Background: Group 1 and 3 pulmonary hypertension (PH) develop through different pathological mechanisms but have similar hemodynamic abnormalities. Systemic sclerosis (SSc) is associated with both pulmonary vascular disease (PVD) and interstitial lung disease (ILD), making it challenging to differentiate group 1 and 3 PH in those patients. A previous study using quantitative evaluation of chest computed tomography (CT) demonstrated that normal lung volume was inversely correlated with mean pulmonary arterial pressure (mPAP) in patients with group 3 PH (1).
Objectives: In this study, we aimed to assess the dominance of PVD or ILD in SSc patients by quantitative evaluation of chest CT and to evaluate each characteristic.
Methods: A total of 76 SSc patients who underwent right heart catheterization (RHC) were included. Chest CT was evaluated by using a software (Synapse Vincent Ver.3.0, Fujifilm) which quantified normal and total area of the lung. Then, we calculated abnormal area by drawing normal area from total area in the lung (%). Pulmonary function test (PFT) and serum biomarkers, such as KL-6 and LDH, were also evaluated. The dominance of PVD or ILD was defined as divergent or parallel change between the first and last assessments, respectively, in mPAP and abnormal area in the lung calculated using the software. Increase or decrease by over 10% in the last assessment compared to the first assessment was considered as a significant change in mPAP or abnormal area in the lung. P values were calculated by Mann-Whitney U test, and correlation coefficients were calculated by direct regression variance.
Results: The median [range] values of mPAP and abnormal area in the lung at baseline were 23 [9-65] mmHg and 30.2 [0-100] %, respectively. Of 37 SSc and PH patients, 18 were defined as having PVD dominance while 19 as ILD dominance. Abnormal area in the lung at baseline was greater in patients with ILD dominance compared to those with PVD dominance (39.1 [16.3-98.3] v.s. 14.0 [0-99] %, p=0.002), whereas mPAP was higher in patients with PVD dominance than those with ILD dominance (42.5 [23.0-65.0] v.s. 26.0 [16.0-42.0] mmHg, p=0.002). PFT parameters including forced vital capacity were not different between the two groups. The ratio of mPAP/KL-6 showed a great difference between the two groups with its significant elevation in patients with PVD dominance (p=0.007).
Conclusion: Quantitative evaluation of chest CT showed great efficiency in differentiating the dominance of PVD or ILD in patients with SSc and PH. In addition, the ratio of mPAP/KL-6 may easily be used as a parameter for dominance evaluation.

POS0864

ELIGIBILITY FOR ANTI-FIBROTIC TREATMENT WITH NINTEDANIB OF PATIENTS WITH SYSTEMIC SCLEROSIS RELATED INTERSTITIAL LUNG DISEASE

E. De Lorenzis[1], G. Natalello[1], L. Verardi[1], L. Gigante[1], M. A. D'agostino[1], S. L. Bosello[1]. [1]*Fondazione Policlinico Universitario A. Gemelli IRCCS - Catholic University of the Sacred Heart, Rheumatology Unit, Rome, Italy*

Background: Pulmonary involvement is the main determinant of disease-related mortality in systemic sclerosis (SSc). The SENSCIS and INBUILD trials have documented the efficacy of the antifibrotic drug Nintedanib (NTN) in the treatment of SSc-related interstitial lung disease (SSc-ILD) and progressive forms of ILD other than Idiopathic Pulmonary Fibrosis[1,2]. The criteria for the use of this drug in patients with SSc-ILD in clinical practice are currently being defined.
Objectives: To evaluate the proportion of patients eligible for NTN treatment based on the enrollment criteria fof the SENSCIS and INBUILD studies in a real-life cohort of SSc-ILD patients.
Methods: We considered consecutive patients with ILD extension on CT ≥10% and disease duration ≤7 years with at least one visit in the period between September 2016 and December 2019. Data of the clinical visits were retrospectively evaluated. For each patient, we examined the visits during which a well-tolerated immunosuppressive therapy was modified because of progression of SSc-ILD and the most recent follow-up visit. Eligibility of patients for NTN was defined according to the inclusion criteria of the SENSCIS and INBUILD trials. Patients with more than 2 acral ulcers at the time of evaluation, history of digital amputation, pulmonary hypertension (functional class III-IV) and increased hemorrhagic or thrombotic risk were judged not eligible to NTN in trials.
Results: A total of 177 visits regarding 78 patients were examined (females 80.8%, diffuse skin disease 51.3%, anti-Scl70 antibodies positivity 55.7%, age 54.8±16.0 years, disease duration 4.0±2.4 years). Considering the visits in which indication for a therapeutic change was given, 54 patients (54.5%) were eligible for NTN according to SENSCIS criteria and of these 31 (31.3%) also according to INBUILD criteria (Figure 1). In this group, 25 patients were treated with mycophenolate mofetil, 11 with azathioprine, 10 with cyclophosphamide, 7 with methotrexate and 8 with rituximab (2 in combination). At the latest available evaluation, 42 patients (62.8%) were eligible for NTN according to SENSCIS criteria and of these 12 (15.4%) also according to INBUILD criteria (Figure 1). In this group, 30 patients were in mycophenolate mofetil (6 in combination with biologic treatment), 5 in azathioprine, 1 in cyclophosphamide, 1 in methotrexate, 6 in rituximab, 2 in tocilizumab and 1 in pirfenidone. Overall, the factors limiting NTN start according to the trial enrollment criteria would have been: uncompromised (19.2%) or too low (6.4%) DLco values, too low FVC (3.4%), severe acral disease with ulcers (16.9%), severe pulmonary arterial hypertension (6.2%), increased thrombotic or haemorrhagic risk (6.2%). In the scenario of eligibility, skin progression was detectable in 43.4% of all visits.
Conclusion: Treatment that can modify the progression of SSc-ILD are currently limited. Based on our retrospective analysis, the use of NTN in accordance with current clinical evidence could be considered in a significant percentage of patients with SSc-ILD.

POS0865

REDUCED BONE MINERAL DENSITY IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES: A CASE CONTROL STUDY

Y. K. Tang[1], V. Lao[1], H. T. Pang[1], T. L. V. Wong[1], T. H. Luk[1], H. So[2]. [1]*Kwong Wah Hospital, Medicine and Geriatrics, Hong Kong, Hong Kong (SAR)*; [2]*The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*

Background: Idiopathic Inflammatory Myopathies (IIMs) patients are at risk of bone mineral density (BMD) loss due to systemic inflammation, use of glucocorticoids (GCs) and disability. Cross sectional study showed 70% of IIMs patients had reduced BMD but whether they were at excessive risk compared to controls were unknown.
Objectives: To compare the prevalence of reduced BMD between IIMs patients, non-rheumatological controls, rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) patients and to determine the clinical determinants of BMD in IIMs patients.
Methods: This was a single centre retrospective case control study. BMD at lumbar spine L1-L4 and neck of femur (NOF) were assessed by dual-energy X-ray absorptiometry (DXA) scans. The prevalence of reduced BMD and osteoporosis in Chinese IIMs patients and age-and-sex-matched non-rheumatological controls were compared. The BMD of female IIMs were then compared to age matched female RA and SLE patients in the secondary analysis. Binary logistic regression was used for adjustment of confounders. The demographics and

clinical variables independently associated with BMD were determined by linear regression.

Results: A total of 230 patients were recruited including 65 IIMs, 65 non-rheumatological controls, 50 RA and 50 SLE patients. The mean age was 58.6±10.96 years and 76.9% were female. There was no significant difference on demographics between the two groups. Almost all IIMs patients (98%) and 52% of controls had exposed to GCs (p<0.001). Significantly more IIMs patients had used immunosuppressants (92.3% vs 38.5%, p<0.001) and biologics (13.8% vs 1.5%, p=0.01). The prevalence of reduced BMD and osteoporosis were significantly higher in IIMs patients than non-rheumatological control (Reduced BMD: 73.8% vs 43.1%, p=0.043; Osteoporosis: 29.2% vs 13.8%, p=0.033) (Table 1). The mean lumbar spine and hip BMD were 0.886±0.181 g/cm^2 and 0.651±0.144 g/cm^2 in IIMs patients, which were significantly lower than that of the control group (0.960±0.143g/cm^2, p=0.011 and 0.751±0.127g/cm^2, p<0.001) (Figure 1). Multivariate analysis confirmed IIMs were associated with increased risk of reduced BMD (Odds ratio:2.118, p=0.048, 95% CI 1.005-4.461). The prevalence of reduced BMD and osteoporosis were not significantly different between IIMs, RA and SLE patients but the mean hip BMD was the lowest in the IIM group (0.641±0.152g/cm^2 vs 0.663±0.102g/cm^2 in the RA group vs 0.708±0.132 g/cm^2 in the SLE group, p=0.035). Lower BMI (p=0.035) and more advanced age (p<0.001) were associated with lower BMD in the IIM patients.

Conclusion: Reduced BMD was more prevalent in IIM patients than non-rheumatological controls. Lower BMI and more advanced age were associated with lower BMD. Vigilant monitoring of BMD and use of antiresorptive treatment should be considered in IIM patients.

POS0866 TWO-DIMENSIONAL HRCT-BASED RADIOMIC FEATURES IN SSC-ILD DISTINGUISH DRUG RESPONDERS FROM NON-RESPONDERS

C. Meier[1], M. Maciukiewicz[1], M. Brunner[1], J. Schniering[1], H. Gabrys[2], A. Kühnis[2], O. Distler[1], T. Frauenfelder[3], S. Tanadini-Lang[2], B. Maurer[1].

[1]University of Zurich, University Hospital Zurich, Department of Rheumatology, Center of Experimental Rheumatology, Zurich, Switzerland; *[2]University of Zurich, University Hospital Zurich, Department of Radiation Oncology, Zurich, Switzerland*; *[3]University of Zurich, University Hospital Zurich, Institute for Diagnostic and Interventional Radiology, Zurich, Switzerland*

Background: Management of patients with systemic sclerosis-associated interstitial lung disease (SSc-ILD) is complicated by high inter-patient variability. To date, no validated predictors of treatment response are available for routine use. High resolution computed tomography (HRCT)-based radiomics, i.e. the high-dimensional, quantitative analysis of imaging metadata, have previously been shown to be successful in discriminating (SSc-)ILD phenotypes in preclinical and clinical studies[1]. Since HRCT is an integral part of the routine work-up in SSc, HRCT-based radiomic features may hold potential as non-invasive biomarkers.

Objectives: To predict treatment response using two-dimensional (2D) HRCT-based radiomics in SSc-ILD patients from a prospectively followed cohort.

Methods: Inclusion criteria were diagnosis of SSc-ILD in HRCT, availability of a suitable chest HRCT scan within 12 months prior to initiation of a new treatment, and availability of clinical baseline and follow-up information. Treatment response was defined as the absence of all of the following over a follow-up period of 12-24 months: relative decrease in forced vital capacity (FVC) ≥5%, increase of ILD in HRCT as assessed by a radiologist, change in treatment regimen due to insufficient response, ILD-related death or lung transplantation. Of each pre-treatment HRCT, 6 slices (15±5 mm apart, starting from the basal lung margin) were manually segmented and 1513 2D radiomic features were extracted using the in-house software Z-Rad (Python 2.7). Features were Z-score transformed and pre-filtered for inter- and intra-reader robustness (intraclass correlation coefficient >0.85) and inter-feature correlation (Spearman's rho <0.9). A categorical linear regression model was created using 3-fold cross-validated elastic nets for feature selection. Features were then summarized and divided by their number. For generation of a score cut-off, Youden's score was used. For two-group analyses of continuous variables, Wilcoxon's test was performed, whereas categorical data was assessed using Fisher's exact test.

Results: A total of 64 pre-treatment HRCTs from 54 patients were analyzed. In 9 patients, >1 asynchronous treatments were assessed, while 45 patients had only 1 eligible treatment approach. The response rate within the assessed follow-up period was 45.3% (n=29). For score generation, 13 radiomic features were selected and an optimal cut-off value of -0.1589 was determined. Univariate linear regression showed significant association between our categorical radiomics-based score and treatment response (p=0.007, area under the curve = 0.65 (0.51-0.79), sensitivity=0.90, specificity=0.43), whereby a high score was predictive for treatment response.

No differences between patients with high (n=46) or low (n=18) scores were detected for baseline age (mean±SD=55.5±12.0 and 55.5±13.6 years, p=0.84), duration of SSc (mean±SD=6.2±8.4 and 4.7±4.4 years, p=0.79), time since ILD diagnosis (2.7±2.9 and 2.4±3.1 years, p=0.59), FVC (77.6±20.6 and 80.1±17.9, p=0.41) or DLco (54.4±21.0 and 57.6±18.9, p=0.40). Distribution of anti-Scl-70 positivity (45.7% vs. 55.6%, p=0.58) and diffuse cutaneous disease (47.7% vs. 61.1%, p=0.41) was not significantly different between patients with high and low scores, respectively, although a trend towards higher percentages in the high score group was observed.

Conclusion: Our results indicate that, following validation in external cohorts, radiomics may be a promising tool for future pre-treatment patient stratification. Moreover, our radiomics-based score seems not to be associated with commonly studied clinical predictors such as anti-Scl-70 positivity or lung function, underlining a possible additive value to 'traditional' clinical parameters.

POS0867

ALTERATION OF DUODENAL HISTOLOGY IN SYSTEMIC SCLEROSIS PATIENTS AFTER FECAL MICROBIOTA TRANSPLANTATION

H. Didriksen[1], N. Strahm[2], Ø. Molberg[1], H. Fretheim[1], T. Garen[1], Ø. Midtvedt[1], O. Distler[2], G. Kania[2], A. M. Hoffmann-Vold[1]. [1]*Oslo universitetssykehus Rikshospitalet, Rheumatology, Oslo, Norway*; [2]*University Hospital of Zürich, Rheumatology, Zürich, Switzerland*

Background: Systemic sclerosis (SSc) is a complex autoimmune, multi-organ disease with gastro-intestinal tract (GIT) involvement significantly contributing to comorbidity. While understanding of mechanisms behind SSc-related GIT disease is incomplete, recent work shows that altered gut microbiota (dysbiosis) is present in many patients and associates with specific GIT symptoms. Intending to improve dysbiosis, we set up the controlled ReSScue pilot trial, where fecal microbiota transplantation (FMT) was conducted by duodenal infusions of Anaerobic Cultivated Human Intestinal Microbiome (ACHIM) or placebo. The results indicated that FMT by ACHIM induced short-term improvement on patient reported GIT symptoms, as evaluated by the validated UCLA GIT score (1). Duodenal biopsies were taken before and after FMT to assess potential effects of ACHIM on small intestinal mucosa.

Objectives: Assessment of duodenal histology and GIT symptoms before and after FMT by ACHIM compared to placebo.

Methods: In this explorative study, we assessed duodenal biopsies collected prior to first FMT (week 0), prior to second FMT (week 2) and at study end (week 16) from ReSScue trial patients who either received ACHIM (n=5) or placebo (n=4). To examine potential effects of FMT on the duodenal mucosa, we performed immunohistochemistry (IHC) staining on paraffin-embedded tissue samples using the following markers: Sirius red (SIR) for collagen fibers and monoclonal antibodies against gp38 (podoplanin, as marker for lymphatic vessels and fibroblasts), CD38 (as preliminary marker for adaptive immune cells) and CD64 (as preliminary marker for innate immune cells). We determined staining per area in the individual tissue slides for each marker using ImageJ Fiji. The mean total UCLA GIT score for the patients were calculated at week 0, 2 and 16, as well as the mean staining per area of the duodenum biopsies at week 0, 2 and 6 for all the markers. Finally, correlations between mean staining per area and mean total UCLA GIT score were assessed for ACHIM and placebo patient groups by Pearson correlation (r).

Results: All nine patients included in the pilot trial were female and had limited cutaneous SSc. Groups receiving ACHIM and placebo had comparable disease duration (1). We found that relative change in staining per area for SIR from week 0 to week 2 differed between the ACHIM group and the placebo group (Figure 1A, left panel). Similar changes were observed for anti-gp38, anti-CD38 and anti-CD64 (left panel in Figures 1B-D). Strong correlations were found between mean total UCLA GIT score and the mean staining per area of the markers SIR (r=0.98), anti-gp38 (r=0.94), anti-CD34 (r=0.85) and CD64 (r=0.93) in the ACHIM group (Figure 1, A-D). In the placebo group, there was no correlation between the UCLA GIT score and anti-gp38 (r=0.22) and anti-CD64 (r=0.21), however, a strong correlation were observed to SIR (r=0.86) and anti-CD38 (r=0.92) staining (Figure 1A-D, right panel).

Conclusion: This explorative data set indicates different effects of FMT by ACHIM and placebo on the duodenal mucosa of SSc patients with GIT affection. Interestingly, we observed correlations between mucosal markers and improved patient reported GIT symptoms in the ACHIM group.

THE FORMULA TO PREDICT TACROLIMUS CONCENTRATION ACCORDING TO GENOTYPING OF CYP3A5 IS USEFUL FOR EFFECTIVE TREATMENT IN INTERSTITIAL LUNG DISEASE WITH DERMATOMYOSITIS

M. Katayama[1], S. Horibata[2,3], S. Takahashi[1,3], M. Takahashi[3], T. Saito[3], N. Amano[1], K. Yoshida[1], S. Hatachi[1], K. Yorifuji[2,3], S. Kumagai[1,3]. [1]*Shinko Hospital, Center for Rheumatic Disease, Kobe, Japan*; [2]*Shinko Hospital, Department of Pharmacy, Kobe, Japan*; [3]*Shinko Institute for Medical Research, Kobe, Japan*

Background: Tacrolimus (TAC), an immunosuppressant, can be used in second-line maintenance therapy for interstitial lung disease (ILD) in patients with dermatomyositis (DM) [1]. Although some studies reported the clinical efficacy of initial high-trough levels of TAC in combination with GC and IVCY in induction therapy for severe DM-ILD [2], there have been no useful clinical tools for deciding suitable initial dose of TAC. Genotype of polymorphisms in cytochrome P450 (CYP) 3A5 enzyme was reported to play an important role in pharmacokinetics of TAC [3], and we made a formula for deciding initial dose of TAC according to CYP3A5 genotypes in our previous study.
Objectives: In our previous study (retrospective study), we set the target trough according to the severity for nine DM-ILD patients, six of whom were CYP3A5 *3/*3 and investigated the dose of TAC that could attain the trough using their CYP3A5 genootyping. Using these results, we developed a formula for deciding initial daily dose of TAC (target trough*weight / [(151.1, if CYP3A5 *3/*3) or (86.5, if CYP3A5 *1 allele)]). In this study, we prospectively examined the usefulness and accuracy of this formula.
Methods: We introduced TAC for new six DM-ILD patients who visited our hospital between November 2019 and May 2020 (prospective study). The starting dose of TAC was decided by using the formula. We assessed the association between predicted and observed trough concentration of TAC at first measurement date (from day 2 to day4), using linear regression analysis. We also assessed the days for attaining the target trough concentration between the patients using the formula (prospective group) and six patients with CYP3A5 *3/*3 (retrospective group).
Results: CYP3A5 genotype of all six DM-ILD patients were *3/*3 and underwent the TAC treatment by using the formula. The predicted and observed trough concentration of first measurement date were significantly correlated in the patients (r 2= 0.897, p=0.0041) (Fig.1). Compared with our retrospective study, target trough was more quickly attained in patients of the prospective study (Fig.2).
Conclusion: The formula which we made for attainment target trough concentration based on CYP3A5 genotype was useful for deciding the starting dose of TAC. We also showed that we could attain the target trough concentration at early stage of initial treatment by using the formula.

POS0869 PREDICTIVE VALUE OF ANTI-INTERFERON-INDUCIBLE PROTEIN 16 ANTIBODIES FOR DIGITAL ULCERS OF SYSTEMIC SCLEROSIS

C. Chen[1], S. Yang[1], Z. Jiang[1], W. Wan[1], H. Zou[1], M. Liang[1]. [1]*Huashan Hospital Affiliated to Fudan University, Department of Rheumatology, Shanghai, China*

Background: Interferon-inducible protein 16 (IFI-16) is constitutively expressed in vascular endothelial cells and can inhibit the proliferation of human endothelial cells and the formation of capillary-like structures *in vitro*. Anti-IFI-16 antibodies were reported in 21%-29% of patients with systemic sclerosis (SSc) and were associated with digital vascular events in a few retrospective studies.
Objectives: To evaluate the presence and the clinical implication of anti-IFI-16 antibodies in Chinese SSc cohort, focusing on the associations with vasculopathy indexes, and to investigate the predictive value of anti-IFI-16 antibodies for the development of digital ulcers (DUs) in SSc prospectively.
Methods: Patients with SSc presenting to our center between July 2018 and September 2018 were prospectively enrolled. Serum from 42 SSc patients and 42 age- and sex-matched healthy controls were analyzed for anti-IFI-16 antibodies by enzyme-linked immunosorbent assay (ELISA), and was considered positive if the optical density (OD) value was above the mean OD of controls plus two standard deviations. Tissue immunofluorescence was used to evaluate the expression of IFI16 in skin biopsy samples obtained from SSc patients and normal controls. At baseline, nailfold video-capillaroscopy was performed to assess nailfold capillary density of SSc patients. Power Doppler ultrasound was used to grade finger pulp blood flow (0-no observed flow; 1-decreased flow; 2-normal flow), and to measure ulnar and radial artery blood flow and resistive index (RI). All patients were followed up for 6 months to see whether they experienced new onset or recurrent DUs. The association of anti-IFI-16 antibodies with DUs was analyzed using logistic regression.
Results: Of the 42 SSc patients, 8 (19.0%) were positive for anti-IFI-16 antibodies. Immunofluorescence of skin biopsy samples from SSc patients exhibited enhanced staining of IFI-16 in the dermis, and colocalization with endothelial marker CD31. SSc patients who were positive for anti-IFI-16 antibodies showed higher ulnar artery RI at baseline (0.95±0.09 vs. 0.86±0.09, p=0.015), while no significant differences were found for other vascular parameters, nor for clinical or demographic profiles. Within 6-month follow-up, 14 (33.3%) patients experienced new-onset or recurrent DUs. Univariate logistic regression revealed the presence of DUs at enrollment (p=0.009), anti-IFI-16 antibody (p=0.012), finger pulp blood flow (p=0.027), and ulnar artery RI (p=0.008) could be the predictors for the development of DUs. Multivariate analysis further identified DUs at enrollment (odds ratio [OR]: 10.85; 95% confidence interval [CI]: 1.61-73.18; p=0.014) and anti-IFI-16 antibody (OR: 15.00; 95% CI: 1.13-199.18; p=0.040) as independent risk factors. Among patients without DUs at enrollment, new-onset ulcers occurred in 80% (4/5) and 4.5% (1/22) of those with and without anti-IFI-16 antibody, respectively (p=0.001).
Conclusion: Anti-IFI-16 antibody is associated with vasculopathy in SSc and could be used as a novel biomarker for indicating the development of DUs.

R. Campanilho-Marques[1,2], I. Cordeiro[1,2]. *[1]Hospital de Santa Maria, Centro Hospitalar Universitário de Lisboa Norte, Centro Académico de Medicina de Lisboa, Lisbon, Portugal, Serviço de Reumatologia e Doenças Ósseas Metabólicas, Lisbon, Portugal*; *[2]Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Lisboa, Portugal, Lisbon, Portugal, Unidade de Investigação em Reumatologia, Lisbon, Portugal*; *[3]Centro Hospitalar Vila Nova de Gaia/Espinho, Serviço de Reumatologia, Vila Nova de Gaia, Portugal*; *[4]Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, Serviço de Reumatologia, Coimbra, Portugal*; *[5]Hospital Garcia de Orta, Almada, Portugal, Serviço de Reumatologia, Almada, Portugal*; *[6]Centro Hospitalar Lisboa Ocidental, Hospital Egas Moniz, Lisboa, Portugal, Serviço de Reumatologia, Lisbon, Portugal*; *[7]Centro Hospitalar e Universitário São João, Porto, Portugal, Serviço de Reumatologia, Porto, Portugal*; *[8]Serviço de Reumatologia, Hospital de Braga, Braga, Portugal*; *[9]Serviço de Reumatologia, Unidade Local de Saúde Do Alto Minho, Ponte de Lima, Portugal, Ponte de Lima, Portugal*; *[10]Centro Hospitalar Universitário do Algarve, Faro, Portugal, Serviço de Reumatologia, Faro, Portugal*

Background: Antisynthetase syndrome (ASyS) may have different clinical phenotypes and outcomes associated with different anti-aminoacyl RNA-synthetase (anti-ARS) antibodies. Its wide clinical spectrum can include inflammatory myopathy, interstitial lung disease (ILD), arthritis, fever, mechanic's hands, and Raynaud phenomenon (RP).
Objectives: To describe a nationwide, multicentre cohort of Portuguese patients with ASyS.
Methods: Retrospective analysis of patients with ASyS from nine Portuguese Rheumatology centers. Data on patients' signs and symptoms, laboratory results, pulmonary radiological findings (computed tomography) and treatment (immunomodulators) were collected.
Results: Among the 70 patients included, 42 patients (60%) were anti-Jo1–positive, 11 (15.7%) were anti-PL12–positive, 10 (14.3%) were anti-PL7–positive, 4 (5.7%) were anti-EJ–positive and 2 (2.9%) were anti-OJ positive. In one patient it was not possible to identify the type of antibody. Antibody overlap was found in 15 patients (21.4%), who were positive for anti-Ro52 antibodies. The general clinical characteristics are shown in Table 1. The diagnostic delay was greater in patients positive for anti-OJ, followed by anti-Jo-1 and anti-PL12. The follow-up was shorter for anti-PL7 and anti-OJ-positive patients. Anti-PL7-positive patients had lower rates of arthritis when compared to anti-Jo1 ($p< 0.01$). When compared with anti-Jo-1 ARS, myositis was less common in anti-PL12 ($p < 0.01$). ILD prevalence was similar in the different ARS subgroups. Glucocorticoids (GCs) were the most frequently used class of drugs. A more conservative treatment plan (e.g. GCs plus methotrexate or azathioprine) was the treatment of choice in ASyS with myositis and/or arthritis involvement. Rituximab or mycophenolate mofetil were preferred when lung involvement occurred. Only two deaths were reported, being one associated with lung neoplasia.
Conclusion: This is the first study investigating the clinical phenotypes of Portuguese patients with ASyS. These results are generally concordant with data retrieved from international cohorts.

POS0871

CHARACTERISTICS OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS DURING LONG TERM FOLLOW-UP, SINGLE CENTER EXPERIENCE

S. Keret[1], Y. Braun-Moscovici[2], M. Yigla[3], V. Shataylo[4], L. Guralnik[5], A. Balbir-Gurman[2]. *[1]Rambam Health Care Campus, Internal Medicine C, Haifa, Israel*; *[2]Rambam Health Care Campus, Rheumatology Institute, Rappaport Faculty of Medicine, Technion, Haifa, Israel*; *[3]Rambam Health Care Campus, Pulmonary Institute, Haifa, Israel*; *[4]Rambam Health Care Campus, Rheumatology Institute, Haifa, Israel*; *[5]Rambam Health Care Campus, Imaging Department, Rappaport Faculty of Medicine, Technion, Haifa, Israel*

Background: ILD is one the leading causes of morbidity and mortality in patients with SSc. Diagnosis of SScILD is based on signs of fibrosis on chest x-rays or HRCT. Particular measurement of lung volumes by FVC and in gas exchange by DLCO supports the diagnosis. Associations between clinically significant SSc ILD and male gender, age, DcSSc, topoisomerase antibodies, low FVC at baseline, widespread lung involvement on baseline HRCT, and higher decline rate of FVC and DLCO during followup were reported. A standardized approach to assessing and treating SSc and SScILD in particular have been proposed. Main treatment regimens include cyclophosphamide and mycophenolate mofetil; recently antifibrotic drug nintedanib showed significant efficacy in hindering FVC decline rate in patients with SSc ILD. The data on survival changes in SSc generally and SScILD are conflicting.
Objectives: To analyze demographic and clinical features and mortality of patients with SSc ILD.
Methods: A retrospective study on Rambam Health Care Campus prospective cohort of SSc patients fulfilled ACR and EULAR Classification Criteria 2013 for the period between January 2000 and September 2020 was performed. Patients were recruited at one of their early visits to the clinic. The majority of recruited patients were included into EUSTAR prospective cohort 042, since 2004 the Rheumatology Institute at Rambam is affiliated to EUSTAR registry project. Data on patients not registered in EUSTAR database but treated at our institution was extracted via hospital electronic records. Patients with lung involvement underwent baseline and annual HRCT and pumonary function tests in addition to clinical assessment during their visit to combined rheumatology-pulmonology clinic. We registered age, gender, ethnicity, date of SSc diagnosis and ILD diagnosis, disease duration, SSc subset, pulmonary, cardiac, renal, and muscle involvement, treatment used, autoantibodies, FVC, DLCO, HRCT and pulmonary artery pressure. Statistical analysis included t-test, Pearson's Chi-squared test, Fisher's test, and Cox Regression analysis with p value less than 0.05 as significant.
Results: Among 446 SSc patients (female 82.3%, mean age 46.5 and disease duration 11.6 years, DcSSc 39.2%; 27.4% dead during follow-up) 141 patients had ILD. Comparison between patient with ILD and witout ILD showed significant differences in term of nationality (Arabs 34% vs 18.7%), SSc related death 78.3% vs 50.7%), DcSSc (68.8% vs 25.6%), topoisomerase antibodies

Table 1. Patient characteristics according to the anti-ARS. ILD - interstitial lung disease; IQR- interquartile range; NSIP - Non-specific interstitial pneumonia; UIP - Usual interstitial pneumonia; yrs - years

Arthritis, n (%) and Comparison Anti-Jo.1 ARS vs PL-12 and PL-7	43 (61.4)	29 (69)	5 (45.4)	2 (20)	2 (50)-	1 (50)-
			p=0.07	***p < 0.01**		
Malignancy, n (%)	4 (5.7)	3 (7.1)	1 (9.1)	0	0	0
Deaths, n (%)	2 (2.9)	2 (2.4)	0	0	0	1 (50)

(61.7% vs 24.9%), myopathy (21.3% vs 10.2%) and pulmonary hypertension (34.8% vs 22.3%). Significantly more SSc ILD patients were treated with cyclophosphamide, mycophenolate mofetil and azathioprine. Survival Kaplan-Meier curve patiets demonstrate reduced survival in patients with ILD ($p<0.01$). Five years survival rates between years 2000 and 2015 have not changed significant. Mortality risk assessed with Cox regression analysis in the whole group was significantly higher in males, Arabs, DcSSc, elder age, heart and muscle involvement, and treatment with CYC. In the ILD group, the mortality was significantly higher in Arabs (3.3 times), elder age (8.9 times), presence of PAH (3.1 times) and treatment with CYC (2.8 times) compared to patients without ILD.

Conclusion: In our SSc cohort, ILD affected about third of patients and had major impact on patients' outcome. Male gender, Arab nationality, elder age, DcSSc, topoisomerase antibodies, heart and muscle involvement were significantly associated with worst prognosis. Despite active approach to assessing and treatment, survival rates of patients with SSc and SSc-ILD have not improved in last decades. Enrichment of the cohort with severe patients to a tertiary center due to reference bias and low efficacy of existed immunomodulatory drugs in SSc and in SSc related ILD particularly, could explain our results.

Background: Systemic sclerosis (SSc) may present distinctive manifestations and survival in different ethnic and geographic groups.

Objectives: To describe the clinical features, treatments, and survival of adult SSc patients registered in Reuma.pt/SSc.

Methods: Demographic features, SSc subsets, fulfilment of classification criteria, clinical and immunologic characteristics, comorbidities, medication and deaths were reviewed. Survival was calculated for patients included in the registry within the first 2 years of diagnosis.

Results: In total, 1054 patients were included, 87.5% female, mean age at diagnosis 52.7 ± 14.8 years. The most common subset was limited cutaneous (lc)SSc (56.3%), followed by diffuse cutaneous (dc)SSc (17.5%), preclinical SSc (13%), overlap syndrome (9.8%) and SSc sine scleroderma (3.3%). Raynaud's phenomenon (93.4%) and skin thickening (76.9%) were the most observed manifestations. Gastrointestinal (62.8% *vs* 47.8%), pulmonary (59.5% *vs* 23%) and cardiac (12.8% *vs* 6.9%) involvement were significantly more prevalent in dcSSc compared to lcSSc (Table 1). 52.5% of patients were ACA positive and 21% anti-topoisomerase positive, with significant differences between lcSSc and dcSSc. One third of patients was treated with immunomodulators, 53.6% with vasodilators, 23% received glucocorticoids and 2.3% biologics.

During the median follow-up 12.4 years, 83 deaths (7.9%) were verified. The overall 1, 2 and 5 years survival was 98.0%, 96.8% and 92.6% respectively, without significant differences between lcSSc and dcSSc (Figure 1).

Conclusion: Reuma.pt/SSc register is useful in routine patient monitoring and contributes to improve knowledge about this rare and complex disease. Clinical features of Portuguese SSc patients are similar to what has been described in other populations although the overall 5-year survival in recently diagnosed patients appears to be higher than previously reported.

Table 1. Cumulative clinical and immunologic characteristics of Portuguese SSc patients

Clinical and immunologic features	Total N=1054	Limited cutaneous SSc N= 576 (56.3%)	Diffuse cutaneous SSc N=180 (17.5%)	*P value*
Skin involvement – N(%) N=987	688 (90.6)	525 (90.7)	180 (100)	<0.01

POS0873 IMPROVEMENT IN MODIFIED RODNAN SKIN SCORE (MRSS) IN SYSTEMIC SCLEROSIS PATIENTS TREATED WITH RITUXIMAB: A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE SCIENTIFIC LITERATURE

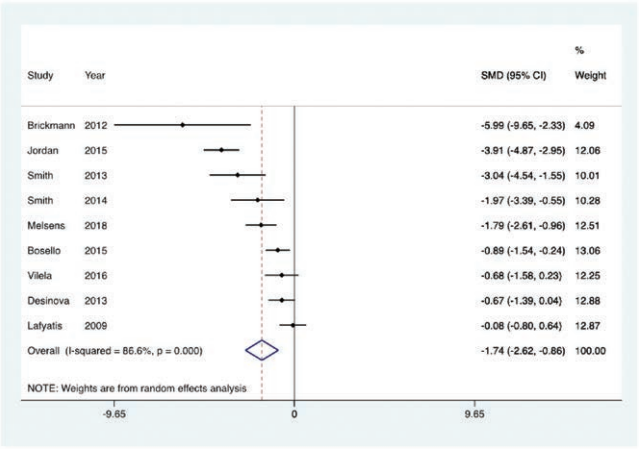
J. L. Puga Guzmán[1], D. Fernández Fernández[2,3], R. Dos-Santos[2,3], I. González Fernández[2,3], E. Perez-Pampín[3,4], A. Souto Vilas[3,4], A. Mera Varela[3,4]. *[1]Facultade de Medicina e Odontoloxía - USC, Medicine, Santiago de Compostela, Spain*; *[2]Hospital Clínico Universitario de Santiago, Rheumatology, Santiago de Compostela, Spain*; *[3]University of Santiago de Compostela, Medicine, Santiago de Compostela, Spain*; *[2]Hospital Clínico Universitario de Santiago, Rheumatology, Santiago de Compostela, Spain*

Background: Systemic sclerosis (SSc) is a chronic autoimmune disease of the connective tissue characterized by vascular disease and fibrosis in different organs and systems such as lung and skin (1). Recently, several case reports and small series of patients reported on the efficacy of rituximab in SSc, showing a possible improvement in skin and lung affectations (2). However, registered clinical trials are lacking to determine factors associated with response, maintenance regimen, and long-term efficacy of rituximab in SSc.

Objectives: To analyze the efficacy of Rituximab in the treatment of skin fibrosis using the changes of the modified Rodnan Skin Score (mRSS) of patients diagnosed with systemic sclerosis from the data published in Registered Clinical Trials (RCTs) in the scientific literature.

Methods: We perform a systematic review and a meta-analysis using the main electronic databases to locate all the articles available so far: Medline, Embase, Cochrane Library and Web of science and ACR and EULAR abstracts congress were extracted to assess efficacy outcomes. That efficacy was measured based on the variation of mRSS at 12, 24 and 48 weeks for patients treated with Rituximab versus patients treated with another drug or placebo.

Results: 3 RCTs contained data regarding mRSS at week 12 of treatment with Rituximab. The estimated SMD was -1.071 (95% CI -1.608, -0.535 [p <0.001]) with a non-significant P value in the Egger Test (P = 0.703) and non-significant heterogeneity through I2 (I2 = 0.00%).
9 studies contained data regarding mRSS at week 24 of treatment with Rituximab. The estimated SMD was -1.743 (CI95% -2.622, -0.864 [p <0.001], *see image below*) with a non-significant P value in the Egger Test (P = 0.072) and significant heterogeneity through I2 (I2 = 86.6%). Meta-regression analysis could not be performed to assess such heterogeneity, due to the lack of comparable data.



8 RCTs contained data regarding mRSS at week 48 of Rituximab treatment. The estimated SMD was -1.327 (CI95% -2.018, -0.636 [p <0.001]) with a significant P value in the Egger Test (P = 0.018), estimating that there may be publication bias in the studies analyzed and significant heterogeneity by I2 (I2 = 85.2%). Meta-regression analysis could not be performed to assess such heterogeneity, due to the lack of comparable data.
Conclusion: Our meta-analysis shows that Rituximab treatment in patients affected with systemic sclerosis shows efficacy in the treatment of cutaneous fibrosis measured by the mRSS, turning this molecule into a potential drug to add to the therapeutic armamentarium of systemic sclerosis. However, more studies are necessary to try to elucidate whether this change is powerful enough to become the new gold standard for the treatment of systemic sclerosis skin involvement.

POS0874 CLOT LYSIS TIME PREDICTS RECURRENT DIGITAL ULCERS IN SYSTEMIC SCLEROSIS AFTER ONE YEAR OF FOLLOW-UP: A NESTED CASE-CONTROL STUDY

J. Colic[1], A. Antovic[2], I. Pruner[3], J. Vojinovic[4], N. Damjanov[5], M. Sefik Bukilica[5,6]. [1]*Institute of Rheumatology, Department of Rheumatology IVb Unit, Belgrade, Serbia*; [2]*Karolinska Institutet,Karolinska University Hospital Solna, Department of Medicine, Rheumatology Unit, Stockholm, Sweden*; [3]*Karolinska Institute, Department of Molecular Medicine and Surgery, Stockholm, Sweden*; [4]*Medical Faculty, University of Nis, Department of Pediatrics, Nis, Serbia*; [5]*School of Medicine, University of Belgrade, Internal Medicine, Belgrade, Serbia*; [6]*Institute of Rheumatology, Department of Rheumatology Unit, Belgrade, Serbia*

Background: Digital ulcers (DU) are a common visible manifestation of vasculopathy in systemic sclerosis (SSc), which could be recurrent and associated with disability and mortality (1). Although vasculopathy is connected with impaired coagulation/fibrinolysis system and aberrant expression of adhesion molecules, there are few data about their role in developing recurrent DU.
Objectives: To evaluate the possible role of Fibrin generation/Fibrinolysis parameters and adhesion molecules in the prediction of new ischaemic DU oncet during a 1-year follow-up and their impact on the time to new DU onset (TD).
Methods: From 58 consecutive patients with SSc who fulfilled the 2013 ACR/EULAR SSc criteria and have never been treated with endothelin receptor antagonist, phosphodiesterase 5 inhibitors or prostanoids, a total of 38 patients with ever had DU, either active at inclusion or in past, were enrolled in a prospective cohort study. Each patient was given a "DU diary". Demografic, clinical and serologycal data were recorded. The serum concentration of ICAM1 and E selectin were measured by ELISA. Haemostatic potential parameters: overall haemostasis (OHP), overall coagulation (OCP) and overall fibrinolysis (OFP) potential were assessed. Maximum absorbance (Cmax), reflects the fibrin clot density and clot lysis time (Lys50t0, time from initiation of clot formation to the time at which a 50% fall in absorbance from Cmax in the lysis assay), reflects fibrinolytic susceptibility, were calculated (2). Fibrin structure was visualised using scanning electron microscopy (SEM).
Results: Over the follow-up period,18 patients (45.5%) developed new DU with the average TD of 7.4±2.9 months. There was no differance in ASA and CCB treatment among two groups (p>0.05). The OFP value was significantly decreased (p<0.01), Lys50t0 prolonged (p<0.05), while OHP was increased (p<0.05) in patients experienced new DU. Lys50t0 showed good validity in identifying patients with new DU oncet (AUC 0.683 95% CI 0.5 - 0.9). By multivariate analysis including clinical data in model the Lys50t0 (HR 1.2, 95% CI 1.1-1.3, p=0.018) and active DU at enrollment (HR 9.6, 95% CI 1.4-66.8, p=0.022) were identified as independent risk factors for the occurrence of new DU. TD was inversly correlated with ICAM1(p<0.001), E selectin (p<0.05), Cmax (p <0.05) and Lys50t0 (p<0.001). Model explaining 81.6% of the TD variability included Lys50t0 (β=- 0.55,p=0.003), E selectin (β=- 0.44,p=0.014) and fibrinogen (β=- 0.49,p=0.017). SEM revealed denser fibrin clots with thinner fibres in group experienced new DU compared to clots formed in plasma of patient without DU.
Conclusion: Our results provide evidence that impaired fibrinolysis has critical role in the progression of microvascular disease, identifing clot lysis time as a strong predictor in the oncet of new digital ulcers in Systemic sclerosis. The higher level of E selectin and the longer lysis time are, the shorter is time until the onset of new digital ulcer. These results could be used in selection of patients at high risk of developing recurrent digital ulcer and therefore allow earlier therapeutic intervention.

POS0875 MYOSITIS-SPECIFIC ANTIBODIES IN A RETROSPECTIVE SINGLE-CENTER OBSERVATIONAL STUDY

J. Álvarez Troncoso[1], S. Carrasco Molina[1], J. Valdivieso[2], P. Nozal[2], Á. Robles Marhuenda[1], E. Martínez Robles[1], C. Soto Abánades[1], J. J. Rios[1], A. Noblejas Mozo[1], F. Arnalich Fernández[1]. [1]*Hospital Universitario La Paz, Internal Medicine, Madrid, Spain*; [2]*Hospital Universitario La Paz, Clinical Immunology, Madrid, Spain*

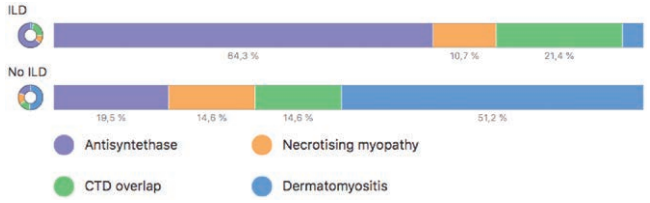
Background: Myositis-specific antibodies (MSA) are highly specific and useful to classify patients as having syndromes with distinct clinical features and prognosis. MSA are almost always mutually exclusive and quite specific, adding value as a useful biomarker for diagnosis. Although individual autoantibodies aren't sensitive enough to detect the full spectrum of idiopathic inflammatory myopathies (IIM), the sensitivity of a myositis panel is increasing as more autoantibodies are discovered, and as better assays become available.
Objectives: We aimed to analyze the usefulness of a myositis-specific immunoblot for the diagnosis of IIM in a hospital cohort from January 2019 to December 2020. We also seek to correlate immunological findings with the risk of associated interstitial lung disease (ILD), cancer, or death.

Methods: Retrospective single-center observational study conducted in a Spanish tertiary hospital. In patients with high clinical suspicion of IIM, a myositis immunoblot was performed including Jo1, PL-7, PL-12, EJ, SRP, Mi2, Ku, MDA-5, TIF1-γ, HMGCR, PM-Scl and Ro52 antibodies. The demographic characteristics, the risk of ILD, cancer and death were analyzed.

Results: In a cohort of 313 patients with high suspicion of IIM, 87 patients (27.8%) presented a positive MSA (MSA+ve). The mean age at diagnosis was 56.7±16.9 years, with no significant differences between MSA+ve and MSA-ve (p=0.597). Most of the patients were women with significant differences between both groups (80.5% MSA+ve vs 68.1% MSA-ve, p=0.030).

IIM were classified as antisynthetase syndrome (ARS) (38%), dermatomyositis (DM) (31%), overlap myopathy (OM) (16.9%) and necrotizing myopathy (NM) (14.1%) according to the manifestations and MSA found (Jo1, PL-12, PL-7, EJ in ARS; Mi-2, MDA-5 and TIF1-γ in DM; Ku and PM-Scl in OM; HMGCR and SRP in NM). The most frequent MSA were anti-Jo1 (16.9%), TIF1-γ (15.5%), Ku (12.7%), Mi-2 (9.9%), PL-7 (9.9%), HMCGR (8.5%), PL-12 (7%), MDA-5 (5.6%), SRP (5.6%) and EJ (4.2%). The presence of Ro52 associated with other MSA was found in 20 patients (22.9%).

ILD was the most frequent manifestation (45.2% of the MSA+ve). Non-specific interstitial pneumonia (NSIP) was the most frequent ILD (39.5%), followed by usual interstitial pneumonia (34.2%). The main risk factors associated with IIM-ILD were some subtypes of the MSAs (p<0.001), the association of Ro52 (p<0.001), and older age (p=0.027). Among the IIM, ARS and OM (p<0.001) were more frequently associated with IIM-ILD. The MSAs most associated with IIM-ILD were Jo1, PL-7, PM-Scl, Ku and SRP (p<0.001).



Cancer was found in 9.6% of MSA+ve patients. The most frequent tumors were gynecological (37.5%), followed by gastrointestinal (25%) and breast cancer (12.5%). Factors associated with cancer were age (p=0.010), TIF1-γ (p<0.001), SRP (p=0.004), PL-12 (p=0.013), PL-7 (p=0.047) and HMGCR (p=0.027).

The mortality of these patients was 3.5%. There were no differences regarding MSA+ve/-ve (p = 0.911). However, MDA-5 (p=0.033) and older age (p=0.001) were associated with higher mortality. There were no significant differences between the IIM classifications, the associated SAD, the presence of cancer or ILD. However, longer follow-up periods and future studies are necessary to confirm these results.

Conclusion: The use of a myositis blot allowed classifying, stratifying the risk of ILD, the risk of cancer and the risk of mortality in IIM. IIM-ILD was the most frequent complication, usually manifested as NSIP. The associated risk factors were ARS, OM, some MSAs, Ro52+ and older age. Cancer was a serious and frequent manifestation in these patients, especially in patients with TIF1-γ and other MSAs, so it is essential to know the risk factors and perform an early screening, especially in older patients.

A better knowledge of the serological profiles of IIM will provide more individualized approaches and better risk stratification, helping in the management and treatment of these patients.

POS0876 SARCOPENIA IN MYOSITIS PATIENTS: A MARKER OF MUSCLE DAMAGE ASSOCIATED WITH HANDICAP

M. Giannini[1], A. L. Charles[2], M. Pizzimenti[3], L. Debrut[3], D. A. Levy[1], R. M. Javier[4], B. Geny[3], A. Meyer[1]. *[1]University of Strasbourg, Service de Physiologie et d'explorations fonctionnelles, Nouvel Hopital Civil, Centre de Référence des Maladies Autoimmunes Rares, Fédération de Médecine Translationnelle, UR3072, Strasbourg, Strasbourg, France*; *[2]University of Strasbourg, Fédération de Médecine translationnelle, UR3072, Strasbourg, Strasbourg, France*; *[3]University of Strasbourg, Service de Physiologie et d'explorations fonctionnelles, Nouvel Hopital Civil, Fédération de Médecine Translationnelle, UR3072, Strasbourg, Strasbourg, France*; *[4]Centre Hospitalier Universitaire, Strasbourg, Department of Rheumatology, Strasbourg, France*

Background: Myositis are systemic autoimmune rare diseases characterized by muscle inflammation and weakness. Even though the signs of active disease have been resolved, myositis patients frequently present residual muscle weakness, decreased physical performance and sustained disability. This condition has been coined on the term "damage" (as opposed to "activity").

Sarcopenia is a frequent, progressive and generalized skeletal muscle disorder characterized by low muscle strength and mass leading to handicap, decreased quality of life and increased mortality.[1]

Prevalence and significance of sarcopenia in myositis patients has never been reported.

Objectives: To study sarcopenia in myositis patients with low or no disease activity.

Methods: Adult myositis patients (2017 ACR/EULAR criteria), with disease duration greater than 12 months, creatine kinase serum level (CK) less than 500 U/l, stable medication for 6 months were enrolled. Patients with inclusion body myositis were excluded. Total (LM) and appendicular (ALM) muscle mass were measured using dual-energy X-ray absorptiometry (DXA, Hologic) and muscle grip strength was measured using Jamar dynamometer. Sarcopenia was defined according to the EWGSOP2 consensus.[1]

Results: 29 patients (20 female, 68.9%), with a median age of 61 years (50.5-71) were enrolled. They suffered from dermatomyositis (DM, n=4), immune-mediated necrotizing myopathy (IMNM), n=8), anti-synthetase syndrome (ASS, n=9), scleromyositis (SM, n=8) since 4.7 years (2.8-8.3). At the evaluation, muscle strength assessed with MMT-8 was 139/150 (136-147), MMT-12 was 210/220 (204-216) and CK were 131.5 U/l (105.5-202). Four patients (13.8%) were sarcopenic. Sarcopenic patients were older (73.4 years (66.2-80.5) vs 58.7 years (44.2-79.6), p=0.03), with a longer disease duration (7.3 years (5.3-11.8) vs 4.3 (2.7-8.3), p = 0.1), longer time with increased CK (449 days (169.8-954) vs 255.5 (124-872.8)), higher maximum CK values (6000 U/l (2205-7000) vs 1636 (900-4457)). They suffered from IMNM (2/4, 50%); DM (n=1) and SM (n=1), had more frequently disease-related cardiac involvement (50% vs 4%, p=0.04), and tended to a longer steroid therapy duration (2.4 years (0.8-5) vs 1.8 (1.3-3.9), p=0.9) and a higher number of immunomodulatory drugs (2.5 (2-5.3) vs 2 (2-3), p=0.3).

At the evaluation, sarcopenic patients were globally weaker as highlighted by lower MMT-12 (201 (196.8-206.8) vs 213 (207-217.5), p=0.02). Head flexo-extensors and proximal upper muscles were especially weaker (respectively, p=0.04 and p=0.03). Muscle performance was also lower in sarcopenic patients as assessed by distance covered at 6-minute walk test (6mWT, p=0.003) and number of squats in 30 seconds (p=0.005). Time to drink a glass of water was significantly longer in sarcopenics (p=0.04) even if any patient referred dysphagia. Health assessment questionnaire score was greater (1.4 (0.8-2) vs 0.6 (0.2-1), p=0.04) indicating higher handicap. LM positively correlated with MMT-8 (ρ=0.5, p=0.01) and MMT-12 (ρ=0.5, p=0.004), with number of squats in 30 seconds (ρ=0.7, p=0.0003) and 6mWT distance covered/lower limit (ρ= 0.5, p=0.01). Moreover, LM negatively correlated with time to drink a glass of water (ρ=-0.6, p=0.002).

Conclusion: Muscle mass measured by DXA is a relevant parameter for muscle damage and disability in myositis patients. Sarcopenic myositis patients represent a subgroup with important muscle damage and handicap.

Background: Digital ulcers (DUs) affect half of the patients with systemic sclerosis (SSc) and can be complicated by gangrene and amputation. The direct involvement of platelets in the development of DUs has been suggested by *in vitro* studies, which encouraged physicians to consider platelet inhibitors as a therapeutic option in the management of DUs. However, until now, there is no clinical study to assess the efficacy of platelet inhibitors for DUs in SSc patients.
Objectives: To demonstrate a possible relationship between treatment with platelet inhibitors and the occurrence of DUs at the next follow-up visit in patients with SSc.
Methods: This study used prospectively collected data from the European Scleroderma Trials and Research group (EUSTAR) registry. Patients fulfilling the 2013 ACR/EULAR SSc classification criteria with complete longitudinal data on the presence of DUs and platelet inhibitors were included in the analysis. Multiple imputation using a random forest algorithm was implemented to handle missing values.
The dataset was split into a derivation and validation cohort. To investigate the response for the binary dependent variable of DUs, a generalized linear mixed model (GLMM) was developed in the derivation cohort and validated using ROC analysis and Brier scores to address discrimination and calibration, respectively.
Results: Of 3,463 patients (2,961 in the derivation cohort, 722 in the validation cohort), 453 had current DUs at the baseline and 245 were exposed to platelet inhibitors (table 1). Our GLMM revealed that the exposure to platelet inhibitors is associated with a reduced risk of DUs at the next follow up visit (OR = 0.33, 95% CI = [0.13 to 0.82]). Further factors associated with absence or presence of DUs at the next follow-up visit are shown in figure 1. This confirmed the previously identified risk factors for the presence of DUs, supporting the overall robustness and the validity of our model.
The performance was evaluated by ROC curve analysis and showed an AUC = 97.97% (95% CI = [96.93% to 97.67%]) for the derivation cohort and AUC = 77.3% (95% CI = [74.01% to 81.39%]) for the validation cohort, respectively, showing an acceptable discrimination. The Brier score was 0.05 in the derivation cohort and 0.07 in the validation cohort, suggesting a good calibration of the model.
Conclusion: Our model, with acceptable discrimination and good calibration, suggests a positive treatment effect of platelet inhibitors on DUs in clinical practice.

Table 1. Baseline characteristics of patients before imputation

Characteristics	Overall	Derivation set	Validation set
n	3,463	2,691	772
Age (median [IQR])	56.00 [47.00, 66.00]	56.00 [47.00, 65.00]	57.00 [48.00, 67.00]
Disease duration (median [IQR])	9.00 [4.00, 16.00]	9.00 [4.00, 16.00]	8.00 [4.00, 15.00]

POS0878 ULTRASOUND ASSESSMENT OF DERMAL THICKNESS AND SKIN STIFFNESS IN UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE AT RISK FOR SYSTEMIC SCLEROSIS

T. Santiago[1,2], M. Luis[1], J. Lima[2], C. Gaspar[2], M. J. Salvador[1,2], J. A. P. Da Silva[1,2]. [1]*Centro Hospitalar e Universitário de Coimbra, Rheumatology Department, Coimbra, Portugal*; [2]*Faculty of Medicine, University of Coimbra, Institute for Clinical and Biomedical Research (iCBR), Coimbra, Portugal*

Background: High-frequency ultrasound (HFUS) and shear-wave elastography (SWE) allow an objective assessment of skin involvement in systemic sclerosis (SSc) patients.[1] Till now it has been applied to patients with established diagnosis.[2,3] However, there is no data concerning its application in Undifferentiated Connective Tissue Disease at risk for SSc (UCTD-risk-SSc), i.e., patients with Raynaud's phenomenon and either SSc marker autoantibodies or typical capillaroscopic findings or both, not satisfying classification criteria for SSc.[4]
Objectives: To compare ultrasound-dermal thickness (DT) and skin stiffness, using high-frequency ultrasound and shear-wave elastography, in UCTD-risk-SSc and healthy controls.
Methods: Forty UCTD-risk-SSc patients and 40 age- and gender-matched healthy controls were included. Ultrasound-DT was measured using an 18MHz probe, and skin stiffness (i.e. shear-wave velocity values, SWV) using the VTIQ software with a 9MHz probe, at the 17 Rodnan skin sites. The mRSS score was, by definition, zero in all sites, both in cases and controls. Continuous data were expressed as the mean (SD), and Mann-Whitney U test was performed to compare differences between the groups, as variables were not normally distributed. Associations between variables were analysed using the Spearman's correlation.
Results: SWV values were significantly higher in patients with UCTD-risk-SSc compared with controls at the right and left hands, and in the right and left fingers (table 1). Higher values of ultrasound dermal-thickness were found in the fingers and hands bilaterally, although differences were only significantly at the hands, compared with healthy controls (table 1). There were no significant differences in the other Rodnan skin sites. There was no significant correlation between ultrasound-dermal thickness and stiffness at the same skin site.
Conclusion: This study provides the first evidence suggesting that ultrasound-DT and stiffness can discriminate patients with UCTD-risk-SSc from healthy controls. Prospective studies including a larger number of patients with different subsets of UCTD-risk-SSc are needed to investigate diagnostic and prognostic value of the ultrasound parameters in this group.

POS0879 CLINICAL FEATURES, PROGNOSTIC FACTORS, AND OUTCOME OF ANTI-MDA5 POSITIVE DERMATOMYOSITIS WITH RAPIDLY PROGRESSIVE INTERSTITIAL LUNG DISEASE: A MULTICENTER STUDY OF 238 PATIENTS

L. Xu[1], L. Wang[1], C. LV[1], W. Tan[1]on behalf of Myositis Study Group Jiangsu cohort. [1]*The First Affiliated Hospital of Nanjing Medical University, Department of Rheumatology, Nanjing, China*

Background: Anti-melanoma differentiation-associated gene 5 positive dermatomyositis (anti-MDA5$^+$ DM) is typically amyopathic and associated with a life-threatening, therapy-resistant, rapidly progressive interstitial lung disease (RP-ILD).
Objectives: The present study aims to characterize the prognostic factors and long-term outcome of MDA5$^+$ DM -associated RP-ILD.
Methods: A multicenter retrospective study was performed across ten tertiary hospitals in China between January 1, 2018 to December 31, 2019.
Results: A total of 238 patients (170 women) with MDA5$^+$ DM enrolled into this retrospective clinical study. The mean age was 53.0 ± 12.2 years. The median follow-up duration was 6.3 ± 12.2 months. Of those 238 anti-MDA5+ patients, ILD is commonly observed in 213 patients, and RP-ILD occurred in 35.29% (84/213) of these patients (RP-ILD defined as progressive dyspnea occurs within 1 month after the onset of respiratory symptoms, and chest radiography or pulmonary function test show progressive interstitial abnormalities). The mortality rate of RP-ILD patients within the 6 months was 58.3% (49/84) in our cohort. Death peaked the first three months after diagnosis, occupying 84.8% (39/46) of died RP-ILD patients. Cox univariate proportional hazard analysis showed that age, gender, disease duration, abnormal laboratory features (LDH, CK, ESR and CRP), anti-Ro52 autoantibody and anti-MDA5 grade were related to the risk of occurrence of RP-ILD in patients with MDA5$^+$ DM. The Cox proportional hazards model identified the disease duration [odds ratio (OR) 0.81 (95% CI 0.68, 0.96), P=0.016] as a protective factor, and anti-Ro52 autoantibody [OR 5.82 (95% CI 1.72, 19.73), P=0.005] as independent risk factors for the occurrence of RP-ILD in MDA5$^+$ DM patients. The 6-month all-cause mortality rate of RP-ILD patients was 58.3% (49/84).
Conclusion: Combined with anti-Ro52 in Myositis-specific antibodies was associated with the occurrence and long-term mortality in MDA5$^+$ DM -associated RP-ILD patients. The results suggest poor overall survival among patients with MDA5$^+$ DM -associated RP-ILD. Survival during the first 6 months is crucial for long-term survival. Early recognition and prompt treatment of this high-risk group of MDA5$^+$ DM -associated RP-ILD patients are therefore important.

POS0880 TWO-MINUTE WALK TEST AS A SIMPLE AND OBJECTIVE OUTCOME MEASURE IN IDIOPATHIC INFLAMMATORY MYOSITIS

S. K. Dunga[1], C. Kavadichanda[2], V. Negi[2]. [1]*Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Clinical Immunology, Puducherry, India*; [2]*Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Clinical Immunology, Puducherry, India*

Background: Manual muscle testing (MMT) and Functional index 2(FI-2) are the usual methods in assessing disease activity in IIM[1]. Limitations of MMT8 include low sensitivity to change, floor/ceiling effect, and under-representation of certain important muscle groups[1] while FI-2 takes a longer time to administer. Several Timed function tests (TFTs) like the 2-minute walk test (2MWT) or 30s raise from a chair test and 30s 1kg arm rise test may be better alternatives and less time taking[2]. Data looking at the performance of these tests are limited to small controlled studies.
Objectives: To assess the performance of timed function tests against MMT8 and FI-2 in assessing muscle strength and endurance at baseline, 3 and 6 months of therapy.
Methods: An observational cohort study, included 41 patients with polymyositis and dermato-myositis attending OPD and IPD service of tertiary centre. MMT8, FI-2 and Timed function tests were done at baseline, at 3 months and at 6 months. (Figure 1)

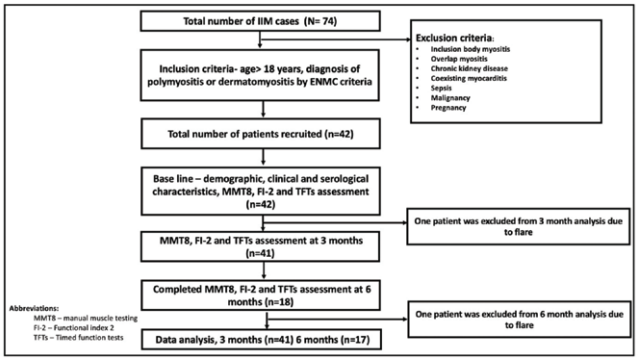

Figure 1. Consort diagram showing the workflow in study population

Results: Forty one patients included in the study had completed three month follow-up assessment, while 17 patients achieved a six-month evaluation. Out of 41 patients, 11 (27%) were polymyositis, and 30 (73%) were dermatomyositis. The mean MMT8 of the total study population at baseline was 57±15, at three months (n=41) was 66 ±10 and at six months (n=17) was 71 ± 10, while in active subgroup was 50 ± 18, 64 ± 9 (n=41), 67 ± 9.6 (n=17)at baseline, three months and six months respectively. The change in TFTs showed a moderate to strong correlation with the change in Fi-2 among the study population at three months and six months (Table 2). Among the TFTs 2MWT showed moderate correlation with both MMT8 and FI-2 in active disease.

Table 1. Spearman Rho Correlation between change in timed function tests with change in MMT8, change in FI-2 at 3 months and 6 months

		At 3 months (n=41)		At 6 months (n=17)	
		Active disease (n=18)	Inactive disease (n=23)	Active disease (n=7)	Inactive disease (n=10)
Correlation of Δ MMT8 with	**Δ30s rise form chair**	0.143	0.346	0.200	0.347
	Δ30s1kg arm lift	0.018	0.284	0.362	0.168
	Δ2MWD	**0.755***	0.313	**0.482***	0.334
Correlation of ΔFI-2 with	**Δ30s rise form chair**	**0.784***	**0.495***	**0.486***	**0.424***
	Δ30s1kg arm lift	**0.671***	0.107	**0.704***	0.301
	Δ2MWD	**0.834***	**0.623***	**0.808***	**0.506***

***p<0.05**

Conclusion: Using timed function tests can be an excellent alternative to FI-2 in assessing muscle endurance. 2-minute walk distance is a better alternative to conventional muscle testing as it measures both power and endurance, and this can overcome the ceiling effect of MMT-8.

POS0881

DETECTION OF THE GENE EXPRESSIONS IN PERIPHERAL BLOOD INVOLVED IN THE PROGRESSION OF PULMONARY VESSEL DISEASE AT THE SUBCLINICAL STAGE OF PULMONARY HYPERTENSION ASSOCIATED WITH SYSTEMIC SCLEROSIS

Y. Koyama[1], Y. Sato[2], T. Shoji[2], S. Fuke[3], T. Umayahara[4], M. Sakamoto[1]. [1]*Japanese Red Cross Okayama Hospital, Rheumatology, Center for Autoimmune Diseases, Okayama, Japan*; [2]*DNA Chip Research Inc., N/A, Tokyo, Japan*; [3]*Japanese Red Cross Okayama Hospital, Cardiology, Okayama, Japan*; [4]*Japanese Red Cross Okayama Hospital, Dermatology, Okayama, Japan*

Background: Pulmonary hypertension (PH) is prominent as a vascular involvement of systemic sclerosis (SSc), which remains a leading cause of death in spite of current best treatments. Recently, hemodynamic definition of PH was updated from mPAP≥25mmHg to mPAP>20mmHg and PVR≥3WU. Although new definition may improve the prognosis of PH associated with SSc by giving a chance to start management early, it may be insufficient as more than 2/3 of the pulmonary circulation is already impaired by the time of meeting the definition. Therefore, the ideal therapeutic intervention should be started at the subclinical stage of PH in SSc patients, but little is known about underlying pathological mechanisms at the stage. In this study, we investigate progression to exercise-induced PH (exPH)[1)], which is considered subclinical PH, in the prospective registry of high-risk population for developing PH associated with SSc.

Objectives: To detect the gene expressions in peripheral blood involved in the progression of pulmonary vessel disease (PVD) at the subclinical stage of PH associated with SSc.

Methods: Total of 180 patients who had not met PH criteria with Raynaud phenomenon, skin sclerosis or SSc-related autoantibody was registered. To detect the early PVD, exercise Doppler echocardiography (exDE) was carried out every 6 or 12 months for up to 6 years. The definition of exPH was maximum sPAP>40mmHg or increase in sPAP>20mmHg estimated by exDE during exercise. For gene expression analysis, total RNAs from whole peripheral blood cells were extracted by PAXgene system, and then multiplex sequencing was done. To identify candidate genes involved in the progression to exPH, random forest machine learning method was employed. Volcano plots, a scatter plots to visualize fold-changes and p-values of differentially expressed genes (DEGs) between exPH and others (exN), were also used for seeking the important genes for disease progression.

Results: At the time of registration, 34.4% of patients met exPH criteria, and 15.6% of patients developed exPH during follow-up period (35.0±18.1 months). Expression of TNF gene was selected as the most useful genes to predict progression to exPH by random forest, and the accuracy of the model was about 87%. Volcano plots indicated that expressions of TMEM176A and TMEM176B were prominent (fold-change >2.4 and -log10 p-value >3.5) in exPH patients. The accuracy was improved to 90% if the expression of TNF and TMEMA/B were used for the prediction of progression to exPH. We found that statistically significant increase in the expression of TNF was eliminated at the time of fulfilling the exPH criteria, while increase in expressions of TMEM A/B were still kept.

Conclusion: It was reported that TNFα drives pulmonary arterial hypertension by suppressing the BMP type-II receptor and altering NOTCH signalling[2)]. Our findings suggest that TNFα plays important role only in the period of pre-exPH. On the other hand, increase in expressions of TMEM A/B were observed through the period of pre-exPH to post-exPH. It suggests that there are multiple phases before developing PH associated with SSc. It is very important to understand the phases for the precise treatment to arrest the progression of PVD.

POS0882

AMINAPHTONE LONG-TERM TREATMENT IN SYSTEMIC SCLEROSIS

A. Sulli[1], E. Gotelli[1], A. Cere[1], E. Hysa[1], G. Pacini[1], C. Pizzorni[1], S. Paolino[1], M. Cutolo[1]. [1]*Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genova, Italy*

Background: Aminaphtone has been used since many years to treat microvascular disorders. Aminaphtone seems to improve clinical symptoms of Raynaud's phenomenon (RP), either primary or secondary to systemic sclerosis (SSc) by increasing peripheral blood perfusion as assessed by Laser speckle contrast analysis (1).

Objectives: To evaluate long-term survival and tolerability of Aminaphtone in SSc patients with secondary RP.

Methods: Eighty SSc patients (mean age 64±12 years; mean disease duration 9±8 years) treated with Aminaphtone due to active RP were enrolled (ACR/EULAR 2013 criteria). Patients were taking also various concomitant treatments, including aspirin, cyclic intravenous iloprost, immunomodulators, endothelin receptor antagonists. SSc patients performed periodic clinical and laboratory assessments on average every four months per our clinical practice. Duration of Aminaphtone administration, side effects, and self-assessment of Raynaud Condition Score (RCS) with a scale from 0 (absence of pain) to 10 (maximal pain) were retrospectively assessed.

Results: The observation period was between twelve and seventy months (mean 36±19 months). Aminaphtone was administered at 75 mg twice daily, as standard initial posology per our clinical practice. During the follow-up, five patients (6.2%) referred headache as side effect: three of them had to reduce Aminaphtone posology to 75 mg per day, while maintaining clinical benefits; two patients had to stop the treatment. No other side effects related to the drug appeared during the treatment period, and repeated blood tests did not reveal any significant alteration ascribable to Aminaphtone. After 3 months of treatment sixty-six patients (83%) referred a subjective improvement of RP (RCS 3.6±0.8, vs baseline RCS 7.4±0.8, p=0.032), whereas fourteen patients (17%) were clinically unsatisfied (RCS 6.1±0.4, p=0.12). In this last group of patients, Aminaphtone posology was increased to 75 mg three times a day with a satisfactory amelioration in further nine patients (94% of total) (RCS 4.0±0.6, p=0.04), while five patients (6.2%) definitively discontinued therapy for subjective ineffectiveness within six months. Patients referred a sustained improvement of RCS along the observational period (36±19 months) (last RCS 3.6±0.7 vs baseline, p=0.031).

Conclusion: During an average observation period of three years, Aminaphtone showed a good tolerability profile along with sustained efficacy in 94% of patients with SSc-related RP, without disabling side effects. The absence of a placebo-control group, the retrospective design limit the results, and a randomized controlled trial for Aminaphtone use in the management of SSc-related RP is needed.

DETECTION OF AUTOANTIBODIES AGAINST MUSCLE-SPECIFIC FOUR-AND-A-HALF-LIM DOMAIN 1 (FHL1) IN INFLAMMATORY MYOPATHIES: RESULTS FROM A SINGLE-CENTER COHORT

A. S. Galindo-Feria[1,2], B. Horuluoglu[1,2], J. Day[3], C. Cerqueira[1,2], S. Proudman[3], I. E. Lundberg[1,2], V. Limaye[3]. [1]*Karolinska Institutet, Solna, Karolinska University Hospital, Division of Rheumatology, Department of Medicine, Stockholm, Sweden*; [2]*Karolinska Institutet and Karolinska University Hospital Solna, Center for Molecular Medicine, Stockholm, Sweden*; [3] *Royal Adelaide Hospital, University of Adelaide, Rheumatology Unit and Discipline of Medicine, Adelaide, Australia*

Background: Autoantibodies targeting a muscle-specific autoantigen, four-and-a-half-LIM-domain 1 (FHL1), have been previously identified in patients with idiopathic inflammatory myopathies (IIM) (1).

Objectives: The aim of this project was to determine the prevalence and associations of anti-FHL antibody in South Australian patients with histologically-confirmed IIM and in an autoimmune disease control (systemic sclerosis (SSc)).

Methods: Sera from patients with IIM (n=267) from the South Australian Myositis Database (SAMD), and SSc (n=174) from the Australian Scleroderma Cohort Study (ASCS) followed at the Royal Adelaide Hospital, and healthy controls (HC, n=100) were analyzed for anti-FHL1 autoantibodies by Enzyme-Linked ImmunoSorbent Assay (ELISA). Clinical, serological and histological details were retrieved from the SAMD and the ASCS.

Results: Autoantibodies to FHL1 were more frequent in patients with IIM (55/267, 20.5%) compared with SSc (18/174, 10%) ($p<0.001$) and HC (4/100, 4%) ($p<0.001$). Muscular vessel inflammation and atrophy were seen more frequently in IIM anti-FHL1$^+$ patients compared with anti-FHL1$^-$ ($p<0.01$ and $p<0.05$). Dysphagia, marked muscle atrophy, and high CK levels were frequent in anti-FHL1$^+$ patients with inclusion body myositis (IBM) and immune-mediated necrotizing myopathy (IMNM). In 35/54 anti-FHL1$^+$ patients, there were no other myositis-specific autoantibodies present. Anti-FHL1 autoantibodies in patients with SSc were associated with gastric antral vascular ectasia.

Conclusion: Anti-FHL1 autoantibodies were detected in 20.5% of IIM patients. In IBM and IMNM, the presence of anti-FHL1-autoantibodies was associated with a severe myopathy as suggested by presence of dysphagia and muscle atrophy.

POS0884 THE ENHANCED LIVER FIBROSIS (ELF) SCORE AS A BIOMARKER OF SKIN FIBROSIS IN SYSTEMIC SCLEROSIS

C. Chen[1], S. Yang[1], Z. Jiang[1], W. Wan[1], H. Zou[1], M. Liang[1]. [1]*Huashan Hospital Affiliated to Fudan University, Department of Rheumatology, Shanghai, China*

Background: Serum fibrotic markers for systemic sclerosis (SSc) remain limited. The Enhanced Liver Fibrosis (ELF) score, originally derived and validated in patients with chronic liver disease, is an algorithm combining 3 serum markers, known as procollagen type III amino terminal propeptide (PIIINP), tissue inhibitor of metalloproteinases 1 (TIMP-1), and hyaluronic acid (HA). The combined score was proved to be superior to the single components in reflecting the severity of liver fibrosis. However, the performance of ELF score and its components has not been fully validated in SSc.

Objectives: To investigate PIIINP, TIMP-1, HA, and the combined algorithm ELF score as fibrotic markers for SSc skin involvement.

Methods: Eighty SSc patients (44 dcSSc and 36 lcSSc), fulfilling the 2013 ACR/EULAR criteria with the absence of chronic liver diseases, were enrolled. Eighty age- and sex- matched healthy controls were also included. Serum PIIINP and HA levels were quantified by chemiluminescence immunoassay. Serum TIMP-1 levels were determined by enzyme-linked immunosorbent assay. The ELF score was calculated using the formula *ELF score= 2.494+0.846*ln(HA) + 0.735*ln(PIIINP) + 0.391*ln(TIMP-1)*. Results were correlated with clinical profiles including modified Rodnan skin score (mRSS) and interstitial lung disease (ILD).

Results: Compared with healthy controls, patients with SSc showed significantly elevated serum PIIINP (11.2±4.8 vs. 5.73±1.4μg/L, p<0.001), TIMP-I (123.7±78.6 vs. 67.8±26.5 ng/ml, p<0.001), and ELF score (10.5±0.9 vs. 9.7±0.4, P<0.001). Even higher levels of PIIINP, TIMP-1, and ELF score were observed in dcSSc patients, compared with lcSSc patients (p<0.001, p=0.024, p=0.003, respectively). No significant difference was found in the levels of serum HA between patients and controls. Strong correlations were observed between mRSS and ELF score (r=0.54, p<0.001), and between mRSS and PIIINP(r=0.62, p<0.001), whereas only weak correlations could be observed between mRSS and TIMP-1 (r=0.28, p=0.02), and between mRSS and HA (r=0.26, p=0.03). When stratified by ELF score, using cutoffs proposed for liver fibrosis and cirrhosis, SSc patients with ELF<9.8 showed the lowest mRSS on average, while patients with ELF>11.3 showed the highest (p<0.001). When stratified by serum PIIINP levels, using the 25th and 75th percentiles, SSc patients with serum PIIINP levels<7.8μg/L showed the lowest mRSS on average, while patients with PIIINP>14.0μg/L showed the highest (p<0.001). Neither the ELF score nor its components showed significant difference between patients with and without ILD.

Conclusion: The ELF score could be used for reflecting the severity of overall skin involvement in SSc, and serum PIIINP also increased in parallel with the increase of mRSS. Longitudinal prospective studies exploring ELF score or serum PIIINP as fibrotic markers and outcome measures of SSc are warranted.

POS0885 HIGH INCIDENCE AND MORTALITY OF PNEUMOCYSTIS JIROVECI INFECTION IN ANTI-MDA5-ANTIBODY POSITIVE DERMATOMYOSITIS: EXPERIENCE FROM A SINGLE CENTER

Q. Yan[1], S. Chen[1], L. Huang[1], Q. Fu[1], Y. Ye[1]. [1]*Renji Hospital, Shanghai Jiaotong University, School of Medicine, Department of Rheumatology, Shanghai, China*

Background: Idiopathic inflammatory myopathies (IIM) was associated with a significantly higher risk of opportunistic infections that including Pneumocystis jiroveci pneumonia(PJP) which is potentially fatal opportunistic infection. However, no prior studies have evaluated the PJP infection in subtypes of IIM.

Objectives: To investigate the incidence rate and mortality rate of PJP infection in subgroups of IIM patients according to myopathy specific antibodies.

Methods: In the first part, we reviewed 463 consecutive patients with IIM retrospectively to analyze incidence of PJP infection. In the next part, we enrolled 30 consecutive PJP infection patients with any rheumatic disease was to identify the mortality rate and risk factors. Kaplan-Meier curve with log rank test was used to access differences in survival. Univariate and multivariate analyses were performed to identify prognostic factors using Cox regression.

Results: We found that 12(7.5%) PJP cases occurred in 160 anti-MDA5-ab-positive DM patients, while only two (0.7%) PJP cases were found in 303 anti-MDA5-ab-negtive DM/PM patients($P < 0.05$). PJP infection typically happened in the first two months of the treatment for anti-MDA5-ab-positive DM patients who have a significant decrease in the CD4+ T cell counts and Lymphocyte counts ($P < 0.05$). Only two (16.7%) anti-MDA5-ab-positive DM patients recover from PJP, with lethally higher mortality than those PJP infection with other rheumatic diseases (83.3% vs. 38.9%, $P < 0.05$). We found no association between the time to anti-PJP treatment and treatment outcomes in anti-MDA5-ab-positive DM; yet we confirmed in PJP infection with other rheumatic diseases that anti-PJP treatment within 6 days crucially increased the survival ($P < 0.05$).

Conclusion: PJP infection has alarming high incidence and mortality in anti-MDA5-ab-positive DM patients. Unlike PJP infection with other rheumatic diseases, timely treatment for PJP doesn't improve the prognosis of this particular subtype. Therefore, the necessity of further study of PJP prophylaxis treatment in anti-MDA5-ab-positive DM patients is verified.

POS0886 COULD BE INTERSTITIAL MYOCARDITIS A FEATURE OF THE ANTISYNTHETASE SYNDROME?

A. Gil-Vila[1], G. Burcet[2], A. Anton-Vicente[1], D. Gonzalez-Sans[1], A. Nuñez-Conde[1], E. Trallero-Araguás[3], J. L. Reyes-Juárez[2], C. P. Simeón-Aznar[1], A. Selva-O'callaghan[1]. [1]*Vall d'Hebron University Hospital, Internal Medicine, Barcelona, Spain*; [2]*Vall d'Hebron University Hospital, Cardiovascular Imaging, Radiology, Barcelona, Spain*; [3]*Vall d'Hebron University Hospital, Rheumatology, Barcelona, Spain*

Background: Antisynthetase syndrome (ASS) is characterized by inflammatory myopathy, interstitial lung disease, arthritis, mechanical hands and Raynaud phenomenon, among other features. Recent studies have shown that idiopathic inflammatory myopathies (IIM) may develop cardiac involvement, either ischemic (coronary artery disease) or inflammatory (myocarditis). We wonder if characteristic lung interstitial involvement (interstitial lung disease) that appears in patients with the ASS may also affect the myocardial interstitial tissue. New magnetic resonance mapping techniques could detect subclinical myocardial involvement, mainly as edema (increase extracellular volume in interstitium and extracellular matrix), even in the absence of visible late Gadolinium enhancement (LGE).
Objectives: Our aim was to describe the presence of interstitial myocarditis in a group of patients with ASS.
Methods: Cross-sectional, observational study performed in a tertiary care center. We included 13 patients diagnosed with ASS (7 male, 53%, mean (SD) age at diagnosis 56,8 years (±11,8)). The patients were consecutively selected from our outpatient myositis clinic. Myositis specific and associated antibodies were performed by means of line immunoblot (EUROIMMUN©). Cardiac magnetic resonance (CMR) was performed on all patients. The study protocol includes functional cine magnetic resonance and standard late gadolinium enhancement (LGE), as well as novel parametric T1 and T2 mapping sequences (modified look locker inversion recovery sequences - MOLLI) with extracellular volume (ECV) calculation 20 minutes after the injection of a gadolinium-based contrast material.
Results: CMR could not be performed in one patient due to anxiety. All patients studied (12) had a normal biventricular function, without alteration of segmental contraction. A third (4 out of 12, 33%) of the studied patients showed elevated T2 myocardial values without focal LGE, half of them (2/4) with an elevated ECV, consistent with myocardial edema. Two patients with normal T2 values showed unspecific LGE focal patterns, one in the right ventricle union points and another with mild interventricular septum enhancement (Figure 1). None of the patients studied refer any cardiac symptomatology. All the four patients with T2 mapping alterations (100%) had interstitial lung involvement, but only 4 out of 8 (50%) of the rest ASS patients without T2 mapping positivity. The autoimmune profile was as follows: 10 anti-Jo1/Ro52, 1 anti-EJ/Ro52, 2 anti-PL12.

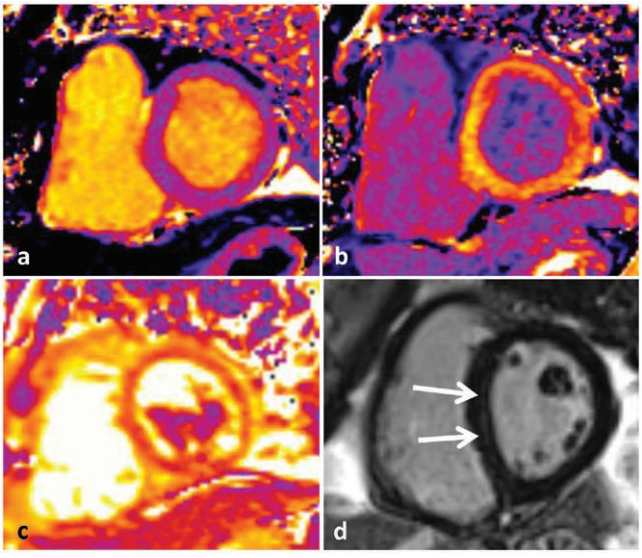

Figure 1. Cardiac magnetic resonance images from ASS patients.

Conclusion: Myocarditis, although subclinical, appears to be a feature in ASS patients. T1 and T2 mapping sequences might be valuable to detect and monitor subclinical cardiac involvement in these patients. The possibility that the same etiopathogenic mechanism may be involved in the interstitial tissue in lung and myocardium is raised. More studies must be done in order to assert the prevalence of myocarditis in ASS.

POS0887 TRANSCRANIAL ELECTRICAL STIMULATION IS SAFE AND EFFICIENT IN PATIENTS WITH SYSTEMIC AUTOIMMUNE MYOPATHIES

L. F. Adsuara de Sousa[1], R. G. Misse[1], L. De Macedo Dos Santos[2], A. Fontes Baptista[3], C. Tanaka[2], J. M. D'andréa Greve[4], S. Katsuyuki Shinjo[1]. [1]*Faculdade de Medicina FMUSP, Universidade de Sao Paulo, Division of Rheumatology, Sao Paulo, Brazil*; [2]*Speech Therapy and Occupational Therapy, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Department of Physical Therapy, Sao Paulo, Brazil*; [3]*Universidade Federal do ABC, Center for Mathematics, Computing and Cognition, Santo Andre, Brazil*; [4]*Institute of Orthopedics and Traumatology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Laboratory of Movement Studies, Sao Paulo, Brazil*

Background: There is currently few information regarding rehabilitation in patients with systemic autoimmune myopathies (SAMs). Transcranial direct current stimulation (tDCS) has shown promising results for the motor performance of healthy individuals as for patients with, e.g., post-stroke hemiparetic limbs.
Objectives: The present study was aimed to assessing the safety and efficiency of tDCS in patients with SAMs.
Methods: This study is a prospective, randomized, sham controlled, double blind, and clinical trial with ethical approval. Eighteen adult patients with dermatomyositis, polymyositis, antisynthetase syndrome or immune-mediated necrotizing myopathies in remission or with minimal disease activity were enrolled from 2018 to 2019. Patients were allocated randomly in two groups to receive sham or active tDCS with 2mA amplitude submitted for 20 minutes for three consecutive days. The 5x7cm sponge-electrodes were positioned with the anode over the left (C1) or right (C2) - contralateral to the dominant limb, whereas the cathode over the FP2 or FP3, respectively (10-10 EEG electrodes placement). The groups were evaluated in four moments: pre-stimulation, and 30 minutes, 3 weeks and 8 weeks post-tDCS. They were evaluated in the different moments with International Myositis Assessment and Clinical Studies Group set scores, Short-Form health survey (SF-36), state-trait anxiety inventory (STAI), Beck depression inventory (BDI), timed up-and-go test (TUG), time-stands test (TST), isokinetic extension and flexion testing of bilateral knee and elbow. A specific security questionnaire for tDCS was used after the active or sham stimulation in all patients.
Results: The demographic data, kind of myositis, disease duration, and disease status (all with low disease activity) were comparable between both active and sham tDCS groups. After interventions, there was improvement of values of patient's VAS (P=0.042) and serum levels of creatine phosphokinase (P=0.005), independent of the group. Moreover, in active tDCS group, the physical aspects of SF-36 in week 8 (P<0.001), mean and better TST at each evaluation (P<0.001), absolute peak tork (P<0.001) and peak tork adjusted for body weight values (P<0.001) of stimulated inferior limb extension also improved. No differences were observed in the STAI, BDI, or TUG in both groups. The patients' adherence to the protocol was 100% and no adverse event was reported, including disease relapsing.
Conclusion: This unprecedented study evidences the safety of tDCS, besides the potential efficiency in improving rehabilitation of tDCS in SAMs. More studies with a large samples and period of tDCS sessions are necessaries to corroborate with the present study.

Selva-O'callaghan[12]on behalf of MEDRA5 (Spanish anti-MDA5 syndrome Register) group (listed contributors at the end of the abstract). *[1]Hospital Vall d'Hebron, Rheumatology, Barcelona, Spain*; *[2]Hospital Universitario Fundación Jiménez Díaz, Rheumatology, Madrid, Spain*; *[3]Hospital Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; *[4]Hospital General de Granollers, Rheumatology, Granollers, Spain*; *[5]Hospital La Princesa, Rheumatology, Madrid, Spain*; *[6]Hospital de Bellvitge, Internal Medicine, Hospitalet de Llobregat, Spain*; *[7]Hospital Universitario Central de Asturias, Internal Medicine, Oviedo, Spain*; *[8]Hospital Universitario La Paz, Internal Medicine, Madrid, Spain*; *[9]Hospital Universitario Mutua de Terrassa, Internal Medicine,Terrassa, Spain*; *[10]Hospital Universitario Basurto, Rheumatology, Bilbao, Spain*; *[11]Hospital Miguel Servet, Internal Medicine, Zaragoza, Spain*; *[12]Hospital Vall d'Hebron, Internal Medicine, Barcelona, Spain*

Background: Idiopathic inflammatory myopathies are a heterogenous group of systemic autoimmune diseases. Several phenotypes have been linked to specific autoantibodies. Clinically amyopathic dermatomyositis with rapidly progressive interstitial lung disease, the most severe form of ILD, is associated with the anti-MDA5 antibodies. However not all the patients with dermatomyositis and anti-MDA5 positive antibodies develop this severe condition.
Objectives: We aim to define different phenotypes from a large cohort of patients diagnosed with dermatomyositis who were positive to anti-MDA5 antibodies.
Methods: We retrospective analyzed the clinical and immunological data of 90 anti-MDA5 patients [50 female, 55.6%, mean (SD) age at diagnosis 47 (15.4) yrs.] with dermatomyositis recruited from a multicenter register in Spain (MEDRA5) including 30 hospitals. All the patients fulfill de International Myositis Classification Criteria (EULAR/ACR) for dermatomyositis (score >90%). Anti-MDA5 were detected by means of commercial immunoblot (EUROIMMUN©). The chi-square test was used to assess the relationships between qualitative variables. The Kruskal-Wallis test was used to compared medians between groups.
Results: Sixty-six patients (73.3%) were diagnosed with clinically amyopathic dermatomyositis. Three different phenotypes linked with the anti-MDA5 antibody were identified. Group 1: patients with rapidly-ILD phenotype (28 patients, 31.1%), group 2: antisynthetase-like phenotype (23 patients, 25.5%), and group 3: non-ILD phenotype (39 patients, 43.3%). Clinical and immunological comparison between the groups disclosed that age at disease onset was higher (median, IQR) in patients from group 1 [53 (43-60)] vs. group 2 [46 (40-56)] or group 3 [42(41-51)] (p=0.01); disease onset was more frequent in spring in patients from group 1 (46.5%) than in the rest of the groups (21.7% and 28.9%) (p<0.01). Cancer was detected in 7 patients, only associated with myositis in 3 cases (3 years interval between cancer and dermatomyositis) without significant differences between phenotypes. Vasculitis (one case ANCA positive) was detected in 9 cases (6 limited to skin, 1 renal and 1 intestinal), 6 of them in the group 3 (statistical significance, in comparison with group 1 and 2, p<0.01). Mortality rate was higher in group 1 (51.9%, 16 out of 17 due to refractory respiratory failure) vs group 2 (12.5%) or 3 (0%) (p<0.001). Anti Ro52 positivity was more frequent in group 1 (65.4%) vs. group 2 (25%) or 3 (35.5%) (p<0.017), although it did not reach statistical significance in terms of mortality (p=0.173) or patients admitted in the intensive care unit (p=0.173). Mechanic hands were more frequent in group 2 (40.6%) than in groups 1 (25%) and 3 (34.4%) (p=0.05). Fever was significantly most frequent in group 1(52.6%) than in group 2 (21.1%) and 3 (26.3%) (p=0.001). Other clinical or immunological features such as arthritis, myositis, or the number of characteristic skin lesions among others were not more frequent in one group or another.
Conclusion: Three different phenotypes of patients positive to anti-MDA5 were identified. The presence or not of ILD, or the different type (rapidly progressive or not) of ILD were the main feature that allow to differentiate these phenotypes, which are relevant in clinical practice.

POS0889 CO PRESCRIPTION OF ANTI-ACID THERAPY REDUCES THE BIO AVAILABILITY OF MYCOPHENOLATE MOFETIL IN SYSTEMIC SCLEROSIS PATIENTS

G. Alex[1], S. K C[2], D. Reachel Varghese[1], S. Babu A S[2], R. Reji[2], P. Shenoy[2]. *[1]Center for Arthritis and Rheumatism Excellence (CARE), Rheumatology, Kochi, India*; *[2]Center for Arthritis and Rheumatism Excellence (CARE), Rheumatology, Kochi, India*

Background: Mycophenolate mofetil (MMF) is an effective treatment option for systemic sclerosis (SSC). However, many patients require co administration of proton pump inhibitors (PPI) or H2 receptor blockers (HRB) because of significant gastrointestinal manifestations in SSC. Co-treatment with PPI or HRB have shown to be associated with reduced drug exposure in post-transplant patients.[1, 2] There is scarcity of data among patients with SSC. We evaluated the drug concentration of MMF over 12 hours of exposure and assessed the impact of ranitidine and PPI in twenty patients with SSC.
Objectives: To assess the effect of esomeprazole or ranitidine on the bioavailability of MMF in SSC patients who are on a stable dose of MMF.
Methods: Twenty SSC patients, who were on a stable dose of MMF (1.5-3 g) for the past 3 months were selected for the study after obtaining informed written consent. All patients were given either MMF (without PPI or HRB), MMF + esomeprazole, MMF + ranitidine for one month each. At the end of each month, EDTA plasma samples were collected at various time points including 0, 1/2, 1, 1½, 2, 2½, 3, 4, 5, 6, 8 and 12 hours following drug administration to determine the 12-hour area under curve (AUC) of mycophenolic acid (MPA) levels. Estimation of MPA levels was carried out using reverse phase high performance liquid chromatography (HPLC). Total gastrointestinal score was calculated at the end of each month using UCLA Scleroderma Clinical Trial Consortium GIT 2.0 scoring. To compare the mean AUC, linear mixed effect model was fit by considering treatment as the fixed effect and subject as the random effect. MMF was set as the reference treatment for the other three treatments and these were analysed together using Linear mixed effect model.
Results: All patients were females with mean age of 45 years. Addition of either ranitidine or esomeprazole significantly reduced the mean AUC and C max of the MMF over 12-hour time period. On the other hand, PPI or HRB helped in reduction of the total GI score at the end of 1 month. Details of pharmacokinetics are depicted in the table 1.

Table 1. Pharmacokinetics and GI score with MMF in combination with PPI / HRB

	MMF	MMF+ R	MMF + E	p
AUC	67.97 (62.73, 73.20)	53.04 (44.80, 61.27)	45.69 (41.10, 50.28)	<0.001*
mean (95% CI) **T- MAX**	42.00 (33.60, 50.40)	46.50 (32.48, 60.52)	79.50 (58.99, 100.01)	<0.001*
mean (95% CI) **C-MAX**	29.61(26.74, 32.48)	15.14 (11.32, 18.97)	12.62 (10.58, 14.66)	<0.001*
mean (95% CI) **Mean GI score**	0.28 (0.15,0.40)	0.19 (0.09, 0.30)	0.14 (0.06,0.23)	0.009
mean (95% CI)				

AUC, area under curve Mycophenolic acid; C-MAX, maximum concentration of MPA in 12 hours following MMF; CI confidence interval;Mean GI score, UCLA Scleroderma Clinical Trial Consortium GIT 2.0 scoring; MMF, mycophenolate mofetil; MMF+E, mycophenolate mofetil + esomeprazole; MMF+R, mycophenolate mofetil+ ranitidine;*p value < 0.05 considered as significant

Conclusion: As co administration of PPI or HRB can significantly reduce the bio-availability of MMF in patients with systemic sclerosis. To avoid therapeutic failure of MMF drug level monitoring is essential when these agents re prescribed with MMF.

POS0890 MACROVASCULAR DYSFUNCTION AND ITS CLINICAL IMPLICATION IN SYSTEMIC SCLEROSIS

D. Bairwa[1], C. Kavadichanda[1], V. Negi[1]. [1]*Jawaharlal Institute of Postgraduate Medical Education and Research, Clinical Immunology, Puducherry, India*

Background: Even though microvascular dysfunction has been implicated in pathogenesis of scleroderma (SSc), there is minimal evidence to suggest presence of macrovascular dysfunction. The clinical implication of macrovascular dysfunction in SSc is unknown. Moreover, data on the correlation between dysfunction in small and large blood vessel is inconclusive. [1-2]

Objectives: To study the correlation between macrovascular dysfunction as assessed by percent change in flow mediated vasodilation (FMD) of brachial artery and microvascular dysfunction as assessed by nail fold capillaroscopy (NFC) findings in SSc. To assess the clinical impact of macrovascular dysfunction.

Methods: This cross-sectional comparative study enrolled patients with SSc and age and gender matched healthy controls. FMD change was calculated using standard USG probe of 5 to 6 MHz in right brachial diameter from the average of 3 consecutive end diastolic frames. NFC was performed using portable nail fold capillary microscope at 800X magnification. Clinical features of SSc were compared between SSc patients with and without macrovascular dysfunction.

Results: This study enrolled 59 SSc patients including 29 (49.2%) diffuse, 20 (20.4%) limited, 08 (10.2%) sine SSc and 2 patients (3.4%) with myositis overlap. SSc patients had significantly (p-<0.0001) lower % FMD change compared to healthy controls. NFC showed significantly higher architecture distortion (p-<0.0001), loss of capillaries (p-<0.0001) and abnormal capillaries (p-<0.0001). There was no correlation between FMD change and capillary density (p-0.381), avascular area (p-0.266) and abnormal capillaries (p-0.899). None of the clinical features like pulmonary hypertension, digital ulcer burden, acro-osteolysis and auto amputation were different between SSc with and without macrovascular dysfunction.

Conclusion: Macrovascular dysfunction in SSc is substantial and it seems to be independent of the microvascular dysfunction. The clinical implications of macrovascular dysfunction are yet to be identified.

POS0891 IMPROVED SURVIVAL IN SYSTEMIC SCLEROSIS PATIENTS DURING LAST DECADE: CURRENT FINDINGS AND COMPARISON WITH DIFFERENT PREVIOUS ITALIAN COHORTS

F. Cacciapaglia[1], E. De Lorenzis[2], M. G. Lazzaroni[3], A. Corrado[4], M. Fornaro[1], G. Natalello[2], F. Montini[1], A. Altomare[4], L. Urso[1], F. P. Cantatore[4], S. L. Bosello[2], P. Airò[3], F. Iannone[1]. [1]*Rheumatology Unit - University and AOUC Policlinico of Bari, Department of Emergency and Organ Transplantations, Bari, Italy*; [2]*Division of Rheumatology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, Roma, Italy*; [3]*Rheumatology and Clinical Immunology Unit, ASST Spedali Civili, Brescia, Italy*; [4]*Rheumatology Clinic, Department of Medical and Surgical Sciences - University of Foggia, Foggia, Italy*

Background: Systemic Sclerosis (SSc) is a chronic rheumatic disease characterized by an autoimmune disorder with vasculopathy that leads to an excess in collagen and other extracellular matrix proteins deposition. This process results in progressive fibrotic and vascular damage of skin and visceral organs.

According to observational studies conducted in last decades, mean survival of SSc patients had improved with significant changes in causes of death.
Objectives: To assess the 10-years survival in a large Italian multicentre cohort of SSc patients in the last decade compared to previous periods published since the 1980s, and to identify features that can justify any change.
Methods: We retrospectively analysed all medical records of our longitudinal SSc cohorts, fulfilling 1980 ARA and/or 2013 EULAR/ACR Classification Criteria, with a median (IQR) follow-up of 91.5 (51-120) months from 4 Scleroderma Units since January 2009. All clinical, laboratory and instrumental findings have been recorded and analysed. Survival rate was calculated with Kaplan-Meier curves and log-rank tests, and Cox proportional hazards models were used to identify any predictor. Then, observed SSc survival was compared to those previously published and to that expected in the general population, calculated using official data published on the website United Nation World Population Prospects (www.macrotrends.net/countries/ITA/italy/death-rate).
Results: Of 912 SSc patients (91.6% female; mean (SD) age at first non-Raynaud symptom (RS) 51 (15.4) years; median (IQR) disease duration from non-RS 24 (0-84.7) months) diffuse cutaneous involvement was defined in 182 (20%) patients. Anti-centromere and anti-topoisomerase-I were detected in 390 (42.8%) and 302 (33.1%) patients, respectively, while 220 (24.1%) presented antibodies for other extractible nuclear antigens. Prevalent non-Raynaud manifestations were interstitial lung disease detected in 459 (50.3%), digital ulcers in 395 (43.3%) and oesophagopathy in 371 (40.7%) patients, respectively, while other gastrointestinal manifestations were reported in 234 (25.7%) patients. Chronic renal failure was observed in 61 (6.7%) patients and pulmonary arterial hypertension (PAH) was confirmed at right heart catheterization in 38 (4.2%) patients. Three hundred twenty-two (35.3%) patients received immunosuppressant, 215 (23.5%) assumed an endothelin receptor antagonist and/or a 5-phosphodiesterase inhibitor, and 72 (7.9%) were treated with a biologic agent. The global 10-years survival was 89.4%; female gender (HR 0.33, CI95% 0.17-0.67), diffuse cutaneous involvement (HR 2.14, CI95% 1.17-3.91), presence of pulmonary hypertension (HR 2.61, CI95%1.31-5.16) and older age at non-RS (HR 1.1, CI95% 1.06-1.12) affected survival. Furthermore, as compared to previous Italian studies, our cohort showed a significant improvement in rate (see Figure 1).
Conclusion: Survival in SSc patients has improved in last 5 decades but still reduced compared to that expected in general population above all 5 years after diagnosis. Early diagnosis, with reduced renal involvement, along with better screening and innovative therapeutic strategies may explain these achievements.

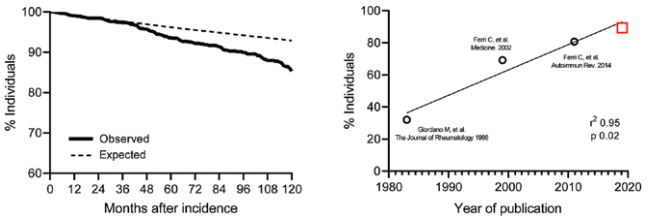

Figure 1. Ten-years survival in SSc patients since 2009 (left); comparison of survival across different Italian SSc cohorts (box: current analysis) (right).

POS0892 QUANTITATIVE CT INDEXES: PROMISING TOOLS FOR OBJECTIVE ASSESSMENT OF PULMONARY FIBROSIS IN SYSTEMIC SCLEROSIS

D. Temiz Karadağ[1,2], O. Cakir[3], S. Şan[1], A. Yazici[1], A. Cefle[1]. [1]*Kocaeli University Faculty of Medicine, Department of Rheumatology, Kocaeli, Turkey*; [2]*Canakkale Mehmet Akif Ersoy State Hospital, Department of Rheumatology, Canakkale, Turkey*; [3]*Kocaeli University Faculty of Medicine, Department of Radiology, Kocaeli, Turkey*

Background: Pulmonary fibrosis (PF) occurs in the majority of patients with SSc and is a leading cause of SSc-related death. SSc related PF has heterogeneous disease progression: many patients will have a chronic, indolent course while others may develop the progressive, life-threatening disease.
Objectives: The objective of this study is to investigate the discrimination performance of quantitative CT indexes in identifying the parenchymal differences between the SSc and the control groups. We also aimed to demonstrate the correlation among quantitative indexes (QI), spirometric pulmonary function tests, and visual CT scores in patients with PF.
Methods: A total of 135 SSc patients (female 87.4%; age, 50±13 years), 41 of whom had pulmonary fibrosis (PF), and 38 healthy subjects (female 89.5%; age, 52±6 years) were enrolled. All participants underwent volume thin-section CT in the supine position at full inspiration and spirometry. Quantitative indexes (QIs) were obtained using dedicated software for the segmentation of the lung (Vital Images Vitrea Workstation; Version 7.12.3.133). QIs included total lung volume (TLV), low attenuation (LA) volume (-1020 HU<pixel<-920 Hounsfield units [HU]), medium attenuation (MA) volume (-920 HU<pixel<-920 HU), and high attenuation (HA) volume (-720<pixel<0 HU). The global extent of pulmonary parenchymal abnormality was measured semiquantitatively by visual scoring (VS) and functional lung volume was derived. The functional lung volume, total MA volume, and ratio of total MA to total lung volume were assumed as the indexes of normal lung parenchyma.
Results: MA volumes, HA volumes, total lung volumes and the ratio of MA volume to total lung volume differed significantly between the patients with PF, patients without PF, and the control group. In the PF group, FVC showed significant correlation with functional lung volume (r=0.45, p=0.014) and total MA volume (r=0.48, p=0.009); DLCO showed significant correlation with VS of normal lung parenchyma (r=0.65, p<0.001), functional lung volume (r=0.53, p=0.006), total MA volume (r=0.54, p=0.005) and ratio of total MA to total lung volume (r=0.42, p=0.031). The functioning lung volume obtained by VS and total MA volume showed excellent correlation (r=0.78, p<0.001).
Conclusion: Quantitative indexes measured by soft-ware differentiated the patients with PF from the patients without PF and healthy subjects. The indexes used to evaluate the normal lung parenchyma showed a good correlation with pulmonary function test results. Quantitative indexes can be used as an objective complementary tool for the evaluation of the lung areas unaffected by PF.

Table 1. Quantitative Indexes of CT in the Control, SSc without PF and SSc with PF Groups

	Control	SSc without PF	SSc with PF	*p*
Right lung LA volume (ml)	372±375	420±446	254±308	0.102
Right lung MA volume (ml)	1230±408	1377±441	987±451	<0.001
Right lung HA volume (ml)	531±152	494±177	625±215	0.004
Left lung LA volume (ml)	342±370	367±383	221±271	0.089
Left lung MA volume (ml)	1014±383	1170±433	805±402	<0.001
Left lung HA volume (ml)	563±176	516±251	620±289	0.037
Total lung LA volume (ml)	712±736	827±959	517±653	0.119
Total lung MA volume (ml)	2212±863	2548±862	1756±850	<0.001
Total lung HA volume (ml)	1072±343	1009±406	1290±522	0.005

POS0893 NON-INVASIVE CUTANEOUS ASSESSMENT OF SYSTEMIC SCLEROSIS- THE NEW OUTLOOKS

P. S. Wong[1], D. Kurzeja[1], B. Ahmed Abdi[1], R. Stratton[1]. [1]*Royal Free Hospital and University College Medical School, Centre for Rheumatology and Connective Tissue Diseases, London, United Kingdom*

Background: Systemic sclerosis (SSc) is a rare connective tissue disease with abnormalities in vasculopathy, immune dysregulation and fibrosis resulting in skin and internal organ damages. Severity of skin involvement is known to correlate with organ-related mortality in particular pulmonary involvement. Variables skin assessment tools are available, modified Rodnan Skin Score (mRSS) is currently best validated and used widely. The immediate action of finding an ideal,

clinically convenient objective methods is crucial to better clinicians' care for SSc patents.

Objectives: Explore the potential of commercially available handheld, non-invasive devices for SSc skin analysis.

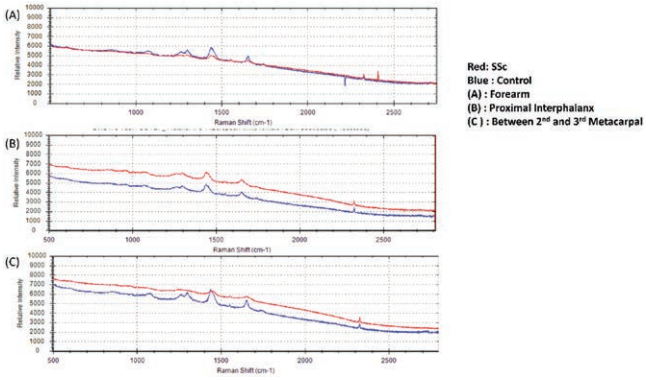
Methods: 1.Measure skin surface Adenosine Triphosphate (ATP) level with handheld ATP bioluminator (SystemSURE Plus, Hygiena) over the forearm of SSc(n= 51) and controls (n=50) 60seconds after sterilization to eliminate extrinsic factors. The bioluminometer expresses ATP test results in Relative Light Units (RLU) that is directly proportional to the amount of ATP on the test sample (Unit conversion: 1RLU = 1fM).

2.In-vivo Raman Spectra measurement of SSc skin comparing with matched healthy controls on proximal phalangeal, area between 2nd and 3rd metacarpal and forearm. Our measurments include laser power of 250mw, excitation length of 785nm and spectral range from 500 to 2800cm^{-1}.

Measurements were analysed with patients' phenotypes and clinical characteristics.

Results: Flow cytometry showed increase expression of P2X7 (purinergic) receptor and CD206 in M2-Macrophage in SSc compare to controls [(724.4 vs 472.9, 776.1 vs 632.2)]. CD206 expression positively correlated with P2X7 levels (p<0.001, r2=0.76) and mRSS (p<0.05, r2=0.26). In real life scenario, measurement of purinergic metabolites is laboratorial tedious. ATP bioluminator measurement reviewed significant higher skin surface ATP in SSc than controls (188fM ± 53 [95% CI = 84, 300] vs 44fM ± 6 [95% CI = 33, 56], p< 0.003). And the intensity is negatively correlate with duration of disease in SSc (r = - 0.25, p = 0.096).

We obtain Raman spectra in SSc patient and control. Our study both groups have similar Raman curve when Raman Spectrometry were performed on skin surfaces. However, the relative intensity of each peaks of the curve were overtly flatter in SSc. This finding were similar for both Limited and Diffuse SSc in gross review of the graph representative. In addition to that, our analysis reviewed a peak at Raman shift of 2410 cm^{-1} that is characteristically present in forearm of a SSc but not in controls (Figure 1). Its significant yet to be determined.



Conclusion: Both ATP bioluminator and Raman Spectrometry is widely available commercially which are widely used in industrial, agriculture and cosmetology and dermatology in particular for Raman Spectrometry. It is commonly for assessing physically property of skin, determine drug administration and diagnosis of variable skin condition in particular cancer diagnosis. The advantages of these tools in SSc skin analysis include:

1.Non-invasive nature of skin analysis (compares to skin biopsy),
2.Portable devices easily mobilized in clinic setting,
3.Advanced technology allows molecular analysis of skin hence able to objectively classify grades of skin inflammation and determine drug efficacy
4.Possible better accuracy compares to other methods (eg. Ultrasound) which are operators dependent,
5.Widely available Raman signal database of different types of chemical compounds and expertise made the collection and analysis of date convenient

Our study has provide preliminary outlook and idea of utilizing commercially available devices on skin analysis in SSc. Further study in larger cohort are to be considered.

POS0894 ANTI-IL-6 THERAPY EFFECT FOR REFRACTORY JOINT AND SKIN INVOLVEMENT IN SYSTEMIC SCLEROSIS: A REAL-WORLD, SINGLE CENTER EXPERIENCE

S. Panopoulos[1], M. Tektonidou[1], V. K. Bournia[1], A. Arida[1], P. Sfikakis[1]. [1]*National and Kapodistrian University of Athens, First Propedeutic and Internal Medicine, Joint Rheumatology Program, Medical School, Athens, Greece*

Background: Emerging evidence during the last two decades supports a pivotal role of Interleukin 6 (IL-6) in the pathogenesis of Systemic Sclerosis (SSc). Standard immunosuppressive agents are often inadequate to control disease activity in SSc patients and treatment failure of multiple regimens is frequent in real-world practice.

Objectives: To examine the efficacy and safety of interleukin-6 receptor inhibition by tocilizumab in selected real-world patients with SSc.

Methods: Twenty-one patients (20 women, 16 diffuse SSc, mean age: 52±10 years, mean disease duration: 6.4±3.7 years, all with negative rheumatoid factor and anti-cyclic citrullinated antibodies, none with overlap syndrome with RA) with active joint and skin involvement refractory to corticosteroids (n=21), methotrexate (n=17), cyclophosphamide (n=10), mycophenolate (n=7), rituximab (n=1), leflunomide (n=2), hydroxychloroquine (n=2), and hematopoietic stem cell transplantation (n=2) who received weekly tocilizumab (162 mg subcutaneously) in an academic center, were monitored prospectively. Changes in Eustar modified activity index (MAI), modified Rodnan skin score (mRSS), disease activity score (DAS)28, lung function tests (LFTs) and patient reported outcomes (PROs) were analyzed at one year of treatment and at the end of follow-up.

Results: One patient discontinued tocilizumab after 3 months due to inefficacy. During the first year of treatment, 12 patients achieved low disease activity (mean MAI change -2.9±1.8, p<0.001) and significant clinical improvement was evident in 12 patients regarding skin involvement (mean mRSS change: -6.9±5.9, p<0.001) and in 16 patients regarding polyarthritis (mean DAS28 change: -1.9±0.8, p<0.001); Accordingly, improvements were recorded for all PROs (all p<0.001) (Table 1). Lung function tests' stabilization was also observed in 16/20 patients. During the second year, 3 patients discontinued tocilizumab (cytomegalovirus infection in 1, inefficacy in 2) and one died. Beneficial effects were sustained in all 16 patients at follow-up end (mean duration of Tocilizumab treatment 2.2 ± 1.1 years), apart from LFTs deterioration in 3. Except for recurrent digital ulcer infection in 3 patients, tocilizumab was well-tolerated.

Conclusion: Tocilizumab was effective in refractory joint and skin involvement irrespective of SSc disease duration or subtype. Long-term retention rates and disease stabilization for most real-world patients suggest that tocilizumab might be a valuable choice for difficult-to-treat SSc.

Table 1. Clinical and laboratory parameters and measures (mean ± SD) at baseline and after one year of treatment with tocilizumab in 20 patients with Systemic Sclerosis

	Baseline	1st year	change	p
Modified activity index	4.9 ± 1.6	2.0± 1.2	-2.9 ± 1.8	**<0.001**

Spondyloarthritis – treatment

POS0895 EFFECT OF TOFACITINIB ON PATIENT-REPORTED OUTCOMES IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: RESULTS FROM A PHASE 3 TRIAL

V. Navarro-Compán[1], J. C. C. Wei[2], F. Van den Bosch[3], M. Magrey[4], L. Wang[5], D. Fleishaker[5], J. C. Cappelleri[5], C. Wang[5], J. Wu[5], O. Dina[6], L. Fallon[7], V. Strand[8]. *[1]University Hospital La Paz, Rheumatology Department, Madrid, Spain*; *[2]Chung Shan Medical University Hospital, Department of Internal Medicine, Taichung, Taiwan, Republic of China*; *[3]Ghent University Hospital, Department of Rheumatology, Ghent, Belgium*; *[4]Case Western Reserve University, Division of Rheumatology, Cleveland, OH, United States of America*; *[5]Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America*; *[6]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; *[7]Pfizer Inc, Inflammation and Immunology, Kirkland, QC, Canada*; *[8]Stanford University, Division of Immunology/Rheumatology, Palo Alto, CA, United States of America*

Background: Ankylosing spondylitis (AS) can significantly impact quality of life. Tofacitinib is an oral Janus kinase inhibitor under investigation for the treatment of adult patients (pts) with AS. The safety/efficacy (including pt-reported outcomes [PROs]) of tofacitinib in pts with AS was assessed in a Phase 3 trial (NCT03502616).[1]

Objectives: To evaluate the effect of tofacitinib on pt-reported pain, fatigue, overall health and work productivity in pts with active AS enrolled in the Phase 3 trial.

Methods: Pts with an inadequate clinical response or intolerance to ≥2 oral NSAIDs were randomised in a double-blind fashion to tofacitinib 5 mg twice daily (BID) or placebo (PBO) for 16 weeks. At Week (W)16, all pts received open-label tofacitinib 5 mg BID up to W48. Least squares (LS) mean changes from baseline (Δ) up to W48 are reported for the following outcomes: pt assessment of nocturnal spinal pain, Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), Short Form-36 Health Survey version 2 (SF-36v2; W16 and W48 only), and Work Productivity and Activity Impairment Questionnaire (WPAI; W16 and W48 only).

Results: At W16, there were greater improvements from baseline in pain (total back pain [previously published[1]] and nocturnal spinal pain) and fatigue (FACIT-F total score; experience and impact domain scores) with tofacitinib vs PBO ($p \leq 0.05$; Table 1); improvements were observed as early as W2. Also, improvements in SF-36v2 physical component summary (PCS) (Table 1), and physical functioning, role-physical, bodily pain, general health and social functioning domains (Figure 1) were greater with tofacitinib vs PBO at W16 ($p \leq 0.05$). Similarly, improvements in WPAI scores at W16 were greater with tofacitinib vs PBO ($p \leq 0.05$), except for % work time missed (Table 1). Improvements with tofacitinib continued up to W48 (Table 1/Figure 1). Generally, pts receiving PBO who advanced to tofacitinib at W16 reported similar improvements after switching to tofacitinib (Table 1/Figure 1).

Table 1. PROs at baseline and Δ at W16 and W48

	Baseline, mean (SD) [N1]		Δ, W16, LS mean (SE)			Δ, W48, LS mean (SE)	
	Tofacitinib 5 mg BID (N=133)	PBO (N=136)	Tofacitinib 5 mg BID	PBO	p value	Tofacitinib 5 mg BID	PBO→ tofacitinib 5 mg BID
Nocturnal spinal pain[a]	6.8 (1.9)	6.8 (1.9)	-2.67 (0.20)	-0.84 (0.20)	<0.0001	-3.52 (0.23)	-3.01 (0.23)

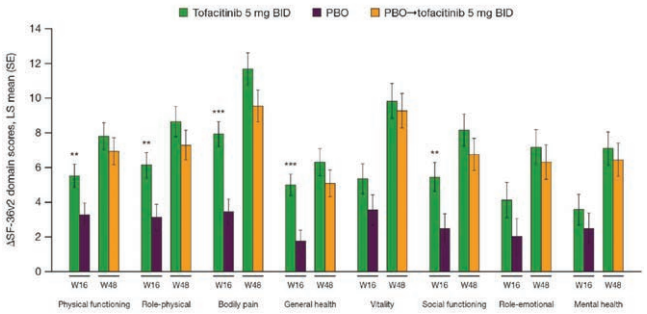
[a]MMRM [b]Global type I error-controlled endpoint [c]Analysis of covariance model for W16 and MMRM for W48MCS, mental component summary; MMRM, Mixed Model for Repeated Measures; N, number of pts in full analysis set; N1, number of pts included in the analysis (if different from N); SD, standard deviation; SE, standard error

Figure. LS mean ΔSF-36v2 domain scores (norm-based) at W16 and W48



**p<0.01, ***p<0.001 for tofacitinib 5 mg BID vs PBO (analysis of covariance model)

Conclusion: In pts with active AS, improvements in spinal pain, fatigue, overall health and work productivity were greater with tofacitinib vs PBO at W16; improvements continued up to W48. These PRO findings support the primary efficacy results of this Phase 3 trial,[1] and add to the overall understanding of the benefit/risk profile of tofacitinib in patients with AS.

POS0896 PREDICTORS OF RESPONSE IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS RECEIVING CERTOLIZUMAB PEGOL IN THE C-AXSPAND STUDY

W. P. Maksymowych[1], T. Kumke[2], S. Auteri[3], B. Hoepken[2], L. Bauer[2], M. Rudwaleit[4,5]. *[1]University of Alberta, Department of Medicine, Division of Rheumatology, Edmonton, Canada*; *[2]UCB Pharma, N/A, Monheim am Rhein, Germany*; *[3]UCB Pharma, N/A, Brussels, Belgium*; *[4]Klinikum Bielefeld, Clinic for Internal Medicine and Rheumatology, Bielefeld, Germany*; *[5]Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology, Berlin, Germany*

Background: Identification of predictive clinical factors of long-term treatment response in non-radiographic axial spondyloarthritis (nr-axSpA) may contribute to improved management of patients with this chronic disease. Certolizumab pegol (CZP) is currently the only FDA-approved tumour necrosis factor inhibitor (TNFi) for treatment of nr-axSpA.[1]

Objectives: To identify whether any demographic or baseline characteristics of nr-axSpA patients from the C-axSpAnd study[2] are predictive of achieving a clinical response after 1 year of CZP treatment.

Methods: C-axSpAnd (NCT02552212) was a phase 3, interventional multicentre study including a 52-week double-blind, placebo-controlled period. Full

study design is reported elsewhere.[2] Multivariate stepwise logistic regression analysis was used to identify predictors of response for the primary efficacy variable (Ankylosing Spondylitis Disease Activity Score – major improvement [ASDAS-MI] at Week 52) and the main secondary efficacy variable (Assessment of SpondyloArthritis international Society 40% [ASAS40] at Week 52) in patients randomised to CZP 200 mg every 2 weeks (Q2W). Predictive factors used in the model included demographic and baseline characteristics, and clinical outcomes at Week 12. A p value ≤0.05 was required for forward selection into the model and p=0.1 for backward elimination from the model. Non-responder imputation was used to account for missing data or values collected after switching to open-label treatment. A sensitivity analysis was conducted to account for patients who had changes in their non-biologic background medication during the 52-week placebo-controlled period.

Results: A total of 159/317 patients were randomised to CZP 200 mg Q2W and 158/317 to placebo. Predictive factors identified for Week 52 ASDAS-MI in the CZP-treated patients included being positive for both presence of sacroiliitis on MRI (MRI+) and human leukocyte antigen (HLA)-B27 (HLA-B27+), having a higher Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) at baseline, and having a larger Week 12 improvement in ASDAS (Figure 1A). For ASAS40 response, MRI+/HLA-B27+ was also identified as a predictor of Week 52 response, along with a lower baseline Bath AS Metrology Index (BASMI) and larger Week 12 improvements in Patient Global Assessment of Disease Activity (PtGADA) and AS Quality of Life (ASQoL; Figure 1B). Sensitivity analysis identified the same predictors for ASDAS-MI and ASAS40, with the exception of change from baseline in PtGADA as a predictor of ASAS40. Sensitivity analysis also identified achievement of Week 12 ASAS40 as a predictor of Week 52 ASAS40. In placebo-treated patients, no meaningful predictors of response at Week 52 were identified.

Conclusion: Presence of sacroiliitis on MRI and HLA-B27 positivity were identified as consistent predictors of Week 52 response (ASDAS-MI and ASAS40) in nr-axSpA patients treated with CZP. To our knowledge, this is the first report from an interventional 52-week placebo-controlled study in nr-axSpA to identify objective clinical features, particularly the presence of sacroiliac joint inflammation, as being predictive of response.

POS0897 REDUCTION OF ANTERIOR UVEITIS FLARES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS DURING CERTOLIZUMAB PEGOL TREAT MENT: 96-WEEK RESULTS FROM THE C-VIEW STUDY

I. Van der Horst-Bruinsma[1], R. Van Bentum[1], F. Verbraak[2], T. Rath[3], B. Hoepken[4], O. Irvin-Sellers[5], T. Kumke[4], L. Bauer[4], M. Rudwaleit[6,7].
[1]Amsterdam University Medical Centre, Location VUmc, Department of Rheumatology, Amsterdam, Netherlands; *[2]Academic Medical Centre, University of Amsterdam, Department of Ophthalmology, Amsterdam, Netherlands*; *[3]St Franziskus-Hospital, Department of Ophthalmology, Münster, Germany*; *[4]UCB Pharma, N/A, Monheim am Rhein, Germany*; *[5]UCB Pharma, N/A, Slough, United Kingdom*; *[6]Klinikum Bielefeld, Clinic for Internal Medicine and Rheumatology, Bielefeld, Germany*; *[7]Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology, Berlin, Germany*

Background: Acute anterior uveitis (AAU) is the most common extra-articular manifestation in axial spondyloarthritis (axSpA), affecting up to 40% of patients and causing significant burden.[1] Previous studies have shown that tumour necrosis factor inhibitors (TNFi) can reduce the incidence of AAU flares in patients with radiographic axSpA (ankylosing spondylitis),[2-4] but few have focused on patients across the full axSpA spectrum.[1]

Objectives: To report 2-year outcomes from the phase 4, open-label C-VIEW study (NCT03020992), which investigated the impact of certolizumab pegol (CZP) treatment on AAU in patients with active axSpA and a recent history of AAU.

Methods: C-VIEW prospectively investigated patients with active axSpA who were HLA-B27 positive and had recurrent AAU, with a history of ≥1 AAU flare in the year prior to baseline (additional study criteria and study design are described elsewhere[5]). The primary efficacy variable was the incidence of AAU flares during 96 weeks of CZP treatment versus the 2-year pre-baseline period. AAU incidence was evaluated using Poisson regression adjusted for duration of time in each period, with period (pre- and post-baseline) and axSpA disease duration as covariates. Secondary efficacy variables were Assessment of SpondyloArthritis international Society 20%/40% (ASAS20/40) response rates, as well as mean Ankylosing Spondylitis Disease Activity Score (ASDAS) and mean Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) to Week 96.

Results: Of 115 enrolled patients, 89 initiated CZP treatment; 83 completed Week 96. The primary analysis revealed an 82% reduction in the incidence of AAU flares during CZP treatment compared with pre-baseline (Figure 1A; rate ratio [95% CI]: 0.18 [0.12, 0.28], p<0.001). The percentage of patients experiencing ≥1 and ≥2 AAU flares reduced from 100% and 59.6% pre-baseline to 20.2% and 11.2% during treatment (Figure 1B). There were also improvements in axSpA disease activity (Table 1): by Week 96, 75.6% and 58.5% of patients had achieved ASAS20 and ASAS40 responses, respectively. ASDAS and BASDAI also improved substantially over the 96-week treatment period. No new safety signal was identified, compared to previous reports.[5]

Conclusion: These data support the use of CZP for the treatment of patients with axSpA and a history of recurrent AAU. During 96 weeks' CZP treatment, there was a significant reduction of 82% in the AAU flare rate compared to pre-baseline. There were also substantial improvements in patients' axSpA disease activity.

POS0899

HOW DOES GENDER AFFECT SECUKINUMAB TREATMENT OUTCOMES AND RETENTION RATES IN PATIENTS WITH ANKYLOSING SPONDYLITIS? - REAL WORLD DATA FROM THE GERMAN AQUILA STUDY

U. Kiltz[1], J. Brandt-Juergens[2], P. Kästner[3], E. Riechers[4], D. Peterlik[5], H. P. Tony[6]. *[1]Rheumazentrum Ruhrgebiet / Ruhr-Universität Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany*; *[2]Rheumatologische Schwerpunktpraxis, Rheumatologische Schwerpunktpraxis, Berlin, Germany*; *[3]Ambulantes Rheumazentrum, Ambulantes Rheumazentrum, Erfurt, Germany*; *[4]Medizinische Hochschule Hannover, Klinik für Immunologie und Rheumatologie, Hannover, Germany*; *[5]Novartis Pharma GmbH, Immunology, Hepatology & Dermatology, Nuremberg, Germany*; *[6]Medizinische Klinik II, Universitätsklinik, Rheumatology/ Immunology, Würzburg, Germany*

Background: Current studies suggest that the phenotype of spondyloarthritis differs between genders and that this may influence the subsequent diagnostic approach and therapeutic decisions[1]. The German non-interventional study AQUILA provides real-world data on the influence of gender on therapeutic effectiveness and retention rate under treatment with secukinumab, a fully human monoclonal antibody that selectively inhibits interleukin-17A.

Objectives: The aim of this interim analysis is to describe selected baseline (BL) demographics, to evaluate secukinumab treatment outcomes on disease activity, global functioning and health and retention rate depending on the gender of AS patients.

Methods: AQUILA is an ongoing, multi-center, non-interventional study including more than 3000 patients with active AS or psoriatic arthritis. Patients were observed from BL up to week (w) 52 according to clinical routine. Real-world data was assessed prospectively and analyzed as observed. Validated questionnaires were used to collect data on disease activity (Bath Ankylosing Spondylitis Disease Activity Index, BASDAI), global functioning and health (Assessment of SpondyloArthritis-Health Index, ASAS-HI) and severity of depressive mood (Beck´s Depression Inventory version II, BDI-II). Patient reported outcomes were reported using patient´s global assessment (PGA). In addition, retention rates (time from study inclusion until premature secukinumab treatment discontinuation) were assessed through Kaplan-Meier plots. This interim analysis focuses on the subgroups of male and female AS patients.

Results: At BL, 683 AS patients were included: 59.7% (n=408) male and 40.3% (n=275) female. Demographic data (Table 1) of male and female AS patients differed numerically in the following parameters: proportion of obese patients, smokers, pretreatment with disease-modifying antirheumatic drugs (csDMARDs), and biologicals/biosimilars (b-bsDMARDs).

Mean BASDAI and PGA were comparable between male and female AS patients over time (♂: 5.2 at BL to 3.8 at w52, ♀: 5.3 at BL to 4.1 at w52 and ♂: 5.9 at BL to 4.1 at w52, ♀: 5.6 at BL to 4.3 at w52, respectively). Mean ASAS-HI over time was higher in women; nevertheless, improvements in global functioning were comparable for both genders from BL to week 52 (Fig. 1A). Severity of depressive mood was numerically lower in male patients; nevertheless, BDI-II reductions were comparable across the genders (♂: 11.2 at BL to 10.0 at w52, ♀: 13.1 at BL to 11.0 at w52). Secukinumab treatment retention rate for men was (not significantly) higher than for women (Fig. 1B).

Conclusion: In a real-world setting, secukinumab improved disease activity, global functioning and severity of depressive mood in AS patients in both men and women. Women showed overall higher disease burden. Altogether, real-world data of this interim analysis are in line with those of Phase 3 studies and show that secukinumab is an effective treatment up to 52 weeks with high treatment retention rates, irrespective of gender.

Background: Axial spondyloarthritis (axSpA) is an inflammatory disease characterised by chronic back pain, and it comprises radiographic axSpA and non-radiographic axSpA (nr-axSpA).[1] Secukinumab (SEC) 150 mg, with (LD) or without loading (NL), dose significantly improved the signs and symptoms of patients with nr-axSpA in the PREVENT (NCT02696031) study through Week 52.[2]
Objectives: To report the long-term clinical efficacy and safety of secukinumab from the PREVENT study through 2 years.
Methods: A detailed study design, key primary and secondary endpoints have been reported previously.[2] In total, 555 patients fulfilling ASAS criteria for axSpA plus abnormal C-reactive protein (CRP) and/or MRI, without evidence of radiographic changes in sacroiliac (SI) joints according to modified New York Criteria for AS were randomised (1:1:1) to receive SEC 150 mg with LD, NL, or placebo (PBO) at baseline. LD patients received SEC 150 mg at Weeks 1, 2, 3, and 4, and then every 4 weeks (q4wk) starting at Week 4. NL patients received SEC 150 mg at baseline and PBO at weeks 1, 2, and 3, and then 150 mg q4wk. 90% patients were anti-tumour necrosis factor (anti-TNF) naïve, 57% had elevated CRP and 73% had evidence of SI joint inflammation on MRI. All images were assessed centrally before inclusion. All patients continued to receive open-label SEC 150 mg treatment after Week 52. Efficacy assessments through Week 104 included ASAS40 in anti-TNF-naïve patients, ASAS40, BASDAI change from baseline, BASDAI50, ASAS partial remission, and ASDAS-CRP inactive disease in the overall population. The safety analyses included all patients who received ≥1 dose of study treatment for the entire treatment period up to Week 104. Data are presented as observed.
Results: Overall, 438 patients completed 104 weeks of study: 78.9% (146/185; LD), 77.7% (143/184; NL) and 80.1% (149/186; PBO). Efficacy results at Week 52 were sustained through Week 104 and are reported in the Table 1. The safety profile was consistent with the previous reports with no deaths reported during the entire treatment period up to Week 104.[2]
Conclusion: Secukinumab 150 mg demonstrated sustained improvement in the signs and symptoms of patients with nr-axSpA through 2 years. Secukinumab was well tolerated with no new or unexpected safety signals.

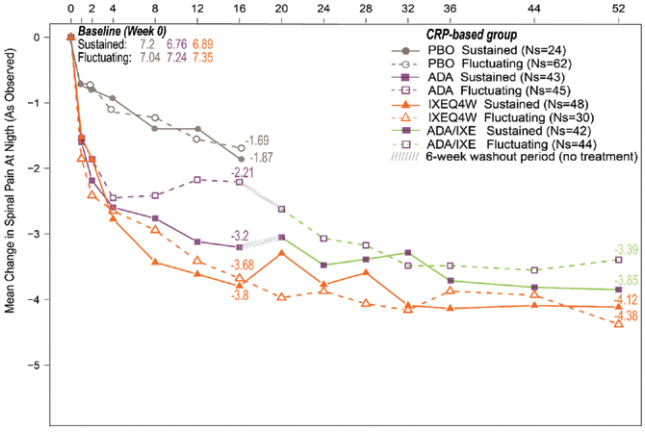
IXEKIZUMAB SHOWS A DISTINCT PATTERN OF PAIN IMPROVEMENT BEYOND INFLAMMATION IN RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

K. De Vlam[1], G. Gallo[2], P. J. Mease[3], P. Rahman[4], V. Krishnan[2], D. Sandoval[2], C. Y. Lin[2], R. Bolce[2], P. G. Conaghan[5]. *[1]University Hospital Leuven, Rheumatology, Leuven, Belgium*; *[2]Eli Lilly and Company, Lilly Corporate Centre, Indianapolis, United States of America*; *[3]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, United States of America*; *[4]Memorial University of Newfoundland, Medicine, St. John's, Canada*; *[5]University of Leeds, School of Medicine, Leeds, United Kingdom*

Background: The efficacy of ixekizumab (IXE) in biologic-naïve patients with radiographic axial spondyloarthritis (r-axSpA) has been previously presented using traditional axSpA outcome measures, such as BASDAI and ASAS.

Objectives: In patients with active r-axSpA, to assess the analgesic efficacy of IXE as it relates to patient-reported and objective measures of inflammation.
Methods: The Phase III COAST-V (NCT02696785) multi-center, randomized, double-blind, placebo (PBO)-controlled and active reference arm with adalimumab (ADA) trial investigated the efficacy of IXE in 341 patients (pts) with active r-axSpA for 52 weeks (W). Pts were initially randomized to IXEQ4W, IXEQ2W, PBO, and ADAQ2W. At W16, pts assigned to PBO and ADA were re-randomized to IXEQ2W or Q4W. Changes in spinal pain at night (SP-N) and spinal pain were measured at each study visit and analysed while controlling for CRP levels or mean of BASDAI questions 5 & 6 (Q5: Duration and Q6: Intensity of morning stiffness). Observed data analyses are presented for each group stratified by treatment arm and compared to PBO. In the initial analysis, pts were categorized into 2 sub-groups defined as "Sustained" and "Fluctuating" depending on: CRP <5 mg/L W4-16 vs. CRP ≥5 mg/L at any point beyond W4 between weeks 4-16 respectively. In a second analysis, pts were categorized based on BASDAI Q5/6 improvement: "Sustained" if ≥2-pt improvement W12-16 vs. "Fluctuating" if <2-pt improvement at any point beyond W12 between W12-16.
Results: Between W0 and W16, pts treated (tx) with IXEQ4W experienced greater reduction in SP-N than pts tx with ADA, in both CRP sustained and fluctuating groups (Fig 1a). Pts in the IXEQ4W and ADA arms showed different trajectories of pain improvement in the CRP fluctuating groups. For the pts with a fluctuating CRP ≥5 mg/L, pts in IXEQ4W arm demonstrated a greater reduction in SP-N compared to pts in PBO arm ($p < .001$) at W16, whereas pts in ADA arm did not experience a reduction in SP-N compared to PBO ($p = .416$). For the pts with a sustained CRP <5mg/L, IXEQ4W and ADA treatments both significantly demonstrated reduction in SP-N compared to PBO at W16 (IXEQ4W: $p = .002$; ADA: $p = .02$), with IXEQ4W treatment showing a greater level of reduction (Fig 1a). The pts randomized to ADA and re-randomized to IXEQ2W or Q4W (ADA/IXE) experienced further improvement in SP-N. This effect was sustained over the 52-wk period (Fig 1b). The same pattern of improvement in SP-N was observed when controlling for the BASDAI Q5/6; the SP-N improvement was greater in pts with a sustained BASDAI Q5/6 compared to pts with a fluctuating BASDAI Q5/6, regardless of treatment (Table 1). In the fluctuating BASDAI Q5/6, for pts in ADA/IXE arm, further reduction of both spinal pain and SP-N were observed (Table 1).

Figure 1: Change in Spinal Pain at Night (SP-N) over 52 weeks by CRP, in active treatment arms, showing IXE and ADA re-randomized to IXE (Q2W and Q4W combined: ADA/IXE)



Conclusion: IXE reduced SP-N and spinal pain irrespective of CRP or morning stiffness. Additionally, pts treated with ADA re-randomized to IXE experienced a further reduction in SP-N and spinal pain. Collectively, these results support the additive benefits of IXE in reducing pain above measurable effects on inflammation.

POS0902 EFFICACY AND SAFETY OF INTRAVENOUS GOLIMUMAB IN ANKYLOSING SPONDYLITIS PATIENTS WITH EARLY VS LATE DISEASE THROUGH WEEK 52 OF GO-ALIVE STUDY

A. Deodhar[1], S. Kafka[2], E. C. Hsia[3,4], K. H. Lo[5], L. Kim[5], S. Xu[5], J. D. Reveille[6].
[1]*Oregon Health & Science University, Division of Arthritis and Rheumatic Diseases, Portland, United States of America*; [2]*Janssen Scientific Affairs, LLC, Immunology, Horsham, United States of America*; [3]*Janssen Research & Development, LLC, Immunology, Spring House, United States of America*; [4]*University of Pennsylvania, Rheumatology, Philadelphia, United States of America*; [5]*Janssen Research & Development, LLC, Biostatistics, Spring House, United States of America*; [6]*University of Texas McGovern Medical School, Rheumatology And Clinical Immunogenetics, Houston, United States of America*

Background: The GO-ALIVE study assessed efficacy and safety of intravenous golimumab (IV GLM) in patients (pts) with ankylosing spondylitis (AS).[1,2]
Objectives: In this post hoc analysis, we assessed IV GLM efficacy and safety in AS pts with early disease (ED) vs late disease (LD) based on pt-reported duration of inflammatory back pain (IBP).
Methods: In this Phase 3, double-blind, placebo (PBO)-controlled trial, pts with active AS were randomized (1:1) to receive IV GLM 2 mg/kg at Week (W) 0, W4, then Q8W or PBO at W0, W4, and W12 with crossover to IV GLM at W16, W20, then Q8W through 52. The primary endpoint was achievement of SpondyloArthritis International Society 20% improvement response (ASAS 20) at W16. In this post hoc analysis, 208 pts were grouped into quartiles based on self-reported duration of IBP symptoms. Efficacy and safety in 60 pts with ED (1st quartile) were compared with 52 pts with LD (4th quartile).
Results: For the overall study population, mean duration of IBP symptoms was 10.9 yr and mean time since diagnosis was 5.5 yr. For ED pts, the mean duration of IBP symptoms ranged from 2.3 yr (IV GLM) to 2.6 yr (PBO), and for LD pts ranged from 23.5 yr (IV GLM) to 24.4 yr (PBO). At W16, ASAS 20 was achieved by 72% IV GLM vs 32% PBO pts with ED and by 67% IV GLM vs 21% PBO pts with LD. Pts with ED had numerically better response than those with LD in Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Metrology Index (BASMI), and across more stringent endpoints, including ASAS 40, Bath Ankylosing Spondylitis Disease Activity Index 50% improvement

Table 1. Change in Pain Outcome at baseline, week 16 and week 52 by Inflammation Status as assessed by BASDAI or CRP levels for patients receiving placebo (PBO), adalimumab (ADA), and ixekizumab every 4 weeks (IXE Q4W)

		Change from baseline								
		PBO			ADA			IXEQ4W		
		baseline	Week 16 (as observed)	Week 52 PBO/IXE (as observed)	baseline	Week 16 (as observed)	Week 52 ADA/IXE (as observed)	baseline	Week 16 (as observed)	Week 52 (as observed)
Spinal pain	BASDAI Q5/6 sustained	7.54	-3.33	-4.65	7.21	-4.07	-4.5	7.4	-4.52	-4.94
	BASDAI Q5/6 fluctuating	7.37	-1.32	-2.82	6.76	-1.2	-2.24	6.97	-1.3	-2.52
	CRP sustained	7	-1.53	-1.93	6.83	-2.9	-3.6	7.23	-3.57	-4.21
	CRP fluctuating	7.51	-1.96	-3.63	7.28	-2	-2.89	7.24	-2.91	-3.93
Spinal pain at night	BASDAI Q5/6 sustained	7.12	-3.21	-4.61	7.26	-4.63	-4.92	7.12	-4.73	-4.91
	BASDAI Q5/6 fluctuating	7.05	-1.15	-2.88	6.6	-1.2	-2.49	7.03	-2.17	-2.92
	CRP sustained	7.2	-1.87	-2.27	6.76	-3.2	-3.85	6.89	-3.8	-4.12
	CRP fluctuating	7.04	-1.69	-3.6	7.24	-2.21	-3.39	7.35	-3.68	-4.38

(BASDAI 50), and Ankylosing Spondylitis Disease Activity Score (ASDAS) inactive disease and major improvement (Table 1). Response rates at W16 among IV GLM-treated pts were generally consistent through 1 year in both ED and LD subgroups; also in ED and LD subgroups, pts crossing over to IV GLM at W16 demonstrated response at W52 consistent with pts who started IV GLM at W0. At W16, improvements in enthesitis score were similar for pts with ED (mean change -2.9 for IV GLM vs 0.1 for PBO) and LD (mean change -2.5 for IV GLM vs 0.6 for PBO); improvements were maintained at W52 for ED and LD pts. Treatment-emergent adverse events and serious adverse events through 1 year were 46% and 3% for pts with ED compared with 61% and 2% for pts with LD, respectively.

Conclusion: While IV GLM provided clinically meaningful improvements in signs and symptoms of AS in pts regardless of disease duration, response generally appeared numerically better in pts with ED than in pts with LD. This supports the principle of prompt diagnosis and early treatment.

CLINICAL AND RADIOLOGICAL MANIFESTATIONS OF COXITIS IN PATIENTS WITH ANKYLOSING SPONDYLITIS (AS) TREATED WITH TNF-ALPHA INHIBITOR GOLIMUMAB: RESULTS OF A 24-MONTHS OBSERVATION (GO-COX STUDY)

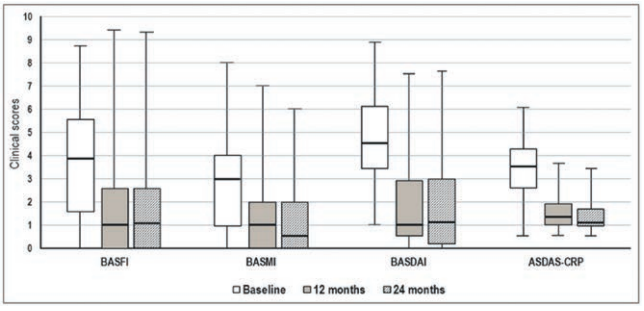
S. Erdes[1], E. Agafonova[1], D. Rumiantceva[1], S. Davidian[2], E. Zemerova[3], A. Kulikov[4], O. Markova[5], E. Lukyanova[6], V. Achikyan[6]. [1]*Federal Rheumatology Research Institute n.a. V.A.Nasonova, Laboratory of Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation*; [2]*National Medical and Surgical Center named after N.I. Pirogov, Rheumatology, Moscow, Russian Federation*; [3]*Khanty-Mansiysk Autonomous Region - Yugra Regional Clinical Hospital, Rheumatology, Khanty-Mansiysk, Russian Federation*; [4]*Rostov-on-Don Regional Clinical Hospital #2, Rheumatology, Rostov-on-Don, Russian Federation*; [5]*Yakutsk Clinic Lotos, Rheumatology, Yakutsk, Russian Federation*; [6]*MSD Pharmaceuticals LLC, Medical Affairs, Moscow, Russian Federation*

Background: Coxitis (hip joint inflammation) in AS is associated with worse BASFI scores due to hip joint involvement and more severe axial disease [1]. Radiological index of BASRI-hip, US and MRI findings may be used for evaluation of hip joint impairment [2, 3, 4]. Number of studies on coxitis in AS patients treated with biologics was limited at time of this study initiation.

Objectives: To evaluate clinical changes measured by BASFI, BASMI, BASDAI, ASDAS-CRP and radiological changes in AS patients with coxitis (BASRI-hip, hip MRI [STIR- and T1-weighted sequences], hip US) after 12 and 24 months of treatment with TNF alpha inhibitor golimumab from baseline.

Methods: A non-interventional prospective cohort study. Bio-naïve patients with AS and coxitis were treated with golimumab according to daily clinical practice in 5 clinics across Russia and followed up for 24 months. 39 patients participated. This analysis includes data from 30 patients who completed the follow up. The whole cohort's data to be presented after consolidation of safety data. MRI and US data were collected for 12 months in up to 28 of 30 patients. The primary endpoint was mean change of BASFI which was expected to be -2.5 (± 2.12) from baseline at week 52 weeks (12 months) of therapy [5]. The power of the study was 90% with minimum sample size of 18 patients. Student's paired t-criteria, Wilcoxon signed rank test were used to compare quantitave and Chi-square test for qualitative variables.

Results: Majority of participants (66,7%; 20 out of 30) were male, with mean (SD) age of 33.2 (9.4) years, mean (SD) duration of AS was 36.2 (42.1) months, mean (SD) duration of coxitis was 36.9 (44.1) months. Baseline mean (SD) scores were: BASFI 3.9 (2.5), BASMI 3.1 (2.5), BASDAI 4.9 (2.0), ASDAS-CRP 3.5 (1.2). Changes of mean clinical scores from baseline after 12 and 24 months of treatment with golimumab were: ΔBASFI= -2.2 (p=0.0001), -2.1 (p=0.0000); ΔBASMI= -1.5 (p=0.0000), -1,8 (p=0.0000); ΔBASDAI= -3.0 (p=0.0000), -3.1 (p=0.0000); ΔASDAS-CRP= -2.0 (p=0.0000), -2.1 (p=0.0000), correspondingly (n=30). The clinical results (medians, interquartile ranges, min and max) are presented below.



Baseline mean (SD)/median BASRI-hip was 1.1 (0.8)/1.0 on the right and on the left. Changes of mean/median BASRI-hip score at 12 and 24 months compared to baseline were: 0.3/0.0 (n=25; p=0.2344) and 0.3/0.0 (n=25; p=0.1368) on the right; 0.4/0.0 (n=25; p=0.0352) and 0.4/1.0 (n=25; p=0.0735) on the left. Rates of patients with MRI and US findings are presented below.

Hip	MRI, paired analysis	Patients (%), n=27		Patients (%), n=23	
		Baseline	At 6 months	Baseline	At 12 months
Right	No findings	33.3	48.1	39.1	56.5
	Subchondral bone marrow edema (SBME)	37.0	11.1	34.8	8.7
	Joint effusion	74.1	25.9*	73.9	17.4*
	Enthesitis	33.3	11.1	34.8	21.7
	Fatty degeneration	37.0	55.6	34.8	52.2
Left	No findings	29.6	51.9	30.4	52.2
	SBME	18.5	3.7	8.7	4.3
	Joint effusion	63.0	22.2*	60.9	21.7
	Enthesitis	22.2	18.5	17.4	21.7
	Fatty degeneration	33.3	55.6	30.4	52.2
Hip	US, paired analysis	Patients (%), n=28		Patients (%), n=27	
		Baseline	At 6 months	Baseline	At 12 months
Right	No findings	14.3	50.0*	18.5	51.9*
	Joint effusion	46.4	25.0	51.9	11.1*
	Enthesitis	25.0	14.3	18.5	14.8
Left	No findings	14.3	50.0*	18.5	55.6*
	Joint effusion	42.9	28.6	48.1	25.9
	Enthesitis	17.9	17.9	11.1	18.5

*$p<0.05$

Conclusion: Therapy with TNF alpha inhibitor golimumab for 24 months in AS patients with coxitis was accompanied with statistically significant improvement of clinical scores with primary endpoint achieved (mean BASFI change -2.5 at 12 months), improvement of MRI and US findings without obvious structural progression measured with BASRI-hip score compared to baseline.

POS0904 FACTORS ASSOCIATED WITH SWITCHING FROM ONE ANTI-TNF AGENT TO ANOTHER ANTI-TNF, OR IL17 AGENT IN PATIENT WITH ANKYLOSING SPONDYLITIS

M. Hwang[1], M. Weisman[2], L. S. Gensler[3], A. Tahanan[4], M. Ishimori[2], T. Hunter[5], R. Bolce[5], J. Lisse[5], M. Rahbar6, M. Shan[5], J. D. Reveille[7]. *[1]McGovern Medical School at UTHealth, Rheumatology, Houston, United States of America*; *[2]Cedars-Sinai Medical Records Office, Rheumatology, Los Angeles, United States of America*; *[3]University of California San Francisco Parnassus Campus, Rheumatology, San Francisco, United States of America*; *[4]University Of Texas Professional Building, Medicine, Houston, United States of America*; *[5]Eli Lilly, Medical Affairs, Indianapolis, United States of America*; *[4]University Of Texas Professional Building, Medicine, Houston, United States of America*; *[7]University of Texas McGovern Medical School, Rheumatology, Houston, United States of America*

Background: A recent study examining Commercial Claims Insurance database found that many patients with ankylosing spondylitis (AS) do not remain on their initial TNF inhibitor two years after initiation, particularly women and those taking opioids.

Objectives: To examine factors associated with switching from one TNF inhibitor (i)agent to either another TNFi, IL-17i or JAKi over time (at <2years and >2 years) in a longitudinal cohort of AS patients.

Methods: Patients enrolled in the Prospective Study of Outcomes in AS (PSOAS), an observational longitudinal study of predictors of AS severity operative since 2002-2020 including over 1250 patients meeting modified New York criteria. Data collected included age, gender, ethnicity, HLA-B27 status, disease activity (BASDAI or ASDAS), erythocyte sedimentation rate (ESR), C-reactive protein (CRP), disease severity,(functional (BASFI) or radiographic (mSASSS)), comorbidities, smoking, exercise, disease duration, depression (either by self report or by the Center for Epidemiologic Studies Depression Scale (CES-D) and other medication usage (NSAIDs, including the NSAID index, nonbiologic DMARDs, opioids, anti-depressants, anxiolytics and hypnotics). Logistic regression models were built to identify clinical and sociodemographic characterstics associated with medication switching to another TNFi, IL-17i, or other biologic therapy (another TNFi, Il-17i, or JAKi) within 2 years and after 2 years of initiation).

Results: Of those patients in PSOAS who had at least two years of follow-up, 496 were prescribed anti-TNF, 34 anti-IL-17 and 3 anti-JAK agents. According to the multinomial logistic regression analysis, patients who switched from their original TNFito another TNFi, IL-17i or JAKi within two years after initiating their original TNFi were more likely to be older, have higher baseline subjective disease activity (BASDAI), less radiographic severity by MSASSS, exercise > 120 minutes/week and less likely to be currently smoking. Patients who switched after two years were less likely be depressed, had shorter disease duration, had greater subjective disease activity, were more likely to be exercising > 120 minutes/week, and had more comorbidities.

Conclusion: Different factors were encountered in AS patients who switched from their initial TNFi to another TNFi, IL-17i or JAKi within 2 years versus after 2 years of treatment.

Table 1. Factors Associated With Switching From One TNFi To A Second TNFi or IL-17i or JAKi Before or After Two Years Based On Multinomial Logistic Regression Model (N=496 Patients)

Variable	Switched within 2 years vs. not switched	p-value*	Switched after 2 years vs. not switched	p-value*
Gender (Male vs. Female)	0.99 (0.637, 1.549)	0.98	0.95 (0.528, 1.719)	0.87
HLA-B27_(+ vs. -)	0.99 (0.639, 1.523)	0.95	0.66 (0.365, 1.192)	0.17
Depression (CESD≥ 16 or self-report)(Yes vs. No)	0.99 (0.676, 1.445)	0.95	0.35 (0.182, 0.672)	0.002
Disease duration at baseline (≥20 vs. <20 years)	0.72 (0.485, 1.062)	0.10	0.27 (0.146, 0.491)	<0.001
Age at baseline (≥40 vs. <40) (years)	2.00 (1.291, 3.101)	0.002	1.23 (0.693, 2.193)	0.48
CRP (≥0.8 vs. <0.8)	1.94 (1.230, 3.056)	0.004	0.90 (0.454, 1.789)	0.77
BASFI (≥40 vs. <40)	1.34 0.852, 2.118)	0.20	0.87 (0.450, 1.688)	0.68
BASDAI (≥4 vs. <4)	1.73 (1.064, 2.797)	0.03	2.31 (1.202, 4.427)	0.01
NSAID index (≥50 vs. <50)	1.32 (0.822, 2.128)	0.25	0.83 (0.437, 1.586)	0.58
NSAIDs used (Yes vs. No)	0.84 (0.534, 1.309)	0.43	0.85 (0.479, 1.510)	0.58
Exercise (≥120 vs. <120) (minutes/week)	1.95 (1.396, 2.731)	<0.001	1.66 (1.057, 2.613)	0.03
ASDAS (≥3 vs. <3)	0.78 (0.454, 1.356)	0.39	1.07 (0.478, 2.399)	0.87
Number of comorbidities (≥2 vs. <2)	1.40 (0.997, 1.951)	0.05	1.63 (1.029, 2.575)	0.04
mSASSS (≥4, vs. <4)	0.63 (0.421, 0.957)	0.03	0.81 (0.474, 1.392)	0.03
Current smoker (Yes vs No)	0.69 (0.385, 1.225)	<0.001	0.79 (0.297, 2.076)	0.20

*p-values calculated based on multinomial logistic regression model when switching is defined as being prescribed a second TNFi or taking IL-17i or JAKi before or after 2 years from first TNFi initiation

POS0905 ACHIEVEMENT OF PARTIAL REMISSION AND INACTIVE DISEASE IN UPADACITINIB-TREATED PATIENTS WITH ANKYLOSING SPONDYLITIS

A. Deodhar[1], A. Ostor[2], A. Maniccia[3], F. Ganz[4], T. Gao[3], A. Chu[3], D. Poddubnyy[5]. *[1]Oregon Health & Science University, Rheumatology, Portland, United States of America*; *[2]Cabrini Hospital, Monash University & Emeritus Research, Melbourne, Australia*; *[3]AbbVie Inc., Rheumatology, North Chicago, United States of America*; *[4]AbbVie, Rheumatology, Baar, Switzerland*; *[5]Department of Gastroenterology, Infectious Diseases and Rheumatology, Charité-Universitätsmedizin, and Epidemiology Unit, German Rheumatism Research Centre, Berlin, Germany*

Background: Assessment of SpondyloArthritis international Society (ASAS) response criteria and AS Disease Activity Score (ASDAS) are both commonly used, rigorous composite indices consisting of components with relevance to patients. Clinically meaningful thresholds for these measures have been defined to reflect partial remission (PR), inactive disease (ID), and low disease activity (LDA).

Objectives: To study the association of ASAS PR and ordinal ASDAS disease categories (including ASDAS ID, which is the most stringent category of this composite score) in upadacitinib (UPA)-treated patients with AS.

Methods: In the SELECT-AXIS 1 (NCT03178487) study, biologic DMARD naïve-patients (pts; ≥18 y) with active AS and intolerance/contraindication or inadequate response to ≥2 NSAIDs were randomized 1:1 to UPA 15 mg once daily (QD) or placebo (PBO).[1] At wk 14, pts entered an open-label extension (OLE) of UPA 15 mg QD; pts randomized to PBO were switched to UPA. This post hoc analysis assessed the responsiveness of individual ASAS and ASDAS core components among pts who achieved ASAS PR. The association of ASAS PR with achievement of ASDAS ID (ASDAS <1.3), ASDAS LDA (ASDAS <2.1 but ≥1.3) or ASDAS high disease activity (HDA)/very HDA (VHDA) (ASDAS ≥2.1 for HDA/VHDA) was also assessed by measures including Youden index, distance to perfect point, and sensitivity/specificity

equality. These evaluations were performed in pts randomized to UPA from baseline (BL; continuous UPA, assessed at wk 14) and those who were randomized to PBO and switched to UPA upon entry in the OLE (PBO to UPA; re-baselined at wk 14 and assessed at wk 32, representing 18 wks of UPA exposure).

Results: At wk 14, for the continuous UPA group, 16 pts (19%) achieved ASAS PR. At wk 32, following 18 wks of UPA exposure for the PBO-to-UPA group, 28 pts (33%) achieved ASAS PR. Among both groups (continuous UPA and PBO-to-UPA), improvements were seen across all core components (Figure 1). Of the 44 total pts who achieved ASAS PR, 91% achieved either ASDAS ID or LDA. The majority of patients who achieved ASAS PR achieved ASDAS ID in the continuous UPA and PBO-to-UPA groups: 11/16 (69%) and 16/28 (57%), respectively. For the continuous UPA group, the remaining 5 pts who achieved ASAS PR also achieved ASDAS LDA (Table 1). ASAS PR was associated with ASDAS categories in the following manner: the highest rate of ASAS PR was achieved for ASDAS ID followed by ASDAS LDA followed by ASDAS HDA/VHDA. The cutoff of 1.3 (the upper threshold for ASDAS ID) was a better discrimination threshold for ASAS PR than the cutoff of 2.1 (the upper threshold for ASDAS LDA).

Conclusion: Nineteen percent of pts receiving UPA from BL achieved ASAS PR after 14 wks of treatment, with similar results seen in pts who were originally randomized to PBO and switched to UPA at wk 14. A consistent improvement was seen across all core components of ASAS among those who achieved ASAS PR with UPA treatment. The achievement of ASAS PR was most closely associated with the achievement of ASDAS ID, providing further clarity on the reduction of disease activity in AS pts treated with UPA.

PREVALENCE OF SLEEP DISTURBANCE IN PATIENTS WITH ANKYLOSING SPONDYLITIS WITHIN THE AUSTRALIAN CLINICAL SETTING (ASLEEP STUDY): A REAL-WORLD OBSERVATIONAL STUDY USING THE OPAL DATASET

K. Tymms[1,2], B. Butcher[3,4], T. Sletten[5], T. Smith[2], C. Osullivan[2], G. Littlejohn[2,6], R. Sadler[7], R. Tronnberg[7], H. Griffiths[2,8]. Background: Sleep disorders are more prevalent in patients with ankylosing spondylitis (AS) compared to the general population. Sleep disturbance in AS, in addition to pain and fatigue, can lead to impaired physical function and reduced quality of life.

Objectives: The primary objective was to determine the prevalence of sleep disturbance in patients with AS in a real-world Australian cohort using the Insomnia Severity Index (ISI) and Multivariate Apnoea Prediction Index (MAPI). ISI score of ≥ 15 is considered clinical insomnia. MAPI values below 0.05 are suggestive of clinical apnoea.

Methods: Routinely collected, de-identified clinical data were sourced from the OPAL dataset. Patients aged between 18 and 95 years with a diagnosis of AS and who had completed at least one ISI or MAPI questionnaire between Jan-2019 and Sept-2020 were included. ISI and MAPI questionnaires were emailed to patients using OPAL's electronic patient reported outcome (ePRO) delivery method or completed in the clinic using a smart device and returned to the patient's file using a QR code. Disease activity was assessed using BASDAI collected at the same time as the sleep questionnaires. Age, sex and duration of symptoms were used to propensity match patients in the Il-17ai and TNFi group in a 1:2 ratio.

Results: 495 of the 5,323 patients identified with AS completed a questionnaire and were included in the analysis (n=395 TNFi, n=48 Il-17ai (secukinumab), n=52 other therapies). 142 were included in the propensity score matched population (n = 94 TNFi, and n = 48 Il-17ai). In the overall population the mean (SD) age was 48.3 (13.6), 55.4% were males, the mean (SD) BMI was 30.1 (19.6) at the index date and 4.8% reported depression. 51.7% had an optimal disease control (BASDAI <4). The mean (SD) ISI score was 8.6 (6.2). 48.1% reported no clinical significant insomnia, 32.7% reported subthreshold insomnia, 16% reported clinical insomnia (moderate severity) and 3.2% reported clinical insomnia (severe). The mean (SD) MAPI score was 0.4 (0.3). 292 patients (59.0%) had low risk of clinical apnoea, 134 patients (27.1%) had high risk of clinical apnoea and 69 patients 13.9% had not completed the MAPI questionnaire. In the propensity scored matched population, the TNFi and Il-17ai groups had mean (SD) ISI scores of 9.1 (6.6) and 8.9 (5.9) at index, respectively (p = 0.83) and mean (SD) MAPI scores of 0.3 (0.2) and 0.4 (0.3) at index, respectively (p=0.046), however a higher percentage of overweight and obese patients were identified in the Il-17ai treatment group. Ordered logistic regression analysis of the relationship between demographics and ISI in the matched population found that patients with BASDAI ≥4 were seven times more likely to experience greater sleep disturbance (OR 7.29, 95%CI 2.37 to 22.46, p=0.001) than those with BASDAI <4.

Conclusion: In this real-world AS cohort, poor disease control was associated with sleep disturbance, despite bDMARD therapy. Little difference was observed between TNFi and Il-17ai treatment. Screening for sleep disturbance and fatigue in routine clinical care may provide a more holistic view of the burden of this disease.

Table 1. Patient characteristics and outcome scores in the propensity score matched population at index.

	TNFi (n=94)	Il-17ai (n=48)	p value
BMI category Underweight	2 (2%)	1 (2%)	0.094
Normal weight	33 (35%)	8 (17%)	
Overweight	24 (26%)	16 (33%)	
Obese	27 (29%)	21 (44%)	
Missing	8 (9%)	2 (4%)

POS0907 EFFECT OF UPADACITINIB ON REDUCING PAIN IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS AND INADEQUATE RESPONSE TO NONSTEROIDAL ANTI-INFLAMMATORY DRUGS

A. Deodhar[1], X. Baraliakos[2], I. Mcinnes[3], K. De Vlam[4], L. Bessette[5], A. Maniccia[6], R. Lippe[7], C. Saffore[6], T. Gao[6], I. H. Song[6], A. Ostor[8]. [1]*Oregon Health & Science University, Rheumatology, Portland, United States of America*; [2]*Ruhr-University Bochum, Rheumatology, Bochum, Germany*; [3]*University of Glasgow, Rheumatology, Glasgow, United Kingdom*; [4]*University Hospitals Leuven, Rheumatology, Leuven, Belgium*; [5]*Laval University, Rheumatology, Québec City, Canada*; [6]*AbbVie Inc., Rheumatology, North Chicago, United States of America*; [7]*AbbVie Deutschland GmbH & Co. KG, Rheumatology, Wiesbaden, Germany*; [8]*Cabrini Hospital, Monash University & Emeritus Research, Melbourne, Australia*

Background: Pain is a debilitating symptom of ankylosing spondylitis (AS) and negatively impacts patient (pt) lives. Upadacitinib (UPA), a Janus kinase (JAK) inhibitor engineered for increased selectivity for JAK1 over JAK2, JAK3, and tyrosine kinase 2, [1] showed significant efficacy vs placebo (PBO) in the randomized phase 2/3 SELECT-AXIS 1 study in active AS.[2]

Objectives: To evaluate the efficacy of UPA on multiple pain assessments through 64 weeks (wks).

Methods: SELECT-AXIS 1 (NCT03178487) enrolled adults with active AS, who had an inadequate response, intolerance or contraindications to ≥2 NSAIDs, were biologic DMARD naive and met the modified New-York Criteria. Pts were randomized 1:1 to UPA 15 mg once daily (QD, n=93) or PBO (n=94) for 14 wks (Period 1), followed by open-label UPA 15 mg QD during 90-wk extension (Period 2); reported here are data through wk 64. Pain endpoints included the proportion of pts achieving ≥30%/≥50%/≥70% reduction in Pt's Global Assessment (PGA) of pain on a 0–10 numeric rating scale (NRS), minimal clinically important difference (MCID, defined as ≥1 point reduction or ≥15% reduction from baseline [BL]) in PGA of pain, and much better improvement (MBI, defined as ≥2 point reduction and ≥33% reduction from BL) in PGA of pain. In addition, mean change from baseline in PGA of pain, BASDAI questions 2 (neck/back/hip pain) and 3 (peripheral pain/swelling), and pt's assessment of back pain and nocturnal back pain NRS scores (NRS 0–10) were assessed. Non-responder imputation (binary endpoints) and mixed-effects model for repeated measurements (continuous endpoints) were used for missing data/dropouts in Period 1; as-observed analysis was used for Period 2.

Results: A significantly higher proportion of pts receiving UPA vs PBO achieved reductions in all PGA of pain assessments as early as wk 2 that was sustained at all time points in Period 1; the only exception was ≥70% reduction in PGA of pain that was significant at wk 4 and sustained thereafter (Figure 1). For ≥30%/≥50%/≥70% reduction and MBI, the response rate increased over time with UPA; the difference for UPA vs PBO also continued to increase over time for ≥50% and ≥70% reduction endpoints. For MCID, an increase from BL to wk 2 was observed and plateaued thereafter. The mean change from BL in PGA of pain, BASDAI Q2, back pain, and nocturnal back pain NRS scores were significantly greater for UPA vs PBO at all time points in Period 1; BASDAI Q3 was significant at wk 8 and 14 (Figure 1). The effect of UPA on pain reduction was sustained through wk 64. PBO pts who switched to open-label UPA at wk 14 generally reached the same level of pain reduction as those initially randomized to UPA (Figure 1).

Conclusion: In pts with active AS and an inadequate response/contraindication to NSAIDs, a greater proportion of patients treated with UPA achieved rapid, significant, and clinically meaningful reductions in pain vs PBO through 14 wks across multiple pain assessments. The reductions in pain were sustained over time, and pts who switched from PBO to UPA reached the same level of improvement as the continuous UPA group.

POS0908

EFFICACY OF IXEKIZUMAB THROUGH 52 WEEKS FOR IMPROVING PERIPHERAL JOINT INVOLVEMENT AMONG PATIENTS WITH RADIOGRAPHIC-AXIAL SPONDYLOARTHRITIS

M. Magrey[1], K. De Vlam[2], A. Kronbergs[3], R. Bolce[3], D. Sandoval[3], X. Li[3], S. Liu Leage[3], D. Poddubnyy[4]. [1]*The MetroHealth System and School of Medicine, Case Western Reserve University, Division of Rheumatology, Cleveland, United States of America*; [2]*Univeristy Hospitals Leuven, Rheumatology Department, Leuven, Belgium*; [3]*Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America*; [4]*Universitätsmedizin Berlin, Division of Rheumatology, Berlin, Germany*

Background: Radiographic-axial spondyloarthritis (r-axSpA) is a progressive chronic inflammatory disease primarily affecting the spine and sacroiliac joints. However, about 30-40% of patients (pts) with axSpA can have peripheral joint involvement, including joint tenderness and swelling, which can contribute significantly to burden of disease. Ixekizumab (IXE), a monoclonal antibody that neutralizes the pro-inflammatory cytokine interleukin-17A, has demonstrated a high level of efficacy in the treatment of r-axSpA.

Objectives: The aim of this study is to evaluate the efficacy of IXE through 52 weeks (wks) in improving peripheral joint pain and swelling for pts with r-axSpA.

Methods: Data was derived from two phase III randomised, double-blind, placebo (PBO)-controlled trials: one in pts with r-axSpA, who were biological disease-modifying anti-rheumatic drug (bDMARD)-naïve (COAST-V: NCT02696785), and the other in pts who were tumor necrosis factor inhibitor-experienced (COAST-W: NCT02696798). All pts had a confirmed diagnosis of r-axSpA and had to meet ASAS (Assessment of SpondyloArthritis international Society) criteria. IXE (80 mg) or PBO were administered subcutaneously every 2 (Q2W) or 4 (Q4W) wks during a 52-wk treatment period, after receiving a starting dose of 80 mg or 160 mg at wk 0. COAST-V/W pts originally randomised to PBO were re-randomised 1:1 to IXE Q4W or Q2W at wk 16. We present a post-hoc analysis of data from an integrated dataset from COAST-V and W (COAST-V/W); with intent to treat (ITT) pts categorized by baseline (BL) peripheral joint status. The presence of peripheral joint involvement was defined using a 46-joint tender joint count (TJC) >0 or 44-joint swollen joint count (SJC) >0. Treatment response through wk 52 was evaluated based on % improvement (20%, 50% or 70%) and resolution of tender or swollen joints of pts with BL TJC>0 or SJC>0, respectively. Missing data were imputed by non-responder imputation (NRI). Treatment comparison vs PBO at wk 16 was performed using Cochran-Mantel-Haenszel test.

Results: This analysis includes 359 pts (63.4% of ITT) with baseline TJC>0 and 203 pts (35.9% ITT) with baseline SJC>0. The mean (SD) baseline TJC and SJC were 7.7 (8.3) and 4.3 (4.5), respectively. Mean BL TJC and SJC values by treatment group are presented in Table 1. A significant improvement of SJC by 20% and 50% was seen in pts treated with IXE Q4W compared to PBO at wk 16. Pts treated with IXE resulted in a numerically higher improvement in TJC and SJC symptoms up to wk 16 compared to PBO, and efficacy was sustained up to wk 52 (Table 1). A higher proportion of IXE-treated pts achieved high-hurdle efficacy endpoints (50% and 70% improvements) in comparison to PBO at wk 16 (Table 1). Over this time period, IXE treatment led to a high proportion of pts experiencing complete resolution of TJC or SJC vs PBO at wk 16, which was sustained up to wk 52 (Fig 1).

Conclusion: In this post hoc analysis, pts with r-axSpA treated with IXE showed substantial improvement in peripheral joint pain and swelling.

Table 1. Improvement of Tender or Swollen Joint Counts for pts with radiographic-axSpA with TJC>0 or SJC>0 at baseline (COAST-V/W)[a] - NRI Results

POS0909 IXEKIZUMAB IMPROVES SIGNS, SYMPTOMS AND QUALITY OF LIFE OF ANKYLOSING SPONDYLITIS IN PATIENTS IRRESPECTIVE OF HLA-B27 STATUS: POOLED RESULTS FROM THE COAST-V AND COAST-W TRIALS

J. D. Reveille[1], P. Rahman[2], D. Sandoval[3], T. Muram[4], R. Bolce[4], S. Y. Park[4], M. Rudwaleit[5]. *[1]University of Texas Houston, Department of Internal Medicine, Houston, United States of America*; *[2]Memorial University of Newfoundland, Clinical Research, St. John's, Canada*; *[3]Eli Lilly and Company, Immunology, Indianapolis, United States of America*; *[4]Eli Lilly and Company Corporate Center, Immunology, Indianapolis, United States of America*; *[5]Charité - Campus Benjamin Franklin (Berlin), Rheumatology, Berlin, Germany*

Background: Human leukocyte antigen-B27 (HLA-B27) is found in most patients (pts) with ankylosing spondylitis (AS). Although a subset of pts with AS are HLA-B27 negative (NEG), ensuring treatment efficacy in this subpopulation is important.

Objectives: This analysis evaluated the efficacy of ixekizumab (IXE), a high-affinity monoclonal antibody selectively targeting interleukin-17A, in AS pts who are either HLA-B27 positive (POS) or NEG.

Methods: COAST-V (NCT02696785) and COAST-W (NCT02696798) were 2 phase 3, multicenter, randomized, double-blind, PBO-controlled trials investigating the efficacy of 80-mg IXE administered every 4 weeks (Q4W) and every 2 weeks (Q2W) in pts naïve to biological disease-modifying anti-rheumatic drugs (bDMARDs; COAST-V) and in those who were inadequate responders or intolerant to 1 or 2 tumor necrosis factor inhibitors (TNFi; COAST-W). Only data from pts randomized at baseline to PBO, IXE Q4W or Q2W in both trials who met per protocol eligibility criteria were integrated and stratified based on HLA-B27 status (POS, NEG) for an *ad hoc* subgroup analysis. Efficacy was assessed using the Assessment of Spondyloarthritis International Society 40 (ASAS40), Bath Ankylosing Spondylitis Disease Activity Index 50 (BASDAI50) and Short Form 36 Physical Component Scores (SF-36 PCS). Missing data were imputed by non-responder imputation (NRI) for binary measure and by modified baseline observation carried forward (mBOCF). Data from PBO was reported up to Week 16 and for pooled IXE Q4W and Q2W up to Week 52.

Results: This analysis includes pts with AS who are HLA-B27 POS (N=453; PBO=155, IXE=298) or NEG (N=62, PBO=21, IXE=41). Overall, more pts were male (82.6%, POS; 77.4%, NEG), and for IXE treated pts, the duration of disease since r-axSpA diagnosis was 10.3 (SD=9.1) and 6.9 (SD=5.6) years, among POS and NEG pts respectively (Table 1). Among IXE treated patients, the mean age of HLA-B27 NEG pts was approximately 7-8 years older than HLA-B27 POS pts. At Week 16, 39.6% (n=118/298) of HLA-B27 POS and 29.3% (n=12/41) of HLA-B27 NEG pts achieved ASAS40, and 34.6% (n=103) of HLA-B27 POS and 17.1% (n=7) of HLA-B27 NEG pts achieved BASDAI50; improvements were seen as early as Week 1 and sustained or improved up to Week 52. The mean baseline SF-36 PCS was 33.2 (SD=7.63) for HLA-B27 POS and 31.4 (SD=7.67) for HLA-B27 NEG pts. At Week 16, the mean change from baseline in SF-36 PCS was 7.3 (SD 7.6) for HLA-B27 POS and 3.7 (SD=6.83) for HLA-B27 NEG pts. Improvements were sustained to Week 52 (Figure 1).

Conclusion: IXE improves signs, symptoms, patient-reported outcomes and health-related quality of life in HLA-B27 POS and NEG pts with AS, however the HLA-B27 POS pts have a faster and more robust response than HLA-B27 NEG pts.

POS0910 EVALUATION OF THE NONSTEROIDAL ANTI-INFLAMMATORY DRUG-SPARING EFFECT OF SECUKINUMAB IN PATIENTS WITH ANKYLOSING SPONDYLITIS: RESULTS OF THE MULTICENTER, RANDOMISED, DOUBLE-BLIND, PHASE IV ASTRUM-TRIAL

U. Kiltz[1,2], X. Baraliakos[1,2], J. Brandt-Juergens[3], U. Wagner[4], S. Lieb[5], C. Sieder[5], C. Mann[5], J. Braun[1,2]on behalf of The study was sponsored by Novartis Pharma GmbH, Germany.. *[1]Rheumazentrum Ruhrgebiet, Claudiusstraße, Herne, Germany*; *[2]Ruhr-Universität Bochum, Universitätsstraße, Bochum, Germany*; *[3]Rheumatologische Schwerpunktpraxis, Seelbergstraße, Berlin, Germany*; *[4]Universitätsklinikum Leipzig AöR, Medizinische Klinik und Poliklinik 3 für Endokrinologie,*

Nephrologie, Rheumatologie, Sektion Rheumatologie, Leipzig, Germany; [5]*Novartis Pharma GmbH, Immunology, Hepatology and Dermatology, Nürnberg, Germany*

Background: Nonsteroidal anti-inflammatory drugs (NSAIDs) are used to treat inflammatory back pain in patients (pts) with ankylosing spondylitis (AS). However, an increased risk of side effects associated with NSAIDs and their dosage has been reported[1]. Therefore, lower doses and a dose reduction is desirable.

Objectives: To evaluate the short-term NSAID sparing effect of secukinumab (SEC) in AS pts with NSAID intake.

Methods: In a prospective controlled trial, 211 adult pts with active AS (BASDAI ≥4) and an inadequate response (IR) to at least 2 NSAIDs at the highest recommended/tolerated dose and pts with an IR, or those who were naïve/intolerant to a maximum of 2 tumour necrosis factor inhibitors (TNFi) were enrolled. NSAID intake was evaluated using the ASAS-NSAID score. To be eligible, pts had to take at least 50% of the highest recommended/tolerated NSAID dose regularly. Pts were randomised (1:1:1) to receive SEC 150 mg s.c. from Week (Wk) 0 (group [gp] 1), Wk 4 (gp 2) and Wk 16 (gp 3). All groups received SEC 150 mg from Wk 16. NSAID tapering was allowed in all groups from Wk 4 onwards. The primary endpoint (PE) was an ASAS20 response of pooled gp 1 and gp 2 *vs.* gp 3 at Wk 12.

Results: There were 71 pts in gp 1, 70 in gp 2 and 70 in gp 3. Baseline (BL) characteristics were comparable across groups; mean age (SD) was 45.2 (12.3) years (yrs), time since diagnosis was 7.4 (9.8) yrs, 57.8% male, 79.0% HLA-B27 positive, 48.6% pts had an elevated CRP 40.8% were current/ever smoker and 72.0% were TNFi-naïve. The ASAS-NSAID (SD) scores at BL were: gp 1 *vs.* gp 2 *vs.* gp 3: 82.9 (37.7) *vs.* 79.9 (45.3) *vs.*82.3 (39.1). BASDAI and ASDAS-CRP scores were similar between groups: 6.0 (1.4) *vs.* 6.2 (1.5) *vs.* 6.2 (1.3), and 3.4 (0.7) *vs.* 3.3 (0.8) *vs.* 3.4 (0.7), respectively. The ASAS20 response at Wk 12 of pooled gp 1 and 2 *vs.* gp 3 was 51.1% *vs.* 44.3% but PE was not met (p=0.35). A higher proportion of pts in gp 1 and 2 achieved ASAS40 and BASDAI50 and other secondary outcomes at Wk 16 (Table 1). More pts in gp 1 and 2 reduced their NSAID intake from BL through Wk 16 *vs.* gp 3 (Table 1 **and** Figure 1).

SIMILAR CLINICAL RESPONSES ACHIEVED WITH LOWER VERSUS STANDARD DOSES OF INFLIXIMAB BIOSIMILAR CT-P13 IN PATIENTS WITH ANKYLOSING SPONDYLITIS: REAL-WORLD RESULTS FROM THE RAAS STUDY

S. S. Lee[1], T. H. Kim[2], W. Park[3], Y. W. Song[4], C. H. Suh[5], S. Kim[6], D. Yoo[2]. *[1]Chonnam National University Medical School & Hospital, Department of Rheumatology, Gwangju, Korea, Rep. of (South Korea)*; *[2]Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea)*; *[3]Inha University, School of Medicine, Incheon, Korea, Rep. of (South Korea)*; *[4]Seoul National University College of Medicine, Seoul National University Hospital, Department of Internal Medicine, Division of Rheumatology, Seoul, Korea, Rep. of (South Korea)*; *[5]Ajou University School of Medicine, Department of Rheumatology, Suwon, Korea, Rep. of (South Korea)*; *[6]Celltrion Healthcare Co., Ltd., Medical Affairs Department, Incheon, Korea, Rep. of (South Korea)*

Background: CT-P13, an infliximab biosimilar, is effective for treating ankylosing spondylitis (AS) at a dose of 5 mg/kg infused once every 6–8 weeks. Evidence suggests that patients with AS may benefit from a lower dose, and individualised dose/interval adjustments should be based on treatment response.
Objectives: To analyse real-world treatment patterns (doses and infusion intervals) and outcomes for CT-P13-treated patients with AS over 5 years.
Methods: The RAAS study collected medical record data for adults with AS treated with CT-P13 at five referral hospitals in the Republic of Korea (2012–2017). Patients were infliximab naïve at CT-P13 initiation ('naïve') or had switched to CT-P13 from reference infliximab ('switched'). Patients were analysed by baseline dose (BD) (<4 mg/kg; ≥4–<5 mg/kg; ≥5 mg/kg), defined as the third (naïve) or first (switched) infusion dose. Baseline infusion intervals were the average of the three infusion intervals after BD. Over time, patients with both constant dose and infusion interval were compared with those with changes in dose and/or infusion interval. Data were analysed by Kruskal–Wallis test, chi-squared test and one-way analysis of variance, and drug survival by log-rank test.
Results: Overall, 337 patients (219 naïve; 118 switched) were identified. Of those with BD data, 71, 117 and 82 patients had BDs of <4 mg/kg, ≥4–<5 mg/kg and ≥5 mg/kg, respectively. Most patients were male (74.8%). Patients with higher BDs tended to have higher Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scores; switched patients had lower scores than naïve patients. Of 186 evaluable patients (118 naïve; 68 switched), 85 (46 naïve; 39 switched) did not have dose and/or interval changes ('combined constant' group). More naïve (n=72; 61.0%) versus switched (n=29; 42.6%) patients had dose and/or interval changes ('combined changed' group). Considering dose and interval separately, 18/235 evaluable patients (152 naïve; 83 switched) had dose changes (12 increased; 6 decreased) and 110/224 evaluable patients (140 naïve; 84 switched) had interval changes (79 increased; 31 decreased). Cumulative annual doses were similar between naïve and switched patients; switched patients had longer infusion intervals than naïve patients (Figure 1). There were no significant differences in drug survival between BD groups overall or for naïve and switched patients. BASDAI scores over time showed that disease activity was well controlled (Table 1). Patients in the combined changed versus combined constant group had greater improvements in BASDAI score.

Table 1. BASDAI scores

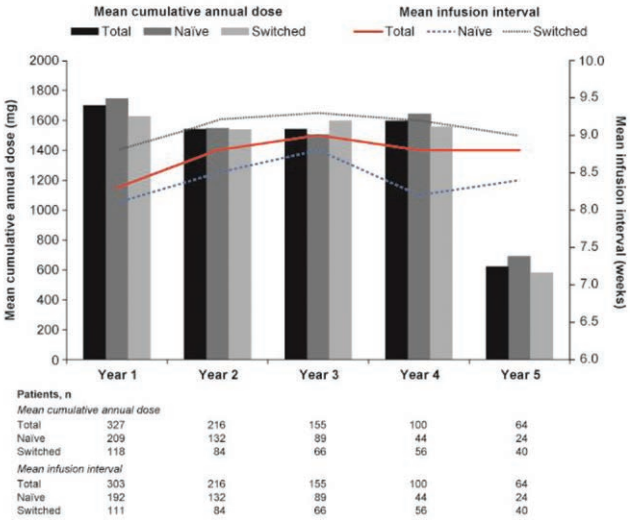
Figure. Mean cumulative annual dose and mean infusion interval by treatment group



Conclusion: These real-world data demonstrate that adjusting dose and infusion interval can improve clinical outcomes for CT-P13-treated patients with AS. Drug survival and BASDAI results show that patients with lower baseline BASDAI receiving low CT-P13 doses can achieve the same outcomes as those dosed with ≥5 mg/kg. Findings support the lack of impact of switching from reference infliximab to CT-P13 on efficacy, underlining conclusions previously drawn for efficacy and safety.[1]

LONG-TERM TREATMENT WITH IXEKIZUMAB IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: TWO-YEAR RESULTS FROM COAST-Y

J. Braun[1,2], U. Kiltz[1,2], A. Deodhar[3], T. Tomita[4], M. Dougados[5], R. Bolce[6], D. Sandoval[6], D. Adams[6], C. Y. Lin[6], J. A. Walsh[7]. *[1]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany*; *[2]Ruhr-Universität Bochum, Rheumatology, Herne, Germany*; *[3]Oregon Health & Science University, Rheumatology, Portland, United States of America*; *[4]Osaka University Graduate School of Medicine, Rheumatology, Osaka, Japan*; *[5]Hôpital Cochin, Rheumatology, Paris, France*; *[6]Eli Lilly and Company, Biomedicines, Indianapolis, United States of America*; *[7]University of Utah, Rheumatology, Salt Lake City, United States of America*

Background: The efficacy and safety of the interleukin-17 inhibitor ixekizumab (IXE) for the treatment of radiographic (r-) and non-radiographic (nr-) axial spondyloarthritis (axSpA) has been shown for up to 52 weeks.[1-2]
Objectives: To study the efficacy and safety of ixekizumab in the treatment of patients with r- and nr-axSpA for up to 116 weeks.
Methods: COAST-Y (NCT03129100) is the 2-year extension of the COAST-V, -W, and -X trials. Patients continued with the dose received at the end of the originating trial at Week 52, either with 80 mg IXE every 4 weeks (Q4W) or every 2 weeks (Q2W). Patients who had been assigned to adalimumab or placebo were re-randomized to IXE Q4W or Q2W at Week 16 in COAST-V and -W. Patients who had received placebo for 52 weeks in COAST-X were switched to IXE Q4W in COAST-Y. Patients who switched from placebo or adalimumab treatment to IXE (COAST-V, -W, or -X) or from IXE Q4W to open-label IXE Q2W (COAST-X) during the originating studies were analyzed separately from patients continuously treated with IXE. Standardized efficacy measures were used (Table 1). Missing data were handled by non-responder imputation for categorical data

and modified baseline observation carried forward for continuous data. Safety data were analyzed for all patients who received ≥1 dose of IXE.

Table 1. Demographic and efficacy results for patients continuously treated with IXE for 116 weeks

	IXE Q4W N=157		IXE Q2W N=195

Change from baseline				
ASDAS	**-1.64 (1.05)**	**-1.60 (1.15)**	**-1.63 (1.03)**	**-1.78 (1.04)**
BASFI	**-2.88 (2.31)**	**-2.76 (2.39)**	**-2.83 (2.38)**	**-3.15 (2.34)**
BASMI	**-0.57 (0.95)**	**-0.57 (0.93)**	**-0.53 (0.92)**	**-0.60 (1.00)**
SF-36 PCS	**9.03 (8.62)**	**8.43 (8.70)**	**8.87 (7.57)**	**9.86 (8.45)**

Data are mean (SD) unless otherwise noted. Non-responder imputation was used for categorical variables, and modified baseline observation carried forward for continuous variables.

Results: Of the 773 patients enrolled in COAST-Y, 86.0% completed Week 116 of treatment (52 weeks of one of the originating trials and 64 weeks of COAST-Y). Among the patients continuously treated with IXE for 116 weeks (IXE Q4W: N=157; IXE Q2W: N=195), 46.9% achieved low disease activity (ASDAS <2.1), and 19.9% achieved ASAS partial remission at 116 weeks (Table 1; Figure 1). In comparison to baseline, 56.0% achieved ASAS40 (Table 1). The mean change from baseline at Week 116 was –1.70 for ASDAS, –2.98 for BASFI, and 9.22 for SF-36 Physical Component Summary (Table 1). Similar observed responses were achieved between the patients continuously treated with IXE and patients initially treated with placebo or adalimumab. For the 932 patients in the safety population, no new safety signals were identified.

Conclusion: Ixekizumab treatment led to consistent and sustained long-term improvements in disease activity and quality of life in patients with r- and nr-axSpA, with no new safety signals after up to 2 years of treatment.

POS0913 UVEAL CATARACT IN PATIENTS WITH SPONDYLOARTHRITIS AND OTHER IMMUNO-INFLAMMATORY DISEASES AND ITS SURGICAL TREATMENT

S. Avetisov[1,2], I. Razumova[3], K. Avetisov[4], A. Godzenko[5]. [1]*Federal State Budgetary Scientific Institution Research Institute of Eye Diseases, Chief Scientific Adviser, Moscow, Russian Federation*; [2]*I.M. Sechenov First Moscow State Medical University (Sechenov University), Department of Eye Diseases, Moscow, Russian Federation*; [3]*Federal State Budgetary Scientific Institution Research Institute of Eye Diseases, Retinal and Optic Nerve Pathologies, Moscow, Russian Federation*; [4]*Federal State Budgetary Scientific Institution Research Institute of Eye Diseases, Department of Modern Methods of Treatment, Moscow, Russian Federation*; [5]*Federal State Budgetary Educational Institution of Additional Professional EducationRussian Medical Academy of Continuous Professional Education, Rheumatology, Moscow, Russian Federation*

Background: Uveitis is a common extra-skeletal manifestation of various systemic diseases, in particular, spondyloarthritis (SpA). Uveal cataract is the frequent complication of endogenous uveitis. Surgical treatment of uveal cataracts is associated with certain problems, the main being a potential risk of recurrence of uveitis, especially in the case of intraocular lens (IOL) implantation.

Objectives: To analyse the results of surgery of complicated uveal cataract in patients with SpA and other rheumatic disorders.

Methods: 30 pts (34 eyes) with uveal cataract as a result of systemic immuno-inflammatory diseases were assessed in the "Research Institute of Eye Diseases" in the period from 2006 to 2018. The postoperative follow-up period ranged from 2 to 12 years. 20 pts had different variants of SpA (Group 1):7 (7 eyes) - ankylosing spondylitis, 1 (1 eye) –reactive arthritis, 1 (1 eye) - psoriatic arthritis, 4 (6 eyes) – juvenile spondyloarthritis, 8 (8 eyes) non-radiological SpA. 10 patients (11 eyes) had other systemic diseases (Group 2): 1 (1 eye) Behcet's disease, 1 (1 eye) - multiple sclerosis, 3 (3 eyes) - Fuchs heterochromic cyclitis, 2 (2 eyes) -cutaneous psoriasis, and 3 (4 eyes) -uveitis of unknown etiology. 4 pts (6 eyes) with juvenile arthritis and pronounced corneal ribbon degeneration were underwent standard intracapsular cryoextraction of the cataract, followed by optical correction of aphakia using spectacle lenses. In other cases, ultrasound phacoemulsification with IOL implantation was used as a surgical aid. All patients had a period of uveitis remission before opreation for at least 2 months.Anti-inflammatory therapy using local glucocorticoid and local and systemic nonsteroidal antiinflammatory drugs was prescribed 2 weeks before and within a month after the operation. Intra and postoperative complications, fluctuations in intraocular pressure (IOP), improvement of visual acuity, and the frequency of uveitis flares after surgery were assessed as the main criteria for analyzing the results of surgery.

Results: A statistically significant decrease in the number of uveitis exacerbations was observed in all pts: in group 1 - from 2,5 ± 0,65 to 1, 2 ± 0,65 per year (p<0.0001), in group 2 - from 2,55 ± 0,21 to 0,89 ± 0,21 per year (p<0.0001), while there were no statistically significant differences between the groups (p=0.31). Statistically significant increase in maximum visual acuity was observed in all groups: in group 1 - from 0,2± 0,38 to 0,58 ± 0,74, p<0.0001, in group 2 – from 0,24 ± 0,05 to 0,69 ± 0,07, p<0.0001. No complications were observed during operations. The phenomena of bullous keratopathy after intracapsular extraction were noted in 2 pts with juvenile arthritis and ribbon-like corneal degeneration. No progression of corneal changes was observed. Opacity in the central zone of the posterior capsule in the period from 2 to 24 months after surgery occurred in 7 cases. In all cases, laser dissection of the posterior lens capsule was performed. Transient increase in IOP in the early postoperative period, normalized by local hypotensive therapy, occurred in 8 cases in groups I. In the long- term follow-up period (2-24 months), persistent IOP decompensation occurred in 6

cases in groups 1 and in 3 cases in groups 2, which required various types of anti-glaucoma operations. Cystic macular edema developed in one case 5 months after surgery as a result of uveitis exacerbation and was stopped by corticosteroid therapy.

Conclusion: Surgery of uveal cataracts in pts with SpA and other immuno-inflammatory diseases providing adequate pre- and postoperative anti-inflammatory therapy improves visual acuity and reduces the frequency of uveitis relapses. Monitoring of IOP is necessary in the postoperative period.

Costa[1]. *[1]Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal*; *[2]Faculdade de Medicina da Universidade do Porto - FMUP, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; *[3]University Hospital Center of Algarve, Rheumatology, Faro, Portugal*; *[4]Centro Hospitalar Vila Nova de Gaia / Espinho - Unit 1, Rheumatology, Vila Nova de Gaia, Portugal*; *[5]Faculdade de Medicina da Universidade do Porto - FMUP, Rheumatology, Porto, Portugal*

Background: Induction of autoantibodies is frequently observed in patients treated with a TNF-α blocker. According to other authors, the incidence of induction of antinuclear antibodies (ANA) and anti-double stranded DNA antibodies (anti-dsDNA) varies between 23-57% and 9-33%, respectively. However, it is unknown whether the induction of these autoantibodies affects the pharmacokinetics and bioavailability of biotherapy and, consequently, reduces the efficacy and safety of the drug.

Objectives: To analyze if there is an association between autoantibodies induction and therapeutic efficacy in a monocentric cohort of patients with axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA) treated with anti-TNF-α agents.

Methods: The authors performed a retrospective analysis of patients with axSpA and PsA treated in our University Hospital with a TNF-α blocker as first biologic agent, and analysed the autoantibodies induction rate after 12 (T12) and 24 (T24) months of therapy. Then, they investigated the influence of autoantibodies in therapeutic efficacy at T12 and T24. Clinical evaluation, laboratory findings including erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) and disease activity and functional scores (Bath Ankylosing Spondylitis Disease Activity Index – BASDAI, AS Disease Activity Score with CPR - ASDAS-CRP, Bath AS Functional Index - BASFI) were collected from reuma.pt and medical records. For PsA patients, Disease Activity Score-28-CRP (DAS28-CRP), Simple Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI) and Health Assessment Questionnaire (HAQ) scores were also collected. Patients with positive ANA (titer > 1/100) prior to anti-TNF-α therapy were excluded. Continuous variables were analyzed using a t-test and categorical variables using a Chi-square test. P-value <0.05 was considered statistically significant.

Results: In the axSpA group, 235 patients were included, 44.5% were females, mean age at diagnosis of 42.3 ± 12.4 years and median disease duration of 11.5 (IQR 6.0-21.0) years. Positive ANA were observed in 16.9% at T12 and 26.3% at T24 and positive anti-dsDNA in 3.4% at T12 and 3.8% at T24, with similar conversion rates between different anti-TNF drugs and no significant gender difference. A significant difference in ASDAS-CPR was found in axSpA patients with and without ANA at T12 (p=0.047). ASDAS-CPR was 1.16 times higher in patients with ANA comparing to patients without them. However, no difference was found in the others disease activity and functional scores at T12. Furthermore, no significant difference, including ASDAS-CPR, was found at T24. Also, there was no significant difference found when comparing patients with and without anti-dsDNA.

In the PsA group, 94 patients were included, 46.8% were females, mean age at diagnosis of 46.7 ± 11.7 years and median disease duration of 11.5 (IQR 6.5-16.5) years. Positive ANA were found in 14.9% at T12 and 21.3% at T24 and positive anti-dsDNA in 2.1% at T12 and 3.2% at T24. When comparing the groups with and without ANA and with and without anti-dsDNA at T12 and T24, no significant difference in disease activity and functional scores was found.

Conclusion: This study revealed high rates of serology conversion, similar to the rates described before. The authors found that ASDAS-CPR was higher in axSpA patients with ANA after 12 months of therapy. However, this difference was no longer evident after 24 months. No other significant difference was found between patients with and without ANA or with and without anti-dsDNA. The authors consider that the induction of autoantibodies may interfere with the response to anti-TNF-α therapy in a short and initial period of time. Long-term follow-up data are lacking to say whether that influence will disappear consistently over the long run, as they observed after 12 months of therapy. However, they can state that, *a priori*, seroconversion should not lead to treatment suspension because of concerns about loss of efficacy.

POS0915 SUSTAINABILITY OF IXEKIZUMAB RESPONSE AT THE INDIVIDUAL PATIENT LEVEL OVER TIME IN RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

S. Ramiro[1], R. Bolce[2], D. Sandoval[2], A. Kronbergs[2], S. Y. Park[2], B. Wu[3], J. A. Walsh[4]. *[1]Leiden University Medical Center (LUMC), Department of Rheumatology, Leiden, Netherlands*; *[2]Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America*; *[3]IQVIA RDS Canada ULC, QC, Canada, Kirkland, Canada*; *[4]University of Utah, Division of Rheumatology and the Department of Dermatology, Salt Lake City, United States of America*

Background: Ixekizumab (IXE) has demonstrated efficacy in treating the signs and symptoms of radiographic axial spondyloarthritis (r-axSpA) in patients (pts) up to week (Wk) 52 [1]. Pts may experience fluctuations in the improvements of their symptoms, which may impact their overall quality of life [2]. Providing data at the pt level is important to support consistency and sustainability of efficacy.

Objectives: To analyse IXE response for sustainability at the individual pt level, between Wks 16 and 52.

Methods: COAST-V (NCT02696785) and COAST-W (NCT02696798) were two phase 3, multicentre, randomised, double-blind, placebo-controlled studies (adalimumab was the active control in COAST-V). Pts with active r-axSpA who were either biologic disease modifying anti-rheumatic drug (bDMARD) naïve (COAST-V) or, inadequate responders or intolerant to up to 2 TNF inhibitors (COAST-W) received IXE every 4 weeks (Q4W) or every 2 weeks (Q2W). Only IXE Q4W pts were included in the present analysis (approved dosage for the indication). Separate analyses were conducted on pts who achieved either endpoint; ASAS40 or ASDAS<2.1. The proportion (%) of pts who achieved either ASAS40 or ASDAS<2.1, at Wk 16 and at each visit out to Wk 52 (total of 8 visits) was assessed. Missing data were imputed as non-response. Heatmaps were used to depict the data analysed at the individual patient level across all visits.

Results: In COAST-V, 81 pts enrolled in the trial were initially randomised to IXE Q4W. Of those, 48% (N=39) of pts achieved ASAS40 at Wk 16 (Figure 1), of which 59% (N=23) maintained ASAS40 at every visit afterwards. In total, 85% (N=33) of the ASAS40 achievers at Wk 16 maintained ASAS40 with some (26% (N=10)) fluctuations, between ASAS40 and ASAS20. In COAST-W, 114 pts enrolled in the trial were initially randomised to IXE Q4W. Of those, 25.4% (N=29) pts achieved ASAS40 at Wk 16, of which, 69% (N=20) maintained ASAS40 at every visit afterwards. In total, 83% (N=24), of the ASAS40 achievers at Wk 16 maintained ASAS40 with some (14% (N=4)) fluctuations, between ASAS40 and ASAS20.

Of the 81 pts initially randomised to IXE Q4W in COAST-V, 35 pts achieved low disease activity (ASDAS<2.1, LDA) at Wk 16. Of those, 54% (N=19) of pts maintained LDA at every visit afterwards. In total, 91% (N=32) of the ASDAS-LDA

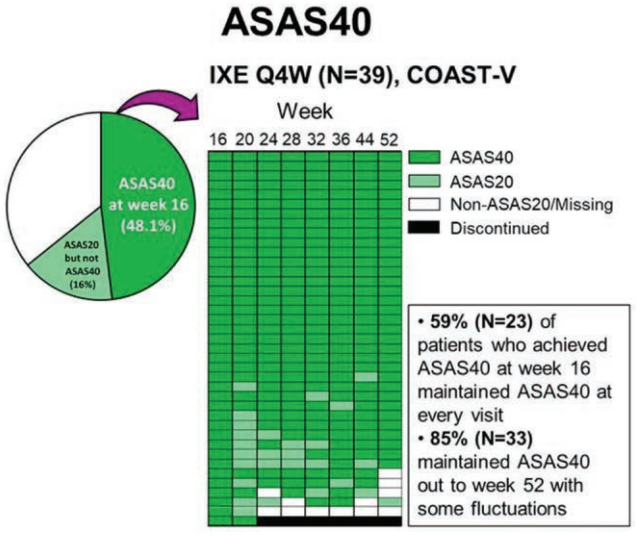

Figure 1. Heatmap diagram depicting the sustained effect of IXE over time at the pt level in pts with r-axSpA from COAST-V. Each row corresponds to an individual ASAS40 responder at Wk 16.

achievers at Wk 16 maintained LDA with some (37% (N=13)) fluctuations, between LDA and high disease activity (ASDAS 2.1-3.5, HDA). Of the 114 pts initially randomised to IXE Q4W in COAST-W, 20 pts achieved LDA at Wk 16. Of those, 50% (N=10) of pts maintained LDA at every visit afterwards. In total, 95% (N=19) of the ASDAS-LDA achievers at Wk 16 maintained LDA with some (45% (N=9)) fluctuations between LDA and HDA.

Conclusion: This analysis demonstrates that pts with r-axSpA and treated with IXE Q4W who achieve ASAS40 or ASDAS-LDA at Wk 16 show a sustainable response, at the individual patient level, with similar levels of efficacy over time and at each visit out to week 52.

POS0916 SAFETY OF BIOLOGIC TREATMENTS IN SOLID ORGAN TRANSPLANT RECIPIENTS: A SYSTEMATIC REVIEW

M. Frederic[1], W. V. Delphine[2], C. Prati[1], D. Wendling[1], F. Verhoeven[1]. [1]*CHRU Besancon, Rheumatology, Besancon, France*; [2]*CHRU Besancon, Hepatology, Besancon, France*

Background: The management of a broad spectrum of autoimmune/inflammatory diseases has been transformed with the development of biological treatments. However, little is known about their use in solid organ transplant recipients, a group of patients with high risk of serious infections and malignancies.

Objectives: To evaluate complications occurring with biologic treatments in solid-organ transplant recipients.

Methods: A systematic review of the literature was performed on the PubMed including Medline, Embase and Cochrane databases, up to 01/10/2020, to identify published case reports/series regarding the use of biologic treatments in solid organ transplant recipients in the context of chronic inflammatory diseases. Collected data were patient's characteristics (age, sex, reason for transplantation, antirejection regimen, type of biological treatment used, autoimmune/inflammatory disease treated, time between transplantation and biotherapy initiation, treatment duration) and their reported complications (deaths, infections, malignancies, graft dysfunction).

Results: 55 papers were included, representing 177 patients (131 liver, 42 kidney, 3 heart, and 1 liver-kidney transplant recipients). Inflammatory bowel diseases represented largely the most common indication of biologic treatment initiation (80.2%), followed by rheumatic diseases (7.3%), hereditary periodic fever syndromes (6.2%) and psoriasis (5.1%). Anti-TNFα were mainly used (81.4%) before anti- $\alpha4\beta7$ integrin Vedolizumab (23.7%) and anti-IL1R Anakinra (7.3%). 25/177 patients had several lines of different treatments. Median treatment duration was 13.5 months. Infections occurred in 48 patients (27.1%) through 76 recorded flares (mostly bacterial 68.4% and viral 19.7%). No therapeutic or epidemiological factor was associated with the occurrence of an infection. 16 patients (9.0%) developed malignancies, especially colorectal (4 cases, 2.3%) and skin cancers (4 cases, 2.3%) or Post-transplantation lymphoproliferative disorders (3 cases, 1.7%). Acute graft rejections occurred in 5 patients (2.8%), mostly in kidney transplants (4/5). Among a total of 177 patients, 6 deaths were identified (3.4%).

Conclusion: This review gathers, to our knowledge, the largest number of published case series/reports about the use of biological treatments in solid organ transplant recipients, providing data about their safety. Caution must be taken about eventual publication bias and the necessity of further head-to-head analysis comparing complications occurring in solid organ transplant recipients cohorts with and without biologic treatments.

POS0917 EFFECTIVENESS AND SAFETY OF COMBINED BIOLOGICAL THERAPY IN PATIENTS WITH REFRACTORY SPONDYLOARTHRITIS

C. Valero[1], J. P. Baldivieso[1], I. Llorente[1], E. Tomero Muriel[1], I. González-Álvaro[1], S. Castañeda[1], R. Garcia de Vicuna[1]. [1]*Hospital La Princesa, Rheumatology, Madrid, Spain*

Background: Biological therapy in combination is discouraged in the guidelines for the treatment of immune-mediated inflammatory diseases, attending to safety reasons. However, combined biological therapy could be a valid alternative in patients with highly refractory spondyloarthritis (SpA) as has been previously demonstrated in some reluctant inflammatory bowel disease patients. Published experiences in the literature are very scarce and the follow-up is limited.

Objectives: The aim of this study is to determine the effectiveness and safety of the association of biological drugs in patients with SpA and describe the clinical profile of these patients.

Methods: This is a retrospective, cross-sectional and descriptive study. We included patients with SpA who had received simultaneously at least two biological drugs with different therapeutic targets. We reviewed the database of our hospital that included all patients diagnosed with SpA meeting the ASAS criteria for axial SpA under active biological treatment.

Demographics, clinical and laboratory data, previous treatments, disease activity index (ASDAS CRP) and adverse events were collected. Remission and low activity criteria were considered according to cut-off descriptions in ASDAS CRP, <1.3 and 2.1, respectively.

Results: We identified six patients with SpA receiving combined biological therapy (Table 1). All patients showed high disease activity at the start of combination treatment and most of them presented several disease domains involvement. The average of previous biologics drugs was 5.33 ± 1.75. Four patients received an anti-TNF in combination with an anti-IL17 agent and one patient with concomitant Crohn disease was prescribed an anti-TNF combined with an anti-IL23 agent. The sixth patient, with SpA and concomitant systemic lupus erythematosus, received rituximab with an anti-IL17 (Table 1). The median treatment duration of the combined biological therapy was 12.5 months (IQR 4-43.5; range: 4-117). All patients achieved low disease activity or clinical remission at some point during follow-up, allowing for initial de-escalation of initial dose in some patients. Only one patient experienced a transient relapse (unic uveitis episode). No relevant adverse effects have been found clearly attributable to combination therapy. A 60-year-old patient with multiple comorbidities has stopped treatment due to aggravation of a previous liver cirrhosis.

Conclusion: Combined biological therapy could be an effective therapeutic alternative to patients with multidomain and refractory SpA. In our series, we provide acceptable safety data for follow-up periods that it are longer than the majority of reported cases to date.

EVALUATION OF SPINAL RADIOGRAPHIC PROGRESSION IN PATIENTS WITH RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS RECEIVING IXEKIZUMAB THERAPY OVER 2 YEARS

D. Van der Heijde[1], M. Østergaard[2], J. D. Reveille[3], X. Baraliakos[4,5], A. Kronbergs[6], D. Sandoval[6], X. Li[6], H. Carlier[6], D. Adams[6], W. P. Maksymowych[7]. *[1]Leiden University Medical Centre, Department of Rheumatology, Leiden, Netherlands*; *[2]University of Copenhagen, Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Denmark*; *[3]University of Texas-McGovern Medical School, Division of Rheumatology and Clinical Immunogenetics, Houston, United States of America*; *[4]Ruhr-University Bochum, Bochum, Germany*; *[5]Rheumazentrum Ruhrgebiet, Herne, Germany*; *[6]Eli Lilly and Company, Indianapolis, United States of America*; *[7]University of Alberta, Department of Medicine, Edmonton, Canada*

Background: It is important to understand the potential effect long-term therapy with biologics can have on structural changes in the spine among patients with active radiographic axial spondyloarthritis (r-axSpA, ankylosing spondylitis).
Objectives: We examined radiographic progression in the spine among patients with active r-axSpA treated with ixekizumab, an IL-17A antagonist, for 2 years, and potential predictors of spinal radiographic progression.
Methods: Patients with active r-axSpA, biologic-naive (COAST-V, NCT02696785) or with prior experience with a maximum of 2 TNF inhibitors (COAST-W, NCT02696798), received 80 mg ixekizumab every 2 or 4 weeks for 2 years (108 weeks, of which 56 weeks were the COAST-Y extension study, NCT03129100). Mean change from baseline of modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) (average score from 2 selected readers, blinded for time order) for patients treated with ixekizumab for 2 years with data at both baseline and year 2 is presented (N=230; 54% of total randomized patients). Non-progression is presented for all patients and subgroups based on TNFi-experience. Predictors were identified in multivariate logistic regression models with stepwise selection criteria of p-value <0.1. All data are observed.
Results: At baseline, patients (N=230) were predominately male (82%) with an average age of 43 years, mean symptom duration of 16 years, 52% were TNFi-experienced, mean (SD) ASDAS score was 4.0 (0.7), most were HLA-B27 positive (87%) and 40% had syndesmophytes (identified by both selected readers at the same location). Baseline mSASSS (SD) was 11.0 (16.3) and change from baseline at year 2 of treatment was 0.3 (1.8) (Table 1). The proportion of non-progressors (mSASSS change from baseline <2) over 2 years was 89.6% (total IXE [all patients]), 90.9% (biologic-naive) and 88.3% (TNFi-experienced), and, if defined as mSASSS change from baseline ≤0, 75.7% (total IXE [all patients]), 78.2% (biologic-naive) and 73.3% (TNFi-experienced) (Table 1). Predictors of structural progression at year 2 (mSASSS change >0) were age, baseline syndesmophytes, HLA-B27 status and gender (Table 1). Week 52 inflammation in MRI SPARCC spine was also identified as a predictor for structural progression at year 2 in a separate model for patients from COAST-V where MRI measures were available at baseline and Week 52 (N=109).
Conclusion: The majority of patients treated with ixekizumab for 2 years did not show radiographic progression, and the overall mean progression was low. Similar levels of non-progression were observed in biologic-naive patients and patients previously exposed to TNFis. Predictors were generally consistent with previous studies.

Table 1. Spinal radiographic changes for patients with active r-axSpA treated with ixekizumab for 2 years

Change in mSASSS at year 2	All patients[a] N=230	Biologic-naive N=110	TNFi-experienced N=120

BIMEKIZUMAB SHOWS SUSTAINED LONG-TERM IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES AND QUALITY OF LIFE IN ANKYLOSING SPONDYLITIS: 3-YEAR RESULTS FROM A PHASE 2B STUDY

X. Baraliakos[1], M. Dougados[2], K. Gaffney[3], R. Sengupta[4], M. Magrey[5], N. De Peyrecave[6], M. Oortgiesen[7], T. Vaux[8], C. Fleurinck[6], A. Deodhar[9]. *[1]Ruhr-University Bochum, Rheumazentrum Ruhrgebiet Herne, Herne, Germany*; *[2]Hôpital Cochin, Department of Rheumatology, Paris, France*; *[3]Norfolk and Norwich University Hospital NHS Trust, Rheumatology Department, Norwich, United Kingdom*; *[4]The Royal National Hospital for Rheumatic Diseases, Department of Rheumatology, Bath, United Kingdom*; *[5]Case Western Reserve University, MetroHealth Medical Center, Cleveland, United States of America*; *[6]UCB Pharma, N/A, Brussels, Belgium*; *[7]UCB Pharma, N/A, Raleigh, United States of America*; *[8]UCB Pharma, N/A, Slough, United Kingdom*; *[9]Oregon Health & Science University, Division of Arthritis & Rheumatic Diseases, Portland, United States of America*

Background: Bimekizumab (BKZ), a monoclonal antibody that selectively inhibits interleukin (IL)-17A and IL-17F, has demonstrated clinical efficacy and safety in patients with ankylosing spondylitis (AS) treated over a period up to 96 weeks.[1,2]
Objectives: To report 3-year interim patient-reported outcomes (PROs) in patients with active AS treated with BKZ in a phase 2b dose-ranging study (BE AGILE; NCT02963506) and its open-label extension (OLE; NCT03355573).
Methods: BE AGILE study design has been described previously.[1] Patients treated with BKZ 160 mg or 320 mg every 4 weeks (Q4W) at Week 48 in BE AGILE were eligible for OLE entry. All OLE patients received BKZ 160 mg Q4W. Outcome measures are reported for the OLE full analysis set (patients who entered the OLE and had ≥1 dose of BKZ and ≥1 valid efficacy variable measurement in the OLE), and include: BASDAI, BASDAI50 responder rate, BASFI, fatigue (BASDAI Q1), morning stiffness (mean of BASDAI Q5+6), total spinal pain (numeric rating scale [NRS]), SF-36 PCS and MCS, and ASQoL. Missing data were imputed using multiple imputation (MI; based on the missing at random assumption) for continuous variables and non-responder imputation (NRI) for dichotomous variables.
Results: 262/303 (86%) patients randomised at BE AGILE study baseline (BL) completed Week 48 on BKZ 160 mg or 320 mg, of whom 255/262 (97%) entered the OLE (full analysis set: 254). From baseline to Week 48 in BE AGILE, BKZ-treated patients showed clinically relevant improvements in disease activity (BASDAI, BASDAI50), physical function (BASFI), fatigue, morning stiffness, spinal pain, and quality of life (SF-36 PCS and MCS, ASQoL) (Figure 1). Group-level improvements in all reported continuous efficacy measures exceeded published minimally important difference (MID), minimum clinically important improvement (MCII), and/or minimum clinically important difference (MCID) thresholds (Figure 1).[3,4] Efficacy in all reported outcome measures was maintained or continued to improve from Week 48 to Week 144 or 156 (Figure 1).
Conclusion: BKZ treatment was associated with sustained and consistent efficacy in patients with active AS over 3 years, including patient-reported disease activity, physical function, fatigue, morning stiffness, spinal pain, and quality of life.

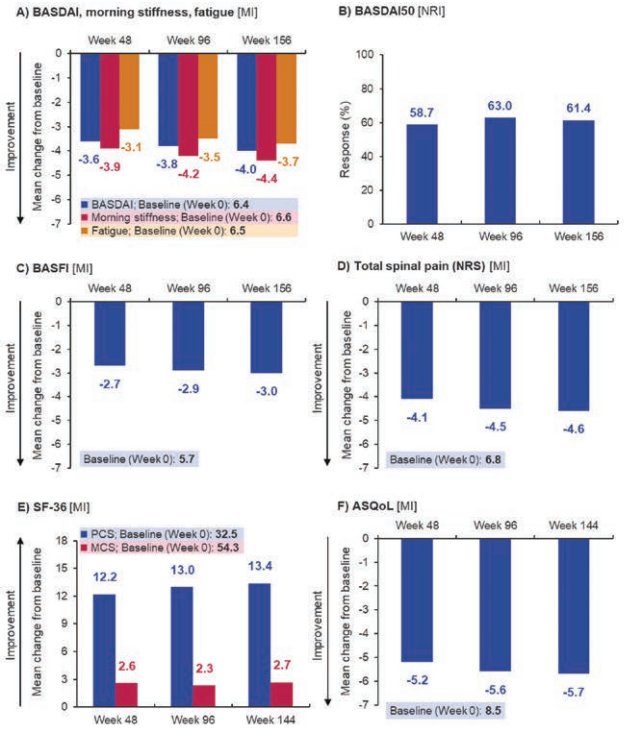
[4] Maruish ME. User's manual for the SF-36v2 Health Survey (3rd ed). 2011; Lincoln, RI: QualityMetric Incorporated.

Figure. Patient-reported outcomes over 3 years of BKZ treatment



Full analysis set (N=254). Weeks 0 and 48 refer to the BE AGILE and OLE baseline, respectively. All patients received BKZ 160 mg during the OLE after completing BKZ 160 mg or 320 mg in BE AGILE. SF-36 PCS, MCS and ASQoL were recorded to Week 144. Arrows indicate improvement: positive change from baseline represents improvement in SF-36 PCS and MCS; negative change from baseline represents improvement for all other outcomes. MID/MCII/MCID thresholds: BASDAI total score MCII = 0.7; fatigue (BASDAI Q1) MCID = 1.1; morning stiffness (mean of BASDAI Q5+6) MCID = 1.7; BASFI MCII = 0.4; total spinal pain MCID = 1.6; SF-36 PCS score MID = 2; ASQoL total score MCID = -2.[3,4] SF-36 MID values are appropriate for groups with baseline mean T-scores of 30–40; for higher T-score ranges, MID values tend to be higher.[4] MID are not applied for improvement for baseline mean SF-36 T-scores >47, which are considered at least as good as the standard US population, hence no improvement is expected.[4] Since mean SF-36 MCS at baseline was 54.3, the MID was not applied here. ASQoL: Ankylosing Spondylitis Quality of Life questionnaire; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BASDAI50: BASDAI 50% improvement from baseline; BASFI: Bath Ankylosing Spondylitis Functional Index; BKZ: bimekizumab; MCII: minimum clinically important improvement; MCID: minimum clinically important difference; MI: multiple imputation; MID: minimally important difference; NRI: non-responder imputation; NRS: numeric rating scale; OLE: open-label extension; SF-36 MCS: 36-Item Short-Form Survey Mental Component Summary; SF-36 PCS: 36-Item Short-Form Survey Physical Component Summary.

POS0920 TARGETED SERUM PROTEOMIC ANALYSIS FOLLOWING UPADACITINIB TREATMENT IN ANKYLOSING SPONDYLITIS SHOWS ROBUST SUPPRESSION OF INNATE AND ADAPTIVE IMMUNE PATHWAYS WITH TISSUE REPAIR MODULATION

T. Sornasse[1], I. H. Song[2], T. Radstake[2], D. Mcgonagle[3]. [1]*AbbVie Inc., Immunology Clinical Development, Redwood City, United States of America*; [2]*AbbVie Inc., Immunology Clinical Development, North Chicago, United States of America*; [3]*University of Leeds, School of Medicine, Leeds, United Kingdom*

Background: Upadacitinib (UPA), an oral JAK inhibitor selective for JAK1, demonstrated efficacy in patients with active ankylosing spondylitis (AS) with an inadequate response (IR) to nonsteroidal anti-inflammatory drugs (NSAID) therapy in the SELECT-AXIS 1[1] trial.
Objectives: To identify pathways modulated by UPA in AS patients with emphasis on those associated with response to treatment.
Methods: A subgroup of patients from the SELECT-AXIS 1 study, with available baseline and at least one follow up plasma sample during the placebo-controlled period, were selected for analysis (PBO, n= 65; UPA 15 mg QD, n=63). The levels of 92 inflammation related protein biomarkers (BioMs) were analyzed using the Olink® platform; change from baseline were expressed as Log_2 Fold Change; a repeated measure mixed linear model identified BioMs differentially modulated by UPA. Relationship between change in BioMs and change in clinical disease activity measures were derived using Pearson's correlation (ASDAS-CRP, BASDAI, and CRP) and Spearman's correlation (MRI Spine SPARCC). Pathway analysis was performed with Ingenuity® Pathway Analysis (Qiagen Inc.).
Results: Treatment with UPA 15 mg QD reduced the levels of BioMs associated with IFN, IL6, T Cells, M1 or "inflammatory" Macrophages, and Dendritic Cells (DC); and increased those of BioMs associated with tissue repair and hematopoiesis. The type of pathways, inferred *in silico* based on BM data, suggests that UPA exerts broad inhibitory activity directly on multiple JAK1-dependent (IFNα/β, IFNγ, IL6, IL2, IL5, IL7, and OSM) and indirectly on JAK1-independent upstream pathways (IL1, IL23, IL17, IL18, and TNFα), resulting in the inhibition of key functional pathways such as leukocyte activation and mobility, inflammatory response, and damage to connective tissue. Improvement in ASDAS-CRP, BASDAI, and MRI spine SPARCC correlated with increase in BioMs associated with tissue repair (FGF5, DNER [Delta/Notch Like EGF Repeat Containing]) and hematopoiesis (FLT3LG,and SCF/KITLG), while improvement in ASDAS-CRP and CRP correlated with decrease in CCL23, CSF1, IL-6, and MMP1; and reduction in only CRP correlated with decrease in IFN- and of TNFα-related BioMs (**Data tables will be presented**).
Conclusion: Treatment of NSAID-IR AS patients with UPA 15 mg QD resulted in the coordinated decrease in multiple BioMs associated with the innate and adaptive immune responses, and in the increase in BioMs generally associated with tissue repair and hematopoiesis. In silico pathway prediction indicates that treatment with UPA directly inhibits JAK1-dependent and indirectly JAK1-independent pathways, resulting in the down modulation of functional pathways related to inflammation and tissue damage which are known to be dysregulated in AS[2]. Based on this observation and on the correlation of change in BioMs with change in clinical measures, we hypothesize that both increase in BioMs associated with tissue repair and hematopoiesis, and decrease in BioMs associated with inflammation may contribute to the clinical activity of UPA in AS patients.

POS0921 EFFICACY AND SAFETY OF ACEMETACIN IN THE TREATMENT OF 1215 ACTIVE ANKYLOSING SPONDYLITIS PATIENTS: DATA FROM A PROSPECTIVE COHORT MANAGED BY SMARTPHONE SPONDYLOARTHRITIS MANAGEMENT SYSTEM

J. Zhang[1], L. Hu[1], X. Ji[1], Y. Wang[1], F. Huang[1]. [1]*Chinese PLA General Hospital, Rheumatology, Beijing, China*

Background: Biological DMARDs have widely used in the treatment of AS in last two decades, but NSAIDs still serves as a cornerstone in the treatment.

Given the wide use of Acemetacin in AS and relative lack of clinical evidence on the selection of NSAIDs in the treatment of AS, the investigation on acemetacin treating AS is of great significance.

Objectives: Our study aims to investigate efficacy and safety of acemetacin in the treatment of AS.

Methods: Data on efficacy and safety is available in 1215 patients from the Chinese Ankylosing Spondylitis Imaging Cohort (CASPIC), which is collected through the Smart-phone SpondyloArthritis Management System (SpAMS)[1]. Patients' self-assessments are completed online at baseline and every subsequent clinic visit. Physician-reported assessments, laboratory tests, and treatments were recorded by rheumatologists at every clinic visit.

Results: 1215 patients with AS were registered, of whom 992 were treated with acemetacin and 123 were treated with other NSAIDs. The results showed that total back pain and BASFI were significantly improved after three-month treatment of acemetacin, while comparing to other NSAIDs (P=0.027 and 0.015, respectively). After six-month treatment, patients taking acemetacin showed greater improvement in PGA (P=0.013), total back pain (P=0.049), night back pain (P=0.047), BASFI (P=0.042), ASDAS (P=0.007) and CRP (P=0.032) compared to those taking other NSAIDs. During the follow-up periods, no serious adverse events were reported. Mild abnormal liver function occurred in nine patients (9/992) treated with acemetacin and in six patients treated with other NSAIDs (6/123). See Table 1 for details.

Conclusion: Acemetacin showed better efficacy and acceptable safety profile in the treatment of active ankylosing spondylitis comparing with other NSAIDs.

POS0922 NON-STEROIDAL ANTI-INFLAMMATORY DRUG USE IS ASSOCIATED WITH DISEASE ACTIVITY AND REDUCED SIGNIFICANTLY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS TREATED WITH TUMOR NECROSIS FACTOR INHIBITORS; DATA FROM A REAL LIFE EXPERIENCE

E. Durak Ediboglu[1], D. Solmaz[1], G. Kabadayi[1], E. Otman Akat[1], H. Cinakli[1], G. Alp[1], E. Erpek[1], S. Gucenmez[1], M. Ozmen[1], S. Akar[1]. *[1]Izmir Katip Çelebi University, Rheumatology, Izmir, Turkey*

Background: Non-steroidal anti-inflammatory drugs (NSAIDs) is the first line treatment option in axial spondyloarthritis (axSpA) patients suffering from pain and stiffness. However there is only limited data regarding the concomitant use of NSAIDs during tumour necrosis factor inhibitor (TNFi) treatment.

Objectives: To evaluate longitudinal concomitant NSAIDs use with the TNFi treatment and the determinant of the ASAS-NSAID index in patients with axSpA.

Methods: In total 429 axSpA patients (253 [59%] male; 272 [63%] with AS and 157 [37%] with non-radiographic (nr)-axSpA) who have followed up one year were included in this observational study. The data regarding disease activity and serum CRP levels were collected on 12, 24 and 52nd week. At each visit NSAID usage, type, dosage and frequency were recorded in order to calculate ASAS-NSAID index. The longitudinal relationship between NSAID-index and other factors tested by using generalized estimating equations (GEE) which is a technique for longitudinal data analysis allowing the use of all available data even deviated from normality.

Results: At baseline 127/138 (92%) patients starting TNFi and 239/291 (82%) conventionally treated patients were using NSAID. Both the rate (p=0.007) and the median (IQR) ASAS-NSAID index were higher in biologic treatment group (100 [50] vs 70.8 [89.4]; p<0.001). During follow-up ASAS-NSAID index was decreased significantly in patients treated with TNFi (median 100 to 8.0;p<0.001), however ASAS-NSAID index was not changed in conventionally treated patients (p=0.154) (Figure 1). In univariate longitudinal analysis revealed that ASAS-NSAID index was significantly associated with BASDAI, ASDAS, BASFI scores and patient global assessment of disease activity, serum levels of CRP and education. We established two multivariable models (Table 1) to assess the associated factors/covariates with ASAS-NSAID index over time (one with ASDAS and the other BASDAI+CRP as disease activity index) and showed that BASDAI and patient global assessment of disease activity were independent determinants of NSAID dosage in biologic treated patients. However, in multivariate analysis there was no significant predictor for NSAID index in conventional treatment group.

Conclusion: Our results showed that NSAID prescription was significantly higher in axSpA patients who have TNFi indication. NSAID use was decreased significantly over time with TNFi and still independently determined by disease activity. However, it is stable in conventionally treated axSpA patients.

POS0923 INFLUENCE OF BASELINE DEMOGRAPHICS ON IMPROVEMENTS IN DISEASE ACTIVITY MEASURES IN PATIENTS WITH ANKYLOSING SPONDYLITIS RECEIVING UPADACITINIB: A POST HOC SUBGROUP ANALYSIS OF SELECT-AXIS 1

F. Van den Bosch[1], D. Poddubnyy[2,3], J. Stigler[4], A. Ostor[5], S. D'angelo[6], V. Navarro-Compán[7], I. H. Song[4], T. Gao[4], F. Ganz[8], L. S. Gensler[9]. *[1]Ghent University Hospital, Department of Rheumatology, Ghent, Belgium*; *[2]Infectious Diseases and Rheumatology, Campus Benjamin Franklin, Charité – Universitätsmedizin Berlin, Department of Gastroenterology, Berlin, Germany*; *[3]German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany*; *[4]AbbVie Inc., Immunology, North Chicago, Illinois, United States of America*; *[5]Cabrini Medical Center, Department of Rheumatology, Melbourne, Victoria, Australia*; *[6]"San Carlo" Hospital of Potenza and "Madonna delle Grazie" Hospital of Matera, Rheumatology Institute of Lucania (IReL) – Rheumatology Department of Lucania, Potenza, Italy*; *[7]University Hospital La Paz, IdiPaz, Department of Rheumatology, Madrid, Spain*; *[8]AbbVie AG, Immunology, Baar, Switzerland*; *[9]University of California, San Francisco, Rheumatology, San Francisco, California, United States of America*

Background: Upadacitinib (UPA), an oral Janus kinase inhibitor, has demonstrated efficacy and safety through 14 weeks in the SELECT-AXIS 1 study in biologic disease-modifying antirheumatic drug-naïve patients with active ankylosing spondylitis (AS).[1]

Objectives: To evaluate the efficacy of UPA 15 mg once daily (QD) in selected subgroups of patients with AS based on different baseline characteristics.
Methods: In SELECT-AXIS 1, patients were randomized to 14 weeks of blinded treatment with UPA 15 mg QD or placebo (PBO). This post hoc analysis evaluated the proportions of patients achieving ≥40% improvement in Assessment of SpondyloArthritis International Society criteria (ASAS40), ≥50% improvement in the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI50), and change from baseline in Ankylosing Spondylitis Disease Activity Score with C-reactive protein (ASDAS[CRP]) at Week 14 across subgroups based on the following baseline patient characteristics: gender, age, body mass index, AS symptom duration, C-reactive protein (CRP) levels, Spondyloarthritis Research Consortium of Canada Magnetic Resonance Imaging index, and human leukocyte antigen B27 status. For missing data, non-responder imputation analysis was used for ASAS40 and BASDAI50, and mixed model repeated measures analysis was used for ASDAS(CRP).
Results: Baseline disease characteristics were balanced between the treatment groups at randomization, as previously reported.[1] ASAS40 and BASDAI50 response rates at Week 14 were numerically higher with UPA 15 mg versus PBO across the demographic and disease characteristic subgroups evaluated (Figure 1), including some subgroups with small sample sizes, such as patients with disease duration <5 years and female patients. Improvements from baseline in ASDAS(CRP) were also consistently greater with UPA 15 mg versus PBO across the subgroups evaluated (Table 1).
Conclusion: Within subgroups evaluated, most patients with active AS receiving UPA 15 mg demonstrated greater improvements versus PBO in disease activity measures assessed by ASAS40, BASDAI50, and change from baseline in ASDAS(CRP). There was some evidence that gender, AS symptom duration, and baseline CRP levels seemed to influence outcomes, though results should be interpreted with caution due to small sample sizes for some subgroups.

POS0924

PREDICTORS OF 1-YEAR TREATMENT RESPONSE AMONG UPADACITINIB-TREATED PATIENTS WITH ANKYLOSING SPONDYLITIS: A POST HOC ANALYSIS OF SELECT-AXIS 1

M. Magrey[1], S. Ramiro[2,3], M. Pinheiro[4], T. Gao[5], F. Ganz[6], I. H. Song[5], A. Biljan[5], N. Haroon[7,8,9], M. Rudwaleit[10]. *[1]MetroHealth System and School of Medicine, Case Western Reserve University, Division of Rheumatology, Cleveland, Ohio, United States of America*; *[2]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*; *[3]Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands*; *[4]Universidade Federal de São Paulo, Rheumatology, São Paulo, Brazil*; *[5]AbbVie Inc., Immunology, North Chicago, United States of America*; *[6]AbbVie AG, Immunology, Baar, Switzerland*; *[7]University of Toronto, Rheumatology, Ontario, Canada*; *[8]University Health Network, Rheumatology, Toronto, Canada*; *[9]Krembil Research Institute, Rheumatology, Toronto, Canada*; *[10]Klinikum Bielefeld Rosenhöhe, Internal Medicine and Rheumatology, Bielefeld, Germany*

Background: Upadacitinib (UPA) is an oral Janus kinase inhibitor that has demonstrated efficacy and safety among patients with ankylosing spondylitis (AS) in the phase 2/3 SELECT-AXIS 1 study.[1] If identified, early predictors of treatment response may inform treat-to-target strategies and optimize patient outcomes in AS.

Objectives: To determine whether baseline (BL) characteristics or early responses predict clinical response at 1 year in UPA-treated patients with AS.
Methods: In the double-blind, randomized, placebo (PBO)-controlled SELECT-AXIS 1 study, patients received UPA 15 mg once daily or PBO until Week 14.[1] At Week 14, PBO-treated patients switched to UPA 15 mg; patients originally randomized to UPA continued UPA therapy. Data from patients in the PBO and UPA arms were combined based on overall exposure to UPA; in the switch arm, exposure was defined as current visit minus 14 weeks (time of switch). The following outcomes were assessed at 1 year: Ankylosing Spondylitis Disease Activity Score with C-reactive protein (ASDAS[CRP]) inactive disease (ID; <1.3) and low disease activity (LDA; <2.1), Assessment of SpondyloArthritis International Society (ASAS) partial remission (PR), and ≥40% improvement in ASAS criteria (ASAS40) response. The ability of BL characteristics, efficacy at Week 12, and back pain at Week 12 to predict 1-year outcomes was assessed using a univariable logistic regression model generating odds ratios (ORs; 95% confidence intervals). LASSO regression was used to select the best-fitted multivariable model at Week 12 for each outcome measure.
Results: Among 187 patients who received or switched to UPA 15 mg, 70 (37.4%), 134 (71.7%), 73 (39.0%), and 131 (70.1%) achieved ASDAS(CRP) ID, ASDAS(CRP) LDA, ASAS PR, and ASAS40, respectively, following 1 year of UPA treatment. No meaningful predictors of 1-year efficacy outcomes were identified based on BL demographics (including disease duration, gender, and human leukocyte antigen B27 status) or BL disease characteristics (including ASDAS, Bath Ankylosing Spondylitis Disease Activity Index, and CRP levels). In univariable analyses, Week 12 responses based on several disease activity measures and patient-reported outcomes (PROs), including reductions (much better improvement [MBI], ≥30/≥50/≥70% reduction, or improvement) in back pain score, along with lower scores for back pain at Week 12, were associated with the achievement of ASDAS(CRP) ID, ASDAS(CRP) LDA, ASAS PR, and ASAS40 at 1 year (Figure 1). In a multivariable analysis, improvement from BL to Week 12 in back pain score consistently predicted several efficacy outcomes at 1 year.
Conclusion: In upadacitinib-treated patients with AS, improvement in PROs and reduction in back pain score at 12 weeks predicted clinical outcomes at 1 year.

POS0925 EFFICACY OF SECUKINUMAB IN TNFI-NAÏVE PATIENTS ACROSS THE AXIAL SPONDYLOARTHRITIS SPECTRUM OVER 52 WEEKS: A POST HOC ANALYSIS OF THE MEASURE AND PREVENT CLINICAL TRIALS

M. Magrey[1], J. A. Walsh[2], F. Huang[3], H. Kameda[4], J. Wang[5], C. Herrem[6], P. Pertel[7], H. Marzo-Ortega[8]. *[1]Case Western Reserve University School of Medicine, Division of Rheumatology, Ohio, United States of America*; *[2]Salt Lake City Veteran Affairs Medical Center; University of Utah Medical Center, Salt Lake City, Division of Rheumatology, Utah, United States of America*; *[3]Chinese PLA General Hospital, Beijing, Department of Rheumatology and Immunology, Beijing, China*; *[4]Toho University (Ohashi Medical Center), Department of Internal Medicine, Division of Rheumatology, Tokyo, Japan*; *[5]Novartis Pharmaceuticals Corporation, Immunology, Hepatology and Dermatology, East Hanover, United States of America*; *[6]Novartis Pharma AG, Rheumatology, Basel, Switzerland*; *[7]Novartis Pharma AG, Immunology, Hepatology and Dermatology, Basel, Switzerland*; *[8]NIHR Leeds Biomedical Research Centre, Leeds Training Hospitals NHS Trust and LIRMM, University of Leeds, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom*

Background: Secukinumab (SEC) has demonstrated significant efficacy in patients (pts) with ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axSpA).[1-5] However, evidence regarding the efficacy of SEC across the axSpA disease spectrum is limited.
Objectives: To assess the efficacy of SEC on key efficacy endpoints in pts with axSpA (nr-axSpA and AS) over 52 weeks from 6 pooled phase 3 clinical trials.
Methods: This post hoc analysis included pooled data from tumour necrosis factor inhibitors (TNFi)-naïve pts in the MEASURE 1-5 (AS) and PREVENT (nr-axSpA) phase 3 trials. Assessments included proportion of patients achieving ASAS40, ASAS 5/6, ASAS partial remission (ASAS-PR), ASDAS-CRP major improvement, ASDAS-CRP inactive disease (ASDAS-CRP ID), BASDAI50 and mean change from baseline in nocturnal back pain and morning stiffness with any SEC 150 mg or SEC 300 mg or placebo (PBO) at Week 16, and sustainability was measured in pts treated with SEC at Week 52. Data are reported as non-responder imputation.
Results: A total of 1558 TNFi-naïve pts (SEC 150 mg, N=932; SEC 300 mg, N=57 and PBO, N=569) with a mean age of 39.3 ± 11.58 years were included in the study. At Week 16, significantly higher improvements in pts treated with SEC versus PBO were observed in all efficacy endpoints (Table 1) with improvements sustained up to Week 52.
Conclusion: SEC 300 mg and 150 mg provided significant and sustained improvement in the signs and symptoms of TNFi-naïve pts with axSpA regardless of radiographic status.

POS0926

NORMALIZATION OF HIGH SENSITIVITY CRP VERSUS CLINICAL RESPONSE TO IXEKIZUMAB AT WEEK 16 IN PATIENTS WITH RADIOGRAPHIC & NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE COAST STUDIES

H. Marzo-Ortega[1], X. Juanola[2], T. Okano[3], Y. Schymura[4], A. Bradley[5], J. Gerwien[5], B. Monsberger[6], S. Liu Leage[5], D. Aletaha[7], M. Østergaard[8].
[1]Leeds Teaching Hospitals NHS Trust & LIRMM, University of Leeds, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; *[2]University Hospital Bellvitge, Rheumatology Service, Barcelona, Spain*; *[3]Osaka City University, Graduate School of Medicine, Osaka, Japan*; *[4]Eli Lilly and Company, Statistics, Indianapolis, United States of America*; *[5]Eli Lilly and Company, Medical Rheumatology, Indianapolis, United States of America*; *[6]Eli Lilly and Company, Dermatology, Indianapolis, United States of America*; *[7]Medical University of Vienna, Division of Rheumatology, Wien, Austria*; *[8]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*

Background: C-reactive protein (CRP), an objective marker of inflammation, can be used to monitor treatment response to biologics in patients with axial spondyloarthritis (axSpA) in addition to evaluating signs & symptoms. CRP is not elevated in all patients with active axSpA questioning its validity as a universal biomarker of response. Ixekizumab (IXE) demonstrated efficacy in axSpA treatment irrespective of baseline (BL) CRP levels. However, response to IXE categorized on CRP change from BL is unknown.
Objectives: To evaluate response to IXE treatment from BL through week (wk) 16 in patients with axSpA categorized according to change in high sensitivity (hs) CRP.
Methods: COAST-V (NCT 02696785),-W (NCT02696798), & -X (NCT02757352), were phase 3, multicentre, randomized, controlled trials, investigating the efficacy of IXE 80 mg every 4 & 2 wks in patients with: r-axSpA naïve to biologic disease-modifying antirheumatic drugs (bDMARDs; COAST-V); or who were inadequate responders/intolerant to tumour necrosis factor inhibitors (TNFi; COAST-W); or who fulfilled Assessment of SpondyloArthritis International Society (ASAS) criteria for non-radiographic (nr)axSpA (COAST-X).
This post hoc analysis focuses on approved dosing regimens. Depending on BL and wk 16 hsCRP values, patients were categorised as stable low (hsCRP ≤5 mg/L at BL & ≤5 mg/L at wk 16), normalized (hsCRP >5 mg/L at BL & ≤5 mg/L at wk 16) or elevated (hsCRP >5 mg/L at wk 16, irrespective of BL hsCRP). An absolute cutoff of 5 mg/L was used as the stratification factor in all COAST studies. Data were analyzed by treatment arm. Each trial was analyzed separately.
For hsCRP subgroups, patient demographics & other characteristics at BL, as well as trajectory over time for the endpoints ASAS40 & Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) 50 are described. Non-responder imputation was used for missing values.
Results: In all studies at BL, disease activity & MRI SPARCC score were higher in normalized & elevated subgroups compared to the stable low subgroup - **a**.
In COAST-V, ASAS40 & BASDAI50 response was observed in IXE-treated patients regardless of hsCRP change status by wk 16 vs placebo. The highest ASAS40 & BASDAI50 response rate was reported in patients with normalized hsCRP - **b**. Similar findings were observed in COAST-W & -X.

Table 1. ***Baseline Patient demographics & other characteristics - ITT population, per CRP subgroup***

	COAST-V (r-axSpA, bDMARD naive)			COAST-W (r-axSpA, inadequate responders /intolerant to TNFi)			COAST-X (non-radiographic axSpA, bDMARD naïve)		
	Stable low (n=79)	Normalized (n=80)	Elevated (n=98)	Stable low (n=58)	Normalized (n=34)	Elevated (n=126)	Stable low (n=78)	Normalized (n=40)	Elevated (n=81)
Parameter									
Age (years)	43.7 (12.1)	38.9 (10.9)	42.7 (12.0)	50.4 (13.3)	46.1 (13.8)	45.7 (12.5)	44.0 (12.8)	37.2 (14.6)	38.7 (12.8)

Background: Axial Spondyloarthritis (axSpA) can be distinguished in radiographic axSpA (r-axSpA) and non-radiographic (nr-axSpA). Secukinumab (SEC) is a novel treatment for axSpA, but data from real-life are still missing.
Objectives: 1)to evaluate the effectiveness and safety of a wide cohort of axSpA patients on SEC followed in 8 Italian Rheumatologic centers for 24-months;2) to compare the features and disease-activity indices of SEC-treated axSpA patients subdivided in naïve biological drugs (**group A**) and in TNF-inhibitors failure patients (**group B**).
Methods: Consecutive patients with active axSpA (diagnosis according Assessment of SpondyloArthritis International Society ASAS criteria), who started SEC treatment, were evaluated prospectively.Data on disease characteristics, previous/ongoing treatments and imaging were collected. Disease-activity/functional/clinical scores and biochemical values were recorded at baseline (T0), at 6 (T6), 12 (T12), and 24 (T24) months. Effectiveness was evaluated over-time with descriptive statistics. Anova (Kruskal Wallis) and generalized linear models were used to compare variables over-time. Infections,adverse events were collected.
Results: One-hundred-seven patients [49.53% men; median age 49years; median treatment duration 18.5years] were enrolled;53(49.53%) had HLA-B27, 47.66% were r-axSpA and 52.34% nr-axSpA. Signs of sacroiliitis were present on MRI in 97 (90.65%) and X-rays in 51 (47.66%). SEC was prescribed as first line biologic treatment in 32 (29.9%) patients and as second or more line biological treatment in 75 (70.1%) patients (Figure 1). In all population significant decrease was achieved in:Visual Analogue Scale of pain and general-health; Leeds Enthesitis Index;Health Assessment Questionnaire modified for spondyloarthritis (HAQ-s);Bath Ankylosing Spondylitis Functional Index (BASFI);C-reactive protein. Bath Ankylosing Spondylitis Metrology Index and Erythrocyte-sedimentation-rate not significantly decreased. Effectiveness was associated to an improvement in Ankylosing Spondylitis disease activity score (ASDAS) [T0=3.4 (2.9-3.9) vs T24=1.9 (1.2-2.7);p=0.02] and in Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) [T0=6.6 (5.0-7.8) vs T24=3.2 (2.0-5.0);p=0.03].At T0 **group B** had a longer disease duration (p=0.04),a greater prevalence of peripheral arthritis (p=0.02),enthesitis (p=0.04) and psoriasis (p=0.05) and was mostly male (p=0.05),while no significant difference was observed for functional and disease-activity indices and signs of sacroiliitis on MRI/X-rays. At T24 **group A** showed better physical functioning and lower disease activity compared to **group B** [HAQs A vs. B=0.1(0.0-0.5) vs 0.3(0.1-0.8); BASFI A vs B=1.6(0.8-4.8) vs 4.0(2.5-4.6); BASDAI A vs B=2.2(1.0-3.8) vs 3.9(2.7-5.0);ASDAS A vs B=1.3(1.0-2.2) vs 2.1(1.6-2.9)].After T24 of treatment 70.2% of **Group A** and 68.4% of **Group B** had a low disease activity,accordingly to ASDAS<2.1. Twenty-three patients (21.5%) stopped the treatment during the follow-up mainly because of primary (7) or secondary loss of efficacy (9).Only 7 patients suspended SEC because of adverse events.A low number of episodes of mild infections (19) occurred;SEC was instead permanently discontinued in 4 cases for:oral refractory mucositis (2);recurrent aphthosis (1);recurrent broncopneumoniae (1).The retention rate at t24 was good in the whole population (73%).Survival curves for **Group A** and **B** were similar (log-rank test=0.81;p=0.69).
Conclusion: In a real-life clinical setting,SEC was safe and effective in axSpA, as shown by a significant decrease of BASDAI and ASDAS over a 24-months follow-up.

Baseline characteristics of 107 axSpA patients treated with secukinumab in the period January 2017- December 2020.

Background: According to previous studies, the effectiveness of interleukin-17 (IL-17) inhibitors was higher in anti-TNF-naïve patients with ankylosing spondylitis (AS) [1,2]. Netakimab (NTK) is a humanized anti-IL-17A antibody approved for the treatment of AS, psoriatic arthritis, moderate-to-severe plaque psoriasis in Russia and Belarus.
Objectives: To compare the efficacy of NTK in anti-TNF-naïve patients with anti-TNF-experienced patients with active AS at week 16 of therapy.
Methods: ASTERA (NCT03447704) is an ongoing phase 3 placebo (PBO)-controlled clinical study, aimed at evaluating NTK efficacy in AS [3]. 228 adult patients with active AS (BASDAI ≥ 4) were randomly assigned (1:1) to receive 120 mg NTK or PBO subcutaneously at week 0,1,2 and then q2w. This analysis includes 112 patients in NTK group. Efficacy endpoints included ASAS20/40, ASAS5/6 and ASAS partial remission (PR) at week 16 of therapy.
Results: 28 (25.0%) of 112 patients in NTK group had previous inadequate response/intolerance to anti-TNF (anti-TNF-IR): 24 (21.4%) – one anti-TNF, and 4 (3.6%) – two anti-TNF. 84 (75.0%) patients were TNF-naive. Achievement of ASAS criteria response at week 16 was similar in both groups (Table 1).

Table 1. Efficacy of NTK at week 16

Parameter	TNF-naïve (n = 84)	anti-TNF-IR (n = 28)	p-value*
ASAS20, n (%)	52 (61.9%)	17 (60.7%)	0.91
ASAS40, n (%)	35 (41.7%)	11 (39.3%)	0.82
ASAS5/6, n (%)	39 (46.4%)	11 (39.3%)	0.51
ASAS(PR), n (%)	15 (17.9%)	4 (14.3%)	0.78

*- Fisher's exact test

Conclusion: NTK 120 mg provided sustained improvements in signs and symptoms of AS in anti-TNF-naive and anti-TNF-IR patients at 16 weeks of therapy.

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease affecting sacroiliac joints and spine as well as peripheral joints and entheses. Tumour necrosis factor inhibitors (TNFi) are widely used in patients with persistently high disease activity despite non-steroidal anti-inflammatory drugs. Some patients fail to respond or loose responsiveness during therapy with TNFi. The development of anti-drug antibodies (ADA) might play a role in non-response or some adverse events. However it has never been evaluated for 2-years period.
Objectives: Therefore, the aim of the present study was to evaluate the development of ADA against TNFi longitudinally during 2-years period in axSpA patients and factors associated with it.
Methods: In total 180 axSpA patients according to ASAS classification criteria with a new TNFi prescription in the last two weeks period were included in this observational study. Clinical data and serum samples were collected at baseline and at every 12 weeks. Serum drug levels and ADAs were measured on 12, 24, 52 and 104 weeks of treatment by ELISA in one center to avoid inter-assay variability. The development of ADA over time was investigated by using generalized estimating equations (GEE) which is a technique for longitudinal data analysis allowing the use of all available data even deviated from normality.
Results: 180 biologic naive axSpA patients (116 male, median [IQR] 44,5 [14,5] years) who started anti-TNF agents (infliximab [20%], adalimumab [27,2%], etanercept [32,2%] and golimumab [20,6%]) were included in the analysis. In comparison to baseline values BASDAI, ASDAS-CRP and CRP values were significantly decreased in third months of follow-up (Figure 1). In total 172 patients had at 12 weeks, 154 at 24, 121 at 52, and 73 at 104 week serum samples available for ADA determination. In longitudinal analysis; baseline age and TNFi type, as well as longitudinal BASDAI, ASDAS, serum CRP levels and the development of adverse events and discontinuation of the drug were found to be associated with the development of ADA. In order to determine independent association/s with the development of ADA two longitudinal multivariable models were run; (a) with ASDAS as an activity measure, (b) with BASDAI and CRP levels and produced that all the variables were independently associated with longitudinally development of anti-drug antibodies (Table 1). Antibodies to adalimumab were related with lower serum drug levels.
Conclusion: The results of the present study with up to 2 years of follow-up, revealed that the development of ADA against TNFi therapy is associated with high disease activity, the development of adverse events and treatment discontinuation in patients with axSpA. And etanercept might be negatively associated with the development of ADA.

POS0930 SECUKINUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS AND AXIAL MANIFESTATIONS: PREDICTORS OF RESPONSE FROM THE DOUBLE-BLIND, RANDOMISED, PHASE 3B MAXIMISE TRIAL

X. Baraliakos[1], E. Pournara[2], L. Gossec[3], H. Marzo-Ortega[4], P. J. Mease[5], R. White[6], E. O'brien[6], B. Schulz[2], L. C. Coates[7]. Background: Psoriatic arthritis (PsA) is a heterogeneous disease with variability of response to different therapeutic modalities.[1] Identifying potential demographic and disease characteristics as predictors of treatment response may define personalised treatment optimisation strategies.[2–3]

Objectives: This post-hoc exploratory analysis of the MAXIMISE trial[4] investigated the differential treatment effect of demographics and baseline characteristics as predictive factors in biologic naïve patients with active PsA and symptoms of active spinal disease.

Methods: The full analysis set (FAS) comprised of all patients from the randomised set assigned to study treatment, fulfilling the predefined clinical criteria for active axial disease and for whom Assessment of SpondyloArthritis International Society (ASAS) 20 data were available at Week 12. The research hypothesis was that the odds ratio associated with the effect of treatment on ASAS20 responder status at Week 12 would be different depending on 12 pre-specified predictor variables. A logistic regression model was initially fitted to the FAS that included 12 pre-specified covariates. A second logistic regression model was then fitted to the FAS that allowed for all 12 pre-specified variables to interact with treatment.[5] The log-likelihood of the two fitted models were compared using a likelihood ratio test at a pre-specified significance level of 20% (i.e. *P*-value ≤0.20) to test whether any of the predefined variables interacted with treatment. If the above test was statistically significant at the 20% level of statistical significance the variables of the second model were formally examined to determine whether the overall effect of treatment is not applicable. Three forest plots were produced, one for each treatment group. Hypothesis tests were employed to determine the strength of evidence for each individual variable.

Results: The likelihood ratio test provided evidence against the assumption that the overall effect of treatment is applicable to all patients (*P*-value = 0.08). Notably, the odds of being an ASAS20 responder if nail dystrophy is present at baseline were 3 times greater in the secukinumab 150mg group and 5 times greater in the 300mg group compared with placebo (interaction *P*-value = 0.029). Although males fare worse than females in the placebo group, in the secukinumab 150mg and 300mg treatment groups the odds of being a responder were similar to females (interaction *P*-value = 0.039). Current smokers were less likely to be ASAS20 responders compared to never smokers regardless of treatment group (interaction *P*-value = 0.589) (Figure 1). Age, CRP level, Berlin MRI spine/SIJ score, time since first axial signs, number of swollen joints, new bone formation and BMI did not show a differential treatment effect on ASAS20 responses.

Conclusion: Of the 12 baseline variables of a unique population of 473 PsA patients with active axial disease diagnosed by clinical criteria, our analyses showed evidence of a differential treatment effect most notably for nail dystrophy suggesting that the presence of nail dystrophy may predict a better response to secukinumab in PsA patients with axial manifestations.

POS0931 RETENTION RATE AND TREATMENT RESPONSE OF BIOLOGICAL AGENTS IN ADVANCED SPINAL ANKYLOSIS AND BAMBOO SPINE: THE REAL LIFE DATA FROM THE HUR-BIO REGISTRY

B. Farisoğulları[1], G. K. Yardımcı[1], E. C. Bolek[1], E. Bilgin[1], E. Duran[1], G. Ayan[1], Z. Özsoy[1], G. Sandal Uzun[1], L. Kılıç[1], A. Akdoğan[1], Ş. A. Bilgen[1], O. Karadag[1], S. Kiraz[1], A. İ. Ertenli[1], U. Kalyoncu[1]. [1]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*

Background: Axial spondyloarthritis (axSpA) may lead to linear radiographic progression and progress to advanced spinal disease and finally to the bamboo spine (1).

Objectives: To assess the demographic, clinical, disease activity and retention rates of patients using biological disease-modifying antirheumatic drugs (bDMARD) with advanced spinal disease and bamboo spine in the Hacettepe University Rheumatology Biologic Registry (HUR-BIO) cohort.

Methods: In the HUR-BIO spondyloarthritis (SpA) registry were available 2952 patients. Of these, 774 patients with lumbar and cervical radiographs were included in the study. Advanced spinal ankyloses (99 patients) was defined as the presence of at least two intervertebral adjacent bridges at the lumbar and/or cervical spine level without bamboo spine. Bamboo spine (78 patients) was defined with a complete fusion of all lumbar and cervical spines. In addition, patients who diagnosed with axSpA for at least 10 years but no develop syndesmophytes on lumbar and cervical spine (92 patients) were used as a control group.

Results: Both the bamboo spine and advanced spinal disease had higher age, higher BMI, more smoking (ever) and hip involvement compared to the without syndesmophytes group. Acute phase reactants, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Ankylosing spondylitis disease activity Score-CRP (ASDAS-CRP) parameters were similar at the beginning of bDMARD in all groups. BASFI was higher in the bamboo spine group than in the without syndesmophytes group at last visit (Table 1). There were no differences between all groups in terms of the retention rate of the first bDMARD (Log rank p=0.86) (Figure 1).

Conclusion: Data on the use of bDMARDs in SpA patients with bamboo spine are limited. This study showed that bDMARDs are an effective treatment option in SpA patients with bamboo spine with high disease activity. Similar drug retention rates were found compared to SpA patients with no syndesmophytes. Although the disease activity decreased similar rates in the groups, functional limitation continued in approximately half of the patients in bamboo spine patients.

REGULATION OF INTESTINAL FLORA RESTORES IMMUNE BALANCE IN PATIENTS WITH UNDIFFERENTIATED SPONDYLOARTHRITIS

T. Cheng[1,2,3], J. Guo[2], S. X. Zhang[1,2,3], Y. Zhang[1,2,3], Y. Li[1,2,3], X. Liu[1,2,3], X. F. Yin[1,2,3], X. Li[1,2,3]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*Shanxi Li Xiaofeng Medical Groups, Department of Rheumatology, Taiyuan, China*; [3]*Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*

Background: Undifferentiated spondyloarthritis (USpA) is the most common subtype of the spondyloarthritides with a prevalence between 0.7% and 2.0%[1]. Inflammatory back pain, peripheral arthritis and less frequently enthesitis are the main clinical features of USpA[2]. Resently the role of dysregulated microbiome along with migration of T lymphocytes and other cells from gut to the joint ("gut-joint" axis) has been recognized[3 4]. However, the detailed lymphocyte statuses of USpA patients and the effect of regulating the intestinal flora on the lymphocyte subsets is unclear.

Objectives: To investigate the status of lymphocyte subsets in peripheral blood (PB) of USpA patients and the variation after regulation of intestinal flora.

Methods: A total of 39 newly diagnosed patients with USpA who fulfilled the European Spondyloarthropathy Study Group (ESSG) classification criteria and 60 age- and sex- matched healthy controls (HC) were enrolled in this study. All patients were given intestinal flora regulation therapy for six months, including clostridium butyricum capsule or bacillus coagulans tablet. The peripheral lymphocyte subsets of these participants were assessed by flow cytometry. Methane hydrogen breath test as well as cytokines were measured in all patients before and after treatment. Mann-Whitney U test was applied for the lymphocyte status between USpA patients and HC and Wilcoxon test for the comparison before and after treatment. The results of methane hydrogen breath were counted by the Chi-Square test. All *P*-values reported herein are two-tailed and *P*-value<0.05 was taken as statistically significant.

Results: Compared with HC, patients with USpA had a lower numbers of T cells (*P*=0.001), NK cells (*P*=0.026), CD8+T cells (*P*=0.046) and Treg cells (*P*<0.05) but higher ratios of Th17/Tregs (*P*=0.001), indicating a disturbance of immune microenvironment (Figure 1). After given therapy, T cells (*P*=0.003), B cells (*P*=0.018), NK cells (*P*=0.003), $CD8^+$T cells (*P*=0.001) and Treg cells (*P*=0.009) were distinctly increased while the ratio of Th17/Treg decreased (*P*=0.046), suggesting a rebalance of immune systems (Figure 2a-c). Moreover, there were increase in the level of IL-6 (*P*<0.001), IL-17 (*P*=0.029) and TNF-α (*P*=0.003) as well as decrease in IL-10 (*P*=0.045) and IFN-γ (*P*=0.001) (Figure 2d). Further, the positive rate of intestinal bacterial overgrowth decreased significantly after regulation (*P*=0.029) (Figure 2e).

Conclusion: Imbalance of immune environment is closely related to the incidence of undifferentiated spondyloarthrosis. The regulation of intestinal flora restores the balance and improve the growth of bacteria in the small intestine simultaneously. Therefore it is essential to focus on the alteration of intestinal flora to prevent the outbreak of inflammation and disease progression.

Background: Access to high-cost treatments is especially limited in low-resource countries. This issue is becoming stronger today given the health and economic crisis caused by the SARS-CoV2 pandemic. There are no reports in our country on limitations to access and adherence to treatment in patients with Spondyloarthritis (SpA) during social preventive and mandatory isolation.
Objectives: Evaluate access and adherence to treatment in patients with Spondyloarthritis during social preventive and mandatory isolation.
Methods: Patients with axial spondyloarthritis (axSpA) radiological (r-axSpA), non-radiological (nr-axSpA) and peripheral spondyloarthritis (pSpA), according to ASAS criteria and psoriatic arthritis (PsA) according to CASPAR criteria, were included. Sociodemographic data, comorbidities, disease activity and treatments were collected at baseline. Data on treatment discontinuation, medical attention for suspected COVID-19 disease, RT-qPCR for SARS-CoV-2 detection and outcome of COVID-19 disease were collected from April to September 2020. Numerical variables were summarized as means and standard deviations (SD) or as medians and interquartiles 25-75 (IQ 25-75).
Results: 320 patients were included, 55% were male, with a mean age of 50 years (SD 13), 21.6% had diagnosis of r-axSpA, 6.9% nr-axSpA, 6.9% pSpA, and 64.7% PsA. Disease duration was 11 (IQ 5-16) years and activity parameters were as follow: BASDAI 3.65 (SD 3), BASFI 3 (1.5-9), PASI 0.3 (0-7), BSA 0.2 (0-6). 14 (4.4%) patients with COVID-19 disease were reported, 10 were confirmed by positive RT-qPCR and 4 by symptoms and history of close contact with SARS patients. 4 (28.6%) received anti TNF (3 adalimumab, 1 certolizumab), 4 (28.6%) anti IL17 (3 secukinumab and 1 ixekizumab), 8 (57%) methotrexate (MTX) and 2 (14%) leflunomide (LF). Among the 320 patients included, 59 (18.4%) discontinued at least one treatment during follow-up. The discontinued medications were: adalimumab (16), MTX (15), secukinumab (9), etanercept (6), certolizumab(4), ustekinumab (3), NSAIDs (2), apremilast (1), golimumab (1), ixekuzumab (1), LF (1), MTX plus LF (1). The main reason for treatment discontinuation was drug shortage: 36 (62%), followed by patient's decision: 12 (21%) and medical indication: 11 (17%). Of the 36 patients who discontinued due to shortage, 11 received adalimumab, 8 secukinumab, 5 MTX, 3 etanercept, 3 certolizumab, 3 ustekinumab, 2 NSAIDs and 1 golimumab.
Conclusion: In our Argentinian cohort of patients with SpA, drug shortage was the main reason for treatment discontinuation. The SARS-CoV2 pandemic exposed limitations to access to treatment for patients with SpA.

POS0934 BIOLOGICAL THERAPY IN UVEITIS ASOCIATED TO AXIAL SPONDYLOARTHRITIS. SINGLE CENTER UNIVERSITY STUDY

A. Herrero-Morant[1], I. González-Mazón[1], V. Calvo-Río[1], J. Rueda-Gotor[1], M. Á. González-Gay[1], R. Blanco[1]. *[1]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*

Background: Uveitis is the most frequent extraarticular manifestation of axial Spondyloarthritis (axSpA). Effects of Biological Therapy (BT) on uveitis associated to axSpA are contradictory (1-3).
Objectives: To assess in uveitis associated to axSpA a) frequency and features of uveitis, and b) efficacy and relation of BT in a single-center university study.
Methods: Observational study from a cohort of 301 consecutive unselected patients with axSpA classified according to the Assessment of SpondyloArthritis International Society criteria. Episodes of uveitis were analyzed before and after BT initiation. Likewise, uveitis incidence rate *(episodes/100 patients/year)* at baseline and after first BT was calculated.
Results: Uveitis was observed in 44 (25 men/19 women) out of 301 (14.6%) patients. Mean age was 45.6 ± 10.3 years. Demographic and clinical features in patients who developed uveitis and those that did not are summarized in Table 1. After 18.6 ± 10.4 years of follow-up, 44 (14.6%) patients suffered from at least one episode of uveitis. Uveitis was anterior and acute in all cases and unilateral in 37 (84.1%) patients. Mean anterior chamber cells was 1.7 ± 1.2 cells.
Per episode of uveitis, 20 patients received BT with: secukinumab (SECU) (n=7, 35%), adalimumab (n=6, 30%), golimumab (n=3, 15%), infliximab (n=2, 10%), certolizumab (n=1, 5%), and etarnecept (ETN) (n=1, 5%). Before the initiation of BT, patients treated with SECU developed 29.7 *episodes/100 patients/year* while those treated with monoclonal anti-TNFα 16.3 *episodes/100 patients/year* and patients with ETN 5.8 *episodes/100 patients/year*. After 5.9 ± 3.7 years of follow-up, patients treated with SECU developed 16.1 *episodes/100 patients/year* while those treated with monoclonal anti-TNFα 7.6 *episodes/100 patients/year* and patients with ETN 0 *episodes/100 patients/year* (Figure 1). No serious adverse effects were observed.
Conclusion: Uveitis was observed in 14.6% of axSpA. Most of them were HLA-B27 positive. Acute, anterior and unilateral was the most frequent pattern of uveitis in axSpA. There was a similar decrease in incidence rate between patients treated with SECU and those treated with monoclonal anti-TNFα.

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease mainly affecting sacroiliac joints and spine. Peripheral arthritis, dactylitis and enthesitis may also occur. Extra musculoskeletal manifestations (EMMs; uveitis [AAU], inflammatory bowel disease [IBD] and psoriasis [Pso] are among the most common ones) are important features and might have an impact on the disease burden in patients with axSpA. The presence of EMM, in particular IBD and AAU could influence the choice of TNFi however little is known regarding the role of peripheral manifestations together with the EMM on the prescribing patterns in axSpA patients.

Objectives: To examine the frequency of peripheral and EMMs in a real-world axSpA cohort and their effect on the choice of first advanced treatment.

Methods: In total 1687 axSpA patients (58% male and the mean age (±SD) was 38.5 ± 10.9) who initiated his/her first biologic were included in the present analysis. The data for the current study was obtained from the TReasure web-based registry; in which RA and SpA patients treated with bDMARDs from different regions of Turkey. Baseline demographic, disease related characteristics, peripheral and EMMs were extracted. Characteristics of patients with and without peripheral/extra-musculoskelatal involvement were compared as well as factors/covariates associated with the choice of first TNFi and secukinumab was analysed.

Results: Enthesis (28.2%) was found the most common peripheral manifestations and peripheral arthritis (26.4%) and hip arthritis (24.4%) followed it. Symptom duration to the first advanced treatment initiation was significantly shorter in axSpA patients with peripheral arthritis, enthesitis, dactylitis and psoriasis and longer in hip arthritis and AAU. HLA-B27 positivity was significantly lower in patients with arthritis, psoriasis and IBD and higher with hip arthritis and AAU. In multivariate analysis the presence of IBD is significantly associated with the preference of monoclonal TNFi (mab) over etanercept (ETA) (OR 5,770; 95%CI 1.788-18.616). However ETA was preferred in patients with hip arthritis (p=0.003), longer symptom duration (p=0.049), and using sulfasalazine (p=0.043). In comparison with mabs, secukinumab (SEC) prescription was found to be significantly associated with higher age (p=0.001), sulfasalazin (p=0.001) and methotrexate usage (p=0.053) among axSpA patients need their first advanced treatment.

Conclusion: The results of the current study confirm the pathophsyologic associations of peripheral involvement and EMM in axSpA patients. Apart from hip arthritis the presence of IBD has an impact on the prescription of advanced treatment in real-life.

Table 1. Clinical characteristics of patients in cohort

POS0936 TREATMENT OF ANKYLOSING SPONDYLITIS WITH TUMOR NECROSIS FACTOR-ALPHA INHIBITORS LOWERS THE RISK OF RENAL FUNCTION DECLINE

S. J. Lee[1], J. S. Lee[1], U. C. Cha[1], E. J. Nam[1]. *[1]School of Medicine, Kyungpook National University, Korea, Internal Medicine, Daegu, Korea, Rep. of (South Korea)*

Background: Ankylosing spondylitis (AS) is associated with reduced renal function, possibly due to chronic inflammation or the use of nephrotoxic drugs. However, the long term effect of tumor necrosis factor (TNF) inhibitors on renal function in patients with AS has not been well established.

Objectives: We therefore investigated the association of TNF inhibitors treatment and change in estimated glomerular filtration rate (GFR) using the Korean College of Rheumatology Biologics (KOBIO) registry (ClinicalTrials.gov, NCT01965132), a prospective nationwide biologics registry.

Methods: We enrolled 1846 patients with AS in KOBIO registry and as disease controls, 471 patients with AS who did not take biologics in Kyungpook National University Hospital. The estimated glomerular filter rate (eGFR) using the Modification of Diet in Renal Disease (MDRD) equation was evaluated in both groups. Renal insufficiency was defined as eGFR <60 mL/min/1.73 m2. Changes and differences of eGFR in each group were assessed at every follow-up year using paired t-test. Risk factors for renal function decline were identified using multivariable analysis.

Results: The changes of eGFR values in patients treated with TNF inhibitors were not significantly decreased during 5 years follow up period. However, those in patients not treated with TNF inhibitors were significantly decreased. Moreover, among patients with renal insufficiency, use of TNF inhibitors did not affect further renal function deterioration during follow up period. Using multivariable logistic regression models, patients treated (versus not treated) with TNF inhibitors had a lower risk of renal function decline after 5 years follow up period (p<0.045).

Conclusion: The use of TNF inhibitors was independently associated with lower risk of renal function decline and TNF inhibitors may be a safe treatment option in AS patients with renal insufficiency.

Federation; [7]*RSMU named after N.I.Pirogov, Department of General Medicine, Moscow, Russian Federation*; [8]*Russian Medical Academy of Continuing Professional Education, Rheumatology, Moscow, Russian Federation*; [9]*CJSC «European Medical Center», Rheumatology, Moscow, Russian Federation*

Background: The number of new biologics in treatment of axial spondyloarthritis (axSpA) is rapidly increasing. It is important to assess timely their place in the treatment of axSpA, especially with regard to retention on therapy.
Objectives: To compare retention on therapy with different biologics in patients with axSpA.
Methods: We retrospectively analyzed the data of axSpA patients receiving biologics from the MUAR register. Predictors of retention on therapy were selected by forward stepwise variable selection within Cox regression proportional hazard model. These predictors were considered as confounders when comparing the risks of biologics withdrawal.
Results: 990 treatment episodes in 640 patients with axSpA were analyzed (non-radiographic axSpA – 4.1%, ankylosing spondylitis - 95.9%). The duration of episodes was 824±920 days. Men were 66,6%, mean age 46,4±11,4.The patients were treated with Adalimumab (ADA) (n= 252 treatment episodes), Golimumab (GOL) (n=82), Infliximab (INF) (n=167), Netakimab (NET) (n=9), Secukinumab (SEC) (n=75), Certolizumab pegol (CER) (n=66), Etanercept (ETA) (n=339).
The following predictors of withdrawal risk were identified –
1.The total duration of the disease
2.The duration of the disease before the onset of biologic treatment
3.Gender
4.Family history of non-inflammatory spondylopathy (degenerative spinal disease)
5.The line of biologic treatment
6.The level of education
The severity of radiographic sacroiliitis and HLA B-27 positivity were not associated with the risk of discontinuation of biologics.
The identified predictors were further considered as confounders. Adjusted for confounders, ETA had the lowest treatment withdrawal risk (Figure 1). ADA, GOL, INF, SEC, CER had significantly higher risk of withdrawal compared with ETA (Table 1).
Conclusion: Our analysis detected predictors associated with risk of biologics withdrawal in axSpA patients in real clinical practice. There are significant differences between biologics regarding retention on treatment.

Table 1. Hazard ratio for treatment withdrawal

Drug	Hazard ratio (Exp B)	p
ADA	1.52*	0.004
GOL	2.95*	0.000
INF	2.574*	0.000
NET	3.680*	0.073

POS0938 A NEW APPROACH FOR ULTRASOUND GUIDED SACROILIAC JOINT INJECTIONS IN SPONDYLOARTHRITIS

P. Todorov[1], A. Batalov[1]. [1]*Medical University of Plovdiv, Rheumatology and Internal Diseases Propaedeutics, Plovdiv, Bulgaria*

Background: Sacroiliac joints (SIJ) inflammation and pain is particularly common in patients with Spondyloarthritis (SpA). SIJs injections represent a valuable therapeutic option in this condition. Traditionally this procedure (irrespective of the guidance method) aims at the lower (synovial) part of the joint. However, there is growing body of evidence that enthesitis rather than synovitis is the cardinal pathological lesion in SpA. Thus, an approach targeting the more superior (ligamentous) part of the joint, with the numerous entheses of the intraspinous sacroiliac ligaments placed there, could be more beneficial in SpA patients with active sacroiliitis. The Posterior sacroiliac ligament (PSIL) is the most superficial of the SIJ ligaments, covering the other dorsally. Thus, using PSIL as a landmark and placing the needle tip beneath it, the injected solution will inevitably spread in the ligamentous portion of the joint.
Objectives: To assess the feasibility and efficacy of a new technical approach of ultrasound (US) guided SIJ injections in SpA targeting the ligamentous part of the joint.
Methods: The feasibility and efficacy of our approach was tested on 22 consecutive SpA patients, after an inform consent, with pain in the SIJ that did not respond to NSAIDS and who were otherwise on a stable medical treatment. A solution consisting of 7 mg Betamethasone (1ml) and 1% Lidocaine (1.5 ml) was administered to all injected SIJs. The efficacy of the procedure was assessed by patients reported outcome measures: mean reported pain level (on VAS), level of disability due to the back pain (Roland Morris Disability Questionnaire – RMDQ) and quality of the night sleep (Jenkins Sleep Evaluation Questionnaire – JSEQ). They were filled by the patients at baseline and two months after the intervention. Methodology of the procedure: All injections were done with patients in a prone position using an Esaote My Lab 7 machine and a linear transducer (3-12 MHz). After visualization of the SIJ cleft, the probe was slide caudally to the level of the second sacral foramen. Then the probe was rotated to a slightly oblique position with its lateral part higher and the medial part lower. In this way the probe became parallel to the PSIL, and latter is visualized sufficiently well in its long axis. Then, in this position, a 22G, 9 mm spinal needle (Spinocan) was inserted at the medial side of the probe following an in-plane free-hand technique and advanced in cranio-lateral direction. When the needle tip was seen to penetrate the PSIL, and thus enter the SIJ ligamentous part, 0.2 ml of the solution was injected to confirm that it spreads beneath the PSIL, rather than above or in this ligament. After that, a Color Doppler (CD) box was activated and placed over the SIJ to monitor the spread of the injected solution and ensure that it keeps bellow the PSIL. The whole solution was injected under this direct US and CD visualization and the needle tip was repositioned again beneath the PSIL if needed during the procedure.
Feasibility of this injection approach was assessed on the basis of the encountered difficulties in adequate visualization of the PSIL and the injected solution flow beneath it from the start until the end of the intervention.
Results: The results of the procedure, assessed in two months showed that the mean pain score decreased by 68% (VAS from7.22±1.23 to 2.28±2.37), the disability score - by 46% (RMDQ from 11.86±5.12 to 6.42±6.39), and the sleep quality improved by 41% (JSEQ from 9.86±4.76 to 5.84±3.43). The procedure was found completely feasible by the performing operator and the visualization of the landmark (PSIL) was adequate in all patients and throughout the whole procedure. The CD allowed to confirm reliably that the solution is injected under the PSIL at any time point.
Conclusion: The SIJ injections performed by our approach and targeting the ligamentous part of the joint, proved to be completely feasible and furthermore – efficient, in alleviating the symptoms of active sacroiliitis in SpA patients.

POS0939 WHEN DO THE ACTIVE SACROILIITIS MRI FINDINGS LOSS IN ANKYLOSING SPONDYLITIS? A RETROSPECTIVE, CROSS-SECTIONAL, OBSERVATIONAL STUDY

A. C. Genç[1], F. Turkoglu Genc[2], Z. Öztürk[3], D. Karatas[3], S. M. Turk[3], E. Gönüllü[3]. [1]*Geyve Government Hospital, Internal Medicine, Sakarya, Turkey*; [2]*Sakarya University, Internal Medicine, Sakarya, Turkey*; [3]*Sakarya Unıversıty, Rheumatology, Sakarya, Turkey*

Background: Ankylosing Spondylitis (AS) is an inflammatory rheumatic disease that affects the spine and sacroiliac joints (SIJ). Non-steroidal anti-inflammatory drugs (NSAIDs), modifying antirheumatic drugs (DMARDs), and recently anti-TNF blockers, which are more costly than NSAIDs but used in resistant cases, are generally used in its treatment (1).
Objectives: While SIJ-MRI is one of the imaging methods in the diagnosis of the disease, it is not yet used in its follow-up (2). We wanted to define when the activated SIJ-MRI findings, which showed early sacroiliitis, regressed according to the treatment option.
Methods: Among the 8100 SIJ-MRIs taken in our hospital in the last 5 years, those that were reported normally were excluded from the study. Among the remaining 1150 patients with active or chronic SIJ findings, a total of 87 patients who were diagnosed with AS and had active SIJ findings in the first imaging and had a second SIJ-MRI examination for any reason were included in our retrospective, cross-sectional and observational study. According to the treatment option, how long the active SIJ-MRI findings disappeared was calculated in months using the Kaplan-Meier method.
Results: Of the 87 patients examined in the study, 41 were women and 46 were men. The average age is 32.7. Active SIJ-MRI findings disappeared in a mean of 30.6 months for 11 of 24 patients who did not use any medication, in a mean of 33.9 months for 6 of 16 patients using NSAIDs, in a mean of 40.7 months for 14 of 34 patients using sulfasalazine, in a mean of 28.2 months for 3 of 6 patients using adalimumab, in a mean of 24.4 months for 3 of 5 patients using methotrexate, 11.9 month for 2 of 1 patient using certolizumab. There was no statistically significant difference between the groups.
Conclusion: The signs of active sacroiliitis disappeared in less time in patients who did not receive any treatment than those using NSAIDs and sulfasalazine. Patients using anti-TNF blockers had earlier results than those using no medication. The reason for this may be the progressive course of patients who are switched to the next level of treatment and their late response to treatment, as well as the mechanism of the disease (2-3). This situation brings to the agenda the tendency of physicians to over-treat the disease. More randomized controlled studies are needed regarding new treatment options.

POS0940 THE IMPACT OF TUMOUR NECROSIS FACTOR-ALPHA INHIBITOR TREATMENT ON WNT SIGNALING INHIBITORS, NOGGIN AND CYTOKINE LEVELS IN AXIAL SPONDYLOARTHRITIS

N. Atas[1], B. Çakır[2], F. Bakır[3], M. Uçar[4], H. Satış[1], G. T. Güz[5], H. Babaoglu[1], R. Bilici Salman[1], A. Avanoglu Guler[1], H. Karadeniz[1], S. Haznedaroglu[1], B. Goker[1], M. A. Ozturk[1], A. Tufan[1]. [1]*Gazi University, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey*; [2]*Alab Laboratory, Department of Clinical Biochemistry, Ankara, Turkey*; [3]*Lokman Hekim University, Department of Clinical Biochemistry, Ankara, Turkey*; [4]*Gazi University, Department of Radiology, Ankara, Turkey*; [5]*Gazi University, Department of Internal Medicine, Ankara, Turkey*

Background: Axial spondyloarthritis (axSpA) is a common chronic inflammatory disease of the axial skeleton. Some cytokines have important roles in initiation and progression of disease and are elevated in active disease. Additionally, Wnt signaling pathway inhibitors and noggin also appear to be involved in pathogenesis of ankylosing spondylitis. Anti-tumor necrosis factor-alpha (TNF) agents have dramatically improved the clinical outcome of axSpa; however, acceptable clinical improvement is not achieved in all patients and capacity of anti-TNF to slow or prevent structural damage still remains controversial.
Objectives: To evaluate the effect of anti-TNF on inflammatory and noninflammatory milieu in patients with axSpA.
Methods: In this prospective study we included 30 biologic treatment naive adult patients with axSpA and 30 healthy controls. All patients with high disease activity were treated with anti-TNF therapy for 6 months. Laboratory and clinical evaluation of all patients were performed at baseline and after 6 months of anti-TNF treatment. Following cytokines and wnt/BMP antagonists were measured; TNF-Alpha, COX-2, IL-6, IL-17, IL-22, IL-23, IL-33, dickkopf-1, sclerostin, noggin.
Results: The mean age of patients with axSpA and healthy controls were 38.1±13.3 and 37.7±7.7 years, respectively (p>0.005). At baseline, the median (IQR) TNF-alpha was higher in axSpA patients when compared to healthy controls, 34.4 pg/ml (31.4-37.03) vs 18.1 pg/ml (12.1-28.4), (p<0.001), while the median (IQR) dickkopf-1 and sclerostin were lower in axSpA patients, 446.7 pg/ml (356.9-529.3) vs 1088.7 pg/ml (951.7-1244.4), (p<0.001) and 312.4 pg/ml (140.8-412.7) vs 412.3 pg/ml (295.4-512.8), (p<0.001), respectively. IL-17, IL-22, IL-33, dickkopf-1 and sclerostin increased with anti-TNF treatment (table 1).
Conclusion: Elevation of some cytokines which are important in pathogenesis of axSpA and nonincrease in noggin with anti-TNF drugs may affect effectiveness of anti-TNF treatment.

Table 1. Changes of cytokines, dickkopf-1, sclerostin and noggin with anti-TNF treatment.

	Pre-Anti-TNF	Post-Anti-TNF	P value
IL-6	45(39.1-68.8)	47.6(27.3-61.1)	0.750
IL-17	93.3 (85.1-104.8)	102.1(86.6-114.6)	**0.026**
IL-22	159,2 (151,9-178.4)	183.5(156.3-304.6)	**0.033**
IL-23	36.5 (26.1-52.9)	41.3(28.4-55.5)	0.658
IL-33	127.8 (106.6-186.1)	147.06(128.5-213.4)	**0.016**
COX2	0.176 (0-0.374)	0.202(0.051-1.151)	0.469
TNFalpha	34.4(31.4-37.03)	30.7(12.8-35.6)	**0.004**
Dickkopf-1	446.7(356.9-529.3)	881.3(663.1-972.2)	**<0.001**
Sclerostin	312.4 (140.8-412.7)	405.1(276.3-452.5)	**0.018**
Noggin	48.3(17.04-153.9)	31.2(11.3-103.7)	0.264

POS0941 IN SPONDYLOARTHRITIS PATIENTS THE PRESENCE OF COMORBIDITIES IS AN INDEPENDENT PREDICTOR OF INSUFFICIENT RESPONSE TO THERAPY WITH BIOLOGIC AGENTS AND TREATMENT DISCONTINUATION

I. Flouri[1], N. Kougkas[1], N. Avgustidis[1], A. Repa[1], A. Eskitzis[1], A. Molla Ismail Sali[1], S. Pitsigavdaki[1], K. Pateromichelaki[1], E. Kalogiannaki[1], G. Bertsias[1], P. Sidiropoulos[1]. [1]*University Hospital of Heraklion, Crete, Rheumatology Department, Heraklion, Crete, Greece*

Background: Long-term observational studies of patients under biologic disease-modifying anti-rheumatic drug (bDMARD) therapies in routine clinical practice can provide us with important data regarding patients with comorbidities, who are usually excluded from randomized controlled studies.
Objectives: To study the impact of comorbidities in the outcome (response and persistence to therapy) of patients with spondyloarthritis (SpA) receiving bDMARDs in real-world clinical practice.
Methods: Prospective study of all patients who start a bDMARD in a tertiary centre University Hospital after their consent. All patient comorbidities [among a list of approximately 100 pre-specified major comorbidities] are registered by treating physicians at baseline and during follow-up.
Comorbidities were studied as total Comorbidities Count (CC) and rheumatic disease comorbidity index (RDCI). Statistical analyses were performed using logistic and Cox regression models, adjusting for the potential confounding of age, sex, disease duration, diagnosis (axial vs. peripheral SpA), number of previous conventional synthetic and biologic DMARDs, year of therapy start, and co-administered methotrexate and corticosteroids (yes/no). Analyses of response to therapy also included baseline BASDAI or ASDAS indices as confounding variables.
Results: A total of 603 biologic treatments (1st: 298, 2nd: 157, ≥3rd: 148) were analyzed. Half (51%) of the patients were female, 413 patients had axial SpA (AxSpA) and 190 peripheral SpA (perSpA). At baseline, median (IQR) age: 48 (38-57) years, disease duration: 11 (4-19) years, CC: 2 (1-4) and RDCI: 1 (0-2). Both comorbidity indices were significantly higher in perSpA compared to AxSpA (p<0.001).
At 6 months of therapy, 31% of patients with AxSpA achieved BASDAI50 and 39% had ASDAS-ESR < 2.1. Higher CC was an independent predictor of insufficient response according to BASDAI50 [OR (95%) = 0.70 (0.52-0.94), p=0.019] and higher RDCI was predicting failure to achieve ASDAS-ESR < 2.1 [OR (95%) = 0.59 (0.37-0.94), p=0.027]. Other independent predictors of non-response were age, longer disease duration and (for ASDAS-ESR<2.1) higher baseline disease activity.
During 1405 patient-years of follow-up, 349 (58%) treatments were discontinued. The adjusted hazard ratio for bDMARD discontinuation within the first 2 years of treatment due to insufficient response was doubled in patients with CC ≥2 versus those with CC ≤1 [HR = 2.27 (1.14-4.53), p=0.020] or with RDCI ≥1 (vs. RDCI =

0) [HR = 2.23 (1.22-4.07), p=0.009]. Comorbidities' indices were not significant predictors of treatment discontinuations due to adverse events.
Conclusion: The presence of comorbidities in patients with SpA is an independent predictor for insufficient 6-month response to bDMARDs and resultant treatment discontinuation due to failure.

Spondyloarthritis - clinical aspects (other than treatment)

POS0942 **THE NEGATIVE IMPACT OF UNDIAGNOSED DEPRESSION IN AXIAL SPONDYLOARTHROPARTHY: RESULTS OF A SCREENING STUDY**

S. Maguire[1,2], F. B. O'shea[1,2]. [1]*St James' Hospital, Rheumatology, Dublin, Ireland*; [2]*Trinity College Dublin, Medicine, Dublin, Ireland*

Background: Previous research in axial spondyloarthropathy(axSpA) has shown this population to have a high prevalence of depression. This co-morbidity has been previously shown to impact disease activity in patients with rheumatic disease.
Objectives: The purpose of this study was to screen for early signs of depression using two validated tools, the Patient Health Questionaire-9 (PHQ-9) and the Hospital Anxiety and Depression Scale for depression (HADs-D) in patients with known axSpA.
Methods: AxSpA patients attending the Rheumatology department in St James' Hospital between February and October 2020 were invited to take a self-administered survey which included the PHQ-9 and the HADs-D. Scores from the HADs-D yielded a numerical result which was then categorised as normal, borderline or abnormal. PHQ-9 numerical results were categorised as normal, mild, moderate, moderate/severe or severe. Patients with a known diagnosis of depression were excluded. In addition to baseline demographics, patient reported outcomes from the clinic visit were also recorded.
Data analysis was performed using IBM SPSS version 26. Continuous variables were recorded as means, categorical variables as frequencies with percentages. A one-way analysis of variance analysis (ANOVA) was used to determine significance of variation in outcomes between patient outcomes as determined by the HADs-D and PHQ-9. A p-value of <0.05 was deemed significant. Consent was obtained prior to participation. Approval was received from the St James'/Tallaght Hospital Joint Ethics Committee.
Results: In total 71 axSpA patients took part in the survey. The population was 70.4%(50) males and 29.5%(21) female, with an average age 47.9 years and mean disease duration 19.7 years (mean outcomes: BASDAI 4.08, BASFI 3.62, BASMI 3.54, ASQoL 6.79). Overall, 7 (9.9%) participants recorded abnormal HADs-D scores, while 17 (23.9%) recorded moderate to severe PHQ-9 scores indicative of underlying depression. AxSpA females had higher mean HADs-D scores (7.5 vs 4.8, p=0.01) than males, with abnormal scores in 19%(4) of females and 6% (3) of males. No significant differences were found in PHQ-9 scores between genders.
Analysis revealed significantly worse BASDAI (6.27 vs 3.42, p<0.01) and AQoL scores (12.57 vs 5.26, p<0.01) in axSpA patients with abnormal compared to normal HADs-D scores. No significant differences were noted in BASFI, BASMI or baseline demographics. A similar pattern was noted on analysis of PHQ-9 scores, with significantly worse BASDAI (7.9 vs 2.55, p<0.01), BASFI (8.05 vs 2.33, p<0.01) and ASQoL (19.5 vs 2.62, p<0.01) noted in those scoring as severe compared to normal. No significant differences were detected in BASMI scores or baseline demographics.
Conclusion: A high percentage of axSpA patients recorded high HADs-D and PHQ-9 scores concerning for undiagnosed depression. These patients were noted to have significantly worse disease activity and quality of life as compared to patients with normal scores. Clinicians treating axSpA should consider screening for depression in this population.

POS0943 **GEOGRAPHIC VARIATION OF ANKYLOSING SPONDYLITIS (AS) DIAGNOSIS AND TREATMENT IN THE UNITED STATES: A REAL-WORLD EVIDENCE STUDY**

A. Deodhar[1], D. Kruzikas[2], L. Zhou[2], A. Biljan[2], C. Saffore[2]. [1]*Oregon Health & Science University, Portland, United States of America*; [2]*AbbVie Inc., North Chicago, United States of America*

Background: AS is a chronic inflammatory immune-mediated disease primarily affecting the sacroiliac joints and spine, with a prevalence of 0.2%–0.5% in the United States.[1] Because radiographic features of the disease can take years to develop, diagnosis may be delayed by up to 10 years[2], which can negatively affect patients' function, ability to work, and overall quality of life.
Objectives: To describe geographic variations in AS diagnostic prevalence and treatment in the United States.
Methods: This study utilized the IBM® MarketScan® Administrative Claims Database from 2014–2019. Patients (pts) ≥18 years of age with AS, continuous medical and pharmacy enrollment during the calendar year, and complete geographic information during the study period were included. Pts were identified by having ≥1 claim with ICD-9-CM or ICD-10-CM codes for AS (720.0 or M45.x, respectively). Two AS diagnosis definitions were used; Definition 1 (D1): Pts with ≥1 claim for an AS diagnosis in the year by any provider and Definition 2 (D2): Pts with ≥2 claims for an AS diagnosis within 18 months by rheumatologists. Annual AS diagnostic prevalence rates were calculated for both groups; treatment was evaluated among pts with D2. Diagnosis and treatment rates were assessed from 2014–2019 at the national and state levels and reported for states where >20 pts received an AS diagnosis (D1 or D2) or respective treatment (D2). The effect of age, sex, race (surrogate for HLA-B27), and rheumatologist per capita on geographic variation was assessed.
Results: The number of pts included per year ranged between 10,811–13,077 (D1) and 3,775–4,901 (D2). AS diagnostic prevalence increased over time for both groups, with the annual prevalence rate per 10,000 persons for D2 pts increasing from 2.5 in 2014 to 3.5 in 2019 (Table 1). The AS diagnostic prevalence by D2 in 2019 was highest for Idaho (13) and Colorado (6), and lowest for Michigan (2). The state variations in prevalence did not appear to be explained by age, sex, racial distribution, or rheumatologists per capita. The percentage of D2 pts receiving advanced therapies (all FDA-approved indicated biologic disease-modifying antirheumatic drugs [bDMARDs] for AS) were >70% and increased each year, whereas the use of conventional synthetic DMARDs (csDMARDs) decreased (Figure 1. next page). While opioid use decreased, 37% of D2 pts were prescribed such treatment in 2019. Percentage of D2 pts receiving advanced therapy in 2019 was highest (91) in Minnesota and South Carolina and lowest in Idaho (69) and Indiana (70). In 2019, the percentage of D2 pts using csDMARDs in 2019 was highest in Oklahoma (33) and lowest (16) in North Carolina and New York, while for opioids it was highest in Idaho (69) and lowest in Wisconsin (28).
Conclusion: The prevalence of AS is increasing each year nationally, with significant variability observed across states that is not explained by differences in age, sex, race, or rheumatologists per capita. Among pts with confirmed AS diagnosis (D2), national rates of csDMARDs and opioids are decreasing although opioid use is still high, and high treatment rates exist for advanced therapies. Rates of all treatments also vary substantially across states. Observed variations may indicate the opportunity for further education that can be targeted based on regional need to improve diagnosis and treatment.

POS0944 AGE AT ONSET IN AXIAL SPONDYLOARTHRITIS AROUND THE WORLD: DATA FROM THE INTERNATIONAL ASAS-PERSPA STUDY

A. Boel[1], C. López-Medina[2], D. Van der Heijde[1], F. A. Van Gaalen[1]. [1]*Leiden University Medical Centre, Rheumatology, Leiden, Netherlands*; [2]*Cochin Hospital, Assistance Publique Hôpitaux de Paris, Rheumatology, Paris, France*

Background: Axial spondyloarthritis (axSpA) typically begins in young adulthood and age at onset is therefore very useful in identifying chronic back patients at an increased risk of axSpA. Age at onset below the age of 45 has been incorporated into the 2009 ASAS classification criteria for axSpA as a mandatory feature. However, inclusion of age at onset before the age of 45 was based on a small number of Western European studies and it is therefore unknown if this age at onset applies to patients in other parts of the world.
Objectives: The aim of this study was to assess age at onset of axSpA as well as its relationship with HLA-B27 throughout the world, using data from the Assessment in SpondyloArthritis international Society (ASAS) peripheral involvement in Spondyloarthritis (ASAS-perSpA) study.
Methods: Analyses were restricted to patients with an axSpA diagnosis who had information available on age at onset of axial complaints. Cumulative probability plots were used to graphically display the cumulative distribution of age at onset of axial symptoms. Linear regression models were built to assess the effect of HLA-B27 status on age at onset of axial symptoms. As axSpA is a multifactorial, multigenetic disease, geographical region was investigated as an effect modifier.
Results: The majority (92%) of patients with axSpA had an age at onset of axial symptoms below 45 years, with only small variation across the various geographical regions (table 1). Cumulative distribution plots showed age at onset of axial symptoms was consistently lower in HLA-B27 positive patients (in blue) than in HLA-B27 negative patients (in red) across all geographical regions (Figure 1 below). Linear regression models showed a significant effect of HLA-B27 status on the age at onset of axial symptoms in the total study population (p<0.001), and Latin American (p<0.001), European & North American (p<0.001), Asian (p=0.006) and Middle Eastern & North African (p=0.005) populations. There was no effect modification of geographical region (p=0.50) on the association between HLA-B27 status and age at onset of axial symptoms.

Conclusion: Irrespective of geographical region, the majority of axSpA patients had an age at onset of axial disease before the age of 45. In all populations, HLA-B27 was associated with earlier disease onset. These results provide crucial data for diagnosis, classification, and policies aimed at improving recognition of axSpA.

Table 1. Percentage of axSpA patients with an age at onset of axial symptoms <40, <45 and <50 years stratified by geographical region and HLA-B27 status.

	HLA-B27 positive				HLA-B27 negative

Figure Cumulative distribution of the age at onset of axial symptoms for Asia (A), Europe & North America (B), Latin America (C), and Middle East & North Africa (D). The black lines represent all patients in a given continent, the blue lines represent HLA-B27 positive patients, and the red lines represent the HLA-B27 negative patients. The horizontal black dashed line represents the 95% point, and the black, blue and red vertical lines represent the age at which 95% of patients developed axial complaints in the total population, HLA-B27 positive and HLA-B27 negative patients respectively.

Figure 1.

POS0945 NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN THE AFRO-CARIBBEAN POPULATION, CLINICAL ASPECTS AND PARTICULARITIES

F. Louis-Sidney[1], D. Morillon[2], M. Blettery[1], L. Brunier[1], P. Numeric[3], M. De Bandt[2]. [1]*Hopital La Maynard Martinique, Rheumatology, Fort-de-France, Martinique*; [2]*Hopital La Maynard Martinique, Radiology, Fort-de-France, Martinique*; [3]*Hopital La Maynard Martinique, Rheumatology, Fort-de-France, Martinique*

Background: Spondyloarthritis is a polymorphic disease and the absence of diagnostic marker has led to propose diagnostic criteria for recognition. All the criteria, established in Caucasian populations, place at the center of the approach sacroiliac imaging and genetic terrain (HLA B27). For this reason, these criteria are not appropriate in populations lacking HLA B27. SPA is known to be rare in African populations and this rarity correlates with that of HLA B27.Prevalence of B27 in French West Indies is 2% (identical to the African populations).
Objectives: We report clinical manifestations of SpA seen at the Fort de France University Hospital, with an emphasis on the so-called "non-radiographic SpA" (NRSPA).
Methods: Adult patients with spondyloarthritis seen over a period of three consecutive months, were invited to participate in a survey and filled-in a self-administered questionnaire. The consulting rheumatologist specified the rheumatologic and extra-articular involvement, BASDAI score, HLAB27 data, markers of inflammation and imaging.

Results: There were 93 patients, 47 with radiographic sacroilitis (RSPA) and 46 patients without but all - these 46 - had magnetic sacroilitis. This population is Afro-Caribbean for 98%. Mean age at onset of clinical signs is 38.5 ± 15.0 years and median age is 37.0 (13-77). An evocative family history is noted in 37%. All these 93 patients suffer from rachialgia.

But the axial complaint is often secondary to the peripheral involvement. 3 patients have a mechanical spinal complaint. All the others have intermittent inflammatory complaint evolving by flares affecting all the spinal stages. 15/93 patients have isolated axial complain without peripheral disease. Enthesopathies are seen in 70%.

Peripheral inflammatory joint complain is observed in 78 patients (84%), it is a bilateral and symmetrical chronic polyarticular pattern affecting (70/78) the small joints of the hands, forefeet and wrists. Ankle bi-arthritis is almost systematic and is observed in 71/78 patients; 8 patients with RSPA had no polyarthritis but oligo (6) or monoarthritis (2). Peripheral inflammatory joint is more frequent in NRSPA than in RSPA (98% vs 70%). Ultrasound individualises grade II synovitis (78/78), rarely with a Doppler effect (5/78). On average, more painful and swollen joints are observed in NRSPA than in RSPA. Extra articular and immunological aspects and activity scores are in table 1.

Good sensitivity of peripheral arthritis to NSAIDs and MTX is noted in 94 and 91%.

Conclusion: NRSpA are not uncommon in the Afro-Caribbean population, but are distinct from Caucasian SpA by several points: female predominance, rarity of B27 and syndesmophytes, frequency of polyalgic pattern, frequency of peripheral arthritis, rarity of extra-articular manifestations, more frequent but less marked inflammation, good response of arthritis to NSAIDs and MTX. Appropriate classification criteria for Afro-descendant populations is an urgent unmet need.

POS0946 DISTRIBUTION OF COMORBIDITIES IN SPONDYLOARTHRITIS WITH REGARD TO THE PHENOTYPE AND THE PRESENCE OF PSORIASIS: DATA FROM THE ASAS-COMOSPA STUDY

M. Á. Puche Larrubia[1], M. L. Ladehesa Pineda[1], F. U. Pilar[2], A. Moltó[3], C. López-Medina[1,3], E. Collantes-Estevez[1]. [1]*Reina Sofía University Hospital, Rheumatology, Córdoba, Spain*; [2]*University of Cordoba, Rheumatology, Córdoba, Spain*; [3]*Cochin Hospital, Rheumatology, Paris, France*

Background: Comorbidities have been reported to be more prevalent in patients with Spondyloarthritis (SpA) compared to the general population. Previous studies have suggested that patients with peripheral phenotypes exhibit a higher prevalence of traditional cardiovascular risk (CV) factors compared to those with a predominantly axial phenotype. However, the role of psoriasis in such differences has not been deeply studied.

Objectives: To compare the prevalence of comorbidities (CV, malignancies and osteoporosis (vertebral or peripheral fracture, or low bone mineral density)) between patients with axial and peripheral phenotypes and to evaluate the role of psoriasis in such comorbidities in the whole spectrum of SpA (including psoriatic arthritis).

Methods: Patients from the cross-sectional ASAS-COMOSPA study were classified as having either axial (presence of sacroiliitis on x-ray or MRI) or peripheral phenotype (absence of sacroiliitis AND presence of arthritis, enthesitis or dactylitis). Patients with each phenotype were divided into two groups depending on the presence or history of psoriasis. Pair-wise comparisons among the four groups (axial and peripheral with psoriasis/without psoriasis phenotypes) were conducted through univariate logistic regressions and generalized linear mixed models using disease duration and country as fixed and random effects, respectively. Multivariate analysis using were used to evaluate whether psoriasis and the phenotype are independently associated with each comorbidity.

Results: A total of 3291 patients were included in this analysis (mean age 43.6 years, 65% males). The peripheral phenotype with psoriasis showed the highest prevalence of hypertension (44.9%), dyslipidaemia (34%) and diabetes (8.8%), while axial phenotype without psoriasis exhibited the lowest prevalence of dyslipidaemia (14.2%), diabetes (4.1%) and stroke (0.9%) (Table 1). Among patients with psoriasis, the axial phenotype showed a significantly [OR, 95%CI] lower prevalence of hypertension [OR 0.5, 0.4-0.8] and lower Framingham score [OR 0.97, 0.95-0.99] compared to peripheral patients even after adjusting for disease duration and country. Among patients with axial phenotype, patients with psoriasis showed higher prevalence of hypertension [OR 1.8, 1.4-2.2], dyslipidaemia [OR 2.0, 1.7-2.5], diabetes [OR 2.1, 1.4-3.0] and Framingham score [OR 1.0, 1.0-1.1] than non-psoriatic patients. Multivariate analysis confirmed that hypertension, dyslipidaemia and the Framingham score are independently associated with both the psoriasis and the peripheral phenotype.

Prostatic cancer and colon cancer were independently associated with the presence of psoriasis but not with the phenotype. No differences were found across groups concerning osteoporosis.

Conclusion: Both a peripheral phenotype and the presence of psoriasis were independently associated with an increased CV risk. Psoriasis seems to be associated with a higher prevalence of some malignant diseases, while osteoporosis do not seem to be associated with either phenotype or the presence of cutaneous involvement.

Table 1. Description of comorbidities across the four groups.

POS0947 PSORIATIC ARTHRITIS WITH HYPERURICEMIA: MORE PERIPHERAL, DESTRUCTIVE AND CHALLENGING TO TREAT

L. Widawski[1], T. Fabacher[2], J. E. Gottenberg[3], L. Spielmann[1], P. M. Duret[1], J. Sibilia[3], L. Messer[1], R. Felten[3]. [1]*Hôpitaux Civils de Colmar, Rheumatology, Colmar, France*; [2]*Nouvel Hôpital Civil - Hôpitaux Universitaires de Strasbourg, Epidemiology and Public Health, Strasbourg,*

France; [3]*Hôpital de Hautepierre - Hôpitaux Universitaires de Strasbourg, Rheumatology, Strasbourg, France*

Background: Gout and psoriatic arthritis (PsA) can co-exist in the same patient. These 2 diseases seem strongly linked, but the pathophysiological mechanisms of this link have not yet been defined. Hyperuricemia could be an important determinant of PsA[1].
Objectives: To study the impact of hyperuricemia on clinical presentation, severity and associated comorbidities of PsA.
Methods: We conducted a retrospective bicenter case–control study in Strasbourg and Colmar, France. Patients with PsA (according to "L40.5 arthropathic psoriasis" ICD-10 coding) and at least one available serum urate level measurement, were included from 2009 to 2019. Demographic, comorbidities, clinical and radiographic data were collected. Hyperuricemia was defined as serum urate level ≥ 360 µmol/L. We defined "good responders to ongoing PsA treatment" as patients with no outbreak of PsA, biological inflammatory syndrome and therapeutic modification at the last follow-up. Patients with "destructive" disease had one or more erosion(s) seen on standard X-ray, ultrasonography, MRI or TDM.
Results: We included 242 patients. 73 (30.2%) had hyperuricemia and 15 (6.2%) met criteria for gout. On univariate analysis, as compared with normo-uricemic patients, hyperuricemic patients were more often male (72.6% vs. 39.1%, p = $1.6x10^{-06}$), had higher BMI (30.9 vs. 28.7 kg/m^2, p = 0.015) and had more comorbidities (Charlson Comorbidity Index: 2.6 vs. 1.8, p = 0.005). In hyperuricemic versus normo-uricemic patients, PsA started at an older age (47.5 vs 43 years, p = 0.016); PsA was more polyarticular (56.2% vs 41.9%, p = 0.049) than axial (9.6% vs 22.8%, p = 0.019) and more destructive (52.8% vs. 37.4%, p = 0.032). Median uricemia was higher in patients with destructive than non-destructive PsA (321 vs 288.8 µmol/l, p = 0.0038), and hyperuricemia was more frequent with than without joint destruction (37.6% vs 25.8%, p = 0.047). The multivariate analysis confirmed hyperuricemia associated with peripheral joint involvement (OR 2.98, p = 0.025) and less good response to PsA treatment (OR 0.35, p = 0.024).

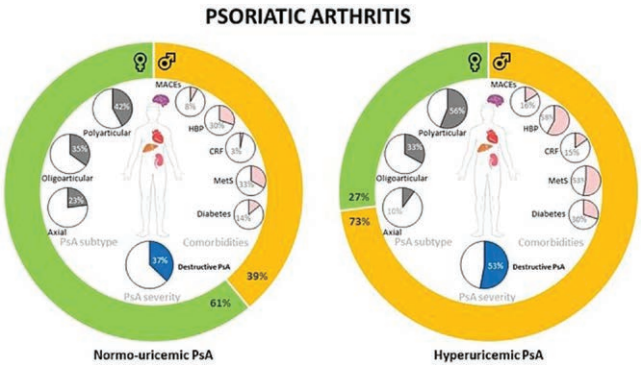

Figure 1. Description of normo- and hyperuricemic psoriatic arthritis

CRF: moderate to severe chronic renal failure. MACEs: major adverse cardiovascular events. HBP: high blood pressure. MetS: metabolic syndrome. PsA: psoriatic arthritis
Conclusion: Patients with hyperuricemic PsA have less good response to PsA treatment than those with normo-uricemia and more peripheral and destructive joint damage. Recognition of PsA in which hyperuricemia would play an aggravating role could modify the management. This would justify a diagnostic reassessment in case of doubt, the possible introduction of hypouricemic treatment and the careful use of NSAIDs in the context of multiple morbidities.

POS0948

HYPERKYPHOSIS IN AXIAL SPONDYLOARTHRITIS: FACTORS THAT PRODUCE ITS APPEARANCE AND EFFECT ON MOBILITY AND FUNCTION

J. L. Garrido-Castro[1], M. L. Ladehesa Pineda[2], C. López-Medina[2], C. Garrido-González[3], F. U. Pilar[3], C. Gonzalez-Navas[1], E. Collantes Estevez[2]On behalf of CASTRO. [1]*Instituto Maimónides de Investigación Biomédica de Córdoba, Motion Analysis Lab, Córdoba, Spain*; [2]*Hospital Universitario Reina Sofia, Rheumatology, Córdoba, Spain*; [3]*Facultad de Medicina y Enfermería, Departamento Medicina, Córdoba, Spain*

Background: Hyperkyphosis (HK) is a characteristic sign in patients with a large level of axial spondyloarthritis (axSpA) involvement. Kyphosis is defined as a sagittal deviation in the spinal alignment. Kyphosis can be graded in severity by the Cobb angle. The occiput-wall distance (OWD) is a surrogate measure of kyphosis. When this distance is greater than 0 cm, it is because the patient has an advanced affectation level that produces a reduction of physical function and other comorbidities. It is important that HK does not appear in the patient.
Objectives: To analyze contributors and effects of HK in patients with axSpA.
Methods: Nonparametric preprocessing for parametric causal inference was used for selection of two matched groups, formed by 42 axSpA patients each one, from the CASTRO cohort with similar covariate distributions (age and sex). Outcomes analyzed, besides OWD, included activity (BASDAI, ASDAS), physical function (BASFI) and mobility (BASMI). An inertial sensor-based system (ViMove) was used to analyze cervical and lumbar mobility and to calculate the UCOASMI index[1]. Structural damage was assesed according the mSASSS and its components (cervical and lumbar).
Results: Mean (sd) values of the different variables for each group are shown in table 1. Significant differences according to an independent t-test (p), variation coefficient (V.C.), effect size (E.S.) and correlation with OWD (Pearson r), are also included in this table.

	OWD=0 (n=42)	OWD>0 (n=42)	P	V.C.	E.S.	r

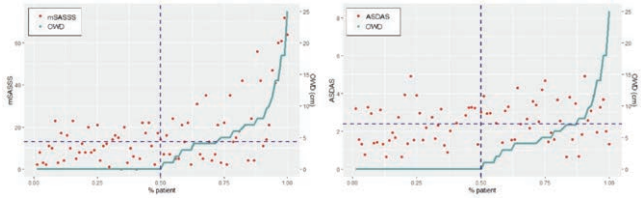
Sign.: *p<0.05, **p<0.01, *** p<0.001. ¥: Large effect size (ES>0.8)

There were not significant differences in age, sex as expected. HK group patients started earlier (5.2 years). The percentage of HLAB27+ is similar, so this antigen has not a relationship with HK. BMI is greater in HK group (14%); this can be a factor for HK appearance or a consequence of HK (less physical activity). Activity (according ASDAS) was slightly higher in HK. There were very significant differences in structural damage, and HK appears to be equally affected by damage at cervical and lumbar regions. BASFI also shown a significant reduction in HK. There was great reduction of mobility according to mobility indexes and cervical range of movement (23%-33%). In a multivariate regression analysis using all variables of the table and OWD as dependent variable, only mSASSS and BMI were included in the final model (adj. r^2= 0.61). In a ROC analysis, mSASSS shown to and acceptable variable to distinguish between groups (AUC=0.70, cutoff=13). ASDAS

obtained lower results (AUC=0.60, cutoff=2.38). Figure 1 shows cumulative probability plots of mSASSS and ASDAS versus OWD, showing cutoff values determined by ROC analysis.



Conclusion: Structural damage, in cervical and lumbar spine, are the main contributor to HK appearance in axSpA patients. Inflammation it is not so determinant and acts only in the short term. HK produces a significant reduction of cervical mobility and physical function. New treatments that decrease radiographical progression, and overweight reduction are the most important factor to avoid HK.

POS0949 HIGH PREVALENCE OF ABDOMINAL OBESITY IN FEMALES WITH AXIAL SPONDYLOARTHROPATHY

S. Maguire[1,2], P. Gallagher[3], F. Wilson[4], F. B. O'shea[1,2]. [1]*St James' Hospital, Rheumatology, Dublin, Ireland*; [2]*Trinity College Dublin, School of Medicine, Dublin, Ireland*; [3]*St Vincent's Hospital, Rheumatology, Dublin, Ireland*; [4]*Trinity College Dublin, Discipline of Physiotherapy, Dublin, Ireland*

Background: Worldwide prevalence of obesity has been steadily increasing, despite significant public health campaigns to raise health awareness. In axial spondyloarthropathy (axSpA) obesity has been shown to be associated with higher levels of disease activity and decreased response to treatment. The waist to hip ratio (WtHpR) is a tool to screen for abdominal obesity. Abdominal deposition of adipose tissue is associated with increased risk of cardiovascular disease, type II diabetes and premature death. Abdominal obesity is more commonly found in males, while females are more prone to gluteal-femoral fat deposition. The Ankylosing Spondylitis Registry of Ireland (ASRI) is a source of epidemiological data of axSpA patients in Ireland.

Objectives: To capture the prevalence of abdominal obesity in a large cohort of axSpA patients and assess for variation in prevalence between sexes.

Methods: Participants were analysed on the basis of sex and presence of obesity by BMI and WtHpR. Obesity was defined by body mass index (BMI) with a result of >30 categorised as obese as per CDC definitions. Abdominal obesity was assessed by WtHpR and defined as per WHO guidelines. Categorical variables were recorded as frequencies, with a chi^2 test for independence used to test for statistical significance. Numerical variables were recorded as means within each group and an independent t-test or Mann Whitney U test was used to test for statistical significance between groups. A p-value of <0.05 was deemed significant. IBM SPSS version 26 was used for statistical analysis of the patient population captured within the ASRI.

Results: At the time of analysis, physical measurements were available on 692 patients in the ASRI made up of 96.2% (666) Caucasians with 22.3% (154) females and 77.7% (538) males. The average age was 45.9 years with a mean disease duration of 18.8 years (mean scores: BASDAI 4.09, BASFI 3.71, BASMI 3.99, HAQ 0.54, ASQoL 6.72). 80.9% (560) of patients had radiographic sacroiliitis while 49.1% (340) had sacroiliitis on MRI.

Overall 29.5% (215) patients were obese based on BMI results, while 37.5% (274) were centrally obese as per the WtHpR. Analysis on the basis of sex revealed no significant variation in mean BMI (28.1 vs 27.7, p=0.45) or prevalence of obesity as assessed by BMI (29.9% vs 28.6%, p=0.49) between males and females(table 1). As expected analysis of WtHpR revealed higher mean ratios in males compared to females (0.96 vs 0.89, p<0.01), however there was a significantly higher prevalence of abdominal obesity in females (29.9% vs 68.2%, p<0.01).

Conclusion: There is a high prevalence of abdominal obesity as assessed by WtHpR in axSpA, this is especially high in females with axSpA. Use of WtHpR should be considered when screening for obesity in this population.

POS0950 ARE THERE GENDER DIFFERENCES IN AXIAL SPONDYLOARTHRITIS: DATA FROM A PORTUGUESE SPONDYLOARTHRITIS COHORT

A. R. Cunha[1], R. Aguiar[1], M. J. Santos[2], V. Afreixo[3], A. Barcelos[1,4,5]. [1]*Centro Hospitalar do Baixo Vouga, Rheumatology, Aveiro, Portugal*; [2]*Hospital Garcia de Orta, Rheumatology, Almada, Portugal*; [3]*University of Aveiro, Department of Mathematics and CIDMA - Center for Research & Development in Mathematics and Applications, Aveiro, Portugal*; [4] *University NOVA, Lisbon, NOVA National School of Public Health, Public Health Research Centre, Lisbon, Portugal*; [5] *University NOVA, Lisbon, Comprehensive Health Research Center (CHRC), Lisbon, Portugal*

Background: Historically, axial spondyloarthritis (particularly ankylosing spondylitis) was considered a men's disease and has been under-recognized in women.

Emerging evidence reveals gender differences in patophysiology, disease presentation and therapeutic efficacy.

Objectives: To determine if there are differences between genders in a Portuguese cohort of patients with axSpA as regards clinical manifestations, disease activity, functional capacity, patient related outcomes and radiographic findings.

Methods: Patients with ≥18 years fulfilling the *ASAS- Assessment of Spondyloarthritis International Society classification criteria* for axSpA and registered in the electronic national database- *Reuma.pt* were included in a multicentric cross-sectional study. Sociodemographic data, clinical features and radiographic findings were collected from the first record in Reuma.pt. These variables were compared between genders using Mann-Whitney test and Chi-Square test. Variables with a significant association with group variable (gender) were considered in the multiple variable analysis to adjust the gender effect on the outcome variables.

Results: A total of 1995 patients were included, 1114 (55.9%) men and 881 (44.1%) women. Men had a lower median age at onset of disease (25.1 vs 28.4, p=0.000) and median age at diagnosis (26.9 vs 30.4, p=0.000) and were more frequently smokers (32.1% vs 15.7%, p=0.000). Comparing to women, men had worse BASMI scores (4.0 vs 3.4, p=0.000), higher levels of CPR (10.5 vs 6.9, p=0.000) and were more often HLA-B27 positive (67.8% vs 54%, p=0.000). In univariable analysis, sacroiliitis on radiograph or/and MRI (95.5% vs 91.7%, p=0.04) was more common in men, however that wasn't confirmed in multivariable analysis.

In contrast, women more frequently had more inflammatory bowel disease (8.8% vs 4.9%, p=0,004), higher levels of ESR (25.0 vs 21.0, p=0.003) and worse PROs- BASDAI (5.7 vs 4.5, p=0.000), PGA (60.0 vs 55.0, p=0.000) and fatigue (6.2 vs 5.4, p=0,000).

Conclusion: Physicians must be aware of differences between genders in axial spondyloarthritis because this can result in less underdiagnosis and misdiagnosis, allow optimization of treatment strategies, and decrease overall disease burden in women with axSpA patients.

ASSOCIATION BETWEEN INDIVIDUAL AND COUNTRY-LEVEL SOCIOECONOMIC FACTORS AND HEALTH OUTCOMES IN AXIAL AND PERIPHERAL SPONDYLOARTHRITIS: ANALYSIS OF THE ASAS PERSPA STUDY

D. Capelusnik[1], S. S. Zhao[2], A. Boonen[3,4], N. Ziade[5,6], C. López-Medina[7,8], M. Dougados[7], E. Nikiphorou[9,10], S. Ramiro[11,12]. *[1]Instituto de Rehabilitación Psicofísica, Rheumatology, CABA, Argentina*; *[2]University of Liverpool, Musculoskeletal Biology, Institute of Life Course and Medical Sciences, Liverpool, United Kingdom*; *[3]Maastricht University Medical Center, Rheumatology, Maastricht, Netherlands*; *[4]Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands*; *[5]Saint Joseph University, Rheumatology, Beirut, Lebanon*; *[6]Hotel-Dieu De France, Rheumatology, Beirut, Lebanon*; *[7]Cochin Hospital, Rheumatology, Paris, France*; *[8]Reina Sofia Hospital, Rheumatology, Córdoba, Spain*; *[9]King's College London, Centre for Rheumatic Diseases, London, United Kingdom*; *[10]King's College Hospital, Rheumatology, London, United Kingdom*; *[11]Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; *[12]Zuyderland Medical Center, Rheumatology, Heerlen, Netherlands*

Background: Health outcomes in spondyloarthritis (SpA) are largely determined by socioeconomic (SE) factors, leading to the great inequity observed between countries across the world. However, the impact of these SE factors on health outcomes across the different SpA phenotypes (axSpA, pSpA and PsA), is less well known.

Objectives: To investigate (1) the association between individual and country-level SE factors and health outcomes in different SpA phenotypes, and (2) to explore whether any effect of these SE factors is mediated by the use of b/tsDMARD therapy.

Methods: Patients with axSpA, pSpA or PsA from the multinational cohort ASAS-perSpA were included in the analysis. The effect of individual (age, gender, education and marital status) and country-level SE factors (Gross Domestic Product [GDP], Healthcare Expenditure [HCE], Human Development Index [HDI], Gini Index) over health outcomes (ASDAS≥2.1, continuous ASDAS, BASFI, fatigue and ASAS-HI) were assessed in multivariable mixed-effects logistic and linear regression models (as appropriate), adjusting for confounders. Interactions between each individual and country-level SE factors and disease phenotype and between both levels of SE factors, were tested. Finally, a mediation analysis was conducted to explore whether the impact of country-level SE factors on ASDAS is mediated through b/tsDMARD uptake.

Results: A total of 4185 patients from 23 countries were included: 61% males, mean age 45 (SD 14), 65% axSpA, 10% pSpA and 25% PsA. Female gender, lower educational level and marital status (single vs married) were associated with higher ASDAS, without significant differences across disease phenotype. Living in lower-(vs higher) GDP countries was also associated with higher ASDAS (β=0.39 [95%CI 0.16; 0.63], with similar results for other economic indicators (Figure 1). 7% of the association between GDP and ASDAS was mediated by b/tsDMARD uptake. The above-mentioned individual and country-level SE factors remained significant to discriminate active disease (ASDAS≥2.1), with greater impact of gender (OR=1.32 [1.13; 1.54]), educational level (primary vs university OR=1.76 [1.40;2.20]) and lower GDP (OR= 1.74 [1.22;2.46]). Higher BASFI was also associated with gender (female vs male: β=0.12 [0.01; 0.24]), lower education (primary vs university: β=0.29 [0.11; 0.46], and marital status (single vs married: β=0.23 [0.09; 0.38]), without effect of country-level SE factors, and no differences across SpA phenotype. Gender and lower educational level were similarly associated with worse ASAS-HI scores (female vs male β=0.88 [0.68;1.09], and primary vs university β=0.61 [0.31;0.91]), while more fatigue was only associated with female gender and, in an opposite direction, with higher country-level SE factors (Figure 1). No interactions were found between individual and country-level SE factors for any of the outcomes.

Conclusion: Individual (female gender and lower education) and country-level SE factors are independently associated with higher disease activity in SpA. Uptake of b/tsDMARD had a small mediating effect on the association between GDP and ASDAS. Lower education and female gender are also associated with worse outcomes of functional disability, global functioning and fatigue. Country-level SE factors are not associated with functional disability or global functioning; in contrast, there is a paradoxical effect with fatigue: living in a country with a higher SE status is independently associated with higher levels of fatigue. Management of disease outcome in SpA requires also awareness of the role of individual and country level SE-factors.

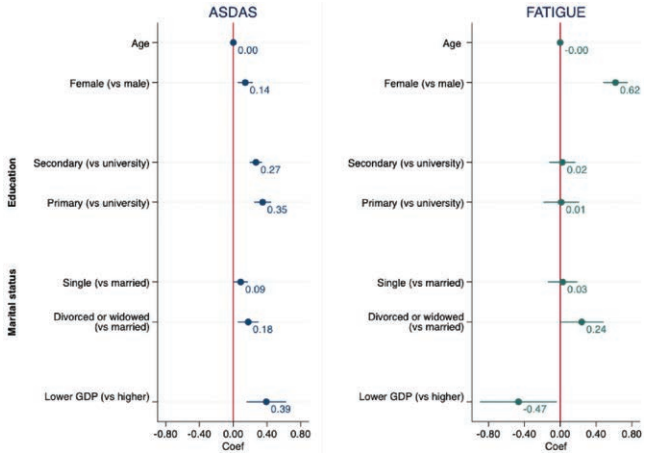

Figure 1. Effect of individual and country-level socioeconomic factors on ASDAS and fatigue, derived from multivariable mixed-effects models adjusted by clinical confounders.

POS0952 RESPONSIVENESS OF SPINAL MOBILITY MEASUREMENTS IN AXIAL SPONDYLOARTHRITIS USING CONVENTIONAL AND ADVANCED METROLOGY: A PILOT STUDY

J. L. Garrido-Castro[1], I. C. Aranda-Valera[2], P. Gardiner[3], P. Machado[4], J. Condell[5], C. Gonzalez-Navas[1], E. Collantes Estevez[2]On behalf of the iMaxSpA study group.. *[1]Maimónides Biomedical Research Institute of Córdoba, Motion Analysis Lab, Córdoba, Spain*; *[2]Hospital Universitario Reina Sofia, Rheumatology, Córdoba, Spain*; *[3]Western Health and Social Care Trust, Rheumatology, Londonderry, United Kingdom*; *[4]University College London, Rheumatology, London, United Kingdom*; *[5]Ulster University, School of Computing, Eng & Intel. Sys, Londonderry, United Kingdom*

Background: Spinal mobility is an important outcome in axial spondyloarthritis (axSpA). Standardized metrology tests have been defined and validated. Nevertheless, conventional metrology measures lack responsiveness, particularly in the context of assessing short term response to treatments. Advanced metrology devices have also been used in axSpA, namely optical motion capture systems (MoCap) and Inertial Measurement Systems (IMU). These systems have better psychometric properties in terms of accuracy and reliability for analysing spinal mobility.
Objectives: To compare the responsiveness of spinal mobility using conventional and advanced metrology.
Methods: Spinal mobility was measured using an IMU based system (ViMove©) with sensors located at: occiput and T3 for cervical mobility, L1 and sacrum for lumbar mobility, and T3 and sacrum for thoracic+lumbar mobility. A MoCap system (UCOTrack©) using 13 markers was also used to record the movements in 3 planes (flexion+extension, rotation, and lateral flexion). The UCOASMI [1] index was calculated using measures obtained by MoCap and by the IMU system. Other metrology indexes based on IMU measures developed by the authors [2} were also calculated. Patients were assessed before (PRE) and 3 months after (POST) TNF blocker treatment. The Wilcoxon signed-rank test was used to test differences between pairs of pre- and post-treatment. Cohen's d was use for calculating the effect size of improvement.
Results: 12 axSpA patients were recruited from the CASTRO cohort (42% female, age 46±11 years, disease duration 16±13 years). Results PRE and POST are shown in Table 1: means (sd), statistical significance, and effect size. Disease activity and functional indexes were lower in POST and these differences were significant, especially in ASDAS. Conventional metrology lacked responsiveness, except for cervical rotation. MoCap showed moderate responsiveness in cervical rotation, in thoracolumbar mobility and with regards to the UCOASMI. Using IMU measures, responsiveness was good in terms of cervical flexion and rotation. For Lumbar (L_) and Lumbar Thoracic (LT_), lateral flexion shown significant improvement and lumbar rotation shown the best responsiveness.

NS, not significant; *, p<0.05; **, p<0.01

Conclusion: Conventional metrology lacks short-term responsiveness. Advanced metrology using MoCap and IMU showed, in this pilot study, better responsiveness compared to conventional measures. Furthermore, IMU provide a feasibility similar to conventional metrology, and could be easily implemented in the context of clinical trials and observational studies.

POS0953 PERIPHERAL ARTHRITIS AND HIGHER DISEASE ACTIVITY LEAD TO MORE FUNCTIONAL IMPAIRMENT IN AXIAL SPONDYLOARTHRITIS: LONGITUDINAL ANALYSIS FROM ESPAXIA

D. Capelusnik[1], S. Ramiro[2,3], E. E. Schneeberger[1], G. Citera[1]. *[1]Instituto de Rehabilitación Psicofísica, Rheumatology, CABA, Argentina*; *[2]Leiden University Medical Centre, Rheumatology, Leiden, Netherlands*; *[3]Zuyderland Medical Centre, Rheumatology, Heerlen, Netherlands*

Background: Preserving functional ability is among the main goals when treating patients with axSpA. Higher disease activity, reduced axial mobility, and increase spinal radiographic damage, and smoking status have shown to be longitudinally associated with functional worsening. The presence of peripheral arthritis has also been associated with worse functional ability during follow-up, though not in a true longitudinal analysis.
Objectives: To investigate whether peripheral arthritis together with disease activity independently contribute to functional impairment over time in patients with axSpA and to evaluate if there are contextual factors modifying this relationship.
Methods: Patients with axSpA from the ESPAXIA cohort were followed-up annually over 7 years. Physical function was assessed by the self-reported questionnaire BASFI, disease activity by ASDAS and peripheral arthritis was also recorded. The association between BASFI (outcome), peripheral arthritis and ASDAS (main variables of interest) over time was tested in generalized estimating equations (GEE) models. Models were autoregressive, i.e. adjusted for BASFI 1 year earlier, to allow for a truly longitudinal interpretation. Interactions between each of ASDAS and peripheral arthritis with contextual factors were tested.
Results: 185 patients were included (77 % male, mean age 42 (SD 13), mean disease duration 9.4 (SD 9.6) years. Mean baseline ASDAS was 2.3 (1.4), mean BASFI

3.9 (2.7) and 17% presented peripheral arthritis during the first visit. After a mean of 3.7 (2.4) years of follow-up, ASDAS and peripheral arthritis independently contributed to explaining BASFI changes over time. Contextual factors did not modify either of the relationships. A true longitudinal relation was proved with the autoregressive GEE model, showing that, adjusted for age, gender, spinal mobility and use of NSAIDs, an increase of one ASDAS unit led to a BASFI 0.48 units higher (ß 0.48 [95% CI 0.39-0.57]), and the presence of peripheral arthritis, to a BASFI 0.44 units higher (ß 0.44 [0.08-0.8]) (Table 1). A gradient was found for ASDAS disease activity states: ASDAS low disease activity (vs ASDAS inactive disease) with an increase in BASFI of 0.67 (0.35-0.98) units compared to ASDAS very high disease activity (vs ASDAS inactive disease) with a BASFI increase of 2.30 (1.90-2.72) units. (Figure 1) No interaction was found between peripheral arthritis and disease activity on BASFI, and similarly, no interactions were found between either ASDAS or peripheral arthritis with age, gender, educational level, smoking status, job type or comorbidities on BASFI.

POS0954

QUALITY OF LIFE IN CHRONIC BACK PAIN PATIENTS, A 2-YEAR COMPARISON BETWEEN PATIENTS WITH AND WITHOUT A DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS: DATA FROM THE SPONDYLOARTHRITIS CAUGHT EARLY COHORT

A. Boel[1], M. Van Lunteren[1], K. M. Fagerli[2], S. Exarchou[3], R. Ramonda[4], M. Van de Sande[5], D. Van der Heijde[1], F. A. Van Gaalen[1]. [1]*Leiden University Medical Centre, Rheumatology, Leiden, Netherlands*; [2]*Diakonhjemmet Hospital, Rheumatology, Oslo, Norway*; [3]*Lund University, Clinical Sciences, Section of Rheumatology, Malmö, Sweden*; [4]*University of Padova, Medicine, Rheumatology Unit, Padova, Italy*; [5]*Amsterdam University Medical Center, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*

Objectives: To study quality of life (QoL) in patients with a diagnosis of axial spondyloarthritis (axSpA) and how this relates to the QoL of patients without axSpA, after two-years of protocolised follow-up.
Methods: QoL was assessed using the Medical Outcomes Study 36-Item Short-Form Health Survey (SF-36). Age, sex and country weighted scale scores were calculated for each of the 8 subscales. Numeric scales ranged from 0 (worst health) to 100 (best health), after recoding and recalibration. The physical (PCS) and mental component summary (MCS) scores were calculated from the adjusted scores; and transformed to enable comparison to the general population mean of 50.
Additionally, the proportion of patients with an improvement or worsening of the PCS and MCS above the minimal clinically important difference (MCID) were assessed. We applied the commonly used MCID in clinical trials with bDMARDs in axSpA of 3 points for the PCS and MCS.
In this study we included patients from the SPACE cohort (patients aged >16 years with chronic back pain suspected of axSpA) with a diagnosis axSpA or no axSpA all with a level of confidence ≥7 (on a 0-10 scale) after locally read imaging. The PCS and MCS had to be available at baseline and 2-year follow-up too.
Linear regression models were used to test the difference between patients with and without axSpA at two-year follow-up for PCS and MCS scores. Baseline PCS and MCS scores and NSAID-use over time were tested as confounders.
Results: Patients with a diagnosis of axSpA were more frequently male (57% vs 27%) and HLA-B27 positive (75% vs 31%) and had more SpA features at baseline [mean (SD) 5(2) vs 3(1)] compared to the patients without axSpA. Age, symptom duration and NSAID-use were similar between groups.
In both groups the PCS significantly improved over two years. The PCS was significantly better in the group with an axSpA diagnosis compared to the no axSpA group at two-year follow-up, after correction for baseline PCS scores and NSAID-use over time (table 1). Despite the improvements over time, PCS scores were still well below the general population mean of 50 in both groups at two-year follow-up. MCS scores were not significantly different between groups at follow-up, and they were close to the general population mean.
In linear regression models with baseline values and NSAID-use over time as covariates, axSpA was an independent predictor of better PCS scores.

Table 1. PCS and MCS scores at baseline and 2-year follow-up for the group with an axSpA diagnosis and those without axSpA (no axSpA)

	Diagnosis axSpA (N=186) Baseline	2 years	no axSpA (N=74) Baseline	2 years	p-values between groups at 2yrs

POS0955 EXTRACELLULAR MATRIX PROTEIN TURNOVER MARKERS ARE ASSOCIATED WITH AXSPA – A COMPARISON WITH CONTROL SUBJECTS WITH OR WITHOUT PELVIC, BUTTOCK OR BACK PAIN

H. Port[1,2], S. Holm Nielsen[1,3], J. Blair[1], S. F. Madsen[1], A. C. Bay-Jensen[1], M. Karsdal[1], S. Seven[4,5], I. J. Sørensen[4,5], L. Morsel-Carlsen[6], M. Østergaard[4,5], S. Juhl Pedersen[4]. [1]*Nordic Bioscience A/S, Immunoscience, Herlev, Copenhagen, Denmark*; [2]*Panum - University of Copenhagen, School of Health and Medical Sciences, København, Denmark*; [3]*Technical University of Denmark, Biomedicine and Biotechnology, Kgs. Lyngby, Denmark*; [4]*Rigshospitalet, Center for Arthritis Research, Glostrup, Denmark*; [5]*University of Copenhagen, Clinical Medicine, København, Denmark*; [6]*Frederiksberg Hospital, Radiology, Frederiksberg, Denmark*

Background: Axial spondyloarthritis (axSpA) is a common chronic inflammatory disease, associated with extracellular matrix (ECM) remodeling of the cartilage, bone and connective tissues. The primary symptom of axSpA is back pain, caused by inflammation. However, there is a medical need to truly identify patients with axSpA from other subjects with buttock or low back pain attributable to other reasons. Tissue-derived extracellular (ECM) markers quantified in serum may serve to differentiate axSpA patients from other diagnostic entities.

Objectives: To investigate circulating ECM turnover markers as potential biomarkers to differentiate patients with axSpA from a control group of subjects with buttock or pelvic pain attributed to other reasons, including postpartum women and healthy subjects.

Methods: Biomarkers of ECM degradation/chronic inflammation (C1M, C3M, C4M, C6M, CRPM, C10C and COL10NC) and ECM formation (PRO-C3 and PRO-C6) were measured in 204 participants from the MASH study [1] (Table 1). Biomarker levels were compared among patients with axSpA and control group, and two new variables (Type 3 and Type 6) were included, corresponding to the index of formation/degradation of type III and type VI collagen respectively. The biomarker data was log10 transformed for normalization when necessary and linear regression models with pairwise comparisons were performed. Clinical scores and the SPARCC MRI scores for sacroiliac joint (SIJ) inflammation were correlated with the biomarkers data (data not shown).

Table 1. Comparison of blood-tested biomarkers levels in MASH study. Data was adjusted for confounders age, gender, and body mass index (BMI).

Biomarkers (Mean (SD))	Patients with axSpA (n = 41)	Control groups (n=163)	p
C1M	84.3 (85.8)	36.2 (22.1)	<0.0001
C3M	15.6 (4.0)	13.9 (3.0)	0.011
C4M	34.9 (10.2)	27.9 (7.7)	<0.0001
C6M	20.5 (5.8)	17.4 (4.2)	<0.0001
CRPM	11.9 (2.9)	11.0 (5.9)	0.027
C10C	2567 (462)	2568 (560)	0.31
COL10NC	9.15 (5.81)	9.43 (8.27)	0.43
PRO_C3	10.2 (2.5)	11.3 (3.0)	0.0052
PRO_C6	6.94 (2.45)	6.86 (2.53)	0.93
Type 3 (PRO-C3/C3M)	0.70 (0.28)	0.86 (0.31)	0.0004
Type 6 (PRO-C6/C6M)	0.36 (0.16)	0.41 (0.14)	0.0024

Results: We found that patients with axSpA had significantly increased MMP-mediated degradation of type I (C1M), type III (C3M), type IV (C4M) and type VI (C6M) collagens (p<0.0001, p=0.01,p<0.001,p<0.001, respectively), and CRP-metabolite (CRPM, p=0.027), and significantly decreased formation of type III collagen (p= 0.052) compared with control groups when adjusting for age, gender and body mass index (BMI). Significantly decreased rates of Type 3 and Type 6 variables were also observed in patients with axSpA (p=0.004, p=0.002, respectively). We further adjusted the analyses by the SPARCC SIJ inflammation scores since differences in these were found among the two groups [1], and similar differences in biomarker levels were found, indicating that the relationship between the level of biomarkers and the SPARCC SIJ inflammation scores was independent between the two groups.

Conclusion: Biomarkers of type I, III, IV and V collagen and a CRP-metabolite showed an altered turnover in patients with axSpA compared with the control group including subjects with or without buttock or pelvic pain attributable to other reasons. Such biomarkers may be used in combination with MRI or independently to separate patients with axSpA from other back pain conditions.

POS0956 MEDITERRANEAN DIET IN AXIAL SPONDYLOARTHRITIS: A NUTRITIONAL INTERVENTION STUDY

F. Ometto[1], D. M. Farber[1], M. Lorenzin[1], A. Ortolan[1], G. Dellamaria[2], M. Felicetti[1], M. Favero[1], R. Valentini[2], A. Doria[1], R. Ramonda[1]. [1]*University of Padova, Rheumatology Unit, Department of Medicine, DIMED, Padova, Italy*; [2]*University of Padova, Dietetics and Clinical Nutrition Unit, Department of Medicine DIMED, Padova, Italy*

Background: Mediterranean diet (MD) proved to be beneficial on disease activity in patients affected by rheumatoid arthritis. A few data are available in other rheumatic conditions.

Objectives: A prospective monocentric study was conducted to evaluate the effect of a nutritional intervention based on the MD and to investigate the impact of such modification on disease activity of axial spondyloarthritis (ax-SpA).

Methods: Patients affected by ax-SpA randomized to a nutritional intervention arm (N) or a control arm (C) and were assessed at baseline (T0) and at month 6 (T6). Patients in N underwent a nutritional evaluation and received suggestions for dietary modification at T0, and then every 2 months. Adherence to the MD was evaluated with the PREDIMED questionnaire (range 0-10) [1]. A multivariable regression analysis was conducted to identify independent predictors of PREDIMED and of ASDAS-CRP improvement at T6.

Results: Eligible patients (161) were randomized to either N (81) or C (80); 47 in N and 63 in C completed the study. No relevant change of anthropometric or laboratory measures was observed at T6 in either group. A ≥20%PREDIMED improvement was more frequent in N (22/47, 46.8%) compared to C (13/63, 20.6%) (p<0.01). Also, a ≥20%ASDAS-CRP improvement was more frequent in N (8/47, 57.1%) compared to C (39/63, 40.6%) (p=0.020); and especially in those who achieved a ≥20%PREDIMED improvement (12/35, 34.3%) vs those who did not (2/73, 2.7%) (p<0.01). The nutritional intervention, a higher age, and a lower BMI increased the odds of achieving a ≥20%PREDIMED improvement; the ≥20%PREDIMED improvement was associated higher odds of achieving a ≥20%ASDAS-CRP improvement; psoriasis was negatively associated to the ASDAS-CRP improvement (Figure 1).

Conclusion: A nutritional intervention is effective in improving adherence to the MD in ax-SpA. A higher adherence to the MD may have a beneficial impact on activity of ax-SpA. Patients with psoriasis may have a limited benefit from the dietary improvement.

POS0957 THE PREVALENCE AND FACTORS RELATED TO SLEEP APNOEA IN ANKYLOSING SPONDYLITIS

H. Forsblad-D'elia[1], A. Wiginder[2], C. Sahlin-Ingridsson[2], M. Geijer[3], K. Franklin[2], A. Blomberg[2]. [1]*Institute of Medicine, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; [2]*Umeå University, Department of Public Health and Clinical Medicine, Umeå, Sweden*; [3]*Institute of Clinical Sciences, Department of Radiology, Gothenburg, Sweden*

Background: An increased prevalence of obstructive sleep apnoea (OSA) has been suggested in ankylosing spondylitis (AS), but few controlled studies have been performed.
Objectives: We thus aimed to study the prevalence of OSA in patients with AS compared to controls and to study if disease-related and non-disease-related factors were determinants of OSA in AS patients.
Methods: One hundred and fifty-five patients with AS were included in the Backbone study that investigates severity and comorbidities in AS. Controls were recruited from the Swedish CardioPulmonary bioImage Study (SCAPIS). Participants were asked to be examined with a home sleep-monitoring device during one night's sleep to evaluate the presence of OSA. For each AS patient, 45-70 years, four controls were matched for sex, age, weight and height. OSA was defined as an apnoea-hypopnea-index ≥5 events/hour.
Results: In total, 63/155(40.6%) patients with AS were examined with a home sleep-monitoring device out of which 46 patients were 45-70 years and therefore matched (mean age 57.2±7.5years, 30(65.2%) men) with 179 controls (mean age 57.2±4.5years, 123(68.7%) men). Twenty-two out of 46(47.8%) patients with AS vs. 91/179(50.8%) controls had OSA, p=0.72. No differences measurements evaluating OSA were noted in AS vs. controls. In logistic regression analysis, based on all 63 examined AS-patients, several AS-related variables were associated with OSA but after adjusting for age and sex, only higher age and BMI, remained to be significant determinants of OSA, Table 1.

Table 1. Univariable and age- and sex-adjusted logistic regression analyses with obstructive sleep apnoea as dependent variable in 63 patients with ankylosing spondylitis.

Variables	Univariable logistic regression analyses, Odds Ratio (95%CI)	P	Age- and sex-adjusted logistic regression analyses, Odds Ratio (95%CI)	P
Sex, male	1.9(0.6-5.5)	0.25	1.5(0.4-4.8)	0.53
Age	1.1(1.0-1.2)	**0.002**	1.1(1.0-1.2)	**0.002**
BMI	1.4(1.1-1.7)	**0.001**	1.6(1.2- 2.2)	**0.001**
Duration of symptoms	1.1(1.0-1.1)	**0.028**	1.0(0.9-1.1)	0.79
BASMI	1.9(1.3-2.9)	**0.002**	1.5(0.9 -2.5)	0.87
BASFI	1.4(1.0-2.0)	**0.038**	1.3(0.9-2.0)	0.88
≥1 Syndesmophyte	3.9(1.3-12.2)	**0.017**	3.0(0.8-11.3)	0.10
mSASSS	1.0(1.0-1.1)	**0.047**	1.0(0.98-1.05)	0.25
Metabolic syndrome	4.3(1.5-12.9)	**0.008**	1.4(0.3-6.6)	0.69
Epworth Sleep Scale	1.2(1.0-1-3)	**0.023**	1.2(1.0-1.4)	0.29

Conclusion: In this case-control study, patients with AS did not have a higher prevalence of OSA compared to controls. AS patients with OSA had higher BMI and were older compared to patients without OSA.
Disclosure of Interests: None declared.

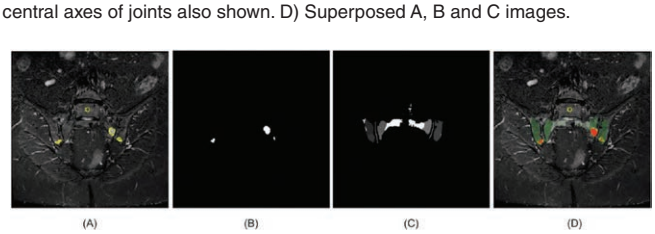
POS0958 RESPONSIVENESS OF CONVENTIONAL, SEMI-AUTOMATIC AND FULL-AUTOMATIC METHODS TO QUANTIFY MARROW BONE EDEMA LESIONS IN MRI OF AXIAL SPONDYLOARTHRITIS PATIENTS: A PILOT STUDY

C. Garrido-González[1], M. L. Ladehesa Pineda[2], J. L. Garrido-Castro[3], Z. Tabor[4], I. Kucybała[5], W. Wojciechowski[5], P. Zarco-Montejo[6], R. Almodovar[6], E. Collantes Estevez[2]on behalf of CASTRO. [1]*Universidad de Córdoba, Facultad de Medicina, Enfermería y Fisioterapia, Córdoba, Spain*; [2]*Hospital Universitario Reina Sofía, Rheumatology, Córdoba, Spain*; [3]*Maimónides Biomedical Research Institute of Córdoba, Rheumatology, Córdoba, Spain*; [4]*AGH University of Science and Technology, Department of Biocybernetics and Biomedical Engineering, Krakow, Poland*; [5]*Jagiellonian University Medical College, Department of Radiology, Krakow, Poland*; [6]*Fundación Hospital Alcorcón, Rheumatology, Madrid, Spain*

Background: The presence or absence of marrow bone edema (MBE) in the sacroiliac joints (SIJ) is very important in the diagnosis of axial Spondyloarthritis (axSpA). The quantification of this lesion and its extension may be important to analyze responsiveness of the treatment. Several scoring systems have been proposed for MRI images of SIJ, some of them being observer dependent (Berlin, SPARCC). Others, works in a semi-automatically way, such as the s-SCAISS[1], which makes it possible to quantify the size of the lesion, based on the indication of the expert. Recently, methods like the KITs4R[2], based on a deep patch-based classification network. allow a fully automated detection and quantification of the MBE lesions.
Objectives: To analyze responsiveness of several scores (observer independent, semiautomatic and full automatic) for quantify MBE in SIJ of axSpA patients.
Methods: Two rheumatologists independently quantified SIJ images from axSpA patients by visual inspection methods (Berlin and SPARCC indexes) and a semiautomatic system (s-SCAISS) on a single semi-coronal MRI slide (STIR). Full semi-coronal MRI images (15 to 18 slices) were used for an automatic detection algorithm (KITs4R), where total MBE was calculated as sum of areas of MBE in each slice. Patients were assessed before TNF-α therapy (PRE) and 3 months later (POST). Spearman correlations was used to analyze relationship between variables, Wilcoxon signed-rank test for significant differences and Cohen's d for calculating the effect size of improvement. Figure 1 shows processing of the MRI images: A) Area of MBE selected by the SCAISS, when the rheumatologist "click" on each MBE; B) Lesions detected automatically by KITs4R; C) Automated deep segmentation of bones and subchondral regions (with split into quadrants with central axes of joints also shown. D) Superposed A, B and C images.



Results: 12 axSpA patients were recruited from the CASTRO cohort (42% female, age 46±11 years, disease duration 16±13 years, BMI 28±5). Results PRE and POST are shown in Table 1: mean values (sd), statistical significance (NS, not significant; *, p<0.05; **, p<0.01), and effect size. Activity indexes and CRP were lower. ASDAS and CRP shown significant differences and a large effect size. All MRI scores showed good responsiveness (ES medium-large, p<0.01), specially KITs4R. Agreement between all MRI scores were high (r>0.8;p<0.01). Between semiautomatic and automatic methods, this agreement was also excellent (r=0.92;p<0.001). Correlation in improvements (reductions in scores) were also significant between all MRI scores (r>0.7;p<0.05).

	PRE	POST	Sign	ES
BASDAI	6.12 (2.45)	4.96 (2.74)	N.S.	0.44-Small
ASDAS	3.61 (1.04)	2.58 (1.25)	*	0.89-Large
CRP	11.26 (8.93)	4.81 (4.08)	**	0.84-Large
BERLIN	2.58 (1.98)	1.17 (1.85)	**	0.74-Medium
SPARCC	3.92 (3.42)	1.58 (2.43)	**	0.69-Medium
SCAISS	295 (332)	95 (163)	**	0.68-Medium
KITs4R	1671 (1596)	258 (421)	**	1.04-Large

NS, not significant; *, p<0.05; **, p<0.01

Conclusion: All MRI scores have good level of agreement between them and good responsiveness. Berlin and SPARCC are observer dependent, and do not quantify the extension of the MBE area. s-SCAIS helps to this quantification. KITs4R is not observer dependent but clinimetric validation, analizing agreement level with human expert, is necessary. New advanced tools are improving quantitative and objective measurement of BME which is important to analyze responsiveness.

POS0959 DIAGNOSTIC DELAY IN AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE NATIONAL EARLY INFLAMMATORY ARTHRITIS AUDIT

M. Russell[1], F. Coath[2], M. Yates[1], K. Bechman[1], S. Norton[1], J. Galloway[1], J. Ledingham[3], R. Sengupta[4], K. Gaffney[2]. *[1]King's College London, Centre for Rheumatic Diseases, London, United Kingdom*; *[2]Norfolk and Norwich University Hospital, Rheumatology Department, Norwich, United Kingdom*; *[3]Portsmouth Hospitals University NHS Trust, Rheumatology Department, Portsmouth, United Kingdom*; *[4]Royal National Hospital for Rheumatic Diseases, Department of Rheumatology, Bath, United Kingdom*

Background: Diagnostic delay is a significant problem in axial spondyloarthritis (axSpA), and there is a growing body of evidence showing that delayed axSpA diagnosis is associated with worse clinical, humanistic and economic outcomes.[1] International guidelines have been published to inform referral pathways and improve standards of care for patients with axSpA.[2,3]

Objectives: To describe the sociodemographic and clinical characteristics of newly-referred patients with axSpA in England and Wales in the National Early Inflammatory Arthritis Audit (NEIAA), with rheumatoid arthritis (RA) and mechanical back pain (MBP) as comparators.

Methods: The NEIAA captures data on all new patients over the age of 16 referred with suspected inflammatory arthritis to rheumatology departments in England and Wales.[4] We describe baseline sociodemographic and clinical characteristics of axSpA patients (n=784) recruited to the NEIAA between May 2018 and March 2020, compared with RA (n=9,270) and MBP (n=370) during the same period.

Results: Symptom duration prior to initial rheumatology assessment was significantly longer in axSpA than RA patients (p<0.001), and non-significantly longer in axSpA than MBP patients (p=0.062): 79.7% of axSpA patients had symptom durations of >6 months, compared to 33.7% of RA patients and 76.0% of MBP patients; 32.6% of axSpA patients had symptom durations of >5 years, compared to 3.5% of RA patients and 24.6% of MBP patients (Figure 1A). Following referral, median time to initial rheumatology assessment was longer for axSpA than RA patients (36 vs. 24 days; p<0.001), and similar to MBP patients (39 days; p=0.30). The proportion of axSpA patients assessed within 3 weeks of referral increased from 26.7% in May 2018 to 34.7% in March 2020; compared to an increase from 38.2% to 54.5% for RA patients (Figure 1B). A large majority of axSpA referrals originated from primary care (72.4%) or musculoskeletal triage services (14.1%), with relatively few referrals from gastroenterology (1.9%), ophthalmology (1.4%) or dermatology (0.4%).

Of the subset of patients with peripheral arthritis requiring EIA pathway follow-up, fewer axSpA than RA patients had disease education provided (77.5% vs. 97.8%; p<0.001), and RA patients reported a better understanding of their condition (p<0.001). HAQ-DI scores were lower at baseline in axSpA EIA patients than RA EIA patients (0.8 vs 1.1, respectively; p=0.004), whereas baseline Musculoskeletal Health Questionnaire (MSK-HQ) scores were similar (25 vs. 24, respectively; p=0.49). The burden of disease was substantial across the 14 domains comprising MSK-HQ in both axSpA and RA (Figure 1C).

Conclusion: We have shown that diagnostic delay remains a major challenge in axSpA, despite improved disease understanding and updated referral guidelines. Patient education is an unmet need in axSpA, highlighting the need for specialist clinics. MSK-HQ scores demonstrated that the functional impact of axSpA is no less than for RA, whereas HAQ-DI may underrepresent disability in axSpA.

POS0960 PRESENCE AND ASSOCIATED FACTORS OF FATIGUE IN PATIENTS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS. RESULTS FROM THE EUROPEAN MAP OF AXIAL SPONDYLOARTHRITIS (EMAS)

M. Garrido-Cumbrera[1], V. Navarro-Compán[2], L. Christen[3], C. Bundy[4], R. Mahapatra[5], S. Makri[6], C. J. Delgado-Domínguez[1], J. Correa-Fernández[1], S. Sanz-Gómez[1], D. Poddubnyy[7]on behalf of IMAS working group. *[1]Universidad de Sevilla, Health & Territory Research (HTR), Seville, Spain*; *[2]Hospital Universitario La Paz, IdiPaz, Madrid, Spain*; *[3]Novartis Pharma AG, Patient Engagement, Basel, Switzerland*; *[4]Cardiff University, School of Healthcare Sciences, Cardiff, United Kingdom*; *[5]Axial Spondyloarthritis International Federation (ASIF), Patient Advocacy, London, United Kingdom*; *[6]Cyprus League Against Rheumatism (CYPLAR), Patient Advocacy, Nicosia, Cyprus*; *[7]Charité - Universitätsmedizin Berlin, Rheumatology Department, Berlin, Germany*

Background: Fatigue/tiredness is an essential aspect of disease for patients with axial spondyloarthritis (axSpA). However, little is known about its prevalence and associated factors.

Objectives: The aim is to assess the prevalence of fatigue and associated factors in a large sample of patients with axSpA patients from 13 European countries.
Methods: Data from 2,846 unselected patients of the European Map of Axial Spondyloarthritis (EMAS) through an online survey (2017-2018) across 13 European countries were analyzed.
The presence of fatigue/tiredness was evaluated using the Visual Analogue Scale from the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI): "How would you describe the overall level of fatigue/tiredness you have experienced? (0-10)". Risk of poor mental health was assessed using the 12-Item General Health Questionnaire (GHQ-12; 0-12).
Possible associated factors included: Socio-demographic and disease characteristics, disease activity and function and mental health disorders.
The Mann-Whitney test was used to compare the means of variables of two categories vs. the numerical variables, the χ^2 test was used to compare the distribution between the categorical variables. Binary logistic regression and multiple linear regression were used to identify possible predictors.
Results: A total of 2,846 axSpA patients participated in the EMAS survey: mean age was 43.9 years, 61.3% female, 48.1% had a university degree, 67.9% were married and 71.3% were HLA-B27 positive. Fatigue/tiredness was associated with younger age (6.4±2.3 vs 5.5±2.4), being female (6.6±2.2 vs 5.7±2.4), lower educational level (6.9±2.4 vs 6.0±2.0) and separated or divorced persons (6.8±2.2 vs 6.2±2.3; all p<0.001). Those reporting work impact (6.8±2.1 vs 5.8±2.4), physically inactive (6.9±2.2 vs 6.1±2.3) or those with sleep disorders (7.0±2.0 vs 5.8±2.4), anxiety (7.0 ± 2.0 vs 5.9±2.4) or depression (7.2±1.9 vs 5.9±2.4; all p<0.001) also presented greater fatigue, as did those with higher morning stiffness (r=0.499) and functional limitation (r=0.257), and poorer mental health GHQ-12 (r=0.419). Finally, the variables independently associated with fatigue were female gender (B=0.427), being physical inactive (B=-0.395) and those with greater morning stiffness severity (B=0.349; see Table 1). In addition, those on temporary and permanent sick leave, along with the unemployed, presented greater fatigue (7.1, 6.8 and 7.1 respectively).

PREVALENCE AND ASSOCIATED FACTORS OF SLEEP DISORDERS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS. RESULTS FROM THE EUROPEAN MAP OF AXIAL SPONDYLOARTHRITIS (EMAS)

M. Garrido-Cumbrera[1], V. Navarro-Compán[2], L. Christen[3], C. Bundy[4], R. Mahapatra[5], S. Makri[6], C. J. Delgado-Domínguez[1], J. Correa-Fernández[1], D. Poddubnyy[7] on behalf of IMAS working group. *[1]Universidad de Sevilla, Health & Territory Research (HTR), Seville, Spain*; *[2]Hospital Universitario La Paz, IdiPaz, Madrid, Spain*; *[3]Novartis Pharma AG, Patient Engagement, Basel, Switzerland*; *[4]Cardiff University, School of Healthcare Sciences, Cardiff, United Kingdom*; *[5]Axial Spondyloarthritis International Federation (ASIF), Patient Advocacy, London, United Kingdom*; *[6]Cyprus League Against Rheumatism (CYPLAR), Patient Advocacy, Nicosia, Cyprus*; *[7]Charité - Universitätsmedizin Berlin, Rheumatology Department, Berlin, Germany*

Background: Sleep is an essential health aspect that is often impacted in patients with axial spondyloarthritis (axSpA).
Objectives: This analysis aims to assess the prevalence and associated factors of sleep disorders in a large sample of European axSpA patients.
Methods: Data were analyzed from 2,846 unselected patients with self-reported clinician-given diagnosis of axSpA of the European Map of Axial Spondyloarthritis (EMAS) through an online survey (2017-2018) across 13 European countries. Socio-demographic data; BASDAI [0-10] scores; engagement in physical activity; axSpA influence on work choice (assessed with yes/no question "Was your current or past work choice in any way determined by axSpA?"); risk of psychological distress (12-item General Health Questionnaire [GHQ-12; 0-12]); functional limitation [0-54] and self-reported anxiety and depression were evaluated. Presence of sleep disorders was assessed by the question: "Please indicate whether you have been diagnosed with any of the following: sleep disorders". A Mann-Whitney test was used to compare the means of numerical variables between dichotomous variables, the Chi-Square test was used to compare the distribution between the categorical variables. Simple and multivariable logistic regression models were used to identify associations between sleep disorders and disease characteristics, mental health and work-related variables.
Results: Age of respondents was 43.9 years; 61.3% were female; 48.1% had a university degree; 67.9% were married and 71.3% were HLA-B27 positive. The prevalence of sleep disorders was 39.0%. In the bivariate analysis, presence of sleep disorders was associated with female gender (68.3% vs. 31.7%; p<0.001); overweight/obese (56.5% vs. 49.8%; p<0.001); increased BASDAI scores (6.1±1.8 vs. 5.0±2.1; p<0.001); fatigue (7.0±2.0 vs. 5.8±2.4; p<0.001); morning stiffness (5.8±2.4 vs. 4.8±2.4; p<0.001), work impact (56.5% vs. 38.2%; p< 0.001); anxiety (56.8% vs. 12.5%; p<0.001); depression (51.8% vs. 10.1%; p<0.001) and higher GHQ-12 scores (6.4±4.0 vs. 3.9±3.9; p<0.001). However, factors that remained independently associated with sleep disorders in the multivariable analysis were anxiety (OR=3.8 p<0.001) and depression (OR=3.1 p<0.001) and female gender (OR=1.4; p=0.002) [Table 1].

Table 1. Regression analysis to predict presence of sleep disorders (N=2191)

GHQ-12 (0-12)**	1.16	1.14-1.19	**<0.001**	1.03	1.00-1.06	**0.029**

*As measured by the respective item of the BASDAI scale.**12-item General Health Questionnaire. A value of 3 or above indicates a risk of poor mental health.

Conclusion: Sleep disorders were highly prevalent among axSpA European patients and strongly associated with female gender and reporting worse mental health, and spinal stiffness. Patients on permanent and temporary sick leave were more likely to report sleep disorders. The strong association between sleep disorders with both anxiety and depression should encourage rheumatologists to screen their patients with sleep disturbance in case they require additional specialist support.

POS0962

PATIENT-REPORTED IMPACT OF AXIAL SPONDYLOARTHRITIS ON WORKING LIFE. RESULTS FROM THE SPANISH ATLAS

M. Garrido-Cumbrera[1], E. Collantes-Estévez[2], V. Navarro-Compán[3], P. Zarco Montejo[4], C. Sastré[5], S. Sanz-Gómez[1], J. Correa-Fernández[1], J. Gratacos-Masmitja[6]on behalf of Atlas working group. *[1]Universidad de Sevilla, Health & Territory Research (HTR), Seville, Spain*; *[2]Reina Sofia University Hospital, Rheumatology Department, Cordova, Spain*; *[3]Hospital Universitario La Paz, IdiPaz, Madrid, Spain*; *[4]Hospital Universitario Fundación Alcorcón, Rheumatology Department, Madrid, Spain*; *[5]Novartis Farmacéutica Spain, Immunology, Hepatology and Dermatology, Barcelona, Spain*; *[6]Hospital Universitaria Parc Taulí, Rheumatology Department, Sabadell, Spain*

Background: Axial spondyloarthritis (axSpA) impacts negatively on multiple dimensions of patient's life, including their working life.
Objectives: The present study aims to evaluate burden of disease ox axSpA patients by working status, work-related issues and their associations and determinants in a Spanish sample.
Methods: The Atlas 2017 is an extensive cross-sectional patient survey conducted in Spain (2016), validated by a multidisciplinary group of experts on spondyloarthritis. Participants were recruited through an on-line panel and patient organizations. Participants were classified as active (employed, unemployed between 15-64 years) and inactive (retirees, on sick leave, students and homemakers). Those employed were asked to report work-related issues (WRIs) due to axSpA (sick-leave, difficulty fulfilling work hours, missing work for doctors' appointments, reducing working hours or taking days off) in the past 12 months. Diagnostic delay, disease activity (BASDAI), spinal stiffness (3-12), functional limitation (0-54) and psychological distress (General Health Questionnaire, GHQ-12 [0-12]) were compared between employed patients with or without WRIs using a Mann-Whitney and Kruskal-Wallis test.
Results: Data from 680 patients were collected: mean age was 47±11 years, 52.5% were female and 36.9% were university educated. Mean disease duration and diagnostic delay were 20.9±12.2 and 8.5±7.7 years, respectively, and mean BASDAI was 5.5±2.2. A total of 63.6% (n=415) were considered active population, of which 49.8% (n=325) were employed. Of those employed, 54.3% reported a WRI, specifically 37.1% took sick leave, 44.1% had difficulties in fulfilling the working hours, 42.9% missed work due to doctor's appointments 37.1% took sick leave, 18.2% reported that their professional life had suffered, 12.3% asked for some days off, 12.3% changed shift sometimes and 7.6% had to give up their previous job. Among all patients, 95.5% faced (or believed they would) difficulties finding a job due to axSpA. Experiencing WRIs due to axSpA was significantly associated in the univariable analysis with higher disease activity, self-reported spinal stiffness, longer diagnostic delay, higher functional limitation and higher level of psychological distress (p<0.001). However, the highest levels of disease burden were reported by unemployed participants (see Table 1).

Table 1. Differences between employees with/without work-related issues and between employed/unemployed participants in relation to sociodemographic and patient-reported outcomes

Reference group	Employed		Active Population	
Subgroup	Any WRI	With no WRIs	Employed	Unemployed
N size	n: 170	n: 143	n: 325	n: 90
Sociodemographic characteristics				
Age (years)	41.9 ± 7.9	44.2 ± 9.4	42.9 ± 8.6*	42.0 ± 9.1*
Gender (Male)	79 (46.5)	75 (52.4)	159 (48.9)	36 (40.0)
Education level (University)	80 (47.1)*	68 (47.6)*	153 (47.1)	21 (23.3)
Marital status (Married)	110 (64.7)	109 (76.2)	231 (71.1)	54 (60.0)
Patient-reported outcomes				
BASDAI (0-10)	5.7 ± 1.8**	4.5 ± 1.9**	5.2 ± 1.9**	6.3 ±1.9**
Spinal Stiffness (3-12)	6.7 ± 2.7**	6.1 ± 2.4**	6.5 ± 2.6**	7.8 ± 2.3**
Functional Limitation (0-54)	43.9 ± 8.8**	36.9 ± 10.3**	40.6 ± 10.1**	45.0 ± 8.4**
GHQ-12 (0-12)	6.6 ± 4.2**	3.0 ± 3.5**	4.9 ± 4.3**	7.6 ± 4.2**
Anxiety	35 (20.6)*	16 (11.2)*	52 (16.0)*	25 (27.8)*
Depression	29 (17.1)*	4 (2.8)*	33 (10.2)**	21 (23.3)**

*Note: WRI: Work-related issue** p-value <0.001; * p-value <0.05*

Conclusion: Results reveal a relevant impact of axSpA in patient working life. Approximately two out of three patients employed experienced WRIs due to axSpA, being associated to worse disease outcomes and poorer psychological health. However, those who were unemployed faced a harsher situation reporting even poorer disease-related and psychological health outcomes. As psychological health appears impaired severely in axSpA patients regardless of their employment status it should be key for a holistic approach to patient care.

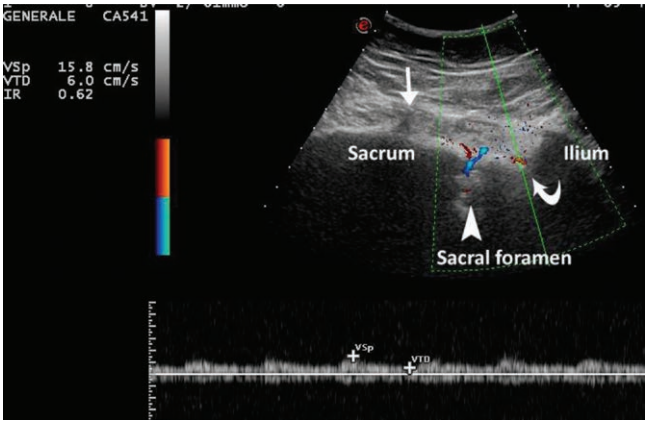
POWER AND SPECTRAL DOPPLER ULTRASOUND AS A SCREENING TOOL IN THE DIAGNOSTIC COURSE OF SUSPECTED AXIAL SPONDYLOARTHRITIS: PRELIMINARY DATA FROM A LARGE MONOCENTRIC COHORT

P. Falsetti[1], E. Conticini[1], C. Baldi[1], M. Bardelli[1], R. D'alessandro[1], S. G. Al Khayyat[1], M. A. Mazzei[2], L. Cantarini[1], B. Frediani[1]. *[1]University of Siena, Rheumatology Unit, Siena, Italy*; *[2]University of Siena, Diagnostic Imaging Unit, Siena, Italy*

Background: Sacroiliac joints (SIJs) involvement is a characteristic feature of Spondylarthritis (SpA). Magnetic resonance imaging (MRI) has been included in the new Assessment of SpA International Society (ASAS) criteria for the classification of non-radiographic axial SpA. Power Doppler ultrasound (PDUS) and spectral Doppler US have been used in few works, also from our group, to evaluate the inflammatory activity of the SIJs, in comparison with MRI, with different results.
Objectives: We aimed to evaluate the value of PDUS with spectral wave analysis (SWA) in the assessment of suspected active sacroiliitis (SI). PDUS of SIJs was used as a screening tool alongside the routine PDUS assessment of peripheral joints.
Methods: 143 patients (114 females and 29 males, mean age 46,2 years, mean BMI 25.9) with new onset of inflammatory back pain (IBP), were included. Peripheral symptoms were allowed. Every patient underwent a PDUS examination of SIJs as previously reported. The sonographer was blinded to the clinical data. An Esaote Twice US machine, with convex 1-8 MHz and linear 6-18 MHz probes, was used, with standardized parameters. PD signals detected in the SIJs, were scored with a 3-points scale: 0= absence of signals, 1= isolate vessels, 2= more than one vessel. The signals were also classified as intra-articular (vascularity from deep joint and inter-osseous ligament) or peri-articular (vascularity along posterior sacroiliac ligament). SWA was applied to the same vessels calculating the Resistive Index (RI) (Figure 1). A PDUS diagnosis of active SI was made with a grade 1 of vascularity and RI<0,60, or grade 2 of vascularity and RI<0,70. PDUS multi-site examination of peripheral joints and entheses was also performed; entheseal involvement was scored with Belgrade Ultrasound Enthesitis Score (BUSES) and as global enthesitic charge (GEC). Every patient underwent MRI of SIJs within 2 weeks, and before to start pharmacologic treatment. The non-parametric Spearman rank test and univariate linear regression analysis was applied using InStat GraphPad statistical package.
Results: A time of 5-8 minutes was sufficient to set and to complete PDUS/SWA examination on both SJJs. All patients considered this examination quick, not painful and substantially comfortable. PD signals were detected in 124 patients (mean RI 0,56). Bone marrow edema (BME) lesions (active SI on MRI) were detected in 94 patients. A final diagnosis of SpA was made in 103 patients (81 females, 22 males). Among SpA patients 24 had psoriasis, 3 inflammatory bowel disease, 3 uveitis, 5 were B27+, and they had mean BUSES of 4,1 and GEC of 1,2. The mean SIJs PDUS score was 1,3 in SpA and 0,52 in not-SpA patients. The mean SIJs RI was 0,53 in SpA and 0,68 in not-SpA patients. A significant correlation was demonstrated between MRI and PDUS diagnosis of SI (r=0,6486, p<0,0001), between MRI diagnosis and PD grading (r=0,4937, p<0,0001). The split analysis of peculiar parameters of imaging between the two methods also showed significant correlation: periarticular vascularity showed correlation with post-contrast MRI evidence of posterior capsulitis and enthesitis (p=0,001), as SIJs BME correlated with intra-articular PD signals (p<0,001). RI from SWA analysis was inversely correlated with MRI diagnosis of active SI (p<0.0001). SIJs PD demonstrated a significant correlation with SIJs pain (p<0,001), but not with inflammatory reactants, GEC, peripheral synovitis, and a weak correlation with BUSES (p=0,038).
Conclusion: SIJs PDUS/SWA may be an optional method for preliminary screening of active SI, as a feasible, cheap and an accurate diagnostic tool, compared with MRI as a gold standard for nr-Axial SpA. PD US in SI. Right SI joint with a PD signal within inter-osseous ligament (curved arrow), where spectral PD analysis shows a RI of 0,62. Normal vessels (with high RI, unshowed) can be observed into the first sacral foramen (arrowhead). The first sacral apophysis (arrow) protrudes from the sacrum profile.



Disclosure of Interests: None declared.

POS0964

CHARACTERISTICS AND BURDEN OF DISEASE IN PATIENTS WITH RADIOGRAPHIC VERSUS NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN THE ANKYLOSING SPONDYLITIS REGISTRY OF IRELAND COHORT

S. Quinn[1], S. Maguire[2], F. B. O'shea[2], L. O'neill[1], E. Molloy[1], U. Fearon[3], P. Gallagher[1], D. Veale[1]. *[1]St. Vincent's University Hospital, Rheumatology, Dublin, Ireland*; *[2]St James's Hospital, Rheumatology, Dublin, Ireland*; *[3]Trinity Biomedical Sciences Institute, Molecular Rheumatology, Dublin, Ireland*

Background: Axial spondyloarthritis (axSpA) is an umbrella term for types of inflammatory arthritis that primarily affect the spine and the sacroiliac joints. It is comprised of patients with both radiographic (r-axSpA) and non-radiographic features (nr-axSpA). R-axSpA was historically known as Ankylosing Spondylitis. Previous studies have shown the burden of disease to be largely similar in patients with radiographic versus non-radiographic axial spondyloarthritis in cohorts both in the US and Europe [1]. The Ankylosing Spondylitis Registry of Ireland (ASRI) was formed with the objective to measure the burden of axial spondyloarthritis in the population and identify early predictors of a poor outcome. All patients in the registry are 18 years or older and meet Assessment of Spondyloarthritis International Society (ASAS) criteria for a diagnosis of SpA.
Objectives: To compare the characteristics and burden of disease in patients with radiographic versus non-radiographic axial spondyloarthritis in the ASRI cohort.
Methods: Patients with radiographic axial spondyloarthritis (r-axSpA) were defined as those with x-ray evidence of sacroiliitis. Patients with non-radiographic axial spondyloarthritis (nr-axSpA) were defined as having MRI evidence of sacroiliitis but no x-ray evidence of sacroiliitis. A standardised clinical assessment was performed on each patient and structured interviews provided patient-reported data. For each patient the following scores were captured: Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Metrology Index (BASMI), Health Assessment Questionnaire (HAQ) assesses the self-reported functional status for performing activities of daily living, and the Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire. Categorical variables were summarized as percentages with frequency counts, and continuous variables with a mean and standard deviation. Statistical comparisons between subgroups were evaluated using 2 sample t-tests for continuous variables and chi-square tests for categorical variables.
Results: 764 patients were available for analysis. Analysis of radiographic status showed 88.1% (n=673) of patients with r-axSpA and 11.9% (n=91) with nr-axSpA. Patients with nr-axSpA were younger (41.3 vs. 46.6 years, p<0.01), had shorter disease duration (14.8 vs. 20.2 years, p<0.01), lower proportion of males (66.6% vs. 78.4%, p=0.02) with lower rates of HLA-B27 positivity (73.6% vs. 90.5%, p<0.01). The nr-axSpA group had lower BASDAI (3.37 vs. 4.05, p=0.01), BASFI (2.46 vs. 3.88, p<0.01), BASMI (2.33 vs. 4.34, p<0.01), ASQoL (5.2 vs. 6.67, p=0.02), and HAQ scores (0.38 vs. 0.57, p<0.01). There were no significant differences in the prevalence of extra-articular manifestations.
Conclusion: This study provides evidence that the burden of disease is less in patients with non-radiographic axial spondyloarthritis than radiographic axial spondyloarthritis, as demonstrated by better BASDAI, BASFI, BASMI, HAQ and ASQoL scores.

ARE SMOKING AND ALCOHOL ASSOCIATED WITH PERIPHERAL MUSCULOSKELETAL INVOLVEMENT IN PATIENTS WITH SPONDYLOARTHRITIS? RESULTS FROM THE ASAS-PERSPA STUDY

M. L. Ladehesa Pineda[1], R. Ortega Castro[1], M. Á. Puche Larrubia[1], M. Dougados[2], E. Collantes Estevez[1], C. López-Medina[1,2]. *[1]Córdoba, Rheumatology Department, Reina Sofia University Hospital, IMIBIC, University of Córdoba, Córdoba, Spain, Córdoba, Spain*; *[2]Paris, Rheumatology Department, Cochin Hospital, Paris, France, Paris, France*

Background: The harmful effect of smoking on axial spondyloarthritis (axSpA) in relation to radiographic progression is well known, but there are controversies around the role of cigarettes in other manifestations of SpA, such as peripheral involvement. Besides, it has been observed an inverse association between alcohol consumption and disease activity and functional impairment[1], although it is still unclear its association with peripheral manifestations of SpA.
Objectives: To evaluate the association between smoking/alcohol intake and the prevalence of peripheral articular manifestations (arthritis, enthesitis or dactylitis).
To assess the association between smoking/alcohol intake and the location of such manifestations.
Methods: Patients from the cross-sectional ASAS-PerSpA study with available data for both the smoking status and alcohol intake were included. Mixed logistic regressions using the peripheral manifestation (or location) as dependent variable, the smoking status or alcohol intake as fixed effect and the country as random effect were used. The interaction between smoking and alcohol was tested.
Results: A total of 4451 patients with either axSpA, peripheral SpA or Psoriatic Arthritis were included. 59.5% had smoked at any moment and 42.7% had been alcohol drinkers. Patients who had ever suffered arthritis showed lower frequency of smoking habit (OR 0.72, 95%CI 0.63-0.82) and lower alcohol intake (OR 0.82, 95%CI 0.71-0.94) (Table 1). Among patients with arthritis, smoking was associated with predominantly upper limbs vs. lower limbs involvement (OR 0.78, 95%CI 0.65-0.94), while alcohol was associated with predominant mono/oligoarticular vs. polyarticular involvement (OR 1.13, 95%CI 0.94-1.36).
Patients who had ever suffered enthesitis also showed lower frequency of smoking habit and alcohol intake (OR 0.75, 95%CI 0.63-0.89 and OR 0.69, 95%CI 0.57-0.83, respectively). No association was found with regard to the prevalence of dactylitis.
At the moment of the study visit, 20.4% patients were current smokers and 32.2% consumed alcohol. Current alcohol intake was associated with lower prevalence of current arthritis (26.9% vs. 33.6% (OR 0.76, 95%CI 0.64-0.91) and current enthesitis (21.1% vs. 34.6% (OR 0.78, 95%CI 0.62-0.96), while current smoking did not show significant differences.
No interaction was found in the association between alcohol and tobacco with regard to the prevalence of peripheral symptoms in the past. However, when assessing current arthritis, current smoking and no drinking was associated with arthritis in the lower limbs.
Conclusion: These results suggest that, taking into account the country, smoking and alcohol are associated with lower prevalence of peripheral manifestations (arthritis

and enthesitis), with no interaction effect between both habits. Smoking seems to be associated with predominantly upper limbs arthritis while alcohol intake seems to be associated with a predominantly oligo/mono articular involvement. Future studies are required including the influence of psoriasis and psoriatic arthritis in the relationship between alcohol and smoking and its association with peripheral manifestations.

IDENTIFICATION OF PATIENTS AFFECTED WITH ANKYLOSING SPONDYLITIS AND INFLAMMATORY BOWEL DISEASE OVERLAP USING COLLAGEN BIOMARKERS

S. Holm Nielsen[1], A. Stahly[2], E. H. Regner[2], A. C. Bay-Jensen[3], M. Karsdal[4], K. A. Kuhn[2]. [1]*Nordic Bioscience & Technical University of Denmark, ImmunoScience, Herlev, Denmark*; [2]*University of Colorado Anschutz Medical Center, Department of Medicine, Division of Rheumatology, Aurora, United States of America*; [3]*Nordic Bioscience, ImmunoScience, Herlev, Denmark*; [4]*Nordic Bioscience, RnD, Herlev, Denmark*

Background: Chronic inflammatory arthritis is a hallmark of Ankylosing Spondylitis (AS), where co-existence of inflammatory bowel disease, such as Crohn's Disease (CD) is prominent. The clinical overlap of AS and CD has raised the hypothesis that these conditions may have similar pathophysiological mechanisms. Both indications are characterized by an altered extracellular matrix turnover, where particularly collagens are remodeled.

Objectives: We investigated the association between biomarkers of collagen degradation in healthy controls and patients with AS, CD and AS/CD overlap, with the aim to investigate the biomarkers' ability to identify patients with AS/CD overlap.

Methods: Patients with AS fulfilling ASAS criteria (n=13), biopsy-proven CD (n=14), subjects with AS and CD overlap (n=10) and healthy controls (n=11) undergoing standard of care colonoscopies were included in the study. The collagen degradation biomarkers measuring type III, IV, VI and X collagen (C3M, C4M, C6M and C10C, respectively) were measured in EDTA plasma samples from all subject groups. Biomarkers were measured by competitive ELISAs. Statistical analysis was performed using an ANCOVA adjusted for age, an AUROC analysis and spearman correlations.

Results: The collagen biomarker C4M was significantly higher in patients with AS/CD overlap compared to AS, CD and HCs (all p<0.0001, Figure 1A). The blood levels of C4M in AS patients were significantly lower than HC (p=0.0003), while CD also showed a lower level compared to HC though not significant (p=0.0798). No difference was found between AS and CD alone. In an AUROC analysis, C4M showed a complete separation between the patients with AS/CD overlap compared to HC, AS and CD with an AUC=1.00; p=0.0001. No differences were found between the patient groups for C3M, C6M and C10C (Figure 1, B-D). 91.3 % of patients with AS, 92.8% of patients with CD and 60 % of patients with AS and IBD overlap were actively treated with TNF-α inhibitors, which may explain the suppression of the collagen degradation biomarker levels in AS, CD and AS/IBD overlap compared to healthy controls[1,2]. No correlations were found between the collagen biomarkers and CRP, BASDAI, SCCAI or HBI scores.

Conclusion: Degradation of type IV collagen quantified by C4M showed a complete separation of patients with AS/IBD overlap, compared to AS, CD and HC patients, which indicates an excessive collagen degradation and epithelial turnover. This biomarker could potentially be used to identify patients affected by both manifestations, and guide treatment decisions.

POS0967

DESCRIPTION OF SACROILIAC CT FINDINGS IN PATIENTS WITH ANKYLOSING SPONDYLITIS AGED OVER 50 YEARS: PRELIMINARY RESULTS OF THE CASIAGE STUDY

O. Fakih[1], M. Chouk[1], C. Prati[1,2], D. Wendling[1,3], F. Verhoeven[1,2]. [1]*Centre hospitalier régional universitaire de Besançon, Rhumatologie, Besançon, France*; [2]*UFR Santé, Université de Franche-Comté, EA 4267 'PEPITE', Besançon, France*; [3]*UFR Santé, Université de Franche-Comté, EA 4266 'EPILAB', Besançon, France*

Background: Diagnosis of axial spondyloarthritis (SpA) is nowadays commonly made with the help of pelvic radiography or MRI. However, there is an important inter-observer variability for radiographs, and MRI is subject to possible false positives, and is not the best modality for studying structural lesions. Conversely, pelvic CT has an excellent specificity and appears to be more effective than radiography for the diagnosis of SpA [1]. However, CT findings in patients over 50 years of age have not been studied.

Objectives: To describe sacroiliac (SI) joint CT characteristics in patients with ankylosing spondylitis (AS), aged 50 years or older.

Methods: An observational, cross sectional study was performed using medical records from Besançon University Hospital's rheumatology department, which were screened to identify patients with AS. A search was then carried out for patients over 50 years old in the hospital's imaging archiving system to identify those who had benefited from a CT which included the SI joints in their entirety. Non-inclusion criteria were the existence of pelvic bone lesions and a history of pelvic radiotherapy. For each patient, CT was interpreted using a score previously used by Diekhoff et al. [2], dividing each SI joint into 12 regions, for each of which joint space narrowing (JSN), erosions, and sclerosis are assessed. For this study, we also observed the existence of

intra-articular gas and diffuse idiopathic skeletal hyperostosis (DISH) lesions for each region. Quantitative variables are expressed as mean ± standard deviation, qualitative variables as numbers and percentages. Wilcoxon rank-sum test was used to determine factors associated with a higher CT score.

Results: A total of 66 patients were included. Mean (SD) age was 65.10 ± 10.59 with a mean (SD) duration of disease of 22.87 ± 14.95 years. 60.29% were male, and 87.04 % were HLA-B27 positive. 40.30% had a bamboo spine. CT findings are described in Table 1. The vast majority of patients have a positive JSN score but significant erosions are found in only a minority of cases. This is partly explained by the fact that 55.9% of the patients had at least one complete bilateral ankylosis (and therefore no erosions) on one of the three slices studied. Bilateral anklylosis was associated with a longer duration of disease (p<0.001) and presence of bamboo spine (p<0.001). Also noteworthy is the low proportion of DISH compared to the general population in this age group, which is 15-25%. Factors associated with a higher total CT score were male sex (p=0.017), longer duration of disease (p<0.001), tobacco use (p=0.033), presence of bamboo spine (p=0.004), absence of DISH (p=0.045) and absence of intra-articular gas (p<0.001). The distribution of lesions appeared to be homogenous over all 24 regions studied (Figure 1).

Conclusion: CT findings in AS patients over 50 years of age are mostly represented by changes in joint space, with bilateral ankylosis present in half of the patients. AS appears to be a protective factor for DISH.

POS0968

ARE THERE CLUES FOR THE SCREENING OF SPONDYLOARTHRITIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES?

B. Farisoğulları[1], O. Keskin[2], B. Usta[3], G. K. Yardımcı[1], E. Parlak[2], T. Kav[2], O. Karadag[1], U. Kalyoncu[1]. [1]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; [2]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Gastroenterology, Ankara, Turkey*; [3]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey*

Background: SpA is the most frequent extra-intestinal manifestation in patients with IBD (1). Questioning IBD patients in terms of SpA and referring patients to the rheumatology clinic is important for early diagnosis and treatment management.

Objectives: We aimed to diagnose SpA early by using the DETAIL questionnaire to IBD patients and to compare it with the study validated for each question (2).

Methods: In the Hacettepe University Gastroenterology Clinic, patients with IBD were questioned for musculoskeletal symptoms between March 2019 and September 2020. For this purpose, a validated DETAIL questionnaire consisting of 6 questions was asked. Patients with at least 1 positive out of 6 questions were consulted in the rheumatology clinic, and patients were evaluated for SpA by physical examination, laboratory, and imaging. For each question in the detection of arthritis in inflammatory bowel diseases (DETAIL) questionnaire, sensitivity, specificity, positive predictive value, negative predictive value, and likelihood ratio (LR) were calculated.

Results: 217 IBD patients were included in the study. Twenty patients with previously known rheumatologic diseases were excluded from the study. 49 (24%) of the remaining 197 patients had a positive answer to at least one question in the DETAIL query. 39 (20%) of these patients were evaluated in the rheumatology clinic, and 16 (8.1%) of them were diagnosed with SpA (spondylitis: 9, peripheral arthritis: 7) (Figure 1). In the DETAIL questionnaire, two patients answered 5/6 yes, five patients answered 4/6 yes, eleven patients answered 3/6 yes, ten patients answered 2/6 yes, and eleven patients answered 1/6 yes. In the six items of DETAIL, the best performances in discriminating patients affected by SpA were found in the second and fourth questions (LR + 2.9 and 1.57, respectively) (Table 1).

Conclusion: 41% of IBD patients who answered yes to at least one question in the DETAIL questionnaire were diagnosed with SpA. Especially those with sausage fingers or low back pain for at least 3 months seem more likely probability to be diagnosed with SpA. Unlike the validated study, the probability of having diagnosis of SpA was not observed in questions five and six, which questioning the inflammatory back pain parameters. The DETAIL questionnaire may be used as a useful screening tool for the detection of SpA.

UNVEILING AXIAL INVOLVEMENT IN PSORIATIC ARTHRITIS: AN ANCILLARY ANALYSIS OF THE ASAS-PERSPA STUDY

D. Benavent[1], C. Plasencia[1], D. Poddubnyy[2], M. Kishimoto[3], F. Proft[2], H. Sawada[4], C. López-Medina[5,6], M. Dougados[5,7], V. Navarro-Compán[1].
[1]Hospital Universitario la Paz-IdiPaz, Rheumatology Service, Madrid, Spain; *[2]Charité Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology, Berlin, Germany*; *[3]Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Tokyo, Japan*; *[4]Juntendo University School of Medicine, Department of Internal Medicine and Rheumatology, Tokyo, Japan*; *[5]Hôpital Cochin. Assistance Publique- Hôpitaux de Paris, Rheumatology Department, Paris, France*; *[6]Reina Sofia University Hospital, IMIBIC, University of Córdoba, Rheumatology Department, Córdoba, Spain*; *[7]INSERM U1153, Clinical Epidemiology and Biostatistics, Paris, France*

Background: Heterogeneity in psoriatic arthritis (PsA) is a current matter of discussion, especially concerning axial involvement.
Objectives: To determine the profile of axial PsA (axPsA) in a worldwide setting. Secondly, to identify predictive factors associated with the development of axial involvement in patients with PsA.
Methods: Data from 3684 patients with axial spondyloarthritis (axSpA) or PsA from the ASAS-PerSpA study were analysed. The ASAS-PerSpA is an observational, cross-sectional study that recruited consecutive patients with SpA from 68 centers worldwide. For this analysis, 367 PsA patients ever presenting axial involvement according to their rheumatologist were defined as axPsA and compared with 2651 axSpA patients, using logistic regression to later identify predictive factors for rheumatologist diagnosis of axPsA. In addition, the axPsA patients were also compared with 666 PsA patients without axial involvement (pPsA) and the characteristics associated with axial manifestations were determined by logistic regression analysis.
Results: Among all patients, 2651 were identified as axSpA and 1033 patients as PsA. Among those with axial involvement, 2651 were identified as axSpA (100% of axSpA) and 367 as axPsA (35.5 % of PsA). In comparison with axSpA, axPsA patients were less frequently males, older, less frequently HLA-B27 positive and had a higher body mass index (Table 1). Additionally, while patients with axPsA had more peripheral manifestations and psoriasis, concomitant IBD and uveitis were higher in axSpA. In the multivariable analysis, older age at diagnosis (OR= 1.04), peripheral arthritis (OR= 7.32) and dactylitis (OR= 2.82) were significantly associated with a diagnosis of axPsA. However, uveitis (OR= 0.22), IBD (OR= 0.12) or HLA*B27 carriership (OR= 0.26) were inversely associated with axPsA diagnosis as compared to axSpA. Furthermore, axial involvement in patients with PsA was significantly associated with male gender (OR= 1.68), elevated CRP (OR= 2.87), and the absence of psoriasis (OR= 0.33).
Conclusion: In this worldwide setting, axPsA was defined by rheumatologists as a unique phenotype, with disease features lying between axSpA and pure pPsA. Male gender, elevated CRP and the absence of psoriasis were associated with axial involvement in patients with PsA.

POS0970 ASSESSMENT OF THE ASSOCIATION BETWEEN ESTIMATED CARDIOVASCULAR RISK AND MASEI INDEX IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

I. C. Aranda-Valera[1,2,3], I. Gómez García[1,2,3], M. L. Ladehesa Pineda[1,2,3], M. C. Ábalos-Aguilera[1,2,3], C. López-Medina[1,2,3], E. Collantes Estevez[1,2,3]. [1]*Reina Sofía Hospital, Rheumatology Service, Córdoba, Spain*; [2]*IMIBIC, Rheumatology Service, Córdoba, Spain*; [3]*University of Córdoba, Rheumatology Service, Córdoba, Spain*

Background: It has been shown that the cardiovascular risk (CV) in spondyloarthritis (SpA) patients is higher than that of the general population. Furthermore, an association has recently been described between structural damage at the axial level and an increase in estimated CV risk [1].
Objectives: To evaluate the association between the estimated cardiovascular risk (CV) and the presence of subclinical atherosclerosis with the MASEI index (Madrid Sonographic Enthesis Index) in patients with axial spondyloarthritis (Ax-SpA) as an expression of peripheral enthesitis.
Methods: Cross-sectional study performed in 103 patients with ax-SpA from the Córdoba AxSpA Task force, Registry and Outcomes (CASTRO), in which patients undergoing treatment with biological therapy and with a previous history of CV event were excluded. Clinical data, disease activity data and factors related to CV risk were collected, as well as the presence of persistently elevated CRP levels in the five years prior to the study visit. The SCORE index was calculated, as well as the thickness of the carotid intima media (CIMT) and the MASEI index, both measured by ultrasound. The association between MASEI-SCORE and MASEI-atheroma plaques was evaluated using generalized linear models (GLM), adjusted for time of evolution of the disease, disease activity and smoking.
Results: Of the patients included, 35 were men (34.0%), with a mean age of 45.2 (±12.1) years and time of evolution of the disease of 18.5 (±13.0) years. The mean MASEI score was 13.6 (±9.1), and the mean SCORE score was 8.1 (±8.9). The GLM regressions showed that the MASEI was independently associated with the SCORE (coefficient β 0.22; 95% CI 0.02-0.43) adjusted for the duration of the disease, smoking, and the presence of persistent CRP (Table 1A). The MASEI index was also significantly associated with the CIMT, although these differences disappeared when the model was adjusted for other factors (Table 1B).

Table 1. A. Association between MASEI and SCORE adjusting for disease duration, smoking status and CRP.

	Crude model		Adjusted for disease duration		Adjusted for disease duration and smoking		Adjusted for disease duration, smoking and CRP	
	β *coefficient (95%CI)*	**p-value**	β *coefficient (95%CI)*	**p-value**	β *coefficient (95%CI)*	**p-value**	β *coefficient (95%CI)*	**p-value**
MASEI	0.37 (0.20-0.55)	<0.001	0.25 (0.08-0.42)	0.006	0.25 (0.09-0.42)	0.004	0.22 (0.02-0.43)	0.039

Conclusion: In patients with ax-SpA, peripheral enthetic damage measured by the MASEI index is associated with an increase in estimated CV risk independently of the time of evolution, smoking and levels of CRP.

POS0971 HOW DO CLINICAL AND SOCIOECONOMIC FACTORS IMPACT ON WORK DISABILITY IN EARLY AXIAL SPONDYLOARTHRITIS? FIVE-YEAR DATA FROM THE DESIR COHORT

E. Nikiphorou[1,2], A. Boonen[3,4], B. Fautrel[5], P. Richette[6], R. B. M. Landewé[7,8], D. Van der Heijde[9], S. Ramiro[7,9]. [1]*King's College London, Centre for Rheumatic Diseases, London, United Kingdom*; [2]*King's College Hospital NHS Trust, Rheumatology, London, United Kingdom*; [3]*Maastricht University Medical Center and Care and Public Health Research Institute (CAPHRI), Rheumatology, Maastricht, Netherlands*; [4]*Academic Hospital Maastricht, Internal Medicine, Division of Rheumatology, Maastricht, Netherlands*; [5]*Sorbonne University – Assistance Publique Hopitaux de Paris, Pitie Salpetriere Hospital, Pierre Louis Institute for Epidemiology and Public Health, INSERM UMRS 1136, PEPITES Teams, Rheumatology, Paris, France*; [6]*Université de Paris, Hopital Lariboisière, Rheumatology, Paris, France*; [7]*Zuyderland MC, Rheumatology, Heerlen, Netherlands*; [8]*Amsterdam University Medical Center, Rheumatology, Amsterdam, Netherlands*; [9]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: There remains substantial unmet need to study work disability (WD) in early axSpA. Previous studies suggest that treatment interventions alone do not improve work outcomes and that socioeconomic (SE) as well as clinical factors may play an important role.
Objectives: To investigate the occurrence of WD and the impact of clinical and SE factors on WD in early axial spondyloarthritis (axSpA).
Methods: Patients with a clinical diagnosis of axSpA from the DESIR cohort up to 5 years of follow-up (6-month visits in the first 2 years, followed by annual visits) were studied. Time to WD and potential baseline and time-varying predictors were explored, with a focus on SE variables: age, gender, smoking status since last visit, ethnicity (Caucasian vs other), job type based on 'collar' (blue vs white), educational status (low vs high -university), marital status (married vs not) and parental status (number of children); and clinical factors: disease activity (ASDAS/BASDAI), function (BASFI), mobility (BASMI), at each time point. The incidence of WD was calculated as the number of WD events over the total number of person-days under observation. Univariable analyses, followed by collinearity and interaction tests, guided subsequent multivariable Cox survival analyses.
Results: A total of 704 axSpA patients with work-related data, mean (SD) age 33.8 (8.6), were studied. The estimated incidence of WD amongst those at risk and across the five years of DESIR, was 0.05 (95% CI 0.03, 0.06) per 1000 days (total person-days of observation of 999,999). Mean (SD) time to WD was 976 days (SD 476), (min 163, max 2021 days). In people who developed WD, 25% did so at 595 days; 50% and 75% at 1050 and 1433 days, respectively. Significant differences in age, level of education, marital and parental status as well as disease activity, function and mobility, all at baseline, were seen between those developing WD vs those who never did. In multivariable models (Table 1), older age, higher ASDAS and BASFI all strongly predicted more WD (p<0.005). In separate models adjusted for age, gender and education, BASFI and BASMI both predicted WD. SE factors, including education attained, were not associated with a risk for WD. There were no relevant interactions between clinical variables and SE factors.

Table 1. Univariable and multivariable model analyses with WD as outcome.

Type of analysis	**Univariable**	**Multivariable model Focus on ASDAS**	**Multivariable model Focus on BASFI/ BASMI**
	HR (95% CI)	**HR (95% CI) (N=653)**	**HR (95% CI) (N=639)**
Explanatory variables			
Age	1.07 (1.04, 1.11)	1.06 (1.02, 1.10)	1.03 (0.99, 1.08)
Male gender	0.68 (0.37, 1.23)	1.10 (0.58, 2.08)	1.00 (0.50, 2.02)
High education	0.25 (0.14, 0.48)	0.57 (0.29, 1.11)	0.42 (0.19, 0.90)
Parental status	1.36 (1.09, 1.70)	NS	NS
ASDAS (CRP)	2.40 (1.77, 3.26)	1.79 (1.27, 2.54)	Not tested
BASFI, 0-10	1.54 (1.36, 1.75)	1.42 (1.22, 1.65)	1.53 (1.29, 1.81)
BASMI, 0-10	2.13 (1.65, 2.75)	NS	1.49 (1.10, 2.00)
Symptom duration	0.79 (0.56, 1.12)	NS	NS
HLA B27 positive	0.64 (0.36, 1.13)	NS	NS
Hip involvement (baseline) vs not	1.98 (1.02, 3.82)	NS	NS
Comorbidity count	2.33 (1.68, 3.21)	NS	NS
NSAID use last 6m (vs no use)	1.01 (1.00, 1.02)	NS	NS
Oral Corticosteroid use (vs no)	2.72 (1.27, 5.83)	NS	NS
csDMARD use last 6m (vs no)	2.20 (0.90, 5.41)	NS	NS
TNFi use	2.15 (1.19, 3.87)	NS	NS

NS=Not significant

Conclusion: In this early axSpA cohort, WD was an infrequent event. Nevertheless, clinical factors are amongst the strongest predictors of WD, over SE factors,

with worse disease activity, function and mobility all independently implicated with more WD in early axSpA. Disease severity remains a strong predictor of adverse work outcome, despite substantial advances in therapeutic strategies in axSpA.

POS0972 CLUSTER ANALYSIS OF ANKYLOSING SPONDYLITIS PATIENTS REVEALS DIFFERENTIAL DRUG SURVIVAL OF ANTI-TNF AGENTS ACCORDING TO DISTINCT CLINICAL PHENOTYPE

S. Lee[1], S. Y. Kang[1], Y. H. Eun[1], H. Kim[1], H. S. Cha[1], E. M. Koh[1], J. Lee[1].
[1]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Republic of (South Korea)*

Background: Previous studies using cluster analysis technique in ankylosing spondylitis (AS) patients have consistently identified distinct groups of patients in terms of their clinical characteristics: those with pure axial symptoms and those with a high frequency of peripheral manifestations [1,2]. Due to the cross-sectional nature of these studies, however, prognostic information such as drug survival of anti-TNF agents in these group were not provided.
Objectives: Using the data retrieved from Korean College of Rheumatology Biologics (KOBIO) registry, which includes longitudinal data of AS patients using anti-TNF agents, this study aims to perform cluster analysis to differentiate AS patients in terms of clinical phenotypes and to examine the differential drug survival of anti-TNF agents in these groups.
Methods: Clinical characteristics and demographic data of AS patients in KOBIO registry were analyzed using hierarchical clustering analysis. After clustering, drug survivals of anti-TNF agents were compared between these groups.
Results: 1,046 patients were included in the study with no missing data. The hierarchical cluster analysis classified patients in two groups; one with predominant isolated axial manifestations (axial group, n=823) and the other with more frequent extra-axial symptoms (extra-axial group, n=223). Almost all extra-axial symptoms (peripheral arthritis, enthesitis, uveitis, dactylitis, and psoriasis) were more frequently observed in extra-axial group than axial group. In addition, patients with shorter disease duration, late disease onset, and high disease activity were classified in extra-axial group (Table 1). Interestingly, the extra-axial group had lower drug survival probability than the axial group (p=0.008, Figure 1).
Conclusion: Cluster analysis of AS patients using anti-TNF agents classified two distinct groups of patients in terms of their clinical phenotypes and revealed that the patients with prominent extra-axial manifestations had lower drug survival with anti-TNF agents.

POS0973 CONTEXTUAL FACTORS SHOULD COMPLETE THE ASSESSMENT OF FUNCTIONING IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS (AXSPA)

U. Kiltz[1], E. Ahomaa[2], B. Buehring[1], X. Baraliakos[1], D. Kiefer[1], J. D. Leicht[1], J. Braun[1]. [1]*Rheumazentrum Ruhrgebiet at Ruhr-University Bochum, Rheumatology, Herne, Germany*; [2]*St. Franziskus-Hospital, Department of Orthopedic Surgery, Cologne, Germany*

Background: Functioning of patients (pts.) with axial spondyloarthritis (axSpA) is influenced by a variety of factors. In contrast to clinical factors, the influence of contextual factors on functioning has not been well studied. According to the According to the International Classification of Functioning, Disability and Health (ICF), functioning is a complex interaction between health status and contextual factors such as social support, relationships and attitudes.
Objectives: The aim of this study is to understand limitations in participation and to investigate barriers and facilitators of contextual factors in pts. with axSpA.
Methods: Consecutive axSpA pts. underwent a standardized assessment with collection of patient and disease characteristics, patient-reported outcomes (ASDAS, BASFI, BASMI, PHQ-9, ICF Measure of Participation and ACTivities questionnaire (IMPACT-S (0-100%)), ASAS Health Index (ASAS HI and environment factor item set (EFIS) (1). The EFIS contains 9 dichotomous questions addressing ICF categories of products and technologies (e1), support and relationship (e3), attitudes (e4) and health services (e5). Validated cut-offs of ASAS HI were used to categorize global functioning.
Results: A total of 200 axSpA pts. were included: 69% males, 44.3±12.5 years, symptom duration 17.9±12.6 years, ASDAS 2.5±1.1, BASFI 4.0±2.7, BASMI 3.5±1.8, ASAS HI 7.0±4.1. Pts. reported limitations in the IMPACT-S activity and participation domain (82.3% (15.2) and 83.5% (16.8), respectively. The majority of pts. reported as barrier that treatment of axSpA requires time (e4, 58.5%). A minority of pts. but quite a few reported as barrier the need for support by family members (e3, 43.5%), the need to modify home and work environment (e1, 39.5%) and that they cannot rely on family members for help (e3, 22%). Some pts. (< 20%) reported that they have problems to be understood by health care professionals when experiencing a flare (e5, 18.5%), that pts. at home are not adequately taken care of (e4, 18.5%), disliking friends' behavior toward them (e4, 13.5%), and that friends are too demanding (e4, 13%). The majority of pts. (e4, 75.9%) identified attitudes of friends as the only and major facilitator. All pts. reporting at least one barrier had significantly worse global functioning (ASAS HI, IMPACT-S), and depression (PHQ-9) compared to patients who reported no barriers in the respective ICF categories (p< 0.01). Similarly, pts. with poor functioning are more likely to report barriers in contextual factors compared to pts. with good functioning (Table 1). Pts. having to ask for more support from their families expressed the feeling that they cannot rely on that.

Conclusion: Barriers more than facilitators of contextual factors are present in pts. with axSpA. This study shows that barriers in contextual factors are more common in pts. with impairments in self-reported and performed functioning as in those without impairments. This underlines the importance of contextual factors in the management of axSpA pts.

POS0974

IMPROVEMENT IN THE DIAGNOSTIC DELAY OF AXIAL SPONDYLOARTHRITIS, RESULTS FROM REAL WORLD DATA

J. Feld[1,2], O. Elkayam[3,4], A. Druyan[4,5], T. Reitblat[6], A. Balbir-Gurman[2,7], A. Hadad[1], T. Gazitt[1], M. Elias[1], V. Furer[3], T. Mashiach[7], D. Zisman[1,2]. *[1]Carmel Medical Center, Rheumatology, Haifa, Israel*; *[2]Technion - Israel Institute of Technology, Medicine, Haifa, Israel*; *[3]ביבא לת בוליכיא מילוח תיב, Rheumatology, Tel Aviv-Yafo, Israel*; *[4]רלקאס ש"ע ביבא לת תטיסרבינוא האופרל הטלוקפה, Rheumatology, ופי ביבא לת, Israel*; *[5]Sheba Medical Center, Rheumatology, Ramat Gan, Israel*; *[6]Barzilai Medical Center, Rheumatology, Ashkelon, Israel*; *[7]Rambam Health Care Campus, Rheumatology, Haifa, Israel*

Background: Diagnostic delay is a major challenge in axial spondyloarthritis (axSpA) with an extended interval of 8-10 years in Europe and 14 years in the United States between symptom onset and disease diagnosis (1, 2).

Objectives: To assess the delay in the diagnosis of axSpA over time in a real world axSpA cohort diagnosed in the last 3 decades and to evaluate factors associated with this delay.

Methods: A cohort of axSpA patients was recruited from a national multicenter registry of inflammatory arthritis. This cohorts' demographic, clinical and diagnostic variables were studied. The diagnostic delay was defined as the time interval between the year of first symptom and year of diagnosis. The mean and median diagnostic delay were calculated. A survival analysis was performed evaluating the association between the demographic, clinical and diagnostic variables on the diagnostic delay.

Results: Of the 373 axSpA patients in the registry, 198 (47%) are men. Ankylosing spondylitis fulfilling New York criteria was diagnosed in 73% of the patients. HLA-B*27 positivity was found in 64% of patients. The majority of the patients (63%) reported symptom onset between the age of 21-45, 21% before the age of 21 and 16% after the age of 45. Nine percent were diagnosed before the age of 21, 28% between 21-30, 23% between 31-40, 21% between 41-50 and 18% after the age of 50. One hundred and ten patients were diagnosed before 2000, 133 between 2001-2009 and 130 between 2010-2020. The mean and median delay in diagnosis was 9.1, 6 (±8.4) years when diagnosed before 2000, 5, 4 (±4.1) years when diagnosed 2001-2009, and 2, 1 (±1.5) years when diagnosed 2010-2020, respectively (graph 1). The only variable which was found to be associated with a shorter delay was the interval between symptom onset and first rheumatology consult: HR of 5.86 (4.3-8, p<0.001) if the rheumatology visit was within the first year of symptoms, HR 3.5 (2.4-5, p<0.001) if assessed 2-3 years after symptom onset. Additionally, age <21 at symptom onset was associated with a shorter delay (p=0.005). Sex, type of axSpA (radiographic vs. non radiographic axSpA), level of education, and HLA-B*27 positivity were not associated with a delay in diagnosis.

Conclusion: Delay in axSpA diagnosis has significantly improved in this real-world cohort during the last decade. The most significant factor associated with a faster diagnosis was the time of the first rheumatology consult relative to symptom onset. Increasing the awareness of disease manifestations and early referral to a rheumatology service can improve the diagnosis delay of axSpA.

Background: Clinical characteristics of nonradiographic axial spondyloarthritis (nr-ax-SpA) are highly variable across patients, and may potentially vary across patient populations, particularly due to differing distributions of human leukocyte antigens (HLA) and other genetic factors. The majority of nr-ax-SpA studies have been conducted in Europe, the United States, and small studies are reported from Asia [1].
Objectives: To delineate clinical characteristics of patients with nr-ax-SpA in Asian countries in comparison to other areas of the world.
Methods: Utilizing the ASAS-COMOSPA data, an international cross-sectional observational study of SpA patients, we analyzed information on demographics, disease characteristics, comorbidities, and risk factors. Patients were classified by region: Asia (China, Japan, Singapore, South Korea, and Taiwan), and non-Asian countries (Europe, Americas, and Africa); patient characteristics, including diagnosis and treatment, were compared.
Results: Among 3984 SpA patients included in the study, 1094 were from centers in Asian countries, and 2890 from other regions. 112/780 (14.4%) of axial SpA patients in Asian countries were nr-ax-SpA, substantially less than in other countries (486/1997, 24.3%). Nr-ax-SpA patients in Asian countries compared to nr-ax-SpA in other countries were more likely male (75.9 vs 47.1%), have onset (22.8 vs 27.8 years) and diagnosis (27.2 vs 34.5 years) at younger age, and experience less diagnostic delay (1.88 vs 2.92 years) (Table 1). Nr-ax-SpA patients in Asian countries have higher prevalence of positive HLA-B27 (90.6% vs 61.9%) and fewer peripheral signs such as arthritis, enthesitis, or dactylitis (53.6% vs 66.3%) but have similar rate of extra-articular manifestations (psoriasis, IBD, or uveitis) and co-morbidities. Disease activity, functional impairment, and inflammation on MRI were less in nr-ax-SpA patients in Asian countries. NSAIDs response was higher and use of methotrexate and b-DMARDs were lower among nr-ax-SpA in Asian countries.
Conclusion: Among axial SpA patients, substantially lower frequency of nr-ax-SpA was observed in Asian countries compared to other regions of the world. Nr-ax-SpA patients in Asian countries were predominantly male, and had younger disease onset with higher HLA-B27 positivity rate and less peripheral signs, and better response to NSAIDs. These results offer an opportunity to improve both early diagnosis and treatment of nr-ax-SpA patients in Asian countries.

Table 1. Characteristics of nonradiographic axial SpA in Asia versus non-Asian regions

Variables	Asia	non-Asian regions	p value
N	112	486	
Age at disease diagnosis, yrs	27.2 [21.1, 39.6]	34.5 [27.7, 41.7]	<0.001
Diagnostic delay, yrs	1.88 [0.27, 5.56]	2.92 [0.59, 9.58]	0.011
Male (%)	85 (75.9)	229 (47.1)	<0.001
Sacroiliitis on MRI among tested (%)	49 (67.1)	341 (82.2)	0.005
HLA B27 positivity among measured (%)	96 (90.6)	273 (61.9)	<0.001
Inflammatory Back Pain (%)	107 (95.5)	478 (98.4)	0.076
Arthritis, enthesitis, or dactylitis (%)	60 (53.6)	322 (66.3)	0.016
Psoriasis (%)	12 (10.7)	82 (16.9)	0.142
Uveitis (%)	20 (17.9)	81 (16.7)	0.870
Inflammatory bowel disease (%)	5 (4.5)	27 (5.6)	0.817
Elevated CRP (%)	37 (33.0)	213 (43.8)	0.048
Physician global assessment (0-10)	2.0 [1.0, 5.0]	2.0 [1.0, 4.0]	0.741
Patient global assessment (0-10)	3.0 [1.0, 6.0]	4.0 [2.0, 6.0]	0.012
ASDAS-CRP	1.40 [0.95, 2.08]	1.97 [1.21, 2.78]	<0.001
BASFI	0.8 [0.05, 2.65]	2.9 [0.8, 5.6]	<0.001
Good response to NSAIDs (%)	80 (71.4)	272 (56.0)	0.004
Methotrexate use (%)	18 (16.1)	134 (27.6)	0.016
Biological DMARDs use (%)	27 (24.1)	191 (39.3)	0.004

Nasonova Research Institute of Rheumatology, Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Medical and Social Problems in Rheumatology, Moscow, Russian Federation*; *[3]I.M. Sechenov First Moscow State Medical University, Rheumatology, Moscow, Russian Federation*; *[4]Municipal Autonomous Institution "City Clinical Hospital No. 40", Rheumatology, Yekaterinburg, Russian Federation*; *[5]Omsk region "Regional clinical hospital", Rheumatology, Omsk, Russian Federation*; *[6]Medical Institute of the Tula State University, Rheumatology, Tula, Russian Federation*; *[7]Tyumen Regional Clinical Hospitai №1, Rheumatology, Tyumen, Russian Federation*

Background: Limited data are available on retention rates of biologic therapy in psoriatic arthritis (PsA) patients (pts) with axial involvement. It has been shown that in the subset of pts with prevalent axial involvement (AS versus PsA and AxSpA versus PsA) a longer duration of anti-TNF-α-therapy was observed as compared to peripheral arthritis [1].
Objectives: To compare retention rates of biologic therapy in PsA pts with and without axial involvement in routine clinical practice.
Methods: 731 pts with PsA according to CASPAR criteria were included in the study. Data were collected from 43 rheumatology clinics over various regions of the Russian Federation. Among the pts, 243 (33.0%) (M/F 132/111) were given biologic therapy. Pts' age 45.9±12.8 years (yrs), disease duration 8.6±6.5 yrs. Pts underwent standard clinical examination of PsA activity and were split into two groups (gr.), with and without axial PsA (axPsA): axPsA(+) and axPsA(-). Pts in the axPsA(+) gr. had inflammatory back pain by ASAS criteria and/or radiographic sacroiliitis (SI) (unilateral grade≥3 or bilateral grade≥2) and/or active MRI SI and/or typical of axPsA changes of the cervical and/or lumbar spine (marginal/paramarginal syndesmophytes, ankylosis of the facet joints). Pts in the axPsA(-) gr. had only peripheral arthritis. The axPsA(+) gr. included 143 (58.8%) pts, the axPsA(-) gr. 100 (41.2%) pts. 163 (67.1%) pts were treated with TNF inhibitors (TNF-i), 80 (32.9%) pts with interleukin inhibitors (IL-i): 55 pts with Ustekinumab, 25 pts with Secukinumab. During the TNF-i treatment courses Infliximab was given to 34 pts, Adalimumab to 53 pts, Etanercept to 36 pts, Golimumab to 27 pts and Certolizumab Pegol to 8 pts. The observation period lasted 12 months. Treatment retention rates were analyzed using Kaplan-Meier curves and the log-rank test.
Results: Analysis of the treatment retention rates revealed statistically significant differences between the axPsA(+) and the axPsA(-) grs. After 12 months of observation, 72.9% of pts in the axPsA(-) gr. continued receiving biologic therapy, while in the axPsA(+) gr. only 53.1% of pts (p=0.0027) received it. The same kind of differences in anti-TNF therapy were found between the axPsA(-) gr. and the axPsA(+) gr.: 82.2% and 62.3% pts respectively (p=0.011) continued receiving TNF-i after 12 months. However no statistically significant differences were found between the two grs. in the treatment retention rates of IL-i therapy: after 12 months of observation 55.5% of axPsA(-) pts and 37% of axPsA(+) pts (p=0.086) continued receiving IL-i.
Conclusion: In routine clinical practice, retention rates of biologic therapy were found to be worse in PsA pts with axial involvement. In clinical practice, TNF-i are prescribed twice as often than IL-i. However, considering the need of personalized therapy, in case of axPsA the use of IL-i is preferable because their treatment retention rates don't depend on axial involvement.

Background: Patients with axial spondyloarthritis (axSpA) may present with concomitant psoriasis (Ps) in approximately 10% of cases. As with axSpA, Ps is also associated with an accelerated atherosclerosis process[1]. However, it is unknown whether the presence of Ps confers an increased cardiovascular (CV) risk in patients with axSpA.

Objectives: To compare factors related to the disease, CV risk factors, atherosclerotic burden, and CV events in patients with axSpA with and without Ps.

Methods: Cross-sectional analysis of the AtheSpAin cohort, a Spanish multicenter cohort designed for the study of atherosclerosis in axSpA. We compared axSpA patients with and without concomitant psoriasis, focusing mainly on CV risk characteristics. Background information on CV risk factors, CV events, and disease-related factors was reviewed, and data on maximum body index, blood pressure, lipid profile, and disease status at the time of the study were also obtained. Carotid ultrasound (US) was performed in all patients at the time of the study, including measurement of carotid intima-media wall thickness (cIMT) and plaque detection according to the Mannhein consensus criteria.

Results: A set of 882 axSpA patients were included. 786 (89.1%) of them had no concomitant Ps, which was present in 96 (10.9%) patients. Although the mean age was similar, male sex was more prevalent in axSpA patients with Ps (79.1% Vs 66.5%, p=0.01) (Table 1).

Furthermore, it was found that axSpA with Ps had a more frequent history of synovitis (50% vs 33%, p = 0.001), dactylitis (13% vs 6%, p = 0.011) and concomitant inflammatory bowel disease (13% vs 6%, p = 0.01). AxSpA patients with Ps had a non-significant trend towards a higher prevalence of asymmetric sacroiliitis (23 vs 16%, p = 0.064) and had a lower frequency of positive HLA-B27 status (56% vs 72%, p = 0.003). Regarding the management of the disease, prednisone (23% vs 12%, p = 0.02), methotrexate (30% vs 15%, p = 0.000) and anti-TNFα therapy (50% vs 34%, p = 0.002) were more commonly used in the group with Ps.

Regarding CV risk characteristics, no differences were observed either in the prevalence of traditional CV risk factors (Table 1), nor in the total serum level, HDL and LDL, blood pressure and body mass index at that time of the study. However, axSpA patients with Ps showed a higher prevalence of CV events (9% vs 4%, p = 0.05), including ischemic heart disease (6% vs 3%, p = 0.042) and ischemic stroke (4% vs 1%, p = 0.016) (Table 1). The subclinical atherogenic burden was also more severe in the group with Ps, with a higher prevalence of carotid plaques (39% vs 31%, p = 0.098), and higher values of cIMT (0.664 ± 0.170 mm vs 0.642 ± 0.142 mm, p = 0.16), although the differences did not reach statistical significance.

Table 1. Main sociodemographic and cardiovascular differences among axSpA patients with and without psoriasis.

	axSpA without psoriasis (n=786)	axSpA with psoriasis (n=96)	p
Men/Women, n	523/268	76/20	**0.010**
Mean age (years) ±SD at the time of study	49 ± 13	49 ± 13	0.81
AS/nr-AxSpa	625/166	77/19	0.79
History of CV risk factors			
Current smokers	267 (34)	30 (31)	0.60
Obesitty	174 (22)	26 (27)	0.29
Dyslipidemia	262 (33)	35 (36)	0.48
Hypertension	211 (27)	28 (29)	0.57
Diabetes Mellitus	56 (7)	8 (8)	0.65
Chronic Kidney Disease	19 (2)	3 (3)	0.72
History of cardiovascular events, n (%)	33 (4)	9 (9)	**0.023**
Ischemic heart disease	20 (3)	6 (6)	**0.042**
Congestive heart failure	2 (0)	1 (1)	0.29
Ischemic stroke	6 (1)	4 (4)	**0.016**
Peripheral artery disease	6 (1)	0 (0)	0.99
CV data at the time of study			
Carotid plaques	244 (31)	38 (39)	0.098
IMT mm	0.642 ± 0.142	0.664 ± 0.170	0.16
IMT >= 900 mm	40 (5)	6 (6)	0.66

Abbreviations: AS = ankylosing spondylitis. AxSpA= axial spondylitis. CV = cardiovascular. IMT = intima-media wall thickness. Nr-axSpA = no-radiographic axial spondylitis.

Conclusion: The presence of Ps may confer additional CV risk to axSpA patients and is associated with particular disease related factors.

POS0978 DISEASE CONTROL IN PSORIATIC ARTHRITIS PATIENTS WITH OR WITHOUT AXIAL MANIFESTATIONS IN REAL CLINICAL PRACTICE IN SPAIN: RESULTS FROM THE MIDAS STUDY

E. De Miguel[1], J. Gratacos-Masmitja[2], A. P. Cacheda[3], J. M. Rodríguez-Heredia[4], A. Gallego[5], E. Beltrán[6], B. Font Ramos[7], C. Sastré[7], C. Sanabra[7]on behalf of MIDAS group. *[1]Hospital Universitario La Paz, Rheumatology Service, Madrid, Spain*; *[2]Hospital Universitario Parc Taulí, Rheumatology Service, Sabadell, Spain*; *[3]Hospital Universitario Son Llatzer, Rheumatology Service, Palma, Spain*; *[4]Hospital Universitario Getafe, RheumatologySservice, Madrid, Spain*; *[5]Complejo Hospitalario Universitario Badajoz, Rheumatology Service, Badajoz, Spain*; *[6]Hospital del Mar, Rheumatology Service, Barcelona, Spain*; *[7]Novartis Farmacéutica, Rheumatology, Barcelona, Spain*

Background: MIDAS study assessed the disease activity in psoriatic arthritis (PsA) patients treated in clinical practice in Spain.

Objectives: This sub-analysis compared disease activity between PsA patients with or without axial manifestations.

Methods: MIDAS is an observational, non-interventional, cross-sectional, multicenter study conducted in Spain. Patients included were ≥18 years old with ≥6 months since diagnosis, were classified by CASPAR criteria and had initiated treatment ≥3 months. Disease activity was measured by Disease Activity in Psoriatic Arthritis (DAPSA) and Minimal Disease Activity (MDA). Axial involvement was defined according to the presence of inflammatory back pain assessed by rheumatologist.

Results: 312 evaluable PsA patients were included in this analysis, 12.2% of which presented with axial involvement. PsA patients with axial manifestations reported longer time from onset of symptoms to diagnosis and disease duration, higher presence of concomitant diseases, HLA-B*27+ status, C-reactive protein

(CRP) levels, perception of uncontrolled disease and presence of swollen and tender joints compared to patients without axial involvement. A higher proportion of PsA patients with axial manifestations were treated with a biologic compared with those without axial involvement 68.4% vs 57.3% (Table 1). Patients with axial involvement showed a higher impairment of their quality of life compared to those without axial manifestations by a worse higher mean (SD) Psoriatic Arthritis Impact of Disease 12-item questionnaire (PSAID12) score (5.0 [2.4] vs 2.7 [2.2], respectively). In terms of disease control more patients with axial manifestations presented with moderate to high disease activity (DAPSA>14: 65.7% vs 36.8%, respectively) and did not meet the MDA criteria for remission (89.5% vs 42.7%, respectively) (Figure 1).

Conclusion: PsA patients with axial manifestations presented with a higher burden of disease and showed a worse disease control compared to those without axial involvement.

Table 1. Baseline demographic and clinical characteristics

	With axial manifestations (n=38)	Without axial manifestations (n=274)	PsA (n=312)
Age (years), mean (SD)	53.1 (10.4)	54.1 (12.4)	54.0 (12.2)
Sex (male), n (%)	17 (44.7%)	153 (55.8%)	170 (54.5%)
Time since diagnosis (years), mean (SD)	13.6 (10.1)	10.1 (8.8)	10.5 (9.0)
Time from onset of symptoms to diagnosis (years), mean (SD)	4.3 (6.1)	2.8 (4.8)	3.0 (5.0)
Presence of concomitant diseases, mean (SD)	26 (68.4%)	166 (60.6%)	192 (61.5%)

POS0979

ASSOCIATION BETWEEN HIGHER INTAKE OF CARBOHYDRATES AND FREE SUGAR WITH HIGHER DISEASE ACTIVITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

V. Rios Rodriguez[1], M. D'urso[1], C. Höppner[1], F. Proft[1], M. Protopopov[1], J. Rademacher[1], B. Muche[1], S. Lüders[1], H. Haibel[1], M. Verba[1], J. Sieper[1], D. Poddubnyy[1,2]. [1]*Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Gastroenterology, Infectiology and Rheumatology, Berlin, Germany*; [2]*Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology, Berlin, Germany*

Background: Diet has been previously described as an impact factor on the course of rheumatic diseases, such as rheumatoid arthritis and systemic lupus erythematosus (SLE). It has been previously reported that dietary sugar intake may contribute to subclinical inflammation and disease activity in SLE. However, there is very little investigation on the possible association between nutritional parameters and their influence on spondyloarthritis (SpA).

Objectives: To investigate the possible impact of nutritional parameters on the disease activity in patients with SpA.

Methods: Patients with radiographic axial SpA and starting a biological therapy were recruited between 2015 and 2019 in an extension of the prospective German Spondyloarthritis Inception Cohort (GESPIC). Dietary habits were collected at baseline using the country-specific validated food frequency questionnaire (FFQ) developed for the use in the German Health examination Survey for Adults 2008-2011. The FFQ includes questions about the frequency and amount of 53 food items, consumed during the past 4 weeks, and enabled to compute individual mean consumptions of foods in grams per day. Total energy intake (in Kcal per day) and nutritional parameters: carbohydrates, free sugars, total fats, saturated fats, mono and poly-unsaturated fats, proteins and dietary fiber, were calculated for each patient using a nutrition organization software and the database of Federal Food Code (Bundeslebensmittelschlüssel), version 3.02. Disease activity measures (BASDAI, CRP and ASDAS), as well as height, weight and body mass index (BMI) were assessed at baseline before starting the biological treatment.

Results: A total of 104 patients from 129 patients with axial SpA enrolled in the cohort were included in this nutritional analysis. The mean age (mean±SD) was 37.0±11.0 years old with symptoms duration of 11.3±9.9 years, 68.3% were males, and 86.5% were HLA-B27 positive. Patients presented BMI of 25.1±4.3 kg/m^2, BASDAI 5.6±1.4, CRP 14.0±18.2 mg/l, and ASDAS 3.5±1.0.

In the univariable and multivariable regression analysis, a higher energy intake and carbohydrates were associated with higher disease activity, measured by ASDAS, BASDAI and CRP. This association was attributable to the full intake of carbohydrates and specifically to the total of free sugars (monosaccharides

and disaccharides) and the decrease of dietary fiber as shown in the multivariable analyses (Figure 1). This effect was independent of age, sex, smoker status and BMI.

Conclusion: A higher intake of carbohydrates and a higher consumption of free sugars are associated with higher disease activity in patients with AS.

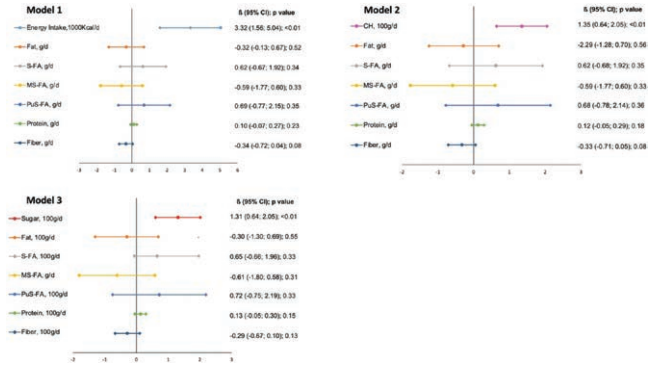

Figure 1. Multivariable linear regression analysis of the association between CRP and nutritional parameters in patients with radiographic axial SpA (n=104), adjusted for age, sex, body mass index and smoker status. Model 1 included variable of total energy intake, model 2 included variable of total intake of carbohydrates (CH) and model 3 included variable of free-sugar (monosaccharides and disaccharides).

B, linear regression coefficient; CH, carbohydrates; CI, confidence interval; MS-FA, monosaturated fatty acids; PuS-FA, polyunsaturated fatty acids, S-FA, saturated fatty acids.

ANALYSIS OF PRIMARY CARE CONSULTATION PATTERNS TO AID DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS – AN EXPLORATORY CASE SERIES

M. Al-Attar[1], W. J. Gregory[1,2], J. Mcbeth[3,4], W. Dixon[1,3,4]. [1]*Rheumatology Department, Salford Royal NHS Foundation Trust, Salford, United Kingdom*; [2]*Faculty of Health, Psychology and Social Care, Manchester Metropolitan University, Manchester, United Kingdom*; [3]*Centre for Epidemiology Versus Arthritis, University of Manchester, Manchester, United Kingdom*; [4]*NIHR Manchester Musculoskeletal Biomedical Research Centre, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom*

Background: Patients with Axial Spondyloarthritis (AxSpA) often suffer a significant delay to diagnosis. This is associated with poorer outcomes in quality of life, functional capabilities and work productivity [1]. These patients are frequent consulters to primary care in the years preceding rheumatology referral [2]. We hypothesise that analysis of primary care consultation patterns may identify as-yet undiagnosed disease, and suggest that implementing an automated diagnostic algorithm may support early action in primary care.

Objectives: To undertake a preliminary exploration of primary care consultation patterns in patients with a delayed diagnosis of AxSpA and identify themes for further research.

Methods: The study was run in Salford, UK, where unique linkage exists across electronic health records (EHR) from primary and secondary care. A dataset of patients with AxSpA was obtained from 2018-2020 hospital physiotherapy clinic records. Ten patients with a time to diagnosis ≥ 5 years were randomly selected for this exploratory analysis. Diagnostic delay was calculated based on rheumatology clinic letter documentation. Age, sex, and HLA-B27 status were recorded. All "Problem" codes from the primary care EHR up to the point of diagnosis were manually reviewed.

Results: Age at diagnosis was 32-49 years with seven males and three females. Seven were HLA-B27 positive. The average delay to diagnosis was 15.8 years (range 5-30).

On average, patients had 15 primary care consultations (range 5-24) between first coded AxSpA-related symptom and rheumatology referral. Around half of these codes were potentially AxSpA-related (for example, see Figure 1).

Six patients had a coded history of back pain. Two patients presented with other axial symptoms, including: rib pain, MSK chest pain and sciatica.

Five patients presented with peripheral joint symptoms, including: ankle pain, shoulder pain, knee problem, pain in arm, medial epicondylitis elbow, hip pain and groin pain. Of these, four had multiple presentations and three had a previous visit with axial pain.

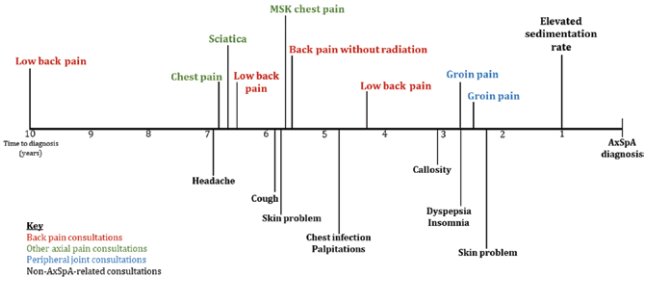
Two patients had uveitis preceding axial symptoms. One patient had peripheral joint symptoms (hip pain) preceding uveitis.

Inconsistent codes were used for the same problem presenting at different times in nine cases, including: back pain, backache, low back pain, lower back pain.

Other relevant codes were used in seven cases, including: stiffness, arthritis, saw physiotherapist and referred to pain clinic.

Figure 1 illustrates the consultation pattern for a male patient who first presented to primary care with back pain at the age of 35. Despite a relatively typical presentation, his diagnosis was made incidentally 10 years later after an ESR was checked for unrelated reasons. He was significantly disabled in function at the point of being referred to rheumatology.

Figure 1: Example of a patient's primary care consultation pattern



Conclusion: Our preliminary analysis suggests that patients with a delayed diagnosis of AxSpA have repeated primary care visits with potentially recognisable symptoms of their disease. These findings support the feasibility of future automated detection, with areas of focus including recognition of non-back pain axial symptoms, extra-articular manifestations, and peripheral joint symptoms.

Whilst half of presentations were not directly AxSpA-related, modern machine learning techniques have the ability to explore whether the pattern or frequency of these consultations are relevant to identifying undiagnosed disease. Such methods can also highlight patterns obscured by extensive data sets and inconsistent coding, with opportunity for implementation back into primary care.

POS0981

COMPUTED TOMOGRAPHY-BASED ASSESSMENT OF RADIOGRAPHIC PROGRESSION IN SPINE AND SACROILIAC JOINTS AFTER PREGNANCY IN WOMEN WITH ANKYLOSING SPONDYLITIS

K. A. Lee[1], S. Y. Lee[2], H. S. Kim[1], H. R. Kim[3], S. H. Lee[2]. *[1]Soonchunhyaung University Seoul Hospital, Internal Medicine, Seoul, Korea, Republic of (South Korea)*; *[2]Kyung Hee University Hospital at Gangdong, Internal Medicine, Seoul, Korea, Republic of (South Korea)*; *[3]Konkuk University Medical Center, Internal Medicine, Seoul, Korea, Republic of (South Korea)*

Background: Mechanical stress are one of the pathogenesis of ankylosing spondlitis (AS). During pregnancy, the mechanical overload on the spine and pelvis increases due to gravid uterus. Recently, computed tomography syndesmophyte score (CTSS) has been developed to analysis of the spinal damage in patients with AS. Indeed, CT has higher sensitivity and reliability compared to conventional radiography in the detection of sacroiliitis.
Objectives: We aimed to investigate whether pregnancy and delivery affect radiographic progression of spine and SIJ in women with AS based on CT evaluation.
Methods: This retrospective study included women aged 19-49 years with AS who performed at least twice CT scans of whole-spine or sacroilliac joints (SIJ) at intervals of 2 to 4 years. To compare the radiographic progression after delivery, we classified into 2 groups: delivery group or controls. Delivery group was restricted to subjects who had the first CT scans ~2 years before delivery and the second CT scans ~2 years after delivery. CTSS (0-522) and SIJ scores (0-40) were used to evaluate the spinal syndesmophyte and erosion, joint space narrowing, and sclerosis of SIJ.
Results: A total of 21 women in delivery group and 38 women in controls were included. The median (Q1-Q3) CTSS at baseline in delivery group and controls were 19 (16-23) and 20 (13.25-27.75), and median progression was 1 (0-3) and 0 (0-1) during the median 2.9 year follow-up. The median (Q1-Q3) SIJ scores at baseline in delivery group and controls were 13 (8-22) and 11 (6-22), and median progression was 1.5 (0-3) and 1 (0-2). The CTSS and SIJ scores significantly increased in both groups, but no difference in absolute score changes per time point between was observed. The changes in SIJ scores was comparable according to the delivery methods.
Conclusion: This study suggests that pregnancy and delivery had no effect on radiographic progression of spine and SIJ in female with AS.

POS0982

DIAGNOSTIC VALUE OF SPECT/CT IN AXIAL SPONDYLOARTHRITIS AND OTHER LOW BACK PAIN

J. S. Kim[1], K. Hyun-Sook[1], L. Kyung-Ann[1]. *[1]Soonchunhyang University Seoul Hospital, Soonchunhyang University College of Medicine, Internal Medicine, Seoul, Korea, Republic of (South Korea)*

Background: Spondyloarthropathies (SpA) including ankylosing spondylitis are characterized by inflammatory arthritis involving the spine and peripheral joints. Bone SPECT/CT is in the spotlight as it can reflect the current level of inflammation.
Objectives: We aimed to investigate the diagnostic performance of bone SPECT/CT for axial SpA (axSpA) at the level of sacroiliac joints.
Methods: Patients with low back pain who had undergone SPECT/CT of the SI joints were selected for inclusion in this study through a retrospective review of medical records from August 2016 and July 2018. We used semi-quantitative scoring methods for SPECT/CT. For visual scoring, a score of 0 was assigned when tracer uptake in the sacroiliac joint was less than that in the sacrum; a score of 1, when equal to that in the sacrum; and a score of 2, when greater than that in the sacrum. A score of 2 was considered positive for the diagnosis of sacroiliitis on SPECT/CT (Figure 1). The diagnosis of axSpA was retained when patients fulfilled the Assessment of SpA International Society criteria.
Results: A total of 164 patients were enrolled (34 patients with axSpA). The remaining 130 patients had non-axSpA rheumatic inflammatory disease (n=24), vertebral disk herniation (n=13), avascular necrosis (n=11), and others such as bursitis, and fracture (n=85). The mean age of aSpA (37.8±15.6 years) was lower than controls (49.8±16.4 years) (p<0.001), and axSpA (64.5 %) had more male than others (42.1 %) (p=0.024). The sensitivity, specificity, positive and negative predictive values of bone SPECT/CT for axSpA were 83.9%, 63.2%, 34.7%, and 94.4%, respectively. The bone SPECT/CT maximal score and BASDAI score has positive correlation (r=0.481, p=0.007). The bone SPECT/CT compared with MRI is marginal correlation (k=0.369, p<0.001).
Conclusion: In patients with low back pain, the bone SPECT/CT has a high negative predictive value that can exclude AS. In addition, when contraindication in MRI the bone SPECT/CT can be an alternative test.

WORK PARTICIPATION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS IN GERMANY: RESULTS FROM A MULTICENTER, OBSERVATIONAL SURVEY (ATTENTUS-AXSPA)

U. Kiltz[1], K. Hoeper[2], L. Hammel[3], S. Lieb[4], A. Haehle[4], D. Meyer-Olson[5]on behalf of The study was sponsored by Novartis Pharma GmbH, Germany.. *[1]Rheumazentrum Ruhrgebiet; Ruhr Universität, Department of Rheumatology, Herne, Bochum, Germany*; *[2]Regionales Kooperatives Rheumazentrum Niedersachsen e. V.; Medizinische Hochschule Hannover, Klinik für Rheumatologie und Immunologie, Department of Rheumatology, Hannover, Germany*; *[3]Deutsche Vereinigung Morbus Bechterew e.V., Patient representative, Schweinfurt, Germany*; *[4]Novartis Pharma GmbH, Immunology, Hepatology and Dermatology, Nürnberg, Germany*; *[5]Medizinische Hochschule Hannover, Klinik für Rheumatologie und Immunologie; m&i Fachklinik Bad*

Pyrmont/MVZ Weserbergland, Rheumatology and Immunology, Hannover; Bad Pyrmont, Germany

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory condition often associated with impaired working participation[1] not only translating to devastating outcomes for patients (pts) but also increased economic and social burden due to a significant amount of indirect costs. Data on the different work participation domains in axSpA pts with access to biologic therapies are limited.
Objectives: To characterise the different domains of work participation [presenteeism, absenteeism, sick leave, unemployment, disability pensions] in axSpA pts and their associations with demographic and clinical confounders.
Methods: Pts with confirmed clinical diagnosis of axSpA were enrolled in a multicenter, observational ATTENTUS survey conducted across Germany (Nov-2019 to Jul-2020). To ensure high data quality, inclusion criteria was verified by external monitoring, followed by evaluation of the domains of impaired work participation, including absenteeism and presenteeism (WPAI). Demographics, clinical parameters and patient related outcomes (PROs) were collected via tablet. This analysis included working age (18–65 years) pts; and excluded students and retired pts. Pts without absenteeism (value=0) and presenteeism ≤20% were defined as no impairment at work.
Results: A total of 787 axSpA pts were enrolled in the survey. Seven students, 68 retired pts and 17 pts not fulfilling the inclusion criteria were excluded from this analysis, leaving 695 pts with complete data sets. Baseline data are outlined in Table 1. 50 pts received disability pensions, 29 pts received unemployment benefits, 590 (84.9%) pts reported paid work [part-time: n=132 (22.4%); full-time: n=458 (65.9%)], with 242 (41.0%) pts having no impairments at work. 379 (64.2%) employed pts took sick leave within the previous 12 months (mo) (<3 mo: n=351; 3–6 mo: n=17; >6 mo: n=11). Absenteeism and presenteeism occurred in 140 (23.7%) and 496 (84.1%) pts, respectively. Pts without impairments were mostly of young age, male sex, well-educated, with low disease activity, less fatigue and shorter duration of morning stiffness, and preserved global and physical functioning. No apparent differences between pts with and without impairment of work participation were observed in terms of biologic treatment, disease duration and BMI.

Table 1. Descriptive characteristics of the study population

Mean (SD), unless specified	Impaired WP (n=453)	Full WP (n=242)	p-value	Total (n=695)
Age (yrs)	46.7 (11.1)	42.8 (10.1)	**<0.001**	45.3 (10.9)
BMI	28.5 (14.0)	27.0 (6.8)	0.146	28.0 (12.0)
Male, n(%)	246 (54)	177 (73)	**<0.001**	423 (61)
Disease duration (yrs)	12.7 (11.3)	12.4 (10.2)	0.813	12.6 (11.0)
University-Education, n(%)	104 (23.0)	82 (33.9)	**0.001**	186 (26.8)
In a committed relation, n(%)	310 (68.4)	159 (65.7)	0.464	469 (6.6)
ASAS-HI	8.0 (3.3)	3.7 (3.0)	**<0.001**	6.5 (3.8)
BASDAI	4.8 (1.9)	2.1 (1.6)	**<0.001**	3.9 (2.2)
BASDAI > 4, n(%)	286 (63.1)	28 (11.6)	**<0.001**	314 (45.2)
Fatigue [BASDAI #1]	5.8 (2.1)	2.8 (2.1)	**<0.001**	4.7 (2.5)
Duration morning stiffness [BASDAI #6]	3.5 (2.4)	1.6 (1.8)	**<0.001**	2.8 (2.4)
BASFI	4.2 (2.3)	1.5 (1.5)	**<0.001**	3.3 (2.4)
Biologic treatment, n(%)	230 (50.8)	134 (55.4)	0.390	364 (52.4)
Full time employment, n(%)	256 (56.5)	202 (83.5)	**<0.001**	458 (65.9)
Absenteeism	17.9 (32.1)	0	-	10.6 (26.2)
Presenteeism	48.6 (21.00)	9.6 (8.3)	-	32.6 (25.6)

ASAS-HI, Assessment of SpondyloArthritis International Society-Health Index; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; BMI, basal metabolic index; n, number of pts; SD, standard deviation; WP, work productivity; years, yrs

Conclusion: There was a substantial impact on work participation for axSpA pts, despite numerous available therapeutic options. Pts with impaired work participation compared to pts with no impairment, reported increased fatigue, longer duration of morning stiffness, decreased functional capacity, female sex and a lower level of education.

PREVALENCE OF AXIAL SPONDYLOARTHRITIS AMONG YOUNG PEOPLE CONSULTING BECAUSE OF CHRONIC LOW BACK PAIN IN A UNIVERSITY HOSPITAL IN ARGENTINA

M. A. Tobar Jaramillo[1], N. Marin Zucaro[1], J. Rosa[1], J. Marin[1], M. L. Acosta Felquer[1], L. Ferreyra[1], J. F. Jaramillo Gallego[1], J. Marcos[2], V. Duarte[2], E. Soriano[1]. [1]*Hospital Italiano De Buenos Aires, Buenos Aires, Buenos Aires, Argentina*; [2]*Novartis, Buenos Aires, Buenos Aires, Argentina*

Background: Axial spondyloarthritis (SpA) is an umbrella term encompassing a number of inflammatory conditions involving the axial skeleton. A substantial delay between disease onset, diagnosis and treatment often occurs, related in part to under-recognition of SpA symptoms. Although several studies have investigated since the publication of the ASAS classification criteria in 2009, the prevalence and incidence of axial SpA in the general population and in patients with SpA-related conditions, the actual prevalence of SpA in many countries (including Argentina) is unknown.
Objectives: To estimate the prevalence of axial SpA and the amount of undiagnosed axial SpA in people under 45 years of age that contacted the health care system for chronic low back pain.
Methods: The setting was a university hospital-based health management organization with a population distribution similary to that of Buenos Aires. All electronic medical records of patients < 45 years of age at the time of onset of symptoms (as per the ASAS 2009 criteria) and chronic low back pain for 3 or more months) seen at the university hospital-based health management organization between 2009 and 2019, were reviewed. If the patient fulfilled the ASAS criteria, was classified as having axial SpA [ankylosing spondylitis (AS) or non-radiographic axial SpA (nr-axSpA)]. Among this group, if the diagnosis was already established in the medical records by the treating physicians, these patients were also classified as diagnosed with axial SpA; if not, they were classified as undiagnosed with axial SpA. We are reporting the results of descriptive analysis.
Results: A total of 796 patients were included (Table 1), 426 were women (53.52%, 95% CI 50.1-57) with a median age of 34 years (IQR 29-40) at initiation of low back pain with a median follow up of 77.7 months (IQR 35.7-136.4). The prevalence of axial SpA among patients with chronic low back pain was 5.78% (n= 46, 95% CI 4.2-7.4). 22 patients had AS (2.76%, 95% CI 1.6-3.9) with a median lag time between the onset of low back pain and diagnosis of 58.7 months (IQR 33.5 - 92). All AS cases were already diagnosed. 24 patients had nr-axSpA (3.02%, 95% CI 1.8 - 4.2). Of those, 14 were diagnosed by treating physicians with a lag time median of 23.2 months (IQR 13.1 - 36.5) between the onset of low back pain and diagnosis. Ten patients fulfilled the ASAS criteria (41.7%, CI 95% 22 - 61.4) but were not diagnosed by the treating physicians (22%, 95% CI 9.82-33.66) among the patients with axial SpA.

Table 1. Demographic, clinical features and therapeutic characteristics of patients with chroniclow back pain stratified by diagnosis

	Axial spondyloarthritis N=46	Ankylosing spondylitis N=22	Diagnosed nr-axSpA N=14	Undiagnosed nr-axSpA N=10	Other diagnosis N=749
Female, n (%, CI)	18 (39.13%, 25.04-53.23)	4 (18.18%, 2.06-34.29)	10 (71.42%,47.76-95.09)	4 (40%, 9.63-70.36)	407 (54.34,50.77-579)
Age at chronic LBP initiation, years, median (IQR)	36 (29.25-40)	32 (32-40)	38 (22-36.75)	39 (35.25-41.5)	34 (29-40)
Follow up, median months (IQR)	88 (33.43-148.66)	33.67 (23.38-90.34)	16.73 (7.64-24.02)	64.77 (11.21-164.7)	77.69 (35.83-135.32)
Inflammatory chronic LBP by any criteria n (%)	44 (95.7)	21 (95.5)	13 (92.8)	10 (100)	56 (7.5, 5.6-9.4)
Seen by a Rheumatologist, n (%)	42 (91.3)	22 (100)	14 (100)	6 (60)	36 (5.1)
Lag time between first LBP to SpA diagnosis, months, median (IQR)	34.6 (22.6-63.2)	58.7 (33.5 – 92)	23.1 (13.1-36.5)	-	-
bDMARDs treatment n, (%, CI)	15 (33; 19.5–48)	10(45; 24.4–67.8)	5(36; 13–64.9)	-	-
Lag time between NSAIDs failure and first bDMARDs, months, median (IQR)	2.66 (2.05-4.63)	2.76 (2.07-11.3).	2.66 (2.04-3.25)	-	-

CI: 95% confidential interval, IQR: interquartile range, bDMARDs: biologic disease modifying anti-rheumaticdrugs, **LBP:** low back pain

Conclusion: In our cohort, 5.78% of the patients < 45 years with chronic low back pain had axial SpA (AS: 2.76%; and nr-axSpA: 3.02%). Approximately, one in every five patients had undiagnosed axial SpA. *Original manuscript made in collaboration with Novartis Argentina S.A*

POS0985 DISEASE CONTROL PERCEPTION BY PHYSICIANS AND PATIENTS WITH ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS IN REAL CLINICAL PRACTICE IN SPAIN: MIDAS STUDY RESULTS

J. L. Pablos[1], X. Juanola[2], C. Barbazán[3], M. L. García Vivar[4], A. C. Valenciano[5], C. Rodriguez-Lozano[6], M. Estadella[7], A. Venegas[8], C. Sanabra[8], C. Sastré[8]on behalf of MIDAS group. [1]*Instituto de Investigación Hospital 12 de Octubre,Rrheumatology Service, Madrid, Spain*; [2]*Hospital Universitari Bellvitge, IDIBELL, Rheumatology Service, L'Hospitalet de Llobregat, Barcelona, Spain*; [3]*Complexo Hospitalario Universitario de Vigo,Rrheumatology Service, Vigo, Spain*; [4]*Hospital Universitario Basurto, Rheumatology Service, Bilbao, Spain*; [5]*Hospital Universitario Severo Ochoa, Rheumatology Service, Leganés, Madrid, Spain*; [6]*Hospital Universitario de Gran Canaria Doctor Negrín, Rheumatology Service, Las Palmas de Gran Canaria, Spain*; [7]*Syneos Health, Rheumatology, Barcelona, Spain*; [8]*Novartis Farmacéutica, Rheumatology, Barcelona, Spain*

Background: There are few published data regarding physician' and patient' perception of the disease control for ankylosing spondylitis (AS) and psoriatic arthritis (PsA).

Objectives: To evaluate the relationship between physician' and patient' disease control perception compared to clinical outcomes for controlled disease (BASDAI<4 in AS or DAPSA≤14 in PsA).

Methods: MIDAS is an observational, non-interventional, cross-sectional, multicenter study. Patients ≥18 years with ≥6 months AS or PsA diagnosis according to ASAS and modified New York criteria or CASPAR criteria, respectively, undergoing treatment ≥3 months before inclusion. The endpoint of this analysis was the relationship between disease control perception by physicians and patients and disease control (BASDAI<4 in AS or DAPSA≤14 in PsA).

Results: 313 AS patients included: 75.7% male, 78.5% HLA-B*27+, a mean (SD) age of 50.4 (12.0) years, a mean (SD) disease duration of 15.5 (11.6) years and a mean (SD) CRP of 5.1 (8.2) mg/l. 313 PsA patients included: 54.3% male, 17.95% HLA-B*27+, a mean (SD) age of 54.1 (12.2) years, a mean (SD) disease duration of 10.5 (9.0) years and a mean (SD) CRP of 4.91 (7.3) mg/l. AS group: in 95.5% of AS patients with BASDAI<4, physician's perception matched the clinical evaluation, while only 42.3% of the patients with BASDAI≥4 matched physician's perception. Positive Predictive Value (PPV) was 75.1%, Negative Predictive Value (NPV) was 83.9% and precision was 76.7%. Patients perceived their own disease as controlled in 95.0% of cases with BASDAI scores <4 and as not controlled in 29.7% of cases with BASDAI score ≥4. PPV was 71.1%, NPV was 76.7% and precision was 71.9%. The same trend was observed when assessing disease control through ASDAS-CRP index. PsA group: in 96.2% of patients with DAPSA≤14, physician's perception matched the clinical evaluation, while only 47.6% of patients with DAPSA>14 matched the physician's perception. PPV was 73.1%, NPV was 89.6% and precision was 76.4%. Patients perceived their own disease as controlled in 93.5% of the cases with DAPSA scores ≤14 and as not controlled in 32.3% of the cases with DAPSA>14. PPV was 66.8%, NPV was 77.4% and precision was 68.4%. The same trend was observed when assessing disease control through the MDA criteria (Table 1).

Table 1. Physician's and patient's perception of the disease control related to disease control variables in AS and PsA

			Controlled disease by physician's perception?			Controlled disease by patient's perception?	
		Valid N	Yes N (%)	No N (%)	Valid N	Yes N (%)	No N (%)
AS							
Disease control (BASDAI)	Controlled (BASDAI<4)	202 (100%)	**193 (95.5%)**	9 (4.5%)	202 (100%)	**192 (95.0%)**	10 (5.0%)
	Not controlled (BASDAI≥4)	111 (100%)	64 (57.7%)	**47 (42.3%)**	111 (100%)	78 (70.3%)	**33 (29.7%)**
Disease activity (ASDAS-CRP)	Inactive (ASDAS-CRP<1.3)	92 (100%)	**90 (97.8%)**	2 (2.2%)	92 (100%)	**91 (98.9%)**	1 (1.1%)
	Active (ASDAS-CRP≥1.3)	221 (100%)	167 (75.6%)	**54 (24.4%)**	221 (100%)	179 (81.0%)	**42 (19.0%)**
PsA							
Disease control (DAPSA)	Controlled (DAPSA≤14)	186 (100%)	**179 (96.2%)**	7 (3.8%)	185 (100%)	**173 (93.5%)**	12 (6.5%)
	Not controlled (DAPSA>14)	126 (100%)	66 (52.4%)	**60 (47.6%)**	127 (100%)	86 (67.7%)	**41 (32.3%)**
Active disease (MDA)	Inactive (MDA criteria ≥5)	161 (100%)	**154 (95.7%)**	7 (4.3%)	160 (100%)	**152 (95.0%)**	8 (5.0%)
	Active (MDA criteria<5)	151 (100%)	91 (60.3%)	**60 (39.7%)**	152 (100%)	107 (70.4%)	**45 (29.6%)**

AS, ankylosing spondylitis; ASDAS-CRP, Ankylosing Spondylitis Disease Activity Score-C-reactive protein; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; DAPSA, Disease Activity in Psoriatic Arthritis; MDA, Minimal Disease Activity; PsA, psoriatic arthritis.

Conclusion: A higher agreement between physician's and patient' perception with the current clinical evaluation was observed when patients were controlled. MiDAS study showed that in real clinical practice in Spain, physicians perceived more disease control than the patients

POS0986 GENDER DIFFERENCES IN DISEASE CONTROL AND HEALTH STATUS IN PATIENTS WITH ANKYLOSING SPONDYLITIS IN CLINICAL PRACTICE IN SPAIN: RESULTS OF THE MIDAS STUDY

C. Fernández-Carballido[1], J. Gratacos-Masmitja[2], E. De Miguel[3], P. S. Del Río Martínez[4], O. Martínez González[5], A. Fernandez-Nebro[6], P. Vela-Casasempere[7], C. Sanabra[8], C. Sastré[8]on behalf of MIDAS group. [1]*Hospital Universitario San Juan de Alicante, Rheumatology Service, Alicante, Spain*; [2]*Hospital Universitario Parc Taulí, Rheumatology Service, Sabadell, Spain*; [3]*Hospital Universitario La Paz, Rheumatology Service, Madrid, Spain*; [4]*Hospital Clínico Universitario Lozano Blesa, Rheumatology Service, Zaragoza, Spain*; [5]*Hospital Universitario de Salamanca, Rheumatology Service, Salamanca, Spain*; [6]*Hospital Regional Universitario de Málaga, Rheumatology Service, Málaga, Spain*; [7]*Hospital General Universitario Alicante, Rheumatology Service, Alicante, Spain*; [8]*Novartis Farmacéutica, Rheumatology, Barcelona, Spain*

Background: Data on disease activity status and health status (HS) in clinical practice in Spain for patients with ankylosing spondylitis (AS) are scarce. The MIDAS study assessed the disease activity and the relationship with the reported HS in patients with AS treated in clinical practice in Spain.

Objectives: This is a sub-analysis to evaluate the differences in disease activity and HS by gender of the patients with AS included in the MIDAS study.
Methods: MIDAS is an observational, non-interventional, cross-sectional, multicenter study. Patients included were ≥18 years old with ≥6 months since diagnosis, were classified by ASAS and modified New York criteria; undergoing treatment ≥3 months. The primary variable was the disease control assessed by the percentage of patients in remission and low disease activity (measured by BASDAI and ASDAS-CRP)[1-2].
Results: We analyzed 313 AS patients; 237 (75.7%) were male and 76 (24.3%) female (Table 1). Disease control: According to BASDAI <4 (total 64.5% (mean (SD) 3.1 (2.2)); 69.2% (2.9 (2.1)) of the males vs 50.0% (3.8 (2.4)) of the females had a BASDAI <4 (Figure 1A). According to ASDAS-CRP, 57,5% of the AS patients showed low disease activity (ASDAS-ID + ASDAS-LDA), with a mean (SD) ASDAS-CRP of 1.9 (1.1); 138 (58.2%) males and 42 (55.3%) females showed low disease activity (Figure 1B). HS impact was low, with a mean (SD) ASAS-HI of 5.8 (4.4) for AS patients, that was 5.5 (4.4) for males and 6.8 (4.2) for females.

Table 1. Baseline demographic and clinical characteristics of the AS patients analysed.

	Total (n=313)	Male (n=237)	Female (n=76)
Age (years), mean (SD)	50.4 (12.0)	50.1 (12.2)	51.2 (11.5)
Years since diagnosis, mean (SD)	15.5 (11.6)	16.8 (12.2)	11.4 (8.5)
Years since the symptoms' onset to the study visit, mean (SD)	20.5 (12.7)	22.2 (13.0)	15.2 (9.9)
Years since the symptoms' onset to diagnosis, mean (SD)	5.0 (7.2)	5.4 (7.7)	3.9 (5.6)
BMI (kg/m^2), mean (SD)	27.0 (4.9)	27.5 (4.6)	25.5 (5.6)
Obesity (BMI>30), n (%)	67 (23.0%)	53 (23.7%)	14 (20.9%)
Smoking habit			
Current smoker, n (%)	75 (24.0%)	61 (25.7%)	14 (18.4%)
Ex-smoker (>6 months), n (%)	81 (25.9%)	68 (28.7%)	13 (17.1%)
Non-smoker, n (%)	137 (43.8%)	96 (40.5%)	41 (53.9%)
Family history of AS, n (%)	66 (21.1%)	48 (20.3%)	18 (23.7%)
Presence of HLA-B27, n (%)	245 (78.5%)	187 (79.2%)	58 (76.3%)
Patients previously treated with bDMARD	99 (31.6%)	77 (32.5%)	22 (28.9%)
Active disease, n (%)*			
BASDAI ≥4	111 (35.5%)	73 (30.8%)	38 (50.0%)
ASDAS-CRP ≥2.1	133 (42.4%)	99 (41.8%)	34 (44.7%)
CRP levels (mg/l), mean (SD)	5.1 (8.2)	5.7 (9.0)	3.3 (4.3)
PASS, n (%)	270 (86.3%)	208 (87.8%)	62 (81.6%)
ASAS-HI, mean (SD)	5.8 (4.4)	5.5 (4.4)	6.8 (4.2)

*Refers to the percentage of patients with active disease according to BASDAI≥4 and ASDAS-CRP ≥2.1.AS, ankylosing spondylitis; ASAS-HI, Assessment of Spondyloarthritis International Society - Health index; ASDAS, Ankylosing Spondylitis Disease Activity Score; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; bDMARD: biologic disease modifying anti-rheumatic drug; BMI, body mass index; CRP, C-reactive protein; HLA-B27, human leukocyte antigen B27; PASS, patient acceptable symptom state; SD, standard deviation.

Conclusion: Our analysis showed a higher proportion of females with active disease when using the BASDAI definition. However, when using the ASDAS-CRP definition, these differences by gender seem to be less pronounced. Also, the impact of disease activity on the HS seems to be higher in females than males. As far as we know, this is the first Spanish study to evaluate gender in this patient population.

POS0987 INFLAMMATION OF THE HIP JOINTS IN EARLY AXIAL SPONDYLOATRITIS: DATA ANALYSIS OF VISUALIZATION METHODS

E. Agafonova[1], T. Dubinina[1], A. Demina[1], D. Rumiantceva[1], S. Erdes[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation*

Background: According to epidemiological studies in Russia, the inflammation of the hip joints occurs in half of patients with ankylosing spondylitis (AS). There have been practically no studies devoted to the investigations of coxitis in patients with early axial spondyloarthritis (axSpA). It is still unknown what factors cause the development of coxitis in axSpA; there is no generally accepted algorithm for diagnosing this condition, especially at an early stage. Previous studies have shown that coxitis in patients with AS develops on average 5–10 years after the onset of the disease, some patients already have irreversible changes in the hip joint at the time of diagnosis, and some do not develop coxitis never.
Objectives: To compare the clinical manifestations of coxitis with the results of magnetic resonance imaging (MRI), ultrasound (US), and radiography of the hip.
Methods: We examined 175 patients (mean age 28.0 ± 5.92 years) with axSpA (ASAS, 2009), with a duration of inflammatory back pain of no more than 5 years, from the CoRSaR cohort. The median duration of the disease was 21 [3–60] months. BASDAI - 4.0 ± 2.0, BASFI - 2.0 [0.4; 3.5]. Among the included patients, 69 (39.4%) had nr-axSpA, and 106 - AS; 87% were HLA-B27 positive. All patients underwent US examination of the hip joint. When synovitis was detected, the patients underwent MRI examination of the hip joint. The increase in the cervical-capsular distance (CCD) more than 7 mm was considered as an ultrasonic coxitis. The median CCD was 7.5 [7.0; 8.2] mm. For coxitis in MRI, osteitis of the head of the hip or acetabulum and synovitis were taken. Radiographic severity of coxitis was determined by BASRI hip.
Results: According to the US data, synovitis of the hip joint was detected in 54 from 175 (30.9%) patients. Pain in the hip joint had 33 (61%) patients. There was no correlation between the intensity of pain and CCD. CCD significantly correlated with laboratory indicators of disease activity, such as ESR (r = 0.34; p <0.05) and CRP (r = 0.3; p <0.05). Only 7 (13.0%) patients had BASRI hip stages II or III and the rest had normal hip joints. 39 (72%) had MRI manifestations of coxitis: 36 (66%) patients had synovitis, 1 (2%) had bone marrow edema, and 2 (4%) had a combination of synovitis with osteitis. Patients with and without radiographic coxitis did not differ in terms of disease activity and functional indices.
Conclusion: In early axSPA:
- 30.9% of patients have hip synovitis, and among them, MRI signs of coxitis have 72%, and X-ray coxitis - 13%;
- ultrasound synovitis is only confirmed by MRI in 70% of cases;
- it seems that the radiological progression of coxitis does not depend on the activity of the disease.
Disclosure of Interests: None declared.

POS0988 FACTORS ASSOCIATED WITH PAIN INTENSITY IN AXIAL SPONDYLOARTHRITIS. RESULTS FROM THE EUROPEAN MAP OF AXIAL SPONDYLOARTHRITIS (EMAS)

M. Garrido-Cumbrera[1], V. Navarro-Compán[2], C. Bundy[3], L. Christen[4], R. Mahapatra[5], S. Makri[6], C. J. Delgado-Domínguez[1], J. Correa-Fernández[1], P. Plazuelo-Ramos[7], D. Poddubnyy[8]on behalf of IMAS working group.
[1]*Universidad de Sevilla, Health & Territory Research (HTR), Sevilla, Spain*; [2]*Hospital Universitario La Paz, IdiPaz, Madrid, Spain*; [3]*Cardiff University, School of Healthcare Sciences, Cardiff, United Kingdom*; [4]*Novartis Pharma AG, Patient Engagement, Basel, Switzerland*; [5]*Axial Spondyloarthritis International Federation (ASIF), Patient Advocacy, London, United Kingdom*; [6]*Cyprus League Against Rheumatism (CYPLAR), Patient Advocacy, Nicosia, Cyprus*; [7]*Spanish Federation of Spondyloarthritis Associations (CEADE), Presidency, Madrid, Spain*; [8]*Charité - Universitätsmedizin Berlin, Rheumatology Department, Berlin, Germany*

Background: Pain is a hallmark of axial spondyloarthritis (axSpA) and can significantly deteriorate patients' health status.
Objectives: This analysis aims to investigate factors associated with pain intensity in a large sample of European axSpA patients.
Methods: 2,846 unselected patients participated in EMAS, a cross-sectional study (2017-2018) across 13 European countries. Data from 2,636 participants who reported pain were analysed. Pain was measured by the mean of two BASDAI questions (range 0 "no pain" to 10 "most severe pain"): "How would you describe the overall level of AS neck, back or hip pain you have had?" and "How would you describe the overall level of pain/swelling in joints other than neck, back, hips you have had?". Linear regression analysis was applied to identify associations between pain intensity and sociodemographic factors, patient-reported outcomes [BASDAI (0-10), spinal stiffness (3-12), functional limitation (0-54), mental health using the 12-item General Health Questionnaire GHQ-12 (0-12)], work life, physical activity and comorbidities, for which 850 patients were included.
Results: The mean age of the sample was 44 years, 61.4% were female, 49.4% had a university degree and 67.7% were married. The average reported pain intensity was 5.3 (±2.2); 76.2% reported pain intensity ≥4, with the greatest intensity reported by women (5.5 vs 4.9, p<0.001), those not university educated (5.6 vs 5.0, p<0.001), separated or divorced compared to singles (5.8 vs 5.2, p=0.004), and not physically active (5.7 vs 5.2, p<0.001). In addition, employed patients who experienced work-related issues reported greater pain (5.2 vs 3.9) as did those who experienced/ believed they would face difficulties finding work due to axSpA (5.9 vs 4.3), and those whose employment choice was determined by axSpA (5.7 vs 4.9; all p<0.001). Moreover, associations with anxiety (5.9 vs 5.0), depression (6.1 vs 5.0) and sleep disorders (5.9 vs 4.9; all p<0.001) were also found. The multiple linear regression model showed that those with higher pain intensity reported at least one work-related issue (B=0.65), difficulties finding work due to axSpA (B=0.48), not having attended university (B=0.38), greater spinal stiffness (B= 0.29), being female (B=0.26) and poorer mental health (GHQ-12) (B=0.10) (Table 1).

[1]Female vs Male; [2]No university studies (no schooling, primary and high school) vs University studies; [3]Divorced/separated vs single, married and widow; [4]Obese vs not obese (underweight, normal and overweight).

Conclusion: Pain was most strongly associated with working life impairment, as well as with spinal stiffness. Pain was also associated with suffering from depression, anxiety and sleep disorders. Understanding how pain affects individuals and shared-decision making between rheumatologists and patients are essential for long-term disease management and preserving quality of life of axSpA patients.

Background: Axial spondyloarthritis (axSpA) is associated with a high burden of disease, which may lead to inability to work and disability.
Objectives: This analysis aims to identify factors associated with inability to work and disability among European axSpA patients.
Methods: Data from 2,846 unselected patients participating in EMAS, a cross-sectional study (2017-2018) across 13 European countries were analysed. The sample was divided into those on permanent sick leave or with a recognised disability (Group 1) and those with neither permanent sick leave nor a recognized disability (Group 2). Mann-Whitney and Pearson's χ^2 tests were used to analyse possible differences between groups regarding sociodemographic characteristics, patient-reported outcomes [BASDAI (0-10), GHQ-12 (0-12), functional limitation (0-54) and spinal stiffness (3-12)], lifestyle habits, working life, and comorbidities). Univariable and multivariable binary logistic regression were used to analyse variables possibly explaining being on permanent sick leave and disability, for which 1,657 patients were included.
Results: Mean age was 43.9 years, 61.3% were female, 48.1% had a university degree, and 67.9% were married. Patients in Group 1 (34.4%; n=978) were more likely to be women (54.3%), married (71.1%), with higher disease activity (BASDAI 5.9 vs. 5.3), functional limitation (25.1 vs. 18.0), spinal stiffness (8.6 vs. 7.3; all p<0.001), and longer diagnostic delay (8.1 vs 7.1 years; p = 0.01) than those in Group 2 (65.6%; n=1,868). In addition, 88.0% of Group 1 (n=728) had difficulties in finding a job due to axSpA throughout life; and more than 30.0% reported a diagnosis of anxiety, depression, or sleep disorders. Moreover, being in Group 1 was associated with higher functional limitation in all daily activities. In the multivariable binary logistic regression, the qualitative variables associated with permanent sick leave or disability were: difficulties finding work (OR= 2.52), belonging to a patient organisation (OR= 1.54) and work choice determined by axSpA (OR= 1.38). The quantitative variables associated with permanent sick leave or disability were: higher spinal stiffness (OR= 1.09), older age (OR= 1.03), longer disease duration (OR= 1.03), shorter diagnostic delay (OR= 0.98), and higher functional limitation (OR= 1.01) (Table 1).

[1]Male vs Female; [2]No university studies vs university studies. [3]95% CI for test H_0: OR=1

Conclusion: One third of patients reported being on permanent sick leave or having a recognised disability. They were more likely to have higher spinal stiffness scores, were older in age, experiencing difficulty finding a job, and belonged to a patient organisation. Increased efforts in relation to early access to effective treatments and the creation of flexible working environments are essential for axSpA patients to continue working and remain active, which benefits their quality of life.

FACTORS ASSOCIATED WITH ENGAGING IN PHYSICAL ACTIVITY IN AXIAL SPONDYLOARTHRITIS. RESULTS FROM THE EUROPEAN MAP OF AXIAL SPONDYLOARTHRITIS (EMAS)

M. Garrido-Cumbrera[1], D. Poddubnyy[2], C. Bundy[3], L. Christen[4], R. Mahapatra[5], S. Makri[6], C. J. Delgado-Domínguez[1], D. Gálvez-Ruiz[1], P. Plazuelo-Ramos[7], V. Navarro-Compán[8]on behalf of IMAS working group. *[1]Universidad de Sevilla, Health & Territory Research (HTR), Seville, Spain*; *[2]Charité - Universitätsmedizin Berlin, Rheumatology Department, Berlin, Germany*; *[3]Cardiff University, School of Healthcare Sciences, Cardiff, United Kingdom*; *[4]Novartis Pharma AG, Patient Engagement, Basel, Switzerland*; *[5]Axial Spondyloarthritis International Federation (ASIF), Patient Advocacy, London, United Kingdom*; *[6]Cyprus League Against Rheumatism (CYPLAR), Patient Advocacy, Nicosia, Cyprus*; *[7]Spanish Federation of Spondyloarthritis Associations (CEADE), Presidency, Madrid, Spain*; *[8]Hospital Universitario La Paz, IdiPaz, Madrid, Spain*

Background: Physical activity is an essential component in axial spondyloarthritis (axSpA) care, improving physical and mental well-being.

Objectives: This analysis aims to identify factors associated with engaging in physical activity among axSpA patients.

Methods: Data from 2,424 unselected patients participating in EMAS (N=2,846), a cross-sectional study (2017-2018) across 13 European countries, were analysed. Engaging in physical activity was assessed by the following item: "Do you do any physical or sporting activity?" for which participants could report at least 1 physical activity or that they did not do any physical activity. BASDAI (0-10), spinal stiffness (3-12), functional limitation (0-54), and mental health using General Health Questionnaire GHQ-12 (0-12) were assessed. Mann-Whitney and Pearson's χ^2 tests were used to analyse relationships between engaging in physical activity and sociodemographic factors, patient-reported outcomes, employment, lifestyle and comorbidities. Univariable and multivariable binary logistic regression were used to analyse variables possibly explaining engagement in physical activity.

Results: Mean age was 43.9±12.3 years, 61.3% were female, 48.1% had a university degree and 67.9% were married. 81.8% (n= 2,329) engaged in at least one kind of physical activity. Those physically active were typically male (85.3% vs 79.7% female, p<0.001), university educated (86.0% vs 78.0%, p<0.001), married (83.1% vs 79.2% unmarried, p=0.046), and members of a patient organisation (86.4% vs 78.9% non-member, p<0.001). 25.1% of obese patients (n=533) did not engage in physical exercise (v. 16.6% not obese, p<0.001). Those not engaging in physical activity reported greater disease activity (6.0 vs 5.4 BASDAI, p<0.001), functional limitation (21.6 vs 20.2, p=0.010), spinal stiffness (8.3 vs 7.6, p<0.001), and poorer mental health (5.9 vs 4.8 GHQ-12, p<0.001). Furthermore, 83.9% of those employed (n=1,457) were physically active, versus 73.7% unemployed (n=205; p<0.001). In the multivariable binary logistic regression, the qualitative variables associated with engaging in physical activity were belonging to a patient organisation (OR= 1.91), not being obese (OR= 1.58), being university educated (OR= 1.54), and being male (OR= 1.39). The quantitative variables associated with engaging in physical activity were lower spinal stiffness (OR=0.90), better mental health (OR=0.96), and one-year age increase (OR=1.02). (Table 1).

Table 1. Regression analysis for variables explaining engagement in physical activity (n=2,424)

GHQ-12 (0-12)	0.94	**0.92, 0.96**	0.96	**0.93, 0.99**
Functional Limitation (0-54)	0.99	0.99, 1.00	1.00	0.99, 1.01
Spinal Stiffness (3-12)	0.90	**0.86, 0.94**	0.90	**0.84, 0.95**
Proportion of life with axSpA (0-1)	2.83	**1.50, 5.35**	2.00	0.91, 4.39

[1]Male vs Female; [2]University vs no university; [3]Married vs unmarried; [4]Member vs not; [5]Not obese (underweight, normal and overweight) vs obese; [6]Employed vs not (unemployed, sick leave, retirement, housework and student).[7]95% CI for test H_0: OR=1

Conclusion: These results show that increasing age, being male, university educated, member of a patient organisation, not obese, having lower spinal stiffness, and better mental health increase the probability of engaging in physical activity. Physical activity is an important part of axSpA care and patient organizations play a critical role in enhancing access to and participation in physical activity.

THE IMPACT OF AXIAL SPONDYLOARTHRITIS ON PATIENTS' SEXUAL LIFE: RESULTS FROM THE SPANISH ATLAS

M. Garrido-Cumbrera[1], J. Gratacos-Masmitja[2], E. Collantes-Estevez[3], P. Zarco-Montejo[4], C. Sastré[5], S. Sanz-Gómez[1], P. Plazuelo-Ramos[6], V. Navarro-Compán[7]on behalf of Atlas working group. *[1]Universidad de Sevilla, Health & Territory Research (HTR), Seville, Spain*; *[2]Hospital Universitaria Parc Taulí, Rheumatology Department, Barcelona, Spain*; *[3]Reina Sofía University Hospital, Rheumatology Department, Cordova, Spain*; *[4]Hospital Universitario Fundación Alcorcón, Rheumatology Department, Madrid, Spain*; *[5]Novartis Farmacéutica Spain, Immunology, Hepatology and Dermatology, Barcelona, Spain*; *[6]Spanish Federation of Spondyloarthritis Associations (CEADE), Patient Advocacy, Madrid, Spain*; *[7]Hospital Universitario La Paz, IdiPaz, Madrid, Spain*

Background: Axial Spondyloarthritis (axSpA) can impact patients' sexual life.

Objectives: The aim is to assess the prevalence of functional limitation in sexual activity in axSpA patients in Spain and its associated factors.

Methods: Data from an online survey of 680 unselected axSpA patients pertaining to the Atlas of Axial Spondyloarthritis in Spain were collected. Functional limitation in intimate relations was assessed through a 3-point Likert scale (low, medium, and high) and the sample was divided into 1) low-medium and 2) high. Mann-Whitney and χ^2 tests were used to analyse relations between sociodemographic, employment, lifestyle, patient-reported outcomes, and comorbidities with respect to functional limitation in intimate relations. Univariate and multivariate binary logistic regression was used to analyse its associated factors.

Results: 605 axSpA patients were included: the mean age was 45.5 years, 51.4% were female, 38.3% had a university degree, and 70.7% were married. A total of 57.7%, 28.9%, and 13.4% participants presented high, medium, and low limitation in intimate relations, respectively. Patient with high functional limitation in intimate relations were younger (44.6 vs 46.7, p=0.032), female (67.2% vs 47.6% of male, p<0.001), did not belong to a patient organisation (62.7% vs 51.5% of members, p=0.006), were on sick leave (73.3% vs 51.9% of employed, p<0.001) and smoked more (67.3% vs 52.6%, p<0.001). The high limitation group presented higher disease activity (6.3 vs 4.9), functional limitation (48.2 vs 34.4) and spinal stiffness (7.9 vs 6.9, all p<0.001), worse mental health (7.0 vs 4.1, p<0.001), longer diagnostic delay (9.2 vs 7.6, p=0.019), and more comorbidities such as anxiety (73.3% vs 53.2%), depression (80.0% vs 53.3%) and sleep disorders (70.9% vs 53.9%, all p<0.001). In addition, 80.3% of patients with decreased frequency of intimate relations presented high functional limitation in intimate relations (vs 10.0% with more frequency) and 81.4% had experienced a worsening relationship with their spouse (vs 55.6% with better relation, all p<0.001). In the multivariate binary logistic regression, the qualitative factors associated with high functional limitation in intimate relations were a reduction in the frequency of intimate relations (OR= 18.66) and smoking (OR= 2.89), while the quantitative factor associated with high functional limitation in the intimate relation was higher overall functional limitation (B= 0.292; Table 1).

[1]p-value for test H_0: OR = 1 [2]p-value for test H_0: B = 0

Conclusion: More than half of patients with axSpA in Spain presented high functional limitation in intimate relations, who more likely presented decreased frequency of relations. This may indicate that avoidance of sexual encounters is a common coping mechanism for the functional limitation accompanying this disease. Healthcare providers can play a key role in the sexual health of axSpA patients by improving patient-physician communication and raising awareness about the benefits of counselling on a healthy sexual life.

PREVALENCE AND ASSOCIATED FACTORS OF SLEEP DISORDERS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS. RESULTS FROM THE SPANISH ATLAS

M. Garrido-Cumbrera[1], V. Navarro-Compán[2], E. Collantes-Estevez[3], P. Zarco-Montejo[4], S. Sanz-Gómez[1], C. Sastré[5], P. Plazuelo-Ramos[6], J. Gratacos-Masmitja[7]on behalf of Atlas working group. *[1]Universidad de Sevilla, Health & Territory Research (HTR), Seville, Spain*; *[2]Hospital Universitario La Paz, IdiPaz, Madrid, Spain*; *[3]Reina Sofia University Hospital, Rheumatology Department, Cordova, Spain*; *[4]Hospital Universitario Fundación Alcorcón, Rheumatology Department, Madrid, Spain*; *[5]Novartis Farmacéutica Spain, Immunology, Hepatology and Dermatology, Barcelona, Spain*; *[6]Spanish Federation of Spondyloarthritis Associations (CEADE), Patient Advocacy, Madrid, Spain*; *[7]Hospital Universitaria Parc Taulí, Rheumatology Department, Barcelona, Spain*

Background: Sleep is an essential aspect of health that is commonly disrupted in patients with axial spondyloarthritis (axSpA).

Objectives: This analysis aims to assess the prevalence and associated factors of sleep disorders in a large sample of axSpA patients.

Methods: In 2016, a sample of 680 unselected patients with axSpA participated in the Atlas of Axial Spondyloarthritis in Spain through an online survey. The sample was divided into: 1) Patients with sleep disorders and 2) Patients without sleep disorders. Disease activity through BASDAI (0-10), spinal stiffness (3-12), functional limitation (0-54) and, mental health through a 12-item General Health Questionnaire GHQ-12 (0-12) were assessed. The Mann-Whitney and Pearson's chi-square tests were used to analyse possible relationships between independent sociodemographic characteristics, employment, lifestyle, patient-reported outcomes and comorbidity variables with sleep disorders. Univariate and multivariate binary logistic regression was used to determine the possible association of the independent variables on sleep disorders.

Results: Mean age was 45.7 years, 52.5% female, 36.9% had a university degree, and 71.5% were married. The prevalence of sleep disorders was 19.7%. Those who reported sleep disorders presented higher disease activity (6.3 vs 5.4, p<0.001), worse mental health (7.7 vs 5.0, p<0.001), greater functional limitation (45.7 vs 41.4, p<0.001), greater spinal stiffness (8.0 vs 7.3, p=0.008), and longer diagnostic delay (10.5 vs 7.9, p=0.021). 29.9% of the patients on sick leave had sleep disorders, compared to only 15.4% of employees (p=0.013). In addition, 23.0% of those who were physically active had sleep disorders compared to only 7.1% of those not physically active (p<0.001). Sleep disorders were more prevalent in patients with other comorbidities such as anxiety (60.0% vs 9.7%, w/o anxiety, p<0.001) and depression (66.0% vs 11.7% w/o depression, p<0.001). In the multivariate binary logistic regression, depression (OR= 3.89), anxiety (OR= 3.84), and a longer diagnostic delay (B=0.034) remained significantly associated with sleep disorders. Excluding mental comorbidity parameters from the model, physical activity (OR= 3.52) and disease activity (B= 0.175) remained significantly associated with sleep disorders (Table 1).

Table 1. Logistic regression to analyses factor associated with sleep disorders (N= 366)

*Excluding mental health factors. [1]p-value for test H_0: OR = 1 [2]p-value for test H_0: B = 0

Conclusion: One of five patients with axSpA reported sleep disorders. The presence of mental comorbidities such as anxiety and depression increases the likelihood of sleep disorders. Moreover, physical activity and disease activity also seem to increase the probability on sleep disorders. Referral to mental health specialists together with optimal healthcare management should be key for the reduction of sleep disorders in axSpA.

POS0993 THE IMPORTANCE OF PHYSICAL ACTIVITY IN RELATION TO BEING OVERWEIGHT/OBESE WITH AXIAL SPONDYLOARTHRITIS. RESULTS FROM THE SPANISH ATLAS

M. Garrido-Cumbrera[1], E. Collantes-Estevez[2], V. Navarro-Compán[3], P. Zarco-Montejo[4], J. Correa-Fernández[1], C. Sastré[5], P. Plazuelo-Ramos[6], J. Gratacos-Masmitja[7]on behalf of Atlas working group. *[1]Universidad de Sevilla, Health & Territory Research (HTR), Seville, Spain*; *[2]Reina Sofia University Hospital, Rheumatology Department, Cordova, Spain*; *[3]Hospital Universitario La Paz, IdiPaz, Madrid, Spain*; *[4]Hospital Universitario Fundación Alcorcón, Rheumatology Department, Madrid, Spain*; *[5]Novartis Farmacéutica Spain, Immunology, Hepatology and Dermatology, Barcelona, Spain*; *[6]Spanish Federation of Spondyloarthritis Associations (CEADE), Presidency, Madrid, Spain*; *[7]Hospital Universitaria Parc Taulí, Rheumatology Department, Barcelona, Spain*

Background: Evidence on the negative effects of being overweight/obese on the health outcomes of patients with axial spondyloarthritis (axSpA) is increasing.
Objectives: This study aimed to identify associations between Body Mass Index (BMI) categories and disease activity, functioning, quality of life, and mental health in a large sample of axSpA patients.
Methods: In 2016, a sample of 680 unselected patients with axSpA participated in the Atlas of Axial Spondyloarthritis in Spain through an online survey. The sample was divided in two groups: 1) Patients with a BMI of 18.5 to <25 Kg/m2 (normal weight), and 2) Patients with a BMI of ≥ 25 Kg/m2 (overweight/obesity), excluding the underweight category (BMI <18.5 Kg/m2). The Mann-Whitney and Pearson's chi-square tests were used to analyse possible relationships between independent sociodemographic characteristics, employment, lifestyle, patient-reported outcomes, and comorbidity variables with those who are overweight/obese. Univariate and multivariate binary logistic regression was used to determine the association of the possible factors with those who are overweight/obese.
Results: Of the 663 patients analysed, the mean age was 45.9 years, 51.4% were female, 37.0% had a university degree, and 72.5% were married. The prevalence of overweight/obese patients was 53.4% compared to 46.6% who were of a normal weight. The patients with the highest prevalence of being overweight/obese were older (49.3 vs 42.0, p<0.001), with no university education (59.8% vs 42.4% of university, p<0.001), often widowers (75.0% vs 30.8% of single people, p<0.001), and reported membership of patient organisations (61.7% vs 46.6%, p<0.001). With respect to patients of normal weight, those who were overweight/obese presented greater spinal stiffness (8.2 vs 6.6, p<0.001) and a longer diagnostic delay (9.2 vs 7.8, p=0.005). In addition, patients who were overweight/obese were more likely physically inactive (63.7% vs 36.3%, p=0.007). In the multivariable binary logistic regression analysis, the qualitative factors associated with the presence of being overweight/obese were physical inactivity (OR= 2.40) and males (OR= 1.81), while the quantitative factor most associated with the presence of being overweight/obese were greater spinal stiffness (B= 0.121) and older in age (B= 0.052) (Table 1).

Table 1. Logistic regression to analyses factor associated with being overweight/obese (N= 469)

Age	0.070	**<0.001**	0.052	**<0.001**
Spinal Stiffness (3-12)	0.220	**<0.001**	0.121	**0.004**
Diagnostic Delay	0.024	**0.035**	0.008	0.568

[1]p-value for test H_0: OR = 1 [2]p-value for test H_0: B = 0.

Conclusion: Being overweight/obese is a common comorbidity among patients with axSpA. The lack of physical activity, male gender, higher spinal stiffness, and older age increase the probability of prevalence of being overweight/obese. Physicians should encourage physical activity in patients with axSpA, especially among men and older people to prevent the factors of being overweight/obese.

POS0994 NON-RHEUMATOLOGISTS FIND IT DIFFICULT TO IDENTIFY AXIAL SPONDYLOARTHRITIS IN WOMEN AND YOUNG PEOPLE. RESULTS FROM THE SPANISH ATLAS

M. Garrido-Cumbrera[1], V. Navarro-Compán[2], J. Gratacos-Masmitja[3], P. Zarco-Montejo[4], J. Correa-Fernández[1], C. Sastré[5], P. Plazuelo-Ramos[6], E. Collantes-Estevez[7]on behalf of Atlas working group. *[1]Universidad de Sevilla, Health & Territory Research (HTR), Seville, Spain*; *[2]Hospital Universitario La Paz, IdiPaz, Madrid, Spain*; *[3]Hospital Universitaria Parc Taulí, Rheumatology Department, Barcelona, Spain*; *[4]Hospital Universitario Fundación Alcorcón, Rheumatology Department, Madrid, Spain*; *[5]Novartis Farmacéutica Spain, Immunology, Hepatology and Dermatology, Barcelona, Spain*; *[6]Spanish Federation of Spondyloarthritis Associations (CEADE), Presidency, Madrid, Spain*; *[7]Reina Sofia University Hospital, Rheumatology Department, Cordova, Spain*

Background: Delayed diagnosis in axial spondyloarthritis (axSpA) in Spain seems to be influenced by the patient diagnostic pathway. In particular, not all patients are diagnosed by rheumatologists, the profession better suited to make an axSpA diagnosis.
Objectives: The aim of this study is to evaluate the differences between patients diagnosed by a rheumatologist and those diagnosed by other healthcare professionals (HCPs).
Methods: In 2016, a sample of 680 unselected patients with axSpA participated in the Atlas of Axial Spondyloarthritis in Spain, an online survey. The sample was divided into: 1) Patients diagnosed by rheumatologists and 2) Non-Rheumatologist diagnosis including general practitioner, orthopaedic specialist, and physiotherapist. The Mann-Whitney and Pearson's chi-square tests were used to assess possible differences between both groups in sociodemographic characteristics, employment, lifestyle, patient-reported outcomes, and comorbidities. Univariate and multivariate binary logistic regression was used to analyse the possible factors associated with diagnosis by a non-Rheumatologist.
Results: A total of 522 axSpA patients participated in this study: the mean age was 45.3 years, 51.0% were female, 38.5% had a university degree, and 71.6% and were married. Prior to diagnosis, axSpA patients visited different HCPs such as a General Practitioner (GP) (88.5%), orthopaedic specialists (71.6%), rheumatologists (71.0%), and physiotherapists (46.9%). The greatest number of visits (mean, median) were made to physiotherapists (3.4, 3), followed by orthopaedic specialists (3.0, 2), rheumatologists (2.0, 1) and GPs (2.6, 2). The majority (81.4%) of patients were diagnosed by a rheumatologist, while 18.6% received their diagnosis from a non-rheumatologist (10.9% orthopaedic specialist, 7.3% general practitioner, and 0.4% physiotherapist). With respect to other specialists such as the GP, orthopaedic specialist or physiotherapist, patients diagnosed by the rheumatologist were younger (44.3 vs 49.5, p<0.001), more frequently female (54.8% vs 45.2% of male, p<0.001), with worse mental health (5.9 vs 4.8, p=0.039), who visited more professionals before being diagnosed (3.0 vs 2.5, p=0.001), were more frequently smokers (40.2% vs 26.0%, p=0.010) and used more biologicals (45.9% vs 33.0%, p=0.021). In the multivariate binary logistic regression, the qualitative factors associated with diagnosis by non-rheumatologists are males (OR= 1.80), and the quantitative factors associated with the diagnosis by non-rheumatologists are older age (B=0.027; Table 1).

Table 1. Logistic regression to analyses factor associated with non-rheumatologist diagnosis (N= 440)

*Reference category of the dependent variable: Non-Rheumatologist; [1]Female vs male; [2]p-value for test H_0: OR = 1 [3]p-value for test H_0: B = 0

Conclusion: One out of five patients with axSpA in Spain were not diagnosed by rheumatologists. Patients diagnosed by non-rheumatologists were more likely male and older, suggesting that the suspicion of axSpA in females and younger patients is low among these healthcare professionals. Beside the rheumatologist, it is essential to educate other HCPs on axSpA diagnostic criteria in order to facilitate correct referrals to rheumatologists and shorten the time to diagnosis and effective treatment.

POS0995 EFFECT OF SEX IN CO-EXISTENT FIBROMYALGIA AND ENTHESITIS IN SPONDYLOARTHRITIS: ANCILLARY ANALYSIS OF THE ASAS-PERSPA STUDY

G. Fitzgerald[1], S. Maguire[2,3], F. B. O'shea[2,3], C. López-Medina[4], M. Dougados[4], N. Haroon[5,6]. [1]*Galway University Hospital, Rheumatology, Galway, Ireland*; [2]*Trinity College Dublin, Medicine, Dublin, Ireland*; [3]*St. James's Hospital, Rheumatology, Dublin, Ireland*; [4]*Cochin Hospital, Rheumatology, Paris, France*; [5]*University Health Network, Rheumatology, Toronto, Canada*; [6]*Toronto Western Hospital, Rheumatology, Toronto, Canada*

Background: Enthesitis is a common feature of axial spondyloarthropathy (axSpA) and psoriatic arthritis (PsA). Up to 25% of individuals with axSpA and PsA have a co-existing diagnosis of fibromyalgia syndrome (FMS). The anatomic overlap between tender points in FMS and sites of entheses is a challenge when differentiating between active SpA and FMS. Literature investigating the co-existence of enthesitis and FMS in individuals with SpA is sparse, in particular the effect of sex. The ASAS Peripheral involvement in Spondyloarthritis (PerSpA) study aims to characterize peripheral musculoskeletal in individuals with SpA across the world.

Objectives: (1)To characterise the co-existence of enthesitis and FMS in individuals with SpA.

(2)To explore the effect of sex on the presence of FMS and enthesitis.

Methods: All individuals from the cross-sectional multinational ASAS-PerSpA study with a diagnosis of axSpA, peripheral SpA (pSpA) or PsA according to their rheumatologist were included. The Fibromyalgia Rapid Screening Tool (FiRST) was used to make the diagnosis of FMS. The baseline descriptive and clinical differences between sexes were performed using T-tests and crosstabs. Sex-stratified comparisons within the following categories were conducted using chi-square analysis and ANOVA as appropriate: (1) enthesitis & fibromyalgia; (2) enthesitis only; (3) fibromyalgia only; (4) neither.

Results: Baseline characteristics of the 4465 included patients are outlined in Table 1, stratified by sex. Enthesitis occurred in 44% (n=1984) of the population and was more common in females than males (48% vs 42%, p<0.01). The majority affected had intermittent episodes of enthesitis (55%, n=1088), with the Achilles tendon and plantar fascia the two most common sites in both sexes. Enthesitis was more often confirmed on imaging in females than males (44% v 35%, p<0.01). The most common treatment for enthesitis was non-steroidal anti-inflammatories (97%, n=1318), with no difference when stratified by sex. FMS occurred in 19% (n=775) of patients and was more common in females than males (28% vs 13%, p<0.01).

Table 1. Participant characteristics, stratified by sex. Values are mean (SD), median (25th, 75th) or n (%). P-values are independent T-tests or Mann-Whitney as appropriate.

Variable	Total	Male	Female	P value
N	4465	2724	1741

Sacroiliitis on MRI	1817 (65)	1128 (68)	689 (60)	<0.01
axSpA ASAS criteria	2910 (65)	1953 (72)	957 (55)	<0.01
pSpA ASAS criteria	555 (12)	250 (9)	305 (18)	<0.01
CASPAR criteria	1043 (23)	508 (19)	535 (31)	<0.01
BMI, kg/m^2	26 (23, 29)	26 (23, 29)	26 (23, 30)	0.24
Axial involvement	3428 (76.8)	2243 (82.3)	1185 (68.1)	<0.01
Peripheral involvement	2541 (56.9)	1404 (51.5)	1137 (65.3)	<0.01
Enthesitis	1984 (44.4)	1149 (42.2)	835 (48.0)	<0.01
Uveitis	738 (17)	482 (18)	256 (15)	0.01
Psoriasis	1212 (27)	615 (23)	597 (34)	<0.01
Inflammatory bowel disease	275 (6)	150 (6)	125 (7)	0.02

Enthesitis and FMS occurred together in 10% of the cohort, was more common in women than men (see Figure 1) and was associated with a significantly (p<0.01) longer delay to diagnosis of 1.8 years and a higher BMI of 2.1 kg/m^2 than people with enthesitis only. Objective confirmation of enthesitis was similar in those with and without FMS (38% vs 38%, p=0.92).

The presence of FMS added to the burden of disease in those with enthesitis as assessed by BASDAI (6.4 vs 3.6, p<0.01) and ASDAS-CRP (3.5 vs 2.5, p<0.01), with no difference between sexes (p>0.05).

Conclusion: In this large cross-sectional multinational analysis, FMS affected 19% of individuals with SpA. The co-existence of enthesitis and FMS occurred in 16% of females compared to 6% of males. The presence of FMS increased the burden of disease in those with enthesitis, as assessed by BASDAI and ASDAS-CRP, with no difference between men and women.

Figure 1: Prevalence of co-existent enthesitis & FMS in individuals with SpA, stratified by sex. P<0.01 denotes significant difference between sex.

Background: Esperanza was a multicenter national health program developed to facilitate an early diagnosis of patients with Spondyloarthritis (SpA) in Spain.

Objectives: To compare the clinical evolution of patients with axial SpA (axSpA) and peripheral SpA (pSpA) included in this program.
Methods: Patients from the Esperanza cohort fulfilling ASAS criteria for axSpA or pSpA and completed the 6-year follow-up were included. Patients were classified according to the predominant symptom. In case of having axSpA and pSpA, they were classified as axSpA. Clinical features, disease activity and treatment aspects at baseline and 6-year visit were evaluated.
Results: From 775 patients recruited at baseline, 6-year follow-up data from 178 (83.5%) fulfilling ASAS criteria at the final visit were available: 133 (74.7%) for axSpA and 45 for pSpA (25.3%). 118 (66.3%) were males (50.6% with axSpA and 62.2%, pSpA, p=0.4). Patients with axSpA had more frequently positive HLA-B27 (90.5%) vs. (9.5%), p<0.001. Follow-up clinical features are shown in Table 1. At the final visit, both axSpA and pSpA presented an improvement in clinical symptoms, disease activity (CRP, BASDAI, ASDAS and VAS-pt) and quality of life (ASQoL). A worsening of mobility (BASMI) was observed in both groups. The prevalence of uveitis, psoriasis and inflammatory bowel disease (IBD) at baseline was 10.7%, 18% and 5.6%, respectively. At the 6-year visit, the cumulative prevalence (CP) was 14% for uveitis (16.5% in axSpA and 6.7% in pSpA), 22.5% for psoriasis (12.8% in axSpA and 51.1% in pSpA) and 7.9% for IBD (5.3% in axSpA and 15.6% in pSpA). Most of the patients were prescribed NSAIDS at baseline and more patients maintained this treatment at the 6-year visit in axSpA compared with pSpA (96.9% vs 87.5%, p=0.02). At the final visit, a higher percentage with pSpA received csDMARDs in comparison with axSpA (81% vs. 35.7%, p<0.001). Sixty (44.4%) patients received biologic therapy at the final visit and no differences were observed in their prescription: 43% in axSpA and 48.6% in pSpA(p=0.6).
Conclusion: The early diagnosis of recent-onset SpA achieves a significant improvement in clinical features, disease activity and quality of life in patients with axSpA and pSpA after 6 years of follow-up. Although previous publications revealed a low radiographic progression in this cohort[1], the worsening of BASMI must aware clinicians of possible evolutive structural damage.

POS0997 PERFORMANCE OF ASDAS VERSUS BASDAI DURING PREGNANCY

P. Fischer[1], A. Zbinden[1], F. Foerger[1]. [1]*University Hospital and University of Bern, Rheumatology and Immunology, Bern, Switzerland*

Background: Disease activity in patients with axial spondyloarthritis (axSpA) can be measured by BASDAI and ASDAS. Both instruments were validated in non-pregnant patients with cutoff values for active diseases. In pregnant women with axSpA, however, BASDAI and ASDAS scores might be biased by signs and symptoms of pregnancy itself.
Objectives: To compare the performance of ASDAS and BASDAI during pregnancy
Methods: Patients with axSpA were prospectively followed before pregnancy, at each trimester and 6 to 12 weeks postpartum. Disease activity was assessed by BASDAI, ASDAS, patient global assessment (PGA) and physician global assessment (PhGA). We analysed the disease course throughout pregnancy and postpartum, the correlation between BASDAI and ASDAS and the agreement in the classification of active disease. We applied receiver operating curves (ROC) to evaluate the cut-off points in pregnant patients.
Results: The study involved 40 women with axSpA. Disease activity scores were higher during pregnancy (median ASDAS score: 2.5, median BASDAI score 3.1) than during a non-pregnant state (median ASDAS score 2.3, median BASDAI score 2.1). Median BASDAI scores were highest at the first trimester, median ASDAS scores were highest at the second trimester. ASDAS strongly correlated with BASDAI, both in the pregnant and in the non-pregnant state (r=0.796, r=0.727). However, there was a discordance when analysing the proportion of patients with high disease activity using the common cut-off values (ASDAS >2.1, BASDAS >4). More patients had high disease activity when measured by ASDAS (1st trimester (T): 63%, 2nd T: 76%, 3rd T: 61%) compared to those measured by BASDAI (1st T 43%, 2nd T: 39%, 3rd T: 34%). The κ coefficient showed only fair agreement (κ=0.39). ROC analysis among pregnant patients showed that the cut-off point estimation for high disease activity using ASDAS >2.75 corresponded to a BASDAI >4. The ASDAS >2.75 cut-off for high disease activity had a good agreement with BASDAI >4 (κ=0.657). When ASDAS >2.75 was applied in pregnant women with axSpA, about 40% experienced high disease activity.
Conclusion: During pregnancy, the majority of women with axSpA experience ongoing disease activity. However, the cut-off values defining low and high disease activity might differ between pregnant and non-pregnant individuals since BASDAI and ASDAS are biased by pregnancy related symptoms like fatigue and mechanical back pain.
Disclosure of Interests: None declared.

POS0998 SPONDYLOARTHRITIS AND SLEEP DISORDERS

S. Lahrichi[1], K. Nassar[1], S. Janani[1]. [1]*University Hospital of IBN ROCHD, Rheumatology, Casablanca, Morocco*

Background: Spondyloarthropathies (SpA) are a group of chronic and progressive diseases, characterized in particular by a progressive stiffening of the spine, spreading to neighboring joints or to certain tissues, which could lead in the long term to progressive stiffening and functional impairment. This conditioncancauseinsomnia problems and impaired sleep quality.
Objectives: To assess the impact of SpA on the quality of sleep.
Methods: This is a retrospective study over a period of 4 years from January 2015 to December 2019, including all the medical records of patients with SpA followed in the Department of Rheumatology of the University Hospital of Ibn Rochd, Casablanca. We evaluated for each patient two validated scores: the Epworth somnolence scale rated from 0 to 24, and the Pittsburgh sleep score rated from 0 to 21 with 7 components. Patients with a psychiatric history or who were followed up for neurological pathologies were excluded.
Results: 178 patients were included. 60.67% were men with an average age of 36.32 years (14-68 years). 45.01% had axial SpA, 29.77% had psoriatic arthritis, and 25.22% were followed for SpA associated with inflammatory bowel disease. 45% had associated comorbidities: there were 18 diabetics and 34 hypertensive, 16.58% were smokers. Clinically, 85.42% presented a back pain initially on examination, 55% presented a polyarthralgia, and 39.88% an oligoarthritis. 63% had radiological sacroiliitis, and 35.14% had bilateral coxitis. 13.48% had a positive HLA B27 and 58.89% had a

positive inflammatory assessment with very high activity indices,with a mean of 4.6. 64.66% of the patients received NSAIDs,of which 11% responded well. 57% were treated with csDMARDs, and 17.86% were treated with biologics. At the time of our study, the mean visual analog scale was 5.84 ± 1.7 out of 10 (2-9). The mean Epworth score was 8.38 ± 5.2 (0-21). 56.1% of patients had no sleep debt, 33.3% had a sleep deficit, and only 10.6% had signs of drowsiness. For the overall Pittsburgh score, the mean was 7.02 ± 3.6 (1-18). The mean of "subjective quality of sleep" was 1.12, "sleep latency" was 1.22, "duration of sleep" was 1.06, "usual sleep efficiency" was 0.74, "Sleep disturbance" of 1.28, "use of a sleep medication" of 0.54, and the average of the component concerning "poor shape during the day" was 1.03 out of 3. The LEQUESNE index went from an average of 6 to 8, which corresponds to an average handicap (P = 0.2) over a period of 3 years. 68% of the patients had an alteration in the quality of sleep, starting on average three years after the onset of symptoms. 11% reported having experiencedanxiety and depressive symptoms, and reported having used antidepressants or anxiolytics in the past 5 years.

Conclusion: Our study showed the negative impact of SpA on the duration and overall quality of sleep. The degree of pain as well as functional impairment can cause and worsen sleep disturbances in SpA. We have shown that the Pittsburg score increases significantly with the increase of pain.The Lequesne score and that the Epworth score increase with disease activity[1].

POS0999 HIGH CORRELATIONS BETWEEN QUESTION 1 & 2 OF THE BASFI: AN OPPORTUNITY TO STREAMLINE THE BASFI

M. Maclean[1], S. Maguire[1], F. B. O'shea[1]. [1]*St. James' Hospital, Rheumatology, Dublin, Ireland*

Background: The Bath Ankylosing Spondylitis Functional Index (BASFI) is a useful tool to quantitatively characterise functional ability in a patient with axial spondyloarthropathy (axSpA). Whether first presentation, decompensated, or routine follow-up, BASFI can help establish a more accurate understanding of disease progression, or response. As with any questionnaire, relevance and absence of redundancy is required. This analysis questions the redundancy of the first two questions of the BASFI:

1) How difficult is it to put socks on your feet?
2) How difficult is it to pick a pen up off the floor?

Objectives: To compare variation in reporting of questions one and two of the BASFI, to establish redundancy or exclusivity of these questions.

Methods: IBM SPSS version 26 was used for data analysis. Data from axSpA patients who attended the Rheumatology department during the study period were included in the analysis where BASFI scores were available. Both variables (pen scores and sock scores) were assessed with a Shapiro-Wilk's test for normal distribution. The variables were also assessed for the presence of a monotonic relationship by visual inspection of a scatterplot of the variables. Once a monotonic relationship was established a Spearman's rank order correlation between the sock score and pen scores for each participant was analysed.

Results: In total data from 82 axSpA patients were included in this analysis. Population was made up of 28% (23) females, 72% (59) males with mean BASDAI score 4.33 and mean BASFI score 3.88(Table 1). Both variables were not normally distributed as assessed by Shapiro-Wilk's test ($p < 0.05$) necessitating a Spearman's rank-order correlation for analysis. Preliminary analysis variables demonstrated the relationship between the variables to be monotonic as determined by visual inspection of the scatterplot (graph 1) with no outliers detected. There was a statistically significant, strong positive correlation between sock scores and pen scores in this axSpA population, $r_{partial}(80) = 0.809$ significant at the $p < 0.01$ level.

Table 1. Descriptive output of data

	% (n)
n	82
Females	28% (23)
Males	72% (59)
Age	45.03
BASDAI	4.33
BASFI	3.88
Pen score	3.93
Sock score	2.88
Sock score greater	7.3% (6)
Pen score greater	50% (41)
Same scores	42.7% (35)

Conclusion: There is a strong positive correlation between sock (question 1) and pen scores (question 2) as captured by the BASFI. It appears that both questions are capturing a similar functional limitation in patients with axSpA. In order to minimise redundancy and improve the relevance of the BASFI our results support the removal of one of these questions to simplify the BASFI. From a practical perspective, putting on socks (question 1) would be a more commonly encountered daily activity than picking up a
pen from the floor(question 2). As such, we would suggest removal of question 2 from the BASFI.

Table 1 & Figure 1

POS1000 COMORBIDITIES ASSOCIATED TO SPONDYLOARTHRITIS

S. Bouden[1], L. Kharrat[1], A. Ben Tekaya[1], O. Saidane[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Hospital Charles Nicolle, Rheumatology, Tunis, Tunisia*

Background: In contrast to other chronic rheumatic diseases such as rheumatoid arthritis, comorbidities associated to spondyloarthritis (SpA) and their impact on disease outcomes are less well studied.

Objectives: The aim of our study was to investigate the prevalence of comorbidities among SpA patients and to determine factors influencing their appearance.

Methods: We conducted a retrospective study including patients meeting the Assessment of SpondyloArthritis International Society (ASAS) criteria between 2000 and 2020.

The following comorbidities were collected: cardiovascular pathologies and their risk factors (smoking, arterial hypertension, diabetes, dyslipidemia and obesity), neoplasms, osteoporosis, depression, infections, gastrointestinal and pulmonary disorders.

Results: We included 138 patients. Sixty-eight per cent of them were males. The mean age was 45.73 ± 12.66 years. The mean age at the disease onset was 28.89 ± 12.54 years. The mean CRP was 33.38 ± 39.65 mg/dL. The mean BASDAI and ASDAS-CRP were 4.21 ±2.23 and 3.06 ± 1.26, respectively. The mean BASFI was 4.77 ± 2.58.

Sixty patients had at least one comorbidity (43.5%): 53 patients had one comorbidity (38.4%), 21 accumulated two types of comorbidities (15.2%) and 7 patients accumulated three types or more (5%).

Osteoporosis was the most frequent comorbidity, it was present in 23.1% of the cases (n=32), followed by tuberculosis 8.7% (n=12), stomach ulcers 5.1% (n=7), pulmonary superinfection 2.9% (n=4), neoplasia 2.2% (n=3) and then depression 1.4% (n=2).

Cardiovascular risk factors were noted in 44 patients (31.9%): hypertension (15.9%), diabetes (12.3%), dyslipidemia (9.4%) and obesity (8.7%).

Thirty-seven per cent of our patients were smokers.

SpA patients with comorbidities were significantly older than those without (50.2±11.07 *versus* 42.3±12.8 years, p<0.0001).

The presence of comorbidities was significantly associated to a higher disease activity evaluated by BASDAI (p=0.005) and ASDAS-CRP (p=0.002). Furthermore, BASFI was significantly higher among patients with comorbidities (5.47±2.38 *versus* 4.31±2.62, p=0.028).

However, no association was found between presence of comorbidities and smocking or CRP.

Conclusion: Our results show that more than 40% of our SpA patients presented with at least one comorbidity. Remarkably, the presence of comorbidities

was associated with high disease activity, suggesting that that inflammation might promotes comorbidities. For optimal management of SpA, a systemic screening for comorbidities is essential.

POS1001 CLINICAL AND SURROGATE CARDIOVASCULAR RISK ASSESSMENT AND ITS RELATIONSHIP WITH PSORIATIC ARTHRITIS PATHOGENESIS

N. Barbarroja Puerto[1], I. Arias de la Rosa[1], C. Román-Rodriguez[2], I. Gómez García[2], C. Perez-Sanchez[2], C. López-Medina[2], M. L. Ladehesa Pineda[2], D. Ruiz[2], A. M. Patiño-Trives[2], M. Luque-Tévar[2], C. Lopez-Pedrera[2], A. Escudero Contreras[2], E. Collantes Estevez[2], M. D. López Montilla[2]. *[1]Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC)/Reina Sofia Hospital/ University of Cordoba, Medicine Department, Cordoba, Spain*; *[2]Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC)/Reina Sofia Hospital/University of Cordoba, Rheumatology Department, Cordoba, Spain*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease associated with an increased prevalence of cardiovascular (CV) events. Traditional CV risk factors do not account for the increased CV disease mortality in PsA. Inflammation seems to have a key role in the development of this comorbidity, however the specific molecular mechanisms involved are not defined yet.

Objectives: To evaluate clinical CV risk factors and surrogate markers and their relationship with inflammation, disease activity and metabolic comorbidities in PsA patients

Methods: This is a cross-sectional study including 100 PsA patients without CV disease recruited in the routine clinical practice at the Rheumatology Department, Reina Sofia Hospital of Cordoba and 100 age-matched healthy donors (HDs). Different parameters related to the cardiometabolic risk were analyzed. Clinical and analytical parameters were collected: lipid profile (cholesterol, HDL, LDL, TG, ApoA and ApoB), glucose and insulin, body surface area (BSA) affected by psoriasis, number of tender and swollen joints, DAPSA, VAS, CRP and ESR. To measure the persistence of inflammation, CRP levels were recorded retrospectively once, twice, or three times during the 5 years prior to study and at the moment of the study. Increased levels of CRP in at least 50% of the determinations was considered as persistent inflammation. Plasma and peripheral blood mononuclear cells (PBMCs) were isolated from peripheral blood of patients and HDs. A panel of 92 proteins involved in CV disease and an adipocytokine profile was measured in plasma and PBMCs. In addition, activation of 18 intracellular pathways involved in cell activation was also measured in PBMCs. *In vitro* experiments in adipocytes treated with serum from PsA patients were also carried out.

Results: Traditional CV risk factors including atherogenic risk, insulin resistance (IR), metabolic syndrome, smoking, obesity, arterial hypertension, apolipoprotein B/A risk, type 2 diabetes mellitus and the levels of SCORE were significantly increased in PsA patients. The presence of IR was associated with disease activity markers (DAPSA, ESR and CRP). In fact, the HOMA-IR index was related to the CRP persistence. PsA patients with obesity had significantly increased the number of tender and swollen joints, the levels of DAPSA and CRP. Twenty-eight proteins involved in CV disease and six adipocytokines were significantly elevated in the plasma of PsA patients. Several of these cardiovascular molecules were associated with higher levels of DAPSA (CTSD, GAL3, CD163, FABP4, IL6 and IL1RT2), acute phase reactants (GAL3, TNFα, Adiponectin, TNFR1 and IL6), affected body surface area (IL2RA, GAL3, CCL15, TRAP, CSTB, CD163, OPG and CNTN1) and onychopaty (TRAP, VWF, MCP-1, GAL3, LTBR, TFPI, CHI3L1, CTSZ and JAM-A). In addition, the mRNA expression of most of those 28 CV molecules were significantly increased in PBMCs from PsA patients. At intracellular level, the activation of 11 kinases (ERK1/2, AKT, S6 Ribosomal, mTOR, HSP27, Bad, p70 S6 kinase, PRAS40, p53 and caspase-3) involved in insulin signaling, inflammation, cell survival and apoptosis were altered in PBMCs. Finally, serum from PsA patients was able to modify the expression of these molecules in adipocytes.

Conclusion: 1) Disease activity and inflammatory burden are closely associated with the presence of metabolic alterations, specifically obesity and IR in patients with PsA. 2) The development of IR is extremely related to the persistence of CRP levels in the previous 5 years. 3) Inflammation is closely associated to the adipose tissue dysfunction in PsA and 4) FABP4, CD163 and GAL3 are surrogate CV markers commonly associated with clinical features of PsA, suggesting the role of these molecules linking CVD and PsA pathogenesis.

POS1002 BASELINE CALPROTECTIN AND VISFATIN LEVELS PREDICT RADIOGRAPHIC SPINAL PROGRESSION AFTER 2 YEARS IN ANKYLOSING SPONDYLITIS PATIENTS ON TNF INHIBITOR THERAPY

J. Rademacher[1,2], M. Siderius[3], L. Gellert[1], F. Wink[4], M. Verba[1], F. Maas[3], L. M. Tietz[1], D. Poddubnyy[1,5], A. Spoorenberg[3], S. Arends[3]. *[1]Charité - Universitätsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology, Berlin, Germany*; *[2]Berlin Institute of Health, BIH, Berlin, Germany*; *[3]University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[4]Medical Center Leeuwarden, Department of Rheumatology, Leeuwarden, Netherlands*; *[5]Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology, Berlin, Germany*

Background: Radiographic spinal progression determinates functional status and mobility in ankylosing spondylitis (AS)[1].

Objectives: To analyse whether biomarker of inflammation, bone turnover and adipokines at baseline or their change after 3 months or 2 years can predict spinal radiographic progression after 2 years in AS patients treated with TNF-α inhibitors (TNFi).

Methods: Consecutive AS patients from the Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort[2] starting TNFi between 2004 and 2012 were included. The following serum biomarkers were measured at baseline, 3 months and 2 years of follow-up with ELISA:

- Markers of inflammation: calprotectin, matrix metalloproteinase-3 (MMP-3), vascular endothelial growth factor (VEGF)
- Markers of bone turnover: bone-specific alkaline phosphatase (BALP), serum C-terminal telopeptide (sCTX), osteocalcin (OC), osteoprotegerin (OPG), procollagen typ I and II N-terminal propeptide (PINP; PIINP), sclerostin.
- Adipokines: high molecular weight (HMW) adiponectin, leptin, visfatin

Two independent readers assessed spinal radiographs at baseline and 2 years of follow-up according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Radiographic spinal progression was defined as mSASSS change ≥2 units or the formation of ≥1 new syndesmophyte over 2 years. Logistic regression was performed to examine the association between biomarker values at baseline, their change after 3 months and 2 years and radiographic spinal progression. Multivariable models for each biomarker were adjusted for mSASSS or syndesmophytes at baseline, elevated CRP (≥5mg/l), smoking status, male gender, symptom duration, BMI, and baseline biomarker level (the latter only in models with biomarker change).

Results: Of the 137 included AS patients, 72% were male, 79% HLAB27+; mean age at baseline was 42 years (SD 10.8), ASDAScrp 3.8 (0.8) and mSASSS 10.6 (16.1). After 2 years of follow-up, 33% showed mSASSS change ≥2 units and 24% had developed ≥1 new syndesmophyte. Serum levels of biomarkers of inflammation and bone formation showed significant changes under TNFi therapy, whereas adipokine levels were not altered from baseline (Figure 1).

Univariable logistic regression revealed a significant association of baseline visfatin (odds ratio OR [95% confidence interval] 1.106 [1.007-1.215]) and sclerostin serum levels (OR 1.006 [1.001-1.011]) with mSASSS progression after 2 years. Baseline sclerostin levels were also associated with syndesmophyte progression (OR 1.007 [1.001-1.013]). In multivariable logistic analysis, only baseline visfatin level remained significantly associated (OR 1.465 [1.137-1.889]) with mSASSS progression. Furthermore, baseline calprotectin showed a positive association with both, mSASSS (OR 1.195 [1.055-1.355]) and syndesmophyte progression (OR 1.107 [1.001-1.225]) when adjusting for known risk factors for radiographic progression.

Univariable logistic regression showed that change of sclerostin after 3 months was associated with syndesmophytes progression (OR 1.007 [1.000-1.015), change of PINP level after 2 years was associated with mSASSS progression (OR 1.027 [1.003-1.052]) and change of visfatin after 2 years was associated with both measures of radiographic progression – mSASSS (OR 1.108 [1.004-1.224]) and syndesmophyte formation (OR 1.115; [1.002-1.24]). However, those associations were lost in multivariable analysis.

Conclusion: Independent of known risk factors, baseline calprotectin and visfatin levels were associated with radiographic spinal progression after 2 years of TNFi. Although biomarkers of inflammation and bone formation showed significant changes under TNFi therapy, these changes were not significantly related to radiographic spinal progression in our cohort of AS patients.

POS1003 CATASTROPHIZING IN PATIENTS WITH SPONDYLOARTHRITIS

B. Coste[1], C. Traverson[1], E. Filhol[1,2], C. Lukas[2,3], S. Laurent-Chabalier[4], J. Morel[3,5], B. Combe[3,5], C. Daien[3,5], C. Hua[1,2], C. Gaujoux-Viala[1,2]. *[1]Nîmes University Hospital, Rheumatology, Nîmes, France*; *[2]University of Montpellier, IDESP, UMR-INSERM, Montpellier, France*; *[3]CHU Lapeyronie, Rheumatology, Montpellier, France*; *[4]Nîmes University Hospital, BESPIM, Nîmes, France*; *[5]University of Montpellier, -, Montpellier, France*

Background: Catastrophizing is a negative cognitivo-affective response to an anxiety-provoking stimulus, especially anticipated or actual pain. It can be assessed quickly using a validated questionnaire: the Pain Catastrophizing Scale (PCS)[1]. Catastrophizing plays a role in maintaining chronic pain and is associated with several pain-related outcomes in osteoarthritis and low back pain. There is a lack of knowledge about catastrophizing in axial spondyloarthritis (AS) with only one study[2] so far.

Objectives: To assess the prevalence of catastrophizing and associated factors in spondyloarthritis.

Methods: We performed an observational, prospective, bi-centric study. All patients aged 18 or over with AS fulfilling the 2009 Assessment in Spondyloarthritis International Society (ASAS) criteria were consecutively included. Sociodemographic data, information on the disease and its treatments were collected as well as questionnaires regarding disease activity (BASDAI), function (HAQ, BASFI), quality of life (SF12, EQ5D), anxiety and depression (HADS, GAD7), fibromyalgia (FiRST), insomnia (ISI) and catastrophizing scores (PCS). Statistical analysis included a samples t-test, one-way variance analysis, Spearman's correlation coefficient, the Chi^2 test, Fisher's exact test, the Wilcoxon test, multivariate linear regression (considering catastrophizing as a continuous variable) and multivariate logistics regression (considering catastrophizing as a categorical variable: PCS ≥ 20 = high level catastrophizing).

Results: From September 2019 to March 2020, 168 AS patients were included: 48.5% were women, the median age was 48.5 years and 100 patients (60.2%) were professionally active. Almost all patients (95.8%) had a disease lasting for more than 2 years; 110 (72%) were HLA-B27+; 84 (50%) had MRI sacroiliitis and 62 (37.6%) radiographic sacroiliitis. In all, 166 (98.8%) had axial involvement, 99 (58.9%) had peripheral involvement and 44 (26.2%) had enthesitic involvement. The median BASDAI score was 6.30 [Q1-Q3 4.65-6.30].

The prevalence of a PCS score ≥20 was 45.5% [38.0;53.0]. The median PCS score was 18 [7-27]. In multivariate logistics regression, high-level catastrophizing was significantly associated with the HADS anxiety score (OR=1.54 [1.22-2.0]), HADS depression score (OR=1.25 [1.10-1.43]) and disease activity (BASDAI OR=1.14 [1.01-1.26]). In multivariate linear regression, catastrophizing was also significantly associated with anxiety (p<0.0001), depression (p<0.0001) and disease activity (p=0.0008).

Conclusion: Almost half the patients with AS were high catastrophizers. Catastrophizing is linked to anxiety, depression, and disease activity. It may be interesting to detect catastrophizing in order to improve the management of our patients.

POS1004 BOTH SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS PATIENTS HAVE STRONG FAMILY HISTORIES

G. K. Yardımcı[1], B. Farisoğulları[1], E. C. Bolek[1], E. Bilgin[1], E. Duran[1], G. Ayan[1], Z. Özsoy[1], G. Sandal Uzun[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], A. İ. Ertenli[1], U. Kalyoncu[1], S. Kiraz[1]. *[1]Faculty of Medicine; Hacettepe University, Rheumatology, Ankara, Turkey*

Background: Family history is one of the hallmarks of spondyloarthritis (SpA) and psoriatic arthritis (PsA) [1, 2]. Some patients have a strong family history that more than 2 relatives have spondyloarthritis related diseases. The effects of strong family history on SpA features were not known very well.

Objectives: The aim of this study is to evaluate the effects of family history in SpA and PsA patients.

Methods: HUR-BIO (Hacettepe University Biologic Registry) is a prospective, single center database of biological treatments since 2005, and to date 3071 SpA and 526 PsA patients have been recorded. Demographic, clinical characteristics, disease activity parameters, a detailed family history of SpA and SpA features (presence of SpA including PsA, psoriasis, inflammatory bowel disease and uveitis) and laboratory data before anti-TNF treatments of the patients were noted.

Results: 2807 SpA (53.6% male) and 506 PsA (31.4% male) patients' family history were available and analysed. A positive family history was noted in 27.6% of the SpA and 31.0% of the PsA patients (ns). 7.4% of the SpA patients and 8.9% of the PsA patients had family history in more than one relative (Table 1). In SpA patients with a family history, uveitis was more frequent than patients without (14.4% vs 10.6%, p=0.006). Except for a higher male predominance and uveitis (53% vs 32% p=0.006 and 9% vs 2% p=0.003 respectively) in patients with ≥2 relatives with SpA features, there were no differences in PsA patients regarding family history. The presence of family history and HLA-B27 (63.7% vs 37.6%, p<0.001) positivity were associated in SpA patients but not in PsA patients (31.2% vs 20.0, p=0.13).

Conclusion: Family history was present in about one third of the patients of PsA and SpA. It is not uncommon for two or more family members to have a SpA feature. Presence of family history may be associated with some clinical conditions, such as uveitis.

Background: Reactive Arthritis (ReA) is an inflammatory joint disease and, as in rheumatoid or psoriatic arthritis, composite indices are the most useful tools to measure disease activity. The Disease Activity Index for Reactive Arthritis (DAREA) is the only developed index for ReA, which requires a 66/68 joint count and CRP for its assessment, the latter being difficult to acquire in our setting. Therefore, we developed a simplified index, the modified DAREA (DAREAm), with a lower joint count and ESR for its evaluation.
Objectives: 1) To evaluate the DAREA and the DAREAm in a cohort of patients with diagnosis of ReA and post-infectious arthritis 2) To assess the correlation of the DAREA and DAREAm with several clinical variables, functional capacity and quality of life in a cohort of patients with ReA.
Methods: Patients with diagnosis of ReA (Calin'79) and post-infectious arthritis were included. Demographic data were collected, patient´s pain and global assessment were evaluated through a visual analog scale (VAS) and a 3-point scale (no pain = 0, mild = 1, moderate = 2, severe = 3), physician´s global assessment, morning stiffness (MS) and VAS fatigue. Functional capacity was assessed by HAQ and quality of life according to EuroQol-5 dimensions (EQ-5D), and the activity indices DAS28, DAREA and DAREAm were calculated. Statistical analysis: a descriptive analysis of the variables and correlation between numerical variables with Spearman rank correlation were performed.
Results: 57 patients were included, 53 with diagnosis of ReA, the majority post urogenital (63%) and gastrointestinal (17%), and 4 with diagnosis of post-infectious arthritis. Fifty six percent were male, mean age: 40 years old (SD ± 14) and median ReA duration: 15 months (IQR 2-45). The number of painful and swollen joints in a 66/68 joint count showed a median of 2 (IQR 0-3) and 1 (IQR 1-2) respectively. Median VAS pain 43 (IQR 15-70), patient´s disease activity 40 (IQR 20-60) and physician´s 40 (IQR 20-60), MS 10 (IQR 0-50) and fatigue 30 (IQR 0-80). Median DAS28 3.6 (IQR 2.3-4.3), DAREA 7.4 (IQR 2.5-10.6), DAREAm 8.6 (IQR 4.6-12.7), HAQ 0.625 (IQR 0.125-1). The dimensions with the greatest compromise in the EQ-5D were pain/discomfort (63%) and anxiety/depression (51%), and the median VAS EQ-5D was 60 (IQR 32-80). DAREA correlated with DAREAm (rs= 0.89; p <0.001), DAS28 (rs= 0.84; p <0.001), medical VAS (rs= 0.60; p <0.001), MS (rs= 0, 50; p <0.001), HAQ (rs= 0.53; p <0.001), VAS fatigue (rs= 0.57; p <0.001) and mobility subscales of the EQ5D (rs= 0.56; p <0.001), pain/discomfort (rs= 0.49; p <0.001) and anxiety/depression (rs= 0.61; p <0.001). The DAREAm correlated with DAS28 (rs= 0.93; p <0.001), physician VAS (rs= 0.58; p <0.001), fatigue VAS (rs= 0.53; p <0.001), HAQ (rs= 0 .51; p <0.001) and the EQ5D subscales: mobility (rs= 0.64; p <0.001), pain/discomfort (rs= 0.56; p <0.001) and anxiety/depression (rs= 0.66; p <0.001)
Conclusion: This is the first study that assess activity indices in a cohort of patients with ReA. The DAREAm demonstrated a very good correlation with both DAREA and DAS28. We encourage the use of this simplified index in daily practice to evaluate patients with ReA.

POS1006 ABERRANT TH17 CELLS EXPANSION AND RISK FACTORS IN ANKYLOSING SPONDYLITIS PATIENTS COMPLICATED WITH CARDIOVASCULAR EVENTS

T. Ding[1], B. C. LI[2], R. Su[2], X. F. LI[2], C. Wang[2]. [1]*The Second Hospital of Shanxi Medical University, Rheumatology, Taiyuan, China*; [2]*Rheumatology, The Second Hospital of Shanxi Medical university, Taiyuan, China, Rheumatology, Taiyuan, China*

Background: The incidence of Ankylosing Spondylitis (AS) complicated with cardiovascular diseases (CVD) has increased in recent years [1]. However, identification of risk factors indicating the development of CAD in AS patients is lacking. Th17 cells are increasingly recognized to be important in atherogenesis [2]. However, the role of these cells in the pathogenesis of ankylosing spondylitis patients complicated with cardiovascular events remains elusive.
Objectives: This study aimed to assess the level of circulating Th17 cells as well as other lymphocyte subsets such as Treg, Th, Ts, and NK cells in AS combined with CVD, and further to evaluate whether elevations in special PBMC subpopulations in AS patients indicate an increased risk of CVD.
Methods: Samples were assessed from 141 AS patients hospitalized at the Second Hospital of Shanxi Medical University (60 AS patients combined with CVD and 81 AS patients without CVD) and 100 healthy controls. The absolute numbers of lymphocytes and CD4+ T cells in peripheral blood were determined using Flow Cytometer. The association between PBMC subpopulations and CVD development in AS patients were analyzed using multivariable logistic regression.
Results: 1. Compared with AS group, AS with CVD group exhibited significant increases in the number of Th17 cells (P=0.001) and Treg cells (P=0.046). The ratio of Th17/Treg was also increased (P=0.085).
2. Analogous increases in the absolute number (P<0.001) and frequency (P<0.001) of Th1 cells, as well as the ratio of Th1/Th2 (P<0.001) and Th1/Treg (P=0.004) were also present in AS with CVD patients, compared to those without CVD.
3. Compared to HCs, 141 AS patients showed significantly decreased Treg cells (P<0.012) and increased Th17/Treg (P=0.001).
4. Logistic regression showed age (odds ratio: 1.09; 95% CI: 1.035-1.137), hypertension (odds ratio: 3.31; 95% CI: 1.152-9.528), diabetes (odds ratio: 8.03; 95% CI: 1.251-51.503), and elevated level of Th1 number (odds ratio: 1.01; 95% CI: 1.003-1.016) and DD (D-dimer) (odds ratio: 1.00; 95% CI: 1.000-1.002) were significantly correlated with the onset of CVD in AS patients.
5. Smoke, increased Th17 level, and use of NSAIDS were also positively correlated with the onset of CVD although the P-values did not reach significant.
Conclusion: Our data indicates aberrant expansion of Th17 cells in AS with CVD patients. Moreover, age, hypertension, diabetes, and increased level of Th1 in PBMC and DD are single independent risk factors for the presence of CVD in AS. The mechanisms of atherogenesis in AS may associate with the elevations in Th1 and Th17 cells. Imbalance of Th1/Th2 and Th17/Treg may be shared etiologic pathways of AS and CVD, providing attractive targets for the prevention and therapy of CVD development in AS patients.

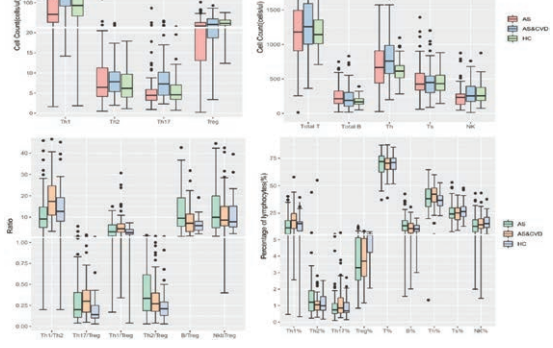

Figure 1. Compared with AS group, AS with CVD group exhibited significant increases in the number of Th17 cells (P=0.001) and Treg cells (P=0.046). The ratio of Th17/Treg was also increased (P=0.085). The absolute number (P<0.001) and frequency (P<0.001) of Th1 cells, as well as the ratio of Th1/Th2 (P<0.001) and Th1/Treg (P=0.004) were also present in AS with CVD patients.

POS1007 OPTIMIZING A REFERRAL STRATEGY FOR PATIENTS WITH A HIGH PROBABILITY OF AXIAL SPONDYLOARTHRITIS: THE ROLE OF AGE AND SYMPTOM DURATION

F. Proft[1], L. Spiller[1], B. Muche[1], M. Protopopov[1], J. Rademacher[1], V. Rios Rodriguez[1], M. Torgutalp[1], D. Poddubnyy[1], I. Redeker[2]. [1]*Charité - Universitätsmedizin Berlin, Division of Gastroenterology, Infectious Diseases and Rheumatology; Department of Rheumatology, Berlin, Germany*; [2]*German Rheumatism Research Centre; Deutsches Rheuma-Forschungszentrum Berlin (DRFZ);, Programmbereich Epidemiologie, Beerlin, Germany*

Background: One of the most important prerequisites for a timely diagnosis of axial spondyloarthritis (axSpA) is the early referral of a patient with back pain to a rheumatologist. In the past years a number of referral strategies has been proposed,

most of them in line with the ASAS referral recommendations [1] and with a similar performance – about 30-40% of the referred patients can be diagnosed with axSpA after examination by a rheumatologist. In addition to physician-based strategies, an online self-referral (OSR) strategy has been recently proposed and evaluated about 20% of the patients being diagnosed with axSpA after rheumatologic evaluation [2].
Objectives: The objective of the current analysis was to investigate the role of age and symptom duration for the optimization of a physician-based and an OSR strategy for axSpA.
Methods: In the OptiRef study, patients with chronic back pain and suspicion of axSpA either referred by primary care physicians /orthopedists using the Berlin referral tool (=physician based) or based on a referral recommendation of an OSR were evaluated by rheumatologists in a specialized center [2]. All patients underwent a structured examination including imaging that resulted into the final diagnosis of axSpA or no axSpA. The relationship between age, symptom duration and the likelihood of axSpA diagnosis was evaluated in this analysis.
Results: A total of 360 patients (180 presented via the OSR and 180 referred by the physician based referral strategy) were included in this analysis. Patient's characteristics are shown in Table 1. A total of 71 patients (39.4%) in the physician-based group and 35 patients (19.4%) in the OSR group were finally diagnosed with axSpA. The heatmaps depicting the relationship between the proportions of patients diagnosed with axSpA and age plus symptom duration (Figure 1) showed a clear decline of the axSpA probability with increasing age. In the physician-referred group, however, axSpA was diagnosed even in patients who were above 50 years at the time-point of the examination, while there were only few patients with axSpA in the self-referred group aged 40-49 years, and none in the age group ≥50 years. Interestingly, there was no clear relationship between symptom duration and probability of the diagnosis: axSpA was diagnosed in a substantial proportion of patients even with a long history of back pain (>12 years) in both subgroups.
Conclusion: The probability of axSpA is high in patients suffering from back pain and aged <40 years with a substantial decline thereafter. Therefore, a referral strategy based on self-evaluation of symptoms should be more focused on a younger patient population, while physician-based strategies do not require such a restriction.

POS1008 THE ROLE OF SERUM CALPROTECTIN IN THE DIAGNOSIS OF INFLAMMATORY BOWEL DISEASE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

P. Kulakova[1], G. Lukina[1], E. Alexandrova[2], A. Novikov[2], A. Klimets[3], N. Savenkova[3], A. Kovshik[3], E. Volnukhin[3]. *[1]The Loginov Moscow Clinical Scientific Center of Moscow Healthcare Department" (The Loginov MCSC MHD), Rheumatology, Moscow, Russian Federation*; *[2]The Loginov Moscow Clinical Scientific Center of Moscow Healthcare Department" (The Loginov MCSC MHD), Immunology, Moscow, Russian Federation*; *[1]The Loginov Moscow Clinical Scientific Center of Moscow Healthcare Department" (The Loginov MCSC MHD), Rheumatology, Moscow, Russian Federation*

Background: Ankylosing spondylitis (AS) and inflammatory bowel diseases (IBD) have many common features. Approximately one in two patients with axial spondyloarthritis have subclinical (histologically confirmed) inflammation of the intestine, and 5-10% of subclinical inflammation turns into Crohn's disease (CD) or Ulcerative colitis (UC) [1]. Colonoscopy is usually used to diagnose IBD, but this procedure is invasive. Laboratory biomarkers, as fecal calprotectin (FC) and serum calprotectin (SC) can used to diagnosis of IBD. But there is no consensus regarding SC clinical utility. SC is exposed to proteolytic enzymes, but its level also increases with inflammation in the intestine and is associated with a higher disease activity [2]. SC levels positively correlate with CRP, ESR, disease activity in AS, but not as obvious as with FC [3,4].
Objectives: The aim of this study was to evaluate the possibility of using SC in the diagnosis of IBD in patients with AS.
Methods: In the analysis were included 50 patients with AS, fulfilling the modified New York criteria, among them man -36 (72%), woman -14 (28%), mean age of patients was 42.5 ±9.9, mean disease duration – 13.4±8.7 years. All patients were examined with ESR, CRP, FC (range: 100-1800 µg /g), esophagogastroduodenoscopy, colonoscopy and quantitative analysis of the SC level using ELISA (BUHLMANN MRP8/14 ELISA, range: 0.4-3.9 µg /ml).
Results: All patients had a high disease activity, mean BASDAI was 5.3 ± 1.8, mean ASDAS CRP 3.7 ± 1.01, mean ASDAS ESR 3.6 ± 1.01. 80 % patients had high FC level (more than 100 µg / g), while only 18% patients had an increase of SC level. IBD were diagnosed in 11 cases: 6 patients (12 %) with CD and 5 patients (10 %) - UC, in the remaining cases (78%) was no intestinal pathology. Only 2 patients with IBD had a high SC level. SC level was more correlated with ESR (r=0.5) and CRP (r=0.5) (p <0.05) levels, than with FC level (r=0.4) (p <0.05).
Conclusion: The results showed that there is currently insufficient data to assess the possibility of using SC in the diagnosis of IBD in patients with AS. There is a significant association between the SC, CRP and ESR, but not fecal calprotectin. Potentially SC may be more representative of systemic inflammation than an intestinal inflammation.

POS1009

ASYMPTOMATIC ENTHESITIS AND DOMINANT SIDE RELATED PATTERNS IN SPONDYLOARTHRITIS – THE ROLE OF ULTRASONOGRAPHY IN EVERYDAY PRACTICE

R. Decianu[1], V. Bojinca[2,3], L. Groseanu[2,3], S. Daia-Iliescu[2,3], A. Borangiu[2,3], C. L. Constantinescu[2,3], C. Cobilinschi[2,3], M. Duna[2], I. R. Gheorghe[4], D. Mazilu[2,3], M. M. Negru[2,3], D. Opris-Belinski[2,3], I. Saulescu[2,3], O. Vutcanu[5], A. Balanescu[2,3], M. Bojinca[3,5], R. Ionescu[2,3]. *[1]National Institute of Rehabilitation, Physical Medicine and Balneoclimatology, III, Bucharest, Romania*; *[2]"Sfanta Maria" Clinical Hospital, Internal Medicine and Rheumatology, Bucharest, Romania*; *[3]"Carol Davila" University of Medicine and Pharmacy, Rheumatology, Bucharest, Romania*; *[4]"Carol Davila" University of Medicine and Pharmacy, Marketing and Medical Technology, Bucharest, Romania*; *[5]"Dr. I. Cantacuzino" Clinical Hospital, Internal Medicine and Rheumatology, Bucharest, Romania*

Background: The spondyloarthritis (SpA) family includes a heterogeneous spectre of inflammatory diseases with several common features, such as the axial and peripheral joint involvement, but also trigger factors, as for instance, mechanical stress, infectious diseases or gut dysbiosis.[1,2]
Entheseal inflammation is the common background in the pathogenesis of SpA, leading to osteitis, periostitis and osteoproliferation. Despite being a central feature in SpA, enthesitis remains underdiagnosed in everyday practice.[3,4]
Objectives: The primary objective is to assess the frequency of ultrasound versus clinically detected enthesitis in a sample of Romanian patients with highly active SpA. A secondary objective is to determine the existence of an enthesitis pattern according to the dominant side in this sample of patients.
Methods: Out of 140 SpA patients, 106 were diagnosed with axial/peripheral SpA and 34 with psoriatic arthritis (PsA), and were clinically (medical history, clinical examination) evaluated, scanned using MSUS during the same visit, then asked which was their dominant side, in order to avoid any biases. The evaluation targeted 16 entheseal sites (Achilles tendon, plantar fascia, quadriceps tendon, proximal and distal patellar tendon, triceps tendon, extensor and flexor tendons of the hand, all evaluated on both sides), reaching a total of 2240 entheses. The medical history form included questions related to present or past spontaneous pain in any of the 16 evaluated sites as well as the clinical examination that evaluated the entheseal pain upon pressure (digital pressure on the enthesis overlying skin).
The MSUS evaluations were conducted using Esaote My Lab machines with 6-12/8-18 MHz linear probes. The same clinician/ultrasonographer performed all evaluations, in order to avoid interobserver variability.
Results: In the studied sample of patients, 68.6% were men, had a mean age of 43,46 (+/- 11,77), 51.4% were diagnosed with peripheral SpA, with a mean disease duration of 61,60 (+/- 71,03) months, and entheseal abnormalities were found in up to 62.7% of the asymptomatic entheses, lacking both spontaneous and elicited pressure pain.
The best performance of clinical and ultrasound examination was observed in the evaluation of the flexor tendons of the hand, with strong agreement between the two methods (kappa = 0,718, p = 0.001). Conversely, the lowest performance of clinical and ultrasound examination was noticed in Achilles (kappa = 0,292, p = 0.001) and distal patellar tendons (kappa = 0,202, p = 0.001), with low agreement indices. Both GS and PD abnormalities were more frequently detected on the right side, in a sample of 98.57% right handed patients. The differences were higher regarding the insertions of the triceps tendon (2.2%) and the plantar fascia (2.1%), in favour of the dominant side.
Conclusion: Entheseal reported pain (spontaneous and elicited by pressure) correlates poorly with MSUS detected enthesitis. This study highlights the high rates of imaging detected, but clinically overlooked entheseal abnormalities in SpA patients. Enthesitis was more frequently detected on the dominant side, emphasizing the role of mechanical stress in the pathogenesis of this feature. This outcome also requires the selection of the most reliable entheseal sites for SpA, being a future direction of research for this ongoing study.

PREDICTING CARDIOVASCULAR EVENTS IN PATIENTS WITH SPONDYLOARTHRITIS: 3 RISK ALGORITHMS

A. S. Pinto[1,2], F. Cunha Santos[1], S. P. Dinis[1], F. Guimarães[2], D. Esperança Almeida[3], H. Parente[2], S. Azevedo[2], C. Vaz[1,4], D. Faria[2], J. F. Ferreira[1,4]. *[1]Unidade Local de Saúde da Guarda, Rheumatology, Guarda, Portugal*; *[2]Unidade Local de Saúde do Alto Minho, Rheumatology, Ponte de Lima, Portugal*; *[3]Hospital de Braga, Rheumatology, Braga, Portugal*; *[4]Universidade da Beira Interior, Faculdade de Ciências da Saúde, Covilhã, Portugal*

Background: In the most recent European League Against Rheumatism (EULAR) cardiovascular risk reduction recommendations[1], the use of the SCORE algorithm has been advocated as a useful tool to identify an increased 10-year cardiovascular risk of first fatal atherosclerotic event. Even though validated inflammatory disease-specific CV risk score algorithms are still lacking, the EULAR task force advocated the use of a 1.5 multiplication factor for RA, but not clear for other inflammatory diseases.
Objectives: To assess the accuracy of several CV risk algorithms to predict an event and determine its sensibility and specificity.
Methods: A retrospective analysis of Spondyloarthritis (SpA) patients, registered in REUMA.PT, followed in two Portuguese centres was done. We calculated risk prediction algorithms such as Framingham, the American College of Cardiology/American Heart Association (ACC/AHA) risk score and the Systematic Coronary Risk Evaluation (SCORE) for low-risk countries. The adaptation of risk algorithms was done, accordingly to EULAR recommendations. Primary outcome was the first CV event. Discriminatory ability for CV risk prediction was evaluated by the area under the ROC curves. Sensibility and specificity were calculated for low-to-intermediate and intermediate-to-high risk cut-offs. Cut-off values of high risk were defined in 5% for SCORE, 20% for Framingham and ACC/AHA.
Results: 362 patients with SpA were included, 53.9% male (195), with a mean age of 51.1 ± 12.7 years. 67.8% of the patients were HLA B27 positive. Overall, the mean BMI was 26.3± 4.4 Kg/m^2 and 24.0% of the patients (87) were smokers in their lifetime. The mean of systolic blood pressure was 130± 16.4 mmHg, diastolic blood pressure of 73.5 ± 10.4 mmHg, total cholesterol of 190.1± 37.2 mg/dL and high-density lipoprotein cholesterol of 53.0 ± 14.8 mg/dL. Anti-hypertensive medication was reported in 24.3% of the patients, cholesterol medication in 19.3% and antidiabetic medications in 6.1%. Twenty-five patients (6.9%) presented a cardiovascular event. Patients with a cardiovascular event were older, with higher BMI, prescribed with medication for CV comorbidities and higher diastolic and systolic blood pressure (p<0.05).
Patients were under biologic therapy in 30.9% (112), 16.9% (61) with methotrexate; 16.3% (59) with sulfasalazine and 2.8% (10) with leflunomide; 68.5% (248) prescribed with NSAID and 10.8% (39) with corticosteroids. Area under the ROC in original and adapted scores were equal: 0.709 (95% CI 0.598 to 0.819) for SCORE, 0.805 (95% CI 0.737 to 0.872) for Framingham and 0.776 (95% CI 0.695 to 0.857) for ACC/AHA (Figure 1).

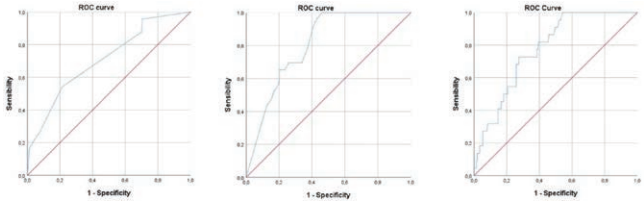

Figure 1. ROC curves for SCORE, Framingham and ACC/AHA

SCORE>1% showed the best sensitivity (96%) but lower specificity. Framingham>20% presented the best specificity (80%) with lower sensitivity (61%). In all cases, specificity raises with higher cut-off with corresponding reduction in sensibility. (Table 1)

Table 1. Sensibility, specificity, positive predictive value (PPV) and negative predictive value (NPV) of CV risk algorithms

	Sensibility (%)	Specificity (%)	PPV (%)	NPV (%)
SCORE > 1%	96	29	12	99
SCORE > 5%	54	78	20	94
Framingham >10%	78	63	15	97
Framingham >20%	61	80	21	96
ACC/AHA >5%	82	55	16	97
ACC/AHA >20%	32	86	20	92

Conclusion: A good discrimination between patients with or without CV events has been demonstrated by area under the ROC curve. The adaptation of CV risk algorithms according EULAR recommendations did not provide an improvement in discriminative ability. Overall, the algorithms studied presented a low sensibility or specificity. Better algorithms are needed to correctly assess cardiovascular risk for SpA patients and they should take into consideration the risk associated with the disease.

POS1011 PREDICTORS OF ENDOTHELIAL DYSFUNCTION IN ANKYLOSING SPONDYLITIS

A. Syngle[1], N. Garg[2], I. Verma[3], P. Krishan[4]. [1]*Healing Touch City Clinic, Chandigarh, & 2. Fortis Multi-specialty Hospital, 1. Cardio Rheuma Division; Internal Medicine and Rheumatology, Chandigarh, India*; [2]*Chitkara University, Chitkara College of Pharmacy, Department of Pharmacy Practice, Patiala, India*; [3]*MM College of Pharmacy, Maharishi Markandeshwar, Department of Pharmacy Practice, Mullana, Ambala, India*; [4]*Punjabi University, Department of Pharmaceutical Sciences and Drug Research, Patiala, India*

Background: Cardiovascular (CV) disease is the leading cause of death in Ankylosing Spondylitis (AS). Chronic systemic inflammation driven endothelial dysfunction leading to accelerated atherosclerosis results in premature mortality. Endothelial dysfunction is potentially treatable hence a therapeutic target. Predictive biomarkers for endothelial dysfunction would allow tailoring therapy to the individual.
Objectives: To assess the endothelial dysfunction in AS in context of markers of inflammation and oxidative stress in AS patients.
Methods: Sub group–analysis of our previous studies of AS[1-3] was carried out and 80 AS patients were compared with 40 healthy controls matched for age and sex that were also part of these studies.[2,3] Such analysis had so far not been performed in this cohort. Patients with traditional CV risk factors had been excluded in these studies. Flow-mediated dilatation (FMD), as a measure of endothelial function, was assessed by AngioDefender (Everist Health, Ann Arbor, MI). Inflammatory measures included: Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS) in AS. We also assayed markers of inflammation, including C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), proinflammatory cytokines (interleukin [IL]-1, IL-6, and tumor necrosis factor [TNF]-α), and endothelial dysfunction, including lipids and nitrite and marker of oxidative stress, TBARS.
Results: FMD was significantly lower in AS patients compared with controls [(5.80±0.35% vs. 9.09±0.35%, p≤0.05) reduced by approximately 36%] whereas serum nitrite, TBARS, total cholesterol and LDL levels were significantly higher in AS compared with controls (p≤0.05). Compared with controls, AS patients had significantly high BASDAI, ASDAS and increased concentrations of ESR, CRP, TNF-α, and IL-6. In AS, FMD inversely correlated with ASDAS, CRP (Figure 1A), TNF-α (Figure 1B), nitrite (Figure 1C) and TBARS (Figure 1) and positively correlated with HDL (p≤0.05).
Conclusion: In AS, FMD was impaired, indicating endothelial dysfunction. ASDAS, CRP, TNF-α, nitrite, and TBARS were independent predictors of FMD in AS. AS-related inflammatory mechanisms (TNF-α, IL-6) and markers of vascular function and oxidative stress (CRP, nitrite and TBARS) may all be involved in the development of cardiovascular disease in AS and these predictors could serve as a novel therapeutic targets for preventing CV risk in AS.

POS1012 HOW IMPORTANT WOULD BE THE IMPACT OF SPONDYLOARTHRITIS ON MILITARY POPULATION'S WORKING LIFE?

T. Mehmli[1], R. Dhahri[1], M. Slouma[1], E. Hannech[1], B. Louzir[2], L. Metoui[1], I. Gharsallah[1]. [1]*Military Hospital of Tunis, Rheumatology department, Tunis, Tunisia*; [2]*Military Hospital of Tunis, Internal medecine department, Tunis, Tunisia*

Background: Spondyloarthritis is a group of chronic inflammatory diseases involving axial and peripheral joints. It mainly affects young patients typically of working age. Therefore, its impact on work outcomes may be considerable particularly in military patients.
Objectives: The aim of this study was to evaluate the impact of spondyloarthritis on work ability and productivity in military patients, and to assess relationship between work productivity loss and disease activity.
Methods: Thirty Three patients diagnosed with spondyloarthritis in the militay hospital of Tunis were included in the study. Age, gender and C-reactive protein were recorded. Data related to duration of the disease, Ankylosing Spondylitis Disease Activity Score (ASDAS) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) were also recorded. Employed patients completed Work Productivity and Activity Impairment (WPAI) questionnaire witch assesses four subscales: presenteism, absenteism, overall work impairemend and daily activity impairement in the 7 past days.
Results: Among the thirty three patients, 63 % were men and 37% were women. The average age was 43,7 ± 13,5. The average duration of disease was 8,5 ± 7,75 years. Mean C-Reactive protein was 27,5 ± 39,3. Mean ASDAS and BASDAI were 3,12 ± 1,39 and 4,26 ± 1,78 respectively. 22 patients (66%) had an active disease and 11 (33%)were in remission. 48,4% of patients were using NSAIDs, 48,4% were under DMARDs and 42% were under biologics (12 patients using TNF-alpha blockers and 2 patients were given IL-17 inhibitors). Among this patients, 27 were employed. Three patients (11%) had a total work disability and were retired from work and two have been outplaced.
Employed patients worked an average of 35,6 ± 10,3 hours per week and missed an average of 3,48 ± 6,49 hours per week. The mean rates of absenteeism, presenteeism and work productivity loss were 8,8 ± 16,9 %, 48,4 ± 19,9 % and 48,6 ± 19,7 %.
There was a statistically significant correlation between BASDAI and work missed hours (p<0,05, r=0,48), absenteeism (p<0,05, r=0,48), presenteeism (p<0,01, r=0,669), work impairement (p<0,01, r=0,669), activity impairement (p<0,05, r=0,475) and work productivity loss (p<0,05, r=0,475), as well as between ASDAS CRP and presenteeism (p<0,05, r= 0,593), work impairement (p<0,05, r=0,593), activity impairement(p<0,05, r=0,460) and work productivity loss (p<0,05, r=0,460). No relation was found between WPAI indexes and C-reactive protein.
Conclusion: This study demonstrates that spondyloarthritis has a major impact on military patients' work productivity with a significant correlation between WAPI indexes and disease activity scores (ASDAS CRP and BASDAI). No relation was found with C-reactive protein.

POS1013 LET'S TAKE A LOOK AT THE SYMPHYSIS PUBIC AREA IN SPONDYLARTHRITIS

H. Hajji[1], H. Ferjani[1], K. Maatallah[1], S. Miri[1], C. Ines[1], M. Yasmine[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Institute, Tunis; Rheumatology, Tunis, Tunisia*

Background: Symphysis pubic (SP) is the frequent site of enthesitis in spondylarthritis (SpA). Radiological changes in SP appear later in the course of the disease. Underdiagnosed, its prevalence varies from 4% to 47% (1), depending on imaging modalities.
Objectives: This study aimed to evaluate the prevalence of SP involvement in patients with spondyloarthritis (SpA). We also focused on the relation between radiographical changes and clinical findings.
Methods: It was a cross-sectional study, including patients with SpA according to the Assessment of SpondyloArthritis International Society (ASAS) criteria. We collected the following data: age, gender, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS), and Bath Ankylosing Spondylitis Functional Index (BASFI).
Pelvic radiographs were examined by 2 experimented rheumatologists. Grading symphysial involvement was made as follow: scores ranged from 0-4 per reading: grade 0 = normal; grade 1 = subtle irregularity and/or subchondral sclerosis, grade 2 = clear erosions, 3 = marked sclerosis, grade 4 = ankylosis.
We divided our patients into two groups: G0 patients without SP changes and G1 patients with SP changes.
Results: One hundred and thirty-one patients were included, 84 were male, and 48 were female. The sex ratio M/F was 1.72. The mean age was 41.32±12.42

years. The mean disease duration was 12.65 ± 9.49 years. The clinical presentation of SpA was peripheral in 61 cases and axial in 118 cases. The mean disease scores activity was: BASDAI: 3.94±2.046 and ASDASCRP: 2.75±1.05. The mean BASFI was 4.17±2.7

SP changes were observed in 31 patients: score 1 (n=14), score 2 (n=8), score 3 (n=8) and score 4 (n=4). Sex ratios M/F were 2.1 and 1.65 in G1 and G0, respectively (p=0.23). No statistically significant differences were reported between the two groups G0 and G1: mean age (40.48 vs. 43.45, p=0.324), mean disease duration (11.19 vs. 14.45, p=0.218), mean BASDAI (3.8 versus 3.9, p=0.850), mean ASDAS-ESR (3.09 vs. 2.55, p=0.113) and mean BASFI (3.76 versus 4.96, p=0.06) respectively. In G1, nine patients had hip involvement (p=0.203). Enthesitis was more common in patients with SP changes (p=0.02).

Conclusion: In our study, the presence of enthesitis was associated with SP changes. Surprisingly, age and disease duration did not influence SP changes (1).

POS1014 CENTRAL SENSITIZATION HAS MAJOR IMPACT ON QUALITY OF LIFE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

S. Kieskamp[1], D. Paap[1], M. Carbo[1], F. Wink[2], R. Bos[2], H. Bootsma[1], S. Arends[1], A. Spoorenberg[1]on behalf of Groningen Leeuwarden Axial Spondyloarthritis (GLAS). [1]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; [2]*Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands*

Background: Maintaining optimal health-related quality of life (QoL) is the ultimate goal of treatment in axial spondyloarthritis (axSpA). Chronic pain has a large potential impact on QoL. Central sensitization (CS) may explain part of the chronic pain in axSpA. However, the role of central sensitization (CS) herein has only been studied to a limited degree and current axSpA guidelines pay little attention to identification and treatment of CS.

Objectives: To explore the relationship between CS and QoL in axSpA.

Methods: Consecutive outpatients with axSpA from the Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort were included. CS was assessed with the Central Sensitization Inventory (CSI; 0-100), QoL with the AS Quality of Life questionnaire (ASQoL; 0-18) and disease activity with the AS Disease Activity Score ($ASDAS_{CRP}$). A high probability of CS was defined as CSI score ≥40 and active disease as $ASDAS_{CRP}$ score ≥2.1. Patient characteristics and clinical assessments were compared between groups with CSI score <40 and ≥40.(1) Multivariable regression analysis was conducted to investigate the relationship between CSI and ASQoL scores, correcting for potential confounders.

Results: Of the 178 axSpA patients with available CSI score, 149 completed the ASQoL. Mean age of the 178 included patients was 47.4 ± 14.1 years, 78 (44%) were female, mean symptom duration was 21.4 ± 13.6 years and 88 (52%) were using bDMARDS. Mean CSI score was 38.0 ± 14.1, mean ASQoL 6.0 ± 5.3 and mean $ASDAS_{CRP}$ 2.1 ± 1.0. CSI score ≥40 was significantly associated with higher mean ASQoL (9.7 vs. 3.3), higher mean $ASDAS_{CRP}$ (2.6 vs. 1.7), female gender (60% vs. 29%) and more often entheseal involvement (61% vs. 26%) (Table 1).

Table 1. Selection of patient characteristics, disease activity and clinical outcome variables for patients with axSpA, divided in subgroups for CSI score with a cutoff point of 40.

Characteristics	All patients n = 178	CSI<40 n = 98 (55%)	CSI≥40 n = 80 (45%)
Age (years)	47.4 ± 14.1	48.7 ± 15.0	45.8 ± 12.7
Female	78 (44)	27 (29)	44 (60)*
Symptom duration (years)	21.4 ± 13.6	21.5 ± 13.5	21.2 ± 13.8
HLA-B27+	133 (79)	70 (79)	54 (79)
Smoker	45 (27)	28 (32)	15 (23)
BMI (kg/m^2)	26.7 ± 5.0	26.2 ± 4.4	27.5 ± 5.8
Completed higher education[1]	81 (71)	48 (70)	34 (76)
Biological use	88 (52)	49 (52)	39 (51)
RDCI (0-9)	0.0 (0.0 – 1.0)	0.0 (0.0 – 1.0)	0.0 (0.0 – 1.8)
Peripheral arthritis[2]	10 (6)	5 (6)	5 (8)
Entheseal involvement[3]	64 (40)	23 (26)	38 (61)*
$ASDAS_{CRP}$	2.1 ± 1.0	1.7 ± 0.9	2.6 ± 1.0*
CRP (mg/ml)	2.9 (1.1 – 6.8)	2.6 (1.1-6.0)	3.6 (1.4 – 7.0)
ASQoL (0-18)	6.0 ± 5.3	3.3 ± 3.6	9.7 ± 4.9*
CSI (0-100)	38.0 ± 14.1	28.0 (23 – 34)	50.0 (43.0 –56.0)[N/A]

Values are n (%), mean ± SD or median (IQR).1International Standard Classification of Education (ISCED) level >4; 2Swollen Joint Count >0; 3Maastricht Ankylosing Spondylitis Enthesitis Score >0. *p<0.001. ASDASCRP: Ankylosing Spondylitis Disease Activity Score; ASQoL: Ankylosing Spondylitis Quality of Life questionnaire; CRP: C-reactive protein; CSI: Central Sensitization Inventory; RDCI: Rheumatic Disease Comorbidity Index.

Patients with low $ASDAS_{CRP}$ (<2.1) and also low CSI score (<40) showed good QoL (median ASQoL 1.1). Patients with low $ASDAS_{CRP}$ combined with high CSI score (≥40) and patients with high $ASDAS_{CRP}$ (≥2.1) combined with low CSI score reported worse QoL (median ASQoL 5.6 and 4.1, respectively). Patients with high $ASDAS_{CRP}$ and also high CSI score reported the worst QoL (median ASQoL 12.0). (Figure 1).

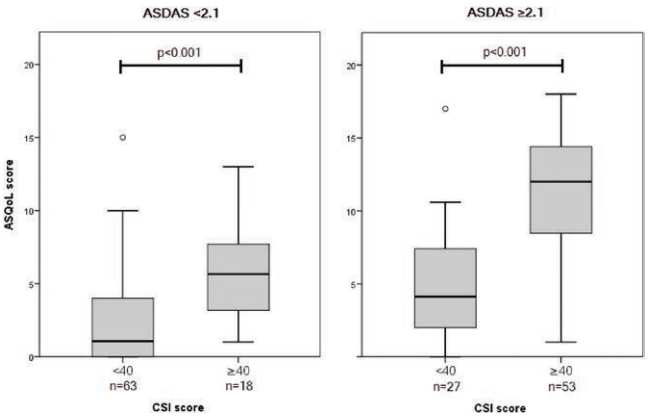

Figure 1. ASQoL score in patients with axSpA with CSI score ≥40 and <40, divided for $ASDAS_{CRP}$ (cutoff 2.1)

Additionally, in univariable analysis, the CSI score explained a large proportion of the variation of the ASQoL (R^2=0.46). This association remained significant after correction for $ASDAS_{CRP}$, gender, symptom duration, entheseal involvement, smoking status, BMI category, educational level and comorbidities in multivariable analysis (CSI p<0.001).

Conclusion: In daily clinical practice, CS seems strongly related to patient-reported QoL in patients with long-term axSpA.

POS1015 ANTI-TNF DRUGS AND CARDIOVASCULAR EVENTS IN PATIENTS WITH SPONDYLOARTHRITIS

C. W. S. Chan[1], P. H. LI[1], C. S. Lau[1], H. Y. Chung[1]. [1]*The University of Hong Kong, Queen Mary Hospital, Hong Kong, Division of Rheumatology and Clinical Immunology, Department of Medicine, Hong Kong, Hong Kong (SAR)*

Background: Cardiovascular (CVS) diseases are the leading cause of death worldwide and patients with rheumatic diseases have an increased CVS risk including stroke and myocardial infarction (MI) (1-3). CVS risk factors and CVS events are common in SpA (4). Delineating the CVS risk and the association with medications in patients with SpA would be useful.

Objectives: The objective of this study was to delineate the CVS risk and the association with medications in patients with SpA.

Methods: Patients with SpA and patients with non-specific back pain (NSBP) were identified in rheumatology and orthopedics clinics respectively. Clinical information and CVS events were retrieved. Incidence rates were calculated. Association analysis was performed to determine the CVS risk of SpA and other modifiable risk factors.

Results: A total of 5046 patients (SpA 2616 and NSBP 2430) were included from eight centers. Over 56 484 person-years of follow-up, 160 strokes, 84 MI and 262 major adverse cardiovascular events (MACE) were identified. Hypercholesterolemia was more prevalent in SpA (SpA 34.2%, NSBP 28.7%, P<0.01). Crude incidence rates of stroke and MI were higher in SpA patients. SpA was associated with a higher risk of MACE (HR 1.66, 95%CI 1.22-2.27, P<0.01) and cerebrovascular events (HR 1.42, 95%CI 1.01-2.00, p=0.04). The use of anti-tumor necrosis factor (TNF) drugs was associated with a reduced risk of MACE (HR 0.37, 95%CI 0.17-0.80, P=0.01) and cerebrovascular events (HR 0.21, 95%CI 0.06-0.78, P=0.02).

Conclusion: SpA is an independent CVS risk factor. Anti-TNF drugs were associated with a reduced CVS risk in these patients.

POS1016 ANKYLOSING SPONDYLITIS IN WEST AFRICAN PATIENTS: A SERIES OF 37 CASES REPORTED IN TOGO

P. Houzou[1], V. E. S. Koffi-Tessio[2], S. Oniankitan[3], K. Kakpovi[1], E. Fianyo[2], K. Tagbor[2], O. Oniankitan[2], M. Mijiyaw[2]. *[1]University of Kara, Rheumatology, Kara,Togo*; *[2]University of Lomé, Rheumatology, Lomé,Togo*; *[3]University of Lomé, Rheumatology, Kara,Togo*

Background: Spondyloarthritis (SpA) is generally uncommon in sub-Saharan Africa, in part because of the rarity of HLA-B27 in this region.

Objectives: The aim of our study was to determine the epidemiological, semiological, paraclinical and therapeutic aspects of ankylosing spondylitis in rheumatology in Togo.

Methods: This was a retrospective multicenter descriptive study on the files of patients suffering from ankylosing spondylitis seen in an outpatient setting or hospitalized in one of the four Rheumatology departments of Togo in the period from January 1, 2000 to December 31, 2019. The diagnosis was essentially radio-clinical based on the modified New York criteria.

Results: In 20 years, and out of a population of 35,304 rheumatic patients, we have collected 37 cases of ankylosing spondylitis, meaning a hospital frequency of 0.10% and an annual frequency of 1.85 cases. There was clearly a male predominance with an M / F ratio of 4.28. The onset of the disease was on average of 29.62 ± 10.27 years and the diagnosis delay on average of 9.45 ± 9.20 years. The clinic was dominated by spinal pain in the form of chronic inflammatory cervical-dorsal-lumbar pain (41.2%) or lumbar pain (29.4%). Common joint injuries were those of the knees (57.69%), ankles (26.9%) and shoulders (23.1%). The most frequent extra-articular manifestations were ocular with conjunctivitis (62.5%) and uveitis (37.5%). Due to the delayed diagnosis, significant spinal deformities including hypercyphosis, straightness and ankylosis were found; the radiography of the spine objectified syndesmophytes (50.0%) with ankyloses and the bamboo column (23.5%) and that of the pelvis objectified sacroiliitis at stage 3 (54.6%) and at stage 4 (27.3%). The HLA B27 antigen was positive in 10.8% of cases. NSAIDs and sulfasalazine were the most commonly used drugs in management, respectively in 94.3% of symptomatic treatment and 92.6% of background therapy.

Conclusion: Ankylosing spondylitis is relatively rare in Togo, affecting more men and young adults. There are no clinical or paraclinical particularity. The delay in diagnosis reflects the importance of the radiological signs. Treatment is mainly done by NSAIDs and DMRADs in particular sulfasalazine, due to their accessibility.

POS1017 CARDIOVASCULAR RISK IN DIFFERENT CLINICAL VARIANTS OF SPONDYLOARTHRITIS

A. Dadalova[1], E. Vasilenko[1], R. Samigullina[1], V. Mazurov[1]. *[1]North-Western State Medical University named after I.I. Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E.Eichwald, St. Petersburg, Russian Federation*

Background: Numerous studies have shown that the life expectancy of patients with spondyloarthritis (SPA) is, on average, 5-7 years less compared to the population, and the overall mortality rate is 1.6-1.9 times higher than the population, while mortality from cardiovascular disease increases by 20-40%.

Objectives: of the current study were to assess the cardiovascular risk in pts with with ankylosing spondylitis, psoriatic arthritis and psoriatic spondyloarthritis and to compare different cardiovascular risk scales in these pts.

Methods: The study included 54 patients with SpA aged 45 to 65 years. The patients were divided into 3 groups: patients with ankylosing spondylitis (AS) who meet the modified New York criteria for AS (1984) (n = 14), patients with psoriatic arthritis (PsA) who meet the CASPAR criteria (Classification criteria of Psoriatic Arthritis, 2006) (n = 18) and patients with psoriatic spondyloarthritis (PsSpA) meeting the modified New York criteria for AS and CASPAR criteria for PsA (n = 22).

The average age in the AS group was 55.5 ± 6.43 years, in the PsA group - 57.4 ± 5.76 years, in the PsSpA group - 55.0 ± 6.45 years. Men made up 64.3% in the AC group, 50% in the PsA group, and 49% in the PsSpA group.

Three indices of cardiovascular risk evaluation (Systematic COronary Risk Evaluation (SCORE) with increasing coefficient 1.5 for inflammatory diseases, Reynolds Risk Score (RRS), and the third modification of QRESEARCH Cardiovascular Risk Algorithm (QRISK3) were calculated.

After the numerical assessment of the indicators, each patient was graded in the degree of CVR with the allocation of low, medium, high and very high degree. To stratify the degrees, an estimate of the total risk on the SCORE scale was used: with a value of less than 1%, the risk was considered low, from> 1% to 5% - medium or moderately increased, from> 5% to 10% - high, and> 10% - very high.

Results: The values of the indices were in the AS group SCORE – 3,05±2,41%, RRS – 5,05±2,67%, QRISK3 – 6,68±3,11%, in pts with PsA SCORE - 4,11±2,22%, RRS - 5.72 ± 2.46%, QRISK3 - 7.25 ± 2.51% and in pts with PsSpA SCORE - 4.78 ± 2.65%, RRS - 6.35 ± 2.34 %, QRISK3 - 8.02 ± 3.25%.

Table 1. The number of pts corresponding to different degrees of risk depending on the used CVD risk assessment scale, n = 54

Degrees of risk	SCORE	RRS	QRISK3
Low	9	2	0
Medium	32	26	16
High	12	23	28
Very high	1	3	10

When assessing CVR using various risk assessment scales (RRS, QRISK3, SCORE), the highest values were obtained in the PsSpA group.

When comparing the results obtained, it was found that the majority of the surveyed belonging to a low degree of CVR according to SCORE (9 people), when evaluated using other scales, fell into the group of medium or high risk. The assessment of the risks of 10-year significant cardiovascular events in patients with SPA using the SCORE index does not coincide with the QRISK3 index data in 70.4% of cases, with the RRS data - in 42.6% of cases, and the SCORE index shows lower values of the expected risk. The highest values were obtained when assessing CVR using the scale QRISK3.

Conclusion: The highest CVR values were obtained in the PsSpA group using various risk assessment scales (RRS, QRISK3, SCORE). There was a discrepancy in the severity of CVR calculated using different rating scales in SpA patients. The largest values were obtained when using the scale QRISK3, and the smallest when calculating the CVR using the scale SCORE.

POS1018 IMPORTANCE OF LATERAL SPINE VIEW IN DXA BONE DENSITOMETRY IN PATIENTS WITH SPONDYLOARTHRITIS

S. Miri[1], H. Ferjani[1], K. Maatallah[1], A. Kasraoui[1], D. Kaffel[1], W. Hamdi[1]. *[1]Mohamed Kassab Institute of Orthopedics, Rhumatology, Manouba,Tunisia*

Background: Osteoporosis is an increasingly important health problem among patients with spondyloarthritis (SPA). The Measure of Bone Mineral Density BMD is routinely carried out in an anteroposterior (AP) view of the spine. However, the syndesmophytes, ligaments calcifications, and the posterior part of vertebrae affect AP scanning. A lateral spine view is a more sensitive tool in assessing bone loss in trabecular bone.
Objectives: We aimed to evaluate the association between lateral lumbar DXA and syndesmophyte grading in patients with SPA.
Methods: We conducted a retrospective study including 75 patients with SPA. Bone density of the hip and lumbar spine was measured with a GE Lunar Prodigy Advance Bone Densitometer equipment. All patients had lumbar lateral, AP, and proximal femur DXA scans. The T-score, which measures the difference between a patient's BMD and young-normal subjects, was computed and age-matched.
Results: The mean age of the patients was 36±11 years. Male predominance was noted with a sex ratio of 4.76. The mean BMI was 25±5 kg/m2. Eight percent were obese. Fifty-two percent had Vitamin D deficiency.
Forty-eight percent of the patients had axial SPA, while 52% had axial and peripheral symptoms.
The mean age of onset was 27±7 years. Fifty-two percent of the patients had high inflammatory biomarkers. The BASDAI, ASDAS-VS, and ASDAS-CRP mean levels were respectively: 3.5±2.4, 3.1±0.9, and 3±0.8. The mean BASRI and mass were respectively 8+4.8 and 16.4+19.4. Analyses of T-score values obtained over the femoral neck revealed osteoporosis in 18.7% of the cases and osteopenia in 32% of the cases. On the other hand, analyses of AP, spine views revealed osteoporosis in 25.3% and osteopenia in 45.3% of patients (p=0.028, r=0.254). We detected the highest percentage of osteoporosis in lateral lumbar view and T-scores matched more closely with femoral neck values; osteoporosis in 29.3%, and osteopenia in 22.7% of the patients (p<10-3, r=0.562). BMD measured in AP, and lateral views were in good agreement (p<10-3, p=0.592). Age was inversely but not significantly associated with BMD in lateral (p=0.442, r=-0.09), AP (p=0.319, r=-0.117) and femoral neck projections (p=0.179, r=-0.157). Femoral neck BMD was associated with the activity of SPA (ASDAS vs (p=0.027, r= -0.295), and the mobility limitation BASMI (p=0.032, r= -0.247). Coxitis, BASRI, or mSASS were independent of BMD.
Conclusion: We conclude that spine lateral view in DXA accurately measures BMD exceeding the AP spine views and femoral neck values. Therefore, structural changes do not affect this measurement

POS1019

INCONSISTENCY OF THE DEGREE OF CARDIOVASCULAR RISK WHEN ASSESSED USING DIFFERENT INDICES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

E. Vasilenko[1], A. Dadalova[1], R. Samigullina[1], V. Mazurov[1]. *[1]North-Western State Medical University named after I. I. Mechnikov, St. Petersburg, Russia, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E. Eichwald, St. Petersburg, Russian Federation*

Background: Evaluation of indicators of cardiovascular risk is one of the main tasks facing a rheumatologist in the tactics of choosing a therapy for patients (pts) with axial spondyloarthritis (axSpA). It is known that pts suffering from axSpA are characterized by a significant increase in cardiovascular risk (CVR). However, there are still no recommendations regulating risk assessment scales in pts with axSpA.
Objectives: were to assess the CVR in pts with axSpA and to compare different cardiovascular risk scales in these pts.
Methods: The study included 55 pts at the age of 45-65 years with diagnosis of axSpA fulfilling ASAS criteria (2009) from St. Petersburg' axSpA register. Three indices of cardiovascular risk evaluation (Systematic COronary Risk Evaluation (SCORE) with increasing coefficient 1.5 for inflammatory diseases, Reynolds Risk Score (RRS), and the third modification of QRESEARCH Cardiovascular Risk Algorithm (QRISK3) were calculated. Risk gradation: low risk (<1%), medium (1.0-4.9%), high (5.0-9.9%), very high (> 10%).
Results: Mean age of the pts was 45.8±10.3 years; males - 37 (67.3%) pts, HLA-B27 positive – 34 (61.8%); mean disease duration 12.5±8.7 years. Mean value of SCORE was 2.83±1.89%, of RRS – 5.04±3.98%, of QRISK3 – 7.91±4.91%.
The gradation of the degree of risk depending on the applied assessment index is presented in Table 1.

Index	Results		
Risk degree	SCORE	RRS	QRISK3
Low	21 (38,2%)	8 (14,5%)	0 (0,0%)
Medium	26 (47,3%)	23 (41,8%)	17 (30,9%)
High	8 (14,5%)	17 (30,9%)	22 (40,0%)
Very high	0 (0,0%)	7 (12,7%)	16 (29,1%)

Particular attention is drawn to the 100% discrepancy of low risk values when comparing SCORE and QRISK3. A similar trend persisted when comparing medium, high and very high risk. Thus, the assessment of the risks of 10-year significant cardiovascular events in pts with axSpA using the SCORE index does not coincide with the QRISK3 index data in 87.27% of cases, and with the RRS data - in 58.18% of cases. In 84.3% of cases, the mismatch between the SCORE and RRS indexes was due to the presence of an increased CRP level.
Conclusion: When assessing cardiovascular risk in pts with axial spondyloarthritis, a discrepancy was found between the degrees of risk when assessed using different scales. SCORE scores were significantly different from Reynolds' and QRISK3 scores. These features can be interrelated with a small number of factors assessed when calculating the SCORE, even though there is a correction factor for rheumatic diseases. For pts with axial spondyloarthritis, it is necessary to use additional indicators that influence cardiovascular risk, such as CRP.
Disclosure of Interests: None declared.

EFFICACY OF TOFACITINIB ON DACTYLITIS IN INDIVIDUAL DIGITS IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

A. M. Orbai[1], P. J. Mease[2,3], P. Helliwell[4], O. Fitzgerald[5], M. Bdewi[6], D. Fleishaker[7], R. Mundayat[8], P. Young[9]. *[1]Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, MD, United States of America*; *[2]Swedish Medical Center/Providence St Joseph Health, Rheumatology Clinical Research Division, Seattle, WA, United States of America*; *[3]University of Washington School of Medicine, Rheumatology Clinical Research Division, Seattle, WA, United States of America*; *[4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*; *[5]Conway Institute for Biomolecular Research, University College Dublin, Dublin, Ireland*; *[6]College of Medicine, King Saud University Medical City, King Saud University, Division of Rheumatology, Riyadh, Saudi Arabia*; *[7]Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America*; *[8]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; *[9]Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America*

Background: Dactylitis, a hallmark of psoriatic arthritis (PsA), is a uniformly diffuse and sometimes painful swelling of the fingers and/or toes.[1] Up to 50% of patients (pts) with PsA may experience dactylitis;[1,2] as such, dactylitis is an accepted domain of PsA that should be considered in treatment decisions.[3] In PsA, dactylitis typically involves feet more than hands; dactylitic joints more frequently have erosive damage, compared with non-dactylitic joints.[2] There remains a need for effective therapies to treat dactylitis in pts with PsA. Improvements in dactylitis have been associated with tofacitinib, an oral Janus kinase inhibitor for the treatment of PsA.[4,5]
Objectives: To assess the effect of tofacitinib on dactylitis by location (hands/feet) and individual digit involvement in pts with PsA.
Methods: These post hoc analyses used data pooled from two Phase 3 studies (12-month OPAL Broaden [NCT01877668];[5] 6-month OPAL Beyond [NCT01882439][4]) in pts with active PsA treated with tofacitinib 5 mg twice daily (BID; approved dose; to Month [M] 6), tofacitinib 10 mg BID (to M6) or placebo (PBO; to M3); pts were treated continuously with a single conventional synthetic disease-modifying antirheumatic drug. Pts were categorised by the presence of dactylitis at baseline (BL) in the hands and/or feet. Endpoints included change from BL in Dactylitis Severity Score (DSS),[6] the number of dactylitic digits and the proportion of pts with dactylitis in individual digits at M1, M3 and M6. Descriptive statistics were generated by visit and treatment arm.
Results: Data were pooled from 373 pts with DSS >0 at BL. BL characteristics, including gender, age, race, body mass index, PsA duration, BL DSS and dactylitic digits count were similar across dactylitis groups and treatment groups, except for pts with dactylitis in both the hands and feet, who had higher DSS compared to those with dactylitis in the hands or feet only, likely due to having more dactylitic digits (data not shown). Regardless of location, pts treated with tofacitinib had cumulative improvements from BL to M6 in DSS (Figure 1a) and in the number of dactylitic digits (Figure 1b); improvements in DSS were greater at M1 and M3, compared with PBO. Pts treated with tofacitinib 10 mg BID typically had numerically greater improvements in DSS, compared with pts treated with tofacitinib 5 mg BID (Figure 1a). Most pts treated with tofacitinib experienced improvement of dactylitis across all fingers and toes (Figure 1c–f); mean dactylitis presence was ≤15% at M6 in pts treated with tofacitinib for all digits. Generally, at M1 and M3, fewer pts treated with tofacitinib had dactylitis in any digit, compared with PBO (Figure 1c–f).
Conclusion: Among pts with pre-existing dactylitis, treatment with tofacitinib resulted in improvements in dactylitis in hands, feet, or both, and in all digits as early as M1, and up to M6.

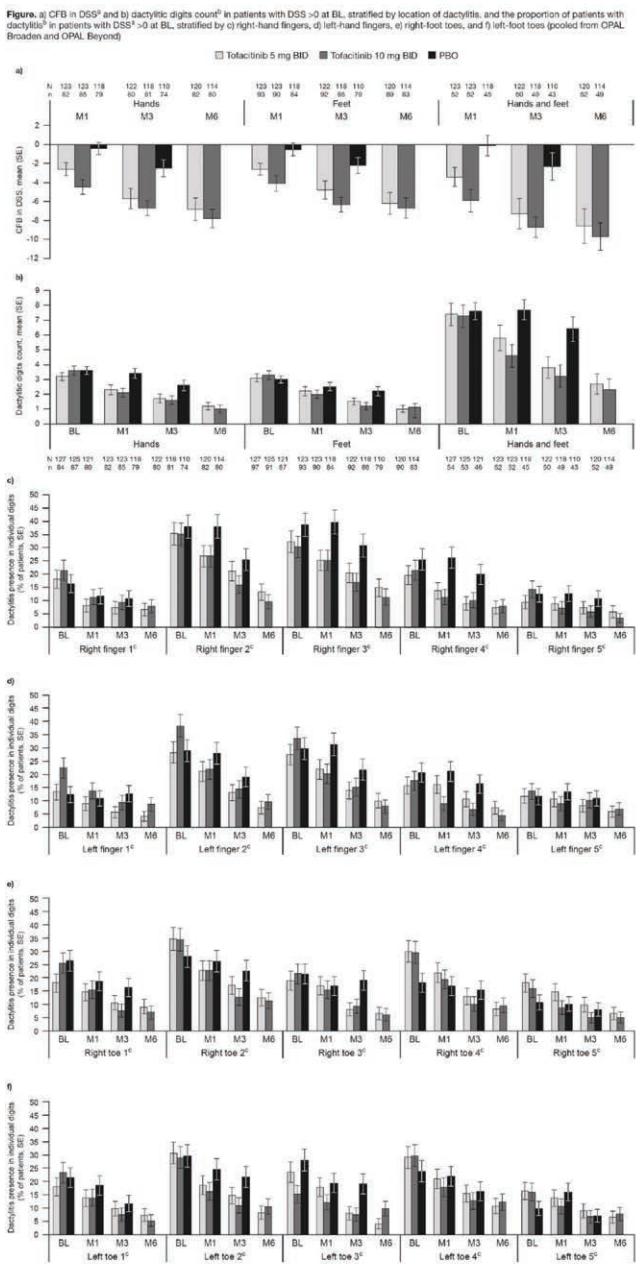

Figure. a) CFB in DSS[a] and b) dactylitic digits count[b] in patients with DSS >0 at BL, stratified by location of dactylitis, and the proportion of patients with dactylitis[b] in patients with DSS[a] >0 at BL, stratified by c) right-hand fingers, d) left-hand fingers, e) right-foot toes, and f) left-foot toes (pooled from OPAL Broaden and OPAL Beyond)

[a]A blinded assessor squeezed each digit of the hands and feet with moderate pressure, and assigned a score for each digit on a scale of 0–3, where 0 = no tenderness, 1 = tender, 2 = tender and winces, and 3 = tender and withdraws. DSS is calculated as the sum of those scores, ranging from 0–60, with a score of 60 being the highest dactylitis severity.[6] [b]Dactylitis was defined as swelling of an entire digit. [c]N ranged from 121–127 at BL, 118–123 at M1, 110–122 at M3 and 113–120 at M6 for all digits. CFB, change from baseline; N, total number of patients with DSS >0 at BL; n, total number of patients with dactylitis in that particular location; SE, standard error

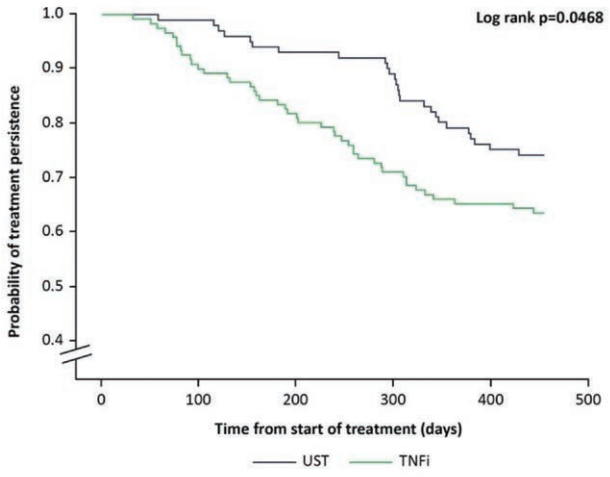
Background: There are still unmet needs in the treatment of psoriatic arthritis (PsA), including in terms of treatment persistence, which is a function of effectiveness, safety and patient satisfaction. Ustekinumab (UST) was the first new biologic drug to be developed for the treatment of PsA after tumour necrosis factor inhibitors (TNFi).

Objectives: To compare treatment persistence, effectiveness and safety of UST and TNFi in Italian patients within the PsABio cohort.

Methods: PsABio (NCT02627768) is an observational study of 1st/2nd/3rd-line UST or TNFi treatment in PsA in 8 European countries. The current analysis set includes 222 eligible patients treated in 15 Italian centres, followed to Month 12 (±3 months). Treatment persistence/risk of stopping was analysed using Kaplan–Meier (KM) and Cox regression analysis. Proportions of patients reaching minimal disease activity (MDA)/very low disease activity (VLDA) and clinical Disease Activity Index for PsA (cDAPSA) low disease activity (LDA)/remission were analysed using logistic regression, including propensity score (PS) adjustment for imbalanced baseline covariates, and non-response imputation of effectiveness endpoints if treatment was stopped/switched before 1 year. Last observation carried forward data are reported.

Results: Of patients starting UST and TNFi, 75/101 (74.3%) and 77/121 (63.6%), respectively, persisted with treatment at 1 year. The observed mean persistence was 410 days for UST and 363 days for TNFi. KM curves and PS-adjusted hazard ratios confirmed significantly higher persistence (hazard ratio [95% confidence interval (CI)]) for UST versus TNFi overall (0.46 [0.26; 0.82]; Figure 1). Persistence was also higher for UST than TNFi in patients receiving monotherapy without methotrexate (0.31 [0.15; 0.63]), in females (0.41 [0.20; 0.83]), and in patients with body mass index (BMI) <25 kg/m^2 (0.34 [0.14; 0.87]) or >30 kg/m^2 (0.19 [0.06; 0.54]). There was no significant difference in persistence between treatments in patients with BMI 25–30 kg/m^2. While patients receiving 1st- and 3rd-line UST or TNFi showed similar risk of discontinuation (0.60 [0.27; 1.29] and 0.36 [0.10; 1.25], respectively), patients receiving 2nd-line UST showed better persistence than those receiving 2nd-line TNFi (0.33 [0.13; 0.87]). Other factors added to the PS-adjusted Cox model did not show significant effects. In patients with available follow-up data, the mean (standard deviation) baseline cDAPSA

Kaplan–Meier estimates of treatment persistence for ustekinumab and TNFi in the overall PsABio Italian cohort



TNFi, tumour necrosis factor inhibitor

was 26.3 (15.4) for UST and 23.5 (12.3) for TNFi; at 1-year follow-up, 43.5% of UST- and 43.6% of TNFi-treated patients reached cDAPSA LDA/remission. MDA was reached in 24.2% of UST- and 28.0% of TNFi-treated patients, and VLDA in 12.5% of UST- and 10.2% of TNFi-treated patients. After PS adjustment (stoppers/switchers as non-responders), odds ratios (95% CI) at 1 year did not differ significantly between UST and TNFi groups for reaching cDAPSA LDA/remission (1.08 [0.54; 2.15]), MDA (0.96 [0.45; 2.05]) or VLDA (0.98 [0.35; 2.76]). In total, 23 (20.4%) patients reported ≥1 treatment emergent adverse event with UST and 30 (22.2%) with TNFi; 6 (5.3%) and 10 (7.4%) patients, respectively, discontinued treatment because of an adverse event.

Conclusion: In the Italian PsABio cohort, UST had better overall persistence compared with TNFi, as well as in specific subgroups: females, patients on monotherapy without methotrexate, with BMI <25 or >30 kg/m^2, and patients receiving UST as 2nd-line treatment. At 1 year, both treatments showed similar effectiveness, as measured by cDAPSA responses and MDA/VLDA achievement.

BIMEKIZUMAB SAFETY AND EFFICACY IN PATIENTS WITH PSORIATIC ARTHRITIS: 3-YEAR RESULTS FROM A PHASE 2B OPEN-LABEL EXTENSION STUDY

L. C. Coates[1], R. B. Warren[2], C. T. Ritchlin[3], L. Gossec[4], J. F. Merola[5], D. Assudani[6], J. Coarse[7], J. Eells[6], B. Ink[6], I. Mcinnes[8]. [1]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Diseases, Oxford, United Kingdom*; [2]*The University of Manchester, Dermatology Centre, Manchester NIHR Biomedical Research Centre, Manchester, United Kingdom*; [3]*University of Rochester, Medical Center, Rochester, United States of America*; [4]*Sorbonne Université and Pitié-Salpêtrière Hospital, Department of Rheumatology, Paris, France*; [5]*Brigham and Women's Hospital, Harvard Medical School, Boston, United States of America*; [6]*UCB Pharma, N/A, Slough, United Kingdom*; [7]*UCB Pharma, N/A, Raleigh, United States of America*; [8]*University of Glasgow, School of Medicine, Glasgow, United Kingdom*

Background: Bimekizumab (BKZ), a monoclonal antibody inhibitor of interleukin (IL)-17A and IL-17F, demonstrated clinical improvements in joint and skin outcomes up to 108 weeks (wks) in patients (pts) with active psoriatic arthritis (PsA).[1,2]

Objectives: To report up to 3-year safety and efficacy of BKZ in pts with active PsA from a 48-week phase 2b dose-ranging study (BE ACTIVE; NCT02969525) and its open-label extension (OLE; NCT03347110).

Methods: BE ACTIVE and OLE study design has been described previously.[1] All OLE pts received BKZ 160 mg Q4W, irrespective of prior dosing regimen. Treatment-emergent adverse events (TEAEs) are reported for the safety set (SS; pts who received ≥1 dose BKZ in the dose-ranging study). Data are presented from dose-ranging study baseline (BL) to Wk 152. Efficacy outcomes are reported for the full analysis set (FAS): ACR50, minimal or very low disease activity (MDA/VLDA), Psoriasis Area and Severity Index (PASI) 90/100, body surface area affected by psoriasis (BSA) 0% and dactylitis/enthesitis resolution.

Results: Over 152 wks, the exposure-adjusted incidence rate (EAIR) per 100 patient-years (PY) was 126.4 for all TEAEs, 4.1 for serious TEAEs, 0.7 for serious infections and 4.6 for *Candida* infections (Table 1). One event was adjudicated by an independent committee as inflammatory bowel disease (microscopic colitis). All *Candida* infections were localised, mild/moderate, and resolved with appropriate anti-fungal therapy. Overall, the proportions of patients with ACR50 response were sustained through Wk 152 (52.9%, non-responder imputation [NRI]; Figure 1). Response rates were also sustained through Wk 152 for MDA (51.5%), VLDA (30.1%), PASI90 (64.2%), PASI100 (57.7%) and resolution of dactylitis (71.2%) and enthesitis (62.6%) (NRI; Table 1).

Wk 152	–	67.6/63.1	–	76.0/61.9	–	71.2/62.6

No anaphylactic reactions or major adverse cardiac events were reported. [a] Includes pts within the indicated analysis set originally assigned to all arms who were subsequently re-randomized to 160 mg, or [b] 320 mg, after double-blind period; [c] Microscopic colitis; [d] Malignant melanoma in situ; [e] Pts with BL BSA ≥3%, NRI: n=79, 58, 137 respectively; [f] Pts with BL LDI >0, NRI: n=34, 25, 59 respectively; [g] Pts with BL MASES >0, NRI: n=65, 42, 107 respectively. LDI: Leeds Dactylitis Index; MASES: Maastricht AS Enthesitis Score; OC: observed case.

Conclusion: The safety profile of BKZ in pts with PsA reflects previous observations[1,2] for up to 3 years. High threshold disease control was achieved by >50% of BKZ-treated pts up to 3 years, reflected in long-term improvements in joint and skin outcomes.

POS1023 HOW DOES GENDER AFFECT SECUKINUMAB TREATMENT OUTCOMES AND RETENTION RATES IN PATIENTS WITH PSORIATIC ARTHRITIS? – REAL WORLD DATA FROM THE GERMAN AQUILA STUDY

U. Kiltz[1], J. Brandt-Juergens[2], P. Kästner[3], E. Riechers[4], D. Peterlik[5], H. P. Tony[6]. *[1]Rheumazentrum Ruhrgebiet/Ruhr-Universität Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany*; *[2]Rheumatologische Schwerpunktpraxis, Rheumatologische Schwerpunktpraxis, Berlin, Germany*; *[3]Ambulantes Rheumazentrum, Ambulantes Rheumazentrum, Erfurt, Germany*; *[4]Medizinische Hochschule Hannover, Klinik für Immunologie und Rheumatologie, Hannover, Germany*; *[5]Novartis Pharma GmbH, Immunology, Hepatology & Dermatology, Nürnberg, Germany*; *[6]Medizinische Klinik II, Universitätsklinik, Rheumatology/Immunology, Würzburg, Germany*

Background: Gender disparities in PsA can affect natural course of disease, clinical presentation and response to medication[1]. The German non-interventional study AQUILA provides real-world data on the influence of gender of patients with psoriatic arthritis (PsA) on therapeutic effectiveness and retention rate under treatment with secukinumab, a fully human monoclonal antibody that selectively inhibits interleukin-17A.

Objectives: The aim of this interim analysis is to describe selected baseline (BL) demographics, to evaluate secukinumab treatment outcomes on disease activity, depressive mood and retention rate depending on the gender of PsA patients.

Methods: AQUILA is an ongoing, multi-center study including more than 3000 patients with active PsA or ankylosing spondylitis. Patients were observed from BL up to week (w) 52. Real-world data was assessed prospectively and analyzed as observed. Data was collected on impact of disease (Psoriatic Arthritis Impact of Disease - 12 items, PsAID-12 score), skin disease activity (Psoriasis Area and Severity Index, PASI), joint counts and severity of depressive mood (Beck´s Depression Inventory version II, BDI-II), in addition to patient´s global assessment (PGA). Moreover, retention rates (time from study inclusion until premature secukinumab treatment discontinuation) were assessed through Kaplan-Meier plots. This interim analysis focuses on the subgroups of male and female PsA patients.

Results: At BL, 1278 PsA patients were included: 41.5% (n=531) male and 58.5% (n=747) female. Demographic data (Table 1) of male and female PsA patients differed most obviously regarding proportion of overweight patients, smokers, pretreatment with nonsteroidal anti-inflammatory drugs (NSAIDs) and biologicals/biosimilars (b-bsDMARDs).

Mean PsAID-12 values over time were higher in women; nevertheless, PsAID-12 improved comparably for both genders from BL to week 52 (♂: 4.8 at BL to 2.9 at w52, ♀: 5.3 at BL to 3.5 at w52, Figure 1A). This was similar to the course of improvements for mean PGA across genders (♂: 4.9 at BL to 3.0 at w52, ♀: 5.6 at BL to 3.5 at w52). In terms of PASI scores, both BL mean values and improvements over time were similar across genders (♂: 6.8 at BL to 1.9 at w52, ♀: 7.0 at BL to 1.0 at w52). Mean joint counts (tender/swollen) also improved similarly (♂: 6.8/3.7 at BL to 3.1/0.9 at w52, ♀: 7.3/3.7 at BL to 2.8/0.9 at w52). Over time, male patients showed overall reduced BDI-II values; nevertheless, BDI-II reductions were comparable across the genders (♂: 10.2 at BL to 8.1 at w52, ♀: 13.0 at BL to 10.6 at w52). Secukinumab treatment retention rate for men was (not significantly) higher than for women (Figure 1B).

Conclusion: In a real-world setting, secukinumab improved disease activity and depressive mood of PsA patients in both men and women. Women showed overall higher burden of disease. Altogether, this interim analysis shows that secukinumab is an effective treatment up to 52 weeks with high treatment retention rates in real-world setting, irrespective of gender.

Background: Guselkumab (GUS) is a human monoclonal antibody specific to the p19-subunit of interleukin-23. GUS significantly improved signs and symptoms of PsA through Week24 (Wk24), and improvements were maintained through Wk52 in the Phase 3 DISCOVER-1[1] and DISCOVER-2[2] studies.
Objectives: Assess GUS efficacy through Wk52 in both studies utilizing composite indices.
Methods: Adult patients (pts) enrolled had active PsA despite standard therapies. Pts in DISCOVER-1 had ≥3 swollen and ≥3 tender joints and C-reactive protein (CRP) ≥0.3 mg/dL; in DISCOVER-2, pts had ≥5 swollen and ≥5 tender joints and CRP ≥0.6 mg/dL. 31% of DISCOVER-1 pts received 1-2 prior tumor necrosis factor inhibitors; DISCOVER-2 pts were biologic-naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at Wk0, Wk4, then every 8 weeks (Q8W); or placebo (PBO); PBO pts crossed over to GUS 100 mg Q4W at Wk24. Composite endpoints pooled across the two studies were: Disease Activity Index for Psoriatic Arthritis (DAPSA), Psoriatic Arthritis Disease Activity Score (PASDAS), Minimal Disease Activity (MDA), and Very Low Disease Activity (VLDA). GUS vs PBO comparisons through Wk24 employed a Cochran-Mantel-Haenszel test with baseline stratification factors or Fisher's exact test; no treatment group comparisons were performed beyond Wk24. P-values were not adjusted for multiplicity. From Wk24 -Wk52, pts with missing data were considered nonresponders (>90% of pts completed study treatment through Wk52).
Results: In randomized and treated pts from DISCOVER-1 (N=381) and DISCOVER-2 (N=739), pooled baseline characteristics were generally well-balanced across treatment groups and reflected active disease. Differences in response rates between GUS Q4W or Q8W and PBO were seen as early as Wk8 and increased over time through Wk24. In pts continuing GUS Q4W or Q8W, respectively, post-Wk24 response rates associated with these composite indices continued to increase through Wk52, at which time they were 54.2% and 52.5% for DAPSA LDA, 45.3% and 41.9% for PASDAS LDA, 35.9% and 30.7% for MDA, 18.2% and 17.6% for DAPSA remission, and 13.1% and 14.4% for VLDA, with no discernable difference between the GUS Q4W and Q8W dosing regimens (Table 1 and Figure 1). After PBO pts crossed over to GUS Q4W at Wk24, response rates increased through Wk52.
Conclusion: GUS 100 mg Q4W and Q8W provided robust and sustained benefits to pts with active PsA across multiple domains, indicating that GUS may provide an alternative treatment option for the diverse manifestations of PsA.

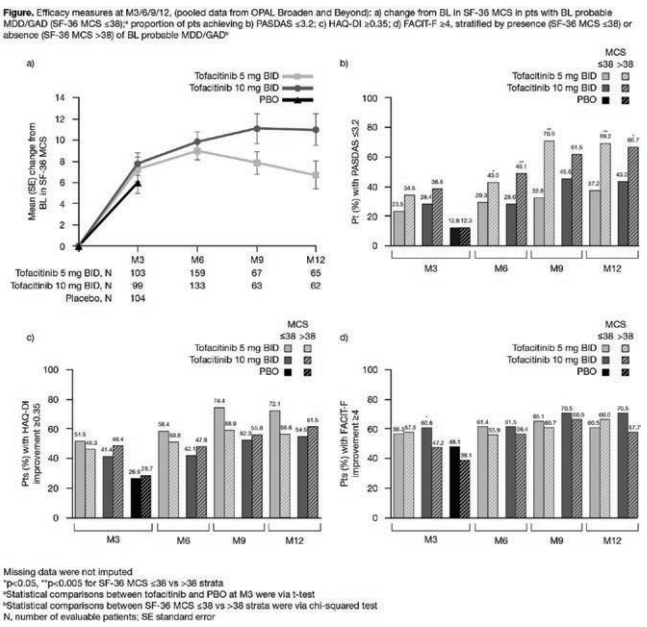
POS1025 TOFACITINIB TREATMENT IN PATIENTS WITH PSORIATIC ARTHRITIS AND PROBABLE DEPRESSION AND/OR ANXIETY: A POST HOC ANALYSIS OF TWO PHASE 3 CLINICAL TRIALS

L. Gossec[1], G. Citera[2], A. Sellas-Fernández[3], D. C. Gruben[4], M. Valderrama[5], S. Gómez[5]. [1]*Sorbonne Université/Hôpital Pitié-Salpêtrière, Paris, France*; [2]*Instituto de Rehabilitación Psicofísica, Section of Rheumatology, Buenos Aires, Argentina*; [3]*University Hospital Vall d'Hebron, Secció de Reumatologia, Barcelona, Spain*; [4]*Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America*; [5]*Pfizer Inc, Inflammation and Immunology, Madrid, Spain*

Background: Depression and anxiety are highly prevalent in patients (pts) with psoriatic arthritis (PsA),[1] with inflammation a key pathogenic feature of depression in these pts.[2] Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. It acts by modulating immune and inflammatory responses. The link between major depressive disorder/generalised anxiety disorder (MDD/GAD), inflammation and tofacitinib effectiveness has not been fully explored.
Objectives: Analyse the prevalence of probable MDD/GAD in pts with PsA initiating tofacitinib treatment and the impact of baseline (BL) probable MDD/GAD status on tofacitinib efficacy in these pts.
Methods: This was a post hoc analysis of data from pts who received tofacitinib 5 or 10 mg twice daily (BID), or placebo (PBO), pooled from two Phase 3 trials (12-month OPAL Broaden [NCT01877668];[3] 6-month OPAL Beyond [NCT01882439][4]). Pts with BL probable MDD and/or GAD were identified by a Short Form-36 Health Survey (SF-36) Mental Component Summary score (MCS) ≤38. Pt demographics/BL characteristics and outcomes were stratified by the presence (SF-36 MCS ≤38) or absence (SF-36 MCS >38) of BL probable MDD/GAD. At Months (M)3/6/9/12, changes from BL in SF-36 MCS were evaluated, and efficacy assessed by the proportions of pts who achieved: Psoriatic Arthritis Disease Activity Score (PASDAS) ≤3.2, Health Assessment Questionnaire-Disability Index (HAQ-DI) improvement ≥0.35 and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) improvement ≥4. BL global pain was measured via visual analogue scale.
Results: Of the 706 pts included in this analysis, BL probable MDD/GAD was identified in 46.2%, 44.9% and 46.2% of pts in the tofacitinib 5 mg BID (108/234), tofacitinib 10 mg BID (106/236) and PBO (109/236) groups, respectively. BL disease activity was similar across the three treatment groups, independent of probable MDD/GAD status (mean PASDAS: 6.1–6.4 in pts with vs 5.8–6.1 in pts without probable MDD/GAD). In the tofacitinib 5 mg BID group, mean BL scores for HAQ-DI (1.4 vs 1.0), FACIT-F total score (20.5 vs 32.4) and global pain (61.3 vs 51.5) indicated worse disability, fatigue and pain, respectively, for pts with vs without BL probable MDD/GAD. Similar findings were seen in the tofacitinib 10 mg BID and PBO groups. At M3, improvements from BL in SF-36 MCS in pts with probable MDD/GAD were numerically, but not significantly, greater with tofacitinib 5 and 10 mg BID vs PBO, and these changes were largely sustained to M12 (Figure 1a). At M3, numerically greater proportions of pts achieved improvements in PASDAS, HAQ-DI and FACIT-F with tofacitinib 5 or 10 mg BID vs PBO, regardless of BL probable MDD/GAD status (Figure 1b–d). Through M3–12, the proportions of pts who achieved PASDAS ≤3.2 with tofacitinib 5 or 10 mg BID were generally significantly greater in pts without vs with probable MDD/GAD (Figure 1b). At all timepoints, rates of improvement in HAQ-DI with tofacitinib 5 mg BID were numerically greater in pts with vs without probable MDD/GAD, whereas the opposite was true for tofacitinib 10 mg BID (Figure 1c). FACIT-F improvement rates with tofacitinib 10 mg BID were consistently numerically greater in pts with vs without probable MDD/GAD, while findings were mixed for tofacitinib 5 mg BID (Figure 1d).



Missing data were not imputed
*p<0.05, **p<0.005 for SF-36 MCS ≤38 vs >38 strata
[a]Statistical comparisons between tofacitinib and PBO at M3 were via t-test
[b]Statistical comparisons between SF-36 MCS ≤38 vs >38 strata were via chi-squared test
N, number of evaluable patients; SE standard error

Conclusion: Around 46% of pts with PsA treated with tofacitinib had BL probable MDD/GAD (SF-36 MCS ≤38). Pts with BL probable MDD/GAD treated with tofacitinib had sustained changes in SF-36 MCS. Rates of clinical improvement with tofacitinib were generally greater in pts without vs with probable MDD/GAD, whereas findings for disability and fatigue improvements varied between tofacitinib doses. Further research is required to evaluate the relationship between PsA and depression, to improve treatment targets and the quality of life of pts with PsA.

POS1026 GUSELKUMAB PROVIDES SUSTAINED IMPROVEMENTS IN WORK PRODUCTIVITY AND NON-WORK ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS THROUGH 1 YEAR OF A PHASE 3 TRIAL

J. Curtis[1], I. Mcinnes[2], S. Peterson[3], P. Agarwal[4], F. Yang[3], A. Kollmeier[5], E. C. Hsia[6,7], C. Han[6], W. Tillett[8], P. J. Mease[9], P. Rahman[10]. Background: DISCOVER-2 was a Phase 3 trial of the first-in-class anti-IL-23-specific mAb guselkumab (GUS) in patients (pts) with psoriatic arthritis (PsA). PsA impacts patients' productivity at work and in daily activity.1
Objectives: To evaluate the effect of GUS on work productivity and daily activity in DISCOVER-2 through 1 year using the Work Productivity and Activity Impairment Questionnaire: PsA (WPAI- PsA).
Methods: Bio-naïve adults with active PsA despite nonbiologic DMARDs &/or NSAIDs received subcutaneous GUS 100 mg every 4 weeks (Q4W); GUS 100 mg W0, W4, then Q8W; or placebo (PBO). At W24, PBO pts crossed over to GUS 100 mg Q4W. WPAI-PsA assesses PsA-related work time missed (absenteeism), impairment while working (presenteeism), impaired overall work productivity (absenteeism + presenteeism), and daily activity during the previous week. A shift analysis evaluated proportions of pts employed vs unemployed (regardless of desire to work) over time. Among pts working at baseline, least-squares (LS) mean changes from baseline in WPAI-PsA domains were determined using a mixed-effects model for repeated measures analysis, whereby mean changes in WPAI-PsA domains were calculated for each multiple imputation (MI) dataset using an analysis of covariance (ANCOVA); the reported LSmean is the average of all MI datasets. Also, among pts employed at baseline, indirect savings from improved overall work productivity were estimated using 2020 EU mean yearly wage estimate (all occupations).2
Results: In pts working at baseline, significant improvement in work productivity and non-work activity vs PBO was observed at W24. Productivity gains seen with GUS at W24 continued to improve through 1 year (Table 1). Shift analysis showed relatively stable employment in pts employed at baseline (62% of shift analysis cohort) through 1 year of GUS (>91% continued to work when assessed at W16, W24, and W52 [data not shown]). For those unemployed at baseline (38% of cohort), the proportion of pts working increased by ~10% following 1 year of GUS (Figure 1). Potential yearly indirect savings from improved overall work productivity were: *€7409* GUS Q4W and *€7039* GUS Q8W vs *€4075* PBO at W24 and were *€8520* GUS Q4W, *€9632* GUS Q8W, and *€6668* PBO→GUS Q4W at W52.
Conclusion: Improvement in work productivity and non-work activity was greater with GUS vs PBO among pts with active PsA through W52. Improvements demonstrated may result in reduction in PsA costs associated with work productivity.

Sinai, Dermatology, New York, United States of America*; [4]*Janssen Research & Development, LLC, Immunology, Spring House, United States of America*; [5]*University of Pennsylvania Medical Center, Rheumatology, Philadelphia, United States of America*; [6]*Janssen Research & Development, LLC, Biostatistics, Spring House, United States of America*; [7]*Janssen Scientific Affairs, LLC, Immunology, Horsham, United States of America*; [8]*Janssen Scientific Affairs, LLC, Immunology, Horsham, United States of America*; [9]*Drexel University College of Medicine, Rheumatology, Philadelphia, United States of America*; [10]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [11]*Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America*

Background: Guselkumab (GUS), a selective IL-23 inhibitor dosed every 4 or 8 weeks (Q4W or Q8W), demonstrated efficacy for joint and skin symptoms, inhibition of structural damage progression (Q4W), and safety vs. placebo (PBO) through Week 24 (W24) of the Ph3, double-blind, PBO-controlled trial in biologic-naïve pts with PsA (DISCOVER-2).[1] Favorable benefit-risk was also seen through 1 year.[2]
Objectives: To assess GUS efficacy and safety through 2 years.

Methods: Biologic-naïve adults with active PsA (≥5 swollen joint count [SJC] + ≥5 tender joint count [TJC]; CRP ≥0.6 mg/dL) were randomized (1:1:1) to GUS 100 mg Q4W; GUS 100 mg at W0, W4, Q8W; or PBO with crossover to GUS 100 mg Q4W (PBO→Q4W) at W24. Clinical efficacy (ACR/PASI/IGA/HAQ-DI) was assessed in the modified intention to treat (mITT) population through W100 with missing data imputation (nonresponse for categorical endpoints; no change/multiple imputation for continuous endpoints). Observed PsA-modified van der Heijde Sharp (vdH-S) scores derived from blinded radiographic images collected at W0, W24, W52, W100 (or at discontinuation [d/c]) and adverse events (AEs) through W112 were collected.

Results: 712/739 (96%) randomized pts continued study agent at W24; 687/739 (93%) continued at W52; 652/739 (88%) completed W100. ACR20 response rates in the mITT population continued to increase after W24, and at W100 were 76% for Q4W and 74% for Q8W (Figure 1). Similar response patterns were seen for ACR50/70, HAQ-DI and PASI90/100 (Table 1), and IGA0/1 and PASI75 response rates were consistent through W100 in pts randomized to Q4W and Q8W; W100 data for PBO→Q4W pts were consistent with pts treated with Q4W and Q8W (Table 1). GUS improvements in SF-36 PCS/MCS at W52 also persisted through W100 (data not shown). Low rates of radiographic progression (as measured by PsA-modified vdH-S scores) were observed during W52-100 for Q4W (n=227; 0.75) and Q8W (n=232; 0.46). In the PBO→Q4W group (n=228), radiographic progression was 1.12 during W0-24 (while on PBO), 0.51 during W24-100 (while on Q4W), and 0.13 during W52-100. Through W112, the incidences of AEs, serious AEs (SAEs), AEs leading to d/c, infections, serious infections, and injection site reactions were generally consistent with the PBO-controlled period and through 1 year. Of the pts in the Q4W (n=245), Q8W (n=248), and PBO→Q4W (n=238) groups, 9%, 9% and 7% had ≥1 SAE; 2%, 3% and 3% had ≥1 serious infection; 2 Q8W pts (fungal esophagitis, disseminated herpes zoster) and 1 PBO→Q4W pt (listeria meningitis) had opportunistic infections; 1 PBO→Q4W pt died (road traffic accident); 1 PBO-randomized pt had IBD; no pt had anaphylactic or serum sickness reaction, or active TB.

Conclusion: In biologic-naïve PsA pts, GUS improvements in joint and skin symptoms, physical function, and low rates of radiographic progression persisted through 2 years. GUS safety in PsA through 2 years was comparable with safety at 6 months and 1 year, similar between Q4W and Q8W, and consistent with GUS safety in psoriasis.

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease characterized by peripheral arthritis, axial inflammation, dactylitis, enthesitis, & skin/nail psoriasis. Patients (pts) with PsA often experience reduced health-related quality of life (HRQoL) due to these features.

Objectives: Using EuroQoL-5 dimension-5 level (EQ-5D-5L) questionnaire index & visual analog scale (EQ-VAS) scores, we assessed HRQoL in pts with PsA & its association with pt characteristics & clinical features of PsA, including fatigue.

Methods: The Phase 3 DISCOVER-2 trial evaluated guselkumab (GUS), a human monoclonal antibody targeting the IL-23p19-subunit, in bio-naïve adults with active PsA (swollen joint count [SJC] ≥5, tender joint count [TJC] ≥5, C-reactive protein [CRP] ≥0.6 mg/dL) despite standard therapies.[1] Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at Week 0 (W0), W4, then Q8W; or placebo (PBO). EQ-5D-5L index assesses mobility, self-care, usual activities, pain/discomfort, & anxiety/depression. EQ-VAS assesses pt health state. Spearman correlation testing was used to evaluate relationships between baseline (BL) pt characteristics & PsA clinical features & BL EQ-5D-5L index & EQ-VAS scores (Figure 1). Employing absolute observed scores at both W0 & W24, univariate linear regression was used to assess the association between EQ-5D-5L index & EQ-VAS scores & pt characteristics/PsA clinical features. Variables with $p<0.20$ in the univariate analysis were included in a multivariate analysis employing mixed-effect model for repeated measures (MMRM), controlling for all other variables; resulting p values <0.05 were considered statistically significant. Least-squares (LS) mean changes in EQ-5D-5L index & EQ-VAS were assessed at W24 using MMRM.

Results: Among 738 pts, BL EQ-5D-5L index & EQ-VAS scores were moderately to strongly correlated (ie, ≥0.4) with BL pt-reported pain (0-10 VAS), physical function (Health Assessment Questionnaire-Disability Index [HAQ-DI]),

fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-F] scale), & 36-item Short Form Health Survey (SF-36) physical & mental component summary (PCS & MCS) scores & weakly correlated with other variables (Figure 1). Based on univariate analyses (p<0.20) & evaluation of collinearity between variables, attributes at W0 & W24 included in the multivariate models were age, sex, CRP, FACIT-F, pain, psoriasis area & severity index (PASI) score, TJC, SJC, enthesitis, & dactylitis. In the final model, CRP, FACIT-F, pain, PASI score, & the presence of dactylitis were significantly associated with EQ-5D-5L index & EQ-VAS scores. A higher TJC was significantly associated with a worse EQ-5D-5L index score. A higher SJC was significantly associated with a worse EQ-VAS score (Table 1). For reference, in the GUS Q4W (N=244), GUS Q8W (N=246), & PBO (N=244) groups, the LS mean changes from baseline at W24 were 0.12, 0.12, & 0.05, respectively, for EQ-5D-5L index & 18.1, 18.4, & 6.8, respectively, for EQ-VAS.

Conclusion: Joint & skin symptoms, dactylitis, fatigue, pain, & elevated levels of CRP were significantly associated with reduced HRQoL (measured by EQ-5D-5L index & EQ-VAS) in bio-naïve pts with active PsA. Treatment of multiple PsA domains may help optimize HRQoL. Improvement across clinical domains[1] & in HRQoL has been observed in GUS-treated pts with PsA.

POS1029 GUSELKUMAB-TREATED PATIENTS WITH PSORIATIC ARTHRITIS ACHIEVED CLINICALLY MEANINGFUL IMPROVEMENTS IN GENERAL HEALTH OUTCOMES MEASURED WITH PROMIS-29 THROUGH 52 WEEKS: RESULTS FROM THE PHASE 3 DISCOVER-1 TRIAL

A. M. Orbai[1], L. C. Coates[2], A. Deodhar[3], P. Helliwell[4], C. T. Ritchlin[5], A. Kollmeier[6], E. C. Hsia[6,7], X. L. Xu[6], S. Sheng[8], Y. Jiang[8], Y. Liu[6], C. Han[6]. *[1]Johns Hopkins University School of Medicine, Psoriatic Arthritis Program, Baltimore, United States of America*; *[2]Oxford University, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; *[3]Oregon Health & Science University, Division of Arthritis and Rheumatic Diseases, Portland, United States of America*; *[4]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[5]University of Rochester Medical Center, Department of Medicine, Allergy/Immunology and Rheumatology, Rochester, United States of America*; *[6]Janssen Research & Development, LLC, Immunology, Spring House, United States of America*; *[7]University of Pennsylvania School of Medicine, Rheumatology, Philadelphia, United States of America*; *[8]Janssen Research & Development, LLC, Biostatistics, Spring House, United States of America*

Background: In the DISCOVER-1 study, the interleukin-23 p19 subunit inhibitor guselkumab (GUS) demonstrated robust efficacy across joint and skin clinical manifestations of psoriatic arthritis (PsA).[1] Patients (pts) with PsA also experience a broad range of symptoms that negatively impact health-related quality of life (eg, pain, fatigue, anxiety, depression, sleep disturbance, poor physical function).[2]

Objectives: Assess the treatment effect of GUS on general health outcomes in pts with PsA in the DISCOVER-1 trial through Week (W) 52 using the Patient-Reported Outcomes Measurement Information System-29 (PROMIS-29) instrument.

Methods: Pts with active PsA (≥3 swollen + ≥3 tender joints; C-reactive protein ≥0.3 mg/dL) and inadequate response to standard conventional therapies were randomized 1:1:1 to GUS 100 mg Q4W; GUS 100 mg at W0, W4, then Q8W; or placebo (PBO). PBO pts switched to GUS 100 mg Q4W at W24. PROMIS-29 contains 4 items for each of 7 domains (anxiety, depression, fatigue, pain interference, physical function, sleep disturbance, social participation) and 1 pain intensity item; 28 items are scored on a 5-point Likert-type scale, and pain intensity is rated from 0-10. The raw score of each domain is converted to a standardized T-score, with norms based on a general population mean score=50 and a standard deviation (SD)=10. Higher scores in anxiety, depression, fatigue, pain interference, and sleep disturbance indicate more severe symptoms; higher physical function and social participation scores indicate better health outcomes. Changes ≥5 points (1/2 SD of T-score) are considered clinically meaningful. Analyses were performed using both observed (mean scores/changes, effect sizes) and imputed (clinically meaningful response, whereby change from baseline was set to 0 at W24/52 for pts who had missing data or at W24 for pts who met treatment failure criteria prior to W24).

Results: At baseline, mean PROMIS-29 T-scores for physical function, social participation, sleep disturbance, pain, and fatigue were worse in the 381 PsA pts enrolled in DISCOVER-1 than in the general US population. Across all 7 domains, observed mean PROMIS-29 T-scores showed improvements in GUS-treated pts from baseline to W24 and W52 (Figure 1). Observed mean changes from baseline to W24 and W52, with calculated effect size, are shown (Table 1). In all pts, including those with imputed data, significantly higher percentages of pts in both GUS treatment groups vs PBO had ≥5-point improvements in fatigue, pain interference, physical function, sleep disturbance, social participation, and pain intensity domains at W24 (all nominal p<0.05). Mean improvements in PROMIS-29 domains were maintained through W52.

Conclusion: In pts with active PsA, PROMIS-29 results indicate that GUS treatment was associated with clinically meaningful reductions in fatigue and pain and improvement in physical function and social participation, which were maintained through 1 year.

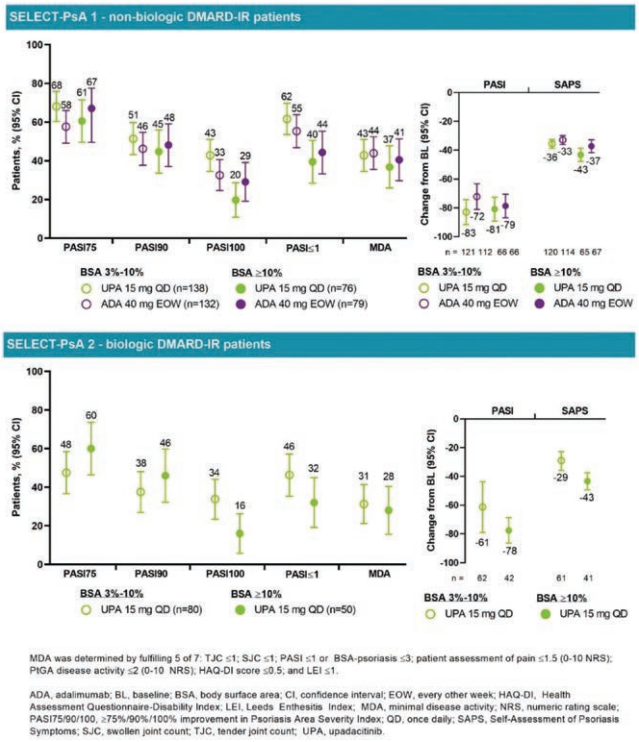
EFFICACY OF UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS STRATIFIED BY BASELINE SKIN SEVERITY: A SUBGROUP ANALYSIS OF TWO PHASE III TRIALS

J. F. Merola[1,2], P. Richette[3], E. Lubrano[4], E. Drescher[5], L. Soto[6], C. Lovan[7], K. Kato[7], R. Lippe[8], M. Lane[7], M. Kishimoto[9]. KG, Immunology, Wiesbaden, Germany*; [9]*Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Tokyo, Japan*

Background: In the SELECT-PsA 1 and 2 clinical trials, upadacitinib (UPA) demonstrated efficacy and safety in patients (pts) with active psoriatic arthritis (PsA).[1,2] PsA is associated with varying degrees of psoriatic symptoms; however, the impact of skin severity on treatment outcomes is not well understood.
Objectives: This post-hoc analysis assessed the effects of baseline skin severity on UPA efficacy.
Methods: SELECT-PsA 1 and SELECT-PsA 2 enrolled pts with PsA and prior inadequate response (IR) or intolerance to ≥1 non-biologic disease-modifying antirheumatic drug (DMARD)[1] or ≥1 biologic DMARD[2], respectively. In both trials, pts received once daily UPA 15 mg or UPA 30 mg or placebo (switched at Wk 24 to either UPA 15 mg or 30 mg); SELECT-PsA 1 also included the active comparator adalimumab (ADA). Only continuous UPA 15 mg and ADA are presented here. In this analysis, pts were divided into subgroups based on the extent of psoriasis at baseline (body surface area [BSA] of ≥3%-<10% or BSA ≥10%); efficacy endpoints were analyzed at Wk 56. Results for binary endpoints are based on non-responder imputation; continuous endpoints are based on mixed model repeated measures analysis with as-observed data.
Results: In the UPA 15 mg and ADA groups, respectively, 32% (138/429) and 31% (132/429) of pts had a BSA ≥3-<10% at baseline in SELECT-PsA 1; 18% (76/429) in each treatment group had a BSA ≥10%. In SELECT-PsA 2, 38% (80/211) had a BSA ≥3-<10% and 24% (50/211) had a BSA ≥10% at baseline in the UPA 15 mg group. Across pt populations (non-biologic DMARD-IR and biologic DMARD-IR), generally consistent results were observed between patients in both skin severity subgroups (Figure 1). In non-biologic DMARD-IR pts, a numerically greater proportion of UPA 15 mg pts with lower skin involvement compared with higher skin involvement achieved PASI100 and PASI≤1, two more stringent

Figure. Efficacy Outcomes at Week 56 Stratified by the Severity of Skin Involvement at Baseline



MDA was determined by fulfilling 5 of 7: TJC ≤1; SJC ≤1; PASI ≤1 or BSA-psoriasis ≤3; patient assessment of pain ≤1.5 (0-10 NRS); PtGA disease activity ≤2 (0-10 NRS); HAQ-DI score ≤0.5; and LEI ≤1.

ADA, adalimumab; BL, baseline; BSA, body surface area; CI, confidence interval; EOW, every other week; HAQ-DI, Health Assessment Questionnaire-Disability Index; LEI, Leeds Enthesitis Index; MDA, minimal disease activity; NRS, numeric rating scale; PASI75/90/100, ≥75%/90%/100% improvement in Psoriasis Area Severity Index; QD, once daily; SAPS, Self-Assessment of Psoriasis Symptoms; SJC, swollen joint count; TJC, tender joint count; UPA, upadacitinib.

Table 1. Additional Efficacy Outcomes at Week 56 Stratified by Severity of Skin Involvement at Baseline

	SELECT-PsA 1	
n/N (%) [95% CI]	**UPA 15 mg**	**ADA**
sIGA 0/1 w/at least 2 point improvement from BL[a]		
≥3%-<10%	71/128 (55.5) [46.9, 64.1]	53/124 (42.7) [34.0, 51.4]
≥10%	29/76 (38.2) [27.2, 49.1]	33/77 (42.9) [31.8, 53.9]
MDA + skin[b]		
≥3%-<10%	58/138 (42.0) [33.8, 50.3]	56/132 (42.4) [34.0, 50.9]
≥10%	19/76 (25.0) [15.3, 34.7]	28/79 (35.4) [24.9, 46.0]
SELECT-PsA 2		
n/N (%) [95% CI]	**UPA 15 mg**	
sIGA 0/1 w/at least 2 point improvement from BL[a]		
≥3%-<10%	24/71 (33.8) [22.8, 44.8]	
≥10%	18/50 (36.0) [22.7, 49.3]	
MDA + skin[b]		
≥3%-<10%	22/80 (27.5) [17.7, 37.3]	
≥10%	9/50 (18.0) [7.4, 28.6]	

[a] defined as achieving an sIGA score of 0 or 1 and at least a 2 point improvement from BL, evaluated in pts with BL sIGA ≥2.

[b] defined as achieving 5 of the 7 criteria, with PASI ≤1 or BSA-psoriasis ≤3 as a required component.

ADA, adalimumab; BL, baseline; CI, confidence interval; MDA, minimal disease activity; sIGA, Static Investigator Global Assessment of psoriasis; UPA, upadacitinib

skin endpoints. The achievement of MDA was generally consistent across skin severity subgroups; when pts were required to achieve the skin component of MDA, results were numerically better in the ≥3-<10% skin severity group (Table 1). In non-biologic DMARD-IR pts, results were similar between UPA 15 mg and ADA.

Conclusion: UPA is a viable treatment option for pts with active PsA regardless of the extent of psoriasis at baseline. Although these results are of interest and hypothesis-generating, they should be interpreted with caution due to low sample size.

LOW INCIDENCE OF GASTROINTESTINAL-RELATED AND OVERALL SERIOUS ADVERSE EVENTS AMONG GUSELKUMAB-TREATED PATIENTS: POOLED ANALYSES OF VOYAGE 1 & 2 AND DISCOVER 1 & 2 THROUGH 1-YEAR

Background: Guselkumab (GUS), a human monoclonal antibody that specifically binds to the p19-subunit of interleukin (IL)-23, demonstrated efficacy in the Phase 3 VOYAGE 1&2 trials of patients (pts) with moderate to severe plaque psoriasis (PsO)[1,2] and in the DISCOVER 1&2 trials of pts with active psoriatic arthritis (PsA).[3,4] IL-17 inhibitors used to treat PsO and PsA have been associated with exacerbation or new onset of inflammatory bowel disease (IBD) (e.g., Crohn's disease or ulcerative colitis).[5]

Objectives: Evaluate the incidence of gastrointestinal (GI)-related and overall serious adverse events (SAEs) from pooled safety data through 1-year of GUS 100 mg treatment from the VOYAGE 1&2 and DISCOVER 1&2 trials.

Methods: Using pooled safety data from the VOYAGE 1&2 PsO trials and DISCOVER 1&2 PsA trials, SAEs related to GI disorders were identified using the Medical Dictionary for Regulatory Activities (MedDRA) system-organ class "GI disorders". Pts with a previous history of IBD were not excluded in these trials; medical history of IBD was collected at baseline in DISCOVER 1&2. Rates of overall SAEs and GI-related SAEs were calculated as the number of SAEs per 100 pt-years (PY) of follow-up (95% confidence intervals). Data are presented for the placebo (PBO)-controlled period (Weeks 0-16 for VOYAGE 1&2; Weeks 0-24 for DISCOVER 1&2) and through 1-year (defined as through Week 48 for VOYAGE 1&2; through Week 60 for DISCOVER 1, and through Week 52 for DISCOVER 2). Events of uveitis and opportunistic infections were also analyzed.

Results: Through the PBO-controlled period, the overall rates of GI-related SAEs per 100 PY for pooled VOYAGE 1&2 were: PBO 0.78 (0.02, 4.34), GUS q8w 0; and for pooled DISCOVER 1&2: PBO 0.58 (0.01, 3.23), GUS q8w 0.58 (0.01, 3.21), GUS q4w 0. The GI-related SAEs included: gastrointestinal hemorrhage (PBO; n=1) for pooled VOYAGE 1&2; and inflammatory bowel disease (PBO; n=1) and mechanical ileus (GUS q8w; n=1) for pooled DISCOVER 1&2. Through 1-year, the overall rates of GI-related SAEs for pooled VOYAGE 1&2 were: Combined GUS group (GUS q8w and PBO→GUS groups) 0.51 (0.17, 1.20); and for pooled DISCOVER 1&2: GUS q8w 0.52 (0.06, 1.88), GUS q4w 0, Combined GUS group (GUS q8w, GUS q4w, and PBO→GUS groups) 0.21 (0.02, 0.74). The GI-related SAEs in the Combined GUS group for pooled VOYAGE 1&2 included: gastritis, hemorrhoids, inguinal hernia, pancreatitis, and umbilical hernia (0.10/100PY [0.00, 0.57]; n=1 for each); and in the Combined GUS group for pooled DISCOVER 1&2: mechanical ileus and pancreatitis chronic (0.10/100PY [0.00, 0.57]; n=1 for each). Overall, no cases of exacerbation or new onset of IBD were reported in GUS-treated pts, including 2 pts with a prior history of IBD in DISCOVER 1&2 (total PY of follow-up for the Combined GUS groups in VOYAGE and DISCOVER were 974 and 973, respectively). Through the PBO-controlled period, rates of overall SAEs for GUS-treated pts were comparable to PBO-pts and SAE rates remained low through 1-year of follow-up in the VOYAGE 1&2 and DISCOVER 1&2 trials. There were no reported cases of uveitis, opportunistic infections, or tuberculosis in GUS-treated pts through 1-year.

Conclusion: Through 1-year of follow-up with GUS treatment in pooled VOYAGE 1&2 and DISCOVER 1&2, GI-related SAE rates were low. There were no reported cases of uveitis, opportunistic infections, or new onset/exacerbation of IBD in GUS-treated pts. No new safety concerns were identified through 1-year.

POS1032

EFFICACY OF UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS STRATIFIED BY NUMBER OF PRIOR BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

P. J. Mease[1], A. Lertratanakul[2], B. Strober[3], S. Tsuji[4], P. Richette[5], C. Lovan[2], D. Feng[2], J. Anderson[2], F. Van den Bosch[6]. [1]*Department of Rheumatology, Swedish Medical Center and University of Washington, Seattle, United States of America*; [2]*AbbVie Inc., Rheumatology, North Chicago, United States of America*; [3]*Yale University School of Medicine, New Haven and Central Connecticut Dermatology, Cromwell, United States of America*; [4]*Department of Orthopaedics/Rheumatology, National Hospital Organization, Osaka Minami Medical Center, Osaka, Japan*; [5]*Department of Rheumatology, Lariboisière Hospital, Paris, France*; [6]*Department of Internal Medicine, Ghent University Hospital, Ghent, Belgium*

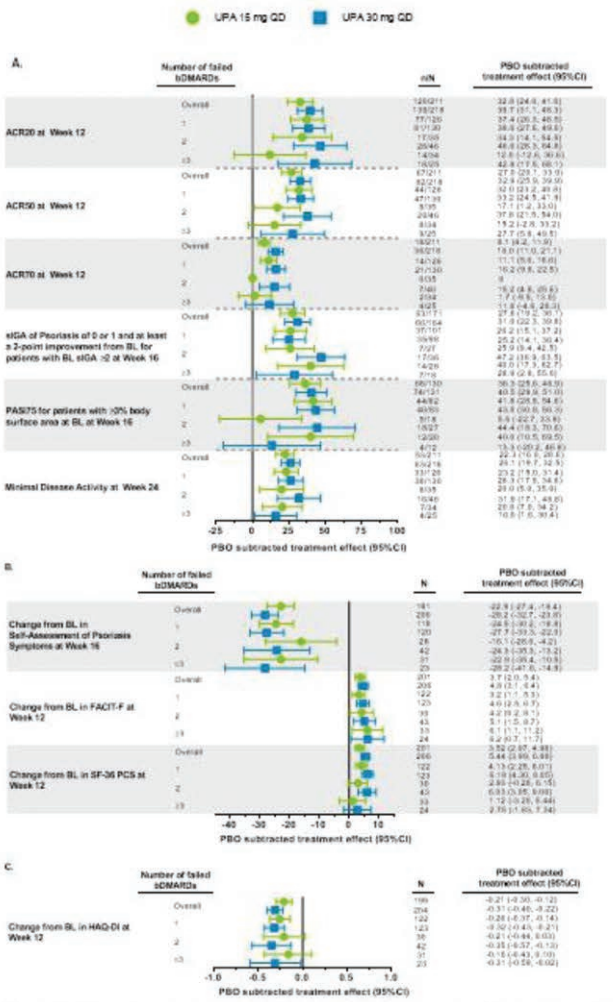
Background: Upadacitinib (UPA) has shown efficacy and safety in patients (pts) with active PsA in the Phase 3 SELECT-PsA 1 and SELECT-PsA 2 clinical trials.[1,2] Historically efficacy has been lower with second- and third-line therapy compared with first-line anti-TNF therapy in PsA;[3,4] however, clinical trial data that describe efficacy in pts who have had an inadequate response (IR) to multiple biologic DMARDs (bDMARDs) are limited.

Objectives: This analysis assessed the effects of prior bDMARD failure on UPA efficacy in the SELECT-PsA 2 trial.

Methods: The SELECT-PsA 2 study enrolled pts with prior IR or intolerance to ≥1 bDMARD (N=642). Pts were randomized to placebo (PBO), UPA 15 mg once daily (QD, UPA15), or UPA 30 mg QD (UPA30). Stable background treatment of ≤2 non-bDMARDs was permitted; background therapy was not required. Only the pts who had IR to ≥1 bDMARD were included in this analysis; pts were subgrouped based on the number of bDMARDs failed prior to enrollment (1, 2, or ≥3). This analysis includes assessment of proportion of pts achieving ACR20/50/70, and change in HAQ-DI, FACIT-Fatigue, and SF-36 Physical Component Summary at Wk 12; static Investigator Global Assessment of Psoriasis of 0 or 1 and at least a 2-point improvement from baseline, PASI75, and change in Self-Assessment of Psoriasis Symptoms at Wk 16; and proportion of pts achieving minimal disease activity (MDA) at Wk 24. Non-responder imputation was used for binary endpoints. Mixed-effects model for repeated measures was used for continuous endpoints. Point estimates and 95% confidence intervals (CIs) of the PBO subtracted treatment effect were calculated.

Results: 641 pts were randomized and received study drug; 92% were bDMARD-IR: 391 (61%) of pts failed 1 bDMARD, 116 (18%) failed 2 bDMARDs, and 83 (13%) failed ≥3 bDMARDs. In the overall study population, UPA15 and UPA30 demonstrated superiority vs placebo for all endpoints evaluated. In this post hoc analysis, the PBO subtracted treatment effect demonstrates generally consistent efficacy as compared to the overall study population for UPA15 and UPA30 across efficacy endpoints in the subgroups of pts with IR to 1, 2, or ≥3 prior bDMARDs (Figure 1). Due to limited sample sizes for pts with IR to >1 bDMARD and the pt subsets analyzed for psoriasis-related endpoints, results should be interpreted with caution.

Figure. Efficacy Outcomes by Prior bDMARD Exposure: Placebo Subtracted Treatment Effect



ACR20/50/70, American College of Rheumatology 20%/50%/70% improvement criteria; BL, baseline; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI, Health Assessment Questionnaire - Disability Index; MDA, minimal disease activity; PASI, Psoriasis Area Severity Index; PBO, placebo; QD, once daily; SF-36 PCS, 36-Item Short Form Health Survey Physical Component Summary Score; sIGA, Static Investigator Global Assessment of Psoriasis.

Conclusion: Upadacitinib demonstrated consistent efficacy in treating clinical manifestations of PsA including musculoskeletal symptoms, psoriasis, physical function, fatigue, and quality of life in pts with IR to 1 or multiple prior bDMARDs. In addition, comprehensive disease control as measured by MDA, was generally consistently achieved with upadacitinib regardless of number of prior bDMARDs tried.

POS1033 SAFETY OF IXEKIZUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS: AN INTEGRATED ANALYSIS OF 4 CLINICAL TRIALS

C. Sesin[1], G. Gallo[2], A. Gellett[2], A. Kronbergs[2], A. T. Sprabery[2], W. Xu[2], H. Patel[2], A. Deodhar[3], B. Combe[4], G. R. Burmester[5]. *[1]Mount Sinai Medical Center, Miami Beach, United States of America*; *[2]Eli Lilly and Company, Indianapolis, United States of America*; *[3]Oregon Health & Science University, Portland, United States of America*; *[4]Montpellier University, CHU Montpellier, Montpellier, France*; *[5]Universitatsklinikum Charite, Berlin, Germany*

Background: Patients with psoriatic arthritis (PsA) require long-term treatment, which may lead to adverse events (AEs). Ixekizumab, an interleukin-17A antagonist, is approved for the treatment of adults with active PsA.

Objectives: We report a summary of safety outcomes for patients enrolled in 4 PsA studies with up to 3 years of exposure to ixekizumab.

Methods: This integrated safety analysis included all patients with PsA who received at least 1 dose of ixekizumab (80 mg every 2 or 4 weeks) in 4 clinical trials (NCT01695239, NCT02349295, NCT02584855, NCT03151551). Safety outcomes included treatment-emergent adverse events (TEAEs), serious AEs (SAEs), discontinuations due to AEs, deaths, and AEs of special interest.

Results: A total of 1401 patients were included in this safety analysis (51.5% female; mean age 49 years), with 2247.6 patient-years of exposure (Table 1). In all, 1131 patients (80.7%) reported ≥1 TEAE (exposure-adjusted incidence rate per 100 patient-years [IR] 50.3, 95% CI 47.5–53.3), mostly mild (32.9%) or moderate (39.7%) in severity. The most common TEAEs were nasopharyngitis (n=202, IR 9.0), upper respiratory infections (n=186, IR 8.3), and injection site reaction (n=156, IR 6.9). SAEs were reported by 134 patients (IR 6.0, 95% CI 5.0–7.1). 115 (8.2%) patients discontinued due to AEs (IR 5.1, 95% CI 4.3–6.1). Six deaths were reported (IR 0.3, 95% CI 0.1–0.6). Allergic reactions/hypersensitivity were reported in 102 patients (IR 4.5, 95% CI 3.7–5.5). Three cases were adjudicated as de novo inflammatory bowel disease (IR 0.13, 95% CI 0.04–0.41); 1 was ulcerative colitis (IR 0.04, 95% CI 0.01–0.32), 2 were Crohn's disease (IR 0.09, 95% CI 0.02–0.36). Major adverse cardiac events occurred in 12 patients (IR 0.5) and malignancies in 15 (IR 0.7), 9 of which were non-melanoma skin cancer. Opportunistic infections occurred in 40 (2.9%) patients (IR 1.8, 95% CI 1.3–2.4). Candidiasis occurred in 24 patients (oral: IR 0.7, 95% CI 0.4–1.2; oral fungal infection: IR 0.3, 95% CI 0.1–0.6; esophageal infection: IR 0.1, 95% CI 0.0–0.4). No active or reactive cases of tuberculosis were reported. Other opportunistic infections included hepatitis B (IR 0.0, 95% CI 0.0–0.3), herpes simplex (IR 1.8, 95% CI 1.3–2.5), and herpes zoster (IR 0.7, 95% CI 0.4–1.2).

Conclusion: The safety profile of ixekizumab across 4 clinical trials and up to 3 years of continuous treatment in patients with active PsA was consistent with the known safety profile reported in previous studies for psoriasis and PsA. No new safety events were found in this analysis.

POS1034 RESPONSE TO SEQUENTIAL LINES OF BIOLOGICAL THERAPY IN PSORIATIC ARTHRITIS: A SINGLE CENTRE COHORT STUDY

A. Abdalla[1], A. Rambojun[2], L. C. Coates[3], E. Korendowych[1], N. Mchugh[2], W. Tillett[1,2]. *[1]Royal National Hospital for Rheumatic Diseases, Rheumatology Department, Bath, United Kingdom*; *[2]University of Bath, Department of Pharmacy and Pharmacology, Bath, United Kingdom*; *[3]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: Biologic interventions using highly specific immuno-modulatory biologic disease-modifying anti-rheumatic drugs (bDMARDs) represent a rapidly developing therapeutic approach to the treatment of Psoriatic Arthritis (PsA). However, despite high rates of response, adverse events, primary and secondary inefficacy are common, and multiple sequential lines of bDMARDs are often required. Data on drug persistence, as a surrogate for response, from national registries indicates switching has become accepted routine practice. One third of patients will fail or discontinue their first biologic with a significant proportion switching on to a 3rd biologic or higher.[1-4] Due to a lack of evidence on the response to sequential therapies, individual patients may not have further lines routinely funded after three bDMARDs in the UK. While limiting lines of therapy remains a UK concern, many countries with rationed healthcare systems follow the UK model of drug usage.

Objectives: To describe the response to sequential lines of bDMARD therapy prescribed in routine care in a UK single centre cohort.

Methods: A retrospective sample of patients with PsA who fulfilled CASPAR criteria and had received at least one bDMARD were taken from the Bath longitudinal cohort for inclusion in the study. Clinical and laboratory variables that constitute physician and patient-reported outcome measures were collected at baseline and after a median (range) follow-up of 3 months (2-5) into their respective therapy line in accordance with the National Institute for Health and Care Excellence (NICE) rules. The mean change with a 95% confidence interval (CI) was used to report the difference between the baseline and follow-up measures. All patients provided consent to use their data collected during routine care, and ethical approval by the local committee was granted.

Results: The patients mean age was 57.7 (SD 12.2) with a median (range) disease duration of 14.4 years (9.7 – 23.2). Data was available for 194 patients commencing 1st line bDMARD, 106 (2nd line), 93 (3rd line), 33 (4th line), 12 (5th line), and 9 (6th line and higher) from a total of 759 patients in the cohort. Mean tender and swollen joint count at baseline 1st bDMARD was 7 (SD 4.7) and 22 (SD 14.0), pain visual analogue scale 50 (SD 27.6) and PASI 1.3 (SD 2.2). Reasons for changing biological therapies include lack or loss of efficacy, intolerance, side effects, and comorbidities. Mean levels of joint disease at drug initiation did not diminish with subsequent lines of therapy. Clinical and patient

reported outcomes by line of therapy are reported in Figure 1. Clinical responses were greatest to first line bDMARD, however clinically relevant DAPSA improvements were seen up to 5th line. Absolute levels of psoriasis in the cohort were low, however improvement in PASI was achieved across all lines of therapy. Patient and Physician Global Assessments (1-5 on Likert scale) and the Pain Visual analogue score (VAS on 1-10 Likert scale) showed a similar trend with greatest improvement to first line treatment across all lines of therapy.

Conclusion: In this study we report the clinical response to sequential lines of bDMARD therapy for active PsA in routine clinical practice. Clinical response was greatest to the first line bDMARD but overall improvement in DAPSA, PASI or pain response did not appear to diminish up to 5th line. Further study in larger cohorts is required to confirm this finding and build on our understanding of clinical response to sequential lines of bDMARD therapy.

POS1035 UPADACITINIB AS MONOTHERAPY AND IN COMBINATION WITH NON-BIOLOGIC DMARDs FOR THE TREATMENT OF PSORIATIC ARTHRITIS: SUBGROUP ANALYSIS FROM TWO PHASE 3 TRIALS

P. Nash[1], P. Richette[2], L. Gossec[3], A. Marchesoni[4], C. T. Ritchlin[5], K. Kato[6], E. Mcdearmon-Blondell[6], E. Lesser[6], R. Mccaskill[6], D. Feng[6], J. Anderson[6], E. Ruderman[7]. [1]*School of Medicine, Griffith University, Brisbane, Australia*; [2]*Service de Rhumatologie, Hopital Lariboisiere Centre Viggo Petersen and Inserm UMR1132 Bioscar, Universite Paris Diderot UFR de Medecine, Paris, France*; [3]*Sorbonne Universite, Pitie Salpetriere Hospital, Paris, France*; [4]*ASST Gaetano, Pini-CTO, Milan, Italy*; [5]*Allergy, Immunology and Rheumatology Division, Center for Musculoskeletal Medicine, University of Rochester Medical Center, Rochester, United States of America*; [6]*AbbVie Inc., Rheumatology, North Chicago, United States of America*; [7]*Northwestern University, Feinberg School of Medicine, Chicago, United States of America*

Background: Approximately 40% of PsA patients (pts) on advanced therapy are on monotherapy.[1,2] Upadacitinib (UPA) showed efficacy and safety in pts with active PsA in the Phase 3 SELECT-PsA 1 and SELECT-PsA 2 clinical trials.[3,4]
Objectives: Assess efficacy and safety in subgroups of pts treated with UPA as monotherapy or in combination with non-biologic disease-modifying antirheumatic drugs (non-bDMARDs).
Methods: The SELECT-PsA program enrolled pts with prior inadequate response (IR) or intolerance to ≥1 non-bDMARD (N=1705) and prior IR or intolerance to ≥1 bDMARD (N=642). Data from both trials was integrated for pts receiving placebo (PBO), UPA 15 mg once daily (QD) and UPA 30 mg QD. Stable background treatment of ≤2 non-bDMARDs was permitted, but not required. Analysis includes UPA monotherapy vs combination therapy for endpoints: ACR20/50/70 responses and change from baseline in pain and HAQ-DI (Wk 12); Static Investigator Global Assessment of Psoriasis of 0 or 1 and at least a 2-point improvement from baseline and PASI75/90/100 responses (Wk 16); proportion of pts achieving resolution of enthesitis, dactylitis, and minimal disease activity (Wk 24). Binary outcomes, using the Cochran-Mantel-Haenszel-method and continuous outcomes, using mixed-effects model, were analyzed for repeated measures in the subgroups of UPA monotherapy and combination therapy. Point estimates and 95% confidence intervals (CIs) of PBO subtracted treatment effect were calculated. Treatment-emergent adverse events (TEAEs) were analyzed.
Results: Of 1916 pts, 574 (30%) received monotherapy and 1342 (70%) received combination therapy; 84% in combination therapy group received MTX +/- another non-bDMARD. Both UPA monotherapy and combination therapy led to improvements in efficacy vs PBO and across endpoints, for each dose, generally consistent point estimates of PBO subtracted treatment effect and associated overlapping CIs were observed (Figure 1). Generally, frequency of AEs and serious AEs, were comparable with UPA administered as monotherapy and combination therapy (Table 1). Frequency of AEs of serious infections and hepatic disorder were lower with monotherapy while frequency of AEs leading to discontinuation of study drug were lower with combination therapy. Most hepatic disorders were transient transaminase elevations.
Conclusion: In the SELECT PsA trials, efficacy and safety of UPA was generally consistent when administered as monotherapy or when given in combination with non-bDMARDs. Results from this analysis support the use of UPA with or without concomitant non-bDMARDs.

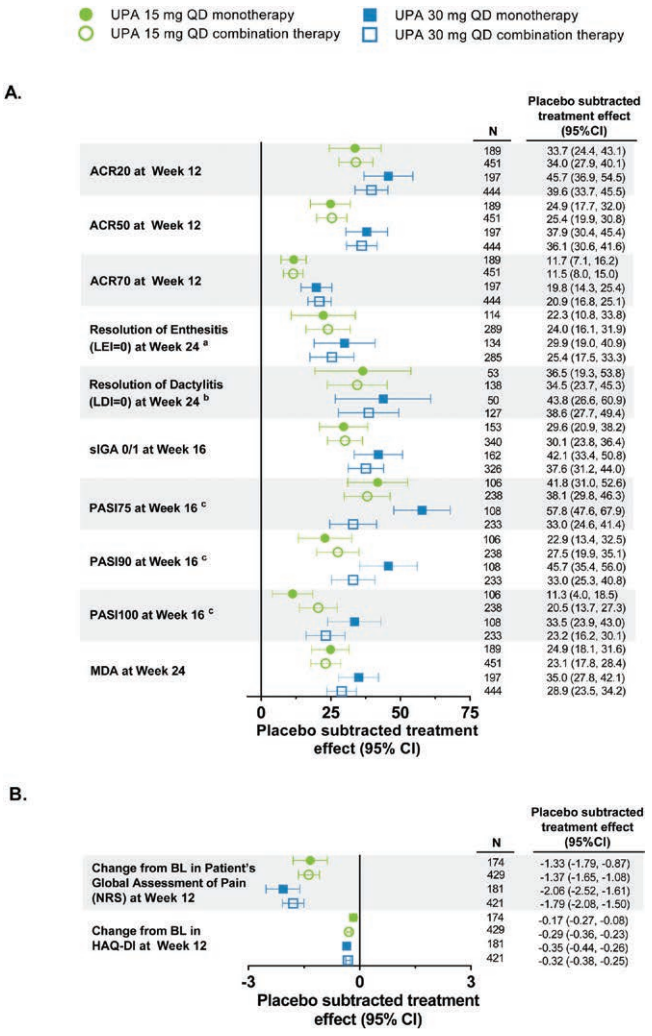
POS1036 COLLAGEN TURNOVER MARKERS ARE ASSOCIATED WITH ACTIVE PSORIATIC ARTHRITIS AND DECREASE WITH GUSELKUMAB TREATMENT IN A PHASE-3 CLINICAL TRIAL

G. Schett[1], M. J. Loza[2], A. Palanichamy[2], O. Fitzgerald[3], C. T. Ritchlin[4], F. Baribaud[2], K. Sweet[2]. [1]*Friedrich Alexander University Erlangen-Nuremberg and*



Universitätsklinikum Erlangen, Internal Medicine, Erlangen, Germany; [2]*Janssen Research & Development, LLC, Spring House, PA, United States of America*; [3]*University College Dublin, School of Medicine, Dublin 4, Ireland*; [4]*University of Rochester, Department of Medicine, Rochester, NY, United States of America*

Background: Guselkumab (GUS), an interleukin-23p19-subunit monoclonal antibody, demonstrated efficacy compared to placebo (PBO) in reducing skin and musculoskeletal signs and symptoms in patients with active psoriatic arthritis (PsA) in two phase-3 studies, DISCOVER-1 & -2, and in retarding structural damage in DISCOVER-2.[1,2]

Objectives: To evaluate tissue-derived extracellular matrix (ECM) products[3,4] in serum of PsA patients in the DISCOVER-2 study and their relationship with radiographic damage, clinical response, and impact of treatment.

Methods: In DISCOVER-2, patients were treated with GUS 100 mg at Week (w) 0, 4, then every 8w (q8w); GUS 100 mg every 4w (q4w); or matching PBO. At w24, PBO patients were crossed over to GUS q4w. A total of 11 serum biomarkers of ECM collagen formation (PRO-C1, PRO-C2, PRO-C3, PRO-C4, and PRO-C6) and degradation (C1M, C2M, C3M, C4M, C6M, and COL10) were measured (by Nordic Bioscience) in a subset of 260 patients from the DISCOVER-2 program at Weeks 0, 4, 24, & 52 and in 76 healthy controls matched for age, sex, and ethnicity. PsA patients were selected randomly, though enriching for subjects with greatest radiographic changes, at Weeks 24 and 52. Significance defined by $p<0.05$ and |fold difference| ≥1.25.

Results: At baseline, collagen degradation markers C1M, C3M, C4M, C6M and collagen formation markers PRO-C3 and PRO-C6 were significantly higher in the serum of PsA patients compared to matched healthy controls. Baseline C3M, C4M, and C6M were positively correlated to baseline skin and joint disease; baseline C1M, C3M, C4M, C6M, and PRO-C1 were positively correlated to baseline radiographic damage (data not shown). Levels of C1M (a maker indicating breakdown of collagen type I, the major collagen subtype in the bone) were significantly decreased after 24w treatment with GUS (Figure 1), reaching significant differences from placebo with the GUS 100 mg q4w group. For the PBO patients who crossed over to GUS at w24, there was also a reduction in this marker observed at w52 (Figure 1). In patients treated with GUS or PBO, there were no significant differences in baseline expression levels of the analytes in responders (patients achieving ACR20 at w24) compared with non-responders. However, ACR20 responders in the combined GUS group had a significantly greater reduction in C1M levels compared to non-responders (p=0.0065) at w24.

Conclusion: This work provides evidence that collagen biomarkers in serum are dysregulated in patients with PsA compared to healthy controls, and that GUS impacts levels of these proteins. Importantly, C1M serves as a biomarker that tracks with joint response. We observed a greater reduction in C1M in ACR responders compared to non-responders, providing insight into how GUS may be working to protect from degradation of bone in PsA.

POS1037 CORRELATION BETWEEN SKIN INVOLVEMENT, JOINT INVOLVEMENT AND ENTHESITIS IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: POST-HOC ANALYSIS OF EQUATOR/EQUATOR2

P. J. Mease[1,2], L. C. Coates[3], F. Van den Bosch[4], D. D. Gladman[5], L. Gheyle[6], M. Trivedi[7], M. Alani[7,8], E. Vetters[9], F. O. Le Brun[10], R. Besuyen[11], P. Helliwell[12]. *[1]Swedish Medical Center, Rheumatology Clinical Research Division, Seattle, United States of America*; *[2]University of Washington, School of Medicine, Seattle, United States of America*; *[3]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; *[4]Ghent University, VIB Center for Inflammation Research, Ghent, Belgium*; *[5]Schroeder Arthritis Institute, Krembil Research Institute, University Health Network, Toronto, Canada*; *[6]Galapagos NV, Clinical Research, Mechelen, Belgium*; *[7]Gilead Sciences, Inc., Clinical Research, Foster City, United States of America*; *[8]University of Washington, Rheumatology Department, Seattle, United States of America*; *[9]Galapagos NV, Biometrics, Mechelen, Belgium*; *[10]Galapagos GmbH, Biometrics, Basel, Switzerland*; *[11]Galapagos BV, Clinical Research, Leiden, Netherlands*; *[12]University of Leeds, School of Medicine, Leeds, United Kingdom*

Background: Psoriatic arthritis (PsA) is a heterogeneous, inflammatory disease involving multiple clinical domains including arthritis/synovitis, enthesitis, dactylitis, spondylitis and psoriasis. Effects on each domain should be assessed to determine the overall quality of treatment. Filgotinib (FIL) is a novel preferential Janus kinase 1 inhibitor that is in development for inflammatory conditions including PsA. EQUATOR (NCT03101670) was a 16-week, Phase 2, double-blind, randomised, placebo (PBO)-controlled trial of FIL for patients with active PsA.[1] EQUATOR2 (NCT03320876) is an open-label extension (OLE) of the study.

Objectives: This post-hoc analysis of EQUATOR and EQUATOR2 assessed the patient-level correlation between changes over time in the three PsA clinical disease domains of skin, joint and enthesitis in patients treated with FIL.

Methods: In EQUATOR, patients with active moderate-to-severe PsA (≥5 swollen joints and ≥5 tender joints, fulfilling Classification for PsA criteria) were randomised 1:1 to receive oral FIL 200 mg or PBO once daily (QD) for 16 weeks. At Week 16, patients could continue into the 304-week OLE, with all patients receiving FIL 200 mg QD regardless of previous treatment in EQUATOR. This post-hoc analysis was limited to patients with skin involvement (≥3% body surface area), joint involvement and enthesitis at baseline, with changes from baseline in the three domains assessed using the Psoriasis Area and Severity Index (PASI), swollen/tender joint count (S/TJC), and the Leeds Enthesitis Index (LEI) and Spondyloarthritis Research Consortium of Canada (SPARCC) index, respectively. Analyses that used LEI as the enthesitis index to assess change from baseline included patients with LEI score ≥1 at baseline; those using SPARCC included patients with SPARCC score ≥1 at baseline.

Results: The EQUATOR study enrolled 131 patients and 122 patients continued into the EQUATOR2 OLE. Of the 131 patients enrolled in EQUATOR, 49 and 56 patients had PsA involving all three domains at core study baseline when enthesitis was assessed using LEI and SPARCC index, respectively. Pooled data for all patients receiving FIL during the OLE indicate that improvements from baseline in the clinical domains continued with long-term treatment, with 22/42 (52%) and 23/38 (61%) patients having both SJC66 and LEI resolution at Weeks 52 and 100, respectively. For the 22 patients with both SJC and LEI resolution at Week 52, the mean percent change from baseline for PASI was –64%; for the 23 patients with both SJC and LEI resolution at Week 100, the mean percent change from baseline for PASI was –60%. The Figure 1 shows correlation between SJC, LEI and PASI at Week 100. A relationship between the three clinical domains was observed at the individual level; within a single patient, an improvement in one domain was generally followed by improvements in the other two domains. With regard to the sequence in which changes were observed, joints improved first, followed by improvements in the skin and enthesitis. There were no notable differences between changes in LEI and SPARCC enthesitis index in terms of their correlation with improvements in joint and skin involvement. Similarly, there were no notable differences in correlation between the three domains when joints were assessed using TJC rather than SJC.

Conclusion: Patients with improvements in skin, joints or enthesitis following treatment with FIL generally also had improvements in the other clinical domains of PsA. The joints were found to be the first of the three domains to improve.

POS1038 THE EFFECT OF FILGOTINIB ON ENTHESITIS: 100-WEEK DATA FROM AN OPEN-LABEL EXTENSION STUDY IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

P. Helliwell[1], L. C. Coates[2], F. Van den Bosch[3], D. D. Gladman[4], L. Gheyle[5], M. Trivedi[6], M. Alani[6,7], F. O. Le Brun[8], R. Besuyen[9], P. J. Mease[10,11]. *[1]University of Leeds, School of Medicine, Leeds, United Kingdom*; *[2]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; *[3]Ghent University, VIB Center for Inflammation Research, Ghent, Belgium*; *[4]Schroeder Arthritis Institute, Krembil Research Institute, University Health Network, Toronto, Canada*; *[5]Galapagos NV, Clinical Research, Mechelen, Belgium*; *[6]Gilead Sciences, Inc., Clinical Research, Foster City, United States of America*; *[7]University of Washington, Rheumatology Department, Seattle, United States of America*; *[8]Galapagos GmbH, Biometrics, Basel, Switzerland*; *[9]Galapagos BV, Clinical Research, Leiden, Netherlands*; *[10]Swedish Medical Center, Rheumatology Clinical Research Division, Seattle, United States of America*; *[11]University of Washington, School of Medicine, Seattle, United States of America*

Background: Filgotinib (FIL), a novel preferential Janus kinase 1 inhibitor, was assessed in patients with active psoriatic arthritis (PsA) in the 16-week, Phase 2, EQUATOR trial (NCT03101670).[1] EQUATOR2 (NCT03320876) is the open-label extension (OLE). As previously reported, an interim analysis of the OLE showed that the majority of patients had clinical resolution of enthesitis by Week 52.[2]

Objectives: This post-hoc analysis evaluated the effect of FIL on clinical enthesitis after 100 weeks of treatment in the OLE, as assessed using the Leeds Enthesitis Index (LEI) and Spondyloarthritis Research Consortium of Canada (SPARCC) index, and evaluated the discriminatory capacity of the two indices. In addition, we assessed which of the sites included in LEI and SPARCC were most frequently involved and whether treatment effect was consistent across sites.
Methods: In EQUATOR, patients with active moderate-to-severe PsA (≥5 swollen joints and ≥5 tender joints, fulfilling Classification for PsA criteria) were randomised 1:1 to receive oral FIL 200 mg or placebo (PBO) once daily (QD) for 16 weeks. At Week 16, all patients could continue into the OLE, receiving FIL 200 mg QD for up to an additional 304 weeks. We compared changes from core baseline in LEI and SPARCC measures, the effect on enthesitis at sites included in LEI and SPARCC assessments and the discriminatory capacity of both enthesitis indices.
Results: Of 131 patients randomised to EQUATOR, 122 entered the OLE. There was strong agreement between LEI and SPARCC at baseline. While most patients had enthesitis at baseline according to either index (76/131 [58.0%] by LEI; 85/131 [64.9%] by SPARCC), a minority had enthesitis at a large number of sites (6.9% with 5–6 LEI sites; 12.2% with ≥9 SPARCC sites). The sites most frequently involved at baseline were the lateral epicondyle humerus and Achilles tendon, sites common to both LEI and SPARCC. There was greater variability in the change from baseline to Week 16 in SPARCC compared with LEI (Table 1). LEI showed a greater discriminatory capacity than SPARCC when change from baseline was compared for FIL vs PBO at Week 16, as shown by higher absolute standardised mean difference: –0.70 (LEI) and –0.30 (SPARCC) (observed cases; Table 1). Subgroup analyses indicated that the treatment effect of FIL vs PBO at Week 16 for all sites was consistent with the overall treatment effect seen for LEI or SPARCC, and indicative of an improvement with FIL vs PBO for nearly all sites. The proportion of patients with enthesitis decreased from baseline up to OLE Week 100 (Figure 1). There were no major differences in long-term effect on enthesitis between sites.
Conclusion: FIL improved enthesitis consistently across sites compared with PBO. Rapid improvement in enthesitis was seen up to Week 16 of the core study and improvements continued up to Week 52, after which responses were generally stable up to Week 100. LEI assesses fewer locations than SPARCC, but reassuringly captured the sites most commonly affected by enthesitis; LEI also had greater discriminatory capacity.

TABLE: Mean change from baseline in enthesitis assessed by LEI and SPARCC

Index	Imputation	Filgotinib		Placebo		Pooled SD	Mean difference	Standardised mean difference	Guyatt effect size
		n	Mean (SD) change from baseline at Week 16	n	Mean (SD) change from baseline at Week 16				
SPARCC	OC	34	−2.9 (3.43)	47	−1.9 (3.24)	3.32	−1.0	−0.30	−0.90
SPARCC	LOCF	37	−2.8 (3.29)	47*	−1.9 (3.24)	3.26	−0.9	−0.28	−0.86
LEI	OC	30	−1.7 (1.49)	43	−0.7 (1.37)	1.42	−1.0	−0.70	−1.24
LEI	LOCF	33	−1.8 (1.49)	43	−0.7 (1.37)	1.42	−1.1	−0.77	−1.31

Includes patients with enthesitis at core study baseline

*One patient with SPARCC enthesitis at baseline had no post-baseline value

POS1039 PSORIATIC ARTHRITIS AND PHYSICAL ACTIVITY, A SYSTEMATIC REVIEW

J. Kessler[1], M. Chouk[2], T. Ruban[1], C. Prati[1], D. Wendling[1], F. Verhoeven[1].
[1]Besançon University Hospital, Rheumatology, Besançon, France; *[2]Besançon University Hospital, Rheumatology, Besançon, France*

Background: The beneficial effects of physical activity (PA) have been demonstrated in rheumatoid arthritis and ankylosing spondylitis on disease and co-morbidities while they are not clearly established in psoriatic arthritis.
Objectives: Thus, the aim of this study was, on the basis of a systematic review of the literature, (i) to assess the level of physical activity in these patients and (ii) to determine the effects of physical activity on joint and extra articular symptoms and on well-being.
Methods: The research strategy was performed on Pubmed, Cochrane,and PEDro databases using the following keywords: “psoriatic arthritis AND physical activity” without restriction. Articles published in English before October 2019 were identified and selected according to the PRISMA methodology by two independent investigators. In case of disagreement, a third investigator was interviewed. To be included in the qualitative synthesis, the studies had to meet the PICOS criteria.
Results: Among the 259 studies identified, 13 were finally included. 241 were excluded because they did not address the topic or were not in English and 5 were duplicated. Two epidemiological studies revealed that 17 and 68 % of patients comply with WHO recommendations for the general population in terms of physical activity. The main explanations expressed by patients are; a lack of promotion of physical activity by the rheumatologist and the fear of pain during the movement also called “kinesiophobia”. Among the three prospective randomized clinical trials, one of them showed a significant 20% reduction in the BASDAI (Bath Ankylosing Spondylitis Disease) and a 25% reduction in pain. Fatigue was significantly reduced by 15% following a physical activity protocol on a cyclergometer for 11 weeks. Muscle strength and maximum VO2 were significantly improved after participation in the physical activity protocol in two of the clinical trials. Four retrospective studies evaluated the effect of physical activity on the risk of enthesitis or dactylitis. None were associated with an increased risk of enthesitis. However, physical activity was found to be a risk factor for structural remodelling of the Achilles tendon. And, avoiding physical activity seems to be a protective factor against the risk of enthesitis. On the other hand, the three clinical trials did not mention any increase in the disease’s activity score. Finally, the effects of four rehabilitation programs have been evaluated in psoriatic arthritis and other inflammatory rheumatism. The beneficial effects were modest and concerned the reduction of pain for all the programs and of fatigue for two of the programs.
Conclusion: The studies showed a beneficial effect of physical activity on disease activity, on well-being and on comorbidities. The data on the risk of enthesitis are reassuring. Further investigations are necessary to confirm these results and to precise the modalities of exercise.

IMPLEMENTATION OF THE OMERACT PSAMRIS IN A PHASE IIB, RANDOMISED PLACEBO-CONTROLLED STUDY OF ABATACEPT IN PSORIATIC ARTHRITIS

M. Østergaard[1,2], P. Bird[3], C. Pachai[4], S. Du[4], C. Wu[5], J. Landis[5], T. Fuerst[6], H. A. Ahmad[7], S. Connolly[8], P. G. Conaghan[9]. *[1]Center for Rheumatology and Spine Diseases, Rigshospitalet, Copenhagen Center for Arthritis Research, Glostrup, Denmark*; *[2]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*; *[3]University of New South Wales (NSW), Division of Medicine, Sydney, Australia*; *[4]Bristol Myers Squibb, Translational Medicine, Princeton, United States of America*; *[5]Bristol Myers Squibb, Translational Bioinformatics, Princeton, United States of America*; *[6]BioClinica, Inc., Medical and Scientific Affairs, Newark, United States of America*; *[7]Bristol Myers Squibb, Medical Affairs, Immunology & Fibrosis, Princeton, United States of America*; *[8]Bristol Myers Squibb, Global Drug Development, Princeton, United States of America*; *[9]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: The semi-quantitative Outcome Measures in Rheumatology (OMERACT) Psoriatic Arthritis Magnetic Resonance Imaging Score (PsAMRIS) was developed for the evaluation of inflammatory and destructive changes in PsA,[1] but has limited trial usage.

Objectives: To retrospectively utilise the PsAMRIS in a multi-dose, randomised Phase IIb study of abatacept in patients with PsA who have inadequate response to DMARDs (NCT00534313).[2]

Methods: Patients were randomised to abatacept (3, 10 or 30/10mg/kg [the 30-mg/kg group switched to 10mg/kg after the first two doses]) or placebo and treated for 169 days, after which all patients received abatacept 10mg/kg through to Day 365. MRI scans of one hand or foot from 123 patients with PsA collected at baseline and on Days 85, 169 and 365 were centrally evaluated by two readers blinded to chronological order and treatment arm. Synovitis, bone oedema, tenosynovitis, periarticular inflammation, bone erosion, bone proliferation and joint space narrowing were assessed as per OMERACT PsAMRIS; a novel total inflammation score was calculated from the sum of synovitis, bone oedema, tenosynovitis and periarticular inflammation. Variables were analysed using all cases (hand or foot) and by hand and foot cases separately.

Results: At Day 169, the abatacept 30/10mg/kg or 10mg/kg group showed the most decrease (improvement) in each inflammatory assessment (Figure 1). The Day 169 change from baseline severity in synovitis and tenosynovitis in the abatacept 30/10mg/kg and 10mg/kg groups, respectively, were significantly reduced (improved) compared with placebo (estimated differences of –0.966 [p=0.039] and –1.652 [p=0.014], respectively) (Table 1). Patients originally randomised to placebo and then switched to abatacept 10mg/kg at Day 169 showed significant improvements in synovitis, tenosynovitis and total inflammation from Day 169 to Day 365 (Table 1, Figure 1). The structural outcomes joint space narrowing and bone erosion remained stable within each treatment group, showing little change from baseline to Days 85, 169 and 365. After separating hand and foot analyses (72 hand and 51 foot cases), only hand tenosynovitis in the 10-mg/kg group and foot synovitis in the 3-mg/kg group were significantly reduced (improved) at Day 169 compared with placebo (differences of –2.331 [p=0.017] and –1.689 [p=0.010], respectively). In general, more comparisons in the hand analysis were statistically significant versus in the foot analysis.

Conclusion: This analysis confirmed the efficacy of abatacept 10 and 30/10mg/kg when assessed with the OMERACT PsAMRIS. The inflammatory pathologies, synovitis and tenosynovitis, appeared to be the most responsive MRI outcomes. Analysing hand and foot cases together yielded results consistent with the primary clinical efficacy endpoint (ACR20 response rate), as the abatacept 10- and 30/10-mg/kg groups showed significant differences versus placebo at Day 169;[2] reduced sample size in separate hand and foot assessments may have prevented finding significant results corresponding to the combined analysis. These results also demonstrate the responsiveness of the PsAMRIS in PsA randomised clinical trials.

POS1041

PREVALENCE, INCIDENCE AND ANTIRHEUMATIC DRUG USE IN PSORIATIC ARTHRITIS (PsA) IN NORWAY

A. Kerola[1,2], J. Sexton[1], S. Rollefstad[1], G. Wibetoe[1], C. S. Crowson[3], E. Haavardsholm[1], T. K. Kvien[1], A. G. Semb[1]. [1]*Diakonhjemmet Hospital, Division of Rheumatology and Research, Oslo, Norway*; [2]*Päijät-Häme Joint Authority for Health and Wellbeing, Rheumatology, Lahti, Finland*; [3]*Mayo Clinic, Department of Quantitative Health Sciences, Rochester, Minnesota, United States of America*

Background: Incidence estimates of PsA in Norway have varied from 6.9/100,000 person-years (pyrs) in Northern Norway to 41.3/100,000 pyrs in Central Norway, and point prevalence estimates have ranged from 1.3 to 6.9 per 1,000 adult inhabitants[1,2], while nationwide epidemiologic data on PsA in Norway have been lacking.
Objectives: To estimate prevalence, incidence and use of disease-modifying antirheumatic drugs (DMARDs) among PsA patients in Norway.
Methods: The Norwegian Cardio-Rheuma register includes pseudonymized data from the total Norwegian population ≥18 years of age during 2008-2017, identified from the National Population register. Demographic and socioeconomic data were retrieved from Statistics Norway. Data on public or private somatic specialized care episodes were collected from the Norwegian Patient register (NPR) [ICD-10 codes for diagnoses and medical procedure codes for biologic DMARD infusions]. Information on dispensed DMARD prescriptions was captured from the Norwegian Prescription Database. Based on NPR data, PsA cases were defined as persons fulfilling three criteria: 1) 1st episode with ICD-10 code M07.0-M07.3 or L40.5 as main or contributory diagnosis (index date), 2) 2nd episode with code M07.0-M07.3 or L40.5 within 2-year period following index date, 3) an episode in internal medicine or rheumatology clinic with recorded M07.0-M07.3 or L40.5 within 2 years from index date. Years 2008-2010 served as a look-back period to identify prevalent PsA cases. To estimate pyrs at risk, we calculated number of individuals aged ≥ 18 years living in Norway on the 1st of January of each year 2011-2015 multiplied by one year (prevalent PsA cases excluded). Age- and sex-standardized incidence rates were calculated with 5-year age groups using the Norwegian adult population on January 1st 2015 as the standard.
Results: During the look-back period 2008-2010, 7,697 cases fulfilled the PsA definition. In total, 6,183 incident PsA cases were identified during 2011-2015 (incidence 32/100,000 pyrs, 28 among men and 35 among women). Based on a sensitivity analysis comprising 5,065 PsA cases with no dispensed DMARD prescriptions ≥12 months before index date, incidence was slightly lower (26/100,000 pyrs). Patient characteristics and DMARD use are shown in Table 1. The incidence was highest among those aged 50-59 years in both sexes (Figure 1). PsA incidence was lower among those with higher education level (crude/age- and sex-standardized incidence per 100,000 pyrs for those below upper secondary education 34/38, upper secondary or post-secondary non-tertiary education 36/36, higher education 26/25). Point prevalence of PsA was 3.3/1,000 adult inhabitants on January 1st 2016.

Table 1. Characteristics and treatment penetration of incident PsA patients 2011-2015

	All		Excluding cases with DMARDs >1 yr prior to index date	
N	6183		5065	
Women, n (%)	3442 (55.7)		2783 (54.9)	
Age at index date, median (IQR)	50.5 (40.7 - 59.8)		49.9 (40.2 - 59.3)	
Use of DMARDs after index date, n (%)	**12 months**	**24 months**	**12 months**	**24 months**
Any conventional DMARD	3706 (59.9)	4048 (65.4)	2894 (57.1)	3184 (62.9)
Methotrexate	3313 (53.6)	3650 (59.0)	2638 (52.1)	2933 (57.9)
Sulfasalazine	440 (7.1)	586 (9.5)	330 (6.5)	457 (9.0)
Any biologic DMARD	842 (13.6)	1197 (19.4)	485 (9.6)	771 (15.2)
TNF-inhibitors	810 (13.1)	1154 (18.7)	477 (9.4)	758 (15.0)
Oral glucocorticoids	1773 (28.7)	2240 (36.2)	1449 (28.6)	1807 (35.7)
Any DMARD or glucocorticoids	4365 (70.6)	4742 (76.7)	3384 (66.8)	3725 (73.5)

Conclusion: Our estimate of PsA incidence and prevalence are in the mid-range compared to studies from smaller regions in Norway. Methotrexate was initiated for more than half of PsA cases within one year from index date, whereas 19% had used biologic DMARDs within two years.

Background: Tyrosine kinase 2 (TYK2) is an intracellular kinase that mediates interleukin (IL)-23, IL-12, and interferon (IFN)α/β signaling. Deucravacitinib is a novel, oral, selective inhibitor of TYK2 acting via binding to the TYK2 regulatory domain.[1] Phase 2 results showed deucravacitinib was efficacious and well tolerated versus placebo in patients with moderate to severe plaque psoriasis or active psoriatic arthritis.[2,3] No herpes zoster infections, opportunistic infections, thromboembolic events, or hematologic or lipid abnormalities characteristic of Janus kinase (JAK) 1–3 inhibitors were reported in the Phase 2 trials.[2,3]
Objectives: To compare the efficacy and safety of deucravacitinib versus placebo and apremilast in plaque psoriasis.
Methods: This Phase 3, double-blinded, 52-week study (NCT03624127) randomized patients with moderate to severe plaque psoriasis (BSA ≥10%, PASI ≥12, sPGA ≥3) to deucravacitinib 6 mg once daily, placebo, or apremilast 30 mg twice daily (2:1:1). Patients receiving placebo were switched to deucravacitinib at Week 16; apremilast-treated patients not achieving PASI 50 at Week 24 were switched to deucravacitinib. Coprimary endpoints were PASI 75 and sPGA 0/1 response versus placebo at Week 16. Key secondary endpoints included superiority versus apremilast, assessed via multiple measures.
Results: 666 patients were randomized. Demographic and baseline disease characteristics were balanced across groups; mean age was 46.1 years, mean

disease duration was 17.3 years, 18.2% of patients had psoriatic arthritis at baseline, and 38.9% had previously used biologic therapy. Mean BSA involvement at baseline was 26.3%, mean PASI was 21.4, and the percentage with severe sPGA (score=4) at baseline was 21.2%. Significantly greater proportions of patients in the deucravacitinib versus placebo and apremilast arms achieved PASI 75 (58.7% vs 12.7% vs 35.1%, respectively; *P*<0.0001) and sPGA 0/1 (53.6% vs 7.2% vs 32.1%, respectively; *P*<0.0001) response at Week 16 (Figure 1). Deucravacitinib was also superior to apremilast at Week 24, with 69.0% versus 38.1% of patients achieving PASI 75 and 58.4% versus 31.0% achieving sPGA 0/1 (*P*<0.0001 for both). In addition, DLQI 0/1 responses at Week 16 were significantly higher with deucravacitinib versus placebo and apremilast, demonstrating improved quality of life (40.7% vs 10.6% vs 28.6%, respectively; Figure 1). During the 16-week, placebo-controlled period, the most common AEs (≥5% in any arm) were nasopharyngitis, upper respiratory tract infection, headache, diarrhea, and nausea (Table 1). Frequencies of SAEs and treatment discontinuations due to AEs were low (Table 1).

Table 1. Summary of adverse events (AEs) through Week 16

Patients, n (%)	Deucravacitinib n=332	Placebo n=165	Apremilast n=168
Any AEs	176 (53.0)	70 (42.4)	93 (55.4)
Severe AEs	5 (1.5)	7 (4.2)	5 (3.0)
Serious AEs	7 (2.1)	9 (5.5)	4 (2.4)
AEs leading to treatment discontinuation	6 (1.8)	7 (4.2)	10 (6.0)
Most common AEs (≥5% in any arm)			
Nasopharyngitis	21 (6.3)	7 (4.2)	14 (8.3)
Upper respiratory tract infection	21 (6.3)	6 (3.6)	3 (1.8)
Headache	16 (4.8)	5 (3.0)	17 (10.1)
Diarrhea	13 (3.9)	6 (3.6)	17 (10.1)
Nausea	7 (2.1)	4 (2.4)	19 (11.3)

Conclusion: Deucravacitinib demonstrated superiority versus placebo and apremilast across multiple efficacy endpoints in patients with moderate to severe plaque psoriasis, and was generally well tolerated. Overall, the efficacy and safety profile of deucravacitinib was consistent with that observed in the Phase 2 plaque psoriasis and psoriatic arthritis trials.[2,3]

№2, Minsk, Belarus; [7]*JSC BIOCAD, Clinical Development Department, St-Petersburg, Russian Federation*

Background: PATERA is an ongoing phase 3 international double-blind, placebo-controlled clinical study of netakimab (NTK) in psoriatic arthritis (PsA) (NCT03598751). Netakimab (NTK) is an anti-interleukin-17A monoclonal antibody approved for psoriasis, ankylosing spondylitis, PsA in Russia and Belarus.
Objectives: A subanalysis was performed to define the impact of NTK on PsA activity depending on the presence of axial disease: a subset of patients with inflammatory back pain (IBP) according to self-reported ASAS IBP criteria, 2009 (IBP(+) was compared to those without IBP (IBP(-)).
Methods: 194 eligible adult patients with PsA fulfilling the CASPAR criteria, with inadequate response to csDMARD or one TNFi, were randomly assigned to receive NTK 120mg or placebo at weeks 0,1,2,4,6,8,10,14,18,22. Patients with missing values for categorical variables were considered as non-responders in the analysis. For quantitative variables, missing values were replaced using the multiple imputation method.
Results: 97 PsA patients (N=54 IBP(+), N=43 IBP(-)) received NTK. Both subpopulations were comparable in gender, age and PsA activity at baseline. The treatment led to a pronounced decline in PsA activity in both subpopulations, significant differences between arms were observed only in DAPSA remission and very low disease activity (VLDA) at week 24 (Figure 1A). Changes from baseline in DAS28-CRP were consistent between IBP(+) and IBP(-) patients with a rapid decline during the first month with further improvement up to week 24 (Figure 1B). A similar trend was observed PsA-specific composite responder index (PSARC) (data not shown). A comparable percentage of IBP(+) and IBP(-) patients achieved PSARC at each timepoint of evaluation with 87% and 86% of responders respectively at week 24.
Conclusion: NTK significantly improved PsA activity regardless of the presence of IBP.

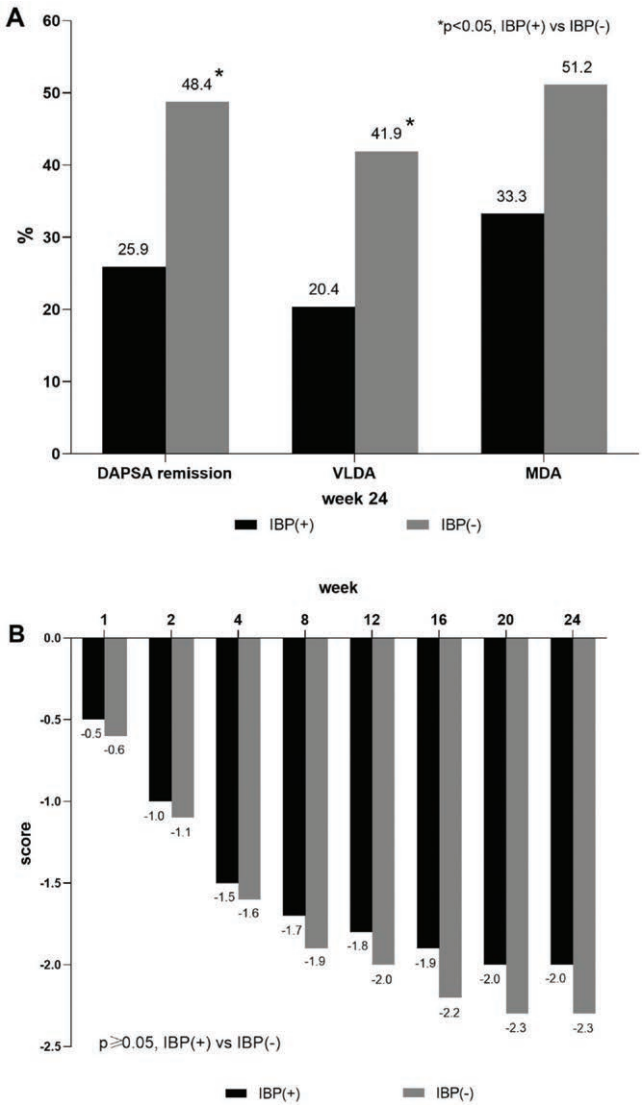

Figure 1. PsA activity after 24-week treatment with NTK. (A) Percentage of patients with DAPSA remission (0-4), very low disease activity (VLDA), minimal disease activity (MDA) at week 24; (B) change from baseline in DAS28-CRP

Background: EXCEED (NCT02745080) was the first fully blinded head-to-head trial to evaluate the efficacy and safety of secukinumab (SEC) versus (vs) adalimumab (ADA) monotherapy in patients with active psoriatic arthritis (PsA) with a primary endpoint of American College of Rheumatology (ACR) 20 at Week 52. Although SEC narrowly missed statistical significance for superiority vs ADA, numerically higher response for other musculoskeletal endpoints and composite indices were observed with SEC.[1]
Objectives: To explore the effect of SEC and ADA on ACR core components, function and Health-related Quality of Life (HRQoL) outcomes.
Methods: Patients were randomised 1:1 to receive SEC 300 mg (N=426) subcutaneous (s.c.) at baseline, Week 1-4, followed by every 4 weeks until Week 48 or ADA 40 mg (N=427) s.c. at baseline followed by same dosing every 2 weeks until Week 50. The primary, key secondary and some exploratory endpoints at Week 52 were previously reported.[1] A supportive analysis for ACR50 response using logistic regression model and trimmed means model for Health Assessment Questionnaire-Disability Index (HAQ-DI) with gender and smoking status as factors was performed to adjust for imbalances in baseline characteristics. An exploratory analysis of ACR core components with SEC vs ADA at Week 52 was conducted using a mixed-effects repeated measures model that included tender and swollen joint counts, patient and physician global assessment, PsA pain (VAS) and erythrocyte sedimentation rate. HRQoL variables were also exploratory and assessed based on Short Form Health Survey Physical/Mental Component Summary (SF-36 PCS/MCS) scores and Dermatology Life Quality Index (DLQI).
Results: The demographic and baseline disease characteristics were comparable across treatment groups, except for an imbalance in sex (females: 51.2% vs 46.4%) and smoking status (yes: 21.8% vs 17.8%) in SEC and ADA group, respectively. At Week 52, ACR50 responses were 49.0% and 44.8% (P=0.0929) and HAQ-DI mean change from baseline were −0.69 and −0.58 (P=0.0314) in SEC and ADA treatment groups, respectively after adjusting for gender and smoking status. No major difference across ACR core components was observed in both treatment groups at Week 52 (Table 1). At Week 52, SEC presented similar improvement in SF-36 PCS/MCS score and numerically higher improvement in DLQI compared to ADA (Figure 1).
Conclusion: Secukinumab provided similar improvements in ACR core components and SF-36 based quality of life at Week 52 with adalimumab. Greater improvement in HAQ-DI response and DLQI was demonstrated with secukinumab compared to adalimumab.

IXEKIZUMAB EFFICACY ON SPINAL PAIN, DISEASE ACTIVITY AND QUALITY OF LIFE IN PATIENTS WITH PSORIATIC ARTHRITIS PRESENTING WITH SYMPTOMS SUGGESTIVE OF AXIAL INVOLVEMENT

A. Deodhar[1], D. D. Gladman[2], R. Bolce[3], D. Sandoval[3], S. Y. Park[3], S. Liu Leage[3], P. Nash[4], D. Poddubnyy[5]. *[1]Oregon Health and Science University, School of Medicine, Oregon, United States of America*; *[2]University of Toronto, Krembil Research Unit, Toronto, Canada*; *[3]Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America*; *[4]Griffith University, School of Medicine, Brisbane, Australia*; *[5]Charité University Hospital, Department of Gastroenterology, Infectiology and Rheumatology, Berlin, Germany*

Background: Many patients with psoriatic arthritis (PsA) experience back pain and stiffness, which may suggest axial involvement [1]. The prevalence of axial involvement in PsA varies between 25-70% [2]. Ixekizumab (IXE), a monoclonal antibody with high affinity for IL17-A, has been studied in Phase 3 trials in patients with PsA (SPIRIT-P1 [Biologic-naïve; NCT01695239] and SPIRIT-P2 [Inadequate response or intolerant to 1 or 2 TNF inhibitors (TNFi); NCT02349295]) [3] [4].
Objectives: To determine the efficacy of IXE up to 52 weeks (Wks) in reducing axial symptoms in patients with active PsA presenting with symptoms suggestive of axial involvement.
Methods: This post-hoc analysis included data from two subpopulations of patients with PsA (pooled SPIRIT-P1 and -P2). Symptoms suggestive of axial involvement were defined as Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) Q2 (back pain) ≥4, and an average of Q5 + Q6 (intensity and duration of morning stiffness in the spine) ≥4 at baseline. Patients included in the sensitivity analysis subgroup 1 were, in addition to the above-mentioned overall analysis criteria, <45 years of age, while patients included in sensitivity analysis subgroup 2 were aged <45 but also had elevated C-reactive protein (CRP) (> 5 mg/l) at baseline. Efficacy of IXE was analysed using BASDAI questions, total BASDAI, mBASDAI (without Q3), and Ankylosing Spondylitis Disease Activity Score (ASDAS) change from baseline, as well as BASDAI50 response and Short-Form-36 physical component summary (SF-36 PCS) improvement, at Wks 16, 24 and 52. Treatment comparison was done using logistic regression for BASDAI50, and analysis of covariance (ANCOVA) model for other endpoints. Missing data for binary and continuous endpoints were imputed by non-responder imputation and modified baseline observation carried forward (mBOCF), respectively.
Results: A total of 313 patients (placebo (PBO), N=151; IXE Q4W, N=162) met the overall analysis inclusion criteria. Baseline values for BASDAI and ASDAS related endpoints were balanced across treatment arms (Table 1). Improvement in axial symptoms were significantly greater in patients treated with IXE compared to PBO at Wks 16 and 24 (Figure 1. next page) Improvement in quality of life (QoL) measures (SF-36 PCS) were also significantly greater in patients treated with IXE compared to PBO at Wks 16 and 24 (Table 1). Similar results were observed for patients < 45 years, and in patients < 45 years with CRP > 5 mg/l at baseline (sensitivity analysis, data not shown).
Conclusion: IXE is effective in reducing axial symptoms and improving QoL in patients with active PsA presenting with symptoms suggestive of axial involvement.

Background: Psoriatic arthritis (PsA) negatively impacts patients' (pts) quality of life (QoL), with a high burden of pain, fatigue and psychological distress. The 12-item Psoriatic Arthritis Impact of Disease questionnaire (PsAID-12) is a validated measure of pt-reported disease impact.
Objectives: To analyse PsAID-12 score changes in the overall population and specific subgroups of interest, and assess correlation of these changes using Health Assessment Questionnaire Disability Index (HAQ-DI).
Methods: PsABio (NCT02627768) is a multinational, prospective, observational study in pts with PsA receiving ustekinumab (UST) or a tumour necrosis factor inhibitor (TNFi) as a 1st/2nd/3rd-line biologic. Descriptive statistics, including 95% CI, are presented at baseline (BL) and 1 year. Linear regression, including propensity score (PS) adjustment for BL covariates, was used to compare change in PsAID-12 total from BL to 1 year between treatments. The relationship between changes in PsAID-12 and HAQ-DI was investigated using Spearman's correlation.
Results: Data were available for 438 UST and 455 TNFi pts. From BL to 1 year, significant improvements were seen in total PsAID-12 scores and in all domains with both treatments (Figure 1). PS-adjusted treatment comparison showed no difference in total PsAID-12 improvement (regression coefficient [95% CI]: 0.14 [-0.22; 0.51], p=0.4433), or in any domain, except skin problems, which improved significantly more with UST than TNFi (-0.55 [-1.04, -0.06], p=0.0277). Improvements in PsAID-12 and HAQ-DI showed strong positive correlation with both treatments (UST: r=0.63, p<0.0001; TNFi: r=0.70, p<0.0001). Effectiveness was demonstrated with UST and TNFi in subgroups of interest, including biologic treatment line, sex and psoriasis extent (Table 1. next page).
Conclusion: Treatment with IL-12/23 (UST) or TNF inhibitors significantly improved pt-reported disease impact at 1 year. PS-adjusted PsAID-12 improvements did not differ significantly between treatments, except skin problems (better with UST). Improvements in disease impact and physical functioning (HAQ-DI) were strongly correlated, emphasising the effect of these biologics on QoL in PsA pts.

Mean PsAID-12 overall and domain scores at baseline and 1 year with UST and TNFi

IMPACT OF UPADACITINIB ON REDUCING PAIN IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS FROM TWO PHASE 3 TRIALS IN PATIENTS WITH INADEQUATE RESPONSE TO NON-BIOLOGIC OR BIOLOGIC DMARDs

I. Mcinnes[1], W. Tillett[2], P. J. Mease[3], K. De Vlam[4], L. Bessette[5], R. Lippe[6], A. Maniccia[7], P. Zueger[7], D. Feng[7], K. Kato[7], A. Ostor[8]. KG, Wiesbaden, Germany*; [7]*AbbVie Inc., Rheumatology, North Chicago, United States of America*; [8]*Cabrini Hospital, Monash University & Emeritus Research, Melbourne, Australia*

Background: Pain is a dominant symptom of psoriatic arthritis (PsA), and pain reduction is a priority for patients (pts) that is often assessed in clinical trials. Upadacitinib (UPA), a Janus kinase (JAK) inhibitor engineered for increased selectivity for JAK1 over JAK2, JAK3, and tyrosine kinase2, has demonstrated safety and efficacy in pts with active PsA in the SELECT-PsA 1 and 2 studies.[1,2]

Objectives: The objective of this analysis was to compare the efficacy of UPA vs placebo (PBO) and adalimumab (ADA) on pain using different assessments through 24 weeks (wks).

Methods: The SELECT-PsA program enrolled adult pts with active PsA with prior inadequate response (IR) or intolerance to ≥1 non-biologic DMARD (SELECT-PsA 1; NCT03104400) or prior IR or intolerance to ≥1 biologic DMARD (SELECT-PsA 2; NCT03104374). Concomitant background therapy with ≤2 non-biologic DMARDs was allowed but not required. Pts were randomized to UPA 15 mg or UPA 30 mg once daily (QD) or PBO (both studies), or ADA 40 mg every other week (EOW; SELECT-PsA 1 only). Pain was assessed as proportion of pts achieving ≥30%, ≥50%, or ≥70% reduction from baseline (BL) in Pt's global assessment (PGA) of pain numeric rating scale (NRS) score (0–10), proportion of pts achieving minimal clinically important difference (MCID) in pain (defined as ≥1 point reduction or 15% reduction from BL on a 0–10 NRS)[3,4] and change from baseline in pain NRS (0–10) at all time points. In addition, change from BL in BASDAI questions 2 (spinal pain) and 3 (joint pain/swelling) and *36*-Item Short Form Survey (SF-36) questions 7 (bodily pain) and 8 (pain interference) at weeks 12 and 24 were assessed. Non-responder imputation was used for binary endpoints and mixed-effects model for repeated measurements for continuous endpoints. The statistical significance defined as $P<0.05$ was exploratory in nature.

Results: In both studies, a significantly higher proportion of pts receiving UPA 15 mg QD and UPA 30 mg QD vs PBO achieved improvements in most pain endpoints as early as wk 2, and improvements were generally either sustained or increased through wk 24 (nominal $P<0.05$). A significant improvement with UPA vs PBO was also observed for change from BL in PGA of pain NRS scores over time, as well as in BASDAI spinal pain and joint pain/swelling and SF-36 bodily pain and pain interference at weeks 12 and 24. In SELECT-PsA 1 significantly higher proportions of pts receiving UPA 30 mg QD vs ADA 40 mg EOW achieved improvements in most pain assessments as early as wk 2 which were sustained through wk 24; improvements in several assessments were also significantly greater with UPA 15 mg QD vs ADA 40 mg EOW at wk 24 (nominal P <0.05; **Data will be presented**).

Conclusion: In pts with active PsA who had inadequate response to non-biologic or biologic DMARDs, a greater proportion of pts treated with UPA vs PBO achieved rapid, significant, and clinically meaningful reductions in pain across multiple pain assessments. The reductions in pain were sustained over 24 wks.

Background: DISCOVER 1 & 2 are phase-3 trials of guselkumab (GUS, an IL-23 inhibitor) in patients with psoriatic arthritis (PsA). In both trials, treatment with GUS led to significantly more improvement than placebo (PBO) in the primary endpoint (American College of Rheumatology 20% improvement criteria [ACR20]) and in other measures of arthritis and psoriasis at week (w) 24,[1,2] and these improvements were maintained through 1 year of active treatment.[3,4]
Objectives: To evaluate the effect of GUS on fatigue in DISCOVER 1 & 2 using the patient reported outcome (PRO) FACIT-Fatigue, which has demonstrated content validity and strong psychometric properties in clinical trials.[5]
Methods: DISCOVER 1 & 2 enrolled patients with active PsA, despite non-biologic DMARDS or NSAIDS, who were biologic naïve except ~30% of patients in DISCOVER 1 who had received 1-2 TNFi. Patients were randomized (1:1:1) in a blinded fashion to subcutaneous GUS 100 mg at w0, w4, then every (q) 8w; GUS 100 mg q4w; or matching PBO. At w24, PBO patients were switched to GUS q4w. Concomitant treatment with select non-biologic DMARDS, oral corticosteroids, and NSAIDs was allowed. The FACIT-Fatigue is a 13-item PRO assessing fatigue and its impact on daily activities and function over the past 7 days, total score ranging from 0 to 52, higher score denoting less fatigue. A change of ≥4 points is considered clinically meaningful.[5] The change from baseline in FACIT-Fatigue presented below is based on observed data. Mediation analysis[6] was applied to the treatment effect of GUS on FACIT-Fatigue to estimate the natural direct and indirect effects, after adjusting for ACR20 response (Table 1).
Results: At baseline in DISCOVER 1 & 2, the mean FACIT-fatigue scores (SD) were 30.4 (10.4) and 29.7 (9.7), respectively, indicating that patients with PsA experienced fatigue worse than the general population. At w24 in the DISCOVER trials, treatment with GUS led to significant improvements in FACIT-Fatigue scores compared with PBO, as early as w16 in DISCOVER 1 and w8 in DISCOVER 2. Improvements in fatigue were similar between GUS q4w and q8w doses, and the improvements at w24 were maintained through w52 (Figure 1). After a switch to GUS q4w at w24, PBO patients achieved FACIT-Fatigue scores that were comparable to those of GUS patients (Figure 1). 54%-63% of GUS patients compared with 35%-46% of PBO patients achieved clinically meaningful improvement (≥4 points) in FACIT-Fatigue at w24 (P≤0.003). At w52, 61%-70% of both GUS and PBO to GUS groups reached this improvement. As evaluated by mediation analysis at w24, GUS had independent positive treatment effects on fatigue (12%-36% in the q8w GUS dosing group and 69%-70% in the q4w GUS group) after adjustment for ACR20 response (Table 1).
Conclusion: In 2 phase-3 trials, GUS treatment improved fatigue when compared to PBO during PBO-controlled periods and maintained improvements through 1 year of active treatment. Substantial proportions of those effects were independent of the effects on ACR20, especially for the q4W dosing group.

Background: EQUATOR (NCT03101670) was a Phase 2, double-blind, randomised placebo (PBO)- controlled trial of the preferential Janus kinase 1 inhibitor filgotinib (FIL) for the treatment of psoriatic arthritis (PsA); EQUATOR2 (NCT03320876) is the open-label extension (OLE).

Objectives: This post-hoc analysis assessed the effect of FIL on individual Psoriatic Arthritis Disease Activity Score (PASDAS) components; and the association between PASDAS disease activity (DA) levels and DA levels achieved for each PASDAS component and patient-reported outcomes (PROs) up to OLE Week (Wk) 100.

Methods: In EQUATOR, patients with active moderate-to-severe PsA were randomised 1:1 to oral FIL 200 mg or PBO once daily (QD) for 16 wks.[1] At Wk 16, patients could continue into the 304-wk OLE, in which all patients received FIL 200 mg QD. The proportions of patients with PASDAS of very low DA (VLDA; ≤1.9), LDA (>1.9–<3.2), moderate DA (MoDA; ≥3.2–<5.4), and high DA (HDA; ≥5.4) at core Wk 16 and OLE Wk 52 and 100 were assessed. The proportion with improved PASDAS status vs baseline (BL) at OLE Wk 52 and 100 was calculated. Percent change from BL in PASDAS components and PROs were assessed at core Wk 16 and OLE Wk 52 and 100 by PASDAS status (VLDA, LDA, other). Multivariate logistic regression analyses performed cross-sectionally identified PASDAS components and PROs associated with not achieving VLDA or LDA at core Wk 16 and OLE Wk 52 and 100; all analyses were observed cases.

Results: At OLE Wk 52, LDA and VLDA were achieved by 27.5% and 16.8% of randomised patients, respectively (44.3% combined). At OLE Wk 100, LDA and VLDA were achieved by 26.0% and 17.6% of patients (43.6% combined; Figure 1). Of patients with HDA at BL, 69% improved to MoDA/LDA/VLDA, <4% remained in HDA and 27% did not reach Wk 100; of those in MoDA at BL, 63% improved to VLDA/LDA, 11% remained stable, <4% worsened and 22% did not reach Wk 100. Patient Global Assessment of Disease Activity (PtGDA), Short Form-36 physical component scale (SF-36 PCS), Functional Assessment of Chronic Illness Therapy, and Health Assessment Questionnaire Disability Index were found to be important components/PRO measures in achieving VLDA vs LDA (Table 1). Logistic regression indicated that factors associated with not achieving LDA at Wk 52 were PtGDA (odds ratio [OR]: 1.20, 95% confidence interval [CI]: 1.07–1.35), physician GDA (PhGDA; OR: 1.58, 95% CI: 1.18–2.12), and SF-36 PCS (OR: 0.79, 95% CI: 0.67–0.95); PtGDA was associated with not achieving VLDA (OR: 1.30, 95% CI: 1.15–1.47).

Conclusion: The proportion of patients achieving PASDAS VLDA or LDA increased over time and remained stable between OLE Wk 52 and 100. Important factors in determining whether VLDA/LDA was met were PtGDA, PhGDA, and SF-36 PCS, although the low patient numbers is a limitation.

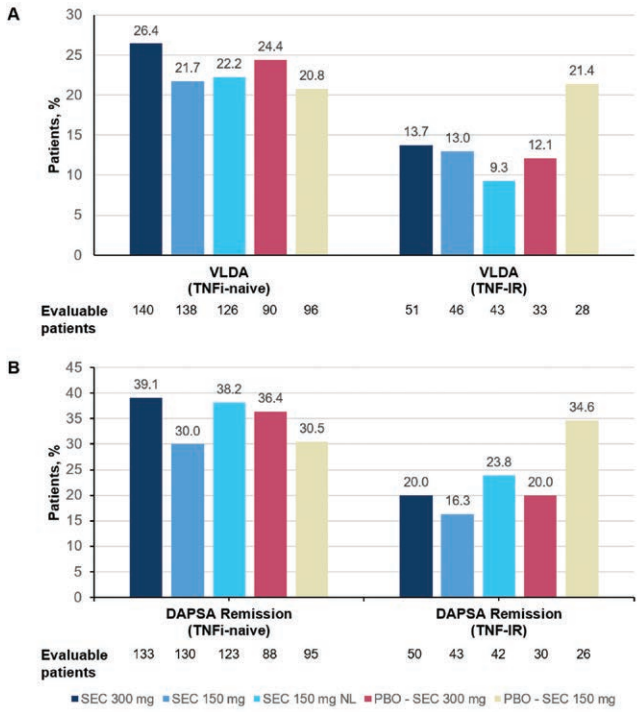
IR, inadequate responder; M, number of evaluable patients; mNAPSI, modified Nail Psoriasis Severity Index; PASI, Psoriasis Area and Severity Index; PBO, placebo; SEC, secukinumab; TJC/SJC resolution, 0 tender/swollen joints; TNFi, tumor necrosis factor inhibitor.a Includes 53 TNFi-naive and 23 TNF-IR patients with dose escalation.b Includes 58 TNFi-naive and 19 TNF-IR patients with dose escalation.c Includes 40 TNFi-naive and 12 TNF-IR patients with dose escalation.

Background: The goal of treating psoriatic arthritis (PsA) is to achieve very low disease activity or remission across disease manifestations. In the phase 3 FUTURE 5 study (NCT02404350), patients receiving secukinumab (SEC) demonstrated sustained clinical improvements across PsA manifestations through Week 104.[1] However, the effect of previous tumor necrosis factor inhibitor (TNFi) exposure on achievement of remission across PsA manifestations was not explored.
Objectives: To report exploratory efficacy analyses of SEC at Week 104 on stringent endpoints across PsA manifestations in patients who were TNFi naive or inadequate responders (TNF-IR).
Methods: Patient data from FUTURE 5 were stratified by previous TNFi exposure and analyzed by treatment arm. At Week 104, patients received SEC 300 or 150 mg with subcutaneous loading dose (LD), SEC 150 mg without LD, or had received placebo up to Week 16 and were switched to SEC 300 or 150 mg between Weeks 16 or 24 based on tender and swollen joint count response. Patients with suboptimal clinical response to SEC 150 mg could escalate to SEC 300 mg after Week 52 per investigator judgment.[2] Exploratory efficacy analyses at Week 104 included resolution of TJC/SJC (0 tender/swollen joints), resolution of enthesitis and dactylitis, 75% improvement in the modified Nail Psoriasis Severity index (mNAPSI75), 100% improvement in the Psoriasis Area and Severity Index (PASI100), very low disease activity (VLDA), and Disease Activity in Psoriatic Arthritis (DAPSA) remission. Descriptive statistics are provided for each endpoint using an observed-case approach.

Figure. Proportion of Patients Achieving **(A)** VLDA and **(B)** DAPSA Remission at Week 104



DAPSA, Disease Activity in Psoriatic Arthritis; IR, inadequate responders; NL, no subcutaneous loading dose; PBO, placebo; SEC, secukinumab; VLDA, very low disease activity based on body surface area.

Results: Regardless of previous TNFi exposure, SEC-treated patients achieved several stringent endpoints across PsA domains, including TJC/SJC resolution, resolution of dactylitis/enthesitis, mNAPSI75, and PASI100 at Week 104 (Table 1). TNFi-naive patients generally experienced greater improvements than TNF-IR patients (Table 1 above). Similar trends were observed for achievement of VLDA and DAPSA remission at Week 104 (Figure 1).
Conclusion: SEC treatment resulted in sustained achievement of stringent endpoints across key PsA manifestations through Week 104 in both TNFi-naive and TNF-IR patients, with generally greater clinical responses among TNFi-naive patients.

POS1051

SECUKINUMAB IMPROVES PHYSICAL FUNCTION AND INHIBITS STRUCTURAL DAMAGE IN PsA PATIENTS WITH SUSTAINED REMISSION OR LOW DISEASE ACTIVITY: RESULTS FROM A PHASE 3 STUDY

L. C. Coates[1], P. J. Mease[2], D. D. Gladman[3], S. Navarra[4], W. Bao[5], C. Gaillez[6].
[1]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; [2]*Swedish Medical Center/Providence St. Joseph Health and University of Washington, Department of Rheumatology, Seattle, Washington, United States of America*; [3]*Toronto Western Hospital, University of Toronto, Schroeder Arthritis Institute, Ontario, Canada*; [4]*University of Santo Tomas Hospital, Section of Rheumatology, Manila, Philippines*; [5]*Novartis Pharmaceuticals Corporation, Immunology, Hepatology and Dermatology, East Hannover, New Jersey, United States of America*; [6]*Novartis Pharma AG, Immunology, Hepatology and Dermatology, Basel, Switzerland*

Background: Disease Activity Index for Psoriatic Arthritis (DAPSA) or the minimal disease activity (MDA) are considered for defining remission (REM) or low disease activity (LDA) in secukinumab (SEC) treated patients (pts) with PsA (Psoriatic Arthritis).[1] Currently, limited SEC data are available on pts with PsA achieving sustained REM in clinical trials or real-world evidence, using these stringent criteria.
Objectives: To report an exploratory analysis on achievement of sustained REM/LDA in pts with PsA treated with SEC and impact on structural outcomes, physical function and health-related quality of life (HRQoL) in the FUTURE 5 study (NCT02404350).

Methods: FUTURE 5 is a randomised, double-blind, placebo-controlled 2-year phase 3 trial in pts with active PsA.[2] Pts randomised to SEC 150 mg could be escalated to 300 mg from Week (Wk) 52 to 104, based on investigators' judgement. The pts were categorised as either not achieving REM/LDA, achieving it once only or sustained REM/LDA, which was defined as pts who achieved REM/LDA between Wks 24-52 and maintained the same response at least 2 of the next 6 visits (visit every 8 Wks). Of pts who did not achieve REM/LDA, achieved REM/LDA (VLDA, DAPSA REM, MDA, DAPSA LDA+REM) between Wk 24 and 52, the relationship between absence of REM/LDA, REM/LDA, sustained REM/LDA, proportion of pts with non-radiographic progression (assessed using the van der Heijde [mTSS]), physical function (health assessment questionnaire disability index [HAQ-DI]), and short form-36 physical component score [SF-36 PCS])[3] were assessed.

Results: In total, 996 pts were randomised to one of 4 treatment groups: SEC 300 mg loading dose (LD; N=222), SEC 150 mg LD (N=220), SEC 150 mg no loading dose (NL; N=222), and placebo (N=332). The baseline clinical characteristics were comparable across treatment groups. Majority of pts could achieve either sustained MDA/sustained DAPSA LDA+REM (Figure 1). Pts achieving REM/LDA, whether at one visit or consistently, showed improved physical function and SF36-PCS at Wk 104.[3]A high proportion of pts did not show radiographic progression at Wk 104 irrespective of achievement of REM/LDA category (Table 1**).**

Conclusion: The majority of patients treated with secukinumab were able to achieve sustained LDA. Sustained LDA/REM was associated with improved HRQoL, physical function and inhibition of structural damage progression.

POS1052

PSORIATIC ARTHRITIS AND OBESITY IMPACT DRUG PERSISTENCE IN USTEKINUMAB-TREATED PATIENTS WITH PSORIASIS IN THE BRITISH ASSOCIATION OF DERMATOLOGISTS BIOLOGIC AND IMMUNOMODULATORS REGISTER (BADBIR): A 10-YEAR FOLLOW-UP STUDY

A. Ogdie[1], W. Tillett[2], A. Passey[3], P. Gorecki[4]. [1]*University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States of America*; [2]*Royal National Hospital for Rheumatic Diseases, Rheumatology, Bath, United Kingdom*; [3]*Janssen Real World Evidence, HEMAR EMEA, High Wycombe, United Kingdom*; [4]*Janssen, Medical Affairs, High Wycombe, United Kingdom*

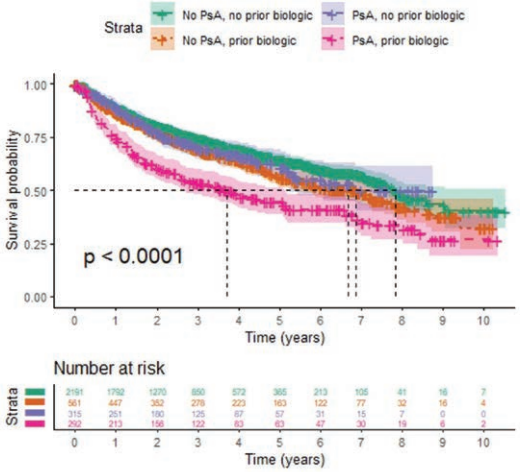
Background: Up to 80% of patients with psoriatic arthritis (PsA) have comorbid psoriasis (PsO).[1] However, data on the impact of comorbid PsA on treatment persistence in PsO patients are limited with mixed findings.[2–4] Other factors have been implicated in predicting response to treatment, including obesity, which is associated with PsA and has demonstrated a varying effect on biologic persistence.[2,3,5,6]

Objectives: The primary objective of this study was to evaluate whether comorbid PsA and obesity impact ustekinumab (UST) persistence in PsO patients using the British Association of Dermatologists Biologic and Immunomodulators Register (BADBIR). Additionally, the effect of line of therapy was investigated.

Methods: This retrospective observational study used data from PsO patients receiving UST in the BADBIR (first enrolled 07/2009; 10/2020 data cut-off). Time to discontinuation (TTD) was defined as time from treatment start date until treatment stop date, censoring for loss to follow-up where patients are lost to follow-up or active in the registry without a recorded treatment stop date. Kaplan–Meier survival analysis was used to estimate probability of discontinuation over time and median TTD. Patients were stratified by PsA diagnosis (recorded as a comorbidity at enrolment) and prior biologic experience (history of treatment with ≥1 other biologic). The log-rank test was used to compare persistence among groups. Hazard ratios (HRs), confidence intervals (CI) and p-values for effect of obesity, PsA status and prior biologic exposure on TTD were generated using Cox proportional hazards regression.

Results: Univariate analysis found that median TTD was shorter for patients with comorbid PsO and PsA (5.04 years; n=585) vs. patients with PsO alone (7.19 years; n=2698; p<0.0001). Biologic-experienced patients with comorbid PsO and PsA (n=292) had a significantly higher likelihood of discontinuation than any other group, with a median TTD of 3.84 years (p<0.0001; Figure 1). In

Fig. 1: Drug survival in patients with PsO treated with UST, stratified by presence of comorbid PsA and prior biologic experience.



p-value for drug survival probability across all groups. PsA, psoriatic arthritis; PsO, psoriasis; UST, ustekinumab.

multivariable models, biologic-experienced patients were more likely to discontinue treatment (HR 1.21 [95% CI 1.04–1.43]; p=0.017) vs. biologic-naïve patients, while PsA had no significant effect on TTD alone vs. no PsA (HR 1.12 [95% CI 0.9–1.4]; p=0.31). However, comorbid PsA increased the likelihood of treatment discontinuation for biologic-experienced patients (HR 1.45 [95% CI 1.06–1.97]; p=0.018). Obesity was a further predictor of discontinuation (HR 1.15 [95% CI 1.02–1.31]; p=0.027) and this was independent of comorbid PsA and prior biologic exposure (Table 1).

Conclusion: Comorbid PsA was associated with reduced time-to-discontinuation of UST in biologic-experienced patients, but not biologic-naïve patients. Obesity also impacted TTD but independently of PsA status.

POS1053 COMPARISON OF BASELINE CHARACTERISTICS BETWEEN PATIENTS CONTINUING OR DISCONTINUING APREMILAST AT TWELVE MONTHS IN THE REWARD STUDY (THE NETHERLANDS)

R. Bos[1], T. Jansen[2], S. De Jong[3], A. Castiglia[4], M. Vis[5]. [1]*Medisch Centrum Leeuwarden, Rheumatology, Leeuwarden, Netherlands*; [2]*Viecurie MC, Rheumatology, Venlo, Netherlands*; [3]*Amgen BV, Medical Affairs, Breda, Netherlands*; [4]*Amgen Europe GmbH, Medical, Rotkreuzt, Switzerland*; [5]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*

Background: Previous analysis of the REWARD study reported that patients with limited joint involvement have a considerable burden of disease[1]. Recent data suggest that patients with moderately active psoriatic arthritis (PsA) and a limited joint involvement have a high likelihood of achieving treatment goals when treated with apremilast[2]. According to EULAR recommendations a PDE4 inhibitor may be considered in patients with mild disease and an inadequate response to at least one csDMARD, in whom neither a bDMARD nor a JAK inhibitor is appropriate and the value of apremilast may be found in treating patients with relatively mild disease (oligoarticular)[3].

Objectives: The objective of this prospective, multicentre, non-interventional study is to describe patient reported outcomes, effectiveness and real-life use of apremilast in patients with PsA. Patients will be followed up for a maximum of 12 months. This interim analysis compared the baseline characteristics and experience on apremilast for two subgroups of patients, those remaining on apremilast versus the ones that discontinued.

Methods: In this interim analysis we included patients with data available at cut-off date of 03 November 2020. Patient enrollment and follow up of current subjects is ongoing. Descriptive statistics (n's and percents for categorical data, means for continuous data) were used to summarize the baseline data by subgroup. Kaplan Meier plots are presented to show patients' experience on apremilast by subgroup.

Results: 85 patients were included in the analysis. 30 patients have completed the study, 39 patients have discontinued and 16 are ongoing. At baseline 22 (26%) patients were biologic experienced and 62 (74%) were biologic naïve. Both groups had a comparable disease activity measured with clinical disease activity in psoriatic arthritis (cDAPSA) scores. Biologic experienced patients had a longer disease duration compared to biologic naïve patients (mean 9.7 vs 6.2 years). Inefficacy of previous medication was the main reason for starting apremilast in both subgroups. Overall, 86% (n=69) of patients were still receiving apremilast at month 3, 60% (n=46) at month 6, and 41% (n=26) at month 12 (Figure 1). Drug survival (length of time until discontinuation of apremilast) for biologic naïve patients was 93% at month 3, 73% at month 6 and 58% at month 12. Drug survival of biologic experienced patients was 67%, 20%, and 0% at months 3, 6, and 12, respectively. At baseline mean values of body mass index (BMI), swollen joint count (SJC), tender joint count (TJC), psoriatic arthritis impact of disease (PsAID) were comparable between both groups (Table 1). Reasons for discontinuation were mainly lack of efficacy (49%) and adverse events (44%). In this analysis the nature and frequency of adverse events is in line with the known profile of apremilast.

Conclusion: In this interim analysis, patients who were biologic naïve had a better probability to remain on treatment than those who were biologic experienced. Baseline characteristics were similar between the two groups, apart from disease duration that was longer in the biologic experienced group. Best drug survival is achieved when apremilast is prescribed earlier in the PsA treatment course, before biologics and after csDMARDs, as per apremilast EU label.

POS1054 UPADACITINIB PHARMACOKINETICS AND EXPOSURE-RESPONSE RELATIONSHIPS FOR EFFICACY AND SAFETY IN PSORIATIC ARTHRITIS – ANALYSES OF THE PHASE 3 SELECT-PsA STUDIES

E. Muensterman[1], B. Engelhardt[1], S. Gopalakrishnan[2], J. Anderson[3], M. E. Mohamed[1]. [1]*AbbVie, Clinical Pharmacology and Pharmacometrics, North Chicago, United States of America*; [2]*Merck KGaA, Translational Medicine, Darmstadt, Germany*; [3]*AbbVie, Clinical Development, North Chicago, United States of America*

Background: Upadacitinib (UPA) is an oral, reversible, JAK inhibitor approved for the treatment of rheumatoid arthritis (RA). The efficacy and safety profile of UPA in psoriatic arthritis (PsA) has been established in the SELECT-PsA program which includes two global Phase 3 studies.

Objectives: These analyses characterize UPA pharmacokinetics and exposure-response relationships for efficacy and safety endpoints using data from the SELECT-PsA studies.

Methods: The SELECT-PsA program enrolled patients with prior inadequate response (IR) or intolerance to ≥1 non-bDMARD1 (N=1705) and prior IR or intolerance to ≥1 bDMARD2 (N=642). Data from both trials was integrated for patients receiving placebo (PBO), UPA 15mg once daily (QD) and UPA 30mg QD; adalimumab data was excluded from this analysis. UPA pharmacokinetics were characterized in PsA patients using Bayesian population pharmacokinetics analyses and utilizing prior information from analyses in healthy subjects and RA patients. Exposure-response analyses were conducted using logistic regression to characterize the relationships between upadacitinib average plasma concentration during a dosing interval (Cavg) and the percentage of patients achieving

ACR20/50/70 at Weeks 12 and 24, static Investigator Global Assessment of psoriasis (sIGA) of 0 or 1 (clear or almost clear) and at least a 2-point improvement from baseline, and PASI75 at Weeks 16 and 24 or experiencing selected clinically relevant safety events through week 24.

Results: Analyses were conducted using data from 1694 subjects (for pharmacokinetics) and 1916 subjects (for exposure-response analyses). UPA model-estimated plasma exposures in subjects with PsA who received 15mg and 30mg QD doses were comparable to previously estimated exposures in subjects with RA. Body weight and methotrexate use had no clinically relevant effects on UPA exposures. There was a statistically significant relationship between UPA Cavg and the percentage of subjects who achieved Week 12 ACR50/70, Week 16 sIGA 0/1, and Week 24 sIGA 0/1 (Figure 1). No statistically significant exposure-response relationship was observed for Week 12 ACR20, Week 16 PASI75, or Week 24 ACR20/50/70 or PASI75, indicating that the 15mg QD exposures are approximately at the plateau of response for these endpoints. No statistically significant relationships were observed between upadacitinib Cavg and the percentage of subjects experiencing pneumonia, herpes zoster, hemoglobin < 8 g/dL, Grade ≥3 lymphopenia, Grade ≥3 neutropenia. There was a shallow but statistically significant exposure-response relationships with the occurrence of serious infections and decrease in hemoglobin from baseline (>2 g/dL and >2 g/dL in combination with hemoglobin < lower limit for normal).

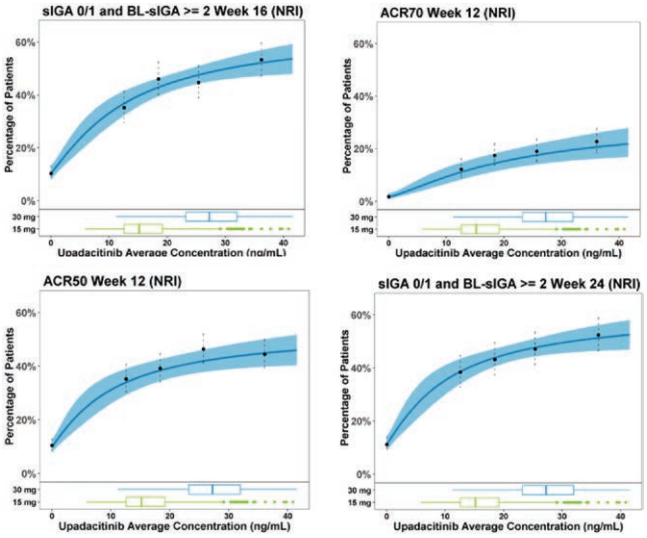

Figure 1. Observed and Model Predicted Efficacy Responses at Week 12 (for ACR50/70) or at Weeks 16 and Week 24 (for sIGA 0/1) Versus Upadacitinib Plasma Exposures

Conclusion: Exposure-response analyses demonstrated that plasma exposures associated with UPA 15 mg QD achieves robust efficacy in subjects with PsA with limited effects on the evaluated safety endpoints. UPA plasma exposures associated with UPA 15 and 30mg QD are predicted to provide similar ACR responses by week 24 while a small additional efficacy benefit with UPA 30mg is predicted for the achievement sIGA 0/1.

POS1055 HIGH SATISFACTION WITH USTEKINUMAB TREATMENT IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS – FINAL RESULTS OF THE NON-INTERVENTIONAL STUDY SUSTAIN DEMONSTRATE EARLY AND LONG-TERM TREATMENT RESPONSE AND HIGH TOLERABILITY

J. Wendler[1], E. Movshovich[2], N. Damann[2], F. Hamann[3], P. Wagener[4], F. Behrens[5]. *[1]Rheumatologische Schwerpunktpraxis, Erlangen, Erlangen, Germany*; *[2]Janssen-Cilag, Neuss, Neuss, Germany*; *[3]Gemeinschaftspraxis für internistische Rheumatologie, Leipzig, Leipzig, Germany*; *[4]Fachpraxis für Rheumatologie und Osteologie, Bruchhausen-Vilsen, Bruchhausen-Vilsen, Germany*; *[5]Goethe-Universität, Rheumatologie and Fraunhofer Institut IME -TMP, Frankfurt, Germany*

Background: From February 2015 to April 2020, patients with active psoriatic arthritis under treatment with ustekinumab in routine clinical care in Germany were included into the prospective, multi-center non-interventional study SUSTAIN.

Objectives: Here, we present final data from SUSTAIN including final week 160 on long term efficacy and safety of ustekinumab treatment, quality of life and further patient reported outcomes.

Methods: In SUSTAIN, 337 patients were treated with ustekinumab according to routine clinical care at 75 centers for 160 weeks with documentation intervals at week 0 and 4 and then every 12 weeks. The collected data included demographics, number of swollen and tender joints, tender entheses, amount of skin symptoms (BSA and PASI), patient reported outcome concerning disease activity and pain, Health Assessment Questionnaire (HAQ), quality of life (SF-12), sleep quality (VAS), satisfaction with therapy of patient and physician, safety (adverse events [AE]/serious adverse events [SAE]), pharmacoeconomic aspects, number of patients with „Minimal Disease Activity“ (MDA) and number of patients with MDA at week 28 und 52. For this analysis, final data of all 337 patients of all documented visits were analyzed.

Results: The visit at week 4 was documented for 31 patients, at week 28 for 282, at week 52 for 216, and at week 160 for 129 of the 337 patients. At baseline, the patients had a mean age of 53.6 years (22-85) and 192 (57%) were female. The patients' mean BMI was 29.6 kg/m^2 (18.6-52). 54.3 % of the patients had at least one TNF inhibitor as prior medication. 54.1 % of the patients used MTX as concomitant medication. At time of inclusion, 73.3% of the patients showed arthritis at small and 52.2% at large joints. 16.9% showed spinal involvement and 13.1% enthesitis. In the course of the treatment, the number of tender joints improved from a mean of 10.0 (CI 95% 8.6/11.3) at baseline to 4.1 (3.2/4.9) at week 28, 3.6 (2.7/4.6) at week 52 and 1.0 (0.6/1.4) at week 160. Number of swollen joints improved from 4.1 (3.4/4.9) at baseline to 1.8 (1.2/2.3) at week 28, to 1.3 (0.8/1.8) at week 52 and to 0.4 (0.2/0.6) at week 160. BSA declined from a mean of 15.6% (rage from 0 to 80.0%) at baseline to 5.2% (0 to 60%) at week 28, to 3.0% (0 to 45.0%) at week 52 and to 1.7 (0 to 35%) at week 160. PASI declined from a mean of 7.3 (range from 0 to 43.0) at baseline to 1.7 (0 to 24.8) at week 28, to 1.3 (o to 28.5) at week 52 and to 0.5 (0 to 3.2) at week 160. Efficacy of the therapy with ustekinumab was assessed as “very good” or “good” by 85.3% of the treating physicians at week 52 and by 94.1% at week 160. The patients assessed the efficacy as “very good” or “good” by 82.8% at week 52 and by 89.8% at week 160. At the end of the study, 96 SAEs have been documented, of which only 16 were related to ustekinumab. All in all, safety of therapy with ustekinumab was assessed as “very good” or “good” by 99% of the treating physicians after 52 weeks and by 99.2 % after 160 weeks. The patients assessed the safety as “very good” or “good” by 97.5% at week 52 and by 100% at week 160.

Conclusion: The non-interventional study SUSTAIN showed relevant disease improvements and good safety with an outstanding high therapy satisfaction in patients with active psoriatic arthritis treated with ustekinumab. Treatment effect was observed as early as after 4 weeks. The treatment effects and satisfaction sustained up end of documentation at week 160 in daily practice life.

Disclosure of Interests: None declared.

DOI: 10.1136/annrheumdis-2021-eular.2495

POS1056 COMPARATIVE EFFICACY OF TNF INHIBITORS VERSUS OTHER CYTOKINE INHIBITOR BDMARDS ON PSORIATIC ARTHRITIS IMPACT OF DISEASE (PSAID) SCORE AND DOMAINS

A. Rauf[1], C. Hughes[1], D. Hill[1], P. Kiely[1,2]. *[1]Rheumatology, Rheumatology, London, United Kingdom*; *[2]St George's, University of London, Institute of Medical and Biomedical Education, London, United Kingdom*

Background: Psoriatic arthritis (PsA) has many consequences, reflecting musculoskeletal and skin inflammation, with the potential to adversely affect overall quality of life. Patient reported outcome measures (PROM) assess a holistic range of aspects of quality of life, including physical and mental components, and provide broad detailed information of the impact of disease. Biologic DMARDs (bDMARDs) targeting TNF have been used to treat PsA for over 10 years whereas inhibitors of IL-17, IL-12/23 and Janus kinases (JAK) have only been available more recently. They all target differing cytokines, including JAK inhibitors which inhibit IL-12 and IL-23 signaling but not TNF signaling. Their relative impact on PROMs is unknown.

Objectives: To assess, in routine care, the relative impact in PsA of TNF inhibitors (TNFi) versus non-TNFi bDMARDs, targeting IL-17, IL-12/23 and JAK, on PROMs.

Methods: We performed a cross section analysis of PsA patients with established disease treated with bDMARDs and JAKi, under routine care at St George's University Hospital, London, UK. Patients completed the 12-item psoriatic arthritis impact of disease (PsAID) tool. The total PsAID score was calculated using the on-line EULAR toolkit (see reference). The PsAID total and individual domain scores were compared between TNFi and non-TNFi groups using the

Mann Whitney U test. A total PsAID score below 4 out of 10 is considered a 'patient-acceptable state'.

Results: A total 95 patients (female n= 53, 56%) completed the PSAID; TNFi n=72 (female 50%, adalimumab n=41, Etanercept n= 24, Golimumab n=4, Infliximab n =2, Certolizumab n=1) and non-TNFi n= 23 (female 74%, Secukinumab n=9, Ixekizumab n=1, Ustekinumab n=9, Tofacitinib n=4). The mean age was 53.6 (TNFi 53.5, non-TNFi 53.7) years, and duration of time on bDMARD treatment was TNFi 49.5 (range 1- 141) months, non-TNFi 25.3 (range 4 -59) months. The total and individual domain PsAID scores are shown in the Table 1. A 'patient acceptable state' total score <4 was recorded in TNFi 36/72 (50%) and non-TNFi 11/23 (48%). There was no significant difference between TNFi and non-TNFi groups in the mean total PsAID score, or proportion achieving a patient acceptable state. Patients on TNFi had lower (better outcome) mean scores for all 12 domains except skin, and the differences, versus non-TNFi treated patients, were significant for pain, functional capacity, discomfort and depression.

PSAID domain	TNFi	Non-TNFi	P value
Total score	3.31	4.64	N.S.
Pain	3.67	5.43	0.02
Fatigue	4.04	5.65	N.S.
Skin problems	3.11	2.78	N.S.
Work/leisure activities	3.56	4.78	N.S.
Functional capacity	3.29	5.04	0.02
Discomfort	3.88	5.65	0.02
Sleep disturbance	3.42	4.78	N.S.
Coping	3.01	4.09	N.S.
Anxiety, fear, uncertainty	2.64	4.17	N.S.
Embarrassment/shame	2.28	3.39	N.S.
Social participation	2.6	3.48	N.S.
Depression	2.11	3.91	0.03

Conclusion: In PsA, TNFi appear to have a greater impact over non-TNFi bDMARDs on some aspects of quality of life, including pain and functional capacity. TNFi and non-TNFi were no different with respect to patients' perspective on skin disease, embarrassment or shame, despite less good cutaneous responses in clinical trials from TNFi agents. Overall, the PsAID tool reveals an unmet burden on quality of life in PsA patients treated with all classes of bDMARDs and JAKi, as 50% fail to achieve a 'patient acceptable state'. This should prompt scrutiny of the high scoring domains and utilization of additional treatment modalities to achieve better holistic outcomes for PsA patients in routine care.

POS1057 DISCONNECT BETWEEN TREATMENT SWITCHES AND DISEASE ACTIVITY STATE IN EARLY PSORIATIC ARTHRITIS

J. Luime[1], M. Kok[2], I. Tchetverikov[3], M. Vis[1], C. Collaboration of Rheumatologists[4]on behalf of DEPAR studygroup. *[1]ErasmusMC, Rheumatology, Rotterdam, Netherlands*; *[2]Maasstad hospital, Rheumatology, Rotterdam, Netherlands*; *[3]Albert Schweitzer Hospital, Rheumatology, Dordrecht, Netherlands*; *[4]Cicero, Rheumatology, Rotterdam, Netherlands*

Background: Receiving adequate treatment early in the disease course is one of the most important prognostic factors to achieve optimal disease outcome in most rheumatological conditions. Treat-to-target strategies and early step-up of treatment are important ingredients to accomplish this. While for Rheumatoid Arthritis this is common practice on accepted targets, for Psoriatic Arthritis (PsA) this is less outspoken practice. In PsA multiple domains must be taken into account and also there is a less established practice to use PsA specific targets, such as MDA, although this is associated with a better quality of life.[1,2] Whether this affects optimal disease outcome is not well described

Objectives: To describe treatment strategies in newly diagnosed PsA with at least one synovitis and, treatment switches over time in those that not achieved MDA.

Methods: For this study we used data from the DEPAR study between August 2013 and February 2019. The DEPAR study is a cohort that includes newly diagnosed PsA patients and follows them for up to 6 years. Patients are classified at baseline according to their prominent features: mono-, oligo-, polyarthritis, enthesitis, dactylitis or axial phenotype. For this study we used the data from the first 2 years for the patients with an articular phenotype. Methotrexate (MTX) and MTX plus another s-DMARD or GCs were addressed separately as they form the cornerstone of treatment in PsA. Next treatment was grouped in the usual drug classes: sDMARD (conventional), bDMARD and Glucocorticoids (GCs). Descriptive statistics were applied in STATA16 and Tableau 2020.3

Results: Out of 620 patients, 478 patients had at least one swollen joint at baseline and were included in this analysis. 349 (73%) had data at 1 year and 267 (56%) at 2 years. Average age was 50.3 years(sd 14.1), and 50% was female. Half of the patients had oligo-arthritis, 30% poly-arthritis and 20% mono-arthritis. At baseline, clinical characteristics were 3.8 swollen joints (sd 4.9), 5.5 tender joints (sd 6.2), 3.1 PASI points (sd 3.7, skin), 0.8 entheseal points (LEI; sd 1.2) and 0.1 dacylitis count (basic count of digits; sd 0.6). Treatment was initiated with Monotherapy MTX in 51% of the patients, while 25% did not start any DMARD, 10% started a combination of s-DMARDs, 9% a single s-DMARD, 3% a b-DMARD and 2% GCs. This differed for the different phenotypes as shown in Table 1.

Minimal Disease Activity (MDA) was achieved by 32% after 3 months increasing to 58% at 24 months. Treatment switches in the non-MDA mono-, oligo- and polyarthritis groups are shown in Figure 1. In the patients not in MDA treatment was not switch in: 70% of patients with mono-arthritis, 50-66% with oligo-arthritis and 50% poly-arthritis. Similar observations were found when using the DAS28(<=3.2) or DAPSA(<14), both including only articular disease activity (data not shown).

Conclusion: Achieving MDA is associated with a better quality of life, though it is not yet common practice to make treatment adjustments based on MDA. Of the newly diagnosed PsA patients not in MDA, more than half of the clinical evaluations did not result in a switch of medication.

POS1058 SUBCLINICAL DACTYLITIS: COMPARATIVE STUDY OF THERAPEUTIC RESPONSE WITH TNF INHIBITORS, SECUKINUMAB AND USTEKINUMAB

C. Guillén-Astete[1], Á. Andreu-Suárez[1], V. García García[1]. *[1]Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: Non tender dactylitis has been recently associated with synovitis, tenosynovitis and enthesitis without fat tissue hyperemia. Dactylitis is a remarkable hallmark of spondyloarthritis and particularly in psoriatic arthritis. Also, dactylitis has been recognized as one of the most difficult musculoskeletal feature of the disease to treat. It has been of interest to compare the effectiveness of available therapies in cases of clinical dactylitis, however, the efficacy on subclinical dactylitis has not studied yet.

Objectives: To determine the effectiveness of three different biological therapy approaches in subclinical (non-tender) dactylitis in patients diagnosed by psoriatic arthritis in terms of changes detected by ultrasound scan.

Methods: A retrospective ultrasound record-based study was conducted to compare the findings of ultrasonographic studies performed before and 6 months after the start of one of the following biologic therapies in patients diagnosed by psoriatic arthritis: TNF-inhibitors, secukinumab and ustekinumab. We included patients with a complete before-after ultrasound scan of the hands from three different rheumatology clinics. To be considered as a subclinical dactylitis two conditions were had to be achieved: non tender finger and absence of fat tissue hyperemia.
Results: Patients included: 22 on TNF-inhibitors (28 subclinical dactylitis), 14 on secukinumab (17 subclinical dactylitis) and 13 on ustekinumab (16 subclinical dactylitis). Median of line of treatment of each biologic therapy: 1, 3 and 3, respectively. In the TNF-inhibtors group, 14/28 achieved synovitis resolution, 12/26 achieved tenosynovitis resolution and 2/28 achieved enthesitis resolution. In the secukinumab group, 11/17 achieved synovitis resolution, 11/17 achieved tenosynovitis resolution and 13/17 achieved enthesitis resolution. In the ustekinumab group, 10/16 achieved synovitis resolution, 10/15 achieved tenosynovitis resolution and 13/16 achieved enthesitis resolution. Complete dactylitis resolution was achieved in 12/28, 11/17 and 10/16 patients, respectively. Differences on independent success ratio of secukinumab and ustekinumab were not statistically significative, however both groups had higher rates of independent success compared to TNF-inhibitors group (P<0.05, both cases). The line of treatment did not affect the resolution rate of non-TNF-inhibitors group.
Conclusion: This is –as far as our knowledge know- the first study comparing the effect of different therapies on subclinical dactylitis. Besides the inherit limitations of a retrospective study, it seems to point that both secukinumab and ustekinumab are better therapeutic options than TNF-inhibitors. Of course, prospective further studies are needed.
Disclosure of Interests: None declared.

Psoriatic arthritis - clinical aspects (other than treatment)

POS1059 ULTRASOUND SYNOVITIS, UNLIKE ENTHESITIS OR CLINICAL JOINT ASSESSMENT, IS ASSOCIATED WITH JOINT DAMAGE PROGRESSION IN PATIENTS WITH PSORIATIC ARTHRITIS

Y. Yamada[1], K. Inui[2], T. Okano[1], K. Mandai[2], K. Mamoto[1], T. Koike[1], C. Tateishi[3], D. Tsuruta[3], H. Nakamura[1]. [1]*Osaka City University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka city, Japan*; [2] *Saiseikai Nakatsu Hospital, Department of Orthopedic Surgery, Osaka city, Japan*; [3]*Osaka City University Graduate School of Medicine, Department of Dermatology, Osaka city, Japan*

Background: We previously reported that ultrasound assessment of enthesitis (US enthesitis) is not consistent with tenderness of the enthesis (clinical enthesitis) in patients with psoriatic arthritis (PsA). Although US enthesitis reflects inflammatory condition and clinical enthesitis is associated with disease activity and physical function, each of them was not associated with joint destruction by cross-sectional analysis1. It is reported that the utility of US for predicting joint destruction remains unclear among patients with PsA2.
Objectives: This study is aimed to longitudinally investigate the relationships between enthesitis or synovitis and joint damage progression in patients with PsA.
Methods: Forty-seven patients with PsA (average age of 56.5 years) underwent US and clinical examination of wrist and finger joints and 14 entheses (the bilateral humeral medial epicondyles and insertions of the triceps, distal quadriceps, proximal/distal patella, Achilles tendons, and plantar fascia). Tender or swollen joint count (TJC/SJC), Gray Scale (GS) and Power Doppler (PD) score of the joints, and US/clinical enthesitis counts were calculated. The relationships between the yearly progression in modified total sharp score (ΔmTSS) at two-time points (baseline and average follow-up of 20.4 months) and US or clinical findings were investigated.
Results: ΔmTSS was significantly correlated with age (r=0.44, p=0.01), joint GS score (r=0.44, p=0.01), and joint PD score (r=0.38, p=0.03). TJC, SJC, inflammatory marker, and disease activity showed no associations with ΔmTSS. US/clinical enthesitis counts also showed no associations with ΔmTSS (Table 1). The joint PD score, adjusted by age, was significant factor for ΔmTSS by multiple regression analysis (b=0.50, p<0.001).
Conclusion: The joint PD score or US synovitis, unlike clinical joint assessment, was significant predictive factor for joint damage progression. It is important to assess joints by US as well as clinical examination.

POS1060 A PROSPECTIVE, LONGITUDINAL STUDY TO EVALUATE REAL-WORLD PATIENT EXPERIENCES AND TREATMENT SATISFACTION WITH SECUKINUMAB FOR PSORIATIC ARTHRITIS

M. E. Husni[1], M. Bozyczko[2], D. Wolin[3], C. Sweeney[3], E. Davenport[3], S. Hass[4], E. Yi[4], P. Hur[4], L. Grinnell-Merrick[5]. [1]*Cleveland Clinic, Rheumatology, Cleveland, United States of America*; [2]*National Psoriasis Foundation, Patient Advocate, Portland, United States of America*; [3]*RTI Health Solutions, Surveys and Observational Studies, Research Triangle Park, United States of America*; [4]*Novartis Pharmaceuticals Corporation, Health Economics and Outcomes Research, East Hanover, United States of America*; [5]*University of Rochester, Rheumatology, Rochester, United States of America*

Background: Psoriatic arthritis (PsA) is an inflammatory disease that impairs quality of life. Despite therapeutic advances, up to a third of patients do not respond or are unable to sustain a treatment response. Thus, data on patient treatment experience in PsA is critical.
Objectives: To assess real-world experiences of patients with PsA treated with secukinumab.
Methods: This is an ongoing 12-month, prospective, longitudinal, web-based survey study of patients with PsA initiating secukinumab. Patient demographics and medical history are collected at baseline using a rheumatologist case report form. Patient experience data are collected at baseline, 3, 6, 9, and 12 months by patient surveys. The primary endpoint is change in the Psoriatic Arthritis Impact of Disease 12-item questionnaire (PsAID12) from baseline to 3 months. In addition, this study will explore other changes at 3 months, including PsA symptoms, treatment satisfaction with secukinumab, and other patient-reported outcome measures. Baseline and available month 3 data from patients enrolled to date were analyzed descriptively.
Results: Baseline demographic and medical history data were available for 72 patients; 32 (44.4%) were male, 59 (81.9%) were White, and 15 (20.8%) reported modifying their diet because of PsA. The mean (SD) time since symptom onset (n = 29) and since PsA diagnosis (n = 53) was 56.3 (45.6) and 34.4 (44.7) months, respectively. More than half of the patients who started treatment with secukinumab were biologic experienced (38/62; 61.3%). Primary and secondary loss of effectiveness were the main reasons for previous biologic discontinuation (Table 1). At 3 months (n = 49), the mean (SD) PsAID12 change from baseline was –1.8 (1.8) points. Additionally, 24.5% of patients reported their PsA symptoms to be "much better," 40.8% reported "moderately better," and 32.7% "a little better" compared with baseline; none reported "no change" or worsened symptoms. On a scale of 1-10, patients rated their overall satisfaction with secukinumab treatment at month 3 with a mean (SD) score of 6.8 (2.1). Patients were also highly

satisfied with their symptom improvement, speed to symptom improvement, and the mode and frequency of secukinumab administration (Table 1).

Table 1. Summary of Prior PsA Treatment and Treatment Satisfaction with Secukinumab at Month 3

Physician-reported treatment characteristics	Baseline measure (N = 62)
Most recent PsA biologic prior to secukinumab, n (%)	n = 31
Adalimumab	12 (38.7)
Certolizumab pegol	8 (25.8)
Etanercept	6 (19.4)
Infliximab, including -dyyb	3 (9.7)
Golimumab	1 (3.2)
Unknown/not sure	1 (3.2)
Primary reasons for discontinuing previous PsA biologic treatment, n (%)[a]	n = 30
Primary and secondary loss of effectiveness	25 (83.3)
Disease progression	6 (20.0)
Worsening of or new comorbidities	1 (3.3)
How the medication was taken	2 (6.7)
Adverse effects/intolerance	4 (13.3)
Other[b]	1 (3.3)
Patient-reported treatment satisfaction with secukinumab, mean (SD)[c]	**Month 3 (N = 49)**
Symptom improvement	6.7 (2.3)
Speed of symptom improvement	6.9 (2.0)
Dose frequency	7.4 (1.9)[c]
Method of administration	7.2 (1.5)
Ease of use	8.2 (1.5)
Side effects, if any	7.9 (1.9)
Patient support services by manufacturer	8.3 (1.7)

PsA, psoriatic arthritis.[a] Rheumatologists may list > 1 reason. Data tabulated based on the number of case report forms received from rheumatologists at analysis cutoff (n = 30).[b] Other reasons included availability of new treatment, patient request, or family history of disease.[c] n = 48.

Conclusion: Most patients were biologic experienced and reported primary or secondary loss of effectiveness as the main reason for discontinuation of their previous biologic. Patients reported overall symptom improvement and satisfaction with secukinumab treatment at 3 months after initiation.

POS1061

THE ITALIAN PROSPECTIVE SIRENA STUDY: FOCUS ON EARLY PSORIATIC ARTHRITIS COHORT AND GENDER DIFFERENCES

A. Zabotti[1], M. M. Luchetti[2], C. Selmi[3], R. Ramonda[4], R. D. Grembiale[5], L. Dagna[6], S. D'angelo[7], G. Cafaro[8], S. De Vita[1], M. Felicetti[4], S. Marelli[9], D. Frigerio[9], E. Favalli[10]on behalf of SIRENA Study Group. *[1]University of Udine, Academic Hospital S. Maria della Misericordia, Rheumatology Clinic, Department of Medical Area, Udine, Italy*; *[2]Università Politecnica delle Marche, Clinica Medica, Dipartimento Scienze Cliniche e Molecolari, Ancona, Italy*; *[3]Humanitas Research Hospital and Humanitas University, Rheumatology and Clinical Immunology, Milan, Italy*; *[4]University of Padova, Rheumatology Unit, Department of Medicine-DIMED, Padova, Italy*; *[5]Università "Magna Graecia", Rheumatology Research Unit, Dipartimento di Scienze della Salute, Catanzaro, Italy*; *[6]IRCCS San Raffaele Scientific Institute and Vita-Salute San Raffaele University, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnIRAR), Milan, Italy*; *[7]San Carlo Hospital, Rheumatology Institute of Lucania (IReL) and Rheumatology Department of Lucania, Potenza, Italy*; *[8]Università di Perugia, Reumatologia, Dipartimento di Medicina, Perugia, Italy*; *[9]Janssen-Cilag, Medical Affairs Department, Immunology, Cologno Monzese (MI), Italy*; *[10]ASST Centro Specialistico Ortopedico Traumatologico Gaetano Pini – CTO, S.C. Reumatologia, Milan, Italy*

Background: Limited data on early Psoriatic Arthritis (PsA) are available[1,2].

Objectives: To describe baseline data of PsA patients naive to any DMARDs.

Methods: SIRENA study is an Italian, prospective Registry of Spondyloarthritis patients diagnosed according to ASAS criteria and naïve to any DMARDs. Data on demographic and clinical characteristics of PsA cohort were collected and analysed, also by gender.

Results: 203/350 (58%) subjects included in SIRENA Registry had PsA (mean age 51.9 years) and in 190/203 (94%) CASPAR classification criteria were fulfilled. In 70% of patients the diagnosis was performed within 24 months from symptom onset. At baseline, 194/203 (95.6%) had mainly peripheral manifestations, 74.4% of patients had skin psoriasis, 40% nail psoriasis, 39.3% clinical enthesitis and 25.9% dactylitis. Mean SJC66 and TJC68 were, respectively, 3 and 7.2; mean PhGA was 46.3; 14.7% of patients were in MDA.

The higher tender joint count in women (mean TJC68 9.3 in women *vs* 5.3 in men) resulted in a higher disease activity according to DAPSA (high disease activity: 11.5% women *vs* 4.1% men), a higher joint VAS score (mean score 47.1 women *vs* 39.8 men) and a lower prevalence of MDA (8.3% women *vs* 20% men). We observed a higher prevalence of moderate or severe psoriasis in men (BSA≥3%: 37% men *vs* 27.8% women) while all PROs collected (PtGA, pain VAS score, sleep VAS score, BASFI, BASDAI, HAQ-DI, WPAI) were worse in women. The most common comorbidities were cardiometabolic (35.5%), endocrine (9.4%), and gastrointestinal disorders (7.4%). Cardiometabolic disorders were more frequently reported by men, endocrine and gastrointestinal disorders by women; depression exclusively by women.

Conclusion: This analysis provides real-life data in a cohort of early PsA subjects. Relevant gender differences were observed, with women showing a higher disease activity and more joint pain and men having more severe psoriasis. Women also perceived a worse disease burden.

POS1062 ULTRASOUND ASSESSMENT OF SUB-CLINICAL HAND JOINT SYNOVITIS: A COMPARATIVE STUDY BETWEEN PSORIATIC AND RHEUMATOID ARTHRITIS

F. Liu[1], Y. Xin[2], D. LI[2], W. LI[2], J. Zhu[1]. [1]*Peking University People' s Hospital, Department of Ultrasound, Beijing, China*; [1]*Peking University People' s Hospital, Department of Ultrasound, Beijing, China*

Background: Ultrasound (US) detected subclinical synovitis can be present in early psoriatic arthritis (PsA) and rheumatoid arthritis (RA), and also in patients fulfilling clinical remission criteria[1-2]. Numerous evidences support that the persistence of subclinical synovitis detected by US is associated with a high risk of disease progression [2-3].
Objectives: To evaluate sub-clinical synovitis of PsA and RA at the level of small joints of the hand and wrist by B-mode and Power Doppler US.
Methods: 21 patients of early PsA and 25 patients of early RA (no clinical evidence of hand joint involvement, PsA disease duration <2 years, and RA disease duration <1 year) were recruited. DAS28 and DAPSA score used for assessment of articular disease activity for RA and PsA, respectively. US [grey scale (GS) and power Doppler (PD)] was performed to assess synovitis of bilateral wrists, metacarpophalangeal joints, proximal and distal interphalangeal joints, altogether 30 joints. A GS score ≥2 and/or a PD score ≥1 were used to identify US detected synovitis.
Results: A total of 25 patients were included in the RA group, including 5 males and 20 females. A total of 21 patients were included in the PsA group, including 7 males and 14 females. There were no significant differences in gender composition, age, and duration of disease between the two groups (*P*>0.05) (Table 1). 14 (66.67%) PsA patients and 12 (48%) RA patients had sub-clinical hand joint synovitis. Among 630 hand joints scanned in PsA group, 49 (7.78%) joints showed evidence of sub-clinical synovitis. Wrist joint was most commonly involved (24.49%), followed by MCP3 (14.29%), MCP1 (12.24%) and DIP3 (10.20%). Among 750 hand joints scanned in RA group, 110 (14.67%) joints showed evidence of sub-clinical synovitis. Wrist joint was most commonly involved (60.00%), followed by MCP3 (8.24%), MCP1 (8.24%) and MCP2 (7.06%). No correlation noted between numbers of joints with subclinical synovitis with DAPSA and DAS28 score. There was no correlation between number of joints with sub-clinical synovitis and disease activity indices.
Conclusion: Almost two-thirds patients with PsA and half patients with RA had US evidence of sub-clinical synovitis in wrist and hand joints, most commonly in wrist. There are some similarities in the joint involvement of sub-clinical synovitis between RA and PsA, physicians should take this into account in clinical work.

Table 1. Demographic characteristics of RA and PsA patients

	RA (n=25)	PsA (n=21)	*P*
Female, n(%)	20 (80.00%)	14 (66.67%)	0.305
Age, years, mean±SD	56.32±12.18	54.31±15.82	0.637
Disease duration, years, mean±SD	1.06±0.59	0.90±0.58	0.363

POS1063 RHEUMATOLOGIST AND PATIENT PERSPECTIVES ON IMPLEMENTING CARDIOVASCULAR RISK PREVENTION IN THE MANAGEMENT OF PSORIASIS: A QUALITATIVE STUDY

A. Ogdie[1], A. Gustafson[2], A. Lieberman[2], J. Mason[3], A. Armstrong[4], N. Mehta[5], R. Beidas[2], J. Gelfand[3]. [1]*University of Pennsylvania, Medicine/Rheumatology, Philadelphia, United States of America*; [2]*University of Pennsylvania, Implementation Science, Philadelphia, United States of America*; [3]*University of Pennsylvania, Dermatology, Philadelphia, United States of America*; [4]*University of Southern California, Dermatology, Los Angeles, United States of America*; [5]*National Institutes for Health, NHLBI, Rockville, United States of America*

Background: Psoriatic arthritis (PsA) is an immune-mediated musculoskeletal disease associated with excess risk for cardiovascular disease (CVD). New US-based guidelines recognize psoriasis as a CVD risk enhancer; however, patients with PsA often do not have CVD risk factors identified nor managed.
Objectives: This study examines strategies to improve CVD prevention care from the perspective of rheumatologists and patients with PsA.
Methods: Semi-structured qualitative interviews were conducted using an interview guide based on the Consolidated Framework for Implementation Research to examine the perspectives of rheumatologists (N = 8) and patients with psoriatic arthritis managed by rheumatologists (N = 8) on barriers/facilitators to CVD prevention. Interviews were transcribed and coded using an integrated approach designed to enhance reliability and validity facilitated by NVivo software.
Results: Most rheumatologists confirmed that they were not regularly engaging in CVD prevention care with psoriatic arthritis patients. Providers reported sometimes counseling and screening for CVD risk, but they were not regularly prescribing statins and not as willing to do so. Reasons included a lack of familiarity or comfort with guidelines, concern about working outside of their scope of practice, confusing boundaries between other clinicians, and time constraints. Most patients confirmed that it was uncommon for their rheumatologists to engage them in CVD prevention care but expressed desire for their rheumatologists inform them of the risk, and were open to CVD prevention care from them.
Conclusion: We identified several potentially modifiable barriers to CVD screening and management. These findings will inform the design of a clinical trial comparing the effectiveness of rheumatologist implementation of CVD guideline-based counseling, screening and prescribing statins when appropriate in patients with PsA.

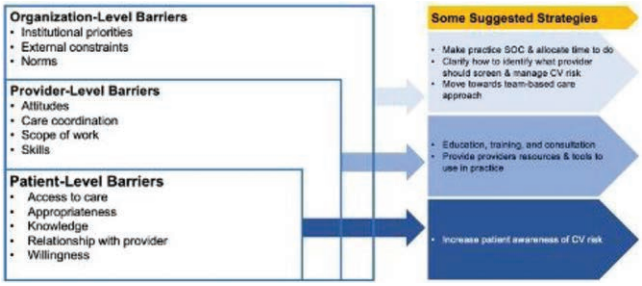

Figure 1. Barriers to CVD screening and management among patients with PsA in a rheumatology practice setting and potential strategies to address those barriers. Abbreviations: CV = cardiovascular; SOC = standard of care.

POS1064 SERUM BIOMARKERS BEFORE AND AFTER A SIX MONTHS STRUCTURED WEIGHT LOSS INTERVENTION IN PATIENTS WITH PSORIATIC ARTHRITIS AND OBESITY COMPARED WITH CONTROLS

L. Torres[1], C. Jonsson[1], B. Eliasson[2], H. Forsblad-D'elia[1], A. Bilberg[3], I. Gjertsson[1], I. Larsson[4], E. Klingberg[1]. *[1]University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; *[2]Institute of Medicine, Sahlgrenska University Hospital, University of Gothenburg, Sweden, Department of Medicine, Gothenburg, Sweden*; *[3]Institute of Neuroscience and Physiology, Sahlgrenska Academy at the University of Gothenburg, Sweden, Section of Health and Rehabilitation, Physiotherapy, Gothenburg, Sweden*; *[4]Institute of Medicine, Sahlgrenska Academy at University of Gothenburg, Sweden, Department of Gastroenterology and Hepatology, Gothenburg, Sweden*

Background: Obesity is highly overrepresented in psoriatic arthritis (PsA) and associated with increased disease activity. We have previously shown in 41 patients with PsA (Caspar criteria) and obesity (here body mass index BMI ≥33 kg/m^2) that weight loss treatment including Very Low Energy Liquid Diet (VLED) resulted in a median weight loss of 18.6% and concomitantly a significant improvement in CRP and disease activity in joints, entheses and skin at six months (M6) follow up.

Objectives: To analyze serum biomarkers associated with inflammation, cartilage and bone metabolism before and after weight loss treatment in PsA patients compared with controls, without PsA or psoriasis, matched for age, sex and weight.

Methods: The weight loss treatment included VLED (640 kcal/day) during 12 or 16 weeks (depending on baseline (BL) BMI <40 or ≥40 kg/m^2), followed by a structured reintroduction of an energy restricted diet. cs/bDMARDs were held unchanged from 3 months before BL until M6. The patients were assessed with 66/68 joints counts.

Serum levels of vascular endothelial growth factor (VEGF), S100A8, S100A9, matrix metalloproteinases (MMP-3, 8 and 13), hepatocyte growth factor (HGF), B-cell activating factor (BAFF), Dickkopf (DKK)-1, sclerostin (SOST), soluble receptor activator of nuclear factor-kB ligand (RANKL), osteprotegerin (OPG) and aggrecan were measured at BL and M6 in PsA patients and controls with Magnetic Luminex Assays (R&D-systems) following the manufacturer's instructions using a Bio-Plex 200 system (BioRad). Serum cartilage oligomeric matrix protein (COMP) (R&D-systems), carboxyterminal telopeptide of type-1 collagen (CTX-1) (Immunodiagnostics systems: IDS) and osteocalcin (IDS) were measured with enzyme-linked immunosorbent assay (ELISA).

Results: Totally 41 PsA patients [age median 54 (IQR 48-62) yrs; 63 % women] and 39 controls [age 55 (46-60) yrs, 72 % women] were included. At M6 the weight-loss since BL was 18.7 (14.6-26.5) kg in the PsA patients and 22.6 (14.7-28.4) kg in the controls (p=0.546). Significant reductions in DAS28CRP [2.9 (2.1–3.7) vs. 2.4 (1.7–3.0)] and DAPSA [15.3(6.6-29.1) vs. 11.0 (2.8–17.6)] (p<0.001) were seen in the PsA patients.

At BL serum levels of the biomarkers were not significantly different in patients vs. controls.

After weight-loss significant reductions were seen in serum VEGF, S100A8, MMP-8, HGF, BAFF, COMP and DKK-1, whereas serum SOST and CTX-1 were significantly increased in both patients and controls (Table 1). The other biomarkers were not significantly changed.

Conclusion: Weight loss in patients with PsA and controls was associated with lowered serum levels of several biomarkers related to inflammation and cartilage degradation, along with increased levels of biomarkers for bone turnover.

Disclosure of Interests: None declared.

POS1065 CIRCULATING ENDOTHELIAL CELLS AS A MARKER OF CARDIOVASCULAR DISEASES IN PATIENTS WITH PSORIATIC ARTHRITIS

S. Smiyan[1], A. Bilukha[1], B. Koshak[1]. *[1]Ternopil State Medical University, Internal Medicine №2, Ternopil, Ukraine*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory joint disease which develops in patients with psoriasis. Mortality among patients with PsA is 1.28 times higher than population levels and in most cases it is caused by cardio-vascular diseases (CVD). Those patients have increased risk of clinical and subclinical CVD, mostly due to endothelial dysfunction (ED) and accelerated atherosclerosis. Elevated levels of circulating endothelial cells (CEC) have been described in different cardiovascular pathologies, suggesting their potential use as diagnostic biomarkers for dysfunction of endothelium.

Objectives: To identify the potential role of circulating endothelial cells as a marker of cardiovascular diseases in patients with psoriatic arthritis.

Methods: In total, ninety-four patients with PsA, who fulfilled the disease criteria (CASPAR) were examined using standard diagnostic methods (including C-reactive protein (CRP), lipid profile) and evaluation endothelium-dependent vasodilation in response to reactive hyperemia (EDVD). Circulating endothelial cells were determined in the peripheral venous blood samples by flow cytometry and counted according to a standardized protocol using a fluorescence microscope after acridine orange labeling. The control group, which were consisted from thirty healthy adults were also examined.

Results: CEC were quantified in patients with PsA (7,15 ± 0,19 cells mL^{-1}) and in the control group (4,05 ± 0,11 cells mL^{-1}). Comparing two groups of patients, endothelial circulating cell level was significantly different (p = 0.0001). Finally, we analyzed the relationship between CEC count, comorbidities, cardiovascular risk factors and EDVD in patients with PsA. Increased CEC levels were associated with obesity (r=0,62), duration of disease (r=0,65), age (r=0,67), increased CRP (r=0,76), high blood pressure (r=0,87) and decreased EDVD (r=–0,91).

Conclusion: CEC counts were significantly higher in patients with PsA, positively correlated with the main factors of CVD, and another specific marker of ED - EDVD. Elevated CEC levels were also associated with high concentrations of CRP, which plays a direct role in promoting vascular inflammation, vessel damage and clinical CVD events. In conclusion, increased CEC counts provide a direct proof of endothelial damage in patient with PsA and a clinically informative diagnostic tool for endothelial damage in pre-symptomatic CVD. As CEC are one of the most sensitive biomarker for ED, further efforts should concentrate on improving the sensitivity of its detection in order to increase diagnostic sensitivity.

POS1066 IS ENTHESITIS A SONOGRAPHIC BIOMARKER OF DISEASE SEVERITY IN PSORIATIC ARTHRITIS? THE LINK BETWEEN ULTRASOUND ENTHESEAL ABNORMALITIES AND PERIPHERAL JOINT EROSIVE DAMAGE

G. Smerilli[1], E. Cipolletta[1], G. M. Destro Castaniti[2], A. DI Matteo[1], M. DI Carlo[1], E. Moscioni[1], F. Francioso[1], W. Grassi[1], E. Filippucci[1]. *[1]Marche Polytechnic*

University, Rheumatology Unit, Department of Clinical and Molecular Sciences, "Carlo Urbani" Hospital, Jesi, Italy; [2]*University of Palermo, Department of Health Promotion, Mother and Child Care, Internal Medicine and Medical Specialties, Rheumatology section, "P. Giaccone" Hospital, Palermo, Italy*

Background: Enthesitis is one of the hallmark of psoriatic arthritis (PsA). Ultrasound (US) accurately detects morphostructural abnormalities indicative of entheseal inflammation and structural damage. Interestingly, in a recent study, US-detected entheseal pathology appeared to be a potential marker of disease severity, being associated with higher radiographic score of structural damage at peripheral joint level. (1) However, a sub-analysis of the impact of each elementary finding of US enthesitis was not performed. Moreover, some US entheseal abnormalities (hypoechogenicity, thickening and calcification/enthesophyte) have been described as frequent findings in healthy subjects and patients with dysmetabolic conditions, undermining their specificity. (2) Thus, we hypothesized that their role as a sonographic biomarker of joint disease severity could be questioned.
Objectives: The main aim of the present study was to explore the association between the US elementary findings of enthesitis defined by OMERACT [i.e. hypoechogenicity, thickening, Doppler signal, calcification/enthesophyte and bone erosion at enthesis] (3) and the presence of US-detected joint bone erosions in patients with PsA.
Methods: Consecutive patients with PsA (CASPAR criteria) were included in this cross-sectional single-centre study. The scanning protocol included bilateral assessment of the main entheses of the lower limbs [plantar fascia, quadriceps, patellar (proximal and distal) and Achilles tendons]. The presence of US joint bone erosions was investigated in the following areas: 2nd and 5th metacarpophalangeal (MCP) joints, ulnar head and 5th metatarsophalangeal (MTP) joint, bilaterally, as well as the most inflamed joint at the physical examination. The US examination was carried out with a 6-18 MHz probe. Univariate and multivariate logistic analysis were performed to identify predictors of US joint bone erosions.
Results: A total of 74 PsA patients were enrolled. The mean disease duration was 7.9±8.0 years. Joint bone erosions were found in 36/75 patients (48.0%), and in 71/600 joints (11.8%), most frequently in the 5th MTP joint (in 26/75 patients, 34.7%). The univariate analysis showed that entheseal bone erosions [odds ratio (OR) 27.1, 95% confidence interval (CI) 3.3-220.2, p value <0.01] and Doppler signal (OR 3.5, 95% CI 1.3 - 9.4, p value 0.01) were associated with joint bone erosions. Only entheseal bone erosions remained significantly associated with joint bone erosions in the multivariate analysis (Table 1).

Table 1. Multivariate regression analysis: predictive value of the entheseal US findings for the presence of joint bone erosions.

	OR (95% CI)	P value
Hypoechogenicity	0.5 (0.1-3.4)	0.45
Thickening	2.2 (0.6-8.3)	0.27
Doppler signal	3.2 (0.9-10.8)	0.06
Calcification/enthesophyte	1.1 (0.1-11.2)	0.99
Entheseal bone erosion	24.2 (2.7-216.2)	**<0.01**

Conclusion: Entheseal bone erosion and, to a lesser extent, Doppler signal, were the only entheseal abnormalities correlated with the presence of US-detected joint bone erosions, representing potential sonographic biomarkers of disease severity in PsA.

POS1067 BASELINE VITAMIN D LEVELS AND DISEASE ACTIVITY AND RESPONSE IN PORTUGUESE PATIENTS WITH PSORIATIC ARTHRITIS UNDER BMDARD: DOES IT MAKE A DIFFERENCE?

F. Oliveira Pinheiro[1], B. M. Fernandes[1], S. Garcia[1], M. Rato[1], D. Fonseca[2], D. Santos Oliveira[1,3], A. Martins[1], F. R. Martins[4], P. Madureira[1], M. Bernardes[1,5], L. Costa[1]. [1]*Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal*; [2]*Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology Department, Vila Nova de Gaia, Portugal*; [3]*Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; [4]*Centro Hospitalar Universitário do Algarve, Rheumatology Department, Faro, Portugal*; [5]*Faculty of Medicine, University of Porto, Medicine Department, Porto, Portugal*

Background: There is growing evidence that vitamin D [25(OH)D]) plays an important role in maintaining skeletal health and modulating the immune system. Epidemiological data indicate that vitamin D deficiency is common in immune-mediated rheumatic diseases, especially in rheumatoid arthritis, but there is little data regarding its association with disease activity and response to therapy in patients with psoriatic arthritis (PsA) under bDMARD therapy.
Objectives: We aimed to assess whether 25(OH)D basal levels correlate with disease activity and clinical response to the first bDMARD, at 6 and 12 months of therapy, in a monocentric cohort of patients with PsA.
Methods: This retrospective study was carried out on PsA patients from a Rheumatology department of a tertiary hospital, fulfilling CASPAR criteria and registered in our national database (Reuma.pt), who started the first bDMARD since 2008. Demographic, clinical and laboratory criteria were evaluated at 0, 6 and 12 months of biologic therapy. Disease activity was assessed using CDAI, SDAI, DAS28(4V), BASDAI, ASDAS, DAPSA and the response was measured using the EULAR, BASDAI50, ASDAS, ASAS, ACR and PsARC responses. Correlations were made between absolute serum levels of 25(OH)D and continuous variables, as well as associations between different vitamin D cutoffs and disease activity measures and response criteria. Multiple linear and logistic regression analyses were performed to determine whether vitamin D is a predictor of disease activity and therapeutic response.
Results: We included 81 patients, 41 (50.6%) females; with a mean age of 48.0±11.7 years, a mean disease duration of 9.5±7.4 years and a mean body mass index of 28.4±5.2kg/m2. Thirteen (16.0%) were smokers. The mean 25(OH)D basal level was 25.5±13.2ng/ml, 21 (25.9%) had 25(OH)D basal levels ≥30ng/mL and 31 (38.3%) ≤20ng/mL. Sixty-two patients (76.5%) were under csDMARD therapy. Golimumab (29, 35,8%), etanercept (28, 34.6%) and adalimumab (10, 12.3%) were the most frequently prescribed bDMARDs. There were only very weak, albeit positive, correlations between 25(OH)D levels and measures of disease activity. The BASDAI50 response at 6 months was associated with higher basal 25(OH)D levels (29.5±14.5 vs 21.5±10.2ng/mL, p = 0.013); the ASAS20 (33.9±15.9 vs 24.2±12.8ng/mL; p = 0.023), ASAS40 (31.9±14.6 vs 25.0±13.8ng/mL; p = 0.023) and ASAS70 (47.0±4.2 vs 26.6±14.2; p = 0.027) responses at 12 months were associated with higher basal levels of 25(OH)D; basal 25(OH)D levels were ≥ 30ng/mL in a significantly higher proportion of patients who achieved CDAI (38.9% vs 10.5%; p = 0.027) and SDAI (38.9% vs 7.7%; p = 0.008) remission and ASDAS disease inactive (29.4% vs 7.3%; p = 0.040) at 1 year. In the regression models, basal levels of 25(OH)D were found to be predictors of good EULAR responders (OR 1.315, 1.017-1.213 95% CI; p = 0.037) at 6 months. Basal levels of 25(OH)D were not significantly different in patients who discontinued bDMARD and no significant correlations or associations were identified regarding more specific PsA activity measures, such as DAPSA and PsARC, nor were they predictive of these responses.
Conclusion: We can conclude that there is a global trend for an association between higher levels of vitamin D and lower measures of disease activity and better therapeutic responses to the first biologic. It was possible to find statistically significant associations with some disease activity measures and response criteria that, although primarily designed for other rheumatic diseases, are often used in PsA.

POS1068 CARDIAC BIOMARKERS ARE ASSOCIATED WITH THE DEVELOPMENT OF CARDIOVASCULAR EVENTS IN PATIENTS WITH PSORIATIC ARTHRITIS AND PSORIASIS

K. Colaco[1,2,3], K. A. Lee[4], S. Akhtari[5], R. Winer[6], P. Welsh[7], N. Sattar[7], I. Mcinnes[8], V. Chandran[9,10], P. Harvey[5,9], R. Cook[4], D. D. Gladman[9,10], V. Piguet[1,9], L. Eder[1,9]. [1]*Women's College Hospital, Women's College Research Institute, Toronto, Canada*; [2]*University Health Network, Krembil Research Institute, Toronto, Canada*; [3]*University of Toronto, Institute of Medical Science, Toronto, Canada*; [4]*University of Waterloo, Statistics and Actuarial Science, Waterloo, Canada*; [5]*Women's College Hospital, Cardiology, Toronto, Canada*; [6]*Rambam Health Care Campus, Neurology, Haifa, Israel*; [7]*University of Glasgow, Institute of Cardiovascular & Medical Sciences, Glasgow, United Kingdom*; [8]*University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom*; [9]*University of Toronto, Medicine, Toronto, Canada*; [10]*University Health Network, Centre for Prognosis Studies in the Rheumatic Diseases, Toronto, Canada*

Background: N-terminal pro-brain-type natriuretic peptide (NT-proBNP) and troponin I (TnI) are established cardiac biomarkers that predict cardiovascular events (CVEs) in the general population. While patients with psoriatic arthritis and psoriasis, collectively termed psoriatic disease (PsD), have an increased risk of developing CVEs, the use of these cardiac biomarkers to predict CV risk has not been investigated in this population.

Objectives: We aimed to evaluate the association between these cardiac biomarkers and incident CVEs, and assess their predictive value beyond the Framingham Risk Score (FRS).
Methods: A longitudinal cohort study was conducted in patients with PsD without prior history of CVEs. NT-proBNP and TnI concentrations were measured using automated clinical assays in the first available serum sample. The study outcome included any of the following CVEs occurring within the first 10 years of biomarker assessment: angina, myocardial infarction, transient ischemic attack, stroke, revascularization and CV death. Associations with incident CVEs were analyzed separately for each biomarker using Cox proportional hazards regression models first adjusted for age and sex, and subsequently for the FRS. The added value of cardiac biomarkers to improve predictive performance beyond the FRS was assessed using the area under the receiver operator characteristic curve (AUC), net reclassification index (NRI) and integrated discrimination index (IDI).
Results: A total of 1000 patients with PsD were assessed between 2002 and 2019 (mean age 49 ± 12.8 years, 44.6% female) (Table 1). During a mean follow-up of 7.1 years, 64 patients developed incident CVEs. Both TnI (Hazard Ratio (HR) 3.02, 95% Confidence Interval (CI) 1.12, 8.16) and NT-proBNP (HR 2.02; 95% CI 1.28, 3.18) predicted CVEs independently of the FRS (Figure 1). The association was stronger in males than females. Including all cardiac biomarkers and the FRS in a single model, NT-proBNP retained statistical significance (HR 1.91, 95% CI 1.23, 2.97), while TnI did not (HR 2.60, 95% CI 0.98, 6.87). When comparing the predictive performance of the base model (FRS alone, AUC 75.4) to the expanded models, there was no significant improvement in any of the predictive indices with the addition of TnI (AUC 73.5, p = 0.21; NRI 0.08, p = 0.67; IDI 0.005, p = 0.37), NT-proBNP (AUC 71.0, p = 0.35; NRI 0.20, p = 0.06; IDI 0.017, p = 0.10), or both TnI and NT-proBNP (AUC 70.0, p = 0.23; NRI 0.27, p = 0.05; IDI 0.021, p =0.05).
Conclusion: In patients with PsD, elevated NT-proBNP and TnI predict incident CVEs independent of the FRS. We did not observe a significant improvement in the performance of the predictive model when combining these cardiac biomarkers with the FRS.

POS1069 VALIDATION OF THE DISEASE ACTIVITY INDEX FOR PSORIATIC ARTHRITIS (DAPSA) WITH A QUICK QUANTITATIVE C-REACTIVE PROTEIN ASSAY (Q-DAPSA) IN PATIENTS WITH PSORIATIC ARTHRITIS (PSA): A PROSPECTIVE, NATIONAL, MULTICENTER STUDY

F. Proft[1], J. Schally[1], H. C. Brandt[2], J. Brandt-Juergens[3], G. R. Burmester[4], H. Haibel[1], H. Käding[1], K. Karberg[2], S. Lüders[1], B. Muche[1], M. Protopopov[1], J. Rademacher[1], V. Rios Rodriguez[1], M. Torgutalp[1], M. Verba[1], S. Zinke[5], D. Poddubnyy[1]. *[1]Charité – Universitätsmedizin Berlin, Division of Gastroenterology, Infectiology and Rheumatology, Campus Benjamin Franklin, Berlin, Germany*; *[2]Praxis für Rheumatologie und Innere Medizin, Praxis für Rheumatologie und Innere Medizin, Berlin, Germany*; *[3]Rheumatologische Schwerpunktpraxis, Rheumatologische Schwerpunktpraxis, Berlin, Germany*; *[4]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[5]Rheumapraxis Berlin, Rheumapraxis Berlin, Berlin, Germany*

Background: Psoriatic arthritis (PsA) is a heterogeneous disease with multiple musculoskeletal and dermatological manifestations. Due to this multifaceted clinical appearance, international guidelines do not provide a clear recommendation for one specific score to assess disease activity in PsA [1]. The Disease Activity Index for Psoriatic Arthritis (DAPSA), a validated, unidimensional score focusing on joint involvement, is one of the recommended options [1]. However, routine determination of C-reactive protein (CRP) to calculate DAPSA values takes hours to days. In contrast, quick quantitative CRP (qCRP) tests require only a few minutes and might facilitate regular assessment of the DAPSA (as Q-DAPSA) in clinical routine.
Objectives: To validate the Q-DAPSA in a prospective, multicenter study of PsA patients. Since the Disease Activity Score 28 (DAS28) is not only used in rheumatoid arthritis, but also in PsA patients, the study also investigated the performance of a qCRP based DAS28 (DAS28-qCRP) in a PsA cohort.
Methods: The study was conducted in five centers in Berlin, Germany. Consecutive adult (≥ 18 years) PsA patients were included. In addition to a rheumatological assessment, including patient reported outcomes (PROs), routine CRP and erythrocyte sedimentation rate (ESR) were measured in the local labs. Additionally, a qCRP testing with the „QuikRead go instrument" (Aidian Oy, Finland) was performed locally at the study center (measurement range 0.5 - 200 mg/l for hematocrit concentrations of 40 – 45%). Statistical analysis included descriptive statistics, cross tabulation and weighted Cohen´s kappa comparing disease activity categories, Bland-Altman plots and intraclass correlation coefficient (ICC) for DAPSA, Q-DAPSA, DAS28-CRP and DAS28-qCRP.
Results: In this study 104 patients were included between January and October 2020 (mean age: 51.2 years, mean disease duration: 7.1 years, 49 patients (47.1%) were male). 53 patients (51.0%) were treated with a bDMARD and 37 patients (35.6%) with csDMARDs. CRP and qCRP showed mean values of 5.20 and 6.17 mg/l, respectively. With the Q-DAPSA, 103 patients (99.0%) were assigned to the same disease activity category when compared to DAPSA (Table 1). Weighted Cohen´s kappa was 0.990 (95%CI 0.970; 1.000). ICC for numerical values of DAPSA and Q-DAPSA was 1.000 (95%CI 0.999; 1.000). The agreement of Q-DAPSA and DAPSA is shown in a Bland-Altman plot (Figure 1). DAS28-CRP and -qCRP were available for 103 patients; 101 patients (98.1%)

Table 1. Disease activity categories by Q-DAPSA vs. DAPSA

		Q-DAPSA (n = 104)			
		Remission (≤ 4)	**Low Disease Activity** (> 4 and ≤ 14)	**High Disease Activity** (> 14 and ≤ 28)	**Very high Disease Activity** (> 28)
DAPSA	**Remission** (≤ 4)	**36 (34.6%)**	**1 (1.0%)**		
	Low Disease Activity (> 4 and ≤ 14)		**39 (37.5%)**		
	High Disease Activity (> 14 and ≤ 28)			**22 (21.2%)**	
	Very high Disease Activity (> 28)				**6 (5.8%)**

The fields highlighted in red indicate that disease activity categories do not match.DAPSA = Disease activity index for Psoriatic Arthritis, Q-DAPSA = DAPSA calculated based on a quick quantitative CRP

showed the same disease activity category in the DAS28-qCRP and weighted Cohen´s kappa was 0.951 (95%CI 0.886; 1.000).
Conclusion: The Q-DAPSA and DAPSA showed an almost perfect agreement on the assignment to disease activity categories (99%) with the important advantage of time. With Q-DAPSA, rheumatologists could base their clinical decision-making on a disease activity measurement by using a composite score immediately. Consequently, Q-DAPSA can be integrated in clinical routine and clinical trials and could be implemented into the treat-to-target concept in PsA patients. For rheumatologists who prefer DAS28-CRP for assessing disease activity in PsA patients, DAS28-qCRP may serve as a suitable alternative.

POS1070 **ANXIETY IN PSORIATIC ARTHRITIS PATIENTS: RESULTS FROM THE HUR-BIO BIOLOGIC REGISTRY**

G. Ayan[1], B. Farisoğulları[1], E. Bilgin[1], E. C. Bolek[1], G. K. Yardımcı[1], E. Duran[1], Z. Özsoy[1], G. Sandal Uzun[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], A. İ. Ertenli[1], U. Kalyoncu[1]. [1]*Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey*

Background: Anxiety is commonly observed, underestimated problem in patients with psoriatic arthritis (PsA). Overall rate has been reported around 20% [1]. However the data on anxiety in PsA patients requiring advanced treatment and change in response to therapy is scarce.
Objectives: Our aim was to understand the frequency of anxiety before starting biologic agents and change in the anxiety scores with the treatment.
Methods: PsA patients from the Hacettepe University biological database (HUR-BIO) were assessed for anxiety (score ≥ 4) using the patient self-reported measure of anxiety on a 0-10 numerical scale, included in the Psoriatic Arthritis Impact of Disease questionnaire (PSAID-12) [2]. The anxiety rate and scores were determined before starting biologic agents and at first visit in 6 months. Change in the scores were compared between patients according to the favourable treatment responses (Table 1). The correlation between the score-changes in anxiety and treatment response parameters was assessed by spearman correlation analysis.
Results: From 520 patients registered, 147 [mean (SD) age 43.3 (12.4) years, 70.7% female] had anxiety score registered both at baseline and first visit in 6 months. Both the frequency and mean (SD) score of anxiety decreased at first visit [63.9% vs 41.4 %, 4.8(3.4) vs 3.2 (3.1) respectively, p<0.001 for both] after a mean (SD) follow-up of 105.7 (22.2) days. There was a statistically significant difference between changes in the anxiety scores in patients with/without treatment responses in pain, PGA, BASDAI, HAQ-DI and DAS-28. A positive correlation between the change in anxiety and all treatment response parameters was observed (Table 1, Figure 1).
Conclusion: Anxiety is a more frequent problem at the time of biologic initiation compared to rates observed in general PsA population which could be related to the high disease activity. The rates are still high in 6 months under treatment, however both the frequency and score of anxiety showed a decreasing trend parallel to the treatment response.

DETERMINATION OF THE RELIABILITY AND VALIDITY OF THE BETY-BIOPSYCHOSOCIAL QUESTIONNAIRE IN PATIENTS WITH A DIAGNOSIS OF PSORIATIC ARTHRITIS

S. Bulut[1], E. Ünal2, J. Karakaya[3], U. Kalyoncu[4]. [1]*Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey*; [1]*Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey*; [3]*Hacettepe University, Faculty of Medicine, Department of Basic Medical Sciences, Ankara, Turkey*; [4]*Hacettepe University, Faculty of Medicine, Department of Internal Medical Sciences, Ankara, Turkey*

Background: In the literature, there is a lack of questionnaires, which is evaluate patients with psoriatic arthritis (PsA) from a biopsychosocial perspective.
Objectives: This study was planned to examine the reliability and validity of the BETY- Biopsychosocial Questionnaire (BQ) in individuals diagnosed with PsA.
Methods: Test-retest method was used to examine the reliability of the BETY-BQ. In comparing the reliability of test-retest results, ıntraclass coefficient (ICC) was checked. For the internal consistency analysis of the BETY-BQ, the total score of the responses given to the first filled scale was calculated and the Cronbach's Alpha coefficient was found. Psoriatic Arthritis Quality of Life Questionnaire (PsAQoL), Health Assessment Questionnaire (HAQ), Hospital Anxiety and Depression Scale (HADS) and Short Form-36 (SF-36) were used in the validity study of 150 individuals with PsA included in the study.
Results: Test-retest method and intraclass coefficient were examined for reliability analysis (for 30 patients). The correlation (r = 0.844, p <0.001) of the answers given to the BETY-BQ by individuals with 30 PsA after one week interval was very high. While the ICC coefficient (0.915, p <0.001) showed excellent reliability. The Cronbach's Alpha coefficient (0.940) was examined for internal consistency and the internal consistency of the scale was also found to be excellent. As a result of statistical analysis, the correlation between the scales used and the BETY-BQ was found between r = -0.432 and 0.807 (p <0.001).
Conclusion: With this study, it was concluded that the BETY-BQ is a reliable and valid assessment tool in individuals diagnosed with PsA, and is also a biopsychosocial tool that can be used to evaluate individuals with PsA.

Background: Limited data are available regarding the burden of nail disease in psoriatic arthritis (PsA). The latest data show that nail involvement in PsA patients (pts) is associated with significantly more severe disease status (1).
Objectives: To analyze, in clinical practice, the association of nail psoriasis with disease activity, quality of life, and work productivity in PsA pts.
Methods: 588 pts (M/F–277 /311) with PsA according to CASPAR criteria were included in the study. Data were collected from 43 rheumatology clinics from different regions of the Russian Federation. Pts' age 48.6±0.5 years (yrs), disease duration 7.0±0.3 yrs. Pts underwent standard clinical examination of PsA activity. Pts were split into two groups (gr.): those with nail psoriasis – gr.1, and those without it – gr.2. Demographics, disease activity, quality of life, and work productivity were compared between pts with and without nail psoriasis using Pearson's chi-square test and Mann–Whitney U test.
Results: Gr.1 includes 312 (53.1%) cases, gr.2 – 276 (46.9%) cases. More pts in gr.1 were males (51.9% vs 44.1%, p=0.013), disabled at work (37.20% vs 26.40%, p=0.000), chronic smokers (18.9% vs 8.7%, p=0.000) and with axial PsA disease signs according to physician (35.0% vs 26.4%, p=0.025) compared to pts in gr.2. Pts in gr.1 had higher tender and swollen joint counts: 8 [4-15] vs 5 [2-12] (p=0.002) and 5 [1-9] vs 2 [0-7] (p=0.003) respectively. Gr.1 pts had higher disease activity measured by DAPSA 25 [15-39] vs 20 [12-33] (p= 0.001), higher frequency of dactylitis (24.4% vs 16.7% p=0.022) and heel enthesitis (17.0% vs 10.1% p=0.016) respectively, higher frequency of erosive radiographic arthritis of feet (45.0% vs 31.2% p=0.003) compared to gr.2 pts. Pts in gr.1 had worse skin psoriasis measured by Psoriasis Area Severity Index – 6 [2-14] vs 3 [1-6] (p=0.000). Less pts in gr.1 than in gr.2 (27.0% vs 52.0% p=0.004) achieved minimal disease activity (MDA). Pts' reported outcomes (PRO's) in gr.1 were worse than in gr.2 in regard to reduced health-related quality of life according to PsAID (4.9±2.3 vs 4.0±2.3, p=0.040) and to EQ-5D (0.56±0.19 vs 0.64 ±0.21, p=0.024) questionnaires, overall work impairment (0.0 [0.0-0.3] vs 0.0 [0.0-0.2], p=0.034) and overall activity impairment (0.4 [0.1-0.7] vs 0.3 [0.0-0.5], p=0.006) according to WPAI.
Conclusion: Nail involvement in PsA pts is associated with male gender and axial disease. PsA pts with nail involvement are more often disabled, more often are chronic smokers, have significantly worse disease status as measured by disease activity; they are more likely to have more severe (erosive) peripheral arthritis of feet, higher frequency of heel enthesitis and dactylitis, higher psoriasis disease severity, lower frequency of MDA achievement, and worse quality of life and work productivity according to PRO's. Detection of nail involvement is critical for choice of treatment approach and better outcomes.

AXIAL PSORIATIC ARTHRITIS AND ANKYLOSING SPONDYLITIS. SAME OR DIFFERENT? A REAL-WORLD STUDY WITH EMPHASIS ON COMORBIDITIES

G. E. Fragoulis[1], M. Pappa[1], G. Evangelatos[1], A. Iliopoulos[2], P. Sfikakis[1], M. Tektonidou[1]. [1]*National and Kapodistrian University of Athens, First Department of Propaedeutic Internal Medicine, Joint Rheumatology Program, Athens, Greece*; [2]*417 Army Shared Fund Hospital "NIMTS", Department of Rheumatology, Athens, Greece*

Background: Axial involvement affects 25-70% of psoriatic arthritis (PsA) patients, depending on the criteria used for its definition. Efforts are underway to clarify the similarities and differences between axial-PsA and ankylosing spondylitis (AS).
Objectives: We aimed to compare, in a real-world setting, axial-PsA and AS, in terms of demographic, radiologic and clinical (musculoskeletal and extra-articular) characteristics, with a focus on comorbidities.
Methods: All AS (New York criteria, n=128) and PsA patients (CASPAR criteria, n=78) with axial involvement who were regularly followed-up in the outpatients' rheumatology clinics from two tertiary hospitals (December 2018-July 2020) were included. Axial-PsA was defined when both of the following were ever present: inflammatory axial symptoms and radiological findings in X-ray or MRI of the sacroiliac joints or the spine. The following findings were considered: sacroiliitis (unilateral ≥ grade 3 or bilateral ≥ grade 2), corner lesions or squaring in the vertebrae, syndesmophytes (marginal or para-marginal) and facet joints arthritis.
Demographic, radiologic and clinical characteristics including comorbidities were compared between AS and axial-PsA. For comorbidities (Major Adverse Cardiovascular Events [MACE: combined coronary disease and cerebrovascular accidents], hypertension, diabetes mellitus, dyslipidemia, depression, osteoporosis, and malignancies), adjustments were made for relevant confounders as follows: MACE were adjusted for: age, gender, smoking, hypertension, dyslipidemia, disease duration, DM and non-steroidal anti-inflammatory drugs [NSAIDs] use; depression for: age, gender and disease duration; malignancy for: age, gender, disease duration; hypertension for: age, sex, BMI, NSAIDs use, smoking for; DM: age, sex, BMI, glucocorticoids treatment; osteoporosis for: age, sex, glucocorticoids treatment. Statistical significance is considered for p-values less than 0.05 and 0.1 in univariate and multivariate analyses, respectively.
Results: AS patients were younger (p=0.05) and were diagnosed at a younger age (p=0.002), more frequently of male gender (p=0.04), had lower BMI (p=0.006) and they were more frequently HLA-B27-positive (p=0.006). In AS patients, peripheral arthritis, dactylitis and nail involvement were less common (p=0.001 for all), in contrast to eye (p=0.001) and bowel involvement (p=0.004). Frequency of radiologic abnormalities in the spine was similar between the two groups while sacroiliitis was more often bilateral in AS and unilateral in axial-PsA (p<0.001 for both) Comorbidities, including MACE, were comparable between AS and axial-PsA, apart from depression which was more frequent in axial-PsA (Table 1. next page).

Table 1. Comorbidities. Comparison between axial-PsA and AS. OR: odds ratio, MACE: Major cardiovascular events. * adjustments are reported in the text

Comorbidities	axial-PsA (n=79)	AS (n=129)	Crude OR (95%CI)	Adjusted OR (95%CI)	p-value
MACE* n (%)	4 (5.1)	6 (4.6)	0.91 (0.25-3.34)	1.73 (0.32-9.34)	0.526
Dyslipidemia n (%)	37 (46.8)	45 (34.9)	0.61 (0.34-1.07)	NA	0.108
Hypertension* n (%)	27 (34.2)	24 (18.6)	0.44 (0.23-0.83)	1.11 (0.38-3.21)	0.843
Diabetes mellitus* n (%)	12 (15.2)	10 (7.7)	0.47 (0.19-1.14)	1.65 (0.43-6.29)	0.463
Depression* n (%)	19 (24.1)	16 (12.4)	0.44 (0.21-0.93)	0.48 (0.22-1.07)	**0.07**
Osteoporosis* n (%)	3 (3.8)	10 (7.7)	2.13 (0.57-7.98)	2.40 (0.56-10.18)	0.235
Malignancies* n (%)	3 (3.8)	3 (2.3)	0.60 (0.12-3.06)	0.87 (0.16-4.70)	0.870

Conclusion: AS and axial-PsA have certain clinical and radiologic differences. Comorbidities were comparable, while depression was more common in axial-PsA.

POS1074 CARDIOVASCULAR RISK FACTORS IN A MEXICAN MESTIZO PATIENTS WITH PSORIATIC ARTHRITIS

S. Lugo-Perez[1], I. J. Colunga-Pedraza[2], J. R. Azpiri-López[1], D. Á. Galarza-Delgado[2], A. B. Rodriguez-Romero[2], N. Guajardo-Jauregui[2], D. E. Flores Alvarado[2], A. Cárdenas[2], O. Ilizaliturri Guerra[2]. [1]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*; [2]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*

Background: Psoriatic Arthritis (PsA) is a chronic inflammatory arthropathy that affects 14%-30% of patients with skin and/or nail psoriasis. Patients with psoriatic arthritis (PsA) have a higher prevalence of traditional cardiovascular (CV) risk factors and an increased risk of developing cardiovascular diseases (1), such as acute myocardial infarction, cerebrovascular accident, peripheral vascular disease and heart failure. Despite the evidence patients with PsA are inadequately screened and undertreated for CV risk factors (CVRF), highlighting a gap in preventive medicine to adjust cardiovascular therapies(2).
Objectives: The aim of the study is to determine the main CVRF in Mexican Mestizo patients with a diagnosis of PsA and to compare it with healthy controls. Additionally, to assess the impact of the diagnosis of PsA on the presence on these cardiovascular comorbidities.
Methods: A cross-sectional, observational, and comparative study of ninety-six patients with PsA between 40-75 years who fulfilled CASPAR criteria 2006. Patients were matched by age and gender with non-PsA subjects. A medical history and physical exam were performed, also a blood sample was collected during the first visit. Chi square and Student´s t test were used for comparations between groups. A binary logistic regression was performed including the traditional CVRF (type 2 diabetes mellitus, hypertension, obesity, and active smoking), age and the diagnosis of PsA. A p value <0.05 was considered statistically significant.
Results: There were 58 (60.4%) women in each group with a mean of 53 years. Patients with PsA showed a higher prevalence of hypertension (HTN) compared to healthy controls (35.4% vs 19.8%, respectively, p = 0.015). Additionally, there was a significant difference in the diagnosis of dyslipidemia (42.7% vs 22.9%, p = 0.003).We found no statistically difference between the two groups in type 2 diabetes mellitus, active smoking and, obesity (Table 1. below).

Table 1. Comparison of cardiovascular risk factors between Psoriatic Arthritis and controls.

	PsA (n=96)	Control (n=96)	p
Age, years ± SD	53.19 ± 11.13	53.34 ± 8.4	NS
Women, n (%)	58 (60.4)	58 (60.4)	NS
T2DM, n (%)	21 (21.9)	12 (12.5)	NS
HTN, n (%)	34 (35.4)	19 (19.8)	**0.015**
Active smoking, n (%)	21 (21.9)	20 (20.8)	NS
Dyslipidemia, n (%)	41 (42.7)	22 (22.9)	**0.003**
Obesity, n (%)	36 (37.5)	25 (26.0)	NS

NS, no significative; SD, standard deviation; HTN, hypertension; T2DM, type2 diabetes mellitus.

The binary logistic regression showed that the diagnosis of PsA (OR 2.235, 95% CI 1.141-4.375, p = 0.019) and active smoking (OR 2.429 95%, CI 1.137-5.186, p = 0.022) are independent risk factors for the presence of dyslipidemia.
Conclusion: Patients with PsA have a higher prevalence of HTN and dyslipidemia. The diagnosis of PsA seems to be an independent factor for the presence of dyslipidemia. It is important for rheumatologists to identify those patients who could benefit from adjust antirheumatic and cardiovascular therapies due to their impact on morbidity and mortality.

POS1075 PREDICTIVE FACTORS ASSOCIATED WITH DEVELOPMENT OF PSORIATIC ARTHRITIS IN PATIENTS WITH UNDERLYING PSORIASIS

W. Y. Loo[1], F. Yahya[1], W. H. Han[2], N. A. A. Fahem[2], S. S. Yong[2], L. S. L. Pok[1], Z. Kwan[2], Y. C. Tee[1]. [1]*University of Malaya, Rheumatology Unit, Medicine, KUALA LUMPUR, Malaysia*; [2]*University of Malaya, Dermatology Unit, Medicine, KUALA LUMPUR, Malaysia*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory condition in which a delayed diagnosis will have health impacts including physical and psychological aspects. Thus, identification of risk factors and early diagnosis are crucial in clinical practice. In Malaysia, 13.7% of patients with underlying psoriasis develop PsA [1]. However, there are limited data on the risk factors in developing PsA in these patients, not just in Malaysia but also in the Southeast Asia region.
Objectives: To analyse sex, clinical features, comorbidities in patients with psoriasis and PsA, and the predictive factors of developing PsA in patients with underlying psoriasis.
Methods: A retrospective study was carried out involving patients with a physician-verified diagnosis of psoriasis who were attending the dermatology and/or rheumatology clinics at the University of Malaya Medical Centre, Kuala Lumpur between 2015 to 2020. Data were retrieved from electronic medical records. Data collected included sex, age, body mass index (BMI), duration of psoriasis, socio-demographics, comorbidities, body area affected, severity of skin involvement, presence of nail involvement and systemic therapy used in treating psoriasis. Systemic therapy is defined as methotrexate, sulfasalazine and/or acitretin used before diagnosis of PsA. Patients with psoriasis who developed PsA had information collected on tender joint count, swollen joint count and erythrocyte sedimentation rate (ESR) at their initial visit to the rheumatologist. Logistic regression analyses were performed to identify the possible risk factors of developing PsA.
Results: A total of 330 psoriasis patients which included 54.5% male and a mean age of 53 (standard deviation, SD 18.85) years were included. Eighty-three (25.0%) patients were diagnosed with PsA. Among patients with PsA, 39.8% were males with a mean age of 54 (SD 15.79) years. Majority of the PsA patients were ethnic Malay (45.8%), followed by 28.9% Chinese and 25.3% Indian. The median duration of developing PsA was at 36 (IQR 3.5 - 114) months after the

diagnosis of psoriasis. 12.3% presented with active polyarthritis at the initial diagnosis of PsA. There was a significant difference in the use of systemic therapy in females, in which there was a higher rate of systemic therapy used in female PsA patients prior to developing PsA as compared to females with psoriasis who did not develop PsA (n=24, 48% vs n=16, 16%; p < 0.001). There was no significant association between ethnicity, education level, comorbidities, BMI, body area affected and family history of psoriasis with development of PsA. The predictive factors in developing PsA are females (OR = 3.14, 95% CI 1.77,5.58), presence of nail involvement (OR = 3.72, 95% CI 1.91,7.26) and the use of systemic therapy (OR = 3.04, 95% CI 1.70,5.43), (all p values <0.001).

Conclusion: This study highlighted that female sex, presence of nail involvement and use of systemic therapy prior to PsA diagnosis are predictive risk factors in developing PsA among patients with underlying psoriasis. Further prospective studies with larger cohorts are needed to better delineate these risk factors.

POS1076 APICAL FIBROSIS AND INTERSTITIAL LUNG DISEASE IN PATIENTS WITH PSORIATIC ARTHRITIS: DO WE UNDERESTIMATE?

G. Ayan[1], E. B. Ata[2], G. Durhan[3], M. Ariyurek[3], U. Kalyoncu[1]. [1]*Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey*; [2]*Hacettepe University Medical Faculty, Department of Internal Medicine, ANKARA, Turkey*; [3]*Hacettepe University Medical Faculty, Department of Radiology, ANKARA, Turkey*

Background: Extra-articular manifestation (EAMs) definition is not clearly defined in psoriatic arthritis (PsA). Nail involvement, enthesitis, dactylitis has been widely studied however, data are needed on pulmonary involvement in PsA.

Objectives: We aimed to understand real-life results of lung involvement in PsA patients.

Methods: From the PsA cohort followed in our outpatient clinic, patients who have been requested a chest computed tomography (CT) for any reason by any department were retrieved from medical records and included in this retrospective cross-sectional analysis. All CTs were assessed by a radiologist who is blinded to the patients` clinical history and findings were categorized as parenchymal, airway, pleural findings and lymphadenopathy (LAM). Moreover, any findings that are radiologically attributed to a specific entity such as previous tuberculosis (Tb) infection were noted. Demographic/clinic data including smoking status, concomitant lung problems, disease characteristics (duration, axial/peripheral involvement) were collected and analyzed.

Results: A total of 80/1072 (7.4 %; 65% female) PsA patients with mean (SD) age 56.1 (13.2) years were included in the study. Median (IQR) PsA duration was 23.5 (55.75) months and 36 (45%) patients had peripheral, 29 (36.3%) patients had axial involvement. For the rest of 15 (18.7 %) patients, radiographic assessment was missing. Smoking status could be retrieved in 47 patients (never=40.4%, ex-smoker= 19.1%, current smoker=40.4%). There were 14 concomitant lung problem in 12 (15%) patients. CT findings showed that 68.8% of patients had at least one lung pathology. Parenchymal findings were seen in 65% of the patients as both non-spesific changes (atelectasis, n= 35; nodules, n=24; ground glass opacity, n= 9; sequelae fibrosis, n= 9; emphysema, n= 7; consolidation, n= 5, interstitial thickening, n= 5; pulmonary cyst, n =4) and specific pathologies as apical fibrosis (AF) (n=5) and intersititial lung disease (ILD) (n=5, NSIP=3, LIP=2). AF was linked to previous Tb infection in 1 patient and radiotherapy in another (Table 1). However, there is no specific pathology in the rest of 3 (3.7%) patients that AF could be attributed to and all of them were male. Other pathologies were seen as airway findings in 28.8% patients (bronchiectasis, n= 17, bronchial wall thickness, n= 10, air trapping n= 7, centrilobular opacity, n= 4,) and pleural findings in 13.8 % of the patients (pleural plaque, n= 5, effusion, n= 3, thickness, n=3). LAM was observed in around 4% of the patients.

Table 1. Patient characteristics with apical fibrosis, interstitial lung disease

	Involvement	Gender	Age	PsA duration, months	Axial Disease (yes/no)	Smoking Status	Smoking pack-age-years	Concomitant Lung Disease (yes/no)	Linked to another problem by radiologist (yes/no)
ID-1	AF	M	58	2	No	Current	40	No	No
ID-2	AF	M	61	1	No	Current	40	No	No
ID-3	AF	M	73	122	Yes	Ex	30	No	No
ID-4	AF	F	55	1	Yes	NA	NA	No	Yes*
ID-5	AF	F	65	#	NA	Never	-	Yes€	Yes€
ID-6	NSIP	F	96	NA	NA	Never	-	No	No
ID-7	NSIP	M	69	NA	NA	Ex	15	Yes$	No
ID-8	NSIP	F	66	156	No	NA	NA	Yes$	No
ID-9	LIP	M	61	200	Yes	Never	-	No	No
ID-10	LIP	F	80	14	Yes	NA	NA	No	No

AF= Apical fibrosis; NSIP= Non-spesific interstitial pneumonia, LIP= Lymphocytic interstitial pneumonia; PsA= Psoriatic Arthritis, NA= Not available*radiotherapy sequelae; # tomography was done prior to PsA diagnosis; € previous tuberculosis infection; $ chronic obstructive pulmonary disease

Conclusion: The real-life experience of our PsA cohort showed that pulmonary findings included variable spesific, non-spesific findings. As a limitation results represent the CT findings of around 8% of our PsA cohort. Within the scope of previous reports male predominant AF and ILD come forward in PsA that requires further attention in future studies [1,2].

POS1077 CLINICAL AND RADIOLOGICAL FEATURES OF SEROPOSITIVE PSORIATIC ARTHRITIS

H. EL Moutaouakil[1], K. Nassar[1], S. Janani[1]. [1]*University Hospital of Ibn Rochd, Department of Rheumatology, casablanca, Morocco*

Background: Rheumatoid factor (RF) and anti-cyclic citrullinated peptides (anti-CCP) are two highly specific laboratory markers for rheumatoid arthritis. However, they can also be found in other chronic inflammatory arthritis such as psoriatic arthritis (Psa).

Objectives: The aim of our study is to analyze the different epidemiological and paraclinical characteristics of seropositive psoriatic arthritis.

Methods: Descriptive and analytical retrospective study from January 2010 to December 2020 conducted in the Department of Rheumatology of the University Hospital of Ibn Rochd, Casablanca.

Inclusion criteria: patients diagnosed with psoriatic arthritis according to the CASPAR or ASAS 2009 criteria, regardless of the immunological status (RF/anti-CCP).

The patients were then divided into two groups: seropositive (positive anti-CCP and / or positive RF) and seronegative. A univariate analytical study was performed by jamovi version 1.2.27

Results: 80 patients were enrolled. 22 patients were seropositive (Group 1) and 58 were seronegative (Group 2). In the group 1, the mean age was 51.1 years (+/- 9.45). The sex ratio M/F was 0.29, the mean age of onset was 43.5 years (+/- 10.4), the mean duration of disease was 9.55 +/- 8 years. All patients had skin involvement. Polyarticular involvement was present in all cases; axial involvement was present in 68.18% of cases and enthesitis in 68.18% of cases. All patients were HLA B 27 negative. The presence of X-ray and / or ultrasound bone

Table 1. Comparison of characteristics of seropositive and seronegative PsA patients

Items	Group 1 Seropositive patients (n=22)	Group 2 Seronegative patients (n=58)	p-value
Age (years)	51.1 +/-9.45	50.7 +/- 15.8	0.9
Sex ratio M/F	0.29	1.14	0.013
Age onset (years)	43.5 +/- 10.4	37.4+/- 16.5	0.123
Skin involvement (%)	100	50	0.009
Bone erosions (%)	81.1	56.9	<0.001
Response to treatment (%)	70.58	51.14	<0.001

erosions in addition to signs of destruction was in 81.8% of cases. The response to treatment with (corticosteroids / NSAIDs / DMARDs) was partial in 70.58%.
In group 2, the mean age was 50.7 years (+/- 15.8). The sex ratio M/F was 1.14, the mean age of onset was 37.4 years (+/- 16.5), the mean duration of disease was 13.3 years (+/- 9.5). Skin involvement was present in 50% of patients. Polyarticular involvement was present in all cases, axial involvement was present in 67.24% of cases and enthesitis in 56.9% of cases. All patients were HLA B 27 negative. The presence of X-ray and / or ultrasound bone erosions in addition to signs of destruction was in 56.9% of cases. The response to treatment with (corticosteroids / NSAIDs / DMARDs) was partial in 57.14%.
Conclusion: The presence of anti-CCP according to several studies is linked to the presence of deformities, dactylites and radiological erosions (1,2). In our series, seropositivity was accompanied by the erosive nature of the destruction, as well as a tendency to resistance to treatment.

POS1078

CURRENT REGISTRIES IN PSA DO NOT WELL REFLECT THE PROFILES OF PATIENTS WITH PsA BECAUSE THEY ORIGINATE IN SIMILAR COUNTRIES: A SYSTEMATIC LITERATURE REVIEW OF 27 REGISTRIES, OR 16183 PATIENTS

G. S. Moysidou[1], K. Aouad[1], A. Rakotozafiarison[1], B. Fautrel[1], L. Gossec[1].
[1]*Sorbonne Université – INSERM; AP-HP, Pitié Salpêtrière Hospital, Rheumatology department, Paris, France*

Background: Psoriatic arthritis (PsA) is a multidimensional inflammatory disease with a great geographic variability and a global average prevalence estimated at 133 every
100,000 subjects according to a recent systematic review and meta-analysis (1). Registries and cohorts reflect more closely real-world data than randomized controlled trials (RCTS) and may indicate ongoing interest of each country on PsA.
Objectives: The purpose of this study is to assess how recent registries and PsA related cohorts reflect its worldwide prevalence.
Methods: A systematic literature review was performed in Pubmed Medline (PROSPERO
CRD42020175745) to identify all articles reporting on either registries or longitudinal cohorts in PsA, published between 2010 and March 2020. Registries centered on drugs or not PsA-specific, trials and long term extension studies were excluded. The data collection comprised registries' and cohorts' originating countries, patient characteristics and the clinical outcome measures reported. Statistics were descriptive.
Results: Of 673 articles, 73 were relevant for analysis, corresponding to 27 registries or PsA specific cohorts, with the participation of 30 countries. The overall number of patients was 16,183 with a mean of 599 per study. Overall, 50.1% were men, weighted mean age was 50,6 years and weighted mean disease duration was 6.9 years.
Most of the registries were based in Europe (67%) or North America (26%) whereas Africa was underrepresented (Figure 1). USA was the most represented country participating in 6 registries. Mean age and mean disease duration were shorter in international registries (Table 1). Caspar diagnostic criteria were the most frequently used, mainly in the national registries (86,4%), whereas the use of diagnostic criteria was more heterogenous in the international registries.
Conclusion: Recent registries and PsA specific cohorts do not cover the worldwide spectrum of the disease.

ASSOCIATION OF C-REACTIVE PROTEIN AND NON-STEROIDAL ANTI-INFLAMMATORY DRUGS WITH CARDIOVASCULAR EVENTS IN PATIENTS WITH PSORIATIC ARTHRITIS: A TIME-DEPENDENT Cox REGRESSION ANALYSIS

S. H. M. Lam[1], H. So[1], I. T. Cheng[1], E. LI[1], P. C. Wong[1], T. K. LI[1], A. P. W. Lee[1], L. S. Tam[1]. [1]*The Chinese University of Hong Kong, Department of Medicine and Therapeutics, Sha Tin, Hong Kong (SAR)*

Background: Psoriatic arthritis (PsA) is associated with accelerated atherosclerosis due to underlying inflammation. Whether inflammatory burden and drugs used to suppress inflammation over time are associated with cardiovascular (CV) events remains unclear.

Objectives: This study aims to examine the time-varying effect of C-reactive protein (CRP) levels and the use of drugs including non-steroidal anti-inflammatory drugs (NSAIDs) on the risk of CV events independent of traditional CV risk factors in PsA patients.

Methods: A retrospective cohort analysis was performed in patients with PsA who were recruited from 2008 to 2015 and followed till the end of 2019. The outcome was occurrence of a first CV event. Framingham risk score (FRS) was used to quantify the traditional CV risk. Cox proportional hazard models with time-varying CRP levels and drugs used were analyzed to identify the risk factors for CV events in PsA patients.

Results: 200 patients with PsA (median age: 47.5[40.0 – 56.0]; male: 119 [59.5%]) were recruited (Table 1. next page). After a mean follow-up of 8.8±3.8 years, 30 (15%) patients developed a first CV event. The Kaplan-Meier survival analysis indicated a significant difference in the CV event-free survival between patients with and without CRP level >3 mg/L (Figure 1A) and an inverse relationship between time-varying NSAIDs exposure and CV event-free survival (Figure 1B). The multivariable Cox regression model showed that time-varying CRP level (HR 1.02, 95% CI 1.00 to 1.04) and NSAIDs exposure (HR 0.30, 95% CI 0.15 to 0.95) were significantly associated with CV events after adjusting for baseline FRS (HR 5.04, 95% CI 1.83 to 13.85).

Table 1. Baseline demographic and clinical characteristics, cardiovascular risk factors and treatments received.

POS1080

HYPERLIPIDEMIA IN PSORIATIC DISEASE: HIGHER PREVALENCE IN PSORIATIC ARTHRITIS AND INVERSE ASSOCIATION WITH SYSTEMIC THERAPY

R. Queiró Silva[1], E. Pardo Campo[1], S. Fernández[1], L. Arboleya Rodríguez[1], I. Zapico[1], F. Jirout[1]. *[1]Hospital Universitario Central de Asturias, Rheumatology, OVIEDO, Spain*

Background: Although the evidence that testifies to a higher prevalence of cardiometabolic risk factors in psoriatic disease is robust, there are not too many studies that have analyzed which disease traits are associated with these risk factors both in psoriasis and psoriatic arthritis[1].

Objectives: We aimed to analyze the frequency and disease-associated features of hyperlipidemia in psoriatic disease.

Methods: Cross-sectional observational study that included 290 patients with psoriatic arthritis (mean age 54 ± 12 years, 54.8 % male, psoriasis average duration 21 ± 10 years) and 310 with psoriasis alone (mean age 53 ± 11.5 years, 52.9% male, psoriasis average duration 22 ± 11 years). We first analyzed the frequency of this comorbidity and then the factors associated with it using conditional logistic regression. The significant factors in this first model were introduced in a multivariate model using a backward stepwise approach.

Results: Main disease features are depicted in Table 1. A total of 124 patients had hyperlipidemia (20.7%). Among arthritis patients, 82/290 (28.3%) had hyperlipidemia, compared with 42/310 (13.5%) of those with psoriasis alone (OR 2.5, 95%CI: 1.7–3.3, p < 0.001). Hyperlipidemia was independently associated with age [OR 1.07, 95%CI: 1.04–1.11, p < 0.001] and systemic therapy [OR 0.4, 95%CI: 0.17–0.89, p = 0.026].

Conclusion: Hyperlipidemia is common in psoriatic disease, but much more among arthritis patients. This comorbid factor seems to go in parallel with increasing age. There is an inverse association between systemic treatment and hyperlipidemia that should be endorsed with well-designed longitudinal studies.

POS1081 OSTEOPOROSIS AND INSUFFICIENCY RISK FACTORS IN PSORIATIC ARTHRITIS

M. P. Martínez-Vidal[1], V. Jovani[2], A. Alvarez de Cienfuegos[3], J. R. Noguera-Pons[4], R. Martín-Domenech[5], M. T. Pedraz-Penalva[5], P. Bernabéu[2]. [1]*Hospital Universitario de San Juan de Alicante, Rheumatology, Alicante, Spain*; [2]*Hospital General Universitario de Alicante, Rheumatology, Alicante, Spain*; [3]*Hospital Vega Baja Orihuela, Rheumatology, Orihuela, Spain*; [4]*Hospital General Universitario de Elche, Rheumatology, Elche, Spain*; [5]*Hospital General Universitario de Elda, Rheumatology, Elda, Spain*

Background: Osteoporosis (OP) has been described to be frequent in spondyloarthritis [1]. However, the specific association of psoriatic arthritis (PsA) and bone fragility remains inconclusive, with a prevalence of OP ranging from 1.4–68.8 [2, 3].
Objectives: The aim of this study was to describe the prevalence of osteopenia and OP in a representative cohort of patients with PsA
Methods: Multi-centric, cross-sectional, descriptive study of patients with clinical diagnosis of PsA. Patients were randomly selected; they were invited to participate and were included after signing informed consent until the calculated sample size was reached. Clinical and demographic characteristics were recorded, as well as several protective and risk factors for osteoporosis and insufficiency fractures. Patients were asked to undergo a hip and lumbar (L2-L4) densitometry by DXA, and lateral X-Ray of the dorsal and lumbar spine if they had not these tests available in the previous year. The prevalence of osteoporosis and the risk factors was calculated. The characteristics of the patients with OP were compared to those without by univariate analyses, and were adjusted by age and sex. Multivariate analyse by ANOVA test was done to study the association of OP and fractures with clinical characteristics of the disease. The Clinical Research Ethics Committee of the Hospital General Universitario de Alicante (ISABIAL- approval number 180264) approved the study
Results: 166 patients were included (Female 69%, male 30,1%), median age 58 (IR 51-65). Basal characteristics are shown in Table 1. Osteopenia or OP was present in 100 patients (60.2%). OP was present in 44 patients (26.5%). Among these, 9 patients (20.5%), all women ≥50 years old, had a total amount of 14 insufficiency fractures (4 vertebrae, 2 hips, 4 distal radius, 4 others). OP was present in 21.7% of the women, and 4.8% of the men. The most frequent risk factors among patients with OP were D-vitamin deficit (54.5%), sedentary life style by WHO standards (43.2%) and low calcium intake (38.6%). The most frequent protector factors in the group without osteopenia/nor OP was the intake of statins for ≥12 months. The presence of vertebral fractures was associated with female sex, sedentary lifestyle and age.
Conclusion: The prevalence of insufficiency fractures among PsA patients was very superior to that recently found in the general population in Spain (prevalence 1.83%) [4]. Fractures are associated, similar to the general population, to female sex, sedentary life and age. Inherent factors to psoriatic disease may be responsible for this increased prevalence

POS1082 CATASTROPHIZING IN PATIENTS WITH PSORIATIC ARTHRITIS

C. Gaujoux-Viala[1,2], B. Coste[1], C. Traverson[1], E. Filhol[1,2], S. Laurent-Chabalier[3], J. Morel[4,5], B. Combe[4,5], C. Daien[4,5], C. Lukas[2,4], C. Hua[1,2]. [1]*Nîmes University Hospital, Rheumatology, Nîmes, France*; [2]*University of Montpellier, IDESP, UMR-INSERM, Montpellier, France*; [3]*Nîmes University Hospital, BESPIM, Nîmes, France*; [4]*CHU Lapeyronie, Rheumatology, Montpellier, France*; [5]*University of Montpellier, Montpellier, France*

Background: Catastrophizing is a negative cognitivo-affective response to an anxiety-provoking stimulus, especially anticipated or actual pain. It can be quickly assessed using a validated questionnaire: the Pain Catastrophizing Scale (PCS)[1]. Catastrophizing plays a role in maintaining chronic pain and is associated with several pain-related outcomes in osteoarthritis and low back pain. To our knowledge, there are no data on catastrophizing in patients with psoriatic arthritis (PsA).
Objectives: To assess the prevalence of catastrophizing and associated factors in PsA.
Methods: We performed a bi-centric observational, prospective study. All patients aged 18 or over with PsA fulfilling the 2006 CASPAR criteria were consecutively included. Sociodemographic data, information on the disease and its treatments were collected as well as questionnaires for disease activity (BASDAI), function (HAQ, BASFI), quality of life (SF12, EQ5D), anxiety and depression (HADS, GAD7), fibromyalgia (FiRST), insomnia (ISI) and catastrophizing scores (PCS). Statistical analysis included samples T-test, one-way variance analysis, Spearman's correlation coefficient, Chi^2 test, Fisher's exact test, Wilcoxon test, multivariate linear regression (considering catastrophizing as a continuous variable) and multivariate logistics regression (considering catastrophizing as a categorical variable: PCS ≥ 20 = high level catastrophizing).
Results: From September 2019 to March 2020, 85 PsA patients were included: 54.1% were women, the median age was 54.0 years and 33 patients (39.8%) were professionally active. The majority of patients (88.2%) had a disease lasting for more than 2 years. Axial involvement was found for 39 patients (45.9%), almost all patients (98.8%) had peripheral involvement, 32 patients (37.7%) had enthesitic involvement and 14 patients (16.7%) had erosions. Median DAS28 CRP was 3.12 [2.13-4.46] and the median BASDAI score was 5.50 [4.30-6.70]. The prevalence of a PCS score ≥20 was 45.9% [35.3;56.5]. The median PCS score was 16 [6-29]. In multivariate logistics regression, high-level catastrophizing was significantly associated with the HADS anxiety score (OR=1.35 [1.15-1.61]) and pain VAS (OR=1.04 [1.02-1.06]). In multivariate linear regression, catastrophizing was significantly associated with the HADS anxiety score (p= 0.004), pain VAS (p=0.001), HADS depression score (p=0.018) and insomnia score (p=0.034).
Conclusion: Almost half the patients with PsA were high catastrophizers. Catastrophizing is related to anxiety, pain, depression and insomnia. It may be interesting to detect catastrophizing in order to improve the care of our patients.

POS1083 PSORIATIC DISEASE – A HETEROGENOUS DISEASE WHO NEEDS A MULTIDISCIPLINARY CARE!

B. Santos[1], J. Antao[2], M. Loureiro[3], A. Barcelos[1]. [1]*Centro Hospitalar do Baixo Vouga, Rheumatology, Aveiro, Portugal*; [2]*University of Aveiro, Medical Statistic, Aveiro, Portugal*; [3]*Centro Hospitalar do Baixo Vouga, Dermatology, Aveiro, Portugal*

Background: Rheumatologists and Dermatologists usually manage Psoriatic Arthritis (PsA) and Psoriasis (PsO) separately, but early diagnosis and integrated management could achieve better outcomes with gains in quality of life of the patients. A multidisciplinary care is essential to achieve these goals.
Objectives: The aim of this study is to describe a model of integrated multidisciplinary approach for early diagnosis of PsA and the multidisciplinary management of PsA patients.
Methods: A retrospective study including patients that attended the multidisciplinary clinical from January 2019 to December 2020 was performed. Patients with PsO complaining articular symptoms and patients with articular symptoms with cutaneous lesions suspected to be PsO was referred to this clinical. Demographic, clinical data and disease activity measures were collected. Descriptive, Student's t and Fisher test and Odds Ratio were estimated.
Results: A total of 50 patients were referred to multidisciplinary clinical. Of these, 40 patients met criteria for psoriatic arthritis according to CASPAR criteria:

22 (55%) were male and median age was 49.5 ± 11.5 years. Family history of psoriasis was present in 19 (47.5%) and 7 (17.5%) had spondyloarthritis family history. Obesity and overweight were the comorbidities most found, 42.9% and 37.1%, respectively, followed by hypertension 25%, dyslipidaemia and depression 22.5% and metabolic syndrome 15%. Thirty-three patients (84.6%) were under topical treatment, 23 (59%) were under csDMARDs and 13 (32.5%) were under bDMARDs. After multidisciplinary clinical evaluation, treatment change was made - switch to another bDMARDs in 5 patients and bDMARD was started in 7 patients. All patients had a previous evaluation for infection risk assessment and 11 patients performed 9 months isoniazid for latent tuberculosis treatment.

Eleven patients (28.9%) presenting moderate to severe PASI. Thirty-one patients presenting prolonged disease duration (> 10 years) with cutaneous (74.2%) and articular (61.3%) involvement. Peripheral disease without axial involvement was present in 28 patients (90%) while the others (10%) had both axial and peripheral involvement. Severe or moderate articular disease activity (DAS28) was present in 52.6% of the patients. The most frequent extra-articular manifestation was dactylitis (23.3%) and enthesitis (19.4%). The average number of multidisciplinary clinical consultations for these patients was 2.

There was a statistically significant difference at the mean age, gender and disease duration > 10 years between patients with psoriatic disease with and without arthritis (p= 0.047; p=0.01 and p=0.03, respectively); there was no statistically significant differences in family history of psoriasis (p=0.711) and spondyloarthritis (p=0.174), nutritional status (p=0.732) and comorbidities such as diabetes mellitus (p=0.545), hypertension (p=0.404), dyslipidaemia (p=0.394) and depression (p=0.089).

In the remaining 10 patients screened, the osteoarthritis and/or tendonitis were responsible for the articular complaints in 6 patients and scalp seborrhoea and eczema were responsible for the cutaneous complaints in the rest.

Conclusion: Despite the small number of patients observed in our multidisciplinary clinical, we found that this kind of clinical care may facilitate the diagnosis of joint disease and offers a more comprehensive treatment approach for patients with both psoriasis and PsA.

POS1084 COMPARISON OF NUMERICAL RATING SCALE (NRS) AND VISUAL ANALOGUE SCALE (VAS) IN THE PATIENT REPORTED OUTCOME MEASURES OF 3VAS AND 4VAS IN PSORIATIC ARTHRITIS

J. Day[1], W. Ye[2], W. Tillett[1], L. C. Coates[3]. [1]*Royal National Hospital for Rheumatic Diseases, Rheumatology, Bath, United Kingdom*; [2]*Oxford University, Rheumatology, Oxford, United Kingdom*; [3]*Oxford University, Nuffield Department of Orthopaedics, Oxford, United Kingdom*

Background: There is a recognised need for a feasible continuous composite measure in routine clinical care for psoriatic arthritis (PsA). Two multidimensional composite Visual Analogue Scales (VAS) have been proposed; the 3 and 4VAS[1], but there may be some advantages to using a numerical rating scale (NRS) over VAS in patient reported outcomes. VAS is a 100mm horizontal line, and the NRS a 21-point scale ranging from 0 to 10 in increments of 0.5. NRS are simple and faster to score, less susceptible to measurement error and may reduce the floor and ceiling effects, whereby patients avoid using the extremes of the scale. A previous study has demonstrated good agreement between VAS and NRS for the separate patient reported outcome measures in PsA, which correlate with disease severity and life impact.[2]

Objectives: To test the performance of NRS, compared with VAS, in the composite 3 and 4VAS scores.

Methods: Data were collected prospectively across three UK hospital trusts from 2018-2019, as part of a study assessing the use of NRS in patient reported outcome measures in PsA.[2] Patients completed the VAS and NRS for pain, arthritis, skin psoriasis, and global disease activity. The 3 VAS comprises of a physician global VAS, patient global VAS and patient skin VAS and the 4 VAS comprises of the physician global VAS, patient pain VAS, joint VAS and skin VAS. NRS and VAS versions of the patient reported measures were tested. Physician global scores were not available from the study data, therefore only the patient reported components are included. Agreement between the scales was assessed using the intraclass correlation coefficients (ICCs), with a two-way mixed absolute agreement model, and Bland-Altman plots. Spearman's rank correlation coefficients were used to assess dependency between scale scores and clinical parameters including tender and swollen joint count, PsAID12 and HAQDI.

Results: Data from 209 patients were analysed. 60.0% were male, with mean age of 51.7 years and median PsA duration of 7.0 years. Mean 3VAS score was 3.57 and the mean NRS-3VAS was 3.79, with ICC 0.98 (95% CI 0.96-0.98). Mean 4VAS was 3.71 and NRS-4VAS was 3.90 with ICC 0.98 (95% CI 0.97-0.98). Average NRS scores were slightly higher than VAS scores. The Bland-Altman plots comparing NRS and VAS for the patient-reported components of 3VAS and 4VAS are demonstrated in Figure 1. 64.1% patients reported a preference for NRS over VAS. Correlation of the 3/4VAS with PSAID, HAQ and joints counts are reported in Table 1. Visual representation of the NRS and VAS scales for 3VAS and 4VAS as histograms demonstrated that there is marginally less floor effect using NRS compared to VAS.

Conclusion: There is good agreement between VAS and NRS for the patient-reported components of 3VAS and 4VAS, supporting that VAS scores are reproducible as NRS scores. Both NRS and VAS versions of the 3 and 4VAS scales correlate with disease activity and life impact.[2] There may be advantages in testing the 3/4VAS as NRS moving forward.

POS1085 OSTEOPOROSIS IN PSORIATIC ARTHRITIS: A 5 YEAR PROSPECTIVE STUDY OF AN OUTPATIENT CLINIC COHORT

S. Brådland[1], A. Kavanaugh[2], G. Haugeberg[1,3]. [1]*Sørlandet Hospital Kristiansand, Division of Rheumatology, Dept of Internal medicine, Kristiansand, Norway*; [2]*University of California San Diego, Division of Rheumatology, Allergy, and Immunology, La Jolla, United States of America*; [3]*Norwegian University of Science and Technology, Division of Rheumatology, Trondheim, Norway*

Background: Data addressing whether patients with psoriatic arthritis (PsA) are at increased risk of osteoporosis have been inconclusive (1). Most studies have reported cross sectional data, and there is a lack of longer-term studies. We have previously reported bone density data from an outpatient PsA clinic cohort (2). Herein, we present 5-year follow up data from that same cohort.

Objectives: To explore longer-term change in bone mineral density (BMD) at femoral neck and spine (L1-4) in an outpatient PsA cohort.

Methods: 140 PsA patients were at baseline examined with dual energy x-ray absorptiometry (DXA) with measurements at femoral neck and spine (L1-4). Trained nurses performed the DXA scans. The DXA machines used at baseline (Lunar Prodigy) and at 5 year follow-up (Lunar iDXA) were stable over the measurement periods. Cross calibration using a spine phantom was performed between the two DXA machines (BMD of the old phantom in the new machine and the old phantom in the old machine, with 55 measurement over a time period of 2 weeks) had a difference of less than 1%. Demographic, disease measures and treatment data was collected at the same day or within 14 days to the date of DXA assessment. For group comparison, we used paired student t-test.

Results: After 5 years, 114 PsA patients (50.4% women) were re-examined. Baseline mean (SD) was for age 51.4 (9.4) years, BMI 28.1 (3.4) kg/m2, disease duration 9.1 (6.7) years.

Disease characteristics at baseline and follow-up presented as mean (SD) were: DAS28 3.05 (1.1) and 2.4 (0.8); CRP 4.3 (6.7) and 5.1 (12.2) mg/dl, ESR 14.9 (11.1) and 10.9 (12.9) mm/hr; mHAQ 0.40 (0.35) and 0.38 (0.37).

The proportions of patients as baseline and follow up using conventional synthetic disease modifying anti-rheumatic drugs (DMARD) were 61.4% vs. 46.5%; for biological DMARDs 37.7% vs. 48.2%; for prednisolone 5.3% vs. 10.5%, for targeted osteoporosis medication 0.9% vs. 3.5%; for calcium and vitamin-D 11.4% vs. 26.3%.

As shown in the table, no significant change in femoral neck and spine BMD and T-scores was found for the 114 patients. However for Z-scores (age and weight adjusted T-score) a significant increase was found both at femoral neck and lumbar spine. When gender was examined separately no significant reduction in bone density was found in men whereas in women a significant reduction during follow up was only found for right femoral neck BMD.

	Baseline	5 years	P value
BMD spine L1-4	1.22 (0.17)	1.23 (0.17)	0.13
T-score spine L1-4	0.21 (1.42)	0.32 (2.01)	0.42
Z-score spine L1-4	0.20 (1.32)	0.78 (2.05)	<0.001
BMD Femoral neck L	0.98 (0.14)	0.97 (0.14)	0.09
T-score Femoral neck L	-0.59 (1.15)	-0.50 (1.02)	0.14
Z-score Femoral neck L	-0.06 (1.02)	0.37 (1.04)	<0.001
BMD Femoral neck R	0.98 (0.14)	0.98 (1.16)	0.57
T-score Femoral neck R	-0.59 (1.10)	-0.52 (0.94)	0.22
Z-score Femoral neck R	-0.08 (1.02)	0.35 (0.90)	<0.001

Conclusion: No reduction in BMD at femoral neck and spine was found in our PsA outpatient clinic cohort at baseline or over 5 years follow up. Rather, we found a statistically significant increase in age adjusted bone density (Z-score) both at femoral neck and spine over time. Our data thus adds evidence that PsA patients treated in ordinary clinical practice do not seem to be at an increased risk of developing osteoporosis.

POS1086 DIFFERENCES IN PROINFLAMMATORY AND LIPID PROFILE BETWEEN PSORIATIC ARTHRITIS, ANKYLOSING SPONDYLITIS AND RHEUMATOID ARTHRITIS

K. Bonek[1], E. Kuca-Warnawin[2], M. Ciechomska[2], P. Głuszko[1], E. Kontny[2]. *[1]National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Rheumatology, Warszawa, Poland*; *[2]National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Pathophysiology and Immunology, Warsaw, Poland*

Background: Patients with rheumatic diseases such as rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS) are at increased risk of developing dyslipidaemia and premature cardiovascular disease (CVD)(1).

Objectives: To investigate the relationship between proinflammatory cytokines, microRNA, and lipid profile in patients with RA, AS, and PsA.

Methods: A group of 65 patients (RA15/ AS25/ PsA25) with high disease activity (mean DAS28 5,98 / ASDAS-CRP 3,7/ DAPSA 38,5) and 25 healthy controls (HC) were compared. Lipid profile comprised triglycerides (TG), total cholesterol(TC), low (LDL), and high-density lipoprotein (HDL). Serum concentrations of IL-6, IL-21, IL-17, TNF and osteoprotegerine (OPG) were measured by commercially available enzyme-linked immunosorbent assays. Expression of miR-233-5p,miR-92-3p,miR-485-3p,miR-10b-5p,let-7d-5p, miR-26 -a-2-3p levels in sera was normalized to miR-16a internal control. The Mann-Whitney test was applied for intergroup comparison, the correlation was assessed using Spearman's Rank test.

Results: Patients with RA revealed mixed dyslipidemia (mean values:TC196; LDL 117; HDL, 48 TG; 124 mg/dl), PsA revealed hypertriglyceridemia (TC 175; LDL 100; HDL 50; TG137 mg/dl) and in AS no specific profile was found (TC 179; LDL98; HDL55; TG103 mg/dl). Higher expression of miR-485was observed in patients with PsA (4,8-fold) and AS (5,9-fold) compared to RA and HC groups (3,1 and 1,5-fold p=0,02). Similarly, miR-26a revealed higher expression in patients with PsA (28,4-fold) and AS (21,5-fold) than in RA and HC (3,5 and 2,9-fold p<0,00). PsA patients had higher expression of miR-146b than patients with RA, AS and HC (40,9-fold vs 12,6 vs 15,7 vs 3,4-fold p=0,002) and higher miR-10b (11,7 vs 1,4 vs 4,9 vs 1,7-fold p=0,004). Patients with RA showed higher expression of let7-d than patients with PsA, AS and HC (22-fold vs 1,8 vs 2,3 vs1,9 -fold p=0,002). In PsA miR-92b expression correlated negatively with HDL levels (r=-0,62 p=0,02) and positively with fasting glucose (r=0,71 p<0,00). TG levels negatively correlated with TNF (r=-0,47 p=0,01), IL-17 (r=-0,49 p=0,01) and OPG (r=-0,51 p=0,00) serum levels. Let-7d correlated negatively with TC (r=-0,58 p=0,03). In RA IL-21 positively correlated with LDL (r=0,71 p=0,00) and TC (r=0,75 p=0,001) concentrations. TG levels correlated positively with expressions of miR-92b (r=6,9 p=0,02) and miR-26a (r=0,69 p=0,03). In AS expression of let-7d was correlated positively with HDL (r=0,41 p=0,00) and TC (r=0,45 p=0,00) levels and negatively with ASDAS-CRP (r=-0,675 p=0,02) and CRP levels (r=-0,53 p=0,01). There were no significant differences in OPG, IL-21 concentrations or miR-146b, miR-92b,miR-233 expressions.

Conclusion: Differences in proinflammatory profile in RA, PsA, and AS seem to be associated with different phenotypes of dyslipidemia. In PsA expression of miR-92b and higher levels of TNF, IL-17 and OPG are associated with altered lipid profile and hypertriglyceridemia. High activity of AS is associated with lowered expression of let-7d, possibly influencing TC and HDL levels. Therefore, measuring lipid profile in active disease might be misleading. In active RA increase of TC and LDL levels was associated with high IL-21 concentration, while hypertriglyceridemia with miR-92b and miR-26a expressions.

Osteoarthritis

POS1087 USING LIPIDOMICS TO PREDICT PREDNISOLONE TREATMENT RESPONSE IN PATIENTS WITH INFLAMMATORY HAND OSTEOARTHRITIS: THE HOPE STUDY

M. Loef[1], T. Faquih[2], J. Von Hegedus[1], M. Ghorasaini[3], A. Ioan-Facsinay[1], F. Kroon[1], M. Giera[3], M. Kloppenburg[1,2]. *[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; *[2]Leiden University Medical Center, Clinical Epidemiology, Leiden, Netherlands*; *[3]Leiden University Medical Center, Center for Proteomics and Metabolomics, Leiden, Netherlands*

Background: Lipidomics analysis has become a valuable technology for understanding patho-physiological mechanisms and may aid the identification of biomarkers of therapeutic responsiveness.

Objectives: To explore the use of lipidomics for prediction of prednisolone treatment response in patients with inflammatory hand osteoarthritis.

Methods: The Hand Osteoarthritis Prednisolone Efficacy (HOPE) study is a blinded, randomized placebo-controlled trial, that investigated the effect of prednisolone treatment in patients with painful, inflammatory hand OA, fulfilling the American College of Rheumatology criteria. The present analyses comprised only patients randomized to daily 10 mg prednisolone treatment for six weeks. Response to prednisolone treatment was defined according to the OARSI-OMERACT responder criteria at six weeks. Baseline blood samples were obtained non-fasted. Lipid species were quantified in erythrocytes with the Lipidyzer™ platform (Sciex). After pre-processing of the data, 286 lipids species were available for further analyses (nmol/mL). In addition, we used an in-house LC-MS/MS platform to analyse oxylipins in plasma, identifying 25 oxylipins (area ratios). Elastic net regularized regression was used to predict prednisolone treatment response. A 10-fold cross-validation (CV) was performed for selection of the optimal tuning parameters based on the smallest CV mean prediction error. First, a model was fit with commonly assessed patient characteristics and patient reported outcomes, measured at baseline (model 1). Second, we fitted model 2 by adding the Lipidyzer™ platform lipids to model 1. Third, we fitted model 3 by adding the oxylipins to model 1. The discriminatory

accuracy of the model was estimated by receiver operating characteristic (ROC) analyses. The area under the curve (AUC) and corresponding 95% confidence intervals (CI) were calculated using 1,000 bootstrap replications.

Results: Among the 40 patients included, 31 (78%) fulfilled the OARSI-OMERACT responder criteria. From the included general patient characteristics (Table 1), elastic net selected baseline hand function as only predictor of treatment response, with an AUC of 0.78 (95% CI 0.60;0.96) (Figure 1). In model 2, we added the 286 Lipidyzer™ platform variables to model 1. In addition to hand function, two lipids were selected: diacylglycerol(DAG)(16:0/16:0) and phosphatidylethanolamine(PE)(O-18:0/20:4), which improved the discriminatory accuracy to an AUC of 0.92 (0.83;1.02). Lastly, model 3 was fit with patient characteristics as well as oxylipins, resulting in selection of AUSCAN function and three oxylipin predictors: 9-hydroxy-octadecatrienoic acid (HOTrE), 5-hydroxy-eicosapentaenoic acid (HEPE) and 10-hydroxy-docosahexaenoic acid (HDHA), with an AUC of 0.85 (0.69;1.02).

Conclusion: The patients' lipid profile improved the discriminative accuracy of the prediction of prednisolone treatment response in patients with inflammatory hand osteoarthritis compared to prediction by commonly measured patient characteristics alone. This exploratory study suggests that lipidomics is a promising field for biomarker discovery for prediction of anti-inflammatory treatment response.

Table 1. Baseline characteristics

	All prednisolone treated n = 40	Responders n = 31 (78%)	Non-responders n = 9 (23%)

POS1088

EFFICACY OF SUBCUTANEOUS TANEZUMAB FOR THE TREATMENT OF OSTEOARTHRITIS OF THE KNEE OR HIP: A POST-HOC SUBGROUP ANALYSIS OF PATIENTS FROM A RANDOMIZED, NSAID-CONTROLLED STUDY WITH A HISTORY OF DEPRESSION, ANXIETY, OR INSOMNIA

P. J. Mease[1], T. Mallick-Searle[2], E. Johnston[3], L. Viktrup[3], D. Menuet[4], R. Yang[5], R. J. Fountaine[6]. [1]*Swedish Medical Center & Providence St. Joseph Health and University of Washington, -, Seattle, United States of America*; [2]*Stanford Health Care, Redwood City, United States of America*; [3]*Eli Lilly and Company, -, Indianapolis, United States of America*; [4]*Pfizer SAS, Paris, France*; [5]*Pfizer Inc., New York, United States of America*; [6]*Pfizer Inc., Groton, United States of America*

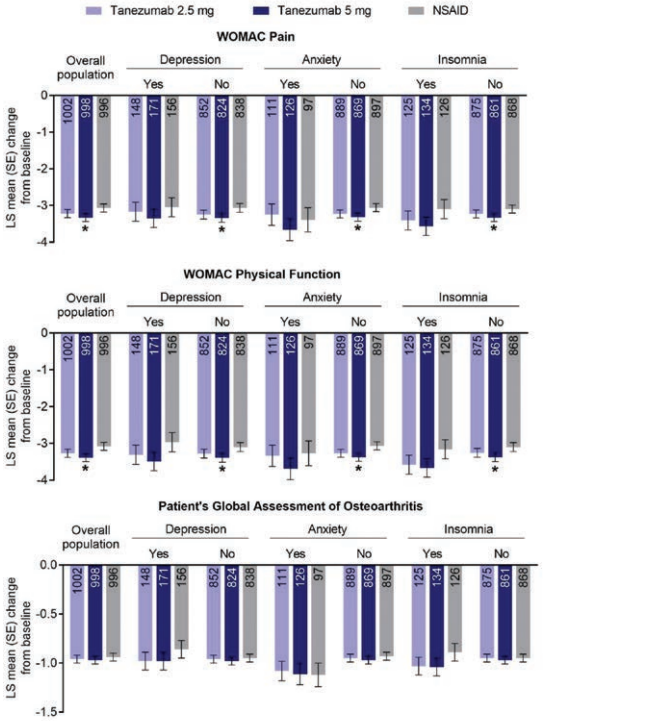
Background: Tanezumab is a monoclonal antibody directed against nerve growth factor. It is in development for the treatment of moderate to severe chronic pain associated with osteoarthritis (OA) in adult patients for whom other treatments are ineffective or not appropriate. Phase 3 clinical trials have demonstrated the efficacy of subcutaneous tanezumab versus placebo for pain and function outcomes over various timepoints. Largely similar change from baseline was demonstrated in an oral nonsteroidal anti-inflammatory drug (NSAID)-controlled study.[1,2,3,4] The efficacy of some other OA therapies can be dampened in patients with depression, anxiety, or insomnia.[5,6,7]

Objectives: A post-hoc analysis to explore the efficacy of subcutaneous tanezumab after 16 weeks treatment, as compared to oral NSAID, in patients with OA and a history of depression, anxiety, or insomnia at baseline.

Methods: Subgroup analysis of data from a randomized, double-blind, double-dummy, active-controlled phase 3 study of subcutaneous tanezumab (2.5 mg or 5 mg every 8 weeks) vs twice daily oral NSAID in patients (≥18 years) with radiographically-confirmed moderate to severe hip or knee OA (Kellgren-Lawrence grade ≥2; NCT02528188).[4] Co-primary efficacy endpoints were change from baseline to week 16 in Western Ontario and McMaster Universities OA Index (WOMAC*) Pain and Physical Function subscale scores (both ≥5/10 at randomisation; increasing score indicates increasing pain/disability), and Patient's Global Assessment of OA (PGA-OA, ≥3/5 at randomisation; increasing score indicates poorer condition). Enrolled patients had a history of inadequate pain relief with acetaminophen; inadequate pain relief with/intolerance to/contraindication to tramadol or opioids; or an unwillingness to take opioids. Patients were on a stable dose of NSAID for ≥30 days before screening. Data are presented as least squares (LS) mean change from baseline to week 16 for the whole population and for subgroups of patients with/without a history of depression, anxiety, or insomnia at baseline. Exploratory statistical analysis was conducted by analysis of covariance. P values were not adjusted for multiplicity. This exploratory post-hoc analysis was not part of the pre-specified hypothesis testing plan or included in any sample size calculations; therefore, comparisons between treatment arms or patient subgroups should be interpreted with caution.

Results: Overall, 2996 patients were randomized and received at least one dose of study treatment (subcutaneous tanezumab 2.5 mg: n=1002; subcutaneous tanezumab 5 mg: n=998; oral NSAID: n=996). In this population (comprising patients with or without a history of anxiety, depression or insomnia), all treatments were associated with notable and largely similar magnitude improvements in WOMAC Pain, WOMAC Physical Function, and PGA-OA at week 16 (Figure 1). Across treatment groups, differences in LS mean change from baseline in patients with

Figure 1: Co-primary efficacy endpoints after 16 weeks of treatment



*p<0.05 vs NSAID

LS, least squares; NSAID, nonsteroidal anti-inflammatory drug; SE, standard error; WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index.

*©1996 Nicholas Bellamy. WOMAC® is a registered trademark of Nicholas Bellamy (CDN, EU, USA)

and without a history of depression, anxiety or insomnia ranged between 0 - 0.34 for WOMAC Pain and Physical Function and 0 - 0.19 for PGA-OA.
Conclusion: Patients with a history of depression, anxiety, or insomnia did not appear to experience dampened improvements in pain or function with tanezumab or NSAID, as compared to those without.

POS1089 ASSOCIATION BETWEEN PAIN SEVERITY AND HEALTHCARE UTILIZATION IN AN OSTEOARTHRITIS POPULATION: AN 18-YEAR RETROSPECTIVE COHORT STUDY

J. Graham[1], T. Novosat[2], H. Sun[3], B. Piper[1,4], J. Boscarino[5], V. Duboski[1], M. Kern[1], E. Wright[1], R. Robinson[6], E. Casey[7], C. Beck[7], J. Hall[8], P. Schepman[9]. [1]*Geisinger, Center for Pharmacy Innovation and Outcomes, Danville, United States of America*; [2]*Geisinger, Interventional Pain, Danville, United States of America*; [3]*Geisinger, Biostatistics Core, Danville, United States of America*; [4]*Geisinger Commonwealth School of Medicine, Department of Medical Education, Scranton, United States of America*; [5]*Geisinger, Department of Population Health Sciences, Danville, United States of America*; [6]*Eli Lilly & Co., Lilly Research Labs, Indianapolis, United States of America*; [7]*Pfizer, Inc., Global Medical Affairs, New York, United States of America*; [8]*Eli Lilly & Co., Global/US Medical Affairs, Indianapolis, United States of America*; [9]*Pfizer, Inc., Global HEOR, New York, United States of America*

Background: Osteoarthritis (OA) is a common disease that varies in severity among patients. A standardized definition to classify patients into different severity levels is lacking, however, due to the disease's complex pathogenesis and presentation. Prior studies have shown associations between pain severity and higher healthcare resource utilization (HRU) and costs. We investigated an association between pain severity and higher healthcare resource utilization by examining the use of specific OA-related treatments across pain intensity levels in a large, integrated health system's OA population over an 18-year period.
Objectives: Our aim was to compare use of medications and other treatments among OA patients experiencing mild, moderate, or severe pain.
Methods: This was a retrospective study of electronic health records from 2001 to 2018 at Geisinger, an integrated health system in Pennsylvania. Patients were included with a diagnosis code for OA (ICD-9: 715.*, ICD-10 M15-19) on a problem list or encounter or an OA-specific procedure (hip or knee replacement, arthroscopy or injection). We examined pain scores (0-10 scale, with 10 being worst pain) taken after the first OA diagnosis date and defined pain episodes starting on the pain score's date and lasting for 90 days. If a new pain score was measured before 90 days elapsed, the episode was extended for an additional 90 days, with this process repeated as necessary. Each episode was categorized as mild (pain score 0-3), moderate (4-6), or severe (7-10) based on initial score, and patients could contribute multiple episodes to the analysis. Descriptive statistics were used to quantify treatment utilization during each patients' mild, moderate and severe episodes. Percentages of patients who had any use of 10 medication types (tramadol, non-tramadol opioids, nonsteroidal anti-inflammatory drugs (NSAIDs), injectable corticosteroids, acetaminophen, salicylates, duloxetine, homeopathic medications, other topical medications, and other over-the-counter (OTC) medications were compared across pain episode types. Percentages of patients with knee or hip surgeries, spine or joint imaging procedures (x-ray, computed tomography or magnetic resonance) and consults to OA-related care (pain management, orthopedics or physical medicine and rehabilitation) were also compared. All analyses used logistic regression with p-values <0.05 considered significant.
Results: We identified 290,897 patients with OA, representing 34% of the health system population in 2018; 58% were female with mean age of 49 years and mean BMI of 30.5 kg/m2. A total of 801,144 pain episodes were defined, with 75% of patients having at least one pain score. The two most frequently occurring pain scores were 0 (17%) and 5 (13%), and pain episodes were classified as 43% mild, 32% moderate and 25% severe. Significantly higher percentages of patients used certain medication types (NSAIDs, injectable corticosteroids, non-tramadol opioid, duloxetine) in both moderate and severe pain episodes as compared to mild episodes, but other medication types were less likely to be used as pain severity increased (acetaminophen, salicylates, homeopathic medications, other OTC medications). Knee or hip surgeries, imaging, and consults to OA-related specialists were all consistently significantly more likely to occur in patients during moderate or severe pain episodes versus mild episodes (relative risk ratios of 1.76, 1.25 and 1.35 for moderate vs mild, respectively, and 2.00, 1.44 and 1.46 for severe vs mild, all p-values <0.05).
Conclusion: While pain is generally recognized to be a subjective measure that could be influenced by other unmeasured factors and can be confounded with treatment effectiveness, it is nevertheless the primary symptom of OA. It is important to understand the relationship between pain intensity and treatment utilization, and our results support an overall association between pain and utilization but provide new details on the extent to which it depends on specific utilization type.

POS1090 ASSOCIATION BETWEEN ANTIBIOTIC USE AND KNEE PAIN AND FUNCTION IN OA: DATA FROM THE OSTEOARTHRITIS INITIATIVE

I. Shirinsky[1], V. Zagainova[2], V. Shirinsky[1]. [1]*Research Institute of Fundamental and Clinical Immunology, Laboratory of Clinical Immunopharmacology, Novosibirsk, Russian Federation*; [2]*Research Institute of Fundamental and Clinical Immunology, Rheumatology Unit, Novosibirsk, Russian Federation*

Background: Recently, gut dysbiosis has been linked with joint pain in osteoarthritis (OA) (1). Thus, it can be hypothesized that antibiotic use impacts symptoms of OA. To date, there have been no studies assessing association between the intake of antibiotics and clinical manifestations of knee OA.
Objectives: To evaluate association between the use of antibiotics and OA-related knee pain and function.
Methods: For the current study we used 4-year longitudinal data obtained from the Osteoarthritis Initiative (OAI) progression (n= 1390) and incidence (n = 3284) subcohorts, which are publically available at https://oai.nih.gov. The outcome variables studied were Western Ontario McMaster Osteoarthritis Index (WOMAC) pain and function subscales. To acquire information about the use of antibiotics, a medication inventory method was used. We excluded participants who used antibiotics at or 30 days prior to baseline (a "new-user" design). Antibiotic users were defined as those with at least one recorded use during first four years of the study. The participants were matched into antibiotic users/non-users pairs using genetic matching based on various demographic and clinical characteristics. The outcomes were assessed at baseline and annually until year 4. Generalized

estimating equations (GEE) were used to model the relationship between outcomes and antibiotic use by time interaction.
Results: A total of 515 new antibiotic users were matched with 515 non-users. After matching, all standardized differences of means were less than 0.05 indicating that covariates were well balanced between groups. No association between the use of antibiotic and changes in WOMAC pain and function scores was found (Table 1). No associations were also observed in multiple stratified analyses based on different duration of antibiotic use, particular classes of antibiotics, or different baseline WOMAC pain or disability levels.

Table 1. Longitudinal analysis (with treatment*time interaction) of WOMAC subcategories and antibiotics use

	β coefficient	95% CI	P value
WOMAC Pain	-0.008	(-0.08 to 0.07)	0.8
WOMAC Function	-0.014	(-0.24 to 0.21)	0.9

Conclusion: These findings do not support the effects of antibiotics on knee OA pain or disability. More research is needed on the role of microbiota and its modulation in OA.

POS1091 KNEE JOINT DISTRACTION RESULTS IN MRI CARTILAGE THICKNESS INCREASE UP TO TEN YEARS AFTER TREATMENT

M. Jansen[1], S. Mastbergen[1], T. D. Turmezei[2,3], J. W. Mackay[3,4], F. Lafeber[1]. *[1]UMC Utrecht, Department of Rheumatology & Clinical Immunology, Utrecht, Netherlands*; *[2]Norfolk & Norwich University Hospital, Department of Radiology, Norwich, United Kingdom*; *[3]University of East Anglia, Norwich Medical School, Norwich, United Kingdom*; *[4]University of Cambridge, Department of Radiology, Cambridge, United Kingdom*

Background: Knee joint distraction (KJD) is a joint-preserving treatment option for younger (age <65 years) knee osteoarthritis (OA) patients. It has shown clinical improvement for up to nine years after treatment. Radiographs and MRI scans have previously shown cartilage regeneration activity, especially in the first two years after treatment. However, MRIs have not been evaluated more than five years after this treatment.
Objectives: To evaluate MRI cartilage thickness up to ten years after KJD treatment.
Methods: Patients (n=20) with end-stage knee OA, indicated for total knee arthroplasty (TKA) but <60 years old, were treated with KJD. 3T MRIs with 3D spoiled gradient recalled imaging sequence with fat suppression (SPGR-fs) were acquired before and one, two, five, seven and ten years after surgical treatment. Stradview v6.0 was used for semi-automatic cartilage segmentation; wxRegSurf v18 was used for surface registration. MATLAB R2020a and the SurfStat MATLAB package were used for data analysis and visualization. For changes over time, linear mixed models were used. Two separate linear regression models were used to show the influence of baseline Kellgren-Lawrence grade and sex on the changes over time. Statistical significance was calculated with statistical parametric mapping; a p-value <0.05 was considered statistically significant. Since KJD has previously shown significant results mostly in the patients' most affected compartment (MAC), patients were separated in two groups based on whether their MAC was the medial or lateral compartment.
Results: The MAC was predominantly the medial side (medial MAC n=18; lateral n=2). The 18 patients with a medial MAC all had MRI scans at baseline, one and two years after treatment. After two years, some patients were lost to follow-up, decreasing data availability at five (n=15), seven (n=11) and ten years (n=7). Figure 1 (top) shows the average cartilage thickness at the different time points for all medial MAC patients together. One and two years after treatment the cartilage in the medial weight-bearing region was on average thicker than before treatment. While from five years after treatment the cartilage thickness gradually decreased, even at ten years the medial cartilage thickness seemed slightly higher than pre-treatment. Figure 1 (bottom) shows cartilage thickness changes compared to baseline for patients with a medial MAC. Patients with a lateral MAC showed a similar pattern, with the biggest changes showing on the lateral side. As indicated by the dark blue areas, the medial femoral cartilage thickness increase, which was up to 0.5 mm after one year and 0.6 mm after two years, was largely statistically significant at both these time points. While the medial tibia showed an increase of up to 0.5 mm at these time points as well, this was not statistically significant at two years. Surprisingly, long-term results showed areas of the lateral (less affected) compartment were significantly thicker, up to 0.7 mm, compared to pre-treatment in both the femur and tibia compared to baseline. Kellgren-Lawrence grade and sex were shown to influence the changes, albeit not statistically significantly. Patients with a higher Kellgren-Lawrence grade and male sex showed a higher short-term (one and two year) but a lower long-term (seven and ten year) cartilage thickness increase.
Conclusion: KJD treatment results in significant short-term cartilage regeneration in the most affected compartment. While after two years this initial gain in cartilage thickness is gradually lost, likely as a result of natural progression, even ten years after treatment the cartilage is thicker than before treatment. In the less affected compartment, a delayed cartilage response seems to take place, with significantly increased cartilage thickness in the long term. In conclusion, in these young OA patients indicated for TKA, KJD results in femoral and tibial cartilaginous tissue regeneration both short- and long-term and in both sides of the joint.

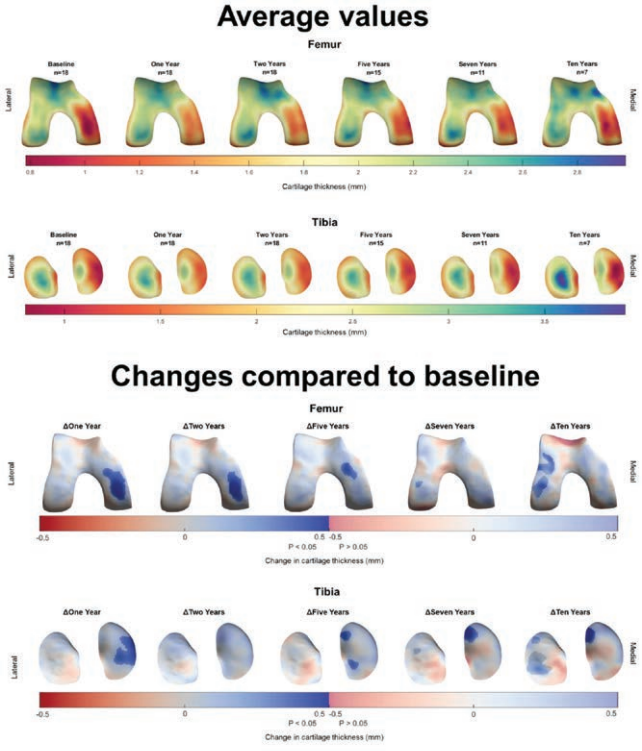

Figure 1: Top: average cartilage thickness of all patients whose medial compartment was the most affected, at baseline (n=18) and one (n=18), two (n=18), five (n=15), seven (n=11) and ten (n=7) years after treatment with knee joint distraction. The color range is based on the minimum and maximum average values of the femur (0.78-3.00) and tibia (0.80-3.92) separately. Bottom: change in cartilage thickness compared to baseline, for all patients whose medial compartment was the most affected, after one (n=18), two (n=18), five (n=15), seven (n=11) and ten (n=7) years after treatment with knee joint distraction. Statistically significant changes are indicated by the darker color map (p<0.05) while non-significant areas are shown with faded colors (p>0.05). Blue indicates an increase and red a decrease in cartilage thickness compared to baseline. All results are viewed on average right femur and tibia articular cartilage surfaces.

POS1092 SUBCHONDRAL BONE NORMALIZATION AFTER KNEE JOINT DISTRACTION TREATMENT AS MEASURED WITH CT

M. Jansen[1], A. Ooms[1], T. D. Turmezei[2,3], J. W. Mackay[3,4], S. Mastbergen[1], F. Lafeber[1]. *[1]UMC Utrecht, Department of Rheumatology & Clinical Immunology, Utrecht, Netherlands*; *[2]Norfolk & Norwich University Hospital, Department of Radiology, Norwich, United Kingdom*; *[3]University of East Anglia, Norwich Medical School, Norwich, United Kingdom*; *[4]University of Cambridge, Department of Radiology, Cambridge, United Kingdom*

Background: In addition to cartilage degeneration, knee osteoarthritis (OA) causes bone changes, including cortical bone thickening, subchondral bone density decrease, and bone shape changes as a result of widening and flattening condyles and osteophyte formation. Knee joint distraction (KJD) is a joint-preserving treatment for younger (<65 years) knee OA patients that has been shown to reverse OA cartilage degradation. On radiographs, KJD showed a decrease in subchondral bone density and an increase in osteophyte formation. However, these bone changes have never been evaluated with a 3D imaging technique.
Objectives: To evaluate cortical bone thickness, subchondral trabecular bone density, and bone shape on CT scans before and one year after KJD treatment.
Methods: 19 KJD patients were included in an extended imaging protocol, undergoing a CT scan before and one year after treatment. Stradview v6.0 was used for semi-automatic tibia and femur segmentation from axial thin-slice

(0.45mm) CT scans. Cortical bone thickness (mm) and trabecular bone density (Hounsfield units, HU) were measured with an automated algorithm. Osteophytes were excluded. Afterwards, wxRegSurf v18 was used for surface registration. Registration data was used for bone shape measurements. MATLAB R2020a and the SurfStat MATLAB package were used for data analysis and visualization. Two-tailed F-tests were used to calculate changes over time. Two separate linear regression models were used to show the influence of baseline Kellgren-Lawrence grade and sex on the changes over time. Statistical significance was calculated with statistical parametric mapping; a p-value <0.05 was considered statistically significant. Bone shape changes were explored visually using vertex by vertex displacements between baseline and follow-up. Patients were separated into two groups based on whether their most affected compartment (MAC) was medial or lateral. Only patients with axial CT scans at both time points available for analysis were included for evaluation.

Results: 3 Patients did not have complete CTs and in 1 patient the imaged femur was too short, leaving 16 patients for tibial analyses and 15 patients for femoral analyses. The MAC was predominantly the medial side (medial MAC n=14; lateral n=2). Before treatment, the MAC cortical bone was compared to the rest of the joint (Figure 1). One year after treatment, MAC cortical thickness decreased, although this decrease of up to approximately 0.25 mm was not statistically significant. The trabecular bone density was also higher before treatment in the MAC, and a decrease was seen throughout the entire joint, although statistically significant only for small areas on mostly the MAC where this decrease was up to approximately 80 HU (Figure 1). Female patients and patients with a higher Kellgren-Lawrence grade showed a somewhat larger decrease in cortical bone thickness. Trabecular density decreased less for patients with a higher Kellgren-Lawrence grade, and female patients showed a higher density decrease interiorly while male patients showed a higher decrease exteriorly. None of this was statistically significant. The central areas of both compartments showed an outward shape change, while the outer ring showed inward changes.

Conclusion: MAC cortical bone thickness shows a partial decrease after KJD. Trabecular bone density decreased on both sides of the joint, likely as a direct result of the bicompartmental unloading. For both subchondral bone parameters, MAC values became more similar to the LAC, indicating (partial) subchondral bone normalization in the most affected parts of the joint. The bone shape changes may indicate a reversal of typical OA changes, although the inward difference that was seen on the outer edges may be a result of osteophyte-related changes that might have affected the bone segmentation. In conclusion, KJD treatment shows subchondral bone normalization in the first year after treatment, and longer follow-up might show whether these changes are a temporary result of joint unloading or indicate more prolonged bone changes.

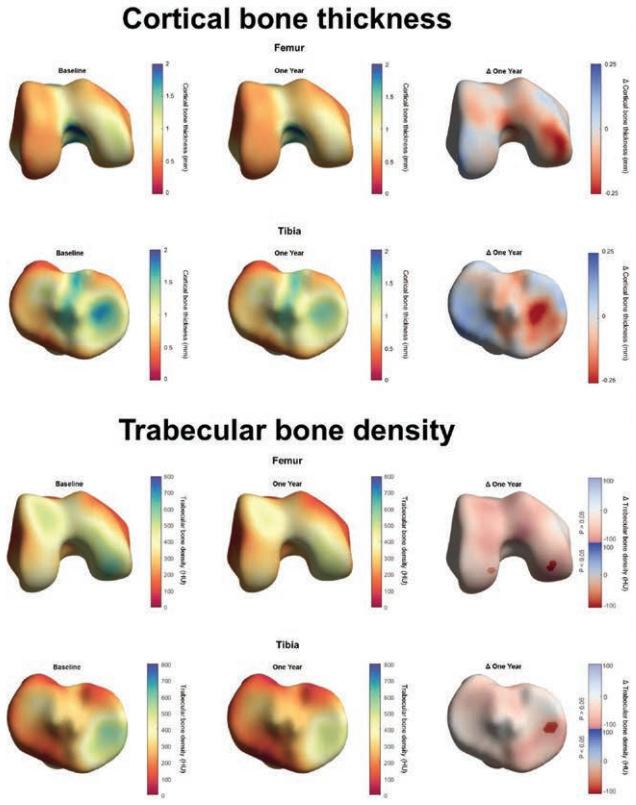

Figure 1: The average cortical bone thickness (top) and trabecular bone density (bottom) of all patients whose medial compartment was the most affected at baseline (left) and one year after treatment with knee joint distraction (mid). On the right a difference map between the two time points is shown; blue indicates an increase and red a decrease. Statistically significant changes are indicated by the darker color map (p<0.05) while non-significant areas are shown with faded colors (p>0.05) for the trabecular bone density; the cortical bone thickness did not show statistically significant differences.

POS1093

KNEE AND HIP OSTEOARTHRITIS ARE ASSOCIATED WITH SUBCLINICAL AND MANIFEST ATHEROSCLEROSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Barguil Macedo[1], V. M. Ostrovski Souza Santos[1], R. M. Pereira[1], R. Fuller[1].
[1]*University of Sao Paulo Faculty of Medicine, Rheumatology, Sao Paulo, Brazil*

Background: An association between osteoarthritis (OA) and atherosclerosis (AT) has long been suggested, with its plausibility based on several guessed commonalities, from shared risk factors to overlapping molecular pathways, given that both conditions represent a state of chronic low-grade inflammation. However, meta-analyses of the impact of OA on hard cardiovascular (CV) endpoints have displayed conflicting results. Those disparate results probably stemmed from the heterogeneous OA population adjoined, as it has been postulated that OA denotes not a single, but a group of diseases with particular pathogenic mechanisms. Also, CV mortality may capture just the extreme of a continuum of atheromatous burden, and miss earlier subclinical disease.

Objectives: In order to discern a more refined association between OA and AT, a systematic review and a meta-analysis of studies that focused on OA of weight-bearing joints (i.e., hip and knee) were performed, and the results stratified by clinical and subclinical AT.

Methods: A search on PubMed, Web of Science, LILACS, and SciELO from inception until August 2020, was done using the MeSH search terms "osteoarthritis", "aorta", "carotid", "intima-media thickness", "coronary artery disease", "atherosclerosis", "cardiovascular disease", and "death". To appraise the quality of the studies, we applied the NewCastle-Ottawa scale. To assess for heterogeneity, I^2 was used. A random-fixed effect model was adopted, and outliers were excluded when detected. Publication bias was ascertained qualitatively by funnel plot, and quantitatively by Egger regression test. Analyses were performed on RStudio version 1.3.1093.

Results: The search retrieved 1335 citations, of which 168 were screened for abstract reading. From those, 127 were selected for full-text reading. After exclusion of duplicates and out of scope aricles, a total of 23 studies, comprising 151,187 individuals with OA and 287,444 controls, were included on the narrative synthesis, and 17 on the meta-analysis. All but one study were deemed as of fair or good quality. Fifteen studies found a positive association between OA and AT, the remaining 8 did not reach statistical significance. Four studies subdivided the OA patients by gender, and in half of those a positive association was found exclusively on females. Thirteen studies worked with a subclinical definition of AT, 1 included both subclinical and manifest disease, and the remainder included only manifest disease. Hip and knee OA increased the risk for both subclinical AT (OR 1.15, 95% CI 1.01-1.31, Figure 1A), and CV disease (OR 1.13, 95% CI 1.05-1.22, Figure 1B), but not for CV death (OR 1.08, 95% CI 0.99-1.19).

Conclusion: Hip and knee OA are associated with AT. This may have practical implications on the management of OA patients, as a more intensive control of traditional CV risk factors may be advised.

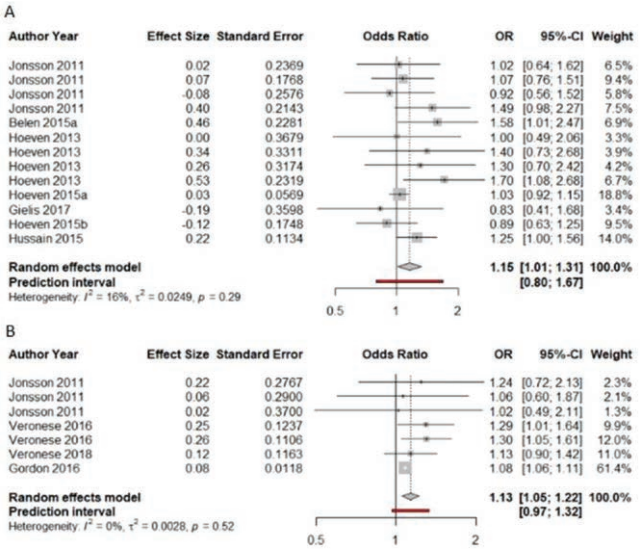

Figure 1. Forest plots showcasing the association between hip and knee OA and subclinical AT (A) and CV disease (B).

POS1094 SYNOVITIS IS FACTOR OF OSTEOARTHRITIS KNEE PROGRESSION IN PATIENTS WITH LESS THAN 5 YEARS OF DISEASE DURATION

L. Alekseeva[1,2], N. Kashevarova[1], E. Taskina[1], D. Kusevich[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of osteoarthritis, Moscow, Russian Federation*; [2]*Russian Medical Academy of Continuous Professional Education, Rheumatology, Moscow, Russian Federation*

Background: There are many studies about investigation of risk factors (RF) of knee osteoarthritis (OA) radiologic progression. Especially, in patients with small disease duration. At the moment, there are ambivalent of results of previous studies, lead to uncertain role of synovitis.
Objectives: The aim of study is to investigate relationship between knee OA synovitis and progression risk in patients with small disease duration during a follow-up period of 5 years.
Methods: Eligible patients had knee OA based on ACR criteria with x-ray confirmation; baseline (BL) disease duration less than 5 years. Patients were evaluated at BL and at 5-year follow-up, using the questionnaires, clinical examination, knee joints pain by visual analog scale (VAS), musculoskeletal ultrasound and X-ray. Unadjusted p-values are presented.
Results: Among 52 adults with knee OA (mean age ± standard deviation, 59.11 ± 8.95 years; 100% female) had the proportion of patients at BL 42.3% (n=22), 46.2 % (n=24), 11.5% (n=6) by disease stage 1,2 and 3, respectively. Patients were categorized into 2 groups by progression during 5 years from BL based on changes of radiological stage. After 5-years follow-up period the progression of knee OA was established in 14 patients (1 group) and in 38 patients (2 group) the progression by radiological stage was absent. BL patients' characteristics were similar across 1st and 2nd groups: mean age 58.29±7.68 vs 56.05±8.74, p>0.05; disease duration 3.43±1.34 vs 3.47±1.33, p>0.05. Individuals with knee OA progression had worse knee joints pain during walking (60.36±18.33 vs 48.71±17.81, p=0.043), higher body mass index (BMI) (34.45±4.60 vs 28.92±4.92 kg/m^2, p=0.001), higher frequency of knee synovitis by clinical examination (42.9% vs 10.5%, RR=4.07; 95%CI (1,3-12,3), p=0.01) and by musculoskeletal ultrasound (57.1% vs 18.4%, RR=3.1; 95%CI (1.38-6.96), p=0.009). At 5-years follow-up knee pain was significantly greater for 1st group (69.64±18,49 vs 55.76±12.76, p = 0.003), higher BMI (35.74±5.83 vs 30.64±4.64, p = 0.002), also higher frequency of knee synovitis by clinical examination (57.1% vs 10.5%, RR = 5.4 (95%CI 1.9-15.2), p=0.001) and by musculoskeletal ultrasound (50% vs 13.2%, RR=3.8 (95%CI 1.4-10.0), p=0.009). Spearman correlation coefficients between radiologic stage and OA progression factors were indicated: between radiologic stage and knee pain during walking (r = 0.34, p<0.05), BMI (r = 0.46, p<0.01), knee synovitis by musculoskeletal ultrasound (r = 0.41, p<0.01). Multivariate (discriminant) analysis was determined that synovitis is a significant predictor of radiographic progression (p < 0.05).
Conclusion: The proportion of patients with knee synovitis by clinical examination and musculoskeletal ultrasound data increased by 5-year follow-up from BL. Synovitis is a significant predictor of radiographic progression of knee OA in patients with small disease duration.
Disclosure of Interests: None declared.

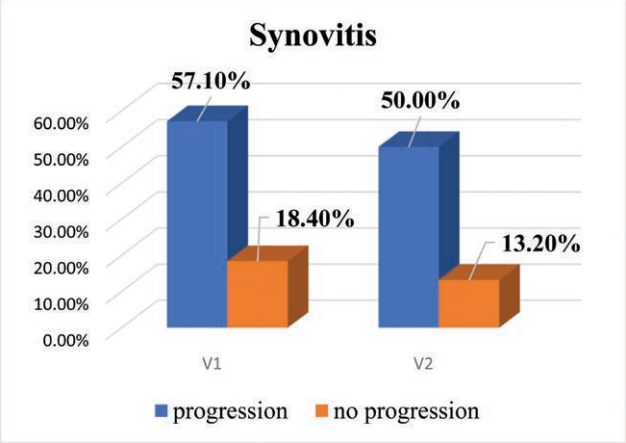

Figure 1.

POS1095 FOOD SOURCES OF DIETARY FIBRE AND RISK OF TOTAL KNEE REPLACEMENT RELATED TO SEVERE OSTEOARTHRITIS, THE SINGAPORE CHINESE HEALTH STUDY

Y.Y. Leung[1], A. Jin2, K. Tan[3], L. W. Ang[4], J. M. Yuan[5,6], W. P. Koh[2,7]. [1]*Duke-NUS Medical School, Health Services and Systems Research, Singapore, Singapore*; [1]*Duke-NUS Medical School, Health Services and Systems Research, Singapore, Singapore*; [3]*Ministry of Health, Policy, Research and Evaluation Division, Singapore, Singapore*; [4]*Ministry of Health, Public Health Group, Singapore, Singapore*; [5]*University of Pittsburgh, Division of Cancer Control and Population Sciences, UPMC Hillman Cancer Centre, Pittsburgh, United States of America*; [6]*University of Pittsburgh, Department of Epidemiology, Graduate School of Public Health, Pittsburgh, United States of America*; [7]*National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore*

Background: Although fibre intake was inversely associated with the risk of symptomatic knee osteoarthritis (KOA) in a US study, this association was partially confounded by lower body mass index (BMI) in those with higher fibre intake.
Objectives: We evaluated the association between fibre intake and its food sources, and the risk of total knee replacement (TKR) due to severe KOA.
Methods: We used data from the Singapore Chinese Health Study, a prospective cohort study that recruited 63,257 participants aged 45-74 years from 1993 to 1998. At baseline, we assessed diet using a validated 165-item semi-quantitative food frequency questionnaire, together with BMI and lifestyle factors. Incident TKR cases were identified via record linkage with nationwide hospital discharge database through 2017. We used multivariable Cox regression models to compute hazard ratio (HR) and the corresponding 95% confidence interval (CI) for risk of TKR.
Results: There were 2,816 cases of incident TKR due to severe KOA. Total fibre intake at baseline was not associated with risk of TKR after adjustment for confounders. Among the food sources of fibre, higher intake of legumes was associated with lower risk of TKR in dose-dependent manner; compared with those having the lowest quartile intake, HR (95% CI) was 0.86 (0.76, 0.96) for the highest quartile (*p* for trend = 0.004). This association was consistent after including BMI in the model, and homogenous across BMI categories. The consumption of other fibre sources, namely grain products, nuts and seeds, soy food, fruits and vegetables, was not associated with risk of TKR.
Conclusion: Intake of legumes, but not total fibre, was associated with a reduced risk of TKR. Further research is needed to replicate our findings, and to evaluate possible biological mechanisms that could explain the effect of dietary legumes in pathogenesis or progression of KOA.

Table 1. Hazard ratios (95% confidence intervals) for risk of total knee replacement according to intake of fibre (only shown total fibre and legumes): The Singapore Chinese Health Study (1993-2017).

THE EFFECT OF ONE DRY NEEDLING SESSION ON PAIN AND CENTRAL PAIN PROCESSING IN PATIENTS WITH KNEE OSTEOARTHRITIS: A RANDOMIZED CONTROLLED TRIAL

S. Vervullens[1], L. Meert[1], I. Baert[1], N. Delrue[2], K. Heusdens[3], A. Hallemans[1], T. Van Criekinge[1,4], R. Smeets[5,6], K. De Meulemeester[7] on behalf of MOVANT (MOvement ANTwerp) of the University of Antwerp. *[1]Antwerp University, Rehabilitation Sciences and Physiotherapy, Antwerp, Belgium*; *[2]Dry Needling Ghent, Rehabilitation Sciences, Ghent, Belgium*; *[3]University Hospital of Antwerp, Orthopedics, Antwerp, Belgium*; *[4]KULeuven, Rehabilitation Sciences, Bruges, Belgium*; *[5]Maastricht University, Rehabilitation Medicine, Maastricht, Netherlands*; *[6]University Hospital of Maastricht, Rehabilitation Medicine, Maastricht, Netherlands*; *[7]Ghent University, Rehabilitation Sciences, Ghent, Belgium*

Background: Osteoarthritis (OA) is the leading cause of chronic disability in the elderly[1,2]. Abnormal central pain processing (CPP) is present in around 30% of the knee OA patients[3] and can be partly induced by peripheral nociception through long term potentiation[4]. An attempt to resolve abnormal CPP can be to eliminate this nociception[5]. Myofascial trigger points (MTrPs) are often present in knee OA[6], can lead to nociception[7] and therefore abnormal CPP if prolonged present[8]. These are usually defined as hypersensitive tender spots within taut bands of a muscle[9]. Additionally, both MTrPs and knee OA can induce disturbed motor control, increased co-antagonist activation and modified gait pattern[10,11]. Dry needling (DN) is often used to deactivate the MTrP and thus resolve the source of nociception, which normally results in reducing pain and restoring muscle dysfunction[12]. However, studies about the effect of DN on CPP and other outcomes than pain are very limiting. Therefore, more high-quality studies concerning DN and its effects on CPP, muscle features and gait are needed[13,14].
Objectives: The aim of this randomized controlled trial is to assess the effect of one DN session compared to one sham needling (SN) session on pain (processing), muscle activity and gait in patients with knee OA.
Methods: 61 patients participated of which 31 were allocated to the DN and 30 to the SN group. Each patient underwent one treatment session. Primary outcomes were pain intensity, measured with questionnaires; and CPP, measured with quantitative sensory testing. Secondary outcomes included muscle co-activation, measured with electromyography; and spatiotemporal parameters, measured with gait analysis. Patients were assessed at baseline, 15 minutes (post 1) and 3 days after intervention (post2- only for the outcome pain). Linear mixed models was used to identify the possible differences over time between the two therapy modalities.
Results: The following significant within group differences were observed: decreased pain, stride- and step time and increased widespread pain pressure threshold and step length. A significant between group difference of the conditioned pain modulation score was found, whereas the SN group showed a decrease in difference between the pain pressure threshold scores (with and without conditioning stimulus) and the DN group remained stable. No other significant between or within group differences were detected. However, if we compared both interventions, the change over time for the visual analogue scale (VAS) behaved different in the DN ($p<0.05$, post 2 - baseline) and SN group ($p<0.05$, post 1 - baseline and post 2 - post 1).
Conclusion: One DN session has no larger effect on all outcome measurements compared to SN. Both therapies seem to be useful to improve pain and widespread pain pressure threshold in short term, however the improvement of pain differs in the groups. Although improvements in some spatiotemporal parameters were observed, it is uncertain they are of clinical relevance or related to treatment. More research is necessary to reveal the ideal number of sessions of DN to improve outcomes and to reveal the effect of DN compared to no treatment, as SN could have hide the real treatment effect.

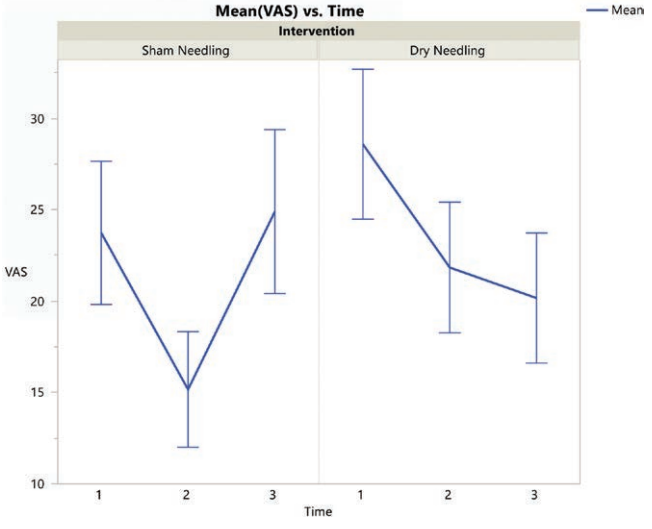

Figure 1. Mean and standard error of VAS scores over time in the DN and SN group

Demetres[7], S. Goodman[8,9]. *[1]Hospital for Special Surgery, Medicine, New York, United States of America*; *[2]Ronald Reagan UCLA Medical Center, Medicine, Los Angeles, United States of America*; *[3]UCLA Santa Monica Medical Center, Medicine, Santa Monica, United States of America*; *[4]Hospital for Special Surgery, Orthopedic Surgery, New York, United States of America*; *[5]Weill Cornell Medicine, Orthopedic Surgery, New York, United States of America*; *[6]Weill Cornell Medicine, Population Health Sciences, New York, United States of America*; *[7]Weill Cornell Medicine, Information Technologies and Services - Library, New York, United States of America*; *[8]Hospital for Special Surgery, Rheumatology, New York, United States of America*; *[9]Weill Cornell Medicine, Rheumatology, New York, United States of America*

Background: Black people are less likely to undergo total joint arthroplasties, despite reporting more severe symptoms. (1) While racial disparities exist in treatment utilization for osteoarthritis, comprehensive studies of the treatment preferences of Black people have not been conducted.
Objectives: The purpose of this manuscript is to systematically review the literature and identify Black osteoarthritis patients' treatment preferences to understand how they may contribute to racial differences in the utilization of different treatment options.
Methods: Searches ran on April 8, 2019 and April 7, 2020 in the following databases: Ovid MEDLINE (ALL - 1946 to Present); Ovid EMBASE (1974 to present); and The Cochrane Library (Wiley). Using the Patient/Population-Intervention-Comparison/Comparator-Outcome (PICO) format, our population of interest was Black people with hip and/or knee osteoarthritis, our intervention was preferences and opinions about treatment options for osteoarthritis, our comparator was white people with hip and/or knee osteoarthritis, and our outcome was preferences of osteoarthritis therapies. The protocol was registered under the PROSPERO international register, and the Preferred Reporting Items of Systematic reviews and Meta-Analyses (PRISMA) guidelines were followed.
Results: Searches across the chosen databases retrieved 10,894 studies after de-duplication, 182 full text, and 31 selected for inclusion in this review. Black people were less likely to use NSAIDs or narcotic analgesics compared to white people. (Figure 1) Black people were more likely than white people to use spirituality and prayer, as well as topical treatments. Utilization of meditation, supplement/vitamin use, and hot/cold treatments was not significantly different between groups. Black people were less willing than white people to consider or undergo joint replacements, even if the procedure was needed and recommended by a physician.
Conclusion: Racial differences persist in OA care across the spectrum of options. Future interventions should focus on providing accessible information surrounding treatment options and targeting perceptions of the importance of joint health.

POS1098 PREVALENT COMORBIDITIES ASSOCIATED WITH CLINICALLY DIAGNOSED OSTEOARTHRITIS: A CASE-CONTROL ANALYSIS INCLUDING 1,936,792 PEOPLE

A. Vivekanantham[1,2], D. Prieto-Alhambra[1,3], D. E. Robinson[1]. [1]*University of Oxford, Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, Oxford, United Kingdom*; [2]*Nuffield Orthopaedic Centre, Rheumatology, Oxford, United Kingdom*; [3]*Erasmus University Medical Center, Health Data Sciences, Rotterdam, Netherlands*

Background: Osteoarthritis (OA) is the most common form of arthritis and a major cause of pain and disability worldwide. Individuals with OA have increased cardiovascular morbidity and mortality, and other comorbidities are also more common amongst them than in the general population. In this study, we examined the prevalence and timing of the diagnosis of co-morbidities prior to the clinical diagnosis of OA.
Objectives: To determine the odds of comorbidities in newly diagnosed OA cases versus matched controls in the up to 10 years prior to diagnosis.
Methods: Case-control study of people registered in the Information System for Research in Primary Care (SIDIAP). SIDIAP includes primary care records covering over 80% of the population of Catalonia, Spain.
Participants with an incident diagnosis of OA, based on ICD-10-CM disease codes, were matched to up to 4 controls by age (within 2 years), gender and primary care practice. The first diagnosis date of OA used the index date, with matched controls using the same index date, to retrospectively review for comorbidities. Patients were required to have at least 3 years continuous registration prior to the index date. A total of 57 comorbidities were considered, based on prior knowledge and clinical consensus.
Descriptive statistics were used to obtain the demographic information about cases and controls. Counts of any comorbidity were calculated, and univariable and multivariable logistic regression were used to calculate odds ratios (ORs) and 95% confidence intervals (CIs) of individual comorbidities adjusted for age, gender and socio-economic status.
Results: In total, there were 455,494 OA cases and 1,481,298 matched controls. The cases and controls were similar with regards to age, gender and deprivation level.
The incident diagnosis of any comorbidity at any time prior to index date was 77% (n= 350,913) in cases versus 61% (n= 909,497) in controls.
The results from the multivariable analysis [Table 1] showed that OA patients had higher prevalence of many comorbidities up to 1 year prior to their diagnosis of OA compared to up to 10 years prior to diagnosis. They were most likely to be diagnosed with another musculoskeletal condition followed by neuro-psychiatric and metabolic and cardiovascular conditions. Conversely, patients with OA were less likely to be diagnosed with cancer up to 10 years prior to index date than matched controls.
Conclusion: Patients with OA have multiple chronic conditions. Our results found that the diagnosis of these other co-morbidities (particularly musculoskeletal and neuro-psychiatric conditions) were more likely to occur in the 1-year prior to their diagnosis of OA, compared to in the 10-year prior, except for lymphoma and solid malignancy. These results help us to further understand the relationship and timing of the development of multiple co-morbidities in patients with OA.

Table 1. Multivariable analysis at 1 year and 10 year prior to index date

POS1099 EFFICACY OF INTRA-ARTICULAR CORTICOSTEROID INJECTIONS IN KNEE OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

A. Najm[1], A. Alunno[2], C. Weill[3], J. Gwinnutt[4], F. Berenbaum[5]. [1]*Institute of Infection, Immunity and Inflammation, College of Medical Veterinary and Life Sciences, University of Glasgow, Rheumatology, Glasgow, United Kingdom*; [2]*University of Perugia, Rheumatology Unit, Department of Medicine, Perugia, Italy*; [3]*Paris Descartes University, Bibliothèque interuniversitaire de Santé, Paris, France*; [4]*Centre for Epidemiology Versus Arthritis, Centre for Musculoskeletal Research, School of Biological Sciences, Faculty of Biology, Medicine and Health, The University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Manchester, United Kingdom*; [5]*Sorbonne Université, INSERM CRSA Saint-Antoine, AP-HP, Saint Antoine Hospital, Paris, France., Rheumatology, Paris, France*

Background: Knee osteoarthritis (OA) is a frequent degenerative disease representing an important health and economic burden. Symptomatic medical treatments available include intra-articular (IA) injections of corticosteroids (GC) but

their efficacy is debated. In addition, safety signals regarding cartilage damage with IA GC have been highlighted in a few studies.
Objectives: To perform a meta-analysis of studies assessing IA GC efficacy and safety in knee OA.
Methods: A systematic literature review and a meta-analysis of randomized controlled trials (RCTs) assessing the effect of GC IA injections versus other interventions (IA Hyaluronic Acid, IA placebo, IA NSAID, oral NSAID or physiotherapy) in knee OA was performed. The effect of the interventions on pain and function were extracted from the single studies and pooled and are presented as short term (<6weeks), medium term (6-24 weeks) and long term (>24 weeks) follow-up period. Standardized mean differences (SMD) are reported.
Results: Of 520 studies screened, 23 were included in the SLR and 14 subsequently included in the MA. While IA GC showed a superior effect compared to control on both pain (SMD -0.61 (95% CI -1,25, 0.03)) and function (SMD -1.02 (95% CI -2.14, 0.10)) in short term follow-up; long term follow-up analysis favored controls (IA HA, IA NSAID, physiotherapy) for both pain (SMD 0.68 (95% CI -0.11, 1.47)) and function (SMD 0.88 (95% CI -0.36, 2.12) outcomes (Figure 1). No difference was found between interventions in the medium term. Safety data were reported in 18/23 studies (n= 1936/2314 patients); and side effects were reported as follows: arthralgia (69 IA GC patients, 146 IA HA patients, and 20 saline patients); site injection pain (7 in the IA GC group, 2 in the IA saline group, 14 in the IA HA group); 16 post injection knee swelling without signs of septic arthritis in the IA GC group and 24 in the IA HA group. In one study assessing cartilage effects of GCs, the rate of cartilage loss was greater in the GC group with a reduction of cartilage thickness at 2 year compared to placebo group. No difference was observed in the progression of cartilage denudation or bone marrow lesion. On the contrary, another study showed no effect of injections on the cartilage structure.

Conclusion: We demonstrate in this work that IA GC injections reduce pain and improve function in the early phase (≤6 weeks) of treatment. In the long term (≥24 weeks), other intervention such as IA HA injections or physiotherapy seem to be more efficient, but this effect was largely driven by single studies with large effect sizes and the comparators were heterogeneous.

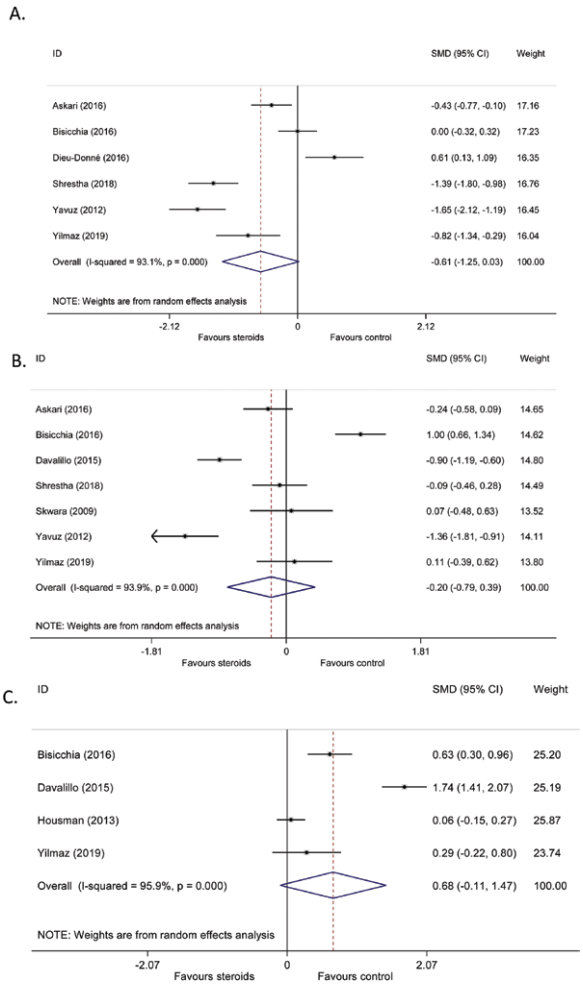

Figure 1. Knee pain outcome at short term (≤6weeks) (A), medium term (>6 & <24 weeks) (B), and long term (≥24 weeks) (C) follow up.

Disclosure of Interests: None declared.

POS1100 THE IMPACT OF CARDIOVASCULAR COMORBIDITIES ON KNEE OSTEOARTHRITIS PROGRESSION

H. Parente[1], F. Guimarães[1], D. Esperança Almeida[2], S. Azevedo[1], J. Rodrigues[1], D. Faria[1], D. Peixoto[1], J. Tavares-Costa[1], C. Afonso[1], F. Teixeira[1]. [1]*Unidade Local de Saúde do Alto Minho, Serviço de Reumatologia, Ponte de Lima, Portugal*; [2]*Hospital de Braga, Serviço de Reumatologia, Braga, Portugal*

Background: Osteoarthritis' (OA) pathophysiology is a complex and evolving subject, resulting in different phenotypes[1]. There is a known association between cardiovascular risk factors (CVRF) and OA, but its subjacent mechanism remains under-documented[2]. Pursuing this logic of direct systemic effect on joints by CV comorbidities[2], new therapeutic approaches could be reached.
Objectives: To determine the impact of CV comorbidities on knee OA, based on radiographic rate of progression and the need for total knee arthroplasty (TKA).
Methods: Cohort retrospective study among non-obese patients with primary knee OA, seen at a Portuguese hospital between 2017 and 2020. Clinical records were reviewed for sociodemographic and clinical data [age at the diagnosis, radiographic scoring through Kellgren Lawrence (KL) classification system at baseline (diagnosis) and 5 years later, KL progression and time to TKA]. CVRF such as Essential Arterial Hypertension (EHA), Dyslipidemia (DLP) and Type 2 Diabetes Mellitus (T2DM) prior to the OA diagnosis, as well as medication history were also recorded. Comparison of both cohorts, with and without the mentioned CVRF, was performed.
Results: A total of 304 patients with knee OA were eligible, 86 (28.3%) men and 218 (71.7%) women. Of those with CVRF (n=169), 121 (71.6%) were women and the mean age was 74.47±0.59 years. Among them, 129 (76.4%) had EAH, 122 (72.2%) had DLP, and 52 (30.8%) had T2DM. Five (3%) were treated with fenofibrate, 114 (67.5%) with statins, 40 (23.7%) with metformin, and 4 (2.4%) with liraglutide. Of those without CV risk factors (n=135), 97 (71.9%) were women and the mean age was 71.36±0.83 years. The presence of CVRF was associated with higher KL score (moderate to severe) at baseline [OR=2.118 (CI 95%: 1.264-3.549)] and 5 years later [OR=14.960 (CI 95%: 3.439-65.079)], faster KL progression, i.e., 2-grade worsening [OR=2.755 (CI 95%: 1.205-6.299)], and greater need for TKA [OR=3.781 (CI 95%:2.257-6.335)]. However, there was no association between the number of CVRF and progression of the KL score nor the rate of this progression, as well as between the number of CVRF and the need for TKA. EAH was associated with higher KL score at baseline [OR=1.819 (CI 95%: 1.108-2.987)] and 5 years later [OR=17.921 (CI 95%: 2.382-134.835)] but not with faster KL progression. It also associated with a greater need for TKA [OR=3.320 (CI 95%:1.197-5.750)]. DLP was associated with higher KL score at baseline [OR=1.843 (CI 95%: 1.120-3.030)] and 5 years later [OR=7.709 (CI 95%: 1.772-33.530)], as well as with faster KL progression [OR=2.560 (CI 95%: 1.249-5.246)], and greater need for TKA [OR=2.493 (CI 95%: 1.457-4.268)]. T2DM was associated with higher KL score 5 years after OA diagnosis [OR=1.103 (CI 95%: 1.059-1.148)], but not with KL score at baseline nor the occurrence of KL score progression during those first 5 years of disease or the need for TKA. Metformin, liraglutide, statins or fenofibrate use (either compounded or isolated) showed no statistically significant association with any of the following: KL score at baseline and 5 years later, occurrence of KL progression, and need for TKA. Time to TKA was not statistically different between patients with or without these medications. The number of medications used was not associated with KL progression or the need for TKA.
Conclusion: CVRF contribute globally to OA progression. Patients with EAH and DLP showed worse radiographic expression of OA features and greater need for TKA, with DLP patients having faster KL progression. The presence of more than one CVRF was not associated with an increased disease progression, and cardiovascular therapeutic medications were not associated with an overall protective role. This study highlights the importance of acting on preventive measures for CVRF, in OA management.

POS1101

THE OMERACT KNEE INFLAMMATION MRI SCORING SYSTEM: VALIDATION OF QUANTITATIVE METHODOLOGIES AND TRI-COMPARTMENTAL OVERLAYS BY COMPARISON WITH THE MRI OSTEOARTHRITIS KNEE SCORE

W. P. Maksymowych[1,2], J. L. Jaremko[3], S. Juhl Pedersen[4,5], I. Eshed[6], U. Weber[7], A. Mcreynolds[3], S. Wichuk[1], J. Paschke[2], R. G. Lambert[3]. [1]*University of Alberta, Medicine, Edmonton, Canada*; [2]*CARE Arthritis, Rheumatology, Edmonton, Canada*; [3]*University of Alberta, Radiology and Diagnostic Imaging, Edmonton, Canada*; [4]*COPECARE, Rheumatology, Copenhagen, Denmark*; [5]*Rigshospitalet, Clinical Medicine, Glostrup, Denmark*; [6]*Sheba Medical Center, Radiology and Diagnostic Imaging, Tel Aviv, Israel*; [7]*Practice Buchsbaum, Rheumatology, Schaffhausen, Switzerland*

Background: Randomized controlled trials have targeted reducing the size of BML and degree of synovitis for the treatment of OA. We have developed the OMERACT Knee Inflammation MRI Scoring System (KIMRISS) and have recently refined it to maximize reliability and sensitivity to change. Innovations include electronic overlays for assessment of BML in 500 subregions, a web-based interface with direct online scoring, and real-time iterative calibration (RETIC) prior to reading exercises. Synovitis-effusion (S-E) is also scored on all consecutive sagittal slices on a web-based interface.
Objectives: We aimed to test the feasibility, reliability, and responsiveness of KIMRISS versus an established method, MOAKS, in two multi-reader exercises.
Methods: KIMRISS incorporates web-based graphic overlays for each of femur, tibia, and patella (range 0-500). S-E is recorded as the largest diameter perpendicular to the longest axis of this feature (range 0-100). All scores are pro-rated for a standardized number of MRI slices. In a pre-reading exercise for KIMRISS, readers scored sufficient cases in RETIC to attain scoring proficiency, pre-specified as an ICC of ≥0.80 and ≥0.70 for status and change scores of BML and S-E compared to developer reads. A new web-based scoring platform with overlays designating different subregions for scoring BML was developed for MOAKS. We compared reliability for status and change scores of BML and S-E in 2 international multi-reader exercises of baseline and one-year MRI scans from the Osteoarthritis Initiative: A. 4 expert readers and an OMERACT fellow scored 38 cases selected for MOAKS BML score ≥1. B. 7 expert readers and an OMERACT fellow scored 60 cases selected for MOAKS BML ≥3 and Kellgren-Lawrence (K-L) grade <3. Reliability was assessed by intra-class correlation coefficient (ICC) and Smallest Detectable Change (SDC), responsiveness by the standardized response mean (SRM), and feasibility using the System Usability Scale (SUS scoring range 0-100).
Results: For exercises A/B, subjects were 55.3%/ 26.7% male, mean(±SD) age 61.7(±9.1)/61.9(8.8) years, and radiographic K-L grade ≤2 in 39.4%/100%. Change was small in both exercises (<5% of scoring range for KIMRISS and MOAKS BML and S-E) with comparable responsiveness (Table 1). Despite this, ICC for change was consistently good to very good for both BML and S-E and consistently better for KIMRISS (Table 1). Mean SUS scores were 88.2 for KIMRISS and 54.3 for MOAKS.

Table 1. KIMRISS and MOAKS scores in Two International Multi-reader Exercises

Method	MRI feature	Scores mean (SD)			SDC (% of max)	P value	SRM
		Baseline	One-year Follow up	Change			
EXERCISE A							
MOAKS	**BML**	3.6 (2.9)	3.4 (2.3)	-0.2 (1.9)	1.0 (2.2%)	0.72	-0.11
	Synovitis-effusion	1.3 (0.8)	1.5 (0.8)	0.2 (0.4)	0.4 (13.3%)	0.017	0.5
KIMRISS	**BML**	15.7 (13.3)	21.2 (22.5)	5.5 (15.3)	5.6 (1.1%)	0.022	0.36
	Synovitis-effusion	21.8 (12.0)	24.3 (11.9)	2.5 (7.4)	2.8 (2.8%)	0.043	0.34
EXERCISE B							
MOAKS	**BML**	4.2 (2.6)	3.7 (2.4)	-0.5 (2.1)	1.1 (2.4%)	0.083	-0.24
	Synovitis-effusion	1.2 (0.7)	1.3 (0.8)	0.0 (0.5)	0.4 (13.3%)	0.59	0.0
KIMRISS	**BML**	18.0 (17.5)	15.9 (14.3)	-2.1 (12.3)	5.9 (1.2%)	0.19	-0.17
	Synovitis-effusion	21.8 (9.3)	22.9 (10.8)	1.1 (7.1)	2.2 (2.2%)	0.25	0.15

Intra-class Correlation Coefficients (95%CI)

Method	MRI feature	Exercise A	Exercise B
KIMRISS status	BML	0.86 (0.78-0.92)	0.80 (0.70-0.87)
KIMRISS change		0.88 (0.81-0.93)	0.72 (0.64-0.80)
MOAKS status	BML	0.71 (0.46-0.85)	0.67 (0.56-0.77)
MOAKS change		0.76 (0.64-0.85)	0.69 (0.60-0.78)
KIMRISS status	Synovitis-effusion	0.88 (0.81-0.93)	0.75 (0.52-0.86)
KIMRISS change		0.87 (0.79-0.92)	0.87 (0.82-0.91)
MOAKS status	Synovitis-effusion	0.66 (0.4-0.79)	0.65 (0.52-0.75)
MOAKS change		0.52 (0.36-0.67)	0.48 (0.37-0.60)

Conclusion: The KIMRISS method for scoring BML and Synovitis-Effusion scores highly for feasibility and demonstrates consistently high reliability when compared to MOAKS. Further validation for responsiveness is necessary in cases with greater change in MRI features than in the OAI dataset.
Disclosure of Interests: None declared.

POS1102

TEMPORAL TRENDS AND FACTORS ASSOCIATED WITH VITAMIN D PRESCRIPTION AND INTAKE

G. Adami[1], D. Gatti[1], O. Viapiana[1], P. Olivi[2], F. Bertoldo[3], A. Fassio[1], M. Rossini[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*; [2]*University of Verona, Orthopedic Unit, Verona, Italy*; [3]*University of Verona, Bone Metabolism and Osteoncology Unit, Verona, Italy*

Background: Vitamin D has proven skeletal effects and its administration is recommended in patients with osteoporosis by many national and international guidelines. Nevertheless, the compliance to treatment of patients with osteoporosis is scarce. Understanding the factors associated with low vitamin D intake and prescription might help design future intervention aimed to improve adherence.
Objectives: This study aims to investigate the temporal trends and factors associated with vitamin D prescription and intake.
Methods: Using a web-based fracture risk-assessment tool, we collected demographic, densitometric and clinical data of women at high risk for fractures. To determine the factors associated with low vitamin D intake we ran a multivariable logistic regression analysis. We described the public general interest in the term "vitamin D" using the Google Trends tool.
Results: 12,419 women were included in the study. 6,748 (54.4%) individuals had a prevalent fragility fracture and 8,950 (72.1%) individuals were on <800 IU of vitamin D per day and 11,434 (92.1%) were taking <1,200 IU of vitamin D per day. The factors associated with vitamin D intake were evaluated with a multivariable logistic regression analysis, which results are presented in Table 1. We found that low BMD levels, the presence of associated comorbidities and glucocorticoid utilization were associated with greater vitamin D intake. Falls were associated only with lower risk of receiving very low dose of vitamin D (<250 IU day). Smoking status was associated with lower vitamin D intake. Overall, the internet interest in vitamin D was higher during the winter season Figure 1.

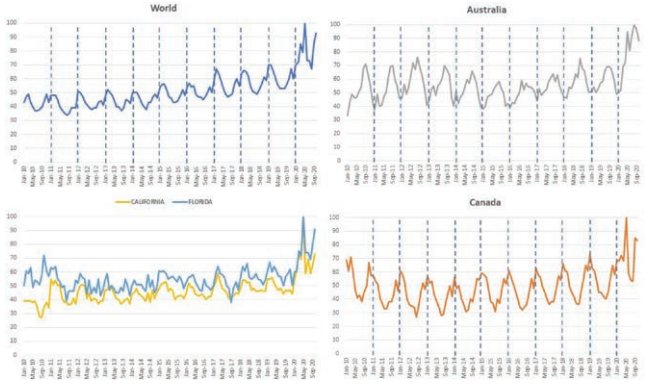

Figure 1. Google trends interest in the term "vitamin D" from January 2010 to October 2020

Conclusion: Low vitamin D intake (<800 IU day) was common in our cohort of women at high risk for fractures. The factors associated with greater vitamin D intake were: having low BMD levels, associated rheumatic diseases and glucocorticoid use. Falls were associated with lower risk of receiving very low dose of vitamin D (<250 IU day). Smoking status was associated with lower vitamin D intake.

POS1103 SLEEP DISTURBANCE AND BONE MINERAL DENSITY, RISK OF FALLS AND FRACTURE: RESULTS FROM A 10.7-YEAR PROSPECTIVE COHORT STUDY

F. Pan[1], J. Tian[1], F. Cicuttini[2], G. Jones[1]. *[1]University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*; *[2]Monash University Medical School, Department of Epidemiology and Preventive Medicine, Melbourne, Australia*

Background: Sleep problems are common in the general population and have been reported to adversely affect bone health and increase risk of falls and fracture. However, no study has investigated whether an increased risk of fracture is attributable to sleep-related low bone mineral density (BMD) and/or an increased risk of falls.
Objectives: This study, therefore, sought to describe the associations of sleep disturbance with BMD, risk of falls and fractures.
Methods: The analyses were performed in a population-based prospective cohort study with 1,099 participants (aged 50–80 years) enrolled at baseline, and 875, 768 and 563 participants traced at a mean follow-up of 2.6, 5.1 and 10.7 years, respectively. At each visit, self-reported sleep disturbance was recorded. BMD (by DXA), falls risk and fracture were measured at each visit. The short-form Physiological Profile Assessment was used to measure falls risk expressed as Z-score. Fractures were self-reported. Mixed-effects model and generalised estimating equations were used for the analyses.
Results: In multivariable analysis, there was a dose-response relationship between extent of sleep disturbance and falls risk score with the strongest association in those reporting the worst sleep disturbance (β=0.15/unit; 95%CI 0.02-0.28). The worst sleep disturbance was associated with an increased risk of any (relative risk [RR] 1.30/unit; 95%CI 1.01-1.67) and vertebral fracture (RR 2.41/unit; 95%CI 1.00-5.80) compared with those reporting no interrupted sleep. This was independent of covariates, hip BMD and falls risk. There was no statistically significant association between sleep disturbance and BMD at hip, spine or total body.
Conclusion: Sleep disturbance was independently associated with a greater falls risk score and an increased risk of fractures, suggesting that correcting sleep disturbance has the potential to reduce both falls risk and fractures.

POS1104 THE DEVELOPMENT AND VALIDATION OF A RISK STRATIFICATION QUESTIONNAIRE TO SCREEN FOR MEDICATION RELATED OSTEONECROSIS OF THE JAW RISK IN OSTEOPOROTIC PATIENTS

Y. El-Miedany[1,2], M. El Gaafary[3], M. Toth[4], S. Bahlas[5], W. Hassan[6], M. H. Abu-Zaid[7] on behalf of Egyptian Academy of Bone Health and Metabolic Bone Diseases. *[1]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom*; *[2]King's College London, Education, London, United Kingdom*; *[3]Faculty of Medicine, Ain Shams University, Public Health and community, Cairo, Egypt*; *[4]Darenth Valley Hospital, Medicine, Dartford, United Kingdom*; *[5]King Abdulaziz University, Rheumatology, Jeddah, Saudi Arabia*; *[6]Faculty Of Medicine - Benha University, Rheumatology and Rehabilitation, Benha, Egypt*; *[7]Faculty Of Medicine - Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt*

Background: Given the gaps in knowledge that exist in relation to risk stratification for osteonecrosis of the jaw (ONJ) amongst patients treated with anti-resorptive agents, there is a high need for an evidence-based measure which would facilitate the identification of those patients at higher risk of ONJ development; particularly, most of the available advice is empirically based.
Objectives: to develop a valid self-administered questionnaire to facilitate risk stratification and risk minimisation of medication related ONJ in osteoporotic patients treated with anti-resorptive agents.
Methods: Development of ONJ risk assessment questionnaire (ONRAQ) followed 5 stages: 1. Review of the literature to Identify the risk factors associated with medication related ONJ. 2. Item pool development: a list of the main risk factors was compiled. Rare or uncommon factors were excluded. 3. A questionnaire was developed. This was based on the idea that the questions should be straight forward and as clear as possible. 4. Pre-testing of the questionnaire. 5. Validation of the questionnaire by comparing the patients answers with their medical records. Patients at risk were advised to seek dental assessment and the dental report was evaluated. The last prescription was reviewed to verify the current medications. 157 patients were invited to participate and were prospectively monitored for 5-years to assess for the incidence of medication related ONJ. Advice was given regarding how to maintain good dental hygiene to prevent dental disease and to ensure that any dental interventions that are considered necessary are carried out as conservative and preservative as possible. Comprehensibility of the model sections was also assessed.
Results: Stages 1 and 2 identified the risk factors chosen for the questionnaire. These risk factors were stratified into 4 sections: Personal, Dental and oral health, current medications and associated comorbidities. Stage 3 led to the development of the 27 items questionnaire. Personal: 3 risk factors (age, elevated BMI and smoking), Dental and oral health (11 risk factors), current medications (3 risk factors) and associated comorbidities (10 risk factors). Analysis of the answers provided by 126 patients, who completed the study, age range 58-82 years revealed that the mean time to answer the questionnaire was 1.9 + 0.153 minutes. The ONRAQ has shown a strong validity when compared to the patients' data record (range 0.89-0.97). All patients rated the questionnaire as easily comprehensible. Comprehensibility of the various questionnaire sections ranged between 96.1% and 98.2% denoting that all the questions were well understood by the great majority of patients. 11/126 (8.7%) had a dental procedure in the past 6-months, 13/126 (10.3%) were advised to stop smoking. Whereas 20/126 (20.6%) had associated comorbidities. Risk stratification led to the advice to start oral bisphosphonates/ denosumab rather than IV zoledronate for patients at moderate risk (comorbidities, personal, medication). Treatment was postponed till complete healing for those with recent history of invasive dental procedure (high risk). No ONJ was identified after 5-years of follow up.
Conclusion: Results of this questionnaire revealed that the ONRAQ is valid screening questionnaire. It can be implemented, as a risk minimisation measure, in standard practice. The questionnaire was able to identify patients at risk of developing medication related osteonecrosis of the jaw and facilitate the prospective risk management of ONJ.

POS1105

EFFECTS OF CHOLECALCIFEROL AND CALCIFEDIOL IN OSTEOPOROTIC WOMEN WITH SECONDARY HYPERPARATHYROIDISM DUE TO SEVERE VITAMIN D DEFICIENCY UNDERGOING ZOLEDRONIC ACID TREATMENT: A RANDOMIZED-CONTROLLED TRIAL

G. Botticella[1], M. Pizzonia[2], B. Cossu[3], R. Bruno[3], D. Camellino[1], G. Girasole[1], A. Giusti[1], M. Pedrazzoni[1], S. Alexovits[1], F. Pleitavino[3], F. Santolini[4], A. Nencioni[2], G. Bianchi[1]. [1]*Local Health Trust 3, Division of Rheumatology, Department of Medical Specialties, Genoa, Italy*; [2]*University of Genoa, Geriatric Clinic, Department of Internal Medicine and Medical Specialties, Genoa, Italy*; [3]*Local Health Trust 3, Orthopedic and Trauma Unit, Department of Surgery, Genoa, Italy*; [4]*Policlinic San Martino Hospital, Orthopaedic and Trauma Unit, Department of Emergency, Genoa, Italy*

Background: Secondary hyperparathyroidism (sHPTH) due to vitamin D deficiency impairs the bone mineral density (BMD) response to alendronate,[1-2] but the optimal strategy for its correction in postmenopausal osteoporotic women (PMO) about to start zoledronic acid (ZOL) therapy is still unknown.

Objectives: To evaluate the effects of cholecalciferol (D3) and calcifediol (25OHD) on serum 25-OH-vitamin D (s25OHD), parathyroid hormone (PTH) and BMD in PMO presenting with sHPTH due to vitamin D deficiency.

Methods: PMO with s25OHD <20 ng/ml, sHPTH (PTH >65 pg/ml) and BMD T-score at the lumbar spine (LS), femoral neck (FN) or total hip (TH) < -2.5, or between -1 and -2.5 plus one vertebral/femoral fracture, were randomly assigned to receive a therapeutic dose of D3 (300.000 IU bolus) followed by 175 mcg/weekly of D3, or 175 mcg/weekly of 25OHD alone, 2 months before receiving a single intravenous infusion of ZOL (5 mg). BMD at the LS, FN and TH was assessed at baseline and after one year from ZOL. Serum calcium, PTH and s25OHD were measured at baseline, and 6- and 12-month after ZOL. Adverse and clinical events were ascertained by 3-and 9-month telephone interviews, and by 6- and 12-month clinical evaluation.

Results: 45 PMO (25OHD N=23, D3 N=22) were enrolled over one year and 32 subjects (mean age ±SD 75±10 years, range 51-91) completed the 1-year of treatment/follow-up (25OHD N=17, D3 N=15). Most PMO discontinued for protocol violation, while three deceased before study ending (25OHD N=1, D3 N=2) for reasons not related to the agents investigated. The baseline characteristics were comparable in both groups. At baseline mean s25OHD (±SE) was 8±1 ng/ml in the 25OHD group and 8±1 ng/ml in the D3 group. The corresponding figures for PTH were 111±6 pg/ml (25OHD) and 117±5 pg/ml (D3). Mean s25OHD (±SE) increased in both groups at 6- and 12-month, being significantly greater in the 25OHD group (12-month, 56±2 ng/ml) compared to the D3 group (12-month, 34±2 ng/ml, P<.001) at both time points (Figure 1). PTH (mean ±SE) decreased in both groups, being significantly lower in the 25OHD group at 12-month (25OHD 46±6 pg/ml versus D3 70±6 pg/ml, P=.007), as shown in Figure 1. BMD at the LS, FN and TH increased in both groups (with significant increases versus baseline only at the FN) without significant differences between s25OHD and D3. In PMO receiving D3 serum calcium remained stable over time, while those receiving s25OHD demonstrated a significant increase of serum calcium, with 2 PMO presenting a value close to the upper limit of the reference range at 12-month. No patient reported incident fractures or adverse events.

Conclusion: Calcifediol 175 mcg weekly appears more potent in improving s25OHD and decreasing PTH concentrations compared to cholecalciferol therapeutic dose (300'000 IU) plus 175 mcg weekly in PMO presenting with sHPTH due to severe vitamin D deficiency about to start ZOL therapy. Further studies are warranted to clarify implications on BMD improvements on the long-term of similar 25OHD and D3 regimens.

POS1106

FRAX AND THE EFFECT OF TERIPARATIDE ON BONE MINERAL DENSITY IN SECONDARY OSTEOPOROSIS

S. Garcia[1], B. M. Fernandes[1], M. Rato[1], F. Oliveira Pinheiro[1], D. Fonseca[2], D. Santos Oliveira[1,3], A. Martins[1], F. R. Martins[4], G. Terroso[1], M. Bernardes[1,5], L. Costa[1]. [1]*São João Universitary Hospital Center, Rheumatology, Porto, Portugal*; [2]*Centro Hospitalar Vila Nova de Gaia/Espinho - Unit 1, Rheumatology, Vila Nova de Gaia, Portugal*; [3]*Center for Health Technology and Services Research (CINTESIS), Faculty of Medicine, University of Porto, Porto, Portugal*; [4]*University Hospital Center of Algarve, Faro, Rheumatology, Faro, Portugal*; [5]*Faculdade de Medicina da Universidade do Porto - FMUP, Rheumatology, Porto, Portugal*

Background: Teriparatide has been shown to increase spine and hip bone mineral density (BMD) and to reduce vertebral and non-vertebral fractures. (1) It is currently not clear whether the effect of teriparatide is dependent on the baseline risk of fracture or osteoporosis (OP) type, a finding that could have an impact on our therapeutic decision.

Objectives: Investigate if there is a relationship between teriparatide effect in BMD and baseline 10-year fracture probability, assessed using FRAX®, in primary and secondary OP patients.

Methods: This is a longitudinal, retrospective study including consecutive patients with the diagnosis of OP treated with teriparatide for 24 months, with a ten-year follow-up period, at our rheumatology department. Demographic, clinical, laboratorial, BMD and occurrence of fracture data were collected. The 10-year risk of osteoporotic fracture was estimated using the fracture risk assessment tool (FRAX) v 4.1 with the Portuguese population reference. Statistical analysis was performed using the software SPSS 23.0. Correlations between continuous variables were evaluated with spearman coefficient. p<0.05 was considered statistically significant.

Results: Eighty patients (88.8% female, median age 65.00 (59; 75)) were included. Forty-nine patients (61.3%) has secondary OP, mainly of cortisonic etiology (61.2%, n=30). Before treatment, median lumbar spine BMD was 0.870 [0.767, 0.964] g/cm^2, median T-score of -2.60 (-3.30, -1.90); median total femur BMD was 0.742 [0.667, 0.863] g/cm^2, median T-score of -2.10 (-2.80, -1.30); median femoral neck BMD was 0.671 [0.611, 0.787] g/cm^2, median T-score of -2.50 [-3.20, -1.85]. Regarding fracture risk, median FRAX-based 10-year major fracture risk (with BMD) at baseline was 16% [10.0; 23], and median hip fracture risk was 7.2% [3.4; 13.8].

The median variation of BMD, after finishing teriparatide treatment, in the spine was 0.107 [0.029; 0.228]; median BMD variation in total femur was 0.013 [-0.013; 0.068] and median BMD femoral neck was 0.046 [-0.002; 0.109]. We observed a numerically superior effect, albeit without any statistical significance, of teriparatide on bone mineral density gain in secondary OP (*versus* primary OP) at lumbar spine, total femur and femoral neck.

Most patients continued anti-osteoporotic treatment with a bisphosphonate (81.2%, n=65) and, during follow-up, 17 patients had an incident fracture (8 hip fractures and 6 vertebral fractures), median of 5 [1.75, 8.25] years after ending teriparatide.

We found a discrete correlation between FRAX-based hip fracture probability and the variation of bone mineral density in total femur (Spearman's coefficient 0.248, p=0.04). There was no correlation between FRAX-based major fracture probability and and the variation of bone mineral density in the spine or femur. When we separately analyze the relationship between the variation in total hip BMD and the FRAX-based fracture risk, depending on whether it is a secondary or primary OP, we find that the correlation is stronger and only remains in secondary OP (Spearman's coefficient 0.348, p=0.03).

Conclusion: Our data suggest that teriparatide could be an important weapon in the treatment of secondary cause OP, particularly cortisonic, and in patients at high fracture risk, although further larger studies are needed to confirm these findings.

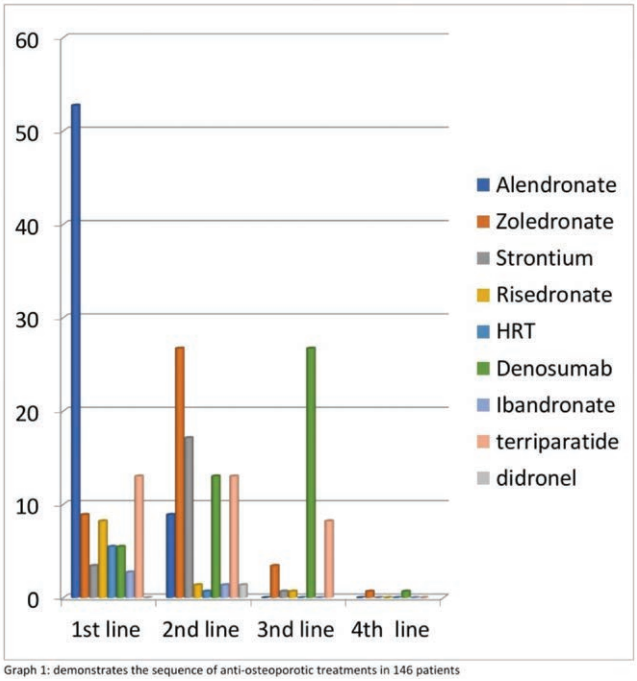
POS1107

THE EFFICACY, SAFETY AND OUTCOME AFTER 5-8 YEARS OF PARENTERAL ANTI-OSTEOPOROTIC THERAPY EVALUATED AT A DISTRICT GENERAL HOSPITAL IN THE UK

Z. Alkutobi[1], D. Laila2, T. Jones[3], A. Nandagudi2. *[1]Basildon and Thurrock University Hospitals NHS Foundation Trust, Rheumatology, Basildon, United Kingdom*; *[1]Basildon and Thurrock University Hospitals NHS Foundation Trust, Rheumatology, Basildon, United Kingdom*; *[3]Basildon and Thurrock University Hospitals NHS Foundation Trust, Internal Medicine, Basildon, United Kingdom*

Background: Parenteral anti-osteoporotic medications are frequently recommended for the management of primary and secondary osteoporosis by NICE (1) and EULAR (2) guidelines.
Objectives: This audit aimed at evaluating the efficacy, adherence and safety profile of denosumab (D), zoledronate (Z) and teriparatide (T).
Methods: The data of patients initiating D, Z and T from 2012-2021 were retrospectively reviewed using electronic medical records at Basildon hospital.
Results: We enrolled 146 patients diagnosed with low bone density and on following treatment (3-6 years D (n: 50), 4-5 years Z (n: 50) and 2 years T (n: 46). More than 92% were Caucasian females; 41.7% were above 80 years.
T group had more pronounced reduction in bone mineral density (BMD) with a mean T-score
(spine:-3.9, hip: -2.6, neck of femur: -2.7; followed by Z group (spine: -2.6, hip:-2, neck of femur: -2.5) and D group (spine: -2.3, hip:-2.2, neck of femur: -2.3).
Primary prevention was in 26% and secondary prevention in 73.9%; with the commonest fractures at the vertebrae at 40%.
Oral bisphosphonate was the first choice in 63.6% of the cases (please see graph1). Intolerance, gastric upset or inefficacies were the commonest reasons to avoid them.



Graph 1: demonstrates the sequence of anti-osteoporotic treatments in 146 patients

After the 3rd Z or 5th D, DXA scan shows improvements or stability in BMD at both hip and spinal areas in 88% and 82% respectively; compared to 69.6% after completing 2 years of T. The rate of improvement or stability plummeted after the 10th D and 5th Z (Please see Table 1).

Table 1. Monitoring BMD after courses of D, Z and T.

DXA scan: changes in BMD:	*After the 5th D*	*After the 10th D*	*After the 3rd Z*	*After the 5th Z*	*After 2 years of T*
Percentage of scanned patients	100%	90%	100%	60%	71.73%
Improved or stable BMD at spine or hip areas	82%	75.5%	88%	85.6%	69.6%
Improved or stable BMD at the spine but declined at hip area	18%	19.9%	12%	13.3%	24.2%
Declined BMD at both spine and hip areas		4.4%			6%

The course of T was stopped earlier in 28.2% of the cases due to the difficulty in taking injections or side effects including nausea, gastric upset, myalgia, insomnia, poor renal function, raised PTH, ALP and calcium. Dental issues (not osteonecrosis) were the reason to stop Z and D in 2% of each group and 8% choose to discontinue D after developing other non-related comorbidities. There were no fragility fractures during the treatment courses.
The outcome after reviewing 91.3% of those who completed or stopped the T course shows 39% commenced on D whereas 35.7% and 19% on Z and alendronate respectively leaving 7.1% on drug holiday. After completion of the 10th D, 78.5% of the reviewed patients were continued on further D injections whereas 3.5% were switched to T and 17.8% given drug holiday. For those who were reviewed after the 5th Z, 94% were switched to D and 5.8% given drug holiday.
Conclusion: D, Z and T were well tolerated and could effectively either maintain or improve the BMD at both spinal and hip sites and prevent fragility fractures and T was associated with the most pronounced soar in BMD. There were few cases of deterioration mainly at the hip area with all groups.
Prior bisphosphonate therapy did not show significant influence on the later effects of D, Z or T on BMD. After completion of the treatment for the 3 groups, only 30.87 % of the reviewed cases were advised for drug holiday and majority were switched to D as Z and T is limited to 5 and 2 years course respectively.
Heterogeneity in decision making exists due to variability in recommending these medications, patient preference and mode of administration. To optimize the adherence and effects of anti-osteoporotic medications, stratified guidelines is required for the long term use of these medications and discontinuation of D.

POS1108

THE ACCURACY OF OSTEOPOROTIC FRACTURE RISK PREDICTION IN PATIENTS WITH RHEUMATOID ARTHRITIS USING THE PREDICTIVE MODEL DEVELOPED AT V.A. NASONOVA REASEARCH INSTITUTE OF RHEUMATOLOGY (RUSSIA) AND FRACTURE RISK ASSESSMENT TOOL (FRAX)

P. Kozhevnikova[1], P. Kovalenko[1], S. Glukhova[1], I. Dydykina[1], A. Lila[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory for the Study of Comorbid Infections and Safety Control of Drug Therapy, Moscow, Russian Federation*

Background: FRAX is a computer-based algorithm that calculates the 10-year probability of a major osteoporotic fracture and the 10-year probability of hip fracture. However, FRAX has several limitations in assessing the risk of fracture in patients with rheumatoid arthritis (RA).
In 2013 V.A. Nasonova Reasearch Institute of Rheumatology (Russia) developed a predictive mathematical model for assessing the risk of osteoporotic fractures in RA, which includes 2 main risk factors: cumulative glucocorticoid dose (GC), decrease in BMD in the femoral neck to osteoporosis, and 2 additional factors: for patients under 65 years of age - the presence of ischemic heart disease, and for people over 65 - a history of gastric ulcer or duodenal ulcer.
Objectives: To compare accuracy of osteoporotic fracture risk prediction in patients with RA using the predictive model developed at V.A. Nasonova Reasearch Institute of Rheumatology (IR) and FRAX.
Methods: This monocentric (single-center) prospective study included 70 patients with RA, aged 40 to 80 years. The follow-up period - 8.0 ± 1.2 years; mean age at the baseline was 55.4±7.8 years old; the mean disease duration at

the baseline - 14,7±10,2 years. All patients retrospectively calculated the 10-year probability of fractures and prognostic model developed by the IR.
Results: According to the Fracture Risk Assessment Tool, 32 (46%) patients had a low risk of osteoporotic fractures, 38 (54%) had a high risk. According to the predictive model of IR 33 (47%) patients had a low risk of osteoporotic fractures, 37 (53%) had a high risk. During the follow-up period, osteoporotic fractures were occurred in 18 (26%) patients: 14 (78%) of them had a high risk of fractures according to the predictive IR model, and 13 (72%) patients - according to the Fracture Risk Assessment Tool. Positive and negative predictive value of the Fracture Risk Assessment Tool was 34% and 84%, respectively, of the predictive model of IR - 38% and 88%, respectively. Prognosis of the predictive model of IR in 73% cases coincided with assessing the 10-year probability of fracture.
Conclusion: The predictive model developed at V.A. Nasonova Reasearch Institute of Rheumatology (Russia) showed a higher sensitivity and specificity in determining the risk of osteoporotic fractures in RA patients vs FRAX algorithm.

POS1109 MULTIVARIATE ANALYSIS OF RISK FACTORS FOR REDUCED BONE MINERAL DENSITY ASSESSED WITH RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS)

Z. Batalov[1], M. Nikolov[2], N. Nikolov[2]. [1]*Medical University of Plovdiv, University Hospital Kaspela, Plovdiv, Bulgaria*; [2]*UMBAL Dr. Georgi Stranski, Rheumatology, Pleven, Bulgaria*

Background: Radiofrequency echographic multi spectrometry (REMS) is an innovative radiation-free approach for the assessment of bone mineral density (BMD) at axial sites. The principle of this technology is based on the analysis of native raw unfiltered ultrasound signals, the so called radiofrequency ultrasound signals, acquired during an echographic scan of the lumbar spine and/or femoral neck. [1]. A previous published study showed a high degree of correlation between the T-score values provided by the two techniques-REMS and dual energy X-ray absorptiometry for both lumbar spine and femoral neck [2]. REMS software outputs information about BMD (g/cm2), T-scores, Z-scores [standard deviations (SD)], percentage of body fat and basal metabolic rate [BMR (kcal/daily)] [3].
Objectives: The aim of the current study is to investigate the multivariate significant risk factors for reduced BMD through REMS technology.
Methods: In this study, a total of 273 women with mean age 62 years (yrs.) ± 12 yrs. (range 25-88 yrs.) underwent REMS assessments. Subjects were divided into two groups after acquiring information about the spinal T-scores: 1st group with T-scores ≥-1 SD and 2nd group with T-scores <-1 SD. Age, weight, height, body mass index (BMI), basal metabolic rate (BMR), body fat and menopausal status were the risk factors included in the multivariate statistical analyses. Binary logistic regression was used to assess which are the significant risk factors for T-score <-1 SD. Youden's indices were calculated for selecting the cut-off points for each risk factor.
Results: 273 women had mean weight of 70.5 kg. ± 15.7 kg. (range 39.4-127 kg.), mean height 157.1 cm. ± 8.8 cm. (range 100-182 cm.) and mean body mass index (BMI) 28.6 kg/cm2 ± 6.1 kg/cm2 (range 14.9-47.5 kg/cm2). The mean body fat of the subjects was 37.8% ± 8.8% (range 9-52%) and the mean BMR was 1274.01 kcal/daily ± 163.17 kcal/daily (range 929.7-1908.4 kcal/daily). 260 women (95.2%) were attributed to postmenopausal. Age (p=0.000), BMI (p=0.015), menopause (p=0.006) and BMR (p=0.000) were the multivariate significant risk factors for T-score <-1 SD. Odds ratio for the risk factor age was 1.16, so each added year of the women's age increased the risk for T-score <-1 SD by 1.16%. Women over the age of 65 yrs. showed the highest risk for spinal T-score <-1 SD. The odds ratio of the menopause as a risk factor for spinal T-score <-1 SD was 9.54, so postmenopausal women showed about 9.5 times higher risk of T-score <-1 SD of the lumbar spine than women who still have their period. The increase of BMI by one kg/cm2 decreased the probability of spinal T-score <-1 SD by 0.15% and the increase of BMR by one kcal/daily decreased this probability by 0.02%. Women with BMI above 28.63 kg/cm2 and those with BMR >1331.75 kcal/daily were unlikely to develop spinal T-score <-1 SD.
Conclusion: In the current study, multivariate regression analysis was used to develop a specific REMS-based risk prediction model for spinal BMD, corresponding to T-score <-1 SD. Postmenopausal women over age of 65 yrs. with BMI lower than 28.63 kg/cm2 and BMR <1331.75 kcal/daily were at the highest risk for T-score <-1 SD of the lumbar spine.

POS1110 RELIABILITY OF VERTEBRAL FRACTURE ASSESSMENT ON DUAL-ENERGY X-RAY ABSORPTIOMETRY

M. Yasmine[1], S. Mariem[1], S. Miladi[1], A. Fazaa[1], E. Fguiri[1], L. Souebni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Vertebral Fracture Assessment (VFA) is a new feature available on modern densitometers. Yet, the assessment of vertebral fracture (VF) status has not become standard practice.
Objectives: Our study aimed to evaluate the reliability of VFA as assessed by a rheumatologist and a radiology technician.
Methods: We conducted a cross-sectional study assessing the performance of low-radiation single energy x-ray absorptiometry VFA for the detection of VF. We selected patients who were assessed for osteoporosis according to screening protocols. Bone mineral densitometry was measured using standard methods over the lumbar spine L1-L4, the total proximal femur, and results were expressed as T-scores. All VFA were independently evaluated by 2 experienced readers: a rheumatologist and a radiology technician for the identification of VF (T4-L4). VF was classified according to the Genant grading system: grade 1 for an anterior, mid or posterior reduction of 20–25% in vertebral height; grade 2 for a reduction of 25– 40% and grade 3 for a reduction of more than 40% in vertebral height. A score for the inter-rater reliability between the readers was expressed using the kappa statistic.
Results: One hundred patients were included with a mean age of 66.9 ± 9.5 years [46.7-83] years. There was a female predominance (91%). Nearly half of patients had osteopenia (48.9%), 27.7% had osteoporosis and 23.4% had a normal bone mineral density. On VFA scans, the non-visible vertebra was mostly located in the upper thoracic spine (60%). The mean number of VF was 1.2 [0-3] for both readers. According to the doctor's evaluation, 25% of patients had at least one VF, of which 75.9% had a Genant grade 1, 17.2% had a Genant 2, and 6.9% had a VF grade 3. According to the technician evaluation, at least one VF was found in 36% of patients. A grade 1 was assessed in 91.7% of cases, a grade 2 in 8.3% of patients but no VF grade 3 was assessed. A kappa score for the inter-rater reliability between the readers for VFA was 0.545 (p=0.000). The overall agreement by grade between the readers was 0.785 (p=0,000). The exclusion of non-visible vertebra resulted in a better agreement (k=0.853). Further analysis excluding vertebra T4 to D10, revealed a very good agreement (k=0.9).
Conclusion: Our study showed a low agreement between the readers on VFA and a better agreement when non-visible vertebrae were excluded. Thus, caution should be advocated when relying exclusively on this device.

POS1111 DIAGNOSIS OF OSTEOPOROSIS USING RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) AT THE LUMBAR SPINE IN PATIENTS WITH DIFFERENT BODY MASS INDEX

B. Cortet[1], E. Dennison[2], A. Diez-Perez[3], M. Locquet[4], M. Muratore[5], D. Ovejero Crespo[3], X. Nogués[3], M. L. Brandi[6,7]. [1]*University-Hospital of Lille, Department of Rheumatology and EA 4490, Lille, France*; [2]*Southampton General Hospital, University of Southampton, MRC Lifecourse Epidemiology Unit, Southapmton, United Kingdom*; [3]*IMIM (Hospital del Mar Medical Research Institute), Centro de Investigación Biomédica en Red en Fragilidad y Envejecimiento Saludable (CIBERFES), ISCIII, Musculoskeletal Research Group, Barcelona, Spain*; [4]*University of Liège, Department of Public Health, Epidemiology and Health Economics, Liège, Belgium*; [5]*Vito Fazzi Hospital, ASL-LE, O.U. of Rheumatology, Lecce, Italy*; [6]*FIRMO Foundation, Florence, Italy*; [7]*The National Observatory on Fragility Fractures, Florence, Italy*

Background: In recent years, the technology based on the analysis of raw ultrasound signals, Radiofrequency Echographic Multi Spectrometry (REMS), has been validated against Dual-energy X-ray Absorptiometry (DXA) for the diagnosis of osteoporosis and risk fracture prediction.
Objectives: The aim of this multicenter observational study was to evaluate the diagnostic performance of REMS with respect to DXA in patients with different body mass index (BMI) categories.
Methods: The inclusion criteria were: Caucasian women; age between 30 and 90 years; referral by their clinician for spinal DXA assessment; absence of significant walking impairment; signed informed consent.

Patients underwent DXA and REMS scans at the lumbar spine, according to the procedures described in Di Paola et al. [1], including an *a-posteriori* quality check of the examinations in order to guarantee the maximum reliability of the diagnostic outputs.

Three groups of patients were considered according to BMI:: underweight (BMI<18.5 kg/m^2), normal weight (BMI≥18.5 kg/m^2 and <25 kg/m^2), and overweight/obese (BMI≥25 kg/m^2). DXA and REMS BMD values were also stratified in 3 diagnostic categories: osteoporotic, osteopenic, or healthy.

The degree of correlation between DXA and REMS BMD values was quantified by calculating Pearson's correlation coefficient (*r*). The diagnostic concordance between REMS and DXA was assessed by Cohen's *K* considering the 3 diagnostic categories. REMS´s sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for discriminating patients with and without osteoporosis were also calculated using DXA outcomes as reference. The same statistics were calculated accepting a 0.3 T-score tolerance on T-score values of borderline cases [1].

Results: Overall, 4282 patients were enrolled and, after the quality check, 3501 couples of scans were included in the analyses. Of these patients, 122 (3.5%) were underweight, 1964 (56.1%) were normal weight, and 1415 (40.4%) were overweight. The results of the diagnostic performance in patients after BMI stratification are reported in Table 1.

Conclusion: We observed an excellent correlation between REMS-based diagnosis with respect to the osteoporosis diagnosis performed by DXA in patients from each BMI category. These results indicate that lumbar spine REMS analysis is a suitable and accurate diagnostic tool for patients with different BMI.

POS1112 COMPARISON OF TWO APPROACHES IN FRACTURES RISK ASSESSMENT IN WOMEN WITH RHEUMATOID ARTHRITIS AND GLUCOCORTICOID USE

N. Grygorieva[1], V. Povoroznyuk[1]. [1]*State Institution "D. F. Chebotarev Institute of Gerontology NAMS of Ukraine", Department of Clinical Physiology and Pathology of Locomotor Apparatus, Kyiv, Ukraine*

Background: Nowadays, FRAX is the most useful tool for osteoporotic fracture risk assessment that is included in many guidelines. Rheumatoid arthritis (RA) and glucocorticoid (CG) use are two crucial factors for osteoporotic fractures included in FRAX algorithm. According to the last ACR guidelines for the treatment of GC-induced osteoporosis [1], it was recommended to divide the patients into three groups of fracture risk (high, medium and low) that have a great impact on treatment decision. Recently, we received own Ukrainian thresholds [2] for the national version of FRAX that are age-dependent and now widely used in clinical practice.

Objectives: Our study was aimed to compare two approaches (ACR-2017 and Ukrainian (2019) recommendations) in fracture risk assessment in women with RA and GC use.

Methods: We examined 195 females with RA aged 40-89 years old who took GC (at dose ≥5 mg/d for ≥3 months) due to RA. The 10-year probabilities of major osteoporotic (MOFs) and hip fractures (HFs) were calculated with and without bone mineral density (BMD) using the Ukrainian FRAX model [3]. The DXA was used to measure the lumbar spine, femoral neck and total body BMDs; T and Z scores were calculated (DISCOVERY Wi, Hologic, Inc., USA).

Results: FRAX indexes for MOFs and HFs without BMD in patients with RA and GC were (Me [25-75Q]) 12.0 [8.1-18.0] and 4.2 [1.7-7.2] %. The correspondent FRAX indexes with BMD were 13.5 [8.5-20.0] and 5.1 [1.8-8.7] %.

50 % of examined women had previous fractures and 20 % had previous vertebral fractures. BMD of the femoral neck consisted of 0.62±0.13 and L1-L4 BMD was 0.85±0.15 g/cm^2. 89 % of females had low BMD at the lumbar spine and / or femoral neck (49 % osteoporosis and 40 % osteopenia).

61 % of women required antiosteoporotic treatment according to ACR-2017 guideline (17.4 % of them a had high risk of MOF and 43.1 % moderate one) without BMD measurement and 64 % of subjects after DXA scan.

According to Ukrainian national guideline, 57 % of patients required antiosteoporotic treatment without BMD measurement and 42 % – after additional DXA examination. After BMD measurement in subjects who required the DXA scan, 78.2 % of females with RA and GC use required antiosteoporotic treatment (additionally to calcium and vitamin D, lifestyle modifications).

Conclusion: Approximately 60 % of subjects with RA and GC use required antiosteoporotic treatment without additional DXA measurement according to correspondent FRAX indexes from both guidelines. The proportion of women requiring treatment after DXA scan is slightly higher according to Ukrainian recommendations. It proves that both of them can be used effectively in daily clinical practice for fracture risk assessment in females with RA.

POS1113 ANTIRESORPTIVE THERAPY AFTER TERIPARATIDE DISCONTINUATION – WHEN IS THE BEST TIME TO STARTING IT?

M. Rato[1], F. Oliveira Pinheiro[1], S. Garcia[1], B. M. Fernandes[1], D. Fonseca[2], D. Santos Oliveira[1,3], A. Martins[1], F. R. Martins[4], A. Bernardo[1], R. Ferreira[1], M. Bernardes[1,5], L. Costa[1]. [1]*Centro Hospitalar Universitário de São João, Rheumatology, Porto, Portugal*; [2]*Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal*; [3]*Faculdade de Medicina da Universidade do Porto - FMUP, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; [4]*Centro Hospitalar Universitário do Algarve - Faro, Rheumatology, Faro, Portugal*; [5]*Faculdade de Medicina da Universidade do Porto - FMUP, Rheumatology, Porto, Portugal*

Background: Treatment with teriparatide (TPTD) is associated with reduction of fracture risk in patients with severe osteoporosis. This drug can only be used for up to 2 years. After that a treatment course with antiresorptives should be considered, in order to prevent the rebound of bone turnover observed after TPTD discontinuation. In this regard, interest in sequential osteoporosis therapy has grown in recent years but the ideal timing for starting another treatment after TPTD is not well established.

Objectives: The aim of this study is to assess if the timing of onset of antiresorptive therapy after TPTD discontinuation has implications in total hip bone mineral density (BMD) and in fracture risk.

Methods: We performed a retrospective cohort study that included patients with severe osteoporosis treated with TPTD 20mcg/day for 24 months and followed for at least 2 more years in the rheumatology department of a tertiary university hospital. For analysis, demographic and clinical data and results of dual-energy X-ray absorptiometry (DXA) after cessation of teriparatide were used. For comparison between groups Mann-Whitney U test was used.

Results: Fifty-five patients with osteoporosis, with a median age of 68 (32-85) years, were included. Forty-nine patients were female (89.1%). Nineteen patients (34.5%) had primary osteoporosis and 36 (65.5%) glucocorticoid-induced osteoporosis. The median time for initiating antiresorptive treatment was 7 (0-35) months after cessation of TPTD. Forty-three patients (78.2%) started a bisphosphonate, 6 denosumab (10.9%) and 6 patients did not receive any other treatment. The most prescribed bisphosphonate was zoledronate (69.8%). All patients received calcium and vitamin D supplementation. After completion of TPTD regimen 8 patients experienced at least one fragility fracture (14.5%). At follow-up, 37 (67.3%) of patients underwent DXA on average 30.0±15.4 months after starting antiresorptive agents. The median total hip BMD in patients who started antiresorptive therapy in the first 12 months (inclusive) after cessation of TPTD regime was 0,738 (0.587-0.993) g/cm^2 and the median total hip BMD of patients who started therapy after one year of discontinuation of TPTD was 0.683 (0.390-0.813) g/cm^2. This difference is marginally significant (p=0.067). The median time in starting antiresorptive treatment is higher in patients with new fragility fractures after TPTD than in patients without new fractures however this difference was not statistically significant (10.0 [2-35] vs 6.0 [0-35] months; p=0.393, respectively).

Conclusion: Although this study is unable to show that anti-resorptive treatment should be started in the first year after discontinuation of TPTD, it is promising since the difference between the medians in the total hip BMD values obtained until one year and after one year are marginally significant. These results can be linked to the small sample size and highlight the need for further studies in this area.

POS1114 INFECTION RISK AMONG RHEUMATIC PATIENTS RECEIVING DENOSUMAB THERAPY: SINGLE CENTRE EXPERIENCE

K. L. Ng[1], M. Mohd Zain[1], I. S. Lau[1]. [1]*Selayang Hospital, Rheumatology, Batu Caves, Malaysia*

Background: Osteoporosis (OS) is common in rheumatic diseasas (RMD). OS fracture leads to morbidity and premature mortality. The treatment for OS is well established with good long term safety profile. Oral bisphosphonate (BIS) is recommended as initial treatment option for both postmenopausal and glucocorticoid induced OS. Denosumab (DSB), is the noninferior alternative option. Despite its efficacy, DSB was linked with elevated infection risk in non RMD. Yet, data in RMD is lacking.

Objectives: To determine the infection risk and associated factors in RMD patients receiving DSB.

Methods: This is retrospective cohort study. Data was extracted from medical database (between Jan 2010 & Dec 2018) at Selayang Hospital, Malaysia. Descriptive statistical analysis, logistic regression (LR) and cox (proportional hazard) regression [CPHR] were the analysis methods.

Results: 50 cases were analysed. 96% were female. The median age was 72.5 ± 12.7 years. The primary rheumatological disorders were rheumatoid arthritis (48%), OS (24%) and systemic lupus erythematosus (10%). 92% had ≥ 1 comorbidity including metabolic/cardiovascular diseases (74%), chronic lung diseases (CLD) (40%) and diabetes mellitus (DM) (22%). 54% had disease modifying anti rheumatic drug (DMARD) therapy; majority (59.2%) received single conventional synthetic DMARD. Only 7.4% received combination biologic DMARD therapy. 28% had received prednisolone therapy, with dose < 7.5mg OD in 78.6%.

The median age at DSB initiation was 71 ± 12.4 years. 38% had fracture history and 88% had received previous OS treatment.

In total, 13 infection episodes were recorded. The infection risk was 26% & incidence rate was 134 cases per 1000 person-years. 84.6% required hospitalisation and 38.5% were severe cases. The mortality rate was 23.1%. The mean DSB treatment duration to first infection was 15.46 ± 11.9 months.

Univariate LR showed infection risk and hospitalisation were higher with longer DSB treatment duration, OR 1.062 (95% CI: 1.010 - 1.117), p = 0.018) & OR 1.057 (95% CI: 1.003 - 1.114, p = 0.037), respectively. These risks were lower in absence of steroid use, OR 0.2 (95% CI: 0.051 - 0.784, p = 0.021) and OR 0.215 (95% CI: 0.052 - 0.889, p = 0.034), respectively. Additionally, infection risk was lower in absence of CLD, OR 0.188 (95% CI: 0.048 - 0.742, p = 0.017) and hospitalisation was lower without concomitant DM, OR 0.050 (95% CI: 0.050 — 0.950, p = 0.043). Yet, multivariate LR did not infer the above predictions, after adjustment made for age, gender, rheumatological diseases, comorbidity, DMARD therapy and steroid dosing. For severe infection and case fatality, no predictive factors were identified.

CPHR showed patients without steroid use had lower fatality risk, HR 0.077 (95% CI: 0.007 - 0.864, p = 0.038). With confounding factors (age, gender, previous infection and comorbidity), the observed difference was insignificant.

Conclusion: Risk of infection and hospitalisation could be higher in rheumatic patients receiving longer DSB treatment duration. Concomitant comorbidities (CLD and DM) might increase the risk of infection and/or hospitalisation.

POS1115 DESCRIPTIVE STUDY OF THE PERCEPTIONS AND PREVENTIVE PRACTICES OF POSTMENOPAUSAL TUNISIAN WOMEN REGARDING OSTEOPOROSIS

S. Ben Jemaa[1], Y. Mejdoub[2], H. Fourati3, J. Damak[2], S. Baklouti3. [1]*Hedi Chaker Hospital, Rheumatology, SFAX, Tunisia*; [2]*Hedi Chaker Hospital, Community Medecine, SFAX, Tunisia*; [1]*Hedi Chaker Hospital, Rheumatology, SFAX, Tunisia*

Background: Due to their serious consequences affecting quality of life, prevention of osteoporosis is considered a priority. Thus, identifying the level of knowledge is useful in developing effective interventions and in guiding public health programs to prevent osteoporosis.

Objectives: The aim of this study is to describe beliefs and practices of menopaused Tunisian women related to health and osteoporosis in order to develop effective and targeted interventions for the prevention of this disease.

Methods: A descriptive cross-sectional study was conducted among menopaused Tunisian women who consult the basic health center in the area of Sfax region in Tunisia. Data collection include socio-demographic characteristics, the “osteoporosis health belief scale” developed by Kim and his colleagues and the daily calcium intake which was calculated by a questionnaire developed by Patrice Fardellone.

Results: We have included 170 women. The mean age was 58.92 ± 9.07 years. Seventy-seven percent of women were housewives, 14.7% were active and 8.3% were retired. Seventy-five percent were married. Forty-two women (24.7%) were illiterate, sixty-three (37.1%) were at primary level and 33.5% were at secondary level. One hundred twelve women (65.3%) live in an urban environment, against 34.7% who belong to a rural environment.

The level of perception of osteoporosis was very altered in 22.9%, altered in 32.4% and moderately altered in 31.8% of women. Women’s perceptions of the benefits of physical exercise and calcium intake were moderately altered in 42.4% and 51.2%, respectively. For obstacles to the practice of physical exercise, the level of perception was altered in 43.5% of women. Regarding the obstacles to calcium intake, the perceptions of our population were altered in 32.9% of cases.

The daily intakes of calcium vary from 215 to 1444 mg per day with an average of 620.20 ± 204.523 mg / day. Only eight women (4.7%) had sufficient daily intake.

Conclusion: Our study showed that all subscale of the “osteoporosis health belief scale” were altered. Promotion programs should aim at creating a supportive physical and social environment for the adoption of safer behaviors and especially education must be targeted.

POS1116 ENHANCING OSTEOPOROSIS MANAGEMENT: THE CONTRIBUTION OF FRAX® AND VFA IN TUNISIAN WOMEN

C. Daldoul[1], N. El Amri[1], S. Laataoui[1], K. Baccouche[1], H. Zegaloui[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: The FRAX® is a tool proposed by the World Health Organization (WHO) to calculate 10-year fracture risk of hip fracture and major osteoporotic fractures. The utility of this tool is to help treatment decision when it is litigious. Previous low trauma fracture represent a factor in FRAX® calculation. However, asymptomatic osteoporotic vertebral fractures (VF) identified on X-rays or Vertebral Fracture Assessment (VFA) scans are rarely included. To the best of our knowledge, there was no previous evaluation of fracture risk in Tunisian women.

Objectives: To compare hip fracture risk and major osteoporotic fractures risk using the FRAX® tool, without and with the consideration of asymptomatic VF on VFA. To evaluate the impact of FRAX® calculation and asymptomatic VF identified on VFA on osteoporosis management.
Methods: We conducted a cross-sectional study over a period of 5 months at the rheumatology department. The study included post-menopausal women without a previous diagnosis of VF referred for BMD (Bone mineral density) measurement. Each participant had a BMD assessment and a VFA scan to detect VF. The FRAX® was calculated using femoral neck BMD initially without then with consideration of VF. The change of therapeutic decision was assessed after taking into consideration FRAX® and the VFA results.
Results: The study included 210 post-menopausal women with a mean age of 61.5±8.5 years. The mean BMI was 31.04±5.52 kg/m^2. One women was a current smoker and alcohol intake was not found in our sample. Thirty-seven percent of our participants had at least one fragility fracture. A severe fragility fracture was recorded in 10.5% and a previous hip fracture was reported in 5.24%. An early menopause was found in 19.5% of our women. Twenty percent of our population were receiving corticosteroids and 8.2% of our population had rheumatoid arthritis. The mean vertebral and total hip BMD was 0.955±0.165 g/cm2 and 0.850±0.135 g/cm2 respectively. Osteoporosis and low BMD were found in respectively 50% and 34.28%. The median probability of major osteoporotic fracture for our population was 1.5% with an interquartile range from 0.9 to 2.5% without using VFA data and 1.65% with an interquartile range from 1 to 2.6% while taking into consideration VFA results and the difference was statistically significant (p<0.0001). The median probability of hip fracture for our population was 0.4% with an interquartile range from 0.1 to 0.9% without using VFA data and 0.4% with an interquartile range from 0.1 to 1% while taking into consideration VFA results and the difference was statistically significant (p<0.0001). In all patients, the FRAX® was under the threshold intervention even after including the asymptomatic VF and it did not change the therapeutic decision. The presence of asymptomatic VF on VFA changed the therapeutic decision in 15% and indicated an anti-osteoporosis drug therapy.
Conclusion: VFA scanning helped in the therapeutic decision in 15% of our population. In this evaluation, we showed that a comprehensive fracture risk pathway incorporating VFA has enhanced diagnosis of vertebral fractures and improved targeting of treatment better than FRAX® tool.

POS1117 AGREEMENT BETWEEN VERTEBRAL FRACTURE ASSESSMENT AND RADIOGRAPHIC SCANS FOR THE DIAGNOSIS OF VERTEBRAL FRACTURE

C. Daldoul[1], N. El Amri[1], K. Baccouche[1], H. Zegaloui[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: Conventional radiography of thoracic and lumbar spine are considered the gold-Standard imaging for vertebral fracture (VF) identification. However, there was a growing interest in the use of vertebral fracture assessment (VFA) as a low radiation tool. In fact, the radiation dose for VFA is about 3 micro Sievert compared to 600 Sievert for lateral standard radiography. Moreover, it costs 2-times less than X-rays. However, the advantage granted by a lower radiation dose is unfortunately counterbalanced by higher noise rates and therefore lower image quality.
Objectives: The aim of this study was to investigate the diagnostic accuracy of VFA compared to lateral spine radiographs.
Methods: We conducted a cross-sectional study over a period of 5 months at the rheumatology department. The study included post-menopausal women without a previous diagnosis of VF. Each participant had a BMD assessment, a VFA scan and a lateral thoracolumbar X-rays (Rx) to detect VF. VF were identified according the Genant semi-quantitative method. The number of unreadable vertebrae were compared between VFA and Rx using a McNemar test. Cohen's kappa coefficient, the sensitivity (Se), the specificity (Sp), the positive (PPV) and negative predictive (NPV)values at each vertebral level and at the individual level were calculated with 95% confidence interval (95% CI) to analyze the agreement between VFA and Rx results.
Results: The study included 62 patients were collected. The mean age was 62.03±7.84 years. the mean body mass index (BMI) was 29.99±5.13 kg/m^2 and the mean menopausal duration was 15.7±8.28 years. Parental history of hip fracture and prior history of fragility fracture were recorded in 25.9% and 40.3% respectively. A premature menopause, Rheumatoid arthritis and use of corticosteroids were found in 12.9%, 4.8% and 19.4% respectively. A historical height loss of more than 4cm and a prospective height loss of more than 2 cm were reported in 21% and 38.7% respectively. Using VFA, 22.6% of our population had at least one VF≥ grade2 and 33.9% had at least one VF≥grade1. Using Rx, 19.4% of our population had at least one VF≥ grade2 and 25.8% had at least one VF≥grade1. Among all vertebral levels, no statistically significant difference was found while comparing the number of unreadable vertebrae on VFA and radiographs. Taking into consideration VF≥grade2, there was an almost perfect agreement between VFA and Rx (k=0.806, p<0.001); the Se, Sp, PPV and NPV of VFA were respectively 91.7% (95% CI 59.8-99.6), 94%(95% CI 82.5-98.4), 78.6% (95% CI 48.8-94.3) and 97.9%(95% CI 87.5-99.9). . Taking into consideration VF≥grade1, there was a moderate agreement between VFA and Rx (k=0580, p<0.001); the Se, Sp,PPV and NPV of VFA were respectively 81.3% (95% CI 53.7-95),82.6% (95% CI 68-91.7), 61.9% (95% CI 38.7-81) and 92.7% (95% CI 79-98.1). At the vertebral level and when including only grade 2 and 3 VF, the Se, Sp, PPV of VFA were 100% (95% CI 82.2-100), 98.9% (95% CI 97.7-99.5), 74.2% (95% CI 55.1-87.5) and 100% (95% CI 99.3-100) respectively. At the vertebral level, the Se, Sp, PPV and NPV of VFA in detection of grade≥1 VF were 65.8% (95% CI 48.6-79.9), 98.3% (95% CI 96.9-99.1), 67.6% (95% CI 50.1-81.4) and 98.1% (95% CI 96.8-99.0) respectively. The analysis by vertebral level revealed substantial to almost perfect agreement for all levels except for T4 and T6 where the test was not applicable. There was a perfect agreement for T5, T8, L3 and L4 vertebrae.
Conclusion: VFA showed a high diagnostic performance compared to Rx. One interesting finding is that the NPV of VFA is very high at the vertebral and the individual level and either grade 1 VF were took into consideration or not. This means that a normal VFA can formally rule out the presence of VF.

POS1118 THE RELEVANCE OF OSTEOPOROSIS DIAGNOSIS AND TREATMENT FOR DOCTORS WORKING IN THE FIELD OF PHYSICAL AND REHABILITATION MEDICINE

L. Marchenkova[1], V. Vasileva[1]. [1]*National Medical Research Center for Rehabilitation and Balneology of Ministry of Health of Russian Federation, Rehabilitation Department for Somatic Patients, Moscow, Russian Federation*

Background: There is a high prevalence of osteoporosis (OP) among patients of the older age undergoing rehabilitation. Therefore, it is obvious that physicians working in the field of physical and rehabilitative medicine should be well oriented in this medical problem.
Objectives: to study the relevance of the problem of osteoporosis (OP) for physicians working in the field of physical and rehabilitation medicine, their awareness of the main methods of diagnosis, treatment and prevention of this disease, as well as the frequency of their use in daily clinical activities.
Methods: A cross-type study was carried out using a questionnaire survey. The study included 157 doctors (M-34, F-123) of 8 medical specialties working in 27 specialized medical institutions on the profile of "medical rehabilitation. The questionnaire for doctors consisted of 21 items of special questions.
Results: 90.45% of the surveyed doctors believed that the problem of OP is relevant for their clinical activities, 100% of the respondents indicated that the presence of OP significantly affects the rehabilitation prognosis and 95.54% - on the degree of effectiveness of medical rehabilitation. According to the respondents, patients with OP make up on average 30.0% [20.0; 50.0] (0-90) of the total flow of patients. 92.36% (145/157) of doctors indicated that they know the risk factors for OP, 98.73% (155/157) - methods for diagnosing OP, 68.79% (108/157) - methods for treating OP, 80.25 % (126/157) - methods of preventing OP, 47.13% (74/157) - what is FRAX. However, 35.01% (55/157) of the respondents considered their level of awareness of the problem sufficient for managing patients with OP. Diagnostic procedures for OP are recommended by all endocrinologists (100%) and the majority of traumatologists (72.73%), gynecologists (66.67) and cardiologists (64.28%), as well as on average half (50%) neurologists and therapists. Endocrinologists (100%), gynecologists (66.67%) and therapists (60%) are mainly involved in the treatment of OP. 32.48% (51/157) of physicians have ever referred their patients to a bone mineral density assessment.
Conclusion: Conclusion. The problem of OP is relevant for the clinical activities of specialists in physical and rehabilitation medicine, and there is the need for advanced training on the problem of OP among these specialists.

POS1119 A SINGLE DOSE OF ZOLEDRONATE INDUCES MODIFICATIONS OF SERUM VEGF IN OSTEOPOROTIC POSTMENOPAUSAL WOMEN

F. Bellone[1], N. Morabito[1], A. Gaudio[2], A. Sottile[1], S. Loddo[1], F. Corica[1], A. Catalano[1]. [1]*University of Messina, Department of Clinical and Experimental Medicine, Messina, Italy*; [2]*University of Catania, Department of Clinical and Experimental Medicine, Catania, Italy*

Background: Zoledronate (Zol) is an aminobisphosphonate commonly used to treat osteoporosis and other benign and malignant skeletal diseases. Exposure to bisphosphonates has been previously associated with the risk of osteonecrosis of the jaw (BRONJ), a rare but serious side effect. In cancer patients,

the Vascular Endothelial Growth Factor (VEGF) has been advocated to take part to BRONJ pathogenesis via interfering with angiogenesis. No information is currently available on the VEGF concentrations after Zol administration for osteoporosis.

Objectives: To explore change of VEGF concentrations after Zol administration in postmenopausal women with osteoporosis.

Methods: A total of twenty-eight postmenopausal women with osteopenia or osteoporosis and at least one prevalent vertebral fracture were recruited and randomized in two groups. Eighteen women received a single i.v. dose of Zol 5 mg, while the other ten served as controls. Serum samples were collected at baseline, after 3 and 30 days, for repeated measurements of VEGF, and measurement of bone turn over markers and 25-hydroxyvitamin D (25(OH)D).

Results: VEGF levels increased significantly after 3 days in women receiving Zol; then levels decreased after 30 days compared with VEGF concentrations at both day-3 and baseline (-18% at day-30 vs. baseline, p=0.01). 25(OH)D level, a surrogate of vitamin D status, was associated with VEGF change at the end of the study (r=0.29, p=0.028), and this association was maintained also after correcting for age, BMI, time since menopause, femoral neck BMD, osteocalcin, C-terminal telopeptide of collagen type 1 and baseline levels of VEGF (β=1.7, SE=0.71, p=0.03).

Conclusion: Zol administration induced a reduction of circulating VEGF in postmenopausal women treated for osteoporosis, and vitamin D status has been showed to modulate this change. Further studies in this setting of women are needed to define whether VEGF modifications may predict the risk of BRONJ.

Crystal diseases, metabolic bone diseases other than osteoporosis

POS1120 PRESENCE OF TOPHI IS ASSOCIATED WITH A RAPID DECLINE IN THE RENAL FUNCTION IN PATIENTS WITH GOUT

Y. J. Oh[1], K. W. Moon[2]. [1]*Kangwon National University Hospital, Division of Rheumatology, Department of Internal Medicine, Chuncheon, Korea, Republic of (South Korea)*; [2]*Kangwon National University Hospital, Division of Rheumatology, Department of Internal Medicine, Chuncheon, Korea, Republic of (South Korea)*

Background: Gout is the most common inflammatory arthritis resulting from a chronic deposition of MSU crystals in the joints and other soft tissues. After the process of repeated tissue damage and repair due to gout, tophi could be formed around the affected joints. Intra-articular tophi may sometimes result in bone destruction, joint deformities, and dysfunction which can adversely affect the patient's quality of life. Furthermore, early-onset tophaceous gout patients are more likely to develop renal dysfunction, however, few studies have investigated if the presence of tophi is related with the progression of renal dysfunction in gout patients.

Objectives: We aimed to compare clinical characteristics of patients with and without tophi at the time of the diagnosis of gout and investigate the effect of tophi on the renal function in gout patients.

Methods: Data of 257 patients who were first diagnosed with gout at the Kangwon National University Hospital from January 2012 to December 2018 were retrospectively studied. Patients were divided into 2 groups according to the presence of tophi at the diagnosis. We compared clinical characteristics and the progression of renal dysfunction between the two groups.

Results: Of all patients, 66 (25.5%) initially presented with tophi. Patients with tophi were older, had a longer duration of symptoms, and had a higher prevalence of multiple joint involvement than those without tophi. The decline in the eGFR was more prominent in patients with tophi than in those without (-4.8±14.5 ml/min/1.73m^2 *vs*. -0.7±11.9 ml/min/1.73m^2, respectively; *P*=0.039). In multivariate logistic regression analysis, a prolonged symptom duration (odds ratio [OR], 1.010; 95% confidence interval [CI], 1.004–1.017; *P*=0.001) and multiple joint involvement (OR, 3.027; 95% CI, 1.831–5.004; *P*<0.001) were significantly associated with increased risk of formation of tophi. The presence of tophi was significantly associated with a rapid decline in the eGFR (β=-0.141; *P*=0.035).

Conclusion: A prolonged symptom duration and multiple joint involvement were independent risk factors for tophi as the presenting symptom in gout patients. The presence of tophi was associated with a declining renal function. Therefore, an early diagnosis and active treatment are important in tophaceous gout.

POS1121 DEMOGRAPHICS, COMORBIDITIES, AND RENAL FUNCTION OF UNCONTROLLED GOUT PATIENTS WHO RECEIVED PEGLOTICASE: FINDING FROM A LARGE US CLAIMS DATABASE

C. Vesel[1], A. Morton[2], M. Francis-Sedlak[1], B. Lamoreaux[1]. [1]*Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*; [2]*Michigan State University, School of Osteopathic Medicine, Internal Medicine, East Lansing, United States of America*

Background: NHANES data indicate that approximately 9.2 million Americans have gout,[1] with a small subset having uncontrolled disease.[2] Pegloticase is a PEGylated recombinant uricase enzyme indicated for treating uncontrolled gout that markedly reduces serum uric acid levels (sUA)[3] and resolves tophi in treatment responders.[4] Despite pegloticase availability in the US for many years, real world demographics of pegloticase users in the treatment of uncontrolled gout have not been previously reported in a population-based cohort.

Objectives: This study utilized a large US claims database to examine demographics and co-morbidities of uncontrolled gout patients treated with pegloticase. Kidney function before and after pegloticase treatment and concomitant therapy with immunomodulators were also examined.

Methods: The TriNetX Diamond database includes de-identified data from 4.3 million US patients with gout (as of September 2019), including demographics, medical diagnoses, laboratory values, procedures (e.g. infusions, surgeries), and pharmacy data. Patients who had received ≥1 pegloticase infusion were included in these analyses. The number of infusions was evaluated for a subgroup of patients who were in the database ≥3 months before and ≥2 years after the first pegloticase infusion (i.e. first infusion prior to September 2017) to ensure only complete courses of therapy were captured. In this subpopulation, kidney function before and after pegloticase therapy was examined, along with the presence of immunomodulation prescriptions (methotrexate, mycophenolate mofetil, azathioprine, leflunomide) within 60 days prior to and 14 days after the first pegloticase infusion.

Results: 1494 patients treated with pegloticase were identified. Patients were 63.1 ± 14.0 years of age (range: 23–91), mostly male (82%), and white (76%). Mean sUA prior to pegloticase was 8.7 ± 2.4 mg/dL (n=50), indicating uncontrolled gout in the identified population. The most commonly reported comorbidities were chronic kidney disease (CKD, 48%), essential hypertension (71%), type 2 diabetes (39%), and cardiovascular disease (38%), similar to pegloticase pivotal Phase 3 trial populations. In patients with pre-therapy kidney function measures (n=134), pre-treatment eGFR averaged 61.2 ± 25.7 ml/min/1.73 m^2, with 44% having Stage 3-5 CKD. In patients with complete therapy course capture and pre- and post-therapy eGFR measures (n=48), kidney function remained stable (change in eGFR: -2.9 ± 18.2 ml/min/1.73 m^2) and CKD stage remained the same or improved in 81% of patients. In 791 patients with complete treatment course capture, patients had received 8.7 ± 13.8 infusions (median: 3, IQR: 2-10). Of these, 189 (24%) patients received only 1 pegloticase infusion and 173 (22%) received ≥12 infusions. As the data cut-off for this analysis pre-dated emerging data on the use of immunomodulation as co-therapy, only 19 of 791 (2%) patients received immunomodulation co-therapy with pegloticase.

Conclusion: This relatively large group of patients with uncontrolled gout treated with pegloticase had similar patient characteristics of those studied in the phase 3 randomized clinical trials. Patients with uncontrolled gout are significantly burdened with systemic co-morbid diseases. The majority of patients had stable or improved kidney function following pegloticase treatment. As these results reflect patients initiating treatment prior to 2018, before co-treatment with immunomodulation was introduced, this cohort only included a small percentage of patients who were co-treated with an immunomodulator. Future studies using more current datasets are needed to evaluate real world outcomes in patients treated with pegloticase/immunomodulator co-therapy and to evaluate the impact of systemic co-morbid diseases.

POS1122 PRELIMINARY FINDINGS OF THE PROTECT CLINICAL TRIAL: PEGLOTICASE EFFICACY AND SAFETY IN KIDNEY TRANSPLANT RECIPIENTS

A. Abdellatif[1], L. Zhao[2], P. M. Peloso[2], K. Cherny[2], B. Marder[3], J. Scandling[4], K. Saag[5]. *[1]Baylor College of Medicine, Nephrology, Houston, United States of America*; *[2]Horizon Therapeutics plc, Research and Development, Deerfield, United States of America*; *[3]Horizon Therapeutics plc, Medical Affairs, Deerfield, United States of America*; *[4]Stanford Medicine, Nephrology, Standford, United States of America*; *[5]University of Alabama, Clinical Immunology and Rheumatology, Birmingham, United States of America*

Background: The prevalence of gout is high in kidney transplant (KT) recipients (up to 13%), largely because of decreased kidney function and calcineurin inhibitor use.[1] Residual chronic kidney disease (CKD) leading to decreased urate lowering therapy clearance and drug interactions make managing gout in KT recipients challenging. Studies show that successful treatment with pegloticase, a pegylated uricase, leads to marked reductions in serum uric acid (sUA)[2] and a subsequent decrease in overall urate load and tophi burden.[3] However, pegloticase use in solid organ transplant recipients has not been systematically studied or well-characterized in the literature.[4,5]

Objectives: To examine the safety and efficacy of pegloticase in KT recipients with uncontrolled gout.

Methods: This ongoing multicenter, open-label, efficacy and safety study of pegloticase in KT recipients (NCT04087720) included patients with uncontrolled gout sUA ≥7 mg/dL, urate lowering therapy [ULT] contraindication/inefficacy, and with either visible tophi, chronic gouty arthritis, or ≥2 flares in past year, who were KT recipients (KT >1 year prior), had a functioning graft (estimated glomerular filtration rate [eGFR] ≥15 ml/min/1.73m^2), and were on a stable immunosuppressant regimen. Pegloticase (8 mg infusion) was administered biweekly for 24 weeks (12 infusions) followed by a safety visit 30 days after the last infusion and 3-month post-treatment follow up visit. The primary endpoint was proportion of patients who were serum uric acid responders during Month 6 (sUA <6 mg/dL for ≥80% of time). Change from baseline (CFB) at 24 weeks was also evaluated for sUA, renal function, and health assessment questionnaire (HAQ) disability index (DI, maximum = 3) and pain (maximum = 100).

Results: Preliminary findings of this study included 15 patients (12 male, 53.5±11.0 years of age) with uncontrolled gout (6.2±6.0 years since diagnosis) who had received a donor kidney 15.1±6.6 years earlier. At the time of analysis, 5 patients had completed the 24-week treatment period and 8 remained on therapy (last visit sUA <0.1 mg/dL in 6 patients, 1 had sUA of 7.4 mg/dL, 1 only received first infusion), and 2 had discontinued treatment (sUA rise [n=1], COVID-19 concerns [n=1]). Of the 5 patients who completed 24 weeks of therapy, all met response criteria and sUA was below detection limits (CFB: -10.2±1.3 mg/dL, baseline [BL]: 10.2±1.3 mg/dL). Patients also had less pain (HAQ-pain CFB: -33.6±22.2, BL: 35.9±22.0; n=5) and disability (HAQ-DI CFB: -0.3±0.6, BL: 0.7±0.8; n=5) at 24 weeks compared to BL. eGFR remained stable during 24 week treatment (eGFR CFB: -0.2±6.3 ml/min/1.73 m^2, BL: 40.9±14.4 ml/min/1.73 m^2; n=5). Urine albumin-to-creatinine ratio showed improvement at 24 weeks (CFB: -223±405 mg/g, BL: 664±870 mg/g; n=5). 80% of patients experienced an AE, and 4 SAEs (duodenal ulcer, cellulitis, dyspnea, skin bacterial infection) deemed unrelated to pegloticase were reported. AEs that occurred in >1 patient included gout flare, pyrexia, arthralgia, and nasal congestion. No anaphylaxis or infusion reactions occurred.

Conclusion: Initial findings suggest that pegloticase therapy is effective at reducing sUA in most KT recipients while preserving renal function. Results suggest that in the setting of profound urate lowering with pegloticase in KT patients, eGFR remains stable and patients experience clinically beneficial reductions in pain and disability with an absence of unexpected safety findings.

Background: The combination of arterial hypertension and gout increases the risk of developing chronic kidney disease in patients.

Objectives: To assess urodynamics and concentration function of the renal parenchyma in patients with arterial hypertension and gout.

Methods: We examined 87 patients with arterial hypertension and gout. 83% of the patients were men with a mean age of 55.4±12.3 years. Grade I arterial hypertension was detected in 43.7% of patients, grade II was in 36.9% and grade III was in 19.3%. The duration of arterial hypertension was 8 [4; 11] years. All the patients had chronic gouty arthritis. 30% of the patients had tophi. The duration of gout was 7 [2; 10] years. Markers of renal lesions, urine sediment and GFR calculation were assessed in all the patients. All the patients were performed a modern systems analysis of nephrological conditions based on comprehensive renoscintigraphy (SENS-CRS) which allows to make an in-depth differential analysis of the renal parenchyma and thus reveals abnormalities in the upper and lower urinary tract function with a minimum of radiation exposure of 0.6 mSv per patient.

Results: Using the standard method of GFR calculation with CKD-EPI formula we found that 10 patients (11.3%) had no signs of CKD (GFR over 90 ml/min); 56 patients (64.5%) had I-II stage of CKD (GFR over 60 ml/min) 21 patients (24.2%) had III-IV stage of CKD (GFR less than 60 ml/min).

The patients were divided into two groups for a differentiated assessment of urodynamics. Group I consisted of 66 patients with a GFR of more than 60 ml/min and Group II consisted of 21 patients with a GFR of less than 60 ml/min. The comparison of the two groups revealed abnormalities in urodynamics. In Group 1 arterial blood flow in the parenchyma (A 14.5±6.8 sec) was slowing down against the background of normal venous outflow (V 17.8%±9.2%). Concentration function of the kidneys was sufficient (Gren 17.6±5.2 o.e.). The total excretion rate of labeled urine from the two kidneys decreased to D = 56.5% ± 16.1% during its transition from the cortical to the cerebral layer of the renal parenchyma. The indixes of the relative urinary stasis in the renal calyx-pelvis system exceeded the standard ones on average by 2 times (KC 4.8 ± 3.2; KP 7.0 ± 4.2), which indicated stagnant disorders in the kidneys, hidden from conventional diagnostic methods. The patients in Group II had those abnormalities even more expressed (A 12.4±4.5 sec, V 12.8%±9.4%, D 51.9%±15.4%, KC 5.0±3.3; KP 9.5±5.2).

16 patients under follow-up who had arterial hypertension with serum creatinine levels greater than 125 μmol/l were classified as a subgroup of patients at an increased risk of developing high stages of CKD. Stages I-II were previously diagnosed in the 16 patients according to the CKD-EPI formula and stage III CKD with a high risk of progression to stage IV CKD was diagnosed in one patient.

A comparative analysis of the SENS-CRS data of the patients with arterial hypertension was performed between the above-mentioned 16 patients and the remaining 71 patients. The nonparametric Mann-Whitney method was used ($p<0.05$) for the purpose. The method was established only by the indicator D (%) of the rate of elimination of the radiopharmaceutical from the renal parenchyma. However, no significant differences were found either for the calculated GFR values, or for all other parameters of complex renoscintigraphy

Conclusion: After the gout diagnosis is made and confirmed by screening, it is important that patients with gout and hypertension should be included in the nephrologic monitoring system to control risk factors associated with the development or aggravation of CKD.

The renocortical parameter D (%), used in the SENS-CRS technology, is a prognostically important preclinical marker of intrarenal congestion in the latent development of serious morphofunctional disorders in the renal parenchyma leading to the development of CKD or the aggravation of an existing stage of CKD.

Background: Classification criteria for calcium pyrophosphate deposition disease (CPPD) will facilitate clinical research on this common crystalline arthritis. ACR/EULAR are jointly sponsoring development of CPPD classification criteria using a multi-phase process.

Objectives: To report preliminary results from the first two phases of a four-phase process for developing CPPD classification criteria.

Methods: CPPD classification criteria development is overseen by a 12-member Steering Committee. Item generation (Phase I) included a scoping literature review of five literature databases and contributions from a 35-member Combined Expert Committee and two Patient Research Partners. Item reduction and refinement (Phase II) involved a Combined Expert Committee meeting, discussions among Clinical, Imaging, and Laboratory Advisory Groups, and an item rating exercise to assess the influence of individual items toward classification. The Steering Committee reviewed the modal rating score for each item (range -3 [strongly pushes away from CPPD] to +3 [strongly pushes toward CPPD]) to determine items to retain for future phases of criteria development.

Results: Item generation yielded 420 items (312 from the literature, 108 from experts/patients). The Advisory Groups eliminated items they agreed were unlikely to distinguish between CPPD and other forms of arthritis, yielding 127 items for the item rating exercise. Fifty-six items, most of which had a modal rating of +/- 2 or 3, were retained for future phases (see Table 1). As numerous imaging items were rated +3, the Steering Committee recommended focusing on imaging of the knee, wrist, and one additional affected joint for calcification suggestive of CPP crystal deposition.

Conclusion: The ACR/EULAR CPPD classification criteria working group has adopted both data- and expert-driven approaches, leading to 56 candidate items broadly categorized as clinical, imaging, and laboratory features. Remaining steps for criteria development include domain establishment, item weighting through a multi-criteria decision analysis exercise, threshold score determination, and criteria validation.

Table 1. Categories of items retained for future phases of classification criteria development

Age in decade at symptom onset
Acute inflammatory arthritis (e.g. knee, wrist, 1st MTP joint*)
Recurrence and pattern of joint involvement (e.g. 1 self-limited episode, >1 self-limited episode)
Physical findings (e.g. palpable subcutaneous tophus*, psoriasis*)
Co-morbidities and family history (e.g. Gitelman disease, hemochromatosis, familial CPPD)
Osteoarthritis location and features (e.g. 2nd or 3rd MCP joint, wrist)
Synovial fluid findings (e.g. CPP crystals present, CPP crystals absent on 1 occasion* or 2 occasions*, monosodium urate crystals present*)
Laboratory findings (e.g. hypomagnesemia, hyperparathyroidism, rheumatoid factor*, anti-CCP*)
Plain radiograph: calcification in regions of fibro- or hyaline cartilage+
Plain radiograph: calcification of the synovial membrane/capsule/tendon+
Conventional CT: calcification in regions of fibro- or hyaline cartilage+
Conventional CT: calcification of the synovial membrane/capsule/tendon+
Ultrasound: CPP crystal deposition in fibro- or hyaline cartilage+
Ultrasound: CPP crystal deposition in synovial membrane/capsule/tendons+
Dual-energy CT: CPP crystal deposition in fibro- or hyaline cartilage+
Dual-energy CT: CPP crystal deposition in synovial membrane/capsule/tendon+

*Potential negative predictor +Assessed in the knee, wrist, and/or 1 additional affected joint

POS1125

DUAL ENERGY CT HAS PROGNOSTIC VALUE IN GOUT BEYOND STANDARD CLINICAL MEASURES: A BEST EVIDENCE SYNTHESIS

S. Stauder[1], P. M. Peloso[2]. *[1]Florida State University, Medical, Tallahassee, United States of America*; *[2]Horizon Therapeutics plc, Research and Development, Deerfield, United States of America*

Background: Dual Energy CT Scan (DECT) can detect monosodium urate crystal deposits in multiple tissues. EULAR gout guidelines (Richette, 2020) recognized the value of DECT in making a clinical diagnosis when joint aspiration is difficult. DECT shows crystal deposits in almost 50% of gout patients without tophi (Dalbeth, 2017). Tophi are known to predict all-cause and cardiovascular mortality (Vincent 2017, Perez-Ruiz 2013) and it is plausible that DECT could as well. A prognostic measure should be reliable and valid. DECT validity would be evident for death, disability and distress.

Objectives: This study used a best evidence synthesis approach to synthesize the evidence for DECT as a prognostic measure in gout.

Methods: PUBMED and EMBASE were searched from initiation to December 2019; keywords (Dual Energy Computed Tomography OR DECT, gout,

tophaceous gout, chronic gout, monosodium urate crystals OR monosodium urate burden OR tophi OR monosodium urate volume OR flares OR pain OR distress OR death OR disability OR function). Human studies in English were considered. Titles, abstracts and full articles were reviewed. A manual search of secondary sources was conducted. Key gaps identified were considered throughout 2020 when reviewing emerging articles and presentations. Data extraction was conducted by both authors; data presented represents consensus.

Results: Of 344 articles, 81 titles/abstracts met screening inclusion criteria (24%) in the 2019 search; review of the full manuscript led to 41 articles selected (51%). Additionally, 3 key papers and 2 ACR 2020 presentations were identified through 2020. DECT is highly reliable with inter-class correlation coefficients >0.9. DECT has content validity. Dalbeth (2015) showed DECT and X-Rays findings correlated in tophaceous patients, r=0.70, p<0.001. Hand function correlates with DECT burden, with r^2=0.59, p=0.024 (Dalbeth 2007). Dalbeth (2017) showed DECT associated with greater flares at 3 and 12 months (p<0.01) in 152 patients. Pascart (2018) confirmed that subjects with flares had nearly doubled DECT feet volumes (0.9 vs 2.1 cm^3, p=0.05) versus those not flaring. Dalbeth (2017) showed abnormal DECT scans occurred in 47% of patients with normal uric acid (<6.0 mg/dL) without palpable tophi and in 90% with elevated uric acid and palpable tophi. DECT is very sensitive to change (Araujo 2015) with 95% volume reduction in 152 patients on pegloticase treated up to 12 months. Three studies show DECT is correlated to cardiovascular risk factor prevalence (Pascart 2020, Gamala 2018, Lee 2017). Marty-Ané reported that DECT volume predicts mortality (Marty-Ané ACR 2020). Limited evidence from 3 studies suggests that the minimum important volume for DECT is 1.0 cm^3 at feet and ankles, including Pascart 2020.

Conclusion: DECT imaging is highly reliable, has evidence for content validity and is highly sensitive to change. DECT appears to predict future gout flares, cardiovascular risk factor prevalence and mortality. Minimum important DECT volume approximates 1.0 cm^3. DECT requires further study but appears to be a relevant outcome for clinical trials and staging gout patients.

POS1126 PREVALENCE OF HYPOPHOSPHATASIA IN ADULT RHEUMATOLOGY PATIENTS SCREENED BY LOW LEVELS OF ALKALINE PHOSPHATASE

P. Karakostas[1], R. Dolscheid-Pommerich[2], M. Hass[3], P. Brossart[4], V. Schäfer[4].
[1]University Hospital of Bonn, Germany, Clinic of Internal Medicine III, Oncology, Hematology, Rheumatology and Clinical Immunology, Bonn, Germany; *[2]University Hospital of Bonn, Germany, Institute of Clinical Chemistry and Clinical Pharmacology, Bonn, Germany*; *[3]Center for Blood Coagulation Disorders and Transfusion Medicine Bonn, Germany, Center for Blood Coagulation Disorders and Transfusion Medicine Bonn, Germany, Bonn, Germany*; *[4]University Hospital of Bonn, Germany, Clinic of Internal Medicine III, Oncology, Hematology, Rheumatology and Clinical Immunology, Bonn, Germany*

Background: Hypophosphatasia (HPP) is a genetic disease caused by one or more mutations in the alkaline phosphatase (ALP) gene, which encodes tissue-specific ALP and affects the mineralization process. Accordingly, arthralgia, fractures, and dental abnormalities have been reported in adults, and fatal courses in children. This metabolic disorder is commonly misdiagnosed with other more prevalent bone diseases due to its low prevalence and lack of recognition (i.e. chrondrocalcinosis). However, no epidemiological studies on the prevalence of HPP in the rheumatological patient population have been available to date.

Objectives: To identify the prevalence of HPP in rheumatological patients screened for persistent low levels of ALP and association with mutations in the ALP gene.

Methods: All adult rheumatology patients were screened for pathological low levels of ALP (< 35 IU/L) between January 1, 2017 and June 30, 2019 at the Department of Rheumatology, Clinic of Internal Medicine III, University Hospital Bonn, Germany. Medical files of patients with pathological low ALP levels were then reviewed for clinical signs and symptoms as well as results of genetic testing for HPP (full sequencing using Next Generation Sequencing).

Results: In total, 2,289 rheumatology patients were screened for low ALP levels. In 60 patients (2.62 %), pathological low ALP levels were identified, while in 30 of these (1.31 %), persistent low ALP levels were detected. In 19 of the 30 patients, genetic tests for ALPL gene mutations were done. Seven out of 19 patients (36.84 %) had HPP-related symptoms (fracture, dental abnormalities) with normal bone densitometry, while four of these patients (21.05 %) had a history of fracture and three patients (15.78 %) showed dental abnormalities. In addition to the typical HPP signs and symptoms, 13 patients (68.42%) showed mutations in the ALPL gene. One of the ALP mutations was found to be a novel genetic variant, classified as pathological. Interestingly, no association with chondrocalcinosis was detected.

Conclusion: In summary, it can be concluded that HPP is an under-diagnosed condition with a higher proportion of affected rheumatologic patients than previously thought (at least 0.56 percent of rheumatologic patients vs. 0,01 percent in a spanish healthy population). If we replicate these numbers for the german population (83 million, 5 percent of whom suffer from rheumatic conditions) the yield is approximately 4.15 million. This possibly indicates that 23,240 potential cases of HPP are currently not diagnosed. Therefore, implementation of a protocol in clinical practice to prevent underdiagnosis of HPP and to treat this disease appropriately is essential.

ULTRASOUND ASSESSMENT OF GOUT LESIONS IN AN ALGERIAN POPULATION WITH ASYMPTOMATIC HYPERURICEMIA

B. Bengana[1], A. Ladjouze-Rezig[2], S. Ayoub[3], N. B. Raaf[4], C. Aimeur[5], A. Boukabous[1], S. Lefkir[1]. [1]*University Hospital of Beni Messous - Algiers, Rheumatology, BeniMessous, Algeria*; [2]*Specialized hospital establishment of Benaknoune, Rheumatology, Benaknoune, Algeria*; [3]*University hospital of Beni Messous, Internal Medicine, BeniMessous, Algeria*; [4]*Hospital of Bitraria, Biochemistry, El Biar, Algeria*; [5]*University hospital of Mustapha Bacha, Radiology, Sidi Mhamed, Algeria*

Background: Hyperuricemia is a common biological abnormality, often clinically asymptomatic. However, it can announce a gout and be linked to many diseases such as metabolic syndrome, high blood pressure or kidney disease.
In fact, the majority of learned societies do not recommend any urate lowering therapy (ULT) as long as the hyperuricemia remains asymptomatic. But it turns out that part of the population with asymptomatic hyperuricemia (AH) develops a gout after a few years particularly with genetic predisposition, but also on certain risk factors that need to be confirmed.
By this way, musculoskeletal ultrasound (MUS) can detect "asymptomatic gout" by visualizing signs of urate deposits (UD) in subjects with AH.
Objectives: Our main objective is already to estimate the prevalence of specific signs of gout in Algerian population with AH and assess the factors exposing to UD.
Methods: This is a descriptive cross-sectional study from January 2017 to February 2019, with the recruitment of subjects with AH and serum urate level > 60 mg / L, who do not take any ULT and have not associated any chronic inflammatory rheumatism, where we performed a MUS of the knees, metatarsophalangeal joints MTP1, MTP2 and metacarpophalangeal joint MCP2 and MCP3 with the Achilles, patellar and quadricipital tendons.
Results: We retained 258 subjects with AH, 132 women and 126 men (sex ratio = 0.95), the mean age was 59 years, the mean body mass index (BMI) was 28.4 kg / m2, 42 patients were under diuretics, 37 patients reported being on low-dose of aspirin 100 mg daily.
The mean rate of serum urate levels was 78 ± 10 mg / L, the prevalence of UD found at the MUS was 22% (n = 58), among them 36 % (21/58) had a sign of the double contour DC on the MTP1 and 29% (17/58) on the knee, 7% (4/58) had tophi on the MTP1 and 3% (2/58) had urate aggregates. The factors reported to be linked to UD in the sample were: the male gender (p = 0.0016); the high uric acid level (p= 0.0355); BMI (p = 0.0427); taking diuretics for women (p= 0.0002).
Conclusion: Through this work, it is clear that elementary ultrasound lesions related to gout disease are common in a population with AH and concerned one fifth of subjects in our study with a higher risk in men and subjects with obesity and high uric acid level, but also in women taking diuretics. These results need to be enhanced with a randomized controlled study in order to better determine the predisposing factors for gout in any subject with AH.
Disclosure of Interests: None declared.

POS1128

COMBINATION TREATMENT OF AR882, A NEW URAT1 INHIBITOR, AND XANTHINE OXIDASE INHIBITORS ALLOPURINOL OR FEBUXOSTAT: EFFECT ON URIC ACID, HYPOXANTHINE AND XANTHINE IN PLASMA OR SERUM AND URINE

Z. Shen[1], C. Colton[1], R. Yan[1], E. Polvent[1], V. Hingorani[1], S. Yan[1], L. T. Yeh[1]. [1]*Arthrosi Therapeutics Inc, Laguna Hills, California, United States of America*

Background: Xanthine oxidase inhibitors (XOI) are commonly used as urate lowering therapy (ULT) for the treatment of gout. Allopurinol, the first-line treatment, demonstrates low response rate (< 40%), defined as serum urate (sUA) lowering effect below 6 mg/dL, in multiple large-scale clinical trials. As recommended in EULAR guidelines and other literatures, targeting sUA <5 mg/dL or even <4 mg/dL, provides a better opportunity to lower incidence of gout flare and resolution of tophi in gout patients. Febuxostat, a more potent XOI, has been classified as a second-line ULT agent due to increased cardiovascular risks in certain patient populations. For XOI intolerance and non-responders, replacing the agent with a potent URAT1 inhibitor or adding an URAT1 inhibitor onto a current treatment regimen provides opportunities to improve response rates in patients with refractory gout. AR882 is a uricosuric agent that blocks the reabsorption of uric acid in the apical side of renal tubule, hence increases excretion of uric acid into the urine. A phase 2a study has demonstrated the additive effects of AR882 in combination with allopurinol or febuxostat.
Objectives: To evaluate the effect of AR882 alone or in combination with allopurinol or febuxostat on circulating levels and urinary excretion of hypoxanthine, xanthine and uric acid. Furthermore, to elucidate the contribution of each drug towards the combination effect in sUA lowering.
Methods: Plasma, serum, and urine samples were collected from 17 patients with gout who received a once-daily dosing of AR882 50 mg, allopurinol 300 mg or febuxostat 40 mg, or in combination for one week in a phase 2a study. Samples were collected to measure hypoxanthine, xanthine and uric acid levels in plasma or serum and the amount of each excreted in the urine. Plasma C_{max} and AUC and 24-hour urine excretion amount (mg) of hypoxanthine and xanthine were calculated by non-compartmental analysis method.
Results: In monotherapy, AR882 demonstrated better sUA lowering effect (↓53%) compared to allopurinol (↓35%) or febuxostat (↓39%). Combination of AR882 and allopurinol lowered sUA by 66% while combination of AR882 and febuxostat lowered sUA by 71%. Based on the change of xanthine in plasma following combination treatments, it can be calculated that allopurinol contributed 28% of the urate lowering effect, whereas AR882 contributed 38% of the effect. Similarly, febuxostat contributed 33% of the urate lowering effect and AR882 contributed to about 36-38% of the effect when used in combination. The combination treatments significantly increased the response ratio for patients achieving sUA levels < 5 mg/dL, 4 mg/dL, and even 3 mg/dL. In the combination with allopurinol, 100%, 100%, 100%, and 44% patients achieved sUA < 6 mg/dL, < 5 mg/dL, 4 mg/dL, and 3 mg/dL, respectively. Similar results were seen with the combination of AR882 and febuxostat. Treatment with allopurinol or febuxostat alone resulted in 8 to 10-fold and 16-fold increases of xanthine exposure, respectively. The combination of AR882 and allopurinol or febuxostat showed approximately 5-8 fold or 13-fold increases in plasma xanthine, respectively. Treatment with allopurinol or febuxostat alone resulted in 2-3 fold increase in hypoxanthine exposure. Relative changes of hypoxanthine were not significantly different in the presence versus absence of AR882. Increased excretion of xanthine and hypoxanthine was also observed in urine. AR882 was well tolerated in gout patients, showing a similar safety profile to that observed in healthy volunteer studies.
Conclusion: AR882 dose alone had no effect on plasma or urine hypoxanthine and xanthine levels. AR882 contributed to a greater portion of the serum urate lowering effects when used in combination with XO inhibitors, and with 100% of patients achieving levels below 4 mg/dL when combined with allopurinol. The use of AR882 in combination with XO inhibitors may provide an option for preventing flares as well as tophi reduction in advanced patients.

POS1129

OPTIMIZATION OF DUAL ENERGY COMPUTED TOMOGRAPHY POST-PROCESSING TO REDUCE LOWER LIMB ARTIFACTS IN GOUT

B. Dubief[1], J. Avril[2], T. Pascart[3], M. Schmitt[1], R. Loffroy[2], J. F. Maillefert[1], P. Ornetti[1], A. Ramon[1]. [1]*Dijon University Hospital, Rheumatology, Dijon, France*; [2]*Dijon University Hospital, Diagnostic and Therapeutic Radiology Department, Dijon, France*; [3]*Lille Catholic Hospital, Rheumatology, Lomme, France*

Background: Dual energy computed tomography (DECT) is highly accurate for the diagnosis of gout. However, many artifacts have been described (1,2) such as nail bed, skin, beam hardening, sub-millimeter and vascular artifacts). Their presence can lead to a risk of over-diagnosis (false positives).
Objectives: Main objective of this case-control study was to determine the optimal DECT settings post-treatment parameters (ratio and attenuation coefficient (HU)) in order to reduce the frequency of lower limb artifacts in patients with suspected gout of the lower limbs.
Methods: Seventy-seven patients hospitalized for suspected gout arthritis (feet/ankles and/or knees) who received a DECT imaging were consecutively included (final diagnosis of 43 gout and 34 other rheumatic disorders). Different post-treatment settings were evaluated from the Syngovia software: an R1 (standard) setting with a ratio at 1.36 and minimum attenuation at 150 HU; an R2 setting with a ratio at 1.28 and minimum attenuation at 170 HU and an R3 setting with a ratio at 1.28 and minimum attenuation at 120 HU. The frequency of each artifact according to the 3 settings was determined. Diagnostic accuracy of R1 and R2 settings has been calculated. Correlations between artefacts and patient's clinical characteristics were obtained by performing a Spearman test.
Results: The R2 setting (170 HU, ratio=1.28) significantly reduced the presence of knee and foot/ankle artifacts compared to the standard R1 setting (85% and 94% decrease in beam hardening and clumpy artifacts in the ankle and foot, respectively ($p < 0.001$); a decrease of 71%, 60% and 88% respectively of meniscal beam hardening, beam hardening and submillimeter artifacts in the knee ($p < 0.001$). The use of R3 setting lead to a significant increase of some artifacts (clumpy artifacts, skin artifacts, beam hardening and nail beds.). In addition, our results found a positive correlation between the presence of deposits of knee menisci beam hardening chondrocalcinosis. Body mass index was

also positively correlated with the presence of knee beam hardening artifact. Compared to standard setting, the use of R2 settings decreased sensitivity (0.79 [95CI: 0.65;0.88] versus 0.90 [95CI: 0.78;0.96] and increased specificity (0.86 [95CI: 0.71;0.93) versus 0.63 [95CI: 0.47;0.77] (p<0.001).

Conclusion: Applying a ratio of 1.28 and a minimum attenuation of 170 HU (R2 settings) in DECT post-processing eliminates the majority of the artifacts located on the lower limbs, particularly the clumpy artifact and the beam hardening artifact.

POS1130 PHARMACOKINETICS AND SERUM URATE LOWERING EFFECTS OF AR882, A NOVEL, POTENT AND SELECTIVE URICOSURIC AGENT, IN PATIENTS WITH GOUT

Z. Shen[1], E. Polvent[1], V. Hingorani[1], A. Clouser Roche[1], C. Colton[1], R. Yan[1], S. Yan[1], L. T. Yeh[1]. [1]*Arthrosi Therapeutics Inc, Laguna Hills, California, United States of America*

Background: AR882 is a novel, potent and selective uric acid transporter 1 (URAT1) inhibitor in Phase 2 development for the treatment of hyperuricemia and gout. In Phase 1 healthy subject studies, AR882 demonstrated good dose proportionality, a long effective half-life and sustained serum urate (sUA) lowering effects, consequently making it suitable for once-daily dosing. In addition, AR882 was well tolerated following single and multiple dosing.

Objectives: This Phase 2a study evaluated the pharmacokinetics (PK), pharmacodynamics (PD), and safety of AR882 following monotherapy in patients with gout. PK and sUA lowering effects in patients with renal impairment and normal renal function were also compared.

Methods: A total of 30 adults with gout (sUA >7 mg/dL) were enrolled and 28 had post-baseline PKPD assessments performed. AR882 was administered at escalating doses of 25, 50 and 75 mg, with each dose administered once daily for 7 days. Serial blood samples were collected to measure AR882 PK and sUA levels at the end of each treatment week. Urine samples were collected for assessment of uric acid excretion. Laboratory safety tests, vital signs, and electrocardiograms were collected throughout the study.

Results: Following once daily administration in patients with gout, AR882 exposures increased dose proportionally between 25 and 75 mg. Mean sUA levels were maximally reduced from baseline (mean 8.9 mg/dL) to 5.6, 4.2 and 3.2 mg/dL at the 25-, 50- and 75-mg dose levels, respectively. The corresponding percent reductions were 36.8%, 52.7% and 61.5%. The effects were sustained throughout the entire dosing day with minimal fluctuation. In patients receiving 25 mg AR882 (N=9), 56% achieved sUA levels below 6 mg/dL. At 50 mg (N=28), 96% of patients had sUA levels below 6 mg/dL and 93% were below 5 mg/dL. At the 75 mg dose (N=8), all patients (100%) achieved levels below 5 mg/dL, and 88% were below 4 mg/dL. Among these 28 gout patients, 17 patients had normal renal function (CrCL>90 mL/min) and 11 patients had mild impairment (CrCL 60-90 mL/min). AR882 exposures were similar between patients with mild renal impairment and those with normal renal function. Both groups showed nearly identical sUA lowering effects following each 7-day dosing period. Response rates were also similar between these groups, including at the 50 and 75 mg dose levels. Consistent with its sUA lowering effects, dose-dependent increases in fractional excretion of uric acid were observed across all doses.

AR882 was well tolerated at all doses tested. All AEs were mild or moderate in severity and most were considered not related to study treatment. There were no serious AEs or AEs resulting in study drug discontinuation. There were no clinically significant laboratory or ECG abnormalities noted.

Conclusion: In patients with gout, AR882 exhibited dose proportional increases in plasma exposure and dose-dependent reductions in sUA. Nearly all patients had sUA levels below 5 mg/dL at doses ≥50 mg, and about 90% of patients had sUA levels <4 mg/dL at 75 mg dosing. Similar PK exposures and sUA lowering effects were observed in patients with mild renal impairment compared to those with normal renal function. Current data suggest that AR882 50 mg may offer improved efficacy over existing standard-of-care for gout and AR882 75 mg may have utility in the treatment of patients with severe or refractory gout disease.

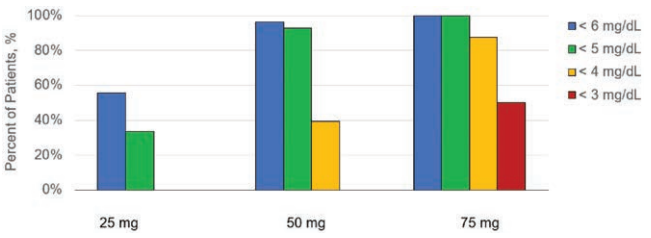

Figure 1. Percent of Patients with sUA below 6 mg/dL, 5 mg/dL, 4 mg/dL or 3 mg/dL Following Once-Daily Oral Doses of AR882.

Table 1. Mean (SD) sUA Levels Following Once-Daily Oral Doses of AR882.

Treatment	N	Time (hr), sUA (mg/dL)			
		0	6	12	24
Baseline	30	8.8 (1.1)	8.8 (1.1)	9.0 (1.0)	8.9 (1.1)
25 mg	9	6.1 (0.4)	5.6 (0.4)	5.6 (0.3)	5.8 (0.4)
50 mg	28	4.7 (0.9)	4.2 (0.9)	4.3 (0.8)	4.7 (1.0)
75 mg	8	3.7 (1.1)	3.2 (0.9)	3.2 (0.8)	3.6 (1.0)
50 mg (normal renal function)	17	4.8 (1.1)	4.3 (1.1)	4.4 (0.9)	4.8 (1.2)
50 mg (mild impairment)	11	4.5 (0.6)	4.1 (0.6)	4.3 (0.5)	4.6 (0.6)

POS1131 THE INCIDENCE AND PREVALENCE OF CARDIOVASCULAR DISEASES IN GOUT: A SYSTEMATIC REVIEW AND META-ANALYSIS

P. Cox[1], S. Gupta[2], S. S. Zhao[3], D. Hughes[4]. [1]*University of Liverpool, Institute of Translational Medicine, Liverpool, United Kingdom*; [2]*University of Liverpool, School of Medicine, Liverpool, United Kingdom*; [3]*University of Liverpool, Institute of Ageing and Chronic Disease, Liverpool, United Kingdom*; [4]*University of Liverpool, Department of Health Data Science, Liverpool, United Kingdom*

Background: Gout is an inflammatory crystal arthropathy characterised by hyperuricaemia and sodium urate crystal deposition. Both gout and subclinical hyperuricaemia are associated with adverse cardiovascular outcomes. Several studies have found gout to cause an increased risk of cardiovascular disease, but the evidence is not unanimous. The conflicting evidence has made it difficult to establish the extent of the cardiovascular risk to patients with gout.

Objectives: To describe the incidence and prevalence of cardiovascular disease in gout, compare these results with non-gout controls.

Methods: PubMed, Scopus and Web of Science were systematically searched in January 2021 for studies reporting prevalence of any cardiovascular disease in a gout population. Studies with non-representative sampling, where a cohort had been used in another study, small sample size (< 100) and where gout could not be distinguished from other rheumatic conditions were excluded. Sample size, prevalence of the investigated cardiovascular disease, definition of gout and cardiovascular disease, demographic data, data source and any comparisons with non-gout controls were extracted from each study. Where prevalence data was reported in ≥3 cohorts meta-analysis was performed using random-effect models.

Results: Of the 6164 titles identified, 105 full texts were assessed for eligibility with 30 included in the review, producing a gout population of 1,125,988. Pooled prevalence estimates were calculated for six cardiovascular diseases: heart failure (8.73%; 95% confidence interval (CI), 2.85 – 23.76), cerebrovascular accident (4.27%; 95% CI, 1.83 – 9.67), myocardial infarction (2.82%; 95% CI, 1.58 – 5.01), venous thromboembolism (2.05%; 95% CI, 1.22 – 3.43), hypertension (63.94%; 95% CI, 24.51 – 90.64) and cardiovascular mortality (4.75%; 95% CI, 3.56 – 6.31). Twenty studies reported comparisons with non-gout controls, illustrating an increased risk in the gout group across all cardiovascular diseases, particularly for myocardial infarction.

Conclusion: Cardiovascular diseases are more prevalent in patients with gout and should prompt vigilance from clinicians to the need to assess and stratify cardiovascular risk. These results are in line with other studies which have shown an increased cardiovascular risk for sufferers of hyperuricaemia, highlighting the need for future research to explain this finding. There are limited studies in the

literature investigating less common cardiovascular conditions, illustrating the need for future work if a more thorough picture of prevalence is to be established.

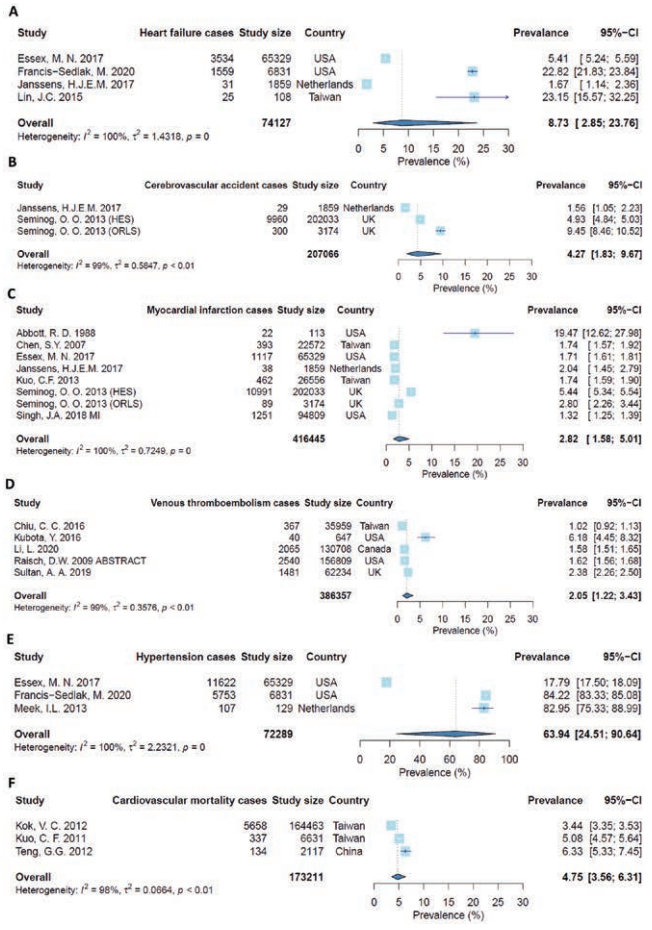

Figure 1. Forest plots of pooled prevalence of: (**A**) 8.73% for heart failure, (**B**) 4.27% for cerebrovascular accident, (**C**) 2.82% for myocardial infarction, (**D**) 2.05% for venous thromboembolism, (**E**) 63.94% for hypertension and (**F**) 4.75% for cardiovascular mortality.

Background: Conventional Radiography (CR) has been widely used in the assessment of knee chondrocalcinosis (CC) and is still considered one of the most important diagnostic methods for the diagnosis. However, there are very few studies that examine the diagnostic accuracy of CR compared to histology of the knee tissues.
Objectives: To assess the diagnostic accuracy of CR of the knee in Calcium Pyrophosphate Deposition Disease (CPPD) by using the recently created definitions for CPPD in CR of the ACR/EULAR taskforce for the new classification criteria for CPPD.
Methods: This is an ancillary study of the Criterion Validity of Ultrasound in CPPD study [1]. Consecutive patients with osteoarthritis (OA) awaiting total knee replacement were enrolled in 4 centres from Romania, Italy, USA and Mexico. All patients underwent CR of the knees taken maximum 6 months before surgery, in posterior-anterior weight baring and lateral projections. DICOM files of the radiographs were anonymised and read independently by two musculoskeletal radiologists with experience in microcrystalline arthropathies. For each patient, a dichotomic score was used (absence/presence of CC) at the level of the menisci and tibiofemoral hyaline cartilage by each reader. The definitions of the ACR/EULAR taskforce for identification of CPPD in CR were used in this study [paper in preparation]. According to these definitions CPPD in CR appears as "linear or punctate opacities in the region of fibro- or hyaline articular cartilage/synovial membrane or joint capsule/within tendons or entheses that are distinct from denser, nummular radio-opaque deposits due to basic calcium phosphate deposition". In case of disagreement a consensus decision was taken by both radiologists after discussion of the case. Menisci and the hyaline cartilage were analysed using compensated polarized light microscopy as described previously [1], patients were considered positive for CPPD if at least one of their tissue specimens revealed the presence of calcium pyrophosphate crystals. All examiners were blind to each other's findings.
Results: We enrolled 33 patients with OA (61% female, mean age 69yo). The accuracy values of CR in the various sites of the knee are indicated in Table 1. CR demonstrated to be a specific exam for identification of CPPD at the knee, but sensitivity remains low in all sites and in the overall evaluation. Identification of CPPD appears challenging and this could be due to the advanced grade of OA in our cohort of patients. Advanced degeneration, dislocation of the menisci and thinning of the hyaline cartilage in these patients is frequent and the eventual presence of calcific deposits in one of these structures could overlap with other anatomical structures making the exact localisation difficult. According to the results of the predictive values, the presence of typical deposition on CR allows a definite confirmation of the diagnosis, but a negative radiography does not exclude CPPD as testified by the low negative predictive value.

Table 1. ***Sensitivity, specificity, PPV, NPV, accuracy and AUC of CR for identification of CPPD by using the new ACR/EULAR taskforce definitions.***

	Medial meniscus	Lateral meniscus	Hyaline cartilage	Overall
Sensitivity	22%	33%	31%	42%
Specificity	100%	100%	85%	90%
Positive predictive value	100%	100%	67%	80%
Negative predictive value	56%	60%	55%	61%
Accuracy	61%	68%	58%	66%
AUC	0.6	0.7	0.6	0.7

Conclusion: CR has been extensively used for the diagnosis of OA and CPPD and has been tested previously for diagnostic accuracy. The results of our study confirm that the presence of typical CPPD calcifications, as defined by the ACR/EULAR task force, are highly specific but have low sensitivity for disease identification when using CR. Absence of CPPD on CR does not exclude the diagnosis.

Background: Conventional Radiography (CR) has been widely used in the assessment of knee chondrocalcinosis (CC) and is still considered one of the most important diagnostic methods for the diagnosis. However, there are no studies on the reliability of CR for CC.

Objectives: To assess the reliability of CR of the knee in the assessment of chondrocalcinosis (CC).

Methods: This is an ancillary study of the Criterion Validity of Ultrasound in Calcium Pyrophosphate Deposition Disease (CPPD) study [1]. Consecutive patients with knee osteoarthritis (OA) that were planned for total knee replacement surgery were enrolled in 4 centres from Romania, Italy, USA and Mexico. All patients underwent CR of the knees taken maximum 6 months before surgery, in posterior-anterior weight baring and lateral projections. DICOM files of the radiographs were retrieved, anonymised and read independently by two musculoskeletal radiologists with experience in microcrystalline arthropathies. Each reader performed a second evaluation 3 weeks after the first one to calculate the inter- and intra-reader agreement. For each patient a dichotomic score was assigned (absence/presence of CC) at the level of the medial and lateral menisci, tibiofemoral hyaline cartilage, quadriceps and patella tendons, synovial membrane/joint capsule. The definitions of the ACR/EULAR taskforce for identification of CPPD in conventional radiography were used in this study [paper in preparation]. According to these definitions CPPD in CR appears as "linear or punctate opacities in the region of fibro- or hyaline articular cartilage/synovial membrane or joint capsule/within tendons or entheses that are distinct from denser, nummular radio-opaque deposits due to basic calcium phosphate deposition". Cohen's kappa was used to calculate the agreement between the two readers.

Results: We enrolled 33 patients with knee OA (60.6% female, mean age 69yo ± 8). The kappa values of the inter-reader and intra-reader agreement in the various sites of the knee are indicated in Table 1. Inter-reader agreement was substantial at the level of both menisci but only moderate or fair at the other sites of assessment. This had a negative impact on the overall evaluation of the knee joint that proved to be unreliable (k of 0.16 – none to slight agreement) if all anatomical structures are included for assessment, and moderately reliable (kappa 0.41) when both menisci and hyaline cartilage are considered. On the other hand, intra-reader kappa values were substantial or higher in all sites (except for synovial membrane/joint capsule for one reader). The striking difference of the intra-reader compared to the inter-reader kappa values, highlight a different interpretation and application of the definitions used for most of the sites with the exception of the menisci.

Table 1. ***kappa values for intra- and inter-reader agreement. Values from 0.01–0.20 are considered as none to slight agreement, 0.21–0.40 as fair, 0.41– 0.60 as moderate, 0.61–0.80 as substantial, and 0.81–1.00 as almost perfect agreement.***

	Medial meniscus	Lateral menis-cus	Hyaline cartilage	Quadriceps tendon	Patellar tendon	Capsule/ synovia	Menisci + cartilage	Entire joint
Inter-reader	0.67	0.71	0.34	0.47	NA	0.37	0.40	0.17
Intra-reader 1st assessor	0.67	0.90	0.84	0.65	NA (insufficient number of categories)	0.53	0.71	0.76
Intra-reader 2nd assessor	1	0.80	1	1	1	0.91	0.86	0.94

Conclusion: CR has been extensively used for diagnosis of OA and CPPD. The results of our study raise some concerns on the reliability of CR in identification of CPPD. Assessment of calcium crystals at the menisci level should be used for identification of CC as other sites of the knee seem to present low reliability.

POS1134

COMPARATIVE ANALYSIS OF THE CLINICAL AND LABORATORY PROPERTIES OF GOUT, OSTEOARTHRITIS, AND CALCIUM PYROPHOSPHATE DEPOSITION DISEASE

D. Kravchenko[1], R. Bergner[2], C. Behning[3], V. Schäfer[4]. *[1]University Hospital Bonn, Department of Diagnostic and Interventional Radiology, Bonn, Germany*; *[2]Klinikum Ludwigshafen, Medical Clinic A: Clinic for Internal Medicine, Hematology, Nephrology, Infektiology and Rheumatology, Ludwigshafen, Germany*; *[3]University Hospital Bonn, Institute for Medical Biometrics, Informatics and Epidemiology (IMBIE), Bonn, Germany*; *[4]University Hospital Bonn, Clinic of Internal Medicine III, Hematology, Oncology, Rheumatology and Clinical Immunology, Bonn, Germany*

Background: The clinical differentiation between gout, osteoarthritis (OA), and calcium pyrophosphate deposition disease (CPPD) still remains a hurdle in daily practice without imaging or arthrocentesis. Although a plethora of clinical data exists, reliable predictor biomarkers for all but gout are still missing.

Objectives: To explore an association between common physical examination, ultrasound and laboratory findings and gout, OA, and CPPD, which can in turn provide reliable diagnostic predictions.

Methods: 277 patients were retrospectively analysed using ANOVA with Scheffe's post hoc tests and conditional inference trees regarding biomarkers such as age, sex, body mass index, hypertension, renal status, cumulative affected joint size, number of afflicted joints, double contour sign, intracartiliginous double contour sign, degree of vascularization on ultrasound (DoV), uric acid, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), ferritin, and leucocyte count. Simple linear regressions were carried out to explore associations between increased inflammatory parameters and the above-mentioned biomarkers. Statistically significant associations were defined as p values < 0.05.

Results: The male sex was associated with gout (p value < 0.05 vs CPPD and < 0.05 vs OA). OA affected younger patients than CPPD (mean 64.5 vs 73.1 years, p < 0.05). Hypertension was correlated with gout (p < 0.05) and CPPD (p < 0.05), impaired renal status with gout when compared to OA (p < 0.05) but not compared to CPPD (p 0.21). A higher number of involved joints was associated with gout (mean 2.2 joints) compared to OA (1.0, p < 0.05) and CPPD (1.6, p 0.01). The double contour sign was not able to differentiate gout and CPPD with a sensitivity/specificity of 71%/55% for gout and 59%/39% for CPPD. The intracartilaginous double contour sign was specific for CPPD (99%) but with a low sensitivity of 26%. DoV was significantly associated with gout (vs OA, p < 0.05) and CPPD (vs OA, p < 0.05). Unsurprisingly, uric acid was associated with gout while ESR and CRP were increased in gout and CPPD, but not in OA. Some associations were statistically significant but arguably clinically unimportant. Conditional inference trees were able to exclude OA (specificity 97.5%) and CPPD (specificity 94.0%) as possible differentials based on just uric acid, CRP, hypertension,

and sex, and diagnose gout with a sensitivity of 95.1%, summarized in Figure 1. Linear regressions demonstrated an elevated CRP response in people suffering from type II diabetes, higher cumulative joint points score, number of affected joints, as well as elevated uric acid, ESR, and leucocyte count.

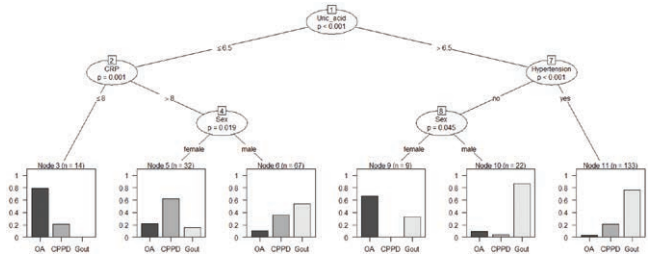

Figure 1. Conditional inference tree using unbiased recursive partitioning to reliably differentiate between gout, osteoarthritis, and calcium pyrophosphate deposition disease.

Conclusion: Gout can be reliably diagnosed, simultaneously excluding OA and CPPD as differential diagnoses by conditional inference trees using just four biomarkers. A correlation between inflammatory reaction severity based on CRP levels was found in patients suffering from type II diabetes, more or larger joint involvement and elevated uric acid levels. The double contour sign remains a questionable differentiator between gout and CPPD with a sensitivity/specificity of 71%/55% for gout and 59%/39% for CPPD, similar to findings reported by Löffler et al (1) with a sensitivity/specificity of only 64%/52% for gout.

POS1135 MONOSODIUM URATE CRYSTALS REDUCE SCHWANN CELLS VIABILITY

Y. Liu[1,2], Y. Huang[1], S. Sun[1], W. Deng[1], T. W. LI[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China*; [2]*University of South China, Guangdong Second Provincial General Hospital, Guangzhou, China*

Background: The prevalence of peripheral neuropathy in patients with gout almostly reaches 25%[1]. Demyelination caused by Schwann cell (SCs) injury and apoptosis is the major pathological feature of peripheral[2]. None of study has focused on the effects of monosodium urate (MSU) crystals on SCs.

Objectives: To assess the effect of MSU crystals on SCs.

Methods: Mouse-derived Schwann cells (RSC96) are stimulated with different concentrations of MSU crystals (0mg/ml,0.25mg/ml,0.5mg/ml) and time (24h,48h,72h). The migration ability of Schwann cells is evaluated by acratch assay, the proliferation level is assessed by the cell counting kit-8 (CCK-8) assay, and the apoptosis rate is detected by flow cytometry.

Results: The acratch assay showed that the migration ability of SCs was worsened, CCK-8 assay suggested that proliferation of SCs was reduced in a dose-dependent manner (P<0.05). According to the result of flow cytometry, the survival rate of SCs at 0.5mg/ml(78.60%±2.26%) was lower than that 0.25mg/ml(87.50%±0.95%)and 0mg/ml (98.80%±0.26%)(p<0.05) at 24h. When the stimulation time increased to 72h, the survival rate at 0.5mg/ml(47.90%±11.70%) dropped significantly, which was significantly different from the other two groups(p<0.05).

Conclusion: MSU crystals can cause damage to Schwann cells. It may help to explain the reason of peripheral neuropathy in gout patients.

POS1136 PHARMACOKINETICS OF PEGLOTICASE AND METHOTREXATE POLYGLUTAMATE(S) IN PATIENTS WITH UNCONTROLLED GOUT RECEIVING PEGLOTICASE AND CO-TREATMENT OF METHOTREXATE

Y. Song[1], Y. Xin[1], M. E. Weinblatt[2], J. Chamberlain[1], K. Obermeyer[3], L. Zhao[3], C. Canavan[3], P. M. Peloso[3], S. Ramanathan[1]. [1]*Horizon Therapeutics plc, Research and Development, South San Francisco, United States of America*; [2]*Brigham and Women's Hospital, Division of Rheumatology, Immunology and Allergy, Boston, United States of America*; [3]*Horizon Therapeutics plc, Research and Development, Deerfield, United States of America*

Background: In an open-label, single-arm trial in adult patients with uncontrolled gout (MIRROR open-label [OL] trial) evaluating pegloticase co-treatment with methotrexate (MTX); 78.6% patients were responders, defined as maintenance of serum uric acid <6 mg/dL for at least 80% of the time during month 6 [weeks 20, 22, and 24]. In comparison, 42% patients achieved a response during month 3 and 6 in historical Phase 3 monotherapy trials of pegloticase (C0405 and C0406)[1]. MTX co-treatment is shown to improve the pharmacokinetics (PK) of biologics by attenuating the formation of anti-drug antibodies[2].

Objectives: To determine the systemic exposures of pegloticase and methotrexate polyglutamate(s) (MTX-PGs) in uncontrolled gout patients receiving pegloticase and MTX; to evaluate the effect of MTX on the PK of pegloticase in comparison to historical pegloticase monotherapy trials (C0405 and C0406)[3, 4]; and to evaluate the immunogenicity of pegloticase in co-treatment with MTX.

Methods: In the MIRROR OL trial, MTX (15 mg/week) was given orally 4 weeks prior to the first pegloticase dose and continued weekly, in combination with pegloticase 8 mg given intravenously every 2 weeks, for a treatment duration of up to 52 weeks. Pre-infusion samples were collected to measure MTX-PGs in red blood cells. Pre- and post-infusion blood samples were obtained to measure the peak (C_{max}) and trough (C_{min}) concentrations of pegloticase at multiple visits. Anti-drug antibody blood samples were collected at multiple visits. The impact of MTX on pegloticase PK was evaluated by comparing pegloticase exposures with MTX from this trial to historical monotherapy data (C0405 and C0406)[3, 4]. The observed pegloticase concentrations with MTX were also overlaid with the 90% prediction interval based on the population PK model[5] from C0405 and C0406.

Results: Pegloticase and MTX-PG levels were determined in 14 patients. The 11 responders were generally associated with higher pegloticase exposures than the non-responders, especially C_{min} (Figure 1). Concomitant treatment of MTX resulted in fewer patients with C_{min} below quantitation limit (BQL) (5/14 [36%] with MTX vs 63/82 [77%] without MTX), and higher overall C_{min} (median: 1.03 µg/ml with MTX vs BQL without MTX); C_{max} was slightly higher (median [Q1, Q3]: 2.11 [1.65, 2.59] µg/mL with MTX vs 1.51 [BQL, 2.48] µg/mL without MTX). Pegloticase co-treatment with MTX resulted in more concentrations above the predicted median value of pegloticase, compared to monotherapy. ADA data is consistent with pegloticase PK and efficacy. Significant increase in ADA titers were only observed in 2 subjects (both were non-responders) at time corresponding to the loss of pegloticase exposure and increases in sUA levels. Concentrations of MTX-PGs were maintained during the treatment course, suggesting compliance of MTX administration. There was no apparent difference in concentrations of MTX-PGs between responders and non-responders.

Conclusion: Pegloticase 8 mg IV every 2 weeks co-treatment with MTX 15 mg weekly resulted in fewer patients with pegloticase C_{min} below the quantification

limit (BQL) and gave higher overall trough concentrations (C_{min}) compared to pegloticase monotherapy in the phase 3 studies.
Pegloticase 8 mg IV every 2 weeks co-treatment with MTX 15 mg weekly was associated with an improved response rate for pegloticase in association with improved drug levels in these patients with uncontrolled gout compared to pegloticase monotherapy in the phase 3 studies.

Background: The most frequent manifestation in adult Hypophosphatasia (HPP) is musculoskeletal pain.[1,2] The unspecific nature of its clinical presentation may prevent correct diagnosis.[3]
Objectives: Identifying adult hypophosphatasia in the rheumatology unit.
Methods: Over a period of 10 years 9,522 patients were screened in a rheumatological outpatient unit. Serum ALP levels ≤ 40 U/l were found in 524 patients. After screening for secondary causes, 73 patients were invited for clinical evaluation. Genetic testing was performed in 23 patients with suspected HPP. Logistic regression models were used to estimate the association of each clinical factor with HPP.
Results: Mutations in the *ALPL* gene were observed in 57% of genetically screened patients. Arthralgia, fractures and pain were the leading symptoms in HPP patients. Chondrocalcinosis (OR 29.12; 95% CI 2.02-1593.52) and dental disease (OR 8.33; 95% CI 0.93-143.40) were associated with HPP independent of BMI. Onset of symptoms in HPP was at 35.1 (14.3) years, with a mean duration from symptoms to diagnosis of 14.4 (8.1) years. Bone mineral density (BMD) and trabecular bone score (TBS) as well as bone turnover markers were not indicative for HPP.
Conclusion: HPP can mimic joint diseases.[4] Thus, in patients with uncertain rheumatologic complaints and low ALP, HPP should be considered as potential diagnosis.

POS1138 SERUM URIC ACID-TO-CREATININE RATIO: A POTENTIAL MARKER FOR GOUT

Z. Huang[1], T. LI[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Serum uric acid-to-creatinine ratio (SUA/Cr) is a useful index of renal function-normalized serum uric acid (SUA), which reflects endogenous SUA levels more precisely than SUA. SUA/Cr relates to disease activity and prognosis of several metabolic disorders, like metabolic syndrome, non-alcoholic fatty liver disease, and diabetes mellitus [1]. Besides, the urine uric acid-to-creatinine ratio is valuable for the assessment of gout [2]. However, no study focuses on the relationship between SUA/Cr and gout.
Objectives: We aimed to investigate the relationship between SUA/Cr and the features of demography, manifestations, laboratory tests, and urate-lowering therapies (ULTs) in gout patients.
Methods: This cross-sectional study was performed from December 2015 to February 2020. Medical records of gout patients who were regularly undergone follow-up were evaluated. Characteristics of gout patients, included age, gender, the duration of gout, body mass index (BMI), tophus, complications, the number of flares, C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR), were recorded. Complications were defined as hypertension, coronary artery diseases, diabetes, strokes, and/or metabolic diseases. Information about ULT was obtained as well. The Spearman correlation analysis was used to assess the relationship between continuous variables. The Mann-Whiney U test or Kruskal-Wallis test was employed to compare the differences of SUA/Cr between genders, ULTs, and whether patients had tophus or complications. A $P<0.05$ was considered as statistically significant.
Results: (1) Of 627 gout patients who were involved, 608 (96.97%) were male. Their median (range) of age and the duration of gout were 30.00 (51.00) years and 5.00 (30.00) years, respectively. (2) SUA/Cr negatively correlated with age ($r=-0.71$, $P<0.05$). SUA/Cr was similar between genders. (3) SUA/Cr positively correlated with BMI ($r=0.14$, $P<0.05$), while the coefficient correlation for the duration of gout and the number of flares did not reach statistically significant ($P>0.05$). SUA/Cr was significantly higher in patients with complications than the others [5.56 (9.26) vs. 4.16 (8.34), $P<0.05$], but whether patients with tophus or not shared similar SUA/Cr. (4) CRP and ESR did not associate with SUA/Cr ($P>0.05$). (5) Patients with combination therapy with xanthine oxidase inhibitor and uricosuric agent had a lower SUA/Cr compared with those who used ULTs monotherapy [3.44 (7.10) vs. 4.53 (7.91), $P<0.05$].
Conclusion: SUA/Cr relates to some features of gout, so it may be a potential marker for its assessment.

POS1139 COMPARISON OF THE FREQUENCY OF DETECTION OF EARLY SIGNS OF ATHEROSCLEROSIS IN PATIENTS WITH CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION DISEASE AND OSTEOARTHRITIS

M. Eliseev[1], A. Novikova[1], O. Sheliabina[1], M. Chikina[1], E. Markelova[2]. [1]*VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation*; [2]*VA Nasonova Research Institute of Rheumatology, Laboratory of Systemic Rheumatic Diseases, Moscow, Russian Federation*

Background: Crystal-induced inflammation can significantly increase cardiovascular risk (CVR) and cause early development of atherosclerosis [1]. However, no studies have been performed in patients with calcium pyrophosphate crystal deposition disease (CPPD).
Objectives: To compare the presence of atherosclerosis early signs (increased thickness of the intima-media complex (CIMT)) in patients with CPPD and osteoarthritis (OA).
Methods: A cross-sectional study included 48 patients, aged 18 to 65 years, 26 patients with crystal-verified diagnosis of CPPD (McCarty criteria) (6 (23%) men and 20 (77%) women) and 22 patients with OA (7 (32%) men and 15 (68%) women). Exclusion criteria are the presence of other rheumatic diseases with symptoms of arthritis, diabetes mellitus, coronary heart disease (CHD), prior myocardial infarction, stroke or myocardial revascularization surgery, estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m2, high and very high CVR on the SCORE scale. The examination of the patients included the history taking, assessment of anthropometric parameters and the following laboratory tests: determination of serum creatinine level (eGFR according to the MDRD formula), total cholesterol (TC), high density lipoprotein cholesterol (HDL cholesterol) and low density lipoprotein cholesterol (LDL cholesterol), C-reactive protein (CRP). Doppler ultrasound of the carotid arteries with an assessment of the thickness of the intima media complex (CIMT) was made for all patients - CIMT up to 0.9 mm was taken as the norm, CIMT> 0.9 mm and <1.3 mm as increased, and CIMT>1.3 mm was regarded as an atherosclerotic plaque. Statistica 12.0 package was used for statistical data processing.
Results: The groups were completely comparable by gender, age and all laboratory parameters (see Table 1), an increase in CRP>5 mg/l was more often detected in patients with CPPD - 31% vs 14% patients with OA (p=0.16).

Table 1. Clinical characteristics of patients included in the study.

Parameters	CPPD (n=26)	OA (n=22)	p value (reliable at p<0,05)
Age, years M±SD	55.9±5.9	52.4±8.3	0.14
Gender, men/women,n (%)	6 (23)/20 (77)	7 (32)/15 (68)	0.50
Smoking, n (%)	5(19)	6(27)	0.50
Systolic blood pressure, mmHg, M±SD	134±20	127±15	0.19
Arterial hypertension, n (%)	13(50)	10(45)	0.75
Family history of CVD, n %	6(23)	7(32)	0.50
TC, mmol/L, M±SD	5.4±1.3	5.3±1.3	0.95
TC >5,0 mmol/L, n (%)	17(65)	10(45)	0.17
HDL, mmol/L M±SD	1.7±0.5	1.4±0.5	0.10
LDL, mmol/L, M±SD	2.9±1.3	3.4±1.4	0.33
Creatinine, µmol/l, M±SD	73.2±13.8	78.9±11.5	0.16
CRP, mg/l, Me [25-75th percentiles]	1.1 [0.6; 6.4]	1.2 [0.3; 2.8]	0.60
CRP ≥5 mg/l, n (%)	8 (31)	3(14)	0.16

Mean CIMT values on the right (0.76±0.22 mm vs 0.70±0.18 mm) and on the left (0.75±0.18 mm vs 0.70±0.17 mm) did not significantly differ in CPPD and OA (p=0.34 and 0.32, respectively), the maximum CIMT values on the right (0.67±0.16 mm vs 0.67±0.16 mm) and on the left (0.67±0.14 mm vs 0,66±0.16 mm) with CPPD and OA were also comparable (p=0.95 and 0.77, respectively). However, an increase in CIMT> 0.9 mm was found in 13 (50%) patients with CPPD and only 5 (23%) with OA (p=0.02). No increase in CIMT>1.3 mm was found in patients of both groups.

Conclusion: Early signs of atherosclerosis are detected in 50% of patients with CPPD without clinical signs of atherosclerosis and with low or moderate CVR according to SCORE, significantly more often than in patients with OA (23%), which can be reflection of chronic crystal-induced inflammation.

POS1140 RISK FACTORS FOR THE DEVELOPMENT OF DIABETES MELLITUS IN PATIENTS WITH GOUT ACCORDING TO A 6-YEAR PROSPECTIVE FOLLOW-UP STUDY

O. Sheliabina[1], M. Eliseev[1], A. Novikova[1], M. Chikina[1]. [1]*VA Nasonova Research Institute of Rheumatology, Laboratory of Microcrystalline Arthritis, Moscow, Russian Federation*

Background: Gout is often associated with diabetes mellitus (DM), but the role of serum uric acid (sUA) and urate-lowering drugs in its development in patients with gout remains controversial [1].
Objectives: To study risk factors for DM in patients with gout based on the results of long-term prospective follow-up study.
Methods: The prospective study included 444 patients with a crystal-verified diagnosis of gout, aged ≥18 years, 49 (11%) women, 395 (89%) men. Patients were followed up at the V.A. Nasonova Research Institute of Rheumatology from 2010 to January 2021, the median follow-up was 6.1 [2.8; 7.8] years. The exclusion criteria were the presence of other rheumatic diseases with symptoms of arthritis, DM. DM was diagnosed on the 1998 WHO criteria. The following parameters were considered as risk factors: gender, family history for diabetes mellitus, body mass index (BMI)>25 kg/m2 and > 30 kg/m2, waist volume ≥88 cm for women and ≥102 cm for men, alcohol consumption > 20 units per week, chronic kidney disease (CKD), intake of diuretics and glucocorticoids, and serum total cholesterol >5 mmol/l, triglycerides>2.25 mmol/l, serum C-reactive protein (CRP) level> 5 mg/l, as well as clinical manifestations of gout: subcutaneous tophi, polyarthritis (simultaneous involvement of ≥5 joints), intake of urate-lowering drugs, sUA (> 480 µmol/L,> 420 µmol/L,> 360 µmol/L,> 300 µmol/L). Statistica 12.0 package was used for statistical data processing.
Results: A total of 444 patients were included, the mean age was 51.0±12.9 years, the median follow-up was 6.1 [2.8; 7.8] years. In dynamics: 35 (8%) patients died, 6 (1%) patients were not available, 403 patients were examined (44 (11%) - women and 359 (89%) - men). 290 (72%) patients received urate-lowering therapy (263 (65%) patients used allopurinol, 27 (7%) - febuxostat). The target sUA <360 µmol/L was reached by 165 (41%) patients and <300 µmol/L - by 92 (23%) patients. All patients with sUA<300 µmol/L received urate-lowering therapy, 62 (67%) patients used allopurinol, 17 (18%) - febuxostat, 13 (14%) - uricosuric drugs. Diabetes mellitus was developed in 106 (26%) patients. The factors influencing the risk of developing diabetes were - the presence of diabetes in family history (odds ratio (OR) 2.27, 95% confidence interval (CI) 1.37; 3.76); BMI> 30 kg / m2 (OR 1.79, 95% CI 1.14; 2.80), diuretics (OR 2.32, 95% CI 1.36; 3.96) and sUA> 300 µmol / l (OR 2.89, 95% CI 1.50, 5.56).
Conclusion: The risk of developing DM in patients with gout is associated with sUA> 300 µmol/l, which may be one of the probable reasons for choosing this as a target level. Large prospective studies are needed to confirm the antidiabetic effect of urate-lowering drugs.

Background: Imaging has been extensively used for the Calcium Pyrophosphate Deposition Disease (CPPD) diagnosis but the prevalence of joint calcifications at imaging in CPPD patients has not been thoroughly assessed.
Objectives: This systematic literature review (SLR) is aimed to estimate the prevalence of calcium crystal deposition in peripheral joints by imaging in suspected or definite CPPD patients to establish relevant joints for CPPD monitoring
Methods: After defining PICOs, Pubmed and Embase were searched from inception to October 2020 for identifying studies that evaluated the use of Conventional Radiography (CR), Ultrasound (US), Computed Tomography (CT) and Dual Energy Computed Tomography (DECT) in detecting calcifications at peripheral joints in patients with defined or probable CPPD. Search strategies based on MeSH terms and free text were applied. Six reviewers independently screened titles and abstracts, eligible article full texts were evaluated for inclusion and data extraction.
Results: The SLR identified 1149 manuscripts. 524 papers entered in the full text evaluation and 181 articles were finally included. Considering excluded abstracts and full texts, 23 and 17 were excluded as duplicate, 156 and 9 for language, 171 and 48 for population, 171 and 20 for intervention, 57 and 117 for outcome, 47 and 70 for study type and 76 for full text unavailability. Among included, 41 papers considered patients with definite CPPD with a total population of 1239 patients, 908 cases and 331 controls and 140 papers referred to patients with suspected CPPD with a total population of 26785 patients, 2896 affected by CPPD and 23889 controls. The results about all joints are summarized in the Table 1. In patients with definite diagnosis, knee and wrist are the joints with the highest prevalence of calcifications at all imaging types, followed by hip and acromion-clavicular joint while in patients with suspected CPPD, the knee is the most prevalent followed by the wrist, hip and ankle (only sites with more than 50 patients assessed considered). The hand joints are characterized by CPPD lowest prevalence at imaging. Bilateral imaging findings varies depending on the technique used, the site and the patient's type.
Conclusion: According to the results of this SLR, knees and wrists could be the sentinel joints for CPPD detection by imaging.

INTERLEUKIN-37: ASSOCIATIONS OF PLASMA LEVELS AND GENETIC VARIANTS IN GOUT

A. Navrátilová[1,2], V. Voclonová[1], H. Hulejova[1], L. Andres Cerezo[1,2], J. Zavada[1,2], K. Pavelka[1,2], L. Šenolt[1,2], B. Stiburkova[1,3,4]. *[1]Institute of rheumatology, Department of Experimental Rheumatology, Prague, Czech Republic*; *[2]First Faculty of Medicine Charles University, Department of Rheumatology, Prague, Czech Republic*; *[3]First Faculty of Medicine Charles University, Department of Pediatrics and Adolescent Medicine, Prague, Czech Republic*; *[4]General University Hospital in Prague, Department of Pediatrics and Adolescent Medicine, Prague, Czech Republic*

Background: IL-37, recently characterized IL-1 family member, has anti-inflammatory effects by suppression of IL-1ß and other proinflammatory cytokines. In this study we investigated the effects of genetics variants in IL-37 link with IL-37 plasma levels in a cohorts of patients with hyperuricemia/gout.
Objectives: The aim of this study was to determine the association of IL-37 gene polymorphism and plasma IL-37 levels in patients with hyperuricemia and gout.
Methods: The cohorts consisted of 50 control subjects, 50 subjects of primary hyperuricemia, 50 subjects of primary gout, 28 subjects of tophaceous gout and 19 subjects of acute gout flare. The analyzed cohorts were selected from a previously reported set of 250 hyperuricemia/gout patients and 132 normouricemic subjects (1) according to the descending level of serum urate. All coding regions and intron-exon boundaries of IL-37, exon 1-5, were amplified and sequenced directly. Comparisons of presence/absence of identified variants was performed using P-values binomial test. Levels of plasma IL-37 were measured using Enzyme-Linked ImmunoSorbent Assay. All tests were performed in accordance with standards set by the institutional ethics committees, which approved the project in Prague (no.6181/2015).
Results: We identified 12 IL-37 genetic variants: five intron (rs28947188, rs2466448, rs3811045, rs3811048, rs2708944), and seven non-synonymous allelic variants (rs3811046, rs3811047, rs2708943, rs2723183, rs2723187, rs2708947, rs27231927). Minor allele frequency (MAF) of those variants in European population from ExAC databases were used for comparison. Our data showed that the rs28947188, rs3811045, rs3811046, rs3811047, rs2723187, rs2708947, and rs27231927 variants were under-represented in the Czech hyperuricemia, gout, and tophaceous gout cohort compared with the control cohort and general European population (P = 0.0082 – 0.0395).
The levels of plasma IL-37 were significantly higher in patients with tophaceous gout compared to control subjects (P 0.0329) whereas no changes were observed in subjects with primary hyperuricemia, primary gout or acute gout flare compared to control subjects. However, IL-37 was elevated in cohorts of patients with gout, tophaceous gout and acute gout flare compared to primary hyperuricemia subjects (P 0.0198, 0.0005, 0.0099; respectively).
Conclusion: Although further analyzes are needed to elucidate the role of IL-37 in the gout, our results show that genetic variants in anti-inflammatory cytokine IL-37 are probably implicated in the pathogenesis of gout.

POS1143 GOUT AND JOINT REPLACEMENTS IN THE US

G. Singh[1], M. Sehgal[2], A. Mithal[3]. [1]*Stanford University, Medicine, Palo Alto, United States of America*; [2]*University of California, Los Angeles, Computer Sciences, Los Angeles, United States of America*; [3]*Institute of Clinical Outcomes Research and Education, Epidemiology, Woodside, United States of America*

Background: Irreversible joint damage in gout has been linked to a possible increase in knee and hip joint replacements[1]. In addition, the strong association between gout and osteoarthritis[2,3] could also lead to an increased risk of joint replacements in patients with gout. Population-based data from the UK and Taiwan have shown hazard rates of 1.14 and 1.16 respectively for knee replacements in patients with gout compared to age and gender matched controls[1]. However, there is little national data in the US on clinical and economic burden of joint replacements in patients with gout.
Objectives: To evaluate total or partial hip and knee joint replacements in patients with gout in the US and to estimate their economic impact
Methods: The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. Detailed information including clinical and nonclinical data elements on each hospital stay including International Classification of Diseases (ICD)10 diagnosis and procedure codes, age, gender, length of stay, payer, charges, comorbidities etc. is available. We examined hospitalizations in patients with gout with hip and knee joint replacements in NIS 2018, the most recent year of data.
Results: In 2018, there were 914,510 hospitalizations with primary or secondary diagnosis of gout in the US. Of these 43,615 were for joint replacement surgeries (knee (24,840) and hip (18,755)). Patients with knee replacement were on an average 68.5 years old (95% confidence intervals 68.2 years -68.8 years). Patients with hip replacement were slightly older (mean age 70.3 years, 95% confidence intervals 69.8 years -70.7 years). Unlike general population statistics, men formed a majority of these joint replacements (68% for the knee and 72% for the hip). The average charge per hospitalization was $69,279 and $72,944 for knee and hip replacement respectively. The total annual national cost estimate was $3.09 billion, with government insurances (Medicare and Medicaid) responsible for 67% of knee replacement and 70% of hip replacement costs.
Conclusion: Joint replacements in gout patients have a large clinical and economic burden in the US. This calls for an increased awareness and management of associated hip and knee arthritis in patients with gout.

POS1144 SERUM URIC ACID TO CREATININE RATIO IS ASSOCIATED WITH URINARY URIC ACID EXCRETION IN PATIENTS WITH GOUT

Z. Zhong[1], Y. Huang[1], X. Huang[1], Q. Huang[1], Y. Liu[1], T. W. LI[1]. [1]*Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Underexcretion of uric acid is the dominant mechanism leading to hyperuricemia [1] and the 24-hour urinary uric acid excretion is an important measurement. However, it is inconvenient due to accurate timing and complete collection of the specimen.
Objectives: The aim of this study was to investigate the relationship between serum uric acid to creatinine ratio (sUACR) and 24-hour urinary uric acid excretion in gout patients.
Methods: A total of 110 gout patients fulfilling 2015 ACR/EULAR classification criteria from Guangdong Second Provincial General Hospital from January 2019 to January 2021 were retrospectively enrolled in this study. Patients were divided into underexcretion group (<3600 μmol/24h) and non-underexcretion group (≥3600 μmol/24h). The correlation between sUACR and 24-hour urinary uric acid excretion was analyzed by the Pearson's correlations analysis. Receiver operation characteristic (ROC) curves were performed to assess the utility of sUACR for discriminating between underexcretion group and non-underexcretion group. Furthermore, the risk factors of uric acid underexcretion were evaluated using binary logistic regression analysis.
Results: sUACR in the underexcretion group was significantly lower than the non-underexcretion group (p=0.0001). Besides, sUACR was positively correlated with 24-hour urinary uric acid excretion (r=0.4833, p<0.0001). Furthermore, ROC suggested that the area under the curve (AUC) of sUACR was 0.728, which was higher that of serum uric acid and creatinine. The optimal cutoff point of sUACR was 5.2312, with a sensitivity and specificity of 71.9% and 67.9%. Logistic analysis results revealed that decreased sUACR (<5.2312) was an independent risk factor of underexcretion of uric acid (OR =5.510, 95% CI: 1.952-15.550, P=0.001).
Conclusion: sUACR is lower in gout patients with underexcretion of uric acid and may serve as a useful and convenient marker of assessing underexcretion of uric acid in gout patients.

POS1145 PREVALENCE OF CHONDROCALCINOSIS IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES – FREQUENTLY FOUND IN PATIENTS WITH RHEUMATOID ARTHRITIS AND VICE VERSA

M. Krekeler[1], X. Baraliakos[1], S. Tsiami[1], J. Braun[1]. [1]*Ruhr-University Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany*

Background: Calcium pyrophosphate deposition disease (CPPD), also known as pseudogout, is a prominent member of the crystal deposition diseases much like gout where urate crystals are the pathogens. CPPD is differentiated from chondrocalcinosis, a radiographic finding showing joint calcification, which may or may not be relevant for the clinical picture of patients (1).
Objectives: To determine the prevalence of chondrocalcinosis in different inflammatory rheumatic diseases.
Methods: In a retrospective cross-sectional study design we reviewed the records of not established new patients presenting to our center between 1.1.2016 and 31.12.2018. Based on the availability of radiographs of hands and feet, 514 patients were identified including 181 patients with CPPD, 273 with rheumatoid arthritis (RA), 143 seropositive (52.4%) and 130 seronegative, 30 with gout and 30 with polymyalgia rheumatica (PMR). Radiographs of hands and feet were available from all patients, of the knee in 376 cases. All images were read by two experienced readers with no access to clinical data.
Results: Almost all patients had a short disease duration of < 1 year. In patients diagnosed with CPPD all radiographs showed chondrocalcinosis (93%) at some location, mostly in the hands. This was different in seronegative (36.5%) and seropositive (30.3%) RA. Chondrocalcinosis was found less frequently also in gout (18.8%) and PMR (12.5%). More data are shown in the Table 1. Radiographic chondrocalcinosis was present in more than one joint in 36.6% patients with CPPD, in 11.9% in seropositive and in 17.3% in seronegative RA. Patients with CPPD were older and had acute attacks more often than RA patients. While RA patients were more frequently on methotrexate (MTX), patients with CPPD were more often on colchicine.

Table 1. Radiographic and clinical features of the examined patients

	CPPD N=181	Seropositive RA N=142	Seronegative RA N=129	Gout N=30	PMR N=30
% women	77,8	76,2	75,3	28,1	44,1
Mean age (years)	73,8± 9,8	58,8± 13,0	58,9± 14,7	56,6± 14,7	65,7± 8,9
Symptom duration (years)	0,3±0,7	0,4± 0,7	0,4± 0,9	1.0±3,0	0,4±1,7
Chondrocalcinosis (radiography, %)	93,0	35,7	34,6	12,5	11,8
Erosions (radiography, %)	50,8	42,9	32,1	50	8,8
Clinical involvement of hands (%)	83,2	76,2	72,8	25	50
Clinical involvement of feet (%)	24,3	33,3	32,1	62,5	11,8
Clinical involvement of knee (%)	42,7	39,3	42	59,4	32,4
Symmetric arthritis (%)	64,6	67,9	74	65,6	44,1
Acute attacks, sudden onset (%)	60,5	40,5	40,7	65,6	38,2
Both diagnoses RA and CPPD in record (%)	27,6	29,7	32,1	6,25	14,7
Therapy with MTX or another csDMARD (%)	13,0	52,4	42,0	3,1	23,5
Therapy with Hydroxychloroquine (%)	7,0	4,8	7,4	0	0
Therapy with Colchicine (%)	43,8	9,5	9,9	75	5,9

Conclusion: There were a lot of similarities but also some important differences between patients with CPPD and RA with no major differences between seropositive and seronegative RA. Of interest, radiographic chondrocalcinosis was seen in more than a third of RA patients. Importantly, clinical symmetry of arthritis and involvement of hands did not differentiate between CPPD and RA, mainly the acuteness of attacks did. Co-occurrence of both diseases was frequently observed. There was no major difference between seropositive and seronegative RA.

POS1146 NONCODING RNA CONTRIBUTE TO PATHOGENESIS IN PRIMARY GOUTY ARTHRITIS

Q. B. Zhang[1], Y. Q. Huang[1], F. N. Xiao[1], G. L. Jian[1], Y. P. Tang[2], F. Dai[2], J. X. Zheng[2], Y. F. Qing[2]. *[1]The Affiliated Hospital of North Sichuan Medical College, Geriatrics, Nanchong, Sichuan, China*; *[2]The Affiliated Hospital of North Sichuan Medical College, Rheumatology and Immunology, Nanchong, Sichuan, China*

Background: Gout is an arthritic disease caused by the deposition of monosodium urate crystal (MSU) in the joints, which can lead to acute inflammation and damage adjacent tissue [1].Over the past decade, noncoding RNAs (ncRNAs) have been shown to have crucial importance in health and disease[2,3]. However, studies evaluating the function of ncRNAs in gout are scarce, and current knowledge of the role of ncRNAs in gout is still limited.

Objectives: To assess the contribution of noncoding RNAs to gout and the clinical importance of these genes in primary gouty arthritis (GA).

Methods: The mRNA expression levels of noncoding RNAs (LINC00173, LINC00963, LINC01330 and miRNA-182-5p) were measured in peripheral blood mononuclear cells (PBMCs) from 60 gout patients(including 30 acute gout patients, 30 intercritical gout patients) and 40 healthy subjects. The relationship between noncoding RNA expression levels and laboratory features was analyzed in GA patients.

Results: The expression levels of LINC00173, LINC00963 and miRNA-182-5p were much lower in the AG and IG group than in the HC groups ($p<0.05$), and no significant difference was detected between AG and IG groups($P>0.05$). The expression levels of LINC01330 were much lower in the AG group than in the IG and HC groups ($p<0.05$), and no significant difference was detected between AG and IG groups($P>0.05$). In GA patients, the levels of noncoding RNAs mRNA correlated with laboratory inflammatory and metabolic indexes.

Conclusion: Altered noncoding RNAs expression suggests that noncoding RNAs is involved in the pathogenesis of GA and participates in regulating inflammation and metabolism.

POS1147 COSTS AND FACTORS AFFECTING HEALTH SERVICE UTILISATION IN PATIENTS WITH GOUT: A LONGITUDINAL, POPULATION-LEVEL LINKED DATA STUDY IN WESTERN AUSTRALIA

E. Kelty[1], J. Nossent[2], W. Raymond[2], P. Robinson[3], C. Hill[4], C. Inderjeeth[2], D. Preen[1], H. Keen[2]on behalf of WARDER. *[1]UWA, School of Population & Global Health, Perth, Australia*; *[2]UWA, School of Medicine, Perth, Australia*; *[3]UQ, School of Medicine, Brisbane, Australia*; *[4]University of Adelaide, School of Medicine, Adelaide, Australia*

Background: Evidence suggests that gout is associated with high health care costs and that many inpatient admissions are preventable (1). Understanding the driver of health care costs will allow more targeted intervention.

Objectives: To examine factors associated with high health service utilisation and cost in patients admitted to hospital with gout, using whole-population linked hospital, WA cancer registration, Emergency Department (ED) and death data (2).

Methods: The study included patients (18 to 84 years) who had been admitted to hospital with a primary or co-diagnosis of gout for the first time between 1 Jan 02 and 31 Dec 09 Hospital costs were calculated per patient using DRG codes and ED costs were calculated from URG codes. Costs are presented in Australian dollars. Follow-up was completed at five years post their initial gout hospitalisation, at death, or at the 31th of December 2014. Both univariable and multivariable analysis was conducted for each patient characteristic. Independent variables were assessed for collinearity. Collinearity was assumed present where the correlation co-efficient was greater than 0.7.

Results: 4,379 individuals were included. In the following five years, there was 22,222 ED attendances (median cost, $1826 per patient (IQR: $433 - $4,414)), and 58,920 hospital admissions, (median cost, $25,009 per patient (IQR: $6,844 - $60,535)). 4,059 (18.3%) ED attendances and 3,834 (6.5%) hospital admissions were potentially preventable. Gout was not a major driver of events, with 341 (1.5%) ED attendances and 620 (1.1%) hospital admissions coded with a primary diagnosis of gout. In the univariable analysis (Table 1), Aboriginality and smoking were associated with an increased number of both ED attendances and hospital admissions. Increased socio-economic status was associated with a reduction in ED attendances, however, this was not reflected in hospital admissions.

Conclusion: Patients admitted to hospital with gout are highly likely to be re-admitted or attend ED in the following 5 years. Many of these contacts are preventable, but are usually driven by comorbidities rather than gout.

POS1148 RISK FACTORS FOR POLYARTICULAR GOUT FLARES—ANALYSIS OF A LONGITUDINAL ONLINE GOUT FOLLOW-UP STUDY

J. Dau[1], N. Mccormick[1], S. Stratton[1], C. Yokose[1], C. Chen[2], T. Neogi[3], D. Hunter[4], K. Saag[5], Y. Zhang[1], H. Choi[1]. [1]*Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America*; [2]*Boston University School of Public Health, Biostatistics & Epidemiology Data Analytics Center, Boston, United States of America*; [3]*Boston University School of Medicine, Section of Rheumatology, Boston, United States of America*; [4]*University of Sydney, Institute of Bone and Joint Research, Sydney, Australia*; [5]*University of Alabama Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, United States of America*

Background: There are known and established risk factors for gout flares; however, no study has examined the factors specifically associated with a polyarticular gout flare.
Objectives: Evaluate risk factors of a polyarticular gout flare in a longitudinal study of individuals with gout.
Methods: We used data from the Boston Online Gout Study, a longitudinal internet-based case-crossover study, where gout patients with at least one flare within the past year were enrolled across the US. Participants (N=903) were followed prospectively for 1 year via the internet to collect information on gout flares and related data including number and specific joints involved, medical comorbidities, diet, exercise and medications.
A polyarticular gout flare was defined as having 3 or more joints involved during a patient-reported flare period. Individuals with at least one flare (to determine flare pattern) during follow-up were included in the analysis. Univariable associations were first assessed to determine factors were associated with polyarticular joint flares. was used to adjust for confounders. When assessing the association of each risk factor with prevalent polyarticular joint involvement, we used multivariable logistic regression, adjusting specific confounders guided by causal diagram.
Results: There were 724 participants with at least one flare with a mean and median age of 55 years. The cohort was 78% male and 89% White with a mean gout disease duration of 8.1 years (median 5). 197 (27%) had a polyarticular gout flare. In univariable analysis (Table 1), female sex, osteoarthritis, obesity, heart failure, hypertension, chronic kidney disease and gout related medication use were each associated with higher odds of polyarticular gout flare, whereas higher education, alcohol use at study enrollment and aspirin use were associated with lower odds. In multivariable analysis, obesity, osteoarthritis and heart failure remained associated with a higher odds of polyarticular gout flare, whereas education remained inversely associated.
Conclusion: In this prospective cohort of gout patients, obesity, heart failure and osteoarthritis were independently associated with higher odds for polyarticular gout flares. Female sex was also positively associated, whereas higher education was protective. The positive association with gout-related medications likely reflects residual confounding by indication. If confirmed, these findings would help identify those at risk for polyarticular flares to help improve clinical care.

Table 1. Associations with Polyarticular Gout Flare (≥ 3 joints)

Risk Factor		Univariable OR (95% CI)	Age- and Sex-Adjusted OR (95% CI)	Multivariable OR* (95% CI)
Age ≥ 55 years (vs < 55)		0.82 (0.59,1.14)	0.77 (0.56,1.08)	0.70 (0.49,1.01)

POS1149 CARDIOVASCULAR RISK STATUS AND OBESITY IN GOUT COMPARED TO HEALTHY MEXICAN SUBJECTS: A CASE-CONTROLS STUDY WITH A PROPENSITY SCORE-MATCHED ANALYSIS

R. Jimenez-Soto[1], A. Sanchez Rodríguez[2], C. Moreno del Castillo[1], A. Turrent[2], P. E. Bermudez Bermejo[2], R. Burgos-Vargas[3], C. Gómez-Ruiz[3], J. Vazquez Mellado[3]. [1]*ABC Medical Center, Internal Medicine, Mexico City, Mexico*; [2]*ABC Medical Center, Rheumatology, Mexico City, Mexico*; [3]*Hospital General de Mexico, Rheumatology, Mexico City, Mexico*

Background: Atherosclerotic cardiovascular diseases (ASCVD), metabolic syndrome and hyperuricemia due to an increment in their incidence world-wide, but information regarding the 10-year estimated risk in gout vs. healthy subjects is scarce.
Objectives: To assess baseline the 10-year cardiovascular risk and high-risk status in gout patients compared to healthy controls.
Methods: Data from 494 gout paired to controls in a ratio of 1:1 matched with age, sex and body mass index (BMI) and stratified by normal (≤ 24.9 Kg/m^2), overweight (25 - 29.9 Kg/m^2) and obese (≥30 Kg/m^2). Controls were asymptomatic subjects attending a preventive clinic in Mexico City. We used the Framingham Risk Score for Coronary Heart Disease (FRS-CHD) and the 2013 American College of Cardiology/American Heart Association (2013 ACC/AHA). Additionally, high risk status was defined according to pre-defined cutoff points for FRS-CHD (≥ 20%) and ACC/AHA 2013 (≥7.5%).
Results: Data from 494 gout and 494 controls. Gout patients were male 97.4%, 47 (SD ± 13) years, mean BMI of 28.4 (SD ± 4.31) Kg/m^2. Age, sex, and BMI and subgroups were equilibrated (p=NS). Gout patients had higher 10-year estimated risk vs. controls nevertheless, only FRS-CHD reached statistically significant difference with 9.38 vs. 7.5 ± 5.74 (p<0.001); For 2013 ACC/AHA 4.94 ± 6.16 vs. 5.23 ± 6.78, (p=0.49). Further stratification by BMI groups revealed that subjects

with gout in normal and overweight categories were had higher risk vs. controls with FRS-CHD score of 8.86 ± 8.05 vs. 6.53 ± 6.41 (p=0.03) and 9.37 ± 7.72 vs. 7.89 ± 5.58 (p=0.01), respectively. No differences for 2013 ACC/AHA in global and BMI-stratified comparisons. Proportion of high-risk subjects were similar in both groups regardless of BMI category: for FRS-CHD 7.5 vs 4.7% (p=0.06) and 2013 ACC/AHA with 21.5 vs. 17.8% (p=0.14).

Conclusion: Normal BMI or overweight Mexican patients with gout may be at higher 10-year estimated cardiovascular risk compared to matched age, gender and BMI healthy controls. Obese gout subjects are at high risk with non-statistical significance scores for FRS-CHD or 2013 ACC/AHA compared to controls.

POS1150

ANATOMICAL LOCATIONS AND CORRELATES OF CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITS OF THE SPINE – PATHOLOGIC EXAMINATION OF 77 SURGICAL CASES

J. Dau[1], G. Ho[2], H. Choi[1], J. Schwab[3], M. Kohler[1]. [1]*Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America*; [2]*New York University Langone Health, Division of Rheumatology, New York City, United States of America*; [3]*Massachusetts General Hospital, Department of Orthopaedic Surgery, Boston, United States of America*

Background: Spinal involvement in calcium pyrophosphate deposition disease (CPPD) is thought to be a rare occurrence and is seen infrequently as crowned dens syndrome. Furthermore, data on anatomical locations and correlates of calcium pyrophosphate (CPP) deposits in spinal CPPD are scarce.

Objectives: To describe the anatomical locations and correlates of pathologically confirmed CPPD of the spine.

Methods: Consecutive patients with spinal CPPD were identified via retrospective chart review of individuals who underwent spine surgery for intractable chronic neck or back pain at Massachusetts General Hospital between 2009 and 2014. These deposits and surrounding anatomical structures were surgically resected and confirmed to have calcium pyrophosphate deposition upon pathologic review. We reviewed musculoskeletal imaging (CT, MRI, XR) and laboratory data from these pathologically confirmed cases.

Results: From April 2009 to August 2014, we identified 77 individuals with pathologically confirmed CPPD of the spine. The mean age was 68 years; 41 (53%) were female; mean BMI was 28.7. Calcium pyrophosphate (CPP) was grossly identified intraoperatively by the surgeon in 38 cases (50%), typically as "chalky white deposits" (Figure 1). CPP deposits were seen most frequently in the ligamentum flavum (23%) and intervertebral disc (23%), followed by other less common locations (Table 1). Imaging findings in the soft tissue or intervertebral disc suggestive of CPPD were found in 5 cases (6%), whereas findings of spinal canal narrowing, facet arthropathy, or ligamentum flavum thickening were eventually correlative with CPP deposits in pathologic specimens. Only 7 (9%) experienced a prior episode of acute CPP arthritis (pseudogout). Chondrocalcinosis on x-ray was seen in 26 cases (34%), most commonly in the wrist and/or knees. Osteoarthritis was present in all spinal imaging, and 65% had comorbid scoliosis. Laboratory abnormalities associated with secondary causes of CPPD (hypercalcemia, hypomagnesemia, hyperparathyroidism) were not seen with spinal CPPD.

Conclusion: Spinal CPPD may occur more frequently than previously perceived. The ligamentum flavum and intervertebral discs were common anatomical locations for spinal CPPD. Advanced imaging of the spine showed low sensitivity for detecting spinal CPPD. Only a small minority had typical peripheral joint involvement or imaging with peripheral joint chondrocalcinosis. Thus, without pathologic confirmation, the vast majority of cases would remain unidentified. These findings call for the need to seek pathologic confirmation to determine the robust epidemiology and also raise the potential role for preoperative CPPD treatment.

Table 1. Spinal Anatomic Locations of Pathologically Confirmed CPPD

Spinal Anatomic Location	No. of Sites (%)*
ligamentum flavum	29 (23)
Intervetebral Disc	28 (23)
Other Location	19 (15)
Posterior Elements	18 (15)
Facet	14 (11)
Synovium	8 (6)
Interspinous Ligament	3 (2)
Subarticular/Lateral Recess	2 (2)
Fibrocartilaginous Tissue	1 (1)
Inner Spine	1 (1)
Other Ligament	1 (1)

*Some patients had more than one anatomic location where CPP was isolated

Infection-related rheumatic diseases

POS1151

IMMUNOGENICITY AND SAFETY OF 23-VALENT PNEUMOCOCCAL POLYSACCHARIDE VACCINE IN PATIENTS WITH SPONDYLOARTHRITIS.

N. Muravyeva[1], B. Belov[1], M. Baranova[1], M. Cherkasova[2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory for Studying Comorbid Infections and Monitoring the Safety of Drug Therapy, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*

Background: Currently, for the treatment of patients with spondyloarthritis (SpA), basic anti-inflammatory drugs and biological drugs are widely used to effectively control the activity of the disease. At the same time, the use of these drugs is associated with an increased risk of developing infections, some of which can be prevented by vaccination.

Objectives: The aim of the study was to evaluate the immunogenicity and safety of the 23-valent pneumococcal polysaccharide vaccine (PPV-23) in patients with SpA.

Methods: The study included 42 patients with SpA: 30 men, 12 women, age 22-60 years, disease duration 14.8±10.6 years. Ankylosing spondylitis was diagnosed in 30 patients, psoriatic spondyloarthritis – in 12 patients. Activity of diseases was assessed as high in 78% of patients (median BASDAI index was 5.3 [4.1; 6.8]). At the time of inclusion in the study, all patients received nonsteroidal anti-inflammatory drugs, 14 patients - methotrexate, 10 - sulfasalazine, 6 - glucocorticoids, 2 - leflunomide, 2 - etanercept, 2 - secukinumab. 15 patients were planned to be prescribed secukinumab, 3 – etanercept, 3 - adalimumab, 1 – golimumab. 7 patients had a history of more than 2 cases of lower respiratory tract infections, 2 patients reported a monthly exacerbation of chronic sinusitis, 1 patient – the development of otitis every 2-3 months, requiring the use of antibacterial drugs. PPV-23 was administered in the amount of 1 dose (0.5 ml) subcutaneously into the deltoid muscle against the background of anti-rheumatic therapy.

The level of antibodies to pneumococcal capsular polysaccharide was determined using the EIA PCP IgG kit (TestLine Clinical Diagnostics s.r.o., Czech Republic) before vaccination, 1, 3 and 12 months after vaccination.
Results: The dynamics of the concentration of antibodies to pneumococcal capsular polysaccharide in patients with SpA is presented in the Table 1.

Table 1. Concentration of pneumococcal antibodies, U/ml, Me [25; 75 percentile]

1 visit (initial)	2 visit (after 1 month)	3 visit (after 3 month)	4 visit (after 12 month)
80.0 [35.2; 154.0]	160.1 [73.5; 245.7] *	214.5 [103.2; 255.0] **	175.0 [120.1; 260.1] *

*p=0.01 **p=0.005

At 1, 3 and 12 months after vaccination, the concentration of antibodies to pneumococcal capsule polysaccharide was significantly higher compared to the baseline values. In 81% of patients, vaccination tolerance was good. Reactions at the injection site (pain, swelling and hyperemia of the skin up to 2 cm in diameter), resolved independently after 1-5 days, were observed in 6 patients. In 2 patients, a severe local reaction was registered in the form of pain in the arm, infiltration and hyperemia of the skin up to 8 and 15 cm in diameter, respectively, accompanied by low-grade fever in one patient for 2 days, and febrile fever in the other for 3 days. In both cases, these symptoms were completely stopped after administration of paracetamol and antihistamines. Exacerbation of SpA and the emergence of new autoimmune disorders were not detected. During the follow-up period, no patients developed lower respiratory tract infections. Patients suffering from frequent sinusitis and otitis reported the absence of these infections after vaccination.
Conclusion: The obtained data indicate satisfactory immunogenicity and good tolerability of PPV-23 in patients with SpA. Further studies are needed to better assess the immunogenicity and safety of vaccine, as well as to study of the influence of anti-rheumatic therapy on the effectiveness of immunization.

POS1152 COMORBID INFECTIONS IN PATIENTS WITH SPONDYLOARTHRITIS.

M. Baranova[1], N. Muravyeva[1], B. Belov[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Department of Study Comorbid Infection and Monitoring Antirheumatic Therapy, Moscow, Russian Federation*

Background: Data on the frequency and structure of comorbid infections (CI) in spondyloarthritis (SpA) are few and contradictory.
Objectives: The aim of the study was to study the frequency and structure of CI in the inpatient population of SpA patients in the course of a one-moment retrospective study.
Methods: The study included 208 patients with SpA (121 men, 87 women, mean age 39.1±12.2 years) who were hospitalized at the V.A. Nasonova Research Institute of Rheumatology. Ankylosing spondylitis was diagnosed in 133 patients, psoriatic arthritis - in 57, spondyloarthritis associated with Crohn's disease - in 1, undifferentiated spondyloarthritis - in 17. The majority of respondents had higher education (60.6%). None of the patients consumed alcohol on a daily basis, 124 patients never smoked. The Charlson comorbidity index, equal to 0, had 98 respondents, 1 - 51, 2 - 27, 3 - 15, 4 - 10, 5 or more - 7. Most patients (n=168) received nonsteroidal anti-inflammatory drugs (NSAIDs), as well as glucocorticoids-GC (average duration of administration 239.5±65.8 months), methotrexate-MT (32.4±46.2), sulfasalazine (21.0±32.1), leflunomide (24.0±46.6), biological drugs - TNF-α inhibitors (21.5±23.3), inhibitors of interleukin (iIL)-12/23 (9.0±5.2), iIL-17 (11.0±9.3). Patients were interviewed by a research doctor with the completion of a unified questionnaire, additional data were obtained from medical documentation.
Results: Leading in the structure of CI in patients with SpA were respiratory tract infections: acute nasopharyngitis (n=168), tonsillitis (74), acute bronchitis (34), sinusitis (33), pneumonia (29, including 9 cases by the virus SARS-CoV-2), influenza (31), tuberculosis-TB (5, including 2 cases on infliximab therapy, which was the reason for withdrawal of the drug). Infectious diseases of other localization include herpes-viral infections (n=109), mycoses (51), urinary tract infections (47), conjunctivitis and blepharitis (37), otitis (25), genital infections (15), skin infections (14), intestinal infections (13), COVID-19 without lung damage (19), nervous system infections (2), bone infections (2), chronic hepatitis B (1), chronic hepatitis C (1), HIV infection (1), rubella in adulthood (1), measles in adulthood (1). 20.2% of patients reported more frequent development of CI after the onset of the of SpA: 35 of them received immunosuppressive therapy, 7 – monotherapy of NSAIDs. In SpA patients receiving immunosuppressive drugs, there was an increase in the frequency of acute nasopharyngitis (more often 3 times a year), sinusitis, acute bronchitis, pneumonia and herpes-viral infections, in particular herpes zoster. 29.8% of patients reported a more severe course of CI against the background of SpA (12 of them did not receive immunosuppressive drugs). Temporary discontinuation of therapy due to the development of CI occurred in 26.4% of patients. At the same time, in 5 patients treated with GC (including in combination with MT, n=3), the development of furunculosis was the reason for changing the treatment regimen. In one patient, MT therapy was discontinued due to the frequent development of purulent tonsillitis. Exacerbation of SpA after CI was diagnosed in 84 patients (70 of them received immunosuppressive therapy).
Conclusion: The data obtained indicate the important of the problem of CI in SpA. Further studies are needed on large samples of patients in order to find significant risk factors for CI, study their relationship with clinical characteristics and influence on the course of SpA.
Disclosure of Interests: None declared.

POS1153 EFFECTIVENESS OF SCREENING IN PATIENTS WITH RHEUMATIC DISEASE ON BIOLOGICAL THERAPY AND RISK OF ACTIVE TUBERCULOSIS

S. Abdulaziz[1], S. Attar[2], W. Bajhammoh[3], E. A. Sindi[1], D. M. Ayish[4], E. Bakhashwain[5]. *[1]King Fahad Hospital, Medicine,Division of Rheumatology, Jeddah, Saudi Arabia*; *[2]King Abdulaziz University, Medicine,Division of Rheumatology, Jeddah, Saudi Arabia*; *[3]King Fahad Hospital, Medicine,Division of Infectious Diseases, Jeddah, Saudi Arabia*; *[4]Prince Mohammed Bin Nasser Hospital, Medicine,Division of Rheumatology, Gizan, Saudi Arabia*; *[5]East Jeddah Hospital, Medicine,Division of Rheumatology, Jeddah, Saudi Arabia*

Background: Treatment with biologic therapy has been associated with a high risk of reactivation of latent tuberculosis (TB). Preventive strategies for tuberculosis remain a crucial step before initiating biologics in rheumatic disease.Treatment with biological therapy has been associated with high risk of reactivation of latent tuberculosis (TB). Prevention strategies remain a crucial step before initiating biologics.
Objectives: We aimed to assess the effectiveness of TB screening before the initiation of biologics and the risk of occurrence of active TB among patients with rheumatic diseases on biologic therapies.
The study aimed to access the effectiveness of TB screening recommendations before the initiation of biological therapy and identify the incidence of active TB among these patients.
Methods: We performed a hospital-based retrospective cohort study among rheumatic disease patients on biological therapy in two centers in Jeddah between January 2005 to December 2019. Medical files were retrospectively reviewed for demographics data, baseline screening for TB, use of prophylaxis, information on DMARDs and biological therapies, and outcomes results were collected.
Results: A total of 365 patients were included over a period of 14 years. Two hundred ninety-two (80%) had Rheumatoid arthritis (RA),13% psoriatic arthritis (PSA), 9% spondyloarthritis (SPA), 2% SLE, and 4% others. The mean age was 47.54 (±14.2), 311 (85%) were females with a mean duration of disease 8.45 years (± 6.58). Hundred forty-nine (42.3%) were on steroids. Anti TNFs were prescribed in 213 (58.4%) patients, Non Anti-TNFs 124 (36.6%) patients, and Jak inhibitors 18 (5%) patients.TB screening was done to all patients except 3 patients (data missing) before commencing biologics. Forty-four (12.1%) patients had latent TB at baseline and all received chemoprophylaxis with isoniazid before starting biologics. Four patients with active TB were identified (one with Behcet's disease and three with RA). One patient had a reactivation of latent TB and 3 patients developed de novo TB. Three out of four had an infection in the first 6 months of treatment (one on infliximab and two on rituximab) and one case after 1 year of stopping adalimumab. Two cases had pulmonary TB and two others with extrapulmonary TB (pericarditis and brain abscess each). All four patients with active TB were treated with standard anti TB medications. Three had complete resolution of their TB and one died.
Conclusion: Baseline screening has been effectively carried out in our cohort as per recommendations. Physician should be vigilant not only for reactivation of latent TB but occurrence of de novo TB in patients on biological therapy.

POS1154 CHARACTERISTICS OF SURGICALLY TREATED TUBERCULOUS AND BRUCELLAR SPONDYLODISCITIS

D. Khalifa[1], N. El Fani[2], R. Moncer[2], E. Toulgui[2], W. Ouanes[2], S. Jemni3. [1]*Farhat hached hospital, rheumatology, sousse, Tunisia*; [2]*sahloul hospital, physical therapy and rehabilitation, sousse, Tunisia*; [2]*sahloul hospital, physical therapy and rehabilitation, sousse, Tunisia*

Background: Although rare in most developed countries, tuberculous and brucellar spondylodiscitis are still frequent in the mediterranean countries. Management of spondylodiscitis may require a surgical intervention in cases of spinal cord or root compression, bone destructions and deformities, unsuccessfull medical treatment or large abcesses.
Objectives: To study characteristics and outcome of surgically treated tuberculous and brucellar spondylodiscitis.
Methods: Medical records of patients who were admitted into the physical therapy and rehabilitation ward immediately post surgery of the spine were retrospectively studied. The study included records from January 2010 to December 2020.
Results: Twenty patients were diagnosed with tuberculous or brucellar spondylodiscitis for which they underwent surgery. The mean age of diagnosis was 49.7± 11.9 years. The sex ratio was 1:1. The diagnosis was delayed in 60% of the cases due to atypical presentations. Fatigue was reported in 45% of the patients, back pain in 60% of the cases, radicular pain in 15% of the cases, fever in 20% of the patients and abnormal gait in 60% of the cases. Tuberculosis was identified in 75% of cases and brucellar infection in 25% of the cases. On biology, elevated inflammatory markers were noted in 60% of the cases. Intradermal reaction for tuberculosis was positive in 9 patients while cultures allowed the diagnosis of tuberculosis in 1 patient. Wright serology test confirmed the diagnosis of brucellar infection in all 5 cases. In the remaing ones, vertebral biopsy or intraoperative samples allowed the diagnosis of the tuberculous spondylodiscitis. Cervical spine involvement was noted in 5% of cases, lumbar spine in 25% and dorsal spine in 30% of the cases. All patients recieved antibiotics and spinal immobilization. Surgery was indicated in 78.6% of cases for spinal cord decompression and in 21.4% of the cases for voluminous abcesses. Anterior approach was used in 7.1% of the cases and posterior approach in 92.9% of cases. 23.1% of the patients benifited concomitantly with spinal fusion surgery. Post operative success was immediately confirmed by recovery of normal gait in 15.4% of the patients. Complications after surgery were reported in 35.7% of the cases. They consisted in spinal instability in 60% of the cases, abcesses in 20% of the cases and the emergence of secondary articular localizations in 20% of the cases. 28.6% of the patients underwent a second surgery mainly to stabalize the spine. Before surgery, walking was impossible for 65% of the patients and 12 months after surgery only 30% of the patients couldn't walk (p=0.001). 15.8% of the patients developed later on pressure ulcers and 45% of the patients were prescribed appropriate wheelchairs.
Conclusion: Spinal surgery in tuberculous or brucellar spondylitis may be indicated if medical treatment is insufficient and especially if neurological complications occur. Surgery may be invasive with various complications but sometimes it could be the only option to treat a neurological deficit.

POS1155 INFECTIOUS RISK DURING BIOLOGIC THERAPY FOR INFLAMMATORY RHEUMATIC DISEASES: DATA FROM THE TUNISIAN BINAR REGISTRY

S. Boussaid[1], R. Ben Aissa[2], S. Kochbati[2], M. Elleuch[1], L. Abdelmoula[3], A. Laatar[4], W. Hamdi[5], I. Gharsallah[6], E. Bouagina[7], S. Baklouti[8], N. Bergaoui[9], M. Younes[10]. [1]*Rabta Hospital, Department of Rheumatology, Tunis, Tunisia*; [2]*Habib Thameur Hospital, Department of Internal Medecine, Tunis, Tunisia*; [3]*Charles Nicolle Hospital, Department of Rheumatology, Tunis, Tunisia*; [4]*Mongi Slim Hospital, Department of Rheumatology, Marsa, Tunisia*; [5]*Med Taieb Kassab Institute, Department of Rheumatology, Mannouba, Tunisia*; [6]*Military Hospital, Department of Internal Medecine, Tunis, Tunisia*; [7]*Farhat Hachad Hospital, Department of Rheumatology, Sousse, Tunisia*; [8]*Hedi Chaker Hospital, Department of Rheumatology, Sfax, Tunisia*; [9]*Fattouma Bourguiba Hospital, Department of Rheumatology, Monastir, Tunisia*; [10]*Tahar Sfar Hospital, Department of Internal Medecine, Mahdia, Tunisia*

Background: The development of biologics for the treatment of systemic rheumatic diseases increased the risk of infections. The management of this complication deserves particular attention since it remains a major cause of morbidity and mortality.
Objectives: The aim of our study was to determine infection frequency under biological treatment and consequences on the therapeutic management.
Methods: Patients included in the Biological National Registry (BINAR) from 2016 to 2020. Data related to the disease, biological agents, and infections occurring under biologic disease-modifying antirheumatic drugs (bDMARDs) were collected.
Results: The study included 298 patients with a mean age of 49.2 years [18-79] 175 patients with rheumatoid arthritis and 123 with spondyloarthritis (Axial Spondyloarthritis=48, Enteropathic Arthritis=41, Psoriatic Arthritis=34). Anti Tumor necrosis factor-alpha (Anti-TNF) agents were the most prescribed bDMARDs in 87.9% (n=263) of patients: Infliximab 20.4% (n=61),Etanercept 23.1%(n=69), Adalimumab 24.6%(n=74) and Certolizumab (n=79). No patients were treated with Golimumab. Tocilizumab and Rituximab were prescribed respectively in 10.4% (n=31) and 5% (n=15) of patients. Infections occured in 9 patients (3.1%) with a total of 13 infectious episodes 12 bacterial and a viral one. The site of infections was: respiratory (38%), urinary (15%), cutaneous (23%), ORL (8%), infective endocarditis (8%), and other (8%). The infectious agent was identified in only 3 patients. The outcomes were favorable in most cases except in one patient where there was a definitive interruption of bDMARDs. The patient was hospitalized for sepsis complicating a cutaneous infection with favorable outcomes under antibiotics within a week. The biological agent with higher risk of infections was Tocilizumab (p = 0.056), unlike Rituximab (p = 0.483) and Anti-TNF (p = 0.082). All patients who had an infectious episode were under corticosteroids.
Conclusion: Our results confirm that bDMARDs are predisposing to infections, but data from BINAR showed that most infections were trivial with no serious outcomes. Therefore, infections should be assessed in patients under bDMARDs for an early therapeutic intervention.
Disclosure of Interests: None declared.

POS1156 INFECTIONS AND OTHER ADVERSE EFFECTS WITH BIOLOGICAL THERAPIES OVER THE PAST 10 YEARS

G. Alvarez[1], A. Perez Jaen[1], A. Uribe Luna[1], M. Rexach Fumaña[1], L. Peries Reverter[2], C. Diez Vallejo[3], L. Viñas Sague[3], A. Castro Guardiola[1]. [1]*Hospital Universitario de Girona Doctor Josep Trueta, Internal Medicine, Girona, Spain*; [2]*Hospital Universitario de Girona Doctor Josep Trueta, Gastroenterology, Girona, Spain*; [3]*Hospital Universitario de Girona Doctor Josep Trueta, Pharmacology, Girona, Spain*

Background: Biological therapies have marked a difference in the treatment of many autoimmune conditions. As all treatments, they have their side effects although little evidence of long-term effects has been reported.
Objectives: Analyze retrospectively the appearance of infections that required hospitalization and other side effects in patients treated with biological therapies over the past 10 years.
Methods: Biological drugs dispensed in our center to non-cancer patients from 2008 to 2018 were reviewed. Health records were collected from our database and all statistical analyzes were performed with the SPSS program.
Results: 24 different biological drugs applied to 34 medical conditions; 847 treatments were dispensed over a total of 555 patients. The median age was 44 years with a mean duration of 3.6 years of treatment. The most commonly used drug were adalimumab (n = 280, 33%), infliximab (n = 119, 12%), etanercept (n = 97.13%), rituximab (n = 63, 7%), vedolizumab (n = 47, 5.5%) and omalizumab (n = 43.5%). The rest of the drugs were administered <30 times each (ustekinumab, golimumab, certolizumab, tocilizumab, secukinumab and abatacept), representing <4% of the total sample.
The underlying conditions included Crohn's Disease (n = 262, 31%), rheumatoid arthritis (n = 133, 16%), ulcerative colitis (n = 118, 14%), spondyloarthropathies (n = 86, 10%), psoriatic arthritis (n = 56, 7%), psoriasis (n = 49, 6%), asthma (n = 34, 4%), nephropathies (n = 19, 2%) and vasculitis (n = 13, 1.5%). The rest were pathologies with <10 cases.
During treatment, infection requiring hospitalization occurred in 10.2% (n = 86). The most frequent focus of infection was respiratory (n = 23, 27%), abdominal (n = 19, 22%), soft tissue-bone (n = 17 cases, 20%), urinary (n = 7, 8%) and tuberculosis (n = 4, 5%). No case of hepatitis reactivation was observed. At the time of hospital admission, 46% of patients were only under biological therapy, 21% had another non-corticosteroid immunosuppressant, 17% were associated with corticosteroid, and 15% had triple therapy (corticosteroids, another immunosuppressant and the biological drug). The drugs associated with more infections were: abatacept 20%, rituximab 16% and adalimumab 13%.
During the study period, 14 deaths (1.7%) were observed; being the cause cancer-related (n=5), infection (n=5), the disease itself for which was receiving biological treatment (n=2), and endocrine metabolic causes (n=2).

At the end of the review, 48% of the treatments were still in use, while 52% had stopped for various reasons: 20% ineffectiveness, 12% side effects, 12% maintained complete remission. The remaining low percentage was due to death, pregnancy, or study entry.

The side effects that led to a change in treatment was: non-immune hematological disorders in 4.1% (14% of tocilizumab, 7% of rituximab and 6% of vedolizumab), immune disorders in 3.8% (6% of secukinumab, 5% of tocilizumab and 4.5% of certolizumab), nervous system involvement in 2.4% (11.5% of golimumab,10% of abatacept, 5% of tocilizumab), debut or worsening of heart failure in 1.4% (9, 5% of tocilizumab, 2.5% of etanercept and 1.4% of adalimumab) and cancer-related in 0.7% (2% of infliximab, 1.7% of etanercept).

Conclusion: In these 10 years of follow-up and and evaluating 847 treatments, there were 10% hospitalizations due to infections (n = 86) causing death in 5 patients. In light of these results, and pending an exhaustive statistical analysis, we did not find high frequencies of serious side effects in our series. Very little long-term evidence exists on the safety of these drugs.

POS1157 CONCORDANCE BETWEEN THE QUANTIFERON-TB GOLD IN-TUBE AND TUBERCULIN TEST FOR THE DIAGNOSIS OF LATENT TUBERCULOSIS INFECTION IN PATIENTS WITH RHEUMATIC DISEASES

C. Pávez Perales[1], A. Quiles Roger[2], E. Grau García[1], M. De la Rubia Navarro[1], S. Leal Rodriguez[1], R. Gonzalez Mazario[1], J. J. Fragío Gil[1], C. Alcañiz Escandell[1], J. Ivorra Cortés[1], I. Chalmeta Verdejo[1], L. Gonzalez Puig[1], I. Martínez Cordellat[1], R. Negueroles Albuixech[1], F. M. Ortiz Sanjuan[1], J. E. Oller Rodríguez[1], E. Vicens Bernabeu[1], C. Nájera Herranz[1], I. Cánovas Olmos[1], J. A. Román Ivorra[1]. *[1]HUP La Fe, Rheumatology Department, Valencia, Spain*; *[2]UCV, Medical School, Valencia, Spain*

Background: Patients with rheumatic diseases (RD) are at higher risk of latent tuberculosis infection (LTBI) reactivation. To detect and treat it before starting treatment, especially with biological therapies, decrease the reactivation risk. Diagnosis is carried out by the tuberculin skin test (TST) or interferon-gamma release assays (IGRAs), IGRAs might be more specific and sensitive.

Objectives: We aim to analyze the concordance between QuantiFERON-TB Gold In-Tube (QTF) and TST for the diagnosis of LTBI in patients with rheumatic diseases.

Methods: A retrospective observational study was conducted including patients diagnosed with RD screened for LTBI with both TST and QTF (2014-2018). Demographical and clinical variables at screening and at follow-up were collected. The concordance between both tests has been estimated as categorical variables using Cohen´s Kappa test, considering "poor" if it is ≤ 0,20; "low" if 0,20 < k ≤ 0,40, "moderate" if 0,40 < k ≤ 0,60, "substantial" if 0,60 < k ≤ 0,80 and "optimal" if k > 0,80.

Results: 167 patients were included (57% women) with a mean age of 52±16 years. 42% of them had systemic autoimmune diseases, 22% spondyloarthropathies and 36% other RD. 2 had history of past active tuberculosis (TB). At the time of screening, 46.11% were treated with GC.

LTBI was diagnosed in 35 patients: 15 had both QTF and TST positive, 16 only QTF positive and 4 only TST positive. 12 from 31 QTF positive patients were treated with GC at the time of screening. 3 from 19 TST positive patients were treated with GC at the time of screening.

After LTBI screening 62 patients received biological treatment, 4 of them had both test positive, 6 only QTF positive and 2 only TST positive. 11 received LTBI treatment according to the hospital protocol (isoniazid for 6 to 9 months). 10 completed treatment, 1 did not because of intolerance and did not receive other treatment. 1 patient with only TST positive was considered a false positive and did not receive treatment. During follow-up no TB reactivation was reported.

23 patients with LBTI received treatment other than biological therapy during follow-up, of them 8 received LBTI treatment. There was no TB reactivation during follow up.

The Kappa concordance between QTF and TST was estimated: moderated in the whole sample, poor in the patients treated with GC at screening, and substantial when the patients treated with GC at screening were excluded. Results are shown in Table 1.

Table 1. Kappa concordance between QTF and TST.

	TOTAL SAMPLE	PATIENTS WITH GC AT LTBI SCREENING	PATIENTS WITHOUT GC AT LTBI SCREENING
Number of coincidences (p1)	147 (88.02%)	64 (83.12%)	83 (92.22%)
Number of randomly expected coincidences (p_e)	124.1 (74.28%)	62.9 (81.73%)	61.8 (68.62%)
Kappa = p1- p_e /1- p_e	**0,534**	**0,117**	**0.752**
IC 95%	(0.358-0.710)	(-0.154-0.305)	(0.579-0.926)

Conclusion: QTF seems to be the most appropriate LTBI screening test in patients with RD treated with GC. Screening and treatment of LTBI in patients with RD treated with or without biological agents was effective in reducing TB reactivation.

Disclosure of Interests: None declared.

POS1158 THE SPECTRUM OF NON-TUBERCULOUS OSTEOARTICULAR INFECTIONS IN A RHEUMATOLOGY DEPARTMENT DURING THE YEARS 2010-2020: A RETROSPECTIVE STUDY OF 102 CONSECUTIVE CASES IN A SINGLE CENTER

M. Chammakhi[1], C. Bendahmane[1], F. Kemiche[1], I. Cerf-Payrastre[1], E. Pertuiset[1]. *[1]Centre Hospitalier René Dubos, Rheumatology, Pontoise, France*

Background: osteoarticular infections (OAI) are characterized by a large variety of sites, causative microorganisms, source and route of infection, risk factors and also by the fact that several medical specialties are involved in diagnosis and treatment. These characteristics are subject to changes over the time.

Objectives: to describe the spectrum of non-tuberculous OAI in the absence of OA material, including native septic arthritis (SA) and non-postoperative SA or infectious spondylodiscitis (SPDI) during the years 2010-2020. This includes demographics, comorbidities, site of infection, causative microorganisms, source of infection, diagnosis, treatment procedures and mortality.

Methods: medical records of patients aged 18 years old or above who were diagnosed with a non-tuberculous OAI in the Department of rheumatology of our hospital during the 2010-2020 period were selected and retrospectively reviewed. OAI with the following characteristics were excluded: SA on prosthetic joints, postoperative SA or SPDI, osteomyelitis, brucellosis, Lyme disease. Only proven cases where included on the basis of an isolated pathologic organism at the site of infection and/or in the blood (with typical clinical, biological and imaging features).

Results: There were 102 consecutive patients (males 62%), aged 62.5±16.8 years, with an IMC of 25.1±5.2. Peripheral SA where observed in 52 cases, SPDI in 33 cases, non-peripheral SA in 10 cases (sacroiliitis 5, pubic symphysitis 2, sternoclavicular 2, posterior interapophyseal 1); in 7 patients, there was an association of SPDI and peripheral SA. At least two non-contiguous sites were involved in 22 patients (21.5%). The sites of the positive sample where: osteoarticular (synovial fluid, vertebral biopsy) in 47 cases; blood in 28 cases; both of them in 27 cases.

In the 102 cases, 105 microorganisms grew in culture including one Candida glabrata. The following bacteria where responsible in the other cases: 42 *Staphylococcus aureus* (including 3 cases of methicillin resistant); 7 coagulase-negative *Staphylococcus spp.;* 6 Group A *Streptococcus*; 12 group B *Streptococcus agalactiae*; 8 groups C/G *Streptococcus*; 3 group D *Streptococcus gallolyticus*; 2 *Streptococcus pneumoniae*; 1 *Neisseria gonorrhea*; 8 enterobacteria; 3 *Enterococcus faecalis;* 3 *Pseudomonas aeruginosa*; 3 *Haemophilus*; 6 others species (2 *Parvimonas micra*, 1 *aerococcus urinae*, 1 *Nesseiria bacilliformis*, 1 *bacteroides fragilis*, 1 *campylobacter fetus*).

The most frequent host risk factors were: diabetes (21%), inflammatory/auto-immune disease (10%; including 3 rheumatoid arthritis), chronic renal insufficiency

(CC<30 ml/mn) (6%), active cancer with local or general extension (6%), immunodeficiency state (SCID revealed by OAI in 2 cases). Three patients where on biological therapy.
The source of infection was known in 76 cases: skin infection in 27; urinary tract infection in 17; joint injection in 7 **cases**; dental infection in 6 cases; infected vascular material in 6 cases; abdominal infection in 5 cases; genital infection in 3 cases; ENT infection in 3 cases; pulmonary disease 2 cases.
Mean duration of symptoms ranged from 13 days for peripheral SA to 39 days for SPDI. Fever (≥38°C) was present in 52% of cases. Mean CRP was 182±128 mg/l. Blood cultures where positive in 55.5%. There was only one case of infectious endocarditis. All patients were treated with antibiotics with a mean duration of 10.2±5.6 weeks. Orthopedic surgery was proceeded in 67% of peripheral septic arthritis and in 10% of the other OAI. Six patients where admitted in the intensive care unit; 4 patients died (4.3%). Mean length of hospitalization was 28.6±15 days.
Conclusion: in the years 2010-2020, non-tuberculous OAI represents a regular cause of hospitalization in rheumatology. Iatrogenic origin accounts for 13% of cases and urinary tract infection for 17%. Staphylococcus species are involved in only 48% of cases and Streptococcal species in 30%.
Disclosure of Interests: None declared.
DOI: 10.1136/annrheumdis-2021-eular.3569

POS1159 **THE ROLE OF URINARY TRACT INFECTIONS AS A SOURCE OF OSTEOARTICULAR INFECTIONS IN A RHEUMATOLOGY DEPARTMENT DURING THE 2010-2020 PERIOD: A RETROSPECTIVE STUDY**

C. Bendahmane[1], M. Chammakhi[1], F. Kemiche[1], I. Cerf-Payrastre[1], E. Pertuiset[1]. [1]*Centre Hospitalier René Dubos, Rheumatology, Pontoise, France*

Background: There are several sources of infection in the pathogenesis of osteoarticular infections (OAI). Urinary tract infections (UTI) have rarely been involved whereas skin infection and Staphy*lococcus aureus* represent the classic pair.
Objectives: To describe the role of UTI as the source of infection in OAI including septic arthritis (SA) on native joints and infectious spondylodiscitis (SPDI). To compare characteristics of these cases with those of others source and those without any known source.
Methods: Medical records of patients aged 18 years old or above who were diagnosed with a non-tuberculous OAI in the department of rheumatology of our hospital during the 2010-2020 period were selected and retrospectively reviewed. The following cases were excluded: SA on prosthetic joint, OIA on surgical material, osteomyelitis, post-operative OAI, SA after joint injection, brucellosis, Lyme disease. Only proven cases where included on the basis of an isolated pathologic organism at the site of OAI infection and/or in the blood (with typical clinical, biological and imaging features). Usually the OAI was considered of urinary source if the same microorganism grew in urine and the OA/blood sample. Cases with probable urinary source were also included on the basis of the type of microorganism and a history of UTI and/or urologic surgery and/or recent antibiotic therapy.
Results: 95 consecutive cases of proven OAI were included. There were 17 cases (18%) of urinary origin. In 12 cases the same micro-organism grew in urine and OA/blood culture: 5 methicillin sensitive *Staphylococcus aureus*, 2 *Streptococcus Gallolyticus* (associated with *E. Coli* in one case), 1 *Escherichia Coli*, 1 *Klebsiella pneumoniae*, 1 *Enterococcus faecalis*, 1 *aerococcus urinae*, 1 candida glabrata. Five patients had a probable urine source. In one patient with SPDI and an history of recurrent UTI, blood culture grew *E. Coli* whereas urine culture grew *Enterococcus faecalis*. In 4 cases, urine was sterile but a sample (OA in 3, blood in 1) was positive for *E. Coli* (n=2) or *Pseudomonas aeruginosa* (n=2).
The type of OAI was: SPDI in 10 cases, peripheral SA in 4 cases, both of them in one case and pubic symphysitis in 2 cases. Blood culture was positive in 10 cases and OA sample in 9 cases. Demographics characteristics were: male 59%; age 68.7±11 years. Risk factors were: diabetes 29%; cancer treated with cytotoxic chemotherapy 2 cases; inflammatory disease 2 cases; urological disease and/or recurrent UTI in 59%; immunodeficiency 1 case. Duration of symptoms was 47.1 +/- 50.7 days. Urinary symptoms where present in 29% of patients and fever in 47%. There was no case of infectious endocarditis. Surgical intervention was realized in only one patient. No patient has been admitted in intensive care unit and no patient died. Length of hospitalization was 28±8.5 days. Duration of antibiotic therapy was 13.6±9 weeks. One patient with pubic symphysitis was not cured.
The comparison between the group of OAI with urinary source (n=17) and the groups with another primary source of infection (n=52) or no known source of infection (n=26) shows in the first one: a higher prevalence of SPDI (59% vs 34% and 19% respectively), an older age (68.7 years vs 61.9 and 59.7 respectively), a higher prevalence of diabetes or cancer, a longer duration of symptoms (47.1+/-50.7 days vs 21.9+/-29.6 and 22.5+/-25.4 respectively) and a lower mean value of CRP (156+/-135 mg/l vs 182+/-124 and 180+/-140 respectively). A UTI was detected in 76% of OAI of urinary source but also in 13% of other cases (including *E. Coli* 5 cases).
Conclusion: In the years 2010-2020, UTI was responsible for 18% of non-tuberculous OAI as we defined them in this study. A UTI does not demonstrate the responsibility of the microorganism isolated. Thoracolumbar SPDI is the main type. This relatively high frequency has not been reported before and is probably the consequence of the increasing population of aged patients with risk factors and urologic diseases. Clinicians have to be aware of it and prevention is required.
Disclosure of Interests: None declared.
DOI: 10.1136/annrheumdis-2021-eular.3611

POS1160 **BRUCELLAR SPONDYLODISCITIS: CLINICAL AND MAGNETIC RESONANCE IMAGING FINDINGS**

C. Daldoul[1], N. El Amri[1], S. Laataoui[1], K. Baccouch[1], H. Zegaloui[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: Osteoarticular involvement is one of the most common complications of brucellosis and it can occur in up to two thirds of patients infected. Vertebral involvement during brucellosis is considered not only as the most prevalent localization but also as the most severe one.
Objectives: The aim of the present study was to describe the clinical and the magnetic resonance imaging features of brucellar spondylodiscitis.
Methods: We conducted a retrospective study including 21 patients who have been hospitalized for spinal brucellosis from 1998 to 2019. The diagnosis of brucellosis was based on clinical symptoms, MRI findings and isolation of brucella species in blood or tissue specimens and/or a positive Wright agglutination test.
Results: Twenty-one patients were included. The mean age was 57.5 years [33-74] (13 males and 8 female). The geographical origin of the patients was rural in 76% of the cases. The median duration of symptoms progression before diagnosis was 4.5 months [1-8].The main symptom leading to seek medical care was an inflammatory back pain and it was found in all cases. It was associated with unilateral radiculopathy in 8 cases and with a bilateral radiculopathy in 1 case. The other clinical features found were fever in 17 patients, sweats in 14 cases, weight loss in 10 cases and hepatomegaly in 1 patient. The physical examination revealed tenderness on palpation in 12 cases, a motor weakness of the two lower limbs in 2 cases. Brucella agglutination test was ≥1/160 in all cases. Blood cultures were negative in all cases. The median erythrocyte sedimentation rate (ESR) and serum C-reactive protein level were 40 mm and 11 mg/dl) respectively. Spondylodiscitis was located in the lumbar dorsal and cervical spine in respectively 10, 8 and 3 cases. The most affected level was the L4-L5 level in 5 cases followed by the T10-T11 level in 3 cases. The involvement of more than 2 vertebrae was found in 4 cases. Associated sacroiliitis was found in one patient. All MRI images of the affected vertebrae showed hypo intense signal on T1 weighted image and hyper intense signal on T2 weighted image. Disc space narrowing was found in 8 cases. Vertebral body osteolysis was found in 10 cases. Epidural collection was documented in 3 cases with a size up to 5cm. Paravertebral and peri-vertebral abscesses were detected in 5 cases. Intradiscal abscesses were observed in 3 cases. Cord compression and involvement of root nerve were noted in respectively 5 and 1 cases. Biopsy was performed in 5 cases, but bacteriological examination was contributory to the diagnosis in 1 case. All patients received antibiotic treatment with a combination of two or three drugs, corticosteroids were prescribed in 5 patients and one patient underwent a surgical intervention. The evolution was good 16 in patients, three patients suffered from chronic back pain, one patient had persistent neuropathic pain and one patient had paresis.
Conclusion: Brucella spondylodicitis is still a serious public health problem in developing countries. MRI findings associated with clinical symptoms may establish the diagnosis even if bacteriological examinations are negatives
Disclosure of Interests: None declared.

COVID-19

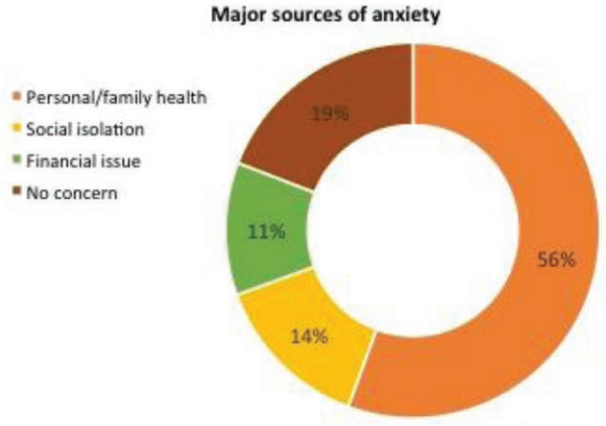
POS1161 **A CITIZEN SCIENCE APPROACH TO CAPTURE POOR MENTAL HEALTH RELATED TO COVID-19 IN RHEUMATIC PATIENTS AFTER CONFINEMENT DURING PANDEMIC IN ITALY**

F. Ingegnoli[1], M. Buoli[2], C. Posio[3], R. DI Taranto[1], A. Lo Muscio[3], E. Cumbo[1], S. Ostuzzi[4], R. Caporali[1]. [1]*Università degli Studi di Milano, Division of Clinical Rheumatology, ASST Pini, Dept. of Clinical Sciences & Community Health, Research Center for Adult and Pediatric Rheumatic Diseases, Milano, Italy*; [2]*Università degli Studi di Milano, Dept. of Pathophysiology and Transplantation, Dept. of Neurosciences and Mental Health, Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Milano, Italy, Milano, Italy*; [3]*Università degli Studi di Milano, Dept. of Pathophysiology and Transplantation, Milano, Italy*; [4]*ALOMAR, Lombard Association for Rheumatic Diseases, Milano, Italy*

Background: A considerable psychosocial burden is one of the relevant consequences of the COVID-19 pandemic. In particular, quarantine measures have been related to negative psychological effects, including symptoms of post-traumatic stress disorder, stress, anxiety, and depression (1). This rise in mental health disorders might be even worse among people more vulnerable to psychological stress such as patients suffering from chronic rheumatic diseases (RDs).
Objectives: The present Italian nationwide survey engages patients with rheumatic conditions through eleven associations of RD patients. It is conducted to establish the COVID-19 related self-reported poor mental health symptoms and to identify potential factors associated with these concerns among RDs who experienced the COVID-19 quarantine in Italy.
Methods: We collected data from May to September 2020 from RD patients living in Italy during the COVID-19 quarantine by an ad-hoc online survey. By using their mailing list and the related webpage and social network, eleven patients' associations sent a call to RD patients asking them to complete an anonymous online survey which included the Perceived Stress Scale (PSS), and the Impact Event Scale-Revised (IES-R). χ^2 tests were performed to detect statistically significant differences in both rating scale scores between groups defined by qualitative variables. Correlation analyses were realized with quantitative variables and rating scale scores. Variables significant in univariate analyses were then inserted in multivariate regression models.
Results: In total, 507 RD patients completed to the survey. 375 (73.9%) patients had inflammatory arthritis (243 rheumatoid arthritis, 76 psoriatic arthritis, 49 ankylosing spondylitis, and 7 Still's disease), and 96 (18.9%) with connective tissue diseases or systemic vasculitis. 31 (6.1%) patients had primary fibromyalgia and 5 osteoarthritis or crystal arthropathies. Self-reported major sources of anxiety are reported in the Figure 1 below.



The mean (SD) scores of the PSS-10 and the IES-R were 18.1 ± 8.1 and 29.7 ± 17.5, respectively. With regard to the IES-R subscale scores, the total sample did not show a prominence of one of the three main domains (intrusion, avoidance and hyperarousal). Higher PSS scores were significantly associated with younger age (p<0.01), female gender (p<0.01), living outside Lombardy (p=0.03), presence of overweight/obesity (p=0.01), ongoing psychopharmacotherapy (p<0.01), and anxiety for loss of incomes (p<0.01). Female gender (p<0.01) and living outside Lombardy (p=0.02) were associated also with higher IES-R scores, together with the presence of intestinal diseases (p=0.03), anxiety disorders (p<0.01), and worries about health (p<0.01).
Conclusion: This nationwide study revealed a high impact of self-reported distress, anxiety, and perceived stress among rheumatic patients after confinement during COVID-19 pandemic in Italy. Different factors were found to be predictive of poor mental health such as having female gender, younger age, living outside Lombardy, having overweight/obesity, or intestinal diseases, having a history of psychiatric symptoms (e.g. anxiety). Moreover, the lockdown experience worsened psychiatric symptoms and increased the assumption of psychopharmacotherapy in this vulnerable population. Prevention strategies focused on specific variables should be implemented to ameliorate psychological well-being of fragile patients during pandemics.

Methods: We examined data on patients and their disease-related characteristics entered into the COVID-19 GRA provider registry from Ireland (24th March 2020 to 31st August 2020). Multivariable logistic regression was used to assess the association of demographic and clinical characteristics with hospitalisation.
Results: Of 105 patients, 47 (45.6%) were hospitalised and 10 (9.5%) died. Multivariable logistic regression analysis showed age (OR=1.06, 95%CI 1.01 to 1.10), number of comorbidities (OR=1.93, 95%CI 1.11 to 3.35), and glucocorticoid use (OR=15.01, 95%CI 1.77 to 127.16) were significantly associated with hospitalisation. A diagnosis of inflammatory arthritis was associated with a lower odds of hospitalisation (OR=0.09, 95%CI 0.02 to 0.32).
Conclusion: Increasing age, comorbidity burden, and glucocorticoid use were associated with hospitalisation, while a diagnosis of inflammatory arthritis was associated with lower odds of hospitalization.

POS1163 CHARACTERISTICS AND OUTCOMES IN A REAL-WORLD COHORT OF RHEUMATOID ARTHRITIS PATIENTS WITH COVID-19

Y. Ye[1], X. Yue[1], W. Krueger[1], L. Wegrzyn[1]. [1]*AbbVie Inc., Global Epidemiology, North Chicago, United States of America*

Background: While some risk factors for severe COVID-19 outcomes have been identified for the general population and patients with rheumatic diseases (1-3), what drives these outcomes in specific rheumatic disease remains unclear. In addition, these findings need to be assessed across various observational data sources to ensure external validity.
Objectives: To describe the demographics, comorbidities, and severe COVID-19 outcomes among rheumatoid arthritis (RA) patients infected with SARS-CoV-2 in the United States.
Methods: A large nationwide electronic health record database (Optum, Inc.) in the United States, with data range between February 1, 2020 and September 17, 2020, was used to describe the demographics, comorbidities, and severe COVID-19 outcomes of RA patients with confirmed COVID-19 diagnosis (diagnosis for COVID-19 or positive PCR or antigen test). Patients with a single diagnosis of RA (ICD-10 code) before the diagnosis of COVID-19 were included. Patients missing age or sex, under 18 years of age on COVID-19 diagnosis date, or having less than 15 months of activity prior to COVID-19 diagnosis in the data source were excluded. We described demographics, comorbidities, and severe COVID-19 outcomes, including death, hospitalization, ICU admission, and acute respiratory insufficiency (ARI) identified between 14 days prior to and 30 days after COVID-19 diagnosis. Mean and standard deviation (SD) was reported for continuous variables. For categorical variables, count (N) and proportion was reported.
Results: We identified 2,948 patients diagnosed with RA and infected with SARS-CoV-2 (mean age± SD: 62 years ± 16, 77% female, 68% white). Of all identified patients, 38% were current or former smokers. For the 2,614 patients with BMI recorded, 78% were overweight or obese (mean BMI±SD: 31.2±8.3). The mean Charlson comorbidity index (CCI) was 3.6 (SD 3.2), with 87% of the study cohort having one or more comorbid condition, including hypertension (55%), type 2 diabetes (26%), COPD (20%), moderate to severe asthma (17%), coronary artery disease (17%), chronic kidney disease (13%), and heart failure (13%). Severe COVID-19 outcomes occurred in 618 (21%) patients. Among all RA patients with COVID-19, 137 patients (4.6%) experienced ARI, 484 patients (16.4%) were hospitalized (including 174 (5.9%) admitted to the ICU), and 155 patients (5.3%) died.
Conclusion: Underlying medical conditions that are known or possible risk factors of severe illness from SARS-CoV-2 infection in the general population are common in this RA cohort from a large national EHR database. However, whether patients with RA are more vulnerable to severe COVID-19 outcome than the general population requires adjustment by age and other important confounders.

POS1164 USE OF TELEMEDICINE FOR FOLLOW-UP OF SLE PATIENTS WITH NEPHRITIS IN THE COVID-19 OUTBREAK ("TELESLE"): THE 6-MONTH RESULTS OF A RANDOMIZED CONTROLLED TRIAL

H. So[1], E. Chow[1], T. K. LI[1], S. L. Lau[1], I. T. Cheng[1], C. C. Szeto[1], L. S. Tam[1]. [1]*The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*

Background: Patients with lupus nephritis (LN) might be more susceptible to COVID-19 due to the underlying disease, co-morbidities and use of immunosuppressants. We hypothesized that telemedicine (TM) could be a well-accepted mode of health-care delivery minimizing the risk of exposure to the severe acute respiratory syndrome coronavirus 2 (*SARS-CoV-2*), while maintaining disease control in these patients.
Objectives: To evaluate the short-term patient satisfaction, compliance, disease control and infection risk of TM compared with standard in-person follow-up (FU) for patients with LN during COVID-19.
Methods: This was a single-center randomized-controlled study. Consecutive patients followed at the LN clinic were randomized to either TM (TM group) or standard FU (SF group) in a 1:1 ratio. Patients in the TM group received scheduled follow-ups via videoconferencing. SF group patients continued conventional in-person outpatient care. The 6-month data were compared.
Results: From June to December 2020, 122 patients were randomized (TM: 60, SF: 62) and had attended at least 2 FU visits. There were no baseline differences, including SLEDAI-2k and proportion of patients in lupus low disease activity state (LLDAS), between the 2 groups except a higher physician global assessment score (PGA) in the TM group (mean 0.67±0.69 vs 0.45±0.60, p=0.003) (Table 1). The mean FU duration was 19.8±4.5 weeks. When comparing the most recent visit, the mean waiting time between entering the clinic waiting room (virtual or real) and seeing a rheumatologist (virtual or in-person) was significantly shorter in the TM group (22.5±28.6 vs 68.9±40.7 minutes, p< 0.001) (Figure 1A). The mean overall patient satisfaction score was higher in the TM group (mean 2.19±0.61 vs 1.89±0.78, p=0.042). The results of the post-consultation satisfaction questionnaire are shown in Figure 1B. The number of visits was similar in the two groups (TM: 3.1±1.3 vs SF: 3.0±1.2, p=0.981). However, there was a trend suggesting that alternative mode of FU was requested more frequently in the TM group than the SF group (TM: 12/60, 20.0% and SF: 5/62, 8.1%; p=0.057). More patients in the TM group had hospitalization (15/60, 25.0% vs 7/62, 11.3%; p=0.049) within the FU period, which was no longer statistically significant after adjusting for the baseline PGA. The proportions of patients remained in LLDAS were similar in the 2 groups (TM: 75.0% vs SF: 74.2%, p=0.919). None of the patients had COVID-19.
Conclusion: TM resulted in better patient satisfaction and could achieve similar disease control in patients with LN in the short-term when compared to standard care.

Table 1. Baseline clinical data of the recruited patients and comparison between the telemedicine/standard follow-up groups

	Overall (n=122)	Telemedicine group (n=60)	Standard follow-up group (n=62)	P-value

POS1165

LIFESTYLE AND MOOD CHANGES IN AXSPA PATIENTS DURING THE QUARANTINE PERIOD

E. Erpek[1], D. Solmaz[1], E. Durak Ediboglu[1], G. Alp[1], E. Otman Akat[1], H. Cinakli[1], G. Kabadayi[1], İ. Kurut Aysin[1], O. Bayindir[1], S. Gucenmez[1], M. Ozmen[1], S. Akar[1]. [1]*Izmir Katip Celebi University Faculty of Medicine, Rheumatology, Izmir, Turkey*

Background: On March 11, 2020, the World Health Organization declared coronavirus disease 2019 (COVID-19) as a pandemic, and mandatory quarantine was applied in Turkey between April and June 2020. With this sanction, sudden changes occurred in a routine lifestyle.
Objectives: This study aimed at evaluating physical activity changes, presence of anxiety and depression, altered eating habits and their relationship with disease activity in axial spondyloarthritis (AxSpA) patients during the quarantine period.
Methods: AxSpA patients, who were examined in the rheumatology clinic in the last year before the pandemic period and their relatives were included in this study and were contacted by phone to participate. A structured questionnaire form was performed which included the following data: questions about demographic characteristics, medication use, disease activity scales; BASDAI, BASFI, Patient acceptable symptom state (PASS), patient-reported physical activity state, Short Questionnaire to Assess Health enhancing physical activity (SQUASH), Three-Factor Eating Questionnaire (TFEQ-21), and Hospital Anxiety and Depression Scale (HADs).
Results: 204 AxSpA patients and 106 patients' relatives were contacted in the study (Figure 1). The frequency of male sex and alcohol consumption was higher in the AxSpA compared to the relatives and, other demographic features were summarized in Table 1. 30% of AxSpA patients and 37% of patient relatives were gained weight with mean 4.5±2.4 and 4.4±3.4 kilograms, respectively. Weight gain were similar male and female in AxSpA (26.2% vs 37.2%, p>0.05). However, the men in the AxSpA group gained more weight than relatives group (26.2% vs 7%, p<0.05). Weight gain group had decreased physical activity than stable group in AxSpA patients (54.8% vs 37.8%, p<0.05). We showed mild negative correlation between BASDAI and BASFI scores with SQUASH- total activity score (r:-0.15, p<0.05; r:-0.25, p<0.001, respectively). Anxiety prevalence were found slightly higher in patients group but not significantly (40.2% vs 32.1%; p>0.05). Depression were much higher in AxSpA group than relatives (43.6% vs 28%, p<0.001). Depression and anxiety were correlated with disease activity (HADs Depression vs BASDAI r:0.380, p<0.001; HADs Anxiety vs BASDAI r:0.418, p<0.001) and function (HADs Depression vs BASFI r:0.342, p<0.001; HADs Anxiety vs BASFI r:0.313, p<0.001). Among eating habits, uncontrolled and emotional eating scores were showed low correlation with anxiety (r:0.169, p<0.05; r:0.163, p<0.05, respectively).
Conclusion: One third of our patients were weight gain and approximately half of them had decreased physical activity but we did not show relation between these parameters and disease related factors in the limited period. In addition to that depression and anxiety were detected significant part of AxSpA patients and both of them were correlated with disease activity.

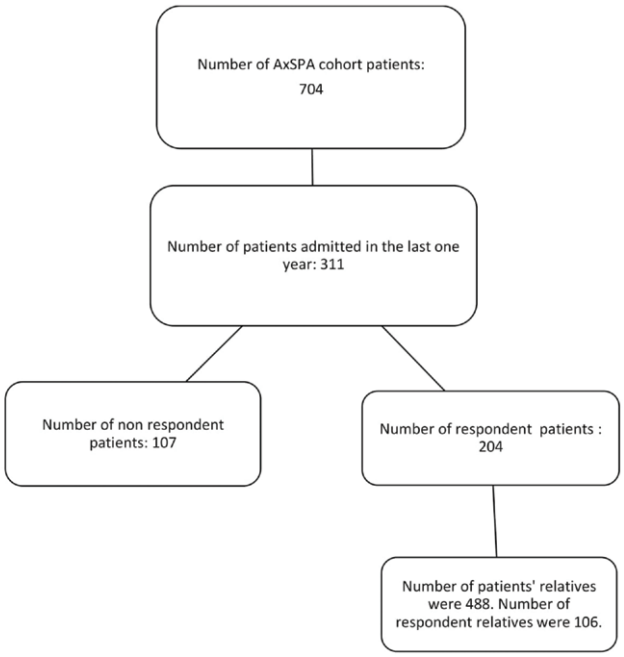

Figure 1: Flow chart of study population

Table 1. Study Population Characteristics

	AxSpa n:204	Controls n:106	p value

POS1166 UNDERSTANDING PRESCRIPTION BEHAVIOR ACROSS HEALTHCARE PROFESSIONALS IN TREATING KNEE OSTEOARTHRITIS BEFORE AND DURING THE 2020 COVID-19 PANDEMIC

D. Baldock[1], E. Baynton[1], H. Hamdan[2]. [1]*Ipsos MORI, Healthcare Service Line, london, United Kingdom*; [2]*Ipsos Sdn Bhd, Healthcare Service Line, Kuala Lumpur, Malaysia*

Background: Knee Osteoarthritis (OA) treatment aims to provide symptom relief, easing joint pain and enabling mobility. The COVID-19 pandemic affected healthcare systems globally, including ways OA patients were treated.
Objectives: This study is to understand how treatment management of knee OA patients and prescribing behavior across US healthcare professionals (HCPs) was affected when COVID-19 impacted healthcare systems and regimes globally
Methods: A multi-center online medical chart review study of patients with OA was conducted between May – July 2019 & 2020 among US rheumatologists (rheums), orthopedic surgeons (orthos), primary care physicians with a focus in sports medicine (SM PCPs), and pain specialists, practicing across hospital and private practices. Recruited from a large access panel, physicians were screened for duration of practice in their specialty (3-50 years) and caseload (35 or more knee OA patients personally managed, at least 10 of which must be classified as moderate-severe). Patient charts were recorded for the next 5 eligible patients seen during the screening period. Respondents abstracted patient demographics and treatment regimes used. Descriptive statistics were used to analyse the data
Results: 275 physicians were recruited and collectively reported 1375 patients between May-Jul 2019; 260 physicians were recruited and collectively reported 1300 patients between May-Jul 2020.
Looking at treatments patients were receiving at time of reporting, oral medications, particularly NSAIDs, were widely used, regardless of the physician specialty. A directional increase of 6% in the proportion of reported patients deriving from sampled primary care SM PCPs from pre-COVID (Q219) to during COVID (Q220), whilst the same is not true for rheums, orthos, and pain specialists.

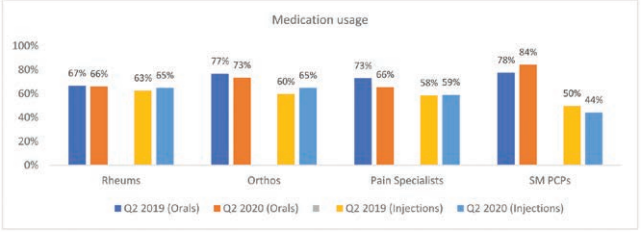

Figure 1. Medication usage in reported knee OA patients across all sampled specialties - Q2 2019 vs Q2 2020

With regards to the usage of injectable therapy, the opposite pattern is seen - higher proportions of reported patients deriving from sampled rheums, orthos & pain specialists receiving injectables vs those deriving from sampled SM PCPs. While focusing on orthos, the proportion of reported patients deriving from them who receive injectables grew by 5% in Q220 (during COVID) vs Q219 (pre-COVID) – directionally more so than other specialties. This is possibly due to limited elective surgeries during the pandemic.
Looking deeper into injectable usage amongst reported patients deriving from sampled rheums and orthos, the proportion of the total reported patient set receiving this treatment type is relatively similar across both specialties, prior to, and during the COVID-19 pandemic. However, among reported patients who received surgery, a directionally higher proportion of this reported patient cohort deriving from orthos are noted to receive injectables vs those from rheums – this is true both pre- and during the pandemic.
Conclusion: From the sample surveyed, it appears that primary care SM PCPs adopted their treatment adjustment during COVID-19 pandemic differently, by prescribing more orals, while other secondary care physicians (rheums, orthos, pain specialists) focused on injection treatment for longer pain relief. Considering movement restrictions and limited elective surgeries during the pandemic, the lack of targeted treatment options for knee OA has been made more apparent. With a burgeoning pipeline, many of which are targeted therapies, it is hopeful that knee OA treaters will be less reliant on symptom remedies and can readily offer patients' longer-acting pain relief or disease modifying options to combat joint deterioration

POS1167 REVIEW OF THE IMPACT OF COVID-19 PANDEMIC ON RHEUMATOLOGY SERVICES AT A LARGE TERTIARY CARE CENTRE IN WALES, UK

R. Asif[1], N. Elndari[2], A. Negi[1]. [1]*Cardiff and Vale University Health Board, Rheumatology, Cardiff, United Kingdom*; [2]*Cardiff and Vale University Health Board, Internal Medicine, Cardiff, United Kingdom*

Background: COVID-19 pandemic had an unprecedented impact on the delivery of patient care. Rheumatology services had to rapidly adapt to virtual consultations at the onset of the pandemic. However, providing a high quality and effective service in a virtual setting can be challenging and therefore its prudent to do a formal review and gain patient feedback to ensure that these clinics are fit for purpose.
Objectives: To evaluate the impact of first wave of COVID-19 pandemic on patients with autoimmune rheumatic conditions, assess delivery of rheumatology outpatient care and record patient feedback.
Methods: This study included patients on the Rheumatology clinic lists between 3rd and 31st August 2020. An electronic survey questionnaire was developed and the survey link was sent to patients via a text message using secure IT platform. Data was collected on patient demographics, diagnosis, comorbidities, treatments, clinical/ laboratory confirmed COVID-19 diagnosis, treatment interruption, impact on work, personal protective measures taken and views on virtual consultations.
Results: 307 patients responded with 287 complete responses. 73.1%(223) were female and 32.4% (99) were >65 years of age. Rheumatoid arthritis was the most common diagnosis 41.6%(127). Hypertension was the commonest comorbidity 21.4%(64) followed by Chronic lung disease 17.3%(52). 28.8%(85) were on Hydroxychloroquine, 26.7%(79) Methotrexate, 14.2%(42) Sulfasalazine and 13.2%(39) on Prednisolone. 22.3%(66) were on Biologics: Anti TNF 12.8%(38), Tocilizumab 3.7%(11) and Rituximab 3%(9). 52.6%(161) shielded, 16.9%(55) self-isolated and 30.3%(93) only maintained social distance. 197 patients self reported as being vulnerable but based on their treatment,only 167 patiemts met the clinically extremely vulnerable (CEV) criteria and all of those received government shielding letter.
3.6%(11) had lab confirmed COVID-19, 3.2%(10) had clinically suspected COVID-19 infection. 14.3% (43) had their treatment interrupted. 4.6%(14) were unable to work from home or maintain social distancing at work. 59.8%(182) had face-to-face consultation changed to virtual. 63.2%(189) were satisfied, 28%(84) neutral and 8.7%(26) reported dissatisfaction with their consultation. 50.5%(153) were happy to continue with virtual consultation but with an option of face to face only if necessary.For consultations post COVID-19, 59.4%(182) preferred a mixture of face to face and virtual appointments.
Conclusion: Majority of our patients seem happy with virtual consultations as long as they are assured of a face-to-face consultation if needed. A minority(8.7%) however, were dissatisfied. Some of the suggestions were,

use of video consultations and improvement in communication before the virtual appointments. Our survey also shows that our patients have adapted well to virtual consultations and many are keen to have virtual consultation in the longer term. In our survey, only 6.8%(21) patients reported definite or clinically suspected COVID-19. Possible explanations for this include strict compliance with government advice on social distancing/shielding and limited testing at the onset of the pandemic. More patients assumed themselves to be clinically CEV than those who were actually CEV based on their treatment which is not surprising because of high level of anxiety among patients due to rapidly spreading pandemic and multiple sources of information.

This feedback provides useful data which will help us to plan the delivery of rheumatology services post COVID-19 pandemic. While face-to-face patient contact is needed for comprehensive disease assessment, teaching and training, a model for the future is likely to include a combination of face-to-face and virtual consultations. This could allow a greater capacity to see new patients and reduce waiting lists. Patients with uncomplicated and stable disease could be followed up in virtual clinics. There is also a need to formally incorportate the virtual consultations into the curriculum for Rheumatology trainees.

POS1168

SELF-REPORTED SARS-CoV2 TESTING AND COVID-19 DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS, AXIAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS IN A SWISS OBSERVATIONAL COHORT

E. Papagiannoulis[1], A. Ciurea[2], D. Dan[3], A. Finckh[4,5], B. Gilbert[4,5], I. Von Loga[1], C. Melong Pianta Taleng[4,5], A. Scherer[1], K. Lauper[4,5,6]. [1]*SCQM, Statistics, Zurich, Switzerland*; [2]*Zurich University Hospital, University of Zurich, Rheumatology, Zurich, Switzerland*; [3]*CHUV, Rheumatology, Lausanne, Switzerland*; [4]*Faculty of Medicine, University of Geneva, Internal Medicine, Geneva, Switzerland*; [5]*Hôpitaux Universitaires de Genève (HUG), Rheumatology, Geneva, Switzerland*; [6]*Centre for Musculoskeletal Research, University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*

Background: Since the beginning of the pandemic in Switzerland, immunosuppressed people were strongly advised to be tested for SARS-CoV2 when symptomatic as it was conjectured that they might be more at risk for infection and/or severe disease. While patients with autoimmune diseases might be indeed more at risk of death from COVID-19[1], it remains unknown, whether there are differences in infection or complication rates between patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (AxSpA), and whether this relates to their disease or their treatment. Additionally, the prevalence of SARS-CoV2 testing in this population is not known.

Objectives: This study aimed to assess and compare the rate of COVID-19 and SARS-CoV2 testing in patients with RA, AxSpA and PsA, the potential association with their treatment and, for testing, the number of symptoms.

Methods: We included patients with RA, AxSpA and PsA from the Swiss Clinical Quality Management register (SCQM) using a smartphone app (mySCQM) to record information between March and December 2020. The outcomes of interest were self-reported SARS-CoV2 testing, symptoms compatible with COVID-19 during the previous month and confirmed COVID-19 through PCR nasopharyngeal swab. Outcomes were evaluated over the complete length of the aforementioned period (i.e. the outcome has been reported at least once during the period). Outcomes were compared between diseases groups, using logistic regression. We also evaluated the association of baseline treatment (TNF-inhibitors, b/tsDMARDs with other modes of action (OMA), no b/tsDMARDs) on the odds of symptoms and testing and the association of the number of symptoms (0-9) on the odds of testing. The analyses of SARS-CoV2 testing and COVID-19 symptoms were additionally adjusted for age, gender, glucocorticoids and csDMARDs. Confirmed cases were not adjusted for treatment and other covariates considering the low number of events.

Results: We included 927 patients with RA, 805 with AxSpa and 453 with PsA (Table 1). 1010 patients reported COVID-19-like symptoms (mostly fever, runny nose and cough), but only 455 of them (45%) reported being tested. 151 patients were tested without symptoms. In between March and December 2020, 7.6% of RA, 8.5% of AxSpA and 10.5% of PsA patients were tested positive for COVID-19 (p=0.678). The odds of testing, symptoms and confirmed COVID-19 were similar between diseases and not associated with treatment for testing and symptoms (Figure 1). The number of symptoms was associated with the odds of testing (OR 1.43, 95%CI 1.37-1.50 by symptom).

Table 1.

		RA	axSpA	PsA	p

Model 1: Adjusted for disease and treatment
Model 2: Model 1 + adjustement for age, gender, csDMARDs (Y/N), glucorticoids (Y/N)
Model 3: Model 2 + adjustment for the numbers of symptoms (fever, cough, shortness of breath, running nose, muscle aches, headaches, fatigue, diarrhoea, sore throat)
Model 4: Adjusted for disease

***In patients with information on tests results (N=565)**

Figure 1.

Conclusion: Prevalence of COVID-19 symptoms and confirmed cases was similar between diseases, and for symptoms, was not associated with treatment. Despite strong advice from health authorities, less than 50% of patients with inflammatory rheumatic diseases and COVID-19 symptoms were tested. This proportion was not significantly different between diseases and not influenced by type of treatment. Efforts should be made to improve rates of SARS-CoV2 testing in patients with rheumatic diseases.

POS1169

IMPACT OF THE COVID-19 PANDEMIC ON MORBIDITY AND MORTALITY AMONG SWEDISH PATIENTS WITH INFLAMMATORY JOINT DISEASES VERSUS THE GENERAL POPULATION

H. Bower[1], T. Frisell[1], D. DI Giuseppe[1], B. Delcoigne[1], G. M. Alenius[2], E. Baecklund[3], K. Chatzidionysiou[1], N. Feltelius[4], H. Forsblad-D'elia[5], A. Kastbom[6], L. Klareskog[1], E. Lindqvist[7], U. Lindström[5], C. Turesson[8], C. Sjowall[5], J. Askling[1]. [1]*Karolinska Institutet, Department of Medicine Solna, Division of Clinical Epidemiology, Stockholm, Sweden*; [2]*Umeå University, Rheumatology Unit, Department of Public Health and Clinical Medicine, Umeå, Sweden*; [3]*Uppsala University, Department of Medical Sciences, Uppsala, Sweden*; [4]*Swedish Medical Products Agency, Swedish Medical Products Agency, Uppsala, Sweden*; [5]*Sahlgrenska Academy, University of Gothenburg, Department of Rheumatology and Inflammation Research, Gothenburg, Sweden*; [6]*Linköping University, Department of Biomedical and Clinical Sciences, Linköping, Sweden*; [7]*Skåne University Hospital, Lund University, Department of Clinical Sciences, Rheumatology, Lund, Sweden*; [8]*Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Sweden*

Background: Studies from COVID-19 case-repositories among patients with rheumatic diseases have assessed associations (relative risks) between characteristics of the disease and adverse COVID-19 outcomes. Such designs are susceptible to bias from selection of cases reported. Few studies have assessed absolute and relative risks for COVID-19 outcomes in population-based cohorts of patients with inflammatory joint diseases, nor compared these risks to those in the general population.

Objectives: To estimate all-cause mortality, absolute and relative risks for severe COVID-19 in patients with chronic inflammatory joint diseases, compared over time and to the general population.

Methods: We updated a multi-register nationwide linkage ("ARTIS") on adults with RA, PsA, AS, SpA or JIA and population referents (matched on sex, age, and region), with data on hospitalizations, admission to intensive care (ICU), and deaths due to COVID-19. We calculated all-cause mortality March-September 2015-2020, and absolute and relative risks for COVID-19 outcomes March-September 2020. Patients were compared to population referents using hazard ratios (HR) from Cox models adjusted for comorbidities and socio-economy.

Results: We identified 110567 individuals with inflammatory joint disease (53455 with RA) in Sweden on March 1st 2020, and 484277 matched general population subjects. In all cohorts, the absolute risk of death from any cause in 2020 was higher than 2015-2019 (Figure 1), with a peak in mid-April, but the relative risks of death (vs. the general population) 2020 remained similar to HRs for 2015-2019 (HR for 2020 in Table 1).

Among all individuals with inflammatory joint disease in 2020, the risk for hospitalization, admission to ICU, and death due to COVID-19 was 0.5%, 0.04% and 0.1%, respectively (Table 1). HRs (vs. the general population) were elevated for almost all outcomes. HRs for COVID-19 related outcomes (Table 1) were higher than for non-COVID-19 outcomes; adjustment for co-morbidities and socio-economy explained much of these increases, somewhat less so for the former.

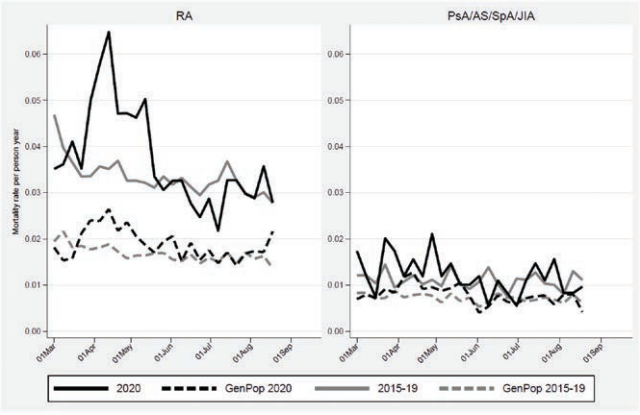

Figure 1. All-cause mortality in Swedish individuals with inflammatory joint disease and general population, March-September 2020 and the average 2015-2019

SELF-PROTECTION STRATEGIES, HEALTH BEHAVIOR AND DISEASE ACTIVITY DURING THE FIRST WAVE, RE-OPENING AND SECOND WAVE OF THE COVID-19 PANDEMIC IN >7000 DANISH PATIENTS WITH INFLAMMATORY ARTHRITIS

B. Glintborg[1], D. V. Jensen[2], S. Engel[1], L. Terslev[1], M. Pfeiffer Jensen[1], O. Hendricks[3], M. Østergaard[1], S. H. Rasmussen[1], T. Adelsten[4], K. Danebod[1], A. Colic[4], M. Kildemand[5], A. G. Loft[6], H. L. Munk[5], J. K. Pedersen[7], R. Østgård[8], C. M. Sørensen[9], N. Steen Krogh[10], J. Nørgaard Agerbo[11], C. Ziegler[11], M. L. Hetland[1]. [1]*Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, DANBIO and Copenhagen Center for Arthritis Research (COPECARE), Copenhagen, Denmark*; [2]*Center for Rheumatology and Spine Diseases Gentofte and Herlev Hospital, Department of Rheumatology, Gentofte, Denmark*; [3]*University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark*; [4]*Zealand University Hospital, Department of Rheumatology, Køge, Denmark*; [5]*Odense University Hospital, Department of Rheumatology, Odense, Denmark*; [6]*Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark*; [7]*Odense University Hospital and Svendborg Hospital, Department of Rheumatology, Odense, Denmark*; [8]*Silkeborg Regional Hospital, Diagnostic Center, Silkeborg, Denmark*; [9]*Horsens Regional Hospital, Department of Medicine, Horsens, Denmark*; [10]*ZiteLab Aps, Copenhagen, Denmark*; [11]*Gigtforeningen/Danish Rheumatism Association, -, Copenhagen, Denmark*

Background: The COVID-19 pandemic has caused lockdown, reduced access to face-to-face consultations, anxiety about taking immunosuppressive agents and self-isolation[1] which potentially impact rheumatic disease control negatively. However, changes in behavior including self-protection strategies during the ongoing pandemic and impact on rheumatic disease activity have only been scarcely described.

The first COVID-19 wave hit Denmark in March 2020 followed by a gradual re-opening from mid-April and the second surge began in the late autumn of 2020.

Objectives: To describe changes over time in self-protection strategies and health behavior during the first 8 months of the COVID-19 pandemic and to explore impact on self-reported disease activity and quality of life (=patient reported outcomes, PROs) in patients with inflammatory rheumatic disease (IRD) in DANBIO.

Methods: Patients were invited to answer two on-line questionnaires regarding current behavior and disease specific PROs: One in June 2020 (including also questions regarding behavior in March 2020), and one in November 2020. Responses were linked to PROs collected as part of routine care before March 2020 (=Before) in DANBIO. For each PRO, changes (=delta values) between the two timepoints were calculated in individual patients.

Results: Overall, 7,836 patients (22% of eligible patients) answered both questionnaires and were included (rheumatoid arthritis(RA): 5270(67%), psoriatic arthritis(PsA): 1217(15%), axial spondyloarthritis(AxSpA): 932(12%), other IRD: 417(5%). Patients reported highest levels of anxiety and self-protection in March with an improvement in June that was largely unchanged in November (Figure 1), e.g. proportions staying at home avoiding others as much as possible (completely or mostly agree) were 87%/49%/51% in March/June/November, respectively (Figure 1**, Panel C**).

Disease activity and proportions of patients reporting acceptable symptom state remained stable at the three time points (Table 1), with all median delta values being close to zero (not shown).

Conclusion: In this large cohort of patients with inflammatory rheumatic diseases followed in the nationwide DANBIO registry, COVID-19 related self-protection strategies were highest in March 2020, but more than half of the patients also reported self-isolation in June and November. We found no negative impact of the pandemic on patient-reported outcomes, which remained largely unchanged and were similar to before the pandemic. The latter finding probably reflects that few patients reduced or withdrew from treatment due to fear of COVID-19.[1]

POS1171

THE COVID-19 PANDEMIC PROMPTS ISOLATION AND BEHAVIORAL CHANGES IN PATIENTS WITH CHRONIC RHEUMATIC DISEASES LEADING TO REDUCED PHYSICAL ACTIVITY, INCREASED PAIN, DISEASE ACTIVITY, AND LOW SEROPREVALENCE OF SARS-COV2 ANTIBODIES

C. Ammitzbøll[1], J. B. Andersen[1], S. R. Vils[1,2], C. M. Jørgensen[1,2,3], E. M. Hauge[1,3], C. Erikstrup[3,4], S. Mikkelsen[3,4], M. K. Thomsen[5], A. Troldborg[1,2,3]. [1]*Aarhus University Hospital, Rheumatology, Aarhus, Denmark*; [2]*Aarhus University, Biomedicine, Aarhus, Denmark*; [3]*Aarhus University, Clinical Medicine, Aarhus, Denmark*; [4]*Aarhus University Hospital, Clinical Immunology, Aarhus, Denmark*; [5]*Aarhus University Hospital, Clinical Microbiology, Aarhus, Denmark*

Background: The coronavirus disease 2019 (COVID-19) pandemic has complicated the management of chronic rheumatic diseases (CRD). Patients with CRDs are immunocompromised and generally prone to infection. The fear of COVID-19 and the degree of the self-imposed shielding strategy implemented by many patients introduced new challenges for the patients. Although recommendations have been developed to manage patients with CRDs by, i.e., EULAR, strong evidence is still lacking to guide treatment decisions.

Objectives: This study aimed to assess the seroprevalence of SARS-CoV-2 antibodies in patients with CRDs and healthy controls during the first wave of the pandemic. We further evaluated the effect of the pandemic on patient behavior regarding medication, exercise, pain, and experienced disease activity. Finally, we investigated the self-perceived consequences of the pandemic and lock-down on anxiety and depression in patients with CRDs compared with healthy controls.

Methods: More than 900 participants were included in the study: 405 patients with rheumatoid arthritis or systemic lupus erythematosus and 513 blood donors. All participants had SARS-CoV-2 antibodies measured (Wantai SARS-CoV-2 total antibody ELISA; sensitivity 96.7%, specificity 99.5%) and answered a questionnaire concerning behavior, anxiety, and symptoms of depression (PHQ-9). The participants with CRD were further asked about physical activity, adherence to medication, and disease-related symptoms.

Results: CRD patients had a sixfold lower seroprevalence of SARS-CoV-2 antibodies compared to controls (p=0.03) (Figure 1). Almost 60% of patients were unable to exercise as usual, leading to increased pain in 34%, and experience of increased disease activity in 27%. Approximately 10% of patients reduced or discontinued their immunosuppressive treatments at their own initiative. Symptoms of moderate depression were present in 19% of patients compared to 6,8% of controls (p<0.001).

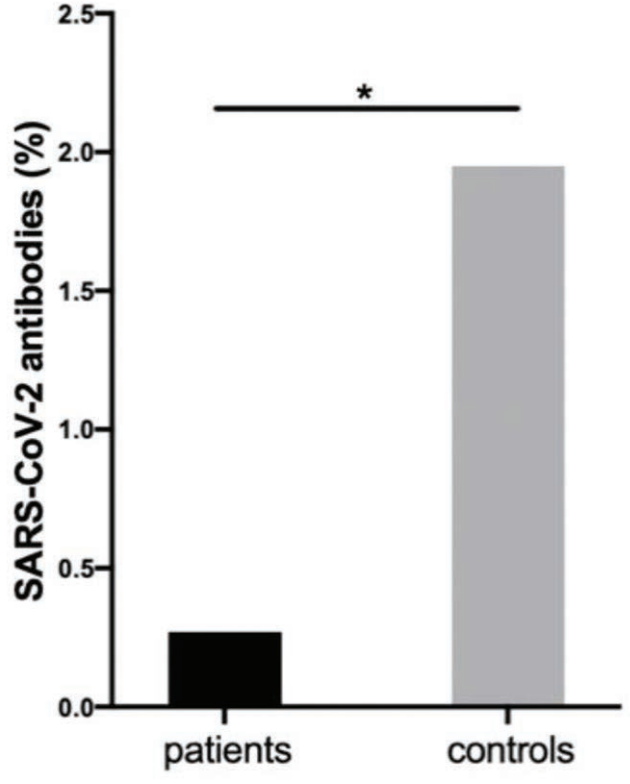

Figure 1. Presence of SARS-CoV-19 antibodies in chronic rheumatic disease patients (1/365, 0.3%) and controls (blood donors (10/513, 1.9%), *(p=0.03).

Conclusion: Low seroprevalence in patients with CRDs indicates successful mitigation of exposure to SARS-CoV-2. However, this appears to occur at the expense of physical activity and adherence to immunosuppressive treatment. Our results raise an important concern regarding the consequences of isolation for patients with CRDs. The result of physical isolation is a risk of severe mental health issues, physical inactivity, self-medication, increased pain, and increased disease activity. The long-term consequences of recommendations for patients with CRDs should be taken into account when tackling the continuing pandemic.

Table 1.

Patient characteristics	**CRD cohort**		**Blood donors**	
Patients included, n	405 (206 SLE, 199 RA)		513

POS1172

COVID-19 ACROSS RHEUMATOLOGY: A BIBLIOMETRIC STUDY

B. Doskaliuk[1], R. Yatsyshyn[1], I. Stoika[1], K. Fedorovych[1], O. Drogomeretska[1], O. Hotsaniuk[1], Y. Delva[1]. [1]*Ivano-Frankivsk National Medical University, Internal medicine #1 clinical immunology and allergology, Ivano-Frankivsk, Ukraine*

Background: The Coronavirus disease 2019 (COVID-19) outbreak spread rapidly among the whole world, becoming the greatest pandemic for the decades. It triggered the enormous challenges for the global health system, forcing doctors and patients to adapt to new realities and the field of rheumatology was not an exclusion.

Objectives: The aim of this study was to analyze articles covering interconnection between COVID-19 and rheumatic diseases; to investigate the common features of papers in this category and indicate the most influential among them; to determine which rheumatic nosologies were most represented.

Methods: For retrieving of literature data, we applied the bibliometric database Scopus and conducted our search on 12th of January using following keywords: “rheumatoid arthritis” OR “systemic lupus erythematosus” OR “systemic sclerosis” OR “vasculitis” OR “myositis” OR “rheumatology” AND “COVID-19”. All selected articles were analyzed according to various aspects: type of document, authorship, journal, citations score, rheumatology field, country of origin, language, and keywords. We have built the visualizing keywords network (Figure 1) with the help of software tool VOSviewer version 1.6.15 (the minimum keyword occurrence threshold was set at 5).

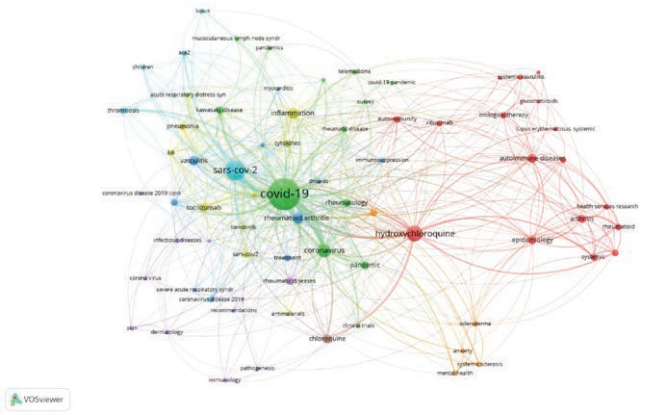

Figure 1.

Results: A total of 844 literature items were obtained. After screening of title, abstract and keywords we excluded 106 records as they were not emphasized the rheumatological perspective on COVID-19 and as a result were inapplicable for this study. The 738 retrieved articles were mostly (86.8%) open access publications. The top five journals that contributed most to the coverage of this topic were: Annals Of The Rheumatic Diseases (n=59), Clinical Rheumatology (n=41), Lancet Rheumatology (n=24), Arthritis And Rheumatology (n=20) and Rheumatology International (n=19). The origin of most studies was not surprisingly from those countries, which belong to the top ten according to the total cases of COVID-19 [1] (USA – 167; Italy – 148; UK – 76; India – 60 and Spain – 58). Most items were written in English but articles in German (n=12), Spanish (n=11), Russian (n=5) and Chinese (n=2) could also be found. Analyzed studies were designed in the form of Original Articles (41.2%), Reviews (23.7%), Letters (21.8), Notes (6.9%), Editorials (5.1%). According to the citations scores, articles of highest interest were dedicated to clinical course of COVID-19 in patients with autoimmune pathologies. The other highly cited studies were about cytokine storm and perspective usage of biological drugs for severe cases of COVID-19. Our analysis of keywords showed that the most widely discussed rheumatic disease in the view of COVID-19 was systemic lupus erythematosus (n=188), followed by vasculitis (n=132), rheumatoid arthritis (n=90), systemic sclerosis (n=32) and psoriatic arthritis (24). The liveliest discussion about disease-modifying antirheumatic drugs in COVID-19 revolved around hydroxychloroquine (n=305), corticosteroids (n=161), tocilizumab (n=83), methotrexate (n=46) and anakinra (n=34).

Conclusion: As far as we know, it is the first bibliometric overview of studies dedicated to interrelation between COVID-19 and rheumatic pathology. The high number of open access items contributes to the increase of research visibility in this emergently developing research field and facilitates the process of scientific data sharing. The conducting of bibliographic studies may provide a valuable guide through this area of knowledge.

POS1173 A SHORT DELAY IN ARTHRITIS CARE IS ASSOCIATED WITH HIGHER DISEASE ACTIVITY - LESSONS FROM THE CORONAVIRUS DISEASE 19 (COVID-19) PANDEMIC

A. Giollo[1], E. Bertoldo[1], C. Benini[1], O. Viapiana[1], L. Idolazzi[1], G. Adami[1], A. Fassio[1], D. Gatti[1], M. Rossini[1]. *[1]University of Verona, Rheumatology Section, Department of Medicine, Verona, Italy*

Background: Although disease activity is a significant outcome in rheumatology, few studies have investigated the relationship between routine care of rheumatic conditions and disease activity control.

Objectives: To determine the association between delay in routine care of chronic inflammatory arthritides (CIAs) and disease activity during the first wave of coronavirus disease 19 pandemic in Verona, Italy.

Methods: This study enrolled patients with an established diagnosis of rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS) and undifferentiated arthritis (UA). Between 01/04/2020 and 30/06/2020, participants were emailed an online questionnaire. Items comprised multiple or single-choice questions evaluating routine rheumatology care disruptions/delays and disease characteristics, treatments, comorbidities, and demographics. Compliance to anti-rheumatic medications was evaluated with I-CQR5. Disease activity was assessed with RAPID3, and active disease was defined as a RAPID3 score>1. Study period referred to the time between the last rheumatology assessment and the date of enrolment.

Results: Of 1210 patients contacted, 450 participated, of whom 219 CIAs patients were included (RA 55.3%, PsA 35.2%, AS 15.1%, UA 3.7%). One hundred twenty-five patients (57.1%) had their routine clinical assessment delayed (median days 68.4; IQR 66.8, 85.9). Patients in this group had significantly higher MDHAQ (p=0.001) and RAPID3 (p=0.031) scores, while they did not differ for disease severity, medications or compliance. Most (87.7%) reported good compliance to therapy; only 5.9% had difficulties in supplying anti-rheumatic medications, and 13.2% discontinued medications for at least four weeks for any reason. However, several patients (37.9%) reported moderate-to-high worse disease activity perception due to routine care delay, and 31.1% self-reported a disease flare (median RAPID3 score 3.8; IQR 2.0, 5.4). One hundred one patients (46.1%) had high disease activity, while only 15.1% were in remission. In logistic regression, active disease was significantly associated with delay of scheduled routine care visit, independent of disease duration, time from last rheumatology assessment, therapy with b/tsDMARDs, and compliance (Table 1, Figure 1 below).

Table 1.

Predictor	Active (n=186)	Remission (n=33)	OR	P-value	95% CI Inf.	95% CI Sup.
Routine care delay (yes vs no)	113 (60.8%)	12 (36.4%)	.030	2.459	1.091	5.543
Disease duration (years)	10 (4.0, 20.0)	10.5 (7.0, 19.8)	.695	1.007	.972	1.044
Time since last rheumatology assessment (days)	68.4 (66.8, 75.8)	71.2 (66.9, 74.9)	.854	1.002	.978	1.027
b/tsDMARDs (yes vs no)	105 (56.5%)	15 (45.5%)	.653	1.202	.538	2.687
I-CPR5 (likely low vs likely high adherent)	36 (19.4%)	10 (30.3%)	.187	.563	.240	1.321

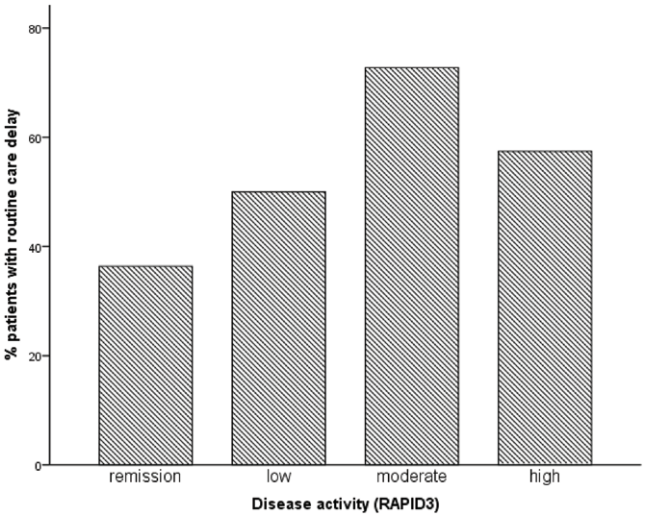

Figure 1.

Conclusion: In patients with established CIAs, a relatively short delay in routine assessment by a rheumatologist resulted in higher disease activity. Frequent rheumatology referrals appear to be a critical factor for disease activity control in CIAs.

Disclosure of Interests: None declared.

POS1174 HYPERINFLAMMATION AND CLINICAL OUTCOMES FOR PATIENTS WITH SYSTEMIC RHEUMATIC DISEASES HOSPITALIZED FOR COVID-19: A COMPARATIVE COHORT STUDY

T. Hsu[1,2], K. D'silva[2,3], N. Serling-Boyd[2,3], J. Wang[1], A. Mueller[1,2], X. Fu[3], L. Prisco[1], L. Martin[1], K. Vanni[1], A. Zaccardelli[1], C. Cook[3], H. Choi[2,3], Y. Zhang[2,3], E. Gravallese[1,2], Z. Wallace[2,3], J. Sparks[1,2]. *[1]Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, United States of America*; *[2]Harvard Medical School, Division of Rheumatology, Inflammation, and Immunity, Boston, United States of America*; *[3]Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America*

Background: COVID-19 can induce a hyperinflammatory state resulting in cytokine storm, which can lead to poor outcomes. Patients with systemic rheumatic diseases may be at increased risk for respiratory failure with COVID-19. Therefore, we investigated the relationship between rheumatic disease, hyperinflammation, and clinical outcomes among hospitalized COVID-19 patients.

Objectives: To compare laboratory values, hyperinflammation, and clinical outcomes of hospitalized COVID-19 rheumatic patients and matched comparators.

Methods: We performed a comparative cohort study of patients with polymerase chain reaction (PCR)-confirmed COVID-19 requiring hospitalization between 3/1/20-7/7/20 at a large health care system. We compared each systemic rheumatic disease case to up to 5 matched (by age, sex, and date of +SARS-CoV-2 PCR) comparators without systemic rheumatic disease. We extracted laboratory values from their hospitalization to compare peaks/troughs of individual laboratory results by case status and derived the COVID-19-associated hyperinflammation score (cHIS), a composite of 6 laboratory domains (0-6, ≥2 indicating hyperinflammation), as previously developed[1]. We used multivariable logistic regression to estimate ORs for COVID-19 outcomes by hyperinflammation and case status.

Results: We identified 57 hospitalized rheumatic disease cases (mean age 67 years, 67% female) and 232 matched comparators hospitalized with PCR-confirmed COVID-19. Among cases, 26 (46%) had rheumatoid arthritis and 14 (25%) had systemic lupus erythematosus. Most cases (34, 60%) had active rheumatic disease. At baseline, 15 (27%) of cases were treated with biologic DMARDs, and 32 (56%) were using glucocorticoids. We analyzed 39,900 total laboratory results (median 85 per patient). Cases had higher peak neutrophil-to-lymphocyte ratio (9.6 vs 7.8, p=0.02), LDH (421 vs 345 U/L, p=0.04), creatinine (1.2 vs 1.0 mg/dL, p=0.01), and BUN (31 vs 23 mg/dL, p=0.03) than comparators but similar peak CRP (149 vs 116 mg/L, p=0.11, Figure 1). Cases had higher peak median cHIS (3 vs 2, p=0.01). Peak cHIS ≥2 had higher odds of intensive care unit (ICU) admission (OR 3.45, 95%CI 1.98-5.99), mechanical ventilation (OR 66.0, 95%CI 9.0-487.8), and mortality (OR 16.4, 95%CI 4.8-56.4) compared to cHIS <2 (Table 1). Cases had increased risk of ICU admission (OR 2.0, 95%CI 1.1-3.7) and mechanical ventilation (OR 2.7, 95%CI 1.4-5.2) than comparators.

Table 1. Associations of peak cHIS and systemic rheumatic disease with COVID-19 hospitalization outcomes

	Intensive care unit admission		Mechanical ventilation		Death	
	%	Adjusted OR (95%CI)	%	Adjusted OR (95%CI)	%	Adjusted OR (95%CI)
Hospitalization outcomes by hyperinflammation on cHIS[1]						
cHIS <2 (n=112)	21%	1.0 (Ref)	1%	1.0 (Ref)	3%	1.0 (Ref)
cHIS ≥2 (n=177)	48%	**3.5 (2.0-6.0)**	37%	**66.2 (9.0-487.8)**	27%	**16.4 (4.8-56.4)**
Hospitalization outcomes by rheumatic disease status						
Comparators (n=232)	30%	1.0 (Ref)	19%	1.0 (Ref)	16%	1.0 (Ref)
Rheumatic cases (n=57)	51%	**1.87 (1.03-3.40)**	39%	**2.46 (1.30-4.67)**	21%	1.32 (0.61-2.88)

Matching factors: age, sex, and date of +PCR.[1]Adjusted for age, sex, and case status.[2]Adjusted for race, smoking, comorbidities, and body mass index.cHIS, COVID-19-associated hyperinflammation score; CI, confidence interval; OR, odds ratio; PCR, polymerase chain reaction; SARS-CoV-2, severe acute respiratory syndrome coronavirus 2.

Conclusion: Patients with systemic rheumatic disease hospitalized for COVID-19 had higher risk for hyperinflammation, kidney injury, and mechanical ventilation than non-rheumatic comparators. We validated the cHIS in our cohort, which was strongly associated with poor COVID-19 outcomes. These findings highlight that hospitalized patients with rheumatic diseases may be vulnerable to poor COVID-19 outcomes.

POS1175

ASSESSMENT OF THE COVID-19 PANDEMIC FROM THE PERSPECTIVE OF PEOPLE WITH RHEUMATIC MUSCULOSKELETAL DISEASES IN EUROPE. RESULTS FROM THE REUMAVID STUDY (PHASE 1)

M. Garrido-Cumbrera[1], H. Marzo-Ortega[2], J. Correa-Fernández[1], S. Sanz-Gómez[1], L. Christen[3], V. Navarro-Compán[4]on behalf of REUMAVID working group. [1]*Universidad de Sevilla, Health & Territory Research (HTR), Sevilla, Spain*; [2]*University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [3]*Novartis Pharma AG, Patient Engagement, Basel, Switzerland*; [4]*Hospital Universitario La Paz, IdiPaz, Madrid, Spain*

Background: The COVID-19 pandemic is an unprecedented public health crisis affecting people worldwide, including those with rheumatic and musculoskeletal diseases (RMDs).

Objectives: REUMAVID aims to assess the impact of the COVID-19 pandemic and lockdown on the wellbeing, mental health, disease activity and function, access to health care and treatment, support services, and hopes and fears of people RMDs.
Methods: REUMAVID is an international collaboration led by the Health & Territory Research group at University of Seville, Spain, together with a multidisciplinary team including patient organization and rheumatologists. This cross-sectional study consisting of an online survey gathering data from patients with a diagnosis of 15 RMDs in Cyprus, France, Greece, Italy, Portugal, Spain and the United Kingdom. Participants are recruited by patient organizations. Data is collected in two phases: 1) during the first peak of the COVID-19 pandemic (Spring 2020), and 2) as a follow-up to the pandemic (Winter 2020). This analysis presents descriptive results of the aggregated data, summarizing continuous and categorical variables.
Results: A total of 1,800 RMD patients have participated in the first wave of the COVID-19 pandemic (from early April to mid-June 2020). The most frequent reported diagnosis were axial spondyloarthritis (37.2%), rheumatoid arthritis (29.2%) and osteoarthritis (17.2%). Mean age was 52.6±13.2, 80.1% were female, 69.6% were in a relationship or married and 48.6% had university studies. In total, 1.1% had tested positive for COVID-19, 10.8 % reported symptoms but were not tested, while 88.1% did not experience any symptoms. 46.6% reported worsening health during the pandemic. 63.9% perceived their health status to be "fair to very bad". Access to care was limited with 58.4% being unable to keep the rheumatologist appointment, of which, 35.2% were cancelled by the provider and 54.4% was attended by phone or online. 15.8% changed their medication, for which 65.5% were changed by the provider and 24.6% by own decision. Reported wellbeing and psychological health during the pandemic was poor, with 49.0% reporting poor wellbeing according to the WHO-5 scale, 57.3% marking as anxiety and 45.8% as depression in the HADS scale. During the pandemic, 24.6% smoked and 18.2% drank more than before and 54.5% were unable to exercise at home.
Conclusion: Results from the first phase of REUMAVID show disturbance of the healthcare quality, substantial changes in harmful health behaviors and an unprecedented impairment of mental health in REUMAVID participants. REUMAVID will continue to collect information in order to assess the impact of the COVID-19 pandemic in people affected by RMDs across Europe.
Acknowledgements: This study was supported by Novartis Pharma AG. We would like to thank all patients that completed the survey as well as all of the patient organisations that participated in the REUMAVID study including: the Cyprus League Against Rheumatism (CYPLAR) from Cyprus, the Association Française de Lutte Anti-Rhumatismale (AFLAR) from France, the Hellenic League Against Rheumatism (ELEANA) from Greece, the Associazione Nazionale Persone con Malattie Reumatologiche e Rare (APMARR) from Italy, the Portuguese League Against Rheumatic Diseases (LPCDR), from Portugal, the Spanish Federation of Spondyloarthritis Associations, the Spanish Patients' Forum (FEP), UNiMiD, Spanish Rheumatology League (LIRE), Andalusian Rheumatology League (LIRA), Catalonia Rheumatology League and Galician Rheumatology League from Spain, and the National Axial Spondyloarthritis Society (NASS), National Rheumatoid Arthritis (NRAS) and Arthritis Action from the United Kingdom.

POS1176 THE IMPACT OF COVID-19 QUARANTINE ON MENTAL HEALTH OF PATIENTS WITH FIBROMYALGIA

F. Ingegnoli[1], M. Buoli[2], C. Posio[3], R. DI Taranto[1], R. Caporali[1]. [1]*Università degli Studi di Milano, Division of Clinical Rheumatology, ASST Pini, Department of Clinical Sciences & Community Health, Research Center for Adult and Pediatric Rheumatic Diseases, Milano, Italy*; [2]*Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Department of Neurosciences and Mental Health, Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Milano, Italy, Milano, Italy*; [3]*Università degli Studi di Milano,Department of Pathophysiology and Transplantation, Milano, Italy*

Background: Detrimental psychological effects, including symptoms of post-traumatic stress disorder (PTSD), stress, anxiety, and depression have been related to COVID-19 quarantine measures (1). These aspects may be particularly relevant in stress-related disorders such as fibromyalgia (FM) in which previous evidence demonstrated a causal effect of psychological stressors on chronic non-inflammatory pain of FM (2). Recent studies highlighted a significant worsening of FM symptoms after COVID-19 related lockdown period (3-4), but the levels of perceived stress and distress have not been evaluated yet.
Objectives: The aim of this study is to establish the COVID-19 related perceived stress and distress among patients with FM who experienced the COVID-19 quarantine in Italy. Data were retrieved from a larger nationwide online survey involving patients affected by different rheumatic diseases (RD).
Methods: We collected data from May to September 2020 from RD patients living in Italy during the COVID-19 quarantine by an ad-hoc online survey. Eleven associations of RD patients sent a call by using their mailing list, webpages and social network. They asked to complete an anonymous online survey which included the Perceived Stress Scale (PSS), and the Impact Event Scale-Revised (IES-R). Descriptive statistics were used to summarize results.
Results: 79 of 507 (15.6%) of RD patients who completed the survey declared to have been diagnosed FM. 77 (97.5%) were females, with a mean (± SD) age of 51.0 ± 12.4 yrs. In FM patients, the mean (SD) PSS score was 23.8 ± 8.1. In particular, 8 (10.1%) reported low, 38 (48.1%) moderate and 33 (41.8%) high PSS scores. Moreover, IES-R mean (SD) score was 38.5 ± 17.2. Among FM patients, 51 (64.6%) reported scores greater than 33, indicating the probable presence of a PTSD. With regard to the IES-R subscale scores, the total sample did not show a prominence of one of the three main domains: intrusion (13.9 ± 7.3), avoidance (11.9 ± 6.1) and hyperarousal (12.6 ± 5.9). In these FM patients, self-reported major sources of anxiety were related to personal and relatives' health (59.5%), followed by social withdrawal (21.5%) and employment loss/financial difficulties (11.4%). There was a slight increase of self-reported use of antidepressants (15 [18.9%] vs 16 [20.2%]) and anxiolytics drugs (4 [5.1%] vs 5 [6.3%]) after lockdown period.
Conclusion: These results confirm that psychosocial stress and distress were highly pervasive in FM after COVID-19 national lockdown. It is known that stressed status may exacerbate and/or precipitate later development of FM symptoms. These data support the substantial worsening of somatic burden of FM after lockdown period reported in previous studies (3-4). Coping strategies should be implemented to ameliorate psychological well-being of these patients in this stressful era.

POS1177 REVAMPING BIOLOGIC THERAPY DURING COVID-19

S. Ahmed Narikkoottungal[1], A. Siddiqui[1], A. Constantin[1], S. Farrow[1], K. Ahmed[1]. [1]*Princess Alexandra Hospital, Department of Rheumatology, Harlow, United Kingdom*

Background: The COVID-19 pandemic has caught us all by surprise – from governments to individuals; the medical fraternity being no exception. It has affected all walks of life; with its immense contagiosity, diverse and intriguing pathogenesis and manifestations differing from other viruses. It has indeed left humanity in dark, unchartered waters; particularly in the early months of the pandemic.
Objectives: This article shares the experience, in a Rheumatology department in a District General Hospital (DGH) in the United Kingdom, of managing patients on Biologic (b) and Targeted Synthetic (ts) DMARDs, in the midst of the COVID-19 Pandemic.
Methods: All Rheumatology patients at the Princess Alexandra Hospital (PAH) in Harlow newly started on a biologic or targeted synthetic DMARD between 3rd July and 3rd Oct 2020 were identified. These patients had active inflammatory arthritis. Each patient was discussed in a dedicated Multi-Disciplinary Team (MDT) meeting and a consensus on treatment reached in-line with local and National guidelines.

Figure 1. A slide presented at the Essex Rheumatology Association (ERA) meeting explaining the process adopted at the Rheumatology Department at Harlow during the peak of COVID-19 pandemic with new b/ts DMARD patients.

Results: Of the 50 patients identified; 39 had Rheumatoid Arthritis, 6 had Ankylosing Spondylitis and 5 had Psoriatic Arthritis. Of these 50 patients, 5 patients decided against treatment during the stage of 'Enhanced Verbal Consent'. These patients were flaring recurrently and were in regular contact with the department. However, they were afraid to start new Biologic treatment because of the risks of Covid-19. The breakdown of the biologic agents used in the remaining 45 patients were as follows: Adalimumab:11, Rituximab: 10, Etanercept: 9, Tofacitinib: 11, Tocilizumab SC: 3, Tocilizumab IV: 1, Sarilumab: 2, Secukinumab: 1, Infliximab: 1, Baricitinib: 1, Apremilast: 1

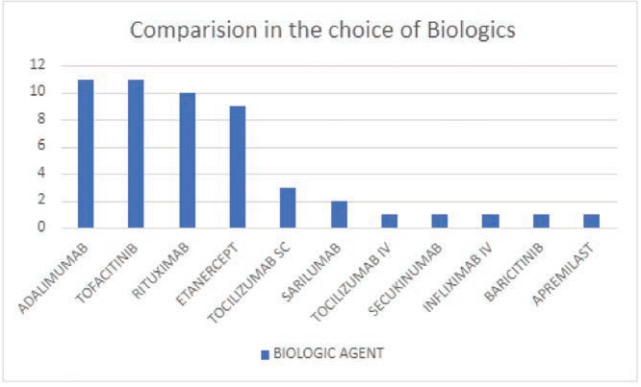

Figure 2. Breakdown of the various b/ts DMARD agents newly started in the 45 patients between 3/7/20 - 3/10/20 at PA Hospital, Harlow, UK

Conclusion: The over-riding principle that guided the Department during the COVID crisis was: *primum non nocere* (first, do no harm). The adherence to the Case Based Discussions (CBDs) positively impacted on decision making, ensuring safe initiation of Biologic DMARDs even during the height of the pandemic. This is vital to achieve early disease remission. The MDT meetings comprising Doctors, Specialist Pharmacist and Nurse Specialists ensured prompt risk stratification of individual patients. It gave patients the opportunity to be part of the decision-making - evident in the five of the fifty patients, who opted to defer the start date of their treatments. The choice of the new Biologic agent was based on the latest National COVID-19 guidelines. The agents with the shortest half-life were selected. Moreover, patients for Rituximab were given one pulsed infusion, as opposed to two infusions. Only one of the 45 patients started on a Biologic agent over this period, either was tested positive or had symptoms suggestive of COVID-19.

POS1178 THE ROLE OF VIRTUAL TELEPHONE VISITS IN THE TIGHT CONTROL OF RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TARGETED THERAPIES DURING THE COVID-19 PANDEMIC

F. Ingegnoli[1], G. Cincinelli[1], A. F. Luppino[1], E. Favalli[1], R. Caporali[1]. [1]*Università degli Studi di Milano, Division of Clinical Rheumatology, ASST Pini, Department of Clinical Sciences & Community Health, Research Center for Adult and Pediatric Rheumatic Diseases, Milano, Italy*

Background: Rheumatic patients' follow-up in terms of treatment adherence, disease control achieved with treat-to-target (T2T) and tight-control strategy have been deeply influenced by nationwide mitigation strategies such as quarantine, travel restrictions, and inadequate access to routine visits, laboratory and imaging investigations. These restrictions could be potentially detrimental for patients' care, but to what extent these measures affected the T2T and tight-control approach in rheumatoid arthritis (RA) is unknown.
Objectives: This study investigated whether the adoption of telephone virtual care imposed by COVID-19 pandemic has been effective in maintaining remission in RA treated with targeted therapies and to identify factors associated with its maintenance.
Methods: This observational retrospective real-life study was conducted from November 2019 through September 2020. Clinical Disease Activity Index (CDAI) of RA patients treated with targeted therapies was analysed retrospectively before, during and after the national lockdown (LD). During LD period, rheumatologists provided virtual care by telephone to assess the clinical status to guarantee the absence of current contraindications to therapy. Then, patients could choose whether to receive home drug delivery or to maintain their face-to-face consultations. Logistic mixed effects regression models were fitted, with CDAI remission as response variable. A multivariate analysis and a parsimonious model were finally obtained by stepwise selection procedure using AIC.
Results: Data were extracted from a longitudinal observational registry, and at baseline, 502 RA patients were eligible for this study. 52 patients failed to complete their follow-up, 450 patients were included in the final analysis. During LD, 359 patients chose in-person visit, 91 patients home drug delivery and virtual visit. Our cohort did not show a statistically significant decrease in the number of patients fulfilling CDAI remission criteria all along the three periods. Among the 450 patients evaluated, the CDAI remission rate was 40.22% (N=181) and 43.78% (N=197) during pre-LD and post-LD, respectively. As for the 359 patients who choose in-person visits during LD, 43.18% (N=155) were in remission according to CDAI. The final model (step-wise selection) applied to the multivariate analysis of factors that potentially could interfere with disease control in patients with CDAI remission showed that the probability to maintain remission was associated with Caucasian ethnicity, male gender and absence of fibromyalgia (Table 1 below).

Table 1.

	Adjusted OR (95% CI)	p-value
Period (LD vs Pre-LD)	1.24 (0.83 - 1.85)	0.292
Period (Post-LD vs Pre-LD)	1.22 (0.84 - 1.77)	0.299
Gender (male vs female)	2.26 (1.15 - 4.61)	0.020
Disease duration (≥10 years vs <10 years)	0.65 (0.36 - 1.15)	0.141
Ethnicity (Hispanic/Asian vs Caucasian)	0.32 (0.12 - 0.83)	0.021
Fibromyalgia (yes vs no)	0.30 (0.11 - 0.82)	0.021

Conclusion: Telephone-based tight control strategy ensured satisfactory management of RA treated with targeted therapies during the first wave of COVID-19 pandemic. All along the three periods, we observed that the probability to be in CDAI remission was significantly associated with Caucasian ethnicity, male

gender, and absence of fibromyalgia. This temporary approach has been a feasible compensation for face-to-face visits, thus reassuring for future months before the end of pandemic.

POS1179 POST COVID ARTHRITIS; REACTIVE ARTHRITIS OR RHEUMATIC DISEASE FLARE OR BOTH

F. Fayed[1], E. Abdelkarim[1]. [1]*Alexandria University Students' Hospital, Rheumatology and immunology department, alexandria, Egypt*

Background: Reactive arthritis (ReA) is an emerging arthritis after viral infection especially respiratory and gastrointestinal related viruses. In 2020, SARS-COV2 virus is sweeping worldwide with diverse symptoms and prolonged post-Covid manifestations in which are arthralgia and myalgia are frequently present for days and even months. Interestedly, arthritis in covid era is a part of ReA or a flare of autoimmune disease, it is challenging.(1)

Objectives: Our objective was to determine the frequency of musculoskeletal symptoms with SARS-COV2 virus and after recovery as well as its relation to autoimmune diseases flares.

Methods: A Prospective study was done on 241 patients who admitted to the Rheumatology clinic from March 2020 to January 2021, complaining from new onset of musculoskeletal symptoms. Detailed history, Examination of systems including Musculoskeletal, laboratory investigation, past history of existing rheumatic disease, and history of infection with covid 19.

Results: Among 241 patients with median age 34.4, 36.92% had an existing Rheumatic disease while 63.08% are not. Moreover, 39% of patients had a post history with covid 19 within weeks. The most frequent Musculoskeletal symptoms are myalgia (74.56%), arthralgia (69.36%), and arthritis (10.78%). Furthermore, ReA (Post covid arthritis) accounted (2.07%) especially monoarthritis of Ankle (68.75%) while rheumatic diseases flares (24.48%) as well as new onset rheumatic diseases (39.68%). ($p \leq 0.001$) patients of ReA improved on NSAID and intrarticular injection of glucocorticosteroid.

Conclusion: Covid 19 is one of environmental triggers for development of rheumatic disease as well as reactive arthritis post viral infections. ReA is commonly affected the Ankle joint mainly monoarthritis and had improved on oral NSAID and intrarticular injection of Glucocorticosteroid.

POS1180 TREATMENT COMPLIANCE OF PATIENTS WITH RHEUMATOID ARTHRITIS DURING THE FIRST WAVE OF THE SARS-CoV-2/COVID-19 PANDEMIC IN PORTUGAL: RESULTS FROM THE COVID IN RA (COVIDRA) SURVEY

F. Araujo[1], N. Gonçalves[2], A. F. Mourão[1,2]. [1]*Hospital de Sant'Ana, Rheumatology and Osteoporosis Unit, Parede, Portugal*; [2]*Hospital Egas Moniz, Department of Rheumatology, Lisboa, Portugal*

Background: The outcomes of the infection by the SARS-CoV-2 in patients with immune-mediated inflammatory diseases were largely unknown during the early days of the COVID-19 pandemic. It was hypothesized that these patients were at higher risk of morbidity and mortality due to their inherent immune dysfunction and immunosuppressive therapy. Several rheumatology societies issued recommendations urging patients not to stop their anti-rheumatic treatments.

Objectives: To assess treatment compliance of patients with rheumatoid arthritis (RA) during the first wave of the SARS-CoV-2/COVID-19 pandemic in Portugal.

Methods: The web-based survey COVIDRA (COVID in RA) was developed to assess the impact of the first wave mandatory confinement in patients with RA focusing on 5 domains: RA symptoms, attitudes towards medication, employment status, physical exercise and mental health. The questionnaire was sent to RA patients through e-mail and social media of the Portuguese Society of Rheumatology and two patient associations; and it was filled locally at two rheumatology centers in Lisbon. Recruitment took place during June and July 2020. Descriptive statistics were generated by the survey software and were afterwards transported and evaluated using appropriate biostatistics software.

Results: We obtained 441 valid questionnaires. Most respondents were female (88.4%), caucasian (93.6%), with a mean age of 58 (+/-13) years. The majority (57.6%) had longstanding disease (>10 years) and were treated with csDMARDs (63.2%) and/or bDMARDs/tsDMARDS (23,7%). Only 14% (N=61) discontinued or reduced the dosage or frequency of their RA treatment. Most of these changes were previously planned by the attending physician (27.9%). Only 11 patients (18%) discontinued their immunosuppressive medication out of fear of becoming infected with SARS-CoV-2 (corresponding to 2.5% of total responders). Another 11 patients did so because they had no prescription, couldn't go to the community/hospital pharmacy or couldn't afford the medication. Although these numbers preclude any statistical analysis, when compared to patients who persisted on their treatment, those discontinuing due to fear of contagion were younger (56.4 vs 58.5 years), all female (100 vs 86.8%), with long-lasting disease (≥ 11 years) (90.9% vs 57.5%), more frequently treated with bDMARDs (36.4 vs 23.1%) and presenting more symptoms of depression (54.5 vs 49.7%).

Conclusion: Most RA patients complied with their treatment during the first wave of the SARS-CoV-2 pandemic in Portugal. Only a minority changed their immunosuppressive treatment due to fear of SARS-CoV-2 infection. Very similar rates of immunosuppressive discontinuation due to fear of contagion were reported by other authors (such as Schmeiser *et al*, Pineda-sic *et al* and Fragoulis *et al*).

POS1181 CLINICAL COURSE OF COVID-19 IN CHILDREN WITH RHEUMATIC DISEASE UNDER BIOLOGIC THERAPY

F. Demir[1], K. Ulu[1], Ş. Çağlayan[1], T. Coşkuner[1], B. Sözeri[1]. [1]*Health Sciences University, Umraniye Training and Research Hospital, Pediatric Rheumatology, Istanbul,Turkey*

Background: Since the beginning of the COVID-19 pandemic in our country, Turkey, more than two million people have been infected and more than 20,000 people have died. Although children infected less frequently and generally have a milder findings of COVID-19, the number of patients with a more severe clinical course as multisystem inflammatory syndrome in children (MIS-C) is increasing significantly. However, it has not been shown exactly how biological disease-modifying antirheumatic drug (bDMARD)s, which we frequently use in our pediatric rheumatology practice, and/or the underlying rheumatological diseases affect the clinical course of COVID-19.

Objectives: Here, we aimed to reveal the outcome of COVID-19 infection in our patients with pediatric rheumatic disease and treated with bDMARDs.

Methods: During the period between April 1, 2020 and December 1, 2020, the patients who received bDMARDs were evaluated at the regular outpatient clinic follow-up or by telemedicine with a maximum of 3 months interval. Clinical and demographic characteristics, COVID-19 data and outcome of these patients were retrospectively collected.

Results: Out of the 436 patients treated with bDMARDs, 39 children were infected with COVID-19. The diagnosis was confirmed in 37 patients by RT-PCR (nasalpharyngeal swab) and in two by antibody test. Twenty-two (56.4%) patients were female (17 male, %43.6) and the median age of patients were 12.3 years (min-max: 1.2-20.9). The primary diagnosis of patients were as follows; 20 juvenile idiopathic arthritis (six were systemic subtype), 12 systemic autoinflammatory diseases, three vasculitis, three chronic recurrent multifocal osteomyelitis and one Sjögren's syndrome. Prior to COVID-19 infection, 13 patients (33.3%) were using canakinumab, seven were infliximab (18%), five were adalimumab (12.8%), four were etanercept 10.2%), four were tocilizumab (10.2%), three were anakinra (7.7%), two were rituximab (5.1%), and one was tofacitinib (2.6%).

Of the 39 patients, 21 had at least one COVID-19-related symptom, while 18 patients were asymptomatic. No laboratory or imaging tests was performed for asymptomatic patients and they were followed up without treatment at home isolation. Laboratory tests revealed that fourteen patients had elevated acute phase reactants, six had elevated D-dimer levels, three had lymphopenia (<1000/mm^3), and three had hyperferritinemia.

Hospitalization was required in 20 patients (51.3%) at median of 7-days (min-max: 3-17) and pediatric intensive care unit admission in one. Five patients developed MIS-C and one of these patients was followed up in the pediatric intensive care unit. Myocardial dysfunction was developed in this patient and he was died. The other four patients fully recovered with no remain morbidity.

Conclusion: Considering the literature data and the results of our study, it is not possible to say that currently used bDMARDs worse the course of COVID-19 infection. In patients with underlying risk factors for hyperinflammation, as in one of our patients, COVID-19 may cause mortality regardless of the use of bDMARDs. Whether bDMARDs does not affect the severity of the disease, but it is still not true to say that these drugs are protective. Since cessation of

bDMARDs for COVID-risk may cause exacerbation of the primary rheumatic disease, continuing with current treatments seems an appropriate approach.

POS1182 MANAGEMENT OF DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS DURING THE COVID-19 PANDEMIC: EVIDENCE FROM THE ITALIAN EPICENTER

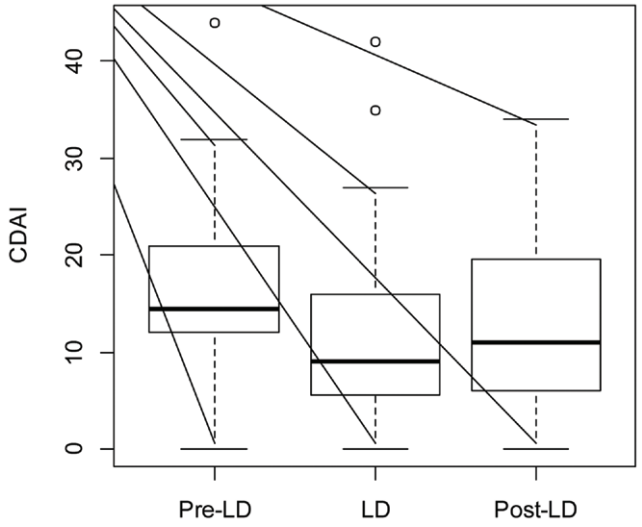
F. Ingegnoli[1], A. F. Luppino[1], G. Cincinelli[1], E. Favalli[1], R. Caporali[1]. [1]*Università degli Studi di Milano, Division of Clinical Rheumatology, ASST Pini, Department of Clinical Sciences & Community Health, Research Center for Adult and Pediatric Rheumatic Diseases, Milano, Italy*

Background: Despite significant improvement in the RA management, up to twenty percent of patients with rheumatoid arthritis (RA) have a difficult-to-treat (D2T) disease. The COVID-19 related mitigation policies, for instance quarantine, and consequent difficult access to in-person visits, laboratory and imaging investigations, adversely affected the follow up of rheumatic patients. Although pandemic-imposed limitations could have negatively influenced disease management particularly in D2T patients, to what degree these restrictions affected the treat-to target (T2T) and tight-control strategy in this subgroup of RA patients has not been investigated yet.

Objectives: To evaluate whether the switch to telehealth imposed by COVID-19 pandemic was effective in the management of D2T RA patients treated with targeted therapies.

Methods: This observational retrospective real-life study was conducted from November 2019 through September 2020. Among RA patients treated with targeted therapies, RA D2T patients according to EULAR definition (1) were identified. Clinical Disease Activity Index (CDAI) of these patients was analysed retrospectively before, during and after lockdown (LD). During LD period, patients could choose whether to receive home drug delivery or to maintain their face-to-face consultations, and in the former rheumatologists provided virtual care. To evaluate the effect of LD on the percentage of patients in remission, logistic mixed effects regression models were fitted, with CDAI remission as response variable.

Results: Data were extracted from a longitudinal observational registry, and at baseline, 52 patients treated with targeted therapies were classified as D2T RA. Among them, during pre-LD, LD, and post-LD 11.54% (N=6), 53.49% (N=23), and 46.15% (N=24) had CDAI remission/low disease activity, while 46 (88.46%), 20 (46.51%) and 28 (53.85%) had CDAI moderate/high. All the patients completed the follow-up. Median values of CDAI during pre-LD, LD, and post-LD were 14.5 [IQR 12-21], 9 [IQR 5.5-16], and 11 [IQR 6-19.2] respectively (see Figure 1 below).



Conclusion: Telephone-based tight control strategy ensured satisfactory management of D2T RA treated with targeted therapies. This temporary approach has been a feasible compensation for the decline of face-to-face visits also in this challenging group of RA patients, thus reassuring for future months before the end of pandemic.

Background: It remains unknown whether children and young people with rheumatic and musculoskeletal diseases (RMD) who acquire COVID-19 infection have a more severe COVID-19 course, due to either underlying disease or immunosuppressive treatments.

Objectives: To describe outcomes among children and young people with underlying RMD who acquire COVID-19 infection.

Methods: All children and young people <18 years of age with COVID-19 (presumptive or confirmed) reported to the EULAR COVID-19 Database, which collects details regarding RMD diagnosis and treatment, COVID infection and outcomes, between 27 March 2020 and 29 January 2021 (cutoff date for this analysis) were included. Patient characteristics and COVID-19 outcomes are presented.

Results: A total of 151 children and young people (age range 2-17 years; Table 1) have been reported to the database from 12 countries; mostly Spain (N=30), France (N=29), Israel (N=29), and Czechia (N=25). Most patients had a diagnosis of juvenile idiopathic arthritis (JIA; N=92; 61%). Other diagnoses were autoinflammatory syndrome (including TRAPS, CAPS, FMF; 12%), and systemic lupus erythematosus (4%). There were 14 (9%) hospitalisations and 1 (0.7%) death reported due to COVID-19. The most commonly reported symptoms were fever (46%), cough (34%), anosmia (19%), and headache (19%). Only 19 (13%) patients reported glucocorticoid use. DMARD therapy was used by 104 (69%) patients; 67 (44%) were on csDMARDs (methotrexate [N=54], antimalarials [N=7]), 45 (30%) on anti-TNF, 9 (6%) on IL-6 inhibitors, and 7 (5%) on IL-1 inhibitors. Among the 145 patients with hospitalisation data, patients on any DMARD therapy (cs/b/tsDMARDs) had similar odds for hospitalisation compared with those not on therapy, adjusted for age (odds ratio 0.7; 95% CI 0.2, 2.4).

		All Patients

Deaths due to COVID-19	Yes	1 (<1%)
Treatment at onset of COVID-19 infection	Glucocorticoids	19 (13%)
	csDMARDs	67 (44%)
	Methotrexate	*54 (36%)*
	Antimalarials	*7 (5%)*
	Mycophenolate	*5 (3%)*
	bDMARDs	64 (42%)
	Anti-TNF	*45 (30%)*
	IL-6	*9 (6%)*
	IL-1	*8 (5%)*
	Any DMARD	104 (69%)

Conclusion: These initial data on outcomes of COVID-19 in paediatric RMDs are very reassuring, with less than 1 in 10 patients reporting hospitalisation. Due to the database design and inherent reporting bias, this is likely an overestimate, suggesting that overall outcomes among this population appear to be generally good, with mild infection. Increasing case reports to the database will allow further exploration of drug- and disease-specific outcomes.

Disclosure of Interests: None declared.

POS1184 AUTOIMMUNE SYSTEMIC DISEASES AND COVID-19 INFECTION

S. Monov[1], R. Shumnalieva[2], D. Monova[3]. [1]*Medical University - Sofia, Departmant of Rheumatology, Sofia, Bulgaria*; [2]*Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria*; [3]*Medical Institute, Medical University - Sofia, Department of Internal Medicine, Sofia, Bulgaria*

Background: Covid-19 infection poses a serious challenge for immune-compromised patients. This is likely due to a combination of immune dysfunction, immunosuppressive therapy and excess co-morbidities. Little is known about the impact of Coronavirus disease 2019 (COVID-19) in patients with inflammatory autoimmune systemic diseases.

Objectives: The aim of this study is to describe clinical characteristics of patients with autoimmune systemic diseases and COVID-19, and to identify baseline variables associated with a severe infection requiring hospitalization.

Methods: A telephone survey investigating the impact of COVID-19 on patients with systemic lupus erythematosus (SLE), systemic sclerosis (SSc), inflammatory arthritis (rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis), idiopathic inflammatory myopathies (IIM), ANCA-associated vasculitis (AAV) was administered. Data extraction included diagnosis, disease activity status, demographics, disease duration, occupational exposure, adherence to social distancing advise, therapy, comorbidities, and laboratory tests. Covid-19 was classified as definite diagnosis of Covid-19 disease: presence of symptomatic Covid-19 infection, confirmed by a nasopharyngeal SARS-CoV-2 polymerase chain reaction test. Comparisons between patients with or without hospitalization were performed.

Results: 512 patients (median age 53,4 ± 14,3 years) with autoimmune systemic diseases (234 IA, 182 SLE, 42 SSc, 31 IIM, 23 AAV) were included in the study. 89 patients (58 woman, 31 men) developed at least one symptom (fever, asthenia, chills, cough, sore throat, dyspnea, chest pain, headaches, arthralgias, myalgias, odynophagia, diarrhea, conjunctivitis, hypo-, ageusia, hypo-, anosmia) of COVID-19 and were PCR test positive. Of patients with COVID – 19 infection 54 patients were treated with methylprednisolone, 36 – with methotrexate, 34 – with hydroxychloroquine, 26- with biologics, 10 - with azathioprine, 6 - with cyclophosphamide prior to their COVID-19 illness.

Conclusion: Covid-19 is more frequent in the subgroup of patients without therapy with modifying anti-rheumatic drugs, which might play some protective role against the most harmful manifestations of Covid-19. 21 patients required hospitalization - these were more frequently men, older and with comorbidities (cardio-respiratory illness, renal diseases, diabetes mellitus). Male sex, previous coronary and lung disease, serum creatinine level, proteinuria, glucocorticoids use > 5 mg/day, were associated to hospitalization. Patients with inflammatory arthritis do not seen to be at higher risk for infection or a severe course of COVID-19.

POS1185 IMPACT OF LOCKDOWN DURING COVID-19 PANDEMIC ON THE ONSET OF POST-TRAUMATIC STRESS DISORDER (PTSD) IN SYSTEMIC SCLEROSIS PATIENTS: A CASE-CONTROL STUDY

D. M. Reza Beigi[1], G. Pellegrino[1], A. Lorello[1], C. Angelelli[1], K. Stefanantoni[1], F. Conti[1], V. Riccieri[1]. [1]*Sapienza University of Rome, Department of Internal Medicine, Anesthesiology and Cardiovascular Sciences, Rome, Italy*

Background: Social distancing due to COVID-19 pandemic had a major impact on the mental health of general population, with a high prevalence of post-traumatic stress disorder (PTSD) related symptoms[1, 2]. Psychological repercussions were notably found in people with chronic diseases, including systemic sclerosis (SSc) patients, where an increasing of anxiety symptoms, related also to low financial resources, emerged[3].

Objectives: To evaluate the impact of COVID-19 lockdown on the onset of PTSD in patients with SSc, firstly during the total confinement period (March-April 2020) and then at the time of less restrictive government measures, following the RT index lowering (June-July 2020)[4].

Methods: We carried out a case-control study on 57 SSc patients, according to the ACR/EULAR 2013 criteria, and on 57 healthy subjects as control group (HC), matched by sex and age. At T0 (March-April) and T1 (June-July) both populations received the "Impact of Event Scale Revised" questionnaire (IES-R) by e-mail, with a cut-off of ≥ 33 defining probable diagnosis of PTSD[5]. A multivariate analysis of possible factors influencing IES-R score, such as age, number of cohabitating people and weekly outings count, was performed in SSc patients at both times of the survey.

Results: At T0 we found a significantly greater number of SSc patients with IES-R score ≥ 33 compared to HC (26/45.6% vs 13/22.8%; median value [quartiles] 31 [19.5;42.5] vs 24 [15.5; 32]; p-value 0.046). At T1, we obtained data from 44 SSc patients and 35 HC but no significant difference was noticed (18 / 40.9% vs 8 / 23.5%; 26 [15.25; 38] vs 26.5 [20.75; 32.5]; p> 0.05). SSc patients also had significantly fewer weekly outings than HC, both at T0 (p <0.001) and T1 (p <0.001) (Table 1). The multivariate analysis performed at T0 on SSc patients showed a significant association of IES-R ≥33 score with age (p 0.025) and with a lower count of weekly outings (p 0.002). The latter data negatively correlated with an IES-R ≥33 score in SSc patients (r -0.267, p 0.004).

Conclusion: We found a significantly higher prevalence of PTSD in SSc patients compared to HC at the strictest lockdown time, turning into comparable when

government measures were less restrictive, due to the minimum RT index values recorded in Italy. Older age and lower count of weekly outings were associated with PTSD in SSc patients during the lockdown, whereas the count of weekly outings was lower than in HC during both the examined periods. The results of this study indicate that COVID-19 lockdown had a worse impact in SSc patients, where the fewer weekly outings may depend on their clinical condition and on a greater concern about their health[6]. These findings strengthen the World Scleroderma Foundation recommendations regarding care to the psychological frailty of SSc patients[7].

POS1186

EFFECT OF SOCIO-ECONOMIC STATUS AND EDUCATIONAL LEVEL ON COVID-19 OUTCOMES IN PATIENTS WITH RHEUMATIC DISEASES FROM ARGENTINA: DATA FROM THE SAR-COVID REGISTRY

L. Sorrentino[1], J. Rebak[1], F. Maldonado[1], V. V. Castro Coello[1], A. Brigante[1], A. Hamaui[1], D. Dubinsky[1], R. Baez[2], C. Pisoni[2], C. Gobbi[2], L. Carlevaris[2], R. Tanten[2], A. K. Cogo[2], M. Delavega[2], R. Perez Alamino[2], M. A. Lazaro[2], M. Pera[2], S. I. Pineda Vidal[2], M. E. Calvo[2], D. Guaglianone[2], C. G. Alonso[2], M. Guinsburg[2], C. Retamozo[2], C. Aeschlimann[2], R. Quintana[3], K. Roberts[3], C. A. Isnardi[3], G. Pons Estel[3]on behalf of SAR-COVID Registry. *[1]Sanatorio Güemes, Department of Rheumatology, Ciudad Autónoma de Buenos Aires, Argentina*; *[2]Argentine Society of Rheumatology, On behalf of SAR-COVID Registry, Ciudad Autónoma de Buenos Aires, Argentina*; *[3]Argentine Society of Rheumatology, Research Unit - SAR-COVID Registry, Ciudad Autónoma de Buenos Aires, Argentina*

Background: SARS-CoV-2 infection can present with a broad clinical spectrum, from asymptomatic to lethal. Different risk factors have been recognized. Socio-economic status and educational level may affect access to the healthcare system and therefore COVID-19 infection outcome.

Objectives: The aim of this study was to assess the association between socio-demographic status and educational level and SARS-CoV-2 outcomes, such as hospitalization, ICU admission, need for mechanical ventilation and death, in Argentinean patients with rheumatic diseases from the SAR-COVID Registry.

Methods: We performed a cross-sectional study of consecutive adult patients with rheumatic diseases and SARS-CoV-2 infection included in the multicentric Argentinean SAR-COVID Registry. The following variables were included: gender, ethnicity, age, health insurance, educational level (under or over 12 years of education), socio-economic level according to Graffar Scale in high, medium-high, medium, medium-low, low; underlying rheumatic disease, its duration and treatment at the time of infection.

SARS-CoV-2 infection outcomes were: hospitalization, admission to ICU, mechanical ventilation requirement and death.

Statistical analysis was performed using Chi^2, Fisher, T-test, ANOVA.

Results: Five hundred and twenty-five patients were included, 422 (80.4%) were female, with a mean age of 51.3 years (SD 15.2). Most of them were caucasians (48%) or mestizos (43%) and 96.8% lived in an urban environment. Almost half of the patients (47%) were categorized as middle-class, 24% middle-high or high class, 21% middle-low or low. 48.4% of the patients were employed. Regarding educational level, 54% had more than 12 years of education.

The most prevalent rheumatic disease was Rheumatoid Arthritis (40.4%), followed by Systemic Lupus Erythematosus (14.9%), Sjögren (5.5%) and Psoriatic Arthritis (5.5%). Treatments used at the time of SARS-CoV-2 infection were corticosteroids (19%), cs-DMARDs (49%), and b- and ts-DMARDs (16%).

Overall hospitalization frequency was 35%, median hospital stay was 10 days (IQR 10 days), 11.6% were admitted to the ICU, 10% required mechanical ventilation and the global mortality was 8%.

Notably, patients with less than 12 years of education required mechanical ventilation more frequently than the more educated ones (11.9% vs. 5.6%, p=0.026) and showed a higher mortality due to COVID-19 (9% vs. 2.8%, p=0.0004).

Patients categorized as upper social classes (middle-high and high) were admitted to the hospital on a more frequent basis (74.4% of cases), when compared with middle class (64.4%) and middle-low and low class (58%) (p=0.77). Median duration of hospitalization for the aforementioned groups was 12.5 (IQR 17.3), 10 (IQR 9) and 10.5 (IQR 9.3) days respectively (p=0.60).

Patients with health insurance were found to be hospitalized more frequently in comparison to those without insurance (42.4% vs. 33.7%, p=0.14), but showed similar admission rates to the ICU (11.8% vs. 12.8%; p=0.78), need for mechanical ventilation (10.7% vs. 8.7%; p=0.70) and mortality (7.1% vs. 6.5%; p=0.99).

Caucasian patients had fewer hospital admissions when compared against other ethnicities (mestizos mostly) (26.1% vs. 43.4%; p<0.0001), but showed no statistically significant difference in need for mechanical ventilation 10.3% vs. 9.9% (p=0.99) or mortality 8.7% vs. 5.1% (p=0.15).

Conclusion: Patients with lower educational level needed twice the frequency of mechanical ventilation, and showed thrice the mortality than those with more than 12 years of education.

Albeit patients in upper social stratus and those with health insurance were admitted to the hospital in a more frequent manner, no statistically significant differences were found regarding the need for ICU, mechanical ventilation or mortality.

Caucasians were hospitalized less frequently than mestizos, but had no significant differences in the other measured outcomes.

POS1187

WILLINGNESS TO GET THE COVID-19 VACCINE AMONG PATIENTS WITH RHEUMATIC DISEASES, HEALTH WORKERS AND GENERAL POPULATION

B. Yurttas[1], B. C. Poyraz[2], N. Süt[3], A. Ozdede[1], M. Oztas[1], Ö. F. Tabak[4], V. Hamuryudan[1], E. Seyahi[1]. [1]*Istanbul University- Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; [2]*Istanbul University- Cerrahpasa, Cerrahpasa Medical Faculty, Department of Psychiatry, Division of Geropsychiatry, Istanbul, Turkey*; [3]*Trakya University Medical Faculty, Department of Biostatistics and Medical Informatics, Edirne, Turkey*; [4]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Infectious Diseases and Clinical Microbiology, Istanbul, Turkey*

Background: As of January 2021 the COVID-19 pandemic has been responsible for more than 2.2 million deaths worldwide (1). Potential vaccines against COVID-19 have been developed swiftly and vaccination programs were started in many countries. Turkey agreed to use inactivated vaccine candidate, 'CoronaVac' produced by Chinese biopharmaceutical company (3). Many of our patients having a rheumatic diseases (RD) call us for permission to get vaccination, while some express their concerns about the efficacy and safety issues.

Objectives: We therefore assessed the willingness to get vaccination among patients with RD compared to health workers and a sample from general population.

Methods: A web-based questionnaire study was conducted in a cross-sectional design in 3 groups of participants: 1. patients with RD, 2. hospital workers and 3. General population. The questionnaire sought socio-demographic variables, COVID-19 related risk factors, willingness to get vaccination, and concerns and thoughts about vaccine. COVID-19 related anxiety (CAS) was also evaluated through the questionnaire.

Results: We studied in total 732 (258 M/ 474 F) patients with RD, 320 (88 M/ 232 F) hospital workers and 763 (258 M/ 505 F) individuals representing general population. Patients with RD were significantly older and less educated and spent less time using social media compared to both control groups (Table 1). CAS scores were similar between the study groups. Of the patients with RD, 29.2% were willing to be vaccinated, 19% were unwilling and 51.8% were undecided. These were similar among the general population (34.6%, 23.3% and 42.1%, respectively), whereas hospital workers were significantly more willing (52.5%, 20.9% and 26.6%, respectively) ($p<0.0001$). About a third in each group thought that vaccination should be obligatory.The major concerns associated with vaccine were fear from side effects, unknown scientific results and lack of confidence. Being male, older age, working in a hospital and increased anxiety levels were found to be independently associated with willingness.

Conclusion: Only about one third of the patients with RD were willing to get vaccination, which was somewhat similar to that observed among the general population. This could be due to rushed vaccine development as well as negative news on vaccines on the social media. Our study also reveals that, after almost one year after the pandemic, about 95% in all study groups did not express dysfunctional anxiety related with COVID-19.

COVID-19 IN PATIENTS WITH RHEUMATIC DISEASES: COMPARISON OF DATA FROM THE ARGENTINE REGISTRY (SAR-COVID), WITH THE LATIN AMERICAN AND GLOBAL REGISTRY (GLOBAL RHEUMATOLOGY ALLIANCE)

A. A. Reyes[1], G. Alle[1], R. Tanten[1], M. Scolnik[1], E. Soriano[1], G. Berbotto[2], M. Haye[2], M. J. Gamba[2], R. Nieto[2], M. García[2], V. Savio[2], L. Gonzalez Lucero[2], P. Alba[2], L. Takashima[2], F. Risueño[2], L. Casalla[2], N. Cucchiaro[2], A. Bertoli[2], S. Porta[2], C. Maldini[2], R. Gallo[2], C. Goizueta[2], E. Picco[2], R. Quintana[3], K. Roberts[3], C. A. Isnardi[3], G. Pons-Estel[3]on behalf of SAR-COVID Registry. [1]*Hospital Italiano de Buenos Aires, Reumatologia, Buenos Aires, Argentina*; [2]*On behalf of SAR-COVID Registry, On behalf of SAR-COVID Registry, Buenos Aires, Argentina*; [3]*Argentine Society of Rheumatology - Research Unit - SAR-COVID Registry, Argentine Society of Rheumatology - Research Unit - SAR-COVID Registry, Buenos Aires, Argentina*

Background: SARS CoV-2 infection has recently burst onto the global scene, and the knowledge of the course of this infection in patients with rheumatic diseases receiving immunomodulatory treatment is still insufficient. The Argentine Society of Rheumatology (SAR) designed a national registry called SAR-COVID in order to get to assess our reality.

Objectives: To identify the particular characteristics of patients with rheumatic diseases and COVID-19 in Argentina (SAR-COVID Registry), and to compare them with the data reported at the Latin American and Global level (Global International Alliance Rheum-COVID Registry).

Methods: A national, multicenter, prospective and observational registry was carried out. Patients older than 18 years, with a diagnosis of rheumatic disease and SARS-CoV-2 infection by PCR or serology, were included between August 13, 2020 and January 17, 2021. Demographic data, underlying rheumatic disease (activity of the disease, current treatment), comorbidities, clinical-laboratory characteristics of the SARS-CoV-2 infection, as well as received treatments (pharmacological, oxygen therapy / ventilatory support) and outcomes (hospitalization, mortality) were recorded. The characteristics of the

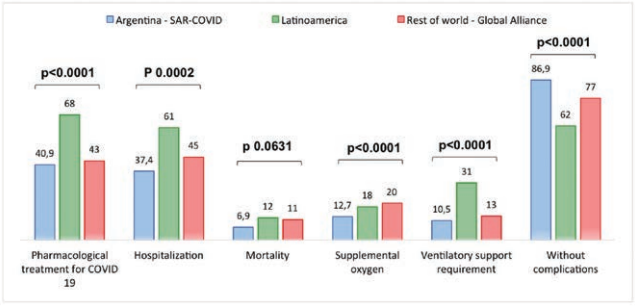
included patients were compared with the data reported at the Latin American and global level. Descriptive statistics were performed. Comparisons between groups were made using ANOVA, chi2 or Fisher's test, according to the type of variable.

Results: Four hundred sixty-five patients from Argentina, 74 patients from Latin America and 583 from the rest of the world were included, mostly women (79.6%, 73% and 71% respectively), with a mean age of 50.2 (SD 15.3), 53.5 (DE 15.6) and 55.8 (15.5), years respectively. The most frequent rheumatic diseases in the three groups were rheumatoid arthritis (43.9%, 35%, and 39%) and systemic lupus erythematosus (16.1%, 22%, and 14%) (Table 1).

In Argentina, fewer patients received specific pharmacological treatment for COVID-19 (40.9%, 68% and 43% respectively, p <0.0001), and there was a lower requirement of NIMV / IMV (Non-Invasive Mechanical Ventilation/Invasive Mechanical Ventilation) than in the rest of Latin America and the world (10.5% vs 31% vs 13%, p <0.0001).

Hospitalization was lower in Argentina than in the rest of Latin America (37.4% vs 61% p 0.0002) and of the world (37.4% vs 45% p 0.0123), and mortality was numerically lower in Argentina, but without statistically significant differences between the three groups (6.9%, 12% and 11%; p 0.6311). Most of the patients, (86.9%) did not present any complications in Argentina, with a statistically significant difference with the rest of the groups (62% and 77%, p <0.0001) (Graph 1).

Conclusion: The patients with rheumatic diseases and SARS-CoV-2 infection reported in this argentinian registry received less specific pharmacological treatment for COVID-19, presented fewer complications and required less ventilatory support, than those reported in the Latinoamerican and Global registry. However, no statistically significant differences were observed in terms of mortality.



Graph 1. Main outcomes and evolution of patients with rheumatic disease and COVID-19.

POS1189 THE IMPACT OF TELEMEDICINE AND COVID-19 ON A TERTIARY RHEUMATOLOGY SERVICE: A RETROSPECTIVE AUDIT

W. Zhu[1], T. De Silva[2], L. Eades[2], S. Morton[2], S. Ayoub[1,2], E. F. Morand[1,2], A. Antony[1,2]. [1]*Monash University, School of Clinical Sciences, Melbourne, Australia*; [2]*Monash Health, Department of Rheumatology, Melbourne, Australia*

Background: Telemedicine was widely utilised to complement face-to-face (F2F) care in 2020 during the COVID-19 pandemic, but the impact of this on patient care is poorly understood.

Objectives: To investigate the impact of telemedicine during COVID-19 on outpatient rheumatology services.

Methods: We retrospectively audited patient electronic medical records from rheumatology outpatient clinics in an urban tertiary rheumatology centre between April-May 2020 (telemedicine cohort) and April-May 2019 (comparator cohort). Differences in age, sex, primary diagnosis, medications, and proportion of new/review appointments were assessed using Mann-Whitney U and Chi-square tests. Univariate analysis was used to estimate associations between telemedicine usage and the ability to assign a diagnosis in patients without a prior rheumatological diagnosis, the frequency of changes to immunosuppression, subsequent F2F review, planned admissions or procedures, follow-up phone calls, and time to next appointment.

Results: 3,040 outpatient appointments were audited: 1,443 from 2019 and 1,597 from 2020. There was no statistically significant difference in the age, sex, proportion of new/review appointments, or frequency of immunosuppression use between the cohorts. Inflammatory arthritis (IA) was a more common diagnosis in the 2020 cohort (35.1% vs 31%, p=0.024). 96.7% (n=1,444) of patients seen in the 2020 cohort were reviewed via telemedicine. In patients without an existing rheumatological diagnosis, the odds of making a diagnosis at the appointment were significantly lower in 2020 (28.6% vs 57.4%; OR 0.30 [95% CI 0.16-0.53]; p<0.001). Clinicians were also less likely to change immunosuppressive therapy in 2020 (22.6% vs 27.4%; OR 0.78 [95% CI 0.65-0.92]; p=0.004). This was mostly driven by less de-escalation in therapy (10% vs 12.6%; OR 0.75 [95% CI 0.59-0.95]; p=0.019) as there was no statistically significant difference in the escalation or switching of immunosuppressive therapies. There was no significant difference in frequency of follow-up phone calls, however, patients seen in 2020 required earlier follow-up appointments (p<0.001). There was also no difference in unplanned rheumatological presentations but significantly fewer planned admissions and procedures in 2020 (1% vs 2.6%, p=0.002). Appointment

non-attendance reduced in 2020 to 6.5% from 10.9% in 2019 (OR 0.57 [95% CI 0.44-0.74]; p<0.001), however the odds of discharging a patient from care were significantly lower in 2020 (3.9% vs 6%; OR 0.64 [95% CI 0.46-0.89]; p=0.008), although there was no significance when patients who failed to attend were excluded. Amongst patients seen via telemedicine in 2020, a subsequent F2F appointment was required in 9.4%. The predictors of needing a F2F review were being a new patient (OR 6.28 [95% CI 4.10-9.64]; p<0.001), not having a prior rheumatological diagnosis (OR 18.43 [95% CI: 2.35-144.63]; p=0.006), or having a diagnosis of IA (OR 2.85 [95% CI: 1.40-5.80]; p=0.004) or connective tissue disease (OR 3.22 [95% CI: 1.11-9.32]; p=0.031).

Conclusion: Most patients in the 2020 cohort were seen via telemedicine. Telemedicine use during the COVID-19 pandemic was associated with reduced clinic non-attendance, but with diagnostic delay, reduced likelihood of changing existing immunosuppressive therapy, earlier requirement for review, and lower likelihood of discharge. While the effects of telemedicine cannot be differentiated from changes in practice related to other aspects of the pandemic, they suggest that telemedicine may have a negative impact on the timeliness of management of rheumatology patients.

POS1190 EXPECTATIONS AND POTENTIAL CONCERNS OF PATIENTS WITH AUTOIMMUNE AND RHEUMATIC DISEASES REGARDING VACCINATION AGAINST SARS-COV-2 (COVID-19): THE WORLDWIDE ONLINE VAXICOV STUDY

R. Felten[1], M. Dubois[1], M. F. Ugarte-Gil[2], J. Fort[1], L. Pijnenburg[1], A. Chaudier[1], L. Kawka[1], C. Costecalde[1], H. Bergier[1], E. Chatelus[1], R. M. Javier[1], C. Sordet[1], J. E. Gottenberg[1], J. Sibilia[1], Y. Fuentes-Silva[3], L. Arnaud[1]. *[1]Hôpitaux Universitaires de Strasbourg, Service de Rhumatologie, Strasbourg, France*; *[2]Universidad Cientifica del Sur, Hospital Nacional Guillermo Almenara Irigoyen, School of Medicine and Rheumatology Department., Lima, Peru*; *[3]Complejo Hospitalario Universitario Ruiz y Páez, Universidad de Oriente, Ciudad Bolívar, Centro Nacional de Enfermedades Reumáticas, Division of Rheumatology, Ciudad Bolívar, Venezuela (Bolivarian Republic)*

Background: Vaccination is an important and effective tool to prevent infections in the general population as well as in patients with systemic autoimmune or inflammatory rheumatic diseases (AIIRDs) who may be at increased risk of serious infection. While the global race for vaccines against COVID-19 has already lead to first authorizations and vaccinations in some countries, multiple questions arise for access and provisions as well as for the acceptance of vaccine policies by immunocompromised patients.

Objectives: We conducted an international survey about expectations and potential concerns regarding SARS-CoV-2 vaccine in patients with AIIRDs and healthcare professionals.

Methods: The online study consisted of 57 questions which addressed determinants associated with SARS-2-CoV-2 vaccine willingness. Dissemination was ensured through social media and patient associations between December 12 and December 21, 2020.

Results: The study included 1266 patients with AIIRDs and 265 healthcare professionals from 56 countries. SARS-CoV-2 vaccine willingness was reported by 54.2% of AIIRD patients (uncertainty in 32.2% and unwillingness in 13.6%) and 74.0% of healthcare professionals. In patients, the willingness to get vaccinated increased significantly with age (p<0.0001) and was strongly associated with the fear to be infected by SARS-CoV-2 (p<0.0001) or to develop severe COVID19 (p<0.0001) but not with presence of additional comorbidities (p=0.71) or immunocompromised status (p=0.94). The most trusted healthcare professional regarding the recommendation to get vaccinated against COVID-19 was their specialist (rheumatologist, internist, etc.) for 69.9%. Vaccine unwillingness was low (7.9%) among healthcare professionals and willingness was significantly increased in those who had been vaccinated against influenza in the last 3 years (p=0.01).

Subject groups	Patients	Healthcare professionals

POS1191

COVID-19 STRESS: DOES IT AUGMENT PAIN IN PEOPLE WITH FIBROMYALGIA AND MIGHT PSYCHOLOGICAL FLEXIBILITY PROTECT AGAINST THIS INFLUENCE?

T. Koppert[1], J. W. G. Jacobs[2], M. Lumley[3], R. Geenen[4,5]. [1]*Leiden University - Faculty of Social Sciences, Developmental & Educational Psychology, Leiden, Netherlands*; [2]*University Medical Center Utrecht, Rheumatology & Clinical Immunology, Utrecht, Netherlands*; [3]*Wayne State University, Psychology, Detroit, United States of America*; [4]*Utrecht University, Psychology, Utrecht, Netherlands*; [5]*Altrecht, Psychosomatic Medicine, Zeist, Netherlands*

Background: Stress might augment pain in people with fibromyalgia, possibly through sensitization of the central nervous system. The COVID-19 pandemic offers a unique opportunity to examine this mechanism. If it holds, the link between COVID-19 stress and pain would be stronger in people with fibromyalgia than in people without it. Additionally, psychological flexibility might act as a resilience factor, reducing pain severity. If psychological flexibility buffers the impact of stress on pain in people with fibromyalgia, then enhancing psychological flexibility may be of value.
Objectives: To determine the association between COVID-19 stress and pain severity in people with fibromyalgia, as compared to people without fibromyalgia, and whether psychological flexibility buffers the impact of stress on pain severity.
Methods: In a repeated cross-sectional design, we analysed questionnaire data from two independent surveys. The data collection has been described in a previous study of mental well-being in people with inflammatory rheumatic diseases. [1] The current study analysed data from people with and without fibromyalgia. Data were collected before the COVID-19 pandemic (2018; fibromyalgia: n=145, no fibromyalgia: n=386) and at the first peak of the pandemic in the Netherlands (2020; fibromyalgia: n=270, no fibromyalgia: n=1259). Stress due to the pandemic, psychological flexibility, and pain were subjected to regression analyses. Two operationalisations of stress were analysed: self-reported stress levels during the peak of the pandemic in 2020, and a comparison of assessments in 2018 and 2020 (assuming higher stress levels during the pandemic peak in 2020).
Results: In regression analyses, stress during the pandemic (p<.001), having fibromyalgia (p<.001), and lower psychological flexibility (p<.001) were all associated with more severe pain, but the interactions showed that the strength of the association of stress with pain was not different in people with fibromyalgia compared to people without fibromyalgia (p=.76 and p=.28 for the two operationalization of stress, respectively). Another interaction indicated that psychological flexibility was a potential buffer against the association between self-reported stress and pain in the first operationalisation of stress (p=.04), but not in the second (p=.44). The significant but small interaction is shown in the Figure 1. It suggests that pain is higher in people with low psychological flexibility and higher stress levels during the pandemic. This effect was not specific to fibromyalgia.
Conclusion: Overall, the significant main effects show that negative states, such as stress related to the pandemic and low psychological flexibility, are associated with another negative state: pain. A small interaction effect suggests that psychological flexibility may protect against the impact of COVID-19 stress on pain, both in people with and without fibromyalgia. However, the analyses reject our hypothesis that COVID-19 stress would augment pain especially in people with fibromyalgia.

POS1192

BEHAVIOR AND FEELINGS OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS DURING LOCKDOWN MEASURES FOR THE COVID-19 OUTBREAK

G. De Marchi[1], D. Azzolina[2], E. Maresio[3], D. Colatutto[4], M. Binutti[4], M. Monte[5], S. Gallipoli[6], F. Zobec[6], A. Palese[7], M. Silano[8], S. De Vita[4], D. Gregori[9], L. Quartuccio[4]. [1]*ASUFC, Rheumatology Clinic, Udine, Italy*; [2]*University of Piemonte Orientale, Statistics, Turin, Italy*; [3]*ProChild Onlus, Psychology, Trieste, Italy*; [4]*University of Udine, Rheumatology Clinic, Udine, Italy*; [5]*Associazione Malati Reumatici - Friuli Venezia Giulia, Section - Udine, Udine, Italy*; [6]*Zeta Research srl, Clinical Project Management & Quality Assurance, Trieste, Italy*; [7]*University of Udine, School of Nursing, Department of Medicine, Udine, Italy*; [8]*Istituto Superiore di Sanità, Unit of Human Nutrition and Health, Department of Food Safety Nutrition and Veterinary Public Health, Rome, Italy*; [9]*University of Padova, Unit of Biostatistics, Epidemiology and Public Health, Department of Cardiology, Thoracic and Vascular Sciences, Padova, Italy*

Background: COVID-19 is a systemic viral disease currently spreading as a pandemic. A more severe course and prognosis of COVID-19 in systemic lupus erythematosus (SLE) and vasculitis has been reported (1).
Several papers have focused on the concerns, healthcare-related behaviors and psychological impact of COVID-19 pandemic among patients with rheumatic diseases, and specifically on SLE patients, showing a trend towards remarkable psychological distress (2-4). To date, no investigation on the psychological effects of quarantine strategy on SLE patients has been carried out.
Objectives: To investigate the psychological impact of the lockdown measures adopted in Italy to contrasting the COVID-19 outbreak, on patients with SLE as compared to the general population.
Methods: Patients affected by SLE were given an online questionnaire focused on psychological impact and self-perception during the lockdown measures contrasting the COVID-19 outbreak. The survey was focused on COVID-19 concerns, emotional impact, self-perception and changes in daily living activities and relationships. Results were compared with those of PRESTO (imPact of quaRantine mEasures againST cOvid19) project, an Italian survey, which used the same questionnaire, directed to the general population, with or without chronic diseases. A propensity matching procedure has been applied to LEPRE (Lupus Erythematosus PRESTO project) cases and the PRESTO responders with a ratio of 2 versus 1.
Results: 64 patients and 1114 unselected people completed the survey. After the matching procedure, patients were compared to 128 matched adults. Missing data were below 6%. The median age among patients was 43 years (I-III interquartile range 35-54.5), 88% were female and 100% Caucasian. The SLE subjects live mainly in detached houses (38/64 vs 348/1114, p<0.0001), having access to a private garden (52/64 vs 625/1112, p<0.0001) and also owning a pet (43/64 vs 508/1114, p<0.001), in comparison with the PRESTO sample living mainly in flats. The psychological impact measured by IES-R, GHQ.12, and CEDS scores were not statistically different between patients and the general population, such as globally COVID-19 concerns and feelings. However, patients perceived more difficulty to find some free time and enjoy it (13/60 vs 48/121, p=0.01) and to be able to solve own problems (47/61 vs 71/120, p=0.02). On the contrary, patients felt more able to cope with the problem and less sad or depressed in comparison with the PRESTO group (17/61 vs 13/120, p=0.003). Moreover, patients missed playing sports/exercise less than general population (12/63 vs 46/128, p=0.02), while they felt more the distance from family and relatives (45/63 vs 42/86, p<0.0001).
Conclusion: the COVID-19 pandemic didn't unveil a greater psychological fragility of people living with SLE than the others. By contrast, a coping strategy, including the role of the family and the lifestyle, contributes to resilience of SLE in difficult scenarios such as those presented by the pandemic.

CLINICAL FEATURES AND THE COURSE OF COVID-19 IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

A. Avanoglu Guler[1], T. Yüce İnel[2], H. Karadeniz[1], R. Bilici Salman[1], H. Satış[1], H. Küçük[1], M. A. Ozturk[1], B. Goker[1], S. Haznedaroglu[1], İ. Sari[2], T. Kasifoglu[3], A. Tufan[1]. [1]*Gazi University Faculty of Medicine Hospital, Rheumatology Department, Ankara, Turkey*; [2]*Dokuz Eylul University Faculty of Medicine Hospital, Rheumatology Department, Izmir, Turkey*; [3]*Eskisehir Osmangazi University Faculty of Medicine Hospital, Rheumatology Department, Eskisehir, Turkey*

Background: The novel coronavirus 2019 (COVID-19) has a wide range of clinical presentation from asymptomatic or mild viral infection to severe life-threating complications, including acute respiratory distress syndrome (ARDS), which develop as a result of immune system dysregulation, exaggerated immune response, and cytokine release syndrome [1]. Familial Mediterranean Fever (FMF) is a hereditary autoinflammatory disorder characterized by dysfunction

of the innate immune system and excessive production of proinflammatory cytokines, including interleukin (IL)-1β, IL-6, interferon-gamma, and tumor necrosis factor-alpha, all of which have increased in severe cases in COVID-19 [1-3].
Objectives: The aim of this study is to report clinical characteristics and outcome of FMF patients with COVID-19.
Methods: This study included 48 consecutive FMF patients who were diagnosed COVID-19 by SARS-CoV-2 nucleic acid RT-PCR in nasopharyngeal swab or sputum, or symptoms and computed tomography findings suggestive for COVID-19. Data on demographic and clinical characteristics of FMF disease, clinical course and outcome of COVID-19 were evaluated.
Results: The median age of patients was 35.5 (29-43.5) years, ranging from 18 to 87 years. The median disease duration of FMF was 10 (6-16) years. The most common presenting symptoms and signs of patients during attacks were peritonitis (85.5%), fever (81.3%), and pleuritis (48%). Twelve (25%) patients had amyloidosis. Comorbidities were present in half of patients with ankylosing spondylitis (21%) and hypertension (17%) being the most frequently seen. Two-third of patients (66%) were in remission for FMF. The median dosage of colchicine treatment for FMF was 1.5 (IQR 1) mg/day. 90% of patients continued colchicine treatment for FMF during the COVID-19 course. The baseline characteristics and treatment modalities of patients were demonstrated in Table 1. Forty-six patients presented with at least one COVID-19 symptoms. Fever (73%), myalgia/arthralgia (69%), and cough (60%) were the most common symptoms. 16 patients were admitted at hospital, 5 of them required oxygen therapy and 2 patients with amyloidosis developed ARDS and went to intensive care unit (ICU) for invasive mechanical ventilation (IMV). One patient who had been followed-up at ICU died.
Conclusion: Our FMF patients with COVID-19 have similar clinical features and outcomes as general population. Dysregulation of innate immune system in FMF might not be risk factors for COVID-19. Besides, colchicine and IL-1 inhibitors intake might have protective and preventive effects on COVID-19 progression.

Table 1. Baseline characteristics, treatment modalities and outcome of patients

Age years, median (IQR)	39.4 (15)
Gender (F/M)	25/23
FMF Disease duration, years, median (IQR)	10 (10)
Mutations*	
Monoallelic mutation, n (%)	6 (14)
Biallelic mutation, n (%)	34 (81)
Homozygous M694V mutation	18 (43)
Heterozygous M694V mutation	15 (36)
Comorbidities, n (%)	24 (50)
FMF treatment	
Colchicine 1 mg/day, n (%)	17 (35.5)
Colchicine 1.5 mg/day, n (%)	18 (37.5)

POS1194 THE EFFECT OF SARS-COV-2 ON THE COURSE AND THE TREATMENT OF RHEUMATIC INFLAMMATORY DISEASES. EXPERIENCE FORM THE NORTHWESTERN GREECE

E. Pelechas[1], E. Kaltsonoudis[1], M. Migos[1], P. Karagianni[2], A. Kavvadias[3], P. Voulgari[1], A. Drosos[1]. [1]*University of Ioannina, School of Medicine, Greece, Internal Medicine - Division of Rheumatology, Ioannina, Greece*; [2]*University of Ioannina, School of Medicine, Greece, Laboratory Medicine, Ioannina, Greece*; [3]*University of Ioannina, School of Medicine, Greece, Gastroenterology, Ioannina, Greece*

Background: COVID-19 has been shown to significantly affect the vulnerable population [1,2]. Among them, patients suffering from inflammatory rheumatic diseases, and especially the immunosuppressed [3].
Objectives: to assess the effect of SARS-CoV-2 on the course and the treatment of rheumatic inflammatory diseases.
Methods: from February to December 2020, 46 patients with inflammatory rheumatic diseases were included (32 female) that got infected with the SARS-CoV-2. Mean age was 65 years old, 17 were smokers, 12 had arterial hypertension, 8 diabetes mellitus, and 3 hypothyroidism. Most of them had their comorbidities well-controlled and their rheumatic disease was in remission. More specifically, 24 patients had rheumatoid arthritis, 13 psoriatic arthritis, and 9 ankylosing spondylitis. All patients were under treatment with conventional synthetic (cs) and/or biological (b) disease-modifying anti-rheumatic drugs (DMARDs), while 7 of them were also on treatment with glucocorticoids (GC) (<5mg/day). Twenty-eight patients were on tumor necrosis alpha (TNF-α) inhibitors (19 as monotherapy), 4 on anti- interleukin (IL)-6 monotherapy, 3 on Janus Kinase (JAK) inhibitors plus on low dose methotrexate (MTX), and the rest (11 patients) were on a csDMARD with or without GCs.
Results: positive patients with the SARS-CoV-2, instructed to discontinue their immunosuppressive treatment, except GCs that were adjusted for their disease. Most patients (37 out of 46) had a mild disease course and their symptomatology was nothing more than a simple flu-like syndrome. Furthermore, on 9 of them olfactory dysfunction and gastrointestinal manifestations as well as low grade fever were noted but without the need of a hospital admission. On the other hand, only 5 patients needed hospitalization (2 on MTX monotherapy and 3 on combination therapy) due to dyspnea with low oxygen saturation (hypoxemia) and high fever. From those 5, 3 had a short in-hospital stay, while 2 developed pneumonia and a longer in-hospital stay was required in order to get the appropriate treatment. None of the patients did not require an intensive care unit admission. Finally, in 14 patients that got infected from February to May 2020, viral antibodies had been measured. All patients had high titres of IgG antibodies in their serum for as long as six months after their infection. Of note, none of the infected patients were smokers.
Conclusion: patients with rheumatic diseases that are in remission using low doses of GCs and DMARDs, have almost the same chances with the general population to have a serious course of their infection with the SARS-Cov-2. In addition, in these patients, the immune response appears to be adequate, both in the production and maintenance of antibodies, which appear to be maintained for at least 6 months after infection.

POS1195 ASSESSING ANTIBODY STATUS FOR SARS-CoV-2 IN PEOPLE WITH CORONAVIRUS INFECTION: A TIME COURSE STUDY IN PEOPLE WITH AUTOIMMUNE CONDITIONS

K. Biddle[1], S. Koushesh[1], A. Blundell[1], D. Clark[1], S. Krishna[1], N. Sofat[1]. [1]*St George's University of London, Institute for Infection and Immunity, London, United Kingdom*

Background: With the emergence of the global coronavirus pandemic, increasing concerns have been raised about the course of SARS-CoV-2 infection in people with immune-mediated disorders.
Objectives: In this study we aimed to assess the time course of proven SARS-CoV-2 infection, development of humoral immunity with detectable antibodies to the virus and evaluate any changes in antibody titres over time.
Methods: We recruited 114 participants in total who had potential symptoms of Covid-19 infection. Participants were recruited from rheumatology or inflammatory bowel disease (IBD) clinics from their records who attended a London Teaching hospital for care. Ethical Approval was in place for the study. Age- and gender- matched control participants without any underlying rheumatological condition/IBD were recruited as a comparator group. Clinical symptoms for Covid-19 infection were assessed using the Covid-19 Rheumatology Global

Alliance assessment criteria (https://rheum-covid.org/). Information about Disease Modifying Anti-Rheumatic Drug (DMARD) drug use was also recorded. Participants' serum samples were collected for quantitative serological assessment of antibodies to SARS-CoV-2 using the Mologic Enzyme-Linked Immuno-Sorbent Assay (ELISA) IgG kit. The optical density values were plotted aganist time using a normalisation as previously described (1). A cut-off above 0 indicated positive serology.

Results: A total of 114 subjects were recruited into the study. Subjects were recruited if they had suspected Covid symptoms. Of the population recruited, the total number subsequently testing positive for SARS-CoV-2 was n=59 (either on serology or PCR). The number of subjects with autoimmune conditions diagnosed with Covid-19 was 32, with 30 subjects being symptomatic (the asymptomatic 2 subjects were excluded from further analyses). Of the 30 symptomatic subjects, the average age was 56, with a female to male ratio of 19:11. The most prevalent diagnoses were RA (30%), Psoriatic Arthritis (16.7%), SLE (10%), sarcoidosis 10%), Ulcerative Colitis (10%), Crohn's disease (10%), seronegative inflammatory arthritis (6.7%), Sjogren's (3.3%) and Juvenile Idiopathic Arthritis (3.3%). The majority were on csDMARDs (60%), biologic DMARDs (20%), tacrolimus (3.3%) and the remaining 16.7% were not on DMARDs. Most subjects required treatment in hospital (56.7%), a smaller number required high dependency care (6.7%) and the rest were treated at home (36.6%). The majority required no oxygen (63.3%), with a further 30% requiring oxygen and 6.7% needed more supportive care i.e. CPAP/ventilation. We also had a matched control group (n=29) of subjects who developed SARS-CoV-2 but had no underlying autoimmune conditions. These subjects had a mean age of 55, female: male ratio 18: 11. Of these 31% had home management, 55.2% had ward level treatments and 13.8% had intensive care treatment. Of the controls, 48.3% did not require oxygen, 37.9% needed simple oxygen and 13.8% were on CPAP. A total of 35 subjects from the original study have attended for follow-up visits. Antibody titres for IgG using the Mologic ELISA detection assay were compared at two visits for the control and autoimmune group. Results showed that subjects with autoimmune conditions and those without who developed SARS-CoV-2 showed very similar antibody titres by optical density (OD) (Figure 1) and maintained antibody responses beyond 6 months in most cases.

Conclusion: Serological assays can assist in the understanding of disease severity of SAR-CoV-2 infection. They can be a useful tool for patient surveillance, especially in people who are on immunomodulatory drugs and are being seen in Rheumatology services. Future work is needed to assess the duration and potential protective nature of humoral antibody responses to SARS-CoV-2.

POS1196 COVID-19 VACCINE WILLINGNESS IN RA? RESULTS FROM THE RA LOUVAIN BRUSSELS COHORT

T. Sokolova[1], V. Pirson[1], T. Xavier[1], E. Curraj[2], L. Bricman[1], E. Sapart[1], S. De Montjoye[1], S. Dierckx[2], A. Avramovska[1], P. Durez[1]. [1]*Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCLouvain) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium*; [2]*CHU Mont-Godinne, UCLouvain, Rheumatology, Mont-Godinne, Belgium*

Background: Over 2 million deaths from the COVID-19 disease have been reported in the world. Since no antiviral treatment is available, the vaccination is the most important option to fight the SARS-CoV-2 infection. Patients living with rheumatoid arthritis (RA) affecting the immune system or under immunosuppressive agent will be considered as a high risk population and will start the vaccination shortly. But many patients could decline the vaccine for several reasons including safety concerns.

Objectives: The aim of this study is to evaluate the proportion of patients with RA who are favourable to COVID-19 vaccination, to know the reasons to decline and to analyse the characteristics of these patients.

Methods: We included patients with RA from the UCLouvain Brussels cohort who met the ACR/EULAR 2010 classification criteria. A simple and standard questionnaire was distributed to patients who attended rheumatology out patient and day care clinic from 14 december 20 to 14 januari 21. All patient and RA characteristics (Age, gender, education, smoking habits, disease duration, ACPA, RF, DAS28-CRP, HAQ and therapies) were collected at the same time.

Results: Data from 460 eligible RA patients were analyzed. The average age of the population is 58.21 years. 72% of the patients are women. 21% are smokers and 65% are positive for anti-citrullinated protein antibody (ACPA) with a mean DAS28-CRP of 2.39 and a mean HAQ of 0.821.

281 patients (61%) indicated they would receive the vaccine as soon as it is available. For the 179 patients (39%) who decline, the reasons for not having vaccine were no trust in the vaccine at this time (53%), fear of side effects (28%), opposition to vaccine (4%), previous SARS-CoV-2 infection (2%) and unknown (5%),

Interestingly, there were differences among RA patients not willing to receive the vaccine. Patient under the age of 50, women, low education grade, smokers, presence of RF/ACPA and treatment with a bioDMARD were less willing to receive the vaccine. No differences were observed for RA disease duration, HAQ and DAS28-CRP (see Table 1).

POS1197 IN DEPTH IDENTIFICATION OF RISK FACTORS FOR SEVERE COVID-19, REQUIRING HOSPITALIZATION, IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES: RESULTS OF A DUTCH NESTED CASE CONTROL STUDY (PRELIMINARY RESULTS)

M. Opdam[1], S. Benoy[2], L. M. Verhoef[1], S. Van Bijnen[3], F. Lamers-Karnebeek[4], R. A. M. Traksel[2], P. Vos[5], A. Den Broeder[1], J. Broen[2]. [1]*Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands*; [2]*Regional Rheumatology Center, Máxima Medical Center, Rheumatology, Eindhoven, Netherlands*; [3]*Elisabeth-TweeSteden Hospital, Rheumatology, Tilburg, Netherlands*; [4]*Bernhoven, Rheumatology, Uden, Netherlands*; [5]*Amphia Hospital, Rheumatology, Breda, Netherlands*

Background: Several risk factors for severe COVID-19 have been identified[1]. An important question is whether in addition to these generic risk factors, patients with a potentially altered immune response, either by disease (inflammatory rheumatic diseases (IRDs)) or use of immunomodulatory agents (IA), carry a higher or lower risk of severe COVID-19. In addition, several other potential risk factors for severe COVID-19 have been suggested, such as vitamin D status and specific medication (NSAIDs, ACE-inhibitors)[2].

Objectives: To identify risk factors for severe COVID-19, requiring hospitalization, in patients with IRDs.
Methods: Multicenter, unmatched nested case control study in four rheumatology centers in the Netherlands. Cases are IRD patients requiring hospitalization for COVID-19 between March 1st 2020 and May 31st 2020. Control patients are IRD patients not hospitalized for COVID-19 within this period and were included in a 1:4 ratio. Patient-, disease- and treatment characteristics were extracted (still ongoing) from electronic patient files, and a questionnaire was used to collect additional data (e.g. on behavioral aspects). Potential risk factors for severe COVID-19 were analyzed using unconditional logistic regression, corrected for confounders.
Results: 77 cases and 198 controls were included. 26 case patients died as a result of COVID-19, 14 were admitted to the ICU. Crude ORs for female sex, age, BMI and presence of one or more comorbidities were 0.46 (95% CI 0.27-0.29), 1.1 (95%CI 1.0-1.1), 1.0 (95%CI 0.98-1.1) and 3.0 (95%CI 1.7-5.2) respectively. Table 1 displays corrected OR, highlighted when OR <0.5/>2.0. Corrected ORs were not significantly increased for any IRD, but a trend for gout was present. Use of hydroxychloroquine (HCQ) shows a protective effect, while use of other csDMARDs than methotrexate or HCQ leads to a higher risk of severe COVID-19. Trends were present for increased risk for rituximab (RTX), glucocorticoids and ACE inhibitors, and protective effect for IL-6R blockers.
Conclusion: The outcomes of this study are in agreement with other research regarding risk of severe COVID-19 related to IRDs and use of IA[1]. The suggested increased risk of severe COVID-19 in RTX use is of concern and should be monitored closely. Strengths of this study include low bias due to behavioral effects as only cases early in the pandemic were included, completeness of the determinants of interest and ultimately, it provides answers to a relevant and urgent question.

POS1198 THE ROLE OF SOCS3 IN COLCHICINE ANTI-INFLAMMATORY EFFECT ON COVID-19 INFECTION

M. Y. Hachim[1], F. Alqutami[1], S. Hannawi[2]. [1]*Mohammed Bin Rashid University Of Medicine and Health Sciences, Basic Sciences, Dubai, United Arab Emirates*; [2]*Ministry of Health And Prevention MOHAP, Rheumatology, Dubai, United Arab Emirates*

Background: In the fight against COVID-19, the use of an old anti-gout agent which is inexpensive and easily administered (1). A meta-analysis suggests a definite benefit with the addition of colchicine in patients with COVID-19(2). It was suggested that colchicine can have efficacy for hospitalized patients with a severe course of COVID-19 and concurrent inflammatory rheumatic diseases who have a higher risk of venous thromboembolism (3). On the other hand, some reports suggested that colchicine is associated with an increased risk of infections (4). Currently, there are nine clinical trials using colchicine for COVID-19(5), nevertheless, the exact mechanism of action is not well understood.
Objectives: Using publicly available transcriptomic data profiling human cells' response to colchicine to identify core differentially expressed genes (DEGs) then examine the dynamics of the identified DEGs in different datasets of COVID-19 transcriptomics databases to suggest the possible mechanisms of action on the molecular level.
Methods: Gene Expression Omnibus was searched for human samples treated with colchicine compared to controls. GSE4090 dataset was identified where global gene expression of HUVEC (human umbilical vein endothelial cell line) cells exposed to various concentrations of colchicine (n=9) compared to controls (n=7). We reanalyzed this datset using GEO2R online tool to identify DEGs. The identified DEGs were searched in SARS-CoV-2 transcriptome datasets using metascape online tool to identify gene sets were the DEGs identified showed significant similarity.
Results: Fifty DEGs were identified in response to colchicine no matter what the concentration is used, (Figure 1A). Two gene sets (COVID323, RNA_Wilk_CD4+T-cells_patient-C2_Up [peripheral immune cells] and COVID008, RNA_Blanco-Melo_A549_Up[lung epithelial cells]) showed significant enrichment of the identified DEGs, (Figure 1B). SOCS3, ZC3H12C, CD55, GLIPR1, BACH1, PHLDA1, JUNB, NFKBIZ, and MYLIP were the shared genes between the identified DEGs, and the two gene sets with top enriched terms related to important immune-related pathways like IL-6, chemotaxis, leukocytes migration, cytokine release, and response to glucocorticoid, (Figure 1C). Only Suppressor of cytokine signaling 3 (SOCS3) was shared in the three datasets. SOCS3 expression was significantly downregulated in the HUVEC cells exposed to colchicine, (Figure 1D). Next, the normalized gene expression of SOCS3 from whole blood of 62 COVID-19 patients was compared to that of 24 healthy controls using (GSE15264) showed significant upregulation of SOCS3 in the blood of CVOID-19 patients indicating its role in COVID-19, (Figure 1E).

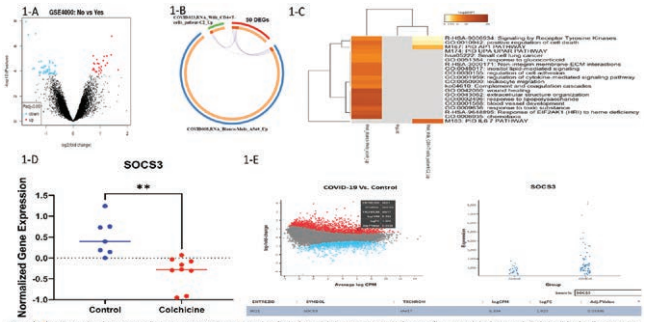

Figure (1-A): Volcano plot showing DEGs between GSE4090 dataset was identified where global gene expression of HUVEC (human umbilical vein endothelial cell line) cells exposed to various concentrations of colchicine (n=9) compared to controls (n=7). Figure (1-B):Overlap between gene lists: (a) only at the gene level, where purple curves link identical genes. The inner-circle represents gene lists, where hits are arranged along the arc. Genes that hit multiple lists are colored in dark orange, and genes unique to a list are shown in light orange. Figure (1-C): Heatmap of enriched terms across input gene lists, colored by p-values. Figure (1-D): The normalized gene expression of SOCS3 in HUVEC (human umbilical vein endothelial cell line) cells exposed to various concentrations of colchicine (n=9) compared to controls (n=7). Figure (1-E): The normalized gene expression of SOCS3 from whole blood of 62 COVID-19 patients was compared to that of 24 healthy controls using (GSE15264).

Conclusion: Our reanalysis showed that the possible beneficial effect of colchicine in COVID-19 patients might be through its direct effect on SOCS3 which is specifically upregulated in COVID-19 by IL6 and interferon (IFN)-gamma.

Klein[7]. *[1]Gernan Rheumatism Research Center Berlin, Epidemiology Unit, Berlin, Germany*; *[2]German Rheumatism Research Center Berlin, Epidemiology Unit, Berlin, Germany*; *[3]Charité – Universitätsmedizin Berlin, Department of Pediatrics, Berlin, Germany*; *[4]Universitätsklinikum Münster - UKM, Klinik für Kinder- und Jugendmedizin, Münster, Germany*; *[5]Krankenhaus im Friedrichshain, Klinik für Kinder- und Jugendmedizin, Berlin, Germany*; *[6]Deutsches Zentrum für Kinder- und Jugendrheumatologie, Kinder- und Jugendrheumatologie, Garmisch-Partenkirchen, Germany*; *[7]Allgemeine Kinder- und Jugendmedizin - Asklepios Klinik Sankt Augustin, Kinderrheumatologie, Sankt Augustin, Germany*; *[8]Olgahospital and Women's Clinic, Pädiatrie 2 - Allgemeine und spezielle Pädiatrie, Stuttgart, Germany*; *[9]University Hospital Carl Gustav Carus Dresden, Kinik und Poliklinik für Kinder- und Jugendmedizin, Dresden, Germany*; *[10]Tübingen University Hospital, Department of Pediatrics, Tübingen, Germany*; *[11]Tirol Kliniken GmbH, Department für Kinder- und Jugendheilkunde, Innsbruck, Austria*; *[12]Klinikum St. Georg, Leipzig, Klinik für Kinder- und Jugendmedizin, Leipzig, Germany*; *[13]Universitätsklinikum Halle (Saale), Klinik für Kinder- und Jugendmedizin, Halle (Saale), Germany*

Background: Although children and adolescents are less likely to develop COVID-19 and generally show milder disease courses, it is unclear what impact the SARS-CoV2 infection has on children and adolescents with rheumatic and musculoskeletal disease (RMD). Due to their underlying disease as well as therapeutic immunosuppression these patients may be at higher risk of being more severely affected by SARS-CoV2. Furthermore, SARS-CoV2 infection might trigger a flare of the underlying disease.

Objectives: To evaluate clinical characteristics and disease course of COVID-19 in children and adolescents with RMD and to analyze possible effects of SARS-CoV2 infection on the underlying disease under different therapeutic regimens.

Methods: Data from juvenile patients with RMD recorded via the SARS-CoV2 questionnaire within the National Pediatric Rheumatology Database and the registry for hospitalized children and adolescents with COVID-19 of the German Society for Pediatric Infectious Diseases were analyzed. In addition to age, sex and diagnosis, information was collected about the date and method of a positive SARS-CoV2 testing, reason for testing, on clinical manifestations, disease course, treatment and outcome of COVID-19, on drug therapy at the time of virus detection, on disease activity (NRS 0 – 10, 0 = best) of the underlying disease at the last visit before and after the SARS-CoV2 infection.

Results: From April 17th 2020 until January 25th 2021, data of 67 patients with RMD and confirmed SARS-CoV2 infection were collected. Mean age was 13.5 ± 3.9 years with equal sex distribution. The majority of patients were diagnosed with juvenile idiopathic arthritis (JIA, 64%), 12 (18%) patients had an autoinflammatory disease (FMF, CAPS, PFAPA, TRAPS) and 5 (7%) a connective tissue disease. Fifty-two patients (78%) were treated with a disease modifying antirheumatic drug (DMARD), 39% with a biological DMARD and 9% systemic glucocorticoids at the time of SARS-CoV-2 infection. Nineteen patients (28%) were tested for SARS-CoV-2 because of typical symptoms, the majority (67%) because of contact to an infected person. PCR was used most often (in 60 %).

52 patients (78%) developed symptoms of COVID-19, 15 patients remained asymptomatic. The most common symptom of COVID-19 was rhinitis (42%) and fever (38%), followed by fatigue (34%), taste/smell disorder (33%), sore throat (27%) and cough (23%).

Disease severity was graded as mild in 44 of 52 (85%) symptomatic patients, only two patients were hospitalized, one of whom required intensive care and died of cardiorespiratory failure 3 days after symptom onset. In 22 of 26 (85%) SARS-CoV2-positive patients, no relevant increase in disease activity (difference in NRS ≤ 1 before/after infection) of the underlying disease was observed 31 days after symptom onset (median, IQR 17-52 days). One patient, who had paused tocilizumab for 2 doses, experienced a flare of his seronegative polyarthritis 2 months after asymptomatic SARS-CoV-2 infection.

Conclusion: In our cohort, the clinical picture of COVID-19 in children and adolescents with RMD was similar to that of healthy peers. The majority of patients showed mild disease course with good outcome under various medications, however, one patient with a severe course of COVID-19 died. In addition, SARS-CoV2 infection does not appear to have a relevant impact on the underlying disease activity, whereas discontinuation of therapy might pose a risk of flare.

POS1200 IL-6 HIGHER LEVEL AFTER TOCILIZUMAB TREATMENT AS A PREDICTOR OF NOT-SURVIVAL IN COVID19 SEVERE PNEUMONIA: THE EXPERIENCE OF THE COVIBAS-STUDY

M. Gilio[1], S. B. Morella[1], M. A. Purgatorio[2], D. Palazzo[1], M. Frontuto[1], A. Erezanu[1], G. Mastroberti[1], A. Linzalone[3], G. Pietromatera[3], A. Fineo[3], M. Onofrio[3], G. Casciano[3], G. De Stefano[2]. *[1]San Carlo Hospital, Infectious Disease, Potenza, Italy*; *[2]San Carlo Hospital and Madonna delle Grazie Hospital, Infectious Disease, Matera, Italy*; *[3] Madonna delle Grazie Hospital, Infectious Disease, Matera, Italy*

Background: Cytokine release storm is the most fearsome complication associated with worse outcomes in COVID-19 patients with severe acute respiratory failure. In COVID-19 patients, interleukin-6 (IL-6) levels are significantly elevated. Blocking IL-6 preliminarily resulted in the improvement of this hyperinflammatory state.

Objectives: To define if the serum level of IL-6 early tested after tocilizumab treatment could be useful to distinguish non-survivors from survivors in patients with severe respiratory failure due to COVID-19 pneumonia.

Methods: This prospective cohort study was conducted at two referral hospitals for management of COVID-19 in Basilicata region, Italy: San Carlo Hospital, Potenza and Madonna delle Grazie Hospital, Matera. All consecutive patients with COVID-19 confirmed by RT-PCR testing of a naso-oropharyngeal swab. The enrollement period was from the 23rd of February to the 15th of August. 37 patients between all 124 underwent tocilizumab 8 mg/kg intravenously at baseline and after 24h. All patients were tested for serum IL-6, 24 hours before and 72 hours after tocilizumab infusion. Comparisons between survivors (Sv) and nonsurvivors (NSv) were performed.

Results: 21 patients were discharged, while 16 patients died. The main clinical or laboratory differences ($p < 0.001$) between the two groups at baseline were mean diseases duration before ward admission and serum troponine levels. IL-6 was not different at baseline ($p = 0.01$), while 72 hours post-tocilizumab IL-6 serum levels were significantly higher in non-survivors than in survivors [(Sv 21.1%)vs(NSv 64%) $p < 0.001$)]. Serum IL-6 post-tocilizumab could be considered a good predictor to discriminate Sv from NSv. At multivariate stepwise analysis including disease duration at admission, baseline serum troponine levels and IL-6 post TCZ) were independent predictors of not survival

Conclusion: Our data confirm the results of Quartuccio et al. In fact the highest burden of inflammation may be revealed by IL-6 levels after tocilizumab. Therefore repeated measurement of the serum level of IL-6 early after tocilizumab could be useful to distinguish non-survivors from survivors and support the choice of deeper targeting IL-6 in COVID-19 pneumonia.

POS1201

INCIDENCE AND OUTCOME OF COVID-19 IN ANCA-ASSOCIATED VASCULITIS: IMPACT OF COVID-19 IN PATIENTS UNDERGOING RITUXIMAB FOR MAINTENANCE

E. Treppo[1], M. Binutti[1], G. Del Frate[1], S. De Vita[1], L. Quartuccio[1]. [1]*University of Udine, Rheumatology Clinic, Udine, Italy*

Background: COVID-19 is an emerging infectious disease caused by SARS-CoV-2. Risk factors for the worst outcome in COVID-19 are pre-existing pulmonary and cardiovascular disease, while the impact of chronic immunosuppression has not yet completely been clarified (1).
Currently, there is no clinical evidence that chronically immunosuppressed rheumatic patients under biologic agent or a small molecule may have a higher risk of COVID-19 or a worse prognosis(2). However, the anti-CD20 antibody monoclonal rituximab may contribute to severe consequences, inhibiting the humoral response to SARS-CoV-2 and capacity to produce efficient antibodies against it (3,4). Rituximab is widely use in the treatment of ANCA-associated vasculitis (AAV). Nowadays, the incidence and impact of COVID-19 in AAV-patients are still unknown and, in particular, in AAV-patients who have been exposed to rituximab since the outbreak (5).
Objectives: Herein we evaluate the incidence and outcome of SARS-CoV-2 infection in our cohort of AAV-patients who had at least one visit in the year 2020.
Methods: We collected clinical data of 100 AAV-patients who had at least one visit in our Centre from February 2020 to December 2020, and we described cases of COVID-19 infection among them. The COVID-19 was proved by detection of SARS-CoV-2 RNA in nose-pharyngeal swabs. In case of infection, anti-SARS-CoV-2 IgM or IgG production was then investigated.
Results: Among 100 patients (53 females; 47 males) regularly followed, the median age was 65, and the mean (SD) duration of disease was 8.8 (6.8) years. The most frequent diagnosis was granulomatosis with polyangiitis (GPA) (56%), followed by granulomatosis eosinophilic with polyangiitis (EGPA) (31%), and microscopic polyangiitis (MPA) (13%). The mean (SD) BVASv3 at the onset of disease was 12.6 (5.6). More than half of the patients (59%) have had lung and/or ENT involvement at the onset of disease. Overall, 84% of our patients received immunosuppressive agents and 45% also received glucocorticoids (GC). Rituximab was administered in 15% of patients during the pandemic. COVID-19 was diagnosed in 2 cases (2%). Both patients have received rituximab as maintenance: the last rituximab infusion was on November 9, 2020 for patient 1 (female, 73 years old, GPA ANCA-PR3+) and was on August 17, 2020 for patient 2 (female, 74 years old, MPA ANCA-MPO+). Both patients had a BVAS 0 and negative ANCA antibodies at the time of the first positive nose-pharyngeal swab RT-PCR test, on December 24 and on November 25, respectively. Both patients were B-cell depleted and IgG levels were 455 mg/dL and 866 mg/dL, respectively. While patient 1 died due to critically ill COVID-19 pneumonia 25 days after the COVID-19 disease onset, patient 2 remained asymptomatic with nose-pharyngeal swab still positive on day 56 after the first detection. Anti-SARS-CoV-2 IgM or IgG antibodies above the cut-off (cut-off value 10 AU/mL) were absent in patient 1, while in patient 2 a low level of anti-SARS-CoV-2 IgG (39 AU/mL, cut-off value 10 AU/mL) was documented.
Conclusion: Prevalence of COVID-19 in AAV seems lower than in general population (prevalence of 29582/466700, 6.3%, in the same geographical area). Rituximab compromises the B-cells function and can lead to humoral immunodeficiency, causing the inability to produce anti-SARS-CoV-2 IgG antibodies. The timing of the last rituximab infusion and the levels of IgG can greatly affect the outcome. Patients who underwent anti-CD20 therapy are at higher risk of severe outcome in case of infection (3), and require prioritization for SARS-CoV-2 vaccination.

Background: COVID-19 is a major challenge worldwide. Although the risk for a severe disease course is low among children with COVID-19, symptoms may be exacerbated by underlying disease and/or immunosuppressive medication. We analysed clinical data from COVID-19 cases in among pediatric patients with juvenile idiopathic arthritis (JIA) in Germany reported to the BIKER registry.
Objectives: This is an analysis of clinical data for 56 COVID-19 cases reported to the German BIKER registry from 29 German pediatric rheumatology centers and clinics from February 2020 to January 2021.
Methods: The major task of the German BIKER (Biologics in Paediatric Rheumatology) Registry is surveillance of biologics used in pediatric rheumatology patients. Following the start of the COVID-19 pandemic in Germany, a survey was established to proactively interview all participating centers regarding the occurrence, presentation and outcome of SARS-CoV-2-infected children with rheumatic diseases. Initially, the interviews were conducted in weekly intervals, later bi-weekly.
A standardized Adverse Event of Special Interest form was developed requesting biographic data, pre-treatment, current medication, data on clinical presentation, course, treatment and outcome of COVID-19 pediatric rheumatology patients.
Results: In all, 56 patients with JIA and SARS-CoV-2 infection were reported (Table 1). Of these patients, 71% were 12 or more years old.

Table 1. Patient characteristics. COVID-19 positive patients.

	JIA patients, n=56 n (%)
Age	
0-5 years / 6-11years / 12-18years	3 (5.4) / 13 (23.2) / 40 (71.4)
JIA category	
• Systemic JIA	5 (8.9)
• Oligoarthritis JIA	9 (16)
• Polyarticular JIA	32 (57)
• Enthesitis-related JIA	2 (3.6)
• Psoriatic JIA	1 (1.8)
• Unknown	7 (12.5)
Uveitis (concomitant)	4 (7.1)
Treatment	
• DMARD / MTX	23/ 22 (41/39)
• Biologics	29 (52)
• TNF inhibitors	20 (36)
• Tocilizumab	5 (8.9)
• Abatacept	1 (1.8)
• Anakinra	1 (1.8)
• Ustekinumab	1 (1.8)
• JAK inhibitors	1 (1.8)
• Steroids	5 (8.9)
Asymptomatic	13 (23.2)
Hospitalized/ICU/Ventilation/Death	1/1/1/1 (1.8)

At the time of infection, 41% of the patients received conventional DMARDs and 52% received biologics (Table 1). Forty-four patients (79%) received either a conventional DMARD or a biologic. Most patients had a polyarticular course of their JIA (57%).
In 49 of the 56 cases (88%) COVID-19 was detected directly by PCR (n=46), by antigen test only (n=1) or an undisclosed method (n= 2). Six patients had detectable SARS-CoV2 antibodies and reported to have had typical symptoms. One patient tested negative but developed typical symptoms at approximately the same time a positive SARS-CoV-2 test was returned for a family member.
Symptoms were reported in 43 of the 56 patients (77%): fever n=15, rhinitis n=14, cough n=12, headache n=10, loss of sense of taste and/or smell n=9, pharyngitis n=8, fatigue n=5, musculoskeletal pain n=5, GI symptoms n=2 (abdominal pain n=1, diarrhoea n=1), dizziness n=3, encephalitis/seizure/respiratory failure/death n=1. Thirteen patients (23%) were asymptomatic.
A 3½ -year-old female patient initially diagnosed with systemic JIA developed intracranial oedema and respiratory failure. Her SARS-CoV2 PCR test was positive and pulmonary imaging displayed typical changes in lung texture. Before her SARS-CoV-2 infection, the patient was treated with methotrexate and low-dose steroids. Unfortunately, she died three days following hospital admission. Genetic testing revealed an inborn immunodeficiency. Except for this one patient, all other cases were treated as outpatients and no deaths were reported.
Conclusion: Apart from one patient with an inborn immunodeficiency who died from her COVID-19 infection, no case of hospitalization or severe COVID-19 was

reported in our cohort of JIA patients. At the time of COVID-19 diagnosis, nearly 80% of patients in our cohort had been treated with conventional DMARD and/or biologics. This seemed not to have a negative effect on severity or outcome of SARS-CoV2 infection.

POS1203 EFFECT OF THE COVID19 PANDEMIC ON RHEUMATOLOGIST PRESCRIPTION BEHAVIOUR OF NEW ADVANCED THERAPY: DATA OF THE TARDIS-RA REGISTRY, A NATIONWIDE BELGIAN BIOLOGIC REGISTRY

D. De Cock[1], P. Durez[2], V. Badot[3], R. Westhovens[1,4], P. Verschueren[1,4]. [1]*KU Leuven, Skeletal Biology and Engineering Research Centre, Leuven, Belgium*; [2]*Cliniques universitaires Saint-Luc, Rheumatology, Brussels, Belgium*; [3]*CHU-UVC Brugmann, Division of Rheumatology, Brussels, Belgium*; [4]*University Hospitals Leuven, Rheumatology, Leuven, Belgium*

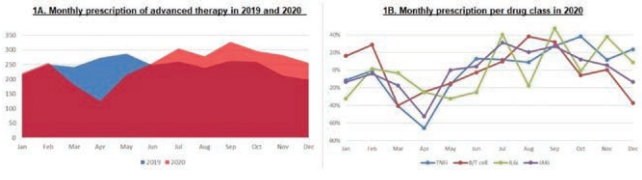
Background: Belgium suffered considerably from the COVID19 pandemic with high hospitalisation rates during 2 periods: a first wave in March and April 2020, and a second starting from October until the end of 2020. Measures of lowering social interaction were taken throughout 2020 and intensified during the first and second wave when needed. This pandemic could have influenced the access to care and advanced therapies for patients with Rheumatoid Arthritis (RA). In the electronic platform "Tool for Administrative Reimbursement Drug Information Sharing" (TARDIS), data from all Belgian RA patients on biologic and targeted therapy are collected during the submission of a request for initiation and prolongation of reimbursement for these drugs.

Objectives: to investigate the effect of the COVID19 pandemic on the monthly prescription behaviour of a new advanced therapy in 2020 by comparing it to 2019.

Methods: Patients were selected for this analysis if they started a new TNFi, B/T cell therapy, IL6 inhibitors or tsDMARD therapy in the TARDIS registry in 2019 or in 2020. Rheumatologists request reimbursement via the online TARDIS tool, which is considered here as a new drug prescription. Prescription behaviour was compared between 2019 and 2020, between bionaive and bioexperienced patients, and between the different drug classes

Results: In 2019, 2949 patients were prescribed any new advanced therapy, including 1153 TNFi, 469 B/T cell therapy, 436 IL6 inhibitors and 891 tsDMARDs. In 2020, 2998 patients were prescribed any new advanced therapy including 1233 TNFi, 382 B/T cell therapy, 496 IL6 inhibitors and 887 tsDMARDs.

On a monthly basis, on average 246 and 250 new advanced therapies were prescribed in 2019 and 2020 respectively. Monthly deviations from this average in 2019 ranged from -19% to +16%. Monthly deviations from this average in 2020 ranged from -50% to +30%. Figure 1A shows the monthly prescription of new advanced therapies in 2019 and 2020.



For bionaive and bioexperienced patients, the same trend can be noted. Monthly deviations in bionaive patients in 2020 ranged from -60% to +38%, compared to -18% to +21% in 2019. Monthly deviations in bioexperienced patients ranged from -40% to +25%, compared to -19% to +17% in 2019.

Comparison per drug class in 2020 show similar trends. IL6 inhibitors show a slightly different timeline than other drugs classes with other periods of less or more prescriptions changes compared to the other drugs classes. See Figure 1B.

Conclusion: The COVID19 pandemic did affect reimbursement requests for patients starting new advanced therapies in March and April 2020, especially for bionaive patients. The latter half of 2020 was apparently used to catch up with reimbursement requests for patients in need for advanced therapies resulting in similar total numbers of patients treated with advanced therapy in 2019 and 2020. The choice for a particular drug type was not clearly influenced by the pandemic. IL6 inhibitor use did seem to be affected differently by the pandemic, yet caution is warranted as these relatively large differences in proportional changes parallel small differences in actual drug numbers.

In sum, the observed effect of the pandemic on initiating advanced therapy during the first wave corresponds with Belgian governmental measures that restricted non-essential care which was less observed in the latter half of 2020.

POS1204 LOW POSITIVITY RATE IN ANTIBODY SARS-COV2 TESTS IN PATIENTS WITH RHEUMATIC DISEASES TREATED WITH RITUXIMAB. A CASE CONTROL STUDY OF A HIGH IMPACT SARS-COV2 INFECTION AREA.

A. García Fernández[1], P. Morán Álvarez[1], J. Bachiller-Corral[1], M. Vázquez Díaz[1]. [1]*Hospital Universitario Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: Diagnosis of previous SARS-COV2 infection may be challenging in immunocompromised patients.

Objectives: To analyze positivity rate to SARS-COV2 antibody tests (SC2AT) in patients diagnosed of rheumatic diseases (RMD) treated with Rituximab.

Methods: We conducted a case-control study of patients diagnosed of RMD followed in a referral hospital in Madrid, Spain. Positivity rate to IgG-SC2AT were analyzed in Rituximab-treated patients (RTX) compared with patients treated with TNF inhibitors (TNFi) and/or conventional DMARDs (cDMARDs) (N-RTX).

We included patients that received Rituximab in the previous year to a confirmed SARS-COV2 infection (defined as a positive polymerase chain reaction test (PCR) and/or compatible chest Xray), to a suspected SARS-COV2 infection (2 or more symptoms) or to SC2AT determination. Patients with RMD treated with other biological DMARDs (bDMARDs) rather than Rituximab or TNFi were excluded.

Results: We included 152 patients with RMD who underwent a SC2AT. Main characteristics are reported in Table 1.

Table 1. Main characteristics. AS, axial spondylitis; bDMARDs, biological disease-modifying anti-rheumatic drugs; cDMARDs, conventional DMARDs; COPD, Chronic obstructive pulmonary disease; CVD, Cardiovascular disease; IMM, immune-mediated myositis; JIA, Juvenile Idiopathic arthritis; PsoA, Psoriatic Arthritis; RA, Rheumatoid Arthrtis; SLE, Systemic Lupus Erythematosus; SSc, Systemic Sclerosis; SSj, Sjogren Syndrome.

- Confirmed	10 (20.8)[b]	20 (19.2)	

[a]Including gout, polymyalgia rheumatica.[b]Two patients had negative PCR but compatible symptoms and chest X-Ray.

Among RTX and N-RTX, 4/48 (8.3%) and 35/104 (33.7%) showed a positive IgG-SC2AT, respectively. Four out of 104 (38.5%) N-RTX tested positive without previous symptoms. No asymptomatic infection was diagnosed among RTX.
Univariable analysis showed a lower rate of positivity to SC2AT in confirmed and suspected infection among RTX [Positive IgG-SC2AT in confirmed infection: RTX 4/10 (40%), N-RTX 16/20 (80%); p=0.045. Positive IgG-SC2AT in suspected infection: RTX 0/3 (0%), N-RTX 15/18 (83.3%); p=0.015].
A logistic binary regression identified previous symptoms [OR 61.2, 95CI(13.3-280.6) p=0.0001], male sex [OR 4.8, 95CI(1.3-17.8) p=0.02], non-rituximab treatment [OR 19.7, 95CI(3.6-106.3) p=0.001] as independent factors associated with a higher probability of positive IgG-SC2AT. Age, previous PCR status, corticosteroid and cDMARD use showed no statistical significance. This model accounted for 47.6% of positive cases.
Conclusion: RTX had a lower rate of positivity to IgG-SC2AT compared to N-RTX. Previous symptoms, male sex and non-RTX treatment were independently associated with higher probability of positive IgG-SC2AT.

POS1205 THE IMPACT OF COVID-19 ON PATIENT MANAGEMENT AND PRESCRIBING STRATEGY ACROSS THE EU AND US: A REAL-WORLD SURVEY OF RHEUMATOLOGISTS, DERMATOLOGISTS, AND GASTROENTEROLOGISTS

E. Holdsworth[1], R. Lukanova[1], M. Hughes[1], J. Hall[1], J. Austin[1], G. Taylor-Stokes[1], J. Piercy[1]. [1]*Adelphi Real World, Real World Evidence, Bollington, United Kingdom*

Background: The COVID-19 pandemic is expected to have impacted patient management on a global level. However, the degree of impact on patient management and prescribing strategy in the fields of rheumatology, dermatology and gastroenterology is unclear.
Objectives: Assess the impact of COVID-19 on patient management and prescribing strategy across the EU and US, as described by rheumatologists, dermatologists, and gastroenterologists.
Methods: Data were drawn from physician surveys in France, Germany, Italy, Spain, UK and US between July and December 2020. Physicians completed an online or telephone survey assessing how COVID-19 has impacted type and frequency of consultations; choice and prescription of medication.
Results: 847 physicians took part; 355 rheumatologists, 200 dermatologists (Germany, Spain, UK, and US only), and 282 gastroenterologists. As a result of COVID-19, most physicians stated they have moved at least some patients to video or telephone consultations (70% rheumatologists; 55% dermatologists; 60% gastroenterologists) and reduced overall frequency of consultations with patients (59% rheumatologists; 64% dermatologists; 51% gastroenterologists) (Table 1).
35% of rheumatologists, 22% of dermatologists, and 14% of gastroenterologists described COVID-19 as changing the way they choose and prescribe medication, with differences observed between countries (Figure 1). Of those who stated they have made medication changes, rheumatologists stated changing medication to self-administration (62%) and not starting new patients on an advanced therapy (biologic DMARD or targeted synthetic DMARD) (58%) as most frequent. Dermatologists stated changes include changing treatment to more COVID-appropriate treatment (71%) and prescribing repeat prescriptions more regularly without consultation (56%). Gastroenterologists stated changes include changing medication to self-administration (55%) and prescribing a longer course of medication (48%).
Comparing across countries, for all specialties, the greatest changes were observed in the UK followed by Spain, with least changes in Germany and Italy.
Conclusion: There have been changes in the process of how healthcare is delivered, although treatment prescription was impacted to a lesser extent than consultation type and frequency. This varies across geographies, which may be due to differences in reported prevalence of COVID-19. Differences are also observed across specialities, which may be due to guidance received from specialty bodies. It is unknown what the long-term impact of changes in the management of patients due to COVID-19 will be on patient outcomes, satisfaction, engagement and adherence, and further research is needed.

POS1206 SEROPREVALENCE OF SARS-CoV-2 ANTIBODIES IN AUTOIMMUNE INFLAMMATORY RHEUMATOLOGIC PATIENTS

T. Eviatar[1,2], D. Levartovsky[1,2], V. Furer[1,2], A. Polachek[1,2], O. Elalouf[1,2], M. Zisapel[1,2], T. Halperin[1,3], D. Turner[1,4], D. Paran[1,2], S. Pel[1,2], S. Nevo[1,2], O. Elkayam[1,2]. [1]*Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv-Yafo, Israel*; [2]*Tel Aviv Sourasky Medical Center, Rheumatology Department, Tel Aviv, Israel*; [3]*Tel Aviv Sourasky Medical Center, Immunology Department, Tel Aviv, Israel*; [4]*Tel Aviv Sourasky Medical Center, Infectious Disease Department, Tel Aviv, Israel*

Background: Immune responses in AIIRD patients may be reduced and influenced by immunosuppressive treatments[1].The effect of immunosuppression on the mounting of SARS-CoV-2 antibodies in AIIRD is not clear.
Objectives: To assess the prevalence of SARS-CoV-2 antibodies in AIIRD patients and to define clinical factors affecting this prevalence.
Methods: Consecutive consenting AIIRD patients from the Rheumatologic department in Tel Aviv Medical Center participated in the study.
Patients answered a questionnaire and were tested for SARS-CoV-2 antibodies. A two stage antibody testing was done in order to increase specificity.
Results: The study included 560 AIIRD patients (229 RA, 149 PsA, 84 SLE, 55 vasculitidies, 40 SpA, 3 other CTD), of them 26 patients were found to have SARS-CoV-2 IgG antibodies (4.6%) (Table 1). This was more than double than a

previous prevalence in the same clinic population studied after the first wave of the pandemic in Israel, which was 2.07% (accepted for publication).

A lower rate of immunosuppression was found for positive SARS-CoV-2 IgG patients compared to negative serology patients (Table 1, p=0.009). There was also a trend for the subgroup of patients on biologic DMARDS (26.92% vs. 47% respectively, p=0.06).

Positive SARS-CoV-2 PCR test was reported and confirmed in 36 patients, of them 14 (38.89%) had negative serology. Patients who did not have antibodies had numerically more than double rates of glucocorticoids and bDMARDs treatment. The time between positive PCR test to positive serology test was significantly shorter (mean±standart deviation 75.57±40.44 days) than the time between positive PCR to negative serology test (130.79±86.47 (p=0.04) (Table 1 and Figure 1) suggesting a fading of the antibody response with time.

Conclusion: The prevalence of SARS-CoV-2 IgG was 4.6% in a population of AIIRD patients from a single tertiary medical center in Israel. SARS-CoV-2 seroprevalence tended to be low among AIIRD patients on immunosuppressive treatment, including in patients with a confirmed history of positive SARS-CoV-2 PCR, similar to other studies [3].

As in individuals without AIIRD, the mounting of SARS-CoV-2 IgG seems to fade with time.

Larger studies are needed to confirm the potential effect of immunosuppression on the antibody response in AIIRDs.

Table 1. ***Demographic and clinical characteristics of patients with negative and positive SARS-CoV-2 IgG, and in the subgroup with positive SARS-CoV-2 PCR test***

	Total population (n=560)			Positive PCR population (n=36)

SARS-CoV-2, severe acute respiratory syndrome-coronavirus-2; IgG, immunoglobulin G; PCR, polymerase chain reaction; n, number; 95%CI, 95% confidence interval; GC, glucocorticoids; csDMARDS, conventional synthetic disease modifying antirheumatic drugs; bDMARDS, biologic disease modifying antirheumatic drugs.

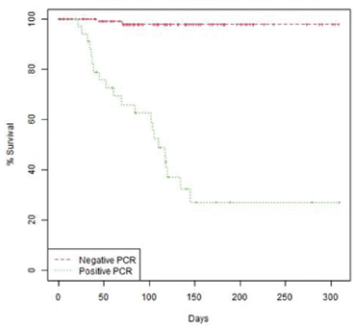

Figure 1. *Kaplan-Meier plot of SARS-CoV-2 IgG survival in days from SARS-CoV-2 PCR test*
There were 160 negative SARS-CoV-2 PCR tests with 2 positive serologies among them, and 35 positive SARS-CoV-2 PCR tests with 21 positive serologies among them (for 3 patients time between PCR test and serology was unknown). The median survival of SARS-CoV-2 serology in PCR positive patients was 110 days and was not applicable to PCR negative patients (p<0.0001).

REAL WORLD POPULATION-BASED ASSESSMENT OF COVID-19 OUTCOMES AMONG RHEUMATOID ARTHRITIS PATIENTS USING BIOLOGIC OR SYNTHETIC DMARDs

L. Wegrzyn[1], K. Winthrop[2], S. Kim[3], Y. Ye[1], C. Huisingh[1], W. Krueger[1], A. Maniccia[4], R. Kilpatrick[1]. [1]*AbbVie, Global Epidemiology, Pharmacovigilance, & Patient Safety, North Chicago, United States of America*; [2]*Oregon Health & Science University, Division of Infectious Diseases, Portland, United States of America*; [3]*Brigham and Women's Hospital/Harvard Medical School, Division of Rheumatology, Inflammation, and Immunity, Boston, United States of America*; [4]*AbbVie, Medical Affairs, North Chicago, United States of America*

Background: While some risk factors for severe COVID have been identified for patients with rheumatic diseases,[1] few studies have investigated whether outcomes differ based on the type of rheumatoid arthritis (RA) treatment. Most existing reports have been limited to individual centers or voluntary reporting registries.[2,3]

Objectives: To compare the occurrence of hospitalizations following COVID-19 diagnosis among patients with RA treated with various classes of DMARDs.

Methods: A cohort of patients with confirmed COVID-19 (ICD10 diagnosis code or positive PCR or antigen test result) were identified within a large US electronic health record (EHR) dataset (Optum, Inc.) during the time period Feb 1, 2020 through Oct 14, 2020. From these, we identified RA patients (ICD10 RA diagnosis code) with treatment (most recent of JAK inhibitor [JAKi], biologic [bDMARD] or conventional synthetic [csDMARD] only) within the 12 months prior to COVID-19 diagnosis (i.e., index). The primary outcome was any hospitalization on or within 30 days after COVID-19 diagnosis. Multivariable logistic regression models compared users of JAKi's to non-TNFi bDMARDs and csDMARDs (separately), as well as users of TNFi's to non-TNFi bDMARDS and csDMARDs (separately), and were adjusted for age, gender, index month and baseline corticosteroid use. Sensitivity analyses included restriction of prevalent treatment use to within 180 days prior to COVID-19 diagnosis and restriction of csDMARDs to a group without hydroxychloroquine or chloroquine.

Results: The study included 910 RA patients on DMARD treatment who were diagnosed with COVID-19 (mean age ± SD: 61±15, 80% female, 62% white. Of those, 26% (n=240) were hospitalized on or within 30 days after COVID-19 diagnosis. The proportion of patients hospitalized was highest in non-TNFi bDMARD users (37/87; 43%), followed by csDMARDs users (161/581; 28%) and lowest in JAKi (13/68; 19%) and TNFi users (29/174; 17%). In multivariable-adjusted models, no differences in risk of hospitalization were found comparing JAKi users to csDMARD users (aOR=0.71; 95% CI 0.37-1.36) or TNFi users to csDMARD users (aOR=0.67; 95%CI 0.43-1.06). Compared to non-TNFi bDMARD users, JAKi use and TNFi use was associated with reduced risk of hospitalization (JAKi aOR=0.32; 95%CI 0.14-0.71; TNFi aOR=0.34; 95%CI 0.18-0.62). Age and corticosteroid use were positively associated with 30-day hospitalization in all models. Results of sensitivity analyses were consistent with the main findings.

Conclusion: In this study, roughly a quarter of RA patients with recent DMARD treatment were hospitalized within 30 days after COVID diagnosis. Patients treated with JAKi and TNFi therapies experienced the lowest risk of hospitalization, with risk of hospitalization significantly lower than non-TNFi bDMARDs. However, recent therapy recorded in the EHR may not reflect exposure at time of COVID-19 diagnosis and small sample size per treatment may limit interpretation.

POS1208

EPIDEMIOLOGY AND OUTCOMES OF PATIENTS WITH RHEUMATIC DISEASES AND SARS-CoV-2 INFECTION: DATA FROM THE ARGENTINEAN SAR-COVID REGISTRY

C. A. Isnardi[1], R. Quintana[1], K. Roberts[1], V. V. Castro Coello[2], A. A. Reyes[2], Y. Tissera[2], M. Cosatti[2], R. Rojas Tessel[2], J. Scafati[2], T. Barbich[2], M. S. Gálvez Elkin[2], G. F. Rodriguez Gil[2], S. Moyano[2], M. L. Werner[2], J. Rebak[2], J. Morbiducci[2], V. Martire[2], M. S. Castaño[2], C. Dieguez[2], G. C. Subils[2], G. Pons-Estel[1]on behalf of SAR-COVID Registry. *[1]Argentina Society of Rheumatology, Research Unit, AAQ, Argentina*; *[2]On behalf of SAR-COVID Registry, Rheumatology, Ciudad Autónoma de Buenos Aires, Argentina*

Background: In the last time, many papers about SARS-CoV-2 have been published in the world. However, data from latinamerican patients is still scarce. In order to assess the impact of SARS-CoV-2 infection in patients with rheumatic diseases in our country and contribute to the global knowledge about the effect of immunosuppressive therapies in this group, the Argentine Society of Rheumatology has developed the National Registry of Patients with Rheumatic Diseases and COVID-19 (SAR-COVID).

Objectives: The aim of this study was to evaluate clinical characteristics and outcomes of SARS-CoV-2 infection in patients with rheumatic diseases, treated or not with immunomodulators and/or immunosuppressants.

Methods: SAR-COVID is a national, multicenter, prospective and observational registry, in which patients, ≥18 years of age, with a diagnosis of a rheumatic disease who had SARS-CoV-2 infection (PCR or positive serology) are consecutively included between August 13, 2020 and January 17, 2021. Sociodemographic data, comorbidities, underlying rheumatic disease and treatment, clinical characteristics, complications, laboratory and treatment of the SARS-CoV-2 infection were recorded. Hospitalization, mechanical ventilation requirements and death were assessed to evaluate COVID-19 outcome. Statistical analysis: Descriptive analysis. Chi^2 or Fischer test and T test or Mann-Whitney U test or ANOVA, as appropriate. Multiple logistic regression.

Results: A total of 525 patients were included, 80.4% were female, with a median age of 52 years (IQR 40-62). Comorbidities were reported in half of them (53.3%). The most frequent rheumatological diseases were rheumatoid arthritis (40.4%) and systemic lupus erythematosus (14.9%). At the time of the infection, most of them were in remission or in minimal/low disease activity (68.2%) and 72.9% were receiving immunosuppressive or immunomodulatory treatment.

Symptoms were present in 96% of the patients, the most frequent being fever (56.2%), cough (46.7%) and headache (39.2%). During infection, 35.1% received some pharmacological treatment, dexamethasone (20%) the most frequently used. One third (35.1%) of the patients were hospitalized, 11.6% were admitted to the ICU, 10.1% needed mechanical ventilation and 6.9% died due to COVID-19. Complications were reported in 12.4%, being acute respiratory distress syndrome the most prevalent (8.8%).

Patients over 65 years of age were more frequently hospitalized, admitted to the ICU, needed mechanical ventilation and died due to COVID-19 (50% vs 31.4%, 22% vs 9%, 16.3% vs 5.2%, 14% vs 5%, respectively; p<0.001 in all cases). Similar results were seen in patients with vasculitis (57.7% vs 33.9%, 46.2 vs 9.8%, 34.6% vs 6 %; 30.8% vs 5.6%, respectively; p< 0.001 in all cases) and those with moderate/high disease activity (55.7% vs 26.5%, 21.3 vs 7.8%, 17.2% vs 4.2 %; 17.2% vs 4.2 %, respectively; p< 0.001 in all cases). Patients with APS were more frequently admitted to the ICU (29.4% vs 11%, p= 0.037). The presence of comorbidities was associated with higher hospitalization (46% vs 22.6%, p<0.001), admission to the ICU (17.2% vs 5.9%, p<0.001) and mechanical ventilation (10.2% vs 4.6%, p= 0.028). Immunosuppressive treatment was not associated with worse outcomes.

Conclusion: In this cohort of patients with a wide distribution of rheumatic diseases, we have found clinical characteristics similar to those reported by other international cohorts. Compared with national data, the mortality reported in these patients is higher. However, it should be noted that these are early data collected during isolation and that there may be an underreporting of asymptomatic patients or with mild symptoms who do not attend the rheumatologist.

Older patients, those with comorbidities, with vasculitis and with higher disease activity showed poor COVID-19 outcomes.

POS1209

SUCCESSFUL TREATMENT OF SEVERE COVID-19 PNEUMONIA AND CYTOKINE RELEASE WITH SIMULTANEOUS TOCILIZUMAB AND ANAKINRA WITH ONE-MONTH FOLLOW-UP

H. Haibel[1], J. L. Vahldiek[2], S. Angermair[3], M. Schumann[4], B. Siegmund[5], D. Poddubnyy[1], T. Schneider[6]. *[1]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Rheumatology, Berlin, Germany*; *[2]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Radiology, Berlin, Germany*; *[3]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Anestesiology and Surgical Intensive Care, Berlin, Germany*; *[4]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Gastroenterology, Berlin, Germany*; *[5]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Gastroenterology, Infectiology and Rheumatology, Berlin, Germany*; *[6]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Infectiology, Berlin, Germany*

Background: Severe and life threating COVID-19 pneumonia is often characterized by local and systemic immune-mediated hyperinflammation At the early disease stage activated monocytes are migrating to the lung and cause the typical opac infiltrates, which lead to an reduction of oxygen uptake. These pathophysiological observations and the fact that corticosteroids are so far the only drug, which has shown significant improvement, was the rationale use this combination anti-inflammatory drugs in severe Covid-19 disease. Interleukin (IL)-6 and IL-1 blockade alone, respectively showed contradictory results in severe COVID-19 pneumonia that might be related to the differences is patient populations (early vs. late stage) and to the fact that blockade of just one cytokine might be not sufficient against the cytokine storm.

Objectives: Here we report results of an open-label treatment with a combination of an IL-6 receptor blocker tocilizumab and an IL-1 receptor antagonist anakinra in patients with early (up to 10 days since symptom onset) severe COVID-19 pneumonia with evidence of cytokine release.

Methods: Adult patients with, according to World Health Organisation criteria, severe to critical COVID-19 infection associated pneumonia and cytokine release, requiring oxygen supplementation and evidence of rapid deterioration and decrease of oxygen saturation to ≤ 95% hospitalized between May 2020 and December 2020 were treated with tocilizumab 8 mg/ kg up to 800 mg intravenously and anakinra 100 to 300 mg for 3 to 5 days, starting at the same day. We excluded patients with a symptom duration of > 10 days, patients with evidence of bacterial infection, indicated by an elevated procalcitonin serum level, patients with severe pre-existing lung disease such as severe COPD or heart failure of > II according to the NYHA classification and patients > 80 years. Laboratory parameters and chest CT were performed on initial presentation and one month after treatment. A semi-quantitative CT score was calculated based on the extent of lobar pneumonia involvement (0:0%; 1, < 5%; 2:5-25%; 3:26-50%; 4:51-75%; 5, > 75%; range 0-5; global score 0-25) for each time point.

Results: 15 patients with severe to critical COVID-19 pneumonia and signs of cytokine release, mean age 55 (range 31-79) years, all male, with a mean

symptom duration of 6 (range 4-10) days were treated. Mean oxygen saturation was 86% (range 76-95%) before initiating therapy. Mean ferritin was 1297 µg/l (range 347 – 2734), mean IL-6 112 ng/L (range 2.2 – 607.4) and CRP 82.4 mg/L (range 36.4 – 125). In all patients we were able to prevent them from intubation and mechanic ventilation, none of our patients died. Fife patients did not need to be referred to the intensive care unit at all, while 9 patients received noninvasive ventilation and high-flow nasal oxygen support. All patients showed typical imaging features of COVID-19 pneumonia at baseline (BL) according to the Radiological Society of North America (RSNA) chest CT classification system. The mean of the global chest CT severity score at BL was 13 (range 7-20) and decreased to 6 (range 0-16) within 1 month which corresponded to a mean reduction of 58%. Chronic fibrotic pulmonary changes were not seen in any patient at BL and after 1 month mild changes were observed in 6 patients. One patient experienced lower abdominal pain, urinary tract infection, gastrointestinal bleeding due to antrum ulcers Forrest III, in another patient atrial fibrillation, urinary tract infection and apoplexy were observed.

Conclusion: In our case series, all patients treated with the combination tocilizumab and anakinra recovered fast and sustained without major infectious side effects, indicating that early interruption of cytocine release might be very effective and safe in preventing patients from mechanical ventilation, death and long-term damage.

Image 1: Chest CT of a patient with active COVID-19 infection before and one month after treatment with a combination of tocilizumab and anakinra

POS1210 PREVALENCE OF COVID-19 AMONG PATIENTS WITH RHEUMATIC DISEASES: AN OBSERVATIONAL SURVEY DURING THE TWO WAVES IN ITALY

S. Fasano[1], I. Pantano[1], D. Mauro[1], D. Capocotta[2], D. Iacono[1], E. Gaggiano[1], M. D. Pasquale[1], G. Rozza[1], C. DI Vico[1], A. Ruggiero[1], E. Tirri[2], F. Ciccia[1].
[1]University of Campania L. Vanvitelli, Rheumatology Unit, Department of Precision Medicine, Naples, Italy; *[2]Ospedale S. Giovanni Bosco, U.O.S.D. di Reumatologia, Naples, Italy*

Background: The new coronavirus 2 (SARS-CoV-2) disease 2019 (COVID-19) is a source of concern for the management of patients suffering from rheumatic and musculoskeletal diseases (RMDs) treated with immunomodulatory therapies (1).

Objectives: We aimed to analyze the prevalence of SARS-CoV-2 infection in patients with RMDs living in Italy.

Methods: During the first wave (March-May 2020) and during the second wave (October-December 2020) of COVID-19, we conducted a survey to investigate the incidence of SARS-CoV-2 infection in patients with RMDs followed at the Rheumatology Unit of the University of Campania, Italy. The demographic data, medication use, the frequency of respiratory symptoms and the incidence of COVID-19 confirmed by nasopharyngeal swab were collected with questionnaires administered by phone. The prevalence of COVID-19 of our cohort was compared to that of the general population (2).

Results: During the first wave, we collected data from 900 patients with RMDs (Table 1): 320 patients with rheumatoid arthritis (RA), 295 patients with spondyloarthropathies (SpA), 283 patients with systemic lupus erythematosus (SLE), 2 patients with vasculitis. 546 (60%) were treated with bDMARD/tsDMARDs. Overall, a total of 11/900 (1%) cases were tested for COVID-19 due to compatible symptoms. 2 (0.2%) adult patients treated with bDMARDs were registered as swab test positive by PCR for COVID-19. 2 patients without confirmed COVID-19 developed pneumonia that required admission to hospital. No deaths occurred among the patients with confirmed COVID-19.

During the second wave, data were collected from 470 patients who accepted to take part of the study (Table 1). 49 presented with symptoms that were compatible with COVID-19. 139 patients were tested whereas 30 patients (6%) had a swab confirmation of SARS-CoV-2 infection. Among them, 16 (53%) were treated with bDMARDs and a patient was treated with tofacitinib. we found no increase in COVID-19 prevalence in patients treated with bDMARD/tsDMARDs (p>0.05). A patient with SLE developed pneumonia that required admission to hospital and died.

Lacking distinct prevalence data between first and second waves, we found no differences in total COVID-19 prevalence between general population living in Campania (215.752/5.802.000; 3.7%) and patients with RMDs (32/900; 3.5%). However, we had a significant increase in COVID-19 prevalence in our cohort during the second wave compared to the first. Nevertheless, no increase in mortality or hospitalization was recorded, confirming the safety of immunomodulatory therapies in patients with RMDs.

Conclusion: In this cohort of patients with RMDs in a geographical region with a high prevalence of COVID-19, the risk of SARS-CoV-2 infection does not appear different from that observed in the general population.

POS1211 IDENTIFICATION OF COMMON FUNCTIONAL PATHWAYS IN PATIENTS WITH LUPUS AND COVID-19 BY TIME-SERIES ANALYSIS

Y. LI[1,2,3], S. X. Zhang[1,2,3], J. Qiao[1,2,3], Q. Wang[4,5], S. Song[1,2,3], R. Zhao[1,2,3], Y. Zhang[1,2,3], T. Cheng[1,2,3], M. J. Chang[1,2,3], G. Y. Liu[1], J. Luo[1], P. F. He[5], X. LI[1,2,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; *[2]Shanxi Li Xiaofeng Medical Groups, Department of Rheumatology, Taiyuan, China*; *[3]Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; *[4]Shanxi Medical University, Basic Medical College, Taiyuan, China*; *[5]Shanxi Medical University, Medical Data Sciences, Taiyuan, China*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disorder characterized by abnormal activity of the immune system, producing the autoantibodies directed against nuclear and cytoplasmic antigens[1]. Infection is known as one of the common trigger factors for SLE. Coronavirus disease in 2019 (COVID-19), a severe acute respiratory syndrome, is now spreading rapidly throughout the world[2].Though previous studies have addressed the susceptibility of lupus patients to the virus but how patients with SLE deal with COVID-19 is unclear up until now.

Objectives: To clarify the common pathogenesis of SLE and COVID-19, and find the appropriate treatment for Lupus and prevent COVID-19.
Methods: The transcription profile of SLE (GSE38351) and COVID-19 (GSE161778) were obtained from the Gene Expression Omnibus database (GEO). R package was used to find differentially expressed genes (DEGs) between lupus patients and HCs. After background adjustment and other pre-procession, DEGs were extracted from the peripheral blood of patients with COVID-19 at three different disease progression(moderate, severe and remission status). The Short Time-series Expression Miner (STEM) was used to cluster and compare average DEGs with coherent changes. The different expression patterns of time-series genes (TSGs) were also compared among these patients. GO and KEGG pathway enrichment analysis of TSGs and DEGs were performed by Metascape.
Results: Compared with HC, patients with SLE expressed 977 DEGs, which were mainly associated with defense response to virus, Epstein-Barr virus infection and response to interferon-γ(INF-γ) (Figure 1a). As for COVID-19 patients, there were 1584 DEGs obtained when compared with those of HCs ($P < 0.05$) (Figure 1b). Gene landscapes suggested the signatures of COVID-19 patients gradually changed during the disease progression, and gradually converge to HCs signatures. Time-series genes in the three stage of disease had different expression patterns and functions. A total of 959 TSGs in profile 3 showed a stable-stable-decreasing expression trend and significantly associated with INF signaling pathway (Figure 1c,1d). Interestingly, patients with SLE and COVID-19 shared common pathways such as INF-γ related functional pathway.
Conclusion: INF-γ is an important common node of SLE and COVID-19. Controlling the production of INF-γ not only has therapeutic effect on SLE patients, but also may prevent COVID-19.

POS1212 SARS-CoV-2 INFECTION AMONG PATIENTS WITH BEHÇET'S SYNDROME

I. Mattioli[1], A. Bettiol[1], M. L. Urban[1], E. Silvestri[1], D. Malandrino[1], A. Palermo[1], F. Fagni[1], D. Prisco[1], G. Emmi[1]. [1]*University Hospital Careggi, Department of Experimental and Clinical Medicine, Florence, Italy*

Background: Studies on SARS-Cov-2 in Behçet's syndrome (BS) patients are limited to two small case series from European centres.[1,2]
Objectives: We aimed to assess the prevalence of SARS-CoV-2 infection among Italian BS patients referring to Careggi University Hospital (Florence, Italy) and to evaluate the possible association between BS disease activity and treatment and the risk of Sars-CoV-2 infection among patients with BS.
Methods: A survey was conducted among 335 subjects diagnosed with BS and followed at Careggi University Hospital. Moreover, we conducted a case-control study. Cases were described in term of SARS-CoV-2 manifestation and prognosis, changes in disease activity, and in pharmacological therapies. Sars-CoV-2 negative controls matched 1:3 by sex, age and disease duration ± 5 years were randomly selected.
Results: Out of 335 BS patients, 12 declared to have/have had SARS-CoV-2 infection (3.6%). Eight were females (median age of 40 years), with a median duration of BS disease of 6 years; five had active disease. Nine patients reported fever, 9 myalgia/arthralgia, 5 gastrointestinal symptoms, 5 anosmia/ageusia, 5 cough, 3 headache, 3 fatigue, 2 breathlessness, panic attacks and dizziness (one each). Before infection, patients were treated with corticosteroids, colchicine, hydroxychloroquine (HCQ), traditional DMARDs [azathioprine (n patients = 4), methotrexate (n=1)], and biologics DMARDs [adalimumab (n=6), infliximab (n=2), secukinumab (n=1), and canakinumab (n=1)]. Therapy was suspended for a median time of 33 days in 9patients and resumed after a median time of 5 days from negativation. Regarding SARS-CoV-2 treatment, most patients started or increased corticosteroids, whereas heparin and antipyretic drugs were used in 4 and 5 patients, respectively. Cases were comparable to controls in terms of disease manifestations, activity, and immunomodulating therapy, with the only exception of corticosteroids, whose daily dose was significantly higher in cases (Table 1).
Conclusion: Prevalence of SARS-CoV-2 infection among Italian BS patients is 3.6%, similarly to the Italian general population (4.2%). Disease activity at time of infection was not associated with an increased risk of SARS-CoV-2 infection. Most patients interrupted biologic DMARDs. However, use of DMARDs, seemed not to be associated with an increased risk of SARS-CoV-2 infection, while higher doses of corticosteroids resulted to be more common among patients with SARS-CoV-2 infection as compared to controls. No patient required hospitalization or died. Our experience shows encouraging data about BS patients who do not appear be at greater risk of SARS-CoV-2 infection or complications than the general population.

Background: The COVID-19 pandemic has impacted the wellbeing of patients with Rheumatic and Musculoskeletal Diseases (RMDs).
Objectives: The aim is to assess emotional well-being and its associated factors in patients with RMDs during the first wave of the COVID-19 pandemic.
Methods: REUMAVID is an international collaboration led by the Health & Territory Research group at the University of Seville, together with a multidisciplinary team including patient organisations and rheumatologists. This cross-sectional study consisting of an online survey gathering data from patients with a diagnosis of 15 RMDs in Cyprus, France, Greece, Italy, Portugal, Spain, and the United Kingdom. 1,800 participants were recruited by patient organisations. Data was collected between April and July 2020. Participants were divided into two groups: 1) Participants with poor wellbeing (World Health Organization-Five Wellbeing Index (WHO-5) ≤ 50), 2) Participants with good wellbeing (WHO-5 >50). The Mann-Whitney and χ^2 tests were used to analyse possible relations between sociodemographic characteristics, lifestyle, and outdoor contact with wellbeing during the first wave of the COVID-19 pandemic. Univariate and multivariate binary logistic regression was used to determine the impact of the independent variables associated with poor wellbeing.
Results: 1,777 patients with 15 different RMDs were included. The mean age was 52.7, 80.2% female, 48.7% had a university degree, and 69.7% were married or in a relationship. The most frequent diagnoses were inflammatory arthritis (75.4%). 49.0% reported poor wellbeing. 57.7% of patients who belonged to a patient organisation reported good wellbeing (vs 46.3% who did not, p<0.001). Those who reported poor wellbeing had higher disease activity (51.4% vs 41.3%, p<0.001), a higher risk of anxiety (54.3% vs 41.7%, p<0.001) and depression (57.0% vs 42.1%, p<0.001), and poorer self-perceived health (53.0% vs 41.8%, p<0.001), compared to those who did not. A higher proportion of those who engaged in physical activity presented good wellbeing (54.0% vs 46.5%, p=0.012). 57.4% of the patients who were unable to attend their appointment with their rheumatologist reported poor wellbeing, compared to 48.2% who did attend (p=0.027). Patients who did not walk outside (56.2%) or who lacked elements in their home to facilitate outside contact (63.3%) experienced poor wellbeing (p<0.001). The factors associated with poor wellbeing were lack of elements in the home enabling contact with the outside world (OR=2.10), not belonging to a patient organisation (OR=1.51), risk of depression (OR=1.49), and not walking outside (OR=1.36) during the COVID-19 pandemic (Table 1).
Conclusion: Almost half of the patients with RMDs reported poor emotional wellbeing during the first wave of the COVID-19 pandemic. The lack of elements in the home that facilitate outdoor contact, not belonging to a patient organisation, the presence of anxiety, and not walking outside during the pandemic increase the probability of poor emotional well-being. These results highlight the importance of environmental factors and the role of patient organisations in addressing the effects of the pandemic and its containment measures.

Background: Levilimab (LVL) is a novel anti-IL6Rmonoclonal antibody against IL6Rα. Cytokine release syndrome plays the key role in the pathogenesis of a range of life-threatening conditions including the acute respiratory distress syndrome in severely ill COVID-19 patients. Thus, the use of LVL could be considered as anti-cytokine therapy with a potency to prevent the complications and progression of respiratory failure in COVID-19.
Objectives: We analyzed the changes in the serum concentrations of inflammatory markers (Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and IL-6) in patients treated with LVL or placebo as part of a phase III multicenter randomized double-blind placebo-controlled adaptive-design CORONA clinical study aimed to evaluate the efficacy and safety of LVL in subjects with severe COVID-19 (NCT04397562).
Methods: A total of 217 patients were enrolled in the study, 206 patients were randomized, and 204 patients received the investigational product (IP, LVL or placebo).
Study included men and non-pregnant women aged ≥18 years, hospitalized for severe COVID-19 pneumonia, receiving standard therapy according to the national guidelines. Patients with acute respiratory failure with the need in invasive respiratory support, septic shock, multiple organ failure or life expectancy

less than 24 hours could not participate in the study. The use of other monoclonal antibodies and glucocorticoids for the treatment of COVID-19 were not allowed. Subjects were stratified according to the CRP level (CRP ≤ 7 mg/L; CRP > 7 mg/L) and then randomized (1:1) into 2 groups to receive LVL 324 mg or placebo. LVL/placebo were administered as a single subcutaneous injection, investigator and patients were unaware of the received therapy.

Among secondary endpoints of the study changes from baseline in ESR, CRP and IL-6 concentrations were assessed. CRP level and ESR were measured before the IP administration and on Days 3, 5, 7, 14, 21, 29 and 30. Blood samples for the measurement of IL-6 concentration were obtained before the IP administration and then every day for 2 weeks after administration.

Results: We observed the pronounced decrease of ESR in LVL group compared to Placebo group. The difference was statistically significant on Days 3 and 7: the median ESR change from baseline was -3 mm/h and +3 mm/h on Day 3, -11 mm/h and -3.1 mm/h on Day 7, in LVL and Placebo groups, respectively (p=0.0319 and p=0.0110, Days 3 and 7). The statistically significant difference in the change of CRP level was detected between the groups on Day 3: -26.6±41.9 mg/L and -19.2±58.2 mg/L in LVL and Placebo groups, respectively (p=0.0241). Numerically the same dynamics of ESR and CRP was observed over entire study period.

The dynamics of IL-6 serum concentrations in LVL and Placebo groups was strikingly different. After LVL administration we detected the rapid significant increase in IL-6 concentration due to IL-6 receptors inhibition. Maximum change from baseline was observed on Day 3 (+91.9±117.7 pg/mL), on Day 14 the value was +31.9±62.7 pg/mL.

In the Placebo group, the IL-6 concentration increased slightly until Day 4 (+5,1±76,5 pg/mL), and then decreased significantly (-39.2±55.1 pg/mL on Day 14) due to clinical improvement in this group.

Conclusion: The significant differences in the dynamics of ESR, CRP and IL-6 after LVL administration compared to placebo confirmed the pharmacodynamic effect and its potency to prevent the excessive release of inflammatory substances in severely ill COVID-19 patients.

POS1215 INFLUENCE OF CONFINEMENT CARRIED OUT BY PATIENTS WITH AUTOIMMUNE AND IMMUNE-MEDIATED INFLAMMATORY DISEASE WITH BIOLOGICAL TREATMENT ON COVID-19 INFECTION

J. Font-Urgelles[1], S. Mínguez[1], B. Rodríguez-Diez[1], L. Creus-Vila[2], M. Esquius Rafat[2], X. Fusta Novell[2], J. Llao Guardia[3], E. Sainz Arnau[3], M. Lopez de Recalde-Martorell[1], A. Arnau Bartes[4], M. Sallés Lizarzaburu[1]. *[1]Althaia, Xarxa Assistencial Universitària de Manresa, Rheumatology, Manresa, Spain*; *[2]Althaia, Xarxa Assistencial Universitària de Manresa, Dermatology, Manresa, Spain*; *[3]Althaia, Xarxa Assistencial Universitària de Manresa, Gastroenterology, Manresa, Spain*; *[4]Althaia, Xarxa Assistencial Universitària de Manresa, Research department, Manresa, Spain*

Background: The disease caused by SARS-CoV-2 is a potentially serious infection. The autoimmune and immune-mediated inflammatory disease (AI/IMID) itself, its activity, the immunosuppression and the presence of comorbidities are associated with an increased risk of serious infections. At this moment the literature shows a similar risk of infection and severity compared to the general population. Some reports noted that these patients might adopt stricter measures of self-care protection than general population which could contribute to an incidence of infection lower than expected.

Objectives: To assess the incidence and clinical presentation of SARS-CoV-2 infection in our cohort of patients with AI/IMID treated with biological agents (BA) or Janus Kinasa (JAK) inhibitors. To analyse the association of the incidence and the type of confinement between the AI/IMID group and the general population.

Methods: A case-control study nested within a retrospective observational study was conducted from March 13th until April 23th, 2020 in Althaia, Xarxa Assistencial Universitària de Manresa. Subjects: cohort of AI/IMID patients followed by Rheumatology (inflammatory arthritis), Dermatology (psoriasis) and Digestology (inflammatory bowel disease) treated with BA/JAK inhibitors. Controls were selected from our Primary Care Centers. Main outcome: Type of confinement: strict: <1 outing / week with safety measures (SM), regular (2-3 outings with SM), lax (> 3 outings or face-to-face work with SM) and without confinement (without SM). Secondary outcome: SARS-CoV-2 infection: confirmed (PCR and/or positive serology), probable (severe illness requiring admission without PCR/serology or mild moderate with epidemiological contact) and possible (mild infection without microbiological check nor epidemiological contact); as well as severity according to the WHO.

Results: 367 patients and 193 controls were included. 45.2% of patients were men, with a mean age of 52 (SD 14.6). 47.4% were patients with rheumatologic disease, 25.3% from dermatology and 27.2% from digestive. 95.6% received a BA (66.6% anti-TNF and 33.4% non-anti-TNF) and the remaining 4.4% received JAK inhibitors. 43.3% patients had at least a risk factor compared to 37.8% in the control group (p=0.761). The Table 1 shows the incidence of COVID divided into confirmed and cumulative cases (confirmed and possible), with no significant differences. One patient (0.3%) in the case group and 3 patients (1.6%) in the control group required hospital admission (p=0.121). In relation to the type of confinement we had significant differences (p=0.013) within the AI/IMID group versus the control group in lax confinement. There were no differences in the incidence of COVID between the different confinement types.

Table 1.

	Case (n=367)	Control (n=193)	p-value	
SARS-CoV-2 infection				
Cumulative COVID	10.1 (7.2-13.6)	13.5 (9.0-19.1)	0.228	
Confirmed COVID	3.3 (1.7-5.6)	5.7 (2.9-10.0)	0.169	
Probable	2.2 (0.9-4.2)	3.1 (1.1-6.6)	0.572	
Possible	4.6 (2.7-7.3)	4.7 (2.1-8.7)	0.987	
Type of confinement				**OR (95% CI)**
Strict	59.1 (53.8-64.2)	50.3 (43.0-57.5)	0.059	1.40 (0.99-1.99)
Regular	15.4 (11.8-19.5)	14.4 (9.9-203)	0.813	1.06 (0.65-1.73)
Lax	25.0 (20.6-29.4)	34.7 (28.0-41.9)	**0.013**	**0.62 (0.42-0.91)**
No confinement	0.5 (0.1-1.9)	0.5 (0.01-0.03)	1.000	1.05 (0.09-11.7)

CI: confidence interval; OR: Odds ratio

Conclusion: The incidence of COVID-19 infection in our cohort is similar to that reported in other series of AI/IMID patients and in general population, both for confirmed cases (3.3% vs 5.7%) as well as for cumulative cases (10.1% vs 13.5%). None of our patients developed a severe form of the infection. We observed that strict confinement was predominant in both groups, being higher in the AI/IMID patients (59.1% vs 50.3%). Furthermore, lax confinement was more frequent in the control group. Although the difference was not statistically significant, the incidence of infection was higher in the control group, especially in the subjects who performed lax confinement.

POS1216 SYMPTOM RATES, ATTITUDES AND MEDICATION ADHERENCE OF RHEUMATIC AND MUSCULOSKELETAL DISEASE PATIENTS DURING THE SARS-CoV2 PANDEMIC

K. Murray[1], S. Quinn[2], M. Turk[1], A. O'rourke[3], E. Molloy[1], L. O'neill[1], A. B. Mongey[1], U. Fearon[4], D. Veale[1]. *[1]Saint Vincent's University Hospital, Rheumatology, Dublin 4, Ireland*; *[2]Saint Vincent's University Hospital, Radiology, Dublin, Ireland*; *[3]St James' University Hospital, Infectious Diseases, Dublin, Ireland*; *[4]Trinity College, Trinity Biomedical Sciences Institute, Dublin 2, Ireland*

Background: SARS-CoV2 has caused over two million deaths globally. The relationship between rheumatic and musculoskeletal disease (RMDs), immunosuppressive medications and COVID-19 is unclear.

Objectives: This study explores the rates of COVID-19 symptoms and positive tests, DMARD adherence and attitudes to virtual clinics. amongst RMD patients.

Methods: An online population survey was disseminated via the Arthritis Ireland website and social media channels.

Results: There were 1381 respondents with RMD, 74.8% were on immunosuppressive medication. COVID-19 symptoms were reported by 3.7% of respondents of which 0.46% tested positive, no different from the general population at that timepoint. The frequency of COVID-19 symptoms was higher for respondents with spondyloarthropathy [odds ratio (OR) 2.06, 95% CI: 1.14, 3.70] and lower in those on immunosuppressive medication (OR 0.48, 95% CI: 0.27, 0.88), and

those compliant with health authority (HSE) guidance (OR 0.47, 95% CI: 0.25, 0.89). Adherence to RMD medications was reported in 84.1%, with 57.1% using health authority guidelines for information on medication use. Importantly, adherence rates were higher amongst those who cited guidelines (89.3% vs 79.9%, P <0.001), and conversely lower in those with COVID-19 symptoms (64.0% vs 85.1%, P =0.009). Finally, the use of virtual clinics was supported by 70.4% of respondents.

Conclusion: The rate of COVID-19 positivity in RMD patients was similar to the general population. COVID-19 symptoms were lower amongst respondents on immunosuppressive medication and those adherent to medication guidelines. Respondents were supportive of HSE advice and virtual rheumatology clinics.

Background: The epidemiology of COVID19 among patients with AIIRD may be influenced by a dysregulated immune system, immunosuppressive therapies and behavioral patterns. Data regarding the epidemiology of COVID19 among patients with AIIRD is scarce.

Objectives: To assess the pattern of COVID19 pandemic among patients with AIIRD compared to the general population in Israel

Methods: At the beginning of the COVID-19 pandemic, we established a national registry of patients with AIIRD, diagnosed with COVID-19, based on voluntary reporting by the treating rheumatologist. All the members of the Israeli Society of Rheumatology were encouraged to participate and repeatedly reminded to report any new cases. Rheumatology centers from 11 hospitals from the Northern and Central part of Israel participated in this study. The registry included demographic data, AIIRD diagnosis and duration, systemic organ involvement, co-morbidities, treatment (conventional synthetic disease modifying drugs (csDMARDs), biologic/targeted (b/ts) DMARDs, corticosteroids use, dose and treatment duration, date of COVID19 diagnosis, severity of the viral disease and complications, duration of hospitalization, if required, treatment for COVID 19, laboratory results and outcome. The diagnosis of COVID 19 was made by a positive SARS CoV2 PCR. The indications for SARS CoV2 PCR testing in Israel comprise clinical symptoms or exposure to a confirmed close contact. Severe illness was defined by SpO_2 <94% in room air, respiratory rate of >30 breaths/min, PaO_2/FiO_2 <300 mm Hg, or lung infiltrates >50% on chest imaging.

The epidemiological data regarding the number of COVID19 confirmed patients, the number of severe cases and the rate of mortality among the general population per day and per week, were extracted from the data dashboard of the Israeli Ministry of Health. We analyzed data from 02.2020 to 15.01.2021.

Results: During the study period we experienced 3 waves of COVID 19 pandemic. The governmental management of COVID19 spread, at the beginning of the pandemic, included inforcement of severe travel restrictions and social distancing, followed eventually by a preventive lockdown, in spite of the relatively low number of cases. Easing of the restrictions, lifting the travel ban, opening of the commerce and schools led to 2 much more severe waves, which triggered 2 new lockdowns. Up to January 2021, 549763 Israelis had confirmed COVID19, 30% of whom had severe disease, 0.84% died (30% of the patients with severe disease). We identified 190 AIIRD patients (mean(SD) age 52(18), 30% males) who had confirmed COVID19. The weekly incidence curve of patients with rheumatic diseases correlated with the curve of the general population (Figure 1).

Sixty-one % of the patients with AIIRD received csDMARDs, 41% were on b/tsDMARDs, 39% on chronic corticosteroids, 12% on ≥10mg prednisone. Forty-seven% of patients required hospitalization, 20% had severe COVID19. Sixteen patients (42% of patients with severe COVID19) (mean(SD), median age 64.7(15.4),67)) died (systemic sclerosis-4 patients, rheumatoid arthritis – 6, systemic lupus erythematosus – 2, antiphospholipid syndrome-2, granulomatous polyangiitis -1, polymyalgia rheumatica-1). The AIIRD was active in 56% of them, 50% received csDMARDs, none of them were on b/tsDMARDs, 31% received chronic prednisone>10 mg. All patients who died had at least 2 comorbidities.

Conclusion: The pattern of spread of COVID19 in AIIRD patients is similar to the general population despite repeated mass media alerts for enhanced social distancing for elderly and immune suppressed patients. The disease tends to be more severe with enhanced mortality, especially in those with active AIIRD disease and organ involvement (lungs, heart, renal), older age and co-morbidities. A reporting bias cannot be excluded.

POS1218 SAFETY AND EFFICACY OF ANAKINRA IN SEVERE SARS-COV2 INFECTION (COVID19) AT A TERTIARY HOSPITAL

O. Rusinovich[1], A. Mora[2], E. Muñez[3], L. Delgado Tellez de Cepeda[3], N. De la Torre[1], M. Pavía[1], J. Sanz[1], M. Espinosa[2], J. L. Andréu Sánchez[1], J. Campos Esteban[1]. *[1]Hospital Universitario Puerta de Hierro Majadahonda, Rheumatology, Majadahonda, Spain*; *[2]Hospital Universitario Puerta de Hierro Majadahonda, Internal Medicine, Majadahonda, Spain*; *[3]Hospital Universitario Puerta de Hierro Majadahonda, Pharmacy, Majadahonda, Spain*

Background: SARS-CoV-2 virus is a novel coronavirus that causes COVID-19 disease, which in its most severe form produces life-threatening atypical pneumonia and ARDS. Coronaviruses induce dysregulation of the immune system resulting in a cytokine storm syndrome with activation of the macrophage mediated mainly by IL-1 and IL-6. Although there is no specific treatment to date, researchers have explored novel approaches through targeting both IL-6 and IL-1. Anakinra is a recombinant human IL-1 receptor antagonist that prevents IL-1β and IL-1α binding and therefore blocks signal transduction. Its high bioavailability, rapid action, relatively short half-life and good safety profile make it a promising drug.

Objectives: Analyse the experience of administering Anakinra for severe forms of COVID19 in patients hospitalised at a tertiary hospital.

Methods: Retrospective single-center study in which all patients admitted for COVID-19 and treated with Anakinra from April 1st to the end of the 1st wave

(July 2020) were included. Medical records were reviewed to collect demographic, clinical and lab test data, using Brescia-COVID respiratory severity scale, SaFi, CRP, Ferritin, LDH and lymphocytes. Variables were assessed at baseline, 72h and 7 days after treatment initiation. Descriptive statistical analysis was performed, including a sub-analysis of patients who received anakinra as the only biological treatment.

Results: 54 patients were included, of which 37 male (68.5%) with a median age of 69.5 years (36-94). Comorbidities were lung disease 14 pts (25.9%), cardiovascular disease 39 pts (72.2%), Diabetes Mellitus 11 pts (20.4%), kidney disease and rheumatic disease each in 6 pts (11.1%), and immunosuppression 13 pts (24.1%). Each patient received a mean of 4.85 doses of anakinra (± 3.96). Other therapies included low-dose steroids (70.3%); high-dose steroids: 1mg/kg (87%), bolus (24%), Tocilizumab (57.4%), Infliximab (24.1%), Lopinavir/Ritonavir (48%), Hydroxychloroquine (94.4%), and Azithromycin (79.6%). Mortality was 22% overall, 75% due to COVID19, 8.3% due to infectious complications and 16.7% due to non-infectious complications. In the group receiving Anakinra as only biological drug, mortality accounted for 17.9% of patients, 75% due to COVID19 and 25% to non-infectious complications. No adverse effects related to anakinra were observed.

POS1219 SARS-COV-2 VACCINE HESITANCY AMONG PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: A MESSAGE FOR RHEUMATOLOGISTS

R. Priori[1,2], G. Pellegrino[1], S. Colafrancesco[1], C. Alessandri[1], F. Ceccarelli[1], M. DI Franco[1], V. Riccieri[1], R. Scrivo[1], A. Sili Scavalli[1], F. R. Spinelli[1], F. Conti[1]. [1]*Sapienza University of Rome, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rome, Italy*; [2]*Saint Camillus International University of Health Sciences, Saint Camillus International University of Health Sciences, Rome, Italy*

Background: Conflicting results have been published regarding the risk of infection with SARS-CoV-2 and development of severe COVID-19 among patients affected by rheumatic musculoskeletal diseases (RMDs). [1-4] Taking into account the lack of effective drugs to treat the COVID-19 and despite the burdensome and costly lockdown measures adopted to counteract the spread of SARS-CoV-2, effective and safe vaccines appear reasonably to be the best strategy for fighting the virus. [6] Before vaccines availability, several reports showed that a non-negligible proportion of subjects, among the general population or within specific categories, would have refused vaccination against COVID-19 once possible;[6, 7] data on vaccination hesitation among patients with RMD are not available yet.

Objectives: This study aimed to evaluate the attitude of patients with RMDs to vaccination against SARS-CoV-2 and explore the factors which may influence it.

Methods: During the first weeks of Europe vaccination campaign, we proposed an online survey to Italian adult patients with RMDs followed up in the Rheumatology Unit. All patients fulfilled the most recent classification criteria for each disease. HCs were recruited using a "best friend" system. The informed consent was collected for all participants. The questionnaires included the following items: demographic features, presence of comorbidities, educational level, and ongoing therapy. The individual's perception of the COVID-19 vaccination, as well as the willingness to receive a COVID-19 vaccination with targeted questions was properly assessed.

For the statistical analyses, Mann-Whitney and Chi-square tests were used. To account for baseline clinical differences among RMD-patients and controls, multivariable logistic regression analysis was used; covariates were selected according to a clinical criterion. The hypothesis that willingness for COVID-19 vaccine varied in specific subgroups of patients was tested using interaction terms at logistic regression analysis. All statistical tests were performed using the RStudio graphical interface and all tests were two-sided with a significance level set at p<0.05.

Results: We provided an online survey to 830 adult RMD-patients and 370 healthy controls (HCs). Overall, 626 RMD-patients and 345 HCs completed the survey. Patients with RMDs were less willing to receive a COVID-19 vaccination compared to HCs (Odds Ratio (OR) 0.24, 95% CI 0.17 – 0.34, p<0.0001) despite they perceived themselves as at higher risk both to get infected (OR 11.3, 95% CI 8 – 15.9, p<0.0001) and develop a severe COVID-19 (OR 11.06, 95% CI 7.8 – 15.6, p<0.0001) and even if they had been vaccinated for influenza and pneumococcus more frequently than controls (OR 1.60 95% CI 1.18 – 2.16, p=0.002; OR 2.23, 95% CI 1.34 – 3.73, p=0.002). However, our results reveal that RMD-patients are more willing to change their minds if properly informed by the rheumatologist (OR 3.08, 95% CI 2.19 – 4.34, p<0.0001) in comparison to controls.

Conclusion: The results of our study indicate for the first time that patients with RMDs are less willing to receive COVID-19 vaccination compared to the general population, despite perceiving themselves as at higher risk of getting infected with SARS-CoV-2 and develop severe COVID-19. However, our data underscored a meaningful aspect: patients with RMDs may change their attitude to COVID-19 vaccination if properly informed about risks and benefits by their trusted specialist.

The results of this study encourage the entire rheumatologist community to become more committed to patient education, increasing their willingness to COVID-19 vaccine, which is the most promising strategy to protect them from the virus.

POS1220 PREGNANT AND POSTPARTUM WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES AND COVID-19: A CASE SERIES

R. A. Rodriguez Chavez[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], G. Figueroa-Parra[1], J. E. Compeán-Villegas[1], L. G. Espinosa Banuelos[1], R. Moyeda Martinez[1], A. Y. Lujano Negrete[1], A. Cárdenas[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology Service, Monterrey, Mexico*

Background: Pregnant women represent a high-risk population during the COVID-19 pandemic. The main cause of maternal deaths in Mexico during 2020 was COVID-19 with 191 (21.2%) deaths registered until December 2020. The age group most affected was 30 to 34 years. Women during their third trimester and during puerperium were the most affected. Information regarding pregnant and postpartum women with autoimmune rheumatic diseases remains scarce.

Objectives: The aim of this study was to describe a COVID-19 case series from a clinic of pregnancy and rheumatic diseases.

Methods: We conducted a descriptive, retrospective study in patients from the clinic of pregnancy and rheumatic diseases of the University Hospital "Dr. Jose Eleuterio Gonzalez" in Monterrey, Mexico. Pregnant patients with RD and documented COVID-19 between March and November 2020 were included. Demographic and clinical features were obtained. Results are shown in descriptive statistics.

Results: From the 18 women with autoimmune rheumatic disease in follow-up during this period, 2 (11.1%) pregnant women, 2 (11.1%) postpartum women, and 1(5.5%) post-miscarriage woman developed COVID-19. The mean age was 28 ± 6.3 years, 3 (60%) had systemic lupus erythematosus, 1 (20%) had rheumatoid arthritis, and 1 (20%) had the antiphospholipid syndrome. Clinical features and treatments are shown in Graphic 1 and Table 1. The most frequent symptoms were fever (80%), cough (60%) and anosmia (60%). Four (80%) had mild symptoms, and 1 (20%) had severe symptoms requiring intensive care unit admission and mechanical ventilation. Three (60%) referred history of contact with a person who had COVID-19. All the patients were using hydroxychloroquine and prednisone. No patient in our study died.

Conclusion: From our population, a total of 27.8% presented COVID-19. Most of our patients had a mild course of SARS-CoV-2 infection consistent with data from the general population. Additionally, none of our patients had risk factors such as hypertension, diabetes, chronic kidney disease or lung disease. Nonetheless, pregnant women remain a vulnerable population. Prevention measures must continue worldwide to avoid additional COVID-19 morbidity and mortality.

POS1221

SARS-COV2 SEROLOGY SCREENING IN SPONDYLOARTHRITIS PATIENTS IN NORTH-EASTERN ITALY: A PILOT STUDY

A. Ortolan[1], C. Cosma[2], M. Lorenzin[1], G. Cozzi[1], A. Doria[1], M. Plebani[2], R. Ramonda[1]. [1]*University of Padova, Rheumatology Unit, Department of Medicine DIMED, Padova, Italy*; [2]*University of Padova, Department of Laboratory Medicine, Department of Medicine DIMED, Padova, Italy*

Background: Serology could help defining the real extent of Severe Acute Respiratory Syndrome CoronaVirus 2 (SARS-CoV2) diffusion in the population, especially in individuals considered at higher risk of SARS-CoV2 infection (COVID-19), such as Spondiloarthritis (SpA) patients undergoing immunosuppressive therapy or health care workers (HCW). In fact, COVID-19 detection is complicated by the fact that many patients can be asymptomatic. In these cases, it has also been suggested that a weaker immune response might be elicited.
In this context, the role of anti-cytokine targeted therapy –commonly used as treatment in SpA- is uncertain, as it is not clear whether it is detrimental or protective towards severe disease forms.

Objectives: The aim of the study was to explore the potential role of serology in detecting previous contact with SARS-CoV2 in SpA patients and HCW, and compare the frequency of positive findings with a control population.

Methods: Consecutive patients affected by axial or peripheral SpA, classified according to Assessment of SpondyloArthritis international Society (ASAS) criteria and undergoing cytokine-targeted therapy, as well as HCW and controls from the pre-COVID-19 era (control group, 2015) were recruited. In SpA patients, disease activity was assessed by Ankylosing Spondylitis Disease Activity Score (ASDAS) and Disease Activity Score on 28-joint-count (DAS28).
Sera from all patients were analysed through chemiluminescent analytical system (CLIA) for the presence of IgG and IgM anti-SARS-CoV2. Patients with a positive serological test (either IgM or IgG) additionally underwent real time Polymerase Chain Reaction (RT-PCR) in nasopharyngeal swabs in order to test for active infection. In SpA patients, serology was repeated after 3 months. Data across the 3 groups were compared by ANOVA or Chi-square, while comparison between 2 groups were conducted by Wilcoxon signed rank test or Chi-Square, for continuous and categorical data respectively. $P \leq 0.05$ were considered as significant.

Results: A total of 396 patients were recruited: 200 SpA, 95 HCW and 101 healthy controls. SpA patients were mostly (54%) males, with mean age 49.6 ±14.7 years, and all were treated with anti-TNFα (78%), anti-IL-17 (9%) and anti-IL-23 drugs (7%), or small molecules (6%). Their disease activity level was moderate-low as assessed by ASDAS (1.95 ±0.98) and DAS28 (2.33 ±2.02). Among HCW and controls, 35% and 62% were male, with mean age 46.7 ±12.9 and 50.6±10.6 respectively.
Positive serology (IgM or IgG, or both) was found in 12.5% SpA patients, 8.4% HCW, 0% controls (p=0.001). Among these, IgM titres were higher in the SpA group than in HCW (2.76±2.94 versus 0.80±0.67 KU/L, p= 0.016), while IgG mean titres were lower in the SpA group than in HCW (0.88±3.18 KU/L versus 1.05±0.88, p= 0.035). SpA patients with positive serology more frequently reported COVID-19 like symptoms than those with negative serology (20% vs 4%, p=0.009) and 2 had COVID-19 as confirmed by RT-PCR, none with a severe disease course. None of the HCW reported symptoms or tested positive by RT-PCR. In the SpA patients, at 3 months, the mean IgM titre decreased from 2.76±2.93 to 2.38±2.95 (p=0.001), while the IgG titres decreased from 0.89±3.25 to 0.31±0.87 (p=ns). Interestingly, the IgM or IgG titer at a single-patient level did not seem to change much in terms of absolute value (Figure 1), except in one patient, with documented COVID-19 (positive RT-PCR), in whom IgG level even decreased at 3 months.

Conclusion: Serology revealed that exposure to COVID-19 in SpA patients, as well as HCW, was higher than expected based on reported symptoms. Targeted anti-cytokine therapy could act as a protective factor for a severe disease course in SpA patients. However, in this population, IgG and IgM titres did not change in a clinically significant manner at 3 months, and patient did not seem to develop an immune profile consistent with durable response. This result could be due to a weaker immune response in mild infections, but further studies are warranted to clarify the pathophysiology beyond these observations.

POS1222

FACTORS ASSOCIATED WITH USE OF TELEMEDICINE FOR FOLLOW-UP OF LUPUS NEPHRITIS IN THE COVID-19 OUTBREAK

H. So[1], E. Chow[1], T. K. LI[1], I. T. Cheng[1], S. L. Lau[1], C. C. Szeto[1], L. S. Tam[1]. [1]*The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*

Background: It is important to weigh the potential risk of exposure to the severe acute respiratory syndrome coronavirus 2 (*SARS-CoV-2*) during a doctor visits against the risk of missing disease controls in patients with lupus nephritis during the COVID-19. Telemedicine (TM) follow-up is a reasonable option. Despite the recent exponential increase in application worldwide, there is no study examining the clinical factors associated with the patients' choice of TM use in lupus nephritis.
Objectives: In this study, we aimed to examine the clinical variables associated with a higher preference for TM follow-up in patients with lupus nephritis.
Methods: Consecutive patients followed at the lupus nephritis clinic were contacted for their preferred mode of follow-up. The demographic, socioeconomic and clinical data of the first 140 patients opted for TM and 140 patients preferred to continue standard in-person follow-up were collected and compared.
Results: The mean age of the 280 recruited patients was 45.6 ± 11.8 years. The mean disease duration was 15.0 ± 9.2 years. The majority of them had lupus nephritis class III, IV or V (88.2%) and were on prednisolone (90%). Three quarters of the patients (67.1%) were on immunosuppressants. The mean SLEDAI-2k was 4.06 ± 2.54, physician global assessment (PGA) 0.46 ± 0.62 and SLICC/ACR damage index 1.11 ± 1.36. A significant proportion of the patients (72.1%) had one or more comorbidities. It was found that patients with higher PGA and family monthly income (> USD3,800) preferred TM, while fulltime employees preferred in-person follow-up (Table 1). These predictors remained significant after controlling for age in the multivariate analysis with odd ratios for PGA 1.05 (95% CI 1.01-1.09), family income >USD3,800 1.90 (95% CI 1.24-3.79) and fulltime employment 0.53 (95% CI 0.32-0.88). PGA was noted to be positively correlated with the perceptions that TM reduces (r=0.13, p=0.036) and routine visit increases (r=0.12, p=0.04) the risk of COVID-19 during the outbreak.
Conclusion: When choosing the mode of care delivery between TM and clinic visit, the patient's disease activity as well as employment and economic status appeared to be important.

Table 1. Demographic, socio-economic and disease data of the recruited lupus nephritis patients with comparison between the telemedicine/standard follow-up groups

	Overall (n=280)	Telemedicine group (n=140)	Standard follow-up group (n=140)	P-value
Age in years	45.6±11.8	44.6±11.4	46.6±12.1	0.159

POS1223

RAS GUANYL RELEASING PROTEIN 1 (RASGRP1) IN PERIPHERAL B CELLS LINKS RA TO COVID-19

S. Hannawi[1], F. Alqutami[2], M. Y. Hachim[2]. [1]*Ministry of Health and Prevention MOHAP, Rheumatology, Dubai, United Arab Emirates*; [2]*Mohammed Bin Rashid University of Medicine and Health Sciences, Basic Sciences, Dubai, United Arab Emirates*

Background: Changes in the B cell subpopulations is a hallmark of the antiviral response against SARS-CoV-2 and is associated with COVID-19 severity (1). Recently our group showed common derangement observed in rheumatoid arthritis (RA) and COVID-19 (2). In RA, synovium attracts potentially autoreactive—B cells and plasma cells that play a central role in RA pathogenesis (3). We were interested to know the similarity in B cell's transcriptomic changes specific to RA and COVID-19.
Objectives: Identify similar upregulated genes in synovium and B cells in RA and at the same time are differentially expressed in B cells infected with SARS-CoV-2 or from COVID-19 patients.
Methods: RNAseq dataset (GSE89408) of (218) samples isolated from joint synovial biopsies from subjects with and without rheumatoid arthritis were retrieved from GEO online database. Differentially expressed genes (DRGs) specific to RA were identified after exclusion of those upregulated in Osteoarthritis or other joint condition samples in the same dataset. The RA specific genes were intersected with DEGs between B cells from healthy versus RA as extracted from (GSE110999) dataset. The shortlisted genes specifically upregulated in B cells of RA were identified and were explored in B cells COVID-19 transcriptome datasets using (https://metascape.org/COVID).
Results: 60 genes were found to be specifically upregulated in RA synovium and B cells and are changed in B cells infected with SARS-CoV-2 or from COVID-19 patients, Figure (1-A). Those genes were involved in interferon signaling, antiviral and immune cell activation. RASGRP1 was common between B cells of RA and COVID-19 and might play a role in the pathogenesis of both, Figure (1-B). RASGRP1 controls ERK/MAPK kinase cascade needed in B-/T-cell differentiation and development. It is vital to protect against viral infection and the autoimmune associated proliferation of activated T-cells like RA (4). We checked its level in another dataset (GSE152641) of the whole blood RNASeq of 62 COVID-19 patients and 24 healthy controls. RASGRP1 was significantly down in COVID-19 compared to healthy control, Figure (1-C).
Conclusion: SARS-CoV-2 impair B and T's cells' immune response through its action on RASGRP1 and that can be a novel mechanistic explanation of how the virus decreases immune cells and impair the B cell's humoral immunity.

RHEUMATIC MANIFESTATIONS IN COVID-19 PATIENTS - SINGLE-CENTER EXPERIENCE AMIDST THE PANDEMIC

S. Bogdanova-Petrova[1,2], T. Georgiev[1,2], G. Gerganov[2,3], S. Hristova[2,4], S. Dimitrov[1,2], T. Shivacheva[1,2]. [1]*Medical University - Varna, First Department of Internal Medicine, Varna, Bulgaria*; [2]*St. Marina's Hospital, Rheumatology Clinic, Varna, Bulgaria*; [3]*Medical University - Varna, Department of Propedeutics of Internal Medicine, Varna, Bulgaria*; [4]*Medical University - Varna, Department of General Medicine and Clinical Laboratory, Varna, Bulgaria*

Background: Recently evolved from a monochromic flu-like disease to a polysyndromic "spectrum of disease", our understanding of coronavirus disease 2019 (COVID-19) is still far from being complete [1]. Hyperinflammation involving not only the lungs but also the musculoskeletal system, skin, cardiovascular, genitourinary systems is immune-mediated resembling the flares of a full-blown rheumatic disease [2,3].

Objectives: To describe the prevalence and type of rheumatic manifestations in a cohort of COVID-19 patients hospitalized in the COVID-19 rheumatology department in University Hospital St. Marina, Varna, Bulgaria.

Methods: In the present single-center cohort study, a retrospective database analysis was performed among all COVID-19 patients hospitalized from 1 Dec 2020 to 22 Jan 2021. All 243 patients (age 19 - 93 years) were treated for moderate or severe SARS-CoV-2 infection confirmed by laboratory tests, including positive polymerase chain reaction (PCR) test, and imaging modality. Inpatient treatment included antibiotics, dexamethasone, anticoagulants, and antiviral drug remdesevir (optional). Detailed disease history and clinical examination were carried out by a fully certified rheumatologist and/or specialist in internal medicine.

Results: Among all 243 COVID-19 patients, those with prominent self-reported myalgia and arthralgia were 26% (n = 63) and 21.3 (n = 52), respectively. We had 4 (1.6%) cases of newly developed cutaneous vasculitis and 2 (0.8%) cases of severe Raynaud's phenomenon after SARS-CoV-2 infection onset. Two patients experienced severe muscle weakness, had elevated creatine phosphokinase, and were diagnosed with inflammatory myopathy secondary to COVID-19. Lupus-like syndrome was observed in 2 (0.8%) patients.

Conclusion: Rheumatic manifestations are part of the heterogeneous spectrum of COVID-19 disease. Amidst the COVID-19 crisis, each newly onset rheumatic manifestation warrants exclusion of SARS-CoV-2 infection. Therefore, a rheumatologist should be a part of a multidisciplinary approach towards the COVID-19 treatment.

POS1225

INFLUENCE OF COLCHICINE PRESCRIPTION IN COVID19-RELATED HOSPITAL ADMISSIONS: A SURVIVAL ANALYSIS

M. P. Álvarez[1], A. Madrid García[1,2], I. Perez-Sancristobal[1], J. I. Colomer[1], L. León[1], J. A. Jover[1], B. Fernandez[1], L. Abasolo[1], L. Rodriguez Rodriguez[1]. [1]*Health Research Institute (IdISSC), Hospital Clínico San Carlos, Rheumatology Department, Madrid, Spain*; [2]*Escuela Técnica Superior de Ingenieros de Telecomunicación (ETSIT), Universidad Politécnica de Madrid, Madrid, Spain*

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), triggers the innate immune system, leading in severe cases, an excessive immune response, which can lead to high levels of pro-inflammatory cytokines promoting a "cytokine storm".

To modulate this exaggerated inflammatory response, several clinical trials with already approved and well-known therapeutic agents that inhibit the inflammatory response, are being carried out. However, none of these drugs seems to achieve the desired results when treating COVID19.

Colchicine, a drug often used in the management of patients with Rheumatic and Musculoskeletal diseases (RMDs), is one of the several drugs that are being currently tested for efficacy in COVID19 due to its anti-inflammatory effects.

Objectives: To analyze association between colchicine prescription and COVID19-related hospital admissions in patients with Rheumatic and Musculoskeletal diseases (RMDs).

Methods: Patients attending a rheumatology outpatient clinic from a tertiary care center in Madrid, Spain, from 1st September 2019 to 29th February 2020 were included.

Patients were assigned as exposed or unexposed based on whether they were prescribed with colchicine in their last visit to the clinic during the 6 months before the start of the observation period. Treatment changes during the observation period were also considered. The primary outcome was COVID19-related hospital admissions occurring between March 1st and May 20th, 2020. Secondary outcome included COVID19-related mortality. Several weighting techniques for data balancing, based and non-based on the propensity score, followed by Cox regressions were performed to estimate the association of colchicine prescription on both outcomes.

Results: 9,379 patients entered in the study, with 406 and 9,002 exposed and unexposed follow-up periods, respectively. Generalized Boosted Models (GBM) and Empirical Balancing Calibration Weighting (EBCW) methods showed the best balance for COVID19-related hospital admissions. Colchicine prescription did not show a statistically significant association after covariable balancing (p-value = 0.195 and 0.059 for GBM and EBCW, respectively). Regarding mortality, the low number of events prevented a success variable balancing and analysis.

Conclusion: Colchicine prescription does not play a significant protective or risk role in RMD patients regarding COVID19-related hospital admissions. Our observations could support the maintenance of colchicine prescription in those patients already being treated, as it is not associated with a worse prognosis.

POS1226

THE COURSE OF CORONAVIRUS DISEASE 2019 (COVID-19) IN PATIENTS WITH SJOGREN'S SYNDROME TREATED WITH ANTI-CD20 MONOCLONAL ANTIBODY (RITUXIMAB)

E. Sokol[1], A. Torgashina[1], B. Chalcev[1], J. Khvan[1], O. Golovina[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Intensive Care of Rheumatic Diseases, Moscow, Russian Federation*

Background: The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) disease 2019 (COVID-19) raised concern for the outcomes in people with different rheumatic diseases and management of these patients. There was an anxiety that biologic therapies, especially anti-B-cell depletion strategies, could lead to more severe disease course and lack of protective antibodies formation.

Information about the course of COVID-19 in patients with certain rheumatic diseases is still lacking.
Objectives: To examine clinical course of COVID-19 in patients with Sjogren's syndrome treated with anti-CD20 monoclonal antibody (rituximab).
Methods: Single center observational study. Diagnosis of SjS was based on ECR/EULAR 2016 criteria. COVID-19 diagnosis was based on positive PCR test even without clinical symptoms and/or typical clinical features (CT signs, fever and anosmia). Rituximab was administrated in two 1000 mg infusions 14 days apart for the 1st course, then 500 mg every 6 months.
Results: 19 patients were included, 18 women and 1 man. Median age was 55 years (29-70 years), and median rituximab treatment duration was 24 months (1-48 months). Five patients had concomitant RA (2 patients), SLAE (1 pt), Systemic sclerosis (2 patients). Patients with RA took baricitinib and methotrexate as well. 3 patients had MALT-lymphoma anamnesis (24, 38 and 24 months before the diagnosis of COVID-19). Only 3 patients had chronic ischemic heart disease and/or arterial hypertension. 12 patients were PCR positive, 6 negative and in 1 the test was not done. 11 patients had full and 4 partial B-cell depletion in peripheral blood. Five patients had <20% lung involvement on CT, 2 patients – 20-40% and 4 patients – 40-60%. Three patients with 40-60% lung involvement required hospitalization due to marked shortness of breath and long febrile period, 2 of them received anti-IL6 treatment and neither of them required mechanical lung ventilation (either non-invasive or invasive). Seventeen patients were treated at home and recovered in 10-24 days. Anti-SARS-CoV-2 IgG were measured in 9 patients, 6 (66.7%) of them were positive.
Conclusion: It seems that neither SjS itself nor anti-CD20 therapy predisposes patients to severe course of COVID-19. Presumably risk factors such as age, diabetes or anamnesis of cardiovascular diseases have far more significant impact on COVID-19 severity. Data hints that anti-CD20 therapy might negatively affect the formation of specific anti-SARS-CoV-2 humoral immunity, but further investigation is required to determine that with any degree of certainty.

POS1227 IMPACT OF A PRE-EXISTING INTERSTITIAL LUNG DISEASE ON SEVERITY OF COVID-19 IN PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES

P. A. Juge[1], E. Hachulla[2], C. Richez[3], E. Drumez[4], A. Duhamel[4], R. Borie[5], P. Dieudé[1]. [1]*Bichat-Claude Bernard Hospital, Rheumatology, Paris, France*; [2]*Chu De Lille, Internal Medecine, Lille, France*; [3]*Hospital Center University De Bordeaux, Rheumatology, Bordeaux, France*; [4]*Chu De Lille, Biostatistic, Lille, France*; [5]*Bichat-Claude Bernard Hospital, Pulmonology, Paris, France*

Background: COVID19 due to SARS-CoV-2 infection implies an important anti-viral immune response leading to a major inflammatory syndrome with increased pro-inflammatory cytokine levels (*i.e*. the cytokine storm paradigm). The impact of a preexisting interstitial lung disease (ILD) on the morbi-mortality of COVID-19 is unclear. An increased mortality rate has been identified in studies that included a limited number of patients with ILD from various etiologies. To date, no studies have investigated the severity of COVID-19 in patients with preexisting ILD in a large population of rheumatic and musculoskeletal diseases (RMD-ILD). Since March 18th, 2020, the French RMD COVID19 dataset (NCT04353609) includes patients with an RMD and SARS-Cov-2 infection.
Objectives: To assess the impact of a preexisting ILD on COVID-19 morbi-mortality within the French RMD COVID-19 dataset.
Methods: Patients from the French RMD COVID-19 dataset were included in the analysis. COVID-19 diagnosis was established by a positive SARS-CoV-2 PCR test and/or typical symptoms or chest CT scans pattern during the period of the pandemic. Baseline phenotypic characteristics of the RMD including pre-existing ILD prior to the SARS-CoV-2 infection were collected. COVID-19 evolution was characterized as benign (ambulatory care), moderate (hospitalization outside intensive care unit [ICU]) and severe (hospitalization in ICU). Association between the ILD status and the severity and mortality rate of COVID-19 was assessed using multivariable logistic regression adjusted on sex, age, body mass index and diabetes.
Results: By June 26, 2020, 897 patients were included. Pre-existing ILD was reported in 27 patients (3%): 11 patients with systemic sclerosis, 8 with rheumatoid arthritis, 2 with auto-immune myositis, 2 with mixed connective tissue disease and 4 with other RMD. Among these 27 patients (11 male, mean age 63.1 ± 16.4 y/o, 56.5% having a usual interstitial pneumonia HRCT pattern), 22 had severe infection. Death related to COVID-19, was observed in 58 patients with RMD without ILD (7.1%) and in 10 patients with RMD-ILD (37%). Having a preexisting ILD was found to be independently associated with an increased risk of severe COVID-19 (adjusted OR=7.6 [2.9 – 20.2], P<0.001) and an increased mortality rate (adjusted OR=12.3 [3.8 – 39.2], P<0.001).
Conclusion: In RMD patients with SARS-CoV-2 infection, preexisting ILD was associated with an increased risk to severe COVID-19 and related mortality. Our findings suggest that RMD-ILD patients should be prioritized for COVID-19 vaccination according to the high morbi-mortality rate during SARS-CoV-2 infection.

Background: COVID-19 pandemic is a global emergency which may overlap on the clinical and radiological scenario of ILD in SSc. In clinical practice, the striking similarities observed at computed tomography (CT) between the diseases make it difficult to distinguish a COVID-19 superinfection from a progression of SSc-ILD.
Objectives: The aim of our study was to identify the main CT features that may help distinguishing SSc-ILD from COVID-19 pneumonia.
Methods: 22 international readers were included and divided in the radiologist group (RAD) and non-radiologist group (nRAD). The RAD group included non-chest RAD and chest-RAD. A total of 99 patients, 52 with COVID-19 and 47 with SSc-ILD, were included in the study.
Results: Fibrosis inside focal ground glass opacities (GGO) in the upper lobes; fibrosis in the lower lobe GGO; reticulations in lower lobes (especially if bilateral and symmetrical or associated with signs of fibrosis) were the CT parameters most frequently associated with SSc-ILD. The CT parameters most frequently associated with COVID- 19 pneumonia were: consolidation (CONS) in the lower lobes, CONS with peripheral (both central/peripheral or patchy distributions), anterior and posterior CONS and rounded-shaped GGOs in the lower lobes. After multivariate analysis, the presence of CONS in the lower lobes (p <0.0001) and signs of fibrosis in GGO in the lower lobes (p <0.0001) remained independently associated with COVID-19 pneumonia or SSc-ILD, respectively. These two variables were combined in a predictive score which resulted positively associated with the COVID-19 diagnosis, with 96.1% sensitivity and 83.3% specificity: 3 different risk class for COVID-19 pneumonia may be identified: high risk for COVID-19 pneumonia (5-9 points); probable overlap COVID-19 pneumonia in SSc-ILD (4 points); low risk for COVID-19 pneumonia (0-3 points).
Conclusion: The CT differential diagnosis between COVID-19 Pneumonia and SSc-ILD is possible and may be fostered in practice by the use of a

radiological score. In the case where an overlap of both diseases is suspected, the presence of consolidation in the lower lobes may suggest a COVID-19 pneumonia while the presence of fibrosis inside GGO may indicate a SSc-ILD.

POS1229 ANTI-MDA5 AND ANTISYNTHETASE ANTIBODIES SCREENING IN SEVERE SARS-COV-2 PNEUMONIA. BE AWARE OF FALSE POSITIVE RESULTS

A. Gil-Vila[1], J. Perurena-Prieto[2], C. Nolla-Fontana[1], O. Orozco-Galvez[1], M. Miarons-Font[3], A. Guillén del Castillo[1], A. Pacheco-Reyes[4], E. Trallero-Araguás[5], M. Hernandez-Gonzalez[2], A. Selva-O'callaghan[1]. *[1]Vall d'Hebron University Hospital, Internal Medicine, Barcelona, Spain*; *[2]Vall d'Hebron University Hospital, Immunology, Barcelona, Spain*; *[3]Vall d'Hebron University Hospital, Pharmacology, Barcelona, Spain*; *[4]Vall d'Hebron University Hospital, Intensive Care Medicine, Barcelona, Spain*; *[5]Vall d'Hebron University Hospital, Rheumatology, Barcelona, Spain*

Background: Several reports have shown that severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection may trigger a vigorous immune response that could lead to the appearance of various autoantibodies such as antinuclear antibodies, antiphospholipid antibodies or anti-neutrophil cytoplasmic antibodies, among others. Moreover, the pulmonary involvement in SARS-CoV-2 may resemble that of patients with anti-MDA5 positive syndrome or acute form of antisynthetase syndrome.

Objectives: Our aim was to analyse the presence of anti-MDA5 and other myositis-specific autoantibodies such as the antisynthetase antibodies in patients diagnosed with severe acute respiratory syndrome caused by SARS-CoV-2.

Methods: Retrospective observational study performed in a tertiary care center. We included 28 patients admitted to the intensive care unit with severe acute respiratory syndrome, 14 at the onset of the disease (group A) and 14 after 30 days of being treated in an intensive care unit (group B). Chest CT was performed at the admission. We analyzed the presence of anti-MDA5 and antisynthetase antibodies by immunoblot (Euroimmune®) and in those who were positive we performed a confirmatory test by immunoprecipitation.

Results: All chest CT showed bilateral ground glass pattern. Three out of 14 patients of group A (12 males, 86%, mean ± SD age 67.1 ± 12.2) were positive for antisynthetase antibodies (2 anti-PL7, 1 anti-Jo1), and 6 out of 14 patients of the group B (6 males, 48%, mean ± SD age 68.7 ± 8.1) were positive to antisynthetase antibodies (2 anti-PL7, 2 anti-PL-12, 1 anti-EJ, 1 anti-OJ+PL7). Immunoblots also show positivity for other myositis-specific or associated antibodies, such as anti-TIF1g, anti-PM75, anti-SAE and anti-SRP. All of these results found by immunoblotting were negative by immunoprecipitation. None of the 28 patients were positive for anti-MDA5 antibodies.

Conclusion: Severe SARS-CoV-2 pneumonia is characterized by ground glass pattern in chest CT, as it is found in anti-MDA5 or antisynthetase syndrome. The positivity of several myositis related autoantibodies showed in immunoblot appears to be more related to the vigorous immune response producing polyclonal immunoglobulins than triggering a real myositis-associated interstitial lung disease. Clinicians must be aware about these false positive results in patients with severe COVID-19 acute respiratory syndrome.

POS1230 OUTCOME FOLLOWING COVID-19 INFECTION IN ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA)-ASSOCIATED VASCULITIS

A. Antovic[1], B. Lövström[2], A. Hugelius[3], O. Borjesson[3], A. Bruchfeld[4], I. Gunnarsson[1]. *[1]Karolinska Institutet, Department of Medicine, Division of Rheumatology, Unit of Rheumatology, Karolinska University Hospital, Stockholm, Sweden*; *[2]Karolinska University Hospital, Unit of Rheumatology, Stockhom, Sweden*; *[3]Karolinska University Hospital, Unit of Rheumatology, Stockholm, Sweden*; *[4]Linköping University, Department of Health, Medicine and Caring Sciences, Linköping, Sweden*

Background: Patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) require immunosuppressive therapy for disease control and reduction of disease relapse and may be at risk for complications during Sars-CoV-2 (COVID-19) infection.

Objectives: To analyze the consequences of COVID-19 in a large cohort of AAV patients regarding occurrence, need of hospitalization, treatment at the intensive care units (ICU), or death.

Methods: Data were retrieved from March 2020 to mid-January 2021 from medical records from the AAV cohort (n=233). Patients diagnosed with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) or eosinophilic granulomatosis with polyangiitis (EGPA) were included. Data included age, gender, diagnosis, ongoing immunosuppressive medication at onset of COVID-19 or at last follow-up in non-COVID individuals. Renal involvement (ever) and estimated glomerular filtration rate (eGFR) were included. COVID-19 was confirmed either by a positive PCR test in the upper airways or by serology. Severe COVID-19 was defined as need of non-invasive ventilation, ICU care, and/or death.

Results: The cohort comprised of 172 patients with GPA, 50 with MPA and 11 with EGPA. There were 121 females (52%). During the study period, 20 patients (8.6%) were diagnosed with COVID-19. The median age at data retrieval in all patients was 68 years (21-93), in the COVID-19 group 63 (29-93) and 68.5 (21-90) years in the non-COVID patients.

Fourty-three patients in all (18%) were hospitalized during the study period of which 11 (4.7%) due to COVID-19 infection. In all, 8 deaths occurred of which 3 were related to COVID-19.

At data retrieval, 110 (47%) patients were on prednisolone treatment, 10/20 (50%) in the COVID-19 group and 100 (47%) in the non-COVID-19 group (p=0.5), with significantly higher doses in COVID-19 patients (p<0.001). In patients hospitalized with COVID-19, 6/11 (54.5%) were on prednisolone, median dose 5 mg/day (0-50). In the total group 112 (48%) were on disease modifying anti-rheumatic drugs (DMARD) and 64 (27.5%) on rituximab as maintenance therapy. Eight patients were on induction treatment with either cyclophosphamide or rituximab.

Of the 20 COVID-19 cases, 8 had severe COVID-19. Of these, 2 were inactive without immunosuppressive treatment, 4 had stable disease with prednisolone (5-7.5 mg/day) in combination with DMARDs, and 2 were active treated with high dose prednisolone (25-50 mg/day) in combination with cyclophosphamide and rituximab (n=1) or rituximab (n=1).

A higher proportion of patients had active AAV (p=0.03) in the severe COVID-19 then in the non-COVID group (10/213 patients).

In the group with the severe COVID-19, 1/8 (12%) patient had rituximab as maintenance therapy, compared to 61/213 (28.6%) in the group of non-COVID-19 patients (p=0.5).

Renal involvement (ever) was present in 144 patients (62%), in 6 patients (30%) with COVID- 19, from which 5 (62%) were in the group of severe COVID-19 patients. Median eGFR did not differ between severe COVID-19 and remaining patients with renal involvement independently of COVID-19 infection.

Conclusion: We found a high rate of severe COVID-19 infection in our cohort of AAV patients which indicates risk for serious complications, especially in patients with active disease and intense immunosuppressive therapy. Maintenance therapy with rituximab did not seem to increase the risk for severe COVID-19. The findings stress the need for continued shielding and early vaccination in AAV patients.

POS1231 COVID-19 INFECTION IN RHEUMATIC IMMUNE-MEDIATED INFLAMMATORY DISEASES. EPIDEMIOLOGICAL STUDY IN A SINGLE UNIVERSITY HOSPITAL

D. Martínez-López[1], D. Prieto-Peña[1], L. Sanchez-Bilbao[1], A. Herrero-Morant[1], C. Álvarez-Reguera[1], M. Trigueros-Vazquez[1], M. A. González-Gay[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*

Background: Immune-mediated inflammatory diseases (IMID) have an increased risk of infections due to the disease itself, and/or immunosuppressive therapy. Risk of COVID-19 infection in the different rheumatic IMID (R-IMID) remains controversial.
Objectives: To assess the epidemiology and comorbidities of COVID-19 in R-IMID from a Single-University hospital.
Methods: Cross-sectional study in a Single-University hospital. We included all consecutive patients with a diagnosis of a R-IMID and a positive test for COVID-19 up to November 6th, 2020. Medical records of 11,199 patients that suffered COVID-19 in our region, and 6891 with R-IMID from our hospital were reviewed. Incidence data in the different underlying R-IMID were calculated for patients with follow-up in our hospital. Confirmed infection was defined if the patient had a positive nasopharyngeal swab for SARS-CoV-2.
Results: We included 147 patients from our region (96 women/51 men), mean age 60±18 years. Underlying R-IMID were: Rheumatoid arthritis (RA) (n=36, 24.5%), Axial spondyloarthritis/Psoriatic arthritis (SpA/PsA) (n=54, 36.7%), Polymyalgia Rheumatica (PMR) (n=16, 10.9%), systemic lupus erythematosus (SLE) (n=10, 6.8%), sarcoidosis (n=5, 3.4%), Sjögren's syndrome (SS) (n=4, 2.7%), giant cell arteritis (GCA) (n=3, 2%), Behçet's disease (n=3. 2%), ANCA-vasculitis (n=2, 1.4%) and systemic sclerosis (SSc) (n=1, 0.7%).
Main comorbidities were hypertension (n=65, 44.2%), dyslipidemia (n=64, 43.5%), age higher than 65 years old (n=55, 37.4%), obesity (n=35, 23.8%), coronary vascular disease (n=27, 18.4%), diabetes mellitus (n=22, 15%), chronic obstructive pulmonary disease (n=15, 10.2%) and chronic kidney disease (n=15, 10.2%).
Total cumulative COVID-19 incidence in all patients from our region was 1.9% (11,199 /582,905). From 147 patients with COVID-19 from our region, 115 (76 women/39 men; mean age, 59±18 years) were followed in our hospital. In the latter, the global cumulative incidence in R-IMID was 1.7% (115/6891), ranging from 1.3% in Systemic Scleroderma (SSc) and Giant Cell Arteritis (GCA) up to 5.3% in Behcet's disease (Table 1 **and** Figure 1**).**

Table 1. Incidence and relative risk of COVID-19 in patients with different R-IMID in a Single-University hospital

R-IMID	Total cumulative incidence in our hospital(%)	Relative risk (95% confidence interval)
Global population 582,905 inhabitants	1.9	-
Global R-IMID 6,891 patients	1.7	0.9 (0.7-1)
Behçet's disease	5.3	2.7 (0.9-8.2)
ANCA-vasculitis	3.5	1.8 (0.4-7.1)
PMR	2.8	1.4 (0.8-2.6)
SS	2.6	1.4 (0.5-3.6)
SLE	2.3	1.2 (0.6-2.3)
Sarcoidosis	2.3	1.2 (0.3-4.7)
SpA/PsA	2.2	1.1 (0.8-1.5)
RA	1.6	0.8 (0.6-1.2)
GCA	1.3	0.7 (0.2-2.8)
SSc	1.3	0.7 (0.1-4.6)

GCA: Giant cell arteritis, PsA: Psoriatic arthritis, RA: Rheumatoid arthritis, SLE: Systemic lupus erythematosus, SpA: Axial spondyloarthritis, SSc: Systemic scleroderma.

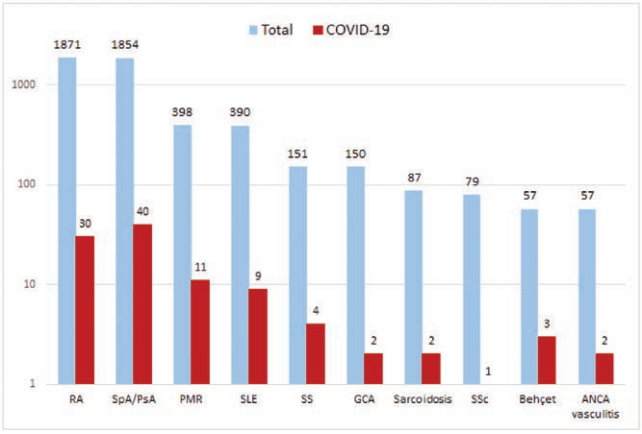

Figure 1. Number of patients with COVID-19 in different R-IMID in a Single-University hospital. Data are presented on a logarithmic scale.

In addition, Relative Risk (RR) in different R-IMID compared to the general population was calculated (Table 1**).** Although RR did not reach statistical significance in any R-IMID, most R-IMID showed a tendency to a higher risk, with the exception of RA, GCA and SSc.
Conclusion: In our series, the total cumulative incidence of COVID-19 in R-IMID was similar to the general population. Higher RR, without statistical significance, was observed in Behçet's disease, ANCA-vasculitis and Polymyalgia Rheumatica. GCA: Giant cell arteritis, PsA: Psoriatic arthritis, RA: Rheumatoid arthritis, SLE: Systemic lupus erythematosus, SpA: Axial spondyloarthritis, SSc: Systemic scleroderma.

POS1232 COVID-19 IN PATIENTS WITH SYSTEMIC SCLEROSIS: ONE RHEUMATOLOGY CENTER EXPERIENCE

M. Starovoytova[1], O. Desinova[1], L. P. Ananyeva[1], O. Koneva[1], L. Garzanova[1], O. Ovsyannikova[1], R. Shayakhmetova[1], V. Babak[1], T. Beketova[1]. [1]*VA Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation*

Background: Severe Acute Respiratory Syndrome-Coronavirus-2 (SARS-CoV-2) virus infection or COVID-19 is a serious problem for patients with systemic autoimmune diseases Given the serious complications, including acute lung injury, patients with systemic sclerosis (SSc), especially SSs associated with interstitial lung disease (ILD), may represent a high risk group for infection and the development of severe COVID-19.
Objectives: We present an analysis of the COVID-19 course and outcomes in 110 SSc pts.
Methods: The study included 147 patients with SSc. The information was clarified by means of telephone survey after 10 months of the pandemic (December 2020). Covid-19 was diagnosed when confirmed by positive oral /nasopharyngeal swab, in the presence of positive antibodies and/or characteristic symptoms, and data from chest computed tomography (CT). 110 pts (77%) out of 147 patients in the SSc registry, gave the necessary information. COVID-19 was diagnosed in 59 pts (53 %). 42 pts (71%) had SSc-ILD. Pts mean age was 54.96 (s.d.11, min 31, max 79), 83% women (49 women and 10 men). 38 pts (65%) had a limited form of SSc, 15 (26%) pts had diffuse form SSc, 6% had overlap (SSc-polymyositis (PM) and SSc had rheumatoid arthritis (RA) and 3% had visceral form of SSc). All patients received low-dose prednisone, and more than half of the pts received immunosuppressive therapy. Rituximab therapy was performed in 24 pts (41%).
Results: Almost all patients had positive swab from the oral cavity/nasopharynx. And only in 4 (7%) pts nasopharyngeal swabs were negative, in these patients specific antibodies and characteristic CT changes were detected. Chest CT was performed in 51 (86%) pts. Novel coronavirus pneumonia developed in the vast majority of pts - in 46 (78 %) pts. CT1 (up to 25% of lung lesions) had 10 (17%) pts, CT2 (25-50%) – 21(36%) pts, CT 3 (50-75%) – 15(25%) pts. In 5 (8.5%) pts no changes were detected on CT. The course of COVID-19 was mild and moderate (20 (34%) pts and 18 (31%) pts respectively), severe course was observed in 21 (35%) pts, including fatal in 12 (20%) pts. Among the deceased pts, only 1 patient with SSc-PM had not had ILD, but 7 patients had been treated with rituximab.
Conclusion: SSc SARS-CoV-2-infected patients may be at risk of severe disease and mortality due to the frequent presence of ILD and the frequent use of immunosuppressive, including biological, therapy.

POS1233 USE OF BARICITINIB AND TOCILIZUMAB FOR THE TREATMENT OF MODERATE TO SEVERE COVID-19 IN HOSPITALIZED PATIENTS

D. X. Xibille Friedmann[1], S. M. Carrillo Vazquez[2]. [1]*Hospital General de Cuernavaca, Internal Medicine, Cuernavaca, Mexico*; [2]*Hospital Regional 1 de Octubre, Rheumatology, Mexico City, Mexico*

Background: SARS-CoV2 infection and COVID-19 associated pneumonia are associated to a dysregulated inflammatory response known as cytokine storm and the use of cytokine inhibitors, especially those targeting IL-6, has been

proposed as a therapeutic alternative in these patients. Janus Kinase (JAK) inhibitors in combination to the antiviral Remdesivir have shown evidence of reducing recovery time and accelerating improvement in clinical status among patients with COVID-19, notably among those receiving high-flow oxygen or non-invasive ventilation[1].

Objectives: To describe the outcomes associated with the use of Tocilizumab (TCZ) and Baricitinib (Bari) in patients hospitalized for COVID-19.

Methods: Descriptive study nested in a cohort. Patients from the General Hospital of Cuernavaca who were hospitalized due to COVID-19 associated pneumonia and/or respiratory failure requiring supplemental oxygen or invasive/non-invasive assisted mechanical ventilation (AMV) were analyzed. All patients had a positive RT-PCR upon hospital admission, sampled under standardized conditions. The clinical and demographic data of the patients upon hospitalization were obtained from the instrument on a specific platform (SISVER) used on a national basis. Severe disease was considered as the need for any type of AMV. TCZ was used at 400-600 mg in two infusions (baseline and at 72 hours), Bari at 4 mg daily for 14 days. The outcomes were the need for AMV, death, or discharge. A p≤ 0.05 was considered statistically significant.

Results: Data from 404 SARS-CoV2 positive patients were analyzed. 269 (65.9%) were men. The mean age of the patients was 57.5 years (18-94; SD 15.3). 59.6% of the patients had one or more comorbidities (Diabetes and Hypertension in most cases [31.8%]). 22.8% of the patients had a history of current or previous smoking. Mean hospital stay was 7.4 days (1-36; SD 5.9). 15.9% of the patients required invasive or non-invasive AMV. 11 patients were treated with TCZ and 30 patients received treatment with Baricitinib. 5 of the 11 patients with TCZ required AMV (all but one were intubated), but only 6 of the 30 (20%) with Bari required AMV (all except one received CPAP). The use of Baricitinib was correlated with a reduction in the use of AMV (p 0.01). 6 patients with TCZ were discharged due to improvement and 5 died. In the case of Bari, 19 improved and were discharged and 11 died, significantly correlating with lower mortality (p 0.05). The use TCZ was not associated with a reduced hospitalization (50% remained hospitalized for more than 10 days) but patients receiving Baricitinib had significantly shorter hospital stays (86.6% had a hospital stay of less than 10 days) than those receiving TCZ (p<0.0001).

Conclusion: The patients that were treated with Baricitinib and required AMV most often improved with non-invasive CPAP while the majority of the patients under AMV receiving TCZ were treated with an invasive mode, although this was due in part to the fact that TCZ can be employed intravenously and is more practical for intubated patients in whom oral drug administration is limited. Baricitinib was significantly associated with a better outcome (hospital discharge due to improvement) and a significantly shorter hospital stay.

POS1234 IMPACT OF THE CHANGE IN ADMINISTRATION ROUTE OF TOCILIZUMAB AND ABATACEPT, DUE TO THE COVID-19 LOCKDOWN ON DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Diebold[1], T. Wirth[1], V. Pradel[2], N. Balandraud[1], E. Fockens[1], C. Paris[1], S. Trijau[1], P. Lafforgue[1], T. Pham[1]. *[1]APHM, Rheumatology Department, Marseille, France*; *[2]APHM, Public Health Department, Marseille, France*

Background: Among therapeutics used to treat rheumatoid arthritis (RA), Tocilizumab (TCZ) and Abatacept (ABA) are both biologic agents that can be delivered subcutaneously (SC) or intravenously (IV). During the first COVID-19 lockdown in France, all patients treated with IV TCZ or IV ABA were offered the option to switch to SC administration.

Objectives: The primary aim was to assess the impact of changing the route of administration on the disease activity. The second aim was to assess whether the return to IV route at the patient's request was associated with disease activity variation, flares, anxiety, depression and low physical activity during the lockdown.

Methods: We conducted a prospective monocentric observational study. Eligibility criteria: Adult ≥ 18 years old, RA treated with IV TCZ or IV ABA with a stable dose ≥3 months, change in administration route (from IV to SC) between March 16, 2020, and April 17, 2020. The following data were collected at baseline and 6 months later (M6): demographics, RA characteristics, treatment, history of previous SC treatment, disease activity (DAS28), self-administered questionnaires on flares, RA life repercussions, physical activity, anxiety and depression (FLARE, RAID, Ricci &Gagnon, HAD).

The primary outcome was the proportion of patients with a DAS28 variation>1.2 at M6. Analyses: Chi2-test for quantitative variables and Mann-Whitney test for qualitative variables. Factors associated with return to IV route identification was performed with univariate and multivariate analysis.

Results: Among the 84 patients who were offered to switch their treatment route of administration, 13 refused to change their treatment. Among the 71 who switched (48 TCZ, 23 ABA), 58 had a M6 follow-up visit (13 lost of follow-up) and DAS28 was available for 49 patients at M6. Main baseline characteristics: female 81%, mean age 62.7, mean disease duration: 16.0, ACPA positive: 72.4%, mean DAS28: 2.01, previously treated with SC TCZ or ABA: 17%.

At M6, the mean DAS28 variation was 0.18 ± 0.15. Ten (12.2%) patients had a DAS28 worsening>1.2 (ABA: 5/17 [29.4%] and TCZ: 5/32 [15.6%], p= 0.152) and 19 patients (32.8%) had a DAS28 worsening>0.6 (ABA: 11/17 [64.7%] and TCZ: 8/32 [25.0%], p= 0.007).

At M6, 41 patients (77.4%) were back to IV route (26 TCZ, 15 ABA) at their request. The proportion of patients with a DAS28 worsening>1.2 and>0.6 in the groups return to IV versus SC maintenance were 22.5%, 42.5% versus 11.1% and 22.2% (p=0.4), respectively. The univariate analysis identified the following factors associated with the return to IV route: HAD depression score (12 vs 41, p=0.009), HAS anxiety score (12 vs 41, p=0.047) and corticosteroid use (70% vs 100%, p=0.021), in the SC maintenance vs return to IV, respectively.

Conclusion: The change of administration route of TCZ and ABA during the first COVID-19 lockdown was infrequently associated with a worsening of RA disease. However, the great majority of the patients (77.4%) request to return to IV route, even without disease activity worsening. This nocebo effect was associated with higher anxiety and depression scores.

POS1235 ASSESSMENT OF RISK FACTORS FOR HOSPITALIZATION OF AUTOIMMUNE AND RHEUMATIC DISEASE PATIENTS WITH COVID-19 – A SINGLE CENTRE OBSERVATIONAL STUDY

J. M N[1], P. Dekate[2], S. Vontari[1], R. Dudam3. *[1]Hyderabad Rheumatology Center, Clinical Pharmacology, Hyderabad, India*; *[2]Hyderabad Rheumatology Center, Rheumatology, Hyderabad, India*; *[2]Hyderabad Rheumatology Center, Rheumatology, Hyderabad, India*

Background: Most of the patients suffering from autoimmune and rheumatic diseases (AIRD) are on immunomodulator or immunosuppressive therapies and they are susceptible to infections including COVID19.

Objectives: To assess the risk factors for hospitalization with COVID-19 in patients with AIRD

Methods: A single centre retrospective observational study including patients with AIRD who had contracted COVID-19. Data was collected from all patients attending our clinic from September 2020 to January 2021. Patients with COVID-19 were divided into hospitalized and non-hospitalized groups. Clinical, demographic, ongoing medications, comorbidities and post COVID flare data were collected and analysed using crosstabs-chi square and Mann-Whitney U test.

Results: 520 patients with AIRD were screened over the study duration, of which 52 patients who had contracted COVID-19 were included in the study. Amongst them, 19 patients (36.5%) required hospitalization. The common symptoms in the hospitalized patients over non-hospitalized were fever (63.2% vs 57.6), fatigue (42.1% vs 21.2%), headache (36.8% vs 18.2%), abdominal pain (26.3% vs 6.1%), myalgias (36.8 vs 18.2%) and dyspnea (31.6% vs 18.2%). The most common rheumatic conditions seen in both the groups were RA (42.1% vs 30.3%), SPA (26.3% vs 36.4%), and SLE with other CTD's (15.8% vs 24.2%). 6 patients (11.5%) required ICU stay, 3 patients (5.7%) were ventilated, and 2 (3.8%) patients died.

Patients requiring hospitalization were aged >50 years (p=0.018), had DM type II (p=0.003), HTN (p=0.035), multimorbidity (p=0.021), and a higher CORAD score (p<0.001). Usage of CsDMARDS, bDMARDS, TsDMARDS, corticosteroids did not show a significant difference between both the groups. Patients with >2 years of disease duration required hospitalization in comparison to <2 years of duration but this was not statistically significant.

84.2% of hospitalized and 69.7% of non-hospitalized patients stopped anti-rheumatic treatment and disease flare was seen in 47.4% and 39.4% patients respectively.

Conclusion: The rheumatic disease and their medications did not increase the risk of COVID-19 hospitalization in this study. However, higher age, DM II, HTN, and high CORAD score were found to be associated with hospitalization in AIRD patients. The findings of this study are limited by a small sample size.

Table 1. Demographic and Rheumatic disease specific data of COVID-19 patients

		All patients (n=52)	Hospitalized (n=19)	Non-hospitalized (n=33)	p-value
Age – n (%)		45.73 (10.829)	50.53 (10.905)	42.97 (9.923)	**0.018**

POS1236 IMPACT OF COVID-19 ON INITIATION AND RENEWAL OF BIOTHERAPIES AND TARGETED SYNTHETIC TREATMENTS

P. Richette[1], M. Allez[2], V. Descamps[3], L. Perra[4], S. Pilet[5], M. Maravic[6].
[1]Lariboisiere Hospital, Rheumatology, France, France; *[2]St Louis Hospital, Gastroenterology, Paris, France*; *[3]Bichat Hospital, Dermatology, Paris, France*; *[4]IQVIA, Ai & Data engine, Courbevoie, France*; *[5]IQVIA, Analytic solutions, Courbevoie, France*; *[6]IQVIA, Real World Solutions, Courbevoie, France*

Background: During the epidemic's peak of COVID-19, scientific societies published recommendations on biotherapy and targeted synthetic treatment (B/TST) use in patients with chronic articular inflammatory diseases, inflammatory bowel diseases, and psoriasis.
Objectives: The objective was to evaluate the impact of COVID-19 in France on initiation and renewal of B/TST.
Methods: LRx contains all anonymized medication dispenses prescribed in outpatient care in a representative panel of French retails pharmacies, including data of near 40 million patients. The impact of B/TST initiation and renewal were studied using 2019 as reference and dispense deliveries data of pharmacies with regular flew in order to perform the comparison. B/TST considered were abatacept, anti-TNF, anti-IL6, anti-IL17, anti-IL12/23 or anti-IL23, JAK inhibitors (JAKi) and other classes such as aprelimast, aminosalicylates (AS), hydroxychloroquine (HCQ), and methotrexate (MTX). A treatment initiated was defined as a treatment not delivered in the past 12 months, and conversely for a treatment renewal. Results were presented as raw one and expressed in percentage of patients having at least one B/TST delivery in each therapeutic classes of interest in 2020 compared to 2019 used as reference year (period from week 12 to week 19 considered and corresponding to the lockdown period in France).
Results: During the lockdown period, a decrease in initiation was observed for patients treated with: abatacept (405 in 2019 vs 227 in 2020: -44%, p<0.001), anti-TNF (1156 vs 1058, -31%, p<0.001), anti-IL17 (415 vs 206, -50%, p<0.001), anti-IL12-23 (395 vs 339, -12%, p=0.16), JAKi (289 vs 174, -39%, p=0.006), contrasting with an increase for Tociliumab (117 vs 445, +152%, p=0,01). We found a decrease of 7% (2171 vs 2015, p=0,35), 44% (405 vs 227, p<0.001), 30% (3430 vs 2390, p p<0.001) of AS, aprelimast and MTX initiation, respectively, and an increase of 173% (1708 vs 4671, p=0.11) of HCQ initiation. No decrease for the renewal of B/TST was observed
Conclusion: During the epidemic's peak, initiation of AS, MTX, biotherapies (except for tocilizumab), and JAKi dramatically decreased without impacting their renewal. Two treatments were mainly initiated, tocilizumab probably due to a switch from intravenous to subcutaneous injection and HCQ in relation to its presumably effect on COVID-19. Overall, recommendations from scientific societies have been followed.

POS1237 ALGORITHM IDENTIFYING CHRONIC INFLAMMATORY DISEASES TREATED BY BIOTHERAPY AND/OR TARGETED SYNTHETIC TREATMENTS IN OUTPATIENT CARE IN FRANCE: FEASIBILITY, PRELIMINARY RESULTS, AND IMPACT OF COVID-19

P. Richette[1], M. Allez[2], V. Descamps[3], L. Perra[4], S. Pilet[5], M. Maravic[6].
[1]Lariboisiere Hospital, Rheumatology, Paris, France; *[2]St Louis Hospital, Gastroenterology, Paris, France*; *[3]Bichat Hospital, Dermatology, Paris, France*; *[4]IQVIA, Ai & Data engine, Courbevoie, France*; *[5]IQVIA, Analytic Solutions, Courbevoie, France*; *[6]IQVIA, Real World Solutions, Courbevoie, France*

Background: Discriminating chronic inflammatory diseases under biotherapy and/or targeted synthetic treatments (B/TST) using medico-administrative databases are challenging but required for medico-economic analyses focusing on these diseases.
Objectives: The objective was to evaluate the feasibility of using a medication dispense data in order to identify patients with chronic inflammatory diseases under B/TST in outpatient care setting and evaluate the impact of COVID-19 in France
Methods: LRx contains all anonymized medication dispenses prescribed in outpatient care in a representative panel of French retails pharmacies, including data of near 40 million patients. Patients having at least one B/TST delivered in 2019 were selected. An algorithm was constructed using different steps, including a machine learning step by transfer learning applied in patient classified as having a rheumatologic condition in order to differentiate rheumatoid arthritis (RA) from spondyloarthritis (SA). We numbered 190,640 patients, of which 87.8% were classified in one of the following diseases: RA, SA, psoriatic arthritis (PA), psoriasis, inflammatory bowel diseases (IBD) (extrapolated data to France). Descriptive analysis was performed. The impact of COVID-19 on biotherapy initiation was evaluated during the lockdown period (W2-W19 2020) in these different conditions.
Results: Among the 167,468 patients under B/TST, 20.7%, 18.4%, 6.5%, 37.9% and 16.5% were considered as having a psoriasis, IBD, PA, RA, and SA, respectively. Female patients were more frequent in RA and PA (> 60%); younger (< 20 years) and older patients (74 years) were found in patients with IBD (5.7%) and RA (12.6%), respectively. Contrasting with IBD, SA, and RA patients were mainly under anti-TNF treatment (> 90% for IBD and SA, 73.5% for RA), psoriasis and PA patients received a range of broadly well-balanced of B/TST. Among the immunosuppressant, methotrexate was mostly prescribed in RA (58.4%), PA (34.1%), and psoriasis (14.1%), and azathioprine in IBD (19.9%). Oral corticosteroid delivered at least 4 times in 2019 were mostly found to be associated with a RA condition (28%). A significant decrease of biotherapy initiation was observed during the lockdown in France in patients with IBD (-20%, p=0.03) and psoriasis (-54%, p<0.0001), not significant decrease in patients with SA (-6%) and increase in RA patients (+23%).
Conclusion: The algorithm was able to identify patients with chronic inflammatory diseases under B/TST delivered in outpatient care and will allow to follow-up its management and study the COVID-19 impact on biotherapy initiation. An external validation needs to be performed

POS1238 ANTIPHOSPHOLIPID ANTIBODIES AND COVID-19: TREND OVER TIME

S. Mancuso[1], S. Truglia[1], A. Capozzi[2], F. Pasquali[1], S. Recalchi[2], G. Riitano[2], F. R. Spinelli[1], M. Sorice[2], R. Misasi[2], C. Alessandri[1], C. M. Mastroianni[3], F. Conti[1]. *[1]Sapienza University of Rome, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Rome, Italy*; *[2]Sapienza University of Rome, Dipartimento di Medicina Sperimentale, Rome, Italy*; *[3]Sapienza University of Rome, Dipartimento di Sanità Pubblica e Malattie infettive, Rome, Italy*

Background: Since the beginning of the SARS-CoV-2 outbreak, antiphospholipid antibodies (aPL), a known thrombotic risk factor, have been studied in COVID-19 patients, in whom thromboembolic events have been associated with poor prognosis. To date, the pathogenetic role of aPL and the trend over time is still unknown.

Objectives: Aim of the study was to investigate whether aPL positivity was correlated with thrombosis in COVID-19 patients and whether it was a transient or persistent.

Methods: We included all consecutive COVID-19 patients hospitalized at Policlinico Umberto I, Sapienza University of Rome from April 1, 2020 to June 7, 2020. In these patients, serum levels of anti-cardiolipin (aCL) IgM, IgG, IgA, anti-β2glycoprotein I (aβ2GPI) IgM, IgG were measured by enzyme-linked immunosorbent assay (ELISA) and Lupus Anticoagulant (LA) was detected with coagulatory tests in patients not in treatment with anticoagulant drugs.

Results: Five out of 73 (6.8%) patients resulted positive for aCL IgM, 3 of them also tested positive for aβ2GPI IgM. aCL IgA were tested positive in 14 out of 46 patients (30.4%). Overall 18 patients resulted positive for at least one test. Seven (9.6%) patients developed thrombotic events during hospitalization, 3 of them resulting positive for aPL (Table 1. below).

We observed that patients showing double positivity for aCL IgM and aβ2GPI IgM had a likelihood positive ratio of 6.3 for thrombotic events (p=0.012) and a likelihood positive ratio of 4.9 for increased D-dimer levels (p=0.027). aCL IgA, the most prevalent aPL in this cohort, was not associated with thrombosis. Of the 18 aPL positive patients, 5 died, 3 were lost to follow-up, and 10 were tested on a second occasion at least 12 weeks, two patients confirmed positivity without clinical signs suggestive of APS.

Conclusion: These results suggest that double positivity for aCL and aβ2GPI IgM increases the risk of thrombosis in COVID-19 patients, unlike aCL IgA. APL positivity may be persistent and it is advisable to monitor it over time.

POS1239 POSITIVE IMPACT OF THE FIRST LOCKDOWN IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISM

C. Gaujoux-Viala[1,2], C. Traverson[1], E. Filhol[1,2], C. Daien[3,4], S. Laurent-Chabalier[5], B. Combe[3,4], C. Lukas[2,3], J. Morel[3,4], C. Hua[1,2]. *[1]Nîmes University Hospital, Rheumatology, Nîmes, France*; *[2]University of Montpellier, IDESP, UMR-INSERM, Montpellier, France*; *[3]CHU Lapeyronie, Rheumatology, Montpellier, France*; *[4]University of Montpellier, -, Montpellier, France*; *[5]Nîmes University Hospital, BESPIM, Nîmes, France*

Background: Since the beginning of 2020, the COVID-19 pandemic has caused a considerable amount of fear, worry and concern in the general population and among certain groups such as the elderly, healthcare providers and people with pre-existing conditions in particular. Our patients suffering from chronic inflammatory rheumatism (CIR), a group of autoimmune pathologies treated by immunosuppressant medication, are particularly concerned. Actions taken – particularly quarantine and its effects on the normal activities, habits or livelihoods of many people – also have a significant impact. There is little information on the impact of the lockdown in patients with CIR with data measured prospectively, in a standardized way, before and during the first lockdown period.

Objectives: The objective of this ancillary study was to evaluate the psychological impact of the first lockdown period (anxiety, depression, sleep disorders, catastrophizing...) as well as the evolution of disease activity in patients suffering from CIR.

Methods: At two French university hospitals, adult patients with rheumatoid arthritis (RA) according to the ACR-EULAR 2010 criteria, spondyloarthritis (SpA) fulfilling the ASAS 2009 criteria and psoriatic arthritis (PsA) according to the Caspar 2006 criteria were consecutively included in the Catastrophism in Chronic Inflammatory Rheumatism (CRIC) study from September 2019. Sociodemographic data, information on the disease and its treatments were collected as well as questionnaires on disease activity (DAS28, CDAI, BASDAI), function (HAQ), quality of life (SF12, EQ5D), anxiety and depression (HADS, GAD7), insomnia (ISI) and catastrophizing scores (PCS). These data were collected prospectively at baseline, 3, 6 and 12 months.

In this ancillary study, data from patients with an assessment before and during lockdown were analyzed. Statistical analyses were descriptive with a paired Student's T-test.

Results: In all, 140 patients (49 RA, 69 SpA and 22 PsA) were evaluated before and during lockdown. The median age was 53.5 [44-63] years and 60.7% were women; 74 patients (53.2%) were professionally active and 102

Table 1. Clinical and demographic features of the 7 Covid-19 patients that presented thrombotic events

(72.9%) were living as couples. The majority of patients (92.9 %) had a disease lasting more than 2 years. Concerning treatments, 63 (45%) were treated by bDMARD monotherapy, 40 (28.5%) by bDMARD+ csDMARD, 17 (12.1%) by csDMARD monotherapy and 2 patients by tsDMARD; 90.7% were not taking any corticosteroids and 8.6% were taking ≤5 mg/d; 30% were on NSAIDs.

When comparing before and during lockdown, pain, tender joint count, swollen joint count, disease activity (CDAI, BASDAI) and function (HAQ, SF12 physical component) were similar. However, there was a significant improvement in psychological status, anxiety (HADS, GAD7), the mental component of SF12, catastrophizing and overall quality of life (EQ5D) (see Table 1 below).

Conclusion: There are very few prospective, standardized data on the impact of lockdown in patients with CIR with an assessment before and during the first lockdown period. In patients with CIR, the first lockdown period had no impact on the activity of the disease and was well experienced psychologically with less anxiety and an improvement in quality of life.

POS1240 HYDROXYCHLOROQUINE CARDIOTOXICITY: A CASE-CONTROL STUDY COMPARING PATIENTS WITH COVID19 AND PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Mancuso[1], F. R. Spinelli[1], L. Agati[2], M. R. Ciardi[3], F. Natalucci[1], E. Molteni[1], S. Truglia[1], V. Riccieri[1], R. Priori[1], C. M. Mastroianni[3], F. Conti[1]. [1]*Sapienza University of Rome, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Rome, Italy*; [2]*Sapienza University of Rome, Dipartimento di Scienze Cardiovascolari e Respiratorie, Rome, Italy*; [3]*Sapienza University of Rome, Dipartimento di Sanità Pubblica e Malattie infettive, Rome, Italy*

Background: Antimalarials have been associated with QT prolongation in COVID19 patients but are generally safe in patients with rheumatologic disease.

Objectives: Aim of the study was to compare the prevalence of QTc prolongation between COVID19 and Systemic Lupus Erythematosus (SLE) patients treated with hydroxychloroquine (HCQ).

Methods: We included consecutive patients with SARS-CoV-2 infection confirmed by nasopharyngeal swab and patients taking HCQ for SLE. A prolonged QTc was defined as an increase in QTc intervals >60 ms (compared with baseline) or as a QTc of ≥500 ms.

Results: We enrolled 58 COVID19 patients (median age 70.5 years, IQR 25). HCQ, without or with azithromycin, was given to 26 (44.8%) and 15 patients (25.9%), respectively; 17 (29.3%) had not received either drug. The median baseline QTc was 432 (IQR 36) and prolonged QTc was observed in 15 (26%) patients (12 QTc≥500 ms and 3 patients ΔQTc>60 ms). We didn't find significant differences in QTc prolongation among the three treatment groups. Baseline QTc (OR 111.5) and D-dimer (OR 78.3) were independently associated to QTc prolongation.

Compared to the 50 SLE patients (median age of 38.5 years, IQR 22), chronically treated with HCQ, patients with COVID19 showed significantly longer QTc ($p < 0.001$) (Table 1).

Conclusion: This is the first study demonstrating that, differently from COVID19 patients, patients with SLE are not susceptible to HCQ-induced long QT syndrome and arrhythmia. The combined arrhythmogenic effect of SARS-CoV-2 infection and HCQ could account for the excess of QTc prolongation and fatal arrhythmias described in patients with COVID19.

POS1241 THE IMPACT OF THE COVID-19 PANDEMIC ON PHYSICAL FUNCTIONING AND MENTAL WELLBEING IN 824 PATIENTS WITH RHEUMATIC DISEASE OVER 8 MONTHS: PHYSICAL FUNCTIONING DECLINES

N. Cleaton[1], S. Raizada2, T. Sheeran[1], J. Bateman[1]. [1]*The Royal Wolverhampton Trust, Rheumatology, Wolverhampton, United Kingdom*; [1]*The Royal Wolverhampton Trust, Rheumatology, Wolverhampton, United Kingdom*

Background: Worldwide the detrimental consequences of the COVID-19 pandemic on physical and psychological health have been recognised. Social distancing and isolation measures have negatively impacted physical functioning (PF) and mental health (MH), and are known to have reduced physical activity (PA) generally within the population. A significant proportion of patients with autoimmune rheumatic disease (ARD) are considered 'clinically extremely vulnerable' (CEV), at high risk from COVID19 and been advised to follow stricter social distancing precautions than the general population. Evidence in ARD patients highlights the importance of PA in maintaining physical and psychological wellbeing. Prior to the pandemic limitations in both PF and MH in patients with ARD were recognised and early in the pandemic MH was noted to be impacted by distancing measures in this population.

Objectives: This is an interim report of a research study (clinicaltrials.gov NCT04542031) exploring the impact of the COVID19 pandemic on the physical and psychological wellbeing of patients with rheumatic disease, to inform guidelines and target service provision as the pandemic continues.

Methods: We distributed two web-based surveys, eight months apart during the first (April-2020) and second wave (December-2020) of the pandemic. Surveys were communicated via a linked mobile-phone SMS message, to all rheumatology patients with a validated mobile number under follow-up at the Royal Wolverhampton Trust. We assessed patients using the Short Form-12 version 2 made up of mental (MCS) and physical component scores (PCS). For each survey, data were collected 4-weeks following distribution; comparative analysis was conducted using SPSS version-27.

Results: Initial surveys were sent to 7911 active follow up patients; 1694/7911 (21.4%) responded and consented for further follow up, of which 1636 were linked to a validated mobile number. 899/1636 (55.0%) responded to the second survey and 824/899 (91.7%) responses were linked across both surveys. These 824 patients were predominately female (69.5%), aged 61 years and 76.3% had an ARD; 388/824 patients were CEV, 436 were in the comparator group. For the CEV group, scores remained significantly lower than the comparator for PCS (survey 1: 36.40 vs 39.61 [P<0.001], survey 2: 36.11 vs 38.66 [P<0.001]) and MCS (41.61 vs 43.44 P<0.001; 41.19 vs 43.60 [P<0.001]); there was no deterioration in CEV scores. In the comparator group, while MCS did not differ in patients with ARD, PCS significantly decreased (1.39; 95% CI: 0.69, 2.08; P<0.001); PCS in the non-inflammatory group did not significantly change (-0.23, P=0.65).

Conclusion: These preliminary data suggest that while the physical and mental health of CEV patients is significantly lower in this cohort, surprisingly, neither aspects of health have been worsened by the impacts of the pandemic over an 8-month period. However, the physical functioning of patients with ARD significantly decreased in this time, which may reflect the reduction in PA faced by society, and reduced contact with secondary care services. These data suggest services need to adapt to provide additional support to patients with ARD to maintain physical functioning during the pandemic. Further work exploring the

evolving pattern of the physical and psychological responses to the pandemic is ongoing.

Background: As of the 25th of January 2021, more than 150 thousand deaths as consequence of COVID-19 have been reported in Mexico [1]. Advanced age, male gender and comorbidities have been described as risk factors for severe disease and mortality in general population [2]. COVID-19 mortality in Mexican patients with rheumatic and musculoskeletal diseases (RMDs) is unknown.

Objectives: To describe characteristics of Mexican patients with RMDs and COVID-19, and to analyse factors associated with mortality.

Methods: The Global Rheumatology Alliance COVID-19 (GRA) physician reported registry, is an international effort to collect information on COVID19 in adult patients with RMDs. GRA is an observational registry. The first patient from Mexico was registered on April 17, 2020. All Mexican patients registered in GRA until October 30, 2020 were included in this analysis. The association of mortality with demographic and clinical variables was estimated using logistic regression analysis.

Results: A total of 323 patients were registered, with a median age of 52 (IQR 41-61) years old, 166 (51.4%) patients lived in Mexico City. The most frequent RMDs were rheumatoid arthritis, 149 (46.1%) and systemic lupus erythematosus, 24 (19.8%). Over a third of patients with RMDs and COVID-19 (119 (36.8%)) were hospitalized, and 43 (13.3%) died. Table 1 shows clinical and demographic characteristics. In the univariable analysis, the absence of comorbidities was a protective factor, OR 0.3 (95% CI 0.1-0.6). Factors associated with mortality at COVID-19 diagnosis were age over 65 years old, having type 2 diabetes, chronic renal insufficiency, treatment at COVID-19 diagnosis with corticosteroids or with CD20 inhibitors. In the multivariable adjusted analysis, these factors remained independently associated with mortality. No associations with other treatments or comorbidities at COVID-19 diagnosis were found.

Conclusion: Mexican patients with RMDs and COVID-19 in the GRA physician reported registry had a mortality of 13.3%. Factors associated with mortality were those described in the general population, such as older age and being on corticosteroids and CD20 inhibitors treatment at COVID-19 diagnosis.

POS1243 TELEMEDICINE AND MANAGEMENT OF THE PATIENT AFFECTED BY GIANT CELL ARTERITIS DURING THE COVID-19 PANDEMIC - TELEMACOV

S. Parisi[1], M. C. Ditto[1], A. Laganà[1], C. L. Peroni[1], E. Fusaro[1]. *[1]AOU Città della Salute e della Scienza di Torino, Rheumatology Unit, Turin, Italy*

Background: Giant cell arteritis (GCA) is the most common primary systemic vasculitis in western countries with the highest incidence among persons 70–79 years of age. Treatment has been with glucocorticoids (GCs) alone for many decades but recently Tocilizumab (TCZ) has demonstrated efficacy in reducing GC dose and flare rates in patients with GCA. Therefore, both early diagnosis and regular monitoring are necessary for the correct management of GCA. The COVID-19 pandemic has led to decisions by the governments of the countries involved, aimed above all at reducing the contagion. This has also led to reductions in health activities, limiting them to those of urgency by reducing or canceling checkups involving the risk of a time gap which for the GCA meant the interruption of clinical monitoring and therapeutic adjustment. At the same time, the pandemic situation has stimulated remote monitoring activities, through telephone contacts or video calls carried out by the rheumatologist. EULAR identified a minimal data set aimed at research and for clinical use, which includes the main clinical and instrumental data to be taken into consideration in monitoring the patient. For many data a clinical examination is not necessary but an interview is sufficient. We activated the TELEMACOV protocol (TELEmedicine and Management of the patient affected by giant cell arteritis during the COVid-19 pandemic) monitoring the follow-up of patients affected by GCA through telemedicine tools in order to maintain an effective and risk-free follow-up in a pathology with a high risk of relapse.

Objectives: The purpose of the study is to evaluate the effectiveness of telemedicine in the follow-up of the patient with GCA.

Methods: We evaluated patients (pts) with a clinical diagnosis of GCA (received in previous periods) who were admitted to the our Rheumatology Unit. They were monitored monthly by telephone from 9 March to 9 June 2020 (during lockdown). All patients were asked questions divided according to the sub-groups listed below:
- Onset of new symptoms or their recurrence
- Exams carried out
- Current therapy
- Satisfaction of telephone call

Results: We performed 148 remote monitoring visits in 37 pts. The cohort was mainly composed by female (77,8%) and had a mean age of 71,85 ± 9,25 years. They were affected by GCA, with a mean duration of 5,3±2,3 months. The characteristics of these pts and the course of the disease are reported in Table 1. Pts treated with TCZ reduced their GC dose more than patients treated with GC alone (p: 0.032). Only one patient (treated with GC alone) had an ocular flare with the need to increase the dosage of the GC with good response and rapid

improvement. Furthermore, all patients considered this type of monitoring very satisfactory according to the Likert scale (1-5) with mean 4,4±0,2.

Conclusion: Our study has shown how telemedicine can be well used in pts with GCA as a possible alternative, for a limited period, to traditional visits, especially in a fragile population such as the elderly and more exposed to the risk of SARS-COV2 infection.

POS1244

PRELIMINARY RESULTS OF LONG-TERM FOLLOW-UP OF THE HEALTH STATUS OF PATIENTS USING CSDMARDS AND B/TSDMARDS FOR RHEUMATIC DISEASES DURING THE COVID-19 PANDEMIC

F. Unlu Ozkan[1], K. Sari[1], I. Aktas[1]. [1]*University of Health Sciences Fatih Sultan Mehmet Training and Research Hospital, Physical Medicine and Rehabilitation, Istanbul, Turkey*

Background: Since its inception, the COVID-19 outbreak has been carefully monitored both by the patients using DMARDs and their physicians. There is no data that patients with rheumatic and musculoskeletal diseases (RMD) are at a higher risk of contracting COVID-19 disease than those without RMD (1). COVID-19-related death in people with RMD has been associated with older age, male gender, concomitant cardiovascular and pulmonary diseases, moderate/high disease activity, and certain treatments (rituximab (RTX), sulfasalazine (SSZ) and some immunosuppressants) (2).

Objectives: To determine the conditions of getting and being affected poorly by COVID-19 and related factors of RMD patients followed in our outpatient clinic.

Methods: 160 patients over 18 years of age who applied to our outpatient clinic between July 2020-January 2021; who used DMARDs for rheumatic diseases and agreed to participate were included in the study. The patients's demographic data, RMDs, csDMARDs and b/tsDMARDs usage, comorbid diseases and smoking status were recorded. The data of the patients on COVID-19 disease between March 2020 and January 2021 were questioned at each visit.

Table 1. Patient characteristics

	All Patients n=160	COVID-19 Patients n=24
Male	61 (38%)	6 (25%)
Female	99 (62%)	18 (75%)
Mean age	49.5	49.5
Ever smoker	88 (55%)	8 (33,3%)
Obesity	51 (32%)	9 (37,5%)
Hypertension (HT)	46 (29%)	7 (29%)
Diabetes (DM)	22 (14%)	2 (8%)
Cardiovascular disease (CVD)	26 (16%)	5 (20%)
Chronic lung disease (CLD)	12 (7,5%)	4 (16%)
SpA	71 (44,3%)	9 (37,5%)
RA	71 (44,3%)	14 (58,3%)
PsA	14 (8,8%)	1 (4,2%)
SLE	2 (1,25%)	-
PMR	2 (1,25%)	-
cDMARD only	82 (51,2%)	14 (58,3%)
b/tsDMARD only	55 (34,4%)	8 (33.3%)
Combined DMARD	23 (14,4%)	2 (8.4%)

The rate of getting COVID-19 infection was 15% in all patients. This rate was 18% in all obese patients, 19% in those with at least one comorbid disease (HT, DM, CVD, CLD), and 22% in those who were obese and had at least one comorbid disease. 16% of non-smokers and 9% of those who ever smoked got COVID-19. Among patients over the age of 65 (n=17), 2 patients (%12) had COVID-19. Treatments of RMDs of patients with COVID-19 were as follows: bDMARD=8 [(Etanercept(ETN) n=2, adalimumab (ADA) n=2, certolizumab pegol (CTZ) n=1, infliximab (IFX) n=1, golimumab (GOL) n=1, RTX n=1)], csDMARD=14 [(methotrexate (MTX) n=4, leflunomid (LEF) n=4, SSZ n=3, HCQ n=2, MTX+SSZ+HCQ n=1)], combined=2 [tofacitinib (TOF)+MTX n=1, TCZ+LEF n=1)], none of them was using glucocorticoids. Overall 17% of patients using csDMARD, 14,5% of patients using b/tsDMARD as monotherapy and 9% of patients using combination treatment had COVID-19. Of the patients using HCQ (n=14), 3 (21%) were diagnosed with COVID-19 disease. 18 of the patients received COVID-19 treatment at home, 6 were hospitalized and 1 of them (RA patient, LEF user) needed intensive care unit. None of them died.

Results: Patient characteristics are presented in Table 1. 57 (36%) of all patients had COVID-19 PCR test, 23 (14%) were positive, and 1 patient was diagnosed with COVID-19 because the CT findings were positive, although the PCR test was negative.

Conclusion: Preliminary results regarding the health status associated with COVID-19 of our patients with RMD are presented. Biologic drugs seems not to increase COVID-19 but final results will be presented after the completion of statistical analysis of all data.

Menchaca", Rheumatology, Guadalajara, Mexico*; [13]*Facultad de Medicina y Ciencias Biomédicas, Rheumatology, Chihuahua, Mexico*; [14]*Colegio Mexicano de Reumatología, Research Unit, Mexico City, Mexico*

Background: COVID-19 outcomes in Mexican patients with rheumatic diseases (RDs) in comparison to general population patients are unknown.

Objectives: To compare mortality and hospitalization of COVID-19 patients with RDs and those without.

Methods: We included for this study all the Mexican patients with RDs and COVID-19 registered from April 17th to October 30th, 2020 in the COVID-19 Global Rheumatology Alliance registry. We compare clinical and demographic characteristics of patients with RDs and COVID-19 to patients with COVID-19 that were selected randomly from the Mexican Epidemiology database (1:3). A logistic regression analysis was performed to adjust for confusion variables.

Results: We included 322 patients with COVID-19 and RDs and 969 controls without RDs. Table 1 shows the demographic characteristics and comorbidities of both groups. Bivariate analysis showed that patients with RDs had higher mortality, were older, and were more frequently hospitalized. Comorbidities, such as diabetes, hypertension, cardiovascular and renal diseases were also more frequent in patients with RDs. In the multivariate analysis, having a RD was no longer associated with mortality (Figure 1).

Table 1. Comparison of patients with COVID-19 with and without RDs

	COVID-19 patients without RDs	COVID-19 patients with RDs	p-value
N	969	323	
Age (mean (SD))	42.6 (17.4)	51.2 (13.9)	<0.001
Sex = Male (%)	455 (47.0)	55 (17.0)	<0.001
Deceased = Yes (%)	55 (5.7)	43 (13.3)	<0.001
Hospitalization = Hospitalized (%)	164 (16.9)	152 (47.1)	<0.001
Intubation = Yes (%)	27 (2.8)	32 (11.8)	<0.001
COPD_Asthma = Yes (%)	37 (3.8)	15 (4.6)	0.522
Diabetes = Yes (%)	114 (11.8)	49 (15.2)	0.116
Obesity = Yes (%)	128 (13.3)	21 (6.5)	0.001
Hypertension = Yes (%)	152 (15.8)	88 (27.2)	<0.001
Cardiovascular disease = Yes (%)	19 (2.0)	14 (4.3)	0.02
CRF = Yes (%)	22 (2.3)	17 (5.3)	0.007
Pregnancy = Yes (%)	5 (0.5)	2 (0.6)	0.827
Smoker = Yes (%)	86 (8.9)	10 (3.1)	0.001

Abbreviations: RDs, rheumatic diseases; COPD, chronic obstructive pulmonary disease; CRF, chronic renal failure.

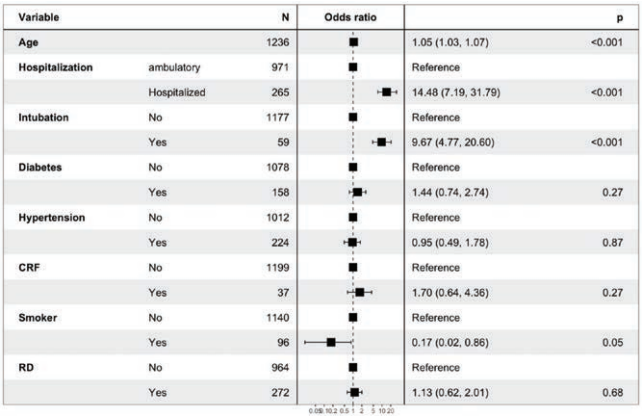

Figure 1. Multivariate analysis of mortality

Conclusion: Patients with RDs had higher comorbidities, hospitalizations, and mortality than the general population in the bivariate analysis. However, adjusted multivariate analysis showed that the odds for mortality were not increased because of having a RD. These findings suggest that the increased mortality of Mexican patients with RDs may be explained by the higher frequency of comorbidities in this population.

Background: SARS-CoV-2 infection poses a serious challenge for patients with rheumatic autoimmune systemic diseases (ASD), characterized by marked immune-system dysregulation and frequent visceral organ involvement.
Objectives: To evaluate the impact of Covid-19 pandemic in a large series of Italian patients with ASD.
Methods: Our multicenter telephone survey (8-week period, March-April 2020) included a large series of 2,994 patients (584 M, 2,410 F, mean age 58.9±13.4SD years) with ASD followed at 34 tertiary referral centers of 14 regions of northern, central, and southern Italian macro areas, characterized by different prevalence of SARS-CoV-2 infection. According to currently used criteria, Covid-19 was classified as *definite* Covid-19 (signs or symptoms of Covid-19 confirmed by positive oral/nasopharyngeal swabs at PCR testing) or *highly suspected* Covid-19 (signs or symptoms highly suggestive of Covid-19, but not confirmed by PCR testing due to limited availability of virological tests in that period). The results were analyzed performing the Odds Ratio by Java-Stat 2-way Contingency Table Analysis.
Results: The main findings of the survey study revealed a significantly increased prevalence of Covid-19 in:
a.the whole series of ASD patients (*definite* Covid-19: 22/2994, 0.73%; p=0.0007; *definite* Covid-19 plus *highly suspected* Covid-19: 74/2,994, 2.47%; p<0.0001) when compared to Italian general population of Covid-19 infected individuals (349/100000 = 0.34%; data from Italian Superior Institute of Health; https://www.epicentro.iss.it/en/coronavirus/sars-cov-2-national-surveillance-system).
b.the subgroup of patients with connective tissue diseases or systemic vasculitis (n = 1,901) compared to the subgroup of inflammatory arthritis (n = 1,093), namely rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis (*definite* Covid-19: 19/1,901, 0.99%, vs 3/1,093, 0.27%; p=0.036; *definite* Covid-19 plus *highly suspected* Covid-19: 69/1,901, 3.6%, vs 5/1,093, 0.45%; p<0.0001)
c.the subgroup of patients with pre-existing interstitial lung involvement (n = 526) compared to those without (n = 2,468) (*definite* Covid-19: 10/526, 1.90%, vs 12/2,468, 0.48%; p=0.0015; *definite* Covid-19 plus *highly suspected* Covid-19: 33/526, 6.27%, vs 41/2,468, 1.66%; p<0.0001).

Of interest, the prevalence of Covid-19 did not correlate with presence/absence of different comorbidities, mainly diabetes, cardio-vascular and/or renal disorders, as well as of ongoing treatments with biological DMARDs; while patients treated with conventional DMARDs showed a significantly lower prevalence of Covid-19 compared to those without. Covid-19 was more frequently observed in the patients' populations from northern and central compared to southern Italian macro area with lower diffusion of pandemic. Clinical manifestations of Covid-19, observed in 74 patients, were generally mild or moderate; 4/9 individuals requiring hospital admission died for severe pneumonia.

Conclusion: The prevalence of Covid-19 observed in ASD patients during the first wave of pandemic was significantly higher than that observed in Italian general population; moreover, the actual prevalence of Covid-19 might be underestimated due to the high number of mild variants as well as the possible clinical overlapping between these two conditions. Patients with ASD should be invariably regarded as 'frail patients' during the pandemic course, considering the risk of worse outcome in the acute phase of Covid-19, as well as the potential long-term effects of viral infection.

The statistically significant association of Covid-19 with connective tissue diseases/systemic vasculitis, as well as with pre-existing interstitial lung involvement, suggests the presence of distinct clinico-pathological ASD subsets, characterized by markedly different patients' vulnerability to SARS-CoV-2 infection.

POS1247 CLINICAL FEATURES AND OUTCOMES OF COVID-19 IN PATIENTS WITH IGG4-RELATED DISEASE. A COLLABORATIVE EUROPEAN MULTI-CENTRE STUDY

G. A. Ramirez[1,2], M. Lanzillotta[1,2], M. Ebbo[3,4], A. Fernandez-Codina[5,6,7,8], G. Mancuso[1,2], F. Martínez-Valle[9,10], O. Orozco-Galvez[9,10], N. Schleinitz[3,4], L. Dagna[1,2], E. L. Culver[11,12], E. Della Torre[1,2]. *[1]IRCCS Ospedale San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*; *[2]Università Vita-Salute San Raffaele, Immunology, Milan, Italy*; *[3]CHU de Marseille - Hôpital de la Timone, Département de Médecine Interne, Marseille, France*; *[4]Aix-Marseille University, Internal Medicine, Marseille, France*; *[5]Windsor Regional Hospital, General Internal Medicine, Windsor, Canada*; *[6]Saint Joseph's Health Care London, Rheumatology, London, Canada*; *[7]University of Western Ontario, Rheumatology, London, Canada*; *[8]Hospital Clinic i Provincial, Emergency Department, Barcelona, Spain*; *[9]Universitat Autònoma de Barcelona, Autoimmune Diseases Research Lab., Barcelona, Spain*; *[10]Vall d'Hebrón Hospital, Systemic Diseases Unit, Internal Medicine Service, Barcelona, Spain*; *[11]Oxford University Hospitals NHS Foundation Trust, Hepatology, Oxford, United Kingdom*; *[12]University of Oxford, Translational Gastroenterology Unit, Oxford, United Kingdom*

Background: Coronavirus disease 2019 (COVID-19) is a pandemic-spread systemic infectious disease with prominent respiratory manifestations and significant associated morbidity and mortality. Elderly people are most significantly affected with mortality ranging from 2.4% (age 60-69) to 19.6% (age>80) in European Countries. The prevalence of COVID-19 and of its complications in patients with immune-mediated disorders, remains unclear. The frequency and impact of COVID-19 on patients with IgG4-related diease (IgG4-RD), many of whom are on concurrent immunosuppression has not been addressed.

Objectives: To assess the epidemiological and clinical relevance of COVID-19 in patients with IgG4-RD.

Methods: This is a multi-centre retrospective observational study of IgG4-RD patients from France, Italy, Spain and the United Kingdom. Demographics, comorbidities, IgG4-RD features, current and past treatment along with COVID-19-suggestive symptoms and COVID-19 diagnoses from February 2020 to January 2021 were recorded by means of direct or phone interviews. Patients with reverse-transcriptase polymerase chain reaction-confirmed (cCOVID) or presumed COVID-19 based on clinical, serological or imaging features (pCOVID) were pooled for analysis (totCOVID) and compared to patients who were not diagnosed with COVID-19. Inter-group comparison of categorical and quantitative variables were performed by using the chi-square test with Fisher's correction and the Mann-Whitney's test respectively. Data are expressed as median (interquartile range) unless otherwise specified.

Results: A total of 305 patients [71% males, median age 64 (54-74) years] were studied. Pancreato-biliary disease was the most frequently observed IgG4-RD phenotype (39%). Fifty-one percent of patients were taking corticosteroids at time of interview and 30% were on biological or conventional immunosuppressants. Thirty-two totCOVID cases (23 cCOVID, nine pCOVID) were identified: 11/32 were hospitalised, two needed intensive care and four (13%; 3/4 aged >80 years) died. Having one or more infected family members was a risk factor for COVID-19 in patients with IgG4-RD (OR=19.9; p<0.001). No other demographic, clinical or treatment features associated with COVID-19. In particular there was no association between adverse outcomes with COVID-19 and higher doses of steroids (>20mg) or rituximab administration.

Conclusion: The prevalence and course of COVID-19 in IgG4-RD patients are similar to those of the general population of the same age, with no evident impact of disease- or treatment-related factors to the basal infectious risk. Effective public health countermeasures might be beneficial for patients with IgG4RD.

POS1248 SAFETY PROFILE OF PFIZER-BIONTECH COVID-19 VACCINE IN PATIENTS WITH RHEUMATIC DISEASES: PRELIMINARY ASSESSMENT

G. Cuomo[1], M. Atteno[2], C. Naclerio[3], L. E. Adinolfi[4], C. Romano[4]. *[1]University of Campania Studies "Luigi Vanvitelli", Precision of Medicine, Napoli, Italy*; *[2]Azienda Ospedaliera di Rilievo Nazionale San Giuseppe Moscati, Internal Medicine, Avellino, Italy*; *[3]P.O. Scarlato, UO. Dipartiemntale di Reumatologia, Scafati, Italy*; *[4]University of Campania Studies "Luigi Vanvitelli", Department of Medical and Surgical Sciences, Napoli, Italy*

Background: Efficacious vaccines are urgently needed to contain the ongoing coronavirus disease 2019 (Covid-19) pandemic of infection with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). On December 11, 2020, the Food and Drug Administration (FDA) issued an Emergency Use Authorization (EUA) for Pfizer-BioNTech COVID-19 vaccine to prevent COVID-19, administered as 2 doses separated by 21 days (1)

On December 27, 2020, Italy started use of Pfizer-BioNTech COVID-19 vaccine and initial doses were reserved for health care personnel

Objectives: The primary end points were the safety of each administered dose in patients with Rheumatic diseases (RD's)

Methods: In this multicenter, observational study, we interviewed by phone 27 patients with rheumatic diseases (RDs) and 30 healthy subjects receiving the Pfizer-BioNTech vaccine (0.3 ml i.m. in two doses 21 days apart, time 0 and 3 weeks).

Results: As of 30 January 2021, 57 subjects (27 patients and 30 healthy subjects) were interviewed. The epidemiological and clinical features of the 27 patients are reported in Table 1. Among the whole population, 35 subjects (16 patients and 19 healthy subjects) complained of an adverse event after the first vaccine dose, with symptom onset occurring within 1 day of vaccination. All adverse events (100%) were classified as nonserious and included: injection site pain (17), fatigue (5), headache (16), fever (3), tachycardia (2), and paresthesia (2).

After 21 days, 6 patients and 11 healthy subjects received the second vaccine dose. Fifteen (5 patients and 10 healthy subjects) of them (88%) reported adverse events, again categorized as nonserious. Specifically, injection site pain (7), fatigue (10), headache (10), fever (10), paresthesia (1), cutaneous vasculitis (1), itchy and scratchy throat (1), diarrhea (4), lymph node enlargement (1) were recorded. No differences were noted between patients with RDs and healthy subjects in terms of adverse events.

Conclusion: This preliminary study shows that the Pfizer-BioNTech COVID-19 vaccine is as safe in patients with RDs as in healthy subjects. Whether patients with RDs will develop protective titers of anti-SARS-CoV-2 antibodies as compared to healthy subjects will be evaluated in further, ongoing studies.

[1]*Hacettepe University School of Medicine, Department of Pediatric Infectious Diseases, Ankara, Turkey*; [2]*Hacettepe University School of Medicine, Department of Pediatrics, Division of Pediatric Intensive Care Unit, Ankara, Turkey*; [3]*Hacettepe University School of Medicine, Department of Pediatrics, Division of Pediatric Rheumatology, Ankara, Turkey*; [4]*University of Health Science Ankara Training and Research Hospital, Department of Pediatric Infectious Diseases, Ankara, Turkey*; [5]*Hacettepe University School of Medicine, Department of Bioistatistics, Ankara, Turkey*

Background: The severity of COVID-19 symptoms can range from mild to severe. Severe COVID-19 cases with excessive hyperinflammation have many overlap features with multisystem inflammatory syndrome in children (MIS-C).
Objectives: We aimed to describe the typical clinical and laboratory features and treatment of children diagnosed with MIS-C and to understand the differences as compared to severe/critical pediatric cases with COVID-19 in an eastern Mediterranean country.
Methods: Children (aged <18 years) who diagnosed with MIS-C and severe/critical pediatric cases with COVID-19, were admitted to hospital between 26 March and 3 November 2020 were enrolled in the study.
Results: A total of 52 patients, 22 patients diagnosed with COVID-19 with severe/critical disease course and 30 patients diagnosed with MIS-C. Although severe COVID-19 cases and cases with MIS-C share many clinical and laboratory features, MIS-C cases had longer fever duration and higher rate of the existence of rash, conjunctival injection, peripheral edema, abdominal pain, altered mental status, and myalgia than in severe cases (p<0.001 for each). Of all, 53.3% of MIS-C cases had the evidence of myocardial involvement as compared to severe cases (27.2%). Additionally, C-reactive protein (CRP) and white blood cell (WBC) are the independent predictors for the diagnosis of MIS-C, particularly in the existence of conjunctival injection and rash. Corticosteroids, intravenous immunoglobulin (IVIG), and biologic immunomodulatory treatments were mainly used in MIS-C cases rather than cases with severe disease course. There were only 3 deaths among 52 patients, one of whom had Burkitt lymphoma and the two cases with severe COVID-19 of late referral.
Conclusion: Differences between clinical presentations, acute phase responses, organ involvements, and management strategies indicate that MIS-C might be a distinct immunopathogenic disease as compared to pediatric COVID-19. Conjunctival injection and higher CRP and low WBC count seem good diagnostic parameters for MIS-C cases.

POS1250 VITAMIN D DEFICIENCY IS MAINLY ASSOCIATED WITH SEVERE LUNG INVOLVEMENT, LONGER DISEASE DURATION AND RISK OF DEATH IN ELDERLY COVID-19 PATIENTS

A. Sulli[1], E. Gotelli[1], A. Casabella[1], M. Grosso[2], C. Schenone[1], C. Pizzorni[1], S. Paolino[1], E. Alessandri[1], V. Smith[3], M. Cutolo[1]. [1]*Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genova, Italy*; [2]*Pneumology Unit, IRCCS San Martino Polyclinic Hospital, Genova, Italy*; [3]*Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, VIB Inflammation Research Centre Ghent University, Ghent, Belgium*

Background: Vitamin D regulates the innate and adaptive immune system responses and low vitamin D levels have been associated with the increased risk of respiratory tract infections (1). Vitamin D deficiency has been recently reported to interfere with the prognosis of COVID-19 (2,3).
Objectives: The aim of this study was to correlate the 25OH-vitamin D serum levels with lung involvement and disease severity, in a cohort of elderly patients hospitalized for SARS-CoV-2 infection.
Methods: Sixty-five COVID-19 patients (mean age 76±13 years) and sixty-five sex- and age-matched control subjects (CNT) were included in the study. Respiratory parameters (PaO_2, SO_2, $PaCO_2$, PaO_2/FiO_2), clinical and laboratory parameters (including 25OH-vitamin D, D-dimer, C-reactive protein) and type of radiological pulmonary involvement were collected at hospital admission. Statistical analysis was performed by non-parametric tests.
Results: Vitamin D sufficiency (>30 ng/ml), insufficiency (between 20 and 30 ng/ml), deficiency (between 10 and 20 ng/ml) and severe deficiency (<10 ng/ml) were observed respectively in 11, 11, 21 and 57 % of COVID-19 patients. Vitamin D serum levels were found significantly lower in COVID-19 patients than in CNT (median 8 vs 16 ng/ml, p=0.001). A statistically significant positive correlation was observed between vitamin D serum levels and SO_2 (p=0.05), PaO_2 (p=0.03), PaO_2/FiO_2 (p=0.02). A statistically significant negative correlation was found between vitamin D serum levels and severity of radiologic pulmonary involvement: vitamin D was significantly lower in COVID-19 patients with either diffuse/severe interstitial lung involvement (p=0.05) or multiple lung consolidations (p=0.0001) than in those with mild radiological lung involvement. Significantly lower vitamin D serum levels were found in COVID-19 patients who died during hospitalization, compared to those who survived (median 3 vs 8 ng/ml, p=0.05). Finally, a statistically significant negative correlation was found between vitamin D serum levels and D-dimer (p=0.04), C-reactive protein (p=0.04) and disease duration (p=0.05).
Conclusion: This study confirms that severe vitamin D deficiency is associated with more severe lung involvement, longer disease duration and risk of death in elderly COVID-19 patients.

POS1251 ROLE OF SYSTEMIC AUTOINMUNE CONDITIONS IN HOSPITAL ADMISSIONS RELATED TO COVID-19

I. Perez-Sancristobal[1], L. Lopez Pedraza[2], M. P. Álvarez Hernandez[1], J. I. Colomer[3], A. Madrid García[2], B. Fernandez[1], C. Martinez Prada[1], L. Rodriguez Rodriguez[2], A. Mucientes[2], L. León[2], L. Abasolo[2]. [1]*Hospital Clínico San Carlos, Reumathology, Madrid, Spain*; [2]*Instituto de Investigación Sanitaria del Hospital Clínico San Carlos, Reumathology, Madrid, Spain*; [3]*Fundación para la Investigación Biomedica, Reumathology, Madrid, Spain*

Background: The COVID-19 pandemic continues worldwide and has had a strong impact on public health, quality of life and economy of the general population. To date, the number of infections and deaths are still increasing. From the beginning of the pandemic, efforts were intensified to identify risk factors for development of the severe form of COVID-19. In this sense underlying medical comorbidities have been shown to have a worse prognosis in these patients.

Objectives: In patients with rheumatic and musculoskeletal diseases (RMDs) and infected with Covid – 19, we aim to investigate the role of systemic autoimmune conditions compared to other type of RMDs in severity of COVID-19 in terms of hospital admissions.

Methods: An observational longitudinal study was conducted during the epidemic peak in Madrid (1stMar to 20thMay2020). All patients attended at the rheumatology outpatient clinic of a tertiary hospital with a diagnosis of RMDs and Covid-19 infection were included (according to a medical diagnosis or confirmed with a positive SARS-CoV-2 PCR diagnostic test). All patients were included since the time of COVID-19 diagnosis. Main variable: hospital admission related to Covid -19 infection. Independent variable: type of RMD including: autoimmune (systemic autoimmune conditions and inflammatory joint disease (IJD)) and non-autoimmune (mechanical diseases, and inflammatory diseases (microcrystalline arthritis and tendonitis)). Covariates: sociodemographic, clinical and therapy used. Statistical analysis: description of the sociodemographic, clinical and treatment characteristics of the patients. A multivariate logistic regression adjusted by age, sex and comorbidities was used to evaluate the risk of the different types of RMDs in hospital admissions related to Covid-19. The results were expressed as OR with its corresponding confidence interval (95% CI).

Results: 406 patients were included with RMDs and Covid- 19 infection. 69.21% were women with a mean age at diagnosis of 60 ± 15.26 years. The evolution time from the diagnosis of RMD was 8 ± 8.38 years. 26% had comorbidity at baseline. 25% were chronically on corticoids prior to the infection. Of the 406 patients, 244 (60.09%) had non-autoimmune RMD (157 mechanic, 87 inflammatory) and 162 (39.9%) (106 (65.43%) IJD, 56 (34.56%) systemic autoimmune condition) had autoimmune RMD. 36% of all patients were admitted (31% from not autoimmune RMDs and 43% from autoimmune RMD (p = 0,013). The risk of hospital admission in autoimmune RMD compared to non-autoimmune RMD was higher (OR: 1.68; [1.11-2.54], p=0.013), being the risk of systemic autoimmune condition compared to both IJD and non-autoimmune RMD higher (OR IJD: 0.41 [0.21-0.51], p=0.01; OR non-autoimmune: 0.33; [0.18-0.61]; p=0.000). After adjusting by confounders, autoimmune RMD had higher risk of hospital admissions compared to the rest (OR: 1.75; [1.04-2.95]; p=0.03), and specifically systemic autoimmune condition had higher risk compared to IJD (OR of IJD 0.33; [0.14-.076]; p=0.009) and compared to non–autoimmune (OR non autoimmune 0.28; [0.13-0.59], p=0.001). Advanced age (OR: 1.10; [1.07-1.12], p<0.001), male (OR 0.58; [0.33-1.02], p=0.06), and more number of comorbidities (OR 1.39; [1.02-1.90] p=0.03) also increased the risk of hospitalization related to COVID-19.

Conclusion: One third of the RMD patients infected with COVID-19 required hospital admission. This study shows that patients with autoimmune and specifically with systemic autoimmune conditions have a higher risk of hospitalization related to COVID-19. We also show that advanced age, male sex and a higher number of comorbidities can contribute to worsen the prognosis of the COVID-19 disease.

Background: The role of chronic use of hydroxychloroquine (HCQ) in rheumatic disease (RD) patients during the SARS-CoV-2 pandemic is still subject of discussion.

Objectives: To compare the occurrence of COVID-19 and its outcomes between RD patients on HCQ use with individuals from the same household not taking the drug during community viral transmission in an observational prospective multicenter study in Brazil.

Methods: Participants were enrolled and monitored through 24-week (From March 29th to Sep 30th, 2020) regularly scheduled phone calls performed by trained medical professionals. Epidemiological and demographic data, as well as RD disease activity status and current treatment data, specific information about COVID-19, hospitalization, need for intensive care, and death was recorded in both groups and stored in the Research Electronic Data Capture (REDCap) database. COVID-19 was defined according to the Brazilian Ministry of Health (BMH) criteria. The statistical analysis was performed using IBM-SPSS v.20.0 software. Group comparisons were made using the Man-Whitney, Chi-Square and Fisher Exact Test, as well as multivariate regression models adjusted to confounders. Survival curves were performed using Kaplan-Meier analysis.

Results: A total of 10,427 participants mean age (SD) of 44.04 (14.98) years were enrolled, including 6004 (57.6%) rheumatic disease patients, of whom 70.8% had systemic lupus erythematosus (SLE), 6.7% rheumatoid arthritis (RA), 4% primary Sjögren's syndrome (pSS), 1.8% mixed connective tissue disease (DMTC), 1% systemic sclerosis (SSc) and others (15.9), including overlap syndromes. In total, 1,132 (10.8%) participants fulfilled criteria for COVID-19, being 6.7% RD patients and 4.1% controls (p=0.002). A recent influenza vaccination had a protective role (p<0.001). Moderate and severe COVID-19 included the need for hospitalization, intensive care, mechanical ventilation or death. Infection severity was not different between groups (p=0.391) (Table 1). After adjustments for multiple confounders, the main risk factors significantly associated with COVID-19 were higher education level (OR=1.29 95%CI 1.05-1.59), being healthcare professionals (OR=1.91; 95%CI 1.45-2.53), presence of two comorbidities (OR=1.31; 95%CI 1.01-1.66) and three or more comorbidities associated (OR=1.69; 95%CI 1.23-2.32). Interestingly, age >=65 years (OR=0.20; 95%CI 0.11-0.34) was negatively associated. Regarding RD, the risk factors associated with COVID-19 diagnosys were SLE (OR= 2.37; 95%CI 1.92-293), SSc (OR=2.25; 95%CI 1.05-4.83) and rituximab use (OR=1.92; 95%CI 1.13-3.26). In addition, age >=65 years (OR=5.47; 95%CI 1.7-19.4) and heart disease (OR=2.60; 95%CI 1.06-6.38) were associated with hospitalization. Seven female RD patients died, six with SLE and one with pSS, and the presence of two or more comorbidities were associated with higher mortality rate.

Conclusion: Chronic HCQ use did not prevent COVID-19 in RD compared to their household cohabitants. Health care profession, presence of comorbidities LES, SSc and rituximab were identified as main risk factors for COVID-19 and aging and heart disease as higher risk for hospitalization. Our data suggest these outcomes could be considered to manage them in clinical practice.

Table 1. Frequency and severity of COVID-19 in patients with rheumatic diseases on chronic use of hydroxychloroquine compared to their household controls

			Groups		
		Total	Patients		P
COVID-19 outcomes		(%)	(%)	Controls (%)	
Diagnosis	No	9256 (89.1)	5300 (88.3)	3956 (90.2)	0.002
	Yes	1132 (10.9)	704 (11.7)	428 (9.8)	
Severity	Mild	1059 (93.6)	662 (94.0)	397 (92.8)	0.391
	Moderate	52 (4.6)	32 (4.5)	20 (4.7)	
	Severe	21 (1.9)	10 (1.4)	11 (2.6)	

HCQ: hydroxychloroquine.Moderate and severe COVID-19 included the need for any of the following: hospitalization, intensive care, mechanical ventilation or death.

POS1253 MORTALITY RATE RELATED TO COVID - 19 IN RHEUMATIC AND MUSCULOSKELETAL DISEASES (RMDS)

D. Freites[1], I. Perez-Sancristobal[1], L. Lopez Pedraza[2], M. P. Álvarez Hernandez[1], I. Hernandez[1], J. I. Colomer[3], A. Madrid García[2], B. Fernandez[1], C. Vadillo[1], L. Rodriguez Rodriguez[2], A. Mucientes[2], L. León[3], L. Abasolo[2]. *[1]Hospital Clínico San Carlos, Reumathology, Madrid, Spain*; *[2]Instituto de Investigación Sanitaria del Hospital Clínico San Carlos, Reumathology, Madrid, Spain*; *[3]Fundación para la Investigación Biomedica, Reumathology, Madrid, Spain*

Background: Spain has been one of the countries most impacted by the COVID-19 pandemic. Among Spanish patients, 56,799 deaths have been reported. Although we have been in this situation of pandemic for a year, studies that show risk mortality rates in patients with rheumatic diseases continue to be scarce.
Objectives: In patients with rheumatic and musculoskeletal diseases (RMDs) and infected with Covid – 19, a) we want to assess the mortality rate (MR) related to COVID-19; and b) to analyze the role of RMDs in mortality risk.
Methods: An observational longitudinal study was conducted during the epidemic peak in Madrid (1stMar to 20thMay2020). All patients attended at the rheumatology outpatient clinic of a tertiary hospital with a diagnosis of RMDs and SARS - CoV 2 infection were included (according to a medical diagnosis or confirmed with a positive SARS-CoV-2 PCR diagnostic test). All patients were included since the time of COVID-19 diagnosis. Main outcome: death related to COVID-19 infection. Independent variable: type of RMDs including: autoimmune (systemic autoimmune conditions (SAC) and inflammatory joint disease (IJD)) and non–autoimmune (mechanical diseases and inflammatory diseases (microcrystalline arthritis and tendonitis)). Covariates: sociodemographic, comorbidities, chronic use of corticoids prior to COVID-19 infection. Survival techniques were used to estimate the MR related to COVID-19, given per 1,000 persons-month with a 95% confidence interval [CI]. The time of observation comprised the elapsed time between the date of COVID-19 diagnosis of infection until the date of patient's death, or end of study. Cox multiple regression analysis was run to examine the effect of autoimmune RMDs compared to non-autoimmune RMDs on mortality risk adjusted by sex, age and comorbidities. Results were expressed by Hazard Ratio (HR) and [CI].
Results: 406 patients were included with RMD and Covid – 19 infection with a total follow-up 642.5 patients-month. 69.21% were women with a mean age at diagnosis of 60 ± 15.26 years. The evolution time from the diagnosis of rheumatic disease was 8 ± 8.38 years. 26% had comorbidity at baseline. 25% were chronically on corticoids prior to the infection. Of the 406 patients, 244 (60.09%) had non-autoimmune RMD (157 mechanic, 87 inflammatory) and 162 (39.9%) (106 (65.43%) IJD, 56 (34.56%) systemic condition) had autoimmune RMD. Of the 406 patients, 45 (11%) died during the follow-up, being 12± 14 days the mean time from infection to death (P50: 6[2-12] and a maximum of 60 days). MR was estimated in 70.03 [52.28-93.79] per 1,000 persons-month. MR was higher for men (MR 105[68-163]) than for women (MR 55 [37.2-81.6]) and in older people (MR <60: 4.4, [0.6-31.7]; MR 60-75 years: 38.7[17.3-86.2]; MR >75Years: 486 [354-1668]). The HR of mortality in autoimmune RMDs compared to non-autoimmune RMDs did not achieved statistical significance (HR: 1.39 [0.77-2.5], p=0.27). After adjusting for confounders, we did not find higher risk of mortality among the different types of RMDs (HR autoimmune vs non-autoinmunes: HR: 1.12 [0.6-2.02], p=0.7; HR IJD vs SAC; 1.5 [0.6-3.6], p=0.34; HR non-autoimmune vs SAC: 1.1 [0.5-2.5], P=0.7). Age (HR: 1.12; [1.10-1.15], p<0.001), and the presence of comorbidities (HR: 2.05; [1.08-3.89], p=0.027) increased the Mortality risk.
Conclusion: In patients with RMD and COVID-19 infection, we found a mortality rate of 7 per 100 persons-month. This study shows that the mortality risk related to COVID-19 is similar between autoimmune and non-autoimmune diseases after adjusting by confounders. We also found that age and comorbidities are risk factors for mortality related to COVID-19 infection.

POS1254 INCIDENCE AND OUTCOME OF COVID-19 IN ROUTINE RHEUMATOLOGY CARE: DATA FROM A SINGLE OUTPATIENT CENTER IN GERMANY

S. G. Werner[1], P. Höhenrieder[2], R. Chatelain[2,3], H. E. Langer[1]. *[1]RHIO (Rheumatology, Immunology, Osteology) Düsseldorf, RHIO Reasearch Institute, Düsseldorf, Germany*; *[2]University of Witten-Herdecke, Faculty of Health, Witten, Germany*; *[3]Evangelical Hospital Düsseldorf, Departement of Dermatology, Düsseldorf, Germany*

Background: Coronavirus SARS-CoV-2 (severe acute respiratory syndrome coronavirus 2) and its associated disease COVID-19 (Corona Virus Disease 2019) has become a worldwide pandemic since its first cases in December 2019 in Wuhan Province in China. Until now little is known about the incidence and the course of the disease in a routine setting of rheumatology outpatient care.
Objectives: Aim of the study was to identify cases with COVID-19, to analyse course and outcome of the disease and the potential role of antirheumatic medication.
Methods: On the occasion of a routine follow-up examination all consecutive patients of our rheumatology outpatient center were questioned about the history of established COVID-19, about typical symptoms or about contacts with patients in the period from March to the end of December 2020. Diagnostic work-up (results of PCR or antibody testing, imaging) was documented. Antibody ELISA-tests (IgG, IgA, IgM, Euroimmun) were performed in patients reporting typical signs and symptoms. Course and outcome of COVID-19 were divided in 5 groups (mild, moderate, severe, most severe, and lethal).
Results: About 2.000 patients were screened. Positive findings for SARS-CoV-2 confirmed by PCR or serological testing were detected in n=33/2000 (1.65%) patients (n=14/33 (43%) rheumatoid arthritis (RA), n=8/33 (24%) psoriatic arthritis (PsA), n=7/33 (21%) spondyloarthritis (SpA), n=4/33 (12%) other diseases).
No patient died and no patient required intensive care or invasive mechanical ventilation. N=2/33 patients (6%) suffered a severe course with hospitalization, one of these required intermittent oxygen administration. Both patients had no ongoing therapy with disease modifying antirheumatic drugs (DMARDs). One patient suffered from SpA, one patient from RA. Both patients had relevant comorbidities with chronic lung disease and breast cancer.
Symptoms were absent or mild in n=21/33 (64%) patients, moderate in n=10/33 (30%). N=22/31 (71%) of patients with absent, mild or moderate symptoms were treated at least with one DMARD.
Conclusion: For an at-risk population, the incidence of COVID-19 was unexpectedly low. Overall, patients had a mild course despite immunosuppressive therapy. This finding is consistent with published data from a single university

center (1) and other university outpatient clinics (2). Possibly DMARD-therapy may protect against the occurrence of cytokine storm and vasculitic complications, which lead to severe courses and lethal outcomes in some of the patients. The data support the recommendation not to discontinue DMARDs for fear of COVID-19.

POS1255 REACTOGENICITY OF SARS-COV-2 VACCINES IN PATIENTS WITH AUTOIMMUNE AND INFLAMMATORY DISEASE

M. Yang[1], P. Katz[1], D. Paez[1], A. Carvidi[1], M. Matloubian[1], M. Nakamura[1], L. S. Gensler[1]. *[1]University of California, San Francisco, Division of Rheumatology, San Francisco, United States of America*

Background: Patients with autoimmune disease often require immunosuppressive medications that may increase their risk of developing severe illness from COVID-19. The importance of immunization in this population is particularly high. While the studied vaccines show efficacy in the general population, nothing is known regarding the immune response or safety profile in patients with autoimmune disease and those taking immunomodulatory medications.

Objectives: To assess the safety profile and degree of adverse events from SARS-CoV-2 vaccines in patients with autoimmune and inflammatory disease.

Methods: This study is part of a larger prospective observational study examining the immunogenicity and safety profile of the SARS-CoV-2 vaccine in patients with immune-mediated diseases taking immunomodulatory medications. Adults with an immune-mediated disease scheduled to receive either a Pfizer or Moderna SARS-COV-2 vaccine were enrolled in this study. Subjects participated in 3 study visits (pre-vaccine, dose 1 (D1) and dose 2 (D2)) where blood, for immunologic assays, and clinical data were collected. Assessments of adverse events (AE), including local and systemic symptoms and validated degree of AE severity were solicited within 7 days of receiving each vaccine dose.

Results: To date, 70 patients with autoimmune and inflammatory disease have been enrolled. Demographic and clinical characteristics are shown in Table 1. Distribution of current immunomodulatory medications included prednisone 18.6%, conventional synthetic DMARD 55.7%, targeted synthetic DMARD 4.3%, and biologic DMARD 68.5%. Almost all participants experienced an adverse event following vaccination (D1 96%, D2 100%). Following D1 AEs were generally mild (76.5%) whereas following D2 a large portion of patients experienced AEs that were moderate (47.8%) and severe (30.5%). Injection site pain was the most common AE following both doses followed by arthralgias (D1 21.6%, D2 78.2%), fever (D1 21.6%, D2 70%) and fatigue (D1 21.6%, D2 65.2%) (Figure 1).

* Spondyloarthritis includes Axial Spondyloarthritis and Psoriatic Arthritis. ‡ Other Connective Tissue Disease includes scleroderma, Sjogren's syndrome, polymyositis, and UCTD.

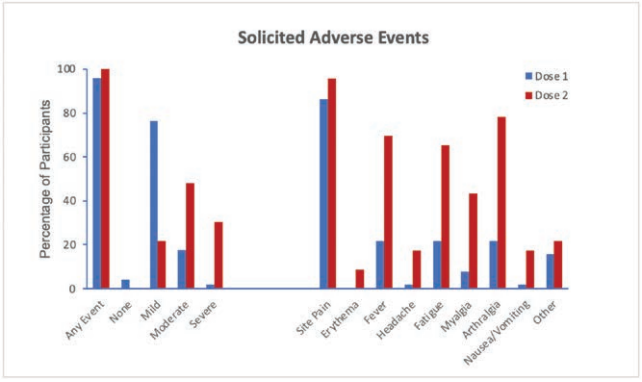

Figure 1. Solicited Local and Systemic Adverse Events. Percentage of participants who had endorsed an adverse event within 7 days of first or second dose of SARS-CoV-2 Vaccine. 'Other' symptoms included chills, blurry vision, brain fog and dizziness.

Conclusion: Patients with autoimmune and inflammatory disease experience a significant burden of adverse events following SARS-CoV-2 vaccination with both frequency and severity appearing greater than that of the reported results from the vaccine clinical trials. Several of the endorsed AEs such as fever, fatigue and arthralgias can also be commonly seen in rheumatologic diseases, mimicking flares. While SARS-CoV-2 immunization is crucial in patients with autoimmune diseases, this study demonstrates the importance of understanding the AEs experienced by this patient population to better inform patients of possible expected side effects of SARS-CoV-2 vaccination and further management in the future.

POS1256 SINGLE DOSE TOCILIZUMAB PHARMACOKINETICS IN GLUCOCORTICOID PRE-TREATED COVID-19 PATIENTS DURING CYTOKINE STORM SYNDROME HYPERINFLAMMATORY EPISODE: LESS IS MORE

N. Boone[1], S. Ramiro[2], D. J. Moes[3], R. Mostard[4], C. Magro Checa[2], C. Van Dongen[2], M. Gronenschild[4], E. Van Haren[4], J. Buijs[5], R. Peeters[2], D. Wong[1], R. B. M. Landewé[2,6]on behalf of COVID-19 Study group Zuyderland Medical Centre. *[1]Zuyderland Medisch Centrum Sittard-Geleen, Clinical Pharmacy, Pharmacology and Toxicology, Geleen, Netherlands*; *[2]Zuyderland MC, Rheumatology, Heerlen, Netherlands*; *[3]Leiden University Medical Center (LUMC), Clinical Pharmacy, Pharmacology and Toxicology, Leiden, Netherlands*; *[4]Zuyderland MC, Pulmonology, Heerlen, Netherlands*; *[5]Zuyderland Medisch Centrum, Internal Medicine, Brunssum, Netherlands*; *[6]Amsterdam UMC, locatie AMC, Amsterdam Rheumatology & Clinical Immunology Center, Amsterdam, Netherlands*

Background: The cytokine storm syndrome (CSS) associated with COVID-19 pneumonia occurs in up to 20% of the admitted patients causing high morbidity and mortality [1]. In the COVID High-intensity Immunosuppression in Cytokine storm syndrome (CHIC) study [1] we reported that CSS patients, who despite high-dose methylprednisolone (MP) treatment still showed severe respiratory deterioration, received subsequent single dose tocilizumab (TCZ) treatment. Our clinical experience with TCZ, every 4 weeks in RA, where a pre-dose serum concentration of > 1 µg/ml is sufficient to block all interleukin (IL)-6 receptors and thereby induce and maintain clinical remission, prompted further investigation of TCZ pharmacokinetics in patients with COVID-19 CSS [1,2].

Objectives: In this pharmacokinetic study we investigated the clinical-pharmacokinetic rationale for a single TCZ dose in a subset of COVID19 induced CSS patients.

Methods: Patients with COVID-19-associated CSS, defined as rapid respiratory deterioration plus at least two biomarker elevations (C-reactive protein (CRP) >100 mg/L; ferritin >900 µg/L; D-dimers >1500 µg/L), received per protocol high-dose intravenous MP for 5 consecutive days. If the respiratory condition had not improved sufficiently, TCZ (8 mg/kg, max. 800 mg) single infusion was added on or after day 2[1]. TCZ serum samples were drawn at TCZ day 1, 3 and 10 to assess TCZ serum concentrations with a validated ELISA-method. A nonlinear-mixed effects model was developed based on all concentration time data to characterise TCZ pharmacokinetics (NONMEM). Subsequently individual pharmacokinetic parameters (AUC0-inf, Cmax, time above 1 µg/ml) were estimated and TCZ concentration-time observations were plotted against the individual predicted concentrations to visualize the complete TCZ concentration-time curve.

Results: In total, 34 patients with COVID19 induced CSS still showing clinical deterioration upon MP treatment received TCZ per protocol [mean (SD) age: 62 (12) years, 22% female, baseline mean (SD) bodyweight: 87 (17) kg, CRP: 108 (833) mmol/L, ferritin: 1653 (911) µg/L, D-dimers 4462 (7272) µg/L]. TCZ clearance was described by a homogeneous population-kinetics model yielding 87 serum samples. TCZ serum concentrations followed a biphasic course [Distribution volume 5.0 L (3.3-7.3), Area Under the Curve$_{0-\infty}$ 1st dose (682 (397-913) mg/L*days), Cmax 137 mg/L (88 – 199), half-life (linear) 3.5 days (2.3-4.1)]. In all patients, TCZ serum concentrations remained above the theoretical maximum IL-6 receptor occupancy concentration of 1 µg/ml for at least 12 days, depicted in Figure 1.

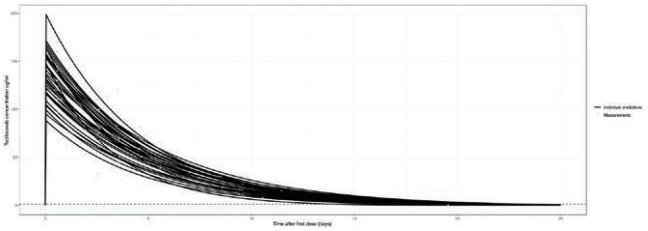

Figure 1. Predicted concentration-time profiles after single dose tocilizumab in 34 methylprednisolone pretreated patients with COVID-19 induced cytokine storm syndrome. Dashed line: maximum IL-6 receptor occupancy concentration 1 µg/ml

Conclusion: Based on our study results on the pharmacokinetics of TCZ in patients with severe COVID-19 induced CSS we conclude that the clearance of TCZ is faster compared to RA-patients at steady state. However, our observations indicate that a single dose of tocilizumab in CSS-patients is enough to cover IL-6 mediated hyperinflammation. Restricting TCZ to a single dosage can prevent overtreatment, drug shortage and saves costs, while still maintaining efficacy, as most patients will have overcome their hyperinflammatory period of the CSS after 10-14 days.

POS1257

HYPOGAMMAGLOBULINEMIA IS A SIGNIFICANT RISK FACTOR FOR MORTALITY IN PATIENTS WITH ANCA ASSOCIATED VASCULITIS AND COVID-19

B. Ince[1], M. Bektas[1], N. Koca[1], B. F. Agargun[2], S. Zaralı[2], D. Y. Guzey[3], Y. Yalçınkaya[1], B. Artim-Esen[1], A. Gül[1], M. Inanc[1]. *[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; *[2]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey*; *[3]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey*

Background: The negative impact of COVID-19 in patients with ANCA associated vasculitis (AAV) and patients on rituximab (RTX) treatment have been reported (1). Risk factors for severe course of COVID-19 and increased mortality in these patients are unclear.

Objectives: To evaluate the course of COVID-19 in our AAV cohort and identifying risk factors for mortality.

Methods: Patients with AAV who were classified according to CHCC and whose scheduled last visit were after December 2019 were screened and evaluated for COVID-19 either by phone call or in the clinic. Records of patients with a history of hospital admission due to COVID-19 were evaluated. Cumulative clinical findings and treatment history were noted. Hypogammaglobulinemia (hIgG) was defined as IgG level below 700 mg/dl. All inpatients with a diagnosis of COVID-19 were screened for hIgG and IVIG was administered if necessary.

Results: Eighty-nine patients (47.2% female, mean age 56 + 12.5 (28-81)) were included into the study. The diagnosis was GPA in 56 (62.9%) and MPA in 33 (37.1%) patients. Mean follow up time was 91 + 53.4 (26-272) months. Anti-PR3 and anti-MPO were positive in 46 (51.7%) and 32 (35.9%) patients, respectively. Lower respiratory tract (LRT) involvement was present in 72 (80.9%) and 10 patients had a history of diffuse alveolar haemorrhage (DAH). Sixty-one patients (68.2%) had a history of rapidly progressive glomerulonephritis (RPGN) and 21 (23.6%) had peripheral nervous system (PNS) involvement.

Fifteen (16.9%) patients had COVID-19; 14 of them were PCR positive, one patient had symptoms and thorax CT findings compatible with COVID-19. Pulmonary infiltrates were observed in 13 patients (86.7%); 9 (60%) had severe pneumonia. Twelve patients (85.7%) were hospitalized, 6 patients (42.9%) needed ICU admission and 5 patients (35.7%) died. Tocilizumab and anakinra for hyperinflammation during COVID-19 were used in 1 (6.7%) and 4 (26.7%) patients, respectively.

Four out of five deceased patients (3 on RTX treatment, 1 with renal transplant) were in remission at the time of COVID-19. COVID-19 was detected in a patient with disease flare and DAH, during treatment with high dose steroids and plasmapheresis. hIgG was detected in all deceased patients from COVID-19 during hospital admission (mean IgG: 495±113.2 mg/dL).

Table 1. Comparison of risk factors for CI and mortality in patients with AAV

	COVID-19 (n=15)	Non-infected (n=74)	p	OR	Death (n=5)	Survive (n=10)	p2	OR2
Age	53.4±11.9	56.6±12.6	NS		51.2±12.6	54.6±12.1	NS	
Sex (female)	6	35	NS		4	2	0.036	14 (0.9-207)
LRT Involvement	14	58	NS		5	9	NS	
DAH	4	6	0.038	4.1 (1-16.9)	1	3	NS	
RPGN	15	46	0.004	8.5 (1-68.4)	5	7	NS	
PNS involvement	3	18	NS		3	0	0.005	9 (1.4 - 57)
RTX treatment	10	33	NS		3	7	NS	
hIgG in outpatient visits	6	7	0.02	6.3 (1.8-23.3)	4	2	0.02	16 (1.5-234)
hIgG during hospitalization due to CI	-	-	-	-	5	4	0.025	2.5 (1.2-5.4)
Flares≥1	7	25	NS		4	3	NS	
Chronic Renal Insufficiency	7	22	NS		4	3	NS	

Symptomatic COVID-19 was more frequent in patients with a history of DAH, RPGN and hIgG. hIgG during the follow-up was significantly associated with COVID-19 in multivariable analysis (p=0.01, OR=20,6 %95 CI (2-210). Comparison of patients who died of COVID-19 and survived showed that female sex, PNS involvement and hIgG during the clinical course and hospital admission were risk factors for increased mortality (Table 1). Age, smoking, treatments, history of flares or serious infections, remission status and chronic renal insufficiency did not differ between groups.

Conclusion: The frequency and mortality from COVID-19 is found to be high in our AAV cohort compared to previous reports (1). Patients with serious lung or renal involvement are prone to symptomatic COVID-19. Previously reported severe outcomes on RTX therapy might be related to consequent hIgG. High dose IVIG treatment may not be sufficient in improving survival in AAV patients with severe COVID-19 and hIgG.

POS1258 MISSING THE WINDOW OF OPPORTUNITY: EARLY ARTHRITIS CLINICS IN TIMES OF COVID-19

B. D'onofrio[1,2], L. De Stefano[1,2], B. L. Palermo[1,2], B. Xoxi[1], A. Manzo[1,2], C. Montecucco[1,2], S. Bugatti[1,2]. [1]*IRCCS Policlinico San Matteo Foundation, Division of Rheumatology, Pavia, Italy*; [2]*University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy*

Background: The outcomes of patients with chronic inflammatory arthritis (IA), such as rheumatoid arthritis (RA), have dramatically improved over the past 20 years. Earlier identification of IA and prompter treatment institution have been key advancements, promoted by the constitution of Early Arthritis Clinics (EAC) and the development of more sensitive classification criteria for RA. The outbreak of new COronaVIrus Disease 2019 (COVID-19) has quickly become a global health emergency and has forced a rearrangement in the management of other non-COVID-19 diseases. The impact of the lock-down of the healthcare systems on chronic inflammatory diseases such as RA is expected to be significant but is at present unknown.

Objectives: To assess the effects of the lock-down imposed by the COVID-19 pandemic on the referral and clinical presentation of patients with new-onset RA.

Methods: Data were retrieved from the Pavia EAC inception cohort, established in 2005 for the early identification of patients with new-onset IA. Referral criteria to the EAC include: ≥3 swollen joints (SJ) and/or <3 SJ and positive squeeze test and/or <3 SJ and morning stiffness >30 min. Demographic and clinical characteristics of the patients are assessed at baseline and regularly over follow-up. At 31 Dec 2020, the Pavia EAC collects information on 2.508 patients. For this study, baseline characteristics of the patients referred in the semester following the COVID-19 lock-down (Jul-Dec 2020) were compared with: (i) patients referred in the semester immediately preceding the lock-down (Jul-Dec 2019); (ii) patients referred in the semester following the publication of the 2010 RA classification criteria (Jan-Jun 2011); (iii) patients referred in the semester preceding the publication of the 2010 criteria (Jul-Dec 2009).

Results: In the semester following the lock-down imposed by the COVID-19 pandemic, there was a decrease in the referral of patients with new-onset suspected IA compared with previous periods (n=71 vs n=91 in the semester before the lock-down, n=96 in the first semester of 2011, n=101 in the second semester of 2009). Furthermore, fewer of the referred patients fulfilled RA criteria at presentation (36.6% vs 44.3%, 46.5% and 42.9% in the other semesters). Among patients with RA, more were autoantibody-positive (72% vs 50%, 49.1% and 52.2%). There was a trend for increased diagnostic delay in the overall cohort of RA after the COVID-19 lock-down (Figure 1A). The delay was particularly longer in autoantibody-positive patients, returning to the values seen before the introduction of the 2010 RA criteria (Figure 1B). In contrast, the few autoantibody-negative patients were referred earlier (Figure 1C). Disease activity at presentation was significantly higher in RA patients presenting after the lock-down compared with the progressive trend for reduction observed over the previous years, irrespective of the autoantibody status (Figure 1D-F). Such increase was determined by an inversion of the trend towards lower levels of objective parameters of inflammation, such as the swollen joint count (Figure 1G-I) and acute phase reactants, and a further increase in the secular trend towards worsening of patient-derived measures, such as the tender joint count and patient global assessment (Figure 1J-L).

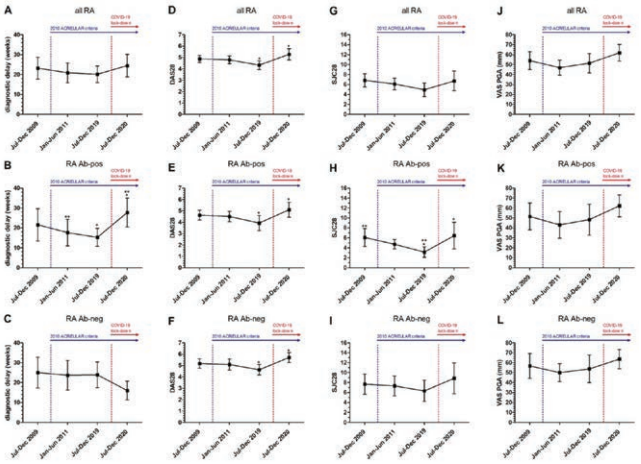

Figure 1. Effects of COVID-19 lock-down on new-onset RA at presentation.

Conclusion: The COVID-19 pandemic is posing unprecedented challenges in the management of patients suffering from chronic diseases. RA has returned to be diagnosed outside the window of opportunity, with a significantly higher inflammatory burden at presentation. The many benefits of early diagnosis, which have dramatically changed the outcomes of autoantibody-positive RA, are at risk of vanishing in short times. Equally important, autoantibody-negative RA is at risk of further under-diagnosis and under-treatment.

POS1259 FAVOURABLE SHORT-TERM COURSE OF COVID-19 IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER USING BIOLOGIC AGENTS

N. Aliyeva[1], B. Ç. Yalçın Dulundu[1], S. Amikishiyev[1], S. Aghamuradov[1], M. Bektaş[1], B. Ince[1], N. Koca[1], Y. Yalçınkaya[1], B. Artim-Esen[1], M. Inanc[1], A. Gül[1]. [1]*İstanbul Medical Faculty, Rheumatology, İstanbul, Turkey*

Background: COVID-19 runs a variable course resulting in acute respiratory distress syndrome and death in a subset of patients. The entry of SARS-CoV-2 into the cell stimulates innate immunity including NLRP3 inflammasome and lead to development of adaptive immunity later. Hyperinflammatory response with the release of proinflammatory cytokines including IL-1β and IL-6 results in cytokine storm in some patients with a worse outcome. Colchicine acts on NLRP3 inflammasome and inhibits and IL-1 mediated inflammatory attacks in gout and familial Mediterranean fever (FMF) patients. Patients with inadequate response to colchicine may benefit from anti-IL-1 biologic agents such as anakinra and canakinumab. Recently, favourable effects of anakinra have been observed in COVID-19 patients with findings of cytokine storm.

Objectives: We aimed to evaluate the impact of COVID-19 among refractory FMF patients followed-up in tertiary referral with the treatment of biologic agents and also document the course of COVID-19 in these patients.

Methods: We searched out database of FMF patients to identify those using biologic agents (anti-IL-1, anti-IL-6 or anti-TNF) for colchicine-refractory FMF. We interviewed the patients using a standard questionnaire by phone call for symptomatic COVID-19 and evaluated those patients who described findings of COVID-19 further by their hospital records or inviting them to the hospital for additional investigations.

Results: We identified 183 patients and contacted 106 of them by phone in May-October 2020. A history of symptomatic COVID-19 was documented in 7 FMF patients who were on a biologic agent. Six were on anti-IL-1 and one was on anti-TNF, and one of the patients was not taking his biologic agents for 1 year. All of 7 patients had a favourable outcome. All but 1 patient followed at home and none of them developed findings of cytokine storm, thromboembolism and secondary bacterial infection. Hospitalized patient did not require intensive care unit (ICU) support or mechanical ventilation, and he was not given additional anti-inflammatory medications.

Conclusion: This series of refractory FMF patients with potentially higher inflammatory characteristics showed COVID-19 did not result in a worse outcome in those patients during the first phase of the pandemic, and none developed findings of cytokine storm. Observations in these patients supports further that biologic agents blocking IL-1 and possibly TNF may contribute to the uneventful course of COVID-19 by preventing the development of hyperinflammatory response. Data collection from a larger group of patients, especially those with amyloidosis, will clarify the protective effects of colchicine and contribution of anti-IL-1 treatments on the favourable disease course during the second phase of the pandemic.
