HKU1.COVID-19 may infect the vessels and trigger inflammatory reactions like those of vasculitis, including vasculitis-like cutaneous lesions. COVID-19 patients develop thrombosis, and increased risk of thrombosis is also present in primary vasculitic syndromes. Children, many of whom tested positive for COVID-19 antibodies, developed Multisystem Inflammatory Syndrome in Children (MIS-C), an inflammatory condition similar to Kawasaki Disease (KD).

Conclusion: Knowledge integration and discovery methods are an efficient and powerful way of retrieving and analyzing relevan information from multiple papers. Their main advantages are finding relations among biomedical concepts, generating new hypotheses, and opening them to literature-based discovery.

SARS-CoV-2 may cause vasculitis or vasculitis-like syndromes. The KD-like syndrome reported mainly in children with COVID-19 revives the previous suspicion of coronavirus as a possible triggering agent of KD and the decades-old hypothesis of infection involvement in the pathogenesis of vasculitis.

SYSTEMIC AND LOCAL THERAPIES FOR EAR, NOSE AND THROAT MANIFESTATIONS IN ANCA-ASSOCIATED VASCULITIS: A SYSTEMATIC REVIEW

R. Krol[1], R. Klaasen[2], H. H. F. Remmelts[3], M. W. Heijstek[1], J. Spierings[1]. [1]*UMC Utrecht, Rheumatology and Clinical Immunology, Utrecht, Netherlands*; [2]*Meander Medical Center, Rheumatology, Amersfoort, Netherlands*; [3]*Meander Medical Center, Nephrology, Amersfoort, Netherlands*

Background: Ear, nose and throat (ENT)-involvement is common in antineutrophil cytoplasmic autoantibody- (ANCA-)associated vasculitis (AAV), can lead to permanent damage and is correlated with reduced quality of life. Yet, guidelines on management of ENT-manifestations are lacking.

Objectives: The aim of this study was to evaluate the efficacy of systemic and local therapies for ENT- involvement in AAV.

Methods: A systematic review was conducted. Clinical studies between January 2005 – April 2020, in adults with AAV and ENT-involvement using outcomes reflecting disease activity, relapse and damage were included. Case reports, congress abstracts and non-English articles were excluded.

Results: The search yielded 4,586 results. For full-text assessment, 109 articles were selected. Finally, 25 articles were included (Figure 1). Two placebo-controlled trials were available. The other observational studies had a limited level of evidence (LoE) of 2b-4 according to the Oxford Centre for Evidence-based Medicine.

Ten studies (n=127) with subglottic stenosis evaluated dilatation (n=94), intralesional steroids (n=63), surgery (n=51) or rituximab (n=8), which mostly resulted in temporary response (12-34 months) (Table 1). Otologic manifestations were treated with various disease modifying anti-rheumatic drugs (DMARDs) in 251 patients in six studies. All studies demonstrated improvement in hearing thresholds, but relapse rates were high (47%). Five studies assessed DMARDs or surgery for sinonasal symptoms showing remission in 21-82%. Six studies, which did not specify ENT-symptoms of the included patients, reported remission in 86-96%. Due to heterogeneity across studies no meta-analysis could be performed.

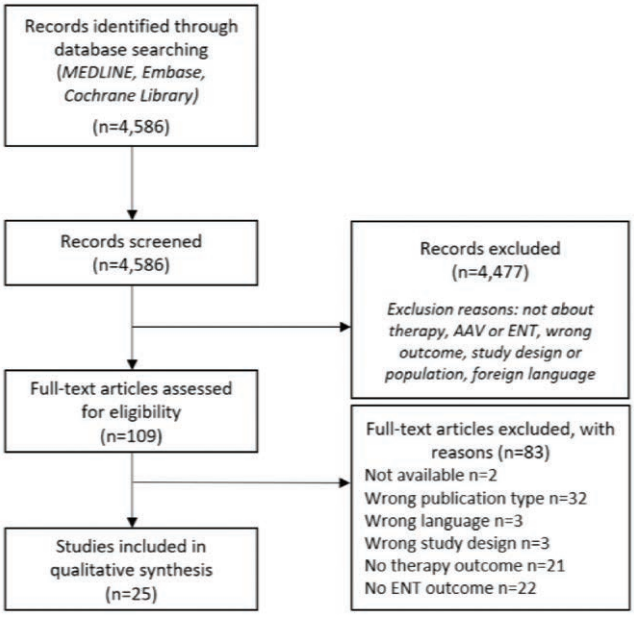

Figure 1. Flowchart of article selection

Table 1. Overview of studies on treatment for ENT-involvement.

ENT-involvement	AAV type per study	Therapy	Results	LoE
Otitis Media / Hearing loss	OMAAV (n=6)	RTX	Remission 100% Mean hearing gain AC 22 dB BC 11 dB	2b
	OMAAV (n=104)	Steroids	Response (hearing) 56% Relapse 47%	4
	OMAAV (n=122)	Steroids + csDMARD	Relapse 36%	4
	OMAAV (n=8) GPA (n=11)		Response (hearing) 68% Relapse 0% Response (hearing) 81% Response (hearing) 100%	4
Vestibular symptoms	OMAAV (n=3)	Steroids + CYC	Remission (patient-reported) 100%	4
Subglottic stenosis	GPA (n=9)	Dilatation	Relapse 78%	4
	GPA (n=15)		Mean number of procedures 4	
	GPA (n=34)	Intralesional steroids + dilatation	Median response 34 months	2b
	GPA (n=8)		Response 88% Median response 12 months Mean number of procedures 3	4
	GPA (n=18)	Intralesional steroids + dilatation + resection	Mean intervention-free interval 26 months	2b
	GPA (n=5)	Dilatation + resection	Response 80%	4
	GPA (n=13)	Surgery	Response (dyspnea) 100% Relapse 39%	4
	GPA (n=11)		Higher QoL 77% Response (airway) 91%	4
	GPA (n=6)	Surgery or dilatation + intralesional steroids or csDMARDs	Relapse 83.3%	4
	GPA (n=8)	RTX	Remission 38% Response 50%	2b
Sinonasal symptoms	GPA (n=3)	RTX	Response: 67%	2b
	EGPA (n=29)	Steroids + csDMARDs	Remission 82%	2b
	EGPA (n=44)		Remission 21% Response 32%	2b
	GPA (n=19)	Surgery	Response 76%	4
	EGPA (n=65)	Mepolizumab	Remission 28%	1b
ENT symptoms NOS	AAV (n=7)	RTX	Relapse 22%	2b
	GPA (n=11)		Drop in daily steroid dosage	
	EGPA (n=61)		Drop in daily steroid dosage Response 93% Relapse 17%	4 2b
	GPA (n=28) EGPA (n=15)	Steroids + csDMARDs	Remission 96% Relapse 42%	4
	GPA (n=51)	RTX (n=51) MTX	Remission 86% 92% of observational period in remission 54%	4 2b

AC: air-conduction, BC: bone-conduction, csDMARD: conventional synthetic disease modifying antirheumatic drug, CYC: cyclophosphamide, dB: decibel, EGPA: eosinophilic GPA, GPA: granulomatosis with polyangiitis, MTX: methotrexate, NOS: not otherwise specified, OMAAV: otitis media associated ANCA-vasculitis, QoL: quality of life, RTX: rituximab.

Conclusion: On the treatment of ENT manifestations in AAV 25 studies were available, mainly with small patient numbers and low LoE (1b-4). Heterogeneity in treatments and outcome measures impaired comparison between studies. More placebo-controlled studies are needed to guide treatment.

AB0388 USE OF MESNA PROPHYLAXIS IN CYCLOPHOSPHAMIDE-TREATED PATIENTS WITH ANCA-ASSOCIATED VASCULITIS: RESULTS OF AN ELECTRONIC SURVEY

L. Joos[1], S. Gonzalez Chiappe[1], T. Neumann[1], A. Mahr[1]. [1]*Kantonsspital St.Gallen, Division of Rheumatology, St. Gallen, Switzerland*

Background: Co-prescribing 2-mercaptoethane sodium sulfonate (mesna) with cyclophosphamide (CYC) for ANCA-associated vasculitis (AAV) aims to prevent the potential urotoxic effects of CYC. The evidence for this practice is often considered weak, and there may be some diversity in what practitioners do in clinical practice.
Objectives: To investigate current clinical practice related to prescribing mesna prophylaxis or not and the underlying rationale for CYC-treated patients with AAV.
Methods: We searched MEDLINE for publications with the MeSH term "ANCA-associated vasculitis" over a 10-year period up to October 2020. Email addresses of authors of these publications were extracted from the online information available in MEDLINE. These authors were invited by email to participate in an anonymous online SurveyMonkey survey of 21 to 24 questions asking about the characteristics of the respondent, their experience with AAV, and their practice in using CYC to treat AAV and using mesna in CYC-treated patients with AAV and the underlying rationale. Respondents were eligible to take the full survey if they were involved in deciding and/or monitoring therapy with CYC for patients with AAV. We compared 15 response variables to identify factors associated with the use or not of mesna. Response variables with multiple categories were first analyzed across all categories; if the omnibus test result was significant, additional analyses were used to identify the categories, which were the sources of group separation. We analyzed by-country variations for only countries with ≥ 10 respondents. Statistical analyses involved Pearson's chi-square test or Fisher's exact test, as appropriate. For multiple-response variables, the Rao-Scott correction was applied.
Results: The invitation for the electronic survey was emailed twice in October 2020 to 1,374 unique email addresses; 156 individuals responded; 139 were eligible and completed the survey. The 139 participants were from 34 countries and were essentially MDs (98%) who mainly worked in rheumatology (50%), nephrology (25%) or internal medicine/clinical immunology (18%). Mesna was given in conjunction with CYC systematically, never, or on a case-by-case basis by 68%, 19% and 13% of respondents, respectively. As compared with systematic mesna-prescribers, never/occasional mesna-prescribers reported a longer time since receiving their degree as a health professional (≥ 15 years: 80% vs 50%, P<0.001), were more frequently based in England/United States (than in France/Germany/Italy) (78% vs 21%, P<0.001), had longer involvement in care of patients with AAV (≥ 15 years: 62% vs 37%, P=0.006), had less practice in using intermittent pulse therapy as the exclusive/predominant CYC administration scheme (62% vs 89%, P<0.001), and, as a rationale underpinning their mesna practice, had less adherence to local operational procedures (47% vs 73%, P=0.002) or (inter)national management guidelines for AAV (16% vs 49%, P<0.001). Never/occasional versus systematic use of mesna did not differ across medical specialties (5 categories, P=0.192) or healthcare settings (3 categories, P=0.437), and was not associated with prior experience of CYC-related urotoxic events (3 categories, P=0.495) or severe mesna toxicity issues (3 categories, P=0.957). The confidence that their practice reflected the best possible patient care did not differ between never/occasional and systematic mesna-prescribers (7-point Likert scale, P=0.794).
Conclusion: Practice with regard to prescribing mesna in conjunction with CYC to treat AAV is heterogeneous, although systematic mesna use prevailed over never or occasional use. The decision to prescribe or not mesna may be based more on circumstantial than structural reasons.

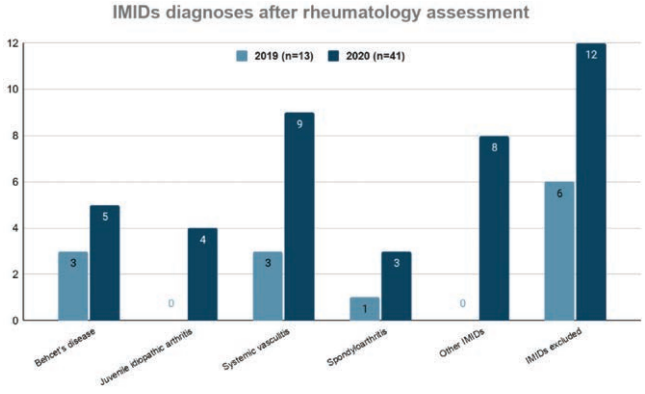
AB0389 A COMBINED RHEUMATOLOGY-OPHTHALMOLOGY CLINIC IMPROVED DIAGNOSIS AND TREATMENT OF IMMUNE-MEDIATED AND INFLAMMATORY DISEASES AMONG PATIENTS PRESENTING WITH INFLAMMATORY EYE DISEASES

A. Giollo[1], F. Bosello[2], A. Bonora[2], M. Rossini[1]. [1]*University of Verona, Rheumatology Section, Department of Medicine, Verona, Italy*; [2]*University of Verona, Ophthalmology Clinic, Department of Neurosciences, Biomedicine and Movement Sciences, Verona, Italy*

Background: Patients presenting with an inflammatory eye disease may have underlying immune-mediated and inflammatory diseases (IMIDs). However, IMIDs are challenging to diagnose. A combined rheumatology-ophthalmology evaluation could enhance detection of IMIDs in this group.
Objectives: To investigate whether the implementation of a combined rheumatology-ophthalmology clinic could increase the sensibility of IMIDs diagnosis.
Methods: A combined rheumatology-ophthalmology clinic started in January 2020. A rheumatologist with expertise in IMIDs assessed outpatients of a tertiary care ophthalmologic clinic specialised in inflammatory eye disease consecutively referred between 01/01/20 and 31/12/20. Two separate visits confirmed

both ophthalmology and rheumatology diagnoses. The same period of the year 2019 was used as a comparator.

Results: We noticed a three-fold increase in the number of ophthalmology patients who underwent an evaluation with a rheumatologist in 2020 compared to 2019 (41 vs 13, +315%; Table). There were no differences in sex distribution or age between the two years. However, the median time before rheumatology assessment was shorter in 2020 than 2019 (median days 0 [range 0-6] vs 12 [range 0-91]). IMIDs diagnoses increased by 27% in 2020 compared to 2019 (29/41 vs 7/13, 71% vs 54%), mainly driven by new diagnoses of systemic vasculitis and Behcet's disease (Figure 1). There was also an increase in diagnoses of non-IMIDs systemic conditions (3 cancers and one infection in 2020 vs none in 2019). After rheumatology evaluation, immune-modulating therapy was initiated in 18/41 (44%) vs 3/13 (23%).



Ophthalmology assessment and referrals to rheumatology	Referrals 2019 (n=13)	Referrals 2020 (n=41)
Inflammatory eye disease, n (%)	6 (46)	36 (88)
Uveitis, n	6	21
Vasculitis, n	2	4
AION, n	3	5
Conjunctivitis, n	1	0
Scleritis, episcleritis, n	0	1
Other, n	1	5

Conclusion: An integrated approach with rheumatologist appeared to remarkably increase the likelihood to detect IMIDs among patients presenting with inflammatory eye diseases.

AB0390

CHARACTERISTICS AND PROGNOSIS OF AGE-DEPENDED ANCA-ASSOCIATED VASCULITIS IN JAPAN

M. Kato[1], T. Kameda[1], H. Shimada[1], S. Nakashima[1], M. Mahmoud Fahmy Mansour[1], R. Wakiya[1], T. Miyagi[1], K. Sugihara[1], Y. Ushio[1], R. Senba[1], M. Mizusaki[1], H. Dobashi[1]. [1]*Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Kagawa, Japan*

Background: It is known that most of ANCA-associated vasculitis (AAV) patients are elderly. A cohort study showed that the mean age of onset was 71.1 years, especially in patients with microscopic polyangiitis (MPA)[1)]. However, the characteristics and prognosis of age-depended AAV patients are still unclear.

Objectives: To clarify the differences in age-related characteristics and prognosis between Japanese patients with AAV.

Methods: We enrolled 44 patients with AAV who underwent remission induction therapy at our hospital from January 2016 to December 2020. They were divided with under 70 years old group (<70 yo group, n=12) and over 70 years old group (≥70 yo group, n=32). We investigated between two groups as follows; clinical characteristics and laboratory data at diagnosis, rates of complete remission (CR) at 6 months, defined as Birmingham Vasculitis Activity Score (BVAS)=0 and prednisone ≤7.5 mg/day, adverse events, and relapse free survival.

Results: Mean age were 61.9 ± 9.74 years old in <70 yo group and 77.5 ± 4.61 years old in ≥70 yo group (p<0.01). There were significantly fewer newly diagnosed cases in the <70 yo group, and half of the patients with relapsing disease. There was no difference in the type of ANCA, organ involvement, or BVAS. Remission induction therapy was performed with CY or RTX, and no difference was observed between these two groups. In addition, there was also no difference in maintenance therapy (Table 1). CR rate in <70 yo group and in ≥70 yo group were 55% and 46 % respectively (p=0.73). Severe infections occurred with no patient (0%) in <70 yo group and with 5 patients (16%) in ≥70 yo group (p=0.30). 5 patients of relapse were observed in the <70 yo group and 1 patient in the ≥70 yo group, and relapse free survival was significantly lower in the <70 yo group (p=0.001) (Figure 1).

Table 1. Clinical characteristics at baseline and treatment drugs between <70 yo group and ≥70 yo group.

	<70 yo 群 (n=12)	≥70 yo 群 (n=32)	p value
Age (year)	61.9 ± 9.74	77.5 ± 4.61	< 0.01*
Female, n (%)	10 (83)	28 (87)	0.66
AAV type	6 (50) / 6 (50)	26 (81) / 6 (19)	0.06
MPA, n (%) / GPA, n (%)			
Newly diagnosed, n (%)	6 (50)	27 (84)	0.045*
ANCA positivity			
MPO, n (%) / PR3, n (%)	11 (92) / 0 (0)	30 (94) / 3 (9)	1 / 0.55
negative, n (%)	1 (8)	1 (3)	0.48
CRP (mg/dl)	3.34 ± 4.01	8.15 ± 6.86	0.03*
eGFR (mL/min)	55.8 ± 25.3	57.7 ± 24.7	0.93
BVAS	12.0 ± 8.0	14.8 ± 6.8	0.23
Remission induction therapy	5 (42) / 7 (58)	16 (50) / 16 (50)	0.74
CY, n (%) / RTX, n (%)			
Maintenance therapy			
AZA, n (%)	7 (58)	14 (44)	0.50
RTX, n (%)	1 (8)	6 (19)	0.65
others, n (%)	2 (17)	3 (9)	0.60
without IS, n (%)	2 (17)	9 (28)	0.70

The p-value was estimated using Fisher's exact or Wilcoxson rank sum test. yo, years old; AAV, ANCA-associated vasculitis; MPA, microscopic polyangiitis; GPA, granulomatosis with polyangiitis; CY, cyclophosphamide; RTX, rituximab; AZA, azathioprine; IS, immunosuppressants. *p<0.05

Conclusion: There was no difference in remission rate between two groups. Severe infections were observed only in the ≥70 yo group. We suggest that younger AAV patients need attention to relapse after the remission because of lower relapse free survival in <70 yo group.

LOW SERUM COMPLEMENT C3 LEVEL AS A RISK FACTOR FOR RELAPSE OF ANTINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS: A RETROSPECTIVE COHORT STUDY

H. Sakai[1], H. Yamashita[1], S. Nakajima[1], Y. Takahashi[1], H. Kaneko[1]. [1]*National Center for Global Health and Medicine, Division of Rheumatic Diseases, Tokyo, Japan*

Background: The alternative pathway of complement activation has recently been recognized as a key pathogenic event in antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Some previous studies have reported that low serum complement C3 level in AAV patients is associated with more severe renal disease, worse renal prognosis, or higher mortality. However, the correlation between low serum C3 level and AAV relapse remains unclear.
Objectives: To analyze the clinical characteristics and outcomes of AAV patients with low serum C3 levels at the time of diagnosis.
Methods: We conducted a retrospective observational cohort study including 83 consecutive patients diagnosed with AAV in our hospital from January 1999 to December 2020. Serum C3 levels were measured at diagnosis. AAV included microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA), and eosinophilic granulomatosis with polyangiitis (EGPA); patients with ANCA-negative AAV were excluded. Patients were divided into low- and high-C3 groups (C3 < 100 and ≥ 100 mg/dL, respectively). We compared the clinical characteristics, and relapse-free and overall survival rates, of the two groups, and identified predictors of AAV relapse.
Results: Of the 83 patients (MPA, n = 61; GPA, n = 18; EGPA, n = 4), 20 (24%) were in the low-C3 group. We found no significant group difference in sex, body mass index, disease type, ANCA subtype, Birmingham Vasculitis Activity Score (BVAS), or treatment. The low-C3 group patients were older (p=0.01), and had a higher Five Factor Score (FFS) (p=0.01) and a lower remission rate (p=0.02), than the high-C3 group. The generalized Wilcoxon test revealed that the relapse-free survival time was significantly shorter in the low-C3 group (29 months; 95% confidence interval [CI]: 15–49) than in the high-C3 group (82 months; 95% CI: 61–NA; p=0.01) (Figure 1A). The overall survival was also shorter in the low-C3 group (83 months; 95% CI: 8-121) than in the high-C3 group (112 months; 95% CI: 77-NA; p=0.03) (Figure 1B). In the Cox proportional hazards model, a low C3 level (< 100 mg/dL) (hazard ratio [HR], 3.01; 95% CI: 1.29–7.04], p=0.01) and GPA (HR, 3.04; 95% CI: 1.32–7.01; p=0.01) were independent predictors of AAV relapse.

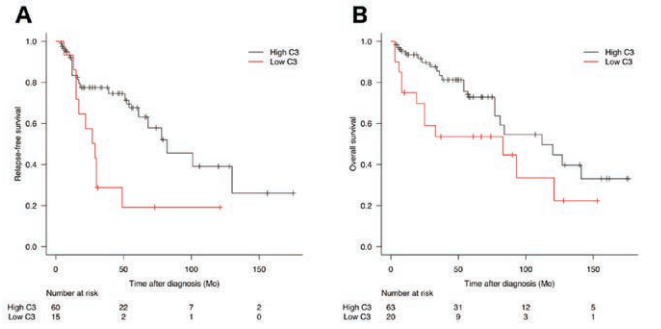

Figure 1. Kaplan-Meier estimates of the relapse-free (A) and overall (B) survival rates of AAV patients by baseline serum C3 levels. Eight patients who did not show remission were excluded in the relapse-free survival analysis. Black line: high-C3 group (≥ 100 mg/dL); red line: low-C3 group (< 100 mg/dL).

Conclusion: AAV patients with low C3 levels at diagnosis were at higher risk of relapse. Larger prospective studies are required to confirm these findings.

AB0392

PRELIMINARY VALIDATION OF THE ITALIAN VERSION OF ANCA-ASSOCIATED VASCULITIS PATIENT-REPORTED OUTCOME (AAV-PRO_ITA) QUESTIONNAIRE: FATIGUE AND CHRONIC PAIN AS UNMET NEEDS BY CURRENT TREATMENTS

E. Treppo[1], A. Palese[2], S. De Vita[1], L. Quartuccio[1]. [1]*University of Udine, Rheumatology Clinic, Udine, Italy*; [2]*School of Nursing, University of Udine, Department of Medicine, Udine, Italy*

Background: The ANCA-associated vasculitis patient-reported outcome (AAV-PRO) questionnaire is a 29-item disease-specific PRO measure for AAV (1), proving to be valid, reliable, feasible, and able to discriminate among disease states.
Objectives: The purpose of this study is to validate the Italian version of AAV-PRO questionnaire (AAV-PRO_ita).
Methods: AAV-PRO has been translated in collaboration with Oxford and Bristol University (UK). Then, consecutive Italian-speaking AAV-patients were collected in order to validate the questionnaire. Inclusion criteria are AAV diagnosis (ANCA positivity at least one time and/or biopsy-proven AAV), and age ≥18 years old. Participants completed the AAV-PRO_ita three different times: at baseline, after 5-7 days, and at month 3. Friedman test was applied to verify internal consistency of the questionnaire over time.
Results: 27 AAV-patients (16 females, 11 males) were recruited and completed the questionnaire at baseline, after 5-7 days, and at month 3. The main diagnosis was granulomatosis with polyangioitis (GPA) (19/27, 70.4%), following by eosinophilic granulomatosis with polyangioitis (EGPA) (8/27, 29.6%). Mean (SD) BVASv3 was 1 (2) at baseline, and it was unchanged at month 3 in 25/27 (92.6%). The mean age at onset of disease was 54.7±17.3 years and the median disease duration was 51 months (1-3 interquartile range 34-76). Their history was characterized by at least one relapse in 10/27 (37%) patients, at least one hospitalization due to AAV in 19/27 (70.4%), and ESRD in 1/27 (3.7%). At the last follow up, 24/27 (88.9%) of patients were taking an immunosuppressive drug [rituximab (8/24), azathioprine (8/24), methotrexate (7/24) or mycophenolate mofetil (1/24)] and more than two-thirds were also taking glucocorticoids (19/27, 70.3%). Fatigue (item 9) and arthralgia (item 6) were the most important symptoms, and half of the patients (14/27, 51.9%) classified them as "moderate" or "severe". Nearly one-third of patients (8/27, 29.6%) admitted to being "usually" or "always" concerned about their future (item 19) and long-term therapy (item 29) (Figure 1). Friedman test was not significant (p>0.05), indicating internal consistency of the questionnaire. A large multicentre Italian study has been organized based on this preliminary data coming from the coordinating centre, and it is now recruiting. The results will be soon available by the Italian Vasculitis Study Group.
Conclusion: The AAV-PRO_ita is a new disease-specific PRO measure for AAV. It is a self-administered questionnaire and could become an important tool to evaluate health-related quality of life in AAV (2). As in other systemic autoimmune diseases, fatigue and chronic pain represent an unmet need to be addressed by future treatment strategies.

PRE-EXISTING MORBIDITY AS A RISK FACTORS FOR MORTALITY IN IgA VASCULITIS

J. Nossent[1,2], D. Preen[3], W. Raymond[1], H. Keen[3,4], C. Inderjeeth[1,2]. [1]*The University of Western Australia, Medical School, Rheumatology Section, Perth, Australia*; [2]*Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia*; [3]*The University of Western Australia, School for Population and Global health, Perth, Australia*; [4]*Fiona Stanley Hospital, Rheumatology, Murdoch, Australia*

Background: IgA vasculitis is generally considered to be a self-limiting condition, but this is at odds with the increased mortality observed in adult patients with IgA vasculitis (1).

Objectives: With sparse data on prognostic factors in IgAV, we investigated whether pre-existing conditions are risk factors for mortality in adult IgAV patients.
Methods: Observational population-based cohort study using state-wide linked longitudinal health data for adults with IgAV (n=267) and matched controls (n=1080) between 1980-2015. Charlson comorbidity index (CCI) and serious infections (SI) were recorded over an extensive lookback period prior to diagnosis. Date and causes of death were extracted from the WA Death Registry. Mortality rate (deaths/1000 person-years) ratios (MRR) and time dependent survival analysis assessed the risk of death. Age and gender specific mortality rate data were obtained from the Australian Bureau of Statistics.
Results: During 9.9 (±9.8) years lookback IgAV patients accrued higher CCI scores (2.60 vs1.50 p<0.001) and had higher risk of SI (OR 8.4, p<0.001), not fully explained by CCI scores. During 19 years follow-up, the risk of death in IgAV patients (n=137) was higher than in controls (n=397) (MRR 2.06, CI 1.70-2.50, p<0.01) and the general population (SMRR 5.64, CI 4.25, 7.53, p<0.001). Survival in IgAV was reduced at five (72.7 vs. 89.7 %) and twenty years (45.2% vs. 65.6 %) (both p<0.05). CCI (HR1.88, CI:1.25 - 2.73, p=0.001), renal failure (HR 1.48, CI: 1.04 - 2.22, p=0.03) and prior SI (HR 1.48, CI:1.01 – 2.16, p=0.04) were independent risk factors. Death from infections (5.8 vs 1.8%, p=0.02) was significantly more frequent in IgAV patients.
Conclusion: Premorbid accrual of comorbidity is increased and predicts premature death in IgAV patients. However, comorbidity does not fully explain the increased risk of serious infections prior to diagnosis or the increased mortality due to infections in IgAV.

AB0394 CLINICAL CHARACTERISTICS OF EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS: A SINGLE-CENTER RETROSPECTIVE ANALYSIS ON 52 CASES OF CHINESE PATIENTS

L. F. Chen[1], Y. Mo[1], Q. H. Li[1], D. H. Zheng[1], L. Dai[1]. [1]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Rheumatology, Guangzhou, China*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare and heterogeneous systemic vasculitis. Different patients or the same patient in different stages show different manifestations, which may lead to misdiagnosis and delay treatment.
Objectives: To analyze the clinical characteristics in Chinese patients with EGPA.
Methods: EGPA patients who fulfilled the 1990 ACR classification criteria were included between December 2003 and April 2020. The demographic and clinical characteristics were collected and analyzed retrospectively.
Results: There were 52 EGPA patients recruited, 34 (65.4%) patients were males and the median age at onset was 47(38~55) years. The median duration from disease onset to diagnosis was 30(4~96) months. For initial symptoms, respiratory manifestations (61.5%) were the most common, including 42.3% patients beginning with asthma, followed by 21.2% with nose/paranasal sinuses manifestations. Respiratory medicine (53.8%) were the most common department at first visit, followed by rheumatology medicine (11.5%, Figure 1A). There were 44.2% EGPA patients definitely diagnosed at the department of rheumatology or after consultation by rheumatologists.
During the whole disease process, the most common clinical manifestations were asthma (88.5%), then nose/ paranasal sinuses (84.6%), pulmonary (76.9%) and nervous system (61.5%) manifestations, followed by constitutional symptom (44.2%), heart (36.5%) and skin (23.1%) involvement. Only 9.6% patients had gastrointestinal tract involvement and 3.8% had renal involvement (Figure 1B).
There were 46 (88.5%) patients showing the ratio of peripheral blood eosinophils >10% at diagnosis. Among the rest 6 patients, 3 had higher eosinophil ratio before diagnosis, while the other 3 patients had been treated with glucocorticoid before diagnosis, of whom 2 patients showed pathological eosinophil infiltration in lung or paranasal sinuses mucosa, respectively. There were 8(15.4%) patients with positive ANCA. Compared with EGPA patients with negative ANCA, they had lower incidence of asthma (62.5% vs. 93.2%), but higher incidence of constitutional symptoms (87.5% vs. 36.4%), arthralgia (50.0% vs. 6.8%) and renal involvement (25.0% vs. 0.0%), higher peripheral eosinophil count [2.06(0.80~4.51) $\times10^9$/L vs. 1.81(0.93~3.32) $\times10^9$/L], ESR [20(7~77) mm/h vs. 18(9~42) mm/h] and CRP [18.5(3.2~65.9) mg/L vs. 3.3(3.2~13.0) mg/L], higher Birmingham vasculitis activity score [17(10~22) vs. 13(9~15)] and vasculitis damage index [3(1~3) vs. 2(1~2), all P<0.05]. There were 21.2% EGPA patients showing poor prognostic factors according to five-factor score (FFS) and 34.6% patients according to the revised FFS.
Conclusion: EGPA patients may have no asthma especially those with positive ANCA. Multi-disciplinary collaboration especially based on rheumatologists and pulmonologists should be emphasized for early identification and prompt treatment.

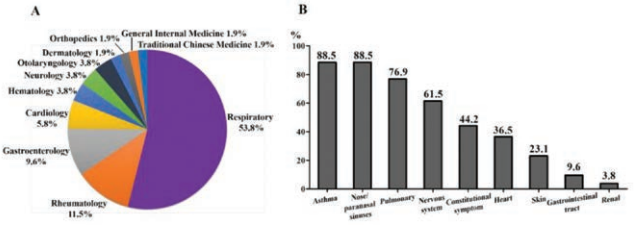

Figure 1. Department at first visit (A) and clinical manifestations during the whole disease process of 52 Chinese EGPA patients(B).

AB0395 RENAL INVOLVEMENT IN HENOCH-SCHÖNLEIN PURPURA

N. Ben Chekaya[1], S. Daada[1], M. Brahim[1], I. Chaabene[1], R. Klii[1], M. Kechida[1], S. Hammami[1]. [1]*Fattouma Bourguiba Hospital, Internal Medicine and Endocrinology Departement, Monastir, Tunisia*

Background: Henoch-Schönlein purpura (HSP), also known as rheumatic purpura, is an immune complex vasculitis affecting small vessels with dominant IgA deposits. Clinical manifestations mainly involve cutaneous purpura, arthralgias and/or arthritis, acute enteritis and glomerulonephritis. HSP is more common among children than adults. Kidney damage is the principal prognostic determinant in HSP. The aim of this study is to evaluate the renal manifestations of HSP.
Objectives: The aim of this study is to evaluate the renal manifestations of HSP.
Methods: This was a retrospective study of 35 patients with diagnosed HSA, who were admitted between the time period may 2008 and november 2018. All of these patients met the American College of Rheumatology classification criteria for a diagnosis of HSP. Renal involvement was defined as the presence of proteinuria or hematuria.
Results: The study group consisted of 35 patients, 20 women (57%) and 15 men (43%). The mean age was 48.8± 18.7 years. The incidence rates of skin, joint, gastrointestinal and central nervous system involvement were 91.4, 77.1, 54.2 and 2.8%, respectively. Elevated serum IgA levels occurred in 5.7 %. Six patients (17.1%) were given corticosteroids during the first 3 months of their HSP, which were indicated for severe gastrointestinal (n=5) or renal involvement (n=1). Eighteen of the thirty five patients (51.42%) had renal involvement. There were 12 women and six men. All patients had proteinuria (100%). Hematuria has been identified in 11 patients (61.1%) and renal insufficiency in 4 patients (22.2%). The renal involvement was mainly detected in the first month. Renal biopsy was affected in four patients (22.2%). An endocapillary glomerulonephritis was found in 3 patients and an extra capillary necrotizing glomerulonephritis in one patient. The immunofluorescence showed the presence of IgA deposits in 4 patients.
Conclusion: Renal involvement dominates the prognosis for the disease. The most common clinical expression is the association of microscopic hematuria with proteinuria.

Background: Cystoid Macular Edema (CME) is the most important cause of blindness in non-infectious uveitis (NIU) **(1).** Corticosteroids and conventional and/or biological immunosuppressant may be required **(1-6).** High-dose intravenous methylprednisolone (IVMP) pulse therapy may induce a rapid improvement.
Objectives: To evaluate the efficacy and safety of IVMP pulse therapy in CME of different immune mediated inflammatory diseases (IMID).
Methods: Multicentre study of 66 patients with severe ocular inflammation who received IVMP. The underlying diseases were: Vogt Koyanagy Harada disease (VKHD)(n=24), Behçet's disease (BD) (19) and idiopathic NIU (23). The main outcome variable was macular thickness and macular edema (Optical coherence tomography [OCT] >300 µm); that was assessed at 0 (basal), 2-5, 7, 15 and 30 days after IVMP.
The results are expressed as mean ±SD for normally distributed variables, or as median [IQR] when are not. Comparison of continuous variables was performed using the Wilcoxon test.
Results: We studied 43♀/ 23♂ patients. The main features are shown in TABLE 1. IVMP dose ranged from 250 to 1000 mg/day administered for 3-5 consecutive days, the dose was established according to the presence or not of other systemic manifestations apart from uveitis. All of them had active intraocular inflammation at the moment of the study.

Table 1. Main features of 66 patients with cystoid macular edema.

	VKHD (n=24)	Idiophatic (n=23)	Behcet's disease (n=19)	Overall (n=66)
Men/Women, n	**5/19**	9/14	9/10	66
Mean age (years)	**42 ± 11**	47 ± 15	33 ± 10	-
Unilateral/Bilateral, n (%)	**2 (8.3) /22 (91.7)**	10 (43.5) / 13 (56.5)	4 (21) / 15 (79)	16/50
Inflammatory ocular patterns, n (%)				
Posterior uveitis	6 (25)	9 (39.1)	3 (15.8)	18
Panuveitis	18 (75)	14 (60.9)	16 (84.2)	48
Laboratory data, n (%)				
ANA	2 (8.34)	2 (8.7)	0 (0)	4
HLA B27	0 (0)	4 (17.4)	0 (0)	4
HLA B29	0 (0)	1 (4.3)	0 (0)	1
HLA B51	0 (0)	5 (21.7)	8 (42)	13

A rapid and maintained statistically improvement was observed in OCT values in all underlying diseases (FIGURE 1**).** No major side effects were observed.
Conclusion: High-dose IVMP pulse therapy is useful and safe in the prompt control of CME, regardless of the underlying IMID.

EPIDEMIOLOGY AND CLINICAL FEATURES OF OPHTHALMOLOGICAL MANIFESTATIONS IN BEHÇET'S DISEASE. STUDY OF 50 PATIENTS OF A SERIES OF 120 PATIENTS IN A REGION IN NORTHERN SPAIN

A. Herrero-Morant[1], G. Suárez-Amorín[1], R. Demetrio-Pablo[1], L. Sanchez-Bilbao[1], C. Álvarez-Reguera[1], D. Martínez-López[1], R. Fernández Ramón[1], J. L. Martín-Varillas[2], M. C. Mata-Arnaiz[3], M. Á. González-Gay[1], R. Blanco[1]. *[1]Hospital Universitario Marqués de Valdecilla, Rheumatology and Ophtalmology, Santander, Spain*; *[2]Hospital de Sierrallana, Rheumatology, Sierrallana, Spain*; *[3]Hospital de Laredo, Rheumatology, Laredo, Spain*

Background: Ophthalmological involvement is one of the most feared manifestations of Behçet's disease [1-6].
Objectives: Our aim was to define the main demographic and clinical features of ophthalmological involvement in a well-defined cohort of patients with Behçet's disease.
Methods: Descriptive study of a cohort of 120 patients diagnosed with Behçet's disease from January 1, 1980 to December 31, 2019. Finally, following the 2014 International Criteria for Behçet's Disease (ICBD) (*J Eur Acad Dermatol Venereol 2014; 28:338-47*) 94 patients were chosen for this study.
Results: 50 patients (28 men/22 women; male to female ratio of 1:0.8) had ocular involvement. Mean age at diagnosis was 37.6±11.8 years. Mean ICBD score was 5.8±1.3 points. Neurological involvement was the most frequent manifestation in this group. Genital ulcers were more frequent in the non-ophthalmological involvement group. Systemic clinical domains are shown in Figure 1.
The most frequent ocular manifestations were uveitis (n=44, 88.0%), retinal vasculitis (n=5, 10%) and dry eye (n=5, 10%). Likewise, the most frequent type of uveitis was anterior (n=17, 38.6%), followed by posterior uveitis (n=14, 31.8%). 26 (59.1%) of all uveitis were unilateral. Panuveitis was more frequent among patients under 60 years. Similarly, anterior uveitis was predominant in patients older than 70 years. There were no remarkable differences between genders. Main clinical features are shown in Table 1.

Table 1. Clinical characteristics of ocular Behçet's disease.

	n (%)	Unilateral, n (%)	Bilateral, n (%)
Uveitis	44 (88.0)	26 (59.1)	18 (40.9)
Anterior	17 (38.6)	13 (76.5)	4 (23.5)
Intermediate	2 (4.5)	-	2 (100)
Posterior	14 (31.8)	9 (64.3)	5 (35.7)
Panuveitis	11 (25.0)	4 (36.4)	7 (73.6)
Retinal vasculitis	5 (10.0)	-	-
Dry eye	5 (10.0)	-	-
Cystoid macular edema	4 (8.0)	-	-
Episcleritis	3 (6.0)	3 (100)	-
Optic neuritis	2 (4.0)	-	-

Conclusion: Ophthalmological involvement in Behçet's disease was more frequent in men. Uveitis and retinal vasculitis were the most frequent ocular manifestation. No remarkable differences in clinical features were observed between genders.

AB0398 CASE SERIES OF PATIENTS WITH CHOLESTEROL CRYSTAL EMBOLISM SYNDROME THAT MIMICS SYSTEMIC VASCULITIS

Z. M. Ouyang[1], W. C. Zeng[1], X. N. Wei[1], D. H. Zheng[1], J. Lin[1], Q. H. Li[1], L. Dai[1], Y. Mo[1]. [1]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China*

Background: Cholesterol crystal embolism (CCE) syndrome is a multisystemic disorder caused by small arteries cholesterol crystal emboli subsequent to small pieces of atheromatous plaques from the aorta or other major arteries break off. CCE is often overlooked because it mimics symptoms of systemic vasculitis due to its clinical characteristics such as ulceration and gangrene of toes, livedo reticularis, renal insufficiency. Acute inflammatory reactants such as ESR, CRP may elevate in CCE patients since the cholesterol crystals trigger a foreign-body inflammatory reaction around the arterioles.
Objectives: This study aimed to explore the clinical characteristics of CCE patients, to make rheumatologists learn more about this disease.
Methods: Peer-reviewed articles in the electronic databases Medline, PubMed, Science Citation Index, China Biomedical Literature Database (CBM), China Journal Full Text Database (CNKI), and WANFANG Data were searched using the terms "cholesterol crystal embolism syndrome", "cholesterol embolism", "atherosclerotic embolism", "atherosclerotic nephropathy", or "CCE". Only articles or case reports containing detailed medical records of CCE patients were included. We also included CCE patients in our department.
Results: A 66-year-old male CCE patient presented with multiple ulceration and gangrene of toes and heels (Figure 1), subacute renal insufficiency, and elevated CRP and ESR. This patient had been considered as "suspected systemic vasculitis" and was referred to our rheumatology department. Another 39 Chinese CCE patients from the above databases were qualified for analysis. Among these 40 patients, 87.5% (35/40) were male and the mean age was 68±6 years. The most common involved was kidney and 90% (36/40) of patients presenting with renal insufficiency including the progressive increase of serum creatinine, hematuria, proteinuria, or sudden (or sharp) aggravation of hypertension. Next common involved was skin that occurred in 87.5% (35/40) of patients, especially in the toes and heels. For skin manifestations, blue toe syndrome occurred in 82.5% (33/40) of patients, ulceration or gangrene in 25% (10/40), and livedo reticularis in 15% (6/40). Additionally, 12.5% (5/40) showed ocular involvement such as visual impairment and visual field defect. In 2 patients, embolized cholesterol crystal in retinal arteries that is called Hollenhorst plaques was detected by fundoscopy. There were 62.5% (25/40) of patients having elevated CRP or ESR. The positive rate for skin or subcutaneous biopsies was 58% (11/19) and for kidney biopsies was 100% (6/6). The precipitating factors preceding the occurrence of classical symptoms such as blue toe syndrome, livedo reticularis and/or subacute renal insufficiency is important for CCE diagnosis especially for patients who had contraindications or were intolerant to biopsy. The precipitating factors include endovascular intervention (80%), vascular surgery (5%), and anticoagulant or thrombolytic therapy (2.5%). Only 12.5% (5/40) of patients were spontaneous and didn't have any predisposing factors. General interventions of CCE included statins (82.5%), antiplatelets (32.5%), and dialysis (32.5%). Twelve patients (30%) received glucocorticoids and 75% (9/12) of them renal function improved and ulceration healed (Figure 1). Among 36 patients who presented with renal insufficiency, the renal function returned to normal after treatment in 2 patients (5.6%), but 27 patients (75%) still showed abnormal renal function even though somewhat improved, and 7 patients (19.4%) needed renal replacement therapy or dialysis for maintenance.
Conclusion: This study reported CCE patients had high prevalence of renal insufficiency, blue toe syndrome, and ulceration or gangrene of toes, as well as elevated CRP or ESR, thus rheumatologists should be alert to this disease as one of the differential diagnosis of systemic vasculitis, especially for elderly patients with evidence of atherosclerosis who undergo a recent cardiovascular procedure.

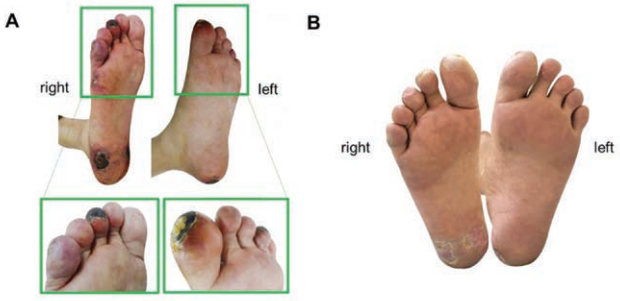

Figure 1: A 66-year-old male CCE patient presenting with multiple ulceration and gangrene of toes and heels (A). Skin gangrene with or without ulceration scab was seen in bilateral heels, the third right toe, and the first and fourth left toes. The fifth right toe showed blue color (named as blue toe syndrome). After 6-month glucocorticoids treatment, the skin ulceration completely healed (B).

JCBD: Japanese diagnostic Criteria of Behçet's Disease; *n*: number of cases; NR: Not Reported

Objectives: In a well-defined Northern Spanish population-based cohort, the aim of this study was **a)** to estimate epidemiological variations, **b)** clinical domains and **c)** to compare our results with other regions.

Methods: Study of unselected all consecutive patients diagnosed with definitive or possible BD by expert rheumatologists between 1980 and 2020 in our health region. Two classification criteria were applied: **a**) International Study Group (ISG) for BD **[1]**, and **b**) International Criteria for BD (ICBD) **[2]**. In addition, a literature review of Medline publications was carried out.

Results: In this study, from a total of 120 patients diagnosed with BD by expert opinion (58 women/62 men), 96 met ICBD and 59 ISG criteria. Mean age of the cohort at diagnosis was 37.6±13.8 years similar to other countries, as well as sex distribution.

Prevalence was higher than in most European populations regardless the diagnostic criteria applied: expert opinion (20.6), ICBD (16.5) or ISG (10.1) (TABLE 1). Incidence was lower (expert opinion: 0.022, ICBD: 0.018, ISG: 0.011). Clinical domains' frequency was in line with other regions except vascular and gastrointestinal involvement, which were lower.

Conclusion: BD's prevalence in Northern Spain is higher than in most European populations. These differences likely reflect a combination of true geographic variation, methodological artifacts as well as the easy access to Public Health System and its efficiency. In contrast, clinical phenotypes are similar to other regions.

URINARY ALBUMIN-TO-CREATININE RATIO INDICATES NECROTIZING AND CRESCENTIC GLOMERULONEPHRITISIN ANCA-ASSOCIATED VASCULITIS

S. Hakroush[1], B. Tampe[2]. [1]*University Medical Center Göttingen, Institute of Pathology, Göttingen, Germany*; [2]*University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany*

Background: Renal involvement is a common and severe complication of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) as it can cause acute kidney injury (AKI), end-stage renal disease (ESRD) or death.

Objectives: We have previously reported that elevated urinary albumin-to-creatinine ratio (uACR) correlates with rapid deterioration of kidney function in ANCA GN. Therefore, we here aimed to describe the association between proteinuric findings and histopathological diagnosis of necrotizing and crescentic ANCA GN in 50 urinary samples at admission and corresponding renal biopsies of patients with AAV.

Methods: A total number of 50 urinary samples at admission and corresponding renal biopsies with confirmed renal involvement of AAV were retrospectively included between 2015 till 2020 in a single-center observational study.

Results: Renal involvement of AAV revealed variable proteinuria ranging from low-range to nephrotic syndromes, however most patients presented with subnephrotic proteinuria. Severe deterioration of kidney function requiring RRT within 30 days after admission was associated with elevated levels of nonselective proteinuria, mostly attributed to albuminuria (uACR). Because we have previously shown that histologically confirmed ANCA GN with glomerular crescents and necrosis is associated with AKI and requirement of RRT during short-term disease course and elevated uACR levels were equally associated with AKI and requirement of RRT during the short-term course after disease onset, we next analyzed the association between uACR measurements at admission and histopathological findings within renal biopsies performed thereafter. Severely increased uACR levels >300 mg/g correlated with reduction of normal glomeruli, attributed to increased glomerular crescents and necrosis. By contrast, no such association was observed for global sclerotic glomeruli, revealing that uACR reflects crescentic ANCA GN rather than adaptive glomerular hyperfilitration in chronic sclerosing stage. Since uACR levels could reflect both, either a specific renal involvement with necrotizing and crescentic ANCA GN or severity of systemic AAV disease, we next correlated uACR levels assessed at admission with extrarenal disease manifestation. We observed no association between uACR levels and extrarenal manifestation of AAV disease including pulmonary hemorrhage, skin involvement and BVAS assessment, suggesting that uACR levels reflected specific renal involvement in AAV. These observations were further confirmed by survival analysis for cumulative incidence of RRT during the short-term course of disease.

Conclusion: Early identification of patients who mostly benefit from aggressive immunosuppressive therapy is of clinical importance. Our observation that uACR levels at disease onset predict necrotizing and crescentic ANCA GN requires further investigation for therapeutic decision especially in patients with severe deterioration of kidney function.

Background: Systemic sclerosis (SSc) is an autoimmune disorder that is characterized by a interplay of vascular abnormalities, immune system activation and an uncontrolled fibrotic response associated with interstitial lung disease affecting about 40% of patients. Identification of ILD relies on high-resolution CT that identify features suggestive of the histologic patterns of SSc(1). CT is used to determine pattern and extent of ILD and participates in the prediction of ILD progression(2).

All group of pulmonary hypertension (PH) may occur with an overall prevalence reported in up to one fifth of patient. Whereas extensive SSc-ILD can be responsible for PH, PH can also be seen as a consequence of myocardial abnormalities or as primarily affecting small pulmonary arteries and classified as pulmonary arterial hypertension.

Dual-energy CT introduction offers perspectives in the evaluation of SSc-related pulmonary manifestations. While these are not strictly perfusion images, they have been reported as adequate surrogate markers of lung perfusion (3). In the field of PH, detection of perfusion defects highly concordant with V/Q scintigraphic findings has been reported in the diagnostic approach of CTEPH but also in the differential diagnosis between PAH and peripheral forms of CTEPH (4).

Objectives: To investigate lung perfusion abnormalities in patients with SSc.

Methods: The study population included 101 patients who underwent dual-energy CT (DECT) angiography in the follow-up of SSc. CT examinations were obtained on a 3rd-generation dual-source CT system with reconstruction of morphologic and perfusion images. All patients underwent pulmonary function tests within two months of the follow-up CT scan. Fifteen patients had right heart catheterization-proven PH.

Results: Our population included patients without SSc lung involvement (Group 1; n=37), patients with SSc-related ILD (Group 2; n=56) of variable extent (Group 2a: ≤10%: n=17; Group 2b: between 11-50%: n=31; Group 2c: >50%: n=8) and patients with PVOD/PCH (Group 3; n=8). Lung perfusion was abnormal in 8 patients in G 1 (21.6%), 14 patients in G 2 (25%) and 7 patients in G 3 (87.5%). Perfusion changes were mainly composed of bilateral perfusion defects, including patchy, PE-type perfusion defects and areas of hypoperfusion of variable size. In G 1 and G 2a (n=54): (a) patients with abnormal lung perfusion (n=14) had a significantly higher proportion of NYHA III/IV scores of dyspnea (p=0.031), a shorter mean walking distance at the 6MWT (p=0.042) and a trend towards lower mean DLCO% (p=0.055) when compared to patients with normal lung perfusion (n=40); (b) a negative albeit weak correlation was found between the iodine concentration in both lungs and the DLCO% (r=-0.27; p=0.059) whereas no correlation was found with PAPs (r=0.16; p=0.29) and walking distance during the 6MWT (r=-0.029; p=0.84).

Conclusion: DECT lung perfusion provides complementary information to HRCT scans, depicting perfusion changes in SSc patients with normal or minimally infiltrated lung parenchyma.

AB0402 **SELF-ASSESSMENT OF SCLERODERMA SKIN THICKNESS: DEVELOPMENT AND VALIDATION OF THE PASTUL QUESTIONNAIRE**

J. Spierings[1,2], V. Ong[1], C. Denton[1]. [1]*Royal Free and University College Medical School, University College London, Division of Medicine, Department of Inflammation, Centre for Rheumatology and Connective Tissue Diseases, London, United Kingdom*; [2]*University Medical Centre Utrecht, Rheumatology and Clinical Immunology, Utrecht, Netherlands*

Background: Evaluation of skin is central to both clinical practice and trials in systemic sclerosis (SSc). This is generally done with the modified Rodnan Skin Score (mRSS). Remote consultations are now widely implemented in response to the COVID-19 pandemic, which has inevitably limited evaluation of skin. To monitor skin during this pandemic and to further explore ways to assess skin, we developed the PASTUL (Patient self-Assessment of Skin Thickness in Upper Limb) questionnaire.

Objectives: This study evaluated feasibility and validity of PASTUL in SSc.

Methods: The PASTUL questionnaire uses a simple self-assessed grading of skin as normal, mild, moderate, or severely thickened at eight sites of upper limb corresponding to mRSS. Assessed grades were converted to an integer scale [0, 1, 2, 3]. Detailed instructions for patients were provided. Scleroderma Skin PRO (SSPRO) and Scleroderma Health Assessment Disability Index (SHAQ-DI) were also completed. For comparison, physician assessed mRSS was performed in a subgroup of patients. Construct validity was evaluated by examining the correlation between PASTUL, mRSS, SSPRO and SHAQ-DI using Pearson's correlation coefficient. Content validity was evaluated by scoring relevance, clarity and practical difficulty. Test-retest reliability was estimated using intraclass correlation coefficient (ICC).

Results: 130 patients were invited of which 104 (80%) completed the questionnaires. The mRSS was undertaken in 78 patients (n=42, 54% limited cutaneous SSc (lcSSc)). The PASTUL was completed by patients (86%) or by a partner/friend (14%). Mean PASTUL score was 11 (SD 7), mean HAQ-DI 1.41 (SD 0.77) and mean SSPRO 48.3 (SD 27.0). PASTUL strongly correlated with total SSPRO and SSPRO subdomain physical limitations (r=0.60 and 0.62, respectively) (Figure 1A). Correlations between PASTUL and mRSS and mRSS upper limbs were moderate (r=0.56 and 0.58, respectively) (Figure 1B). An overview of all correlations is provided in Table 1. Correlation between PASTUL and mRSS was stronger in lcSSc compared to diffuse cutaneous SSc patients (r=0.53 vs 0.43) and when assessed by a partner/friend compared to patients themselves (r=0.90 vs 0.54). The PASTUL demonstrated excellent test-retest reliability (ICC of 0.93, p<0.001) and good content validity.

Table 1. Correlations between PASTUL, mRSS, SHAQ-DI and SSPRO.

Outcome measure	Pearson's correlation coefficient	P-value
mRSS	0.56	<0.001
mRSS upper limbs	0.58	<0.001
SHAQ-DI	0.38	<0.001
SHAQ VAS scores		
- VAS pain	0.28	0.004
- VAS GI	0.01	0.333
- VAS breathing	0.17	0.168
- VAS RP	0.16	0.114
- VAS DU	0.26	0.008
- VAS Limitations	0.32	0.001
SSPRO	0.60	<0.001
SSPRO subdomains		
- Physical effects	0.59	<0.001
- Physical limitations	0.62	<0.001
- Emotional effects	0.48	<0.001
- Social effects	0.42	<0.001

DU, digital ulcers; GI, gastrointestinal; mRSS, modified Rodnan Skin Score; PASTUL, Patient self-Assessment of Skin Thickness in Upper Limb; RP, Raynaud's Phenomenon; SD, standard deviation; SHAQ-DI, Scleroderma Health Assessment Questionnaire Disability Index; SSPRO, Scleroderma Skin Patient-Reported Outcome; VAS, visual analogue score

Conclusion: The significant correlation of PASTUL scores with total SSPRO and physical limitation scores and moderate correlation with mRSS support the potential of PASTUL for remote evaluation of skin thickness in virtual clinical settings. Future studies may explore sensitivity to change and utility in clinical trials.

AB0403 ORBITAL MYOSITIS: AN UNCOMMON OPHTHALMIC PRESENTATION IN RHEUMATIC DISEASES - CASE SERIES AND SYSTEMIC REVIEW OF CASE REPORTS

P. S. Wong[1], B. G. T. Coumbe[1], P. Mangat[1], H. Beynon[1], R. Stratton[1]. [1]*Royal Free Hospital and University College Medical School, Centre for Rheumatology and Connective Tissue Diseases, London, United Kingdom*

Background: Ophthalmic conditions are common manifestations in patients with rheumatic diseases (RDs), orbital myositis (OM) remain rare. Only 1 case each for scleroderma and undifferentiated connective tissue disease (UCTD) reported.
Objectives: Report frequency of Rheumatic Diseases with OM (RDs-OM), diagnosis and treatments.
Methods: Patients database were obtained from trust electronic record and literature review of case reports were performed.
Results: 4 out of 7 patients in our clinic with RDs-OM. Both Scleroderma-myositis (SCM) patients were positive for anti-PM/SCL antibody. All received glucocorticosteroid (GCS) and Mycophenolate as steroid-sparing or rescue therapy with good tolerance and outcome. One idiopathic OM has residual muscle paresis.

Table 1. Case series of patients with Orbital Myositis

	Idiopathic OM (n=3)	Rheumatology Diseases (n=4)	p-value
Age (years)	48 (27-72)	42.75 (21-60)	P= 0.8571
Gender – Female (Male)	2 (1)	4(0)	
Median Period Of Follow Up (months)	24.60 (7-37)	47.25(1-120)	
Underlying RD			
I.UCTD	-	1	
II.Overlap Scleromyositis	-	2	
III.Behcet's Disease	-	1	
Biopsy			
I.Pathological significant	1	1	
II.Normal	1	1	
III.Not done	1	2	

Total 93 cases with RDs-OM reviewed and the characteristic of patients represented in Figure 1.

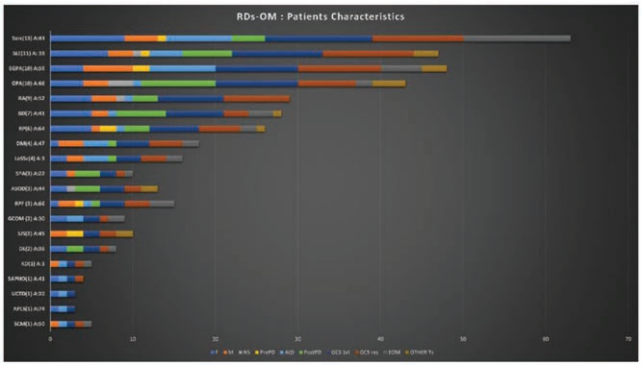

Figure 1. Characteristics of orbital myositis in patients with rheumatic diseases. F: female, M:male, NS: not-specified, PrePD: onset before RD, AtD: onset with RD,PostPD: onset after RD, GCS 1st: Glucocorticoid as first line treatment, GCS res: Glucocorticoid responder, BxEOM: biopsy of extra-ocular muscle, OtherTs: Other Biopsy A: Median age at diagnosis, Sarc: sarcoidosis, SLE: Lupus, EGPA: Eosinophilic Granulomatous Polyangitis, GPA: Granulomatous Polyangitis, RA: rheumaoid Arthritis, BD: Behcet;s Disease, RP: Relapsing Polychondritis, DM: Dermatomyositis, LoSSC: Localized Sclerderma, SPA: Spondyloarthropathy, ASOD: Adult Onset Still's Disease, RPF: Retroperitoneal Fibrosis, GCOM: Giant Cell OM, SJS: Sjogren Syndrome, DL: Discoid Lupus, KD: Kawasaki Disease, SAPHO: Synovitis, acne, pustulosis, hyperostosis, and osteitis, APLS: Antiphospholipid Syndrome.

OM although is rare but can present in most RDs. Our review showed OM commonest in patients with RA, GPA, EGPA and sarcoidosis. Only 1 each for SCM, APLS, UCTD, SAPHO and Kawasaki Disease.
Most RDs-OM patients are female. 89.2% OM diagnosed concurrently with primary RD diagnosis. Majority RA, BD and GPA developed OM along the course of RDs (83%-90%).
Except for routine RDs screening, thyroid eye disease, infections, malignancy (eg. lymphoma) and myasthenia gravis, atypical infective screenings include mycobacterium, fungal, *Borrelia* and spirochetes were excluded. Histopathological diagnosis is important diagnostic tool for IgG4 disease, neoplasm, sarcoidosis and vasculitis. 59% patients underwent tissue biopsy, 71% of these were sampled from EOM, some from involved organs. Orbital MRI or CT were the commonest diagnostic imaging, 5 reported had Ocular ultrasound as single or complementary imaging and 1 had PET-CT for exclusion of other diagnosis.
Only 40% GPA and 20% of EGPA patients were positive for ANCA either c-ANCA, p-ANCA and MPO which is similar in other literatures.
97.8% (n=91) patients received GCS with 79% of these patients reported improvement or resolution of ocular symptom with or without steroid-sparing agents. Immunosuppressants used are those not foreign among rheumatologists while biologics prescribed for refractory cases were Rituximab(2), Infliximab(4), Adalimumab(2) and Tocilizumab(1). Orbital decompression and orbital radiation were other measures. 13 patients had residual EOM paresis.
Conclusion: 1.RDs-OM is increasing recognized.
2.Most OM in RA, BD and GPA occurs along its primary RDs.
3.40% GPA and 20% of EGPA patients were ANCA positive.
4.GCS remain the primary treatment, three quarter patients responded.

AB0404 EXTENDED MYOSITIS PANEL AND THE CLINICAL ASSOCIATION IN PATIENT WITH SUSPECTED INFLAMMATORY DISEASE, A RETROSPECTIVE STUDY

S. Al Nokhatha[1], E. Alfares[2], N. Conlon[2], R. Conway[1]. [1]*St James's Hospital, Rheumatology, Dublin, Ireland*; [2]*St James's Hospital, Immunology, Dublin, Ireland*

Background: The idiopathic inflammatory myopathies (IIMs) are a heterogeneous group of conditions characterized by proximal muscle weakness. Autoantibodies are identified in more than 80% of patients with polymyositis (PM) or dermatomyositis (DM). Some are also found in other connective tissue diseases (CTD), while others are more specific to IIM. Thus, they are classified into two categories named myositis associated antibodies (MAA) and myositis specific antibodies (MSA). MSA have been reported as being 90% specific for IIM while MAA are found in up to 50% of myositis patients. [1]
Objectives: The aim of the study was to evaluate the myositis antibody prevalence and to assess the associations of these antibodies with clinical manifestations, final diagnosis, medication received and outcomes.
Methods: A retrospective chart review study was conducted at St. James's Hospital from 2015-2020. All positive myositis panels were obtained. The MAA evaluated were PMScl (100/75), U1snRNP, Ku and Ro52, while MSA were Mi2a, Mi2b, TIF1, MDA5, NXP2, SAE1, Jo-1, SRP, PL-7, PL-12, EJ and OJ.
Results: We identified 52 patients who were positive for one or more MSA/MAAs. The mean age was 58.9 years, the majority were female (65.3%). The most prevalent MAA was anti-Ro52 (29/52) followed by anti-PMScl 100/75 (7/52), anti-Ku and anti-U1RNP were seen in (3/52) each. The prevalence of MSA were (4/52) for anti-PL12 and (3/52) for anti-SAE1 followed by (2/52) for each of anti-Mi2b, anti-NXP2, anti-Jo, anti-SRP, anti-PL7, anti-EJ and anti-OJ while only (1/52) for anti-MDA5. The most common observed clinical phenotypes in our cohort were arthralgia (20/52), ILD (18/52) and cutaneous manifestations (15/52). Less than a quarter of the studied population had arthritis (8/52), myositis (7/52), raynauds (7/52) and malignancy (4/52). Various diagnosis were allocated for these patients, while only eight cases were diagnosed with dermatomyositis. Medication received and the final outcome for those with strong positive MSA were summarized in table1.
Conclusion: IIM was the final diagnosis in only 15% of positive myositis panels and the presence of antisynthetase antibodies didn't necessarily indicate the presence of antisynthetase syndrome thus signifying low specificity in our cohort.

AB0405 FIBROBLAST GROWTH FACTOR-23 IS ASSOCIATED WITH HIGH-DENSITY LIPOPROTEIN IN SYSTEMIC SCLEROSIS PATIENTS

A. Alvarez de Cienfuegos[1], L. Cantero-Nieto[2], J. A. García-Gómez[3], R. Ríos Fernández[4], J. Martin Ibanez[5], M. A. González-Gay[6], N. Ortego[4]. *[1]Hospital Vega-Baja, Department of Rheumatology, Alicante, Spain*; *[2]Hospital Santa Ana, Department of Emergency, Granada, Spain*; *[3]Hospital General de Elche, Infectious Diseases Unit, Alicante, Spain*; *[4]Hospital Universitario San Cecilio, Systemic Autoimmune Diseases Unit, Granada, Spain*; *[5]IPBLN-CSIC, Institute of Parasitology and Biomedicine López-Neyra, Granada, Spain*; *[6]University of Cantabria, School of Medicine, Santander, Spain*

Background: Systemic sclerosis (SSc) is characterized by calcification, vasculopathy, and endothelial wall damage, all of which can increase the risk for atherosclerosis and cardiovascular disease. Mechanisms by which atherosclerosis is promoted in connective tissue diseases remain unknown, but is believed to be secondary to chronic inflammation, altered lipid profiles and function, autoantibodies, and endothelial dysfunction. Fibroblast growth factor-23 (FGF23) is a circulating regulator of phosphate and vitamin D metabolism and has been implicated as a putative pathogenic factor in cardiovascular disease. FGF23 could exert hormonal control on fat mass and glucose metabolism, since it shares structural similarities with the other FGF subfamily members (FGF15/19 and FGF21) that are involved in carbohydrate and lipid metabolism.

Objectives: The objectives of this study were: to compare serum FGF23 levels between SSc patients and healthy controls and to investigate possible associations between FGF23 and serum lipid profile in SSc patients.

Methods: This cross-sectional study was performed in San Cecilio Hospital, Granada (Spain) from November 2017 to May 2019. Sixty-two women with SSc and 62 age and sex matched healthy controls were enrolled in this study. All patients included in this study had normal serum creatinine (Cr) levels and met the 2013 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria for SSc. Total cholesterol and triglyceride levels were determined by fully enzymatic techniques. High-density lipoprotein (HDL) was determined after precipitation of apolipoprotein B (apoB)–containing lipoproteins with magnesium sulfate and dextran sulfate. Low-density lipoprotein (LDL) was calculated using the Friedewald formula. Serum FGF23 was analyzed using ELISA.

Results: A total of 62 female patients were included in our study, with a mean (SD) age of 53 ± 10 years. The majority were Caucasian (90.5%). The mean disease duration was 8.8 ± 6.9 years. Forty-four (70.9%) patients had a limited form of the disease and 18 (29.1%) had a diffuse form.

There was no significant differences in FGF23 levels between the patients and controls (78.2 ± 60.5 vs. 80.3 ± 56.3 pg/mL, p= 0.662), but we found a statistically significant inverse relationship between FGF23 and HDL-c measurements (r= -0.27; p= 0.03) in women with SSc. In addition, in the linear regression model, higher FGF23 concentrations were associated with lower HDL-c [β = -1.45 95% CI (-2.81, -0.08); $p < 0.05$].

Conclusion: We report an association between circulating FGF23 and HDL-c in SSc female patients, representing a novel pathway linking high FGF23 to an increased cardiovascular risk.

AB0406 ASSOCIATION OF ENDOTHELIN-1 WITH PULSE WAVE VELOCITY IN SYSTEMIC SCLEROSIS PATIENTS

A. Alvarez de Cienfuegos[1], L. Cantero-Nieto[2], J. A. García-Gómez[3], J. L. Callejas-Rubio[4], J. Martin Ibanez[5], N. Ortego[4]. *[1]Hospital Vega-Baja, Department of Rheumatology, Alicante, Spain*; *[2]Hospital Santa Ana, Department of Emergency, Granada, Spain*; *[3]Hospital General de Elche, Infectious Diseases Unit, Alicante, Spain*; *[4]Hospital Universitario San Cecilio, Systemic Autoimmune Diseases Unit, Granada, Spain*; *[5]IPBLN-CSIC, Institute of Parasitology and Biomedicine López-Neyra, Granada, Spain*

Background: Systemic sclerosis (SSc) is a multisystemic disease featured by vascular and immunological disorders along with an excessive accumulation of the components of the connective tissue that cause cutaneous sclerosis and

fibrosis of different organs. The occurrence of endothelial dysfunction together with fibrosis indicates that endothelial cell-derived factors, such as endothelin-1 (ET-1), may have an important role in the pathogenesis of SSc. The upregulation of ET-1 activates inflammatory cells and leads to nitric oxide synthase inhibition associated with arterial stiffness.

Objectives: The purpose of this study was to evaluate ET-1 serum levels in women with systemic sclerosis (SSc) compared with healthy controls and to examine possible associations between ET-1 and markers of arterial stiffness.

Methods: This cross-sectional study was performed in San Cecilio Hospital, Granada (Spain) from November 2017 to May 2019. Sixty-two women with SSc and 62 age and sex matched healthy controls were enrolled in this study. Pulse Wave Velocity (PWV) was measured non-invasively along the carotid–femoral arterial segment. Serum ET-1 was analysed using indirect enzyme-linked immunosorbent assay (ELISA).

Results: A total of 62 female patients were included in our study, with a mean (SD) age of 53 ± 10 years. The majority were Caucasian (90.5%). The mean disease duration was 8.8 ± 6.9 years. Forty-four (70.9%) patients had a limited form of the disease and 18 (29.1%) had a diffuse form.

There was a significant difference in ET-1 serum levels between SSc female patients and healthy controls (28.4 ± 10.6 vs. 21.1 ± 11.7 pg/ml, $p = 0.001$). Serum levels of ET-1 were positively associated with PWV ($r = 0.26$, $p < 0.05$), within the study group. In addition, in the linear regression model, higher ET-1 concentrations were associated with higher PWV [$\beta = 0.03$ 95% CI (0.001, 0.060); $p < 0.05$].

Conclusion: This study shows that ET-1 serum levels are associated with PWV in women with SSc. Therefore, drugs that block ET-1 may be effective in reducing large artery stiffness in women with SSc, and thus cardiovascular risk.

AB0407 CARDIOVASCULAR BURDEN IN SYSTEMIC SCLEROSIS: QRISK3 VERSUS FRAMINGHAM FOR RISK ESTIMATION

M. Di Battista[1], S. Barsotti[1], A. Della Rossa[1], M. Mosca[1]. [1]*University of Pisa, Rheumatology Unit, Pisa, Italy*

Background: Cardiovascular (CV) diseases, namely myocardial infarction and stroke, are not among the most known and frequent complications of systemic sclerosis (SSc), but there is growing evidence that SSc patients have a higher prevalence of CV diseases than the general population [1].

Objectives: To compare two algorithms for CV risk estimation in a cohort of patients with SSc, finding any correlation with clinical characteristics of the disease.

Methods: SSc patients without previous myocardial infarction or stroke were enrolled. Traditional CV risk factors, SSc-specific characteristics and ongoing therapies were assessed. Framingham and QRISK3 algorithms were then used to estimate the risk of develop a CV disease over the next 10 years.

Results: Fifty-six SSc patients were enrolled. Framingham reported a median risk score of 9.6% (IQR 8.5), classifying 24 (42.9%) subjects at high risk, with a two-fold increase of the mean relative risk in comparison to general population. QRISK3 showed a median risk score of 15.8% (IQR 19.4), with 36 (64.3%) patients considered at high-risk. Both algorithms revealed a significant role of some traditional risk factors and a noteworthy potential protective role of endothelin receptor antagonists ($p=0.003$). QRISK3 was also significantly influenced by some SSc-specific characteristics, as limited cutaneous subset ($p=0.01$), interstitial lung disease ($p=0.04$) and non-ischemic heart involvement ($p=0.03$), with the first two that maintain statistically significance in the multivariate analysis ($p=0.02$ for both).

Conclusion: QRISK3 classifies more SSc patients at high-risk to develop CV diseases than Framingham, and it seems to be influenced by some SSc-specific characteristics. If its predictive accuracy were prospectively verified, the use of QRISK3 as a tool in the early detection of SSc patients at high CV risk should be recommended.

AB0408 SYSTEMIC SCLERODERMA AND ENVIRONMENTAL RISK FACTORS: IDENTIFYING ASSOCIATIONS MINING THE BIOMEDICAL LITERATURE

A. Rodriguez-Pla[1]. [1]*Mayo Clinic Scottsdale Campus, Rheumatology, Scottsdale, United States of America*

Background: A debate still exists concerning the role of occupational and environmental factors in the pathogenesis of systemic scleroderma (SSc).

Objectives: Our aim was to explore associations between SSc and environmental factors utilizing an automatic semantic interpretation of PubMed results.

Methods: The literature search string: ("systemic sclerosis" OR "scleroderma") AND ("occupational exposure" OR "environmental" OR "risk factor") was used to retrieve abstracts from the entire PubMed database, using Semantic MEDLINE 2, on 6/14/2020. This application represents a network of semantic predications (triples of the form subject-predicate (or relation) -object, e.g. Occupational Exposure *causes* Systemic Scleroderma) on a knowledge graph. Subject and object arguments of each predication are concepts from the Unified Medical Language System (UMLS) Metathesaurus and the relation is taken from the UMLS Semantic Network. The system allows for choosing the central topic ("Systemic Scleroderma"), the length of the network (3 nodes), and automatic summarization, eliminating the less informative predications.

Results: The search string retrieved 864 citations and identified 6,397 predications by using 34 types of relations. Initially, we focused our attention on the 'CAUSES' type of relation (Figure 1), displaying a network with 59 nodes and 57 edges.

The central concepts of this network, identified as having causal relationship with SSc are autoimmune diseases/autoimmunity, chemicals such as bleomycin, occupational and environmental exposure, especially silica, vinyl chloride and trichloroethylene, genes, including HLA and non-HLA genes, genetic polymorphisms, transcription factors (TFs) such as Fli1 and KLF5, and fibrosis. Eosinophilia-myalgia syndrome, toxic oil syndrome and infection were all causally linked to autoimmune diseases. Minerals were associated with occupational exposure and with autoimmune diseases. Concepts causally linked to fibrosis were rare diseases, HLA genes, other non-HLA genes, such as STAT4, IR4, IR5, TLR4, TLR7 and Rho-associated Kinase, and vinyl chloride monomer. Pathogenic factors associated with SSc were endothelial dysfunction and extracellular matrix proteins. Many of the papers in the network also suggested that hormonal factors are involved.

Conclusion: Inspection on the knowledge graphs reveals concepts central to research on the etiopathogenesis of SSc. The relations in which these concepts participate, provide more specific information. The Semantic MEDLINE graph supports the kind of patterns that underpin literature-based discovery.

Although the pathogenesis of SSc remains elusive, it is accepted that initial vascular damage driven by autoimmunity and environmental factors causes abnormalities in the vasculature resulting in the activation of fibroblasts in various organs. Silica and solvents such as trichloroethylene seem to be the most consistently suspected environmental agents in SSc.

AB0409 INTRAVENOUS ILOPROST: A REGION WIDE SURVEY OF CURRENT PRESCRIBING AMONGST HOSPITALS IN THE WESSEX MULTI-DISCIPLINARY CONNECTIVE TISSUE DISEASE NETWORK

L. Parker[1], A. Mason[2], B. Davidson[2]. [1]*University Hospitals Dorset NHS Foundation Trust, Rheumatology Department, Christchurch, United Kingdom*; [2]*University Hospital Southampton NHS Foundation Trust, Rheumatology Department, Southampton, United Kingdom*

Background: Digital ulceration in systemic sclerosis is a severe and disabling aspect of this complex, multi-system disease. Traditionally, intravenous (IV) iloprost has been prescribed to treat the problem. Alternative oral medications including sildenafil and bosentan are now readily available, although NHS clinical commissioning policy is yet to be updated to reflect changes in drug costs. Use of IV iloprost across Wessex was audited to review current practice across the region.
Objectives: To compare use of IV iloprost across 7 different hospital rheumatology departments
Methods: Data was collected across 7 different NHS hospital sites using rheumatology specific pharmacy records for high cost drug prescribing and a single uniform data collection proforma, which was then analysed by 1 person to ensure uniformity of results. Case notes were reviewed retrospectively to determine diagnosis, frequency and duration of iloprost treatment, if patients had been considered for sildenafil treatment (including if sildenafil was prescribed, any cautions or contra-indications to treatment, dose and any reason for discontinuation of treatment) and if patients had been considered for bosentan treatment and if it was prescribed.
Results: 45 patients were identified currently receiving IV iloprost. 32/45 (71%) had a diagnosis of systemic sclerosis, mixed connective tissue disease (CTD) or undifferentiated CTD (to be called scleroderma group). 13/45 had other miscellaneous diagnoses which had resulted in digital ulceration. These 13 patients were excluded from further analysis relating to sildenafil or bosentan prescribing as these medications were not indicated for other causes of digital ulceration. In the scleroderma group, 27/32 (84%) had been considered for sildenafil treatment. Of these, 8/27 started and discontinued due to intolerance and 17/27 remained on sildenafil. In the scleroderma group, 9/32 had been considered for bosentan treatment, and of these 7/9 remained on bosentan.
Conclusion: The authors have identified that IV iloprost is still widely used for management of digital ulceration in rheumatology departments across seven different hospitals in Wessex. Most of this group of patients would likely be eligible for treatment with sildenafil or bosentan. Sildenafil intolerance is a challenge to management. Consideration of bosentan as a treatment option was limited in this group, and may be a cost-effective alternative to IV iloprost which would also eliminate the risk of infection associated with IV access in a potentially immunosuppressed group of patients.

AB0410 S100A4 PLASMA LEVELS CORRELATE WITH DISEASE ACTIVITY, SKIN FIBROSIS AND INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS PATIENTS

H. Štorkánová[1,2], L. Andres Cerezo[1], S. Oreska[1,2], M. Špiritović[1,3], B. Heřmánková[1,3], M. Komarc[4], K. Pavelka[1,2], J. Vencovský[1,2], J. H. W. Distler[5], L. Šenolt[1,2], R. Bečvář[1,2], M. Tomcik[1,2]. [1]*Institute of Rheumatology, -, Prague, Czech Republic*; [2]*1st Faculty of Medicine, Charles University, Prague, Czech Republic, Department of Rheumatology, Prague, Czech Republic*; [3]*Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic, Department of Physiotherapy, Prague, Czech Republic*; [4]*Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic, Department of Methodology, Prague, Czech Republic*; [5]*University of Erlangen-Nuremberg, Erlangen, Germany, Department of Internal Medicine III and Institute for Clinical Immunology, Erlangen, Germany*

Background: In our previous study we demonstrated that S100A4 is overexpressed in scleroderma (SSc) skin, SSc fibroblasts and preclinical models of SSc in a TGF-β dependent manner. We showed that S100A4 is a new regulator of TGF-β signalling and its inhibition prevents the pro-fibrotic effects of TGF-β. Inactivation of S100A4 prevented dermal fibrosis induced by bleomycin and in Tsk-1 mice
Objectives: The aim of this study was to evaluate S100A4 in the peripheral blood of SSc patients and characterize its potential association with SSc-related features.
Methods: A total of 33 patients (29 females; mean age 52.8; disease duration 4.2 years; dcSSc/lcSSc = 8/25) who met the 2013 EULAR/ACR classification criteria for SSc and 20 healthy age- and sex-matched individuals were included in this study. Plasma levels of S100A4 were measured using ELISA (CUSABIO, Houston, USA). Data are presented as median (IQR).
Results: S100A4 plasma levels were significantly increased in SSc patients compared to healthy controls (78.6(32.3-146.5) vs. 43.4(32.3-53.4)ng/mL,p=0.011). Patients with diffuse cutaneous (dc)SSc had significantly higher levels of S100A4 than patients with limited cutaneous (lc)SSc or healthy controls (168.5(81.5-347.5) vs. 63.4(30.9-130.6),p=0.017,p=0.001, respectively). Plasma levels of S100A4 positively correlated with mRSS (r=0.556,p=0.001). Furthermore, S100A4 negatively correlated with forced vital capacity (FVC) and peripheral oxygen saturation (SpO2) (r=- 0.362,p=0.038;r=-0.414,p=0.029, respectively). S100A4 levels positively correlated with ESSG activity score (r=0.750,p<0.001). However, only correlations between S100A4 and mRSS, and ESSG activity score were approved at corrected level of statistical significance after Bonferroni's correction (p<0.01). In a prospective analysis of patients (n=40) with progressive SSc-ILD treated with 6 (n=24) or 12 (n=16) monthly i.v. pulses of cyclophosphamide (CPA, 500 mg/m^2), we observed a significant decrease in plasma S100A4 levels between the baseline samples (month 0) and blood drawn after 6 months of CPA treatment (76.3(52.9–98.6) vs. 73.2(44.4–98.6)ng/mL,p=0.013). Furthermore, baseline S100A4 levels predicted the change (m0-m6) in CRP and ESR levels after 6 months of CPA therapy (r=0.472,p=0.004;r=0.528,p=0.003, respectively).
Conclusion: We demonstrate that plasma S100A4 levels are significantly increased in SSc patients compared with healthy controls. Increased S100A4 is associated with the dcSSc subset, skin involvement, deteriorated parameters of interstitial lung disease and higher disease activity. In patients with progressive SSc-ILD, S100A4 declines after 6 months of cyclophosphamide therapy and predicts the systemic inflammatory response. These data further support our previous findings on the role of S100A4 as a regulator of TGF-β induced fibrosis in SSc.

AB0411 CHALLENGES IN THE MANAGEMENT OF MIXED CONNECTIVE TISSUE DISEASE: A RETROSPECTIVE ANALYSIS OF THE MCTD COHORT IN A TERTIARY REFERRAL CENTRE

A. Wanzenried[1], A. Garaiman[1], S. Jordan[1], O. Distler[1], B. Maurer[1]. [1]*University Hospital Zurich, Department of Rheumatology, Zürich, Switzerland*

Background: As a rare, complex, and heterogeneous disease, mixed connective tissue disease (MCTD) represents a challenge for clinical practice.
Objectives: We aimed to unravel potential pitfalls including correct referral diagnosis, fulfilment of diagnostic criteria, distinction from other CTDs, disease course and activity, and treatment modalities.
Methods: We analysed the prospectively collected MCTD cohort at our tertiary referral centre. The patients' medical histories were investigated for fulfilment of Sharp's (1), Kasukawa's (2), and Alarcón-Segovia's (3) diagnostic MCTD criteria. We defined overlap syndromes as simultaneous fulfilment of clinical as well as immunological criteria of two defined rheumatic diseases. Disease conversion was defined as emergence of new symptoms and autoantibodies consistent with another rheumatic disease. Remission was defined by simultaneous systemic lupus erythematosus disease activity index 2000 (SLEDAI-2 K) of 0 and European League Against Rheumatism scleroderma trial and research (EUSTAR) activity index <2.5. Disease phenotype and disease activity were monitored over time and all patients were evaluated for fulfilment of classification criteria of various connective tissue diseases.
Results: Out of 85 patients initially referred as MCTD, only one third fulfilled the diagnostic MCTD criteria. Most of the remaining patients had undifferentiated CTD (29%) or overlap syndromes (20%). In our final cohort of 33 MCTD patients, 6 (48%) also met the classification criteria of systemic sclerosis, 13 (39%) those of systemic lupus erythematosus (SLE), 6 (18%) those of rheumatoid arthritis, and 3 (9%) those of primary myositis. Over the median observation period of 4.6 (1.6, 9.9) years, only two patients (6%) underwent disease conversion from MCTD to SLE and no patient converted towards other diseases. The number of patients in remission increased from 6 (18%) to 15 (45%) due to introduction of immune modulatory treatment. Combination therapy was favoured in most cases (17 patients, 52%), whereas monotherapy was less frequent (12 patients, 36%), and only 4 (12%) patients remained without immune modulators until the end of the follow-up period. Hydroxychloroquine, prednisone, and methotrexate were the most frequently used medications in our cohort.

Conclusion: Our study showed a high risk for misdiagnosis for patients with MCTD. Phenotype conversion was a very rare event. As a multi-organ disease, MCTD required prolonged (combined) immunosuppressive therapy to achieve remission. The establishment of an international registry with longitudinal data from observational multi-centre cohorts might represent a first step to address the many unmet needs of MCTD.

AB0412 LIPID PROFILE IN IIM PATIENTS AND ITS ASSOCIATION WITH DISEASE ACTIVITY, DURATION, AND GLUCOCORTICOID TREATMENT

S. Oreska[1,2], H. Štorkánová[1,2], M. Špiritović[1,3], B. Heřmánková[3], M. Vrablik[4], K. Pavelka[1,2], L. Šenolt[1,2], H. Mann[1,2], J. Vencovský[1,2], M. Tomčík[1,2]. *[1]Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic*; *[2]1st Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic*; *[3]Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Prague, Czech Republic*; *[4]General University Hospital and 1st Faculty of Medicine, Charles University, 3rd Department of Internal Medicine, Prague, Czech Republic*

Background: Systemic inflammation, limited mobility, and glucocorticoid treatment in idiopathic inflammatory myopathies (IIM) can have a negative impact on intermediate metabolic pathways, especially on lipid metabolism.

Objectives: The aim of this study was to assess the differences in the lipid profile of IIM patients and healthy controls (HC) and the association with disease-specific features.

Methods: 133 patients with IIM (106 females; mean age 60.3; disease duration 2.2 years; DM 47 / PM 41 / IMNM 45) and 133 age-/sex-matched HC (106 females, mean age 60.2) were included. Patients with DM and PM fulfilled the Bohan/Peter criteria for PM/DM; patients with IMNM fulfilled the ENMC criteria. Levels of selected parameters of lipid metabolism were measured in sera. In IIM patients, disease activity, damage, and muscle involvement were evaluated (MITAX, MDI, MMT-8); comorbidities and current treatment were recorded. Data are presented as median.

Results: Several differences in disease activity, the dose of glucocorticoids, prevalence of comorbidities, and serum lipid levels were observed in IIM compared to HC, and among the three subtypes of IIM; the most significant changes were observed in IMNM. All the differences in lipid profile between IIM and HC, as well as the correlations of lipid profile parameters with disease-specific features in IIM patients, are demonstrated in the table 1.

Conclusion: We have observed significant alterations in serum lipid parameters in our IIM patients compared to healthy age-/sex-matched individuals. Differences were also found among the three subtypes of IIM. These alterations were associated with laboratory parameters of disease activity and the current dose of corticosteroids.

AB0413 HIGH-RESOLUTION COMPUTED TOMOGRAPHY FOR THE SCREENING, RE-SCREENING AND FOLLOW-UP OF SYSTEMIC SCLEROSIS RELATED INTERSTITIAL LUNG DISEASE: RESULTS OF A EUSTAR-SCTC SURVEY

C. Bruni[1,2], L. Chung[3], A. M. Hoffmann-Vold[4], S. Assassi[5], A. Gabrielli[6], D. Khanna[7], E. Bernstein[8], O. Distler[2]on behalf of European Scleroderma Trials and Reserach (EUSTAR) group and Sclerodermia Clinical Trial Consortium (SCTC).. *[1]Careggi University Hospital, Experimental and Clinical Medicine, Division of Rheumatology, Firenze, Italy*; *[2]University Hospital of Zürich, University of Zurich - Department of Rheumatology, Zürich, Switzerland*; *[3]Stanford University School of Medicine and Palo Alto VA Health Care System, Department of Medicine and Dermatology, Division of Immunology and Rheumatology, Palo Alto (CA), United States of America*; *[4]Oslo University hospital, Rheumatology, Oslo, Norway*; *[5]The University of Texas Health Science Center at Houston, Division of Rheumatology, Houston, United States of America*; *[6]Marche Polytechnic University Faculty of Medicine, Clinical and Molecular sciences, Ancona, Italy*; *[7]University of Michigan, Scleroderma Program, Ann Arbor, United States of America*; *[8]Columbia University Irving Medical Center, Division of Rheumatology, Department of Medicine, New York, United States of America*

Background: High-resolution computed tomography (HRCT) is the gold standard diagnostic test for Interstitial lung disease (ILD), a significant cause of morbidity and mortality in systemic sclerosis (SSc). Different algorithms have been proposed for the screening of SSc-ILD, including the use of pulmonary function tests (Forced Vital Capacity - FVC, Lung Diffusion of Carbone Monoxyde - DLCO). A prior survey reported that 50-66% of general rheumatologists and SSc experts ordered HRCT for ILD screening in newly diagnosed SSc patients (1).
Objectives: Given the recent availability of on-label treatment for SSc-ILD (2), the publication of consensus recommendations for the identification of SSc-ILD (3) and recent awareness programs for the use of HRCT to detect SSc-ILD, we aimed to re-evaluate the use of HRCT for screening, re-screening and follow-up of SSc-ILD.
Methods: An invitation was sent to the European Scleroderma Trials and Research (EUSTAR) and Scleroderma Clinical Trials Consortium (SCTC) members, also advertised through social media. Answers were recorded between Nov 25th and Dec 31st 2020. Questions were asked on the use of chest HRCT at baseline, the re-screening of patients with a negative baseline HRCT and the follow-up of HRCT positive SSc-ILD patients. When HRCT was not routinely requested, additional details were collected about the parameters guiding its use. The results of the survey were tested for association with geographical origin, medical specialty, working environment, SSc referral institute and scientific group membership of the responders, using Chi-squared test.
Results: 205/630 (32.5%) physicians replied to the survey. Participants were widely distributed in terms of geographical origin (130 Europe, 23 Asia, 23 North America, 31 other continents), medical specialty (156 rheumatology, 21 internal medicine, 14 clinical immunology, 14 other), working environment (176 University Hospital, 12 community hospital, 17 other), SSc dedicated clinic (179 referral and 26 non-referral) and scientific group membership (98 EUSTAR, 42 SCTC, 42 EUSTAR and SCTC, 23 not declared).
At SSc diagnosis, 95.7% of responders would perform HRCT: 66.7% as routine screening for ILD (67,4% of SSc referral and 62% for non-referral physicians) and 29% for diagnostic purposes (among the latter, if crackles on auscultation – 92.5%, FVC<80% predicted - 86.6%, FVC±DLCO relative decline reaching the current definition of ILD progression, 86.6% or dyspnea at rest/exercise - 85.1/83.3%).
During follow-up, 78.8% of responders would repeat an HRCT in baseline negative cases: 20.3% as a yearly routine screening and 64.5% for diagnostic aims (decision on the latter group was more frequently driven by FVC±DLCO relative decline indicative of ILD progression– 90.6%, new onset or worsening of dyspnoea at rest/exercise – 80.5/86.6%, new onset or worsening of lung crackles on auscultation – 82.6%).
Finally, 94.5% of responders would repeat a chest HRCT after SSc-ILD diagnosis: 36.8% as a yearly routine and 56.7% according to clinical evaluation (driven by new FVC±DLCO relative decline based ILD progression – 90.8%, new onset or worsening of dyspnoea at rest/exercise – 83.2/81.7%; 5.2% to evaluate treatment effects). We found no difference in the distribution of answers among groups.
Conclusion: The use of baseline HRCT for the screening of SSc-ILD has slightly increased in non-referral and remained stable in referral centers compared to previous surveys, indicating that the implementation of guidelines might be successful and awareness programs should be continued. In addition, we provide new data on use of HRCT in re-screening and follow-up. The development of validated algorithms to further support the appropriate application of HRCT at follow-up is highly needed.

AB0414 CROSS-CULTURAL ADAPTATION, CONVERGENT VALIDITY, AND RELIABILITY OF THE TURKISH VERSION OF THE COCHIN 17-ITEM SCLERODERMA FUNCTIONAL SCALE

N. G. Tore[1], D. Oskay[1], A. Avanoglu Guler[2], A. Tufan[2]. [1]*Gazi University, Physiotherapy and Rehabilitation, Ankara, Turkey*; [2]*Gazi University, Internal Medicine, Ankara, Turkey*

Background: The Cochin 17-item Scleroderma Functional (CSF-17) Scale is a patient-reported outcome measure evaluating activities and participation in patients with systemic sclerosis (SSc).
Objectives: The aim of the present study was to translate and cross-culturally adapt the CSF-17 into the Turkish language and investigate its convergent validity and reliability in Turkish-speaking patients with SSc.
Methods: The CSF-17 was cross-culturally adapted according to Beaton's guideline. Participants completed CSF-17 Scale, Scleroderma Health Assessment Questionnaire (SHAQ), Short Form-12 (SF-12) Health Survey and Hospital Anxiety and Depression Scale (HADS). Internal consistency and test-retest reliability were determined interpreting Cronbach's alpha and Intraclass Correlation Coefficient (ICC) values, respectively. Convergent validity was tested using Pearson's correlation coefficient.
Results: Fifty-six patients with SSc were enrolled in the study. Cronbach's alpha and ICC values of the CSF-17 total score were found to be as 0.963 and 0.958, respectively, indicating excellent reliability. As for the convergent validity, it was determined that CSF-17 total score has a good correlation with SHAQ. Correlations of subscales of CSF-17 with subscales of SF-12 and HADS ranged from poor to moderate (Table 1).
Conclusion: Tukish version of CSF-17 met the set criteria of reliability and convergent validity. According to the results of the analysis, it was concluded that the Turkish version of the CSF-17 is a reliable and valid tool for Turkish-speaking SSc patients.

AB0415

ANXIETY AND DEPRESSION IN SSc – ASSESSING FUNCTION, QUALITY OF LIFE AND GASTROINTESTINAL INVOLVEMENT

B. Samões[1], D. Fonseca[1], T. Beirão[1], M. Guerra[2], R. Vieira[1], F. Campos Costa[1], T. Videira[1], A. Aleixo[1], P. Pinto[1]. [1]*Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal*; [2]*Centro Hospitalar Universitário Cova da Beira, Rheumatology, Covilhã, Portugal*

Background: Systemic Sclerosis (SSc) is a chronic disease with multi-organ manifestations that may contribute to disability and low quality of life.[1] Therefore, anxiety and depression are more frequent in SSc patients than in general population.[2]
Objectives: To assess the prevalence of anxiety and depression in a SSc cohort and to evaluate its correlation with function, quality of life and assessment of gastrointestinal (GI) involvement scores.
Methods: A cross-sectional study was conducted evaluating a cohort of SSc patients. All patients answered to the Hospital Anxiety and Depression Scale (HADS) questionnaire. A cut-off score < 8 was considered normal. Health Assessment Questionnaire (HAQ), Scleroderma HAQ (SHAQ), 36-Item Short Form Health Survey (SF-36), EuroQol-5D (EQ-5D) and University Of California, Los Angeles, Scleroderma Clinical Trials Consortium Gastrointestinal Scale (UCLA SCTC GIT) 2.0 questionnaires were also obtained. Clinical data was obtained and analyzed.
Results: We included 20 patients, 17 females [n = 17 (85%)], median (min, max) age was 52.5 (28, 75) years-old. Regarding disease classification, 13 (65%) had limited SSc, 4 (20%) had diffuse SSc and 3 (15%) had early SSc. A score ≥ 8 was found in 14 (70%) patients on HADS-A [median (min, max) = 9 (2, 19)] and in 12 (60%) patients on HADS-D [median (min, max) = 8 (1, 15)]. Depressive patients had significantly worst scores on the measures of function, such as HAQ and lung and gastrointestinal involvements and patient global assessment of SHAQ, of quality of life, such as EQ-5D and physical functioning, role physical, bodily pain, vitality, social functioning and mental health domains of SF-36, and on the UCLA SCTC GIT 2.0 scale. Anxious patients had significantly worst scores on social functioning and mental health domains of SF-36 and on the UCLA SCTC GIT 2.0 scale (Table 1).
Conclusion: The prevalence of depression and anxiety on SSc patients is high and should not be neglected. Overall disability and multiorgan manifestations, particularly GI involvement, may contribute to a low quality of life and consequently to depression and anxiety.

THE IMPACT OF FATIGUE ON SYSTEMIC SCLEROSIS PATIENTS

B. Samões[1], D. Fonseca[1], T. Beirão[1], M. Guerra[2], R. Vieira[1], F. Campos Costa[1], T. Videira[1], A. Aleixo[1], P. Pinto[1]. [1]*Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal*; [2]*Centro Hospitalar Universitário Cova da Beira, Rheumatology, Covilhã, Portugal*

Background: Fatigue is a frequent and commonly undervalued symptom among rheumatic disease, including Systemic Sclerosis (SSc).[1,2]
Objectives: To determine the prevalence of severe fatigue in a SSc cohort and to evaluate how it correlates with disability, quality of life and mental illness.
Methods: A cross-sectional study was conducted evaluating a cohort of SSc patients. Fatigue was evaluated using Functional Assessment Chronic Illness Therapy (Fatigue) (FACIT-F) questionnaire. A value < 30 was defined as severe fatigue. Health Assessment Questionnaire (HAQ), Scleroderma HAQ (SHAQ), 36-Item Short Form Health Survey (SF-36), EuroQol-5D (EQ-5D) and Hospital Anxiety and Depression Scale (HADS) questionnaires were also filled. Clinical data was obtained and analysed.
Results: We included 20 patients, 17 females [n = 17 (85%)], median (min, max) age was 52.5 (28, 75) years-old. Regarding disease classification, 13 (65%) had limited SSc, 4 (20%) had diffuse SSc and 3 (15%) had early SSc. The median FACIT-F score was 34 (3, 48). The prevalence of severe fatigue was 40% (n = 8). Fatigue had a moderate negative correlation with HAQ (τ = -0.641; p < 0.001) and a weak negative correlation with lung (τ = -0.345; p = 0.039) and gastrointestinal (τ = -0.419; p = 0.011) involvements and with patient global assessment (τ = -0.325; p = 0.047) subtopics of SHAQ. A moderate positive correlation was found between FACIT-F and EQ-5D (τ =0.625; p < 0.001) and physical functioning (τ = 0.560; p = 0.001) and vitality (τ = 0.777; p < 0.001) domains of SF-36. The remaining SF-36 domains had a weak positive correlation with FACIT-F (Table 1). Regarding mental illness, there was a moderate negative correlation between FACIT-F and HADS-D (τ = -0.638; p < 0.001) and HADS-A (τ =-0.535; p = 0.001).
Conclusion: Severe fatigue is frequent among SSc patients. The greater the fatigue, the greater the disability, the lower the quality of life and the worse the score on the scale of depression and anxiety.

AB0417

COMPARATIVE ANALYSIS OF THE FREQUENCY OF GASTRO-INTESTINAL SYMPTOMS IN THE CLINICAL EVALUATION VERSUS WITH UCLA SCTC GIT 2.0

B. Samões[1], D. Fonseca[1], R. Vieira[1], T. Videira[1], A. Aleixo[1], P. Pinto[1], M. Guerra[2]. [1]*Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal*; [2]*Centro Hospitalar Universitário Cova da Beira, Rheumatology, Covilhã, Portugal*

Background: It is estimated that the gastrointestinal (GI) tract is involved in about 90% of patients with Systemic Sclerosis (SSc).[1] The UCLA Scleroderma Clinical Trials Consortium Gastrointestinal Tract 2.0 (UCLA SCTC GIT 2.0) questionnaire has been validated in several countries as a useful tool in the assessment of GI symptoms in this pathology.[2]
Objectives: To assess whether the application of the questionnaire has an added value in clinical practice by comparing the frequency of GI symptoms found during the clinical evaluation in the consultation vs. application of the questionnaire.
Methods: A cross-sectional study was carried out in a cohort of patients with SSc. During the consultation, patients were asked about the presence of GI symptoms and the UCLA SCTC GIT 2.0 questionnaire was handed in for completion. Subgroups that analyse reflux, bloating, dirt, diarrhea and constipation were evaluated and their responses were transformed into dichotomous variables (present/absent). Clinical data was obtained and analysed.
Results: 27 patients were included, most of them female [n = 23 (85.2%)], with an average age of 53.3 ± 13.5 years. All patients met the classification criteria of Leroy/Medsger of 2001 or ACR/EULAR of 2013: 14 (51.9%) had limited ES, 6 (22.2%) had Overlap Syndrome, 4 (14.8%) had diffuse ES and 3 (11.1%) had early SS. The prevalence of symptoms in all evaluated subgroups was higher in the questionnaire than in the clinical evaluation, with a statistically significant difference in the reflux subgroup [n = 16 (59.3%) vs. n = 13 (48.1%), p = 0.018]. In the remaining subgroups, this difference, although not statistically significant, was also found [abdominal distension n = 20 (74.2%) vs. n = 1 (3.7%), p = 1.0; dirt n = 2 (7.4%) vs. n = 0 (0%); diarrhea n = 22 (91.7%) vs. n = 3 (11.1%), p = 1.0; constipation n = 11 (40.7%) vs. n = 4 (14.8%), p = 0.273]. In the clinical evaluation, 12 patients said they were asymptomatic from the GI point of view, but all of them reported some GI symptoms when filling out the questionnaire. The subgroups in which the disagreement between the answers during the clinical evaluation and the filling out of the questionnaire were more frequent were distension [n = 19 (70.4%) and diarrhea [n = 19 (79.2%)].
Conclusion: The results of the present study reinforce the usefulness of the UCLA SCTC GIT 2.0 questionnaire, usually more applied in clinical trials, in clinical practice, concluding that it allows to find more GI symptoms in patients with SSc than the clinical evaluation in a consultation, this difference being statistically significant in the subgroup that evaluates reflux. The considerable difference found in the subgroups that assess symptoms of the low GI tract, such as diarrhea and constipation, although non statistical significant, may be due to the fact that the patient does not feel comfortable talking about it, a struggle that can be overcome with application of the questionnaire. On the other hand, this tool can also be a means of quantifying the severity of symptoms, monitoring their progress and making the consultation time more profitable. More studies with larger samples are needed to continue studying its role in clinical practice.

AB0418 SHEAR WAVE ELASTOGRAPHY FOR THE ASSESSMENT OF LIVER FIBROSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS AND SYSTEMIC SCLEROSIS/ PRIMARY BILIARY CHOLANGITIS OVERLAP COMPARED TO PRIMARY BILIARY CHOLANGITIS

V. Korendovych[1], J. G. Rademacher[1], G. Petzold[2], P. Korsten[1].
[1]Universitätsmedizin Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany; *[2]Universitätsmedizin Göttingen, Department of Gastroenterology, Gastrointestinal Oncology and Endocrinology, Göttingen, Germany*

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by vasculopathy and skin as well as organ fibrosis. The lungs, skin, and gastrointestinal care frequently affected. Primary biliary cholangitis (PBC) is an autoimmune disease of the liver associated with potential progression to liver fibrosis. More recently, these two disorders have been described as an overlapping entity, especially in patients with limited, anti-centromere (CENP-B) positive SSc (1). Here, we report the first results of a pilot study of shear wave elastography (SWE) in patients with SSc and SSc/PBC compared to PBC patients.
Objectives: To assess liver stiffness in patients with SSc, SSC/PBC overlap, and PBC with shear wave elastography.
Methods: We analyzed a sample of 10 SSc to 11 PBC patients. In all patients, a baseline US examination of the liver and liver stiffness measurement by 2D SWE were performed using a GE logiq E10 ultrasound machine. Normal values for SWE in healthy people have recently been published (2). Liver stiffness measurement was performed according to the recommendations of the manufacturer and the recommendations of the current "EFSUMB Guideline and Recommendation on the Clinical Use of Liver Elastography" (3). In addition, age, body mass index (BMI), and antibody profiles were assessed.
Results: Of 8 SSc patients without PBC, 6 were anti-CENPB pos., 1 had Scl70, and 1 Pm/Scl antibody. Median age was 59.5 (47-71). Median BMI was 23.1 (19.6-25). 1 patient had SSc/PBC overlap, 1 had hepatic steatosis. 1 was positive for CENP-B/AMA-M2 antibodies, the other patient was Scl70 positive. Median age of these 2 patients was 55.5 (55-56), BMI was 23.86 (20.9-26.8). 11 patients with PBC were positive for AMA-M2 antibodies, median age was 58 (41-78) years, BMI was 27.8 (15.8-50.3). The differences were not statistically different. Liver stiffness is expressed in kPa. Measurements had an interquartile range/median ratio <30%, indicating sufficient quality of the measurement. Liver stiffness was higher in patients with SSc/PBC overlap/hepatic steatosis (9.4±0.18, **p=0.0133) and PBC alone (7.359±2.51, **p=0.0163) compared to SSc alone (4.526±0.89 kPa). The results indicate that PBC is the main driver of liver stiffness in patients with SSc, and SSc alone may not necessarily lead to an increased liver stiffness (figure 1).

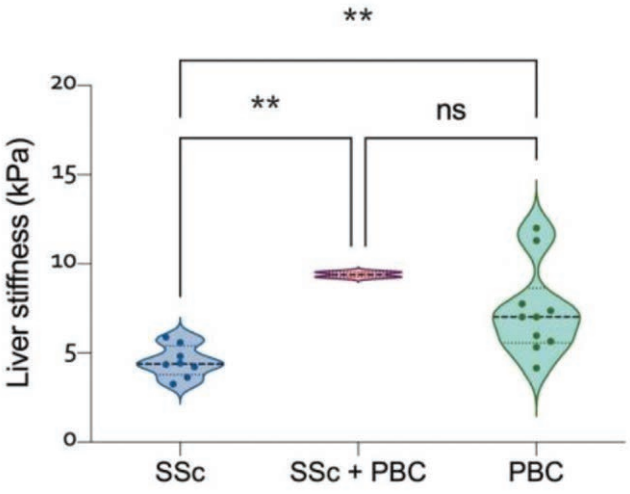

Figure 1.

Conclusion: Our results indicate that SWE is a useful tool in for the non-invasive assessment of liver stiffness in SSc and SSc/PBC overlap. We will further increase the sample size, especially of patients with SSc/PBC overlap. Of note, other liver diseases, such as hepatic steatosis, have to be kept in mind when SWE is performed as they may contribute to liver stiffness.

AB0419 ACCESS TO TREATMENT FOR RAYNAUD'S PHENOMENON AND DIGITAL ULCERS FOR PATIENTS WITH SYSTEMIC SCLEROSIS DOESN'T FOLLOW EULAR/EUSTAR GUIDELINES

L. Martin Calderon[1], M. Baron[2], J. Pope[3]on behalf of Canadian Scleroderma Research Group (CSRG). *[1]Western University, Medicine, London, Canada*;

[2]McGill University, Rheumatology, Montreal, Canada; [3]Western University, Rheumatology, London, Canada

Background: Patients with Raynaud's Phenomenon (RP) from systemic sclerosis (SSc) may experience severe complications. Digital ulcers (DUs), occur in approximately half the patients with SSc, and cause hand dysfunction, severe pain, and decreased quality of life. DUs lead to increased healthcare utilization and systemic economic burden through hospitalizations, ED visits, and ambulatory services (1). However, access to medications such as PDE5 inhibitors and prostacyclins that are within the EULAR/EUSTAR SSc guidelines (2) in a country with global health care but patchy pharmacare such as Canada has not been studied.

Objectives: The purpose of this study was to elucidate the access to treatment of medications for RP and DU in patients with SSc in Canadian provinces through identifying the provincial and private insurance coverage of PDE5 inhibitors (PDE5i) and prostanoids, the timelines and procedures of requesting these medications, and the process of administering IV prostanoids if required for patient care.

Methods: We designed an online survey and collected data through the Survey Monkey platform. The survey was administered to rheumatologists affiliated with the Canadian Scleroderma Research Group (CSRG) from December 2020 to January 2021. Responders were asked to report if the province or private insurance automatically provided PDE5i for patients with RP and DU or if a dedicated process was required to attain these medications. Additionally, responders were asked to describe the process of administering Iloprost, Epoprostenol and Alprostadil and the barriers inherent to their administration. Of note, there is no DIN number for Iloprost in Canada so every time it is used there must be an application to Health Canada.

Results: The survey was completed by 100% of CSRG researchers (17/17), representing 8 provinces in Canada. None of the provincial governments provided coverage for PDE5i without special requests that were adjudicated on a case by case basis with approximately half the provinces paying for PDE5i upon special request if a patient was eligible for provincial drug insurance (ex elderly, youths, low income families). Two provinces, Quebec and Saskatchewan, provided PDE5i "all the time". Whereas NS, MB, ON, BC, and AB provided them "sometimes"; NFLD provided them "never". Provincial governments and private insurance fulfilled requests "within 1 month" 62% of the time and the other requests took longer to be answered. Private insurance approved coverage with special request in AB, MB, QC, ON, and NS. Respondents described administration of IV prostanoids as "inconsistent", requiring "a lot of work", and that patients in most jurisdictions be admitted as in-patients for provinces to cover these medications.

Conclusion: Most jurisdiction within Canada do not provide coverage for PDE5i and the process to obtain access for patients is delayed, non-uniform, and often not approved. Intravenous prostanoid infusions are difficult to obtain and have system barriers. Advocacy and cost effectiveness data should be used to advocate for access to medications that are recommended within SSc recommendations.

CIRCULATING MONOCYTES HAVE DISTINCT PHYSICAL PROPERTIES THAT CORRELATE WITH DISEASE ACTIVITY AND SEVERITY AND PREDICT PROGRESSION IN SYSTEMIC SCLEROSIS

A. E. Matei[1], K. Markéta[2], A. H. Györfi[1], E. Boxberger[1], D. Soteriou[2], M. Papava[1], J. Muth[1], M. Kräter[2,3], G. Schett[1], J. Guck[2,3], J. H. W. Distler[1]. [1]Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology; 2Deutsches Zentrum für Immuntherapie (DZI), Erlangen, Germany; [2]Max Planck Institute for the Science of Light & Max-Planck-Zentrum für Physik und Medizin, Guck Division, Erlangen, Germany; [3]Center for Molecular and Cellular Bioengineering,Technische Universität Dresden, Biotechnology Center, Dresden, Germany

Background: Systemic sclerosis (SSc) is associated with high morbidity and is one of the autoimmune rheumatic diseases with the highest mortality. However, tools to evaluate disease activity, response to treatment or to predict disease progression are scarce. Dysregulated immune responses are major pathogenic players at the onset and in the progression of SSc. Recent evidence demonstrates that mechanical properties of circulating leukocytes reflect their states and functions, and during activation ensure their adaptation to the changing physical requirements (e.g. softening to extravasate and migrate in the tissues) (1). Real-time fluorescence and deformability cytometry (RT-FDC) is a novel technique that allows the identification of cells from a heterogenous population by marker expression, with their subsequent mechanical phenotyping in a high-throughput manner (2, 3).

Objectives: Here we characterized the physical properties of circulating immune cells in SSc patients, aiming to identify disease-related changes in their phenotypes, clinical correlates of these changes and their potential to predict disease progression.

Methods: 51 patients fulfilling the 2013 ACR/EULAR classification criteria for SSc and 17 age- and sex-matched healthy controls were included in the study. Blood was collected from the donors between 05.2019 and 10.2020. Peripheral blood mononuclear cells (PBMCs) were isolated and stained with antibodies against major circulating lymphoid ($CD8^+$, $CD4^+$ T cells, B cells, NK cells, NKT-like cells) and myeloid subpopulations (classical, intermediate and inflammatory monocytes, conventional dendritic cells and plasmacytoid dendritic cells). Each subpopulation was identified in RT-FDC by standard gating based on its marker expression and its area, deformation and apparent Young's modulus (a measure of cell stiffness) were determined. The analysis was conducted using a custom Python script. For the patients included, demographic and clinical data were collected at every visit. Correlations with clinical parameters were analyzed in R.

Results: All three subpopulations of monocytes identified by expression of HLA-DR, CD14 and/or CD16 had higher deformation and cross-sectional area in SSc patients as compared to healthy controls. From the SSc patients, monocytes had higher deformation and area in those with diffuse cutaneous SSc, extensive lung fibrosis and active disease as compared to those with limited cutaneous SSc, limited lung fibrosis and stable disease, respectively. Moreover, monocyte deformation and area significantly correlated with the EUSTAR activity index, with mRSS, with the extent of lung involvement on HR-CT (positive correlation), with DLCO and FVC (negative correlation). Follow-up data collected one year after the measurements showed that a higher monocyte deformation and cross-sectional area at baseline predicts future progression of lung disease, defined according to the INBUILD study, as well as future progression of skin fibrosis.

Conclusion: We demonstrated that circulating subsets of monocytes in SSc patients show an increase in deformation and cross-sectional area, that these changes correlate with current disease activity and can identify patients with high risk of future progression of skin or lung fibrosis. These changes might reflect an activated state of circulating monocytes in SSc that facilitate their tissue migration. Mechanical phenotyping of monocytes by RT-FDC might thus serve as a useful tool for clinical evaluation of SSc patients.

MANAGEMENT OF ULCERATION IN SYSTEMIC SCLEROSIS BY A SPECIALIST PODIATRY SERVICE; A CASE SERIES

L. Parker[1], R. Field2, J. Marks[1]. *[1]University Hospitals Dorset NHS Foundation Trust, Rheumatology Department, Christchurch, United Kingdom*; *[1]University Hospitals Dorset NHS Foundation Trust, Rheumatology Department, Christchurch, United Kingdom*

Background: Systemic sclerosis is a chronic disorder characterised by diffuse fibrosis and vascular abnormalities in the skin and major organs. Digital ulceration is a common complication, often resulting in patient disability. These ulcers can form through a variety of processes and management should be tailored according to aetiology. In Dorset, the specialist podiatry service has created a unique facility for optimal wound care in the setting of digital ulceration.
Objectives: In this case series, we outline podiatric management of 4 common causes of digital ulceration in systemic sclerosis.
Methods: Tissue ischaemia, infection, micro-trauma and calcinosis were identified as four major contributory factors resulting in ulceration or delayed wound healing. Four cases exemplifying management of each different contributory factor were identified and their case notes reviewed in order to extract clinically relevant data and images.
Results: Case 1 illustrates treatment of ischaemic tissue injury to promote earlier healing, using careful wound care, debridement under local anaesthetic and low-level laser therapy.
Case 2 illustrates the importance of identifying repeated micro-trauma as a contributing factor to non-healing ulceration.
Case 3 demonstrates how surgical debridement or removal of the subcutaneous calcinosis in an outpatient setting can be a useful adjunct in encouraging ulcer healing.
Case 4 illustrates the complexity of correctly identifying infection in the setting of ulceration, with prompt management promoting wound healing.
Conclusion: The pathophysiology of ischaemic tissue damage in scleroderma is complex and can reflect a broad range of vascular pathologies, often occurring concurrently[1] including vasospasm, macrovascular disease and microvascular vasculopathy, leading to digital ulceration. Rapid identification of which processes are driving the ischaemia is critical in targeting therapy to the affected individual. A local podiatry service with expertise in management of tissue -related complications of systemic sclerosis is invaluable in promoting wound healing and preventing further complications.

AB0422

DIAGNOSTIC PERFORMANCE OF THE ACR/EULAR 2013 CLASSIFICATION CRITERIA FOR SYSTEMIC SCLEROSIS IN A ROUTINE CARE SETTING

M. T. Schiaffino[1], B. Serrano-Benavente[2], M. DI Natale[1], K. Carpio[2], J. Martínez-Barrio[2], P. Sanchez-Mateos[1], J. M. Alvaro-Gracia[2], I. Castrejón Fernández[2]. *[1]Hospital Gregorio Marañón, Immunology, Madrid, Spain*; *[2]Hospital Gregorio Marañón, Rheumatology, Madrid, Spain*

Background: An ACR/EULAR task force released new criteria in 2013 to classify patients with systemic sclerosis (SSc).
Objectives: This study evaluates the diagnostic performance of these criteria in a multidisciplinary care setting.
Methods: Patients with an active follow-up in a Systemic Autoimmune Diseases Unit with a clinical diagnosis of SSc were matched by age and gender with consecutive patients referred to a capillaroscopy clinic. The classification criteria were tested on discrimination and diagnostic accuracy between both groups of patients defined as cases-SSc and controls. Receiver operating characteristic (ROC) curve and the area under the curve (AUC) was calculated for the global score to define the best cut off to classify the patients as having SSc.
Results: A total of 130 patients with SSc and 130 matched-controls were included in this analysis, 90% women, with a mean age of 61.5. Main diagnosis for the control groups were primary Raynaud´s phenomenon (34.6%), undiferentiated connective tissue disease (13.1%), and mixed connective tissue disease (9.2%). The 92% and 8% of patients in the SSc-cases and control groups met the 2013 ACR/ EULAR SSc classification criteria respectively. Sensitivity and specificity of the criteria were 81.5% and 93.7%, respectively. The best cut offs for the total score were 8 and 9, and the AUC (95%CI) was 0.962 (0.939-0.985). The individual items with a better discriminatory capacity were abnormal capillaroscopy, telangiectasia and anticentromere antibody positivity.

Table 1. Demographic data and ACR/ EULAR SSc classificacion criteria of SSC patients and controls.

	Cases-SSc, n= 130	Controls, n= 130	p
Age, mean (SD)	62.4 (16.0)	61.3 (14.8)	0.58
Female, %	90.5	90.8	0.92
Disease duration from onset of symptoms, mean (SD)	7.5 (6.4)	7.8 (6.7)	0.73
% Patients with individual ACR/EULAR 2013 Criteria Items			
Skin thickening	15.8	0.7	<0.001
Sclerodactily	45.5	6.1	<0.001
Puffy fingers	27.7	1.5	<0.001
Digital tip ulcers	30.2	5.3	<0.001
Fingertip pitting scars	18.8	4.6	0.001
Telangiectasia	51.5	6.1	<0.001
Abnormal nailfold capillaries	79.4	0.8	<0.001
Pulmonary Arterial Hypertension	16.3	3.8	0.001
Pulmonary fibrosis	18.8	6.2	0.002
Raynaud´s phenomenon	90.7	66.9	<0.001
Anticentromere antibody	60.7	18.9	<0.001
Scl70	12.0	0	<0.001
Total Score	**12.5 (4.8)**	**3.4 (2.9)**	**<0.0001**

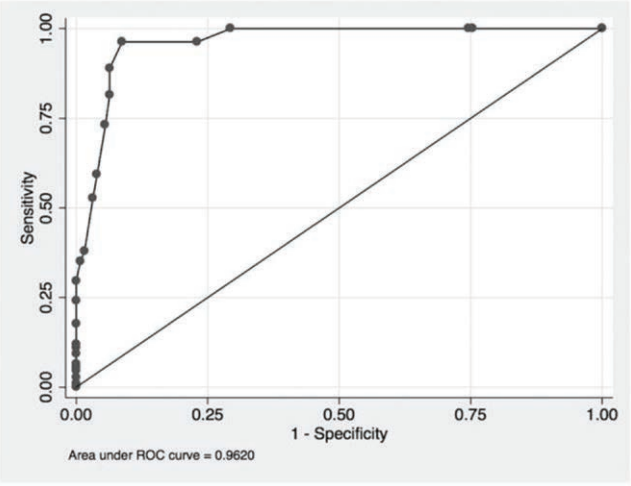

Figure 1. ROC curve for global score of the ACR/EULAR2013 SSc classification criteria.

Conclusion: The ACR/EULAR 2013 criteria showed good diagnostic properties in this cohort reflecting daily practice. Individual items showing the highest discriminatory capacity were abnormal capillaroscopy, telangiectasia and anticentromere antibody positivity.

AB0423

SAFETY AND TOLERABILITY OF RITUXIMAB IN THE TREATMENT OF SYSTEMIC SCLEROSIS: LONG-TERM FOLLOW-UP

L. Garzanova[1], L. P. Ananyeva[1], O. Koneva[1], O. Desinova[1], O. Ovsyannikova[1], M. Starovoytova[1], R. Shayakhmetova[1], S. Glukhova[2]. *[1]VA Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation*; *[2]VA Nasonova Research Institute of Rheumatology, Educational and Methodical Department, Moscow, Russian Federation*

Background: Rituximab (RTX) has been used for the treatment of systemic sclerosis (SSc) for a long time, but data on tolerance and long-term adverse events (AE) are insufficient.
Objectives: To assess the tolerability and safety of RTX in the patients (pts) with SSc in long-term prospective follow-up.
Methods: Data on the safety and tolerability of RTX were evaluated in 149 SSc pts who received at least one RTX infusion in a long-term open-label prospective observational study. The mean age was 48±13,5 years (17-74), women - 122 (82%), diffuse cutaneous subset of the disease had 52%, limited-37% and overlap-11%.

The mean disease duration was 6,4±5,8 years (0,5-30). The observation period was 12 years. All pts received prednisolone at a dose of 11,7±4,8mg/day, and 73 patients (49%) received immunosuppressants at inclusion. The indications for the appointment of RTX were ineffectiveness or impossibility of standard therapy and a severe course of the disease with high activity and unfavorable prognosis factors. AE were assessed and recorded by a physician at a hospital immediately after the infusion of RTX, then by patient reported outcome during the observation period. Severe AE were defined as those that required hospitalization for more than 24 hours, exacerbation of the disease requiring therapy, malignancies, life-threatening situations. All causes of death were considered, regardless of treatment.

Results: The mean follow-up period after the first infusion of RTX was 5,6±2,6 years [834,4 patient-years (PY)]. Pts received a mean of 3,4 courses of RTX (1–10). The cumulative mean dose of RTX was 3,2±2,4 gr (0,5-11). AE were reported in 77 patients (52%), the overall frequency of AE was 9,3/100 PY (95% Confidence Interval (CI) 8-11). The highest frequency of all AE was observed in the first 2-6 months after the first infusion of RTX, however these were mainly mild AE (71%). There was a decrease of AE in the follow-up period (3,4/100 PY, 95% CI 2,4-4,9 – at the period from 3 to 10 course of RTX). The overall incidence of serious AE was 2,22/100 PY (95% CI 1,4–3,5). The specter of serious AE included: pneumonia in 7 pts, infusion reactions in 5, as well as in one case: cerebral ischemia, acute pancreatitis, allergic pneumonitis, lymphoma of pharynx, purulent arthritis, lower limb vein thrombosis, pulmonary embolism of small arteries. The most frequent AE were infections (n=53), with no serious opportunistic infections reported. The overall incidence of all infections was 6,4/100 PY (95% CI 4,9-8,3), serious infections – 1,32/100 PY (95% CI 0,7-2,4). The level of immunoglobulin G during follow-up period decreased from 12,9±4,9 to 10,1±3,4g/l (p=0,0001), but remained within normal limits. Infusion reactions occurred in 15 pts (1,8/100 PY, 95% CI 1-3). Other AE were observed in 9 pts (6%) (1,1/100 PY, 95% CI 0,53-2,12). Sixteen deaths were recorded – 10,7% or 1,91/100 PY, 95% CI 1,2-3,1. In most cases, pts died from the progression of the major organ failure. The causes of death were: progression of the interstitial lung disease (ILD) in 4 pts, heart failure associated with SSc cardiomyopathy (2), renal crisis (4), pulmonary arterial hypertension and ILD (2), pneumonia (2), sepsis after tooth extraction (1), acute pulmonary embolism (1).

Conclusion: In our study, we considered the overall safety profile of RTX in SSc as favorable. It was similar to the AE profile in other autoimmune diseases treated with RTX. With an increase of the cumulative dose of RTX, there was no increase in AE. RTX could be considered as a relatively safe drug for the complex therapy of SSc when standard therapy is ineffective or impossible.

AB0424 **NUTRIENT DEFICIENCIES IN SYSTEMIC SCLEROSIS: A SYSTEMATIC REVIEW**

A. Nguyen[1], Z. Mcmahan[2], E. Volkmann[3]. [1]*David Geffen School of Medicine at UCLA, Medicine, Los Angeles, United States of America*; [2]*Johns Hopkins University School of Medicine, Medicine - Rheumatology, Baltimore, United States of America*; [3]*David Geffen School of Medicine at UCLA, Medicine - Rheumatology, Los Angeles, United States of America*

Background: Malnutrition is a critical concern in patients with systemic sclerosis (SSc).[1,2] However, the extent and types of nutrient deficiencies in SSc remain unclear.

Objectives: 1) To identify the nutrient deficiencies commonly reported in SSc; 2) To evaluate associations between specific nutrient deficiencies and SSc subtype and clinical manifestations.

Methods: We conducted a systematic review of all published reports on SSc and nutrition in PubMed from its inception to August 2020. Clinical trials, observational studies, and case series (with ≥20 cases) containing data on nutritional deficiency and SSc were included. We followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) for reporting our findings. Two reviewers (ADN and ERV) studied the titles and abstracts of all search results with pre-specified inclusion and exclusion criteria (Figure 1).

Results: Among 790 retrieved publications, 35 full-length articles and 3 abstracts met the inclusion criteria. Included studies took place across multiple geographic locations and included patients with both diffuse and limited cutaneous SSc. Vitamin D deficiency was the most commonly reported deficiency described in SSc, followed by vitamin B12, folate, selenium, zinc, and iron (Table 1). In addition, some small studies found deficiencies in thiamine, pyridoxine, alpha-tocopherol, and carotene. Interstitial lung disease was associated with vitamin D deficiency and elevated homocysteine (Hcy), while pulmonary hypertension was associated with elevated Hcy. Vitamin D deficiency was also associated with increased modified Rodnan skin score (mRSS) and increased risk of SSc-related organ involvement.

Conclusion: Nutrient deficiencies are common in SSc and are associated with specific SSc features. Routine screening for nutrient deficiencies may lead to early detection of malnutrition. Future studies are needed to understand how nutritional interventions affect patient outcomes in SSc.

AB0425 CLINICAL AND PATHOLOGICAL FEATURES OF BREAST CANCER IN PATIENTS WITH SYSTEMIC SCLEROSIS: PRELIMINARY DATA FROM THE SCLERO-BREAST STUDY

A. Spinella[1], A. Toss[2], C. Isca[2], C. Vacchi[1], A. Iannone[3], L. Magnani[4], P. Castrignanò[1], M. De Pinto[1], C. Laura[2], A. Maiorana[5], C. Salvarani[1,4], M. Dominici[2], D. Giuggioli[1]. *[1]University of Modena and Reggio Emilia, Scleroderma Unit, Rheumatology Unit, Modena, Italy*; *[2]University of Modena and Reggio Emilia, Department of Oncology and Hematology, Modena, Italy*; *[3]University of Modena and Reggio Emilia, Department of Surgery, Medicine, Dentistry and Morphological Sciences with Transplant Surgery, Oncology and Regenerative Medicine Relevance, Modena, Italy*; *[4]AUSL-IRCCS of Reggio Emilia, Italy, Rheumatolgy, Reggio Emilia, Italy*; *[5]University of Modena and Reggio Emilia, Pathology Unit, Modena, Italy*

Background: Systemic Sclerosis (SSc) is a rare and life-threatening connective tissue disease characterized by vascular dysfunction, specific autoimmune abnormalities and fibrosis of the skin and internal organs. Previous studies have shown a 1.5-fold increase in cancer risk in SSc patients compared with the general population, including breast cancer (BC). The relationship between BC and SSc has long been discussed but past research has been contradictory and inconclusive on this topic.
Objectives: The aim of our project was to analyze clinical and pathological characteristics of BC developed by SSc subjects and possible correlations with scleroderma features. Here we present the preliminary data from the Sclero-Breast study.
Methods: Our observational retrospective multicenter study enrolled 33 SSc women with a personal history of BC identified at two Rheumatology/SSc Units in the north of Italy between January 2017 and December 2019 (lc/dcSSc 23/9, 1 unknown; mean age at SSc onset 57 years, range 32-73). All patients underwent general and instrumental assessment: smoking habits; presence of skin ulcers, calcinosis, teleangectasia; presence of gastro-intestinal and kidney involvement; interstitial lung disease (at HR-CT); pulmonary function tests; ECG abnormalities; echocardiographic assessment of pulmonary arterial hypertension (PAH); videocapillaroscopic pattern; autoantibody profile; exposure to immunosuppressive and vasoactive therapies; status at last follow-up evaluation and cause of death. Clinical and pathological characteristics of BC were also evaluated: age at diagnosis; menopausal status; histotype; hormone receptor status; MIB1, HER2 expression; clinical and pathological stage at diagnosis; metastatic sites; type of loco-regional treatment (surgery and radiotherapy); type of systemic treatment (neoadjuvant/adjuvant chemotherapy and endocrine treatment); other cancers and time from diagnosis of the first disorder to the second one.
Results: A total of 54.5% of subjects developed BC before SSc (median interval of 5 years), whereas 45.5% of patients developed BC after SSc (median delay of 8 years). 54.5% of patients showed interstitial lung disease and the cause of death of the 6 deceased subjects was PAH. A significant association ($p<0.05$) was observed between the use of immunosuppressive therapy and diffuse skin extension, negative ACA, positive Anti-Scl-70 and interstitial lung disease, but not with BC status. 93.1% of patients were diagnosed with an early-stage tumor, 70.8% of invasive carcinomas with a low MIB-1, 8.3% with a tubular histotype, while 42.8% presented with a Luminal A-like tumor. 66.6% underwent breast conserving surgery and 55.5% RT after surgery. 40% of patients developed interstitial lung disease after RT and 20% dcSSc.
Conclusion: According to our preliminary data, SSc patients developed BC at good prognosis, suggesting a de-escalation strategy of cancer therapies. On these grounds, a proper screening is mandatory in order to allow for early cancer detection in SSc patients. Further investigations on larger numbers of patients are needed. First of all, they would further clarify the intriguing relationship between BC and SSc. Secondly, they would help to explore the common biological and molecular pathways at the basis of these two disorders, with the aim to improve BC diagnosis and prognosis and to personalize oncological targeted treatments in this subset of fragile patients.

AB0426 CANCER SCREENING IN IDIOPATHIC INFLAMMATORY MYOPATHIES: TEN YEARS EXPERIENCE FROM A SINGLE CENTER

E. Trallero-Araguás[1], A. Gil-Vila[2], X. Martínez-Gómez[3], M. Alvarado-Cardenas[2], M. Simo-Perdigó[4], J. Ros[5], I. Pinal-Fernandez[6], A. Selva-O'callaghan7. *[1]Vall d'Hebron Hospital, Rheumatology, BARCELONA, Spain*; *[2]Vall d'Hebron Hospital, Medicine, Barcelona, Spain*; *[3]Vall d'Hebron Hospital, Preventive Medicine and Epidemiology, Barcelona, Spain*; *[4]Vall d'Hebron Hospital, Nuclear Medicine, Barcelona, Spain*; *[5]Vall d'Hebron Hospital, Medical Oncology, Barcelona, Spain*; *[6]National Institutes of Health, Rheumatology, Bethesda, Spain*; *[2]Vall d'Hebron Hospital, Medicine, Barcelona, Spain*

Background: There is a well-recognized association between cancer and myositis, so cancer screening at diagnosis is recommended.
Objectives: We aim to report the results of our cancer screening strategy and to ascertain the reliability of using PET/CT to identify cancer-associated myositis (CAM) in a large cohort of patients with myositis from a single center over 10 years.
Methods: This retrospective observational study included all patients diagnosed with any type of myositis except for inclusion body myositis. Cancer screening strategy was individualized according to clinical and serological data, including PET/CT as the main test to detect occult cancer (OC). Procedures derived from a positive PET/CT were registered. Qualitative data expressed as percentages, and quantitative data as the median with the interquartile range were analyzed. A ROC curve was used to estimate the reliability of PET/CT for CAM diagnosis.
Results: Seventy-seven out of 131 patients underwent a PET/CT for OC screening. The performance of the PET/CT in patients with myositis at disease onset yielded an area under the curve ROC of 0.87 (0.73-0.97) for CAM diagnosis. Invasive procedures in 7 (9%) patients without a final diagnosis of cancer did not cause derived complications. Patients not evaluated for OC did not develop cancer after a median follow-up of 3.3 years (1.7-6.7).
Conclusion: Cancer screening strategy should be individualized. PET/CT at myositis onset seems to be an efficient approach to rule out CAM. This practice does not seem to significantly increase harm to patients related to the additional tests needed to clarify inconclusive results.

AB0427 ANTI-NOR90 AUTOANTIBODIES: FAVORABLE OR UNFAVORABLE PROGNOSIS?

C. Valero[1], J. P. Baldivieso[1], I. Llorente[1], E. F. Vicente-Rabaneda[1], L. Esparcia Pinedo.[2], R. Garcia de Vicuna[1], M. A. Alfranca[2], S. Castañeda[1]. *[1]Hospital Universitario de la Princesa, Rheumatology, Madrid, Spain*; *[2]Hospital Universitario de la Princesa, Immunology, Madrid, Spain*

Background: Anti-NOR 90 autoantibodies (anti-NOR90 Ab) are autoantibodies that target nucleolar transcription factor 1 or hUBF, involved in transcription of RNA polymerase I. These autoantibodies have been detected in 6.1% of patients with Systemic Sclerosis (SSc), but their clinical or prognostic significance has not been clearly defined. Anti-NOR90 Ab have been mostly associated with limited scleroderma with mild organ involvement and can also be found in other rheumatic diseases such as rheumatoid arthritis, systemic lupus erythematosus or Sjogren's syndrome.
Objectives: The aim of this study was to identify the main clinical characteristics of patients with positive anti-NOR90 in our Centre.
Methods: This is a retrospective, descriptive, cross-sectional study of all patients with positive anti-NOR90 Ab between January 2013 and December 2020 in a single center. Autoantibodies testing was performed using Euroimmun EUROLINE SSc profile IgG autoAb assay kit. Patient demographics, clinical characteristics, associated diagnoses, laboratory and immunological findings were collected.
Results: We identified a total of 26 patients with at least a positive value for anti-NOR90 Ab (Table 1). In most cases anti-NOR90 patients were ANA positive, predominantly with nucleolar pattern and coexisted with other SSc autoantibodies. 12 patients had rheumatic diseases and two had SSc, both with limited cutaneous SSc and absence of organ involvement. 14 patients had no definite diagnosis. Clinical features of anti-NOR90 patients are represented in Figure 1. Five patients presented Raynaud's phenomenon, two cases with pathological nailfold capillaroscopy and one patient had SSc. There was no patient with skin ulcers, calcinosis, interstitial lung disease or pulmonary hypertension. Four patients had gastroesophageal reflux disease and one patient presented antral vascular ectasia. Six patients developed some neoplasm.

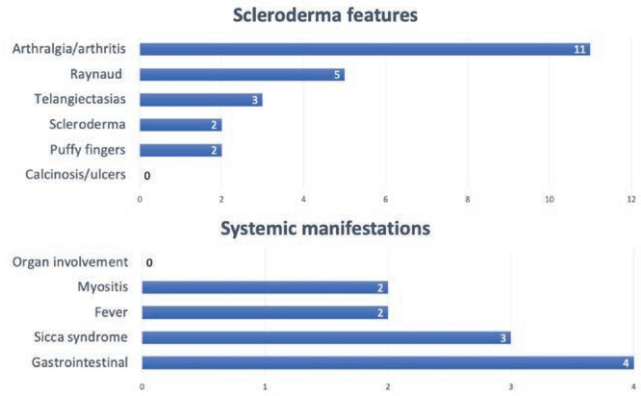

Figure 1. Clinical characteristics of anti-NOR90 Ab patients.

Conclusion: In our case series anti-NOR90 Ab were associated with multiple rheumatic diseases with heterogeneity of clinical manifestations. We did not observe a further progression to SSc or presence of organ involvement or severe scleroderma, so these autoantibodies could be related with a favorable prognosis. In contrast with previous reports, a striking association with cancer has been detected in our population.

Table 1. Demographic characteristics and main diagnoses of anti-NOR90 positive patients.

Characteristics	Total Anti-NOR90: 26 patients
Sex, n	19 women/ 7 men
Age, mean (years)	58,9 IQR [46,3-72,2]

AB0428

ULTRASOUND ASSESSED NAIL BED THICKNESS AS AN EARLY SCREENING MARKER FOR INTERSTITIAL LUNG DISEASE IN SCLERODERMA

P. Dekate[1], S. Vodnala[2], R. Dudam3. [1]*Hyderabad Rheumatology Center, Rheumatology, Hyderabad, India*; [2]*Hyderabad Rheumatology Center, Radiology, Hyderabad, India*; [1]*Hyderabad Rheumatology Center, Rheumatology, Hyderabad, India*

Background: Interstitial lung disease (ILD) is the most frequent pulmonary manifestation of scleroderma and is seen in 80% of the patients with diffuse and in 20% of the limited forms of scleroderma.[1] Even seen in early stages of the disease with varying degrees of severity, it does not correlate with the clinical manifestations.[2] Hence, it is difficult to select patients for ILD screening based on symptoms. Digital clubbing is a common feature of ILD and has been associated with poor prognosis.[3]
Objectives: To assess the ultrasound measured nail bed thickness (NBT) in cases of scleroderma as a screening marker to detect ILD and its inter-digital variation.

Methods: A prospective observational study involving 15 patients each of scleroderma with ILD, without ILD and controls visiting our clinic from August 2020 to December 2020 were included. The presence of ILD was confirmed by HRCT thorax. Patients with a history of smoking, alcohol intake or pre-existing cardio-respiratory illnesses were excluded. Ultrasound assessed NBT was calculated using Philips affiniti 70 eL18-4 probe. A total of 436 nail beds were recorded (142 of scleroderma with ILD, 144 of scleroderma without ILD and 150 of control group). 14 nails were excluded due to trauma. Statistical analysis was done using ANOVA test. Results were considered significant at p value < 0.05.
Results: On comparing nail bed thickness among scleroderma with ILD, scleroderma without ILD and control groups, the difference in NBT was statistically significant in all the three groups, except for left 1st finger (Table 1). NBT's among scleroderma patients without ILD and control group did not show significant difference between the two groups. Whereas, when scleroderma patients with ILD were compared with control group, statistical significance were found (p<0.001) in all the fingers of both the hands, except 1st and 2nd finger of left and right hand respectively. On comparing NBT's among individual fingers of right hand in patients of scleroderma with ILD and without ILD, a statistically significant difference among the two groups in 2nd (p =0.002), 4th (p=0.009) and 5th finger (p=<0.001) was noted. In left hand, same fingers had statistically significant difference (p<0.001).
Conclusion: Patients of scleroderma with ILD are predisposed for an increase in the NBT, which can be detected using ultrasound. Thus, an increased NBT may have a role in early screening for the detection of ILD in scleroderma patients. Further studies with large patient data should be done to look at ultrasound assessed NBT as it may be utilized as a marker for ILD in scleroderma, as a widely available and an inexpensive tool.

AB0429 BELFAST TRUST EXPERIENCE OF IDIOPATHIC INFLAMMATORY MYOPATHIES

S. Loughrey[1], A. Herron[1], M. Mchenry[1], E. Ball[1]. [1]*Musgrave Park Hospital, Rheumatology, Belfast, United Kingdom*

Background: The Idiopathic Inflammatory Myopathies (IIM) are a heterogeneous group of diseases where there is a growing field of knowledge and experience. Presentation is usually of onset of muscle weakness in combination with typical muscle biopsy findings and specific serum autoantibodies. There is a significant morbidity and mortality associated with IIM, due to its potential systemic nature, associated malignancy risk and side effects of immunosuppressive therapy1. There is no published guideline on management of IIM, with treatment limited to best practice experience.
Objectives: Review Belfast Trust experience of Adult IIM from 2009-2020
Methods: Review of Electronic Records of 18 patients diagnosed with IIM between 2009-2020
Results: 18 patients diagnosed with IIM. Mean age at diagnosis is 64, with age range of 46-83. Mean duration of treatment is 4 years. 14 patients are in remission, 2 have active disease and 2 are deceased with cause of death unrelated to IIM.
Muscle Biopsy was performed in 17 patients. 11 patients biopsies were diagnostic and 6 were supportive. Of the patients with DM who did not have diagnostic muscle biopsies, all 3 had diagnostic skin biopsies. Of 6 patients with a negative ANA, 5 had a muscle biopsy performed (diagnostic in 4 patients and supportive in 1 patient.)
Conclusion: Extended myositis panels have only readily become available in the Belfast Trust in recent years. This has enhanced patients phenotypes and vigilance for extra-muscular complications. There is a recognised elevated risk of cancer in patients with IIM2. In our patients, with a mean disease duration of 4 years, none have developed malignancy. All of our patients had a tissue sample obtained, either muscle or skin. In the Belfast Trust, Rheumatologists perform muscle biopsies and all of the samples contributed to diagnosis. A limitation of diagnostic tests is restricted access to EMGs. We introduced a variety of DMARDs to limit exposure to steroids. 50% of our patients are in remission and off steroids. The only biologic we used was Rituximab. In contrast to other rheumatological conditions, there is no published protocol for administration of Rituximab in IIM. For patients with refractory disease, IVIG was used in the short term to allow for introduction of alternative immunosuppressants to maintain remission. This review highlights the complex nature of this group of diseases, and our experience with a variety of treatment options. We have diagnosed and treated 18 patients, and although we have experience with the medications used to treat IMM further work is needed to establish evidence based treatment.

AB0430 CONTRIBUTION OF SCLERODERMA/MYOSITIS-RELATED ANTIBODIES DETECTED BY IMMUNOBLOT TO THE DIAGNOSIS OF SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES IN 134 PATIENTS FROM A SINGLE REFERRAL CENTER

D. Prieto-Peña[1], B. Atienza-Mateo[1], M. A. González-Gay[1], R. Blanco[1], M. Lopez-Hoyos[2]. [1]*Hospital Universitario Marques de Valdecilla, IDIVAL, Rheumatology, Santander, Spain*; [2]*Hospital Universitario Marques de Valdecilla, IDIVAL, Immunology, Santander, Spain*

Background: Immunoblot assays are increasingly used in clinical practice as part of the diagnostic armamentarium of systemic autoimmune rheumatic diseases (SARDs).
Objectives: To assess the contribution of an extended scleroderma/myositis-related antibodies (Ab) determination by immunoblot to the diagnosis of patients with SARDs.
Methods: We reviewed all medical records of patients with positive scleroderma/myositis-related Ab line blot determinations (Euroimmune AG, Lübeck, Germany) in our center from November 2017 to September 2020. These assays were requested due to high suspicion of SARDs in patients presenting with non-specific symptoms.
Results: 134 patients (37men/97women; mean age 59.6 ± 14.8 years) were positive for at least 1 Ab, 25 of them were positive for 2 Abs. Main clinical features at the time of immunoblot requests were: arthralgia/arthritis (n=88), Raynaud's phenomenon (n=59), rash (n=27), sicca syndrome (n=14.9%), myopathy (n=18). During follow-up, 28 patients were diagnosed with undifferentiated connective tissue disease (UCTD), 26 scleroderma, 23 overlap myositis, 18 interstitial pneumonia with autoimmune features (IPAF), 8 other inflammatory diseases, 8 Sjögren's syndrome, 7 systemic lupus erythematosus, 5 dermatomyositis, 1 necrotizing myositis. In 10 patients the diagnosis of SARD was finally ruled out (Figure 1). Interstitial lung disease (ILD) was present in 50 patients, being particularly frequent in those with anti-PL12, anti-PL7 and anti-MDA5 Abs. Cancer was detected in 9 (6.7%) patients, 6 of them were anti-Ro52 + (Table 1).
Conclusion: Immunoblot assays are of great help in the diagnosis of patients with high clinical suspicion of SARDs. While some Abs, such as anti-Ro52, anti-Ku and anti-PMScl75/100, remain to be nonspecific, other Abs including anti-PL12, anti-PL7 or anti-MDA5 are particularly helpful in detecting SARDs patients with associated ILD.

EXPLORING THE UTILITY OF THE AMERICAN COLLEGE OF RHEUMATOLOGY (ACR) CRISS IN PATIENTS WITH DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS

F. Del Galdo[1], O. Distler[2], C. Denton[3], Y. Allanore[4], D. Wachtlin[5], M. Alves[6], D. Khanna[7]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine and NIHR Biomedical Research Centre, Leeds, United Kingdom*; *[2]University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland*; *[3]University College London Division of Medicine, Centre for Rheumatology and Connective Tissue Diseases, London, United Kingdom*; *[4]Descartes University, APHP, Cochin Hospital, Department of Rheumatology A, Paris, France*; *[5]Boehringer Ingelheim Pharma GmbH & Co. KG, Biostatistics + Data Sciences, Ingelheim, Germany*; *[6]Boehringer Ingelheim International GmbH, TA Inflammation Med, Ingelheim, Germany*; *[7]University of Michigan, Department of Medicine, Ann Arbor, United States of America*

Background: The ACR Composite Response Index in diffuse cutaneous Systemic Sclerosis (CRISS) was developed to measure the probability of improvement in response to treatment in patients with early diffuse cutaneous SSc (dcSSc), accounting for new/worsening cardiopulmonary involvement and/or renal crisis, and changes in modified Rodnan skin score, forced vital capacity, health assessment questionnaire disability index, and patient's and physician's global impressions. In patients with SSc-ILD, treatment response may be reflected as slower progression, stabilisation or improvement.

Objectives: Using data from patients with dcSSc and ILD in the placebo group of the SENSCIS trial, we analysed the probability of improvement using the ACR CRISS score at week 52. We also evaluated whether the CRISS numerator could provide information on the spectrum of responses in this patient population.

Methods: The SENSCIS trial enrolled subjects with SSc-ILD with onset of first non-Raynaud symptom ≤7 years before screening, FVC ≥40% predicted, and fibrotic ILD ≥10% extent on an HRCT scan. Subjects on prednisone ≤10 mg/day (or equivalent) and/or stable therapy with mycophenolate or methotrexate were allowed to participate. Subjects were randomised to receive nintedanib or placebo. Subjects were not randomised by use of mycophenolate. In patients randomised to receive placebo who had dcSSc and/or mRSS >15 at baseline, we analysed the ACR CRISS and its numerator at week 52 in subgroups by use of mycophenolate at baseline. Analyses were exploratory and descriptive.

Results: Of 117 analysed subjects in the placebo group who had dcSSc and/or mRSS >15 at baseline, 60 (51.3%) were taking mycophenolate at baseline. Compared with patients not taking mycophenolate at baseline, those taking mycophenolate had a lower mean age (48.4 [SD 11.8] vs 53.1 [13.4] years), lower mean FVC % predicted (68.8 [17.0] vs 73.0 [14.6]), and a greater proportion were female (76.7% vs 71.9%); median time since first onset of non-Raynaud symptom was similar (3.9 vs 4.5 years, respectively) as was mean (SD) mRSS (16.5 [7.7] vs 15.9 [8.0], respectively). One patient (taking mycophenolate at baseline) had limited cutaneous SSc. At week 52, median (Q1, Q3) ACR CRISS score was 0.036 (0.001, 0.601) in subjects taking mycophenolate and 0.002 (0.000, 0.112) in subjects not taking mycophenolate at baseline, and mean (SD) ACR CRISS score was 0.28 (0.37) in subjects taking mycophenolate and 0.16 (0.31) in subjects not taking mycophenolate at baseline (Figure 1). In these groups, respectively, 25.0% and 14.0% of subjects had CRISS score >0.6 (considered improved) at week 52. The CRISS numerator provided a broader distribution of response values, but was not informative in this patient population.

Conclusion: In exploratory analyses, among subjects with dcSSc and ILD who received placebo in the SENSCIS trial, the proportion considered improved at week 52 based on ACR CRISS score was numerically greater in patients taking than not taking mycophenolate at baseline. There remains a need for composite scores that provide better interpretation of the magnitude of response in patients with SSc.

Figure. Box-and-whisker plot of CRISS score at week 52 in subjects with SSc-ILD with dcSSc and/or mRSS >15 at baseline in the placebo group of the SENSCIS trial by use of mycophenolate at baseline

SURVIVAL AND PROGNOSIS IN SYSTEMIC SCLEROSIS: RESULTS FROM A SINGLE-CENTER COHORT

M. Rojas-Giménez[1], R. Ortega Castro[1], C. López-Medina[1], J. Calvo Gutierrez[1], M. Á. Aguirre-Zamorano[1], A. Escudero Contreras[1]. *[1]Reina Sofía University Hospital, Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC), Córdoba University (UCO), Córdoba, Spain., Cordoba, Spain*

Objectives: To analyze survival, causes of death, and risk factors associated with mortality in a cohort of patients with Systemic Sclerosis (SSc) at a single center

Methods: We performed a retrospective observational study of a cohort of patients with SSc undergoing follow-up during 2012 and until August 2020. We used the Kaplan-Meier method to estimate survival from onset of symptoms and multivariate Cox regression analysis to obtain independent risk factors associated with mortality

Results: The study population included 85 patients (women, 85.8%; mean age at diagnosis, 64.4 ± 12.7 years). A total of 19 patients (22.6%) died (table 1). Of these 11 (57.9%) died of a cause related to the disease itself (interstitial lung disease [ILD], 5 (26.3%); pulmonary hypertension, 2 (10.5%); or a combination of both, 3 (15.8%). The main cause of non–SSc-related death was cancer (21.1%). Survival rates at 5, 10, and 20 years were 98%, 92%, and 75%, respectively. Survival was statistically significantly poorer for the absence of ACA, the presence of antitopoisomerase I antibodies, proximal skin thickening, pulmonary hypertension, ILD, cancer and the diffuse subtype. The multivariate analysis performed to determine which factors were independently associated with mortality confirmed that older age at diagnosis of the disease, lower FVC in spirometry at diagnosis of ILD, and proximal skin thickening were associated with greater mortality

Table 1. Clinical and immunological characteristics of patients who died and patients who lived

Olsen[10], M. E. Pesonen[10], Ø. Molberg[1], A. M. Hoffmann-Vold[1]. *[1]Oslo University Hospital, Department of Rheumatology, Oslo, Norway*; *[2]Oslo University Hospital, Department of Gastroenterology, Oslo, Norway*; *[3]University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland*; *[4]University of Michigan, Division of Rheumatology, Ann Arbor, United States of America*; *[5]University of California, Division of Rheumatology, Los Angeles, United States of America*; *[6]St. Olavs hospital, Department of Rheumatology, Trondheim, Norway*; *[7]University of Bergen, Department of Clinical Science, Bergen, Norway*; *[8]Haukeland University Hospital, Department of Rheumatology, Bergen, Norway*; *[9]University Hospital of Northern Norway, Department of Rheumatology, Tromsø, Norway*; *[10]Oslo University Hospital Research Support Services, Oslo Centre for Biostatistics and Epidemiology (OCBE), Oslo, Norway*

Background: Gastro-intestinal tract (GIT) symptoms is highly prevalent in patients with systemic sclerosis (SSc). The GIT-symptoms impact on the quality of life is significant, and available treatment alternatives are limited. Recently published articles show associations between gut microbiota changes and GIT-symptoms in SSc. We, therefore, performed a successful feasibility trial on faecal microbiota transplantation (FMT) in SSc patients using the single-donor bacterial culture "Anaerobic Cultivated Human Intestinal Microbiome (ACHIM)". Based on the promising results from the feasibility trial, we aim to evaluate the safety and efficacy of FMT by ACHIM in SSc patients. (NCT04300426)

Objectives: To design a clinical trial that explores the safety and efficacy of FMT in SSc patients.

Methods: The ReSScue trial is a phase II, placebo-controlled, randomised 20-week, multicentre trial. The trial comprises three parts. In the induction phase (A1) lasting from week 0 to week 12, participants are randomised 1:1 to repeat infusions of 30 ml ACHIM or placebo at week 0 and 2 by gastro-duodenoscopy. In the maintenance phase (A2), all study participants will receive 30 ml ACHIM at week 12 and are followed continued blinded until week 20.

For longer-term data on intervention effects and safety, the participant will be followed for a maximum extended monitoring period of 16 weeks (part B).

The primary endpoint is change from baseline to week 12 in UCLA GIT scores on bloating or diarrhoea, depending on the worst symptom at baseline evaluated separately for each patient. Secondary endpoints are changes in UCLA GIT scores (bloating, diarrhoea and total) and safety measures.

Results: We aim to enrol 70 SSc patients based on the power calculations for the primary endpoint "change in worst symptom from baseline to week 12", with a considered drop out rate of 10%. This number of patients is expected to give a power of 80% of detecting a change in mean (p=0.05, two-sided) of -5.0 (or higher) if the relating standard deviation is 0.70 or lower. The patient screening started in September 2020, and we expect the study to be completed in May 2022.

Conclusion: The ReSScue-study is to our knowledge the first FMT-study in SSc. This trial will assess the safety and efficacy of FMT in SSc patients with lower GI-symptoms, possibly leading to a novel treatment approach in SSc patients.

AB0434 VITAMIN D IN SYSTEMIC SCLEROSIS PATIENTS

M. M. Sirufo[1], F. De Pietro[1], M. Raggiunti[1], M. De Martinis[1], L. Ginaldi[1]. *[1]Department of Life, Health & Environmental Sciences, University of L'Aquila, Italy; Allergology and Clinical Immunology Unit, AUSL 04, Teramo, Italy., Department of Life, Health & Environmental Sciences, University of L'Aquila, Italy; Allergology and Clinical Immunology Unit, AUSL 04, Teramo, Italy., Teramo, Italy*

Background: Systemic Sclerosis (SSc) is a generalized and systemic autoimmune disease that affects the connective tissue of the skin and internal organs, especially kidneys, heart and lungs [1].
Objectives: Numerous data from recent literature confirm the regulatory action of vitamin D on the immune system and, therefore, how a deficit of this micronutrient can lead to alterations in the immune response, as is known to happen in many allergic and autoimmune diseases [2]. We studied the association between vitamin D levels and SSc, evaluating their correlation with the characteristic manifestations of the pathology.
Methods: We dosed the serum levels of 25 hydroxy-vitamin D in 42 patients with SSc (average age 64.63 +/-7.33) and 40 healthy controls comparable for sex and age. The diagnosis of SSc was formulated in accordance to 2013 ACR/EULAR criteria. None of the subjects involved in the study took vitamin D products.
Results: Patients' vitamin D levels (26.22+/-9.82 ng/ml), although they tended to be lower than controls (27.80 +/- 16.53 ng/ml), showed no significant decrease. In patients with pulmonary fibrosis, vitamin D levels were 23.28 +/- 12.30 lower than in patients with trophic ulcers and compared to patients without complications 26.07 +/- 9.92, although with not statistically significant values. No statistically significant difference was found between vitamin D levels in patients with trophic ulcers compared to controls without complications.
Conclusion: According to the studies in the literature, in our sample, vitamin D deficiency was therefore greater in patients with SSc, especially with pulmonary fibrosis, than in controls [3,4]. Vitamin D levels in diffused-type SSc patients were significantly lower than those in limited-type SSc patients. Further studies are needed to clarify the role that vitamin D deficiency plays in SSc, but lower vitamin D levels in these patients may suggest the need to monitor blood levels of vitamin D and supplement it appropriately.

AB0435 CAPILAROSCOPY DOES NOT PREDICT CARDIOVASCULAR EVENTS IN PATIENTS WITH SYSTEMIC SCLEROSIS: A RETROSPECTIVE STUDY

I. Coman[1], L. Groseanu[1,2], V. Bojinca[1,2], D. Mazilu[1,2], S. Daia[1,2], I. Saulescu[1,2], C. L. Constantinescu[1,2], M. Abobului[1,2], A. Borangiu[1,2], M. M. Negru[1,2], C. Cobilinschi[1,2], M. Duna[1], D. Predeteanu[1,2], F. Berghea[1,2], A. Balanescu[1,2], R. Ionescu[1,2]. *[1]Saint Mary Hospital, Rheumatology, Bucureşti, Romania*; *[2]Carol Davila University of Medicine and Pharmacy, Medicine, Bucureşti, Romania*

Background: Systemic sclerosis is associated with increased risk of cardiovascular disease (CVD) (1) and studies using MRI suggest that microvascular disease has an important role (2). Capillaroscopy is a non invasive and safe technique that assesses peripheral microvascular damage (3).
Objectives: The objective of this study was to evaluate the predictive value of the capillaroscopy in relation to major adverse cardiovascular events (MACE).
Methods: Retrospective study with three timepoints (at baseline, at 5 and 10 years) including patients with scleroderma from EUSTAR center 096. Data were collected from the registry and observation papers. We performed capillaroscopy to all patients at the time of inclusion in the EUSTAR registry (2004) and at baseline (2009). Also, CV risk scores were calculated at baseline and were reassessed at 5 and at 10 years using the SCORE calculator. Risk score was considered low if was between 0 and 2, moderate 3-9 and high >10. The relation between capillaroscopy and MACE was tested in using bivariate regression.
Results: Of 22 patients, mean (standard deviation (SD)) age was 43.1 (11.5), all patients were females, mean (SD) disease duration was 5.4 (4.5). During the 10 years of follow up, 5 (22.7) patients had been lost of follow up and 8 (36.4) patients had died. Only 9 (40.9) patients completed the 10 year follow up.
At the time of inclusion in the EUSTAR, one patient showed early scleroderma pattern at capilaroscopy, 15 had active pattern and 6 patients had late pattern. Capillaroscopic scoring showed 2 (9.1) patients with disarranged (<50%) aspect, 5 (22.7) patietns with disarranged (>50%) aspect, 4 (18.2) patients with local paucity, 10 (45.5) patients with enlarged loop bordering local paucity and 1 patient (4.5) with complete paucity.
Capilaroscopy at baseline showed active pattern in 4 patients and late pattern in 18 patients. Thus, 13 (59.1) of patients had a progression of the disease at capilaroscopy before follow up.
At baseline, 14 (63.6) patients had traditional CV risk factors. Cardiovascular risk scores found 21 (95.5) patients with a low risk score and 1 (4.5) patient with a moderate risk score. At 5 years 11 (0.5) patients had a low risk score and 1 (4.5) patient had moderate risk score and at 10 years, 5 (22.7) and 2 (9) patients had low and moderate risk scores, respectively. We found 6.2 MACE/100 patient-year and 5.5 deaths/100 patient-year.
Capillaroscopy (p=0.684), disease progression on capillaroscopy (p=0.781), capillaroscopic scoring (p=0.92) and CV risk score (p=0.98) were not predictive factors of MACE.
Conclusion: Patients with systemic sclerosis are at high risk of MACE and traditional CV risk scores underestimate this risk. Changes/progression on capilaroscopy is not predictive for MACE. However, this hypothesis needs to be tested on a bigger cohort.

AB0436 OUTCOMES OF DOSE-REDUCTION OR DISCONTINUATION OF TOCILIZUMAB IN PATIENTS WITH EARLY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS

Y. Isomura[1], Y. Yamasaki[1], Y. Shirai[1], M. Kuwana[1]. *[1]Nippon Medical School, Graduate School of Medicine, Department of Allergy and Rheumatology, Tokyo, Japan*

Background: Potential efficacy and favorable safety profiles of tocilizumab (TCZ) have been demonstrated in patients with diffuse cutaneous systemic sclerosis (dcSSc) [1, 2]. However, clinical outcomes after dose-reduction or discontinuation of TCZ due to an improvement of skin thickness remain unclear.
Objectives: To investigate the clinical outcomes after dose-reduction or discontinuation of TCZ in patients with dcSSc in a real-world setting.
Methods: This is a single-center, retrospective, observational study using a database of consecutive SSc patients who visited our center between April 2014 and October 2020. For this study, we selected eligible patients from the database based on the following criteria: patients who (i) fulfilled the ACR/EULAR classification criteria, (ii) were classified as having dcSSc, (iii) had been treated with TCZ for at least 6 months, and (iv) were follow-up >6 months after TCZ introduction. Clinical information including demographic and clinical characteristics at TCZ introduction; dosing, administration route, and adherence of TCZ; and serial clinical parameters

(modified Rondan total skin thickness score [mRSS], and percent predicted forced vital capacity [%FVC]), safety profiles, and outcomes after TCZ introduction regardless of TCZ continuation were extracted from the database.

Results: Of 404 patients enrolled in the database, 13 dcSSc patients were eligible for this study. Baseline characteristics included a mean age of 51 ± 9 years, 85% female, disease duration of 27 ± 24 months, and mRSS of 19.5 ± 10.6. Seven patients (54%) had HRCT-confirmed ILD at baseline, and 9 (69%) were positive for anti-topoisomerase I antibody. Two (14%) and 11 (85%) were on mycophenolate mofetil and low-dose prednisolone (7.2 ± 6.0 mg/day), respectively. Seven patients (54%) each had active skin disease and elevated inflammatory markers defined in the phase III clinical trial [2], while only 4 (31%) fulfilled the inclusion criteria. TCZ was initially administered intravenously (8 mg/kg every 4 weeks) in 8 patients and subcutaneously in 5 (162 mg every 2 weeks in 4 and every week in one). At one year, mRSS was improved from 20.9 ± 11.4 to 10.7 ± 8.9 in 11 patients (p = 0.007), and %FVC was stable in 7 patients with ILD (76.8 ± 15.0 to 78.6 ± 16.1). During the observation period of 60.4 ± 26.7 months, 4 patients were treated with a stable dose of TCZ, while TCZ dose was reduced and/or discontinued in 9. Four of them discontinued TCZ due to adverse events (n = 2; acute lung injury and phlegmon) or prominent improvement of skin thickening (n = 2). Of 9 patients with dose reduction/discontinuation of TCZ, 4 patients who discontinued TCZ (n = 3) or received dose reduction of TCZ (n = 1) experienced a recurrence of progressive skin thickening together with inflammatory complications, including edematous induration of the skin, progression of ILD, polyarthritis, and/or pericarditis with increased inflammatory markers. The interval between dose-reduction/discontinuation of TCZ and clinical worsening ranged from 2 to 11 months. These manifestations were promptly improved by dose-escalation or resumption of TCZ in all patients except one who experienced progressive ILD and died of respiratory failure 27 months later.

Conclusion: In dcSSc patients who experienced improvement of skin thickness during treatment with TCZ, dose-reduction or discontinuation of TCZ may result in a recurrence of the disease. Randomized comparative studies are necessary to examine optimal timing for dose-reduction or discontinuation of TCZ in dcSSc patients after improvement of skin thickness.

AB0437 OESOPHAGEAL DILATATION ON HIGH-RESOLUTION CT CHEST IN SYSTEMIC SCLEROSIS: SIGNIFICANT INDEX?

Y. Erez[1], A. Karakas[1], S. Gulle[1], E. Yılmaz[2], G. Can[1], İ. Sari[1], F. Onen[1], M. Birlik[1]. [1]*Dokuz Eylul University School of Medicine, Division of Rheumatology, İzmir, Turkey*; [2]*Dokuz Eylul University School of Medicine, Division of Radiology, İzmir, Turkey*

Background: Systemic sclerosis (SSc) is chronic, autoimmun multisystem disorder presented by thickening and fibrosis of the skin and internal organs. Esophageal involvement is one of the most common manifestation. Esophageal enlargement on HRCT is a common finding in scleroderma patients and may also be associated with other scleroderma-related clinical findings (1).

Objectives: The aim of this study to evaluate the association between esophageal dilatation on chest HRCT at diagnosis with the other SSc features.

Methods: The study was planned for SSc patients registered between October 2007 and September 2020 in Dokuz Eylul University Rheumatology Department database. Demographics, clinical features and medical history were recorded. The baseline HRCT reports were screened in terms of esophageal dilatation. Then, the initial HRCT images were assessed for esophageal dilatation by an experienced chest radiologist according to recommendation of *Pitrez et al.*

Results: In our study, there were 233 SSc patients (f:206 M:27, mean age 59.9±12.7 years) 71 (31.4%) of them diagnosed with diffuse disease. Median follow-up of study was 73 (1-272) months. Esophageal dilatation on HRCT was detected in 60 (25.8%) of SSc patients. 67 out of 155 patients (43.2%) had proof of esophageal involvement in esophageal transit scintigraphy. There is no statistical correlation was found between esophageal dilatation on HRCT with gender, smoking, arthritis, pulmonary hypertension and autoantibody subtypes. Development of digital ulcer and telangiectasia is statistically higher in SSc patients with oesophageal dilatation on baseline chest HRCT (p=0.001 and p=0.039, respectively). There was a positive correlation between Modified Rodnan Skin Score (mRss) and esophageal dilatation (r=0.213, p: 0.004).

Conclusion: HRCT can be a reproducible and non-invasive method for evaluating esophageal dilatation. Presence of esophageal dilatation at baseline HRCT might be indicative for pulmonary involvement and SSc related gastrointestinal complications. Consecutive chest HCRT should be evaluated to obtain more reliable data about the relationship between esophageal dilatation and SSc related clinical features.

AB0438 SERUM HOMOCYSTEINE AND BONE STATUS IN SYSTEMIC SCLEROSIS PATIENTS

S. Paolino[1], A. Cere2, A. Casabella2, C. Pizzorni2, A. Sulli2, E. Alessandri2, A. Lercara2, E. Hysa2, C. Schenone2, G. Pacini2, E. Gotelli2, M. Cutolo2. [1]*Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS Polyclinic San Martino, Genova, Italy, Genova, Italy*; [1]*Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS Polyclinic San Martino, Genova, Italy, Genova, Italy*

Background: Systemic sclerosis (SSc) is a complex autoimmune connective tissue disease characterized by self-amplifying microvascular damage sustained by autoimmune response and progressive skin and visceral fibrosis. Besides, SSc patients show higher incidence of bone micro/macroarchitectural damages and bone fractures. Emerging data demonstrate that high serum levels of homocysteine (Hcy) could modulate osteoclastogenesis and are recognized as risk factors for osteoporosis (2). Furthermore, serum levels of Hcy were found to be higher in SSc patients than in healthy controls (3).

Objectives: to evaluate the bone status according to HCy serum levels in a cohort of SSc patients.

Methods: 20 female patients fulfilling ACR 2013 criteria for SSc underwent a dual-energy X-ray absorptiometry scan (DXA) (Lunar Prodigy) to evaluate bone status. We analysed bone quantity and quality respectively by bone mineral density (BMD) and trabecular bone score (TBS). According to the WHO criteria, osteoporosis was defined as a bone density of 2.5 standard deviations below that of a young adult (T-Score). Fasting blood samples were obtained from all patients in order to test serum Hcy level and bone turnover markers after obtaining the informed consent. All subjects underwent morphometric spine X-Ray to evaluate vertebral fractures. Statistical analysis was performed using non-parametric tests.

Results: The mean age of patients was 64.15 ± 10.8 years with a mean disease duration of 9.1 ± 2.3 years. The mean modified Rodnan Skin Score (mRSS) was 10.7 ± 8.5. All patients showed a "scleroderma pattern" at nailfold Videocapillaroscopy (NVC): in particular, 7 patients showed the "Late*"* pattern, 9 patients the "Active" pattern and 4 patients the "Early" NVC pattern. Hyperomocisteinemia (HHcy) was found in 25% of patients. Interestingly, SSc patients with the "Late" NVC pattern showed a significantly higher serum level of Hcy compared to the "Early/Active" group (11.15 ± 4.4 *vs* 17.17 ± 6.4, p=0.03). No significant differences were observed in relation to the autoantibody profiles. Of note, 60% of patients with HHcy were found osteoporotic and 40% had bone fractures.

Considering the bone status, patients with Hcy showed a significantly lower TBS (p=0.03); the average values of BMD on the lumbar spine (p=0.79) and femoral neck (p=0.13) were found lower compared to, but without any statistical significance. Furthermore, no significant differences were observed in bone turnover markers according to Hcy levels.

Conclusion: The study demonstrates a relationship between higher levels of Hcy and lower TBS values within SSc patients, particularly in those with most severe microvascular damage al NVC ("Late" SSc pattern). Therefore it is concluded that higher serum levels of Hcy associate to both bone microarchitectural and microvascular damage in SSc.

AB0439 CAPILLAROSCOPIC PATTERNS IN PATIENTS WITH SYSTEMIC SCLEROSIS-POLYMYOSITIS/ DERMATOMYOSITIS (SSc-PM/DM) OVERLAP SYNDROME

O. Desinova[1], M. Starovoytova[1], L. P. Ananyeva[1]. [1]*VA Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation*

Background: Impaired microcirculation is one of the leading factors in local and general pathogenesis of SSc. Widefield nail-fold video-capillaroscopy (NFVC) stands as the most informative and at the same time simple method used for evaluation of capillary circulation.

Objectives: To identify characteristic and specific for SSc– PM/DM capillaroscopic features.

Methods: Both hand II – V fingers of 68 pts with SSc-PM/DM were subjected to widefield NFC, evaluated using a binocular 20x magnification Olympus microscope and analyzed in view of specific skin lesions discriminating diffuse and limited SSc forms.

Results: SSc-specific dilatations of capillary loops were the most common for SSc-PM/DM and were found in all pts; 50% of them had signs of active scleroderma pattern, such as capillary loss or "avascular areas" (50%) and hemorrhages (51.5%), associated with generalized microvascular spasm in early disease and capillary sclerosis in advanced disease. The morphological capillary abnormalities such as varying degrees of capillary loops tortuosity/vascular inhomogeneity were present in 63% of examined nailfolds, branching bushy behavior of capillary loops and mega-capillaries predominated; architectural disorientation/disarrangement of capillary loops with formation of subcutaneous plexus was seen in more than 50% of them. Capillaroscopic changes consistent with active scleroderma pattern were present in 54 % and were associated with lab signs of inflammatory muscle syndrome and immunological disorders: giant capillaries (p<0.02), disorientation of capillary loops (p<0.02) and ramified/ bushy capillaries (p<0.04) were significantly more frequent in patients with severe muscle syndrome, increased CPK, ANF -positivity and hemorrhages (p<0.03).

Conclusion: Thus, widefield NFVC revealed a "mixed" nature of capillaroscopic changes, combining features specific for SSc (capillary dilation, avascular areas, hemorrhages) and for PM/DM (bushy and giant capillaries, disorientation of capillary loops of the nailfold with formation of subcutaneous plexuses.)

AB0440 CLINICAL AND IMMUNOLOGICAL FEATURES OF THE SYSTEMIC SCLEROSIS-OVERLAP SYNDROMES

O. Desinova[1], M. Starovoytova[1], L. P. Ananyeva[1], O. Koneva[1], L. Garzanova[1], R. Shayakhmetova[1], O. Ovsyannikova[1]. [1]*VA Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation*

Background: Systemic Sclerosis (SSc) overlap syndromes (SSc with polymyositis / dermatomyositis (PM/DM), rheumatoid arthritis (RA), etc.) still remain a group of very heterogenous and not very well studied clinical variants of SSc that are characterized by certain clinical and immunological features.

Objectives: Identify clinical and immunological features of the SSc-overlap syndromes

Methods: 80 pts with SSc-PM/DM and 35 pts with SSc-RA undergoing standard clinical examination and laboratory immunological evaluation.

Results: ANA Hep2 was positive in 98% of SSc-PM/DM pts; a-Scl-70 was in 34%, a - PM-Scl and RF were in 20%. ACA (6%), a-RNP (9%), and a - Jo-1 (5%) were significantly less common. Correlation analysis showed significant prevalence of conduction abnormalities in pts with a-Scl-70- (p<0.03); PM-Scl was rarely associated with cardiac arrhythmia (p<0.02) and pericarditis (p<0.03), but there was an association between ACA and presence of digital ischemia (p<0.04). Three pts with limited skin had Scl-70 and PM-Scl antibodies, two of them manifested clinical features of DM. A-Jo-1 was found in 3 pts with a longstanding disease (14,10 and 7 years), and one of these pts was also positive for a-Scl-70. All pts had limited skin and two had interstitial lung disease with FVC values of 79% and 74.8%.

ANA Hep2 was positive in 96% of SSc-RA pts; a-Scl-70 – in 28%, and a-RNP - in 30%. RF-positivity was in 72% of pts, and Anti-CCP - in 27%. Simultaneous Anti-CCP and a-Scl-70 was found in one case, and Anti-CCP - anti-RNP – in another, both were associated with low RF titers. All pts had early joint involvement which became prevailing in subsequent years, and onset of the disease between 30 and 36 years. There was a correlation between laboratory signs of inflammatory activity and immunological disorders: ESR and a-Scl-70 (p<0.03). Anti-CCP and a-Scl-70 co-positivity was a significantly less frequent phenomenon (p<0.04). There was a remarkable 28% proportion of a-Scl-70 cases in SSc-RA with limited cutaneous which is usually characterized by ACA-positivity.

Conclusion: SSc-PM/DM and SSc-RA appear to be an active disease from the immunological point of view, confirming therefore an important role of immune alterations in disease progression. Laboratory findings display specific pathogenetic features of SSc-overlap syndromes; laboratory abnormalities can be used to measure the activity and specify characteristics of the pathological process.

AB0441 NAILFOLDCAPILLAROSCOPY AND CANDIDATE BIOMARKER LEVELS IN SYSTEMIC SCLEROSIS-ASSOCIATED PULMONARY HYPERTENSION; PROFILING OF NON-INVASIVE MARKERS, A COHORT STUDY

J. Lemmers[1], C. H. M. Van den Ende[1], R. Smeets[2], B. Kersten[1], A. Van Caam[3], S. Van Leuven[1], J. Van Haren-Willems[4], A. Van Dijk[5], M. Vonk[1]. [1]*Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*; [2]*Radboud University Medical Center, Laboratory for Clinical Chemisty, Nijmegen, Netherlands*; [3]*Radboud University Medical Center, Laboratory of Experimental Rheumatology, Nijmegen, Netherlands*; [4]*Radboud University Medical Center, Pulmonology, Nijmegen, Netherlands*; [5]*Radboud University Medical Center, Cardiology, Nijmegen, Netherlands*

Background: Systemic sclerosis (SSc) is characterized by inflammation, vasculopathy and progressive fibrosis. Pulmonary Hypertension (PH) is one of the leading causes of death in SSc (1). Currently, most patients with SSc are screened for the presence of PH, and focus lies on early detection and early treatment. Recent literature describes potential for both nailfoldcapillaroscopy (NCM) and several biomarkers to serve as non-invasive tools to identify SSc patients at risk for developing PH (2). Ideally this could attribute to further improvement of risk stratification in SSc and PH screenings algorithms.

Objectives: To explore NCM characteristics and plasma levels of selected candidate biomarkers in a cross-sectional cohort of SSc patients with and without different forms of PH.

Methods: From 02-2018 until 02-2019 we included 40 consecutive SSc patients with associated PH (30 (75%) were female, 32 (80%) LcSSc, median age 72 years (IQR 69-77), median SSc duration 10.7 years (IQR 4.3-17.8), median PH duration 3.9 years (IQR 1.5-7.06)) and 40 without PH (28 (70%) were female, 26 (65%) had a LcSSc, median age 59 years (IQR 51-71), median SSc duration 6 years (IQR 3.1-8.6). In each group NCM characteristics (both quantitative and qualitative) and plasma levels of IL4, IL6, IL8, IL13, PDGFAA, PDGFAB-BB, 6Ckine, sTRAIL, MMP1, MMP7, sICAM1, sVCAM, CCL19/MIP3b, Endostatin, sVEGFR1, sVEGFR2, sVEGFR3, CXCL4, Endothelin1, FGF1, FGF2, VEGF-A, VEGF-C, and VEGF-D using Luminex kits, and vascular auto-antibodies AT1R and ETAR using ELISA (Celltrend GmbH, Luckenwalde, Germany) were determined. NCM characteristics were compared using t-tests, biomarker levels were compared by using Mann-Whitney U tests.

Results: We observed no differences in mean capillary density, number of abnormally shaped capillaries, number of fingers with density <3 capillaries/mm and in overall NCM pattern between patients with and without PH. Plasma levels showing significant differences between the two groups are presented in table 1.

Conclusion: We found significant differences in several of the selected biomarkers in SSc patients with and without PH, but not in NCM characteristics between the groups. However, we did observe a tendency toward more morphologic abnormalities and an overall late pattern in the SSc-PH group. Future longitudinal research should explore the added value of these NCM parameters and biomarkers in personalized risk stratification for the development of PH.

AB0442 CLINICAL FEATURES OF POLYMYOSITIS AND DERMATOMYOSITIS PATIENTS WITH SEVERE DYSPHAGIA

Y. Hayashi[1], K. Izumi[1], S. Hama[1], M. Higashida-Konishi[1], M. Ushikubo[1], H. Oshima[1], Y. Okano[1]. [1]*National Hospital Organization Tokyo Medical Center, Rheumatology, Tokyo, Japan*

Background: Polymyositis (PM) and dermatomyositis (DM) are autoimmune inflammatory diseases characterized by proximal myositis. Dysphagia has been reported to develop in 35 to 62% of PM/DM patients and known as poor prognosis factor.

Objectives: The purpose of this study is to determine the clinical characteristics of PM/DM patients who present with deglutition disorder.

Methods: Consecutive patients with PM/DM who visited National Hospital Organization Tokyo Medical Center between April 2010 and January 2021 are included in this study. We compared clinical features between the patients with and without dysphagia. The diagnosis of dysphagia was based on videofluorography swallow study, and dysphagia requiring gastrostomy was defined as severe dysphagia. The clinical characteristics compared in this study were following: age of onset, levels of serum creatine kinase (CK) and lactate dehydrogenase(LDH), sense of dysphagia, manual muscle test (MMT) score, and complication of malignancy or interstitial pneumonia.

Results: A total of 73 patients with PM/DM were identified. Among them, 12 patients were diagnosed with dysphagia, and 5 patients developed severe dysphagia. Patients with dysphagia had the following characteristics compared to patients without dysphagia: higher levels of serum LDH (833.7 ± 500.1 U/L vs 471.9 ± 321.0 U/L, p = 0.0088), higher levels of serum CK at initial examination (6070.3 ± 7184.8 IU/L vs 1534.7 ± 2978.8 IU/L, p = 0.0086) and more frequent sense of dysphagia (90.9% vs 10.6%, p< 0.0001), lower MMT score(3.18 ± 1.07 vs 4.31 ± 0.75, p = 0.0017). In addition to those, patients with severe dysphagia presented older age of onset (mean age 69.4 ± 12.0 vs 51.7 ± 14.8, p = 0.014), more frequent complication of malignancy (80.0% vs 14.8%, p= 0.0048) and less frequent complication of interstitial pneumonia (0.0% vs 55.5%, p= 0.023).

Conclusion: These results indicate that dysphagia develops frequently in PM/DM patients with higher levels of serum LDH or CK, sense of dysphagia and low MMT score. Among them, patients with elderly onset or malignancy are at risk for sever dysphagia, and should be treated carefully.

AB0443 BIOMARKER SUCH AS IL-17, IL-21 AND TIMP-1, IS USEFUL FOR PREDICTING THE PATHOPHYSIOLOGY OF CONNECTIVE TISSUE DISEASE-ASSOCIATED PULMONARY HYPERTENSION

S. Nakashima[1], T. Kameda[1], H. Shimada[1], M. Mahmoud Fahmy Mansour[1], R. Wakiya[1], M. Kato[1], Y. Ushio[1], K. Sugihara[1], H. Dobashi[1]. [1]*Kagawa University, Division of hematology, Rheumatology and Respiratory Medicine, Department of Internal medicine, Kagawa, Japan*

Background: Connective tissue disease-associated pulmonary hypertension (CTD-PH) is constructed by a variety of pathologies, including cardiac, pulmonary, and vascular involvement, as well as immune abnormalities. Because of its various constructs, it is difficult for many respiratory physicians, cardiologists, and rheumatologists to determine a treatment strategy for CTD-PH. In addition, CTD-PH has different pathologies from iPAH, and there are cases in which immunosuppressive therapy is effective. These suggests that the two PAHs may have different pathogenesis, including inflammation in the pulmonary artery. However, there are not enough biomarkers to distinguish pathologies. On the other hand, it has been reported that various cytokines such as TIMP-1, Interleukin (IL)-6, IL-17, and IL-21 are involved in the pathogenesis of CTD-PH or vasculitis. (1,2) However, the relationship between these cytokine expression and the pathogenesis or treatment of CTD-PH has not been fully clarified.

Objectives: To clarify the relationship between cytokine profile and clinical features, change in cytokines and hemodynamics by treatment, association with the effectiveness of immunosuppressive therapy.

Methods: Patients suspected PH was included. At the time of cardiac catheterization(RHC), sera in pulmonary pre and post-capillary were collected and TIMP-1, MCP-1, IL-17 and IL-21, IL-12p70 and IL-6 were analyzed by ELISA(ABCAM UK, Ella simple plex USA). The following clinical data were collected: age, gender, underlying disease, complication of interstitial lung disease, treatment (immunosuppressant and pulmonary vasodilator), hemodynamics. Furthermore, we investigated the relationship between cytokines and clinical data.

Results: 15 cases of CTD-PH, 13 cases of non-CTD-PH, and 6 cases of non-PH were analyzed. (SSc 12 cases, MCTD 7cases, SLE 2 cases, and others 13 cases) 28 cases were diagnosed with PH by RHC. There was a positive correlation between IL-6 and mean pulmonary arterial pressure in all PH case. In addition, MCP-1, IL-6, and TIMP-1 tend to be high in SSc-PH cases. On the other hand, in Non-SSc-PH, IL-12p70 and IL-17 were high. In cases who pulmonary vascular hemodynamics improved by treatment, IL-17, IL-21, and TIMP-1 decreased.

Conclusion: Biomarker profiles in pulmonary capillaries may differ depending on the disease. Furthermore, it suggested that IL-17, IL-21 and TIMP-1 may be biomarkers of therapeutic effect.

AB0444 CLINICAL-IMMUNOLOGICAL CHARACTERISTICS OF PATIENTS WITH INFLAMMATORY MYOPATHIES

A. Khelkovskaia-Sergeeva[1], O. Desinova[1], M. Starovoytova[1], L. P. Ananyeva[1], M. Cherkasova[2], R. Shayakhmetova[1]. [1]*VA Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation*; [2]*VA Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology, Moscow, Russian Federation*

Background: Inflammatory disorders of the skeletal muscle include polymyositis (PM), dermatomyositis (DM), amyopathic dermatomyositis ADM, (immune mediated) necrotizing myopathy (NM), overlap syndrome with myositis (overlap myositis, OM) and including anti-synthetase syndrome (ASS).

The detection of myositis-specific antibodies, the clinical effect of which remains to be determined, may be of great importance for diagnosis.

Objectives: To study clinical-immunological characteristics of patients with inflammatory myopathies.

Methods: 57 pts were enrolled in this study: 28 (47%) pts were diagnosed with DM, 14 (23%) pts – OM, 5(8%) pts – PM, 5 (8%) pts-NM, 4 (7%) pts-ADM, 1 (2%)- ACC. Duration of disease in average 11,29 (2-48) month. Standard clinical examination and laboratory immunological evaluation including myositis-specific autoantibodies were performed.

Results: There were 3 age groups: 18-39 years old – 16 (28%) pts, 40-49 yo – 28 (49%) pts and > 60 yo – 13 (33%) pts. Symptoms of myositis were muscle weakness 57 (100%) pts, dysphagia 29 (51%) pts, arthritis -12 (21%) pts, Raynaud's phenomenon 21 (37%) pts, skin lesions- 37 (65%) pts (Gottron signs- 7 (12%) pts, digital ulcers -11 (19) pts, panniculitis – 6(11%) pts, hand of mechanic 16(28%) pts). MMT 8 was 55,57 (SD 18,49) (20-80) score. Clinical features of myositis were myocarditis 8 (14%) pts and arrhythmia 9 (16%) pts, interstitial lung

disease 20 (35%) pts, esophageal involvement 29 (51%) pts of them 5 (9%) pts needed enteral feeding. 2 (4%) pts had oncopathology. CK was increased in 49 (86%) pts: < 10 N -15 (26%) pts, >10 N – 28 (49%) pts, > 50 N – 6 (11%). ANA positive - in 39 (70%) pts. Antibodies identified in 25(44%) pts: Pm-Scl 7 (12%) pts, PL-7 1 (2%), Mi-2 10 (17,5%), Ku 2 (3,5%) pts, AMA-M2 2 (2%)pts, a-SRP 4 (7%) and SS-A/Ro-52 13 (23%), SS-A/Ro-60 2 (3%) pts.

Conclusion: The group of inflammatory myopathies is characterized by clinical and immunological heterogeneity. Finding antibodies specific for myositis can help diagnose the disease.

Disclosure of Interests: None declared.

DOI: 10.1136/annrheumdis-2021-eular.3101

AB0445 FIRST CLINICAL ANALYSIS OF MYOSITIS PATIENTS REGISTERED AT REUMA.PT/MYOSITIS PROTOCOL: DATA FROM A SINGLE-CENTER

A. T. Melo[1,2], E. Dourado[1,2], P. Martins[1,2], N. Khmelinskii[1,2], J. E. Fonseca[1,2], I. Cordeiro[1,2], R. Campanilho-Marques[1,2]. DM – dermatomyositis; CADM – clinically amyopathic dermatomyositis; MCTD – mixed connective tissue disease; PM – polymyositis; UCTD – undifferentiated connective tissue disease; ILD – interstitial lung disease; NSIP – nonspecific interstitial pneumonia; LIP – lymphocytic interstitial pneumonitis; UIP – usual interstitial pneumonia; COP – cryptogenic organizing pneumonia; RP – Raynaud phenomenon

Objectives: To clinically characterize patients with inflammatory myopathies followed at an hospital's Rheumatology Department, using the Rheumatic Diseases Portuguese Register (Reuma.pt).

Methods: An observational transversal study was performed. Data on demographic variables, clinical features, antibodies and treatment were collected.

Results: Of the 121 included patients, 78% were female, with a median age of 56 [44-68] years and a median disease duration of 2 [0-4] years. The most frequent diagnosis was dermatomyositis (DM; n=28, 23%) followed by antisynthetase syndrome (ASyS; n=21, 17.4%). At the time of the analysis, the median Manual Muscle Test (MMT-8) was 80 [78-80], the median modified skin Disease Activity Score was 0 [0-2] and global disease activity was 0.5 [0-0.75]. Calcinosis was found in 6% of the patients (n=7), mostly DM cases. Interstitial lung disease (ILD) was present in 29 patients (24%), of those, 52% (n=15) had antisynthetase syndrome (ASyS). Three patients presented as a paraneoplastic syndrome. Ninety-nine patients (82%) had a myositis autoantibody identified: antisynthetase autoantibodies were the most commonly identified (n=20, 16%). 62% of the patients were treated with steroids and 35% with ≥2 disease-modifying anti-rheumatic drugs.

Table 1 depicts the main clinical characteristics and the immunologic profile for each diagnosis

Conclusion: In our cohort the most frequent myositis subtype was DM. Almost a quarter of patients had associated ILD, which is an important cause of morbidity and mortality. ILD was more frequent in ASyS patients and was most commonly related to anti-Jo1 antibodies, which is consistent with the literature.

AB0446 DEMOGRAPHIC AND CLINICAL FEATURES OF IDIOPATHIC INFLAMMATORY MYOSITIS AND PREVALENCE OF MYOSITIS-RELATED ANTIBODIES

G. K. Yardımcı[1], E. Erul[2], B. Farisoğulları[1], G. Ayan[1], L. Kılıç[1], O. Karadag[1], Ş. A. Bilgen[1]. [1]*Faculty of Medicine; Hacettepe University, Rheumatology, Ankara, Turkey*; [2]*Faculty of Medicine; Hacettepe University, Internal Medicine, Ankara, Turkey*

Background: Idiopathic inflammatory myopathies (IIM) are heterogeneous groups of connective tissue diseases. Diagnosis of IIM is sometimes challenging, but newly defined myositis specific autoantibodies (MSAs) are helpful in diagnosing of IIM and revealing the clinical signs [1].

Objectives: To describe demographic and clinical features of IIMs and to evaluate the frequency and clinical associations of myositis-specific and myositis associated antibodies (MAAs) in IIM.

Methods: Samples obtained from patients tested for MSA/MAA as of 2017 to 2020 were retrospectively evaluated. Patients were diagnosed with IIM according to clinician diagnosis. The prevalence and clinical associations of myositis-related antibodies were assessed with univariate and multivariate analysis.

Results: 152 patients (70.4% female) were tested for myositis-related antibodies during the study period. 81 patients were diagnosed with IIM (38 DM, 43PM). DM patients were diagnosed at an earlier age and its association with malignancy was more relevant, although the relationship with malignancy was not statistically significant. Differences of clinical characteristics between DM and PM patients were skin features which were more frequent in DM, and interstitial lung disease which was more common in PM patients.

MSAs/MAAS were found in 65.4% and 43.2% in IIM patients, more frequently than patients without IIM (p=0.000 and 0.0225, respectively). MSAs were equally frequent in both IIM groups, whereas MAAs were more common in the PM group (although no significant difference in overlap with other connective tissue diseases within these two diseases). The most common MSAs in DM were anti-TIF1-γ (23%), anti-MDA5 (16%), anti-NXP2 (13%) and in PM were anti-Jo-1 (28%), anti-MDA5 (12%), anti-ku (12%), anti-PL7 (12%) respectively. Predictors of ILD in IIM were Anti-Jo-1 positivity and age (RR:10 [CI:2-41] p=0.003 and RR:1.07 [CI:1.02-1.12] p=0.04 respectively)

Conclusion: The general characteristics of DM and PM patients and the frequencies of myositis-specific autoantibodies were similar to the literature, except that anti-TIF1-γ antibodies (14%) were more common in our Turkish cohort [2].

AB0447 PREVALENCE OF PRIMARY BILIARY CIRRHOSIS IN SYSTEMIC SCLEROSIS AND SJÖGREN'S SYNDROME OVER TIME: A SYSTEMATIC REVIEW

S. Upadhyaya[1], D. Starcevic[2], M. Turk[3], J. Pope[1]. [1]*Western University, Rheumatology, London, Canada*; [2]*Western University, Schulich School of Medicine & Dentistry, London, Canada*; [3]*Western University, Medicine, London, Canada*

Background: Primary biliary cirrhosis (PBC) is a rare slowly progressive autoimmune disease characterized by inflammatory destruction and fibrosis of intrahepatic bile ducts. It is known to coexist together with rheumatological conditions such as Sjögren's syndrome (SS) and systemic sclerosis (SSc). There is a wide range in reported prevalence of disease overlap with these entities; however, the exact prevalence rates remain unclear.
Objectives: The objectives were to determine the prevalence of: 1) PBC in patients with SS and SSc (and the subsets of limited cutaneous SSc (lcSSc) and diffuse cutaneous SSc (dcSSc)), 2) SSc and SS in patients with PBC, and 3) to analyze changes in frequency over time. SSc occurs in 3/10,000 and PBC in 4-40/10,000 but these rare autoimmune diseases are known to coexist together. We speculated that there could be more cases diagnosed due to increasing availability of standardized antibody tests such as ANA, centromere antibodies, ENA and mitochondrial antibodies.
Methods: A systematic review of the literature was performed using Medline, EMBASE, CINAHL, and the Cochrane Library databases up till June 16, 2020. Only full text articles in the English language with at least 40 patients were included. Cohorts, case series, cross-sectional studies, correspondences and registries with reported prevalence rates of both PBC in patients with SS and SSc as well as SSc and SS in patients with PBC were included. Data on frequency of co-existent diseases was studied by year of publication to determine if prevalence changed over time using linear regression. We used the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) checklist to assess the quality of the studies.
Results: Of 2876 citations identified, 67 were included in the analysis (n=33 for PBC, 15 for SSc, 18 for SS and 1 for SSc/SS). STROBE checklist scores ranged from 7-21. The prevalence of PBC was 5% in patients with SSc. Within the subsets, the prevalence of PBC in lcSSc was 8% and in dcSSc was 1%. In patients with SS, the prevalence of PBC was 4%. The prevalence of SSc overall in those with PBC was 5% and, within the subsets was 6% in lcSSc and 0% in dcSSc. The prevalence of SS in PBC was 18%. There was also no significant association between year of publication and prevalence. There was a lack of standardized definitions so misclassification may have occurred.
Conclusion: PBC is increased in SSc but mostly in the lcSSc subset. SS in PBC is common at nearly 1 in 5. Over the years, there was no change in the prevalence of PBC in SSc indicating stability over time.

AB0448 SYSTEMIC SCLEROSIS ASSOCIATED PULMONARY ARTERIAL HYPERTENSION: PREDOMINANCE OF PULMONARY FIBROSIS AS A RISK FACTOR FOR MORTALITY IN A SINGLE CENTER COHORT

S. Amikishiyev[1], Y. Yalçınkaya[1], N. Aliyeva[1], K. Mammadova[2], B. Artim-Esen[1], A. Gül[1], A. K. Bilge[3], G. Okumuş[2], M. Inanc[1]. [1]*Istanbul Faculty of Medicine, Istanbul University, Division of Rheumatology, İstanbul, Turkey*; [2]*Istanbul Faculty of Medicine, Istanbul University, Department of Chest Diseases, İstanbul, Turkey*; [3]*Istanbul Faculty of Medicine, Istanbul University, Department of Cardiology, İstanbul, Turkey*

Background: Pulmonary arterial hypertension (PAH) is a severe vasculopathic complication for systemic sclerosis (SSc) patients. The availability of oral-specific vasodilator therapies has provided better outcomes.
Objectives: We aimed to analyze the characteristics of SSc-PAH patients and factors associated with mortality.
Methods: Medical records of 291 SSc patients fulfilling ACR/EULAR criteria (2013) and followed–up during 2008-2020 years were screened and the patients who diagnosed PAH evaluated by right heart catheterization (mean PAB≥20 mmHg) (n=26, 8,9%) were included into this retrospective cross-sectional study.
Results: The characteristics of 26 SSc-PAH(24 females) patients were summarised in Table 1.

Table 1. Characteristics of SSc patients with PAH

	SSc-PAH (n=26)
Demographics	
Age(yrs)	53.6±8.9
Duration of Raynaud's(yrs)	16.1±11.8
Duration of Non-Raynaud's(yrs)	9.2±6.6
Raynaud's to ***Diagnosis of PAH***(yrs)	10.8±6.7
Clinical Characteristics (%)	
LcSSc	9 (34.6)
DcSSc	18 (65.4)
Digital ulcer	14 (53.8)
Gastrointestinal	20 (69.0)
Synovitis	5(19.2)
Flex contractures	7 (26.9)
Tendon friction rubs	3(11.5)
Renal crisis	1 (3.8)
Pulmonary fibrosis	19 (73.1)
Auto-antibodies (%)	
ANA	23 (88.5)
Anti-centromere	6(23.1)
Anti-Scl70	13(50)
Treatment (%)	
Specific vasodilator	
ERA (bosentan/macicentan/ambricentan)	15 (51.7)
PDE5-i (sildenafil/tadalafil)	17 (58.6)
Prostacyclin-analog (İloprost/treprostenil/selexipag)	15 (51.7)
Riociguat	5 (17.2)
Immunosuppressives	21(80.8)
Steroids	16(61.5)

Twenty-four (92,3%) of the SSc-PAH patients had PAH-related symptoms at the time of diagnosis, 2 (7,7%) were asymptomatic and diagnosed by screening. RHC and treatment details were stated in Table 2.

Table 2. Right Heart Catheterization (RHC) ve treatment details of SSc-PAH patients

	n=26
Initial RHC	
-mean PAB	30,4±7,9 (median 28, 20-53mmHg)
-PVR	5,1±2,4 (median 4, 3-9 woods)
-PCWP	10,8±5,5 (median 10, 0-15 mmHg)
Initial treatment	
-monotherapy	5 (19,2%)
-combination	10 (38,5%)
-add-on combination	12 (46,2%)

Eleven out of 26 patients (42,3 %) were deceased after a mean follow up of 43,7±24,6 (median 48,1-84) from PAH diagnosis and 15,1±9,9 (median 13, 0,6-34) years after SSc diagnosis. Deceased patients were younger and had younger age at disease onset (49,1± 8,8 vs 56,9±7,7, p=0.032 and 30,8±13,0 vs 42.0 ±10,9, 0.027). All deceased patients had associated pulmonary fibrosis (100 vs 53.3%, p=0.01). No significant difference was observed for initial RHC parameters between deceased and survived SSc-PAH patients. Specific monotherapy was found to be more frequent in deceased patients (45,5 vs 0%, p=0,007).

Conclusion: The prevalence of SSc-PAH was found to be 8.9% with increased mortality in our cohort. SSc-PAH patients predominantly had diffuse cutaneous involvement with digital vasculopathy, pulmonary fibrosis, and anti-Scl70 positivity. PAH was diagnosed after a median of 10 years of the Raynaud's, mainly in symptomatic patients. Mortality in PAH-SSc patients was associated with early onset of disease, pulmonary fibrosis, and monotherapy. Initial RHC parameters were not found to be related to mortality.

AB0449 CLINICAL CHARACTERISTICS AND RISK FACTORS OF SYSTEMIC SCLEROSIS WITH HEMATOLOGIC SYSTEM DAMAGES

J. Zheng[1], Z. R. Dong[1], Y. P. Tang[1], Y. Q. Huang[2], Q. B. Zhang[2], F. Dai[1], Y. F. Qing[1]. [1]*Institute of Rheumatology and Immunology, Department of Rheumatology and Immunology, Nanchong, China*; [2]*Institute of Rheumatology and Immunology, Department of Geriatrics, affiliated Hospital of North Sichuan Medical College, Nanchong, China*

Background: SSc characterized by varying degrees of fibrosis of the skin and internal organs, clinicians pay more attention to skin and viscera conditions, tend to ignore hematologic system damage. Studies have shown that rheumatic disease such as SLE, RA, pSS often accompanied with hematologic system damages, and hematologic system damages is multiple organ involvement and risk factor of poor prognosis[1-2].

Objectives: To investigate the the clinical features, laboratory characteristics and risk factors of Systemic Sclerosis (SSc) patient with hematologic system damages.

Methods: The clinical data of 180 patients were collected from January 2010 to April 2020, at the Affiliated Hospital of North Sichuan Medical College. The demographic information, laboratory tests, and clinical symptoms were analyzed retrospectively.

Results: Among 180 SSc patients, 70(38.9%) cases were complicated with hematologic system damages. 51(72.9%) cases had anemia, 24 cases (34.3%) had leukopenia, 24 cases (34.3%) had thrombocytopenia, and 22 cases had hematologic system damages associated with more than two cell line involvement. Clinical symptoms: arthritis was significantly higher in the hematologic system damages group than patient without (P<0.05), however, there was no significantly difference in gender, age, disease course, respiratory symptoms, gastrointestinal symptoms, Raynaud's phenomenon, interstitial lung disease and pulmonary hypertension (all P>0.05). Laboratory tests: ESR and hsCRP were increased in the hematologic system damages group, while the albumin decreased (all P<0.05). The positive rates of resistance to anti-dsDNA antibody and anti-ribosomal P protein antibody was higher in the hematologic system damages group (all P<0.05). Prognosis: During follow-up, leukopenia was more likely to recover, while the thrombocytopenia was more difficult to recover. Logistics regression analysis showed that positive of anti-ribosomal P protein antibody maght be a risk factor for SSc complicated with hematologic system damages [OR = 3.930(P<0.05)] (Table 1).

Conclusion: SSc complicated with hematologic system damages is common, and patients with hematologic system damages have more serious clinical symptoms, some of whom have difficulty in recovey. Anti-ribosomal P protein antibody may be a risk factor of SSc hematologic system damages.

Table 1. Bivariate logistics regression analysis on risk factors associated with hematologic damages in SSc.

Factor	*B*	*SE*	*Wald*	*OR(95%CI)*	*P* value
arthritis	0.654	0.347	3.543	1.922(0.973-3.797)	0.060
ESR	-0.081	0.487	0.028	0.922(0.355-2.393)	0.868
hsCRP	-0.007	0.492	0.000	0.993(0.379-2.607)	0.989
anti-dsDNA	0.868	0.673	1.664	2.393(0.637-8.916)	0.197
anti-Rib-P	1.369	0.636	4.633	3.930(1.130-13.666)	0.031

AB0450 PERIPHERAL MACROVASCULAR INVOLVEMENT IN SYSTEMIC SCLEROSIS AS COMPARED WITH HEALTHY CONTROLS: A SMALL COHORT STUDY BY COLOR AND SPECTRAL DOPPLER ULTRASONOGRAPHY

R. D'alessandro[1], E. Garcia Gonzales[1], P. Falsetti[1], C. Baldi[1], F. Bellisai[1], E. Selvi[1], B. Frediani[1]. [1]*Rheumatology Unit, Policlinico Le Scotte, Department of Medical Sciences, Surgery and Neuroscience, Siena, Italy*

Background: Together with autoimmune-inflammation and fibrosis, microvasculopathy is a hallmark of SSc. However, also macrovascular changes may occur including peripheral proliferative vasculopathy. Whether this changes may represent a specific SSc marker with a predictive value remains a matter of debate. [1,2,3]

Objectives: To study peripheral macrovascular involvement by color doppler ultrasound (CDUS) with spectral wave analysis (SWA) in a cohort of 40 SSc patients as compared to healthy controls. To further analyze any differences among the SSc population.

Methods: Forty SSc patients and 36 healthy controls were examined by CDUS with SWA of both hands. Macrovascular involvement was assessed by measuring the resistivity index (RI) of distal ulnar and radial arteries. Examinations were performed with an Esaote MyLab Twice machine equipped with a linear 10-22 MHz probe. Ultrasound examination was carried out by two independent rheumatologists blinded to clinical conditions of the patients. Statistical analysis was performed by using MaxStat software.

Results: The RI index resulted increased in the SSc cohort as compared with healthy controls (left ulnar RI 0.977 vs 0.715; right ulnar RI 0.996 vs 0.699; left radial RI 0.988 vs 0.706; right radial RI 0.999 vs 0.688; p<0.001). SSc patients with an increased RI in one artery were more probable to have an increased RI in the other vessels too ($r^2 = 0.35$; p<0.01). In addition, 8 out of 40 SSc patients presented left ulnar artery occlusion (UAO) and 7 out of 40 SSc patients presented right UAO, of which 6 presented bilateral UAO. Awaiting to enlarge the cohort for further analysis, descriptive data regarding increased RI at CDUS/SWA and clinical features, including years from onset of the disease, subtype of SSc, mRSS, history of digital ulcers, interstitial lung disease and PAH are described in Table 1.

Conclusion: Peripheral macrovascular involvement was observed in SSc patients as compared with healthy controls. Further studies will determine whether this feature may have specificity for diagnosis/prognosis in SSc.

TO EVALUATE THE PREVALENCE OF INTERSTITIAL LUNG DISEASE (ILD) AND/OR PULMONARY ARTERIAL HYPERTENSION (PAH) IN PATIENTS AFFECTED BY SYSTEMIC SCLEROSIS (SSC) AND TO DETERMINE THE FACTORS ASSOCIATED WITH ILD

R. Ortega Castro[1], R. Mariscal-Ocaña[2], M. Rojas-Giménez[1], J. Calvo Gutierrez[1], A. Escudero Contreras[1], C. López-Medina[1]. *[1]Reina Sofia Universitary Hospital/Maimonides Institute of Biomedical Research of Córdoba (IMIBIC), University of Cordoba, Clinical Management Unit of Rheumatology, Córdoba, Spain*; *[2]Reina Sofia Universitary Hospital/University of Cordoba, Clinical Management Unit of Rheumatology, Córdoba, Spain*

Background: Systemic sclerosis (SSc) is a chronic autoimmune disease that carries significant mortality. Despite diagnostic and therapeutic advances in recent years, there is still a significant percentage of patients who do not present a complete clinical response, with the associated increase in morbidity and mortality. Specifically, pulmonary disease is frequent and entails a poor prognosis, with interstitial lung disease (ILD) and pulmonary hypertension (PAH) being the two most important complications, the first and second cause of mortality, respectively.

Objectives: To evaluate the prevalence of ILD and/or PAH in patients affected by SSc and to determine the factors associated with ILD.

Methods: Cross-sectional observational study of 102 patients diagnosed with SSc (Limited, Diffuse, SSc without scleroderma or Pre-scleroderma), treated between 1975 and 2020 at the Reina Sofia University Hospital in Cordoba. A descriptive study of the cohort was carried out and factors independently associated with ILD were evaluated using a multiple logistic regression model.

Results: 102 patients were included, 87.3% of these were female with an average age of 50.8 (14) years. There were 20 deaths (19.8%), from which 55% died because of SSc and the main reason was ILD and/or PAH. Respiratory complications (as ILD or as PAH) were present in 59 patients (57.8%), of whom 52 were diagnosed with ILD (90.4% with a pattern of non-specific interstitial pneumonia) and 25 PAH, whose mean pulmonary artery systolic pressure was 47.16 (18.54) mmHg. Anti-topoisomerase I antibodies were positive in 34.6% of patients who developed ILD, while anticentromere antibodies were more frequent in SSc without interstitial lung disease (80%). Independent factors associated with ILD were type of SSc, proximal skin involvement, anticentromere antibodies, current treatment with corticoids and the death.

Conclusion: Just over half of the patients with SSc have lung disease (as ILD or as PAH). The main risk factors associated with ILD are proximal skin involvement and treatment with glucocorticoids, probably in the context of more severe forms that require more treatment. Anticentromere antibodies are more prevalent in patients with Limited SSc and their expression decreases the risk of developing ILD in these patients.

GENDER FEATURES IN PSYCHOLOGICAL STATUS IN PATIENTS WITH LUNG ULTRASOUND SYNDROME

N. Shamsutdinova[1], D. Abdulganieva[2], E. Kirillova[2], D. Gaisina[1], A. Fatikhova[1]. *[1]Kazan State Medical UniversIty, Hospital Therapy, Казань, Russian Federation*; *[2]Kazan State Medical UniversIty, Hospital Therapy, Kazan, Russian Federation*

Background: The use of lung ultrasound (LUS) in the management of patients with ILD has the advantage of lower cost and the absence of x-ray radiation.

Objectives: to establish the relationship between ultrasound manifestations of interstitial syndrome and indicators of psychological status in patients with secondary ILD in patients with rheumatic diseases.

Methods: 25 patients with secondary ILD in patients with rheumatic diseases (15 patients with systemic scleroderma, 8 patients with ANCA associated systemic vasculitis, 2 patients with dermatomyositis) were investigated. All patients underwent a standard clinical examination, high-resolution RCT of lungs. To assess depression and anxiety were used the following scales: State-Trait Anxiety Inventory, symptomatic questionnaire SCL-90-R, Beck Depression Inventory. LUS was carried out for the evaluation of the location and number of B-lines on both right and left hemithoraces using commercially available echographic equipment with a 5-12 MHz linear transducer (Accuvix A30, Samsung Medison).

Results: Most patients had an average number of B-lines 24,5[11,5;34,0]. In woman the total number of B-lines correlated with the situational anxiety (r=-0,71, p<0,05), with the personal anxiety (r=-0,6, p<0,05) and with somatization (r=-0,67, p<0,05). Also there was a trend between somatic (r=-0,49, p=0,08) and affective (r=-0,51, p=0,07) subscales, general depression (r=-0,48, p=0,1), but did not achieve statistical significance, probably due to the small number of patients. Among patients, including men and women, no statistically significant correlation was found.

Conclusion: The relationship between situational, personal anxiety, somatization and the total number of B-linesamong women with secondary ILDwas found. More research is needed to clarify details.

AB0453

THE CHARACTERISTICS OF SSc-ILD PATIENTS WITH ACTIVE THERAPY IN DIFFERENT PROGNOSIS INTERVALS BASED ON DISCRIMINANT ANALYSIS

O. Ovsyannikova[1], L. Garzanova[1], L. P. Ananyeva[1], O. Koneva[1], S. Glukhova[2], O. Desinova[1], M. Starovoytova[1], R. Shayakhmetova[1]. *[1]VA Nasonova Research Institute of Rheumatology, Laboratory of microcirculation and inflammation, Moscow, Russian Federation*; *[2]VA Nasonova Research Institute of Rheumatology, Educational and methodical department, Moscow, Russian Federation*

Background: Interstitial lung disease (ILD) frequently complicates SSc and can be a debilitating disorder with a poor prognosis. Several risk factors for progressive SSc-ILD have been identified and prognostic scoring systems have identified predictors of mortality. It's important to develop treatment recommendation.

Objectives: To use the discrimination function for pts with SSc-ILD and highlight pts with different prognosis.

Methods: It was a longitudinal study involving 140pts with SSc-ILD. The mean age was 46.7±13.9ys, females 82%, SSc duration 6.2±5.8ys, diff subset-54%. The mean duration of follow up was 73,2±27,8months. All pts received low- and moderate-dose glucocorticoids (Gc), RTM (the mean dose 3,14±2,38g) and 77 pts had received parenteral CyP(mean dose 15,9±15,6g).

We have got the discrimination function that included: ground glass opacities (GGO)(1–the absents of GGO; 2–the presents of GGO); index EScSG(the digital value); FVC(FVC≥75=0, FVC<75=1); the maximum daily dose of Gc (the digital value,mg); Gamma globulins (the digital value,%); cyclophosphamide (CYC) (the absence of CyP=0, the treatment of CYC =1);DLco(DLco<52% =0, DLco≥52=1). We assessed all parameters at the entry in the study except DLco evaluated after one year of follow up. Based on this analysis the equation was developed.

The equation of prognosis is 3.14GGO+0,70index EScSG–1,326 FVC-0,1 the maximum daily dose of glucocorticoids+0,136 Gamma globulins+1.066 CYP–1.075DLCO≤5,8.

Value of equation of prognosis to 5.8 corresponds to stabilization or good prognosis and value after 5.8 corresponds to poor prognosis.

Results: On results of discrimination function pts were distributed in the following order: 22 pts(16%) were into zone of stabilization(Group 1) and 118(84%) - in zone of poor prognosis, among which 13pts died during the study. That`s why pts in zone of poor prognosis were divided into group 2 - survived pts (n=105(75%)) and group 3– died pts(n=13 (9%)).So we have got 3groups; the age, SSc duration, gender proportion and SSc forms, were similar in the all groups(p>0,05).

Table 1. Baseline characteristics of the groups

Parameters	Group 1 (n=22) M±SD	Group 2 (n=105) M±SD	Group 3 (n=13) M±SD
CRP mg/ml	9,4±10,4	11,5±23,4	21,5±27,1
ME [25‰/75‰]	7,5 [1,9;11,2]	5 [1,6;10,4]	9,9 [5;32,8]
ESR mm/h	17±16,35	23,6±17	22,9±14,3
a-Scl-70 u/ml	62,5±85*	118,6±93,09*	102,1±96
Skin score	9,63±7,7	11,5±9,9	9±9,23
Index EScSG	1,9±1,7**	3,4±1,9**	2,9±1,1
Mean PAP mm hg	31,9 ±7β ββ	35±11,9 β	47,5±23,3ββ
Cumulative dose of CyP g	1,5±3γ γγ	11,4±14,4γ	18,9±23,3γγ
ME [25‰/75‰]	0 [0;2]	4,9 [0;17]	4 [0;46,5]
Cumulative dose of RTM, g	3,15±1,6	2,63±1,36	2,2±1,5

* - p=0,01; **p=0,0008; β - p=0,006; ββ - p=0,03; γ- p=0,002; γγ - p=0,0018Mean level a-Scl-70, Index EScSG were significantly lower in group 1 vs group 2. Mean value of PAP and dose of CyP were significantly increased in group 3. It should be noted that pts with good prognosis have had low level of all parameters and high dose of RTM.

Conclusion: The discrimination function is a proposed screening algorithm for pts with SSc-ILD who could develop progression disease. Usage of discrimination function revealed that 84% pts with ILD-SSc have got poor prognosis and 9% of them have got fatal outcome. Usage the equation of prognosis is very useful to choice of treatment and observation pts SSc-ILD.

AB0454 SPECIFICITY OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS POSITIVE FOR A-TOPO-1 AND A-RNP

R. Shayakhmetova[1], L. P. Ananyeva[1], O. Koneva[1], M. Starovoytova[1], O. Desinova[1], O. Ovsyannikova[1], L. Garzanova[1], A. Khelkovskaia-Sergeeva[1], S. Glukhova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology;, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: The classification criteria of SSC (EULAR/ACR 2013) compared to the criteria of 1980 showed high sensitivity and allow to detect the full spectrum of systemic sclerosis (SSc). The use of the new criteria led to the fact that some of the patients who were diagnosed with MCTD began to meet the criteria of SSc. Since these patients have hyperproduction of antibodies to RNP, but no other SSc-specific autoantibodies, we believe that they represent a special clinical and immunological phenotype of SSc. Lung involvement in SSc impaires the quality of life and the prognosis, so the study of interstitial lung disease(ILD) in different phenotypes is relevant.
Objectives: To compare the main manifestations of ILD in two groups of patients who meet the classification criteria of SSc 2013 - positive for a-Topo-1 and for a-RNP.
Methods: The study included 100 patients. The first group - 50 patients positive for a-Topo-1 (45 women and 5 men, mean age 55±10 years, duration of the disease 10.2±8 years, subset of the disease: diffuse 52%, limited 48%) and the second group - 50 patients positive for a-RNP (43 women and 7 men, mean age 44.5±14 years, duration of the disease 11.7±8 years; form of the disease: diffuse 14%, limited 86). The diagnosis of ILD was established by HRCT.
Results: In patients of group I ILD was detected in 94% of cases, in group II - 68% (p<0.05). In both groups a decrease in functional lung tests was noted with a high frequency, but a severe decrease in the lung diffusion capacity was significantly more often observed in group I.

Table 1. Data of laboratory and instrumental parameters

Parameters	a-Topo-1- positive n (%)	a-RNP-positive n (%)	p
Decrease of DLCO < 80%	49 (98)	43 (86)	p<0,05
DLCO <55%,	33 (66)	16 (32)	p<0,05
Decrease of FVC< 80 %	19 (38)	10 (20)	p<0,05
FVC<70%	13 (26)	7 (14)	NS
Ground glass opacity	25 (50)	26 (52)	NS
Honeycombing	17 (34)	8 (16)	p<0,05
SPAP >40mm.Hg,	6 (12)	10 (20)	NS
including PAH**	2 (4)	3 (4,6)	NS
ANA> 1:640	37 (74)	45 (90)	p<0,05

** ANA – antinuclear antibodies, PAH – pulmonary arterial hypertension, SPAP - systolic pulmonary artery pressure ** confirmed by the data of catheterization of the right heart*

Typical changes according to HRCT were detected in both groups, but fibrotic changes dominates in group I. There were no significant differences in the frequency of occurrence of PAH. Patients of group II had high level of ANA more often.
Conclusion: In both groups, a high frequency and similar manifestations of ILD were noted. In patients with SSc positive for anti-U1RNP, despite the predominance of limited skin lesions (in 86% of patients), a high incidence of ILD was detected, while the frequency of PAH was comparable to SSc in general. Compared with a-Topo-1 positive patients, ILD was significantly less frequent in anti-U1RNP positive patients and was accompanied with a smaller reduction of DLCO and/or FVC and a lower frequency of severe lung fibrosis. These data confirm the similarity of lung involvement in compared phenotypes of SSc and indicate the importance for screening for ILD in patients with hyperproduction of a-RNP, especially at an early stage of the disease.

AB0455 MODIFICATION OF PROGNOSIS INTERVALS WAS DERIVED BY THE DISCRIMINATION FUNCTION FOR SSc-ILD PATIENTS

O. Ovsyannikova[1], L. P. Ananyeva[1], L. Garzanova[1], O. Koneva[2], S. Glukhova[2], M. Starovoytova[1], O. Desinova[1], R. Shayakhmetova[1]. [1]*VA Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation*; [2]*VA Nasonova Research Institute of Rheumatology, Educational and Methodical Department, Moscow, Russian Federation*

Background: Systemic sclerosis (SSc) is a multisystem autoimmune disease. Pulmonary alterations are the major cause of mortality in SSc. SSc-ILD has heterogeneous disease progression: many patients will have a chronic, indolent course while others may develop progressive, life-threatening disease.
Objectives: To assess prognosis intervals for pts with SSc-ILD.
Methods: It was a longitudinal study involving 140 pts with SSc-ILD. The mean age was 46.7±13.9years, females 82%, SSc duration 6.2±5.8 years, diffuse subset - 54%. The mean duration of follow up was 73,2±27,8 months. Clinical, laboratory, and immunologic data were collected on all patients.
Based on analysis of discrimination function the equation of prognosis was developed. The equation is 3.14GGO (ground glass opacities) + 0,7 index EScSG – 1,326 FVC - 0,1 the maximum daily dose of glucocorticoids + 0,136 Gamma globulins + 1.066 CYP – 1.075 DLCO ≤ 5,8. Value of equation of prognosis to 5.8 corresponds to stabilization or good prognosis and value after 5.8 corresponds to poor prognosis. The equation of prognosis had 86% sensitivity and 56% specificity. The cut-off point 4.7 was represented 65% sensitivity and 67% specificity. The prognosis intervals were following: value of equation to 4.7 corresponds to good prognosis; value from 4.8 to 5.8 corresponds to stabilization and value after 5.8 corresponds to poor prognosis.

Results: Pts were distributed into groups depending on results of discrimination function: 14 pts (10%) - zone of good prognosis; 8 pts (6%) - zone of stabilization and 118 (84%) - zone of poor prognosis. We have decided to join pts from zone good prognosis and zone stabilization into united group (U-group) - 22 pts (16 %).

Table 1. Comparative characteristics of the groups

Parameters	Group 1 (n=14)	Group 2 (n=8)	U-Group (n=22)	Group 3 (n=118)
Age years	45,4±16,4	50,2±15,8	47,2±16	47,5±13
P>0,05				
Gender				
Male	3(21%)	1(12,5%)	4(18%)	21(18%)

p>0,05				
ANA-hep-2	525±322*	420±190	487±281*	774±430*
p: Gr1 vs Gr3 =0,038; Gr2 vs Gr3=0,02; Gr1,2 vs Gr3 =0,032				
a-Scl-70 u/ml	59,9±82,7*	67±94,5	116±93**	62,5±85* **
p: Gr1 vs Gr3 =0,03; Gr1,2 vs Gr3 =0,013				
Ejection fraction(EF)(%)	67,3±5,3*	65,5±6,1	66,7±5,5**	63±6,8* **
	p: Gr1 vs Gr3 =0,02; Gr1,2 vs Gr3 =0,017			
PAP mm hg	31,6±5,8	32,4±9,3	31,9±7	36,4±14
p>0,05				
6MWT m	490±110	477±104	485±104	430±100
(6 Minute walk test)				

p>0,05

The age, SSc duration, gender proportion and SSc forms, were similar in the all groups (p>0,05). In the study mean dates of ANF-hep-2, a-Scl-70 were significantly lower and EF was significantly higher in groups 1 and U-group than in group 3. In groups 1,2 and U-group the mean levels of ESR, CRP, PAP were lower and value of 6MWT were higher than mean levels in group 3 accordingly. So separately group 2 didn't have significant differences with group 1 and 3.
Conclusion: In the study we didn't find any correlation between meanings of group 2 and groups 1,3 but the meanings of group 1 and U-group have had the

same correlation. It would be rational to highlight only one zone of prognosis before and after 5,8.

AB0456 HYDROXYCHLOROQUINE MIGHT REDUCE MORTALITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

M. Ozmen[1], E. Otman Akat[1], S. Gucenmez[1], G. Kabadayi[1], E. Durak Ediboglu[1], G. Alp[1], H. Cinakli[1], E. Erpek[1], İ. Kurut Aysin[1], O. Bayindir[1], D. Solmaz[1], S. Akar[1]. [1]*Izmir Katip Celebi University Faculty of Medicine, Rheumatology, Izmir, Turkey*

Background: Systemic sclerosis (SSc) is a devastating disease that has a profound impact on life expectancy, reflected by a standardised mortality ratio of 3,5. There is still limited data regarding the predictive factors for mortality in patients with SSc. Determining those factors could guide in disease management and follow up.[1]

Objectives: We aimed to identify the predictive factors for death in SSc.

Methods: Patients followed in a tertiary rheumatology clinic in the last 5 years were included in this retrospective study. All of the patients met the ACR / EULAR SSc 2013 criteria. Medical records of the patients were reviewed. Follow up time was defined as the time period from the first admission of the patient to our rheumatology clinic until the date of death or the date on which the study was performed. Candidate predictive factors for mortality were tested by Kaplan-Meier (with Log rank) and Cox-regression analyses.

Results: In total 146 patients (mean age 55.6±12.3 years, female 89.7%, diffuse cutaneous type SSc 45.2%) were included in the study (Table 1). The mean age at diagnosis of study group was 48±13.7 years. The median duration of follow up was 71 (6-228) months. Fourteen (10%) patients died during follow-up. The causes of death were: pulmonary (7), renal (2) and cardiac diseases (1), infection (3) and cancer (1).

Univariate analysis revealed that age at diagnosis (p=0.028), SSc subtype (p=0.035), the presence of interstitial lung disease (p=0.002), oesophageal involvement (on computed tomography) (p=0.030), pulmonary artery systolic pressure of ≥35 mmHg (measured by transthoracic echocardiography) (p=0.004), glucocorticoid (p=0.029), hydroxychloroquine (p=0.002) and cyclophosphamide (p=0.006) usage at any time were associated with mortality (Figure 1). Multivariate analyses model formed with age at diagnosis (B: 0.055, 95% CI, 1.005-1.112; **p=0.033**), SSc subtype (B: 0.963, 95% CI 0.541-12.684; p=0.231), glucocorticoid (B: 1.396, 95% CI, 0.487-33.507; p=0.196) and hydroxychloroquine usage (B: -1.50, 95% CI, 0.061-0.816; **p=0.023**) showed that age at diagnosis and hydroxychloroquine usage were independent predictive factors for mortality in patients with SSc.

Conclusion: The results of the study revealed for the first time that apart from the age at diagnosis hydroxychloroquine might reduce mortality in patients with SSc. Further studies are needed to prove of this information.

AB0457 HIPPOCAMPAL SUBFIELDS VOLUMES REDUCTION IN PATIENTS WITH SYSTEMIC SCLEROSIS: A LONGITUDINAL MAGNETIC RESONANCE IMAGING (MRI) VOLUMETRIC STUDY

D. Pereira[1], M. Freschi[1], R. Frittoli[1], A. C. Londe[1], T. Amaral[2], S. Dertkigil[3], A. P. Del Rio[4], F. Cendes[5], L. Rittner[6], S. Appenzeller[4]. [1]*UNICAMP, Pathophysiology Graduate Program, Campinas, Brazil*; [2]*UNICAMP, Medicine, Campinas, Brazil*; [3]*UNICAMP, Radiology, Campinas, Brazil*; [4]*UNICAMP, Orthopedics, Rheumatology and Traumatology, Campinas, Brazil*; [5]*UNICAMP, Neurology, Campinas, Brazil*; [6]*UNICAMP, Electrical Engeneering, Campinas, Brazil*

Background: Systemic sclerosis (SSc) is a multisystem disease characterized by functional and structural abnormalities of small blood vessels, fibrosis of the skin and internal organs. In addition, volume reduction and shape abnormality of the hippocampus have been demonstrated in rheumatic and neurodegenerative diseases. However, the neuroanatomy of the hippocampus is complex and is not a uniform structure, consisting of subfields with distinct morphology: cornu ammonis (CA) subfields CA1–4, dentate gyrus (DG), fimbria, and adjacent subiculum and presubiculum [1].

Objectives: To investigate the hippocampal subfields volumes reduction in SSc patients using MRI.

Methods: In this study we included 37 SSc patients (33 women, mean age of 53.46, SD ± 12.29; range 30 - 78) and 37 healthy controls (HC) (31 women, mean age of 48.41, SD±12.20; range 29 - 80). Cognitive evaluation was performed using the Montreal Cognitive Assessment (MoCA), mood disorders were determined through Beck's Depression (BDI) and Beck's Anxiety Inventories (BAI). SSc patients were further assessed for clinical and laboratory SSc manifestations, disease activity (Valentini Activity Index), severity activity (Medsger Severity Index). MRI protocol consisted of: Sagittal T1-weighted images performed with a Philips 3.0T MRI scanner. MRI brain structure volumetric was done through volBrain [2]. After 48 months MRI acquisition were repeated in 26 SSc patients and 12 healthy volunteers. Statistics was performed according nature of the variable.

Results: We observed a significant reduction in hippocampal subfields volumes in SSc patients when compared to controls: Total hippocampi (SSc: mean volume = 4.78 cm^3; SD = 0.38; HC: mean volume = 5.01 cm^3; SD = 0.38; p = 0.033). Reduction in volume of the total hippocampi was associated with Raynaud's phenomenon (p = 0.006). A longitudinal study showed a reduction in volume of the hippocampus subfields volumes when compared to patient's baseline: Total hippocampi (mean initial volume = 4.78 cm^3; mean follow-up volume = 4.50 cm^3, p = 0.027); Total CA1 (mean initial volume = 1.59 cm^3; mean follow-up volume = 1.58 cm^3, p < 0.0001); Reduction in volume of the total hippocampi was associated with presence of current use of prednisone (p = 0.008). Reduction in left CA1 left associated with current use of prednisone (p = 0.014). Reduction in total subiculum was associated with presence of calcinosis (p = 0.023). No significant changes were observed in hippocampal subfields volumes in controls over the follow-up period.

Conclusion: This study provides evidence of hippocampus subfields volumes reductions in SSc patients when compared to controls and was associated with

Raynaud's phenomenon, current use of losartan and correlated with BAI scores. Also, a longitudinal study showed a reduction in volume of the hippocampus subfields volumes when compared to patient's baseline associated with calcinosis and current use of prednisone.

AB0458 SURVIVAL OF SCLERODERMA PATIENTS WITH INTERSTITIAL LUNG DISEASE: OBSERVATION DATA FROM A MALAYSIAN TERTIARY CENTRE

J. Raja[1], S. Muthusamy[1], C. M. Ng[2]. [1]*University of Malaya, Division of Rheumatology, Department and Faculty of Medicine, Kuala Lumpur, Malaysia*; [2]*University of Malaya, Institute of Mathematical Sciences, Faculty of Science, Kuala Lumpur, Malaysia*

Background: Interstitial lung disease (ILD) is the leading cause of death in scleroderma (SSc) with decline in FVC as a predictor of mortality in patients with SSc-ILD, especially in the early course of the disease.

Objectives: The aim of this study is to determine the survival rate of SSc-ILD in a Malaysian cohort of patients from University Malaya Medical Centre (UMMC).

Methods: 61 patients clinically diagnosed with SSc-ILD were identified and prospectively recruited. Baseline demographic data were collected. Kaplan-Meier analysis was used to estimate the survival.

Results: Females were predominant (56, 91.8%). 39 (64%) had limited cutaneous SSc. Majority were ethnicity Chinese 30 (49.2%), followed by Malays 20 (32.8%), Indians 7 (11.4%) and others 4 (6.6%). Mean age was 56.25 (SD ± 12.5) years while mean duration of disease (non-Raynaud's disease onset) was 10.5 years (SD ± 9.2) (range of 1 year to 44 years) years. 29 (47.5%) patients were positive for anti-ScL-70, whereas 6 (9.8%) patients were anti-centromere positive. There were 16 (26.2%) deaths. Median survival was 24 years. Patients had a sharper drop in survival probability for the first 10 years compared to the next 20 years (Figure 1). Median survival in limited subset was 24 years whereas in diffuse subset was 11 years. Patients from the limited subset appeared to have higher chance of surviving for 10 years and above, compared to those in the diffuse subset (Figure 2).

Conclusion: The results demonstrate the poor survival in SSc-ILD patients. The survival rate tends to be worse in the first 10 years of SSc disease duration. Survival rate was poorer in patients with diffuse cutaneous subset.

AB0459 ARTICULAR INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Karakas[1], Y. Erez[1], S. Gulle[1], G. Can[1], İ. Sari[1], F. Onen[1], M. Birlik[1]. [1]*Dokuz Eylul University Faculty of Medicine, Rheumatology, Izmir, Turkey*

Background: SSc (systemic sclerosis) is a connective tissue disease characterized by small vessel vasculopathy, production of autoantibodies, and fibroblast dysfunction leading to increased deposition of extracellular matrix in the skin and internal organs mainly. Therewithal, many SSc patients develop musculoskeletal symptoms during the course of their illness. Different rheumatic complaints such as arthralgia, arthritis, contractures, tendon friction rubs, calcinosis, and acroosteolysis can be seen as musculoskeletal symptoms in SSc patients [1].

Objectives: To provide an overview of the spectrum of articular involvement in SSc and determine the relationship between these involvements and Rheumatoid factor (RF) and Anti-cyclic citrullinated peptide (Anti-CCP) positivity and organ involvements.

Methods: We performed a retrospective cohort study involving 232 SSc patients who were followed up in our department of rheumatology between 2000 and 2020 years. The patients were divided into two groups as limited and diffuse SSc. Age, gender, weight, height, smoking habits, duration of illness, follow-up duration, other systemic organ involvement, and radiographic findings were recorded. Diagnostic tests such as RF, Anti-CCP, ANA, ENA panel tests, direct radiographs were examined.

Results: The mean age of the patients was 59.9 ± 12.8 and 88.4% of them were women. 69.3% of patients were limited SSc. At any stage of the disease, 39.1% of all patients had arthralgia and 34.1% had arthritis. The arthritis rate was similar between the SSc groups (p = 0.396). RF and anti-CCP positivity rates were similar between the SSc groups. Although RF and anti-CCP positivity rates were higher in the patient group with arthritis, it was not statistically significant (respectively p=0.563, p=0.072). Interestingly, the lung involvement rate was higher in patients with arthritis (63.3% versus 46.4%) (p=0.015). Other clinical, demographic characteristics, laboratory, and radiographic findings of the patients are shown in Table 1.

Conclusion: Articular involvement in SSc is a common clinical feature seen in one-third of patients regardless of the type of disease. Although RF and Anti-CCP positivity are more common in patients with arthritis, it was not statistically significant. Interestingly, arthritis is a more common manifestation in patients with lung involvement.

AB0460 THE UTILITY OF USB CAPILLAROSCOPE FOR ASSESSMENT OF RAYNAUD'S PHENOMENON PATIENTS

S. Lambova[1]. [1]*Medical University - Plovdiv, Department of propaedeutics of Internal Diseases, Plovdiv, Bulgaria*

Background: Videocapillaroscopy is the gold standard for evaluation of nailfold capillaries and the major tool used for differentiation of primary and secondary Raynaud's phenomenon (RP) in rheumatology practice. However, nowadays, there are also accessible alternatives such as USB capillaroscopes, which offer the opportunity to apply capillaroscopic examination at a significantly lower price.

Objectives: The aim of the current study was to study the utility of USB capillaroscope (Dinolite) *via* assessment of capillaroscopic images obtained by patients with primary and secondary RP in rheumatic diseases.

Methods: The study represents analysis of capillaroscopic images of 32 patients with RP – primary and secondary in the context of SSc or other rheumatic diseases i.e., undifferentiated connective tissue disease (UCTD) and systemic lupus erythematosus (SLE). All the patients had signed an informed consent for participation in a study of their capillaroscopic, laboratory and clinical associations. The study represents retrospective analysis of the capillaroscopic images obtained from 8 fingers (II-V bilaterally) using USB capillaroscope (Dinolite) at magnification 200x. Capillary diameters were measured (arterial, venous and apical loop) as well as the number of capillaries per millimeter. The capillaroscopic images were categorized into the following groups i.e., I. Absence of microangiopathy: i) normal pattern, ii) nonspecific changes (dilated capillaries with arterial diameter > 0.015mm, venous > 0.020mm; haemorhhages and/or other nonspecific changes), II. Presence of microangiopathy i.e., "scleroderma"/"scleroderma-like" pattern. Presence of giant capillaries with capillary diameter >0.050mm was considered as a sufficient criterion for classifying the image as "scleroderma"/"scleroderma-like" pattern. For "scleroderma" type images in SSc patients staging of Cutolo et al (2000) was used i.e., "early", "active", "late" phase (1).
Results: Images suitable for analysis with good visibility that permits analysis of the major capillaroscopic parameters were available in all patients. Among 32 included patients, 9 patients were with SSc, 12 cases with primary RP, and 10 patients with secondary RP in other CTD (7 patients with UCTD and 3 patients with SLE). „Scleroderma" pattern was detected in 6 patients with SSc and in all these cases the capillaroscopic images were classifiable into one of the three distinct phases i.e., "early", "active" and "late" phase. Presence of microvascular changes ("scleroderma-like" pattern) was detected also in 5 among the 10 patients with other CTD i.e., UCTD and SLE. In primary RP patients capillaroscopy revealed either normal pattern or nonspecific findings but without features of microangiopathy.
Conclusion: Good capillaroscopic images, which could be analyzed and interpreted, are usually obtained using USB capillaroscope. This permits evaluation of the major capillaroscopic parameters. The available software although less sophisticated *vs* those of videocapillaroscopes, gives the opportunity for measurement of capillary diameters, mean capillary density, etc. The images received from USB capillaroscope are easily classified into "scleroderma", "scleroderma-like", non-specific changes and normal pattern. The most important conclusion from capillaroscopy is about presence or absence of microangiopathy. This was easily detected *via* USB capillaroscope that could be suggested as an ideal alternative for videocapillaroscopes in every day rheumatology practice especially at low budget cases. Measurements of capillary diameters and capillary density provide quantitative data that make these devises also appropriate for scientific research.

AB0461 "SCLERODERMA-LIKE" PATTERN AS A PRESENTING FEATURE OF CONNECTIVE TISSUE DISEASES

S. Lambova[1]. [1]*Medical University - Plovdiv, Department of Propaedeutics of Internal Diseases, Plovdiv, Bulgaria*

Background: The role of capillaroscopy for early diagnosis of systemic sclerosis (SSc) is well-known and pathological capillaroscopic pattern is a component of the new set of criteria for SSc (EULAR/ACR 2013). While it is also known that similar microvascular changes i.e., "scleroderma-like" could be observed in other rheumatic diseases i.e., undifferentiated connective tissue disease (UCTD), overlap syndromes, systemic lupus erythematosus (SLE), etc., the data about the time of their appearance in other rheumatic diseases different from SSc are scarce.
Objectives: The aim of the study was to evaluate the prevalence of capillaroscopic features of microangiopathy in Raynaud's phenomenon (RP) patients at the time of their first referral to rheumatology setting.
Methods: 22 in- and outpatients were included in the study that were referred for consultation in our rheumatology unit in the last 6 months. Inclusion criteria were presence of RP at their first consultation or still unclear diagnosis. Presence of known rheumatic disease diagnosed at previous consultation with rheumatologist as well as signs of definite diagnosis SSc were exclusion criteria. All the patients underwent capillaroscopic examination with USB capillaroscope Dinolite (magnification 200x). Routine laboratory tests were ordered i.e., complete blood count, ESR, CRP, biochemistry as well as immunological tests. ANA test was performed in all patients while antibodies against extractable nuclear antigens, antiphospholipid antibodies or other tests were ordered depending on the clinical presentation and overall context. The patients signed an informed consent for participation of the study.
Results: 12 of the examined patients were diagnosed with primary RP and their capillaroscopic examination revealed absence of microangiopathy i.e., normal pattern or non-specific changes (mainly dilated capillaries). In 7 patients the final diagnosis was UCTD and 4 of them exhibited microvascular pathology i.e. "scleroderma-like" pattern, while in 3 cases the capillaroscopic findings were non-specific. Among other patients 1 case was diagnosed with prescleroderma with "early" phase "scleroderma" pattern (according to definition of Cutolo et al., 2000 (1)), 1 case was with onset of SLE ("scleroderma-like" pattern, active phase) and in one case the microvascular pathology that included single giant capillary loop no other signs of connective tissue disease were found and the final conclusion was "suspected secondary" RP with necessity for a regular follow-up.
Conclusion: In conclusion, definite features of microvascular pathology, known as "scleroderma-like" capillaroscopic pattern, could be observed as an initial pathological feature in CTD different from SSc such as UCTD and SLE and the overall diagnosis should be made in the overall context. Capillaroscopy inherits its high significance in patients with UCTD, in whom clinical presentation could be obscure in the beginning and identification of microvascular capillaroscopic pathology is among the crucial signs to support the diagnosis. Future studies are necessary to delineate the role of microvascular pathology for prediction of future evolution of UCTD.

Spondyloarthritis – treatment

AB0462 BMI IS ASSOCIATED WITH BOTH DISEASE ACTIVITY AND TNF-α INHIBITOR SERUM TROUGH LEVELS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS ON LONG-TERM TREATMENT WITH TNF-α INHIBITORS

L. De Wolff[1], S. Arends[1], E. Brouwer[1], H. Bootsma[1], A. Spoorenberg[1]. [1]*University Medical Centre Groningen and University of Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: TNF-α inhibitors (TNFi) are widely used in axial spondyloarthritis (axSpA) patients with active disease. Approximately half of patients stop TNFi treatment, often due to loss of treatment efficacy.[1] TNFi serum trough levels have been associated with initial therapeutic response in axSpA patients.[2] Additionally, a relation was found between serum trough TNFi levels and BMI.[3]
Objectives: To explore in axSpA patients on long-term TNFi therapy associations between randomly measured TNFi serum trough levels, disease activity and BMI.
Methods: Patients from the UMCG on adalimumab or etanercept and a regular visit in the Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort were approached for a random TNFi serum trough level measurement. Based on reference values of Sanquin[3], serum trough levels were stratified in therapeutic and below therapeutic levels. The Ankylosing Spondylitis Disease Activity Score (ASDAS) from a regular outpatient GLAS visit was used for analyses, if assessed <2 months of the serum trough level measurement. Active disease according to ASDAS was defined as ≥2.1. Correlations and univariable logistic regression were performed. Multivariable logistic regression was performed to correct the relation between therapeutic drug levels and ASDAS for potential confounders.
Results: 94 axSpA patients on adalimumab or etanercept were approached for a random TNFi serum trough level measurement, of which 55 (59%) had a measurement taken. See Table 1 for patient characteristics. No significant correlations were found for adalimumab or etanercept serum trough levels (as continuous variable) with ASDAS (adalimumab: r=-0.16, p=0.39; etanercept: r=-0.29, p=0.20). According to Sanquin definitions of therapeutic TNFi levels, 26 patients (47%) had therapeutic serum trough levels: 19/34 (56%) for adalimumab and 7/21 (33%) for etanercept. Univariable logistic regression showed no significant associations between therapeutic levels (yes/no) and ASDAS. In multivariable analyses, BMI was identified as the only confounder for the relationship between therapeutic drug levels and ASDAS. Median BMI was higher, although not statistically significant, in patients with below-therapeutic serum trough levels compared to therapeutic levels (27.1, IQR 24.6-31.7 vs. 24.3, IQR 22.7-31.4, p=0.08). Furthermore, BMI had a significant, negative correlation with adalimumab and etanercept serum levels (adalimumab: r=-0.48, p=0.01, etanercept: r=-0.46, p=0.04) (Figure 1). Patients with active disease according to ASDAS had higher BMI than patients with inactive disease (median 29.7 vs. 24.5, p=0.01).
Conclusion: In this cross-sectional, observational study of axSpA patients on long-term TNFi treatment, BMI was significantly correlated with adalimumab and etanercept serum trough levels. Furthermore, BMI was significantly higher

in patients with active disease. Therefore, overweight /obese patients on TNFi treatment and active disease, might benefit from an increase in TNFi dose.

IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES IN ANKYLOSING SPONDYLITIS PATIENTS TREATED WITH GOLIMUMAB: SUB-ANALYSIS OF ASIAN PATIENTS ENROLLED IN PHASE-3 CLINICAL TRIALS

W. C. Tsai[1], C. Bao[2], D. Furtner[3], K. H. Lo[4], Y. Zhou[4], E. C. Hsia[4,5]. [1]*Kaohsiung Medical University, Department of Internal Medicine, Kaohsiung, Taiwan, Republic of China*; [2]*Renji Hospital, Department of Rheumatology, School of Medicine, Shanghai Jiao Tong University, Shanghai, China*; [3]*Janssen, a Division of Jonson & Johnson Pte Ltd., Singapore, Singapore*; [4]*Janssen Research & Development, LLC, Spring House, United States of America*; [5]*University of Pennsylvania Medical Center, Rheumatology, Philadelphia, United States of America*

Background: Clinical efficacy and safety of golimumab (GLM) for patients with ankylosing spondylitis (AS) who have not received prior biologic therapy were studied in two phase-3 clinical trials (NCT00265083 - GO RAISE and NCT01248793). In both studies, a greater proportion of patients treated with GLM 50 mg every 4 weeks achieved improvement in clinical signs and symptoms measured by ASAS20 and in patient-reported outcomes, such as Health Related Quality of Life (HRQoL) and sleep disturbance when compared with placebo (PBO) at Weeks 14 and 24.
Objectives: To assess the effect of GLM on HRQoL, back pain, and sleep disturbances in phase-3 studies in Asian patients with AS.
Methods: Post-hoc sub-analysis to examine HRQoL, measured with the Short Form 36 (SF-36) Physical and Mental Component Summary (PCS and MCS), total back pain (VAS) and sleep disturbance, assessed with the Jenkins Sleep Evaluation Questionnaire (JSEQ) in active AS patients enrolled from Asian countries (China, including Taiwan region and South Korea). Improvement from baseline to Week 24 was expressed as mean and standard deviation (SD) for SF-36 PCS and MCS and total back pain. Reduction of sleep disturbance was expressed as the proportion of patients with improvement from baseline ≥2 points in the JSEQ, defined as baseline value minus post-baseline value with lower scores indicating the better sleep evaluation.
Results: At Week 24, active AS patients treated with GLM 50 mg had greater mean improvements in SF-36 and total back pain than PBO. The pooled results were comparable with patients enrolled from other regions (Table 1). A higher proportion of Asian patients who received GLM had reduced sleep disturbance (JSEQ ≥2) after 24 weeks than PBO (59.7% [83/139] vs 38.5% [47/122]; Δ21.2) and the results were similar with AS patients on GLM (67.4% [64/95] vs 45.6% [26/57]; Δ21.8) pooled from other regions.
Conclusion: Asian patients with AS treated with GLM demonstrated improved HRQoL, total back pain, and reduced sleep disturbance. The pooled results were comparable with other regions.

Table 1. Mean Improvement from Baseline in HRQoL and total back pain at Week 24: Randomized Patients in AS Studies Pooled for Asia and all other regions

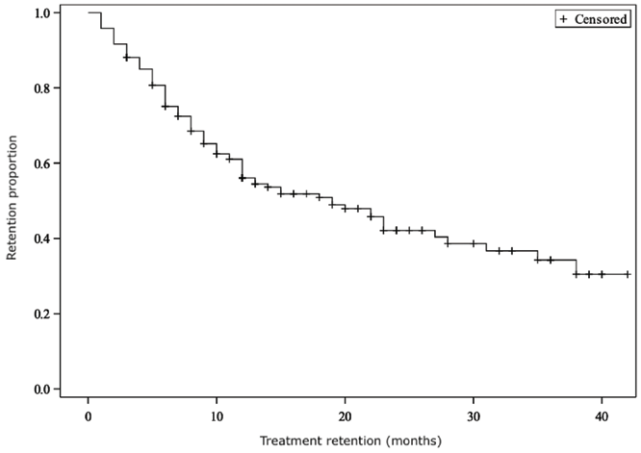
DRUG SURVIVAL OF TNFI AND SECUKINUMAB IN AXIAL SPONDYLARTHRITIS: A REAL-WORLD MULTICENTRIC COHORT OF 370 PATIENTS

T. Delepine[1], P. Philippe[1], E. Cailliau[2], E. Houvenagel[3], X. Deprez[4], R. M. Flipo[1], J. G. Letarouilly[1]. [1]*Lille University Hospital, Department of Rheumatology, Lille, France*; [2]*Lille University Hospital, Biostatistics, Lille, France*; [3]*Saint-Philibert Hospital, Rheumatology, Lomme, France*; [4]*Valenciennes Hospital, Department of Rheumatology, Valenciennes, France*

Background: IL17 inhibitors (IL17i) are an alternative for patients with axial spondyloarthritis (axSpA) who did not respond to TNF inhibitors (TNFi). Secukinumab (SEC) is the first human monoclonal antibody that binds to the protein interleukin-17A.
Objectives: The objectives of this study were to describe the characteristics of axSpA patients treated with IL17i and TNFi and to assess the persistence with IL17i and TNFi in a real world cohort.
Methods: A retrospective multicenter observational study was conducted. axSpA patients (pts) according to ASAS criteria initiating a IL17i or TNFi between June 2016 and December 2019 were included. Demographic features, current and previous use of biologic Disease-modifying antirheumatic drugs (bDMARDs) were collected. Date and reasons of discontinuation – i.e., lack of efficacy, safety issue, sustained remission or others – were collected. Kaplan-Meyer analysis were performed.
Results: 370 pts were included. Among the 202 patients who received TNFi, 90 (44.6%) were female, mean age was 43.2 +/- 13.2 years, mean body mass index was 26.1 kg/m^2 +/- 5.4, 49 pts (46.7%) were smokers. The most common SpA phenotype was axial radiographic (n = 89, 54,9%) and 114 (68.3%) pts were HLA B27 positive, mean BASDAI was 57.5 +/- 14.6, median disease duration was 8.6 years [3.0-10.5]. Among the 168 patients who received SEC, 78 (46.4%) were female, mean age was 47.7 +/- 11.8 years, mean body mass index was 27.2 kg/m^2 +/- 5.8, 45 pts (44.1%) were smokers. The most common SpA phenotype was axial radiographic (n = 106, 76,3%) and 114 (78.1%) pts were HLA B27 positive, mean BASDAI was 62.8 +/- 14.8, median disease duration was 9 years [5.0-19.0]. TNFi was the first line bDMARD in 116/202 pts (57.4%) and SEC was the first line bDMARD in 15/168 pts (8.9%). SEC was prescribed at 150mg every month in 121/168 (73.3%) pts. The median persistence with TNFi and SEC were 18.0 months [11.0-27.0] and 12.0 months [6.0-22.0],

respectively. During the 3-year follow-up, 130 pts (42 with TNFi and 88 with SEC) discontinued treatment: 80 (22 with TNFi and 58 with SEC) for lack of effectiveness, 41 (16 with TNFi and 25 with SEC) for adverse events. No patient



treated with SEC presented a new-onset inflammatory bowel disease.

Figure 1. Persistence with SEC after 3 years of follow-up

Conclusion: In this real world cohort of AxSpA pts, SEC was mostly prescribed at second and third-line, contrary to axSpA pts treated with TNFi. Most reason of discontinuation were related to lack of effectiveness with both therapeutic classes.

INDIVIDUAL COMPONENTS CONTRIBUTING TO THE ACHIEVEMENT OF ASAS40 RESPONSE IN BIOLOGIC NAÏVE PATIENTS WITH RADIOGRAPHIC AXSPA: RESULTS FROM THE COAST-V TRIAL

D. Poddubnyy[1], S. Attar[2], M. J. Nissen[3], E. Filippi[4], H. Russ[5], A. Erdogan[6], Y. Schymura[7], S. Liu Leage[8], E. Collantes Estevez[9], F. Ciccia[10]. Background: Ixekizumab (IXE), an IL-17A antagonist, is effective in patients with radiographic axial spondyloarthritis (rad-axSpA). Assessment in SpondyloArthritis International Society (ASAS) 40 response – the primary study endpoint – was achieved at week (wk) 16 by 48% of those treated with 80mg subcutaneous IXE every 4 wks (Q4W) in the phase 3 COAST V trial (NCT 02696785) [1]. Until now, no information has been available on the efficacy of IXE on the components of ASAS40 composite endpoint.

Objectives: To describe which individual components of ASAS40 drive achievement of efficacy response.

Methods: This exploratory post-hoc analysis was based on COAST V data. Patients enrolled in COAST V met ASAS criteria for rad-axSpA and were biological disease-modifying antirheumatic drug (bDMARD)-naïve. Patients were assigned 1:1:1:1 to subcutaneous placebo (PBO), IXE Q4W, IXE Q2W or 40 mg adalimumab (ADA). Only data for approved doses are shown.

To reach ASAS40 response, patients must have an improvement of at least 40% and at least 2 units for at least 3 of 4 individual components which define response (patient global assessment of disease activity, spinal pain, inflammation (defined as the mean of Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) questions 5 and 6), and function (Bath Ankylosing Spondylitis Functional Index - BASFI)), without worsening in the remaining component. We describe the percentage of patients who achieved this change, had an insufficient response, or deteriorated in each component out to wk 16 for IXE Q4W, ADA and PBO. The time course of the change from baseline in individual components of the ASAS response is depicted descriptively per treatment arm by use of the mean and standard deviation. Observed data have been utilised.

Results: IXE Q4W response at 16 wks was driven by all 4 individual components of the ASAS40 with the largest improvements for patients treated with IXE Q4W seen in inflammation and spinal pain (Figure 1).

At wk 16, at least 50% of all patients treated with IXE Q4W achieved response on spinal pain (60.3%), inflammation (60.3%) and patient global assessment (50%), with 43.6% of patients meeting the response criteria for function (Table 1). The corresponding results for ADA were 43.2%, 47.7% 39.8%, and 35.2%.

Conclusion: Our findings show that meeting ASAS40 response criterion for an individual component at 16 wks by patients treated with IXE Q4W was broadly similar between individual components. However, a clinically relevant improvement was more frequently observed for the spinal pain and inflammation components.

AB0466 RETENTION RATE AND EFFECTIVENESS OF SECUKINUMAB VERSUS TNF INHIBITOR SWITCHING IN ANKYLOSING SPONDYLITIS PATIENTS WITH A HISTORY OF TNF INHIBITOR TREATMENT: DATA FROM A KOREAN NATIONWIDE REGISTRY

H. K. Min[1], K. Y. Kang[2]. [1]*Konkuk University Medical Center, Internal Medicine, Seoul, Korea, Republic of (South Korea)*; [2]*The Catholic University of Korea Incheon St. Mary's Hospital, Internal Medicine, Incheon, Korea, Republic of (South Korea)*

Background: The choice of second-line biologics for ankylosing spondylitis (AS) patients previously treated with a tumour necrosis factor inhibitor (TNFi) remains unclear

Objectives: Here, we compared drug retention and clinical efficacy between AS patients who switched biologics to secukinumab and those who switched to a different TNFi.

Methods: AS patients enrolled in the Korean College of Rheumatology BIOlogics registry were included. Patients with previous TNFi exposure were divided into the secukinumab group and the TNFi switching group. Drug retention and clinical efficacy (BASDAI50, ASAS20, ASAS40, ASDAS <2.1, ASDAS clinically important improvement, and ASDAS major improvement) were assessed at the 1 year follow-up. Propensity score (PS)-matched and covariate-adjusted logistic regression analyses were performed.

Results: 246 had available 1 year follow-up data. Secukinumab as third- or later-line biologics was more frequent than alternative TNFi (54% vs. 14%). PS-matched and multiple covariate-adjusted analyses showed that the odds ratio (OR) for drug discontinuation was comparable between the secukinumab and TNFi switching groups (OR=1.136; 95% CI, 0.843–1.531 and OR=1.000; 95% CI, 0.433–2.308, respectively). The proportion of patients who achieved BASDAI50 was also comparable between the two groups (OR=0.833; 95% CI, 0.481–1.441 in PS-matched analysis). Other clinical efficacy parameters were also comparable. In the subgroup analysis of AS patients with previous TNFi discontinuation due to ineffectiveness, all clinical efficacy parameters were comparable between the two groups.

Conclusion: In AS patients with previous exposure to a TNFi, switching biologics to secukinumab and switching to an alternative TNFi resulted in comparable drug retention and clinical efficacy.

Background: Golimumab showed trial efficacy in subjects with active rheumatoid arthritis (RA) previously treated with TNF-inhibitors (TNFi); no trial data are available for psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA).

Objectives: To assess the effectiveness of golimumab after TNFi failure in patients with RA, PsA, or axSpA in a real-world setting.

Methods: GO-BEYOND-Italy is an ongoing, multicenter, prospective, observational study of RA, PsA, or axSpA patients starting golimumab after TNFi failure. Patients were enrolled between July 2017 and December 2019, and followed for 1 year, with evaluations at 3, 6, and 12 months. This interim analysis estimates the effectiveness after 3 months of golimumab therapy. Differences from baseline were tested by paired t-tests.

Results: 193 patients were enrolled: 38 (19.7%) with RA (median age 54 years; median disease duration 9.5 years), 91 (47.2%) with PsA (median age 53 years; median disease duration 9.0 years) and 64 (33.2%) with axSpA (median age 54 years; median disease duration 7.2 years). Majority of the RA (73.7%), PsA (51.6%) and axSpA (53.1%) were females. Previous TNFi treatment included etanercept (44.6% of patients), adalimumab (42.0%), infliximab (8.8%) and certolizumab (4.7%). The main reason for switching to golimumab was loss of efficacy of TNFi (78.9% in RA, 83.5% in PsA, 75% in axSpA). Comorbidities were highly prevalent (RA 65.8%, PsA 65.9%, axSpA 75%); hypertension (31.1%), dyslipidaemia (13.5%), fibromyalgia (10.4%) were the most common ones. DAS28-CRP significantly reduced in RA and PsA ($p<0.01$) after 3 months of treatment. In RA, rates of DAS28-CRP remission and low disease activity (LDA) were 29.6% and 22.2%, respectively, and 65.2% of patients achieved good/moderate EULAR response. As for PsA, good/moderate EULAR response was observed in 78.8% of patients and 28% of patients achieved minimal disease activity. In axSpA, ASDAS-CRP ($p<0.01$), BASDAI ($p<0.01$) and ASAS-HI ($p=0.032$) significantly reduced; rates of ASDAS-CRP inactive disease and LDA were 15.2% and 26.1%, respectively; 14% of patients had a ≥50% improvement in baseline BASDAI. After 3 months of golimumab treatment, there was a decrease in the prevalence of enthesitis (32.9% to 16.5%), nail (17.6% to 12.9%) and skin psoriasis (42.4% to 34.1%) in PsA patients; the frequency of extra articular manifestations tended to decrease also in axSpA patients.

Conclusion: Preliminary results of the GO-BEYOND-Italy study showed a good short-term effectiveness of golimumab in RA, PsA and axSpA after TNFi failure.

AB0468

IS THE USE OF INTERLEUKIN 17 INHIBITORS IN SPONDYLOARTHRITIS RELATED TO THE CLINICAL MANIFESTATIONS? 12-MONTH EXPERIENCE OF ONE RHEUMATOLOGY CENTER

M. Khapsirokova[1], Z. Kolkhidova[1], S. Erdes[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Clinic, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia., Clinic, Moscow, Russian Federation*

Background: Therapy with interleukin 17 (iIL17) inhibitors in Russia is indicated for patients with ankylosing spondylitis (AS) or psoriatic arthritis (PSA). If standard therapy is ineffective in these diseases, both tumor necrosis factor inhibitors (iTNF) and iIL17 can be prescribed as the first biologics.

Objectives: To study the clinical features of patients with spondyloarthritis (SPA) who were first prescribed iIL17 in a rheumatology center for 12 months.

Methods: During the period from January to December 2019, iIL17 was initiated to 43 SPA patients. To compare the clinical picture, the study additionally included 40 SPA patients who were prescribed iTNF during the same period. The diagnosis of AS was based on the mNY criteria, and psoriatic arthritis was based on the CASPAR criteria. In the combined group of 83 patients, AS was in 52 (62.7%), and PSA – in 31; the age of patients was 39.3±10.8 years, and the duration of the disease was 15.1±8.2 years; men were 47 (56.6%).

Results: In the iIL17 group, AS had 23 (53.5%) patients, and PSA – 20 (46.5%), while in the iTNF group, respectively, 29 (72.5%) and 11 (27.5%; $\chi 2$=3.2, p=0.76). Among the patients who were prescribed iIL17, men were 29 (67%), and in the iTNF group – 18 (45%; $\chi 2$=4.2, p=0.04). In terms of activity indicators (ESR, CRP, BASDAI ASDAS-CRP), patients who were prescribed iIL17 or iTNF did not differ significantly from each other. Peripheral arthritis, dactylitis, and entesitis were observed with almost the same frequency in both groups. In the iIL17 group, there were almost 2 times more patients with psoriasis (53.5% and 25.0%; p<0.05) than in group iTNF and among them, significantly more frequent the patients had previous experience of iTNF treatment (41,9% and 17.5%; p<0.05). Disease-modifying antirheumatic drugs often received patients in iTNF group (80.0% and 48.8%; p<0.05).

Conclusion: Thus, in clinical practice iIL17 often prescribed for SPA male patients with psoriasis and previous treatment experience by iTNF. The activity of the disease and the presence of non-axial manifestations practically do not affect the choice of biological therapy.

Disclosure of Interests: None declared.

AB0469

PROTON PUMP INHIBITORS MAY IMPAIR RESPONSE TO TNF-INHIBITORS IN SPONDYLOARTHRITIS PATIENTS

M. Masson[1], M. Kostine[1], T. Barnetche[1], A. Saraux[2], A. Ruyssen-Witrand[3], T. Thomas[4], D. Wendling[5], M. E. Truchetet[1], C. Richez[1], T. Schaeverbeke[1]. *[1]Bordeaux University Hospital, Rheumatology, Bordeaux, France*; *[2]Brest University Hospital, Rheumatology, Brest, France*; *[3]Toulouse University Hospital, Rheumatology, Toulouse, France*; *[4]Saint-Etienne University Hospital, Rheumatology, Saint-Etienne, France*; *[5]Besançon University Hospital, Rheumatology, Besaonçon, France*

Background: Considering the potential role of the gut microbiota in the pathophysiology of spondyloarthritis (SpA) as in the therapeutic response to biologics (1), we evaluated the hypothesis that co-medications known to interfere with the gut microbiota could impair the therapeutic response to TNF-inhibitors (TNF-i) in SpA patients. This was first suggested by the results of a retrospective cohort showing that a co-medication with proton pump inhibitors (PPIs), non-steroidal anti-inflammatory drugs (NSAIDs) or antibiotics was significantly associated with a decreased chance to respond to a first TNF-I, independently of each other (2).

Objectives: To validate in a replication cohort the potential negative association between therapeutic response to TNF-i and co-medication with commonly used drugs.

Methods: Demographic information and disease characteristics were retrospectively collected. Patients were classified as responder (R) or non-responder (NR) according to the BASDAI (< 40/100) value at month 6 or to the clinician judgment (when BASDAI was not available). We collected all drugs known to interfere with the gut microbiota that were administered 1 month before and during the first 3 months of the TNF-i treatment. We only considered drugs given to more than 5% of patients. Univariate and multivariate analyses were performed to evaluate the relationship between co-medications, predictors of response known from literature and TNF-i response. All analyses were computed on STATA 13.1 with a statistically significant threshold of 0.05.

Results: We included from 4 different centres 185 patients having axial SpA with radiographic or magnetic sacroiliitis in 75% and 73% of cases, respectively. One third of them had peripheral involvement. 73% were B27 positive. TNF-i administrated were infliximab (8%), etanercept (22%), adalimumab (44%) golimumab (19%), certolizumab (7%). 127 patients (69%) were considered as R. 59.4% of patients who received NSAIDs were R, compared to 81% not treated with NSAIDs (p< 0.0001). 43,3% of patients receiving PPIs were R compared to 83% of patients PPI free (p< 0.0001). Differences were not significant for antibiotics, methotrexate (MTX), psychotic drugs and corticosteroids. Considering known predictors of response, a magnetic sacroiliitis and the age at TNF-i initiation were significantly associated with a higher proportion of R patients (p=0.048 and 0.018 respectively). In multivariate analysis, PPIs intake remained associated with a poorer response to a first TNF-i (p<0.001), even though 88% of patients exposed to PPIs received also NSAIDs.

	Univariate analysis	Multivariate analysis
	Odd Ratio (95% Confidence Interval)	
Gender	1.43 (0.76; 2.72)	
Disease duration	1.02 (0.99; 1.06)	
Age at TNF-I initiation	0.97 (0.95; 0.995)	0.97 (0.94; 0.999)
Magnetic sacroiliitis	0.46 (0.21; 0.99)	0.63 (0.26; 1.52)
Baseline BASDAI	1.02 (0.99;1.04)	
Baseline CRP	0.99 (0.98; 1.02)	
Positive B27	0.81 (0.4;1.68)	
Peripheral involvement	0.79 (0.4; 1.56)	
NSAIDs	2.91 (1.47; 5.77)	1.08 (0.41; 2.79)
PPIs	6.4 (3.25; 12.7)	6.9 (2.8;17)
Antibiotics	1.87 (0.84; 4.16)	
Psychotics	1.94 (0.75; 4.97)	
Corticosteroids	1.11 (0.39; 3.11)	
Methotrexate	2.29 (0.97; 5.38)	

Conclusion: Co-medication with PPIs was considered as an independent factor associated with TNF-i failure. The hypothesis that this effect is due to their interference with the gut microbiota is only speculative but, regardless of the reason for this interaction, clinicians should be aware of the potential negative effect on TNF-i response.

AB0470 EXPERIENCE WITH THE USE OF INTERLEUKIN 6 INHIBITOR IN SEVERE ANKYLOSING SPONDYLITIS

D. Rumiantceva[1], E. Agafonova[1], M. Urumova[1], S. Erdes[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation*

Background: Inhibitors of interleukin 6 (IL6) have been found to be ineffective in ankylosing spondylitis (AS) based on the results of randomized clinical trials (RCTs) on tocilizumab (TCZ) and sarilimumab [1, 2]. However, there is evidence that IL6 is actively involved in the pathogenesis of the disease [3]. In addition, the efficacy of IL6 inhibitors has been shown in patients with secondary AA amyloidosis [4].

Objectives: to analyze the effectiveness of IL6 inhibitor - TCZ in patients with AS with high disease activity and secondary AA-amyloidosis.

Methods: The analysis included 10 patients with AS receiving TCZ therapy, of which 8 (80%) men, 2 (20%) women, and 100% HLA B27 positive. The average age of the patients was 40 ± 8.6 years, the average age of disease onset was 13.4 ± 7.5 years, the average duration of AS was 25.6 ± 6.5 years. 9 patients had histologically confirmed secondary AA-amyloidosis: 100% had kidney amyloidosis, 6 (66.6%) patients also had gastrointestinal amyloidosis and 3 (33.4%) patients had heart amyloidosis. All patients had arthritis and coxitis.

Results: As the first biological drug, TCZ was prescribed to 2 patients due to the presence of manifestations of secondary AA-amyloidosis, and 8 patients had previous experience of treatment with one or more inhibitors of tumor necrosis factor-α (TNF-α). The average duration of TCZ treatment was 22.0 months [1.0; 36.0]. 8 (80%) patients continue to take TCZ therapy to date, and 2 (20%) - are transferred to TNF-α inhibitors. Table 1 shows the main clinical and laboratory characteristics of patients at the initiation of TCZ therapy and during the last hospitalization at the V.A. Nasonova Research Institute of Rheumatology. As you can see, against the background of TCZ therapy, both the level of CRP, proteinuria and the indices of AS activity (BASDAI, ASDAS CRP) significantly decreased. The number of patients with inflammatory back pain (IBP), arthritis and coxitis also decreased significantly.

Table 1. The main clinical and laboratory characteristics of patients at the initiation and after of TCZ therapy.

	Before TCZ	After TCZ	p
CRP, Me [25‰; 75‰], mg/l	95.2 [52.2; 189.0]	10,8 [0.8; 8.0]	**p<0,05**
Proteinuria, Me [25‰; 75‰], g/day.	1,6 [1,0; 2,1]	0,08 [0; 0,3]	**p<0,05**
BASDAI, Mean (SD)	6,1 (1,6)	3,3 (0,9)	**p<0,05**
ASDAS CRP, Mean (SD)	4,3 (1,1)	2,2 (0,7)	**p<0,05**
IBP, N (%)	10 (100%)	2 (20%)	**p<0,05**
Arthritis, N (%)	10 (100%)	2 (20%)	**p<0,05**
Cocxitis, N (%)	10 (100%)	5 (50%)	**p<0,05**
Enthesitis, N (%)	7 (70%)	6 (60%)	p>0,05

Conclusion: The above data showed that the method of treating AS with IL6 inhibitors, in certain clinical situations, primarily such as ineffectiveness of TNF-α inhibitors, high CRP level and the development of secondary AA-amyloidosis, can be highly effective. Therefore, it is advisable to continue the set of clinical observations on the treatment of especially severe patients with AS treated with non-standard methods.

AB0471 PATIENTS WITH RADIOGRAPHIC AXSPA WHO PROGRESSED FROM ASAS20 AT WEEK 16 TO ASAS40 AT WEEK 52: RESULTS FROM COAST-W

X. Baraliakos[1], A. Deodhar[2], S. Liu Leage[3], Y. Schymura[4], R. Bolce[5], D. Sandoval[5], J. A. Walsh[6], J. Sieper[7]. [1]*Ruhr-University Bochum, Rheumatology, Bochum, Germany*; [2]*Oregon Health & Science University, Division of Arthritis & Rheumatic Diseases, Portland, United States of America*; [3]*Eli Lilly and Company Corporate Center, Rheumatology, Indianapolis, United States of America*; [4]*Eli Lilly and Company Corporate Center, Statistics, Indianapolis, United States of America*; [5]*Eli Lilly and Company Corporate Center, Medical Affairs, Indianapolis, United States of America*; [6]*University of Utah, Rheumatology, Salt Lake City, United States of America*; [7]*Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Rheumatology, Berlin, Germany*

Background: The timeframe for maximum treatment response varies across patients with radiographic axial spondyloarthritis (r-axSpA). Understanding which patients may benefit from additional time on treatment could influence treatment decisions.

Objectives: This post-hoc analysis aims to determine the percentage of patients, previously exposed to TNFi, who progressed from ASAS20 at week 16 to ASAS40 response at week 52 with ixekizumab (IXE) treatment and to explore factors that may associate with additional improvement after 16 weeks.

Methods: Patients who achieved Assessment of SpondyloArthritis International Society (ASAS)20 at week 16 from COAST-W (NCT02696798), a Phase 3, randomized, double-blind, placebo-controlled trial, in tumour necrosis factor inhibitor (TNFi)-experienced patients who fulfilled the ASAS criteria for r-axSpA, were analysed. Patients treated with IXE 80 mg Q4W were categorized according to their ASAS response at week 52: sustaining ASAS20 but not reaching an ASAS40 response or achieving ASAS40. Patient demographics and disease characteristics at baseline were analysed by descriptive statistics, and the individual components determining ASAS response at baseline and at week 52 are provided.

Results: At week 16, 22.8% (n=26/114) of patients achieved ASAS20 but not ASAS40; of these, 2 patients discontinued the study before week 52. Amongst the patients who continued through week 52, 50% (12/24) of patients achieved ASAS40; the other 50% sustained their ASAS20 response. Patients who achieved ASAS40 at week 52 were older, had longer disease duration, were less likely to be HLA-B27 positive, and had worse BASDAI and BASFI scores at baseline (Table 1, part a). Achieving ASAS40 appeared to depend most on the Patient Global Assessment of Disease Activity and spinal pain score over time (Table 1, part b).

Table 1. a) Demographics and Characteristics at Baseline (week 0) and b) Descriptive observed data for the individual components of the ASAS response criteria at week 52, mean (SD)

a)	IXEQ4W

AB0472

DISEASE ACTIVITY AND OUTCOME IN PREGNANCIES OF PATIENTS WITH SPA - DATA FROM THE GERMAN PREGNANCY REGISTER RHEKISS

A. Weiß[1], C. Bungartz[1], J. Richter[2], S. Spaethling-Mestekemper[3], X. Baraliakos[4], P. M. Aries[5], R. Fischer-Betz[2], A. Strangfeld[1]. *[1]German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany*; *[2]University Hospital Düsseldorf, Department of Rheumatology & Hiller Research Unit, Düsseldorf, Germany*; *[3]Rheumapraxis München-Pasing, Rheumatology, München, Germany*; *[4]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*; *[5]Rheumatologie, Rheumatology, Hamburg, Germany*

Background: Spondyloarthritis (SpA) is a severe chronic inflammatory disease, which affects quality of life and functional status. It frequently occurs in women of childbearing age. Active disease and TNFi discontinuation at early pregnancy were found to be risk factors for flares during pregnancy (1).

Objectives: To compare disease activity during pregnancy in patients with or without bDMARD exposure at conception and during pregnancy and to assess pregnancy outcomes.

Methods: RHEKISS is a prospective longitudinal cohort study including patients with confirmed diagnose of inflammatory rheumatic disease. Pregnant patients are eligible to be enrolled until the 20th week of gestation regardless of drug treatment. During observation, information on treatment, disease and pregnancy course, and outcome is collected from rheumatologists and patients. For this analysis, pregnancies of patients with SpA were selected and stratified into three groups according to their exposure to bDMARDs.

Results: Of 140 SpA pregnancies included, 74 (53%) were not exposed to bDMARDs at conception (group 1), 38 (27%) were exposed to bDMARDs at conception, but not during pregnancy (group 2) and 28 (20%) were continuously exposed to bDMARDs at conception and during pregnancy (group 3). Certolizumab (50%), Adalimumab (20%), Etanercept (8%) and Infliximab (8%) were the most frequently prescribed bDMARDs at beginning of pregnancy. Baseline characteristics according to treatment exposure are shown in Table 1. Frequency of flares was highest in group 2: 21%, 38%, and 39% of patients flared during the 1st, 2nd, and 3rd trimester. These rates were 20%, 25%, and 21% in group 1 and 8%, 20%, and zero in group 3. The difference in flare rates was also mirrored in the course of physician assessed global disease activity (Figure 1). Whereas patients in group 1 seemed to have a quite stable disease activity during pregnancy, those who were in group 2 had an increasing activity of disease during pregnancy with an even higher increase of disease activity after giving birth. Patients in group 3 had the lowest disease activity.

Of 137 singleton pregnancies, 130 (95%) ended in live birth. Of 6 spontaneous abortions 2 were in every of the three groups. One pregnancy in group 1 was terminated in gestational week 22 due to suspect malformation. One baby of the triple pregnancy was born and two aborted. All babies of the twin pregnancies were born healthy.

Conclusion: SpA patients treated with bDMARDs at conception are not at higher risk for adverse pregnancy outcomes. Our results in a larger patient population confirmed that discontinuation of bDMARDs after conception is associated with increased disease activity during pregnancy and after birth and a higher risk of flares.

AB0473 TREATMENT OF ANKYLOSING SPONDYLITIS (AS) DURING PREGNANCY

O. Krichevskaya[1], T. Dubinina[1], E. Ilinykh[1], S. Glukhova[1], A. Demina[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Medical and Social Problems of Rheumatology, Moscow, Russian Federation*

Background: The use of medications during pregnancy remains a challenge for both rheumatologists and patients. The lack of compelling evidence of the safety of a line of different drugs, as well as the traditional idea of the incompatibility of therapy and gestation that is common view in Russia, lead to unjustified withdrawal of drugs by both pregnant women and rheumatologists.
Objectives: to describe the frequency of drug usage in pregnant women with AS, to determine the relationship of AS activity and pregnancy complications.
Methods: 49 pregnant women with confirmed AS (modified New York criteria, 1984) were included for prospective observation. 50 pregnancies in total were traced. The average age of the patients was 31.6±4.9 years, the duration of the disease was 134.4±85.8 months. The visits were conducted at 10-11, 20-21, and 31-32 weeks of pregnancy. The BASDAI in the month of conception and in the trimesters of pregnancy was: 1,4[0,6; 3,3]; 2,3[1,2; 4,4]; 2,8[1,4; 4,2] and 2,2[1,6; 4,0], respectively. 48 pregnancies ended with the birth of alive children at an average of 39±1.1 weeks, the height of newborns-51.6±2.1 cm, weight-3397.3±433.1 g. 8 (16.3%) newborns had malformations, 7 of them - minor heart development anomalies, 1 - hydronephrosis. Pregnancy complications: early toxicosis - 18% of pregnant women, threatening of early abortion - 10%, threatening of late abortion-4.1%, threatening of early preterm birth - 6.3%; premature birth – 3 (6.3%) at 36.8±0.1 weeks.
Results: NSAIDs. After inclusion in the study, the drug of choice was ibuprofen, which was canceled for all women no later than the 32-nd week of pregnancy. At the time of conception and in the first, second and third trimesters of pregnancy, NSAIDs were taken by 23 (46%), 20 (40%), 30 (60%) and 21 (43.8%) women, respectively. No effect of NSAIDs on the activity of AS was revealed.
Sulfasalazine (SS) was taken for 3 months before pregnancy by 11(22%) women, during pregnancy – 6 (12%) at a dose of 1.25±0.25 g because of arthritis. The withdrawal of SS was not associated with the recurrence of arthritis.
Glucocorticoids (GC) at a dose of 7.5±2.5 mg 3 months before pregnancy and in the trimesters of pregnancy were taken: 1 (2%), 4 (8%), 8 (16%) and 10 (20.8%) women, of whom 1 patient had arthritis and 1 had inflammatory bowel disease. The remaining patients received GC due to the high activity of AS due to axial manifestations and the unavailability of bDMARDs) intake. Against the background of taking GC, the AS activity did not decrease: BASDAI in the 2nd and 3rd trimesters was 5.5±0.6 and 5.8±1.3 (p>0.05).
bDMARDs. TNF inhibitors for 3 months before pregnancy and on trimesters were received by 11 (22%), 7 (14%), 6 (12%) and 2 (4.2%) patients, of which 1 woman in the second trimester obtained firstly initiated therapy with certolizumab pegol due to the recurrence of uveitis. In those who canceled bDMARDs therapy (both independently and due to the recommendation of a rheumatologist), an increase in AS activity was noted on the eve of pregnancy; BASDAI in the month of conception and in the I, II, and III trimesters was: 2,7 [0,8; 3,5]; 5,1[3,1; 5,9]; 5,5 [5;6] and 6,7 [5,3; 7;3], p<0,05 compared to the month of conception. Undoing the bDMARDs in the month of conception is a risk factor for high activity as (BASDAI>4) in the second trimester (OR OF 30.4; 95% CI 1,5-612,3; p=0.03) and in the third trimester (OR A 32.7; 95% CI 1,6-662,2; p=0.02).
The relationship between pregnancy complications, malformations of the newborns and the used medications was not revealed.
Conclusion: NSAIDs and GC in low doses do not reduce the activity of AS. Withdrawal of TNF inhibitors on the eve of pregnancy is a predictor of high AS activity. It is necessary to increase the knowledge of rheumatologists and patients about the therapeutic possibilities during pregnancy to avoid unjustified drug withdrawal.
Disclosure of Interests: None declared.

AB0474 THE USE OF NONSTEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDS) IN WOMEN WITH ANKYLOSING SPONDYLITIS (AS) DURING PREGNANCY

O. Krichevskaya[1], T. Dubinina[1], E. Ilinykh[1], S. Glukhova[1], A. Demina[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Medical and Social Problems of Rheumatology, Moscow, Russian Federation*

Background: NSAIDs remain the first-line drugs in treatment of AS. During pregnancy, COX-2 non-selective NSAIDs are allowed for intake up to 32 weeks, but the question of the dose-dependent effect of NSAIDs on fetal organogenesis in the 1st trimester and on fetal kidney function and the increased risk of bleeding in childbirth when taken in the second half of pregnancy continues to be discussed. At the same time, data on the effectiveness of NSAIDs, including their low and medium doses, during pregnancy are extremely small.
Objectives: to describe the frequency of using NSAIDs during pregnancy, to determine relationship between the dose of NSAIDs, adherence to therapy with the activity of AS.
Methods: 50 pregnancies were followed in 49 pregnant women with confirmed AS (modified New York criteria, 1984). The average age of the pts was 31.6 ± 4.9 years, the duration of the disease was 134.4 ± 85.8 months. The visits were conducted at 10-11, 20-21, and 31-32 weeks of pregnancy. The BASDAI in the month of conception and in the trimesters (trim.) of pregnancy was: 1,4[0,6; 3,3]; 2,3[1,2; 4,4]; 2,8[1,4; 4,2] and 2,2[1,6; 4,0], respectively. The level of nocturnal back pain according to the NRS in the first, second and third trim. was: 3.2±2.0; 5.4±2.5 and 5.2±2.6, respectively. The drug of choice was ibuprofen at a maximum daily dose of 1200 mg, its withdrawal - no later than 32 weeks of pregnancy.
Adherence to NSAID therapy was defined as the ratio of the actual dose taken to the prescribed dose; an indicator of less than 80% was regarded as non-adherence to therapy. The total dose of NSAIDs was determined by the NSAID intake index (M. Dougados, 2001). The" actual daily dose" of ibuprofen was the sum of the doses of ibuprofen taken, divided by the number of actual days of taking the drug. The "average daily dose" was defined as the sum of the ibuprofen doses taken, divided by the number of days in the trimester.
Results: At the time of conception and in the first, second and third trim. of pregnancy, NSAIDs were taken 23 (46%), 20 (40%), 30 (60%) and 21 (43.8%) women, respectively. The NSAID intake index, the actual and average daily dose of ibuprofen are shown in the Table 1.

	month of conception	trim. 1	trim. 2	trim. 3
the actual daily dose, mg	-	700 [425; 800]	800 [400; 1000]	750 [400; 1200]
the average daily dose, mg	-	158 [87,9; 307,7]	355,1 [138,5; 685,7]	580 [320; 1200]
NSAIDs intake index	28,6 [16,7; 50]	5,8 [2,9; 11,8]	15,5 [4,7; 30,9]	24,4 [9,5; 50]

The index of NSAID intake in the first trim. was lower than before pregnancy and in the second half of gestation (p<0.05 compared to the month of conception, II and III trim.). The average daily dose of ibuprofen was also lower in the first trim. than in the second and third trim. (p<0.05), while the actual daily dose in the second trim. was higher than in the first and third trim. (p<0.05 in all cases).
There was no correlation between BASDAI AS activity, the level of nocturnal pain and the ibuprofen intake index, likewise the fact of NSAID withdrawal throughout pregnancy. In addition, there were no differences in BASDAI levels and back pain in women with a subjective need for NSAIDs, who did and did't take ibuprofen.
50% of women were committed to NSAID therapy in the first trim., 43.5% in the second trim., and 67.4% in the third trim. In pts with non-adherence to NSAID therapy, the BASDAI level was higher than in those who followed the recommendations of the rheumatologist throughout pregnancy: in the first trim. – 3.8[3.4; 4.7] and 1.7[0.8; 2.2]; in the second trim. - 3[2.3; 4.6] and 1.4[0.8; 2.7]; in the

third trim. - 3.1[2.1; 4.0] and 1.7[1.1; 4.0], p<0.05 in all cases. However, women with adherence > 80% were initially less active and NSAIDs were prescribed "on demand", which increased their compliance.
Conclusion: intake of ibuprofen in low doses does not affect the activity of AS. Due to the ongoing discussion about the effect of NSAIDs on neonatal outcomes, further international studies are required for development an optimal treatment regimen during pregnancy with a possible extension of the indications for the appointment of TNF inhibitors (BASDAI<4).
Disclosure of Interests: None declared.

AB0475 COMPARATIVE EFFECTIVENESS OF BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN REAL CLINICAL PRACTICE ACCORDING TO THE MOSCOW UNIFIED ARTHRITIS REGISTER (MUAR)

E. Rozochkina[1], E. Koltsova[2], G. Lukina[1,3], E. Shmidt[4], K. Lytkina[5], A. Zagrebneva[6], E. Zhilyaev[7,8]. *[1]A.S.Loginov Moscow Clinical Scientific Center, Rheumatology, Moscow, Russian Federation*; *[2]Research Institute of the Organization of health and healthcare management, Rheumatology, Moscow, Russian Federation*; *[3]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*; *[4]N.I.Pirogov City Clinical Hospital 1, Rheumatology, Moscow, Russian Federation*; *[5]City Clinical Hospital 4, Rheumatology, Moscow, Russian Federation*; *[6]City Clinical Hospital 52, Rheumatology, Moscow, Russian Federation*; *[7]Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Rheumatology, Moscow, Russian Federation*; *[8]European Medical Center, Rheumatology, Moscow, Russian Federation*

Background: This study is the first analysis of biological disease-modifying anti-rheumatic drugs (bDMARDs) for ankylosing spondylitis (AS) within the Moscow Unified Arthritis Register (MUAR).
Objectives: to compare the effectiveness of bDMARDs in patients with AS using data from the MUAR.
Methods: The analysis included the data of patients with AS who were included in the MUAR and received biological therapy for at least 6 months. The effectiveness of the drugs was assessed by the achieved values of the indices of diseases activity and its manifestations: ASDAS(C-RP), BASDAI, LEI, MASES, indicators of the functional ability of patients (BASFI, HAQ) at the last completed visit. Comparison of indicators between drugs was in a general linear model, adjusted for the identified confounders. The search for confounders was in 2 stages: first, by univariate analysis, were identified indicators significantly related to the achieved ASDAS. Then, within the multivariate general linear model, by backward stepwise selection were determinate variables significantly and independently associated with ASDAS.
Results: The current study included 363 episodes of treatment with bDMARDs in 361 patients. There were 240 men (66.5%). The average age of the included patients was 46.3 ± 11.2, the age at the onset of the disease was 27.3 ± 11.4. The average duration of a treatment episode until the patient was assessed 1135 ± 900 days. Significant differences of the values of ASDAS(p = 0.033) and ESR (p = 0.007) between bDMARDs were revealed. In pairwise comparisons of the achieved ASDAS using the Shidak adjustment, demonstrated that the values on infliximab and adalimumab were significantly lower than on certolizumab pegol (p = 0.009 and p = 0.041, respectively). Also significantly higher ESR values on certolizumab compared to all other drugs (p < 0.001 for all) were found. There were no statistically significant differences between the drugs for other studied parameters.
Conclusion: The studied bDMARDs (infliximab, adalimumab, etanercept, certolizumab pegol, golimumab, secukinumab) demonstrate generally similar clinical efficacy in real clinical practice. The effect of golimumab and sekukinumab which have been recently introduced into clinical practice doesn't differ significantly from the effect of TNF inhibitors which has been used for a long time.

Table 1. Achieved values of the indices of activity and functional ability against the background of treatment with bDMARDs.

AB0476 VITAMIN D SERUM CONCENTRATION VARIES ACCORDING TO DISEASE ACTIVITY IN SPONDYLOARTHRITIS

M. Rato[1], F. Oliveira Pinheiro[1], S. Garcia[1], B. M. Fernandes[1], D. Fonseca[2], D. Santos Oliveira[1,3], A. Martins[1], F. R. Martins[4], A. Bernardo[1], M. Bernardes[1,5], L. Costa[1]. *[1]Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal*; *[2]Centro Hospitalar de Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal*; *[3]Faculdade de Medicina da Universidade do Porto - FMUP, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; *[4]Centro Hospitalar Universitário do Algarve - Faro, Rheumatology, Faro, Portugal*; *[5]Faculdade de Medicina da Universidade do Porto - FMUP, Rheumatology, Porto, Portugal*

Background: Several studies have shown dissimilar results for the relationship between serum 25-hydroxyvitamin D concentration (25-OH-D) and disease activity in spondyloarthritis (SpA).
Objectives: This study aims to assess whether vitamin D levels vary according to disease activity in patients with SpA before and after starting treatment with biologic disease-modifying anti-rheumatic drugs (bDMARDs).
Methods: An observational retrospective study was performed in SpA patients followed in the Rheumatology department of a tertiary university hospital. Demographic and clinical data were collected from the Rheumatic Diseases Portuguese Register (Reuma.pt). Patients were assessed for 25-OH-D levels before and after 6 months of treatment with the first bDMARD. Correlation between 25-OH-D levels and disease activity measured by Ankylosing Spondylitis Disease Activity Score (ASDAS) at baseline and after 6 months were assessed using student's t-test for two samples and one-way ANOVA and with post hoc tests for multiple comparisons.
Results: A total of 189 patients were included. Ninety-seven patients were females (51.3%). The mean age at diagnosis was 34.8±11.2 years and the median disease duration at the start of the first bDMARD was 4.9 years (min: 0.1; max: 46.0). All patients fulfilled the ASAS criteria for SpA. Nonsteroidal anti-inflammatory drugs were used by 102 patients (54.0%) and conventional synthetic DMARDs by 69 patients (36.5%). At 6 months, 188 patients were treated with tumor necrosis factor inhibitors and one with interleukin-17 inhibitor. According to ASDAS criteria, at baseline 36.8% of patients had high disease activity and 59.5% had very high disease activity. After 6 months of treatment with bDMARD 14.7% of patients have inactive disease, 21.6% low disease activity, 36.3% high activity and 12.6% very high disease activity. The mean value of 25-OH-D at baseline was significantly lower in the group of patients with very high disease activity compared to the patients with high disease activity (21.9±11.1 ng/ml vs 26.1±11.6 ng/ml, p= 0.02). At 6 months of treatment the mean value of 25-OH-D in inactive, low, high and very high disease activity was 31.0±17.1ng/ml, 28.5±11.2ng/ml, 25.8±10.8ng/ml and 19.3 ±9.5ng/ml, respectively. There was a statistically significant difference between the groups, as determined by one-way ANOVA (p = 0.001). A post hoc Dunnett T3 test revealed that patients with very high disease activity have significantly lower mean 25-OH-D levels (19.29 ± 9.5) than patients with inactive disease (31.0 ± 17.1, p = 0.025) and low activity (28.5 ± 11.2, p = 0.009). Among the groups with high and very high disease activity, the significance is only marginal (p = 0.068).
Conclusion: Vitamin D serum concentration varies according to disease activity in SpA. In fact, SpA patients with lower levels of 25-OH-D are associated with higher rates of disease activity, even in patients treated with biologics agents. It is important to be aware of vitamin D level as it can play a role in the management and treatment of the disease, mainly in the most severe patients.

AB0477

EFFECT OF ANTI-TNF THERAPY ON BONE MINERAL DENSITY IN ANKYLOSING SPONDYLORTHITIS

A. Ajerouassi[1], K. Nassar[1], S. Janani[1]. [1]*faculté de médecine et de pharmacie de cabalanca, centre hospitalier universitaire ibn rochd, rhumatologie, Casablanca, Morocco*

Background: Osteoporosis is common in spondyloarthritis, due to reduced spinal mobility, and inflammation. Anti-inflammatory treatments have a beneficial effect on the bone, and there is a significant increase in bone density during treatment with anti-TNF alpha.
Objectives: to study bone mineral density in patients with ankylosing spondyloarthritis (AS) treated with anti-TNF alpha.
Methods: This is a retrospective descriptive study of patients with AS meeting the modified New York criteria. Bone mineral density, assessed by dual energy x-ray absorptiometry (DXA), of AS patients treated with anti-TNF alpha was compared to that of a control group of AS patients not treated with anti-TNF alpha.
Inclusion criteria:
- Male patients
- Patients who do not have an abnormality disrupting phosphocalcic and bone metabolism
- For Patients on anti-TNF alpha: the treatment must be received for more than 6 months
Results: A total of 22 patients were included, including 11 patients on anti-TNF alpha and 11 patients not on anti-TNF. The mean age (standard deviation) was 28 (± 7.2) years and 41 (± 14.8) in the cases and controls respectively. The mean body mass index in the AS group on anti-TNF was 22.16 kg / m2 and in the control group was 19.64 kg / m2. In the AS group on anti-TNF alpha, the mean bone mineral density of the spine was 1.092 g / cm2 (mean T score = -0.63) and that of the femoral neck, the mean bone mineral density was 0.888g / cm2 (mean T score = -1.04). In the control group, the mean bone mineral density of the spine was 0.959 g / cm2 (mean T score = -1.91) and the mean bone mineral density of the femoral neck was 0.774 g / cm2 (mean T score = -1.99). Bone mineral density in the spine and cervix was higher in the group receiving anti-TNF alpha (p = 0.09, p = 0.173 respectively)
Conclusion: Our study shows the increase, although not statistically significant, in bone mineral density in AS patients receiving anti-TNF alpha agents compared to controls. Our results agree with those of the literature which support the bone protective effect of anti-TNF alpha. The non-significant difference can be explained by the delay in the introduction of biotherapy at the advanced stage of the structural evolution of AS. The best solution is to start TNF inhibitors at the early inflammatory stage of AS.

AB0478

IN PREVIOUSLY BIOLOGIC-NAÏVE RHEUMATIC PATIENTS WITH DRUG INDUCED LUPUS SECONDARY TO A FIRST ANTI-TNF THERAPY, IS IT SAFE TO SWITCH TO A SECOND ANTI-TNF-α AGENT?

A. Martins[1], D. Santos Oliveira[1,2], F. R. Martins[3], F. Oliveira Pinheiro[1], M. Rato[1], D. Fonseca[4], S. Garcia[1], B. M. Fernandes[1], S. Pimenta[1,5], M. Bernardes[1,5], L. Costa[1]. [1]*Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal*; [2]*Faculdade de Medicina da Universidade do Porto - FMUP, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; [3]*University Hospital Center of Algarve, Rheumatology, Faro, Portugal*; [4]*Centro Hospitalar Vila Nova de Gaia / Espinho - Unit 1, Rheumatology, Porto, Portugal*; [5]*Faculdade de Medicina da Universidade do Porto - FMUP, Rheumatology, Porto, Portugal*

Background: Drug-induced lupus erythematosus (DILE) secondary to anti-TNF-α agents results from an immunogenicity phenomena not yet fully understood and is a rare condition. Withdrawal of anti-TNF- α therapy usually leads to total resolution of symptoms, however sometimes immunosuppression is needed. It is not clear if this condition is drug specific or class related. Therefore, there are doubts about the safety of switching to a second TNF inhibitor: will a further anti-TNF-α agent increase the risk of DILE recurrence?
Objectives: To analyze the outcomes in patients with DILE secondary to an anti-TNF-α agent that switch to a second anti-TNF-α agent.
Methods: We performed a retrospective analysis of patients with spondyloarthritis, psoriatic arthritis and rheumatoid arthritis from our University Hospital, who developed DILE secondary to an anti-TNF-α agent as a first biologic and switch to a second anti-TNF-α agent. Because specific criteria for the diagnosis of DILE have not been established, DILE diagnosis was considered when a temporal relationship between clinical manifestations and anti-TNF alpha treatment was found and ACR/EULAR 2019 classification criteria for SLE were fulfilled. Clinical and laboratorial features and outcomes were collected from the Portuguese Rheumatic Diseases Register (Reuma.pt) and medical records.
Results: Six of 617 patients developed DILE secondary to anti-TNF-α agents (2 secondary to etanercept, 2 to adalimumab and 2 to infliximab). These patients had total resolution of symptoms and autoantibodies (ANA and anti-DNAds), induced by the therapy, disappeared after withdrawal of the anti-TNF-α agent implied.
Afterwards, 4 of these 6 patients switched to a second anti-TNF-α agent: 1 to etanercept, 1 to certolizumab, 1 to adalimumab and another to golimumab. The time interval between the two therapies was 2,0 ± 0,8 months. Regarding the outcomes, in all four patients, no DILE recurrence or autoantibodies induction recurrence was observed. These patients have a good response to the new biotherapy, without side effects reported, and a significant clinical improvement was observed.
Conclusion: Our study results are in agreement with the literature described before. It seems that exist a low rate of DILE recurrence with an alternative anti-TNF-α agent. Thus, this condition seems to be drug specific rather than class related. Therefore, it seems secure to use a second anti-TNF-α agent, even in a short period of time after DILE development. There is no evidence about the best or securest second TNF inhibitor, so any anti-TNF-α agent can be prescribed. A carefully monitoring of symptoms of relapse should be ensured. In conclusion, DILE secondary to a TNF inhibitor should not be an absolute contraindication to the use of a subsequent anti-TNF-α agent.

AB0479

LONGTERM RETENTION RATE OF CERTOLIZUMAB PEGOL IN AXIAL SPONDYLOARTHRITIS IS HIGHER: DATA FROM TURKBIO

S. S. Koca[1], Y. Pehlivan[2], S. Akar[3], S. Şenel[4], A. Avanoglu Guler[5], O. Sosyal[6], A. Yazici[7], S. Yılmaz[8], R. Piskin Sagir[1], N. Inanc[9], A. Karatas[1], G. Yildirim Cetin[10], P. Atagündüz[9], F. Onen[11]on behalf of TURKBIO Study Group. [1]*Firat University School of Medicine, Department of Rheumatology, Elazig, Turkey*; [2]*Uludağ University, School of Medicine, Department of Rheumatology, Bursa, Turkey*; [3]*Katip Çelebi University, School of Medicine, Department of Rheumatology, Izmir, Turkey*; [4]*Erciyes University School of Medicine, Department of Rheumatology, Kayseri, Turkey*; [5]*Gazi University School of Medicine, Department of Rheumatology, Ankara, Turkey*; [6]*Celal Bayar University School of Medicine, Department of Rheumatology, Manisa, Turkey*; [7]*Kocaeli University School of MEdicine, Department of Rheumatology, Kocaeli, Turkey*; [8]*Selcuk University School of Medicine, Department of Rheumatology, Konya, Turkey*; [9]*Marmara University School of Medicine, Department of Rheumatology, Istanbul, Turkey*; [10]*Kahramanmaraş Sutçu Imam University School of Medicine, Department of Rheumatology, Kahramanmaraş, Turkey*; [11]*9 Eylul University School of Medicine, Department of Rheumatology, Izmir, Turkey*

Background: Choosing the best treatment strategy for a patient is one of the most difficult issues in modern rheumatology, as there are various factors affecting drug therapy in chronic diseases, such as efficacy, safety, and compliance. Physicians take care of long-term retention rate and responses for discontinuation of candidate drug.
Objectives: The purpose of this study to assess the drug survival of certolizumab pegol (CZP) in patients with axial spondyloarthritis (ax-SpA) and to identify the predictors and reasons for discontinuation.
Methods: Data on patient characteristics, demographics, diagnosis, duration of disease, treatment and outcomes have been collected since 2011 in Turkish Biologic (TURKBIO) Registry. By the end of December 2020, 410 ax-SpA patients received CZP and were included. Kaplan Meier plot was used for drug survival analysis. Cox regression analysis was performed to evaluate the predictor associated with drug survival.
Results: During the median 54 months follow-up, 92 (22.4%) patients discontinued the CZP treatment. The reasons for discontinuation: ineffectivity was 58.7% (n=54), adverse events was 6.5%, pregnancy was 3.3% and surgery was 4.3%. The baseline characteristics of patients continue with CZP and discontinuation due to ineffectiveness were shown in the Table 1. Patients who discontinued CZP had higher HAQ, BASFI and BASDAI values. Moreover, they were more co-treated with NSAIDs and csDMARDs. At the month 36, retention rate of CZP was 71.5% in patients with ax-SpA (Figure 1).

Conclusion: Real life experience from this nationwide TURKBIO registry show higher long-term retention rate of CZP in ax-SpA. Higher baseline disease activity and functional limitation predict discontinuation of CZP. Adding NSAIDs and csDMARDs to the treatment of the patient with poor prognosis cannot increase retention rates.

INFLUENCE OF ANTI TNF THERAPIES AND HYPERHOMOCYSTEINEMIA ON BONE MINERAL DENSITY IN ANKILOSING SPONDYLITIS PATIENTS

D. Anghel[1], E. M. Hoinoiu[1], M. M. Negru[2], O. G. Petrache[1], N. O. Costache[1], V. Iachim[1], R. A. Bursuc[3], A. Ghiatau[4], A. Manolache[4], V. V. Smedescu[4], C. F. Plesa[5]. *[1]Central Military Emergency University Hospital Carol Davila, Rheumatology, Bucharest, Romania*; *[2],Sfânta Maria" Clinical Hospital, Rheumatology, Bucharest, Romania*; *[3]Central Military Emergency University Hospital Carol Davila, Nefrology, Bucharest, Romania*; *[4]Central Military Emergency University Hospital Carol Davila, Internal Medicine, Bucharest, Romania*; *[5]Central Military Emergency University Hospital Carol Davila, Neurology, Bucharest, Romania*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease associated with an important risk factor of osteoporosis. A high serum level of Homocysteine (Hcy) has been recently recognized as a risk factor for osteoporosis and osteoporotic fractures. Treatment with TNF-α blockers might influence bone metabolism and prevent structural bone damage in AS.
Objectives: The aim of the study was to evaluate the influence of anti-TNF therapies and hyperhomocysteinemia on bone mineral density in AS patients.
Methods: In our retrospective study were enrolled 73 AS patients with anti TNF-α therapies (29 Adalimumab 40mg/2weeks, 24 Etanerceptum50mg/week, 20 Infliximabum5 mg/kg/8 weeks) and 45 AS patients non anti TNF-α therapies. All patients included in this study met the modified New York criteria. The current medications used by the non anti TNF-α therapies patients were nonsteroidal anti-inflammatory drugs.
We used Dual energy *x* ray absorptiometry (DXA) method for measuring bone mineral density (BMD). Osteoporosis is defined as a T score of ≤ −2.5 SD, according to the WHO criteria. BMD of the hip and lumbar spine (L1-L4) was determined at baseline and after 6 months. Hcy concentrations were measured by using a chemiluminescence immunoassay method. The normal serum Hcy level is considered to be below 15mmol/L. In both group we followed the activities disease (C reactive protein-CRP, eritrocytes sedimentation rate-ESR, Bath ankylosing spondylitis disease activity index-BASDAI score) and determined vitamin D3 level.
All parameters were determined at baseline and after 6 months.
Results: The mean age of study group1 was 47.4±11.1 years and 42±9,8year in group2. The mean disease duration was 11.9 ± 6.1 years. 83,5% of patients were HLA-B27 positive in group1 and 71,1% in group2.
BMD measurements revealed more severe osteoporosis in patients with positive HLA-B27 in both groups at baseline. After 6 months in group1 BMD increased by 0.4% at lumbar spine and 0.1% in the hip and in group2 decreased by 0.9% and 0.6% in the same sites. No significant differences between type of anti-TNF therapies and BMD. In group 1, HLA-B27 positive status was positive correlated with decrease BMD(p=0.001) after 6 months. Hcy levels were found significantly increased (14.8 ± 3.8 mg/mL vs. 12.4 ± 4.2 mg/mL; P < 0.001) at baseline in both groups. Serum levels of Hcy were inversely correlated to lumbar spine BMD ($p<$ 0.005) and femur neck BMD(p=0,001) after 6 months in group1. At baseline the mean level of 25-hydroxyvitamin D_3 was 22.8 ± 14.1 ng/mL in group1 *and* 26.6 ± 12.5 ng/mL in group2. In anti TNF patients group, we found a positive correlation between decrease BMD, low level of 25-hydroxyvitamin D_3 and high level of Hcy(p=0,001) after six months. No correlation was found between BMD and BASDAI score and inflammatory parameters (ESR, CRP).
Conclusion: Bone mineral density measurements revealed more severe osteoporosis in positive HLA-B27 AS patients and hyperhomocysteinemia. Association of low level of 25-hydroxyvitamin D3 and hiperhomocysteinemia is correlated with high-risk fracture in positive HLA-B27 patients. Anti TNF therapies reduce this risk.

AB0481 PATIENT'S PERSPECTIVE ON PATIENT EDUCATION IN AXIAL SPONDYLOARTHRITIS: A QUALITATIVE STUDY

Y. M. van der Kraan[1], D. Paap[1,2], N. Lennips[1], E. C. A. Veenstra[1], S. Kieskamp[1], A. Spoorenberg[1]. [1]*University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands*; [2]*University Medical Center Groningen, Department of Rehabilitation, Groningen, Netherlands*

Background: Within the EULAR recommendations patient education (PE) is stated as the basis of axial spondyloarthritis (axSpA) management, since PE contributes to reaching treatment goals.[1] However, educational needs are scarcely qualitatively studied in patients with axSpA and the EULAR recommendations of PE are primarily based on research in patients with rheumatoid arthritis. The World Health Organization advocates the incorporation of qualitative research into the development of guidelines and recommendations,[2] since it generates rich and detailed data providing explanations and understanding of the complexity of human behaviour and decision-making.[3]
Objectives: To explore perceptions, experiences and needs of PE in patients with axSpA.
Methods: An interpretive phenomenological approach was applied and data was collected through semi-structured in-depth interviews with axSpA patients with a broad variation in characteristics. The data collection and analysis was conducted in an iterative manner. Thematic analysis was applied to translate experiences and perceptions from the interviews into themes.[4] Multiple strategies were used to enhance credibility: data saturation, research triangulation, bracketing, member checking, theoretical notes, and peer debriefing.
Results: Twelve patients participated, for characteristics see Table 1. From the participants' perspective three interrelated themes regarding PE are important for healthcare professionals (HCP) to pay attention to: *illness perception, content* and *availability*. 1) *Illness perception*, defined as patients' personal understanding and belief about their disease, affects how patients experience and process PE which consequently influences coping strategies with their disease. 2) The following topics concerning *content* are reported as most important in PE for patients with axSpA: prognosis, treatment, and the influence of lifestyle aspects. 3) *Availability* of PE: face-to-face contact with a HCP is the preferred method for exploring patients' personal needs in PE. Additionally, active self-education is preferred to learn more about the different subjects which patients can apply when preferred. Furthermore, participants reported a relationship of trust between patient and HCP and sufficient amount of time in combination with a comprehensible amount of information to support their understanding (health literacy) as prerequisites for effective PE.

Table 1. Characteristics of the patients with axSpA in this study

Participants	Sex	Age	Symptom years	Diagnosis years	ASDAS	Disease activity	PASS	Level of education	Marital status
1	M	39	18	15	0.47	ID	Yes	ISCED 7	Single
2	M	56	30	30	2.90	HDA	No	ISCED 3	Divorced
3	M	24	10	9	0.88	ID	Yes	ISCED 7	In a relationship
4	M	32	20	13	1.04	ID	Yes	ISCED 6	In a relationship
5	M	66	24	23	1.33	LDA	Yes	ISCED 3	Married
6	M	33	7	5	1.20	ID	Yes	ISCED 7	Married
7	M	56	9	6	2.72	HDA	-	ISCED 2	Married
8	F	30	15	9	2.11	HDA	No	ISCED 3	Single
9	F	36	14	12	1.22	ID	Yes	ISCED 7	Married
10	F	56	18	17	3.23	HDA	-	ISCED 2	Married
11	F	33	10	5	1.66	LDA	Yes	ISCED 3	Divorced
12	F	27	3	2	1.90	LDA	No	ISCED 7	In a relationship

M = Male; F = Female; ASDAS = Ankylosing Spondylitis Disease Activity Score; ID = inactive disease, LDA = low disease activity, HDA = high disease activity; PASS = Patient Acceptable Symptom State Questionnaire; ISCED 2011 = International Standard Classification of Education 2011

Conclusion: This first bottom-up qualitative study exploring perceptions, experiences and needs of PE in patients with axSpA, shows that HCP should pay attention to patients illness perception to promote effective delivery of PE. Additionally, diagnosis, treatment and lifestyle aspects are important subjects and a combination of face to face contact and self-education is preferred by the patients. These results will provide disease specific content for future guidelines regarding PE in axSpA.

AB0482 PHARMACOLOGICAL TREATMENT OF ENTHESITIS - A SYSTEMATIC REVIEW ON THE EFFICACY OF THE AVAILABLE OPTIONS

R. Pinheiro Torres[1,2], S. Rodrigues-Manica[1,2], F. Pimentel Dos Santos[1,2,3]. [1]*Hospital Egas Moniz, Rheumatology, Lisboa, Portugal*; [2]*CEDOC, Rheumatology, Lisboa, Portugal*; [3]*Nova Medical School, Rheumatology, Lisboa, Portugal*

Background: Enthesitis is a recognized as a hallmark of spondyloarthrtis (SpA), including psoriatic arthritis (PsA). However, it is an underestimated disease domain in both in clinical trials and clinical practice (1).
Objectives: This systematic literature review (SLR) assessed the efficacy of the available pharmacological options for enthesitis.
Methods: A SLR was conducted following the PRISMA reporting guidelines. Studies were sourced from PubMed and Embase databases, using the MeSH terms: enthesitis, entheses, treatment, spondylarthritis, ankylosing spondylitis and psoriatic arthritis. The search was limited to articles in English published between January 2000 and July 2020. Two independent reviewers screened the titles and abstracts.
Results: A total of 65 articles matched the research criteria. The included populations, the time to assessment of the primary endpoint and the chosen outcome for assessment of enthesitis was heterogeneous across studies. There were no studies assessing the effect of non-steroidal anti-inflammatory drugs, glucocorticoids, or csDMARDs. In PsA, all TNFis showed superiority in monotherapy against placebo (PBO). However, when combined with methotrexate (MTX), only some TNFi showed superiority against MTX monotherapy. In SpA, there was conflicting evidence regarding the efficacy of TNFi in enthesitis. Regarding IL23i in PsA, Ustekinumab was superior to PBO, and to TNFis. Guselkumab was superior to PBO when given every 4 weeks. Regarding IL7i, Secukinumab (SEC) was superior to PBO, only for some dosing schemes. Ixekizumab (IXE) was superior to PBO for the treatment of enthesitis only in TNF-naïve patients. Studies comparing SEC and IXE to ADA, showed no difference. There was no reported data on IL17i for enthesitis in SpA. In PsA, Tofacitinib was superior to PBO in naïve patients, and Tofacitinib 10mg was superior to PBO in bioexperienced patients. Apresmilast 30mg showed superiority to PBO for enthesitis. All finding are summarized on Table 1.

AB0483 CAN WE PREDICT WHICH PATIENTS WITH SPONDYLOARTHRITIS WILL NEED DOSE ESCALATION OF SECUKINUMAB TO 300 MG MONTHLY?

D. Fonseca[1], F. Oliveira Pinheiro[2], M. Rato[2], B. M. Fernandes[2], S. Garcia[2], A. Martins[2], D. Santos Oliveira[2,3], F. R. Martins[4], M. Bernardes[2,5], L. Costa[2]. *[1]Centro Hospitalar de Vila Nova de Gaia / Espinho, Rheumatology, Vila Nova de Gaia, Portugal*; *[2]Centro Hospitalar Universitário de São João, Rheumatology, Porto, Portugal*; *[3]Center for Health Technology and Services Research (CINTESIS), University of Porto, Faculty of Medicine, Porto, Portugal*; *[4]Centro Hospitalar Universitário do Algarve, Rheumatology, Faro, Portugal*; *[5]Faculdade de Medicina da Universidade do Porto (FMUP), Rheumatology, Porto, Portugal*

Background: Secukinumab is a fully human monoclonal antibody against interleukin-17A, approved in several countries for the treatment of ankylosing spondylitis (AS) and psoriatic arthritis. It is known that some patients benefit from increasing the monthly dose of secukinumab from 150mg, the most commonly used dose, to 300mg. However, the baseline clinical characteristics that differentiate these patients are not yet fully understood.

Objectives: This study aimed to investigate whether there are any variables at the beginning of biologic therapy that might predict a greater probability of having to increase the dose of secukinumab to 300mg in order to obtain a response to treatment.

Methods: This is a retrospective cohort study, including all the spondyloarthritis and psoriatic arthritis patients under secukinumab at our Rheumatology Department and registered in the national database (Reuma.pt).

Demographic, clinical and laboratorial characteristics and disease activity measures were collected from the first visit before the patient began secukinumab. For comparison between the 2 groups, continuous variables were analyzed using Mann-Whitney U and T-tests and categorical variables were analyzed using a Chi-square test. Multivariate regression analyses assessed the impact of selected variables on the need to increase the dose of secukinumab to 300mg.

Results: Thirty-two patients with a mean age of 53±11.96 years were included, 19 (58%) were females and 16 (48.5%) had psoriasis. Twenty-seven (81.8%) patients were under a nonsteroidal anti-inflammatory drug (NSAID), 11(33.3%) were under corticosteroid and 11(33.3%) were under conventional synthetic disease-modifying antirheumatic drug (csDMARD); 25 (75,8%) had previously been treated with a biological disease-modifying antirheumatic drug (bDMARD). The mean patient baseline VAS and physician baseline VAS were 74,39±19,77 and 47,55±23,38, respectively; the mean erythrocyte sedimentation rate (ESR) and C-Reactive Protein (CRP) were 26,33±22,62 mm/hr and 10,81±16,88 mg/dL, respectively; the mean swollen joint count (SJC) and tender joint count (TJC) were 1,30±1,63 and 3,67±3,14, respectively; the mean Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS) were 6,18±2,06 and 3,41±0,84, respectively; the mean Bath Ankylosing Spondylitis Metrological Index (BASMI) and Bath Ankylosing Spondylitis Functional Index (BASFI) were 4,22±1,58 and 6,28±2,53, respectively; the mean Maastrich Ankylosing Spondylitis Enthesitis Score (MASES) was 2,85±3,23.

Nineteen patients (57.6%) had the dose of secukinumab increased to 300mg. At the baseline visit, the group of patients which had their secukinumab monthly dose increased to 300mg were more frequently men (12 vs 2, p=0.005) and had psoriasis (12 vs 4, p=0.049). On the other hand, these patients also exhibited lower MASES values (2±1.089 VS 4±0.501, p=0.022).

A regression analysis was conducted, estimating the relationships between the outcome binary variable of the monthly dose of secukinumab and the following predictors: gender, psoriasis, MASES value and use of corticosteroid. Female gender (OR 0.070, CI95% 0.005-0.890; p=0.040) and absence of psoriasis (OR 0.104, CI95% 0.011-0.952; p=0.045) were predictors for maintaining secukinumab at a dose of 150mg monthly.

Conclusion: Our data suggest that the most common characteristics of patients in need of increasing the monthly dose of secukinumab from 150 to 300 mg to achieve a better treatment response are: male gender, coexistence of psoriasis and lower MASES value at baseline. The first two variables remained statistically significant in a multivariate model of regression analysis. Nonetheless, we insist it is of paramount importance to conduct larger studies to confirm these findings.

AB0484 TROUGH LEVELS OF TNF-A INHIBITORS AND THEIR IMMUNOGENICITY IN THE TREATMENT OF RHEUMATIC DISEASES AND INFLAMMATORY BOWEL DISEASES

T. Nuriakhmetova[1], I. K. Valeeva[2], J. Shevnina[3], D. Abdulganieva4. *[1]Kazan State Medical University, Hospital therapy, Kazan, Russian Federation*; *[2]Kazan State Medical University, Central Scientific Research Laboratory, Kazan, Russian Federation*; *[3]Republican clinical hospital n.a. N.A. Semashko, consultative polyclinic, Simferopol, Russian Federation*; *[1]Kazan State Medical University, Hospital therapy, Kazan, Russian Federation*

Background: The features of the underlying immune-mediated disease can affect the efficacy, pharmacokinetics and immunogenicity of the biologic agents, which are among the important predictors of loss of response to TNF-α inhibitors (TNFi).

Objectives: To compare the frequency of TNFi low trough levels and their immunogenicity in the treatment of rheumatic diseases (RD) (ankylosing spondylitis (AS) and rheumatoid arthritis (RA)) and inflammatory bowel diseases (IBD) (Crohn's disease (CD) and ulcerative colitis (UC)).

Methods: Among 120 patients (40 with AS (33.3%), 19 with RA (15.8%), 42 with CD (35%), and 19 with UC (15.8%)), trough level of infliximab (INX) (n=36, 30%), adalimumab (ADM) (n=45, 37.5%) and certolizumab pegol (CZP) (n=39, 32.5%) and the level of anti-drug antibodies (ADAb) were measured in the serum samples drawn directly before the planned drug administration.

Results: Low drug level (below 0.5 μg/mL for INX[1], 4.9 μg/ml for ADM[2], and 20 μg/l for CZP[3]) was found in 54 (45%) patients: in 33 (55.9%) patients with RD and 21 (34.4%) patients with IBD. In the RD group, low drug trough level was observed more often than in IBD (55.9% vs 34.4%, OR 2.418, 95% CI 1.157 to 5.052, p=0.018). Only in UC was there a relationship between the received low dose of the drug (up to 200 mg of INX, 40 mg of ADM, and 200 mg of CZP) and its low level in the serum (p=0.026). Among the additional factors associated with a low TNFi level, lower dose of concomitant therapy at the time of a biologic initiation (66.7% vs 20.8%, OR 7.6, 95% CI 1.388 to 41.617, p=0.033) and the absence of pseudopolyps (78.9% vs 21.1%, p=0.045) were found in IBD, and in case of RD these factors included the age of 30 to 45 years (72.7% vs 41.9%, OR 3.692, 95 % CI 1.136 to 12.0, p=0.026), the absence of comorbidities (58.6% vs 41.4%, OR 3.44, 1.09 to 10.858, p=0.032) and male gender (78.8% vs 50% in women, OR 3.714, 95% CI 1.194 to 11.552, p=0.02).

ADAb were detected in 29 (24.2%) patients (7 to INX (19.4%), 8 (17.8%) to ADM, 14 (35.9%) to CZP), 23 (79.3%) of which had also a concomitant low trough level of the drug. There were no significant differences in the frequency of ADAb formation between the pathologies. In the AS group, antibodies to CZP were detected in all patients with a low level of the biologic, while only in 25% of patients receiving ADM, a low level was associated with the formation of ADAb (p=0.019). In addition, among patients with AS, ADAb were detected only in those patients who did not take prednisone at the time of blood serum sampling (100% vs 37.9%, p=0.037).

Conclusion: Low level of TNFi is more common in RD than in IBD. For each group, the factors associated with a low trough level of TNFi were identified. There were no significant differences in the frequency of ADAb formation between nosologies.

AB0485 DOES THE REASON OF DISCONTINUATION OF THE FIRST TNF INHIBITOR INFLUENCE THE RESPONSE TO THE SECOND TNF INHIBITOR IN SPONDYLOARTHRITIS? PILOT STUDY FROM THE MOROCCAN RBSMR REGISTRY

T. Fatima Zahrae[1], T. Latifa[2], H. Rkain[2], I. Hmamouchi[2], L. Achemlal[2], I. El Bouchti[3], A. Elmaghraoui[2], I. Ghozlani[4], H. Hassikou[5], T. Harzy[6], L. Ichchou[7], O. Mkinsi[8], R. Niamane[9], R. Bahiri[2], F. Allali[2]. [1]*Faculty of Medicine and Pharmacy of Tangier, Adelmalek Essaadi University, Rheumatology, Tangier, Morocco*; [2]*Faculty of Medicine and Pharmacy of Rabat, Mohammed V University, Rheumatology, Rabat, Morocco*; [3]*Arrazi University Hospital, Rheumatology, Marrakech, Morocco*; [4]*University Hospital of Agadir, Rheumatology, Agadir, Morocco*; [5]*Military Hospital Moulay Ismail, Hassan II University Hospital, Rheumatology, Meknes, Morocco*; [6]*Hassan II University Hospital, Rheumatology, Fez, Morocco*; [7]*Mohammed VI University Hospital, Rheumatology, Oujda, Morocco*; [8]*Ibn Rochd University Hospital, Rheumatology, Casablanca, Morocco*; [9] *Military Hospital Avicenne, Mohammed VI University Hospital, Rheumatology, Marrakech, Morocco*

Background: In rheumatoid arthritis, studies have shown that the response to a second TNF inhibitor is better if the first TNF inhibitor was stopped for a secondary failure or adverse event compared to a primary failure [1,2]. However, few studies have provided evidence regarding the response to a second TNF inhibitor based on the reason for discontinuation of the first TNF inhibitor in patients with a diagnostic of spondyloarthritis (SpA).
Objectives: To evaluate the efficacy of the 2nd TNF inhibitor in real life from a cohort of patients with SpA from the Moroccan registry of biological therapies in rheumatic diseases (RBSMR Registry), according to the reason for discontinuation of the 1st TNF inhibitor.
Methods: We have included from the RBSMR Registry any patient with a diagnosis of SpA starting a 2nd TNF inhibitor on inclusion in the registry or during the 1st year of follow-up. A descriptive study was conducted by measuring the therapeutic maintenance of the 2nd TNF inhibitor as well as the disease activity in different groups of patients according to the reason for stopping the first TNF inhibitor: stopping for ineffectiveness, side effect or non-availability of the drug.
Results: Of the total 194 patients with SpA included in the RBSMR registry, 40 patients were on their 2nd TNF inhibitor at one year follow-up. The mean age of the patients was 43.6 ± 15.1 with a male predominance (57.5%) and a mean of disease duration of 13.75±6.95 years. At 1 year, treatment was maintained in 72.5% of all patients: 100% after ineffectiveness, 82% after discontinuation for side effects and 52.9% for unavailability of the first TNF inhibitor. Moderate disease activity as defined by an Ankylosing Spondylitis Disease Activity Score using ASDAS-CRP <2.1 was achieved at 1 year in 75%, 64.7% and 52.9% respectively in patients who stopped their first TNF inhibitor for side effects, ineffectiveness or unavailability of treatment.
Conclusion: This pilot study gives us a small insight into the fate and efficacy of the 2nd TNF inhibitor based on the reason for discontinuation of the first. The follow-up data at 2 and 3 years will allow us to include more patients and thus be able to do a real statistical study with a comparison between the different groups.

Background: NA
Objectives: To estimate the annual direct costs of biological therapies in Spondyloarthropathies (SpA) and to establish possible factors associated with those costs.
Methods: The main data source was the Moroccan registry of biological therapies in rheumatic diseases (RBSMR). We included SpA patients with available 1-year data. Variables related to socioeconomic status, disease and biological therapy were collected. Differences in costs across groups were tested by Mann–Whitney and Kruskal–Wallis tests. Correlations analysis was performed in search of factors associated with high costs.
Results: We included 89 SpA patients. The mean age was 40.6± 13.6 years, with male predominance 68.9 %. Patients received one of the following therapies: TNF-blockers (n =79), Biosimilar of TNF-blockers (n =8) and Il17-blockers (n =2). Median one-year biologic costs per patient were 9 569, 39 €. The total annual of biotherapies in AS patients was 851 675, 98 €.

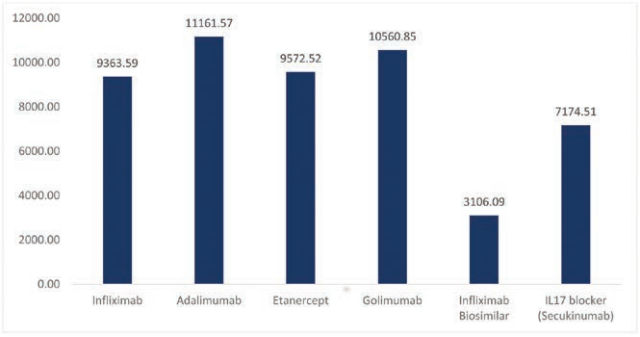

Figure 1 Annual mean drug costs per treated patient (€: Euro)

The costs are presented in Euro using an exchange rate of (1 Moroccan Dirham = 0.091Euro).
TNF-blockers constituted 95 % of the total annual budget. Biosimilar of TNF-blockers and Il17-blockers represented 3 % and 2 % of this overall budget, respectively. Although the costs were not significantly different in terms of gender or level of study, the insurance type significantly affected the cost estimation.
No correlation was found between the annual direct costs of biotherapies and body mass index nor with BASFI or BASDAI.
Conclusion: In Morocco, a developing country, the annual direct costs of biological therapies are high in AS patients. Our results may contribute to the development of strategies for better governance of these costs.
Disclosure of Interests: None declared.

Spondyloarthritis - clinical aspects (other than treatment)

AB0487 HEPSIDINE LEVEL IN PATIENTS WITH ANKYLOSING SPONDYLITIS, RELATIONSHIP WITH HEMOPOESIS AND FERROKINETICS

O. Zviahina[1], S. Shevchuk[1]. [1]*National Pirogov Memorial Medical University, Vinnytsya, Internal Medicine Chair # 2, Vinnytsya, Ukraine*

Background: Hypoferimia, as a manifestation of systemic inflammation, is quite common in patients with ankylosing spondylitis (AS). Anemic syndrome can be represented by anemia of chronic disease (ACD), iron deficiency anemia (IDA) and their combination. Its frequency of occurrences ranges from 18.5 to 45.8 %. The discovery of the hormone hepcidin in 2001 changed the perception of iron metabolism disorders and demonstrated its association with the inflammatory component. Over the last decade, scientific databases have accumulated a lot

of information about hepcidin and its role in the development of anemia and the response to inflammation. However, in the context of the AS, such data are contradictory and therefore need further study.

Objectives: To determine the level of hepcidin in patients with ankylosing spondylitis and to assess its relationship with hematopoiesis and ferrokinetics.

Methods: The hepcidin levels of 76 patients with ankylosing spondylitis (13 women and 63 men with a mean age of 43.67±0.97 years). The diagnosis of AS was made according to the New York modified criteria of 1984. All patients were divided into three groups: without anemia (n=47), with anemia (n=29) and the control group, representative by age and sex (n=26). According to the percentile analysis, all patients were divided into a group with an optimal <25 ng/ml, extremely high - 25-35 ng/ml and a high level of hepcidin > 35 ng/ml. In addition to hepcidin, hematopoiesis and ferrokinetic parameters were measured in each patient: hemoglobin (Hb), erythrocyte, MCV, serum iron, total serum iron-binding capacity (TIBC), serum ferritin, transferrin saturation (TS). Statistical processing of the obtained results was performed with the use of statistical software package "Microsoft Office Excel 2007".

Results: When conducting a percentile comparison in 95 % of people in the control group, the level of hepcidin was in the range of 17.97-38.8 ng/ml (P_5 - P_{95}), and in patients with AS in 95 % - 14.62-87.38 ng/ml. At P_{95}, the level of hepcidin in patients with AS was 2.3 times higher than in P_{95} control group. Comparing the mean values of hepcidin, a significant difference was found between the group of patients without anemia, where it was 36.08±2.57 ng/ml and the group of patients with anemia, where the level of hepcidin was 51.77±4.62 ng/ml. The lowest level of hepcidin was in patients with IDA (35.8 ±7.50 ng/ml), and the highest (62.78±5.94 ng/ml) - among patients with ACD. The group of patients with ACD and iron deficiency, according to the levels of hepcidin (48.53±9.50 ng/ml) took an intermediate place.

In terms of hematopoiesis and ferrokinetics, the level of hemoglobin and erythrocytes did not differ significantly between the groups of optimal, extremely high and high levels of hepcidin. According to the levels of serum iron, TS and ferritin in the group of patients with anemia, a significant association with hepcidin was established (with increasing levels of hepcidin, the values of serum iron, TS and ferritin also increased). In contrast,sTfR levels were the highest in the group with optimal hepcidin levels (6.02±0.71 mg/l) and decreased to 4.88±0.64 mg/l in the group with high hepcidin levels. Such changes in hematopoiesis and ferrokinetics were explained by the accumulation of mostly people with symptoms of ACD in the group with high levels of hepcidin, and the group with optimal levels of hepcidin consisted mainly of patients with IDA.

Conclusion: Patients with AS have elevated serum hepcidin levels, it is higher in individuals with anemic syndrome than in patients without anemia and is associated with serum iron, TS and ferritin levels.

Disclosure of Interests: None declared.

Background: Previous studies have compared Patient-Reported Outcomes (PROs) in Spondyloarthritis (SpA); a recent one has found similarity in Psoriatic Arthritis (PsA) and axial patients[1].

Objectives: To describe PROs at SpA diagnosis (new or confirmed), by type of SpA and by gender.

Methods: SIRENA is an Italian, prospective Registry of SpA patients diagnosed according to ASAS criteria and naïve to any DMARDs. At inclusion, patients were classified as predominant axial (AxSpA) or mainly peripheral (pSpA). PROs showed in the Table 1 were collected and analysed descriptively.

Table 1. PhGA and PROs at diagnosis*

* The sum does not add up to the total because of some missing values.

Results: From 23 sites, 123 AxSpA and 227 pSpA patients were analysed. Diagnosis was new in 58% of AxSpA and 77% of pSpA. 85.5% of the pSpA had PsA, while in AxSpA the most frequent type was Ankylosing Spondylitis (48.8%). Time from symptom onset to diagnosis was higher in AxSpA than in pSpA (median 36 vs 24 months, respectively). At inclusion, composite disease activity measures showed high disease activity for AxSpA (mean ASDAS-CRP 3.1) and moderate disease activity for pSpA (mean DAS28 3.6; mean DAPSA 22.5). AxSpA patients had numerically worse values than pSpA in all the PROs collected, except for BASDAI score that was similar (mean 5.2). For both AxSpA and pSpA, all PROs were worse in women than men, except

for the % of work time missed. PtGA scores were higher than PhGA, in each group and gender.
Conclusion: At diagnosis, SpA patients perceive a slightly higher disease burden than assessed by Physicians. For PROs other than BASDAI, AxSpA reported a worse impact than pSpA. Overall, women showed a higher disease impact than men.

AB0489 CORRELATION BETWEEN DISEASE ACTIVITY AND SERUM TNF-ALPHA LEVELS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

K. Kraev[1,2], M. Geneva-Popova[1,3], S. Popova[1,3]. [1]*Medical University Plovdiv, Propedeutics of Internal Diseases, Plovdiv, Bulgaria*; [2]*Multiprofile Hospital for Active Treatment "Kaspela", Rheumatology, Plovdiv, Bulgaria*; [3]*Multiprofile Hospital for Active Treatment "St.George", Rheumatology, Plovdiv, Bulgaria*

Background: Ankylosing spondylitis (AS) is an immune-mediated rheumatic disease, it belongs to the spectrum of the axial spondyloarthritis. Several elements are important for the pathogenesis of AS - they include interactions in the context of a specific genetic origin between the intestinal microbiome, innate immunity, lymphoid cells and anatomical structures, which are the entheses of the axial skeleton and peripheral joints. The main mediators of the inflammatory process are TNF - α, IL-17 and IL-17A.
Objectives: To study the level of TNF-alpha in the serum of patients with ankylosing spondylitis and to assess its relationship with the indices of disease activity before starting therapy with TNF-alpha blockers and in the dynamics after initiation of treatment.
Methods: The present study included 50 patients with ankylosing spondylitis and 31 healthy controls similar in age, sex, and BMI. Clinical and non-clinical methods of examination and evaluation were used for proper assessment and follow-up of patients. The disease activity indices that were used were BASDAI and ASDAS. Statistical analysis was performed with the IBM SPSS program, v.24., To prove the relationship between the level of TNF-alpha in the serum of patients and disease activity, a correlation analysis of Spearman Rho was used.
Results: The level of TNF-α in patients with AS was highest before treatment initiation with biologics, 89.77 ± 36.89 pg / ml, and was significantly higher than that of healthy controls. At the next visit, the TNF-α level decreased to 27.59 ± 23.88 pg / ml, the difference being significant from baseline. 24 months after initiation of treatment with biological therapy average level of TNF-α in patients with AS did not differ reliably from its levels in 6 and 12 month after initiation of treatment, respectively, 22.36 ± 22.38 pg/ml, 19,29 ± 21.07 pg/ml. The level of this cytokine significantly correlates with the activity of the disease, measured by the activity indices BASDAI, ASDAS.
Conclusion: The level of the pro-inflammatory cytokine TNF-alpha is significantly higher in patients with ankylosing spondylitis and significantly correlates with the disease activity in them, measured by the respective indices (BASDAI, ASDAS).

AB0490 IMPACT OF SPONDYLOARTHRITIS ON WORK PRODUCTIVITY: A REAL LIFE STUDY

M. Ben Majdouba[1], S. Boussaid[1], S. Rekik[1], S. Jemmali[1], H. Ajlani[1], H. Sahli[1], M. Elleuch[1]. [1]*La Rabta hospital, Rheumatology, Tunis, Tunisia*

Background: Work productivity of patients with spondyloarthritis is frequently affected by their disease.
Objectives: We aim to identify disease-related factors associated with poor work productivity in patients with spondyloarthritis.
Methods: A cross-sectional study was performed in patients with spondyloarthritis. Data on disease characteristics were collected as well as specific indices: Visual analogue scale (VAS) for fatigue and pain, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score with CRP (ASDAS-CRP), Bath Ankylosing Spondylitis Functionnel Index (BASFI) and Bath Ankylosing Spondylitis Metrology Index (BASMI). EuroQol-5D (EQ5D) was used to assess health-related quality of life. Work productivity was assessed by the Work Productivity and Activity Impairment scale (WPAI:SpA). Factors associated with presenteeism, absenteeism and work productivity loss were evaluated.
Results: One hundred patients were enrolled (73 men and 27 women); mean age was 43.68 ± 10.3 years. Fifty nine percent of patients were employed, 26% were off work and 15% were retired of which 8% were in early retirement. Sixty seven percent of patients had ankylosing spondylitis, 17% had rheumatism associated with inflammatory bowel disease and 16% had psoriatic rheumatism. The average disease duration was 12.24 ± 8.73 years. Mean age at onset was 33.2 ± 10 years [18-59]. The average diagnostic delay was 2.41 ± 3 years; it was more than five years in 17% of cases. Sacroiliac pain has been noted in 69 patients, lumbar or cervical stiffness in 78 patients and peripheral joint involvement in 18 cases. Thirty one percent of patients had hip joint involvement and 49% had extra-articular manifestation. Fifty percent had inflammatory biological syndrome, 63% were treated with anti-TNFα and 58% needed symptomatic treatment regularly. The mean fatigue and pain VAS was respectively 5.58 ± 2.5 and 5.56 ± 2.9. The mean BASDAI was 4.4 ± 2.4, the average BASFI was 4.6 ± 2.7 and the average ASDAS-CRP was 2.77 ± 1.18. The mean BASMI was 4.4 ± 2.8. The mean EQ5D score was 0.485 ± 0.378. Among employed patients, mean absenteeism, presenteeism and work productivity loss was 21.8 ± 33.13%, 42 ± 32% and 46.5 ± 35.31%, respectively. These work outcomes were correlated to diagnostic delay ≥ 2 years ($p<0.03$), peripheral joint involvement ($p=0.006$), psoriasis ($p=0.02$), inflammatory biological syndrome ($p<0.001$), need of symptomatic treatment ($p=0.001$), fatigue and pain VAS ≥ 4 ($p<0.001$), BASDAI ≥ 4 ($p<0.001$), ASDAS-CRP ≥ 2.1 ($p<0.001$), BASFI ≥ 4 ($p<0.001$), BASMI ≥ 4 ($p=0.002$) and low EQ5D score ($p<0.001$). Work productivity loss was in addition correlated to age at onset < 25 years ($p=0.03$).
Conclusion: Active disease, reduced physical function and poorer quality of life are associated with reduced work productivity. Early diagnosis and good disease management especially fatigue and pain can potentially improve work outcomes in patients with spondyloarthritis.
Disclosure of Interests: None declared.

AB0491 THE IMPORTANCE OF MUSCULOSKELETAL SYMPTOM QUESTIONING IN INFLAMMATORY BOWEL DISEASES

B. Farisoğulları[1], O. Keskin[2], B. Usta[3], G. K. Yardımcı[1], E. Parlak[2], T. Kav[2], U. Kalyoncu[1], O. Karadag[1]. [1]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; [2]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Gastroenterology, Ankara, Turkey*; [3]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey*

Background: Spondyloarthritis (SpA) occurs in up to 13% of patients with inflammatory bowel disease (IBD) (1). Early diagnosis and treatment of SpA in IBD patients prevents irreversible musculoskeletal diseases.
Objectives: The aim of this study is to emphasize the importance of questioning musculoskeletal symptoms in patients with IBD.
Methods: In the Hacettepe University Gastroenterology Clinic, patients with IBD were questioned for musculoskeletal symptoms between March 2019 and September 2020. For this purpose, a validated DETAIL questionnaire (2) consisting of six questions was asked (1. Have you ever had a finger or a toe and/or another joint swollen and painful for no apparent reason? 2. Occasionally, has an entire finger or toe becomes swollen, making it look like a 'sausage'? 3. Have you had pain in your heels? 4. Have you ever had back pain lasting at least 3 months that was not injury related? 5. Do you have low back pain in the morning and/or after resting that improves with exercise? 6. Do you wake up at night because of low back pain?). Patients with at least 1 positive out of 6 questions were consulted in the rheumatology clinic, and patients were evaluated for SpA by physical examination, laboratory, and imaging. Demographic and clinical characteristics of IBD patients with and without SpA were compared.

Results: 217 IBD patients were included in the study. Twenty patients with previously known rheumatologic diseases were excluded from the study. 49 (24%) of the remaining 197 patients had a positive answer to at least one question in the DETAIL query. 39 (20%) of these patients were evaluated in the rheumatology clinic, and 16 (8.1%) of them were diagnosed with SpA (spondylitis: 9, peripheral arthritis: 7) (Figure 1). There were no significant differences in terms of age, gender, IBD type, duration of IBD, current treatment, fibromyalgia syndrome (FMS) and depression according to Beck depression inventory between patients with IBD with and without SpA (Table 1).

Table 1. Clinical, demographic characteristics of the IBD patients according to SpA.

	IBD with SpA n= 16	IBD without SpA n= 23	p
Age, years, median (IQR)	47.03 (27.4)	35.9 (14.1)	0.052
Female, n (%)	8 (50)	17 (74)	0.12
IBD disease duration, months, median (IQR)	66.7 (70.7)	44.8 (70)	0.26
IBD type, n (%)			
CD	6 (37)	11 (48)	0.19
UC	9 (56)	12 (52)	
IC	1 (7)		
Smoking (ever), n (%)	10 (62.5)	11 (48)	0.37

-minimal	1 (9)	5 (22)	0.13
-mild	8 (73)	7 (30)	
-moderate	2 (18)	9 (39)	
-severe	0	2 (9)	

Harvey-Bradshaw Index for CD disease activity and Mayo score for UC disease activity were used.**SD:** standard deviation, **IQR:** inter-quartile range**IBD:** inflammatory bowel disease; **SpA:** Spondyloarthritis**, bDMARD:** biological disease modifying anti-rheumatic drug**, CD:** Crohn's disease, **UC:** Ulcerative colitis, **IC:** indeterminate colitis; **HBI:** Harvey-Bradshaw Index **ASA:** 5-aminosalicylic acid; **AZA:** azathioprine; **MTX:** methotrexate; **FMS:** Fibromyalgia syndrome

Conclusion: By questioning the musculoskeletal system in IBD patients, 20% of the patients were evaluated in the rheumatology department, and nearly half of these patients (8%) were diagnosed with SpA. The findings point to the importance of musculoskeletal symptom questioning in routine outpatient clinic control in IBD patients.

AB0492 DETERMINING FACTORS RELATED TO POOR QUALITY OF LIFE IN PATIENTS WITH SPONDYLOARTHRITIS: A REAL LIFE STUDY

M. Ben Majdouba[1], S. Boussaid[1], S. Rekik[1], S. Jemmali[1], H. Ajlani[1], H. Sahli[1], M. Elleuch[1]. [1]*La Rabta hospital, Rheumatology, Tunis, Tunisia*

Background: When treating people with spondyloarthritis (SA), rheumatologists are focused on reducing disease activity based on activity measurement scores; but there may be other factors not directly captured by these tools, which impact on quality of life.

Objectives: We aim to identify factors associated with poor quality of life in patients with spondyloarthritis.

Methods: A cross-sectional study was performed in 100 patients with spondyloarthritis. Data on sociodemographic and disease characteristics were collected as well as specific scores: Visual analogue scale (VAS) for fatigue and pain, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score with CRP (ASDAS-CRP), Bath Ankylosing Spondylitis Functionnel Index (BASFI) and Bath Ankylosing Spondylitis Metrology Index (BASMI). EuroQol-5D (EQ5D) was used to assess health-related quality of life.

Results: A total of 100 Patients were enrolled (73 men and 27 women); the mean age was 43.68 ± 10.3 years. Thirteen percent of patients had high level of education (> 12 years), 47% had BMI ≥ 25 and 47% were smoking. Sixty seven percent of patients had ankylosing spondylitis, 17% had rheumatism associated with inflammatory bowel disease and 16% had psoriatic rheumatism. The average disease duration was 12.24 ± 8.73 years. Mean age at onset was 33.2 ± 10 years. The average diagnostic delay was 2.41 ± 3 years. Sacroiliac pain has been noted in 69 patients, lumbar or cervical stiffness in 78 patients and peripheral joint involvement in 18 cases. Thirty one percent of patients had hip joint involvement and 49% had extra-articular manifestation. Fifty percent had inflammatory biological syndrome, 63% were treated with anti-TNFα and 58% needed symptomatic treatment regularly. The mean fatigue and pain VAS was respectively 5.58 ± 2.5 and 5.56 ± 2.9. The mean BASDAI was 4.4 ± 2.4, the average BASFI was 4.6 ± 2.7 and the average ASDAS-CRP was 2.77 ± 1.18. The mean BASMI was 4.4 ± 2.8. EQ5D questionnaire showed that: 37 patients had no problems with mobility, 61 had some problems and two had extreme problems; 39 patients had no problems with self-care, 55 had some problems and six had extreme problems; 35 patients had no problems with performing usual activities, 60 had some problems and five had extreme problems; 13 patients had no pain or discomfort, 61 had moderate pain or discomfort and 26 had important pain or discomfort; 42 patients had no anxiety or depression, 46 had moderate anxiety or depression and 12 had extreme anxiety or depression. The mean EQ5D score was 0.485 ± 0.378 [-0,448-1] and the mean general health EQ5D VAS was 59 ± 25% [7-100]. Poor quality of life was associated with smoking (p=0.03), physical inactivity (p<0.001), cervical and lumbar stiffness (p=0.001), peripheral joint involvement (p=0.006), inflammatory biological syndrome (p<0.001), need of symptomatic treatment (p<0.001), BASDAI > 4 (p<0.001), ASDAS > 2.1 (p<0.001), BASFI > 4 (p<0.001) and BASMI > 4 (p<0.001).

Conclusion: Active disease and reduced physical function are the main causes of poor quality of life in patients with spondyloarthritis. Good disease management, smoking cessation and encouragement of physical activity can potentially improve patients' quality of life.

Disclosure of Interests: None declared.

AB0493 WHAT IS THE DIAGNOSTIC VALUE OF IMPAIRED SPINAL MOBILITY MEASUREMENTS IN INFLAMMATORY BACK PAIN PATIENTS? DATA FROM THE DESIR COHORT

C. Lukas[1,2], G. Khoury[3], M. A. D'agostino[4,5], B. Combe[1,2], J. Morel[2,6]. [1]*University Montpellier, IDESP, Montpellier, France*; [2]*University hospital Montpellier, Rheumatology, Montpellier, France*; [3]*University hospital Montpellier, rheumatology, Montpellier, France*; [4]*University Paris Ouest-Versailles-Saint-Quentin-en-Yvelines, Rheumatology, Boulogne Billancourt, France*; [5]*Ambroise Pare Hospital, Rheumatology, Boulogne Billancourt, France*; [6]*University Montpellier, IGMM, Montpellier, France*

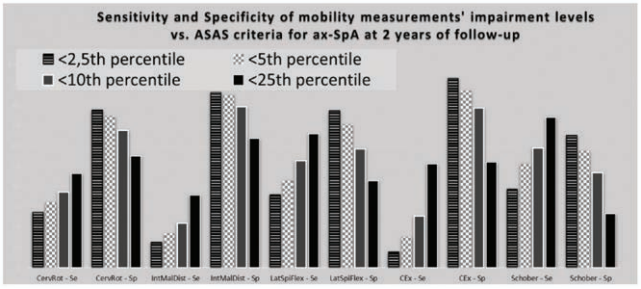
Background: The diagnostic process in a patient with early inflammatory back pain suggestive of axial spondyloarthritis (ax-SpA) requires assessment and integration of multiple aspects, including clinical examination, biological measurements and radiologic assessments. Among the physical examination features, alteration of spinal mobility is often observed in ax-SpA. However,

whether mobility impairment might really increase diagnostic likelihood, and which of the measurements made have relevant diagnostic value remains unknown.

Objectives: To describe the frequency and severity of mobility impairment in multiple traditional measurements in patients suspect of early ax-SpA at initial assessment time, and to analyze their individual diagnostic performances in reference to usual classification criteria applied after 2 years of follow-up.

Methods: Data from the DESIR cohort, which included patients aged 18-50 with inflammatory back pain lasting for 3 months to 3 years and a clinical suspicion of ax-SpA diagnosis were used. Baseline measurements of Schober's test (Schober), chest expansion (CEx), lateral spinal flexion (LatSpiFlex), cervical rotation (CervRot) and intermalleolar distance (IntMalDist) collected at baseline were classified according to reference data from the general population adjusted for age and -when appropriate- for height. Cutoffs were defined as above 2.5th, 5th, 10th and 25th percentiles. With ASAS classification for ax-SpA applied at 2 years follow-up visit as external reference, diagnostic performances (Sensitivity [Se], Specificity [Sp], Positive [PPV] and Negative [NPV] Predictive Values) were calculated.

Results: Complete data were available for 575 patients (of whom 377 (66%) fulfilled the ASAS criteria at 2 years). Schober, CEx, LatSpiFlex, CervRot and IntMalDist were above 5th percentile in respectively 278 (48%), 82 (14%), 220 (38%) and 93 (16%) patients. None of the measurements showed a clinically relevant compromise between both Se and Sp, but Sp was highest for CEx-most impaired cutoffs (Figure 1). The highest PPV (73.6%) and NPV (39.4%) were observed for LatSpiFlex.



Conclusion: Measures of mobility and their levels of impairment do not show sufficient individual diagnostic value for ax-SpA among patients with early inflammatory back pain. However, highest degrees of impairment when compared to general population are more specifically observed in patients finally classified with ax-SpA for CEx, which was –consistently- 1 of the 2 mobility measures that was retained in the modified New York criteria for ankylosing spondylitis.

Background: There is some evidence that neuropsychiatric changes occur in systemic lupus(1) and rheumatoid arthritis(2). However, little is known regarding a possible disease-related impairment of cognitive abilities in axial spondyloarthritis (axSpA).

Objectives: To evaluate patients with axSpA regarding cognitive impairments.

Methods: Patients with axSpA attending two rheumatology practices were routinely evaluated by rheumatologists and underwent a computer-based memory and attention test (MAT) (3, 4) with subscale scores ranging from 0 (worst) to 15 (best). The results of short-term memory and working memory were compared to an age-, sex- and education-matched control group of healthy subjects. Descriptive results are presented as median (IQR) for interval data and n (%) for nominal data if not stated otherwise. Two-tailed Wilcoxon signed-rank tests including Bonferroni-Holm adjustment for multiple tests were conducted to investigate the magnitude of potential differences in cognitive abilities.

Results: 101 consecutive patients were tested (Table 1). After multiple testing adjustment for two subscales, Wilcoxon signed-rank tests returned significant findings for working memory ($V = 539.5$, $p = 0.006$, $|r| = 0.204$) but not for short-term memory ($V = 1075$, $p = 0.351$, $|r| = 0.078$). Regarding the scales' anchors, descriptive results on pairwise differences suggested axSpA patients to have working memory scores that are on average 10.7% lower compared to control participants (mean $\Delta = -1.64$, SD $\Delta = 5.95$).

Table 1. Patients and disease characteristics

	n	%	Mean	SD	Median	25% Quantile	75% Quantile
Age	101	100	51.1	11.6	52	42	60
Age (female)	48	47.5	52.6	11.7	54	44.5	61
Age (male)	53	52.5	49.8	11.5	51	41	57
< 13 years formal education	47	46.5					
≥ 13 years formal education	54	53.5					
HLA B27 positive n/N	64/92	63.4					
Disease duration (years)	101	100	13.7	11.7	12	4	21
Disease duration (female, years)	48	47.5	11.6	9.9	9	4	17.2
Disease duration (male, years)	53	52.5	15.5	12.9	15	5	23
BASDAI	92	91.1	3.7	1.7	3.8	2.4	5
BASFI	91	90.1	3	2.4	2.3	1.2	4.5
BASMI	75	74.3	1.9	2.3	1	0	3
ASDAS	98	97	2.3	0.8	2.3	1.8	2.8

Conclusion: The MAT computerized testing is a feasible test and was well accepted by patients. Results regarding working memory suggest that cognitive abilities needed to accomplish everyday tasks may be impaired in axSpA patients. Further work is needed to characterise possible causes of or associations with this cognitive impairment.

AB0495 BIOMECHANICAL STRESS IN THE CONTEXT OF COMPETITIVE SPORTS TRAINING TRIGGERS ENTHESITIS

D. Simon[1], A. Kleyer[1], S. Bayat[1], J. Knitza[1], L. Valor[1], M. Schweiger[1], G. Schett[1], K. Tascilar[1], A. Hueber[2]. [1]*Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany*; [2]*Sozialstiftung Bamberg, Section Rheumatology, Erlangen, Germany*

Background: Preclinical models have indicated that biomechanical stress can trigger entheseal inflammation (1). Furthermore, enthesitis is a hallmark of psoriatic arthritis (PsA) and spondyloarthritis (SpA), suggesting that mechanoinflammation is an important step in their pathogenesis (2). However, the relation between mechanical stress and enthesitis in humans is poorly investigated. Competitive badminton is a demanding stop-and-go sport that strains entheseal sites in particular and provides an opportunity to assess the impact of physical activity on the development of an instant inflammatory response in the entheses.

Objectives: To evaluate the influence of mechanical stress on the development of immediate enthesitis.

Methods: BEAT (Badminton Enthesitis Arthrosonography Study) is an interventional study that assessed entheses in competitive badminton players before and immediately after a 60-minute intensive training session by ultrasound. Power Doppler (PD) signal and Gray-Scale (GS) changes were evaluated at the insertions sites of both Achilles tendon, patellar tendons and lateral humeral epicondyles and quantified using a validated scoring system (3). Pre- and post-training scores were compared using linear mixed-effects models. We used interaction terms to assess possible differential effects on patellar, elbow and Achilles entheses.

Results: Thirty-two badminton players (22 men, 10 women) with an average age of 31.1±13.0 years were included (Table 1). On average, they had been playing badminton for 16.2±10.1 years. 192 entheseal sites were examined twice. The respective empirical total scores for PD examination were 0.1 (0.3) before and 0.5 (0.9) after training (Figure 1). Mean total GS scores were 2.9 (2.5) and 3.1 (2.5) before and after training, respectively. The mean total PD score difference of 0.4 between pre- and post -training was significant with a p value of 0.0014, whereas the p value for the mean total GS score difference of 0.2 was 0.63. Overall, seven participants (22%) showed an increased empirical total PD score. A mixed-effects model showed a significant increase of PD scores after training, with a mean increase per site of 0.06 (95%CI 0.01 to 0.12, p=0.017).

Table 1. Baseline characteristics

Demographic characteristics	
N, total	32
Females, N (%)	10 (31.3)
Age, years (mean ± SD)	36.1 ± 13.0
Height, cm (mean value ± SD)	178.6 ± 9.9
Body weight, kg (mean value ± SD)	74.7 ± 13.5
Smoking, N (%)	11 (34.4)
Alcohol, N (%)	24 (75.0)
Concomitant Diseases

Sports history	
Years Badminton (mean ± SD)	16.2 ± 10.1

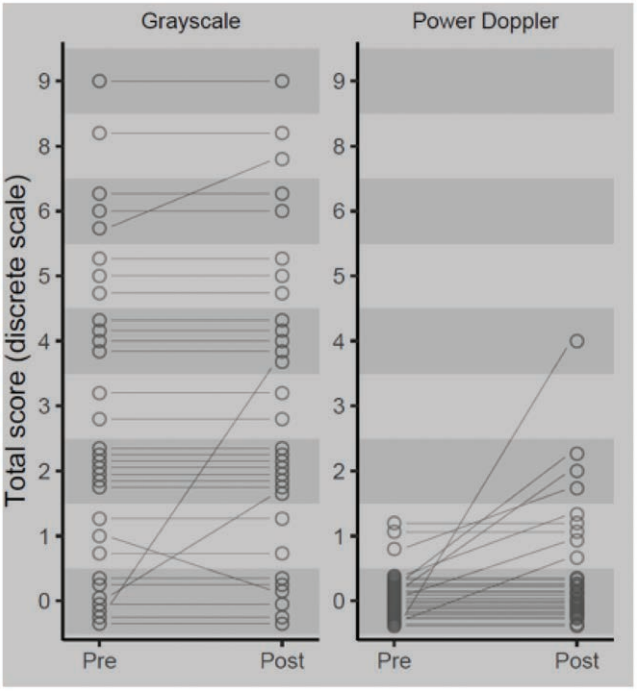

Figure 1. Ultrasound scores before and after trainingFigure 1. A Spaghetti plots depicting inividual Gray-Scale and Power Doppler ultrasound scores before and after training

Conclusion: Mechanical stress leads to rapid inflammatory responses in the entheseal structures of humans. These data support the concept of mechanoinflammation in diseases associated with enthesitis. However, while such responses may be self-contained in healthy subjects, they may be prolonged and more pronounced in certain risk groups, such as patients with PsA or SpA.

AB0496 COMPARISON OF THE DISTRIBUTION BY DEPARTMENT OF THE PREVALENCE OF SPONDYLOARTHRITIS AND INFLAMMATORY BOWEL DISEASES IN METROPOLITAN FRANCE AND THEIR EVOLUTION BETWEEN 2008 AND 2018

O. Fakih[1], C. Prati[1,2], D. Wendling[1,3], F. Verhoeven[1,2]. [1]*Centre hospitalier régional universitaire de Besançon, Rhumatologie, Besançon, France*; [2]*UFR Santé, Université de Franche-Comté, EA 4267 'PEPITE', Besançon, France*; [3]*UFR Santé, Université de Franche-Comté, EA 4266 'EPILAB', Besançon, France*

Background: Epidemiology of spondyloarthritis (SpA) has been rarely described in France. One study based on a phone survey found a prevalence of 0.30% in 2001 [1], and another study based on a national cohort showed an estimated prevalence of 0.43% in 2010 [2]. To our knowledge, there is no data regarding the geographical distribution of SpA in France. Furthermore, it is known that SpA occurs in up to 13% of patients with inflammatory bowel disease (IBD), and that there is a significant north-south gradient in IBD cases in France.

Objectives: To determine the prevalence of SpA and IBD in metropolitan France and compare the geographical distribution of SpA and IBD in 2008 and 2018.

Methods: Age-and sex-standardized prevalences were collected from data freely available on the French national health insurance website concerning patients with long-term disability (LTD) #27 (SpA) and #24 (IBD). Data for December 31, 2008 and December 31, 2018 were collected. National data are available by diagnosis coded according to the ICD-10 classification, and data by department only concern all patients benefiting from a given LTD.
Results: National prevalence of SpA is estimated at 0.11% in 2008 (43.8% of women, average age 50 years) and 0.27% in 2018 (54% of women, average age 53 years). National prevalence of IBD is estimated at 0.19% in 2008 (55.6% of women, average age 46 years) and 0.27% in 2018 (55% of women, average age 49 years). Standardized prevalences by pathology are detailed in Table 1. Standardized prevalences by department are shown in Figure 1.

Table 1. Standardized SpA and IBD prevalence (per 100000) by disease in 2008 and 2018.

	Ankylosing Spondylitis	Psoriatic Arthritis	Crohn's Disease	Ulcerative colitis
2008	95	31	103	84
2018	181	57	153	126

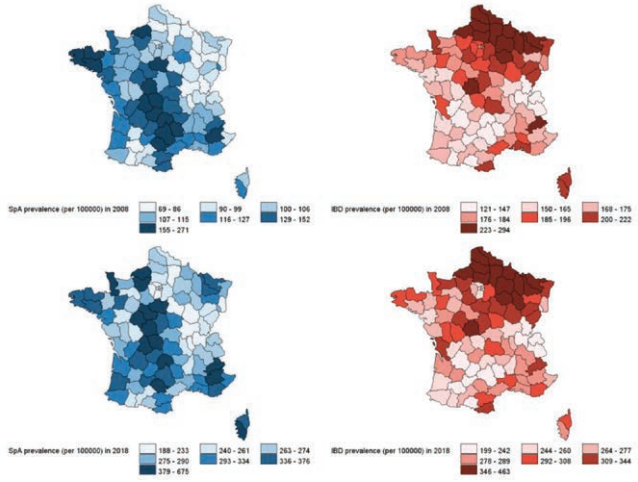

Figure 1. Standardized SpA and IBD prevalence by department in 2008 and 2018.

SpA prevalences found in this study are lower than those indicated in the literature: 0.27% versus 0.43% [2]. This may be explained by the fact that not all patients suffering from SpA or IBD benefit from LTD. Moreover, there is a 2.42-fold increase over ten years, which may correspond to the increase in prescription of biotherapies, which requires the benefit of LTD. North-south gradient in the prevalence of IBDs has been found, which is not the case for SpA, which seems to be less prevalent in the north-eastern quarter of the country. These differences in geographical distribution appear to be stable between 2008 and 2018. While IBD and SpA share many physiopathological similarities, their different geographical distributions suggest the importance of different environmental factors in the development of each condition.
Conclusion: The north-south gradient in the distribution of IBD in metropolitan France is not found in SpA. Despite an increasing prevalence, these distributions appear to be stable over time suggesting an important impact of environmental factor in the expression of these close diseases.

AB0497 IMPACT OF COXITIS ON THE BONE MINERAL DENSITY OF THE HIP IN ANKYLOSING SPONDYLITIS

A. Feki[1], I. Sellami[2], R. Akrout[1], S. Ben Jemaa[1], Z. Gassara[1], M. Ezzeddine[1], M. H. Kallel[1], H. Fourati[1], S. Baklouti[1]. [1]*Hedi Chaker Hospital, Rheumatology, Sfax, Tunisia*; [2]*Hedi Chaker Hospital, Occupational medicine, Sfax, Tunisia*

Background: Ankylosing spondylitis (AS) is an inflammatory disease, with new bone formation and ossification of the ligamentous apparatus as the primary pathological changes. The osteoporosis is coexisting with new bone formation. It is well known a common complication of this chronic disease. Hip involvement is common in AS [1].
Objectives: The objective of this work is to assess the impact of chronic inflammation of the hip (coxitis) on the bone density at this site.
Methods: This is a cross-sectional study of patients who fulfil the modified New York criteria for AS. These patients had not medical history of osteoporosis or other condition that may affect bone metabolism. Hip involvement was appreciated by physical examination and pelvic x-ray. The functional hip gene was assessed by Lequesne Algofunctional Index (LFI). Bone mineral density at the femoral site was measured using Lunar Prodigy dual-energy X-ray absorptiometry. Osteoporosis is defined when T score is ≤ -2.5 DS (standards deviations). Osteopenia is defined when T score is ≤ -1 DS but more than -2.5 DS. A p value <0.05 was considered significant.
Results: Forty-seven AS patients were collected, 12 women and 35 men with a mean age of 43.8 ± 13.4 years. Smoking was noted in 25% of cases. AS clinical form was axial in 33 cases (70.2%) and mixed (axial and peripheral) in 14 cases (29.8%). The mean duration of AS was 15 ± 10.9 years. Nineteen patients (40.4%) were on DMARD at the time of the study. Coxitis was present in 31 patients (66%). It was bilateral in 13 cases (42.5%). The mean of the LFI was 7.1 ± 6.5 with extremes of 0 to 18. Coxitis form was early in 18 cases (40.9%), synostosis in 15 cases (34.1%) and destructive in 11 cases (25%). Twenty-nine patients (61.7%) had normal femoral bone densitometry, 13 patients (27.7%) had osteopenia and 4 patients (8.5%) had osteoporosis. The mean T-score value at femoral neck site was -0.5 SD ± 1.303 [-3– -2]. Patients with coxitis had a significantly lower T score at the femoral site compared to those without coxitis (-0.77 ± 1.31 DS versus 0.07 ± 1.11 DS respectively with p = 0.036).
Conclusion: Our study confirms the role of chronic inflammation in the genesis of bone loss in AS. Given the risks of developing secondary complications as a result of low bone density, early management of AS should be recommended in order to control the inflammatory process and prevent the onset of osteoporosis.

AB0498 INFLUENCE OF SYNOVITIS OF THE HIP JOINTS ON X-RAY PROGRESSION OF COXITIS IN AXIAL SPONDYLOARTHRITIS. RESULTS OF TWO YEARS FOLLOW-UP

E. Agafonova[1], S. Erdes[1], T. Dubinina[1], A. Demina[1], D. Rumiantceva[1], A. Smirnov[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of spondyloarthritis and psoriatic arthritis, Moscow, Russian Federation*

Background: Almost half of patients with axial spondyloarthritis (axSpA) in Russia have hip joint lesions (HJ), but only in 7% of cases it becomes so severe and requires arthroplasty. The causes and rates of progression of coxitis have not been studied.
Objectives: To assess the relationship between disease activity and the sonographic synovitis of the hip joint with the progression of X-ray coxitis in patients with axSpA with a 2-year follow-up.
Methods: The study included 77 patients (mean age 28 ± 5.92 years) with axSpA (ASAS criteria 2009), who were followed up for at least 2 years. Among them, AS (mNY criteria, 1984) had 66 (86%) patients, and nonradiographic axSpA - 11 (14%). The median duration of the disease was 30 [3–60] months, BASDAI - 4.5 [3.2; 5.9], BASFI - 2.4 [0.9; 4.8]. All patients underwent clinical examination, X-ray and ultrasound investigation of the hip joint during the monitoring period. For ultrasound, coxitis was considered an increase in the cervical-capsular distance (CCD) of more than 7 mm. An increase in BASRI hip by 1 stage in 2 years was considered as progression of radiographic coxitis (PRC).
Results: At the time of enrollment, 66 (86%) patients out of 77 patients had pain in the hip joint, and after 24 months - 48 (62%) (p> 0.05). At the time of inclusion, the median pain in the hip joint was 4 [2; 5]; severe pain (≥4.0) had 38% of patients. The median CCD at the time of inclusion was 7.3 [6.4; 8.2] mm, and two years later 6.6 [5.9; 8.2] mm (p> 0.05). At the sonographic examination at the beginning of follow-up 63 (82.0%) patients had coxitis, and after 2 years - 45 (58%) (p <0.05). X-ray coxitis at the time of inclusion was present in 19 (25%) patients, and after 2 years - in 48 (62%) (p <0.05). Depending on the presence or absence of PRC after 2 years, the patients were divided into 2 groups (Table 1). All patients with PRC at the start of the study had sonographically diagnosed synovitis, while among those without progression, only half of them; relative risk of X-ray progression in the presence of ultrasound of synovitis (RR) = 10.5 (p

<0.05). The groups did not differ in terms of activity indicators and the presence of extra-axial manifestations.

Table 1. Characteristics of patients with axSpA at the time of inclusion in the study who had PRC after 24 months of observation.

Parametrs	ΔBASRI hip=0 n=33	ΔBASRI hip >0 n = 44	p
Sex (m/w), n	22/11	32/12	>0,05
The duration of the disease, m., Me [25;75‰]	36 [19;132]	48 [24;84]	>0,05
Age, years, Me [25;75 ‰]	30 [26;34]	28 [24;34]	>0,05
BASDAI, Me [25;75 ‰]	4,3 [3,1;5,8]	4,7 [3,8;6,3]	>0,05
BASFI, Me [25;75 ‰]	3,4 [0,6;5,6]	2,1 [1,1;4,2]	>0,05
ASDAS (SRP), Me [25;75 ‰]	2,6 [1,6;3,9]	3,2 [2,3;4,2]	>0,05
ESR, mm/h, Me [25;75 ‰]	15 [7;30]	23,0 [12;35]	>0,05
SRP, mg/l, Me [25;75 ‰]	12,8 [1,8;31,0]	17,8 [5,6; 50,3]	>0,05
Peripheral arthritis, n %	26 (79%)	32 (73%)	>0,05
US synovitis n%	19 (58%)	44 (100%)	<0,05*
Pain in HJ n%	28 (85%)	38 (86%)	>0,05

Conclusion: X-ray progression of coxitis is associated with ultrasound synovitis and does not depend on the activity of the disease.

AB0499 PHYSICAL ACTIVITY ASSESSMENT IN TUNISIAN PATIENTS WITH SPONDYLOARTHRITIS: THE IPAQ EVALUATION

F. Majdoub[1], M. Sellami[1], S. Miladi[1], A. Fazaa[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, La Marsa, Tunis, Tunisia*

Background: The occurrence of Spondyloarthritis (SpA) often conditions patients' quality of life and hinders their well-being. Physical activity (PA) is associated with various health-related benefits among adults with chronic inflammatory rheumatism but may be insufficiently performed.

Objectives: This study aimed to assess PA in patients with SpA and explore its associated factors.

Methods: This is a single-center cross-sectional study, involving patients with SpA, visiting our outpatient hospital over eight weeks. Patients responded to the International Physical Activity Questionnaire-Short form (IPAQ-S).

Results: Sixty patients were included (39 M/21 F) with an average age of 45.8 years [25-78]. The mean duration of SpA was 13.2 years [1-25]. About 80% of patients were from an urban setting. Sixty-three percent of patients had a professional activity, while 13.3% were retired. Twenty-nine patients (48.3%) had axial and peripheral form, 18 patients (30%) had SpA with enteropathic arthritis, 8 (13.3%) with psoriatic arthritis, 3 patients (5%) had axial spondyloarthritis, and only 2 patients (3.3%) with SAPHO-Syndrom. About 23% of patients had hip arthritis and only 5% had uveitis. Fifty-eight patients were on TNF-inhibitor (21/58 Adalimumab, 15/58 Infliximab, 14/58 Etanercept, 8/58 Golimumab). The average BASDAI was 2.7/10. The average $ASDAS_{CRP}$ was 2.1/10. The average BASFI was 3.3/10. IPAQ results were distributed as follows: 78.3% of patients were in the « low physical activity » category, 21.7% were in the « moderate physical activity » while none of the patients were in the « high physical activity ». Patients without employment had lower levels of physical activity (29.7%) but no association was observed between those two items (p=0.082). Disease activity objectified with BASDAI was related to low physical activity (p=0.045) whereas no association was observed with $ASDAS_{CRP}$ (p=0.870) or BASFI (p=0.056). Otherwise, TNF-inhibitor treatment was not related to different levels of PA (p=0.09).

Conclusion: Tunisian patients with SpA don't perform enough physical activity. Except for high disease activity, the different levels of PA did not appear to be explained by other disease-related variables. Thereby, physical activity should be encouraged in SpA.

AB0500 IMPACT OF COVID-19 PANDEMIC IN OVERALL HEALTH AND FUNCTIONING IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE REUMAVID STUDY (PHASE 1)

D. Benavent[1], M. Garrido-Cumbrera[2,3], C. Plasencia[1], L. Christen[4], H. Marzo-Ortega[5], J. Correa-Fernández[2], P. Plazuelo-Ramos[3], D. Webb[6], V. Navarro-Compán[1]. [1]*Hospital La Paz, IdiPAZ, Rheumatology Department, Madrid, Spain*; [2]*Universidad de Sevilla, Health & Territory Research, Sevilla, Spain*; [3]*Axial Spondyloarthritis International Federation (ASIF), London, United Kingdom*; [4]*Novartis Pharma, AG, Basel, Switzerland*; [5]*University of Leeds, NIHR Leeds Biomedical Research Centre, LTHT and LIRMM, Leeds, United Kingdom*; [6]*NASS, London, United Kingdom*

Background: Evidence on the impact of the COVID-19 pandemic on the overall health and functioning in patients with axial spondyloarthritis (axSpA) is scarce.

Objectives: To analyse the impact of the COVID-19 pandemic on the overall health and functioning in patients with axSpA.

Methods: Data from axSpA patients participating in the first phase of the REUMAVID study were analysed. REUMAVID is a cross-sectional, observational study collecting data through an online questionnaire of unselected patients with rheumatic and musculoskeletal diseases (RMDs), recruited by patient organizations. The survey was disseminated during the beginning of the COVID-19 pandemic (April-July 2020) in seven European countries (Cyprus, France, Greece, Italy, Portugal, Spain, and the United Kingdom). Patients with axSpA who completed the ASAS health index (ASAS-HI) questionnaire were included in this analysis. Descriptive analyses were used to present socio-demographic and clinical characteristics, as well as daily habits. Overall health and functioning were defined according to the ASAS-HI (0-17), as follows: good health (ASAS-HI ≤5), acceptable health (ASAS-HI 6-11), and poor health (ASAS-HI ≥12). As secondary outcomes, well-being (WHO-5), self-perceived health status, and HADS for anxiety and depression were assessed.

Results: Out of 670 axSpA patients, 587 (87.6%) completed ASAS-HI. Of these, 70.4% were female, 72.6% were married or in a relationship, 46.7% had university studies and 37.6% were currently employed. Mean age was 49.9±12.8 years and mean BMI was 26.7±5.5. Regarding extraarticular manifestations, 13.6% had psoriasis, 12.1% inflammatory bowel disease and 18.7% uveitis. Before the COVID-19 pandemic, 50.9% were receiving biological drugs, 46.3% NSAIDs, 26.4% painkillers, 24.7% conventional DMARDs, and 11.9% oral corticosteroids. According to the ASAS-HI, 19.6 % of patients were classified as having poor health, with the most affected aspects being pain (92.0%), movement (86.5%), maintenance of body position (80.6%), energy (79.0%) and sleep (75.3%). Regarding self-perceived health status, 14% reported their health status as "bad" or "very bad", and 46.8% reported worsening health during the pandemic (Table 1). A distribution of the results of the total ASAS-HI scores can be seen in Figure 1.

Table 1. Overall health and well-being, disease activity, and mental health.

Primary Outcome (ASAS-HI)	**Mean ± SD or n (%)**
ASAS-HI (0-17), n=587	8.0 (±3.9)
ASAS-HI	
<5 (good health)	159 (27.1)
5-12 (acceptable health)	313 (53.3)
≥12 (poor health)	115 (19.6)
Secondary Outcomes	
WHO-5	
WHO-5, (0-100), n=584	46.3 (±23.1)
WHO- 5 Poor wellbeing WHO- ≤50	330 (56.5)
Self-perceived health status, n=585	
Very good	33 (5.6)
Good	214 (36.6)
Fair	256 (43.8)
Bad	69 (11.8)
Very bad	13 (2.2)
Change in health status during lockdown, n=587	
Much worse than before	54 (9.2)
Moderately worse	220 (37.6)
Same as before	270 (46.0)
Moderately better	35 (6.0)
Much better than before	6 (1.0)
HADS	
HADS Anxiety (0-21), n=587	8.4 (±4.1)
HADS Anxiety	
No case (0-7)	248 (42.7)
Borderline case (8-10)	151 (26.0)
Case (11-21)	182 (31.3)
HADS Depression (0-21), n=587	7.0 (±4.3)
HADS Depression	
No case (0-7)	329 (56.6)
Borderline case (8-10)	134 (23.1)
Case (11-21)	118 (20.3)

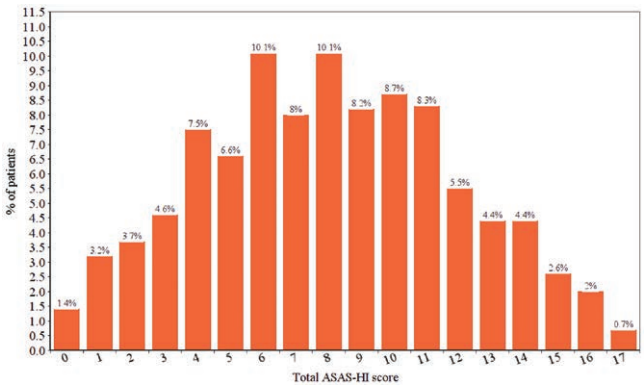

Figure 1. Distribution of the result of ASAS-HI scores (N= 587)

Conclusion: One out of five patients with axSpA reported poor health and functioning according to the ASAS-HI, and almost half of patients reported worsening self-perceived health status during the first wave of the COVID-19 pandemic.

AB0501 CORRELATION BETWEEN AXIAL AND PERIPHERAL ENTHESIS IN SPONDYLARTHRITIS

H. Ferjani[1], M. Yasmine[1], K. Maatallah[1], E. Labbene[2], H. Riahi[2], D. Kaffel[1], M. Bouaziz[2], W. Hamdi[1]. [1]*Kassab Institute of Orthopedics, Rheumatology,Tunis, Tunisia*; [2]*Kassab Institute of orthopedics, Radiology,Tunis,Tunisia*

Background: Enthesitis is the clinical hallmark of spondylarthritis. It refers to the inflammation of joint attach in the bone. Several sites enthesitis may be affected, and a wide variety of scoring systems were available.

Objectives: We aimed to determine the prevalence of axial enthesitis in the anterior chest wall (ACW), and its correlation with peripheral sites especially, the Achilles tendon (AT).

Methods: We conducted a prospective study including patients with SpA according to the ASAS criteria. Sociodemographic data, as well as disease characteristics, were recorded. The Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) was used to assess clinical entheses (first and seventh costochondral joints, posterior superior iliac spine, anterior superior iliac spine, iliac crest, and Achilles tendon insertion). The presence of enthesitis on the US was then assessed in the right and left sternoclavicular (SCJ), manubriosternal (MSJ) joints, as well as in the AT, using Esaote My Lab 50.

Results: The study included 47 patients with SpA: axial (n=26), axial and peripheral (n=21). There was a female predominance (sex ratio: 0.2). The mean age was 42.2 years ± 12.6 [11-70]. The age of onset of the disease was <40 years in 59.6% of cases. Tenderness in entheseal sites was found in 63.8% of patients, especially in the plantar fascia and AT (32.7%, 6%, respectively). The mean MASES score was 2.9 [0-13]. Clinical ACW involvement (29.1%) was at follows: 1st right chondro-sternal joint (CSJ) (19.1%), 1st left CSJ (25.5%), 7th right CSJ (27.7%) and 7th left CSJ (31.9%).US involvement of the ACW was 14.3%. Enthesitis of the AT was found in 70% of cases on US examination. ACW US involvement was correlated neither to the BMI nor to MASES score (p=0.16, p=0.6 respectively). Similarly, there was no correlation between the presence of US ACW enthesitis and clinical nor the US AT enthesitis (p=0.09, p=0.209, respectively).

Conclusion: Our study showed that ACW enthesitis is frequent in SpA, especially by US screening. This axial enthesitis, don't necessarily reflect a simultaneous clinical or US involvement of the peripheral entheses. Further studies are needed to characterize this subtype of SpA.

AB0502 HEALTH-RELATED QUALITY OF LIFE MEASURES IN SPONDYLOARTHROPATY PATIENTS UNDER BIOLOGICAL THERAPIES IN REAL LIFE

E. Grau García[1], M. De la Rubia Navarro[1], C. Pávez Perales[1], S. Leal Rodriguez[1], C. Riesco Barcena[1], A. V. Huaylla Quispe[1], E. Vicens Bernabeu[1], R. Negueroles Albuixech[1], J. Ivorra Cortés[1], F. M. Ortiz Sanjuan[1], I. Martínez Cordellat[1], I. Chalmeta Verdejo[1], J. J. Fragío Gil[1], L. Gonzalez Puig[1], J. E. Oller Rodríguez[1], C. Alcañiz Escandell[1], I. Cánovas Olmos[1], C. Nájera Herranz[1], A. J. Cañada Martinez[2], J. A. Román Ivorra[1]. [1]*HUP La Fe, Rheumatology Department, Valencia, Spain*; [2]*IIS La Fe, Biostatistics Unit, Valencia, Spain*

Background: Spondyloarthropathy patients have reduced health-related quality of life (HRQL) compared to general population. Biological treatment strategies in real life aim to reduce patients' symptoms and different HRQL parameters would share the same behavior as patients' symptoms and disease activity.

Objectives: We aim to assess the differences in HRQL reported by spondyloarthropathy patients during the first six months of biological therapy according to the treatment effectiveness.

Methods: We performed a prospective observational study of six months of follow-up in spondyloarthropathy patients who are newly on biological therapy. A basal visit and 1, 3 and 6 months follow-up visits were conducted. We analyzed changes during follow-up in the HRQL parameters reported by patients through AsqoL and ASAS-health-index questionnaires. Moreover we measured functional disability through HAQ and BASFI index, disease activity by BASDAI, ASDAS-CRP and ASDAS-ESR index.

Statistical analyses were achieved using R software, through multivariate linear regression models for continuous data and Bayesian mixed ordinal regression models with monotonic effect for ordinal data. The corresponding odd ratios (OR) were calculated with their confidence intervals (CI 95%).

Results: We included 53 patients (71.77% male), the 73.58% diagnosed with ankylosing spondylitis (AS) and the 26.42% with axial spondyloarthritis. Mean age at the beginning of treatment was 48.74 (11.21) years, mean age at diagnosis was 41.57 (11.97) and mean disease evolution was 7.19 (9.24) years. 60.42% of them exhibited HLAb27 positivity.

34 patients started biological therapy with TNF-α inhibitors and 19 with IL-17 inhibitors. The 81.13% of patients were under monotherapy, and the other 18.87% was treated with DMARDs. The 77.36% of the total number of patients was on the biological therapy at 6 months of follow-up, while the 22.64% discontinued at 6 months of follow-up (9 due to inefficacy and 3 due to adverse effects).

42 patients completed the follow-up at 6 months, and 3 patients achieved until visit 3 due to treatment failure. In 1 case visit 1 and in 7 cases visit 3 could not be performed due to COVID19 pandemic situation.

We observed a significant correlation among AsqoL and ASAS-hi values with disease activity indexes (BASDAI, ASDAS-CRP, ASDAS-ESR) and functional disability (HAQ, BASFI). The statistical analyses showed a significant association where AsqoL and ASAS-hi values are significantly decreased in treatment failures compared to the successful treatment (, and in patients with previous biological therapy compared to naïve patients. No effect of years of disease evolution and the type of biological treatment in the AsqoL and ASAS-hi values was observed. (See Table 1) These results were consistent with the significant association found among the disease activity and functional disability with the biological therapy efficacy and the previous biological treatment.

Table 1.

Comparison with effectiveness of biological therapy	Odds Ratio (OR)	95% CI	Comparison with previous biological therapy	Odds Ratio (OR)	95% CI
AsqoL	1.502	1.123–2.033	AsqoL	10.704	1.232–108.504
ASAS-HI	1.56	1.184–2.078	ASAS-HI	11.553	1.299–108.974
BASDAI	1.5	1.199–2.04	BASDAI	11.96	1.823–86.901
BASFI	1.348	1.036–1.76	BASFI	18.37	2.15–176.988
ASDAS-CRP	1.538	1.176–2.036	ASDAS-CRP	8.869	2.001–42.272
ASDAS-ESR	1.944	1.166–3.384	ASDAS-ESR	44.621	2.886–1077.816
HAQ	1.524	1.154–2.027	HAQ	24.111	1.779–371.742

Conclusion: The AsqoL and ASAS-hi questionnaire results are correlated with disease activity and functional disability and showed the same behaviour as these parameters, being also associated to the biological therapy efficacy as

well as to previous biological therapies. The HRQL variables would be additional clinical results that make it possible to achieve a better management of biological therapies in spondyloarthropathy patients.

AB0503 DISEASE CONTROL IN ANKYLOSING SPONDYLITIS PATIENTS WITH PERIPHERAL ARTHRITIS IN REAL CLINICAL PRACTICE IN SPAIN: MiDAS STUDY RESULTS

X. Juanola[1], C. Fernández-Carballido[2], A. Muñoz Jimenez.[3], J. Sanz[4], A. Urruticoechea-Arana[5], P. Moya[6], J. M. Belzunegui Otano[7], C. Sanabra[8], C. Sastré[8]on behalf of MIDAS group. [1]*Hospital Universitari Bellvitge, IDIBELL, rheumatology service, L'Hospitalet de Llobregat, Barcelona, Spain*; [2]*Hospital Universitario San Juan de Alicante, rheumatology service, Alicante, Spain*; [3]*Hospital Universitario Virgen Rocío, rheumatology service, Sevilla, Spain*; [4]*Hospital Universitario Puerta de Hierro, rheumatology service, Madrid, Spain*; [5]*Hospital Can Misses, rheumatology service, Ibiza, Spain*; [6]*Hospital de la Santa Creu i Sant Pau, rheumatology service, Barcelona, Spain*; [7]*Hospital Universitario de Donostia, rheumatology service, San Sebastián, Spain*; [8]*Novartis Farmacéutica, rheumatology, Barcelona, Spain*

Background: MIDAS study assessed disease activity in patients (pts) with ankylosing spondylitis (AS) treated in clinical practice in Spain.
Objectives: This subanalysis compared disease activity status between AS pts with and without peripheral arthritis (PA).
Methods: Observational, non-interventional, cross-sectional, multicenter study. Pts ≥18 years with ≥6 months diagnosis, fulfilling ASAS and modified New York criteria; undergoing treatment ≥3 months. Disease activity was measured by BASDAI and ASDAS-CRP. The number of painful and swollen joints was recorded in AS pts according to the OMERACT recommendations.[1]
Results: 313 AS pts included: 251 (80.2%) without PA and 62 (19.8%) with PA (Table 1). The most frequently involved painful joints in pts with PA were knees (29.0%) and hips (25.8%), while the swollen ones were proximal interphalangeal joints of the hands (17.7%), knees (9.7%) and wrists (8.1%). According to BASDAI (Figure 1A), pts with PA showed a higher score 4.2 (2.4) and a lower percentage 58.1% had disease activity controlled (BASDAI<4) than total AS pts (3.1 [2.2] and 64.5%, respectively) and pts without PA (2.8 [2.1] and 70.1%, respectively). According to ASDAS-CRP (Figure 1B), mean (SD) score was 1.9 (1.1) for AS pts, 2.4 (1.1) for pts with PA and 1.8 (1.1) for pts without PA, while 29.4% AS pts, 14.5% pts with PA and 33.1% pts without PA had inactive disease (ASDAS-PCR<1.3). By combining both indices (ASDAS-CRP and BASDAI), 51.8% AS pts showed adequate control (inactive disease/remission) of disease activity, 29.0% of pts with PA and 57.4% of pts without PA.

Table 1. Baseline demographic and clinical characteristics of the AS pts

	AS (n=313)	AS without PA (n=251)	AS with PA (n=62)
Age (years), mean (SD)	50.4 (12.0)	50.1 (11.9)	51.5 (12.5)
Sex (male), n (%)	237 (75.7%)	193 (76.9%)	44 (71.0%)
Time since diagnosis (years), mean (SD)	15.5 (11.6)	15.4 (11.4)	16.0 (12.6)
Time from onset of symptoms to diagnosis (years), mean (SD)	5.0 (7.2)	4.9 (7.1)	5.6 (7.6)
Presence of HLA-B*27+, n (%)	245 (78.5%)	197 (78.8%)	48 (77.4%)
Family history of AS, n (%)	66 (21.1%)	55 (21.9%)	11 (17.7%)
Family history of psoriasis, n (%)	43 (13.7%)	34 (13.5%)	9 (14.5%)
Pts previously treated with bDMARD, n (%)	99 (31.6%)	79 (31.5%)	20 (32.3%)
Swollen joint count (0-66), mean (SD)	0.1 (0.9)	0.0 (0.0)	0.7 (1.9)
Painful joint count (0-68), mean (SD)	0.6 (2.4)	0.0 (0.0)	3.0 (4.7)
CRP levels (mg/l), mean (SD)	5.1 (8.2)	4.7 (7.6)	6.7 (10.3)
Active disease, n (%)*			
BASDAI ≥4	111 (35.5%)	26 (41.9%)	75 (29.9%)
ASDAS-CRP ≥2.1	133 (42.4%)	93 (37.1%)	40 (64.5%)
BASFI, mean (SD)	3.4 (2.7)	3.1 (2.6)	4.5 (2.8)
MASES index, mean (SD)	0.2 (0.8)	0.2 (0.7)	0.4 (1.2)
SPARCC index, mean (SD)	0.4 (1.1)	0.3 (1.0)	0.6 (1.4)
Pts perceived disease control (PASS), n (%)	270 (86.3%)	221 (88.0%)	49 (79.0%)
ASAS-HI, mean (SD)	5.8 (4.4)	5.4 (4.2)	7.6 (4.6)

*Refers to the percentage of pts with active disease according to BASDAI≥4 and ASDAS-CRP ≥2.1.

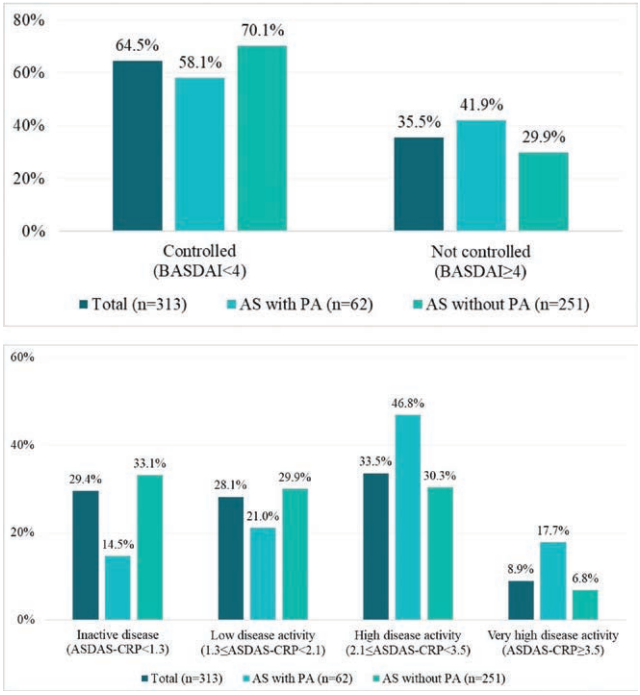

Figure 1. Disease status according to peripheral joints involvement**A)**Disease control according to BASDAI**B)**Disease activity according to ASDAS-CRP

Conclusion: Patients of the MiDAS study with peripheral disease showed higher disease activity and worse physical function, suggesting a severe and complex phenotype more than the one of the AS pts without PA.

AB0504 TOPOGRAPHY OF 18F-FDG PET/CT INFLAMMATORY SITES IN SPONDYLOARTHRITIS IN COMPARISON TO POLYMYALGIA RHEUMATICA AND TO PATIENTS WITHOUT INFLAMMATORY RHEUMATIC DISEASE

N. Giraud[1], M. Sondag[1], M. Chouk[1], F. Verhoeven[1], D. Wendling[1], C. Prati[1]. [1]*University Hospital Besancon, Rheumatology, BESANCON, France*

Background: Spondyloarthritis (SpA) is a common inflammatory rheumatism, characterized by axial and/or peripheral enthesitis. The positron emission tomography (PET/CT) allows the detection of inflammation.
Objectives: Our objective was to study the rhizomelic fixation with 18F-FDG (18-Fluorine deoxyglucose) PET/CT in SpA, compared to a Polymyalgia Rheumatica (PMR) group and to a control without rheumatological manifestations
Methods: Monocentric and retrospective study, including patients who have benefited from PET/CT. 2 groups of patients, with SpA on the one hand, and PMR on the other hand, fulfilling standard diagnostic criteria. A third group of controls (CN) benefiting from PET/CT in the context of assessment of a neoplasia. The rhizomelic fixations were evaluated according to the average of semi-quantitative scores. This in different rhizomelic sites, articular (gleno-humeral, coxo-femoral) and extra-articular (sub acromial (BSAD), trochanteric bursitis).
Results: 147 patients were included: 44 SpA, 50 PMR, and 53 CN. The rhizomelic fixations were significantly lower in SpA compared to PMR: on the pelvic girdle [0.31(0.7)

vs 1.15(1.04), p=1.2*10-10], the scapular girdle [0.15(0.44) vs. 1.35(1.2), p=7.09*10-15], the hip joints [0.27(0.62) vs 1.16(1.16), p=1.6*10-5], glenohumeral joints [0.18(0.49) vs. 1.71(1.04), p=4.75*10-12], the trochanteric bursae [0.36(0.77) vs 1.14(0.91), p=3.54*10-6], BSADs [0.11(0.38) vs. 0.98(1.24),p=4.63*10-5], or overall rhizomelic fixation. [0.23(0.59) vs. 1.26(1.14), p= 4.47*10-24]. The fixation was also significantly lower for SpA compared to CN, in trochanters [0.36(0.77) vs 0.58(0.68),p=3.54*10-6], at the glenohumeral joints [0.18(0.49) vs 0.58(0.66),p=3.27*10-5], pelvic girdle [0.31(0.7) vs. 0.49(0.67),p=0.0028] and scapular girdle [0.15(0.44) vs. 0.41(0.66), p=7.09*10-15] and on the global overall rhizomelic fixation [0.23(0.59) vs. 0.49(0.67), p=1.22*10-6].

Conclusion: Our study is the first to study the rhizomelic fixations with 18f-FDG in SpA, compared to another rheumatism inflammatory and controls. We found a lower fixation in SpA compared to PMR, confirming the major and specific rhizomelic fixation of PMR. We found a lower fixing of SpA compared to CN, without anatomical, articular or extra-articular systematization. SpA seems to be a condition with low uptake on 18f-FDG PET/CT, particularly at the rhizomelic level, compared to PMR and controls.

AB0505 DISEASE FEATURES ASSOCIATED WITH A HIGH DISEASE IMPACT IN AXIAL SPONDYLOARTHRITIS: POST HOC ANALYSIS OF A SINGLE-CENTER CROSS-SECTIONAL STUDY

R. Queiró Silva[1], S. Alonso Castro[1], L. C. Charca Benavente[1], M. Pino Martínez[1], S. Burger[1], M. Alperi-López[1]. [1]*Hospital Universitario Central de Asturias, Rheumatology, OVIEDO, Spain*

Background: Currently available information on disease factors associated with a high life impact on axial spondyloarthritis (axSpA) is still very limited. Therefore, information on disease factors associated with a high life impact is crucial for the optimal management of this condition.

Objectives: To define disease factors associated with a high disease impact (HDI) in axSpA.

Methods: *Post hoc* analysis of a cross-sectional observational study conducted in 111 consecutive patients diagnosed with axSpA[1]. We defined the Assessment of SpondyloArthritis international Society-Health Index (ASAS HI) functioning and health status groups thresholds using the Ankylosing Spondylitis Disease Activity Score (ASDAS) as external anchor. To establish the ASAS HI cut-off, receiver operating characteristic (ROC) curves of the different activity categories of the ASDAS were constructed. A multivariate analysis was carried out to evaluate the disease factors associated with HDI.

Results: Median ASDAS was 2.1 (IQR: 1.5-2.7). Average score for ASAS-HI was 5.4 ± 3.8 (IQR: 3-8). ASAS HI values > 6, area under the ROC curve 0.86 (95%CI: 0.78-0.92), identified the patients belonging to the groups of high-very high disease activity. Among the study population, 69 patients had an ASAS HI ≤ 6 while 42 showed an ASAS HI > 6 (Table 1). In the multivariate regression model, HLA-B27 [OR 0.15 (95%CI: 0.05-0.48), p=0.001], NSAID intake [OR 5.4 (95%CI: 1.2-23.3), p=0.023, and a family history of SpA [OR 3.1 (95%CI: 1.01-10.6), p=0.043] were independently related to HDI.

Table 1. Disease features among patients with and without high disease impact

Feature	ASAS HI ≤ 6 (n: 69)	ASAS HI > 6 (n: 42)	P-values
Age, yrs (SD)	42.7 (11.2)	44.3 (9.8)	NS
Disease duration, yrs (SD)	7.6 (7.5)	7.8 (5.2)	NS
Men, n (%)	49 (71)	25 (59.5)	NS
Women, n (%)	20 (29)	17 (40.5)	NS

ASAS HI: Assessment of SpondyloArthritis international **Society**-Health Index, yrs: years, SD: standard deviation, AS: ankylosing spondylitis, HLA: human leukocyte antigen, CVRF: cardiovascular risk factors, HBP: high blood pressure, SI: sacroiliitis, SpA: spondyloarthritis, IBD: inflammatory bowel disease, NSAID: non-steroidal anti-inflammatory drugs, DMARDs: disease modifying antirheumatic drugs.

Conclusion: In this study, patients with regular NSAID intake and those with a positive family history of SpA were more likely to be in a high-impact category according to the ASAS HI. On the other hand, HLA-B27 carriers reduced that possibility by 85%. Our data may contribute to providing more personalized attention focused on patients` needs.

AB0506 PREVALENCE AND CLINICAL CHARACTERISTICS OF SPONDYLOARTHRITIS IN CENTRAL AMERICA AND CARIBBEAN (PRECAES)

A. Garcia Kutzbach[1,2,3], P. Camilo Estrella[4], V. Khoury[4], H. Alonzo[5], C. S. Pastelín[5], G. Guerra Batista[6], A. Ogdie[7]on behalf of AGAR team. [1]*Guatemalan Association Against Rheumatic Diseases (AGAR), Rheumatology, Guatemala City, Guatemala*; [2]*UFM School of Medicine, Internal Medicine - Rheumatology Section, Guatemala City, Guatemala*; [3]*Private Practice, Rheumatology, Guatemala City, Guatemala*; [4]*Private Practice, Rheumatology, Santiago de los Caballeros, Dominican Republic*; [5]*Private Practice, Rheumatology,Tegucigalpa, Honduras*; [6]*Private Practice, Rheumatology, Panama, Panama*; [7]*Perelman School of Medicine, University of Pennsylvania, Rheumatology, Philadelphia, United States of America*

Background: Spondyloarthritis (SpA) is a group of interrelated disorders: axial spondyloarthritis (Ankylosing Spondylitis [AS] /Non Radiographic Axial Spondyloarthritis [Nr-AxSpA]), psoriatic arthritis (PsA), reactive arthritis (ReA), inflammatory bowel disease-associated arthritis (IBD), and undifferentiated SpA (USpA).[1]

Objectives: The objectives of this study were: a) to examine the epidemiology, disease subsets, and clinical characteristics of patients with SpA in Central America and the Caribbean region; and b) to describe the natural history of these conditions in their acute and chronic forms, to determine clinical sub-types and severity.

Methods: PRECAES is a cross-sectional observational study, including patients from private rheumatology clinics in three Central American countries (Guatemala, Honduras and Panama) and one in the Caribbean (Dominican Republic). Patients were enrolled between April 25th, 2018 and July 31st, 2019. Inclusion criteria: SpA diagnosis fulfilling ASAS classification criteria, age 18 - 45 years, sign informed consent and willing to perform protocol procedures during a single visit. Exclusions: any other rheumatic diseases, malignancy or HIV.

Results: Each center identified 50 consecutive patients with SpA. The main reason for exclusion from this analysis was not meeting the age requirement (N=94). Therefore, we analyzed 25 from Dominican Republic (DR), 25 from Guatemala, 32 from Honduras and 24 from Panama.

When applying ASAS axial and peripheral SpA definitions, all countries had high number of AS Patients. Subclinical classification by country showed the most frequent diagnosis was AS (64.1%), followed by PsA (16%), ReA (9.4%), Undifferentiated SpA (7.5%), IBD associated arthritis (1.9%) and Nr-AxSpA (0.9%) (p<0.001); characteristics of patient population and sub-clinical classification by country, Table 1. When clinical manifestations were classified as axial or peripheral SpA, 70.7% were axial in the four countries.

Table 1. Patient population characteristics and Sub-clinical classification by Country

	IBD associated arthritis	1	1	0	0	**02 (1.9%)**
	PsA	2	5	4	6	**17 (16%)**
	p < 0.001					

SD or ± = Standard DeviationUndifferentiated SpA (USpA), Reactive Arthritis (ReA), Nonradiographic Axial SpA (Nr-AxSpa), (AS), Inflammatory Bowel Disease-Associated Arthritis (IBD), Psoriatic Arthritis (PsA)

Time from onset symptoms to diagnosis ranged in years, from 3.15 (Guatemala) to 8.2 (Honduras), among the four countries. BASMI scores were higher in Honduras (mean 5.15) and lowest in Panama (mean 1.61). Of note, the time from symptom onset to diagnosis was also longest in Honduras.

NSAIDs and DMARDs were used in most countries. Glucocorticoids were rarely used in this population. Biologics are mainly used in Panama (16%), and Honduras (11%); only 8% of the enrolled patients in Dominican Republic and 2% in Guatemala.

Conclusion: The most prevalent SpA diagnosis in the region is Ankylosing Spondylitis. Patient diagnosis is delayed up to 8.2 years and only 2 to 16% of the patients receive a proper treatment with a biologic therapy.

This data invites to further investigation and brings opportunity to improve patients care.

AB0507 ASSESSMENT OF FIBRINOGEN TO ALBUMIN RATIO IN RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: CORRELATION WITH DISEASE ACTIVITY

M. Slouma[1,2], S. Bouzid[1,3], K. Lahmar[1,3], R. Dhahri[1,3], I. Gharsallah[1,3], L. Metoui[1,3], B. Louzir3. [1]*The Military Hospital of Tunis, Rheumatology, Tunis, Tunisia*; [2]*The Military Hospital of Tunis, Internal Medicine, Tunis, Tunisia*; [2]*The Military Hospital of Tunis, Internal Medicine, Tunis, Tunisia*

Background: Radiographic axial spondyloarthritis is a chronic inflammatory disease that involves the spine and the sacroiliac joints. No specific biomarker that reflects disease activity is yet available.

Objectives: This study aimed to assess the relationship between fibrinogen (Fib) to albumin (ALB) ratio (FAR) and disease activity in radiographic axial spondyloarthritis.

Methods: We performed a cross-sectional study including 51 patients with radiographic axial spondyloarthritis. Disease activity was assessed using Ankylosing Spondylitis Disease Activity Score (ASDAS). C-reactive protein (CRP), fibrinogen (Normal value: 2 -4g/L), erythrocyte sedimentation rate (ESR) and albumin levels (Normal value: 35 -50 g/L) were measured. The fibrinogen to albumin ratio (FAR) was calculated. We excluded patients with infectious disease, hematological disease, and those with malabsorption syndrome

Statistical analysis was performed using SPSS 26.

Results: The study included 43 males and 8 females with a mean age of 41.25 ± 10.97 years. The mean disease duration was 117.92 (85.4 months). The mean fibrinogen and albumin levels were 3.94 ± 1.24 g/L and 36.94 ± 5.89 g/L, respectively. Fibrinogen level was elevated in 45% patients and albumin levels was decreased in 51% cases. Mean FAR was 0.11 ± 0.44.

ESR levels were elevated in 67% with a mean of 40.22 ± 34.64 mm. CRP levels were high in 61% with a mean of 28.57 ± 33.25 mg/L. Mean ASDAS was 3.32 ± 1. 27 patients had very high disease activity (ASDAS>3.5).

Significant correlation was found between FAR and following parameters: ESR (r = 0.836, p< 0.001), CRP (r = 0.785, p < 0.001), and ASDAS (r = 0.463, P < 0.001).

The ability of FAR to distinguish patients with very high disease activity from those without very high disease activity was excellent, with Aire under the curve of 0.819. The optimal FAR cutoff value with the highest accuracy was 0,1065 with a sensitivity of 0,792 and specificity of 0,852.

Conclusion: Our study showed that fibrinogen to albumin ratio correlate with ESR, CRP and ASDAS. This finding suggests that this ratio may be a used to assess disease activity in radiographic axial spondyloarthritis (1).

AB0508 PHYSICAL ACTIVITY IN TUNISIAN ADULTS WITH ANKYLOSING SPONDYLITIS

A. Feki[1], I. Sellami[2], R. Akrout[1], S. Ben Jemaa[1], Z. Gassara[1], M. Ezzeddine[1], M. H. Kallel[1], H. Fourati[1], S. Baklouti[1]. [1]*Hedi Chaker Hospital, Rheumatology, Sfax, Tunisia*; [2]*Hedi Chaker Hospital, Occupational medicine, Sfax, Tunisia*

Background: Physical activity (PA) is associated with multiple health-related benefits among the general population and adults with chronic diseases like Ankylosing spondylitis (AS) [1]. As known, AS affects primarily enthesis and can lead to loss of function and decreased mobility.

Objectives: The aim of this study was to explore the PA levels of adults with AS and to examine associations between PA, sociodemographic characteristics, immunological features, disease activity and treatment type.

Methods: Cross-sectional clinical and laboratory data were collected on 68 AS patients. BASDAI (Bath ankylosing spondylarthritis disease activity index) and BASFI (Bath ankylosing spondylarthritis functional index) were calculated. Physical activity was measured using IPAQ-SF (International Physical Activity Questionnaire-Short Form). Its items record the time spent on physical activity of three intensity levels (vigorous, moderate and walking) as well as the time spent on sitting (referred to as sedentary in this study) in the past week. Both continuous (expressed as metabolic equivalent of task (MET)-min /week) and categorical (3 levels proposed: low, moderate and high level of PA) scores of IPAQ-SF were determined. Sedentary time (median) was reported in minutes/week. A p value < 0.05 was considered significant.

Results: Cross-sectional clinical and laboratory data were collected on 68 AS patients. BASDAI (Bath ankylosing spondylarthritis disease activity index) and BASFI (Bath ankylosing spondylarthritis functional index) were calculated. Physical activity was measured using IPAQ-SF (International Physical Activity Questionnaire-Short Form). Its items record the time spent on physical activity of three intensity levels (vigorous, moderate and walking) as well as the time spent on sitting (referred to as sedentary in this study) in the past week. Both continuous (expressed as metabolic equivalent of task (MET)-min /week) and categorical (3 levels proposed: low, moderate and high level of PA) scores of IPAQ-SF were determined. Sedentary time (median) was reported in minutes/week. A p value < 0.05 was considered significant.

Conclusion: Our study proved that physical activity in people with AS decreased with age and activity disease with a concomitant increase in sedentary activity. Given the risks of developing secondary chronic disease as a result of low levels of physical activity, physical exercise should be recommended as part of comprehensive AS care.

AB0509 FREQUENCY AND RISK FACTORS OF HIP INVOLVEMENT DURING SPONDYLOARTHRITIS IN MILITARY PATIENTS

L. Kharrat[1], M. Slouma[1], S. Rahmouni[1], R. Dhahri[1], I. Gharsallah[1], L. Metoui[1], B. Louzir[1]. [1]*The Military Hospital of Tunis, Rheumatology, Tunis, Tunisia*

Background: Hip involvement can reveal a spondyloarthritis (SA) or appear later. It hampers patient's life quality and can be responsible of significant handicap (1). Military patients are a special population. They are more exposed to physical stress which makes their SA characteristics quite different to other patients.

Objectives: We aimed to determine the frequency of hip involvement in SA and to study its characteristics and associated factors in military patients.

Methods: We conducted a cross-sectional study carried out in Rheumatology department of Military Hospital of Instruction of Tunis over a 10-year period (2010-2020) including SA patients meeting The Assessment of SpondyloArthritis international Society (ASAS). For each patient we collected the following informations: age, characteristics of hip involvement, ASDAS (Ankylosing Spondylitis Disease Activity Score), BASDAI (Bath Ankylosing Spondylitis Disease Activity Index), BASMI (Bath Ankylosing Spondylitis Metrology Index) and BASRI (Bath Ankylosing Spondylitis Radiology Index). We also measured Erythrocyte Sedimentation rate (ESR) and C-reactive protein (CRP).

Results: One hundred forty-one patients were included. They were 103 men and 38 women. The mean age was 43.01± 12.9 years. The mean age at the onset was 34.28±12.05 years. The mean delay of the disease was 9.16±8.98 years.

The mean BASDAI and l'ASDAS-CRP were 3.89±2.29 and 3.07±1.83, respectively.

Hip involvement was noted in 35.5% of the cases (n=50). It was bilateral in 41 of the cases. The number of affected hips was thus 91. The mean delay between the onset of SA and the discovery of hip involvement was 32.24±53.58 months [0-264 months].

A significant difference was noted in the axial mobility between patients who have hip involvement and those who don't (BASMI was 3,8±2.45 *versus* 1,45±1.8, p<0.0001).

Moreover, functional impact was higher in patients with hip involvement (BASFI was 5.7±2.24 versus 3.45±2.86, p<0.0001).

Patients with hip involvement had significantly higher BASRI compared to patients with no hip involvement (5.79±3.17 *versus* 3.14±2.42, p<0.0001).

However, no difference was found between patients who have hip involvement and those who don't with these following parameters: ESR, CRP, BASDAI and ASDAS-CRP.

Conclusion: Our study showed that hip involvement is quite common in military SA patients. It is responsible of an important functional impact and it seems to be associated to a major limitation of axial mobility. Nevertheless, hip involvement was not associated neither to inflammation parameters levels nor to the disease activity, this suggest that hip involvement may progress independently of the disease activity in military patients due to physical stress and micro traumas.

AB0510 THE ROLE OF BONE SCINTIGRAPHY FOR THE FOLLOW-UP EVALUATION OF INFLAMMATORY ACTIVITY IN PATIENTS WITH SERONEGATIVE SPONDYLOARTHRITIS

I. Borges[1], T. Barroso[2], F. Nunes[2], J. Caetano[2], B. Grima[2], J. Antonio Pereira Delgado Alves[2]. *[1]Hospital do Divino Espírito Santo de Ponta Delgada, E.P.E:R, Internal Medicine, Ponta Delgada, Portugal*; *[2]Hospital Professor Doutor Fernando da Fonseca E.P.E, Amadora, Internal Medicine, Lisboa, Portugal*

Background: The use of bone scintigraphy (Sc) in spondyloarthritis (SpA) as a technique for diagnosis, assessment of activity and treatment decision has been questioned by the scientific community. Due to its low cost compared to Magnetic Resonance Imaging - MRI (the gold standard)[1], some studies proposed to evaluate Sc's diagnostic accuracy. These studies have shown that Sc has a low diagnostic sensitivity of 50-55%[2]. Also, there is a poor correlation between symptoms and scintigraphic uptake[3]. We aimed to evaluate the use of Sc for management and follow-up of patients with SpA.

Objectives: To determine if Sc activity correlates with patients' complaints (peripheral and axial), inflammatory markers, disease activity scores and whether it influenced physicians' treatment decisions during the follow-up of the disease.

Methods: We performed a retrospective review of all patients at our department with SpA with at least one Sc from 2018 to 2020. The following variables were analyzed: demographic data, spondyloarthropathy subtype (ankylosing, enteropathic, psoriatic and undifferentiated SpA), axial or peripheral pain, Sc findings (inflammatory vs no-inflammatory activity), inflammatory markers (sedimentation rate - ESR and C-Reactive Protein - CRP), disease activity scores within one year since the Sc (Ankylosing Spondylitis Disease Activity Score with Erythrocyte Sedimentation Rate - ASDAS-ESR and Bath Ankylosing Spondylitis Disease Activity Index - BASDAI) and treatment at the time of the Sc (non-steroidal anti-inflammatory drugs, conventional synthetic disease-modifying antirheumatic drugs (DMARDs), target synthetic DMARDs and biologic DMARD. Treatment decisions (escalation, de-escalation or maintenance) in accordance to Sc results were also reviewed.

We used the non-parametric Mann-Whitney's U test for comparisons between ordinal or numerical variables. For correlations between categorical variables we used the Fisher's exact test and the $\chi 2$-independence test. Tests with $p < 0.05$ were statistically significant.

Results: Fifty-five patients were reviewed, 75% women; median age of 48 years. Seventy-one percent had ankylosing SpA, 15% enteropathic SpA, 5% psoriatic SpA, 5% undifferentiated and 4% reactive SpA. Sixty-two percent of the patients had both axial and peripheral pain and 24% only axial complaints. Sixty-two percent of the patients had a Sc with no inflammatory changes, 27% had peripheral and 25% had axial inflammatory changes; 15% had evidence of both peripheral and axial inflammation. For ankylosing SpA, the median ASDAS-ESR was 2.89 and according to the BASDAI, 66% had active disease. The median CRP and ESR in patients with inflammatory vs a normal Sc was not different (p=0.02 vs p=0.36, respectively). Similarly, Sc findings were not correlated with patients' axial (p=0.10) or peripheral pain (p=1.0), neither with the ASDAS-ESR (p=0.29) or the BASDAI (p=0.29). There was no correlation between inflammatory activity in Sc and the decision to maintain, escalate or de-escalate treatment (p=0.65), including the decision to start a biological DMARD (p=1.0) or to switch between biological DMARDs (p=0.19).

Conclusion: There was no correlation between Sc findings and ESR, patients' complaints, disease activity or treatment decisions. Considering previous research showing a low diagnostic sensitivity, our findings seem to support a limited role of bone Sc for the follow-up and management of patients with seronegative SpA.

AB0511

EFFECT OF SECUKINUMAB ON THE REDUCTION OF MYOCARDIAL DYSFUNCTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

S. Lapshina[1], L. Feiskhanova[1]. [1]*Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation*

Background: In ankylosing spondylitis (AS), early subclinical changes in the myocardium mostly remain undiagnosed. The impact of genetic engineering biological therapy on these changes is also unclear.
Objectives: Aim: to establish the relationship between taking of secukinumab and changes in systolic and diastolic myocardial function in patients with AS.
Methods: 69 patients with AS were examined, of which the first group included 33 people (average age 38.8±4.74, 63.6% of men) who received the interleukin 17 inhibitor (IL17) - secukinumab, the second group - 36 people who did not receive biological therapy, average age 42.5±11 years, 66.7% of men. The control group included 40 healthy individuals, comparable in gender and age. Patients underwent tissue dopplerography of the heart and transthoracic echocardiography. The research materials were subjected to statistical processing using the program STATISTICA 10.0.
Results: The patients with AS had significantly higher left ventricular mass index and ejection fraction (p<0.01) compared to the control group. Moreover, among patients who do not take biological therapy, the indicators were the highest (tabl.1).

Table 1. Comparison of transthoracic echocardiography parameters in the study groups according to the Craskell-Wallis test.

Показатель	group 1	group 2	control group	p
LVMI	85 [81; 100]	93 [81,3; 114,2]	79,5 [72; 86,5]	p=0,002
EF	63 [62; 64]	64,5 [63; 66]	60 [59,5; 64,5]	p=0,003

LVMI – ventricular myocardial mass index, *EF – ejection fraction.*

A comparison of tissue dopplerography of the heart between the groups established statistically higher values of peak velocity of the ring of the mitral valve in early diastole (e'L) in the 1st group (14 [9,5; 14]) and control (13 [11; 15,5]) compared with the indicator of the second group (10,5 [8,3; 13]), p<0,01; the peak speed of movement of the septum in early diastole, (e'S) in patients with secukinumab is higher (11 [9; 11]) compared to 2th (8.1 [7; 12]) and control groups 10 [8.5; 11]), p<0.05, and in the 2nd group lower than in the control (p=0.03). Significant differences in the parameters were supported by a comparison of the frequency of detection of diastolic dysfunction in the study groups. Diastolic dysfunction was diagnosed only in this group - in 38.9%. Against the background of the use of secukinumab, an increase in the systolic function of the myocardium was revealed.
Conclusion: The patients with AS are characterized by a high frequency of subclinical heart dysfunction. Inhibition of IL17 can reduce diastolic dysfunction, which is confirmed by an improvement in myocardial contractility during secukinumab therapy.

CLINICAL AND RADIOLOGICAL FEATURES OF SHOULDER INVOLVEMENT IN SPONDYLARTHRITIS

C. Ines[1], H. Ferjani[1], K. Maatallah[1], S. Miri[1], H. Hajji[1], M. Yasmine[1], D. Kaffel[1], W. Hamdi[1]on behalf of Rheumatology department of Med kassab institute of orthopaedics.. [1]*Manouba, Rheumatology, Mannouba, Tunisia*

Background: Peripheral joint involvement is frequent among patients with peripheral spondylarthritis (SA). However, the root joint involvement, such as hip involvement, has been described as being associated with axial spondylarthritis, while data for shoulder involvement are scarce. Cuff tendonitis and enthesitis are common features in the shoulder in patients with SA.
Objectives: This study aimed to identify the prevalence of shoulder involvement in SA patients and describe its clinical and radiological features.
Methods: We conducted a retrospective study including SA patients, all fulfilling the assessment of Spondyloarthritis International Society (ASAS) criteria.
For all patients, we collected the following data: Age, the clinical presentation of SA, the inflammatory biomarkers C-reactive protein (CRP), and the disease activity assessed by the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI).
Regarding shoulder involvement, we assessed the following items: tenderness, mobility, rotator cuff tests, as well as the results of X-ray and Ultrasound examination (US).
Results: We included one hundred and thirty-one SA patients (mean age 39,77 years). Among them, sixty-two percent were male. Ten percent of patients were smokers, 46,6% had the peripheral beginning of the disease. Fourteen patients complained of shoulder pain. The majority of them were male.
X-rays showed no abnormalities (n=2), while a destructive form was noted in (n=7).
Rotator cuff rupture or enthesopathy was also revealed by the reduction of subacromial space (n=5), condensation of the greater tuberosity (n=3), crooked aspect of the acromion (n=2), and Moloney's line disruption(n=1).
US showed no abnormalities (n=1), supraspinatus tendinopathy (n=5), supraspinatus transfixing tear (n=1), infraspinatus tendinopathy (n=2), supraspinatus enthesopathy (n=2), infraspinatus enthesopathy (n=1), moderate synovitis (n=1), subacromiodeltoid bursitis (n=1).
Shoulder involvement was correlated significantly with the peripheral beginning of SA (P < 0.05). There were no significant differences in gender, tobacco use, CRP value, and the disease activity between the two groups (P > 0.05).
Conclusion: The shoulder involvement was rare in our study. It is characterized by cuff tendonitis and enthesitis, especially in supraspinatus insertion. However, the glenohumeral synovitis was uncommon in our series, even in the peripheral form of the disease.

AB0513

THE RELATIONSHIP OF PERIARTICULAR TISSUES LESIONS AND JOINTS DEGENERATIVE CHANGES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES

G. Gainullina[1], E. Kirillova[1], D. Abdulganieva[1], E. Belousova[1], A. Odincova[2]. [1]*Kazan State Medical University, Therapy, Kazan, Russian Federation*; [2]*Republican Clinical Hospital, Gastroenterology, Kazan, Russian Federation*

Background: Inflammatory bowel diseases (IBD) are associated with a variety of extra-intestinal manifestations. The most frequent of these is joint involvement, which affects 16–33 % of IBD patients, whereas 5–10 % are affected by enthesitis [1, 2]. Recent studies have shown the superiority of ultrasound over clinical findings in the evaluation of joints and periarticular tissues [3].
Objectives: To assess of joint and entheseal involvement in patients with Crohn's disease (CD) and ulcerative colitis (UC) using ultrasound with Power Doppler.
Methods: We prospectively included 70 IBD patients into the study. Peripheral joints and entheses were imaged by ultrasound, using Samsung Accuvix A30 5-13 MHz linear array transducer. Ultrasound examination of 14 peripheral joints (hip, knee, ankle, shoulder, acromioclavicular, elbow, wrist) and 35 entheses was performed. Vascularization was assessed with Power Doppler (PD). Statistical analysis was done by Mann-Whitney test by "Statistica" software.
Results: In 70 patients UC was in 40 (57%), CD - in 30 (43%). The mean age of patients was 32 (27; 36) years. The mean duration of the disease was 48 (12; 84) months. The majority of patients had highly active disease: moderate and severe activity was observed in 47 (67%).
Osteophytes were found in 32 (46%) IBD pts, in 10 pts (14%) - osteophytes were found in three or more joints. We divided pts into two groups. In first group we included pts without degenerative changes in the joints, in the second - with identified osteophytes.
Osteophytes were found more often in the acromioclavicular joints - 13 pts (41%) and in the hip joints - 10 pts (31%). With the same frequency (9 pts), osteophytes were detected in the wrist, knee and ankle joints. The mean age of pts and mean duration of IBD were significantly higher in the second group patients (p = 0.00002 and p = 0.019).
Enthesitis (echogenicity reduction and thickening) without vascularization were detected in 26 patients of the first group (68%) and 29 patients of the second group (91%) (p = 0.009). The rate of vascularized enthesitis in the two groups was the same: enthesitis with vascularization were observed in 14 pts of the first group (37%) and 14 of the second group (44%) (p = 0.822). Structure damage (erosions and enthesophytis) was more frequent in the second group (p = 0.025 and p = 0.001). There were no significant differences in the incidence of tendinitis and tenosynovitis between two groups.
Conclusion: Joint and periarticular tissues damage in IBD patients increases with age and duration of the disease. The presence of degenerative changes in the joints is associated with more frequent detection of enthesitis and enthesopathies.

AB0514 PRELIMINARY DATA ON THE STUDY OF THE POSSIBILITY OF USING ULTRASOUND TO OBJECTIFY THE MOBILITY OF THE SPINE IN ANKYLOSING SPONDYLITIS

M. Kurbanmagomedov[1], K. Sakharova[1], A. Demina[1], S. Erdes[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Clinic, Moscow, Russian Federation*

Background: Spinal damage with limited mobility requires the search for diagnostic methods that allow us to accurately and quantitatively assess the developing decline in function and track this change in dynamics. One of these possible methods is ultrasound examination of the spine, which was recently described in the article Yurdakul O. V. [1].
Objectives: to study the possibility of using ultrasound for dynamic monitoring of sagittal mobility of the spine in ankylosing spondylitis (AS).
Methods: Ultrasound of the spine was performed in 15 patients with AS according to the method described in the article Yurdakul O. V. - determination of the sonographic distance between the spinous processes C5-C6, Th11-Th12 and L4-L5 of the vertebra (initial - vertical position, and when tilted - maximum sagittal flexion). All patients underwent a double examination: at inclusion in the study and after 2 weeks. The average age of the patients was 40.8±11.4 years, and the average duration of the disease was 5.5±3.5 years. 93.3% of patients were positive for HLA-B27. All patients were treated with nonsteroidal anti-inflammatory drugs, and 9 (60%) had biological therapy. The differences (Δ) between the indicators obtained on the first day and after 2 weeks - were calculated and further compared.
Results: During 2 weeks of follow-up, ESR practically did not change (it was 16 [6;48], after 2 weeks 14 [6;27], p=0.45), CRP decreased by 3.5 times (22.3 [2.5;40.5] and 5.9 [3.0;23.7], p=0.4), BASDAI (7.2-3.1,p=0.003), ASDAS-CRP (3.7-2.2,p=0.001) and BASFI (5.5-2.5, p=0.001), but not BASMI 10 (24-22, p=0.18). There were also no significant changes in mobility indicators according to sonographic measurements for 2 weeks. However, the correlation analysis of the dynamics of indicators for the study period showed the following results (see the Table 1):

Table 1. Correlation (r) between spinal ultrasound parameters and AS activity indices and metrological indices at the beginning of the study and after 2 weeks.

Δ of the indicators	$\Delta_i C_5$-C_6	$\Delta_s C_5$-C_6	$\Delta_i Th_{11}$-Th_{12}	$\Delta_s Th_{11}$-Th_{12}	$\Delta_i L_4$-L_5	$\Delta_s L_4$-L_5
ΔESR	-0.5*	-0.4*	-0.3	-0.2	-0.5*	-0.4*
ΔCRP	-0.3	-0.1	-0.4	-0.5	-0.4*	-0.7*
ΔASDAS	-0/4	-0.5	0.1	-0.3	0.1	0.2
ΔBASDAI	-0.2	-0.1	-0.2	-0.3	-0.3*	-0.5*
ΔBASFI	-0.6*	-0.5*	-0.5	0.2	0.3	-0.3
ΔBASMI 10	-0.2	-0.1	-0.2	-0.3	-0.3*	-0.5*

Note: *-p<0.05, Δi - C5-6, Th11-12, L4-5, mm – the difference between the indicators obtained by ultrasound in the vertical position at admission and after 2 weeks, Δs – the difference between the indicators at maximum sagittal flexion.

A correlation was found between an increase in the interspinous distance in the cervical and lumbar spine and a decrease in the level of ESR, and in the lumbar spine - with CRP. There is also a significant relationship between the activity of AS according to the BASDAI index and the mobility of the spine at the level of L4-5, which was manifested by an increase in the interspinous distance with a decrease in the activity of the disease. Sonographic measurements of all three levels of the spine show a negative correlation with the combined metrological index BASMI 10, most significantly with the L4-5 level of the spine.
Conclusion: The method of ultrasound examination of spinal mobility in AS allows not only to objectify the indicators, but can also be used to monitor the function of the axial skeleton during follow-up.

AB0515 MICRONUTRIENT DEFICIENCIES IN PATIENTS WITH SPONDYLOARTHRITIS: AGE AND GENDER IMPLICATIONS

P. Triggianese[1], F. Caso[2], A. D'antonio[1], P. Conigliaro[1], S. Ferrigno[1], L. Costa[2], M. Tasso[2], M. S. Chimenti[1], R. Perricone[1]. *[1]Rheumatology, Allergology and Clinical Immunology, Department of "Medicina dei Sistemi", University of Rome Tor Vergata, Roma, Italy*; *[2]Rheumatology Unit, Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy*

Background: Micronutrient deficiencies (MNDs) are common among patients with chronic inflammatory diseases. These are associated with a pro-inflammatory status and co-morbidities, and influenced by several factors, such as age and gender.
Objectives: No any study has investigated MNDs and their correlation with gender in Spondyloarthritis (SpA). With this purpose, this study analyzed the occurrence of anemia and the status of ferritin (Fe), vitamin D [25(OH)D], vitamin B12 (B12), and folic acid (FA) in a cohort of patients with SpA.
Methods: Levels of Hb, Fe, 25(OH)D, B12, FA, were evaluated in 220 SpA outpatients (137 females and 83 age-matched males) with Psoriatic arthritis (PsA, n=110) and SpA (n=110). Disease activity was assessed by DAPSA or ASDAS-CRP as appropriate and functional status was evaluated with HAQ score. Body Mass Index (BMI) was selected as a metabolic clinic parameter.
Results: Male and female patients were similar for disease duration and severity as well as the distribution of diagnosis and treatments (Table 1). In males, BMI was higher than in females (P=0.03) and positively correlated with the age (P=0.01). In female patients, BMI directly correlated with HAQ (P=0.03). The prevalence of anemia (Hb<12) was 13.6% of the study cohort; half of anemic patients had PsA, the others had enteropathic SpA (ESpA). Anemia resulted almost wholly in female patients (99%). In the male group, Hb resulted inversely related to age (P=0.01) and CRP levels (P=0.008). Ferritin was lower in females than in males (P=0.0003). 25(OH)D deficiency (≤20 ng/ml) was present in 23.2% of the cohort: males had lower 25(OH)D than females (P=0.02). Among male patients, disease duration correlated positively with ferritin (P<0.001) and inversely with 25(OH)D (P=0.02). Low levels of serum B12 (≤200 pmol/l) were rare (13.2%), while deficiency in FA (≤4 ng/ml) was frequent (22%) and associated with B12 defect in 31% of cases, with almost similar occurrence in males and females. A diagnosis of ESpA occurred in 55% of cases with B12 deficiency and 62.5% of FA defect, without gender difference. Mean levels of ferritin, 25(OH)D, B12, and FA did not differ significantly between PsA and SpA patients.

Table 1. Data from the study population.

Low D.A. (N/%)	**62/45.25**	**47/56.6**	***NS***
Moderate-high D.A. (N/%)	**75/54.75**	**36/43.4**	***NS***
COXIB-inhibitors (N/%)	**21/15.4**	**8/9.6**	***NS***
cDMARDs monotherapy (N/%)	**35/25.5**	**10/12**	***NS***
bDMARDs (N/%)	**81/59.12**	**65/78.4**	***NS***

BMI, body mass index; CRP, C-reactive protein; Hb, haemoglobin; Fe, ferritin; 25(OH)D, vitamin D; PsA, psoriatic arthritis; SpA, spondyloarthritis; IBD, inflammatory bowel disease; D.A., disease activity; cDMARDs, conventional Disease Modifying Antirheumatic Drugs; bDMARDs, biological DMARDs; § mean ± SD; * median [min-max].

Conclusion: Our study describes for the first time the possibility of a relevant prevalence of MNDs in SpA patients. Furthermore, we show that MNDs could be also influenced by gender difference and age. Of note, our findings highlight the importance of a screening focused on MNDs in SpA patients. This could be key in optimizing management of SpA patients, in which inflammatory-dependent dysmetabolism is frequent.

AB0516

THE INCONSISTENCY IN THE ASSESSMENT OF SACROILIAC JOINTS MRI PERFORMED BY A BLINDED AND UNBLINDED RHEUMATOLOGISTS AND A RADIOLOGISTS AFTER AND WITHOUT SPECIAL MRI TRAINING

E. Vasilenko[1,2], I. Gaydukova[1], V. Mazurov[1], R. Samigullina[1], A. Dadalova[1], I. Crylov[3], A. Krylova[3]. [1]*North-Western State Medical University named after I. I. Mechnikov, St. Petersburg, Russia, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E. Eichwald, St. Petersburg, Russian Federation*; [2]*Clinical Rheumatology Hospital №25, outpatient department, St. Petersburg, Russian Federation*; [3]*Clinical Rheumatology Hospital №25, radiology department, St. Petersburg, Russian Federation*

Background: Despite of the development the criteria for the diagnosis of axial spondyloarthritis (axSpA) the problem of late axSpA diagnostics is not resolved. The difficulties in the assessment of MRI sacroiliitis (SI) could be of the reasons of axSpA diagnostic delay.

Objectives: to evaluate the inconsistency in the assessment of sacroiliac joints MRI that was performed by a blinded and unblinded rheumatologists and a radiologists.

Methods: The assessment of 80 magnetic-resonance tomograms of sacroiliac joints (SIJ) was performed by 4 independent readers, one which was blinded to clinical data radiologist (BR), another radiologist was informed that the study was performed for axSpA (unblinded radiologist - UR), another 2 readers were blinded to diagnosis rheumatologists. One of the rheumatologists was trained in SIJ MRI (BTRh), another rheumatologist was not trained specially in MRI of SIJ (BURh). The study was carried out on the magnetic resonance tomography (GE Discovery MR750W 3.0T) in T1 and STIR regimens. 65 MRI were performed in pts that fulfilled the ASAS criteria for the axSpA and history of active SII (bone marrow edema) on previous SIJ MRI. According CT of SIJ 25 (38.5%) of these pts had nr-axSpA, 22 (33.8%) had SI grade II / III, in 18 (27.7%) of the pts SI grade IV was detected. 15 MRI scans were performed in healthy volunteers who did not meet the ASAS 2009 criteria at the time of the study and had no CT changes in SIJ.

The number of detected by each reader cases of active SII as defined by ASAS were analyzed with the calculation of the inter-reader reliability.

Results: There was found that there was inter-reader reliability between results of blinded and unblinded radiologists (73.8%) with statistical differences in the number of detected and undetected signs of SII ($p < 0.05$).

The inter-reader reliability scores between the unblinded rheumatologist and the radiologist were 97.5% and did not have statistically significant statistical differences ($p \geq 0.05$).

And for a trained rheumatologist and a blinded untrained rheumatologist it was 53.5% and had significant statistical differences ($p<0.05$).

The results of 4 readers SIJ MRI assessments are presented at Table 1.

Table 1. The results of MRI sacroiliitis assessments performed by blinded and unblinded radiologists and rheumatologists

	BR	UbR	BtRh	BURh
Revealed SII in axSpA (n = 65), n(%)	44 (67.7)*	64 (98.5)#	62(95.4)	26 (40)*
Undetected SII in axSpA (n = 65), n(15)	21(32.3)*	1(1,5)	3(4.6)	39(60)*
Revealed SII in controls (n = 15), n(%)	2 (13.3)*	3 (20) #	3(20)	1(6.7)*
Undetected SII in controls (n=15), n(%)	13(86.7)*	12(80) #	12(80)	14(93.3)*

*inter-reader reliability with the results of all another reader with $p<0.05$. # inter-reader reliability between unblinded radiologist (UR) and blinded treated rheumatologist (BtRh) with $p<0.05$. BURh – blinded untreated rheumatologist. BR – blinded radiologist.

Conclusion: The better agreement in inter-reader reliability in MRI of SIJ assessment was detected between unblinded radiologist and trained blinded rheumatologist. Blinded radiologist had shown lower inter-reader agreement with another specialists. The lowest of all inter-reader agreement had shown untrained blinded rheumatologist. Special MRI of SII assessment trainings for rheumatologists and radiologists are unmet need for the improvement of in-time axSpA diagnostics.

THE HIDDEN FACE OF SMOKING IN AXIAL SPONDYLOARTHRITIS

S. Bouden[1], L. Kharrat[1], A. Ben Tekaya[1], O. Saidane[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Hospital Charles Nicolle, Rheumatology, Tunis, Tunisia*

Background: The deleterious effect of smoking on spondyloarthritis has been studied for several decades. Indeed, smoking increases inflammation and disease activity, hence, promotes bone damage.

Objectives: The aim of our study was to evaluate the clinical, biological and radiological impact of smoking on axial spondyloarthritis (axSpA).

Methods: We conducted a retrospective study including patients meeting the Assessment of SpondyloArthritis international Society (ASAS) criteria between 2000 and 2020.

The following parameters were collected: age, smoking, ASDAS, BASDAI, and BASFI. We also measured inflammatory biomarkers (erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)).

Results: We included 138 patients. Sixty-eight per cent of them were males. The mean age was 45.73 ± 12.66 years. The mean age at the disease onset was 28.89 ± 12.54 years. The mean CRP was 33.38 ± 39.65 mg/dL. The mean BASDAI and ASDAS-CRP were 4.21 ±2.23 and 3.06 ± 1.26, respectively. The mean BASFI was 4.77 ± 2.58.

Fifty-one of our patients were smokers (37%). They were 48 men and 3 women. The mean pack-year was 45 ± 17.15.

Smokers had a significantly younger age of the disease onset (25.21 ± 11.37 *versus* 31.96 ± 12.67, p=0.009).

Moreover, patients who smoke Tabaco had developed significantly more ankylosis compared to patients who don't (p=0.026).

Osteoporosis was also more frequent in smoking patients (p=0.032).

However, no association was found between smoking and ESR, CRP, ASDAS-CRP, BASDAI and BASFI.

Conclusion: Our results reveal that smoking can be responsible of a younger axSpA onset, and can lead to more severe structural damages regardless the disease activity. This highlights the importance of smoking cessation in preventing early bone damage in axSpA.

Disclosure of Interests: None declared.

AB0518

ATHEROSCLEROTIC RISK IN PATIENTS WITH ANKYLOSING SPONDYLITIS: BIOMARKERS VERSUS SCORE

R. Dhahri[1], S. Miri[1], M. Slouma[1], B. Louzir[1], L. Metoui[1], I. Gharsallah[1]. [1]*The Military Hospital of Tunis, Rhumatology, Tunis, Tunisia*

Background: Chronic inflammatory rheumatic diseases are associated with a high cardiovascular risk. However, data in ankylosing spondylitis (AS) are still limited.

Objectives: The aim of our study was to assess the atherosclerotic risk in patients with AS, by comparing the Systematic coronary risk evaluation: SCORE, with biomarkers of atherosclerosis: High sensitivity C-reactive protein (Hs-CRP), LDL/HDL ratio and apoliprotein A1 (Apo A) /apolipoprotein B (Apo B) ratio.

Methods: We conducted a cross-sectional observational study of 40 patients with AS, over a period of 3 months. Socio-demographic data, clinical characteristics of the disease, as well as biological, radiological and therapeutic data were collected for each patient. Coagulated blood samples were collected following a 12-hour fast. Cardiovascular risk was considered high for Hs-CRP>3.0 mg/L [1], LDL/HDL> 3.5 in men and 3.0 in women [2], and ApoB/ApoA level>0.9 [3,4]. SCORE was calculated for all patients.

Results: The mean age of our population was 44±10 years. Male predominance was noted with a sex ratio =11.1. The mean ASDAS-CRP and BASDAI levels were 2.1±0.95 and 2.25±1.33. Thirty-two percent of the patients had a high risk of cardiovascular diseases according to Hs-CRP level, with an average of 10.7 mg/L. The mean LDL/HDL ratio was high in twenty-two percent of the patients. The mean value of ApoA1 and ApoB was respectively 1.3 g/l. and 0.9 g/l. Low values of Apo A1 were determined in 12.5% of the subjects, and high values of ApoB were found in 15% of subjects. The mean value of ApoA/ApoB ratio was 0.7. Ten percent of the studied subjects had an unfavourable ApoB/ApoA1. The predicted 10-year risk of CV mortality according to SCORE was high in 5% of the patients, very high in 2.5% and moderate in 35% of them. Over 17 patients with moderate, high and very high risk according to SCORE: Four patients (23.5%) had high LDL/HDL ratio, 8 (47%) had high waist/hip ratio, 5 (29.4%) had high Hs-CRP level, and 2 (11.7%) had high ApoB/ApoA ratio.

We found ApoB/ApoA to be positively correlated with Hs-CRP (r=0.31, p=0.05). The SCORE was correlated to the age at the onset of the disease (r=0.78, $p<10^{-3}$).

Conclusion: The atherosclerotic risk in our population ranged from 10 to 43%. SCORE presented with the highest percentage, making it more suitable for mass screening. Biomarkers on the other hand are more precise. Hs-CRP is biomarker to be included in daily practice, even when AS is in remission. Accuracy of the apoB/apoA ratio is significantly great and appears to be associated with inflammation.

AB0519 PHYSICAL ACTIVITY AND OBESITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS

R. Dhahri[1], S. Miri[1], M. Slouma[1], B. Louzir[1], L. Metoui[1], I. Gharsallah[1]. [1]*The Military Hospital of Tunis, Rhumatology, Tunis, Tunisia*

Background: Ankylosing Spondylitis (AS) is associated with an increased cardiovascular risk. Obesity and limited activity in patients with AS may contribute to this cardiovascular risk.
Objectives: We aimed to evaluate physical Activity and obesity in patients with AS.
Methods: We conducted a cross-sectional observational study of 40 patients with AS, over a period of 3 months. We evaluated the level of physical activity using the IPAQ (International Physical Activity Questionnaire). We also measured body mass index (BMI), body fat percentage, waist circumference, hip circumference and their ratio in all patients.
Results: The mean age of our population was 44±10 years. A male predominance was noted with a sex ratio =11.1. The mean ASDAS-CRP and BASDAI levels were 2.1±0.95 and 2.25±1.33. The mean of IPAQ was 3900 MET minutes per week, with a median of 3069 and extremes of 339 and 11000. 45.5% of patients had moderate physical activity and 20% had low activity.The mean BMI was 26.5 + 4.7 kg/m^2. Twenty percent of patients were obese. The mean body fat percentage was 25% with a median of 23.7% and extremes of 8-46%. Forty-five percent of the patients had a high fat mass. The mean waist circumference was 95±13 cm, hip circumference 104±9.5 cm. The mean waist to hip ratio was 0.9±0.07. Thirty-seven percent of patients had a high waist to hip ratio. BMI and body fat percentage were negatively correlated with HDL level; (r=-0.365,p=0.024)and(r=-0.393,p=0.015) respectively.
Conclusion: The majority of our patients have moderate or low levels of physical activity. The increase in BMI and fat mass appear to be associated with disturbance of the lipid balance, with low HDL values.
Disclosure of Interests: None declared.

AB0520 PUBIC SYMPHYSIS INVOLVEMENT IN NON-RADIOGRAPHIC SPONDYLARTHRITIS

H. Ferjani[1], M. Moalla[1], K. Maatallah[1], D. Ben Nessib[1], W. Triki[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab institute of Orthopedics, Rheumatology, Manouba, Tunisia*

Background: Structural change within pubic symphysis (PS) occurs in 20–25% of patients with spondylarthritis (SpA). It occurs in all developmental stages, even in the early stages of the disease. Changes in the symphysis can sometimes precede spine and sacroiliac involvement. Radiological findings in PS were poorly described in the SpA, especially on its non-radiographic form (nr-axSpA).
Objectives: We aimed in this study to evaluate pubic symphyseal features in patients with a confirmed diagnosis of nr-axSpA and to assess the correlation of these changes with clinical and imaging features of nr-axSpA in these patients. We also focused on the relationship between parity and radiographic changes in pubic symphysis (PS).
Methods: We retrospectively reviewed the data of 40 patients diagnosed with nr-axSpA according to the ASAS criteria. Radiological-morphological changes of PS were assessed in pelvic radiography by two distinct rheumatologists. Grading symphysial involvement was made as follow: scores ranged from 0-4 per reading: grade 0 = normal; grade 1 = subtle irregularity and/or subchondral sclerosis, grade 2 = clear erosions, 3 = marked sclerosis, grade 4 = ankylosis.
For all patients, we calculated the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the BASRI (Bath Ankylosing Spondylitis Radiology Index).
For all patients, we recorded the sacroiliac changes showed by the previous pelvic radiography and/or the pelvic scanner and/or by magnetic resonance imaging (MRI).
Results: We enrolled forty patients with a sex-ratio H/F=1/3. Mean age of patients at diagnosis was 39,9 +/- 10,8 [17-59]. Forty percent of patients had peripheral enthesitis, and 45% had peripheral arthritis. BASDAI mean score was 4,63 +/- 0,9 [0-8,6]. HLA B-27 was present in 32,3% of cases. We noted radiographic changes in PS in 37,5% (15 patients): grade 1 (n=1), grade 2 (n=10), grade 3 (n=3) and grade 4 (n=1). There was not a significant difference between the sex group (p=0,85). A comparison of 2 groups (women with 3 children or more and women with less than 3 children) concluded that childbirth did not modify PS changes (p=0,9). Also, PS changes did not differ with age (p=0,5). There was no correlation between the BASRI value with the presence of PS changes nor with its grades (p=0,5 and p=0,89, respectively). Also, disease activity did not influence the PS involvement (p=0,4). Radiological findings in PS was not correlated with the sacroiliac features found on MRI or pelvic CT scan (p=0,59 and p=0,1).
Conclusion: In SpA criteria, PS changes were not considered. It can be an additional help in making the diagnosis. Interestingly, pubic symphysis may exist without sacroiliitis.
Disclosure of Interests: None declared.

Psoriatic arthritis – treatment

AB0521 EARLY REAL-WORLD EXPERIENCE OF TOFACITINIB FOR PSORIATIC ARTHRITIS: DATA FROM A UNITED STATES HEALTHCARE CLAIMS DATABASE

P. J. Mease[1,2], P. Young[3], D. C. Gruben[4], L. Fallon[5], R. Germino[6], A. Kavanaugh[7]. [1]*Swedish Medical Center/Providence St Joseph Health, Rheumatology Clinical Research Division, Seattle, WA, United States of America*; [2]*University of Washington School of Medicine, Rheumatology Clinical Research Division, Seattle, WA, United States of America*; [3]*Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America*; [4]*Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America*; [5]*Pfizer Inc, Inflammation and Immunology, Kirkland, QC, Canada*; [6]*Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; [7]*University of California, San Diego School of Medicine, Division of Rheumatology, Allergy, and Immunology, San Diego, CA, United States of America*

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA). It was approved in the United States (US) in December 2017 for use in combination with non-biologic disease-modifying antirheumatic drugs (DMARDs).
Objectives: This analysis of real-world data assessed demographic and baseline clinical characteristics, as well as treatment persistence/adherence, in patients (pts) with PsA who had newly initiated tofacitinib treatment.
Methods: This retrospective cohort study included pts aged ≥18 years in the Truven MarketScan™ US Commercial and Medicare Supplemental Claims and Encounters database with ≥1 tofacitinib claim (first = index) between 14 December 2017–30 April 2019, and PsA diagnoses (≥1 inpatient or ≥2 outpatient [30–365 days apart]) on or within 12 months pre-index. Pts were continuously enrolled for 12 months pre-index and 6 months post-index, with no pre-index claims for tofacitinib. Pt demographic and clinical characteristics on the day of index, history of advanced therapy treatment (≥1 claim for biologic DMARDs or apremilast within 12 months pre-index) and tofacitinib treatment regimen (monotherapy or combination therapy [≥1 claim for conventional synthetic DMARDs or apremilast on or within 90 days post-index]) were recorded. Outcomes at 6 months post-index included tofacitinib persistence (<60-day gap without tofacitinib treatment) and adherence (proportion of days covered ≥80% and medication possession ratio [data not shown]). A sensitivity check was performed by analysing a sub-cohort that excluded pts with a diagnosis of rheumatoid arthritis (RA) on or within 12 months pre-index and within 6 months post-index.
Results: Of 17 321 pts receiving tofacitinib, 440 pts met the inclusion criteria for the overall cohort, with 315 pts included in the sub-cohort. In the overall cohort, pts were mostly female, with a mean age of 52.3 years and a mean PsA duration of 738 days (data not shown). Most pts were exposed to ≥1 advanced therapy within 12 months pre-index (mean = 1.1; range = 0–4); most commonly secukinumab (Table 1). Overall, 60.7% of pts received monotherapy and 39.3% of pts received tofacitinib combination therapy post-index; most commonly methotrexate (data not shown). At 6 months post-index, persistence was similar in pts receiving tofacitinib monotherapy vs combination therapy; adherence was slightly lower in pts receiving tofacitinib monotherapy vs combination therapy (Figure 1). Results were similar in the sub-cohort (Table 1, Figure 1).

Table 1. History of advanced therapy on or within 12 months pre-index in pts with PsA

	All pts (N=440)	Pts with no RA[a] (N=315)
Pts exposed to advanced therapy, n (%)[b]		
Any advanced therapy[c]	336 (76.4)	241 (76.5)
Secukinumab	113 (25.7)	91 (28.9)
Adalimumab	93 (21.1)	58 (18.4)
Apremilast	81 (18.4)	59 (18.7)
Etanercept	70 (15.9)	47 (14.9)
Unique advanced therapy prescriptions		
Mean (SD)	1.1 (0.8)	1.1 (0.8)
Median (IQR)	1 (1–2)	1 (1–2)
Range	0–4	0–4
Number of unique advanced therapies, n (%)		
0	104 (23.6)	74 (23.5)

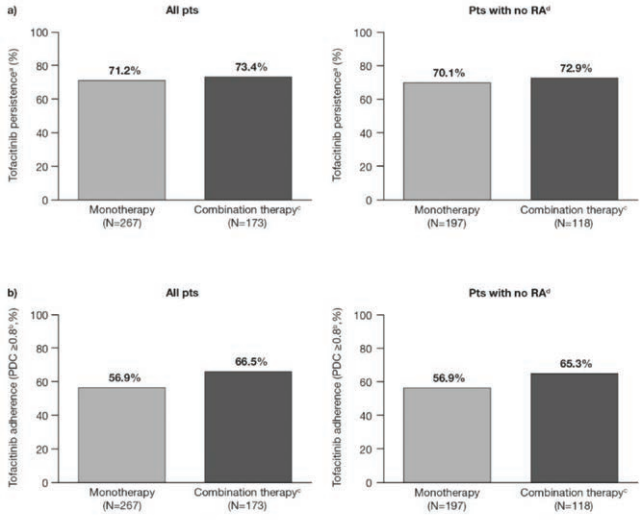
2	100 (22.7)	73 (23.2)
≥3	22 (5.0)	15 (4.8)

[a]Excludes pts with a diagnosis of RA on or within 12 months pre-index and within 6 months post-index; [b]Pts with ≥1 claim for biologic DMARDs or apremilast within 12 months pre-index; [c]Other advanced therapies reported in <10% of all pts were abatacept, certolizumab, golimumab, infliximab, ixekizumab and ustekinumabIQR, interquartile range; N, number of pts per cohort; n, number of pts per category; SD, standard deviation

Figure. Tofacitinib treatment a) persistence[a] and b) adherence (PDC ≥0.8)[b] in pts with PsA at 6 months post-index



[a]Pts with <60-day gap without tofacitinib treatment; [b]Pts achieving ≥80% of days covered; [c]Pts with ≥1 claim for a conventional synthetic DMARD or apremilast on or within 90 days post-index; [d]Excludes pts with a diagnosis of RA on or within 12 months pre-index and within 6 months post-index
N, number of pts in each cohort; PDC, proportion of days covered; SD, standard deviation

Figure 1

Conclusion: This analysis of US-based claims data indicated that pts newly initiated tofacitinib treatment an average of 2 years after PsA diagnosis, with the majority (>60%) of pts receiving tofacitinib as monotherapy. High levels of persistence and adherence to tofacitinib were observed 6 months after treatment initiation. Findings were similar when pts with PsA who also had a diagnosis of RA were excluded. Data were limited in that claims data cannot confirm that pts took the medication for which they filed a claim.

KG, Immunology, Wiesbaden, Germany*; *[11]Northwestern University, Feinberg School of Medicine, Chicago, United States of America*

Background: The efficacy and safety of upadacitinib (UPA), an oral Janus kinase inhibitor, in patients (pts) with active psoriatic arthritis (PsA) were demonstrated through 24 weeks in the phase 3 SELECT-PsA 1 and SELECT-PsA 2 placebo-controlled clinical trials.[1,2]

Objectives: To describe the long-term integrated safety profile of UPA relative to adalimumab (ADA) in pts with PsA treated in the SELECT program.

Methods: The SELECT-PsA program enrolled pts with prior inadequate response or intolerance to ≥1 non-biologic DMARD (SELECT-PsA 1) or ≥1 biologic DMARD (SELECT-PsA 2). Both trials include UPA 15 mg and 30 mg, and only SELECT-PsA 1 includes long-term comparison with ADA 40 mg every other week. Treatment-emergent adverse events (TEAEs: AE onset ≥first dose and ≤30 days after last dose for UPA and ≤70 days for ADA) were summarized for the following: pooled UPA 15; pooled UPA 30; and ADA. TEAEs are reported as exposure-adjusted event rates (EAERs; events/100 pts years [E/100 PY]) up to a cut-off date of 20 June 2020.

Results: 2257 pts received ≥1 dose of UPA 15 (N=907; 1247.2 PYs), UPA 30 (N=921; 1257.4 PYs), or ADA (N=429; 549.7 PYs), with median (max) exposures of 69 (155), 69 (154), and 68 (152) weeks, respectively. EAERs of TEAEs and serious AEs were generally similar between UPA 15 and ADA and higher with UPA 30; rates of AEs leading to study drug discontinuation were generally similar across all groups (Table 1). Similarly, rates of serious infection were comparable between UPA 15 and ADA and higher with UPA 30 (Figure 1 next page). The most common serious infection was pneumonia. Rates of herpes zoster were lower with UPA 15 than UPA 30 but higher than ADA. Most herpes zoster events involved a single dermatome; no events involved the central nervous system or other internal organs. Lower rates of opportunistic infections (OI) excluding tuberculosis were observed with UPA 15 vs UPA 30; the most common OI was mucosal candida infection. Malignancies were reported at similar rates across all treatment groups; no events of lymphoma were reported. Age-gender-adjusted standardized incidence ratios for malignancies excluding NMSC indicated no increased risk with UPA compared to the general population. Rates of adjudicated major adverse cardiovascular events and venous thromboembolic events were ≤0.3 E/100 PY for both UPA arms; all pts had ≥1 risk factor. One adjudicated gastrointestinal perforation was reported with UPA 15.

Table 1. Overall Treatment-emergent AEs for Upadacitinib and Adalimumab (E/100 PY [95% CI])

	UPA 15 mg QD N=907 (1247.2 PY)	UPA 30 mg QD N=921 (1257.4 PY)	ADA 40 mg EOW N=429 (549.7 PY)
AEs	263.9 (254.9, 272.9)	321.5 (311.6, 331.5)	286.5 (272.4, 300.7)
Serious AEs	10.3 (8.6, 12.1)	13.2 (11.2, 15.2)	9.6 (7.0, 12.2)
AE leading to discontinuation	6.7 (5.2, 8.1)	7.8 (6.2, 9.3)	7.8 (5.5, 10.2)
Deaths[a]	0.2 (-0.1, 0.4)	0.2 (-0.0, 0.5)	0.2 (-0.2, 0.5)

[a]Deaths included non-treatment emergent deaths: UPA 15, 1; UPA 30, 1.ADA, adalimumab; AE, adverse event; CI, confidence interval; E, event; EOW, every other week; PY, patient years; QD, once daily; UPA, upadacitinib.

Hepatic disorders were mostly transient, non-serious transaminase increases. Creatine phosphokinase elevations were reported more frequently with UPA 30 vs UPA 15; most were asymptomatic with no rhabdomyolysis reported. AEs of anemia, neutropenia, and lymphopenia were generally mild or moderate, non-serious. Except for rates of lymphopenia (higher with UPA 15), hepatic disorders, and neutropenia (both higher with ADA), lab-related TEAEs occurred at generally consistent rates between UPA 15 and ADA. Study drug discontinuation due to lab-related TEAEs was uncommon.

Conclusion: The safety profiles of UPA 15 and ADA were generally similar; the rates of most AEs were higher with UPA 30 compared with ADA. Through the cut-off date, the safety profile of UPA 15 and UPA 30 in PsA pts demonstrated consistent results compared to what has been observed with UPA in rheumatoid arthritis.[3]

KG, Immunology, Wiesbaden, Germany*; [11]*Goethe University & Fraunhofer IME-TMP and CIMD, Frankfurt, Germany*

Background: In the SELECT-PsA 1 study, through 24 weeks (wks), once daily upadacitinib 15 mg (UPA15) and 30 mg (UPA30) showed improvements in musculoskeletal symptoms, psoriasis, physical function, pain, fatigue, and quality of life, as well as inhibition of radiographic progression in patients (pts) with psoriatic arthritis (PsA) and inadequate response or intolerance to ≥1 non-biologic disease-modifying antirheumatic drug (DMARD).[1]

Objectives: To report the efficacy and safety of UPA vs adalimumab (ADA) up to 56 wks from the ongoing long-term extension of SELECT-PsA 1.

Methods: Pts received UPA15 or UPA30, ADA 40mg every other wk for 56 wks, or PBO through wk 24 switched thereafter to either UPA15 or UPA30 until wk 56. Efficacy endpoints as listed and defined in the Table 1 were analyzed at wk 56. Results for binary endpoints are based on non-responder imputation analysis; treatments were compared using the Cochran-Mantel-Haenszel test. Results for non-radiographic continuous endpoints are based on mixed model repeated measures model based on as observed data. Radiographic endpoints were analyzed based on linear extrapolation. Treatment-emergent adverse events (TEAEs) per 100 pt years (PY) were summarized for pts who received ≥1 dose of study drug.

Table 1. Efficacy Endpoints at Week 56

Endpoint	PBO → UPA15	PBO → UPA30	UPA15	UPA30	ADA
ACR20, %	73.0	74.1	74.4	74.7#	68.5
ACR50, %	54.5	60.4	59.7*	60.5#	51.3
ACR70, %	29.9	35.8	40.6*	43.7#	31.2
Minimal Disease Activity, %	29.4	35.8	44.8	47.3#	39.6
PASI75[a], %	58.3	60.2	65.4	63.3	61.1
PASI90[a], %	41.7	53.7	49.1	49.5	46.9
PASI100[a], %	22.3	38.9	34.6	39.5	31.3
Resolution of enthesitis by Leeds Enthesitis Index[b], %	38.1	45.5	59.3	58.1	54.0
Resolution of dactylitis by Leeds Dactylitis Index[c], %	47.7	59.0	75.0	74.8	74.0
Δ from BL in Bath Ankylosing Spondylitis Disease Activity Index[d]	-3.1	-3.1	-3.3	-3.2	-2.8
Δ from BL in modified total Sharp/van der Heijde Score (mTSS)	0.44[e]		-0.05†	0.02‡	-0.06

* and †, p≤0.05; for UPA15 vs ADA and PBO, respectively; # and ‡, p≤0.05; for UPA30 vs ADA and PBO, respectively.[a] for pts with psoriasis affecting ≥3% of body surface area at BL. [b] for pts with LEI >0 at BL. [c] for pts with LDI >0 at BL. [d] for pts with psoriatic spondylitis at BL. [e]pooled PBO.ACR20/50/70, ≥20%/50%/70% improvement in American College of Rheumatology criteria; ADA, adalimumab; BL, baseline; PASI75/90/100, ≥75%/90%/100% improvement in Psoriasis Area and Severity Index; PBO, placebo; pts, patients; UPA, upadacitinib.

Results: Of 1704 pts who received ≥1 dose of study drug, 1419 (83.2%) completed 56 wks of treatment on study drug. Across all treatment groups, the proportions of pts who had achieved ACR20/50/70, MDA, PASI75/90/100, resolution

of enthesitis, and resolution of dactylitis were maintained or further improved from wk 24[1] through wk 56; these proportions were generally greater for pts originally randomized to UPA vs ADA (Table 1). At wk 56, mean change from BL in mTSS was similar with UPA15, UPA30, and ADA. Improvements in pts who switched from PBO to UPA were generally similar to those originally randomized to UPA at wk 56. Through wk 56, the rates of TEAEs and serious AEs, including serious infections, were similar in the UPA15 and ADA arms and higher with UPA30 (Figure 1). The rate of herpes zoster was higher with UPA vs ADA in a dose-dependent manner. Malignancies were reported at similar rates among all treatment groups. Adjudicated venous thromboembolic events and major adverse cardiovascular events were reported in all groups with comparable rates. Two deaths were reported with UPA15, 2 with UPA30, and 1 with ADA; 1 death was reported with PBO during the 24-wk PBO-controlled period.

Conclusion: Efficacy responses were maintained or further improved with UPA15 and UPA30 over 56 wks and were numerically higher vs ADA. The inhibition of radiographic progression was maintained at wk 56 and was similar with UPA and ADA. At wk 56, improvements in efficacy were observed in pts who switched from PBO to UPA. No new safety findings were observed with longer exposure to UPA.

Background: The monoclonal antibody guselkumab (GUS; anti- IL-23p19-subunit) is approved to treat psoriatic arthritis (PsA). Post hoc analyses of DISCOVER-1&2 suggested that GUS may be effective in improving symptoms of axial manifestation of PsA.

Objectives: Evaluate the efficacy of GUS across components of the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) in improving symptoms of axial manifestations of active PsA patients (pts) using data from Phase 3, randomized, placebo (PBO)-controlled studies.

Methods: DISCOVER-1&2 enrolled pts with active PsA; pts were randomized to subcutaneous injections of guselkumab 100 mg every 4 weeks (Q4W) or at Wk0, 4, and Q8W, or PBO. These post hoc analyses included pts who were identified by the investigator as having axial symptoms and sacroiliitis (prior X-ray or MRI or screening X-ray). BASDAI scores were assessed at Wks 0, 8, 16, 24, and 52. Mean BASDAI component scores through Wk52 are reported by treatment group. Pooled data from the two studies are reported. Mean BASDAI component scores are reported using observed data; total BASDAI scores with missing components were set to missing. The proportion of pts achieving ≥50% improvement in BASDAI (BASDAI 50) was also determined; pts with missing data or who met the treatment failure criteria (discontinued study agent or used prohibited medications) were considered nonresponders at all subsequent timepoints.

Results: These analyses included 312 pts from DISCOVER-1&2 (103 GUS Q4W, 91 GUS Q8W, 118 PBO); mean total BASDAI scores at Wk0 were 6.4, 6.5, and 6.6, respectively. Demographics and mean baseline BASDAI component scores (ie, fatigue, spinal pain, joint pain, enthesitis, qualitative morning stiffness, and quantitative morning stiffness) were similar across treatment groups (Table 1). In comparison with the total study population, this subgroup of pts had a higher mean C-reactive protein level at baseline and a higher proportion of pts with enthesitis and included a slightly higher proportion of males. Mean scores for all six BASDAI components, including spinal pain, decreased through

Wk24 in GUS-treated pts, with separation from PBO observed as early as Wk8; improvements were maintained at Wk52. At Wk24, BASDAI 50 response rates were higher in the Q4W and Q8W groups vs PBO (38% and 40% vs 19%).[1] At WK52, mean BASDAI component scores for PBO pts who crossed over to GUS Q4W at Wk24 were similar to those for pts who were randomized to GUS.[2] A similar trend was observed for BASDAI50 response.

Conclusion: Among PsA pts with axial symptoms and sacroiliitis (via investigator-confirmed imaging) in the DISCOVER-1&2 trials, GUS treatment resulted in lower mean scores for all six BASDAI components compared with PBO as early as Wk 8 and through Wk24, with mean scores maintained at Wk52.

Background: Guselkumab (GUS), an anti-interleukin-23p19-subunit monoclonal antibody, demonstrated efficacy vs placebo (PBO) in achieving American College of Rheumatology 20% improvement (ACR20) response in patients (pts) with active psoriatic arthritis (PsA) in two phase 3 trials, DISCOVER-1 & 2.[1,2]

Objectives: To assess the differential treatment effects of GUS across individual components of ACR response in PsA pts participating in the DISCOVER-1 & 2 trials.

Methods: In DISCOVER-1 & 2, 1120 pts were randomized & treated with GUS 100 mg every 4 weeks (Q4W; N=373); GUS 100 mg at Week (W)0 and W4, then Q8W (N=375); or matching PBO (N=372). Pts were evaluated by independent joint assessors at study visits. ACR20 response is defined as ≥20% improvement from baseline in both tender joint count (0-68 [TJC68]) and swollen joint count (0-66 [SJC66]) and ≥20% improvement from baseline in ≥3 of 5 assessments: Patient Assessment of Pain [Pt Pain], Patient Assessment of Global Disease Activity (arthritis) [PtGA], Physician Assessment of Global Disease Activity [PGA], Patient assessment of physical function as measured by Disability Index of the Health Assessment Questionnaire (HAQ-DI), and C-reactive protein (CRP). For each ACR component, achievement of ≥20% improvement from baseline was assessed over time through W24 for the combined (Q4W+Q8W) GUS groups, and median time to onset of treatment effect was determined with Kaplan-Meier curves by randomized group.

Results: Median time to response for all components except SJC66 occurred earlier with GUS than PBO. Time to onset of ACR20 treatment effect is shown in Figure 1. CRP data show 56% of GUS-treated pts had diminution of systemic inflammation by W4 (Table 1). Reduction in systemic inflammation was accompanied or rapidly followed by GUS-related improvement in both PtGA and PGA (median W4-8). Although SJC66/TJC68 data showed similar patterns, there was also a high PBO response (data not shown). Consistent with early reductions in systemic inflammation, 48-61% of GUS-treated pts had ≥20% improvement in TJC68/SJC66/PGA at W4 (Table 1), and 45-48% had ≥20% improvement in HAQ-DI, PtGA, and Pt Pain by W8. By W24, >80% of GUS-treated pts had ≥20% improvement in SJC66/TJC68/PGA, followed by 63-64% with this degree of improvement in PtGA, CRP, and Pt Pain, and 57% for HAQ-DI.

Conclusion: GUS demonstrated ACR20 improvements with separation from PBO in ACR components as early as W4, which is consistent with reduced inflammation by GUS and prior serological studies.[3] At early study time points, both pts and physicians were able to discern improvements in signs and symptoms of arthritis that rapidly followed reductions in systemic inflammation (CRP). The predominant drivers of ACR20 response rates at W24 in GUS pts were SJC66/TJC68/PGA.

Background: In the Phase 3 DISCOVER-1[1] & DISCOVER-2[2] trials, guselkumab (GUS), a human monoclonal antibody targeting the IL-23p19-subunit, was effective in psoriatic arthritis (PsA) across joint & skin endpoints. At Week 24 (W24), GUS benefit was consistent regardless of baseline (BL) demographic & disease characteristics.[3]
Objectives: We assessed whether GUS efficacy was sustained through W52 in pooled DISCOVER-1 & -2 patients (pts) across select BL subgroups.
Methods: Adults with active PsA despite standard therapies were enrolled in DISCOVER-1 (swollen [SJC] ≥3 & tender joint count [TJC] ≥3, C-reactive protein [CRP] ≥0.3 mg/dL) & DISCOVER-2 (SJC ≥5 & TJC ≥5, CRP ≥0.6 mg/dL). 31% of DISCOVER-1 pts had received 1-2 prior tumor necrosis factor inhibitors; DISCOVER-2 pts were biologic naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO). Pts randomized to PBO received GUS 100 mg Q4W starting at W24 & were excluded from these analyses assessing maintenance of effect from W24 to W52. GUS effects on joint (American College of Rheumatology [ACR]20/50/70) & skin (Investigator's Global Assessment [IGA=0/1 + ≥2-grade reduction from W0] in pts with ≥3% body surface area [BSA] with psoriasis & IGA ≥2 at W0) endpoints were evaluated by pt BL SJC, TJC, conventional synthetic disease-modifying antirheumatic drug (csDMARD) use, body mass index (BMI), PsA duration, & % BSA with psoriasis. Missing data were imputed as nonresponse through W52.
Results: BL pt characteristics in DISCOVER-1 (N=381) & DISCOVER-2 (N=739) were well balanced across randomized groups.[1,2] Among 1120 pooled pts, mean SJC was 11, mean TJC was 21, & 68% used csDMARDs (primarily methotrexate [MTX]). At W24, 62% (232/373) & 60% (225/375), respectively, of GUS Q4W- & Q8W-treated pts achieved ACR20 vs 29% (109/372) of PBO, with GUS effect consistently observed across pt BL subgroups (Figure 1). ACR20 response rates were sustained or increased at W52 in the GUS Q4W (72%) & Q8W (70%) groups & across SJC (61-79%), TJC (68-76%), & csDMARD use (68-80%) subgroups (Table 1) & pt subgroups defined by BL BMI, PsA duration, & % BSA with psoriasis (data not shown). ACR50 & 70 response patterns were similar to ACR20 (Table 1). In pts with ≥3% BSA psoriasis & IGA ≥2 at BL, 71% (193/273) & 66% (171/258) of GUS Q4W- & Q8W-treated pts, respectively, vs 18% (47/261) of PBO, achieved IGA 0/1 at W24, with GUS effect consistently observed across pt BL subgroups (Figure 1). IGA 0/1 response rates were also sustained or increased at W52 in the GUS Q4W (80%) & Q8W (71%) groups & across % BSA with psoriasis (67-87%) & csDMARD use (68-87%) subgroups (Table 1) & pt subgroups defined by BL BMI and PsA duration (data not shown).
Conclusion: Treatment with GUS 100 mg Q4W & Q8W resulted in sustained improvement in signs & symptoms of active PsA through W52 regardless of pt BL characteristics.

Background: In patients (pts) with psoriatic arthritis (PsA), fatigue is a major driver of perceived impact of disease and has been identified as an important domain to be assessed in clinical trials.[1,2] The association between fatigue and other PsA domains (eg, physical function) or clinical response is not well understood.

Objectives: Fatigue was measured with the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue questionnaire in the pivotal DISCOVER-1 and DISCOVER-2 Phase 3 studies of guselkumab (GUS) vs placebo (PBO). This post hoc analysis explores the correlation between FACIT-Fatigue and physical function and clinical response in the DISCOVER program.

Methods: This analysis used pooled data from pts (N=1120) treated with GUS or PBO. In DISCOVER-1 and DISCOVER-2, 381 pts with active PsA (swollen joint count [SJC] ≥3, tender joint count [TJC] ≥3, C-reactive protein [CRP] ≥0.3 mg/dL) and 739 pts with active PsA (SJC ≥5, TJC ≥5, CRP ≥0.6 mg/dL) and inadequate response to standard therapies, respectively, were randomized 1:1:1 to GUS 100 mg Q4W; GUS 100 mg at W0, W4, then Q8W; or PBO. PBO pts switched to GUS 100 mg Q4W at W24. The FACIT-Fatigue questionnaire has 13 items that assess self-reported fatigue/tiredness over the last 7 days. Items are scored from 0 (very much fatigued) to 4 (not at all fatigued). FACIT-Fatigue response was defined as an increase of ≥4 points from baseline. Physical function was evaluated with the Health Assessment Questionnaire-Disability Index (HAQ-DI). HAQ-DI response was defined as a decrease of ≥0.35 points from baseline. Clinical response was defined as achievement of ≥20%

improvement in the American College of Rheumatology (ACR 20) criteria. Relationships between FACIT-Fatigue and HAQ-DI at W8/16/24 were assessed by Pearson correlation coefficients. Mean changes in HAQ-DI scores at W8/16/24 were summarized in FACIT-Fatigue responders and nonresponders. A logistic regression model was applied to estimate odds ratios (ORs) for achievement of HAQ-DI and ACR 20 response by FACIT-Fatigue response status at each visit. A multiple linear regression model was used to evaluate the association between FACIT-Fatigue and HAQ-DI at W24 after adjusting for SJC, TJC, CRP, and pt assessment of pain.

Results: FACIT-Fatigue and HAQ-DI scores and changes from baseline were negatively correlated at W8, W16, and W24 (Table 1). Mean changes in HAQ-DI were −0.31, −0.43, and −0.48 at W8, W16, and W24, respectively, in FACIT-Fatigue responders and −0.06, −0.07, and −0.09, respectively, in FACIT-Fatigue nonresponders. FACIT-Fatigue responders were significantly more likely than nonresponders to achieve HAQ-DI and ACR 20 response (OR [95% CI] at W8, 2.8 [2.2-3.7] and 2.4 [1.9-3.1]; at W16, 3.6 [2.8-4.7] and 2.9 [2.3-3.7]; and at W24, 4.4 [3.4-5.7] and 3.2 [2.5-4.2], respectively; Figure 1). Correlations between FACIT-Fatigue and HAQ-DI remained significant after adjusting for SJC, TJC, CRP, and pt assessment of pain.

Conclusion: In pts with PsA, fatigue response is a clinically meaningful predictor of improvements in physical function and achievement of ACR 20 response, reinforcing the importance of assessing fatigue in PsA disease management.

Background: DISCOVER 1&2 (PsA) and VOYAGE 1&2 (PsO) are Phase 3 trials of guselkumab (GUS).

Objectives: Compare safety results through up to 1yr of GUS in PsA and PsO pts.

Methods: In DISCOVER, 1120 pts with active PsA despite standard therapy were treated. Most pts were biologic-naïve; ~30% in DISCOVER 1 had previous exposure to 1-2 TNFi. Concomitant MTX (57%), oral corticosteroids (17%), and NSAIDs (64%) were permitted. Pts were randomized to SC GUS 100mg at W0, W4, then Q8W; GUS 100mg Q4W; or PBO. At W24, PBO patients were switched to GUS 100mg Q4W. In VOYAGE, in which concomitant MTX use was prohibited, 1245 pts with moderate to severe PsO were treated and randomized to SC GUS 100 mg at W0, W4, W12, then Q8W; or PBO at W0, W4, W12, with crossover to GUS at W16, W20, then Q8W. AEs and laboratory parameters, analyzed by National Cancer Institute-Common Terminology Criteria for AEs [NCI-CTCAE] toxicity grades, were summarized through the PBO-controlled periods and 1yr.

Results: Safety profiles were generally consistent across the GUS PsO and PsA clinical programs (Table 1). Time-adjusted incidence rates for numbers of AEs, serious AEs, serious infections, malignancy, MACE and AEs leading to d/c were generally similar between PsO and PsA. No cases of anaphylaxis or opportunistic infections were reported. Proportions of pts with decreased neutrophil counts and elevations in hepatic transaminases were slightly higher in PsA vs PsO. These abnormalities were mostly of NCI-CTCAE Grade 1 or 2 (<LLN-1000/mm^3 for neutrophils; <5.0 x ULN for AST/ ALT), generally transient, required no medical interventions, resolved spontaneously, and did not lead to interruption or d/c of treatment. Through 1yr, proportions of pts with ALT/AST elevations in PsA trials were slightly higher for GUS Q4W than Q8W and in pts with vs without baseline MTX use.

Conclusion: The GUS safety profile was generally consistent in PsA and PsO GUS-treated pts through 1yr of the DISCOVER and VOYAGE trials.

KG, Wiesbaden, Germany*; *[9]Sorbonne Université and Rheumatology Department, Hôpital Pitié Salpêtrière, Paris, France*

Background: For patients (pts) with PsA, several disease activity measures are available including very low/minimal disease activity (VLDA/MDA), cutoffs based on the Disease Activity in PsA (DAPSA) score, and on the Psoriatic Arthritis Disease Activity Score (PASDAS) score.
Objectives: To assess the rates of pts achieving these remission or low disease activity (LDA) criteria at Wk 24 using data from the SELECT-PsA 1 and SELECT-PsA 2 phase 3 studies;[1,2] Additionally, we assessed the distribution of individual MDA components among pts who did or did not achieve MDA criteria at Wk 24.
Methods: In SELECT-PsA 1 and SELECT-PsA 2, pts with PsA and prior inadequate response (IR) or intolerance to ≥1 non-biologic DMARD (N=1705) or ≥1 biologic DMARD (N=642), respectively, were randomized to once daily upadacitinib (UPA) 15mg, UPA 30mg, adalimumab (ADA) 40mg every other week (SELECT-PsA 1 only), or placebo (PBO). Remission and LDA were assessed using VLDA/MDA, DAPSA scores of ≤4/≤14, and PASDAS scores of ≤1.9/≤3.2, at Wk 24 (Table 1). Non-responder imputation (NRI) was used for handling missing data; pts rescued at Wk 16 were considered non-responders. Pairwise comparisons between UPA doses and PBO or ADA were conducted using the Cochran-Mantel-Haenszel test.
Results: Overall, 2345 pts were analyzed; mean age 51 years, 53% female. In both studies, higher rates of remission and LDA were observed with both UPA doses vs PBO at Wk 24 (nominal P-values <0.05 for both time points; Table 1). Generally, higher rates of remission and LDA were also observed with UPA30 vs ADA in non-biologic DMARD-IR pts (nominal P-values <0.05). Greater rates of MDA/VLDA were observed at Wk 24 with UPA15 and UPA30 vs PBO in both studies and with UPA30 vs ADA in non-biologic DMARD-IR pts (nominal P-values <0.05 for all comparisons). The proportion of responder or non-responder pts receiving UPA15 or UPA30 was similar for each of the MDA components in both studies. At Wk 24, more responder and non-responder pts in both studies achieved Swollen Joint Count (SJC) 66 ≤1, Psoriasis Area and Severity Index (PASI) ≤1 or Body Surface Area-Psoriasis (BSA-Ps) ≤3%, and Leeds Enthesitis Index (LEI) ≤1 (Figure 1). Conversely, the proportion of pts Achieving Tender Joint Count (TJC) 68 ≤1 and Pt's Global Assessment of Pain ≤1.5 tended to be lower.

Conclusion: Regardless of previous biologic DMARD failure, pts treated with UPA15 or UPA30 achieved a higher rate of remission or LDA measured by various disease activity measures vs PBO at Wk 24; higher rates of response were observed in most of the remission and LDA measures with UPA30 vs ADA in non-biologic DMARD-IR pts. Among pts who did or did not achieve MDA criteria at Wk 24, a greater proportion of UPA-treated pts achieved physician derived measures such as SJC ≤1, PASI ≤1 or BSA-Ps ≤3%, and LEI ≤1.

Background: Psoriatic arthritis (PsA) is characterised by musculoskeletal symptoms, and patients (pts) with PsA usually experience psoriasis concurrently. Real-world data reflecting impact of skin symptoms on PsA disease burden are limited.

Objectives: Analyse effectiveness of ustekinumab (UST) and tumour necrosis factor inhibitor (TNFi) therapy on extent of skin involvement, and the impact this has on PsA disease burden and drug persistence.

Methods: PsABio (NCT02627768) is a prospective, observational study of 1st/2nd/3rd-line UST or TNFi treatment in PsA in 8 European countries. Extent of skin involvement was categorised as body surface area (BSA): clear/almost clear; <3% but not clear/almost clear; 3–10%; or >10%. Pt-reported disease impact was evaluated by PsAID-12, including assessment of two skin-related domains (D): D3 (skin problems, including itching) and D10 (embarrassment and/or shame because of appearance). Estimated persistence at 1 year was assessed across baseline (BL) BSA categories.

Results: At BL, significantly more pts receiving UST than TNFi had BSA >10% (Figure 1). BL disease impact (PsAID-12) was worse in pts with BSA >10% than <3% in D3, D10 and total (non-overlapping 95% CIs suggest significance) (Table 1). BSA improved from BL to 1 year with both treatments. At 1 year, 64% of pts in both groups had clear/almost clear skin and only 3% had BSA >10% (Figure 1). At 1 year, both treatments significantly reduced disease impact (PsAID-12 total), and D3 and D10 scores, irrespective of BL BSA category, but most markedly in pts with higher BL BSA (Table 1). Worse BL psoriasis was generally associated with longer persistence for both treatments; however, at 1 year, pts

with BSA >10% had significantly shorter persistence with TNFi (mean [95% CI]: 361 [336; 387] days) than with UST (410 [394; 426] days).

Conclusion: In PsA, interleukin-12/23 inhibition (UST) and TNFi therapy in routine care rapidly and substantially reduced extent of skin involvement and related disease impact. Pts with highest BL skin involvement had significantly longer drug persistence with UST than with TNFi. Together, PsABio data suggest that successful treatment of skin involvement in PsA with biologics reduces disease burden and may improve persistence, especially in pts with worse BL psoriasis.

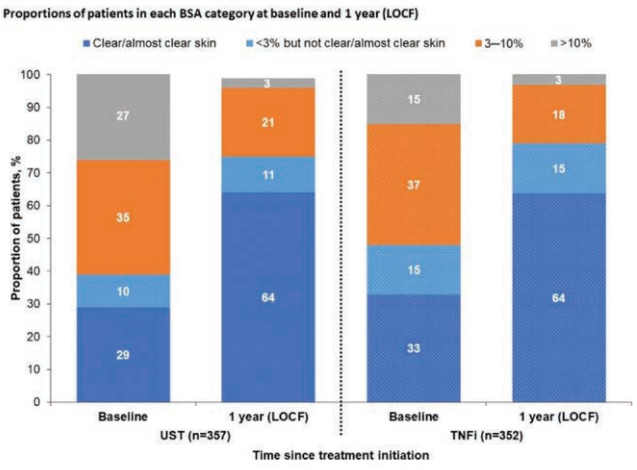

Figure 1

Table 1. PsAID-12 scores at BL and change from BL scores at 6 months and 1 year, by BL BSA category

Mean (95% CI)	Domain 3 (skin problems, including itching)		Domain 10 (embarrassment and/or shame because of appearance)		Total PsAID-12	
	UST	TNFi	UST	TNFi	UST	TNFi
PsAID-12 score at BL by BL BSA						
<3%	4.2 (3.7; 4.8)	3.1 (2.7; 3.6)	3.9 (3.3; 4.4)	3.1 (2.6; 3.6)	5.7 (5.3; 6.0)	5.0 (4.6; 5.3)

Background: Much new information has been reported since the last evidence-based GRAPPA recommendations for the treatment of psoriasis and psoriatic arthritis (PsA).

Objectives: We aimed to compile the evidence for the efficacy and safety of established and newly developed drugs targeting the peripheral arthritis domain in PsA so as to provide information for the revised GRAPPA treatment recommendations.

Methods: A working group consisting of clinicians and patient research partners (PRPs) was convened. We performed an updated systematic literature review (SLR) of randomized controlled trials (RCTs) for the treatment of PsA, including peripheral arthritis, from the date of the last GRAPPA SLR, from February 19, 2013 to August 28, 2020. The working group reviewed the evidence supporting the efficacy on peripheral arthritis for each class of drug, according to the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) approach, for three patients groups: 1) naïve to treatment; 2) refractory to conventional (-c) DMARDs; and 3) with prior biological (-b)DMARD experience. We also evaluated the evidence for non-pharmacological treatments. A set of important outcomes for the peripheral arthritis domain was assessed for each class of medication. The certainty of evidence supporting each class of drugs for each patient group was evaluated. Recommendations were derived through consensus meetings.

Results: 87 articles from 52 RCTs were included. For patients with mild disease who are naïve to treatment, the working group strongly recommends csDMARDs (methotrexate, sulfasalazine, leflunomide) and PDE4i, and weakly recommends them for severe disease, where TNFi are preferred over csDMARDs. Other bDMARDs (IL-17i, IL-12/23i, IL-23i) and JAKi are strongly recommended to treat peripheral arthritis for treatment naïve patients. For patients with inadequate response to csDMARDs, we strongly recommend TNFi, IL-17i, IL-12/23i, IL-23i and JAKi. For those who had prior experience with bDMARDs,

we strongly recommend a second TNFi, IL-17i, IL-23i and JAKi. Certainty of evidence (GRADE) and recommendations for peripheral arthritis domain of PsA for different population groups are shown in Table 1. While the evidence supporting non-pharmacological treatments was low, we derived the recommendations from clinician/PRP expert opinion, included advocating an increase in physical activity, smoking cessation and a healthy diet to control weight gain.

Conclusion: Evidence supporting drug treatment for the peripheral arthritis domain of PsA was compiled, providing required information for the revised GRAPPA treatment recommendations. Further work seeking agreement from a broader group of stakeholders is in progress.

Table 1. Certainty of evidence (GRADE) and Recommendation for peripheral arthritis of PsA

	Treatment naive		csDMARD inadequate response		bDMARD inadequate response	
Drug class	**evidence (GRADE)**	**Recommendation**	**evidence (GRADE)**	**Recommendation**	**evidence (GRADE)**	**Recommendation**
PDE-4i	Mod to high	**Strong for** (mild/ mod disease) **Conditional for** (severe disease)	Mod to High	**Strong for**	bDMARD exp: Mod bDMARD IR: Mod (NS)	**Conditional for** (bDMARD exp) **Conditional against** (bDMARD IR)
TNFi	High	**Strong for**	High	**Strong for**	Mod	**Strong for a 2nd TNFi**
TNFi Vs. MTX	High	**Strong for TNFi as 1st line for severe disease**	-	**-**	-	**-**
IL-17i	High	**Strong for**	High	**Strong for**	Mod to high	**Strong for**
IL-12/23i	Mod to high	**Strong for**	Mod to High	**Strong for**	Low	**Conditional for**
IL-23i	High	**Strong for**	High	**Strong for**	Mod	**Strong for**
JAKi	Mod*	**Strong for**	High	**Strong for**	Mod to High	**Strong for**
CTLA4i	Very Low	**Conditional for†**	Low	**Conditional for†**	Mod (NS)	**Conditional for†**

MAINTENANCE OF RESPONSE THROUGH 5 YEARS OF CONTINUOUS GUSELKUMAB TREATMENT: RESULTS FROM THE PHASE-3 VOYAGE 1 TRIAL

C. E. M. Griffiths[1,2], K. Papp[3,4], M. Song[5], M. Miller[5], Y. You[6], Y. K. Shen[6], A. Blauvelt[7]. *[1]NIHR Manchester Biomedical Research Centre, University of Manchester, Dermatology Centre, Manchester, United Kingdom*; *[2]Salford Royal NHS Foundation Trust, Dermatology Department, Salford, United Kingdom*; *[3]K. Papp Clinical Research, Department of Dermatology, Waterloo, Ontario, Canada*; *[4]Probity Research Inc., Clinical Research, Waterloo, Ontario, Canada*; *[5]Janssen Research & Development, LLC, Department of Immunology, Spring House, Pennsylvania, United States of America*; *[6]Janssen Research & Development, LLC, Clinical Biostats, Spring House, Pennsylvania, United States of America*; *[7]Oregon Medical Research Center, Department of Dermatology, Portland, Oregon, United States of America*

Background: VOYAGE 1, a phase-3, double-blinded, placebo- and active comparator-controlled study evaluated the efficacy and safety of guselkumab (GUS; a fully human anti-interleukin-23 monoclonal antibody) in patients with moderate-to-severe plaque psoriasis.[1,2,3]

Objectives: To assess the efficacy and safety through 5 years of continuous GUS treatment.

Methods: In VOYAGE 1, patients were randomized to GUS 100 mg at Weeks 0, 4, 12, then every 8 weeks (q8w); placebo at Weeks 0, 4, 12 followed by GUS 100 mg at Weeks 16, 20 then q8w; or adalimumab 80 mg at Week 0, 40 mg at Week 1, then 40 mg every 2 weeks (q2w) through Week 47. At Week 52, all patients continued open-label GUS through Week 252. Efficacy assessments included proportions of patients achieving ≥90% or 100% improvement in Psoriasis Area and Severity Index (PASI 90, PASI 100), and Investigator's Global Assessment scores of cleared/minimal or cleared (IGA 0/1, IGA 0). Three statistical methods were used to analyze efficacy: prespecified Treatment Failure Rules (TFR), Nonresponder Imputation (NRI), and As Observed (OBS). For TFR analyses, patients who discontinued study agent due to lack of efficacy, worsening of psoriasis, or use of a protocol-prohibited psoriasis treatment were considered nonresponders. For NRI analyses, patients with missing efficacy data (regardless of the reason) after application of TFR were counted as nonresponders. For OBS analyses, missing data were not imputed. Safety was assessed through Week 264.

Results: Among a total of 494 patients randomized to GUS at Week 0 (N=329) and placebo patients who crossed over to GUS at Week 16 (N=165), 76.9% (380/494) continued study agent through Week 252. PASI 90 responses were well-maintained with up to 5 years of continuous GUS use. At Week 52, PASI 90 response rates were 79.7%, 75.5%, and 80.6% based on TFR, NRI, and OBS analyses, respectively; corresponding rates at Week 252 were 84.1%, 66.6%, and 86.6%. Likewise, PASI 100, IGA 0/1, and IGA 0 responses were maintained from Week 52 through Week 252 (Table 1). Efficacy was also maintained through Week 252 in patients randomized to GUS at Week 0 (N=329). Through the end of the study for all patients (GUS group and adalimumab→GUS crossover group; N=774), the proportion of patients reporting at least one adverse event (AE), serious AE, or discontinuation due to AEs were 87.7%, 16.4%, and 6.1%, respectively. Rates of AEs of interest through Week 264 were as follows: serious infections (2.8%), malignancies (nonmelanoma skin cancer [1.7%]; cancer other than nonmelanoma skin cancer [2.3%]), major adverse cardiovascular events (1.0%), and suicidal ideation and behavior (0.6%).

Conclusion: High efficacy response rates were maintained (regardless of the method used to analyze data) and no new safety concerns were identified through 5 years of continuous GUS treatment in VOYAGE 1.

AB0533 COMBINATION OF METHOTREXATE AND LEFLUNOMIDE IS SAFE AND HAS GOOD DRUG RETENTION AMONG PATIENTS WITH PSORIATIC ARTHRITIS

M. Haroon[1], S. Batool[2], S. Asif[2], F. Hashmi[2], S. Ullah[2]. *[1]Fatima Memorial Hospital & FMH College of Medicine and Dentistry, Department of Rheumatology, Lahore, Pakistan*; *[2]Fatima Memorial Hospital & FMH College of Medicine and Dentistry, Department of Rheumatology, Lahore, Pakistan*

Background: Among patients with psoriatic arthritis (PsA), there remains a considerable confusion regarding the effectiveness of conventional synthetic DMARDs (csDMARDs), especially methotrexate (MTX). The availability of biologic DMARDs and targeted synthetic DMARDs have revolutionised the management of psoriatic disease; however, it comes with a significant cost burden. We believe that combination of DMARDs, especially combining MTX and Leflunomide (LEF) provides a valuable low-cost treatment option for patients with PsA after failure of MTX monotherapy. Hence, in our practice, we are inclined to use combination of potent DMARDs after MTX failure, prior to considering biologic therapies. Little is known about the combination use of LEF and MTX in PsA, especially in the context of drug retention time and tolerability.

Objectives: We aimed to review our PsA cohort data especially examining the drug retention of first-line csDMARD monotherapy and combination csDMARDs.

Methods: In our centre, MTX is a preferred first line csDMARD, unless contraindicated, and patients are followed up with a protocol on 4-6 weekly basis unless complete remission is achieved. MTX if needed is escalated to the maximum tolerated dose (up to 25mg/week), and if PsA is still active then preferably LEF is added (usual starting dose for add-on therapy is 10mg a day and if needed escalated to 20mg a day, without any loading dose). Other csDMARDs, such as sulphasalazine are used, if needed. For this study, after written-informed consent, only those adult patients were included who had a follow up of at least 6 months with our rheumatology services, and were fulfilling CASPAR criteria. Moreover, only patients who were DMARD-naïve (no prior DMARD therapy for any cause, including psoriasis), and initiated DMARD as monotherapy after 1 April 2018 were included. If any patient had already been on any DMARDs prior to attending our rheumatology services was excluded.

Results: A total of 81 PsA patients [mean age 45.6±6 years; 52% male; mean PsA disease duration=9±4 years; 35% with dactylitis, 42% with enthesitis, 17% with sacroiliitis, median current PASI=2.6, median number of swollen joints=8.0, median number of tender joints= 11.0] fulfilled the inclusion and exclusion criteria. As regards first-line csDMARD monotherapy, 88% (n=71) of patients were commenced on MTX. In total, 79% (n=56 out of 71) of patients who were started on MTX as their first-line csDMARD therapy failed this monotherapy during follow-up (51=ineffective, 5=intolerance). After a median follow-up of 22 months, MTX median drug retention among all MTX monotherapy users (n=71) was only 7 months (IQR 5-7); and among MTX failures (n=56), MTX monotherapy median drug retention was 6.0 months (IQR 4-8). Eighty percent (n=45 out of 56) of the MTX monotherapy failure cohort was started on combination therapy of MTX and LEF (combo MTX+LEF); among them, only 7 patients needed escalation of therapy to bDMARDs, and the rest are still using combo MTX+LEF. It was noted that to date median drug retention time of combo MTX+LEF has been 8 months (IQR 7-11), and 84% (n=38 out of 45) of these patients are still using this combo therapy. Significantly more patients managed to continue the combo MTX+LEF therapy compared to MTX monotherapy (84% vs. 21%, p<0.001)

Conclusion: Among csDMARD naïve PsA patients, 79% of patients failed MTX monotherapy with median drug retention time of only 6 months. Combination of MTX and LEF was well tolerated and had good drug retention time, with 84% of patients having ongoing treatment to date. Our data provides initial evidence that MTX and LEF combination therapy could be an effective treatment option for PsA

AB0534 THE IMPACT OF AXIAL INVOLVEMENT ON ACR RESPONSE IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS OF SUBANALYSIS OF THE PATERA STUDY

T. Korotaeva[1], I. Gaydukova[2], V. Mazurov[2], A. Samtsov[3], V. Khayrutdinov[3], A. Bakulev[4], A. Kundzer[5], N. Soroka[6], A. Eremeeva[7]. *[1]Nasonova Research Institute of Rheumatology, Laboratory of Spondyloarthritides and Psoriatic Arthritis, Moscow, Russian Federation*; *[2]Mechnikov North-Western State Medical University, Department of Therapy and Rheumatology of Temporary Disability and Medical Care Quality Expertise, St-Petersburg, Russian Federation*; *[3]Kirov Military Medical Academy, Department of Skin and Veneral Diseases, St-Petersburg, Russian Federation*; *[4]Razumovsky Saratov State Medical University, Department of Dermatovenereology and Cosmetology, Saratov, Russian Federation*; *[5]Belarusian Medical Academy of Postgraduate Education, Department of Cardiology and Rheumatology, Minsk, Belarus*; *[6]Belarusian State Medical University, Department of Internal Diseases №2, Minsk, Belarus*; *[7]JSC BIOCAD, Clinical Development Department, St-Petersburg, Russian Federation*

Background: Inflammatory back pain (IBP) is a common symptom of axial disease in patients with psoriatic arthritis (PsA). The reported prevalence of axial disease in patients with PsA is quite variable and must be taken into account while choosing treatment strategy. Netakimab (NTK) is an anti-interleukin-17A monoclonal antibody approved for psoriasis, ankylosing spondylitis, PsA in Russia and Belarus.

Objectives: A subanalysis was aimed to investigate the ACR (American College of Rheumatology) 20/50/70 response rate in PsA patients with/without the axial disease, defined by the presence of IBP according to self-reported ASAS IBP criteria, 2009 at baseline.

Methods: PATERA is an ongoing phase 3 international double-blind, placebo-controlled clinical study (NCT03598751). 194 adult patients with PsA (CASPAR criteria, 2006) with inadequate response to csDMARD or one TNFi, were randomly assigned to receive NTK 120mg or placebo at weeks 0,1,2,4,6,8,10,14,18,22. The ACR response was calculated in NTK-treated patients with IBP (IBP(+)) and NTK-treated patients without IBP (IBP(-)) according to self-reported ASAS IBP criteria, 2009. Patients with missing values for categorical variables were considered as non-responders in the analysis.

Results: 97 PsA patients (N=54 IBP(+), N=43 IBP(-)) received NTK. Both subpopulations were comparable in gender, age, and PsA activity at baseline. There were no significant differences in ACR20 achievement between the groups (Figure 1). The percentage of patients with ACR50 was significantly (p<0.05) higher in the IBP(-) subpopulation at weeks 4-20 (data not shown), but not at week 24 with 63% IBP(+) and 79% IBP(-) responders (p≥0.05). Similarly, IBP(+) patients had a lower frequency of ACR70 response (Figure 1).

Conclusion: NTK is effective in PsA treatment irrespectively of the presence of axial disease. Both IBP(-) and IBP(+) subpopulations achieved ACR20/50/70 as well, however, the benefit in IBP(-) patients was more pronounced.

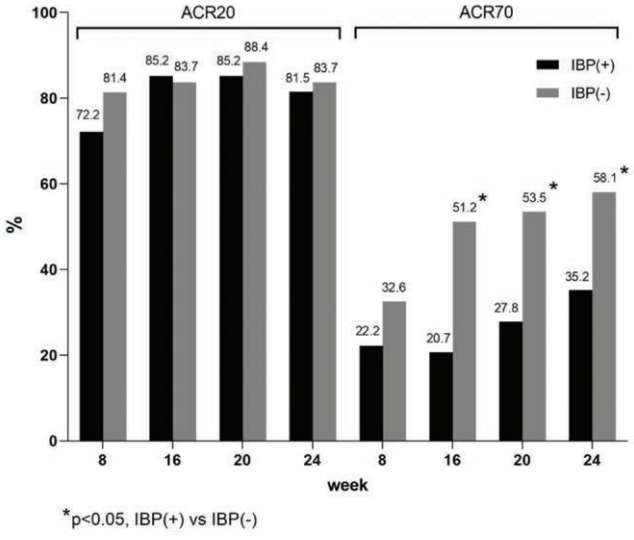

Figure 1 ACR response rates

AB0535 PRESCRIPTION PATTERNS OF THE SECOND BIOLOGIC DMARD IN PSORIATIC ARTHRITIS THROUGH THE LAST DECADE: HURBIO-PsA REAL LIFE EXPERIENCE

U. Kalyoncu[1], O. Karadag[1], L. Kılıç[1], A. Akdoğan[1], I. Dogan[1], Ş. A. Bilgen[1], E. Bilgin[1], E. C. Bolek[1], A. Erden[2], B. Armagan[2], A. Sarı[3], E. Duran[1], B. Farisoğulları[1], G. K. Yardımcı[1], Z. Özsoy[1], G. Ayan[1], A. İ. Ertenli[1], M. Çalgüneri[1], S. Kiraz[1]. *[1]Hacettepe University, Internal Medicine, Rheumatology, Ankara, Turkey*; *[2]Ankara City Hospital, Internal Medicine, Rheumatology, Ankara, Turkey*; *[3]Yenimahalle Research and Education Hospital, Internal Medicine, Rheumatology, Ankara, Turkey*

Background: Psoriatic arthritis (PsA) is a multi-dimensional chronic disease, which can affect joints, skin and enthesis. Extrapolation of the positive treatment results of anti-tumor necrosis factor (TNF) alpha agents on spondyloarthritis and rheumatoid arthritis to the treatment practice of PsA lead to a new era for the management of PsA. However, unmet needs in the management of PsA lead to development of several drugs targeting different molecules and cytokines. The impact of these developments on PsA patients who are intolerant/unresponsive to the first biological disease-modifying anti-rheumatic drugs (bDMARD) still needs to be defined.
Objectives: To explore the second biologic agent trends on PsA patients of our 10-years of single-center experience.
Methods: HURBIO-PsA (Hacettepe University Rheumatology Biologic Registry) is a single center biological disease modifying anti-rheumatic drug (DMARD) registry since 2005 on PsA patients. Until the end of the 2020, 19 different rheumatologists contributed to the development of HURBIO-PsA. Anti-TNF drugs were approved as first line bDMARD for PsA patients. Distribution of the second-line biological agents (switch from first-line biological agent because of either adverse events or unresponsiveness) was calculated according to 5-year periods starting from the 2011. Also, demographic and serologic data of RA patients were reported.
Results: A total of 225 PsA (225/443, 50.8%) patients, who was prescribed a second biological agent, was registered in HURBIO-PsA by the end of 2020. Of these patients, 74.7% was female. Mean age at the starting of bDMARD was 47.1 ± 11.6 years. 90 (40.0%) and 135 (60.0%) patients were prescribed with their second bDMARD in 2011-2015 and 2016-2020, respectively. There was a trend towards the increasing prescription of non-Anti-TNF bDMARDs as second-line over time, especially for secukinumab.

Table 1. Distribution of second biologic DMARDs in PsA patients according to 5-years periods

	2011-2015	2016-2020	Total
Adalimumab	30 (33.3)	33 (24.4)	66 (29.3)
Etanercept	33 (36.7)	8 (5.9)	41 (18.2)
Infliximab	9 (10)	15 (11.1)	24 (10.6)
Golimumab	9 (10)	5 (3.7)	14 (6.2)
Certolizumab	5 (5.6)	34 (25.2)	39 (17.3)
Anti-TNF	86 (95.6)	95 (70.4)	181 (80.5)
Secukinumab	0	26 (19.3)	26 (11.5)
Ustekinumab	0	10 (7.4)	10 (4.4)
Abatacept	4 (4.4)	2 (1.5)	6 (2.6)
Tofacitinib	0	2 (1.5)	2 (0.9)
Non-Anti-TNF	4 (4.4)	40 (29.6)	44 (19.5)
Total	90 (100)	135 (100)	225 (100)

***Approval years of drugs in Turkey**; Infliximab: 2003, etanercept:2004, adalimumab: 2005, golimumab: 2013, certolizumab: 2014, secukinumab: 2018, ustekinumab: 2018; abatacept and tofacitinib were given with the permission from the Ministry of Health of Turkey for off-label use authorization*

Conclusion: Almost half of the PsA patients switched their anti-TNF drugs to others. Non-Anti-TNF bDMARDs, especially secukinumab, becoming more frequently used as a second-line biologic agent in PsA in recent years. These bDMARD prescription trend is appropriate to EULAR PsA recommendations.

AB0536 EFFICACY OF TNF INHIBITORS IN MONOTHERAPY VERSUS COMBINATION THERAPY WITH csDMARDs IN PORTUGUESE PATIENTS WITH PSORIATIC ARTHRITIS: A REAL-WORLD STUDY

F. Oliveira Pinheiro[1], B. M. Fernandes[1], S. Garcia[1], M. Rato[1], D. Fonseca[2], D. Santos Oliveira[1,3], A. Martins[1], F. R. Martins[4], P. Madureira[1], M. Bernardes[1,5], L. Costa[1]. *[1]Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal*; *[2]Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology Department, Vila Nova de Gaia, Portugal*; *[3]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; *[4]Centro Hospitalar Universitário do Algarve, Rheumatology Department, Faro, Portugal*; *[5]Faculty of Medicine, University of Porto, Medicine Department, Porto, Portugal*

Background: Tumor necrosis factor inhibitors (TNFi) are a key therapeutic weapon in psoriatic arthritis (PsA), and can be used as monotherapy or in combination with other csDMARDs, which are usually used as first line therapy in these patients, although its efficacy is not as well documented as in other rheumatic diseases. The optimal use of iTNF in PsA, as monotherapy or in combination therapy with csDMARDs, is still under debate.
Objectives: We aimed to compare the response to treatment with TNFi in monotherapy and combined with csDMARDs, as first biologic, in patients with PsA.
Methods: Retrospective study that included PsA patients followed at our Rheumatology department under TNFi as first biologic, fulfilling CASPAR classification criteria and registered in Reuma.pt. Clinical and laboratory data were collected at the start of the first iTNF and in the last visit of 2019. Disease activity was assessed using CDAI, SDAI, DAS28(4V), BASDAI, ASDAS, and the response measured using the BASDAI50, ASDAS, ASAS, ACR and PsARC responses. Comparison between groups was performed using the chi-square test, Mann-Whitney U/t-test (categorical and continuous variables, respectively). Logistic regression analyses were performed to determine predictors of bDMARD failure, and survival analysis to measure persistence under the first bDMARD regarding csDMARD status at baseline.
Results: We included 99 patients, 47 (47.5% females) with a mean age of 47.9 ± 11.7 years at the start of the first iTNF. Fifty-one patients (51.5%) had symmetric polyarthritis, 26 (26.3%) spondyloarthritis, 16 (16.2%) asymmetric oligoarthritis, 3 (3.0%) distal arthritis and 1 (1.0%) arthritis mutilans. Sixty-three percent were under corticosteroid therapy and 77.8% under csDMARD therapy at the start of the first iTNF (mostly methotrexate, in 55.6% of patients under csDMARD). Etanercept (41, 41.4%), golimumab (25, 25.3%), adalimumab (22, 22.2%), infliximab (9, 9.1%) and certolizumab (2, 2.0%) were the iTNF started in these patients.
Patients who started iTNF as monotherapy had more frequent involvement of axial skeleton compared with combined therapy (54.5% vs 19.5%, p=0.001), were less exposed to corticosteroids (26.3% vs 72.6%, p<0.001) and had higher mean BASMI (3.7±1.8 vs 3.0±0.8, p=0.021) and BASFI (6.7±1.3 vs 4.7±2.5, p=0.036). Patients who were on iTNF monotherapy at the last consultation (43.4%) had lower mean tender (1.0±1.5 vs 3.6±4.3, p=0.002) and swollen (0.2±0.7 vs 0.8±1.0, p=0.012) joint counts, median patient VAS (30±46 vs 50±44, p=0.023), mean CDAI (5.6±4.4 vs 8.7±4.9, p=0.019), SDAI (6.2±4.6 vs 9.1±5.1, p=0.032), and DAS28(4V) (2.2±0.8 vs 2.7±0.9, p=0.047). iTNF failure was not significantly different in both groups. In the regression models, we found that basal DAS28(4V) (OR 1.874, 1.147-3.062 95%CI; p=0,012) was a predictor of first iTNF failure; there were no differences regarding csDMARD status.
When evaluating only patients without spondyloarthritis, we found that, at the last visit, iTNF monotherapy patients still had less exposure to corticosteroids (26.9% vs 54.3%, p=0.002), fewer mean tender (0.7±1.0 vs 2.6±4.4, p=0.006) and swollen (0.2±0.7 vs 1.1±2.5, p=0.025) joint counts, with no other differences observed. In the regression models, we found no differences regarding csDMARD status in these patients, while adalimumab (OR 0.009, 0.001-0.139 95% CI; p=0.009) was a negative predictor of bDMARD failure. Survival analysis revealed no differences between mono- and combined therapy.
Conclusion: We can conclude that the differences observed regarding csDMARD status in patients with PsA are mainly due to different patterns of arthritis, namely, predominance of axial involvement. In patients without spondyloarthritis, iTNF monotherapy did not differ significantly in terms of response to treatment and disease activity measures, nor does monotherapy predict bDMARD failure and treatment response. These results suggest that iTNF monotherapy is possible in PsA without compromising treatment response.

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease associated with substantial psychosocial burden and health-related quality of life (HRQoL) and functional ability impairments.
Objectives: To characterize the profile of patients with PsA initiating therapy with apremilast in routine care settings, in terms of the physician-assessed clinical disease burden and the patient-reported generic and disease-related HRQoL and functional disability.
Methods: This is an ongoing 52-week multicenter, prospective study conducted in the Greek healthcare environment. Eligible patients are bio-naïve adults with active peripheral PsA, inadequate (within the first 12 months of treatment) response/intolerance to a prior conventional synthetic disease-modifying antirheumatic drug (csDMARD), and no prior use of tofacitinib, initiating apremilast as per the approved label. Data are being collected by physician assessments, as performed in routine clinical practice, and by patient-reported outcomes. 170 patients enrolled in the study; data at apremilast initiation (baseline) from the first 100 eligible consenting patients are presented in this interim analysis as per protocol.
Results: 99 evaluable patients were consecutively enrolled in 19 rheumatology departments between 15-Apr-2019 and 13-Jan-2020. At baseline (Table 1) [mean (SD) age: 53.8 (11.7) years], 43.4% of the patients had at least one (30.3% had ≥2) ongoing comorbidity other than PsA/PSO. The median [interquartile range (IQR)] PsA and psoriasis duration were 1.9 (1.0-3.5) and 7.5 (3.9-16.8) years, respectively. All subjects were on csDMARD while 24.2% received combination therapy, oral non-steroid anti-inflammatory drugs (32.3%), topical treatments (20.2%) and systemic steroids (11.1%). Based on the Clinical Disease Activity in PsA (cDAPSA) score, 58.6% of the patients had moderate, and 29.3% high disease activity. In the EuroQol (EQ) 5-Dimensions (5D) 5-Levels questionnaire, 93.9, 82.8, 82.8, 73.7, and 51.5% of the patients reported problems in 'pain/discomfort', 'anxiety/depression', 'usual activities', 'mobility', and 'self-care', respectively. The median (IQR) baseline UK-weighted EQ-5D index and EQ-Visual Analogue Scale scores were 0.55 (0.44-0.70) and 50.0 (40.0-70.0), respectively. The median (IQR) Health Assessment Questionnaire-Disability Index (HAQ-DI) and mean (SD) PsA Impact of Disease 12-item (PsAID12) scores were 1.0 (0.5-1.4) and 4.6 (2.0), respectively.
Conclusion: More than 8 out of 10 bio-naïve patients initiated on apremilast in the routine clinical care in Greece have at least moderate disease activity, active psoriasis, and problems with pain/discomfort, anxiety/depression, and performance of usual activities at a median of 2 years post-diagnosis. HAQ-DI and PsAID12 scores indicate moderate impairment of physical functionality and PsA-related HRQoL. The findings underscore considerable disease burden early in the disease course.

Table 1. Baseline characteristics

	N	%/Mean/ Median

Background: DISCOVER 1 & 2, two double-blind, phase-3, psoriatic arthritis (PsA) trials of guselkumab (GUS, an IL-23 inhibitor), demonstrated significant improvement with GUS vs placebo (PBO) in signs and symptoms of PsA, with good tolerability, at week (w) 24 during the PBO-controlled period.[1,2] Beyond w24, all patients (pts) switched to GUS. Continued treatment maintained efficacy through w52.[3,4]
Objectives: To describe pooled safety results from the DISCOVER 1 & 2 trials through 1-year of GUS treatment.

Table 1. Number of Patients with AEs per 100 PY and Incidence of AEs of Interest

*Through w60 for DISCOVER 1 and w52 for DISCOVER 2; †Combined GUS q8w and q4w; ‡For patients who switched from PBO to GUS, only data on and after first GUS administration were included in this group; §PBO N=370.AE, adverse event; CI, confidence interval; GUS, guselkumab; PBO, placebo; PY, patient year; q4w, every 4 weeks; q8w, every 8 weeks; SC, subcutaneous; w, week

Methods: Adults with active PsA (DISCOVER 1: ≥3 tender/swollen joints and C-Reactive protein [CRP] ≥0.3 mg/dL; DISCOVER 2: ≥5 tender/swollen joints and CRP ≥0.6 mg/dL) were randomized to subcutaneous GUS 100 mg at w0, w4, then every 8 w (q8w); GUS 100 mg q4w; or PBO. At w24, PBO pts switched to GUS 100 mg q4w. Pts were biologic naive except ~30% pts in DISCOVER 1. Safety was reported through w60 in DISCOVER 1 and through w52 in DISCOVER 2.

Results: Baseline characteristics were similar between treatment groups in the pooled studies. Through w24 and 1 year, numbers of pts per 100 patient years with ≥1 event were similar among treatment groups for adverse events (AEs), serious AEs, infections, serious infections, and discontinuations due to AE (Table 1). At 1 year, there were no cases of active tuberculosis, opportunistic infections (including candida), or inflammatory bowel disease in GUS-treated pts; 2 deaths in PBO pts; and low incidences that were similar across treatment groups for malignancy, major adverse cardiac events, and injection-site reactions. Incidence of anti-GUS antibodies was 4.5%, and most were not neutralizing. Mild elevations in serum hepatic transaminases and decreases in neutrophil counts were consistent at 1 year with the results at w24 (Table 1).

Conclusion: GUS regimens of q8w and q4w were well tolerated in PsA pts through 1 year of treatment in the phase-3 DISCOVER trials, consistent with the w24 results. No meaningful differences between incidences of AEs were reported in the q8w and q4w groups. The safety profile of GUS in PsA pts is generally comparable with the previously established safety profile of GUS.

IXEKIZUMAB TREATMENT RESPONSE: CONSISTENCY OVER TIME AND AT EACH VISIT IN PSORIATIC ARTHRITIS

L. C. Coates[1], D. Sandoval[2], R. Bolce[2], C. Y. Lin[2], K. Stenger[2], A. T. Sprabery[2], A. Kavanaugh[3]. *[1]Oxford University, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, London, United Kingdom*; *[2]Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America*; *[3]UC San Diego, School of Medicine, San Diego, United States of America*

Background: Ixekizumab (IXE), a high-affinity monoclonal antibody targeting IL-17A, has demonstrated superiority in achieving the combined endpoint of ACR50 and PASI100 at week (Wk) 24 compared to adalimumab (ADA) in the SPIRIT-H2H trial [1]. In this analysis, we looked at the efficacy responses at the individual patient (pt) level to assess consistency over time and at each visit.

Objectives: To determine the American College of Rheumatology 50% (ACR50) response and Disease Activity in psoriatic arthritis (PsA) (DAPSA) response in pts treated with IXE and describe response consistency over time and at each visit from Wk 24 through Wk 52.

Methods: This post-hoc analysis used data from SPIRIT-H2H (NCT03151551), a phase3b/4 randomised, open-label parallel-group study between IXE and ADA. Pts were randomised to receive either IXE 80 mg, every 4 Wks (IXE Q4W)) or ADA 40 mg, every 2 Wks (ADA Q2W)). The proportion (%) of pts in the intent-to-treat population who achieved each endpoint, either ACR50 or DAPSA≤14, at Wk 24 and at each post-baseline visit out to Wk 52 was assessed. Nine pts with active psoriasis and body surface area (BSA) ≥3% were assessed as PASI=0 at baseline, a medical inconsistency that was resolved using medical judgement. These pts were considered PASI100 responders if PASI=0 and BSA=0 at post baseline visits.

Results: A total of 566 patients enrolled in the trial received either IXE (N=283) or ADA (N=283). Of the 143 pts treated with IXE who achieved ACR50 at Wk 24, 65% (N=93) maintained ACR50 at every visit. In total, 83% (N=118) of the ACR50 achievers at Wk 24 maintained ACR50 with some (18% (N=25)) fluctuations, between ACR50 and

ACR20 (Figure 1). Of the 132 pts treated with ADA who achieved ACR50 at Wk 24, 55% (N=72) maintained ACR50 at every visit. In total, 80% (N=105) of ACR50 achievers maintained ACR50 with some (25% (N=33)) fluctuations between ACR50 and ACR20 (Table 1). Furthermore, of the174 pts treated with IXE who achieved low DA (DAPSA≤14) at Wk 24, 68% (N=119) maintained low DA at every visit. Of the low DA achievers at Wk 24, 82% (N=142) of pts maintained low DA with some (13% (N=23)) fluctuations between moderate and low DA (Figure 1B). Of the 171 pts treated with ADA who achieved low DA at Wk 24; 57% (N=97) maintained low DA at every visit. In total, 77% (N=131) of low DA achievers at Wk 24 maintained low DA with some (20% (N=34)) fluctuations between moderate and low DA (Table 1).

Conclusion: This analysis demonstrates that a numerically higher proportion of pts treated with IXE versus ADA show consistency of response, as measured by ACR50 and DAPSA responses, over time and for each visit at the pt level.

COMPARISON OF EQ-5D HEALTH STATUS IN PSORIATIC ARTHRITIS PATIENTS WITH OR WITHOUT AXIAL DISEASE: RESULTS OF SUBANALYSIS OF THE PATERA STUDY

I. Gaydukova[1], T. Korotaeva[2], V. Mazurov[1], A. Samtsov[3], V. Khayrutdinov[3], A. Bakulev[4], A. Kundzer[5], N. Soroka[6], A. Eremeeva[7]. *[1]Mechnikov North-Western State Medical University, Department of Therapy and Rheumatology of Temporary Disability and Medical Care Quality Expertise, St-Petersburg, Russian Federation*; *[2]Nasonova Research Institute of Rheumatology, Laboratory of Spondyloarthritides and Psoriatic Arthritis, Moscow, Russian Federation*; *[3]Kirov Military Medical Academy, Department of Skin and Veneral Diseases, St-Petersburg, Russian Federation*; *[4]Razumovsky Saratov State Medical University, Department of Dermatovenereology and Cosmetology, Saratov, Russian Federation*; *[5]Belarusian Medical Academy of Postgraduate Education, Department of Cardiology and Rheumatology, Minsk, Belarus*; *[6]Belarusian State Medical University, Department of Internal Diseases №2, Minsk, Belarus*; *[7]JSC BIOCAD, Clinical Development Department, St-Petersburg, Russian Federation*

Background: Netakimab (NTK) is an anti-interleukin-17A monoclonal antibody approved for psoriasis, ankylosing spondylitis, psoriatic arthritis (PsA) in Russia and Belarus. PATERA is an ongoing phase 3 international double-blind, placebo-controlled clinical study of NTK in PsA (NCT03598751).

Objectives: A subanalysis was performed to assess the effect of NTK on domains of the 5-level EuroQol 5 Dimensions questionnaire (EQ-5D-5L) in patients with inflammatory back pain (IBP) (IBP(+)) and without (IBP(-)) at baseline according to self-reported ASAS IBP criteria, 2009.

Methods: 194 adult patients with PsA (CASPAR criteria, 2006) with inadequate response to csDMARD or one TNFi, were randomly assigned to receive NTK 120mg or placebo at weeks 0,1,2,4,6,8,10,14,18,22. The proportion of patients reported >1 problem in each domain was evaluated. Patients with missing values were considered as non-responders in the analysis.

Results: 97 PsA patients (N=54 IBP(+), N=43 IBP(-)) received NTK. The subpopulations didn't differ significantly in gender, age, and PsA activity at baseline. Comparable percentage of patients reported any problems for each domain at baseline (p≥0.05) (data not shown). IBP(-) subpopulation had a greater improvement for all domains except of anxiety/depression. The absolute declines for IBP(+) vs IBP(-) patients were as followed: 24.1% vs 41.9% (mobility), 18.5 vs 41.9% (self-care), 24.0% vs 51.1% (usual activities), 24.1% vs 37.2% (pain/discomfort), 33.3% vs 9.3% (anxiety/depression). However, the only significant difference between IBP(+) and IBP(-) was observed in usual activity (Figure 1).

Conclusion: NTK resulted in the growing improvement of each EQ-5D-5L domain through 24 weeks irrespectively of the presence of IBP. IBP(-) subjects showed trend to greater benefit compared to IBP(+).

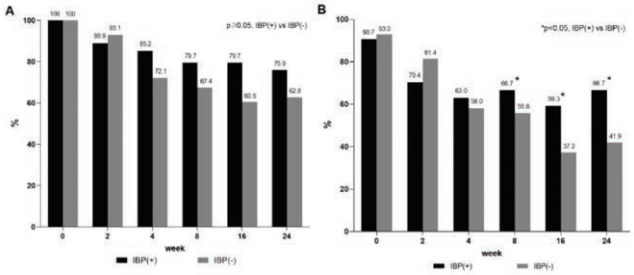

Figure 1 Percentage of patients reported any problems in (A) pain/discomfort, (B) in usual activity at each visit

AB0541

PREDICTING THE INITIATION OF BIOLOGIC DMARDS IN EARLY PSORIATIC ARTHRITIS WITHIN 1-YEAR OF TREAT-TO-TARGET STRATEGY

E. Loginova[1], T. Korotaeva[1], E. Gubar[1], Y. Korsakova[1], S. Glukhova[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Medical and Social Problems in Rheumatology, Moscow, Russian Federation*

Background: According to the EULAR recommendations and treat-to-target (T2T) strategy synthetic (s) DMARDs are the first-line of PsA therapy and biologic (b) DMARDs are the second one [1]. The value of early intervention by bDMARDs in PsA has been demonstrated recently [2]. But factors which can predict bDMARDs initiation have not been evaluated yet.

Objectives: To identify prognostic factors for initiation of bDMARDs within 1-year of T2T strategy in early PsA.

Methods: 70 patients (pts) (M/F=35/35) with active early PsA fulfilling the CASPAR criteria treated by T2T strategy were included. Mean age 36.9±10.2 years (yrs), PsA duration 11.3±10.6 months (mos.), psoriasis duration 80.6±89.9 mos. Median DAPSA= 29.4 [23.1;36.0]. At baseline (BL) all pts were given therapy with Methotrexate (MTX) s/c with escalating dose from 5 to 25 mg/wk, then over a period of 12 mos pts with ineffectiveness of MTX were added bDMARDs. At BL and every 3 month of therapy all pts underwent standard clinical examinations of PsA activity. DAPSA, ESR (mm/h), CRP (mg/l), the number of pts with dactylitis, enthesitis by LEI and plantar fascia, BSA (%), HAQ and fatigue by FACIT (Functional Assessment of Chronic Illness Therapy) Fatigue Scale (Version 4), BMI (kg/m^2) were evaluated. DAPSA > 28 indicate high activity, a score FACIT < 30 - severe fatigue, BMI >25 overweight and obese. At 12 mos. pts were divided into two groups. Group 1 included 42 pts who were treated with MTX only and group 2 - 28 pts those with added bDMARDs during 12 mos. Multi-dimensional step-by-step discriminant analysis was used to identify a group of signs associated with the need to initiate bDMARDs within 12 mos.

Results: Comparative analysis of two groups showed the following features proved to be the most informative at BL and at 3 mos. of sDMARDs therapy with MTX: high PsA activity by DAPSA ≥ 30 (p = 0.009), BMI (kg/m^2) ≥ 27 (p = 0.019), entesitis ≥ 1 (p= 0.005), ESR ≥ 20 mm/h (p= 0.007), FACIT < 30 (p= 0.074), male sex (p = 0.098). Early PsA pts with combination of these features at the first visit and at 3 mos. of MTX monotherapy have more chance to initiate bDMARDs in comparison to pts without them. Area Under ROC Curve (AUC) 0.892; 95% CI (0.818-0.966). Sensitivity/ Specificity of model 82% / 76% accordingly. (Figure 1).

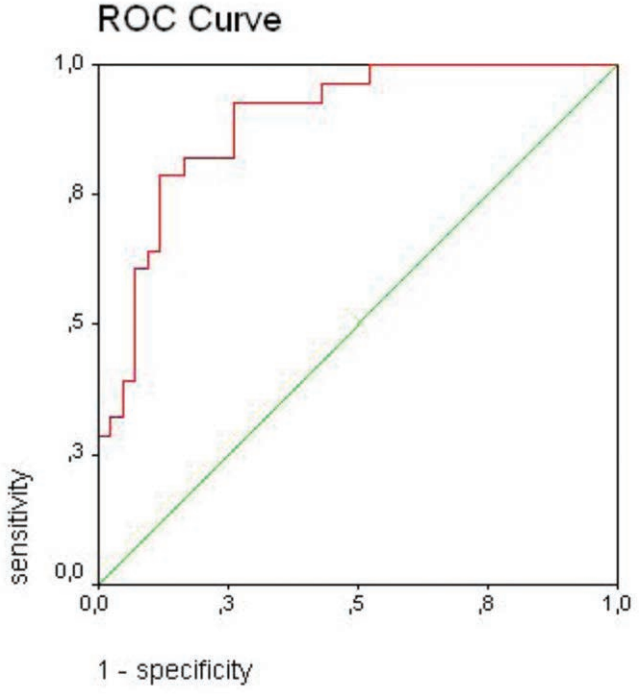

Figure 1.

Conclusion: It is a combination of features from first visit to clinic and at 3 mos. of MTX monotherapy – high PsA activity by DAPSA, male gender, persistent entesitis, obesity, ESR increase and severe fatigue by FACIT - that constitutes a prognostic factor for the initiation of bDMARDs at an early-stage of PsA. These factors should be considered in clinical practice to avoid losing time for the early initiation of bDMARDs and improved outcomes of PsA.

Torre[13]. *[1]Hospital Parc Tauli, Barcelona, Rheumatology, Barcelona, Spain*; *[2]Hospital Infanta Cristina, Badajoz, Rheumatology, Badajoz, Spain*; *[3]Hospital del Mar, Rheumatology, Barcelona, Spain*; *[4]Hospital Can Misses, Rheumatology, Eivissa, Illes Balears, Spain*; *[5]Complejo Hospitalario de Navarra, Rheumatology, Pamplona, Navarra, Spain*; *[6]Complejo Universitario de Vigo, Rheumatology, Pontevedra, Spain*; *[7]Hospital Universitario Donostia, Rheumatology, Donostia, Gipuzkoa, Spain*; *[8]Hospital Universitari Son Espases, Rheumatology, Palma, Illes Balears, Spain*; *[9]Hospital de Merida, Rheumatology, Mérida, Badajoz, Spain*; *[10]Hospital Virgen del Puerto, Rheumatology, Plasencia, Cáceres, Spain*; *[11]Hospital Universitario Son Llàtzer, Rheumatology, Palma, Illes Balears, Spain*; *[12]Amgen S.L., Medical, Barcelona, Spain*; *[13]Hospital Monte Naranco, Rheumatology, Oviedo, Asturias, Spain*

Background: Apremilast is a non-biologic systemic agent approved for the treatment of plaque psoriasis, oral ulcers of Behcet's disease and PsA with proven efficacy in clinical trials [1,2]. However, more real-world evidence of apremilast use and effectiveness is needed to identify the patient profile most likely to benefit from this treatment [3].

Objectives: To evaluate the persistence of apremilast treatment in patients with PsA naïve to biological treatments in routine clinical practice and assess its effectiveness. Baseline clinical characteristics on patients who started apremilast were also evaluated.

Methods: Observational, prospective, multicenter (20 centers) study including consecutive adult patients with PsA naïve to biological therapies who had started treatment with apremilast during the previous 5 to 7 months and were followed-up during 12 months. Variables recorded were persistence of treatment with apremilast at 6 months (6mo) and number of swelling joints, presence of enthesitis and dactylitis, and disease activity, measured by the Disease Activity in Psoriatic Arthritis (DAPSA) score and Physician Global Assessment (PGA) of psoriasis, collected at baseline (BL) (i.e., apremilast treatment start) and 6mo; comorbidities were retrospectively collected at BL. Categorical and quantitative variables were compared using McNemar's and Wilcoxon test, respectively. Data sets analyzed included all assessable patients.

Results: Of the 60 patients recruited at the time of this interim analysis, 54 (90.0%) [mean (SD) age 53.4 (13.9) years] were assessable; 41 (75.9%) of these continued treatment with apremilast at 6mo. At BL, 34 (63.0%) patients had at least one comorbidity, the most frequent being cardiovascular disease (n=15, 27.8%), including hypertension (n=8, 14.8%), metabolic/endocrine disease (n=18, 33.3%), including obesity (n=8, 14.8%) and dyslipidemia (n=10, 18.5%). Psychiatric disease (i.e., depression) (n=5, 9.3%) and neoplasia (n=8, 14.8%) were also observed. The number of swelling joints decreased from median (Q1, Q3) 4.0 (2.0, 7.0) at BL to 1.5 (0.0, 4.0) at 6mo (p=0.0012). Patients with dactylitis and enthesitis decreased from 19 (35.2%) and 16 (29.6%) at BL to 10 (18.5%) and 9 (16.7%) at 6mo (p=0.0225 and p=0.0391), respectively. The distribution of patients in the different disease activity categories according to DAPSA scale changed between BL and 6mo, indicating a favorable disease evolution (Figure 1 next page). According to PGA, at BL (n=53), disease activity was categorized as mild in 18.0%, as moderate in 72.0%, and as severe in 10% of patients and, at 6mo (n=54), as mild in 70.6%, as moderate in 25.5%, and as severe in 3.9% of patients. Fifteen (27.8%) patients interrupted treatment permanently (n=13, 24.1%) or temporarily (n=2, 3.7%), due to no/partial response (n=8, 14.8%), tolerability issues leading to adverse events (n=3, 5.6%), patient decision (n=2, 3.7%), and other reasons (n=2, 3.7%) after a mean (SD) treatment of 3.05 (2.20) months.

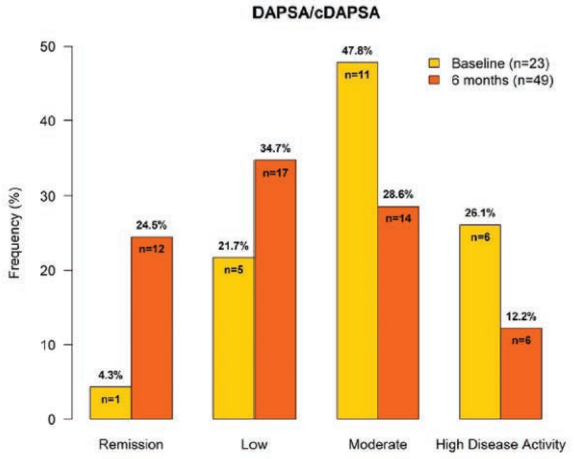

Figure 1. Classification of disease activity according to DAPSA at the indicated timepoints. Percentages in each category were calculated based on the number of patients with available data at each timepoint. DAPSA, Disease Activity in Psoriatic Arthritis.

Conclusion: Forty-one (75.9%) patients with PsA naïve to biological therapies were treated with apremilast during ≥6 months. After treatment, the number of swelling joints, and dactylitis and enthesitis decreased and changes in disease activity according to DAPSA and PGA pointed to a favorable disease evolution. Apremilast treatment provides a clinical benefit to patients with PsA treated in clinical practice.

AB0543 CHARACTERISTICS AND TREATMENT CHANGES IN PATIENTS WITH PSORIATIC ARTHRITIS SEEN IN A COMBINED DERMATOLOGY-RHEUMATOLOGY CLINIC

K. Klavdianou[1], M. Stavropoulou[2], P. Panagakis[3], M. Papoutsaki[4], A. Panagiotopoulos[1], C. Koutsianas[1], A. Stratigos[4], D. Rigopoulos[4], D. Vassilopoulos[1]. [1] *Hippokration General Hospital, 2nd Department of Medicine and Laboratory, Clinical Immunology - Rheumatology Unit, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece*; [2]*National and Kapodistrian University of Athens, MSc Program "Rheumatology – Musculoskeletal Health", Athens, Greece*; [3]*A. Syggros Hospital, Department of Dermatology-Venereology, Athens, Greece*; [4]*A. Syggros Hospital, 1st Department of Dermatology and Venereology, National and Kapodistrian University of Athens, Athens, Greece*

Background: Data on patients with Psoriasis (PSO) referred to a combined Dermatology-Rheumatology outpatient Clinic (Derm-Rheum) with suspected psoriatic arthritis (PsA) are limited.

Objectives: To assess patient characteristics and treatment changes in PsA patients referred to a Derm-Rheum Clinic.

Methods: Prospective study of PSO patients referred to a combined Derm - Rheum Clinic from February 2018 to June 2020 in a Tertiary University Hospital.

Results: Among 151 patients with PSO referred to the Clinic, 129 (85%) with a final diagnosis of PsA were included. In 73% of patients (n=94) PsA was diagnosed there for the 1st time. 56% were females with a mean age of 55 years and a median disease duration of 14.2 years. At initial evaluation, 95% had peripheral arthritis, 45% nail involvement, 23% axial involvement, 12% enthesitis and 6% dactylitis with a median DAPSA score of 20.5 and PASI score of 1.6, respectively. 31% of the patients were not receiving any systemic treatment, 45% were on biologics (30% as monotherapy, 15% in combination with non-biologics), 29% were on non-biologics (14% as monotherapy, 15% in combination with biologics or targeted synthetic agents] and 10% were on targeted synthetic (ts) agents. At last visit (median follow-up: 15 months) only 8% did not receive any systemic therapy ($p<0.001$ compared to 1st visit), 62% were on biologics (39% monotherapy – 23% in combination with non-biologics, $p=0.009$), 46% were on non-biologics (20% as monotherapy – 26% in combination with biologics or ts agents, $p=0.01$) and 10% of the patients were on apremilast. The median DAPSA and PASI scores at last visit were 5.3 and 0, respectively.

Conclusion: About 2/3 of patients with PSO referred to a combined Derm - Rheum Clinic with suspicious musculoskeletal complaints were diagnosed for the 1st time as PsA. During follow-up the percentage of PsA patients who started or continued systemic therapy significantly increased with significant improvement of disease activity indices. These data emphasize the value of combined Derm - Rheum Clinics for earlier diagnosis and more efficacious treatment of PsA patients.

AB0544 EFFICACY AND SAFETY OF TILDRAKIZUMAB IN PATIENTS WITH AND WITHOUT METABOLIC SYNDROME: 5-YEAR POOLED DATA FROM reSURFACE 1 AND reSURFACE 2

A. B. Gottlieb[1], N. Mehta[2], A. Menter[3,4], A. M. Mendelsohn[5], S. Rozzo[5], M. Lebwohl[1]. [1]*Icahn School of Medicine at Mount Sinai, Department of Dermatology, New York, United States of America*; [2]*National Institutes of Health, National Heart, Lung and Blood Institute, Bethesda, United States of America*; [3]*Baylor Scott & White, Division of Dermatology, Dallas, United States of America*; [4]*Texas A&M College of Medicine, Division of Dermatology, Dallas, United States of America*; [5]*Sun Pharmaceutical Industries, Inc., Medical Affairs, Princeton, United States of America*

Background: Patients with psoriasis and metabolic syndrome (MetS) may have reduced absolute Psoriasis Area and Severity Index (PASI) response and long-term drug survival. Tildrakizumab is approved for the treatment of moderate to severe plaque psoriasis in the US, EU, Australia, and Japan. Efficacy and safety of tildrakizumab were previously shown to be comparable in patients with vs without MetS after 1 and 3 years of treatment.[1]

Objectives: This post hoc analysis of pooled data from reSURFACE 1 and reSURFACE 2 (NCT01722331/NCT01729754) assessed tildrakizumab efficacy and safety through up to 5 years of treatment in patients with psoriasis with and without MetS.

Methods: reSURFACE 1 and 2 were 3-part, double-blind, randomized controlled phase 3 trials with long-term extensions evaluating tildrakizumab 100 or 200 mg monotherapy at Weeks 0, 4, and every 12 weeks thereafter in adults with moderate to severe plaque psoriasis.[2] Patients who achieved ≥50% improvement from baseline PASI score (PASI 50 response) at both week 28 and at the end of the phase 3 studies could enter the long-term extension studies continuing the same dose of tildrakizumab.[1] This post hoc analysis reports results from a pooled data analysis through up to 5 years of tildrakizumab exposure from patients with and without MetS by National Cholesterol Education Program-Adult Treatment Panel III criteria who continuously received the same dose of tildrakizumab throughout the base studies and entered the long-term extensions. Efficacy was assessed as change from baseline PASI score; missing data were handled using multiple

imputation. Safety was assessed from exposure adjusted incidence rates of serious adverse events (SAEs) and treatment-emergent AEs of special interest.
Results: Analyses included 70/265 patients with/without MetS receiving tildrakizumab 100 mg and 64/241 patients with/without MetS receiving tildrakizumab 200 mg. Median percentage change from baseline PASI score is shown in Figure 1. Among patients with/without MetS receiving tildrakizumab 100 mg, 78.6%/87.9% achieved PASI 75, 57.1%/63.8% achieved PASI 90, and 25.7%/32.5% achieved PASI 100 response at week 244; the PASI 75, PASI 90, and PASI 100 response rates at week 244 in patients with/without MetS receiving tildrakizumab 200 mg were 76.6%/85.1%, 46.9%/61.4%, and 26.6%/36.5%, respectively. Safety outcomes over the 5-year extension period were consistent with the known safety profile of tildrakizumab. Rates of SAEs were <8.5 per 100 patient-years among all patients, and there were no new safety signals in patients with vs without MetS (Table 1).

Table 1. SAEs and TEAEs of special interest by MetS status through up to 5 years of tildrakizumab exposure

	TIL 100 mg		TIL 200 mg	
	Without MetS	With MetS	Without MetS	With MetS

AB0545

COMPARISON BETWEEN METHOTREXATE AND APREMILAST IN PSORIATIC ARTHRITIS-A SINGLE BLINDED RANDOMIZED CONTROLLED TRIAL (APREMEPsA STUDY)

J. Samanta[1], G. Naidu[1], A. Chattopadhyay[2], A. Basnet[1], T. Narang[3], S. Dogra[3], A. Sharma[1]. [1]*Post Graduate Institute of Medical Education and Research, Clinical Immunology and Rheumatology Division, Internal Medicine, Chandigarh, India*; [2]*Institute of Post Graduate Medical education and Research, Rheumatology, Kolkata, India*; [3]*Post Graduate Institute of Medical Education and Research, Dermatology, Chandigarh, India*

Background: Both methotrexate and apremilast were found to be effective in controlling joint disease in psoriatic arthritis (PsA) patients [1-4]. However, there are no head-to-head trials comparing the efficacy of these two drugs in PsA.
Objectives: Primary outcome measure was rate of major cDAPSA response (>85% change in cDAPSA score from baseline) at week 24 and secondary outcome measures were ACR 20 response, change in Psoriasis Area and Severity Index (PASI), Maastricht enthesitis score, Leeds dactylitis index, and health assessment questionnaire-disability index (HAQ-DI) and number of adverse events at week 24 between methotrexate and apremilast groups.
Methods: Single blinded (physician), parallel group, randomized controlled trial was conducted at a single centre in India between October 2019 and December 2020. Adult PsA patients (age>18 years), fulfilling CASPAR criteria, not receiving methotrexate/apremilast in last 3 months and never receiving bDMARDs or, JAK inhibitors, having active articular disease (one or more swollen joint or, having one or more tender entheseal point) were recruited in this study.
Results: A total of 31 patients were recruited (15 in apremilast arm and 16 in methotrexate arm) amongst whom 26 patients completed 24 weeks follow up (13 patients in apremilast arm and 13 patients in methotrexate arm). At baseline, median (IQR) swollen joints were 2 (1) in apremilast group and 2.5 (4) in methotrexate group. Median cDAPSA score at baseline was 23 (9) in apremilast group and 20 (21) in methotrexate group. Major cDAPSA response at week 24 was achieved in three (20%) subjects in apremilast arm and six (37.5%) subjects in methotrexate arm (p=0.433). Seven (46.67%) subjects in apremilast group and nine (56.25%) subjects in methotrexate group achieved ACR 20 response at 24-weeks (p=0.724). The change of PASI score from baseline was significant in apremilast group (2.0, p=0.003) and methotrexate group (0.35, p=0.003), but when compared between the two groups, there was no significant difference(p=0.378). Change in enthesitis score was not significant in both the groups (0.0 in apremilast group, p=0.285; 0.0 in methotrexate group, p=1.0). The median change in dactylitis score [0.0 (9.1), p=0.028] and HAQ-DI score (0.33, p=0.01) were significant in methotrexate group only. However, when compared to the change in apremilast group, the difference was not significant for both the parameters. A total of 9 minor adverse events, 3 with apremilast and 6 with methotrexate, were observed with transaminitis (number of events) being the commonest event noted with methotrexate. There were no serious adverse events noted in either of the groups.
Conclusion: There was no significant difference between methotrexate and apremilast in terms of efficacy as measured by cDAPSA and ACR20 responses. Both the drugs were well tolerated by the study population. A larger study with head-to-head comparison between methotrexate and apremilast is needed to conform these findings.

AB0546 5 YEARS FOLLOW-UP OF PSORIATIC ARTHRITIS PATIENTS TREATED ACCORDING TREAT-TO-TARGET STRATEGY. PRELIMINARY RESULTS

P. Tremaskina[1], E. Loginova[1], T. Korotaeva[1], S. Glukhova[2], A. Lila[1,3]. [1]*V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and psoriatic arthritis, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, medical and social problems in rheumatology, Moscow, Russian Federation*; [3]*Medical Academy of Continuing Professional Education, Rheumatology, Moscow, Russian Federation*

Background: The concept of treat to target (T2T) in psoriatic arthritis (PsA) has been established recently and already shown its benefits [1]. But the long-term outcomes of the T2T have not been studied yet.
Objectives: To study 5 years (yrs) follow-up of PsA patients (pts) treated according to T2T strategy at the early stage.
Methods: 35 (M/F–17/18) PsA pts fulfilling CASPAR criteria, who were treated according to T2T strategy at the early stage (PsA duration≤2 yrs) within 24 months (mos) were analyzed. At the time of evaluation mean age is 42.7±11.2 yrs, median (Me) PsA duration 72 [60;95] mos, psoriasis duration 120 [88;180] mos. All pts underwent standard clinical examinations of PsA before started T2T therapy and at follow-up. Within 24 mos of T2T strategy all pts were taking Methotrexate (MTX) monotherapy in increasing dose up to 25 mg/wk and 18 out of 35 (51%) pts received MTX in combination with iTNF. When T2T study was stopped all pts were treated according to standard care with NSAIDs, bDMARDs, MTX, tsDMARDs based on PsA activity and physician decision. The number of pts achieved minimal disease activity (MDA, 5 of 7) and remission by DAPSA (≤4)/ low disease activity (LDA)≤14) at the 24 mos of T2T strategy and at 5 yrs follow-up were calculated. The results are presented in the form of mean values, median, upper and lower quartiles.
Results: Me duration of follow-up is 68 [53.5;81.5] mos. At 24 mos Me DAPSA 3.48 [0.45;21.76], remission by DAPSA (REM-DAPSA) were seen in 20 out of 35 (57%) pts, LDA-DAPSA in 4 (12%) pts, moderate activity (MoA) by DAPSA in 6 (17%) pts and high disease activity by DAPSA (HDA-DAPSA) in 5 (14%) pts. MDA was noted in 21 out of 35 (60%) pts. At 5 yrs Me DAPSA 7.4 [2.22;13.87], REM-DAPSA was noted in 12 (34%) pts, LDA-DAPSA in 14 (40%), MoA-DAPSA in 5 (14%), HDA-DAPSA in 4 (12%) pts. MDA was observed in 17 of 35 pts (49%). Among 20 pts who had REM-DAPSA at 24 mos only 6 pts (30%) remained in remission at 5 yrs follow-up and 12 out of 21 pts (57.14%) remained in MDA status.
Conclusion: In early PsA pts remission and MDA are achievable goal of T2T strategy. But most pts lost remission/MDA after this strategy was changed to a standard care, despite being in remission/MDA status before change of therapy. Further investigations of the long-term outcomes of T2T strategy in PsA, including radiographic outcomes are needed.

AB0547 ASSOCIATION BETWEEN ACHIEVEMENT OF LOW DISEASE ACTIVITY OR REMISSION WITH IMPROVEMENT IN QUALITY OF LIFE IN UPADACITINIB-TREATED PATIENTS IN THE PHASE 3 SELECT-PsA 1 AND 2 STUDIES

A. Kavanaugh[1], P. J. Mease[2], K. Douglas[3], F. Behrens[4], D. Haaland[5], P. Palominos[6], A. Lertratanakul[3], M. Lane[3], R. Lippe[7], D. Aletaha[8], P. Nash[9]. KG, Immunology, Wiesbaden, Germany*; [8]*Medical University of Vienna, Währinger Gürtel, Department of Medicine III, Division of Rheumatology, Vienna, Austria*; [9]*Griffith University, Rheumatology Research Unit, Sunshine Coast, Brisbane, Queensland, Australia*

Background: The efficacy and safety of upadacitinib (UPA) in patients (pts) with active psoriatic arthritis (PsA) was demonstrated in the phase 3 SELECT-PsA 1 and SELECT-PsA 2 clinical trials.[1,2]
Objectives: To explore the relationship between achievement of low disease activity (LDA) or remission (REM) and pt-reported outcomes (PROs) in SELECT-PsA 1 and 2.
Methods: The SELECT-PsA program enrolled pts with prior inadequate response or intolerance to ≥1 non-biologic disease-modifying antirheumatic drug (DMARD; SELECT-PsA 1) or ≥1 biologic DMARD (SELECT-PsA 2). Pts were randomized to 56 weeks (wks) of blinded treatment with UPA 15 or 30 mg once daily (QD), placebo switched to UPA 15 or 30 mg QD at Wk 24, or adalimumab (SELECT-PsA 1 only) 40 mg every other wk. LDA and REM were evaluated using the minimal disease activity (MDA; fulfillment of 5 out of 7) criteria and the Disease Activity index for Psoriatic Arthritis (DAPSA; cutoff ≤4), respectively. PROs assessed included Health Assessment Questionnaire-Disability Index (HAQ-DI), 36-Item Short-Form Survey physical component summary (SF-36 PCS), 5-Level EuroQol 5-Dimension (EQ-5D-5L) Index, and EQ-5D-5L Visual Analog Scale (VAS). Integrated data through Wk 56 from SELECT-PsA 1 and 2 from the full analysis set with both continuous UPA 15 mg and 30 mg groups were analyzed by responder status at Wks 24 and 56. Changes from baseline (BL) in PROs were analyzed using mixed effects repeated measures models (fixed effects for study, current use of non-biologic DMARDs, treatment group, visit, responder status, and continuous BL PROs). As-observed data were used in the models.
Results: A total of 1281 pts were included in the analysis (UPA 15 mg, n=640; UPA 30 mg, n=641). MDA was achieved by 33% (UPA 15 mg) and 40% (UPA 30 mg) of patients at
Wk 24, and 40% (UPA 15 mg) and 43% (UPA 30 mg) at Wk 56; and DAPSA-REM by 10% (UPA 15 mg) and 17% (UPA 30 mg) at Wk 24, and 16% (UPA 15 mg) and 18% (UPA 30 mg) at Wk 56. Pts who achieved MDA or DAPSA-REM (responders) at Wk 56 achieved larger reductions in HAQ-DI and larger increases in SF-36 PCS, EQ-5D-5L Index and EQ-5D-5L VAS compared with non-responders (Table 1) (all p<0.0001; statistical significance was exploratory in nature). MDA or DAPSA-REM response at Wk 24 was also associated with greater PRO improvements at Wk 56 (Figure 1). Consistent with the results presented for MDA and DAPSA-REM, patients who achieved Very Low Disease Activity or DAPSA-LDA also experienced greater improvements in PROs than those who did not.

Table 1. Change from BL in PROs at Wk 56 by MDA and DAPSA-REM responder status at Wk 56

*p<0.0001 vs non-responder (statistical significance was exploratory in nature)[a]n may vary by PRO assessed

Conclusion: Among UPA-treated pts with PsA, improvements in quality of life and physical function were greater in pts who achieved MDA or DAPSA-REM than in those who did not. Despite DAPSA-REM being a more stringent measure (achieved by a smaller proportion of patients), these improvements were similar between MDA and DAPSA-REM responders.

EFFECTIVENESS OF IXEKIZUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM A REAL-WORLD EUROPEAN SURVEY

W. Tillett[1,2], V. Navarro-Compán[3], N. Booth[4], T. Holzkaemper[5], J. Hill[5], E. Lubrano[6], T. Truer[5]. [1]*Royal National Hospital for Rheumatic Diseases, Department of Rheumatology, Bath, United Kingdom*; [2]*University of Bath, Department of Pharmacy and Pharmacology, Bath, United Kingdom*; [3]*University Hospital La Paz, IdiPaz, Madrid, Spain*; [4]*Adelphi Real World, Adelphi Real World, Bollington, United Kingdom*; [5]*Eli Lilly & Company, Eli Lilly & Company, Indianapolis, United States of America*; [6]*Università degli Studi del Molise, Academic Rheumatology Unit, Dipartimento di Medicina e Scienze della Salute "Vincenzo Tiberio", Campobasso, Italy*

Background: Limited real world (RW) data are available for IL-17A blocker ixekizumab (Ixe), approved for psoriatic arthritis (PsA) in EU Feb 2018.
Objectives: Describe RW outcomes for PsA patients (pts) receiving Ixe.
Methods: Cross-sectional, observational study of PsA pts treated with Ixe in the 2020 Adelphi PsA Plus Program (FR, DE, ES & UK). Rheumatologists recruited the first 6 consecutive consulting Ixe pts and provided demographics, PsA manifestations, clinical measures (66 swollen joint count (SJC), 68 tender joint count (TJC), psoriasis area and severity index [PASI], body surface area [BSA] affected by psoriasis [PsO]), rheumatologist-recorded pt measures (skin/joint pain & fatigue [0-10 numeric rating scales (NRS)], health assessment questionnaire [HAQ-DI]) & prescribed dose. All outcomes recorded for pts with scores available at Ixe initiation (II) & at last assessment (LA).
Results: 124 rheumatologists provided data for 698 Ixe pts, mean age 49 years (19-79), 48% female, mean BMI 27 (18-44), 56% dermatologist co-managed and mean time diagnosed 6 years (0-35). At Ixe initiation, 78% of pts with known BSA had concomitant mod-sev-PsO defined as BSA≥10% (mean 19.8, n=428) and mean PASI 26.3 (n=164). The predominant PsA phenotype was polyarthritic in 49% (n=345), mono/oligoarthritic in 30% (n=208), axial in 12% (n=81) and enthesitic in 8% (n=55). Previous treatment before Ixe included ≥1 conventional synthetic DMARD (csDMARD) for 71% of pts. Of bio-experienced pts (57%), 40% had received ≥2 biologics. Mean Ixe treatment duration (n=698) 39.4 weeks (wks, 0-170), of which 575 (82%) had received >12 wks of Ixe. 71% of pts received label recommended dose (80mg every 4wks). 52% pts received csDMARD in combination with Ixe. In the RW, Ixe improved TJC, SJC, joint pain, BSA, fatigue and HAQ-DI, Table 1.

Table 1. Outcomes for pts receiving Ixe >12weeks (n=575)

	Overall	BSA ≥10% at Ixe initiation	Mod-sev-PsO physician judgement	Predominant mono/oligo arthritis	Predominant polyarthritis	With csDMARD	Without csDMARD

II	1.8 [0.7, 5]	1.9 [0.6, 0]	1.8 [0.7, 2]	1.9 [0.7, 10]	1.8 [0.8, 7]	1.9 [0.6, 3]	1.7 [0.8, 7]
LA	0.8 [0.6, 41]	0.8 [0.6, 32]	0.8 [0.7, 45]	0.7 [0.7, 60]	0.7 [0.6, 36]	0.7 [0.5, 32]	0.7 [0.8, 50]

*Additional analysis for pts whose fatigue/joint pain rating improved (from ≥4 at Ixe initiation to ≤3 at LA), their mean TJC was 2.7 & SJC 4.3 at LA for fatigue, TJC 1.7 & SJC 2.7 at LA for joint pain.When BSA was not recorded, physician judgement of PsO severity was used. No imputation of missing data.

Conclusion: We report RW outcome data amongst pts treated with Ixe including mono/oligo arthritis and a limited sample of enthesitis and dactylitis pts. Our results are consistent with clinical trial populations across disease domains, including an improvement in joint pain.

AB0549 PREDICTIVE FACTORS FOR SWITCHING IN PATIENTS WITH PSORIATIC ARTHRITIS UNDERGOING ANTI-TNFA, ANTI-IL12/23 OR ANTI-IL17 DRUGS: A FIFTEEN-YEAR MONOCENTRIC REAL-LIFE STUDY

M. Lorenzin[1], A. Ortolan[1], G. Cozzi[1], A. Calligaro[1], M. Favaro[1], T. Del Ross[1], A. Doria[1], R. Ramonda[1]. [1]*University of Padova, Rheumatology Unit, Department of Medicine DIMED, Padova, Italy*

Background: Biological Disease-Modifying Anti-Rheumatic Drugs (bDMARDs) targeting Tumor Necrosis Factor (TNF) alpha, Interleukin (IL) 12/23 and IL17, have been approved for Psoriatic Arthritis (PsA) treatment, in this chronological order.

Objectives: The aims of our study were to evaluate 1) predictors of first bDMARD failure, including mechanism of action 2) factors associated to failure of multiple (>=2) therapies.

Methods: Consecutive patients attending our Rheumatology Unit, classified as PsA according to CASPAR criteria and beginning treatment with bDMARDs in the period 2004-2020, were enrolled. Disease characteristics, previous/ongoing treatments, comorbidities and follow-up duration were recorded. Demographic, clinical and laboratory data, disease-activity and functional indexes [including Disease Activity in PSoriatic Arthritis (DAPSA), PASI (Psoriasis Area and Severity Index) and Health Assessment Questionnaire (HAQ)], were recorded at baseline and yearly and were compared between switchers (>=1 switch/swap) and non-switchers. Date and reason for switching were collected. Effectiveness was evaluated over-time with descriptive statistics. A multivariable Cox-Proportional-Hazard (PH) model was built to evaluate the influence of mechanism of action (anti-TNFalpha/anti-IL12/23/anti-IL17) and of negative prognostic factors for drug response on time to first bDMARD discontinuation. Furthermore, a multivariable logistic regression model was built to assess the association between negative prognostic factors for drug response (independent variables) and failure of>=2 bDMARDs ("multifailure", outcome). Kaplan-Meier curves were used to assess differences in time-to-first bDMARD discontinuation according to the targeted cytokine. P values <=0.05 were considered significant. Infections and adverse events were recorded.

Results: Our study included 264 patients, 117 (44.32%) females, mean age 56±12 years, mean PsA duration 15±3 years;117 (44.32%) switched bDMARDs at least once. Switchers were mostly females, with higher PASI and worse HAQ at baseline (Figure 1). Mean time-to-first bDMARD discontinuation was 72 months; 2-year and 5-year retention rate was 75% and 60%, respectively. Survival curves for anti-TNFalpha/anti-IL12/23/anti-IL17 were similar (log-rak test=0.83;p=0.66). Main reasons for switching were inefficacy (79) and adverse events (38). The Cox PH model showed that female sex was independently associated to a higher risk of first bDMARD discontinuation (HR=2.39; 95%CI:1.50-3.81), while initiating therapy before 2015 was protective (HR=0.40; 95%CI:0.22-0.73). Other independent variables, including mechanism of action (HR=0.76; 95%CI:0.30-1.74 for anti-IL17; HR=0.53; 95%CI 0.15-1.86 for anti-IL12/23; reference: anti-TNFalpha), age (HR=1.00; 95%CI:0.99-1.03), baseline DAPSA (HR=0.98; 95%CI:0.96-1.00), PASI (HR=0.95; 95%CI:0.86-1.04), HAQ (HR=1.29; 95%CI:0.91-1.83), Body Mass Index BMI (HR=1.02; 95%CI:0.98-1.07) and comorbidities (HR=1.10; 95%CI:0.92-1.31) were not associated to the outcome. In the logistic regression model, only female sex was significantly associated to failure of>=2 therapies (OR=1.99, 95%CI:1.07-3.69); bDMARD mechanism of action, age, and initiating therapy before 2015 were instead not independently associated.

Conclusion: Survival rate was good for anti-TNFalpha and other bDMARDs. Female sex was a predictor of first bDMARD discontinuation, unlike mechanism of action, comorbidities and BMI.

Baseline characteristics of the monocentric cohort at the beginning of bDMARDs, comparison between switchers and non-switchers.

AB0550 EFFICACY OF UPADACITINIB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND A LOW OR HIGH SWOLLEN JOINT COUNT: A SUBGROUP ANALYSIS OF 2 PHASE 3 STUDIES (SELECT-PSA 1 AND SELECT-PSA 2)

L. Gossec[1,2], D. D. Gladman[3], E. Mcdearmon-Blondell[4], P. Sewerin[5], C. T. Ritchlin[6], D. Feng[4], A. Lertratanakul[4], R. Ranza[7], L. S. Tam[8], A. Marchesoni[9], L. C. Coates[10], P. Nash[11]. Background: Although most patients with psoriatic arthritis (PsA) enrolled in clinical trials have polyarticular arthritis, patients in clinical practice may present with oligoarthritis. Data on the efficacy of Janus kinase inhibitors in patients with PsA with low joint counts are limited.

Objectives: To evaluate the efficacy of upadacitinib (UPA) in subgroups of patients with PsA with a low (baseline swollen joint count [SJC] <5) or high (SJC ≥5) SJC (LSJ or HSJ).

Methods: Data were pooled across the SELECT-PsA 1[1] (non-biologic disease-modifying antirheumatic drug [non-bDMARD] inadequate response [IR] or intolerance) and SELECT-PsA 2[2] (bDMARD IR or intolerance) trials, which both enrolled patients with ≥3 involved joints (SJC ≥3 and tender joint count [TJC] ≥3). Subgroup analysis was performed for patients with LSJ or HSJ treated with UPA 15 mg once daily (QD) or placebo (PBO). Efficacy endpoints included minimal disease activity (MDA), very low disease activity (VLDA), Psoriatic Arthritis Disease Activity Score (PASDAS) low disease activity (LDA; ≤3.2), PASDAS remission (≤1.9), and 20/50/70% improvement in American College of Rheumatology (ACR) criteria (ACR20/50/70), all at Week 24, and Psoriasis Area Severity Index (PASI) 75 and static Investigator Global Assessment of Psoriasis (sIGA) 0/1 at Week 16.

Results: At baseline, patients with HSJ (n=1060) had similar demographic characteristics but tended to have higher overall disease activity than patients with LSJ across multiple disease domains (n=215; Table 1). UPA efficacy appeared comparable in patients with LSJ and HSJ, with similar proportions of patients achieving composite (MDA, VLDA, PASDAS LDA, and PASDAS remission) measures at Week 24, and skin endpoints (PASI 75 and sIGA 0/1) at Week 16 (Figure 1). At Week 24, 60.0/36.8/22.1% of patients with LSJ receiving UPA 15 mg achieved ACR20/50/70 vs 40.0/17.5/5.8% in the PBO group; rates were 70.3/49.7/26.2% (UPA 15 mg) and 36.1/15.3/3.3% (PBO) in those with HSJ.

BSA-Ps ≥ 3%, n (%)	57 (47.5)	285 (55.3)	44 (46.3)	300 (55.0)	101 (47.0)	585 (55.2)
PASI (baseline BSA-Ps ≥ 3%), mean (SD)	7.7 (7.5)	12.1 (11.9)	8.2 (7.0)	10.2 (10.0)	7.9 (7.2)	11.1 (11.0)
PASI (baseline BSA-Ps ≥ 3%), median (range)	5.3 (0.1–39.4)	7.9 (0.3–64.8)	6.5 (0.2–35.4)	6.8 (0.1–70.8)	6.0 (0.1–39.4)	7.3 (0.1–70.8)

Conclusion: UPA efficacy was generally similar in patients with PsA with LSJ or HSJ, with both patient groups showing improvements in composite clinical endpoints and skin responses vs PBO.

AB0551

TREATMENT WITH IXEKIZUMAB FOLLOWING SECUKINUMAB FAILURE IN PATIENTS WITH PSORIATIC ARTHRITIS: REAL-LIFE EXPERIENCE FROM A RESISTANT POPULATION

J. Berman[1], V. Furer[2], M. Berman[2], O. Isakov[1], D. Zisman[3], A. Haddad[3], H. Matz[4], O. Elkayam[2]. [1]*Sourasky Medical Center, Department of Medicine 'T', Tel Aviv, Israel*; [2]*Sourasky Medical Center, Department of Rheumatology, Tel Aviv, Israel*; [3]*Carmel Medical Center, Department of Rheumatology, Haifa, Israel*; [4]*Sourasky Medical Center, Department of Dermatology, Tel Aviv, Israel*

Background: Anti-IL17 agents, such as Secukinumab (SEC) and Ixekizumab (IXE) have been shown to be efficacious for the treatment of psoriasis and PsA[12]. In the field of psoriasis, there is growing evidence of a successful switching between the two anti-IL-17 agents in case of an insufficient response to one of the treatments[3] There is no information on the efficacy of switching between anti IL17 agents in PsA.
Objectives: To assess the clinical response to IXE in patients with PsA following SEC failure.
Methods: A retrospective observational study was conducted in two rheumatology centers in Israel, including PsA patients with a history of treatment with SEC, further treated with IXE for a minimum of 3 months. Lack of efficacy, loss of efficacy, and side effects over time were reported as a reason for switching to another anti-IL17 agent. The mean difference between the beginning of the follow up period and the different follow up points (6 and 12 months) was tested using a one-sample t-test. Time until treatment failure was estimated using Kaplan–Meier curves, and compared using the log-rank test. Hazard ratios (HRs) and corresponding 95% confidence intervals (CIs) were calculated using the Cox proportional-hazards model to test the association between each variable and the time to treatment failure.
Results: The study included 23 PsA patients (11♀/12♂), mean age 58.7 years±13.4 SD. Most patients (n=20, 86%) received 2+ TNFi and 10 patients (43%) received both TNFi and ustekinumab. Median number of biologics prior to SEC was 3 (IQR 2-4). There was a significant improvement in TJC at 6 and 12 months (-2.16 [-4.0, -0.3]; p=0.025 and-1.69 [-3.09, -0.28]; p=0.022, respectively). SJC was significantly improved at 6 months but not at 12 months (-2.68 [-5.3, -0.04]; p= 0.046 and -1.50 [-4.25,1.25]; p=0.26, respectively). CDAI score was significantly improved at 6 months (-10.19, [-16.26, -4.1], p=0.002) and at 12 months (-9.29 [-14.8, -3.71], p=0.003) as was SDAI score (-10.13 [-16.4, -3.8], p=0.003 and -12.2 [-17.1, -7.2], p=0.0002). At six months, PASI50 was achieved by 81% (13 patients), PASI75 was achieved by 63% (10 patients), PASI90 was achieved by 50% (8 patients) and PASI100 by 31% (10 patients). At 12 months, PASI50 and PASI75 was achieved by 57% (8 patients), PASI90 was achieved by 43% (6 patients) and PASI100 by 21% (3 patients).
Over time, of the 23 patients treated with IXE, 15 patients (65%) had experienced treatment failure, with a median treatment period of 8 months (IQR 6.5-13.5), of which 4 (17%) had primary treatment failure and 11 patients (48%) secondary treatment failure. Reasons for treatment cessation were: worsening psoriasis (4 patients (27%)), worsening peripheral arthritis (4 patients (27%)), both (7 patients (47%)), worsening of axial disease (2 patients (13%)) and adverse events (1 patient, 6%).
Conclusion: patients after failure of multiple biologic treatments experienced significant response of peripheral arthritis and dermatologic disease on IXE after they had previously failed SEC. . However, in this refractory cohort of PsA, the effect was limited on time with 65% failure after a median time of 8 months.Within class switch from SEC to IXE is a plausible therapeutic option in PsA patients following secukinumab failure.

AB0552

PROBABILITY OF ACHIEVING TREATMENT TARGETS WITH APREMILAST MONOTHERAPY IN BIOLOGIC-NAIVE PSORIATIC ARTHRITIS PATIENTS IN ACTIVE WITH MODERATE AND HIGH BASELINE DISEASE ACTIVITY

P. Nash[1], S. Richter[2], S. Jardon[2], L. Teng[3], J. A. Walsh[4]. [1]*Griffith University, Medicine, Brisbane, Australia*; [2]*Amgen Inc., Global Medical Affairs, Thousand Oaks, United States of America*; [3]*Amgen Inc., Statistics, Thousand Oaks, United States of America*; [4]*University of Utah, Rheumatology, Salt Lake City, United States of America*

Background: Patients with psoriatic arthritis (PsA) in moderate disease activity (ModDA) who are naive to disease-modifying antirheumatic drugs (DMARDs) have a higher probability of achieving the Clinical Disease Activity Index for PsA (cDAPSA) treatment targets after receiving apremilast 30 mg BID (APR) than those in high disease activity (HDA). In Europe, APR is indicated for the treatment of active PsA in adult patients who had an inadequate response or were intolerant to a prior DMARD therapy. Achievement of cDAPSA treatment targets with APR monotherapy in biologic-naive patients with PsA who had previously taken a maximum of 1 conventional synthetic DMARD (csDMARD) has not been evaluated.
Objectives: To assess the predictive value of baseline clinical disease status on achieving long-term cDAPSA treatment targets at Week 52 among biologic-naive patients with PsA in the phase 3b, randomized, placebo-controlled Assessing Apremilast Monotherapy in a Clinical Trial of Biologic-Naive Patients With PsA (ACTIVE).
Methods: ACTIVE enrolled adults with PsA who had ≥3 swollen and ≥3 tender joints and were biologic naive with prior failure of a maximum of 1 csDMARD. In this post hoc analysis, we assessed the probabilities of achieving cDAPSA treatment targets of remission (REM; ≤4) or low disease activity (LDA; >4 to ≤13) at Week 52 in patients randomized to APR and stratified by cDAPSA ModDA (>13 to ≤27) or HDA (>27) at baseline. Patients with enthesitis at baseline in each stratum were analyzed separately.
Results: Of the 109 patients randomized to APR, 35 were in ModDA (32.1%) and 71 were in HDA (65.1%) at baseline (Table 1). For patients with ModDA vs HDA at baseline, swollen (4.6 vs 10.8) and tender (6.7 vs 21.7) joint counts were lower, and the prevalence of enthesitis was lower (42.9% vs 57.7%) (Table 1). Patients in ModDA at baseline were estimated to be more than twice as likely to achieve treatment targets at Week 52 vs patients in HDA at baseline (Figure 1). Consistent with these results, a higher proportion of patients with ModDA + enthesitis at baseline achieved treatment targets at Week 52 than patients with HDA + enthesitis at baseline (58.9% vs 32.8%).

Table 1. Baseline Demographics and Disease Characteristics

Baseline cDAPSA Category	ModDA (n = 35)	HDA (n = 71)
Age, mean (SD), years	48.5 (12.9)	51.6 (11.8)
Women, n (%)	20 (57.1)	36 (50.7)
White, n (%)	34 (97.1)	71 (100.0)
PsA duration, mean (SD), years	4.5 (4.6)	3.8 (4.5)
Enthesitis, n (%)	15 (42.9)	41 (57.7)
SJC (0-66), mean (SD)	4.6 (1.6)	10.8 (4.3)
TJC (0-68), mean (SD)	6.7 (2.2)	21.7 (11.5)
PtGA (0-10 NRS), mean (SD)	4.9 (1.4)	6.5 (2.0)
PhGA (0-10 NRS), mean (SD)	5.4 (1.2)	6.6 (1.5)

The n represents the total sample. The number of patients with data available may vary. Not included are 3 patients in LDA at baseline. NRS = Numeric Rating Scale; PhGA = Physician's Global Assessment of Disease Activity; PtGA = Patient's Global Assessment of Disease Activity; SJC = swollen joint count; TJC = tender joint count.

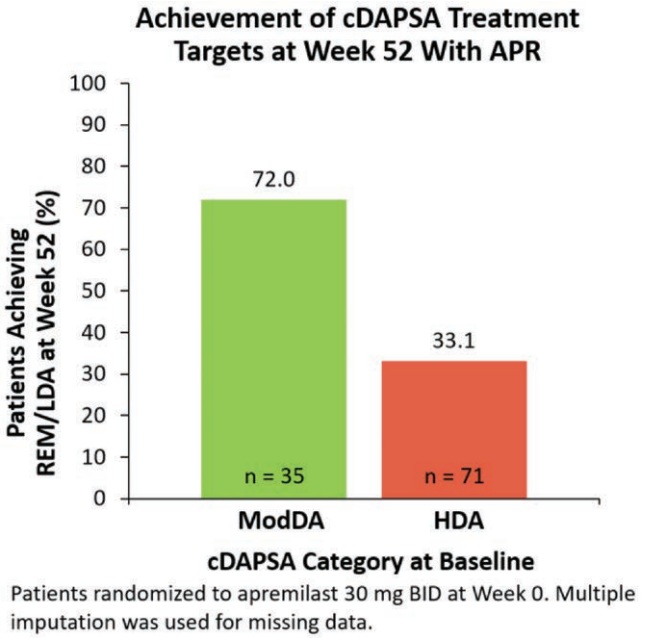

Figure 1.

Conclusion: Similar to observations in DMARD-naive patients with PsA, patients who were biologic naive but may have had experience with a maximum of 1 csDMARD, including those with enthesitis, and who were in ModDA at baseline had a higher probability of achieving treatment targets (cDAPSA REM or LDA) at Week 52 with continued APR treatment compared with those with HDA.

BASELINE DISEASE ACTIVITY AS A PREDICTOR FOR ACHIEVING cDAPSA TREATMENT TARGETS WITH APREMILAST IN DMARD-NAIVE PATIENTS WITH MANIFESTATIONS OF ACTIVE PSORIATIC ARTHRITIS

P. J. Mease[1], A. Kavanaugh[2], A. Ogdie[3], A. F. Wells[4], M. Bergman[5], D. D. Gladman[6], F. Behrens[7], Y. Klyachkin[8], S. Richter[8], L. Teng[8], J. S. Smolen[9].

Background: In PALACE 4, DMARD-naive patients (pts) with moderately active (ModDA) psoriatic arthritis (PsA) at baseline (BL) were more likely to achieve Clinical Disease Activity Index for PsA (cDAPSA) treatment targets (cDAPSA remission [REM] or low disease activity [LDA]) at Week 52 with continued apremilast 30 mg BID (APR) treatment than pts with high disease activity (HDA) at BL. Pts who achieved cDAPSA treatment targets also had no or mild articular and extra-articular disease activity by Week 52. Whether specific PsA manifestations other than arthritis impact the achievement of cDAPSA treatment targets in this population is unknown.

Objectives: To assess the predictive value of BL clinical disease status on achieving cDAPSA treatment targets in DMARD-naive pts in PALACE 4 with PsA in ModDA or HDA who exhibited manifestations of skin involvement, enthesitis, and/or dactylitis at BL.

Methods: This post hoc analysis included APR-treated pts in ModDA or HDA with available cDAPSA data at BL and Week 52 who exhibited any of the PsA manifestations at BL, including skin-involved body surface area (BSA) ≥3%, Maastricht Ankylosing Spondylitis Entheses Score (MASES) >0, or dactylitis count >0. Pts were divided into 4 subgroups based on number of manifestations: ≥1, only 1, any 2, or all 3. The proportions of pts who shifted across ModDA (>13 to ≤27) and HDA (>27) cDAPSA categories at BL to REM (≤4) and LDA (>4 to ≤13) treatment targets at Week 52 were calculated (data as observed).

Results: In 176 PALACE 4 pts with PsA receiving APR, 165 had involvement in ≥1 PsA manifestation in addition to peripheral arthritis (ie, skin/enthesitis/dactylitis) at BL. This population had a mean age of 48.8 years, PsA duration of 3.6 years, Psoriasis Area and Severity Index (PASI) score of 6.6, MASES of 3.8, and dactylitis count of 3.5 (Table 1). Within this subgroup, 32.7% had only 1 of these non-arthritic PsA manifestations, 50.9% had any 2, and 16.4% had all 3. In pts with ≥1 manifestation, a greater proportion in ModDA achieved REM/LDA at Week 52 than those in HDA (66.7% vs 32.2%; risk difference: 0.34) (Figure 1). Similarly, greater rates of treatment target achievement were observed in subgroups of pts in ModDA vs HDA and only 1 (72.2% vs 39.1%; risk difference: 0.33), any 2 (57.1% vs 28.6%; risk difference: 0.29), or all 3 (75.0% vs 33.3%; risk difference: 0.42) PsA manifestations (Figure 1).

Conclusion: In DMARD-naive pts exhibiting various non-arthritic manifestations of active PsA (ie, skin/enthesitis/dactylitis), those in ModDA at BL were more likely to achieve cDAPSA REM or LDA at Week 52 of APR treatment than pts in HDA. This observation was consistent whether pts had only 1 or multiple manifestations. These findings are consistent with the probability of achieving treatment targets demonstrated in the overall population in PALACE 4 (61.7% ModDA vs 28.2% HDA).

SLEEP QUALITY IN PATIENTS WITH PSORIATIC ARTHRITIS

P. Benzin[1], Z. R. Stisen[1], M. Skougaard[1], T. Schjødt Jørgensen[1], R. L. Hansen[1], L. M. Perez-Chada[2], M. Mogensen[3], J. F. Merola[2], L. E. Kristensen[1]. [1]*Parker Institute, Clinical Research Unit, Frederiksberg, Denmark*; [2]*Brigham And Women's Hospital, Department of Dermatology and Department of Medicine, Division of Rheumatology, Boston, United States of America*; [3]*Bispebjerg and Frederiksberg Hospital, Department of Dermatology, København, Denmark*

Background: Psoriatic arthritis (PsA) is a chronic immune-mediated inflammatory disease. It has a heterogeneous clinical presentation with main features being joint swelling and pain, skin and nail psoriasis, enthesitis, and dactylitis. Self-reported outcomes such as quality of sleep and fatigue are often neglected topics although having great impact on patients' everyday lives.

Objectives: The primary objective was to analyze the prevalence of PsA patients suffering from poor quality of sleep, defined by Pittsburgh Sleep Quality Index (PSQI) score ≥ 5, and to study the association between being a good or poor sleeper and clinical- and patient-reported outcomes.

Secondary, the effects on outcomes after initiation of treatment.

Methods: Patient characteristics, disease activity and self-reported outcomes were obtained from the PIPA cohort. To evaluate the primary objective, a cross-sectional analysis was conducted including PSQI score at baseline and corresponding data. Patients were divided into two groups, defined as good or poor sleepers (Table 1).

Data from initiation of treatment (baseline) and 4 months follow-up were included when assessing the effect of treatment. Transition of good and poor sleepers from baseline to 4 months follow-up was depicted by a chi-squared test.

A crosstab analysis was performed with baseline PSQI and whether they had widespread pain to investigate a possible link, additionally a Mann-Whitney U test.

Results: From January 2018-November 2020 a total of 109 patients were included. The prevalence of PsA patients suffering from poor quality of sleep at baseline were 66.1% whereas the remaining 33.9% were deemed good sleepers. There was no statistically significant difference in patient demographics when comparing good and poor sleepers at baseline. There was a statistically significant difference in patient-reported outcomes such as Visual Analogue Scale (VAS) pain, VAS global, Health Assessment Questionnaire (HAQ) score and Disease Activity Score (DAS28-CRP), with poor sleepers scoring higher.

57 patients had complete data at 4 months follow-up. At baseline 71.9% of them were classified as poor sleepers (Figure 1). A chi-squared test presented the transition at 4 months follow-up. 47.4% of the patients were now classified as poor sleepers.

While 27 poor sleepers became good sleepers, 13 good sleepers became poor sleepers, with data being statistically significant (p 0.001).

The crosstab analysis exposed 75 patients without widespread pain (mean 7.13±3.79) and 31 patients with widespread pain (mean 9.52±4.93).

Baseline PSQI and whether the patients had widespread pain was statistically significant (p 0.018).

Conclusion: Overall, PsA patients with poor quality of sleep have higher levels in terms of self-reported pain and disease activity.

The amount of good sleepers after 4 months increased, but there was a negative transition of patients going from good to poor sleepers. This could indicate that more factors are important for quality of sleep, e.g. sociopsychological aspects like anxiety, depression, ability to work.

Table 1. Patient characteristics

	Total n = 109	Good sleepers PSQI ≤ 5 n = 37		Poor sleepers PSQI > 5 n = 72

IMPACT OF ADALIMUMAB VERSUS NON-BIOLOGIC THERAPY ON CLINICAL AND PATIENT-REPORTED OUTCOMES IN PSORIATIC ARTHRITIS OVER 24 MONTHS – RESULTS OF THE COMPLETE-PsA CANADIAN OBSERVATIONAL STUDY

M. Khraishi[1], S. Silverberg[2], Y. Setty[3], M. C. Laliberté[4], L. Bessette[5]. [1]*Memorial University of Newfoundland, Memorial University of Newfoundland, St. John's, Canada*; [2]*Etobicoke General Hospital, Etobicoke General Hospital, Toronto, Canada*; [3]*Grey Bruce Health Services, Grey Bruce Health Services, Owen Sound, Canada*; [4]*AbbVie Corporation, Montreal, AbbVie Corporation, Montreal, Montreal, Canada*; [5]*Laval University, Centre Hospitalier de l'Université Laval, Laval University, Centre Hospitalier de l'Université Laval, Quebec City, Canada*

Background: COMPLETE-PsA was a Canadian observational study of biologic-naïve adults with active psoriatic arthritis (PsA) treated with adalimumab (ADA) or conventional systemic disease-modifying anti-rheumatic drugs (csDMARDs) after switch from a previous conventional therapy.

Objectives: To compare the impact of ADA vs csDMARDs on clinical and patient-reported outcomes due to PsA over 24 months.

Methods: Eligible patients were biologic naïve adults with active PsA who required change in their treatment due to inadequate response or non-tolerance, as per treating physician judgement. Patients were enrolled between July/2011 and December/2017 and followed for a maximum 24 months. Treatment was as per routine care. Outcome measures included tender/swollen joint count (TJC/SJC), morning stiffness (min/day), patient's global assessment of disease activity (PtGA) and pain (both 100 mm VAS), quality of life (DLQI), and functional disability (HAQ-DI). Outcome changes over time were evaluated using multivariable models adjusting for baseline measures. Achievement of modified minimal disease activity [mMDA, 5/7 of: TJC and SJC ≤1 each, psoriasis BSA ≤3%, pain ≤15 (VAS, mm), PtGA ≤20, HAQ-DI ≤0.5, and no enthesitis], and presence of enthesitis and dactylitis, were assessed descriptively. Analyses were conducted in the intent-to-treat population.

Results: A total of 277 ADA and 148 csDMARD-treated patients were included in the analysis. At baseline, 61.7% of ADA and 81.1% of csDMARD patients reported concomitant methotrexate. Compared to the csDMARD group, ADA-treated

patients demonstrated significantly (p<0.05) greater baseline disease severity with respect to mean (SD) joint count [TJC: 8.9 (6.2) vs. 7.4 (6.6); SJC: 7.4 (5.0) vs. 5.9 (4.6)], morning stiffness [83.5 (98.2) vs. 61.8 (77.4) min/day], PtGA [56.1 (24.1) vs. 45.1 (24.7) mm], pain [58.5 (24.3) vs. 50.1 (24.0) mm], DLQI scores [6.1 (6.9) vs. 4.3 (5.3)] and HAQ-DI [1.1 (0.6) vs. 0.8 (0.6)]. The rate of baseline mMDA was slightly lower for ADA patients (4.3% vs. 7.4%; p=0.178). Baseline prevalence of enthesitis was comparable (ADA: 28.4% vs. csDMARD: 23.4%; p=0.276), while dactylitis was significantly more prevalent for csDMARD patients (26.2% vs. 36.3%; p=0.031).

Overall effect of treatment group, over 24 months, significantly (p<0.05) favored the ADA vs. csDMARD-treated patients for TJC [estimate (95%CI): -2.4 (-3.4, -1.4)] SJC [-1.8 (-2.5, -1.2)], PtGA [-3.7 (-9.3, 1.9)], DLQI [-1.5 (-2.5, -0.5)], and HAQ-DI [-0.1 (-0.2, 0.0)] (Figure 1). There was no significant difference for morning stiffness and pain.

At month 24, statistically comparable (p>0.05) baseline-adjusted values (the least square means: LSM) were observed for ADA- vs. csDMARD-treated patients for TJC [LSM (95%CI): 1.8 (1.2, 2.4) vs. 3.0 (2.1, 3.8)], SJC [1.2 (0.8, 1.7) vs. 2.1 (1.5, 2.7)], morning stiffness [32.4 (19.1, 45.6) vs. 29.9 (11.1, 48.6) min/day], PtGA [31.6 (28.1, 35.2) vs. 36.9 (31.8, 41.9) mm], pain [35.3 (31.5, 39.0) vs. 38.4 (33.1, 43.7) mm], DLQI [2.9 (2.2, 3.6) vs. 2.9 (2.0, 3.8)], and HAQ-DI [0.7 (0.6, 0.8) vs. 0.9 (0.8, 1.0)].

Achievement of mMDA at month 24 was reported by 34.1% and 34.9% of ADA- and csDMARD-treated patients, respectively (p=0.892). Rates of dactylitis (10.6% vs. 10.0%) and enthesitis (9.6% vs. 14.4%) were comparable in the ADA vs. csDMARDs groups respectively.

Conclusion: The results of this real-world Canadian study indicate a physician selection bias for treatment with ADA for PsA patients with more severe disease burden, indicated by greater baseline disease activity and PROs. ADA-treated patients experienced a greater treatment effect over 24 months compared to csDMARD-treated patients. However, despite the greater treatment effect of ADA, residual disease burden in the two groups was comparable at 24 months.

AB0556 COMPARING EFFICACY OF GUSELKUMAB VERSUS USTEKINUMAB IN PATIENTS WITH PSORIASIS ARTHRITIS: AN ADJUSTED COMPARISON USING INDIVIDUAL PATIENT DATA FROM DISCOVER 1&2 AND PSUMMIT TRIALS

J. Diels[1], P. Thilakarathne[2], A. Schubert[3], F. Hassan[4], S. Peterson[5], W. Noel[1]. [1]*Janssen Pharmaceutica, HEMAR Department, Beerse, Belgium*; [2]*JanssenCilag Ltd, HEMAR Department, Beerse, Belgium*; [3]*Janssen-Cilag Poland, HEMAR Department, Warsaw, Poland*; [4]*Janssen-Cilag Ltd, HEMAR Department, High Wycombe, United Kingdom*; [5]*Janssen Global Services, LLC, Janssen Immunology Global Commercial Strategy Organization, Raritan, NJ, United States of America*

Background: Guselkumab is an anti-interleukin (IL)-23 monoclonal antibody recently approved for a treatment of Psoriasis arthritis (PsA). In two large Phase III trials of patients with PsA (DISCOVER -1 & -2) guselkumab has shown to be superior versus placebo. In this indication no direct comparison is available between guselkumab and ustekinumab, a monoclonal antibody targeting IL-12 and IL-23. Indirect comparisons based on relative treatment effects versus a common comparator (placebo) only allow for analyses up to week 24 due to cross-over to active arms in available PsA trials.

Objectives: To compare indirectly joint and skin efficacy of guselkumab versus ustekinumab up to week 52, using pooled patient-level trial data from DISCOVER 1&2 and PSUMMIT 1&2, adjusting for cross-trial population differences.

Methods: Patient level data, including baseline characteristics and outcome data on American College of Rheumatology (ACR) response, Psoriasis Area Severity Index (PASI) response from the guselkumab arms of DISCOVER -1 & -2 were pooled with the data from the ustekinumab trials PSUMMIT -1&-2. Analyses were performed for bio-naïve and bio-experienced populations separately. Differences in patient characteristics across trial populations were adjusted for using multivariate logistic regression, including: gender, age, body mass index, previous TNF use, disease duration, PASI level, number of swollen and tender joints. This method of indirect comparisons allows for analysis of comparative efficacy beyond controlled induction period and odds ratios' resulting from this model were translated into predicted response rates for ustekinumab, assuming same patient population, as enrolled in the guselkumab trial arms.

Results: Majority of baseline characteristics for patients on guselkumab (100mg q8w; 100mg q4w) were comparable to patients on ustekinumab 45/90mg, in both in bio-naïve and bio-experienced group of patients. The probability of reaching a ACR 20 in both the bio-naïve & bio-experienced population was significantly higher for guselkumab vs ustekinumab at weeks 52 for both dosing regimens of guselkumab (bio-naïve ACR 20: q8w OR= 1.88 [1.28;2.76]), q4w (OR= 1.92 [1.29;2.86]; bio experienced ACR20 q8w OR= 2.72[1.17;6.31], q4w OR=4.77 [1.95;11.63]). Similarly guselkumab was superior over ustekinumab on PASI 90 outcome at week 52 in both bio-naïve & bio-experienced patients with BSA ≥3 % at baseline (bio-naïve: q8w OR= 2.59 [1.68;3.99]), q4w OR= 3.19 [2.03;5.00], and bio-experienced q8w OR= 3.96[1.39,11.27], q4w OR=13.10[4.18,41.04]). Figure 1 represents unadjusted pooled DISCOVER 1&2 trial results and estimated proportions of ustekinumab treated patient group achieving ACR 20 in bio-naïve patient group up to week 52 using the method described above.

Conclusion: An adjusted comparison using patient level data from pivotal Phase III studies demonstrates both dosages of guselkumab to be significantly more effective versus ustekinumab in both skin and joint outcomes in both bio-naïve & bio experienced patients up to week 52.

AB0557 ACHIEVING TREATMENT TARGETS IN PSORIATIC ARTHRITIS WITH APREMILAST IN CANADIAN PRACTICE: REAL WORLD RESULTS FROM APPRAISE

V. Chandran[1], L. Bessette[2], C. Thorne[3], M. Sheriff[4], P. Rahman[5], D. D. Gladman[1], S. Anwar[6], J. Jelley[7], A. J. Gaudreau[7], M. Chohan[7], J. S. Sampalis[8]. [1]*Schroeder Arthritis Institute, Rheumatology, Toronto, Canada*; [2]*Laval University, Rheumatology, Quebec City, Canada*; [3]*Southlake Regional Health Centre, Rheumatology, Newmarket, Canada*; [4]*Nanaimo Regional General Hospital, Rheumatology, Nanaimo, Canada*; [5]*Memorial University of Newfoundland, Rheumatology, New Foundland, Canada*; [6]*Windsor Regional Hospital, Rheumatology, Windsor, Canada*; [7]*Amgen Canada Inc., Global Medical Affairs, Mississauga, Canada*; [8]*McGill University and JSS Medical Research, Epidemiology, Montreal, Canada*

Background: Real-world evidence on achieving treatment targets with apremilast (APR) in patients (pts) with PsA is limited. In the phase 3 PALACE trials, pts reached remission (REM)/low disease activity (LDA) targets at 52 wks most frequently when early APR treatment was initiated and pts were in moderate disease activity, as measured by Clinical Disease Activity Index for PsA (cDAPSA) score. In APPRAISE, we assessed APR effectiveness/tolerability in pts with PsA in routine clinical practice in Canada.

Objectives: This interim efficacy analysis focused on the available data on APR effectiveness measuring rate of achieving cDAPSA REM or LDA at 12 mos and Pt Acceptable Symptom Status (PASS) results.

Methods: The prospective, multicenter, observational APPRAISE study assessed APR effectiveness/tolerability in adults with active PsA in routine clinical care enrolled from July 2018-March 2020. Pts were followed from treatment initiation to 12 mos, with visits suggested every 4 mos. The primary effectiveness endpoint was the rate of achieving at least LDA (cDAPSA <14) at 12 mos. Pt-reported outcome measures were assessed. Data reported are as observed in pts continuing APR treatment.

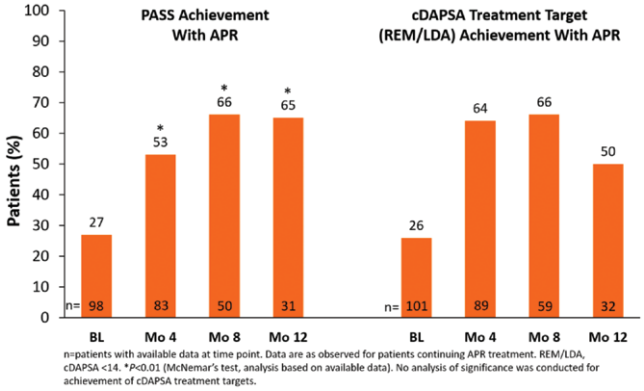
Results: In total, 101 pts were enrolled in APPRAISE. Mean age was 52 yrs; 56% were women. Mean (SD) PsA duration at baseline (BL) was 6 (8) yrs. Oligoarticular disease (≤4 joint involvement) was most common (41%), followed by polyarticular (35%). Most pts (92%) received prior conventional DMARDs and 17% received prior biologic therapy; concomitant MTX was reported in 41% at BL. By 12 mos, 41/101 enrolled pts discontinued, 35 reached 12 mos follow-up (4 mos: n=92; 8 mos: n=61), and 25 have yet to reach 12 mos. The majority (92%) of discontinuations due to lack/loss of effectiveness or AEs occurred within 4-8 mos. AEs were primarily GI related early in treatment. The proportion of pts with continued APR achieving cDAPSA REM/LDA treatment targets increased significantly over time (Figure 1). Significant reductions were seen over 12 mos in swollen/tender joint counts and plaque psoriasis, with reduced mean (SD) body surface area of –4% (9%) (Table 1). Prevalence of dactylitis/enthesitis at BL, 4, 8, and 12 mos was 17%/33%, 9%/24%, 5%/19%, and 0%/21%, respectively. Pain assessment (VAS) significantly improved over time. The proportion of pts achieving PASS with continued APR increased significantly over 12 mos (BL: 27%; 12 mos: 65%) (Figure 1). COVID restrictions impacted in-office assessment visits, necessitating reliance on virtual visits.

Conclusion: Pts with PsA receiving APR were assessed at regular intervals in routine clinical care in Canada. This interim analysis revealed a greater number of pts receiving APR (66%) who completed the 12-mo follow-up achieved REM or LDA, as measured by cDAPSA over 12 mos. A majority of pts (65%) reported satisfaction with their disease state, as measured by PASS. No new safety signals were observed.

Table 1. Change in Clinical Parameters and Pt-Reported Outcomes From BL to 4, 8, and 12 Mos

Outcome Measure*, Mean (SD)	BL (n = 101)	4 Mos (n = 92)	8 Mos (n = 61)	12 Mos (n = 35)
Disease/Clinical Parameters				
Tender joint count (0-68)	7.5 (6.7)	–2.5 (6.3)*	–3.9 (5.2)*	–2.2 (6.4)
Swollen joint count (0-66)	5.4 (5.4)	–3.0 (4.5)*	–3.1 (4.3)*	–3.1 (4.4)*
PhGA	42.9 (18.8)	–19.0 (24.6)*	–24.2 (24.2)*	–21.2 (26.3)*
Body surface area, %	3.1 (6.1)	–2.2 (6.0)*	–2.7 (7.5)*	–4.2 (9.1)*
cDAPSA	22.2 (13.3)	–7.9 (12.1)*	–10.1 (13.5)*	–6.9 (12.0)*
Pt-Reported Outcomes				
PtGA, mm	50.0 (24.6)	–10.2 (27.5)*	–9.1 (31.9)*	–3.6 (39.7)
Pain, mm	48.3 (25.3)	–9.5 (26.2)*	–12.2 (28.7)*	–7.3 (26.0)
HAQ-DI	0.9 (0.7)	–0.13 (0.5)*	–0.15 (0.6)	–0.1 (0.7)

*Denotes significant change from BL ($P<0.05$) from paired-sample *t*-tests; note that mean change from BL may be greater than the mean BL value when improvements of large magnitude, for pts with relatively elevated BL values, are observed in samples with lower n's. HAQ-DI = Health Assessment Questionnaire-Disability Index; PhGA = Physician's Global Assessment; PtGA = Patient's Global Assessment.



n=patients with available data at time point. Data are as observed for patients continuing APR treatment. REM/LDA, cDAPSA <14. *$P<0.01$ (McNemar's test, analysis based on available data). No analysis of significance was conducted for achievement of cDAPSA treatment targets.

AB0558

CLINICAL EFFECTIVENESS AND SAFETY OF ADALIMUMAB VERSUS NON-BIOLOGIC THERAPY IN PSORIATIC ARTHRITIS PATIENTS OVER 24 MONTHS – RESULTS OF THE COMPLETE-PsA CANADIAN OBSERVATIONAL STUDY

M. Khraishi[1], J. Stewart[2], Y. Setty[3], M. C. Laliberté[4], L. Bessette[5]. [1]*Memorial University of Newfoundland, Memorial University of Newfoundland, St. John's, Canada*; [2]*University of British Columbia, University of British Columbia, Penticton, Canada*; [3]*Grey Bruce Health Services, Grey Bruce Health Services, Owen Sound, Canada*; [4]*AbbVie Corporation, AbbVie Corporation, Montreal, Canada*; [5]*Laval University, Centre Hospitalier de l'Université Laval, Laval University, Centre Hospitalier de l'Université Laval, Quebec City, Canada*

Background: COMPLETE-PsA was an observational study of biologic-naïve Canadian adults with active psoriatic arthritis (PsA) treated with adalimumab or non-biologic disease-modifying anti-rheumatic drugs (nbDMARD) after switch from initial therapy.

Objectives: The aim of this analysis was to assess the 24-month clinical effectiveness and safety of adalimumab vs. nbDMARD in the treatment of PsA in a real-life setting.

Methods: Eligible patients were biologic naïve adults, with active PsA who required change in their treatment regimen due to inadequate response or intolerance, per the judgment of the treating physician. Patients were enrolled between July/2011 and December/2017 and followed for up to 24 months. Patients were treated as per routine care. The primary endpoint, change in DAS-28 to month 24, was assessed with baseline-adjusted multivariable models and the least square mean (LSM) estimates were generated; Physician's Global Assessment of disease activity (PGA, 100mm VAS) was assessed using similar methodology. Probability of achieving the following therapeutic response thresholds was ascertained and odds ratios (ORs) were generated: 50%/70% improvement in the American College of Rheumatology criteria (ACR50/ACR70), DAS-28<3.2 (low disease activity or remission; LDA/remission), DAS-28<2.6 (remission), modified minimal disease activity (mMDA: achievement of 5/7 of: TJC and SJC ≤1 each, BSA ≤3%, pain ≤15 (VAS, mm), Patient Global Assessment [PtGA] ≤20, HAQ-DI ≤0.5, and no enthesitis), and psoriasis (PsO) BSA <3%.

Results: A total of 277 adalimumab and 148 nbDMARD- treated patients were included as part of the intent-to-treat population. Baseline methotrexate was reported by 61.7% and 81.1% of adalimumab and nbDMARD-treated patients, respectively. PsO BSA at baseline was predominantly <3% for both adalimumab (60.2%) and nbDMARD (64.6%) patients. Adalimumab-treated patients reported significantly ($p<0.05$) higher mean (SD) disease activity for both DAS-28 [4.8 (1.2) vs. 4.3 (1.1)] and PGA [59.4 (19.5) vs. 51.0 (21.8) mm] at baseline.

For the primary endpoint, baseline-adjusted month 24 DAS-28 levels were significantly lower for adalimumab vs. nbDMARD patients [LSM (95%CI): 2.4 (2.2-2.6) vs. 3.0 (2.7-3.3); p=0.037]. In addition, rapid and sustained reductions in DAS-28 were observed for adalimumab-treatment patients, with overall treatment effect significant ($p<0.001$) in favor of adalimumab [estimate (95%CI): -1.1 (-1.4, -0.7)]; similar results were observed for PGA [-12.9 (-1.7, -8.0)]. Adalimumab-treated

patients were at significantly higher (p<0.001) odds of attaining therapeutic response thresholds compared to DMARD-treated patients, specifically: DAS-28 LDA/remission [OR (95%CI): 4.5 (2.8, 7.3)] or remission [OR (95% CI): 4.1 (2.7-6.3)], ACR50 [OR (95% CI): 3.0 (2.0-4.6)], ACR70 [OR (95% CI): 3.1 (2.0-4.9)], mMDA [OR (95% CI): 2.4 (1.6-3.6)], and PsO BSA <3% [OR (95% CI): 2.2 (1.2-3.7)].

Overall, 32 (10.7%) of adalimumab-treated patients reported 86 AEs, the most common related to infections [16 events in 10 (3.3%) patients].

Conclusion: Real-world treatment with adalimumab was more effective in improving disease activity and psoriasis severity, over 24 months when compared to nbDMARDs and was associated with significantly greater likelihood of achieving minimal disease activity. Observed AEs were consistent with the established safety profile of adalimumab.

Background: Risankizumab (RZB) is a humanized immunoglobulin G1 monoclonal antibody that specifically inhibits interleukin 23 by binding to its p19 subunit. RZB is being investigated as a treatment for adults with psoriatic arthritis (PsA).

Objectives: To compare the efficacy and safety of RZB vs placebo (PBO) for the treatment of active PsA in patients who have had inadequate response or intolerance to ≥ 1 conventional synthetic disease modifying antirheumatic drug (csDMARD-IR).

Methods: In KEEPsAKE 1 (NCT03675308), eligible adults (csDMARD-IR with ≥ 5 swollen joints [SJC] and ≥ 5 tender joints [TJC]) were randomized (1:1) to receive blinded subcutaneous RZB 150 mg or PBO at weeks 0, 4, and 16. The primary endpoint was the proportion of patients achieving 20% improvement in American College of Rheumatology score (ACR20) at week 24. Ranked secondary and other secondary endpoints are shown in the Table 1. Safety was assessed throughout the study. Results reported here are from the 24-week double-blind period; the open-label period with all patients receiving RZB is ongoing.

Results: 964 patients (RZB, N = 483; PBO, N = 481) were evaluated at week 24. Demographics and baseline characteristics were generally balanced between treatment groups (mean duration of PsA: 7.12 years; mean SJC: 12.2; mean TJC: 20.6; mean body surface area involved with psoriasis [BSA] in patients with BSA ≥ 3%: 16.7%). A significantly greater proportion of RZB- vs PBO-treated patients (57.3% and 33.5%, respectively) achieved the primary endpoint of ACR20 at week 24 (P < .001; Table 1). Significant differences were also observed for RZB vs PBO for the first 8 ranked secondary endpoints (P < .001 for all; Table 1). Serious adverse events were reported for 2.5% and 3.7% of RZB- and PBO-treated patients, respectively; serious infections were reported for 1.0% and 1.2%. There was 1 death in the RZB group.

Conclusion: RZB resulted in significantly greater improvements in signs and symptoms of PsA compared with PBO and was well tolerated in patients who were csDMARD-IR.

Table. Efficacy Results

	RZB 150 mg N = 483	PBO N = 481	Difference (95% CI)	*P* value
Primary endpoint				
ACR20, %	57.3	33.5	24.0 (18.0, 30.0)	< .001***

Background: Tyrosine kinase 2 (TYK2) is an intracellular kinase that mediates IL-23, IL-12, and IFNα/β signaling. Deucravacitinib is a novel, oral selective inhibitor of TYK2 via the TYK2 regulatory domain. Phase 2 results showed deucravacitinib was efficacious and well tolerated versus placebo (PBO) in patients (pts) with active psoriatic arthritis (PsA). The Psoriatic Arthritis Impact of Disease (PsAID) questionnaire is a EULAR-developed, validated instrument designed to specifically assess the impact of PsA on health-related quality of life (HRQoL) from the pt's perspective and is available as separate versions for clinical practice (PsAID-12) and clinical trials (PsAID-9).[1]

Objectives: To compare the effect of deucravacitinib vs PBO on PsAID-12 and PsAID-9 responses and to assess relationships between PsAID scores and clinical and pt-reported outcome (PRO) measures.

Methods: This is an ongoing, 1-year, double-blind, Phase 2 trial (NCT03881059). Pts with active PsA were randomized 1:1:1 to deucravacitinib 6 mg or 12 mg once daily, or PBO for 16 weeks (wk). PsAID-12 and PsAID-9, other PROs, and clinical response outcomes were assessed at baseline (BL) and Wk 16. Mean changes from BL in PsAID-12 and PsAID-9 total scores at Wk 16 were determined for each treatment group as well as by response outcomes (ie, achievement of response at Wk 16 for PROs and select clinical response outcomes; Table 1). Spearman correlations between PsAID-12 and PsAID-9 scores and clinical and PRO measures were also assessed.

Results: 203 pts were randomized and BL characteristics were similar across groups. Adjusted mean changes from BL in PsAID-12 and PsAID-9 scores at Wk 16 were significantly greater in the deucravacitinib groups vs PBO (Figure 1). Adjusted mean changes from BL in PsAID-12 and PsAID-9 scores at Wk 16 were significantly improved with deucravacitinib vs PBO in pts who achieved response for PROs, as well as PASDAS low disease activity and PASI 75 response (Table 1). Adjusted mean changes from BL were generally similar with deucravacitinib vs PBO in nonresponders. Spearman correlation analysis revealed significant correlations at BL and Wk 16 between PsAID-12 and PsAID-9 scores and clinical and PRO measures (P<0.0001).

Conclusion: With deucravacitinib vs PBO, PsAID-12 and PsAID-9 scores were significantly improved vs BL at Wk 16. PsAID detected additional improvements among pts achieving response for multiple other PROs and select clinical outcome measures.

Background: Several factors such as effectiveness, safety and compliance affect the drug survival in chronic disorders. Physicians take care of long-term retention rate and responses for discontinuation of candidate drug. Identification of predictors of clinical response to certolizumab-pegol (CZP) may aid the decision-making process for treating patients psoriatic arthritis (PsA).

Objectives: The purpose of this study to assess the drug survival of certolizumab pegol (CZP) in patients with PsA and to identify the predictors and reasons for discontinuation.

Methods: Data on patient characteristics, demographics, diagnosis, disease duration, treatment and outcomes have been collected since 2011 in Turkish Biologic (TURKBIO) Registry. By the end of December 2020, 68 PsA patients received CZP and were included. Kaplan Meier plot was used for drug survival analysis. Cox regression analysis was performed to evaluate the predictors associated with drug survival.

Results: During the median 47 months follow-up, 17 patients discontinued the CZP treatment. The reasons for discontinuation were ineffectivity (35.3%), adverse event (17.6%) and pregnancy (5.9%). The baseline characteristics of the patients who continued and discontinued CZP were shown in the Table 1. Patients who discontinued CZP had higher mean age and disease duration. HLA-B27 positive patients had lower retention rate while bDMARD naive patients had higher retention rate. At the month 36, retention rate of CZP was 61.6% on patients with PsA (Figure 1).

Conclusion: Real life experience from this nationwide TURKBIO registry show that the retention rate of CZP in PsA are lower in older patients and with longer disease duration. Moreover, bDMARD naive patients have higher retention rate.

Background: Psoriatic Arthritis (PsA) displays increased traditional cardiovascular (CV) risk factors, such as insulin resistance (IR), metabolic syndrome or obesity. Thus, it is an urgent need to treat and manage these

cardiometabolic comorbidities associated. Some evidence points out that methotrexate could improve CV risk due to its anti-inflammatory properties, however the effect of PDE4 inhibitor treatment on CV risk have not been elucidated yet.

Objectives: 1) To evaluate the effect of conventional therapy and PDE4 inhibitor in PsA patients with high prevalence of cardiometabolic comorbidities. 2) To identify a molecular patient profile susceptible of being benefit from each therapy regarding disease activity and CV risk.

Methods: Thirty biological-naïve patients with PsA were treated with the PDE4 inhibitor (Apremilast), Methotrexate or combined therapy (Apremilast and Methotrexate) following the clinical routine practice for 6 months. A cohort of 30 age and sex-matched healthy donors (HDs) was included. Plasma and peripheral blood mononuclear cells (PBMCs) were isolated from peripheral blood of patients and HDs. Different parameters related to the cardiometabolic risk were analyzed, including: atherogenic index, ratio apolipoprotein B (apo B)/apolipoprotein A (apo A), insulin resistance (IR), metabolic syndrome, obesity, arterial hypertension, and the SCORE. Clinical and analytical parameters were collected: lipid profile (total cholesterol, HDL-cholesterol, LDL-cholesterol, triglycerides, apo A and apo B), glucose and insulin, body surface area (BSA) affected by psoriasis, number of tender and swollen joints, DAPSA, C-reactive protein and erythrocyte sedimentation rate. A panel of 92 proteins involved in cardiovascular disease (cardiovascular panel II, Olink) and an adipocytokine profile was measured in plasma and PBMCs. Hard cluster analysis was carried out in order to identify two distinctive molecular phenotypes depending on the treatment response related to the reduction of CV risk.

Results: Among the 92 CV-related proteins, the higher levels of two molecules, CD163 and FABP4 observed in PsA patients compared to HDs, were strongly associated with elevated rates of CV risk factors such as apolipoprotein B/A and atherogenic risks, metabolic syndrome, obesity, IR, arterial hypertension and smoking. Thus, we could identify two clinical profiles of patients according to the plasma levels of these molecules: cluster 1 defined by 20 patients with low levels of CD163 and FABP4 and low prevalence of CV comorbidities and cluster 2 defined by 10 patients with high levels of CD163 and FABP4 and high prevalence of CVD comorbidities. Regarding cluster 2, those patients that were treated with Apremilast or combined therapy had a significant reduction of CD163 and FABP4 associated with a drop in total cholesterol, apo B, IR state and body mass index. In addition, both PDE4 inhibitor and combined treatment reduced activity disease. However, Methotrexate in monotherapy did not show a beneficial effect in PsA patients displaying higher levels of CD163, FABP4, total cholesterol and no changes in disease activity after treatment. In regard to cluster 1, the three therapy strategies reduced disease activity after 6 months. Even with low rates of comorbidities, those patients treated with Apremilast had reduced levels of total cholesterol and apolipoprotein B and body mass index after 6 months of therapy. However, no changes were observed in the treatment with Methotrexate or Methotrexate combined with Apremilast.

Conclusion: 1- CD163 and FABP4 could be considered as potential biomarkers of treatment efficacy regarding cardiometabolic comorbidities. 2- Apremilast might target metabolic alterations in PsA modulating lipid profile, insulin resistance and body mass index, decreasing the levels of surrogate CV-related molecules. 3- Apremilast treatment should be considered in PsA patients with higher rates of cardiometabolic comorbidities.

AB0563 DISCONTINUATION OF ANTI-TNFA IN PATIENTS WITH PSORIATIC ARTHRITIS: A SINGLE-CENTER EXPERIENCE

D. Graceffa[1], V. Lora[1], A. Cristaudo[1], F. Elia[1], A. Morrone[1], C. Bonifati[1]. [1]*San Gallicano Dermatological Institute, IRCCS, Clinical Dermatology, Rome, Italy*

Background: TNF inhibitors have been largely demonstrated to be effective and reasonably safe for the treatment of psoriatic arthritis (PsA). Current EULAR guidelines recommend the use of an anti-TNF as first choice treatment in patients with PsA for whom a synthetic DMARD (usually methotrexate or leflunomide) is not efficacious or not well tolerated [1]. In a scenario where biologic treatments are easily available, and the treat to target strategy is widely accepted, a complete disease remission or at least a minimal disease activity are considered realistic goals to be achieved in a growing proportion of patients [2]. However, there remains very little research regarding anti-TNF discontinuation in patients who achieved a complete remission [3-5].

Objectives: The primary aim of this study was to measure the disease-free interval after anti-TNF discontinuation, secondary it was investigated whether the use of Power Doppler Ultrasound (PDUS) and Contrast Enhanced Ultrasound (CEUS) could improve the diagnostic accuracy in the recognition of the relapse. Finally, we wanted to characterize the clinical features of the disease recurrence.

Methods: From June 2018, 35 patients with PsA (27 males and 8 female) treated with anti-TNF, in stable remission were prospectively monitored for 1 year after treatment discontinuation. Remission was defined as documented absence of clinical and ultrasonographic signs of arthritis or enthesitis. Complete rheumatological and dermatological examinations were performed in all participants, at baseline and every 8-12 weeks: American College of Rheumatology (ACR) 66-68 joint count; Psoriasis Area Severity Index (PASI); patient pain visual analog score (VAS); patient global disease activity VAS; Health Assessment Questionnaire (HAQ); Leeds Enthesitis Index (LEI); Bath Ankylosing Spondylitis Disease Activity Index (BASDAI); Bath Ankylosing Spondylitis Functional Index (BASFI); Power Doppler Ultrasound (PDUS) of the involved joints and entheses, Contrast Enhanced Ultrasound (CEUS) of a selected joint or enthesis and laboratory inflammation tests.

Results: 31 out of the 35 enrolled patients, experienced a disease recurrence with an average disease-free interval of 27.9±21.1 weeks (Figure 1). In 3 patients the treatment was restored for a relapse of the skin psoriasis, 8 patients reported only axial symptoms of disease relapse and 20 patients had both axial and peripheral joints involvement (average DAPSA score of 23.6±11.1; average BASDAI score of 4.7±2.6; average BASFI score 4.5±2.9). In all cases the disease flare was moderate and all patients promptly regained remission after restarting the treatment. Both PDUS and CEUS were safe and reliable showing a good percentage of accordance (95,4%) in detecting synovitis and enthesitis.

Conclusion: The rate of disease relapse of PsA after anti-TNF discontinuation is relevant. However the disease-free interval was not short. Retreatment with the same anti-TNF was effective and safe.

AB0564 RHEUMATOLOGISTS' VIEWS AND EXPERIENCES IN MANAGING PSA PATIENTS BASED ON TREATING TO TARGET STRATEGY: A CROSS-SECTIONAL STUDY IN CHINA

L. Xu[1], Z. Wang[1], J. Xue[1], M. Bai[1], H. Zhong[1], Y. Su[1]. [1]*Peking University People's Hospital, Department of Rheumatology and Immunology, Beijing, China*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis with progressive, erosive destruction associated with functional impairment. Principles of treat-to-target (T2T) have been widely used in rheumatoid arthritis, which has powerfully improved patient outcomes. In 2017, the concept of T2T has proposed to apply in PsA patients. However, the awareness and implementation of evidence-based T2T treatment guidelines varies across different geographical regions of China, hospital grades, professional status and specialities.
Objectives: The study aimed to investigate Rheumatologists' views and experiences in managing PsA patients with T2T strategy in china.
Methods: A cross-sectional questionnaire survey of Rheumatologists in China from 5 August to 15 August 2020 was conducted for this study. Rheumatologists were contacted by WeChat (a Chinese cell/web app) and asked to complete a web-based questionnaire anonymously. The electronic questionnaire was sent out by the internet platform of WenJuanXing via WeChat (https://www.wjx.cn/). The questionnaire was designed to collect: (a) demographic information; (b) patient management in clinical practice for Rheumatologists; (c) familiarity and application of T2T strategy in Rheumatologists. *P* values ≤0.05 were considered significant.
Results: (1) A total of 823 rheumatologists (69.87% female, 30.13% male) provided valid answers to the questionnaire. 71.09% of the participants major in Modern Western Medicine, 28.91% major in traditional chinese medicine. A total of 75.94% worked in Grade-A Tertiary Hospital. A total of 52.73% had more than 10 years of work experience and 63.55% had High-level title. **(2)** More than half of the patients were followed up by 69% Rheumatologists in their daily practice. The proportion of follow-up patients increased powerfully in the group of Rheumatologists who major in Modern Western Medicine (P=0.014), work in Grade-A Tertiary Hospital (P<0.001), have more than 10 years of work experience (P<0.001) and High-level title (P<0.001). **(3)** 36.45% Rheumatologist thought the frequency for patient disease activity assessment was every 1 month and 53.1% was every 3 months. And 41.7% Rheumatologist prefer to use PASDAS for disease activity criteria, and only 3.6% choose MDA. **(4)** A total of 62.43% thought they were familiar with T2T strategy, and 83.6% Rheumatologists applied T2T strategy in clinical practice. Among 135 Rheumatologists who did not apply T2T strategy, 62.2% of Rheumatologists thought that the main barrier to T2T application was that they did not fully understand the strategy. The frequency of application of T2T strategy in clinical practice was significantly different between Rheumatologists who major in Modern Western Medicine (60.75%) and traditional chinese medicine (22.84%) (P=0.023).
Conclusion: In china, the management of PsA patients need to be standardized to improve patient outcomes. And the promotion of T2T strategy in PsA need to be further strengthened.

AB0565 **JAK INHIBITORS AND PSORIATIC ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS**

F. Campanaro[1], A. Zaffaroni[2], A. Batticciotto[1], A. Cappelli[1], M. P. Donadini[3], A. Squizzato[3]. *[1]ASST Sette laghi, Ospedale Di Circolo - Fondazione Macchi, Rheumatology Unit, Internal Medicine Department, Varese, Italy*; *[2]University of Varese Insubria, Department of Medicine and Surgery, Varese, Italy*; *[3]University of Varese Insubria, Department of Medicine and Surgery, Research Center on Thromboembolic Diseases and Antithrombotic Therapies, Varese, Italy*

Background: Despite the therapeutic armamentarium for the treatment of psoriatic arthritis (PsA) has considerably expanded over the last thirty years, there is a huge necessity of finding effective drugs for this disease. JAK inhibitors (JAKi) are small molecules able to interfere with the JAK/STAT pathway, involved in the pathogenesis of PsA (1). Up to now Tofacitinib is the only JAKi approved by the European Medicines Agency (EMA) for the treatment of PsA but in the next few years the number of approved JAKi is expected to rise significantly.
Objectives: To assess the efficacy and safety of different JAKi for the treatment of PsA.
Methods: A systematic review of the literature was performed to identify randomized controlled trials (RCTs), by electronic search of MEDLINE and EMBASE database until October 2020. Studies were considered eligible if they met the following criteria: I) study was a RCT; II) only patients with PsA were included; III) JAKi was compared to placebo in addition to the standard of care. Two reviewers (FC and AZ) performed study selection, with disagreements solved by the opinion of an expert reviewer (AS). The outcomes were expressed as odds ratio (OR) and 95% confidence intervals (95% CI). Statistical heterogeneity was assessed with the I^2 statistic.
Results: We identified 557 potentially relevant studies. A total of 554 studies were excluded based on title and/or abstract screening. Three RCTs for a total of 947 PsA patients treated with JAKi were included (2,3,4). Two were phase III studies on the efficacy and safety of Tofacitinib (OPAL Beyond and OPAL Broaden) and one was a phase II study on Filgotinib (Equator). All three studies were judged at low risk of bias according to Cochrane criteria (5). The primary efficacy outcome in all the studies was the number of patients who achieved the response rate of the American College of Rheumatology 20 score (ACR20). The outcomes evaluation was performed at 12 week for the Filgotinib trial and at 16 week for the Tofacitinib trials. We used for the main analyses the group of patients randomized to Tofacitinib 5 mg because this is the only dosage approved by the EMA for the treatment of PsA. JAKi showed a significantly higher ACR20 response rate compared to placebo (OR 3.54, 95% CI 1.76 - 7.09, I^2 = 74%). JAKi also showed a significantly higher ACR50 response rate (OR 3.36, 95% CI 2.22 - 5.09, I^2 = 0%), ACR70 response rate (OR 2.82, 95% CI 1.67 - 4.76, I^2 = 20%), PsARC response rate (OR 2.67, 95% CI 1.26 - 5.65, I^2 = 79%), PASI75 response rate (OR 3.15, 95% CI 1.61 - 6.15, I^2 = 45%) compared to placebo. JAKi were also associated with significantly better HAQ-DI (mean difference -0.23 95% CI -0.31 - -0.14) and fatigue, measured with FACIT-F (mean difference 3.54 95% CI 2.13 - 4.94). JAKi compared to placebo were associated with a non-statistically significant different risk of serious adverse events (OR 0.56, 95% CI 0.11 - 2.91, I^2 = 38%).
Conclusion: This is the first published systematic review that performed a comprehensive and simultaneous evaluation of the efficacy and safety of JAKi for PsA in RCTs. Our analysis suggests a statistically significant benefit of JAKi, that appears to be effective and safe over placebo. The impact of these data on international clinical guidelines needs further investigation.

AB0566 CONSENSUS-BASED RECOMMENDATIONS FOR THE MANAGEMENT OF PSORIATIC ARTHRITIS IN THE KINGDOM OF SAUDI ARABIA

H. Alrayes[1], M. Alazmi[2], K. Alderaan[3], M. Alghamdi[4], N. Alghanim[5], A. Alhazmi[6], N. Alkhadhrawi[7], M. Almohideb[8], S. Attar[9], Z. A. Alzahrani[10], M. Bedaiwi[11], N. Zakaria[12], H. Halabi[13]. *[1]Prince Sultan Military Medical City, Department of Rheumatology, Riyadh, Saudi Arabia*; *[2]Prince Mohammed Medical City, Department of Rheumatology, Al Jouf, Saudi Arabia*; *[3]King Fahad Specialist Hospital, Department of Rheumatology, Dammam, Saudi Arabia*; *[4]University of Bisha, Department of Rheumatology, Bisha, Saudi Arabia*; *[5]King Saud Medical City, Department of Rheumatology, Riyadh, Saudi Arabia*; *[6]King Fahad Armed Force Hospital, Department of Rheumatology, Jeddah, Saudi Arabia*; *[7]Prince Sultan Military Medical City, Department of Family Medicine, Riyadh, Saudi Arabia*; *[8]King Saud bin Abdulaziz University for Health Sciences and King Abdulaziz Medical City, Department of Dermatology, Riyadh, Saudi Arabia*; *[9]King Abdulaziz University, Department of Rheumatology, Jeddah, Saudi Arabia*; *[10]King Abdulaziz Medical City, Department of Rheumatology, Jeddah, Saudi Arabia*; *[11]King Saud University Medical City, Department of Rheumatology, Riyadh, Saudi Arabia*; *[12]Novartis Saudi Limited, Medical - I&D, Riyadh, Saudi Arabia*; *[13]King Faisal Specialist Hospital and Research Center, Department of Rheumatology, Jeddah, Saudi Arabia*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory condition associated with psoriasis. The common clinical features of PsA include peripheral arthritis, dactylitis, enthesitis, spondylitis, skin and nail disease[1]. Considering the heterogeneous course of disease and the different patient characteristics, there is a need to standardize management of PsA patients. At present, no established guidelines are available on PsA care pathway in Saudi Arabia.
Objectives: To provide consensus-based guidance to all Saudi health care providers (HCPs) on the management of PsA patients including referral pathway, definition of remission and treat-to-target approach.
Methods: A Delphi technique was used to understand PsA patient care pathway. In first step, a targeted literature review was conducted and a survey questionnaire including 16 questions was developed to explore PsA patient journey. In second step, this questionnaire was submitted to 127 HCPs and 33 of them provided their response. In third step, a panel of 12 experts including 10 rheumatologists, 1 dermatologist and 1 general physician reviewed the available evidence along with survey results to align on final recommendations.
Results: The most common management guidelines recommended for PsA were European League against Rheumatism (EULAR, 100% agreed) and American College of Rheumatology (ACR, 100% agreed). Psoriasis Epidemiology Screening Tool (PEST) was recommended by 67% of experts as validated screening tool for PsA in dermatology clinic. The laboratory investigations included were C-reactive protein (CRP, 100%), erythrocyte sedimentation rate (ESR, 100%), complete blood count (92%), urea and creatinine (92%), liver function (92%), rheumatoid factor (56%) and X-ray of affected joints (75%). For patients with additional symptoms of back pain, X-ray of sacroiliac joints and human leukocyte antigen B27 (HLA-B27) test to be included. Only rheumatologists should recommend a magnetic resonance imaging based on the individual clinical picture. The agreement criteria for HCPs for referring patient to a rheumatologist were presence of psoriasis (100%) and one of the following features: dactylitis [100%], joint pain [100%], arthritis [100%], nail dystrophy [91%]. Patient with active arthritis should be referred to rheumatologist within 4 weeks. The referral pathway agreed by the experts for PsA patients is presented in Figure 1. Majority of experts (57%) defined clinical remission as absence of disease activity in all facets of disease assessed using the disease activity in psoriatic arthritis (DAPSA) or minimal disease activity (MDA) index. For treat-to-target, 71% of experts agreed on EULAR recommendations[2]. For remission and treat-to-target, experts identified a need for more clear definition.
Conclusion: This expert consensus aimed to provide guidance to Saudi HCPs on standardizing diagnosis and care of PsA patients. Most experts recommended PEST as validated screening tool for PsA along with laboratory investigations such as CRP, ESR, X-ray, etc. Referral to a rheumatologist should be considered for patient with presence of psoriasis and one of the other defining features for PsA. There is a need for more clear definition of remission and treat-to-target.

AB0567 USING Q-RISK SCALE FOR CHECKING CARDIOVASCULAR RISK IN PATIENTS WITH PSORIATIC ARTHRITIS

S. Smiyan[1], A. Bilukha[1]. *[1]Ternopil State Medical University, Internal Medicine №2, Ternopil, Ukraine*

Background: Psoriatic arthritis (PsA) is an inflammatory arthritis associated with psoriasis. In addition to skin and joint involvement, there is a growing evidence suggesting that patients with PsA also have increased risk of clinical and subclinical cardiovascular disease (CVD), mostly due to endothelial dysfunction and accelerated atherosclerosis, which are the main causes of elevated mortality rate among patients with PsA. For prevention and monitoring progression of CVD in clinical practice scale SCORE usually used, but it isn't adapted for checking in patients with autoimmune diseases and can be used only for patients after forty years old.
Objectives: To check a cardiovascular risk in patient with PsA using Q-risk scale.

Methods: In total, ninety-four patients with PsA, who fulfilled the disease criteria (CASPAR) were examined using standard diagnostic methods (including C-reactive protein, lipid profile). The QRISK-3 and SCORE scales were used to assess the 10-year risk of CVD.
Results: Intermediate (12.4 ± 0,75 %) risk of adverse cardiovascular events within the next 10 years was estimated for PsA patients and it was 7 to 8 – fold higher than the Q - score of a healthy age, sex, and ethnicity – matched subjects. Using classical SCORE, the risk was estimated as low (1,9±0.24 %). Healthy Heart Age was about 25 % higher than predicted as assessed by QRISK.
Conclusion: The Q-risk Scale considers not only classical of such risk factors as age, sex, smoking, systolic blood pressure, total cholesterol (which used SCORE) but also index of atherogenity, BMI, family history of coronary artery disease, treatment with antihypertensive drugs and glucocorticosteroids, comorbidity, systemic inflammatory disease and can be used for different age groups and ethnicity.
Q-risk scale appears to be adaptive and informative in patients with chronic inflammatory and autoimmune diseases as compared with SCORE, because it uses mostly all important etiological and trigger factors of CVD especially presence autoimmune inflammatory process in our case.

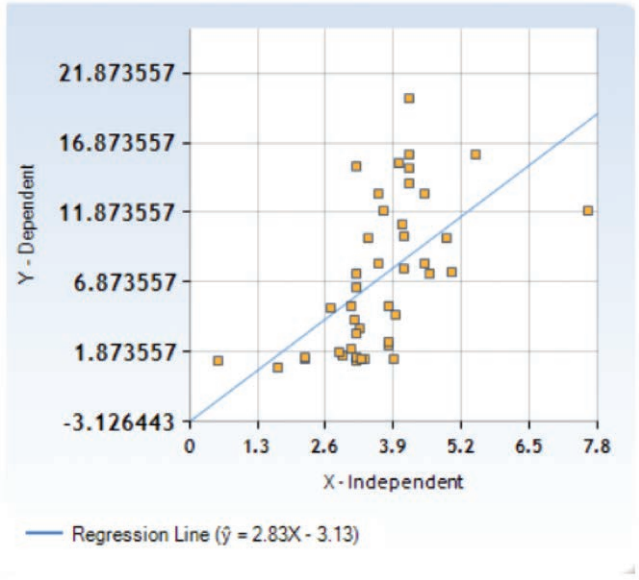
AB0568 CORRELATION BETWEEN SKIN AND JOINT INVOLVEMENT IN PATIENTS WITH PSORIATIC ARTHRITIS: EXPERIENCE FROM A THIRD LEVEL HOSPITAL

C. Sieiro Santos[1], C. Moriano[1], C. Álvarez Castro[1], X. E. Larco Rojas[1], E. Diez Alvarez[1], T. Pérez Sandoval[1]. [1]*Complejo Asistencial Universitario de León, Rheumatology, León, Spain*

Background: Determining the relationship between severity of skin and joint disease is essential for better phenotyping of patients and determine whether clinical features of arthritis can associate with psoriasis.
Objectives: To characterize the relationship between skin and joint activity in patients with psoriatic arthritis (PsA) and psoriasis (PsO) at enrolment.
Methods: We performed a retrospective and descriptive study including patients diagnosed with PsA with a history of PsO. Age, sex, disease onset and duration, pattern of PsA and PsO, sites of skin and joint involvement were collected. PsA patients were evaluated at enrolment for skin activity by Psoriasis Area and Severity Index (PASI), joint activity by Disease Activity Score 28 (DAS28) for peripheral arthritis and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) for axial involvement. A PASI>10% was used to define moderate-severe psoriasis (MS-P). We compared clinical characteristics of patients with PsA based on PASI score and evaluated the relationship of skin and joint activity with linear regression.
Results: A total of 50 patients were collected, 64% were women with a mean age of 57.4 ±11.9 years. Patients with MS-P had a long-standing history of PsO (16.6±7.9 vs 14.15±8.2 years, p 0.03) and arthritis (12.2±7.6 vs 10.6±7.6 years, p 0.05). PsO was diagnosed more frequently before arthritis in the group of MS-P (73% vs 42%, p 0.03). Nail (73% vs 34%, OR 4.27 (1.38-20.14), p 0.015) and hairline psoriasis (67% vs 29%, OR 5 (1.36-18.35), p 0.03) were more frequent in the group of MS-P. Polyarthritis was the most common clinical pattern (60% vs 26%, p 0.02) and peripheral arthritis, in shoulder, elbows and wrists was more associated to patients with MS-P. No significant difference regarding sex, age, arthritis onset, dactylitis, enthesitis or HLA-B27 was found. Patients with MS-P had a higher joint activity for peripheral arthritis (4.1 vs 2.44, p 0.02). The correlation between the skin and joint activity was positive and statistically significant r=0.568 (p 0.02), (graph 1).
Conclusion: Patients with PsA with MS-P associate nail and hairline psoriasis, polyarthritis, and peripheral joint involvement more often. Cutaneous disease activity is correlated with joint activity. Collaboration between dermatologists and rheumatologists is recommended for a proper assessment of psoriatic arthritis with skin involvement.



Graph 1. Correlation between skin and joint activity

AB0569 PSORIATIC ARTHRITIS, ALLIED DISEASES AND MORTALITY - A POSTMORTEM CLINICOPATHOLOGIC STUDY OF 12 PATIENTS

Á. Apáthy[1], M. Bély[2]. [1]*St. Margaret Clinic, Department of Rheumatology, Budapest, Hungary*; [2]*Hospital of the Order of the Brothers of Saint John of God, Department of Pathology, Budapest, Hungary*

Background: Psoriasis (**P**) may be complicated by psoriatic arthritis (psoriatic arthropathy (**PsA**), in 15 % of psoriatic patients [1]. The risk of mortality is increased in **PsA** outpatients compared to the general population [2].
Objectives: The **aim** of this study was to determine the mortality of **PsA** or associated diseases in an in-patient autopsy population.
Methods: At the National Institute of Rheumatology **11860** patients died between 1968 and 1998; among them **12** patients with **PsA** (**females** 6. mean age of 68.17 years, range 86 – 52, onset of **PsA** 53.60, average duration of **PsA** 15.40 years; **males** 6, mean age of 62.83 years, range 82 – 33, onset of **PsA** 46.67, average duration of **PsA** 3.67 years). All patients were autopsied.
The basic disease, complication(s), and cause of death were determined by a detailed review of extensive histological material, all the available clinical and pathological reports retrospectively. From each patient a total of 50-100 tissue blocks of 16 organs were studied microscopically.
PsA was confirmed clinically according to the criteria of the **ACR** updated by Sukfa (2019) [1].
Results: The cause of death was related to **PsA** only in **one** (8.33 %) of 12 patients; a 33 year old man who died of pulmonary embolism after synovectomy. In **11** (91.66 %) of 12 **PsA** patients the cause of death was related to allied diseases namely **atherosclerosis** (**Ath**) in **9** (75 %), **tuberculosis** complicated by miliary dissemination (**TB- mTB**) in **1**(8.33 %), and **alcoholic cirrhosis** (**AC**) in **1** (8.33 %). **Ath** was complicated by hypertension (**HT**) and adult type diabetes mellitus (**DM**) in 4, was associated with **TB** in 1 and with **AC** in 1 of 9 patients; **HT** and **DM** were present in one **PsA** patient without **Ath** (Table 1).
AA amyloidosis (**AAa**) complicated **PsA** in **2** (16.66 %) of 12 **PsA** patients; in one case due to the long standing and severe inflammation of **PsA**, and in the other case the **AAa** was associated with **TB** and **mTB**.

Table 1.

	P-PsA	Basic disease (leading to death)	Complication(s)	Cause of death
1	P-PsA	Ath, TB	Adhesive pericarditis and pleuritis	Circulatory failure
2	P-PsA	Ath-HT-DM Hyperplasic prostate	Postoperative complication	Pulmonary embolism
3	P-PsA	Ath-HT-DM	Brain necrosis, Pulmonary embolism	Circulatory failure
4	P-PsA	Ath	Purulent bronchitis-Bronchopneumonia	Circulatory failure
5	P-PsA	TB-mTB	AAa, Arosion bronchial artery	Massive bronchial bleeding
6	P-PsA	Ath	AAa, Coronary artery thrombosis	Myocardial infarction
7	P-PsA		Synovectomy	Pulmonary embolism
8	P-PsA	Ath-HT-DM	Coronary artery thrombosis	Myocardial infarction
9	P-PsA	Ath	Myocardial fibrosis	Circulatory failure
10	P-PsA	Ath, Alcoholic cirrhosis	Ascites, Purulent bronchitis	Circulatory failure
11	P-PsA	Alcoholic cirrhosis, HT-DM	Ascites	Hepatorenal syndrome
12	P-PsA	Ath-HT-DM	Myocardial fibrosis	Circulatory failure

Conclusion: In our autopsy population **Ath** (with or without **HT** and **DM**) was the most important basic disease leading to circulatory failure and death of **PsA** patients. Diseases of the circulatory system were also the most common cause of death in Wong's outpatient **PsA** population as well [2].
PsA is not a mild disease, but is not a life-threatening complication of **P**, however in association with **Ath**, **HT**, **DM** or **TB** it may increase mortality, as was also found by Arumugam and McHugh (2012): 'the mortality of **PsA** may be increased in a more severe disease' [3].

AB0570 BONE MINERAL DENSITY, TRABECULAR BONE SCORE AND PROXIMAL FEMUR 3D-DXA ANALYSIS IN PSORIATIC DISEASES

E. Toussirot[1], R. Winzenrieth[2], M. Desmarets[1], D. Wendling[3], F. Aubin[4], G. Dumoulin[5]. *[1]CHU de Besançon, INSERM CIC-1431, BESANCON, France*; *[2]GALGO MEDICAL, Imaging software, Barcelona, Spain*; *[3]CHU de Besançon, Rhumatologie, Besancon, France*; *[4]CHU de Besançon, Dermatologie, Besancon, France*; *[5]CHU de Besançon, Biochimie, Besancon, France*

Background: current data regarding areal bone mineral density (aBMD) in patients with psoriasis (PsO) or psoriatic arthritis (PsA) are conflicting. Results on Trabecular Bone Score (TBS) in these patients are lacking. 3D-analysis of cortical and trabecular bone from hip DXA is a new method for non-invasive bone structure assessment, providing separate assessment of the cortical layer and trabecular macrostructure.
Objectives: Case-control study (NCT02849795)
Methods: 52 PsO and 52 PsA cases (CASPAR criteria) were each paired to a control subject matched for age, sex and body mass index (BMI). aBMD measurements at (L2-4) lumbar spine (LS), femoral neck (FN) and total hip (TH) were performed using DXA, Lunar GE. TBS was calculated from antero-posterior L2-L4 BMD image using TBS iNsight V1.8 (Med-Imaps, Pessac, France). 3D-SHAPER software (version 2.10, Galgo Medical S.L, Barcelona, Spain) was used to derive a 3D analysis from the hip DXA scans.
Results: LS and TH aBMD measurements did not differ between patients with PsO or PsA and their respective controls (Table 1). Left FN BMD was higher in patients with PsO compared to controls (p = 0.028), a difference not observed on the right FN. TBS was similar in PsA patients and their controls while decreased values were observed in PsO patients (p = 0.04). In 3D analysis, none of the parameters differed between patients with PsA and their controls. For patients with PsO, no difference was found with the controls for 3D-DXA parameters from the right FN, while total hip cortical surface BMD (sBMD) of the left FN was higher in PsO compared to their controls (p = 0.037). Similarly, cortical thickness (Cth) of the intertrochanteric and shaft regions of the left FN was also higher in PsO (p = 0.032 and p = 0.033). Finally, analysis by region (neck, intertrochanteric and shaft) showed higher values for cortical sBMD from each region of the left FN in the patients with PsO (all p <0.05).
Conclusion: Our results showed comparable aBMD, TBS and 3D proximal femur parameters in patients with PsA and controls. This supports that PsA population is not at increased risk of osteoporosis. In patients with PsO, while LS bone microarchitecture seems impaired, FN displayed better cortical parameters than the controls. Although these results seem marginal, they support the fact that patients with PsO are not at high risk for osteoporosis and hip fracture.

AB0571

RELATIONSHIP BETWEEN SERUM CALPROTECTIN LEVEL AND PRESENCE OF SUBCLINICAL ATHEROSCLEROSIS AND ARTERIAL STIFFNESS IN PATIENT WITH PSORIATIC ARTHRITIS

I. T. Cheng[1], M. LI[1], E. K. LI[1], A. P. W. Lee[1], L. S. Tam[1]. [1]*The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*

Background: Calprotectin is a member of S100 leukocyte. Serum calprotectin is a sensitive biomarker of disease activity in patients with psoriatic arthritis (PsA). While various CV risk score only shown modest correlation with augmented CV risk in patient with PsA, whether calprotectin could play an addition role remains uncertain.

Objectives: To elucidate the association between serum calprotectin and subclinical atherosclerosis and arterial stiffness in patient with PsA

Methods: Seventy-eight PsA patient (age: 53±11 years, 47(54%) male) without CV event was recruited into this cross-sectional study. High resolution carotid ultrasound was performed to assess the presence of carotid plaque and intima-media thickness (IMT). Arterial stiffness was measured by branchial-ankle pulse wave velocity (PWV) and augmentation index (AIx). Serum calprotectin level was measured by QUANTA Lite Calprotectin Extended Range ELISA kit from (INOVA Diagnostics, San Diego, CA, USA).

Results: 29/78 (38%) of patient had carotid plaque (CP+). Subject in CP+ group were of older age and higher inflammatory burden in terms of higher number of swollen joint and longer disease duration. The use of statins were also higher in CP+ group. Serum calprotectin level were significantly higher in CP+ group (639.2ng/ml ±378.2 in CP- group vs 911.8ng/ml ±429.4 in CP+ group, p=0.005) (Figure 1). Using multivariate logistic regression analysis, higher level of ln calprotectin were significantly associated with presence of carotid plaque (OR: 3.25, 95%CI: 1.22 to 8.69, p=0.019) after adjusting for baseline covariates. There was also significant correlation between calprotectin level and C-Reactive Protein (CRP) (r=0.237, p=0.037), mean IMT (r=0.301, p=0.021) and maximum IMT (r=0.265, p=0.043). However, no significant association were observed between calprotectin level and PWV or AIx.

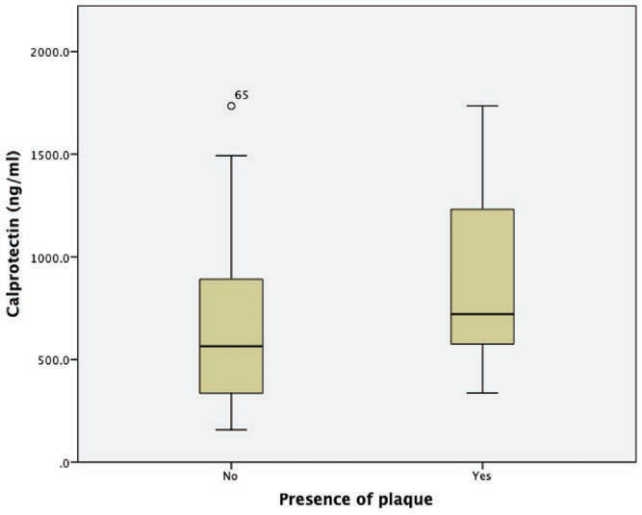

Figure 1.

Conclusion: Increased calprotectin level were associated with presence of plaque and increased IMT. Serum calprotectin may be a novel biomarker for assessing CV risk in patient with PsA.

Table 1. Multivariate analysis for factors associated with presence of carotid plaque.

	OR	95% CI	*p*
Disease duration (years)	1.10	1.02 to 1.19	0.018
Ln Calprotectin	3.25	1.22 to 8.69	0.019

*Factors included in the multivariate analysis: age, gender, disease duration, swollen joint count, hyperlipidemia, Framingham 10-year CVD risk >10%, current use of statins, and calprotectin level

AB0572

CARPAL TUNNEL SYNDROME IN PATIENTS WITH PSORIATIC ARTHRITIS; ULTRASONOGRAPHY AND MAGNETIC RESONANCE IMAGING FINDINGS

E. Akyildiz Tezcan[1], F. Levendoglu[2], M. S. Durmaz[3], H. Kara[4], E. Balevi Batur[2], I. Albayrak Gezer[2], M. K. Korez[5]. [1]*Cumra State Hospital, Department of Physical Medicine and Rehabilitation, KONYA, Turkey*; [2]*Selcuk University Medical Faculty, Department of Physical Medicine and Rehabilitation, KONYA, Turkey*; [3]*Selcuk University Medical Faculty, Department of Radiology, KONYA, Turkey*; [4]*Erzurum Horosan State Hospital, Department of Physical Medicine and Rehabilitation, ERZURUM, Turkey*; [5]*Selcuk University Medical Faculty, Department of Statistics, KONYA, Turkey*

Background: Carpal tunnel syndrome(CTS) is the most common form of entrapment neuropathies,caused by compression of the median nerve in the carpal tunnel at the wrist. But there is no gold standard technique for diagnosing CTS. Electrodiagnostic studies (EDS) are generally used but have some limitations. Recent years, magnetic resonance imaging(MRI) and ultrasonography(US) have facilitated the diagnosis of CTS. The median nerve cross section area(CSA) measured by US or MRI has been found to be associated with CTS[1]][2].CTS is usually idiopatic but it can be seen more in some disease. Psoriatic arthritis(PsA) occurs in up to 30% of people with psoriasis and can have serious debilitating effects on the peripheral joints, spine, tendon insertions, and fingers[3]. Because of arthritis, steroid use and flexor tenosynovitis play an important role in the pathogenesis of CTS, we think that CTS can be seen more in PsA patients.

Objectives: We aimed to investigate the CTS in PsA patients with EDS, US and MRI than compare them with healthy controls.

Methods: 68 people, including 39 PsA (according to CASPAR criteria) and 28 healthy volunteers were included in study within 1 year. EDS, US and MRI were performed within maximum 2 weeks, and measurements were made by different doctors who were blind to other measurments. EDS was started with median and ulnar nerve motor conduction study than continued with sensory conduction studies. CTS diagnose was made according to the routine laboratory standards. The CSA measurement was made from the inner border of the hyperechoic ring around median nerve by using continuous tracing method at psiform bone level. US examinations were performed with a high frequency linear transducer (4-14 MHz), MRI examinations were performed on a 3-T imaging system. The statistical analyses were performed with Statistical Package for the Social Science Program Version 22. Descriptive statistics, T tests, chi-square test, Pearson correlation test were used.

Results: No statifically significant difference was found between the groups for demographic characteristics. 12 (30.76%) of 39 PsA patients had CTS, whereas CTS was not detected in the control group(p= 0.001). US and MRI show larger CSA in PsA patients compared to the healthy control group(9,49 ± 3,00 mm^2 vs 8,30 ±1,73mm^2 p=0,005, 11,24 ± 3,41mm^2 vs 9,35 ± 1,81mm^2 p<0,001); in patients with CTS compared to others(11,63 mm^2 ± 3,25 vs 8,60 ± 2,26mm^2 p=0,002, 13,37 ± 3,37 mm^2 vs 9,90 ± 1,58mm^2 p<0,001) and in PsA patients which have CTS compared to PsA patients with normal EDS(11,63 ± 3,25 mm^2 vs 8,87 ± 2,64 mm^2 p=0,001, 13,37 ± 3,37 mm^2 vs 10,52 ±3,15 mm^2 p=0,003). When the CSA compared PsA patients which have normal EDS and healthy volunteers; US (8,87 ± 2,64 vs 8,30 ±1,73 p=0,180) and MRI (10,52 ±3,15 vs 9,35 ± 1,81 p=0,026) show larger CSA in PsA patients. But differance isn't statistically significant for US measurments. The Pearson correlation coefficient between MRI and US measurements of the CSA was 0.85 (P<0,001).

Conclusion: CTS is more common in patients with PsA. The relationship between CTS diagnosed by EDS and CSA measured by US or MRI was observed in both PsA patients and all participants. Diagnosis can be supported by US or MRI in patients who can not undergo EDS or who do not accept EDS. For PsA patients, cut off values obtained from normal people should not be used. The limitations of our study were that our CTS population was small and most of them was mild. We think that this study will be the precursor of CTS studies in PsA patients.

DUPILUMAB-INDUCED ENTHESITIS/ARTHRITIS IN PATIENTS WITH ATOPIC DERMATITIS: A RETROSPECTIVE OBSERVATIONAL STUDY

J. Nathan[1], C. Hughes[1], S. Patel[1], L. Mathew[2], C. Smith[2], A. Pink[2], R. Woolf[2], B. Menon[1], L. B. Kirkham[1]. [1]*Guys and St Thomas' NHS Foundation Trust,*

Rheumatology, London, United Kingdom; [2]*Guy's and St Thomas' NHS Foundation Trust, St John's Institute of Dermatology, London, United Kingdom*

Background: Atopic dermatitis (AD) is a common skin condition with a prevalence of 2–10% in adults[1]. IL-4 and IL-13 play a key role in the pathogenesis. Dupilumab, a human IgG_4 monoclonal antibody binding the alpha subunit of the IL-4 receptor, blocking IL-4 and IL-13 signaling, has important efficacy in this difficult to treat disease. We first reported a musculoskeletal (MSK) adverse effect of enthesis/arthritis developing in 3 patients in 2019[2].

Objectives: To report the ongoing experience at our centre of this new clinical paradigm, incidence and patient progress including clinical presentation, imaging and management.

Methods: Clinical and radiological data was collected from electronic case records of all cases presenting with features of enthesitis/arthritis between October 2018 and January 2021.

Results: Since initiation of dupilumab at GSTT, approximately 400 adults with moderate-to-severe AD have received at least one dose. Of these, 23 patients (14 men, 9 women) had the clinical syndrome of inflammatory enthesitis/tenosynovitis/arthritis. Nine patients had both enthesitis and arthritis, 10 enthesitis, 3 enthesitis and tenosynovitis and 1 arthritis only. Four of these also reported new onset inflammatory back pain symptoms. None had a preceding history of arthritis or enthesitis. Median onset of symptoms following initiation of dupilumab was 4 months. However, onset of symptoms ranged between 2 weeks and 48 months. Imaging (US/MRI) was performed in 18 patients, 11 with Doppler US positive enthesitis confirming clinical findings. Most common sites were lateral epicondyles, achilles and patella tendons. Two patients with more disabling symptoms had MRI confirmed gluteus medius and hamstring enthesitis and arthritis. Spine and SI joint MRI in 4 patients was negative. Most patients had normal inflammatory markers except 2; CRP 117, ESR 96 and CRP 13, ESR 10. All patients had very good AD response to dupilumab, average EASI score before and after Dupilumab was 21 and 4.2 respectively. One patient developed skin manifestations of guttate psoriasis, with subsequent disabling arthritis/enthesitis. Due to the life-changing beneficial effect of dupilumab therapy most patients did not want to stop therapy. We used NSAID therapy, etoricoxib/celecoxib/naproxen for symptom relief which was usually partly effective allowing continuation of dupilumab treatment in most. Five patients with severe MSK symptoms stopped Dupilumab completely. Some patients temporarily paused therapy but re-started as their AD became worse, often changing from the usual 2 weekly to 4 weekly dosing. Most patients continuing dupilumab had persistent MSK symptoms. Four patients who stopped dupilumab were treated with baricitinib, which has potential efficacy for both MSK symptoms and AD. Two did not tolerate it and remained on NSAID therapy.

Conclusion: These data further characterize a new syndrome of enthesitis and/or arthritis induced by Dupilumab. In those with mild MSK symptoms use of NSAIDs allows continuation of full-dose dupilumab, in moderate cases reducing dupilumab dose frequency plus NSAID therapy maintains function. Most patients had on-going MSK symptoms. In more severe cases JAKi therapy may be an effective strategy. Our initial hypothesis that inhibition of IL-4/13 by dupilumab triggers an IL-17/23/TNF-mediated inflammatory MSK syndrome in some patients is supported by a recent in vitro study[3].

AB0574 UVEITIS IN 406 PATIENTS WITH PSORIATIC ARTHRITIS. STUDY FROM A SINGLE UNIVERSITARY CENTER

A. De Vicente-Delmás[1], L. Sanchez-Bilbao[2], D. Martínez-López[2], I. González-Mazón[2], V. Calvo-Río[2], N. Barroso García[1], N. Palmou-Fontana[2], M. A. González-Gay[2], R. Blanco[2]. [1]*Hospital Universitario Puerta del Mar, Rheumatology, Cádiz, Spain*; [2]*Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*

Background: Uveitis is an extraarticular manifestation of psoriatic arthritis (PsA) and it has been described as the most frequent ocular manifestation in PsA. Uveitis in PsA has been described to be more likely insidious in onset, continuous, posterior, and active bilaterally compared with uveitis in patients with Spondyloarthritis *(Paiva ES, et al. Ann Rheum Dis. 2000;59: 67-7)*. Anti-TNF agents, especially monoclonal antibodies have been effective in prevention and treatment of refractory non-infectious uveitis.

Objectives: Our aim was to assess **a)** epidemiology and clinical features of uveitis associated to PsA, **b)** to compare patients who developed uveitis and those who did not and **c)** its relationship with biological treatment used in PsA.

Methods: We conducted a cross-sectional study of 406 patients with PsA from a single reference University Hospital with: **a)** PsA classified by CASPAR criteria and, **b)** diagnosis of uveitis by expert ophthalmologists. Demographic features, clinical findings, complementary tests, occurrence of other extraarticular manifestations and treatment were recorded.

Results: We studied 406 (202 women/204 men) patients with PsA, mean age of 46.3±12.3 years.

Uveitis was observed in 20 (12 women/8 men) of 406 patients (prevalence 4.9%); mean age of 43.1±14.5 years. Uveitis was most frequently anterior (80%), unilateral (80%), of acute onset (100%), and recurrent (50%).

In the comparative study between patients who developed uveitis and who did not (Table 1), in patients with uveitis was more frequent the presence of HLA-B27 positive (45%), sacroiliitis in MRI (25%), ocular surface pathology (10%), and higher mean PsAID score (4.8±2.5).

Ten (50%) patients with PsA related uveitis received biological therapy, 12 (60%) of the treatments were anti-TNF monoclonal antibodies and 1 (5%) was etanercept. The 2 (10%) remaining therapies were other biological therapy non anti-TNF (Figure 1).

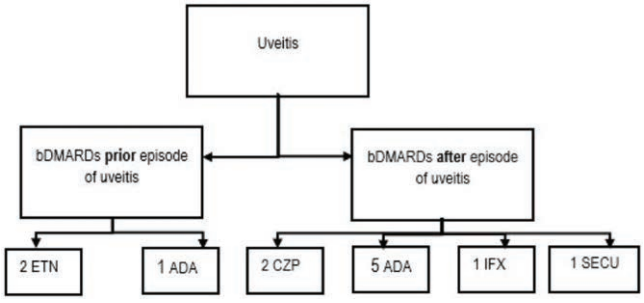

Figure 1. Biologic immunosuppressive drugs in PsA patients related uveitis.

Conclusion: Uveitis was observed in 4.9% of patients with PsA.Most of the PsA related uveitis had an acute onset with anterior and unilateral pattern. HLA-B27 positive, presence of sacroiliitis on MRI and ocular surface pathology were more frequent in patients who developed uveitis. PsAID score is higher in patients with uveitis.

Table 1. General features of 406 patients with PsA. Comparison between with and without uveitis.

AB0575 FACTORS ASSOCIATED WITH PSORIATIC ARTHRITIS ACTIVITY IN CLINICAL PRACTICE

Y. Korsakova[1], E. Loginova[1], T. Korotaeva[1], E. Gubar[1], S. Glukhova[2], E. Vasilenko[3], A. Vasilenko[4], N. Kuznetsova[5], I. Patrikeeva[6], E. Nasonov[1,7]on behalf of RU-PsART study group. *[1]V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Medical and Social Problems in Rheumatology, Moscow, Russian Federation*; *[3]North-Western State Medical University named after I. I. Mechnikov, Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E.Eichwald, Saint Petersburg, Russian Federation*; *[4]Novgorod Regional Clinical Hospital, rheumatology, Veliky Novgorod, Russian Federation*; *[5]Municipal Autonomous Institution, "City Clinical Hospital No. 40", Yekaterinburg, Russian Federation*; *[6]Tyumen Regional Clinical Hospital No.1, Tyumen Regional Clinical Hospital No.1, Tyumen, Russian Federation*; *[7]I.M. Sechenov First Moscow State Medical University, Ministry of Health of Russia, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Background: Psoriatic Arthritis (PsA) is a multifaceted disease with various clinical domains. A number of composite indices has been developed recently [1, 2]. DAPSA (**D**isease **A**ctivity in **PS**oriatic **A**rthritis) is the valid instrument for assessment of PsA activity focused on peripheral arthritis. But other factors can influence on PsA activity and haven't studied yet.

Objectives: to identify factors that are associated with PsA activity based on the data from RU-PsART cohort.

Methods: 117 (M/F=63(54%)/54(46%)) patients (pts) with active PsA fulfilling the CASPAR criteria mean age 44.3 ± 10.9 yrs, mean DAPSA 37.8±21.4, mean PsA duration 73.4±78.4 mo, mean PsO duration 213.4±152.5 mo, were included. Data was collected from 43 rheumatology centers of the Russian Federation. All pts underwent standard clinical examination of PsA activity at enrollment. DAPSA, ESR (mm/h), CRP (mg/L), dactylitis, enthesitis by LEI plus Plantar Fascia, BSA (%), HAQ-DI and fatigue by Fatigue Scale (V.4) FACIT (Functional Assessment of Chronic Illness Therapy), BMI (kg/m^2) were evaluated. DAPSA > 28 indicate high activity. Multi-dimensional step-by-step discriminant analysis was used to identify a group of features that are associated with high PsA activity by DAPSA. M±SD, %, OR 95% (CI) were performed.

Results: The following features proved to be the most informative: LEI (p=0.739), tenderness of the Plantar Fascia (p=0.003), age (p=0.0004), FACIT (p=0.092), PsA duration >2 yrs (p=0.013), BSA>3% (p=0.021), Nail PsO (p=0.092), BMI (kg/m^2) (p=0.22). The area under the ROC-curve (AUC) 0.768, 95% CI (0.624-0.913). Sensitivity/ Specificity of model 77.0%/ 69% accordingly (Figure 1).

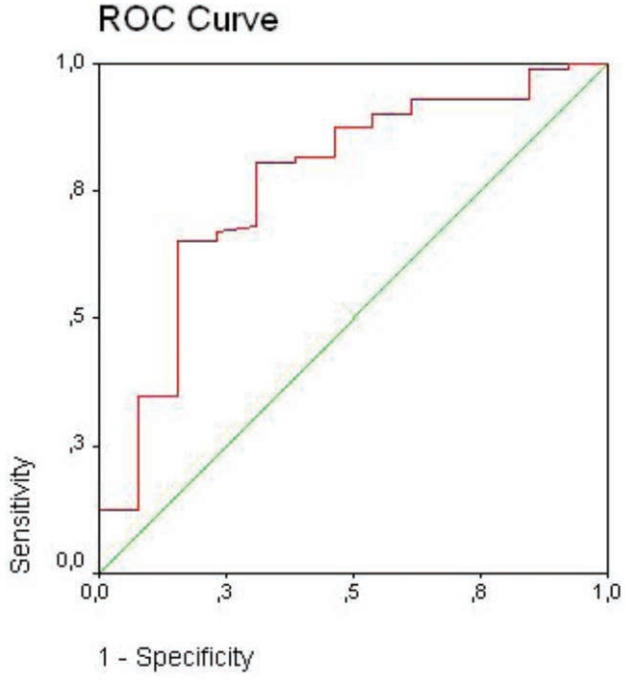

Figure 1 ROC analysis of the Sensitivity and Specificity of the model.

Conclusion: Weight, enthesitis, skin and nail PsO severity, fatigue and PsA duration >2 yrs are associated with high PsA activity as well as articular symptoms. New combination indices based on these features should be developed and validated in clinical practice.

AB0576 BONE EROSION IN PSORIATIC ARTHRITIS ASSOCIATED WITH PSORIASIS DURATION, SKIN, NAIL AND JOINT DISEASE SEVERITY

M. Chamurlieva[1], E. Loginova[1], T. Korotaeva[1], Y. Korsakova[1], E. Gubar[1], S. Glukhova[1], E. Nasonov[1,2], N. Kuznetsova[3], I. Umnova[4], V. Sorotskaya[5], I. Patrikeeva[6], I. Shchendrigin[7]. *[1]V.A.Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*; *[2]I.M.Sechenov First Moscow State Medical University (Sechenov University), Ministry of Health of Russia, Rheumatology, Moscow, Russian Federation*; *[3]Municipal Autonomous Institution "City Clinical Hospital No. 40", Rheumatology, Yekaterinburg, Russian Federation*; *[4]Omsk region "Regional clinical hospital", Rheumatology, Omsk, Russian Federation*; *[5]Medical Institute of the Tula State University, Rheumatology, Moscow, Russian Federation*; *[6]Tyumen Regional Clinical Hospital №1, Rheumatology, Tyumen, Russian Federation*; *[7]Center of responsible rheumatology "Induktsia", Rheumatology, Stavropol, Russian Federation*

Background: Psoriatic arthritis (PsA) is heterogeneous in its clinical presentation and disease course, but many patients (pts) develop a destructive form of arthritis. Psoriasis (PsO) precedes arthritis by an average of 7 years. [1]. Theory of transition from PsO to PsA has been proposed recently [2]. But association between skin disease severity and joint disease are still unclear.

Objectives: to evaluate association between bone erosion, PsO duration, skin and nail disease severity in PsA pts based on data from clinical practice (RU-PsART cohort).

Methods: 737 (M/F=350/387) PsA pts fulfilling the CASPAR criteria were included. Mean age 47.4±12.7 years (yrs), PsA duration 55[17;120] mos., PsO duration 165[74.5;292] mos., mean DAPSA 23.3[14;36.9] mos., HAQ-DI - 0.98 [0.5;1.38], CRP - 7.4 [2.1;18] mg/l. All pts underwent standard clinical examination (tender joins count (TJC)/68, swelling joints count (SJC)/66, CRP (mg/l), DAPSA, dactylitis, enthesitis by LEI + Plantar Facia (PF), HAQ-DI. Mild disease was defined as body surface area (BSA)≤10%, moderate to severe as BSA>10%. The presence/absent of nail PsO was evaluated. X-ray of feet and hand were done in 622 out of 737 pts. The one-factor model of logistic regression was used to identify a group of features that are associated with achievement MDA. M±SD, Me [Q25; Q75], Min-Max, %, t-test, Pierson-χ2, Manna-Whitney tests, ORs with 95% CI were performed. All p<0.05 were considered to indicate statistical significance.

Results: PsO precedes of PsA by an average of 9.2 years. BSA≤10% was found in 615 out of 672 pts (91.5%), BSA>10% - in 57 out of 672 pts (8.5%). Nail PsO were seen in 230 out of 737 (31.2%). Bone erosion was found in 237 out of 622 of pts (38.1%). Among these pts nail PsO were seen in 67 out of 237 pts (28.3%). Enthesitis found in 236 out of 737 pts (42.1%), dactylitis – in 197 out 731 pts (27%), axial PsA – in 315 out of 731 pts (43.1%). Bone erosion significantly associated with PsO duration more than 5 yrs., skin and nail PsO severity, high PsA activity by DAPSA, axial manifestation and duration of PsA > 36 mos. (Figure 1).

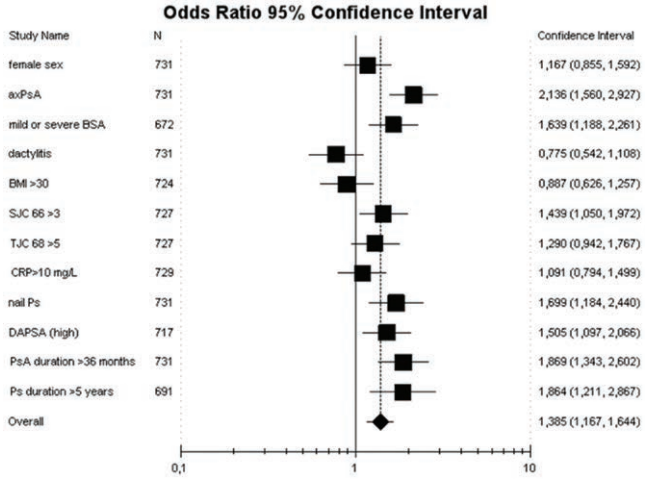

Figure 1 Forest plot of factors associated with bone erosion in PsA pts.

Conclusion: In our cohort the majority of PsA pts had mild PsO preceded PsA on average of 9.2 yrs. Bone erosion was found in 30% of PsA pts which associated with PsO duration, skin and nail disease severity as well as with PsA activity. Early diagnosis and therapeutic intervention within a "window of opportunity" are very important for improving outcomes and prevent structural damage in PsA.

AB0577 METABOLIC SYNDROME IN PSORIATIC ARTHRITIS SEEMS ASSOCIATED TO INFLAMMATORY STATUS OF THE DISEASE

C. L. Iñíguez[1], J. A. Mosquera Martínez[2], L. Fernández-Dominguez[3], F. Maceiras-Pan[4], C. García-Porrúa[1], J. L. Guerra-Vázquez[5], V. Quevedo Vila[6], M. Caeiro-Aguado[7], J. Lorenzo-Alvarez[8], J. A. Pinto Tasende[7,9]on behalf of GIGAPs. *[1]Hospital Lucus Augusti, Rheumatology, Lugo, Spain*; *[2]Hospital Montecelo (Pontevedra), Rheumatology, Pontevedra, Spain*; *[3]Complexo Hospitalario Universitario de Ourense, Rheumatology, Ourense, Spain*; *[4]Hospital do Meixoeiro, Rheumatology, Vigo, Spain*; *[5]Hospital Arquitecto Marcide, Rheumatology, Ferrol, Spain*; *[6]Hospital Comarcal de Monforte de Lemos, Rheumatology, Monforte de Lemos, Spain*; *[7]Hospital Universitario da Coruña, Rheumatology, La Coruña, Spain*; *[8]Hospital Universitario da Coruña, Internal Medicine, La Coruña, Spain*; *[9]INIBIC, Rheumatology, A Coruña, Spain*

Background: Evidence suggests that inflammation plays a causal role in the development of Metabolic Syndrome (MetS) and elevated peripheral levels of proinflammatory mediators, such as C-reactive protein (CRP) confering cardiovascular and metabolic risk.

Objectives: The objective of this study was to evaluate Metabolic Syndrome among patients with PsA naïve to biologics and to evaluate its association with inflammatory activity status previous start them.

Methods: We performed a retrospective cross-sectional study of a cohort of patients ≥18 years of age, all patients with a diagnosis of PsA (CASPAR criteria), included in the Sueiro Cohort. Patients were managed according to a standard protocol adopted at the Rheumatology outpatient clinic of six hospitals and they were patients on follow-up for at least 6 months. Collected variables included age and gender, blood biochemistry, blood count, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), HLA-B27 and rheumatoid factor, glucocorticoid, NSAID and conventional or biologic DMARD, smoking habit, hyperuricemia, type 2 diabetes mellitus, obesity (BMI kg/m2). MetS was defined by a combination of abdominal obesity, impaired fasting glucose, atherogenic dyslipidemia, and elevated blood pressure. Status of disease activity was supported by tender and swollen joint counts (TJC68 and SJC66) from patients who were going to start treatment with biologics and Patient-reported outcome measure were collected with Patient Global Assessment (0-10 cm) and Patient Pain Assessment (0-10 cm). Remission and low disease activity status was obtained by DAPSA score and its defined cut-off. Tests were two-tailed with a significance level of 5%. Data were analyzed using SPSS V21.0 statistical software (IBM Corp. NY, USA).

Results: A total of 416 were included in the study: 222 PsA patients treated with csDMARD kept in remission or low disease activity and 194 patients needed to be treated with bDMARD. The mean age of the patients was 53.0 years (SD: 11.8). Two hundred and twenty-eight were males (56.2%).

Fifty-six patients had MetS (13.8%) and it was more frequent in patients who were in clinical activity and they needed biologics (17.9% vs 10.4%, p 0.028) with mean (SD) of DAPSA of 16.7 (11.1). Patients starting treatment with biologics and with MetS had more proportion of patients older than 50 years (24.2 % vs 8.3%, p 0.006) and CRP >5 mgr/L (71.4% vs 52.6%, p 0.042) and DAPSA had higher values than in patients without MetS (18.6 vs 16.2) but there were not significant statistical differences. Binary regression analysis showed increased risk of MetS for age > 50 years old (OR 3.287 [95%CI: 1.258-8.591], p 0.015) and CRP > 5 mgr/L (OR 2.684 [95%CI: 1.141-6.313], p 0.024) but not for gender (OR 2.136 [95%CI: 0.932-4.893], p 0.073) neither for DAPSA>14 (OR 1.539 [95%CI: 0.695-3.409], p 0.288).

Conclusion: Patients with PsA active despite csDMARD had more prevalence of MetS and this was associated with those patients over 50 years old and CRP higher than normal values. DAPSA was higher in patients with MetS but without reaching significant statistical difference.

AB0578 SUBCLINICAL ENTHESITIS IN PSORIASIS PATIENTS AS PREDICTOR OF ARTHRITIS (EPESCA STUDY): PRELIMINARY RESULTS

E. Di Donato[1], A. Becciolini[1], S. DI Nuzzo[2], N. Chernyschova[3], C. Commisso[4], S. Lamorte[4], M. Brusasco[2], E. Pierobon[2], D. Santilli[1], G. Lucchini[1], M. Riva[1], N. Sverzellati[4], F. Mozzani[1], A. Ariani[1]. *[1]Azienda Ospedaliero-Universitaria di Parma, Internal Medicine and Rheumatology Unit, Parma, Italy*; *[2]University of Parma, Department of Medicine and Surgery, Parma, Italy*; *[3]Azienda Ospedaliero-Universitaria, Section of Radiology, Parma, Italy*; *[4]University of Parma, Department of Radiological Sciences, Parma, Italy*

Background: Enthesitis is one of the typical pathological signs of spondyloarthritis such as psoriatic arthritis (PsA) and it seems to be the *Primum movens* of the disease. Clinical assessment of enthesitis showed to be less sensitive, compared to ultrasound (US) evaluation, in identifying enthesitis in patients with PsA [1].

OMERACT defined US enthesitis as: "hypoechoic and/or thickened insertion of the tendon close to the bone (within 2 mm from the bony cortex), which exhibits Doppler signal if active and that may show erosions, enthesophytes/calcifications as a sign of structural damage" [3]

The reported prevalence of subclinical enthesitis in psoriasis (PsO) patients in different countries ranges between 7% and 20% [2].

Objectives: The main objective of this study was to estimate, by US evaluation, the prevalence of subclinical enthesitis in PsO patients without any clinical signs of enthesitis. Secondary objectives were to analyze differences, in terms of age, sex, BMI, PsO onset and diagnosis, among patients with enthesitis (active or not active), enthesopathy and without any alteration of enthesis.

According to the OMERACT definition of ultrasound enthesitis, patients were divided into 4 groups: patients with active enthesitis (AE) defined as the presence of power-Doppler signal in a hypoechoic and/or thickened insertion of the tendon close to the bone; patient with enthesitis (En) defined as hypoechoic and/or thickened insertion of the tendon close to the bone without PD signal; patients with enthesopathy (Ep) defined as the presence of structural damage (erosions, enthesophytes/calcifications); patients without any alteration of enthesis (WE).

Methods: Patients with at least 18 years and a diagnosis of PsO made by a Dermatologist were included. Exclusion criteria were the presence of clinical symptoms or signs of articular or entheseal involvement, diagnosis of arthritis and therapy with bDMARDs or tsDMARDs.

All patients underwent US examination on grey scale and Power Doppler (PD) ultrasonography of 6 sites (Achilles, quadriceps, distal and proximal patellar, plantar fascia and triceps enthesis) bilaterally. Ultrasound was performed by an experienced sonographer, using a Logiq P9 equipped with 6-12 MHz broad band linear transducer. Data were reported as frequencies and median with interquartile range. To check differences among these four groups, we used chi-square test or Kruskall-Wallis test. P-value ≤ 0.05 is considered statistically significant.

Results: We enrolled 124 consecutive psoriasis patients (47 [37.9%] female) with median age 57.7 (45.3-66.5) years, median disease duration 20.4 (10.1-30.8) years, median BMI 27 [24-29]. Patients with AE, En, Ep were 20.2% (25/124), 49.2% (61/124) and 18.5% (23/124), respectively.

Patients WE (12.1%, 15/124) showed significantly lower BMI, younger age and shorter diagnostic delay compared to the other patients.

All signs of enthesopathy/enthesitis were more frequently observed at Achilles (33.1%, 41/124), triceps (23.4%, 29/124), quadriceps (20.2%, 25/124), distal patellar (18.5%, 23/124) and proximal patellar (4.8%, 6/124) enthesis.

Conclusion: Subclinical enthesitis is quite common in PsO patients, and about 20% showed active enthesitis. The enthesopathy seems to be more frequent in patients with increased delay in PsO diagnosis, older age and higher BMI.

Background: Timely diagnosis is essential for the optimal management of psoriatic arthritis (PsA). Several instruments have been developed for screening PsA among patients with psoriasis. However, a delay in diagnosis is still frequently reported, possibly due to the lack of a wide use of these instruments.

Objectives: We aimed to identify and compare the reported performance of these instruments with special emphasis on the PsA phenotypes.

Methods: We conducted a systematic literature search on PubMed until 15 August 2020 using the keyword 'psoriatic arthritis'. Two independent reviewers identified all studies published in English, that report on the validation, psychometric evaluation or use of an instrument for screening PsA. Any disagreements were resolved by the third investigator. Data on sensitivity, specificity, positive (PPV) and negative (NPV) predictive values were extracted or calculated for each instrument. Additionally, instruments were assessed for their performance in patients with different disease phenotypes.

Results: A total of 10754 references were screened, and 42 were identified that reported on 15 different screening instruments. Psoriatic Arthritis Screening and Evaluation (PASE), Psoriasis Epidemiology Screening Tool (PEST), Early Arthritis for Psoriatic Patients questionnaire (EARP) were the most commonly used instruments. There was important variability across studies regarding the sensitivity, specificity, PPV and NPV of these instruments based on the cut-offs for positivity, setting, patient population and disease phenotypes (Table 1). Specificity was higher when patients with a previous diagnosis of other rheumatic diseases were excluded. Lower sensitivity was reported among patients with shorter disease duration and when patients with a prior diagnosis of PsA were excluded from the study, whereas higher sensitivity was reported among patients with prior NSAID use. Screening tools showed differences in sensitivity in different domains (Figure 1).

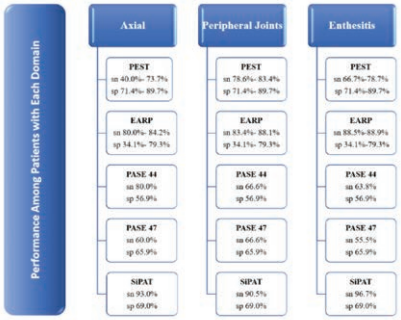

Figure: Range of sensitivity (sn) and specificity (sp) among patients with PEST and EARP, sensitivity and specificity value among patient with PASE 44, PASE 47, SiPAS. ***PEST**:Psoriasis Epidemiology Screening Tool, **EARP**: Early Arthritis for Psoriatic Patients, **PASE 44**:* Psoriatic Arthritis Screening and Evaluation 44, ***PASE 47**:* Psoriatic Arthritis Screening and Evaluation-47, ***SiPAT**: Siriraj Psoriatic Arthritis Screening Tool*

Figure 1. Performance Among Patients with Each Domain

Conclusion: This systematic literature review revealed wide variability in the diagnostic estimates of currently available questionnaire-based screening instruments for identifying PsA among psoriasis patients, depending on study populations and disease phenotypes. There is an unmet need for a screening instrument with a better performance in all disease domains.

Table 1. Diagnostic estimates of screening tools in different studies

Instrument	Number of studies	Sensitivity %	Specificity %	PPV %	NPV %

AB0580

EFFECT OF FATIGUE ON DISEASE ACTIVITY AND PATIENT-REPORTED OUTCOMES (PROS) IN PATIENTS (PTS) WITH PSORIATIC ARTHRITIS (PSA)

L. Vorobyova[1], T. Korotaeva[1], E. Loginova[1], Y. Korsakova[1], E. Gubar[1], P. Tremaskina[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Department of Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation*

Background: Fatigue is an important symptom in patients (pts) with psoriatic arthritis (PsA) and was recently added to the core domain set for PsA randomized controlled trials (RCTs) due to the impact that it has on a PROs.

Objectives: to study the influence of fatigue on disease activity and PROs in pts with PsA.

Methods: 187 (M/F=97 (50.2%)/90(48.8%) PsA pts fulfilling the CASPAR criteria were included. Mean age 45.6 + 11.7 years (yrs), median (Me) PsA duration 88 [16;421] mo. 67,8% of pts 67,8% were treat biological DMARDs, 32,1% of pts was monotherapy conventional synthetic disease-modifying antirheumatic drugs (csDMARDs, mostly Methotrexate). On visit PsA activity was evaluated by Tender Joint Count (TJC68), Swollen Joint Count (SJC66), DAPSA. PROs were measured by PtGA VAS, PtPain VAS, BASDAI, HAQ, EQ-5D, PsAID12, WPAI. Fatigue symptoms were assessed by the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-Fatigue) scale. Higher PsAID12 scores are considered to be worse and correspond to poorer PsA-specific health-related quality of life. M±SD, Me [Q25; Q75], %, t-test, Manna-Whitney tests were performed. All p<0.05 were considered to indicate statistical significance.

Table 1. The effect fatigue on disease activity and PROs

Parameters, M±SD	No fatigue n=99	Fatigue n=68	Severe fatigue n=20
TJC68	9.51±7.86	14.5±9.89*	19.05±8.15**
SJC66	7.66±5.5	11.5±8.2*	13.4±6.9**
BASDAI	2.6±1.85	5.8±2.47*	7.2±2.0**
DAPSA	21.05±21.03	39.9±21.13*	47.9±15.6**
CRP (mg/l)	12.6±9.4	30.0±25.4*	20.9±11.6**
PtPain, VAS, mm	33±24.7	59±25.2*	66.8±18.1**
PtGA, VAS, mm	30.7±23.8	54.0±22.2*	64.7±16.2**
ESR (mm/h)	15.19±11.7	30.1±23.7*	30.1±20.8**
Total PsAID12 score (over past week, 0- 10)	1.87±1.76	5.41±2.17*	6.5±1.93**
HAQ	0.72±0.59	1.37±0.84*	2.04±0.86**
EQ-5D TTO	0.75±0.17	0.46±0.16*	0.51±0.15**
Work time missed (absenteeism)	0.08±0.26	0.11±0.25	0.31±0.15**
Impairment while working (presenteeism)	0.085±0.15	0.258±0.256*	0.23±0.13**
Overall work productivity impairment (absenteeism + presenteeism)	0.15±0.26	0.35±0.34*	0.37±0.26**
Daily activity impairment	0.22±0.23	0.59±0.25*	0.73±0.22**

*p<0.001 – differences from "No fatigue" to "Fatigue"; ** p<0.0001 – differences from "No fatigue" to "Severe Fatigue";

Results: According to the results of the FACIT-F, the patients were identified: no fatigue (52-34 points) – 99 (53.1%), the presence of fatigue (21-33and less points) – 68 (36.3%) and severe fatigue (20 and less points) -20 (10.6%). By patient with fatigue and severe fatigue significant worse in all activity indexes and PROs than in patients not experiencing fatigue (p<0,001 and p<0,0001), (Table 1). Similar results were demonstrated across all PsAID12 domains (Figure 1), especially the domains "Pain", "Skin problems", "Work and/or leisure activity", "Sleep disturbance", "Function capacity" and "Discomfort" (p<0.0001).
Conclusion: In patients with PsA fatigue affected significant and clinically considerable impairment of PsA activity and PROs.

AB0581

NAIL PSORIASIS AMONG PATIENTS WITH PSORIATIC ARTHRITIS IS MORE ASSOCIATED WITH THE SEVERITY OF SKIN PSORIASIS THAN WITH FEATURES OF SEVERE ARTHRITIS

M. Haroon[1], S. Farrukh[2], S. Batool[1], S. Asif[1], O. Fitzgerald[3]. *[1]Fatima Memorial Hospital & FMH College of Medicine and Dentistry, Department of Rheumatology, Lahore, Pakistan*; *[2]University Hospital Kerry, Department of Rheumatology, Tralee, Ireland*; *[3]University College Dublin, Conway Institute for Biomolecular Research, Dublin, Ireland*

Background: Nail disease is an important feature of psoriasis arthritis (PsA), and has been recognised as one of the 6 important clinical domains by GRAPPA. Little is known about how patients with PsA and nail disease compare to patients without nail disease. Nail disease has been found to associate with severe PsA.
Objectives: The objective of this study was to examine the association of nail disease with patient demographics and features of active psoriasis and PsA.
Methods: For this cross-sectional study, data from 3 PsA cohorts was studied (St Vincent's University Hospital Dublin, Ireland; University Hospital Kerry, Ireland; and Fatima Memorial Hospital Lahore, Pakistan). Following informed consent, patients underwent detailed skin and rheumatologic assessments including disease activity measures. Since a large number of patients were in clinical remission at the time of assessment, we made 2 documentations of reversible clinical variables (e.g., current skin scores (PASI), current nail disease, current tender and swollen joint counts, current enthesitis, current dactylitis) at the time of study entry and, through extensive medical record review, we identified patient's maximum skin and joints disease activity scores ever documented, e.g., maximum skin scores (PASI max), TJC max, SJC max, nail disease ever, dactylitis ever, enthesitis ever. Nail disease was stratified by the presence or absence of nail psoriasis.
Results: Data on 476 PsA patients was assessed (age 53.8±10.8, PsA duration 13.9±10 years, BMI 29±5; current PASI 2.5±3.2, current TJC 1.8±2.6 years, current SJC 1.4±2.2 years; 37% of the cohort had enthesitis ever, 46% had dactylitis ever, 30.7% had current dactylitis, and 28% with current enthesitis). 63.4% (n=302) of the cohort ever had nail disease, and 45.4% (n=216) had current nail disease at the time of assessment. On univariate analysis, significant or marginally significant statistical association of current nail disease was noted with current PASI (p<0.001), enthesitis ever (p=0.004), current enthesitis (p=0.11), dactylitis ever (p=0.027), current dactylitis (p=0.07), MDA not achieved (p<0.001), current SJC (p=0.08), and current TJC (p=0.32); however, no statistical association was noted with age, gender, disease duration, smoking status, low education status.The following variables were included in multiple stepwise regression analysis: current PASI, current enthesitis, current dactylitis, current TJC, current SJC, MDA not achieved, and low education status; a significant association of current nail disease was noted with current PASI (OR 2.2, CI 1.83-2.54, p<0.001) with a borderline association of current dactylitis (OR 1.6, CI 0.94-2.58, p=0.083). When we used nail disease ever as a dependent variable in the multiple regression model using covariates of PASI max, TJC max, SJC max, dactylitis ever, enthesitis ever, MDA not achieved and low education status, a significant association of nail disease ever was noted with PASI max (OR 1.09, CI 1.01-1.17, p=0.01), TJC max (OR 1.08, CI 1.02-1.14, p=0.005) and borderline association with dactylitis ever (OR 1.74, CI 0.96-3.15, p=0.067)
Conclusion: The presence of nail disease among patients with PsA is significantly associated with severity of skin psoriasis with only borderline associations with measures of active musculoskeletal involvement.

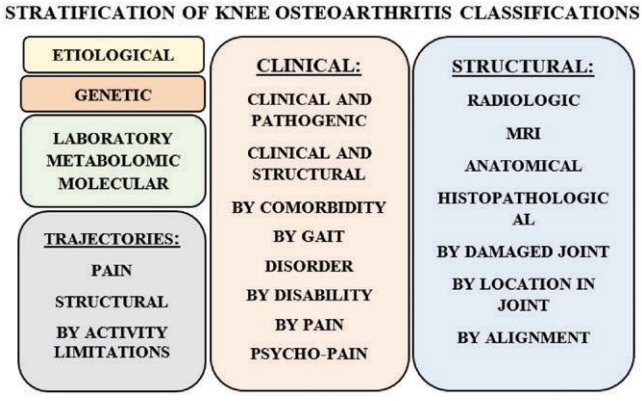
Osteoarthritis

AB0582

KNEE OSTEOARTHRITIS PHENOTYPES STRATIFICATION

K. Korochina[1], T. Chernysheva[1], I. Korochina[2], V. Klementeva[1], G. Kuznetsov[1]. *[1]Orenburg State Medical University, The Department of Internal Diseases, Orenburg, Russian Federation*; *[2]Orenburg State Medical University, The Department of Polyclinic Therapy, Orenburg, Russian Federation*

Background: Osteoarthritis (OA) relevance is determined by its record prevalence with progredient growth throughout the world [1]. Clinical and pathogenic heterogeneity of disease actualizes problem of its stratification [2]. Lack of unified understanding of OA and its phenotype determination results in incredible number of attempts to group OA, using of different classification criteria in last decade.
Objectives: To analyze and systematize available OA classifications, proposals and phenotypes, to highlight the most promising of them.
Methods: We studied publications from MEDLINE / PubMed and Google Scholar databases found by the keywords "osteoarthritis", "phenotypes", "subphenotypes", "classification", "subtypes", "subsets", "subgroups", "subpopulations", "profiles" and "endotypes" in various combinations in English and Russian. We did not set a time frame, but aimed to include as many different methods as possible in order to reflect evolution of scientists' views on structuring of this disease.
Results: A total of 55 OA grouping methods were covered so that OA was structured by different determinants into 6 big boxes.



First OA classifications were characterized by complex etiopathogenetic approach, while subsequent studies differed in joint-mediated approach, and the knee joint was undisputed "champion" in this "race". One of the first attempts to group OA was division into primary, or idiopathic, and secondary, due to known causes. It is now obvious that it is becoming obsolete, and criteria for OA primacy are difficult to determining. Genomic highly specialized studies based on isolation of "favorable" and "unfavorable" genes develops prerequisites to genetic OA classifying. Clinical variants occupy central place as they are the most fully consistent with modern phenotype conception [3], considerating as subtypes of disease shared by underlying pathobiological and pain mechanisms and their structural and functional consequences. Trajectories of OA progression are distinguished by longitudinal design, that is, the determinants for grouping here are disease characteristics in dynamics. The ancestor of structural OA trajectories can be considered Kellgren-Lawrence grades;

subsequent studies identified complex of clinical, laboratory and morphological factors contributing to development of trajectories. Structural OA variants are diverse depending on visualization methods, and many of them can be naturally considered phenotypes, since they drive certain clinical OA manifestations. Morphological changes were described at macro- and microscopic levels; it is interesting to note the absence of histopathological norm in patients without OA. Laboratory profiles of patients are determined by content of systemic (serum, urinary) or local, "proximal" (in synovial fluid) biomarkers, which seem to be more precise. Metabolomic analysis is perspective new direction of laboratory studies based on joint metabolic products identification in the synovial fluid. New trend in OA research is molecular phenotyping. The specific molecular pathway explaining observed phenotype properties is called "endotype". Endotype is related to certain pathobiological scenario, and laboratory markers are potentially effective for its diagnosis.

Conclusion: Thus, a large amount of accumulated information and its diversity soon will probably lead to qualitatively new knowledge level with deep understanding of phenotype-associated strategy for managing OA patients.

AB0583 FRAILTY IN THE PATIENTS WITH OSTEOARTHRITIS OF THE KNEE WAS NOT CAUSED BY SARCOPENIA

K. Inui[1,2], K. Mandai[1], T. Ikawa[1], Y. Minami[1], K. Ueno[1], H. Ohashi[1]. [1]*Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan*; [2]*Osaka City University Graduate School of Medicine, Orthopaedic Surgery, Osaka, Japan*

Background: Osteoarthritis of the knee (knee OA) decreases mobility of the elderly, which function could be significantly improved with artificial joint replacement in many cases. Successful results of the surgery depend on several factors including preoperative muscle strength of lower limbs.

Objectives: We assessed morbidity and skeletal muscle mass and strength in patients with knee OA immediately before undergoing arthroplasty and investigated the relationship between impairment of mobility and skeletal muscle function.

Methods: All patients scheduled to undergo knee arthroplasty at our hospital after July 2020 were assessed for basic attributes, clinical assessment, blood tests, radiography, whole-body mode DXA, knee muscle strength by dynamometer with written consent (UMIN ID: 000040940). And Japanese Cardiovascular Health Study criteria for frailty, and sarcopenia by Asian Working Group for Sarcopenia 2019 criteria were evaluated.

Results: Among 46 patients (40 women, mean age 75.4 years) the overall distribution in frailty is no: 15.9%, pre-frailty: 56.8%, and frailty: 27.3%. That in sarcopenia is no: 91.3%, yes: 2.2%, and severe: 4.3%. Ninety-one % of the patients with frailty did not suffer from sarcopenia. Between the patients with frailty and those without frailty there was a significant difference in walking speed (0.71±0.29m/sec, 1.12±0.29m/sec; p=0.004 adjusted by age and sex). Meanwhile, between those 2 groups of patients no significant differences were observed in skeletal muscle mass (6.40±0.87 kg/m^2, 6.59±1.09 kg/m^2; p=0.35) and knee extension power (120.4±37.4 N, 143.7±67.9 N; p=0.88) adjusted by age and sex. Together with these results, decrease in lower limb motor functions of the patients with knee OA was not caused by sarcopenia. In other words, improvement of mobility in the patients with knee OA could be expected by surgical intervention because of pain relief and ROM improvement.

Conclusion: In the patients with knee OA immediately before arthroplasty, frailty was not caused by sarcopenia.

AB0584 THE QUALITY OF REPORTING IN RANDOMIZED CONTROLLED TRIALS OF HOME BASED REHABILITATION FOR KNEE OSTEOARTHRITIS: UTILIZING PEDRO SCORE AND CONSORT CRITERIA

M. Meran[1,2], B. Unver[1], E. Çağlar[3]. [1]*Dokuz Eylul University, School of Physical Therapy and Rehabilitation, Izmir, Turkey*; [2]*Istanbul Beykoz University, School of Physical Therapy and Rehabilitation, Istanbul, Turkey*; [3]*Istanbul Gelisim University, Faculty of Health Science/ Physical Therapy and Rehabilitation, Istanbul, Turkey*

Background: Osteoarthritis of the knee (KOA) is a very common rheumatic disease, and its global burden is gradually increasing (1). The benefits of exercise in patients with KOA are supported by high-level evidence and take their place in primary care therapy (2). Today, coronavirus disease 2019 has developed as a pandemic all over the world, creating difficulties in healthcare and highlighting home-based rehabilitation (HBR) (3). Randomized controlled trials (RCTs) are considered the gold standard for evaluating the effects of clinical interventions, but poorly reported results can have negative consequences. The Physiotherapy Evidence Database (PEDro) evaluates the methodological quality of RCTs (4). The CONSORT (Consolidated Standards of Reporting Trials) statement has been developed to improve the reporting quality of RCTs (5).There are no studies examining the quality of RCTs related to HBR in patients with KOA.

Objectives: The aim of this study was to assess the reporting quality of HBR trials for KOA, and explore the factors associated with the reporting.

Methods: Two independent researchers investigated HBR RCTs in patients with KOA published between 1999 and 2020 were sourced from PubMed, the Cochrane Reviews and Web of Science. Each researcher evaluated the methodological quality of the included studies using the PEDro scoring and reporting aspects using 9 items from CONSORT. The relationship between adherence to the CONSORT criteria and the PEDro score were evaluated.

Results: Twenty-five RCTs met our eligibility criteria. The mean PEDro score of studies is 5.76 ± 1.48. Only one study found high quality (PEDro score: ≥ 9). The PEDro scores were: randomization type (96%, 24/25) and baseline comparability (92%, 23/25); all studies described group comparisons and variablity measures. In contrast, concealed allocation (18%, 7/25), blinding of participants (16%, 4/25) and therapists (0%) were not included in most studies. The CONSORT criteria were: flow diagram (92%, 23/25), sample size, subgroup analysis and sources of funding (56%, 11/25 for all three), while the majority of studies the trial registration number (16%, 4/25) was not available. A high level of correlation was found between meeting the CONSORT criteria and PEDro scores ($r=0.820$, $p<0.001$).

Conclusion: The majority of RCTs based on HBR for KOA are low-to-modarate quality studies based on the PEDro score. Adherence to the CONSORT criteria is linked to high quality scores. If the studies are planned and written in accordance with the CONSORT criteria, we think that better quality studies will emerge.

AB0585 COMPARISON OF THE EFFECTIVENESS OF HYALURONIC ACID PREPARATIONS WITH DIFFERENT MOLECULAR WEIGHTS AND IN COMBINATION WITH CHONDROITIN SULFATE DEPENDING ON THE STAGE OF OSTEOARTHRITIS OF THE KNEE JOINT

V. Bialik[1], M. Makarov[1], E. Bialik[1], S. Makarov[1], V. Nesterenko[1], M. Nurmukhametov[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Rheumoorthopedic and Rehabilitation, Moscow, Russian Federation*

Background: intra-articular (IA) injections of hyaluronic acid (HA) preparations are one of conservative treatment of the knee osteoarthritis (OA). However, the results of this treatment are inconsistent.

Objectives: to evaluate the effectiveness of HA preparations with different molecular weights and in combination with chondroitin sulfate (HS) for IA injections in the treatment of patients with stage I-III knee OA.

Methods: IA HA injections were performed 160 patients with primary and post-traumatic knee OA of the I-III stages at the department of rheumoorthopaedic and rehabilitation, V. A. Nasonova Research Institute of Rheumatology for the period from September 2017 to June 2019. Patients were divided into 4 groups. Group 1 consisted of 80 patients treated with low molecular weight (LMW) HA, group 2 - 20 patients treated with medium molecular weight (MMW) HA, group 3 - 30 patients treated with high molecular weight (HMW) HA, and group 4 - 30

patients who were intraarticular introduced HA with HS. The course of IA injections was 2 for LMW, HMW, and HA with HS, and 3 for MMW HA. Injections were performed with an interval of 1 week. To evaluate the results of treatment, we studied the intensity of pain according to VAS and the total score of KOOS before treatment and on follow-up examinations 1, 3 and 6 months after the course of IA HA injections.

Results: the maximum reduction in pain with IA HA injections at stage I of knee OA occurred by 3 months after the course of treatment. Moreover, improvement was detected by 1 month in 84.3% of cases, and remained until the end of the study in 71.1% of patients. All HA preparations used in stage I of knee OA were effective. At stage II of the knee OA after 3 months after the course of IA HA, different efficiencies of HA preparations were revealed. So, in the groups of LMW, MMW and HA with HS, the improvement persisted up to 3 months, and in the group of HMW HA - up to 1 month. After 3 months, the best results were shown by HA with HS, by 6 months the results were comparable. IA HA injections at the II stage of knee OA led to good and excellent results 1 month after the course of treatment in 53.9% of cases, but by the end of the study, improvement remained in only 30.8% of patients. In the case of the use of HA in stage III of the knee OA, the effectiveness of the studied drugs was comparable, and the maximum improvement was achieved by 1 month. The positive effect of IA HA injections in patients with stage III of the knee OA one month after the course of treatment was obtained in 40.6% of cases, by 3 months it decreased to 18.8%, and by 6 months - to 15.7% of patients.

Conclusion: IA injections of HA at stage I of the knee OA is a highly effective method of conservative treatment, which allows to relieve pain and improve the condition of the knee joint for a period of 6 months or more. The use of HA preparations at stage II of the knee OA allows reducing pain up to 3 months with IA injections of LMW and MMW HA, as well as HA with HS. HMW HA helps reduce pain intensity for a period of 1 month. The use of HA preparations in stage III of the knee OA leads to a short-term relief of symptoms of OA.

AB0586 PREVALENCE OF EARLY SYMPTOMATIC KNEE OSTEOARTHRITIS ACCORDING TO THREE CLINICAL CLASSIFICATION CRITERIA

M. Törnblom[1,2], A. Bremander[2,3,4,5], K. Aili[2,6,7], M. Andersson[2,4], A. Nilsdotter[8,9], E. Haglund[2,4,10]on behalf of The Halland Osteoarthritis study group.
[1]Helsingborg Hospital, Department of Rehabilitation, Helsingborg, Sweden; *[2]Spenshult, Research and Development Centre, Halmstad, Sweden*; *[3]Department of Regional Health Research, University of Southern Denmark, Odense, Denmark*; *[4]Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund, Sweden*; *[5]Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark*; *[6]Halmstad University, School of Health and Welfare, Halmstad, Sweden*; *[7]Karolinska Institutet, Institute of Environmental Medicine, Stockholm, Sweden*; *[8]Department of Orthopaedics, Clinical Sciences, Sahlgrenska Academy, Gothenburg University, Göteborg, Sweden*; *[9]Sahlgrenska University Hospital, Department of Orthopaedics, Göteborg, Sweden*; *[10]Rydberg Laboratory of Applied Sciences, Halmstad University, Halmstad, Sweden*

Background: Knee osteoarthritis (KOA) is a heterogeneous disease. Different classification criteria for symptomatic KOA (SKOA) have been proposed. Determining the prevalence and comparing the different criteria of SKOA in patients with knee pain will serve as a base when studying the predictive ability of these criteria in a longer perspective.

Objectives: To study the prevalence of SKOA in individuals with knee pain according to three different classification criteria: the American College of Rheumatology (ACR), (1), the European League Against Rheumatism (EULAR)(2), and the National Institute for Health and Care Excellence (NICE) (3).

Methods: Baseline data from an ongoing longitudinal study (HALLOA) including 296 individuals with knee pain, recruited by advertisement, were analysed. The individuals were categorized according to the classification criteria of SKOA (ACR, EULAR and NICE) based on age, clinical examination (crepitation), and self-reported data from KOOS (pain, symptoms, ADL, and sport/recreation), and dichotomized as fulfilling the criteria (SKOA) or not (no SKOA). BMI was measured (kg/m^2). Radiographic KOA (RKOA) was assessed according to Ahlbäck criteria (1-5), defined as RKOA with grade 1 or more in at least one knee. Prevalence was calculated (frequencies, %) for each criterion, and Chi-Square test or the Independent-Samples t-test were used for comparisons between individuals fulfilling SKOA or not.

Results: The mean age was 52 (min-max 24-73) years, 70% were women and 22% were classified with RKOA. The prevalence of SKOA according to each criterion was 57% (ACR), 51% (EULAR) and 73% (NICE) respectively. In total, 48% had SKOA according to all three criteria and whereof 32% had RKOA, compared to 10% RKOA among individuals with no SKOA. Regardless of the criterion, significantly more individuals classified with SKOA also had RKOA compared to individuals with no SKOA, p<0.001. Those classified as SKOA were significantly older and had higher BMI compared with no SKOA (Table 1).

Conclusion: Approximately 50-70% of the individuals with knee pain were classified as having SKOA, where EULAR criteria had the lowest prevalence. A better understanding of early knee pain classification according to different clinical criteria is essential for the ability to capture and follow the long-term prognosis of early SKOA. Further longitudinal studies are needed.

AB0587 ASSESSING THE CHARACTERISTICS AND MANAGEMENT OF KNEE OSTEOARTHRITIS PATIENTS WITH HYPERTENSION BY CLINICIAN SPECIALITY

D. Baldock[1], E. Baynton2, C. F. Ng[3]. *[1]Ipsos MORI, Healthcare Service Line, london, United Kingdom*; *[1]Ipsos MORI, Healthcare Service Line, london, United Kingdom*; *[3]Ipsos Sdn Bhd, Healthcare Service Line, Kuala Lumpur, Malaysia*

Background: Though the pathogenesis of knee osteoarthritis (OA) is complex, patients with OA frequently have other comorbidities, including hypertension, which eludes to other considerations needed when deciding appropriate treatment management.

Objectives: This study aims to examine the profiles of knee OA patients with hypertension vs. those without any comorbidities, and to elucidate key differences between these patient groups as potential areas of consideration.

Methods: A multi-center, online medical chart review study of patients with OA was conducted between May – July 2020 among US rheumatologists (rheums), orthopedic surgeons (orthos), primary care physicians with a focus in sports medicine (SM PCPs), and pain specialists. Physicians recruited were screened for duration of practice in their specialty (3-50 years) and caseload (>=35 knee OA patients personally managed, at least 10 being moderate-severe). Patient charts were recorded for the next 5 eligible patients seen during the screening period. Respondents abstracted patient demographics and treatments used. Descriptive statistics were used to analyse the data.

Results: 260 physicians were recruited and collectively reported 796 knee OA patients; 559 were reported to experience hypertension whilst 237 were reported as not experiencing any comorbidities.

Reported hypertension patients were significantly older (mean 67 vs 59 years old, respectively; p≤0.01) and weighed more (mean 82kg vs 77kg, respectively; p≤0.01) than patients without comorbidities; they were also significantly more likely to be previous smokers compared to those without comorbidities (23% vs 8%, respectively; p≤0.01). With regards to current knee OA severity, both orthos and SM PCPs reported a significantly higher proportion of hypertension patients that were deemed 'severe' (physician opinion) vs patients without comorbidities (orthos: 50% vs 32%, respectively; SM PCPs: 42% vs 23%, respectively; p≤0.01). Rheums and pain specialists reported greater mild opioid usage amongst hypertension patients compared to those without comorbidities (rheums: 28% vs 10%, respectively (p≤0.05); pain specialists: 40% vs 9%, respectively; (p≤0.01)); orthos and SM PCPs stated significantly greater use of corticosteroid injections amongst their reported hypertension patients vs those without comorbidities (orthos: 60% vs 41%, respectively; SM PCPs: 40% vs 19%, respectively; p≤0.01). Hypertension patients reported by orthos and SM PCPs are more likely to be

considered for total knee replacement (TKR) surgery compared to those without comorbidities (orthos: 59% vs 32%, respectively; SM PCPs: 37% vs 19%, respectively; p≤0.01). Conversely, hypertension patients reported by rheums are less likely to be considered for TKR vs those without comorbidities (41% vs 18%, respectively; p≤0.05).

Reported hypertension patients had a significantly higher mean Visual Analogue Scale for Pain (VAS) score than patients without comorbidities (6.6 vs 5.9, respectively; p≤0.01). A significantly higher proportion of patients with hypertension demonstrate radiographic evidence of bone erosion compared to those without comorbidities (69% vs 56%, respectively; p≤0.01).

Conclusion: From the sample surveyed, knee OA patients with hypertension may require a more specific and holistic treatment approach that takes into account their CV status and managing physician specialty. Further investigation using comparator cohort is warranted.

AB0588 "ESORT" ITALIAN SOCIETY OF RHEUMATOLOGY (SIR) REGISTER ON OSTEOARTHRITIS (OA): PRELIMINARY DATA

G. Gigliucci[1], O. De Lucia[2], A. Fioravanti[3], F. Galluccio[4], S. Guiducci[5], A. Moretti[6], M. Matucci-Cerinic[5], A. Murgo[2], S. Parisi[7], R. Ramonda[8], S. Tenti[3], E. Tirri[9], A. Migliore[1]on behalf of Study group on osteoarthritis - Italian Society of Rheumatology (SIR). [1]*San Pietro Hospital, Rheumatology Unit, Roma, Italy*; [2] *ASST Gaetano Pini-CTO Institute, Division of Clinical Rheumatology, Milan, Italy*; [3]*Azienda Ospedaliera Universitaria Senese - Policlinico Le Scotte, Department of Medicine, Surgery and Neuroscience - Rheumatology Unit, Siena, Italy*; [4]*Careggi University Hospital - University of Florence, Department of Clinical and Experimental Medicine - Division of Rheumatology, Firenze, Italy*; [5]*Careggi University Hospital - University of Florence, Department of Clinical and Experimental Medicine - Department of Geriatric Medicine - Division of Rheumatology and Scleroderma Unit, Firenze, Italy*; [6]*University of Campania Luigi Vanvitelli, Multidisciplinary Department of Medical and Surgical Specialties and Dentistry, Naples, Italy*; [7]*Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino, Department of General and Specialty Medicine - Unit of Rheumatology, Turin, Italy*; [8]*University of Padova, Department of Medicine-DIMED - Rheumatology Unit, Padova, Italy*; [9]*Hospital San Giovanni Bosco, UOSD Reumatologia, Naples, Italy*

Background: In Italy Osteoarthritis (OA) is a widespread and disabling disease that affects an increasingly large number of patients in the population, representing one of the main causes of morbidity and disability with high socio-economic costs. The etiology of OA is multifactorial, even if the significant association with some modifiable risk factors like mechanical overload and obesity is now well demonstrated. Early diagnosis and treatment strategies in OA could reduce both patient morbidity and associated costs.

Objectives: Promoted by the Italian Society of Rheumatology (SIR), The Early Symptomatic OsteoaRThritis (ESORT) registry has the aim to study the natural history of OA from the earliest stages (pre- radiographic) considering risk factors in the progression of the disease, and the influence of therapeutic factors on long-term disease outcomes. The ESORT register aims to describe the socio-demographic and clinical characteristics of patients affected by OA in Italy; evaluates the extent of symptoms, functional damage, comorbidities, the frequency of use of drugs currently indicated in our country, and differences related to clinical subsets according with comorbidities and geographical localization of the patient.

Methods: Actually 8 Italian Rheumatology centers are involved in the online data entry data of the SIR registry (developed and validated by SIR Study Center), considering patients affected by OA. In particular, the electronic database collects information about main demographic variables, significant anamnestic elements (risk factors and comorbidities), localization of OA, laboratory data, clinimetric indices with WOMAC / FIHOA / VAS scales, radiographic instrumental data and therapy in act. These data are reported in specific forms in the register with annual reassessment.

Results: Currently, 318 patients with OA are included in the "ESORT" registry with an extension of observation up to 48 months, 214 women and 104 men with an average age of 71 years and an average weight of 72 kg. About 14% of patients affected by knee OA show Kellgren and Lawrence radiological stage 0 in presence of painful symptoms at the knees. The most frequent localization of OA is the knee (63%), followed by the hip (41%), hand (36%), spine (34%), and other sites (16%). The Table 1 shows details of some parameters (average age, average weight, intake of NSAIDs, intake of opioids and intake of chondroprotectors) according to the localization of the disease. From the registry data, patients with OA results treated mainly with NSAIDs and chondroprotectors, and patients with knee OA are the most frequently treated with opioid analgesics (44%), less used in other OA locations.

Conclusion: The "ESORT" register is a useful tool for epidemiological and clinical information relating to patients with OA and for monitoring the evolution of the disease and the response to therapy.

	Average age (years)	Average weight (kg)	Intake of NSAIDs (% of patients)	Intake of opioids (% of patients)	Intake of chondroprotectors (% of patients)
OA hand	70	67	74%	10%	25-31%
OA knee	74	75	85%	44%	53-59%
OA hip	69	70	75%	25%	24-28%
OA spine	75	75	76%	14%	19-28%
OA other localization	74	73	69%	13%	15-35%

AB0589 STUDY OF THE EFFECTIVENESS OF PELOID THERAPY IN THE TREATMENT OF OSTEOARTHRITIS OF THE KNEE JOINTS IN THE CONDITIONS OF THE SANATORIUM " CHUVASHIYAKURORT»

N. Zhuravleva[1], L. Karzakova[1], S. Kudryashov[1], A. Arkhipova[2]. [1]*Federal State Budgetary Educational Institution of Higher Education "The Chuvash State University named after I.N. Ulyanov", Department of Internal Medicine, Cheboksary, Russian Federation*; [2]*Budget Institution "Republican Clinical Hospital" of Public Health Ministry of the Chuvash Republic, rheumatology department, Cheboksary, Russian Federation*

Background: Peloids are successfully used in the treatment of various diseases. The sapropel mud-silt deposits of freshwater reservoirs are the most widely used for joint diseases. The sapropel mud from the freshwater lake «Kogoyar»

(Russia, Cheboksary) has unique properties. The right to extract and use sapropel belongs to the sanatorium "Chuvashiyakurort" (Russia) [1]. The organic biostimulants of the sapropel mud (bitumen, fatty and humic acids, amino acids, hormones, lipids) have a pronounced anti-inflammatory effect on cartilage. High humidity (87%) provides sapropel high thermal qualities.

Objectives: The aim of the research was to study the effectiveness of peloid therapy in patients with osteoarthritis of the knee joints at the II X-ray stage using the sapropel mud of Lake «Kogoyar».

Methods: The object of the study was 150 patients of the sanatorium "Chuvashiyakurort" aged from 55 to 62 years (89 women and 61 men). The patients were randomly divided into 2 groups. The first group (75 people) received basic therapy - chondroprotectors (Teraflex) and nonsteroidal anti-inflammatory drugs (NSAIDs) on demand. The second group (75 people) received basic therapy with the addition of peloid application. The peloid was used in the natural, minimally modified, undiluted form. The peloid therapy protocol: the peloid was heated to 50 °C before use and applied to the affected joint with a layer of 4-5 cm thick and wrapped with a warm cloth on top. The procedure took 30 minutes. Five three-day cycles of applications with one-day breaks were performed. At the end of the procedure, a patient was unraveled, the mud was removed from him and he took a warm shower. Then he had a rest for 30 to 40 minutes in the recreation room. Before the start of treatment and after its completion, a survey of patients was conducted with the fixation of pain on the VAS scale, the duration of morning stiffness, fatigue and decreased performance, general discomfort, dependence on taking NSAIDs.

Results: The analysis of the survey results revealed a decrease in VAS pain and morning stiffness in both groups. However, patients in the second group had a more pronounced reduction in the average VAS pain score (26% lower compared to the first group) and the duration of morning stiffness (20% lower compared to the first group). In addition, the number of patients who indicated a decrease in dependence on taking NSAIDs was 28% higher than in the group that received only standard therapy.

Conclusion: Peloid therapy enabled to reduce the pain on the back, reduce the frequency of the need for NSAIDs, improve the condition of patients, which is the reflection of the positive clinical dynamics in patients with osteoarthritis of the knee joints, and contributed to the effectiveness of treatment.

AB0590 ARTHRITIS OF THE KNEE AND BALANCE DISORDER

W. Belhaj[1], S. Miladi[2], A. Fazaa[2], M. Sellami[2], K. Ouenniche[1], L. Souebni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. *[1]University of tunis el manar, Faculty of Medicine of Tunis, Mongi slim Hospital, Rheumatology Department, Tunis, Tunisia*; *[2]University of Tunis el manar, Faculty of Medicine of Tunis, Mongi slim Hospital, Rheumatology Department, TUNIS, Tunisia*

Background: Knee osteoarthritis has been identified as a risk factor for falls and balance disorders. Several clinical scales have been put in place to assess this risk.

Objectives: The aim of this work was to assess the risk of falls in patients followed for osteoarthritis of the knee.

Methods: A prospective study was conducted over a period of 4 weeks. Sixty-six patients followed for knee osteoarthritis at different stages of the disease were included into this work. Epidemiological data, physical examination data and x-ray data were collected. The impact of knee osteoarthritis was evaluated by the Lequesne and WOMAC indices. The patients were asked about the history of a fall since the onset of knee osteoarthritis and they had the Tinetti test where a score less than 20 reflects a very high risk of falling, from 20 to 23 significant risk, from 24 to 27 moderate risk and 28 means a normal test.

Results: In the studied population, the majority of patients were women (87%) with an average age of 55 years and an average body mass index of 29kg / m2. The most common comorbidities were high blood pressure (61%), diabetes (38%) and osteoporosis (36%). Sixty-nine percent of patients took more than two oral treatments. The average duration of development of osteoarthritis of the knee was 9 years. The most common radiological stage was stage 1 (58%) followed by stage 2 (31%). The site was femorotibial in 88% of cases, patellofemoral in 4% of cases and bi or tri compartmental in 8% of cases. The arthritis most often affected both knees: 86% of cases. The average of the Lequesne index was 11. The mean WOMAC index was 12 in pain, 1.5 in stiffness and 48 in dysfunction. Patients who had a normal Tinetti score represented 39% of the studied population, those who had a score from 24 to 27 were 35% of the studied population, those who had a score between 20 and 23 were 14% of the studied population, and those who had a score below 20 were 12% of the studied population.

Patients reporting a history of one or multiple falls were 19%. Among these patients 93% were women and 88% were hypertensive under antihypertensive treatment. The average age of these patients was 61 years. The Tinetti test revealed in this group of patients that 40% had a very high risk of falling, 48% had a high risk of falling, 10% had a moderate risk and 2% had a normal Tinetti test. These patients had been followed for knee osteoarthritis for an average of 10 years. The average Lequesne index was 12.5. The average WOMAC index was 12 for pain, 2 for stiffness and 55 for dysfunction.

In the following Table 1 we summarized the different stages of risk of falling according to the Tinetti score according to the epidemiological data and the characteristics of knee osteoarthritis:

Tinetti score	Less than 20	From 20 to 23	From 24 to 27	Equal to 28
Average age (years)	66	65	56	47
Women (%)	78	81	88	89
Men (%)	22	19	12	11
Average BMI (kg/m^2)	31,7	30,4	29,3	28,6
High blood pressure (%)	77	60	67	57
Average Lesquene	12,5	11	11	10,5
WOMAC pain	14	12	12	10
WOMAC stiffness	2	1,5	1	1
WOMAC dysfunction	58	49	46	44

Conclusion: The epidemiological characteristics as well as the knee osteoarthritis characteristics are statistically close in the different groups of stages of risk of fall according to Tinetti test. Indeed, according to this study, knee osteoarthritis does not represent a significant risk factor for falls.

AB0591 ASSESSMENT OF KNEE-RELATED SYMPTOMS, ACTIVITIES, AND QUALITY OF LIFE IN PATIENTS WITH POLYCYSTIC OVARY SYNDROME

P. Kabakchieva[1,2], T. Georgiev[3,4], A. Gateva[1,2], Z. Kamenov[1,2]. *[1]Medical University - Sofia, Department of Internal Medicine, Sofia, Bulgaria*; *[2]Aleksandrovska University Hospital, Clinic of Endocrinology, Sofia, Bulgaria*; *[3]Medical University - Varna, First Department of Internal Medicine, Varna, Bulgaria*; *[4]St. Marina's Hospital, Rheumatology Clinic, Varna, Bulgaria*

Background: Osteoarthritis (OA) is a slowly progressive disease that probably begins in young adulthood when a timely treatment would present the possibility to reverse or slow down the disease process. Obesity and sex hormones play an essential role in the pathogenesis of OA in women and their influence on joint function persists throughout the whole life [1]. Polycystic ovary syndrome (PCOS) is the most common endocrine disorder among women of reproductive age characterized by sex-hormonal disbalance, metabolic abnormalities, and most commonly obesity. It seems that PCOS presents the best opportunity to study the complex interactions among hormonal disbalance, obesity, and (pre) osteoarthritis.

Objectives: Our study aims to assess the knee-related symptoms, activities, and quality of life in young women with PCOS and to compare them with healthy volunteers using Knee Injury and Osteoarthritis Outcome Score (KOOS) developed for younger and more active individuals [2].

Methods: Fifty-four patients with PCOS who met the Rotterdam criteria were compared with 26 healthy women. Both groups were matched by age and body mass index (BMI). The exclusion criteria of the study were: the presence of inflammatory/autoimmune rheumatic disease and/or another endocrine disorder. Pregnant women and participants, who used systemic corticosteroids, antiandrogens, or insulin-sensitive drugs in the last 3 months were also excluded from the study. After written informed consent all participants filled in the questionnaire. KOOS was scored in each of its 5 domains: pain, symptoms, activities of daily living (ADL), sport and recreation function, and knee-related quality of life (QoL). Additionally, detailed anthropometric data, clinical examination, and hormonal assessment (testosterone, dehydroepiandrosterone sulfate [DHEAS], androstenedione, 17-OH-progesterone, luteinizing hormone [LH], follicle stimulating hormone [FSH], and estradiol) were carried out in all overnight-fasted participants during a follicular phase of a menstrual cycle.

Results: Patients and healthy volunteers had similar anthropometric and demographic characteristics but PCOS women were expectedly more hyperandrogenic and hirsute than controls. Patients and controls did not differ significantly in their knee pain, knee-related QoL, and sport and recreation function. Knee-related symptoms were more prominent in the PCOS group compared to controls ($p = 0.035$). ADL associated with the knee joint were also more impaired in patients ($p = 0.001$). Obese PCOS women had a significantly lower score in the ADL domain than normal and overweight patients ($p = 0.035$). In the PCOS group, both knee-related ADL and sport and recreation function correlated significantly with weight ($p = 0.025$ and $p = 0.034$, respectively) and waist circumference ($p = 0.011$ and $p = 0.016$, respectively), among all studied anthropometric parameters. Sex hormones did not correlate with any of the evaluated KOOS subscales.

Conclusion: PCOS patients may experience impaired physical function related to daily life due to knee problems. Obesity may further contribute to knee-related ADL dysfunction. Hormonal disturbances did not show any association with knee complaints in our study.

AB0592 ASSESSMENT OF KNOWLEDGE OF THE APPLICATION OF TOPICAL ANALGESICS

S. Miladi[1], W. Belhaj[1], A. Fazaa[1], M. Sellami[1], K. Ouenniche[1], L. Souebni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*University of Tunis el Manar, Faculty of Medicine of Tunis, Mongi slim Hospital, Rheumatology Department, Tunis, Tunisia*

Background: In chronic osteoarticular pain, especially knee osteoarthritis, topical analgesics and topical non-steroidal anti-inflammatory drugs represent an interesting therapeutic alternative for patients with several comorbidities in order to avoid side effects and medical interactions.

Objectives: The aim of this work was to assess how patients apply a topical analgesic.

Methods: A prospective study has been conducted over a period of 4 weeks. Sixty-six patients followed for knee osteoarthritis at different stages of the disease and under topical analgesic treatment were integrated into this study. Epidemiological data, physical examination and x-ray data were collected. The impact of knee osteoarthritis was evaluated by the Lequesne and WOMAC indices. Patients were asked about how long they apply the treatment, how often they use the treatment per week and whether they are massaging the aching area while applying the treatment.

Results: In the studied population, the majority of patients were women (87%) with an average age of 55 years. Forty percent of the patients were illiterate as long as 21% received a college education. Patients' occupations were distributed as follows: 59% housewives, 21% retirees, 12% manual occupations and 8% non-manual occupations.

The most common comorbidities were high blood pressure (61%), diabetes (38%) and osteoporosis (36%).

The average duration of development of osteoarthritis of the knee was 9 years. The most common radiological stage was stage 1 (58%). The site was femorotibial in 88% of cases, patellofemoral in 4% of cases and bi or tri-compartmental in 8% of cases. The osteoarthritis most often affected both knees: 86% of cases

The average of the Lequesne index was 11. The average WOMAC index was 12 for pain, 1.5 for stiffness and 48 for dysfunction.

All the interviewed patients were on topical analgesics for an average of 5 years. The average frequency of application of topical analgesics was 9 times per week. Housewives and retirees used the treatment on average 14 times per week while working patients use the treatment on average 5 times per week. Seventy-two percent of patients reported that they performed an average massage lasting 11 minutes with each application.

Among patients with secondary and university education, 64% of patients reported that they performed a massage on the painful knee while applying the medication.

Patients followed for knee osteoarthritis for more than 10 years tend to apply the local analgesic for a shorter period of time (an average of 5 minutes).

Conclusion: Patients followed for osteoarthritis of the knee who are taking topical analgesics tend to make misuse, including massaging for a long time and applying treatment less frequently than recommended. The level of education does not seem to play a role in knowing the right way to apply. However, patients who have been followed for a longer period for knee osteoarthritis use the treatment more correctly.

AB0593 PERCEPTION OF THE EFFECTIVENESS OF TOPICAL ANALGESICS IN PATIENTS WITH OSTEOARTHRITIS OF THE KNEE

W. Belhaj[1], S. Miladi[1], A. Fazaa[1], M. Sellami[1], K. Ouenniche[1], L. Souebni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*University of Tunis el Manar, Faculty of Medicine of Tunis, Mongi slim Hospital, Rheumatology Department, Tunis, Tunisia*

Background: Osteoarthritis of the knee is one of the most common joint diseases. It mainly manifests as pain and can become disabling over time. Several symptomatic therapeutic methods are used to relieve patients with knee osteoarthritis and give them more autonomy. Topical analgesics are considered as an interesting alternative for old and poly-medicated patients.

Objectives: The aim of this work was to assess the perception of the effectiveness of topical analgesics by patients followed for knee osteoarthritis.

Methods: A prospective study has been conducted collecting 66 patients followed for knee osteoarthritis at different stages of the disease and under topical analgesic treatment. Epidemiological data, physical examination and x-ray data were collected. The impact of knee osteoarthritis was evaluated by the Lequesne and WOMAC indices. Patients were asked to evaluate their perception about: the time that makes the medication to act, the duration of action and overall satisfaction with the topical analgesic by rating it from 0 to 5. Zero represents complete dissatisfaction while 5 represents complete satisfaction. Patients were also asked about the side effects observed after the use of the topical treatment and whether they recommended this treatment to a friend or a parent.

Results: In the studied population, the majority of patients were women (87%) with an average age of 55 years. The most common comorbidities were high blood pressure (61%), diabetes (38%) and osteoporosis (36%). Sixty-nine percent of patients were taking more than two oral treatments. The average duration of development of osteoarthritis of the knee was 9 years. The most common radiological stage was stage 1 (58%). The site was femorotibial in 88% of cases, patellofemoral in 4% of cases and bi or tri compartmental in 8% of cases. The osteoarthritis most often affected both knees in 86% of cases.

The average of the Lequesne index was 11. The average WOMAC index was 12 for pain, 1.5 for stiffness and 48 for dysfunction.

All the patients surveyed were on topical non-steroidal anti-inflammatory drugs (NSAIDs), 37.7% combined local herbal medicine with local NSAIDs, 53% were taking oral analgesics, and 19% were using oral non-steroidal anti-inflammatory drugs in the past month.

The average rating for time that takes the topical treatment to act was 2.9, for duration of action was 1.2, and for overall satisfaction was 2.8. No adverse effects of topical treatment have been reported.

For patients over 60 years old, better satisfaction was noted (the average score for overall satisfaction was 3.2).

Patients with a WOMAC Pain Index greater than 10 were less satisfied (the average overall satisfaction score was 1.1). Patients who took both topical NSAIDs and topical herbal medicine reported that topical NSAIDs were more effective in 66% of cases. Forty percent of patients recommended topical treatment to a friend or a family member.

Conclusion: In patients with chronic pain associated to osteoarthritis of the knee, topical analgesics are considered a good long-term therapeutic alternative. Patients are generally satisfied with the effectiveness of the local treatment, in particular the immediate effect felt after application, but less satisfied with the duration of action. Perception of effectiveness appears to be affected by age and degree of pain.

AB0594 IMPROVING OSTEOARTHRITIS CARE BY AUTOMATIC MEASUREMENT OF HIP EFFUSION USING AI

J. L. Jaremko[1], B. Felfeliyan[2], A. Rakkunedeth[1], B. Thejeel[1], V. Quinn-Laurin[1], M. Østergaard[3], P. G. Conaghan[4], R. Lambert[5], J. Ronsky[6], W. P. Maksymowych[5]. [1]*University of Alberta, Radiology and Diagnostic Imaging, Edmonton, Canada*; [2]*University of Calgary, Biomedical Engineering, Calgary, Canada*; [3]*Copenhagen University, Department of Clinical Medicine, København, Denmark*; [4]*University of Leeds, School of Medicine, Leeds, United Kingdom*; [5]*University of Alberta, Department of Medicine, Edmonton, Canada*; [6]*University of Calgary, Department of Mechanical and Manufacturing Engineering, Calgary, Canada*

Background: Osteoarthritis (OA) is the commonest disease affecting hip joints and has high prevalence across various age groups [1,2]. Effusion is a hallmark of OA and could represent a potential target for therapy [3–5]. Positive correlations of effusion to clinical outcomes are not well established, partly due to variability in manual assessment. Voxel-based volume quantification could reduce this variability [6].
Objectives: We examine the inter-observer agreement of manual assessment of voxel-based effusion volume from coronal STIR MRI sequences at two time points and examine the feasibility of using Artificial Intelligence (AI) for standalone volume assessment.
Methods: Our algorithm is based on Mask R-CNN [7] and was trained on labeled effusion regions in MRI slices from 68 patients with hip osteoarthritis. For validation, 2 human readers measured effusion from MRI STIR sequences of 25 patients at baseline and at 8 weeks follow-up. AI was used to measure effusion volume as an independent reader. Agreement between human readers and AI was assessed using absolute difference in volume (DV), Coefficients of Variation (CoV) and intraclass correlation coefficient (ICC).
Results: Effusion regions detected by AI closely correlated with manual segmentation (Figure 1) for all samples. Differences in volumes measured by each pair of readers are summarized in Table 1. Agreement was excellent between human readers (ICC=0.99) and for each reader vs AI (ICC = 0.85-0.87).

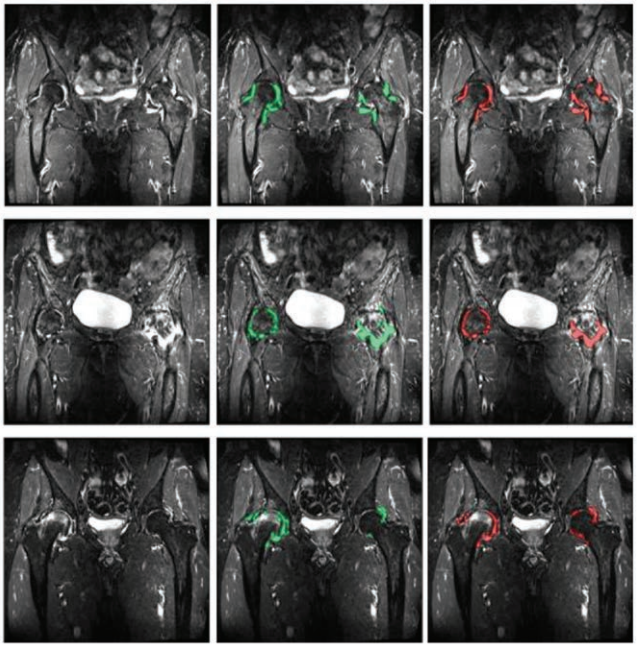

Figure 1. Mask overlays of regions of joint fluid detected by human readers (green, column 2) and AI (red, column 3) from 3 different patients. Raw MRI images are shown in column 1.

Table 1. Comparison of volumes measured in cubic millimeters and agreement between each pair of readers (with AI as the 3rd reader)

Volumes measured by readers		Agreement between reader pairs			
Reader	Overall Volume Mean ± Standard Deviation	Reader Pair	Difference in Volume Mean ± Standard Deviation	CoV	ICC
Reader 1	6943 ± 5845	Reader 1-2	1127 ± 900	0.21	0.99 [0.98, 1.0]
Reader 2	7638 ± 5619	Reader 1-AI	3311 ±1643	0.35	0.87 [0.7, 0.94]
AI	11014 ± 4454	Reader 2-AI	4151 ± 4986	0.27	0.85 [0.66,0.94]

Conclusion: Initial results of automatic effusion measurement using AI show high agreement with human experts. This has potential to reduce variability and save expert time in OA MRI assessment, and to lead to improved OA care.

AB0595 CURCUMA LONGA AND BOSWELLIA SERRATA FOR OSTEOARTHRITIS PAIN MANAGEMENT: A LITERATURE REVIEW OF SPECIFIC FORMULATED EXTRACTS FOR COMBINATION

V. Sethi[1], K. Siddiqui[1], M. Garg[2]. [1]*GSK Consumer Healthcare Pte Ltd, Pain Relief Medical Affairs, Singapore, Singapore*; [2]*University of Newcastle Callaghan, Nutraceuticals Research Program, Newcastle, Australia*

Background: The need for safe, effective pain management for osteoarthritis (OA) is important as the number of australian people with OA is expected to grow by 30% from year 2015 to year 2030. Extracts from *Boswellia serrata* and *Curcuma longa* are described to have anti-inflammatory and analgesic properties. Clinical studies have also reported efficacy for improving joint pain and stiffness and tolerability. A combination of *Boswellia serrata* and *Curcuma longa* formulated extracts might provide benefits in OA pain management.
Objectives: To review the literature describing the efficacy, safety and bioavailability of a formulated *Boswellia serrata* extract enriched with boswellic acids and a *Curcuma longa* extract formulated with piperine for OA pain management.
Methods: PubMed searches for studies reporting efficacy, safety, and/or bioavailability data for Boswellia and Curcumin formulations were conducted on 4 December 2020 with no publication date limitations.
Results: For the enriched Boswellia formulation, two clinical studies in OA assessing efficacy and one preclinical bioavailability study were identified[1,2,3]. For the curcumin formulation, 2 clinical studies were identified[4,5]. Two double-blind, randomized, parallel, placebo-controlled studies (each N=60) demonstrated significant improvement in Western Ontario and McMaster Universities OA index (WOMAC) pain and stiffness subscale scores in patients with knee OA receiving the enriched Boswellia formulation (100mg/d): In the first study[1], a 30-day treatment with enriched Boswellia, compared with placebo, significantly reduced WOMAC pain (–23.6; placebo, –5.6; P<0.0001) and stiffness (–18.8; placebo, –3.4; P=0.0014) scores. Improvement in pain visual analog scale (VAS) score was significant versus placebo at day 5 (P<0.05). In the second study[2], A 90-day treatment with enriched Boswellia also significantly improved WOMAC pain (–31.1; placebo, –8.4; P<0.0001) and stiffness (–27.7; placebo, –9.9; P<0.0001) scores versus placebo; Of note, a significant reduction in pain score and functional ability was observed as early as day 7. For the curcumin/piperine formulation, piperine was added to increase the bioavailability of curcumin in humans as established in a comparative bioavailability and pharmacokinetic study[4]. The results obtained in his study demonstrates that piperine enhances the oral bioavailability of curcumin without side effects. Curcumin/piperine monotherapy (350-400mg curcumin TID) was also shown to significantly reduce WOMAC, VAS and Lequesne's pain functional index (LPFI) compared to placebo in a randomized double-blind placebo-controlled parallel-group study (N=40)[5]. In a sub-study that measured inflammatory biomarkers (N=40), there is no significant difference in the magnitude of changes

in the inflammatory biomarkers (IL-4, IL-6, hs-CRP, TNF-α, TGF-β and mean ESR between the curcuminoid treatment group and the placebo group ($p>0.05$)[6].

Conclusion: Enriched boswellic acid and curcumin/piperine formulations demonstrate efficacy and safety for suitable treatment option: both ingredients, often cited as natural alternatives to address OA pain and stiffness could be evaluated to explore the potential benefit as a formulated combination.

AB0596 THE POSSIBLE CONTRIBUTION OF DEHYDROEPIANDROSTERONE SULFATE FOR OSTEOARTHRITIS OF THE KNEE

I. Bashkova[1,2], I. Madyanov[1,3], K. Misko[1], E. Preobrazhenskaia[4]. [1]*Chuvash State University named after I.N. Ulyanov, Department of Hospital Therapy, Cheboksary, Russian Federation*; [2]*Federal Center of Traumatology, Orthopedics and Endoprosthesis, Consultative polyclinic, Cheboksary, Russian Federation*; [3]*Republican Clinical Hospital, Department of Endocrinology, Cheboksary, Russian Federation*; [4]*Federal Center of Traumatology, Orthopedics and endoprosthesis, Scientific and Educational Department, Cheboksary, Russian Federation*

Background: Genetic, biochemical, metabolic, hormonal (primarily imbalance of sex hormones) factors are involved in the progression of osteoarthritis (OA). Dehydroepiandrosterone and its metabolite, dehydroepiandrosterone sulfate (DHEA-S), have a stress-limiting, anti-atherogenic, anti-diabetic, antihypertensive, anti-infective, immunomodulatory effects. Heroprotective effect is not excluded. Experimental studies have identified a relationship between an age-related decrease in DHEA-S levels and various adverse effects of aging.

Objectives: To identify the contribution of DHEA-S to the pathogenesis of OA, it`s advisable to conduct a comparative analysis of connection of the adrenal hormones with clinical, laboratory, radiological signs of the course of OA.

Methods: Patients with primary OA with a lesion of the knee joints (n=90, including 22 men) were examined. The age of the patients - 29-69 years, the duration of the disease – 1.5-20 years. The control group (n=114, including 26 men) was formed by random sampling of the population from healthy people, it`s representative by gender and age. We investigated the serum levels of cortisol, DHEA-S, estradiol (in women), testosterone (in men) and carried out radiography of the knee joints. OA was diagnosed using R.D. Althman, the x-ray stage-according to the classification of Kellgren and Lawrence. Statistically determined the mean value, standard deviation. Differences between the samples were considered statistically significant at $p<0.05$. To create a model of OA pathogenesis, the method of principal components of factor analysis was used.

Results: The DHEA-S level in the blood of patients with OA was lower than that of the control group (2.40±1.20 vs 3.66±1.45 μg/ml, $p=0.001$),in women-was lower, than in men (2.25±1.17 vs 2.89±1.23 μg/ml, $p=0.045$). In the control group, gender differences were not statistically significant ($p>0.05$). All patients with OA showed an inverse correlation between age and DHEA-S ($r=-0.511$, $p=0.0001$, and $r=-0.549$, $p=0.0001$ respectively). For factor analysis the most important signs for the course of OA are ESR levels, C-reactive protein (CRP) in the blood (as markers of inflammatory component of OA, or factor 2) were selected, and the radiological stage of OA (degenerative component, or factor 1). In women, we regarded factor 1 as «degenerative», the maximum contribution to total dispersion was made by the «x-ray stage» (+0.72). This symptom was opposed by the «DHEA-S level» (-0.79) and «estradiol blood level» (-0.68), which suggests a link between degenerative and dystrophic processes in the knee joint in women with OA and a decrease in blood levels of DHEA-S and estradiol. Factor 2 we interpreted as «inflammatory». This was indicated by the values of «CRP» (+0.66) and «ESR» (+0.64). The «inflammatory» factor in women from hormonal indicators was opposed by the «blood cortisol content» (-0.31) and «DHEA-S level» (-0.26). Factor 1 in men accounted for 46% of the total variance. Since factor 1 in men included the most significant «CRP» (+0.85), «X-ray stage» (+0.77) and «ESR» (+0.72), we called it «antidegenerative anti-inflammatory factor». The maximum value (modulo) in factor 1 is for DHEA-S (-0.76) and the lower is for testosterone (-0.53). So, in men, a sufficient level of DHEA-S is closely related to the «antidegenerative-anti-inflammatory» factor of OA pathogenesis and DHEA-S counteracts 2 key pathogenetic processes simultaneously-degenerative and inflammatory.

Conclusion: In women, a decrease in DHEA-S is a risk factor for the predominantly degenerative component of OA, in men it`s a universal risk factor, predisposing both to the development of inflammation and degenerative changes in the joints

AB0597 COMPLIANCE WITH CLINICAL PRACTICE GUIDELINES IN KNEE OSTEOARTHRITIS

M. Yasmine[1], L. Souebni[1], S. Miladi[1], A. Fazaa[1], S. Mariem[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Knee osteoarthritis (OA) is a leading cause of disability among older adults. Recently, evidence-based guidelines for the comprehensive management of osteoarthritis (OA) were developed by the American College of Rheumatology (ACR).

Objectives: The aim of this study was to assess compliance of doctors with ACR 2019 clinical practice guidelines for the management of knee OA.

Methods: We conducted a prospective study including rheumatologists and general practitioners. The doctors were invited to answer a structured questionnaire via Google Form. The outcomes of interest concerned the medical management of knee OA as well as alternative medicine.

Results: The study included 100 doctors: 75 rheumatologists and 25 general practitioners. Almost half of them (49%) have been practicing medicine for more than 10 years. Forty four percent of doctors see between 10 to 20 patients with knee OA per month and 47% of them declared seeing more than 20 patients. Regarding the pharmacological treatment of knee OA flares, oral Non-steroidal Anti-inflammatory drug (NSAIDs) was the initial molecule of choice (91%) followed by grade I analgesics (86 %) and topical NSAIDs (68%). Tramadol and non-Tramadol opioids as well as intraarticular glucocorticoid injections were prescribed respectively in 41% and 46 % of cases. Glucosamine and chondroitin sulfate were prescribed in 49% and 54% of cases respectively and as a combination in 20% of cases. The reasons for non-prescribing these molecules were non-affordable prices (n=19), a lack of efficacy (n=6) and potential sides effects (n=1). Seventy three percent of doctors prescribe hyaluronic acid injections, with a frequency of three weekly injections in 38.7 % of cases and according to the response to the first injection in 61.3% of cases. The combination of both corticosteroids and hyaluronic acid injection was preferred in 38% of cases. The majority of doctors (84%) referred their patients to physical therapy as a first-line prescription (82.1%) or after medical treatment failure (17.9%). The use of alternative medicine was at follows: acupuncture (42.7%), prolotherapy (28.1%) and platelet-rich plasma injections (16.7%). Thirty eight doctors recommended against alternative medicine.

Conclusion: Our study showed a poor compliance to guidelines regarding the use of intra-articular injections and alternative medicine. Even though, these guidelines provide direction for clinicians, doctors and patients should engage in shared decision-making that accounts for patients' values, preferences, and susceptibilities.

Disclosure of Interests: None declared.

AB0598 EFFICACY OF ULTRASOUND GUIDED INJECTIONS OF A CROSS-LINKED SODIUM HYALURONATE COMBINED WITH TRIAMCINOLONE HEXACETONIDE FOR OSTEOARTHRITIS OF THE KNEE

F. Porta[1], G. Filippou[2], G. Sakellariou[3]. [1]*Florence, Istituto di Neuroscienze, Florence, Italy*; [2]*Luigi Sacco University Hospital, Rheumatology Department, Milano, Italy*; [3]*University of Pavia, Istituti Clinici Scientifici Maugeri IRCCS, Pavia, Italy*

Background: According to guidelines, the use of steroid and/or hyaluronate (HA) intra-articular injections for knee osteoarthritis (KOA) is controversial. Heterogeneity of studies and difference in HAs characteristics does not allow to draw safe conclusions. One of the major concerns is the accuracy of the procedure as up to 1/3 of injections could miss joint space when performed blindly (1), negatively affecting the efficacy of HA that needs to be placed correctly in the joint space

Objectives: The aim of our study was to evaluate the longterm efficacy of a novel association of a Cross-Linked Sodium Hyaluronate Combined With Triamcinolone Hexacetonide (SHCTH) in patients with KOA in a real life setting.

Methods: We retrospectively evaluated the clinical and ultrasonographic (US) data of patients (pts) affected by symptomatic KOA with intra-articular injections of SHCTH (1 injection every 6 months). Pts with concomitant inflammatory arthropaties were excluded. US guidance was carried out with the "in plane" technique choosing either the lateral suprapatellar or midpatellar approach. All pts were evaluated for pain with a VAS 0-10 for pain at baseline and after 2 weeks, 1, 3, 6, 9 and 12 months, with the WOMAC questionnaire and with US, scoring joint effusion, synovial hypertrophy (SH) and power Doppler (PD) synovial signal. Due to the retrospective design, the WOMAC data were available as VAS or Likert scales; to allow comparability these values were standardized. Clinical and US variables at different time points were compared using the Wilcoxon rank sing test, the McNemar test or the paired samples t-test, depending on the variable.

Results: 49 knees (43 pts, median age 70.6 years, 24 women) were included in the study. Kellgren Lawrence grade was 1 for 5 knees, 2 for 10, 3 for 17 and 4 for 9. SHCTH was delivered correctly in the joint space in all patients as assessed by US check during the injection and no side effects occurred. Of the 49 knees, 28 had an available 6 months follow-up, while 21 completed the 12 months follow-up, with an attrition mostly related to the COVID 19 pandemic. A rapid and sustained statistically significant decrease of both VAS pain and the WOMAC subscales was observed. The reduction of pain was already significant at 2 weeks, probably thanks to the corticosteroid component. At US evaluation, effusion significantly decreased at all time points. Although SH scores also significantly decreased, the effect on the proportion of affected joints was not as relevant. The reduction of PD was significant until month 9. Detailed results are presented in Table 1.
Conclusion: Our data show that US guided SHCTH injections provide a rapid and sustained clinical response in patients with symptomatic OA. Besides the effect on pain, the US data confirm the effect of the drug on the inflammation. US guidance guaranteed the correct placement of the product in all patients and eliminated the bias of wrong placement that may occur with blind injections, thus allowing to draw safe conclusions on the efficacy of SHCTH for the treatment of KOA.

AB0599 EFFICACY AND SAFETY OF COMBINATION THERAPY WITH NSAIDS AND ANTICONVULSANT, COMPARED WITH NSAID MONOTHERAPY FOR CHRONIC PAIN IN PATIENTS WITH OSTEOARTHRITIS OF THE KNEE JOINTS

E. Filatova[1], L. Alekseeva2, E. Taskina[1], N. Kashevarova[1], A. Lila[1], E. Sharapova3. *[1]VA Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*; *[1]VA Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*; *[1]VA Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: In 20-44% of patients with osteoarthritis of the knee joints neuroplastic changes occur due to central sensitization (1,2), which is the rationale for complex therapy, including centrally acting drugs, for more effective pain control.
Objectives: To evaluate the efficacy and safety of combination therapy with NSAID and anticonvulsant in comparison with NSAID monotherapy in patients with osteoarthritis of the knee joints and signs of central sensitization or nocyplastic pain
Methods: The study included 60 women with osteoarthritis of the knee joints (OAK) with signs of nocyplastic pain. Nocyplastic pain were revealed by neuropathic scales (DN4 questionnaire > 4 points), subject to the absence of patients lesions of the somatosensory nervous system. All patients were randomized into two age- and sex-matched groups: group I (n=30) received combination therapy with aceclofenac and pregabalin, group II (n=30) - monotherapy with aceclofenac. The observation period was 42 days and included three visits. All patients underwent a clinical and neurological examination, we assessed the overall WOMAC index, pain intensity at rest with the visual analogue scale (VAS), nocyplastic pain (DN4 and Pain DETECT questionnaires), anxiety and depression (HADS questionnaire) and the quality of life (EQ-5D questionnaire).
Results: The intensity of pain at rest according to VAS in patients of group I significantly decreased after 14 days (visit 2) and even further after 42 days (visit 3) (64.0 [50.0; 72.0] vs 49.0 [33.0; 55.0] vs 33.5 [22.0; 49.0] p = 0.006). In group II the intensity of pain at rest also decreased after 14 days (visit 2) (63.0 [41.0; 72.0] vs 48.0 [35.0; 58.0] p <0.001), however, did not change significantly from visit 2 to 3 (48.0 [35.0; 58.0] vs 44.0 [35.0; 60.0]) (p = 0.57).
The dynamics of neuropathic pain indicators according to the DN4 and Pain DETECT questionnaires was as follows: group I (visit 1-3) DN4 (6.0 [5.0; 7.0] vs 3.0[1.0; 4.0], p=0.001) and Pain DETECT (17.0 [16.0;20.0] vs 8.0 [5.0; 14.0], p=0.001). Group II DN4 (6.0[5.0;6.0] vs 5,0 [3,0; 6,0],p=0,05), Pain DETECT (17,0 [15,0; 19,0] vs 16.0 [14,0; 19,0],p=0,53).
The overall WOMAC index decreased significantly in both groups.
Significant positive dynamics in terms of the level of anxiety (9.0 [7.0;14.0] vs 7.0 [4.0;10.0], p=0.001), depression (8.0 [5.0;10.0] vs 6.5 [4.0;9.0], p= 0.03) and quality of life (0.52 [-0.02;0.52] vs 0.52 [0.52;0.59], p=0.01) was observed compared to baseline in group I but not in group II. Before the start of therapy, the groups were comparable in the studied parameters, however, after 42 days, anxiety (7.0 [4.0;10.0] vs 9.0 [7.0;12.0], p=0.02) and depression levels (6.5 [4.0;9.0] vs 8.0 [6.0;9.0], p=0.05) were statistically different. Moreover, the median anxiety and depression levels still exceeded 7 points in group II, indicating the presence of anxiety and depression.
Conclusion: Combination therapy of chronic pain with signs of nocyplastic pain with pregabalin and aceclofenac in patients with knee osteoarthritis has been shown to be effective in terms of pain intensity, the presence of neuropathic descriptors and the severity of anxiety compared with aceclofenac alone.

AB0600 VISCOSUPPLEMENTATION VERSUS PHYSICAL REHABILITATION IN KNEE OSTEOARTHRITIS COMPARATIVE STUDY ABOUT 117 CASES

S. Lahrichi[1], K. Nassar[1], S. Janani[1]. *[1]University Hospital of IBN ROCHD, Rheumatology, Casablanca, Morocco*

Background: Viscosupplementation with hyaluronic acid, and physical rehabilitation are part of the adjunct treatments for osteoarthritis, and particularly knee osteoarthritis.They can be used alone or combined.
Objectives: To compare the efficacy of rehabilitation and viscosupplementation in patients followed for stage II and III osteoarthritis.
Methods: This is a cross-sectional study, conducted in the department of rheumatology of the University Hospital ofIbn Rochd, Casablanca, between August 2020 and December 2020. Inclusion criteria: patients with stage II and III knee osteoarthritis fulfilling the ACR criteria. The diagnosis was made on standard x-rays including antero-posterior and lateral views. The functionalassessmentwas made with functional algo indices, WOMAC and Lequesnne. Pain was assessed with a visual analogue scale (VAS) on Day 0 and after 3 months. The patients were divided into 3 groups of 39 patients, the first (G1) received an infiltration of hyaluronic acid according to different protocols (multiple injections or single injection), the second (G2) benefited from a rehabilitation program twiceor three timesa week for three months, and the third group (G3) benefited from viscosupplementation associated with rehabilitation. Patients who received an intra-articular corticosteroid injection in the last 3 months were excluded.
Results: There were 117 patients. The mean age was 59.6 ± 8.6, with a female predominance of 96.8%. Knee osteoarthritis was clinically patent for 5.8 years, with an average of 7.4 painful flares. Gonarthrosis was bicompartmental in 52 patients and tri-compartmental in 18 patients. 45% had a family history of osteoarthritis. 28% were hypertensive, 18 patients were diabetic and 51.87% were obese according to the body mass index, with an average of 30.5 ± 5.2 kg/m^2. 65% had already received oral anti-arthritis drugs for an average of 1 year. Functional improvement was approximately 38% in G1, 26% in G2, and 42% in G3. A significant algo-functional improvement was noted in G1 (p = 0.04) and G3 (p = 0.03). LEQUESNE's index went from an average of 8 in the 3 groups to an average of 4 inG1 and G3 versus 6 in G2, which corresponds to an average handicap (p = 0.2). The final value of the WOMAC index in G1 was 26.57 versus 32.21 in G2 (p = 0.01) and versus 22.36 in G3 (p = 0.02).
Conclusion: In our study, the final evaluation showed a decrease in pain and an improvement in functional capacity ranging from 36 to 58%. This improvement in algo-functional indices was significantly more marked in G3[1]. Our study shows that the combination of visco-supplementation with physical rehabilitation gives better results by improving the algo-functional indices than by visco-supplementation alone. Our findings are consistent with the results of the literature[2].

COMPARISON OF THE EFFECT OF DIFFERENT PHYSICAL THERAPY PROGRAM IN THE REHABILITATION OF KNEE OSTEOARTHRITIS PATIENTS

A. Vizdoaga[1], V. Salaru[2], M. Cebanu[3], V. Sadovici-Bobeica[4], N. Loghin-Oprea[4], L. Mazur-Nicorici[4], T. Rotaru[4], M. Garabajiu[2], M. Mazur[4]. *[1]Nicolae Testemitanu State University of Medicine and Pharmacy, University Medical Rehabilitation Center, Chisinau, Moldova, Republic of*; *[2]Nicolae Testemitanu State University of Medicine and Pharmacy, Family Medicine, Chisinau, Moldova, Republic of*; *[3]Nicolae Testemitanu State University of Medicine and Pharmacy, Emergency medicine, Chisinau, Moldova, Republic of*; *[4]Nicolae Testemitanu State University of Medicine and Pharmacy, Internal Medicine, Chisinau, Moldova, Republic of*

Background: Knee osteoarthritis (OA) is an increasingly common and disabling problem in worldwide. Exercises are considered the cornerstone of non-surgical management of knee OA and is recommended in all current clinical guidelines. The diversity of exercise programs determines the need to compare their efficiency, in order to recommend the best option for the patient.
Objectives: The aim of the present study was to compare the effect on knee functionality of conventional exercises program and combinate with manual therapy in patients with knee osteoarthritis.
Methods: 164 patients that fulfilled the ACR classification criteria for knee osteoarthritis (127 females and 37 males) ranging in age from 42 to 84 years (mean 62,2 SD 8,76), participated in a 10 days two-arm randomized trial. One group (Gr.1) received an exercises program, the other group additionally manual therapy methods (Gr.2). Pain and function were measured with a Visual Analogue Scale (VAS, mm) and Knee Injury and Osteoarthritis Outcomes Score (KOOS) with 5 domains (Pain, Symptoms, Activity in Daily Living (ADL), Sport and recreation (Sport/rec.) and Quality of life (QoL)).
Results: In the Gr.1 were 82 patients mean age 61,8±9,2 years and in Gr.2 – 82 patients 62,7±8,3 years (p>0.05). The initial level of pain (63,4±14,2 vs 60,2±18,8mm) and knee functionality according to KOOS (Tab1.) were similar in both groups, p>0.05. After 10 days rehabilitation program, VAS in Gr.1 was 39,6±14,8 mm, in Gr.2- 28,5±11,6 mm, (p<0.01). The KOOS results at the end of the rehabilitation program were with improvement, statistically significative in the Gr.2 (p<0,05).

Table 1. The KOOS results at baseline and after 10 days of rehabilitation program.

KOOS scales	Group 1		Group 2	
(M±SD), %	Baseline	After 10 days	Baseline	After 10 days
Pain	55,5 ±13,8	63,4±13,6	53,0±22,3	64,3±19,1
Symptoms	59,0±18,7	65,6±18,1	56,6±19,0	69,0±15,9
ADL	46,3±15,5	54,5±16,0	43,0±19,9	55,1±18,2
Sport/rec	15,6±17,3	23,1±19,6	16,0±24,3	30,5±23,6
QoL	29,3±22,2	36,5± 22,9	34,8±23,9	50,6±18,9

Conclusion: The reduction of pain and recovery of function were found in both groups, with better results in patients who received manual therapy and exercises program. This study supports the routine manual therapy in rehabilitation program in patients with knee osteoarthritis.

AB0602

IMPACT OF SOCIOECONOMIC FACTORS ON PAIN AND FUNCTION IN KNEE OSTEOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

T. W. Swinnen[1], M. Willems[2], I. Jonkers[2], F. P. Luyten[3], J. Vanrenterghem[1], S. Verschueren[1]. *[1]KU Leuven, Research Group for Musculoskeletal Rehabilitation, Department of Rehabilitation Sciences, Leuven, Belgium*; *[2]KU Leuven, Human Movement Biomechanics Research Group, Department of Movement Sciences, Leuven, Belgium*; *[3]KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium*

Background: The personal and societal burden of knee osteoarthritis (KOA) urges the research community to identify factors that predict its onset and progression. A mechanistic understanding of disease is currently lacking but needed to develop targeted interventions. Traditionally, risk factors for KOA are termed 'local' to the joint or 'systemic' referring to whole-body systems. There are however clear indications in the scientific literature that contextual factors such as socioeconomic position merit further scientific scrutiny, in order to justify a more biopsychosocial view on risk factors in KOA.
Objectives: The aims of this systematic literature review were to assess the inclusion of socioeconomic factors in KOA research and to identify the impact of socioeconomic factors on pain and function in KOA.
Methods: Major bibliographic databases, namely Medline, Embase, CINAHL, Web of Science and Cochrane, were independently screened by two reviewers (plus one to resolve conflicts) to identify research articles dealing with socioeconomic factors in the KOA population without arthroplasty. Included studies had to quantify the relationship between socioeconomic factors and pain or function. Main exclusion criteria were: a qualitative design, subject age below 16 years and articles not written in English or Dutch. Methodological quality was assessed via the Cochrane risk of bias tools for randomized (ROB-II) and non-randomized intervention studies (ROBIN-I) and the Newcastle-Ottawa Scale for assessing the quality of non-randomised studies. Due to heterogeneity of studies with respect to outcomes assessed and analyses performed, no meta-analysis was performed.
Results: Following de-duplication, 7639 articles were available for screening (120 conflicts resolved without a third reader). In 4112 articles, the KOA population was confirmed. 1906 (25%) were excluded because of knee arthroplasty and 1621 (21%) because of other issues related to the population definition. Socioeconomic factors could not be identified in 4058 (53%) papers and were adjusted for in 211 (3%) articles. In the remaining papers covering pain (n=110) and/or function (n=81), education (62%) and race (37%) were most frequently assessed as socioeconomic factors. A huge variety of mainly dichotomous or ordinal socioeconomic outcomes was found without further methodological justification nor sensitivity analysis to unravel the impact of selected categories. Although the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) was the most popular instrument to assess pain and function, data pooling was not possible as socioeconomic factors estimates were part of multilevel models in most studies. Overall results showed that lower education and African American race were consistent predictors of pain and poor function, but those effects diminished or disappeared when psychological aspects (e.g. discrimination) or poverty estimates were taken into account. When function was assessed using self-reported outcomes, the impact of socioeconomic factors was more clear versus performance-based instruments. Quality of research was low to moderate and the moderating or mediating impact of socioeconomic factors on intervention effects in KOA is understudied.
Conclusion: Research on contextual socioeconomic factors in KOA is insufficiently addressed and their assessment is highly variable methodologically. Following this systematic literature review, we can highlight the importance of implementing a standardised and feasible set of socioeconomic outcomes in KOA trials[1], as well as the importance of public availability of research databases including these factors. Future research should prioritise the underlying mechanisms in the effect of especially education and race on pain and function and assess its impact on intervention effects to fuel novel (non-)pharmacological approaches in KOA.

AB0603

THE NEW POSSIBILITIES OF USING CHONDROITIN SULFATE IN PATIENTS WITH KNEE OSTEOARTHRITIS

E. Sharapova[1], N. Kashevarova[1], E. Taskina[1], D. Kusevich[1], L. Alekseeva[1,2], A. Lila[2,3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation*; *[2]Russian Medical Academy of Continuous Professional Education, Rheumatology, Moscow, Russian Federation*; *[3]V.A. Nasonova Research Institute of Rheumatology, director, Moscow, Russian Federation*

Background: Administration of Chondroitin Sulfate for treatment of osteoarthritis included treatment types include systemic and parenteral therapies. The benefits of local therapies between difference route is ambivalent.
Objectives: To evaluate effectiveness and safety of Chondroitin Sulfate (CS) by intramuscular and concomitant (intramuscular and intraarticular) route of administration in patients with knee osteoarthritis (OA).
Methods: In total 150 patients with knee OA according by ACR criteria and with radiological stages 2 and 3 according to Kellgren-Lawrence were enrolled. Patients were divided by 2 groups: 75 patients (R) received course of 25 intramuscular injection every other day: at the first 3 injection's in dose 100 mg, and in continue in dose 200 mg, 75 patients in 2nd group (N) received 5 intra-articular injections in target knee in dose 200 mg once per 3 days, in continue 16 intramuscular injections every other day in dose 200 mg. All patients received NSAID - meloxicam in stable dose 15 mg per day. All patients were checked by WOMAC, pain by visual analog scale (VAS), McGill Pain Questionnaire (MPQ).

At the baseline, standard clinical examination for all patients were blood tests, urine test, coagulation panel and ECG.
Results: After comparing of two groups by the end of course the intensity of pain by VAS was significantly greater in R group (21,88±13,24 vs 16,81±13,49; p<0,0001). There were no significant differences between groups in improvement of WOMAC, WOMAC subscales and MPQ from baseline. Serious adverse events (AE) were absent. 11 AE's were detected 3,3% (5/150), but in 100% of cases AE's were resolved by the end of course.
Conclusion: CS is effective decreased intensity of pain and stiffness, improved functional ability of joints both intramuscular and concomitant route of administration. However, significantly greater results at pain intensity by VAS shows combination: pain intensity by the end of course was significantly lower in group with concomitant intramuscular and intra-articular injections. Probably, it was associated with faster resolution of synovitis by intraarticular route of administration, that leads to choose this route for patients with comorbidity.

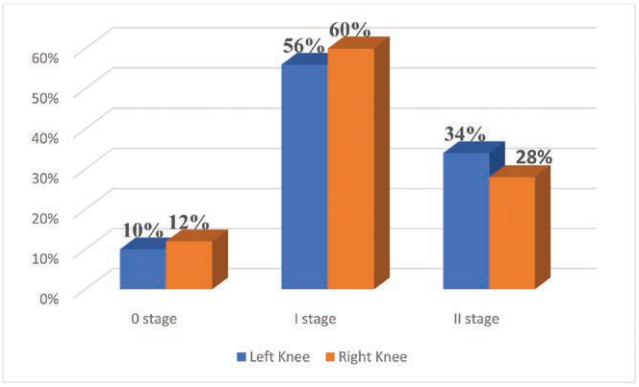
AB0604 FACTORS ASSOCIATED WITH PAIN IN EARLY KNEE OSTEOARTHRITIS (PRELIMINARY DATA)

L. Alekseeva[1,2], E. Taskina[1], N. Kashevarova[1], K. Telyshev[1], E. Strebkova[1], S. Anikin[1], E. Sharapova[1], A. Lila[1,2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Osteoarthritis, Moscow, Russian Federation*; [2]*Russian Medical Academy of Postgraduate Education, Rheumatology, Moscow, Russian Federation*

Background:
Objectives: To identify factors associated with pain in patients with early knee osteoarthritis fulfilling ESKOA criteria [1].
Methods: 50 patients (46 women (92%); 4 men (8%)) fulfilling ESKOA criteria were enrolled in the trial, every participant signed up the consent form. Median age of patients was 47 ± 8 yrs (36 – 63 yrs), body mass index (BMI) was 28.5 ± 4.9 kg/m^2 (40% of patients had obesity). Every patient, after signing the standard informed consent form, was addressed to a physician, who would fill in an individual case report form (CRF), including anthropometric parameters, history of OA, comorbidities and physical examination data. Knee pain was also assessed with the use of visual analog scale (VAS). All participants underwent knee X-ray according to the standardized fixed flexion protocol with the use of positioning frame [2].
Results: Most of the patients (70%) were between the ages of 35 and 50 and only 15 of them (30%) were older than 50 years. Median knee pain duration was found to be 16 (12-20) weeks, intensity of VAS – knee pain was 46 mm (42-50). Median number of episodes of knee pain (in the last 6 months) was 3 (2-6); 30 participants (60%) had episodes of knee pain lasting less than a week, 8 of them (6%) had pain lasting for around a week, 12 of them (24%) had episodes of pain lasting more than one week. In most patients (74%) pain relieved with time, without any additional therapy. Most of the patients had episodes of knee pain linked to increased overload (48 (96%)), when squatting (41 (82%)), most of the patients also reported pain when climbing up and down the stairs (80%) and short joint stiffness when starting movement (76%). Knee pain after sitting was reported in 54% of cases and 20 participants (40%) also reported some walking limitations due to knee discomfort.
Knee X-ray revealed that most of the patients had I Kellgren&Lawrence (K&L) stage knee OA (picture 1). All the included participants had ESR (7 (5-10 mm/hr)) and CRP (1.24 (0.8-2.2 mg/l)) within normal range.
Picture 1 – Radiological knee OA stage (K&L) distribution in the study group



In the Spearman correlation analysis, we have estimated the factors, which may be associated with more severe pain in patients with early knee OA fulfilling the ESKOA criteria. We found out that higher BMI (r=0.38, p=0.02), presence of metabolic syndrome (r=0.37, p=0.008) and hypertension (r=0.29, p=0.04), as well as walking limitations (r=0.33, p=0.008) are associated with knee pain.
Conclusion: The use of ESKOA criteria in patients with short duration of knee pain can facilitate diagnosis of osteoarthritis on an early stage. In addition, the acquired data show that timely diagnosis and correction of certain components of metabolic syndrome may be beneficial for the course of knee pain intensity in patients with early knee OA, further continuation of this trial is necessary.

AB0605 ACTIGRAPHY-BASED PHYSICAL ACTIVITY MONITORING IN PATIENTS WITH KNEE OSTEOARTHRITIS AND COMORBID FIBROMYALGIA

O. Dzekan[1]. [1]*Vinnytsya Regional Clinical Hospital, Rheumatology, Vinnytsya, Ukraine*

Background: Low physical activity (PA) levels are common in patients with diseases associated with pain syndrome, such as osteoarthritis (OA) of the knee joints. Recent studies show that OA may be accompanied by concomitant fibromyalgia (FM) – a chronic pain syndrome associated with sedentary behavior [1]. As far as low PA levels are associated with poor quality of life and higher all-cause mortality, PA measurement in patients with knee OA and concomitant FM is of considerable interest [2,3].
Objectives: The aim of this study was to investigate and compare physical activity measured by an actigraph in knee OA patients with and without comorbid FM.
Methods: A total of 70 patients with painful knee osteoarthritis (OA) – 35 subjects - (30 females and 5 males) with concomitant fibromyalgia (FM) aged 59.8±14.9 (M±SD) years and 35 patients (30 females and 5 males) without concomitant FM aged 58.5±15.7 (M±SD) years were enrolled in the study. 35 healthy controls of the same age and gender underwent the same investigation. OA diagnosis was established according to ACR 1986 Osteoarthritis Knee Criteria. FM was diagnosed if both modified 2010 ACR diagnostic criteria and 2016 Fibromyalgia Diagnostic Criteria were met. All participants wore an actigraph (GT3X model accelerometer) on the wrist for the period of 5 working days. Average daily minutes in light, moderate and vigorous PA were calculated.
Results: All OA patients with and without FM spent significantly less time in vigorous PA compared to controls. Obtained results did not indicate significant difference between time in vigorous activity in OA patients with and without FM. Patients with OA alone showed insignificant decrease in time in moderate activity in comparison with healthy subjects. OA patients with comorbid FM showed significantly less time in moderate activity compared to OA patients without FM and healthy individuals.
Conclusion: Our study results revealed that patients with painful knee OA and comorbid FM have greater activity limitations than patients with painful knee OA alone and healthy individuals.

Osteoporosis

AB0606 IMPACT OF ABDOMINAL AORTIC CALCIFICATION AND SERUM CREATININE-TO-CYSTATIN C RATIO TO BONE FRAGILITY FRACTURE

I. Yoshii[1]. [1]*Yoshii Hospital, Rheumatology and Musculoskeletal Medicine, Shimanto City, Japan*

Background: Relationship between bone fragility fracture (BFF) and abdominal aortic calcification (AAC) has been discussed in recent decade.
Objectives: Now we investigated the relationship between the two and a new factor of BFF: serum creatinine-to cystatin C ratio (Cr/CysC).
Methods: A total of nine-hundred and thirty one osteoporotic patients were recruited. Diagnosis of osteoporosis was indexed by the criteria of Japanese Primary Osteoporosis Diagnostic Criteria. Patient's lumbar spine X-ray pictures were taken and dual-energy X-ray absorptiometry (DXA) of lumbar spine and hip joint were tested at the same time, and all of them were followed us for more than one year up to nine years with at least an administration of vitamin D. Anti-osteoporotic drugs were administrated for 660 patients.
Vertebral compression fracture (VF) and AAC were evaluated with lateral view of X-ray picture. VF was classified in accordance with Semi-quantified method (SQ), and AAC was classified as follows: Grade0; No calcification, Grade1; Partial calcification not continued over one vertebral height, Grade2; Calcification continuous over one vertebral height. BFF history of the patients except of VF was harvested from the medical record and with interview. Patients' background at first measurement were measured and Cr/CysC was calculated as well. Prevalence of BFF at the baseline for each grade with SQ was compared according to the grade of AAC. Background factors including bone mineral densities (BMD) of the lumbar spine and hip joint measured using DXA were compared for each AAC grade.
Occurrence of BFF was picked up during following up (BFF_F/U) of the patients. Prevalence of BFF_F/U for each ACC grade was statistically compared, and relationship between BFF_F/U and factors at the baseline was statistically evaluated.
Results: A total of 219 of Grade0, 428 of Grade1, and 278 of Grade2 were recruited. Prevalence of BFF at baseline for each VF group was 182, 16, 9, and 12 for Grade0, 138, 98, 122, and 70 for Grade1, and 53, 45, 82, and 144 for Grade2, with Grade-0, Grade-1, Grade-2, and Grade-3 by SQ, respectively (p<0.01). Factors that demonstrated significant correlation with occurrence of BFF were sex, age, BMD of the lumbar spine and the hip joint, and Cr/CysC with univariate mode binary logistic regression anaysis. However, Cr/CysC did not demonstrate significant correlation using multivariate model.
Occurrence of BFF_F/U for each AAC group was 26, 90, and 82 for Grade0, Grade1, and Grade2, respectively (p<0.01). The only factor that demonstrated significantly correlated with occurrence of BFF_F/U was Cr/CysC in the Grade1 and the Grade2 of the AAC classification.
Conclusion: ACC grade significantly correlates with occurrence of BFF. Cr/CysC also significantly correlates with occurrence of BFF after follow up under presence of AAC.
Disclosure of Interests: None declared.

AB0607 DO HIP STRUCTURAL ANALYSIS MEASUREMENTS PREDICT FRACTURE RISK IN PATIENTS WITH POLYMYALGIA RHEUMATICA?

R. Ark[1,2], M. Bukhari[1,2]. [1]*Lancaster University, Lancaster Medical School, Lancaster, United Kingdom*; [2]*University Hospitals of Morecambe Bay NHS Foundation Trust, Royal Lancaster Infirmary, Lancaster, United Kingdom*

Background: Polymyalgia Rheumatica (PMR) is an inflammatory condition which commonly affects the elderly. Risk of fracture is higher in this group of patients compared to the general population and can lead to increased morbidity and mortality (1). Hip structural analysis (HSA) is a technique that uses dual-energy X-ray absorptiometry (DEXA) images to assess hip bone structure (2).
Objectives: To identify whether HSA measurements help predict fracture in patients with PMR.
Methods: Data were collected from June 2004 to October 2010 from PMR patients who had a DEXA scan at a District General Hospital. This included hip axis length (HAL), cross-sectional area (CSA), cross-sectional moment of inertia (CSMI), distance from centre of femoral head to centre of femoral neck (D1) and to inter-trochanteric line (D2), mean femoral neck diameter (D3), shaft angle (A) neck/shaft angle (Θ) and proximal femur strength index (SI) and distance from centre of mass of femoral neck to superior neck margin (Y). Fracture was predicted by a series of binomial logistic regression models, adjusted for age and sex. Odds ratios with 95% confidence intervals and area under the receiver operating characteristic curve (AUC) were calculated.
Results: 714 patients with PMR were identified, 182 were male and the mean age was 70.5. HAL, CSMI, D1, D2, D3, A, Θ, SI and Y were not significant predictors of fracture in regression models; odds ratios are included in Table 1. CSA predicted fracture risk; odds ratio was 0.988 with a 95% confidence interval of 0.980-0.997. The AUC for the CSA regression model was 0.6739.

Table 1. Odds ratios of fracture for different HSA parameters

HSA Parameter	Odds Ratio (95% confidence interval)
HAL	1.008 (0.982 - 1.035)
CSMI	1.000 (0.999 - 1.000)
CSA	0.988 (0.980 - 0.997)
D1	1.029 (0.972 - 1.089)
D2	1.010 (0.981 - 1.040)
D3	1.033 (0.962 - 1.109)
Y	1.087 (0.966 - 1.223)
A	0.983 (0.940 - 1.029)
Θ	1.007 (0.975 - 1.039)
SI	0.683 (0.406 - 1.150)

Conclusion: These data suggest that CSA helps predict the risk of fracture in patients with PMR. HAL, CSMI, D1, D2, D3, A, Θ, SI and Y do not predict fracture risk. Limitations of the study are that it was retrospective and only studied patients who underwent DEXA scans. The study may have been underpowered to detect the impact of some HSA measurements on fracture risk.

AB0608 BONE MINERAL DENSITY, VITAMIN D STATUS AND BONE METABOLISM IN A COHORT OF ADULT PATIENTS WITH INFLAMMATORY BOWEL DISEASE

B. M. Fernandes[1], M. Bernardes[1], D. R. Gonçalves[2], F. Magro[3], L. Costa[1]. [1]*Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal*; [2]*Centro Hospitalar Entre Douro e Vouga, Rheumatology, Santa Maria da Feira, Portugal*; [3]*Centro Hospitalar Universitário São João, Gastroenterology, Porto, Portugal*

Background: Patients with inflammatory bowel disease (IBD) have an increased risk of low bone mineral density (BMD) and bone fractures due to several mechanisms. However, the best management of osteoporosis in this population is yet to determine.
Objectives: To evaluate bone mineral density and other clinical, analytical and demographic features related with the risk of bone fractures in an IBD cohort.
Methods: Retrospective monocentric study including all the patients with IBD consecutively reffered from Gastroenterology to the Rheumatology Department in a tertiary university hospital between January of 2013 and October 2020. Demographic, clinical and analytical data and BMD by dual-energy X-ray absorptiometry (DXA) (total hip, femoral neck and lumbar spine) were collected at the time of the first visit in the Rheumatology outpatient center. Correlations between variables were evaluated by Spearman rank test and Mann-Whitney U test was used in the comparison analysis between groups (significance level at p<0.05), using SPSS 25.0 software.
Results: A total of 222 patients were included: 128 (57.7%) females, mean age of 43.4 (±13.6) years, mean IBD duration of 11.6 (±9.7) years. Regarding IBD: 163 (73.4%) had Crohn's disease (CD) and 59 (26.6%) had ulcerative colitis

(UC); azathioprine (41.9%) and infliximab (29.8%) were the most frequently used drugs; 10 patients (4.5%) were taking glucocorticoids, 104 (46.8%) had been previously treated with glucocorticoids and 65 (29.3%) had already been exposed to high doses of glucocorticoids (prednisolone equivalent dose ≥ 7.5 mg/day).
Ten patients (4.5%) had previous fragility fractures and 32 (14.4%) fulfilled diagnostic criteria of osteoporosis by DXA (T score ≤ -2.5). One hundred eighty-one (81.5%) patients exhibited low levels of 25-hydroxy vitamin D (<30ng/mL), 24 (10.8%) had high levels of parathormone and 150 (67.6%) showed elevated serum concentrations of beta-carboxy-terminal type-1 collagen crosslinks (beta-CTX). Three patients (1.4%) were under treatment with bisphosphonates and 18 (8.1%) were taking calcium and/or vitamin D supplements.
Of interest, serum levels of albumin correlated negatively with beta-CTX (r=-0.401; p<0.001) and positively with osteocalcin (r=0.259; p<0.001). Correlations between clinical/analytical variables and BMD are presented in Table 1.
Patients under glucocorticoids had lower mean total hip BMD (0.874±0.159 vs 1.008±0.176; p=0.022) and femoral neck BMD values (0.797±0.174 vs 0.933±0.179; p=0.014) in comparison with the group of patients that were not taking glucocorticoids.
No statistically significant differences in BMD values were found between the following subgroups: DC vs UC; normal vs low levels of 25-hydroxy vitamin D; patients exposed vs not exposed to high doses of glucocorticoids.

Table 1. Correlations between clinical/analytical variables and the BMD in an IBD population (BMD: Bone Mineral Density; IBD: Inflammatory Bowel Disease; n.s. not significant).

	Total hip BMD	Femoral neck BMD	Lumbar Spine BMD
Age	r=-0.356;p<0.001	r=-0.469;p<0.001	r=-0.259;p<0.001
Age at IBD diagnosis	r=-0.254;p<0.001	r=-0.327;p<0.001	r=-0.226;p=0.001
IBD duration	r=-0.147;p=0.031	r=-0.218;p=0.001	n.s.
Hemoglobin	r=0.249;p<0.001	r=0.209;p=0.002	n.s.
Albumin	r=0.189;p=0.005	r=0.208;p=0.002	n.s.
Erythrocyte sedimentation rate	r=-0.231;p=0.001	r=-0.206;p=0.003	n.s.

Conclusion: Our results show an important prevalence of undiagnosed and untreated osteoporosis in patients with IBD. Stronger correlations were found between clinical/analytical variables and femoral neck BMD. Of note are the weak correlations of BMD with acute-phase markers (negative correlation with erythrocyte sedimentation rate and positive correlations with hemoglobin and albumin) and of nutritional status (evaluated by albumin) with bone markers (negative correlation with the bone reabsorption marker beta-CTX and positive correlation with the bone formation marker osteocalcin).

AB0609 RADIOFREQUENCY ECHOGRAPHIC MULTI-SPECTROMETRY FOR THE ASSESSMENT OF BOTH FEMORA IN PREGNANT WOMEN

E. Kirilova[1], N. Kirilov[2], S. Vladeva[3]. [1]*UMBAL Dr. Georgi Stranski, Rheumatology, Pleven, Bulgaria*; [2]*UMBAL Dr. Georgi Stranski, Orthopedics and Traumatology, Pleven, Bulgaria*; [3]*Trakia University, Rheumatology, Stara Zagora, Bulgaria*

Background: Radiofrequency Echographic Multi-Spectrometry (REMS) is a non-ionizing innovative approach for the assessment of REMS-$_{based}$ bone mineral density (BMD) of the axial skeleton. The principle of the REMS technology is based on the analysis of native raw unfiltered ultrasound signals during an echographic scan of the lumbar spine or the femoral neck [1]. Several studies demonstrated the high concordance with dual energy X-ray absorptiometry (DXA) in terms of measured BMD with this novel technology [2,3]. In previous published literature it was envisaged to apply this technology for the examination of the axial bone density in pregnant women. Pregnancy-associated bone loss has been demonstrated as decreased bone mineral density (BMD) in previous studies [4].
Objectives: The aim of the current study is to compare the BMD values of both femora between pregnant and non-pregnant women matched for age and BMI using the novel REMS technology.
Methods: Of total fifty women twenty pregnant women (40%) and thirty non-pregnant women (60%) were included in the study. The mean age of the pregnant women was 32 years ± 5 standard deviations (SD), (range 25-41 years) and the mean age of the non-pregnant women was 30 years ± 6 standard deviations (SD), (range 24-39 years). REMS approach was used to assess REMS-$_{based}$ BMD and REMS-$_{based}$ Z-score values of the femoral neck. Furthermore, body mass index (BMI) and gestational age in weeks were evaluated.
Results: The mean BMI of the pregnant women was 26 kg/m^2 ± 7 kg/m^2 (range 14 kg/m^2-42 kg/m^2) and those of the non-pregnant women was 25 kg/m^2 ± 5 kg/m^2 (range 16 kg/m^2-35 kg/m^2). The mean gestational age was 20 weeks' gestation ± 5 weeks' gestation (range 13-27 weeks' gestation). REMS-$_{based}$ mean BMD of the left femoral neck of the pregnant women was 0.793 g/cm^2 ± 0.167 g/cm^2 (range 0.563 g/cm^2-1.154 g/cm^2). REMS-$_{based}$ mean BMD of the right femoral neck of the pregnant women was 0.828 g/cm^2 ± 0.153 g/cm^2 (range 0.570 g/cm^2-1.161 g/cm^2). After comparing left femoral neck BMD with the right femoral neck BMD of the pregnant women, we found a linear correlation (R=0.764). Left femoral neck BMD value (0.793 g/cm^2) of the pregnant women was significantly lower than those of the non-pregnant women (0.854 g/cm^2), p=0.002. The mean left femoral Z-score of the pregnant women (-0.1 SD with range -2.5 SD-2.9 SD) was also significantly lower compared to those of the non-pregnant women (1.2 SD with range -1.5 SD-3.1 SD), p=0.003.
Conclusion: This is the first study which provides data about BMD and Z-score values of both femora in pregnant women assessed with the radiation-free REMS technology. Pregnant women demonstrated significantly lower femoral neck BMD values and Z-scores compared to those of the non-pregnant women. Innovative REMS method could be very helpful for making decision about the treatment of pregnant women who are at risk of lower BMD due to concomitant diseases and/or treatment associated with osteoporosis.

AB0610 NORMOCALCAEMIC HYPERPARATHYROIDISM AND BONE HEALTH – WORSE THAN ANTICIPATED?

D. Masieh[1], S. Deshpande[1], M. K. Nisar[1]. [1]*Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom*

Background: Since the formal recognition of normocalcaemic hyperparathyroidism (nHPT) as a distinct entity in 2008, several studies have been published describing the characteristics of these individuals. Controversy exists regarding diagnostics and the role of parathyroidectomy in such cases. A chief reason for lack of consensus is the disagreement among experts regarding the potential complications and a bias towards perhaps benign nature of this condition.
Objectives: In order to understand the challenges posed by this cohort, we aim to characterise these patients at presentation to our metabolic bone diseases unit with a focus on bone health.
Methods: We interrogated our departmental database and undertook retrospective analysis of all patients presenting to metabolic bone service at our large university teaching hospital with a catchment population of 350,000. Individuals were included in the survey based on criteria of Vit D >70 nmol/L, normal calcium (2.20-2.60 mmol/L), eGFR>60ml/min and PTH >6.9 pmol/L measured twice at least three months apart.
Results: Over six months review period, of 134 referrals, 42 (31%) were identified with nHPT. Follow up duration was two years. Mean age was 60 years (25-86). 38 (90%) were women with 31 (81%) post menopause. 34 (80%) were of Caucasian descent. All had comorbidities with median of five (1-14). Polypharmacy (>4 prescribed medicines) was common (36/42, 85%) with mean of seven prescribed medications (0-22). Mean Vit D was 88 (70.4-133.6), calcium 2.43 (2.26-2.58), creatinine 69.8 (48-115) and PTH 8.8 (7.2-14.2). Ten (24%) had already had fragility fractures with mean of two (0-4). 21 had DXA scan with mean T score of -3.78 (-2.1 - -6.0). 13/21(31%) had osteoporosis. Oral and IV bisphosphonates, denosumab and teriparatide were prescribed to 12 (28.5%), 14 (33%), 4 (10%) and one patient respectively.
Conclusion: Our study suggests high prevalence of nHPT among patients referred to metabolic bone service with confirmed bone health issues. Nearly a third of patients have nHPT in this secondary care setting and a quarter have already suffered fragility fractures. These patients carry high comorbidity, polypharmacy and osteoporosis burden. Management of such patients is challenging owing to complex interplay of various ailments. Bone active agents are required for nearly two-thirds of this group. Though the natural course of nHPT is an area of active research, our data adds to the growing body of evidence that this is not a benign condition with particularly high fracture burden and poor bone quality.

nHPT is perhaps responsible for the onset and progression of the similar osseous complications as described in classical PHPT. Further longitudinal studies are required to help devise best management plan to mitigate against the skeletal encumbrance of nHPT.

AB0611 OSTEOPOROSIS IN RHEUMATOID ARTHRITIS: A NECESSARY EVIL?

S. Athimni[1], S. Bouden[1], A. Ben Tekaya[1], A. Dghais[1], O. Saidane[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Charles Nicolle Hospital, Rheumatology,Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease that is characterized by local and general bone loss. Osteoporosis (OP) is one of the most frequent comorbidities associated with RA. Many factors are incriminated in bone loss in RA such as inflammation, glucocorticoid (GC) use, and immobility.

Objectives: -To determine the prevalence of OP in a population of actual RA patients.

-To determine the risk factors of bone mineral density (BMD) reduction

Methods: One hundred-fifty-two RA followed in the rheumatology department between 2015-2020 were enrolled in the study. The diagnosis of RA was established according to the American College of rheumatology/European League Against Rheumatism (ACR/EULAR) criteria 2010. BMD in lumbar spine and total hip was systematically measured in the recruited patients. Measures were taken with dual-energy x-ray absorptiometry (DEXA), and age-specific values were compared with pooled values from a local population of healthy subjects free from earlier fractures.

Results: The mean age was 42.7±13 years. The sex ratio M/F was 0.24. The mean onset disease was 6±1.8 years. Fifty-sex patients (36.3%) were receiving conventional treatment DMARDs and 96 (63.6%) were under biological treatment. 35.5% were taken steroids with mean doses at 7.7±3.3mg/day. RF and ACPA were positive respectively in 87.3% and 82.4% of the patients. The mean disease activity score DAS28CRP was 4.8 ±2.7.

Sixty-eight point eight 68.8% of the RA population had bone loss: 37.5% had osteopenia and 31.3% had OP. Regarding the OP group, sex ratio M/F was 0.45. The mean age was 42±5.3 years. Among the 31 women, 77.4% had postmenopausal OP. The BMI average was 31.18 ± 6.19 kg/m^2. Fifteen patients (33.33%) had OP in the hip site and 20 patients had OP in the lumbar site (48.8%). Ten patients had both trabecular and cortical OP.

Advanced age, glucocorticoid use and high DAS28CRP were independent risk factors for OP (respectively p=0.04, p=0.02 and p=0.01). Body mass index, smoking, disease duration high Health Assessment Questionnaire (HAQ) score (p=0.545) and smoking (p=0.326) were not associated with high risk of OP. The biological treatment was not a protective factor in OP (p=0.972). All the population subjects were free from earlier fractures, the fractural risk estimated by dint of the mean FRAX™ score was at 1.4 ± 2.3.

Conclusion: Previous studies estimated that, approximately, osteoporosis affected one-third of RA patients which is in concordance with our study. Advanced age, glucorticoid treatment and severe disease were the most common risk factor in our study.

Disclosure of Interests: None declared.

AB0612 THE FRACTURE PREVENTION UNIT OF THE VIRGEN MACARENA HOSPITAL REDUCES THE GAP IN THE MANAGEMENT OF OP, PARTICULARLY IN MALES AND MEETS IOF/ESCEO QUALITY STANDARDS

B. Hernández-Cruz[1], F. J. Olmo Montes[2], M. J. Miranda García[2], M. D. Jimenez Moreno[2], M. A. Vázquez Gómez[3], M. Giner García[3], M. A. Colmenero Camacho[2], J. J. Pérez Venegas[1], M. J. Montoya García[3]. [1]*Hospital Universitario Virgen Macarena, Rheumtology, Sevilla, Spain*; [2]*Hospital Universitario Virgen Macarena, Internal Medicine, Sevilla, Spain*; [3]*University Medical School, Internal Medicine, Sevilla, Spain*

Background: The Virgen Macarena University Hospital belongs to the Public Health System of Andalusia and serves 481,296 inhabitants in Seville, Spain. In 2018 the Fracture Liaison Service switched to a multidisciplinary unit.

Objectives: To describe FLS, to know the characteristics of patients with emphasis on gender differences and to know the completion of International Osteoporosis Foundation quality standards.

Methods: Prospective, observational, analytical, research of usual clinical practice. All the consecutive patients attended from May 2018 to October 2019, ≥50 years, with a fragility fracture (occurred in the previous 24 months) were included. The study was approved by the Ethics Committee, Code 1084-N-16.

Results: Our FLS is a type A multidisciplinary Unit, with a high level of intervention in the evaluation, estimation of fracture risk and fall risk, treatment prescription and follow-up of the patients. We included 408 patients, 80% females, one third with ≥80 years. Fragility fractures recorded in 328 women were hip (132, 40%), clinical vertebral (81, 25%) and no hip no vertebral (115, 35%). Those recorded in 82 males were hip (53, 66%), clinical vertebral (20, 24%) and no hip no vertebral (9, 10%), p=0.0001. Males had a higher rate of secondary causes of OP, drinker, and smoking. The most relevant gender difference was the low percentage of patients receiving pre-FF OP treatment. Forty-nine (16%) women versus 9 (7%) males had received it at some point in their life, p=0.04. Two hundred and seventy-one (86%) women vs 48 males (63%) had received it at after their FF in their reference unit, and all them were treated after the FLS evaluation. The probability of a male not receiving prior treatment was 2.5 (95% CI 1.01- 6.51); p=0,04. This probability was 0.64 (0.38-1.09) after the FF. After twelve months of follow-up in FLs, 96% continued treatment, with no differences between men and women. The completion of IOF quality standards was bad (red light) for patient identification items and FLS reference time. It was poor (amber traffic light) for initial OP screening standard and was good (green light) for the remaining 10 indicators. The completion of IOF quality standards was bad (red light) for patient identification items and FLS reference time. It was poor (amber traffic light) for initial OP screening standard and was good (green light) for the remaining 10 indicators (Figure 1).

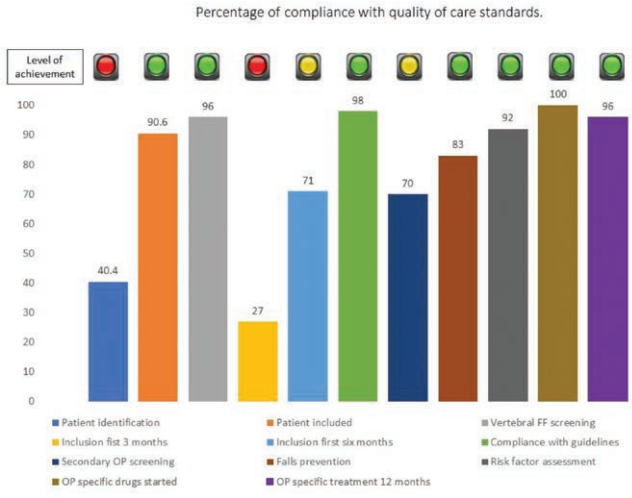

Figure 1.

Conclusion: The FLS is a multidisciplinary type A. Its operation has narrowed the gap in diagnosis, treatment, and follow-up of FF patients, especially males. It is essential to improve patient recruitment, reduce referral times and increase the overall assessment of the patients.

AB0613 FREQUENCY AND RISK OF FRAGILITY FRACTURES IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Efremova[1], O. Nikitinskaya[1], N. Toroptsova[1], O. Dobrovolskaya[1], N. Demin[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation*

Background:
Objectives: To assess the frequency of fragility fractures and the 10-year risk of major osteoporotic fractures using the fracture risk assessment tool (FRAX) tool in patients with systemic sclerosis (SSc).
Methods: The study included 136 patients with SSc who met the ACR/EULAR 2013 criteria: 110 (80.9%) postmenopausal women and 26 (19.1%) men over 50 years of age, mean age 59,3+7.5 years. The duration of the disease was 10,0 [6.0; 15.0] years in women and 6,0 [3.5; 9.0] years in men. A questionnaire was conducted and the risk of major osteoporotic fractures was calculated according to FRAX tool, as a result of which patients were divided into groups of low, moderate or high risk. Individuals at moderate risk underwent dual-energy X-ray absorptiometry (DXA) of the proximal femur, followed by a 10-year probability of major osteoporotic fractures recalculation with the inclusion of the femoral neck T-score. According to the obtained fracture risk assessment tool value, patients were assigned as having a low, high or very high risk.
Results: Fragility fractures of various localization were found in 50 (36,7%) people: 41 (37,3%) women and 9 (34.6%) men. Vertebral and peripheral bone fractures occurred with the same frequency (19,8%) without significant differences depending on the patient's gender. Only 1 (3,8%) male had a history of proximal femoral fracture. Fractures of both the vertebra and the peripheral bone occurred in 4 (2,9%) people: 3 (2,7%) women and 1 (3,8%) man.
9 (8,2%) women and 16 (61,5%) men had a low risk of major osteoporotic fractures according to FRAX, 60 (54,5%) and 10 (38,5%) - a moderate risk, respectively, while 41 (37,3%) women were at high risk. Among 86 patients without a history of low-energy fractures (69 women and 17 men), 8 (11,6%) women and 16 (94,1%) men were at low risk of major osteoporotic fractures, and 57 (82,6%) and 1 (5,9%), respectively, were at moderate risk. Only 4 (5,8%) women were assigned to the high-risk group. After recalculation of the fracture risk assessment tool with inclusion of the femoral neck T-score in persons with moderate risk without a history of fragility fractures, 9 (13,0%) women and 1 (5,9%) man were found to be at high risk, 14 (20,3%) women - at very high risk and 34 (49,3%) women - at low risk.
Among moderate-risk patients with prior fractures after FRAX recalculation 3 (7,3%) women and 7 (77,8%) men became at low risk, 1 (11,1%) male - at high and 1(11,1%) male – at very high risk. Thus, 55 (50,0%) women and 1 (3,8%) man were at very high, 12 (10,9%) and 2 (7,7%), respectively, - at high, and 43 (39,1%) and 23 (88,5%), respectively, - at low risk of major osteoporotic fractures.
Conclusion: In the examined cohort of patients with SSc, the frequency of fragility fractures was 37,3% in women and 34,6% in men. A high and very high risk of major osteoporotic fractures was found in 60,9% of women and 11,5% of men. 3 (2,7%) women and 6 (23,1%) men with a history of previous fractures were in the low-risk group by FRAX, but they need to consider the appointment of anti-osteoporotic therapy as for patients at high and very high risk.

AB0614 DENSITOMETRIC VERTEBRAL FRACTURE ASSESSMENT: FACTORS LIMITING GOOD VISIBILITY OF THE VERTEBRA

S. Mariem[1], M. Yasmine[1], S. Miladi[1], A. Fazaa[1], E. Frigui[1], L. Souebni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: The radiograph of the spine is the gold standard for identifying vertebral fractures (VF). Vertebral Fracture Assessment (VFA) is a new feature available on modern densitometers that could assess VF. This technique offers the advantage of low irradiation over standard radiography but at the cost of lower image quality.
Objectives: The aim of this study was to assess factors associated with good vertebra visibility when using VFA.
Methods: This is a cross-sectional study including patients referred by their physicians for bone mineral density (BMD) measurement. Anthropometric data were recorded. BMD was measured using standard methods over the lumbar spine L1-L4, the total proximal femur. Results were expressed as T-scores using Dual-energy X-ray absorptiometry (DEXA). The screening for VF was performed by VFA. A professional operator analyses VFA scans and assessed the good visibility of the vertebra.
Results: The study included 100 patients. The mean age was 61.7 ±12.6 years [18-83].The average body mass index (BMI) was 28.9 ± 24.2 kg/m2 [14.2-45.3]. The mean T-score at the vertebral site was -1.5 DS [-4.9-1.5] with a mean mass of 0.95g/cm^2 [0.58-1.371]. Osteoporosis was found in 27.7 % of patients. A vertebral fracture was diagnosed in 25% of cases. The visualization of the vertebra was impaired in the upper thoracic region in 60% of cases. Poor visibility was observed in 19% of cases in the mid-thoracic spine and only in 2% of cases in the lumbar spine. No statistically significant correlation was found between good vertebral visibility and age (p=0.2), weight (p=0.5), or BMI (p=0.7). However, good visibility of the vertebra was associated with a lower height (1.7 m vs 1.5 m, p=0.03). A better vertebrae visualization was correlated neither to the BMD of the right hip (0.84 vs 0.87, p=0.4) nor to the left hip (0.85 vs 0.89, p= 0.3). Similarly, the absence of vertebral osteoporosis was not correlated with a better vertebral visualization (p=0.6).
Conclusion: Visibility of the vertebra on VFA does not appear to be altered by the BMD and vertebral osteoporosis, suggesting safe use in the elderly. However, precautions may be taken when interpreting VFA in patients with high heights.
Disclosure of Interests: None declared.

AB0615 ASSESSMENT OF THE IMPACT OF OBESITY ON BONE LOSS

M. Yasmine[1], S. Mariem[1], S. Miladi[1], A. Fazaa[1], E. Frigui[1], L. Souebni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Most of the available evidence supports a lower risk of vertebral fracture in obese adults. This belief was partially suggested by the positive correlation between bone mineral density (BMD) and body mass index (BMI).
Objectives: We aimed to assess the association of BMI with BMD and to explore their relation with age and gender.
Methods: This is a cross-sectional study including Tunisian patients referred for an assessment of BMD through dual-energy X-ray absorptiometry (DXA). BMD was measured using standard methods over the lumbar spine L1-L4, the total proximal femur. The results were expressed as T-scores according to the World Health Organization definition. Patients were sub-grouped according to age (≤50 and >50 years). Association between BMD and age as well as BMI was also assessed (G1: obese patients and G2: non-obese patients). The level of significance was fixed for p<0.05
Results: The study included 100 patients with a female predominance (sex ratio =10.1). The mean age for women was 61.9 ±13 [18-83] years and the mean age for men was 59.7± 7.5 [47-72] years. The mean body mass index was 29.1± 5 kg/m^2 [15-45] for women and 27.6 ±3.6 Kg/m^2 [22.8-32.9] for men. Forty percent of all patients were obese with a mean BMI of 32.9 kg/m^2 ± 4.3. Osteopenia was diagnosed in half of the men (55.5%) and most of the women (70%). Twenty-nine percent of patients suffered from osteoporosis. BMD of the spine was similar between men and women (p=0.53). Men had higher BMD of the hip than women (p=0,038). The mainstream of the subjects >50 years had more vertebral fractures, suffered more from osteoporosis and had a higher BMI than those < 50 years (95% % vs 5%; p=0.04), (92.3% vs 77 %; p=0.03) and (82.5% vs 17.5%; p=0.05) respectively. There was no correlation between BMD of the spine and higher BMI (0.94 in G1 vs 0.98 in G2, p=0.3). Similarly, there was no correlation between BMD of the hip and higher BMI (0.9 in G1 vs 0.84 in G2, p=0.2). Moreover, Obese patients had less a vertebral fracture but with no statistically significant correlation (21% in G1 vs 25% in G2; p=0.2).
Conclusion: Our study showed that obesity was frequent among Tunisian patients but was not associated with a higher BMD. Older age was directly associated with a lower BMD and higher risk for vertebral fracture.
Disclosure of Interests: None declared.

AB0616 RISK FACTORS FOR PREVALENT VERTEBRAL FRAGILITY FRACTURES - STUDY IN A LONDON URBAN BOROUGH

N. Mothojakan[1], M. Zaman[2], A. Perren[1], S. Mahendrakar[1], R. Rajak[1]. [1]*Croydon University Hospital, Rheumatology, Croydon, United Kingdom*; [2]*St George's Hospital, Rheumatology, London, United Kingdom*

Background: Vertebral fragility fractures (VFFs) are commonly underdiagnosed, often resulting in chronic pain and reduced quality of life. It is particularly important to identify and manage VFFs, as they are important predictors of future VFFs and non-VFFs. Patients with VFFs often have multiple risk factors, which are important to identify to formulate a tailored and appropriate management plan. There is a paucity of studies that have investigated risk factors specifically for VFFs.
Objectives: To identify the prevalence of osteoporosis risk factors in patients with VFFs.

Methods: Retrospective review of patients seen between July 2018 and July 2019 at Purley Memorial Hospital, covering a large urban borough. Patients included in the study had prevalent moderate and severe VFFs (defined by Ghent criteria).
Results: 84 patients were included, of which there were 71 females and 13 males. Median age was 76 (IQR 67 – 82) and BMI was 25 (IQR 21 – 27), with 6% of patients noted to be underweight (BMI <18.5). 38% of patients had a family history of osteoporosis and 21% of patients reported a history of parental hip fracture. 21% of patients had experienced recurrent falls. Over half (56%) of patients were noted to have had 2-or-more previous fragility fractures. Of the female cohort, 24% had early menopause, 13% were nulliparous and 1% had late menarche. Of the modifiable risk factors, alcohol (24%), sedentary lifestyle (21%) and smoking (13%) were the most common. Thyroid-disease (18%) was the most common medical condition associated, followed by coeliac/malabsorption (7%), endocrinopathy (6%) and COPD (6%). Proton Pump Inhibitors (PPIs) and steroids were the most common medications associated with 16% and 14% of cases respectively. 73% of patients had good calcium intake and 62% had calcium supplements. Overall, 27 patients had 3-or-fewer risk factors, 35 patients had 4-to-6 risk factors, 19 had 7-to-9 risk factors, and 3 had greater than 10 risk factors.
Conclusion: Our study identified several risk factors and their prevalence. The majority of patients were female, of which 24% had early menopause. Several modifiable risk factors such as low BMI, alcohol, smoking and sedentary lifestyle were commonly seen, emphasising the need to identify these risk factors in the initial consultation. Over half of patients (56%) had had 2-or-more previous non-VFFs, suggesting the need to screen for VFFs in patients with multiple fragility fractures at baseline assessment. A number of co-existing medical conditions were also observed with thyroid disease being the most prevalent. PPIs and steroids were found to be important risk factors, which may lead to the consideration of alternative medications. Overall, it was found that patients had multiple risk factors, thus it is important to have a holistic assessment of VFF patients and a multi-system management approach to prevent future fractures.

AB0617 BISPHOSPHONATES DANS L'OSTÉOPOROSE ET LE RISQUE D'OSTÉONÉCROSE DE LA MÂCHOIRE, ENVIRON 896 CAS

A. R. Halidou[1], K. Nassar[1], S. Janani[1]. [1]*Université Hassan II, médecine, Casablanca, Morocco*

Background: Bisphosphonates (BF) are used in the treatment of osteoporosis, Paget's disease of bone, hypercalcemia and in patients with cancer. When used to treat osteoporosis, the optimal duration of treatment is 3 to 5 years; however, their long-term use has been rarely associated with osteonecrosis of the jaw.
Objectives: To assess the risk of developing osteonecrosis of the jaw in patients followed for osteoporosis and on bisphosphonates (BP).
Methods: Type of study: retrospective study conducted at the rheumatology department of the IBN ROCHD CHU in Casablanca.
Duration: from October 2013 to October 2020 (7 years).
Inclusion criteria: all patients followed for osteoporosis in the weakening osteopathies unit of the bone and treated with oral or intravenous bisphosphonates.
Exclusion criteria: patients followed for other than osteoporosis.
Results: 896 patients were treated during this period. The average age was 62.74 years (28 to 90 years), of which 85.16% were women and 14.84% were men, for a sex ratio (F / M) of 5.74. As a history, 18.75% of patients are diabetic, 26.56% followed for breast neoplasm, 14.06% of patients had received long-term corticosteroid therapy for various pathologies such as chronic inflammatory rheumatism. Osteoporosis was postmenopausal in 687 patients, ie 76.67% of cases, 14.06% after long-term corticosteroid therapy, 8.15% following hormone therapy (anti-aromatases) and 6.92% following chemotherapy; note that 18.16% of these patients were found in at least two of the situations. The mean bone mineral density (BMD), T-score pair considered in all [T-score (BMD)] is -3 (0.736) in the lumbar spine (L1-L4), -2.9 (0.658) at the femoral neck, -2.6 (0.804) at the total hip before the start of treatment. 69.97% of the patients were put on Alendronic acid, 12.50% on Residronic acid, 10.93% on Zolidronic acid, 3.46% on Pamidronic acid and 3.14% received Strontium Ranelate, note that before the start of the treatment all the patients benefited from a dental consultation followed by care of any lesions, the bisphosphonates were only introduced after having ruled out all their dental contraindications, the average duration of treatment for all the molecules was 4.71 years (2 to 5 years) and no patient developed osteonecrosis of the jaw. The change in control BMD on average after 2 years of treatment was -2.7 (0.782) at the lumbar spine, -2.6 (0.749) at the femoral neck and -2.4 (0.713) at the hip total, after 5 years -2.4 (0.874) at the spine, -2.1 (0.809) at the femoral neck and -1.93 (861) at the total hip.
Conclusion: The occurrence of ONJ in the treatment of osteoporosis with the use of BFs is rare, and appears to be unpredictable; but maintaining therapeutic caution, consisting in diagnosing and treating any dental lesions before starting treatment, can considerably reduce or even cancel the risk of occurrence; especially in patients treated with long-term intravenous pamidronate.

AB0618 GLUCOCORTICOID INDUCED OSTEOPOROSIS PREVENTION IN THE OUTPATIENT RHEUMATOLOGY CLINIC

Z. Vaghaiwalla[1], G. Kaeley[1]. [1]*University of Florida College of Medicine-Jacksonville, Rheumatology, Jacksonville, United States of America*

Background: Patients with rheumatic disease are at risk of developing glucocorticoid induced osteoporosis (GIOP) as many are prescribed systemic oral glucocorticoids as an adjunct to their maintenance therapy. Based on the 2017 ACR Guideline for the Prevention and Treatment of Glucocorticoid-Induced Osteoporosis, a good practice recommendation exists that "initial clinical fracture risk assessment should be performed as soon as possible, but at least within six months of the initiation of long term glucocorticoid treatment.[1]" Long-term glucocorticoid use is defined by duration of 3 months or greater. Fracture risk assessment should include dual energy-ray absorptiometry (DEXA) scan. Patients on greater than or equal to 2.5 mg of prednisone should be treated with an optimal dose of calcium and vitamin D and may benefit from oral bisphosphonate as primary prevention against GIOP if their fracture risk is moderate to high.[1]
Objectives: The aim of this Quality Improvement Project is to assess the current status of provider implementation of GIOP recommendations in the rheumatology clinic. Ultimate goal is to improve osteoporosis prevention in the rheumatology clinic.
Methods: We conducted a retrospective chart review of 60 patients in two outpatient rheumatology clinics. Clinic 1 follows patients with lower socioeconomic status and Clinic 2 follows patients with higher socioeconomics. Inclusion criteria were patients on long-term glucocorticoid use, defined as at least 3 months of corticosteroid use of at least 2.5 mg prednisone daily, as well as age less than 65. Females aged 65 or older were omitted to prevent overlap of the United States Preventative Taskforce recommendation for all women ≥ 65 years to be screened for osteoporosis with DEXA scans.[2] DEXA scan orders, calcium and vitamin D prescriptions, and osteoporosis medication prescriptions were abstracted. After baseline data obtained, intervention of education of the rheumatology fellows and faculty, and internal medicine residents in the guidelines for GIOP prevention was implemented. In addition, a smartphrase in the electronic medical record was created for provider use when treating patients on chronic corticosteroids. Subsequently, two audit cycles were completed for retrospective chart review.
Results: Upon completion of second audit cycle, there was no change in percentage of DEXA scan orders at Clinic 1, however there was a 10% overall improvement in DEXA scan orders in the Clinic 2.
In terms of Calcium and Vitamin D prescriptions, there was an overall improvement in both clinics of 19.7% and 13.3% in Clinics 1 and 2 respectfully after the second audit cycle.
Additionally, there was a 3.4% increase in osteoporosis medication prescriptions overall subsequent to the second audit cycle in Clinic 1. However in Clinic 2 there was an overall decrease in osteoporosis medication prescriptions of 6.6%.

Clinic 1	Prior to Audit	Audit cycle 1	Audit cycle 2
Patient percentage without DEXA scan orders	30%	33.30%	30%
Patient percentage without Vitamin D/Calcium orders	26.40%	8.30%	6.70%
Patient percentage with osteoporosis medication orders	23.30%	8.30%	26.70%
Clinic 2			
Patient percentage without DEXA scan orders	50%	37.00%	40%
Patient percentage without Vitamin D/Calcium orders	30%	26.00%	16.70%
Patient percentage with osteoporosis medication orders	23.30%	11.10%	16.70%

Conclusion: Overall, the results of the intervention were strongest for improvements in Vitamin D and Calcium orders in both clinics. Improvements in DEXA scan orders and osteoporosis medications were present in Clinic 2 and not present in Clinic 1. This reveals continued efforts and education of providers need to be made for improvement in bone health monitoring.

AB0619 CLINICAL RISK FACTORS, BONE DENSITY AND FALL'S HISTORY AND FRACTURES RELATION: STUDY BY HOSPITAL SURVEY ABOUT 448 CASES

K. Nassar[1], S. Janani[2]. [1]*Ibn Rochd University Hospital, Hassan II University of Medicine and Pharmacy, Rheumatology Department, CASABLANCA, Morocco*; [2]*Ibn Rochd University Hospital,. Hassan II University of Medicine and Pharmacy, Rheumatology Department, CASABLANCA, Morocco*

Background: Osteoporosis is a disease that affects bone mineral density (BMD) and bone microarchitecture at the origin of an increased risk of fracture. The reduction in bone density assessed by dual-energy X ray absorptiometry (DXA) and fall history represent the first two risk factors of non-vertebral fracture after menopause. Given the high prevalence of osteoporosis among fallers subjects with common risk factors, causing a surisk of fracture. Several publications including the osteoporosis recommendations indicate DXA in women experienced falls in search of bone fragility may justify a treatment for osteoporosis, especially as the FRAX tool does not include at present the fall of history, an important parameter in the assessment of fracture risk.
Objectives: Because of the low attention given to the evaluation of falls'risk, the main objective of the study was to determine the prevalence and the relationship between the past history of fall, reduction of bone mineral density and prevalent fracture.
Methods: Transversal and descriptive epidemiological cohort study conducted for 24 months in 448 patients referred by physicians regularly use prescription of BMD. The realization of this exploration by the same DXA-Hologic in the rheumatology department at Ibn Rochd University Hospital was the criterion for entry into the study. All patients were interviewed on the same day on the risk factors for osteoporosis and fractures justifying the prescription of a BMD.
Results: Data included 413 women and 35 men. Most women were postmenopausal (89.6%). The average age was 59 years (σ = 13.40), 33.7% were ≥ 65 years. The mean BMI was at 27.50 (σ = 5,2). 18.5% of patients had at least a history of falls in the previous 12 months and 22.5% a history of fracture after a low-energy trauma. 42.9% were osteoporotic and 57.1% had osteopenia in at least one of these sites: lumbar spine, femoral neck, total hip. We did not find significant association between BMD osteoporosis and fall history (p = 0.916). Thus, cases of osteoporosis fractures were not statistically associated with a fall (p = 0.170). Also, the falls were occurring than 18.4% of osteopenic patients (p = 0.220). However, in our study, the fall was an independent risk factor for fracture (p = 0.003) and osteopenic fractures were significantly higher among fallers (p = 0.009 and 0.006 respectively, a drop of history and at least one past fall history).
Conclusion: The fall history is a independent risk factor for fracture. This risk is particularly important in case of fragility bone densitometry. The clinical history and fall risk factors should be taken into consideration in the assessment of fracture risk and in the anti-ostoporotique treatment strategy. Thus, the fall seems to be a legitimate indication for DXA and as a parameter to be integrated into the assessment of fracture risk by the FRAX score.

AB0620 MODIFICATION OF THE DECISION OF THE ANTI-OSTEOPOROSIS TREATMENT AFTER PERFORMING THE VFA

H. Tantaoui[1], K. Nassar[1], S. Janani[1]. [1]*Faculty of Medicine and Pharmacy, Hassan II University, Ibn Rochd University Hospital Center, Rheumatology, Casablanca, Morocco*

Background: Spinal fractures are the most common of all osteoporotic fractures. Its diagnosis is essential, because the discovery of a vertebral fracture testifies the gravity of osteoporosis and modifies the therapeutic intervention threshold by justifying a specific anti-osteoporosis treatment. The evolution of densitometers now makes it possible to take a true X-ray image using software called "Vertebral Fracture Assessment" or VFA.
Objectives: To assess the impact of VFA results on therapeutic decision-making after measuring bone mineral density.
Methods: We conducted a retrospective and descriptive study in the rheumatology department.
We included all patient followed at the consultation for bone pathologies, in whom a measurement of bone mineral density and a supplementation of VFA were performed. Clinical data, BMD, VFA and the therapeutic decision by anti-osteoporosis treatment before and after VFA were collected.
Results: Sixty-one patients were included. The mean age was 62.8 years [38 - 85 years]. Sex ratio (female / male) was 19.3. At BMD level, patients with osteoporosis and osteopenia were 49% and 51% respectively. VFA objectified at least one spinal fracture in 64% of patients. Prior to VFA, anti-osteoporosis therapy was indicated to 49% of patients, based on clinical data and BMD. After performing VFA, the prescription of anti-osteoporosis therapy was indicated to 80% of patients.
Conclusion: Patients who had no indication for osteoporosis treatment based on BMD data, VFA was able to modify their therapeutic treatment by detecting vertebral fractures in patients who had back pain.
Disclosure of Interests: None declared.

AB0621 THE MAIN CAUSES OF MORTALITY IN PATIENTS WITH OSTEOPOROTIC HIP FRACTURES

J. Averkieva[1], M. Letaeva[1], O. Malyshenko[1], M. Koroleva[1], T. Raskina[1]. [1]*Kemerovo State Medical University, Department of Propedeutics of Internal Medicine, Kemerovo, Russian Federation*

Background: Increasing life expectancy is one of the main achievements of modern medicine. However, longevity is inevitably associated with the growth of so-called "age-associated diseases," among which osteoporosis occupies an important place.
Objectives: To study the causes of mortality in patients with hip osteoporotic fractures during 12 months after injury.
Methods: Traced the causes of mortality 432 patients with osteoporotic hip fractures were under observation: 328 women and 104 men. The mean age of women was 75.4 ± 9.27 years, the mean age of men was 71.5 ± 10.39 years.
Results: This study traced the causes of deaths by the main classes of ICD-10. It was found that 6 months after a hip fracture in 63 (66.3%) patients, death occurred from diseases of the circulatory system: in men - 13 (59.0%) cases and in women - 50 (68.4%) (p = 0.9). Respiratory diseases, as a cause of death, were identified in 18 (18.9%) patients (in men - 5 (22.9%) cases and in women - 13 (17.8%) (p = 0.1)), neoplasms - in 10 (10.5%) men and women: 2 (9.1%) and 8 (10.9%) cases, respectively (p = 0.5). Diseases of the digestive system accounted for a small percentage of the total number of deaths (3.2%), without statistically significant differences by gender (in men - 1 (4.5%) case and in women - 2 (2.9%) cases (p = 0.75)). Among the dead men, 1 (1.1%) death from an infectious disease was registered. 12 months after the fracture, most of the deaths in both men and women were due to diseases of the circulatory system. The total number of deaths was 93 (67.8%): in men - 22 (66.0%) cases, in women - 71 (68.3%) (p = 0.65). Respiratory diseases caused death in 23 (16.8%) patients: in men - 5 (15.1%) cases and in women - 18 (17.3%) (p = 0.31). There is an increase in the number of deaths from neoplasms to 15 (10.9%) cases without statistically significant differences by gender: in men - 3 (9.09%) cases and in women - 12 (11.5%) (p = 0, 45). Diseases of the digestive system, as a cause of death, were identified in 5 (3.6%) men and women (2 (6.06%) and 3 (2.9%) cases, respectively (p = 0.1)). No new cases of deaths from infectious diseases were registered.

Conclusion: Most of the deceased men and women had cardiovascular and respiratory diseases. There were no statistically significant differences registered in the structure of mortality by gender for all classes of diseases.
Disclosure of Interests: None declared.

AB0622 WHEN OSTEOPOROSIS, COELIAC DISEASE AND MULTIPLE MYELOMA CO-EXIST

S. Khalid[1], R. Smith[1]. [1]*Salisbury District Hospital, Rheumatology, Salisbury, United Kingdom*

Background: Secondary causes of bone loss are sometimes overlooked in patients who are diagnosed as having osteoporosis. This is especially true if more than one risk factor for secondary osteoporosis is present, with clinicians focusing on the more common cause. Here we present a case of secondary osteoporosis caused by coeliac disease *and* multiple myeloma.
Objectives: Secondary osteoporosis should be suspected in patients with very low bone mineral density and those with no obvious risk factors. Comprehensive examination and investigations must be done to look for all secondary causes because sometimes, as seen in our patient, you may find more than one.
Methods: A 74 year old gentleman presented to the rheumatology clinic for assessment of osteoporosis. He had been recently diagnosed with coeliac disease. DXA scan showed a T score of -3.5 at the lumbar spine, -2.5 at the left hip and a low Z score of -2.9. He had not sustained any fractures in the past. There was no history of corticosteroid exposure and no parental history of hip fracture or osteoporosis. He drank up to 21 units of alcohol a week and was an ex-smoker. He was managing a gluten-free diet. His testosterone and vitamin D levels were normal. Serum electrophoresis, done as part of the osteoporosis workup, revealed a diagnosis of multiple myeloma. He then developed back pain and given his new diagnosis of myeloma, prompt investigations were carried out. A skeletal survey showed T7 fracture and a subsequent MRI scan showed impending cord compression, which were treated successfully with radiotherapy. He underwent chemotherapy and autologous stem cell transplantation for his myeloma.
He recently had an OGD following one week post gluten rechallenge after an established gluten free diet. His biopsy shows no evidence of coeliac disease. Interestingly, the stem cell transplantation did not only treat our patient's myeloma, but also his coeliac disease.
Results: Z-score is a useful indicator of possible secondary osteoporosis. A score of –2.0 or less is below the expected range for age and should prompt careful scrutiny for an underlying cause.
Coeliac disease is a gluten-sensitive enteropathy and a known cause for secondary osteoporosis. It likely causes bone loss by secondary hyperparathyroidism from vitamin D deficiency. Multiple myeloma is a disease of aging adults resulting in osteolytic and/or osteoporotic bone disease through increased bone resorption and decreased bone formation from pro-inflammatory cytokines. While coeliac disease patients are at increased risk of all malignancies, association with multiple myeloma is rare, but has been described.
Conclusion: This case highlights the importance of evaluating for secondary causes for low bone mineral density and often, one may find more than one contributory factor. It also shows that a Z-score of –2.0 could help identify patients with a secondary cause for osteoporosis and those who would especially benefit from a thorough history and examination.

AB0623 OSTEOPOROSIS: SCREENING, DIAGNOSIS AND TREATMENT IN TUNISIA: INVENTORY

S. Jriri[1], N. El Amri[1], K. Baccouche[1], S. Lataoui[1], H. Zeglaoui[1], E. Bouajina[1]. [1]*Farhat Hached, rhuematology, sousse, Tunisia*

Background: Osteoporosis has become a public health issue due to the increasing number of complications in osteoporotic women in terms of morbidity and mortality.His screening has improved since the refund of the bone densitometry, but prevention, diagnosis and treatment of this pathology remain suboptimal.
Objectives: a qualitative study to understand barriers towards care initiation and levers to improve awareness and management of osteoporosis among general and specialist practitioners.
Methods: The survey was conducted among a random sample of general practitioners and specialists.An anonymous questionnaire was used for this study carried out by mail.It contained 22 questions concerning the socio-demographic characteristics of each practitioner and his patient group, general questions on osteoporosis and questions on the practice in terms of management.The survey lasted about six weeks.
Results: 102 doctors have answered.55,3% were experienced doctors and 44.7% were young doctors in training.They were 43 general practitioners,21 rheumatologists,15 orthopedists,13 gynecologists and 10 endocrinologists.The sector of activity in urban and periurban areas was noted in 90% of casesand 5% in rural.43% exercised a liberal activity and57% had a hospital-university activity.60% of participants believed that osteoporosis is a condition associated with morbi-mortality and 85% confirmed that it is an underestimated disease. In 72% of physicians,women over 50 accounted for 25 to 75% of their female patient base.86% of doctors looked for recent information on osteoporosis from medical journals andrecommendations and 11% from representatives of pharmaceutical companies.In a recently menopausal patient,68% of physicians often looked for risk factors for osteoporosis which were: Age in 90% of cases, early menopause in 84%,presence of a family or personal history of fracture in 65 %,a history of prolonged systemic corticosteroid therapy in 46% ofcases;endocrine pathologies in 29%;Chronic inflammatory rheumatism was investigated in 19% of cases,Smoking and alcoholism were investigated in 11% of cases.The diagnosis of osteoporosis was mentioned in case of bone transparency on standard X-rays in 76% of cases,a low-energy trauma fracture in 43.5% and the presence of a risk factor in 35% of cases.98% of responding physicians rely on bone densitometry to make the diagnosis of osteoporosis.41.2% of doctors said they were looking for a secondary cause of osteoporosis or a differential diagnosis by requesting a biology.This assessment included:blood phosphocalcic assessment in 88%,vitamin D in 90%,thyroid assessment in 35%,protein electrophoresis in 38%, inflammatory biologic markers in 20% and immunological factors were requested in 6% of cases.The choice of anti-osteoporosis treatment depended on the bone densitometry result in 88% of casesand the presence of a personal history of fractures in 36.5% of cases.Bisphosphonates were at the top of the therapeutic arsenal of general practitioners and specialists (99.8%).100% of the participants knew the reimbursement criteria for anti-osteoporosis treatment by the national health insurance fund and take them into account when prescribing in 91% of cases.The duration of a therapeutic sequence varied from one practitioner to another: 13% of the doctors did not specify it, 45% treated their patients for five years and 42% kept the treatment for 3 years.When a fracture occurred during treatment, 64% of general practitioners had recourse to a rheumatologist, the rest carried out a densitometric reassessment.
Conclusion: The deficits found in the knowledge of both the general practitioners and among others specialists, should be addressed by providing updated information and better awareness of health professionals in order to improve osteoporosis prevention and treatment.

AB0624 COMPARISON OF DIFFERENT FRAX SCORES WITHOUT BONE MINERAL DENSITY FOR THE EVALUATION OF RISK FRACTURE IN MEXICAN PATIENTS WITH RHEUMATIC DISEASES

G. Figueroa-Parra[1], A. Y. Lujano Negrete[1], R. Moyeda Martinez[1], C. M. Gamboa-Alonso[1], D. Á. Galarza-Delgado[1], C. M. Skinner Taylor[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Universidad Autónoma de Nuevo León, Servicio de Reumatología, Monterrey, Mexico*

Background: Osteoporosis (OP) is characterized by compromised bone strength and deterioration of quality, often leading to fragility fractures(1). Dual-energy x-ray absorptiometry (DXA) is the recommended test for OP screening(1). However, there are limitations to perform DXA on all patients, and the clinicians use screening tools to identify those patients with higher risk, like the FRAX score(2).

Nevertheless, these scores have showed low to moderate correlation with DXA in RD patients(3).

Objectives: To evaluate the fracture risk in RD patients, using different versions of FRAX scores without a bone mineral density (BMD) measure.

Methods: An observational prospective study was performed at the Rheumatology Clinic in the University Hospital "Dr. Jose Eleuterio Gonzalez" in Monterrey, Mexico, between August and October 2020. Consecutive patients with a RD were evaluated as part of a "Bone Health Program"(3). Demographics and the risk factors included in FRAX tool was collected from ≥40 years-old patients; FRAX score was calculated online at https://www.sheffield.ac.uk/FRAX/ (algorithm for Mexicans). Four versions were calculated: 1) FRAX score without (w/o) BMD; 2) FRAX score with a T-score of -1.0 (w/Op); 3) FRAX score with a T-score of -2.5 (w/OP) and a FRAX score with positive previous fracture (Fx+). Then were classified as low (<10% for OP or <1% for hip), intermediate (10%-19% for OP or 1%-<3% for hip) and high risk (≥20% for OP or ≥3% for hip). Results are shown in means (SD) or frequency (%). A chi-square test was used to compare groups. Spearman's correlation test (rho) was done between OP risk and Hip risk in each version of FRAX. P<0.05 was considered statistically significant.

Results: One hundred and three patients were included, 93.2% were woman. The most frequent diagnosis was RA in 51.5% of patients, followed by osteoarthritis in 7.8%. 62.1% of patients had a previous BMD measured by DXA. 21.4% had history of previous fracture. 61.2% of patients were taking glucocorticoids. (Table 1). According to FRAX risk w/o BMD, 82 (79.6%) had low risk, 13 (12.6%) had intermediate risk, and 8 (7.8%) had high risk for OP. According to FRAX risk w/o BMD, 59 (57.3%) had low risk, 24 (23.3%) had intermediate risk, and 20 (19.4%) had high risk for hip fracture (Table 2). The correlations between OP risk and Hip risk in each version were as follow: FRAX w/o BMD (rho= .734, P= <.001) FRAX w/Op (rho= .308, P= .002); FRAX w/OP (rho= .476, P= <.001); FRAX with Fx+ (rho= .634, P= <.001).

Conclusion: There is a wide variability among the different FRAX risk scores evaluated, and moderate to high correlation between the OP and Hip risk in patients with RD.

AB0625 ARE TUNISIAN WOMEN PRONE TO VERTEBRAL FRACTURES AT A YOUNGER AGE?

C. Daldoul[1], N. El Amri[1], S. Laataoui[1], K. Baccouche[1], H. Zegaloui[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: There is an evident increased risk of vertebral fractures (VF) related to ageing. This is due to alterations in trabecular microarchitecture and a decrease in cortical thickness. The International Society of Clinical Densitometry (ISCD) recommend an age threshold of 70 years for VF screening in women. However, a large proportion of VF occurs below this threshold. In Tunisia, there was no previous study evaluating the association between age and VF.

Objectives: The aim of this study was to evaluate the relationship between age and prevalent VF in Tunisian women.

Methods: We conducted a cross-sectional study over a period of 5 months at the rheumatology department. The study included post-menopausal women without a previous diagnosis of VF referred for BMD measurement. Each participant had an extensive medical history investigation, a BMD assessment and a VFA scan to detect prevalent VF using dual energy X absorptiometry DeXa. VF were identified according the Genant semi-quantitative method and grade 1 VF were ruled out. We used the WHO criteria for the diagnosis of osteoporosis and osteopenia. For age, the results were expressed as means with standard deviations (SD) and extreme values and then analyzed with two-tailed Student t test. The receiver operating characteristics curve (ROC) determined cut-offs for age. Statistical significance was set at 5%.

Results: Two hundred and ten women were included in this study. The mean age of our patients was 61.51±8.49 with extremes ranging from 40 to 81 years. The distribution of our patients in 10 years age groups showed that: 9% were aged between 40 and 50 years, 34.3% were aged between 50 and 60 years, 38.6% were aged between 60 and 70 years, 17.1% were aged between 70 and 80 years and 1% were aged above 80 years. The mean BMI was 31.04±5.52 kg/m2. Thirty-seven percent of our participants had at least one fragility fracture and a severe fragility fracture was recorded in 10.5%. An early menopause was found in 19.5% of our women. Twenty percent of our population were receiving corticosteroids. The mean vertebral and total hip BMD was 0.955±0.165 g/cm2 and 0.850±0.135 g/cm2 respectively. Osteoporosis and low BMD were found in respectively 50% and 34.28%. The mean age in the VF group was significantly higher compared to the non-VF group (64.37 years vs. 60.50 years, p=0.003). The ROC curve identified an age cut-off of 60 years for VF. Age above 60 years was significantly associated with VF (65.5% vs. 43.9%, p=0.006) with an unadjusted risk of 5.42 (95%CI [1.278-4.597]). Among women with VF, 74.5% (41 women) were aged under 70 years which is the threshold proposed by the ISCD for VF screening. Among women aged under 70 years and having at least one VF (41 women), 6 women (14.63%) had an indication for VF screening as they reported a historical height loss of 4 cm and 8 women (19.51%) had an indication for VF screening as they were receiving corticosteroids. Hence, 27women (65.85%) had at least one VF and no indication for VF screening according to the ISCD.

Conclusion: Tunisian women over 60 years were at higher risk of VF. Applying the ISCD criteria for VF screening would miss 65.85% of women with VF. Those findings highlight the particularity of this population experiencing osteoporotic VF at an early age.

AB0626 THE CHARACTERISTICS AND TREATMENT OF PATIENTS ADMITTED WITH FRAGILITY FRACTURE OF THE HIP

H. Baharuddin[1,2], R. Nasadurai[2], S. S. Ch'ng[2], Y. Z. Cheng[2], D. R. Ramakrishna Rao[2], P. A. Megat Mohamad Zainuddin[2], S. Sabir Husin Athar[3], M. Mohd Zain[2]. [1]*Universiti Teknologi MARA, Department of Internal Medicine, Sungai Buloh, Malaysia*; [2]*Selayang Hospital, Department of Medicine, Batu Caves, Malaysia*; [3]*Selayang Hospital, Department of Orthopaedics, Batu Caves, Malaysia*

Background: Hip fractures are associated with significant morbidity, mortality, loss of independence and financial burden.[1] There is a positive influence of calcium and vitamin D supplementation on the fracture-healing outcome.[2]

Recent evidence supports starting bisphosphonate in the acute post-fracture period.[3]

Objectives: To investigate the characteristics and treatment of patients admitted with fragility fracture of the hip.

Methods: This is a retrospective study on all patients admitted with fragility fracture of the hip throughout 2018, included in the hospital registry. Data collected included patients' characteristics, place of falls, types of fracture, in-patient surgical treatment and medical treatment prescribed up until one year follow-up. Outcome of hospitalisation were reported as alive, death and at-own-risk discharge. Continuous and categorical data were described using mean (±SD) and no of patients (%). Comparison of continuous data was performed using student t-test.

Results: One-hundred and sixty-seven patients were admitted with fragility fracture of the hip. There were 44 (26.3%) male and 123 (73.7%) female patients, with a mean age of 77.1(±9.8) years. Male patients were significantly younger compared to female patients [73.1(±10.5) years vs 78.5(±9.1) years, p=0.002]. Eighty-six (51.5%) patients were Chinese, followed 57 (34.1%) Malay and 24 (14.4%) Indian patients. Chinese patients were significantly older than Malay patients [80.4(±8.2) years vs 74.6(±9.8) years, p<0.001] and Indian patients [80.4(±8.2) years vs 71.0(±10.5), p<0.001].

Most patients, 96 (57.5%) fell within the vicinity of their homes while the other 26 (12.7%) patients fell outside of their home. The place of fall was not documented for 45 (26.9%) patients. The types of fractures were neck of femur in 70 (41.9%), inter-trochanteric fracture in 93 (55.7%) and subtrochanteric in 4 (2.4%) patients.

Of 167 patients, 100 (59.9%) patients underwent surgical treatment and 67 (40.1%) patients were treated conservatively. The prescription of calcium and vitamin D was significantly higher in female patients (Table 1). Of 167 patients, 148 (88.6%) were discharged home, 12 (7.2%) patients died during hospital admission and 7 (4.2%) patients opted for at-own-risk discharge.

Table 1. Treatment prescribed to patients admitted with fragility fracture of the hip.

Treatment		Male, no of patients (%)	Female, no of patients (%)	p-value
Surgery	Yes (n=100)	30 (30)	70 (70)	0.209
	No (n=67)	14 (20.1)	53 (79.1)	
Calcium	Yes (n=91)	18 (19.8)	73 (80.2)	0.035
	No (n=76)	26 (34.2)	50 (65.8)	
Vitamin D	Yes (n=88)	16 (18.2)	72 (81.8)	0.011
	No (n=79)	28 (35.4)	51 (64.6)	
Bisphosphonate	Yes (n=13)	0	13 (100)	NA
	No (n=154)	44 (28.6)	110 (71.4)	

Conclusion: There was a high proportion of female patients admitted with fragility fracture of the hip. Majority of patients were Chinese, who were significantly older compared to Malay and Indian patients. We found a low prescription of osteoporosis medications for patients following fragility fracture of the hip. The care of osteoporosis can be improved through multidisciplinary approach.

AB0627 THE EFFECT OF BIOLOGICALLY ACTIVE FOOD SUPPLEMENT WITH CALCIUM AND VITAMIN D3 ADMINISTRATION ON CALCIUM HOMEOSTASIS AND FALLS INCIDENCE IN PATIENTS WITH HIGH FRACTURE RISK UNDERGOING MEDICAL REHABILITATION

L. Marchenkova[1], V. Vasileva[1]. [1]*National Medical Research Center for Rehabilitation and Balneology of Ministry of Health of Russian Federation, Rehabilitation department for somatic patients, Москва, Russian Federation*

Background: Vitamin D and calcium deficiencies is of particular importance in older patients undergoing medical rehabilitation and having a high risk of fractures. Preventing falls and fractures, including during the course of rehabilitation, is an important challenge that can be addressed in these patients, in particular through improved nutrition and vitamin D and calcium supplementation.

Objectives: to evaluate the effect of long-term calcium and vitamin D3 intake on calcium homeostasis and fall's rate in patients with high fracture risk starting rehabilitation course.

Methods: The study enrolled 119 men and women aged 50-80 y.o. with high absolute fracture probability by FRAX who started medical rehabilitation. 41 patients have been receiving antiresorptive therapy already comprised group 1, other patients were randomized into groups 2 (n=39) and 3 (control, n=39). In groups 1 and 2, a food supplement containing calcium citrate 1000 mg and vitamin D3 600 IU was prescribed for 12 months. All patients undergo laboratory examination, food calcium intake and fall assessment at baseline, in 6 and 12 months.

Results: Daily calcium intake in the study sample (n=119) was 782.9±243.4 mg. Vitamin D deficiency was detected in 38.4% of the examined. An increase in 25(OH)D level was noted in groups 1 and 2 after 6 and 12 months (p<0.01). Patients in group 1 showed an increase in serum osteocalcin and calcium levels after 6 and 12 months (p<0.05). In group 3, there was an increase of immunoreactive parathyroid hormone levels after 6 (p<0.05) and 12 months (p<0.01), C-terminal telopeptide of type I collagen level and alkaline phosphatase activity after 12 months (p<0.05). In group 1, there was also a decrease in proportion of patients who fell after 6 months ($\chi 2$=4.97, p=0.026) and a decrease in the total number of falls after 12 months ($\chi 2$=4.89, p=0.027). Group 2 showed a decrease in the number of patients who fell after 6 and 12 months ($\chi 2$=48.58, p=0.0034 at both stages of the study) and the number of falls in general after 6 months ($\chi 2$=6.02, p=0.0142).

Conclusion: The obtained data allow us to recommend prescription of dietary supplements containing calcium and vitamin D3 as a part of complex rehabilitation of patients with high fracture risk.

Disclosure of Interests: None declared.

Crystal diseases, metabolic bone diseases other than osteoporosis

AB0628 PRE-INFUSION GLUCOCORTICOID ELIMINATION IN PATIENTS WITH UNCONTROLLED GOUT TREATED WITH PEGLOTICASE: A CASE SERIES

V. Newsome[1], A. Amatucci[2], T. Stainbrook[1], B. Lamoreaux[2]. [1]*Penn Highlands Healthcare, Rheumatology, DuBois, United States of America*; [2]*Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*

Background: Pegloticase is indicated for treating uncontrolled gout, but some patients develop anti-drug antibodies that have been associated with a loss of efficacy and infusion reactions (IRs).[1] Per the pegloticase prescribing information, pre-infusion medications, including glucocorticoids (GCs), should be given to minimize IR risk.[2] Given that GCs have a significant side effect profile and patients with uncontrolled gout generally have multiple comorbidities,[3,4] minimizing steroid exposure is desirable.

Objectives: The current case series examines a community rheumatology practices' experience with pre-infusion GC elimination in uncontrolled gout patients treated with pegloticase.

Methods: This retrospective chart review was conducted at a rheumatology practice that discontinues pre-infusion GC use in patients treated with pegloticase. Patients treated from 2016-2020 who had pre-infusion GCs discontinued during therapy were included. Pre-infusion prophylaxis at this practice includes methylprednisolone (125 mg IV), diphenhydramine (50 mg oral + 12.5 mg IVP), famotidine (40 mg oral), and acetaminophen (1000 mg) administered immediately before infusions. All other IR prophylaxis continued when GCs were stopped without tapering. Demographics, number of pegloticase infusions, and safety (adverse events [AEs], clinical lab values) were examined. Patients self-managed gout flares with oral methylprednisolone (24 mg then 5-day taper).

Results: Nine patients (8 male) with tophaceous gout met inclusion criteria. Mean age was 72.3 ± 6.9 years (65-84 years), mean BMI was 28.7 ± 5.6 kg/m^2, and mean pre-therapy serum uric acid (sUA) was 7.3 ± 2.7 mg/dL (3.9-12.7 mg/dL). Two patients were co-treated with oral methotrexate (15 and 20 mg/week) and one patient was on hemodialysis. Most common comorbidities included osteoarthritis (9 patients), hypertension (8 patients), chronic kidney disease (5 patients), kidney stones (5 patients), and diabetes (5 patients). A median of 27 pegloticase infusions (range: 9-84) were administered, with 8 of 9 patients receiving ≥12 infusions. Median number of infusions before and after initial GC

discontinuation was 7 (range: 2-56) and 10 (range: 2-48), respectively. Pre-infusion steroids were re-started in 3 patients after a rise in sUA, with 1 regaining sUA response (patient 2) and 2 discontinuing therapy (patients 4 and 9). An additional patient had a loss of sUA response (patient 7) and discontinued, 1 patient discontinued due to hospitalization (patient 6), and 1 patient chose to discontinue therapy (patient 8). At the time of data collection, 4 patients remained on therapy (patients 1-3, 5). Eight patients had at least one AE (all deemed unrelated to treatment), including influenza, hypertensive crisis, and toe amputation. No IRs occurred.

Conclusion: In this case series, 8 of 9 patients received 6 months or more (≥12 infusion) of pegloticase. These cases suggest that pre-infusion GC discontinuation may be possible in some patients treated with pegloticase (particularly those over 70 years). Further investigation exploring this concept is warranted, including evaluating the optimal time and conditions to discontinue pre-infusion GCs with pegloticase.

Background: Synovial fluid analysis (SFA) via compensated polarized light microscopy is still considered the gold standard for the identification and diagnosis of Calcium Pyrophosphate Deposition disease (CPPD)-related arthropathies[1], but very few studies have been published about its diagnostic accuracy.

Objectives: The aim of this study was to evaluate the accuracy of SFA in the identification of calcium pyrophosphate dihydrate (CPP) crystals compared to microscopic analysis of joint tissues as the reference standard.

Methods: This is an ancillary study of an international, multicentre cross-sectional study performed by the CPPD subgroup of the OMERACT Ultrasound working group[2]. Consecutive patients with knee osteoarthritis (OA) waiting for total knee replacement surgery were enrolled in the study from 2 participating centres, Mexico and Romania. During surgical procedures synovial fluid (SF), menisci and hyaline cartilage were collected and analysed within 48 hours after surgery under transmitted light microscopy and compensated polarised light microscopy for the presence/absence of CPP crystals. All slides were analysed by expert examiners on site, blinded to other findings. A dichotomic score (absence/presence) was used for scoring both SF and tissues. Microscopic analysis of knee tissues was considered the gold standard. Sensitivity, specificity, accuracy, positive and negative predictive values (PPV and NPV) of SFA in the identification of CPP crystals were calculated.

Results: 15 patients (53% female, mean age 68yo ± 8.4) with OA of grade 3 or 4 according to Kellgren-Lawrence scoring were enrolled. 12 patients (80%) were positive for CPP crystals at SFA and 14 (93%) at tissues microscopic analysis. Among 12 SFA positive patients, all were positive for CPP crystals in either medial or lateral meniscus, and 11 were positive in both; 10 patients were positive at the hyaline cartilage, and all 10 were also positive for at least one meniscus. Regarding the 3 SFA negative patients, only one had no crystals in the examined tissues, while the other 2 patients had CPP crystals in both menisci and hyaline cartilage. The overall diagnostic accuracy of SFA compared to histology analysis for CPPD was 87%, with a sensitivity of 86% and a specificity of 100%, the PPV was 100% and the NPV was 33% (Table 1).

Table 1. sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic accuracy of synovial fluid analysis compared to the reference standard. CI: Confidential Interval. SF: synovial fluid, in parentheses: numerators and denominators for all percentages provided.

	Sensitivity	Specificity	PPV	NPV	Accuracy
SF analysis	86% (12/14) (0.65-0.99) CI 95%	100% (1/1) (0.0-0.25) CI 95%	100% (12/12) (0.65-0.99) CI 95%	33% (1/3) (0.0-0.25) CI 95%	87% (13/15)

Conclusion: SFA demonstrated to be an accurate test for the identification of CPP crystals in patients with advanced OA. However, is not always feasible and carries some risks for the patient. Considering the availability of validated imaging techniques for the detection of CPPD, such as US, SFA could be used in those patients where imaging and clinical data are not definitely confirmatory of the disease.

AB0630 PEGLOTICASE/METHOTREXATE CO-THERAPY IMPROVED JOINT AND PATIENT-REPORTED HEALTH ASSESSMENTS IN PATIENTS WITH UNCONTROLLED GOUT: 12-MONTH EXPLORATORY OUTCOMES OF THE MIRROR OPEN-LABEL TRIAL

J. Botson[1], P. M. Peloso[2], K. Obermeyer[2], B. Lamoreaux[3], L. Zhao[2], M. E. Weinblatt[4], J. Peterson[5]. *[1]Orthopedic Physicians Alaska, Medical,*

Anchorage, United States of America; [2]*Horizon Therapeutics plc, Research and Development, Deerfield, United States of America*; [3]*Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*; [4]*Brigham and Women's Hospital, Division of Rheumatology, Immunology and Allergy, Boston, United States of America*; [5]*Western Washington Medical Group, Arthritis Clinic, Bothell, United States of America*

Background: Gout development follows persistent serum uric acid (sUA) elevation. Patients who are refractory to or cannot tolerate oral urate lowering therapies (ULTs) have limited treatment options. Pegloticase is effective in treating refractory gout, but many patients develop anti-drug antibodies (ADAs), which are associated with loss of urate-lowering efficacy[1-3] and infusion reactions (IRs).[1,2] In phase 3 trials, the pooled pegloticase responder rate during Months 3 and 6 combined was 42% (8 mg infusion every 2 weeks), with high-titer ADA positive patients losing efficacy prior to 6 months.[1] The 6-month results from the MIRROR open-label trial (79% response rate [11/14], 95%CI 49-95%)[4] suggest that methotrexate (MTX) administered in conjunction with pegloticase increases treatment responder rate.

Objectives: To examine longer-term (12-month) exploratory endpoints from the MIRROR open-label trial, including joint, overall health, and gout global assessments. Serial dual-energy computed tomography (DECT) images were also examined when available.

Methods: Adult patients with uncontrolled gout (sUA ≥6 mg/dL with ≥1 of the following: sUA ≥6 mg/dL despite ULT use, intolerance to ULT, or functionally limiting tophaceous deposits) were included. Patients with immunocompromised status, G6PD deficiency, severe renal impairment, or MTX contraindication were excluded. Patients were administered oral MTX (15 mg/week) and folic acid (1 mg/day) 4 weeks prior to and throughout pegloticase therapy (8 mg biweekly infusion for up to 52 weeks). Exploratory outcomes included mean change from baseline (CFB) in number of affected joints (tophi, swollen, tender), Health Assessment Questionnaire (HAQ) scores (Disability Index [DI; score 0–3], Pain [score 0–100], Health [score 0–100]), and Gout Global Assessments (Patient, Physician; score 0–10). A decrease in these measures reflects clinical/patient-reported health improvement. Change in urate deposition volume, as measured on DECT imaging, was also examined as available. Analyses were performed on the modified intent-to-treat (mITT) population (≥1 pegloticase infusion received).

Results: 14 patients (all male, mean±SD age: 49.3±8.7 years) made up the mITT population. Mean±SD sUA prior to pegloticase treatment was 9.2±2.5 mg/dL and 13 patients had visible tophi. 3 patients discontinued due to 2 consecutive sUA levels >6 mg/dL and 1 patient completed the study at week 24 (pre-protocol amendment extending treatment from 24 to 52 weeks). 10 patients completed the 52-week study. Of these, 8 patients received 26 infusions and 2 patients received 12 infusions, discontinued pegloticase after meeting their treatment goal at 24 weeks, and started allopurinol while remaining in study under observation. At week 52 (n=10, sUA=1.1±2.5 mg/dL), the number of affected joints improved, along with HAQ measures (Figure 1). Global Assessments of Gout also improved (Physician: CFB=-5.7±2.6, Patient CFB=-4.6±2.1) and majority of subjects had a score of 0 or 1 (0="excellent health") at week 52 (Physician: 0.3±0.5, Patient: 1.1±1.3). Two patients had available DECT imaging. One received pegloticase/methotrexate co-therapy thru week 52 and had a marked reduction in total urate volume (baseline: 128.76 cm^3, week 52: 1.33 cm^3). The other received only 5 pegloticase infusions, but also showed total urate volume reduction (baseline: 59.20 cm^3, week 10: 25.07 cm^3). Both patients displayed improvement in bone erosion healing.

Conclusion: These 12-month exploratory endpoints of the MIRROR open-label trial suggest that MTX/pegloticase co-therapy results in meaningful changes in clinical evaluations (tophaceous, tender, and swollen joint counts), and patient-reported outcomes (pain, disability) in patients with uncontrolled gout.

Figure. Summary of gout clinical assessments and patient-reported outcomes. Data represent mean values and error bars represent standard error. Patients were co-treated with pegloticase/methotrexate for up to 52-weeks (light blue bar; 52 weeks in 8 patients, 24 weeks in 2 patients). Week 64 and 76 represent the 3 and 6 month follow-up visits, respectively. DECT imaging shows progressive urate volume decrease in this knee (BL: 22.6 cm^3, Week 52: 0.1 cm^3) and bone erosion healing concomitant with clinical improvement. BL, baseline; HAQ, health assessment questionnaire; DI, disability index.

THE PREVALENCE AND FACTORS ASSOCIATED WITH CORONARY HEART DISEASE IN PATIENTS WITH GOUT

E. Markelova[1], M. Eliseev[2], E. Ilinykh[3], S. Glukhova[4], T. Popkova5. [1]*V.A. NASONOVA RESEARCH INSTITUTE OF RHEUMATOLOGY, Laboratory of Systemic Rheumatic Diseases, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Moscow, Laboratory of Crystal Diseases, Moscow, Russian Federation*; [3]*V.A. NASONOVA RESEARCH INSTITUTE OF RHEUMATOLOGY, Laboratory of Crystal Diseases, Moscow, Russian Federation*; [4]*Moscow, Laboratory of Systemic Rheumatic Diseases, Moscow, Russian Federation*; [1]*V.A. NASONOVA RESEARCH INSTITUTE OF RHEUMATOLOGY, Laboratory of Systemic Rheumatic Diseases, Moscow, Russian Federation*

Background: Gout is associated with increased risk of cardiovascular disease (CVD) morbidity and mortality. Therefore, an association between coronary heart disease (CHD) and gout deserves careful examination.
Objectives: The aim of this study was to determine the prevalence of CHD and factors associated with CHD in patients (pts) with gout.
Methods: 286 male patients fulfilling Wallace proposed criteria for gout were included: age 51.2 [42.8;59.4] years (ys), disease duration – 6.2 [3.8;12.1] ys. All patients underwent standard clinical examination, screening traditional risk factors (TRF) of CVD, blood chemistry test with estimation of serum uric acid, serum creatinine, C-reactive protein (CRP), as well as lipid profile. Carotid intima-media thickness (cIMT) was measured using a high-resolution B-mode ultrasound machine. CHD included history of angina pectoris and/or myocardial infarction. We estimated the adjusted odds ratio (OR) and 95% confidence interval (95% CI).
Results: CHD was found in 111 out of the 286 pts (38.8 %). Compared to individuals with CHD, participants without CHD were older (56.7[52.1; 61.1] vs 46.2[40.6; 53.4] ys), had longer duration of gout (9.3[4.7; 15.1] vs 5.6[3.3; 9.7] ys), higher number of joints involved during disease course (8[6; 15] vs 6[4; 10]), duration of smoking (24[10; 40] vs 20[10; 28]), higher serum creatinine level accordingly, (for all $p<0.05$). The frequency of family history of CHD (63% vs 46.8%), intraosseous tophi (61.3% vs 33.1%), was higher in pts with CHD compared pts without CHD accordingly, (for all $p<0.01$). Prevalence of arterial hypertension, diabetes mellitus, nephrolithiasis, heart failure and renal failure was greater in pts with CHD than pts without CHD ($p<0.001$). Gout pts with CHD had a significantly higher cIMT compare to those without CHD - 0.95[0.8;1.08]/0.8[0.7;0.9] accordingly, $p<0.001$. We didn't find differences of lipid profile, serum uric acid, and CRP level in gout pts with/without CHD.
Abdominal obesity (OR, 5.5; 95% CI, 2.2-13.6), body mass index >30 kg/m^2 (OR, 5.8; 95% CI, 1.8-18.5), family history of CHD (OR, 2.7; 95% CI, 1.3-5.4), disease duration of gout more 10 ys (OR, 2.6; 95% CI, 1.3-5.1), age of gout onset < 35 ys (OR, 3.0; 95% CI, 1.5-6.1), intraosseous tophi (OR, 3.1; 95% CI, 1.4-7.0), C-RP (OR, 2.2; 95% CI, 1.1-4.7), renal failure (OR, 18,8; 95% CI, 1.1-312.9), increased the risk for CHD in patients with a gout.
Conclusion: The prevalence of CHD was 38.8% among individuals with gout. Our study showed that both TRFs of CVD and the severity of gout and a history of renal failure contribute to the development of CHD in patients with gout.

AB0632

COMORBIDITIES AND DRUG-INDUCED LIVER INJURY DUE TO NSAIDS INTAKE IN PATIENTS WITH GOUT

E. Mikhnevich[1], P. Tatsiana[1], R. Tatsiana[1], H. Diana[1]. [1]*Belarusian State Medical University, Internal Disease, Minsk, Belarus*

Background: One of the side effects of NSAIDs is hepatotoxicity or Drug-Induced Liver Injury (DILI). Despite the short course of NSAIDs, the patients with gout may develop DILI. At the same time, besides NSAIDs, there are additional factors that affect the functional state of the liver: demography, comorbidities or concomitant medication (1).
Objectives: To determine comorbidities associated with the risk of DILI when taking NSAIDs during the attack of gouty arthritis.
Methods: Our retrospective study included 200 patients with GA. Inclusion criteria for the study: presence of gout (ACR, 1977), initially normal serum ALT level, NSAIDs as anti-inflammatory drugs in gout. Exclusion criteria: presence of a known liver disease. All patients were divided into 2 groups: those who developed DILI (n = 86) and the control group without cytolysis during NSAID treatment (n = 114). The severity of the cytolytic syndrome was revealed as follows: mild form (2-3-fold excess of the ALT norm) in 81,4 % (n = 70); moderate (3-5 times higher ALT) in 15.1% (n = 13); severe (5-10 fold excess of ALT) in 3.4% (n = 3). The mean age of 55 (49-60) years and 54 (44-59.5) years as well as the sex distribution (men made 90.1% and 93.3%, respectively) were compatible in both groups ($p>0,05$). When studying the age distribution, statistical differences were revealed in the groups under 52 years ($p<0,05$), so, this parameter was included into logistic regression model. During the follow-up period, all patients took NSAIDs above average doses. Patients in both groups were comparable in duration of gout. The following parameters were compared: AH, IHD, diabetes mellitus, obesity, dyslipidemia, metabolic syndrome according to ATPIII, CKD, alcohol abuse, age under 52.
Results: After conducting logistic regression analysis, the next comorbidities have been revealed to be statistically significant: obesity (OR – 2,15; 95%CI 1,16-3,98), dyslipidemia (OR – 3,41; 95% CI 1,56-7,44) and alcohol abuse (OR – 2,45; 95%CI 1,22-4,91). Worth to note that age under 52 was also a risk factor for DILI (OR – 2,14; 95%CI 1,13-4,04). Thus, among our patients, the younger ones with an unhealthy lifestyle and no serious comorbidities, including cardiovascular, were at a greater risk for developing DILI while taking NSAIDs during the gout attack.
Conclusion: In the study group of patients with gout, the hepatotoxicity (cytolysis syndrome) risk due to NSAIDs intake increased in younger patients in the presence of signs of metabolic syndrome (obesity, dyslipidemia) and alcohol abuse.

HEALTH RELATED QUALITY OF LIFE IN GOUT, PSORIATIC ARTHRITIS, RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS: RESULTS FROM A QUESTIONNAIRE STUDY

A. Landgren[1], M. Dehlin[1], L. T. H. Jacobsson[1], U. Bergsten[2], E. Klingberg[1]. [1]*Institute of Medicine, Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*; [2]*County of Halland, R&D Department at Region Halland, Halmstad, Halmstad, Sweden*

Background: Gout, psoriatic arthritis (PsA), rheumatoid arthritis (RA), ankylosing spondylitis (AS), are common inflammatory joint diseases (IJD) that substantially affect HRQoL (Health Related Quality of Life). To our knowledge, this is the first study comparing HRQoL in gout, PsA, RA and AS in the same setting.
Objectives: To compare HRQoL assessed with the Short Form health survey (SF-36) between gout, PsA, RA and AS.
Methods: We performed a cross-sectional questionnaire study in Sweden. Individuals ≥18 years and with at least one ICD-10 diagnosis for gout, PsA, RA, or AS, recorded at a health care visit to a physician at a rheumatology clinic (for all diagnoses) or at a primary care center (for gout patients) from 2015 through 2017 were identified. Patients with gout (n=1589), PsA (n=1200), RA (n=1246) and AS (n=1095) were sent a questionnaire including questions regarding Visual Analogue Scales (VAS) for General Health, Pain, Fatigue, Health Asssessment Questionnaire (HAQ), as well as the SF-36. The eight domains (a higher score indicating a better health status) as well as the overall physical (PCS) and mental (MCS) component scores (a value of 50 corresponds to unaffected HRQoL) of the SF-36 are presented. Respondents were matched on age, sex. ANOVA was used for between group comparisons of mean values. For non-normally distributed data, Kruskal Wallis test was used. For comparing distributions, the Chi-Square test was used.
Results: In total, 2896 (56.5%) individuals responded. After matching for age, sex, 249 individuals per diagnosis group remained. Gout patients reported significantly higher scores on SF-36 subscales as well as PCS (consistent with results seen before matching for age and sex). Lower values of HRQoL were noted in physical domains as compared to mental domains in all IJDs. Disability measured by HAQ was significantly lower in gout and VAS scores were more favourable compared to other IJDs.
Conclusion: Patients with gout report higher HRQOL compared to PsA, RA, AS.

BELIEFS ABOUT URATE LOWERING THERAPY DIFFER BETWEEN GENERAL PRACTITIONERS AND RHEUMATOLOGISTS

F. Veenstra[1], J. Vriezekolk[1], H. J. Schers[2], N. Van Herwaarden[1,3], B. Van den Bemt[4,5], M. Flendrie[1]. [1]*Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands*; [2]*Radboud University Medical Center, Primary and Community Care, Nijmegen, Netherlands*; [3]*Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*; [4]*Sint Maartenskliniek, Rheumatology & Pharmacy, Ubbergen, Netherlands*; [5]*Radboud University Medical Center, Pharmacy, Nijmegen, Netherlands*

Background: Uric acid lowering therapy (ULT) can be effective in gout if taken correctly (1), but non-adherence is a known problem (2). Although patients' adherence barriers regarding ULT, such as lack of knowledge on disease and therapy, and beliefs, have been widely studied (3), less is known physicians' beliefs.
Objectives: To investigate the physicians' beliefs on ULT treatment in both primary and secondary care in the Netherlands.
Methods: Cross-sectional study among all rheumatologists of the Sint Maartenskliniek and to all General Practitioners (GPs) of 17 practices, participating in the practice-based research network Family Medicine Network Nijmegen, Netherlands. All participants filled out the beliefs about medication questionnaire (BMQ), adjusted for physicians; in addition data were collected on physician characteristics including working experience in total and gout consultations. The BMQ consists of two parts, a specific part with 10 questions about beliefs on necessity (N=5) and concerns (N=5) regarding ULT and a general part with 8 questions about beliefs on harms (N=4) and overuse (N=4) regarding medication in general. Each question is scored on a Likert-scale from 1-5, a higher score corresponds to higher beliefs on that category. Sum scores for all four categories were calculated. With the total scores on the specific BMQ including necessity and concerns beliefs, physicians were classified in four different categories (Table 1)(4).
Results: In total 112 physicians received the questionnaire, 28 of 37 rheumatologists (76%) and 45 of 75 GPs (60%) responded. Rheumatologists had less years of experience than GPs (median 8.5 years (IQR 3 – 14) versus (vs) 13 years (IQR 8-20)) and less hours of patient contact per week (15 hours (IQR 8.5 – 20) vs 24 hours (IQR 20 – 30)). Rheumatologists reported more consultations for gout per week than GPs: median 4 (IQR 1 – 6.6) vs 1 (IQR 0.2– 1).
Rheumatologists scored higher on the BMQ necessity scale, 17.5 (95% CI 16.6 – 18.5) compared to GPs 16.1 (95% CI 15.1 – 17.1). GPs scored higher on BMQ concern scale, 12.1 (95% CI 11.4 – 12.7) compared to rheumatologists, 10.4 (95% CI 9.7 – 11.2). On medication in general, GPs scored higher on both overuse and harms scales compared to rheumatologists, 11.3 (95% CI 10.7 – 12) versus 9.9 (95% CI 9 – 10.7)and 8.3 (95% CI 7.9 – 8.7) vs 7.1 (95% CI 6.5 – 7.7), respectively. Table 1 shows classification according to the BMQ specific for both groups.

Table 1. Classification based on the adapted BMQ

	Rheumatologists (N=28)	GPs (N=45)
Acceptant (%)	19 (67.9)	16 (35.6)
Ambivalent (%)	0	8 (17.8)
Sceptic (%)	1 (3.6)	5 (11.1)
Indifferent (%)	8 (28.6)	16 (35.6)

Conclusion: For the majority of rheumatologist the necessity beliefs outweighs concern beliefs towards the use of ULT outweighs concern beliefs. GPs show a more heterogenic profile, including acceptant, indifferent and ambivalent beliefs towards ULT use. GPs also show higher harm and overuse concerns regarding medication in general. Next step is to investigate possible associations with actual ULT use and disease outcome.

EVALUATION OF THE INTIMA-MEDIA THICKNESS INDEX BY CAROTID DOPPLER IN PATIENTS WITH MONOSODIUM URATE DEPOSITION ARTHRITIS OF THE HOSPITAL DOCENTE PADRE BILLINI, DOMINICAN REPUBLIC

A. Cornelio[1,2], J. Santana Peralta[2], T. Polanco Mora[2], Y. Cruz[2], E. Rodriguez Bautista[2], T. Valdez[2], R. Muñoz[2], A. Feriz[2]. [1]*Hospital Docente Padre Billini, Reumatologia, Santo Domingo, Dominican Republic*; [1]*Hospital Docente Padre Billini, Reumatologia, Santo Domingo, Dominican Republic*

Background: Hyperuricemia and gout are risk factors for atherosclerosis subclinical and cardiovascular complications. (1) However, it is still debated whether uric acid is an independent predictor of cardiovascular risk. (2) Vascular Doppler and in particular the measurement of the intima-media thickness and the detection of plaques are useful in the evaluation of cerebrovascular disease and cardiovascular risk. (3) An intima-media thickness greater than 0.9mm and / or the presence of atheromatous plaques in the carotid are predictive of high cardiovascular risk and silent heart disease. (4) Gouty arthritis has been associated with alteration of the carotid intima media thickness (cIMT) and subclinical atherosclerosis. Cukurova et al studied patients with gout, finding an increase in cIMT compared to patients with asymptomatic hyperuricemia. (5)
Objectives: Assess the carotid intima-media thickness in patients with monosodium urate deposits arthritis

Methods: Prospective, observational, cross-sectional study. Carotid Doppler was performed on patients in the outpatient clinic with a diagnosis of gout from November 2019 to 2020 of the rheumatology service of the Hospital Docente Padre Billini and healthy controls. Inclusion criteria, patients> 18 years, diagnosis of monosodium urate deposits arthritis according to the ACR / EULAR 2015 classification criteria, carotid Doppler, measurement of the cIMT. Controls without disease, matched by sex and age. The data was analyzed with SPSS V23 for Windows 10.
Results: Of 37 patients with a diagnosis of arthritis due to deposition of monosodium urate crystals, (34) met inclusion criteria, 100% male, 34 healthy controls. Average of 61.5 years. Average of the disease 8.2 years. Distribution 61% (21) intercritical gout, 32% (11) chronic tophaceous gout, 0.5% (2) acute gouty arthritis. Comorbidities 67% (23) dyslipidemia, 35% (12) hyperglycemia. 26% (9) presented arterial hypertension. 20% (7) have diabetes mellitus. 58% (20) are alcohol drinkers, 11% (4) smokers. Mean uric acid 8.6 mg / dl at Doppler, 52% (18) elevated serum creatinine. Carotid Doppler in patients with gout showed a 55% (19) increase in the cIMT > 0.9mm, with a mean of 2.03mm (1.95 SD). Carotid Doppler in healthy controls 17% (6) increased cIMT, mean of 1.8mm (2.2 SD) (P = 0.040). Patients with gout had 29% (10) atheromatous plaques, 17% (6) calcified plaques versus 14% (5) atheromatous plaques, 8% (3) calcified in healthy controls.
Conclusion: Our study showed that half of the patients with gout had increased cIMT compared to a third of the healthy controls. The presence of atheromatous and calcified plaques was mainly associated with dyslipidemia, so we can conclude that the evaluation of the intima-media thickness by carotid Doppler allows it to be a predictor of cardiovascular disease in patients with gout.

AB0636 ASYMPTOMATIC HYPERURICEMIA IN INFLAMMATORY RHEUMATIC DISEASES

A. Fonturenko[1], R. Bashkinov[1,2], V. Mazurov[1,2], M. Petrova[2,3], O. Inamova[2,3], I. Gaydukova[1,2]. [1]*Clinical Rheumatological Hospital No25, Center for diagnosis and treatment of autoimmune diseases, Saint-Petersburg, Russian Federation*; [2]*North-Western State Medical University named after II Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E. E. Eichwald, Saint-Petersburg, Russian Federation*; [3]*Clinical Rheumatological Hospital No25, City Clinical Center of Gout, Saint-Petersburg, Russian Federation*

Background: Uric acid (UA) is well-known biomarker of cardiovascular risk and inflammation. However, the data about interrelations between asymptomatic hyperuricemia (AHU) and rheumatic diseases (RD) are limited and contradictory [1].
Objectives: to identify the occurrence of AHU in pts with different RD and to evaluate the interrelations between the AHU and clinical features of the RD.
Methods: The study included data from 822 pts with AHU and RD involved in the Saint-Petersburg Register of Pts with AHU in period from the 01jan2000 to the 01apr2020. The AHU was defined as the serum level of uric acid (UA) that exceeded 360 µmol/l without signs of gouty arthritis. Pts with the secondary reasons of AHU (an oncologic diseases, late stages of chronic kidney disease, ets), and inflammatory diseases another than RD were excluded from the study.
Patient's demographical characteristics, duration of AHU, level of UA, activity of RD, ESR, CRP, urate-lowering therapy (ULT) were analyzed. The study was approved by local ethic committee. Statistics was performed with SPSS17.
Results: Characteristics of the Patients with the RD and AHU are present in Table 1. The duration of AHU in pts with the RD was 3.4±3.4 [0.08-18] years, mean duration of follow-up 2.7±4.0 years, mean number of visits during the period of follow-up was 3,2 [min 1; max 7], ESR 26.0±14.1 mm / h, CRP 19.6±21.0 mg/l.

Table 1. Characteristics of the Patients with the Rheumatic diseases and asymptomatic hyperuricemia.

	Age, years (Mean±SD)	Male, %**	Serum UA, µmol/l (Mean±SD)	Normalization of UA during the follow-up, n (%)
RD, n=822	56.7±14.5	40.27	493.3±98.5	242 (29.44)[##]
RA, n=329	64.2±12.1	3.74	504.8±107.5[#]	99 (30.09)[##]
PsA, n= 149	56.6±12.9	53.69	531.5±94.9[#]	32 (21.48)[##]
SpA, n= 107	45.6±15.1*	33.43	520.8±86.5[#]	18 (16.82)[##]
SLE, n=137	50.3±14.1*	20.44	451.6±91.4	57 (41.61)
SSc, n= 57	61.0±12.4	22.81	456.2±99.5	20 (35.09)
SD, n= 43	62.0±10.7	16.28	442.4±107.5	16 (37.21)

RD – rheumatic disease; RA — rheumatoid arthritis; PsA — psoriatic arthritis; SpA — spondyloarthritis; SLE — systemic lupus erythematosus; SSc — systemic sclerosis; SD — Sjogren's disease; * — p<0.001 for the differences with RD, RA, PsA, SSc, SD; ** — p < 0.01 for all intergroup differences; [#] — p < 0.01 for the differences with RD, RA, SSc, SD; [##]— p < 0.01 for the differences with RA, SSc, SD.

Were revealed the interrelations between the level of UA and ESR (Spearmen's R=0.1, p=0.01), and UA and CRP (Spearmen's R =0.12, p=0.001).
The level of UA in male pts was 507.0 [361-940], in female pts 450.0 [361-1010] µmol /l (p<0.0001), in SLE pts with elevated anti-nuclear factor (ANF) UA was 429 [361-940] and with normal 494 [361-973] (p<0.0001). In pts with high and low RD activity UA was 490 [361-940] and 454 [363-1010]) µmol /l respectively, (p<0.0001). The higher UA level was found in any RD as compared with UA in low activity of the same RD (p<0.0001 for all the differences).
Normalization of UA was found in 243 (29.6 %) pts, lack of normalization of UA in 434 (52.8 %) of cases, n = 677, Table 1. ULT received 219 (26.6 %) pts. Normalization of UA without ULT was registered in 16 (1.9 %) of the pts.
Conclusion: UA level is higher and normalize less often in patients with SpA and PsA as compered with RA, SLA, SSc and SD pts. In any of analyzed rheumatic diseases the level of UA is higher in male pts and in pts with high disease activity.

AB0637 THE STATE OF GOUT MANAGEMENT IN WALES RHEUMATOLOGY UNITS

M. Saleh[1]. [1]*University Hospital of Wales, Rheumatology, Cardiff, United Kingdom*

Background: Gout is the most common inflammatory arthritis with both the prevalence and incidence showed significant rise in the UK in recent years[1].
The most frequent reasons for referral from primary care were diagnostic uncertainty 54%, failure to respond to primary care management 28%, and complex comorbidity 25%[2].
From primary care perspective, increased urate level (p=0.0001), young age (p=0.009), fewer comorbidities (p=0.039) constituted the most common risk for gout General Practice consultations and in addition to poor compliance to urate lowering treatment ULT (p=0.004) and lower CVS risk scores (p=0.038) these all factors comprised the independent risk factors for Gout flares[3].
Objectives: To compare the management of gout in the rheumatology services in Wales against the 2017 British Society for Rheumatology (BSR) Guidelines.
Methods: •A descriptive study over an 8-week period from January to February 2019, used Simple Analysis in calculating the frequency (%).
•Data were collected from notes of 79 patients referred to rheumatology departments across Wales using the British Society for Rheumatology (BSR) 2017 Gout Guidelines Audit Tool.
•The audit cohort comprised 62% of chronic gout patients and 38% of acute admissions.

Results:

Gout Audit	All Wales 2019 (BSR Guidelines 2017)	UK National Audit (BSR Guidelines 2007)*
Education material	54%	No available data
Newly start ULT	59%	42%
ULT was prescribed	87%	33%
ULT was continued	78%	76%
Prophylaxis	94%	94%
Febuxostat	21%	10%
ULT main indication	>2 attacks (71%)	Tophi (81%)
eGFR <60 ml/min	40%	30%
Urate level checked	83%	72%
Urate <300 umol/L	36%	25%
Urate <360 umol/L	58%	45%

Conclusion: •Gout management by rheumatologists across Wales concords well with the recent BSR guidelines for most audit standards and showed an improvement in percentage of patients who achieved a target serum uric acid level <300 and <360 umol/L according to the BSR and EULAR guidelines, respectively.
•Areas for improvement include documentation of Patient Education, improvement of audit tool (Age, Alcohol, current ULT).
•To spread the message to primary care setting, where gout is predominantly managed, to ensure that ULT is optimized to achieve target serum uric acid level to benefit patients.

AB0638 CYTOKINE STATUS IN METABOLIC SYNDROME IN PATIENTS WITH GOUTY ARTHRITIS

K. Zhigulina[1], S. Spitsina[1,2]. *[1]Federal State Budgetary Educational Institution of Higher Education "Volgograd State Medical University" of the Ministry of Healthcare of the Russian Federation, Department of hospital therapy, Volgograd, Russian Federation*; *[2]Federal State Budgetary Institution "Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky", Clinical Biochemical Laboratory, Volgograd, Russian Federation*

Background: Gout is an inflammatory and metabolic disease. Hyperuricemia can contribute to inflammation, hypertension and cardiovascular disease, adipogenesis and lipogenesis, impaired insulin and glucose metabolism, and the development of liver disease. In turn, non-alcoholic fatty liver disease is the most common chronic liver disease worldwide; is closely related to obesity, type 2 diabetes mellitus, dyslipidemia and other metabolic risk factors included in metabolic syndrome (MS). Interest in the problem of MS has not faded for many years, which is associated with its extremely rapid spread in the world.
Objectives: To assess the cytokine status in patients with gouty arthritis (GA) in combination with metabolic syndrome (MS).
Methods: There were 60 patients with reliable GA under observation. Among the surveyed men and women accounted for 60% and 40%, respectively, with an average age of 54 years, an average duration of the disease of 8 years. A family history of gout was present in 42% of patients. The onset of gouty arthritis was observed at 35.6 ± 10 years. Hypouricemic therapy was prescribed in 70% of patients. Thirty-six patients were diagnosed with the tofus form, 24 had no tofus. Patients were included in the study during arthritis remission. Blood samples were taken for general clinical and biochemical analyzes (ESR according to Westergren and uric acid levels were estimated), as well as for determination of serum concentrations of TNF-alpha and IL-6 by enzyme immunoassay.
Results: The patients were divided into two groups: group 1 - 40 people with GA without signs of MS, group 2 - 20 patients with GA and MS. Patient groups were matched by sex, age, form and severity of the disease. In the 1st group, the body mass index ranged from 28.00 to 34.25 kg / m2, in the 2nd group - from 29.05 to 49.39 kg / m2. In patients with isolated gout, the waist in men averaged 96 cm, in women - 86.5 cm; in the 2nd group: in men - 98 cm, in women - 88 cm. Among the criteria for MS, in addition to abdominal obesity, in the 2nd group, arterial hypertension (in 64%), dyslipidemia (mainly types IIa and IIb) were significantly more frequent, violation of carbohydrate metabolism (fasting glycemic level 8.0 + 2.0 mmol / l), a higher level of uricemia (from 397.8 to 660.5 mmol / l) compared with the 1st group. The average level of IL-6 in the serum of patients in group 1 was 1.46 pg / ml, in group 2 - 14.03 pg / ml, the average level of TNF-alpha in group 1 was 0.51 pg / ml, in group 2 - 1.28 pg / ml.
Conclusion: In GA patients with signs of MS, there is a significant increase in the production of key proinflammatory cytokines, namely IL-6, TNF-alpha. It was found that with a combination of MS and GA, the concentrations of IL-6, on average, 9.6 times, and TNF-alpha - 2.5 times, exceed the parameters of patients without signs of MS. A direct relationship was established between the expression of IL-6 and TNF-alpha with body mass index, as well as with insulin resistance and fluctuations in blood pressure. Thus, the cytokine imbalance is associated with increased risks of both cardiometabolic complications and the progressive course of GA.

AB0639 EXOSOMES DERIVED FROM ENDOTHELIAL CELLS PREVENT OSTEOBLAST APOPTOSIS IN STEROID-INDUCED OSTEONECROSIS OF THE FEMORAL HEAD RAT MODEL VIA THE PI3K/AKT/Bcl-2 SIGNAL PATHWAY

J. Sun[1], W. Zheng[2], Y. Zhang[1], Z. Gu[3]. *[1]Affiliated Hospital of Nantong University, Department of Orthopaedics, Nantong, China*; *[2]Affiliated Hospital of Nantong University, Research Center of Clinical Medicine, Nantong, China*; *[3]Affiliated Hospital of Nantong University, Department of Rheumatology, Nantong, China*

Background: Osteonecrosis of the femoral head (ONFH) is a common disease caused by many trauma factors and un-trauma factors. Among those un-trauma factors, steroid-induced osteonecrosis of the femoral head (SNFH) accounted for a large proportion and mainly concentrated in young people. SNFH has been reported as an irreversible disease and associated with the damage of blood vessels and the loss balance of bone homeostasis. Circulating endothelial progenitor cells (CEPCs), one part of circulating endothelial cells (CECs), are immature precursor cells with proliferative potential. The damage of vascular endothelial cells in SNFH has been confirmed by many studies, but the changes of CECs and CEPCs in the peripheral blood of patients with SNFH have not been studied yet.
Objectives: The objective of the study is to explore the number of CECs and CEPCs in SNFH patients and normal people and then investigate whether EC-secreted exosomes (EC-exos) could prevent the progression of SNFH in rat model and its mechanism of action.
Methods: We collect peripheral blood of 3 SNFH patients and 3 heathy people and detected the levels of CECs and CEPCs by Flow cytometer. TEM, NTA and western blot was used to characterize the isolated EC-exos. Annexin V-FITC/PI double staining with flow cytometric analysis and western blot were used to evaluate MC3T3-E1 cells apoptosis. CCK-8, scratching experiment and transwell were used to evaluate MC3T3-E1 cells viability and migration ability. Micro-CT and morphological staining were used to evaluate the progress of SNFH in rat model.
Results: Firstly, we found that the number of CECs and CEPCs in the peripheral blood was decreased in SNFH patients than normal people. Then our results indicated that EC-exos could improve the migration, viability and prevent apoptosis of osteoblasts under dexamethasone by activating the PI3K/AKT/Bcl-2 signal pathway in vitro. Finally, our Micro-CT and morphological staining results in SNFH rat model revealed that EC-exos prevented the progression of SNFH.
Conclusion: EC-exos could enhance the cell viability and migration ability of osteoblasts under dexamethasone and play an anti-apoptosis role against steroids-induced osteoblast apoptosis by activating the PI3K/AKT/Bcl-2 signal pathway. EC-exos prevented the progression of SNFH in rat model.

AB0640 MORTALITY IN CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION DISEASE: PRELIMINARY DATA

M. Eliseev[1], A. Novikova[1], O. Sheliabina[1], M. Chikina[1]. *[1]VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation*

Background: Calcium pyrophosphate crystal deposition disease (CPPD) is associated with a high frequency of comorbidities and vascular calcification [1], but it is unknown whether these factors affect cardiovascular mortality.
Objectives: To study the structure of mortality in patients with CPPD and compare with the structure of mortality in the Russian Federation.
Methods: 217 patients with crystal-verified diagnosis of CPPD (McCarty criteria) were included in the prospective study, aged ≥18 years, mean age 59.2 ± 12.6 years, 82 (38%) men and 134 (62%) women. The median follow-up was 3.9 [1.9; 7.2] years, patients were followed up for at least a year. The exclusion criteria are the presence of other rheumatic diseases with arthritis symptoms. The examination of patients included the history taking, assessment of anthropometric parameters, the presence of comorbidity and the following laboratory tests: determination of serum creatinine level (with calculation of glomerular filtration rate (eGFR) using the MDRD formula), total cholesterol (TC), C-reactive protein (CRP). Statistica 12.0 package was used for statistical data processing.
Results: A total of 217 patients were included. Arterial hypertension was detected in 115 (53%) patients, coronary heart disease in 51 (24%) patients, diabetes mellitus in 26 (12%) patients, chronic renal failure in 17 (8%) patients, hyperparathyroidism in 18 (8%) patients, chronic heart failure in 22 (10%) patients. 65 (30%) patients had a family history for CVD, 31 (14%) patients were smokers. 122 (56%) patients had an increased level of total cholesterol> 5.0 mmol/L and 54 (25%) patients – the level of CRP>5 mg/L.
23 (11%) patients, 12 (52%) men and 11 (48%) women, died, the average age of the deceased being 62.7±9.2 years. In 15 (65%) cases out of 23, death occurred due to cardiovascular complications, which is higher than the cardiovascular mortality rate in the Russian Federation (53%). Among CVD, the distribution was as follows: acute myocardial infarction - 6 (40%) patients,apoplectic attack - 5 (33) patients, thrombosis - 2 (13%) patients, rhythm disturbances – 1 (7%) patient and decompensation of chronic heart failure - 1 (7%) patient.
Conclusion: CVD is the main cause of death in patients with CPPD and the total frequency of mortality from CVD exceeds the population one. Further research is needed, including studies of the risk factors for overall and cardiovascular mortality in patients with CPPD.

AB0641 EFFECT OF AGE ON PARATHYROID HORMONE RESPONSE TO VITAMIN D INSUFFICIENCY IN PRIMARY HYPERPARATHYROIDISM

V. Deshani[1], M. Khalid[1], K. Jadoon[1]. [1]*The Royal Wolverhampton NHS Trust, Diabetes and Endocrinology, Wolverhampton, United Kingdom*

Background: Primary hyperparathyroidism (PHPT) is a common endocrine condition, commonly seen with increasing age. In vast majority, it is diagnosed incidentally and causes no particular symptoms. Symptoms are usually related to acute hypercalcaemia or the complications of chronically elevated serum calcium level. Vitamin D deficiency is common among general population and in patients with PHPT. Studies in secondary hyperparathyroidism (SHPT) have shown that parathyroid hormone (PTH) response is affected by age, with those over 80 showing greater rise in PTH levels. We wanted to see if age has a similar impact on PTH response to vitamin D in those with PHPT.
Objectives: To evaluate the impact of age on PTH response to vitamin D insufficiency in those with PHPT.
Methods: Patients with primary hyperparathyroidism (PHPT), attending general endocrine clinic of a district general hospital, were divided into two groups based on age; less than 70 (n=73) and 70 and above (n=61).Each group was subdivided into vitamin D insufficient (VDI) and vitamin D sufficient (VDS) subgroups. We compared calcium and parathyroid hormone levels and forearm BMD (presented as T score) in VDI and VDS subgroups in the two age groups, at the time of diagnosis. Data were analyzed using unpaired t-test and presented as mean ± SEM, using Graphpad Prism 9.0.1.
Results: There was significant difference in Vitamin D levels in VDI and VDS subgroups, in both age groups (<70; mean vitamin D 27.98 vs. 68.44, p<0.0001; ≥70; mean vitamin D 34.44 vs. 75.74, p<0.0001). The two groups were significantly different in terms of age (mean age 58 vs. 76, p<0.0001). Although there was no difference in calcium and forearm BMD in VDI and VDS, in both age groups, those under 70 showed a greater PTH response to vitamin D insufficiency (mean PTH 19.29 vs. 12.91 respectively, p<0.001).
Conclusion: While in SHPT, those with increasing age show greater rise in PTH levels, our data show that in PHPT, younger patients show a greater PTH rise in response to vitamin D insufficiency. Further work is needed to elucidate the underlying mechanisms.

AB0642 CLINICAL CHARACTERISTICS AND FACTORS ASSOCIATED WITH BONE EROSION IN GOUT PATIENTS WITH TOPHI

W. Deng[1], Y. Huang[1], Y. Liu[1], Z. Huang[1], S. Chen[1], Q. Huang[1], T. W. LI[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Bone erosion is a frequent complication of gout patients with tophi and can lead to joint damage, deformity and musculoskeletal disability. Few studies have focused on clinical characteristics and factors associated with bone erosion in gout patients with tophi.
Objectives: The aim of this study was to describe clinical characteristics of bone erosion in gout patients with tophi.
Methods: Bone erosion was detected by X-ray. Gout patients with tophi were divided into bone erosion group and non bone erosion group. The clinical characteristics were recorded. Comparison of clinical characteristics and risk factors for bone erosion were analyzed between two groups. Multivariate logistic regression analysis was conducted.
Results: A total of 171 gout patients with tophi were enrolled, 121 patients with bone erosion and 50 patients without bone erosion. Bone erosion group were older, with prolonged duration with gout and tophi, higher levels of serum creatinine, lower levels of glomerular filtration rate (GFR), C-reactive protein and BMI. In univariate regression analysis, age, gout duration, tophi duration, GFR were associated with bone erosion. In multivariable logistic regression analysis, tophi duration was independently associated with bone erosion.
Conclusion: Gout patients with bone erosion present different clinical characteristics compared with those without bone erosion. Tophi duration was strongly associated with bone erosion in patients with gout.

Table 1. Comparison of clinical characteristics between bone erosion patients and non bone erosion patients.

	Non Bone erosion	Bone erosion	*P* Value

AB0643 IL-1 BLOCKAGE WITH ANAKINRA IN GOUT PATIENTS. SCOPING REVIEW OF THE PUBLISHED LITERATUR.

S. Jeria Navarro[1], H. Park[1], M. A. Pou[2], E. Calvo-Aranda[3], C. Diaz-Torne[1]. [1]*Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; [2]*EAP Encants, ICS Atenció Primària, Barcelona, Spain*; [3]*Hospital Universitario Infanta Leonor, Rheumatology, Madrid, Spain*

Background: Gout is the most common inflammatory arthritis in adults. It is caused by the chronic deposition of monosodium urate crystals in joints. Hypertension, diabetes mellitus, chronic kidney disease (CKD) and cardiovascular disease are highly prevalent in gout patients.
Nonsteroidal anti-inflammatory drugs (NSAIDs), corticosteroids or colchicine are the first line therapeutic agents for flares. These drugs can be contraindicated in a large group of gout patients. Off label prescription of IL-1 receptor blockage with anakinra can be an alternative for this complex patients.
Objectives: The main objective of this study is to perform a scoping review about patient characteristics, comorbidity, effectivity and safety profile of patients with gout treated with anakinra.
Methods: A total of 1119 citations were screened. The reviewers performed a two-stage screening by title/abstract and full-text screening. Thirty six articles that finally met selection criteria, were included for data extraction and synthesis. Treatment duration of ≥12 weeks was considered chronic.
Results: Four hundred forty three patients were included in the study. 20 patients (4,5%) received chronic treatment and 423 (95,5%) flare treatment. Outcomes from 496 flares were finally analyzed.
The mean age of the patients was 63.6 years and 84% were men. The clinical presentation was polyarticular in 47.9% and tophaceous gout in 66.5%. Some of these patients presented atypical forms of the disease such as spinal gout, autoinflammatory syndromes or sternoclavicular joint arthritis.
Most of the patients presented comorbidities, the most prevalent being arterial hypertension in 127 (70.5%) and chronic kidney disease (≥ 3 stage) in 220 (51.8%). History of transplant in 37 (14.6%) with stem cell, kidney, heart, and liver transplant. More than half of patients had more than one associated comorbidity. Demographic and clinical characteristics of gouty arthritis patients are presented in Table 1. Flare was present in admitted patients in 260 (57.5%). Anakinra was administered in 52 patients with an active infection.
Different treatment regimens were described. Daily administration was used in 98% of the patients. 92.8% of the flares were treated seven days or less, being the three days regimen the most prevalent. In the chronic group the longest treatment reported was 5 years.
Efficacy of treatment with anakinra was evidenced, in flare 426 patients (93%) and chronic 19 patients (91%). Overall, anakinra was well tolerated. In the case of flares, thirty-three (7.9%) adverse effects related to anakinra administration were registered: seven (1.6%) site injection reactions, five (1.1%) reversible hematological alterations and five acute infections (H1N1, herpes zoster, severe cold, pulmonary abscess and nosocomial pyelonephritis). In chronic treated patients, adverse infectious events were more prevalent, seven (32%) infections (*Staphylococcus aureus* tophus (2), *Staphylococcus aureus* lung abscess, erysipela of the leg, *Streptococcus B* urinary tract infection, *Staphylococcus aureus* knee arthritis and tuberculous cervical lymphadenitis).
Conclusion: Anakinra has been shown to be effective and safe in treatment for flares in gout complex or resistant patients. It has been shown in multiples scenarios like active infections, dialysis, transplants, chronic kidney disease, tophi and polyarticular disease refractory to standard treatment. It has also shown its effectiveness as chronic treatment, but there are more concerns about its safety. These findings need to be confirmed with controlled clinical trials for anakinra inclusion in treatment recommendations in special situations of flares in complex or resistant gout patients.
Disclosure of Interests: None declared.

AB0644 EVALUATION OF MONOCYTE TO HIGH-DENSITY LIPOPROTEIN RATIO AND CAROTID INTIMA MEDIA THICKNESS IN GOUT PATIENTS

C. Kadıyoran[1], A. Kucuk[2], H. Aydemir[2], A. U. Uslu[3]. [1]*Necmettin Erbakan University, Radiology department, Konya, Turkey*; [2]*Necmettin Erbakan University, Rhomatology Department, Konya, Turkey*; [3]*Eskisehir Yunus Emre State Hospital, İnternal Medicine Department, Eskisehir, Turkey*

Background: The aim of this study is to investigate, evaluation of monocyte to high density liporotein ratio and carotid intima media thickness in gout patients.
Objectives: Gout disease is an autoinflammatory disease caused by the accumulation of monosodium urate crystals (MSU) in tissues and organs due to hyperuricemia (1). It is a common cause of arthritis due to the changes in lifestyle and eating habits. The effects of the inflammatory process and hyperuricemia in gout are not limited to the joints, but are associated with increased atherosclerosis and cardiovascular disease (1,2) Monocyte to high-density lipoprotein cholesterol ratio (MHR) is a systemic inflammatory marker and has recently been used quite widely for the evaluation of inflammation in cardiovascular disorders (3,4).
Methods: Fourty eight patients who were evaluated in the rheumatology clinic with an arthritis attack and diagnosed with Gout, and 48 healthy individuals whose age, gender and body mass index were matched were included in our study. Basic laboratory and biochemical parameters of the period when gout patients were asymptomatic were examined. Carotid intima-media thickness (CIMT), which is a non-invasive procedure due to its widespread use, was used as a marker.
Results: MHR and CIMT values were 18.22 ± 9.01 and 0.76 ± 0.11 mm in patients with gout. In the control group, it was 13.62 ± 4.48 and 0.65 ± 0.13 ($p = 0.002$, $p < 0.0001$, respectively). When evaluated within the study group, it was found that there was a positive correlation between MHR and CIMT ($r = 0.253$, $p = 0.013$), and according to linear regression analysis, there was an independent relationship between MHR and CIMT (beta [β] = 0.293, $p = 0.049$). When assessing Gout patients in the study population, a cutoff value of 13.85 with sensitivity of 66 %, specificity of 53 %, and $p = 0.011$ (area under curve: 0.650, 95% confidence interval 0.540-0.760), was observed according to receiver-operating characteristic curve analysis (Figure 1).

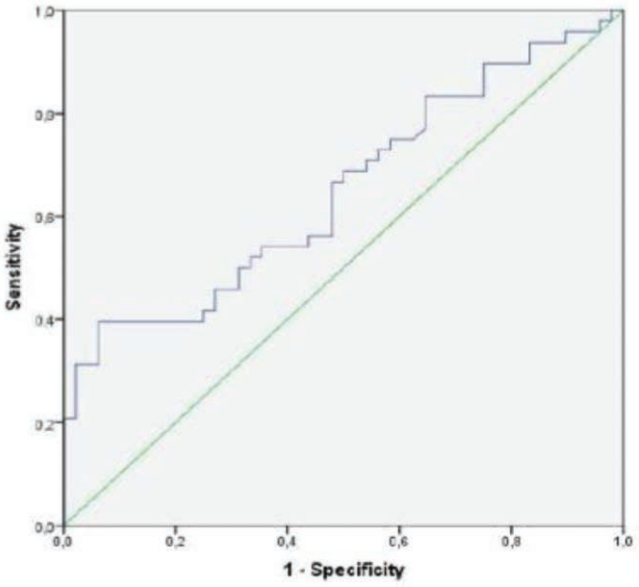

Figure 1. Receiver-operating characteristic curve analysis.

Conclusion: This study showed us that MHR can be an inexpensive and easily accessible marker that can be used in the evaluation of atherosclerotic lesions. We think that studies with larger number of patients are needed on this subject.

AB0645 CLINCAL CHARACTERISTICS OF GOUT PATIENTS WITH RENAL CYSTS

F. Feng[1], Y. Huang[1], Y. Liu[1], Z. Zhong[1], W. Deng[1], T. W. Li[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou Shi, China*

Background: Gout is a crystal-related arthropathy caused by monosodium urate deposition, which is a common and treatable form of inflammatory arthritis and becoming more prevalent[1]. A few studies have found that gout patients have an increased prevalence of simple renal cysts[2, 3]. The relationship between gout and renal cysts is still insufficient.
Objectives: Compare the difference between gout with renal cyst and without renal cyst.
Methods: We retrospectively collected data on 200 gout patients. The data includes age, gender, uric acid, creatinine, glomerular filtration rate, 24-hour urine collection, and whether they have kidney stones, renal cysts, coronary heart disease, hypertension, and diabetes. Chi-square and exact Fisher's tests were utilized, while continuous variables were assessed by Student's t-test. A P value of less than 0.05 was considered statistically significant.
Results: Of the 200 gout patients, 56 have kidney cysts(28%). In gout patients who had a renal cyst, were significantly older than patients without renal cysts

(59.14 vs. 46.87, P = 0.000), more number of people suffering from coronary heart disease (7 vs. 5, P = 0.016). The glomerular filtration rate was lower (58.5 vs. 71.6, P = 0.000), with lower urinary creatinine, uric acid, and urinary potassium.
Conclusion: Gout patients with and without simple renal cysts have significant differences in age, hypertension, cardiovascular disease, GFR, serum creatinine, urine creatinine, and urine potassium.

AB0646 COMPARATIVE ANALYSIS OF ASYMPTOMATIC HYPERURICEMIA AND GOUT - AN IMPACT ON KIDNEY STRUCTURE AND FUNCTION

M. Hristova[1], A. Kundurdzhiev[1], T. Kundurzhiev[2], R. Gancheva[3]. [1]*University Hospital St Ivan Rilski, Medical University Sofia, Internal Medicine, Sofia, Bulgaria*; [2]*Faculty of Public Health, Medical University Sofia, Department of Occupational Medicine, Sofia, Bulgaria*; [3]*University Hospital St Ivan Rilski, Medical University Sofia, Rheumatology, Sofia, Bulgaria*

Background: The significance of asymptomatic hyperuricemia (AH) continues to be debated. At the population level, asymptomatic hyperuricemia is associated with multiple comorbidities, including hypertension, coronary artery disease, diabetes and chronic kidney disease.[1]
Objectives: To investigate the impact of asymptomatic hyperuricemia on renal functional and structural parameters in comparison with symptomatic gout.
Methods: The subjects included in the study were divided into two groups - 46 patients with asymptomatic hyperuricemia and 18 diagnosed with gout according to ACR/EULAR 2015 criteria.[2] For renal function assessment urine analysis, albuminuria, estimated glomerular filtration rate (eGFR) based on Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation were used. Diagnostic ultrasound as well as renal biopsy were performed to evaluate structural and histological kidney changes. Statistical analysis was performed using SPSS 22.0 software (SPSS Inc, Chicago, USA).
Results: There were no significant differences between the two groups on serum uric acid levels, albuminuria, and eGFR. However, erythrocyturia (p=0.047) and nephrolithiasis (p<0.001) prevailed significantly in patients with gout, 66.7% and 61.1% respectively. We did not find any histological differences between the two groups regarding the number of affected glomeruli, tubular atrophy and percentage of interstitial fibrosis based on light microscopy scans.
Conclusion: Our results indicate that patients with AH need renal screening since both AH and gout show similar kidney changes. Further research is needed to elucidate the role of early treatment with xanthine oxidase inhibitor for asymptomatic hyperuricemia as prevention of complications such as erythrocyturia and nephrolithiasis.

Infection-related rheumatic diseases

AB0647 CATASTROPHIC ANTIPHOSPHOLIPID SYNDROME TRIGGERED BY CONCURRENT VZV AND HSV INFECTION. A CASE REPORT

L. Kakoullis[1], K. Parperis[2,3], S. Psarelis[4], E. Papachristodoulou[1], G. Panos[5,6]. [1]*University of Cyprus Medical School, Department of Medicine, Nicosia, Cyprus*; [2]*University of Cyprus Medical School, Department of Medicine, Division of Rheumatology, Nicosia, Cyprus*; [3]*University of Arizona College of Medicine, Department of Medicine, Division of Rheumatology, Phoenix, Arizona, United States of America*; [4]*Nicosia General Hospital, Department of Rheumatology, Nicosia, Cyprus*; [5]*University General Hospital of Patras, Department of Internal Medicine, Section of Infectious Diseases, Patras, Greece*; [6]*University of Cyprus Medical School, Department of Internal Medicine, Nicosia, Cyprus*

Background: Catastrophic antiphospholipid syndrome (CAPS) is a severe autoimmune condition, characterized by multiorgan failure due to thromboses and/or hemorrhage. Concurrent HSV/VZV infection is an exceedingly rare event, occurring mostly in immunocompromised patients. Herein, we report the first case of CAPS triggered by concurrent HSV/VZV infection, manifesting with zosteriform rash and haemorrhages at multiple sites.
Objectives: To describe a case of CAPS provoked by concurrent HSV/VZV infection, manifesting with zosteriform rash and haemorrhages at multiple sites.
Methods: A 36-year-old male, with a history of antiphospholipid syndrome (APS) presented with a 5-day history of epigastric pain, associated with fever, hematuria, rash and swelling in bilateral ears. Past medical history was remarkable for APS, based on 4 episodes of DVT/PE and triple positive antiphospholipid antibodies, on chronic well-maintained warfarin anticoagulation. On examination, a purpuric rash was evident on the right side of the neck as well as on both ears, consistent with a C3 dermatomal distribution (Figure 1). Laboratory studies revealed anemia, thrombocytopenia and acute kidney injury.

Figure 1.

Results: A full-body CT scan demonstrated the presence of multifocal lymphadenopathy, alveolar infiltrates suggestive of diffuse alveolar haemorrhage, and haemorrhage in both kidneys and the left adrenal gland; anticoagulation was held, despite the INR being within the patient's baseline therapeutic levels. He was admitted with a working diagnosis of CAPS and possible zoster infection. Appropriate immunologic workup was requested. He was prescribed intravenous acyclovir, antibiotics, pulse dose of glucocorticoids, and IVIG. Bronchoscopy with bronchoalveolar lavage revealed the presence of haemosiderin-laden macrophages. The rash regressed, and the patients' condition improved. He was discharged with glucocorticoid tapering regimen, hydroxychloroquine, aspirin and warfarin.

Antibody titers were taken prior to IVIG administration at presentation, and at 4 weeks. High VZV IgG titers found at presentation regressed over four times on follow-up. Furthermore, at 4 weeks the patient had developed IgM antibodies against both VZV and HSV. These findings confirmed a concurrent infection.

Conclusion: This is the first report of coexisting HSV/VZV infection associated with CAPS. A literature review identified a total of 28 patients with coexisting HSV/VZV infection, whereas only one case of CAPS triggered by HSV was identified[1]. This case illustrates that concurrent infection can occur in the absence of immunosuppressive therapy in patients with APS, serving as a trigger for hemorrhagic CAPS. Simultaneous treatment with antiviral against herpesviruses, glucocorticoids and IVIG may mitigate the inflammatory cascade associated with CAPS.

AB0648 REACTIVE ARTHRITIS IN SYPHILIS MIMICKING RHEUMATOID ARTHRITIS: A CASE REPORT

S. M. Lao[1], J. Patel[2]. [1]*Mount Sinai West, Internal Medicine, New York, United States of America*; [2]*Mount Sinai West, Rheumatology, New York, United States of America*

Background: Reactive arthritis is a form of spondyloarthritis with aseptic joint involvement occurring after a gastrointestinal or urogenital infection. Most commonly associated with *Chlamydia trachomatis*, *Salmonella, Shigella, Campylobacter*, and *Yersinia.* Syphilis is an infection caused by the spirochete *Treponema pallidum* and is not usually associated with reactive arthritis. Syphilis is a great imitator of other diseases due to its broad presentation including painless chancre, constitutional symptoms, adenopathy, rash, synovitis, neurological and ocular findings.

Objectives: To discuss a patient who presented with symptoms of rheumatoid arthritis (RA) but was later diagnosed with syphilis.

Methods: 31 year old male, former tobacco smoker, referred to Rheumatology for sudden onset joint pains, elevated anti-cyclic citrullinated peptide (anti-CCP), and elevated inflammatory markers. He reported pain in bilateral wrists, fingers, and right elbow for 6 weeks. Associated with 45 minutes of morning stiffness and new onset lower back pain without stiffness. He denied trauma, fever, chills, skin rash, dysuria, or diarrhea. Initiated trial naproxen 500mg twice a day only to have minimal relief. Patient is sexually active with men and was recently diagnosed with oropharyngeal gonorrhea treated with azithromycin 4 months prior. All other STI screening including syphilis, gonorrhea, HIV were negative at that time. Patient is on emtricitabine and tenofovir disoproxil fumarate for HIV pre-exposure prophylaxis. He denied family history of immune mediated conditions. Exam was significant for mild synovitis of both wrists and bilateral 2nd metacarpophalangeal joints. Initial labs revealed weakly positive anti-CCP 21 (normal <20), sedimentation rate 64 (normal ESR 0-15 mm/hr), C-reactive protein 24 (normal CRP 0-10 mg/L), and negative RF, ANA, HLA B27. During a short trial of prednisone taper, there was temporary improvement in symptoms, however synovitis recurred upon completion. Hydroxychloroquine (HCQ) 200mg twice a day was started for possible RA and he was referred to Ophthalmology for baseline retinopathy screening. Incidentally, he developed right sided blurry vision 2 weeks after initiation of HCQ. He was diagnosed with panuveitis of the right eye with inflammation of the optic nerve head and prednisone 40mg daily was initiated for presumed ocular manifestation of RA. However, further workup of panuveitis revealed reactive *Treponema pallidum* antibody and RPR quantity 1:32. Prednisone was immediately discontinued and he was referred to the emergency department for possible neurosyphilis.

Results: Lumbar puncture showed cerebral spinal fluid with 260 red blood cells, 1 white blood cell, 27mg/dL protein, 60mg/dL glucose, non reactive VDRL, reactive pallidum IgG antibody, and negative cultures. Meningitis and encephalitis panels were negative. Patient completed a 14 day course of IV penicillin G with complete remission of joint pain, visual symptoms, and normalization of anti-CCP, ESR, and CRP.

Conclusion: This case highlights how syphilis may mimic signs and symptoms of RA including symmetrical small joint pain, morning stiffness, elevated inflammatory markers, and positive anti-CCP. Anti-CCP is >96% specific for RA but was a false positive in this patient. There have only been few reported cases noting positive anti-CCP with reactive arthritis. This is a rare case of reactive arthritis secondary to syphilis with resolution of symptoms upon treating the syphilis.

AB0649 INFECTION PROFILE OF IMMUNE-MODULATORY DRUGS USED IN AUTOIMMUNE DISEASES: ANALYSIS OF SUMMARY OF PRODUCT CHARACTERISTIC DATA

M. Dey[1,2], K. Bechman[3], C. Smith[4], A. Cope[3], E. Nikiphorou[3], J. Galloway[3]. [1]*University of Liverpool, Institute of Life Course and Medical Sciences, Liverpool, United Kingdom*; [2]*Aintree University Hospital, Liverpool University Hospitals NHS Foundation Trust, Department of Rheumatology, Liverpool, United Kingdom*; [3]*King's College London, Centre for Rheumatic Disease, Weston Education Centre, London, United Kingdom*; [4]*King's College London, St John's Institute of Dermatology, London, United Kingdom*

Background: The number of immune-modulatory drugs used to treat immune-mediated inflammatory diseases (IMIDs) has exponentially increased in recent decades. While effective in controlling disease, serious infection remains a concern.

Accurate information on immune-modulatory drugs, including infections, is required to guide prescribing decisions. The "summary of product characteristics" (SmPC) by the European Medicines Agency (EMA) provides a useful repository of information on adverse events e.g. infections, from clinical trials and post-marketing pharmacovigilance (1).

To date, no comparison has been undertaken on reported infection frequencies across SmPCs for immune-modulators.

Objectives: To compare infection frequency, site and type across the most commonly-prescribed immune-modulatory drugs used to treat IMIDs, using information provided by SmPCs.

Methods: A drug was included if licensed in Europe for treatment of one of the following: rheumatoid arthritis, axial spondyloarthritis, connective tissue disease, autoimmune vasculitis, autoinflammatory syndromes, inflammatory bowel disease (Crohn's and ulcerative colitis), psoriasis, multiple sclerosis and other rarer conditions.

The Electronic Medicines Compendium (EMC) was searched for commonly prescribed immune-modulatory drugs used for the above indications. SmPC documents were manually searched for information on infection frequency, extracted from sections 4.4 and 4.8. Infection frequency was recorded as per convention in the SmPC: very common (≥1/10); common (≥1/100 to <1/10); uncommon (≥1/1,000 to <1/100); rare (≥1/10,000 to <1/1,000); very rare (<1/10,000) (1), for each drug. Information was further extracted on infection site (e.g. respiratory, skin etc), type (e.g. bacterial, viral etc) and individual pathogenic organisms.

25% of included SmPCs were screened and extracted by a second reviewer. Disagreements were resolved with input from a third reviewer.

Results: In total, 39 drugs were included, used across 20 indications: nine conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs), six targeted synthetic DMARDs (tsDMARDs; four Janus kinase [JAK] inhibitors, two sphingosine 1-phosphate receptor modulators) and 24 biologic DMARDs (17 cytokine-targeted; seven cell-targeted).

Twelve sites of infection were recorded. Minimal or no site information was available for most csDMARDs and siponimod, certolizumab pegol and rituximab. The most common sites of infection are listed by drug group in Figure 1. Upper respiratory tract was the most common site, especially with bDMARDs. Lower respiratory, ear/nose/throat (including sinusitis) and urinary tract infections were moderately common, with clustering within drug groups. No drugs reported risk of cardiac infections; the eye, musculoskeletal, neurological, oral and reproductive sites were the least commonly-reported sites of infection.

Infection data for 27 distinct pathogens were recorded, the majority viruses, especially with bDMARD use. Herpes simplex and zoster were the most frequently

listed (mainly with bDMARDs and tsDMARDs), followed by influenza. Common non-viral causes of infection were candida and tinea species.
Variable or absent reporting was noted for opportunistic infections (e.g. tuberculosis and fungi) and certain high-prevalence viruses e.g. Epstein-Barr.
Conclusion: The SmPC literature reports differences in infection risk, by site and pathogen, between immune-modulatory drugs. The findings can be used to visualise differences and aid treatment decisions. However, some of the patterns we have shown lack face-validity to clinicians familiar with real-world safety data. The data fail to capture risk of rare infections, are likely skewed by trial selection criteria, varying number of trials per drug and quirks of individual study-reporting methodologies.
The findings highlight the need for robust post-marketing pharmacovigilance studies.

Background: The screening and treatment of latent tuberculosis infection (LTBI) is required before starting biologic therapy. Tuberculin skin test (TST) and interferon γ gamma release assay (IGRA) are the two commonly used tests.
Objectives: The aim of our study was to analyze data from the Biological National Registry BINAR between 2016 and 2020 in order to compare the diagnostic value of TST and IGRA tests.
Methods: We collected data of patients diagnosed with LTBI (having had a TST and/or IGRA before receiving any biotherapy) from the BINAR registry (a National Tunisian registry of patients with inflammatory rheumatic diseases under biologic therapy since less than two years from the inclusion date).
Results: From a total of 298 patients included in our study, 199 patients (66.8%) were screened by TST and 159 patients were screened (53.4%) by IGRA.
Thirty-four patients (11.4%) had a positive TST and 27 patients (9.1%) had a positive IGRA test.
Three patients having negative TST and two having negative IGRA developed tuberculosis.
There was no significant difference in our study between these two tests for LTBI diagnosis. The reactivation of tuberculosis can occur even when LTBI screening is negative using TST and IGRA tests.
Conclusion: Our results show that the predictive diagnostic value for these two tests is the same. It would be more interesting to practice one of those tests prior to biotherapy.
Disclosure of Interests: None declared.

COVID-19

AB0651 CASE-REPORT: ORGANIZING PNEUMONIA IN A PREGNANT WOMAN WITH RHEUMATOID ARTHRITIS DURING COVID-19 PANDEMIC

A. Cornillie[1], C. Grivegnee[2]. [1]*Erasme-ULB, Pneumology, Bruxelles, Belgium*; [2]*Erasme-ULB, Pneumology, Bruxelles, Belgium*

Conclusion: Case-report: Organizing pneumonia in a pregnant woman with rheumatoid arthritis during Covid-19 pandemic
CORNILLIE Alexia, GRIVEGNEE Camille, CHU Charleroi Marie-Curie
Introduction
Rheumatoid arthritis (RA) is a systemic inflammatory disease characterized by destructive polyarthritis and extra-articular organ involvement. Lungs are one of the most commonly affected organ in RA, and the lung involvement in RA results in a various clinical features including interstitial lung disease (ILD) and organizing pneumonia (OP).
OP is a histologic term characterized by the presence of buds of granulation tissue in bronchioles and alveoli. OP can be either idiopathic (cryptogenic organizing pneumonia) or secondary to underlying disease such as infection, drugs or connective tissue disease including RA.
Lung biopsy is usually recommended for the diagnosis, but the following criteria fulfilled by patients can lead to the diagnosis: (1) specific radiological manifestations (nonsegmental randomized consolidation with/without ground grass opacities in chest CT), (2) no causative infectious agent, (3) no response to antibiotics and (4) good response to corticosteroid therapy.
We describe here the case of organized pneumonia discovered in a pregnant woman with known rheumatoid arthritis during COVID-19 pandemic.
Case description
A 39-year old moroccan woman, gravida 4, para 1, was admitted during COVID-19 pandemic at 30 weeks' gestation to maternity hospital with a 1-week history of cough, dyspnea and fever. Her medical history included rheumatoid arthritis and gestational diabetes. She was treated with 5mg of prednisolone daily for her RA. Blood sample showed white blood cell count and C reactive protein at a level of 6860/mm3 and 42mg/L respectively. Chest CT performed at her admission revealed diffuse irregular nodular condensations associated with ground glass infiltrates and a right lower lobe parenchymal condensation with airbronchogram in favor of superinfection. Given circumstances, she was tested twice for SARS-Cov-2 48 hours apart by PCR on nasopharyngeal sample and results came back negative. She was treated empirically with ceftriaxone and azithromycin during the first week and described an improvement in her clinical condition but symptoms reappeared 4 days after stopping treatment. During the 2 following months, until the delivery, the patient remained subpyretic with a nonproductive cough and moderate dyspnea. 5 days after the delivery, due

to persistant dyspnea and fever, a new chest CT was performed and revealed similar image findings but some of the irregular nodular condensations showed a reversed halo sign and had a migrating character. Considering this typical image findings, the absence of causative infectious agents (excluded by bronchoalveaolar lavage performed after delivery) and the absence of response to antibiotics, we concluded with a diagnosis of OP secondary to RA without performing lung biopsy samples. A treatment with 48mg of methylprednisolone (and 100mg of azathioprine a few weeks later) was initiated. One month later, she showed a spectacular improvement in her clinical condition. A new chest CT highlighted disappearance of the majority of the ground glass areas and of all the condensations previously described. Methylprednisolone was then progressively tapered.

Conclusion

OP is a common pulmonary complication that can develop in RA. However, despite ou research, we have not found any other clinical case describing this disorder during pregnancy with RA. Since OP is a non-specific inflammatory response to an aggression of the organism, could we consider that the pregnancy is a state of aggression capable of causing such a response?

In addition, this clinical case illustrates the diagnostic challenge of this pathology during the Covid-19 pandemic.

AB0652 FERRITIN IS ASSOCIATED WITH THE SEVERITY OF LUNG INVOLVEMENT BUT NOT WITH WORSE PROGNOSIS IN PATIENTS WITH COVID-19: DATA FROM TWO ITALIAN COVID-19 UNITS

F. Carubbi[1], A. Alunno[2], L. Salvati[3], C. Ferri[1], D. Grassi[1]. [1]*Internal Medicine and Nephrology Unit, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy*; [2]*Rheumatology Unit, University of Perugia, Department of Medicine, Perugia, Italy*; [3]*Infectious Diseases Unit, Ospedale SS Filippo e Nicola ASL 1 Avezzano-Sulmona-L'Aquila, Department of Medicine, Avezzano, Italy*

Background: The coronavirus 2019 disease (COVID-19) is characterised by a heterogeneous clinical presentation and a wide range of imaging findings, depending on disease severity and time course. The pathophysiology is complex, involving immune and hematologic systems, epithelial cells and vascular system and to date reliable biomarkers aimed at stratifying patients and predicting worse outcomes have not been identified

Objectives: The aim of this study was to describe clinical, serological and CT imaging features of a cohort of patients with COVID-19 pneumonia and identify possible relationships between the variables and disease outcomes (admission to intensive care unit (ICU) and/or death).

Methods: We evaluated hospitalized patients with proven SARS-CoV-2 infection, clinical signs of COVID-19 and computed tomography (CT) scan-proven pulmonary involvement. Clinical and serological records of patients admitted to two COVID-19 Units in Italy with proven SARS-CoV-2 pulmonary involvement investigated with CT scan, assessed at the time of admission to the hospital, were retrospectively collected.

Results: Sixty-one patients (22 females and 39 males) of median age 65 years were enrolled. Fifty-six patients were discharged while death occurred in 5 patients. None of the lung abnormalities detected by CT was different between discharged and deceased patients. No differences were observed in the features and extent of pulmonary involvement according to age and gender. Logistic regression analysis with age and gender as covariates demonstrated that ferritin levels over the 25th percentile were associated with the involvement of all 5 pulmonary lobes (OR=14.5, 95% CI=2.3-90.9, p=0.004), the presence of septal thickening (OR=8.2, 95% CI=1.6-40.9, p=0.011) and the presence of mediastinal lymph node enlargement (OR=12.0, 95% CI=1.1-127.5, p=0.039) independently of age and gender.

Conclusion: We demonstrated that ferritin levels over the 25th percentile are associated with a more severe pulmonary involvement, independently of age and gender, but not with disease outcomes (admission to ICU/death). The identification of reliable biomarkers in patients with COVID-19 may help guiding clinical decision, tailoring therapeutic approaches and ultimately improving the care and prognosis of patients with this disease.

AB0653 COURSE OF COVID-19 INFECTION IN A SERIES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Cetin[1], N. Aliyeva[1], Y. Yalçınkaya[1], A. Gül[1], M. Inanc[1], B. Artim-Esen[1]. [1]*Istanbul Faculty of Medicine, Rheumatology, İstanbul, Turkey*

Background: Infection is a remarkable cause of morbidity and mortality in patients with SLE.

Objectives: We aimed to determine the clinical course of COVID-19 infection in our patients with SLE and the factors affecting this course

Methods: SLE patients (2012 SLICC criteria) diagnosed with COVID-19 infection by a positive PCR test and/or typical findings of lung involvement in CT (computed tomography) imaging were included. Data regarding cumulative clinical and laboratory characteristics, histopathology results, autoantibody profiles, immunsuppressives and damage (SLICC damage index/**SDI**)) were retrieved from the existing database and revised. SLE Disease Activity Index (**SLEDAI-2K**) was determined at the time of infection.

Results: Sixteen SLE patients with COVID-19 infection were identified. Most (87.5%) of these patients were female. Seventy % (n=11) had lupus nephritis. Twenty-five % had thrombotic antiphospholipid syndrome.

PCR was positive in 70% (n=11) of the patients. Pulmonary parenchymal findings compatible with COVID-19 were observed in 56% (n=9) of those patients. Regarding complaints upon admission, 50% (n=8) had fever, 44% (n=7) cough, 44% (n=7) dyspnea, 19% (n=3) myalgia, 12.5% (n=2) headache, 12.5% (n=2) nausea /vomiting, 6% (n=1) diarrhea, and 6 % (n=1) had anosmia. Eight patients were hospitalized. Six of these patients needed oxygen therapy via nasal cannula. None needed a follow-up in the intensive care unit. The mean hospitalization duration was 14 ± 5 (8-25) days.

Regarding disease activity at the time of infection, 9 had inactive disease with a SLEDAI-2K score of 0 whilst in 5 patients SLEDA-2K score was ≥4. The mean SLEDAI-2K score at the time of infection was 1.7 ± 2.3 (0-6). System/organwise, 1 patient with chronic thrombocytopenia presented with a worsening platelet count accompanied by serologic activity. This patient was a non-adherent to treatment who had stopped taking mycophenolic acid months before COVID19. Three patients 2 of whom had proliferative nephritis experienced nephritic flares.1 patient who had a history of cutaneous lupus and was in remission presented with oral ulcer, leukopenia and hypocomplementemia during infection. Of 16 patients, 7 had system damage at the time of infection. The mean SDI score of the patients was 1.4±1.8. Comparison of patients with and without damage revealed no significant differences in disease activity, symptoms associated with COVID, in the need for hospitalization, hospitalization duration, and the requirement for oxygen therapy. However,CT findings compatible with COVID19, were more common in patients with damage (87% vs.33%,p=0.04) and their mean CRP levels were higher at diagnosis (65 ± 47 vs.22 ± 48 mg/l;p=0.032).

All patients received similar treatment for COVID-19 except active patients who required high dose steroids (2 with active renal, 1 with thrombocytopenia and 1 with oral ulcer, leukopenia and hypocomplementemia).The patient with thrombocytopenia also received intravenous immunoglobulin and 1 with cutaneous active disease received tocilizumab as she developed macrophage activation syndrome. Six patients (37.5%) had received rituximab (RTX) in the last 6 months before COVID. No significant difference, in terms of hospitalization and need for oxygen therapy due to COVID19 was found between patients who had received RTX vs who had not. No hypogammaglobulinemia was detected in patients who received RTX despite lower levels of IgG (998 ± 184 vs 1481± 51 mg/dl, p=0.02)

Conclusion: Although half of the patients in our series of COVID19 infected SLE patients required hospitalization, there were no mortalities. More patients with damage (none pulmonary) displayed CT findings compatible with COVID19 and further follow up will reveal whether they will suffer from fibrotic lung disease. Patients can experience disease flares during COVID. But it is also important to consider that some manifestations such as thrombocytopenia may also be a sign of severe infection. Immunosupressive agents may not have a negative impact on the course of infection.

AB0654 TOCILIZUMAB IS PROTECTIVE AGAINST SARS-COV2 INFECTION OR NOT?

F. Fayed[1], E. Abdelkarim[1]. [1]*Alexandria University Students` Hospital, Rheumatology and Immunology Department, Alexandria, Egypt*

Background: SARS-COV2 (Covid19) pandemic has a scaring burden on hospitals and health care providers all over the world. Unfortunately, after one year of pandemic, millions of persons are infected either mild symptoms or critical ones and unexplained deaths. Till now, No effective treatment or vaccination. Researches showed that Covid 19 associated with elevated interleukin-6. Subsequently, Studies reported that tocilizumab (IL-6 antagonist) may be effective in critical patients even though other were shown that it is not associated with reduction in the mortality.[1,2] Therefore the question is that patients with rheumatic diseases who are already receiving tocilizumab having a primary

protection against infection of Covid 19 in comparing to other receiving the other biologicals or conventional Therapy or not.
Objectives: Our objective was to determine if tocolizumab had a primary protection against SARS-COV2 in comparing to patients were on other biologics.
Methods: A Retrospective study was done among 100 patients with rheumatic diseases (Group 1: 10 on tocilizumab, Group2: 40 (30 on antiTNF and 10 on IL17 antagonist), Group3: on cDMARDs) from March to Dec 2020. Detailed history, clinical presentation, laboratory, computed tomography of chest and PCR for covid 19 if presented among infected patients.
Results: Among 100 patients of median age 21, 19 patient (19%) had infected with Covid 19 (2 on tocilizumab, 6 on antiTNF, 1 on IL17 antagonist, 10 on cDMARDs). Symptoms were reported fever (89.4%), Fatigue (78.9%), myalgia (78.9%), Headache (73.7%), Dyspnea (52.6%), Cough (47.3%), chest pain (26.3%) and hypoxia (5%). CT findings were positive in 10 patients (52.63%) while PCR was done and positive in 15 out of 19 (78.94%). Nevertheless, there was no significant statistically difference between groups according to infection with SARS-COV2. (p=0.704)
Conclusion: Tocilizumab is not shown to be protective against SARS-COV2 (COVID 19) infection compared to other biological or cDMARDs in patients with rheumatic diseases.

AB0655 RHEUMATOID ARTHRITIS ACTIVITY BEFORE AND AFTER COVID-19 LOCKDOWN PERIOD

M. Jordhani[1], D. Ruci2, F. Skana2, E. Memlika2. [1]*UHC Mother Teresa,Tirana, Albania, Internal Medicine,Tirana, Albania*; [1]*UHC Mother Teresa,Tirana, Albania, Internal Medicine,Tirana, Albania*

Background: The COVID-19 global pandemic has had a great impact on world population due to morbidity, mortality and restriction measures in order to stop the progression of COVID-19.
Patients with rheumatic and musculoskeletic diseases, and especially rheumatoid arthritis (RA) patients, being one of the vulnerable classes of chronic patients, were recommended to follow the government's rules[1].
Objectives: The aim of this study was to evaluate DAS-28-ESR in patients with rheumatoid arthritis before and after lockdown period.
Methods: This is a multi-center observational study including 85 patients which were evaluated before and after lockdown for their disease activity score according to DAS-28-ESR score. They had been diagnosed with rheumatoid arthritis more than 5 years ago. A thorough physical examination was performed before and after the lockdown period. It included examination of tender and swollen joints and patient's global health. They were completed with all required laboratory data, including erythrosedimentation rate. For a more accurate calculation, DAS-28-ESR was used in an electronic version. Patients with other inflammatory or infective diseases were excluded from the study. All data were statistically evaluated using statistical tests such as t-student test.
Results: The first group (the one before lockdown) had an average DAS-28-ESR of 4.7 while after the lockdown period, the average DAS-28-ESR was 5.16.
After statistically evaluating all data, it was found that there exists a significant difference between DAS-28-ESR score before and after COVID-19 lockdown (p=0.0011).
Conclusion: Our study showed that lockdown period due to COVID-19 pandemic, has aggravated disease activity in patients with Rheumatoid Arthritis. This may be consequence of various causes such as physical inactivity and difficulty to follow-up or to take the medication properly.

AB0656 SARS-COV-2 INFECTION IN PATIENTS WITH RHEUMATIC DISEASE: A TERTIARY SINGLE-CENTER EXPERIENCE

A. Halbac[1], B. Balan[1], C. Tamas[1], M. M. Tamas[1,2], I. Felea[1], I. Filipescu[1,2], L. Damian[1], L. Muntean[1,2], S. P. Simon[1,2], S. Rednic[1,2]. [1]*County Emergency Hospital, Rheumatology, Cluj Napoca, Romania*; [2]*University of Medicine and Pharmacy "Iuliu Hatieganu", Rheumatology, Cluj-Napoca, Romania*

Background: In the context of the coronavirus (SARS-CoV-2) pandemic, several studies looked at the relation between rheumatic disease and SARS-CoV-2. It remains unclear whether these patients are at increased risk of developing more severe cases of coronavirus disease (COVID-19) or not.
Objectives: The objective of this descriptive study is to report the characteristics and outcomes of rheumatic patients that had a history of confirmed SARS-CoV-2 infection. Findings have also been compared to some of the existing publications on COVID-19 in these patients.
Methods: Between November 17, 2020 and January 18, 2021, a single-centre observational study was conducted in the rheumatology department of the Emergency Clinical County Hospital and the University of Medicine and Pharmacy "Iuliu Hatieganu" in Cluj-Napoca, Romania. The sample consisted of 62 rheumatic patients with a positive polymerase chain reaction test from nasopharyngeal/oral swab. Data on both systemic autoimmune disease and COVID-19 was collected using a survey, by means of telephone or in the outpatient clinic setting. Data on the patient rheumatologic condition was also collected from the electronic health records available within our department
Results: 62 patients were included, with 85.48% females and 14.51% males, and a median age of 52 years (SD +/- 14).
The most frequent comorbidities were high blood pressure (HBP) 46.77%, dyslipidaemia 19.35%, liver disease 17.74%, and interstitial lung disease (ILD) 12.90%. Recurrent COVID-19 symptoms included: cough (62%), fever (46,77%), anosmia (46.77%), ageusia (30.64%), headache (29.03%), gastrointestinal symptoms (27.41%) and myalgia (25.80%).
Out of the entire 62 sample, 41 patients had an inflammatory arthritis (IA) diagnosis, with the most frequent being rheumatoid arthritis (RA) - 68.29%, followed by ankylosing spondylitis - 21.95%, psoriatic arthritis - 7.31% and 2.43% with Still disease. Only 10 patients suffered from connective tissue disease (CTD): 3 systemic lupus erythematosus, 2 poli/dermatomyositis, 2 Sjogren syndrome (SjS), 2 mixed connective tissue disease, 1 systemic sclerosis (SSc). Another 10 patients had overlapping syndromes with the most frequent (40%) overlap between RA and SSc. One patient had osteoarthritis.
49 patients followed a treatment with conventional synthetic disease-modifying anti-rheumatic drugs with 51.2% of them being treated with Methotrexate.
14 of our patients received glucocorticoids (GC), but no relation between the GC dose and COVID-19 severity could be observed. Only 3 patients with doses greater than 10mg/day were present in the cohort and 2 developed mild while 1 developed an asymptomatic COVID-19 course.
22 patients had received biological treatment. Anti TNF alpha medication was administered to 13 of these, and mostly consisted of Adalimumab, Etanercept and Golimumab. The anti TNF alpha patients were asymptomatic or had mild forms of COVID-19 (93.30%).
8 cases had ILD: 3 RA patients, 3 overlapping syndromes, 1 SSc and 1 SjS. The median age was 59,5 years (SD +/- 10). 25% exhibited severe, 37,5% moderate, 25% mild and 12.5% asymptomatic COVID-19.
The COVID-19 severity in our sample was as follows: 12.90% of the patients were asymptomatic, 59.67% exhibited a mild form, 19.35% a moderate one, and out of the 8.06% with a severe case of COVID-19, 1 patient died. The median age in the severe cases of COVID-19 was 66 years (SD +/- 12) and HBP was the most common comorbidity.
Conclusion: Most patients in this sample were either asymptomatic or had a mild COVID-19 evolution. Although the research design has multiple limitations, rheumatic pathology does not seem to be a higher risk factor for severe COVID-19 than other associated comorbidities. With that in mind, ILD patients should be closely monitored as even in on our limited sample size a worse evolution of COVID-19 has been observed. Biological treatments, especially anti TNF alpha might help in reducing the severity of COVID-19, but this outcome could have been associated in our sample with other factors like lower median age and less comorbidities.

AB0657 PERCEIVED STRESS AND FOOD INSECURITY IN PREGNANT AND POSTPARTUM WOMEN WITH RHEUMATIC DISEASES DURING THE COVID-19 PANDEMIC

L. G. Espinosa Banuelos[1], P. R. Ancer Rodríguez[2], M. G. Herrera López[2], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], R. Moyeda Martinez[1], R. A. Rodriguez Chavez[1], A. Y. Lujano Negrete[1], A. Cárdenas[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Servicio de Reumatología, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Clínica de Nutrición, Departamento de Medicina Interna, Monterrey, Mexico*

Background: The SARS-CoV-2 pandemic has directly impacted the psychological and physical health of individuals worldwide, as well as the global economy. Food insecurity rates have risen especially in vulnerable countries like Mexico. Furthermore, social isolation and economic uncertainty have multiplied depression and anxiety disorders. Pregnant and postpartum women are particularly vulnerable to food insecurity, increased stress, depression, and anxiety.
Objectives: The aim of this study is to determine the perception of food insecurity (FI) and perceived stress in pregnant and postpartum women with rheumatic disease during the SARS-CoV-2 pandemic.
Methods: An observational, cross-sectional and descriptive study was conducted. Patients from to the pregnancy and rheumatic diseases clinic of the University Hospital "Dr. José E. González" in Northeast Mexico evaluated between August to October 2020 were included. The Spanish validated versions of the Household Food Security Access Scale (HFIAS) and the Perceived Stress Scale (PSS-10) were applied by telephonic interview. The WHO recommendations were employed to determine the appropriate intake for each food group in a week. The Kolmogorov-Smirnov test was used to determine normality of the data. The Spearman correlation coefficient and the Kruskal-Wallis test were used for statistical analysis.
Results: A total of 29 women were included. Six (20.6%) women were found to have moderate or severe degrees of food insecurity. In addition, 12 (40.30%) perceived moderate and severe levels of stress in the PSS-10. No relationship was found between food insecurity and perceived stress (p= 0.059). The food groups that exceeded the recommended weekly frequency were oils and sugars exceeded 3.9 and 2.9 frequencies, respectively.
Conclusion: We found that 20.6% women suffered household food insecurity and 40.3% suffered moderate and severe levels of stress. No relationship was found between food insecurity with the HIFAS scale and perceived stress measures with the PSS-10. We found that oils and sugars exceeded more by the double of the recommended frequency per week.

AB0658 **FEAR OF COVID-19 IN POSTPARTUM WOMEN WITH RHEUMATIC DISEASE**

L. G. Espinosa Banuelos[1], M. E. Corral Trujillo[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], R. A. Rodriguez Chavez[1], A. Y. Lujano Negrete[1], R. Moyeda Martinez[1], A. Cárdenas[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Servicio de Reumatología, Monterrey, Mexico*

Background: In Mexico, the SARS-CoV-2 pandemic has totaled almost two million cases and exceeded 150,000 deaths (29/01/2021). Currently, COVID-19 has become the leading cause of death in pregnant women in Mexico. COVID-19 has additionally impacted the psychological health of individuals including women with rheumatic diseases.
Objectives: The aim of this study is to compare the Fear of COVID-19 Scale (FCV-19S) in postpartum women with and without autoimmune rheumatic diseases.
Methods: A cross-sectional, descriptive, and comparative study was conducted. The Spanish FCV-19S version was applied by telephone or e-mail. The instrument consists of seven items, each with a five-point Likert scale of options. The participant must choose the options that best represent their perception about the statements presented. The maximum possible total is 35 points. Sociodemographic information was collected from the clinical charts. The Kolmogorov-Smirnov test was used to determine normality of the data. Statistical analysis was done using the Mann-Whitney U test.
Results: Forty-four postpartum women were included (22 from the Pregnancy and Rheumatic Diseases Clinic and 22 from the Obstetrics Department, both groups from the University Hospital "Dr. José E. González in Monterrey, México). The mean level of fear found in women with rheumatic disease was 16 (6.6) points versus 14 (4.6) points in the non-rheumatic patients group. No significant difference was found between groups (p=0.65). Regarding the rheumatic diseases group, women in the category of other diagnoses (that included Sjögren's Syndrome, antiphospholipid syndrome, and dermatomyositis) had a greater mean FCV-19S score (20.2), than patients with systemic lupus erythematosus (17.3) and rheumatoid arthritis (15.4).
Conclusion: Women with postpartum rheumatic disease had a higher FCV-19S score than postpartum women without rheumatic diseases, although this difference was not statistically significant.

AB0659 THE LOCKDOWN REPERCUSSION ON THE RHEUMATOLOGIST'S LIFE

P. Lemesle[1], L. Poulain[2], X. Grapton[3], N. Bouhedja[2]on behalf of CREER. [1]*Hospital of Courbevoie, Clinic Rives de Seine, Courbevoie, France*; [2]*La Garenne-Colombes, Private practice, La Garenne-Colombes, France*; [3]*Neuilly-sur-Seine, Private practice, Neuilly-sur-Seine, France*

Background: We have just experienced an exceptional period of time and it seemed interesting to know what this particular time of isolation in a population of rheumatologists has brought about
Objectives: To analyze what the doctor felt in his personal and professional life as a result of the crisis. To determine the reactions, feelings and attitudes that may have emerged during these weeks of confinement.
Methods: 38 private practice rheumatologists from the Ile-de-France region, average age 63 yo, 58% male (M). 13 questions, 9 appendices, ranking of the most frequently cited reactions
Results: 3 feelings stand out: anger 71-84%, fear of being contaminated and of transmitting M 91/F 69%, concern about an unknown pandemic M 86/F69%.
Anger at the indifference to the exposure of doctors in the city 84%, the unpreparedness of the authorities M 95/F 62%, the mortality in EHPAD (Nursing homes) 81%, the media cacophony 79%, the hidden reality 71%.
On a personal level, according to 61%, the Rh is not anxious about the world after, has no psychological repercussions (sleep, melancholy, etc.) 58% and his degree of commitment was guilt-free 55%.
Professionally: perplexity in the face of the contradictions of experts and scientific journals 79%, wide acceptance of constraints in the practice (10h/d mask wearing, 92%, spaced reception of patients 95%, education of barrier gestures 97%), adaptation of the exercise (teleconsultation, telephone consultation) 78%, fear of abandoning treatment or diagnostic delay M82/F62%, financial arrangements necessary M86/F53%.
For M: worries about the pandemic, anger and uncertainty about what will happen next predominate in this order. For F, anger (untruths and lack of means) is the main feeling. Anger, fear and uncertainty are the most frequently cited feelings
Conclusion: The Rh at the end of this period of confinement is worried M>F and anger especially in front of the sanitary unpreparedness M>F. On a personal level the private life has been little affected F>M and he has been able to adapt professionally. Nevertheless, the de-confinement has not been a banal return to normal 63% M= F.
Disclosure of Interests: None declared.

AB0660 COVID-19 SHARES CLINICAL FEATURES WITH ANTI-MELANOMA DIFFERENTIATION ASSOCIATED PROTEIN 5 POSITIVE DERMATOMYOSITIS AND ADULT STILL'S DISEASE

Y. Kondo[1], Y. Kaneko[1], H. Takei[1], H. Tamai[1], T. Takeuchi[1]. [1]*Keio University, Division of Rheumatology, Shinjuku City, Japan*

Background: The coronavirus disease 2019 (COVID-19), caused by a novel corona virus named SARS-CoV-2, has emerged as a global pandemic. Severe inflammatory process is one of main pathogenesis of COVID-19 and this involves cytokine storm along with overactivation of macrophage. On another front, cytokine storm with macrophage activation is frequently observed in various connective tissue diseases including dermatomyositis with positive antimelanoma differentiation-associated protein 5 (anti-MDA5) autoantibodies and adult Still's disease. Macrophage activation during inflammatory states is partially characterized by an increased serum ferritin levels and hyperferritinaemia and characteristics shared by the three diseases are a topic of interest to rheumatologists, however, no study has evaluated anti-MDA5-positive dermatomyositis and adult Still's disease in comparison to COVID-19.
Objectives: The aim of this study was to highlight the homology and heterogeneity of COVID-19, anti-MDA5 dermatomyositis, and adult Still's disease by comparing clinical pictures of each disease in order to discuss their respective pathogeneses.
Methods: We reviewed consecutive, newly diagnosed, untreated patients with COVID-19, anti-MDA5 dermatomyositis, or adult Still's disease. We compared their clinical, laboratory, and radiological characteristics, including the prevalence of macrophage activation syndrome and lung involvement in each disease.
Results: The numbers of patients with COVID-19, anti-MDA5 dermatomyositis, and adult-onset Still's disease with hyperferritinaemia (serum ferritin ≥ 500ng/dL) who were included for main analysis were 22, 14, and 59, respectively. COVID-19 and adult Still's disease both featured hyperinflammatory status, such as high fever and elevated serum C-reactive protein, whereas COVID-19 and anti-MDA5 dermatomyositis both presented with severe interstitial lung disease and hypoxaemia. While two-thirds of the patients in each group met the criteria for macrophage-activated syndrome that is used in systemic juvenile idiopathic arthritis, the HScore, an indicator of haemophagocytic lymphohistiocytosis, was low in anti-MDA5 dermatomyositis and COVID-19 even in severe or critical cases. The findings of chest computed tomography were similar between COVID-19 and anti-MDA5 dermatomyositis (Figure 1).
Conclusion: COVID-19 shared clinical features with rheumatic diseases characterised by hyperferritinaemia, including anti-MDA5 dermatomyositis and adult Still's disease. These findings should be investigated further in order to shed light on the pathogenesis of not only COVID-19 but also the aforementioned rheumatic diseases.

AB0661

EFFECT OF COVID-19 PANDEMIC ON SLEEP DISORDERS IN PATIENTS WITH INFLAMMATORY ARTHRITIS

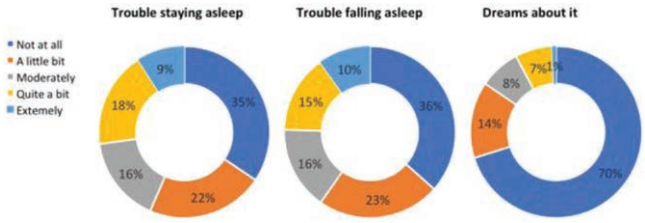
F. Ingegnoli[1], M. Buoli[2], C. Posio[3], R. DI Taranto[1], R. Caporali[1]. [1]*Università degli Studi di Milano, Division of Clinical Rheumatology, ASST Pini, Dept. of Clinical Sciences & Community Health, Research Center for Adult and Pediatric Rheumatic Diseases, Milano, Italy*; [2]*Università degli Studi di Milano, Dept. of Pathophysiology and Transplantation, Dept. of Neurosciences and Mental Health, Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Milano, Italy*; [3]*Università degli Studi di Milano, Dept. of Pathophysiology and Transplantation, Milano, Italy*

Background: A decrease in physical activity, exposure to daylight and a decline in psychological wellbeing due to COVID19 pandemic have led to increased incidence of sleep disorders such as difficulties falling asleep, sleep disruption, insomnia, nightmares and daytime sleepiness (1). Patients with inflammatory arthritis are more vulnerable to pain, depression, anxiety and sleep disorders. These complaints are linked in a cyclical pattern that may negatively affect daily-life activities (2-4). To our knowledge, the impact of pandemic on sleep disturbances in patients with inflammatory arthritis has not been evaluated yet.

Objectives: The aim of this study is to establish the COVID-19 related impact on sleep disturbances among patients with inflammatory arthritis who experienced the COVID-19 quarantine in Italy.

Methods: Data about chronic inflammatory arthritis (rheumatoid arthritis [RA], psoriatic arthritis [PsA] and ankylosing spondylitis [AS]) were retrieved from a large nationwide online survey involving patients affected by different rheumatic diseases. From May to September 2020, eleven patients' associations sent a call to rheumatic patients asking them to complete an anonymous online survey with specific questions also about sleep disturbances and pre- and post-lockdown self-reported use of psychopharmacotherapy. Data were analysed by a binary logistic regression model having the presence of sleep disturbances during COVID 19 pandemic as dependent variable.

Results: 375 of 507 (74%) of patients had inflammatory arthritis: 249 RA, 77 PsA and 49 AS. 291 (77.6%) were females with a median (IQR) age of 54 (44-63) years. There was an increase in the use of psychiatric compounds after quarantine period (59 [15,7%] vs 65 [17,3%]), especially for sleep medications (23 [6,1%] vs 28 [7,5%]) and anxiolytics (15 [4%] vs 18 [4,8%]). 246 (65.6%) of patients had trouble staying asleep, 238 (63.5%) had trouble falling asleep, and 112 (29.9%) had dreams about pandemic (Figure 1 below).



The binary logistic regression suggests that older age (OR= 1.038, p = .040), assumption of medication for psychiatric symptoms before COVID-19 (OR = 25.819, CI 11.465-58.143) and presence of COVID infection (OR = 2.783, CI 1.215-6.372) were predictive of insomnia during pandemic.

Conclusion: These results confirm that sleep disturbances have been a relevant concern in patients with inflammatory arthritis after COVID-19 national lockdown. Changes in daily life related to confinement have influenced psychological distress leading to a significant impact on sleep difficulties such as inability to fall early asleep or to maintain adequate sleep. Furthermore, older patients who had coronavirus infection and were previously treated for psychiatric disorders were at higher risk developing sleep disorders.

AB0662

IMPACT OF THE SARS-CoV-2 PANDEMIC IN A POPULATION OF PATIENTS FOLLOWED IN A RHEUMATOLOGY DEPARTMENT

S. Lahrichi[1], K. Nassar[2], S. Janani[3]. [1]*University Hospital of IBN ROCHD, rheumatology,Ccasablanca, Morocco*; [2]*University Hospital of IBN ROCHD, Rheumatology, Casablanca, Morocco*; [3]*University Hospital of IBN ROCHD, Rheumatology, Casablanca, Morocco*

Background: The COVID-19 pandemic had various impacts onpatients' realities. It had many physical but also psychological repercussions. It led to the onset of general stress, anxiety and depression affecting different age groups. In this study, we report the frequency of anxiety in patients followed in the department of rheumatology during the COVID-19 outbreak.

Objectives: To assess the impact of the COVID-19 pandemic in patients followed for inflammatory rheumatic disorders (IRD) or degenerative diseases in the Department of Rheumatology during the period of breakdown and health restrictions.

Methods: This is a cross-sectional study conducted in the department of rheumatology over a 5-month period from August 2020 to December 2020. Included patients were followed for IRD or degenerative pathology in the department. A pre-established questionnaire collected the symptoms and results of COVID-19 tests, the possible deterioration of the general condition since breakdown, as well as the increase of the disease activity of the rheumatism, pain, fatigue, anxiety, and the onset of signs of depression or sleep disturbances.The impact of the decrease in physical activity and the cessation of basic treatments of rheumatism with the different causes was also collected.

Results: 159 patients were included: 27 with Rheumatoid arthritis, 58 with Spondyloarthropathies, 32 with chondrocalcinosis, 9 with gouty arthropathies, and 33 with osteoarthritis. Of these, 15% had symptoms consistent with COVID-19. 25 patients performed the PCR test, of which 17 were positive and only 3 required hospitalization.None were put on oxygen. 32% reported a worsening of their rheumatism since the beginning of the epidemic, of which 35.9% reported increased pain and 21 noted a decrease in physical activity. 27.1% felt more stressed and irritated, and 14% felt more depressed. 54% had more sleepdisturbance, 22.2% had more fatigue compared to their state before the epidemic. 41.2% were afraid to come for consultation or hospitalization. 11.8% had stopped the basic treatment of their rheumatism, either for a shortage of the product in the pharmacy, or for the inability to obtain a travel authorization from the authorities

Conclusion: The physical and mental impact of the COVID-19pandemic affected approximately one-third of our population. Patients described worsening rheumatism and pain, as well as impaired sleep, fatigue and anxiety[1].Decreased physical activity was associated with increased rheumatism activity and pain. More than 50% of the patients presented a deterioration in their physical and mental health linked to the health situation[2]. Our results are consistent with the literature. It is classically admitted that rheumatic pathologiesare disabling and therefore lead to a withdrawal into oneself, generating an anxious state. It is essential to assess the psychological status of patients followed for rheumatism in order to develop preventive treatments and prevent its worsening linked to the impact of the pandemic[3].

AB0663

COMPARING METHODS FOR DETERMINING ANTIBODIES TO SARS-COV-2 USING A RAPID TEST AND ENZYME-LINKED IMMUNOSORBENT ASSAY

G. Gridneva[1], E. Aronova[1], S. Glukhova[1], M. Cherkasova[1], B. Belov[1], K. Nurbaeva[1], E. Salyanova[1]. [1]*V.A.Nasonova Rheumatology Research Institute, Laboratory for the Study of Comorbid Infections and Monitoring the Safety of Drug Therapy, Moscow, Russian Federation*

Background: An accessible and sensitive and sensitive method for determining antibodies to a new coronavirus infection is often the key to timely provision of the necessary medical care to patients with rheumatic diseases
Objectives: Compare methods for determining antibodies to SARS-CoV-2 using a rapid test and enzyme-linked immunosorbent assay (ELISA)
Methods: Methods for determining antibodies to SARS-CoV-2 using an express test (Chromatographic express test SARS-CoV-2 IgG / IgM (Xiamen Biotime Biotechnology, China)) and by ELISA (Reagent kit for enzyme immunoassay of class G immunoglobulins and class M to SARS-CoV-2 (Vector-Best, Russia)) were compared.
80 patients were included with a diagnosis of rheumatoid arthritis 26 (33%), psoriatic arthritis - 9 (11%), osteoarthritis - 15 (19%), rheumatic heart disease 1 (1%), SLE 2 (3%), deramtomyositis 3 (4%), systemic sclerosis 5 (6%), systemic connective tissue diseases 4 (5%), including Sjogren's syndrome, spondyloarthritis 15 (19%).
17 (21%) denied a history of COVID-19 symptoms. 63 (79%) noted any signs of COVID-19 3.095 ± 1.45 months before the test (Median 3 [2; 4] months). 63 (79%) noted any signs of COVID-19 109 ± 43 days before the test (Median 111 [78; 135] months). The ELISA method was considered the standard.
Results: When comparing the results of the express test and the determination of IgG antibodies to SARS-CoV-2 in serum, the following was obtained: the sensitivity of the express test is 99%. When comparing the results of the express test and the determination of IgM antibodies to SARS-CoV-2 in serum, it was obtained: among 66 samples with a negative result by the express test method, IgM was detected in 6 cases by ELISA/ So, 7.5% of 80 samples were false negative. In 3 of 14 samples with a positive result by the express test, IgM by ELISA was not detected. So, 3.75% of 80 samples were false-positive. (Table 1). When comparing the results of the IgM express test and ELISA, the following was obtained: the sensitivity of the express test was 33%, the specificity was 85%.

Table 1.

	Antibodies, express-test	Antibodies (ELISA), absent	Antibodies (ELISA), present	Row Totals
IgG	absent	0	1	1
	Row %	0.00%	100.00%	
	present	3	76	79
	Row %	3.80%	96.20%	
	Totals	3	77	80
IgM	absent	60	6	66
	Row %	90.91%	9.09%	
	present	11	3	14
	Row %	78.57%	21.43%	
	Totals	71	9	80

Conclusion: When comparing the results of the express test and the determination of IgG antibodies to SARS-CoV-2 in serum, the sensitivity of the express test is 99%. Determination of IgM antibodies to SARS-CoV-2 using a rapid test is less reliable than determination using ELISA.
Disclosure of Interests: None declared.

AB0664 THE PSYCHOLOGICAL STATE OF THE PATIENTS WITH RHEUMATIC DISEASES AND HOSPITAL WORKERS DURING THE CORONAVIRUS DISEASE (COVID-19) OUTBREAK

T. Lisitsyna[1], D. Veltishchev[2], A. Borisova[2], E. Nasonov[3], A. Lila[4]. [1]*V.A. Nasonova Research Institute of Rheumatology, Vascular rheumatology, Moscow, Russian Federation*; [2]*Moscow Research Institute of Psychiatry, Serbsky NMRC PN MoH, Department of mental disorders in somatic diseases, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, scientific director of the Institute, Moscow, Russian Federation*; [4]*V.A. Nasonova Research Institute of Rheumatology, director of the Institute, Moscow, Russian Federation*

Background: Patients with rheumatic diseases are more likely to suffer from anxiety-depressive disorders and, in the context of the current coronavirus pandemic, are most likely to be more susceptible to stress response, depression, and anxiety.
Objectives: to evaluate the frequency of anxiety-depressive symptoms and stress levels in patients with various rheumatic diseases (RD) and hospital workers of the Moscow Institute of Rheumatology in Russia
Methods: 148 RD inpatients, mostly with rheumatoid arthritis (44 (30%)), spondyloarthritis (31 (21%)), systemic lupus erythematosus (28 (19%)), systemic sclerosis (10 (7%)), primary Sjögren syndrome (7 (5%)), polymyositis (6 (4%)), and 32 hospital workers of the Nasonova Research Institute of Rheumatology were screened using the DASS-21 (The Depression, Anxiety, Stress scales-21, *Lovibond* S.H. & *Lovibond* P.F. (1995)) in the period from July to November 2020. The majority of RD-patients and hospital workers were women (73 and 93% resp). The mean age (M±SD) of RD-patients and hospital workers was 43,2±16,2 and 40,7±14,6 years resp.
Results: The frequency of depression (34,5% vs 34,4%), anxiety (41,9% vs 34,4%) and post-traumatic stress (27,7% vs 25,0%) in RD-patients were found to be comparable to that found among the hospital workers, and the level of anxiety was statistically significantly higher in patients (2,0 [1,0; 6,0] vs 1,0 [0; 4,5], p=0,038). There was no association of depression, anxiety and stress with RD activity. There was a weak positive correlation between the level of depression (R=0,30), anxiety (R=0,26) and stress (R=0,33) with a higher dose of glucocorticoids taken by patients, as well as a negative correlation between the severity of depression (R=-0,7) and stress (R=-0,17) with the age of patients and hospital workers.
19 (12,8%) of RD-patients and 7 (21,9%) of hospital workers had contracted COVID-19 in previous months. Survivors of the COVID-19, both among RD-patients and hospital workers, were more likely to experience symptoms of depression, anxiety and stress: accordingly, depression had 31,6% vs 27,9%, anxiety – 47,4% vs 41,9% and stress – 26,3% vs 28,7% RD-patients who had been ill or not, and among hospital workers: depression – 28,6% vs 36,0%, anxiety – 42,8% vs 28,0%, stress – 42,8% vs 20,0%. 66,4% of RD-patients and 71,9% of hospital workers reported that the pandemic had a psychological impact on them.
Conclusion: The COVID-19 pandemic has had and continues to have a significant negative psychological impact on both RD-patients and hospital workers. About 25-47% of patients and hospital workers experienced significant level of depression, anxiety and stress, and their frequency was higher in those who had contracted COVID-19.
Disclosure of Interests: None declared.

AB0665 SWITCHING INTRAVENOUS ABATACEPT AND TOCILIZUMAB TO SUBCUTANEOUS INJECTIONS DURING THE COVID-19 PANDEMIC: A FRENCH EXPERIENCE

A. Combier[1], S. Wanono[1], L. Poiroux[1], C. Frantz[1], E. Descamps[1], O. Fogel[1], M. Boisson[1], X. Ayral[1], C. Bottois[2], Y. Allanore[1], J. Avouac[1]. [1]*Cochin Hospital, Rheumatology, Paris, France*; [2]*Cochin Hospital, Pharmacy Department, Paris, France*

Background: The COVID-19 pandemic requires measures to reduce patient exposure to the risk of contamination, in particular by limiting hospital admissions and promoting lockdown. In order to respond to these healthcare measures, patients were offered to replace intravenous infusions (IV) of abatacept (ABT) and tocilizumab (TCZ) to subcutaneous injections (SC).
Objectives: To assess the outcome of patients who switched from IV ABT or TCZ to SC during the COVID-19 pandemic.
Methods: A survey was conducted in December 2020 in partnership with the national AFP-RIC patient association to assess the outcome and satisfaction of patients who switched from ABT or TCZ IV to SC during the first wave of COVID-19 pandemic.
We also analysed the outcome of patients who switched from IV ABT or TCZ to SC in the rheumatology department of Cochin Hospital during the lockdown in April/may 2020. Articular activity parameters (swollen joint count, pain joint count, visual analogic pain scale, CRP, DAS-28 activity score) were assessed at medical visits before and 6 months after switching from IV to SC.
The data collected from the AFP-RIC patient association and the rheumatology department of Cochin Hospital were then aggregated and analyzed by Chi-square and Wilcoxon tests.
Results: 81 patients responded to the survey carried out by AFP-RIC patient association, including 29 treated with IV ABT (n=15, 52%) or TCZ (n=14, 48%). 17/29 (59%) were offered to switch from IV to SC, 14/17 patients (82%) accepted and 7 patients were still receiving ABT or TCZ SC injections in December 2020. In the rheumatology department of Cochin hospital, 71 patients were scheduled in April/May 2020 to receive IV ABT or TCZ, and 27 (38%) switched to SC. After 6 months, 19 patients (70%) had maintained SC injections, were satisfied with this injection route of administration and their articular activity parameters were unchanged (Table 1).

Table 1. Course of Disease parameters evaluated in the 19 patients who maintained abatacept or tocilizumab SC injections in the Rheumatology department of Cochin Hospital

Parameter, mean(SD)	Inclusion visit Switch to SC (n=19)	6 month visit (n=19)	*P-value*
DAS28	2.3 (1.2)	2.3 (0.7)	0.62
Tender joint count	2.5 (3.5)	1.3 (1.7)	0.49
Swollen joint count	1.3 (2.5)	0.9 (0.6)	0.35
Patient Global Health (cm)	3.2 (1.9)	2.6 (1.8)	0.60
CRP (mg/L)	3.2 (4.1)	5.2 (4.9)	0.56

CRP: C-Reactive Protein, SD: Standard Deviation

The combined analysis of these two populations included 41 patients (33 rheumatoid arthritis, RA, 7 juvenile idiopathic arthritis, JIA and 1 polymyalgia rheumatica) who switched to SC ABT or TCZ. 26/41 (63.5%) patients maintained SC injections and IV was re-established in 15/41 (36.5%). Reasons for returning to IV were poor tolerance of SC injections (n=6, 40%), worsening symptoms (n=11, 73%), patient preference to see a rheumatologist in hospital (n=10, 67%) and the high number of SC injections (n=2, 13%). The proportion of patients returning to IV was higher in RA patients compared to patients with JIA (42% vs. 14%, p = 0.08). Age and disease duration were not significantly different between patients who maintained SC injections and those who returned to IV (respectively p=0.97 and p=0.63).

Conclusion: Our study suggests that switching from IV ABT or TCZ to SC is an acceptable procedure during the COVID-19 pandemic, especially for patients with JIA.

AB0666 PROGNOSTIC VALUE OF SERUM KREBS VON DEN LUNGEN-6 GLYCOPROTEIN CIRCULATING LEVELS IN COVID-19 PNEUMONIA: A PROSPECTIVE COHORT STUDY

D. Lobo Prat[1], I. Castellví[1], D. Castillo[2], S. Orozco[2], A. Mariscal[3], L. Martínez-Martínez[3], A. M. Millán Arciniegas[1], P. Moya[1], A. Laiz[1], C. Díaz-Torné[1], B. Magallares[1], S. P. Fernandez-Sanchez[1], S. Jeria Navarro[1], L. Sainz Comas[1], H. Codes[1], J. Casademont[4], P. Domingo[5], H. Corominas[1]. *[1]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; *[2]Hospital de la Santa Creu i Sant Pau, Pneumology, Barcelona, Spain*; *[3]Hospital de la Santa Creu i Sant Pau, Immunology, Barcelona, Spain*; *[4]Hospital de la Santa Creu i Sant Pau, Internal Medicine, Barcelona, Spain*; *[5]Hospital de la Santa Creu i Sant Pau, Infectious Diseases, Barcelona, Spain*

Background: Currently, there are no biomarkers to predict respiratory worsening in patients with Coronavirus infectious disease, 2019 (COVID- 19) pneumonia.

Objectives: We aimed to determine the prognostic value of Krebs von de Lungen-6 circulating serum levels (sKL-6) predicting COVID- 19 evolving trends.

Methods: We prospectively analyzed the clinical and laboratory characteristics of 375 COVID- 19 patients with mild lung disease on admission. sKL-6 was obtained in all patients at baseline and compared among patients with respiratory worsening.

Results: 45.1% of patients developed respiratory worsening during hospitalization. Baseline sKL-6 levels were higher in patients who had respiratory worsening (median [IQR] 303 [209-449] vs. 285.5 [15.8-5724], P=0.068). The best sKL-6 cut-off point was 408 U/mL (area under the curve 0.55; 33% sensitivity, 79% specificity). Independent predictors of respiratory worsening were sKL-6 serum levels, age >51 years, time hospitalized, and dyspnea on admission. Patients with baseline sKL-6 ≥ 408 U/mL had a 39% higher risk of developing respiratory aggravation seven days after admission. In patients with serial determinations, sKL-6 was also higher in those who subsequently worsened (median [IQR] 330 [219-460] vs 290.5 [193-396]; p<0.02).

Conclusion: sKL-6 has a low sensibility to predict respiratory worsening in patients with mild COVID-19 pneumonia. Baseline sKL-6 ≥ 408 U/mL is associated to a higher risk of respiratory worsening. sKL-6 levels are not useful as a screening tool to stratify patients on admission but further research is needed to investigate if serial determinations of sKL-6 may be of prognostic use.

AB0667 A PROSPECTIVE STUDY INTO COVID-19 LIKE SYMPTOMS IN PATIENTS WITH AND WITHOUT IMMUNE MEDIATED INFLAMMATORY DISEASES OR IMMUNOMODULATING DRUGS

L. van Ouwerkerk[1], A. Van der Meulen[2], M. Ninaber[3], Y. K. O. Teng[4], T. Huizinga[1], C. Allaart[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[2]Leiden University Medical Center (LUMC), Gastorenterology, Leiden, Netherlands*; *[3]Leiden University Medical Center (LUMC), Pulmonology, Leiden, Netherlands*; *[4]Leiden University Medical Center (LUMC), Nephrology, Leiden, Netherlands*

Background: Patients with an immune mediated inflammatory disorder or post solid organ transplantation (IMIDT), are at risk for infectious complications especially if they are treated with immunosuppressive drugs (imeds). There is still great uncertainty whether these IMIDT patients are more susceptible to COVID-19 than controls, and/or should be advised to avoid taking their immunosuppressive treatment.

Objectives: To evaluate whether patients with IMIDT are more at risk for CLS than controls.

Methods: The IENIMINI study is a prospective cohort study in patients with IMIDT and controls (healthy or no IMIDT) who were identified based on the registration database of the Leiden University Medical Center. Over time, participants registered COVID-like symptoms (CLS) as they occurred, and filled in additional questionnaires. Univariate and multivariate regression analyses were done to identify variables associated with having CLS.

Results: Of the 8670 individuals approached, 2110 with IMIDT and 1067 controls agreed to participate. In March and April, 454 (22%) of IMIDT patients and 242 (23%) of controls recorded to have CLS, mostly mild with a median (IQR) duration of seven (3-14) days in the IMIDT group and six days (4-11) in the control group. Eleven (5%) of the IMIDT patients with immunosuppressive medication (imed), 6 (3%) of IMIDTs without imed and 2 (1%) of controls were hospitalized with CLS (p=0.04). In May and June, fewer episodes overall were recorded. Being female (OR 1.45 95%CI 1.15;1.82), having a lung disease (OR 1.50 95%CI 1.20;1.88) and wearing a face mask (OR 1.42 95%CI 1.13-1.77) were independently associated with a higher risk, while higher age (OR 0.96 95%CI 0.96;0.97) and having an IMIDT with immunosuppressive medication use (OR 0.68 95%CI 0.51;0.91) were independently associated with a lower risk (see Table 1). Similar results were found after data imputation.

Table 1. Univariate & multivariate analysis of variables associated with having CLS or not (OR with 95% CI)

	n⁰	Univariate	Multivariate*
Sex, female	2546	1.89 (1.58;2.25)	1.45 (1.15;1.82)
BMI	2391	0.99 (0.97;1.01)	1.00 (0.98;1.03)
Age	2546	0.97 (0.96;0.97)	0.96 (0.96;0.97)
IMIDT without imed†	2546	1.00 (0.82;1.23)	0.94 (0.72;1.24)
IMIDT with imed †	2546	0.79 (0.65;0.97)	0.68 (0.51;0.91)
Smoking (current)	2463	1.35 (1.02;1.78)	1.05 (0.74;1.50)
Physical contact with family**	2220	1.47 (1.22;1.78)	1.22 (0.98;1.53)
Visiting other people (not family)	2205	1.26 (1.05;1.51)	0.96 (0.77;1.20)
Wearing a face mask	2196	1.46 (1.20;1.76)	1.42 (1.13;1.77)
Close contact (at work)	2180	1.65 (1.34;2.03)	1.27 (0.97;1.66)

**** in autumn 2019† control group = reference group*

Conclusion: Between March and July 2020, IMIDT patients, whether or not taking imeds, did not show an increased risk of reported COVID-like symptoms compared to controls. Continuing immunosuppressant drugs as long as not ill, while following the Dutch COVID rules, appears to be safe.

AB0668 THE ONSET OF RHEUMATOID ARTHRITIS AFTER COVID-19 – COINCIDENCE OR CONNECTED?

V. Derksen[1], T. Kissel[1], F. Lamers-Karnebeek[2], A. Van der Bijl[3], A. C. Venhuizen[4], T. Huizinga[1], R. Toes[1], A. H. E. Roukens[5], D. Van der Woude[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[2]Bernhoven hospital, Rheumatology, Uden, Netherlands*; *[3]Isala hospital, Rheumatology, Zwolle, Netherlands*; *[4]Rivierenland Hospital, Rheumatology, Tiel, Netherlands*; *[5]Leiden University Medical Center (LUMC), Infectious Diseases, Leiden, Netherlands*

Background: COVID-19, caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), has been suggested to induce autoimmune phenomena. Multiple studies have reported the presence of autoantibodies in patients with COVID-19. Also the presence of anti-citrullinated protein antibodies (ACPA) and flaring of rheumatoid arthritis (RA) after COVID-19 has been described.[1, 2] Furthermore, in rheumatology clinics patients may present with polyarthritis compatible with RA shortly after SARS-CoV-2 infection. However, it is unclear how often ACPA occur after COVID-19 and whether preceding COVID-19 impacts on disease presentation of RA and phenotype of the ACPA response.

Objectives: This study aims to determine the seroprevalence of ACPA after COVID-19 and to investigate the association between preceding COVID-19 infection and disease presentation of new-onset RA, including clinical phenotype and autoantibody response.

Methods: To estimate the prevalence of ACPA after COVID-19 we measured ACPA IgG in samples from 61 patients visiting the specialized post-COVID outpatient clinic of the LUMC 5 weeks after hospitalization, using routine tests or in-house ELISA. Furthermore, we identified 5 patients presenting with polyarthritis compatible with RA after SARS-CoV-2 infection. To study the impact of COVID-19 on disease presentation, we examined clinical phenotype, autoantibody isotype positivity and ACPA IgG variable domain (V-domain) glycosylation of these patients and compared these features to regular RA patients. Autoantibody isotypes, including rheumatoid factor (RF) IgM/IgA, anti-CCP2 IgG/ IgM/ IgA and anti-carbamylated protein antibodies (anti-CarP) IgG were measured using in-house ELISA's. The percentage of V-domain glycosylation of purified ACPA IgG was measured with UHPLC.

Results: None of the 61 post-COVID patients tested positive for ACPA 5 weeks after hospitalization, except two patients previously diagnosed with ACPA-positive RA. Thus, we could not observe an increase in ACPA-positivity shortly after COVID-19. Of the 5 patients who developed polyarthritis compatible with RA after SARS-CoV-2 infection, the average age was 63.6 years and 2/5 were female. 4/5 patients had been hospitalized due to severe COVID-19. On average, joint complaints started 6.6 weeks after infection, although two patients reported symptoms before infection. 4/5 patients fulfilled the ACR 2010 criteria for RA. Three patients (patient 1, 4, 5) were phenotypically very similar to regular new-onset RA patients. Patient 3 had a history of seronegative RA and had been in DMARD-free remission for 5 years. She flared 6 weeks after SARS-CoV-2 infection. Patient 2 had a remarkably different presentation. He was admitted with a suspected septic polyarthritis or pneumonia with reactive polyarthritis 6 weeks after COVID-19. ACPA level was low positive. The patient died unexpectedly after two days and autopsy revealed dilating myocarditis of unclear underlying cause. No causative pathogen could be identified.

Previous studies have shown that RA-patients are most often either seronegative or triple-positive for RF, ACPA and anti-CarP antibodies. Autoantibody measurements on sera of the post-COVID polyarthritis patients revealed a similar pattern (Figure 1A) with two patients being completely seronegative, and three patients positive for a range of autoantibodies. In all post-COVID samples, the percentage of ACPA IgG V-domain glycosylation was significantly increased compared to total IgG (Figure 1B), similar as in regular RA.

Conclusion: In conclusion, we found that the seroprevalence of ACPA is not increased post-COVID and that most patients presenting with polyarthritis after COVID-19 resemble regular RA patients, both regarding clinical phenotype and autoantibody characteristics. Although sample size and follow-up was limited, it appears that RA post-COVID may be coincidence rather than connected.

AB0669 DEPRESSION AND ANXIETY MIGHT NOT BE INCREASED DURING COVID-19 PANDEMIC IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

E. Erpek[1], D. Solmaz[1], D. Bayraktar[2], G. Duran[3], G. Kabadayi[1], E. Durak Ediboglu[1], E. Otman Akat[1], G. Alp[1], H. Cinakli[1], İ. Kurut Aysin[1], S. Gucenmez[1], O. Bayindir[1], M. Ozmen[1], S. Akar[1]. *[1]Izmir Katip Celebi University Faculty of Medicine, Rheumatology, Izmir, Turkey*; *[2]Izmir Katip Celebi University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey*; *[3]Dokuz Eylul University, Institute of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey*

Background: Anxiety and depression are most common psychiatric disorders in chronic inflammatory rheumatic condition as well as axial spondyloarthritis (axSpA) (1). The prevalence of depression has been reported as 11-64% depending on the criteria used. Also self-reported depression and anxiety were found to be associated with disease activity and function in axSpA (1,2). It is observed that mental health is affected among healthy subjects during the COVID-19 pandemic, but this condition has not been systematically reviewed in axSpA patients.

Objectives: We aimed to compare frequency of self-reported depression and anxiety before and during the Covid-19 pandemic in patients with axSpA.

Methods: Seventy-six axSpA patients who were evaluated for the presence of depression and anxiety by using Hospital Anxiety and Depression scale (HADs) before pandemic were included in this study. All participants were classified according to the ASAS axSpA classification criteria. Patients were contacted by phone to participate and complete the HADS questionnaire. Demographic and disease related characteristics including BASDAI, BASFI and Patient Acceptable Symptom State (PASS) were recorded during interview. The HADs cut off value was taken as >7 in both groups to define the presence of anxiety or depression. Before and during pandemic period anxiety and depression scores were statistically compared.

Results: The demographic and disease related characteristics of axSpA patients with and without anxiety/depression were summarized in Table 1. The frequency of anxiety (43.4% vs %43.4; p>0.05) and depression (46.1% vs 44.7%; p>0.05) were found to be similar before and during pandemic period. Patients with anxiety (HADs>7) and depression (HADs>7) had higher BASDAI and BASFI scores and much less PASS positivity (Table 1). Although the frequency of depression was similar between before and during the pandemic period, symptom severity in depression was slightly increased during the pandemic (Figure 1).

Table 1. Patients' demographics and characteristics according to the presence of anxiety and depression

Variables	Presence of depression n:35	Absence of depression n:41	P	Presence of anxiety n:33	Absence of anxiety n:43	P
Age (years) mean ± SD	41.8±11.2	44.1±9.3	>0.05	42.0±10.9	43.6±10.0	>0.05
Male n(%)	21(60.0)	26(63.4)	>0.05	18(54.5)	29(67.4)	>0.05
Education time (years) mean ± SD	9.6±4.8	11.0±4.2	>0.05	9.7±5.0	10.6±4.1	>0.05
Current smoker n(%)	18(51.4)	15(36.6)	>0.05	15(45.5)	18(41.9)	>0.05
Alcohol consumption n(%)	12(34.3)	12(29.3)	>0.05	10(30.3)	14(32.6)	>0.05
Current BMI kg/m^2 mean ± SD	26.0±4.8	26.8±4.5	>0.05	26.4±5.0	26.5±4.3	>0.05
Sleep time (hours) mean ± SD	7.6±1.7	7.6±1.3	>0.05	7.5±1.6	7.7±1.4	>0.05
Current BASDAI mean ± SD	2.5±1.6	1.4±1.6	**<0.05**	2.7±1.8	1.3±1.3	**<0.001**
Current BASFI mean ± SD	2.4±2.1	1.1±1.3	**<0.05**	2.4±2.0	1.2±1.4	**<0.05**
PASS positivity n(%)	16(45.7)	29(70.7)	**<0.05**	14(42.4)	31(72.1)	**<0.05**

Current depression and anxiety scores were correlated with disease activity (HADs Depression vs BASDAI r:0.530, p<0.001; HADs Anxiety vs BASDAI r:0.500, p<0.001) and function (HADs-Depression vs BASFI r:0.519, p<0.001; HADs-Anxiety vs BASFI r:0.391, p<0.001). These relationships were also observed in the pre-pandemic period (HADs-Depression vs BASFI r:0.326, p<0.05; HADs-Anxiety vs BASDAI r:0.342, p<0.05).

Conclusion: Depression and anxiety symptoms seems to be comparable before and after the COVID-19 pandemic. Regardless of this period, the presence of both depression and anxiety are associated with disease activity, function and less patient acceptable symptom state.

AB0670 THE COURSE AND OUTCOMES OF COVID-19 IN PATIENTS WITH ANCA-ASSOCIATED SYSTEMIC VASCULITIS, RECEIVING ANTI-B CELL THERAPY WITH RITUXIMAB

T. Beketova[1], V. Babak[1], M. Suprun[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Currently, the issues of the effect of anti-B cell therapy on the risk of severe course of COVID-19 in patients (pts) with ANCA-associated vasculitis (AAV) has not been completely studied.

Objectives: We present an analysis of the COVID-19 incidence and outcomes in 126 AAV pts treated with rituximab (RTX) from one rheumatology center registry.

Methods: Data were collected with telephone/online surveying between 11-15th November 2020 from all 126 AAV pts (58- granulomatosis with polyangiitis, GPA; 38- microscopic polyangiitis, MPA; 22- eosinophilic granulomatosis with polyangiitis, EGPA (54% ANCA-negative); and 8- uncertain AAV). Pts age was 51 (20-81) yr, 62% women. Due to AAV activity or risk of relapse, during the pandemic RTX was prescribed in 48% pts.

Results: The incidence of COVID-19 in AAV pts was 3.5% during the first 3 months of the pandemic, the course was uneventful, and all pts recovered. Since September 2020 a 4-fold increase in the incidence alongside with more severe course of COVID-19 were reported. After 8 months of the pandemic, COVID-19 was diagnosed in 21 (16.6%) pts with median age 55 yr, 57% women. COVID-19 incidence was lower in GPA (15.5%) vs MPA (21.1%) or EGPA (27.7%). The mortality rate was 14.3% (2- MPA, 1- GPA). When analyzing the 5-year survival rate of AAV pts treated with RTX, prognosis worsening was noted; in 2020 there were 3 deaths due to COVID-19, in the previous 5 years- only 2 deaths.

Conclusion: Taking into account the fact the mechanisms of AAV and severe COVID-19 are largely synergistic (Table 1), primarily in the context of obstructive thromboinflammation as manifestation of acute inflammatory syndrome in COVID-19 [1], AAV can potentially contribute to the severe course of COVID-19. Anti-CD20 therapy seems to have a protective effect against severe COVID-19 [2], which, however, can be insufficient in AAV pts with active disease and multiple organ damage. Further analysis of COVID-19 cases in pts with AAV and other rheumatic diseases is exceptionally important.

Table 1. Comparison of AAV and severe COVID-19

Parameter	AAV	Severe COVID-19
Lung damage	High frequency of lung damage	Possibly destructive lung damage
Damage to other organs	Typically affects the upper and lower airways and kidneys; Other organs can be involved	Possible extrapulmonary localization
Vascular involvement	Systemic necrotizing vasculitis of small vessels; In the active phase, hypercoagulation	Obstructive thromboinflammation of the microcirculation of lungs and extrapulmonary vessels; Increased incidence of Kawasaki syndrome during the pandemic
Inflammation	High or very high	Very high
Autoantibodies	ANCA pathogenetic role	Dominant extrafollicular B cell responses; Correlation between SARS-CoV-2 antibody titer and severity of COVID-19; High titers of IFN-α2/ω autoantibodies
Neutrophil	Neutrophils are the most important effector cells in the pathogenesis	Changes in the morphology of neutrophils were noted; Netosis, the release of proteases from neutrophils promote the complement system activation, hypercoagulation, endotheliitis, production of pro-inflammatory cytokines; An increase of neutrophils in the blood and bronchoalveolar lavage fluid were noted
Complement	Complement is crucial in the pathogenesis; C5a receptor antagonist Avacopan efficacy	Activation of alternative/lectin complement pathways; C5 antagonist Eculizumab has been reported to be effective
Treatment	Immunosuppressants; In the active phase, anticoagulants	Anticoagulants; Glucocorticoids, pro-inflammatory cytokine antagonists, JAK inhibitors, cyclosporine
Prognosis	Serious	High mortality rate

AB0671 NO EVIDENCE OF SARS-COV-2 IN THE KNEE JOINT: A CADAVER STUDY

M. Grassi[1], V. Giorgi[2], M. Nebuloni[3], P. Zerbi[3], M. R. Gismondo[4], F. Salaffi[5], P. Sarzi-Puttini[2], S. G. Rimoldi[4], A. Manzotti[1]. [1]*ASST-Fatebenefratelli L. Sacco University Hospital, Orthopaedic and Traumatology Unit, Milan, Italy*; [2]*ASST Fatebenefratelli L.Sacco University Hospital, Rheumatology Unit, Milan, Italy*; [3]*ASST-FBF Sacco, University of Milan, Pathology Unit, Department of Biomedical and Clinical Sciences, Milan, Italy*; [4]*ASST-Fatebenefratelli L. Sacco University Hospital, Microbiology Unit, Milan, Italy*; [5]*Università Politecnica delle Marche, Rheumatology Department, Jesi, Italy*

Background: Despite the considerable research efforts being made to learn more about COVID-19, little is known about the presence of SARS-CoV-2 genetic material in biological fluids other than respiratory droplets, blood, and feces [1,2]. In particular, little is known about the presence of SARS-CoV-2 in the joints either *post mortem* [3] or *in vivo* [4]. To the best of our knowledge, only Lopéz-Gonzalez *et al.*[5] have published a description of acute arthritides occurring during hospitalisation due to COVID-19, and they did not find any SARS-CoV-2 genetic material in the patients' synovial fluid samples.

Objectives: The aim of this *post mortem* study was to assess the presence of SARS-CoV-2 RNA in the knee synovial fluid, synovial tissue, and bone tissue of COVID-19 patients in order to discover whether the joint is a possible route of transmission during orthopaedic surgical procedures, and clarify the possible role of SARS-CoV-2 as a directly arthritogenic virus.

Methods: *Post mortem* synovial fluid, synovial tissue and bone tissue samples were collected from the knees of five patients who died of COVID-19 in our hospital between September and October 2020, and analysed for the presence of SARS-CoV-2 using a commercial real-time polymerase chain reaction (RT-PCR) panel. Quantitative RT-PCR was used to test *post mortem* nasopharyngeal swabs of all of the patients.

Results: No SARS-CoV-2 RNA was detected in any of the knee samples, despite the positivity of the throat swab.

Conclusion: Our findings indicate that SARS-CoV-2 was not detected in knee synovial fluid, synovial membrane or bone. Therefore, our results suggest that all

healthcare professionals performing surgical procedures on the joints of COVID-19 patients are exposed to a risk of contagion due to exposure to respiratory droplets, blood and body fluids, but not to direct exposure to joint- or bone-related tissues. Furthermore, given that some case reports of arthritis in COVID-19 patients [5-8] show that it is possible that COVID-19 patients display viral-mediated arthralgias and arthritis, the absence of the virus in the knee highlighted by our study suggests that it is unlikely that SARS-CoV-2 has a direct inflammatory action on the joint, but it could induce an inflammation-related reaction, manifesting as a reactive arthritis [9].

AB0672 PSYCHOLOGIC STATE OF PATIENTS WITH RHEUMATIC DISEASES AFTER THE OUTBREAK OF SARS-COV2

M. Yasmine[1], S. Mariem[1], S. Miladi[1], A. Fazaa[1], L. Souebni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: The ongoing Coronavirus-19 disease epidemic is a public health emergency of international concern which could pose a challenge to psychological resilience. This is mainly the case of patients with rheumatic diseases (RD).
Objectives: The aim of this study was to establish the prevalence of psychiatric symptoms in patients with RD and to identify factors associated with psychological stress.
Methods: A cross-sectional study was conducted among patients with RD. They were invited to respond to a survey designed to assess their psychological response after the outbreak of the SARS-COV2 pandemic. Mental health status after the Covid-19 was evaluated using the Depression and Anxiety Scale (DASS-21). The total depression subscale score was divided into normal (0–9), mild depression (10–12), moderate depression (13–20), severe depression (21–27), and extremely severe depression (28–42). The total anxiety subscale score was divided into normal (0–6), mild anxiety (7–9), moderate anxiety (10–14), severe anxiety (15–19), and extremely severe anxiety (20–42).The Impact of Event Scale-Revised (IES-R) is a 22-item self-administered questionnaire that assesses the post-traumatic state (PTS). A cut-off point of 33 provided the best diagnostic accuracy for PTS. The level of significance was fixed at 0.05.
Results: Sixty patients were included (42 with rheumatoid arthritis and 18 with spondylarthritis) with a mean age of 51.3 ± 13.1 years [18-75]. The majority of patients were women (63.3%), married (81.7%), with a household size of 3–5 people (67.9%). The mean disease duration was 11.9 ±5.6 [1-23] years.
According to DASS depression score almost half of the patients (47%) suffered from depression, which was classified as severe in 10% of cases. The mean DASS anxiety subscale was 12.6 ± 8.2 [1-35]. The level of anxiety was mild in 23% of cases, moderate in 25% of cases, and severe in 23.3% of cases. The mean ILES-R score was 20.4 ± 10.2 [20-38]. Women experienced more PTS than men (26.3% vs 22.7%) without reaching a statistically significant correlation (p=0.9). Patients with higher education had lower IES-R, depression, and anxiety subscale scores as compared to those who were illiterate without a statistically significant correlation (p=0.5, p=0.2, p=0.4 respectively). A positive correlation was found between anxiety score and IES-R (p=0.00). Other sociodemographic variables including disease duration, parental status, marital status, and household size were not associated with IES-R and DASS subscale scores (p>0.05).
Conclusion: Our study showed that many of our patients with RD experienced anxiety, depression, and PTS after the outbreak of Covid-19. Professional status as well as other sociodemographic data was not associated with psychological stress.

AB0673 THE ROUTINE HEALTH CARE OF PATIENTS WITH RHEUMATIC DISEASES DURING THE PANDEMIC OF COVID-19

S. Mariem[1], M. Yasmine[1], S. Miladi[1], A. Fazaa[1], L. Souebni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: The coronavirus pandemic poses a great threat to patients with rheumatic diseases (RD). Because of the state of immunodepression, they are perceived as vulnerable and at high risk of contracting the virus. This may lead to a delay in the health care routine.
Objectives: The aim of our study was to assess the routine of patients with rheumatic diseases in the era of covid-19.
Methods: We conducted a prospective study after the outbreak of Covid-19 including patients with RD: rheumatoid arthritis (RA) and Spondylarthritis (SpA). All of them were invited to answer a questionnaire about adherence to protective measures, health services, hospital visits, treatment modalities, as well as the level of satisfaction with the medical support or information received for COVID-19. We also evaluated the post-traumatic state (PTS) with the Impact of Event Scale-Revised (IES-R). A cut-off point fixed at 33 provided the best diagnostic accuracy for PTS. The level of significance was fixed at 0.05.
Results: The study included 60 patients with a female predominance (sex ratio=1.7). The mean age was 51.3 ± 13.1 years [18-75] and the mean disease duration was 11.9 ±5.6 [1-23] years. Forty-two patients had RA and 18 patients had SpA. The majority of respondents were women (63.3%), married (81.7%), with a household size of 3–5 people (67.9%). The mean DASS depression and anxiety subscale was 9.5 ±7.6 [2-32] and 12.6 ± 8.2 [1-35] respectively. PTS was found in 25% of cases. Twenty-two patients stopped working in the second outbreak. The adherence to protective measures was as follows: compliance with lock-down (92.5%), adherence to stay home warnings (82%), wearing masks (96.3%), social distancing (68%), and washing hands immediately after sneezing (59.3%). Information was mainly sourced from both social media and the Internet in 78.2% of cases. Most of the patients were satisfied with the information provided and only 5 demanded more information about vaccination protocol. Of the patients having direct contact with a person affected with Covid-19 (20%), seven patients experienced symptoms. Three patients were diagnosed with SARS-COV2 and three other patients were hospitalized because of flares. The majority of the respondents (98.2%) had confidence in their own doctors' ability to recognize Covid-19. The majority of patients (91%) were afraid of getting sick and 83.1% feared stigma and discrimination after the infection. Fifty patients did attend their consultation appointment and 13.3% had a phone consultation. About a third of patients (26.7%) of patients experienced a delay in treatment. A positive correlation was found between marital status and the fear of other family members getting Covid-19 (p=0.029). Patients who did not consult experienced more PTS and severe anxiety than those who did not delay hospital visits (p=0.07, p=0.04 respectively).
Conclusion: Our study showed that during the outbreak of Covid-19, patients with RD exhibited a high level of protection towards the virus. Despite these precautionary measures, a delay in hospital routine was observed.

Background: The COVID-19 pandemic led to a rapid increase in remote consultations in rheumatology care. Due to the potential impact of this change on rheumatology clinical training, we investigated trainees' experiences with telemedicine.
Objectives: To assess the impact of telemedicine use during the COVID-19 pandemic on rheumatology training, including supervision.
Methods: A voluntary, anonymous web-based survey was administered in English, Spanish, or French from 19/08/2020 to 05/10/2020. Adult and paediatric rheumatology trainees worldwide in training in 2020 were invited to participate via social media and email. Using multiple choice questions, Likert scales, and free text answers, we collected data regarding prior and current telemedicine use, training, and supervision.
Results: 302 respondents from 33 countries completed the survey, with most (83%, 252/302) in adult rheumatology training. Reported use of telemedicine increased from 13% (39/302) pre-pandemic to 82% (247/302) (Table 1). European trainees predominantly utilised audio-only compared to trainees from the rest of the world (ROW) who predominantly utilised audio-video telemedicine.
Most trainees continued to evaluate new patients using telemedicine (65%, 161/247). A larger proportion of trainees were comfortable using telemedicine to evaluate follow-up (69% 170/247) versus new patients (25%, 41/161) (Figure 1). Only 32% (97/302) were trained in telemedicine, with the highest proportion among United States (US) trainees (59%, 69/116); subjects included software, clinical skills, and billing. The majority of trainees found this helpful (92%, 89/97). Supervision was most frequently in the form of verbal discussion after the consultation (Table 1); 24% (59/247) had no telemedicine supervision during the pandemic. In general, trainees found telemedicine negatively impacted their supervision (51%, 123/242) and clinical teaching quality (70%, 171/244); only 9% reported a positive impact on these areas.
Conclusion: Adoption of telemedicine during the COVID-19 pandemic has led to areas of concern for rheumatology trainees including inadequate supervision and clinical teaching. Our results suggest a need for education on evaluation of new patients using telemedicine, increasing telemedicine training, and ensuring adequate supervisory arrangements.

Table 1. Telemedicine use, supervision, and training by region. Data is presented as n (%). Rest of the world (ROW) data includes Asia (50), Central and South America (23), Canada (12), Australia (8), and Africa (4).

		Europe n = 89	US n = 116	ROW n = 97	Combined n = 302
Telemedicine use	Pre-pandemic	15 (17)	9 (8)	15 (15)	39 (13)

Background: The COVID-19 pandemic has impacted every aspect of life of European patients with rheumatic and musculoskeletal diseases (RMDs).
Objectives: The aim is to evaluate country differences on the impact of the first wave of the COVID-19 pandemic on life habits, healthcare access, health status, mental health and wellbeing in European patients with RMDs.
Methods: REUMAVID is an international collaboration led by the Health & Territory Research group at the University of Seville, together with a multidisciplinary team including patient organisations and rheumatologists. This cross-sectional study consisting of an online survey gathering data from patients with a diagnosis of 15 RMDs in Cyprus, France, Greece, Italy, Portugal, Spain, and the United Kingdom. Participants were recruited by patient organisations (April-July 2020). The Kruskal-Wallis and χ^2 tests were used to analyse differences between countries and independent variables.
Results: 1,800 patients participated in the first wave of the COVID-19 pandemic (REUMAVID). 37.8% of Spanish patients increased their smoking consumption

during the pandemic followed by Cyprus (32.1%) and Portugal (31.0%), while alcohol consumption was higher in the UK (36.3%) and France (27.0%). 82.3% of patients in Spain unable to attend their appointment with their rheumatologist, either due to cancellations or other personal reasons. Access to primary care was most limited in Portugal and Italy, where only 45.0% and 51.6% got access. 61.9% in Italy and 53.3% in Spain experienced a worsening of their health during the pandemic. 68.5% in Spain and 67.8% in Portugal were at risk of anxiety. The highest proportion at risk of depression was found in Greece (55.4%), Cyprus (55.1%), and Italy (54.8%). 66.9% of patients in Spain reported poor wellbeing, compared to 23.8% in Italy and 30.1% in Portugal (Table 1).

Conclusion: The first wave of the pandemic and the related containment measures heterogeneously affected patients with RMDs across European countries, who overall increased harmful habits, experienced more difficulties in accessing healthcare and, reported poor mental health and well-being.

Table 1. Bivariate analysis between European countries (N=1,800, unless specified)

	Mean ± SD or n (%)						
	UK n: 558	**Spain n: 464**	**France n: 229**	**Greece n: 57**	**Cyprus n: 101**	**Italy n: 127**	**Portugal n: 264**
