Results: 1. Among 134 RA patients who received synovial biopsy at baseline and finished one-year follow-up, 105 had qualified synovial tissue. The mean age was 50.2±13.3 years with 77.1% female. The median disease duration was 24 (9-120) months. All patients were active RA, and 64.8%, 26.7% and 8.6% patients in high, moderate and low disease activity, respectively. There were 41 (39%) patients who have never been treated with corticosteroids or disease-modifying anti-rheumatic drugs.

2. During one-year follow-up, there were 48.6%, 63.8%, 71.4%, and 69.5% patients achieved CDAI LDA target, and 12.4%, 30.5%, 34.3%, and 32.4% patients achieved CDAI remission after 1, 3, 6, and 12 months, respectively. A total of 33 (31.4%) patients had radiographic progression.

3. All patients were divided into three clusters using cluster analysis based on the seven synovial cellular scores. Patients in cluster 1 (*n*=50, 47.6%) had higher scores of sublining CD68+ macrophages, CD31+ endothelial cells and CD90+ fibroblasts, thus named as myeloid-stromal pathotype. Patients in cluster 2 (*n*=26, 24.8%) had higher scores of CD20+ B cells, CD38+ plasma cells, CD4+ T cells and CD8+ T cells, thus named as lymphoid pathotype. Patients in cluster 3 (*n*=29, 27.6%) had lower scores of all seven cell types, thus named as pauci-cellular pathotype (Figure 1).

4. RA patients with baseline synovial myeloid-stromal pathotype showed higher rate of one-year radiographic progression versus lymphoid and pauci-cellular pathotypes (48% vs. 16.4%, *P*<0.001), whereas there was no difference between lymphoid and pauci-cellular pathotypes (11.5% vs. 20.7, *P*=0.475). Adjusted for confounding factors including age, sex, smoking, disease duration, RF status, ACPA status, CDAI, HAQ-DI and mTSS at baseline, multivariate logistic regression analysis showed that baseline synovial myeloid-stromal pathotype independently predicted one-year radiographic progression (*AOR*=3.602, 95%CI:1.257-10.324, *P*=0.017, Table 1).

Conclusion: Baseline synovial myeloid-stromal pathotype in RA can predict one-year radiographic progression.

POS0453 VALIDATION OF THE SIMPLIFIED DISEASE ACTIVITY INDEX (SDAI) WITH A QUICK QUANTITATIVE C-REACTIVE PROTEIN ASSAY (SDAI-Q) IN PATIENTS WITH RHEUMATOID ARTHRITIS: A NATIONAL, MULTICENTER STUDY

J. Schally[1], H. C. Brandt[2], J. Brandt-Juergens[3], G. R. Burmester[4], H. Haibel[1], H. Käding[1], K. Karberg[2], S. Lüders[1], B. Muche[1], M. Protopopov[1], V. Rios Rodriguez[1], M. Torgutalp[1], M. Verba[1], S. Zinke[5], D. Poddubnyy[1], F. Proft[1]. *[1]Charité – Universitätsmedizin Berlin, Division of Gastroenterology, Infectiology and Rheumatology, Campus Benjamin Franklin, Berlin, Germany*; *[2]Praxis für Rheumatologie und Innere Medizin, Praxis für Rheumatologie und Innere Medizin, Berlin, Germany*; *[3]Rheumatologische Schwerpunktpraxis, Rheumatologische Schwerpunktpraxis, Berlin, Germany*; *[4]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; *[5]Rheumapraxis Berlin, Rheumapraxis Berlin, Berlin, Germany*

Background: Therapeutic decisions in RA patients should be based on regular disease activity assessment using scores like the Simplified Disease Activity Index (SDAI) or the Clinical Disease Activity Index (CDAI) [1]. The CDAI has the benefit of being immediately available, while the SDAI encompasses with the C-reactive protein (CRP) an acute phase reactant and therefore is the recommended score for the use in clinical trials. However, CRP determination takes hours to days, thus hindering the treat-to-target concept using the SDAI. Quick quantitative CRP (qCRP) tests allow CRP measurement within a few minutes. Therefore, qCRP based SDAI (SDAI-Q) could combine the advantages of both scores.

Objectives: To validate the SDAI-Q in a prospective, multicenter study of RA patients.

Methods: The study was conducted in five centers in Berlin, Germany. Consecutive adult (≥ 18 years) RA patients were included. In addition to a rheumatological assessment, including patient reported outcomes, routine CRP was measured in the local labs. Additionally, a qCRP testing with the „QuikRead go instrument" (Aidian Oy, Finland) was performed locally (measurement range 0.5 - 200 mg/l). Statistical analysis included descriptive statistics, cross tabulation and weighted Cohen´s kappa comparing disease activity categories, Bland-Altman plots and intraclass correlation coefficient (ICC) for CRP, qCRP, SDAI, SDAI-Q and CDAI.

Results: In this study 100 RA patients were included (mean age: 60.9 years, mean disease duration: 11.4 years, 73.0% were female, 63.0% RF positive, 57.0% ACPA positive, 49.0% positive and 29% negative for both parameters). 75.0% were treated with csDMARD, 15% with tsDMARDs, 39.0% with bDMARDs and 40% with glucocorticoids (mean prednisolone equivalent: 5.4 mg prednisolone/d). Mean CRP and qCRP-levels were 6.97 and 7.89 mg/l, respectively (ICC 0.992; 95%CI: 0.987; 0.995). Comparing SDAI-Q and SDAI, all patients (100%) achieved the same disease activity status (Table 1A); weighted Cohen´s kappa was 1.000 (95%CI: 1.000; 1.000). ICC for SDAI-Q- and SDAI-values was 1.000 (95%CI: 1.000; 1.000). The agreement of SDAI-Q and SDAI is shown in a Bland-Altman plot (Figure 1). When comparing the CDAI with the SDAI-Q 93 patients (93%) were assigned to the same disease activity category (Table 1B); weighted Cohen´s kappa was 0.929 (95%CI: 0.878; 0.981). ICC for numerical values of SDAI-Q and CDAI was 0.989 (95%CI: 0.978; 0.994).

Conclusion: SDAI-Q showed an absolute agreement with SDAI on the assignment to disease activity categories with the important advantage of time. With SDAI-Q, rheumatologists could base their clinical decision-making immediately on an index-based disease activity measurement by using a composite score considering acute phase reactants. Consequently, SDAI-Q can be integrated in clinical routine and clinical trials and could be implemented into the treat-to-target concept in RA patients.

POS0454

COMPARISON OF MBDA SCORE, PATIENT GLOBAL ASSESSMENT AND EVALUATOR GLOBAL ASSESSMENT FOR PREDICTING RISK OF RADIOGRAPHIC PROGRESSION

L. Calabrese[1], M. E. Weinblatt[2], N. Shadick[2], C. Heegaard Brahe[3], M. Østergaard[3], M. L. Hetland[3], M. Horton[4], D. Flake[4], E. Sasso[5]. [1]*Cleveland Clinic, Clinical Immunology, Cleveland, United States of America*; [2]*Brigham and Women's Hospital, Rheumatology, Boston, United States of America*; [3]*University of Copenhagen, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark*; [4]*Myriad Genetics, Inc., MMM Informatics, Salt Lake City, United States of America*; [5]*Myriad Autoimmune, R&D Medical, South San Francisco, United States of America*

Background: Busy rheumatologists may assess disease activity and risk for radiographic progression (RP) in RA with informal, qualitative versions of evaluator and/or patient global assessments (EGA and PGA). RA patient care may be improved by having a convenient, objective disease activity measure that predicts risk for RP more accurately than EGA or PGA.

Objectives: To compare the abilities of MBDA score, patient global assessment and evaluator global assessment to assess risk for radiographic progression (RP), and to assess the ability of MBDA score to predict RP among patients with concordant or discordant PGA and EGA.

Methods: Patients were pooled from two RCTs of patients with recent onset RA treated with conventional and biologic DMARDs (OPERA and SWEFOT, N=386) and from a registry of patients with predominantly established RA and diverse treatments (BRASS, N=380). Pearson correlations were determined between MBDA scores (adjusted for the effects of age, sex and adiposity) (scale 1-100), PGA and EGA (each on a scale of 1-10) at baseline. PGA and EGA were considered discordant when they differed by >2.5. Univariable logistic regression assessed ability to predict RP (change in TSS >5 over 1 year) for MBDA score, PGA and EGA as continuous variables; and for discordance of PGA and EGA as 2-level (concordant vs. discordant) or 3-level (PGA>EGA, concordant, EGA>PGA) categorical variables. Multivariable regression considered the main effect and interaction terms of the MBDA score, as a continuous variable, paired with each other variable, to test the ability of each pair to assess risk of RP. All models included a random effect on cohort. Odds ratios were reported for every 10-unit increase in MBDA score. Frequency of RP was determined in subgroups with MBDA score low (<30), moderate (30-44) or high (>44) for patient groups based on PGA/EGA concordance or discordance.

Results: The 766 patients studied were 76% female, 76% positive for RF and/or anti-CCP Ab, with mean age 55 years, DAS28-CRP 4.7, CRP 22 mg/L, CDAI 26, SJC 9.1, PGA 4.4, EGA 3.4, MBDA score 53. No interaction was seen between MBDA score and type of cohort (early vs established RA). PGA and EGA were discordant in 294 of 766 (38%) patients and were weakly to moderately correlated (r=0.38). Among discordant patients, PGA was >EGA in 227 cases and EGA was >PGA in 67 cases. Correlations between MBDA score and PGA or EGA were r=0.41 and r=0.34, respectively. In univariable analyses, MBDA score was a statistically significant predictor of radiographic progression (OR=1.53, $p=6.3x10^{-8}$) whereas PGA, EGA, 2-level discordance and 3-level discordance were not (p=0.38, 0.47, 0.74, 0.83, respectively). In multivariable analyses, significant interactions were observed between MBDA score and discordance (2-level, p=0.0029; 3-level, p=0.0087). The interaction analysis demonstrated, in PGA/EGA-concordant patients, low risk of radiographic progression when MBDA score was low and elevated risk when it was high (OR=1.33 [1.1, 1.59]). A relationship between MBDA score and RP risk was also demonstrated, with heightened trend, among discordant patients with PGA >EGA (OR=2.04 [1.53, 2.81]) and EGA >PGA (OR=3.43 [1.37, 13.8]) (Figure 1).

Conclusion: MBDA score was a significant predictor of radiographic progression, whereas PGA and EGA were not. MBDA score predicted progression whether PGA and EGA were concordant or discordant. These results suggest that MBDA score detects joint-damaging disease activity more accurately than PGA and EGA and it does so whether or not PGA and EGA are in agreement.

Figure 1. Rate of radiographic progression (RP) by MBDA category for patient groups based on concordance or discordance of Patient Global Assessment (PGA) and Evaluator Global Assessment (EGA).

POS0455 EFFECT OF ANTI-Ro/SSA ANTIBODIES FOR TREATMENT RESPONSE TO METHOTREXATE IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE MULTICENTER OBSERVATIONAL STUDY

R. Yokochi[1], H. Tamai[2], T. Kido[3], Y. Yagyu[4], D. Waki[5], R. Yanai[6], K. E. Sada[7]. *[1]Teikyo University Chiba Medical Center, Division of Hematology and Rheumatology, Ichihara, Japan*; *[2]Keio University School of Medicine, Division of Rheumatology Department of Internal Medicine, Tokyo, Japan*; *[3]Toyama University Hospital, The First Department of Internal Medicine, Toyama, Japan*; *[4]Tokyo Kyōsai Hospital, Department of Internal Medicine, Tokyo, Japan*; *[5]Kurashiki Central Hospital, Department of Endocrinology and Rheumatology, Kurashiki, Japan*; *[6]Showa University Hospital, Division of Rheumatology, Tokyo, Japan*; *[7]Kochi Medical School, Kochi University, Department of Clinical Epidemiology, Kochi, Japan*

Background: Several previous observational studies have suggested that patients with anti-Ro/SSA antibody-positive rheumatoid arthritis (RA) may respond poorly to treatment, including tumor necrosis factor inhibitors[1]. However, its influence on methotrexate (MTX) treatment, which is the anchor drug of treat-to-target strategy in RA treatment, remains unclear.
Objectives: We compared the clinical response to MTX in both anti-Ro/SSA antibody-positive and -negative patients with MTX-naiive RA and investigated the reasons for the difference in response.
Methods: We recruited 210 consecutive patients with RA who were newly started on MTX in this retrospective cohort study. The effect of the presence of anti-Ro/SSA antibodies on achieving low disease activity (LDA) of DAS28-CRP at six months after initiating MTX was investigated by using logistic regression analysis. CDAI, SDAI, concomitant using DMARDs and painkillers, patient's and evaluator's VAS, tender joint counts, and swollen joint counts at six months were also compared between the anti-Ro/SSA-positive patients and -negative patients. Missing data were imputed by using multiple imputations before multivariate analysis.
Results: 32 anti-Ro/SSA antibody-positive patients and 178 anti-Ro/SSA antibody-negative patients were included. The rate of achieving DAS28-LDA at six months was significantly lower in the anti-Ro/SSA antibody-positive patients than those in the anti-Ro/SSA antibody-negative patients (56.2% versus 75.8%, *P*=0.03). in the logistic regression analysis, the presence of anti-Ro/SSA antibodies was an independent negative predictor for achieving DAS-28-LDA at six months (OR:0.431, 95%CI: 0.190-0.978, *P*=0.044) (Table1). Anti-Ro/SSA antibody-positive patients had significantly higher patient's VAS at six months (median [IQR]: 22 [15-41] vs 19 [5-30], *P*=0.038), and prescribed NSAIDs (37.5% vs 18.0%, *P*=0.018). CDAI and SDAI after six months were not significantly different between the group.
Conclusion: The presence of anti-Ro/SSA antibodies might be one of the predictive factors for the insufficient response to treat to target strategy in RA treatment. Residual pain was suspected as one of the mechanisms contributing to the lesser clinical response of MTX in anti-Ro antibody-positive RA.

POS0456 EXTERNAL VALIDATION OF A MULTI-BIOMARKER-BASED CARDIOVASCULAR DISEASE RISK PREDICTION SCORE FOR RHEUMATOID ARTHRITIS PATIENTS

J. Curtis[1], E. Sasso[2], E. Hitraya[2], C. Chin[2], R. Bamford[2], R. Ben-Shachar[3], A. Gutin[4], D. Flake[4], B. Mabey[4], J. Lanchbury[4]. *[1]University of Alabama at Birmingham, Immunology & Rheumatology, Birmingham, United States of America*; *[2]Myriad Autoimmune, R&D Medical, South San Francisco, United States of America*; *[3]Myriad Genetics, Inc., Clinical Development, Salt Lake City, United States of America*; *[4]Myriad Genetics, Inc., MMM Informatics, Salt Lake City, United States of America*

Background: A novel score for predicting 3-year risk for CVD events in RA patients combines age, four traditional CVD risk factors (diabetes, hypertension, smoking, history of high-risk CVD event), a personalized assessment of RA-related inflammation based on the multi-biomarker disease activity (MBDA) score and, individually, 3 of its 12 biomarkers, TNF-R1, MMP-3 and leptin (log-transformed). This score was developed and internally validated using patient data from the Medicare database.
Objectives: The purpose of this analysis was to externally validate the MBDA-based CVD risk prediction score in a younger cohort from the Symphony claims database.
Methods: A cohort of patients greater than or equal to 18 years old with RA diagnosis from a rheumatologist and evidence of an RA-specific treatment, excluding patients with malignancy, past myocardial infarction (MI) or stroke, was created by a third party (Symphony) by matching medical and pharmaceutical claims and linking them to MBDA scores from a database of tests done for routine care. Medicare patients were excluded to avoid overlap with the internal validation cohort. Only the first MBDA test was used for each patient. The study endpoint was time from MBDA testing to first CVD event within a 3-year time horizon. CVD event was defined as MI or stroke, based on ICD-9 or ICD-10 diagnosis codes in hospital claims. Analyses focused on relative risk, not absolute risk, because CVD event data in Symphony may be incomplete. A univariate Cox proportional hazards regression model was fit with the MBDA-based CVD risk score as the sole predictor of time to CVD event to obtain a hazard ratio (HR) estimate (95% CI) and p-values from a likelihood ratio test (LRT). Sensitivity analyses determined HR for patient subgroups, with p-values determined for the interaction between subgroups and the MBDA-based CVD risk score. Using a multivariate Cox proportional hazard regression model, the MBDA-based CVD risk score was compared to a simpler model that included only age, sex, diabetes, hypertension, history of other CVD, smoking and CRP (log-transformed) for ability to predict time to a CVD event.
Results: 48,868 patients with 337 CVD events met eligibility criteria and had linked biomarker data. Mean age was 54.4 years. 81.7% were female (Table 1).

Mean follow-up was 24.4 months. The MBDA-based CVD risk score (mean 3.3, IQR 2.8–3.8) was highly significant in univariate analysis, with HR = 3.99 (95% CI: 3.52-4.51, p = 4.4×10^{-95}); i.e., for every 1-unit increase in risk score, the CVD event rate in this cohort was ~4 times as high. Similar results were seen in the subset of 44,379 patients <65 years old, with HR=4.26 (95% CI: 3.53-5.14, p = 1.2×10^{-47}). In sensitivity analyses, after adjusting for multiple comparisons, there were no significant differences between HR of complementary subgroups (Figure 1). The MBDA-based CVD risk score added significant prognostic information to a simpler, clinical model (HR=2.28 [95% CI: 1.69-3.08, p = 1.6×10^{-7}] after accounting for all other factors).

Conclusion: The MBDA-based CVD risk prediction score has been externally validated in a cohort that is younger than and independent of the Medicare cohort used previously for test development and internal validation.

Table 1. Cohort characteristics of RA patients with linked biomarker data and at risk for CVD events.

Variable	Median (IQR) or N (%)
Total patients	48,868()
Age, years	54 (46-60)
Sex, male	8,940 (18.3%)
Diabetes	7,974 (16.3%)
Hypertension	19,132 (39.2%)
History of high-risk CVD event	6,713 (13.7%)
Smoking	7,487 (15.3%)
CRP, mg/L	4.1 (1.4-11.5)
Leptin, ng/mL	24.3 (10.6-47.1)
MMP-3, ng/mL	21.1 (14.3-36.2)
TNF-RI, ng/mL	1.4 (1.1-1.7)
MBDA score	40 (31-48)
MBDA-based CVD risk score	3.3 (2.8-3.8)

Shahril[4]. *[1]Allergy and Immunology Research Center, Institute for Medical Research, Ministry of Health Malaysia, Selangor, Malaysia*; *[2] Department of Medicine, Division of Rheumatology, Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden*; *[3]Department of Medicine, Selayang Hospital, Selangor, Malaysia*; *[4]Department of Medicine, Putrajaya Hospital, Putrajaya, Malaysia*; *[5]Department of Medicine, Raja Permaisuri Bainun Hospital, Perak, Malaysia*; *[6]Department of Medicine, Tuanku Ja'afar Hospital, Negeri Sembilan, Malaysia*; *[7]Medical Resource Research Centre, Institute for Medical Research, Ministry of Health Malaysia, Selangor, Malaysia*; *[8]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden*; *[9]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden*

Background: Presence of autoantibodies such as anti-cyclic citrullinated peptide (anti-CCP2) and rheumatoid factor (RF) is of considerable diagnostic and prognostic value in patients with rheumatoid arthritis (RA). Limited data are available for autoantibody profile changes over time in patients with RA.

Objectives: Thus, we compared the presence of anti-CCP2 and different RF isotypes in individual RA patients at baseline and during 10 years follow-up.

Methods: A total of 320 RA patients from the Malaysian Epidemiological Investigation of Rheumatoid Arthritis (MyEIRA) case-control study was included in this study. The presence of anti-CCP2, IgM RF, IgG RF, and IgA RF at baseline and at later time point (±10 years) were determined using enzyme-linked immunosorbent assays, with identical techniques in paired samples. Seropositive RA is defined by the presence of at least one autoantibody, whilst seronegative RA is defined by the absence of all investigated autoantibodies.

Results: The proportion of seropositive RA were higher for the follow-up samples (n=263, 82.2%) as compared to the baseline samples (n=251, 78.4%). Among the baseline samples, 105 (41.8%) were positive for anti-CCP2 and all RF isotypes. Of these individuals, 85 (81.0%) remained positive for all antibodies at the follow-up, while 20 (19.0%) lost one or more RF isotypes (4 IgM RF, 19 IgG RF and 13 IgA RF). Interestingly, 14 (5.6%) RA patients who were seropositive at baseline became totally seronegative after follow-up. Among the 69 patients seronegative at baseline, 26 (37.7%) acquired one or more autoantibodies at follow-up (14 IgM RF, 2 IgG RF, 9 IgA RF and 8 anti-CCP2) (Figure 1).

Conclusion: Anti-CCP2 present at baseline usually remained at follow-up. Among Malaysian RA patients, changes in status were mainly found for RF of all isotypes.

Background: Rheumatoid arthritis (RA) is a chronic, inflammatory synovitis based systemic disease of unknown etiology[1]. The genes and pathways in the inflamed synovium of RA patients are poorly understood.
Objectives: This study aims to identify differentially expressed genes (DEGs) associated with the progression of synovitis in RA using bioinformatics analysis and explore its pathogenesis[2].
Methods: RA expression profile microarray data GSE89408 were acquired from the public gene chip database (GEO), including 152 synovial tissue samples from RA and 28 healthy synovial tissue samples. The DEGs of RA synovial tissues were screened by adopting the R software. The Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis were performed. Protein-protein interaction (PPI) networks were assembled with Cytoscape software.
Results: A total of 654 DEGs (268 up-regulated genes and 386 down-regulated genes) were obtained by the differential analysis. The GO enrichment results showed that the up-regulated genes were significantly enriched in the biological processes of myeloid leukocyte activation, cellular response to interferon-gamma and immune response-regulating signaling pathway, and the down-regulated genes were significantly enriched in the biological processes of extracellular matrix, retinoid metabolic process and regulation of lipid metabolic process. The KEGG annotation showed the up-regulated genes mainly participated in the staphylococcus aureus infection, chemokine signaling pathway, lysosome signaling pathway and the down-regulated genes mainly participated in the PPAR signaling pathway, AMPK signaling pathway, ECM-receptor interaction and so on. The 9 hub genes (PTPRC, TLR2, tyrobp, CTSS, CCL2, CCR5, B2M, fcgr1a and PPBP) were obtained based on the String database model by using the Cytoscape software and cytoHubba plugin[3].
Conclusion: The findings identified the molecular mechanisms and the key hub genes of pathogenesis and progression of RA.

Background: Single biomarkers have limited utility to date in guiding RA clinical care. Machine learning algorithms may better identify and stratify RA patients with differential outcomes.
Objectives: To determine if unsupervised machine learning methods can be employed in a racially and ethnically diverse RA cohort to identify clusters of patients with different disease activity trajectories, as measured by DAS28ESR.
Methods: Data are derived from the longitudinal, observational University of California, San Francisco RA Cohort. Along with routine labs, medications and disease activity assessments, a multiple biomarker of disease activity (MBDA)

Table 1. Demographics and clinical characteristics of the RA cohort. Biomarkers significantly associated with DAS28ESR were determined by Lasso regression Values listed are per standard deviation of each biomarker.

panel was obtained at each visit. The MBDA measures 12 serum biomarkers. Four patient clusters were identified by unsupervised K-prototype clustering after collapsing all observations into a cross sectional dataset. Plots were created to display longitudinal disease activity trajectories for each cluster. Lasso regression was applied to identify biomarkers associated with DAS28ESR.

Results: We identified 4 distinct clusters in our cohort (Table 1) with visually different disease activity trajectories (Fig. 1). Cluster 1 (n=116) was older (63.6±9.7), had the highest proportion of Asian participants (n=73, 63%) with the most study visits and longest disease duration. Cluster 2 (n=70) had the highest mean DAS28ESR (5.5±0.7), and the highest mean dose of prednisone (8.6±4.9mg/day). Cluster 3 had the lowest number of participants (n=14), study visits and lowest biologic use (28.6%). Cluster 4 was the largest cluster (n=173) with the shortest disease duration (4.9±3.8 years) and highest biologic use (61.3%). In the Lasso regressions, leptin was found to have significant positive associations with DAS28ESR in the whole group as well as Clusters 2 and 4. EGF had negative associations with DAS28ESR in the whole group, Cluster 1 and 4. CRP had positive associations with DAS28ESR in the whole group and Cluster 1. YKL40 and VCAM1 were found to have significant associations in Clusters 1 and 3, respectively.

Conclusion: We identified 4 unique clusters of RA patients in a racially and ethnically diverse longitudinal cohort with different disease activity trajectories and biomarkers associated with disease activity. Although additional work is needed to explore longitudinal outcomes in each cluster, the application of machine learning methods may identify unique combinations of patient and disease characteristics influencing RA clinical outcomes.

ASSOCIATION OF ANTI-CITRULLINATED PROTEIN ANTIBODIES OF IgA SUBCLASSES WITH SUSTAINED REMISSION AND FLARE IN RHEUMATOID ARTHRITIS

M. V. Sokolova[1,2], J. Rech[1,2], M. Hagen[1,2], G. Schett[1,2], U. Steffen (née Harre)[1,2].
[1]*Friedrich-Alexander-University Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany*; [2]*Friedrich-Alexander-University Erlangen-Nuremberg and Universitätsklinikum Erlangen, Deutsches Zentrum für Immuntherapie, Erlangen, Germany*

Background: Understanding key mechanisms of flare development and sustained remission is one of the acute goals in modern rheumatology. Anti-citrullinated protein antibodies (ACPA) are the most abundant and specific autoantibodies in rheumatoid arthritis (RA) patients. However, the impact of ACPA of IgA isotype is poorly defined. IgA ACPA were previously shown to have a higher percentage of IgA2 in comparison to total IgA; and a correlation between IgA2% ACPA with the DAS28 score was observed in a previous study [1]. Of note, IgA1 and IgA2 were shown to exhibit different effector functions, with IgA2 being pro-inflammatory, which might be the background for its role in RA [1].

Objectives: We aimed to investigate, whether IgA ACPA could be used as a predictive factor for flare development in RA; and to look further into the changes in IgA ACPA levels in patients remaining in stable remission versus patients developing flare.

Methods: We analysed serum of 111 patients from a multicentre randomized controlled trial 'RETRO'. The study observational period was 12 months. Patients in the trial had to be in stable remission (DAS28-ESR<2.6) for a minimum of 6 months and were randomized into 3 different treatment arms: continuation of treatment, tapering by 50% or a gradual tapering until discontinuation [2]. IgA ACPA concentrations were measured with an enzyme-linked immunosorbent assay on CCP2-pre-coated plates.

Results: 60% of patients had IgG-ACPA. IgA ACPA levels were higher among the IgG-ACPA-positive patients (median 4.7 versus 2.24 µg/ml, p<0.0001). Baseline IgA1 and 2 ACPA levels were not different between patients who had a flare later on in the study period and those remaining in remission, showing no predictive value for flare development. However, the percentage of IgA2 in ACPA was correlating with the first registered DAS28 after flare (r=0.36, p=0.046). After the 12 months study period, IgA2 ACPA as well as IgA2% ACPA decreased significantly in patients who remained in stable remission by 17.5% (median, p<0.0001) and 13.6% (p=0.0006), respectively. By contrast, there was no significant change in IgA2 ACPA levels over time in patients who developed a flare. IgA1 ACPA levels remained stable over time. Disease management strategies did not seem to influence IgA ACPA levels in a specific way, as baseline levels were similar between patients on biological and conventional DMARDs and changes in levels after 12 months did not depend on the assignment to either of the study arms.

Conclusion: Neither IgA1 nor IgA2 ACPA levels were predictive of flare development or associated with treatment strategies (though rituximab, JAK-inhibitors and abatacept were not amongst treatment options). However, in patients remaining in sustained remission after 1 year a decrease in IgA2 and IgA2% ACPA was observed and IgA2% ACPA was associated with DAS28 score registered after flare. This could be an indication towards ACPA of IgA2 isotype contributing to the severity of flare, alongside other factors, and its reduction being associated with a prolonged state of remission.

POS0461 RESPONSE TO BIOLOGIC THERAPY IN RHEUMATOID ARTHRITIS: RETHINKING OUR CLASSIFICATION

E. Vallejo-Yagüe[1], S. Kandhasamy[1], E. Keystone[2], A. Finckh[3], R. Micheroli[4], A. M. Burden[1]. [1]*ETH Zurich, Department of Chemistry and Applied Biosciences, Institute of Pharmaceutical Sciences, Zurich, Switzerland*; [2]*University of Toronto, Medicine, Toronto, ON, Canada*; [3]*University Hospitals Geneva, Division of Rheumatology, Geneva, Switzerland*; [4]*University Hospital of Zurich, Department of Rheumatology, Zurich, Switzerland*

Background: In rheumatoid arthritis (RA), primary failure with biologic treatment may be understood as lack of initial clinical response, while secondary failure would be loss of effectiveness after an initial response. Despite these clinical concepts, there is no unifying operational definition of primary and secondary non-response to RA treatment in observational studies using real-world data. On top of data-driven challenges, when conceptualizing secondary non-responders, it is unclear if the mechanism behind loss of effectiveness after a brief initial response is similar to loss of effectiveness after previous benefit sustained over time.

Objectives: This viewpoint aims to motivate discussion on how to define primary and secondary non-response in observational studies. Ultimately, we aim to trigger expert committees to develop standard terminology for these concepts.

Methods: We discuss different methodologies for defining primary and secondary non-response in observational studies. To do so, we shortly overview challenges characteristic of performing observational studies in real-world data, and subsequently, we conceptualize whether treatment response should be a dichotomous classification (Primary response/non-response; Secondary response/non-response), or whether one should consider three response categories (Primary response/non-response; Primary sustained/non-sustained response; Secondary response/non-response).

Results: RA or biologic registries are a common data source for studying treatment response in real-world data. While registries include disease-specific variables to assess disease progression, missing data, loss of follow-up, and visits restricted to the year or mid-year visit may present a challenge. We believe there is a general agreement to assess primary response within the first 6 month of treatment. However, conceptualizing secondary non-response, one could wonder if a patient with brief initial response and immediate loss of it should belong to the same response category as a patient who relapses after a period of prior benefit that was sustained over time. Until this concern is clarified, we recommend considering a period of sustained response as a pre-requisite for secondary failure. This would result in the following three categories: a) Primary non-response: Lack of response within the first 6 months of treatment; b) Primary sustained response: Maintenance of a positive effectiveness outcome for at least the first 12 months since treatment start; c) Secondary non-response: Loss of effectiveness after achieved primary sustained response. Figure 1 illustrates this classification through a decision tree. Since the underlying mechanisms for treatment failure may differ among the above-mentioned categories, we recommend to use the three-category classification. However, since this may pose additional methodological challenges in real-world data, optionally, a dichotomous 12-month time-point may be used to assess secondary non-response (unfavourable outcome after 12-months) in comparison to primary non-response or non-sustained response (unfavourable outcome within the first 12-months). Similarly, to study primary response, the solely 6-month timepoint may be used.

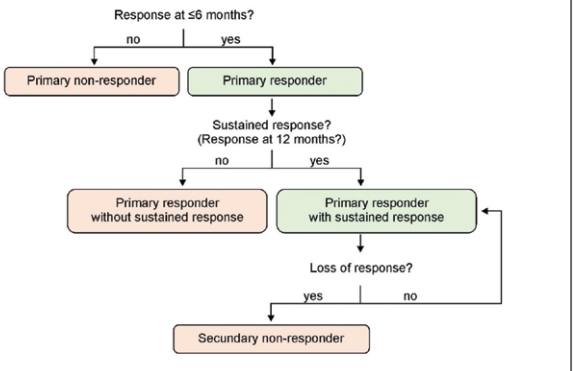

Figure 1. Decision tree to classify treatment response to biologics in rheumatoid arthritis (RA) based on evidence of an initial response, assuming a sustained benefit as pre-requisite prior secondary non-response. Patients discontinuing treatment due to remission or safety reasons are not reflected in the decision tree.

Conclusion: A unified operational definition of treatment response will minimize heterogeneity among observational studies and help improve the ability to draw cross-study comparisons, which we believe would be of particular interest when identifying predictors of treatment failure. Thus, we hope to open the room for discussion and encourage expert committees to work towards a common approach to assess treatment primary and secondary non-response in RA in observational studies.

POS0462 ALCOHOL AND INFLAMMATORY ARTHRITIS DISEASE ACTIVITY: PERSPECTIVES FROM A 979-PATIENT COHORT WITH SYSTEMATIC REVIEW AND META-ANALYSIS

M. Turk[1], A. Gorman[1], K. Murray[1], Y. Alammari[1], F. Young[1], J. Turk[2], E. Zahavi[2], P. Gallagher[1], L. Freeman[1], U. Fearon[3], D. Veale[1]. [1]*St. Vincent's University Hospital, Rheumatology, Dublin, Ireland*; [2]*Queen's University, Life Sciences, Kingston, Canada*; [3]*Trinity College Dublin, Rheumatology, Dublin, Ireland*

Background: The effect of alcohol on disease activity in inflammatory arthritis remains poorly understood. Studies of alcohol and the incidence or risk of inflammatory arthritis are conflicting [1,2]. Alcohol does downregulate pro-inflammatory cytokines and may therefore reduce immune-mediated disease activity.

Objectives: This study investigates the relationship between alcohol consumption and disease activity in our inflammatory arthritis patient cohort and performs a systematic review with meta-analysis.

Methods: *Cohort Study Design and data analysis*

Patients attending a rheumatology clinic between 2010-2020 were prospectively followed. Information on demographics, alcohol use, smoking habits, and disease outcome measures were collected. Statistical analysis included univariate and multivariate linear and binary logistic regressions, Mann Whitney-U tests, and one-way ANOVA with Tukey's HSD.

Meta-analysis

EMBASE, Pubmed, the Cochrane library, and Web of Science were searched. Studies reporting on alcohol consumption and disease activity in a cohort of RA patients were included for further investigation. Forest plots were generated from 95% confidence intervals of extracted data using mean differences. Linear regression was used to determine correlations between alcohol and antibody status, gender, and smoking status.

Results: *Cohort Study*

Of the 979 analysed patients, 62% had RA, 26.7% had PsA, and 11.2% had AS. Mean DAS28-CRP in RA and PsA at one year was 2.96 ± 1.39, and 64.2% of patients were in remission (DAS28-CRP ≤ 2.6 or BASDAI ≤ 4). Both male gender and risky drinking (>15 units of weekly alcohol) were both significantly associated with remission. Compared to women, men had an odds ratio of 1.78 [1.04, 2.52] (p=0.034) for any alcohol consumption and 6.9 [4.7, 9.1] (p=0.001) for drinking at least 15 weekly drinks. when adjusted for gender, there was no significant association between alcohol and disease activity. Yet, when adjusted for alcohol consumption, gender still influenced disease activity.

Meta-analysis

The search identified 4126 citations of which 14 were included. The pooled mean difference in DAS28 (95% CI) was 0.34 (0.24,0.44) (p<10-5) between non-drinkers and drinkers, 0.33 (0.05,0.62) (p=0.02) between non-drinkers and heavy drinkers, and 0 (-0.3,0.3) (p=0.98). between low- and high-risk drinkers. There was a significant difference in the mean difference of HAQ assessments between those who drink alcohol compared to those who do not (0.3 (0.18,0.41), p<10-5). There was no significant correlation between drinking and gender, smoking status, or antibody positivity.

Conclusion: While it appears that alcohol is linked to remission in inflammatory arthritis, this association is lost when adjusted for gender. Men with inflammatory arthritis drink significantly more than women and men generally have less severe disease activity. However, the meta-analysis suggests alcohol consumption is associated with lower disease activity and self-reported health assessment in rheumatoid arthritis.

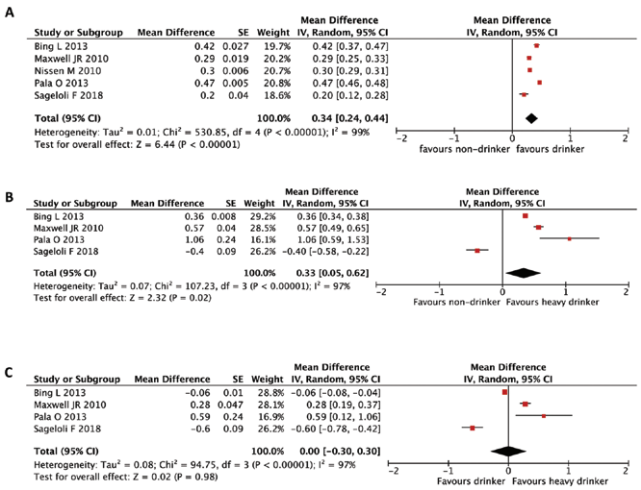

Figure 1. Mean differences in DAS28 between drinking groups. A between non-drinkers and drinkers. B between non-drinkers and high-risk drinkers. C between low-risk and high-risk drinkers.

POS0463 BEST CARDIOVASCULAR RISK CALCULATOR TO PREDICT ABNORMALITIES IN LEFT VENTRICULAR GEOMETRY IN RHEUMATOID ARTHRITIS

S. Lugo-Perez[1], J. R. Azpiri-López[1], D. Á. Galarza-Delgado[2], I. J. Colunga-Pedraza[2], N. Guajardo-Jauregui[2], A. B. Rodriguez-Romero[2], A. Cárdenas[2], J. A. Davila-Jimenez[2], H. Azpiri-Diaz[1], O. A. Cepeda-Ayala[1], A. Garcia-Heredia[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*; *[2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*

Background: A relationship between rheumatoid arthritis (RA) and the presence of abnormalities in left ventricular (LV) geometry such as eccentric remodeling has recently been determined, even in the absence of cardiovascular risk factors and before clinical manifestations (1). The 2016 European League Against Rheumatism (EULAR) recommendations that cardiovascular (CV) risk prediction models should be adapted by a 1.5 multiplication factor in RA patients. Risk prediction algorithms based on the CV risk factors (CVRF) have been an important tool for adopting preventive measures and intensifying therapies based on the estimated risk but their application in predicting cardiac structural abnormalities has never been studied.

Objectives: The aim of the study is to determine the CV risk calculator that best predicts alterations in ventricular geometry in RA.

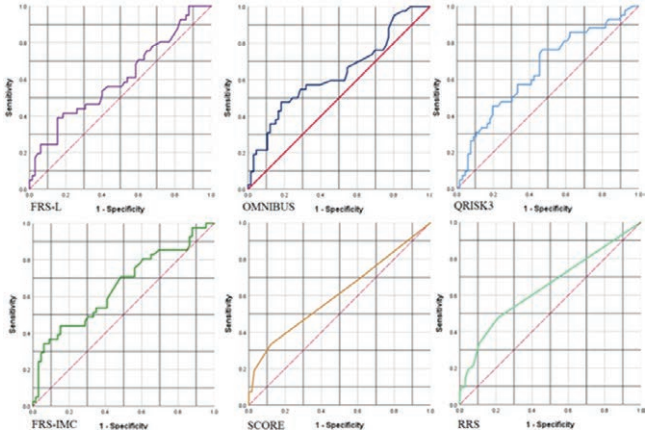
Methods: A cross-sectional, observational study of 108 RA patients between 40-75 years (ACR / EULAR 2010 classification criteria). The QRISK3, OMNIBUS, Framingham Risk Score Lipids (FRSL), Framingham Risk Score BMI (FRS-BMI) and Reynolds Risk Score (RRS) calculators were compared. The diagnostic performance was determined by ROC curves, and the discriminative capacity by the Area Under the Curve (AUC) 95% CI. The echocardiogram was the diagnostic gold standard. A *p* value <0.05 was considered statistically significant.

Results: The prevalence of abnormalities in ventricular geometry was 38.9%. QRISK3 reported AUC of 0.656, 95% CI (0.550-0.762, *p*=0.006), cut-off point ≥4.6, sensitivity of 73.8% and specificity of 54.5%, and likelihood ratio of +1.62. FRS-BMI showed AUC of 0.653, 95% CI (0.543-0.762, *p*=0.008), cut-off point ≥11.02, sensitivity and specificity of 61.9% and 57.6% respectively, and likelihood ratio of +1.46. OMNIBUS showed AUC of 0.635, CI 95% (0.525-0.746, *p*=0.018), cut-off point ≥3.8, sensitivity and specificity of 57.1% and 68.2%. While RRS had AUC 0.644, 95% CI (0.534-0.755, p=0.012), cut-off point of 2.25, sensitivity of 47.6% and specificity 78.8%, and likelihood ratio of +2.24 (Figure 1 and Table 1).

Table 1. Discriminatory capacity of the different cardiovascular risk calculators.

Calculators (cut-off point).	AUC	CI 95%		*p*	Sensitivity	Specificity
		Inferior	Superior			
QRISK (≥4.60)	0.646	0.537	0.754	**0.012**	73.8%	54.5%
SCORE	0.591	0.475	0.706	NS	-	-
OMNIBUS (≥3.80)	0.621	0.509	0.734	**0.038**	57.1%	68.2%
FRSL	0.594	0.480	0.707	NS	-	-
FRS-BMI (≥11.02)	0.642	0.530	0.754	**0.015**	61.9%	57.6%
RRS (≥2.25)	0.627	0.514	0.741	**0.029**	47.6%	78.8%

Figure 1. ROC curves of the different cardiovascular risk calculators.



Conclusion: The QRISK3 calculator showed the highest discriminative ability and sensitivity to predict abnormalities in LV geometry. However, all calculators demonstrated the need for a lower cut-off point to predict alterations in ventricular geometry. Our findings require adequate reproducibility in other population groups to determine the applicability of CV risk algorithms as predictors of structural alteration of LV.

POS0464 IS IT POSSIBLE TO IDENTIFY INDIVIDUALS AT IMMINENT-RISK OF SUB-CLINICAL JOINT INVOLVEMENT?

A. Di Matteo[1], K. Mankia[1], L. Duquenne[1], E. Cipolletta[2], J. Nam[1], L. Garcia-Montoya[1], R. Wakefield[1], M. Mahler[3], P. Emery[1]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom., National Institute for Health Research Leeds Biomedical Research Centre, Leeds, United Kingdom*; *[2]Polytechnic University of Marche, Rheumatology Unit,"Carlo Urbani" Hospital, Jesi, Ancona, Italy., Department of Clinical and Molecular Sciences, Jesi, Italy*; *[3]United States, Inova Diagnostics, INC, San Diego, California, USA, San Diego, United States of America*

Background: In anti-CCP antibody (Ab) positive at-risk individuals with MSK symptoms but without clinical synovitis, the detection of ultrasound (US) subclinical inflammation is associated with an increased risk of progression to inflammatory arthritis (IA) [1]. Studies suggest that in these at-risk individuals, MSK symptoms develop before subclinical joint inflammation occurs on US. As such, anti-CCP Ab positive individuals with MSK symptoms in the absence of clinical or sub-clinical inflammation may be at the critical time-point for preventive treatments, before joint inflammation occurs and eventually becomes established (i.e., before the 'second-hit' in RA pathogenesis); however, identifying these individuals is challenging.

Objectives: To identify, in second generation anti-CCP Ab (CCP2+) at-risk individuals with MSK symptoms, but without clinical or sub-clinical synovitis, predictors of US sub-clinical synovitis.

Methods: In 186 CCP2+ at-risk individuals with normal baseline US scan (i.e., no synovitis or bone erosions), and a complete dataset, US data were analyzed at 6, 12 months, then annually until occurrence of IA. US synovitis was identified according to the EULAR/OMERACT definitions[2]. Relevant demographic (age and gender), clinical [early morning stiffness (EMS), tenderness in the small joints of the hands] and serological [anti-CCP2 Ab level, third generation anti-CCP Ab

(CCP3) and rheumatoid factor (RF)] data were collected at baseline. Regression analyses, Kaplan-Meier analysis and Log-Rank test were performed.
Results: US synovitis was detected in ≥1 longitudinal US scan in 69/186 (37.1%) at-risk individuals (median time to first developing US synovitis: 53 weeks, IQR 27.0-105.8; median number of joints with US synovitis: 2.0, IQR 1.0-2.0). As shown in Table 1, only anti-CCP3 Ab were significantly associated with development of US sub-clinical synovitis in the multi-variable analysis while borderline results were observed with age.

Table 1. Regression analyses for the development of US synovitis.

	Univariable analysis		Multivariable	analysis
	OR (95% CI)	p-value	OR (95% CI)	p-value
Gender (male)	1.02 (0.52-2.02)	0.95	/	/
Age	**1.03 (1.01-1.06)**	**<0.01**	*1.03 (1.00-1.06)*	***0.03***
Tenderness in the hands	0.86 (0.46-1.61)	0.64	/	/
EMS	1.60 (0.87-2.95)	0.13	/	/
Anti-CCP2 Ab (high titre)	**2.79 (1.37-5.67)**	**<0.01**	1.20 (0.50-2.89)	0.69
Anti-CCP3+	**4.44 (2.28-8.66)**	**<0.01**	**3.30 (1.39-7.89)**	**<0.01**
RF+	**2.96 (0.46-1.61)**	**0.01**	1.45 (0.68-3.11)	0.33

CCP2+ individuals with positive anti-CCP3 Ab show a significantly reduced sub-clinical synovitis-free survival rate compared with individuals with negative anti-CCP3 Ab (Figure 1). At 1- and 2-year follow-up, respectively 23.3% and 38.3% of individuals with dual CCP2/CCP3 positivity developed sub-clinical synovitis on longitudinal scans, compared with 8.4% and 13.3% of CCP2+ individuals with negative anti-CCP3 Ab (p=0.01) (Figure 1a).

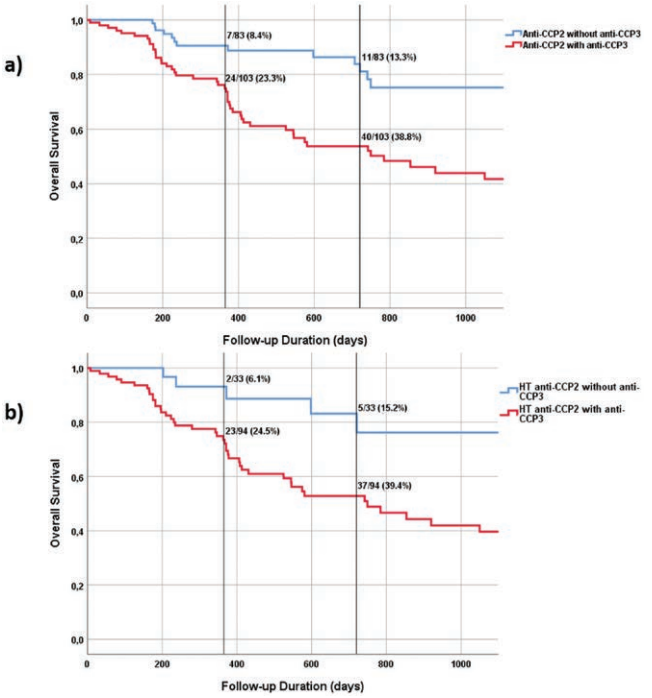

Figure 1. Kaplan-Meier analysis shows US sub-clinical synovitis free survival time in CCP2+ at-risk individuals.

Similar results were observed in the subgroup of high level CCP2+ individuals. At 1- and 2-year follow-up, respectively 24.5% and 39.4% of high level CPP2/anti-CCP3+, but only 6.1% and 15.2% of CCP2+ individuals with negative anti-CCP3 developed sub-clinical synovitis on longitudinal scans (p<0.01) (Figure 1b).
Conclusion: In anti-CCP2+ at-risk individuals with MSK symptoms, anti-CCP3 antibodies improve prediction of imminent development of subclinical joint inflammation. This may represent the critical time-point for interventions to prevent the onset of joint disease. This is also a unique population for investigating the drivers of joint involvement in the development of RA.

POS0465 DIFFERENT CLINICAL RELEVANCE OF ANTI-CITRULLINATED PROTEINS ANTIBODIES IN RA PATIENTS

A. Avdeeva[1], M. Cherkasova[2], E. Nasonov[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Early Arthritis Laboratory, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology Rheumatic Diseases, Moscow, Russian Federation*

Background: Anti-citrullinated proteins antibodies (ACPA) are a broad group of antibodies, including antibodies to citrullinated fibrinogen, antibodies to cyclic citrullinated peptide (anti-CCP), antibodies to modified citrullinated vimentin (anti-MCV), antibodies to citrullinated α-enolase.
Objectives: To find a potential relationship between ACPA and disease activity, bone destruction, and ACPAs responses to various therapeutic regimens.
Methods: The study included 232 patients (pts) with rheumatoid arthritis (RA); 90 pts (74 women, Me;IQR age 53.0 (38.0–58.5) years had early RA, with mean disease duration 5.0 (4.0–9.0) months, DAS 28 5.3 (4.4–6.1)); 142 pts had advanced stage of the disease (123 women, median age 51.0 (43.0–60.0) years, disease duration 56.0 (24.0–96.0) months, DAS 28 6.2 (5.5–6.8)). Pts with early RA received methotrexate (MTX) subcutaneously at average 17.5 mg dose once weekly. Pts with advanced RA received the following anti-B-cell therapy: 34 pts - rituximab (RTX); 20 pts - RTX biosimilar; 43 pts - tocilizumab (TCZ) in combination with conventional DMARDs. Serum anti-CCP and anti-MCV concentrations were measured using ELISA.
Results: 77 (85.6%) pts with early RA were high positive for anti-CCP, and 29 (70.7%) pts - high positive for anti-MCV. A positive correlation was found between anti-MCV and DAS 28 (r=0.4, *p*=0.04). As for advanced RA, 78 (80.4%) pts were high positive for anti-CCP, and 70 (79.5%) - for anti-MCV. There was a positive correlation between anti-MCV concentration and SDAI (r=0.4, *p*=0.02), as well as CDAI (r=0.4, *p*=0.02). No significant correlations were found between the anti-CCP levels and activity indices, anti-CCP and acute-phase parameters in both early and advanced RA groups. Higher total Sharp scores (96.5 (65.0-122.0)) were found in pts high positive for anti-MCV (n=79), compared to low-positive/negative (57.0 (31.0–88.0), respectively, (n=27, *p*<0.05). anti-MCV levels dropped significantly in pts on RTX and TCZ therapy at weeks 12 and 24 after initiation of treatment, while high anti-CCP concentration persisted throughout the treatment (Table 1)

Table 1.

Indicators	Anti-CCP, U/ml	Anti-MCV, U/ml
RTX group, *n*=34		
- baseline	100,0 (37,9–100,0)	559,4 (139,2–1000,0)
- 12 weeks	100,0 (26,1–100,0)	295,9 (74,0–962,7) [1]
- 24 weeks	100,0 (29,0–100,0)	194,7 (58,3–844,8) [1]
RTX biosimilar group, *n*=20		
- baseline	112,7 (18,3–264,8)	392,6 (75,7–1000,0)
- 12 weeks	71,7 (12,4–161,6)	210,5 (40,3–940,6) [1]
- 24 weeks	61,3 (13,12–129,4)	153,8 (43,1–702,8)
TCZ group, *n*=43		
- baseline	354,8 (67,9–500,0)	762,3 (106,9–2393,1)
- 8 weeks	500,0 (84,4–500,0) [1]	266,6 (85,8–927,0) [1]
- 24 weeks	355,8 (39,8–500,0)	135,7 (27,0–662,1) [1]

Note: [1] *p*<0,05 vs baseline

Conclusion: anti-MCV levels correlated with inflammatory activity and development of bone destruction, and were decreasing in pts on treatment. Anti-CCP was less responsive, showed minor changes during treatment, therefore its' thorough monitoring was not feasible.

POS0466 RHEUMATOID ARTHRITIS PER SE IS NOT RISK FACTOR FOR CLINICAL FRACTURES: NINE-YEAR FINDINGS OF THE TOMORROW STUDY

K. Mamoto[1], T. Koike[2,3], Y. Yamada[1], T. Okano[1], Y. Sugioka[2], M. Tada[4], K. Inui[5], H. Nakamura[1]. *[1]Osaka City University Graduate School of Medicine, Department of Orthopaedic Surgery, Osaka, Japan*; *[2]Osaka City University Medical School, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan*; *[3]Shirahama Foundation for Health and Welfare, Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan*; *[4]Osaka City General Hospital, Department of Orthopaedic Surgery, Osaka, Japan*; *[5]Osaka Saiseikai Nakatsu Hospital, Department of Orthopaedic Surgery, Osaka, Japan*

Background: Patients with rheumatoid arthritis (RA) who have sarcopenia and stiff or painful joints might be at increased risk of falls and fractures.
Objectives: The present study aimed to prospectively identify the incidence of clinical fractures and associated risk factors in patients with RA in a cohort study named the TOMORROW (UMIN000003876) that started in 2010.
Methods: We evaluated anthropometric parameters, bone mineral density (BMD), disease activity, RA medication at baseline and observed the incidence of clinical fractures during nine years in 202 patients with RA (mean age, 58.6 y; medication with biological agents, 54.9%) and 202 age- and sex-matched non-RA volunteers (mean age, 57.4 y). We compared the incidence of clinical fractures between patients with RA and controls for nine years, and analyzed the risk factors for fractures using Cox proportional hazard model.
Results: The incidence of clinical fractures in RA patients was significantly higher compared to controls (27.5 vs 18.3%, p=0.04). However, Cox proportional hazard model, adjusted by age, sex, smoking and body mass index, revealed that low BMD at thoracic vertebrae (< 0.7 g/cm^2) significantly associated to the incidence of clinical fractures (hazard ratio [HR], 1.86, p=0.02), but not RA morbidity (HR 1.47, p=0.10) (Table 1). Among patients with RA, low BMD at the thoracic vertebrae (< 0.7 g/cm^2) was the most prominent risk factor for clinical fractures (HR, 2.66, p=0.02) (Table 1). Although the use of glucocorticoid (GC) at baseline (HR, 1.68, p=0.09) was not a significant risk factor for fractures, a mean GC dose (≥ 2 mg/day) at entry increased risk for clinical fractures in the patients (HR, 1.91, p=0.04) (Table 1).

Table 1. Cox proportional hazard model (adjusted for fracture risk factors including age, sex, smoking, and body mass) of risk factors for clinical fractures.

		hazard ratio	95% CI	*p*
All participants	History of fractures	0.24	0.77-1.98	0.38
N=404	Morbidity of RA	1.47	0.92-2.34	0.10
	Low BMD at thoracic vertebrae (< 0.7 g/cm^2)	1.86	1.09-3.17	0.02
RA patients	History of fractures	1.27	0.70-2.29	0.43
N=202	GC medication	1.68	0.92-3.06	0.09
	A mean GC dose ≥ 2 mg/day at entry	1.91	1.05-3.49	0.04
	Low BMD at thoracic vertebrae (< 0.7 g/cm^2)	2.66	1.20-5.89	0.02

CI, confidence interval; RA, rheumatoid arthritis; GC, glucocorticoid; BMD, bone mineral density.

Conclusion: RA per se was not a risk factor for clinical fractures in this cohort. Low BMD at the thoracic vertebrae and the use of GC with even low dose at entry were apparently significant risk factors for the incidence of clinical fractures among patients with RA.

POS0467 STUDY OF METHOTREXATE METABOLITES CONCENTRATIONS IN RED BLOOD CELLS AND MONONUCLEAR CELLS IN RHEUMATOID ARTHRITIS

V. Sygyrta[1], G. Gridneva[1], A. Lila[1], E. Samarkina[1], N. Baymeeva[2], Y. Muraviev[1], E. Aronova[1], A. Kudryavtseva[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Antirheumatic Drugs Safety Monitoring Laboratories, Moscow, Russian Federation*; *[2]Mental Health Research Center, Mental Health Research Center, Moscow, Russian Federation*

Background: Studying the dynamics of the methotrexate metabolites concentration in cells will help to predict the therapeutic effect and assess patient compliance. We suggest that studying the dynamics of changes in the concentration of methotrexate metabolites in mononuclear cells (MO) may be a more accurate method than measuring in red blood cells (RBC).
Objectives: To study the dynamics of changes in the concentration of MTX and its metabolites in RBC and MO in methotrexate-naive patients with RA.
Methods: 33 patients (26 women, 7 men) aged 53.2 ± 11.7 years with a diagnosis of rheumatoid arthritis, according to the ACR / EULAR 2010 criteria, were included. All patients had GFR >60 ml/min. Patients were monitored after 4, 12, 24 and 36 weeks from the start of MTX. Mean Cell Volume (MCV) of RBC was measured by standard methods. Samples of RBC and MO were collected separately to determine the concentrations of MTX (basic monoglutamate form), total concentration of MTPG2, MTPG3 and MTPG4 (MTPG2-4), 7- hydroxymethotrexate (7-OH-MTX) by tandem mass spectrometry.
RESULTS:
A pairwise comparison of MTX, MTPG2-4 and 7-OH-MTX concentrations, according to the Wilcoxon method did not reveal statistically significant differences at weeks 4, 12 and 24. The concentration of the studied substances did not correlate with the value of the body mass index, taking statins, glucocorticoids, a cumulative dose of MTX, and the frequency of adverse reactions. At the week 4, of therapy, the level of MTPG4 in MO was inversely correlated with the duration of the disease (correlation coefficient - 0.58, p 0.05) The concentration of MTX and its metabolites in MO was lower in smokers (MTX 11.2 [2.6;21.9], 7-OH-MTX 2.1 [0.5; 10.4], MTPG2 0.5 [0.1;1.3]) than in non-smokers (MTX 46.5 [25.3;97.5], 7-OH-MTX 28.2 [7.1; 64.7], MTPG2 8.2 [4.1;32.9]), p = 0.02, 0.01 and 0.003, respectively. At week 24 of therapy, a negative correlation was found between age and MTPG4 level (correlation coefficient 0.51, p <0.05).

Table 1. Total concentration of MTPG2, MTPG3 and MTPG4 (MTPG2-4), nmol/l

		Me	[25;75]	Min	Max
Week 4	RBC	42.8	19.0;155.0	3	987.7
	MO	6.2	5.3;11.9	1.6	147.2
Week 12	RBC	48.1	17.1;89.0	0.1	519.9
	MO	10.9	3.9;31.0	0.9	147.6
Week 24	RBC	39.4	17.2;70.6	2.7	191.8
	MO	8.3	2.7;14.0	0.4	72.4

Conclusion: The inadequate response to MT therapy in smokers, described in many previous studies,
may be associated with a low concentration of the MTX metabolites in mononuclear cells.
The level of MTPG4 in mononuclear cells increases more slowly in patients with a longer duration of the disease.

POS0468 PREDICTION OF RHEUMATOID ARTHRITIS DISEASE ACTIVITY BY AN ADAPTIVE DEEP NEURAL NETWORK: BETTER RESULTS IN SEROPOSITIVE PATIENTS WITH LONGER DISEASE DURATION

M. Hügle[1], G. Kalweit[1], J. Boedecker[1], R. Muller[2], A. Finckh[3], A. Scherer[4], U. Walker[5], T. Hügle[6]. *[1]University of Freiburg, Department of Computer Science, Freiburg, Germany*; *[2]Kantonsspital Aarau, Department of Rheumatology, Aarau, Switzerland*; *[3] University Hospital Genev, Division of Rheumatology, Geneva, Switzerland*; *[4]SCQM Foundation, Rheumatology, Zürich, Switzerland*; *[5]University Hospital Basel, Department of Rheumatology, Basel, Switzerland*; *[6]Lausanne University Hospital, CHUV, Department of Rheumatology, Lausanne, Switzerland*

Background: Deep neural networks learn from former experiences on a large scale and can be used to predict future disease activity as potential clinical decision support. AdaptiveNet is a novel adaptive recurrent neural network optimized to deal with missing clinical data. In rheumatoid arthritis (RA) it is unknown how disease characteristics influence the predictability by deep learning in terms of classification (e.g. active disease yes/no) or regression (numeric values such as DAS28).
Objectives: To investigate in which clinical RA subtypes AdaptiveNet achieves the best results for the prediction of individual disease activity
Methods: Demographic and disease characteristics from over 9500 patients and 65.000 visits from the Swiss Quality Management (SCQM) database were used to train and evaluate the network. Patient characteristics, clinical and patient reported outcomes, laboratory values and medication were used as input features. DAS28-BSR served as a target to predict active RA and future numeric individual disease activity by classification and regression. Feature importance

was determined by a Random Forest to define the relative importance of variables for disease prediction.
Results: AdaptiveNet predicted active disease defined as DAS28-BSR >2.6 at the next visit with an overall accuracy of 75.6% (SD +- 0.7%) and a sensitivity and specificity of 84.2% (SD +- 1.6%) and 61.5% (SD +- 3.6%), respectively. The performance of the prediction for correct disease status was significantly higher in patients with a disease duration >3 years and positive rheumatoid factor. Regression allowed forecasting individual DAS28-BSR values with a Mean Squared Error (MSE) of 0.9 (SD +- 0.05). Compared to Linear Regression, Random Forests and Support Vector Machines, AdaptiveNet showed an increased performance of 7% in MSE. MSE was significantly lower in patients with disease duration > 3 years and with positive anti-CCP antibodies. Feature importance identified number of painful joints, longer disease duration and age as most relevant factors for prediction of remission, whereas medication played a smaller role.
Conclusion: Predictability of disease activity in RA by this deep neural network was stronger in patients with a longer disease history and a positive auto-antibody status, potentially due to a more stable disease course. Generally, AdaptiveNet had a superior capacity to predict numeric RA disease activity compared to classical machine learning architectures, however all investigated models had limitations in low specificity.

POS0469 FALL RISK ASSESSMENT IN RHEUMATOID ARTHRITIS PATIENTS

O. Jomaa[1], H. Migaw[2], I. Loubiri[2], M. Slama[2], S. Zrour[1], I. Bejia[1], M. Touzi[1], J. Mahbouba[1], N. Bergaoui[1]. *[1]University Hospital Fattouma Bourguiba Monastir, TUNISIA, Rheumatology Department, Monastir,Tunisia*; *[2]University Hospital Fattouma Bourguiba Monastir,TUNISIA, Physical Medicine and Functional Rehabilitation Department, Monastir,Tunisia*

Background: Rheumatoid arthritis patients may have an increased risk of falls due to changes caused by the disease such as muscle weakness, joint impairment, reduced mobility and postural instability.
Objectives: The aim of this study was to analyze the occurrence of falls in RA patients and its risk factors.
Methods: Between January2020 and July 2020, 51 patients with RA were included in the study. fall history, and the number of falls within the past 12 month were questioned. All participants were assessed with Timed Up and Go Test (TUGT), One-Leg Stand Test (OLST), Walking and Talking Test (WTT), Sternal Push Test (SPT), Tinetti Test (TT), Four Test Balance Scale (FTBS), The Short Falls Efficacy Scale-International (FES-I), Pain Severity and Patient Global Assessment (PGA) by Visual Analog Scale (VAS), disability by the Health Assessment Questionnaire (HAQ), and disease activity by Disease Activity Score in 28 joints (DAS28) were evaluated in for for each patient. The Kolmogorov-Smirnov, Mann-Whitney and chi-square tests were performed with a significance level of $P \leq 0.05$.
Results: 22 patients had at least one or more falls. The average age was 54.9±11.5 years with a female predominance (sex ratio = 0.13). Comparing the two groups of patients: those with a history of falls and those without, patients with previous falls were mainly married women (p=0.57), with a low intellectual level (p=0.63). The body mass index in this group was higher (p=0.01) with respectively a higher number of painful and swollen joints (p=0.16, p=0.07); the mean HAQ was higher (p=0.03), and the mean VAS was more important (p=0.05). 12/22 patients had co-morbidities and were poly-medicated.20/22 had joint feet deformities (hallux valgus was the most common deformity). 21/22 were on low dosage corticosteroid therapy. The mean TUGT was 18.5 seconds (>14 seconds). The OLST was less than 5 seconds in 12/22, the sternal push test was positive in 9/22, WTT was positive in 6/22 and the mean tinetti test was 22.4±5.4 suggesting a high risk of falls. The average Short FES-I was 14.6 ±4.4 reflecting a high fear of falls in this group of patients.
Conclusion: Knowledge about risk factors can help to identify high-risk patients in order to decrease their risk of falling, thus preventing fall-related injuries.

POS0470 GLUCOCORTICOID DISCONTINUATION IN EARLY RHEUMATOID AND UNDIFFERENTIATED ARTHRITIS PATIENTS. A SUB-ANALYSIS OF THE BeSt AND IMPROVED STUDIES

J. M. Maassen[1], R. Dos-Santos[2], S. A. Bergstra[1], R. Goekoop[3], T. Huizinga[1], C. Allaart[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[2]Clinical University Hospital, Rheumatology, Santiago de Compostela, Spain*; *[3]Haga Hospital, Rheumatology,The Hague, Netherlands*

Background: Discontinuation of glucocorticoids (GC) as bridging therapy in rheumatoid arthritis (RA) treatment is recommended as rapidly as clinically feasible. Little is known about the rate of, and possible characteristics associated with successful GC discontinuation.
Objectives: To evaluate the success rate of GC discontinuation, and to study which factors are associated with successful GC discontinuation.
Methods: Data from two treat-to-target studies; BeSt (target DAS ≤2.4, LDA), and IMPROVED (target DAS <1.6, remission) were evaluated for all patients initially treated with a tapered high-dose of oral GC with conventional DMARD(s). GCs were discontinued when DAS ≤2.4 was maintained for 28 weeks in BeSt, and as soon as DAS was <1.6 in IMPROVED. GC discontinuation could be attempted twice: first attempt called 'primary', second attempt after GC restart called 'secondary'. Discontinuation was considered successful if the treatment target was maintained at the next visit. Univariable, and exploratory forward and backward multivariable logistic regression analyses were performed to identify potential characteristics associated with successful discontinuation (p-value <0.2 included in final model).
Results: From the 131 patients initiating combination therapy with prednisone in the BeSt study, 93 attempted discontinuation. Primary discontinuation was successful in 60% (56/93) and secondary discontinuation in 54% (19/35). A lower DAS at the visit prior to GC discontinuation and ACPA negativity were associated with successful discontinuation (table 1). Of the 610 patients in the IMPROVED, 400 attempted discontinuation. Primary discontinuation was successful in 61% (242/400), and secondary in 51% (71/139). A lower DAS both at baseline and at the visit prior to GC discontinuation were associated with successful discontinuation (table 1).
Conclusion: Primary GCs discontinuation was successful in approximately 60% and secondary in 50% of patients, independent of the treatment target and associated threshold for GC discontinuation. Most baseline characteristics were not predictive of successful GC discontinuation, but ACPA negativity (only in BeSt), baseline DAS (only in IMPROVED) and in both studies DAS prior to GC discontinuation were predictive for successful discontinuation. Based on this data it seems that 'standard' baseline characteristics are insufficient to 'personalize' the duration of temporary GC bridging but the DAS at the moment of GC discontinuation might give guidance.

Table 1. Results logistic regression analyses

	Univariable		**Multivariable [a]** $R^2 = 0.173$

POS0471 ASSOCIATION OF HLA-DRB1 HAPLOTYPES WITH CARDIOVASCULAR MORTALITY IN INFLAMMATORY POLYARTHRITIS: RESULTS FROM THE NORFOLK ARTHRITIS REGISTER

S. Sharma[1], D. Plant[1], J. Bowes[1], A. MacGregor[2,3], S. Verstappen[1,4], A. Barton[1,4], S. Viatte[1,5]. *[1]Centre for Genetics and Genomics Versus Arthritis, Centre for Musculoskeletal Research, Manchester, United Kingdom*; *[2]Norwich Medical School, University of East Anglia Faculty of Medicine and Health Sciences, Norwich, United Kingdom*; *[3]Rheumatology Department, Norfolk and Norwich University Hospitals NHS Foundation Trust, Norwich, United Kingdom*; *[4]NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester NHS Foundation Trust, Manchester, United Kingdom*; *[5]Lydia Becker Institute of Immunology and Inflammation, Faculty of Biology, Medicine and Health; The University of Manchester, Manchester, United Kingdom*

Background: Haplotypes defined by amino acids at HLA-DRB1 positions 11, 71 and 74 associated with susceptibility to rheumatoid arthritis (RA), are associated with radiological outcome, anti-TNF response and all cause-mortality in RA.(*1, 2*) RA is associated with cardiovascular (CV) morbidity and mortality, but the increased prevalence of risk factors of CV disease in RA only partially explains this association.

Objectives: The aim was to investigate whether haplotypes associated with RA disease susceptibility and disease severity are also associated with CV mortality.

Methods: The Norfolk Arthritis register (NOAR) is a primary care-based inception cohort of patients with inflammatory polyarthritis (IP).(*1, 2*) NOAR patients with at least 2 years of follow-up and available mortality and genetic data were included in this study. Mortality data was provided by the Office for National Statistics.

Univariate Cox proportional hazard models were applied using STATA/IC 14.0. Models for CV mortality were adjusted for CV risk factors selected using stepwise regression: namely obesity, gender and hypertension. Hazard models were applied to the entire cohort of patients with inflammatory polyarthritis (IP). When calculating differences between highest and lowest risk genetic factors, bivariate analysis was used.

Results: HLA-DRB1 amino acids, haplotypes or haplotype groups associated with RA susceptibility are also associated with CV mortality as shown in the table 1. HLA-DRB1 polymorphisms encoding amino-acid haplotypes associated with an increased or decreased susceptibility to RA consistently show the same magnitude and direction of association for overall and CV mortality in IP. For example, the SEA-haplotype, associated with the lowest susceptibility to RA, and the best radiographic outcome, was found to be associated with decreased CV mortality (HR 0.67, 95% CI 0.47, 0.91, p=0.023). The relative difference in CV mortality between carriers of the high susceptibility VKA haplotype and carriers of the SEA haplotype was significant (HR 1.67, 95% CI 1.13, 2.48, p=0.01).

Table 1. ***Hazard ratios for CV mortality by genetic factors among patients with IP. Total number (n) of deaths are also displayed alongside the total number (n) of patients included in each analysis.***

Amino acid / Haplotype /Group	Hazard Ratio (95% CI)	N
valine 11	1.10 (0.93, 1.30)	343 (2514)
serine 11	0.82 (0.70, 0.96)*	343 (2514)
Difference	*1.23 (1.01, 1.49)**	
VKA haplotype	1.16 (0.94, 1.43)	310 (2328)
SEA haplotype	0.67 (0.47, 0.94) *	310 (2328)
Difference	*1.67 (1.13, 2.48)**	
Group 1 †	1.10 (0.93, 1.31)	319 (2328)
Group 4 †	0.73 (0.60, 0.89)*	319 (2328)
Difference	*1.37 (1.09, 1.72)**	

** p<0.05† Haplotype groups as defined previously (2)*

HLA-DRB1 haplotypes can be ranked according to the magnitude of their association with RA susceptibility and this hierarchy is conserved for various measures of disease outcome and overall mortality.(*2, 3*) The figure 1 shows that this risk hierarchy is also conserved for CV mortality: HLA-DRB1 haplotypes that predispose to RA also predispose to increased CV mortality, independent of known CV risk factors.

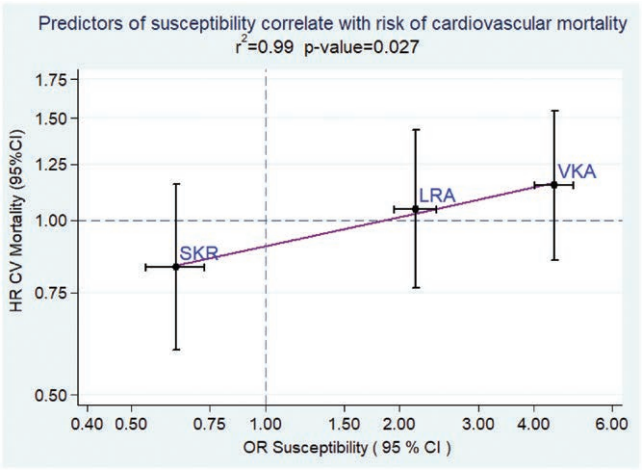

Figure 1. Haplotypes with frequency >12% in NOAR are shown. X axis: susceptibility to ACPA-positive RA as ORs.(2) Y axis: CV mortality risk in IP as HRs, derived from multi-variate cox-proportional hazard models adjusted for CV risk factors. Values are on a logarithmic scale. A one-tailed p value was calculated using linear regression to determine the association between β coefficients of susceptibility and CV mortality.

Conclusion: The originally reported genetic associations between HLA-DRB1 polymorphisms and overall mortality were likely driven by associations with CV mortality.

POS0472 COMPARATIVE METABOLOMIC ANALYSIS OF SERUM SAMPLES FROM PATIENTS WITH COINCIDENTAL RHEUMATOLOGICAL AND MALIGNANT DISEASES

D. Marx[1], L. Diekmann[1], K. Klika[2], H. M. Lorenz[1], K. Benesova[1], M. Souto-Carneiro[1]. *[1]Heidelberg University Hospital, Medicine 5 - Rheumatology, Heidelberg, Germany*; *[2]DKFZ Heidelberg, Molecular Structure Analysis, Heidelberg, Germany*

Background: Rheumatic and musculoskeletal diseases (RMDs) and malignancies are both caused by a dysfunctional immune system and the probability of their coincidence in one individual is rising due to advances in cancer treatment and demographic changes. However, the lack of understanding of the complex interrelationship of both conditions often leads to undertreatment and high level of suffering in affected patients. Herein, the MalheuR project breaks new ground by systematic analysis of concomitant malignant and rheumatic diseases and closes the knowledge gaps on the clinical and molecular level.

Objectives: To enable early diagnosis of concomitant malignancy and/or identification of patients at risk in the future, changes in serum metabolome were explored in order to create a diagnostic classification model.

Methods: Serum samples from patients with concomitant RMD and cancer or obligate precancerous lesions (n=78, breast cancer (23), melanoma (14), MGUS (12), prostate cancer (8) and others (21)) were collected as a pilot study within the MalheuR project, a registry-based study initiated in 2018 at the university hospital Heidelberg, Germany. The following groups were defined by the underlying RMD: rheumatoid arthritis (n=42), psoriasis arthritis (n=23), spondylarthritis (n=9) and systemic lupus erythematosus (n=4). RMD patients without any malignancies were used as controls (n=280: 122 RA, 81 PsA, 46 SpA, 31 SLE).

Samples were analyzed by 1H NMR spectroscopy. For all samples, regular 1H acquisition with presaturation and Carr-Purcell-Meiboom-Gill (CPMG) spectra were acquired using a 600 MHz Bruker NMR spectrometer. Spectra were processed with TopSpin using 0.2 Hz of line broadening and manual phasing. Molar concentrations of 26 metabolites were acquired by integration of NMR spectra. With GraphPad Prism, univariate and ANOVA statistical analysis was performed to find significant differences between each malignant group and their control group as well as between all four malignant groups.

Results: Mean disease duration was 11.8 ±10.5 years for cancer and 12.8±10.8 years for RMDs since diagnosis. 1.4% received cancer treatment (6.4% of malignancy group), 69.3% csDMARDs, 42.3% b/tsDMARDs and 46.4% glucocorticoids at the time of sample collection.
Most metabolites tested were significantly lower in the malignancy groups versus associated controls: Concentrations of amino acids V and L were significantly reduced in all malignancy samples. Additionally, T, D, N, Q, E, A, I were altered in RA, SpA and PsA, changes in G were seen in RA, PsA and SLE and P was altered in RA and PsA only. Furthermore, lower concentrations of short chain fatty acids and tricarboxylic acid cycle intermediates were present in the malignancy groups. In no case was a metabolite concentration significantly higher in the malignancy group than in the associated control. When comparing the metabolome within the four malignancy groups, only the concentrations of creatine, threonine and isoleucine were found higher in RA patients with malignancy.
Conclusion: Significant differences between the metabolomic fingerprints of RMD patients with and without malignancies could be observed. These changes might be characteristic for cancer burden, as in most cases the underlying RMD was not relevant when comparing the concentrations between the malignancy groups. Our results may promote understanding of the interrelationships of both disease entities as well as prove useful as biomarkers for diagnostic and therapeutic purposes.

POS0473 AUTOIMMUNITY AGAINST COLLAGEN IN RHEUMATOID ARTHRITIS (RA): SERUM LEVELS OF IgG AGAINST DENATURED TYPE II COLLAGEN SIGNIFICANTLY ELEVATED IN RA

P. Drobinski[1], E. Aighobahi[2], A. C. Bay-Jensen[3], M. Karsdal[3]. [1]*University of Copenhagen/Nordic Bioscience, Department of Biomedical Sciences, Copenhagen, Denmark*; [2]*Technical University of Denmark, Department of Biotechnology and Biomedicine, Copenhagen, Denmark*; [3]*Nordic Bioscience, ImmunoScience, Herlev, Denmark*

Background: The presence of autoantibodies in Rheumatoid Arthritis (RA) is a hallmark of the disease and one of main criteria for diagnosis and clinical classification. Identification of anti-citrullinated protein antibodies (ACPA) and RF-Factors in circulation of RA patients remains the most characteristic and established criteria for diagnosis. However, due to diagnostic limitation of these biomarkers, only approximately 70% of patients with RA can be identified. As a consequence, there is a lack of diagnostic biomarkers for large number of patients. Diagnosis of these patients relies mainly on assessment of their clinical symptoms such as swollen and tender joints. This problem leaves a need for diagnostic improvement and development of more sensitive biomarkers.
Objectives: In this study, we aimed to develop a sensitive biomarker assay capable to identify and quantify presence of autoantibodies against denatured type II collagen in circulation of patients with RA.
Methods: The presence and levels of autoantibodies was measured in serum samples from 50 patients with moderate to severe RA who had inadequate response to Methotrexate (average age 51.2, 86% of female, 78% of white race patients). Control cohort involved serum from 42 healthy age matched patients (average age 48.6, 50% of female, 60% of white race patients). Denaturation of the type II collagen was performed by heat treatment for 15 min at 72 °C. Improvement of assay sensitivity was investigated by measurements of autoimmunity levels against denatured and native type II collagen. Assay specificity was assessed by comparison of presence of autoantibodies against type II collagen versus albumin (non-sense control). The normality of data distribution was checked with Shapiro-Wilk test, significance between cohorts with Mann-Whitney nonparametric test and correlations with Spearman's correlation coefficient (rho).
Results: Serum levels of autoantibodies against denatured type II collagen were significantly higher in RA patients than in healthy controls ($P < 0.0001$) (Figure 1). We observed nearly 4-fold difference between both cohorts. Denaturation of type II collagen showed high improvement of assay sensitivity and increased accessibility of collagen for binding of autoantibodies. Developed assay showed specificity for detection of type II collagen autoantibodies by displaying no levels of autoimmunity against other control proteins (albumin). The levels of serum autoantibodies correlated significantly ($P < 0.03$) with patient disease activity (DAS28) at baseline, displaying rho = 0.3. Our assay showed good technical performance with acceptable inter- and intra- assay variations (18% and 5% respectively).

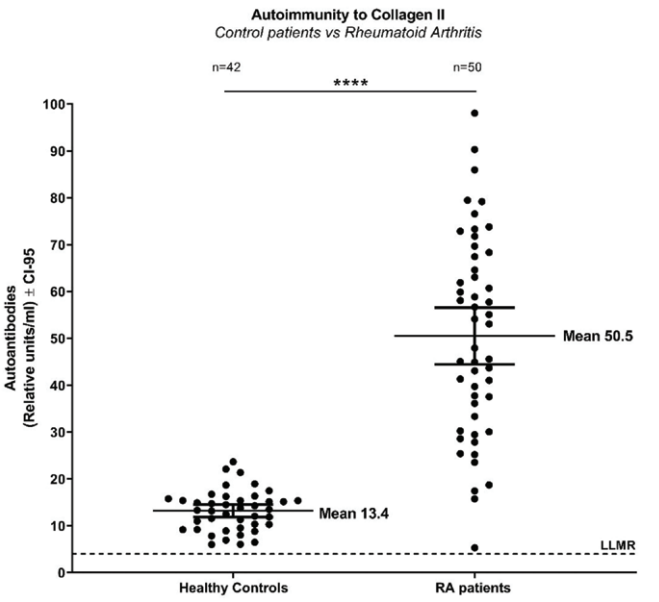

Figure 1. Differences in serum levels of autoantibodies against denatured type II collagen between healthy controls and patients with Rheumatoid Arthritis.

Conclusion: Present findings show that patients with RA carry upregulated levels of circulating autoantibodies directed against type II collagen. Heat-treatment of type II collagen increased exposure of immunogenic epitopes of collagen and enabled for more sensitive detection of autoantibodies directly in patient serum. Developed assay demonstrated potential for specific detection of autoantibodies and may provide additional diagnostic value in RA patients.

POS0474 SUBSTANTIAL IMPACT OF AUTOANTIBODY ENRICHMENT ON OUTCOMES IN EARLY RHEUMATOID ARTHRITIS TREATED WITH ABATACEPT: DATA FROM A LARGE POOLED ANALYSIS OF 4 RCTS

K. Michaud[1,2], S. S. H. Park[3], K. Lozenski[4], J. Vaile[5], V. Khaychuk[6], J. Pope[7], P. G. Conaghan[8,9]. [1]*University of Nebraska Medical Center, Internal Medicine Division of Rheumatology, Omaha, NE, United States of America*; [2]*FORWARD, The National Data Bank for Rheumatic Diseases, Wichita, KS, United States of America*; [3]*Bristol-Myers Squibb, US HEOR, Princeton, NJ, United States of America*; [4]*Bristol-Myers Squibb, Medical Data Generation, Princeton, NJ, United States of America*; [5]*Bristol-Myers Squibb, Worldwide Medical, Princeton, NJ, United States of America*; [6]*Bristol-Myers Squibb, US Medical Immunology and Fibrosis, Princeton, NJ, United States of America*; [7]*Western University, Schulich School of Medicine, Division of Rheumatology, London, Ontario, Canada*; [8]*University of Leeds, Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; [9]*Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Biomarkers are commonly used as prognostic tools in rheumatoid arthritis (RA) and have additional potential to guide treatment decisions. Previous clinical trials of abatacept (ABA) such as the Early AMPLE trial (eAMPLE) and real-world data suggest differential treatment effects of ABA based on the presence of biomarkers and disease stage.[1-4]
Objectives: To supplement evidence of enhanced efficacy of ABA among patients with enriched autoantibody biomarkers and early disease stage by applying key inclusion criteria from the eAMPLE trial retrospectively to historic ABA RCTs.
Methods: Individual patient data (IPD) from four early-RA ABA trials (AGREE [NCT00122382], AMPLE [NCT00929864], AVERT [NCT01142726], AVERT-2 [NCT02504268]) were pooled. Patients were defined as enriched at baseline if they had: 1) RA disease duration ≤ 12 months, 2) DAS28-CRP ≥ 3.2, 3) ≥ 3 times the upper limit of normal on an anti-cyclic citrullinated peptide (anti-CCP) test, and 4) were rheumatoid factor positive (RF+). Patients were grouped according to treatment status (ABA [monotherapy or with methotrexate (MTX)] or non-ABA [MTX or adalimumab (ADA) plus MTX]). Outcomes included DAS28-CRP mean

change from baseline to week 24, DAS28-CRP remission and ACR 20/50/70 at week 24. IPD mixed-effects meta-regressions were estimated with trial fixed effects, main effects and interaction of enrichment status and treatment type, trial-level random effects on the interaction, and baseline DAS28-CRP score for DAS28-CRP outcomes. These regressions were conducted in the full population and among ABA patients only. Sensitivity analyses defining enrichment using only criteria 3 and 4 were also conducted.

Results: 2,087 patients [1,328 (64%) enriched, 759 (36%) non-enriched] were included (AGREE 492 [24%], AMPLE 509 [24%], AVERT 339 [16%], AVERT-2 747 [36%]). Disease duration, RF+, and anti-CCP values differed as expected between the two groups, while DAS28-CRP was high regardless of enrichment status (Table 1). Among ABA-treated patients, outcomes were more favorable for enriched patients compared to non-enriched patients across all outcomes, either statistically or directionally (Figure 1, ABA treatment arm only analysis). The differences in outcomes between enriched vs. non-enriched patients were larger for ABA than for comparators across all outcomes with the exception of ACR 50, where the difference was directionally consistent (Figure 1, ABA vs. comparator analysis). The relative odds of improved efficacy of ABA vs. comparators ranged from 37% to 87% for remission and ACR responses. The results were consistent in the sensitivity analysis using only anti-CCP and RF seropositivity to define enrichment.

Table 1. Baseline characteristics

	All patients	Non-enriched patients		Enriched patients	
		Abatacept	Comparators	Abatacept	Comparators
	N = 2,087	N = 385	N = 374	N = 784	N = 544
Demographics					
Age (years)	49.3 ± 12.9	49.4 ± 12.6	50.6 ± 12.9	48.6 ± 12.5	49.2 ± 13.5
Female	79.3%	81.3%	83.4%	77.2%	77.9%
Disease characteristics					
Disease duration (months)	8.5 ± 12.5	19.9 ± 15.9	18.3 ± 15.1	2.4 ± 2.8	2.4 ± 2.9
RF Positive	91.0%	74.2%	76.1%	100%	100%
Anti-CCP Positive	81.8%	52.2%	47.3%	100%	100%
DAS28-CRP Score	5.71 ± 1.13	5.72 ± 1.19	5.66 ± 1.20	5.68 ± 1.09	5.76 ± 1.08

Comparators included MTX and MTX+ADA.

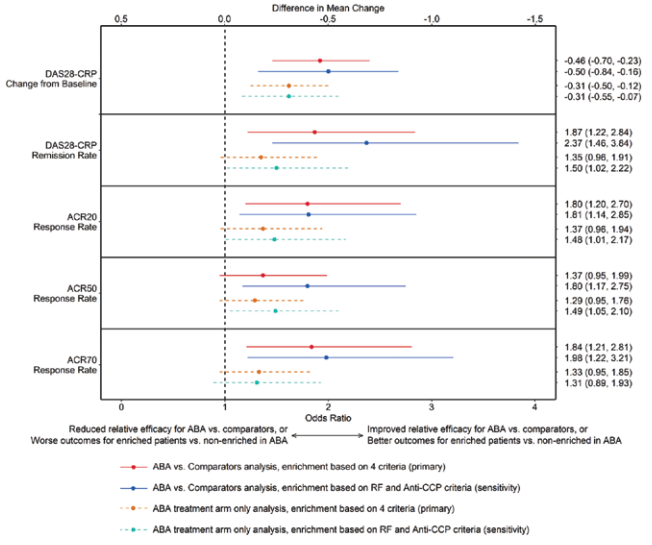

Figure 1. Analysis results

Conclusion: This post-hoc study corroborates previous evidence of improved outcomes among ABA-treated, seropositive early RA patients by applying eAMPLE inclusion criteria retrospectively to ABA RCTs. The findings support a differential treatment effect for costimulation blockade using ABA among enriched and double antibody positive early RA patients, suggesting a potential for patient-tailored RA treatment approaches.

Lopez-Pedrera[1]. *[1]IMIBIC/Hospital Reina Sofia/Universidad de Cordoba (UCO), IMIBIC/Hospital Reina Sofia/Universidad de Cordoba (UCO), Cordoba, Spain*; *[2]Hospital Universitario de Jaen, Hospital Universitario de Jaen, Jaen, Spain*; *[3]Hospital Universitario Virgen Macarena, Hospital Universitario Virgen Macarena, Sevilla, Spain*; *[4]Hospital Clínico Universitario, Hospital Clínico Universitario, Malaga, Spain*; *[5]Hospital Regional Universitario de Malaga, Hospital Regional Universitario de Malaga, Malaga, Spain*; *[6]Hospital Universitario Virgen de Valme, Hospital Universitario Virgen de Valme, Sevilla, Spain*; *[7]Hospital Universitario de Jerez de la Frontera, Hospital Universitario de Jerez de la Frontera, Cadiz, Spain*

Background: TNF inhibitors (TNFi) represent an extraordinary advance in the management of Rheumatoid Arthritis (RA). Despite their benefits, there is a percentage of patients (20–40%) that do not achieve clinical improvement. Therefore, it is necessary to search for new and easily accessible biomarkers predictive of therapeutic response that might guide precision medicine.

Objectives: 1. To explore changes in the molecular profile of RA patients following TNFi therapy in serum samples. 2. To search for new and reliable biomarkers predictive of TNFi response, based on clinical and molecular profiles of RA patients, by using machine learning algorithms.

Methods: In a prospective multicenter study, 79 RA patients undergoing TNFi and 29 healthy donors (HD) were enrolled. Twenty-two RA patients were further included as a validation cohort. Serum samples were obtained before and after 6 months of treatment, and therapeutic efficacy was evaluated. Patients' response was determined following EULAR response criteria. Serum inflammatory profile was analyzed by a multiplex immunoassay, along with oxidative and NETotic profiles, evaluated by commercial kits. A circulating miRNA array was also performed by next-generation sequencing. Clustering analysis was carried out to identify groups of patients with distinctive molecular signatures. Then, clinical and molecular changes induced by TNFi were delineated after 6 months of therapy. Finally, integrative clinical and molecular signatures as predictors of response were assessed at baseline by supervised machine learning methods, using regularized logistic regressions.

Results: Inflammatory, oxidative stress and NETosis-derived biomolecules were found altered in RA patients versus HD, closely interconnected and associated with several deregulated miRNAs. This altered molecular profile at baseline allowed the unsupervised division of three clusters of RA patients with distinctive clinical phenotypes, further linked to TNFi effectiveness. Cluster 1 included RA patients with low levels of pro-inflammatory cytokines, associated with a medium-low disease activity score and good clinical response. Clusters 2-3 comprised patients with high levels of pro-inflammatory cytokines, associated with a high disease activity and a non-response rate of 30%.

After 6 months of therapy the molecular profile found altered in RA patients was reversed in responder patients, who achieved a molecular phenotype similar to HDs. However, non-responder patients' molecular profile remained significantly deregulated, including alterations in inflammatory mediators (IL-6, L-8, TNFα, VEGF, IL-1RA, IL-5, IL-15, GMCSF, GCSF, FGFb), oxidative stress markers (LPO) and NETosis-derived products (Elastase), along with specific miRNAs (miR-199a-5p). These molecular changes further correlated with changes in disease activity score. Machine-learning algorithms identified clinical (Creatinine, IgM, Vitamin D, Swollen Joints, C4, Disease Duration and Tryglicerides) and molecular (Nucleosomes, IL-10, miR-106a-5p, IL-13, IL-12p70, IL-15 and

LPO) signatures as potential predictors of response to TNFi treatment with high accuracy. Furthermore, the integration of both features in a combined model increased the predictive value of these signatures (AUC: 0.91). These results were further confirmed in an independent validation cohort.
Conclusion: 1. RA patients display distinctive altered molecular profiles directly linked to their clinical status and associated with TNFi effectiveness. 2. Clinical response was associated with a specific modulation of the inflammatory profile, the reestablishment of the altered oxidative status, the reduction of NETosis and the reversion of related altered miRNAs. 3. The integrative analysis of the clinical and molecular profiles using machine learning allows the identification of novel signatures as potential predictors of therapeutic response to TNFi therapy.

Background: In rheumatic diseases, specifically in chronic inflammatory arthritis (IA), there are no data about the effectiveness of LDA in preventing pregnancy complications.
Objectives: To assess the potential benefit of LDA administration during pregnancy to prevent adverse pregnancy outcomes (APO) in IA.
To compare pregnancy outcomes in IA pregnancies treated during pregnancy with LDA with those untreated.
Methods: Italian P-RHEUM.it register is designed as a nationwide, web-based longitudinal observational cohort study collecting data on pregnancies in inflammatory rheumatic diseases. At baseline, socio-demographic parameters, obstetric history, comorbidities and clinical/laboratoristic characteristics are registered. During pregnancy, the course of maternal disease, medications, development of fetus and complications are collected for each trimester.
Results: From May 2018 to May 2020, 349 patients were enrolled. Forty-five patients with IA had completed their pregnancy with known outcome (20 Rheumatoid Arthritis, 10 Psoriatic Arthritis, 6 Ankylosing spondylitis, 5 Juvenile Idiopathic Arthritis, 4 Undifferentiated Arthritis): 13 (28.89%) treated with LDA during pregnancy and 32 (71.11%) without LDA prophylaxis. LDA was used with a higher frequency in women with previous APO, anti-phospholipid positivity and on biological DMARDs even if it's not statistically significant (Table 1). All the LDA-treated women had a live-birth rate of 100%, whereas among women not treated with LDA the live birth rate was of 84.4% with 27 live-birth pregnancies, 3 early miscarriages, 1 fetal loss and 1 stillbirth observed. There were no significant differences between the LDA and the not LDA groups regarding pregnancy/peripartum obstetric complications (p=0.14), although less adverse pregnancy/peripartum outcomes were registered in LDA patients' group (Table 1).

Table 1. Comparison between inflammatory arthritis pregnancies treated with low-dose aspirin and those untreated.

	LDA (n 19)	Not LDA (n 39)	p
Maternal age at conception, median (IQR)	33 (30.5 - 36.5)	33 (28.2 - 35)	
BMI, median (IQR)	25.4 (22.9 - 28.5)	22.5 (20.4 - 24.5)	
Smoking, n (%)	3 (15.8%)	4/36 (11.1%)	0.68
Previous APO, n (%)	7/11 (63.7%)	7/13 (56.1%)	0.34
aPL+, n (%)	3 (15.8%)	1/36 (2.8%)	0.1
CRP+, n (%)	5/15 (33.3%)	11/27 (40.7%)	0.75
GC at baseline, n (%)	9 (47.4%)	15/34 (44.1%)	0.82
cDMARDs at baseline, n (%)	1 (5.3%)	3/34 (8.8%)	1
bDMARDs at baseline, n (%)	6 (31.6%)	11 (28.2%)	0.79
Live-birth pregnancy, n (%)	18 (94.7%)	32 (82.1%)	0.25
Pregnancy loss, n (%)	1 (5.3%)	7 (17,9%)	0.25
Hypertensive disorders, n (%)	2/18 (11.1%)	6/38 (15,8%)	1

POS0477 HIGH DISEASE ACTIVITY AT BASELINE AND SEROPOSITIVITY ARE ASSOCIATED WITH TREATMENT RESPONSE AT ONE YEAR POST SYNOVIAL BIOPSY IN RHEUMATOID ARTHRITIS PATIENTS

K. Murray[1], C. Low[1], F. Young[1], M. Bienicka[1], E. Mylod[2], U. Fearon[2], D. Veale[1]. *[1]Saint Vincent's University Hospital, Rheumatology, Dublin, Ireland*; *[2]Trinity College,Trinity Biomedical Sciences Institute, Dublin, Ireland*

Background: Despite recent therapeutic advances, our ability to predict prognosis and therapeutic response in RA remains imprecise.
Objectives: To determine biomarkers predictive of outcome at one year following arthroscopy.
Methods: RA patients were prospectively recruited and underwent knee arthroscopy performed under local anaesthetic. Each patient underwent a careful systematic assessment of demographic, clinical, and serologic factors on the day of arthroscopy and were reviewed at 2 weeks, 3, 6 and 12 months post arthroscopy. Erosive disease was defined based on plain-film radiographs of hands and feet. Disease activity at one year was used to define treatment response into responders (moderate/good EULAR Response) and non-responders.
Clinical characteristics, synovial tissue cell profiles and immunohistochemistry were analysed for T Cells (CD3), B Cells (CD20, CD138), macrophages (CD68) and vascularity (Factor VIII) to establish predictors of treatment response. All areas of each biopsy section were examined and the sub-lining layer independently scored by 2 observers using a well-validated semiquantitative scoring method, ranging from 0 to 4 (0=no staining, 1=<25%, 2=25–49%, 3=50–74%, and 4=75–100% staining). Factor 8 was scored by calculating the mean count of stained blood vessels per high-power field (at 20X magnification).
Results: There were no significant differences between responders and non-responders regarding gender, age, disease duration, medications, erosive status, ESR, CRP or synovitis or vascularity at arthroscopy (Table 1). Interestingly, rates of RF and ACPA positivity, tender and swollen joint counts, DAS28 and DAS28CRP were all higher amongst treatment responders. Immunohistochemistry was a very poor predictor of treatment response. There were no significant differences between the two groups in CD3, CD20, CD138, CD68 or Factor 8 score.

Table 1. Baseline Characteristics

	Responder (n=30)	Non-responder (n=18)	p value
Female	20 (66.7%)	14 (77.8%)	NS
Age	51.5 (11.2)	54.2 (10.9)	NS
Disease duration	0.5 (0-16)	0.5 (0-10)	NS
RF positive	22 (73.3%)	5 (27.8%)	0.003
ACPA positive	22 (73.3%)	8 (44.4%)	0.045
Erosions	8 (26.7%)	5 (27.8%)	NS
Medications			
No DMARD	23 (76.7%)	10 (55.6%)	NS
csDMARD only	4 (13.3%)	3 (16.7%)	NS
TNFi	2 (6.7%)	3 (16.7%)	NS
Other bDMARD	1 (3.3%)	2 (11.1%)	NS
Patient global health, VAS (mm)	54.2 (10-100)	51.5 (0-90)	NS
SJC (28 Joints)	4.5 (0-16)	1 (0-18)	0.001
TJC (28 Joints)	7 (1-25)	1 (0-15)	0.001
ESR, mm/hr	23 (2-120)	24 (2-81)	NS
CRP, mg/L	5 (1-95)	6.5 (1-64)	NS
DAS28	5.01 (1.95-7.36)	3.93 (1.40-6.62)	0.003
DAS28CRP	4.78 (2.82-7.13)	3.39 (1.21-6.26)	0.002
Synovitis, VAS	65 (10-100)	70 (30-100)	NS
Vascularity, VAS	60 (10-90)	70 (30-100)	NS

Conclusion: In this small study, seropositivity and disease activity were higher in responders. Baseline immunohistochemical staining was not a good discriminator of treatment respons

POS0478 ASSOCIATION BETWEEN BODY SHAPES AND BODY SHAPE TRAJECTORIES, AND THE RISK OF RHEUMATOID ARTHRITIS IN THE FRENCH E3N COHORT

C. Salliot[1,2,3], Y. Nguyen[4,5], X. Mariette[3,6], M. C. Boutron-Ruault[2,7], R. Seror[3,8]. *[1]Centre Hospitalier d'Orleans, Rheumatology, Orleans, France*; *[2]Center for Research in Epidemiology and Population Health (CESP), Université Paris-Saclay, Institut pour la Santé et la Recherche Médicale (INSERM) U1018, Villejuif, France*; *[3]Center of Immunology of Viral Infections and Auto-immune Diseases (IMVA), Université Paris-Saclay, Institut pour la Santé et la Recherche Médicale (INSERM) U1184, Le Kremlin Bicetre, France*; *[4]Hôpital Beaujon, Université de Paris, Internal Medicine, Clichy, France*; *[5]Center for Research in Epidemiology and Population Health (CESP), Paris-Saclay, Institut pour la Santé et la Recherche Médicale (INSERM) U1018, Villejuif, France*; *[6]Assistance Publique-Hôpitaux de Paris (AP-HP), AP-HP. Université Paris-Saclay – Hôpital Bicêtre, Rheumatology, Le Kremlin Bicetre, France*

Background: Several cohort and case-control studies have suggested that overweight or obesity is associated with the risk of Rheumatoid Arthritis (RA). Associations were based on Body Mass Index (BMI), although this measurement does not reflect the fat distribution [1].

Objectives: To study the relationships between anthropometric measurements and the risk of RA in women involved in the E3N cohort.

Methods: E3N is an ongoing French prospective cohort that enrolled 98,995 women aged 40-65 years in 1990. Women completed mailed questionnaires every 2-3 years on lifestyle and health-related information. A total of 698 incident RA cases have been validated among 78,452 women [2]. Available anthropometric measurements include birth height and weight, height and weight (collected at baseline and regularly updated during follow-up), and age-related body shapes (BS). Women had to identify the silhouette among 8 BS that best described their BS at 8 years, puberty, 20-25 years, 30-35 years, and study baseline. BS trajectories (from 8 to 30-35 years) were constructed using Nagin's approach to group-based trajectory modeling that identifies 6 different trajectories [3]. Hazard ratios (HRs) and 95% confidence intervals (CIs) for the risk of incident RA were estimated using Cox proportional hazards regression models with age as the time scale. Models were first adjusted for known risk factors of RA (model 1), and then multi-adjusted (model 2).

Results: Taking lean BS as reference, medium BS at puberty was associated with an increased risk of RA [HR=1.23 (95% CI 1.0-1.5)], in the fully adjusted model (table 1), as was large BS at baseline [HR =1.32 (95% CI 1.1-1.6)] (in model 1). Obesity (BMI>30 kg/m^2) was marginally associated with RA in model 1 [HR=1.30 (95% CI 1.0-1.7)], but the association was no longer statistically significant in the multi-adjusted model, taking normal BMI [18-25 kg/m^2[as the reference.

Birth weight and height, BS (at 8, 20-25 and 30-35 years), and BS trajectories were not significantly associated with RA in any model.

Table 1. Cox proportional-hazards analysis of anthropometric factors associated with RA

	RA	Non-cases	MODEL 1		MODEL 2

Large	110	9,838	**1.32 (1.1-1.6)**		1.20 (0.9-1.6)	

ptrend: p for trend. Ref: reference.

Model 1 adjusted for age, smoking (past/current/never), passive smoking during childhood and/or adulthood (ever/never), educational level (<high–school, up to 2 years of university, ≥ 3 years of university).

Multi-adjusted model 2 included model 1 + body mass index (<18, 18–25, 25–30, >30 kg/m^2), body shape at puberty, body shape at baseline adjusted for age, baseline physical activity (in quartiles), age at menarche (<13, 13–15, ≥15 years), age at menopause (≤45, 45–53, ≥53 years), age at the first pregnancy (<22, 22–27, ≥27 years), number of full-term pregnancies (≤1, 2, ≥3), and duration of premenopausal use of progestogen (0, 0–24, >24 months).

Conclusion: In E3N cohort, medium body shape at puberty was associated with an increased risk of RA independently of the BMI and smoking exposure.

POS0479 THE IMPACT OF FLARES ON PATIENT REPORTED OUTCOMES IN RHEUMATOID AND UNDIFFERENTIATED ARTHRITIS PATIENTS – A SUB-ANALYSIS OF THE IMPROVED STUDY

J. M. Maassen[1], S. A. Bergstra[1], P. D. de Buck[2], M. van Oosterhout[3], T. Huizinga[1], C. Allaart[1]. *[1]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[2]Haaglanden Medical Center, Rheumatology,The Hague, Netherlands*; *[3]Groene Hart Hospital, Rheumatology, Gouda, Netherlands*

Background: In rheumatoid arthritis (RA) patients in low disease activity, flares are associated with symptom deterioration. Patients in clinical remission may flare but still have low disease activity. How does this affect patient reported outcomes?

Objectives: To evaluate the prevalence of disease flares in patients treated to target drug free remission, and to study the impact of disease flares on patient-reported outcomes (PROs) for flares with different impact on disease activity.

Methods: In the IMPROVED study 610 patients with rheumatoid arthritis (RA) or undifferentiated arthritis (UA) were treated to target drug free remission (DAS <1.6) for 5 years. As soon as DAS was <1.6, treatment was tapered to discontinuation. Patients with at least 8 months follow-up were selected. A flare was defined according to three definitions; **A)** DAS ≥1.6 and ≥0.6 increase from the previous visit regardless of the previous DAS; **B)** minor flare from remission; a DAS ≥1.6 with <0.6 increase and previous DAS <1.6; **C)** major flare from remission; a DAS ≥1.6 with ≥0.6 increase and previous DAS <1.6. Linear mixed models were used to compare functional ability, measured by the health assessment questionnaire (HAQ), at visits where a flare occurred versus visits without a flare. Fisher's exact test were used to compare percentages with ≥0.22 HAQ increases between groups with and without LDA at the moment of flare. A generalized linear mixed model was used to calculate the odds ratio for a deterioration of ≥20 mm in VAS of PROs global health (GH), disease activity, pain and morning stiffness (from the preceding visit) during a flare.

Results: Of the 585 patients with sufficient follow-up, 75% experienced a flare **A**, 26% a flare **B**, and 68% a flare **C**, at least once. Most flares were observed after t=8 and t=12 months. In 55%, 100%, and 69% of visits with a flare A, B or C, the patients were still in LDA (DAS=<2.4). In 55% of the visits where a flare was associated with a DAS increase ≥0.6 (flare A & C) there was also clinically relevant increase in HAQ of ≥0.22. The mean difference in HAQ was 0.27 with flare **A** (p<0.01), 0.03 with flare **B** (p=0.72) and 0.18 with flare **C** (p<0.01). If was DAS >2.4 (LDA) at the moment of flare, HAQ increased ≥0.22 in 68% of all flares A, and 77% of all flares C (p-values <0.01, compared to flares where patients were still in LDA, DAS=<2.4). The odds ratios of a >20 mm deterioration in VAS global health, VAS disease activity, VAS pain and VAS morning stiffness was significant ≥1 for flares with a ≥0.6 increase in DAS (flares A and C), and ≤1 for minor flares (B) (table 1).

Conclusion: In early arthritis patients, during 5 years treated to target drug free DAS-remission, disease flares with loss of DAS-remission were common. Although the majority of patients who flared were still in LDA, most reported more pain, morning stiffness, increased disease activity and a diminished global health. On average, deterioration in HAQ only exceeded the minimum clinically important difference (delta HAQ >=0.22) in case of a ≥0.6 increase in DAS, independent of the previous DAS. Depending on the definition of flare, up to 45% of patients lost DAS LDA, and in this group the functional deterioration significantly more often exceeded the MCID as compared to the patients that flared but were still in LDA. More research is needed to find out which patients are most at risk for clinically relevant flares, and to evaluate the impact of flares in patients with remission on long term outcomes.

Table 1. Odds Ratios and 95% confidence intervals for > 20 mm increase in PROs on 100mm visual analogue scales

	Flare A		Flare B (minor)		Flare C (major)	
	Prevalence ≥20 mm[a]	OR (95% CI)	Prevalence ≥20 mm[a]	OR (95% CI)	Prevalence ≥20 mm[a]	OR (95% CI)
Global health	62%	2.1 (1.5; 2.8)	45%	0.5 (0.4; 0.7)	62%	1.4 (1.1; 1.8)
Disease activity	62%	2.5 (1.7; 3.8)	45%	0.4 (0.3; 0.6)	62%	2.1 (1.4; 3.0)
Pain	87%	2.0 (1.3; 3.1)	78%	0.5 (0.3; 0.8)	87%	1.8 (1.2; 2.5)
Morning stiffness	84%	1.7 (1.1; 2.6)	77%	0.6 (0.4; 0.9)	86%	2.1 (1.5; 2.9)

POS0480 ASSOCIATION OF NEUTROPHIL LYMPHOCYTE AND PLATELET LYMPHOCYTE RATIOS WITH JOINT INFLAMMATION IN RHEUMATOID ARTHRITIS

D. Pearce-Fisher[1], D. Orange[1,2], B. Mehta[1,3], D. Jannat-Khah[1,3], S. Goodman[1,3]. [1]*Hospital for Special Surgery, Medicine, New York, United States of America*; [2]*The Rockefeller University, Clinical Investigation, New York, United States of America*; [3]*Weill Cornell Medicine, Medicine, New York, United States of America*

Background: Some patients with rheumatoid arthritis (RA) have high disease activity scores (DAS) and low synovial inflammation, and others have high synovial inflammation and low DAS (subclinical synovitis)[1]. It would be clinically useful to identify blood biomarkers of synovial inflammation. Neutrophil-lymphocyte (NLR) and platelet-lymphocyte ratios (PLR) have been reported to distinguish RA patients with moderate/high DAS28 scores from low DAS28 [2]. However, it is not known if these inexpensive, accessible tests are associated with inflammation in synovial tissue at the histological level.

Objectives: The objective of this study was to evaluate the relationship of pre-operative NLR and PLR with synovial inflammation of the operative joint in RA patients undergoing arthroplasty.

Methods: 230 patients meeting ACR/EULAR 1987 and/or 2010 criteria were recruited prior to elective total hip, knee, shoulder, and elbow replacement. Demographics, RA characteristics, medications, disease activity, and routine tests including complete blood tests (CBC) were collected pre-operatively. Hematoxylin and eosin (H&E) stains were prepared from the synovium of the operative joint and systematically scored by a pathologist as described previously [3]. Synovial lymphocytic inflammation was graded as none, mild, moderate, marked, or band-like. Linear regression was performed to distinguish differences in the NLR, PLR, and CRP in patients with synovial lymphocytic inflammation (SLI).

Results: As expected, patients on glucocorticoids (GCs) had higher NLR (mean 5.52 (SD 7.68) vs mean 2.82 (SD 1.66) (p<0.001) and higher PLR (mean 233.73 (SD 237.21) vs (mean 162.93 (SD 65.35)) (p-value=0.04)) and those patients (N=92) were therefore excluded from down-stream analyses. On the remaining 138 patients, we tested for associations of PLR, NLR and CRP with SLI using linear regression. In all the models the highest category for synovial lymphocytic inflammation was found to be statistically significantly associated with NLR, PLR and CRP, separately (Table 1).

Table 1. Results from linear regressions evaluating the association of NLR, PLR, and CRP with synovial lymphocytic inflammation.

Linear regression Results	NLR	PLR	CRP
Synovial Lymphocytic Inflammation	Coef (95% CI)	Coef (95% CI)	Coef (95% CI)
None	Reference	reference	reference
Mild	0.31 (-0.51, 1.13)	26.54 (-8.83, 61.90)	-1.00 (-2.37, 0.36)
Moderate	0.73 (-0.18, 1.64)	28.66 (-10.22, 67.53)	0.46 (-1.09, 2.01)
Marked	0.21 (-0.80, 1.22)	24.62 (-22.80, 72.05)	0.81 (-0.87, 2.49)
Band-like	**1.92 (0.81, 3.02)**	**80.42 (31.46, 129.38)**	**2.32 (0.49, 4.16)**

OR= Odds ratio, Coef = Coefficient, NLR= neutrophil lymphocyte, PLR= platelet lymphocyte ratio, CRP= C-reactive proteinAll significant associations are bolded.

Conclusion: NLR, PLR and CRP are associated with high synovial lymphocytic inflammation of the operative joint. This suggests that these inexpensive, routinely performed blood tests may be a useful blood biomarker of synovial inflammation.

POS0481 DOES OLDER REALLY MEAN WISER?

D. Khalifa[1], S. Belghali[1], M. Limam[2], N. El Amri[1], K. Baccouche[1], H. Zeglaoui[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*; [2]*Farhat Hached Hospital, Preventive Medicine, Sousse, Tunisia*

Background: One of the main challenges in Rheumatoid arthritis (RA) is to maintain remission or low disease activity by adhering to the prescribed treatments. However, it is believed that adherence to long term treatments is inadequate in chronic diseases. Does this apply to older people too?

Objectives: To assess treatment adherence among an elderly RA population and to study determining factors of non-adherence

Methods: A cross-sectional study over a period of 4 months was conducted in a rheumatology clinic (September 2020-December 2020). Consenting elderly over the age of 65 presenting with RA were included. Exclusion criteria involved associated connective tissue diseases and troubles communicating. During clinical visits, sociodemographic information, clinical, radiological and therapeutic data were collected. Treatment adherence was assessed by the 5-item compliance questionnaire of rheumatology (CQR-5). Patients were also asked about the degree of satisfaction vis-à-vis the therapeutic effect detected. Univariate and multivariate analysis were conducted using the statistical tool SPSS.20.

Results: Forty patients consented to join the study, 82.5% of them were women. The median of age was 66.5 years old with a minimum of 65 and a maximum of 83. Comorbidities were noted in 55% of the patients. 75% of the patients had health insurance. The mean pain score was 5 out of 10 on a visual analog scale (VAS). The mean DAS 28 was 4.65±1.77 with 72.5%

of the patients having an active disease. Deformities were reported in 60% of the cases and bone destruction on radiographs in 87.2% of the cases. Methotrexate was the most prescribed treatment in 95% of the cases and biologics in 12.5% of the cases. The median number of pills taken (on the day of MTX) was 12.5 (min=6; max=23). Up to 35.5% of the patients were not satisfied with treatment results. 90% of the patients took their medication because they had fewer problems afterwards. 72.5% of them did not dare to miss their RA treatment. 95% of them had their pills stored in the same place to not forget them, 97.5% took their medication because they had complete confidence in their rheumatologist and 92.5% of them hung on to what the doctor told them. The overall results of the CQR-5 revealed that 72.5% of the patients were adherent to their RA medication and 27.5% of them were non-adherent. The study of factors associated to non-adherence showed that being younger (p=0.01), not having a health insurance (p=0.014), having comorbidities (0.03), and not being satisfied with treatments' results (p=0.014) were associated to non-adherence. Multivariate analysis showed that risk factors associated to non-adherence were elevated pain scores (odds ratio=4.11, p=0.042), not having health insurance (odd ratio=7.54, p=0.006) and having to take many pills at once (odds ratio=4.48, p=0.034). Being older was a protector factor of non-adherence (odds ratio=0.81, p=0.034).

Conclusion: Adherence among RA elderly patients is optimal and they have good trust in their medication and confidence in their rheumatologist. Older seems wiser when it comes to treatment taking behaviors in RA.

POS0482 WOOD SMOKE EXPOSURE IS ASSOCIATED WITH HIGHER ANTI-CCP ANTIBODY TITERS IN HISPANIC PATIENTS WITH RHEUMATOID ARTHRITIS

A. B. Rodriguez-Romero[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], I. J. Colunga-Pedraza[1], N. Guajardo-Jauregui[1], S. Lugo-Perez[2], A. Cárdenas[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology Service, Monterrey, Mexico*; *[2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology Service, Monterrey, Mexico*

Background: Wood smoke exposure is a risk factor for the development of chronic obstructive pulmonary disease (COPD), lung cancer and cardiovascular disease and it has also been linked to higher anti-CCP antibodies in patients with rheumatoid arthritis (RA) and COPD (1).

Objectives: The objective of the present study is to report the correlation between anti-CCP, IgG, IgM and IgA rheumatoid factor (RF) to wood smoke exposure in patients with RA. Additionally, evaluate the impact of disease activity, biomass exposure, and disease duration on anti-CCP antibody levels.

Methods: A cross-sectional, observational study was designed based on a cohort of Hispanic RA patients. All fulfilled the 2010 ACR/EULAR classification criteria for RA. Biomass smoke exposure was expressed using the biomass exposure index (BEI) calculated from the mean of exposed hours per day multiplied by the number of years exposed. Subjects were divided into two groups: those exposed to wood smoke with BEI ≥1 and subjects not exposed to wood smoke. They were matched by age, gender, and comorbidities. Anti-CCP antibodies and RF were measured by ELISA with cutoff points of <5 U/mL and <20 U/mL respectively.

Results: A total of 318 subjects were included, 159 (50%) of them had a history of exposure to wood smoke. Anti-CCP antibody positivity was present in 102 (64.2%) with a median titer of 97.1 U/mL (1.7-198) in the RA exposed group, and in 89 (56%) with a median titer of 8.5 U/mL (1.1-145) in the RA non-exposed group. A significant difference was found in anti-CCP antibody titers between groups (p=0.003). (Table 1). Spearman's rho showed a small but statistically significant correlation between BEI and anti-CCP antibody titers (rho= 0.170, p=0.002). Biomass exposure was independently related to higher anti-CCP antibody titers (B=35.4, p<0.001).

Conclusion: RA patients who were exposed to wood smoke had higher titers of anti-CCP antibodies than non-exposed RA patients. Furthermore, biomass exposure was shown to be independently related to higher titers of anti-CCP antibodies.

Table 1. Comparison of demographic, seropositivity and clinical characteristic between patients with RA exposed and matched non-exposed RA patients.

POS0483 SUBCLINICAL ATHEROSCLEROSIS IN THE FIRST FIVE YEARS OF RHEUMATOID ARTHRITIS DIAGNOSIS

N. Guajardo-Jauregui[1], I. J. Colunga-Pedraza[1], J. R. Azpiri-López[2], D. Á. Galarza-Delgado[1], A. B. Rodriguez-Romero[1], S. Lugo-Perez[2], A. Cárdenas[1], A. C. Garza Acosta[3]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*; *[2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*; *[3]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Radiology, Monterrey, Mexico*

Background: Patients with rheumatoid arthritis (RA) have a higher risk of developing a cardiovascular (CV) event than the general population, due to an accelerated process of atherosclerosis (1), which has been documented to begin in early stages of the disease and is directly associated with systemic inflammation (2).

Objectives: The aim of this study was to compare the prevalence of subclinical atherosclerosis detected by carotid ultrasound (US) in patients with RA in the first five years of diagnosis and healthy controls.

Methods: This was a cross-sectional, observational, and comparative study. A total of 53 patients aged 40-75 years old, with RA diagnosis, in the previous five years, according to the 2010 ACR/EULAR classification criteria, and 53 controls matched by age (±5 years), gender and comorbidities were included in this study. Subjects with a previous CV event, such as myocardial infarction, cerebrovascular event and peripheral arterial disease, another connective tissue disease and pregnant women were excluded from this study. A high-resolution B-mode carotid US was performed in all study subjects. Subclinical atherosclerosis was evaluated as the presence of carotid plaque (CP) or an increased carotid intima media thickness (cIMT). CP was defined as a cIMT ≥1.2mm or a focal narrowing ≥0.5mm of the surrounding lumen, and an increased cIMT was defined as a value ≥0.8mm. Distribution was evaluated with the Kolmogorov-Smirnov test. Comparisons were done with χ^2 test and Fisher's exact test for qualitative variables, and Student's t test and Mann-Whitney's U test for quantitative variables. A *p*-value <0.05 was considered statistically significant.

Results: Comparisons of demographic characteristics showed no differences between the RA group and the control group (Table 1). When comparing carotid US findings there was a difference in the presence of CP, being more prevalent in RA patients (26.4% vs 11.3%, *p*=0.047), in the presence of an increased cIMT, being more prevalent in RA patients (34.0% vs 3.8%, *p*=<0.001), in the cIMT as a quantitative variable, being higher in RA patients (0.70mm vs 0.59mm, *p*=<0.001 in the right carotid artery, and 0.75mm vs

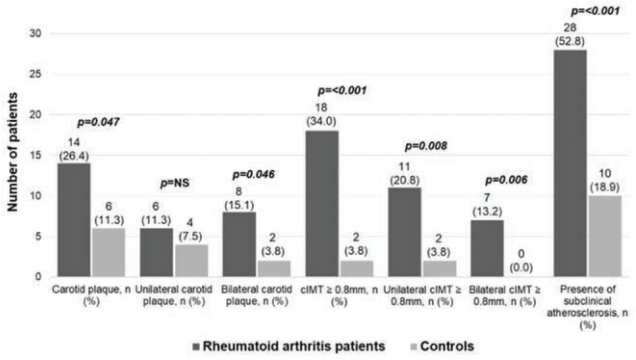
Figure 1. Carotid ultrasound findings.



0.60mm, *p*=0.001 in the left carotid artery), and in the presence of subclinical atherosclerosis overall, being more prevalent in RA patients (52.8% vs 18.9%, *p*=<0.001) (Figure 1).

Conclusion: Patients with RA in the first five years of diagnosis have a higher prevalence of subclinical atherosclerosis than the general population. CV evaluation including a carotid US should be done at the time of diagnosis of RA patients, and subsequently it must be individualized according to the CV risk of each patient, with a maximum of five years to identify those patients who would benefit from an opportune treatment.

POS0484

THE ASSOCIATION BETWEEN SOCIAL STRESSORS AND DISEASE REMISSION AMONG MEN AND WOMEN WITH EARLY RHEUMATOID ARTHRITIS

L. Hedenstierna[1,2,3], A. K. Hedström[4], L. Klareskog[1,2], L. Alfredsson[3,5], J. Askling[6,7], S. Ernestam[2], S. Saevarsdottir[8], L. Ljung[2,6,9]. *[1]Karolinska Institutet, Department of medicine, Solna, Stockholm, Sweden*; *[2]Stockholm Health Services, Academic Specialist Center, Stockholm, Sweden*; *[3]Karolinska Institutet, Institute of Environmental Medicine, Stockholm, Sweden*; *[4]Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, Sweden*; *[5]Karolinska Institutet, Center for Occupational and Environmental Medicine, Stockholm, Sweden*; *[6]Karolinska Institutet, Department of Medicine, Solna, Division of Clinical Epidemiology, Stockholm, Sweden*; *[7]Karolinska University hospital, Unit of Rheumatology, Stockholm, Sweden*; *[8]School of Health Sciences, University of Iceland, Faculty of Medicine, Reykjavik, Iceland*; *[9]Umeå Univeristy, Department for Public Health and Clinical Medicine/Rheumatology, Umeå, Sweden*

Background: The role of psychosocial conditions on the disease course of rheumatoid arthritis (RA) is getting increased attention. In our previous study, low social support and low decision latitude at work were associated with known modifiable risk factors for RA disease development, such as smoking and low educational level (1). Further, smoking and low educational level have previously been shown to be associated with worse RA disease outcome (2-4). Whether psychosocial characteristics are related to RA disease outcome needs further investigation.

Objectives: To investigate the relationship between two psychosocial characteristics: low social support and low decision latitude at work, and achievement of remission in patients with RA.

Methods: At inclusion in the Swedish EIRA study, incident RA cases (N=3724) and controls (N=5937), matched for age, sex and residential area, responded to a questionnaire including questions on social support and decision latitude at work. The answers were recoded into separate scores and the distribution of the scores among controls were used to define the exposures. Low social support and low decision latitude at work, respectively, among patients, were set as the level corresponding to the lowest quartile among controls, and were compared with scores corresponding to the remaining three quartiles.

The outcome, disease activity score 28-joint count (DAS28) remission, defined as DAS28<2.6, was captured through linkage with the Swedish Rheumatology Quality Register (SRQ) with data available from diagnosis for 2693 out of 3700 cases for social support and for 847 out of 1248 cases for decision latitude at work.

Logistic regression was used to evaluate the association between low social support or low decision latitude at work, respectively, and the chance of remission at the time-points 3 months, 12 months and 60 months after inclusion. All results were adjusted for age, sex and residential area and the fully adjusted models were also adjusted for smoking, obesity, physical activity and educational level.

Results: Low social support (n=655) was associated with a reduced chance for remission at all three time points in the model adjusted for age, sex and residential area; OR 3 months 0.77 (95% CI 0.61-0.97), OR 12 months 0.78 (95% CI 0.64-0.95) OR 60 months 0.77 (95% CI 0.59-0.99). This association was diminished after further adjustment. After stratifying for sex, this association was enhanced in women but inverse among men (Figure 1).

No association between low decision latitude at work (n=166) and chance for remission was observed neither in the analyses stratified for matching variables, nor in the full model. This result was only marginally changed after stratifying for sex (Figure 1).

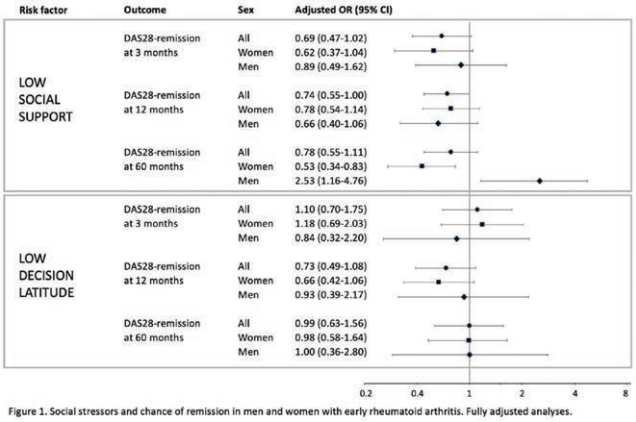

Figure 1. Social stressors and chance of remission in men and women with early rheumatoid arthritis. Fully adjusted analyses.

Figure 1. Odds ratios for assiciation between social stressors and DAS 28 remission

Conclusion: Low social support was associated with lower chance of remission in early RA, but the association was not independent of other risk factors for worse outcome (smoking, physical activity, obesity and low educational level). The interrelationship between social stressors and previously known risk factors for worse outcome highlights the importance of supportive actions at many levels to increase the possibility for the individual to make healthy decisions.

POS0485 TRAJECTORY CLUSTERS OF RADIOGRAPHIC PROGRESSION IN RHEUMATOID ARTHRITIS PATIENTS: ASSOCIATIONS WITH CLINICAL VARIABLES

S. Blüml[1], A. Platzer[1], F. Alasti[1], D. Aletaha[1], J. S. Smolen[1], H. Radner[1].
[1]*Medical University Vienna, Rheumatology, Wien, Austria*

Background: Joint damage is a defining feature of rheumatoid arthritis (RA), a major driver of functional impairment and of reduction of quality of life. Many factors are associated with damage accrual however, the course of structural damage of individual patients over time and factors associated with such trajectories have not been investigated.
Objectives: Identification of trajectories of radiographic damage in RA by clustering patients according to the shape of their curve of Sharp-van der Heijde scores (SHS) over time. Developing models to predict their progression cluster from baseline characteristics.
Methods: Patient-level data over a two-year period from 5 large randomized controlled trials on TNF-inhibitors in RA (ERA, PREMIER, TEMPO, GO-BEFORE and GO-FORWARD) were used. SHSs were clustered in a shape-respecting manner to identify distinct clusters of radiographic progression. Characteristics of patients within different progression clusters were compared at baseline and over time. Logistic regression models were developed to predict trajectory of radiographic progression using information at baseline.
Results: In total 1887 patients with 7738 x-rays were used for cluster analyses. We identified 4 distinct clusters with characteristic shapes of radiographic progression: one with a stable SHS over the whole 2-year period (C0/lowChange; 86%); one with relentless progression (C1/rise; 5.8%); one with decreasing SHS (C2/improvement; 6.9%); and one going up and down (C3/bothWays; 1.4%) of the SHS. Robustness of clusters and shapes of progression over time were confirmed using different clustering methods and cut-offs to define radiographic progression (Figure 1). Regression models identified disease duration, baseline CRP and SHS and treatment status as predictors for cluster assignment (Table 1), showing good performance (PCC 87.5%; Nagelkerke r^2 0.36*)*.
Conclusion: We were able to identify 4 different clusters of radiographic progression over time in patients with RA, most remarkably one with relentless progression and another one with amelioration of joint damage over time, suggesting the existence of distinct patterns of joint damage accrual in RA. The nature of the identified trajectories is mostly explained by inflammatory load, disease duration and especially type of treatment.

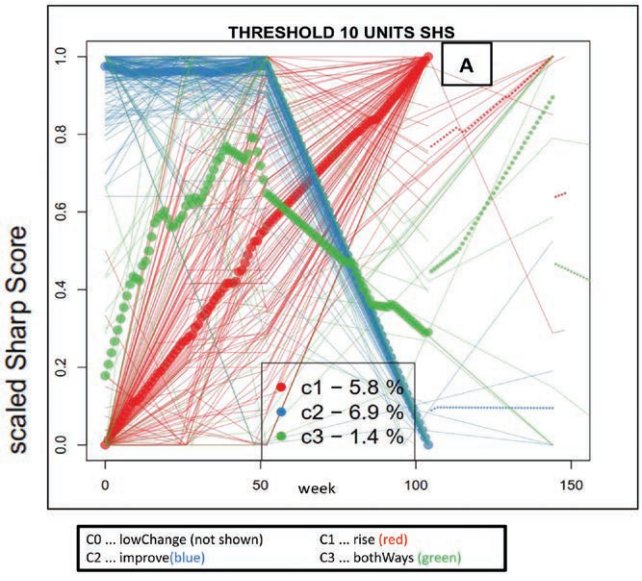

Figure 1. Representations of the major three clusters of radiologic progression curves.*(A) shows the curves of all patients with a SHS-range >= 10, colored by their cluster. Values between visits were linearly interpolated. Big dotted line is the median of particular cluster, thinner lines represent single patient values. Cluster C0 /lowChange are patients without enough variation in SHS to be seen as a curve, therefor not shown in the diagrams.*

POS0486 FACTORS ASSOCIATED WITH CHRONOTROPIC RESPONSE IN PEOPLE WITH RHEUMATOID ARTHRITIS

A. Osailan[1]on behalf of Physical activity in Rheumatoid arthritis research team and Research department in Dudley Hospital. [1]*Prince Sattam Bin Abdulaziz University, Health and Rehabilitation Sciences, Alkharj, Saudi Arabia*

Background: People with rheumatoid arthritis (RA) are at high risk for cardiovascular diseases (CVD) and CVD mortality. Reduced Chronotropic response (CR), which produces exercise intolerance, is known as a contributing factor to CVD and mortality. Studies have shown that people with RA have reduced CR. However, knowledge about the factors associated with CR in people with RA is limited.
Objectives: To explore the factors associated with CR including CVD risk factors, inflammatory markers and cardiorespiratory fitness (VO_2 peak).
Methods: 106 people with RA completed a treadmill exercise tolerance test while heart rate (HR) was monitored via 12 leads ECG. CR was defined as the percentage of [(achieved peak HR minus resting HR) divided by (age-predicted maximum HR minus resting HR)]. Serological CVD risk factors and inflammatory markers including lipids profile, markers of insulin resistance and sensitivity (HOMA, QUICKi), high sensitivity C-reactive protein (hsCRP), erythrocyte sedimentation rate (ESR), fibrinogen and white blood cells (WBC) were examined via a fasted blood sample. VO_2 peak was assessed via breath-by-breath gas analysis.
Results: 34% had reduced CR based on the cut-off value (≤ 80%) and the average CR was 86.2 ± 21%. Body mass index (r=-0.33, p=.001), HOMA (r=-0.26, p=.009), hsCRP (r=-0.23, p=.02), ESR (r=-0.21, p=.04), fibrinogen (r=-0.2, p=.05), WBC (r=-0.21, p=.04) were inversely associated with CR, whereas, high density lipoprotein (HDL) (r=0.43, p<.001), QUICKi (r=0.31, p=.002), and VO_2 peak (r=0.4, p<.001) were positively associated with CR. When all the variables were entered into a stepwise linear regression, HDL (p<.001) and VO_2 peak (p=.009) were independently associated with CR.
Conclusion: The current findings suggest that CR in RA was associated with many CVD risk factors, inflammatory markers, and cardiorespiratory fitness. Among all the varibales, HDL and cardiorespiratory fitness were moderately and independently associated with CR. Future studies should investigate the effect of improving these associated variables on CR in people with RA via exercise training programes.

POS0487 ASSOCIATION OF RHEUMATOID ARTHRITIS WITH MORTALITY IN A COHORT OF CHRONIC KIDNEY DISEASE PATIENTS

M. Ezeanuna[1], D. Prince[2], S. A. Alexander[3], J. S. Richards[4], G. Kerr[5], D. Jala[6], N. Bansal[7], J. Liew[8], N. Singh[9]. *[1]Skagit Regional Health, Internal Medicine, Mount Vernon, Washington, United States of America*; *[2]University of Washington, Kidney Research Institute, Seattle, WA, United States of America*; *[3]University of Connecticut, Internal Medicine, Hartford, CT, United States of America*; *[4]UPMC Presbyterian Shadyside, Rheumatology, Pittsburgh, PA, United States of America*; *[5] Howard University Hospital, Rheumatology, Washington, DC, United States of America*; *[6]University of Iowa, Department of Medicine- Nephrology, Iowa, United States of America*; *[7]Kidney research institute, University of Washington, Nephrology, Seattle, WA, United States of America*; *[8]University of Washington, Division of Rheumatology, Seattle, United States of America*; *[9]University of Washington, Division of Rheumatology, Seattle, WA, United States of America*

Background: Rheumatoid Arthritis (RA) is associated with an increased risk of cardiovascular disease. RA is also associated with increased risk of chronic kidney disease (CKD) (1, 2), which is a known cardiovascular risk factor (3). We hypothesized that RA (compared with no RA) would be associated with increased risk of mortality among a cohort of patients with CKD.
Objectives: To determine the risk of mortality in RA patients with CKD.
Methods: This study was conducted using participants from the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) prospective Chronic Renal Insufficiency Cohort (CRIC) study. Approximately 3600 participants were enrolled from seven US clinical centers. Patients aged 21 – 74 years with mild to moderate CKD were eligible for enrollment. The primary outcome of interest was all-cause mortality. Secondary outcomes of interest included: kidney event defined as end stage renal disease (ESRD) or 50% decline in estimated glomerular filtration rate (eGFR), myocardial infarction (MI), cerebrovascular accident (CVA), heart failure and a composite cardiovascular endpoint. The association of RA mortality over time was examined using Cox multivariate proportional hazards regression, adjusting for potential covariates (age, sex, race/ethnicity, BMI, current smoker, education).
Results: The study cohort included 492 participants with self-reported RA with a mean follow up of 9.5 years. Compared to the non-RA group, RA patients tended to be older, female, Black. Hypertension, diabetes, use of prednisone was more prevalent among the RA cohort. The unadjusted hazards ratio (HR) for mortality based on RA status was 1.45 (1.26, 1.67) but this association was attenuated after adjusting for the confounding factors [aHR 1.09 (0.94, 1.27)] (Table 1). Participants with RA had a significantly higher risk for heart failure than those without RA [aHR 1.17 (1.02, 1.34)]. We did not observe a statistically significant association between RA status and other secondary outcomes.

Table 1. Estimated hazard ratios (HR) for various outcomes from Cox proportional hazards regression for RA status

	Unadjusted	Model 1	Model 2
	HR (95% CI)	HR (95% CI)	HR (95% CI)
Death	1.45 (1.26, 1.67)	1.09 (0.94, 1.27)	1.13 (0.97, 1.32)
MI or death	1.43 (1.25, 1.63)	1.09 (0.95, 1.26)	1.15 (0.99, 1.33)
CVA or death	1.42 (1.24, 1.63)	1.07 (0.92, 1.24)	1.11 (0.95, 1.29)
CHF or death	1.54 (1.35, 1.75)	**1.17 (1.02, 1.34)**	**1.22 (1.06, 1.40)**

Kidney event	1.09 (0.94, 1.27)	0.91 (0.78, 1.07)	1.01 (0.85, 1.20)

Model 1 adjusted for: age, sex, race/ethnicity, BMI, current smoker, educationModel 2 adjusted for: model 1 + cardiovascular risk factors (urine albumin creatinine ratio, systolic blood pressure, estimated glomerular filtration rate)

Conclusion: RA was not associated with higher mortality among participants with CKD. However, RA was associated with higher rates of heart failure. Further studies evaluating the mechanisms behind this association are needed.

POS0488 THE IMPACT OF ANTINUCLEAR ANTIBODIES INDUCED BY ANTI-TUMOUR NECROSIS FACTOR ALPHA AGENTS ON THE LONG-TERM TREATMENT OUTCOMES IN RHEUMATOID ARTHRITIS PATIENTS

D. Santos Oliveira[1,2], A. Martins[1], F. R. Martins[3], M. Rato[1], F. Oliveira Pinheiro[1], D. Fonseca[4], S. Garcia[1], B. M. Fernandes[1], C. Vaz[1,2,5], M. Bernardes[1,5], L. Costa[1]. *[1]Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal*; *[2]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; *[3]Centro Hospitalar Universitário do Algarve, Rheumatology Department, Faro, Portugal*; *[4]Centro Hospitalar Vila Nova de Gaia / Espinho, Rheumatology Department, Vila Nova de Gaia, Portugal*; *[5]Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal*

Background: The seroconversion of antinuclear antibodies (ANA) induced by anti-tumour necrosis factor alpha (anti-TNF-α) therapy remains a matter of concern in various inflammatory conditions namely rheumatoid arthritis. However, evidence is still scarce regarding the impact of these autoantibodies on the clinical response to treatment in these patients.

Objectives: This study aimed to explore the impact of ANA induced by anti-TNF-α therapy on the outcomes of treatment in patients with rheumatoid arthritis over two years of follow-up.

Methods: An observational retrospective cohort study was conducted with two years of follow-up. Patients diagnosed with rheumatoid arthritis, according to the American College of Rheumatology (ACR) criteria, and registered on the Rheumatic Diseases Portuguese Register (Reuma.pt) who started their first anti-TNFα agent as first biologic between 2003 and 2018 were included. Patients with positive ANA (titer ≥100) and/or positive anti-double stranded DNA (anti-dsDNA) antibodies and/or with a diagnosis of SLE at their first visit were excluded. Demographic, clinical and laboratory data were obtained by consulting Reuma.pt. Disease Activity Score for 28 joints (DAS28), DAS28 delta, Health Assessment Questionnaire (HAQ), HAQ delta were assessed at baseline, 6, 12, 18 and 24 months. Clinical response was evaluated by EULAR criteria and three response categories were defined: good, mild and no response. The rate of switch of biological treatment was assessed over 24 months. To examine the differences between groups with and without ANA seroconversion independent samples t test for normally distributed continuous data, Mann-Whitney U-tests for non-normally distributed continuous data and Chi-square tests for categorical data were used. Logistic regression models were used to assess the effects of ANA seroconversion on clinical response to treatment

over 6, 12, 18 and 24 months.

Results: A total of 185 patients (mean age of 49.3±10.9 years old; 85.4% female) with a median follow-up of 7 [4-14] years were included. We found an ANA seroconversion rate (titer ≥100) of 77.3% (n=143) with median time of 36 [15-72.3] months. There were no differences among groups regarding age, gender, disease duration, be seropositivity or not (for rheumatoid factor and/or anti-citrullinated protein antibodies) and have an erosive disease or not. DAS28 delta was significantly different (p=0.035) between group with positive ANA (2.01±1.29) and negative ANA (1.15±1.51) at 6 months. DAS28 was significantly different (p=0.014) between group with positive ANA (5.06±3.39) and negative ANA (3.99±1.43) at 12 months. No statistically significant differences were found in the DAS28, DAS28 delta, HAQ, HAQ delta at 18 and 24 months and in the EULAR response at any time. Switch rate was significantly different between patients with ANA seroconversion (median 1[0-1]) versus absence of seroconversion (median 0[0-1]), p=0.025. In the regression model ANA seroconversion did not predict switch rate and EULAR response over time.
Conclusion: This study showed that the majority of patients with rheumatoid arthritis treated with an anti-TNF-α agent developed ANA and that their presence may be associated with worse clinical results (DAS28) at 6 and 12 months. In fact, previous research suggested that a decrease in anti-TNF-α drug concentration due to the production of autoantibodies may lead to worse outcomes of treatment. Moreover, our data demonstrated that patients with ANA seroconversion

had a higher switch rate. Despite these results, there are no differences in the EULAR response between the two groups and ANA seroconversion did not predict this response over time. Therefore, ANA induced by anti-TNF-α agents should be monitored in patients with rheumatoid arthritis and its impact on treatment must be considered. Further research is needed to explore these results through large-scale prospective studies.

POS0489 DOES TIME TO REMISSION DIFFER DEPENDING ON ROUTE OF ADMINISTRATION OF METHOTREXATE IN AN EARLY ARTHRITIS TREAT TO TARGET (T2T) COHORT?

I. Ali[1]. [1]*Our Lady's Hospital Manorhamilton, Rheumatology, Manorhamilton, Ireland*

Background: Rheumatoid arthritis (RA) is a multisystem inflammatory disorder that affects the joints and other body tissues. Approximately 1% of the worldwide population is living with RA 1. Methotrexate is the first line DMARD used for treatment of RA 2.

Objectives: The aim of this study was to analyse MTX use in achieving remission in early arthritis patients and to compare the route of administration to see whether it affects the time interval to remission.

Methods: An observational, prospective study was performed on patients' data available from our Early Arthritis Cohort. Newly diagnosed patients with RA meeting the American College of Rheumatology (ACR) criteria were enrolled in T2T programme led by Advanced Nurse Practitioner (ANP) with consultant supervision. To assess their response to treatment, we used the Clinical Disease Activity Index (CDAI). SPSS was used to analyse the data.

Results: A total of 353 have completed the programme and of these, 341were commenced on MTX. 208 patients (61%) were female. The MTX starting dose was 15mg for 88.4% (305/341) of patients. The median time to first increment in MTX dose was 7 weeks and the figure 1 was identical for the second increment. Of the 238 patients who started oral MTX, 18.48% (44) discontinued. 21.4% (22) of the 103 who started on SC-MTX discontinued (The p-value for discontinuation was 0.538). P-value for likelihood of achieving remission based on oral versus SC MTX was 0.248 and the p-value for time to achieve remission was 0.671 for oral versus SC MTX groups, see figure 1 attached.

Conclusion: Patients in this cohort are being started promptly on an appropriate dose of MTX and are escalated in a timely manner in-line with guidelines. Analysis showed no statistically significant difference in terms of time to remission, likelihood of achieving remission or discontinuation of MTX between oral and SC-MTX groups.

POS0490 SERUM MATRIX METALOPROTINASE 3 AS A MARKER TO DISCRIMINATE SUBCLINICAL DISEASE ACTIVITY FROM ULTRASOUND DEFINED REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

F. Hamdy[1], A. F. Enein[2], N. Morad[1], S. Tharwat[2], A. M. Abd el-Khalek[3], E. E. Eltoraby[4]. [1]*Mansoura University, Rheumatology and Immunology Unit, Mansoura, Egypt*; [1]*Mansoura University, Rheumatology and Immunology Unit, Mansoura, Egypt*; [3]*Mansoura University, Dignostic Radiology, Mansoura, Egypt*; [1]*Mansoura University, Rheumatology and Immunology Unit, Mansoura, Egypt*

Background: Rheumatoid arthritis (RA) is a systemic disease which results in chronic inflammation that primarily involves synovial joints resulting in progressive joint destruction [1]. Detection of subclinical disease activity is important as radiographic progression was observed during remission course in some cases [2]. Ultrasound can detect subclinical activity and synovial inflammation, which predict relapse and radiographic progression [3].

Matrix Metaloprotinase 3 (MMP-3) is an enzyme, which is involved in joint destruction in RA patients. MMP-3 was found to correlate with disease activity, joint erosions, radiographic progression, drug responsiveness and disease outcome in patients with active RA [4]. However no data about its role in detection of subclinical activity in patients with clinical remission.

Objectives: To assess the role of MMP-3 as a marker to discriminate subclinical activity from ultrasound remission in rheumatoid arthritis patients with remission.

Methods: This study was conducted on 45 RA patients fulfilling remission or low disease activity criteria according to DAS 28 AND 45 healthy controls. Ultrasound evaluation was done for all patients using modified German US7 score. According to US7 score patients were classified into two groups: group with sonographic remission in which GS is 0±1 and the other group with subclinical disease activity with higher GS. Both groups underwent clinical and laboratory evaluation including MMP-3.

Results: Sonographic remission was achieved in 44% of patients (20 patients). There was no statistically significant difference as regard age, gender, smoking, disease duration, morning stiffness duration, CDAI, treatment and laboratory data apart from hemoglobin level between patients with subclinical disease activity and patients with remission. However, there is statistically significant difference between the two groups as regard joint deformity, extra articular manifestations, DAS 28, SDAI and hemoglobin level.
There was statistically significant difference in serum MMP-3 between RA patients and healthy control group. Serum MMP-3 was higher in RA patients with subclinical activity than patients with sonographic remission but the difference was not statistically significant (figure 1). Serum MMP-3 was positively correlated with ESR and synovitis score.

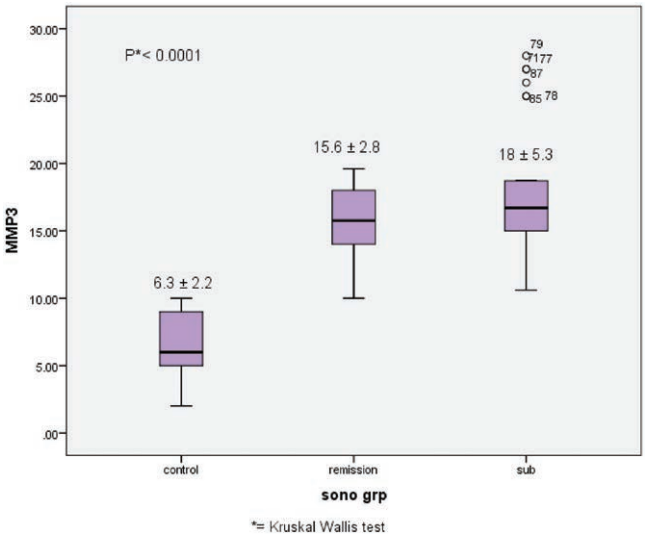

Figure 1.

Conclusion: Serum MMP-3 has correlation with US synovitis score. However, serum MMP-3 was not able to differentiate patients with sonographic remission from patients with subclinical disease activity. Ultrasound is still the gold standard for detection of subclinical disease activity.

LEFT VENTRICULAR GEOMETRIC ABNORMALITIES ASSOCIATED WITH HIGHER TITERS OF RHEUMATOID FACTOR AND ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODIES IN RHEUMATOID ARTHRITIS PATIENTS

N. Guajardo-Jauregui[1], J. R. Azpiri-López[2], D. Á. Galarza-Delgado[1], I. J. Colunga-Pedraza[1], S. Lugo-Perez[2], A. B. Rodriguez-Romero[1], A. Cárdenas[1], O. A. Cepeda-Ayala[2], H. Azpiri-Diaz[2]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*; *[2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*

Background: Rheumatoid arthritis (RA) patients have a higher risk of developing left ventricular (LV) geometric abnormalities which can result in the development of heart failure and cardiac death (1). High titers of rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP) antibodies are associated with a worse cardiovascular (CV) prognosis in RA patients (2).
Objectives: The aim of this study was to assess the association between RF and anti-CCP antibody titers, and the LV geometric abnormalities detected by a transthoracic echocardiogram.
Methods: This was a cross-sectional, observational, and comparative study. Patients aged 40-75 years who fulfilled the 2010 ACR/EULAR classification criteria for RA underwent a transthoracic echocardiogram. Patients with RA and an alteration of LV geometry were matched to RA patients with normal LV geometry, by age, gender, comorbidities, and disease characteristics to eliminate confounders. LV geometry was evaluated with LV mass index and relative wall thickness. A blood sample was taken to measure RF and anti-CCP antibody titers. Distribution was evaluated with the Kolmogorov-Smirnov test. Comparisons were done with Chi square test for qualitative variables and Student's t test and Mann-Whitney's U test for quantitative variables. A p-value <0.05 was considered statistically significant.
Results: A total of 82 RA patients were included in this study, 41 patients with altered LV geometry and 41 patients with normal LV geometry. Of the 41 patients with LV geometric abnormalities, 37 (90.2%) presented LV concentric remodeling and 4 (9.8%) presented LV concentric hypertrophy. We found no significant differences in the demographic and clinical characteristics between both groups (Table 1). Patients with altered LV geometry showed higher titers of IgA-RF (102.11 U/ml vs 21.70 U/ml, p=0.011) and anti-CCP antibodies (193.04 U/ml vs 18.29 U/ml, p=0.005) (Figure 1).

Table 1. Demographic and disease characteristics.

	RA patients with altered LV geometry (n=41)	RA patients with normal LV geometry (n=41)	p
Age years, mean ± SD	53.12 ± 7.62	52.34 ± 7.74	NS
Women, n (%)	39 (95.1)	39 (95.1)	NS
T2DM, n (%)	7 (17.1)	4 (9.8)	NS
HTN, n (%)	13 (31.7)	10 (24.4)	NS
Dyslipidemia, n (%)	9 (22.0)	11 (26.8)	NS
Active smoking, n (%)	4 (9.8)	3 (7.3)	NS
Obesity, n (%)	11 (26.8)	14 (34.1)	NS
BMI kg/m^2, median (p25-p75)	27.95 (25.33-31.45)	28.42 (25.84-32.00)	NS
Disease duration years, median (p25-p75)	10.37 (2.72-17.80)	6.40 (3.43-13.29)	NS
CDAI, median (p25-p75)	14.00 (2.00-22.00)	10.00 (3.00-16.50)	NS
DAS28-CRP, mean ± SD	3.52 ± 1.42	3.09 ± 1.11	NS
Treatment			
MTX, n (%)	33 (80.5)	34 (82.9)	NS
Glucocorticoids, n (%)	25 (61.0)	23 (56.1)	NS
Antihypertensive, n (%)	13 (31.7)	8 (19.5)	NS
Statins, n (%)	6 (14.6)	4 (9.8)	NS

RA, rheumatoid arthritis; LV, left ventricular; NS, not significant; T2DM, type 2 diabetes mellitus; HTN, hypertension; BMI, body mass index; CDAI, clinical disease activity index; DAS28, disease activity score using 28 joints; CPR, C-reactive protein; MTX, methotrexate.

Conclusion: RA patients with altered LV geometry had higher titers of IgA-RF and anti-CCP antibodies. This suggests an association between antibody titers and CV prognosis in RA patients. Rheumatologists should take these data into account when evaluating CV risk in RA patients, assessing the possibility of performing an echocardiogram for early detection of CV abnormalities and an opportune treatment in this group of patients.

POS0492

A MOLECULAR SIGNATURE RESPONSE CLASSIFIER PREDICTS THE LIKELIHOOD OF EULAR NON-RESPONSE TO TNF INHIBITOR THERAPIES IN RA: RESULTS FROM A RETROSPECTIVE COHORT ANALYSIS

L. Zhang[1], C. van der Tog[2], A. den Broeder[2], T. Mellors[1], E. Connolly-Strong[1], J. Withers[1], A. Jones[1], V. Akmaev[1]. *[1]Scipher Medicine Corporation, Science and Technology, Waltham, United States of America*; *[2] Sint Maartenskliniek, Department of Rheumatology, Ubbergen, Netherlands*

Background: Following RA treatment recommendations, most people with rheumatoid arthritis (RA) begin targeted therapy with TNF inhibitors (TNFi), even though inadequate response to TNFi therapies is widespread. Treatment changes from one medication to the next are currently fueled by disease-activity measures and eventually result in disease control for most patients; however, this "trial-and-error" approach wastes precious time on ineffective treatments. A delay in reaching treat-to-target goals has a negative effect on patient burden and, possibly, disease progression.[1] Useful predictors for TNFi response have been challenging to identify but a specific molecular signature response classifier (MSRC) test was shown to be predictive for inadequate response to TNFi therapies.[2] The impact of such identification has the potential to result in improved patient outcomes, but further validation would be welcome, especially for response criteria other than ACR50, and in a stringent treat-to-target setting with lower baseline disease activity.
Objectives: To validate the predictive value of the MSRC test in identifying those patients who do not meet EULAR good response criteria after 6 months of TNFi treatment.
Methods: Data from a prospective cohort study conducted in the Sint Maartenskliniek (Nijmegen, the Netherlands) of RA patients who started adalimumab or etanercept TNFi as their first biologic were included.[3] Baseline RNA samples and clinical assessments were used to identify patients who had a molecular signature[1] of non-response to TNFi therapy. Outcomes were calculated at six months using DAS28-CRP-based EULAR good response, and high and low confidence responders and non-responders were identified using Monte Carlo simulation with 2,000 repeats and 70% precision cut off. Outcome measurements were blinded for test results. Treatment switch before 6 months was imputed as non-response. Odds ratios and area under the ROC curve (AUC) assessments were used to evaluate the ability of the MSRC test to predict inadequate response at 6 months against EULAR good response criteria.
Results: A total of 68 out of 88 RA patients were identified to have a high-confidence response status and were included in analyses (Table 1). EULAR good response was observed in 45.5% (31/68) of patients. Patients were stratified according to detection of a molecular signature of non-response with an AUC of 0.61. The odds that a patient with the molecular signature of non-response at baseline failed to achieve a EULAR good response at 6 months was four times greater than that of a patient lacking the molecular signature (odds ratio 4.0, 95% confidence interval 1.2-13.3).

Table 1. Patient demographics

Characteristic	RA patients (N = 68)
Age, median (SD)	57 (11)
Female, n (%)	43 (63.2)
CCP positive, n (%)	34 (50.0)
RF positive, n (%)	38 (55.9)
Prescribed adalimumab at baseline, n (%)	11 (16.2)
Prescribed etanercept at baseline, n (%)	57 (83.8)

Conclusion: In this validation study, the molecular signature of non-response identified patients who did not fulfill the EULAR good response criteria to TNFi therapies. The patient selection process for this study had limitations; additional analysis in an alternative cohort would further verify the performance of the MSRC test. Nevertheless, the test, previously validated for ACR50, now has been validated using EULAR good response in a treat-to-target setting.

Background: Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease characterized by cartilage and bone destruction, which can lead to joint dysfunction and disability. Antibodies' role as biomarkers in RA has been recently increasing: Anti-citrullinated protein antibodies (ACPAs) are the most specific one (60–70% of cases); whereas rheumatoid factor (RF) is seen in nearly 70% of cases, however, it is less specific than ACPA for RA diagnosis[i]. ACPA/RF positivity is related to a more severe phenotype and a rapid progression to clinically apparent RA[ii]. Other biomarkers are Antinuclear Antibodies (ANAs), which have been related to a worse response to bDMARD treatment[iii].

iiLingampalli N, Sokolove J, Lahey LJ, et al. Combination of anti-citrullinated protein antibodies and rheumatoid factor is associated with increased systemic inflammatory mediators and more rapid progression from preclinical to clinical rheumatoid arthritis. Clin Immunol. 2018;195:119-126.

iiiIshikawa Y, Hashimoto M, Ito H, Tanaka M, Yukawa N, Fujii T, et al. Anti-nuclear antibody development is associated with poor treatment response to biological disease-modifying anti-rheumatic drugs in patients with rheumatoid arthritis. Semin Arthritis Rheum. 2019;49(2):204–10.

Objectives: Our aim was to compare in terms of mean differences the disease activity according to the presence of RF, ACPA, and ANA in an outpatient clinic-based cohort of Colombian RA patients.

Methods: We conducted a retrospective cohort study with clinical-epidemiological data obtained from May 2013 to Feb. 2020 of patients with RA diagnosis based on the 2010 ACR/EULAR classification criteria. The patients were stratified into eight subgroups according to their autoantibody status. Disease activity, assessed by the DAS28-ESR, was recorded at baseline and after 3, ≈ 12, ≈ 24, and ≈ 36 (+/- 3) months. Mean DAS28-ESR differences were calculated by applying the Wilcoxon non-parametric rank test for two independent samples.

Results: Data of 384 patients who all completed 36 months of follow-up, from an ongoing cohort of ≈1100 patients, were included in the analysis. On our primarily female (n=294, 76,8%) population, RF$^+$ / ACPA$^+$ / ANA$^+$ subgroup was the most prevalent (n=183; 47,8%); interestingly, it was the one with the highest disease activity at baseline. After three months, all showed disease activity reduction; however, when completing follow-up, triple-positive, triple-negative and ANA-positive patients did not reach remission. Statistically significant mean differences were displayed when comparing overall and baseline mean DAS28-ESR scores for ANA$^+$ vs ANA$^-$ patients, as shown in table 1.

Table 1. Disease activity mean differences when comparing ANA$^+$ vs ANA$^-$ patients

	ANA$^+$ (n = 218)	ANA$^-$ (n = 165)	Mean difference	p value
Baseline	**4,05**	**3,62**	**0,43**	**0,014**
3	3,32	3,14	0,18	0,396
12	3,13	2,89	0,24	0,059
24	2,80	2,68	0,11	0,563
36	2,80	2,58	0,22	0,098
Overall	**3,22**	**2,98**	**0,24**	**0,002**

Conclusion: In our study population, triple-positive and ACPA$^+$/ANA$^+$ patients showed higher disease activity at baseline and on average during the follow-up period; furthermore, ANA positivity was shown to be conditional on a significant difference for higher disease activity. RF and ACPA positive have long since been described as determinants for disease activity; nonetheless, our research provides insights for the consideration of ANA titers as a novel addition that enables the preamble of *triple-positivity* as something to be acknowledged. Caution must be applied when interpreting these results, understanding the need for this matter to be subject of future research with greater sample size, and taking into account other potentially confounder variables.

POS0494 AN INVESTIGATION OF JOINT INFLAMMATION DEFINED BY COMPREHENSIVE ULTRASOUND ASSESSMENT AND PAIN SENSITISATION IN PATIENTS WITH ACTIVE RA

K. Chaabo[1], E. Chan[2], T. Garrood[2], Z. Rutter-Locher[2], A. Vincent[2], J. Galloway[3,4], S. Norton[5], B. Kirkham[2]. *[1]St George's Hospital, Rheumatology Department, London, United Kingdom*; *[2]Guy's Hospital, Rheumatology Department, London, United Kingdom*; *[3]King's College Hospital, Rheumatology Department, London, United Kingdom*; *[4]King's College London, Rheumatology, London, United Kingdom*; *[5]King's College London, Psychology and Inflammation Biology, London, United Kingdom*

Background: Treat-to-target strategies have improved outcomes in patients with RA. Targets based on clinical assessments of tender (TJC) and swollen joints (SJC) were developed when most patients had active inflammatory disease. It is now recognised some patients have pain sensitisation often termed fibromyalgia (FM), making clinical assessment of inflammatory disease more complex. An indicator of pain sensitisation is the difference between TJC and SJC, an observation we described in a pilot study (1).

Objectives: To study patients with RA to describe the relationships between enhanced clinical and patient-reported outcome measures (PROMS) and active inflammatory joint disease detected by comprehensive PDUS.
Methods: 158 sequential patients with RA with a DAS28ESR score >¬3.2 were enrolled from GSTT Rheumatology after informed consent. They were assessed by a rheumatologist for 66SJC, 68TJC, fibromyalgia tender points & physician global. Recorded PROMS were: patient global, widespread pain index (WPI), symptom severity score (somatic & fatigue), FACIT fatigue, HAQ, EQ5D QoL, GAD7, PHQ9 and PHQ15. All patients had a 44 joint US scored for PD and grey scale by the EULAR scale blind to all patient data. Data were recorded on MedSciNet and statistical analysis used STATA.
Results: Patients meeting the ACR 2010 criteria for FM2(n=72) vs those that did not(n=86) had similar demographics. SJC and US doppler scores were higher in the non-FM group, whereas rheumatoid factor, DAS28 and PROMs were higher in the FM group. Analysis of group differences using multinomial logistic regression and subsequent regularised (lasso) logistic regression, showed the FM group related to higher 28TJC, FACIT-F and PHQ15, with the non-FM group related to higher 28SJC, logESR, and lower Differences in 28S/TJC, Physician Global and FACIT-F. Patients were divided into four groups based on presence or absence of at least one PDUS+ joint and FM criteria; -FM-PD, -FM+PD, +FM-PD and +FM+PD, data summarised Table 1. The -FM-PD and -FM+PD groups related to Physician Global and negatively related to FACIT-F, Difference in 28S/TJC, and PHQ15 (-FM-PD). The +FM-PD group related positively to FACIT-F, Difference 28S/TJC, PHQ15, and negatively to Physician Global with +FM+PD related to PHQ9, FACIT-F and DAS28ESR.

TABLE 1. -FM -PD -FM +PD +FM -PD +FM +PD p-value

Female	34 (79%)	33 (77%)	35 (83%)	22 (73%)	0.77
Total power doppler score	0.0 (0.0-1.0)	16.0 (10.0-25.0)	0.0 (0.0-0.0)	9.0 (8.0-20.0)	<0.001
Total gray scale score	40.0(34.0-48.0)	57.5(45.0-82.0)	34.5(20.0-43.0)	60.0(46.0-84.0)	<0.001
Total Swollen JC	3.0 (1.0-5.0)	6.0 (3.0-9.0)	2.0 (0.0-5.0)	5.5 (2.0-10.5)	<0.001
Total Tender	5.5 (3.0-12.0)	8.0 (4.0-11.0)	13.0 (8.0-20.0)	15.0 (8.0-20.0)	<0.001
Tender-Swollen JC Difference	4.0 (0.0-8.0)	2.0 (0.0-4.0)	8.0 (4.0-18.0)	5.5 (2.5-13.5)	<0.001
ESR mm/hour	10.0 (8.0-16.0)	14.0 (10.0-30.0)	12.0 (7.0-23.0)	19.5 (11.5-42.5)	0.021
Pain VAS	50.0 (40.0-65.0)	50.0 (30.0-60.0)	60.0 (47.5-77.5)	67.5 (55.0-80.0)	<0.001
Patient VAS	50.0 (30.0-70.0)	40.0 (30.0-70.0)	60.0 (40.0-80.0)	65.0 (50.0-80.0)	0.006
Physician VAS	30.0 (20.0-50.0)	50.0 (40.0-60.0)	30.0 (20.0-40.0)	50.0 (32.5-70.0)	<0.001
DAS28 (ESR)	4.2 (3.7-4.9)	4.7 (4.1-5.2)	4.7 (3.9-5.8)	5.6 (4.9-6.6)	<0.001

Conclusion: These data using comprehensive US assessment to detect inflammatory joint disease, demonstrate that active inflammation defined as at least 1PDUS+ joint, may account for disease activity in slightly less than half of unselected patients with RA with a DAS28ESR score >3.2. This study shows how frequently pain sensitisation accounts for symptoms and signs in RA. We suggest in addition to central sensitisation, often called FM, another group identified here as -FM-PD, may have pain from joint damage or peripheral pain sensitisation of joints, likely due to different mechanisms than central pain sensitisation.

POS0495

LARGE JOINT DISEASE IN RHEUMATOID ARTHRITIS AND THE ROLE OF RHEUMATOID FACTOR. RESULTS FROM THE EARLY RHEUMATOID ARTHRITIS STUDY

S. S. Zhao[1], E. Nikiphorou[2], A. Young[3], P. Kiely[4,5]. [1]*University of Liverpool, Institute of Life Course and Medical Sciences, Liverpool, United Kingdom*; [2]*King's College London, Centre for Rheumatic Diseases, London, United Kingdom*; [3]*University of Hertfordshire, Center for Health Services and Clinical Research and Post Graduate Medicine, Hatfield, United Kingdom*; [4]*St George's, University of London, Institute of Medical and Biomedical Education, London, United Kingdom*; [5]*St George's University Hospitals NHS Foundation Trust, Rheumatology, London, United Kingdom*

Background: Rheumatoid arthritis (RA) is classically described as a symmetric small joint polyarthritis with additional involvement of large joints. There is a paucity of information concerning the time course of damage in large joints, such as shoulder, elbow, hip, knee and ankle, from early to established RA, or of the influence of Rheumatoid Factor (RF) status. There is a historic perception that patients who do not have RF follow a milder less destructive course, which might promote less aggressive treatment strategies in RF-negative patients. The historic nature of the Ealy Rheumatoid Arthritis Study (ERAS) provides a unique opportunity to study RA in the context of less aggressive treatment strategies.
Objectives: To examine the progression of large joint involvement from early to established RA in terms of range of movement (ROM) and time to joint surgery, according to the presence of RF.
Methods: ERAS was a multi-centre inception cohort of newly diagnosed RA patients (<2 years disease duration, csDMARD naive), recruited from 1985-2001 with yearly follow-up for up to 25 (median 10) years. First line treatment was csDMARD monotherapy with/without steroids, favouring sulphasalazine for the majority. Outcome data was recorded at baseline, at 12 months and then once yearly. Patients were deemed RF negative if all repeated assessments were negative. ROM of individual shoulder, elbow, wrist, hip, knee, ankle and hindfeet joints was collected at 3, 5, 9 and 12-15 years. The rate of progression from normal to any loss of ROM, from years 3 to 14 was modelled using GEE, adjusting for confounders. Radiographs of wrists taken at years 0, 1, 2, 3, 5, 7, 9 were scored according to the Larsen method. Change in the Larsen wrist damage score was modelled using GEE as a continuous variable, while the erosion score was dichotomised into present/absent. Surgical procedure data were obtained by linking to Hospital Episodes Statistics and the National Joint Registry. Time to joint surgery was analysed using multivariable Cox models.
Results: A total of 1458 patients from the ERAS cohort were included (66% female, mean age 55 years) and 74% were RF-positive. The prevalence of any loss of ROM, from year 3 through to 14 was highest in the wrist followed by ankle, knee, elbow and hip. The proportion of patients at year 9 with greater than 25% loss of ROM was: wrist 30%, ankle 12%, elbow 7%, knee 7% and hip 5%. Odds of loss of ROM increased over time in all joint regions, at around 7 to 13% per year from year 3 to 14. There was no significant difference between RF-positive and RF-negative patients (see Figure 1). Larsen erosion and damage scores at the wrists progressed in all patients; annual odds of developing any erosions were higher in RF-positives OR 1.28 (95%CI 1.24-1.32) than RF-negatives OR 1.17 (95%CI 1.09-1.26), p 0.013. Time to surgery was similar according to RF-status for the wrist and ankle, but RF-positive cases had a lower hazard of surgery at the elbow (HR 0.37, 0.15-0.90), hip (HR 0.69, 0.48-0.99) and after 10 years at the knee (HR 0.41, 0.25-0.68). Adjustment of the models for Lawrence assessed osteoarthritis of hand and feet radiographs did not influence these results.

Figure 1. Odds of progression to any loss of ROM (from no loss of ROM) per year in the overall population and stratified by RF status.

Conclusion: Large joints become progressively involved in RA, most frequently affecting the wrist followed by ankle, which is overlooked in some composite disease activity indices. We confirm a higher burden of erosions and damage at the wrists in RF-positive patients, but have not found RF-negative patients to have a better prognosis over time with respect to involvement of other large joints. In contrast RF-negative patients had more joint surgery at the elbow, hip, and knee after 10 years. There is no justification to adopt a less aggressive treatment strategy for RF-negative RA. High vigilance and treat-to-target approaches should be followed irrespective of RF status.

YOUNG VERSUS LATE-ONSET RHEUMATOID ARTHRITIS: A PROSPECTIVE 12 MONTH-FOLLOW-UP COHORT STUDY IN AN EARLY ARTHRITIS COHORT

A. R. Prata[1], M. Sousa[1], H. Assunção[1], L. Saraiva[1], L. Brites[1], M. Luis[1,2], P. Freitas[1], F. Campos Costa[1], T. Santiago[1,2], J. A. P. da Silva[1,2], C. Duarte[1,2]. *[1]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; *[2]University of Coimbra, Faculty of Medicine, Coimbra, Portugal*

Background: Rheumatoid Arthritis (RA) is a chronic inflammatory arthropathy that can present at any age. Data regarding differences in the clinical course and outcome in Late-Onset Rheumatoid Arthritis (LORA) comparing to Young-Onset RA (YORA) are conflicting. Some studies suggested that LORA may represent a more benign form of RA (1), while others have shown a poorer prognosis in these patients (2,3). Only a few publications have included patients with early disease (3).
Objectives: To compare demographic and clinical features between LORA and YORA patients, and clinical activity at baseline and after 12 months of initial therapy, in patients with early disease.
Methods: We conducted a prospective cohort study of 12 months of follow-up based on an early arthritis clinic. Consecutive patients with early RA – less than 12 months duration – fulfilling ACR/EULAR 2010 and/or ACR 1987 RA classification criteria, were included and classified in LORA (disease onset ≥60 years) and YORA groups. Variables were collected from patients' registries at first appointment after symptoms onset and after 12 months of treatment, according to a treat-to-target strategy. Independent t-test and chi-square test were performed to compare variables between groups.
Results: We included 72 patients (40 (55.6%) YORA; 32 (44.4%) LORA), mean age at diagnosis 44.9±1.78 and 72.5± 1.34 years, respectively. In LORA group, the symptoms duration at first observation was shorter (17.0±2.26 vs. 23.8±2.45 weeks; p=0.046) and rheumatoid factor (RF)/ anti-citrullinated protein antibodies (ACPA) positivity was lower (28.1% vs 65.0%; p= 0.002; 31.3% vs 72.5%; p<0.001). At baseline, LORA had higher mean number of tender joints (9.76±1.29 vs 6.50±0.67; p=0.021), erythrocyte sedimentation rate (ESR) (45.7±4.98 vs. 29.3±3.74; p=0.011), C-reactive protein (CRP) (4.63±0.91 vs 2.22±0.46; p=0.022) and disease activity using DAS28-3V (5.11±0.28 vs 4.42±0.19; p=0.046), CDAI (33.7±3.39 vs 23.6±2.18; p=0.015) and SDAI (37.4±3.43 vs 26.3±2.57; p=0.015). At the end of follow-up, there were no statistically significant differences between LORA and YORA groups regarding treatment, disease activity and patient-reported outcomes at 12 months (Table 1).

Table 1. Clinical variables assessment at 12 months of follow-up.

	EORA	YORA	*p*-value
Treatment, % users			
Corticosteroids	93.3	97.4	p= 0.576
Methotrexate	76.7	74.4	p=0.825
Hydroxychloroquine	43.3	46.2	p= 0.815
Sulfasalazine	10.0	15.4	p=0.722
Leflunomide	3.30	5.10	p=1.000
TNF blockers	3.30	5.10	p=0.717
DAS28-3V, mean (SD)	1.99±0.15	2.22±0.15	p=0.286
SDAI, mean (SD)	4.64±1.35	7.68±1.39	p=0.128
CDAI, mean (SD)	4.15±1.17	6.56±1.32	p=0.180
Swollen joints, mean (SD)	1.29±0.49	1.03±0.25	p=0.613
Tender joints, mean (SD)	0.32±0.13	1.28±0.53	p=0.084
ESR, mean (SD)	10.6±1.79	9.43±1.14	p=0.585
CRP, mean (SD)	0.44±0.09	0.50±0.15	p=0.730
PtGA, mean (SD)	21.8±5.90	29.2±6.11	p=0.387
PhGA, mean (SD)	10.6±3.26	13.1±3.11	p= 0.593
Pain intensity (VAS), mean (SD)	20.7±5.82	32.7±6.30	p=0.169
HAQ, mean (SD)	0.23±0.089	0.54±0.13	p=0.060

Legend: DMARD- disease-modifying anti-rheumatic drug; TNF- tumoral necrosis factor; SDAI-simplified disease activity score; CDAI- clinical disease activity score; PtGA/ PhGA – patient's/ physician's global assessment of general health; VAS- visual analogic scale; HAQ- health assessment questionnaire.

Conclusion: LORA patients presented with higher disease activity manifested by higher joint counts and laboratory inflammatory markers but lower RF and ACPA positivity proportion. Despite the more aggressive clinical presentation, the clinical and functional outcomes at 12 months were similar between LORA and YORA patients.

A RELIABILITY EXERCISE USING CONSENSUAL DEFINITIONS FOR THE ULTRASONOGRAPHY OF THE SHOULDER IN RHEUMATOID ARTHRITIS

K. Ben Abdelghani[1], S. Miladi[1], I. Mahmoud[2], H. Ajlani[3], E. Haddouche[4], A. Maghraoui[5], S. Slimani[6], A. Fazaa[1], A. Ben Tekaya[2], L. Abdelmoula[2], A. Laatar[1], R. Bahiri[7]. *[1]Université de Tunis El Manar, Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*; *[2]Université de Tunis El Manar, Chrles Nicolle Hospital, Rheumatology, Tunis, Tunisia*; *[3]El Yasminet Hospital, Ben Arous, Rheumatology, Tunis, Tunisia*; *[4]Department of Rheumatology, Ben Aknoun Specialized Hospital in the Musculoskeletal System, Rheumatology, Algers, Algeria*; *[5]Rheumatology Private Office, Rheumatology, Rabat, Morocco*; *[6]Atlas Clinic of Rheumatology, Rheumatology, Batna, Algeria*; *[7]El Ayachi Hospital, CHU Rabat-Salé, Rheumatology, Rabat, Morocco*

Background: Although numerous clinical tests for the diagnosis of painful shoulder are available, differentiating articular from periarticular lesions may be difficult in daily practice. Fortunately, the precise diagnosis of shoulder pain in RA benefited from a reliable imaging modality to detect its exact origin as ultrasonography (US).
Objectives: This study aimed to assess the intraobserver and interobserver reliabilities of the ultrasonographic findings for patients with established RA having shoulder pain in a patient-based exercise among maghrebian rheumatologists experts on US.
Methods: A total of 7 operators examined 10 patients in 2 rounds independently and blindly of each other.
Each patient underwent a US scanning of the painful shoulder in four sites based on US technical guidelines of the European society of musculoskeletal radiology: long head of Biceps (LHB), subscapularis recess, posterior recess and axillary recess. The presence of a subdeltoid or subcoracoid bursitis or the presence of transfixiant tear of the suprasupinatus were notified if present. Intra and inter-observer reliabilities were calculated.
Results: Intraobserver reliability was excellent for GS synovitis in subscapularis and posterior recesses (k=0.91 for both) and for subcoracoid bursitis (k=0.81). It was good in case of presence of a subdeltoid bursitis (k=0.79), transfixiant tear of the suprasupinatus (k=0.65), GS synovitis and effusion in LHB (k=0.67 and 0.6 respectively) and subdeltoid bursitis (k= 0.79). Interobserver reliability was good for PD for LHB signals searched longitudinally (k=0.78) and transversally (k=0.78). It was moderate for GS for LHB synovitis (k=0.55). Interobserver agreement was poor for effusion and GS synovitis for subscapularis, posterior and axillary recesses. It was very poor and/or absent for PD signals in these recesses.
Conclusion: US is a reliable imaging tool for shoulder in RA especially with regard to LHB effusion, GS and PD synovitis. Interobserver reliability of subscapularis, posterior and axillary recesses could be optimized by standardization of sites to assess.

POS0498

RELATIONSHIP BETWEEN IMPAIRED MELATONIN SECRETION AND DURATION, RADIOLOGICAL STAGE AND PHYSICAL ACTIVITY OF RHEUMATOID ARTHRITIS

Y. Sikalo[1], L. Zhuravlyova[1], M. Oliinyk[1], V. Fedorov[1]. *[1]Kharkiv National Medical University, Internal Medicine No.3 and Endocrinology, Kharkiv, Ukraine*

Background: There is a close relationship between the development of severe autoimmune diseases and disorders of the neuroendocrine immune regulation of the body [1]. The role of melatonin as the main mediator of neuroendocrino-immune interactions in rheumatoid arthritis (RA) remains poorly understood [2].
Objectives: The aim of the study was to determine the daily serum melatonin profile of RA patients with different duration of the disease, radiological stage and physical activity.
Methods: The daily serum melatonin profile of patients with active RA (n=105, mean age 49.8±12.6 years, 75.5% of women) was compared with that of healthy subjects from the general population (n=30). In addition, we investigated daily serum melatonin secretion in relation to duration of the disease, radiological progression and physical activity (HAQ). Patients were divided into 4 groups depending on the RA duration (mean 8.4±6.6 years): 1st group - up to 2 years (n=12), 2nd group - 2-5 years (n=37), 3rd group - 6-10 years (n=26), 4th group - more than 10 years (n=30). Depending on the radiological progression, patients were divided into stages: 1st stage (n=16), 2nd stage (n=64), 3d stage (n=25). Melatonin serum levels was determined by the enzyme immunoassay at 8 and 20 o`clock. For statistical analysis were used the Man - Whitney test and the Spearman rank correlation method.

Results: The melatonin serum levels in RA patients were in 2 and 3 times higher in the morning and evening time than those of healthy individuals in the control group (p=0.001). We noticed significant correlations between melatonin level and disease duration (r_S =-0.5, p <0.01). Significant differences in melatonin levels were revealed in RA patients in 1st and 3rd groups (p=0.049), in 1st and 4th groups (p = 0.012), in 2nd and 3rd groups (p=0.001), in 2nd and 4th groups (p=0.001). Also we determined significant differences in melatonin levels between 1st and 2nd radiological stages (p =0,001) of RA patients. However, melatonin levels were not related to physical activity (HAQ).
Conclusion: We found a close relationship between serum melatonin levels, duration of the disease and radiological progression in RA patients. The most significant changes in melatonin metabolism occur in patients with the duration of the disease up to 5 years and with lower radiological stages. Our data indicate the important role of neurotransmitter in the pathogenesis of RA, especially at the initial stage of the disease.

POS0499 WORK ABSENCE DUE TO MUSCULOSKELETAL SYMPTOMS IN PATIENTS AT-RISK OF RHEUMATOID ARTHRITIS IS COMPARABLE TO THOSE WITH ESTABLISHED DISEASE

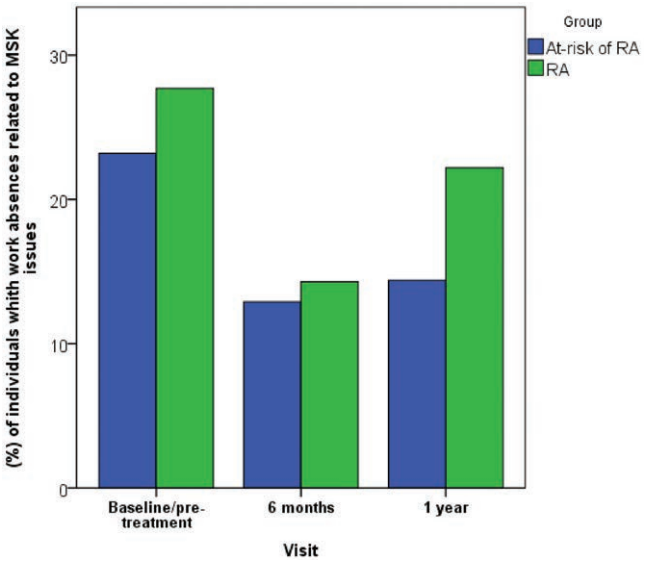
L. Garcia-Montoya[1,2], K. Mankia[1,2], L. Duquenne[1,2], J. Nam[1,2], A. Di Matteo[1,2], J. Peill[1,2], E. Mumba[1,2], P. Emery[1,2]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*; [2]*Leeds Biomedical Research Centre, NIHR, Leeds, United Kingdom*

Background: Rheumatoid arthritis (RA) is an established cause of disability and work absence; however, little is known about the impact of musculoskeletal (MSK) symptoms on sick leave in patients at-risk of developing the disease.
Objectives: To describe the sick leave of individuals at-risk of RA, compared to patients who had recently been diagnosed with RA, over a 12-month period. Additionally, to investigate baseline predictors for sick leave within the first 12 months.
Methods: A prospective observational cohort for individuals at-risk of RA was conducted. A total of 591 consecutive anti-citrullinated protein antibodie positive (ACPA+) individuals, with no clinical synovitis were recruited. A MSK ultrasound scan and a blood test were performed at baseline, and information about employment regime (retired, not in a paid job, part time and full time), days of sick leave and reasons for absences within the previous months were collected every 3 months and analysed at baseline, 6 months, 12 months and at the moment of diagnosis of an inflammatory arthritis (IA) (if the patient had progressed). Subjects who had retired (n=80) were excluded from the analysis.
A comparison was made with 114 RA patients from an observational study. Employment information was collected at pre-treatment, 6 months and 1 year after diagnosis. Univariable and logistic regression analyses were performed to assess predictors of work absence due to MSK reasons in the next 12 months from baseline for at-risk individuals.
Results: Even though the reasons for unemployment were not available, there were no statistically significant differences between employment rates across the timepoints of the study for the at-risk individuals' group (p=0.778). A similar pattern was observed in the RA patient group; which also maintained the same employment rates throughout the study (p=0.311) and these were comparable to the at-risk individuals' (p=0.480).
Over 35% of at-risk individuals in paid employment had work absences in the 3 months prior to the baseline visit. Of these 65.5% were due to MSK related issues, meaning 23.2% of the total absences were MSK related. The other reasons for work absence can be seen in table 1. This fell to 12.9% of the total absences at 6 months (which probably reflects clinical intervention) and increased to 38% if the patient progressed to an IA (graph 1).

Table 1. REASONS FOR SICK LEAVE AT BASELINE IN INDIVIDUALS AT-RISK OF RA (%)

MSK related issues	65.5
Flu-like symptoms	20.1
Gastrointestinal issues	19.4
Stress/anxiety	14.4
Headaches	11.5
Infection	3.6
Fatigue	1.4
Other	3.6

The percentage of individuals who took absence from work due to MSK related issues, was similar in both the at risk and RA group, including an initial reduction possibly due to drug intervention (graph 1). However, the median number of days off work 3 months prior baseline, 6 months and 1 year in RA patients tended to be higher than those in the at-risk group (10, 2 and 6 versus 5, 4 and 3 respectively).
Several factors were assessed to predict sick leave within 12 months in at-risk individuals: age, gender, smoking status, ACPA, rheumatoid factor (RF), anti-nuclear antibodies (ANA), C-reactive protein (CRP), early morning stiffness, shared epitope, joint pain, joint tenderness and abnormal findings in the ultrasound scan (erosions or power doppler); however, only RF [OR 0.18; p=0.018; 95% CI (0.04-0.84)] and CRP [OR 1.3; p=0.021; 95%CI (1.04-1.60)] were statistically significant in the multivariable analysis.
Conclusion: Even though being at-risk of RA is not considered a potential cause of disability, results show that the burden on the workplace, due to MSK related absences, was comparable to subjects diagnosed with RA. Although further investigation is required, initial data suggests that clinical intervention may reduce this burden; which tends to be higher in at-risk individuals with a negative RF and a high CRP.



Graph 1. Percentage of individuals who had work absences related to MSK issues 3 months prior to each timepoint.

POS0500 NUMBER AND CO-EXPRESSION OF TNF RECEPTORS TYPE 1 AND 2 ON IMMUNOCOMPETENT CELLS ARE ASSOCIATED WITH STABILITY OF REMISSION IN RHEUMATOID ARTHRITIS PATIENTS

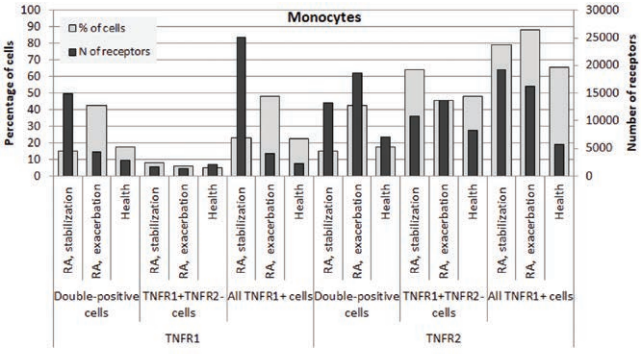
A. Alshevskaya[1], J. Lopatnikova[1], J. Zhukova[1], O. Chumasova[2], N. Shkaruba[2], A. Sizikov[2], S. Sennikov[1,3]. [1]*RIFCI, Laboratory of Molecular Immunology, Novosibirsk, Russian Federation*; [2]*RIFCI, Rheumatology Department, Novosibirsk, Russian Federation*; [3]*Novosibirsk State University, Institute of Medicine and Psychology, Novosibirsk, Russian Federation*

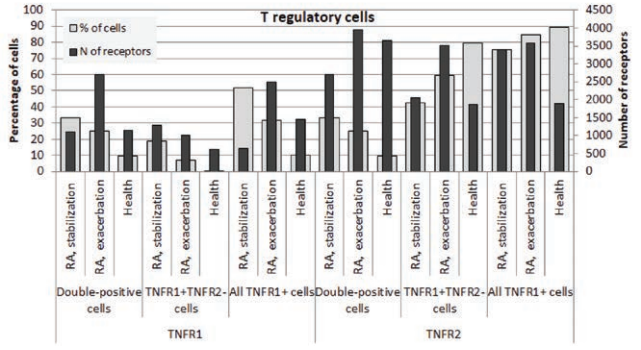
Background: The balance of TNFα receptors expression on cells which are actively involved in immunopathological processes affects both the density of distribution of receptors on cells and co-expression in subsets. Previously it was shown that basic effective RA therapy with methotrexate and glucocorticoids leads to equalization of the expression profile either in the percentage of cells or in the number of receptors, approaching those of healthy donors, but not simultaneously. However, questions about the relationship between the effectiveness of biological therapy and receptors co-expression remain unknown.
Objectives: To assess the differences in co-expression and quantitative expression of TNF receptors type 1 and 2 in subsets of cells associated with the severity of the disease, depending on the response to rituximab therapy.
Methods: Subanalysis of patients with high disease activity level successfully treated with rituximab (alone or in combination treatment scheme) during

hospitalization was performed (n = 14). The first group included 6 patients who retained low disease activity during 1 month follow-up (RA, stabilization). The second group consisted of 8 patients who had exacerbation during follow-up period. As a control group, we used data from 43 comparable healthy donors. Subsets of T regulatory cells and monocytes were studied. A comparison was made among the indicators of receptors number and proportion of cells expressing the corresponding receptor.

Results: For T regulatory cells, the key differences for patients who did not retain low disease activity were significantly higher number of TNF type 1 and type 2 receptors on double-positive cells with a lower percentage of these cells compared to stable patients. At the same time, higher differences between proportions of double-positive cells in comparison with control values of healthy donors were associated with higher probability of maintaining in remission.

For monocytes, the key differences in stable patients were the very high quantitative expression of type 1 receptors on double-positive cells, with a lower percentage of these cells compared to patients with exacerbation. At the same time, lower differences between proportions of double-positive cells in comparison with control values of healthy donors were associated with higher probability of maintaining in remission.





Conclusion: Obtained data confirm the previously proposed hypothesis about the essential role of balance in quantitative expression of TNF receptors type 1 and 2 on double-positive cells to determine the intensity and type of cell response to the mediator and its association with the level of disease activity and response to therapy.

POS0501 SUSTAINED 2-YEAR REMISSION OF THE DISEASE IN A CLINIC OF EXCELLENCE IN RHEUMATOID ARTHRITIS. EXPERIENCE OF THE CLINICAL REGISTRY IN COLOMBIA

J. M. Bello-Gualtero[1,2], E. Peña[3], P. I. Santos Moreno[4], J. Vesga Gualdrón[3], G. Saavedra[5], C. Perez[6]on behalf of Grupo Inmunología Clínica Aplicada de la Universidad Militar Nueva Granada. *[1]Hospital Militar Central, Rheumatology and Immunology, Bogotá, Colombia*; *[2]Universidad Militar Nueva Granada, Grupo Inmunología Clínica Aplicada, Bogotá, Colombia*; *[3]Pontificia Universidad Javeriana, Health Economics, Bogotá, Colombia*; *[4]BIOMAB IPS, Rheumatology, Bogotá, Colombia*; *[5]Hospital Militar Central, Epidemiology, Bogotá, Colombia*; *[6]Hospital Militar Central, Cuenta de alto costo, Bogotá, Colombia*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease with no cure, characterized by episodes of exacerbation and remission, which requires permanent use of medications. Clinics of excellence are multidisciplinary and centralized programs that improve adherence to treatments. Information on the benefits of these models of care has been published but is not definitive. In Colombia, the clinical registry of patients with RA is kept in the Cuenta de Alto Costo (CAC).

Objectives: To demonstrate the difference in the percentages of sustained remission at 2 years, between an institution with non-centralized management or standard of care (Hospital Militar Central-HMC) compared to another institution with centralized management or clinic of excellence (BIOMAB-IPS) and determine if the results are determined by any of the intervention variables or by the program.

Methods: The 2-year clinical records for the CAC were compared between an institution with non-centralized management (HMC) in comparison with another institution with centralized management (BIOMAB-IPS), performing a sociodemographic description, measuring control of the disease DAS28 clinimetry, Fisher's test non-parametric bivariate analysis, multiple regression model, and population matching with Propensity score Matching (PSM).

Results: Complete information was obtained from 2 years of follow-up, in centralized management 3457 patients and for the non-centralized unit 114 patients. Most of them corresponded to 2962 women (82%), with time of illness of 9.5 years and 10.2 years, respectively, without statistically significant differences. A difference was observed in the 2 programs to maintain remission at 2 years, in favor of the centralized program 54.7% vs 28.6.2% (p <0.00). With the binomial generalized linear regression model, it was confirmed that this difference was not explained by variables such as the use of biological therapy (RR = 0.77; 95% CI 0.69-0.86), use of DMARDs (RR = 0.71; 95% CI 0.62-0.82) and number of rheumatology consultations (RR = 0.97; 95% CI 0.92-1.02) in comparison with the centralized care model (RR = 2.32; 95% CI 1.58-3.35). Due to the biases between the groups due to the non-probability sampling, a PSM was performed, with a 1: 1 match, caliper of 0.065, obtaining a pseudo population with well-balanced covariates (see table 1). In the common support area, statistically significant differences were documented in sustained remission over 2 years, in favor of the centralized care group 45 vs 17.9% (p = 0.001).

Conclusion: With the information from the clinical records, statistical strategies can be used to evaluate important differences in centralized care programs, observing favorable results of these types of care that are not related to isolated elements of the program, but to the overall effect of the program.

POS0502 WHAT IS THE ROLE OF VITAMIN D STATUS IN DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH bDMARDs? – DATA FROM A RHEUMATOLOGY CENTER

D. Fonseca[1], M. Rato[2], F. Oliveira Pinheiro[2], B. M. Fernandes[2], S. Garcia[2], A. Martins[2], D. Santos Oliveira[2,3], F. R. Martins[4], M. Bernardes[2,5], L. Costa[2]. *[1]Centro Hospitalar de Vila Nova de Gaia / Espinho, Rheumatology, Vila Nova de Gaia, Portugal*; *[2]Centro Hospitalar Universitário de São João, Rheumatology, Porto, Portugal*; *[3]Center for Health Technology and Services Research (CINTESIS), University of Porto, Faculty of Medicine, Porto, Portugal*; *[4]Centro Hospitalar Universitário do Algarve, Rheumatology, Faro, Portugal*; *[5]Faculdade de Medicina da Universidade do Porto (FMUP), Rheumatology, Porto, Portugal*

Background: Vitamin D is a fat-soluble vitamin, mainly involved in the regulation of calcium metabolism, and it has gained increasing interest in recent years because of its potential role in immunomodulatory activity. Recent data suggest that it is negatively associated with disease activity in rheumatoid arthritis (RA), however this is not yet fully understood.

Objectives: This study's aim was to investigate if there is any correlation between vitamin D serum levels at baseline, before taking the first biological disease-modifying antirheumatic drug (bDMARD), and at 6 months after, with disease activity in a cohort of RA patients.

Methods: This is a cross-sectional study, including all the rheumatoid arthritis patients taking the first bDMARD with evaluation of the vitamin D status at baseline and 6 months after biologic therapy at our Rheumatology Department and registered in the national database (Reuma.pt).

Demographic, clinical and laboratorial characteristics and disease activity measures were collected from the baseline visit and the visit after 6 months of treatment with the first biologic. For the statistical analysis, two groups were defined, based on the serum levels of 25(OH) vitamin D, considering the most common cut-off of 30 ng/mL. For comparison analyses between groups, chi-square test was used for categorical variables and Mann-Whitney U and T-tests were applied for continuous variables.

Results: Seventy-seven patients were included, 58 (75.3%) were females; the mean age was 54.24 ±11.0 years and seropositivity was founded in 65 (84.4%) for anti-citrullinated protein antibodies and in 58 (75.3%) for rheumatoid factor. The first bDMARD most commonly prescribed were etanercept (28.6%) and rituximab (26%). Regarding the vitamin D status at baseline, the mean serum level for 25(OH)vitamin D was 28.35 ± 18.21 ng/mL, with the majority of patients having vitamin D insufficiency (25(OH)vitamin D < 30 ng/mL) (63.6%). After 6 months of treatment with the first bDMARD, disease activity measures showed that remission or low activity were achieved in 29.9% of the patients, using DAS28 criteria; in 42.9% and 46.8%, according CDAI and SDAI criteria, respectively. Vitamin D serum levels at 6 months were 26.81 ±11.72, with the majority of patients still with vitamin D insufficiency (62.3%).

At baseline, patients with vitamin D insufficiency had greater patient VAS (79.00 ± 19,14 vs 71.71 ± 21.95), greater erythrocyte sedimentation rate (ESR) (40.67 ± 23.17 vs 32.46 ± 26.09) and greater Health Assessment Questionnaire (HAQ) score (1.75 ± 0.609 VS 1.61 ± 0.659) with neither of them having statistical significance. However, when comparing CRP levels at 6 months, it achieved statistical significance with the Mann-Whitney U-test (1.05 ± 1.79 VS 1.41 ± 5.22; p=0.026). The same tendency was confirmed when analyzing vitamin D levels at 6 months. Patients with vitamin D insufficiency presented greater patient VAS (55.33 ± 28.82 vs 42.86 ± 28.28), greater ESR (26.19 ± 21.57 vs 21.00 ± 20.38) and greater HAQ score (1.35 ± 0.662 VS 1.34 ± 0.705), although without statistical significance. However, it did achieve statistical significance when comparing baseline DAS28 and HAQ (5.60 ± 0.91 VS 5.38 ± 1.31; p=0.013 and 1.76 ± 0.53 VS 1.59 ± 0.75; p=0.007, respectively).

Conclusion: Our data failed to demonstrate a statistically significant association between vitamin D serum levels at baseline and at 6 months with disease activity in our RA sample. However, it revealed a positive trend of vitamin D insufficiency related to higher activity disease. Interestingly, it showed that vitamin D insufficiency after 6 months of bDMARD treatment is related to higher DAS28 and HAQ at baseline. Nonetheless, we insist it is of paramount importance to conduct larger studies to confirm these findings.

POS0503 THE DISCORDANCE BETWEEN PATIENT-REPORTED AND CLINICAL/BIOLOGICAL OUTCOMES COULD HELP IN PREDICTING FUTURE DISEASE IMPACT IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Pazmino[1], A. Lovik[2], A. Boonen[3,4], D. De Cock[1], V. Stouten[1], D. Bertrand[1], M. Doumen[1], J. Joly[5], R. Westhovens[1,5], P. Verschueren[1,5]on behalf of CareRA study group. [1]*Katholieke Universiteit Leuven, Skeletal Biology and Engineering Research Centre, Department of Development and Regeneration, Leuven, Belgium*; [2]*Katholieke Universiteit Leuven, I-Biostat, Leuven, Belgium*; [3]*Academic Hospital Maastricht, Department of Internal Medicine, Division of Rheumatology, Maastricht, Netherlands*; [4]*Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands*; [5]*UZ Gasthuisberg Campus, Department of Rheumatology, Leuven, Belgium*

Background: Treatment of Rheumatoid Arthritis (RA) has improved significantly based on early treat-to-target (T2T) strategies. Still, decreased health related quality of life (QoL), restricted ability to work and other unmet needs are reported by RA patients even in the absence of disease activity. We previously identified 3 factors representing the broader impact of RA using exploratory factor analysis: a patient-reported factor (patients global health, pain, fatigue and HAQ), a clinical factor (physician's global health, tender and swollen joint count), and a laboratory factor (ESR and CRP)[1].

Objectives: To test whether the discordance between patient-reported (PRF) and clinical(CF)/laboratory(LF) measures can predict QoL, or has a mediating effect in predicting future disease burden based on disease activity (DAS28CRP).

Methods: This is a post-hoc analysis of the 2-year CareRA trial. PRF, CF and LF scores were calculated as weighted (by factor loading) sum of their components at week 16, 52 and 104 after treatment initiation. A discordance score (DS) between PRF and the mean of the other two scores was also computed.

Mediation analyses were fitted to test the hypothesis (Figure 1) that DS could be a mediator for predicting PRF, CF and LF at a future time point (week 16, 52 and 104) using DAS28CRP at a previous time point (baseline and week 16). Confidence intervals were estimated via 10 000 bootstraps. Finally, a linear regression was fitted for DS to predict future QoL (RAQoL questionnaire; range 0-30; higher values indicating worse QoL).

Results: Patients with early RA (n=379) were included with a mean (SD) age of 53.9 (13.0), 77% seropositive and 69% women.

The DS was shown to be mediating the effect of DAS28CRP on any future PRF (Table1). On the other hand, there was no mediation effect of the DS in the prediction of the CF and an inconsistent mediation effect when predicting the LF. Moreover, the DS at week 16 significantly predicted (p<0.0001) RAQoL scores at year 1 with an effect of β 19.05 (SE 1.58) and an R^2 of 0.30 (CI 0.22-0.38). Similarly, it predicted RAQoL (p<0.0001) at year 2 with a β 19.74 (SE 1.56) and R^2 of 0.32 (CI 0.24-0.40).

W: week BL: baseline DS: discordance scoreDAS28CRP: disease activity score in 28 joints with C-reactive protein*p<0.01

Conclusion: Early discordance between patient-reported and biological/clinical factors mediates the effect of disease activity on future patient-reported outcomes, but also predicts QoL. Paying attention to this early discordance might provide opportunities to prevent patient's unmet needs by additional non-pharmacological interventions, hence broadening the scope of T2T.

POS0504 IS BIOELECTRICAL PHASE ANGLE ASSOCIATED WITH FUNCTIONAL STATUS AND DISEASE IMPACT IN PATIENTS WITH RHEUMATOID ARTHRITIS?

M. Ferro[1], S. Charneca[1], J. Vasques[1], E. Dourado[2,3], C. Sousa Guerreiro[1,4], J. E. Fonseca[2,3]. [1]*Laboratório de Nutrição, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*; [2]*Serviço de Reumatologia e Doenças Ósseas Metabólicas, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Centro Académico de Medicina de Lisboa (CAML), Lisbon, Portugal*; [3]*Unidade de Investigação em Reumatologia, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, CAML, Lisbon, Portugal*; [4]*Instituto de Saúde Ambiental, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease in which an abnormal body composition was reported to be highly prevalent. (1) Bioelectrical phase angle (PhA) is a measure of the relationship between electric resistance and reactance obtained via bioelectrical impedance analysis (BIA). (2) As an indicator of cellular health, PhA has been described as a predictor of worse clinical outcome and higher mortality in various conditions. (3) Since there is evidence that PhA is related to disease progression and prognosis when considering chronic inflammatory conditions, a lower PhA may also be considered an indicator of a worse prognosis in RA. (1)
Objectives: To study the association between PhA, functional status and impact of disease in RA patients.
Methods: Observational and cross-sectional study, including 53 patients with RA diagnosis according to the ACR/EULAR 2010 criteria. Each patient demographic data was recorded, and body composition, including PhA by BIA, was obtained. BIA was performed using Bodystat QuadScan 4000 equipment. Functional status and impact of disease were assessed using the Health Assessment Questionnaire (HAQ) and the Rheumatoid Arthritis Impact of Disease (RAID) scores, respectively. PhA was stratified by tertiles (lowest, middle and highest) to create groups of patients. Statistical analysis was performed using student's t-test (IBM SPSS version 26) for comparisons between groups.
Results: A total of 53 patients with RA (81.1% women) with an average age of 62.2 ± 10.2 years were assessed. Mean PhA was 5.8 ± 1.7 º. A PhA lower than 5.2 º (lowest tertile) was recorded in 17 patients; A PhA ranging from 5.2 º to 6.0 º (middle tertile) was observed in 18 patients; A PhA greater than 6.0 º (highest tertile) was seen in 18 patients. Mean HAQ score was 1.43 ± 0.61 in the lowest tertile, 0.85 ± 0.57 in the middle tertile and 0.67 ± 0.57 in the highest tertile. Mean RAID score was 5.86 ± 1.69 in the lowest tertile, 4.73 ± 2.05 in the middle tertile and 3.00 ± 1.94 in the highest tertile. The statistical analysis showed significant differences in both HAQ and RAID scores between the lowest and the highest tertiles (p=0.001 and p <0.001, respectively). Significant differences were also found between the lowest and the middle tertile for HAQ score (p=0.007) and between the middle and the highest tertile for RAID score (p=0.017).
Conclusion: In our cohort a lower PhA was significantly associated with higher HAQ and RAID scores, indicating higher disease impact and higher disability in RA patients with lower PhA. These results support the hypothesis that PhA may be investigated as a possible indicator of disease prognosis in RA.

Rheumatoid arthritis - comorbidity and clinical aspects

POS0505

DEPRESSION, ANXIETY AND STRESS AMONG OUTPATIENTS WITH RHEUMATOID ARTHRITIS FOLLOWED UP AT A TERTIARY CARE HOSPITAL IN SRI LANKA; A CROSS-SECTIONAL STUDY

T. Wijewardena[1], S. Wijewantha[1], N. Wijethunga[1], N. L. de Silva[2], D. Fernando[3]. *[1]Faculty of Medicine, University Of Colombo, Medical Student, Colombo, Sri Lanka*; *[2]General Sir John Kotelawala Defence University, Department of Clinical Sciences, Ratmalana, Sri Lanka*; *[3]Faculty of Medicine, University Of Colombo, Department of Parasitology, Colombo, Sri Lanka*

Background: Increased prevalence of depression, anxiety and stress have been shown among patients with rheumatoid arthritis. Patient and disease characteristics and psychosocial factors associated with these mental health issues are shown to vary among different populations. South Asian studies comprehensively assessing the prevalence and associations of these factors are lacking.
Objectives: To determine the prevalence of depression, anxiety and stress among patients with rheumatoid arthritis and to identify associated patient and disease factors.
Methods: A cross-sectional study was carried out among outpatients at three specialized rheumatology clinics at the National Hospital of Sri Lanka. Individuals with a diagnosis of rheumatoid arthritis were recruited consecutively. An interviewer-administered questionnaire was used to record sociodemographic and clinical data including the Clinical Disease Activity Index. A score 10.1-22.0 was taken as moderate and more than 22.1 was taken as high disease activity. The self-administered Depression, Anxiety, Stress Scale-21 (DASS-21) tool which has been validated for the Sri Lankan population was used. Statistical analysis was done using descriptive analysis and Chi-Square.
Results: A total of 118 participants were recruited in this study. Majority of the participants (n=105) were female and had received a secondary school education (70%). Based on the CDAI assessment most were in the moderate (39%) and high disease activity groups (36%). Prevalence of Depression, Anxiety and Stress were found to be higher than the baseline level of 1% in the general population. A breakdown of the prevalence is shown in Figure 1. Further analysis of each arm, depression anxiety and stress were carried out independently excluding the non-responders. A higher level of prevalence of all three parameters was observed with the deterioration of functional status evidenced by the inability to walk and grip a ball firmly in the palm without it falling. Prevalence of depression was associated with age > 60 years (p=0.035), increased disease activity (p=0.004) and the loss of their job due to poor health (p=0.01). Higher prevalence of anxiety was associated with increased disease activity (p=0.023). A marked increase in stress level was associated with loss of the job (p=0.009) and morning stiffness > 60 minutes (p=0.001). Several Pre-existing co-morbidities were associated with depression and anxiety (Table 1). No association was observed between stress and pre-existing comorbidities.

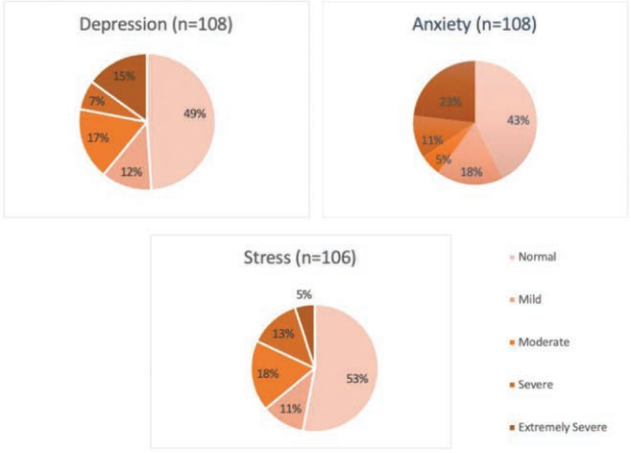

Figure 1. Prevalence of depression, anxiety and stress among patients with rheumatoid arthritis

Table 1. Correlation of comorbidities with depression and anxiety.

		Depression		Anxiety	
Associated Factors		Yes	No	Yes	No
Diabetes Mellitus (%)	Identified	18(72)	07(28)	16(66)	08(34)
	Not Identified	37(45)	46(55)	46(55)	38(45)
P-value		0.016		0.298	
Ischaemic heart disease (%)	Identified	14(82)	03(18)	14(78)	04(22)
	Not Identified	41(45)	50(55)	48(53)	42(47)
P-value		0.005		0.056	
Dyslipidaemia (%)	Identified	20(67)	10(33)	25(78)	07(22)
	Not Identified	35(45)	43(55)	37(49)	39(51)
P-value		0.042		0.005	

Conclusion: Prevalence of depression, anxiety and stress among patients with rheumatoid arthritis is higher than the general population. Functional deterioration, disease activity and presence of co-morbidities are associated with these mental health issues. These can guide clinicians to screen high risk individuals for the mental health issues so that measures to relieve them would potentially improve quality of life and disease outcome.

POS0506

TENOSYNOVITIS HAS A HIGH SENSITIVITY FOR EARLY ACPA-POSITIVE AND ACPA-NEGATIVE RA: A LARGE CROSS-SECTIONAL MRI STUDY

X. Matthijssen[1], F. Wouters[1], N. Sidhu[1], E. Niemantsverdriet[1], A. van der Helm - van Mil[1,2]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*

Background: Clinically evident tenosynovitis can be seen in established Rheumatoid arthritis (RA). Imaging research has recently shown that tenosynovitis at small joints occurs in early RA, contributes to typical RA symptoms (including joint swelling) and is infrequent in healthy controls. Imaging-detectable tenosynovitis is often not recognizable at joint examination, hence its prevalence can therefore be underestimated.
Objectives: We hypothesized that if MRI-detectable tenosynovitis is a true RA-feature, the sensitivity for RA is high, in both ACPA-positive and -negative RA, and lower in other diseases that are associated with enthesitis (such as Spondyloarthritis (SpA) and Psoriatic Arthritis (PsA)). So far, no large MRI-study addressed these questions.
Methods: Consecutive early arthritis patients (n=1211) from one health-care region underwent contrast-enhanced 1.5T MRI of hand and foot at diagnosis. MRIs were scored for synovitis and tenosynovitis by two readers blinded for clinical data. All included patients with ACPA-positive RA (n=250), ACPA-negative RA (n=282), PsA (n=88), SpA with peripheral arthritis (n=24), reactive arthritis (n=30) and self-limiting undifferentiated arthritis (UA;n=76) were studied. Sensitivity was calculated.
Results: The sensitivity of tenosynovitis in RA was 85%; 88% for ACPA-positive RA and 82% for and ACPA-negative RA (p=0.19). The sensitivity for RA was significantly higher than for PsA (65%;p=0.001), SpA (53%;p<0.001), reactive arthritis (36%;p<0.001) and self-limiting UA (42%;p<0.001). The observed sensitivity of MRI-synovitis was 91% in RA and ranged 83-54% in the other groups.
Conclusion: MRI-detected tenosynovitis has a high sensitivity for early ACPA-positive and ACPA-negative RA. This supports both juxta-articular (tenosynovitis) and intra-articular synovial involvement is characteristic for RA.

UNUSUALLY HIGH PREVALENCE OF ATRIAL FIBRILLATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

B. Mukerji[1], F. Wang[1], R. Markert[2], V. Mukerji[3]. [1]*Dayton Veteran Administration Medical Center, Rheumatology, Dayton, United States of America*; [2]*Wright State University, Medicine, Dayton, United States of America*; [3]*Dayton Veteran Administration Medical Center, Cardiology, Dayton, United States of America*

Background: In rheumatoid arthritis, circulating autoantibodies like anticyclic citrullinated peptides and rheumatoid factor may be present for years prior to symptom onset. In RA, there are high levels of circulating tumor necrosis factors, interleukins, matrix metalloproteinases, growth factors, and adhesion molecules that cause tissue damage[1,2]. This can affect different organs in different ways. It is possible that in the heart, they cause inflammation of cardiac tissue [3,4].
Objectives: This study was conducted to determine if patients with RA, an inflammatory arthritis, and osteoarthritis (OA), a degenerative arthritis, differ in the prevalence of cardiac arrhythmias.
Methods: This was a retrospective study. We enrolled 300 consecutive patients, 150 with RA and 150 with OA. Patients were assessed for age, race, gender, body mass index (BMI), smoking status, hypertension (HTN), hyperlipidemia (HLD), diabetes mellitus (DM), cardiovascular disease (CVD), coronary artery disease (CAD), cardiac arrhythmias including conduction abnormalities, cerebrovascular accident (CVA), congestive heart failure (CHF), abdominal aortic aneurysm (AAA), pulmonary embolism (PE), deep vein thrombosis (DVT), and peripheral vascular disease (PVD). RA and OA groups were compared with the chi square test and the Mann-Whitney test.
Results: The RA and OA groups did not differ on the demographic characteristics of age or race. The presence of DM was similar in the two groups. The RA group had more women than the OA group (12.7% vs. 5.3%, p=0.026). The OA group had a higher mean BMI (33.1 vs 30.0, p<0.001) and higher prevalence of HLD (78.9% vs 64.6%, p=0.007) and HTN (79.3% vs. 66.7%, p=0.013). RA patients had a higher rate of smoking (70.0% vs 56.7%, p=0.017) and longer duration of smoking (34.3 years vs. 28.2 years, p=0.003). The RA group had a higher prevalence of CVD (58.7% vs. 42.7%, p= 0.006). Further data analysis among CVD showed there was no difference between the two groups for the prevalence of CAD, CHF, CVA, AAA, PVD or DVT/PE. RA patients had a higher prevalence of cardiac arrhythmias (31.3% vs. 12.0%, p<0.001). Among all types of cardiac arrhythmias, no significant difference was found between two groups for the prevalence of supraventricular tachycardia, ventricular arrhythmias, or conduction abnormalities. Patients with RA had a significantly higher prevalence of atrial fibrillation (15.3% vs. 6.0%, p = 0.015).
Conclusion: Cardiac arrhythmias occur more frequently in RA patients than in OA patients. Among all the arrhythmias, atrial fibrillation has a significantly higher prevalence in RA patients.

EVALUATION OF RESPONSE TO PNEUMOCOCCAL VACCINATION IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING UPADACITINIB: RESULTS FROM A PHASE 2 OPEN-LABEL EXTENSION STUDY

K. Winthrop[1], J. Ignacio Vargas[2], E. Drescher[3], C. Garcia Garcia[4], A. Friedman[5], J. Enejosa[5], N. Khan[5], Y. Li[5], J. Klaff[5], A. Kivitz[6]. [1]*Oregon Health & Science University, Infectious Disease, Portland, United States of America*; [2]*Quantum Research, Medicine, Puerto Varas, Chile*; [3]*Veszprém Csolnoky, Ferenc County Hospital, Veszprém, Hungary*; [4]*Hospital General de México,"Dr. Eduardo Liceaga", Mexico City, Mexico*; [5]*AbbVie Inc., Rheumatology, North Chicago, United States of America*; [6]*Altoona Center, Clinical Research, Duncansville, United States of America*

Background: Pneumococcal vaccination is recommended in patients with RA who are receiving conventional synthetic/biologic DMARDs.[1] Upadacitinib (UPA) is an oral Janus kinase (JAK) inhibitor engineered to have a greater selectivity for JAK1 versus JAK2, JAK3, and tyrosine kinase 2, and is approved for the treatment of RA.
Objectives: The aim of this analysis was to assess the impact of long-term treatment with UPA + background MTX on immunologic responses to Prevnar 13® (Pneumococcal 13-valent Conjugate Vaccine [Diphtheria CRM_{197} Protein];

PCV13) in patients with RA enrolled in the ongoing Phase 2 open-label extension study BALANCE-EXTEND.

Methods: Patients from BALANCE-EXTEND receiving PCV13 vaccination were required to be on UPA 15 mg once daily (QD) or 30 mg QD and background MTX for ≥4 weeks prior to, and after, PCV13 vaccination; MTX was not interrupted prior to vaccination. Vaccination antibody titers were collected pre-vaccination (Week 0) and post-vaccination (Weeks 4 and 12). The primary variable was the proportion of patients with satisfactory humoral response to PCV13 (≥2-fold increase in antibody concentration from pre-vaccination [Week 0] in ≥6/12 pneumococcal antigens [1, 3, 4, 5, 6B, 7F, 9V, 14, 18C, 19A, 19F, and 23F]) at 4 weeks post-vaccination.

Results: Of 111 patients (UPA 15 mg, n=87; UPA 30 mg, n=24), 86% were female, most (98%) were white, and mean (standard deviation) age was 58.4 (12.0) years. Prior to vaccination, patients had a median (range) duration of RA of 9.3 (3.4–35.0) years and had been receiving UPA for a median (range) of 3.9 (3.0–4.9) years. All but 3 patients were taking concomitant MTX, and 44.1% were taking a CS (median daily dose, 5.0 mg). All 111 patients received PCV13, none discontinued UPA during the first 4 weeks, and blood samples were available from 83/23 and 79/22 patients in the UPA 15/30 mg groups at Weeks 4 and 12, respectively. At 4 weeks, satisfactory humoral response to PCV13 occurred in 67.5% (95% confidence interval [CI]: 57.4–77.5) and 56.5% (95% CI: 36.3–76.8) of patients receiving UPA 15 and 30 mg, respectively. At 12 weeks, satisfactory humoral response to PCV13 occurred in 64.6% (95% CI: 54.0–75.1) and 54.5% (95% CI: 33.7–75.4) of patients receiving UPA 15 and 30 mg, respectively (Figure 1). There was no clear difference in response between patients receiving and not receiving concomitant CS. Within 30 days post-vaccination, 2 adverse events (AEs) were considered as possibly related to UPA (1 case of diverticulitis, UPA 15 mg; 1 case of anemia, UPA 30 mg) and no serious AEs were reported (Table 1). Two patients experienced pyrexia and 1 subject each experienced vaccination-site pain and headache within 1 day post-vaccination (all in UPA 15 mg group).

Table 1. Safety through 30 days post-PVC13 vaccination in UPA-treated patients

Event, n (%)	UPA 15 mg QD (n=87)	UPA 30 mg QD (n=24)
Any AE	15 (17.2)	3 (12.5)
Serious AE	0	0
AE leading to discontinuation of study drug	0	0
AE with reasonable possibility of being related to UPA[a]	1 (1.1)[b]	1 (4.2)[c]
Death	0	0

[a]As assessed by the investigator. [b]Diverticulitis. [c]Anemia. AE, adverse event; PVC13, Pneumococcal 13-valent Conjugate Vaccine [Diphtheria CRM_{197} Protein]; QD, once daily; UPA, upadacitinib.

Conclusion: Satisfactory humoral response to PCV13 at 4 weeks occurred in ~two-thirds of patients with RA receiving long-term treatment with UPA 15 mg QD + background MTX. This is broadly consistent with pneumococcal vaccine humoral responses observed in patients with RA treated with other JAK inhibitors, biologics, or placebo.[2–4]

POS0509 PREVALENCE OF RHEUMATOID CACHEXIA AND ITS ASSOCIATION WITH SERUM FETUIN-A LEVELS IN CAUCASIAN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Papichev[1], B. Zavodovsky[1], L. Seewordova[1], J. Polyakova[1], Y. Akhverdyan[1].
[1]*FSBI "Research Institute of Clinical and Experimental Rheumatology n.a. A.B. Zborovsky", Treatment and Prevention of Joint Disease Laboratory, Volgograd, Russian Federation*

Background: Rheumatoid cachexia is an under-recognized pathological condition, which is characterized by a loss of muscle strength and can be presented as a low fat-free mass and normal or high BMI in patients with rheumatoid arthritis determined by dual-energy X-ray absorptiometry (DEXA) [1]. Though fetuin-A is one of a major noncollagen proteins in bone tissue it is of interest to clarify its association with rheumatoid cachexia.

Objectives: To define the prevalence of rheumatoid cachexia in Caucasian patients with rheumatoid arthritis determined by DEXA method and to study the association of serum fetuin-A levels with body composition and rheumatoid cachexia in this group.

Methods: 110 Caucasian patients with rheumatoid arthritis undergone DEXA with «Total Body» program. All patients fulfilled the 2010 ACR/EULAR classification criteria for rheumatoid arthritis. The diagnosis of rheumatoid cachexia was based on Engvall I.L. criteria: fat-free mass index less than 10th percentile with fat mass index above 25th percentile [1]. We used values for these indexes from the study performed in 2008 by Coin A. et al. on Italian population due to a lack of standard values [2]. Fetuin-A in serum was determined by enzyme-linked immunosorbent assay. 72 patients have been taking glucocorticoids for more than 3 months in dose equivalent or higher than 5 mg of prednisolone daily. Statistical analysis was performed using a software package "Statistica 12.0". Parametric data is presented as M±St.dev, and nonparametric as Me [Q1-Q3].

Results: Rheumatoid cachexia was diagnosed in 25 patients (22,7%) with mean age of 52,2±8,14 years. The prevalence of cachexia was the same in groups of patients who took glucocorticoids (n=16, 22,2%) and who didn't (n=9, 23,7%; p = 0,465). Median cumulative dose of oral glucocorticoids in patients with rheumatoid cachexia was higher but fell just short of statistical significance (8,0 [2,9-13,5] g vs 5,4 [0,2-11,6] g; Z=-1,42; p = 0,156). Median serum fetuin-A levels were only slightly significantly lower in patients with rheumatoid cachexia (757,7 [700,5-932,0] μg/ml vs 769,3 [660,3-843,4] μg/ml; Z=-1,35; p=0,175). Positive statistically significant correlations were observed between serum fetuin-A levels and bone mass in right (r=0,222, p = 0,027) and left (r=0,263, p = 0,008) lower limbs, trunk (r=0,268, p = 0,007), gynoid region (r=0,293, p = 0,003), both lower limbs (r=0,246, p = 0,014) and whole-body (r=0,235, p = 0,019).

Conclusion: Rheumatoid cachexia was diagnosed in 22,7% of patients with rheumatoid arthritis. No association was observed between glucocorticoids intake and rheumatoid cachexia, despite the expected influence of them on muscle mass. We may suggest that occurrence and pathogenesis of this condition is complex and should be studied more precisely. It is well-known that patients with such condition have a higher risk for metabolic syndrome, arterial hypertension and mortality. We observed positive correlations between serum fetuin-A levels and bone mass in lower limbs, trunk, gynoid region and whole-body. Considering

that fetuin-A is also associated with bone mineral density [3], it may be regarded as a marker of bone remodeling.

POS0510 EPIDEMIOLOGY OF COCAINE AND HALLUCINOGEN USE DISORDER HOSPITALIZATIONS IN RHEUMATIC DISEASES

J. Singh[1]. [1]*University of Alabama at Birmingham, Medicine, Birmingham, United States of America*

Background: Cocaine use disorder is a frequent cause of drug use disorders in the U.S. Although hallucinogen use disorder is less common, both are potentially preventable public health issues. To our knowledge, epidemiological studies estimating burden of cocaine or hallucinogen use disorders in common Musculoskeletal diseases (MSDs) are lacking.

Objectives: To assess national time-trends in cocaine use and hallucinogen use disorders in people with MSDs

Methods: This study used the U.S. National Inpatient Sample (NIS), a de-identified national all-payer inpatient health care database (https://www.hcup-us.ahrq.gov/nisoverview.jsp) from 1998-2014. The NIS is a 20% stratified sample of hospital discharges in the U.S. It is commonly used to derive national estimates of hospitalization and outcomes. Cocaine or hallucinogen use disorder hospitalization was defined in a validated approach as the presence of the following International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) diagnostic codes: cocaine use disorder, 304.2x, or 305.6x; and hallucinogen use disorder, 304.5x or 305.3x; hospitalizations for drug use in remission, drug counseling, rehabilitation or detoxification were excluded, as in previous studies. MSDs were identified based on the respective ICD-9 codes, a validated approach (5-9), in non-primary position: Gout: 274.xx; rheumatoid arthritis (RA): 714.xx; Fibromyalgia: 729.1; osteoarthritis (OA): 715.xx; or low back pain (LBP): 724.

Results: In 1998-2000, the highest frequency of cocaine use hospitalizations was in people with LBP: LBP (n=5,914), followed by OA (n=4,931), gout (n=2,093), RA (n=2,026), and fibromyalgia (n=1,620). In 2013-2014, the order changed slightly with OA (n=22,185), followed by LBP (n=16,810), gout (n=10,570), RA (n=8,975), and fibromyalgia (n=5,680). Respective rates per 1 million U.S. NIS hospitalizations in 2013-2014 and the relative increase from 1998-2000 to 2013-2014 were: Gout, 10.2 (increase, 4.1-fold); OA, 21.4 (3.5-fold); fibromyalgia, 5.48 (2.5-fold); RA, 8.66 (3.4-fold); and LBP, 16.22 (1.8-fold; figure 1).

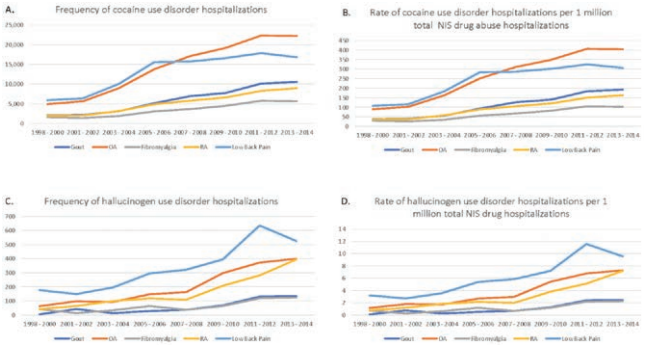

Figure 1. Time-trends in the rates of hospitalization with cocaine use and hallucinogen use disorder (A), non-home discharge (B), and in-hospital mortality (C) per 100,000 NIS hospitalization claims.The x-axis shows rate per 100,000 NIS hospitalization claims and the y-axis the study periods

In 1998-2000, hallucinogen use disorder hospitalizations were as follows: LBP (n=176), followed by OA (n=63), RA (n=42), fibromyalgia (n=41) and gout (n<10; cells with frequency of 10 of fewer are reported as <10 per NIS guidance). In 2013-2014, the frequency order was the similar, with the highest numbers for LBP (n=525) followed by OA (n=400), RA (n=395), gout (n=135) and fibromyalgia (n=125). Respective rates per 1 million US NIS hospitalizations in 2013-2014 and the relative increase from 1998-2000 to 2013-2014 were: Gout, 0.13 (increase, 25-fold); OA, 0.39 (5.5-fold); fibromyalgia, 0.12 (2-fold); RA, 0.38 (8.5-fold); and LBP, 0.51 (2-fold; figure 1).

Conclusion: This study confirmed an increasing rate of both, cocaine use and hallucinogen use disorder hospitalizations in people with 5 MSDs over a 17-year period from 1998-2014 in the U.S.

POS0511 USING HIP STRUCTURAL ANALYSIS MEASUREMENTS TO PREDICT FRACTURE IN RHEUMATOID ARTHRITIS

R. Ark[1,2], M. Bukhari[1,2]. [1]*Lancaster University, Lancaster Medical School, Bailrigg, United Kingdom*; [2]*University Hospitals of Morecambe Bay NHS Foundation Trust, Royal Lancaster Infirmary, Lancaster, United Kingdom*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease and increases the risk of developing osteoporosis. Incidence of fracture is higher in this group of patients compared to the general population and can lead to increased morbidity (1). Bone strength of the proximal femur is not only linked to bone mineral density; it also depends on the geometric properties of the bone mass (2). Hip structural analysis (HSA) is a technique used to assess hip bone structure that takes geometric measurements of the femur from dual-energy X-ray absorptiometry (DEXA) images (3).

Objectives: To determine whether HSA measurements help predict fracture in patients with RA.

Methods: Data were collected from June 2004 to August 2017 from RA patients who underwent a DEXA scan at a District General Hospital. This included hip axis length (HAL), cross-sectional area (CSA), cross-sectional moment of inertia (CSMI), distance from centre of femoral head to centre of femoral neck (D1) and to inter-trochanteric line (D2), mean femoral neck diameter (D3), shaft angle (A) neck/shaft angle (Θ) and proximal femur strength index (SI) and distance from centre of mass of femoral neck to superior neck margin (Y). Fracture was predicted by a series of binomial logistic regression models, adjusted for sex, age and bone mineral density (BMD). Odds ratios with 95% confidence intervals and area under the receiver operating characteristic curve (AUC) were calculated.

Results: 2077 patients with RA were identified, 1632 were female and the mean age was 66.7. HAL, D1, D2, D3, A, Θ and Y were not significant predictors of fracture in regression models; odds ratios are included in table 1. CSA, CSMI and SI predicted fracture risk. The AUC for CSA, CSMI and SI regression models were 0.632, 0.609 and 0.625 respectively.

Table 1. Odds ratios of fracture for different HSA parameters in RA patients

HSA Parameter	Odds Ratio (95% Confidence Interval)
HAL	1.01410 (0.99958 - 1.02883)
CSMI	0.99994 (0.99990 - 0.99998)
CSA	0.98523 (0.98065 - 0.98982)
D1	1.01683 (0.98925 - 1.04518)
D2	1.01286 (0.99886 - 1.02705)
D3	1.00664 (0.96958 - 1.04511)
Y	1.04580 (0.98633 - 1.10886)
A	1.00898 (0.98878 - 1.02959)
Θ	1.00276 (0.98672 - 1.01906)
SI	0.56769 (0.43400 - 0.74258)

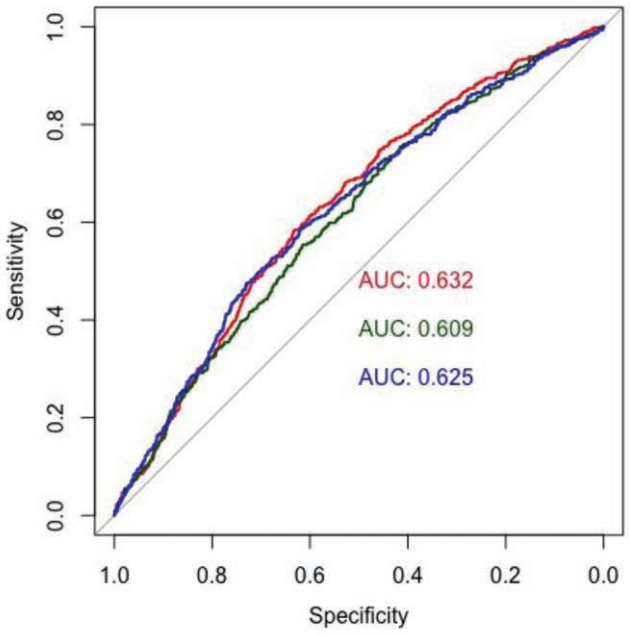

Figure 1. Receiver operating characteristic curves for CSA (red), CSMI (green) and SI (blue). AUC for CSA was 0.632, CSMI-0.609 and SI-0.625.

Conclusion: These data suggest that CSA, CSMI and SI help predict the fracture risk in patients with RA. HAL, D1, D2, D3, A, Θ and Y do not predict risk of fracture. The CSA regression model was the strongest predictor of fracture. HSA measurements can therefore help predict risk of fracture in conjunction with other factors. Limitations of the study are that it was retrospective and only studied patients who had a DEXA scan.

DIFFERENCES IN TREATMENT SATISFACTION, PATIENT PREFERENCES, AND TREATMENT PATTERNS BETWEEN EUROPEAN, SOUTH AMERICAN, AND JAPANESE PATIENTS WITH SUBOPTIMALLY CONTROLLED RHEUMATOID ARTHRITIS: A SUBGROUP ANALYSIS OF THE SENSE STUDY

P. C. Taylor[1], P. Sidiropoulos[2], C. Ancuta[3], I. Lagunes-Galindo[4], M. Delavega[5], U. Kalyoncu[6], O. Nagy[4], A. Kawakami[7]. *[1]University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; *[2]University of Crete, Faculty of Medicine, Heraklion, Greece*; *[3]"Grigore T. Popa" University of Medicine and Pharmacy, Department of Rheumatology, Iași, Romania*; *[4]AbbVie, Inc,., North Chicago, United States of America*; *[5]CEIM Investigaciones Medicas,., Buenos Aires, Argentina*; *[6]Hacettepe University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[7]Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Nagasaki, Japan*

Background: Despite the availability of advanced therapies, many patients with rheumatoid arthritis (RA) do not achieve their treatment goals. Understanding geographic influence on patient perspectives and physicians' attitudes toward treatment adjustments may inform region-specific strategies to improve outcomes in RA.

Objectives: To explore differences in treatment satisfaction, patient preferences, and treatment strategies between patients from Europe (EU), South America (SA), and Japan (JP) with suboptimal control of RA.

Methods: This is a subgroup analysis of SENSE, a non-interventional cross-sectional study in adults with RA who had moderate/high disease activity as measured by Disease Activity Score in 28 joints with erythrocyte sedimentation rate (DAS28[ESR]) >3.2, despite disease-modifying antirheumatic drug (DMARD) treatment. Patient satisfaction and preferences, treatment adherence, patient-reported outcomes, and physicians' plans for DMARD switch were assessed as previously described.[1] Predictors of good treatment satisfaction and physician's decision not to switch DMARDs were identified using multiple logistic regression analyses.

Results: Of 1234, 272, and 118 patients enrolled from EU, SA, and JP, respectively, 13.9%, 15.4%, and 5.9% reported good treatment satisfaction. Irrespective of region, patients reported impaired quality of life and good treatment adherence, and around one-third of patients received targeted synthetic (ts) or biologic (b) DMARDs. Among patients treated with ts/bDMARDs, monotherapy was most common in SA (45.3%), followed by EU (26.3%) and JP (18.8%), consistent with a greater acceptance of combination therapy in JP. More than 80% of JP patients preferred oral treatments versus <60% of EU/SA patients. DMARD switches were planned in 51.8% (EU), 57.4% (SA), and 38.1% (JP) of patients, most commonly to a tumor necrosis factor inhibitor. Predictors for good treatment satisfaction included treatment with ts/bDMARDs and the presence of psychiatric disorders in EU and SA; however, current disease activity was not a common predictor (Table 1). Reluctance to switch treatments was predicted by lower disease activity assessed by DAS28(ESR) (all regions) and current treatment with ts/bDMARDs (EU/SA).

Table 1. Predictors for good treatment satisfaction and no treatment switch planned

OR (95% CI)	Europe (n=1234)	South America (n=272)	Japan (n=118)
Good treatment satisfaction (TSQM global treatment satisfaction ≥80)			
Current treatment with ts/bDMARDs	3.8 (2.7, 5.4)****	4.9 (2.2, 10.8)****	—
Psychiatric disorders	2.4 (1.3, 4.6)**	3.1 (1.2, 8.4)*	—
Number of comorbidities	—	—	2.3 (1.2, 4.3)*
Worst joint pain	—	1.3 (1.1, 1.5)**	
SF-36 MCS	1.0 (1.0, 1.1)****	—	1.3 (1.1, 1.5)**
SF-36 PCS	1.1 (1.0, 1.1)****	—	—
Work Productivity and Activity Impairment–Rheumatoid Arthritis: Total activity impairment	—	1.0 (1.0, 1.0)***	—
DAS28(ESR) >5.1	—	0.3 (0.1, 0.7)**	—
Female	—	—	0.1 (0.0, 0.9)*
No treatment switch planned			
Current treatment with ts/bDMARDs	3.9 (3.0, 5.2)****	2.4 (1.4, 4.2)**	—
Number of comorbidities	1.2 (1.1, 1.4)****	—	—
Age	—	—	1.0 (1.0, 1.1)*
TSQM effectiveness subscore	1.0 (1.0, 1.0)***	1.0 (1.0, 1.0)***	—
Number of concomitant medications	0.9 (0.8, 1.0)**	—	—
DAS28(ESR)	0.5 (0.5, 0.6)****	0.6 (0.5, 0.8)***	0.6 (0.4, 0.9)*

X^2 test: ****p<0.0001, ***p<0.001, **p<0.01, *p<0.05CI, confidence interval; OR, odds ratio; SF-36M/PCS, 36-Item Short-Form Survey mental/physical component summary; TSQM, Treatment Satisfaction Questionnaire for Medication

Conclusion: In patients with moderate to high RA disease activity, current disease control was a common determinant of treatment switches. Predictors for good treatment satisfaction revealed region-specific patient attitudes to treatment acceptance despite poor disease control.

Background: Interstitial lung disease (ILD) is a severe complication of RA. Abatacept (ABA) have demonstrated efficacy in RA-ILD [1,2], although combined treatment with MTX or others DMARDs remain controversial.

Objectives: To assess the efficacy and safety of ABA in monotherapy (ABA_{MONO}) versus combined-ABA, ABA plus MTX(ABA_{MTX}) or ABA plus other non-MTX DMARDs ($ABA_{NON-MTX}$), in RA-ILD.

Methods: Observational multicenter study of RA-ILD caucasian patients treated with ABA. We analyzed in three groups (ABA_{MONO}, ABA_{MTX}, $ABA_{NON-MTX}$) the following outcomes: **a)** Dyspnea, **b)** FVC and DLCO, **c)** HRCT, **d)** DAS28-ESR, **e)** corticosteroid-sparing effect. Differences between basal and final follow-up were evaluated. Multivariable linear regression was used between the three groups.

Results: We studied 263 RA-ILD patients (mean age 64.6±10 years) [ABA_{MONO} (n=111), ABA_{MTX} (n=46) and $ABA_{NON-MTX}$ (n=106)]. At baseline, ABA_{MONO} patients were older (67±10 years) and took higher prednisone dose (10 [IQR 5-15] mg/day). There was no statistically significant differences in sex, seropositivity, ILD patterns, FVC, DLCO or disease duration. In all groups, most patients experienced stabilization or improvement in FVC, DLCO, dyspnea, HRCT as well as improvement in DAS28-ESR. A statistically significant difference between basal and final follow-up was only found in corticosteroid-sparing effect in ABA_{MTX} or $ABA_{NON-MTX}$(Figure 1**).** However, in the multivariable analysis, there were no differences in any outcome between the three groups(Table 1).

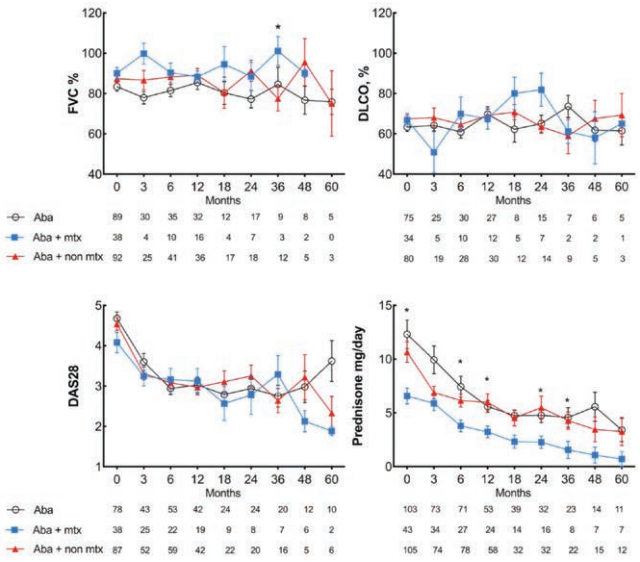

Figure 1.

Conclusion: In caucasian individuals with RA-ILD, ABA_{MONO} or ABA_{MTX} or $ABA_{NON-MTX}$ seems to be equally effective and safe. However, a corticosteroid-sparing effect is only observed in combined-ABA.

POS0514

IMPORTANCE OF BODY MASS MEASUREMENT AND THE GRIP STRENGTH TEST TO PREDICT FALLS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Tada[1], Y. Yamada[2], K. Mandai[3], N. Hidaka[1]. [1]*Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan*; [2]*Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan*; [3]*Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan*

Background: We previously reported that the prevalence of sarcopenia was 28% in patients with rheumatoid arthritis (RA) in a cohort study [1]. RA patients have a high risk of falls and fractures [2]. However, the predictors of falls and fractures in RA patients are not known.

Objectives: Whether evaluation of muscle mass and function at baseline could predict falls and fractures during four-year follow-up was investigated.

Methods: The four-year follow-up data from a prospective, observational study (CHIKARA study: Correlation researcH of sarcopenIa, sKeletal muscle and disease Activity in Rheumatoid Arthritis) were used. Muscle mass was measured by a body impedance analyzer, and leg muscle mass was calculated. The leg muscle score (max: 100, min: 0) reflected the ratio of leg muscle mass to overall weight. Grip strength as an indicator of muscle function was evaluated using a digital, hand-held, isokinetic dynamometer. The correlations between muscle mass or function and falls or fractures were analyzed by survival rates and Cox hazard ratios. Leg muscle mass and grip strength were investigated by receiver operating characteristic (ROC) curve analysis for correlations with falls or fractures.

Results: A total of 100 RA patients (female: 78%, mean age: 66.1 years) were enrolled; 35 patients had falls, and 19 patients had fractures during the four-year follow-up. The leg muscle score, grip strength, age, and fractures at baseline were significantly correlated with falls. The cut-off values of the leg muscle score and grip strength were calculated to be 84.5 points (sensitivity: 0.79, specificity: 0.43) and 15.9 kg (sensitivity: 0.56, specificity: 0.70), respectively, by ROC curve analysis. The patients were divided into four groups by their leg muscle scores and grip strength; the numbers of falls and fractures are shown in Table 1 for each group. The fall-free survival rate was significantly lower in the group with low leg muscle score and low grip strength (35.3%) than in the other groups (P=0.002) (Figure 1). The hazard ratio for the both low group was significantly increased, 3.6-fold (95%CI: 1.1-11.5), compared to that in the both high group.

Table 1. Numbers of falls and fractures by category of leg muscle score and grip strength

	LG + GS+ (n=34)	LG - GS+ (n=12)	LG + GS- (n=37)	LG - GS- (n=17)	P value*
Falls, N	6	5	15	11	0.010
Fractures, N	3	4	6	6	0.072

LG+: leg muscle score >84.5 points, GS+: grip strength >15.9kg, LG-: leg muscle score ≤84.5 points, GS+: grip strength ≤15.9kg *: compared in four groups by Kruskal-Walls test.

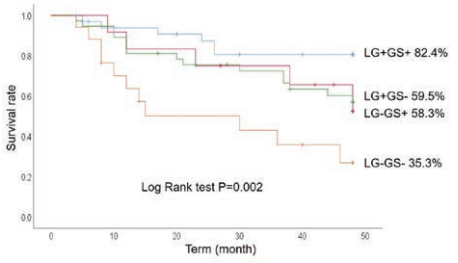

Figure 1. Fall-free survival rate in the four groups

Conclusion: RA patients with both low leg muscle score and low grip strength at baseline were at high risk for falls during the four-year follow-up period. Evaluation of muscle mass and function can predict falls in RA patients.

POS0515

FIBROMYALGIA IN MEXICAN PATIENTS WITH RHEUMATOID ARTHRITIS

L. D. Fajardo Hermosillo[1]. [1]*Instituto Mexicano del Seguro Social, Centro Médico Nacional de Occidente, Rheumatology, Guadalajara, Mexico*

Background: Rheumatoid Arthritis (RA) is a disabling chronic inflammatory disease that shows an unpredictable and severe clinical course [1]. Global assessment, functional status and disease activity of patients with RA can be influenced also by non-inflammatory factors as concomitant presence of fibromyalgia (FM) [1,2]. FM occur up to 20% in RA patients, who present chronic widespread pain, fatigue and cognitive symptoms that impacts achieving a complete disease remission, having more comorbidities, bearing a higher medical cost and finally exhibiting a worse quality of life [1,3,4]. Range of manifestations of FM varies according ethnical and cultural differences between patients [1]. Here is presented the impact of fibromyalgia in Mexican patients with RA.

Objectives: To determinate the frequency and factors associated to fibromyalgia in Mexican RA patients.

Methods: 624 patients with RA that fulfilled ACR/EULAR 2010 criteria (≥18 years) from a Mexican population recruited from 2012 to 2020 were examined. Patients with or without presence of FM diagnosed by ACR 2010/2011 criteria were included. Demographic factors, clinical features, disease activity measured using DAS28 (Disease Activity Score 28-joint counts), functional status evaluated by HAQ (Health Assessment Questionnaire), comorbidities and pharmacologic treatments were explored for RA patients with and without FM. Charlson's comorbidity index (CCI) was used to analyze comorbidities. Chi-square, Student´s-t, U Mann-Whitney tests were performed by univariate analysis and logistic regression was executed by multivariate analysis adjusted for age and gender. Statistical tests were conducted at 5% level of significance.

Results: Of 624 patients with RA 88.8% were women. The mean age [standard deviation (SD)] was 55.0 (12.3) years. The mean of time at onset of RA (SD) was 11.2 (9.1) years. A total of 311(49.8%) patients had FM; of them 91.6% were women and the mean age (SD) was 54.5 (12.2) years. In the univariate analysis RA patients with FM were more likely to be older and smokers, have seropositive RA, higher body mass index and longer time at onset of RA, show worse functional status by HAQ and more radiographic progression, present more extra-articular and Sicca manifestations, exhibit increased demand of hip and knee arthroplasty, also reveal a higher frequency of comorbidities including depression, osteoporosis and type 2 diabetes mellitus, besides to use a greater number of disease-modifying anti-rheumatic drugs (DMARDs), more biologic agents and higher doses of corticosteroids. Also, CCI was higher in RA patients with FM. Nevertheless, no differences were found for RA disease activity in both groups. In multivariate analysis, higher score of CCI (OR 1.21, 95% CI 1.01–1.44, p=0.037) remained significant in RA patients with FM.

Conclusion: This study suggests that RA patients from Mexico have high prevalence of the FM. Those with FM have a worse functional status, a higher frequency and score of comorbidities that impact in a reduction of their quality of life. On the other hand, no differences were found for RA disease activity in both groups. However, these observations must be confirmed in larger and prospective studies.

POS0516 REDEFINING THE CLINICAL AND LABORATORY FEATURES OF RHEUMATIC PLEURAL EFFUSION: A 30-CASE SERIES

S. Minoda[1], R. Sada[2], S. Matsushita[2], Y. Nakayama[3], H. Akebo[2], Y. Tsugihashi[4], H. Ishimaru[2], K. Hatta[2]. *[1]Osaka University Graduate School of Medicine, Department of Respiratory Medicine and Clinical Immunology, Osaka, Japan*; *[2]Tenri Hospital, Department of General Internal Medicine, Nara, Japan*; *[3]Graduate School of Medicine, Kyoto University, Department of Rheumatology and Clinical Immunology, Kyoto, Japan*; *[4]Tenri Health Care University, Department of Health Care, Nara, Japan*

Background: Rheumatoid pleural effusion (RPE) is a common extra-articular complication in patients with rheumatoid arthritis (RA). Previous studies have shown that RPE usually occurs in middle-aged men with rheumatoid factor (RF)-positive RA. RPE usually has features of pleural fluid acidosis, high lactate dehydrogenase (LDH) levels, and very low glucose levels[(1)]. However, to the best of our knowledge, these findings were based on very few case series and reports, and most of these reports were published by the early 2000s[(1, 2)].

Objectives: To investigate the clinical and laboratory characteristics and typical clinical courses of patients with RPE in a single centre of Japan since the beginning of the 21st century.

Methods: Medical records of RPE patients were retrospectively reviewed between May 2006 and September 2020. RPE was identified by fulfilling these five conditions: (1) confirmation of the RA diagnosis; (2) having an exudative pleural effusion according to Light's criteria; (3) negative results of pleural fluid culture; (4) negative results of pleural fluid cytology; and (5) exclusion of a parapneumonic effusion or empyema defined as no antibiotic use or ineffectiveness of antibiotics during the clinical course. Patients were divided into two groups according to their age at diagnosis: <60 years (Group A) and ≥60 years (Group B).

Results: A total of 30 cases of RPE were included in the study. The median age was 71 years (interquartile range [IQR], 66–78 years). Of these patients, 16 (53%) were women. The median disease duration of RA was 98 months (IQR, 8–162 months). The two groups comprised six patients aged <60 years old and 24 patients ≥60 years. The median age was 54 years (IQR, 49–56 years) in Group A and 74 years (IQR, 69–78 years) in Group B. The median disease duration of RA was longer in Group B than that in Group A (132 *vs*. 3 months, p=0.008). Compared with Group A, Group B had fewer patients with fever (14% *vs*. 83%, p=0.003), and had lower serum C-reactive protein levels (3.3 *vs.* 11.1 mg/dL, p=0.03). Moreover, Group B was more likely to show mild inflammatory pleural fluids with higher pH (7.5 *vs.* 7.2, p=0.005) and lower LDH levels (155 *vs*. 1810 IU/L, p=0.046). Corticosteroids were started or increased in five (83%) and nine (38%) patients, and biologic disease-modifying anti-rheumatic drugs were started in one (17%) and two (8%) patients in groups A and B, respectively. One patient (16%) died within 5-years in Group A, and seven patients (29%) died in Group B.

Conclusion: In contrast to previous studies, RPE was seen in older patients as well as middle-aged adults, and the pleural fluid analysis in older patients with RPE showed milder inflammation than the middle-aged patients.

Table 1. Comparison of clinical and laboratory findings between Group A and Group B.

POS0517 A LONGITUDINAL STUDY OF SARCOPENIA, LOCOMOTIVE SYNDROME, AND FRAILTY IN PATIENTS WITH RHEUMATOID ARTHRITIS: FROM THE CHIKARA STUDY

K. Mandai[1], M. Tada[2], Y. Yamada[3], T. Koike[4,5], T. Okano[3], N. Hidaka[2], H. Nakamura[3]. *[1]Osaka Saiseikai Nakatsu Hospital, Department of Orthopedic Surgery, Osaka, Japan*; *[2]Osaka City General Hospital, Department of Orthopedic Surgery, Osaka, Japan*; *[3]Osaka City University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka, Japan*; *[4]Osaka City University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan*; *[5]Search Institute for Bone and Arthritis Disease (SINBAD), Department of Orthopedic Surgery, Shirahama, Japan*

Background: Rheumatoid arthritis (RA) patients have a high frequency of sarcopenia, and they commonly have reduced physical function. We previously reported that the prevalence of sarcopenia was 28%, that of frailty was 18.9%, and that of pre-frailty was 38.9% in RA patients[1,2], and 13.2% of RA patients developed sarcopenia within a year [3].

Objectives: To investigate the risk factors for new onset of sarcopenia, locomotive syndrome, and frailty in patients with RA and the course of each disease.

Methods: Two-year follow-up data from the rural group of the prospective, observational CHIKARA study were used. Sarcopenia was diagnosed using the criteria of the Asian Working Group for Sarcopenia 2014, locomotive syndrome was diagnosed using locomotive 5, and frailty was diagnosed using the basic checklist. New onset of the disease over the 2-year follow-up period was studied, excluding cases that had the disease at baseline. Improvement was defined as cases with disease at baseline that no longer met the diagnostic criteria after 2 years. Differences in the characteristics of each disease were tested using the Chi-squared test and the paired *t*-test.

Results: The 81 patients with RA (82.7% female) had mean age 66.9±11.5 years, mean DAS28-ESR 2.9±1.2, methotrexate use in 81.5% (with a dose of 9.9±2.7 mg/week), and glucocorticoid (GC) use in 22.2% (with a dose of 3.1±1.7 mg/week). The baseline prevalence was 44.4% for sarcopenia, 35.8% for locomotive syndrome, and 25.9% for frailty, and the new onset rate was 4.4% for sarcopenia, 15.4% for locomotive syndrome, and 13.3% for frailty. Of the patients with each disease at baseline, 36.1% had sarcopenia, 20.7% had locomotive syndrome, and 33.3% had frailty, and of those with each disease at 2 years, 36.1% had sarcopenia, 20.7% had locomotive syndrome, and 33.3% had frailty. The new onset sarcopenia and locomotive syndrome groups had significantly higher rates of GC use (p=0.036, p=0.007, paired *t*-test) and significantly higher doses (p=0.01, p=0.001, paired *t*-test) than the groups without new onset sarcopenia and locomotive syndrome. High baseline disease activity was an independent predictor of new onset of locomotive syndrome on multivariate logistic regression analysis (OR=3.21, p=0.015).

Conclusion: The new onset rates at 2 years were 4.4% for sarcopenia, 15.4% for locomotive syndrome, and 13.3% for frailty. In the new onset sarcopenia and locomotive syndrome groups, both GC use and dosage were significantly higher.

POS0518

DIAGNOSTIC VALUE OF MUSCLE STRENGTH TESTS FOR THE DIAGNOSIS OF SARCOPENIA IN RHEUMATOID ARTHRITIS PATIENTS

O. Dobrovolskaya[1], A. Efremova[1], N. Toroptsova[1], O. Nikitinskaya[1], A. Feklistov[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Department of osteoporosis, Moscow, Russian Federation*

Background: Motor disorders in patients with rheumatoid arthritis (RA) may be associated with sarcopenia (SP). The frequency of secondary SP in RA patients reaches 17 - 37% [1, 2]. Currently, in patients with RA muscle strength is evaluated by methods proposed in geriatric practice [3].
Objectives: To determine the sensitivity, specificity, diagnostic accuracy, positive and negative predictive value of handgrip strength (HS) and chair stand test (5-times sit-to-stand, CST) for the diagnosis of sarcopenia (SP) in women with rheumatoid arthritis (RA).
Methods: 87 women (aged 40-75 years) with RA were enrolled in the study. We did not include patients with aseptic bone necrosis, femoral and knee endoprostheses and comorbidity that negatively affected on the bone tissue. All patients underwent handgrip strength by mechanical dynamometer and CST. Handgrip strength less than 16kg and CST more than 15 seconds were the criteria for probable SP. Assessment of muscle mass was carried out by dual-energy x-ray absorptiometry («Discovery A» Hologic, USA). Reduced muscle mass was determined as a decrease in appendicular muscle mass (AMM) < 15kg or appendicular mass index (AMI) < 5.5kg/m2. Confirmed SP was diagnosed when there was a combination of low muscle strength and reduced muscle mass. For both tests of muscle strength assessment, the sensitivity, specificity, diagnostic accuracy of the method, as well as their positive and negative predictor value for the diagnosis of SP were calculated.
Results: Low handgrip strength and 5-times CST more than 15 seconds were found in 63 (72%) and 54 (62%) women, respectively. Among them only 20 (23%) patients had low AMM or AMI, so in these women SP was confirmed. For the handgrip strength the sensitivity of the method was 95%, and the specificity - only 34%, the diagnostic accuracy was 48%. The positive prognostic value of this test was 30%, and the negative value - 96%. The sensitivity, specificity and diagnostic accuracy of the CST were significantly lower than the handgrip strength and amounted to 50%, 21% and 28%, respectively. The prognostic value of this test, both positive (16%) and negative (58%), was also significantly lower than the assessment of handgrip strength in RA patients.
We evaluated the diagnostic value of combination of two tests to identify individuals with probable SP: the sensitivity, specificity and diagnostic accuracy were 65%, 30% and 39%, respectively. Negative and positive predictive values were 71% and 24%, respectively, for combination of 2 tests, which was better than using only CST, but worse than using only hand dynamometry.
Conclusion: Muscle strength tests proposed by the European Working Group on Sarcopenia in Older People have a low specificity, diagnostic accuracy and positive predictive values for detecting SP in RA patients, which requires the development of other methods of the first step of diagnosis of SP in RA patients.

POS0519

BONE MINERAL DENSITY, LEAN AND FAT MASS IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

N. Toroptsova[1], O. Dobrovolskaya[1], A. Feklistov[1], O. Nikitinskaya[1], A. Efremova[1], N. Demin[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Department of osteoporosis, Moscow, Russian Federation*

Background: The relationship between lean mass (LM), fat mass (FM) and bone mineral density (BMD) remains controversial. Some population studies have emphasized the positive association between them, while others have found an inverse relationship. RA patients are characterized by a decrease in muscle mass and an increase in fat mass. Such changes in body composition may be associated with low BMD.
Objectives: To study the relationship between BMD, LM and FM in postmenopausal women with RA.
Methods: 68 postmenopausal women with RA (median age 59 [54; 63] years) were included in the study. BMD and body composition were evaluated using two-energy X-ray absorptiometry. Correlation analysis between body composition parameters and BMD was performed with the Spearman method, correlation coefficients R for p<0.05 are presented.
Results: The average L1-L4 BMD was 0,92±0,16g/cm^2, total hip BMD - 0,84±0,15g/cm^2 and femoral neck - 0,73±0,13g/cm^2. 33 (48.5%) women had osteopenia, and 17 (25.0%) - osteoporosis (OP). Low appendicular LM was found in 5 (7.4%) and low appendicular muscle index (appendicular LM/height^2, AMI) – in 10 (14.7%) patients. Overfat was revealed in 47 (69.1%) women, but only 20 (29.4%) women had BMI corresponding to obesity. The positive correlations between BMD in L1-L4, total hip and femoral neck regions and body weight (R=0.46, R=0.56 and R=0.50, respectively), trunk fat (R=0.4, R=0.51 and R=0.37, respectively), total FM (R=0.27, R=0.43 and R=0.34, respectively), trunk LM (R=0.55, R=0.54 and R=0.51, respectively), total LM (R=0.51, R=0.50 and R=0.52, respectively), appendicular LM (R=0.31, R=0.29 and R=0.37, respectively) and AMI (R=0.26, R=0.33 and R=0.51, respectively) were found out. In the multivariate linear regression analysis total LM was associated with BMD of lumbar spine (β=0.638, p=0.001) and total hip (β=0.473, p=0.008), and AMI - with femoral neck BMD (β=0.360; p=0.014). We found that FM hadn't a significant effect on BMD in any region.
Conclusion: 73.5% of patients with RA had a reduced BMD, and 14.7% women – low AMI. LM was positively associated with BMDs in different regions of interest, but FM had no effect on BMD. Further researches are needed to identify associations between body composition, inflammatory activity and bone health in patients with RA.

POS0520

ASSOCIATIONS BETWEEN THE NEOVASCULARIZATION OF CAROTID ATHEROSCLEROTIC PLAQUES, LIPID PARAMETERS AND IMMUNOLOGICAL DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Gerasimova[1], T. Popkova[1], O. Pogorelova[2], O. Fomicheva[3], I. Kirillova[1], T. Balakhonova[2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases Laboratory, Moscow, Russian Federation*; [2]*National Medical Research Center of Cardiology, Department of functional diagnostics, Moscow, Russian Federation*; [3]*National Medical Research Center of Cardiology, 4 cardiology department, Moscow, Russian Federation*

Background: Development of carotid atherosclerotic plaques (CAP) in patients (pts) with rheumatoid arthritis (RA) is associated with accumulation of traditional risk factors and immunological disorders. CAP neovascularization is associated with its' inflammation and increasing vulnerability. Therefore, early detection of CAP neovascularization is important for prevention of potential cardiovascular complications, preferably using a non-invasive technique, such as contrast-enhanced ultrasound (CEUS) of the carotid arteries.
Objectives: to identify the relationship between the severity of CAP neovascularization, lipid parameters and RA-related parameters.
Methods: Evaluation of 23 RA pts, 8 males and 15 females, mean age 61 [58; 65] years, with a longstanding disease (7 [3;12] years), seropositivity for IgM rheumatoid factor (RF) (76%) and anti-cyclic citrullinated peptide (ACCP) (62%) and moderate clinical disease activity (DAS 28 3,9 [3,2;4,8]). Nineteen RA pts (83%) received Methotrexate, 35% - biological agents, 35% - low-dose glucocorticoids. All patients underwent bilateral CEUS of the carotid arteries using a PHILIPS IU22 ultrasound system with 3-9 MHz linear array transducer and i/v administration of SonoVue contrast agent. The severity of carotid intraplaque neovascularization (IPN) was visually assessed on a scale from 0 to 3 (Shah et al. 2007): 0 - no neovascularization, 1 (mild) - limited to moderate neovascularization, 2 (severe) - extensive appearance of neovascularization, 3 - in the presence of a pulsating vessel in the plaque image.
Results: Carotid IPN was found in all RA pts. Grade 1 of neovascularization was established in 39% pts (group I) and Grade 2 - in 61% pts (group II). Groups were comparable in terms of age, sex, body mass index, smoking, disease duration and activity RA (DAS 28 score). The degree of carotid IPN positively correlated with the LDL-C level (R = 0,46, p=0,04), and the TG level (R=0,56, p=0,01) and negatively correlated with the HDL-C level (R= -0,52, p=0,02) in all pts. The degree of neovascularization was also associated with RA duration (R=0,52, p<0,05) and ACCP-positivity (R=0,57, p=0,007). Aforementioned correlations were significant for both groups of RA pts. No association was found between the severity of IPN and the levels of RF, DAS28. Association between the degree of carotid stenosis and CRP concentrations (R=-0,73, p<0,05) was found in pts of group II.
Conclusion: CEUS of carotid arteries demonstrated the presence of a predominantly extensive carotid IPN in RA pts. Cases of more severe carotid IPN were associated with lipid parameters (positively with the LDL-C, TG levels and negatively with the HDL-C level), RA duration and ACCP-positivity. The relationship between the degree of carotid artery stenosis and CRP requires additional studies to determine the role of immunological disorders in the development of carotid intraplaque neovascularization in RA pts.

POS0521 FACTORS ASSOCIATED WITH SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Mena-Vázquez[1], F. G. Jiménez-Núñez[1], M. Rojas-Giménez[2], L. Cano Garcia[1], S. Manrique Arija[1], A. Fernandez-Nebro[1]. [1]*Instituto de Investigación Biomédica de Málaga (IBIMA). Hospital Regional Universitario de Málaga (HRUM), Reumatología, Málaga, Spain*; [2]*Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC). UGC de Reumatología, Hospital Universitario Reina Sofía de Córdoba., Reumatología, Córdoba, Spain*

Objectives: To describe the prevalence of subclinical atherosclerosis measured as carotid intima-media thickness (cIMT) in patients with rheumatoid arthritis (RA) and to analyze the associated factors.

Methods: We performed an observational study of 60 patients with RA and 60 sex and age-matched controls. Patients with dyslipidemia were excluded. The main variable was the cIMT measured by ultrasound. The maximum cIMT was measured and atheromatous plaque was defined as focal thickening of the arterial wall protruding toward the lumen and measuring >0.5 mm or more than 50% of the neighboring cIMT. The other variables included were clinical and laboratory values, lipid metabolism, the 28-joint Disease Activity Score (DAS28), International Physical Activity Questionnaire (METs) and Adherence to a Mediterranean diet (MEDAS). Descriptive, bivariate and two multivariate models were constructed to identify factors associated with pathologic cIMT in all subjects and other in RA patients.

Results: The baseline characteristics of both groups are shown in Table 1. The RA patients did not have differences in the mean (SD) of maximum cIMT in relation to the controls (0.77 [0.1] vs 0.75 [0.1]; p = 0.392), nor in the number of plaques (16 [26.7%] vs 10 [16.7]; p = 0.184). The factors associated with maximum cIMT in the total sample were male sex (ß= 0.182; p = 0.039), age (ß = 0.010; p <0.001), METs (ß= -2.19; p = 0.008), MEDAS (ß = -0.177; p = 0.038); While the factors associated with maximum cIMT in patients with RA were: male sex (ß = 0.155; p = 0.003), age (ß = 0.005; p = 0.007), MEDAS (ß = -0.022; p = 0.017), DAS28 (ß = 0.036; p = 0.003) and ACPA (ß = 0.082; p = 0.052).

Table 1. Baseline characteristics of 60 patients with RA and 60 controls.

Variable	Patients n=60	Controls n=60	p-value
Age in years, mean (SD)	54.0 (11.1)	54.2 (110.4)	0.943
Female sex; n (%)	53 (88.3)	51 (85.0)	0.591
Smoking			0.300
Never smoked, n (%)	27 (45.8)	30 (54.5)	
Exsmoker, n (%)	23 (39.0)	14 (25.5)	
Active smoker, n (%)	9 (15.3)	11 (20,0)	
BMI (kg/m^2), mean (SD)	28.0 (5.5)	27.3 (4.9)	0.540
MET-minute, median (IQR)	533.2 (605.1)	809 (716.9)	0.028
MEDAS, median (IQR)	9.4 (1.8)	9.1 (2.1)	0.349
Progression of RA, months, mean (SD)	119.7 (84.1-170.5)	-	-
Diagnostic delay, months, median (IQR)	5.7 (5.1-14.4)	-	-
Erosions, n (%)	25 (43.1)	-	-
RF >10, n (%)	45 (75.0)	0 (0.0)	<0,001
ACPA >20, n (%)	48 (80.0)	0 (0,0)	<0,001
High-sensitivity CRP (mg/dl), median (IQR)	8.1 (4.2)	2.0 (4.5)	0.009
ESR (mm/h), median (IQR)	21.1 (16.6)	13.9 (12.3)	0.008
DAS28 at protocol, mean (SD)	3.1 (2.2-4.2)	-	-
Synthetic DMARDs, n (%)	52 (88.1)	-	-
Methotrexate, n (%)	36 (61.0)	-	-
Leflunomide, n (%)	6 (10.2)	-	-
Sulfasalazine, n (%)	7 (11.9)	-	-
Hydroxychloroquine, n (%)	4 (6.8)		
Biologic DMARDs, n (%)	32 (54.2)	-	-
Anti TNF-α, n (%)	23 (39.0)	-	-
Jak inhibitor, n (%)	1 (1.7)	-	-
Anti-IL-6, n (%)	6 (10.2)	-	-
Abatacept, n (%)	1 (1.7)	-	-

Abbreviations: RA, rheumatoid arthritis; ACPA, anti-citrullinated peptide antibodies; RF, rheumatoid factor; SD, standard deviation; MEDAS: Mediterranean Diet Adherence Survey; DAS28, 28-joint Disease Activity Score; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; DMARD, disease-modifying antirheumatic drug; IL-6, interleukin 6; Anti TNF, anti–tumor necrosis factor.

Conclusion: In patients with well-controlled established RA, subclinical atherosclerosis is associated, in addition to sex, age, and mediterranean diet, with inflammatory activity and ACPA value.

POS0522 PREVALENCE OF BRONCHIECTASIS IN RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

L. Martin[1], L. Prisco[1], W. Huang[1], G. Mcdermott[1], N. Shadick[1], T. Doyle[2], J. Sparks[1]. [1]*Brigham and Women's Hospital, Rheumatology, Boston, United States of America*; [2]*Brigham and Women's Hospital, Pulmonology, Boston, United States of America*

Background: Bronchiectasis is a known extra-articular manifestation of rheumatoid arthritis (RA) and can lead to decreased quality of life as well as increased risk for infection and mortality. Understanding the burden of bronchiectasis in RA may lead to a better understanding of pathogenesis and improved management. We performed a systematic review and meta-analysis to determine the prevalence of bronchiectasis in RA.

Objectives: We investigated the prevalence of RA-related bronchiectasis (RA-BR) using a systematic review and meta-analysis.

Methods: We followed the PRISMA-P 2015 guideline for systematic reviews and registered this analysis (ID#199080) on PROSPERO. We queried PubMed and EMBASE databases using the search strategy "rheumatoid arthritis; AND; bronchiectasis" as of July 31, 2020. The inclusion and exclusion criteria were assessed for study eligibility by two independent abstractors. Exclusion criteria included: (1) non-primary literature (i.e., review articles, editorials); (2) case reports involving less than 5 patients; (3) published in a language other than English; (4) did not relate to both RA and bronchiectasis; and (5) studies not involving humans (e.g., mouse models). After the initial screen, we conducted a full text review to verify that inclusion criteria were met: (1) reported frequency of RA-BR and denominator of all RA patients in the study sample. Data including type of study design, method of RA-BR detection, and RA characteristics were extracted by two independent abstractors. We performed meta-analyses using random effects models to estimate prevalence of RA-BR among RA overall and restricted to retrospective or prospective studies.

Results: Out of a total of 208 studies, 37 studies were identified that reported frequency of RA-BR among RA. The included studies had heterogeneous methods to identify RA-BR that were based on either clinical or research chest computed tomography (CT) imaging and had varying methods to adjudicate images. Some studies focused on patients with respiratory symptoms or suspected RA-associated interstitial lung disease (RA-ILD). There were a total of 8,646 patients with RA, and 612 were identified as having RA-BR. The pooled overall prevalence of RA-BR in the random effects meta-analysis was 18.2% (95%CI 13.3-23.7%, Figure 1). Among prospective studies (n=24), the prevalence of RA-BR in the meta-analysis was 20.7% (95% CI 14.7-27.4%). Among retrospective studies (n=13) reporting RA-BR, the prevalence was 14.5% (95% CI 7.2-23.7%). Prevalence was lowest in retrospective studies where RA-BR was identified through clinical care (e.g., two large retrospective studies that investigated 4,000 and 1,129 RA patients reported RA-BR prevalence of 0.6% and 2.7%, respectively). The two largest prospective studies that incorporated a research protocol performing chest CT imaging on all enrolled patients investigated 150 and 332 patients with RA and reported a RA-BR prevalence of 8.0% and 9.6%, respectively. Smaller studies of both study design types generally reported higher prevalence of RA-BR.

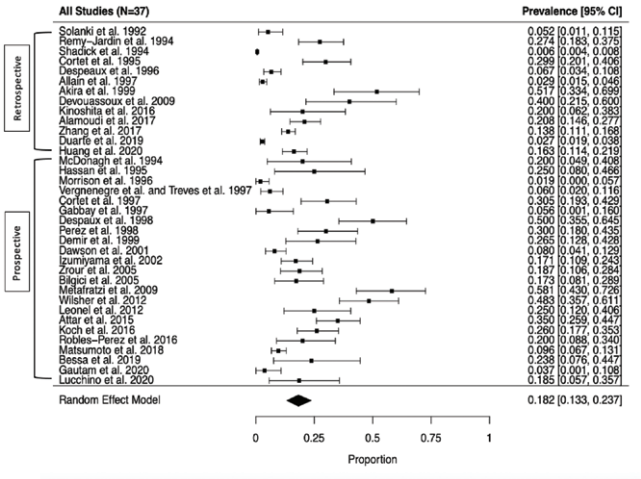

Figure 1. Pooled prevalence of RA-related bronchiectasis in RA among all studies identified (n=37).

Conclusion: The prevalence of RA-BR in this systematic review and meta-analysis was 18.2%, emphasizing that bronchiectasis is a common extra-articular feature of RA. However, some studies may have identified subclinical RA-BR through research imaging or RA-BR may have been secondary to RA-ILD. Future studies should standardize methods to identify RA-BR cases and investigate the natural history and clinical course given the relatively high prevalence that we report.

POS0523 RISK OF CARDIOVASCULAR DISEASE IN NEWLY DIAGNOSED RHEUMATOID ARTHRITIS: A CURRENT RISK ASSESSMENT

R. Raadsen[1], R. Hansildaar[1], M. Heslinga[1,2], A. W. van Kuijk[1], M. Nurmohamed[1,2]. [1]*Amsterdam Rheumatology and Immunology Center, Location Reade, Rheumatology, Amsterdam, Netherlands*; [2]*Amsterdam Rheumatology and Immunology Center, Location VU University Medical Center, Rheumatology, Amsterdam, Netherlands*

Background: Patients with rheumatoid arthritis (RA) are known to have an increased risk of developing, mainly ischemic cardiovascular diseases (CVD). This is partly explained by a higher incidence of traditional CV risk factors as hypertension and/or hypercholesterolemia but also due to the systemic inflammation characteristic to RA. RA is considered an independent CV risk by National and International CVD risk management guidelines, and therefore CVD risk screening is recommended. However, the implementation of CV risk management is often poorly performed in daily clinical practice.

Objectives: The aim of the current study was to investigate the cardiovascular disease risk of newly diagnosed RA patients, and review if and to what extent implementation of CVD risk management had previously taken place.

Methods: Every newly diagnosed RA patient in a large Dutch outpatient rheumatology clinic had CV screening within their first year post-diagnosis during a regularly scheduled visit, where among others smoking habits, blood pressure and lipid profile were measured. A 10-year cardiovascular risk was calculated using a modified SCORE calculator from www.u-prevent.com, which predicts the risk of myocardial infarction, stroke, heart failure, peripheral arterial disease and CV death based on several CV risk factors. To account for RA as a risk factor, the calculator multiplies the risk by 1.5, in accordance with the Dutch CV risk management guideline. The calculated 10-year cardiovascular morbidity risk was categorized in low (<10%), intermediate (10-19%) and high (≥20%), and the 10-year mortality risk was also categorized in low (<1%), intermediate (1-4%) and high (≥5%).

Results: A total of 53 patients were included up to this point. Of these, the average age was 57 (±8.5), and 39 (74%) were women. Mean systolic blood pressure was 129 (±17.7) mmHg, with 38 (72%) patients having hypertension. Mean total cholesterol, LDL and HDL were respectively 5.5 (±1.0) mmol, 3.43 (±0.82) mmol and 1.78 (±0.54) mmol, with 30 patients having hypercholesterolemia. The average calculated 10-year morbidity risk of all patients was 13%, and the mortality risk was 3%. Distribution of the 10-year risk in low, intermediate and high is presented in figure 1. Only one patient reported having previous used medication for hypercholesterolemia, but not at the time of enrollment in this study.

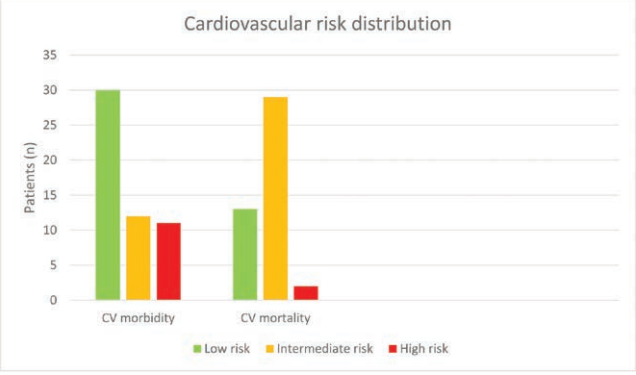

Figure 1. Distribution of 10-year cardiovascular risk in rheumatoid arthritis patients. CV = cardiovascular

Conclusion: 43% of newly diagnosed RA patients had an intermediate or high calculated 10-year CV morbidity risk, and 76% had an intermediate or high mortality risk. Patients with early RA still often have underdiagnosed and severely undertreated risk factors of CVD, such as hypertension and hypercholesterolemia. Early CV risk assessment and management in patients with RA is critical and needs to be implemented as standard care.

POS0524 CARDIOVASCULAR DISEASE RISK IN INFLAMMATORY ARTHRITIS PATIENTS STILL SUBSTANTIALLY ELEVATED IN 2020

R. Raadsen[1], F. Hooijberg[1], L. Boekel[1], E. Vogelzang[2], M. Leeuw[1], R. van Vollenhoven[3], W. Lems[1,4], G. J. Wolbink[1], A. W. van Kuijk[1], M. Nurmohamed[1,4]. [1]*Amsterdam Rheumatology and Immunology Center, location Reade, Rheumatology, Amsterdam, Netherlands*; [2]*Amsterdam University Medical Center, Vanderbilt University Medical Center, Medical Microbiology, Amsterdam, Netherlands*; [3]*Amsterdam Rheumatology and Immunology Center, Location Academic Medical Center, Rheumatology, Amsterdam, Netherlands*; [4]*Amsterdam Rheumatology and Immunology Center, Location VU University Medical Center, Rheumatology, Amsterdam, Netherlands*

Background: Patients with inflammatory rheumatic diseases such as rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) are at a higher risk for developing cardiovascular diseases (CVD) than the general population. This increased risk is partly due to a higher incidence of traditional cardiovascular (CV) risk factors, such as hypertension and dyslipidemia, and partly due to the underlying systemic inflammation. During the past two decades, the burden of the systemic inflammation has been reduced by more efficacious anti-inflammatory treatment, which somewhat attenuated the increased CV risk of rheumatic patients. However, it remains important to monitor the effects of these new treatment strategies on the prevalence of CVD in patients with a rheumatic disease in systematically controlled cohorts.

Objectives: The aim of the current report was to evaluate whether the CV risk of patients with inflammatory rheumatic diseases still differs from the general population, despite advances In anti-rheumatic treatment strategies.

Methods: In March 2020, all adult patients with an inflammatory rheumatic disease from the Amsterdam Rheumatology and Immunology Center, location "Reade" were systematically asked to participate in a prospective cohort study. The primary aim of this study was to monitor the impact of the COVID-19 pandemic on patients with inflammatory rheumatic diseases compared to age and sex matched healthy controls. Between April 26, 2020 and May 27, 2020, participants completed the first online questionnaire of the study. Amongst others, information on demographic data, including CV comorbidities and risk factors, and medication use was collected. The baseline characteristics and prevalence of CVD were compared between RA, PsA or AS and healthy controls.

Results: In total, 1455 consecutive patients with an inflammatory rheumatic disease (979 RA patients, 261 PsA patients and 215 AS patients), and 414 healthy controls completed the first questionnaire, as shown in table 1. CV comorbidities were more frequently reported in RA, PsA and AS patients compared to healthy controls; 107 (11%), 28 (11%) and 22 (10%) compared to 30 (7%), respectively.

Table 1. Biological DMARD usage in RA, PsA and AS patients

Patient characteristics	All patients (n=1455)	RA (n=979)	PsA (N=261)	AS (n=215)	Controls (n=414)
Mean age - yr	55 ± 13	58 ± 12	55 ± 13	48 ± 13	53 ± 13
Female sex - no (%)	934 (64)	728 (74)	119 (46)	87 (41)	298 (72)
BMI (IQR)	25 (23-28)	25 (22-28)	26 (24-30)	25 (22-28)	24 (22-27)
Smoking - no (%)	178 (12)	126 (13)	17 (7)	35 (16)	34 (8)
Cardiovascular disease – no (%)	157 (11)	107 (11)	28 (11)	22 (10)	30 (7)
Rheumatic medication - no (%)					
csDMARDs	877 (60)	712 (73)	148 (57)	17 (8)	N.A.
Oral glucocorticoids	161 (11)	139 (14)	17 (7)	5 (2)	2 (0.4)
TNF inhibitor	563 (39)	336 (34)	121 (46)	106 (49)	N.A.
IL-6 inhibitor	19 (1)	19 (2)	0	0	N.A.
IL-17 inhibitor	17 (1)	2 (0.2)	7 (3)	8 (4)	N.A.

Table 1. Baseline characteristics. Values are displayed as mean ± standard deviation (SD), median with interquartile range (IQR) or frequencies with percentages (%). RA = rheumatoid arthritis, PsA = psoriatic arthritis, AS = ankylosing spondylitis, BMI = body mass index, TNF = anti-tumor necrosis factor, IL = interleukin.

Conclusion: We demonstrated that the prevalence of CVD is approximately 1.5 times higher in patients with rheumatic diseases compared to healthy controls (11% vs. 7%, respectively). This corresponds with previous research, although the reported prevalence of CVD in PsA and AS patients is even higher compared to prior studies. This suggests that the CVD risk of patients with rheumatic diseases is still elevated in 2020 compared to the general population, despite the improved management of rheumatic disease activity. Therefore, adequate and timely treatment of CV risk factors remains relevant, not only in patients with RA, but in patients other rheumatic diseases as well.

POS0525 ARTHRITIC PAIN AS A SURROGATE MARKER FOR ASYMPTOMATIC CARDIOVASCULAR RISK FACTORS: OFFERING PRACTITIONERS A 'TEACHABLE MOMENT'

J. Sewell[1], S. M. Hussain[1], Y. Wang[1], A. Wluka[1], M. Carrrington[2], K. Samaras[3], F. Cicuttini[1]. *[1]Monash University, Department of Epidemiology and Preventive Medicine, School of Public Health and Preventive Medicine, Melbourne, Australia*; *[2]Baker Heart and Diabetes Institute, Pre-Clinical Disease and Prevention, Melbourne, Australia*; *[3]University of New South Wales, St Vincent's Clinical School of Medicine, Sydney, Australia*

Background: Cardiovascular diseases (CVD) are the number one cause of death worldwide. CVDs are linked to well established risk factors: obesity, hypertension (HTN), dyslipidaemia (DL) and diabetes mellitus (DM)[1]. While targeting risk factors reduces the burden of CVD, this is often challenging because they are largely asymptomatic and patients are therefore unlikely to seek medical attention. Arthritis, in contrast, causes pain and functional impairment prompting presentation to a healthcare practitioner. Patients with arthritis of varying aetiologies (such as osteoarthritis[2], gout[3], rheumatoid arthritis[4]) have been shown to have an increased risk of CVD.

Objectives: To examine the relationship between arthritis and DM, HTN and DL in adults of all age groups. A secondary objective was to examine whether this relationship existed independent of obesity.

Methods: Data from the 2017-18 Australian Bureau of Statistics National Health Survey included 13,776 participants, categorised into young (18-39 years), middle aged (40-64 years) and older (≥65 years) adults. Blood pressure, height and weight were measured. BMI was calculated and participants classified as obese (≥30 kg/m^2) or non-obese. HTN was defined as > 140/90mmHg. Participants were asked if they had arthritis of any form, DL or DM diagnosed by a doctor. Logistic regression models estimated odds ratios with 95% CI for prevalence of arthritis associated with CVD risk factors.

Results: Arthritis was reported by 3.9% of young adults, 28.8% of middle-aged adults, and 54.5% ofolderadults. In all three age groups, arthritis was associated with significantly increased odds of obesity, HTN, DL and DM. For example, in middle-aged adults, having arthritis was associated with increased odds of obesity (1.75, 95% CI 1.54-2.01), HTN (1.78, 1.60-2.04), DL (2.14, 1.84-2.49) and DM (1.64, 1.33-2.03). These associations remained statistically significant after adjustment for obesity.

Conclusion: Compared to those without arthritis, adults with arthritis were at increased risk of obesity, HTN, DM and DL. The increased risk of HTN, DM and DL was independent of obesity and tended to be higher in younger adults. These data suggest that a patient's presentation with symptomatic arthritis of any aetiology and at any age, may be used opportunistically as a "teachable moment" for screening for asymptomatic CVD risk factors in higher-risk individuals. This provides practitioners an opportunity to manage both arthritis and CVD risk in parallel, rather than in silos.

POS0526 SEXUAL FUNCTION IN MALE AND FEMALE PATIENTS WITH RHEUMATOID ARTHRITIS: A POST-HOC ANALYSIS OF THE FINCH STUDIES

L. F. Perez-Garcia[1], M. Micu[2], L. Gheyle[3], Z. Yin[4], Y. Tan[5], K. Chen[6], P. Papazian[7,8], K. Van Beneden[9], R. Dolhain[1], R. Westhovens[10]. *[1]Erasmus University Medical Centre, Department of Rheumatology, Rotterdam, Netherlands*; *[2]Rehabilitation Clinical Hospital, Rheumatology Division, 2nd Rehabilitation Department, Cluj-Napoca, Romania*; *[3]Galapagos NV, Clinical Research, Mechelen, Belgium*; *[4]Gilead Sciences, Inc., Department of Clinical Data Science, Foster City, United States of America*; *[5]Gilead Sciences, Inc., Clinical Research (Inflammation Therapeutic Area), Foster City, United States of America*; *[6]Gilead Sciences, Inc., Department of Clinical Data Science, Foster City, United States of America*; *[7]Pitié-Salpêtrière Hospital, Infectious Diseases Department, Paris, France*; *[8]Galapagos France, Medical Affairs, Puteaux, France*; *[9]Galapagos NV, Medical Affairs, Mechelen, Belgium*; *[10]University Hospitals Leuven, Department of Development and Regeneration, Skeletal Biology and Engineering Research Centre, Division of Rheumatology, Leuven, Belgium*

Background: While sexual function is impaired in a high proportion of patients with rheumatoid arthritis (RA), it is often neglected in patient care.[1] FINCH 1 (NCT02889796), FINCH 2 (NCT02873936) and FINCH 3 (NCT02886728) were Phase 3 studies to assess the safety and efficacy of filgotinib (FIL) for moderate-to-severe RA; patient-reported sexual function was also evaluated.

Objectives: To analyse disease characteristics associated with sexual function and explore the effect of FIL and adalimumab (ADA) on sexual function in males and females in the FINCH studies.

Methods: Post-hoc analyses included data from patients who were randomised and received ≥1 dose of study drug in the FINCH studies. Male and female subgroup analyses were performed to describe the correlation between baseline disease characteristics and baseline visual analogue scale (VAS) sexual function score (using Pearson correlation coefficient) and to assess the treatment effect on the change from baseline in VAS sexual function (mm) up to Week 52 (FINCH 1 and 3) or Week 24 (FINCH 2). Patients indicated how RA affected their ability to have sex during the last week using an exploratory 0–100 VAS (0: no effect; 100: complete inhibition). Changes from baseline were analysed with a mixed-effects model for repeated measures. All P values are nominal for exploratory purposes.

Results: Baseline characteristics are shown in the Table 1. Univariate analyses revealed significant positive correlations (P<0.05) between disease duration and baseline VAS sexual function score in male and female subgroups in FINCH 1; no significant correlations were seen in male and female subgroups of FINCH 2 and 3. In all studies, significant correlations (P<0.05) were observed between baseline VAS sexual function score and baseline disease characteristics (swollen/tender joint count 28, Disease Activity Score-28, Health Assessment Questionnaire Disability Index, 36-Item Short Form Survey, patient global VAS, pain VAS or fatigue) in males or females. In all studies, analysis of least-squares mean changes from baseline in VAS sexual function revealed improvements in both males and females on FIL as early as Week 2, until Week 52 (Week 24 in FINCH 2). Figure 1 shows data for FINCH 1.

Conclusion: Sexual function should be considered as an important patient outcome in RA treatment. At baseline in the FINCH studies, disease activity

negatively impacted sexual function in both male and female patients. Active treatment with FIL or ADA resulted in early and sustained improvements from baseline in sexual function.

POS0527 ACUTE KIDNEY INJURY (AKI) IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

A. Nakashima[1], K. Suzuki[1], H. Fujii[1], Y. Fujisawa[2], I. Mizushima[3], T. Zoshima[3], M. Kawano[3], H. Nomura[4]. *[1]Ishikawa Prefectural Central Hospital, Division of Nephrology and Rheumatology, Kanazawa, Japan; [2]Ishikawa-ken Saiseikai Kanazawa Hospital, Division of Internal Medicine and Rheumatology, Kanazawa, Japan; [3]Kanazawa University Hospital, Department of Rheumatology, Kanazawa, Japan; [4]Kanazawa University Hospital, Department of General Medicine, Kanazawa, Japan*

Background: Methotrexate has been an anchor drug for patients with rheumatoid arthritis (RA). However, it is strictly prohibited to prescribe MTX to patients with severely decreased renal function because it can induce a fatal adverse event such as pancytopenia in these patients. On the other hand, since the average age of RA patients is gradually increasing, and many of them already have mildly to moderately impaired renal function, their renal function can easily decrease to below the critical level of the estimated glomerular filtration rate. Therefore, new development of acute kidney injury (AKI) during MTX administration might induce a fatal adverse event, making the identification of patients susceptible to AKI very important.

Objectives: To clarify the frequency of AKI and the factors involved in it in RA patients.

Methods: Two hundred and fifty-two RA patients (211 females, 41 males, mean age 62.3 ± 12.5 years, disease duration 11.0 ± 9.5 years) diagnosed more than 3 years earlier and followed for more than 5 years, and also, others diagnosed ≥3 years earlier but followed for ≤5 years were enrolled. We measured BUN, Cr, RF and aCCP in patient serum, urinary proteins, urinary blood, and urinary casts and evaluated CDAI, SDAI, disease activity score (DAS) 28-CRP and DAS28-ESR. Steinbrocker functional classification and radiological grading were evaluated. History of diabetes mellitus, hypertension and hyperlipidemia was determined from the medical records. Medications for RA, including non-steroid anti-inflammatory drugs (NSAIDs), prednisolone, csDMARD (MTX, Tacrolimus, etc.), bDMARDs and tsDMARDs were evaluated. Estimated glomerular filtration rate (eGFR) was calculated by the new Japanese coefficient-modified Modification of Diet in Renal disease (MDRD) study equation. The criteria of AKI were that serum Cr increased by 0.3 mg /dl or increased by 1.5-fold between consecutive visits according to the KIDIGO criteria [1)] and the report of Leither et al[2)].

Results: Twenty (7.9%) patients developed AKI, 22 times. The causes of AKI were 10 infections, 6 dehydrations, 2 enteritis, 1 urticaria, 2 hypercalcemia due to VitD administration, and 1 ureteral stone. We divided our patients into group A (with AKI) and group B (without AKI). Group A was older (69.9±10.1 vs 61.7±12.6 years), had greater physician VAS (29.5±27.7 vs 15.7±18.3 mm), higher serum creatinine (0.79±0.19 vs 0.60±0.16 mg/dl), higher BUN (18.4±5.7 vs 15.1±4.4 mg/dl), lower eGFR(65.5±23.3 vs 86.4±22.4 ml/min), more frequent prednisolone administration (75.0% vs 41.9%), more frequent hyperlipidemia (50.0% vs 19.2%) and more frequent hypertension (60.0% vs 30.6%) than Group B by univariate analysis significantly (p<0.01). We then performed multifactorial analysis using logistic regression analysis. Greater physician VAS (OR 1.02, 1.00-1.04), lower eGFR (OR 1.04, 1.01-1.08) and prednisolone administration (OR 3.29, 1.02-10.63) were found as independent relevant factors for group A.

Conclusion: Our study indicated that AKI developed in RA patients and suggested that renal function decline and prednisolone administration may be implicated. RA patients with impaired renal function and prednisolone administration need to be treated with special attention to the onset of AKI.

POS0528 SCORES OF CARDIOVASCULAR RISK CALCULATORS AS PREDICTORS OF EARLY ATHEROSCLEROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Gerasimova[1], T. Popkova[1], D. Gerasimova[2], S. Glukhova[3], E. Nasonov[1,4], A. Lila[1,5]. [1]*V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases Laboratory, Moscow, Russian Federation*; [2]*Sechenov First Moscow State Medical University (Sechenov University), Department of Organization and Economics of Pharmacy, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Laboratories of Medical and Social Problems of Rheumatology, Moscow, Russian Federation*; [4]*Sechenov First Moscow State Medical University (Sechenov University), Department of Rheumatology, Moscow, Russian Federation*; [5]*Russian Medical Academy of Continuing Professional Education, Department of Rheumatology, Moscow, Russian Federation*

Background: Rheumatoid arthritis (RA) is a systemic inflammatory disease leading to significant increase in cardiovascular morbidity and mortality. Development of cardiovascular diseases (CVD) in RA patients is associated with the accumulation of traditional risk factors and immunological disorders. Carotid Artery Doppler Ultrasound (DUS) Exam is the gold standard to identify early atherosclerosis.
Objectives: To evaluate the cardiovascular risk and analyze its relationship with detection of early carotid artery atherosclerotic lesion in patients with rheumatoid arthritis (RA).
Methods: One hundred and nine RA patients (female/male 93/16), aged 45 to 60 without established CVD were included in the study. The median age was 52 [48; 54] years, duration of RA was 120 [36; 204] months, DAS28 was 4,7 [3,5; 5,6] points. 54% (n=59) of patients received methotrexate (median dose 20 [15;27]mg/week), 12% - leflunomide (20mg/day), 12% - sulfasalazine (2000mg/day), 40% - glucocorticoids (median dose 4 [2;8]mg/day), 44% - non-steroidal anti-inflammatory drugs. None of study participants had biologics or statins in their therapeutic regiments at the time of inclusion. CVD risk was calculated with mSCORE, RRS, ASSIGN, QRISK3, ERS-RA scales and results of Carotid Artery DUS imaging in all patients.
Results: Traditional risk factors were highly among RA patients without CVD, including: arterial hypertension - in 73%, dyslipidemia - 68%, overweight - 53%, family history of CVD - 43% and smoking - 39% patients. A combination of three traditional risk factors was found in 60% of patients with RA, and combination of two – in 25%. High risk was found in 5, 5, 14, 6, and 38% of patients according to mSCORE, RRS, ASSIGN, QRISK3, ERS-RA scales, respectively. Carotid atherosclerotic plaques were found in 30% of patients, more often in men (48%) than in women (28%, p=0,049), with similar prevalence regardless RA activity or stage od disease. Positive correlations of carotid intima-media thickness were established with scores of all CVD risk calculators: mSCORE (R = 0,50), RRS (R = 0,40), ASSIGN (R = 0,40), QRISK3 (R = 0,36), ERS-RA (R = 0,26), p <0,05 in all cases, as well as with age (R = 0,41; p = 0,04), the level of total cholesterol (R = 0,23; p = 0,01), systolic blood pressure (R = 0,66; p = 0,02), diastolic blood pressure (R = 0,33; P = 0,03), erythrocyte sedimentation rate (R = 0,26; p = 0,04), IL-6 levels (R = 0,65; p = 0,01). The sensitivity and specificity of the CVR algorithms in prognostication of atherosclerotic carotid artery lesions were 73 and 67% for mSCORE, 64 and 63% for RRS, 64 and 56% for ASSIGN, 73 and 49% for QRISK3, respectively, p<0.05 in all cases, 67 and 50% for ERS-RA, p=0,06.
Conclusion: RRS, mSCORE, ASSIGN, QRISK 3 calculators equally predicted the presence of carotid atherosclerotic plaques in RA patients. The optimal ratio of specificity and sensitivity is shown for the mSCORE scale. Stratification of CVR in RA patients should include assessment of the carotid intima-media thickness. mSCORE calculation and carotid intima-media thickness were the most informative methods identify CVR assessment in RA patients.

POS0529 ANTI-TNF AND METHOTREXATE PROTECT AGAINST RHEUMATOID ARTHRITIS ATHEROSCLEROSIS

M. Rojas-Giménez[1], M. Á. Puche Larrubia[1], I. Gómez García[1], J. Calvo Gutierrez[1], M. C. Ábalos-Aguilera[2], A. Escudero Contreras[1]. [1]*Reina Sofia University Hospital, Cordoba, Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC), Córdoba University (UCO), Córdoba, Spain., Cordoba, Spain*; [2]*Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC), Córdoba, Spain, Cordoba, Spain*

Objectives: To analyze the effect of differents anti-rheumatic treatments on the carotid intima-medial thickness (cIMT) in patients with Rheumatoid Arthritis (RA).
Methods: Controlled cross-sectional observational study of a cohort of patients with RA. 146 patients with RA (ACR/EULAR2010).cIMT was measured by semi-automatic carotid ultrasound.Other variables: atheroma plaques, bilateral plaques, DAS28-VSG, lipid metabolism, apoB, apoA1, apoB/apoA1, uric acid, homocysteine. Biological or conventional synthetic disease-modifying antirheumatic drug therapy (bDMARDs/csDMARDs), glucocorticoids. Descriptive, bivariate, Spearman's test and multivariate model were constructed to identify factors associated with cIMT.
Results: The baseline characteristics are shown in Table 1.Significant positive correlation was found between cIMT and apoB (r=0.22; p=0.014), apoB/apoA1 (r=0.18; p=0.044), cholesterol(r=0.23; p=0.006),triglycerides(r=0,21, p=0.013),uric acid(r=0.26; p=0.009),age(r=0.65, p>0.001),RF(r=0.16, p=0.05) homocysteine (r=0.5, p<0.001), BMI (r=0.19, p=0.023),CRP(r=0.18, p=0.032) and negative correlation with anti-TNFα treatment time(r=-0.20, p=0.02).Patients receiving bDMARDs alone or combined with csDMARDs had less cIMT than those taking only csDMARDs[median (IQR): 0.54 (0.50-0.63), 0.57(0.53-0.65) and 0.65(0.53-0.75); p=0.046].The factors associated with cIMT were age(ß= 0.007, p<0.001),anti-tnf-α treatment ever(ß= -0.06, p=0.027) and methotrexate treatment ever(ß= -0.07, p=0,08).

Table 1. Baseline characteristics

Variables	RA n=146
Epidemiological characteristics and comorbidities	
Age (years), mean (SD)	55.9 (13.1)
Female sex; n (%)	112 (76.7)
Smoker, n (%)	30 (21.6)
Arterial hypertension, n (%)	45 (30.8)
Diabetes mellitus, n (%)	5 (3.4)
Previous Cardiovascular disease, n (%)	10 (14.6)
Hyperlipidemia, n (%)	46 (31.5)
BMI (kg/m^2), median (IQR)	26.8 (23.4-29.7)
Clinical-laboratory characteristics	
Disease duration, years, median (IQR)	6.77 (2.2-14.2)
Erosions, n (%)	53 (36.6)
RF positive, n (%)	119 (81.55)
ACPA positive, n (%)	123 (84.2)
CRP (mg/dl), median (IQR)	4.8 (1.6-11.5)
ESR (mm/h), median (IQR)	12 (6-24)
DAS28 at protocol, median (IQR)	2.8 (2.1-3.7)
HAQ, mean (SD)	0.78 (0.6)
ApoB (mg/dl), mean (SD)	86.8 (21.8)
ApoA1 (mg/dl), mean (SD)	149.8 (32.7)
Cholesterol (mg/dl), mean (SD)	198.7 (37.3)
cLDL (mg/dl), mean (SD)	119.3 (30.3)
cHDL (mg/dl), median (IQR)	56 (47-70)
Triglycerides (mg/dl), median (RIQ)	92 (73-121)
Homocisteyne (mg/dl), median (RIQ)	2.08 (1.7-2.8)
cIMT mean (mm), median (IQR)	0.6 (0.53-0.7)
Atherosclerotic plaques, n (%)	51 (34.9)
Bilateral plaques, n (%)	22 (15.1)
Anti-rheumatic treatment	
Synthetic DMARDs ever, n (%)	146 (100)
Methotrexate ever, n (%)	132 (90.4)
Time with methotrexate (years), median (IQR)	4.4 (1.04-9.5)
Leflunomide ever, n (%)	83 (56.8)
Sulfasalazine ever, n (%)	13 (8.9)
Hydroxychloroquine ever, n (%)	99 (67.8)
Biological DMARDs ever, n (%)	76 (52.05)
Anti TNFα ever, n (%)	47 (32.2)
Time with antiTNF-α (years), mean (SD)	1.18 (2.8)
Jak inhibitor ever, n (%)	10 (6.8)
Anti-IL-6 ever, n (%)	28 (19.2)
Rituximab ever, n (%)	15 (10.3)
Glucocorticoids at protocol, n (%)	82 (56.5)
Glucocorticoids dose at protocol (mg), median (IQR)	5 (0-5)

Abbreviations: RF: rheumatoid factor; ACPA: anti-citrullinated peptide antibodies, cIMT: carotid intima media thickness; ApoB: apolipoprotein B, ApoA1: apolipoprotein A1, LDL: low-density lipoprotein; HDL: high-density lipoprotein; DAS28: 28-joint Disease Activity Score; HAQ: Health Assessment Questionnaire; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; IL-6: interleukin 6; Anti TNF, anti–tumor necrosis factor

Conclusion: biological disease-modifying antirheumatic drug therapy, in particular Anti TNFα, could protect against the development of atherosclerosis in RA

POS0530 HOW DOES MULTIMORBIDITY IMPACT ON THE DIRECT AND INDIRECT COSTS IN PATIENTS WITH RHEUMATOID ARTHRITIS?

P. H. Hsieh[1,2], C. Geue[1], O. Wu[1], E. McIntosh[1]. [1]*Institute of Health and Wellbeing, University of Glasgow, Health Economics and Health Technology Assessment, Glasgow, United Kingdom*; [2]*Tri-Service General Hospital, National Defense Medical Centre, Clinical Pharmacy Department, Taipei, Taiwan, Republic of China*

Background: Comorbidities are prevalent in patients with rheumatoid arthritis (RA) and associated with worse outcomes as well as higher economic burden. Little is known about the impact of multimorbidity on the direct and indirect costs

of RA. Evidence of the incremental scale of these multimorbidity costs will usefully inform RA interventions and policies.

Objectives: The aim of this study was to describe how multimorbidity impacts on the cost-of-illness, including direct and indirect costs, in patients with RA.

Methods: The Scottish Early Rheumatoid Arthritis (SERA) is a registry of patients newly presenting with RA since 2011. It contains data on patient characteristics, clinical outcomes, health-related quality of life, and employment status data. These data were linked to routinely recorded hospital admissions and primary care prescribing data. Direct costs were estimated by applying relevant unit costs to healthcare resource use quantities. Indirect cost estimates were obtained from information on employment status and hospital admissions, valued by age and sex specific wages. Two-part models (probit followed by generalized linear model) were used to estimate direct and indirect costs, adjusting for age, gender, and functional disability. The Charlson Comorbidity Index (CCI) score was calculated using patient ICD-10 diagnoses from hospital records. The number of comorbidities was categorized into "RA alone", "single comorbidity" and "multimorbidity (>1 comorbidity)".

Results: Data were available for 1,150 patients, 65.7% were female and a mean age of 57.5±14 years. The majority of patients only had RA (54.1%), followed by a single comorbidity (23.4%) and multimorbidity (22.5%). Annual total costs were significantly higher for patients with multimorbidity (£6,669 95% CI £4,871-£8,466; OR 11.3 95% CI 8.14-15.87) and for patients with a single comorbidity (£2,075 95% CI £1,559-£2,591; OR 3.52 95% CI 2.61-4.79), when compared with RA alone (£590). The excess costs were mainly driven by direct costs (£6,281 versus £1,875 versus £556). Although the difference in indirect costs between patients with multimorbidity and a single comorbidity were not statistically significant (£1,218 versus £914, p=0.11), patients with multimorbidity were associated with significantly higher costs than those with RA only (£594, p<0.01).

Conclusion: The presence of comorbidity contributes significant excess to both direct and indirect costs among RA patients. In particular, patients with multimorbidity incurred substantially higher direct costs than those with a single comorbidity or RA only.

Acknowledgements: The study analysed the data from the Scottish Early Rheumatoid Arthritis (SERA) study with a linkage to routinely recorded health data from Information Service Division, National Service Scotland. We would like to thank all the patients, clinical and nursing colleagues who have contributed their time and support to the study, the SERA steering committee for the approval, and Allen Tervit from the Robertson Centre for Biostatistics, University of Glasgow for the timely technical supports.

Barra[1,3,5]on behalf of on behalf of CATCH Investigators. *[1]University of Western Ontario, Epidemiology and Biostatistics, London, Canada*; *[2]University of Western Ontario, Family Medicine, London, Canada*; *[3]Lawson Health Research Institute, London, Canada*; *[4]University of Toronto, Sinai Health System, Toronto, Canada*; *[5]University of Western Ontario, Department of Medicine, London, Canada*; *[6]McGill University, Department of Medicine, Montreal, Canada*; *[7]Johns Hopkins University, Department of Medicine, Baltimore, United States of America*; *[8]Université de Sherbrooke, Department of Medicine, Sherbrooke, Canada*; *[9]Université de Laval, Department of Medicine, Quebec City, Canada*; *[10]University of Manitoba, Department of Medicine, Winnipeg, Canada*; *[11]University of Calgary, Department of Medicine, Calgary, Canada*; *[12]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada*; *[13]Southlake Regional Health Center, Division of Rheumatology, Newmarket, Canada*; *[14]Weill Cornell Medical College, Hospital for Special Surgery, New York City, United States of America*; *[15]University of Toronto, Department of Medicine, Toronto, Canada*

Background: It is not well understood why hypertension (HTN) is so common in rheumatoid arthritis (RA) patients. Reported prevalence of HTN in RA patients ranges from 4-73%.(1)

Objectives: This study explored the prevalence of HTN at time of RA diagnosis and which demographic, behavioural and clinical factors were associated with HTN.

Methods: Data from the Canadian Early Arthritis Cohort (CATCH), a prospective inception cohort of patients with RA <1 year duration, were used to analyze baseline demographic, behavioural and clinical characteristics associated with HTN, which was reported by physicians. Univariate logistic regression models were created to explore associations with baseline HTN. A multivariate logistic regression model was built based on goodness of fit indicated by likelihood ratio tests. Variables included in the model were age, sex, race, body mass index (BMI), education, smoking, alcohol servings, seropositivity, disease activity and comorbidities.

Results: In total, 2052 subjects were included with mean (±SD) age of 55 (±14) years and symptom duration 5.60(5.47, 5.73) months, 71% of subjects were female and 85% were Caucasian. HTN was reported in 26% of subjects at baseline. Hypertensive subjects were older and more likely to be male. Other factors significantly associated with HTN at baseline were lower education, ever smoking, high BMI, diabetes, hyperlipidemia, worse RA disease activity, longer duration of RA symptoms, being seropositive, as well as the use of NSAIDs and/or corticosteroids (Table 1). In multivariable analysis HTN was associated with older age, overweight and obese BMI, diabetes, and hyperlipidemia. Expression of anti-citrullinated protein antibodies was inversely associated with HTN (Table 1). Other RA disease factors and treatments were not significantly associated with HTN on multivariable analysis.

Table 1. Results of univariate and multivariate logistic regression analyses exploring the association between baseline characteristics and HTN in early RA.

		Univariate Logistic Regression	Multivariable Logistic Regression
	Variable	**Crude OR (95% CI)**	**Adjusted OR (95% CI)**
Socio-Demographic	20-39 years old	0.15 (0.07, 0.26)	0.14(0.05, 0.34)
	40-59 years old	Reference	
	60-79 years old	2.81 (2.26, 3.50)	2.26(1.65, 3.11)
	80-99 years old	5.87 (3.36,10.25)	3.80(1.53, 9.41)
	Female	0.55 (0.45, 0.68)	1.10(0.78, 1.54)
Lifestyle/Behavioural	Normal weight (18.5- 24.9kg/m^2)	Reference	
	Overweight (25-29.9 kg/m^2)	2.33(1.74, 3.11)	1.63(1.10, 2.43)
	Obese (30+ kg/m^2)	3.19(2.38, 4.27)	2.84(1.91, 4.23
	Ever-smoking	1.41(1.15, 1.73)	1.02(0.75, 1.40)
	Post-secondary education	0.58(0.47, 0.71)	0.88(0.65, 1.20)
Clinical Characteristics	Symptom duration	0.99(0.99, 0.99)	1.00(1.00, 1.00)
	DAS-28	1.09(1.09, 1.17)	1.02(0.92, 1.13)
	ACPA+	0.68(0.56, 0.85)	0.64(0.44, 0.92)
	Corticosteroid use pre-baseline	1.37(1.04, 1.81)	Omitted
	NSAID use at baseline	0.68(0.55, 0.84)	Omitted
	Diabetes	5.62(4.09, 7.73)	3.20(1.99, 5.15)
	Hyperlipidemia	4.75(3.74, 6.03)	2.80(1.94, 4.02),
	CVD	15.59(3.35, 72.64)	Omitted

DAS-28; Disease activity score 28, ACPA; Anti-citrullinated protein antibody, CVD; Cardiovascular disease. Pre-baseline is 29 to 365 days before entering the cohort. Baseline is within 28 days before entering the cohort. Omitted variables either failed likelihood ratio test or were colinear. Additional variables tested but found insignificant: race, alcohol servings, depression, RF+, and use of DMARDs.

Conclusion: Approximately 1 in 4 diagnosed with RA had HTN reported by their rheumatologists, which is similar to that of the general population. This suggests that increased risk of HTN in RA patients may develop as RA disease or treatment time progresses. Factors that may be predictive of this excess risk will be explored in further analysis.

POS0532 AVERAGE PREDNISOLONE DOSE OF ONLY 1 MG PER DAY WAS RISK FACTOR FOR CLINICAL FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS - NINE-YEAR FINDINGS OF THE TOMORROW STUDY

H. Yoshimura[1], T. Koike[2,3], K. Mamoto[4], Y. Sugioka[2], T. Okano[4], M. Tada[5], K. Inui[6], H. Nakamura[4]. *[1]Izumi City General Hospital, Orthopaedic Surgery, Osaka, Japan*; *[2]Center for Senile Degenerative Disorders (CSDD), Osaka City University Medical School, Orthopaedic surgery, Osaka, Japan*; *[3]Search Institute for Bone and Arthritis Disease (SINBAD), Orthopaedic Surgery, Wakayama, Japan*; *[4]Osaka City University Medical School, Orthopaedic Surgery, Osaka, Japan*; *[5]Osaka City General Hospital, Orthopaedic Surgery, Osaka, Japan*; *[6]Osaka Saiseikai Nakatsu Hospital, Orthopaedic Surgery, Osaka, Japan*

Background: Previous cohort studies showed that the use of prednisolone (PSL) was a risk factor for clinical fractures in patients with rheumatoid arthritis (RA). However, there are few reports on relationship between PSL dose and clinical fractures.
Objectives: The present study aimed to determine the effect of PSL dose on the incidence of clinical fractures in the RA patients treated with PSL.
Methods: We evaluated anthropoetric parameters, bone mineral density (BMD), disease activity score 28-erythrocyte sedimentation rate (DAS28-ESR), RA medication (methotrexate (MTX) dose, use of biologic disease modified anti-rheumatic-drugs (bDMARDs), and PSL dose) and the incidence of clinical fractures during nine years in RA patients who participant the TOMORROW study (UMIN000003876), which is a 10-years prospective cohort study. Data on clinical fracture was self-reported on the questionnaires. In this analysis, the data of RA patients treated with PSL at least once during nine-year period were evaluated. We analyzed the average dose of PSL until the incidence of the clinical fractures. The risk factor for clinical fractures were analyzed by using Cox proportional hazard model with adjustment for age, sex, body mass index (BMI), and smoking history.
Results: We analyzed the data of 67 RA patients treated with PSL. Among them, median age was 61.8 year, 56 patients (83.6%) were female, 47 patients (70.1%) were never smoker and median disease duration was 12.1 year. The number of patients treated with PSL at baseline was 48 (69.1%). During 9 years, 23 clinical fractures were observed in 67 patients, and the incidence of clinical fracture was 0.046/person-year. In 19 patients, who were not treated with PSL at baseline but treated with PSL at least once during 9 years, 5 clinical fractures were observed. In 67 RA patients, Cox proportional hazard analysis revealed that baseline disease activities, BMD at thoracic vertebrae and medication were not significant risk factors for clinical fractures. However, average PSL dose of more than only 1 mg/day was a significant risk factor for the incidence of clinical fracture (hazard ratio (HR): 2.80; p=0.03) (Table 1).

Table 1. Adjusted hazard ratio for clinical fractures in patients with rheumatoid arthritis treated with PSL.

	* Adjusted Hazard ratio	95% Confidence interval	P value
CRP (mg/dL)	1.29	0.88-1.91	0.19
RF (IU/mL)	0.99	0.99-1.00	0.07
ACPA (U/mL)	0.99	0.98-1.00	0.18
DAS28-ESR	0.99	0.71-1.39	0.97
BMD at thoracic vertebrae (mg/cm^2)	0.02	0.00-1.00	0.05
bDMARDs use	0.55	0.23-1.32	0.18
Bisphosphonate use	2.33	0.95-5.71	0.07
average dose of MTX (mg/week)	1.02	0.92-1.12	0.74
average score of DAS28-ESR	1.15	0.76-1.75	0.52
average dose of PSL more than 1mg/day	2.8	1.09-7.24	0.03

*Hazard ratio was adjusted for age, sex, body mass index (BMI), and smoking history. RF, Rheumatoid factor; ACPA, Anti-cyclic citrullinated peptide antibody; DAS28-ESR, disease activity score 28-erythrocyte sedimentation rate; BMD, Bone mineral density; bDMARDs, biologic disease modified anti-rheumatic-drugs; MTX, methotrexate; PSL, prednisolone.

Conclusion: In RA patients treated with PSL, average PSL dose of only 1mg/day significantly increased the risk for the incidence of clinical fractures. Even for established RA patients, continuous use or initiation of low PSL dose was apparently significant risk factor for clinical fractures.

POS0533 EFFECT OF CAROTID ULTRASOUND ON THE ACHIEVEMENT OF LDL-CHOLESTEROL TARGETS IN THE ROUTINE CLINICAL CARE OF PATIENTS WITH RHEUMATOID ARTHRITIS

I. Ferraz-Amaro[1], A. Corrales[2], N. Vegas-Revenga[2], B. Atienza-Mateo[2], V. Portilla[2], R. Blanco[2], J. Llorca[2], M. A. González-Gay[2]. *[1]Hospital Universitario de Canarias, Division of Rheumatology, Santa Cruz de Tenerife, Spain*; *[2]Hospital Universitario Marqués de Valdecilla, Division of Rheumatology, Santander, Spain*

Background: Cardiovascular disease (CVD) risk in patients with rheumatoid arthritis (RA) is substantially elevated compared to the general population. In RA, as in the general population, CVD control includes the detection and treatment of CV risk factors based, among others, on blood pressure, smoking, diabetes, and lipid profiles. Little is known about the real impact of the use of carotid ultrasound in the prevention of CVD in patients with RA.
Objectives: To determine whether the use of carotid ultrasound in the routine clinical care of patients with RA can improve the achievement of LDL-cholesterol targets over time.
Methods: We conducted a retrospective, real-world study of 327 RA patients in which a carotid ultrasound was performed as part of routine clinical care. Participants were followed from 2012 to 2018. LDL-c levels were measured before and after the carotid ultrasound intervention. The achievement of the LDL-c goals recommended by the international guidelines was compared before and after the carotid ultrasound. Predictive factors of achievement of LDL-cholesterol targets were studied.
Results: When considering the 2010 EULAR RA SCORE risk categories, serum LDL-c levels in the moderate CV risk category was significantly lower when follow-up finished (126 ± 33 to 109 ± 29 mg/dl, p=0.000) (Table 1). This was not the case for other CV risk categories. Similarly, LDL-c goal attainment in the moderate CV risk category was significant higher at the end of the study compared to baseline. Based on the 2016 European Society of Cardiology LDL-c targets, the achievement of a LDL-cholesterol inferior to 115 mg/dl for the moderate CV risk category significantly increased from 35 to 64% (p=0.000) after follow-up. However, significant changes were not observed in this regard for the low, high, and very-high CV risk categories.

Table 1. LDL cholesterol serum levels and LDL goals differences between baseline and final follow-up

			LDL, mg/dl			LDL (mg/dl) ESC 2016 goals			
	n	%	Baseline	Final follow-up		Goal	Baseline	Final follow-up	p
2010 EULAR RA SCORE									
Low	120	37	116 ± 37	119 ± 32	0.081	< 130	68%	66%	0.99
Moderate	195	60	126 ± 33	109 ± 29	**0.000**	< 115	35%	64%	**0.000**
High	7	2	121 ± 26	104 ± 22	0.14	< 100	14%	33%	0.99
Very High	5	0	131 ± 41	115 ± 46	0.080	< 70	0%	20%	0.99

ESC: European Society of Cardiology; EULAR: European League Against Rheumatism. SCORE: Systematic COronary Risk Evaluation; RA: Rheumatoid Arthritis; LDL: low-density lipoprotein. Significant 'p' value are depicted in bold.

When patients with RA, regardless the SCORE risk they had, were divided between those that attained LDL-cholesterol target or not, those that achieved their LDL goal, were more frequently female and had less diabetes mellitus. Moreover, the probability of achieving LDL-cholesterol goal was higher in those with an inferior total cholesterol, LDL-c and atherogenic index at baseline. Interestingly, no differences were observed in both populations regarding the baseline use of statins, aspirin or hypertension treatment at baseline. Concerning disease related data when study started, no differences about disease duration and activity or treatments were observed between dose that reached LDL-cholesterol goal and those that did not.
Those that achieved LDL-c objectives had a higher decrease in smoking quit and a superior control of hypertension. Besides, in those that attained objectives a

superior increase in statins prescription was observed (36% vs. 13%, p=0.000), as well in hypertension and aspirin treatment. However, no differences were noticed in the changes in disease-related data that occur during the time the study was carried out.

Conclusion: This real-world study demonstrates that incorporating carotid ultrasound into routine clinical practice in RA patients is effective in achieving LDL-cholesterol targets for the prevention of cardiovascular disease. This effect is not only mediated by the increase in the prescription of statins, but also by the better control of other cardiovascular risk factors that occurred after carotid ultrasound evaluation.

POS0534 THE PREVALENCE OF HYPERTENSION AND ITS POTENTIAL ASSOCIATED FACTORS IN CHINESE PATIENTS WITH RHEUMATOID ARTHRITIS

Y. W. Zou[1], C. Chen[2], J. Lin[1], J. D. Ma[2], Y. Y. Zou[1], L. Dai[1]. [1] *Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China*; [2]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China*

Background: Cardiovascular disease (CVD) is the leading cause of mortality in patients with rheumatoid arthritis (RA), and hypertension is a modifiable risk-factor for CVD. In addition, comorbidities may shorten the life span of RA patients, which appears to be the consequence of an increased prevalence of CVD. RA patients with comorbidities might not be given the equal treatment in daily practice compared with patients without comorbidities.

Objectives: To investigate the prevalence of hypertension and its associated factors in Chinese RA patients.

Methods: Consecutive patients with RA were recruited from August 2015 to September 2019 at Department of Rheumatology, Sun Yat-sen Memorial Hospital. Demographic and clinical characteristics were collected including indicators of disease activity, functional assessment and radiographic assessment and CV-related comorbidities.

Results: There were 674 RA patients recruited with 82.3% female and mean age 49.9±13.0 years. The prevalence rate of hypertension in RA patients was 32.9%, followed by dyslipidemia (9.9%), type 2 diabetes (8.8%), hyperuricemia (8.5%), fatty liver disease (8.0%), CVD (6.2%) and chronic kidney disease (3.3%). The prevalence of hypertension was 38.7% and 31.7% in male and female RA patients respectively (P = 0.144). Further age stratification showed no hypertension in RA patients at 16-19 years, 2.0% at 20-29 years and 8.1% at 30-39 years. The prevalence of hypertension greatly increased after 40 years old with 24.5%, 38.6%, 54.9%, and 63.6% in RA patients of 40-49, 50-59, 60-69, ≥ 70 years old respectively, and there was no significant difference between male and female RA patients of different age (Figure 1). Compared with those without hypertension, RA patients with hypertension had advanced age (57.3 ± 9.3 years vs. 46.3 ± 13.0 years), long-standing disease duration (median 60 months vs. 48 months), higher disease activity indicators [including PtGA (median 4 vs. 3), PrGA (median 3 vs. 3) and ESR (median 33 mm/h vs. 27 mm/h)], higher functional indicator [HAQ-DI (median 0.25 vs. 0.13)], worse joint destruction [JE subscore (median 10 vs. 6)] and higher proportions of comorbidities [including type 2 diabetes (14.9% vs. 5.8%), hyperuricemia (13.1% vs. 6.1%), chronic kidney disease (6.3% vs. 1.8%), dyslipidemia (15.8% vs. 7.1%), CVD (10.4% vs. 4.2%) and fatty liver disease (13.5% vs. 5.3%), all P < 0.005]. Multivariate logistic regression analysis showed that comorbidities including hyperuricemia (OR = 1.977, 95% CI: 1.002-3.900), dyslipidemia (OR = 1.903, 95% CI: 1.102-3.288) and fatty liver disease (OR = 2.335, 95% CI: 1.278-4.265) were associated factors of hypertension after adjustment for age and gender

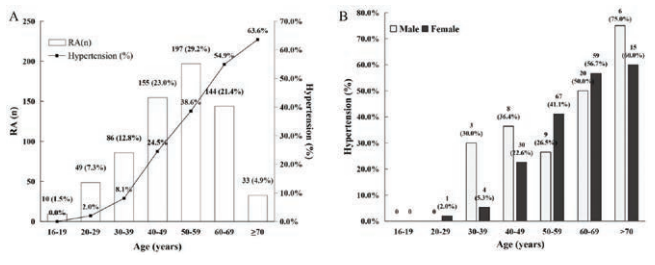

Figure 1. The prevalence of hypertension in different age and sex groups of RA patients.

Conclusion: Hypertension is the most common CV-related comorbidity in Chinese RA patients which is associated with hyperuricemia, dyslipidemia and fatty liver disease. Detection and management of hypertension and other CV-related comorbidities in RA patients should be emphasized.

POS0535 QUERY ALGORITHMS AND MACHINE LEARNING METHODS AS TOOLS TO IDENTIFY COMORBIDITIES IN LARGE-SCALE FREE-TEXT BASED FIELDS: A CASE-REPORT

D. Rohrich[1], T. Maarseveen[2], A. de Boer[1], C. van den Ende[1], A. den Broeder[1], C. Popa[1], R. Knevel[2]. [1]*Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands*; [2]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: Inflammatory rheumatic conditions (IRC) are associated with comorbidity, two most important being cardiovascular diseases (CVD) and infections [1, 2]. A crucial initial step when proceeding with studying CVD and infections in these patients is identification of events. The large scale EHR datasets enable studies to assess low incident and clinically important events, but requires both accurate as well as efficient data extraction. Studying Electronic Health Records (EHR) using query-based algorithms (QBA) and machine learning algorithms (MLA) offers a valuable tool to screen large-scale collections for rare events, thus replacing resource intensive manual chart review.

Objectives: To explore the (comparative) usefulness of QBA and MLA to identify CVD and infection events in EHR free-text data in patients with chronic IRC.

Methods: To independently develop and validate the algorithms we used two EHR databases, i.e. a training set with psoriatic arthritis patients (N=977, dataset A, Golden Standard) and a validation set of rheumatoid arthritis patients (N=1098, dataset B). Using both QBA and MLA, we aimed to identify (yes/no and timing) CVD and infections. We assessed the performances of the algorithms by calculating the specificity, sensitivity, positive predictive value (PPV) and the negative predictive value (NPV), respectively.

Results: In the final performance analysis on dataset B, both QBA and MLA showed a high performance in identifying CVD (sensitivity, specificity, PPV, NPV for QBA ((95% CI)= 0.69 (0.66-0.72), 0.99 (0.96-1.02), 0.84 (0.81-0.87), 0.98 (0.95-1.01)) and for MLA (sensitivity = 0.69 (0.66-0.72), 0.98 (0.95-1.01), 0.68 (0.65-0.71), 0.98 (0.95-1.01), respectively) Infections showed similar performance (QBA sensitivity, specificity, PPV, NPV is 0.64 (0.61-0.67), 0.96 (0.93-0.99), 0.66 (0.63-0.69), 0.96 (0.93-.0.99) and for MLA = 0.61 (0.58-0.64), 0.93 (0.90-0.96), 0.49 (0.46-0.52), 0.96 (0.93-0.99), respectively). For infections the specificity was slightly higher for QBA relative to MLA.

Conclusion: We found a consistent high performance of both the QBA and MLA algorithms for the identification of CVD and infections in our free text EHR of patients with chronic IRC (Table 1). The performance of QBA highly depends on the domain knowledge of the builders, which might allow it to outperform a Gold Standard. MLA is efficient as it does not require any domain knowledge, but its performance is restricted by the quality of the Gold Standard.

Table 1. Overlap and differences in event identification of the query based and machine learning based algorithms compared to the Gold Standard dataset B (chart review by specialized health care professional). The results of non-event and event identification by the algorithms is represented in numbers of events and percentages of the total non-event or event.

POS0536 FILGOTINIB DEMONSTRATES CLINICAL EFFICACY IN RHEUMATOID ARTHRITIS INDEPENDENT OF SMOKING STATUS: A POST-HOC SUBGROUP ANALYSIS OF THREE PHASE 3 CLINICAL TRIALS

P. Emery[1], B. Downie[2], J. Liu[2], R. Hawtin[2], J. R. Curtis[3], G. R. Burmester[4]. *[1]University of Leeds, School of Medicine, Leeds, United Kingdom*; *[2]Gilead Sciences, Inc., Foster City, United States of America*; *[3]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, United States of America*; *[4]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Filgotinib (FIL), an oral janus kinase 1 (JAK1) inhibitor, has been evaluated in three phase 3 clinical studies (FINCH 1-3) in adults with moderately-to-severely active rheumatoid arthritis (RA). Patients with RA who currently smoke (a predisposing factor for RA) have been reported to be less likely to respond to anti-TNFα treatment and more likely to discontinue or switch treatment.[1,2,3] However, the impact of smoking on JAKi efficacy in RA patients is unknown.
Objectives: A post-hoc sub-group analysis of FINCH patient (pt) data was performed in order to identify associations with smoking status.
Methods: Data from 3452 RA pts participating in the FINCH3 (MTX-naïve; NCT02886728), FINCH1 (MTX-IR; NCT02889796), or FINCH2 (bDMARD-IR; NCT02873936) clinical trials were included for analysis of clinical response at weeks 12 and 24. Logistic regression models were fitted to assess the effects of smoking status on categorical clinical endpoints (ACR20/50/70, CDAI ≤ 10, DAS28(CRP) ≤3.2 or < 2.6). Adjustments were made for covariates selected based on previously published work[1] and listed in the Figure 1 caption. No adjustments of p-values were made for multiple testing.
Results: In the MTX-IR population (FINCH1), current (12% of enrolled patients) and former (13%) smokers treated with ADA+MTX had a lower week 12 ACR50 response rate compared to non-smokers (25% and 28% vs. 39%, nominal p = 0.095 and p=0.21, respectively). In contrast, the ACR 50 response at week 12 in FIL+MTX treated pts showed no association with smoking status. Former smokers had higher response rates than non-smokers in the MTX-IR (FINCH1) and MTX naïve (FINCH3) populations (Table 1). Direct comparison between non-smoking pts in the MTX-IR FIL200+MTX-arm and ADA+MTX-arm showed no significant difference in ACR50 response rate (46% vs. 39%, p=0.08). In contrast, former and current smokers showed significantly better week 12 ACR50 response rates under FIL200+MTX treatment compared to ADA+MTX patients (former smoker: 62% vs. 28%, p=0.0017, current smoker: 50% vs. 25%, p=0.016, Figure 1. Similar observations were made at both weeks 12 and 24 for other clinical endpoints, including ACR20/50/70, DAS28(CRP) < 2.6 or ≤3.2, and CDAI ≤ 10 response criteria.

Table 1. Difference in adjusted ACR50 response rate compared to non-smokers for FINCH1/2/3.

		PBO+MTX‡	FIL100+MTX	FIL200+MTX
FINCH1	Current	-1%	+2.4%	+3.3%
	Former	-6%	+12%	+16% (*)
FINCH2†	Current	0%	+13%	-9%
	Former	+9%	-7%	+4%
FINCH3	Current	0%	+1%	+4%
	Former	+4%	+20% (*)	+17% (*)

ACR50 response rate based on fully adjusted logistic regression model. †: FINCH2 patients received either MTX or csDMARD. ‡FINCH3 had active comparator arm of MTX together with PBO to maintain blind. *: p < 0.05, **: p < 0.01, ***: p < 0.001

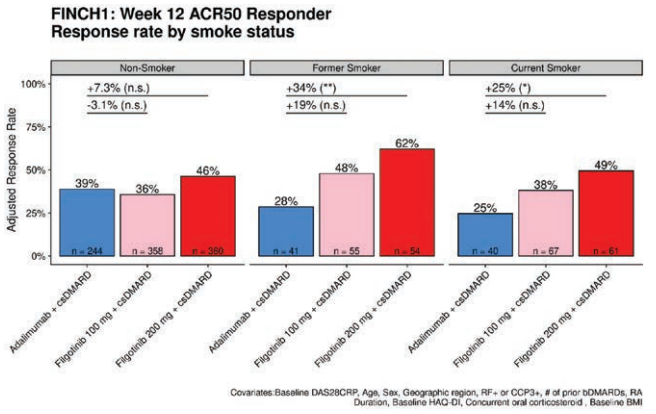

Figure 1. FINCH1 adjusted Week 12 ACR50 response rate stratified by smoking status. ACR50 response rate based on fully adjusted logistic regression model. *: p < 0.05; **: p < 0.01; ***: p < 0.001. Former and current smokers that received FIL200mg + MTX showed a higher response rate compared to similar ADA+MTX patients.

Conclusion: This exploratory analysis showed that current and former smokers with RA who received ADA+MTX trended toward a lower response rate compared to non-smokers. In contrast, FIL+MTX was found to be similarly efficacious independent of smoking status within both the MTX-IR and MTX-naïve RA populations. Current or former smokers were more likely to respond to FIL200mg + MTX compared to ADA+MTX across a range of endpoints. Given the small number of current and former smokers enrolled in these studies, further studies of the efficacy of JAK inhibitors and the mechanism of reduced response to anti-TNFs in patients with a history of smoking are warranted.

POS0537 TRENDS AND PREDICTORS OF INPATIENT MORTALITY IN PATIENTS WITH CLOSTRIDIODES DIFFICILE INFECTION AMONG THOSE WITH AND WITHOUT RHEUMATOID ARTHRITIS: A NATIONWIDE ANALYSIS

M. Tahir[1,2], S. Alexander[3,4], R. Tariq[2], K. Wysham[5], J. Andrews[5], H. Aly[6], S. Khanna[7], N. Singh[5]. *[1]Rochester General Hospital, Internal Medicine, Rochester, United States of America*; *[2]1425 Portland Ave, Internal Medicine, Rochester, United States of America*; *[3]University of Connecticut, Internal Medicine, Storrs, United States of America*; *[4]263 Farmington Ave, Internal Medicine, Farmington, United States of America*; *[5]1959 NE Pacific St, Internal Medicine, Seattle, United States of America*; *[6]740 S Limestone, Internal Medicine, Lexington, United States of America*; *[7]200 1st St SW, Internal Medicine, Rochester, United States of America*

Background: People with rheumatoid arthritis (RA) have a higher risk of serious infections. The most common nosocomial infection in the United States (US) is *Clostridioides difficile* infection (CDI) and yet, little is known regarding the impact of comorbid RA on outcomes in persons hospitalized with CDI.
Objectives: To evaluate the trends over time and predictors of inpatient mortality in hospitalized patients with CDI comparing those with and without RA.
Methods: We used the National Inpatient Sample (NIS) database, the largest available all-payer database of inpatient hospitalizations in the US. Patients aged

≥18 years admitted with CDI from 2006-2018 were included. Patients with RA were identified using the International Classification of Diseases (ICD) 9 and 10 codes. Categorical variables between CDI patients with and without RA were compared using Chi-squared test. Temporal trends of hospitalization charges, length of stay (LOS) and inpatient mortality were assessed using the Cochrane Armitage test. Predictors of inpatient mortality were assessed using multivariable logistic regression adjusting for: age ≥65, sex, race, presence of RA, and Elixhauser comorbidity index.

Results: There were 4,396,945 hospitalizations with a discharge diagnosis of CDI in the study period, of which 111,336 (2.5%) had a coexisting diagnosis of RA. Over the study period, the proportion of CDI patients with a diagnosis of RA increased from 1.7% in 2006 to 3.3% in 2018 with a statistically significant trend of rise (p trend<0.001). There were significantly more females in the RA group (78.2%) than without RA (57.5%), p <0.001. RA group was significantly younger (68.0 vs 70.7, P<0.001). Races were similar between the groups.

The inflation-adjusted average charge for hospitalization for CDI without RA was significantly higher than for CDI with RA ($95,863 vs $73,025, p<0.001). There was an increasing trend in inflation-adjusted average charge for hospitalization for both CDI without RA ($76,966 in 2006 to $104,552 in 2018, p<0.001) and CDI with RA ($55,689 in 2006 to $77,295 in 2018, p<0.001). Patients with or without RA had the same median length of stay (LOS) of 7 days. But when trended over time, for patients without RA, the median LOS decreased from 8 days in 2006-08 to 6 days in 2016-18 whereas for patients with RA, the median LOS fluctuated between 6 and 7 days over the course of study period.

CDI patients without RA had a significantly higher mortality over the study period than those with RA (7.8% vs 6.1%, p<0.001). Among non-RA CDI patients, mortality decreased from 9.3% in 2006 to 6.3% in 2018 (p trend <0.001). Hospitalizations of people with CDI and comorbid RA showed an overall decreasing trend (p trend <0.001).

The multivariable analyses found age≥65 was associated with increased inpatient mortality (adjusted odds ratio [aOR], 1.77, 95% confidence interval [CI], 1.73-1.80), whereas a diagnosis of RA was associated with a decreased mortality (aOR 0.86, 95% CI, 0.81-0.91) (Table 1).

Table 1. Predictors of inpatient mortality

	aOR	95% C.I. for aOR		P-value
		Lower	Upper	
Age ≥ 65	1.765	1.730	1.801	<0.001
Hospitalization years				
-Years 2006-2011	Ref			
-Years 2011-2014	0.707	0.693	0.721	<0.001
-Years 2015-2018	0.582	0.569	0.594	<0.001
Elixhauser Comorbidity Index	1.056	1.055	1.056	<0.001
Rheumatoid Arthritis	0.859	0.810	0.911	<0.001
Female	0.870	0.855	0.885	<0.001
Race				
-White	Ref			
-African American	1.071	1.044	1.099	<0.001
-Hispanic	1.144	1.108	1.180	<0.001
-Asian/Pacific Islander	1.267	1.200	1.337	<0.001
-Native American	1.022	0.910	1.147	0.716
-Other races	1.263	1.201	1.329	<0.001

aOR = Adjusted Odds Ratio; C.I.= confidence interval

Conclusion: In this nationwide study, among hospitalized patients with CDI, those with comorbid RA had significantly decreased odds of inpatient mortality than those without RA. Further studies are needed to understand this association.

POS0538 RELATIONSHIP BETWEEN HINDFOOT DEFORMITIES AND ULTRASOUND TENOSYNOVITIS IN RHEUMATOID ARTHRITIS

K. Maatallah[1], H. Boussaa[1], H. Riahi[2], H. Ferjani[1], M. Habechi[1], W. Triki[1], D. Ben Nessib[1], M. Bouaziz[2], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rheumatology, La Manouba, Tunisia*; [2]*Mohamed Kassab Institute of Orthopedics, Radiology, La Manouba, Tunisia*

Background: Rheumatoid arthritis (RA) is an inflammatory disease that frequently affects the joints and soft tissues of the feet. Tibialis posterior tenosynovitis has a reported prevalence between 13 and 64% in RA. The condition is associated with a progressive flat foot deformity and significant gait disability. However, few studies have investigated the relationship between foot deformities and the involvement of tendons. Recently, ultrasonography (US) has been reported as the gold standard for the investigation of tendons.

Objectives: This study aimed to assess the relationship between hindfoot deformities and US tenosynovitis in RA.

Methods: We conducted a cross-sectional study including patients with RA (ACR/EULAR 2010). Demographic data and disease parameters were collected. For each patient, a podoscope examination of both feet was performed by a rheumatologist. A radiologist experienced in musculoskeletal imaging performed a US examination using a Philips HD11 device with a high-frequency linear transducer. The assessed lesions were synovitis of the tibiotalar, talonavicular, and subtalar joints, and tenosynovitis of tibialis anterior (TA), extensor hallucis longus (EHL), extensor digitorum longus (EDL), tibialis posterior (TP), flexor digitorum longus (FDL), flexor hallucis longus (FHL), fibularis brevis (FB) and fibularis longus (FL) tendons. The presence or absence of synovitis and tenosynovitis was recorded, and the composite synovitis score (power doppler/grayscale ultrasound (PDUS)) was measured for each joint. The US score of each patient was defined by the sum of the composite scores of the joints studied (0-30). A p-value <0.05 was considered significant.

Results: Sixty-two feet were examined in 31 RA patients (25 women and six men) with a mean age of 54.8±10.8 years old [32-70]. The mean disease duration was 8.5±7.2 years [1-37]. Rheumatoid Factor (RF) and Anti-Citrullinated Peptides Antibodies (ACPA) were positive in respectively 61.3% and 83.8% of cases. The mean DAS28 ESR was 3.8±1.5 [0.6-7].

Podoscope examination revealed pes planus valgus (PPV) in 55.6% of cases and pes cavus varus (PCV) in 18.5% of cases. US showed tibiotalar synovitis in 59.3% of cases, talonavicular synovitis in 64.8% of cases, and subtalar synovitis in 46.3% of cases. In the anterior compartment, tenosynovitis of TA was noted in 5.6% of cases, of EHL in 1.9% of cases, and EDL in 9.3% of cases. In the medial compartment, tenosynovitis of TP was found in 22.2% of cases, of FDL in 5.6% of cases, and FHL in 0% of cases. In the lateral compartment, tenosynovitis of FB and FL was found in 25% and 11.1% of cases respectively.

An association between PPV and synovitis of the tibiotalar joint (p<0.001) and the subtalar joint (p=0.007) was found. An association was also noted with FL tenosynovitis (p=0.045) but not with the other assessed tendons.

No association was noted between PCV and synovitis or tenosynovitis of the assessed structures.

Conclusion: PPV was frequent among RA patients. This condition was associated with tibiotalar and subtalar synovitis and FL tenosynovitis. It is important to detect and correct foot deformities in order to ensure optimal control of the disease.

POS0539 PAIN IS AN INDEPENDENT ASSOCIATED FACTOR ON FUNCTIONAL LIMITATION IN CHINESE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

Y. W. Zou[1], C. Chen[1], Q. Zhang[1], S. Y. Lian[1], K. M. Yang[1], Y. H. Xu[1], J. Lin[1], J. D. Ma[1], Y. Y. Zou[1], L. Dai[1]. [1]*Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Department of Rheumatology, Guangzhou, China*

Background: Rheumatoid arthritis (RA) is a leading cause of extremity disability in Chinese female population according to 2006 national survey. However, less epidemiological data about functional limitation in Chinese RA patients have been published.

Objectives: To investigate the prevalence, characteristics and associated factors of functional limitation in Chinese RA patients.

Methods: Consecutive patients with RA were recruited. The demographic and clinical data were collected including indicators of disease activity, functional assessment and radiographic assessment. According to Health Assessment

Questionnaire Disease Index (HAQ-DI), functional limitation was defined as: mild (0 < HAQ-DI ≤ 1), moderate (1 < HAQ-DI ≤ 2), and severe (2 < HAQ-DI ≤ 3).
Results: There were 643 RA patients recruited with 82.3% female and mean age 49.7 ± 12.9 years. The median (IQR) of total HAQ-DI was 0.25 (0.00-0.75) and there were 399 (62.1%) RA patients with functional limitation including 293 (45.6%), 73 (11.4%), 33 (5.1%) with mild, moderate, and severe functional limitation, respectively. The highest prevalence of functional limitation subdimension was "walking" (43.5%), followed by "grip" (36.1%), "reach" (35.5%), "common daily activities" (33.4%), "hygiene" (33.0%), "dressing and grooming" (29.7%), "arising" (29.1%), while the lowest was "eating" (18.4%). Further age stratification showed that the prevalence of functional limitation was increased with age ($P < 0.001$), but no difference between male and female RA patients (58.8% vs. 62.8%, $P = 0.426$). The prevalence of functional limitation of RA patients with disease duration < 1 years (early), 1-10 years (intermediate) and ≥ 10 years (long) were 70.2%, 55.9% and 74.5% respectively, showing a U-shaped curve (Figure 1A), which indicated that early RA also had high rate of functional limitation. Furthermore, early RA patients had the highest proportion of severe functional limitation (14.3% vs. 2.0% vs. 8.7%, Figure 1B), together with higher prevalence of functional limitation of all eight subdimension than those with intermediate disease duration ($P < 0.05$, Figure 1C). There were significant differences in Pain VAS, indicators of disease activity, functional and radiographic assessment among RA patients with different disease duration. Compared with those with intermediate disease duration, early RA patients had higher Pain VAS, higher disease activity indicator (including ESR, CRP, CDAI), higher HAQ-DI, but lower radiographic indicators (all $P < 0.05$). There was no significant difference in disease activity and functional indicators between early RA patients and those with long disease duration. Multivariate ordered logistic regression analysis showed that Pain VAS (*OR* = 2.116, 95% *CI*: 1.483-3.019), disease activity indicators [including CRP (*OR* = 1.047, 95% *CI*: 1.011-1.084) and CDAI (*OR* = 1.128, 95% *CI*: 1.054-1.208)] were associated factors of functional limitation in early RA patients.

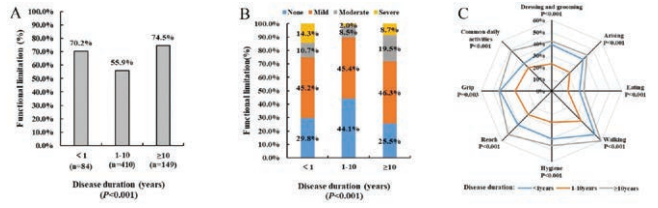

Figure 1. The prevalence of function limitation in RA patients. (A) The prevalence of functional limitation in different disease duration groups of RA patients. (B) The different degrees of functional limitation in different disease duration groups of RA patients. (C) The subdimension characteristics of functional limitation in different disease duration groups of RA patients.

Conclusion: Near two third early RA patients have functional limitation, in which both pain and active disease are independent associated factors. Management of pain and target treatment in early RA patients should be emphasized.

POS0540 SEXUAL DYSFUNCTION IN MALE PATIENTS WITH RHEUMATIC DISEASES

A. P. Stanciu[1], L. Groseanu[1,2], A. Balanescu[1,2], D. Predeteanu[1,2], D. Opris-Belinski[1,2], V. Bojinca[1,2], F. Berghea[1,2], C. L. Constantinescu[1,2], I. Saulescu[1,2], S. Daia-Iliescu[1,2], A. Borangiu[1,2], D. Mazilu[1,2], M. M. Negru[1,2], C. Cobilinschi[1,2], R. Ionescu[1,2]. [1]*Saint Mary Hospital, Rheumatology and Internal Medicine, București, Romania*; [2]*Carol Davila University of Medicine and Pharmacy, Rheumatology, București, Romania*

Background: Sexual health is an essential element of overall health and well-being. Rheumatic diseases may affect sexual functioning in many ways related to pain, fatigue, stiffness, functional impairment, depression, anxiety, negative body image, reduced libido, hormonal imbalance and drug treatment. However, these issues are rarely addressed in clinical practice.
Objectives: The aim of this study was to evaluate sexual function in a cohort of men with rheumatic disease compared to healthy controls.
Methods: This was an observational, single-center, cohort study conducted between august 2019 and march 2020 in the Rheumatology department of "Saint Mary" Clinical Hospital in Bucharest which included 120 men with ages between 18 and 60 years - 60 patients with rheumatic diseases and 60 healthy controls. The study tools were the Sexual Health Inventory for Men (SHIM) questionnaire and one questionnaire referring to personal data, history of the rheumatic disease, comorbidities, treatment and sexual impairment. Also, the disease activity was assessed using specific scores for each condition.
Results: In this cohort of 60 patients, the mean age was 45.26 (7.8) years and the diagnoses wereankylosing spondylitis (AS) - 37%,psoriatic arthritis (PsA) - 18%, rheumatoid arthritis (RA) - 17%, systemic sclerosis (SS) - 15% and gout - 13%. More than half of the patients (62%) had active disease based on specific scores (ASDAS for AS, DAS28-CRP for RA, EScSG disease activity indices for SS, DAPSA for PsA). Regarding sexual life, this study showed a significant decrease in sexual life quality after rheumatic disease diagnosis(before diagnosis: 71,67% - satisfying and 16,67% - not satisfyingversus after diagnosis: 21,67% - satisfying and 68,33% - not satisfying). Most patients (90%) reported impairment of their sexual life after diagnosis. In terms of sexual dysfunction (SD), a significantly higher proportion of patients (40%) mentioned reduced libido compared to the control group (18,33%) (p=0.043). Also, 21,66% of the patients reported erectile dysfunction (ED) in comparison with only 8,33% in the control group (p=0.009). Most patients with AS, RA, PsA and gout had mild ED while most patients with SS presented with mild to moderate ED. Also, the SHIM score mean value was significantly lower in the study group (17,65)compared to the control group (20,15) (p=0.009). The importance of SD in this cohort is emphasized by the fact that only one patient conceived after rheumatic disease diagnosis. Concerning treatment, more than half of the patients (55%) reported no effect of the therapy on their sexual life while 38.33% mentioned that medication improved their sexual life and very few (7%) reported a worsening.
Conclusion: This study revealed a higher prevalence of sexual dysfunction in male patients with rheumatic disease in comparison with healthy controls. Considering the importance of sexual and reproductive health, rheumatologists should approach this topic with their patients and offer them guidance.

POS0541 LOW PREVALENCE OF SSA (anti-Ro) AND SSB (anti-La) AUTOANTIBODIES IN FEMALE RHEUMATOID ARTHRITIS PATIENTS WITH A WISH TO CONCEIVE

H. T. Smeele[1], L. F. Perez-Garcia[1], J. M. J. Cornette[2], M. W. Schreurs[3], R. Dolhain[1]. [1]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*; [2]*Erasmus MC, Department of Gynaecology and Obstetrics, Rotterdam, Netherlands*; [3]*Erasmus MC, Department of Immunology, Rotterdam, Netherlands*

Background: The presence of SSA (anti-Ro) and SSB (anti-La) autoantibodies has important clinical implications for female patients with a wish to conceive. The association between maternal levels of these autoantibodies and complete congenital heart block and neonatal Lupus syndrome is well established. Currently guidelines advise to test for these antibodies in all Rheumatoid Arthritis (RA) patients with a wish to conceive (1).
Objectives: The objective was to determine the prevalence and titers of SSA and SSB autoantibodies in female patients with rheumatoid arthritis and a wish to conceive or who are pregnant.
Methods: Patients were derived from 2 large prospective cohorts on RA and pregnancy (PARA-cohort and PreCARA-cohort). The presence and titers of SSA and SSB were tested using Phadia, an automated system which uses fluorescence enzyme immunoassays (FEIA) (Thermo-Fisher Scientific).
Results: We included a total of 647 patients with RA and a wish to conceive, 417 (64.5%) conceived during the follow-up period. A detailed description of the study population, stratified for the presence of SSA and SSB antibodies autoantibodies is presented in table 1. A total of 25 out of 647 patients had detectable SSA or SSB antibodies: SSA n = 25 (SSA-52 n = 17, SSA-60 n = 19), SSB n = 7. This corresponds with a prevalence of 3.9% for SSA antibodies and 1.1% for SSB antibodies. 13 (52% of the SSA positive patients, 2.0% of the total population) patients had a titer of >240 units/ml of SSA antibodies, and 3 (42.9% of the SSB positive patients, 0.46% of the total

population) patients had a titers >340 units/ml of SSB antibodies. The percentage of patients positive for RF antibodies was higher in SSA and/or SSB positive patients (p = 0.01).

Table 1. Clinical and demographic features from 647 patients with rheumatoid arthritis and a wish to conceive.

Variable	SSA and SSB antibodies [-], n = 622	Positive SSA and/or SSB antibodies [+], n = 25	p-value
Age at inclusion in the cohort (y, SD)	32.3 (4.0)	32.3 (4.4)	0.98
Median disease duration at first visit, years (IQR)	5.2 (2.2 – 9.8)	4.9 (2.1 – 11.4)	0.77
ACPA positive, n (%)	408/614 (66.5)	16 (69.6)	0.75
Rheumatoid Factor positive, n (%)	426/617 (69.0)	23 (92.0)	0.01

Conclusion: Our study shows an overall low prevalence of SSA and SSB autoantibodies in female RA patients with a wish to conceive. Moreover, about half of the patients positive for SSA or SSB had, based on literature, moderate or low titers of these antibodies (2). Especially for RF negative patients, the current advise to test for SSA and SSB antibodies in all RA patients with a wish to conceive should be reconsidered.

DISEASE ACTIVITY IN PREGNANT WOMEN WITH RHEUMATOID ARTHRITIS: IMPACT ON THE SOLUBLE FMS-LIKE TYROSINE KINASE-1 TO PLACENTAL GROWTH FACTOR RATIO

H. T. Smeele[1], R. I. Neuman[2,3], A. H. J. Danser[2], R. Dolhain[1], W. Visser[2,3].
[1]Erasmus MC, Rheumatology, Rotterdam, Netherlands; *[2]Erasmus MC, Department of Internal Medicine; Division of Pharmacology and Vascular Medicine, Rotterdam, Netherlands*; *[3]Erasmus MC, Department of Gynecology and Obstetrics, Rotterdam, Netherlands*

Background: An elevated sFlt-1 indicates soluble Fms-like tyrosine kinase-1 (sFlt-1)/ placental growth factor (PlGF) ratio has recently been validated as significant predictor of preeclampsia (PE)(1). However, raised sFlt-1 levels due to inflammation are observed in patients with rheumatoid arthritis (RA)(2). The use of the sFlt-1/PlGF ratio for the prediction of PE has not been evaluated in pregnant women with diseases that are characterized by high levels of inflammation, such as RA

Objectives: We investigated whether sFlt-1 and/or PlGF are altered in pregnant women with RA according to disease activity, and evaluated whether a sFlt-1/PlGF ratio of ≤38 could be used to predict the absence of PE in pregnant RA-patients.

Methods: This study was embedded in a nationwide, observational, prospective cohort study on pregnant women with RA (PARA-study). sFlt-1 and PlGF levels were measured, using automated analyzer (Cobas-6000, e-module; Roche-Diagnostics), in the third trimester of pregnancy.

Results: A total of 221 women, aged 21–42 years, were included. Values of sFlt-1, PlGF and sFlt-1/PlGF ratio were not significantly correlated with the DAS28-CRP (Figure 1). CRP correlated weakly with PlGF (r=-0.14, p=0.03), while no correlation was found with sFlt-1 or the sFlt-1/PlGF ratio.

Preeclampsia occurred in four out of 214 women with a ratio ≤38 (2%) in contrast to three out of seven women with a ratio >38 (43%), p<0.001 (Table 1). When stratified to a sFlt-1/PlGF ratio of ≤38 only 2% of women developed preeclampsia, compared to 43% of the women with a ratio >38. The observed sensitivity and specificity for a sFlt-1/PlGF ratio cut-off of ≤38 were 42.1% and 98.1%, respectively, with a negative predictive value (NPV) of 98%. All women that developed PE, developed PE >4 weeks after collecting of blood samples in the 3rd trimester, therefore the observed NPV could be even higher.

Table 1. Pregnancy Outcome according to sFlt-1/PlGF ratio with a cut-off value of 38.

Parameter	Ratio ≤38	Ratio >38	P-value
N	214	7	
GA at birth, weeks	39 (38 - 40)	37 (36 - 40)	0.05
<34	2 (1)	0(0)	1.00
34 - 37	18 (8)	2 (29)	0.12
Male, n (%)	113 (53)	5 (71)	0.45
Birth weight, grams	3420 (2998 - 3800)	2620 (2360 - 2850)	<0.01
Maternal Outcome			
Gestational Hypertension	15 (7)	2 (29)	0.09
Preeclampsia	4 (2)	3 (43)	<0.001
Time to delivery, days	66 (52 - 75)	52 (44 - 66)	0.08
Fetal Outcome			
Birth weight percentile <10	33 (15)	5 (71)	<0.01
Fetal/Neonatal Death	1 (1)	0 (0)	1.00

Data are reported as median (interquartile range) or number (percentage). sFlt-1 indicates soluble Fms-like tyrosine kinase-1; PlGF, placental growth factor; GA, gestational age. Time to delivery is defined as the amount of days between blood sampling and delivery.

Conclusion: Our study shows that in pregnant women with RA, the sFlt-1/PlGF ratio is not altered due to disease activity, and a cut-off of ≤38 of this ratio can be used to exclude preeclampsia.

POS0543

MORNING STIFFNESS IN CLINICALLY SUSPECT ARTHRALGIA IS EXPLAINED BY LOCAL SUBCLINICAL SYNOVITIS AND SYSTEMIC INFLAMMATION

D. Krijbolder[1], F. Wouters[1], E. van Mulligen[2], A. van der Helm - van Mil[1,2]. [1]*Leiden University Medical Centre, Department of Rheumatology, Leiden, Netherlands*; [2]*Erasmus Medical Center, Department of Rheumatology, Rotterdam, Netherlands*

Background: Morning stiffness (MS) is considered a cardinal symptom in the clinical appraisal of arthralgia patients, suggesting presence of subclinical inflammation, which could indicate an increased chance of progression to rheumatoid arthritis (RA). However, the pathophysiology behind MS in arthralgia patients that is clinically suspect for progressing to RA (clinically suspect arthralgia; CSA) has never been studied. In RA, it is presumed that both and local- and systemic inflammation underlie MS. We therefore hypothesize that, in patients with CSA, MS can also be explained by local- and systemic inflammation.
Objectives: To determine if MS can be explained by MRI-detected local inflammation (subclinical synovitis and tenosynovitis) and systemic inflammation (C-reactive protein(CRP)).
Methods: 514 CSA patients underwent a contrast-enhanced 1.5T MRI of metacarpophalangeal (MCP) 2-5, wrist and metatarsophalangeal (MTP) 1-5 joints, next to clinical assessment and laboratory investigations. MRIs were scored for synovitis and tenosynovitis in line with the RAMRIS-method. MS was dichotomized as present (duration ≥60 minutes) or absent (duration <60 minutes). Associations of MRI-detected synovitis, tenosynovitis and increased CRP with MS were tested with univariable and multivariable logistic regression. Since earlier research in arthritis patients showed that the effect of combined presence of MRI-detected synovitis and tenosynovitis was increased, compared to the effect of these features separately, interaction between MRI-detected synovitis and tenosynovitis, and between synovitis and increased CRP, was assessed.
Results: In the studied CSA-patients, mean age was 44 years (sd 13), 397 patients (77%) were female, median tender joint count (TJC-70) was 5 (interquartile range 2-10), and 67 (13%) patients were ACPA-positive. MS was present in 191 (37%) CSA-patients. Baseline characteristics among patients with and without MS were similar. MRI-detected synovitis was more often present in patients with MS compared to patients without MS (34% versus 19%), OR 2.12 (95% CI 1.41-3.19). Also, MRI-detected tenosynovitis was more frequently present in patients with MS (36% versus 24%), OR 1.74 (1.18-2.57). Likewise, increased CRP levels (≥5 mg/L) were more often found in patients with MS (31% versus 18%), OR 2.00 (1.32-3.04). In multivariable analyses, ORs were 1.90 (1.22-2.96) for MRI-detected synovitis and 1.82 (1.18-2.82) for increased CRP. With an OR of 1.20 (0.77-1.87) MRI-detected tenosynovitis was not significantly associated with MS in a multivariable analysis. Interaction between synovitis and tenosynovitis, and between synovitis and CRP was not significant (p-value of 0.13 and 0.15, respectively).
Conclusion: Presence of MRI-detected synovitis and increased CRP levels are associated with presence of MS in patients with CSA. This indicates that MS in CSA patients could indeed be induced by both local- and systemic inflammation.

POS0544

INFLUENCE OF EATING HABITS ON FRAILTY AMONG PATIENTS WITH RHEUMATOID ARTHRITIS: KURAMA COHORT

M. Katsushima[1], H. Minamino[2], M. Torii[3], M. Hashimoto[4], W. Yamamoto[5], R. Watanabe[4], K. Murakami[1], K. Murata[4], M. Tanaka[4], H. Ito[4], A. Morinobu[1]. [1]*Kyoto University Graduate School of Medicine, Department of Rheumatology and Clinical Immunology, Kyoto, Japan*; [2]*Kyoto University Graduate School of Medicine, Department of Diabetes, Endocrinology and Nutrition, Kyoto, Japan*; [3]*Kyoto University Graduate School of Medicine, Department of Human Health Sciences, Kyoto, Japan*; [4]*Kyoto University Graduate School of Medicine, Department of Advanced Medicine for Rheumatic Diseases, Kyoto, Japan*; [5]*Kurashiki Sweet Hospital, Department of Health Information Management, Kurashiki, Japan*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disorder that contributes to accelerating frailty, a clinical state of increased vulnerability due to declined physiological function. Although accumulating evidence suggests the importance of nutritional therapy for frailty in the general population, there is little evidence on dietary recommendations for preventing frailty in patients with RA.
Objectives: The present study aimed to reveal clinical associations between frailty status, eating habits and RA disease activity.
Methods: We conducted a cross-sectional study of 306 female outpatients enrolled from the KURAMA (Kyoto University Rheumatoid Arthritis Management Alliance) cohort database. The participants were classified into three groups (robust, prefrail and frail) according to simplified frailty scale (SOF index), and dietary data were collected using a self-reported food frequency questionnaire as previously reported. We performed multivariate logistic analyses for the presence of frailty/prefrailty with or without eating habits.
Results: Frail group showed physical decline such as decreased skeletal muscle index, hand grip strength and walking speed, and DAS28-ESR in the frail group was significantly higher compared to that in the others. In multivariate logistic analysis, the presence of frailty/prefrailty was correlated with DAS28-ESR (OR 1.71, p=0.00004) and methotrexate use (OR 0.47, p=0.0097). Cochran-Armitage trend test also showed that the intake frequency of five ingredients (meat, fish, milk, fruits and vegetables) was inversely associated with the prevalence of frailty/prefrailty. In additional multivariate logistic analyses with dietary habits, habitual intake of fish (at least three times per week), rather than meat or other foods, was independently correlated with the presence of frailty/prefrailty (OR 0.33, p=0.00027).
Conclusion: Our results suggest that habitual intake of fish, rather than meat or other foods, may be beneficial in preventing frailty among RA patients.

POS0545 DISCORDANCE BETWEEN PATIENT'S AND PHYSICIAN'S DISEASE ACTIVITY ASSESSMENT IN RHEUMATOID ARTHRITIS: WHICH DOMAINS CAN INFLUENCE THIS DISCREPANCY WHEN REMISSION IS ACHIEVED?

L. Moschetti[1,2], C. Bazzani[1], F. Villanova[2], R. Gorla[1], F. Franceschini[1,2]. [1]*ASST Spedali Civili, Rheumatology and Clinical Immunology Unit, Brescia, Italy*; [2]*University of Brescia, Clinical and Experimental Sciences, Brescia, Italy*

Background: In daily clinical practice, it is not rare to observe a relevant discordance between patient's global assessment (PGA) and physician's global assessment (PhGA), because of different illness perceptions.

Objectives: To evaluate the presence of PGA/PhGA discrepancy in patients with rheumatoid arthritis (RA) who achieved biological remission and to explore whether this discordance could be influenced by the presence of additional elements affecting patients' quality of life, such as comorbidities, sleep disturbances and psycho-emotional factors.

Methods: Our study included adult RA patients, followed in a single rheumatology centre, fulfilling three out of four Boolean remission criteria: tender joint count ≤1, swollen joint count ≤1 and C reactive protein ≤1 mg/dl[1]. Medical records including demographic data, clinical characteristics and outcomes measures were collected. To evaluate the impact of comorbidities we used the Rheumatic Disease Comorbidity Index (RDCI). Pain assessment, PGA and PhGA were rated on a visual analogue scale (0-100 mm) on the same day of the clinical evaluation. To analyse the discrepancy between PGA and PhGA, the [PGA-PhGA] variable was calculated, considering as discordant a difference ≥ 30 mm. All the subjects completed the following questionnaires: Health Assessment Questionnaire (HAQ), SF36 Health Survey, State-Trait Anxiety Inventory (STAI-Y1/Y2), Self-rating Depression Scale (SDS Zung) and Insomnia Severity Index (ISI). Statistical analysis was performed to compare concordant and discordant groups.

Results: The study included 90 patients (64 women, 26 men) with a median age of 60 [50-67] and a median RA duration of 10 [5-16] years; 80% of patients were RF and/or ACPA positive. According to DAS28 (median 1.7 [1.5-2.2]), 90% of patients achieved remission, 9% LDA and 1% MDA. Nevertheless, in 81% of cases PGA>PhGA and in 33% [PGA-PhGA] ≥30. The discordant group showed higher median disease activity scores (DAS28: 2.2 [1.9-2.4] vs 1.5 [1.4-1.9], *p<0,001*; SDAI: 6.7 [3.9-8.1] vs 2.0 [0.7-3.2], *p<0.001*). No differences were found in gender, age, comorbidities, RA duration, serology and treatment (cs-/b-DMARDs). Median prednisone dose was higher in the discordant group (0 [0-21] vs 0 [0-7.5] mg/week, *p:0,024*). Data about patient-reported outcomes and differences between two groups are reported in the table 1.

Conclusion: In our study we found discordance between the global disease assessment reported by patients, although considered in biological remission, and their physicians in 33% of the cases. As previously described[2], our data seems to confirm that potential causes for this discordance could be pain due to non-inflammatory processes, functional disability and compromised physical health. In the present study also psychological stress, particularly state anxiety, seems to negatively affect PGA/PhGA concordance. These results confirm the importance, in clinical practice, of exploring and managing inflammatory and non-inflammatory parameters separately, also in patients achieving biological remission.

POS0546 RENAL DYSFUNCTION AND METABOLIC CHANGES IN PATIENTS WITH RHEUMATOID ARTHRITIS ARE ASSOCIATED WITH ANGIOPOIETIN-LIKE PROTEIN TYPE 4

V. Aleksandrov[1,2], A. Aleksandrov[1,2]. [1]*Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation*; [2]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Department of clinical and laboratory diagnostics, Volgograd, Russian Federation*

Background: Along with chronic inflammation, the development of renal damage in rheumatoid arthritis (RA) is promoted by the presence of metabolic syndrome (MS), which may be an independent risk factor for the progression of chronic kidney disease.

Objectives: To establish a correlation between serum angiopoietin-like protein type 4 (ANGPTL4) and the presence of renal dysfunction and metabolic disorders in RA patients.

Methods: We examined 158 patients with RA (91.8% - women and 8.2% - men) aged 21 to 80 years old with an average duration of the disease - 9 [4; 15] years. The majority of patients were seropositive for RF-IgM (57.6%) and for anti-citrullinated protein antibody (ACPA) (60.1%), with an advanced clinical stage (45.6%) and moderate activity (3.2 <DAS28 ≤ 5.1) of the pathological process (58.2%).

The laboratory examination included the determination of serum concentrations of angiopoietin-like protein type 3 (Human Angiopoietin-like Protein 3 ELISA, Bio Vendor, Czech Republic) and type 4 (RayBio Human ANGPTL4 ELISA Kit; RayBiotech, USA).

To assess renal function in RA patients, the estimated glomerular filtration rate (GFR) was used according to the 2009 CKD-EPI formula. On the basis of GFR measurements, the patients were divided into three groups: I - optimal renal function (> 90 ml / min); II - a slight decrease in renal function (89-60 ml / min); III - reduced renal function (<59 ml / min).

A combination of the increased blood pressure (≥140 / 90 mmHg), the increased triglyceride levels (≥1.7 mmol / L), and the impaired carbohydrate metabolism (increased fasting plasma glucose ≥6.1 mmol / L) with a background of central obesity (waist circumference> 94 cm in men and> 80 cm in women) served as the basis for inclusion into the group of RA patients with signs of MS.

Results: A multivariate analysis of variance was performed comparing ANGPTL indices depending on GFR in the groups of RA patients without signs of MS and

RA patients with MS. It was revealed that there are significant differences in the level of both ANGPTL3 (F = 8.86, p = 0.0034) and ANGPTL4 (F = 29.6, p <0.001) between RA patients with varying severity of metabolic disorders.
The study of the influence of several factors (MS and renal dysfunction) on the content of ANGPTL in RA patients showed that the presence of metabolic disorders had an insignificant effect on the parameters of ANGPTL3 in the groups of patients with optimal and slightly reduced GFR, acquiring significance only with a more intense decrease in GFR (<59 ml / min / 1.73 m2). These factors and their interactions explain the insignificant share of the variability in ANGPTL3 (R^2 = 0.11), which indicates a low quality of the model.
There was a more pronounced difference in the level of ANGPTL4 in the presence of metabolic disorders in the groups of RA patients with varying degrees of renal dysfunction. The factors under consideration and their interactions do not make this model significant (p = 0.1), although they can explain a significant proportion of the variability in ANGPTL4 (R^2 = 0.32).
We differentiated RA patients into patients with high or optimal GFR (≥89 ml / min) and patients with reduced GFR (<89 ml / min) when combining groups of RA patients with varying degrees of renal dysfunction (group II and group III). Multivariate analysis of variance using the new characteristics showed a significant increase in ANGPTL 4 in the blood serum of RA patients with reduced GFR (F = 18.5, p <0.001) and severe metabolic changes (F = 24.2, p <0.001).
Thus, the concentration of ANGPTL4 in RA patients is directly influenced by two factors (renal dysfunction and the presence of MS), which can describe the variability of this sign in more than 30% of cases. The squared multiple correlation coefficient (R^2) in this model is 0.33.
Conclusion: ANGPTL type 4 should be considered as a key factor linking the development of the renal dysfunction in RA patients and the metabolic changes caused by rheumatoid inflammation.

POS0547 METEOROLOGICAL VARIABLES HAVE DIFFERENT INFLUENCE ON CORE MEASURES OF DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Mandl[1], P. Studenic[1], F. Alasti[1], R. Kaltenberger[2], A. Kerschbaumer[1], T. Krennert[3], J. S. Smolen[1], D. Aletaha[1]. [1]*Medical University of Vienna, Rheumatology, Vienna, Austria*; [2]*Central Institute for Meteorology and Geodynamics, Climate Research, Vienna, Austria*; [3]*Central Institute for Meteorology and Geodynamics, Weather Forecast, Vienna, Austria*

Background: The notion that weather conditions may influence the symptoms and course of rheumatic and musculoskeletal diseases goes back to ancient times. However, despite the seemingly obvious relationship, previous studies assessing how meteorological variables affect pain and disease activity have yielded contradictory results.
Objectives: To evaluate whether meteorological variables influence disease activity in patients with rheumatoid arthritis (RA).
Methods: We assessed correlations between clinical measures of disease activity (pain, patient global assessment [PGA], tender- and swollen 28 joint counts [TJC and SJC]) and individual meteorological variables: temperature (temp.), effective (eff.) temperature, saturation vapor pressure (SVP), absolute humidity (AH), relative humidity (RH), dew point, vapor pressure (VP) and precipitation. Assessments documented in the Care for Rheumatoid Arthritis database of our institution were matched with these meteorological variables on a daily basis for a period of 12 years between 2005 and 2017 and analyzed utilizing generalized estimating equations. Patients with <5 visits in the study period, those with <1 visit/quarter or with no pain (VAS=0) in ≥3 consecutive visits and those living outside of the catchment area were excluded. Patients were grouped into remission or low (≤11) vs. moderate or high (>11) disease activity based on the simplified disease activity index (SDAI).
Results: A total of 461 patients with an average disease duration at first visit of 5.7±7.4 years, average age of 55.3±14.5 years and a mean SDAI of 22.1±12.7 were analyzed. Among patients with moderate or high disease activity, higher temp./eff. temp. and SVP were associated with lower pain, TJC and SJC (Figure 1); on the contrary, higher RH was associated with higher pain and higher SJC. In those in remission or low disease activity, higher RH, AH, VP or dew point were associated with lower PGA. Higher precipitation was associated with lower SJC.

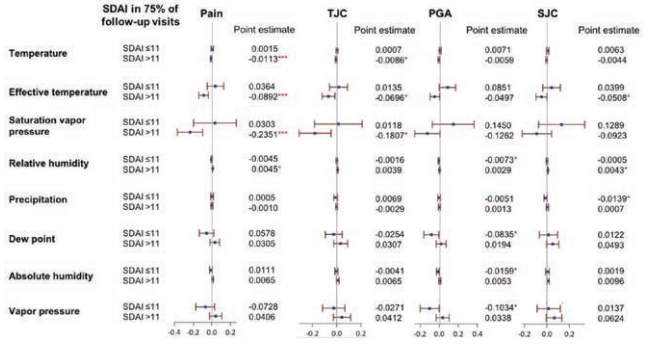

Figure 1. Association of meteorological parameters and clinical measures of disease activity. PGA: patient's global assessment, SDAI: simplified disease activity index, SJC: swollen joint count, TJC: tender joint count. * p≤ 0.05, ** p≤ 0.01, *** p≤ 0.001

Conclusion: In this large association study of meteorological parameters with RA, both temperature and humidity parameters were modestly inversely associated with pain, TJC and SJC.

POS0548 OPTIMAL ASSESSMENT OF THE RHEUMATOID ARTHRITIS ANKLE AND HINDFOOT: A COMPARATIVE STUDY BETWEEN CLINICAL EXAMINATION AND ULTRASONOGRAPHY

K. Maatallah[1], H. Boussaa[1], H. Riahi[2], H. Ferjani[1], M. Habechi[1], W. Triki[1], D. Ben Nessib[1], M. Bouaziz[2], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rheumatology, La Manouba, Tunisia*; [2]*Mohamed Kassab Institute of Orthopedics, Radiology, La Manouba, Tunisia*

Background: Foot disease is a common problem in rheumatoid arthritis (RA). Therapeutic decisions are often based on clinical examination (CE) alone, which can be adversely affected by factors such as deformity, obesity, and peripheral edema. Ultrasonography (US) has previously been shown to be more sensitive than CE for detecting synovitis and tenosynovitis in RA forefeet, but few data exist for the hindfoot and ankle.
Objectives: The aim of this study was to compare CE and US for the detection of hindfoot and ankle synovitis and tenosynovitis in patients with established RA.
Methods: We conducted a cross-sectional study including patients with RA (ACR/EULAR 2010). Demographic data and disease parameters were collected. CE was performed by a rheumatologist for the presence or absence of tenderness, swelling, and mobility restriction of both ankles. The following tendons were examined for tenosynovitis: tibialis anterior (TA) and posterior (TP), fibularis longus (FL), and brevis (FB) (assessed together). In a second time, US examination of the tibiotalar, talonavicular, and subtalar joints and the same tendons as CE was performed by a blinded radiologist experienced in musculoskeletal imaging using a Philips HD11 device with a high-frequency linear transducer. The presence or absence of synovitis and tenosynovitis was recorded, and the composite synovitis score (power doppler / grayscale ultrasound (PDUS)) was measured for each joint. The US score of each patient was defined by the sum of the composite scores of the joints studied (0-30). A p-value <0.05 was considered significant.
Results: Sixty-two feet were examined in 31 RA patients (25 women and six men) with a mean age of 54.8±10.8 years old [32-70]. The mean disease duration was 8.5±7.2 years [1-37]. Rheumatoid Factor (RF) and Anti-Citrullinated Peptides Antibodies (ACPA) were positive in 61.3% and 83.8% of cases. The mean DAS28 ESR was 3.8±1.5 [0.6-7].
Clinical examination of ankles revealed tenderness in 57.4% of cases, swelling in 38.8% of cases, and restriction in the range of motion in 11.1% of cases. TA tenosynovitis was noted in 14.8% of cases, TP tenosynovitis in 22.2% of cases, and FL and FB tenosynovitis in 31.5% of cases.
US showed tibiotalar synovitis in 59.3% of cases, talonavicular synovitis in 64.8% of cases, and subtalar synovitis in 46.3% of cases. TA tenosynovitis was noted in 5.6% of cases, TP tenosynovitis in 22.2% of cases, and FB and FL tenosynovitis in 25% and 11.1% of cases respectively.

An association was found between clinical tenderness and US synovitis of the tibiotalar joint (p=0.013) and the talonavicular joint (p=0.027). No association was noted between clinical swelling and US synovitis in these joints.
No association was noted between clinical and US tenosynovitis of TA (p=0.279), TP (p=0.436), FB (p=0.495) and FL (p=0.315).
Conclusion: Clinical examination of RA ankles may be challenging and needs to be coupled with US, which is more sensitive and accurate in the detection of synovitis and tenosynovitis.

POS0549 FUNCTIONAL IMPACT OF FOREFOOT INVOLVEMENT IN RHEUMATOID ARTHRITIS

K. Maatallah[1], H. Boussaa[1], H. Riahi[2], H. Ferjani[1], W. Triki[1], M. Habechi[1], D. Ben Nessib[1], M. Bouaziz[2], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rheumatology, La Manouba,Tunisia*; [2]*Mohamed Kassab Institute of Orthopedics, Radiology, La Manouba,Tunisia*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease that mainly affects small joints of the hands and feet. Foot deformities may affect the patient's gait, thus compromising their daily activities and autonomy.
Objectives: The aim of this study was to analyze its functional impact.
Methods: We conducted a cross-sectional study including patients diagnosed with RA according to the ACR/EULAR 2010 criteria. Demographic variables, Foot Function Index (FFI), and Health Assessment Questionnaire (HAQ) scores were analyzed. We collected data on the following clinical variables: The pain Visual Analog Scale (VAS), forefoot deformities, erythrocyte sedimentation rate (ESR), and Disease Activity Score 28 (DAS28). All patients had feet X-rays and the Larsen score was calculated. A blinded radiologist experienced in musculoskeletal imaging using a Philips HD11 device with a high-frequency linear transducer performed ultrasonography (US) of MTP joints. Synovitis was defined as an abnormal hypoechoic synovial tissue within the capsule that is not displaceable and poorly compressible and that may exhibit Doppler signals. The composite synovitis score (power doppler / grayscale ultrasound (PDUS)) was measured for each joint. The US score of each patient was defined by the sum of the composite scores of the joints studied (0-30). A p-value <0.05 was considered significant.
Results: We included 31 patients (25 men and six women) with a mean age of 54.8±10.8 years old [32-70]. The mean disease duration was 8.5±7.2 years [1-37]. The mean ESR and DAS28 ESR were 33±26 mm [5-102] and 3.8±1.5 [0.6-7], respectively. Twenty-nine percent of patients had a high disease activity.
Metatarsalgia was reported by 54.8% of patients with a mean VAS of 4.5±3.7 [0-9]. Forefoot deformities were noted in 42% of patients: round forefoot in 13% of cases, triangular forefoot in 29% of cases, hallux valgus in 29% of cases, Quintus varus in 29% of cases, and claw toes in 13% of cases. Corns and calluses were noted in 42% and 29% of cases respectively.
X-rays showed abnormalities in 75% of patients. The mean Larsen score was 9.8±6.2 [0-28].
US showed synovitis in 46.3% of MTP1, in 53.7% of MTP2, in 48.3% of MTP3, in 42.6% of MTP4, and in 37% of MTP5 joints. Doppler signal was detected in 5.6% of MTP1 and MTP2, and in 3.7% of MTP3, MTP4, and MTP5 joints. The mean US score was 5.3±4.3 [0-15].
The mean FFI was 66.5%. Mean rates of pain, difficulty, and disability were 89.5%, 40%, and 70% respectively. The mean HAQ score was 0.5±0.5 [0-2]. Severe disability was noted in 20% of patients.
A significant positive correlation was noted between FFI and, Larsen score (r=0.214, p=0.014) and US score (r=0.420, p=0.021). A significant positive correlation was also noted between HAQ score and, foot pain VAS (r=0.555, p=0.009).
Conclusion: Foot involvement is frequently seen in RA. This condition may affect patients' autonomy. Early diagnosis and appropriate treatment are necessary in order to preserve the quality of life.

POS0550 EVALUATION OF THE INTIMA-MEDIA THICKNESS INDEX BY CAROTID DOPPLER IN PATIENTS WITH RHEUMATOID ARTHRITIS AT HOSPITAL DOCENTE PADRE BILLINI, DOMINICAN REPUBLIC

T. Polanco Mora[1], J. Santana Peralta[2], A. Cornelio[1], Y. Cruz[1], E. Rodriguez Bautista[1], T. Valdez[1], R. Muñoz[1], A. Feriz[1]. [1]*Hospital Docente Padre Billini, Reumatologia, Santo Domingo,*; [2]*Hospital Docente Padre Billini, Reumatologia, Santo domingo,*

Background: Rheumatoid arthritis (RA) is an autoimmune disease systemic, affects 0.5 - 1% of the world population, predominantly female. (1) Carotid Doppler is used to detect endothelial dysfunction by measuring intima-media thickening, flow velocities, subclinical atherosclerosis markers, and vascular tone.(2,3) Measurement of carotid intima-media thickness (cIMT) is useful in assessing cerebrovascular disease and cardiovascular risk in patients with rheumatoid arthritis (4) Intima-media thickness value> 0.9mm and presence of plaques Atheromatous cells in the carotid artery are predictive of increased cardiovascular risk and silent heart disease. (5,6)
Objectives: To evaluate the carotid intima-media thickness in patients with rheumatoid arthritis
Methods: A prospective, observational, cross-sectional study. Carotid Doppler was performed on outpatient patients with a diagnosis of rheumatoid arthritis from November 2019 to 2020 of the rheumatology service of the Hospital Docente Padre Billini and healthy controls. Inclusion criteria:> 18 years, diagnosis of RA according to ACR / EULAR 2010 classification criteria, carotid Doppler with measurement of the carotid intima-media thickness. Controls without disease, matched by sex and age. The data were analyzed with SPSS V23.
Results: Of 251 patients with a diagnosis of RA, 100 met criteria inclusion, 96.2% female, 100 healthy controls were included. Average evolution of the disease 7.5 years, 88%(88) Positive rheumatoid factor, 33% (33) Positive anti-CCP. 82% (82) concomitant scDMARD, 70% (70) bDMARD, 18% (18) ctDMARD. 53% (53) Dyslipidemia, 23% (23) obesity, 10% (10) hyperglycemia, 8% (8) smokers. DAS28 showed 57% (57) low activity, 20% (20) moderate activity, 15% (15) remission, 8% (8) high activity. Carotid Doppler in patients with RA showed 32% (32) atheromatous plaques, 18.75% (6) calcified plaques, 1.44% (1) stenosis bilateral carotid. C-reactive protein and erythrocyte sedimentation rate high 35% (35) / 58% (58) respectively. Carotid Doppler in healthy controls revealed 17% (17) atheromatous plaques, 47.05% (8) calcified plaques. 69% (69) of RA patients had increased cIMT, mean (SD) cIMT 3.82mm (1.11), controls 58% (58) increase in cIMT, Mean (SD) 3.12mm (0.93) (p = 0.0435).
Conclusion: Our study showed that 69% of patients with Arthritis Rheumatoid featured increased intima-media thickness associated with low DAS28, we recommend assessing cardiovascular risk using carotid Doppler in patients with low to moderate activity. It was observed that in patients with RA and healthy controls more than half present increased carotid intima-media thickness.

POS0551 MEDICAL COSTS FOR PATIENTS STARTING TREATMENT FOR RHEUMATOID ARTHRITIS WHO HAVE COMORBID DIABETES MELLITUS IN JAPAN

E. Tanaka[1], E. Inoue[1,2], R. Sakai[1], I. Katsuhiko[3], A. Shoji[3], M. Harigai[1]. [1]*Tokyo Women's Medical University School of Medicine, Department of Rheumatology, Tokyo, Japan*; [2]*Showa University, Showa University Research Administration Center (SURAC), Tokyo, Japan*; [3]*Medilead Inc., Tokyo, Japan*

Background: Rheumatoid arthritis (RA) patients can experience various comorbidities[1]. The incidence of diabetes mellitus (DM) is reported higher in patients with RA[2] and comorbid DM is likely to affect treatment outcomes[3] and then healthcare resource uses, however, no previous study has not focused on it.
Objectives: To evaluate medical costs and resource use in patients starting treatment for RA with and without DM using a large claims database in Japan.
Methods: We used a large Japanese administrative claims database constructed by the Japan Medical Data Center (JMDC)[4]. Patients with the International Classification of Diseases 10th revision (ICD-10) codes for RA who started medication with disease-modifying antirheumatic drugs (DMARDs) after 6 months without them in the period from 1/1/2012 to 12/31/2017 and who were observable for 12 months as a follow-up period were enrolled. These patients were categorized as DM or non-DM group with ICD-10 codes for DM plus use of antidiabetic drugs in 6 months before starting DMARDs (baseline period). To adjust baseline characteristics between the 2 groups, they were matched by sex, age, Charlson Comorbidity Index (CCI) except for DM, months from the first RA codes to starting DMARDs, and medications. The primary endpoint was mean medical cost per patient in the 12-month follow-up period. Costs in JPY were converted into EUR (1 EUR = 125 JPY in 2020). Costs for drugs, treatments, and materials and their subcategories were evaluated both with and without DM-specific costs. The secondary endpoints were the proportions of patients using the subcategories of each resource.
Results: Patients of 161 for the DM group and 2,974 for the non-DM group were eligible, and 109 patients were matched from each group. The medians of age and CCI were 59 years and 2.0 in both groups and no significant difference was observed in all baseline characteristics used for matching between the groups. Total mean costs were significantly higher in the DM group (DM, 5,331 EUR, non-DM 3,200 EUR; P< 0.05). After excluding DM-specific costs, drug costs were significantly higher in the DM group than in the non-DM group (DM 1,883 EUR, non-DM 896 EUR; P < 0.05), especially costs for biological DMARDs (DM 1,156 EUR, non-DM 292 EUR; P < 0.05), mainly because a higher proportion of patients used these drugs in the DM group (Table 1). Treatment costs (DM 2,380 EUR, non-DM 2,133 EUR) and material costs (DM 74 EUR, non-DM 149 EUR) were not different between the groups, but only costs for examinations were significantly higher in the DM group (DM 970 EUR, non-DM 779 EUR; P < 0.05).

Table 1. Number and proportion of patients who used drugs

Type of drug		Drug use, n (%)		
		DM (N = 109)	Non-DM (N = 109)	*P*-value
csDMARDs	Total	109 (100.0)	109 (100.0)	1.000
	Methotrexate	101 (92.7)	102 (93.6)	1.000
	Others	46 (42.2)	51 (46.8)	0.583
bDMARDs	Total	16 (14.7)	6 (5.5)	0.041
	TNFi	11 (10.1)	4 (3.7)	0.118
	IL6i	6 (5.5)	2 (1.8)	0.219
	T-cell	4 (3.7)	0 (0.0)	0.125
tsDMARDs		0 (0.0)	0 (0.0)	1.000
CSs		65 (59.6)	62 (56.9)	0.711
Analgesics	Total	103 (94.5)	96 (88.1)	0.167
	Acetaminophen	24 (22.0)	23 (21.1)	1.000
	Acetaminophen /Opioids	10 (9.2)	6 (5.5)	0.454
	NSAIDs	102 (93.6)	93 (85.3)	0.093
	Opioids	0 (0.0)	4 (3.7)	0.125
	Others	25 (22.9)	17 (15.6)	0.185

bDMARDs=biological disease-modifying antirheumatic drugs; CSs=corticosteroids; csDMARDs=conventional synthetic disease-modifying antirheumatic drugs; DM=diabetes mellitus; IL6i=interleukin-6 inhibitor; NSAID=non-steroidal anti-inflammatory drug; T-cell=selective T-cell co-stimulation modulator; TNFi=tumor necrosis factor α inhibitor; tsDMARDs=targeted synthetic disease-modifying antirheumatic drugs; P-values were calculated using McNemar test

Conclusion: Medical costs for RA were higher in the DM group than in the non-DM group because of more prevalent use of biological DMARDs in the DM group.

POS0552 DIASTOLIC DYSFUNCTION ASSOCIATED WITH INCREASED ACTIVITY IN RHEUMATOID ARTHRITIS

S. Lugo-Perez[1], D. Á. Galarza-Delgado[2], J. R. Azpiri-López[1], I. J. Colunga-Pedraza[2], N. Guajardo-Jauregui[2], A. B. Rodriguez-Romero[2], A. Cárdenas[2], H. Azpiri-Diaz[1], O. A. Cepeda-Ayala[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*; [2]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*

Background: Cardiovascular disease (CVD) is the main cause of mortality in patients with rheumatoid arthritis (RA) reflected by a higher prevalence of cardiovascular risk factors (CVRFs), a chronic systemic inflammatory state and heart failure compared to the general population (1). Left ventricular diastolic dysfunction (LVDD) is attributable to structural abnormalities such as hypertrophy or interstitial fibrosis and impaired myocyte relaxation resulting from ischemia and is frequently asymptomatic (2). The presence of LVDD it could be considered as the first step to development of heart failure.
Objectives: The aim of the study is to identify the association of disease activity and the presence of LVDD in patients with RA.
Methods: A cross-sectional, observational, and comparative study of RA subjects that fulfilled ACR / EULAR 2010 classification criteria, aged 40-75 years. Subjects were evaluated by a transthoracic echocardiogram performed and reviewed by two certified echocardiographers. A total of fifty-one RA patients diagnosed with LVDD were included according to the 2016 American Society of Echocardiography (ASE). Distribution was evaluated with the Kolmogorov-Smirnov test. Descriptive analysis was done using measures of central tendency. Chi square, Student´s t test and Mann-Whitney U test were used for comparations between groups. A *p* value <0.05 was considered statistically significant.
Results: We found no statistical difference between groups regarding age, gender, comorbidities (type 2 diabetes mellitus, hypertension, dyslipidemia and, active smoking) and body mass index. Patients with LVDD demonstrated a higher disease activity evaluated by disease activity score using 28 joints-C reactive protein (DAS28-PCR) (4.88 vs 3.56, *p*= 0.004) (Table 1). It was observed that patients with LVDD have a higher prevalence of being in the high disease activity category (41.2% vs. 13.7%, *p*= 0.002) (Figure 1). When performing a binary logistic regression, it was found that a high disease activity was the only independent predictor for the presence of LVDD, with an OR 4.70, (95% CI 1.63-13.50, *p*= 0.004).

Table 1. Demographic and disease characteristics

	RA patients with LVDD (n=51)	RA patients without LVDD (n=51)	*p*
Women, n (%)	50 (98)	47 (92.2)	NS
Age, years ± SD	56.12 ± 8.76	53.91 ± 5.61	NS
HTN, n (%)	17 (33.3)	13 (25.5)	NS
T2DM, n (%)	6 (11.8)	10 (19.6)	NS
Dyslipidemia, n (%)	17 (33.3)	11 (21.6)	NS
Active smoking, n (%)	5 (9.8)	5 (9.8)	NS
BMI kg/m^2 ± SD	28.20 ± 4.89	29.40 ± 5.13	NS
Disease duration, years (p25-p75)	10.70 (5.16-17.87)	5.66 (2.67-15.64)	**0.033**
DAS28-CRP, median (p25-p75)	4.88 (3.53-5.45)	3.56 (3.00-4.69)	**0.004**

NS, no significative; HTN, hypertension; T2DM, type 2 diabetes mellitus; BMI, body mass index; DAS28, disease activity score using 28 joints; CPR, C reactive protein

Conclusion: Patients with RA and LVDD have a higher disease activity, so emphasis should be placed on strict antirheumatic treatment and cardiovascular therapies to avoid the risk of developing CVD and the progression to heart failure. Logistic regression demonstrates that inadequate disease control is an independent factor from traditional CVRFs for the presence of LVDD.

POS0553

IMPACT OF RHEUMATOID ARTHRITIS ON LEFT VENTRICULAR REMODELING

S. Lugo-Perez[1], J. R. Azpiri-López[1], I. J. Colunga-Pedraza[2], D. Á. Galarza-Delgado[2], A. B. Rodriguez-Romero[2], N. Guajardo-Jauregui[2], A. Cárdenas[2], H. Azpiri-Diaz[1], O. A. Cepeda-Ayala[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*; [2]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*

Background: Patients with Rheumatoid Arthritis (RA) have a higher prevalence of cardiovascular diseases (1) and a strong association with abnormalities in the left ventricle (LV) geometry. Both concentric and eccentric remodeling have been determined as an independent factor for sudden cardiac arrest in the general population with normal or slightly decreased ventricular function (2) but there is still controversy about the factors involved and the pathophysiology in patients with RA.

Objectives: The aim of the study is to determine the characteristics of LV geometry and the impact of RA.

Methods: A cross-sectional, observational, and comparative study of fifty-two RA patients that fulfilled ACR / EULAR 2010 classification criteria, aged 40-75 years. Controls were included and matched by age, gender, and comorbidities. Subjects were evaluated using a transthoracic echocardiogram performed and reviewed by two certified echocardiographers. Ventricular geometry was evaluated with indexed left ventricular mass and relative wall thickness. Distribution was evaluated with the Kolmogorov-Smirnov test. Descriptive analysis was done using measures of central tendency. Chi square, Student's t test and Mann-Whitney U test were used for comparations between groups. A logistic binary regression was performed with the traditional cardiovascular risk factors (CVRFs), age and RA diagnosis. A p value <0.05 was considered statistically significant.

Results: No significant differences were found in the traditional CVRFs (type 2 diabetes mellitus, dyslipidemia, active smoking, and hypertension) (Table 1). Most of the subjects reported normal geometry in both groups (55.8% for RA group vs 64.0% for controls). A higher prevalence of eccentric hypertrophy was found in the RA group, 13 (25%) subjects versus 3 (6%) in the control group, p = 0.009. The binary regression showed that the diagnosis of RA was the only independent risk factor for the presence of eccentric hypertrophy, OR 7.22 95% CI (1.68-31.02, p = 0.008).

Table 1. Demographic characteristics and echocardiographic findings.

	RA (n=52)	Control (n=50)	*p*
Age, years ± DE	51.4 ±6.2	51.1 ± 5.5	NS
Women, n (%)	51 (98.1)	49 (98.0)	NS
Active smoking, n (%)	8 (15.4)	8 (16.0)	NS
Dyslipidemia, n (%)	11 (21.2)	13 (26.0)	NS
Type 2 Diabetes Mellitus, n (%)	5 (9.6)	5 (10.0)	NS
HTN, n (%)	8 (15.4)	10 (20.0)	NS
BMI kg/m^2, median (p25-p75)	27.8 (24.5-31.4)	28.3 (25.4-30.3)	NS
BSA, median (p25-p75)	1.7 (1.6-1.8)	1.8 (1.6-1.9)	**0.003**
Systolic blood pressure, mmHg (p25-p75)	119.5 (110.0-127.5)	120.0 (110.7-130.0)	NS
Echocardiography findings			
LVPWTd, median (p25-p75)	0.9 (0.8-1.0)	0.9 (0.8-1.0)	NS
LVIDd, median (p25-p75)	4.8 (4.3-5.2)	4.6 (4.5-4.9)	NS
LV mass, median (p25-p75)	131.2 (119.5-155.7)	131.2 (113.2-154.3)	NS
LV mass index, median (p25-p75)	78.6 (69.7-95.6)	76.0 (66.7-84.6)	NS
RWT, mean ± SD	0.4 ± 0.09	0.4 ± 0.07	NS

NS, no significant; BMI, body mass index; BSA, body surface area; LVPWTd, left ventricular posterior wall thickness at end-diastole; LVIDd, left ventricular internal dimension at end-diastole; RWT, relative wall thickness.

Conclusion: There is a higher prevalence of eccentric remodeling in patients with RA independently of traditional CVRF. The diagnosis of RA is an independent risk factor for the presence of eccentric hypertrophy that is associated with higher mortality. Treatment of cardiovascular comorbidities should be intensified in those patients with abnormalities in LV geometry in order to prevent cardiovascular diseases such as heart failure.

POS0554

MEDICAL COST AND RESOURCE USE IN PATIENTS STARTING TREATMENT FOR RHEUMATOID ARTHRITIS TREATED WITH AND WITHOUT CORTICOSTEROIDS IN JAPAN

E. Tanaka[1], E. Inoue[1,2], R. Sakai[1], I. Katsuhiko[3], A. Shoji[3], M. Harigai[1]. [1]*Tokyo Women's Medical University School of Medicine, Department of Rheumatology, Tokyo, Japan*; [2]*Showa University, Showa University Research Administration Center (SURAC), Tokyo, Japan*; [3]*Medilead Inc., Tokyo, Japan*

Background: The 2019 update of the European League Against Rheumatism (EULAR) treatment recommendations strongly recommends co-administration of corticosteroids (CSs) with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) in patients with RA as bridging therapy to improve the success rate of the first-line treatment and to avoid disease flare-ups[1]; however, current treatment guidelines for RA in Japan do not clearly mention about their use. Poor disease management after the initial diagnosis can affect the overall use of health services and the economic burden on patients.

Objectives: To describe medical costs and resource use in patients with early RA treated with and without oral or injectable corticosteroids (CSs) as part of their initial treatment with disease-modifying antirheumatic drugs (DMARDs) in Japan.

Methods: We used a large Japanese administrative claims database constructed by the Japan Medical Data Center (JMDC)[2]. Patients with the International Classification of Diseases 10th revision (ICD-10) codes for RA were enrolled at the first DMARDs prescription after no DMARDs prescription period for 6-months (index date) in the period from 1/1/2012 to 12/31/2017. Patients who were observable for 12 months after the index date as a follow-up period were included. Patients treated with CSs within the follow-up period were compared with those without them (CS and non-CS group). The primary endpoint was mean medical cost per patient in the 12-month follow-up period. The secondary endpoints were costs for drugs, treatments, and materials and the proportions of patients using the subcategories of each resource. Drugs were divided into medications for RA or for comorbidities including adverse events (AEs). Costs in JPY were converted into EUR (1 EUR = 125 JPY in 2020).

Results: Eligible patients of 1,670 and 1,487 were identified as the CS and non-CS group (median age: 51 years and 50 years). Total mean costs were significantly higher in the CS group (CS, 4,448 EUR, non-CS 3,208 EUR; P< 0.05). Drug, treatment, and material costs were significantly higher in the CS group than in the non-CS group (drug for RA and AEs, CS 2,367 EUR, non-CS 1,581 EUR, P < 0.05; drug for RA only, CS 2,265 EUR, non-CS 1,516 EUR, P < 0.05; treatment, CS 1,987 EUR, non-CS 1,562 EUR, P < 0.05; material, CS 94 EUR, non-CS 65 EUR; P < 0.05). The resource use in almost all drug subcategories were higher in the CS group (Table 1), as well as in all treatment and material subcategories.

Table 1. Number and proportion of patients who used drugs

Type of drug		Drug use, n (%)		
		CS (N = 1,670)	Non-CS (N = 1,487)	*P*-value
csDMARDs	Total	1,635 (97.9)	1,447 (97.3)	0.328
	Methotrexate	1,481 (88.7)	1,315 (88.4)	0.870
	Others	790 (47.3)	551 (37.1)	< 0.001
bDMARDs	Total	342 (20.5)	181 (12.2)	< 0.001
	TNFi	252 (15.1)	129 (8.7)	< 0.001
	IL6i	93 (5.6)	40 (2.7)	< 0.001
	T-cell	40 (2.4)	17 (1.1)	0.012
Analgesics	Total	1,512 (90.5)	1,274 (85.7)	< 0.001
	Acetaminophen	379 (22.7)	273 (18.4)	0.003
	Acetaminophen / Opioids	84 (5.0)	37 (2.5)	< 0.001
	NSAIDs	1,459 (87.4)	1,214 (81.6)	< 0.001
	Opioids	16 (1.0)	10 (0.7)	0.491
	Others	198 (11.9)	101 (6.8)	< 0.001
Antibiotics	Total	1,086 (65.0)	873 (58.7)	< 0.001
	Antibacterial drugs	1,022 (61.2)	800 (53.8)	< 0.001
	Antifungal drugs	133 (8.0)	86 (5.8)	0.019
	Antiviral drugs	172 (10.3)	129 (8.7)	0.136
	Antiparasitic drugs	5 (0.3)	8 (0.5)	0.443
Anti-osteoporotic drugs		341 (20.4)	95 (6.4)	< 0.001

bDMARDs=biological disease-modifying antirheumatic drugs; CSs=corticosteroids; csDMARDs=conventional synthetic disease-modifying antirheumatic drugs; IL6i=interleukin-6 inhibitor; NSAID=non-steroidal anti-inflammatory drug; T-cell=selective T-cell co-stimulation modulator; TNFi=tumor necrosis factor α inhibitor; P-values were calculated using Chi-square test

Conclusion: Patients with early RA treated with CSs in the first year after starting DMARDs tended to use more resources and have higher medical costs than patients not treated with CSs.

POS0555 THE NATURAL COURSE OF RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE FOCUSING ON LUNG PHYSIOLOGY: A PROSPECTIVE OBSERVATIONAL COHORT STUDY (PART 1)

S. H. Chang[1], J. S. Lee[2], J. S. Lee[3], C. H. Park[4], M. U. Kim[5], Y. J. Ha[6], E. H. Kang[6], Y. A. Lee[7], Y. Park[8], J. Y. Choe[9], E. Y. Lee[10]on behalf of KOrean Rheumatoid Arthritis Interstitial Lung disease (KORAIL) cohort study group. *[1]Soonchunhyang University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Cheonan, Korea, Rep. of (South Korea)*; *[2]Clinical Research Center, Asan Institute for Life Sciences, Asan Medical Center, Department of Medical Stastics, Seoul, Korea, Rep. of (South Korea)*; *[3]GENOME INSIGHT Inc.,., Seoul, Korea, Rep. of (South Korea)*; *[4]Soonchunhyang University College of Medicine, Department of Radiology, Cheonan, Korea, Rep. of (South Korea)*; *[5]SMG-SNU Boramae Medical Center, Department of Radiology, Seoul, Korea, Rep. of (South Korea)*; *[6]Seoul National University Bundang Hospital, Division of Rheumatology, Department of Internal Medicine, Seongnam, Korea, Rep. of (South Korea)*; *[7]Kyung Hee University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[8]Yonsei University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[9]Catholic University of Daegu College of Medicine, Division of Rheumatology, Department of Internal Medicine, Daegu, Korea, Rep. of (South Korea)*; *[10]Seoul National University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). However, there are few prospective studies for the natural course of lung physiology in most patients with RA-ILD.

Objectives: To assess the natural course of lung physiology of RA-ILD and the relation between arthritis activity and pulmonary physiology in patients with RA-ILD.

Methods: The KOrean Rheumatoid Arthritis ILd (KORAIL) cohort is the prospective observational cohort and aims to investigate the natural course of RAILD. Based on either 1987 or 2020 ACR criteria, patients diagnosed with RA and ILD based on CT scan were recruited from six tertiary medical hospitals in Korea since January 2015. RA disease activity was assessed using swollen and tender joint count by treating physician, inflammatory markers including CRP and ESR, and patient's global assessment annually. Pulmonary function tests (PFT), including FVC, FEV1, DLCO, and chest CT scan, were conducted annually.

Results: We analyzed 163 patients at baseline (V1), 141 at 1-year (V2), 122 at 2-year (V3), and 88 at 3-year follow-up (V4). The mean (±SD) duration since RA diagnosis and since ILD diagnosis was 7.6±8.0 and 2.7±3.1 years, respectively. The female to male ratio was about 2:1, and 58.9% of patients (n=96) were 65 years old or older. Only two patients were negative for RF and anti-CCP; 98.7% of patients (n=161/163) were positive for RF (n=143, 87.7%) or anti-CCP antibody (n=154, 94.5%). At enrollment, one-hundred-nine patients (66.9%) had FVC ≥80 % of predicted. Twenty-five patients (15.3%) showed FEV1/FVC≥0.7, of which seventeen patients, only ten percent of a total cohort (10.4%), had FVC ≥80% of predicted, which corresponds to the obstructive pattern. Proportion of patients showed a ≥10-point decline from the enrollment in FVC of the predicted value were around 10% at every year (Table 1). The proportion of patients with a relative decline of ≥10% from the enrollment in FVC predicted was increased every year because of cumulation. The proportion of patients with a relative decline of ≥10% from the previous visit in FVC predicted was also around 10-15% every year. Proportions of patients with 55% or more DLco % pred. has been decreased annually; 78.5% (n=128/158) at V1, 72.9% (n=105/139) at V2, 68.7% (n=90/117) at V3, and 56.6% (n=56/85) at V4. Patients with a relative decline of ≥10% from the enrollment in DLco predicted was 38 (27.5 %) at V2 and 37 (31.9%) at V3. Patients with a relative decline of ≥10% from the previous visit in DLco predicted was 29 (25.2%) at V3. Of note, thirty patients (21.7%) showed a relative 10% or more increase from enrollment in DLco predicted at V2, and so did 30 patients (25.9%) at V3.

Table 1. The analysis of forced vital capacity (FVC) in KORIL cohort

	V1 (enrollment)	V2 (1-year)	V3 (2-year)	V4 (3-year)
FVC (mL), mean±SD	2549.5 ± 743.3	2479.5± 764.4	2435.8 ± 742.8	2405.7 ± 731.2
FVC % of predicted, mean±SD	84.70 ± 16.74	84.7±18.1	84.3 ± 17.6	83.1 ± 19.1
Rate of FVC decline, mL·year^{-1} (95% CI)	-	-14 (-49, 21)	-62 (-104, -21)	-
A 10-point decline from V1 in predicted FVC value, n (%)	-	10 (7.1)	16 (13.3)	8 (9.4)
Relative decline of 10% from V1 in predicted FVC value, n (%)	-	17 (12.1)	23 (18.9)	17 (19.3)
Relative decline of 10% from the previous visit in predicted FVC value, n (%)	-	17 (12.1)	17 (14.2)	13 (15.3)

Conclusion: Annually, about 10-15% of patients experience a relative ≥10% decline from the previous visit in FVC predicted value in RA-ILD.

POS0556 USEFULNESS OF FDG-PET/CT FOR PREDICTING SPONTANEOUS REGRESSION IN MTX ASSOCIATED LYMPHOPROLIFERATIVE DISORDER WITH RHEUMATOID ARTHRITIS

T. Kameda[1], S. Nakashima[1], H. Shimada[1], R. Wakiya[1], M. Mahmoud Fahmy Mansour[1], M. Kato[1], K. Sugihara[1], Y. Ushio[1], H. Dobashi[1]. [1]*Kagawa University, Department of Internal Medicine, Division of Haematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kita-gun, Japan*

Background: Recently, there are many reports from Japan about methotrexate associated lymphoproliferative disorder (MTX-LPD). We are investigating the predictive factor of spontaneous regression (SR) in MTX-LPD. On the other hand, FDG-PET/CT is used for diagnosis of LPD including malignant lymphoma. In addition, it was reported that imaging biomarkers such as metabolic tumor volume (MTV) and total lesion glycolysis (TLG) could predict the prognosis of malignant tumor (1, 2). However, there is no report that these imaging biomarkers could predict the SR of MTX-LPD.

Objectives: We investigate the usefulness of FDG-PET/CT for predictive factor of SR in MTX-LPD.

Methods: We enrolled 24 RA patients who diagnosed MTX-LPD and performed FDG-PET/CT from 2005 to 2019. We divided these cases into spontaneous regression cases (SR group; 15 cases) and cases that treated with chemotherapy after MTX discontinuation (CTx group; 9 cases), and compared the difference as follow subjects between two groups; clinical data including histopathological findings, SUVmax to evaluate malignant tumor activity by FDG-PET/CT, MTV and TLG which refer to metabolically active volume of the tumor segmented FDG-PET/CT. In addition, we analyzed cut off levels, sensitivity and specificity using statistical software JMP.

Results: Diffuse large B cell lymphoma (DLBCL) and Hodgkin lymphoma (HL) were 5 and 1 cases in SR group, and 1 and 5 cases in CTx group. In addition, MTV and TLG by FDG-PET/CT was significantly lower in SR group, although SUVmax is no difference between two groups (figure 1). Cut off levels of MTV and TLG were 103.12 ml (sensitivity; 88.9%, specificity; 86.7%) and 361.75 ml (sensitivity; 88.9%, specificity; 86.7%), respectively.

Conclusion: We suggested that MTV and TLG were useful for predict of SR in MTX-LPD.

POS0557 THE RELATION BETWEEN INVOLVEMENT OF INDIVIDUAL JOINTS OF THE UPPER EXTREMITY AND GRIP FORCE IN EARLY RHEUMATOID ARTHRITIS

M. Rydholm[1,2], A. Sharma[2], I. Wikström[1,2], L. T. H. Jacobsson[2,3], C. Turesson[1,2]. [1]*Skåne University Hospital, Department of Rheumatology, Malmö, Sweden*; [2]*Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden*; [3]*Gothenburg University, Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, Gothenburg, Sweden*

Background: Rheumatoid arthritis (RA) has a major impact on hand function in many patients.

Objectives: The objective of this study was to investigate the relation between swelling and tenderness of individual joints in the upper extremities and grip force in patients with early RA.

Methods: An inception cohort of patients with early RA (symptom duration ≤12 months), recruited in 1995-2005, was investigated and followed in a structured program. All patients were examined by the same rheumatologist according to a structured protocol, and swelling and tenderness of individual joints was recorded. Grip force (Newton, N) was measured using the electronic instrument Grippit (AB Detektor, Gothenburg, Sweden). Average grip force values of each hand were evaluated and compared to the expected, based on age- and sex-specific reference values from the literature (1). Grip force was expressed as % of expected values. Linear regression analyses were used to assess the relation between upper extremity joint involvement in individual joints and grip force, using the presence/absence of synovitis/tenderness in each joint as covariates. For the multivariate analysis, covariates with $p<0.10$ in the univariate analyses were selected. In cases with major collinearity (Spearman's $r>0.3$), the covariate with the stronger association in the univariate analysis was included.

Results: A total of 215 patients with early RA (71 % women; mean age 60 years) were investigated. The median symptom duration at inclusion was 7 months; interquartile range 5-10. The median 28 joint counts for swollen joints was 7 (interquartile range, IQR 5-11) and for tender joints 4 (IQR 1-9). In univariate analyses, swelling of the wrist, each metacarpophalangeal (MCP) joint and proximal interphalangeal (PIP) joints III and V, as well as tenderness of the elbow, wrist and each MCP and PIP joint were associated with significantly reduced grip force in the right hand. In the left extremity, corresponding associations were observed for swelling of the wrist, each MCP joint and PIP joints I and V, and for tenderness of the wrist and each MCP and PIP joint. In multivariate analysis, wrist synovitis was associated with reduced grip force (β -11.0 and -14.3 % of expected, respectively). There were also independent significant associations for tenderness of MCP IV and the elbow with reduced grip force in the right hand, and for swelling of MCP I and MCP V with reduced grip force in the left hand (Table 1).

Table 1. Joint involvement associated with average grip force (% of expected value), multivariate linear regression

	Unstandardized β	95 % CI
Right hand		
Swollen Wrist	-11.0	-17.5 to -4.5
Tender MCP IV	-15.6	-25.2 to -6.0
Tender PIP V	-2.3	-12.0 to 7.3
Tender Elbow	-11.7	-22.1 to -1.3
Left hand		
Swollen Wrist	-14.3	-20.4 to -7.6
Swollen MCP I	-7.6	-14.6 to -0.6
Swollen MCP V	-11.7	-21.9 to -1.5
Swollen PIP I	-0.8	-9.2 to 7.5

MCP: Metacarpo phalangeal jointPIP: Proximal interphalangeal joint

Conclusion: Involvement of several different joints in the upper extremity contributes to impaired hand function. Clinical synovitis of the wrist was associated with reduced grip force in both hands. In the left hand, arthritis of the thumb had a major impact on grip force. In general, MCP involvement was found to be more important for the grip than PIP involvement.

POS0558 STATE OF ADIPOCYTOKINES IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH SUBCLINICAL ATHEROSCLEROSIS

I. Krivotulova[1], T. Chernysheva[1]. [1]*Orenburg State Medical University (OrSMU), Department of Internal Diseases, Orenburg, Russian Federation*

Background: The causes of accelerated atherosclerosis in rheumatoid arthritis (RA) are not completely understood [1]. Therefore, there is a need to identify new biomarkers of increased cardiovascular risk in RA.

Objectives: To establish the relationship of adipocytokines (adiponectin and leptin) with metabolic and inflammatory markers of subclinical atherosclerosis in RA patients.

Methods: The study included 88 women with RA according to the ACR (American College of Rheumatology)/EULAR (European League Against Rheumatism) criteria, 2010 [2] who visited the adaptation therapy clinic of Orenburg State Medical University. The mean±SD age was 46.43±8.5 years and the mean±SD disease duration was 8.21±5.56 years.

We evaluated the following laboratory parameters in all patients: erythrocyte sedimentation rate (ESR), total cholesterol, triglycerides (TAG), high-density lipoproteins (HDL), low-density lipoproteins (LDL) and C-reactive protein (CRP). Serum concentrations of adiponectin, leptin, rheumatoid factor (RF), tumor necrosis factor-α (TNF-α), and interleukin-17 (IL-17) were determined by enzyme-linked immunosorbent assay (ELISA).

We carried out ultrasound (US) duplex scanning of the carotid arteries by the device "Philips Epiq 7" with linear transducer with frequency of 4-18 MHz with the division into 2 groups of patients: group I consisted of 44 women with US signs of subclinical atherosclerosis, group II – 44 women without these signs. The control group included 30 women without inflammatory joint diseases and US signs of subclinical atherosclerosis and similar in gender, age and body mass index (BMI) to RA patients.

The program STATISTICA, 12.0 was used for statistical analysis.

Results: The serum adiponectin level was significantly higher in RA patients compared to the control group (p<0.0001): 40.88±13.60 ng/ml versus 22.75±11.27 ng/ml. The level of leptin in the blood serum of women with RA and healthy individuals was approximately the same and amounted to 18.07±14.02 ng/ml and 16.60±11.45 ng/ml respectively. When comparing the levels of adipocytokines in RA patients, the predominance of concentrations of both adipokines in patients with paraclinical atherosclerosis were noted. The adiponectin concentration was 46.08±14.44 ng/ml versus 35.70±10.51 ng/ml (p<0.001). The leptin level was 26.40±20.06 ng/ml versus 14.96±16.62 ng/ml (p<0.01).

Correlation analysis showed an negative relationship between adiponectin levels and metabolic markers of atherosclerosis: BMI (r=-0.52; p<0.05), neck circumference (NC) (r=-0.50; p<0.05), levels of LDL (r=-0.77; p<0.001) and TAG (r=-0.59; p<0.05) as well as proinflammatory cytokines: TNF-α (r=-0,48; p<0.05), IL-17 (r=-0.60; p<0.01) in patients of both groups. The increase in adiponectin concentration in group II patients was associated with the duration of administration of methotrexate (r=0.49; p<0.05) and glucocorticosteroids (r=0.71; p<0.001). Direct correlations were found between the level of leptin and BMI (r=0.48; p<0.05), NC (r=0.48; p<0.05), LDL (r=0.54; p<0.05) and TAG (r=0.45; p<0.05), CRP (r=0.49; p<0.05) and IL-17 (r= 0.52; p<0.05) in group I patients.

Conclusion: There is a significant increase in the production of adipocytokines in RA with subclinical atherosclerosis. Correlations of levels of adipokines with metabolic and inflammatory markers of atherosclerosis, on the one hand, indicate the influence of adipose tissue on systemic inflammation and, on the other hand, confirm the involvement of proinflammatory cytokines in the development of atherosclerotic vascular damage in patients with RA.

POS0559 SPECKLE TRACKING BETTER DETECTS SUBCLINICAL MYOCARDIAL DYSFUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

I. Kirillova[1], T. Popkova[1], Y. Gorbunova[1], A. Volkov[1], E. Nasonov[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Systemic Rheumatic Diseases, Moscow, Russian Federation*

Background: The risk of developing cardiovascular complications and death in rheumatoid arthritis (RA) is 50% higher than in the total population. These clinical events depend from risk factors for cardiovascular diseases, chronic inflammation and inflammatory myocardial infiltration. A new method for detecting early myocardial dysfunction is echocardiography using speckle tracking echocardiography.

Objectives: to determine the frequency of myocardial dysfunction (lower global longitudinal epicardial strain of left ventrical (LV), diastolic dysfunction of left ventricle (LVDD)) using standard and novel echocardiographic methods in patients (pts) with RA prior to therapy with bDMARDs, examine its relationship with markers of inflammation.

Methods: a total of 28 pts with a valid diagnosis of RA (ACR/EULAR, 2010): 23 f (82%) /5 m (18%) were included, median (Me) age - 56 [interquartile range (IR) 34;65] years, Me RA duration-14,5 [IR 7;87] months; all pts with RA demonstrated a high disease activity (Me DAS28 6.06, [IR 5,4;6,6]), seropositive for IgM RF (88%) and/or ACCP (84%) without any experience of administration of bDMARDs. The control group consisted of 10 healthy subjects, which were matched by sex and age. All pts were assessed for traditional risk factors for cardiovascular disease (ESC guidelines, 2011), echocardiography, tissue Doppler imaging, and the speckle tracking assessment of left ventricle longitudinal strain. DD was allocated according to the ESC guidelines for the diagnosis and treatment of heart failure (2018). Arterial hypertension was detected in 5 pts with RA.

Results: In pts with RA LVDD was more often detected (8 (31%) vs 0%, p=0.05) than in controls. The values of E LV (0.77 [0.62;0.94] ms vs 1.25 [1.03;1.51] ms, p=0.0001) were lower than in control group. Speckle-tracking method detected lower global longitudinal epicardial strain (–16.5 [-18.9; -13.6]% vs –21.58 [-22.1;-20.4] %, p=0.0001). 17(61%) RA pts showed a decrease global longitudinal epicardial strain. There were no between-group differences in left ventricular ejection fraction, LV sizes, LV myocardial mass index in RA pts with controls. There were correlations between the global longitudinal epicardial strain and DAS28 (r=0,9, p<0,02), tender joint score (r=0,6, p<0,02), radiological stage (r=0,6, p<0,008); the presence of systemic manifestations (r=0,5, p<0,03).

Conclusion: In pts with RA frequently (61%) were detected lower global longitudinal epicardial strain, which are associated with a high activity of the inflammatory process. Speckle-tracking echocardiography is better at detecting early myocardial dysfunction than tissue Doppler.

POS0560 CO-MORBIDITIES MAY NOT CHANGE TREATMENT CHARACTERISTICS OF THE RHEUMATOID ARTHRITIS PATIENTS

M. E. Tezcan[1], G. Geçmez[2], Ö. Volkan[1], N. Şen[1], S. Yilmaz-Oner[1]. [1]*Kartal Dr. Lütfi Kırdar Şehir Hastanesi, Rheumatology, İstanbul, Turkey*; [2]*Kartal Dr. Lütfi Kırdar Şehir Hastanesi, Internal Medicine, Istanbul, Turkey*

Background: Several co-morbidities may usually accompany rheumatoid arthritis (RA)(1). These can have direct or indirect implications for the severity of rheumatoid arthritis, the doctors' decision of disease-modifying treatment, and the functional disability of RA patients.

Objectives: It has been previously shown that various co-morbidities can have negative effects on the functional status, quality of life and life expectancy of RA patients individually (2). Here, we evaluated the effect of weight of all co-morbidities on treatment of RA patients and functional disability. Our hypothesis "The functional status of RA patients with moderate and severe co-morbidities is impaired compared to patients with mild co-morbidities, and the treatment characteristics of RA are different between these groups".

Methods: We included 246 RA patients who met the ACR / EULAR 2010 rheumatoid arthritis classification criteria. We divided the patients into two groups according to the Charlson comorbidity index (scores 0-2 mild,> 2 moderate and severe) (3). We compared the functional status of the two groups assessed by the health assessment questionnaire disability index (HAQ-DI). In addition, we compared disease-related characteristics between groups. We performed the Mann-Whitney U and chi-square tests where appropriate. Lastly, we also adjusted the age when comparing the continuous variables with ANCOVA.
Results: The patients with moderate and severe co-morbidities were older (p<0.001). All other demographic features were similar between the groups. Extra-articular involvement was more frequent in moderate and severe co-morbidity group (p=0.03). All other disease features and treatment modalities were similar between the groups. Additionally, after adjusting the age, none of the continuous features were different between the groups.

Table 1. Disease and demographic features and treatment characteristics of the patients.

	Mild co-morbidity group (n=180)	Moderate and severe co-morbidity group (n=66)	P	p** (age adjusted)
Age (year)	44.5±9.2	65.0±7.0	**P<0.001**	N/A
Gender (M/F)	34/146	16/50	0.5	
Smoking (%)	24 (13.3)	7 (10.6)	0.63	
Charlson co-morbidity index	1.38±0.48	3.3±0.6	**p<0.001**	**p<0.001**
Disease duration (month)	65.2±77.1	65.1±75.3	0.97	0.23
Swollen joint	0.3±1.5	0.2±0.6	0.92	0.86
Tender joint	0.6±1.6	0.3±1.0	0.38	0.50
ACPA positivity (%)	84 (46.6)	29 (43.9)	0.92	
RF positivity (%)	93 (51.6)	66 (58.3)	0.39	
DAS28-CRP	2.2±1.2	2.1±0.7	0.85	0.37
HAQ-DI	0.16±0.20	0.27±0.39	0.05	0.64
Extra-articular involvement (%)	3 (1.6)	5 (7.5)	**0.03**	
Joint deformity (%)	21 (11.6)	7 (10.6)	077	
Number of received DMARD	1.3±0.5	1.3±04	0.55	0.48
Steroid dosage (mg)	1.7±2.4	1.4±1.9	0.73	0.60
Ever receiving bDMARD (%)	21 (11.6)	3 (4.5)	0.09	

M: Male; F: Female; ACPA: Anti-Cyclic Citrullinated Peptide Antibody; RF: Rheumatoid factor; DAS-28: Disease activity score-28; HAQ-DI: Health assessment questionnaire disability index; DMARD: Disease modifying drugs; bDMARD: Biologic disease modifying drugs. **For continuous variables. Continuous variables shown as Mean ± SD. p<0.05 is significant

Conclusion: The only different disease feature was the increased frequency of extra-articular involvement in the more severe co-morbidity group. All other disease characteristics were similar. In addition, the severity of the co-morbidities may not change the doctors' decision to prescribe biological or synthetic DMARDs and steroid dosage.

POS0561 OBESITY PHENOTYPES IN EARLY RHEUMATOID ARTHRITIS

Y. Gorbunova[1], T. Popkova[1], L. Kondrateva[1], M. Cherkasova[2], E. Nasonov[3], A. Lila[3]. *[1]VA Nasonova Research Institute of Rheumatology, Laboratory of Systemic Rheumatic Diseases, Moskva, Russian Federation*; *[2]VA Nasonova Research Institute of Rheumatology, Laboratory of Immunology, Moskva, Russian Federation*; *[3]VA Nasonova Research Institute of Rheumatology, Scientific Department, Moskva, Russian Federation*

Background: Patients with rheumatoid arthritis (RA) and obesity have a lower risk of early death than patients with normal weight due to the so-called "obesity paradox". Available publications discuss three phenotypes of obesity: classical obesity, metabolically healthy overweight/obesity, and latent obesity (normal weight associated with metabolic disorders, most importantly - with insulin resistance and adipocytokines imbalance).
Objectives: To clarify the prevalence of obesity phenotypes and to identify factors predisposing to «latent obesity» in early RA without diabetes mellitus or hyperglycemia.
Methods: The study included 35 pts (23 women, 12 men) with early RA (criteria ACR / EULAR, 2010), 56 [43,0; 60,0] years old, naïve to treatment with glucocorticoids and disease-modifying anti-rheumatics, without established diabetes mellitus. Pts were seropositive for IgM RF and anti-CCP, with highly active RA (DAS28 5,9 [5,2; 6,4]; SDAI 35,4 [27,0; 45,8], and CDAI 31,0 [26,0; 44,0]) scores, and median disease duration of 8.0 [6,0;15.0] months. Electrochemiluminescence assay Elecsys (Roche Diagnostics) was used to measure patients' insulin levels, and ELISA (DBS – Diagnostics Biochem Canada Inc.) - for evaluation of serum leptin concentrations. Insulin resistance (IR) was defined as Homeostasis Model Assessment of Insulin Resistance index (HOMA-IR) ≥2,77. Leptin levels were considered elevated at values ≥11,1 ng/ml for women, ≥5,6 ng/ml for men. The overweight/obesity status was determined by World Health Organization criteria in pts with body mass index (BMI) ≥25kg/m^2.
Results: Overweight/obesity were documented in 19 (54, 3%) pts with early RA, 4/19 (21%) had high leptin levels and IR, 11/19 (58%) had isolated hyperleptinemia. Normal BMI was found in 16 (45,7%) pts with early RA, 2/16 (12,5%) had elevated leptin levels and IR, and 6/16 (37,5%) – only hyperleptinemia. Four (21%) out of 19 overweight and 8 (50%) out of 16 pts with normal BMI did not show any metabolic disorders (p=0,02). Classical obesity was found in 15 (43%), and latent obesity – in 8 (23%) pts with early RA. Leptin levels correlated with waist circumference (r=0,58, *p*=0,02), BMI (r=0,71, *p*=0,0006), ESR (r=0,5, *p*=0,02) in the overweight/obese pts, and with waist circumference (r=0,59, *p*=0,03), IgM RF (r=0,58, *p*=0,03), triglyceride levels (r=0,77, *p*=0,003), and atherogenic index (r=0,62, *p*=0,03) in pts with normal weight.
Conclusion: The classical obesity phenotype associated with abdominal obesity and inflammation was the most common and prevailing over other phenotypes in early RA. Latent obesity was less common and was associated with an unfavorable lipid profile and accumulation of abdominal fat, therefore increasing the risk of cardiovascular diseases in RA. Metabolically healthy overweight/obesity in early RA was really a rare phenotype.

POS0562 PULSE PRESSURE AS AN INDICATOR OF SUBCLINICAL ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS

S. Lugo-Perez[1], I. J. Colunga-Pedraza[2], J. R. Azpiri-López[1], D. Á. Galarza-Delgado[2], N. Guajardo-Jauregui[2], A. B. Rodriguez-Romero[2], A. Cárdenas[2], A. C. Garza Acosta[3]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*; *[2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*; *[3]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Radiology, Monterrey, Mexico*

Background: Pulse pressure (PP) is defined as the difference between systolic and diastolic blood pressure and represents arterial compliance and reflective properties of blood flow (1). It is well known that gender, age, and race / ethnicity are intrinsic factors of the patient that influence PP. Brachial PP has recently been associated with markers of subclinical cardiovascular disease after adjustment with traditional cardiovascular risk factors in the general population (2). However, this relationship has not been studied in patients with rheumatoid arthritis (RA) and its identification would allow earlier adjustments of cardiovascular therapies in this high-risk group.
Objectives: The aim of the study is to analyze the difference in PP between patients with RA and healthy controls. Additionally, to analyze the difference between patients with carotid plaque (CP) and without CP.
Methods: A cross-sectional, observational, and comparative study of ninety-two patients with RA aged 40-75 years and who fulfilled ACR/EULAR 2010 classification criteria. Also, we included ninety-two controls without RA, matched by gender, age and comorbidities. A carotid ultrasound was performed in patients with RA and it was divided into two subgroups, with the presence of CP and without CP. A blood pressure measurement was taken after 15 minutes of rest on the right arm of all patients. Distribution was evaluated with the Kolmogorov-Smirnov test. Descriptive analysis was done using measures of central tendency. Chi square, Student's t test and Mann-Whitney U test were used for comparations between groups. A *p* value <0.05 was considered statistically significant.
Results: We found no statistical difference between groups regarding age, gender and, comorbidities (type 2 diabetes mellitus, hypertension, dyslipidemia and, active smoking) (Table 1). There was a significant difference in PP between patients with RA and controls (50 mmHg vs 41 mmHg respectively, *p* = 0.032). Patients with RA had a significant difference in PP of patients with CP and without CP (50 mmHg vs 44 mmHg respectively, *p* = 0.008) (Figure 1). When performing a binary logistic regression, it was found that PP was the only independent factor for the presence of CP in patients with RA, OR 1.054 (95% CI 1.008-1.101, *p* = 0.020).
Conclusion: Patients with RA had a higher PP than controls. Binary logistic regression showed PP as the only independent factor for the presence of subclinical atherosclerosis in patients with RA. PP is a parameter that all rheumatologists should consider when evaluating cardiovascular risk in patients with RA.

Background: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). However, the effect of RA disease activity on the course of ILD is not yet known.
Objectives: To assess the natural course of lung physiology of RA-ILD and the relation between arthritis activity and pulmonary physiology in patients with RA-ILD.
Methods: The Korean Rheumatoid Arthritis ILd (KORAIL) cohort is the prospective observational cohort and aims to investigate the natural course of RAILD. Based on either 1987 or 2020 ACR criteria, patients diagnosed with RA and ILD based on CT scan were recruited from six tertiary medical hospitals in Korea since January 2015. RA disease activity was assessed using disease activity (DAS)28-ESR and CRP, annually. Pulmonary function tests (PFT), including FVC and DLCO were conducted annually. According to the transition of DAS28-ESR status, we classified patients into four groups: Group A. persistent remission or low disease activity, Group B. improvement, Group C. worsening, Group D. persistent moderate to high disease activity.
Results: We analyzed 143 patients who completed a 2-year follow-up (visit 2) or had died with available PFT results at least twice. Mean duration since RA diagnosis and since ILD diagnosis was 7.6±8.0 and 2.7±3.1 years, respectively. Twenty-four patients were Group A, 33 Group B, 10 Group C and 30 Group D. The mean of FVC (mL) and % of the predicted value in FVC was significantly lower in Group D than in other groups (Table 1). The annual rate of decline in FVC was -42 (95% CI -93~10) mL·year^{-1} in Group B while -113 (95% CI -206~-21) mL·year^{-1} in Group C (Figure 1A). The annual decline rate in Group C was further exaggerated in patients with ≥ 80% of FVC predicted (-141, 95% CI -251~-32 mL·year^{-1}). During two years of follow-up, patients ever experienced a relative decline of ≥10% from the enrollment in FVC predicted was 27.3%(n-9/33) in Group B whereas 30.0% (3/10) in Group C. The annual rate of decline in % of DLco predicted value was also the largest in Group C (-4.6 %·year^{-1}, 95%CI -8.5~-0.7), which further exaggerated in patients with ≥ 80% of FVC predicted (-4.9%·year^{-1}, 95 %CI -8.3~-1.5, Figure 1B). Of note, about half of patients with maintained not only low disease activity (Group A) but also moderate to severe disease activity (Group D) improved in DLco at least 10% or more from the enrollment of DLco predicted value (Group A: 54.2%, n=13/24, Group D: 46.7%, n=14/30).
Conclusion: RA disease activity is associated with the change of lung physiology in patients with RA-ILD; worsening disease activity associated with a further decrease of annual change in FVC and maintaining low disease activity associated with a further increase of annual change in % of DLco predicted value.

Background: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). However, the effect of RA treatment on the course of ILD is not yet known.
Objectives: To assess the effect of RA treatment on the course of lung physiology of RA-focusing on biologic DMARDs treatment.
Methods: The Korean Rheumatoid Arthritis ILd (KORAIL) cohort is the prospective observational cohort and aims to investigate the natural course of RAILD. Based on either 1987 or 2020 ACR criteria, patients diagnosed with RA and ILD based on CT scan were recruited from six tertiary medical hospitals in Korea since January 2015. RA disease activity was assessed using disease activity (DAS)28-ESR and CRP, annually. Pulmonary function tests (PFT), including FVC and DLCO were conducted annually. In the current study, we analyzed patients who completed a 2-years follow-up or had died during those terms till October 2020. They classified patients into three groups: patients treated with abatacept ≥24 weeks ever (Group 1), those with other bDAMRDs ≥24 weeks ever (Group 2), and those without any bDMARDs or with bDMARDs <24 weeks (Group 3).
Results: Of a total of 125 patients who completed 2-year follow-up, 21 patients were classified as Group 1, 26 for Group 2, and 78 for Group 3. The mean age or the number of patients with ≥ 65-year-old was comparable between groups(Table 1). The mean duration since RA diagnosis was shorter in Group 3, but that since ILD diagnosis was comparable. DAS28-ESR score was comparable between Group 1 and 2 at enrollment, so was in 1-year-follow-up (p=0.75) and 2-year-follow-up (p=1.00). FVC and % of the predicted value in FVC, FEV1, and DLco were also comparable among the three groups at enrollment. The numbers of patients with ≥10-point decline in % of FVC predicted was 2 (10.0%) for Group 1, 1 (3.8%) for Group 2, 3 (3.9%) for Group3 during the first 1-year follow-up, and 3 (15.8%), 3 (11.5%), 10 (14.1%) during the last 1-year follow up. The percent of FVC predicted was 81.6 ± 17.5 %, 87.4 ± 17.9 %, 85.2 ± 17.7 % for Group 1,2 and 3, respectively, at 1-year-follow-up, and 79.5 ± 18.8 %, 89.0 ± 16.8 %, 83.5 ± 17.3 % at 2-year-follow-up. (Figure 1A). The percent of DLco predicted was 75.5 ± 23.4 %, 66.7 ± 18.1 %, 67.5 ± 16.7 % for Group 1,2 and 3, respectively, at 1-year-follow-up, and 74.0 ± 23.7 %, 69.1 ± 18.9 %, 67.0 ± 18.5 % at 1-year-follow-up (Figure 1B).
Conclusion: Treatment of bDMARDs did not exacerbate FVC than without bDMARDs treatment and mitigated the decline of DLCO compared to without bDMARDs treatment during 2-year-follow-up.

POS0565

IS ACTIVE SYNOVITIS OF METACARPOPHALANGEAL JOINTS A NEUROPATHIC CONDITION IN RHEUMATOID ARTHRITIS PATIENTS? RESULTS FROM A ULTRASOUND STUDY AT LEVEL OF THE PALMAR DIGITAL NERVES

M. Di Carlo[1], J. Di Battista[1], R. Chiorrini[1], E. Cipolletta[1], G. Smerilli[1], A. Di Matteo[1], T. Okano[2], F. Salaffi[1], E. Filippucci[1]. [1]Università Politecnica delle Marche, Dipartimento di Scienze Cliniche e Molecolari - Rheumatology Clinic, Jesi, Italy; [2]Osaka City University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka, Japan

Background: Rheumatoid arthritis (RA) is a chronic inflammatory arthritis that primarily affects the joints of hands, wrists, and feet. Anatomical damage (at bone, cartilage and tendon level) occurs as a consequence of a persistent synovial inflammation (1). In RA, periarticular soft tissues, including nerves, may also be involved. In particular, there is a high prevalence of neuropathic conditions such as carpal tunnel syndrome (CTS) in RA patients. In fact, the presence of inflammatory changes can frequently be documented by ultrasound (US) at the level of median nerve (2). Currently available very-high frequency US transducers allow high spatial resolution of small anatomical structures, including the palmar digital nerves.
Objectives: The objectives of this study were: to document the presence of dimensional alterations of the palmar digital nerves, particularly in terms of increased cross-sectional area (CSA), and to determine the variables associated with increased CSA, in RA patients.
Methods: From September 2020 to December 2020, adult RA patients from a tertiary outpatient clinic were consecutively included regardless of disease activity status. Patients underwent a clinical assessment to determine disease activity using the Clinical Disease Activity Index (CDAI), functional capacity using the QuickDASH, and the presence of neuropathic pain features using the PainDetect Questionnaire (PDQ). In the same visit, patients underwent a US examination of the 2nd to 5th metacarpophalangeal joints (MCPj) of the clinically more involved hand by an operator blinded to the clinical assessment. The presence/absence and US grading of synovitis was recorded for each joint. A third operator, blinded to the clinical and joint US assessment, measured the CSA of each pair of palmar digital nerves from 2nd to 5th finger scanned for assessment joint involvement. The CSA of the palmar digital nerves was measured at the MCPj. The US examinations were conducted with a MyLab Class C (Esaote, Genoa, Italy), with a 6-18 MHz probe for the articular examination, and with an 10-22 MHz probe for the examination of the palmar digital nerves. The serological status, respectively rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA), and the presence of radiographic erosive disease were also recorded for each patient. Statistical analysis was conducted by considering the sum of the CSA for each nerve pair of each finger. CSA was compared with respect to body mass index (BMI), disease duration, disease activity, US synovitis grading, functional capacity, neuropathic pain features, serological characteristics, and erosive status.
Results: Sixty-three patients with RA were included, 48 women, 15 men, with a mean age of 62.2 (11.8, standard deviation [SD]) years, a mean disease duration of 10.9 (8.2) years, for a total of 252 MCPj and 504 palmar digital nerves. The CSA of the palmar digital nerves taken individually was 2.3 (0.9) mm^2, ranging from 1 mm^2 to 8 mm^2, and 4.2 (1.5) mm^2 as a pair for finger. There was a statistically significant association with disease activity as assessed by the CDAI (p <0.001), and with the grading of US synovitis (p <0.001), while there were no significant associations with any of the other variables.

Conclusion: The presence of active RA, both in terms of clinical and ultrasonographic indices, correlates with an increased CSA of the palmar digital nerves. This alteration is probably due to inflammatory mechanisms of the perineural tissues at the level of the MCPj. Active synovitis during RA can somehow be framed as a condition capable of causing neuropathic damage to the palmar digital nerves.

POS0566 CATASTROPHIZING IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. Traverson[1], B. Coste[1], E. Filhol[1,2], C. Daien[3,4], S. Laurent-Chabalier[5], S. Benamar[3], B. Combe[3,4], C. Lukas[2,3], J. Morel[3,4], C. Hua[1,2], C. Gaujoux-Viala[1,2]. *[1]Nîmes University Hospital, Rheumatology, Nîmes, France*; *[2]University of Montpellier, IDESP, UMR-INSERM, Montpellier, France*; *[3]CHU Lapeyronie, Rheumatology, Montpellier, France*; *[4]University of Montpellier, -, Montpellier, France*; *[5]Nîmes University Hospital, BESPIM, Nîmes, France*

Background: Catastrophizing is conceptualized as a negative cognitive–affective response to an anxiety-provoking stimulus, especially anticipated or actual pain. Catastrophizing can be assessed quickly using a validated questionnaire: the Pain Catastrophizing Scale (PCS)[1]. Catastrophizing plays a role in maintaining chronic pain and is associated with several pain-related outcomes in osteoarthritis and low back pain.

Objectives: To assess the prevalence of catastrophizing and associated factors in rheumatoid arthritis (RA).

Methods: We performed an observational, prospective, bi-centric study. All patients aged 18 or over with RA and fulfilling the ACR-EULAR 2010 criteria were consecutively included. Sociodemographic data, information on the disease and its treatments were collected as well as questionnaires for disease activity (DAS28), function (HAQ), quality of life (SF12, EQ5D), anxiety and depression (HADS, GAD7), fibromyalgia (FiRST), insomnia (ISI) and catastrophizing scores (PCS). Statistical analysis included the samples t-test, one-way variance analysis, the Spearman's correlation test, the Chi^2 test, Fisher's exact test, the Wilcoxon test, multivariate linear regression (considering catastrophizing as a continuous variable) and multivariate logistics regression (considering catastrophizing as a categorical variable: PCS ≥ 20 = high level catastrophizing).

Results: From September 2019 to March 2020, 201 patients with RA were included: 78.1% were women and the median age was 63.0 years. In all, 64.1% of patients were RF+, 65.7% ACPA+, and 46% had erosive disease. Median DAS28 CRP was 2.9 [2.1-4.0]. with 45% of patients in remission, 14.8% with low, 31.2% moderate and 9 % high activity. The majority of patients (92 %) had a disease lasting for more than 2 years.

The prevalence of a PCS score ≥20 was 48.0% [41.0;54.9]. The median PCS score was 18 [7-28]. In multivariate logistics regression, high-level catastrophizing was significantly associated with DAS28-CRP (OR= 1.61 [1.18-2.20]), HADS anxiety score (OR=1.25 [1.11-1.40]) and the HADS depression score (OR=1.19 [1.07-1.33]). In multivariate linear regression, catastrophizing was significantly associated with the HADS anxiety score (p< 0.0001), HADS depression score (p=0.0055), HAQ (p=0.0015) and the ISI insomnia score (p=0.005).

Conclusion: Almost half the patients with RA were high catastrophizers. Catastrophizing is linked to anxiety, depression, disease activity, function impairment and insomnia. It may be interesting to detect catastrophizing in order to improve the management of our patients.

POS0567 HEPCIDIN IS POTENTIAL BIOMARKER TO DISTINGUISH BETWEEN IRON DEFICIENCY ANEMIA AND ANEMIA OF INFLAMMATION IN RHEUMATOID ARTHRITIS

E. Galushko[1], A. Semashko[1], A. Gordeev[1], A. Lila[1]. *[1]V.A.Nasonova Research Institute of Rheumatology, Department of Early Arthritis, Moscow, Russian Federation*

Background: Anemia of inflammation (AI) and iron deficiency anemia (IDA) are the two most prevalent forms of anemia in patients with rheumatoid arthritis (RA). Diagnosis becomes challenging if AI is associated with true ID (AI/ID), as there is still a lack of a gold standard for differentiation between AI and AI/ID. However, as therapies to overcome anemia differ, proper diagnosis and understanding of underlying pathophysiological regulations are necessary.

Objectives: The aim of the study was to evaluate the clinical efficiency of hepcidin, a key regulator of iron metabolism, in the diagnosis of IDA, as well as the differential diagnosis of AI/ID and AI in patients with RA.

Methods: The study was undertaken 96 patients with RA, 67 of them were diagnosed anemia according to WHO criteria (104,3±21,4 g/l). Anemic patients and anemia-free patients with RA (n=29) were comparable (p>0.05) in age (44.4±14.8 and 49.8±9.3 years), disease duration (73.5±65.4 and 59.8±48.3 months) and DAS28 (6.3±1.6 and 5.9±1.9). All cases were subjected to following tests: complete blood count with peripheral smear, serum C-reactive protein, serum interleukin-6, iron studies, serum soluble transferrin receptor (sTfR), and serum hepcidin. Patients with RA and anemia were divided two groups: 25 patients with IDA and 42 - with AI. The AI cases were subdivided into pure AI and AI with coexistent ID (n=15).

Results: The mean serum hepcidin concentration was significantly increased in pure AI patients (123.85±25.8 ng/mL) as compared to those in IDA patients (63.9±22.8 ng/mL, P < 0.05) and anemia-free patients with RA (88.1±39.09 ng/mL). Also, compared to pure AI patients [normal sTfR levels (<3 μg/mL)], the serum hepcidin concentration was reduced significantly in AI patients with ID [high sTfR levels (≥3 μg/mL)] with a mean of 79.0±23.97 ng/mL.

Conclusion: Hepcidin measurement can provide a useful tool for differentiating AI from IDA and also help to identify an iron deficiency in AI patients. This might aid in the appropriate selection of therapy for these patients.

POS0568 OBESITY RATES AND BMI ARE SIMILAR IN AGE AND SEX MATCHED RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND SPONDYLOARTHRITIS PATIENTS

G. K. Yardımcı[1], B. Farisoğulları[1], E. C. Bolek[1], E. Bilgin[1], E. Duran[1], G. Ayan[1], Z. Özsoy[1], G. Sandal Uzun[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], U. Kalyoncu[1], A. İ. Ertenli[1]. *[1]Faculty of Medicine; Hacettepe University, Rheumatology, Ankara, Turkey*

Background: Obesity has been suggested to be a chronic inflamatory condition and therefore, obesity may be considered as a risk factor for developing immune-mediated diseases, including inflammatory arthritis. In larger biologic registiries, obesity was found frequently in psoriatic arthritis than other inflammatory diseases such as rheumatoid arthritis and spondyloarthritis. [1-4]. However, obesity may be a reason of aging, moreover, there are strong sex differences between those diseases.

Objectives: The aim of this study was to evaluate the obesity rates in sex and aged matched patients with inflammatory arthritis before the initation of biological therapy.

Methods: HUR-BIO (Hacettepe University Biologic Registry) is a prospective, single center database of biological treatments since 2005 and to date 5635 patients have been recorded. Demographic, clinical and laboratory data before bDMARD of SpA, RA and PsA patients were noted. The patients were divided into two groups: non-obese patients (<30 kg/ m^2) and obese (≥30 kg/m^2) patients. When investigeting the changes in BMI by diagnosis, the effects of gender and age were adjusted using two-way ANOVA and ANCOVA tests. The selection was made for the gender and age indifferences of the relevant groups by using propensity score.

Results: 5059 patients' (1834 RA, 2741 SpA and 484 PsA) BMI data before the bDMARD treatments were avaliable and analysed. Baseline characteristics of RA, SpA and PsA patients were given in Table 1. 72.3% of the RA patients were seropositive. HLAB27 was positive in 64.7% and 22.9% of the SpA and PsA patients. Anti-TNF therapy was started as first bDMARD in 57.2% of the RA patients, others were started with non-Anti-TNF bDMARDs. In SpA (99.2%) and PsA (100%) patients anti-TNFs were the first biologics. Overall, the proportion of obese patients was significantly higher in RA and PsA than in SpA patients (Table 1) and age and sex affected BMI significantly (p<0.001) (Figure 1). After adjusting age and sex indifference between groups, the difference between the BMI of the patients disappeared (Table 1).

Table 1. Baseline characteristics and BMI of the patients

		RA	SpA	PsA	p
All bDMARD patients	**N**	1834	2741	484	
	Female, n (%)	1470 (80.2)	1257 (45.9)	334 (69.0)	0.000*
	Age, years*	52.9±13.4	43.1±11.4	47.4±12.2	0.000*
	Disease duration, years¥	11 (7-17)	8 (5-13)	7 (3-12)	0.000*
	Body mass index*	29.6 ± 6.5	27.7 ± 5.4	29.2 ± 5.8	0.000*
	Obesity, n (%)	811 (44.2)	815 (29.7)	199 (41.1)	0.000*
Age and sex matched group	**N**	481	483	484	
	Female, n (%)	315 (65.7)	324 (67.1)	334 (69.0)	0.545
	Age, years*	47 (36-59)	48 (39-57)	47 (38-56)	0.691
	Disease duration, years¥	10 (6-15)	5 (5-13)	7 (3-12)	0.000*
	Body mass index*	28.5 ± 6.1	28.5 ± 5.8	29.2 ± 5.8	0.150
	Obesity, n (%)	183 (38.0)	176 (36.4)	199 (41.1)	0.316

* Mean ±S.D ¥Median (IQR)

Conclusion: Although obesity was more frequently reported in RA and PsA patients, age and gender seemed to be the major factors in the occurrence of this difference rather than inflammatory arthritis subgroups. Therefore, when considering obesity as a factor in the registries, for instance biological registries, sex and age should be kept in mind.

Popa University of Medicine and Pharmacy, Clinical Hospital of Rehabilitation, Iasi, Romania*; [10]*University of Brescia, Clinical and Experimental Sciences, Brescia, Italy*; [11]*Spedali Civili Hospital, Rheumatology and Clinical Immunology, Brescia, Italy*

Background: Children born to women with rheumatoid arthritis (RA) have increased incidences of adverse neonatal outcomes and a potential excess risk of specific diseases during childhood and adolescence [1]. Further studies aimed at confirming long-term consequences in the offspring are needed.
Objectives: To evaluate whether maternal RA has an impact on the health and developmental outcomes of the offspring.
Methods: A retrospective descriptive study was conducted on data regarding 43 children born to mothers diagnosed with either RA or juvenile idiopathic arthritis (JIA) prior to conception. Participants were recruited from several Clinics of Rheumatology located across Romania. Data on neonatal outcomes, lactation, developmental milestones, childhood illnesses, and hospitalizations was collected using a patient-reported questionnaire completed by maternal participants in 2020.
Results: Favorable neonatal outcomes were found in 81% of the participants; however, children of mothers with RA had a higher occurrence of favorable outcomes than those with JIA (p = 0.009). Adverse neonatal outcomes reported include the following: small for gestational age (11.6%), intrauterine growth restriction (4.65%), and preterm births (2.75%). There were no incidences of congenital malformations. The mean birth weights of offspring born to mothers with RA are higher than those with JIA (p = 0.00829).
While the majority of the children were breastfed (88.4%), those who were not breastfed were hospitalized more often than those who were breastfed for any period of time (p = 0.03). Mothers who experienced a postpartum flare up within the first 4 months breastfed their children significantly less than those who did not have a flare up (14.62 versus 48 weeks, p = 0.00011).
The mean age of the children at inclusion was 7.6 ± 5.5 years.
Developmental milestones were considered to be within the expected average limits, except for an increased incidence of delayed speech (12%).
51.2% of the children were hospitalized at some point during their childhood, with viral enterocolitis, tonsilitis, bronchiolitis, and pneumonia being the most frequently encountered reasons for admission. Surprisingly, children with favorable neonatal outcomes were hospitalized more often than those with unfavorable outcomes (p = 0.0000436). Additionally, children born to mothers under the age of 35 were hospitalized more often than those over 35 (p = 0.02).
77.3% of offspring experienced recurrent ear/nose/throat (ENT) infections, 55.8% had allergies, and 39.5% were diagnosed with atopic dermatitis. Childhood allergies were strongly associated with an increased incidence of atopic dermatitis (p = 0.0000585), as was a concurrent maternal thrombophilia diagnosis (p = 0.03). Of the remaining childhood afflictions that were assessed asthma/chronic respiratory diseases (4.65%), juvenile idiopathic arthritis (2.33%), ulcerative colitis (2.33%), diabetes, anxiety/personality disorders, thyroid diseases, febrile seizures, and epilepsy did not yield statistically significant results.
Conclusion: Maternal RA was found to be associated with increased incidences of adverse neonatal outcomes, childhood hospitalizations, recurrent ENT infections, allergies, and atopic dermatitis. However, overall health outcomes of offspring did not show alarmingly significant excess morbidities.

POS0570 ASSOCIATION OF BODY FAT MASS AND ITS DISTRIBUTION WITH DISEASE ACTIVITY, PAIN AND DISABILITY IN RHEUMATOID ARTHRITIS

O. Lamkhanat[1], H. Azzouzi[1], I. Linda[1]. [1]*Mohammed VI University Hospital, Mohammed I University, Faculty of Medicine, Rheumatology, Oujda, Morocco*

Background: Rheumatoid arthritis (RA) and body composition are closely related. Recent studies have found a significant association between fat mass and disease activity and disability in RA [1].
Objectives: We aimed to study the association between body fat mass and its distribution with disease activity, disability, and pain in RA patients.
Methods: This is a cross-sectional study of patients with RA diagnosis according to ACR-EULAR 2010 classification recruited from first January 2021. Those with prior cancer, hyperparathyroidism, hyperthyroidism, diabetes, chronic kidney disease, and cirrhosis were excluded. Body fat mass (BFM) and its distribution (gynoid (GFM), android (AFM), visceral (VFM), limbs (LFM), trunk (TFM)) were measured with dual-energy X-ray absorptiometry (Hologic, Horizon QDR®). Clinical data and laboratory tests of the same day of the DXA scan were analyzed. The associations between BFM and its distribution with disease activity score (DAS28CRP), pain visual analogue scale (VAS), and disability measured by health assessment questionnaire (HAQ) were explored. Obesity was defined as a body mass index (BMI) ≥ of 25kg/m^2. Our statistical analysis was based on descriptive study, comparisons and linear regressions using SPSS 20.
Results: It is about 69 RA patients. Their mean age was 49.86 ± 14.33 years, mean DAS28CRP was 2.56 ± 1.27, and mean disease duration was 14.84 ± 10.99 years. Sixty-two (89.9%) were women. The mean BMI was 26.46 ± 5.26 kg/m^2, and 41 patients were obese (59.4%). Compared with non-obese patients, obese patients had a higher C-reactive protein (p = 0.03). DAS-28CRP was higher in obese patients (2.77 ± 1.41 vs 2.25 ± 0.97) but did not reach significance (p = 0.07). We did not find any difference between the two groups regarding pain and disability. In univariate regression analysis, the LFM was positively associated with disease activity (p = 0.001; β = 0.38), pain (p = 0.001; β = 0.38) and disability (p = 0.007; β = 0.32). Adjusted on BMI, LDL cholesterol, triglyceride, cumulative dose of corticosteroid, disease and corticosteroid duration, menopause duration, dose and duration of methotrexate, we found a significant association between LFM, disability (p = 0.02; β = 0.51), disease activity (p = 0.02; β = 0.54) and pain (p = 0.009; β = 0.57). However, we had no association between disease activity, pain, and disability with BFM and the other components.
Conclusion: Limbs fat mass was significantly associated with the activity, disability, and pain in RA patients.

POS0571 NON-OBESE RHEUMATOID ARTHRITIS PATIENTS WITH LOW LOW-DENSITY LIPOPROTEIN HAVE GREATER CORONARY ATHEROSCLEROSIS BURDEN, PLAQUE PROGRESSION AND CARDIOVASCULAR EVENT RISK

G. Karpouzas[1], S. Ormseth[1], E. Hernandez[1], M. Budoff[2]. [1]*The Lundquist Institute, Rheumatology, Torrance, United States of America*; [2]*The Lundquist Institute, Cardiology, Torrance, United States of America*

Background: Rheumatoid arthritis (RA) patients with low body weight incur higher mortality than obese patients. Paradoxically, RA patients in the lowest low-density lipoprotein group (LDL <70 mg/dl) may also experience higher cardiovascular disease (CVD) risk.

Objectives: We here explored whether abdominal obesity (waist-to-height ratio >0.58 in females and >0.63 in males) might moderate the effect of low LDL (<70mg/dl) on coronary atherosclerosis burden, progression and long-term CVD risk in RA.

Methods: One hundred fifty patients without symptoms or diagnosis of CVD underwent coronary computed tomography angiography. Plaque progression was evaluated 6.9±0.3 years later in 101 patients. Coronary artery calcium, number of segments with plaque (segment involvement score), and extensive (>4 segments with plaque) or obstructive disease (>50% stenosis) were assessed. CVD events were prospectively recorded, including cardiac death, myocardial infarction, unstable angina, revascularization, stroke, claudication, and heart failure hospitalization over 6.0±2.4 years of follow-up. Lipoprotein classes were directly measured. Oxidized LDL (oxLDL) was assessed with monoclonal antibody E06. Adjusted robust linear regression evaluated interactions between abdominal obesity and LDL groups on plaque outcomes. Per segment, adjusted robust logistic regression models explored obesity x LDL group interactions on new plaque formation and stenotic progression of prevalent plaques. Robust Cox regression models stratified by abdominal obesity evaluated the effect of LDL group (<70 vs. >70 mg/dl) on CVD events.

Results: Non-obese patients with low LDL had the highest plaque burden (Figure 1A, all p < 0.02). Obesity moderated the effect of LDL on likelihood of extensive/obstructive disease (*P* for interaction = 0.061); specifically, LDL<70 associated with an increased likelihood of extensive/obstructive plaque in non-obese (adjusted OR 4.75 [95% CI 1.18-19.07], *P* = 0.028) but not obese patients (adjusted OR 1.55 [95% CI 0.39-6.08], *P* = 0.532). No differences in disease activity or inflammatory markers were seen across groups. Compared to LDL>70 mg/dl, low LDL predicted an increased likelihood of high oxLDL (>median) in non-obese patients (adjusted OR 5.10 [95% CI 1.46-17.75], *P* = 0.011) but not obese patients (adjusted OR 0.50 [95% CI 0.11-2.21], *P* = 0.36, Figure 1B). Obesity further moderated the effect of LDL on likelihood of future development of plaque (*P* for interaction = 0.002) and increased stenotic severity of existing plaques (*P* for interaction = 0.040); in non-obese patients, low LDL associated with a greater likelihood of new plaque forming in segments without baseline plaque (adjusted OR 4.68 [95% CI 2.26-9.66]) and worsening stenotic severity in segments with prevalent plaque (OR 5.35 [95% CI 1.62-17.67]). This was not observed in obese patients (Figure 1C). Notably, in non-obese patients, low LDL associated with higher CVD event risk compared to those with LDL>70 mg/dl (HR 7.94 [95% CI 1.52-41.36], *P* = 0.015). This was not the case in obese patients (HR 0.32 [95% CI 0.04-2.40], *P* = 0.27, Figure 1D).

Conclusion: In non-obese RA patients, LDL<70 mg/dl may reflect higher LDL oxidation and was associated with higher baseline coronary atherosclerosis burden, new plaque formation, stenotic plaque progression and greater CVD risk than LDL>70 mg/dl.

POS0572 THE ASSOCIATED FACTORS OF ULTRASONOGRAPHIC TENOSYNOVITIS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN REMISSION

R. Fakhfakh[1], N. El Amri[1], K. Baccouche[1], H. Zeglaoui[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: Tenosynovitis is a common manifestation of rheumatoid arthritis (RA), but, is difficult to assess appropriately by clinical examination. In clinical remission, musculoskeletal ultrasound (MSUS) showed a predictive value of tenosynovitis for flares and joint destruction in RA (1).

Objectives: To assess the prevalence, the characteristics, and the factors associated with tenosynovitis in ultrasound examination of patients with RA in clinical remission.

Methods: A Cross-sectional study including patients with RA in clinical remission (DAS28 ESR ≤ 2.6) for at least 6 months. MSUS of 20 tendons (in wrists, hands and ankles) was performed in mode B and power Doppler (PD). Tenosynovitis was defined and scored according to the Outcome Measures in Rheumatology Clinical Trials (OMERACT). A total score for the tenosynovitis in B-mode (TBI) and PD (TDI) was calculated by summing the grades for each patient. SDAI and CDAI were calculated. Functional disability was assessed by the Health Assessment Questionnaire (HAQ). For the radiographic evaluations, we used the Van der Heijde score.

Results: Thirty-seven patients were enrolled, the mean age was 54.2 years±12.7 years and the sex ratio was 0.37. The mean disease duration was 8.1 years±5.1. The mean remission duration was 36.5 months ± 32.7. The prevalence of tenosynovitis was 40.5% in B-mode and 13.5% for PD. The most affected tendons were: extensor carpi ulnaris (B-mode: 21.6%, PD: 8.1%), tibialis posterior (B-mode: 10%, PD: 2.7%), peroneal (B-mode: 8.1%, PD: 2.7%), flexor digitorum superficialis and profundus (B-mode: 5.4%, PD: 0%) and extensor digitorum (B-mode: 2.7%, PD: 2.7%). Tenosynovitis was most frequently grade1 in B-mode (32.4%) and grade 2 in PD (10.8%). Grade 3 was identified only in B-mode in the peroneal tendons. The mean of TBI was 7.1±5.3 and the mean of TDI was 2.2.±3.1. We found a significant association between remission duration and PD tenosynovitis (mean: 16.2 vs 39.7 months, p = 0.05). Tenosynovitis, in B-mode and PD, weren't associated with the swollen joints, the tender joints, the patient

global health assessment, the HAQ, erythrocyte sedimentation rate, C-reactive protein, rheumatoid factor and anti-cyclic citrullinated peptide, DAS28, CDAI, SDAI, biologic treatment and radiographic structural damage. Multivariate logistic regression analysis didn't show any association.

Conclusion: Ultrasound tenosynovitis was commonly found in RA in remission and the extensor carpi ulnaris tendon was most involved. A shorter duration of remission was associated with PD tenosynovitis in univariate analysis. The MSUS assessment of tendons can be an additional feasible method to assess clinical remission.

POS0573 IMPACT OF JOINT DESTRUCTION IN THE HANDS, THE WRISTS AND THE ANKLES ON THE ULTRASOUND ASSESSMENT AND THE FUNCTIONAL OUTCOMES IN RHEUMATOID ARTHRITIS IN REMISSION

R. Fakhfakh[1], N. El Amri[1], K. Baccouche[1], H. Zeglaoui[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: Joint destruction is a strong predictive factor for residual synovitis among rheumatoid arthritis (RA) patients in clinical remission. Both of them were associated with functional impairment.

Objectives: To assess the ultrasound findings and functional outcomes of RA patients in remission according to the site of joint destruction.

Methods: A Cross-sectional study including RA patients in remission DAS28 ESR≤ 2.6 for at least 6 months. A B-mode and power doppler (PD) ultrasound of 42 joints was performed. Synovitis was defined and scored using the combined OMERACT-PDUS (gray scale and power doppler (PD)) scoring system graded from 0 to 3. The health assessment questionnaire (HAQ) and the radiological Sharp score of the wrists, hands and feet were calculated.

Results: Thirty-seven patients were included. The sex ratio was 0.37 and the mean age was 54.2 years ± 12.7. The mean disease duration was 8.1 years±5.1. The mean remission duration was 36.5 months ± 32.7. The mean DAS28vs was 2.1 ± 0.5. Rheumatoid factor and anti-citrullinated peptide antibodies were found in 62% and 75% of patients, respectively. The mean HAQ was 0.35 ± 0.38. Bone erosion was found in 81% of patients. In patients with hands and feet erosions (54%), synovitis was found in 90% of cases associated with PD in 70% of cases. The mean total score of synovitis was 7.8 ± 5.4. The mean HAQ was 0.37 ± 0.44. In patients with only erosions in the hands or wrists (18.9%), synovitis was found in 100% of cases associated with PD in 57% of cases. The mean total score of synovitis was 4.5±4.7. The mean HAQ was 0.48 ± 0.34. In patients with only feet erosions (8.1%), synovitis was found in 100% of cases associated with PD in 66.7% of cases. The mean total score of synovitis was 4.6±3.5. The mean HAQ was 0.31 ± 0.26. RA was not erosive in 18.9% of patients. In these patients, synovitis was found in 100% of cases associated with PD in 28.6% of cases. The mean total score of synovitis was 5.6±4.3. The mean HAQ was 0.21 ± 0.23. There is no significant difference between these groups(p>0.05).

Conclusion: In RA in remission, PD synovitis and functional incapacity were less frequent in the absence of erosion. PD synovitis was more frequently found in patients with erosions, especially, in the feet. The HAQ was higher in patients with hands erosions.

POS0574 RELATIONSHIP BETWEEN INVOLVED JOINT FOR REGION AND MODIFIED HEALTH ASSESSMENT QUESTIONNAIRE SCORE IN JAPANESE PATIENT WITH RHEUMATOID ARTHRITIS

I. Yoshii[1]. [1]*Yoshii Hopital, Rheumatology and Musculoskeletal Medicine, Shimanto City, Japan*

Objectives: Rheumatoid arthritis (RA) is a chronic inflammatory disease that involves various joints in whole body. For evaluation of daily life activities (ADL), modified Health Assessment Questionnaire (mHAQ) is usually used. This index configures eight ADL functions these are separated by predominant extremities. This study aimed to evaluate how involved joint affect ADL predominantly in real world setting.

Methods: A total of 24,450 times of consultation with RA patient were visited in the institute. Here, patient with RA was interviewed every another visit, and involved joint in whole body, pain score with visual analog scale (PS-VAS), and mHAQ were recorded. Involved joints were divided by four regions in accordance with joint size and part; small joint in upper extremities (US), large joint in upper extremities (UL), small joint in lower extremities (LS), and large joint in lower extremities (LL). mHAQ was also separately evaluated in accordance with predominant regions; upper extremities predominant mHAQ (mHAQ_UE), and lower extremities predominant mHAQ (mHAQ_LE). Adding to these parameters, as an index for disease activity monitoring, components of the simplified disease activity index score (SDAI) was also recorded. Relationship between mHAQ for each predominant extremities, and these parameters and sex, age, disease duration of RA, anti-cyclic citrullinated polypeptide antibodies (ACPA), rheumatoid factor (RF), and Sharp/van der Heijde score (SHS), were statistically evaluated using linear regression analysis.

Results: mHAQ_UE significantly correlated with age, ACPA and RF titre, SHS, tenderness joint count (TJC), patient's global assessment (PGA), evaluator's global assessment (EGA), C-reactive protein (CRP), US, UL, LL, and PS-vas, whereas mHAQ-LE significantly correlated with all parameters that demonstrated significant correlation with mHAQ-UE and disease duration. mHAQ also correlated with all parameters those that demonstrated significant correlation with mHAQ-LE. Interestingly, all of mHAQ-UE, mHAQ-LE, and mHAQ did not correlated significantly with swollen joint count (SJC) and LS.

Conclusion: mHAQ is influenced by various factors, however, SJC and involvement of small joint in lower extremities did not affect mHAQ.

POS0575 THE PATIENT GLOBAL ASSESSMENT (PGA) OF DISEASE ACTIVITY COLLECTS DIFFERENT INFORMATION IN EARLY COMPARED TO ESTABLISHED RHEUMATOID ARTHRITIS

L. De Stefano[1,2], S. Bugatti[1,2], B. D'Onofrio[1,2], E. Favalli[3], A. Manzo[1,2], R. Caporali[3,4], C. Montecucco[1,2]. [1]*Fondazione I.R.C.C.S. Policlinico San Matteo, Division of Rheumatology, Pavia, Italy*; [2]*The University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy*; [3]*ASST Pini-CTO - Presidio Gaetano Pini, Department of Rheumatology, Milano, Italy*; [4]*University of Milan, Department of Clinical Sciences & Community Health, Milano, Italy*

Background: The patient global assessment (PGA) is the most widely used patient-reported measure in rheumatoid arthritis (RA), being a component of disease activity scores and definitions of remission. Studies have however shown that, at least in established RA, PGA is mostly associated with pain, functional limitation, psychological distress and comorbidities, rather than with objective measures of inflammation. As such, the inclusion of PGA as a driver of intensification of immunosuppressive therapy is been questioned. Determinants of PGA may however differ in the earliest stages of RA, when pain processing mechanisms and damage accrual have not occurred yet. Whether the association of PGA with disease activity in RA changes over time is at present undetermined.

Objectives: To analyze the associations between PGA and disease activity measures in patients with RA across different phases of the disease.

Methods: 1.002 RA patients from two independent cohorts were included: 1) a prospective longitudinal cohort of early RA (<12 months of symptoms) (n=601) with an observation period of 24 months upon initiation of therapy with methotrexate; 2) a cross-sectional cohort of established RA (duration >5 years) (n=401) with inadequate response to methotrexate. Determinants of PGA were assessed by Pearson's correlation coefficients and multivariable linear regression.

Results: In early RA, median (IQR) symptom duration at inclusion was 15 (9-27) weeks, 71.5% of the patients were female, 49.3% were autoantibody-positive, and 30% had radiographic evidence of ≥1 erosion. The mean (SD) DAS28 was 4.94 (1.19), and the mean (SD) PGA 57.6 (26.6). The proportion of patients at least in low disease activity (DAS28 <3.2) after 6, 12 and 24 months of treatment was 49.9%, 57.4% and 67% respectively. The associations of PGA with pain and functional limitation were moderate to good (r >0.40) at all time points, and were independent of other co-variates (Table 1). Swollen joints (SJC28) were independently and directly associated with PGA at all time points until 12 months, whilst the association become indirect at 24 months (Table 1). In ACPA-positive patients, PGA at 6 and 12 months was weakly but still significantly associated with SJC28 even in low disease activity states (adj r 0.15 and 0.13, p<0.05). Patients with established RA had a mean [SD] DAS28 of 5.3 [1.2] and were ACPA-positive in 69.6% of the cases. Independent determinants of PGA were pain, HAQ and tender joints, whilst no associations with SJC28 and acute phase reactants were found neither in the overall cohort nor in ACPA-positive patients.

Conclusion: In established RA, PGA appears mostly related to factors outside the core domains of disease activity. In contrast, in the early phases of the disease, PGA may more strictly collect information on inflammatory-related symptoms. Better understanding of the relationship between patient reported outcomes and disease activity in the various phases of RA may thus be needed before introducing definitive changes in the current definitions of disease activity.

POS0576 EFFECTS OF ACUTE EXERCISE ON SERUM BDNF LEVEL IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Baglan Yentur[1], Z. Ercan[1], G. Deniz[2], A. Karatas[3], M. Gur[3], G. Alkan[4], S. S. Koca[3]. *[1]Firat University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Elazig, Turkey*; *[2]Firat University School of Medicine, Department of Anatomy, Elazig, Turkey*; *[3]Firat University School of Medicine, Department of Rheumatology, Elazig, Turkey*; *[4]Firat University School of Medicine, Department of Physical Therapy and Rehabilitation, Elazig, Turkey*

Background: Brain derived neurotrophic factor (BDNF) is a neurotrofic factor that may show healing, survival-promoting and protective effects on neurons in central and peripheral nervous system. The effect of physical exercise on serum BDNF is unclear. Also, BDNF level was found significantly lower in rheumatoid Arthritis (RA) patients with depression.
Objectives: Aim of this study is to investigate the variation of BDNF levels following acute exercise and potential correlation between BDNF levels and depression.
Methods: This study included 44 RA patients and 44 age and sex matched healthy controls (HC). Aerobic exercise was performed to all participants for a single session. The intervention was performed on a treadmill and included 5 minutes of warm-up, 20 minutes of walking exercise reaching at 60- 80% of Maximal heart rate and 5 minutes of cool-down. Depression and anxiety levels were evaluated with Beck Depression Inventory (BDI) and Hospital Anxiety and Depression Scale (HADS). Blood samples from all subjects were taken and centrifuged before and immediately after the exercise intervention.
Results: Serum BDNF levels (both baseline and post-exercise) were similar in the RA and HC group (Table 1). Although after aerobic exercise serum BDNF levels were significantly decreased in both RA and HC groups (Wilcoxon Rank $P < 0.05$) ΔBDNF levels was significantly higher in the RA group than HC group. Serum BDNF level was increased in 30.2% of healthy subjects and 4.5% of RA patients ($P = 0.002$). On the other hand, BDI, HADS depression and HADS anxiety indices were correlated significantly with ΔBDNF levels in the RA group ($p<0.05$) but not in HC group.
Conclusion: A single bout of exercise may be effective on serum BDNF levels in patients with RA and healthy subjects. However, psychological comorbidities affect the amelioration of BDNF level, in RA. The long-term effect of alterations on BDF level is candidate to evaluate by prospective studies.

Table 1. Clinical and laboratory characteristics in the study groups

	RA (n=44)	HC (n=44)	P

POS0577 EVALUATION OF COPING STRATEGIES IN RHEUMATOID ARTHRITIS PATIENTS

B. A. Hiba[1], S. Meriem[2], S. Miladi[2,2], F. Alia[2,2], S. Leila[2], O. Kmar[2], S. Kassab[2], S. Chikili[2], K. Ben Abdelghani[2], A. Laatar[2]. *[1]Mongi Slim University Hospital, Rheumatology, Tunis, Tunisia*; *[2]Mongi Slim University Hospital, Rheumatology, TUNIS, Tunisia*

Background: Studies have shown that the association of pain, stiffness, disability, and social restrictions in rheumatoid arthritis (RA) patients induce a significantly increased level of depressed mood and stress. The use of favorable coping strategies could lead to improve physical and psychological well-being.
Objectives: To evaluate coping strategies of RA patients and their associations with health-related quality of life (HRQoL) outcomes.
Methods: A cross-sectional sample of patients with established RA was evaluated using measures of coping: the Brief-COPE (scores presented for the two overarching coping styles: Approach coping including active coping, emotional support, use of informational support, positive reframing, planning and acceptance, and Avoidant coping including self-distraction, denial, substance use, behavioral disengagement, venting and self-blame), the HRQoL (Mental and Physical Components [MCS/PCS] of the Short Form 12), and the Rheumatoid Arthritis Impact of Disease score (RAID). Multiple linear regression analyses were performed to evaluate the associations between coping strategies and HRQoL outcomes.
Results: The study sample comprised 45 patients with a female predominance (91.9 %), and a mean age of 55.7± 9.9 years [38-77]. The median disease duration was 10 years [38-77]. The majority of patients (82.8 %) were positive for either rheumatoid factor or anti-CCP. Half of the patients were on biological disease-modifying antirheumatic drugs. Two active coping strategies were identified: Approach coping (E = 4.29) and Avoidant Coping (E=3.86), which explained 40% of the total variance. Mean RAID was 4.8± 1.6, while the mean PCS and MCS were 31.9 ± 9.4 and 39.7 ± 9.4, respectively. Approach coping and avoidant coping were associated with PCS (r= 0.4, p = 0.03), (r=0.3, p=0.008) respectively. However, no association was found between coping strategies and MCS or RAID (p>0.05). In the multivariate model, approach coping and avoidant coping were significant to explain lower disease-specific HRQoL (PCS) (Beta= 0.4, p= 0.008), (Beta=0.3, p=0.02) respectively.
Conclusion: Approach and avoidance are associated with lower disease-specific HRQoL (PCS) but not with lower disease-specific HRQoL (MCS). Doctors should not forget to help their patients developing adaptive coping strategies.

POS0578 CORRELATION BETWEEN EXPRESSION LEVELS OF MIR-155 AND MIR-223 IN SYNOVIAL FLUID AND ULTRASOUND SCORES FOR ACTIVE SYNOVITIS IN RHEUMATOID ARTHRITIS PATIENTS

R. Shumnalieva[1], D. Kachakova[2], R. Kaneva[2], Z. Kolarov[1], S. Monov[1]. *[1]Clinic of Rheumatology, Department of Rheumatology, Medical University-Sofia, Bulgaria, Sofia, Bulgaria*; *[2]Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Medical University-Sofia, Bulgaria, Sofia, Bulgaria*

Background: MicroRNAs (miRNAs) are a class of small, non-coding RNAs that negatively regulate gene expression at posttranscriptional level. In rheumatoid arthritis studies have shown that miRNA are differentially expressed systemically as well as locally in the inflamed joints [1,2]. The correlation between their systemic or local expression levels and scores for disease activity and progression in RA make them possible candidate for biomarkers in the clinical practice.
Objectives: To analyze the expression levels of miR-155 and miR-223 in synovial fluid (SF) from RA patients in regard to the ultrasound scores for disease activity.
Methods: A total number of 48 RA patients according to the 1987 ACR criteria were included in the study. Expression levels of miR-155 and miR-223 SF were determined by qPCR (SybrGreen technology) and compared to healthy controls (HCs). Relative changes of gene expression levels of the studied miRNAs were calculated by $2^{-\Delta\Delta Ct}$ method. Musculoskeletal ultrasound (MSUS) examination was performed by two

independent examiners on ESAOTE, MyLab60 using both grey scale and power Doppler technic. A semi-quantitative assessment of the peripheral joints was performed for detecting joint inflammation and determining the grade of synovial thickening and the degree of vascularization. Ultrasound features for active disease were correlated to the local expression of the studied miRNAs. SPSS was used for statistical analysis.

Results: RA SF showed overexpression of miR-155 (in 79.17%, $p=1.63x10^{-4}$) and of miR-223 (in 79.17%, $p=1.64x10^{-3}$) when compared to HCs and both miRNAs could be used to differentiate RA patients from HCs ($p=8.0x10^{-5}$ and $p=2.8x10^{-4}$, respectively). When we analyzed the correlation between the diagnosis, the expression of miRNAs and the changes on the musculoskeletal ultrasound examination we found a statistically significant correlation between the presence of synovitis and the degree of the power Doppler signal on MSUS and the local expression of miR-223 ($p=6.19 \times 10^{-4}$ and p=0.003, respectively). SF levels of miR-223 correlated also with the degree of synovial hypertrophy on MSUS (p=0.013). The results for miRNA-155 were not statistically significant.

Conclusion: The correlation between the local expression of miR-223 and the ultrasound features of active joint inflammation shows that this miRNA might be a better candidate for local disease biomarker than miR-155. Further analysis with larger sets is needed to confirm if altered local miRNA expression could be used in the clinical practice as biomarker for disease activity especially in cases with subclinical synovitis.

POS0579 LOCAL ADAPTATION OF RECOMMENDATION-BASED MATERIALS FOR SHARED DECISION-MAKING AND MANAGEMENT OF COMORBIDITY IN RHEUMATOID ARTHRITIS

J. M. Alvaro-Gracia[1], C. Barbazan[2], J. F. Garcia Llorente[3], S. Muñoz-Fernández[4], A. Gomez-Centeno[5], A. Urruticoechea-Arana[6], M. A. Caracuel-Ruiz[7], E. Loza[8], J. Calvo[9]. *[1]University General Hospital Gregorio Marañón, Rheumatology, Madrid, Spain*; *[2]Complexo Hospitalario Universitario de Vigo, Rheumatology, `Vigo, Spain*; *[3]Hospital de Galdakao Usansolo, Rheumatology, Bilbao, Spain*; *[4]University Hospital 'Infanta Sofía', Rheumatology, Madrid, Spain*; *[5]University Hospital 'Parc Taulí', Rheumatology, Sabadell, Spain*; *[6]Hospital 'Can Misses', Rheumatology, Ibiza, Spain*; *[7]University Hospital 'Reina Sofía', Rheumatology, Cordoba, Spain*; *[8]Instituto de Salud Musculoesquelética, Rheumatology, Madrid, Spain*; *[9]University Hospital of Araba, Rheumatology, Vitoria-Gasteiz, Spain*

Background: Evolving the management of rheumatoid arthritis (eRA) is a European-wide educational initiative aiming to support improved patient care through practical and educational tools addressing specific unmet needs. The aims of the eRA program were: (1) To identify priority unmet needs with the greatest impact on disease outcomes; (2) To develop practical, educational and guidance tools in line with EULAR recommendations to address identified unmet needs; and (3) To improve RA management and patient care.

Objectives: To describe the process by which local adaptations were made of materials derived from evidence-based recommendations in a training programme in rheumatoid arthritis (RA).

Methods: A multidisciplinary Steering Committee (17 members, 12 countries) identified unmet needs within the management of RA and prioritised those with the greatest impact on patient outcomes. Practical educational tools addressing priority needs were then developed for dissemination and implementation by the rheumatology community across Europe, including shared decision making practises and a checklist for managing comorbidity in RA, among others. These materials were evaluated in detailed and discussed in small regional groups by practicing rheumatologists. Voting, open discussions and recommendations were extracted from the meetings.

Results: Thirty-five Spanish rheumatologists from diverse geographic regions discussed a comorbidity checklist and a shared decision making tool. The results of the local meetings were synthesised as (1) a judicious commitment to check agreed comorbidities, and (2) a list of barriers and facilitators for the implementation of shared decision making at the local settings. With regards to ways to implement the agreed list and periodicity, two issues standed-out: (1) patient education and (2) the need of easy access to information and the use of local organisational systems in place. With respect to shared decision-making, issues raised included messages for self-awareness, challenges, and practical facilitators.

Conclusion: Discussion, adaptation, and planning are needed before implementing any evidence-based recommendation and materials if we want to achieve a successful implementation. Further studies should demonstrate whether this initiative was successful in achieving the goals of improved patient care. Our experience could be used as a guidance or example for implementation elsewhere.

POS0580 COMORBIDITY BURDEN IS HIGH IN RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS PATIENTS STARTING BIOLOGICS AND PREDICTS THE INCIDENCE OF SERIOUS ADVERSE EVENTS DURING THERAPY

I. Flouri[1], A. Repa[2], N. Avgustidis[2], N. Kougkas[2], A. Eskitzis[2], A. Molla Ismail Sali[2], S. Pitsigavdaki[2], K. Pateromichelaki[2], E. Kalogiannaki[2], M. Terizaki[2], G. Bertsias[2], P. Sidiropoulos[2]. *[1]University Hospital of Heraklion, Crete, Rheumatology Department, Heraklion, Crete, Greece*; *[2]University Hospital of Heraklion, Crete, Rheumatology Department, Heraklion, Crete, Greece*

Background: There is limited information on the burden of comorbidities in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA) in real-world clinical practice and its impact on the incidence of serious adverse events (SAE) during biologic disease-modifying anti-rheumatic drug (bDMARD) therapy.

Objectives: To evaluate the number of comorbidities in patients with RA and SpA initiating a bDMARD in everyday clinical practice and to explore its association with the occurrence of a SAE during therapy.

Methods: Prospective study of all patients who start any bDMARD treatment in a tertiary centre University Hospital. All comorbidities and SAEs (AEs necessitating hospitalization or resulting in significant incapacity/death) are registered by treating physicians. Comorbidities' number was evaluated using two different indices: total comorbidities count (CC) and Rheumatic Disease Comorbidity Index (RDCI). Statistical analysis was performed using multinomial logistic and Cox regression models.

Results: A total of 799 patients were analysed, of which 428 (54%) had ≥3 comorbidities (Table 1). Comorbidity burden was higher in RA, however in multivariable analyses, comorbidities were not significantly associated with diagnosis, but mainly with increasing patient age. Patients received 1701 bDMARD treatments. During a follow-up of 4019 patient-years, 198 patients (RA:134, SpA:64) had a total of 295 SAE (RA: 217, SpA:78). Each one additional comorbidity in CC index was resulting in 16% increased adjusted risk for the first SAE [HR (95%CI) = 1.16 (1.12-1.20), p<0.001], and each additional comorbidity of the RDCI index was resulting in 28% increased risk [HR (95%CI) = 1.28 (1.20-1.37), p<0.001]. Other baseline independent predictors of the first SAE were greater age [HR=1.04, p<0.001] and use of corticosteroids [HR=1.42, p=0.006].

Table 1. Biologic treatments and clinical characteristics at baseline

Patients, N	Total	RA	SpA	p
	799	501	298	
Females, N (%)	535 (67)	404 (81)	131 (44)	<0.001
Age, median (IQR) έτη	55 (45-65)	60 (51-68)	46 (36-54)	<0.001
Disease duration, median (IQR) έτη	6.0 (2.5-13)	5.4 (3-11)	7.4 (2.0-15)	<0.001
Comorbidities count, median (IQR)	3 (1-5)	3 (2-6)	2 (1-4)	<0.001
Patients with no comorbidities, N (%)	103 (13)	43 (9)	60 (20)	<0.001
Patients with 1 comorbidity, N (%)	134 (17)	77 (15)	57 (19)	0.172
Patients with 2 comorbidities, N (%)	134 (17)	76 (15)	58 (19,5)	0.118
Patients with ≥3 comorbidities, N (%)	428 (54)	305 (61)	123 (41)	<0.001
RDCI, median (IQR)	1 (0-2)	2 (0-3)	1 (0-2)	<0.001
Patients with RDCI = 0, N (%)	267 (33)	128 (25.5)	139 (47)	<0.001
Patients with RDCI = 1, N (%)	185 (23)	119 (24)	66 (22)	0.665
Patients with RDCI = 2, N (%)	163 (20)	113 (23)	50 (17)	0.057
Patients with RDCI ≥ 3, N (%)	184 (23)	141 (28)	43 (14)	<0.001
Total bDMARDs initiated by patients, N	**1701**	**1098**	**603**	
Co-administered methotrexate, N(%)	946 (56)	674 (61)	272 (45)	<0.001
Co-administered corticosteroids, N (%)	493 (29)	397 (36)	96 (16)	<0.001
DAS28, median (IQR) (in RA and perSpA)	5.8 (4.9-6.6)	5.8 (5.0-6.6)	5.4 (4.2-6.3)	<0.001
BASDAI, median (IQR) (in axSpA)	-	-	5.6 (4.5-7.0)	

Conclusion: Patients with RA and SpA initiating a bDMARD treatment in real-world clinical practice have a significant comorbidity burden which increases with age and is an independent predictor for an SAE during therapy.

POS0581

PERIODONTAL DISEASE IN RHEUMATOID ARTHRITIS: RESULTS FROM A COHORT AT TREATMENT WITH BIOLOGICAL, CLASSICAL AND TARGETED SYNTHETIC DMARDS

R. Dos-Santos[1], F. Otero[1], E. Perez-Pampín[1], A. Mera Varela[1]. [1]*Clinical University Hospital in Santiago de Compostela, Rheumatology Department, Universidad de Santiago de Compostela, Santiago de Compostela, Spain*

Background: Periodontal disease (PD) has been widely studied in the pathogenesis of rheumatoid arthritis (RA). As well, its relationship with severity and disease activity, has also been investigated with ambiguous results. It has been suggested that the improvement of oral health could enhance disease activity scores.[1] PD prevalence worldwide stands around 60% in older adults (>65 years) and its frequency increases with aging.[2]
Objectives: To asses oral health in RA patients and to identify predictors of PD in this population.
Methods: Patients diagnosed of RA at treatment with biological, classical or targeted synthetic disease modifying anti-rheumatic drugs (b/cs/tsDMARDs) in the aforementioned hospital during 2020 performed a dental review with a specialized periodontal odontologist. Oral health patterns were given for all patients, following criteria of American Academy of Periodontology, and reevaluation of disease activity was made 2 months later.
Clinical, demographic and treatment data were collected from participants.
Univariable logistic regression was performed to identify predictors of PD. Variables with p<0.20 were selected for multivariable analysis.
Stata 15.1 was used to perform statistical analysis.
Results: 81 patients were recruited. 82.72% were female. Mean age was 56.17 years (SD 14.15) and mean time since diagnosis was 15.58 years (SD 8.17). 25% were current or past smokers. 21 patients had comorbidities (arterial hypertension the most frequent). 66.67% were rheumatoid factor (RF) positive and 72.73% anti-citrullinated peptide autoantibody (ACPA) positive. Median erythrocyte sedimentation rate (ESR) was 12 mm (IQR 6;23) and mean C-reactive protein (CRP) was 0.48 mg/dl (SD 1.18). Mean disease activity score (DAS28-VSG) at the testing time was 2.62 (SD 1.21) and after 2 months was 2.39 (SD 0.97). 96.30% of patients were at treatment with csDMARDs, 64.20% with glucocorticoids, 96.30% with bDMARDs and 6 patients with tsDMARDs.
Univariable analysis identified higher age, at least one autoantibody positive and ESR/CRP as potential predictors of medium/severe PD (p<0.20). Multivariable testing including these variables pointed out higher age, lower ESR and at least one autoantibody positive (OR 1.09 [CI95% 1.04-1.14] p=0.001, OR 0.18 [CI95% 0.04-0.95] p=0.044 and OR 0.94 [CI95% 0.88-1.00] p=0.042, respectively) as predictors of medium or severe PD (≥3 mm interdental clinical attachment loss).
Univariable analysis identified higher age, the presence of any comorbidity and anti tumour-necrosis factor alpha treatment (anti-TNF) as potential predictors of severe PD (p<0.20). Multivariable testing including these variables pointed out higher age (OR 1.15 [CI95%1.02-1.30] p=0.026) as predictor of severe PD (≥5 mm interdental clinical attachment loss).
Conclusion: Periodontal disease is still an extended health problem among the entire population. Its prevalence in RA is increased, therefore higher age and RF or ACPA positive are risk factors for developing severe PD. This analysis might suggest that an aggressive management of PD could implement better responses in DAS28. Also anti-TNF treatment could delimit a "penumbra" group of patients at risk of developing severe PD, where intensive manage could modify the final outcome.

POS0582

RHEUMATOID ARTHRITIS AND ORAL MICROBIOME: PREDICTORS OF DISTURBANCES AND ITS IMPLICATIONS. RESULTS FROM A COHORT AT TREATMENT WITH cs/b/tsDMARD

R. Dos-Santos[1], F. Otero[1], E. Perez-Pampín[1], A. Mera Varela[1]. [1]*Clinical University Hospital in Santiago de Compostela, Rheumatology Department, Universidad de Santiago de Compostela, Santiago de Compostela, Spain*

Background: Oral microbiome (OM) seems to be significant in the pathogenesis of some immune-mediated diseases, such as rheumatoid arthritis (RA), psoriasis or inflammatory bowel disease.[1] Some microorganisms, as *Porphyromonas gingivalis* have been related with the production of autoantibodies. Also it has been suggested that composition of OM could change RA disease course, being more difficult-to-treat and having higher disease activity scores.[2]
Objectives: To identify which variables could predict the appearance of altered OM and its implications in clinical practice.
Methods: Patients were recruited if they were diagnosed of RA and were at active treatment (biological, classical or targeted synthetic disease modifying anti-rheumatic drugs [b/cs/tsDMARDs]). Patients performed a dental review with a specialized odontologist that made an OM test (semiquantitative PCR), and oral health standards were instructed (following criteria of American Academy of Periodontology). Recruitment was made during 2020 in the Clinical University Hospital in Santiago de Compostela, Spain. Disease activity reevaluation was made 2 months later.
Treatment, demographic and clinical data were collected from participants.
Univariable logistic and linear regression were performed to identify predictors of OM. Variables with p<0.20 were selected for multivariable analysis.
Stata 15.1 was used to perform statistical analysis.
Results: 47 patients were selected of whom 40 were female. Mean age was 55.43 years (SD 14.42). 30.77% were current or ex-smokers. Mean time since RA diagnosis was 14.89 years (SD 8.47). 63.83% were anti-citrullinated peptide autoantibody (ACPA) positive and 70.21% were rheumatoid factor (RF) positive, letting only 6 patients double negative. 46.81% had moderate/severe periodontal disease (PD). 32.61% of patients had any comorbidity. Mean DAS28 at the OM test was 2.67 (SD 1.28) and after 2 months 2.37 (SD 1.03). Mean C-reactive protein (CRP) was 0.64 mg/dl (SD 1.48) and median erythrocyte sedimentation rate (ESR) was 13 mm (IQR 7;27). All patients were under glucocorticoid treatment, 46 with bDMARD, 1 with tsDMARD and 46 with csDMARD. *Treponema denticola* was detected in 44.68% of patients, *P. gingivalis* in 29.79%, *Actinomyces* spp in 8.51%, *Tanerella forsythia* in 36.17% and *Prevotella intermedia* in 25.53%. Only 15 patients were full-negative for OM test.
Univariable analysis identified RF positive, double autoantibody positive (RF and ACPA) and moderate/severe PD as potential predictors of the presence of at least one oral microorganism (p<0.20). Multivariable testing pointed out moderate/severe PD as predictor of the presence of at least one oral microorganism (OR 22.91 [CI95% 2.38-220.4] p=0.007).
Univariable analysis identified higher age, presence of any comorbidity, RF positive, higher CRP, treatment with anti-tumour necrosis alpha (aTNF) and moderate/severe PD as potential predictors of the presence of multiple species in OM (p<0.20). Multivariable testing pointed out moderate/severe PD as predictor of the presence of multiple species in OM (ß 0.39 [95%CI 0.19-0.58] p=0.000).
Conclusion: Oral microbiome is closely related with periodontal disease, added to our results, a relationship between OM and disease activity has been exposed. In this analysis the role of OM and autoantibody profile is manifest, as being double positive or RF positive is associated with the presence of altered OM. Also patients with high acute-phase reactants, active disease and under aTNF treatment could delineate a specific RA population under risk of altered OM, where intensive strategies for changing oral microbiome could have any repercussion in the disease course.

POS0583

ENGINEERED GLOVE TO EVALUATE THE SPEED OF THE HANDS' MOVEMENTS IN RHEUMATOID ARTHRITIS

M. Patanè[1], L. Carmisciano[2], E. Hysa[3], E. Gotelli[3], A. Signori[2], V. Smith[4], M. Cutolo[3]. [1]*Ospedale Alessandria, Internal Medicine, Alessandria, Italy*; [2]*University of Genoa, Department of Health Sciences, Genoa, Italy*; [3]*University of Genoa, Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, IRCCS "San Martino" Polyclinic Hospital, Genova, Italy*; [4]*Ghent University, Department of Internal Medicine; Department of Rheumatology; Unit for Molecular Immunology and Inflammation, Ghent University Hospital, Gent, Belgium*

Background: Rheumatoid arthritis (RA) is a long-term, progressive, and disabling autoimmune disease1. The disease activity can be quantified by the Disease Activity Score 28-joint count – C reactive protein (DAS28crp)2; the evaluation of disability function (DF) is actually mainly performed only by subjective Patient Reported Outcomes (PROs) like Health Assessment Questionnaire (HAQ)3; to investigate the functional aspects of RA hands it is usually used the grip strength (GS)4. However, in the scientific literature no tool, which objectively evaluates movement speed, has been reported. The Hand Test System (HTS, ETT) is an engineered glove (RAGLOVE), nowadays applied for neuroscience studies to evaluate hand motility5

Objectives: To objectively evaluate the RA hand's speed of the fine movements, through the HTS and to compared with a group of age and sex matched healthy controls. To verify the correspondence with the HAQ, DAS28, GS.
Methods: 55 consecutives RA patients (pts) (6 males, age 61 ± 16 years, mean duration of disease 12 ± 8 years), classified according to 2010 ACR/EULAR criteria6, and 50 matched healthy controls (HCs) were enrolled. After consent, all participants undergone HTS test that recognizes the touches between the finger tips during the opposition movements of the hands in standard sequences of movements, after dressed the glove. A multiple finger evaluation (MFE) and a single finger evaluation (SFE) were performed using a dedicated software that provided the physician the following quantitative parameters: Touch Duration (TD), Inter Tapping Interval (ITI) and Movement Rate (MR). Average time for hand 2 minutes. RA pts compiled the HAQ, performed the GS and a DAS28cpr was performed.
The student's t-test was used to compare the glove's parameters between the groups whereas the analysis of variance (ANOVA) was utilized to verify potential differences between the populations. In order to evaluate the single correlations, the r and p values of Pearson were employed.
Results: For MFE, glove parameters TD and ITI were significantly higher in RA pts than HCs, whereas; MR was significantly lower in RA pts compared to HCs (all p <0.001).
For SFE non-affected fingers (not swollen and not tender) of RA pts performed better than a clinically affected fingers, but in any case significantly worse than average HCs fingers (p < 0.001).
There is a statistically significant correlation between the GS and MR (r= 0.39 p=0.003) and TD (r=-0.33 p=0.015).
TD, ITI e MR of RA pts showed a significant correlation with the total score of the HAQ (r = 0.56, r = 0.39, r = -0.56, all p < 0.001;). DAS28, considered as a continuous variable, proved to be significantly correlated with the TD (r = 0.36, p = 0.009). When the RA patients were grouped according to the disease activity by DAS28cpr7, there was an increase of one third of the TD's logarithm for each increase in the activity class (linear regression with ordinal predictors, beta = 0.33; 95%CI 0.03, 0.63,p < 0.0297). Finally, even RA pts in remission showed a TD significantly higher compared with HCs (p= 0.034).
Conclusion: The RAGLOVE is shown as a new safe and fast tool to evaluate a new objective parameter in the hand's functionality: the speed of finger movements. In RA pts, an inversely proportional correlation emerges between the speed of movement and disease activity.
The significant correlation found with HAQ, highlights the loss of motility of the hands as one of the main determinant of disability. The RAGLOVE is now tested in RA patients undergoing treatment.

POS0584 ULTRASONOGRAPHY OF THE MEDIAN NERVE IN PATIENTS WITH RHEUMATOID ARTHRITIS UNDER SUSPICION OF CARPAL TUNNEL SYNDROME

S. Tsiami[1], E. Ntasiou[2], C. Krogias[2], R. Gold[2], J. Braun[1], M. Sarholz[3], X. Baraliakos[1]. [1]*Ruhr-University Bochum, Rheumazentrum Ruhrgebiet, Herne, Germany*; [2]*Ruhr-University Bochum, St. Josef-Hospital, Bochum, Germany*; [3]*St. Marien-Hospital Vreden, Klinik fuer Rheumatologie, Vreden, Germany*

Background: Carpal tunnel syndrome (CTS) is the most common nerve compression syndrome and a common extra-articular manifestation of rheumatoid arthritis (RA). Different causes of CTS are known, among them inflammatory and non-inflammatory pathologies. Electroneurography (ENG) of the median nerve, the method of choice to diagnose CTS, measures impairment of nerve conduction velocity without explaining its underlying cause. However, because the electrical stimulation is often not well tolerated, ENG results may come out inconclusive. Using greyscale ultrasonography (GS-US) provides anatomic information including a structural representation of the carpal tunnel.
Objectives: To investigate the performance of nerve GS-US in the diagnosis of CTS in patients with RA.
Methods: Consecutive patients with active RA under suspicion of CTS presenting to a large rheumatologic center were included. Both hands were examined by an experienced neurologist including ENG and a GS-US (ML linear probe with 6-15 Hz) of the median nerve. An established grading system for ENG (1), and an established system for GS-US based on cut-offs for the nerve cross sectional area (CSA) [mild: 0,11-0,13cm^2, moderate: 0,14-0,15 cm^2, severe: > 0,15 cm^2 CTS (2)] were used. In addition, the Boston Carpal Tunnel Syndrome Questionnaire (BCTSQ) was used to assess CTS symptoms (3).
Results: Both hands of 58 patients with active RA (n=116) and clinical suspicion of CTS (in 38 cases bilaterally) were included. After clinical examination, CTS was suspicious in 96 hands (82.8%), and 59 of all hands had a final diagnosis of CTS (50.9%). Of the latter, 43 hands (72.9%) had a positive ENG and 16 (27.1%) a positive GS-US finding only, while 30 hands (50.8%) were positive in both examinations.

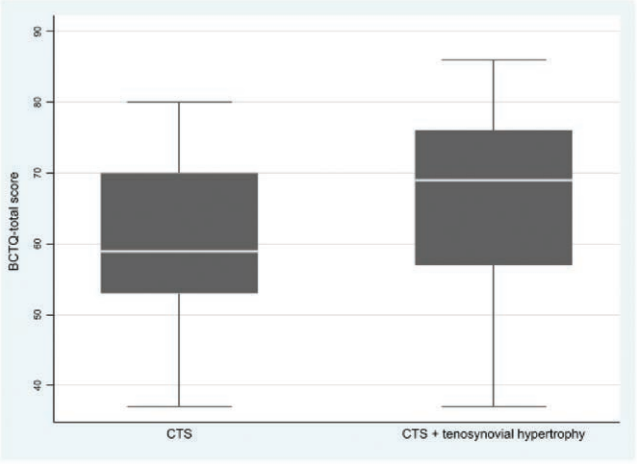

Figure 1. BCTSQ scores in patients with diagnosis of CTS and absence or presence of RA-related tenosynovial hypertrophy

There was a good correlation of the cross-sectional area (CSA) as well as the CSA-ratio to the ENG findings: the larger the CSA, the more severe was the CTS as assessed by ENG (Spearman's rho=0.554; p<0.001). The more severe the GS-US findings of CTS were, the more definite were the distal motor latency (Spearman's rho=0.554; p<0.001) and sensible nerve conduction velocity of the median nerve (Spearman's rho=-0.5411; p<0.001).
In the 46 hands positive in GS-US, tenosynovial hypertrophy of the flexor tendons was detected in 19 hands (41.3%), 7 of which (36.8%) also showed an additional cystic mass. In these 19 patients, clinical complains were more severely present than in patients with non-inflammatory CTS, as assessed by the BCTSQ with a total score of 68.8±13.4 vs. 59.3±13.7, respectively (p=0.007).
Conclusion: In patients with active RA and clinical complains of CTS, ultrasound examinations provide additional information about inflammation which is helpful for a diagnosis of CTS. Thus, ENG and nerve GS-US should be used complementary for a diagnostic workup of CTS in RA patients with a suspicion of CTS. Power-Doppler may further improve the diagnostic performance of GS-US.

POS0585 ORAL STATUS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Ben Salem[1], M. Brahem[1], H. Hachfi[1], R. Sarraj[1], S. Abdellatif[1], R. Ben Tekaya[1], C. Baccouche[2], Y. Mohamed[1]. [1]*Tahar Sfar Hospital, Rheumatology, Mahdia, Tunisia*; [2]*Tahar Sfar Hospital, Dentistry, Mahdia, Tunisia*

Background: Rheumatoid arthritis (RA) is a systemic auto immune inflammatory disorder, which primarily affects the synovial joints, but it may have an impact on oral health.
Objectives: The present study aimed to describe oral manifestations in patients with Rheumatoid arthritis (RA).
Methods: A cross sectional study including RApatients, which consulted or were hospitalized in Rheumatology department in Taher Sfar Hospital of Mahdia Tunisia, during a period of 10 months. The diagnosis of RA was based on ACR/EULAR 2010 criteria. Oral and periodontal examination was practiced by a trained dentist in the same hospital. Oral hygiene, teeth status (missing teeth) and paradental parameters (bleeding index of Loe and Silness (IG), plaque indexed O'Leary (IP) were determined for each patient, to assess oral and periodontal diseases in RA.
Results: Our study included 51 patients with an average age of 51.11 years ±12.4 [21-74years].50patients (92.6%of cases) were women and 8patients (14.8%) were diabetic. Only one patient was a smoker. The mean duration of RA was 10.7 years 7.7± [10months-35years]. Rheumatoid factor (RF) was positive

in 25 Patients (46.3%of cases). Anti-citrullinated peptide antibody (ACPA) was positive in 32 patients (59.3 %).41patients (75.4%) had radiological impairments and 28(51.9%) had specific deformations of RA. The average disease activity score (DAS28-VS) and (DAS28-CRP) were respectively 4.1±1.5[1.4-7.3] 3.4±1.5 [1.24-6.71]. Oral examination revealed a poor oral hygiene in 36patients (69.2% of cases) and 4.7% of our patients (2 cases) were toothless. Xerostomia was observed in 32 patients (80%). Gingivitis was diagnosed in 26 Patients (52%): localized in 6 patients (26.1%) and generalized in 17 patients (73.9%). 21 patients had periodontitis (41.2%). Basing on bleeding index of Loe and Silness (IG),27 patients (55.1%) had degree 2 and9 patients (18.8 %) had degree 3. Supragingival plaque and subgingival plaque were detected respectively in 45 patients (90 %) and 47 patients (95.9 %). In our study, tooth loss was significantly correlated with increased age (p=0.001) and post-menopausal status (p=0.03). Xerostomia, gingivitis and periodontitis were associated with increased age. But no association was found between oral manifestations and DAS28 nor biological inflammatory parameters.

Conclusion: Rheumatoid arthritis is destructive and disabling rheumatism with a great risk to develop dental and periodontal diseases. So, it is important to systematically control oral hygiene of our patients to prevent complications.

POS0586 RHEUMATOID ARTHRITIS IS AN INFLAMMATORY DISEASE WITH A HIGH CARDIOVASCULAR RISK

L. Nacef[1], H. Riahi[2], Y. Mabrouk[1], H. Ferjani[3], K. Maatallah[3], E. Labbene[4], D. Kaffel[1], M. Bouaziz[2], W. Hamdi[1]. [1]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Rheumatolgy, Manouba, Tunisia*; [2]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Radiology, Tunis, Tunisia*; [3]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Rheumatolgy, Tunis, Tunisia*; [4]*Mohamed Taieb Kassab Institute of Orthopedic Surgery and Traumatology, Radiology, Manouba, Tunisia*

Background: Hypertension, diabetes, and dyslipidemia are traditional risk factors of cardiac events. Carotid ultrasonography is an available way to detect subclinical atherosclerosis.

Objectives: This study aimed to compare the intima-media thickness in RA patients based on their personal cardiovascular (CV) history of hypertension (hypertension), diabetes, and dyslipidemia.

Methods: The present study is a prospective study conducted on Tunisian RA patients in the rheumatology department of Mohamed Kassab University Hospital (March and December 2020). The characteristics of the patients and those of the disease were collected.

The high-resolution B-mode carotid US measured the IMT, according to American Society of Echocardiography guidelines. The carotid bulb below its bifurcation and the internal and external carotid arteries were evaluated bilaterally with grayscale, spectral, and color Doppler ultrasonography using proprietary software for carotid artery measurements. IMT was measured using the two inner layers of the common carotid artery, and an increased IMT was defined as ≥0.9 mm. A Framingham score was calculated to predict the cardiovascular risk at 10-year.

Results: Forty-seven patients were collected, 78.7% of whom were women. The mean age was 52.5 ±11.06 [32-76]. The rheumatoid factor (RF) was positive in 57.8% of cases, and anti-citrullinated peptide antibodies (ACPA) were positive in 62.2% of cases. RA was erosive in 81.6% of cases. Hypertension (hypertension) was present in 14.9% of patients, diabetes in 12.8% of patients, and dyslipidemia in 12.8% of patients. Nine patients were active smokers. The mean IMT in the left common carotid (LCC) was 0.069 ±0.015, in the left internal carotid (LIC) was 0.069 ±0.015, in the left external carotid (LEC) was 0.060 ±0.023. The mean IMT was 0.068 ±0.01 in the right common carotid (RCC), 0.062 ±0.02 in the right internal carotid (RIC), and 0.060 ±0.016 in the right external carotid (REC). The IMT was significantly higher in the left common carotid (LCC) in patients with hypertension (p=0.025). There was no significant difference in the other ultrasound sites (LIC, LEC, RCC, RIC, and REC) according to the presence or absence of hypertension. The IMT was also significantly increased in patients with diabetes at LCC (p=0.017) and RIC (p=0.025). There was no significant difference in the IMT at different ultrasound sites between patients with and without dyslipidemia.

Conclusion: Hypertension was significantly associated with the increase in IMT at the LCC level in RA patients. Diabetes had an impact on IMT in LCC and RIC. However, dyslipidemia did not affect the IMT at the different ultrasound sites.

Background: Patients with rheumatoid arthritis (RA) are exposed to a multifactorial cardiovascular risk: chronic inflammation, endogenous and exogenous factors, and treatment.

Objectives: The aim of this study was to investigate the impact of RA treatments on cardiovascular risk and the influence of supra aortic trunks.

Methods: This is a prospective study conducted on RA patients followed-up between March and December 2020 at the rheumatology department of the Mohamed Kassab Institute of Orthopedics and Traumatology. Socio-demographic data of patients and characteristics of the disease were collected. The disease activity was evaluated by the Disease Activity Score 28. Prescribed treatments were specified. Ultrasonography of the supra aortic trunks was performed by measuring, in centimeters, the Intima-media Thickness (IMT) at the level of the left (LCC) and right (RCC) common carotid arteries, the left (LIC) and right (RIC) internal carotid arteries and the left (LEC) and right (REC) internal carotid arteries.

Results: Of the 47 patients surveyed, 78.7% were female. The mean age was 52.5 ±11.06 [32-76]. The average RA progressed from 86.25 ±63 [5-288] and was erosive in 81.6% of cases. The rheumatoid factor (RF) was positive in 57.8% of patients, and citrullinated antipeptide antibodies (ACPA) were present in 62.2%. The treatments taken were: Methotrexate (MTX) (54.5%), Sulfasalazine (SLZ) (1.8%), Leflunomide (LFN) (3.6%), a combination of cs-DMARDs (5.5%), and biotherapy (10.9%). The prescribed biotherapies were: Etanercept (3.6%), Adalimumab (1.8%), Certolizumab (1.8%), Infliximab (3.6%). Corticosteroids (CT) were prescribed in 38.2% of patients, non-steroidal anti-inflammatory drugs (NSAIDs) (3.6%), and analgesics (41.8%).

CT had a protective effect on IMT in LIC (p=0.031) and RIC (p=0.016). MTX had a significant protective effect on IMT in RIC (p=0.002) and LEC (p=0.033).

SLZ was associated with an increase in IMT at the RIC level (p=0.05). There was no association between NSAID use and IMT. MTX and CT were significantly associated with a decrease in SCORE (p=0.02; p=0.05, respectively). There was a non-significant association between SLZ or LFN and decreased SCORE (p=0.140, p=0,970).

Conclusion: In our series, patients taking MTX and CT had a lower IMT than those not taking these drugs. SLZ was associated with an increase in IMT. NSAIDs did not affect IMT in our study.

POS0588 USUAL INTERSTITIAL PNEUMONIA DURING RHEUMATOID ARTHRITIS: PREVALENCE AND ASSOCIATED FACTORS

C. Daldoul[1], N. El Amri[1], A. Guiga[2], S. Laataoui[1], K. Baccouche[1], H. Zegaloui[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*; [2]*Farhat Hached Hospital, Internal Medicine, Sousse, Tunisia*

Background: Lung involvement is the second common extraarticular manifestation of rheumatoid arthritis (RA). Its prevalence varies widely according to the screening tool used and it could reach up to 80% of patients. This lung disease can affect all the lung compartments. However, interstitial lung disease during RA needs a particular attention due to the increased morbidity and usual interstitial pneumonia (UIP) pattern especially due to its higher rate of mortality.

Objectives: To determine the frequency and associated factors of UIP among RA patients
Methods: This was a retrospective study conducted at the Rheumatology department of Farhat Hached University Hospital from 2005 to 2020. We included all RA patients who had undergone high-resolution computed tomography (HRCT) scans of the lung. Demographic data, disease characteristics, pulmonary function tests (PFT) and drugs intake were collected at the time of the realization of the HRCT. UIP pattern and NON-UIP patterns were based on HRCT results. Khi-2 and T-student tests were used in the univariate analysis. Binary logistic regression was used in the multivariate analysis. Statistical significance level was set at 5%.
Results: Fifty-nine patients with RA patients having HRCT of the lung were identified among them 27.1% (16) were male. The mean age of the patients was 60.27± 11.3 years; the mean disease duration was 7.16 ± 2.9 years and current or previous smoking habits were recorded in 18.8% (11) of our population with a median. Secondary Sjogren's syndrome and cutaneous rheumatoid nodules were documented in 33.9% (20) and 10.17% (6) respectively. RA was erosive in 81.5% (48) of our population. The median tender joint count and the median swollen joint count were 10 and 4 respectively. The mean erythrocyte sedimentation rate (ESR) and the mean C-reactive protein (CRP) were 49±20.31 mm and 32±14.07 mg/dl respectively. The mean disease activity score (DAS 28 ESR) was 5.49±1.66. The median rheumatoid factor and Anti-CCP levels were 260UI/ml and 68 UI/ml respectively. Exertional dyspnea (stage 2 or higher) was present in 42.37% (25) and inspiratory crackles were found in 22.4% (13) of our patients. PFT revealed a restrictive ventilatory defect, an obstructive pattern and a mixed pattern were found in 20.3% (12), 13.6 (8) and 3.4% (2) respectively. The mean DLCO value was 70±24.6%. According to HRCT results, parenchymal involvement was found in 83.1% (49) of our patients and among them, we documented UIP pattern in 18 (36.73%), Non Specific Interstitial Pneumonia (NSIP) in 14.28% (7), unclassifiable fibrosis in 14.29 (7), organizing pneumonia in 2% (1) and isolated pulmonary nodules in 32.6% (16). Pleural effusion was found in 5.1% (3) and airways disease in 15.3% (9). Mediastinal lymphadenopathy was found in 15.25% (9). Abnormalities on HRCT lead to a change in treatment in 30.5% (18) of our patients. Compared to the group with a non-UIP pattern, male sex was significantly associated with UIP pattern on HRCT (47.4% vs. 17.5%, p=0.016). UIP pattern was significantly associated with smoking (37.5% vs. 9.4% p=0.022, Unadjusted OR=5.88, 95%IC=[1.217-27.634]), with cutaneous rheumatoid nodules (31.3% vs.3.4%, p=0.017, Unadjusted OR=12.72, 95IC=[1.331-121.658]) and with the presence of lymphadenopathy on HRCT (41.2% vs. 6.5%, p=0.004, Unadjusted OR=10.15, 95%IC=[1.803-57.140]). There was no significant difference between the two groups regarding age (p=0.454), disease duration (p=0.126), DAS28 (p=0.447), anti-CCP level (p=0.454). After multivariate analysis, male sex (Adjusted OR=11.58, 95%IC=[1.622-82.67] p=0.015), Presence of lymphadenopathy on HRCT (Adjusted OR=10.53, 95%IC=[1.146-96.87], p=0.037) and exertional dyspnea (Adjusted OR=6.43, 95%IC=[1.036-40.011], p=0.046) were independently associated with UIP pattern.
Conclusion: UIP was present in 36.73% and it was the most prevalent pattern of lung involvement in RA. It was associated with male sex, mediastinal lymphadenopathy and exertional dyspnea.

POS0589 **PREVALENCE AND SEVERITY OF STRESS AT HOME AMONG PATIENTS WITH RHEUMATOID ARTHRITIS: SINGLE CENTRE RESULTS FROM THE PRIME REGISTRY COHORT**

M. Haroon[1], F. Hashmi[1], S. Ullah[1], A. Ashraf[2], H. J. Shaheen[1], S. Asif[1], S. Batool[1]. [1]*Fatima Memorial Hospital & FMH College of Medicine and Dentistry, Department of Rheumatology, Lahore, Pakistan*; [2]*CMH Lahore Medical College & Institute of Dentistry, Medicine, Lahore, Pakistan*

Background: In chronic inflammatory diseases like rheumatoid arthritis (RA), psychological stress is widely recognised as an important risk factor to negatively affect the disease course. Stress activates the hypothalamic-pituitary adrenal axis and the autonomic nervous system, which associate with the release of neurotransmitters (i.e. norepinephrine), hormones (i.e. cortisol) and activation of immune cells. Perceived stress can potentially induce the disease exacerbation, but on the other hand, the disease itself might produce significant stress to patients thus the vicious circle is formed and maintained.
Objectives: We aimed to examine the prevalence of mental/emotional stress at home and its associations among patients with Rheumatoid arthritis. We addressed this question using real-world data from the PRIME registry.
Methods: This was a cross-sectional study conducted using data collected at the time of patient enrolment in the PRIME registry. The PRIME Registry is a large, independent, prospective, observational cohort initiated in October 2019 that comprises patients diagnosed with RA, SLE, PsA or AS by a rheumatologist, and is being actively followed up. IRB approval and informed consent was obtained. We assessed the data for RA patients. The clinical variables studied were gender, age, smoking habits, body mass index, education status, marital status, disease duration, comorbidities (using Charlson Comorbidity Index). Education status was stratified by whether participants completed secondary (high) school education. Evaluation of disease activity and severity was made as per internationally agreed definitions, such as: swollen joint counts, tender joint counts, deformed joint counts, and DAS-28. All participants were directly inquired at the interview during the time of patient enrolment about the presence or otherwise of mental/emotional stress at home, and to rate it from 1-3 (mild, moderate, severe). For better understanding and ease of statistical analysis, dichotomous variable was made with moderate-to-severe stress patients were categorised into one group and none-to-mild stress patients into second group.
Results: The data of consecutive 507 RA patients (mean age 42.3±12.6 years, 73.6% female, disease duration of 80±22 months) was reviewed. Forty-eight percent of patients accepted to have moderate-severe stress at home (moderate stress=29.9%, severe stress=18.3%). On univariate analysis, significant association of moderate-severe stress at home was noted with deformed joint counts (p=0.036), higher DAS-28 scores (p<0.001), and being married (p=0.001). Weak statistical association of age (p=0.11), disease duration (p=0.13), low education status (p=0.14), female gender (p=0.24) was noted. On multiple logistic regression analysis, a significant association of moderate-severe stress at home was observed with higher DAS-28 scores (OR 1.76, CI 1.29-2.41, p<0.001) and deformed joint counts (OR 1.15, CI 1.00-1.31, p=0.040). Following variables were included in multiple stepwise regression analysis: age, disease duration, low education status, married, Das-28 scores, and deformed joint counts. However, when gender was included in the regression analysis, a significant association of moderate-severe stress at home was observed with female gender (OR 3.99, CI 1.47-10.83, p=0.007), higher DAS-28 scores (OR 1.8, CI 1.31-2.51, p<0.001), with marginal association with deformed joint counts (OR 1.13, CI 0.99-1.30, p=0.061).
Conclusion: Stress at home is common among patients with RA, and nearly half of the cohort was noted to have moderate-severe level of stress at home. Ongoing stress at home has significant association with higher RA disease activity and deformities suggesting a bidirectional relationship. These findings demonstrate an important need for integration of rheumatologic, social workers and mental health services

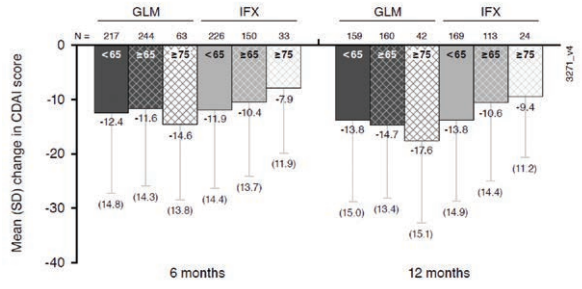
Background: AWARE is a real-world evidence-based (RWE) study evaluating the safety and efficacy of IV golimumab (GLM) and infliximab (IFX) in adults with RA.
Objectives: Evaluate safety and efficacy of IV GLM and IFX in elderly AWARE participants.
Methods: AWARE, a prospective non-interventional study (88 US sites), enrolled patients (pts) initiating either IV GLM or IFX. Pt management was at the discretion of treating rheumatologists. In a post hoc analysis, pts were grouped by age (<65/≥65/≥75 yrs). Adverse events (AEs) were collected through the Week (W) 52 database lock (DBL; completed W52 or discontinued study) and at the end-of-study DBL (W104). The primary endpoint was proportion of pts with ≥1 infusion reaction through W52. Change from baseline in Clinical Disease Activity Index (CDAI) scores at Months 6 and 12 were secondary endpoints evaluated in bionaïve pts, including those with IFX dose escalation.
Results: 1270 pts were enrolled (685 IV GLM; 585 IFX). 1047 (82%) pts were female; mean age was 60 yrs (57% <65 yrs, 43% ≥65 yrs, and 7% ≥75 yrs). Mean disease durations were 9 yrs (IV GLM) and 7 yrs (IFX). Comorbidities were generally similar between IV GLM and IFX groups but more common among pts ≥65

vs <65 yrs. Through W52, 66% of IV GLM pts and 62% of IFX pts discontinued the study. Discontinuation due to lack of efficacy was generally similar across age groups within treatment groups, although somewhat higher for IV GLM (29%) vs IFX (19%). For both treatments, AEs and discontinuations due to AE through W52 were more common in pts ≥65 vs <65 yrs (Table 1). Consistent with general trends observed in elderly individuals,[1] rates of serious AEs (SAEs) and serious infections increased with age for both IV GLM and IFX; however, increases were more notable in IFX- than IV GLM-treated pts ≥65 yrs. The incidence of serious infections was highest in pts ≥75 yrs for both treatments, although small sample size may limit data interpretation. No increase in opportunistic infections, including Varicella, was observed in pts ≥65 vs <65 yrs. Infusion reactions were more common in pts <65 yrs in both treatment groups, and more prevalent in IFX- than IV GLM-treated pts within each age group through W52. Generally similar safety results were seen between W52 and W104 for each treatment group (data not shown). Both IV GLM and IFX in bionaïve pts showed improvement in CDAI scores across age groups, which was maintained over time (Figure 1).

Table 1. % of pts with ≥1 AE through W52 DBL

	IV GLM			IFX		
	<65 yrs	≥65 yrs	≥75 yrs	<65 yrs	≥65 yrs	≥75 yrs
Patients, n	351	334	91	370	215	46
Discontinued due to AE	8.5%	12.6%	16.5%	15.1%	17.7%	21.7%
AE	52.4%	58.4%	57.1%	63.5%	66.5%	71.7%
Most common AEs (≥5% of pts in either treatment group)						
Nausea	3.7%	3.3%	3.3%	8.4%	6.0%	2.2%
Worsening of RA	5.4%	4.5%	3.3%	7.3%	7.0%	4.3%
Upper respiratory tract infection	5.7%	5.1%	4.4%	6.2%	5.6%	2.2%
Pruritis	1.4%	2.4%	3.3%	6.8%	2.8%	2.2%
Sinusitis	7.1%	3.3%	0%	3.8%	3.7%	2.2%
Urinary tract infection	4.8%	5.1%	5.5%	4.3%	5.1%	6.5%
SAE	7.7%	16.8%	20.9%	9.7%	18.6%	26.1%
Infection	30.5%	27.2%	27.5%	32.2%	28.8%	32.6%
Serious infection	3.7%	6.3%	7.7%	3.5%	7.9%	15.2%
Neoplasms benign, malignant and unspecified	0.6%	2.7%	1.1%	0.8%	2.3%	6.5%
Latent tuberculosis	0.3%	0%	0	0.3%	0%	0%
Opportunistic infection	1.4%	1.8%	4.4%	1.9%	1.4%	4.3%
Infusion reaction	5.1%	2.7%	1.1%	17.3%	8.8%	8.7%
Death	0.3%	2.4%	2.2%	0%	2.3%	6.5%

Figure. Mean (SD) change from baseline CDAI score at 6 months and 12 months (observed data) for bionaive population[a]



[a] Efficacy conducted for bionaive population including pts who had IFX dose escalation

Conclusion: Elderly RA pts receiving IV GLM or IFX in this RWE study demonstrated similar safety and efficacy as reported in Phase 3 trials.[2,3] The higher rates of AEs, discontinuations due to AE, and SAEs (mainly serious infections) observed in pts ≥65 yrs are in line with increased safety events seen in elderly vs younger individuals in the general population. Rates of AEs, SAEs, and infusion reactions were higher for IFX vs IV GLM. Infusion reactions were more common in pts <65 vs ≥65 yrs for both GLM and IFX, but more prevalent with IFX.

Background: Although seronegative RA patients often present with substantial disease burden [1], patients are underrepresented in research cohorts or clinical trials. Consequently, less knowledge about this subgroup has been accumulated.
Objectives: To describe outcome of seronegative vs. seropositive RA patients treated with sarilumab in regular care in Germany.
Methods: The prospective, observational, 24-month single-arm PROSARA study (SARILL08661) is currently running in Germany at 96 sites, aiming to enroll up to 750 RA patients treated with sarilumab. RA patients are prospectively selected at physician's discretion according to label, and medical history is documented before treatment. This interim analysis included patients with data available up to 24 months. Here we focus on sustained treatment response after 6 and 12 months, respectively. Patients were stratified according to serostatus (RF- AND ACPA- as seronegative or RF+ AND/OR ACPA+ as seropositive). All analyses are descriptive only.
Results: To date 473 patients were included in the study, of which 22.2% (n=105) were seronegative and 59.0% (n=279) were seropositive (Table 1). For 89 patients (18.8%) serostatus was not specified.
The mean time since diagnosis of RA was shorter in seronegative than in seropositive patients (7.9±7.6 years vs. 11.5±9.9 years) (Table 1).
At baseline, CDAI score was 27.7±14.7 (n=104) and 23.0±12.9 (n=272) in seronegative and seropositive patients, respectively. After 12 months of sarilumab treatment, CDAI improved to 15.6±12.3 (n=38) and 9.1±8.7 (n=101) in seronegative and seropositive, respectively, for patients with post-baseline data available. At that time, remission/low disease activity according to CDAI was reached by 5.3% (n=2/38) / 39.5% (n=15/38) of seronegative patients, respectively and by 26.7% (n=27/101) / 68.3% (n=69/101) of seropositive patients, respectively (Fig. 1A, B).
Physical function, assessed by HAQ-DI, was slightly more impaired in seronegative patients (1.4±0.7) than in seropositive patients (1.2±0.7) at baseline. HAQ-DI improved over 12 months to 0.9±0.7 in seropositive patients (n=90) but showed no change in seronegative patients (1.4±0.7; n=37) (Fig. 1C).
Safety was consistent with the anticipated profile of IL-6-R-inhibition and no new safety signals occurred. Adverse events and serious adverse events were described in 61.7% and 12.8% of seronegative patients, respectively and in 55.2% and 13.7% of seropositive patients, respectively.

Table 1. Baseline data regarding patient characteristics, prior treatment and disease activity

		seronegative		seropositive	
	patients [n] (%)	105	(22.2)	279	(59.0)
patient characteristics	Sex female [n] (%)	81	(77.1)	207	(74.2)
	Age mean [years] (SD)	56.6	(12.5)	59.6	(10.9)
	BMI mean (SD) [kg/m^2]	29.2	(6.7)	28	(6.0)
	Smoking history current/ former [%]	22.1/11.5		25.5/20.4	
	Time since diagnosis of RA mean [years] (SD)	7.9	(7.6)	11.5	(9.9)
prior RA treatment	csDMARD [n] (%)	102	(97.1)	273	(97.8)
	bDMARD (TNFi) [n] (%)	54	(51.4)	167	(59.9)
	bDMARD (non-TNFi) [n] (%)	32	(30.5)	83	(29.7)
	tsDMARD (JAKi) [n] (%)	25	(23.8)	57	(20.4)
disease activity	CRP [mg/l] (SD)	12.9	(30.9)	14.2	(31.0)
	ESR [mm/h] (SD)	23.7	(20.5)	25.3	(22.4)
	SJC mean (SD)	5.3	(5.5)	4.6	(4.8)
	TJC mean (SD)	10.2	(8.2)	7.2	(6.6)
	HAQ-DI mean (SD)	1.4	(0.7)	1.2	(0.7)
	DAS28-ESR mean (SD)	5.0	(1.5)	4.6	(1.5)
	CDAI mean (SD)	27.7	(14.7)	23.0	(12.9)
	Fatigue [VAS] (SD)	64.0	(25.5)	51.1	(28.1)

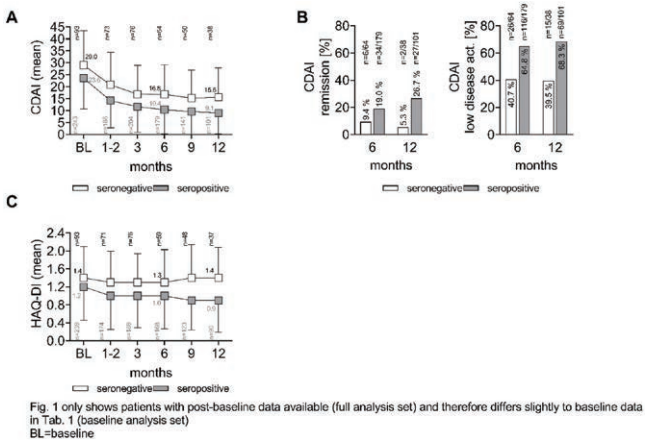

Fig. 1 only shows patients with post-baseline data available (full analysis set) and therefore differs slightly to baseline data in Tab. 1 (baseline analysis set)
BL=baseline

Figure 1. CDAI (A, B) and HAQ-DI (C) outcomes in seronegative and seropositive patients

Conclusion: Sarilumab treatment ameliorated CDAI in both seronegative (ΔCDAI -17.0±16.5) and seropositive (ΔCDAI -15.4±14.3) patients to the same extent over the course of 12 months, with a higher remission rate in seropositive patients. Functional capacity improved meaningfully in the seropositive cohort but had no significant impact in seronegative patients. The safety profile was consistent with data reported from controlled clinical trials.

POS0592

BIOSIMILAR INFLIXIMAB THERAPY IN RHEUMATOID ARTHRITIS, ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS: A LONG-TERM FOLLOW-UP STUDY ON INFLIXIMAB-NAÏVE PATIENTS AND PATIENTS SWITCHED FROM THE ORIGINATOR TO THE BIOSIMILAR CT-P13

B. Fautrel[1], M. Assing[2], N. Mammar[2], H. Marotte[3]. [1]*Sorbonne University - Assistance Publique-Hopitaux de Paris, Pitié-Salpêtrière Hospital, Paris, France*; [2]*PFIZER, Inflammation & Immunology, Paris, France*; [3]*SAINBIOSE INSERM U1059 and Rheumatology department, University of Lyon and University Hospital of Saint-Etienne, Saint-Etienne, France*

Objectives: The ReFLECT study was carried out to investigate real life use of CT-P13, the first monoclonal antibody biosimilar to infliximab originator.

Methods: ReFLECT is a multicentre, prospective, observational study conducted in France to determine the characteristics of patients (pts) receiving CT-P13, its effectiveness and safety in a real-life setting. Eligible were both pts who had been switched from infliximab originator (IFX_S) and infliximab-naïve pts started on CT-P13 (IFX_N). Intermediate results in pts with rheumatic diseases using descriptive statistical analyses from inclusion to a 24-month-follow-up period are described here.

Results: Among the 1370 adult pts included between October 2016 and April 2019, data were analysed for 142 pts with rheumatoid arthritis (RA; 23.9% males; mean age: 61.5±10.9 years; 80 IFX_N/61 IFX_S), 411 with ankylosing spondylitis (AS; 58.9% males; 48.1±13.1 years; 228 IFX_N/179 IFX_S), and 96 with psoriatic arthritis (PsA; 41.7% males; 53.4±14.1 years; 55 IFX_N/40 IFX_S) after a median of between 8.7 and 12.9 years since diagnosis. At inclusion, 66.9%, 24.3% and 50% had one concomitant treatment, mainly methotrexate. At the time of the first administration of CT-P13, disease had been active in 94.2%, 76.6% and 83.3% of the IFX_N pts compared with 45.3%, 24.0% and 32.0% of the IFX_S pts. After 24 months of follow-up, both CRP levels and disease activity remained stable compared to baseline in the IFX_S pts: median $\Delta CRP/RA_S = 1$, $\Delta CRP/AS_S = 0$, $\Delta CRP/PsA_S = 0$ and median $\Delta DAS28/RA_S = 0$, $\Delta BASDAI/AS_S = 0$, $\Delta DAS28/PsA_S = 1$. As expected, improvement was observed in the IFX_N pts: median $\Delta CRP/RA_N = -2$, $\Delta CRP/AS_N = -2$, $\Delta CRP/PsA_N = 0$ and median $\Delta DAS28/RA_N = -1$, $\Delta BASDAI/AS_N = -2$, $\Delta DAS28/PsA_N = -1$. In naïve pts, CT-P13 brought both CRP and disease activity down to levels comparable to those seen in patients switched from the IFX originator: median [Q1;Q3] $CRP/RA_N = 5$ [2;9] *vs* $CRP/RA_S = 5$ [2;8]; $CRP/AS_N = 3$ [2;9] *vs* $CRP/AS_S = 3$ [2;5]; $CRP/PsA_N = 2$ [1;4] *vs* $CRP/PsA_S = 2$ [1;3] and median [Q1;Q3] $DAS28/RA_N = 3$ [3;4] *vs* $DAS28/RA_S = 2$ [2;3]; $BASDAI/AS_N = 3$ [1;4] *vs* $BASDAI/AS_S = 2$ [1;3]; $DAS28/PsA_N = 3$ [2;3] *vs* $DAS28/PsA_S = 3$ [2;3], (Figure 1). At 24 months, 62.7%, 74.9% and 75.0% remained on treatment with CT-P13 in RA, AS and PsA pts respectively. The reasons for treatment withdrawing and safety results are reported in Table 1.

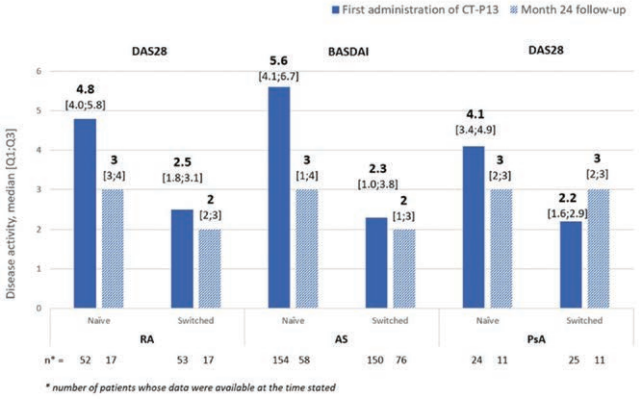

Figure 1. Disease activity at the time of first administration of CT-P13 and after 24 months

Table 1. Reasons for treatment withdrawing and safety results

Reasons for treatment withdrawing						
IFX pts, n (%)	**RA_N, 37**	**RAs, 15**	**AS_N, 64**	**ASs, 38**	**PsA_N, 11**	**PsAs, 12**
Missing	1	0	0	0	0	1
Remission	0	2 (13.3)	2 (3.1)	0	0	0
Therapeutic failure *	25 (69.4)	8 (53.3)	41 (64.1)	23 (60.5)	5 (45.5)	6 (54.5)
Intolerance	5 (13.9)	1 (6.7)	5 (7.8)	2 (5.3)	1 (9.1)	1 (9.1)
Other	6 (16.7)	4 (26.7)	16 (25.0)	13 (34.2)	5 (45.5)	4 (36.4)
Safety data, n (%)	**RA, 142**		**AS, 411**		**PsA, 96**	
Pts with ≥ 1 adverse event (AE)	67 (47.2)		222 (54.0)		48 (50.0)	
Pts with ≥ 1 AE related to CT-P13	33 (23.2)		84 (20.4)		19 (19.8)	
Pts with ≥ 1 serious AE	19 (13.4)		42 (10.2)		9 (9.4)	
Pts with ≥ 1 allergic infusion reaction †	4 (2.8)		11 (2.7)		1 (1.0)	
Pts with ≥ 1 infection ‡	10 (7.0)		18 (4.4)		3 (3.1)	

* Encompassing primary failure in IFX_N pts and loss of efficacy in IFX_N and IFX_S pts† Including acute and delayed hypersensitivity reactions‡ Including severe infections, tuberculosis, opportunistic infections, hepatitis

Conclusion: Year 2 follow-up data indicate that CT-P13 effectively induced improvement in disease activity in pts with RA, AS and PsA receiving infliximab for the first time and maintained stable disease activity in pts switched from

IFX originator to CT-P13. This real-life study did not highlight any new safety concerns.

THE REDUCTION OF RETINAL MICROVASCULAR ALTERATIONS AND THE DECREASE OF A POTENTIALLY RELATED T-CELL SUBSET IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS TREATED WITH ABATACEPT

S. Piantoni[1], F. Regola[1], S. Masneri[1], C. Nalli[1], C. Bazzani[1], C. Rossini[2], G. Chiarini[2], C. De Ciuceis[2], F. Franceschini[1], D. Rizzoni[2], P. Airò[1].
[1]Rheumatology and Clinical Immunology Unit, ASST Spedali Civili and University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy; *[2]Internal Medicine Unit, ASST Spedali Civili and University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy*

Background: T-cells play a pivotal role in the pathogenesis of rheumatoid arthritis (RA) and in its cardiovascular (CV) comorbidities, acting at microvascular level [1]. Since small artery remodeling is the earliest form of target organ damage in hypertension, the evaluation of microvascular alterations might provide clinically useful information. The evaluation of retinal arterioles is a non-invasive technique to identify a precocious microvascular damage, which is related to an increase of the wall-to-lumen ratio (WLR) [2]. CD3+CD31+CXCR4+ T-cells may be involved in damaged endothelium repair and are increased in patients with morphological microvascular alterations [3]. In addition to its effect on disease activity, abatacept (ABA), a co-stimulator blocker which is approved for the treatment of RA, may have specific CV protective action, modulating the numbers of certain subtypes of lymphocytes [4].

Objectives: To non-invasively investigate morphological characteristics of retinal arterioles and to evaluate CD3+CD31+CXCR4+T-cells in a cohort of RA patients treated with ABA.

Methods: Eleven RA patients [median (25th-75thpercentile) age=58 (50-65) years, baseline C-reactive protein (CRP)-DAS28=4.4 (3.8-4.6), body mass index (BMI)=23.4 (21.6-25.6) kg/m^2, rheumatoid factor (RF) positive:45%, anti-citrullinated peptide autoantibodies (ACPA) positive:73%] without known CV risk factors (arterial hypertension, diabetes, hypercholesterolemia, previous CV events, smoking) were evaluated by adaptive optics, a validated technique quantifying microvascular damage [5], before and every 6 months of therapy with ABA (T0, T6 and T12). Phenotypic analysis of peripheral blood T lymphocytes was made by flow-cytometry in 5 patients of the cohort at T0 and T6.

Results: A progressive significant reduction of the WLR of retinal arterioles was observed [T0=0.28 (0.25-0.30), T6=0.27 (0.24-0.31), T12=0.23 (0.23-0.26); p T0 vs T6=0.4; p T6 vs T12=0.01; p T0 vs T12=0.01] (Figure 1), without significant variations in the other parameters [internal diameter: T0=94.4 (84.1-104.0), T6=94.8 (84.6-107.7), T12=99.2 (89.1-109.1) µm; external diameter: T0=125.8 (111.1-131.0), T6=122.4 (109.1-134.5), T12=125.6 (113.9-134.4) µm; wall thickness: T0=13.2 (12.2-14.4), T6=13.4 (11.7-14.4), T12=12.5 (11.6-13.0) µm; wall cross-sectional area: T0=4581.0 (3788.7-5263.7), T6=4563.3 (3788.5-5295.2), T12=4099.7 (3899.0-5145.7) µm^2)]. In 5 patients evaluated also for T-cell immunophenotyping a negative correlation was observed between CD3+CD31+CXCR4+ T-cell number and the retinal wall thickness at baseline (R=0.871;p=0.05). After ABA therapy a trend for reduction of CD3+CD31+CXCR4+T-cells [19.0 (13.8-38.3) vs 12.4 (5.2-18.0) % of CD3+], was observed as well as of significant reduction of retinal wall cross-sectional area [5123.3 (4385.0-5470.3) vs 4852.3 (4118.3-5228.0) µm^2;p=0.04].

Conclusion: In a cohort of RA patients without known CV risk factors, a reduction in retinal microvascular alterations arterioles was demonstrated after treatment for 12 months with ABA. CD3+CD31+CXCR4+T-cell number was inversely related to the possible presence of subclinical CV involvement. These results may suggest the possibility of microvascular abnormalities regression induced by the immune system modulation.

POS0594

MEANINGFUL IMPROVEMENT AND WORSENING IN PATIENTS WHO DO NOT ACHIEVE LDA AND SWITCH THERAPY TO A NEW BIOLOGIC OR TARGETED THERAPY: RESULTS FROM THE CORRONA REGISTRY

J. Curtis[1], S. Fiore[2], K. Ford[3], J. Janak[4], H. Chang[5], D. A. Pappas[4], T. Blachley[5], K. Emeanuru[6], V. Bykerk[7]. *[1]University of Alabama at Birmingham, Division of Clinical Immunology & Rheumatology, Birmingham, AL, United States of America*; *[2]Sanofi, Medical Affairs, Bridgewater, NJ, United States of America*; *[3]Sanofi, Medical Affairs, Cambridge, MA, United States of America*; *[4]Consortium of Rheumatology Researchers of North America (CORRONA), Clinical Epidemiology, Waltham, MA, United States of America*; *[5]Consortium of Rheumatology Researchers of North America (CORRONA), Bio-statistics, Waltham, MA, United States of America*; *[6]Consortium of Rheumatology Researchers of North America (CORRONA), Epidemiology, Waltham, MA, United States of America*; *[7]Inflammatory Arthritis Center, Hospital for Special Surgery, New York, NY, United States of America*

Background: Guidelines recommend adjusting therapy in patients with rheumatoid arthritis (RA) who fail to reach and sustain low disease activity (LDA) or remission (disease control). Many factors can affect the decision to change therapy, including the potential for improvement as well as the fear of potential worsening or loss of improvement already achieved. Although data exist on response to treatment in patients who switch therapy, data addressing the likelihood of worsening are limited.

Objectives: The aim of this analysis was to describe the demographic, clinical characteristics, and change in clinical outcomes in patients on biologic/targeted synthetic disease-modifying anti-rheumatic drugs (b/tsDMARDs) who had some improvement in clinical disease activity index (CDAI) but did not achieve LDA after ~ 6-12 months of treatment and then switched to a different b/tsDMARD.

Methods: This study included adult inadequately responding RA patients from the CORRONA registry who: (1) started a biologic or Janus kinase inhibitor (JAKi) between January 2010 to November 2020 (V1), (2) had any CDAI improvement (i.e., decrease ≥1 unit) but were not in LDA or remission at a subsequent visit (baseline [BL]) occurring 3 to 15 months after V1; (3) had a third visit (follow-up [F/U]) 6 (±3) months after BL with a valid CDAI measure; (4) switched therapy at the BL or between BL and F/U, with the switch occurring at least 3 months prior to the F/U. CDAI >10 and ≤22 was defined as moderate disease activity (MDA) and CDAI >22 was defined as high disease activity (HDA). Two thresholds of change in CDAI (≥6 and ≥12 units) were used to define meaningful improvement and meaningful worsening after the switch. If there was no meaningful improvement or meaningful worsening, this was considered as no meaningful change (-5 to +5 for 6 units change and -11 to +11 for 12 units change). These thresholds for meaningful change were set for all switchers regardless of their pre-switch CDAI value. Descriptive statistics were generated for demographic and clinical characteristics for the switchers at BL, and the change of clinical outcomes was evaluated from BL to F/U.

Results: Of the 1,224 patients fulfilling the inclusion criteria, 93 (7.6%) switched therapy and 1,131 (92.4%) did not switch therampy after not achieving an adequate response on the initial b/tsDMARD. At BL, 42.5% and 70.0% of patients had no meaningful improvement to their prior therapy based on ≥6 and ≥12-unit change, respectively; mean (SD) age was 53.1 (14.0) years; duration of RA 10.7 (10.4) years; CDAI 22.2 (10.8); 81.7% were female; 64.5% had MDA, 35.5% had HDA; 21.5 % reported being disabled, 24.7% were current smokers, and 50% were obese. In terms of prior biologic use 57.0%, 22.6%, and 20.4% had been on 1, 2, and 3+, respectively. From BL to F/U, meaningful worsening occurred in 30.1% and 12.9% using a threshold of 6 and 12, respectively, with the remaining patients experiencing meaningful improvement or no meaningful change (Figure 1).

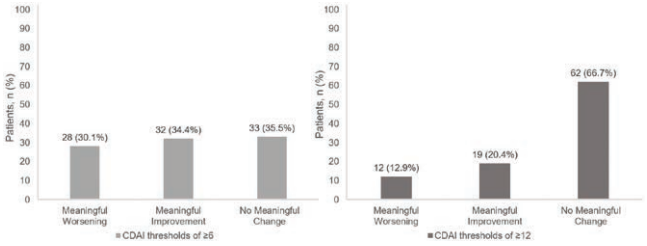

Figure 1. Meaningful Worsening, Meaningful Improvement, and No Meaningful Change Based on CDAI Change Thresholds of ≥6 and ≥12 From BL to F/U (N=93)

Conclusion: In our analysis, a large proportion of patients who initiated a biologic/JAKi and experienced some improvement but failed to attain LDA or remission, did not switch therapy within approximately a year. This analysis consisted of many patients who did not have a meaningful response to their prior biologic/JAKi, patients who had received multiple prior biologics, and a large portion of patients with poor prognostic factors. Despite this, the proportion of patients with meaningful worsening was low compared with most patients who had either meaningful improvement or no meaningful change. Additional research is warranted to understand the reasons for not switching and whether the likelihood of a meaningful change correlates with prior response, poor prognosis, or other factors.

Background: Interstitial lung disease (ILD) is a severe complication of Rheumatoid Arthritis (RA). Usual interstitial pneumonia (UIP) is considered to be more frequent and severe in RA than non-specific interstitial pneumonia (NSIP). Abatacept (ABA) and Rituximab have demonstrated efficacy in RA-ILD **[1-3].**

Objectives: To compare the efficacy of ABA in RA-ILD patients according to radiological patterns of UIP or NSIP.

Methods: From an observational multicenter study of 263 RA-ILD patients treated with ABA, we selected those with UIP or NSIP **[2].** We analyzed in the 2 groups from baseline up to 24 months the following outcomes: **a)** Forced Vital Capacity (FVC), **b)** Carbon monoxide diffusing capacity (DLCO), **c)** Chest High Resolution Computed Tomography (HRCT), and **d)** dyspnea. Differences between final follow-up and basal visit were calculated as the average difference and 95% Confidence Interval (95% CI). Multivariable linear regression was used to assess the differences between the 2 groups.

Results: We studied 190 patients with UIP (n=106) and NSIP (n=84). Patients with UIP were older, had more positivity for rheumatoid factor and had received more sulfasalazine (Table 1). ILD duration up to ABA initiation was relatively short in both groups, with a median [IQR] of 16 [4-50] and 11 [2-36] months in UIP and NSIP patterns, respectively. Mean baseline values of FVC and DLCO were > 80% and > 60%, respectively, in the 2 groups, with a lower FVC in UIP (82% vs 89% in NSIP, p<0.05). The evolution of FVC and DLCO is shown in Figure 1. Both parameters remained stable during 24 months of ABA therapy. Available chest HRCT images improved/ stabilized in 73.1% and 72.9% of UIP and NSIP patterns, respectively. With multivariable linear regression analysis, no differences were found in the changes of FVC, DLCO, or HRCT images. Stabilization or improvement of dyspnea was found in 91% and 95% of UIP and NSIP patterns, respectively.

Conclusion: ABA seems to be equally effective in stabilizing of DLCO, FVC and HRCT in UIP and NSIP in RA-ILD. Our results suggest that an early administration of ABA in ILD, before significant structural lung damage development, may be preferable to prevent interstitial progression, regardless of the radiological pattern.

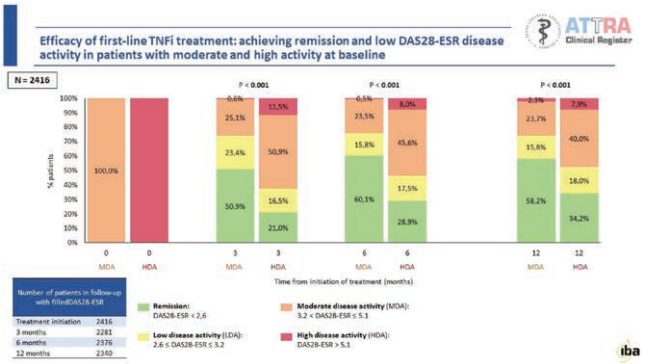
POS0596 THE THERAPEUTIC TARGET IS REACHED MORE OFTEN IN RA PATIENTS STARTING TNF INHIBITORS WITH MODERATE ACTIVITY THAN WITH HIGH DISEASE ACTIVITY – AN ANALYSIS FROM THE ATTRA REGISTRY

K. Pavelka[1], L. Nekvindova[2], J. Zavada[1]. [1]*Institute of Rheumatology, Rheumatology, Praha 2, Czech Republic*; [2]*Institute of Biostatistics and Analyses LTD, Biotatistics, Brno, Czech Republic*

Background: Treat to target guidelines recommend achieving remission or low disease activity in rheumatoid arthritis (RA). In the Czech Republic, anti-TNF therapy has been reimbursed only for patients with highly active RA until 2019, when pts with LDA have been also included in the reimbursement policy.
Objectives: The aim of the study was to compare the results of treatment in patients with rheumatoid arthritis and moderate disease activity (MDA) or high disease activity (HDA) starting the therapy with the first anti-TNF drug in routine clinical practice.
Methods: This was a retrospective cohort study of patients treated with the first anti-TNF drug in the Czech Republic. Propensity score was used to match pts starting anti-TNF in MDA or HDA for other important predictive factors. The propensity score was obtained by logistic regression with 10 covariates (gender, age, disease duration, seropositivity, comedication with MTX, comedication with other csDMARDs, number of previosu csDMARDs, anti-TNF drug),.Within the paired groups, one-dimensional logistic models were then calculated to estimate the odds of remission / low activity after 6 and 12 months of treatment.
Results: A total of 2416 patients were analyzed in the study. 2231 patients had high activity (DAS 28> 5.1) and 185 patients had moderate activity (3.2 <DAS28 ≤ 5.1) at baseline. After 12 months, the low activity state (DAS28 < 3.2) was achieved by patients with MDA in 74.0% and patients with HDA in 52.2%, (p <0.001) (FIG 1). The differences btw groups were significant in all evaluated intervals of 0, 3, 6, 12 months. Furthermore, a comparison of patients with MDA and HAD by propensity score matching, who no longer differ in the baseline characteristics (except for disease activity and quality of life) was performed. Patients with MDA were 2.4x more likely to achieve remission or low activity according to DAS28-ESR after 6 months and 1.7x more likely to achieve remission or low activity after 12 months of treatment compared to patients with HDA at the beginning of treatment.



Conclusion: This analysis of the results of treatment with anti-TNF drugs in the ATTRA Registry has shown that starting anti-TNF therapy in patients with RA and MDA leads more often to the target of remission or low activity, than in pts with HDA.

POS0597 EFFECTS OF RITUXIMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS-RELATED INTERSTITIAL LUNG DISEASE: A SINGLE-CENTRE EXPERIENCE FROM TURKEY

D. Sahin Eroglu[1], A. Colaklar[2], S. Baysal[3], M. Torgutalp[1], A. Baygul[4], M. E. Yayla[1], T. M. Turgay[1], G. Kınıklı[1], A. Ates[1]. [1]*Ankara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; [2]*Ankara University Faculty of Medicine, Department of Radiology, Ankara, Turkey*; [3]*Ankara University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey*; [4]*Ankara University Faculty of Medicine, Department of Pulmonology, Ankara, Turkey*

Background: Rheumatoid arthritis-related interstitial lung disease (RA-ILD) is the most common type of lung involvement in rheumatoid arthritis (RA). The existence of RA-ILD is associated with worse survival. There is no mainstay treatment for RA-ILD. However, in recent studies, rituximab (RTX) seems to be effective in RA-ILD.
Objectives: To determine the effects of RTX in patients with RA-ILD from a single-centre.
Methods: In our biological treatment outpatient clinic, a retrospective study was conducted in patients with RA who were treated with RTX. Among them, patients with RA-ILD were analysed. For lung response to RTX, progression was defined as a decline of 10% ≥ in forced vital capacity (FVC) and/or a decline of 15% ≥ in diffusion capacity of carbon monoxide (DLCO). Computed tomography of the chest (chest-CT) were integrated to lung response so as to constitute missing data of pulmonary function tests (PFTs).
Results: A total of 165 patients who are followed-up in our biological treatment outpatient clinic have been using RTX for their RA diagnosis. Among 165 patients, 26 (15.8%) patients with RA-ILD were initiated RTX. Five patients were diagnosed with RA-ILD while using RTX (incidence rate 3%). Patients' characteristics were demonstrated in table 1. Of 26 patients, the most commonly used concomitant disease-modifying antirheumatic drugs was leflunomide (46.2%) followed by mycophenolate mofetil (11.5), methotrexate (11.5%) and azathioprine (3.8%). Twenty-four (92.3%) patients used steroids. For the evaluation of lung response, 20 patients who had follow-up PFTs and/or chest-CT were compared.

Median DLCO values for pre- and post RTX were 71.0% (60.0-77.0) and 63.0% (47.0-74.0), respectively (p= 0.061). Median pre and post-RTX FVC were 74.0% (61.0-99.0) and 84.0% (63.0-100.0), respectively (p= 0.28). After a median of 2.7 years, 11 (55.0%) patients had stable disease, 2 (10.0%) patients had regression of RA-ILD and 7 (35.0%) patients had progressive disease. Sex, age, seropositivity and radiographic patterns were not associated with progression. In total, 23 adverse events were detected in 11 (42.3%) patients. Five of them were serious infections requiring hospitalization, mostly pneumonia. Other adverse events were simple infections and surgeries such as arthroplasty. RTX was stopped in 4 (15.4%) patients due to infections secondary to hypogammaglobulinemia in 2, malignancy in 1 and allergic reaction in 1.

Conclusion: RTX seems to achieve stabilization/improvement of RA-ILD with fewer adverse events. However, given that RA-ILD develops post-RTX, it is not a panacea; therefore, we need more effective treatment modalities in the case of RA-ILD.

Table 1. Characteristics of 26 patients with RA-ILD treated with rituximab

Age at first RTX infusion, median (IQR), years	61.2 (57.1-65.1)
RA disease duration at first RTX, median (IQR), years	10.1 (4.3-29.7)
ILD disease duration at first RTX, median (IQR), years	1.9 (0.1-4.5)
Age at RA diagnosis, median (IQR), years	51.1 (40.0-60.6)
Age at ILD diagnosis, median (IQR), years	58.3 (53.9-63.3)
Male patient, n (%)	16 (61.5)
RF positivity, n (%)	25 (96.2)
ACPA positivity, n (%)	20 (90.9)
CRP levels,mg/L, mean (SD)	40.3 (58.9)
ESR levels, mean (SD)	37.7 (18.2)
Smoking status, n (%)	16 (64.0)

POS0598 COMPARISON OF INJECTION SITE REACTIONS AND INJECTION SITE ERYTHEMA BETWEEN YLB113 AND ETANERCEPT REFERENCE PRODUCT FROM PHASE 3 ACTIVE COMPARATOR STUDY (STUDY NO. YLB113-002)

D. Stefanidis[1], U. G[2], J. Sánchez-Bursón[3], C. Shah[4], D. Bakhle[4]. *[1]Viatris GmbH, Medical Affairs, Bad Homburg, Germany*; *[2]Viatris, Biostatistics, Bangalore, India*; *[3]Hospital Infanta Luisa, Rheumatology, Sevilla, Spain*; *[4]Lupin LTD, Clinical, Pune, India*

Background: YLB113 is an etanercept biosimilar approved in all indications of its etanercept Reference Product (RP). Therapeutic equivalence in terms of clinical efficacy, safety and immunogenicity was previously demonstrated in a pivotal multicenter, double-blind, randomized, parallel-group, active-control, comparative study (YLB113-002) in rheumatoid arthritis (RA) subjects.[1,2] Similar incidence of treatment emergent adverse events (TEAEs) was seen in both treatment arms except for injection site reactions (ISRs) and injection site erythema (ISE), both of which were less frequent in subjects treated with YLB113.

Objectives: This post-hoc analysis was performed to further evaluate the differences in the incidence of ISRs and ISE during the 24 week treatment when the subjects with RA were treated with 50 mg of YLB113 or RP given once a week as a SC injection along with methotrexate.

Methods: Safety analysis set (263 in YLB113 arm and 254 in RP arm) was considered for this analysis.

Local reactions at the site of injection were assessed at each of eight study visits. The number of subjects who experienced ISRs and ISE were statistically compared for YLB113 and RP. The risk difference and 95% confidence interval (CI) were computed between arms to understand the magnitude of difference in the incidence of events. The statistical significance of between group difference was tested using chi-square test.

Results: The result of this analysis showed a statistically significant difference in the incidences of ISRs and ISE between subjects who received YLB113 and RP. The risk difference between YLB113 and RP arms for ISR was -9.98% (95% CI, WALD -14.81%, -5.15%) and, for ISE it was -7.94% (95% CI, WALD -11.96%, - 3.92%; Table 1). This could be possibly explained by the absence of latex in the syringe needle cap of YLB113.[3]

Table 1. Differences in ISRs and ISEs between YLB113 and Reference Product (RP)

Event	YLB113 N=263	RP N=254	YLB113 vs RP	
	No of subjects with events [n(%)]	No of subjects with events [n(%)])	Risk Diff (95%CI, WALD)	P-value (Chi-Square)
Injection-site reactions	10 (3.8%)	35 (13.8%)	-9.98% (-14.81%, -5.15%)	<0.0001
Injection-site erythema	5 (1.9%)	25 (9.8%)	-7.94% (-11.96%, -3.92%)	0.0001

Conclusion: YLB113 has shown statistically significant lower incidences of ISRs (P-value <0.0001) and ISEs (P value 0.0001) compared to RP. This property may translate to a better acceptability by patients.

POS0599 DISEASE ACTIVITY IN PATIENTS WITH RA BY SEROSTATUS AND TREATMENT LINE, FOLLOWING TREATMENT WITH ABATACEPT: RESULTS FROM AN INTERNATIONAL OBSERVATIONAL STUDY

Background: RF and anti-citrullinated protein antibodies (ACPAs) are associated with a severe and aggressive disease course in patients with RA.[1] Abatacept is a selective co-stimulation modulator for the treatment of RA.[2] ASCORE (Abatacept SubCutaneOus in Routine Clinical PracticE; NCT02090556) was a 2-year, observational, prospective, multicentre study of SC abatacept for the treatment of RA in routine clinical practice.[3]

Objectives: To determine if serostatus and treatment line impacted disease activity in patients enrolled in the ASCORE study.

Methods: Eligible patients, aged ≥18 years, with active moderate-to-severe RA (ACR/EULAR 2010 criteria) who were IV abatacept-naive and initiated SC abatacept 125 mg once weekly, were enrolled into two cohorts: biologic (b) DMARD-naive patients and those with ≥1 prior bDMARD treatment failure. This *post hoc* analysis assessed the mean change in disease activity (CDAI, SDAI and DAS28 [ESR]) from baseline (BL) at 6, 12, 18 and 24 months in response to treatment with abatacept. Patients were stratified by BL serostatus (all patients, RF/ACPA double positive [+/+] RA; RF/ACPA single positive [+/–; RF+/ACPA– or RF–/ACPA+] RA and RF/ACPA double negative [–/–] RA) and by line of therapy (all patients, patients receiving abatacept as a first-line or ≥ second-line therapy and those receiving abatacept following 1 or ≥2 prior bDMARDs). Overall patient data, as well as data for patients who were +/– or those who had 1 or ≥2 previous bDMARDs, are not shown. Estimates of mean difference are from *t*-test.

Results: Among 2892 eligible patients in ASCORE, 1748 patients with RF/ACPA status available at BL were included in this analysis (1079 +/+ RA, 326 +/– RA and 343 –/– RA). After 6 months, patients with +/+ RA on first-line abatacept therapy had better improvements in CDAI and SDAI scores from BL than patients on ≥ second-line abatacept therapy (mean difference [95% CI]: –3.4 [–5.6, –1.1]; p=0.0032 and –3.9 [–6.5, –1.3]; p=0.0035, respectively); better improvements in SDAI were also seen after 12 months (mean difference [95% CI]: –3.5 [–6.5, –0.5]; p=0.0207). Changes in CDAI and SDAI scores were comparable after 18 and 24 months. At 6 and 12 months, patients with +/+ RA on first-line therapy had better improvements from BL in DAS28 (ESR) than those on ≥ second-line therapy (mean differences [95% CI]: –0.5 [–0.8, –0.2]; p=0.0002 and –0.4 [–0.7, –0.0]; p=0.0317, respectively); changes were comparable at 18 and 24 months (Figure 1). For patients on ≥ second-line therapy, at 18 months those with +/+ RA had better improvements from BL in DAS28 (ESR) than those with –/– RA (mean difference [95% CI]: –0.7 [–1.2, –0.1]; p=0.0232). For patients not stratified by line of therapy, changes in DAS28 (ESR) were comparable between the +/+ and –/– RA subgroups over time, with the exception of 6 months where patients with –/– RA had better improvements from BL compared with patients with +/+ RA (mean difference [95% CI]: –0.3 [–0.6, –0.0]; p=0.0495).

Conclusion: In this real-world, *post hoc* analysis, patients with +/+ RA who received abatacept as a first-line therapy had greater early improvements in disease activity compared with patients who received abatacept as a ≥ second-line therapy. Improvements in disease activity at 24 months were comparable between patients who were +/+ and those who were –/–. Larger studies are needed to further corroborate these findings.

POS0600 IMMUNOGENICITY OF RITUXIMAB BIOSIMILAR GP2013: A RARE EVENT, BUT NOT WITHOUT CONSEQUENCES ...

J. Avouac[1], R. Cougnaud Murail[1], C. Goulvestre[2], S. Dumas[3], A. Moltó[1], C. Miceli Richard[1], O. Conort[3], F. Batteux[2], Y. Allanore[1]. [1]*Cochin Hospital, Rheumatology Department, Paris, France*; [2]*Cochin Hospital, Immunology Department, Paris, France*; [3]*Cochin Hospital, Pharmacy Department, Paris, France*

Background: The bioequivalence between rituximab (RTX) originator and its biosimilar GP2013 has been demonstrated in rheumatoid arthritis (RA) (1). A recent randomized controlled trial suggested in a selected population a very low immunogenicity of GP2013 in RA (<1%) (2).

Objectives: To study in daily practice the risk of immunogenicity of patients treated with GP2013 for their chronic inflammatory rheumatic disorder.

Methods: Prospective routine care study carried out between September 2018 and August 2020 in the Rheumatology department of Cochin Hospital. We consecutively included patients treated with the biosimilar RTX GP2013, systematically used in the department since March 2018. Samples were taken before each infusion in order to detect anti-RTX antibodies (Ab) and RTX residual concentrations by ELISA (Lisa Tracker Duo Rituximab, LTR005, Theradiag).

Results: We included 159 consecutive patients treated with GP2013 (124 women, 78%) with a mean age of 59±13 years and a mean disease duration of 18±11 years. Among these 159 patients, 108 (68%) had RA and 51 had another disease (16 systemic sclerosis (SSc), 15 mixed connective tissue disease (MCTD), 5 systemic lupus (SLE), 5 inflammatory myopathies (MI), 5 undifferentiated polyarthritis, 2 juvenile idiopathic arthritis (JIA) and 3 primary Sjögren's syndromes). 137 patients (86%) were receiving associated disease-modifying therapy (DMARD), mainly methotrexate (111/137 patients, 81%). 120 patients (75%) were in maintenance therapy with originator RTX (cumulative dose of RTX: 3.5±6g) before the switch to GP2013 in March 2018. Originator RTX was not re-established during the entire treatment period. The other 39 patients (25%) treated with GP2013 were naïve of originator RTX.

The analysis of the first sample, performed before the second GP2013 infusion, identified 8 patients (5 RA, 1 SLE, 1 MCTD and 1 SSc) with positive anti-RTX antibodies (prevalence 5%), with rates varying between 6 and >100ng/mL and undetectable residual RTX concentrations. Among these 8 patients, 6 had previously received originator RTX and 2 were RTX-naïve patients. There was a trend for higher body mass index in patients with positive anti-RTX antibodies (28±7 vs. 25±6 kg/m^2, p=0.12), and no association was observed between anti-RTX immunization and age, disease duration, combination with conventional DMARD, mean interval between infusions or cumulative RTX dose.

Among the 8 immunized patients, two groups could be isolated: i) a group of 5 patients (3 RA, 1 SLE, 1 SSc) with low antibody levels (6-22 ng/mL) and no significant clinical consequences (absence of treatment discontinuation and loss of efficacy after 13±4 months of follow-up, only one minor allergic reaction) and ii) a group of 3 patients (2 RA, 1 MCTD) with a high antibody levels (≥100ng/mL) and meaningful clinical consequences: one severe allergic reaction during the second GP2013 infusion leading to treatment discontinuation, and a loss of efficacy with incomplete B depletion in 2 patients leading to RTX dose escalation from 500 mg to 1 g. Among the 151 patients not immunized at the time of the first sample, no severe allergic reaction and 6 minor allergic reactions were noted under GP2013.

Conclusion: The immunogenicity of patients treated with RTX is a rare event with possible clinical and biological consequences, especially in patients with high antibody levels.

POS0601 DIFFERENCES IN DRUG SURVIVAL BETWEEN ORIGINATOR AND BIOSIMILAR PRODUCTS AMONG FIRST USERS OF EACH MOLECULE

D. Di Giuseppe[1], H. Bower[1], B. Delcoigne[1], T. Frisell[1], K. Chatzidionysiou[1,2], U. Lindström[3], C. Sjowall[4], E. Lindqvist[5], J. Askling[1]on behalf of ARTIS. *[1]Karolinska Institute, Department of Medicine Solna, Stockholm, Sweden*; *[2]Nya Karolinska, Rheumatology Unit, Stockholm, Sweden*; *[3]Sahlgrenska Academy, University of Gothenburg, Rheumatology Unit, Karolinska University Hospital, Gothenburg, Sweden*; *[4]Linköping University, Division of Inflammation and Infection, Department of Biomedical and Clinical Sciences, Linköping, Sweden*; *[5]Lund University, Skåne University Hospital, Department of clinical sciences, Rheumatology, Lund, Sweden*

Background: Biosimilar products of biological disease-modifying antirheumatic drugs (bDMARDs) entered the Swedish market in 2015, with regulatory approvals based on head to head trials of limited duration. Longer-term comparative drug survival, in clinical practice, remains less well documented.

Objectives: To compare survival on drug between biosimilars and their originator products among first starters of etanercept, infliximab, adalimumab and rituximab.

Methods: Data from the Swedish Rheumatology Quality register (SRQ) was used to identify and follow patients who started a first ever treatment with etanercept since April 2015 (originator=ETA,biosimilar= SB4), infliximab since March 2014 (originator=IFX,biosimilar= CT-P13), adalimumab since January 2018 (originator=ADA biosimilars=SB5, ABP501), or rituximab since January 2018 (originator=RIT,biosimilar= GP2013), through December 31st, 2019, date of first discontinuation of the drug, or death. Discontinuation was defined as lack of effectiveness or adverse events, while other reasons for interruption of the drug (including non-medical switch) were considered censoring events. Descriptive characteristics were collected from the SRQ and tabulated. Hazard ratios (HR) of discontinuation were estimated using Cox regression, with each drug analyzed separately, adjusted for age,sex,indication,line of treatment,disease duration,year of treatment start,region and concomitant use of csDMARD.

Results: 9274 patients started etanercept(49% SB4), 3609 started infliximab(64% CT-P13), 3117 started adalimumab(27% SB5, 14% ABP 501), and 763 started rituximab(39% GP2013), Table 1. Patients starting CT-P13 and GP2013 were less likely to be biologics-naïve compared to those starting the originator product. Initiators of SB5,ABP501 and GP2013 were more likely,and those starting CT-P13 were less likely,to be on concomitant csDMARDs compared to those starting the originator products. Patients characteristics of ETA and SB4 were similar.

The introduction of a biosimilar was typically followed by a decrease in the uptake of the originator, but for ETA a change in pricing in 2018 later led to a reversal of this pattern (Figure 1).

For IFX,ADA,and RIT, survival on drug was similar for the originator and its biosimilar(s). For ETA,risk of discontinuation was somewhat lower for the biosimilar than for the originator(adjusted HR:0.87,95% confidence interval:0.79-0.95), Table 1.

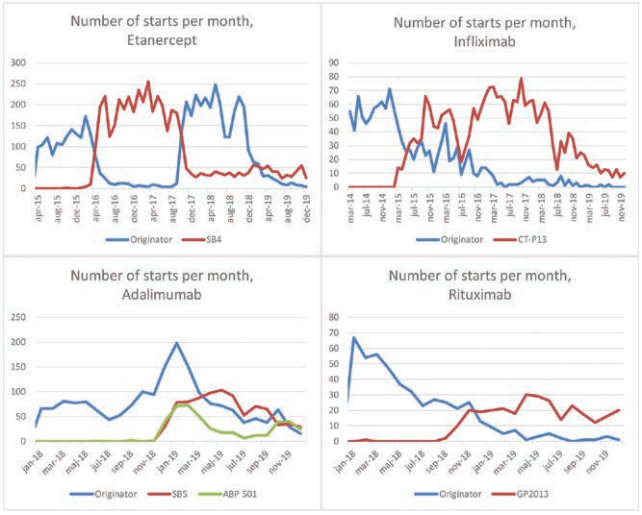

Figure 1. Number of starts of biosimilars compared to the originator during the follow-up time, by molecule

Conclusion: Despite their identical indications and therapeutic positioning, there are some differences in the baseline characteristics between patients who start ADA, IFX and RIT and their biosimilars. There are no differences in drug survival between originator and biosimilar with the possible exception of etanercept although the observed difference should be interpreted in light of possible unmeasured or residual channeling.

POS0602 ROLE OF INTRAARTICULAR BIOLOGICS AND METHOTREXATE IN THE MANAGEMENT OF ACTIVE INFLAMMATORY MONOARTHRITIS

F. Aslam[1], M. Meyer[1], M. Pham[2]. *[1]Mayo Clinic, Rheumatology, Scottsdale, United States of America*; *[2]Mayo Clinic, Medicine, Scottsdale, United States of America*

Background: Expansion of immunosuppressive medications has greatly improved disease activity control in rheumatoid arthritis (RA) patients. However, persistent symptomatic monoarthritis can be a problem in some patients who otherwise have satisfactory disease control. Intra-articular (IA) corticosteroid (CS) injections have remained a treatment cornerstone for these patients, but the need for other therapies is clear. Patients can fail such therapy, may develop adverse effects or have comorbidities that are exacerbated by IA CS. 50% of patients relapse after IA CS therapy. Several studies have looked at other agents such as methotrexate (MTX) or tumor necrosis factor inhibitors (TNF-i) as IA treatment options.

Objectives: To systematically review the evidence regarding utility of IA methotrexate and biologics in managing inflammatory monoarthritis in patients with RA.

Abbreviations: RA=rheumatoid arthritis. csDMARDs=conventional synthetic DMARD, std=standard deviation.

Methods: A systematic literature review, in accordance with PRISMA guidelines, was conducted looking at trials investigating the use of IA MTX and/or TNF-i, against IA CS, in managing inflammatory monoarthritis in patients with RA. A trained librarian conducted search of Ovid MEDLINE, Ovid EMBASE, Scopus, and Web of Science databases. Included studies were assessed for risk of bias as per the Cochrane tool.

Results: A total of 1013 citations were retrieved from the medical database searches. 12 studies were included in the final review. 6 studies investigated IA MTX while 5 studied IA etanercept. One study investigated different biologic agents: infliximab, etanercept, or adalimumab. Multitude of dosing regimens and administration protocols were used in various studies. 5 of the 6 MTX studies only included knees. IA MTX was compared against saline, CS and as combined MTX/CS vs CS alone. There was no evidence to support the use of IA MTX as a superior or equivalent agent to the comparator groups. Unlike MTX, etanercept was investigated in multiple joint types e.g. elbows, knees and wrists. IA etanercept was found to have utility as a successful IA alternative to CS. The only study investigating infliximab and adalimumab found them to be superior to IA CS across multiple joint types. All therapies were generally well tolerated. Etanercept studies had low risk of bias while the MTX studies mostly suffered from higher risk of bias.

Conclusion: Etanercept may be used as an IA agent in select patients with inflammatory arthritis when systemic treatment is not an option and IA corticosteroids cannot be used. Limited data also supports the utility of IA adalimumab and infliximab as better IA agents compared to CS. IA MTX, however, did not have such supporting data.

POS0603 ANALYSIS OF FACTORS ASSOCIATED WITH THE EFFECTIVENESS OF ABATACEPT IN THE ORIGAMI STUDY

K. Misaki[1], E. Tanaka[2], E. Inoue[3], K. Tsuritani[4], S. Matsumoto[5], H. Yamanaka[2,6], M. Harigai[2]. *[1] Kita-Harima Medical Center, Rheumatology, Ono, Japan*; *[2]Tokyo Women's Medical University School of Medicine, Department of Rheumatology, Tokyo, Japan*; *[3] Showa University, Showa University Research Administration Center, Tokyo, Japan*; *[4]Bristol-Myers Squibb K.K., Immunology Medical, Tokyo, Japan*; *[5]Ono pharmaceutical Co, Ltd., Medical Affairs, Tokyo, Japan*; *[6] Sanno Medical Center, Rheumatology, Tokyo, Japan*

Background: The ORIGAMI study is a multicenter, observational study to evaluate the effectiveness, safety, and patient-reported outcomes of abatacept (ABA) in Japanese patients with csDMARD-resistant, Simplified Disease Activity Index (SDAI)-moderate, biologic-naïve rheumatoid arthritis (RA). ABA has shown better effectiveness/efficacy in RA patients with anti-cyclic citrullinated peptide antibody (ACPA) positive (1) and high ACPA titer (2) compared to ACPA negative and low ACPA titer, respectively. However, more accurate predictors of effectiveness in clinical practice are needed than ACPA status.

Objectives: This post-hoc analysis is aimed to determine the association between ACPA and ABA effectiveness (disease activity and physical function) or retention rate and to investigate other factors associated with the effectiveness of ABA in patients enrolled in the ORIGAMI study.

Methods: Of the 279 patients in the effectiveness analysis set of the ORIGAMI study, 270 patients with baseline ACPA measurement were analyzed. The patients were divided into the ACPA-positive group (ACPA +ve, ≥4.5 U/mL at baseline) and the ACPA-negative group (ACPA –ve, <4.5 U/mL). Patients' characteristics, changes in disease activity and physical function (Japanese Health Assessment Questionnaire; J-HAQ) through 52 weeks, and retention rates of ABA at week 52 were evaluated. Baseline characteristics and use of concomitant drugs were analyzed as independent variables by multiple regression analysis using a standard linear model adjusted by SDAI at week 0 to identify factors associated with SDAI change at week 52. In addition, the interaction effects among ACPA status, RF status, and the factor that was significantly associated with SDAI change in multiple regression analysis on changes in SDAI were explored.

Results: The numbers of ACPA +ve and –ve patients were 226 and 44, respectively. ACPA values (mean ± SD, U/mL) were 280.3 ± 376.8 and 0.9 ± 0.7, and rheumatoid factor (RF) values were 174.8 ± 302.6 and 20.9 ± 61.7 in the ACPA +ve and –ve groups, respectively. Mean (95% confidence interval) changes in SDAI at week 52 were −11.3 (−12.4 to −10.3) and −8.0 (−10.5 to −5.5), and those in J-HAQ were −0.27 (−0.34 to −0.20) and −0.16 (−0.34 to 0.01) in the ACPA +ve and –ve groups, respectively. In the Kaplan–Meier analysis, the retention rates of ABA at week 52 in the ACPA +ve and –ve groups were 72.1% and 58.7%, (discontinuation for any reason), and 91.6% and 75.7% (discontinuation because of lack of effectiveness), respectively. In a multiple regression analysis, the duration of disease (< 1 year) was associated with the change in SDAI at week 52. With respect to SDAI changes, the estimated difference of ACPA +ve and disease duration (< 1 year), ACPA +ve and disease duration (≥1 year), and ACPA –ve and disease duration (< 1 year), versus ACPA –ve and disease duration (≥ 1 year), were −4.26 (p = 0.022), −0.82 (p = 0.618), and −0.93 (p = 0.716), respectively (Fig. 1). The estimated difference of ACPA +ve and RF +ve, ACPA +ve and RF –ve, and ACPA –ve and RF +ve, versus ACPA –ve and RF –ve, were −2.48 (p = 0.060), −2.77 (p = 0.107), and −5.48 (p = 0.087), respectively.

Conclusion: A higher retention rate as well as better effectiveness of ABA on disease activity and physical function in ACPA +ve group versus ACPA –ve group were shown in the simple subgroup analysis. ABA effectiveness on the SDAI change was significantly better in patients with disease duration <1 year and ACPA +ve compared to those with ACPA –ve and disease duration ≥ 1 year.

LONG TERM SAFETY AND TOLERABILITY WITH ETANERCEPT BIOSIMILAR (YLB113), RESULTS FROM A 2-YEAR OPEN LABEL EXTENSION STUDY (STUDY NO. YLB113-003)

Y. Hisashi[1], Y. Tanaka[2], T. Hibino[3], C. Shah[4], D. Bakhle[5], D. Stefanidis[6]. [1]*Sanno Medical Center, Rheumatology, Tokyo, Japan*; [2]*University of Occupational and Environmental Health, Japan, Professor, Fukuoka, Japan*; [3]*YL Biologics Ltd, Clinical, Tokyo, Japan*; [4]*Lupin LTD, Clinical Development, Pune, India*; [5]*Lupin LTD, Medical Research, Pune, India*; [6]*Viatris GmbH, Medical Affairs, Bad Homburg vor der Höhe, Germany*

Background: Eligible subjects with moderate-to-severely active rheumatoid arthritis (RA) who completed a phase 3 double-blind comparative efficacy and safety study (Study No. YLB113-002; Yamanaka et al, 2019) of 50 mg etanercept biosimilar (YLB113) or etanercept reference product (RP) by subcutaneous administration with concomitant MTX treatment for 52 weeks, were enrolled in this open label extension (OLE) study (Study No. YLB113-003) to assess the long-term safety and tolerability of YLB113 through to 3 years.

Objectives: This OLE study aimed to evaluate the long-term safety of YLB113 administration in subjects with RA who received RP or YLB113 in a phase 3 active comparator study. The main parameters assessed were safety and tolerability in terms of adverse events (AEs) and injection site reactions (ISRs), incidence of immunogenicity and efficacy as DAS28 improvement (disease activity score in 28 joints).

Methods: Subjects received 50 mg of YLB113 subcutaneously once every 1 to 2 weeks. Safety was assessed by AEs after study drug administration, ISRs, physical examination findings, and immunogenicity. Efficacy (DAS28 score) was assessed at the time of transition to the OLE study (Week 0), and at weeks 12, 24, 48, 72, 96 and at the end of the study.

Results: 201 (Full analysis set [FAS]) subjects received the study drug and 184 subjects completed the study (91.5% completion rate). The average drug exposure in 94 subjects who continued to receive YLB113 and completed the study (94.0% completion rate) and 90 subjects who switched from RP to YLB113 and completed the study (89.1% completion rate) was 103 weeks providing the long-term drug exposure data of YLB113.

The CTCAE Grade of TEAEs and ADRs observed were Grade 2 or less in severity (with no Grade ≥3). The overall incidence of ISRs was 10.0% (20/201 subjects) 77 events. All the ISRs reported were Grade 1 except for one Grade 2. An overview of the AEs experienced by the subjects is summarized in the Table 1.

Table 1. Overview of Adverse events in OLE study

FAS	n (%)	Number of events
Number of subjects	201	-
Treatment emergent adverse events (TEAEs)	188(93.5)	975
Adverse drug reactions (ADRs)	82(40.8)	221
Serious adverse events (SAEs)	21(10.4)	27
Serious adverse drug reactions (SADRs)	7(3.5)	7
AEs leading to premature study discontinuation	4(2.0)	6
ADRs leading to premature study discontinuation	3(1.5)	4
SAEs leading to premature study discontinuation	3(1.5)	4
SADRs leading to premature study discontinuation	2(1.0)	2

n - number of subjects with at least 1 AE in the category

The mean DAS28 (mean ± S.D.) of 2.22 ± 0.95 at the study transition was 2.10 ± 0.91 at Week 72 and 2.06 ± 0.89 at the end of the study. It was confirmed that DAS28 slightly decreased with time after the study transition and continued until the end of the study. The average DAS28 value remained low even with long-term administration of YLB113, suggesting that the effects of the study drug was sustained (Figure 1).

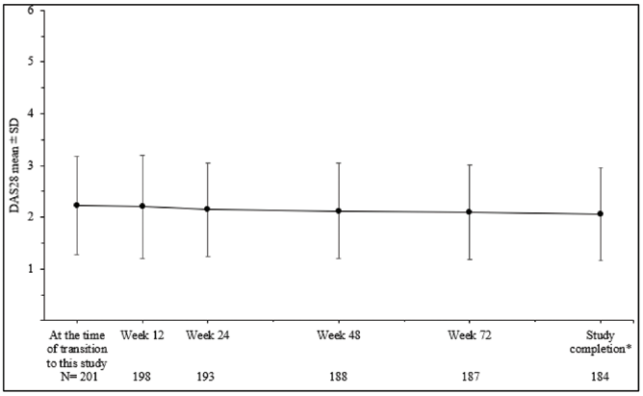

Figure 1. DAS28 over time with YLB113N: Number of subjects. * The administration period at the study completion differs for each subject, because the study transition time differs for each subject.

cts who tested positive for anti-drug antibodies (ADA) at least once in the OLE study were 1.0% (2/200 subjects). All ADA were transient and disappeared at study completion. Such transient ADA formation was reported in the phase 3 study as well. In the phase 3 study, ADA formation was more frequent in subjects who received RP at 24 weeks, but all subjects were negative in the OLE study after switching. Therefore, switching did not affect immunogenicity.

Conclusion: The safety, efficacy and immunogenicity profile of YLB113 was maintained over the long-term through to 3 years. Switching from RP to YLB113 did not impact safety or immunogenicity.

DISEASE ACTIVITY AND PATIENTS-REPORTED OUTCOMES AFTER SWITCHING BETWEEN IL-6 RECEPTOR INHIBITORS AND JAK INHIBITORS: AN ANALYSIS FROM THE CORRONA REGISTRY

A. Dua[1], K. Ford[2], S. Fiore[3], D. A. Pappas[4], J. Janak[4], T. Blachley[5], C. Roberts-Toler[5], K. Emeanuru[6], J. Kremer[7,8], A. Kivitz[9]. [1]*Northwestern University Feinberg School of Medicine, Department of Medicine, Division of Rheumatology, Chicago, IL, United States of America*; [2]*Sanofi, Medical Affairs, Cambridge, MA, United States of America*; [3]*Sanofi, Medical Affairs, Bridgewater, NJ, United States of America*; [4]*Consortium of Rheumatology Researchers of North America (Corrona), Clinical Epidemiology, Waltham, MA, United States of America*; [5]*Consortium of Rheumatology Researchers of North America (Corrona), Biostatistics, Waltham, MA, United States of America*; [6]*Consortium of Rheumatology Researchers of North America (Corrona), Epidemiology, Waltham, MA, United States of America*; [7]*Albany Medical College, Department of Medicine, Center for Rheumatology, Albany, NY, United States of America*; [8]*Corrona LLC, Consortium of Rheumatology Researchers of North America (Corrona), Waltham, MA, United States of America*; [9]*Altoona Center for Clinical Research, Altoona Arthritis & Osteoporosis Center, Duncansville, PA, United States of America*

Background: Rheumatoid arthritis (RA) patients who fail therapy may be switched to any of the five classes of biological disease-modifying antirheumatic drugs (DMARDs) and targeted synthetic DMARDs, to meet treatment goals. Physicians may hesitate to switch between Janus Kinase inhibitors (JAKi) and interleukin-6 receptor inhibitors (IL-6Ri) since they both impact IL-6 signalling and due to limited data on switching between the two classes.

Objectives: This retrospective, observational study based on the real-world Corrona RA registry aimed to describe the response in RA patients switching between IL-6Ri and JAKi.

Methods: Adult RA patients who initiated either IL-6Ri or JAKi after November 2012 and had a six-month post-initiation follow-up visit were eligible. Patients in 'Cohort A' initiated an IL-6Ri following discontinuation of a JAKi and those in 'Cohort B' initiated a JAKi following discontinuation of an IL-6Ri. Disease activity measures and patient-reported outcomes (PROs) were evaluated at baseline and at six-month follow-up. Within each group, change from baseline was assessed for Clinical Disease Activity Index (CDAI), Health Assessment Questionnaire (HAQ), pain, fatigue, tender joint count (TJC), swollen joint count (SJC), physician global assessment (MDGA), patient global assessment (PtGA) and morning stiffness duration. Proportion of patients achieving CDAI low disease activity (LDA), CDAI remission and minimal clinically important difference (MCID) for HAQ, pain, fatigue, MDGA, PtGA were assessed. Adjusted linear and logistic regression models were performed for between-group comparisons (Cohort A vs Cohort B) excluding initiators who switched therapy prior to six-month visit.

Results: Cohorts A and B included 122 and 144 initiators, respectively. Patients who switched to

IL-6Ri (vs JAKi) were younger (mean [SD] age, 56.2 [11.3] vs 58.9 [12.6] years), had higher baseline CDAI (23.2 [12.9] vs 20.2 [12.8]), had higher prior use of ≥2 csDMARDs (75% vs 65%), and were less likely to initiate therapy as monotherapy (44% vs 50%).

In Cohort A, significant changes from baseline were observed for all continuous outcomes except HAQ and fatigue. In Cohort B, a significant improvement was observed only for patient-reported pain (Table 1).

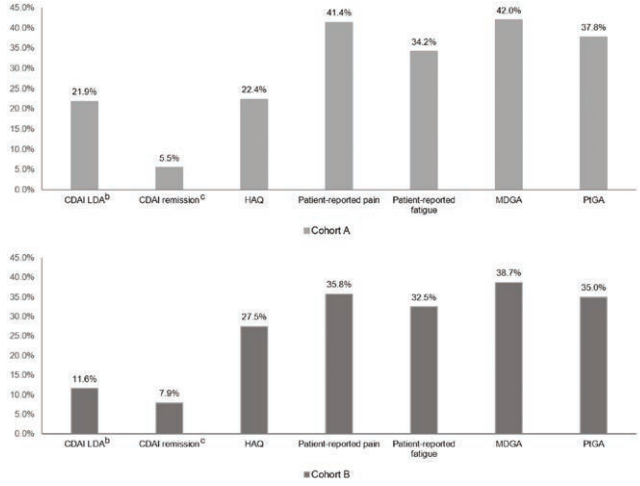
Table 1. Unadjusted Within-Group Change from Baseline to Six Months, Mean (95% CI), n

Outcomes	Cohort A, N = 122	Cohort B, N = 144
CDAI	-4.7 (-7.6, -1.9), 109	-2.4 (-5.2, 0.4), 116
HAQ	-0.0 (-0.1, 0.1), 105	-0.1 (-0.1, 0.0), 118
Patient-reported pain	-8.2 (-13.4, -3.0), 109	-5.9 (-11.5, -0.2), 120
Patient-reported fatigue	-4.4 (-9.0, 0.2), 109	-1.7 (-6.6, 3.3), 117
TJC	-1.6 (-3.0, -0.1), 112	-1.2 (-2.6, 0.3), 117
SJC	-1.5 (-2.5, -0.4), 112	-0.4 (-1.3, 0.6),117
MDGA	-10.9 (-15.6, -6.3), 112	-4.3 (-8.7, 0.2), 117
PtGA	-6.0 (-11.2, -0.8), 109	-4.8 (-10.5, 0.8), 120
Morning stiffness duration[a]	-1.3 (-2.2, -0.5), 109	-0.1 (-1.1, 0.8), 118

[a]Among those reporting morning stiffness at baseline.

In the adjusted between-group comparison (data not shown) of change from baseline, there were no significant differences in clinical outcomes between Cohorts A and B.

In both cohorts, patients achieved CDAI LDA, CDAI remission, and MCIDs across other PROs (Figure 1). In the adjusted between-group comparison (data not shown), the results were similar with the exception of achievement of CDAI LDA among patients with moderate to high disease activity at baseline.



[a]CDAI LDA: >2.8 to ≤10 units; CDAI remission: ≤2.8 units; MCID for PROs were assessed, MCID for HAQ: ≥0.3 units; MCID for VAS of pain, fatigue, MDGA, and PtGA: ≥10 units. [b]Among those in moderate or high disease activity at baseline. [c]Among those in low, moderate, or high disease activity at baseline.

Figure 1. Rates of CDAI LDA, CDAI Remission, and MCID for PROs[a] at Six Months

Conclusion: In general, in both cohorts a substantial proportion of patients achieved CDAI LDA and MCID across PROs. Despite some overlap of JAKi and IL-6Ri therapies' on the IL-6 pathway, there are some distinct mechanisms of action which may result in meaningful improvements for a subset of patients.

POS0607

PROMIS ASSESSMENT OF RESPONSE TO TREATMENT WITH GOLIMUMAB IV OR INFLIXIMAB IN RHEUMATOID ARTHRITIS PATIENTS: RESULTS FROM THE PHASE-4 AWARE STUDY

C. Bingham[1], S. Kafka[2], S. Black[3], S. Xu[4], W. Langholff[5], J. Curtis[6]. [1]*Johns Hopkins University, Division of Rheumatology, Baltimore, United States of America*; [2]*Janssen Scientific Affairs, Med Group Rheum, Horsham, United States of America*; [3]*Janssen R&D US, Immunology General, Horsham, United States of America*; [4]*Janssen Research & Development, Clinical Biostats, Spring House, United States of America*; [5]*Janssen Research & Development, Clinical Biostats, Horsham, United States of America*; [6]*University of Alabama at Birmingham, Dept of Medicine, Birmingham, United States of America*

Background: AWARE is a phase-4 observational study designed to provide real-world assessment of Golimumab (GLM) IV & infliximab (IFX) in patients (pts) with rheumatoid arthritis (RA).
Objectives: To assess patient-reported aspects of social, mental, & physical health through the 8th infusion (≈1 year of treatment) using Patient Reported Outcomes Measurement Information System (PROMIS), a validated, disease-agnostic set of health assessment instruments.
Methods: AWARE enrolled 1270 RA pts initiating treatment with GLM/IFX. The 52 week analysis set included pts with ≥1-year treatment or those discontinued and, while enrolled, completed PROMIS-29 or PROMIS short form (SF) questionnaires. PROMIS instruments were administered at baseline & prior to infusions 2, 5, & 8. The raw score was converted into a standardized T-score with a mean of 50 and SD of 10.
Results: At baseline, treatment groups were balanced on demographics & medical characteristics. Most pts were white (87.0% GLM, 86.2% IFX) & female (83.4% GLM, 82.4% IFX). Mean ages were 58.5 ±12.96 years for GLM & 59.6 ±13.24 years for IFX. Overall, 35.3% GLM & 42.9% IFX pts were bio-naïve. The proportion of GLM & IFX pts with prior exposure to 1 or 2 biologics was similar; however, 20.1% GLM pts vs 10.8% IFX pts had exposure to ≥3 biologics. Methotrexate use was similar between GLM (76.4%) & IFX pts (75.0%). Based on mean PROMIS T-scores at baseline (Table 1), Fatigue, Pain Interference, & Physical Function domains approached or exceeded 1 SD worse than those of general US population. Through the 8th infusion, GLM- & IFX-treated pts achieved meaningful improvement based on mean changes from baseline in most PROMIS-29 domains & respective SFs with no significant difference between GLM and IFX. The percentage of GLM or IFX pts with improvements of ≥3, ≥5, or ≥10 units change in T-scores increased from infusion 2 through infusion 8.
Conclusion: RA pts treated with GLM or IFX achieved comparable improvements across PROMIS-assessed social, mental, & physical health. PROMIS-29 was able to detect change to subsequent anti-tumor necrosis factor-α therapies.

POS0608

SWITCHING OF TREATMENT FROM REFERENCE ETANERCEPT TO SANDOZ ETANERCEPT BIOSIMILAR IN PATIENTS WITH RHEUMATIC DISEASES: AN INTERIM ANALYSIS OF REAL-WORLD DATA FROM THE COMPACT STUDY

M. Schmalzing[1], A. Askari[2], T. Sheeran[3], D. Walsh[4], J. De Toro Santos[5], J. C. Vazquez Perez-Coleman[6], C. Both[7], F. Furlan[7], S. Hachaichi[7], H. Kellner[8]. [1]*University Hospital, Wuerzburg, Rheumatology/Clinical Immunology, Department of Internal Medicine II, Wuerzburg, Germany*; [2]*Robert Jones and Agnes Hunt Orthopedic Hospital NHS Foundation Trust, Department of Rheumatology, Oswestry, United Kingdom*; [3]*Cannock Chase Hospital, Department of Rheumatology, Cannock, United Kingdom*; [4]*University of Nottingham and Sherwood Forest Hospitals NHS Foundation Trust, Pain Centre Versus Arthritis, Nottingham, United Kingdom*; [5]*University Hospital Coruña, Servicio de Reumatología, A Coruña, Spain*; [6]*University Hospital Complex of Ferrol, Rheumatology Department, Ferrol, Spain*; [7]*Sandoz Hexal AG, Global Medical Affairs, Holzkirchen, Germany*; [8]*Hospital Neuwittelsbach, Center for Rheumatology and Gastroenterology, Munich, Germany*

Background: Sandoz etanercept (SDZ ETN) is a biosimilar of etanercept (ETN). COMPACT is an ongoing, non-interventional study, evaluating the effectiveness, safety, and quality of life with SDZ ETN treatment in patients (pts) with rheumatoid arthritis (RA), axial-spondyloarthritis (axSpA) or psoriatic arthritis (PsA) in real-world conditions.

Objectives: We have reported an interim analysis, with the effectiveness and safety data focusing on pts who were in clinical remission or low disease activity under treatment with reference ETN or biosimilar ETN other than SDZ ETN (initial ETN; iETN) and switched to SDZ ETN.

Methods: Pts aged ≥18 years for whom treatment with SDZ ETN were initiated are being enrolled. Pts were categorized under four treatment groups based on prior treatment status: Group A,
pts on clinical remission or low disease activity under treatment with iETN and switched to SDZ ETN; Group B, pts who received targeted therapies and switched to SDZ ETN; Group C, biologic naïve considered uncontrolled with conventional therapy; Group D, DMARD naïve with recent diagnosis of RA considered suitable for treatment initiation with a biologic and started on treatment with SDZ ETN. Effectiveness assessments included Disease Activity Score 28-joint count Erythrocyte Sedimentation Rate (DAS28-ESR) or Ankylosing Spondylitis Disease Activity Score (ASDAS) until Week 24 after enrollment (baseline; BL) in the study. Functional disability was measured by the Health Assessment Questionnaire Disability Index (HAQ-DI). The effectiveness and safety results are reported for the pts who switched from iETN (Group A).

Results: Of the 1437 pts recruited (analysis cut-off date: 16 Oct, 2020), 567 pts were switched from iETN, 163 were switched from other targeted therapies, 697 were biologic-naïve, and 10 were RA DMARD-naïve. Among pts who switched from iETN, 51.5% had RA, followed by axSpA (28.0%) and PsA (20.5%). Comorbidities were more frequent in pts with RA (70.2%) followed by PsA (58.6%) and axSpA (49.7%); musculoskeletal and connective tissue disorders were reported in 31.8% and 15.7% of pts with RA and axSpA, respectively. At BL, whilst receiving iETN, the mean (SD) DAS28-ESR scores were 2.5 (1.1) and 2.1 (1.1) in pts with RA and PsA, respectively (figure 1). The mean change from BL in DAS28-ESR score at Week 24 after switch to SDZ ETN was -0.1 (1.1) and 0 (1.0) in pts with RA and PsA, respectively. In pts with axSpA, the mean (SD) ASDAS score was 1.5 (0.7) at BL; mean change from BL in ASDAS score at Week 24 was 0.1 (0.5). At BL, the mean (SD) HAQ-DI scores were 0.8 (0.7), 0.5 (0.7) and 0.5 (0.6) in pts with RA, PsA and axSpA, respectively. Overall, the proportion of patients with at least one adverse event (AE) was 37.3%, 33.6% and 25.8% in pts with RA, PsA and axSpA, respectively. Serious AEs were reported in 6.5%, 1.7% and 3.1% of pts with RA, PsA, and axSpA, respectively. Injections site reactions were reported in 2.7%, 0.9% and 1.3% of pts with RA, PsA and axSpA, respectively.

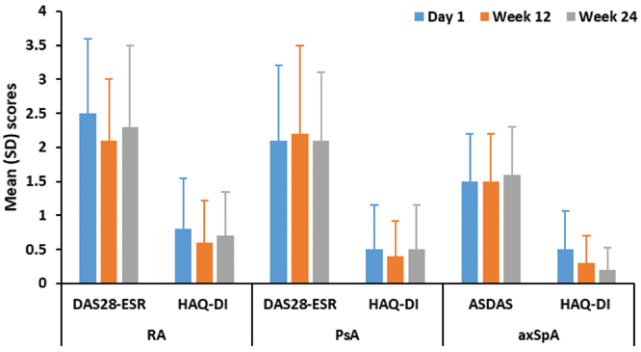

Figure 1. Disease activity in patients who switched from iETN to SDZ ETN

Conclusion: The interim analysis results shows that switch from iETN to SDZ ETN does not impact the effectiveness of ETN in pts with RA, axSpA or PsA, without any new safety signals.

A TOCILIZUMAB DOSING STRATEGY IN RHEUMATOID ARTHRITIS PATIENTS WITH STABLE DISEASE AIMING TO PREVENT OVERTREATMENT AND UNNECESSARY COSTS

K. van Soest[1], N. W. Boone[1], S. Ramiro[2,3], M. Starmans[2], N. C. Punt[4], R. B. M. Landewé[2,5]. [1]*Zuyderland MC, Clinical Pharmacy, Pharmacology and Toxicology, Heerlen, Netherlands*; [2]*Zuyderland MC, Rheumatology, Heerlen, Netherlands*; [3]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [4]*Medimatics, PKPD/TDM, Maastricht, Netherlands*; [5]*Amsterdam UMC, locatie AMC, Rheumatology & Immunology, Amsterdam, Netherlands*

Background: Tocilizumab (TCZ) is a humanized interleukin 6 (IL-6) antibody that competitively inhibits IL-6 signalling by binding both membrane-bound and soluble IL-6 receptors. The EULAR recommends the use of TCZ, as a biological disease-modifying antirheumatic drug (DMARD), as second line therapy in rheumatoid arthritis (RA) when

conventional DMARDs have failed achieving treatment target. The labelled dosing regimen for TCZ in RA is 8mg/kg (maximum 800mg) every 4 weeks. A TCZ predose serum concentration (TCZpsc) >1mg/L normalizes C-reactive protein, while clinical trials found mean TCZpsc of 19.9 ±17.0 mg/L in patients receiving the standard regimen. On the basis of these data, it can be hypothesized that cost-effectiveness of therapy can be improved.

Objectives: In this study we evaluated TCZpsc in stable RA-patients to determine whether the TCZ 8mg/kg dose could be lowered while meeting the minimal required concentration for effective blockage of the IL-6 inflammatory cascade.

Methods: Adult RA patients with stable disease (i.e. at least 3 months without treatment change) treated with intravenous TCZ were investigated in a prospective cohort study. TCZpsc before two different TCZ infusions over time was assessed. A validated ELISA was used to measure TCZpscs, immunogenicity was measured by quantifying human antibodies using antigen-binding tests (radioimmunoassay).

A population pharmacokinetic (PK) model was constructed using maximum a posteriori Bayesian estimation applied on the available PK data in the literature combined with the collected data on dosing and predose concentrations in the study patients. Body surface area, creatinine clearance and gender were included as covariates in the model. A patient individual dose tapering strategy was predicted based on the derived model.

The target TCZpsc was set on 8-10mg/L taking the measurement error of 15%, the use of the entire content of the vials and intra-individual variation into consideration.

Results: A total of 44 patients were included [median (IQR) age: 63 (58-72), 75% female, mean (SD) DAS28-ESR: 1.5 (0.8)]. Half of the patients received TCZ in combination with a conventional DMARD, 32% used methotrexate (MTX). Patients received 7.7 ±0.8mg/kg (range 5.7-9.7) TCZ. Mean TCZpsc was 27.6 ±12.6mg/L. The intra-individual variance of TCZpsc was low; mean difference in individual TCZpscs was 0.56 (5.2)mg/L. Higher dosages (in mg/kg) were significantly associated with higher TCZpsc (regression coefficient 7.32 95%CI 2.73;11.9), suggesting overtreatment. No drug-neutralizing auto-antibodies were measured. Co-treatment with MTX did not influence the median TCZpsc (21.0mg/L versus 26.5mg/L without MTX, p=0.84).

According to the measured TCZpsc, TCZ dosage could be lowered in 36 patients (92%). In a 28-days regimen, target-TCZpsc would be reached with a 0.4-4.6mg/kg dose-reduction (Figure 1). Extending the interval between two administrations would lead to low TCZpsc (<1mg/L).

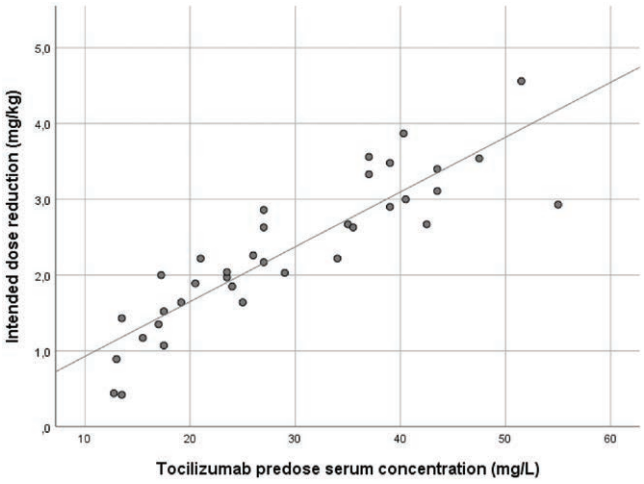

Figure 1. Intended dose reduction related to the measured tocilizumab predose serum concentration

Considering the aimed average dose-reduction of 2.1 mg/kg per administration, efficacy would be expected to maintain (TCZpsc >1 mg/L) while reducing yearly costs with ±€3.900,- per patient. On average patients were started on TCZ treatment 63 months (SD26) earlier. As maximum efficacy of TCZ treatment can be achieved after 3 months, TCZpsc-guided dose reduction 3 months after start could have resulted in a total drug cost reduction of ±€750.000,- in our study population (±€19.500,- per patient).

Conclusion: Measured TCZpsc under standard TCZ therapy was much higher than the minimal required concentration. These results suggest that the labelled TCZ dose leads to overtreatment and unnecessary costs in patients with stable RA. The TCZpsc seems supportive as an instrument for dose reduction strategies. Future prospective studies should assess its use in TCZ dose adjustment and confirm whether treatment efficacy is maintained.

POS0610 EPIDEMIOLOGIC PROFILE AND CHANNELING TO TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT OVER THE LAST 5 YEARS: DATA FROM THE SPANISH REGISTER BIOBADASER 3.0

S. C. Rodriguez-García[1], C. Sánchez-Piedra[2], R. Castellanos-Moreira[3], D. Ruiz-Montesinos[4], M. Pombo[5], F. Sánchez-Alonso[2], J. J. Gómez-Reino[6]on behalf of the BIOBADASER Working group. [1]*Hospital de La Princesa, Rheumatology, Madrid, Spain*; [2]*Spanish Society of Rheumatology (SER), Research Unit, Madrid, Spain*; [3]*Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain*; [4]*Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain*; [5]*Hospital Clínico Universitario de Santiago, Rheumatology, Santiago de Compostela, Spain*; [6]*Fundación IDIS, Rheumatology, Madrid, Spain*

Background: Abatacept (ABA) is a selective T-cell co-stimulatory modulator. After its approval, changes in therapeutic recommendations, the arrival of new drugs (e.g., biosimilars or Janus kinase inhibitors) and growing focus on comprehensive patient care may have changed prescription patterns, channeling ABA use towards specific patient subtypes. To date, studies analyzing these aspects in clinical practice settings are scarce.
Objectives: We aimed to evaluate the epidemiological profile of ABA users and compare it to other DMARD groups included in the register.
Methods: We performed an observational study based on the nationwide Spanish register BIOBADASER, which includes patients with rheumatic diseases receiving biologic disease-modifying antirheumatic drugs (bDMARDs) or targeted synthetic DMARDs (tsDMARDs) from 28 tertiary centers. For this analysis, all RA patients included from December 2015 to December 2020 were examined. Baseline features were analyzed descriptively grouping all b/tsDMARDs by mode of action. Clinical effectiveness was assessed through drug survival obtained by the Kaplan-Meier method. Patients were right-censored if data were not available if they were still on treatment at the time of data analysis. The safety profile was assessed by the adverse events (AE) and serious AE incidence rates (IR) expressed as events per 1000 patient-years.
Results: There were 628 ABA-treated patients, 471 (75%) using the subcutaneous presentation. Only 142 (23%) were on first-line while 381 (61%) were on third or later-line therapy. ABA users were older and more likely to present certain comorbidities compared to the other b/tsDMARD groups. The biggest relative differences were seen for interstitial lung disease (ILD), chronic obstructive pulmonary disease (COPD), diabetes and ischemic heart disease. (Table 1)

Table 1.

N	ABA	IL-6	CD20	JAKi	TNFi
	628	786	181	669	1787
Mean age, years (SD)	64.1 (12.0)	50.7 (12.7)	63.2 (12.3)	59.6 (12.3)	60.7 (13.1)
Female sex, n (%)	482 (77)	652 (83)	135 (75)	537 (80)	1418 (79)
Median disease duration	10.1	9.4	13.3	10.4	7.4
(p25-p75)	(5.1-16.5)	(4.6-15.9)	(8.3-20.6)	(5.0-17.2)	(3.2-13.7)

RF, n (%)	380 (77)	454 (75)	124 (86)	411 (70)	915 (72)
Current smokers, n (%)	98 (16)	137 (17)	338 (19)	90 (20)	259 (18)
ILD, n (%)	64 (13)	21 (3)	25 (2)	8 (2)	19 (2)
COPD, n (%)	38 (6)	23(3)	52 (3)	14 (3)	43 (3)
Chronic Kidney Disease, n (%)	18 (3)	13 (2)	19 (1)	13 (3)	18 (1)
Diabetes	73 (12)	66 (8)	13 (7)	46 (10)	100 (7)
Ischemic Heart Disease, n (%)	36 (6)	23 (3)	0	12 (3)	30 (2)
Hypertension, n (%)	197 (31)	198 (25)	416 (23)	131 (30)	338 (23)
Heart Failure, n (%)	19 (4)	12 (2)	10 (1)	6 (2)	5 (1)
Osteoporosis, n (%)	133 (21)	141 (18)	26 (14)	72 (16)	215 (15)

IL-6: Tocilizumab and Sarilumab; CD20: Rituximab and biosimilars; JAKi: Janus kinase inhibitors (Tofacitinib and Baricitinib); TNFi: TNF inhibitors and biosimilars; ACPA: anti-citrullinated peptide antibodies; RF: rheumatoid factor; ILD: interstitial lung disease; COPD: chronic obstructive pulmonary disease.

Overall, 63% of patients remained on ABA at 1 year, 48% at 2 and 31% at 5 years after drug initiation. The corresponding proportions were 79%, 65% and 52% for bionaïve and 59%, 43% and 30% for those in third or later-line therapy. From 394 total discontinuations, loss of efficacy in 225 (57%) and AE in 98 (25%) were the main reasons. This trend was consistent among all therapy lines.
The total IR of AE was 886.5 (837.3-938.5) and 156.4 (136.5-179.2) for SAE. Infections were the most frequent AE overall, IR 44.4 (34.4-57.3), and the highest IR was seen among bionaïve patients (69.6 (44.9-107.9)).
Conclusion: ABA-treated RA patients in Spain are older and have more comorbidities (vs other b/tsDMARDs), especially ILD, COPD, ischemic heart disease and diabetes and receive ABA as third or later-line therapy. Although these features are associated with worse response to treatment and a higher risk of infection, ABA presents a good drug survival and infectious AE are not the main cause of discontinuation.

POS0611 THE EFFECT OF RITUXIMAB BIOSIMILAR THERAPY ON THE EXPRESSION OF INTERFERON-STIMULATED GENES ("INTERFERON SIGNATURE") IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Avdeeva[1], E. Tchetina[2], G. Markova[2], E. Nasonov[2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Early Arthritis Laboratory, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Early Arthritis Laboratory, Moscow, Russian Federation*

Background: Type I interferons (IFN-Is) are a group of molecules with pleiotropic effects on the immune system forming a crucial link between innate and adaptive immune responses. The type I interferon pathway has been implicated in the pathogenesis of a number of rheumatic diseases, including rheumatoid arthritis. IFN activity is usually quantified using expression of interferon-stimulated genes (ISGs) referred to as an IFN signature. Acellbia (BIOCAD) is the first Russian rituximab (RTX) biosimilar which was approved for medical use in rheumatoid arthritis (RA) patients in Russia and some CIS countries.
Objectives: To evaluate the changes in expression of ISGs in patients (pts) with RA during RTX biosimilar therapy
Methods: 20 RA pts (18 woman, Me;IQR age 61.5(54-66.5) years, disease duration 39.5(20-84) months, mean DAS 28 5.6(4.9-6.8)) received two intravenous RTX biosimilar infusions (600 mg №2) in combination with DMARDs and glucocorticoids. Laboratory biomarkers were assessed at baseline and 24 weeks after the first infusion of RTX. 5 genes (IFI44L, MX1, IFIT 1, RSAD2, EPSTI1) were selected for evaluation of the "interferon signature" (Type I IFN gene signature – IFNGS). IFI44L and IFIT1 expression was undetectable, therefore the remaining three genes (MSX1, EPSTI1, RSAD2) were included into further analysis. IFNGS was calculated as the average expression values of the three selected genes. The control group included 20 age and gender matching healthy donors.
Results: The baseline expression levels of MX1-11.48 (5.45-19.38), EPSTI1-12.83 (5.62-19.64), RSAD2-5.16 (2.73-10.4), and IFNGS-10.3 (5.18-17.12) in RA patients were significantly higher compared to healthy donors– 1,26 (0,73-1,6); 1,06 (0,81-1,48); 0,93 (0,72-1,19); 1,09 (0,92-1,42), (p<0.05, respectively). IFNGS was detected in 15 (75%) patients, and was not found in 5 (15%) patients. RTX induced reduction in disease activity, and the level of acute phase reactants (ESR, CRP) after 12 and 24 weeks of therapy, p<0.05 (fig.1). Increased RSAD 2 expression (p<0.05) and a trend to increasing IFNGS levels (p=0.06) were documented in the whole group, and also in patients with moderate treatment effects by week 24. Among patients with a good EULAR response to therapy, changes in expression were not significant (p> 0.05) (fig.1)

Parameters	Week	Patients with RA (n=20)	Moderate/no EULAR response by week 24 (n=15)	Good EULAR response by week 24 (n=5)

*p<0.05 from baseline

Figure 1.

Conclusion: Expression of IFN-stimulated genes was increased in RA patients compared to healthy donors. Increased RSAD2 and IFNGS expression was documented in patients with moderate effect of RTX therapy, therefore, these findings have important clinical relevance as predictors of RA clinical course which necessitates personified approach to treatment.

POS0612

EXPLORING EQUIVALENCE BETWEEN BIOSIMILAR SB4 AND REFERENCE ETANERCEPT BY ASSESSING EFFECTIVENESS IN RHEUMATOID ARTHRITIS PATIENTS TREATED IN ORDINARY CLINICAL PRACTICE

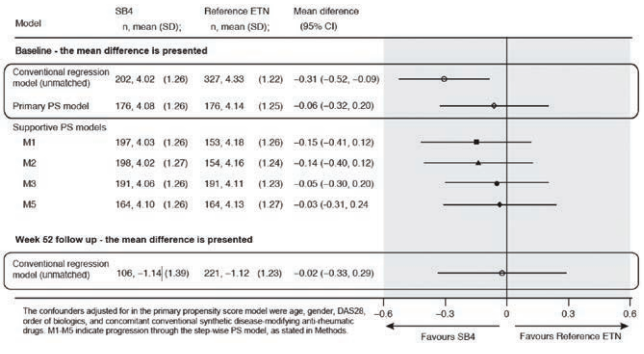
G. Haugeberg[1,2], G. Bakland[3], E. Rødevand[4], I. J. Widding Hansen[1], A. Diamantopoulos[5], A. H. Pripp[5]. *[1]Sørlandet Hospital, Division of Rheumatology, Department of Medicine, Kristiansand, Norway*; *[2]Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, NTNU, Trondheim, Norway*; *[3]University Hospital of Northern Norway, Department of Rheumatology, Tromsø, Norway*; *[4]St Olav's Hospital, Department of Rheumatology, Trondheim, Norway*; *[5]Martina Hansens Hospital, Oslo Centre of Biostatistics and Epidemiology, Oslo, Norway*

Background: Biosimilar drugs follow a tailored approval pathway that usually includes a Phase III comparative efficacy randomized controlled trial with a high internal but low external validity. Therefore, observational studies with high external validity are important to reassure patients and physicians that there are no clinically meaningful differences in effectiveness between a biosimilar and its reference drug. A EULAR Task Force systematic review and others have noted that recent comparative effectiveness studies often do not disclose applied analytical methods in sufficient detail, with many studies not adjusting for confounders nor accounting for attrition or missing data. [1,2]

Objectives: To apply the EULAR Points to Consider for Comparative Effectiveness Research (CER) in an analysis of reference etanercept (ETN) and SB4 biosimilar ETN in patients with rheumatoid arthritis (RA) treated in ordinary clinical practice in Norway.

Methods: ETN-naïve patients with RA starting ETN treatment between January 2010 and July 2018 at five centres in Norway were followed for at least 1 year; the 2 cohorts remained on either ETN or SB4 throughout. The primary outcome was DAS28 at Week 52. This CER has been designed to formally assess equivalence for DAS28, based on the accepted equivalence margin of 0.6.[3] Conventional regression and propensity score (PS) models have been applied for the primary outcome evaluation of DAS28 at Week 52. Based on clinical knowledge, the confounders adjusted for in the step-wise PS model were age, gender, DAS28, order of biologics, and concomitant conventional synthetic disease-modifying anti-rheumatic drugs. A standardized difference (d) of <0.1 indicates a good match.

Results: In the unmatched sample, there were 575 patients treated with reference ETN and 299 treated with SB4. Before PS matching, baseline mean (SD) DAS28 was different between the ETN and SB4 groups, 4.3 (1.2) vs 4.0 (1.3), (d) = 0.25. After PS matching, there were 176 RA patients in each group; baseline mean (SD) DAS28 was 4.1 (1.2) vs 4.1 (1.3), (d) = 0.05. At Week 52, the difference (mean [95% confidence interval (CI)]) between reference ETN and SB4 for primary outcome DAS28 at Week 52 was -0.02 (-0.33 to 0.29) in the unmatched analysis. Since the entire 95% CI is within the pre-defined equivalence margin of 0.6, equivalence at Week 52 has formally been shown. The analysis of the PS matched groups to Week 52 is ongoing and results will be presented in the poster.



Conclusion: Our results show the importance of adopting proper analytical techniques when comparing a biosimilar with its reference product. A conventional regression model may not fully account for differences in key clinical measures (in this instance, disease activity) between the two groups at baseline, and therefore the Week 52 results might be biased. The propensity score matched model ensures comparability of the groups at baseline and therefore the validity of the Week 52 results should be more robust.

TOCILIZUMAB DECREASES ANGIOGENESIS IN RHEUMATOID ARTHRITIS THROUGH ITS REGULATORY EFFECT ON EMMPRIN/CD147

D. Zisman[1,2], M. Safieh[1,3], E. Simanovich[3], J. Feld[1,2], A. Kinarty[3], L. Zisman[3], T. Gazitt[1], A. Haddad[1], M. Elias[1], I. Rosner[2,4], L. Kaly[4], M. Amit Rahat[2,3]. *[1]Carmel Medical Center, Rheumatology Unit, Haifa, Israel*; *[2]Technion-Israel Institute of Technology, Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel*; *[3]Carmel Medical Center, Immunotherapy Laboratory, Haifa, Israel*; *[4]Bnei Zion Medical Center, Rheumatology Unit, Haifa, Israel*

Background: Angiogenesis is an important contributor to the development of Rheumatoid arthritis (RA). Tocilizumab (TCZ), an anti-IL-6 receptor antibody, is an immunosuppressant used in the treatment of RA patients, but its effects on angiogenesis and the molecular mechanisms regulating new blood vessel formation are not fully elucidated.

Objectives: To evaluate the concentrations of pro- and anti-angiogenic factors in serum samples of RA patients, before and after the initiation of TCZ treatment and to explore in an in vitro co-culture system the mechanisms of TCZ action.

Methods: We evaluated the concentrations of EMMPRIN, VEGF, MMP-9, IL-6, NGAL, endostatin and thrombospondin-1 (Tsp-1) using commercial ELISA kits from 40 RA patients, before and 4 months after the initiation of TCZ treatment. The levels of secreted EMMPRIN, VEGF MMP-9 and Tsp-1 were measured in an in vitro co-culture system of HT1080 fibroblasts and U937 monocytes with and without addition of anti-EMMPRIN blocking antibody. In the tube formation assay serum samples and supernatnats from the co-cultures were added to endothelial layer. Images were obtained after 6 hours of incubation and the number of closed lumens were counted in two separate fields. In the wound assay, supernatants from the co-cultures, with or without the addition of the anti-EMMPRIN antibody were added to the endothelial layer after scratching. The scratch site area was measured immediately and compared to the area after 24 hours of incubation to assess the distance of cell migration.

Results: Study population included 40 RA patients, 33 (82.5%) females, mean age of 57.5±11.1 years, disease duration of 7.7±5.6 years, and 53.9% positive for rheumatoid factor initiating treatment with TCZ. In this patient cohort, 25/40 (62.5%) patients were classified as "responders" according to EULAR criteria.

Following 4 mounts of treatment, statistically significant reductions in the levels of EMMPRIN/CD147 (p=0.035), without significant changes in serum levels of MMP-9, VEGF, MMP-3 and MMP-7 and of the anti-angiogenetic factors Tsp-1 and endostatin were found. A statistically significant decrease in the ratio between the pro-angiogenic factor EMMPRIN and the anti-angiogenic factor Tsp-1 that was calculated for each patient 4 months after initiating TCZ was found(p=0.031). The decrease in angiogenesis was manifested by the reduced number of closed lumen tube-like structures formed by EaHy926 endothelial cell line after incubation with serum samples 4 months after initiation of TCZ, relative to the number of closed lumens formed prior to TCZ initiation (p=0.007). The ratio between EMMPRIN and Tsp-1 was significantly reduced in the responding patients versus non-responders (p=0.033), while the levels of VEGF, MMP-9, Tsp-1, and EMMPRIN were unchanged.

In vitro, the accumulation of the pro-angiogenic factors EMMRPIN, VEGF and MMP-9 in the supernatants was increased in the co-culture, while the accumulation of the anti-angiogenic factor Tsp-1 was decreased. When EMMPRIN was neutralized with a blocking antibody, supernatants derived from these co-cultures exhibited reduced migration, proliferation, and tube-like structure formation in functional assays.

Conclusion: Our findings suggest an important role for EMMPRIN in mediating pro-angiogenic signals in RA patients, with EMMPRIN/Tsp-1 ratio serving as a marker of angiogenesis in RA. When administered to RA patients, TCZ in turn, exerts an anti-angiogenic effect through its regulation of EMMRPIN/CD147 levels.

POS0614

PERFUSE: A FRENCH PROSPECTIVE/ RETROSPECTIVE NONINTERVENTIONAL COHORT STUDY OF INFLIXIMAB-NAÏVE AND TRANSITIONED PATIENTS RECEIVING INFLIXIMAB BIOSIMILAR SB2; 12-MONTH ANALYSIS

B. Fautrel[1], Y. Bouhnik[2], M. Dougados[3], U. Freudensprung[4], J. Addison[5]. *[1]Sorbonne University, Pitié-Salpêtrière Hospital, AP-HP, Paris, France*; *[2]Beaujon Hospital, Paris Diderot University, Department of Gastroenterology, AP-HP, Clichy, France*; *[3]CHU Paris Centre - Hôpital Cochin, Service de Rhumatologie B, Paris, France*; *[4]Biogen GmbH, Medical Data Science and Analytics, Biosimilars, Baar, Switzerland*; *[5]Biogen IDEC, Clinical Research, Biosimilars, Maidenhead, United Kingdom*

Background: SB2 is approved in the EU as an infliximab (IFX) biosimilar, having demonstrated bioequivalence and similar efficacy, safety and immunogenicity as the reference. PERFUSE is an ongoing non-interventional study of 1233 patients (496 with rheumatology diagnoses, 737 with gastroenterology diagnoses) receiving SB2 as routine therapy.

Objectives: The aim of the study is to provide data on long-term outcomes in patients initiating SB2 in the real-world setting.

Methods: Adult patients eligible for inclusion in the rheumatology study cohorts have a diagnosis of Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) or Axial Spondyloarthritis (axSpA) and had initiated SB2 in routine clinical practice after September 2017, either as their first IFX or transitioning from treatment with IFX reference or another IFX biosimilar. Outcome measures include SB2 dose, disease activity scores and persistence on SB2, over time and up to 24 months after initiation. This interim analysis is the first complete analysis of 12 month data on all rheumatology patients enrolled into the study at 9 specialist sites and followed up to the data extract date of 29th October 2020. The analysis provides an overview of baseline characteristics, disease scores, SB2 dose and persistence at 12 months post-initiation of SB2.

RESULTS:

Table 1. This 12-month interim analysis includes 496 patients (336 with axSpA, 98 with RA and 62 with PsA)

	axSpA cohort (N=336; IFX naïve 81, IFX-prior 255)		RA cohort (N=98; IFX naïve 22, IFX-prior 76)		PsA cohort (N=62; IFX naïve 14, IFX-prior 48)	
Baseline characteristics						
Age in years, mean (SD):						
IFX-naïve	43.1 (11.1)		53.1 (15.9)		48.5 (12.2)

IFX-naïve	56.26 (44.43; 66.51)		59.09 (36.10; 76.21)		64.29 (34.33; 83.31)	
Transitioned from IFX	79.86 (74.37; 84.30)		80.26 (69.42; 87.60)		85.04 (71.11; 92.58)	

*Blank as disease score data for both baseline and Month 12 were provided by a single patient who was IFX-naïve and had PsA; IFX = infliximab; axSpA = Axial Spondyloarthritis; RA = Rheumatoid Arthritis; PsA = Psoriatic Arthritis; BASDAI = Bath Ankylosing Spondylitis Disease Activity Index; DAS28 = Disease Activity Score 28; CI = confidence interval; SD = standard deviation; KM = Kaplan Meier.

Conclusion: This 12-month analysis indicates that patients with axSpA or RA can be successfully initiated on SB2 as the first infliximab therapy, and patients with axSpA, RA or PsA can be transitioned from originator or biosimilar IFX to SB2 without loss of disease control and with no dose penalty over 12 months post-transition. Over 56% of IFX- naïve patients and over 79% of patients transitioned from prior IFX remained on SB2 at 12 months post-initiation. With follow-up of patients ongoing to 24 months post-initiation of SB2, the study will continue to provide pertinent information about clinical outcomes of initiation on SB2 as first IFX or after transition from reference or IFX biosimilar to SB2.

POS0615

TOCILIZUMAB IS SAFE AND EFFECTIVE IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

C. Specker[1], M. Aringer[2], G. R. Burmester[3], M. Peters[4], M. W. Hofmann[5], H. Kellner[6], F. Moosig[7], H. P. Tony[8], G. Fliedner[9]. *[1]Clinic Essen-Mitte, Clinic of Rheumatology and Clinical Immunology, Essen, Germany*; *[2]Dresden University of Technology, University Medical Centre Carl Gustav Carus, Dresden, Germany*; *[3]Free University and Humboldt University Berlin, Department of Rheumatology and Clinical Immunology Charité - Universitätsmedizin Berlin, Berlin, Germany*; *[4]Roche Pharma AG, Grenzach-Wyhlen, Germany*; *[5]Chugai Pharma Germany GmbH, Rheumatology, Frankfurt am Main, Germany*; *[6]Rheumatology and Gastroenterology Specialty Practice, Rheumatology, Munich, Germany*; *[7]Rheumatology Centre Schleswig-Holstein Middle, Rheumatology, Neumünster, Germany*; *[8]Medical Clinic II, Department of Rheumatology and Clinical Immunology, University Clinic Würzburg, Würzburg, Germany*; *[9]Rheumatology Practice, Osnabrück, Germany*

Background: Average life spans of patients with rheumatoid arthritis (RA) are approaching those of the general population. This results in a large proportion of RA patients being elderly at some point and underlines effective RA treatments needed for this population. Pivotal clinical trials have demonstrated the efficacy of tocilizumab (TCZ) for the treatment of RA. However, real-world studies that explore the effectiveness of TCZ especially in the elderly are lacking. ICHIBAN was a large, observational study that followed patients with RA treated with TCZ under real-world conditions in Germany for up to 2 years.

Objectives: In this analysis of ICHIBAN, we examined the safety and effectiveness of long-term TCZ treatment according to patient baseline (BL) age (<50, 50–65, >65 years).

Methods: ICHIBAN (NCT01194401) was a prospective, non-interventional study that observed adult patients with active moderate to severe RA in German rheumatology clinics and practices. Patients were treated with TCZ according to the local label. The safety analyses set (SAF) included all patients who received at least one dose of TCZ. The effectiveness set (EFF) included all patients from the SAF who had no prior TCZ therapy. Patient-reported outcomes (PROs) were assessed using the visual analogue scale. Last observation carried forward was used to substitute for missing values.

Results: At baseline (BL), 3,164 patients were included in the SAF: 29.2% <50 years, 47.3% 50–65 years, and 23.5% >65 years old (1.2% ≥80 years). Patients >65 years old were not only the most likely to have comorbidities such as hypertension, anaemia, renal insufficiency, osteoporosis, diabetes, and coronary heart disease, but also had the highest BL disease activity according to Disease Activity Score-28 erythrocyte sedimentation rate (DAS28-ESR) and Clinical Disease Activity Index (CDAI) (Table 1).

Proportions of patients with adverse events (AEs) considered related to treatment were similar in patients <50 (22.3%), 50–65 (21.9%) and >65 years (22.2%). More patients >65 years (20.2%) and 50–65 years (14.4%) experienced serious AEs (SAEs) than patients <50 years (11.5%). Slightly more patients >65 years old experienced infectious SAEs (4.8%) than younger patients (<50 years, 3.2% and 50–65 years, 3.1%). Yet, similar proportions of patients across all age groups discontinued TCZ due to AE (7.0% <50 years; 9.6% 50–65 years; 7.8% >65 years).

2,902 patients were included in the EFF. Patients <50 years experienced DAS28-ESR remission at least once during the treatment period (65.4%) more often than patients aged 50–65 years (59.8%) or >65 years (59.5%). However, patients >65 years had numerically greater improvements in DAS28-ESR (Table 1). Patients <50 years had the best physical functioning at BL and the greatest reduction in

Health Assessment Questionnaire Disease Index (HAQ-DI) score (Figure 1A). All age groups had similar improvements in PROs such as fatigue, strength of pain, and sleep disturbances (Figure 1B).

Table 1. Mean Disease Activity Score-28 erythrocyte sedimentation rate (DAS28-ESR) and Clinical Disease Activity Index (CDAI) over the course of ICHIBAN. BL, baseline; SD, standard deviation.

		<50 years	50–65 years	>65 years
DAS28-ESR, mean ± SD	n*	777	1237	617
	BL	4.9 ± 1.4	5.3 ± 1.3	5.4 ± 1.3
	Last visit	2.8 ± 1.7	3.1 ± 1.7	3.2 ± 1.7
	Change from BL	-2.0 ± 1.7	-2.2 ± 1.7	-2.2 ± 1.8
CDAI, mean ± SD	n*	768	1217	590
	BL	25.7 ± 12.8	28.4 ± 13.3	28.8 ± 12.8
	Last visit	13.3 ± 12.8	14.6 ± 13.2	14.5 ± 12.8
	Change from BL	-12.5 ± 13.6	-13.8 ± 14.0	-14.3 ± 13.8

*271 patients with missing data at BL**327 patients with missing data at BL

Conclusion: Although elderly patients experienced a higher rate of infections, the proportion of patients withdrawing due to AE was not higher than in the other age groups. Starting with higher baseline disease activity, patients >65 years had similar benefits to disease activity and PROs when compared with younger patients. Overall, these results indicate that long-term TCZ treatment of elderly patients is effective and has an acceptable safety profile.

POS0616

LONG-TERM EFFECTIVENESS AFTER MULTIPLE CYCLES WITH RITUXIMAB FOLLOWING AN ON-FLARE RETREATMENT STRATEGY IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. Bertrand[1], N. Pype[1], T. Conings[1], D. De Cock[1], S. Pazmino[1], M. Doumen[1,2], J. Joly[2], B. Neerinckx[1,2], R. Westhovens[1,2], P. Verschueren[1,2]. [1]*KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium*; [2]*UZ Leuven, Rheumatology, Leuven, Belgium*

Background: Rituximab is known as an efficacious drug for the treatment of Rheumatoid Arthritis (RA). The recommended administration schedule consist of 2 infusions of 1000 mg with a 2-week interval. In Belgium an on-flare retreatment strategy is followed, making evaluation of effectiveness over time challenging. Moreover the patient's view on this strategy is unclear.

Objectives: To explore long-term effectiveness and safety of rituximab in daily clinical practice in patients with RA.

Methods: Data of patients diagnosed with RA and treated with rituximab in a tertiary university hospital were retrospectively collected. For every cycle, clinical data were recorded at the time of the first and second infusion, the 16-week visit and the visit on which the treating rheumatologist decided to prescribe a new cycle. Data on demographics, previous RA treatment, disease activity, patient-reported outcomes, adverse events related to rituximab, dose and number of cycles were collected from 01/01/2006 until 01/12/2019 or until discontinuation of rituximab. The visit on which rituximab was prescribed for the first time was considered as the baseline visit. The data were analysed descriptively.

Results: Data of 66 patients with RA were collected. The median (IQR) age was 57.0 (47.0-65.0) years at baseline and 56% (37/66) were female. Most patients were seropositive (RF 91% and ACPA 92%), and had erosive (71%) or nodular disease (53%). The median (IQR) disease duration was 12.5 (4.0-18.3) years. In total, 94% of the patients had failed at least one other biological Disease-modifying Antirheumatic Drug (bDMARD) before starting rituximab. Overall, patients received a median (IQR) of 3 (2-7) cycles of rituximab. Seven of the 66 patients (11%) discontinued rituximab and changed to another bDMARD after a median (IQR) of 1 (1-6) cycles and 11% were treated with a lower dose than 2x1000mg. The median (IQR) interval between the first 2 cycles was 7.0 (6.0-10.0) months, after which this increased to up to one year (interval between cycle 2-3: 10.0 (7.0-13.0) months, cycle 3-4: 12.0 (7.3-15.5) months). The overall median (IQR) follow-up time was 45.5 (14.8-82.3) months. The efficacy of rituximab remained after repeated cycles: after every treatment with rituximab, a reduction in disease activity based on the disease activity score in 28 joints (DAS28) could be noticed (figure 1A). The evolution in patients' (PaGH) and physicians' global health (PhGH) assessment followed the same pattern as the DAS28-score (Figure 1B). High PaGH-scores could be noticed at every start of a new rituximab cycle. The proportion of patients with a PaGH-score above 20 ranged from 84% - 100%, 74% - 100% and 66% - 86% at the first infusion, second infusion and week 16 visits, respectively. Rituximab was considered to be well-tolerated. In total, 23 adverse events in 12 patients were recorded and none of them were serious.

Conclusion: Rituximab can be considered a highly efficacious drug for RA treatment in daily practice. There were no major side effects and there was an increasing treatment interval over time. However, a healthy survivor effect should be kept in mind when interpreting the results. It should be noted that with the on-flare retreatment strategy, every new rituximab cycle was preceded by a rise in PaGH-scores, which reflects a state of impaired wellbeing reported by patients. This should be further studied with qualitative methods and in a randomized trial setting comparing on-flare with fixed-interval retreatment to evaluate optimal effectiveness.

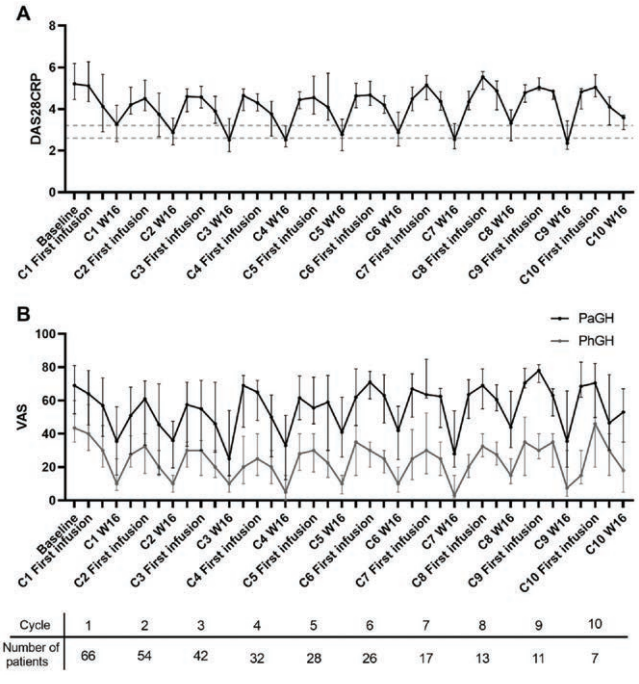

Figure 1. Evolution in median - interquartile range disease activity (DAS28CRP) (A) and patients' (PaGH) and physicians' global health (PhGH) (B) over the different rituximab cycles. The disease activity, PaGH and PhGH were measured at baseline, the time of the first and

second infusion, W16 and the visit on which a new rituximab cycle was prescribed. The dotted lines represent a DAS28CRP-score of 2.6 (remission cut-off) and 3.2 (low disease activity cut-off). C: cycle; W: week; VAS: visual analogue scale.

POS0617 ANTI INFLIXIMAB ANTIBODIES DETECTED BY A DRUG TOLERANT ASSAY ARE FREQUENT BUT, IN MANY CASES, WITHOUT RELEVANT CLINICAL SIGNIFICANCE

A. Martínez-Feito[1,2], B. Hernández-Breijo[2], M. Novella-Navarro[2,3], V. Navarro-Compán[2,3], C. Diego[1], I. Monjo[2], L. Nuño[2], A. Villalva[3], D. Peiteado[3], D. Pascual-Salcedo[2], P. Nozal[1], A. Balsa[2,3], C. Plasencia[2,3]. [1]*La Paz University Hospital, Immunology, MADRID, Spain*; [2]*IdiPaz. La Paz University Hospital, Immuno-Rheumatology Research Group, MADRID, Spain*; [3]*La Paz University Hospital, Rheumatology, MADRID, Spain*

Background: Infliximab (Ifx) has proven effective in treating rheumatoid arthritis (RA) and spondyloarthropathies (SpA), although around 40% of cases fails, mainly due to immunogenicity. Formation of immunocomplexes between antibodies to Ifx (ATI) and Ifx can increase drug clearance, leading to treatment failure. Standard ELISA assays which are drug -sensitive are frequently used, being able to detect only free ATI. Interest in drug-tolerant assays to measure total ATI (free and complexed) is increasing.
Objectives: To compare the development of ATI using both drug-tolerant and drug-sensitive assays at early stages of Ifx therapy. To analyse the relationship of ATI detected by both assays with the drop-out of treatment.
Methods: This is a prospective observational study including 45 patients with RA and 61 with axial-SpA treated with standard doses of Ifx (3mg/kg and 5mg/kg, respectively) enrolled at Biological Therapy Unit of Hospital La Paz. Serum samples were obtained at 2, 6, 12 and 22 weeks (W) after Ifx initiation. The data about discontinuation for inefficacy was obtained from the database. ATI presence was evaluated by a drug-sensitive in-house two-site (bridging) ELISA (bELISA) and a drug-tolerant commercial ELISA assay (Immundiagnostik®,IDK). All comparisons were performed throughout non-parametrical test. In SpA group, due to the low number of ATI+ patients at W12 by bELISA the statistical analysis to compare both assays were not performed.
Results: ATI detection by both assays at early stages (≤22W) of treatment is shown in Table 1a. ATI were always detected earlier by IDK than bELISA and also in RA than in SpA patients probably reflecting the effect of lower Ifx doses. Three out of 106 (3%) vs 0 (0%) patients had ATI at W 2 and 62 (58%) vs 20 (18%) patients at W22, by IDK and bELISA, respectively.

Table 1.

	W2		W6		W12		W22	
	AR	SpA	AR	SpA	AR	SpA	AR	SpA
a) ATI+ patients (n, %) at early stages								
bELISA	0	0	3(7%)	0	10(22%)	1(2%)	13(29%)	7(12%)
IDK	1(2%)	2(3%)	7(16%)	2(3%)	16(36%)	16(26%)	28(62%)	34(56%)
b) Patients who discontinued (n, %) Ifx therapy considering ATI status at early stages								
bELISA+					9(90%)*	1(100%)*	12(92%)	4(57%)
bELISA-					23(66%)	22(37%)	20(63%)	19(35%)
IDK+					15(94%)*	7(44%)	24(86%)	13(38%)
IDK-					17(59%)	11(24%)	13(77%)	10(27%)

*p<0.05 comparing between ATI+ vs ATI- in each assay.

Once ATIs appeared, regardless both methods, they persisted throughout the follow-up, indicating that immunogenicity was not transient.
At W22, only 13/28 (46%) and 7/34 (21%) patients with ATI detected by IDK were also positive by bELISA in RA and SpA, respectively.
ATI levels by IDK were higher in ATI+ by bELISA than in ATI- patients at early stages: ATI levels by IDK at W12: 91[74-348] ng/ml ATI+ vs 21.7[15-59.5] ng/ml ATI- (p<0.01) and at W22: 132 [89-372] ng/ml ATI+ vs 23[13-66] ng/ml ATI- (p<0.001). However, only in 4% (2/45) patients with RA and in 13% (8/61) patients with SpA the detection by IDK was earlier than by bELISA at W12.
Free IFX in serum was not detected in bELISA ATI+ patients. In IDK ATI+ patients low circulating Ifx levels were present as compare to ATI- since W6 to the end of follow-up (p<0.01).
More ATI+ patients dropped out Ifx at W12 and W22 regardless de assay (Table 1.b), being statistically significant for both assays in patients with RA and only for bELISA in patients with SpA.
Conclusion: ATI measured by a drug-tolerant assay are always detected earlier than ATI detected by bELISA, indicating that immunogenicity, at least with Ifx, is usually an early event. High levels of ATI by IDK are associated with an earlier detection by bELISA in case of RA patients. ATI detected only by drug tolerant assays are associated with low levels of circulating Ifx but not with a complete drug neutralization and may do not have clinical relevance compared to ATI detected by bELISA. Many patients have low levels of ATI which can only be detected by drug tolerant assays after long-term of follow-up.
The reasons why ATI levels rise rapidly in some patients while in others remain low are currently unknown but may be relevant if the clinical effect of immunogenicity is to be minimized.

POS0618 PERSISTENCE OF REMISSION AFTER TAPERING OF GOLIMUMAB IN INFLAMMATORY JOINT DISEASE (IJD)

A. Damiani[1], F. Bartoli[1], V. Gori[1], S. Bellando-Randone[1], G. Fiori[1], M. Matucci-Cerinic[1], S. Guiducci[1]. [1]*University of Florence, Rheumatology Unit, Firenze, Italy*

Background: In refractory IJD, remission may be obtained with antiTNFa drugs and other biological disease modifying anti-rheumatic drugs (bDMARDs). The last EULAR recommendations suggest tapering of bDMARD when remission persists[1]. However, best timing and modality of tapering are uncertain and specific knowledge on patients' characteristics associated to a better outcome is still lacking.
Objectives: To evaluate the persistency of remission after increasing the interval between injections of Golimumab in a group of patients affected by rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS) and juvenile idiopathic arthritis (JIA) and to identify any variables associated to disease flare after tapering.
Methods: Between 2011 and July 2020, 80 patients affected by RA, PsA, AS and JIA treated with Golimumab were enrolled. Their demographic and clinical data, including inflammation (ESR and cRP) and clinimetric indices (DAS28 or BASDAI), were collected at baseline and during the follow up visit (T1). In 22/80 patients that reached clinical remission at T1, the time between Golimumab injections has been prolonged (mean time between injection: 43.7 days); ESR and cRP, DAS28/BASDAI, and time since the start of the tapering (weeks) were evaluated in the next control visit (T2).
Results: 80 patients were enrolled (32 male, mean age 50.6 years +/- 13.91), 34 AS, 33 PsA, 9 RA and 4 JIA. At baseline they have an active disease with a DAS 28 of 4.74+/-0.85 and a BASDAI of 5.23+/- 1.31. At T1, 60/80 patients were in remission (75%), with a mean DAS 28 of 1.84+/- 0.6 and an average BASDAI of 1.32+/-0.6, and 22/60 patients started drug tapering. At T2, 20/22 patients (91%) were in remission, (DAS 28 1.9+/-0.49, BASDAI of 0.8+/- 0, 67). A significantly higher BASDAI was observed at T1, even though in the range of absence of disease activity (2.2, +/- 0.28 *vs* 0.58, +/- 0.47; p <0.001) in patients who, after extending the therapeutic interval (T1) were no longer in remission at T2. Patients with a flare of disease activity (2/22) were taken back to the 28 days window of Golimumab with a prompt recovery of disease remission. Out of the 38 patients maintained at the standard dose, 4 experienced a disease flare with necessity to switch or swope bDMARD, with a retention rate in this group of 90%. Difference of retention rate between patients on standard *vs* reduced dose was not statistically significative.
Conclusion: Tapering of Golimumab was successful in 91% of the cases without flare. Moreover, the prolongation of the increase of the treatment window provided the same result as that obtained in patients that continued in the standard time window. This evidence suggests that the extension of the gap between Golimumab administrations may be feasible and safely applied in practice.

POS0619 MODELLING OF DISEASE ACTIVITY IN PATIENTS WITH INFLAMMATORY ARTHROPATHIES TREATED WITH ETANERCEPT ORIGINATOR OR BIOSIMILAR AS FIRST-LINE BIOLOGIC IN AN AUSTRALIAN REAL-WORLD DATASET

C. Deakin[1], G. Littlejohn[1,2], H. Griffiths[1,3], T. Smith[1], C. Osullivan[1], P. Bird[1,4]. *[1]OPAL Rheumatology, Ltd., Sydney, Australia*; *[2]Department of Medicine, Monash University, Clayton, Australia*; *[3]Barwon Rheumatology, Services, Geelong, Australia*; *[4]Department of Medicine, UNSW Sydney, Sydney, Australia*

Background: The availability of biosimilars as non-proprietary versions of established biologic disease-modifying anti-rheumatic drugs (bDMARDs) is enabling greater access for patients with rheumatic diseases to effective medications at a lower cost. Since April 2017 both the originator and a biosimilar for etanercept (trade names Enbrel and Brenzys, respectively) have been available for use in Australia.

Objectives:

[1] To model effectiveness of etanercept originator or biosimilar in reducing Disease Activity Score 28-joint count C reactive protein (DAS28CRP) in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or ankylosing spondylitis (AS) treated with either drug as first-line bDMARD

[2] To describe persistence on etanercept originator or biosimilar as first-line bDMARD in patients with RA, PsA or AS

Methods: Clinical data were obtained from the Optimising Patient outcomes in Australian rheumatoLogy (OPAL) dataset, derived from electronic medical records. Eligible patients with RA, PsA or AS who initiated etanercept originator (n=856) or biosimilar (n=477) as first-line bDMARD between 1 April 2017 and 31 December 2020 were identified. Propensity score matching was performed to select patients on originator (n=230) or biosimilar (n=136) with similar characteristics in terms of diagnosis, disease duration, joint count, age, sex and concomitant medications. Data on clinical outcomes were recorded at 3 months after baseline, and then at 6-monthly intervals. Outcomes data that were missing at a recorded visit were imputed.

Effectiveness of the originator, relative to the biosimilar, for reducing DAS28CRP over time was modelled in the matched population using linear mixed models with both random intercepts and slopes to allow for individual heterogeneity, and weighting of individuals by inverse probability of treatment weights to ensure comparability between treatment groups. Time was modelled as a combination of linear, quadratic and cubic continuous variables.

Persistence on the originator or biosimilar was analysed using survival analysis (log-rank test).

Results: Reduction in DAS28CRP was associated with both time and etanercept originator treatment (Table 1). The conditional R-squared for the model was 0.31. The average predicted DAS28CRP at baseline, 3 months, 6 months, 9 months and 12 months were 4.0 and 4.4, 3.1 and 3.4, 2.6 and 2.8, 2.3 and 2.6, and 2.2 and 2.4 for the originator and biosimilar, respectively, indicating a clinically meaningful effect of time for patients on either drug and an additional modest improvement for patients on the originator.

Median time to 50% of patients stopping treatment was 25.5 months for the originator and 24.1 months for the biosimilar (p=0.53). An adverse event was the reason for discontinuing treatment in 33 patients (14.5%) on the originator and 18 patients (12.9%) on the biosimilar.

Conclusion: Analysis using a large national real-world dataset showed treatment with either the etanercept originator or the biosimilar was associated with a reduction in DAS28CRP over time, with the originator being associated with a further modest reduction in DAS28CRP that was not clinically significant. Persistence on treatment was not different between the two drugs.

Table 1. Model summary for prediction of DAS28CRP using time and etanercept originator (relative to biosimilar)

Fixed Effect	Estimate	95% Confidence Interval	p-value
Time (linear)	0.90	0.89, 0.91	1.5e-63
Time (quadratic)	1.01	1.00, 1.01	1.3e-33
Time (cubic)	1.00	1.00, 1.00	7.1e-23
Originator	0.91	0.86, 0.96	0.0013

POS0620 TREATMENT PATHWAYS OF RHEUMATOID ARTHRITIS PATIENTS LEADING TO BIOLOGIC THERAPY VISUALIZED IN A SANKEY DIAGRAM

T. Coppes[1], N. Jessurun[1], J. Jansen[1], K. Velthuis[1], P. ten Kloster[2,3], H. Vonkeman[3,4]. *[1]Netherlands Pharmacovigilance Centre Lareb, Monitoring, 's-Hertogenbosch, Netherlands*; *[2]Transparency in Healthcare B.V., Hengelo, Netherlands*; *[3]University of Twente, Psychology, Health & Technology, Enschede, Netherlands*; *[4]Medisch Spectrum Twente, Rheumatology and Clinical Immunology, Enschede, Netherlands*

Background: Treatment of rheumatoid arthritis (RA) has changed in the past 20 years due to the arrival of biologic disease-modifying antirheumatic drugs (bDMARDs) and the application of treat to target strategies. Many different combinations of conventional synthetic (cs)DMARDS and bDMARDS are being applied in daily practice. It is difficult to visualize and understand all the different treatment pathways that are sequentially being used over longer periods of time in a real-world setting. We therefore investigated whether a Sankey diagram is a suitable tool to study and visualize which treatment pathways exist and to what extent a RA treatment protocol is being followed.

Objectives: To illustrate the treatment pathways over longer periods of time in a cohort of early RA patients and to assess adherence to the treatment protocol using Sankey diagrams.

Methods: This single-centre retrospective, observational cohort study used data from the DREAM-RA registry. Patients were treated according to a treat to target strategy with a step-up DMARD treatment protocol when remission was not achieved, initial steps were starting with MTX 15 mg/wk, week 8 MTX 25 mg/wk, week 12 MTX+SSZ 2dd1000mg, week 20 MTX+SSZ 3dd1000mg, week 24 MTX+adalimumab 40mg/2wk, week 36 MTX+adalimumab 40mg/wk. Although the protocol met full consensus, adherence to the protocol in individual patients was at the discretion of the treating rheumatologist. In this study, patients were included if they received a continuous treatment with a conventional synthetic or biologic DMARD between 1 January 2002 and 30 April 2020. During treatment, corticosteroids per protocol were allowed but not considered as an individual treatment. Evaluated outcomes included: the consecutive treatments that patients followed including start- and stop-date of treatments, the proportion of patients that received bDMARDs, the number of switches until first bDMARD, and time to first bDMARD. Furthermore, the lower limit of adherence to the protocol was estimated by considering all patients (% of total) treated according to the protocol. This information was determined by verifying whether the patient was being treated according to the protocol after each switch.

Results: A total of 372 patients were included in this study (Table 1). The mean overall follow-up time of the cohort was 8.83 (± 3.59) years. The follow-up time for the first 4 treatments, depicted in the Sankey diagram was 6.28 (± 3.31) years. At least 45 (12%) patients started with a bDMARD before all previous protocol steps were followed. At the start of treatment, 81% of the patients were treated according to the protocol, this was reduced to 28% after one switch. The lower limit of adherence to the predefined protocol after 3 switches were roughly 5% of all patients.

Table 1. Patient characteristics of all included patients

	All patients (n=372)
Gender, female, n (%)	246 (66.1)
Age, year, mean ± SD	67.9 ± 13.61
Overall follow-up, years ± SD	8.83 ± 3.59
Follow-up first 4 treatments, years ± SD	6.28 ± 3.31
Baseline DAS-28 score, mean ± SD	3.60 ± 1.41
Rheumatoid factor positive, n (%)	336 (90.3)
Patients who eventually received a bDMARD, n (%)	108 (29.0)
Number of switches until first bDMARD, mean ± SD	2.7 ± 1.41
Time to first bDMARD, years ± SD	3.66 ± 3.00

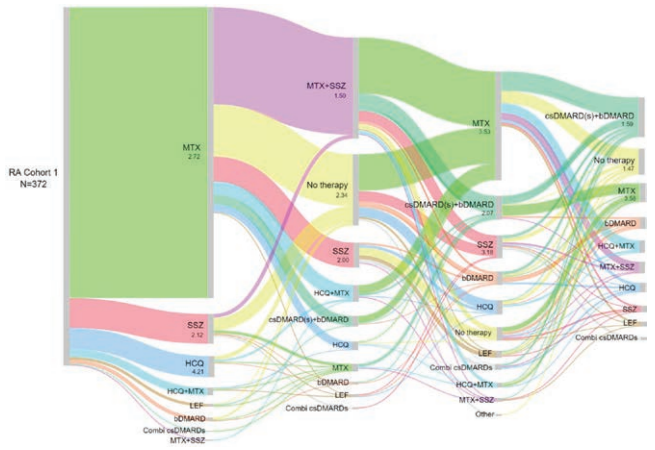

Figure 1. Sankey diagram of the treatment pathway of the first 3 switches of RA patients. The average duration of treatment of a flow is displayed in years if the flow included more than 20 patients. (MTX= methotrexate; SSZ= sulfasalazine; HCQ = hydroxychloroquine; LEF= leflunomide; bDMARD= monotherapy bDMARD; Combi csDMARDs= combination therapy of csDMARDS; csDMARD(s)+bDMARD= combination therapy of one or two csDMARD(s) + a bDMARD; No therapy= no treatment received >3 months; Other = medication that is not a (cs)(b)DMARD)

Conclusion: Sankey diagramming can be used to illustrate complex real-world treatment data of a treat to target cohort of RA patients. Treatment protocol adherence can be assessed with the help of a Sankey diagram. After 3 switches, the lower limit of adherence to the protocol was roughly 5%.

POS0621 DISEASE-SPECIFIC ADVERSE DRUG REACTION PROFILES OF ADALIMUMAB AND ETANERCEPT AS REPORTED BY IMMUNE-MEDIATED INFLAMMATORY DISEASE PATIENTS

L. Roest[1], L. Kosse[1], J. van Lint[1], J. Scholl[1], M. van Doorn[2], S. Tas[3], M. Nurmohamed[4], H. Vonkeman[5,6], R. Hebing[7], P. Spuls[8], F. Hoentjen[9], E. van Puijenbroek[10,11], B. van den Bemt[10,12], N. Jessurun[1]. *[1]Netherlands Pharmacovigilance Centre Lareb, Department of Monitoring,'s-Hertogenbosch, Netherlands*; *[2]Erasmus MC, Department of Dermatology, Rotterdam, Netherlands*; *[3]Amsterdam UMC, Location Academic Medical Center, University of Amsterdam, Amsterdam Infection & Immunity Institute and Amsterdam Rheumatology & Immunology Center (ARC), Department of Rheumatology & Clinical Immunology, Amsterdam, Netherlands*; *[4]Reade and Amsterdam Rheumatology & Immunology Center (ARC), Department of Rheumatology, Amsterdam, Netherlands*; *[5]Health & Technology, University of Twente, Department of Psychology, Enschede, Netherlands*; *[6]Medisch Spectrum Twente, Department of Rheumatology, Enschede, Netherlands*; *[7]Amsterdam Rheumatology and Immunology Center Location Reade, Department of Pharmacy, Amsterdam, Netherlands*; *[8]Amsterdam UMC, Amsterdam Public Health, Immunity and Infections, University of Amsterdam, Department of Dermatology, Amsterdam, Netherlands*; *[9]Radboud UMC, Department of Gastroenterology, Nijmegen, Netherlands*; *[10]Sint Maartenskliniek, Department of Pharmacy, Nijmegen, Netherlands*; *[11]Netherlands Pharmacovigilance Centre Lareb, Department of Signal Detection,'s-Hertogenbosch, Netherlands*; *[12]Radboud UMC, Department of Pharmacy, Radboud UMC, Netherlands*

Background: Information on adverse drug reactions (ADRs) is generally clustered for all indications of a drug in the patient information leaflet. However, previous research has shown that participants of the Dutch Biologic Monitor (DBM) that use a biologic for their immune-mediated inflammatory disease (IMID) prefer to receive ADR information tailored to their own biologic an IMID (1). Currently, it is unclear whether the ADR profile of a specific biologic may differ between patients with different IMIDs, which would be vital information for health care providers (HCPs) in their patient guidance.

Objectives: To determine whether the profiles of ADRs attributed to adalimumab (ADA) and etanercept (ETN) reported by patients in the DBM differ between IMIDs.

Methods: The DBM is a prospective cohort event monitoring system for patient-reported ADRs attributed to biologics (2). Study data was extracted from the DBM for the period Jan 2017 – Oct 2020. ADRs were coded according to their corresponding Preferred Term (PT) following MedDRA terminology. Unique PTs were selected per participant and grouped under System Organ Classes (SOCs) (Figure 1) for ADA and ETN. SOCs contributing for <1% to the total number of reported ADRs were grouped as 'other'. Participants with more than one of the included IMIDs, i.e. Psoriatic Arthritis (PsA), Inflammatory Bowel Disease (IBD, i.e. Crohn's disease and ulcerative colitis), rheumatoid arthritis (RA), and axial spondyloarthritis (axSpA) including Ankylosing Spondylitis (AS), were excluded. Differences in ADR profiles between IMIDs were tested using the Fisher-Freeman-Halton's Exact Test with Monte Carlo simulation. SOCs of interest were separately tested with the Fisher-Freeman-Halton's Exact Test (no simulation) and subsequently corrected for multiple comparisons using the Benjamini-Hochberg (BH) correction.

Results: A total of 572 ADR reports from 218 participants using ADA and 450 ADR reports from 185 participants using ETN were analyzed (Table 1).

Overall, a statistically significant difference in patient-reported ADR profile between the assessed indications was found for ADA (p=0.011), but not for ETN (p=0.057). The following separate tests for selected SOCs of interest showed a significant difference in the frequencies of 'respiratory, thoracic and mediastinal disorders' and 'musculoskeletal and connective tissue disorders' between the different IMIDs for ADA after BH correction, but none for ETN.

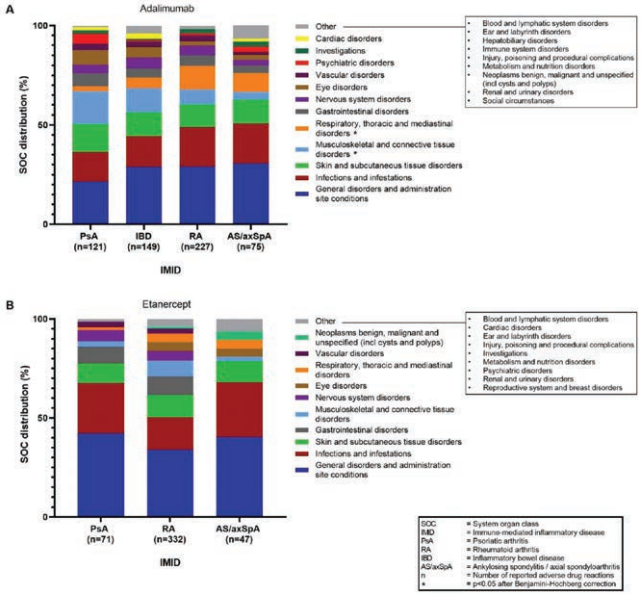

Figure 1. The disease-specific patient-reported ADR profile of ADA (A) and ETN (B) in IMID patients resulting from the Dutch Biologic Monitor

Table 1. Respondent characteristics.

Characteristics	ADA		ETN	
	n=218	%	*n*=185	%
Female gender, *n* (%)	140	64.2	129	69.7
Median age (IQR), years	56.0 (46.0-64.0)		58.0 (48.0-66.0)	
ADR reports	572	100.0	450	100.0
Indication for biologic therapy				
Rheumatoid arthritis	90	41.3	127	68.6
Psoriatic arthritis	46	21.1	35	18.9
Ankylosing spondylitis/axSpA	32	14.7	23	12.4
IBD[a]	50	22.9	0	0.0
Combination therapy[b]				
Methotrexate	63	30.3	70	40.2
Corticosteroids	25	12.0	21	12.1
Thiopurines	18	8.7	1	0.6
No combination therapy	87	41.8	59	33.9
Other	31	14.9	48	28.2

IQR: interquartile range; IBD: inflammatory bowel disease; axSpA: axial spondyloarthritis.[a]IBD includes Crohn's disease and ulcerative colitis.[b]The overall percentage exceeds 100% since patients can have a combination therapy consisting of one or more drugs.

Conclusion: Although only ADA shows a statistically significant difference in ADR profile between different IMIDs, more research with a larger sample size might show similar results for ETN. Furthermore, explanations for the differences found, such as disease-drug interactions, must be examined. This would help HCPs in providing disease-specific information and patient guidance.

POS0622 THE BLOOD T-CELL SUBSETS IN RHEUMATOID ARTHRITIS PATIENTS ON LONG-TERM IL-6 RECEPTOR BLOCKER THERAPY

E. Gerasimova[1], T. Popkova[1], A. Aleksankin[2], D. Tabakov[3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases Laboratory, Moscow, Russian Federation*; *[2]Research Institute of Human Morphology, Reproductive Pathology Laboratory, Moscow, Russian Federation*; *[3]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*

Background: Pleiotropic effects of IL-6 receptor antagonist tocilizumab (TCZ) in rheumatoid arthritis (RA) involve circulating T-cells. Preliminary reports have suggested that TCZ therapy can modulate T cell function and humoral immune responses in RA [1,2]. According to other studies, TCZ had no influence on T-lymphocyte subdifferentiation [3].
Objectives: To assess the effect of 12 months (m) TCZ therapy on T-cell phenotype, and to analyze the association between T-cell subsets and RA activity.
Methods: 36 active RA pts (29F/7M); median age 55[46; 64] years; disease duration 120[72; 1928]m; DAS28 score 6,3[5,7;6,7]; RF+100%, ACCP+ 86% were treated with TCZ (8 mg/kg every 4 weeks) in an open-label study. Immunophenotyping was performed at baseline, 6m and 12m. T-cell subpopulations and key laboratory parameters (CRP, RF, ACCP, MCV, MMP-3) were assessed.
Results: At baseline, the absolute counts of T cell subpopulations in RA pts - (CD3+), Th (CD3+CD4+), Tc (CD3+CD8+), NK cells (CD3-CD56+) - were comparable with counts in healthy donors (table1). At baseline, the absolute NK cells (CD3-CD56+) count correlated with MCV (r=0,35, p<0,05) and with MMP-3 (r=0,57, p<0,05) in RA pts. After 6m of TCZ therapy, 34% of pts were classified as good responders, 66% - as moderate responders; after 12m of TCZ therapy 68% of pts - as good responders, 32% - as moderate responders, according to the response criteria of the EULAR. Tc (CD3+CD8+) absolute count reductions were documented after 6m of TCZ therapy, absolute of T cells (CD3+) count and Th (CD3+CD4+) count - after 12m of TCZ therapy (table1). A positive correlation between Tc (CD3+CD8+) absolute counts and RF (r=0,50, p<0,05) was found after 6m of TCZ therapy. A negative correlation of Δ CRP was established with Δ T cells (CD3+) (r=-0,45], Δ Th (CD3+CD4+) (r=-0.47), and Δ Tc (CD3+CD8+) (r=-0,59, p<0,05 in all cases) after 12m of TCZ. The median absolute counts of T cells (CD3+), Th (CD3+CD4+) was lower than on healthy donors after 12m of TCZ therapy. NK cells (CD3-CD56+) counts and Th/Tc index did not change after 12 m of TCZ therapy vs healthy donors and baseline values.
Conclusion: Immunophenotyping in pts with active RA showed no difference in the absolute counts of T-cell subpopulations (T cells (CD3+), Th (CD3+CD4+), Tc (CD3+CD8+), NK cells (CD3-CD56+)) compared to healthy donors. T cells (CD3+), Th (CD3+CD4+) and Tc (CD3+CD8+) T cell counts dropped after 6 or 12m of TCZ therapy. Significant correlation between the T-cell subpopulations counts and values of RA laboratory indicators (CRP, MCV, RF, MMP-3) suggest potential T-lymphocytes involvement in RA pathogenesis.

POS0623 CYTOKINE PRODUCTION BY BLOOD LYMPHOCYTES DEFINES A PROFILE ASSOCIATED WITH NON-REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TNF INHIBITORS

B. Hernández-Breijo[1], E. Rodríguez-Martín[2], C. García-Hoz[2], V. Navarro-Compán[1,3], C. Sobrino[4], A. Martínez-Feito[1,5], I. Nieto-Gañán[2], J. Bachiller-Corral[4], P. Lapuente-Suanzes[2], G. Bonilla[3], C. Pijoán-Moratalla[4], M. Vázquez[4], A. Balsa[1,3], D. Pascual-Salcedo[1], L. M. Villar[2], C. Plasencia[1,3]. *[1]IdiPaz, La Paz University Hospital, Immuno-Rheumatology Research Group, Madrid, Spain*; *[2]Ramón y Cajal University Hospital and IRYCIS, Immunology, Madrid, Spain*; *[3]La Paz University Hospital, Rheumatology, Madrid, Spain*; *[4]Ramón y Cajal University Hospital and IRYCIS, Rheumatology, Madrid, Spain*; *[5]La Paz University Hospital, Immunology, Madrid, Spain*

Background: In clinical practice no more than 50% of the patients treated with TNF inhibitors (TNFi) achieve remission (REM). Previous investigations suggested that peripheral blood mononuclear cells (PBMC) may be markers associated with the TNFi treatment success[1].
Objectives: This study aims to analyse the intracellular cytokine production by PBMC and its association with REM achievement after 6 months (m) of TNFi treatment in patients with RA.
Methods: This was a prospective study including 62 patients with RA starting the 1st TNFi. PBMC were isolated from patients at baseline and after 6m of treatment with TNFi and cryopreserved until studied. In vitro stimulation and intracellular cytokine production by PBMC was performed as follow: in the presence of 2µg/mL brefeldin and 2µmol/L monensin monocytes were stimulated with 20ng/mL LPS during 4h whereas lymphocytes were stimulated with 50ng/mL phorbol 12-myristate 13-acetate and 750ng/mL ionomycin for 4h at 37ºC. To identify IL10-producing B cells, PBMC were pre-incubated with 3µg/mL of CpG oligonucleotide during 20h at 37°C prior to stimulation. Intracellular cytokine production (TNFα, IL6, GM-CSF, IL10) by the different cell subsets (monocytes, $CD4^+$ and $CD8^+$ T cells, naïve and memory B cells) was analysed by flow-cytometry. Clinical activity at baseline and after 6m was assessed by DAS28-ESR. REM was defined as DAS28≤2.6 at 6m. The association between cytokine production by each PBMC subset and REM was analysed through univariable and multivariable logistic regression models. Receiving operating curve (ROC) analysis was used to select the optimal ratio of cytokine production associated with REM status.
Results: After 6m of TNFi treatment, 30 (48%) patients achieved REM. No significant differences between REM and non-REM groups were observed for patients' characteristics at baseline except for DAS28, which was lower in the REM group (non-REM: 5.4±0.9; REM: 4.3±0.9; p<0.0001) (Table 1). Therefore, further analyses were adjusted by baseline DAS28. A lower ratio between calculated with the IL10 and TNFα production by B cells and by $CD4^+$ T cells (IL10 B/TNF CD4) at 6m was found for non-REM patients (non-REM: 0.31 vs REM: 0.54; p=0.007). Based on a ROC analysis, we found that a (IL10 B/TNF CD4)<0.54 at 6 m was

significantly associated with a higher probability of non-REM at 6 months (OR: 5.0; 95% CI: 1.1-21.7) (Figure 1).

Table 1. The table shows mean±SD, median (IQR) or absolute number (percentage) for all patients included (n=62). RF, rheumatoid factor; ACPA, anti-citrullinated protein antibodies; DAS28, Disease Activity Score-28; csDMARD, conventional synthetic disease-modifying anti-rheumatic drug; MTX, methotrexate; OD, other conventional synthetic disease-modifying anti-rheumatic drugs than methotrexate. The differences between DAS28 groups were analysed considering p-value<0.05 as statistically significant result.

Baseline patients' characteristics	Total patients (n=62)	DAS28>2.6 (n=32; 52%)	DAS28≤2.6 (n=30; 48%)	p-value
Age (years)	53±12	53±13	52±10	0.8
Female	55 (89)	30 (94)	25 (83)	0.2
Disease duration (years)	8 (4-11)	8 (4-12)	7 (3-11)	0.7
RF positive	49 (79)	23 (72)	26 (87)	0.1
ACPA positive	54 (87)	26 (81)	28 (93)	0.2
Smoking habit (n=55)				0.2
Non-smokers	26 (47)	16 (55)	10 (38)	
Smoker	29 (53)	13 (45)	16 (51)	
Body mass index (kg/m^2)	25.9±5.6	25.8±5.7	26.0±5.6	0.9
DAS28	4.9±1.0	5.4±0.9	4.3±0.9	**<0.0001**
Concomitant csDMARDs	60 (97)	32 (100)	28 (93)	0.3
MTX [±OD]	46 (74)	26 (81)	20 (67)	0.3
Only OD	14 (23)	6 (19)	8 (26)	0.3
Prednisone	36 (58)	19 (59)	17 (57)	0.9

Conclusion: Our results show that the proinflammatory IL10 B/TNF CD4 ratio is associated with non-REM status. It could be useful to analyse the success of TNFi treatment in patients with RA.

Background: Previously, the results of phase II AURORA clinical study of levilimab in subjects with active rheumatoid arthritis (RA) have been reported[1]. Here we report topline 24-weeks results of preliminary primary efficacy and safety analysis of phase 3 double-blind, placebo-controlled randomized clinical study (SOLAR).

Objectives: To confirm that levilimab in combination with methotrexate is superior to placebo in combination with methotrexate in achieving ACR20 at week 12 and low disease activity (LDA) at week 24 in subjects with methotrexate (MTX) resistant active RA.

Methods: The study is ongoing at 21 clinical sites in Russia and Belarus. All randomized subjects have completed 24 weeks of study between November 2019 and January 2021.

154 adults, aged ≥18 years with the diagnosis of RA (ACR 2010) for at least 24 weeks, and confirmed disease activity at screening despite treatment with MTX for the last 12 weeks (in a stable dose 15-25 mg/week, for at least 4 weeks) were randomly assigned (2:1) to receive either levilimab (162 mg, SC, QW) + MTX (n=102) or placebo + MTX (n=52). The randomization and treatment allocation were carried out by a central computer-based system. Subjects, caregivers, and those assessing the outcomes were blinded to group assignment.

The hypothesis of superiority of levilimab over placebo was tested for two co-primary efficacy outcomes: proportion of subjects who achieved ACR20 at week 12 and proportion of subjects who achieved LDA of RA (DAS28-CRP <3.2) at Week 24 of the study.

For ethical reasons, subjects who haven't achieved minimal clinical response at week 12 (≥20% reduction in the number of tender/swollen joints; 66/68) received rescue therapy at the discretion of the Investigator, and all subsequent efficacy assessments for those were considered missing.

For the primary efficacy analysis, subjects with missing data due to study discontinuation or rescue therapy prescription were considered non-responders (non-responder imputation, NRI). Otherwise, the analysis was performed on observed cases.

Safety was assessed through monitoring of adverse events (AEs).

Results: The primary analysis was based on 149 randomized subjects (n=99 and n = 50) for ACR20 and 154 randomized subjects (n= 102 and n = 52) for LDA. 70/99 (71%) of subjects who received levilimab and 20/50 (40%) who received placebo achieved ACR20 response at week 12. The difference in proportion was 30% with a lower bound of 97.5% CI 12.8%; p=0.0003 (Pearson's chi-squared test).

53/102 (52%) of subjects received levilimab and 3/52 (6%) received placebo achieved LDA at week 24. The difference in proportion was 46% with a lower bound of 97.5% CI 31.2 %; p<0.0001 (Pearson's chi-squared test).

The safety population included all subjects, who received investigational product (n=154).

The most common adverse events (reported in ≥5% of subjects) in levilimab and placebo arms, respectively were: blood cholesterol increase (19% vs. 10%), ALT increase (11% vs. 8%), lymphocyte count decrease (9% vs. 8%), blood bilirubin increase (11% vs. 0%), blood triglycerides increase (9% vs. 2%), AST increase (7% vs. 4%), IGRA with *M.tuberculosis* antigen positive (5% vs. 6%), ANC decrease (8% vs. 0%). No deaths were occurred.

Conclusion: The study confirmed superior efficacy of levilimab + MTX over placebo + MTX in subjects with MTX resistant active RA. No new safety signals were detected.

Trial registration: Clinicaltrials.gov identifier NCT04397562

POS0625 ASSOCIATIONS OF REMISSION AND PERSISTENCE OF BIOLOGICS AT 1 AND 12 YEARS

K. Murray[1], M. Turk[1], Y. Alammari[1], F. Young[1], P. Gallagher[1], T. P. Saber[1], U. Fearon[2], D. Veale[1]. [1]*Saint Vincent's University Hospital, Rheumatology, Dublin 4, Ireland*; [2]*Trinity College, Trinity Biomedical Sciences Institute, Dublin, Ireland*

Background: Biologic therapies have greatly improved outcomes in rheumatoid arthritis (RA) and psoriatic arthritis (PsA). Yet, our ability to predict long-term remission and persistence or continuation of therapy remains limited.
Objectives: To compare RA and PsA outcomes at 1 and 12 years after commencing biologic DMARDs and to identify predictors of remission and persistence of therapy.
Methods: RA and PsA patients were prospectively recruited from a biologic clinic. Outcomes on commencing therapy, at 1 year and 12 years were reviewed. Demographics, medications, morning stiffness, patient global health score, tender and swollen joint counts, antibody status, CRP and HAQ were collected. Outcomes at 1 and 12 years are reported and predictors of EULAR-defined remission (DAS28-CRP <2.6) and biologic persistence are examined with univariate and multivariate analysis.
Results: A total of 403 patients (274 RA and 129 PsA) were analysed. PsA patients were more likely to be male, in full-time employment and have completed higher education. PsA had higher remission rates than RA at both 1 year (60.3% versus 34.5%, $p<0.001$) and 12 years (91.3% versus 60.6%, $p<0.001$). This difference persisted when patients were matched for baseline disease activity ($p<0.001$). Biologic continuation rates were high for RA and PsA at 1 year (49.6% versus 58.9%) and 12 years (38.2% versus 52.3%). In PsA, patients starting on etanercept had lower CRP at 12 years ($p=0.041$). Multivariate analysis showed 1-year continuation [OR 4.28 (1.28–14.38)] and 1-year low-disease activity [OR 3.90 (95% CI 1.05–14.53)] was predictive of a 12-year persistence. Persistence with initial biologic at 12 years [OR 4.98 (95% CI 1.83–13.56)] and male gender [OR 4.48 (95% CI 1.25–16.01)] predicted 12 year remission.
Conclusion: This is the first real world data to show better response to biologic therapy in PsA compared to RA at 12 years. Long-term persistence with initial biologic agent was high and predicted by biologic persistence and low-disease activity at 1 year. Interestingly, PsA patients had higher levels of employment, educational attainment, and long-term remission rates compared to RA patients.

POS0626 MONEY MATTERS: ASSESSING THE VALUE OF THE ADALIMUMAB BIOSIMILAR SWITCH FOR RHEUMATOLOGY PATIENTS

S. Gohil[1]. [1]*University Hospitals of Coventry and Warwickshire NHS Trust, Pharmacy, Coventry, United Kingdom*

Background: The adalimumab biosimilar switch plan, actioned 2018-19 was one of the most complex of all biologic switches across several specialties. Non-medical switches are considered to ensure the best value medicines are prescribed for patients in line with NICE Technology Appraisals.
Objectives: This 2 year follow up review explores the value of the switch for Rheumatology (R) patients in comparison to two other major specialisms; Dermatology (R) and Gastroenterology (G).
Methods: 403 homecare (HC) patients had been identified as eligible for switch to a citrate containing biosimilar (R;189, G;176, D;38) between April-December 2019. 35 hospital FP10 patients receiving the citrate-free originator biologic were also identified for switch to the citrate containing biosimilar and prescription processing via HC (R; 24, G; 9, D;2). Biosimilar switch information was communicated via patient letters/clinic reviews. FP10 patients also received remote pharmacist telephone support, as part of a PDSA (Plan, Do, Study, Act) quality improvement pilot. Data in regard to switch refusal, treatment cessation, withheld treatment and patient satisfaction ratings for pharmacist phonecalls (1 = unsatisfactory, 5=very satisfied) was documented.
Results: 235/403 HC patients successfully switched (R;99, G;107, D;29). 64/403 HC patients switched back to the originator (R;47, G;12; D;5). Of the 64 switch back HC patients; 52% = reported lack of efficacy; 27% = injection site pain and 21% = various other factors such as blepharitis, insomnia and hair loss. 38/403 HC patients refused the switch and remained on the originator biologic (R;11, G;27, D;0). 31/403 HC patients switched to an alternative biologic (R;19, G;9, D;3). 32/403 HC patients stopped treatment (R;13, G;19, D;0). Treatment was withheld for 3/403 HC patients (R;0, G;2, D;1). 100% of FP10 patients switched to HC. 31/35 FP10 patients switched to the biosimilar (R; 22, G; 7, D; 2). 3/31 patients switched back to the originator due to lack of efficacy or side effects. 4 patients refused the switch to biosimilar (R;3, G;1, D;0). 89% of patients were very satisfied with the pharmacist telephone support.
Conclusion: In summary, 58% of all eligible HC patients switched in comparison to 89% of FP10 patients who received pharmacist telephone support; total cost saving following HC and FP10 switch = £270,000. Rheumatology demonstrated the least success in HC switching (52%) and the highest HC switch back figure (25%). Injection site pain and subjective lack of efficacy appear to be the main reasons for ongoing switch backs. The PDSA project demonstrates that a thorough pharmacist assessment of patient concerns in rationalising the use of a biologic agent versus biosimilar can be valuable for patients. Further cost effective adalimumab biosimilars have recently been launched. This seminal review emphasises the ongoing need for robust critical appraisals of biosimilars, with consideration for both clinical and cost effective parameters, before establishing their placement in treatment pathways.

Background: Adiponectin is an adipokine with anti-inflammatory, anti-atherosclerotic and cardioprotective effects that also contributes to the pathogenesis of metabolic syndrome (MetS) [1]. MetS is frequently observed in patients with rheumatoid arthritis (RA), increasing the risk of cardiovascular (CV) morbidity and mortality in these patients [1-3]. A recent study of our group disclosed a short-term effect of anti-IL-6 therapy on serum levels of leptin (another adipokine with pro-inflammatory functions, related with MetS and CV disease) in RA patients [4]. Accordingly, it is plausible to think that such treatment may also have an effect in adiponectin levels.
Objectives: To determine the short-term effect of the anti-IL-6 receptor tocilizumab (TCZ) administration on circulating adiponectin serum levels in patients with RA, as well as the potential association of adiponectin with demographic and clinical features of these patients.

Methods: 50 consecutive Spanish patients undergoing periodic treatment with TCZ who fulfilled the 2010 classification criteria for RA [5] were recruited. Adiponectin serum levels were assessed in samples obtained immediately prior to (pre-infusion) and 60 minutes after the end of a TCZ intravenous infusion (post-infusion) by a commercial Enzyme-Linked ImmunoSorbent Assay (ELISA) kit.
Results: Similar serum levels of adiponectin were found following the TCZ infusion (mean ± standard deviation: 23.01 ± 18.58 µg/mL *versus* 22.35 ± 17.84 µg/mL, pre- and post-infusion, respectively, p=0.69). Additionally, there was a negative correlation between adiponectin basal levels and body mass index (r=-0.45, p<0.01), insulin (r=-0.33, p=0.02), insulin/glucose index (r=-0.32, p=0.03) and C-peptide levels (r=-0.32, p=0.03) of RA patients, whereas a strong positive correlation was observed with HDL-cholesterol levels (r=0.51, p<0.01). Moreover, basal levels of adiponectin were significantly lower in obese patients when compared to those with normal weight (p=0.03).
Conclusion: Our study suggests that anti-IL-6 therapy has no short-term effect on adiponectin serum levels in patients with RA. Furthermore, our results support that low adiponectin levels are associated with MetS features and, therefore, with CV disease in RA.

POS0628 FAILURE TO SUSTAIN TREATMENT TARGET AFTER TAPERING TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS: 4-YEAR LONGITUDINAL DATA FROM A NATIONWIDE COHORT

J. W. Park[1], M. J. Kim[2], H. A. Kim[3], J. Kim[4], E. B. Lee[1], K. Shin[2]. *[1]Seoul National University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[2]Seoul Metropolitan Government - Seoul Boramae Medical Center, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[3]Ajou University School of Medicine, Department of Rheumatology, Suwon, Korea, Rep. of (South Korea)*; *[4]Chungnam National University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Daejeon, Korea, Rep. of (South Korea)*

Background: Tapering biologic therapy after achieving clinical remission or low disease activity (LDA) has become a viable option in daily clinical practice of treating patients with rheumatoid arthritis (RA). There are yet few studies investigating its effectiveness and safety compared with those of standard biologic treatment, especially with non-tumor necrosis factor inhibitors.
Objectives: To investigate the effectiveness and safety of tapering tocilizumab (TCZ) in patients with RA who attained LDA after TCZ therapy.
Methods: Data were collected from a nationwide cohort of patients with RA receiving biologic therapy in South Korea (KOBIO-RA). This study included 350 patients who were treated with TCZ and achieved Clinical Disease Activity Index (CDAI)-LDA or remission (CDAI ≤ 10) after one year of treatment. We performed a longitudinal analysis utilizing clinical data measured in all 1-year intervals using generalized estimating equations (GEE). A total of 575 one-year intervals were divided into two groups according to the dose quotient (DQ, 0-100%) of TCZ within the interval (tapering group vs. standard treatment group). The main outcome of this study was loss of CDAI-LDA in the following 1-year interval.
Results: Tapering TCZ was conducted in 282 (49.0%) intervals with a mean (SD) DQ of 66.0 (15.5). Loss of CDAI-LDA occurred in 91 (15.1%) intervals. Multivariable GEE showed significantly increased loss of CDAI-LDA (adjusted OR (95% CI): 1.76 [1.01 to 3.07]) in the tapering group after adjusting for previous biologics use, route of TCZ administration, concomitant glucocorticoid use, and CDAI measured in the previous follow-up. In addition, the likelihood to achieve DAS28-deep remission (DAS28-ESR < 1.98) was also significantly lower in the tapering group (adjusted OR 0.68 [0.46 to 0.99]). In contrast, there was no significant difference in the proportion of fulfilling other remission criteria between the two groups (Table 1). Development any adverse drug event or event of special interest was comparable in both groups except for hypercholesterolemia, which was lower in the tapering group.

Table 1. The effect of tapering tocilizumab on achieving outcomes

	Loss of CDAI-LDA	DAS28-remission	DAS28-deep remission	CDAI-remission	SDAI-remission	ACR/EULAR remission
Unadjusted OR (95% CI) (vs. standard-dose group)	1.02 (0.67 to 1.55)	1.03 (0.71 to 1.49)	0.76 (0.54 to 1.06)	1.23 (0.75 to 2.00)	0.92 (0.59 to 1.44)	0.98 (0.65 to 1.48)
Adjusted OR (95% CI) (vs. standard-dose group)	**1.76 (1.01 to 3.07)**	0.87 (0.54 to 1.38)	**0.68 (0.46 to 0.99)**	0.94 (0.57 to 1.55)	0.87 (0.54 to 1.38)	0.76 (0.50 to 1.18)

CDAI, clinical disease activity index; CI, confidence interval; DAS, disease activity score; LDA, low disease activity; OR, odds ratio; SDAI, simplified disease activity index.

Conclusion: Tapering TCZ after achieving LDA in patients with RA increases the risk of losing the benefit of LDA without a significant merit in safety.

POS0629 PREDICTORS OF CHANGE IN DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS AFTER START OF TREATMENT WITH ABATACEPT

J. Liukkonen[1], G. Cagnotto[1,2], J. Å. Nilsson[1,2], S. Saevarsdottir[3,4], C. Turesson[1,2]. *[1]Lund University, Rheumatology, Department of Clinical Sciences, Malmö, Malmö, Sweden*; *[2]Skåne University Hospital, Department of Rheumatology, Malmö, Sweden*; *[3]Karolinska Institutet, Division of Clinical Epidemiology, Department of Medicine, Stockholm, Sweden*; *[4]University of Iceland, Faculty of Medicine, School of Health Sciences, Reykjavik, Iceland*

Background: Abatacept is a biologic disease-modifying anti-rheumatic drug (bDMARD) used to treat rheumatoid arthritis (RA) since 2006, acting by inhibition of T-cell co-stimulation. There are limited data on factors predicting clinical outcomes in RA after start of treatment with abatacept.
Objectives: The primary aim was to identify predictors of change in disease activity in RA-patients after start of treatment with abatacept.
Methods: This cohort study was based on data from the Swedish Rheumatology Quality register (SRQ). All patients with RA who started treatment with abatacept between 2006 and 2017 were included. Clinical data from the SRQ included demographics, disease characteristics and antirheumatic treatment. Disease activity was measured according to DAS28-ESR (Disease Activity Score of 28 joints based on erythrocyte sedimentation rate) at inclusion and at follow-up visits at 6 and 12 months from start of treatment with abatacept. Baseline predictors of change in disease activity were investigated using linear regression models bivariately and adjusted for baseline values of DAS28. Covariates with a p-value of <0.1 were retained for the final multivariate model. In case of covariates with major collinearity, the one with the stronger association with change of DAS28 was selected.
Results: In a total of 2716 patients, 872 had data on change in DAS28 at 12 months. Among these, most patients were women (79.6%) and the mean age at start of abatacept was 58.4 years (SD 13.6). The majority of patients had established RA, with a mean disease duration of 13.5 years (SD 11.1). Most patients had severe, active disease, with substantial pain and disability, despite extensive treatment. The mean number of bDMARDs that a patient had been exposed to was 1.90 (SD 1.32). DAS28 decreased significantly over the first year (mean 1.22: 95 % CI 1.12, 1.32). The greatest decrease in DAS28 (mean 1.09) occurred during the first 6 months from start of abatacept. The multivariate regression model identified male sex and limited previous bDMARD exposure as independent predictors of change in DAS28 at 12 months from start of abatacept – adjusted for baseline DAS28, RA duration and current treatment with methotrexate or prednisolone (Table 1).
Conclusion: In this national register study, male sex and limited previous exposure to bDMARDs were independent predictors of reduction of disease activity one year after start of treatment with abatacept for RA, possibly reflecting a better prognosis overall in such patients.

Table 1. Baseline predictors of reduction of disease activity at 12 months from start of abatacept. Linear regression.

POS0630 COMPARISON OF THE EFFICACY AND SAFETY OF ORIGINAL AND BIOSIMILAR ADALIMUMAB MOLECULES IN CHILDHOOD RHEUMATIC DISEASES

K. Ulu[1], F. Demir[1], T. Coşkuner[1], Ş. Çağlayan[1], B. Sözeri[2]. *[1]Umraniye Training and Research Hospital, Pediatric Rheumatology, Istabul, Turkey*; *[2]Umraniye Training and Research Hospital, Pediatric Rheumatology, Istabul, Turkey*

Background: The TNF-α inhibitor adalimumab is a biological disease modifying anti-rheumatic drug (bDMARD) that has been used in different rheumatic diseases with a resistant course. ABP-501 is a biosimilar product (BP) of adalimumab, recently approved by the FDA and EMA. To our knowledge, there is no study assess the efficacy and safety of these two molecules on pediatric patients.

Objectives: We aimed to compare the efficacy and safety of the original and biosimilar adalimumab (ABP-501) molecules in childhood rheumatic diseases.

Methods: This non-interventional, retrospective, single-centre analysis carried out in Umraniye Training and Resrach Hospital, Pediatric Rheumatology Clinic, Istanbul, Turkey. The study group consisted of patients who were followed due to chronic rheumatic disease between January 1, 2016 and June 1, 2020, and received reference or biosimilar adalimumab therapy for at least three months. Demographic and clinical data of patients were collected at baseline, 3rd, 6th, and 12th months of treatment. Disease activity assessment was made with JADAS-27 in JIA patients, with SUN criteria in uveitis patients, and with Behçet's Disease Activity Index in BD patients. Efficacy and safety of treatments were compared between reference and biosimilar adalimumab groups.

Results: A total of 89 patients (65 with original and 24 with biosimilar molecule) treated with adalimumab, were included in the study. There were 45 female and 44 male in the study, and the median age at the initiation of the adalimumab was 166 months (min-max: 36-231). Of the 89 patients evaluated, the primary diagnoses of 62 were juvenile idiopathic arthritis, 13 were idiopathic uveitis, eight were Behçet's disease, three were Blau syndrome, two were chronic recurrent multifocal osteomyelitis and one was Vogt-Koyanagi-Harada syndrome. 63 of the patients were biologic-naïve, and 13 were switched from etanercept, 11 from infliximab, and two from other bDMARDs. The median exposure time of adalimumab was 16 months (min-max:3-70) in RP and 14.5 months (min-max: 3-23) in BP. All patients had active disease before treatment. In the group treated with RP, inactive disease was achieved in 60%, 76.6% and 87.2% of the patients at the 3rd, 6th and 12th months, respectively. Also, inactive disease was achieved in 62.5%, 78.2% and 78.2% of the patients at the 3rd, 6th and 12th months in the group treated with BP, respectively. There was no statistically significant difference in efficacy between the groups at the 3rd, 6th and 12th months (p=0.83, 0.07 and 0.32). Serious adverse events were seen in one patient in each groups (lymphoma in RP group, tuberculous meningitis in BP group). Non-serious adverse events were observed in eight patients (12.3%) in the RP group and in two patients (8.3%) in the BP group, without statistically significant difference between groups (p=0.86).

Conclusion: No significant difference was observed between the biosimilar adalimumab ABP-501 and RP adalimumab in terms of efficacy and safety.

POS0631 COMPARATIVE EFFICACY OF COMBINATION THERAPY WITH BIOLOGIC OR TARGET SYNTHETIC DRUGS FOR RHEUMATOID ARTHRITIS: A BAYESIAN NETWORK META-ANALYSIS

F. Cacciapaglia[1], V. Venerito[1], S. Stano[2], M. Fornaro[1], G. Lopalco[1], F. Iannone[1]. *[1]University and AOUC Policlinico of Bari, Department of Emergency and Organs Transplantation, Bari, Italy*; *[2]School of Medicine University of Bari, Department of Emergency and Organs Transplantation, Bari, Italy*

Background: Biologic agents and small molecules have shown long term benefit when added in patients with active RA non-responders to conventional DMARDs treatment (1). In head-to-head trials only adalimumab was compared to other drugs in combination with methotrexate, with some evidence of superiority but no data on multiple comparisons have been reported (2). The availability of biosimilar agents led in clinical practice to prefer mainly the cheaper one, so the choice of the most effective treatment remains a clinical unmet need (3).

Objectives: To assess the relative efficacy of different therapeutic strategies for achieving ACR50 response at 24 weeks of treatment in patients with active RA, based on direct and indirect evidence.

Methods: We performed systematic reviews of MEDLINE, EMBASE, and Cochrane Library databases, searching for all published phase 3 Randomised Controlled Trials (RCTs) comparing adalimumab originator to its biosimilars, abatacept, baricitinib, certolizumab pegol, tofacitinib or upadacitinib, combined to MTX, in patients with active RA inadequate responders to previous conventional DMARDs. American College of Rheumatology (ACR) 50% response at 24 weeks of treatment had to be evaluated both in adalimumab branch and in examined drug branch. Bayesian fixed-effect network meta-analysis was performed to combine the direct and indirect evidence using the WinBUGS 1.4 software (MRC Biostatistics Unit, Cambridge, UK).

Results: Eleven RCTs evaluating 6'004 patients were included in the analysis, namely originator (1) and biosimilars (2) adalimumab, abatacept (3), baricitinib (4), certolizumab pegol (5), tofacitinib (6) and upadacitinib (7). Convergence was reached at n.100'000 iterations. Upadacitinib seems to be more effective than both originator and biosimilar adalimumab in achieving ACR 50 (OR 1.65 95% CI 1.25-2.14 and OR 1.22 95%CI 1.10-2.18; see Figure 1). Similarly, tofacitinib was more effective of originator adalimumab (OR 1.25 95%CI 1.01-155). Upadacitinib was ranked first among treatments with a probability of being the agent more likely to induce ACR 50 response of 86.3%. In this regard tofacitinib had a probability of 4.8%, hence it was ranked second among treatments.

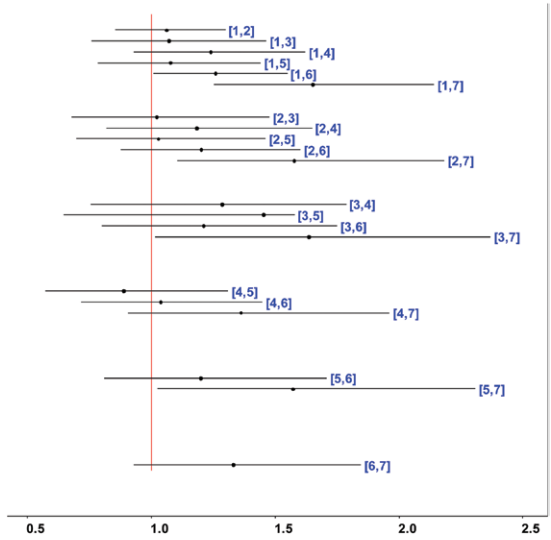

Figure 1. Caterpillar plot OR for ACR50 at 24 weeks (originator [1] and biosimilars [2] adalimumab; abatacept [3]; baricitinib [4]; certolizumab pegol [5]; tofacitinib [6]; upadacitinib [7]).

Conclusion: Although patients with active RA and inadequate response to MTX have different therapeutic combination of biologics or small molecules options, the best relative efficacy in terms of ACR50 response after 24 weeks of treatment is for upadacitinib 15 mg/day.

POS0632 THE LONGITUDINAL ASSOCIATIONS OF METHOTREXATE AND BIOLOGIC USE ON HOSPITAL ADMISSION FOR RHEUMATOID ARTHRITIS PATIENTS IN WESTERN AUSTRALIA POPULATION (1995- 2014)

K. Almutairi[1], J. Nossent[1], D. Preen[2], H. Keen[1], C. Inderjeeth[1]. [1]*The University of Western Australia, School of Medicine, Perth, Australia*; [2]*The University of Western Australia, School of Population and Global Health, Perth, Australia*

Background: Rheumatoid arthritis (RA) carries a substantial burden for patients and society in terms of morbidity, enduring disability, and costs [1]. The Australian Pharmaceutical Benefits Scheme (PBS) has subsidised biological disease-modifying anti-rheumatic drugs (B-DMARDs) since 2003 [2].

Objectives: We examined the impact of B-DMARDs availability on RA hospitalisation rate in the Western Australia (WA) population pre- and post- B-DMARDs introduction to the PBS (1995-2002 and 2003-2014).

Methods: Population PBS dispensing data for WA of DMARD were obtained and converted to defined daily doses (DDD)/1000 population/day using the WA population census. RA inpatient records were extracted from the WA Hospital Morbidity Data Collection using ICD-9 codes 714 and ICD-10 codes M05.00–M06.99). Principal component analysis (PCA) was applied to determine the relationship between DMARDs use and RA hospital admission rates.

Results: There was a total of 17,125 patients who had 50,353 admissions with a diagnostic code for RA during the study period. DMARD use for RA rose from 1.45 to 3.19 DDD/1000 population/day over 1995-2014 (Figure 1). In 1995-2002, the number of RA admissions fell from 7.9 to 2.6 per 1000 hospital separations, then dropped further from 2.9 to 1.9 per 1000 hospital separations in 2003-2014. Based on PCA analysis, conventional DMARDs (methotrexate) and B-DMARDs dispensing had an inverse association with hospital admissions for RA.

Conclusion: The increased availability of conventional and biological DMARDs for RA was associated with a significant decline in hospital admissions for RA patients in WA.

POS0633 DURATION OF STARTING BDMARDS ARE ALMOST 3 TIMES LONGER IN RA PATIENTS THAN PSA PATIENTS: HUR-BIO REAL LIFE RESULTS

G. K. Yardımcı[1], B. Farisoğulları[1], E. C. Bolek[1], E. Bilgin[1], E. Duran[1], G. Ayan[1], Z. Özsoy[1], G. Sandal Uzun[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], A. İ. Ertenli[1], U. Kalyoncu[1]. [1]*Faculty of Medicine; Hacettepe University, Rheumatology, Ankara, Turkey*

Background: Before using biological DMARDs, EULAR suggests the use of synthetic DMARDs (especially methotrexate) for RA and PsA [1-2].

Objectives: It was aimed to evaluate the differences of disease duration and csDMARDs till first bDMARD in RA and PsA patients.

Methods: HUR-BIO (Hacettepe University Biologic Registry) is a prospective, single center database of biological treatments since 2005 and to date 2070 RA and 520 PsA patients have been recorded. Demographic, clinical and laboratory data before bDMARDs of the patients were noted. When investigating the differences between groups, the effects of gender, age and disease duration wereadjusted using two-way ANOVA and ANCOVA tests. The selection was made for the gender, age and for indifference of the relevant groups by using prospensity score matching.

Results: We incuded 481 RA, and 482 PsA age and gender matched patients in the study. Age, gender and disease duration information were given in the Table 1. 72.8% of the RA patients were RF or anti-CCP positive. Overall, 56.3, 100% of the RA, and PsA patients first biologic therapies were anti-TNFs, respectively. All RA patients started with csDMARDs before bDMARD treatments, whereas 450 of 482 (93.4%) PsA patients. Methotrexate was the anchor csDMARD for both diseases. RA patients more frequently used all csDMARDs included methotrexate, leflunomide, sulphasalazine hydroxychloroquine and corticosteroids as well. Median disease duration till bDMARD treatments in RA and PsA patients were 55 and 18.5 months respectively (p<0.001) (Table 1).

Table 1. Demographic characteristics and csDMARDs before first bDMARD

		RA (n=481)	PsA (n=482)	P value
Female, n (%)		319 (66.3)	332 (68.9)	0.218
Age, years (mean±SD)		48.2 ± 13.5	47.4 ± 12.2	0.332
Disease duration, years*		10 (6-16)	7 (3-12)	**0.000**
Symptom duration before diagnosis, years¥		0 (0-1)	1 (0-4)	**0.000***
The period of time between diagnosis and bDMARD initiation, months¥		55 (24-115)	18.5 (8-58)	**0.000***
The period of time between symptoms and bDMARD initiation, months¥		70 (35-151)	48 (20-124)	**0.000***
Methotrexate	**Ever n (%)**	400 (83.3)	373 (77.5)	**0.015**
	Just before bDMARD initiation n (%)	251 (52.2)	230 (47.7)	0.093

	Just before bDMARD initiation n (%)	262 (54.5)	99 (20.5)	**0.000***
Leflunomide	**Ever n (%)**	237 (49.4)	129 (26.8)	**0.000***
	Just before bDMARD initiation n (%)	160 (33.3)	96 (19.9)	**0.000***
Sulphasalazine	**Ever n (%)**	353 (73.5)	265 (55.1)	**0.000***
	Just before bDMARD initiation n (%)	156 (32.4)	146 (30.3)	0.259*
Corticosteroids	**Ever n (%)**	419 (87.3)	281 (58.4)	**0.000***
	Just before bDMARD initiation n (%)	335 (69.6)	187 (38.8)	**0.000***

¥Median (IQR)

Conclusion: According to HUR-BIO real life data, for inflammatory arthritis patients who started bDMARDs, the periods of time between diagnosis and bDMARDs were more reasonable (18 months) in PsA patients than RA patient's periods which were approximately three times longer. RA patients were used much more and longer duration of csDMARDs. This explicit distinction may be explained by synthetic DMARDs on activity differences between the RA and PsA.

POS0634 DO BIOLOGICS IMPROVE FATIGUE IN PATIENTS WITH RHEUMATOID ARTHRITIS?

A. Fazaa[1], H. Boussaa[1], K. Ouenniche[1], S. Miladi[1], M. Sellami[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim University Hospital, Rheumatology, Sidi Daoud, Tunisia*

Background: Fatigue is a significant issue in rheumatoid arthritis (RA) with no accepted evidence-based management guidelines. Several studies suggested that biologic Disease Modifying Anti-Rheumatic Drugs (bDMARDs) have a direct role on fatigue in RA.
Objectives: This study aimed to compare fatigue between patients treated with bDMARDs and conventional synthetic Disease Modifying Anti-Rheumatic Drugs (cs DMARDs).
Methods: We conducted a longitudinal study including patients with RA (ACR/EULAR 2010). Patients with other acute or chronic diseases that may induce fatigue (such as cancer, infection or depression) were excluded. Demographic data and the following disease-related parameters were collected: pain Visual Analog Scale (VAS), Global Patient Assessment (GPA), tender joint count (TJC), swollen joint count (SJC), Erythrocyte Sedimentation Rate (ESR), C Protein Reactive (CRP), Disease Activity Score 28 (DAS28), Health Assessment Questionnaire (HAQ) and DMARDs used. Fatigue was assessed at baseline (T0), at 6 months (T6) and at 12months (T12) using the Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) which is a short 13-item questionnaire validated in RA. The score FACIT-F ranges between 0 and 52. Fatigue was considered mild if the FACIT-F score was ≥40, moderate if 20≤FACIT-F<40 and severe if 0≤FACIT-F<20. A p value inferior to 0.05 was considered significant.
Results: We included 100 RA patients (84 women and 16 men) with a mean age of 49.5±10 years old [18-65]. The mean disease duration was 87.3 months [1-360]. The mean pain VAS was 49 cm [0-100] and the mean GPA was 47.8 cm [0-100]. The mean TJC and SJC were 5.3 [0-36] and 1 [0-9] respectively. The mean levels of ESR and CRP were 38.1 mm [10-120] and 10.8 mg/l [2-61] respectively. The mean DAS28 ESR was 3.68 [1.90-8.33] and the mean HAQ score was 0.90 [0-2.75].
Eighty-three percent of patients used csDMARDs: Methotrexate (n=96), sulphasalazine (n=28), leflunomide (n=21), and hydroxychloroquine (n=12). bDMARDs were prescribed in 17% of patients: Rituximab (n=10), Infliximab (n=9), and Etanercept (n=5).
At baseline, the mean FACIT-F score was 27.1 [0-51]. Moderate fatigue was noted in 57% of cases and severe fatigue in 26% of cases. Patients on csDMARDs had a lower FACIT-F score when compared to patients on bDMARDs (26.89 versus 28.41), but the difference was not statistically significant (p=0.630).
The mean FACIT-F score was 27.41 in bDMARDs patients versus 29.80 in csDMARDs patients (p=0.497) at T6, and 32.35 versus 33.65 respectively at T12 (p=0.695).
The mean delta FACIT-F was 2.18 in bDMARDs patiens versus 2.73 in csDMARDs patients between T6 and T0 (p=0.815), and 3.94 versus 7.2 respectively between T12 and T0 (p=0.807).
When considering all patients, a significant positive correlation was noted between delta FACIT-F and delta DAS28 at T6 (r=0.418, p<0.001) and at T12 (r=0.338, p<0.001).
Conclusion: RA patients treated with bDMARDs didn't show significant improvement of fatigue in comparison with those treated with csDMARDs. Further studies are needed to determine if biologics improve fatigue, and whether the improvement results from a direct action on fatigue or indirectly through reduction in disease activity.

POS0635 COMPARING THE ULTRASONOGRAPHIC EVALUATION IN PATIENTS WITH JAPANESE RHEUMATOID ARTHRITIS BETWEEN BARICITINIB AND TNF ANTAGONIST THERAPY

Y. Kanayama[1], A. Nagata[2], M. Shimotake[2], F. Miyachi[2], K. Fujita[2], M. Koyama[2], S. Uno[2]. [1]*Toyota Kosei Hospital, Orthopedic Surgery and Rheumatology, Toyota, Japan*; [2]*Toyota Kosei Hospital, Clinical Technology, Toyota, Japan*

Background: Baricitinib (BAR) and TNF antagonist are the important therapeutic agent for the treatment of rheumatoid arthritis.However there is still few studies of improvement of ultrasonographic findings in RA treated comparison with BAR and TNF.
Objectives: To evaluate the clinical efficacy of BAR and TNF therapy patients with rheumatoid arthritis (RA) using ultrasonography (US).
Methods: Participants comprised 16 and 45 Japanese RA patients who had recently received BAR and TNF. All patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria. Patients underwent clinical and laboratory assessments every 4 weeks from baseline to 24 weeks, and US assessments at baseline, 4, 12 and 24 weeks. Gray scale (GS) and power doppler (PD) signals were scored using a semi-quantitative scale from 0 to 3 at 26 (0-78) synovial sites (22 joints) in the following joints: bilateral first to fifth metacarpopharangeal (MCP) joints (dorsal recess); first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) (dorsal recess) joints; and the wrists (dorsal radial, median and ulnar). We evaluated the improvement of GS and PD score from baseline to week 24.
Results: In the patients receiving BAR (n=16) and TNF (n=45), the mean age was 55.9 vs 54.6 years old (p=0.682), disease duration was 10.2 vs 6.1 years (p=0.094), the rate of MTX use was 75% vs 89% (p=346), the mean MTX dose was 9.3 vs 10.2 mg/w (p=0.443), the rate of ACPA positive was 94% vs 82% (p=0.476), DAS28-ESR was 4.25 vs 4.61 (p=0.289), CDAI was 15.8 vs 18.5 (p=0.210), GS score was 21.6 vs 16.3 (p=0.436) and PD score was 15.0 vs 9.5 (p=0.260). The degree of improvement respective changes in GS and PD score after 4, 12 and 24 weeks were as follows: GS: -7.2 vs -3.7 (p=0.268) and PD: -7.6 vs -2.3 (p=0.158) after 4 weeks, GS: -10.9 vs -5.0 (p=0.161) and PD: -9.2 vs -3.8 (p=0.049) after 12 weeks, GS: -12.9 vs -6.1 (p=0.485) and PD: -11.3 vs -5.7 (p=0.062) after 24 weeks between BAR and TNF (Fig.1, 2). Next, The improvement rate of respective changes in GS and PD score after 4, 12 and 24 weeks were as follows: GS: -23.8% vs -11.6% (p=0.580) and PD: -30.3% vs -16.5% (p=0.343) after 4 weeks, GS: -39.6% vs -15.6% (p=0.129) and PD: -47.1% vs -30.8% (p=0.210) after 12 weeks, GS: -52.2% vs -22.2% (p=0.248) and PD: -77.1% vs -50.1% (p=0.048) after 24 weeks between BAR and TNF.
Conclusion: The present study provides evidence supporting both the BAR and TNF therapy showed improvement effect over time, but in a comparison between BAR and TNF, the PD score of BAR showed a siginificant improvement effect compared to TNF at 12 and 24 weeks. It was suggeted that BAR may improve inflammatory synovitis earlier compared to TNF.

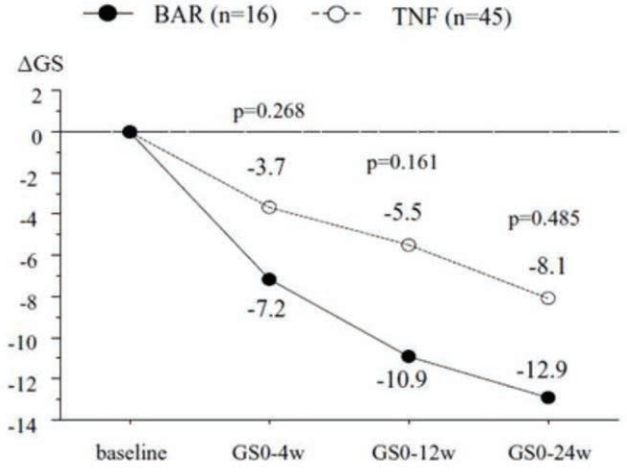

Figure 1 : The degree of improvement respective changesin GS score from baseline to Week 24 between BAR and TNF patients

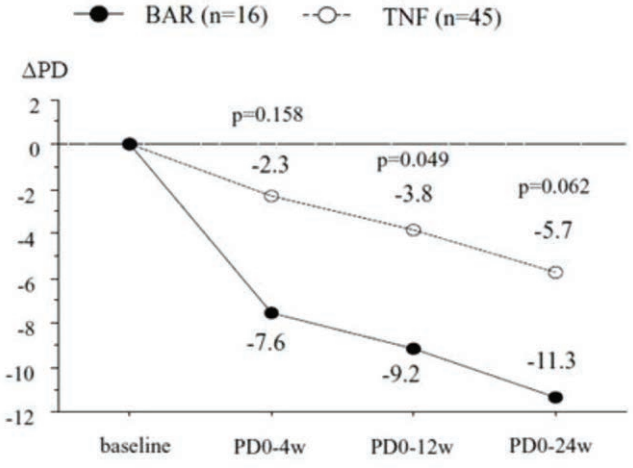

Figure 2 : The degree of improvement respective changesin PD score from baseline to Week 24 between BAR and TNF patients

POS0636

INFLUENCE OF DEMOGRAPHIC AND DISEASE RELATED FACTORS ON EFFICACY OF INFLIXIMAB OR GOLIMUMAB IN RHEUMATOID ARTHRITIS. A META-ANALYSIS ON RANDOMIZED PLACEBO-CONTROLLED TRIALS

M. A. Sparfel[1], S. Derolez[1], J. Law-Wan[1], N. Azzopardi[2], P. Goupille[1], D. Mulleman[1], T. Bejan-Angoulvant[3]. [1]*Université de Tours, EA 7501, Service de Rhumatologie CHRU de Tours, Tours, France*; [2]*Université de Tours, EA 7501, ERL CNRS 7001, Tours, France*; [3]*Université de Tours, EA 4245, Service de Pharmacologie Clinique, CHRU de Tours, Tours, France*

Background: TNF inhibitors have changed the course of rheumatoid arthritis (RA). Yet, detailed analysis on factors influencing clinical response to TNF inhibitors in RA is lacking.
Objectives: Herein we aimed at studying the impact of demographics and disease-related factors on therapeutic response to golimumab and infliximab in RA.
Methods: Randomized clinical trials (RCTs) that evaluated golimumab and infliximab versus placebo or conventional therapy were sought. We selected the following factors: age, sex, ethnicity, body mass index (BMI), smoking status, physical activity, disease duration, disease activity at baseline, presence of auto-antibodies. We studied the impact of these factors on clinical response using firstly aggregate data in a Mantel-Haenszel random effects model, and secondly individual data in a multivariate regression model.
Results: Individual data from 8 RCTs, 2 on infliximab (n=1477) and 6 on golimumab (total =3041) were obtained. In the aggregate model analysis, none of the selected factors had a significant impact on clinical response. In the multivariate analysis, male sex and physical activity were significantly associated with a lower DAS28-CRP after 6 months of treatment (regression coefficients -0.264 ($p<0.001$) and -0.193 ($p=0.004$) respectively), while a high initial DAS28-CRP was significantly associated with a higher DAS28-CRP (regression coefficient 0.579 ($p<0.001$)). The baseline disease activity was the only significant interaction factor with the effect of the treatment.
Conclusion: Male gender and practicing physical activity are associated with lower disease activity 6 months after golimumab or infliximab initiation. High baseline disease activity significantly influences negatively the effect of the treatment on disease activity score.

POS0637

INCIDENCE AND DETERMINANTS ASSOCIATED WITH RETRANSITIONING FROM BIOSIMILAR SB4 TO ORIGINATOR ETANERCEPT

R. Meijboom[1,2], H. Gardarsdottir[2,3,4], M. Becker[1,5], S. Ten Wolde[6], T. Egberts[2,3], T. Giezen[1,2,5]. [1]*Pharmacy Foundation of Haarlem Hospitals, Pharmacy Foundation of Haarlem Hospitals, Haarlem, Netherlands*; [2]*Utrecht Institute for Pharmaceutical Sciences, Division of Pharmacoepidemiology & Clinical Pharmacology, Utrecht, Netherlands*; [3]*University Medical Center Utrecht, Department of Clinical Pharmacy, Utrecht, Netherlands*; [4]*University of Iceland, Department of Pharmaceutical Sciences, Reykjavik, Iceland*; [5]*Spaarne Gasthuis, Department of Clinical Pharmacy, Haarlem and Hoofddorp, Netherlands*; [6]*Spaarne Gasthuis, Department of Rheumatology, Haarlem, Netherlands*

Background: The market entry of the etanercept biosimilar SB4 (BS-ETA) reduced prices; and, therefore, many patients in clinical practice are transitioned from originator etanercept (OR-ETA) to BS-ETA. However, previous studies demonstrated that 2.7-17.1% of patients who transitioned from OR-ETA to BS-SB4, retransitioned to OR-ETA (i.e. restarted originator), which might reduce the (financial) benefits of biosimilars. Insight in the incidence of retransitioning and characteristics of patients who are most likely to retransition, can provide lessons to clinicians for successful introduction of biosimilars.
Objectives: To assess the incidence of retransitioning from BS-ETA to OR-ETA in patients with a rheumatic disease (RD) and to identify determinants thereof.
Methods: All patients diagnosed with RD who transitioned in 2016 from OR-ETA to BS-ETA in a Dutch general teaching hospital (the Spaarne Gasthuis, Haarlem/Hoofddorp) were included in this cohort study. All patients were followed until retransitioning, switching to another biological, discontinuing of biological treatment death, loss to follow up or until censor date. The incidence of retransitioning and duration of BS-ETA use was assessed using the Kaplan-Meier method. Potential determinants for retransitioning, including age, gender, BS-SB4 dosing interval, use of other biologicals prior to OR-ETA, initiation or intensification of corticosteroids or immunomodulators, hospitalisations and the number of outpatient visits to the rheumatology department, were assessed in a nested case control study, using (multivariate) conditional logistic regression.
Results: In total, 342 patients (median age 57.8 years, 53.5% females, median follow-up 2.7 years) were included. 9.4% of patients had retransitioned to OR-ETA one year after transitioning. Additionally, one year after transitioning 69.7% of patients were still treated with BS-ETA, 3.8% switched to other treatment and 17.1% discontinued all biological treatment. At the end of follow-up (median 2,7 years), 46 patients (13.5%) retransitioned to OR-ETA; median time until retransitioning was 0.50 (IQR 0.98) years.
Univariate determinants for retransitioning included female gender (OR 2.37, 95% CI 1.18-7.74), initiating or intensifying corticosteroids or immunomodulators (OR 3.24, 95% CI 1.38-7.63) and number of visits to the rheumatology department (OR 2.32, 95% CI 1.70-3.17). Based on the multivariate analysis, only the number of visits to the rheumatology department was associated with retransitioning (OR 2.19 95% CI 1.60-3.00), as demonstrated in Table 1.
Conclusion: When introducing BS-SB4 in clinical care, clinicians should anticipate on about one in seven patients retransitioning to OR-ETA. These patients might be identified prior to retransitioning based on their contacts to the rheumatology department. Information specifically aiming for their concerns might prevent them from retransitioning. However, more qualitative studies are needed to explore patients' underlying reasons for retransitioning, in order to improve the introduction of biosimilars in clinical care.

DISEASE SEVERITY AND OUTCOMES AMONG PATIENTS WITH RHEUMATOID ARTHRITIS WHO RECEIVE A NEWLY APPROVED BIOLOGIC: REAL-WORLD US EXPERIENCE WITH SARILUMAB FROM THE ACR RISE REGISTRY

S. Fiore[1], L. Chen[2], C. Clinton[2], H. Yun[2], A. Praestgaard[3], K. Ford[2], J. Curtis[2]. [1]*Sanofi, Sanofi, Bridgewater, United States of America*; [2]*University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, United States of America*; [3]*Sanofi, Sanofi, Cambridge, United States of America*

Background: Patients with rheumatoid arthritis (RA) who have received multiple biologics or targeted therapies over time tend to have more refractory and more severe disease, which may lead to worse clinical response to treatment.
Objectives: We used data from the ACR RISE registry to assess whether disease severity was greater in those who received sarilumab shortly after its FDA approval (May 2017) than in subsequent time periods and to evaluate the effectiveness of sarilumab in populations with various degrees of disease severity.
Methods: Patients with RA who initiated sarilumab treatment in the period 2017-2020 were identified in the ACR RISE registry and divided into Cohort 1 (2017, year of the FDA approval) and the calendar year-based Cohorts 2-4 (2018-2020). Patient demographics, RA-related features, and comorbidities were determined using data prior to sarilumab initiation. The cohorts were compared using chi-square test (categorical variables) and a nonparametric test (continuous variables). Sarilumab effectiveness was assessed using 3 cohorts assembled based on progressively restrictive criteria: Active Disease cohort (Clinical Disease Activity Index [CDAI] >10 or Routine Assessment of Patient Index Data 3 [RAPID3] >6, and C-reactive protein, if measured, ≥8 mg/L), TARGET Eligibility cohort (patients who satisfied enrolment criteria for TARGET,[1] a Phase 3 sarilumab trial in patients with RA and an inadequate response to TNF inhibitors), and TARGET Baseline cohort (patients from TARGET Eligibility cohort with characteristics weighted to match those from the TARGET trial baseline,[1] using the matching-adjusted indirect comparison method[2]). In all 3 effectiveness cohorts, mean changes in CDAI and RAPID3 at 6 and 12 months post-initiation of sarilumab were evaluated using a model adjusted for baseline score, age, sex, race, calendar year, and seropositivity.
Results: A total of 2949 patients, treated by 585 rheumatologists, initiated sarilumab treatment in the period 2017–2020. The 4 yearly cohorts were relatively similar in terms of patients' age, sex, race, and most clinical characteristics. However, patients receiving sarilumab shortly after FDA approval (Cohort 1) had more ambulatory visits, a greater number of previously used non-TNFi biologics (particularly tocilizumab), and a higher comorbidity burden, and were more likely to be current users of glucocorticoids or opioids than sarilumab initiators in the subsequent 3 years. In the 3 cohorts used to assess sarilumab effectiveness, the greatest improvement was observed in the TARGET Baseline cohort, which also had the greatest mean baseline CDAI score (43), compared with the other two (24 both).
Conclusion: In this real-world cohort, we observed modest evidence for channeling of patients with greater RA severity and greater prior exposure to non-TNFi biologics to sarilumab shortly after its FDA approval. This cohort effect did not diminish the effectiveness of sarilumab. All cohorts showed improvement, with the greatest clinical improvement observed in the cohort with the highest baseline CDAI score who most closely resembled those enrolled in a phase 3 trial of patients with an inadequate response to TNF inhibitors.

POS0639 LONG-TERM EFFECTIVENESS OF THE RITUXIMAB HALF DOSE REGIMEN FOLLOWING A RESPONSE TO THE LICENSED DOSE IN RHEUMATOID ARTHRITIS

L. Garcia-Montoya[1,2], M. Y. Md Yusof[1,2], G. Eugénio[1,2], J. B. Candelier[1,2], S. Das[1,2], E. Vital[1,2], P. Emery[1,2]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*; [2]*Leeds Biomedical Research Centre, NIHR, Leeds, United Kingdom*

Background: Following initial treatment with rituximab (RTX) full dose (2x1000mg), B-cell numbers are often lower than baseline. The half dose regime (2x500mg) has been reported to be similarly effective [1]; however, there is limited long-term data on the effectiveness of switching to RTX half-dose from the real-world perspective.
Objectives: To compare the 3-year RTX regime retention between patients receiving retreatment with half-dose and full-dose of RTX, and assess factors associated with maintenance of 2x500mg, with a view to establish an optimal long-term retreatment strategy in RA.
Methods: An observational study was conducted on 755 consecutive RTX-treated RA patients in a single centre for over 20 years. Of these, 165/755 (22%) received at least one cycle of 2x500mg. Long-term effectiveness was assessed using RTX retention rate. Drug survival of patients treated with 2x500mg was compared with 200 RA patients receiving 2x1000mg throughout the study, matched to the number of cycle when the 2x500mg regime was initiated.
Results: Of the 165 patients who received 2x500mg, 81.8% were female; mean age was 63.4 (26-91) years; mean disease duration 15.5 (2-53) years; 57 (34.5%) were bDMARDs-naïve; 121 (74%) were on concomitant DMARDs and mean DAS-28 was 3.9 (SD 1.29) at the half dose initiation. At 3 years, the retention rate was 38% for patients recieving 2x500mg compared to 87% for those on 2x1000mg; HR for half dose discontinuation was 6.17 [95%CI (3.91-12.27); p<0.001] (Figure 1A).
The main reasons for 2x500mg discontinuation were poor EULAR response (30%); moderate EULAR response (30%); shorter duration of response compared to the full dose (22%); and incomplete B-cell depletion (17%). The majority of these patients (87.9%) were switched back to 2x1000mg, 5.1% received other bDMARDs and 7.1% did not receive further DMARDs.
In multivariable analysis, previous TNFi use was associated with 3-year maintenance of the 2x500mg dose [OR 2.63 (1.12-6.10); p=0.024]; while higher plasmablasts at 2x500mg initiation was associated with shorter maintenance of this regime [OR 0.78 (0.67-0.97); p=0.028].
There were no significant differences in 5-year RTX retention rates between patients receiving 2x500mg and switched back to 2x1000mg vs those receiving 2x1000mg throughout the study (Log-Rank=0.186) (Figure 1B).
Conclusion: The use of RTX half-dose regimen was associated with poor retention at 3 years. Nevertheless, where loss of effectiveness occurs post-2x500mg initiation, switching back to 2x1000mg appears to be a pragmatic option. Patients with previous TNFi exposure and lower plasmablasts may be most suited to be commenced on the 2x500mg dose for long-term disease control.

EFFECTIVENESS AND SAFETY OF ORIGINAL AND BIOSIMILAR ETANERCEPT IN BDMARD-NAÏVE PATIENTS IN A REAL-WORLD COHORT OF PORTUGAL

A. S. Pinto[1,2], M. Cunha[3], F. Oliveira Pinheiro[4], M. Bernardes[4], H. Assunção[5], J. Martinho[6], M. C. Tenazinha[6], A. M. Duarte Monteiro[6], S. Silva[7], F. R. Martins[8], L. Silva[9], M. Couto[10], M. Faria[11], F. Araújo[12], T. Fontes[13], D. Faria[2], J. Tavares-Costa[2]. Background: The patent expiration of the original etanercept in Europe has facilitated the development of biosimilar products. Non-significant differences in efficacy and safety were noted in clinical trials which are not expected to influence clinical performance. Nonetheless, daily practice data should be gathered to support the claim for biosimilarity.
Objectives: To compare the effectiveness and safety of original and biosimilar etanercept, in biological-Disease Modifying Antirheumatic Drug (bDMARD)-naïve patients.
Methods: A retrospective multicenter non-interventional study, using data collected prospectively from Reuma.pt (The Rheumatic Diseases Portuguese Register) was done, including patients with: age ≥ 18 years old; diagnosis of Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) or Spondyloarthritis (SpA) (axial or peripheral); active disease who initiated treatment with etanercept as first line of biological treatment after 2010. Kaplan-Meyer was used to calculate the persistence rate in treatment. Disease activity at baseline and follow-up data at 6, 12, 18 and 24 months of treatment was compared using the chi-square for categorical variables and t-student or Mann-Whitney tests for continuous variables. Reasons for discontinuing therapy were summarized using descriptive statistics. Statistical significance was assumed for 2-sided p-values >0.05.
Results: We included 1694 patients (413 on biosimilar and 1280 on original etanercept) 864 with RA, 335 with PsA and 494 with SpA. The population's baseline characteristics were not significantly different among both groups, except concomitant treatment in RA (higher use of conventional DMARDs in biosimilar group and higher use of NSAIDs in original group) and in SpA patients (higher use of corticosteroids in original group).
At baseline, a higher joint count was found in patients treated with original etanercept with a statistical difference for swollen (p=0.03) and tender (p=0.01) joints count (SJC and TJC, respectively) in RA and in TJC in SpA patients (p=0.02). In RA patients, CDAI and SDAI were higher in patients who started original (p=0.03; p=0.04, respectively). Pain measured by visual analogic scale was higher in SpA patients treated with biosimilar (p=0.03).
The 3-year PR was not significantly different between both treatment groups in RA, PsA and SpA (Figure1). In RA, PR in biosimilar was 72.6%, with a median time-on-drug (TOD) of 28.3 months; for original etanercept PR was 63.6%, with a median TOD of 27.4 months (p=0.566). In PsA patients, the PR for biosimilar was 70.6%, with a median TOD of 27.6 months, and in original drug 67.0%, with a median TOD of 28.1 months (p=0.743). In SpA patients, the PR were 78.4% for biosimilar (median TOD of 27.4 months) and 71.5% for original treatment (median TOD of 28.0 months (p=0.816)).

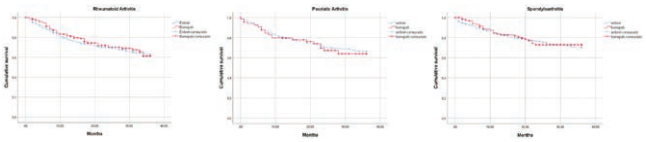

Figure 1. Drug survival in biosimilar and original etanercept in Rheumatoid Arthritis, Psoriatic Arthritis and Spondyloarthritis

In RA patients, we did not find differences between the two treatment groups for the proportion of patients in remission or low disease activity by CDAI ≤10, SDAI≤11 or DAS28 <3.2 at 6, 12, 18 and 24 months of treatment. For PsA, no differences were found in the same timelines for DAPSA≤14, DAS28<3.2, BASDAI<4, ASDAS<2.1 or PsARC response. Also, in SpA patients, no differences were found in BASDAI<4, BASFI<4, ASDAS<2.1, ASDAS response and BASDAI response in all the timelines with the exception of BASDAI response at 18 months, which was achieved in fewer patients in biosimilar therapy (p=0.02).
Overall, 535 (31.6%) patients stopped etanercept (428 patients on original and 107 patients on biosimilar). Discontinuations due to inefficacy were the most frequent, but there were no significant differences between both groups as for adverse events. Discontinuations due to "other reasons" were higher for the original group, both in RA (p=0.01) and in SpA (p=0.04).
Conclusion: Biosimilar and original used as first-line biological treatment showed similar effectiveness and safety in our long-term cohort of patients with RA, PsA, and SpA

POS0641

INCIDENCE OF GASTRO-INTESTINAL COMPLICATIONS IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING BIOLOGICAL DMARDS IN OBSERVATIONAL COHORT STUDIES: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

A. Charlotte[1], D. Jerome[2], C. Lukas[3], C. Rempenault[3], A. Constantin[4], J. Morel[3]. *[1]Lapeyronie Hospital, Montpellier, Rheumatology Department, Montpellier, France*; *[2]Purpan University Hospital and University Toulouse III – Paul Sabatier, Rheumatology Department, Montpellier, France*; *[3]Lapeyronie Hospital, Montpellier, Rheumatology Department, Montpellier, France*; *[4]Purpan University Hospital and University Toulouse III – Paul Sabatier, Rheumatology Department, Toulouse, France*

Background: Rheumatoid arthritis (RA) patients are at increased risk of gastro-intestinal (GI) perforations compared with non-RA patients, resulting in increased mortality. Clinical trials, post-marketing studies and registries have reported an increased risk of GI perforations in RA patients treated with tocilizumab.
Objectives: The aim of our study was to assess the incidence of GI complications among RA patients receiving bDMARDs in observational cohort studies
Methods: A systematic literature review was carried out through September 2020 on the Pubmed, Embase and international congress databases, selecting observational cohort studies assessing the incidence of GI complications, including perforations and diverticulitis, in RA patients receiving bDMARDS. Keywords were "gastrointestinal perforation", "gastrointestinal disease", "diverticulitis", "biological DMARDs" and "rheumatoid arthritis" with no publication date limit. Studies were selected independently by two readers. Data were extracted by one investigator and independently checked by another. A meta-analysis was performed with Review Manager Software, with random-effects models, whenever methodologically possible and relevant.
Results: The literature search revealed 232 articles and abstracts of potential interest, and further examination resulted in 7 studies fulfilling required criteria. Among bDMARDs, Tocilizumab was associated with an increased incidence of GI perforations, with an overall incidence of 2.40 per 1000 person-years (95% confidence interval [95% CI] 1.45-3.35). The overall incidences of GI perforations were 1.01 per 1000 PY [0.75-1.27] for TNF inhibitors, 1.07 per 1000 PY [0.53-1.62] for abatacept and 1.12 per 1000 PY [0.16-2.08] for rituximab (Figure 1). In RA patients treated with tocilizumab, most of the perforations were located in the lower GI tract, with an incidence of 2.24 per 1000 PY [1.24-3.52]. The incidences of upper GI perforations were similar across the different bDMARDs. The incidences of diverticulitis were 4.99 per 1000 PY [4.08-5.99] in RA patients receiving tocilizumab and 1.81 per 1000 PY [1.47-2.19] in those receiving TNF inhibitors.
Conclusion: In our meta-analysis, focused in RA patients receiving bDMARDs in observational cohort studies, tocilizumab was associated with an increased incidence of GI perforations, mainly located in the lower GI tract. An history of diverticulitis and long-term corticosteroid therapy were associated with an increased risk of GI perforations.

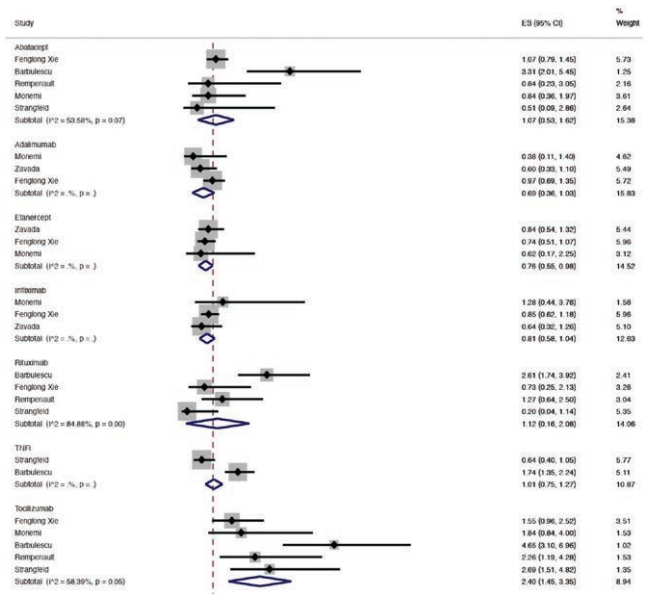

Figure 1. Meta-analysis of the incidences of gastro-intestinal perforations in RA patients receiving bDMARDs in observational cohort studies

POS0642

THE IMPACT OF AGE ON DISCONTINUATION OF BIOLOGIC DMARDs IN PATIENTS WITH RHEUMATOID ARTHRITIS

V. Rivera Teran[1], S. Sicsik[1], D. Vega-Morales[2], F. Irazoque-Palazuelos[1], D. Miranda[2], J. C. Casasola[1], S. Carrilo[2], A. Peña[1], A. Castillo Ortiz[2], O. E. Muñoz-Monroy[1], S. Duran Barragan[2], A. Paz[1], E. Torres Valdéz[2], L. F. Valdés Corona[1], D. X. Xibille Friedmann[2], E. Zamora[1], A. Ramos[2], N. Santana[1], M. Vazquez[2], F. Guerrero[1], C. Zepeda[2], K. Alvarado[1], M. Rivera[2], D. Alpizar-Rodriguez[1]on behalf of Mexican Registry of Adverse Events involving Biological Therapies in Rheumatic Diseases (BIOBADAMEX). *[1]Colegio Mexicano de Reumatología, Unidad de Investigación, Mexico City, Mexico*; *[2]Colegio Mexicano de Reumatología, Unidad de Investigación, Ciudad de México, Mexico*

Background: Rheumatoid arthritis (RA) is the most common autoimmune disease. Older patients treated with biologic DMARDs (bDMARDs) are at a significantly greater risk of adverse effects (AEs) [1]. However, the rate of drug discontinuation because of adverse effects caused by bDMARDs has not differed in elderly compared to younger patients in different registries.
Objectives: Determine if drug discontinuation of bDMARDs differs by age in patients with rheumatoid arthritis in the Mexican Adverse Events Registry (BIOBADAMEX).
Methods: BIOBADAMEX is a Mexican ongoing cohort of patients using bDMARDs since 2016. In this analysis we included all patients with diagnosis of RA with at least two assessments. Survival on bDMARDs was estimated using Kaplan-Meier analysis. Predictors of discontinuation, including age older than median age in the sample were investigated by Cox regression analyses.
Results: Among 743 patients in the registry, 497 had RA diagnosis, from which, 214 had at least two assessments. At baseline, patients had a median (IQR) age of 53.4 (45-61) years old, median disease duration of 10.7 (6-17) months and median DAS28 of 4.7 (3-6). Conventional DMARDS were used by 185 (87%) patients and 94 (44%) patients used corticosteroids. Comorbidities were present in 194 (91%). The most common bDMARDs received at baseline were abatacept 59 (27%), tocilizumab 45(21%), adalimumab 31 (15%) and certolizumab 30 (14%). At the time of analysis, the median bDMARDs treatment duration was 21.0(13-34) months, 128 (59%) had discontinued treatment, 66 for inefficacy, 32 for adverse events and 30 for others. Fig 1 shows discontinuation rate curves in patients younger and older than median age. Cox proportional-hazards demonstrated no significant differences regarding age older than median age (HR 1.1, 95% CI 0.8-1.4, p=0.7), female sex (HR 1.2, 95% CI 0.7-1.9, p=0.44), use of corticosteroids (HR 1.2, 95% CI 0.9-1.6, p=0.20), comorbidities (HR 0.9, 95% 0.6-1.5, p=0.78), DAS28 (HR 0.9, 95% 0.9-1.1, p=0.93) or other factors.
Conclusion: This analysis did not show a role of age on discontinuation of bDMARDs in Mexican RA patients. Further longitudinal analyses will be performed including more patients to assess retention rate of bDMARDs and identify predictive variables of discontinuation in Mexican population.

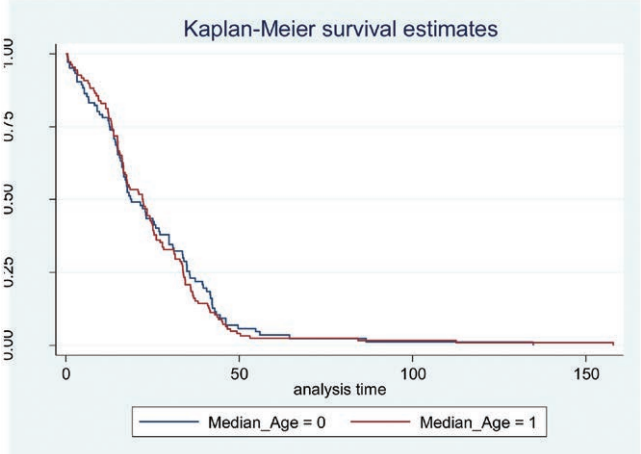

Figure 1. Discontinuation rate curves in patients younger and older than median age (< 53.4 and >=53.4 years old)

POS0643 ARE BIOLOGIC AND TARGETED SYNTHETIC DMARDS SAFE TO USE IN PATIENTS WITH RENAL IMPAIRMENT?

F. Rees[1], M. Jasim[1]. [1]*Cannock Chase Hospital, Rheumatology, Cannock, United Kingdom*

Background: Chronic kidney disease (CKD) is defined as a permanent (minimum three month) reduction in glomerular filtration rate. [1] 10-30% of rheumatoid arthritis (RA) patients have CKD, compared to 5% of the general population.[1] There are several causes of CKD associated with RA including persistent inflammation, cardiovascular risk factors, frequent use of non-steroidal anti-inflammatory drugs and amyloidosis.[1] CKD in RA patients is associated with increased mortality.[2]
The use of biologic and targeted synthetic DMARDs for treating RA has increased significantly in recent years. Studies have shown these therapies might reduce the risk of developing CKD in RA. [3] However, conversely, biologics have been linked to the development of glomerulonephritis.[4]
Surprisingly few studies have explored the use of biologics in patients with pre-existing renal disease and whether they contribute to renal impairment themselves.
Objectives: Our objectives were to explore the renal safety profile of biologic and targeted synthetic DMARDs in a real-world cohort of RA patients with and without pre-existing CKD.
Methods: A retrospective observational study was completed using the Biologic Therapy Database at Cannock Chase Hospital. Inclusion criteria were a diagnosis of RA and current treatment with a biologic or targeted synthetic DMARD.
Demographic data, renal function at biologic initiation and any deterioration of renal function were among the recorded information for each patient. Patients with insufficient information available via electronic patient records were excluded.
Results: 998 RA patients on biologics were identified, of whom 213 were excluded. Of the 785 remaining patients, a 3:1 female to male ratio was noted with a mean age of 62. 40% of patients were on an anti-TNF, 22% rituximab, 15% abatacept, 15% JAK inhibitors and 9% anti-IL6 respectively. At biologic initiation 92% of the patients had a GFR of >60 ml/min per 1.73m^2, 4.8% had a GFR of 30-60 (CKD stage 3a-3b), <1% stage 4 CKD. No patients in the cohort had CKD stage 5 at biologic initiation.
Overall, 13 patients had significant pre-existing CKD (eGFR <45) of these, 6 were treated with abatacept. 7/13 patients had no co-morbid risk factors for CKD – of those remaining, 2 were hypertensive, 2 diabetic and 2 both. None of these 13 patients experienced a drop in renal function by more than 1 stage since initiation of current biologic.
Of those patients without prior CKD at the point of biologic initiation (GFR >45), only 15 patients (2%) developed new renal impairment whilst on biologic treatment. 10 patients' renal function dropped by one stage and five patients by two stages. Crucially, 12 of the 15 patients were aged ≥75yrs and 10 patients had at least one other associated risk factor (e.g. diabetes). Only one patient in the cohort developed renal impairment as a direct result of a biologic - minimal-change disease secondary to etanercept.
Conclusion: Our findings indicate that biologic treatments have a good renal safety profile – even with pre-existing CKD. RA patients most at risk of developing CKD whilst on biologics are likely to have other risk factors such as diabetes or hypertension. As previously stated, there is a very rare association of anti-TNF biologics causing glomerulonephritis.

POS0644 AIR POLLUTION IS A PREDICTOR OF POOR RESPONSE TO BIOLOGICAL THERAPIES IN CHRONIC INFLAMMATORY ARTHRITIDES

G. Adami[1], D. Gatti[1], A. Fassio[1], O. Viapiana[1], A. Giollo[1], E. Bertoldo[1], M. Rossini[1]. [1]*University of Verona, Rheumatology Unit, Verona, Italy*

Background: There is increasingly evidence that environmental air pollution is associated with both development of chronic inflammatory arthritides (CIA). The role of air pollutants on the treatment response of CIA (including psoriatic arthritis [PsA] and ankylosing spondylitis [AS]) is still unclear.
Objectives: The objective of the present study is to determine the association between the concentration of air pollutants and biological drug retention rates in CIA.
Methods: We retrieved longitudinal data of patients affected by CIA on biological therapies and of the daily concentration of air pollutants in the Verona area. We designed a case-crossover study to compare the exposure to pollutants in the 30-day and 60-day periods preceding a drug switch or swap due to disease progression referent to the 30-day and 60-day periods preceding a visit with stable treatment for at least 6 months.
Results: 1,286 patients with CIA (888 with RA, 260 with PsA and 138 with AS) with 5,454 follow-up visits were included in the study. 13,636 daily air pollution records were retrieved. We found an exposure-dependent relationship between exposure to air pollutants and CRP serum levels in CIA. At PM10 exposures of >50 µg/m3 and >40 µg/m3 we found a 150% and 65% higher risk of having CRP above 5 mg/L respectively (OR 2.564, 95% CI 2.114-3.110 and OR 1.659, 95% CI 1.440-1.910, respectively.). If the threshold was set at >30 µg/m3 of PM10 (below the European Union health protection limit) we still found a 38% higher risk of having altered CRP (OR 1.383, 95% CI 1.206-1.588). Among CIA patients, 280 patients (21.7%) had at least 2 follow-up visits with at least one drug switch or swap due to drug inefficacy and one visit with stable treatment for at least 6 months, serving as our sample for the case-crossover study. We found that air pollutants concentrations were higher before a switch or swap due to drug inefficacy (Figure 1A). Figure 1B shows the receiver operating characteristic (ROC) curve for the prediction of switch or swap due to drug inefficacy. Discriminatory capacity of disease activity alone was the highest (AUC 0.841) but when the prediction model included the concentrations of air pollutants in the 60 days before the visit the discriminatory capacity increased (AUC 0.879).
Conclusion: We found that environmental air pollution was a determinant of poor response to biological treatment in a cohort of patients with CIA followed over a 5-year period. Intervention aimed to decrease the fossil combustion emissions might have beneficial effects on biologics persistence rate of patients with CIA.

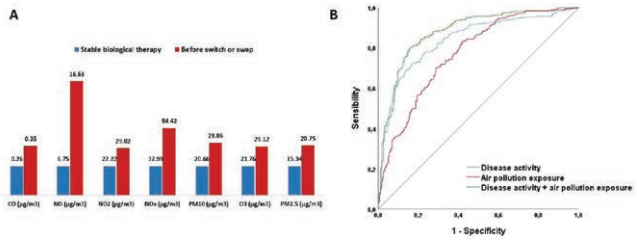

Figure 1. A) Mean concentrations of air pollutants in the 60-day period before switch or swap visit compared to the stable treatment visit. p <0.001 between all groups. B) Receiving operating characteristics (ROC) curves for the prediction of switch or swap due to drug inefficacy

POS0645 RITUXIMAB THERAPY IN THE INTERSTITIAL LUNG DISEASE OF RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW

E. F. Vicente-Rabaneda[1], J. De la Macorra[1], J. P. Baldivieso[1], F. Gutiérrez-Rodríguez[1], A. García-Vadillo[1], R. Garcia de Vicuna[1], S. Castañeda[1]. [1]*Hospital Universitario de la Princesa, IIS-P, Rheumatology, Madrid, Spain*

Background: Interstitial lung disease (ILD) is a severe manifestation of rheumatoid arthritis (RA), linked to increased mortality. There is still no consensus on the best therapeutic strategy as there aren't yet randomized controlled trials.
Objectives: To analyze the available scientific evidence on the efficacy and safety of rituximab (RTX) treatment of interstitial lung disease (ILD) associated with rheumatoid arthritis (RA).
Methods: A systematic search was carried out in PubMed until April 2020 following the PRISMA recommendations. Studies were selected according to the

following inclusion criteria: (1) original research, including case series, case/control studies, cohort studies, and clinical trials; (2) population with RA and associated ILD, either monographically or together with other connective tissue diseases (CTD), provided that individualized data on patients with RA were provided; (3) patients treated with RTX; (4) objective and quantifiable results on the evolution of ILD after treatment with available data of FVC, DLCO and/or HRCT.

Results: Of the 64 papers identified, 9 articles were selected. The studies showed great heterogeneity in design, both in the sample selection criteria and in the objectives of the analysis. Most were observational, retrospective (n = 6) or prospective (n = 2) studies, with only one open prospective experimental study. Those focused on RA predominated, but 3 of them also included patients with other CTDs. The mean age of the patients in the different studies ranged between 52 and 70 years, predominantly women. 40-79% had a history of smoking and were mostly positive for rheumatoid factor (83-100%) and anti-CCP (82-100%). The most frequent radiological patterns were NSIP, UIP and undefined. The outcome measures were diverse: changes in respiratory function tests (LTF) and HRCT, incidence of pulmonary dysfunction, mortality rates, effect on glucocorticoid deprivation, delay in inclusion in the lung transplant list and/or serious adverse events. The initiation of RTX was motivated by pulmonary and/or joint pathology, in patients with failure to other synthetic or biological DMARDs. A total of 393 treatment cycles were collected in 114 patients, with a mean of 3.45 cycles per patient. The RTX regimen was 2 infusions of 1g 2 weeks apart in all patients, except for 1 who received the lymphoma-like regimen. With regard to the efficacy of the treatment with RTX, improvement and especially stabilization of HRCT and LFT predominated, with numerically greater improvement for DLCO than for FVC. There was also a favorable trend in the evolution of patients treated with RTX compared to controls, although it did not reach statistical significance, and a lower risk of deterioration of lung function in patients treated with RTX versus those who had received other DMARDs. The mortality rate found at 5 years was lower than that previously described for the disease and half for the patients treated with RTX compared to those treated with anti-TNF. The adverse events described in the studies did not show additional safety alerts to those already described for RTX.

Conclusion: RTX seems to be postulated as a promising therapy for patients with ILD associated with RA, showing a stabilizing effect on the lung function, with an acceptable safety profile. However, further research of higher methodological quality prospective studies is needed to confirm these favorable preliminary results.

Rheumatoid arthritis - non biologic treatment and small molecules

POS0646 RAPID AND CONCURRENT IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES OF RHEUMATOID ARTHRITIS WITH BARICITINIB IN RA-BEAM

V. Strand[1], A. Sebba[2], B. Jia[3], J. Birt[3], A. Quebe[3], H. Zhang[4], P. C. Taylor[5]. [1]*Stanford University School of Medicine, Division of Immunology/Rheumatology, Palo Alto, United States of America*; [2]*University of South Florida, Department of Rheumatology, Tampa, United States of America*; [3]*Eli Lilly and Company, Lilly Research Laboratories, Indianapolis, United States of America*; [4]*TechData Services, Statistics, King of Prussia, United States of America*; [5]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences and the Kennedy Institute of Rheumatology, Oxford, United Kingdom*

Background: The efficacy and safety of baricitinib (BARI), an oral selective Janus kinase (JAK)1/JAK2 inhibitor, were evaluated in the randomized, controlled trial, RA-BEAM (NCT01710358), in patients (pts) with active rheumatoid arthritis (RA) and inadequate responses (IR) to methotrexate (MTX).[1,2,3]

Objectives: To compare the time to onset and magnitude of improvement across different patient-reported outcomes (PROs) of BARI, adalimumab (ADA) and placebo (PBO) during the first 12 weeks of treatment in RA-BEAM.

Methods: 1,305 patients on stable background MTX were randomized 3:3:2 to PBO, BARI 4 mg, or ADA 40 mg. In this intent-to-treat analysis, least-squares mean changes and percentage changes from baseline were assessed up to Week 12 for pain (0-100 mm visual analog scale [VAS]), SF-36 physical component summary (PCS, 0-100), morning joint stiffness (MJS) severity (0-10), Health Assessment Questionnaire-Disability Index (HAQ-DI, 0-3), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F, 0-52), and Patient Global Assessment of disease activity (PtGA, 0-100 mm VAS) scores. PROs were compared between treatments with ANCOVA; the model included change from baseline as the response variable, baseline of interest, regional baseline, joint erosion status, and treatment as explanatory variables. Last-observation-carried-forward was applied to impute missing data. Speed of onset and magnitude of PRO improvement are presented in spydergrams.

Results: Statistically significant improvements (P<0.05) with BARI and ADA vs. PBO were reported as early as Week 1 for pain, MJS severity, HAQ-DI, and PtGA and at Week 4 for FACIT-F and SF-36 PCS scores. Statistically significantly larger improvements (P<0.05) with BARI vs. ADA were observed as early as Week 2 for pain, PtGA, Week 3 for MJS severity, and Week 4 for HAQ-DI and SF-36 PCS scores. These improvements were maintained to Week 12.

Conclusion: Among MTX-IR pts, BARI and ADA treatment resulted in improvements across all PROs by Week 4, and as early as Week 1, for all but FACIT-F and SF-36 PCS scores. Statistically significant larger improvements for BARI compared with ADA were reported for all PROs, except FACIT-F, by Week 12.

POS0647 EFFICACY, SAFETY AND CHARACTERISTICS OF IGURATIMOD-BASED THERAPY IN THE TREATMENT OF UA, ERA AND RA PATIENTS FOR 24 WEEKS: A PROSPECTIVE COHORT STUDY

X. Liu[1], Z. Sun[1], W. Guo[1], F. Wang[1], L. Song[1], J. Li[1], Q. Liu[1], Q. Shu[1]. [1] *Qilu Hospital of Shandong University, Department of Rheumatology, Jinan, China*

Background: Experts emphasize early diagnosis and treatment in RA, but the widely used diagnostic criterias fail to meet the accurate judgment of early rheumatoid arthritis. In 2012, Professor Zhanguo Li took the lead in establishing ERA "Chinese standard", and its sensitivity and accuracy have been recognized by peers. However, the optimal first-line treatment of patients (pts) with undifferentiated arthritis (UA), early rheumatoid arthritis (ERA), and rheumatoid arthritis (RA) are yet to be established.

Objectives: To evaluate the efficacy and safety of Iguratimod-based (IGU-based) Strategy in the above three types of pts, and to explore the characteristics of the effects of IGU monotherapy and combined treatment.

Methods: This prospective cohort study (ClinicalTrials.gov Identifier NCT01548001) was conducted in China. In this phase 4 study pts with RA (ACR 1987 criteria[1]), ERA (not match ACR 1987 criteria[1] but match ACR/EULAR 2010 criteria[2] or 2014 ERA criteria[3]), UA (not match classification criteria for ERA and RA but imaging suggests synovitis) were recruited. We applied different treatments according to the patient's disease activity at baseline, including IGU monotherapy and combination therapies with methotrexate, hydroxychloroquine, and prednisone. Specifically, pts with LDA and fewer poor prognostic factors were entered the IGU monotherapy group (25 mg bid), and pts with high disease activity were assigned to combination groups. A Chi-square test was applied for comparison. The primary outcomes were the proportion of pts in remission (REM)or low disease activity (LDA) that is DAS28-ESR<2.6 or 3.2 at 24 weeks, as well as the proportion of pts, achieved ACR20, Boolean remission, and good or moderate EULAR response (G+M).

Results: A total of 313 pts (26 pts with UA, 59 pts with ERA, and 228 pts with RA) were included in this study. Of these, 227/313 (72.5%) pts completed the 24-week follow-up. The results showed that 115/227 (50.7%), 174/227 (76.7%), 77/227 (33.9%), 179/227 (78.9%) pts achieved DAS28-ESR defined REM and LDA, ACR20, Boolean remission, G+M response, respectively. All parameters continued to decrease in all pts after treatment (Fig 1).

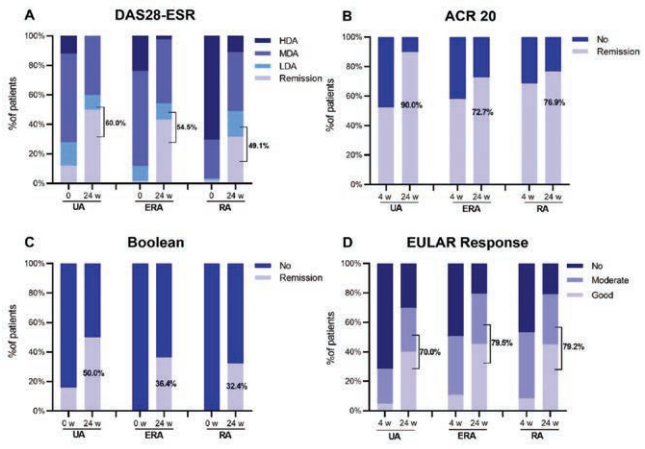
Compared with baseline, the three highest decline indexes of disease activity at week 24 were SW28, CDAI, and T28, with an average decline rate of 73.8%, 61.4%, 58.7%, respectively. Results were similar in three cohorts.

We performed a stratified analysis of which IGU treatment should be used in different cohorts. The study found that the proportion of pts with UA and ERA who used IGU monotherapy were significantly higher than those in the RA cohort. While the proportion of triple and quadruple combined use of IGU in RA pts was significantly higher than that of ERA and UA at baseline and whole-course (Fig 2).

A total of 81/313 (25.8%) pts in this study had adverse events (AE) with no serious adverse events. The main adverse events were infection(25/313, 7.99%), gastrointestinal disorders(13/313, 4.15%), liver dysfunction(12/313, 3.83%) which were lower than 259/2666 (9.71%) in the previous Japanese phase IV study[4].

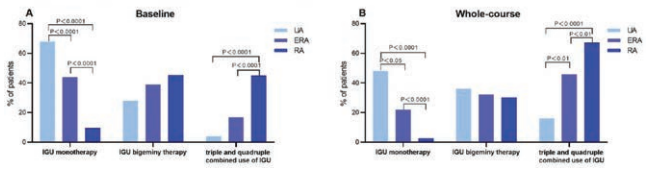
The most common reasons of lost follow-up were: 1) discontinued after remission 25/86 (29.1%); 2) lost 22/86 (25.6%); 3) drug ineffective 19/86 (22.1%).

Figure 1: Change of various disease activity assessment criteria of UA, ERA and RA



(A) DAS28-ESR disease activity of patients at baseline and week 24(Remission, DAS28-ESR≤2.6; Low disease activity (LDA), 2.6< DAS28-ESR ≤ 3.2; Moderate disease activity (MDA), 3.2< DAS28-ESR≤ 5.1; and High disease activity (HDA), DAS28-ESR> 5.1); (B) ACR20 response rate of all patients at week 4 and week 24; (C) Boolean remission rate of patients at baseline and week 24; (D) EULAR response rate of patients at week 4 and week 24.
DAS28=Disease Activity Score 28 joints; ESR=erythrocyte sedimentation rate; EULAR=European League Against Rheumatism; ACR=American College of Rheumatology;

Figure 2: Comparison of proportion of monotherapy and combined use of IGU in UA, ERA and RA



Conclusion: Both IGU-based monotherapy and combined therapies are tolerant and effective for treating UA, ERA, and RA, while the decline in joint symptoms was most significant. Overall, IGU combination treatments were most used in RA pts, while monotherapy was predominant in ERA and UA pts.

POS0648 SURVIVAL ANALYSIS OF TIME TO FIRST ADVERSE DRUG REACTION AND DRUG SURVIVAL IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH METHOTREXATE AND HYDROXYCHLOROQUINE MONOTHERAPIES OR COMBINATION THERAPY

K. Velthuis[1], M. Nguyen[1], J. Scholl[1], J. Jansen[1], J. Van Lint[1], P. Ten Klooster[2,3], H. Vonkeman[3,4], N. Jessurun[1]. [1]*Netherlands Pharmacovigilance Centre Lareb, Research Department, 's-Hertogenbosch, Netherlands*; [2]*Transparency in Healthcare B.V., Hengelo, Netherlands*; [3]*University of Twente, Department of Psychology, Health & Technology, Enschede, Netherlands*; [4]*Medisch Spectrum Twente, Department of Rheumatology and Clinical Immunology, Enschede, Netherlands*

Background: Methotrexate (MTX) and hydroxychloroquine (HCQ) are first line treatments of rheumatoid arthritis (RA). Adverse drug reactions (ADRs) during treatment with these drugs are common. Survival analysis on time to first ADR and on first time drug use duration have not yet been performed for these drugs in real-world settings.

Objectives: To compare proportions of patients with ADRs during first time use of either MTX monotherapy, HCQ monotherapy or MTX+HCQ combination therapy and to compare survival to first ADR and drug survival between these drugs.

Methods: Retrospective single centre cohort study including adult RA patients treated with either MTX monotherapy, HCQ monotherapy or MTX+HCQ combination therapy. First time users between 1 January 2003 and 30 April 2020 were followed until discontinuation of their first time drug use. The proportion of patients with ADRs was defined as the percentage of patients experiencing an ADR during their first time drug use. Survival to first ADR and drug survival of first time drug use were also assessed. MTX+HCQ use was considered combination therapy when the start dates of these drugs differed less than 14 days. For both monotherapies, end of first time drug use was defined as drug discontinuation for more than 90 days. For MTX+HCQ combination therapy, end of first time drug use was defined as discontinuation of either MTX, HCQ or both for more than 90 days. Differences in the proportion of patients experiencing an ADR during first time drug use of MTX, HCQ or a combination of both was statistically tested using Fisher's Exact Test. Survival to first ADR and drug survival were studied by Kaplan-Meier analysis and statistically tested by performing Log Rank tests.

Results: In total, 794 patients were included (MTX 363, HCQ 77, MTX+HCQ 354). For 156 patients (19.6%) at least one ADR was registered during first time drug use (MTX 59 [16.3%], HCQ 9 [11.7%], MTX+HCQ 88 [24.9%]). Proportions of ADRs differed significantly between MTX monotherapy and MTX+HCQ combination therapy (p=0.005) and between HCQ monotherapy and MTX+HCQ combination therapy (p=0.011). Survival to first ADR also differed significantly for both monotherapies compared to MTX+HCQ combination therapy (medians not reached, p<0.001 and p<0.008, respectively (figure 1A)). Drug survival differed significantly between MTX and HCQ monotherapy and between MTX monotherapy and MTX+HCQ combination therapy (median survival MTX 3.32 years (95% CI [2.81-3.83]; HCQ 1.39 years (95% CI [1.03-1.75]); MTX+HCQ 1.23 years (95% CI [1.11-1.34]), both p<0.001 (figure 1B)).

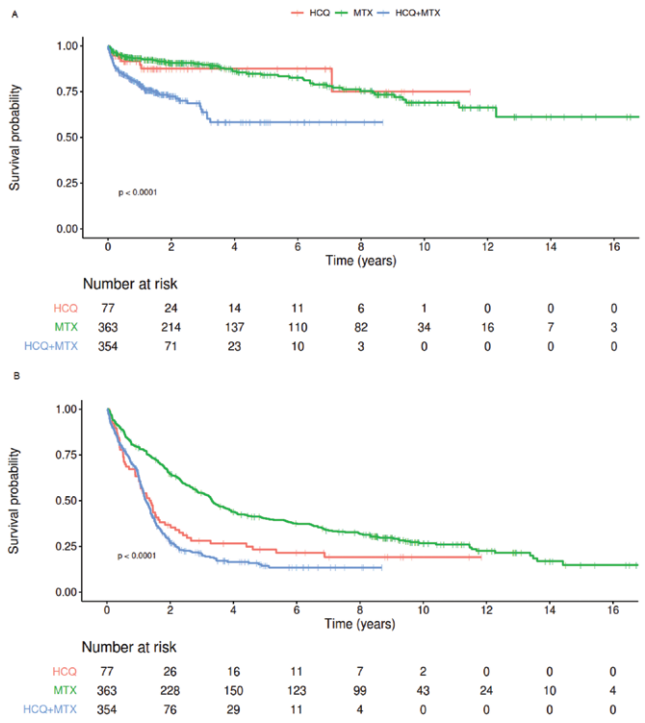

Figure 1. Kaplan-Meier curves of MTX and HCQ monotherapies and MTX+HCQ combination therapy, with (a) survival to first ADR and (b) drug survival.

Conclusion: Patients using MTX+HCQ combination therapy are more likely to experience an ADR during the first time drug use compared to MTX and HCQ monotherapies. MTX+HCQ combination therapy also leads to experiencing an ADR sooner compared to both monotherapies. Drug survival of patients treated with HCQ monotherapy as well as MTX+HCQ combination therapy is shorter compared to MTX monotherapy.

POS0649 BARICITINIB PROVIDES GREATER IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES ACROSS ALL DISEASE ACTIVITY LEVELS COMPARED TO PLACEBO AND ADALIMUMAB IN RHEUMATOID ARTHRITIS

P. C. Taylor[1], R. Blanco[2], K. Ikeda[3], B. Jia[4], Y. F. Chen[4], C. Walls[4], E. Haladyj[4], B. Fautrel[5]. [1]*University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; [2]*Hospital Universitario Marqués de Valdecilla, Department of Rheumatology, Santander, Spain*; [3]*Chiba University Hospital, Department of Allergy and Clinical Immunology, Chiba, Japan*; [4]*Eli Lilly and Company, Lilly Research Laboratories, Indianapolis, United States of America*; [5]*Sorbonne University – Assistance Publique Hôpitaux de Paris, Pitie Salpetriere Hospital, Rheumatology Department, Paris, France*

Background: Baricitinib (BARI) is a JAK1/JAK2 inhibitor which provides improvements to clinical signs, symptoms, and patient-reported outcomes (PROs) in patients with rheumatoid arthritis [1, 2].

Objectives: The effect of BARI on the relationship between disease activity and pain has been explored previously [3]. The purpose of this post hoc analysis was to determine the association between additional PROs (physical function, fatigue, and duration of morning joint stiffness) and disease activity status after 12 weeks of treatment and to evaluate whether patients with an inadequate response to methotrexate treated with BARI 4 mg experienced greater PRO improvement than patients treated with either placebo (PBO) or adalimumab (ADA) across all levels of disease activity.

Methods: Data for these analyses were derived from the Phase 3 study RA-BEAM (N=1305; NCT01710358). Pain was evaluated using a 0-100 mm visual analog scale, physical function was assessed using the Health Assessment Questionnaire-Disability Index (HAQ-DI), fatigue was measured using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scale, and duration of morning joint stiffness (MJS, minutes) was reported by the patient. Disease activity was measured using the Clinical Disease Activity Index (CDAI) and categorized as remission (REM, ≤2.8), low disease activity (LDA, >2.8 to ≤10), moderate disease activity (MDA, >10 to ≤22), or high disease activity (HDA, >22). Linear regression was used to model the relationship between change in PROs at Week 12 (response) and CDAI values at Week 12 (primary explanatory variable) to evaluate the extent of improvement in PROs with BARI relative to PBO and ADA across a spectrum of disease activity levels. Last observation carried forward was used to impute missing values.

Results: At baseline, 91% of patients were classified as having HDA and 9% as having MDA by CDAI across all treatment groups. After 12 weeks of treatment, 2%, 7%, and 9% of patients achieved REM; 16%, 27%, and 33% of patients achieved LDA; and 33%, 40%, and 38% of patients achieved MDA with PBO, ADA, and BARI, respectively [3].

At Week 12, the estimated changes in measures of pain and physical function, as well as duration of MJS, for BARI 4 mg were greater than both PBO and ADA at all disease activity level threshold values of CDAI (Table 1). The estimated change in fatigue for BARI 4 mg was similar to that of ADA, and greater than PBO, at all disease activity level threshold values (Table 1).

Table 1. Estimate of PRO Improvement by Disease Activity Threshold Level (CDAI) at Week 12

PRO	CDAI=2.8			CDAI=10			CDAI=22		
	PBO	ADA	BARI 4 mg	PBO	ADA	BARI 4 mg	PBO	ADA	BARI 4 mg
Pain VAS[a] (mm)	-28.4	-37.9	-40.9	-24.5	-32.6	-36.1	-18.0	-23.7	-28.1
HAQ-DI[b]	-0.6	-0.7	-0.9	-0.5	-0.7	-0.7	-0.4	-0.5	-0.6
FACIT-F[c]	9.8	11.8	11.1	8.8	10.6	10.2	7.0	8.7	8.7
Duration of MJS (min)	-6.9	-37.8	-64.9	-6.3	-35.3	-55.7	-5.3	-31.3	-40.2

[a]Pain VAS scores range from 0 (no pain) to 100 (worst pain).
[b]HAQ-DI scores range from 0 (no disability) to 3 (completely disabled).
[c]FACIT-F scores range from 0 (worst fatigue) to 52 (no fatigue).
Abbreviations: ADA, adalimumab; BARI, baricitinib; CDAI, Clinical Disease Activity Index; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI, Health Assessment Questionnaire-Disability Index; MJS, morning joint stiffness; PBO, placebo; PRO, patient-reported outcomes; VAS, visual analog scale.

Conclusion: Estimates of treatment differences suggest that patients treated with BARI 4 mg may experience greater improvements in pain, physical function, and MJS duration than patients treated with PBO or ADA regardless of their disease activity status reached after 12 weeks of treatment. Using this approach, improvements in fatigue with BARI 4 mg may be greater than with PBO and similar to ADA after 12 weeks.

POS0650 PREDICTORS OF DURABLE CLINICAL RESPONSE TO TOFACITINIB 11 MG ONCE DAILY WITH OR WITHOUT METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS: POST HOC ANALYSIS OF DATA FROM A PHASE 3B/4 METHOTREXATE WITHDRAWAL STUDY

K. Yamaoka[1], S. B. Cohen[2], N. Sugiyama[3], H. Shi[4], J. L. Rivas[5], A. Diehl[4], J. S. Smolen[6]. [1]*Kitasato University, Department of Rheumatology and Infectious Diseases, Sagamihara, Japan*; [2]*Metroplex Clinical Research Center, Dallas,*

TX, United States of America; [3]*Pfizer Japan Inc, Inflammation and Immunology, Tokyo, Japan*; [4]*Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America*; [5]*Pfizer SLU, Inflammation and Immunology, Madrid, Spain*; [6]*Medical University of Vienna, Department of Rheumatology, Vienna, Austria*

Background: ORAL Shift, a global Phase 3b/4 non-inferiority study, demonstrated sustained efficacy and safety of tofacitinib modified-release (MR) 11 mg once daily (QD) following methotrexate (MTX) withdrawal in patients with rheumatoid arthritis (RA) who achieved Clinical Disease Activity Index (CDAI) low disease activity (LDA) after treatment with tofacitinib + MTX.[1]

Objectives: To assess predictors of durable clinical response in patients receiving tofacitinib MR 11 mg QD in ORAL Shift.

Methods: ORAL Shift (NCT02831855) enrolled patients aged ≥18 years with moderate to severe RA and an inadequate response to MTX. Patients received open-label tofacitinib MR 11 mg QD + MTX for 24 weeks. Patients achieving LDA (CDAI score ≤10) at Week (W)24 entered the 24-week double-blind MTX withdrawal phase and were randomised 1:1 to receive tofacitinib MR 11 mg QD + placebo (tofacitinib monotherapy; ie blinded MTX withdrawal) or continue tofacitinib + MTX. In this post hoc analysis of randomised patients, we assessed predictors of durable response (maintenance of response from W24–48) per CDAI LDA and remission (CDAI score ≤2.8) criteria. All covariates were initially assessed for significance in a univariate logistic regression. Highly correlated covariates were reviewed to assess which would be removed prior to modelling in a multivariable logistic regression. Remaining significant (p≤0.10) covariates in the univariate regression were selected in the model using a stepwise selection process with p≤0.15 entry and p≤0.05 stay criteria. From the final model, estimated odds ratios (ORs) with 95% confidence intervals (CIs) are presented.

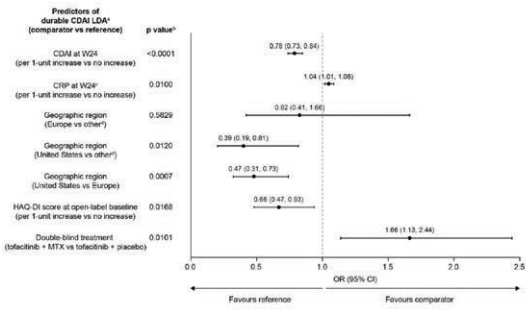
Results: In the double-blind phase of ORAL Shift, durable CDAI LDA and remission rates were: 66.2% and 14.7%, respectively, with tofacitinib + MTX (N=266); and 55.3% and 11.0%, respectively, with tofacitinib + placebo (N=264) (Table 1). In the multivariable analysis, five patient covariates significantly predicted durable CDAI LDA (Figure 1; discussed hereafter). Each unit increase in CDAI score at W24 reduced the likelihood of maintaining CDAI LDA by 22.0%. Each unit increase in C-reactive protein (CRP) at W24 increased the likelihood of maintaining CDAI LDA by 4.0%; this may have been due to imbalanced CRP levels at W24 (randomisation) between treatment groups (Figure 1, footnote c). The odds of durable CDAI LDA were 53.0% lower in the US vs Europe and 61.0% lower in the US vs 'other' regions. Each unit increase in baseline Health Assessment Questionnaire-Disability Index (HAQ-DI) score reduced the odds of durable CDAI LDA by 34.0%. Patients receiving tofacitinib + MTX had 66.0% greater odds of durable CDAI LDA vs patients receiving tofacitinib + placebo. CDAI at W24 was the only significant predictor of durable CDAI remission in the multivariable analysis: OR (95% CI) 0.32 (0.24, 0.43); p<0.0001. Each unit increase in CDAI score at W24 reduced the odds of durable CDAI remission by 68.0%.

Table 1. Durable CDAI LDA and remission[a] in patients receiving tofacitinib MR 11 mg QD with MTX or placebo in the double-blind phase of ORAL Shift

	Tofacitinib + MTX (N=266)	Tofacitinib + placebo (N=264)
Durable CDAI LDA, n (%)	176 (66.2)	146 (55.3)
Durable CDAI remission, n (%)	39 (14.7)	29 (11.0)

[a]Durable CDAI LDA or remission was defined as achievement of LDA (CDAI score ≤10) or remission (CDAI score ≤2.8), respectively, at W24–48
N, number of patients in each group; n, number of patients achieving outcome

Figure. Multivariable regression results for predictors of durable CDAI LDA[a] in patients receiving tofacitinib MR 11 mg QD with MTX or placebo in the double-blind phase of ORAL Shift



[a]Durable CDAI LDA was defined as achievement of LDA (CDAI score ≤10) at W24–48; [b]The Wald chi squared test p value for that comparison; [c]Mean CRP levels at W24 (randomisation) were 25.6% higher in the tofacitinib + MTX group (mean CRP=5.05 mg/L) vs tofacitinib + placebo group (mean CRP=4.02 mg/L). During the double-blind phase, CRP stabilised with tofacitinib + MTX but increased with tofacitinib + placebo. The CRP differences between treatment groups may have impacted the CDAI LDA durability outcome; [d]'Other' refers to Australia, Korea, Philippines, Mexico and South Africa

Conclusion: This post hoc analysis of data from ORAL Shift found that CDAI and CRP at W24, geographic region, baseline HAQ-DI and treatment could be predictors for durable CDAI LDA. As these findings were limited to patients who achieved CDAI LDA at W24 with tofacitinib MR 11 mg QD + MTX, additional data in the general patient population need to be investigated.

POS0651 CLINICAL AND FUNCTIONAL RESPONSE TO TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS: PROBABILITY PLOT ANALYSIS OF RESULTS FROM A 48-WEEK PHASE 3B/4 METHOTREXATE WITHDRAWAL STUDY

S. B. Cohen[1], Y. H. Chen[2], N. Sugiyama[3], J. L. Rivas[4], A. Diehl[5], T. Lukic[6], J. Paulissen[6], H. Fan[5], T. Hirose[3], E. Keystone[7]. [1]*Metroplex Clinical Research Center, Dallas, TX, United States of America*; [2]*Taichung Veterans General Hospital, Division of Allergy, Immunology, and Rheumatology, Taichung, Taiwan, Republic of China*; [3]*Pfizer Japan Inc, Inflammation and Immunology, Tokyo, Japan*; [4]*Pfizer SLU, Inflammation and Immunology, Madrid, Spain*; [5]*Pfizer Inc, Inflammation and Immunology, Collegeville, PA, United States of America*; [6]*Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; [7]*Mount Sinai Hospital, Toronto, ON, Canada*

Background: The Phase 3b/4 study ORAL Shift (NCT02831855) demonstrated sustained efficacy/safety of tofacitinib modified-release 11 mg QD following MTX withdrawal, that was non-inferior to continued tofacitinib + MTX use, in patients (pts) with moderate to severe RA who achieved LDA with tofacitinib + MTX at Week (W)24.[1]

Objectives: To assess differences and similarities in clinical/functional responses in pts receiving tofacitinib ± MTX in ORAL Shift.

Methods: In ORAL Shift, pts received open-label tofacitinib + MTX to W24; at W24, pts who achieved CDAI LDA were randomised to receive tofacitinib + MTX or tofacitinib + placebo (PBO) from W24–48. In this post hoc analysis, clinical efficacy endpoints were ACR-N (minimum % change from baseline [BL; Δ] at W48 achieved by each pt in 3 efficacy measures), ΔDAS28-4(ESR), and DAS28-4(ESR) remission/LDA (scores ≤3.2) and moderate/high disease activity (scores >3.2). Functional efficacy endpoints were ΔHAQ-DI and HAQ-DI clinically relevant functional progression (CRFP) status at W48, defined as failure to achieve improvement in HAQ-DI ≥ minimum clinically important difference (MCID; ≥0.22 decrease from BL in HAQ-DI). Thus, CRFP was defined as <0.22 decrease, no change or increase from BL in HAQ-DI at W48. All efficacy endpoints were summarised descriptively. Cumulative probability plots of ACR-N and ΔHAQ-DI were produced. Median of mean CRP values from BL–W24 and >W24–48 were assessed by response subgroups.

Results: 266 pts receiving tofacitinib + MTX and 264 pts receiving tofacitinib + PBO in W24–48 were included. At W48: mean ACR-N was numerically greater with tofacitinib + MTX vs tofacitinib + PBO (60.8 vs 53.1); mean decrease in HAQ-DI was generally similar between groups (-0.71 vs -0.67); mean decrease in DAS28-4(ESR) was numerically greater with tofacitinib + MTX vs tofacitinib + PBO (-2.95 vs -2.68). The differences/similarities between groups in ACR-N and ΔHAQ-DI were also seen in cumulative probability plots (Figure 1). CRFP rates were numerically lower with tofacitinib + MTX (18.7%) vs tofacitinib + PBO (23.5%), and in pts with remission/LDA (tofacitinib + MTX, 12.1%; tofacitinib + PBO, 16.8%) vs moderate/high disease activity (tofacitinib + MTX, 26.2%; tofacitinib + PBO, 30.8%). Median of mean CRP over time was generally numerically lower in pts with CRFP vs non-CRFP and DAS28-4(ESR)-defined remission/LDA vs moderate/high disease activity; and in those receiving tofacitinib + PBO vs tofacitinib + MTX, irrespective of CRFP or DAS28-4(ESR) disease status (Table 1).

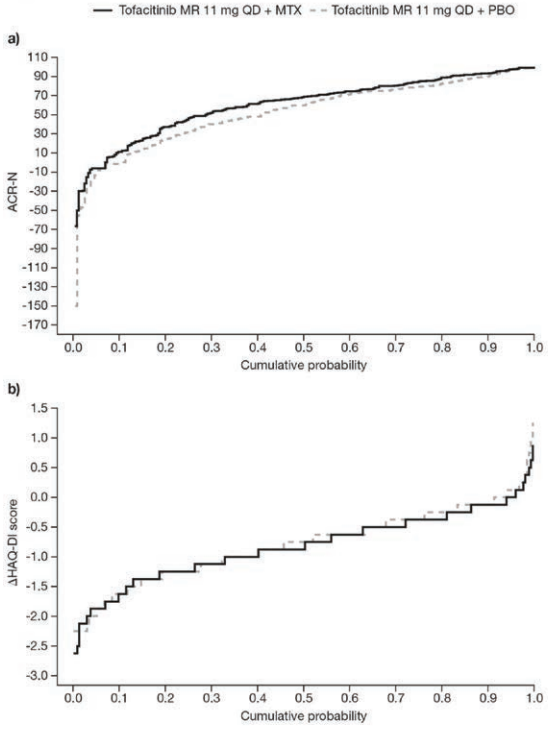
Table 1. Median of mean CRP[a] up to W48 by response subgroups

	Tofacitinib 11 mg QD + MTX		Tofacitinib 11 mg QD + PBO	
Mean CRP,[a] median (IQR) [n]	**>BL–W24**	**>W24–48**	**>BL–W24**	**>W24–48**
HAQ-DI CRFP	2.84 (1.15–7.30) [45]	2.30 (0.82–4.75) [46]	1.45 (0.77–4.42) [56]	2.28 (0.53–7.28) [56]
HAQ-DI non-CRFP	2.81 (1.09–6.19) [195]	2.91 (1.19–5.84) [195]	2.26 (0.98–4.63) [176]	2.47 (1.13–5.53) [178]
DAS28-4(ESR) remission/LDA	2.48 (1.05–4.95) [126]	2.46 (1.07–4.76) [127]	1.70 (0.89–4.14) [115]	1.95 (0.81–3.82) [117]
DAS28-4(ESR) moderate/ high disease activity	3.56 (1.17–7.13) [107]	3.58 (1.36–8.33) [107]	2.60 (0.87–5.16) [115]	2.68 (1.34–8.23) [115]

[a]Mean CRP was calculated as the average CRP value during each time period (>BL–W24 or >W24–48)

CRP, C-reactive protein; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; IQR, interquartile range; LDA, low disease activity; MTX, methotrexate; n, number of pts meeting assessment criteria; QD, once daily

Figure. Cumulative probability plot at W48 for a) ACR-N; b) ΔHAQ-DI score



Endpoints were assessed using the full analysis set (defined as all pts receiving ≥1 dose of study drug with ≥1 value post-baseline), with no imputation for missing values
ACR-N, American College of Rheumatology response, where N represents the minimum amount of improvement expressed by each pt in % ΔTJC28, % ΔSJC28, and the median of % Δ in PtGA, PGA, Pain, HAQ-DI and CRP; CRP, C-reactive protein; HAQ-DI, Health Assessment Questionnaire-Disability Index; MR, modified release; MTX, methotrexate; PGA, Physician Global Assessment; PtGA, Patient Global Assessment; QD, once daily; SJC28, swollen joint count in 28 joints; TJC28, tender joint count in 28 joints

Conclusion: Although clinical/functional responses were generally similar between treatment groups, numerical improvements were seen for some efficacy endpoints with tofacitinib + MTX vs tofacitinib + PBO. A numerically higher CRFP rate may be associated with higher DAS28-4(ESR) disease activity. CRP changes up to W48 may not trend with CRFP status.

POS0652

SEX DIFFERENCES IN THE EFFICACY AND SAFETY OF TOFACITINIB IN RHEUMATOID ARTHRITIS PATIENTS: A POST HOC ANALYSIS OF PHASE 3 AND LONG-TERM EXTENSION TRIALS

H. N. Jones[1], V. Strand[2], H. Schulze-Koops[3], E. Mysler[4], C. Kinch[5], D. C. Gruben[6], R. Germino[7], C. A. Connell[8], L. Eder[9]. *[1]University of Alberta, Division of Rheumatology, Edmonton, AB, Canada*; *[2]Stanford University, Division of Immunology/Rheumatology, Palo Alto, CA, United States of America*; *[3]University of Munich, Division of Rheumatology and Clinical Immunology, Department of Internal Medicine IV, Munich, Germany*; *[4]Organización Médica de Investigación, Buenos Aires, Argentina*; *[5]Pfizer Canada ULC, Inflammation and Immunology, Kirkland, QC, Canada*; *[6]Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America*; *[7]Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*; *[8]Pfizer Inc, Clinical Development and Operations, Groton, CT, United States of America*; *[9]University of Toronto, Women's College Research Institute, Department of Medicine, Toronto, ON, Canada*

Background: Differences in efficacy outcomes favouring males vs females with rheumatoid arthritis (RA) have been reported with conventional synthetic (cs) disease-modifying antirheumatic drugs (DMARDs) and tumour necrosis factor inhibitors; results with Janus kinase inhibitors are less clear.

Objectives: To assess the impact of sex on efficacy, safety and persistence in tofacitinib RA clinical trials.

Methods: Efficacy and safety analyses included data pooled from Phase (P)3 randomised controlled trials (RCTs) of patients (pts) with RA and an inadequate response (IR) to methotrexate (NCT00847613; NCT00853385) or ≥1 DMARD (NCT00856544) who received tofacitinib 5 or 10 mg twice daily (BID), adalimumab (ADA) 40 mg Q2W or placebo (PBO), with background csDMARDs. Persistence analyses of pts receiving tofacitinib 5 or 10 mg BID ± csDMARDs used data pooled from two long-term extension trials (NCT00661661; NCT00413699). Efficacy outcomes to Month (M)12 included: ACR20/50/70 responses, changes from baseline (Δ; BL) in DAS28-4(ESR), CDAI, HAQ-DI and FACIT-F, and DAS28-4(ESR) remission (<2.6). Safety was evaluated to M24 for tofacitinib and ADA. Kaplan-Meier persistence analysis estimated time to discontinuation.

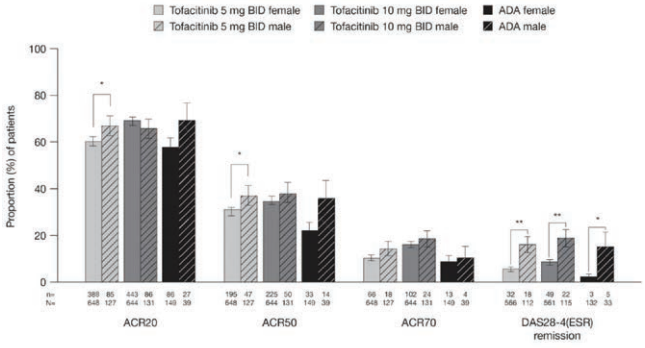
Results: 2265 pts were included from P3 RCTs. Demographics and BL characteristics were comparable across sexes and treatments. Tofacitinib or ADA vs PBO generally led to significantly higher ACR20/50/70 responses in both sexes through M6. To M12, ACR20/50/70 responses were broadly comparable across active treatments and between sexes, with significant differences favouring males at some time points, including M3 (Figure 1). Statistically significant differences favouring males vs females were observed in DAS28-4(ESR) remission rates at most time points, including M3 (Figure 1); a similar trend was observed for ΔDAS28-4(ESR). ΔCDAI, ΔHAQ-DI and ΔFACIT-F significantly favoured males vs females receiving tofacitinib 5 mg BID at most time points, while ΔHAQ-DI and ΔFACIT-F tended to favour females receiving tofacitinib 10 mg BID. Rates of adverse events (AEs), serious AEs (SAEs), severe AEs and discontinuations due to AEs were slightly higher in females vs males with tofacitinib 5 mg BID; this was generally reversed with tofacitinib 10 mg BID and ADA (Table 1). AEs of special interest (AESI) were comparable between sexes with tofacitinib and ADA, although low event numbers limit interpretation (Table 1). Time to all-cause discontinuation and discontinuation due to AEs/lack of efficacy with tofacitinib 5 mg BID was similar between sexes. Numerical differences favouring females vs males were observed for time to all-cause discontinuation and discontinuation due to AEs with tofacitinib 10 mg BID.

Table 1. Safety summary to M24 in pooled DMARD-IR P3 RCTs

	Tofacitinib 5 mg BID		Tofacitinib 10 mg BID		ADA	
Pts with events, n (%)	**Females (N=707)**	**Males (N=133)**	**Females (N=698)**	**Males (N=137)**	**Females (N=162)**	**Males (N=42)**
AEs	562 (79.5)	85 (63.9)	529 (75.8)	107 (78.1)	119 (73.5)	30 (71.4)
SAEs	107 (15.1)	17 (12.8)	71 (10.2)	24 (17.5)	13 (8.0)	6 (14.3)
Severe AEs	86 (12.2)	12 (9.0)	55 (7.9)	22 (16.1)	14 (8.6)	5 (11.9)
Discontinuations due to AEs	87 (12.3)	10 (7.5)	88 (12.6)	10 (7.3)	17 (10.5)	5 (11.9)
Death	6 (0.8)	4 (3.0)	0	3 (2.2)	1 (0.6)	2 (4.8)
AESI						
Serious infections	28 (4.0)	6 (4.5)	27 (3.9)	6 (4.4)	2 (1.2)	1 (2.4)
All HZ (non-serious/serious)	35 (5.0)	7 (5.3)	43 (6.2)	5 (3.6)	2 (1.2)	3 (7.1)
MACE	5 (0.7)	0	2 (0.3)	3 (2.2)	0	3 (7.1)
Malignancies (excl. NMSC)	7 (1.0)	1 (0.8)	9 (1.3)	1 (0.7)	0	1(2.4)
NMSC	2 (0.3)	5 (3.8)	4 (0.6)	2 (1.5)	1 (0.6)	1 (2.4)
Venous thromboembolism	3 (0.4)	0	3 (0.4)	1 (0.7)	0	0

HZ, herpes zoster; MACE, major adverse cardiovascular events; NMSC, non-melanoma skin cancer

Figure. Proportion of pts achieving ACR20/50/70 and DAS28-4(ESR) remission at M3, stratified by sex and treatment group (P3 RCTs)



*p<0.05, **p<0.001
Pts from ORAL Standard who were found to be non-compliant with study procedures were excluded; PBO data not presented
ACR20/50/70, American College of Rheumatology ≥20/50/70% response criteria; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; n, number of responders; N, number of patients assessed at each visit

Conclusion: Efficacy outcomes with tofacitinib and ADA were generally higher in males and comparable in females vs previously reported mixed population response rates for advanced therapies. Safety findings did not reveal a consistent pattern between sexes. Tofacitinib persistence was similar between sexes.

Background: In the randomized, double-blinded, Phase 3 SELECT-COMPARE study, upadacitinib (UPA) + MTX demonstrated greater clinical and functional responses vs adalimumab (ADA) + MTX in patients (pts) with RA and inadequate response to MTX.[1,2] Pts with insufficient response to initial therapy were switched from UPA to ADA (and vice versa) according to treat-to-target (T2T) principles.

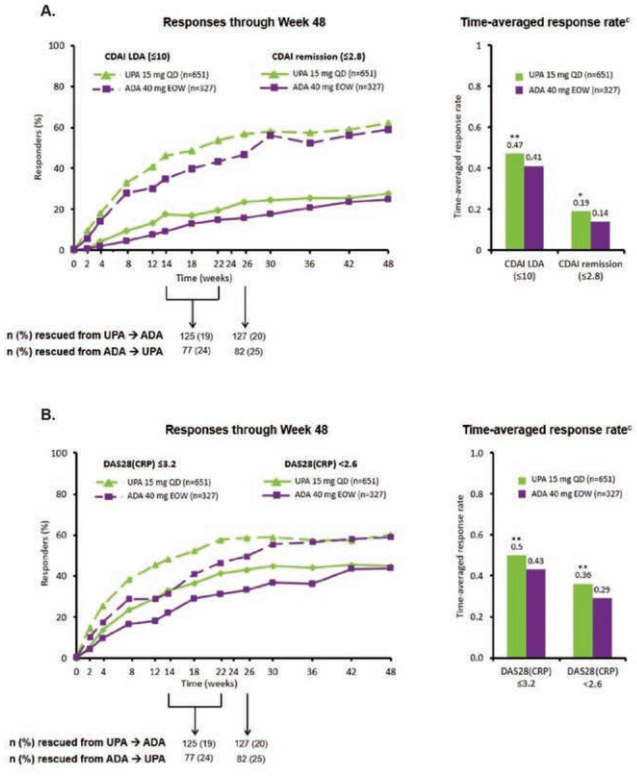
Objectives: We analyzed 1-year treatment outcomes in SELECT-COMPARE according to initial randomization group, regardless of whether pts subsequently switched therapy.

Methods: Pts initially randomized to UPA 15 mg once daily (QD) or ADA 40 mg every other week (EOW; both + MTX) for up to 48 weeks in SELECT-COMPARE were included in the analysis. As per the protocol-directed rescue strategy, pts experiencing <20% improvement in tender or swollen joint counts at Week 14, 18, or 22, or Clinical Disease Activity Index (CDAI) >10 at Week 26, were switched from UPA to ADA or ADA to UPA in a blinded fashion. Efficacy outcomes included CDAI remission (≤2.8) and low disease activity (LDA; ≤10), DAS of 28 joints using CRP (DAS28[CRP]) <2.6 and ≤3.2, and a composite of "deep response" (CDAI remission, HAQ-Disability Index <0.5, and pain score <20). Data are presented and attributed to initial randomized group (UPA or ADA) regardless of any subsequent switch in therapy. Time-averaged response rates were calculated as area under the curve of response rate standardized by 48 weeks. The proportions of pts who maintained Week 26 responses through 6 months of follow-up are also reported.

Results: This analysis included 651 pts initially randomized to UPA (of whom 245 switched to ADA) and 327 pts initially randomized to ADA (of whom 157 switched to UPA). Baseline characteristics including age, sex, and BMI were generally well balanced between randomized groups. At Week 48, similar proportions of pts initially randomized to UPA or ADA therapy achieved CDAI remission/LDA (27.6%/61.9% vs 24.8%/59.0%) and DAS28(CRP) <2.6/≤3.2 (45.0%/60.2% vs 43.7%/59.0%) (Figure 1). However, a small but significantly greater proportion of pts achieved a deep response with initial UPA vs initial ADA therapy (17.8% vs 12.8%; p<0.05). In addition, time-averaged response rates over 48 weeks were higher for initial UPA vs initial ADA therapy across efficacy outcomes. Similar trends were observed for other outcomes. Additionally, similar proportions of pts maintained Week 26 responses with initial UPA vs initial ADA therapy based on CDAI remission/LDA and DAS28(CRP) <2.6/≤3.2 during 6-month follow-up (Table 1).

Conclusion: Using a stringent T2T approach to RA management, rates of LDA or remission at 1 year were similar, regardless of whether pts were initially randomized to UPA or ADA. However, initial UPA therapy led to more frequent deep responses and higher time-averaged response rates vs initial ADA therapy.

Figure 1. Achievement of CDAI (A) and DAS28(CRP) (B) responses corresponding with time-averaged response rates over 48 weeks by initial therapy with UPA or ADA in SELECT-COMPARE



**p<0.01, *p<0.05 vs ADA.
[a]Non-responder imputation. [b]Blinded rescue from UPA to ADA or ADA to UPA was permitted at Weeks 14, 18, and 22 for <20% improvement in TJC/SJC and at Week 26 for CDAI <10. Data are presented and attributed to original randomized group (UPA or ADA) regardless of any subsequent switch in therapy. [c]Calculated as area under the curve of response rate standardized by length of study (48 weeks).
ADA, adalimumab; CDAI, Clinical Disease Activity Index; DAS28(CRP), DAS of 28 joints using CRP; EOW, every other week; QD, once daily; SJC, swollen joint count; TJC, tender joint count; UPA, upadacitinib.

POS0654

IMPACT OF CONCOMITANT GLUCOCORTICOIDS ON THE CLINICAL EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS: AN AD HOC ANALYSIS OF DATA FROM THREE PHASE 3 STUDIES

B. Combe[1], F. Buttgereit[2], A. Ostor[3], R. Xavier[4], A. Saraux[5], C. Daridon[6], K. Famulla[7], Y. Song[8], I. Lagunes-Galindo[8], G. R. Burmester[2]. KG, Rheumatology, Wiesbaden, Germany*; [8]*AbbVie Inc., Rheumatology, North Chicago, United States of America*

Background: Glucocorticoid (GC) therapy has strong anti-inflammatory effects and helps slow radiographic progression in RA[1]; however, GCs can be associated with adverse events (AEs) such as infection, especially with long-term use and higher doses.

Objectives: To evaluate the impact of baseline GCs on the efficacy and safety of upadacitinib (UPA) with or without concomitant conventional synthetic DMARDs (csDMARDs).

Methods: In this ad hoc analysis of three Phase 3 studies, patients with inadequate response to MTX (MTX-IR) receiving UPA 15 mg once daily (QD) or placebo (PBO) + csDMARDs in SELECT-NEXT, and MTX-IR/MTX-naïve patients receiving UPA 15 mg QD monotherapy or MTX monotherapy in SELECT-MONOTHERAPY/SELECT-EARLY, respectively, were included. Efficacy outcomes, including measures of remission and low disease activity (LDA) determined by DAS in 28 joints using CRP (DAS28[CRP]; <2.6/≤3.2) and Clinical Disease Activity Index (CDAI; ≤2.8/≤10), were assessed and stratified by baseline GC use. Patients were permitted to receive oral GCs ≤10 mg/day (prednisone equivalent) at baseline with no adjustment permitted until Week 24/26/48. Safety was reported as number and proportion of patients with AEs. Data were analyzed descriptively with no statistical comparisons between groups or doses.

Results: Of 1,506 patients included in the analysis, 737 (48.9%) were receiving baseline GCs (mean dose 6.2 mg/day). Baseline characteristics were broadly similar across treatment groups; SELECT-EARLY, which enrolled MTX-naïve patients, generally had the shortest duration of RA and higher CRP levels. Across UPA treatment groups, concomitant GCs generally did not influence the proportions of patients achieving remission (Figure 1). In SELECT-NEXT, clinical responses with UPA 15 mg in combination with csDMARDs were similar irrespective of concomitant GC use (Figure 1). Within SELECT-MONOTHERAPY, responses in patients receiving UPA 15 mg without concomitant csDMARDs or GCs were higher than those in patients receiving MTX alone, but were numerically lower than in those receiving UPA 15 mg with GCs (Figure 1). However, this was not observed within SELECT-EARLY, where clinical responses in patients receiving UPA 15 mg monotherapy without GCs were higher than in those patients receiving UPA 15 mg with GCs for both DAS28(CRP) <2.6 (40.6% vs 29.9%, respectively) and CDAI ≤2.8 (20.0% vs 11.6%, respectively) (Figure 1). A similar trend was observed for LDA. Serious AEs, AEs leading to discontinuation, and AEs of special interest, including infections (such as herpes zoster), were broadly similar in the UPA groups irrespective of concomitant GC use (**table of safety data will be presented**).

Conclusion: UPA 15 mg in combination with csDMARDs or as monotherapy was effective in achieving remission and LDA, irrespective of concomitant GC use. Safety of UPA, including incidence of infection, appeared largely unaffected by concomitant GC use.

POS0655 LONG-TERM SAFETY AND EFFICACY OF UPADACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS: 3-YEAR RESULTS FROM THE SELECT-EARLY STUDY

R. van Vollenhoven[1], T. Takeuchi[2], J. Aelion[3], N. Chávez[4], P. Mannucci Walter[5], A. Singhal[6], J. Swierkot[7], A. Friedman[8], N. Khan[8], Y. Li[8], X. Bu[8], J. Klaff[8], V. Strand[9]. Background: Upadacitinib (UPA), an oral Janus kinase inhibitor, demonstrated significant improvements in signs, symptoms, and structural inhibition as monotherapy (mono) vs methotrexate (MTX) in MTX-naïve patients (pts) with rheumatoid arthritis (RA) through 48 weeks (wks).[1]

Objectives: To report the efficacy and safety of UPA vs MTX mono up to 156 wks in pts with RA from the ongoing long-term extension (LTE) of the SELECT-EARLY trial.

Methods: During the 48-wk double-blind study period, pts were randomized to UPA 15 or 30 mg once daily (QD) or MTX (titrated to 20 mg/wk by Wk 8). At Wk 26, pts who did not achieve Clinical Disease Activity Index (CDAI) remission (≤2.8) and had <20% improvement from baseline in tender or swollen joint count received blinded rescue therapy (addition of MTX for UPA groups and UPA 15 or 30 mg for MTX group). In the LTE, pts received open-label treatment once the last pt reached Wk 48. Efficacy assessments up to Wk 156 were summarized by randomized group and included American College of Rheumatology (ACR) responses, remission and low disease activity (LDA) measures, and change in modified Total Sharp Score (mTSS; up to 96 wks). Treatment-emergent adverse events (AEs) per 100 pt-years (PY) for pts on continuous mono were summarized through 156 wks. Non-responder imputation was used for binary endpoints for missing data and when pts received rescue therapy or prematurely discontinued the study drug.

Results: Of 945 pts randomized and treated, 775 entered the LTE on study drug (including 57 rescued pts; MTX, 33; UPA 15 mg, 17; UPA 30 mg, 7). Overall, 161 (21%) pts discontinued during the LTE. At Wk 156, higher proportions of pts randomized to UPA achieved a 20/50/70% improvement in ACR response (ACR20/50/70), LDA, and remission vs MTX (Figure 1). Change from baseline in mTSS at Wk 96 favored UPA vs MTX (data not shown). Most AEs were numerically more frequent with UPA 30 mg. The overall rate of serious infection was numerically higher with UPA vs MTX (Table 1). Herpes zoster (HZ), neutropenia, non-melanoma skin cancer (NMSC), and creatine phosphokinase (CPK) elevation were more frequent with UPA vs MTX. Two active tuberculosis (TB) events were reported in each UPA arm; 3 adjudicated gastrointestinal (GI) perforation events were observed in the UPA 30 mg arm. Adjudicated major adverse cardiovascular events (MACEs) or venous thromboembolic events (VTEs) were comparable across treatment arms.

Conclusion: UPA monotherapy showed sustained clinically meaningful responses including remission vs MTX through Wk 156 but higher rates of several AEs, including HZ, neutropenia, and CPK elevations; no new safety risks were observed compared with previous results.[1,2]

POS0656 RELATIONSHIP BETWEEN CHANGES IN LIPID LEVELS AND IMPROVEMENT IN DISEASE ACTIVITY OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING UPADACITINIB TREATMENT: POOLED ANALYSIS OF DATA FROM TWO PHASE 3 STUDIES

C. Charles-Schoeman[1], J. T. Giles[2], N. Lane[3], E. Choy[4], H. Camp[5], Y. Song[5], S. Anyanwu[5], I. McInnes[6]. [1]*University of California, Rheumatology, Los Angeles, United States of America*; [2]*Columbia University, Rheumatology, New York, United States of America*; [3]*University of California, Davis, Sacramento, United States of America*; [4]*Cardiff University, School of Medicine, Cardiff, United Kingdom*; [5]*AbbVie Inc., Rheumatology, North Chicago, United States of America*; [6]*University of Glasgow, Rheumatology, Glasgow, United Kingdom*

Background: Upadacitinib (UPA) is an oral Janus kinase (JAK) inhibitor engineered to have greater selectivity for JAK1 vs JAK2, JAK3, and tyrosine kinase 2, and is approved for the treatment of RA. Across 2 double-blind, placebo (PBO)-controlled Phase 3 studies of UPA in patients with RA, after an initial increase through Week 8, lipid levels remained stable up to Week 24.[1,2] Previous studies of JAK or IL-6 receptor inhibitors have reported a negative correlation between changes in lipid levels and RA disease activity.[3,4]

Objectives: To determine the relationship between changes in lipid levels and disease activity outcomes in patients with RA treated with UPA.

Methods: Patients with RA and an inadequate response to conventional synthetic/biologic DMARDs (cs/bDMARD-IR) from SELECT-NEXT/SELECT-BEYOND, respectively, were randomized to receive UPA 15 mg once daily (QD), UPA 30 mg QD, or PBO for 12 weeks followed by an extension of up to 5 years; patients randomized to PBO switched to UPA 15 or 30 mg after 12 weeks. Spearman correlations of maximum changes from baseline (BL) through Week 12 in fasting-state lipid levels (low- and high-density lipoprotein cholesterol [LDL-C; HDL-C], and total cholesterol [TC]) with clinical disease activity outcomes measured by change from BL in Clinical Disease Activity Index (CDAI), DAS of 28 joints using CRP (DAS28[CRP]), tender/swollen joint count in 28 joints (TJC28/SJC28), and pain by visual analog scale (VAS) at Weeks 12 and 24, were determined. Spearman correlations of maximum changes from BL in lipid levels and CRP through Week 12 were also determined.

Results: Available fasting samples from 1,160 pooled patients (UPA 15 mg, n=386; UPA 30 mg, n=384; PBO, n=390) were included. Modest, but statistically significant, negative correlations were observed between maximum changes from BL in TC through Week 12 and change from BL in CDAI, DAS28(CRP), SJC28, and pain (VAS) at Week 12 with UPA 15 or 30 mg (Figure 1); similar trends were observed at Week 24. Significant correlations between changes in LDL-C and HDL-C and disease activity outcomes were also observed, but were not consistent across UPA doses and time points. No significant correlations were noted between changes in lipid levels and disease activity outcomes in the PBO group. Statistically significant weak negative relationships were observed between maximum changes from BL in lipid levels and CRP levels through Week 12 with UPA 15 mg (HDL-C and TC) or UPA 30 mg (LDL-C and TC) (Table 1).

Conclusion: In this large pooled data set of patients receiving UPA, increases in lipid levels showed modest, but statistically significant, correlations with improvement in clinical disease activity outcomes in patients with cs/bDMARD-IR RA. These results add to evidence suggesting a relationship between systemic inflammation and lipid metabolism in patients with RA, which is modifiable with effective interventions, and reinforce the importance of monitoring for hyperlipidemia in these patients.

Background: The Janus kinase-1 preferential inhibitor filgotinib (FIL) improved signs and symptoms of rheumatoid arthritis (RA) in the FIL clinical program.[1–3]

Objectives: To assess FIL safety across regions.

Methods: This was an analysis of patients (pts) meeting 2010 ACR/EULAR RA criteria in pooled phase (P)2 DARWIN 1–2 (D1–2), P3 FINCH 1–3 (F1–3), and long-term extension studies (DARWIN 3, FINCH 4). Data were analyzed by region: North America, South and Central America, Western Europe, Eastern Europe, Asia, South East (SE) Asia, and Other. Week (W)12 placebo (PBO)-controlled analysis included data from pts receiving once-daily FIL 100 mg (FIL100), FIL 200 mg (FIL200), or PBO for ≤12W (D1–2, F1–2); long-term as-treated data included pts from all 7 studies receiving FIL100 or FIL200; data after rerandomization were included and contributed to treatment received. Data presented as exposure-adjusted incidence rates (EAIRs)/100 patient-years of exposure (PYE) of treatment-emergent (TE) adverse events (TEAEs).

Results: Table 1 shows EAIRs of TEAEs in PBO-controlled analysis. EAIRs/100 PYE of all TEAEs in Western Europe, Asia, and Other were higher than in remaining regions and for PBO vs FIL arms; EAIRs for FIL200/FIL100 in North America and SE Asia were higher vs PBO. EAIRs/100 PYE of TE serious AEs were higher in SE Asia for FIL100 and for FIL200/FIL100 in Other, with high PBO EAIRs in Western Europe. EAIRs/100 PYE of TEAEs leading to study discontinuation were higher in FIL arms vs PBO in Western Europe and Other (FIL200); in Asia and SE Asia, EAIRs were higher for PBO vs FIL200/FIL100.

Table 1. EAIR of TEAEs (placebo-controlled)

	North America N = 481	South and Central America N = 350	Western Europe N = 141	Eastern Europe N = 933	Asia N = 236	South East Asia N= 135	Other N = 70

PBO[c]	16.1 (7.2, 35.9)	7.5 (1.9, 30.0)	29.6 (9.5, 91.7)	4.6 (1.3, 15.8)	11.4 (2.8, 45.5)	10.2 (1.4, 72.4)	0.0 (0.0, 69.2)
TEAE leading to discontinuation							
FIL200[a]	8.6 (2.8, 26.6)	3.8 (0.1, 21.2)	16.6 (4.2, 66.5)	12.9 (5.5, 30.5)	0.0 (0.0, 20.2)	9.2 (1.3, 65.1)	16.5 (0.4, 92.1)
FIL100[b]	10.6 (4.0, 28.3)	7.2 (0.9, 26.0)	19.9 (5.0, 79.7)	1.9 (0.2, 13.8)	5.4 (0.1, 30.1)	9.6 (1.4, 68.2)	0.0 (0.0, 75.5)
PBO[c]	5.4 (1.3, 21.5)	0.0 (0.0, 13.8)	9.9 (1.4, 70.0)	12.9 (5.4, 30.7)	17.1 (3.5, 49.9)	20.4 (5.1, 81.6)	0.0 (0.0, 69.2)

Data presented as EAIR (95% CI)/100 patient-years

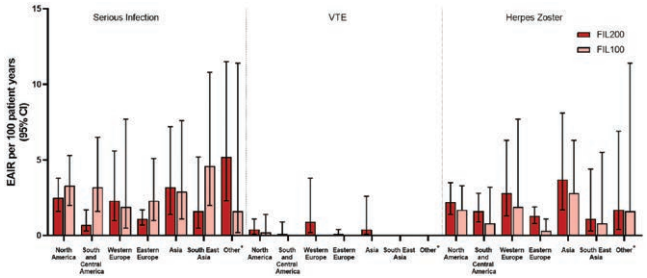
[a]N = 777, 179.8 PYE [b]N = 788, 181.6 PYE [c]N = 781, 178.4 PYE

A subject may contribute to more than one treatment group if they received more than one treatment of interest.

EAIR and corresponding 95% CI were estimated using Poisson regression model by treatment, including study and treatment with an offset of natural log of exposure time, except when 0 events occurred; Poisson model was not adjusted by study.

AE, adverse event; CI, confidence interval; EAIR, exposure-adjusted incidence rate; FIL, filgotinib; PBO, placebo; PYE, patient-years of exposure; TE, treatment-emergent

Figure shows serious infections (SI), venous thromboembolism (VTE) and herpes zoster (HZ) EAIRs.



EAIRs for SI were highest in Other for FIL200 and SE Asia for FIL100. While VTE EAIRs were low, pts in 5/7 regions had VTE. HZ EAIRs were highest in Asia.

Conclusion: Although EAIR of TEAEs varied between regions, no consistent trend was reflected in any particular region.

POS0658 GEOGRAPHIC VARIATION OF EFFICACY IN THE FILGOTINIB RHEUMATOID ARTHRITIS PROGRAM

M. H. Buch[1], T. Matsubara[2], B. Combe[3], A. Pechonkina[4], Y. Tan[5], Z. Yin[6], J. Hong[6], R. Besuyen[7], A. Gomez-Centeno[8]. [1]*University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom*; [2]*Matsubara Mayflower Hospital, Department of Orthopaedic Surgery, Kato, Japan*; [3]*University of Montpellier, Department of Rheumatology, Montpellier, France*; [4]*Gilead Sciences, Inc., Inflammation and Respiratory Therapeutic Area, Foster City, United States of America*; [5]*Gilead Sciences, Inc., Inflammation Therapeutic Area, Foster City, United States of America*; [6]*Gilead Sciences, Inc., Biostatistics, Foster City, United States of America*; [7]*Galapagos BV, Clinical Development, Leiden, Netherlands*; [8]*Hospital Universitari Parc Taulí, Department of Rheumatology, Barcelona, Spain*

Background: The Janus kinase-1 preferential inhibitor filgotinib (FIL) improved signs and symptoms of rheumatoid arthritis (RA) across the FIL clinical program.[1–3]

Objectives: To assess FIL efficacy across geographic regions.

Methods: Pooled data from patients (pts) meeting 2010 ACR/EULAR RA criteria randomised to once-daily FIL 200 mg (FIL200), FIL100 mg (FIL100), or placebo (PBO) with background conventional synthetic disease-modifying antirheumatic drugs in DARWIN 1 (P2; up to week [W]12) and FINCH 1–2 (P3; up to W24) studies were evaluated. Data were analysed by region: North America, South and Central America, Western Europe, Eastern Europe, Asia, South East (SE) Asia, and Other. W12 American College of Rheumatology 20% improvement (ACR20) and W24 Disease Activity Score in 28 joints (C-reactive protein) (DAS28[CRP]) <2.6 and ≤3.2 response rates were analysed by a logistic regression model. Change from baseline (CFB) in Health Assessment Questionnaire-Disability

Index (HAQ-DI) at W12 was analysed by a mixed-effects model for repeated measures. Analyses were exploratory and not adjusted for multiplicity.

Results: Despite high PBO response rates in Eastern Europe and South and Central America, greater proportions of pts receiving FIL200 or FIL100 vs PBO achieved ACR20 at W12 (*P* <0.05) in all regions, except Other (with lowest sample size, n = 69), where both FIL doses were numerically greater than PBO (Table 1). At W12, least-squares mean CFB in HAQ-DI improved for pts receiving FIL200 or FIL100. vs PBO (*P* <0.05) in all regions, except SE Asia, where improvement was numeric (Table 1).

Table 1. Proportion of pts achieving ACR20 and LSM change from baseline HAQ-DI at week 1

POS0659

REAL WORD EXPERIENCE WITH TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS: AN INTERIM ANALYSIS FROM A FRENCH PROSPECTIVE OBSERVATIONAL STUDY DeFacTo

C. Gaujoux-Viala[1], A. Basch[2], S. Lassoued[3], F. Coury-Lucas[4], M. Kessouri[5], N. Mammar[5], T. Lequerre[6], C. Salliot[7]. *[1]University Hospital Carémeau, Rheumatology, NIMES, France*; *[2]Infirmerie Protestante de Lyon, Rheumatology, Caluire et Cuire, France*; *[3]Cahors Hospital Center, Rheumatology, Cahors, France*; *[4]Lyon Sud Hospital, Rheumatology, Pierre-Bénite, France*; *[5]Pfizer, Immunologie & Inflammation, Paris, France*; *[6]Rouen University Hospital & Inserm U905, Rheumatology, Rouen, France*; *[7]Orléans Régional Hospital Center, Rheumatology, Orléans, France*

Background: Tofacitinib is an oral JAK inhibitor indicated for moderate to severe active rheumatoid arthritis (RA).

Objectives: To present baseline patients characteristics and effectiveness data at 6 months of DeFacTo real life study ("I**De**ntification of **Fa**ctors predictive of **To**facitinib's survival").

Methods: DeFacTo is an observational, open-label, prospective, multi-center, national study designed to evaluate the predictive factors of tofacitinib's survival in patients with moderate-to-severe active rheumatoid arthritis according to the SmPC[1]. Here we present the 1st interim results involving a descriptive analysis of the 221 patients included between January 2019 and March 2020 (POP1). Effectiveness results at 6 months of 145 patients having ≥ 6 months follow-up (POP2) are also described.

Results: The baseline characteristics of the POP1 patients (n = 221) were: 78.3% women with a mean age (± SD) of 60.4 ± 11.1 years, disease duration of 12.0 ± 9.8 years, TJC: 7.3 ± 5.7 and SJC: 5.1 ± 4.7; 44.0% of patients had erosions, 79.5% were RF+ and 75.9% were ACPA+. The mean CRP was 15.3 ± 21.8 mg/l, the ESR at one hour was 28.7 ± 23.6 mm, DAS28-4 CRP was 4.6 ± 1.0, DAS28-4 ESR was 4.9 ± 1.1 and the FACIT-Fatigue score was 27.6 ± 11.3. A total of 97.3% of patients had been previously treated by ≥1 csDMARD (mean number 1.9 ± 1.0) and 66.1% by b/tsDMARDs (mean number 2.9 ± 2.5), tofacitinib was prescribed as monotherapy (without csDMARD) in 49.3% of patients. The characteristics of the POP2 patients were similar to those of POP1. At 6 months in POP2, 29 patients have discontinued their treatment with tofacitinib. The results showed a decrease from baseline in inflammatory markers (CRP from 14.2±17.1 to 4.7±4.2 mg/l), pain (Pain VAS from 58.3±23.4 to 27.6±22.1) and DAS28 activity scores with 23% of patients in DAS28-CRP remission and 36% of patients in DAS28-CRP LDA (figure 1). This interim analysis didn't identifyany new safety findings (Table 1).

Conclusion: *Preliminary results from this prospective observational study on the use of tofacitinib in patients suffering with RA in France indicate that its* effectiveness *and safety are similar to those found in the clinical studies*[1-3]. *In this study, tofacitinib was prescribed as monotherapy (without csDMARD) in more than 49% of cases.*

Burmester[9]. *[1]University of Oxford, Botnar Research Center, Oxford, United Kingdom*; *[2]UCLA Medical Center, Department of Medicine, Los Angeles, United States of America*; *[3]Gilead Sciences, Inc., Clinical Research, Foster City, United States of America*; *[4]University of Washington, Department of Rheumatology, Seattle, United States of America*; *[5]Gilead Sciences, Inc., Rheumatology Therapeutic Area, Foster City, United States of America*; *[6]Gilead Sciences, Inc., Biostatistics, Foster City, United States of America*; *[7]Galapagos BV, Department of Rheumatology, Leiden, Netherlands*; *[8]Amsterdam Rheumatology & Immunology Center, Department of Rheumatology, Amsterdam, Netherlands*; *[9]Charité - Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: The Janus kinase-1 preferential inhibitor filgotinib (FIL) improved rheumatoid arthritis (RA) signs and symptoms in phase (P)3 trials.[1–3] RA elevates cardiovascular disease risk; statins are used to reduce risk.
Objectives: To assess safety of statin and filgotinib coadministration across the clinical program.
Methods: Patients (pts) meeting 2010 ACR/EULAR RA criteria in P2 DARWIN 1–2 (D1–2; NCT01888874, NCT01894516), P3 FINCH 1–3 (F1–3; NCT02889796, NCT02873936, NCT02886728), and long-term extensions DARWIN 3 and FINCH 4 (D3, F4; NCT02065700, NCT03025308) receiving FIL 100 mg (FIL100) QD, FIL 200 mg QD (FIL200), adalimumab (ADA), methotrexate (MTX), or placebo (PBO) were included. Events related to statin use were analysed as exposed by treatment received. N and % were provided.
Week (W)12 PBO-controlled safety analysis included pts receiving FIL100, FIL200, or PBO for ≤12W (D1–2, F1–2); as-treated safety analysis included pts receiving long-term FIL100 QD (n=1647), FIL200 QD (n=2267), ADA (n=325), MTX (n=416), or PBO (n=781) (D1–3, F1–4); P3 as-randomised analysis included data up to W52 (F1–3) per assigned treatment.
Results: In each arm, similar proportions of pts took statins at baseline (9.4%–11.9%); initiation during study was low (1.2%–6.8%). Through W12 in PBO-controlled analysis, mean creatine phosphokinase (CPK; Figure 1), alanine aminotransferase (ALT), and aspartate aminotransferase (AST) levels were similar regardless of statin use and remained within normal levels across all arms.

Figure: CPK levels through W12 in PBO-controlled analysis*

Data are n (%). Grading per Common Terminology Criteria for Adverse Events v4.03
*FINCH 1–2**DARWIN 1–2, FINCH 1–2ALT, alanine aminotransferase; AST, aspartate aminotransferase; CPK, creatine phosphokinase; csDMARD, conventional synthetic disease-modifying antirheumatic drug; FIL200/100, filgotinib 200/100 mg + csDMARDs; Grade, G; PBO, placebo; ULN, upper limit of normal.

In the long-term as-treated analysis, 1 (0.5%)/6 (3.2%)/0/0/0 treatment-emergent adverse events (AE) of myalgia occurred in pts on statins at baseline receiving FIL200/FIL100/ADA/MTX/PBO and in 12 (0.6%)/8 (0.5%)/3 (1.0%)/2 (0.5%)/1 (0.1%) pts not on statins. Muscle spasms occurred in 2 (0.9%)/3 (1.6%)/1 (3.2%)/0/1 (1.1%) pts on statins at baseline receiving FIL200/FIL100/ADA/MTX/PBO and 21 (1.0%)/8 (0.5%)/0/3 (0.8%)/1 (0.1%) pts not on statins at baseline. One patient not on statins receiving FIL200 reported rhabdomyolysis. For all treatment arms in P3 as-randomised analysis, mean LDL and HDL increased similarly from baseline (108–110 and 56–59 mg/dL, respectively) to W52 (119–130 and 59–71 mg/dL, respectively).
Conclusion: No increases in statin-induced AEs such as muscle or liver toxicities occurred with statins and filgotinib coadministration; results are supported by a drug-drug interaction study.[4] Mean LDL and HDL increased at W52 in all treatment arms.

POS0661 RAPID RESPONSE TO BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS AND AN INADEQUATE RESPONSE TO METHOTREXATE AND AT LEAST ONE BIOLOGIC DMARD: A CLINICAL AND POWER DOPPLER ULTRASOUND STUDY

C. Baldi[1], P. Falsetti[1], E. Conticini[1], S. G. Khayyat[1], M. Bardelli[1], S. Gentileschi[1], L. Cantarini[1], B. Frediani[1]. [1]*Rheumatology Unit, University of Siena, Siena, Italy*

Background: Baricitinib, an oral Janus kinase (JAK) 1-2 inhibitor, is currently used among biologic DMARDs (bDMARDs) after the failure of methotrexate (MTX) in rheumatoid arthritis (RA). Power Doppler ultrasound (PDUS) is a promising, non-invasive imaging method to assess synovitis in RA: results from numerous studies suggest that it provides additional information to clinical and conventional radiographic examinations.

Objectives: The main objective of our study was to evaluate short-term efficacy of Baricitinib in reducing synovitis, using the composite semi quantitative scale (0–3 grades) PDUS synovitis score, developed by the Outcome Measures in Rheumatology– European League Against Rheumatism (OMERACT–EULAR)-Ultrasound Task Force. Moreover both synovial hyperplasia and intrasynovial power Doppler (PD) signal were also scored as single components/parameters on 0-3 scales. Secondary objective was to assess the concordance between patient reported outcomes (PROs), markers of inflammation, physical examination and US.

Methods: We enrolled 30 patients fulfilling 2010 ACR and EULAR criteria for RA. All patients had failed at least one anti-TNF. Each patient was prescribed Baricitinib 4 mg/daily at T0, in addition to MTX and/or oral steroids at a dosage ≤ 7, 5 mg/day of Prednisone or equivalent, at T'. All patients were evaluated at baseline (T0) and then after one month (T1), 3 months (T2) and 6 months (T3) of treatment. Swollen and tender joints (out of 28)were evaluated and recorded, as well as patient (PGA) and physician global assessment (PhGA) and pain, expressed in a visual analog scale (VAS). Disease activity was evaluated at each visit using DAS28 (Disease activity score 28), CDAI (Clinical disease activity index)and SDAI(Simplified disease activity index), accompanied by a complete blood count, Erythrocyte sedimentation rate (ESR) and C- reactive protein (CRP) collection. Statistical analysis was performed using GraphPad version 9.0.0. PDUS examination, was carried out by two rheumatologists (PF and CB) blinded to clinical conditions of the patients, using an Esaote Mylab Twice (Genoa, Italy), equipped with a high-frequency (6-18 MHz) linear probe. With standardised Doppler parameters (pulse repetition frequency between 500-750 Hz; Doppler frequency between 7–11.1 MHz). PDUS was performed at each visit bilaterally for 22 joint sites [MCPs 1–5, proximal interphalangeal joints (PIPs) 1–5, wrist, elbow, glenohumeral, knee, tibiotalar, talonavicular and calcaneocuboidal and metatarsophalangeal joints (MTPs) 1–5] for a total of 44 joints for each patient.

Results: we observed a reduction of VAS pain (T0 vs, T6<0,0001) PDUS composite score (T0 vs. T6 p<0,0001), Power Doppler (T0 vs. T6 p<0,0001) synovial hyperplasia (T0 vs. T6 p=0,0002), CRP (T0 vs. T6 p<0,0001) and ESR (T0 vs. T6 p <0,0001) was observed in our patients. Accordingly, DAS-28, CDAI and SDAI displayed a significant reduction too (DAS-28: T0 vs. T6 p< 0, 0001; CDAI: T0 vs. T6 p< <0, 0001; SDAI: T0 vs. T6 p= 0, 0003).

Conclusion: We investigated the efficacy of Baricitinib in real life, evaluating both from a clinimetric and ultrasound point of view. Baricitinib, demonstrated a significant parallel and fast improvement in VAS, PDUS and CRP was found at follow up assessment as early as one month of therapy. In conclusion, these results demonstrated the short term efficacy of Baricitinib 4mg for up to 6 months and providing a prompt improvement of PROs within the first weeks of treatment.

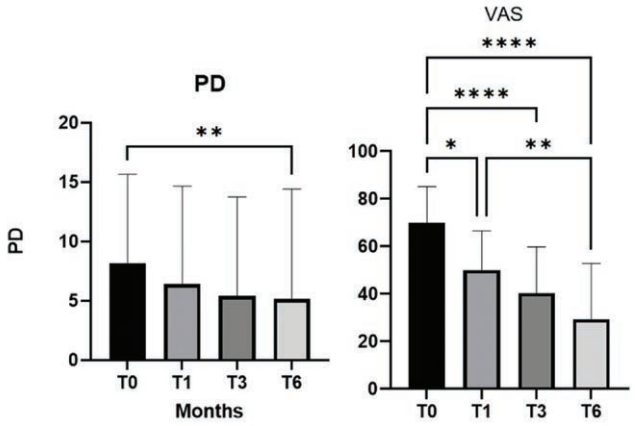

Figure 1. The difference between the means of PD and of the VAS pain over time (T0, T1, T3 and T6).Power Doppler (T0 vs. T6** p<0,0001), VAS: (T0 vs. T1 *p<0,0098;T0 vs. T3 **** p<0,0001; T0 vs. T6 ****p<0,0001)

Disclosure of Interests: None declared

POS0662 PREDICTORS OF TOXICITY WITH HYDROXYCHLOROQUINE AND CHLOROQUINE USE: A SYSTEMATIC REVIEW

N. Citeroni[1], S. Rampes[1], P. Kotecha[1], J. Schoones[2], E. Nikiphorou[3,4], J. Galloway[3,4]. [1]*King's College London, GKT School of Medical Education, Faculty of Life Sciences & Medicine, London, United Kingdom*; [2]*Leiden University Medical Center, Walaeus Library, Leiden and the Hague, Netherlands*; [3]*King's College London, Centre for Rheumatic Diseases, London, United Kingdom*; [4]*King's College Hospital, Rheumatology Department, London, United Kingdom*

Background: Hydroxychloroquine (HCQ) has attracted much attention especially during the COVID-19 pandemic. HCQ and closely related chloroquine (CQ) have known ocular and cardiac toxicity. However, although screening guidance now exists from the Royal College of Ophthalmologists for the former (RCOphth)[1], little is known regarding predictors of both forms of toxicity.

Objectives: To systematically explore the literature on predictors of toxicity limited to cardiac and ocular toxicity.

Methods: A detailed search of the following databases was conducted: PubMed, Medline, Embase, Web of Science, The Cochrane library, EMCare and Academic Search Premier. Studies addressing predictors of HCQ toxicity with relevant search terms used were included. Exclusion criteria were: non-English articles, pre-clinical and paediatric studies. Three authors (SR, NC, PK) independently screened titles and abstracts for inclusion, ensuring each article was screened twice. Disagreement over inclusion was adjudicated by senior reviewers (EN, JG). Data extraction (SR, NC, PK) focused on predictors of toxicity.

Results: The search strategy retrieved 3103 studies. 147 studies were included for data extraction, of which 92 were eventually excluded due to: not identifying predictors (n=17), reviews (n=19), not ocular or cardiovascular toxicity (n=18), case reports (n=3), paediatrics (n=1), screening articles that focused on detecting retinopathy (n=30), article unobtainable at time of abstract submission (n=4), leaving 55 studies for full review.

Studies addressing cardiac toxicity (n=16) included: cohort, retrospective observational, a comparative pharmacovigilance, systematic monitoring protocol and a randomised control trial (RCT). The majority of these involved high-dose (>5mg/kg/day) use for acute COVID-19 infection. The main significant predictors identified were: Hydroxychloroquine (HCQ) use in combination with azithromycin (6/7 studies), cumulative dose (2 studies), pre-existing cardiovascular morbidity (2/3 studies) and prolonged baseline QTc (2 studies). Individual associations were also identified in the following: longer treatment duration, daily dosage, increased age, male gender, severe COVID-19 infection, abnormal liver function tests (LFTs) and concurrent use of loop-diuretics.

Regarding predictors of ocular toxicity (n=39), only one study was a RCT. The remainder were observational studies: case-control, cohort, retrospective chart reviews and letters to the editor which included original patient data.

Several predictors of retinopathy and maculopathy were examined in two or more studies and included: duration of use (16/18 studies), daily dosage (7/13 studies), cumulative dose (11/14 studies), increased age (10/11 studies), body weight or BMI (3/5 studies), renal impairment (5 studies), HCQ blood levels (2 studies),

keratopathy (2 studies) and tamoxifen use (2 studies). Sex (2 studies) and history of cataract surgery (2 studies) were not found to be predictors of toxicity.
Only few studies performed regression analysis presenting odds and/or hazard ratios with confidence intervals.
Conclusion: The most recognised predictor of cardiac toxicity was co-administration with azithromycin. In ocular toxicity, commonly cited predictors included those already recognised by the RCOphth[1], as well as cumulative dose, increased age, weight considerations, HCQ blood levels and keratopathy. Further research is warranted on better characterising predictors of cardiac and ocular toxicity in patients on HCQ and CQ therapy.

POS0663 SAFETY AND EFFICACY OF COMBINING METHOTREXATE AND LEFLUNOMIDE AMONG PATIENTS WITH INFLAMMATORY ARTHROPATHIES: FINDINGS FROM THE PRIME REGISTRY

M. Haroon[1], A. Ashraf[2], H. J. Shaheen[1], S. Asif[1], S. Batool[1], F. Hashmi[1], S. Ullah[1]. [1]*Fatima Memorial Hospital & FMH College of Medicine and Dentistry, Department of Rheumatology, Lahore, Pakistan*; [2]*CMH Lahore Medical College & Institute of Dentistry, Medicine, Lahore, Pakistan*

Background: Currently, conventional synthetic DMARDs (csDMARDs) are the most commonly prescribed drugs as first-line treatment for peripheral arthritis. In resource-constrained settings where biologic agents are not widely available, there are limited therapeutic options for patients with rheumatoid arthritis (RA) and seronegative inflammatory arthropathies refractory to other csDMARD therapies. Hence, in our practice, we are inclined to use combination of potent DMARDs after MTX failure, prior to considering biologic therapies. We believe that combination of DMARDs, especially combining MTX and Leflunomide (LEF) provides a potent and valuable low-cost treatment option. Efficacy of MTX and LEF is very well established, but there have been lot of concern as regards their combination use due to potential risk of hepatotoxicity.
Objectives: We aimed to review our inflammatory arthropathies cohort data especially examining the safety, efficacy and drug retention of the combination usage of MTX and Leflunomide. We addressed this question using real-world data from the PRIME registry.
Methods: This was a cross-sectional study conducted using data collected at the time of patient enrolment in the PRIME registry. The PRIME Registry is a large, independent, prospective, observational cohort initiated in October 2019 that comprises patients diagnosed with RA, SLE, PsA or AS by a rheumatologist, and is being actively followed up. IRB approval and informed consent was obtained. A number of clinical variables were recorded. Detailed history was gathered from every patient regarding their present and past medications usage. Questions were asked directly about the usage or otherwise of all available DMARDs and biologics. The duration of usage, any adverse events, or the reasons for discontinuation were recorded. Evaluation of disease activity and severity was made as per internationally agreed definitions.
Results: The data of 766 inflammatory arthritis patients (RA=663, PsA=103) was reviewed. Among them, 241 patients (RA=196, PsA=45) were using combination therapy of MTX and LEF (combo MTX+LEF) with mean age 42.3±6 years; 42% male]. These patients had failed MTX or LEF monotherapy. Among these 241 patients, 49 patients were also on concomitant hydroxychloroquine therapy. It was noted that median drug retention of combo MTX+LEF therapy has been 9.5 months (IQR 6-16). Regarding any adverse events of combo MTX+LEF therapy, hepatotoxicity (ALT ≤3 times the upper limit of normal) was noted among 15 (6.2%) patients, hepatotoxicity (ALT ≥3 times the upper limit of normal) was noted among 8 (3.3%) patients, and troublesome gastrointestinal upset (nausea, or vomiting, or diarrhoea) in 3 (1.2%). Overall, only 13 (5.4%) patients had to discontinue this combo MTX+LEF therapy due to adverse events. Disease activity among combo MTX+LEF users was as follows: 64% (n=29) of PsA patients had achieved MDA; 42% (n=83) of RA cohort were in DAS28 remission, 46% (n=91) of RA patients were having DAS low disease activity.
Conclusion: Combination of MTX and LEF was well tolerated and had good drug retention time, with 94.6% of patients having ongoing treatment to date. In low-income countries, where bDMARD availability is limited, financial arguments significantly influence decision making process, and our data provides initial evidence that MTX and LEF combination therapy could be an effective treatment option.

Background: Iguratimod (IGU) has demonstrated efficacy and safety for active rheumatoid arthritis (RA) patients in double-blind clinical trials in China and Japan as a new disease-modifying anti-rheumatic drug (DMARD). There are no studies evaluating the radiographic progression of structural joint damage of IGU for the treatment of RA using the mTSS as the primary endpoint.
Objectives: Our study was to evaluate the efficacy and safety of IGU monotherapy and IGU combined methotrexate (MTX) compared with MTX monotherapy, including the inhibitory effects of joint destruction.
Methods: This randomized, double-blind, parallel-controlled, multicenter study in patients with active RA who have not previously used MTX and biological DMARDs (bDMARDs) (ClinicalTrials.gov Identifier NCT01548001) was carried out in China. Patients were randomized 1:1:1 to receive IGU 25 mg twice a day (bid), MTX 10mg once a week(qw) for the first 4 weeks and 15 mg once a week(qw) for week 5 to 52, or IGU combined MTX (IGU+MTX) for 52 weeks. The primary endpoints were to assess and compare American College of Rheumatology 20% (ACR20) response and the change of modified total Sharp scoring (mTSS) score over 52 weeks (Intention-to-treat, ITT analysis). The non-inferiority test was used to analyze the difference of ACR20 response at 52 weeks between the IGU monotherapy and the MTX monotherapy arms, and the non-inferiority

limit value was 10%. The difference test was used for the comparison between the IGU+MTX and MTX monotherapy arms. Two-way ANOVA was used to analyze the difference of the changes of mTSS score of each arm compared with baseline value (0 week).

Results: A total of 895 patients were randomized to IGU 25mg bid (n =297), MTX 10-15mg qw(n=293), and IGU+MTX (n=305). Baseline characteristics were comparable between the arms (Table 1).

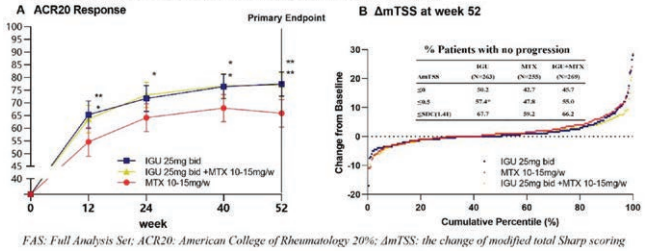
Table 1. Demographic and Other Baseline Characteristics (SAS)

	IGU	MTX	IGU+MTX
Number of Subjects	**297**	**293**	**305**
Age, mean (SD) years	46.87(10.67)	47.63(10.70)	48.37(10.69)
Female/male, %	77.44/22.56	79.18/20.82	78.03/21.97
Duration of RA, mean(SD) years	11.67±7.16	11.60±7.98	11.67±7.27
CRP, mean(SD) mg/L[2]	22.32±35.47	20.67±26.61	19.74±31.38
Tender joint count, mean (SD)	14.59±9.16	14.83±9.30	14.93±9.88
Swollen joint count, mean (SD)	9.81±6.63	9.73±7.20	9.51±6.22
DAS28-CRP, mean (SD)	5.084±0.994	5.102±0.979	5.103±0.956
HAQ score, mean (SD)	15.82±11.25	15.24±10.93	16.06±10.92

SAS: Safety Analysis Set; CRP: C-reactive protein;
DAS28: disease activity score; HAQ: Health Assessment Questionnaire

The study met its primary endpoints. More concretely, IGU monotherapy and IGU+MTX were found to be superior to MTX at week 52 with a higher ACR20 response of 77.44%(230/297, P=0.0019) and 77.05%(235/305, P=0.0028) versus 65.87%(193/293) (fig 1). As shown in fig 1
, the structural remission (ΔmTSS≤0.5) was statistically significant for IGU monotherapy (57.4%, P=0.0308) but not for IGU+MTX arm (55%) versus MTX monotherapy (47.8%).

Figure 1. ACR20 response and the percent of patients with no progression (FAS)



FAS: Full Analysis Set; ACR20: American College of Rheumatology 20%; ΔmTSS: the change of modified total Sharp scoring

Overall incidence of the adverse events (AEs) leading to study discontinuation were reported in 13.8% (41/297) in IGU monotherapy arm, 11.26% (33/293) in MTX monotherapy arm and 11.51% (35/305) patients in IGU+MTX arm. The incidence of adverse drug reactions (ADR) leading to study discontinuation were 11.45% (34/297), 8.53% (25/293) and 9.21% (28/305), respectively. There was no one death and no significant difference in all the safety indicators among the three arms.

Conclusion: Iguratimod alone or in combination with MTX demonstrated superior efficacy with acceptable safety compared to MTX for patients with active RA who have not previously used MTX bDMARDs.

POS0665 TRAJECTORIES OF GLUCOCORTICOID-THERAPY IN EARLY RHEUMATOID ARTHRITIS: FIRST RESULTS OF A SCOPING SYSTEMATIC REVIEW AND META-ANALYSIS OF OBSERVATIONAL COHORT STUDIES

A. Palmowski[1], F. Buttgereit[1]. [1]*Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Glucocorticoids (GCs) are regularly used as a bridging therapy in early rheumatoid arthritis (eRA). As long-term treatment, especially at higher dosages, may lead to undesirable adverse events, GCs should be tapered as rapidly as clinically feasible.

Objectives: To assess real-world trajectories of GC-therapy initiated in patients with eRA and in methotrexate-naïve RA patients.

Methods: We conducted a scoping search in MEDLINE (via PubMed) to find articles (years 2005 – 2020) reporting on eRA (or methotrexate-naïve RA) patients from observational cohorts who start or take GCs at baseline. Articles had to describe either dosages or proportions of patients who took GCs or were able to taper GCs at two (minimum) pre-specified time points. The articles were screened by one reviewer (AP). Random-effects meta-analyses pooled results per outcome and time point if ≥3 studies were available. *R* software with package *metafor* was used for statistical analyses. A research protocol was published with protocols.io (10.17504/protocols.io.bpyfmptn).

Results: Our highly specific search strategy yielded 165 results. Twelve articles on nine cohorts were finally included. Eight cohorts originated in Europe, one in Africa. At baseline, about half of the patients with eRA were prescribed GCs with a mean dosage of 8mg/d prednisone equivalent (fig 1
). Over time, both the proportion taking GCs and the mean dosage declined. There was substantial heterogeneity between studies.

Conclusion: Our results indicate that GCs remain regularly used drugs in eRA patients and in methotrexate-naïve patients with RA. While about 40% of patients still receive GCs after 24 months, mean dosages were tapered to "low" dosages (≤7.5mg/d prednisone equivalent)[1] in all cohorts that reported respective data. Heterogeneity might be caused by country-specific differences. Unfortunately, the validity of sensitivity analyses would be poor due to the paucity of published data regarding GC dosages and proportions of patients taking GCs in observational RA cohorts. Major limitations of this scoping review are the very specific (and consequently less sensitive) search strategy and that the screening was conducted by one reviewer only.

POS0666 TREATMENT EFFECTIVENESS OF UPADACITINIB AT 3 MONTHS IN US PATIENTS WITH RHEUMATOID ARTHRITIS FROM THE UNITED RHEUMATOLOGY NORMALIZED INTEGRATED COMMUNITY EVIDENCE (NICE[TM]) REAL-WORLD DATA

A. Gibofsky[1], B. Dhillon[2], M. E. Pearson[3], N. Tundia[4], Y. Song[4], K. Dunlap[4], G. Wright[5]. [1]*Weill Cornell Medical College, Hospital for Special Surgery, New York, United States of America*; [2]*United Rheumatology, Rheumatology, Hauppauge, United States of America*; [3]*West Suburban Center for Arthritis, Rheumatology, Brookfield, United States of America*; [4]*AbbVie Inc, Immunology, North Chicago, United States of America*; [5]*Association of Women in Rheumatology, Rheumatology, New York, United States of America*

Background: Upadacitinib (UPA), an oral Janus kinase inhibitor (JAKi), has demonstrated efficacy in the phase 3 SELECT clinical program, conducted across a range of patients (pts) with rheumatoid arthritis (RA).[1–6] Real-world data for UPA, including in pts previously treated with a JAKi, have not yet been reported since global approvals beginning in 2019.

Objectives: To assess the characteristics of US-based pts receiving UPA and its effectiveness in clinical practice at 3 months.

Methods: This observational study included US-based pts from the United Rheumatology Normalized Integrated Community Evidence (UR-NICE) database who initiated UPA 15 mg once daily from FDA approval (August 2019) to July 31, 2020 and had ≥6-month pre-baseline data available. Effectiveness was assessed in pts with a reported Clinical Disease Activity Index (CDAI) score at 3 months after UPA initiation and included proportions of pts achieving CDAI remission (≤2.8), CDAI low disease activity (≤10), other disease activity measures, and pt-reported outcomes. A subgroup analysis assessed UPA effectiveness in pts with or without prior tofacitinib (TOFA) treatment.

Results: This analysis included 252 pts treated with UPA 15 mg, of whom 98 (38.9%) received UPA monotherapy and 154 (61.1%) received UPA combined with conventional synthetic (cs) disease-modifying antirheumatic drugs (DMARDs). 64.3% of pts were from the Southern region of the USA. 86.1%, 72.2%, and 47.6% of pts had been previously treated with csDMARDs, biologic DMARDs, and JAKis, respectively. Baseline characteristics were largely similar between UPA monotherapy and combination therapy groups and those with or without prior TOFA treatment (Table 1). Pts with prior TOFA treatment had a longer duration of RA since diagnosis and higher steroid use versus those without. UPA 15 mg improved disease activity scores (including CDAI) and pt-reported outcomes (including physical function and pain) after 3 months of treatment (Figure 1). Similar effectiveness was observed with UPA 15 mg in pts with or without prior TOFA treatment.

Conclusion: In the UR-NICE real-world database of US-based pts, improvements in clinical and pt-reported outcomes were observed at 3 months in UPA-treated pts with RA, including those with or without prior TOFA treatment, despite the treatment-refractory population included in this dataset.

POS0667 TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS IN REAL-WORLD SETTINGS: A NATIONAL MULTICENTER STUDY OF 167 PATIENTS FROM ARGENTINA

M. D. R. Maliandi[1], Y. S. Malvano[2], A. Cusa[3], M. J. Gamba[4], R. Gomez[4], J. Got[5], O. Gut[6], U. V. Paris[7], M. A. Spinetto[8], C. Mariach[8], A. I. Abalo[9], A. Estevez[9], J. L. Velazco Zamora[10], J. P. Vinicki[11]. [1]*Sanatorio Garay, Rheumatology, Santa Fe, Argentina*; [2]*Sanatorio Modelo Adrogué, Rheumatology, Burzaco, Argentina*;

[3]*MR Medicina Reumatológica, Rheumatology, GHP, Argentina*; [4]*Hospital Posadas, Rheumatology, El Palomar, Argentina*; [5]*Instituto Medico Humanitas, Rheumatology, Resistencia, Argentina*; [6]*Private Practice, Rheumatology, Ciudad Autonoma de Buenos Aires, Argentina*; [7]*Hospital Madariaga, Rheumatology, Posadas, Argentina*; [8]*Private Practice, Rheumatology, Buenos Aires, Argentina*; [9]*Hospital El Cruce - Nestor Kirchner, Rheumatology, Florencio Varela, Argentina*; [10]*Clinical Research Institute Quilmes, Rheumatology, Quilmes, Argentina*; [11]*Hospital De Quilmes, Rheumatology, Quilmes, Argentina*

Background: Tofacitinib (TOF), an oral JAK inhibitor, is approved for the treatment of rheumatoid arthritis (RA) either as monotherapy or in combination with background methotrexate (MTX). Despite the current evidence of efficacy from randomized controlled trials and open-label long-term extension studies, evidence of effectiveness and safety in real-world settings is limited, not only in Argentina but also in Latin America.

Objectives: To describe effectiveness, safety and persistence of TOF therapy in RA patients from public and private medical centers from Argentina. In addition, establish prognostic factors for clinical remission at 3 months and TOF monotherapy at 12 months.

Methods: A retrospective, observational and multicentre study was performed from an analysis of medical records of 10 medical centers. RA patients (ACR/EULAR, 2010) and age ≥ 18 years who had received or are under treatment with TOF until June 2020 were included. The data collection was done on a standard database that included baseline data and at 3, 6 and 12 months. Clinical remission was defined as DAS28-ESR < 2,6. Adverse events, treatment duration, TOF treatment persistence at last visit and discontinuation cause were assessed. Comparison to baseline values was performed using Wilcoxon sign for numerical variables and McNemar´s test for categorical variables. Treatment persistence was analyzed using Kaplan Meier´s technique. Multivariate analysis was performed using R software and its library packages (Lme4, Tidyverse and ggpubr). A p value < 0.05 was considered significant.

Results: A total of 167 patients were included (78.4% were female). At baseline, the median age was 53 years (IQR 43-63 years), median disease duration was 4 years (IQR 2-13 years). RF was positive in 85.6% of patients, ACPA in 80.8% and structural radiological damage was present in 71.8%. Previous use of MTX was 97%, leflunomide 74.8% and biologic therapy 42.5% (28.74% 1 biologic, 11.98% 2 biologics and 1.8% ≥ 3 biologics). TOF dose: 48% 11 mg/day and 52% 5 mg BID. A statistically significant difference was observed not only in disease activity (p<0.0001) but also in the requirement of MTX and PDN (p<0.0001) in the 12 months evaluated. Remission significantly increased from baseline to month 3 and to a much lesser extent to month 6 (p < 0.001). The mean duration of treatment with TOF was 20.10 ± 15.25 months. Treatment persistence was 93.84% at 3 months and 91.24% at 6 months. In those patient who achieved REM at month 3, a statistically significant differences in duration of RA (p 0.0002), structural radiological damage (p 0.011), basal disease activity (p 0.018) and prior treatment with biological therapy (p 0.017) was found when compared with patients who remained active. Furthermore, in univariate logistic regression analysis, 5 years or more of disease duration was associated with a 3 times higher risk of not achieving clinical remission at 3 months (odds ratio = 0.35, 95% CI = 0.15-0.83). In the multivariate logistic regression analysis, previous biological therapy was the only predictor associated with a decrease in the probability of clinical remission (p < 0.008). Adverse events were registered in 26 patients (herpes zoster, n = 9).

Conclusion: The effectiveness of TOF was observed not only in the clinical response achieved but also in the dose titration or withdrawal of MTX and PDN. The safety profile did not show any difference from long-term extension studies. At 12 months, 86.81% of the patients persisted with TOF therapy. We found prognostic factors associated with clinical remission at 3 months but those associated with monotherapy at 12 months could not be defined due to small number of patients analyzed that could have generated lack of statistical power, although more studies are required to confirm these assumptions.

POS0668 REAL WORLD EFFECTIVENESS OF BARICITINIB IN THE SWISS RHEUMATOID ARTHRITIS REGISTER (SCQM-RA)

B. Gilbert[1], D. Courvoisier[1], D. Mongin[1], K. Lauper[1,2], C. Perrier[3], R. Muller[4], A. Finckh[1]. [1]*Geneva University Hospitals, Division of Rheumatology, Geneva, Switzerland*; [2]*University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom*; [3]*Eli Lilly SA (Suisse), Medical Department, Vernier, Switzerland*; [4]*Kantonsspital Aarau, Medical University Department, Aarau, Switzerland*

Background: When not responding to conventional synthetic DMARDs (csDMARDs), rheumatoid arthritis (RA) patients may receive biological DMARDs (bDMARDs) or targeted synthetic DMARDs (tsDMARDs) including baricitinib (BARI). While BARI has demonstrated efficacy in randomized controlled trials, limited studies have established comparative effectiveness in real world settings, in particular when used in b/tsDMARD-naïve patients.

Objectives: To analyze the effectiveness of BARI versus alternative bDMARDs, as assessed by drug maintenance over time and by response rates at 12 months.

Methods: This is a nested study of RA patients, within the prospective Swiss Clinical Quality Management (SCQM) observational cohort.

All treatment courses (TC) with BARI or alternative bDMARDs initiated between 2017-09-01 and 2020-06-01, with at least one follow-up visit, were included. TC with BARI were compared to TC with alternative bDMARDs (non-BARI), including all b/tsDMARDs except rituximab. The non-BARI group was then subdivided into TNF inhibitors (TNFi) and other mode of action bDMARDs (OMA), excluding tsDMARDs. A secondary analysis focusing specifically on b/tsDMARD naïve patients was conducted.

Baseline characteristics were compared using ANOVA or $\chi 2$ tests. A Cox-model survival analysis assessed drug maintenance. 12-month response rates were estimated using an attrition-corrected, confounder-adjusted approach (1). CDAI score ≤10 defined low disease activity state (LDA), and CDAI score ≤2.8 defined remission.

Table 1. Baseline characteristics of studied population

Variable	Overall comparison: BARI vs non-BARI			Subgroup analysis 1: by bDMARD type (tsDMARD excluded)			Subgroup analysis 2: In b/tsDMARD-naïve patients			
	BARI (TC = 273; 273 patients)	Non-BARI (altogether) (TC = 945; 755 patients)	p values	TNFi (TC = 473; 408 patients)	OMA (TC = 318; 298 patients)	p values (vs BARI)	BARI (n = 46)	TNFi (n = 225)	OMA (n = 65)	p values
	Mean (SD) Otherwise: n %			Mean (SD) Otherwise: n %			Mean (SD) Otherwise: n %			
Concomitant csDMARD	41 %	46 %	0.17	54 %	41 %	**<0.01**	50 %	61 %	48 %	0.1
Line of Therapy	17 %	35 %	**<0.01**	48 %	20 %	**<0.01**	100 %	100 %	100 %	
-1st (= bio-naive)										
-2nd	20 %	23 %		23 %	23 %					
-3rd	19 %	16 %		11 %	24 %					
-4th or later	44 %	26 %		18 %	33 %					
Female	78%	74 %	<0.21	74 %	73 %	0.28	70 %	71 %	74 %	0.88
Age	59 (14)	56 (14)	**0.01**	52 (15)	58 (13)	**<0.01**	57 (15)	51 (14)	57 (16)	**<0.01**
Disease duration (years)	13 (10)	10 (9)	**<0.01**	8 (9)	11 (9)	**<0.01**	5.5 (6.45)	5 (7)	6.5 (9)	0.243
CDAI baseline	15 (9)	15 (10)	0.9	14 (9)	16 (11)	0.05	13 (7)	14 (9)	14 (10)	0.72
Previous tsDMARD (non-BARI)	33 %	8 %	**<0.01**	4 %	11 %	**<0.01**	0 %	0 %	0 %	
TC duration > 12-months	37 %	29 %	**0.01**	27 %	30 %	**0.02**	37 %	29 %	34 %	0.52

BARI = baricitinib, TNFi = TNF inhibitors, OMA = other mode of action, Non-BARI = TNFi + OMA + other tsDMARDs, SD = standard deviation.

Results: Overall, 1218 eligible TC (from 1028 patients) were initiated during the study period (273 in BARI, 154 other tsDMARD, 473 in TNFi and 318 in OMA). Drug maintenance was significantly shorter for TNFi compared to BARI, even after adjustment for potential confounders (Hazard ratio (HR) for drug discontinuation 1.85 (95% CI [1,40 – 2,43]); p < 0.001). Drug maintenance was also numerically shorter for the OMA group compared to BARI, but the difference was not significant (HR 1.18 (95% CI [0.87 – 1.60]); p = 0.28). These differences were larger when analysing only bDMARD-naïve patients (Figure 1a).

All TC taken together, the rates of LDA and remission did not differ significantly between the 3 groups at 12 months. LDA ranged from 63% to 67% (BARI vs OMA p = 0.87; BARI vs TNFi p = 0.81) and remission from 19% to 23% (BARI vs OMA p = 0.30; BARI vs TNFi p = 0.77; Figure 1b).

Conclusion: BARI demonstrated a significantly higher overall drug maintenance than TNFi, and a similar drug maintenance to OMA, both in a bDMARD-naïve population and in the overall population. The adjusted 12-month response rates did not differ between BARI, TNFi and OMA groups. These results suggest that prescription of BARI after csDMARD has at least similar outcomes as alternative bDMARDs.

Background: Janus kinase (JAK) inhibitors are effective small molecular drugs for rheumatoid arthritis (RA) and other immune mediated inflammatory diseases (IMIDs). JAK inhibitors exert their immunosuppressive effects by suppressing the action of JAK, an intracellular tyrosine. Although infections are the most reported side effects, potential glucose lowering effects in patients with diabetes mellitus (DM) have been described in literature and have also been reported as suspected adverse drug reactions (ADRs) to the National Pharmacovigilance Centre Lareb in the Netherlands (1).

Objectives: To assess and describe suspected adverse effects of JAK inhibitors on glucose levels in diabetic patients with rheumatic diseases and other IMIDs, as reported in daily practice.

Methods: We describe ADR reports of tofacitinib and baricitinib in the European pharmacovigilance Eudravigiliance (EV) database from initiation to 12 January 2021. All ADRs in EV are coded according to the Medical Dictionary for Regulatory Activities (MedDRA). We included all reports indicating hypoglycaemia in patients with reported DM type 1 and 2 or with antidiabetic drugs as concomitant medication. This could include oral antidiabetics as well as insulins.

Results: On 12 January 2021 the EV database included 32 ADR reports, concerning 32 diabetic patients, indicating hypoglycaemia associated with the use of JAK inhibitors (15 tofacitinib, 17 baricitinib), out of 32,484 ADR reports in total concerning tofacitinib or baricitinb (Table 1). Most patients (25 patients, 78%) used the JAK inhibitor for rheumatoid arthritis. The suspected ADR with MedDRA Preferred Term 'Hypoglycaemia' was reported for 16 patients and MedDRA Preferred Term 'Decreased blood glucose' was reported for 15 patients. In one case, increased insulin sensitivity was described as suspected ADR of baricitinib. In this case, the insulin dose had to be reduced to prevent hypoglycaemia. Of note, the insulin dose had to be increased after temporary discontinuation of baricitinib and was reduced again after baricitinib was restarted. Additionally, in six cases improvements of glycaemic control were described after discontinuation or dose reduction of the JAK inhibitor or antidiabetic drug. Improvements were also described after unknown action or unchanged treatment with JAK inhibitor in eight cases.

Conclusion: JAK inhibitors may induce hypoglycaemia by increasing insulin sensitivity, and consequently may reduce the need for antidiabetic medication (2-3). Healthcare professionals should be alert for these potential ADRs when starting a JAK inhibitor in patients with DM as comorbidity. More research is needed to support our findings and elucidate the underlying pharmacological mechanisms of this potentially beneficial effect of JAK inhibitors.

Table 1. Suspected adverse drug reaction reports indicating hypoglycaemia in diabetic patients using tofacitinib or baricitinib in the Eudravigilance database

	Tofacitinib N (%)	Baricitinib N (%)
No. of reports	15 (100)	17 (100)
Mean age years (range)	65 (56 - 78)	62.2 (48 - 78)
Female gender	13 (87)	13 (76)
Indication for JAK inhibitor		
Rheumatoid arthritis	11 (73)	14 (82)
Unknown	3 (20)	3 (18)
Arthritis	1 (7)	
Reported adverse drug reaction		
Hypoglycaemia	6 (40)	11 (65)[a]
Decreased blood glucose	9 (60)	6 (35)[a]
Time to onset after start JAK inhibitor[b]		
Within 1 month	6 (40)	3 (18)
2-6months	2 (13)	2 (12)
More than 6 months	1 (7)	
Improvement after action:		
Drug withdrawal	3 (20)[c]	1 (6)[d]
Dose adjustments		1 (6)[e]
Other	1 (7)[f]	

a.In one case of baricitinib hypoglycaemia as well as decreased blood glucose were reported as adverse drug reactions.
b.Time to onset was unknown in 6 reports of tofacitinib and 12 reports of baricitinib
c.Tofacitinib withdrawal: 1, sitagliptin withdrawal: 1, tofacitinib and insulin withdrawal: 1
d.Baricitinib withdrawal: 1
e.Baricitinib: after insulin dose adjustments: 1
f.After tofacitinib withdrawal and insulin dose adjustments

ROUTINE ASSESSMENT OF PATIENT INDEX DATA 3 (RAPID3) IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH LONG-TERM UPADACITINIB THERAPY

M. Bergman[1], M. H. Buch[2], Y. Tanaka[3], G. Citera[4], S. Bahlas[5], E. Wong[6], Y. Song[7], N. Tundia[7], J. Subotički[7], V. Strand[8]. *[1]Drexel University College of Medicine, Rheumatology, Philadelphia, Pennsylvania, United States of America*; *[2]School of Biological Sciences, University of Manchester and NIHR Manchester Biomedical Centre, Centre for Musculoskeletal Research, Manchester, United Kingdom*; *[3]University of Occupational and Environmental Health Japan, Rheumatology, Kitakyushu, Japan*; *[4]Instituto de Rehabilitación Psicofísica, Ciudad Autónoma de Buenos Aires, Rheumatology, Buenos Aires, Argentina*; *[5]King Abdulaziz University, Medicine, Jeddah, Saudi Arabia*; *[6]Queen Alexandra Hospital, Rheumatology, Portsmouth, United Kingdom*; *[7]AbbVie Inc., Immunology, North Chicago, Illinois, United States of America*; *[8]Stanford University, Division of Immunology/Rheumatology, Palo Alto, California, United States of America*

Background: Routine Assessment of Patient Index Data 3 (RAPID3) is a pooled index of 3 patient-reported measures: patient global assessment, pain, and physical function. RAPID3 was shown to correlate with other composite measures of disease activity[1] and is recommended by the American College of Rheumatology for use in clinical practice.[2]
Objectives: To evaluate the impact of upadacitinib (UPA) versus comparators on RAPID3 over 60 weeks, as well as the correlation of RAPID3 scores with other disease measures in the UPA phase 3 SELECT clinical program.
Methods: This post hoc analysis included placebo-controlled (SELECT-NEXT, -BEYOND, and
-COMPARE) and active comparator-controlled (SELECT-EARLY, -MONOTHERAPY, and
-COMPARE) trials. Patients received UPA as monotherapy or in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs). Mean change from baseline in RAPID3 and the proportion of patients reporting RAPID3 remission (≤3), low (LDA, >3 to ≤6), moderate (MDA, >6 to ≤12), and high disease activity (HDA, >12) were assessed. Correlations between absolute scores for RAPID3 and Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI), and 28-joint Disease Activity Score with C-reactive protein (DAS28[CRP]) were assessed using Spearman correlation coefficients. All data are as observed.
Results: A total of 661, 498, 648, 1629, and 945 patients were included from SELECT-NEXT,
-BEYOND, -MONOTHERAPY, -COMPARE, and -EARLY. At baseline, the majority of patients across all studies were in RAPID3 HDA (mean baseline RAPID3 [across all studies], 17.2–19.2) (Table 1 and Figure 1). Improvements from baseline in RAPID3 were observed with UPA 15 mg and 30 mg through Week 60, with numerically greater improvements observed with UPA compared with active comparators (Table 1). Across studies, mean improvements in RAPID3 exceeded the minimal clinically important difference (MCID) with UPA and adalimumab (ADA) treatment (MCID=3.8[3]). By Week 60, approximately one-half of UPA-treated patients were in RAPID3 remission or LDA, with only 10–25% remaining in HDA, except for the more refractory population in SELECT-BEYOND, in which ~38% of patients remained in HDA (Figure 1). RAPID3 scores moderately to strongly correlated with CDAI (ρ=0.69–0.83), SDAI (ρ=0.69–0.82), and DAS28(CRP) (ρ=0.58–0.77), across all studies, at Week 60 (all p<0.001).
Conclusion: UPA, as monotherapy or in combination with csDMARDs, was associated with improvements in patient-reported disease activity, pain, and physical function, as assessed by RAPID3 over 60 weeks in the phase 3 SELECT clinical program. RAPID3 continues to be an important tool in clinical practice to assess disease activity, as it was shown to correlate to other disease activity measures and allows for rapid scoring.

CLINICAL RESPONSES TO UPADACITINIB OR ABATACEPT IN PATIENTS WITH RHEUMATOID ARTHRITIS BY TYPE OF PRIOR BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUG: DATA FROM THE PHASE 3 SELECT-CHOICE STUDY

A. Rubbert-Roth[1], R. Xavier[2], B. Haraoui[3], H. S. B. Baraf[4,5], M. Rischmueller[6,7,8], N. Martin[9], Y. Song[9], J. Subotički[9], J. Cush[10].
[1]*Kantonsspital St Gallen, Division of Rheumatology, St Gallen, Switzerland*; [2]*Hospital de Clínicas de Porto Alegre, Division of Rheumatology, Porto Alegre, Brazil*; [3]*Institut de Rhumatologie de Montréal, Clinical Research Unit, Montreal, Quebec, Canada*; [4]*The Center for Rheumatology and Bone Research, Rheumatology, Wheaton, Maryland, United States of America*; [5]*The George Washington University, Rheumatology, Washington DC, United States of America*; [6]*The Queen Elizabeth Hospital, Rheumatology Department, Woodville South, Australia*; [7]*Basil Hetzel Institute, Rheumatology Research Group, Woodville South, Australia*; [8]*Adelaide Medical School, University of Adelaide, Rheumatology, Adelaide, Australia*; [9]*AbbVie Inc., Immunology, North Chicago, Illinois, United States of America*; [10]*The University of Texas Southwestern Medical School, Rheumatic Disease Division, Dallas, Texas, United States of America*

Background: In the phase 3 double-blind SELECT-CHOICE study of patients (pts) with prior inadequate response (IR) or intolerance to biologic disease-modifying antirheumatic drugs (bDMARDs), upadacitinib (UPA) showed superiority to abatacept (ABA) in change from baseline in 28-joint Disease Activity Score using C-reactive protein (DAS28[CRP]) and in the proportion of pts achieving DAS28(CRP) <2.6 at Week 12.

Objectives: To describe clinical responses in pts receiving UPA or ABA by number and mechanism of action of prior bDMARDs.

Methods: 612 pts were randomized to once-daily UPA 15 mg or monthly intravenous ABA (<60 kg, 500 mg; 60–100 kg, 750 mg; >100 kg, 1000 mg). All pts continued background therapy with stable conventional synthetic DMARDs. From Week 12, pts who did not achieve ≥20% improvement in both tender and swollen joint counts vs baseline at 2 consecutive visits had background medication(s) adjusted or added. In this post hoc analysis, pts were grouped by the number and/or type of bDMARD received prior to enrollment: 1) lack of efficacy (LoE) to ≥1 tumor necrosis factor (TNF) inhibitor; 2) LoE to ≥1 interleukin-6 (IL-6) inhibitor; 3) intolerance to prior bDMARDs; 4) number of prior bDMARDs (1, 2, or ≥3). Mean change from baseline in DAS28(CRP) and DAS28(CRP) <2.6 and other clinical endpoints were evaluated at Weeks 12/24.

Results: Most pts had LoE to ≥1 TNF inhibitor (536, 87.6%); 96 (15.7%) had LoE to an IL-6 inhibitor; 79 (12.9%) had intolerance to prior bDMARDs; 408 (66.7%), 134 (21.9%), and 64 (10.5%) had received 1, 2, or ≥3 prior bDMARDs, respectively. Mean change from baseline in DAS28(CRP) was generally greater with UPA vs ABA across the different pt subgroups at Weeks 12/24 (Figure 1). Across endpoints, regardless of prior bDMARD therapy (except in those who failed ≥3 prior bDMARDs), UPA and ABA demonstrated similar responses at Week 12 compared with those observed for the overall treatment groups, even with more stringent criteria such as ACR70 and Clinical Disease Activity Index (CDAI) ≤2.8 (Table 1. below) Responses at Week 24 followed a similar trend to those at Week 12 for DAS28(CRP) <2.6 and other endpoints (Table 1). The safety profile across subgroups was consistent with each respective treatment in the overall study population (data not shown).

Conclusion: Although sample sizes were small for some subgroups, treatment with UPA led to greater clinical responses vs ABA at Week 12, including in pts with LoE to TNF or IL-6 inhibitors, and those with IR or intolerance to 1, 2, or ≥3 prior bDMARDs.

Figure Mean change from baseline in DAS28(CRP) at Weeks 12 and 24 by prior bDMARD subgroup

FIRST-IN-HUMAN STUDY OF GS-5718, AN ORAL IRAK-4 INHIBITOR, IN HEALTHY SUBJECTS: PHARMACOKINETICS, SAFETY, TOLERABILITY, AND ASSESSMENT OF EFFECT OF FOOD AND ACID REDUCING AGENTS ON EXPOSURE

K. Anderson[1], C. H. Hsueh[1], O. Gurtovaya[1], A. Mathur[1], J. Taylor[1], A. Serone[1], A. A. Othman[1]. [1]*Gilead Sciences, Inc., Foster City, United States of America*

Background: GS-5718 is a potent and selective interleukin-1 receptor-associated kinase 4 (IRAK4) inhibitor in clinical development for treatment of inflammatory diseases.
Objectives: The aim of this first-in-human study was to evaluate the pharmacokinetics, safety, and tolerability of GS-5718; and the effect of food and acid-reducing agents (ARA) on GS-5718 pharmacokinetics in healthy subjects.
Methods: This was a blinded, randomized, placebo-controlled, single and multiple (once daily for 10 days) oral dose study. Healthy male and female subjects were enrolled in ascending dose cohorts and randomized to receive GS-5718 (15, 50 or 150 mg) or placebo. GS-5718 was administered fasted in the single ascending dose cohorts, and under fed conditions (standard meal) in the multiple dose cohorts. The effects of a high-fat meal and omeprazole (a representative ARA) on GS-5718 50 mg dose pharmacokinetics were also evaluated. Serial blood samples were collected and GS-5718 pharmacokinetic parameters were characterized. Safety was assessed by review of adverse events (AEs), clinical laboratory tests, and vital signs.
Results: A total of 74 subjects (n = 62 GS-5718; n = 12 placebo) enrolled and completed study drug treatments in this study. GS-5718 was generally well tolerated at all evaluated dose levels; AEs were mild in severity and no dose-limiting toxicities, serious AEs, nor clinically relevant electrocardiogram or vital sign abnormalities were observed in subjects administered GS-5718. GS-5718 exposure was approximately dose proportional across the evaluated multiple ascending dose range. GS-5718 showed low-to-moderate pharmacokinetic variability with median half-life of 25 to 33 hours and 1.6 to 2.4- fold accumulation at steady-state, which was achieved by Day 5-7 of dosing. Food had no clinically meaningful impact on GS-5718 exposure (AUC and C_{max}) at the 50 mg dose. Co-administration of omeprazole with GS-5718 reduced GS-5718 exposure (AUC and C_{max}) by 23% and 43%, respectively, at the 50 mg dose.
Conclusion: GS-5718, administered once daily, was well tolerated following single or multiple dosing up to 150 mg. The pharmacokinetic and safety profile of GS-5718 support the further development in inflammatory diseases with once-daily administrations.

TOLEROGENIC DENDRITIC CELLS IN RHEUMATOID ARTHRITIS PATIENTS: NEWS AND PROMISES

Y. Kurochkina[1], E. Chernykh[2], A. Sizikov[3]. [1]*Research Institute of Clinical and Experimental Lymphology - Branch of the Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Sciences, Rheumatology, Novosibirsk, Russian Federation*; [2] *Federal State Budgetary Scientific Institution Research Institute of Fundamental and Clinical Immunology, Laboratory of Cells Immunotherapy, Novosibirsk, Russian Federation*; [3]*Federal State Budgetary Scientific Institution Research Institute of Fundamental and Clinical Immunology, Rheumatology, Novosibirsk, Russian Federation*

Background: Dendritic cells (DCs) are known to contribute to the pathogenesis of rheumatoid arthritis (RA) through presentation of cartilage glycoprotein, production of proinflammatory cytokines and activation of Th1/Th17 responses. Along with stimulating activity, DCs may exhibit suppressive functions via capacity to induce T cell apoptosis/anergy and to generate regulatory T cells. Since these DCs have potential to control autoreactive T-lymphocytes, the enhancing of tolerogenic properties of DCs seems to be a new important strategy in treatment of RA. Dexamethasone is widely used in clinical practice and can be used as a tolerogenic substance. Therefore, the properties of DCs generated in presence of dexamethasone are of great clinical interests.
Objectives: The aim of our study is to describe the properties of tolerogenic DCs, generated with dexamethasone in patients with RA and their influence on autologous T-cells.
Methods: Sixty five patients with RA with high and moderate activity of disease were recruited in this study. All patients follow ACR/EULAR criteria (2010). All studies were performed after receiving informed consent. All patients received conventional synthetic DMARDs. DCs were generated from blood monocytes culturing for 5 days with GM-CSF and IFN-α in the presence dexamethasone (dexDCS), applied on third day. LPS as maturation stimuli was added on fourth day. The expression of CD14, CD83, HLA-DR, TLR-2 on the surface of DCs was measured by flow cytometry. The functions of DCs were evaluated by measuring cytokine production and DCs allostimulatory activity in mixed lymphocyte culture. Mature DCs generated in absence of dexamethasone used as control.
Results: We revealed that dexDCs are characterized by enhanced expression of CD14+cells and decreased number of CD83+cells but percent of HLA-DR+cells were constant (about 85). DexDCs show high expression of TLR-2 is seen as tolerogenic molecule (75%vs51%, p=0.05 compared to control). DexDCs also have marked prominent increase of TNFα/IL-10 ratio in contrast to control (0.59 vs 1.8, p=0.03). DexDCs suppressed proliferation of allogenic T-cells (2005 vs 7980 cpm, p=0.0002). To assess the stability of the DC in the proinfflamatory micro-environment after assessing stimulatory activity dexDCs were then cultivated with LPS and allostimulatory activity were evaluated one more. The stimulation activity dexDCs after incubation with LPS were not increase (4692 vs 6053 cpm, p=0.7). Also earlier we showed possibility of dexDCs induse apoptosis of autologous T-cells, activation of CD4+IL10+Tr1 and possession of antigen-specific suppression.
Conclusion: The data obtained indicate that dexDCs from RA patients have the main tolerogenic features and stable in inflammatory environment that proves their potential in the treatment of rheumatoid arthritis.

DIRECT COMPARISON OF EFFECTIVENESS AND SAFETY OF TOFACITINIB AND BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS IN REAL-WORLD SETTINGS

N. Iwamoto[1], T. Suzuki[2], A. Okada[3], K. Fujikawa[4], T. Aramaki[5], A. Mizokami[4], Y. Ueki[5], A. Kawakami[1]. [1]*Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, Nagasaki, Japan*; [2]*Sasebo City General Hospital, Department of Internal Medicine, Sasebo, Japan*; [3]*Nagasaki Atomic Bomb Museum, Department of Rheumatology, Nagasaki, Japan*; [4]*Japan Community Healthcare Organization, Isahaya General Hospital, Department of Rheumatology, Isahaya, Japan*; [5]*Sasebo Chuo Hospital, Department of Rheumatology, Sasebo, Japan*

Background: Tofacitinib is a non-selective first-generation JAK inhibitor and baricitinib was approved for the treatment of Rheumatoid arthritis several years after approve of tofacitinib. Randomized controlled trials have shown good treatment response for RA in these two drugs. However, the evaluation of these two drugs in real-world setting have been rarely reported, moreover, until now, no published data of a direct comparison among JAK inhibitors in RA have been available.
Objectives: To compare the efficacy and safety of the JAK inhibitors tofacitinib and baricitinib in patients with rheumatoid arthritis (RA) by using propensity score matching in a real-world setting.
Methods: A total of 242 patients with RA who were treated with tofacitinib (n=161) or baricitinib (n=81) were enrolled. To avoid confounding, we performed propensity score matching based on multiple baseline characteristic variables, and then 80 baricitinib-treated patients and 57 tofacitinib-treated patients were extracted for the direct comparison. A mixed effect model with a repeated measures analysis of variance (ANOVA) was performed to ascertain whether there were significant differences in clinical efficacy between the two treatment groups during the treatment period.Finally, We evaluated the predictive factor of clinical responses by performing univariate and multivariable logistic regression analyses.
Results: The mean delta disease activity scores (DAS)28-ESR from baseline to 6 months were −1.60 (tofacitinib) and −1.46 (baricitinib). The remission rate defined by the DAS28-ESR at 24 weeks were 21.1% (tofacitinib) and 25.0% (baricitinib). There was no significant difference in the clinical response between the baricitinib-treated and tofacitinib-treated groups. Although there was no significant difference, the concomitant use of methotrexate (MTX) showed better clinical efficacy in the cases of baricitinib treatment as compared with in the case of tofacitinib treatment. In both groups, the most common AE was herpes zoster infection, and the AE rates were similar between the two groups. However, the predictive factors contributing to clinical response differed. The concomitant use of oral steroid was independently associated with the achievement of DAS-low disease activity in both groups, whereas in the baricitinib group, the number of biological and/or targeted synthetic DMARDs previously used and the DAS28-ESR at the time of initiation were associated with DAS-low disease activity.
Conclusion: This study indicate that tofacitinib and baricitinib had comparable efficacies and safety profiles in a real-world setting. However, the influence of clinical characteristics on the treatment response differed between these two drugs. Direct comparison between two JAK inhibitors provide useful information to optimal use of JAK inhibitors in real-world settings.

Background: Long-term observational data on the real-life use of JAK inhibitors (JAKis) for rheumatoid arthritis (RA) and their comparison with biological drugs are still very limited. Large population-based registries have been increasingly used to investigate the performance of targeted drugs in a real-life setting.
Objectives: The aim of this study is to evaluate and compare the 3-year retention rate of JAKis, TNF inhibitors (TNFis) and biologic drugs with other mechanisms of action (OMAs) in the large cohort of RA patients included in the Italian national GISEA registry.
Methods: Data of all RA patients treated with targeted synthetic or biologic drugs were prospectively collected in the Italian multicentric GISEA registry. The analysis was limited to patients who started a first- or second-line targeted drug in the period after the first JAKi was marketed in Italy (1st December 2017). The 3-year retention rate was calculated by the Kaplan-Meier method and compared between different drug classes by a log-rank test. A descriptive analysis of reasons for discontinuation was performed.
Results: The study population included 1027 RA patients (79.8% females, mean age [±SD] 56.9 [±13.5] years, mean disease duration 9.8 [±9] years, mean baseline SDAI 17.5 [±11.9], ACPA positive 67.4%, RF positive 62.7%) who received JAKis (baricitinib or tofacitinib, n=297), TNFis (n=365), or OMAs (n=365) as first or second targeted drug. Main baseline characteristics of study population were overall well balanced between treatment groups. Retention rate was numerically but not statistically higher (p=0.18) in patients treated with JAKis compared with TNFis or OMAs (80.6, 78.9 and 76.4% at 1 year and 73, 56.8 and 63.8% at 3 years, respectively) (Figure 1). Drug survival was significantly higher in patients receiving concomitant methotrexate (MTX) compared with monotherapy only in TNFis (66.8 vs 47.1%, p=0.04) but not in JAKis (76.1 vs 70.1%, p=0.54) and OMAs (66.1 vs 61.9%, p=0.41) group. Therapy was discontinued in a total of 211 patients because of ineffectiveness (n=107), adverse events (n=88), or compliance/other reasons (n=16). The most frequent reason for treatment withdrawal was ineffectiveness in both JAKis (n=30 out of 56) and TNFis (n=45 out of 74) groups, whereas OMAs were discontinued more frequently because of adverse events (n=41 out of 81).

Conclusion: Our data confirmed in a real-life setting a favorable 3-year retention rate of all available targeted mechanisms of action for RA therapy. As expected, concomitant MTX significantly impacted persistence on therapy of TNFis only. Discontinuations of JAKis for adverse events were infrequent overall, confirming the safety profile observed in randomized clinical trials.

POS0676 SURVIVAL OF THE FIRST COURSE OF BIOLOGIC OR JAK INHIBITOR IN RHEUMATOID ARTHRITIS: ASSOCIATION WITH THE CHOICE OF AGENT AND CONCOMITANT CONVENTIONAL SYNTHETIC DMARDS

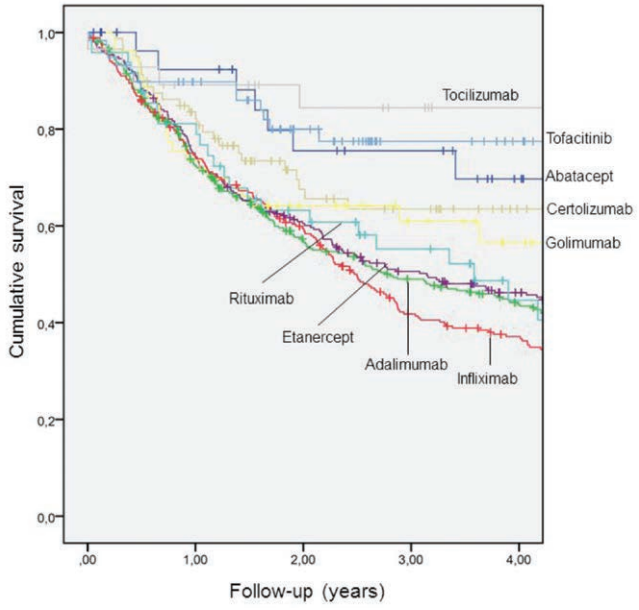
M. Bredemeier[1,2], A. Duarte[1], M. Pinheiro[1], B. Stadler[2], J. C. Macieira[1], R. Ranza[1], J. Miranda[1], V. Valim[2], G. Castro[1], M. Bertolo[2], M. D. F. Sauma[2], V. Fernandes[2], A. Medeiros[2], R. Botelho[2], C. Brenol[2], D. Negrão Gonçalo Dias[2], H. Carvalho[2], S. Studart[2], G. Da Rocha Castelar Pinheiro[2], L. Rocha[2], I. Pereira[2], M. Ohira Gazzeta[2], A. Maria Kakehasi[2], P. Louzada Jr[2], A. L. S. Hayata[2], F. Pina[2], C. Lupo[2], L. Balarini[2], I. Silveira[2], S. Kowalski[2], D. Titton[2], R. Chakr[2], A. Ranzolin[2], I. Laurindo[1], R. Xavier[1]on behalf of BiobadaBrazil. [1]*BiobadaBrasil, Brazilian Society of Rheumatology, SAO PAULO, Brazil*; [2]*BiobadaBrasil, Brazilian Society of Rheumatology, Sao Paulo, Brazil*

Background: After failure of conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) in the therapy of rheumatoid arthritis (RA), treatment may be escalated to biologic (bDMARDs) or JAK inhibitors (JAKi) (1). Analysis of drug survival can provide useful information on the effectiveness of these therapeutic schemes.
Objectives: to evaluate the association of the choice of therapeutic agent with the survival of treatment course in RA patients receiving their first bDMARD or JAKi.
Methods: BiobadaBrasil is a multicentric registry-based cohort study of Brazilian patients starting their first bDMARD/JAKi (2). This analysis includes RA patients recruited from Jan 2009 to Oct 2019, followed-up over the first course of treatment with a bDMARD/JAKi until censoring (latest date, Nov 19, 2019) or occurrence of the outcome of interest. A treatment course is defined as a period during which the medication scheme does not change, except for dose adjustments. The primary outcome was the interruption of treatment course for any reason (except for pregnancy or disease remission); interruption of treatment due to adverse events (AEs) or death and due to inefficacy served as secondary outcomes. Multivariate Cox proportional hazards models were used for analyses.
Results: In total, 1177 patients (3800 patient-years [PY]) were enrolled. The overall incidence of treatment interruption was 17.5/100 PY. Adalimumab was the most frequently prescribed agent, followed by infliximab (n= 267). The hazards ratios (HR) of the primary and secondary outcomes are presented in Table 1. Figure 1 compares the survival of treatment curves of different bDMARDs/JAKi.

Table 1. Hazard ratios (HR) of interruption of therapy course of each therapeutic agent (the reference category for bDMARDs/ JAKi is infliximab). Results are HR, 95% CIs, and P values*.

Agent (number of patients)	Interruption for any reason (665 events)	Interruption due to adverse events or death (196 events)	Interruption due to inefficacy (319 events)
Adalimumab (354)	0.83 (0.68 to 1.01), P= 0.062	0.68 (0.48 to 0.96), P=0.029	1.08 (0.80 to 1.44), P=0.621
Etanercept (257)	0.81 (0.66 to 1.01), P=0.063	0.56 (0.37 to 0.83), P=0.004	0.93 (0.68 to 1.29), P=0.674
Certolizumab (80)	0.74 (0.47 to 1.16), P=0.185	0.33 (0.13 to 0.86), P=0.024	1.32 (0.74 to 2.35), P=0.350
Golimumab (53)	0.86 (0.53 to 1.38), P=0.530	0.46 (0.18 to 1.19), P=0.111	1.07 (0.53 to 2.15), P=0.849
JAKi (tofacitinib) (59)	0.54 (0.30 to 0.99), P=0.047	0.19 (0.04 to 0.82), P=0.026	0.89 (0.41 to 1.96), P=0.779
Rituximab (48)	0.87 (0.55 to 1.37), P=0.540	0.48 (0.20 to 1.18), P=0.109	0.58 (0.26 to 1.34), P=0.205
Abatacept (30)	0.52 (0.25 to 1.07), P=0.077	0.46 (0.14 to 1.56), P=0.215	0.46 (0.14 to 1.52), P=0.203
Tocilizumab (29)	0.29 (0.14 to 0.63), P=0.002	0.40 (0.12 to 1.30), P=0.126	0.28 (0.09 to 0.90), P=0.033
Methotrexate (792)	0.95 (0.79 to 1.14), P=0.561	0.86 (0.62 to 1.19), P=0.362	0.98 (0.75 to 1.28), P=0.860
Leflunomide (497)	1.17 (0.99 to 1.39), P=0.061	1.44 (1.06 to 1.96), P=0.020	1.02 (0.80 to 1.30), P=0.856
Sulfasalazine (48)	1.18 (0.80 to 1.75), P=0.401	1.94 (1.07 to 3.54), P=0.030	0.85 (0.45 to 1.59), P=0.605
Antimalarials (230)	0.80 (0.65 to 0.98), P=0.027	0.67 (0.45 to 0.99), P=0.043	0.67 (0.50 to 0.92), P=0.011

* All tests adjusted for other variables presented in the table and for age, baseline DAS28, disease duration, gender, smoking, seropositivity (RF/anti-CCP), previous malignancy, diabetes, hypertension, hypercholesterolemia, renal failure, ischemic cardiomyopathy, COPD, heart failure, use of corticosteroids, starting year, hypercholesterolemia, osteoporosis, hepatitis B and C.



Conclusion: In our study, infliximab was related to an overall higher hazard of treatment course interruption than tolicizumab and tofacitinib, and higher hazard of interruption due to AEs than most other anti-TNF agents and tofacitinib. Maintaining antimalarials in patients receiving advanced therapies for RA may reduce interruption of treatment due to inefficacy and AEs.

POS0677

THE ROLE OF MUSCULOSKELETAL ULTRASOUND IN PREDICTING THE RESPONSE TO JAK INHIBITORS: RESULTS FROM A LARGE MONOCENTRIC COHORT

C. Garufi[1], F. Ceccarelli[1], F. R. Spinelli[1], S. Mancuso[1], C. Pirone[1], F. Conti[1].
[1]*Sapienza University of Rome, Reumatologia, Dipartimento di Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Roma, Italy*

Background: In the management of chronic arthritis, such as Rheumatoid Arthritis (RA), Ultrasound (US) assessment can provide relevant information about the joint inflammatory status in the diagnostic phase and even more in the monitoring of disease activity and structural damage[1,2].
Objectives: In this longitudinal study, we aimed to assesse the role of US in predicting the efficacy of JAK-inhibitors (JAKi) in RA patients.
Methods: We enrolled RA patients starting baricitinib or tofacitinib. All patients were evaluated at baseline and after 4, 12, 24, 48 weeks. Disease activity was calculated by DAS28CRP. US examination in 22 joints (I–V MCPs and PIPs, wrists) aimed at evaluating inflammatory features (synovial effusion and hypertrophy, power Doppler-PD), through a semi-quantitative scale (0-3). The total US (0-198) and PD (0-66) scores were calculated. We scanned bilateral flexor (I–V fingers of hands) and extensor compartments (1-6) tendons: tenosynovitis was scored as absent/present (0/1), resulting in a total score (0-22).
Results: We studied 102 patients (M/F 15/87; median age 59.2 years, IQR 17.75; median disease duration 144 months, IQR 126), 61 treated with baricitinib and 41 with tofacitinib. At baseline, the median total US score was 18 (IQR 19) and the median PD score 2 (4). We observed a significant reduction in both total and PD US scores at all time-points (p<0.0001) (Figure 1). At baseline, 75.4% of patients showed tenosynovitis involving at least one tendon, with a median score of 2 (IQR 3.5) significantly decreasing after 24 weeks (p=0.02). Multivariate analysis, adjusted for baseline $DAS28_{CRP}$ and other concomitant treatments (including glucocorticoids and methotrexate treatment), confirmed the independent association between baseline US (PD and tenosynovitis) scores and the reduction of disease activity at follow-up evaluations.
Conclusion: The present study confirmed the early efficacy of JAKi in RA patients by using US evaluation. Furthermore, power doppler and tenosynovitis scores could play a predictive role in response to treatment.

DOES SILDENAFIL IMPROVE ENDOTHELIAL DYSFUNCTION IN RHEUMATOID ARTHRITIS? – A PILOT CLINICAL TRIAL

K. Liang[1], D. Landsittel[2], Y. Li[2], L. Hope[3], L. Ruffalo[3], J. Peat-Fircak[3], J. Avolio[4], P. Biswas[3], E. Roth[3], M. Simon[5], L. Moreland[6]. [1]*University of Pittsburgh, Rheumatology and Clinical Immunology, Pittsburgh, PA, United States of America*; [2]*University of Pittsburgh, Biomedical Informatics, Pittsburgh, United States of America*; [3]*University of Pittsburgh, Rheumatology and Clinical Immunology, Pittsburgh, United States of America*; [4]*University of Pittsburgh, Clinical and Translational Science Institute, Pittsburgh, PA, United States of America*; [5]*University of California San Francisco, Cardiology, San Francisco, CA, United States of America*; [6]*University of Colorado, Rheumatology, Aurora, CO, United States of America*

Background: Rheumatoid arthritis (RA) is independently associated with an increased risk of cardiovascular disease (CVD). One of the early stages of atherosclerosis is endothelial dysfunction, which is increased in RA. Using drugs to target endothelial dysfunction is a promising novel strategy for CVD prevention in RA. Sildenafil has been shown to improve endothelial function in diabetics, who have similar increased CVD risk. Our hypothesis was that sildenafil use may be a novel primary CVD prevention strategy in RA.

Objectives: To determine if sildenafil use in RA patients improves endothelial dysfunction (as measured by brachial artery flow-mediated dilation [FMD] and peripheral arterial tone [PAT]), as well as serum inflammatory and atherosclerosis biomarkers.

Methods: This NIH-funded study was a phase II, randomized double-blind placebo-controlled crossover efficacy trial of 25 RA patients, with no known history of CVD, but at least one traditional CVD risk factor. Patients were randomized 1:1 to receive either sildenafil or placebo for 3 months, then after a 2-week washout, crossed over to each respective group for an additional 3 months. Vascular studies (FMD and PAT) and serum atherosclerosis biomarkers (e-Selectin, ICAM-1, VCAM-1) were performed at baseline, 3 months pre- and post-washout, and 6 months. Adverse events were collected. Given the cross-over design, analyses included a random effects model for within-subject comparisons of sildenafil versus placebo periods, adjusting for the baseline (FMD or EndoPAT) within that period and a term for treatment order. All tests were 2-sided with α=0.05.

Results: A total of 233 subjects were assessed for eligibility, with 25 subjects being randomized after written informed consent. A total of 13 subjects were randomized to placebo first, and 12 to sildenafil first. Baseline characteristics were similar between those randomized to Placebo vs. Sildenafil first. Mean age was 62.0+/-10.9 years; 84% were female; and 92% were white. A total of 6 adverse events experienced in 3 subjects occurred. The primary endpoint (increase in %FMD in Sildenafil period vs. Placebo period) was not significant (p=0.19). However, note the study was powered at 80% to detect an effect size of 0.37 for change in %FMD or biomarker with a sample size of 60, not 25. However, sildenafil use was associated with a significant increase (improvement) by 0.200 units of PAT ratio (p=0.003) compared with placebo, adjusted by treatment order and baseline PAT ratio (within the given treatment period). Exploratory linear mixed models comparing e-Selectin, ICAM-1, and VCAM-1 between Sildenafil vs. Placebo periods, adjusted for treatment order and the baseline biomarker level, did not show any significant differences except for ICAM-1 (55.3 units higher in Sildenafil vs. Placebo periods, p=0.011).

Conclusion: In this pilot trial of 25 RA subjects, sildenafil use was associated with a significant increase (improvement) in endothelial function as measured by PAT. However, there was no significant difference in FMD. The study is limited due to the small sample size, which was impacted by slow recruitment as well as the COVID-19 pandemic. Future larger studies are required to assess whether other PDE5 inhibitors may improve endothelial dysfunction in RA and other autoimmune disease patients at high risk of CVD.

POS0679

A NEW QUESTIONNAIRE AND SCORE (MISA) FOR ASSESSING METHOTREXATE INTOLERANCE IN RHEUMATOID ARTHRITIS

V. Dhir[1], D. V[1], S. Jain[1], V. Pai[2], A. Sharma[1], S. K. Sharma[1], G. Naidu[1], S. Jain[1]. [1]*Postgraduate Institute of Medical Education and Research, Rheumatology Division, Department of Internal Medicine, Chandigarh, India*; [2]*All India Institute of Medical Sciences, Rishikesh, Rheumatology, Medicine, Rishikesh, India*

Background: Methotrexate (MTX) intolerance refers to unpleasant symptoms that accompany use of MTX and may lead to its discontinuation. However, it lacks a validated score in RA patients; with the only option being to use the MISS score which was validated for use in children and not adults.

Objectives: To develop and validate a questionnaire and score (s) for measuring MTX intolerance and its severity in rheumatoid arthritis.

Methods: A 10-item questionnaire called 'Methotrexate Intolerance and Severity assessment in Adults' (MISA) was validated in 105 RA patients. A score was calculated by adding the scores of first 7 questions (0 to 3 based on severity on symptoms), to last 3 questions (0 or 1); it ranged from 0 to 24 (MISA score) and was assessed for correctly classifying MTX intolerance (compared to an interview) by ROC analysis. Its area-under-curve (AUC) was compared with 'Methotrexate Intolerance Severity Score' (MISS), developed for children. Subsequently, it was administered to 414 RA patients to assess the prevalence and associations of MTX intolerance. In addition, the MISA cross-products score, that was calculated by adding the cross-products (severity (1 to 3) x duration per week (0.5 to 7 days)) of symptoms, was compared to MISA and MISS for assessing severity of intolerance.

Results: In the initial phase, 105 RA patients on MTX≥6 months were included, a majority were female (87%), mean age was 51 (13.4) years and methotrexate dose was 18.8±6 mg/week. Thirty-five (33%) were found to be intolerant to MTX based on interview. MISA score had a good predictive ability (AUC of 0.904), to correctly classify MTX intolerance, and was better than MISS score (AUC of 0.823) (Figure 1A). The optimal cut-off for MISA was ≥1, with a sensitivity and specificity of 91.4% and 84.3%. Using the MISA score (≥1), 38.4% of 414 RA patients were found to have MTX intolerance: with nausea, lethargy and irritability being common symptoms. (Figure 1B, C) On multivariable analysis, age (OR 0.972) and BMI (OR 1.061) were significant predictors of MTX intolerance. (Table 1) On assessing for severity of intolerance, MISA cross product score performed the best, with an area-under-curve of 0.899 (95% CI 0.831-0.966), being higher than AUC for MISS and MISA score which were 0.847 (95% CI 0.768-0.927) and 0.837 (95% CI 0.754-0.920).

Conclusion: MISA is the first validated questionnaire for assessing methotrexate intolerance in rheumatoid arthritis, with the MISA score having a good accuracy (at cut-off ≥1), to detect MTX intolerance. Methotrexate intolerance was present in more than one-third of RA patients, with nausea, lethargy and irritability being most common.

POS0680 BELIMUMAB ADD-ON THERAPY MOBILISES MEMORY B CELLS INTO THE CIRCULATION OF PATIENTS WITH SLE

E. J. Arends[1], M. Zlei[2], C. M. Tipton[3], Z. Osmani[1], S. Kamerling[1], T. Rabelink[1], I. Sanz[3], J. J. M. Van Dongen[2], C. Van Kooten[1], Y. K. O. Teng[1]. *[1]Leiden University Medical Center (LUMC), Nephrology, Leiden, Netherlands*; *[2]Leiden University Medical Center (LUMC), Immunology, Leiden, Netherlands*; *[3]Emory University-School of Medicine, Division of Rheumatology, Department of Medicine, Atlanta, United States of America*

Background: Belimumab (BLM), a recombinant human monoclonal antibody directed against B-cell activating factor (BAFF), is the first approved biological agent for patients with active severe systemic lupus erythematosus (SLE) and lupus nephritis (LN). There is clinical evidence that combining BLM with B cell depleting therapy can ameliorate disease activity in severe, refractory SLE patients[1]. Although BLM is a B cell directed therapy and has been shown to significantly decrease total B cells, flow cytometry observations suggest a rapid increase of circulating memory B cells (MBC)[2].
Objectives: To investigate dynamics of B-cell subsets in SLE patients treated with or without BLM, with a focus on assessing MBC characteristics.
Methods: Extensive B cell subset phenotyping was performed by high-sensitivity (HS) flow cytometry (acquisition of 10^7 leukocytes; per EuroFlow protocols[3]) on samples from active LN or SLE patients with major organ involvement treated with standard of care (SOC) consisting of high dose steroids and mycophenolate mofetil combined with or without the addition of BLM. MBC gene expression profiles were characterized with single-cell RNA and V(D)J sequencing (ScRNA-SEQ).
Results: By employing HS flowcytometry, we established that the absolute increase in circulating MBC in SLE and LN patients was significant for patients who initiated BLM (Figure 1). The increase was observed in a broad range of MBC subsets (Unswitched, IgG1+, IgG2+, IgA1+, IgA2+) at 2 and 4 weeks following initiation of BLM treatment. This rise in MBC could hypothetically be attributed to either proliferation of blood MBC, BLM induced migration of tissue-resident MBCs or BLM related retention of tissue-destined MBC in the blood. ScRNA-SEQ analysis of cell cycle gene-expression was performed and established in both groups a non-proliferating phenotype [in approximately ~94%] of MBC post-treatment, including absence of MKI67 as active proliferation marker. Clonal diversity analysis comparing week 2 with baseline revealed an unexpected decrease of the largest MBC clones in BLM, whereas no change in clonality was observed with SOC alone. Together these data indicate that proliferation is unlikely to be responsible for the observed increase in MBC by BLM. Furthermore, a clear difference was found in gene-expression levels between both treatment groups:

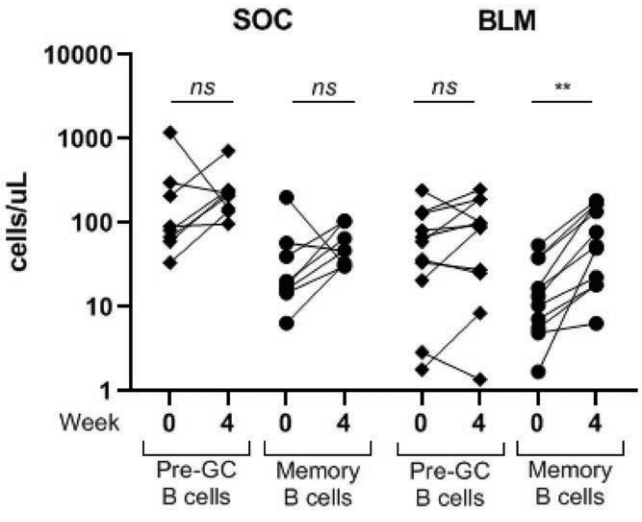

Figure 1. Change in pre-germinal center and memory B cell counts from baseline to week 4 of patients with SLE or LN treated with SOC (n=8) or SOC+BLM (n=11).

BLM was responsible for the upregulation of 72 vs 10 genes in SOC, likewise 162 vs 32 genes were downregulated. Most importantly, a significant downregulation of the migration genes SELL (CD62L), CCR7, ITGB1, RAC2 and ICAM2, were specifically seen in BLM treated patients. This may reflect disrupted lymphocyte trafficking, preventing MBCs from transmigrating from the blood into tissue owing to reduced migration molecules, or preventing MBCs from being retained at the tissue level owing to reduction in tissue adhesion proteins.
Conclusion: The addition of BLM to SOC significantly increases MBCs in patients with SLE independently of proliferation, accompanied by a strong modulation of gene expression, including reduced expression of migration markers pointing towards disrupted lymphocyte trafficking. These data may have important implications for improving treatment strategies in patients with LN or severe SLE, as a deeper depletion of autoreactive MBCs could be established by adding B-cell-depleting therapy after the initiation of BLM.

POS0681 VOCLOSPORIN FOR LUPUS NEPHRITIS: INTERIM ANALYSIS OF THE AURORA 2 EXTENSION STUDY

A. Saxena[1], P. Mina-Osorio[2], C. Mela[3], V. Berardi[2]. *[1]NYU Langone Health, Rheumatology, New York, United States of America*; *[2]Aurinia Pharmaceuticals, Inc., Medical Affairs, Victoria, Canada*; *[3]Aurinia Pharmaceuticals, Inc., Clinical Science, Victoria, Canada*

Background: Voclosporin, a novel calcineurin inhibitor (CNI), has been tested successfully in two pivotal trials in adult patients with lupus nephritis.
Previously reported results from the Phase 3 AURORA 1 study and the Phase 2 AURA-LV study showed that compared with mycophenolate mofetil (MMF) and low-dose steroids alone, the addition of voclosporin significantly increased the renal response rate and reduced proteinuria, as measured by urine protein creatinine ratio (UPCR), in patients with lupus nephritis (LN) at approximately one year of treatment (48 weeks in AURA-LV and 52 weeks in AURORA 1).
Objectives: Patients that completed one year of treatment in the AURORA 1 study were eligible to enroll into the two-year, blinded, controlled extension study, AURORA 2. Here we report the first interim analysis of the ongoing AURORA 2 study.
Methods: Patients completing AURORA 1 were eligible to continue the same randomized treatment of voclosporin (23.7 mg BID) or placebo, in combination with MMF (1 g BID) and low-dose oral steroids in the AURORA 2 extension. This interim analysis evaluated UPCR and estimated glomerular filtration rate (eGFR) in patients with up to two years of total treatment: one year from AURORA 1 and up to one year in AURORA 2.
Results: 116 patients in the voclosporin arm and 100 patients in the control arm enrolled in the extension study, of which 73 patients in the voclosporin arm and 51 patients in the control arm had received two years of treatment at the time of this interim analysis. Mean UPCR at pre-treatment (AURORA 1) baseline was 3.94 mg/mg in the voclosporin arm (n=116) and 3.87 mg/mg in the control arm (n=100). The LS mean change in UPCR from pre-treatment baseline to year two was -3.1 mg/mg for the voclosporin arm (n=73) and -2.1 mg/mg for control arm (n=51; Table 1). Mean eGFR at pre-treatment (AURORA 1) baseline was 79.6 mL/min for the voclosporin arm (n=116) and 78.9 mL/min for the control arm (n=100) and at year two, was 79.0 mL/min for the voclosporin arm (n=73) and 82.9 mL/min for the control arm (n=51). There was a small early decrease in mean eGFR in the first four weeks of treatment (in AURORA 1) after which eGFR remained stable throughout year one and year two. Additionally, there

were no unexpected new AEs observed in patients who continued with voclosporin treatment compared to control-treated patients for more than one year.

Table 1. UPCR

	Control (n=100)		Voclosporin (n=116)		Treatment Comparison of Voclosporin to Control	
	n	UPCR (mg/mg)	n	UPCR (mg/mg)	UPCR (mg/mg)	p-value
Pre-treatment baseline, mean	100	3.87	116	3.94	NC	NC
Change from pre-treatment baseline, LS mean						
Year 1	100	-2.4	116	-3.0	-0.6	0.0080
Year 2	51	-2.1	73	-3.1	-1.0	0.0004

LS, least squares; NC, not calculated; UPCR, urine protein creatinine ratio.Mixed effects model for repeated measures (MMRM) analysis of LS mean change from pre-treatment baseline for UPCR included terms for baseline covariate, treatment, visit and treatment by visit interaction. Integrated results include data from pre-treatment baseline of AURORA 1, the one-year treatment period in AURORA 1 and up to a one-year treatment period in AURORA 2.

Conclusion: Patients in the voclosporin treatment arm maintained meaningful reductions in proteinuria with no change in mean eGFR at two years of treatment. Additional AURORA 2 efficacy and safety data will be provided at the conclusion of the study.

POS0682 RETROSPECTIVE ANALYSIS OF PREGNANCY OUTCOMES IN PATIENTS WITH OBSTETRIC ANTIPHOSPHOLIPID SYNDROME (OAPS), NON-CRITERIA OAPS (NC-OAPS) AND ANTIPHOSPHOLIPID CARRIERS

M. E. D'amico[1], M. S. Ciliento[1], P. Melissa[1], M. Govoni[1]. [1]*Rheumatology Unit; Azienda Ospedaliera Universitaria Sant'Anna – Cona (Ferrara, Department of Medical Sciences - University of Ferrara, Ferrara, Italy*

Background: Antiphospholipid (aPL) antibodies are considered in obstetric morbidity even when Sydney criteria for OAPS are not met. Classification and treatment of NC-OAPS patients and aPL carriers during pregnancy are still debated.
Objectives: To increase knowledge, we evaluated and compared aPL serum profiles, exposure to antithrombotic therapies and pregnancy outcomes in OAPS, NC-OAPS and aPL carrier patients, accessing to our centre.
Methods: A retrospective observational study was conducted on pregnant outpatients from January 2003 to April 2020. According to Sydney revised classification criteria, we considered lupus anticoagulant (LA), IgM and IgG anti-cardiolipin antibodies (aCL), IgM and IgG antibeta2 glycoprotein I antibodies (aβ2-GPI), to stratify aPL risk profiles [Ref]. In each pregnancy, after case stratification into high (≥ 2 aPL or LA serum positivity) versus low (single aPL positivity) risk profile, we evaluated antithrombotic treatment strategy and subsequent pregnancy outcomes as live-births, spontaneous abortions (SA) or foetal losses.
Results: A total of 78 pregnancies were followed: 17 in OAPS, 9 in NC-OAPS and 52 in aPL carrier patients. Rheumatic diseases (RD) coexisted predominately in carriers (73.1%), mainly systemic lupus erythematosus (57.9%). As presented in Table 1, in OAPS and aPL plus RD carrier groups the association of acetyl-salicylic acid (ASA - mean dose 100 mg q.d.) and low-molecular weight heparin (LMWH - mean dose 4000 UI q.d.) showed a better rate of positive outcomes (97.8% of pregnancies) in high aPL risk profile, compared to monotherapy, especially with LA or triple aPL positivity. Conversely, negative outcomes occurred mostly with triple aPL positivity in the first group and double aPL in the second, despite therapy approaches. No significant data were obtained in NC-OAPS group, due to its paucity, though adverse outcomes were observed with monotherapy both in high and low risk profiles. Except aPL carriers with RD, in all other low risk subgroups, a prevalence of negative outcomes occurred using ASA alone, without statistical significance (OR 0; p= 0.45). Similarly, considering the whole population, the use of a mono or a combination therapy in high risk subgroups had not a significant correlation with pregnancy outcomes (OR 1.79; 95%CI 0.31-10.15; p= 0.50).
Conclusion: In our study, negative pregnancy outcomes were sporadic, occurring mostly with ≥ 2 aPL positivity. Combination treatment showed better results overall in high aPL risk profile patients, both in OAPS and NC-OAPS or aPL carriers. Though no significant correlation between outcomes and treatments were found, we hinted how aPL-based risk stratification may be useful in adopting personalised therapies to prevent obstetric failures.

Background: Patients with systemic lupus erythematosus (SLE) who received anifrolumab, a type I interferon receptor antibody, had greater BILAG–based Composite Lupus Assessment (BICLA) response rates vs placebo at Week (W)52 in the phase 2 MUSE[1] and the phase 3 TULIP-1[2] and TULIP-2[3] trials. Patients receiving anifrolumab also had fewer flares, and more patients were able to taper glucocorticoids (GC) vs placebo.[1–3]

Objectives: To evaluate anifrolumab treatment response vs placebo in patients with SLE from MUSE, TULIP-1, and TULIP-2 using more stringent BICLA definitions, as well as a novel endpoint that requires dual BICLA and SLE Responder Index (SRI[4]) responses.

Methods: MUSE (NCT01438489), TULIP-1 (NCT02446912), and TULIP-2 (NCT02446899) were randomized, placebo-controlled, 52-week trials of intravenous anifrolumab (every 4 weeks for 48 weeks) in patients with moderate to severe SLE despite standard therapy.[1–3] Sustained GC taper was defined as taper to ≤7.5 mg/day in patients receiving GC ≥10 mg/day at baseline, or to less than or equal to baseline dose in patients receiving GC <10 mg/day at baseline, achieved by W40 and sustained through W52. Response rates were compared between anifrolumab 300 mg vs placebo groups for patients who **1)** attained a W52 BICLA response with sustained GC taper; **2)** attained a W52 BICLA response and no flares after W12 (flare defined as ≥1 new BILAG-2004 A or ≥2 new BILAG-2004 B scores vs the prior visit); **3)** attained a W52 BICLA response with sustained GC taper and no flares after W12; **4)** attained an enhanced BICLA (eBICLA) response at W52 that required complete resolution of all baseline BILAG-2004 activity (all baseline A/B scores to D; no worsening of C or D scores); and **5**) met both BICLA and SRI(4) response criteria.

Results: Evaluated patients received anifrolumab 300 mg (MUSE, n=99; TULIP-1 and TULIP-2, n=180) or placebo (MUSE, n=102; TULIP-1, n=184; TULIP-2, n=182). Response rate differences favoring anifrolumab 300 mg over placebo were observed for all 5 endpoints across MUSE, TULIP-1, and TULIP-2 (Figure 1). A greater proportion of patients had BICLA responses at W52 with sustained GC taper with anifrolumab vs placebo. More patients had BICLA responses at W52 with no flares after W12 with anifrolumab vs placebo. More patients had BICLA responses at W52 with both sustained GC taper and no flares after W12 with anifrolumab vs placebo (treatment difference, 15.3%–19.3%; nominal $P \leq 0.006$). More patients attained eBICLA responses (requiring complete resolution of baseline disease activity) at W52 with anifrolumab vs placebo (treatment difference, 11.1%–14.1%; nominal $P \leq 0.017$). In addition, more patients were dual BICLA and SRI(4) responders at W52 with anifrolumab vs placebo (treatment difference, 14.3%–28.6%; nominal $P \leq 0.004$).

Figure. Stringent BICLA response definitions and dual BICLA and SRI(4) response at Week 52 in patients with SLE

W52 endpoint, Trial	Placebo, n/N (%)	Anifrolumab 300 mg, n/N (%)	Treatment difference (95% CI)	Treatment difference (95% CI), nominal *P*
BICLA response

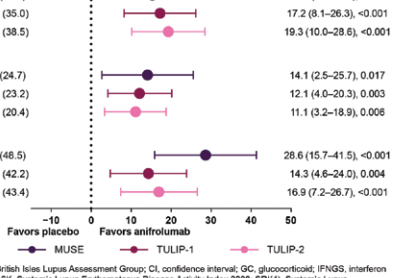
TULIP-2	48/182 (26.4)	78/180 (43.4)		16.9 (7.2–26.7), <0.001



BICLA, BILAG–based Composite Lupus Assessment; BILAG, British Isles Lupus Assessment Group; CI, confidence interval; GC, glucocorticoid; IFNGS, interferon gene signature; PGA, Physician's Global Assessment; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000; SRI(4), Systemic Lupus Erythematosus Responder Index of 4; W, Week.

Rates, differences, 95% CIs, and nominal *P* values were calculated using a stratified Cochran–Mantel–Haenszel approach (stratification factors SLEDAI-2K score at screening, Day 1 GC dose, and IFNGS test status at screening). Response for all endpoints required no trial treatment discontinuation and no use of protocol-restricted medications.

BICLA response, vs baseline: improvement in all BILAG-2004 organ domains (A and B scores to B/C/D and C/D, respectively), no BILAG-2004 domain worsening; no SLEDAI-2K worsening; no PGA worsening (≥0.3 points).

SRI(4) response, vs baseline: reduction ≥4 points in SLEDAI-2K; no new BILAG-2004 organ involvement (≥1 A or ≥2 B items); no PGA worsening (≥0.3 points).

Conclusion: In phase 2 and 3 trials in patients with SLE, anifrolumab treatment was consistently associated with improved disease control vs placebo using stringent endpoint definitions, including BICLA response with sustained GC taper and no flares, an enhanced BICLA response requiring complete resolution of baseline disease activity, and dual BICLA and SRI(4) responses.

POS0684 RELATIONSHIP OF ANIFROLUMAB PK WITH EFFICACY AND SAFETY IN PATIENTS WITH SLE

Y. L. Chia[1], J. Zhang[2], R. Tummala[3], T. Rouse[4], R. Furie[5], E. F. Morand[6]. [1]*AstraZeneca, BioPharmaceuticals R&D, South San Francisco, United States of America*; [2]*Fate Therapeutics Inc, Department of Data Science, San Diego, United States of America*; [3]*AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, United States of America*; [4]*AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden*; [5]*Zucker School of Medicine at Hofstra/Northwell, Division of Rheumatology, Great Neck, United States of America*; [6]*Monash University, Centre for Inflammatory Disease Monash Health, Melbourne, Australia*

Background: In patients with systemic lupus erythematosus (SLE), the type I interferon (IFN) receptor inhibitor anifrolumab was well tolerated and was associated with greater percentages of patients with BILAG–based Composite Lupus Assessment (BICLA) responses vs placebo in 2 phase 3 trials: TULIP-1[1] (secondary endpoint) and TULIP-2[2] (primary endpoint).

Objectives: To characterize the relationship of anifrolumab pharmacokinetics (PK) with BICLA response and safety using pooled data from the TULIP trials.

Methods: This analysis included patients with moderate to severe SLE despite standard therapy who had ≥1 dose of investigational product and ≥1 quantifiable PK observation in the randomized, placebo-controlled, 52-week TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) trials of intravenous anifrolumab (every 4 weeks).[1,2] The distributions of average anifrolumab serum concentrations (C_{ave}) during treatment were similar between TULIP-1 and TULIP-2, allowing for data pooling for all analyses. For the exposure–BICLA analysis, the proportions of patients with BICLA responses at Week (W)52 (and corresponding 95% confidence intervals [CIs]) in each quartile/tertile of C_{ave} were compared for anifrolumab 300 mg and placebo groups in all patients, patients who completed treatment, and IFN gene signature (IFNGS) test–high patients who completed treatment, using average marginal effect logistic regression (stratified by SLE Disease Activity Index 2000 total score at screening, IFNGS status at screening, and Day 1 glucocorticoid dosage [mg/day]). The relationships between exposure and key safety events were similarly assessed. Analyses presented focus on the anifrolumab 300 mg dose.

Results: Of the patients in TULIP-1/TULIP-2 who received anifrolumab 300 mg (n=356) or placebo (n=366), 574 completed treatment, of whom 470 were IFNGS test–high at screening. In the exposure–BICLA response analyses, differences favoring anifrolumab 300 mg vs placebo were observed across C_{ave} subgroups among all patients, patients who completed treatment, and IFNGS test–high patients who completed treatment (Table 1). Among IFNGS test–high patients who completed treatment, logistic regression identified C_{ave} as a significant covariate for BICLA response. There was no evidence that the incidence of non-opportunistic serious infections, or increased incidence of herpes zoster (HZ) or infusion-related reactions associated with anifrolumab, were exposure-driven (Figure 1); the incidence of malignancy was low in the anifrolumab 300 mg and placebo groups (<1%), with no evidence that malignancy was exposure-driven through W52.

Conclusion: Consistent benefit in favor of anifrolumab 300 mg vs placebo was observed in W52 BICLA responses across C_{ave} subgroups. C_{ave} was a significant covariate of efficacy in IFNGS test–high patients who completed treatment. There was no evidence of exposure-driven HZ, non-opportunistic serious infections, infusion-related reactions, or malignancy during the TULIP trials.

POS0685 MYCOPHENOLATE MOFETIL IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: FIVE-YEARS DRUG SURVIVAL IN RENAL AND NON-RENAL INVOLVEMENT

G. Olivieri[1], F. Ceccarelli[1], F. Natalucci[1], F. R. Spinelli[1], C. Alessandri[1], F. Conti[1]. *[1]Lupus Clinic, Sapienza Università di Roma, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Roma, Italy*

Background: The updated EULAR recommendations for the management of systemic lupus erythematosus (SLE) underline the use of Mycophenolate Mofetil (MMF) in the treatment of different disease related manifestations (1). Several randomized controlled trials have demonstrated the efficacy of MMF in lupus nephritis (LN) patients but only case series and open-labelled trials have analyzed the use of this drug in other than LN features. Moreover, no data are available about the MMF retention rate in a real-life setting.

Objectives: The present study aims at evaluating the 5-years drug retention rate (DRR) of MMF in a large monocentric SLE cohort. Secondly, we investigated the influence of MMF in disease activity changes and chronic damage progression.
Methods: We performed a longitudinal study including all the SLE patients (ACR 1997 criteria) starting MMF treatment in our Lupus Clinic. Data about indications, mean dosage, duration of treatment and reasons for drug withdrawal were registered. The DRR was estimated using the Kaplan–Meier method. Disease activity and chronic damage were assessed by SLE Disease Activity Index 2000 (SLEDAI-2K) and SLICC Damage Index (SDI), respectively.
Results: The present analysis included 162 SLE patients (M/F 22/140, median age at the disease diagnosis 25.5 years, IQR 13). At the beginning of MMF treatment, we registered a median age of 34 months (IQR 21) and a median disease duration of 72 months (IQR 123). The most frequent indications for prescribing MMF were LN (101 patients, 62.3%) and musculoskeletal manifestations (39, 24.1%), followed by neuropsychiatric involvement (10, 6.2%), and others disease related manifestations (12, 7.4%; in particular skin involvement, hematological features, myositis, vasculitis). MMF was administered at a mean daily dosage of 2.1±0.6 grams; no differences in dosage were found between the different indications (p=ns).
At the longitudinal analysis, we registered a median treatment duration of 30 months (IQR 55). Figure 1 reported data about DRR: in particular, at 60 months follow-up we observed a DRR of 61.1% for LN patients, which was similar to that registered for patients without renal involvement (NLN) (60.5%; p=ns). Interestingly, the DRR at 60 months was higher in the subgroup of patients treated for joint involvement (75.4%), even without reaching a statistically significant difference. During the observation period, 92 patients (59.2%) discontinued MMF (median treatment duration at discontinuation 25 months, IQR 35). Interestingly, the main cause of withdrawal was the achievement of persistent remission, observed in 20 patients (21.7%), followed by loss of efficacy (19 patients, 20.5%), drug intolerance and pregnancy planning (17 patients for both reasons, 18,4%). Furthermore, our analysis confirmed MMF efficacy, as demonstrated by the significant reduction in SLEDAI-2k values after 4, 12 and 24 months of treatment (p< 0.0001 for all the time-points in comparison with baseline). In addition, MMF resulted able to control chronic damage progression, as demonstrated by the lack of significant increase in SDI values (baseline: 0.6, IQR 1; last observation: 0.93, IQR 1; p=ns).
Conclusion: The evaluation of a large SLE cohort demonstrated a good retention rate for MMF. In particular, our results demonstrated that MMF is also a safe and effective drug for SLE manifestation other than LN, in particular for joint involvement. Moreover, it is able to control disease activity and to prevent the progression of chronic damage.

POS0686 BARICITINIB DECREASES ANTI-DSDNA AND IGG ANTIBODIES IN ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS FROM A PHASE 2 DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED TRIAL

T. Dörner[1], R. Van Vollenhoven[2], A. Doria[3], B. Jia[4], D. Fantini[4], J. Ross Terres[4], M. Silk[4], S. De Bono[4], P. Fischer[4], D. J. Wallace[5]. *[1]Charite Universitätsmedizin Berlin and Deutsches Rheumaforschungszentrum (DRFZ), Division of Rheumatology, Berlin, Germany*; *[2]University Medical Center, Department of Rheumatology, Amsterdam, Netherlands*; *[3]University of Padova, Department of Medicine, Padova, Italy*; *[4]Eli Lilly and Company, Lilly Research Laboratories, Indianapolis, United States of America*; *[5]Cedars-Sinai Medical Center/ University California at Los Angeles, Division of Rheumatology, Los Angeles, United States of America*

Background: Baricitinib (BARI), an oral, selective Janus kinase (JAK)1 and JAK2 inhibitor, improved disease severity in adults with systemic lupus erythematosus (SLE) receiving standard background therapy in a phase 2 trial[1]. There were no meaningful reductions in least squares mean change from baseline (BL) in levels of serologic biomarkers for SLE with BARI treatment, including anti-double-stranded deoxyribonucleic acid (anti-dsDNA) antibodies and complement component (C)3 and C4[1].

Objectives: Evaluate the median change from BL in serologic biomarkers in subgroups and the overall population of BARI-treated SLE patients, in addition to the Systemic Lupus Erythematosus Responder Index-4 (SRI-4) response by normalization of anti-dsDNA.

Methods: Data were assessed from the phase 2 trial JAHH (NCT02708095). The median change from BL in anti-dsDNA, IgG, C3, and C4 was evaluated over time among the following populations at BL: anti-dsDNA positive (≥30 IU/mL), low C3 (<90 mg/dL), low C4 (<10 mg/dL), and all patients for IgG. Statistical tests were conducted for BARI 2-mg and 4-mg compared with placebo (PBO). Among patients who were anti-dsDNA positive at BL, SRI-4 responder rate was compared for those who stayed positive or achieved normal levels by Week (Wk) 24.

Results: Among patients who were anti-dsDNA positive at BL, significant decreases of anti-dsDNA antibodies were observed for BARI 2-mg and 4-mg compared to PBO beginning at Wks 2 and 4, respectively, and continuing through Wk 24 (Figure 1 and Table 1). Moreover, reductions of IgG levels were found for BARI-treated patients including significant decreases for BARI 4-mg compared to PBO at Wks 12 and 24 (Table 1). Among patients who had low levels of C3 and C4 at BL, no significant differences in median change from BL were observed over time with BARI compared to PBO. For patients who were anti-dsDNA positive at BL, no relationship in SRI-4 responder rate was observed for those who stayed positive or achieved normal levels by Wk 24, possibly due to the limited sample size.

Conclusion: BARI treatment resulted in a rapid and sustained significant decrease in anti-dsDNA antibodies compared to PBO among anti-dsDNA positive SLE patients at BL, as well as a significant decrease in IgG levels in the 4-mg group at Wks 12 and 24. These data suggest that BARI may have an effect on B cell activity in SLE.

Background: In patients with SLE, activation of the CD40–CD40L pathway results in stimulation and proliferation of B cells and other inflammatory cell types. The subsequent generation of autoantibodies and their deposition in the kidney, as well as activation of myeloid and resident kidney cells, result in local inflammation and eventually, kidney injury. Thus, CD40 is an appealing therapeutic target in lupus nephritis (LN). BI 655064 is a humanised anti-CD40 monoclonal antibody that blocks the CD40 pathway in a nanomolar range and downregulates activated B cells.

Objectives: To assess the efficacy and safety over 52 weeks of three doses of subcutaneous BI 655064 compared with placebo, as add-on to mycophenolate and steroids, in patients with active proliferative LN (ClinicalTrials.gov number: NCT02770170).

Methods: Overall, 121 patients with LN were randomised, double blind, in a 2:1:1:2 ratio to placebo or BI 655064 120 mg, 180 mg or 240 mg, and received a weekly loading dose for the first 3 weeks, followed by dosing every 2 weeks for the 120 and 180 mg doses, and weekly (120 mg) for the 240 mg group. Key inclusion criteria included an active ISN/RPS class III or IV (±V) renal biopsy within 3 months prior to screening and a screening protein/creatinine ratio of ≥1 mg/mg. Randomisation was stratified based on race (Asian vs non-Asian) and screening protein/creatine (UP/UC) ratio (<3 vs ≥3). The primary efficacy endpoint was complete renal response (CRR), defined as 24 h proteinuria <0.5 g/day and stable eGFR at Week 52.

Results: The placebo response in this trial was higher than expected (48.3%; Table 1); none of the

BI 655064 doses increased rates of CRR at Week 52 compared with placebo. However, CRR at Week 52 based on creatinine-adjusted proteinuria, assessed using spot urine, showed a better response in the 180 mg group (50%) vs placebo (42.5%), and the 180 mg dose showed a greater change from baseline over

time vs placebo from Week 4. Time to CRR was shorter in the 180 mg group (17.3 weeks) vs placebo (20.4 weeks). The 180 mg group also showed improvement vs placebo in total SLEDAI (SELENA) and its subscores.

The unexpected high placebo response prompted a post hoc analysis evaluating confirmed CRR (cCRR), whereby confirmation of the endpoint was required at both Weeks 46 (penultimate visit on treatment) and 52. A 15.2% higher cCRR in the 180 mg group (44.3%) vs placebo (29.1%) was observed (p=0.26).

While based on a small sample size, there were more reports of infection-related severe and serious adverse events and neutropenia in the 240 mg group compared with placebo. Of note, in those who experienced neutropenia, a clinical impact (e.g. increase in infections) was not established. Aside from these observations, safety data were comparable across treatment groups.

Larger decreases from baseline were observed in the percentage of CD27–IgD–CD95+, CD27–IgD+CD95+, CD27+IgD+CD95+ and CD27+IgD–CD95+ B-cell subsets in the 180 and 240 mg groups compared with placebo.

Treatment-emergent anti-drug antibodies (ADAs) were detected in five patients treated with BI 655054, all at low titre, and in one who received placebo; ADAs had no impact on pharmacokinetics or safety.

Conclusion: The trial did not meet its primary CRR endpoint. However, when confirmation of CRR was required at both Weeks 46 and 52, the resultant decrease in the placebo response generated an effect size of 15.2% and 9.1% in favour of 180 mg and 240 mg BI 655064, respectively.

Table 1. Efficacy endpoints at Week 52

	Placebo (n=40)	BI 655064

POS0688 CHARACTERIZATION OF PK/PD OF ANIFROLUMAB IN PATIENTS WITH MODERATE TO SEVERE SLE

Y. L. Chia[1], R. Tummala[2], T. Mai[3], T. Rouse[4], W. White[2], E. F. Morand[5], R. Furie[6]. *[1]AstraZeneca, BioPharmaceuticals R&D, South San Francisco, United States of America*; *[2]AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, United States of America*; *[3]Genentech, Clinical Pharmacology and Modeling & Simulation, South San Francisco, United States of America*; *[4]AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden*; *[5]Monash University, Centre for Inflammatory Disease Monash Health, Melbourne, Australia*; *[6]Zucker School of Medicine at Hofstra/Northwell, Division of Rheumatology, Great Neck, United States of America*

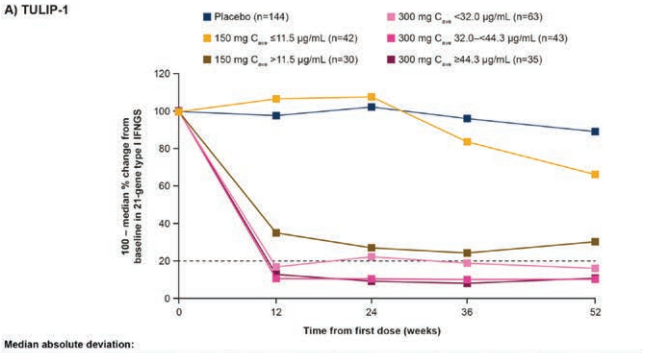
Background: In the TULIP-1 and TULIP-2 trials, anifrolumab, a type I interferon (IFN) receptor antibody, at a dosage of 300 mg once every 4 weeks (Q4W), demonstrated consistent median pharmacokinetic (PK) concentrations[1] and sustained neutralization of the pharmacodynamic (PD) 21-gene type I IFN gene signature (IFNGS)[2–4] in patients with moderate to severe systemic lupus erythematosus (SLE) despite standard therapy.

Objectives: To characterize the PK/PD relationship of anifrolumab and to confirm anifrolumab 300 mg provides adequate PD neutralization in IFNGS test–high patients.

Methods: This study included IFNGS test–high patients from the phase 3 randomized, placebo-controlled, 52-week TULIP-1[2] (NCT02446912) and TULIP-2[3] (NCT02446899) trials of intravenous anifrolumab 150 mg or 300 mg Q4W plus standard therapy. IFNGS test status (high or low) at screening was classified with an analytically validated 4-gene qPCR based test on whole blood.[2] PD neutralization was measured with 21-gene type I IFNGS and expressed as a percentage change from baseline.[3] For the graphic PK/PD analysis, patients with ≥1 quantifiable serum PK sample and ≥1 PD measurement before discontinuation were categorized depending on C_{ave} (individual predicted average anifrolumab concentration over treatment duration) median and tertiles (T) for anifrolumab 150 mg and 300 mg, respectively. Median PD IFNGS neutralization and medium absolute deviations were compared across C_{ave} subgroups. PK/PD modeling was assessed in patients with ≥1 quantifiable serum PK sample and a baseline and ≥1 postbaseline PD measurement before discontinuation, using a nonlinear mixed-effects model (NONMEM; version 7.3; ICON) to estimate parameters and characterize the PK/PD data. The PD/efficacy analysis included patients with ≥1 postbaseline PD measurement before discontinuation. BILAG-based Combined Lupus Assessment (BICLA) response rates at Week (W)52 were compared across median PD neutralization quartiles (Q) for pooled anifrolumab 300 mg and 150 mg groups.

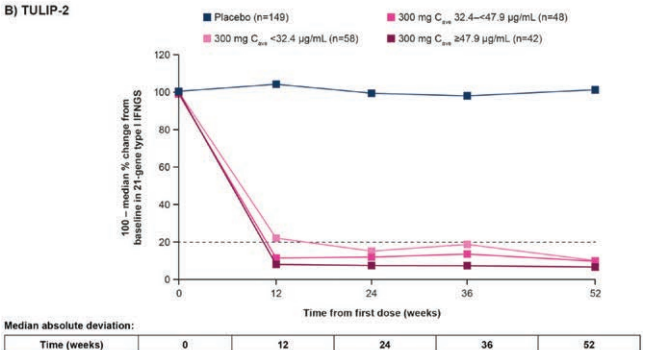
Results: The PK/PD graphic analysis included 654 IFNGS test–high patients (placebo [n=293]; anifrolumab 150 mg [n=72] or 300 mg [n=289]). C_{ave} was generally higher with anifrolumab 300 mg (μg/mL, TULIP-1: T1 <32, T2 32–<44.3, T3 ≥44.3; TULIP-2: T1 <32.4, T2 32.4–<47.9, T3 ≥47.9) than with anifrolumab 150 mg (median 11.5 μg/mL); overlap between anifrolumab 300 mg and 150 mg C_{ave} subgroups was small owing to nonlinearity. Anifrolumab 300 mg elicited rapid

Figure. Observed PD neutralization of the 21-gene type I IFNGS according to C_{ave} subgroup over the 52-week treatment duration in A) TULIP-1 and B) TULIP-2



Median absolute deviation:

Time (weeks)		0	12	24	36	52
Placebo		0	29.5	33.3	32.7	29.0
150 mg	C_{ave} ≤11.5	0	26.6	36.6	41.6	28.5
	C_{ave} >11.5	0	26.5	20.7	18.3	19.0
300 mg	C_{ave} <32.0	0	8.9	15.9	12.4	11.2
	C_{ave} 32.0–<44.3	0	4.7	4.9	5.1	5.9
	C_{ave} ≥44.3	0	6.8	5.0	4.1	8.0



Median absolute deviation:

Time (weeks)		0	12	24	36	52
Placebo		0	38.7	34.4	27.4	34.3
300 mg	C_{ave} <32.4	0	16.6	10.1	11.8	4.0
	C_{ave} 32.4–<47.9	0	7.3	7.8	10.6	4.5
	C_{ave} ≥47.9	0	3.6	3.2	4.1	2.8

C_{ave}, average anifrolumab concentration over the treatment period; IFNGS, interferon gene signature; PD, pharmacodynamic; PK, pharmacokinetic. Figure includes patients with ≥1 quantifiable serum PK observation and ≥1 PD measurement prior to discontinuation; PD collected after discontinuations were not included.

(by W4[4]) and sustained median PD neutralization >80%, vs a lower and delayed PD neutralization (median >50% at W52) with anifrolumab 150 mg, and minimal PD neutralization with placebo. The median PD neutralization increased with higher C_{ave} subgroups, plateauing at ~90% at W12–W52. All anifrolumab 300 mg C_{ave} tertiles had a median PD neutralization ~80%; however, the variability was greater in the lowest C_{ave} tertiles vs higher C_{ave} tertiles across trials (Figure 1). The PK/PD modeling, which included 646 IFNGS test–high patients (placebo [n=289], anifrolumab 150 mg [n=70] or 300 mg [n=287]), gave an IC_{80} estimate of 3.88 µg/mL. The median W24 (study midpoint) C_{trough} was higher with anifrolumab 300 mg vs 150 mg (15.6 vs 0.2 µg/mL); thus, the W24 C_{trough} exceeded the IC_{80} in a higher proportion of patients treated with anifrolumab 300 mg vs 150 mg (~83% vs ~27%). The PD/efficacy analysis included 341 patients who received anifrolumab. Higher median percentage PD neutralization quartiles (Q1 <51.7%, Q2 51.7%–85.3%, Q3 85.3%–92.6%, Q4 >92.6%) were associated with higher W52 BICLA response rates (Q1 37.6%, Q2 49.4%, Q3 51.8%, Q4 58.1%).

Conclusion: In TULIP-1 and TULIP-2, anifrolumab 300 mg yielded higher anifrolumab C_{ave} vs 150 mg. High C_{ave} was associated with rapid (W4[4]–W12), substantial, and sustained PD neutralization of the 21-gene IFNGS in IFNGS test–high patients, which in turn was associated with higher efficacy.

POS0689

A 6-MONTH OPEN-LABEL EXTENSION STUDY OF THE SAFETY AND EFFICACY OF INTRAVENOUS BELIMUMAB IN PATIENTS WITH LUPUS NEPHRITIS

R. Furie[1], B. H. Rovin[2], F. Houssiau[3], G. Contreras[4], P. Curtis[5], A. Madan[6], A. Jones-Leone[7], M. Okily[8], D. Roth[9]. [1]*Northwell Health, Division of Rheumatology, Great Neck, NY, United States of America*; [2]*The Ohio State University, Division of Nephrology, Columbus, OH, United States of America*; [3]*Cliniques Universitaires Saint-Luc, Pôle de Pathologies, Brussels, Belgium*; [4]*University of Miami Miller School of Medicine, Division of Nephrology, Division of Hypertension, Department of Medicine, Miami, FL, United States of America*; [5]*GlaxoSmithKline, Department of Quantitative Sciences, Brentford, United Kingdom*; [6]*GlaxoSmithKline, Clinical Sciences, Collegeville, PA, United States of America*; [7]*GlaxoSmithKline, Medical Affairs, Collegeville, PA, United States of America*; [8]*GlaxoSmithKline, R&D ImmunoInflammation, Collegeville, PA, United States of America*; [9]*GlaxoSmithKline, Research and Development, Collegeville, PA, United States of America*

Background: BLISS-LN (GSK Study BEL114054; NCT01639339), the largest lupus nephritis (LN) study to date, showed that intravenous (IV) belimumab (BEL) + standard therapy (ST) improved outcomes compared with ST alone in patients (pts) with active LN.[1]

Objectives: To assess additional safety and efficacy data of BEL + ST in pts with LN in a 6-month open-label (OL) phase beyond 2 years of double-blind (DB) treatment in BLISS-LN.

Methods: In this OL phase, eligible completers of the DB phase received monthly BEL 10 mg/kg IV + ST for 6 months. Endpoints: safety; Primary Efficacy Renal Response (PERR; uPCR ≤0.7; eGFR no worse than 20% below OL baseline eGFR or ≥60 ml/min/1.73 m^2; no prohibited medications) and Complete Renal Response (CRR; uPCR <0.5; eGFR no worse than 10% below OL baseline eGFR or ≥90 ml/min/1.73 m^2; no prohibited medications) at OL Week 28; proportion of pts with SLEDAI score <4; corticosteroid use; biomarkers. Analyses were based on observed data and summarised relative to the OL baseline (last value measured prior to the first dose of OL treatment).

Results: We enrolled 257 pts (57.4% of pts in BEL114054) and treated 255 pts. All treated pts were included in the safety population (123 pts switched from placebo [PBO] to BEL; 132 pts remained on BEL). Efficacy was assessed in the safety population, excluding 1 pt due to non-compliance (mITT population; PBO to BEL: 122 pts; BEL to BEL: 132 pts). 96.5% of pts completed the OL phase; 3.5% withdrew, mainly due to adverse events (AE; 2.0%).

Overall, 168/255 (65.9%) pts had ≥1 AE (76/123 [61.8%] PBO to BEL pts; 92/132 [69.7%] BEL to BEL pts); 15/255 (5.9%) pts had ≥1 serious AE (5/123 [4.1%] PBO to BEL pts; 10/132 [7.6%] BEL to BEL pts); 1 (0.8%) pt died in the PBO to BEL group.

Proportions of PERR and CRR responders increased from OL baseline to OL Week 28 (Table 1. below)

Proportions of pts who attained SLEDAI scores <4 increased from OL baseline to OL Week 28 in the BEL to BEL group and decreased in the PBO to BEL group.

Among pts receiving average daily prednisone-equivalent doses of ≤5 mg or ≤7.5 mg dose was maintained from OL baseline to OL Week 28 (Table 1. below)

In pts with autoantibodies at OL baseline, anti-dsDNA and anti-C1q levels decreased from OL baseline to OL Week 28 in both groups. Among pts with low C3/C4 levels at OL baseline, C3/C4 levels increased from OL baseline to OL Week 28 in both groups (Table 1. below)

Conclusion: In this OL phase of BLISS-LN, proportions of PERR and CRR responders increased in both the BEL-naïve and BEL-experienced groups; and no new safety signals were observed. Improvements in biomarker levels were observed, especially in pts who switched from PBO to BEL.

Background: Anifrolumab, a type I interferon receptor antibody, has shown efficacy in patients with systemic lupus erythematosus (SLE),[1,2] >30% of whom develop lupus nephritis (LN).

Objectives: To evaluate the efficacy and safety of anifrolumab vs placebo alongside standard therapy in patients with active proliferative LN.

Methods: TULIP-LN (NCT02547922) was a phase 2 double-blind trial in adult patients with active, biopsy-proven LN and 24-hour (h) urine protein–creatinine ratio (UPCR) >1 mg/mg. Patients were randomized (1:1:1) to anifrolumab basic regimen (BR, 300 mg, based on SLE dosing[1,2]), anifrolumab intensified regimen (IR, 900 mg for 3 doses, 300 mg thereafter), or placebo, intravenously every 4 weeks alongside standard therapy of oral glucocorticoids (GCs; mandatory taper ≤10 mg/day by Week [W]12, ≤7.5 mg/day by W24) and mycophenolate mofetil (target 2 g/day by W8). The primary endpoint was the relative difference in change from baseline to W52 in 24-h UPCR, measured with a geometric mean ratio (GMR) of the change in the combined anifrolumab vs placebo groups (GMR <1 favors anifrolumab). The key secondary endpoint was complete renal response (CRR) at W52 (24-h UPCR ≤0.7 mg/mg, estimated glomerular filtration rate ≥60 mL/min/1.73 m^2 or no decrease ≥20%, no treatment discontinuation, and no restricted medication use). Sustained GC taper (≤7.5 mg/day, W24–52) was an exploratory endpoint. $CRR_{0.5}$ (CRR with UPCR ≤0.5 mg/mg) and time to $CRR_{0.5}$ sustained to W52 were analyzed post hoc. Responder rates were calculated with a stratified Cochran–Mantel–Haenszel approach.

Results: Patients received anifrolumab BR (n=45) or IR (n=51) or placebo (n=49); demographics and baseline disease characteristics were generally balanced between groups. No difference in change from baseline to W52 in 24-h UPCR was observed for combined anifrolumab vs placebo groups (Table 1). Anifrolumab clearance was higher in patients with LN vs SLE; proteinuria in LN elicited suboptimal anifrolumab serum concentrations (early trough from BR 50%–60% lower than in SLE trials[1,2]), so anifrolumab IR results are presented. CRR rate at W52 was numerically higher with the IR vs placebo (45.5% vs 31.1%) (Table 1). Time to sustained $CRR_{0.5}$ (Figure 1), rate of $CRR_{0.5}$ at W52, and rate of sustained GC taper to ≤7.5 mg/day (Table 1) were improved with the IR vs placebo. Most adverse events were nonserious, mild, or moderate and did not lead to discontinuation; rates were similar in the combined anifrolumab vs placebo groups (89.8% vs 93.8%). In the combined anifrolumab vs placebo groups, there was a higher incidence of herpes zoster (HZ, 16.7% vs 8.2%); most HZ cases were of mild to moderate intensity, cutaneous, and resolved with treatment.

Conclusion: Although the primary endpoint was not met, the anifrolumab IR was associated with numeric improvements across clinical endpoints vs placebo; thus, intensified dosing may be required to reach clinical efficacy in LN vs SLE without active renal disease. Anifrolumab had a similar safety profile in patients with LN and SLE; despite higher frequency of HZ vs placebo, anifrolumab was well tolerated.

POS0691 EFFECTS OF ANIFROLUMAB ON RENAL DISEASE IN PATIENTS WITH SLE

E. F. Morand[1], R. Furie[2], Y. Tanaka[3], T. Takeuchi[4], G. Abreu[5], R. Tummala[6], C. Lindholm[5]. [1]*Monash University, Centre for Inflammatory Disease Monash Health, Melbourne, Australia*; [2]*Zucker School of Medicine at Hofstra/Northwell, Division of Rheumatology, Great Neck, United States of America*; [3]*University of Occupational and Environmental Health, Japan, First Department of Internal Medicine, Kitakyushu, Japan*; [4]*Keio University School of Medicine, Department of Internal Medicine, Tokyo, Japan*; [5]*AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden*; [6]*AstraZeneca, BioPharmaceuticals R&D, Gaithersburg, United States of America*

Background: The type I interferon (IFN) receptor antibody anifrolumab has shown efficacy in patients with systemic lupus erythematosus (SLE) in the phase 3 TULIP-1 and TULIP-2 trials.[1,2] Type I IFN dysregulation is associated with lupus nephritis (LN) pathogenesis.[3]
Objectives: Pooled TULIP data were analyzed post hoc to assess baseline characteristics of patients with and without renal involvement and to evaluate the effects of anifrolumab on renal disease.
Methods: TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) were randomized, placebo-controlled, 52-week trials of intravenous anifrolumab every 4 weeks in patients with moderate to severe SLE despite standard therapy, which excluded patients with severe active LN.[1,2] Renal involvement at baseline was defined as any of the following: BILAG-2004 renal score A–C; SLEDAI-2K renal score >0; urine protein–creatinine ratio (UPCR) >0.5 mg/mg. Baseline characteristics were evaluated in patients with and without renal involvement, and the following endpoints were compared for the anifrolumab 300 mg and placebo groups: cumulative UPCR (area under the curve, AUC) through Week (W)52; percentage of patients with UPCR >0.5 mg/mg at baseline who improved to UPCR ≤0.5 mg/mg at W52; percentage of patients with renal flares (new BILAG-2004 A/B renal score vs prior visit); cumulative glucocorticoid (GC) use (AUC) through W52; and percentage changes in complement C3/C4 from baseline to W52.
Results: Of the 726 patients in TULIP-1/-2 (anifrolumab, n=360; placebo, n=366), 99 had renal involvement at baseline (anifrolumab, n=45; placebo, n=54), 57 of whom had UPCR >0.5 mg/mg (anifrolumab, n=24; placebo, n=33). Patients with renal involvement vs without renal involvement had a lower mean age (37.8 vs 42.4 years) and were more likely to be male (14.1% vs 6.1%), Asian (16.2% vs 9.6%), IFN gene signature test–high (89.9% vs 81.5%), and anti-dsDNA positive (69.7% vs 40.4%); have a SLEDAI-2K score ≥10 (91.9% vs 68.4%); and be receiving GC ≥10 mg/day (67.7% vs 49.1%) or mycophenolate (26.3% vs 11.5%) at baseline. Among patients with baseline renal involvement, anifrolumab treatment was associated with a numerically greater improvement vs placebo in cumulative UPCR (AUC) through W52 (LS mean difference [SE]: –54.1 [54.26]) (Table 1). Numerically more patients improved from UPCR >0.5 mg/mg at baseline to ≤0.5 mg/mg at W52 with anifrolumab vs placebo (difference [SE], 4.9% [13.3]). Among all TULIP patients, fewer had ≥1 BILAG-2004 renal flare with anifrolumab vs placebo (5.0% vs 7.4%).[4] Among patients with renal involvement, cumulative GC use (AUC) through W52 was lower with anifrolumab vs placebo (LS mean difference [SE]: –210.3 mg [332.6]) and there were numerically greater improvements in C3 and C4 from baseline to W52 (Table 1).
Conclusion: TULIP data suggest renal benefit with anifrolumab in patients with SLE with mild/stable renal disease, supporting further investigation into anifrolumab's efficacy in patients with active LN.

Background: Sjogren's syndrome (SS) is an autoimmune disease affecting excretory glands and characterised by B-cell hyperactivity. Ianalumab (VAY736) is a human monoclonal antibody to B-cell activating factor receptor, engineered for direct ADCC-mediated B-cell depletion. A Phase 2b study evaluated the dose-response of VAY736 vs placebo (PBO) in EULAR SS Disease Activity Index (ESSDAI) change from baseline (CHB) and other secondary endpoints.
Objectives: Primary results at Week (Wk) 24 were reported previously[1]. Here we report 52 Wk safety and efficacy from extended blinded treatment period 2 (TP2).
Methods: 190 patients (pts) were randomised equally to receive s.c. doses of VAY736 (5, 50, 300 mg) or PBO every 4 Wks (q4w). Eligible pts fulfilled American European Consensus Group (AECG) criteria, were anti-Ro/SSA+, had ESSDAI ≥6 and EULAR SS Patient Reported Index (ESSPRI) ≥5. At Wk 24, after completion of the first blinded TP (TP1), PBO-treated pts were switched to VAY736 150 mg, and pts on 300 mg were re-randomised to continue 300 mg or PBO for 28 Wks in TP2. Pts were followed post-treatment for ≥20 Wks. Safety was assessed for all periods. Due to lack of PBO-control in TP2, descriptive efficacy analysis was performed for ESSDAI, ESSPRI, Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F), Physician's (PhGA) and Patient's Global Assessments (PaGA), SF-36, and SS symptom diary (SSSD).
Results: Overall, there was no dose dependency of treatment emergent adverse events (TEAEs) except for injection site reactions, which were mostly mild to moderate in severity. Lymphopenia and neutropenia were mostly grade (G)1 and G2, no G4. Most common TEAEs were infections and infestations in exposure-adjusted analysis of incidence rates. Nasopharyngitis and upper

respiratory tract infections were the most common TEAEs, with no dose response (Table 1). Tracheobronchitis and pneumonia, were mild to moderate severity, not associated with absolute neutrophil count G3, and none led to treatment withdrawal.

At Wk 52, efficacy was sustained for pts who continued 300 mg in TP2 (ESSDAI, ESSPRI, PaGA, PhGA CHB: –9.06, –1.91, –22.03, –35.80, respectively). Efficacy was partially lost for pts switched to PBO at Wk 24 (Figure 1). Improvement was noted for PBO pts switched to 150 mg. Stimulated whole salivary flow at Wk 24 was improved for 300 mg (PBO-adjusted CHB 0.20 ml/min; P=0·037); last measurement at Wk 48 was 0.45 and 0.22 ml/min CHB in pts who continued 300 mg or PBO in TP2, respectively.

Conclusion: Ianalumab 300 mg was well tolerated up to 52 Wks. Exploratory efficacy showed that continuous dosing of 300 mg s.c. q4w provided sustained clinical benefit. PaGA was the outcome that showed the most prominent change following switch to PBO or VAY736.

Background: LN is still a severe manifestation of Systemic lupus erythematosus (SLE) and multitarget therapy is needed to control the disease especially in refractory cases.

Objectives: To evaluate renal response in SLE patients with glomerulonephritis (GN) treated with Belimumab in real-life setting.

Methods: Patients with proteinuria >0.5 g/24 h and/or active sediment at baseline enrolled in a multicentre Italian cohort of SLE patients (BeRLiSS study), treated with monthly iv Belimumab 10 mg/kg plus standard of care were considered in this study. *Complete renal response (CRR)* was defined as proteinuria <0.5 g/24 h, estimated glomerular filtration rate (eGFR)≥90ml/min/1.73m^2 and no rescue therapy. *Primary efficacy renal response (PERR)* was defined as proteinuria ≤0.7 g/24 h, eGFR ≥60ml/min/1.73m^2 and no rescue therapy. Prevalence and predictive factors of CRR and PERR at 12 and 24 months after Belimumab initiation were analyzed by multivariate logistic regression analysis.

Results: A total of 91 patients were considered in this study, 79 female, mean age 40.51±9.03 years, mean disease duration 12.18±8.15 years, median follow-up time after Belimumab initiation 22 months. Twenty patients had baseline proteinuria ≥0.5 <1 g/day, 17 ≥1 <2 g/day, 13 ≥2 g/day. Belimumab was started at GN onset in 20 (22%) patients and at the time of a renal flare in all other cases. Seventy-five patients underwent a renal biopsy: 1 class I, 4 class II, 14

class III, 47 class IV and 9 class V. Baseline serum creatinine was 82.44±29.26 umol/L; 15 patients showed eGFR<60ml/min/1.73m^2 at baseline. Immunosuppressants were taken by 70 (76.9%) patients: 47 micofenolate, 15 azathioprine and 5 ciclosporine. Sixty patients (65.9%) were on antimalarials. During follow-up 34 (37.4%) patients achieved CRR. Among them 5 (14.7%) patients relapsed and 29 (85.3%) patients maintained remission. Mean time to achieved CRR was 9.71±5.91 months.

High levels of baseline proteinuria were a negative independent predictor of CRR and PERR at 6 months (OR 0.044 CI95% 0.006-0.320 *p=0.002* and OR 0.232 CI95% 0.091-0.596 *p=0.002)* and 12 months (OR 0.029 CI95% 0.002-0.556 *p=0.019* and OR 0.056 CI95% 0.009-0.327 *p=0.001)*. High levels of baseline creatinine were a negative independent predictor of renal response. Renal response at 6 months was a strong predictive factor of renal response at 12 and 24 months.

Conclusion: Belimumab is an effective add-on therapy in the treatment of GN in real-life practice setting.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2021-eular.1757

POS0694 REAL-WORLD ECONOMIC IMPLICATIONS OF ACHIEVING LOW DISEASE ACTIVITY IN LUPUS NEPHRITIS

M. Dall'era[1], T. Hermes[2], M. Eaddy[3], A. Ogbonnaya[3], E. Farrelly[3], P. Mina-Osorio[4]. *[1]UCSF, Rheumatology, San Francisco, United States of America*; *[2]Aurinia Pharmaceuticals Inc., Commercial, Rockville, United States of America*; *[3]Xcenda, Health Economics, Carrollton, United States of America*; *[4]Aurinia Pharmaceuticals Inc., Medical Affairs, Victoria, Canada*

Background: Lupus nephritis (LN) is a common and severe manifestation of systemic lupus erythematosus (SLE) affecting 50% of SLE patients and leading to end-stage kidney disease (ESKD) in up to 30% of patients with LN.[1] Previous studies have reported higher healthcare costs in patients with SLE that develop LN compared to patients without LN.[2-5] These studies captured overall treatment costs associated with LN, regardless of disease activity or severity, and were conducted in small patient populations.

Objectives: The aim of this study was to assess the real-world economic implications of achieving low disease activity compared to active disease or ESKD in a large LN population.

Methods: This study was a retrospective observational analysis of patients with LN within Optum's health plan identified with ICD9 or ICD10 codes to have LN between January 1, 2015, and December 31, 2019. Patients were ≥18 years of age and had ≥2 months of follow-up data available. Patients were followed until death, loss to follow-up, or December 31, 2019. Low disease activity was defined by evidence of glucocorticoid doses ≤5 mg/day, evidence of mycophenolate mofetil (MMF) doses ≤2 g/day, and no use of cyclophosphamide for ≥6 consecutive months. Follow-up time that could not be defined as low disease activity was defined as active disease periods, except for periods with evidence of ESKD. Healthcare payer costs for medical and pharmacy services were compared between periods of low disease activity, active disease, and ESKD. A univariate generalized estimating equation model accounting for interdependence was used to compare differences in costs between periods of active and low disease activity.

Results: A total of 21,251 patients with LN met study criteria with a mean follow-up time of 31.0 months. The mean age was 60.3 years; 86.9% of patients were female and 35.2% of patients were non-White race. Low disease activity was evident in 51.3% of patients with a mean duration of 27.5 months. Mean monthly medical costs were $2,523 during periods of low disease activity and $4,777 during periods of active disease. After factoring in pharmacy costs, mean monthly total costs were $3,584 during periods of low activity and $6,612 during periods of active disease (P<0.001). The mean monthly costs of ESRD were $18,084 for medical and $3,760 for pharmacy.

Conclusion: Achieving low disease activity in patients with LN is associated with reduced economic burden to healthcare payers, with monthly medical costs averaging $2,254 less and total monthly costs averaging $3,028 less than costs during periods of active disease.

POS0695 KZR-616, A SELECTIVE IMMUNOPROTEASOME INHIBITOR FOR THE TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM THE COMPLETED DOSE ESCALATION PHASE 1B PORTION OF THE MISSION STUDY

R. Furie[1], S. Parikh[2], J. Wang[3], D. Bomba[4], R. Leff[5], C. Kirk[6], N. Henig[7]. *[1]Northwell Health, Chief, Division of Rheumatology, Great Neck, United States of America*; *[2]Ohio State University Wexner Medical Center, Division of Nephrology, Columbus, United States of America*; *[3]Kezar Life Sciences, Drug Metabolism, South San Francisco, United States of America*; *[4]Kezar Life Sciences, Clinical Operations, South San Francisco, United States of America*; *[5]Kezar Life Sciences, Clinical Science, South San Francisco, United States of America*; *[6]Kezar Life Sciences, Chief Science Officer, South San Francisco, United States of America*; *[7]Kezar Life Sciences, Chief Medical Officer, South San Francisco, United States of America*

Background: KZR-616 is a first-in-class selective inhibitor of the immunoproteasome, which is active in >15 autoimmune disease models, including murine models of systemic lupus erythematosus (SLE)/lupus nephritis (LN).[1,2,3] Selective inhibition of the immunoproteasome modulates both innate and adaptive immune effector cells, resulting in reduced inflammatory T helper cell subsets (Th1 and Th17), increased regulatory T cells, and decreased plasma cells and autoantibodies. KZR-616 was well tolerated in two healthy volunteer studies of 100 subjects receiving up to 75 mg subcutaneously (SC). Target levels of immunoproteasome inhibition were observed at doses ≥30 mg.[3,4] KZR-616 is currently in Phase 2 studies for several autoimmune indications, including the ongoing Phase 2 portion of the MISSION Study (KZR-616-002; NCT0339013) in patients with LN.

Objectives: Results of the completed MISSION Phase 1b dose escalation portion of the study are reported.

Methods: In the open-label, multicenter, dose escalation Phase 1b portion, SLE patients (per SLICC Classification Criteria) with SLEDAI ≥4 despite stable background immunosuppressant, anti-malarial, and/or corticosteroid therapy were administered weekly KZR-616 subcutaneously at doses of 45 mg (cohort 1), 60 mg (cohort 2), 60 mg following step-up doses of 30 mg and 45 mg (cohort 2a), 60 mg following a step-up dose of 30 mg (cohorts 2b, 2c) or 75 mg following a step-up dose of 30 mg (cohort 3) for 13 weeks with follow-up through Week 25 (W25); a lyophilized formulation was used for cohorts 2b, 2c and 3. The disease activity measures assessed were: SLEDAI-2K, Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI), 28 tender and swollen joint counts, Physician and Patient Global Assessments, and Patient Assessment of Pain. Safety and tolerability were assessed in the safety population (patients receiving at least one dose of KZR-616).

Results: The Phase 1b portion of MISSION enrolled 47 SLE patients, including 2 patients with active proliferative LN. The most common treatment-emergent adverse events (TEAE) were injection site reactions, which were mostly mild. Infections occurred at a low rate, and there were no reports of peripheral neuropathy, prolonged hematologic AEs, or clinically significant laboratory abnormalities. No discontinuations were observed in cohorts 2b and 2c; no serious AEs were reported in cohort 3 and TEAEs were consistent with those reported in earlier cohorts. Mean values of all measures of disease activity improved in evaluable patients who completed the 13-week treatment period, and improvements were generally maintained at W25. All patients with

elevated anti-double-stranded DNA antibody (anti-dsDNA) levels at baseline (n=7) had a reduction in levels with 3 of 7 experiencing a >50% reduction in their levels. Two of two patients with active proliferative LN had a >50% reduction in UPCR and experienced reductions in SLEDAI-2K scores as well as anti-dsDNA levels. Exposure to KZR-616, similar to that reported in healthy volunteers, was dose-proportional across doses, and no accumulation was observed.

Conclusion: KZR-616 SC, once weekly for 13 weeks up to 75 mg, appears to be safe and well-tolerated in patients with active SLE on stable background therapy in the MISSION Phase 1b. At doses ≥45mg, efficacy was noted, including improvements in proteinuria in two of two patients with LN and serologic improvement in all 7 patients with quantifiable levels of anti-dsDNA antibodies at baseline. KZR-616 60 mg SC weekly for 24 weeks is currently being evaluated in the MISSION Phase 2 in patients with LN. Based on the results of MISSION, inhibition of the immunoproteasome with KZR-616 represents a novel strategy to treat autoimmune diseases.

POS0696 SAFETY AND EFFICACY OF BELIMUMAB IN OLDER ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF AN INTEGRATED ANALYSIS

D. D'cruz[1], G. Eriksson[2], Y. Green[3], A. Hammer[4], B. Ji[5], P. Meizlik[6], D. Roth[7]. *[1]Guy's Hospital, Louise Coote Lupus Unit, London, United Kingdom*; *[2]GlaxoSmithKline, Global Clinical Delivery, Collegeville, PA, United States of America*; *[3]GlaxoSmithKline, Clinical Development, Brentford, Middlesex, United Kingdom*; *[4]GlaxoSmithKline, Biostatistics, Collegeville, PA, United States of America*; *[5]GlaxoSmithKline, Research and Development, Brentford, Middlesex, United Kingdom*; *[6]GlaxoSmithKline, Global Safety, Collegeville, PA, United States of America*; *[7]GlaxoSmithKline, Research and Development, Collegeville, PA, United States of America*

Background: Systemic lupus erythematosus (SLE) is a chronic, autoimmune disease characterised by persistent B-cell activation. Belimumab (BEL), a monoclonal antibody that inhibits B-lymphocyte stimulator, is approved in patients aged ≥5 years with active autoantibody-positive SLE; however, safety and efficacy data of BEL in older adults are limited.

Objectives: Assess the safety and efficacy of BEL in older adults with SLE.

Methods: A meta-analysis (GSK study 116559) was performed on the subpopulation of patients aged ≥65 years and compared with the overall population pooled from six controlled, repeat-dose (CRD) BEL trials in adults with SLE (GSK studies: 110752, 110751, LBSL02 [safety only], 112341, 113750, and 115471). Additional safety data were obtained from GSK study 115467.

In each trial, patients were randomised to BEL or placebo (PBO) and received ≥1 treatment dose (GSK studies 110752 and 110751: intravenous [IV] BEL 1 or 10 mg/kg; LBSL02: IV BEL 1, 4, or 10 mg/kg; GSK study 112341: subcutaneous BEL 200 mg; GSK studies 113750, 115471, and 115467: IV BEL 10 mg/kg) plus standard therapy. Safety assessments included: incidence of serious adverse events (SAE), mortality and adverse events of special interest (AESI). The primary efficacy analysis for the CRD trials was the SLE Responder Index 4 (SRI4) response rate.

Results: Older adults (CRD studies: N=63; study 115467: N=156) had lower disease activity and more organ damage compared with the overall populations, and a greater proportion were of white race compared with the overall population in the CRD studies. There were no clinically relevant differences in the incidence of SAE or death between older adults and the overall populations (Table 1). Rates of AESI (post-infusion/injection systemic reactions [PISR], serious infections of special interest, malignancies, psychiatric events) were generally similar or lower in older adults compared with the overall populations with no imbalances between BEL and PBO in older adults (Table 1). No malignancies were reported in older adults. The SRI4 response rate in older adults favoured BEL vs PBO (OR [95% CI], 1.49 [0.49, 4.58]), consistent with the overall populations of the individual CRD studies (110752 and 110751 pooled [10 mg/kg IV]: 1.68 [1.32, 2.15]; 112341: 1.68 [1.25, 2.25]; 113750: 1.99 [1.40, 2.82]; 115471: 1.42 [0.94, 2.15]).

Conclusion: In patients with SLE, the safety and efficacy of BEL in older adults were generally consistent with the overall population and suggest a favourable benefit–risk profile. Due to the small number of older adults analysed, these data should be interpreted with caution.

POS0697 SAFETY OF BELIMUMAB IN ADULT PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A LARGE INTEGRATED SAFETY ANALYSIS OF CONTROLLED CLINICAL TRIAL DATA

D. J. Wallace[1], T. Atsumi[2], M. Daniels[3], A. Hammer[4], P. Meizlik[5], H. Quasny[6], A. Schwarting[7], F. Zhang[8], D. Roth[9]. *[1]Cedars-Sinai, Division of Rheumatology, Los Angeles, CA, United States of America*; *[2]Hokkaido University Hospital, Department of Rheumatology, Sapporo, Japan*; *[3]GlaxoSmithKline, Clinical Science Lupus, Collegeville, PA, United States of America*; *[4]GlaxoSmithKline, Biostatistics, Collegeville, PA, United States of America*; *[5]GlaxoSmithKline,*

Global Safety, Collegeville, PA, United States of America; [6]*GlaxoSmithKline, Global Medical Affairs, Chapel Hill, NC, United States of America*; [7]*University Medical Center, Division of Rheumatology and Clinical Immunology, Mainz, Germany*; [8]*Peking Union Medical College Hospital, Internal Medicine Department, Beijing, China*; [9]*GlaxoSmithKline, Research and Development, Collegeville, PA, United States of America*

Background: Belimumab (BEL), a monoclonal antibody that antagonizes B-lymphocyte stimulator, was first approved in 2011 for active, autoantibody-positive systemic lupus erythematosus (SLE). BEL has been studied for over 10 years; and while safety data from individual trials have been informative, a large integrated safety analysis has not yet been conducted.

Objectives: Perform pooled analyses to evaluate the safety of BEL in adult patients with SLE.

Methods: Aggregate analyses were performed using safety data for patients ≥18 years of age pooled from six randomised, placebo (PBO)-controlled BEL clinical trials (GSK studies: LBSL02, 110752, 110751, 112341, 113750, and 115471). Patients from GSK studies LBSL02, 110752, and 110751 received intravenous (IV) BEL 1, 4 (LBSL02 only), or 10 mg/kg, or PBO on Days 1, 14, 28, and every 28 days thereafter. Patients from GSK studies 113750 and 115471 received IV BEL 10 mg/kg or PBO on Days 1, 14, 28, and every 28 days thereafter. Patients from GSK study 112341 received subcutaneous (SC) BEL 200 mg, or PBO weekly. Safety analyses included the incidence of adverse events (AEs), serious AEs (SAEs), severe AEs, AEs of special interest (AESI), and mortality of BEL (all doses and formulations combined) vs PBO at Week 52.

Results: The pooled analysis included 4170 patients. Overall, 81.0% (n=2280/2815) of patients receiving BEL and 76.6% (n=1038/1355) of patients receiving PBO completed their respectively enrolled study; the most common reason for withdrawal was occurrence of an AE in both groups. The majority of patients were female (BEL: 94.5%; PBO: 93.6%), the mean age in both groups was 38 years, and baseline characteristics (race, SLE duration, disease activity, SLE damage, complement levels, anti-dsDNA binding, SLE medication usage) were similar between treatments.

The incidence of patients experiencing ≥1 AE, ≥1 SAE, and mortality was similar across treatments (Table 1); the most commonly reported SAEs in both groups were infections and infestations (BEL: 5.4% [n=151/2815]; PBO: 5.9% [n=80/1355]). The mean duration of treatment exposure was similar between groups (BEL: 334.1 days; PBO: 325.3 days).

A greater proportion of patients experienced AESI with BEL vs PBO for post-infusion/injection systemic reactions (from IV or SC administration) and depression/suicide/self-injury (Table 1). The proportion of patients experiencing an AESI of infections and malignancies was similar between groups.

Conclusion: Consistent with individual studies, BEL demonstrated a similar safety profile to PBO in this large integrated safety analysis of six trials. These results support a positive benefit–risk profile of BEL in the treatment of adult SLE.

BIIB059 DEMONSTRATED A CONSISTENT THERAPEUTIC EFFECT ON SRI-4 RESPONSE ACROSS SUBGROUPS OF PARTICIPANTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN THE LILAC PHASE 2 STUDY

R. Van Vollenhoven[1], R. Furie[2], K. Kalunian[3], S. Navarra[4], J. Romero-Diaz[5], V. Werth[6,7], X. Huang[8], H. Carroll[9], C. Musselli[10], C. Barbey[11], N. Franchimont[10]. Background: Type I interferons and other inflammatory mediators derived from plasmacytoid dendritic cells (pDCs) are implicated in systemic lupus erythematous (SLE) pathology. BIIB059 is a humanized monoclonal antibody that targets blood dendritic cell antigen 2 (BDCA2), a pDC-specific receptor. The binding of BIIB059 to BDCA2 leads to rapid internalization of BDCA2 from the surface of pDCs and subsequent inhibition of interferon, cytokine, and chemokine production. In Part A of the 2-part, phase 2 LILAC study (NCT02847598), BIIB059 significantly reduced SLE activity, as evidenced by reduced total active joint count (primary endpoint) and higher SLE Responder Index (SRI-4)[1] response (a secondary endpoint) versus placebo.[2]

Objectives: To evaluate SRI-4 response for BIIB059 versus placebo at Week 24 in SLE participant subgroups.

Methods: Enrollment in LILAC Part A was open to adults fulfilling ≥ 4 of 11 revised 1997 ACR criteria for classification of SLE, with ≥ 4 tender and ≥ 4 swollen joints, active skin disease, and positive lupus antibodies. Participants were randomized to receive either BIIB059 450 mg or placebo subcutaneously every 4 weeks for 20 weeks (with an additional dose at Week 2). SRI-4 response at Week 24 was analyzed in subgroups, though analyses were limited by small sample sizes and were not powered for statistical testing.

Results: In LILAC Part A, 64 and 56 participants were dosed with BIIB059 450 mg and placebo, respectively. At week 24, SRI-4 response rate was observed in favor of BIIB059 regardless of the baseline disease activity, such as SLEDAI-2K <10 versus ≥10, presence of BILAG-2004 grade A or B arthritis, oral corticosteroid usage, positivity for anti-ds DNA autoantibody and/or complement status, with point estimates for least-squares mean differences as well as corresponding 95% CIs consistently favoring BIIB059 (Figure 1). The incidence of adverse events in the overall study population was similar between the placebo and BIIB059 groups.[2]

Conclusion: BIIB059 treatment was associated with greater SRI-4 response rate, consistent among different subgroups of baseline disease activity as measured by SLEDAI-2K and BILAG-2004, glucocorticoid dosage, and serology. These findings provide additional evidence of the potential benefit of BIIB059 for the treatment of patients with active SLE.

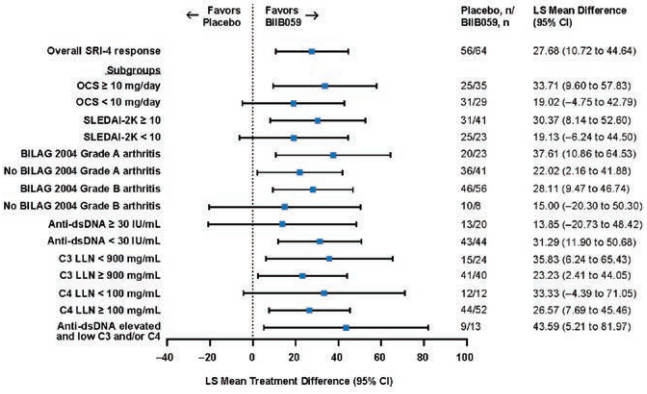
Figure. Subgroup Analysis of SRI-4 Response Between BIIB059 and Placebo at Week 24



BILAG 2004 = British Isles Lupus Assessment Group 2004; dsDNA = double-stranded DNA; LLN = lower limit of normal; LS = least-squares; OCS = oral corticosteroid; SLEDAI-2K = Systemic Lupus Erythematosus Disease Activity Index 2000; SLE = systemic lupus erythematosus; SRI-4 = SLE Responder Index

SRI-4 was defined as a reduction from baseline of ≥ 4 points in SLEDAI-2K, no new BILAG-2004 Grade A domain score or no more than 1 new BILAG-2004 Grade B domain score, no worsening from baseline in Physician's Global Assessment (< 10%), and no violations of protocol-specified medication rules. Participants who were considered as treatment failures or discontinued treatment were considered as nonresponders at visits after treatment failure or discontinuation. Participants who completed treatment but had a missing score at a primary timepoint were classified as nonresponders for that timepoint. Results are based on a generalized linear regression model adjusted for treatment using an identity link function (linear probability model) for the LS mean differences. Only BIIB059 450 mg and placebo are included in the statistical modeling.

GREATER REDUCTION IN CLASI-A SCORES ACHIEVED WITH BIIB059 VERSUS PLACEBO INDEPENDENTLY OF DISEASE SEVERITY AT BASELINE

V. Werth[1,2], R. Furie[3], K. Kalunian[4], R. Van Vollenhoven[5], S. Navarra[6], F. Nyberg[7], J. Romero-Diaz[8], M. Tee[9], X. Huang[10], H. Carroll[11], C. Barbey[12], C. Musselli[13], N. Background: Patients with cutaneous lupus erythematosus (CLE) experience symptoms including photosensitivity, rash, pain, and skin damage that can impact their quality of life. No targeted therapies are approved for CLE. BIIB059 is a humanized monoclonal antibody that targets blood dendritic cell antigen-2 (BDCA2), expressed exclusively on the surface of plasmacytoid dendritic cells (pDCs). The binding of BIIB059 to BDCA2 leads to rapid internalization of BDCA2 from the cell surface of pDCs, thereby inhibiting the production of pDC-derived type I interferons, cytokines, and chemokines, which are involved in CLE pathology. In Part B of the 2-part, phase 2 LILAC study (NCT02847598), the primary endpoint was met: BIIB059 significantly reduced CLE activity, as evidenced by a statistically significant dose response and statistically significant differences in least-squares mean percent changes in Cutaneous Lupus Erythematosus Disease Area and Severity Index – Activity (CLASI-A) score[1] versus placebo.[2]

Objectives: To determine the proportion of patients with CLE who presented at baseline with moderate or severe disease (CLASI-A ≥ 10) or with the higher category of mild disease (CLASI-A < 10 [i.e., 8 or 9]) and experienced a shift in CLASI-A score to a mild skin disease category or clear/almost clear skin status.

Methods: Adults with histologically confirmed CLE with or without systemic manifestations were enrolled if they had CLASI-A ≥ 8 at baseline, despite prior use of or intolerance to topical corticosteroids (CS) and/or antimalarials, in addition to ≥ 1 lesion diagnostic of subacute CLE (CLASI-A erythema score ≥ 2) and/or chronic CLE (CLASI-A erythema score ≥ 2 and CLASI-Damage scarring score ≥1). Concomitant CLE/SLE therapy was allowed if doses were initiated ≥ 12 weeks and kept stable ≥ 4 weeks before randomization and throughout the treatment period. Systemic corticosteroid doses could not exceed 15 mg/day of prednisone (or equivalent). BIIB059 (50, 150, 450 mg) or placebo was subcutaneously administered once every 4 weeks for 12 weeks, with an additional dose at Week 2. An ad hoc analysis was conducted to determine the proportion of participants (CLASI-A ≥ 10 or < 10 at baseline) with a shift in CLASI-A score to ≤ 1, ≤ 3, ≤ 6, and ≤ 8 at Week 16.

Results: In this ad hoc analysis from LILAC Part B, 106 (80.3%) and 26 (19.7%) of participants had a baseline CLASI-A score ≥ 10 and < 10, respectively. Compared with placebo, higher proportions of participants treated with BIIB059 achieved a shift in CLASI-A score from either ≥ 10 or < 10 at baseline to ≤ 1, ≤ 3, ≤ 6, and ≤ 8 at Week 16 (Figure 1). Treatment with BIIB059 resulted in higher proportions of participants achieving reduced scores, indicating shifts to more mild disease activity, compared with placebo. A score ≤ 1 (clear or almost clear skin) at Week 16 was achieved by 0.0% (0/25), 5.0% (1/20), 14.3% (3/21), and 12.5% (5/40) of participants with baseline CLASI-A ≥ 10 who were treated with placebo and BIIB059 50, 150, and 450 mg, respectively. Two of 26 participants with baseline CLASI-A < 10 achieved a score ≤ 1 (both received BIIB059 150 mg).

Conclusion: A greater proportion of participants achieved milder skin disease or clear/almost clear skin status in the BIIB059 groups as compared with the placebo group. This effect was observed in participants with moderate or severe disease as well as in those in the higher range of the mild category of disease severity at baseline, indicating the ability of BIIB059 to improve skin lesions in patients with a broad range of cutaneous disease activity.

TREATMENT OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH PRIMARY SJOGREN SYNDROME: A SINGLE-CENTER RETROSPECTIVE ANALYSIS

T. Y. Lan[1], H. T. Huang[2], J. H. Kao[1], C. F. Cheng3, C. H. Lu3, C. Y. Shen3, K. J. Li3, S. C. Hsieh[1]. [1]*National Taiwan University Hospital, Department of Internal Medicine, Rheumatology Division, Taipei, Taiwan, Republic of China*; [2]*National Taiwan University Hospital, Department of Oncology, Taipei, Taiwan, Republic of China*; [1]*National Taiwan University Hospital, Department of Internal Medicine, Rheumatology Division, Taipei, Taiwan, Republic of China*

Background: Interstitial lung disease (ILD) is one of the main contributor to morbidity and mortality in patients with primary Sjogren syndrome (pSS), and whether immunosuppressive treatments are effective for pSS-ILD is uncertain. Cyclophosphamide (CYC) and rituximab (RTX) are effective in stabilizing pulmonary function in patients with ILD caused by systemic sclerosis, inflammatory myositis, and rheumatoid arthritis[1,2]. Reports regarding the treatment response for cyclophosphamide or rituximab in pSS-ILD patients are lacking.

Objectives: To investigate whether add-on CYC or RTX in addition to steroid and oral DMARDs leads to greater improvement in pulmonary function test than conventional treatment in patients with pSS-ILD with impaired baseline pulmonary function.

Methods: pSS-ILD patients with ILD confirmed by a chest computed tomography were screened. Those with imparied baseline pulmonary function test (FVC<80% and DLCO<80%) and available results of pulmonary function tests at 6th-18th month post-treatment were retrospectively enrolled. The patients were clustered into two groups: steroid and oral DMARDs alone (steroid/oDMARD group), and add-on CyC and/or RTX (Add-on CyC/RTX group).

Results: This study enrolled 22 patients. The median age of these patients was 65. Among them, 68% were female and 18% were smokers. The median baseline FVC was 63.5% and the median DLCO was 54.4%. The predominant CT pattern was NSIP (54%), followed by UIP (22%), LIP (13.6%) and OP (9%) (table 1).

Five patients received steroid and oral DMARDs alone (hydroxychloroquine +/- azathioprine), while 17 patients received add-on CYC and/or RTX (8 patients received CYC, 3 received RTX, and 6 received CYC and RTX). There was no significant difference in baseline characteristic between these two groups (table 1).

With a median follow-up period of 9.8 months (interquartile range 7.6 - 13.4 months) after treatment, the FVC improved significantly from 61.3% to 65.5% (p=0.013) in CYC/RTX group, while the FVC improvement was not significant in steroid/oDMARD group (figure 1A). In CYC/RTX group, patients with non-UIP pattern (NSIP, LIP and OP) on chest CT had significant FVC improvement (p=0.021), contrasting to the patients with UIP pattern on chest CT (figure 1B).

Conclusion: In pSS patients with ILD and impairment of pulmonary function at baseline (FVC<80%, DLCO<80%), FVC improved significantly in patients received add-on cyclophosphamide and/or rituximab therapy.

POS0701 ANIFROLUMAB, AN ANTI-INTERFERON-A RECEPTOR MONOCLONAL ANTIBODY IN SYSTEMIC LUPUS ERYTHEMATOSUS- A META ANALYSIS

A. Abdul Razzack[1], S. Abdul Razzack[1], P. Shenasan[2], N. Shenasan[2], S. Mishra[2], R. Zarrar[2], J. Pablo Sosa[2], M. Mercedes Ferreira Caceres[2], R. Garimella[1], K. Andrews[3], S. Mukhtar[2], A. Agolli[2], O. Agolli[2], S. Hassan[4], D. M. Rocha Castellanos[5], S. Pothuru[6], K. Theja Reddy[7]. [1]*Dr. N.T.R University of Health Sciences, Department of Medicine, Vijaywada, India*; [2]*Larkin Community Hospital, Department of Clinical and Translational Research, South Miami, United States of America*; [3]*Prince Mohammad Bin Fahad University, Department of Mathematics and Natural Sciences, Al Khobar, Saudi Arabia*; [4]*University of Louisville, Department of Medicine, Louisville, United States of America*; [5]*Tecnológico de Monterrey, Escuela de Medicina y Ciencias de la Salud, Departamento de Cirugía, Nuevo León, Mexico*; [6]*Ascension Via Christi Hospital, Department of Medicine, Manhattan, United States of America*; [7]*UHS Southern California Medical Education Consortium, Department of Medicine, California, United States of America*

Background: Type I interferons such as Anifrolumab have been implicated in Systemic lupus erythematosus (SLE) pathogenesis on the basis of increased interferon-stimulated gene expression and genetic susceptibility. Little is known regarding its efficacy and safety profile.

Objectives: To assess the efficacy and safety of Anifrolumab in patients with SLE.

Methods: Electronic databases (PubMed, Embase, Scopus, Cochrane) were searched from inception until December 15th, 2020. Unadjusted odds ratios (OR) were calculated from dichotomous data using Mantel Haenszel (M-H) random-effects with statistical significance to be considered if the confidence interval excludes 1 and p<0.05. The primary outcome of interest was British Isles Lupus Assessment Group (BILAG)-based Composite Lupus Assessment (BICLA). Secondary outcomes included the proportion of patients who achieved an SLE responder index of 4 (SRI-4) reduction of 50% or more in the Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI), reductions in the glucocorticoid dose and adverse effects.

Results: A total of three studies[1,2,3] with 839 participants (Anifrolumab=372, Placebo=467) were included in our analysis. Follow-up duration was at week 52. A statistically significant different was observed in the Anifrolumab arm in terms of BICLA response (OR 0.44 95%CI 0.34-0.59;p<0.00001, I^2=4), ≥50% reduction in CLASI activity score (OR 0.36 95%CI 0.21-0.60;p=0.0001, I^2=0), glucocorticoid reduction (OR 0.41 95%CI 0.28-0.59;p<0.00001; I^2=0) and SRI-4 response (OR 0.52 95% CI 0.30-0.90; p=0.02, I^2=75). However, Adverse events were less likely in the placebo arm as compared to Anifrolumab (OR 1.54 95%CI 1.05-2.25; p=0.03; I^2=0).

Conclusion: Anifrolumab was found to be more effective than placebo for the management of SLE, but may also cause more severe adverse effects.

POS0702 PREGNANCY IN SLE PATIENTS TREATED WITH BELIMUMAB: EXPERIENCE FROM 3 ITALIAN CENTERS

F. Crisafulli[1], M. C. Gerardi[1], L. Moschetti[1], M. Fredi[1], C. Nalli[1], M. L. Urban[2], G. Emmi[2], F. Saccon[3], M. Zen[3], L. Iaccarino[3], A. Doria[3], F. Franceschini[1], L. Andreoli[1], A. Tincani[1]. [1]*ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy*; [2]*University of Florence, Department of Experimental and Clinical Medicine, Firenze, Italy*; [3]*University of Padova, Unit of Rheumatology, Padova, Italy*

Background: Belimumab (BEL) is a monoclonal antibody approved for SLE treatment but few data are available about its use before or during pregnancy.

Objectives: Our study aims to describe pregnancies in SLE patients who have discontinued BEL before conception, at positive pregnancy test or during pregnancy.

Methods: Data from prospectively-followed pregnancies (2014-2020) in SLE patients treated with BEL in 3 Italian centers where retrospectively collected, focusing on maternal disease activity, obstetric and neonatal outcome. Continuous data are expressed as median [min-max].

Results: Thirteen SLE pregnancies were analyzed (median age at conception 32 [24-41] years; 77% spontaneous, 69% primigravidae). All patients had positive ANA and anti-dsDNA antibodies; 4 had anti-Ro antibodies (31%); 4 had anti-phospholipid antibodies (aPL; 1 single, 2 double and 1 triple positivity). Seven patients (54%) had a history of lupus nephritis (LN); 2 patients (15%) had a concomitant diagnosis of antiphospholipid syndrome (1 thrombotic-APS and 1 thrombotic+obstetric-APS).

Ten (77%) pregnancies were planned and the use of BEL with regard to pregnancy was agreed with the patient during preconception counseling. At preconception visit, 8 patients were in remission while 5 had active disease (median SLEDAI 3 [0-8]).

BEL (11 intravenous, 2 subcutaneous) was stopped in 2 cases before conception, in 7 at positive pregnancy test and in 4 during pregnancy (2 at 11th week, 1 at 22nd, 1 at 24th); median duration of treatment at discontinuation was 29 [4-68] months. Other treatments during pregnancy were: oral prednisone in 12 cases (92%); intravenous methylprednisolone in 1 (8%); hydroxychloroquine in 10 (77%); chloroquine in 1 (8%); azathioprine in 5 (39%); calcineurin inhibitors in 5 (39%); low-dose acetylsalicylic acid in 10 (77%); low molecular weight heparin in 9 (69%).

Three flares occurred during the 3rd trimester in patients who stopped BEL at positive pregnancy test.

Live-births occurred in 92% of the pregnancies. A patient with thrombotic+obstetric-APS and LN, underwent assisted reproductive technology (embryo donation) and developed eclampsia (25thweek), an urgent cesarean section was performed and the newborn died after 3 days. One pre-eclampsia occurred in a patient with history of LN, double aPL positivity and active disease. One miscarriage at 11th week occurred; no early miscarriages (<10th week) were recorded. Pregnancy complications and outcomes are reported in Table 1.

No malformations were recorded. Two newborns were transferred to the Intensive Care Unit (1 for milk protein intolerance and 1 for desaturation).

Table 1. Pregnancy complications and outcomes according to the timing of discontinuation of BEL.

	BEL STOPPED PRECONCEPTIONALLY (2)	BEL STOPPED AT POS PREGNANCY TEST (7)	BEL STOPPED DURING PREGNANCY (4)
Pre-eclampsia	0/2	0/7	1/4 (25%)
Eclampsia	0/2	0/7	1/4* (25%)
Gestational Diabetes	0/2	1/7 (14%)	0/4
IUGR	0/2	1/7 (14%)	1/4* (25%)
pPROM/PROM	0/2	0/7	1/4 (25%)
Live birth	***1/2 (50%)***	***7/7 (100%)***	***4/4 (100%)***
Severe pre-term birth (≤ 34thweek)	0/2	0/7	1/4* (25%)
Late pre-term birth (35th- 37thweek)	0/2	3/7 (43%)	0/4
Small for Gestational age neonate	0/2	4/7 (54%)	1/4 (25%)
Late miscarriage (>10thweek)	***1/2 (50%)***	0/7	0/4
Perinatal death	0/2	0/7	***1/4* (25%)***

IUGR: IntraUterine Growth Restriction; PROM: Premature Rupture of Membrane; pPROM: pretermPROM;*in the same patient (history of thrombotic and obstetric-APS and lupus nephritis) who underwent Assisted Reproductive Technologies (embryo donation).

Eight newborns received vaccinations according to national schedule (missing data for 3). Five newborns were breastfed, 1 received formula milk and 5 mixed-feeding. BEL was resumed in 7/13 patients after pregnancy (in 4 cases for flare), after a median period of 5 [4-22] months.

Conclusion: While more data are needed, this small series suggests that BEL might be a therapeutic option for SLE patients during pregnancy planning, similarly to other biological drugs used in chronic forms of arthritis.

POS0703 CARDIAC ADVERSE EFFECTS OF LONG-TERM USE OF HYDROXYCHLOROQUINE IN SYSTEMIC LUPUS ERYTHEMATOSUS. SINGLE UNIVERSITY CENTER STUDY OF 109 PATIENTS

A. Herrero-Morant[1], A. Margarida-de Castro[1], R. Pérez-Barquín[1], J. Zubiaur-Zamacola[1], M. Á. González-Gay[1], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology and Cardiology, Santander, Spain*

Background: Hydroxychloroquine (HCQ) is a widely used drug especially in connective tissue disorders such as Systemic Lupus Erythematosus (SLE). Cardiac adverse effects of long-term use of HCQ remains controversial.

Objectives: To assess cardiac adverse effects of long-term use of HCQ in SLE.

Methods: Observational single center study of 109 patients with SLE treated with HCQ for more than 3 months. The main outcomes were cardiac structural and conduction disorders in a 12-lead electrocardiogram and/or echocardiogram at baseline and during HCQ treatment.

Results: We studied 109 patients (95 women/14 men; mean age 66.9±14.7 years). Main cardiovascular history was hypertension (n=61, 56.0%), diabetes mellitus (n=16, 14.7%) and renal impairment (n=11, 10.1%). HCQ was used for 11.7±8.9 years. Initial median SLE Disease Activity Index 2000 (SLEDAI-2K) was 7 [3.75-11]. At baseline, 27 (24.8%) patients had conduction disorders and 15 (13.7%) had structural abnormalities: Most prevalent cardiac alterations were Left Anterior Fascicular Block (LAFB) (n=9, 8.3%), left ventricular hypertrophy (n=9, 8.3%) and right bundle branch block (n=8, 7.3%). After 11.7±8.9 years of follow-up (mean HCQ cumulative dose: 1042.2±267.5 g; median SLEDAI-2K 1 [0-4]), there was a significant increase in conductions disorders (n=41, 37.6%, p=0.011) and in LAFB (n=16, 14.7%, p=0.021). There was no statistically significant increase in structural abnormalities (n=21, 19.7%, p=0.629).

Table 1. Main cardiac abnormalities at baseline and after follow-up.

	Baseline	After follow-up	*p*
Conduction disorders, n (%)	27 (24.8)	41 (37.6)	0.011
Left anterior fascicular block	9 (8.3)	16 (14.7)	0.021
Right bundle branch block	7 (6.4)	8 (7.3)	1.0
Atrioventricular block	4 (3.6)	11 (10.1)	0.092
Incomplete right bundle branch block	4 (3.6)	5 (4.6)	1.0
Short PR interval	2 (1.8)	4 (3.7)	0.5
Prolonged QT corrected interval	2 (1.8)	4 (3.7)	0.625
Left bundle branch block	1 (0.9)	5 (4.6)	0.125
Atrial Fibrillation	1 (0.9)	5 (4.6)	0.219
Structural abnormalities, n (%)	15 (13.7)	21 (19.7)	0.629
Ventricular hypertrophy	9 (8.3)	9 (8.3)	1.0
Atrial enlargement	6 (5.5)	13 (11.9)	0.096

Main cardiac abnormalities at baseline and after 11.7±8.9 years of follow-up are summarized in Table 1. Time of occurrence of cardiac adverse effect in relation to HCQ cumulative dose is shown in Figure 1.

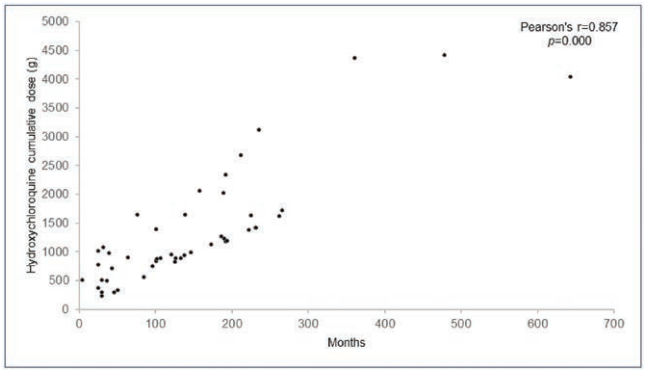

Figure 1. Time of occurrence of cardiac adverse effect in relation to hydroxychloroquine cumulative dose.

Conclusion: Conduction disorders were more prevalent than structural abnormalities. Patients with SLE treated with HCQ had a significant increase in LAFB. Use of electrocardiogram and/or echocardiogram may be helpful in monitoring cardiac adverse effects.

POS0704 LONG-TERM CLINICAL OUTCOMES OF PATIENTS WITH LUPUS NEPHRITIS TREATED WITH AN INTENSIFIED B-CELL DEPLETION PROTOCOL: A PROSPECTIVE STUDY

D. Roccatello[1], S. Sciascia[1], C. Naretto[1], M. Alpa[1], R. Fenoglio[1], M. Ferro[1], G. Quattrocchio[1], E. Rubini[1], E. Rahbari[1], D. Rossi[1]. [1]*University of Torino, Department of Clinical and Biological Sciences, Turin, Italy*

Background: B cells play a key role In the pathogenesis of Lupus Nephritis (LN).

Objectives: we aim to investigate the safety and efficacy of an intensified B-cell depletion induction therapy (IBCDT)without immunosuppressive maintenance regimen compared to standard of care in biopsy-proven LN.

Methods: Thirty patients were administered an IBCDT (4 weekly Rituximab 375mg/m2 and 2more doses after 1&2 months;2 infusions of 10 mg/kg cyclophosphamide (CYC),3 methylprednisolone pulses), followed by oral prednisone (tapered to 5 mg/day by the 3rd month). No immunosuppressive maintenance therapy was given. Thirty patients matched for LN class and age were selected as controls: 20 received 3 methylprednisolone pulses days followed by oral prednisone and mycophenolate mofetil (MMF) 2-3 g/day, while 10 were given the Euro Lupus CYC.

Results: At 12 months, complete renal remission was observed in 93% of patients on IBCDT, in 62.7% on MMF, and in 75% on CYC (p=0,03); the dose of oral prednisone was lower in the IBCDT group (mean±SD 2.9±5.0mg/dl) than MMF (10.5±8.0 mg/day,p<0.01) or CYC group (7.5±9.0mg/day,p<0.01). Mean follow-up after treatment was 44.5 months (IQR 36–120months), 48.6 months (IQR36–120months), and 45.3 (IQR36–120months) for IBCDT, MMF and CYC, respectively. At their last follow-up visit, we observed no significant differences in proteinuria and serum creatinine, nor in the frequency of new flares among the three groups.

Conclusion: In biopsy proven LN, the IBCDT without further immunosuppressive maintenance therapy was shown to be as effective as conventional regimen of MMF or CYC followed by a 3-year maintenance MMF regimen. Moreover, the use of IBCDT was associated with a marked reduction of glucocorticoid cumulative dose.

Background: BILAG-2004 Index (BILAG-2004) has undergone construct and criterion validity and is used to assess disease activity in SLE. However, its predictive validity has yet to be established.

Objectives: This study was to determine if disease activity according to BILAG-2004 was predictive of development of damage in an inception cohort.

Methods: This was a prospective multi-centre longitudinal study in the UK of an inception cohort of SLE patients (recruited within 12 months of achieving 1997 ACR revised criteria for SLE). Data were collected on disease activity (BILAG-2004 and BILAG2004-Pregnancy Index during pregnancy), SLICC/ACR DI (SDI), cumulative drug exposure and death at every visit. Information on cardiovascular risk factors (hypertension, diabetes mellitus, hypercholesterolaemia and smoking status) and antiphospholipid syndrome status were also collected. This study ran from 1st January 2005 to 31st December 2017. Longitudinal analysis using Poisson regression with random effects model was used to determine predictors of development of new damage. Death was not included in the analysis due to small numbers.

Results: 273 patients were recruited (91.2% female, 59.3% Caucasian, 17.2% African/Caribbean, 17.2% South Asian) with mean age at recruitment of 38.5 years (SD 14.8). 97.8% had no damage at recruitment (2.2% had SDI score of 1). Median follow-up was 73.4 months (range: 1.8, 153.8) with total follow-up of 1767 patient-years. Prevalence of risk factors during follow-up were: hypertension 23.1%, hypercholesterolaemia 35.5%, diabetes mellitus 5.5%, smoker or ex-smoker 44% and antiphospholipid syndrome 7%. There were 13 deaths and 114 new damage items occurred during follow-up.

There were 6674 assessments with disease activity score: 293 assessments with Grade A activity in 95 patients (92.4% had only 1 system with grade A, range: 1 - 4) and 1704 assessments with Grade A or B activity in 239 patients (78.7% had only 1 system with Grade A or B, range: 1 - 5).

Univariate analysis showed that gender, cardiovascular risk factors, antiphospholipid syndrome and most drug exposure (except hydroxychloroquine, glucocorticoids, mycophenolate and cyclophosphamide) were not associated with new damage (they were not included in the multivariate analysis).

Table 1 summarises multivariate analysis. Similar results were obtained when the disease activity variable was changed to Number of Systems with Grade A per assessment (RR 2.04 with 95% CI: 1.05, 3.94). Analysis using BILAG-2004 systems tally showed that persistent minimal disease was protective of development of damage (RR 0.74 with 95% CI: 0.57, 0.95). Cumulative drug exposure since recruitment for mycophenolate was protective against new damage (RR 0.99 with 95% CI 0.99, 0.99) but not cumulative drug exposure since last visit.

Variable	Risk Ratio (95% CI) for New Damage
Ethnicity	
Afro-Caribbean	1.21 (0.68, 2.17)
South Asian	1.81 (0.97, 3.36)
Others	2.37 (0.68, 8.20)
Age at diagnosis	**1.06 (1.04, 1.08)**
Prior SDI score	0.69 (0.44, 1.08)
Constitutional A or B	unreliable estimate due to low numbers
Mucocutaneous A or B	**1.80 (1.04, 3.14)**
Neuropsychiatric A or B	**4.68 (1.68, 13.05)**
Musculoskeletal A or B	0.76 (0.33, 1.73)
Cardiorespiratory A or B	0.35 (0.05, 2.59)
GIT A or B	unreliable estimate due to low numbers
Ophthalmic A or B	unreliable estimate due to low numbers
Renal A or B	2.08 (0.99, 4.40)
Haematological A or B	**4.37 (1.15, 16.65)**
Hydroxychloroquine since last visit (per g)	**0.99 (0.98, 0.99)**
Prednisolone since last visit (per 100mg)	**1.01 (1.00, 1.02)**
Cyclophosphamide since last visit (per g)	1.42 (0.94, 2.14)

Conclusion: Active disease (Grade A or B) according to BILAG-2004 index is predictive of development of new damage in SLE patients.

POS0706 PERFORMANCES OF DIFFERENT CLASSIFICATION CRITERIA FOR SYSTEMIC LUPUS ERYTHEMATOSUS IN A SINGLE CENTER COHORT FROM TURKEY

E. S. Torun[1], E. Bektaş[2], F. Kemik[2], M. Bektaş[1], C. Cetin[1], Y. Yalçınkaya[1], B. Artim-Esen[1], A. Gül[1], M. Inanc[1]. [1]*Istanbul University Istanbul Medical Faculty, Departmemt of Rheumatology, Istanbul, Turkey*; [2]*Istanbul University Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey*

Background: Recently developed EULAR/ACR classification criteria for systemic lupus erythematosus (SLE) have important differences compared to the 2012 Systemic Lupus International Collaborating Clinics (SLICC) SLE classification criteria and the revised 1997 American College of Rheumatology (ACR) criteria: The obligatory entry criterion of antinuclear antibody (ANA) positivity is introduced and a "weighted" approach is used[1]. Sensitivity and specificity of these three criteria have been debated and may vary in different populations and clinical settings.

Objectives: We aim to compare the performances of three criteria sets/rules in a large cohort of patients and relevant diseased controls from a reference center with dedicated clinics for SLE and other autoimmune/inflammatory connective tissue diseases from Turkey.

Methods: We reviewed the medical records of SLE patients and diseased controls for clinical and laboratory features relevant to all sets of criteria. Criteria sets/rules were analysed based on sensitivity, positive predictive value, specificity and negative predictive value, using clinical diagnosis with at least 6 months of follow-up as the gold standard. A subgroup analysis was performed in ANA positive patients for both SLE patients and diseased controls. SLE patients that did not fulfil 2012 SLICC criteria and 2019 EULAR/ACR criteria and diseased controls that fulfilled these criteria were evaluated.

Results: A total of 392 SLE patients and 294 non-SLE diseased controls (48 undifferentiated connective tissue disease, 51 Sjögren's syndrome, 43 idiopathic inflammatory myopathy, 50 systemic sclerosis, 52 primary antiphospholipid syndrome, 15 rheumatoid arthritis, 15 psoriatic arthritis and 20 ANCA associated

vasculitis) were included into the study. Hundred and fourteen patients (16.6%) were ANA negative.
Sensitivity was more than 90% for 2012 SLICC criteria and 2019 EULAR/ACR criteria and positive predictive value was more than 90% for all three criteria (Table 1). Specificity was the highest for 1997 ACR criteria. Negative predictive value was 76.9% for ACR criteria, 88.4% for SLICC criteria and 91.7% for EULAR/ACR criteria.
In only ANA positive patients, sensitivity was 79.6% for 1997 ACR criteria, 92.2% for 2012 SLICC criteria and 96.1% for 2019 EULAR/ACR criteria. Specificity was 92.6% for ACR criteria, 87.8% for SLICC criteria 85.2% for EULAR/ACR criteria.
Eleven clinically diagnosed SLE patients had insufficient number of items for both 2012 SLICC and 2019 EULAR/ACR criteria. Both criteria were fulfilled by 16 diseased controls: 9 with Sjögren's syndrome, 5 with antiphospholipid syndrome, one with dermatomyositis and one with systemic sclerosis.

Table 1. Sensitivity, positive predictive value, specificity and negative predictive value of 1997 ACR, 2012 SLICC and 2019 EULAR/ACR classification criteria

	SLE (+)	SLE (-)	Sensitivity (%)	Positive Predictive Value (%)	Specificity (%)	Negative Predictive Value (%)
1997 ACR	(+) **308**	15	78.6	95.4	94.9	76.9
	(-) 84	**279**				
2012 SLICC	(+) **357**	26	91.1	93.2	91.2	88.4
	(-) 35	**268**				
2019 EULAR/ ACR	(+) **368**	28	93.8	92.9	90.5	91.7
	(-) 24	**266**				

Conclusion: In this cohort, although all three criteria have sufficient specificity, sensitivity and negative predictive value of 1997 ACR criteria are the lowest. Overall, 2019 EULAR/ACR and 2012 SLICC criteria have a comparable performance, but if only ANA positive cases and controls are analysed, the specificity of both criteria decrease to less than 90%. Some SLE patients with a clinical diagnosis lacked sufficient number of criteria. Mostly, patients with Sjögren's syndrome or antiphospholipid syndrome are prone to misclassification by both recent criteria.

POS0707 SALIVARY GLAND ULTRASONOGRAPHY AND THE CLINICAL FEATURES USING ESSDAI IN PATIENTS OF EARLY-ONSET VERSUS LATE-ONSET WITH PRIMARY SJÖGREN'S SYNDROME

N. Hashimoto[1], S. Uchiyama[2], T. Nakazawa[3], T. Iwasaki[4], T. Hashimoto[1]. *[1]Hashimoto Rheumatology Clinic, Rheumatology, Osaka, Japan*; *[2]Kansai Medical University,Temmabashi General Clinic, Osaka, Japan*; *[3]Osaka Saiseikai Nakatsu Hospital, Department of Rheumatology, Osaka, Japan*; *[4]Keiseikai Medical Corporation, Department of Internal Medicine, Higashiosaka, Japan*

Background: Primary Sjögren's syndrome (pSS) is a chronic inflammatory autoimmune disease characterized by lymphocyte infiltration in salivary and lacrimal glands. pSS affects primarily middle-aged and elderly patients, although younger age groups may also be involved. However, differences of etiology and pathogenesis between early-onset pSS (EOpSS) and late-onset pSS (LOpSS) are unknown. Recently, standardized outcome tools for measuring disease-specific activity and patients' reported symptoms have been formulated by the European League Against Rheumatism (EULAR) SS study group: the EULAR SS Disease Activity Index (ESSDAI) for systemic features of pSS [1]. Also, as the new imaging techniques, salivary gland ultrasonography (SGUS) proved valuable for assessing salivary gland involvement in SS and seemed to exhibit good diagnostic properties. In addition, previous studies have demonstrated usefulness of SGUS for the prognostic stratification of patients with pSS [2], [3], [4].
Objectives: The aim of this study was to examine the differences of etiology and pathogenesis between EOpSS and LOpSS using ESSDAI and SGUS.
Methods: Fifty-six pSS patients who fulfilled the American College of Rheumatology (ACR) / European League Against Rheumatism (EULAR) classification criteria for SS were studied. Based on the disease onset age, all pSS patients were divided into two groups as those with the onset age of 40 years old or younger (EOpSS: n=26) and those with the onset age of older than 65 years old (LOpSS: n=30). The clinical findings were evaluated ESSDAI and OMERACT SGUS score at the first visit to our hospital. The ESSDAI (0–123) proposes the evaluation of 12 domains or organ systems (constitutional, lymphadenopathy, glandular, articular, cutaneous, pulmonary, renal, peripheral nervous system, central nervous system, muscular, hematological and biology). All patients were examined SGUS by a single investigator who was blinded to device (TUS-A300; Canon Medical Systems, Tokyo, Japan) with a linear transducer (7.5-10MHz). The OMERACT SGUS score was used for graded changes in the parenchymal homogeneity of salivary glands: grade 0, normal-appearing salivary gland parenchyma; grade 1, minimal change: mild inhomogeneity without hypo/anechoic areas; grade 2, moderate change: moderate inhomogeneity with focal hypo/anechoic areas; grade 3, severe change: diffuse inhomogeneity with hypo/anechoic areas occupying the entire gland surface [5].
Results: The proportions of positive sera of RF, anti-SS-A and anti-SS-B antibodies were not different in the two groups, but the disease activities were higher in the EOpSS than in the LOpSS patients by measuring ESSDAI (7.30 vs 4.23, p=0.008), especially in constitutional domain (1.50 vs 0.60, p=0.03), articular domain (1.54 vs 0.40, p=0.0002) and biological domain (1.35 vs 0.90, p=0.04). No difference in salivary secretion was found between two groups (EOpSS: 8.02 vs LOpSS: 6.31 mL/10min.), but the OMERACT SGUS score was higher in LOpSS than in EOpSS patients (2.00 vs 2.70, p=0.0002).
Conclusion: Although serological findings were not different, EOpSS patients had higher disease activity but less severe salivary gland degeneration than that in LOpSS patients, suggesting the pathogenesis of these two groups was different.

POS0708 PSYCHIATRIC DISORDERS IN PATIENTS WITH DIFFERENT PHENOTYPES OF NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS (NPSLE)

R. Monahan[1], A. Blonk[2], H. Middelkoop[3], M. Kloppenburg[1,4], T. Huizinga[1], N. Van der Wee[2], G. M. Steup-Beekman[1]. *[1]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*; *[2]Leiden University Medical Center, Department of Psychiatry, Leiden, Netherlands*; *[3]Leiden University Medical Center, Department of Neurology, Leiden, Netherlands*; *[4]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, Netherlands*

Background: Patients with systemic lupus erythematosus (SLE) may present with psychiatric disorders. These are important to recognize, as they influence quality of life and treatment outcomes and strategies.
Objectives: We aimed to study the frequency of psychiatric morbidity as classified by the Diagnostic and Statistical Manual of Mental Disorders (DSM-V) in patients with SLE and neuropsychiatric symptoms of different origins.
Methods: In the neuropsychiatric SLE (NPSLE) clinic of the Leiden University Medical Center, patients undergo a standardized multidisciplinary assessment by a neurologist, neuropsychologist, vascular internal medicine, rheumatologist, physician assistant and psychiatrist. After two weeks, a multidisciplinary consensus meeting takes place, in which the symptoms are attributed to SLE requiring treatment (major NPSLE) or to minor involvement of SLE or other causes (minor/non-NPSLE). Consecutive patients visiting the NPSLE clinic between 2007-2019 were included. Data of psychiatric evaluation and current medication use were extracted from medical records. The presence of cognitive dysfunction was established during formal neuropsychological assessment.
Results: 371 consecutive SLE patients were included, of which 110 patients had major NPSLE (30%). Mean age was 44 ± 14 years and 87% was female.
The most frequently diagnosed psychiatric disorders in the total group were cognitive dysfunction (42%) and depression (23%), as shown in Table 1. Furthermore, anxiety was present in 5% and psychotic disorders in 4% of patients. In patients with minor/non-NPSLE, especially depression (26% vs 15%) and anxiety (6% vs 2%) were more common than in major NPSLE. Cognitive dysfunction (54% vs 36%) and psychotic disorders (6% vs 4%) were more common in patients with major NPSLE than minor/non-NPSLE.
Psychiatric medication was used in 33% of patients, of which antidepressants and benzodiazepines the most frequently (both: 18% in both subgroups). Antipsychotics were more often used in patients with NPSLE (10% vs 7%) and benzodiazepines more often in minor/non-NPSLE (20% vs 14%).
In addition, 17 patients (5%) had a history of suicide attempt, which was more common in patients with minor/non-NPSLE than major NPSLE (6% vs 2%).
Conclusion: Psychiatric morbidity, especially cognitive dysfunction and depression, are common in patients with lupus and differ between underlying cause of the neuropsychiatric symptoms (minor/non-NPSLE vs major NPSLE).

POS0709 LUPUS FOG IS NOT DISSOCIATIVE FOG

R. Monahan[1], A. Blonk[2], H. Middelkoop[3], M. Kloppenburg[1,4], T. Huizinga[1], N. Van der Wee[2], G. M. Steup-Beekman[1]. [1]*Leiden University Medical Center (LUMC), Department of Rheumatology, Leiden, Netherlands*; [2]*Leiden University Medical Center, Department of Psychiatry, Leiden, Netherlands*; [3]*Leiden University Medical Center, Department of Neurology, Leiden, Netherlands*; [4]*Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, Netherlands*

Background: The presence of a 'fog' is frequently reported by patients with systemic lupus erythematosus (SLE). However, little is known about this lupus fog: it is thought to be a result of cognitive dysfunction, but fogs can also be the result of dissociation. The Dissociative Experience Scale-II (DES) is a standardized tool to study dissociation. In the general adult population, scores range from 4.4-14.[1-3]
Objectives: We aimed to study the prevalence of dissociative symptoms including dissociative fog in patients with SLE and neuropsychiatric symptoms.
Methods: Patients visiting the tertiary referral center for neuropsychiatric systemic lupus erythematosus (NPSLE) of the LUMC between 2007-2019 were included. All patients underwent a standardized multidisciplinary assessment. Patients were classified as NPSLE if neuropsychiatric symptoms were attributed to SLE and immunosuppressive or anticoagulant therapy was initiated, otherwise patients were classified as minor/non-NPSLE. Dissociation was studied using the DES. The DES separates different types of dissociative symptoms: amnesia, absorption/imagination and derealization/depersonalization. It also contains one question regarding evaluating the presence of a dissociative fog: *"Some people sometimes feel as if they are looking at the world through a fog, so that people and objects appear far away or unclear".* All statements (n = 28) regarding dissociative symptoms are rated from 'none of the time' to 'all of the time' (0-100%); scores >25 are considered abnormal. A multiple regression analysis (MRA) were performed to compare dissociation in patients with and without NPSLE. DES results are presented as median (range) and MRA as odds ratio (OR) and 95% confidence interval (CI).
Results: DES questionnaires were available for 337 patients, of which 97 had the diagnosis NPSLE (29%). Mean age in patients with NPSLE was 41 ± 13 years and 84% was female. In minor/non-NPSLE, median age was 44 ± 14 years and 87% was female.
Median dissociation was 7 (0-75) and did not differ between patients with minor/non-NPSLE and NPSLE (OR: 1.0 (95% CI: -0.9; 1.1)). The most common type of dissociation was absorption/imagination (median: 12, range 0-75) and depersonalization/derealization was infrequent (median: 1, range 0-84). 43 patients (13%) had an abnormal score (>25) on the dissociative fog question.
Conclusion: Dissociative symptoms are within normal range in patients with SLE and neuropsychiatric symptoms, regardless of underlying etiology. Dissociative fog seems uncommon and therefore lupus fog is most likely not the result of dissociation.

POS0710 ANALYSIS OF 5-YEAR HOSPITALIZATION DATA OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: DAMAGE IS A RISK FACTOR FOR FREQUENT AND LONGER STAYS

C. Cetin[1], M. G. Can[2], S. Oztaskin[2], Y. Yalçınkaya[1], A. Gül[1], M. Inanc[1], B. Artim-Esen[1]. [1]*Istanbul Faculty of Medicine, Rheumatology, İstanbul, Turkey*; [2]*Istanbul Faculty of Medicine, Internal Medicine, İstanbul, Turkey*

Background: The rates of hospitalization in patients with SLE is around 10% per year.[1]
Objectives: In this study, we aimed to examine the hospitalization data of patients with SLE in the last 5 years at our center and determine the factors that affect hospitalization.
Methods: Hospitalization data of patients with SLE (2012 SLICC classification) admitted to our rheumatology ward between January 2015 and 2020 were analyzed. Cumulative clinical and laboratory findings were retrieved from the existing SLE database and revised. SLICC SLE damage index (SDI), and the disease activity at admission were determined (SLEDAI-2K).
Results: Eighty-six % (n=138) of 161 hospitalized patients were female. The mean age of the patients was 38 ± 13 years whilst mean duration of disease was 97.3 ±96.9 months. Thirty-eight% of the patients were hospitalized more than once and the mean number of hospitalizations was 1.8±1.5 The mean hospitalization duration covering all stays for each patient was 25±27 days. Active disease followed by infection and damage-related complications ranked the first three among all causes of hospitalization.
Compared to patients hospitalized for active disease or other reasons, patients hospitalized for infection had a significantly higher number of readmissions (**p<0.05)** and their total duration of hospitalization was longer **(p<0.01**). Duration of disease was significantly shorter in patients hospitalized for active disease compared to patients hospitalized for infection and damage related causes (p<0.05).
The frequency of patients with damage and the mean SDI score was significantly lower in the group with active disease (68% and 1.9 ± 2) compared to patients hospitalized for infection (90% and 2.7±1.6) and other causes (96% and 3±1.7) (p<0.05 for both). Distribution of damage according to organ/systems is presented in Graph 1. Highest frequency of damage was detected in the cardiovascular (30%), followed by neuropsychiatric (26.7%), renal (23%), pulmonary (23%) and musculoskeletal (20.5%) domains. A positive correlation was found between the mean SDI score and duration of hospitalization (r=0.551, **p<0.001**) as well as the number of hospitalizations (r=0.393, **p<0.001**). Regarding disease activity at the time of admission, the mean score of patients hospitalized for active disease was 11.0 ± 6.1 whilst was 3.2 ± 2.8 in patients hospitalized for infection and 2.9 ± 3.3 in patients hospitalized for other reasons (**p<0.001**). Renal active disease was the most common (44%), followed by hematological (34.8%), articular (21.7%) and mucocutaneous (21%) activity. Ten% of the patients all of whom had damage were admitted to intensive care unit (ICU). **Total hospitalization duration** (p=0.012), **mean SDI** (p=0.008), **antiphospholipid syndrome** (p=0.033), **lupus anticoagulant** (p=0.010), **thrombocytopenia** (p=0.015),

serositis (p=0.034), **pulmonary hypertension** (p=0.021), history of **alveolar haemorrhage** (p<0.001) and **cardiac valve involvement** (p=0.002) were associated with ICU hospitalization.

Conclusion: Disease activity, infections and damage are the leading causes of hospitalization in patients with SLE. Damage increases the frequency of hospitalizations, prolongs the duration of stay, and increases the need for follow-up in the ICU. Tight control of disease activity with rational use of immunosuppressive treatment is important to reduce damage and hospitalizations.

POS0711 SUICIDAL BEHAVIOUR IN SLE PATIENTS: A SYSTEMATIC LITERATURE REVIEW

A. Kyriakou[1], A. Chatzittofis[1], K. Parperis[1,2]. [1]*University of Cyprus, Medical School, Nicosia, Cyprus*; [2]*The University of Arizona College of Medicine - Phoenix, Rheumatology, Phoenix, United States of America*

Background: Previous studies have demonstrated that SLE patients have a higher risk of suicidal behaviour, including suicidal ideation, attempt and complete suicide (1,2). Data describing the SLE patients' clinical characteristics and risk factors of suicidal behaviour are lacking.

Objectives: To determine the magnitude of suicidal behaviour among SLE patients and to examine predictors associated with suicidal behaviour.

Methods: According to the PRISMA guidelines, we conducted a systematic literature review of the online databases, PubMed/Medline, EMBASE, and Web of Science, from inception to December 2020 (Figure 1). Full-text original articles that examined the relationship between SLE patients with suicidal behaviour were eligible for our review. Two reviewers independently review articles to assess eligibility using the Newcastle-Ottawa Scale and the Joanna Briggs Institute tools. Systematic reviews, metanalysis, narrative review, case reports, case series, including less than 10 patients and conference abstracts, were excluded.

Results: Of the 64 articles identified, 22 were relevant to the study question; cross-sectional (n=8) and prospective cohorts (n=6) were the most frequently retrieved studies. Among the 27106 SLE patients with SLE, 802 had suicidal behaviour (2.9%), and of those, 87.9% were female. Suicide attempt occurred in 573/802 (71.4%) and complete suicide in 18/802 (2,3%). Major depressive disorder (MDD) was the most frequently reported coexisting psychiatric condition associated with suicidal behavior, followed by psychosis and social phobia. Several clinical manifestations were linked to suicidal behaviour, particularly neuropsychiatric lupus, mucocutaneous, renal involvement and serositis. Further, high scores in disease activity and damage indices were associated with suicidal behaviour.

Conclusion: Suicidal behavior in SLE patients was associated with MDD, NPSLE, active disease and damage. Awareness of these findings can guide clinicians to recognize suicide behavior promptly and prevent suicide attempts.

POS0712 "EXTRA"- CRITERIA ANTIPHOSPHOLIPID ANTIBODIES IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME AND SYSTEMIC LUPUS ERYTHEMATOSUS (PRELIMINARY DATA)

F. Cheldieva[1,2], T. Reshetnyak[1,2], M. Cherkasova[1], N. Seredavkina[1], A. Lila[1,2]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Vascular Rheumatology, Moscow, Russian Federation*; [2]*Russian Medical Academy of Continuing Professional Education, Ministry of Health of Russia, Department of Rheumatology, Moscow, Russian Federation*

Background: The study of antiphospholipid antibodies (aPL), not included in the Sydney diagnostic criteria, in antiphospholipid syndrome (APS) and systemic lupus erythematosus (SLE) is poorly understood.

Objectives: To determine the frequency of detection of IgA-aCL and IgA-aβ2GP1 and IgG antibodies to β2GP1 domain 1 (IgG-aβ2GP1-D1) in patients with APS with and without SLE.

Methods: ELISA and chemiluminescence assays (CMA) were used to test 63 sera of patients: 22 (35%) with primary APS (pAPS) and 41 (65%) patients with APS and with SLE (secondary APS (sAPS)), with mean age 38,0 [33,0 – 43,0] years and disease duration 4,0 [0,1 – 9,9]. Both methods were used to test of IgG/IgM-aCL and IgG/IgM-aβ2GP1. CMA was used for research IgG/IgM/IgA-aCL, IgG/IgM/IgA-aβ2GPI and IgG-aβ2GP1-D1. Of them 49 (78%) (18 – with pAPS; 31 – with sAPS) displayed major thrombotic events and 18 of 22 pregnant women had pregnancy morbidity in past history. Lupus anticoagulant (LA) positivity was in 9 out of 12 patients who had it determined. LA was not investigated due to anticoagulant therapy in the remaining 52 patients.

Results: IgG/IgM-aCL and IgG/IgM-aß2GP1 were recorded in 44/18 and 50/17 patients by ELISA and in 55/19 and 59/16 by CMA, respectively.

IgA-aCL positivity was found in 35 (56%) of 63 patients. Thirty IgA-positive patients were positive for IgG-aCL by ELISA: 22 – IgG-aCL – highly positive, 6 – medium positive and 2 – low positive patients. IgM-aCL by ELISA was detected in 13 (37%) of 35 IgA-aCL positive patients: 11 – highly positive, 1 – medium positive and 1 – low positive. IgA-aCL was combined with IgG-aCL in 34 patients and with IgM-aCL in 16 patients in the CMA. IgG-aß2GP1 in ELISA was detected in 32 patients with IgA-aCL (24 –highly positive, 5 – medium positive and 3 – low

positive) and in 34 – in CMA. IgM-aß2GP1 was combined with IgA-aß2GP1 with the same frequency in both methods (in 13 patients).
IgA-aß2GP1 was detected in 30 (48%) of 63 patients. They were combined with both IgG-aCL and IgG-aß2GP1 in all cases in both methods. IgM-aCL and IgM-aß2GP1 were detected in 14 and 11 of 30 patients with IgA-aß2GP1, respectively. The combination of IgA-aß2GP1 with IgG-aCL by ELISA was in 27 (in most cases highly positive – 20) and with IgM-aCL – in 10 (highly positive - 8). IgG-aß2GP1 was detected in 28 patients with IgA-aß2GP1 (high positive – 21) and in 11 patients with IgM-aß2GP1 (high positive –7).
IgG-aß2GP1-D1 was revealed in 48 (76%) patients. It was combined with IgG-aCL – in 38, with IgM-aCL – in 15 patients by the ELISA. The combination of IgG-aß2GP1-D1 by CMA was as follows: with IgG-aCL – in 46, with IgM-aCL – in 17, and with IgA-aCL – in 33 patients. In most cases, IgG-aß2gp1-D1 was combined with highly positive aCL levels. IgG-aß2GP1-D1 positivity was associated with IgG-aß2GP1 positivity in 42 – by ELISA and 47 – by CMA, IgM-aβ2GP1 – in 13 and 14 patients by ELISA and CMA, respectively, and IgA-aß2GP1 – in 29. Isolated IgG-aß2GP1-D1 positivity was not observed.
Conclusion: The frequency of IgA-aCL detection was 56% (35 patients out of 63), IgA-aβ2GP1 – 48% (30 patients out of 63), IgG-aβ2GP1-D1 – 76% (48 patients out of 63). There was not isolated positivity of this "extra" criterial antibodies. The presence of IgA-aCL, IgA-aβ2GP1, IgG-aβ2GP1-D1 was associated with highly positivity of IgG/IgM-aCL and IgG/IgM- aβ2GP1.

POS0713 PREDICTORS OF HOSPITALIZATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A 10-YEAR COHORT STUDY OF 398 PATIENTS FROM A TERTIARY CENTRE

H. Assunção[1], M. Rodrigues[2], A. R. Prata3, J. A. P. Da Silva[1,4], L. Inês[1,5].
[1]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; *[2]Hospital Distrital de Leiria, Rheumatology, Leiria, Portugal*; *[1]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; *[4]University of Coimbra, Coimbra Institute for Clinical and Biomedical Research (iCBR), Faculty of Medicine, Coimbra, Portugal*; *[5]University of Beira Interior, School of Health Sciences, Covilhã, Portugal*

Background: Patients with systemic lupus erythematosus (SLE) often require hospitalization. The cause of admission may vary, but active disease and infection are consistently reported as the main reasons for hospitalization and are associated with worse survival and damage accrual. Recent improvements in the standard of care, including minimization of glucocorticoid dose and more effective and safe immunosuppressive regimens, may have changed the incidence and risk factors for hospitalization due to these causes. Hence, it is useful to identify predictors of hospitalization to further reduce the risk of admission for disease activity and severe infection in patients with SLE.
Objectives: To identify predictors of hospitalization in patients with SLE, according to the underlying cause.
Methods: Patients with SLE fulfilling classification criteria (ACR'97 and/or SLICC), regularly followed at an academic lupus clinic from January 2009 to December 2020 and with at least two outpatient visits were included in this cohort study. Time to first hospitalization up to 120 months was identified separately for the following admission causes: (a) any cause; (b) active SLE; (c) infection. Predictors of hospitalization were sought through survival analysis, with distinct models for each of the major admission causes. Univariate analysis was performed using Kaplan-Meier curves and Log-Rank tests. Tested variables assessed at baseline included: gender; age at SLE onset; age; disease duration; SLE Disease Activity Index (SLEDAI-2K) score; ongoing antimalarial use; ongoing immunosuppressants; ongoing prednisolone daily dose; lupus nephritis up to baseline; SLICC Damage Index (SDI) score. Variables with p<0.1 were further tested in multivariate Cox regression models. Hazard ratios (HR) were determined with 95% confidence intervals (95%CI).
Results: We included 398 patients (female: 86.2%, mean age: 41.2±15.1 years, mean disease duration: 10.1±9.2 years; previous lupus nephritis: 28.9%; mean SLEDAI-2K score: 3.4±2.7; ongoing antimalarials: 78.9%; ongoing immunosuppressant: 29.9%; ongoing prednisolone >7.5 mg/day: 17.1%; SDI score ≥1: 28.4%). During the follow-up period, 50.5%, 23.6% and 17.3% were hospitalized at least once for any cause, active SLE or infection, respectively.
In the multivariate model, significant baseline predictors for hospitalization due to active disease were (table 1): SLEDAI-2K score >5; disease duration ≤2 years; ongoing immunosuppressants; SDI score ≥1. Baseline independent predictors of hospitalization for infection included (table 1): male gender; SDI score ≥1; ongoing antimalarials were protective.

Table 1. Predictors of hospitalization in multivariate Cox regression according to the admission cause

Predictors	Hospitalization for active SLE	Hospitalization for infection
SLEDAI-2K score >5	2.43 (1.53-3.88)	n.s.
SLE duration ≤2 years	1.70 (1.04-2.77)	n.s.
Ongoing immunosuppressant	1.91 (1.24-2.95)	n.s.
SDI score ≥1	1.82 (1.16-2.86)	2.14 (1.33-3.45)
Male gender	n.s.	2.19 (1.23-3.89)
No antimalarial treatment	n.s.	2.20 (1.34-3.60)

Risk for each predictor reported as Hazard Ratio (95% Confidence Interval); n.s.: non-significant

Conclusion: Tight control of disease activity, prevention of damage accrual, and treatment with antimalarials may contribute to minimize the risk of hospitalization for these two major causes of admission in patients with SLE.

POS0714 WHITE MATTER HYPERINTENSITIES LEAD TO REDUCED PSYCHOMOTOR SPEED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND NEUROPSYCHIATRIC SYMPTOMS

R. Monahan[1], F. Inglese[2], H. Middelkoop[3], M. Van Buchem[2], T. Huizinga[1], M. Kloppenburg[1,4], I. Ronen[2], G. M. Steup-Beekman[1], J. De Bresser[2]. *[1]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*; *[2]Leiden University Medical Center, Department of Radiology, Leiden, Netherlands*; *[3]Leiden University Medical Center, Department of Neurology, Leiden, Netherlands*; *[4]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, Netherlands*

Background: Cognitive impairment is common in patients with systemic lupus erythematosus (SLE) and neuropsychiatric (NP) symptoms, but the exact underlying structural brain correlates are unknown.
Objectives: We aimed to compare cognitive function between groups of patients with different phenotypes of (NP)SLE and assessed the association between brain volumes, white matter hyperintensity (WMH) volume and cognitive function.
Methods: Patients who visited the NPSLE clinic of the Leiden University Medical Center between 2007-2015 were included in this study (n=151; 42 ± 13 years, 91% female). In a multidisciplinary consensus meeting, phenotypes were established and neuropsychiatric symptoms were attributed to SLE (NPSLE, inflammatory (n=24) or ischemic (n=12)) or to minor involvement of SLE or other causes (minor/non-NPSLE (n=115)). All patients underwent standardized cognitive assessment of the four cognitive domains: global cognitive functioning (GCF), learning and memory (LM), executive functioning and complex attention (EFCA) and psychomotor speed (PS)). Cognitive dysfunction was defined as a T-score <40, with age, sex, gender and education matched individuals of the Dutch population as reference. In addition, automated volume measurements on brain MRI (white matter, grey matter, white matter hyperintensities (WMH) and total brain volume (TBV)) were performed. Patients with brain infarcts >1.5 cm were excluded. Cognitive function (Z-score) was compared between different NPSLE phenotypes using multiple regression analyses corrected for age, sex and education. Associations between brain volumes, WMH and cognitive function were assessed per phenotype using multiple regression analyses corrected for age, sex and intracranial volume.
Results: Global cognitive functioning was impaired in 5%, learning & memory in 46%, and executive functioning & complex attention in 39% and psychomotor speed in 46% of all patients. Patients with inflammatory NPSLE showed the most cognitive impairment and reduced cognitive function compared to ischemic NPSLE (all domains) and minor/non-NPSLE (EFCA) (p <0.05).
Lower total brain volume and grey matter volume were associated with lower cognitive functioning in all domains (β: 0.00/0.01 (0.00; 0.01)) and lower white matter volume associated with lower LM, EFCA and PS (β: 0.00/0.01 (0.00; 0.01)) in all patients. Higher WMH volume associated with lower psychomotor speed (β: -0.14 (-0.32; -0.02)), especially in patients with inflammatory NPSLE (β: -0.36 (-0.60; -0.12).
Conclusion: Reduced brain volume leads to reduced cognitive function in multiple cognitive domains in all patients with SLE and neuropsychiatric symptoms. Increased WMH volume leads to reduced psychomotor speed, especially in patients with inflammatory NPSLE.

Table 1. Prevalence of cognitive impairment in patients with minor/non-NPSLE, inflammatory NPSLE and ischemic NPSLE

	Global cognitive functioning	Learning & memory	Executive functioning & complex attention	Psychomotor speed
All patients	8 (5)	70 (46)	57 (39)	69 (46)
(n = 151) Inflammatory NPSLE	3 (13)	14 (58)	12 (50)	12 (50)
(n = 24) Ischemic NPSLE	0 (0)	6 (50)	2 (17)	2 (17)
(n = 12) Minor/non-NPSLE	5 (4)	50 (44)	43 (38)	55 (49)
(n = 115)				

NPSLE = neuropsychiatric systemic lupus erythematosus.Data represent n (%) of patients with cognitive impairment in the mentioned cognitive domain. Cognitive impairment was defined as cognitive function at least 1SD lower than the mean of an age, sex and education matched general Dutch population. The percentages were calculated from total number of patients with available scores: Global functioning: 23/24 inflammatory NPSLE and 113/115 minor/non-NPSLE; psychomotor speed 113/115 minor/non-NPSLE, executive function & complex attention: also 113/115. All tests were available for ischemic NPSLE.

POS0715 QUANTIFYING THE PSYCHOSOCIAL IMPACT OF UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE (UCTD)

C. Siegel[1,2], E. Sevim[3,4], B. Stamm[5], J. Vega[5], J. Kleinman[6], J. Barnhill[7], M. Lockshin[2,5], L. Sammaritano[2,5], M. Barbhaiya[2,5]. *[1]Hospital for Special Surgery, Rheumatology, New York, United States of America*; *[2]Weill Cornell Medicine, Internal Medicine, New York, United States of America*; *[3]Montefiore Medical Center, Internal Medicine, Bronx, United States of America*; *[4]Albert Einstein College of Medicine, Internal Medicine, Bronx, United States of America*; *[5]Hospital for Special Surgery, Barbara Volcker Center for Women and Rheumatic Diseases, New York, United States of America*; *[6]Hospital for Special Surgery, Department of Social Work Programs, Division of Rheumatology, New York, United States of America*; *[7]Weill Cornell Medicine, Psychiatry, New York, United States of America*

Background: Only half of patients diagnosed with SLE fulfill classification criteria; the rest have "SLE-like" illnesses such as UCTD. SLE patients are known to experience impaired health-related quality of life (HRQoL) and significant anxiety, depression, and fatigue,[1] yet the psychosocial aspects of UCTD are less established. In a qualitative study, we found that most UCTD patients had engaged in psychotherapy and felt additional support was needed.[2]
Objectives: Using multiple validated instruments, this study aims to quantify the psychosocial impact of UCTD.
Methods: The Hospital for Special Surgery UCTD and Overlap Registry includes UCTD patients aged ≥ 18 years with ANA ≥ 1:80 and ≥ 1 sign or symptom of rheumatic disease who do not fulfill classification criteria for a defined CTD. We administered the 36-Item Short Form Health Survey (SF-36), General Anxiety Disorder-7 (GAD-7), Beck Depression Inventory (BDI), and Fatigue Severity Scale (FSS) to all patients to assess HRQoL, anxiety, depression, and fatigue. Instruments were scored based on established algorithms and results were summarized using predefined scales and severity thresholds.
Results: The composite questionnaire was administered to 85 UCTD patients and completed by 75 (97.3% female, 60% white, mean age ± SD 48.8 ± 13.6 years). The SF-36 Physical Component Summary mean score was 37.8 and Mental Component Summary mean score was 41.1. Across the 8 SF-36 subscales, mean scores were lowest for role limitations due to physical health (39.3) and vitality (39.7) and highest for physical functioning (67.2), role limitations due to emotional health (67.1), and mental health (67.1). Approximately half of UCTD patients reported anxiety (GAD-7 ≥ 6); 20% had moderate/severe anxiety (GAD-7 ≥ 10). The prevalence of depression (BDI ≥ 14) was 26.7%; 13.3% had moderate/severe depression (BDI ≥ 20). Fatigue (FSS ≥ 3) was reported by 82.8% of patients (median FSS score of 4.7) [Table 1].

Table 1. Psychosocial Survey Scores of Patients with Undifferentiated Connective Tissue Disease (n=75)

36-Item Short Form Health Survey (SF-36)	Physical Component Summary	38.2 (11.2)
	◦Physical functioning	67.2 (26.3)
	◦Role-Physical	39.3 (46.3)
*Range 1-100 – Mean (SD)**	◦Bodily Pain	49.5 (22.1)
	oGeneral Health	42.9 (21.5)
	Mental Component Summary	41.3 (10.7)
	◦Vitality	39.7 (21.7)
	◦Social Functioning	59.3 (25.9)
	◦Role-Emotional	67.1 (41.9)
	oMental Health	67.1 (18.3)
Generalized Anxiety Disorder-7 (GAD-7)	None [0-5]	38 (50.7)
	Mild [6-10]	22 (29.3)
	Moderate [11-15]	14 (18.7)
*Range 0-21 – N (%)***	Severe [16-21]	1 (1.3)
Beck Depression Inventory (BDI)	Minimal [0-13]	55 (73.3)
	Mild [14-19]	10 (13.3)
*Range 0-63 – N (%)***	Moderate [20-28]	7 (9.3)
	Severe [29-63]	3 (4.0)
Fatigue Severity Scale (FSS) *Range 1-7 – Median (IQR)***		4.7 (1.5)

*Higher number indicates better health state. **Higher number indicates greater severity.

Conclusion: UCTD patients have significantly impaired HRQoL and a high prevalence of anxiety, depression, and fatigue, suggesting substantial psychosocial impact of UCTD comparable to that reported in SLE.[3,4] Impaired HRQoL in UCTD is driven to similar degrees by aspects of physical and mental health. In future studies, we will compare age- and sex- matched UCTD to SLE patients and longitudinally evaluate psychosocial metrics alongside clinical trajectories.

POS0716 FACTORS ASSOCIATED WITH FERTILITY OUTCOMES IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A SYSTEMATIC REVIEW

S. Giambalvo[1], C. Garaffoni[1], E. Silvagni[1], F. Furini[2], M. Govoni[1], A. Bortoluzzi[1]. *[1]Unit of Rheumatology, Azienda Ospedaliera-Universitaria Sant'Anna, Department of Medical Sciences, University of Ferrara, Ferrara, Italy*; *[2]Unit of Rheumatology, Ospedale Maggiore, Bologna, Italy*

Background: Fertility is thought to be not reduced in women affected by systemic lupus erythematosus (SLE), however disease-related factors, psychosocial effects of chronic disease as well as medication exposure might impair gonadal function.
Objectives: The aim of this systematic review was to explore clinical, hormonal, serological, instrumental and management factors associated with fertility outcomes in women of childbearing age with SLE.
Methods: This systematic review was conducted following the Preferred Reporting Items for systematic reviews and Meta-analysis (PRISMA) statement. All articles available in English, published from 1972 to 15th August 2020 in Pubmed, EMBASE, Scopus and Cochrane Library. Study selection and data collection were performed by two independent reviewers. All data were extracted using a standardized template. Risk of bias of the included studies was assessed by using the NIH risk-of-bias tool [1].

Results: Of 788 abstracts, we included in the review 45 studies of which 1 systematic literature reviews, 16 cross-sectional studies, 15 cohort studies, 12 observational studies and 1 case-series study, with a total of 4656 patients. The mean age was 33.5 ± 5.4 years, while the mean disease duration was 97.4 ± 65.2 months. Figure 1 illustrates the quality of the included studies. Definitions of fertility/premature ovarian failure (POF) adopted in the studies varied in terms of the number of months of amenorrhea considered. Most studies did not use a hormonally based definition of fertility. Clinical factors associated with the development of POF were older age at the time initiation of therapy and older age at the onset of SLE disease. Cyclophosphamide exposure (CYC) and its cumulative dose influenced gonadal function in SLE women, leading to amenorrhoea and ovarian failure, as reported in 19 studies. Mycophenolate, azathioprine, calcineurin inhibitors and steroids seem to be associated with a lower risk of ovarian failure compared to CYC. 3 studies demonstrated that POF was more frequent in patients treated with CYC not receiving gonadotropin-releasing hormone analogues (GnRH) in comparison to those co-treated with GnRH. 11 studies evaluated the impact of damage and disease activity on ovarian reserve in patients with SLE with conflicting evidence. Finally, 18 studies investigated exposure to hormonal and serological factors able to influence fertility outcomes; among others nor Anti-Müllerian Hormone, neither anti-corpus luteum antibodies were associated with POF.

Conclusion: The role of disease activity on fertility in SLE patients is contradictory. Regarding management factors associated with fertility in SLE women of childbearing age, the strongest evidence is about the treatment with CYC and its cumulative dose. Hormonal and serological factors did not impact on fertility outcome but might be used as a surrogate of fertility, especially after treatment with disease-specific drugs.

POS0717 AUTOIMMUNE LIVER DISEASE IN ANTICENTROMERE ANTIBODY POSITIVE PRIMARY SJOGREN'S SYNDROME

B. Chalcev[1], A. Torgashina[1], E. Sokol[1], J. Khvan[1], V. Vasiliev[2], S. Palshina[3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Intensive Care of Rheumatic Diseases, Moscow, Russian Federation*; *[2]MEDSI, Department of Rheumatic Diseases, Moscow, Russian Federation*; *[3]Clinic of Heart and Joint Diseases, Department of Rheumatic Diseases, Moscow, Russian Federation*

Background: studies have shown that anticentromere antibody (ACA) positivity in primary Sjogren's syndrome (pSS) is associated with autoimmune liver diseases, most often primary biliary cholangitis (PBC) and autoimmune hepatitis (AIH) [1, 2, 3], but detailed characteristics of the frequency and severity of liver disease in these patients is not presented in the literature.

Objectives: to identify the frequency, structure and characterize the course of autoimmune liver diseases in pSS+ACA.

Methods: we observe 82 patients with pSS+ACA. The diagnosis of pSS was established on the basis of Russian 2001 criteria, SSc was excluded based on the ACR/EULAR 2013 criteria [4]. 18 of 82 patients (22%) had a persistent increase in alkaline phosphatase, 11 of them were positive for antimitochondrial antibodies (AMA) and, according to the recommendations of the American Association for the Study of Liver Diseases [5], they were diagnosed with PBC. 7 of 18 patients were AMA-negative, 2 of them had a liver biopsy and the diagnosis of AMA-negative PBC was confirmed, 4 patients who did not have a liver biopsy and 1 patient with hepatitis B were excluded from the study. Also, in 6 of 64 patients without signs of liver damage, an increase in AMA was detected, in 1 of them a liver biopsy was performed and the diagnosis of PBC was confirmed. Thus, the group of patients with pSS+ACA and autoimmune liver diseases included 19 patients: 12 patients with AMA-positive PBC, 2 patients with AMA-negative PBC, and 5 patients with asymptomatic AMA positivity.

Results: The median follow-up for 19 patients with pSS+ACA and autoimmune liver diseases was 4 years. AMA were detected in 89.5% of patients, an increase in IgM - in 42.1%, an increase in ALT / AST - 63.2%, a decrease in albumin, prothrombin index and cytopenia - 15.8% (were associated with the development of liver cirrhosis). In most cases, the clinical course of liver disease was characterized by an asymptomatic, slowly progressing course, with no signs of progression during observation. Cirrhosis and portal hypertension were detected in 15.8% of patients, hepatic encephalopathy - in 10.5%. Liver biopsy was performed in 9 patients, PBC was diagnosed in all cases (overlap syndrome with AIH was established in 3 cases). Assessment of PBC histological stages showed signs of stage 1 in 5 patients, stage 2 in 1 patient, stage 3 in 3 patients. Observation of 5 patients with stage 1 PBC and 5 AMA-positive patients without signs of liver damage (median follow-up was 2 years), showed the absence of clinical, laboratory and instrumental progression of liver disease, which is why we believe that these patients have epithelitis of the biliary ducts as manifestation of glandular lesions in pSS, but not PBC.

Conclusion: autoimmune liver diseases in pSS+ACA are detected in 23.2% of patients, most of whom develop PBC and epitheliitis of the biliary ducts with the same frequency, less often overlap syndrome of PBC and AIH, and characterized by a mild, slowly progressing course and rarely lead to liver cirrhosis.

POS0718 CLINICAL CHARACTERISTICS ASSOCIATED WITH GLANDULAR INVOLVEMENT EVALUATED BY SALIVARY GLAND ULTRASONOGRAPHY IN SJÖGREN'S SYNDROME

T. Shimizu[1], H. Nakamura[1], Y. Takagi[2], S. Y. Nishihata[1], R. Sumiyoshi[1], T. Igawa[1], T. Koga[1], S. Y. Kawashiri[1], N. Iwamoto[1], K. Ichinose[1], M. Tamai[1], T. Origuchi[1], A. Kawakami[1]. *[1]Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Nagasaki, Japan*; *[2]Nagasaki University Graduate School of Biomedical Sciences, Department of Radiology and Cancer Biology, Nagasaki, Japan*

Background: Sjögren's syndrome (SS) is a systemic autoimmune disease characterized by periductal lymphocytic infiltration of the salivary and lacrimal glands, which results in reduced secretory functions and oral and ocular dryness (1). In addition, patients often have extraglandular manifestations, such as interstitial pneumonia and interstitial nephritis, and the appearance of autoantibodies such as anti-Ro/SS-A and La/SS-B antibodies. Salivary gland ultrasonography (SGUS) is typically used to evaluate the findings of salivary glands; thus, we can evaluate the severity of salivary gland disorders due to SS using SGUS in real time (2).
Objectives: To identify clinical indices, including disease activity, associated with glandular involvement evaluated using SGUS in patients with SS.
Methods: We enrolled patients with SS (n=115) and non-SS sicca subjects (n=90) who visited Nagasaki University Hospital between 1995 and 2019. The patients' SS classifications were based on the 2002 American–European Consensus Group (AECG) SS classification criteria (3). The non-SS sicca subjects exhibited sicca symptoms but did not fulfill the AECG SS classification criteria. SGUS and clinical indices such as age, sex, the focus score (FS), sicca symptoms, the Saxon test results, Schirmer's test results, anti-SS-A/Ro antibody positivity, anti-SS-B/La antibody positivity, anti-centromere antibody (ACA) positivity, serum immunoglobulin G levels, and the clinical European League Against Rheumatism SS disease activity index were examined. The ultrasonography (US) score was calculated based on SGUS imaging (hypoechoic area, hyperechoic band, and irregular border) (4).
Results: The US score was significantly higher in patients with SS than that in non-SS sicca subjects. In addition, we found significant correlations between the US score and FS in patients with SS. Multivariate analysis revealed the FS, Saxon test positivity, and ACA positivity as the variables independently associated with the US score in patients with SS. These results were the same in the primary SS patient group (n=96). Patients with ACA positivity had significantly higher US scores compared to those in patients with ACA negativity, whereas the FS was not significantly high. In addition, patients with ACA positivity had significantly greater positivity of hyperechoic bands than that in patients with ACA negativity.
Conclusion: This study indicated that ACA positivity, which is not reflected in sialadenitis of SS, is associated with the US score in patients with SS. These results suggest that US findings of patients with ACA positivity might show specific changes in salivary glands, such as fibrosis, and not only sialadenitis (5).

POS0719 ADVERSE OUTCOMES AND REHOSPITALIZATION AFTER DELIVERY AMONG WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS OR RHEUMATOID ARTHRITIS AND THEIR INFANTS

J. Sabo[1], N. Singh[1], D. A. Crane[2], D. R. Doody[3], M. A. Schiff[4,5,6], B. A. Mueller[3,6]. *[1]University of Washington, Division of Rheumatology, Seattle, United States of America*; *[2]University of Washington, Department of Rehabilitation Medicine, Seattle, United States of America*; *[3]Fred Hutchinson Cancer Research Center, Public Health Sciences Division, Seattle, United States of America*; *[4]University of Washington, Department of Obstetrics and Gynecology, Seattle, United States of America*; *[5]University of New Mexico, Albuquerque, Division of Epidemiology, Biostatistics & Preventive Medicine, Albuquerque, United States of America*; *[6]University of Washington School of Public Health, Department of Epidemiology, Seattle, United States of America*

Background: Women with rheumatoid arthritis (RA) or systemic lupus erythematosus (SLE) have greater risk of adverse obstetric and birth outcomes than women without these conditions. Infant outcomes are less well-studied. It is unknown whether re-hospitalization after delivery occurs more often for affected mothers and their infants.
Objectives: We compared obstetric outcomes among women with and without RA or SLE, and birth outcomes among their infants. Maternal and infant rehospitalizations <2 years of delivery were also compared.
Methods: This population-based cohort study used linked birth-hospital discharge data from Washington State for 1987-2014. International Classification of Disease 9th revision (ICD9) codes identified all women with RA (ICD9 714.X, 725.X) and SLE (ICD9 710, 710.0, 710.1) in the hospital discharge record at delivery, and a 10:1 comparison group of women without these codes. Analyses were restricted to singleton live births (1,223 RA; 1,354 SLE). Poisson regression with robust standard errors estimated relative risks (RR) and 95% confidence intervals (CI) for selected outcomes, accounting for delivery year, maternal age, and parity.
Results: Many adverse outcomes were more common among RA and SLE cases than among comparison women. Preeclampsia occurred more often during pregnancies of women with RA (RR 1.42, 95% CI 1.17-1.71) or SLE (RR 2.33, 95% CI 2.01-2.70), as did preterm rupture of membranes (PROM, RR 2.85, 95% CI 2.20-3.72 for RA; RR 3.28, 95% CI 2.54-4.23 for SLE). Cesarean deliveries were more common among nulliparous women in both groups (RR 1.32, 95% CI 1.18-1.48 for both conditions). Infants of women with RA or SLE were more likely to weigh <2500 g (RR 2.08, 95% CI 1.72-2.52 for RA; RR 4.88, 95% CI 4.27-5.58 for SLE), be small for gestational age (RR 1.25, 95% CI 1.07-2.50; RR 2.30; 2.04-2.59, respectively), delivered at <32 weeks gestation (RR 1.83, 95% CI 1.13-2.97; RR 5.13, 95% CI 3.75-7.01, respectively), and require neonatal intensive care unit admission (NICU, RR 1.89, 95% CI 1.56-2.30; RR 2.71, 95% CI 2.25-3.28, respectively). Infants of women with SLE were more likely to have a malformation (RR 1.46, 95% CI 1.21-1.75) or die within 2 years (RR 2.11, 95% CI 1.21-3.67). Rehospitalization levels among both women with RA (RR 2.22; 1.62-3.04) and SLE (RR 2.78, 95% CI 2.15-3.59) were greatest <6 months of delivery and declined over time. Infants of women with SLE had increased rehospitalization <6 months (RR 1.64, 95% CI 1.36-1.98).
Conclusion: Consistent with prior literature, we found women with RA or SLE experienced many adverse outcomes. In our data, these included preeclampsia, PROM, and cesarean deliveries, with increased risks more notable among women with SLE. Infants of women with either condition were more likely to weigh <2500g, be <32 weeks gestation, small for gestational age, and require NICU admission than infants of comparison women. Only infants of women with SLE had increased malformations. Maternal rehospitalization after delivery was more common in both groups; most marked at <6 months. Infant rehospitalizations were increased in both cohorts to a lesser extent. Close follow-up during this time period is crucial to minimize adverse outcomes.

POS0720 MORTALITY PATTERNS AND THEIR PROGNOSTIC VALUE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN CUBA

H. Hernández-Negrín[1], Y. Roque-Dapresa[2]. *[1]Universidad de Ciencias Médicas de Villa Clara, Internal Medicine, Santa Clara, Cuba*; *[2]Hospital Universitario Arnaldo Milián, Internal Medicine, Santa Clara, Cuba*

Background: There is an increase over time in studies adopting cluster analysis (CA) to identify causes, patterns and severity in rheumatic diseases.[1] However, CA has not been used to identify patterns of causes-of-death in patients with systemic lupus erythematosus (SLE).
Objectives: 1) to identify homogeneous groups of patients according to their causes-of-death, 2) to identify homogeneous groups of cause-of-death combinations and 3) to determine the potential prognostic value of the identified patterns.
Methods: This is a population-based study using the mortality register of Villa Clara (province of Cuba) between 1990 and 2019. Based on International Classification of Disease (ICD), Nine and Tenth Revision (ICD-9, code 710.0 and ICD-10, code M32), there were identified the SLE-related deaths (any mention on the death certificate) and their associated causes-of-death. Two hierarchical CA with Ward's method was carried out, based on the associated causes-of-death: one to conglomerate patients and another one to conglomerate variables. To identify differences in socio-demographic characteristics and causes-of-death between each cluster, Chi-square test, Fisher's exact test and Kruskal-Wallis test were used as appropriate. Multivariate Poisson regression model corrected for over-dispersion was used to determine the prognostic value of the clusters. Years of potentially life lost (YPLL) was defined as a dependent variable. To calculate

YPLL, each decedent's age at death was subtracted from a predetermined age of 75 years.

Results: A total of 141 patients were analyzed, which were grouped into three clusters. The socio-demographic features and causes-of-death that characterized each cluster are summarized in Table 1. Figure 1 shows the cause-of-death patterns identified by clustering the variables. After adjusting for sex, skin color, and the presence of pregnancy in the last year, cluster 1 was significantly associated with the number of YPLL in the multivariate analysis (adjusted rate ratios= 1.32; 95% confidence interval= 1.03 to 1.70; p= 0.028).

Table 1. Socio-demographic characteristics and top ten causes-of-death according to clusters.

Variable	Cluster 1	Cluster 2	Cluster 3	*P* value
	n=40	n=71	n=30	
Age at death median (IR)	36(28.5 to 50.2)	46(30.0 to 56.0)	49(39.0 to 63.2)	0.022
Sex n(%)				
Male	4(28.6)	8(57.1)	2(14.3)	0.873
Female	36(28.3)	63(49.6)	28(22.0)	
Skin color n(%)				
White	18(21.4)	45(53.6)	21(25.0)	0.070
Non White	22(38.6)	26(45.6)	9(15.8)	
Associated causes-of-death n(%)				
Acute respiratory failure	2(11.8)	6(35.3)	9(52.9)	0.006
Chronic kidney disease	31(96.9)	0(0)	1(3.1)	0.000
Essential hypertension	2(22.2)	6(66.7)	1(11.1)	0.734
Heart failure	3(25.0)	9(75.0)	0(0)	0.093
Lupus nephritis	39(95.1)	2(4.9)	0(0)	0.000
Multiple organ failure	2(18.2)	5(45.5)	4(36.4)	0.496
Pericarditis	4(40.0)	5(50.0)	1(10.0)	0.569
Pneumonia	5(14.7)	6(17.6)	23(67.6)	0.000
Pulmonary embolism	4(20.0)	15(75.0)	1(5.0)	0.043
Septicemia	4(22.2)	0(0)	14(77.8)	0.000

YPLL: Years of potentially life lost. IR: interquartile rank.

Conclusion: Three clusters of patients were identified, the one with higher prevalence of causes-of-death expressing renal damage presented higher mortality burden. The patterns of causes-of-death were mainly shaped by renal, cardiovascular and infectious causes. Better understanding of the association among causes of death, improves our comprehension of SLE and facilitate its clinical management.

Background: Factors associated with the development of chronic heart failure (CHF) in systemic lupus erythematosus (SLE) have received little attention. On the other hand, recent data from the use of hydroxychloroquine in the treatment of SARS-CoV-2 infection during the COVID19 pandemic have cast some doubts on its cardiological safety.

Objectives: To identify factors associated to CHF in SLE.

Methods: Retrospective cross-sectional study, including all patients with SLE (≥4 ACR-1997 criteria) recruited in RELESSER registry. The objectives and methodology of the registry have been described previously (1). CHF was defined according to the Charlson index item. Patients with CHF before diagnosis of SLE were excluded. Cumulative damage was measured with the SLICC/ACR index, excluding cardiovascular (CV) items (mSDI). Multivariate analysis exploring factors associated with CHF was carried out.

Results: 117 patients (3% of the entire cohort) with SLE and CHF and 3,506 controls with SLE without CHF were included. 90% were women. Disease duration: mean (SD), 120.2 (87.7) months. CHF appeared after a median (P25-P75) of 9.40 (4.2-18.3) years from SLE diagnosis. Patients with CHF were older (59.8 ± 18.2 vs. 46.2 ± 4.3). In the bivariate analysis, the

association of CHF with greater severity [Katz severity index: median (IQR): 4 (3-5) vs. 2 (1-3)], damage [mSDI: 3 (2-4) vs 0 (0-1)], comorbidity [modified Charlson- excluding CV items: 4 (3-6) vs 1(1-3)] and both CV (37.5% vs 6.7%) and overall mortality (43.2% vs 4.7%) (p<0.0001 for all comparisons). Also, CHF patients were more refractory to SLE treatments (33.3% vs 24%, p=0.0377) and were more frequently hospitalised due SLE [median 3 (1-5) vs 1(0-2), p<0.0001]. The results of the multivariable model are depicted in table 1.

Table 1. Congestive heart failure associated factors (multivariable analysis)

	Odds Ratio	95% CI	P-value
Sex (female)	0.46	0.25 - 0.88	0.0147
Ischaemic cardiopathy	7.96	4.01 - 15.48	<0.0001
Cardiac arrhythmia	7.38	4.00 - 13.42	<0.0001
Pulmonary hypertension	3.71	1.84 - 7.25	0.0002
Cardiac valvulopathy	6.33	3.41 - 11.62	<0.0001
Hospitalization (due to SLE)	3.74	1.81 - 8.65	0.0008
Calcium or vitamin D	5.29	2.07 - 16.86	0.0015
Antimalarials	0.28	0.17 - 0.45	<0.0001
mSDI *	1.29	1.16 - 1.44	<0.0001

*mSDI = modified SLICC/ACR damage index (without cardiovascular items)

Conclusion: - CHF is a rather late complication of SLE.
- Patients with SLE and CHF have more severe SLE, with greater refractoriness to SLE treatments and higher overall mortality.
- Treatment with antimalarials, as routinely used in SLE patients, is not only safe to heart, but even appears to have a cardioprotective effect.

POS0722 HISTOPATHOLOGICAL ANALYSIS OF LUPUS NEPHRITIS INCORPORATING BANFF CRITERIA EMPHASIZES THE IMPORTANCE OF TUBULOINTERSTITIAL CHANGES FOR CREATININE AND PROTEINURIA AT 12 MONTHS AFTER RENAL BIOPSY

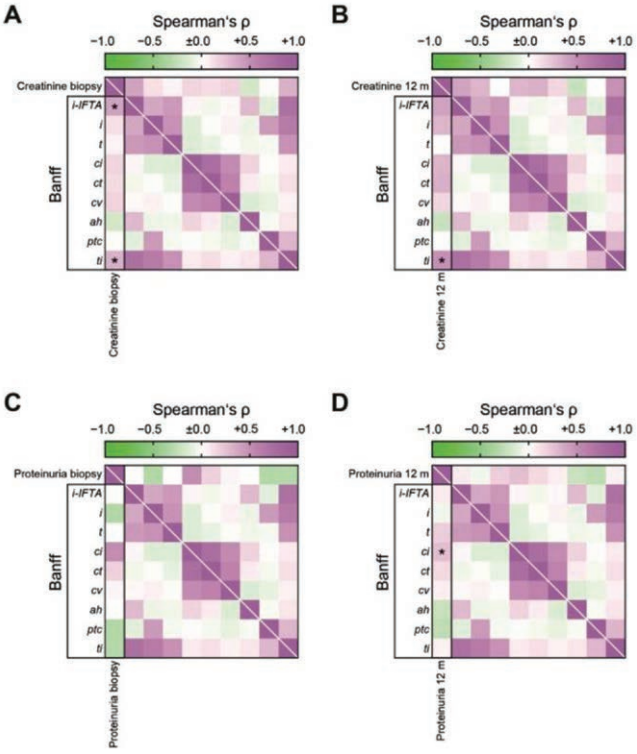
M. Plüß[1], S. Hakroush[2], N. Niebusch[1], B. Tampe[1], P. Korsten[1].
[1]Universitätsmedizin Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany; *[2]Universitätsmedizin Göttingen, Institute of Pathology, Göttingen, Germany*

Background: Lupus nephritis (LN) occurs in about 30-60% of patients with systemic lupus erythematosus (SLE). LN is associated with increased mortality. Currently, the diagnosis relies on histopathologic characteristics according to the ISN/RPS classification (1). This classification relies heavily on glomerular changes and may not accurately reflect all changes occurring in LN. For the description of transplanted kidney, the BANFF classification has been established which, in addition to glomerular changes, also incorporates tubular pathologies (2).

Objectives: With the present study, we aim to describe histopathologic changes according to the BANFF classification in a single-center cohort of LN patients.

Methods: We retrospectively recorded epidemiological, clinical and laboratory data of 58 patients with LN over a ten-year period. Histopathologic diagnoses according to ISN/RPS classification or the former WHO classification were also documented. We then re-analyzed representative kidney samples according to the BANFF classification and performed Spearman rank correlation for BANFF findings and creatinine at biopsy and 12 months as well as proteinuria at biopsy and at 12 months.

Results: We analyzed 58 patients with LN. 9 were male, 49 were female. Median age was 38 (15-78) years. According to ISN/RPS, 3 had class I LN, 6 had class II, 14 had class III, 16 had class IV, 6 had class V, and 0 had class VI. Median eGFR at biopsy was 60 ml/min/1.73m2 (13-137). According to the BANFF classification, tubulointerstitial inflammation (ti) was associated with creatinine at 12 months. Proteinuria at 12 months was associated with interstitial fibrosis (ci) (Figure 1).



Conclusion: In LN, the current ISN/RPS classification puts emphasis on glomerular changes. Nevertheless, for the long-term outcome, tubulointerstitial changes (tubulointerstitial inflammation and interstitial fibrosis) may at least be as important as glomerular changes. These findings have to be corroborated in larger cohorts with prespecified renal endpoints.

POS0723 HERPES ZOSTER IN A MULTI-ETHNIC SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) COHORT: CLINICAL FEATURES AND RISK FACTORS

S. S. Shaharir[1], S. Rajalingham[1], R. Mohd[2], N. Kori[3], A. Jamil[4]. *[1]Universiti Kebangsaan Malaysia Medical Centre, Rheumatology Unit, Department of Internal Medicine, Kuala Lumpur, Malaysia*; *[2]Universiti Kebangsaan Malaysia Medical Centre, Nephrology Unit, Department of Internal Medicine, Kuala Lumpur, Malaysia*; *[3]Universiti Kebangsaan Malaysia Medical Centre, Infectious Disease Unit, Department of Internal Medicine, KL, Malaysia*; *[4]Universiti Kebangsaan Malaysia Medical Centre, Dermatology Unit, Department of Internal Medicine, Kuala Lumpur, Malaysia*

Background: Systemic Lupus Erythematosus (SLE) patients are at risk of Herpes Zoster (HZ) infection due to the underlying immunosuppressed state. The reported incidence of HZ in SLE is 6 to 10-times higher than the general population.

Objectives: To determine the clinical characteristics of SLE patients who develop Herpes Zoster (HZ) infection and their associated risk factors.

Methods: Medical records review was performed on consecutive SLE patients in Universiti Kebangsaan Malaysia Medical Centre (UKMMC) from 2018 until 2019. Previous history of HZ and their demographic characteristics, clinical and medications used at the time of infection were recorded. Univariate and multivariate analyses were performed to compare the clinical and treatment characteristics

between SLE patients with history of HZ and patients who had never had experienced HZ.

Results: A total of 229 patients with predominantly Malay patients (n=123, 53.7%), followed by Chinese (n=90, 39.3%) and others (n=16, 7.0%) were included. A total of 37 patients had history of HZ (16.2%). Their mean age during HZ episode was 34.4 ± 13.8 years and their SLE disease duration was 68.7 ±57.1 months. More than half of them (n=21, 56.8%) developed HZ when the SLE disease was active with the mean dose of prednisolone at the time of infection was 20.7 ± 9.2 mg daily. A total of 21 HZ patients (56.8%) had ever received cyclophosphamide with the median interval of the last infusion was 6 (0.2-84) months. Almost half of the HZ patients (n=18, 48.6%) developed the infection while on cyclosporine A. Meanwhile, 4 (10.8%) were on azathioprine and mycophenolate mofetil respectively. Chinese patients tend to have HZ as compared to other ethnics (27% vs 41.7%), p=0.07. HZ occurred in a higher proportion among male patients (29%) as compared to female patients (14.1%), p=0.05. The use of azathioprine (10.8% vs 55.2%, p<0.01) and mycophenolate mofetil (10.8% vs 31.8%, p=0.009) were less associated with HZ. On the other hand, the use of cyclosporine A (48.6% vs 32.3%, p=0.05) and prednisolone ≥ 60mg daily (44.4% vs 28%, p=0.04) were associated with HZ. Higher HZ patients had hematological manifestation (81.1% vs 62.5%, p=0.04) and positive lupus anticoagulant (LA), 32.4% vs 14.6%, p=0.02. A forward logistic regression which included all factors with p<0.1 in the univariate analyses revealed that the use of prednisolone ≥ 60mg daily and hematological manifestation were the independent predictors of HZ with OR= 2.28 (95% C.I = 1.01-5.17), p=0.049 and OR= 2.78 (95% C.I = 1.09-7.04), p=0.03 respectively. The use of azathioprine was associated with a lower risk of HZ with OR 0.08 (95% C. I= 0.03-0.25), p=<0.01.

Conclusion: Our study demonstrated the possible influence of male gender, Chinese ethnicity and disease characteristics such as hematological manifestation and lupus anticoagulant positivity with the occurrence of HZ. In addition, the use high dose oral prednisolone ≥ 60mg daily was the independent predictor of HZ while on the other hand, the use of azathioprine was associated with a lower risk of developing HZ as compared to other immunosuppressive agents. Further larger studies are needed to confirm these associations.

POS0724 GENDER DIFFERENCES IN THROMBOTIC PRIMARY ANTIPHOSPHOLIPID SYNDROME IN A LARGE COHORT OF PATIENTS FROM FOUR EUROPEAN CENTERS

L. Moschetti[1], L. Dal Pozzolo[1], V. Le Guern[2], N. Morel[2], C. M. Yelnik[3], M. Lambert[3], E. Hachulla[3], Y. Benhamou[4], F. Franceschini[1], L. Andreoli[1], N. Costedoat-Chalumeau[2], A. Tincani[1]. *[1]ASST Spedali Civili - University of Brescia, Rheumatology and Clinical Immunology Unit - Clincal and Experimental Sciences, Brescia, Italy*; *[2]2AP-HA Cochin Hospital - Université Descartes-Sorbonne Paris Cité, Internal Medicine Departement, Centre de Référence Maladies auto-immunes et systémiques rares d'ile de France, Paris, France*; *[3]Univ Lille, INSERM, CHU Lille, Service de médecine interne et d'immulogie clinique, Centre de Réference des Maladies auto-immunes systèmiques rares du nord-ouest de France (CeRAINO), U1167 - RID AGE, Lille, France*; *[4]CHU Charles Nicolle - Normandie University, UNIROUEN, Départemend de Médecine Interne - INSERM U1096 EnVI, Rouen, France*

Background: Autoimmune diseases occur more frequently in females and their course and severity can be affected by gender. Antiphospholipid syndrome (APS) is a systemic autoimmune disorder in which antiphospholipid antibodies (aPL) exert a pathogenic role resulting in vascular thrombosis and/or pregnancy morbidities. Data about gender differences in thrombotic APS (t-APS) are still scarce[1,2].

Objectives: To evaluate the differences in frequency, disease expression and severity between females and males affected by primary t-APS.

Methods: Retrospective study enrolling subjects with a formal diagnosis of primary APS (Miyakis 2006) with vascular thrombosis at onset. Women who presented with obstetric events as first aPL-related manifestation were excluded. All the patients were followed from 1967 to 2019 in four European centers: three French centers and one Italian center.

Results: The study included 433 patients (68% females, 32% males). Median age at t-APS onset [31 (24-46) vs 41 (29-53) years, *p<0.001*] and at diagnosis [34 (27-50) vs 46 (34-57) years, *p<0.001*] was significantly lower in females.

The most common presenting manifestations were venous thrombosis (60%) followed by arterial events (37%) and catastrophic APS (3%). Venous events were more frequent in women as compared to men (64% vs 51% *p:0.012* OR:1.7 [1.1-2.5]). Sites of venous thrombosis included: limbs (35%), pulmonary (17%), cerebral (3%), portal and inferior cava (2%) and retinal (1%) veins, without gender differences. The arterial events were more frequent among men (43% vs 34% *p:0.053*). Strokes (27%) and myocardial infarctions (4%) were the most frequent manifestations, followed by thrombosis of limbs (2%), retina (2%) and abdominal organs (1%). Noteworthy, only men presented with visceral ischemia. During the follow-up, new thrombosis occurred in 41% of patients (179/433). 33% out of them had at least two episodes and these occurred especially among males (22% vs 10% *p:0.001* OR:2.5 [1.3-4.8]). New events were mostly of the same type, but ⅓ of patients presented a switch from venous to arterial side and viceversa, with no gender differences.

Complete aPL profile was available in 357 subjects: 33% had single aPL positivity, 24% double positivity and 43% triple positivity, with no differences between women and men. About 80% of the patients had a concomitant risk factor (RF) for thrombosis. Established cardiovascular RFs were more represented among men as shown in table 1. In women, estrogenic exposure was the main RFs, present in almost 40% of them.

Table 1.

	MALES n= 137	FEMALES n= 296	*P* OR [IC 95%]

Congenital thrombophilia	9/94 (10)	33/204 (16)	*ns*

Data were compared using contingency tables, *p value* was calculated with Chi-Squared or Fisher exact test. *= hormonal therapy, pregnancy, post-partum

Conclusion: This gender-oriented analysis of patients with primary t-APS showed that women had the first vascular event at a younger age and mostly on the venous side, while men presented mainly with arterial events, later in life and suffered from more recurrent events. No differences were observed in the distribution of the aPL profile. The different frequency of arterial and venous events in the two groups could be attributed mainly to the presence of additional RFs rather than to biological gender-specific issues. However, it should be underlined that some RFs, such as the use of estrogens or classic cardiovascular RFs, are exclusive or more represented in one gender rather than the other, making it difficult to assess the link of causality between gender and manifestations of t-APS.

POS0725 CLINICAL AND IMMUNOLOGICAL CHARACTERISTICS OF PATIENTS WITH JUVENILE-, ADULT- AND LATE-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

O. Iaremenko[1], D. Koliadenko[1], I. Matiyashchuk[2]. *[1]Bogomolets National Medical University, Department of Internal Medicine #3, Kyiv, Ukraine*; *[2]Medical Center "Consilium Medical", Rheumatology Department, Kyiv, Ukraine*

Background: Systemic lupus erythematosus (SLE) predominantly develops in women of child-bearing age. However, nearly 20% of cases present during childhood, generally after puberty (juvenile-onset SLE, JSLE). On the other hand, 10-20% of patients develop SLE after the age of 45-50 years (late-onset SLE, LSLE) [1]. It is known that age at disease onset can influence the clinical presentation and course of SLE, but the findings are not always consistent across the studies [2].

Objectives: The aim of this study was to evaluate the spectrum of clinical manifestations and autoantibody profile in patients with SLE in the central region of Ukraine regarding age at onset.

Methods: The study included 258 SLE patients before starting an adequate therapy, comprising 225 females (87.2%) and 33 males (12.8%). The median age at SLE onset was 28 (20-39) years. The patients were classified into 3 groups: I – age at SLE onset ≤18 years (JSLE; n=52; 20.2%), II – SLE onset at age 19-44 years (adult-onset SLE, ASLE; n=161; 62.4%), III – age at disease onset ≥45 years (LSLE; n=45; 17.4%). The clinical and demographic data, SLE Disease Activity Index (SLEDAI), erythrocyte sedimentation rate (ESR), C-reactive protein

(CRP) and autoantibody profile were analyzed. Quantitative and categorical data were compared using Kruskal-Wallis test and chi-square test, respectively.
Results: There was a difference in prevalence of malar rash between the groups (p=0.022): it was more common in JSLE (40.4%) and ASLE (34.4%) than in LSLE patients (15.6%; p=0.04 and 0.05, respectively). Similar distribution was found for renal involvement: JSLE and ASLE patients presented higher rates of nephritis (55.8% and 49.4%, respectively) than LSLE patients (23.8%; p=0.012 and 0.014, respectively). But the groups did not differ significantly with regard to nephrotic syndrome (p=0.224). ASLE was associated with more frequent alopecia (38.8%) comparing with JSLE (19.2%; p=0.04). Moreover, ASLE patients also had the highest frequency of lymphadenopathy (56.3%) whereas in LSLE it was observed only in 25.0% of patients (p=0.001). Serositis was more common in LSLE (54.5%) and ASLE (43.8%) than in JSLE (23.1%; p=0.011 and 0.034, respectively). Although secondary Sjögren's syndrome was more frequently observed in ASLE (7.6%) and LSLE (7.3%) than in JSLE (0.0%), the difference did not achieve statistical significance (p=0.157). Also, no differences were observed in the occurence of arthritis, pulmonary and neurological manifestations, constitutional symptoms, SLEDAI score among the groups. Median CRP level in LSLE was significantly higher (14.0 (1.1-46.4) mg/L) than in JSLE (0.7 (0.0-12.0) mg/L) (p<0.05). But all groups did not differ significantly with regard to ESR levels. When differences in antinuclear antibodies were analyzed, we disclosed that the frequency of anti-dsDNA positive results was significantly higher in JSLE (68.6%) and ASLE (70.1%) patients when compared with that found in LSLE patients (31.3%) (p=0.016 and 0.001, respectively). There were no significant differences between groups with regard to positivity for other antibodies (anti-Sm, -Ro, -La, -RNP, antiphospholipid antibodies).
Conclusion: JSLE and ASLE patients are more likely to have malar rash, nephritis and anti-dsDNA positivity. Alopecia and lymphadenopathy are most frequent in ASLE patients. JSLE are far less likely to have serositis than any other group. Patients with LSLE demonstrate comparatively low frequency of major organ involvement, but they have higher levels of CRP.

POS0726 POST-TRAUMATIC STRESS DISORDER AND QUALITY OF LIFE IN SYSTEMIC LUPUS ERYTHEMATOSUS. A CROSS SECTIONAL WEB SURVEY-BASED STUDY

L. Moroni[1,2], M. Mazzetti[3], G. A. Ramirez[1,2], S. Zuffada[3], N. Farina[1,2], E. Bozzolo[1], V. Di Mattei[2,3], L. Dagna[1,2]. *[1]San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy*; *[2]Vita-Salute San Raffaele University, Milano, Italy*; *[3]San Raffaele Hospital, Clinical and Health Psychology Unit, Milano, Italy*

Background: Exposure to severe or chronic life stressors may alter immune function and high levels of subsequent distress have been implicated in autoimmune disease pathogenesis. Post-traumatic stress disorder (PTSD) is a debilitating psychiatric condition affecting 1-12% of the general population[1], occurring in response to traumatic events. Growing evidence supports an association between trauma exposure and PTSD with systemic lupus erythematosus (SLE) onset[2].
Objectives: To cross-sectionally assess PTSD prevalence in a cohort of patients with SLE and to examine its correlation with quality of life.
Methods: A 189-item anonymous questionnaire including demographics, disease features, the 9-domain Trauma and Loss Spectrum – Self Report (TALS-SR) and the 8-domain Lupus Quality of Life (Lupus QoL) was administered via web to a cohort of patients with SLE. Patients were classified as PTSD cases based on TALS-SR items corresponding to the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) criteria for PTSD.
Results: Ninety-nine (95% female and 5% male) patients with a median follow-up of 16.5 years completed the questionnaire. Self-reported fatigue prevalence was 75%. Fifteen patients (15%) reportedly were on psychological and/or psychiatric support. Thirty-one patients (31%) met the DSM-5 criteria for PTSD. The average LupusQoL interdomain score was 80/100. PTSD cases reported significantly lower scores compared to non-cases in three LupusQoL domains: planning (83 vs. 100, p=0.035), body image (85 vs. 95, p=0.031), and fatigue (67 vs. 92, p=0.001). An inverse correlation between TALS-SR scores and Lupus QoL subscales was found (Table1). In particular, the degree of stress secondary to losses or upsetting events was strongly correlated to fatigue intensity (rho= -0.458, p<0.001).
Conclusion: PTSD prevalence might be higher in SLE than in the general population and have a detrimental influence on quality of life. Fatigue perception might be more significantly affected by PTSD. Intervention studies are needed to assess the therapeutical effects of psychological support in patients with SLE.

POS0727 INSULIN RESISTANCE AND LEPTIN LEVELS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITHOUT DIABETES MELLITUS OR FASTING HYPERGLYCEMIA

L. Kondrateva[1], T. Panafidina[1], T. Popkova[2], M. Cherkasova[3], A. Lila[4], E. Nasonov[4]. *[1]V.A. Nasonova Research Institute of Rheumatology, Department of Systemic Rheumatic Diseases, Moscow, Russian Federation*; *[1]V.A. Nasonova Research Institute of Rheumatology, Department of Systemic Rheumatic Diseases, Moscow, Russian Federation*; *[3]V.A. Nasonova Research Institute of Rheumatology, Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*; *[4]V.A. Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation*

Background: Insulin resistance (IR) is considered as initial stage of diseases continuum from development of prediabetes to eventual progression to type 2 diabetes mellitus (T2DM). Individuals with prediabetes have also elevated leptin levels, so this adipocytokine along with IR can be considered as predictive laboratory markers of higher risk of T2DM. It is not yet clear whether presence of individual or multiple SLE-related and/or known traditional risk factors of T2DM (such as unhealthy diet, physical inactivity, family history of diabetes, or being overweight) can precipitate the development of IR.
Objectives: To analyze the relationship between IR and increasing leptin levels rates. To identify the presence and evaluate the potential role of traditional and disease-related risk factors for IR in SLE patients without T2DM or hyperglycemia.

Methods: A total of 49 SLE pts (46 women, 3 men, 40 [33;48] years old) without established DM and with normal fasting glucose levels (<6,1 mmol/l) were enrolled in the study. Median disease duration was 3,0[0,7;8,0] years, SLEDAI-2K was 5[2;8]. SLE pts were treated with glucocorticoids (GC) (84%), hydroxychloroquine (78%), immunosuppressive drugs (20%) and biological agents (10%). Insulin levels were measured using electrochemiluminescence assay Elecsys (Roche Diagnostics), serum leptin concentrations were estimated using ELISA (DBS-Diagnostics Biochem Canada Inc.). IR was defined as Homeostasis Model Assessment of Insulin Resistance index (HOMA-IR) ≥2,77. Leptin levels were considered elevated at values ≥11,1 ng/ml for women, ≥5.6 ng/ml for men. Eight traditional T2DM risk factors from the FINDRISK (Finnish Type 2 Diabetes Risk Assessment Form) questionnaire (older age, being overweight, abdominal obesity, family history of diabetes, sedentary lifestyle, lack of regular dietary fiber intake, taking antihypertensive medications as a surrogate marker of high blood pressure, documented episodes of hyperglycemia) were evaluated. This study used 5 risk categories for developing T2DM proposed by FINDRISK questionnaire: low, slightly elevated, moderate, high or very high.

Results: Median HOMA-IR levels were 1,7 [1,2;2,5]. HOMA-IR correlated with leptin levels (r=0,7, p<0,001), body mass index (BMI) (r=0,6, p<0,001), waist circumference (WC) (r=0,5, p<0,001), T2DM risk categories by FINDRISK (r=0,3, p=0,03), SLEDAI-2K (r= -0,4, p<0,01), and duration of GCs therapy (r=0,3, p=0,03). Current GC use had no influence on HOMA-IR in SLE. IR was detected in 10 (20%) SLE pts. The traditional T2DM risk factors profiles were similar in pts with (Group 1) or without IR (Group 2) except for higher anthropometric parameters in group 1 (for BMI 27,2[24,8;32,2]kg/m^2 vs 23,7[20,6;26,7]kg/m^2, p<0,01; for WC: 93[86;102]cm vs 83[76;93]cm, p=0,02). Leptin levels were also higher in SLE pts with IR compared to pts without IR (74,2[30,4;112,7]ng/ml vs 25,0[6,7;42,4]ng/ml, p<0,01). Increased leptin levels were found in 35 (71%) pts, more often in pts with IR (100 vs 64%, p=0,04).

Conclusion: IR was found in 20% of SLE pts without T2DM having normal serum fasting glucose concentration. Emergence of IR was commonly preceded by increased leptin levels. IR values were closely associated with accumulation of adipose tissue facilitated by long-term GCs use and disease activity decrease. Contribution of other traditional risk factors of T2DM seemed insignificant.

POS0728 QRISK3 RELATION TO CAROTID PLAQUE IS HIGHER THAN THAT OF SCORE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J. C. Quevedo-Abeledo[1], C. Palazuelos[2], J. Llorca[2], L. Cáceres Martín[1], I. Ferraz-Amaro[3], M. A. González-Gay[4]. [1]*Hospital Universitario de Gran Canaria Dr Negrín, Rheumatology, Las Palmas de GC, Spain*; [2]*University of Cantabria, CIBER Epidemiología y Salud Pública (CIBERESP), Santander, Spain*; [3]*Hospital Univeritario de Canarias, Rheumatology, La Laguna, Spain*; [4]*Hospital Universitario Marqués de Valdecilla, University of Cantabria, Rheumatology, Santander, Spain*

Background: Systemic lupus erythematosus (SLE) has been described as an independent risk factor for the development of cardiovascular (CV) disease. Recently, QRESEARCH risk estimator version 3 (QRISK3) calculator has been released for the assessment of CV risk in general population. QRISK3 now includes the presence of SLE as one of its variables for the calculation of CV risk.

Objectives: We aim to compare, in patients with SLE, the predictive capacity between QRISK3 and Systematic COronary Risk Evaluation (SCORE) for the presence of carotid subclinical atherosclerosis.

Methods: 296 patients with SLE were recruited. The presence of carotid plaque and carotid intima media thickness (cIMT) were assessed through ultrasound. QRISK3 and SCORE were calculated. The relation of QRISK3 and SCORE between themselves and to the presence of carotid subclinical atherosclerosis (both carotid plaque and cIMT) was studied.

Results: Most of the patients were female (95%) and average age was 51 ± 12 years. Traditional cardiovascular risk factors were prevalent, as shown in table 1. Most SLE patients were in the no activity (41%) or mild activity (29%) categories as shown by the SLEDAI scores. SLICC and Katz indexes were, respectively, 1 (IQR 0-2) and 2 (IQR 1-4). Seventy-one percent of the patients had a SLICC/ACR DI score equal to or higher than 1, and 39% had a Katz index equal to or higher than 3. Almost half of the patients (47%) were taking prednisone (the median dose of those 139 patients on prednisone was 5 [IQR 2.5-5] mg/day at the time of the study). DMARDs use was reported in 77% of the patients and 69% were taking hydroxychloroquine at the time the study was performed. SCORE and QRISK3 did not correlate between them in patients with SLE. In this sense, QRISK3, both calculated including the SLE item (Rho Spearman r=-0.008, p=0.90) or not (Rho Spearman r=-0.009, p=0.96), did not correlate with SCORE. This lack of correlation was also found when the corresponding categorizations of both scores were used. For example, patients with a QRISK> = 10 did not show a higher SCORE when compared to patients with a QRISK3 <10 (1.26 vs. 1.30, p=0.90). Similarly, QRISK3 was not different between the low, moderate, high and very-high SCORE CV risk categories.

Relation of QRISK3 and SCORE to cIMT and to the presence of carotid plaque is shown in Figure 1. QRISK3 was statistically significantly correlated with cIMT (Rho Spearman r=-0.420, p=0.000). However, this relation was not found between SCORE and cIMT (Rho Spearman r=-0.005, p=0.93). Moreover, QRISK3 showed a statistically significant discrimination for the presence of carotid plaque (AUC 0.765 (95%CI 0.711-0.820). This relation was found to be significant both when QRISK3 was calculated with the SLE variable item or not. However, in patients with SLE, SCORE did not show a significant discrimination for the presence of carotid plaque (0.561 (95%CI 0.494-0.629). Additionally, a statistical significant difference was observed between the AUC of QRISK3 and SCORE (p=0.000).

Table 1. Characteristics of SLE patients

	SLE patients (n=296)
Age, years	51 ± 12
Female, n (%)	280 (95)
Body mass index, kg/m2	27 ± 6
Systolic blood pressure, mmHg	127 ± 19
Cardiovascular co-morbidity	
Smoking, n (%)	74 (25)
Diabetes, n (%)	14 (5)
Hypertension, n (%)	119 (40)
Dyslipidemia, n (%)	115 (39)
Analytical and lipid profile	
CRP, mg/dl	1.9 (0.9-4.9)
Cholesterol, mg/dl	198 ± 38
LDL cholesterol, mg/dl	110 ± 29
SLE related data	
Disease duration, years	17 (10-25)
SLICC	1 (0-2)
SLEDAI	2 (0-4)
Current prednisone, n (%)	139 (47)
Hydroxychloroquine, n (%)	205 (69)
Subclinical atherosclerosis	
Carotid IMT, microns	630 ± 122
Carotid plaques, n (%)	108 (36)

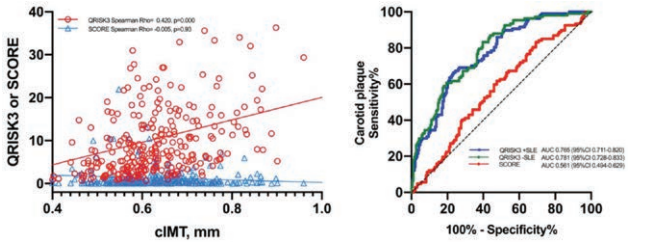

Figure 1. Relation of QRISK3 and SCORE to cIMT and carotid plaque.

Conclusion: QRISK3 discrimination for carotid plaque is higher than that of the SCORE. QRISK3, and not SCORE, should be use for the calculation of CV risk in patients with SLE.

POS0729 INFLUENCE OF VARIOUS FACTORS ON THE IMMUNOGENICITY OF 23-VALENT POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

G. Tarasova[1], B. Belov[1], M. Cherkasova[2], E. Aseeva[3], T. Reshetnyak[4], N. Kosheleva[4], T. Popkova[5]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory for the Study of Comorbid Infections and Monitoring the Safety of Drug Therapy, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Systemic Rheumatic Diseases Laboratory, Moscow, Russian Federation*

Background: Immunosuppressive therapy increases the risk of pneumococcal infection in patients with systemic lupus erythematosus (SLE). The therapy, as well as some features of the course of the disease, can lead to a decrease in the immunogenicity of the pneumococcal vaccine in these patients.
Objectives: The aim of the study was to identify "risk factors" that negatively affect the immunogenicity of the 23-valent polysaccharide pneumococcal vaccine (PPV-23) in patients with SLE.
Methods: The study included 60 patients aged 19 - 68 years with a reliable diagnosis of SLE, disease duration from 9 months. up to 42 years old. Nine patients had high disease activity, 12 had medium, 33 had low, and 6 had remission. Therapy: 58 patients received glucocorticoids (GC) 5-40 mg / day, 46-hydroxychloroquine, 33- cytostatics (CS), 23- biologics: 12-rituximab (RTM), 10-belimumab (BLM), 1- RTM and BLM. 1 dose (0.5 ml) of PPV-23 was administered subcutaneously. During the year, standard clinical and laboratory studies were carried out, the level of antibodies to polysaccharides of the S. pneumoniae cell wall in the blood serum was determined.
Results: After 1-2 months. after vaccination, 78.7% of patients showed a more than twofold increase in protective antibodies, a year later - in 56.7% of patients ("responders"). The severity of the vac-cine response did not depend on age: in the subgroup of patients under 50 years of age (n = 46), the proportion of "responders" remained 52.2%, and in patients over 50 years of age (n = 14) -50%. With different duration of the disease, the vaccine response did not differ significantly: with a disease period of up to 5 years, the vaccine response was observed in 47.6%, from 5 to 10 years - in 66.7%, over 10 years - in 55.6% of patients. Patients in remission had the lowest vaccine response (33.3%), while with high SLE activity, 100% response to the vaccine was recorded (p = 0.02), which is probably due to the fact that remission requires long-term and active immunosuppressive therapy, and patients with high activity such therapy has just been initiated or is to be. With an average and low degree of activity, the number of "respondents" was the same (50% and 51.5%, respectively). In patients receiving biologics therapy, a full-fledged vaccine response was observed less frequently than in patients without biologics (39% and 68%, respectively, p = 0.03), while no differences were found against the background of RTM and BLM therapy (41.6% and 40% of "respondents", respectively). The effect of the duration of biologics therapy on the severity of the vaccine response was analyzed.
There was a tendency for the predominance of "responders" in the group with a duration of therapy before vaccination up to 1 year, as well as in the group of initiation of biologics after vaccination, however, the differences were not statistically significant.
Conclusion: RTM and BLM have a negative effect on the immunogenicity of the PPV-23 vaccine. However, if the timing of administration is observed (initiation of biologics therapy after vaccination or vaccination against the background of biologics therapy lasting less than a year), the number of "responders" increases. Further recruitment of patients is needed to clarify and confirm the results obtained.

POS0730 DECREASED RISK OF OSTEONECROSIS OVER TIME IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS USING JAPANESE HEALTH INSURANCE DATABASE

R. Sakai[1], E. Tanaka[1], M. Yamagishi[1], M. Majima[1], M. Harigai[1]. [1]*Tokyo Women's Medical University School of Medicine, Department of Rheumatology, Tokyo, Japan*

Background: In patients with systemic lupus erythematosus (SLE), prevalence of osteonecrosis (ON) was 20–40% [1], and 4–10 times higher risk of ON than the general population was observed [2,3]. Because ON can influence patients' physical activity and quality of life, it is essential for rheumatologists to manage ON appropriately. Recently, medications such as mycophenolate mofetil (MMF) and hydroxychloroquine (HCQ) were approved for SLE in Japan. Considering the changes in treatments for SLE over time, it is clinically important to investigate the risk and risk factors of ON in patients with the disease. However, to date, only evidence is found in the literature.
Objectives: To estimate incidence rate (IR) and identify risk factors of ON in patients with SLE using a Japanese health insurance database.
Methods: This retrospective longitudinal population-based study was conducted using claims data provided by Medical Data Vision Co., Ltd (Tokyo, Japan). We defined individuals as SLE cases if they met all of the following: 1) having at least one ICD10 code (M321 or M329); 2) having at least one prescription of oral corticosteroids (CS), methylprednisolone (mPSL) pulse therapy, immunosuppressive drugs (IS) (azathioprine, mizoribine, tacrolimus, MMF, cyclophosphamide, methotrexate), biologics (belimumab, rituximab) or HCQ between January 2010 and January 2017; 3) being 16 years old or over. The start of observation was defined by the first month in which cases met all of the above criteria. Patients were followed until the earliest of date of first ON, date of loss of follow-up, or the end of follow-up (December 2017). ON was defined when patients had at least one ICD code (M87.0, M87.1, M87.2, M87.3, M87.8, M87.9, M90.5) during the observation period. Patients were excluded if they had a previous diagnosis of ON during the first 3 months of the observation period. We defined baseline characteristics using the data in the month of starting observation, and calculated incidence rate (IR) in each year, adjusted relative risk (RR [95% CI]) of ON using a Poisson regression model, and adjusted odds ratio (OR [95% CI]) of risk factors of ON after adjusting for age and sex at baseline, and medications and comorbidities during the observation period using a logistic regression model.
Results: In this study, 16,386 cases were included. The median age was 55 years and 81.3% were female. Median observation period was 33 months, and total observation period was 47,138 patient-years (PY). IR/1,000 PY of ON in each year from 2010 to 2017 was 13.2, 10.6, 11.0, 13.3, 13.1, 9.8, 8.5, and 7.3, respectively. Adjusted RR in each year from 2011 to 2017 compared to 2010 was 0.5 [0.2–1.4], 0.3 [0.1–0.9], 0.6 [0.3–1.4], 0.7 [0.3–1.6], 0.4 [0.2–0.8], 0.4 [0.2–0.8], and 0.3 [0.1–0.7], respectively. Adjusted OR was 1.22 [1.10–1.34] for younger age by decade, 1.41 [1.11–1.79] for male, 2.69 [1.52–4.76] for use of oral CS (> 0 and < 5 mg/day of prednisolone [PSL] equivalent dose versus no use), 2.21 [1.26–3.86] for oral CS (≥ 5 and < 10mg/day versus no use), and 1.25 [1.02–1.54] for dyslipidemia.
Conclusion: Significant decrease in IR of ON after 2015 was observed in Japanese patients with SLE for the first time. Younger age, use of CS, and dyslipidemia were identified as significant risk factors of ON.

POS0731

CLINICAL ASSOCIATIONS OF COGNITIVE DYSFUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

S. Raghunath[1,2], V. Golder[1,2], R. Kandane-Rathnayake[1], E. F. Morand[1,2], Y. Glikmann-Johnston[3], J. C. Stout[3], A. Hoi[1,2]. [1]*Monash University, Centre for Inflammatory Diseases, Melbourne, Australia*; [2]*Monash Health, Rheumatology Department, Melbourne, Australia*; [3]*Monash University, Turner Institute for Brain and Mental Health, School of Psychological Sciences, Melbourne, Australia*

Background: Cognitive symptoms are commonly reported by SLE patients, but the prevalence and clinical associations of cognitive dysfunction (CD) is poorly understood.

Objectives: To examine the relationship between SLE disease parameters and CD.

Methods: Patients with SLE were consecutively recruited from 2018-2020. Cognitive assessment was performed using the one-hour conventional neuropsychiatric test battery recommended by the American College of Rheumatology for SLE[1]. Three binary definitions of CD and seven cognitive test z-scores were included in analysis. Clinical parameters included disease activity (SLEDAI-2K) and damage (SDI). Multivariate regression analysis was performed to determine associations with cognitive endpoints using variables with p <0.1 on univariate testing; likelihood ratio tests were used to select for inclusion from collinear pairs. A subgroup univariate analysis was performed to look for associations with interferon gene signature (IGS) and metabolic indices.

Results: 91 SLE patients and 48 age, sex, and premorbid IQ matched controls were recruited. The median (range) age was 45 (21-64) and median disease duration 13 years (0.2-39). 60% were Caucasian and the rest predominantly Asian, and all had good English proficiency. Prevalence of CD varied based on definition used; 18% had ≥2 cognitive domains ≥2 SD below the healthy control mean, whereas 48% were considered impaired if this threshold was reduced to ≥1.5 SD below. Age and premorbid IQ were significantly associated with multiple cognitive endpoints, and SDI was associated with four endpoints including the most severe definition of CD. Increased parity and past strokes correlated with poorer cognition in two endpoints. In contrast, clinical variables such as SLEDAI, antiphospholipid antibodies and past seizures only correlated with one endpoint each. There were no associations with other antibodies or any medications including glucocorticoids. Subgroup analysis showed univariate associations of CD with increased waist circumference, hypertriglyceridemia and low IGS.

Conclusion: Clinical associations of CD in SLE vary according to the cognitive domain or impairment definition used. SDI was the disease-related factor most consistently associated with CD, while IGS was negatively and metabolic features positively associated with CD. Studies of CD in SLE should use standardised methods to determine CD.

IDENTIFICATION OF AUTOPHAGY-RELATED PHENOTYPES IN PRIMARY SJOGREN'S SYNDROME

R. Zhao[1,2,3], S. X. Zhang[1,2,3], J. Qiao[1,2,3], S. Song[1,2,3], Y. Zhang[1,2,3], M. J. Chang[1,2,3], Q. Wang[4,5], G. Y. Liu[1], P. F. He[5], X. Li[1,2,3]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*Shanxi Li Xiaofeng Medical Groups, Department of Rheumatology, Taiyuan, China*; [3]*Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; [4]*Shanxi Medical University, Department of Basic Medical College, Taiyuan, China*; [5]*Shanxi Medical University, Medical Data Sciences, Taiyuan, China*

Background: Primary Sjogren's syndrome (pSS) is a chronic systemic autoimmune disease characterized by disorders of effector T cell subpopulations such as Th1, Th2, Th17, regulatory T cells, and follicular helper T cells [1 2]. Autophagy is an evolutionarily conserved self-digestion process that plays an important role in T cell-mediated immune response[3]. The relationship between autophagy and T cell subsets was unclear in pSS up till now.

Objectives: To landscape the autophagy-related multiple gene expression signature in pSS classification and discover the influence of autophagy in T cell subsets.

Methods: Gene expression profiles of pSS samples (GSE66795, GSE51092, GSE154926) were acquired from GEO database. A set of significant G-ATGs were intersected from the global gene of patients and 232 autophagy genes (ATGs) which were obtained from the Human Autophagy Database (HADb, http://www.autophagy.lu/). In training dataset (GSE66795, including 155 patients and 29 healthy controls), non-negative matrix factorization was used to divided patients by G-ATGs expression microarray data. An autophagy score model divided patients into the high-autophagy score and low groups by ssGSEA scores of gene according to normalized G-ATGs training data. Further, new classifications were validated by both peripheral blood samples (GSE51092, 90 patients) and salivary gland tissue (GSE154926, 43 participants).

Results: Two distinct subtypes were identified and validated by 206 selected significant G-ATGs in training datasets (figure 1A,B) and validation datasets according to the autophagy score (figure 1D,E,F) Combined with clinical information of salivary gland dataset, it was found that most patients with early pSS were grouped in the high autophagy, while advanced patients were grouped in the low (figure 1G). Patients in high-autophagy group had higher levels of Treg cells and Th2 cells but lower concentrations of Th17 and Th1 in peripheral blood (figure 1C, P <0.05). Similar results were also observed in salivary gland tissue (figure 1H, P <0.05).

Conclusion: Patients with different autophagy status differs from each other. Autophagy is closely corelated with lymphocyte subpopulations in patients with pSS. This work may help inform therapeutic decision-making for the treatment of pSS.

POS0733 REAL-LIFE PHYSICAL ACTIVITY IN SLE PATIENTS: ASSOCIATIONS WITH FATIGUE AND QUALITY OF SLEEP

H. Wohland[1], N. Leuchten[1], M. Aringer[1]. [1]*University Medical Center and Faculty of Medicine TU Dresden, Department of Medicine III, Division of Rheumatology, Dresden, Germany*

Background: Fatigue is among the top complaints of patients with systemic lupus erythematosus (SLE), but only in part associated with SLE disease activity. Physical activity can help to reduce fatigue and should therefore be recommended to SLE patients. Vice versa, fatigue may arguably lead to reduced physical activity.

Objectives: To investigate the extent of physical activity and the perception of fatigue and sleep quality in patients with SLE.

Methods: Starting in February 2019, SLE patients were invited to participate in a cross-sectional survey study of fatigue and physical exercise during their routine outpatient clinic visits. Participants filled out a ten-page paper questionnaire focused on physical activity. To evaluate fatigue, we primarily used a 10 cm visual analogue scale (0-100 mm, with 100 meaning most fatigued), but also the FACIT fatigue score (range 0-52). Sleep quality was estimated using grades from 1 (excellent) to 6 (extremely poor).

Results: 93 SLE patients took part in the study. All patients fulfilled the European League Against Rheumatism/ American College of Rheumatology (EULAR/ ACR) 2019 classification criteria for SLE. 91% of the patients were female. Their mean (SD) age was 45.5 (14.3) years and their mean disease duration 12.1 (9.4) years. The mean BMI was 25.2 (5.6). Of all patients, 7.5% had a diagnosis of (secondary) fibromyalgia. The mean fatigue VAS was 32 (27) mm and the mean FACIT fatigue score 35.7 (10.3). As expected, fatigue by VAS and FACIT was correlated (Spearman r=-0.61, p<0.0001). The mean SLEDAI was 1 (1) with a range of 0 to 6. Median glucocorticoid doses were 2 mg prednisolone equivalent, with a range from 0 to 10 mg.

Out of 66 patients in payed jobs, 64 (97%) reported details on their working space. One person (2%) worked in a predominanty standing position, 37 (58%) worked in essentially sedentary jobs and 26 (40%) were in positions where they were mildly physically active in part. The mean fatigue VAS was 31 (24) mm for patients with partly active jobs and 27 (30) mm for those in sedentary jobs. Sleep was graded 2.9 (0.9) by those with active and 3.1 (1.3) by those with sedentary jobs.

Half of the patients (51%) reported more than one physical recreational activity. 44 (47%) were walking and for five persons (5%) this was the only form of activity. Cycling was reported by 19 patients (20%), 18 of whom also practiced other activities. For transport, 52 (56%) in part chose active modes, such as walking and cycling. Patients who reported any of the above activities showed a mean fatigue VAS of 28 (25) mm, compared to 36 (28) mm in the patient group without a reported activity. Sleep quality was very similar: 3.1 (1.2) and 3.2 (1.1) for more active and more passive patients, respectively.

65 (70%) patients regularly practiced sports. Of these, 39 (60%) practiced one kind of sport, 15 (23%) two, 7 (11%) three, and 2 (3%) each four and five kinds of sports. Fatigue VAS of patients practicing sports was 27 (25) mm versus 43 (28) in those who did not (p=0.0075). Sleep quality was 2.9 (1.1) in the sports cohort and 3.5 (1.1) in the no-sports cohort (p=0.0244).

Conclusion: A majority of SLE patients in remission or low to moderate disease activity regularly practiced sports, and those doing so reported lesser fatigue and better sleep quality. The absolute values on the fatigue VAS were in a moderate range that made fatigue as the main cause of not performing sports rather unlikely for most patients.

POS0734 EXTRAPOLATION OF LONG-TERM OUTCOMES IN SYSTEMIC LUPUS ERYTHEMATOSUS: REPLICATING A HOPKINS LUPUS COHORT ANALYSIS WITH THE SYSTEMIC LUPUS INTERNATIONAL COLLABORATING CLINICS (SLICC) INCEPTION COHORT

A. E. Clarke[1], Y. St-Pierre[2], V. Paly[3], I. N. Bruce[4], C. Malmberg[5], A. Briggs[6], Y. Zhang[7], J. Choi[7], A. Brennan[8]on behalf of Systemic Lupus International Collaborating Clinics. [1]*University of Calgary, Division of Rheumatology, Calgary, Canada*; [2]*McGill University Health Centre, Research Institute, Montreal, Canada*; [3]*ICON plc, Global Health Economics and Outcomes Research (GHEOR), New York, United States of America*; [4]*University of Manchester, The Kellgren Centre for Rheumatology, Manchester, United Kingdom*; [5]*ICON plc, Global Health Economics and Outcomes Research (GHEOR), Stockholm, Sweden*; [6]*London School of Hygiene & Tropical Medicine, Department of Health Services Research and Policy, London, United Kingdom*; [7]*Bristol Myers Squibb, Worldwide HEOR, Lawrenceville, United States of America*; [8]*University of Sheffield, Health Economics and Decision Science, School of Health and Related Research, Sheffield, United Kingdom*

Background: A disease model of systemic lupus erythematosus (SLE) that predicts short-term outcomes (disease activity and prednisone use) and links them to long-term outcomes (accrual of organ damage and mortality) was previously developed in a single center SLE cohort (Johns Hopkins [JH]) to support health economic analyses (Watson 2015), which has not been comprehensively replicated in other cohorts or contexts.

Objectives: As part of an effort to develop and refine this existing disease model, the aim of this study was to replicate the previously estimated network of risk equations for short- and long-term outcomes in the SLICC Inception Cohort, an international cohort of patients (33 centers,11 countries).

Methods: The SLICC Inception Cohort enrolled patients fulfilling ACR Classification Criteria for SLE within 15 months of diagnosis from 1999-2011 with annual follow-up through April 2020. The network of risk equations included two linear random effects models to predict (1) change in annual average Systemic Lupus Disease Activity Index (SLEDAI) score based on patient characteristics and the presence of renal, hematological, and immunological involvement in the prior year and (2) average annual prednisone dose based on SLEDAI score in the same year. These equations were then linked to parametric survival models that predicted time to the occurrence of organ damage (system-specific based on the ACR/SLICC Damage Index) and mortality. We compared model performance between the SLICC Cohort and the original analysis from the JH Cohort.

Results: In comparison to the JH cohort (N=1354), the SLICC cohort (N=1697) had a smaller fraction of patients of African descent (39% vs 17%) and shorter

disease duration at entry (4.8 vs 0.5 years). In the first equation predicting change in annual SLEDAI score, predictors were generally aligned with the same direction and significance, with the exception of renal involvement in the prior period, which had a positive association with change in SLEDAI in the SLICC cohort but was negatively associated in the JH cohort (Table 1). The second equation predicting prednisone dose was also consistent with the original analysis showing a significant positive association between higher disease activity and prednisone use. In all of the parametric survival analyses (individual organ damage and mortality models), coefficients were generally in the same direction and magnitude, though some were no longer significant in the SLICC cohort.

Conclusion: The relationships identified in the original analysis were broadly replicated in the SLICC Inception Cohort. Observed differences may reflect differences in the patient populations, structure of the two cohorts (prevalent vs inception), and frequency of visits (quarterly visits in the JH cohort vs annual visits with the SLICC cohort may more closely capture a decrease in SLEDAI associated with treatment specifically related to renal involvement). Additional analyses relaxing the requirement to completely align with the original structure are underway to further assess the predictive accuracy of these models.

POS0735 ULTRASOUND-GUIDED CORE NEEDLE BIOPSY FOR SALIVARY GLAND ENLARGEMENT IN SJÖGREN'S SYNDROME: PROCEDURE SAFETY AND PATIENT TOLERANCE

A. Zabotti[1], I. Giovannini[1], S. Z. Callegher[1], V. Manfrè[1], M. Lorenzon[2], E. Pegolo[3], C. A. Scott[3], A. Tel[4], M. Robiony[4], C. Zuiani[2], S. De Vita[1].
[1]Rheumatology Clinic, Department of Medicine, University of Udine, c/o Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy; *[2]Institute of Radiology, Dipartimento di Diagnostica per Immagini, Udine, Italy*; *[3]Institute of Anatomic Pathology, Department of Medical and Biological Sciences, Udine, Italy*; *[4]Maxillofacial Surgery, Department of Specialistic Surgery, Udine, Italy*

Background: Persistent enlargement of major salivary glands (SGs) is one of the main risk factors for B-cell lymphoma in primary Sjögren's syndrome (pSS). The Ultrasound-guided Core Needle Biopsy (US-guided CNB) could be a novel technique for the management of SGs enlargement in pSS (1).

Objectives: To evaluate the procedure safety and the patient tolerance of US-guided CNB in pSS patients with major SGs enlargement.

Methods: Consecutive patients, with either definite or clinically suspected pSS, and with clinical indication for SGs biopsy due to persistent glandular enlargement were screened for US-guided CNB from September 2019 to December 2020. All patients were evaluated clinically between 1 and 2 weeks and 12 weeks following US-guided CNB. All patients were asked to complete a questionnaire to report post-procedural complications (Figure 1, *English version*) and intra- and post-procedural pain Visual Analogue Scale (VAS). The complications were classified as transient (<12 weeks) or persistent (≥12 weeks).

Results: US-guided CNB was performed in 21 glands (12 parotid and 9 submandibular glands) in 20 pSS patients. 16/20 (80%) patients fulfilled the ACR-EULAR classification criteria for pSS (2). The mean age at the time of biopsy was 62.1 (±11.7) years. US-guided CNB was well tolerated, no long-term complications were reported in the follow-up period (mean 9.5 ±5.7 months). Only transient complications were noticed in 11 patients (55%). In particular, two cases of local swelling at the biopsy site lasting no more than 6 days, one case of local bleeding and subsequently hematoma of the submandibular area, one case of transient facial paresis (lasting less than one hour), seven cases of post-procedural mild local pain, that resolved within 10 days without the need of analgesics (Table 1). The procedure was well tolerated, with a very low reported intra-operative pain (mean VAS 1.74 ±2.49) and a mean post-operative pain VAS of 1.39 (±2.33). The biopsy sampling was diagnostic in 19/20 patients (95%).

Conclusion: US-guided CNB represents a novel approach for the management of pSS patients with SGs enlargement. This procedure shows a remarkable patient safety and tolerance, allowing an adequate glandular sampling and definite diagnosis in almost all the studied patients.

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with highly heterogeneous clinical presentation characterized by disease unpredictable flares and multi-systemic involvement[1 2]. This clinical heterogeneity calls for design a molecular stratification to improve clinical trial design and formulate personalization treatment therapies.

Objectives: This research was conducted to develop a reliable method to stratify SLE patients combined gene expression information and disease status.

Methods: The mRNA expression profile of GSE138458 (contained 307 patients and 23 controls) and GSE49454 (contained 111 patients and 16 controls) were downloaded from the publicly GEO databases. After background adjustment, batch correction, and other pre-procession, obtaining a big gene matrix to identify the differentially expressed genes (DEGs) in SLE compared with healthy controls, which were screened by P value < 0.01. SLE subtypes were identified by non-negative matrix factorization (NMF) based on DEGs. Acquired signature genes in different SLE subtypes were conducted to process pathway enrichment analysis in Metascape. SLEDAI score and immune cell infiltration was also performed between subtypes by software package R (version 4.0.3).

Results: Total 1202 DEGs were imputed to NMF unsupervised machine learning method. Patients with SLE were stratified into two subsets based on 184 signature genes derived from obtained DEGs(Fig.1A, 1B). GO and KEGG enrichment analysis showed that signature genes were mainly involved in negative regulation of innate immune response, toll-like receptor signaling pathway, regulation of immune effector process and so on(Fig.1C). Patients in Sub1 group had severe disease activity measures compared with those in Sub2(Fig.1D). SLEDAI scores from GSE49454 dataset were also higher in Sub1 compare with Sub2(-Fig.1E). Further, immune cell infiltration results revealed an insufficient of regulatory T cell, CD8 T cells and naive CD4 T cells in Sub1 and neutrophils cells in Sub2(P<0.05)(Fig.1F).

Conclusion: Our findings indicate that patients with SLE could be stratified into 2 subtypes which had different lymphocyte status and closely related to disease activity. This phenotyping may help us understand the etiology of the disease, inform patient in the design of clinical trials and guide treatment decision.

Background: The role of complement in the antiphospholipid (aPL) related pathology has been widely studied in animal models. Antiphospholipid antibodies can induce fetal loss in experimental animals but mice deficient in specific complement components (C4, C3, C5) appear somehow protected. In addition, in pregnant mice injected with aPL, antibody deposition has been found at decidual level causing focal necrosis, apoptosis and neutrophil infiltrates and supporting aPL pathogenetic potential. On the other hand, human studies did find hypocomplementemia associated to pregnancy complications in patients with obstetric antiphospholipid syndrome (APS). These results, however, are not unanimously confirmed and, in addition, some studies only show increased levels of complement activation products (i.e. Bb) and not decreased levels of C3 and/or C4. A recently study focusing on complement level in early pregnancy and before pregnancy showed a significant correlation with pregnancy complications and loss in a large cohort of primary APS.

Objectives: To investigate if the simple detection of low C3 and/or C4 could be considered a risk factor for adverse pregnancy outcome in APS and aPL carriers pregnancies.

Methods: We performed a multicentric study including patients from 10 Italian and 1 Russian Centers. Data on pregnancies in women with primary APS (n=434) and asymptomatic carriers with persistently positive aPL but not fulfilling clinical criteria for APS (n=218) were retrospectively collected. Serum C3 and C4 levels were evaluated by nephelometry; hypocomplementemia was defined by local laboratory reference values. Statistical analysis was performed using GraphPad.

Results: Preconceptional complement levels and gestational outcome were available for 107 (25%) pregnancies in APS out of 434 and for 196 (90%) pregnancies in aPL carriers women out of 218. In pregnancies with low preconceptional C3 and/or C4, a significantly higher prevalence of pregnancy losses was observed (p=0.019). A subgroup analysis focusing on triple aPL positive patients was also performed. Preconceptional low C3 and/or C4 levels were found to be associated with an increased rate of pregnancy loss (p = 0.027) in this subgroup also. Otherwise, adverse pregnancy outcomes in single or double aPL positive women were not related to preconception complement levels (p = 0.44) (Table 1). Of note, all the pregnancy losses in the triple positive group occurred in patients treated with low dose aspirin and low molecular weight heparin from the time of positive pregnancy test.

Conclusion: Our findings confirm that decreased complement levels before pregnancy are associated with increased risk of adverse outcome. This has been seen only in in women with triple aPL positivity, indeed single or double positivity does not show this trend. Complement levels are cheap and easy to be measured therefore they could represent a useful aid to identify patients at increased risk of pregnancy loss. test positivity.

POS0738

BLUNTED CEREBRAL OXYGENATION DURING EXERCISE IN NON-NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

N. Koletsos[1], K. Dipla[2], A. Triantafyllou[1], A. Lazaridis[1], N. Papadopoulos[3], A. Zafeiridis[2], S. Aslanidis[4], S. Douma[1], E. Gkaliagkousi[1]. Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease affecting multiple organs, including the central nervous system. Subclinical brain lesions have been reported in SLE patients, even without overt neuropsychiatric manifestations (non-NPSLE). Studies using PET/MRI, examining structural or functional brain abnormalities in SLE, have been previously performed, either at rest or during a mental task (1–3). Exercise can be used to identify early alterations in brain oxygenation that might not detectable during resting conditions (4).

Objectives: Our study aimed to examine possible differences in cerebral oxygenation during a handgrip exercise test between SLE patients without neuropsychiatric manifestations and age-matched controls.

Methods: Fifty-two participants (26 non-NPSLE and 26 controls), following evaluation of handgrip strength, underwent a protocol involving a seated rest (baseline), a 3-min handgrip exercise (at 30% of maximal strength), and a 3-min recovery. Continuous-near-infrared-spectroscopy (NIRS) was used to monitor changes in cerebral-oxygenated hemoglobin (O2Hb), de-oxygenated (HHb) and total-hemoglobin (tHb). Beat-by-beat blood pressure (Finapres) was continuously monitored.

Results: There were no differences between the two groups in age, body mass index, blood pressure, and smoking status. Median SLE duration was 7.5 (3.0 – 16.0) years. During exercise, cerebral -O2Hb increased in both groups; however, non-NPSLE exhibited a significantly lower increase in O2Hb vs. controls (average response:1.20±0.89 vs. 2.33±1.61μM, respectively, p<0.005) and lower tHb responses (p<0.05), with no differences in HHb.

Conclusion: Our data show, for the first time, that SLE patients even without overt neuropsychiatric manifestations exhibit a blunted increase in cerebral-O2Hb during a submaximal exercise stimulus compared to age-matched controls. Examining brain oxygenation during a simple exercise task may assist in identifying patients with early alterations in cerebral function.

POS0739

DEVELOPMENT OF A CONCEPTUAL MODEL TO UNDERSTAND DISEASE BURDEN IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND LONG-TERM ORGAN DAMAGE

L. Broderick[1], W. H. Chen[2], R. Levy[3], A. Foster[1], C. Umanzor[1], D. Chauhan[4].
[1]QualityMetric, Johnston, RI, United States of America; *[2]GlaxoSmithKline, Value Evidence and Outcomes, Collegeville, PA, United States of America*; *[3]GlaxoSmithKline, Global Medical Affairs, Collegeville, PA, United States of America*; *[4]GlaxoSmithKline, Value Evidence and Outcomes, Brentford, Middlesex, United Kingdom*

Background: Systemic lupus erythematosus (SLE) is a chronic, multisystem, autoimmune disease resulting in increased morbidity and mortality and reduced health-related quality of life (HRQoL). Patients with SLE are at risk of developing irreversible long-term organ damage (LTOD) caused by both disease activity and cumulative medication toxicities. Data regarding the overall disease burden and impact of LTOD in patients with SLE are limited.
Objectives: The primary objective of this qualitative study was to develop a conceptual model to describe the burden experienced by patients with SLE and LTOD.
Methods: This study (GSK Study 209754) was conducted in three phases. First, a targeted literature review was performed to aid the development of an initial draft conceptual model. Key opinion leaders (KOLs) with experience in SLE and LTOD were then interviewed to assess the clarity, language, comprehensibility, and potential use of the conceptual model, and to help shape the patient interview materials. Finally, one-on-one interviews were performed with patients with SLE and LTOD in any of the 12 organ areas (defined by the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index [SDI]), to gather patient perspectives on the common symptoms, functional impacts, treatment experiences, and HRQoL factors associated with LTOD. Data from the interviews were coded and analysed using NVivo software to identify patterns in responses concerning the key concepts of the overall patient burden of LTOD, and used to identify concepts to include in the model.
Results: The literature review produced the preliminary conceptual model of LTOD. Results of the KOL interviews (n=5 clinicians and n=1 patient advocate) indicated that the preliminary conceptual model broadly captured the patient experience of LTOD. KOLs emphasised the difference between SLE activity (flares) and LTOD; the conceptual model was subsequently updated in accordance with these recommendations. Interviews conducted with patients with confirmed single (n=9) and multiple LTOD (n=31) indicated that the burden of LTOD associated with SLE was more severe, debilitating, and life threatening than that caused by SLE flares. Almost all patients (39/40) reported aspects of their lives that were more severely affected since their LTOD diagnosis. All 40 patients reported LTOD-related physical impacts, which often affected patients' ability to perform everyday tasks. The most frequent physical impacts reported were a loss of vitality (39/40), long-term complications (e.g. unstable blood pressure, extreme pain, poor mobility, inflammation, dialysis, infection; 36/40), and severe fatigue (29/40). Cognitive impairments that became more pronounced after their LTOD diagnosis were reported by 27/40 of patients. Typically characterised as "brain fog," these impairments were described as slower cognitive processing, forgetfulness, confusion, and aphasia. Economic impacts associated with LTOD included patients' inability to work (31/40), costs of care (33/40), and non-medical-related costs (17/30). Psychosocial impacts reported by patients with LTOD affected their emotional state (39/40), ability to socialise (40/40) and relationships (30/40). Additionally, 30/40 patients reported symptoms as more severe since their LTOD diagnosis, including pain (14/40), fatigue (9/40), and oedema (8/40). Patients' treatment goals were largely aligned with their experienced impacts of LTOD, including managing the disease and symptoms (25/40), limiting further organ damage (15/40), and improving HRQoL (11/40).
Conclusion: The findings from this research clearly indicate that the patient burden of LTOD far surpasses that of SLE without LTOD. These data were incorporated and refined into a conceptual model that fully represents the patient experience of LTOD. The model will help researchers, clinicians, and patients to better understand the impact of SLE-related LTOD progression.

EPIDEMIOLOGY AND CLINICAL FEATURES OF OCULAR SARCOIDOSIS. STUDY OF 65 PATIENTS OF A SERIES OF 384 PATIENTS FROM A SINGLE UNIVERSITY HOSPITAL

C. Álvarez-Reguera[1], J. J. Gaitán-Valdizán[2], R. Fernández-Ramón[2], R. Demetrio-Pablo[2], J. L. Martín-Varillas[3], L. Sanchez-Bilbao[1], D. Martínez-López[1], I. González-Mazón[1], M. Á. González-Gay[1], R. Blanco[1].
[1]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain; *[2]Hospital Universitario Marqués de Valdecilla, Ophthalmology, Santander, Spain*; *[3]Hospital de Sierrallana, Rheumatology, Santander, Spain*

Background: Ocular involvement in sarcoidosis can be present in up to 80% of patients. If not treated, it can lead to significant visually complications **(1-5).**
Objectives: Our aim was to assess the main **a)** epidemiology and **b)** clinical features of ocular sarcoidosis in a wide and unselected series from a single university hospital.
Methods: Study of a large cohort (n=384) of all consecutive patients diagnosed with sarcoidosis from January 1, 1999 to December 31, 2019. Finally, 344 patients were included according to the ATS/ERS/WASOG criteria *(Eur Respir J. 1999;14:735-7).*
Results: 65 (33 men/32 women) of 344 (18.9%) patients had ocular involvement. Mean age at diagnosis was 45.6±15.9 years. The most frequent extraocular clinical clusters were respiratory (80%), osteoarticular (30.8%) and cutaneous (29.2%) (figure 1). Ocular manifestations and complications are shown in table 1. Uveitis (83.1%), orbital lesions (7.7%) and retinal vasculitis (6.2%) were the most common ocular lesions. Median Best Corrected Visual Acuity (BCVA) at diagnosis and after one year of follow-up was 0.6 [0.3-0.8] and 0.9 [0.30-1], respectively. Retinal vasculitis was associated to the worst BCVA outcome, and panuveitis to more frequent and severe complications.
Conclusion: Ocular manifestations, especially uveitis, are frequent in sarcoidosis. A more aggressive and early treatment may be indicated in panuveitis and retinal vasculitis.

POS0741 HISTOPATHOLOGIC PATTERNS OF LUPUS NEPHRITIS PREDICT THE RISKS OF MORTALITY-A SINGLE-CENTER RETROSPECTIVE STUDY

Y. W. Liao[1], W. T. Hung[1], Y. M. Chen[1], C. W. Hsieh[1], T. Y. Hsieh[1], Y. H. Chen[1], W. N. Huang[1]. [1]*Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Taichung, Taiwan, Republic of China*

Background: Lupus nephritis is a significant complication of systemic lupus erythematosus and is associated with increased risks of end-stage kidney disease and mortality.

Objectives: The retrospective observational study aims to investigate which component of the National Institutes of Health activity and chronic indices of lupus nephritis can predict mortality.

Methods: We identified 528 SLE patients with biopsy-proven lupus nephritis between 2006 and 2019. Two patients with class VI lupus nephritis were excluded, and a total of 526 patients were analyzed. Serum creatinine, urine protein-to-creatinine ratio (UPCR), and serologic markers for SLE disease activity were measured at the time of the renal biopsy. The histopathologic findings of renal biopsies were classified by utilizing the International Society of Nephrology/ Renal Pathology Society (ISN/RPS) classification.

Results: Among 526 patients enrolled, 64 expired, and 44 were female (68.8%, p=0.004). Class IV (± V) comprised the most (n= 39, 60.9%), followed by class V (n= 18, 29.7%). Lower eGFR was observed in the death group, compared with the survival group (median: 24.7 vs. 80.5, p<0.001). There were no significant differences in UPCR and serologic markers for SLE (dsDNA, C3, and C4). Total scores of chronicity index and the scores for each index were higher in the death group. Interestingly, although total scores of activity index in death and survival groups did not differ significantly, the scores for cellular crescents tended to be higher in the death group (1.38 ±1.77 vs. 0.72 ±1.24, p=0.002)

In the univariable analysis, age, male sex, eGFR, activity index scores, cellular crescents, chronicity index scores, and all CI components (global obsolete glomeruli, tubular atrophy, interstitial fibrosis, fibrous crescents) and tubulointerstitial nephritis were significantly associated with an increased risk of death. When patient characteristics and NIH activity/ chronicity indices were jointly examined in a multivariable analysis, fibrous crescents were significantly associated with increased risk of death in females (HR 5.23 [95% CI: 1.51, 18.09]) (Table 1). In males, the risks of death increased with cellular crescents (HR 1.73 [95% CI: 1.10, 2.73]) but decreased with global obsolete glomeruli (HR 0.12 [95% CI: 0.02, 0.91]).

Conclusion: In this single-center observational study, fibrous crescents in females and cellular crescents in males were significantly associated with increased risks of mortality.

Background: Primary Sjögren's syndrome (pSS) is an autoimmune disease that featured as lymphoplasmacytic infiltration of the exocrine glands leading to sicca symptoms[1]. However, its underlying molecular mechanisms remain elusive.

Objectives: This study aims to identify differentially expressed genes (DEGs) and pathways associated with the progression of pSS using bioinformatics analysis and explore its pathogenesis.

Methods: The pSS-associated gene chip data set GSE66795 was obtained from the Gene Expression Omnibus (GEO) database, which included 131 cases of fully-phenotyped pSS patients' whole blood samples and 29 cases of control samples. DEGs were screened Using R software. Online tool Metascape[2] was used to make Gene Ontology (GO) and KEGG pathway enrichment. The PPI network was performed using String database. Hub genes were identified by Cytoscape.

Results: A total of 108 DEGs were captured, including 101 up-regulated genes and 7 down-regulated genes. GO enrichment showed that these DEGs were primarily enriched in defense response to virus, response to interferon-gamma, regulation of innate immune response, response to interferon-beta, double-stranded RNA binding, response to interferon-alpha. KEGG pathway enrichment analysis showed these DEGs were principally enriched in Influenza A, RIG-I-like receptor signaling pathway, necroptosis, Staphylococcus aureus infection. Finally, 9 hub genes (STAT1, IRF7, OAS2, GBP1, OAS1, IFIT3, IFIH1, OAS3, DDX60) had highest degree value.

Conclusion: The findings identified molecular mechanisms and the key hub genes that may involve in the occurrence and development of pSS.

Background: Nephritis is one of the predominant causes of morbidity and mortality in patients with lupus[1,2].The lack of understanding regarding the molecular mechanisms of lupus nephritis(LN) hinders the development of specific targeted therapy for this progressive disease[3].
Objectives: In this study, we use bioinformatics method to analyze the genes involved in regulating the potential pathogenesis of LN.
Methods: The expression profile of LN(GSE104948 and GSE32591) was obtained from the GEO database.GSE104948 was a memory chip, which included 32 LN glomerular biopsy tissues and 3 glomerular tissues from living donors.GSE32591 dataset included 32 LN glomerular biopsy tissues and 15 glomerular tissues from living donors. The Oligo package was used to process the data to obtain the expression matrix files of all the related genes.P<0.05 and |log2(FC)|>2 were setted as cut-off criteria for the DEGs.Ggplot2, heatmap packages were used to DEGs visualization. Metascape online tool was used to annotating DEGs for Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis performed.We used STRING online database to construct protein-protein interaction (PPI) network. Hub genes were identified by Cytoscape.
Results: In differential expression analysis,357 DEGs were identified,including 248 up-regulated genes and 109 down-regulated genes (Figure 1A,B). GO enrichment showed that these DEGs were primarily enriched in biological pathways, cell localization and molecular function and revealed that LN-related genes mainly involved in immune response.KEGG pathway annotation enrichment analysis revealed these DEGs were closely associated with Staphylococcus aureus infection,Complement and coagulation cascades (Figure 1D). Fourteen hub genes(IFT3,IRF7,OAS3,GBP2,RSAD2,MX1,IFIT2,IFI6,MX2,ISF15,IFIT1,QAS2,OASL,OAS1) were identified from PPI network (Figure 1C,E).
Conclusion: Illuminating the molecular mechanisms of LN was help for deep understanding of LN.

POS0744 A NEGATIVE INTERFERON BIOMARKER CD169 / SIGLEC-1 RULES OUT SYSTEMIC LUPUS ERYTHEMATOSUS

L. Zorn-Pauly[1], A. S. L. Von Stuckrad[2], J. Klotsche[3], T. Rose[1], T. Kallinich[2], F. Hiepe[1], P. Enghard[4], L. Ostendorf[4], T. Dörner[1], C. Meisel[5], U. Schneider[1], N. Unterwalder[5], G. R. Burmester[1], T. Alexander[1], R. Biesen[1]. [1]*Charité - Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany*; [2]*Charité - Universitätsmedizin Berlin, Pediatric Pneumology and Immunology, Berlin, Germany*; [3]*German Rheumatism Research Centre, Epidemiologic Unit, Berlin, Germany*; [4]*Charité – Universitätsmedizin Berlin, Nephrology and Intensive Care Medicine, Berlin, Germany*; [5]*Institute for Medical Immunology, Labor Berlin – Charité Vivantes, Immunology, Berlin, Germany*

Background: While there have been advances in the therapy of systemic lupus erythematosus (SLE) in recent years, there have been no major new findings in SLE biomarkers [1, 2]. Type I interferon (IFN) plays a pivotal role in the pathogenesis of SLE [3]. In 2008, we first described CD169 / SIGLEC-1 (sialic acid-binding immunoglobulin-like lectin-1), an interferon-induced adhesion molecule on monocytes in SLE patients [4]. For over five years SIGLEC-1 has been routinely assessed in our clinic.
Objectives: To evaluate and compare the diagnostic utility of the type I IFN induced SIGLEC-1 with established biomarkers in the initial diagnosis of the disease.
Methods: We analyzed retrospectively 232 patients who were on suspicion of SLE at Charité University Hospital Berlin between October 2015 and September 2020. Patients underwent full clinical characterization, and biomarkers were

determined in the routine laboratory. Based on the final diagnosis, we divided patients into two groups: A) initial diagnosis of SLE and B) Non-SLE mimicking condition.

Results: In 76 patients (32.3 %) SLE was confirmed by fulfilling the EULAR / ACR 2019 classification criteria [5]. SIGLEC-1 was dramatically increased in patients with an initial diagnosis of SLE compared to patients without SLE ($p<0.0001$). For a threshold of 2500 molecule per monocyte, a sensitivity of 98.7 %, a specificity of 82.1 %, a negative predictive value (NPV) of 99.2 %, and a positive predictive value (PPV) of 72.8 % were calculated for SIGLEC-1. Adjusted to the prevalence of SLE in Germany (36.7 per 100,000 inhabitants [6]) NPV and PPV turned out to > 99.9 % and 0.2 %. We further aimed to compare not only the performance of the tests at a given cutoff but also across all possible measured values. Therefore, we conducted ROC curves analyses (see figure 1). The area under the curve (AUC) of SIGLEC-1 test was significantly higher than that of ANA test (AUC=0.88, p=0.031), C3 (AUC = 0.83, p=0.001), C4 (AUC=0.83, p=0.002), but not than that of the Anti-dsDNA ELISA (AUC=0.90, p=0.163).

Conclusion: Our study shows that IFN activity is a hallmark at the onset of the disease and that the interferon biomarker SIGLEC-1 is valuable to rule out SLE in suspected cases.

POS0745

RISK FACTORS FOR HOSPITALIZATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A LATIN COHORT

I. E. Garcia Cañas[1], E. Cuevas Orta[1], D. A. Herrera Van Oostdam[1], C. Abud-Mendoza[1]. [1]*Hospital Central Dr. Ignacio Morones Prieto, Rheumatology, San Luis Potosí, Mexico*

Background: Systemic lupus erythematosus (SLE) is the prototype of autoimmune diseases and is characterized by multisystemic affection. Hospitalization is a frequent eventuality in the course of the disease with a rate of 0.50 admissions/person-year estimated; infections and disease activity explain the highest percentage of admissions, risk factors depend on the population studied, among which are cardiopulmonary disease, elevated creatinine, thrombocytopenia, high disease activity and use of immunosuppression, however, the risk factors in the Mexican population are unknown.

Objectives: To identify risk factors for hospitalization in patients with generalized lupus erythematosus, and as a secondary result, identify the main causes of hospitalization in our population.

Methods: Observational, analytical, case-control and ambilective study of patients with a diagnosis of SLE at the Hospital Central Dr. Ignacio Morones Prieto in San Luis Potosí, Mexico, evaluated from January 2019 to October 2020; for each hospitalized patient with SLE, a non-hospitalized patient with SLE evaluated in the Rheumatology outpatient clinic was taken as a control, to establish a 1: 1 relationship. Continuous variables were expressed as mean or median; and standard deviation or interquartile ranges (IQR) according to the distribution. The categorical variables were expressed in proportion. The comparison of continuous variables was carried out with the unpaired Student's t test or Mann Whitney's U according to their distribution, while the categorical variables were compared with Fisher's exact test or X^2 and logistic regression analysis was performed.

Results: A total of 202 patients were collected, 179 were women (88.6%); of all patients, 89 (45.1%) were hospitalized, who were younger at diagnosis and time of evolution of the disease and greater SLEDAI and accumulated damage than non-hospitalized patients. The main causes of hospitalization were disease activity in 60.7% of cases, with kidney disease being the most important, followed by infectious in 22.5% and pharmacological toxicity in 5.6%. In the multivariate analysis, the risk factors associated with hospitalization identified were creatinine (p 0.018), CRP (p 0.046), neutrophils (p 0.013), constitutional condition (p 0.044), hematological (p 0.003) and renal (p. p 0.004), see Table 1. Factors associated with mortality were creatinine (p 0.022), INR (0.019), days of ICU stay (p 0.020) and the use of vasopressors (p 0.003). The use of antimalarials was a protective factor for hospitalization with p 0.0003. Survival analysis was performed where it was observed that patients with infection acquired in the hospital had a lower probability of survival with p 0.012.

Conclusion: In our center, disease activity continues to be the most frequent cause of hospitalization and elevated creatinine is a risk factor for hospitalization and mortality in patients with SLE. In-hospital infections were a factor of poor survival.

Vital[1,2]. *[1]NIHR Leeds Biomedical Research Centre, Rheumatology, Leeds, United Kingdom*; *[2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Rheumatology, Leeds, United Kingdom*; *[3]Bradford Teaching Hospitals NHS Foundation Trust, Rheumatology, Bradford, United Kingdom*; *[4]Royal Blackburn Hospital, Rheumatology, Blackburn, United Kingdom*; *[5]Doncaster & Bassetlaw Hospitals NHS Trust, Rheumatology, Doncaster, United Kingdom*; *[6]Guy's and St Thomas' Hospital, Rheumatology, London, United Kingdom*; *[7]University College Hospital, Rheumatology, London, United Kingdom*; *[8]Centre for Adolescent Rheumatology, Rheumatology, London, United Kingdom*; *[9]University Hospital Southampton NHS Foundation Trust, Rheumatology, Southampton, United Kingdom*

Background: SLE disease activity tools do not optimally define disease activity and response. The SLEDAI arthritis item is common, and sufficient to define SRI response. Lupus patients with arthralgia often have no swelling. Glossary definitions of arthritis in different versions of the SLEDAI have included: swelling, swelling between visits, effusion, tenderness, warmth and erythema. MSK ultrasound in SLE can identify synovitis without swelling, ultrasound synovitis is associated with worse symptoms and serology, predicts response to therapy, and is more responsive to therapy than clinical variables.

Objectives: To validate different glossary definitions for SLEDAI arthritis using musculoskeletal ultrasound.

Methods: We analysed baseline data from a multicentre longitudinal study. Physicians scored SLEDAI-2K in 133 patients with joint pain that was considered inflammatory, but not necessarily swelling. Stable immunosuppressants and prednisolone <=5mg were permitted. If the arthritis criterion was scored, we asked physicians to report which glossary features drove their decision. Musculoskeletal ultrasound of hands and wrists was performed on the same day, blinded to clinical findings. We defined abnormal grey-scale in joints as 1 joint with GS>=2, and in tendons as >=1 tendon with GS >=1, and abnormal power Doppler as >=1 joint or tendon with PD >=1.

Results: 78/133 patients had arthritis scored on SLEDAI-2K. In 21/78, swelling was not a reason for that decision. These 21 patients had either tenderness (16/21), swelling reported between visits (4/21) or both of these (1/21). No patient was scored for warmth, erythema or effusion alone. Comparison of SLEDAI definitions and ultrasound is shown in Table 1. Of 57 patients with SLEDAI arthritis scored due to swelling, 90% had an abnormal ultrasound. The positive predictive value was 89% (95% CI 79 – 94). Of 21 patients with SLEDAI arthritis scored without swelling, 48% had an abnormal ultrasound. The positive predictive value was 48% (95% CI 31 – 67). There was no substantive difference in clinical and serological variables comparing patients with SLEDAI arthritis without swelling and patients without SLEDAI arthritis. In contrast, patients with SLEDAI arthritis with swelling had worse ESR (p=0.0003), Physician MSK disease activity VAS (p<0.001) and patient EMS VAS (p=0.0019) and IgG (p=0.0625) compared to the other two groups.

Conclusion: Although ultrasound proven synovitis in the absence of swelling is not uncommon, it is not reliably identified using other signs or symptoms. The arthritis item of the SLEDAI was likely to be associated with ultrasound synovitis if scored because of swelling, but not if scored because of tenderness or swelling between visits. Our results support raising the threshold criteria for arthritis so that it should only be scored when there is joint swelling. Previous clinical trial datasets could be re-analysed excluding SLEDAI arthritis scores not confirmed by a swollen joint count greater than one.

POS0747

MAPPING THE NATIONWIDE CLINICAL PROFILE AND PATTERNS OF CARE OF SLE IN BRAZIL – FINDINGS FROM THE MACUNAÍMA STUDY

M. Abreu[1,2], O. Monticielo[3], V. Fernandes[4], A. Cristovão Maiorano[2], F. Dos Santos Beserra[2], F. Lamarao[5], N. David[5], B. De Veras[5], B. Bica[1], D. Sávio Nunes de Lima[6], M. Maria Das Chagas Medeiros[7]. *[1]Universidade Federal do Rio de Janeiro, Faculdade de Medicina, Rio de Janeiro, Brazil*; *[2]Universidade Federal do Rio de Janeiro, Laboratório para Pesquisa em Desfechos Centrados no Paciente, Rio de Janeiro, Brazil*; *[3]Universidade Federal do Rio Grande do Sul, Serviço de Reumatologia do Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*; *[4]Universidade de Cuiabá, Department of Medicine, Cuiabá, Brazil*; *[5]GlaxoSmithKline, Medical Department, Rio de Janeiro, Brazil*; *[6]Universidade Federal do Amazonas, Serviço de Reumatologia do Hospital Universitário Getúlio Vargas, Manaus, Brazil*; *[7]Universidade Federal do Ceará, Faculdade de Medicina, Fortaleza, Brazil*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with wide clinical variability. Brazil has vast regional diversity, both from an ethnic and socio-cultural point of view.

Objectives: To map the clinical profile of SLE in Brazil and explore how this distribution is associated with regional disparities.

Methods: This cross-sectional study (GSK Study 207353) evaluated 300 Brazilian patients ≥18 years old with SLE (American College of Rheumatology [ACR] criteria, 1997) who had been under SLE care for ≥1 year. Five SLE reference teaching facilities were selected, one in each of the following Brazilian regions: North (NO), Northeast (NE), Midwest (CO), Southeast (SE), and South (SU). Each region included 60 patients. Clinical and demographic characteristics, and patterns of care were measured through questionnaires completed by physicians or nurses. The SLE Disease Activity Index (SLEDAI) score described disease activity and the Systemic Lupus International Collaborating Clinics/ACR Damage Index (SDI) described damage accrual. To assess the potential association between regional disparities and clinical outcomes, a hospitalisation profile was described. A bootstrapping approach of logistic regression was used to explore potential factors associated with hospitalisation.

Results: Overall, 92.3% of patients were female, with a mean (standard deviation; SD) age of 41.8 (12.7) years and a mean (SD) disease duration of 11.8 (7.9) years. Overall, 161 (53.7%) patients were of Latino origin; in the NO this proportion was 88%. White patients predominated in the SU (58.3%); and black patients in the SE (31.7%). The mean (SD) number of years of schooling was 11.3 (4.6), and was highest in the NO (14.2 [3.6]) and lowest in the SU (9.0 [4.0]; p<0.001). With regard to the distribution of the SLE clinical profile according to ACR criteria, arthritis was found in 221 patients and predominated in all regions (mean 73.7%), with a lower prevalence in the CO (40%; p<0.001; Figure 1A). The mean (SD) SLEDAI score was 4.33 (5.39) at the time of interview. The main contributing factors to disease activity, according to SLEDAI, were complement consumption (18%), arthritis (15.3%), and alopecia (15%). The SDI scale was scored for cataracts (15%), proteinuria (8.7%), and thrombosis (7.3%). Among the associated comorbidities, hypertension was predominant in the NO (35%; p=0.001). Smoking predominated in the SU (23%; p<0.001); obesity (27%; p=0.059) and dyslipidemia (35%; p=0.023), in the SE. Regarding patterns of care (Figure 1B), antimalarials were most frequently prescribed in the SE (88.3%) and the SU (91.7%). Corticosteroids prevailed in the NO (96.7%). The mean (SD) time between home and care facility was 4.5 (12.6) hours. Patients in the NO reported the longest transport time to reach the care facility (11.5 [25.4] hours; p<0.001). The hospitalisation rate during the study period was 21.3% across all regions, with no statistical difference between centres (p=0.651). Reasons for

SLEDAI-2K at baseline	Ultrasound Abnormalities at Baseline					Test statistics for any ultrasound abnormality			
	GS joints	PD joints	GS tendons	PD tendons	Any abnormality	Sensitivity	Specificity	PPV	NPV
	n/N (%)	n/N (%)	n/N (%)	n/N (%)	n/N (%)	% (95% CI)	% (95% CI)	% (95% CI)	% (95% CI)
All patients (n=133)	77/133 (58)	33/133 (25)	36/133 (27)	27/106 (20)	83/133 (62)	-	-	-	-
MSK SLEDAI = No (n=55)	20/55 (36)	2/55 (4)	9/55 (16)	3/55 (6)	22/55 (40)	-	-	-	-
MSK SLEDAI = Yes (n=78)	57/78 (73)	31/78 (40)	27/78 (35)	24/78 (31)	61/78 (78)	73 (62, 82)[b]	66 (51, 78)[b]	78 (70, 84)[b]	60 (49, 69)[b]
-Due to swelling (n=57)	48/57 (84)	28/57 (49)	21/57 (37)	19/57 (33)	51/57 (90)	61 (50, 71)[c]	88 (75, 95)[c]	89 (79, 94)[c]	57 (50, 64)[c]
-Without swelling (n=21)[a]	9/21 (43)	3/21 (14)	6/21 (29)	5/21 (24)	10/21 (48)	31 (16, 50)[d]	75 (60, 87)[d]	48 (31, 67)[d]	60 (45, 68)[d]

hospitalisation included disease activity (36 [12%]), infection (19 [6.3%]), surgery (10 [3.3%]), and management of clinical morbidities (6 [2.0%]). Hospitalisation was associated with ethnicity (p<0.016), occupational status (p<0.001), age (p=0.02), and the use of hydroxychloroquine (HCQ) or chloroquine (CQ; p<0.001).

Conclusion: This nationwide study highlights ethnic, social, and patterns-of-care disparities among Brazilian patients with SLE. The modelling shows evidence that such disparities contribute to the divergent clinical spectrum observed in Brazil.

POS0748 EASY-BILAG: A NEW TOOL FOR FASTER AND MORE ACCURATE RECORDING OF BILAG-2004 DISEASE ACTIVITY IN SLE

L. M. Carter[1], C. Gordon[2], C. S. Yee[3], I. N. Bruce[4], D. Isenberg[5], S. Skeoch[6], E. Vital[1]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[2]University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom*; *[3]Department of Rheumatology, Doncaster and Bassetlaw NHS Foundation Trust, Doncaster, United Kingdom*; *[4]University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom*; *[5]University College London, Centre for Rheumatology, London, United Kingdom*; *[6]Department of Rheumatology, Royal National Hospital For Rheumatic Diseases, Bath, United Kingdom*

Background: BILAG-2004 index is an important disease activity instrument for SLE which is widely used in clinical trials and in treatment commissioning. It is more comprehensive and responsive than SLEDAI. However, BILAG-2004 may be difficult or time-consuming to complete during routine clinic visits. To derive the eventual scores from A (highly active) to E (no current or prior disease involvement) for each of the 9 organ domains, the current BILAG-2004 relies on a separate index form, glossary and scoring algorithm.

Objectives: The Easy-BILAG project aimed to develop and validate a simplified tool for scoring the original BILAG-2004 index more rapidly and accurately in routine clinical care.

Methods: Data from the UK BILAG-Biologics Registry (BILAG-BR) were used to measure the frequency with which the 97 BILAG-2004 clinical items occurred in a population with active SLE. These data and a series of prototypes were used to draft a new tool for simplified scoring of the BILAG-2004 index - the "Easy-BILAG". After preliminary testing, a validation study was conducted to test accuracy, speed and usability of Easy-BILAG compared to the standard BILAG-2004 template. Rheumatologists and specialty trainees from centres around the UK were invited to score BILAG-2004 disease activity in a timed workbook of 10 exemplar case vignettes, using either Easy-BILAG or standard BILAG-2004 reference documents. The case vignettes tested clinicians in scoring both frequent and uncommon SLE manifestations as well as longitudinal scoring of items in flare and remission. All workbooks contained an overview and detailed instructions on BILAG-2004.

Results: Among 2395 submissions to BILAG-BR the 6 most frequently scored clinical items were each present in more than 20% of records; arthralgia (72%), mild skin eruption (47%), moderate arthritis (38%), mild mucosal ulceration (34%), mild alopecia (34%), pleurisy / pericarditis (22%). Twenty-five items were active in less than 1% of assessments. Easy-BILAG was therefore designed to enhance the visibility of the most frequently scored items and capture all clinical items scoring >5% in a rapid single-page assessment. All remaining, less common items, are scored, only when necessary, on a second page. Easy-BILAG incorporates an abridged glossary definition immediately adjacent to clinical each item. A new colour-blindness compatible, colour-coding system directs clinicians instantly to the overall A-E score for each domain.

In the validation exercise, clinicians were asked to identify active disease and assign BILAG-2004 scores, from A-E, for all 9 organ domains in a workbook of 10 case vignettes. Twenty clinicians, with a range of prior experience, have so far participated. Among clinicians working with the standard BILAG-2004 reference documents (n = 11), scoring 10 case vignettes took 90 +/- 9 minutes (mean +/- SEM) to complete. Clinicians using Easy-BILAG (n = 9) completed the exercise significantly faster at 66 +/- 8 minutes (p = 0.05). Crucially, Easy-BILAG yielded significantly higher percentage accuracy (mean +/- SEM) at 95.3 +/- 0.8 % across all domains, as compared with 81.8 +/- 6.2 % achieved by clinicians using standard BILAG-2004 documentation (p = 0.05). The difference was most apparent when specifically comparing accuracy across domains where the case exercises registered active disease. Here, Easy-BILAG showed no decline in accuracy at 94.9 +/- 1.0 % compared 75.7 +/- 5.3% achieved with standard BILAG-2004 documents (p = 0.005). In a usability survey, all (9/9) clinicians testing the Easy-BILAG template rated it as intuitive and simple to navigate.

Conclusion: Easy-BILAG facilitates more rapid and accurate scoring of BILAG-2004 and provides a format which is amenable to use in routine clinical practice. Following completion of validation, it will be made widely available to clinicians.

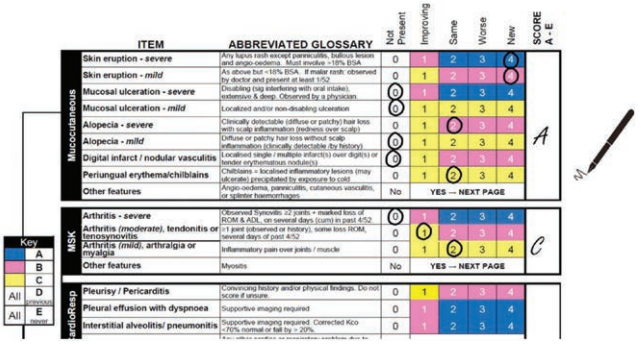

Figure 1. Illustration of the Easy-BILAG template shows format, colour scheme and method of scoring highest prevalence items mucocutaneous and musculoskeletal domain.

POS0749 ASSOCIATION BETWEEN IMMUNE-SEROLOGICAL PROFILE AND PULMONARY MANIFESTATIONS IN COLOMBIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (LES)

S. Herrera[1], J. C. Diaz-Coronado[1,2], S. Monsalve[2], S. Guerra-Zarama[2], M. F. Saavedra Chacón[2], J. Barbosa[2], J. D. Serna Giraldo[2], J. D. Lopez[2], J. M. Gutiérrez[2], T. Vega[2], D. Orozco[2], D. Ocampo[2], N. Zuluaga[2], D. Hernandez-Parra[1], D. Rojas-Gualdrón[3], R. Pineda.Tamayo[1]. *[1]Artmedica, Clinical Information Group, Medellín, Colombia*; *[2]CES University, Department of Internal Medicine, Medellín, Colombia*; *[3]CES University, Facultad de Medicina, Medellín, Colombia*

Background: Pulmonary involvement is common in Systemic Lupus Erythematosus (SLE) patients with varying degrees of parenchymal, vascular, and pleural compromise. In GLADEL, pulmonary involvement was reported in 28.4% of the cohort, but its occurrence ranges between 30-90% due to diversity in populations and the methods used to define it.

Objectives: To describe the immune-serological profile of a Colombian cohort of SLE patients and to establish its association with pulmonary manifestations.

Methods: Retrospective analysis of observational data from the follow-up of a cohort of adult patients with SLE. We included 559 patients that fulfilled the SLICC 2012 classification criteria with at least 6 months of disease history and being treated in a rheumatology specialized medical center between 2015 and 2018. The immuno-serological profile was characterized, and pulmonary involvement was monitored for 1 year. Diagnosis of pulmonary involvement was performed with the rheumatologist report in the clinical chart. Prevalence of pulmonary manifestations and immune-serological profile was determined, and logistic regression was performed afterward adjusted by age, sex, and level of education to establish the association between pulmonary manifestations and a positive auto-antibodies profile.

Results: The median age of the cohort was 45 years, 96.5% were female. Pulmonary involvement was documented in 113 patients (20.5%) at the beginning of the study. Their frequency was: pleuritis (14.3%), lupus pneumonitis (3.6%), pulmonary hypertension (3.2%), interstitial lung disease (ILD) (2.3%), pulmonary embolism (2.3%), lung fibrosis (2.14%), alveolar hemorrhage (1.4%), shrinking lung (0.2%). At 1 year of follow up. there were no statistically significant differences in the frequency of pulmonary manifestations. As for the immune-serological profile, there were positive ANA in 92%, anti-dsDNA in 53.1%, anti-B2GP IgM 15.2%, anti- B2GP IgG in 17.2%, and ENA in 97.2%; as for the ENA 41.7% had positive anti-RNP, 40.2% anti-Ro, 36.4% anti-SM and 16.5% anti-La. Low complement levels was characterized as follows: C3 53.1% and C4 29.2%. In the logistic regression adjusted by age, sex and level of education, there was an association between anti-SM and pulmonary manifestations with an adjusted OR of 1.85; 95% CI 1.13-3.01.

Conclusion: An association between anti-SM positivity and pleuro-pulmonary manifestations was found. In other cohorts with a greater size, anti-La and anti-RNP have been associated with pulmonary involvement (OR 2.51; 95% CI 1.39-4.57 and OR 1.32; 95% CI 1-1.75 respectively). Anti-RNP positivity has been associated in particular with ILD, pulmonary hypertension and shrinking lung. Although these manifestations prevalence was similar in our cohort, an association with this antibody was not found (OR 1.01, 95% CI: 0.2-4.9). This could be explained by the smaller sample size. As for anti-La positivity, its prevalence in our cohort was less than what was found in the GLADEL cohort (16.5% vs 24.3% respectively). It is possible that this could explain the poor association between anti-La positivity with the presence of pulmonary manifestations in our study compared with those of the GLADEL cohort. There are data that indicates that anti-SM and anti-RNP simultaneous positivity is related mainly to pleuritis OR 1.98 (95% CI: 1.31-3); and this kind of involvement was found to be more frequent in our study. Our results suggest an association between positive anti-SM and pulmonary manifestations in Colombian patients with SLE, pleuritis in particular.

POS0750 THE CHARACTERISTICS OF SYSTEMIC LUPUS ERYTHEMATOSUS WHO HAVE CONSTITUTIONAL SYMPTOMS AND LYMPHADENOPATHY

Y. Erez[1], S. Gulle[1], A. Karakas[1], R. Bekis[2], A. Balcı[3], M. Birlik[1], G. Can[1], F. Onen[1], İ. Sari[1]. *[1]Dokuz Eylul University School of Medicine, Division of Rheumatology, İzmïr,Turkey*; *[2]Dokuz Eylul University School of Medicine, Division of Nuclear Medicine, İzmïr,Turkey*; *[3]Dokuz Eylul University School of Medicine, Division of Radiology, İzmïr,Turkey*

Background: Systemic lupus erythematosus (SLE) is the prototype of systemic autoimmune diseases. It may affect any organ system and may present with a variety of clinical symptoms. Lymphadenopathy (LAP) is a nonspecific finding of SLE and often associated to the active disease state. LAP associated SLE pose a significant diagnostic challenge especially in the presence of constitutional symptoms.

Objectives: In this retrospective cohort study, we evaluated the clinical and imaging characteristics of SLE patients who presented with LAP and constitutional symptoms.

Methods: SLE Patients with lymphadenopathy who had constitutional symptoms were reviewed retrospectively. The characteristics of the patients such as age, sex, disease duration, clinical features, and laboratory tests including autoantibodies against ANA, dsDNA and ENA were recorded. Imaging findings such as positron emission tomography–computed tomography (PET/CT), thoracal or abdominal CT or diagnostic lymph node biopsy were identified.

Results: There were 28 patients in this study. The mean age at the time of LAP was 38.9±15.2 years, 22 (78.6%) were female. All patients were fulfilling SLICC 2012 classification criteria for SLE. LAP was the presenting feature of SLE in 15 (53.6%) patients. The most common clinical features associated with LAP were arthritis (42.8%), fever (35.7%), acute lupus rash (32.1%) and serositis (28.5%). There were 11 (39.2%) who had significant proteinuria and 4 (14.3%) had class III or IV renal histology. Anti-phospholipid antibodies were present in nearly one-third of the patients and 12 of them had venous or arterial thrombosis or pregnancy co-morbidity. Cervical LAP was present in 57.1%, axillary LAP in 82.1% and inguinal in 36%. On CT, the prevalence of thoracal and abdominal LAP and hepatomegaly and splenomegaly were 61.5%, 37,5%, 40% and 16% respectively. The pericardial and pleural effusion and intra-abdominal free fluid were 19.2%, 30.8% and 10.2% respectively. There were 19 (67.8%) patients who underwent PET/CT imaging and all were reported as reactive LAP. In terms of SUV max 7 (36.8%) of them had a threshold ≥2.5. 17 (60.7%) patients required lymph node biopsy; 2 did not include lymphoid tissue, 4 (30.7%) with atypical lymphoid hyperplasia suggestive of viral infection and remaining were reactive lymphoid hyperplasia. Autoantibody testing showed that anti-dsDNA was positive in 66.7% and the most common anti-ENAs were anti-nucleosome (35.7%) and anti-Sm-RNP (35.7%) followed by anti-SSA (25%), anti-ribosomal P (17.9%) and anti-histone (14%). The clinical and laboratory features of the clinical and laboratory features of the group is summarized in Table 1.

Table 1. Data at the time of LAP

Age, years	38.9±15.2
Disease duration, months	3 (2- 300)
SLE-DAI, median (min-max)	9 (2-30)
Sex, female n(%)	22 (78.6)
Clinical features	**n (%)**
Acute cutaneous	9 (32.1)
Arthritis	12 (42.8)
Fever	10 (35.7)
Other constitutional symptoms	18 (64.2)
Serositis	8 (28.5)
Renal involvement	11 (39.2)
Neurologic involvement	1 (3.6)
Leucopenia	7 (25.0)
Trombositopenia	5 (17.8)
Hemolitic anemia	7 (25.0)
ANA (+)>1/320	28 (100)
Anti-dsDNA (+)	18 (66.7)
Anti-Sm(+)	5 (17.9)
Anti-phospholipid antibody (+)	9 (32.1)
Low complement	16 (88.5)

Conclusion: We showed that SLE patients who had constitutional findings and LAP could be the presenting feature and may confer a significant diagnostic challenge in which the patients might require invasive procedures and advanced imaging modalities. PET/CT revealed reactive changes in lymph nodes in all patients but lymph node biopsy revealed atypical changes in some patients suggestive of viral infections. On the other hand, LAP patients with constitutional symptoms represents a severe phonotype of the SLE as there were significant renal and thrombotic disease.

Background: Congenital heart block (CHB) is due to placental transfer of maternal anti-Ro/SSA autoantibodies to the fetus. The prevalence of CHB has been estimated as 1-2% in anti-Ro/SSA women while the recurrence rate is 16-19% (1). This condition is associated with a high rate of fetal/neonatal mortality and most of the cases requires pacemaker (PM) pacing. Given the rarity of CHB, limited data are available regarding the long-term follow-up of the offspring other than the cardiovascular complications.

Objectives: The results of the Italian Registry of the autoimmune congenital heart block were recently described (2). A peculiarity of this cohort was that most of the mothers had an established diagnosis of systemic autoimmune disease at CHB detection, in contrast with other registries where CHB was mostly incidentally detected in healthy women. Here we report an update, with the preliminary data regarding the long-term outcome of patients with CHB, their unaffected siblings and health controls born from mothers positive for Ro/SSA.

Methods: Data regarding demography, treatment, maternal, neonatal outcome, and follow-up were collected through an online electronic datasheet. A dedicated questionnaire was created with the aim to investigate general health, cardiovascular follow-up, and frequency of autoimmune diseases.

Results: One-hundred and five cases of CHB in 99 patients were included from 1969 to December 2020. CHB was mostly detected in utero (97 cases, 92.3%) with 8 neonatal cases. Third degree CHB occurred in 71 cases (67.6%). Child mortality was observed in 29 (27.6%) cases: 20 in utero, 7 during neonatal period and 2 during childhood. Overall, a PM was implanted in 54 out of the 85 live births (63.5%). Then, our cohort was divided into 2 subgroups: pregnancy that occurred before (N=61) and after 2010 (N=44) with the aim to evaluate possible differences among the subgroups. Whereas mortality, PM, CHB degree were similar, CHB more frequently occurred in the last 10 years among Ro/SSA asymptomatic carriers than in the group of pregnancies before 2010 (53.6% vs 32.8%, p=0.038). Questionnaires from 14 surviving CHB cases, 8 unaffected siblings 12 controls born from mothers Ro/SSA positive were collected. Among CHB cases, 6 were males and 8 females, median age 12 years (range 6-28). All presented a third degree CHB, 10 required a neonatal PM pacing and one had an implantable ECG recorder. PM was substituted at least once in 9 patients, the oldest patient had to change it four times. No dilated cardiomyopathy occurred and most of the patients maintain an annual follow-up. Two cases of autoimmune diseases were registered among CHB cases, one idiopathic juvenile arthritis and one Cogan's vasculitis, both born from mothers with Sjogren Syndrome. Four cases of neurodevelopmental disorders occurred: three cases of learning disabilities (one in each group) and one case of speech disorder in the sibling group. In addition, a CHB case presented a stress disorder linked to frequent hospitalizations.

Conclusion: This registry is an ongoing project aiming at collecting all Italian CHB. Moreover, here we reported the preliminary data concerning the evaluation of long-term follow-up of CHB patients. Our data, even if need to be confirmed in larger cohort, seems reassuring: no differences were reported comparing CHB patients with unaffected siblings or controls.

POS0752 INTERSTITIAL LUNG INVOLVEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS: RELEVANT CLINICAL CHARACTERISTICS. OUR EXPERIENCE IN A THIRD LEVEL HOSPITAL

I. González Fernández[1], C. Moriano[1], E. Diez Álvarez[1], X. E. Larco Rojas[1], A. López Robles[1], M. E. Vallejo Pascual[2], M. T. Perez Sandoval[1]. [1]*Complejo Asistencial Universitario de León, Reumatología, León, Spain*; [2]*Universidad de León, Facultad de CC. EE y Empresariales, León, Spain*

Background: Lung involvement[1] in Systemic Lupus Erythematosus (SLE) is heterogeneous, with the pleura being more frequently affected. Associated diffuse interstitial lung disease (ILD) is rare (3-13%) with difficult diagnosis and therapeutic management.

Objectives: Assess the main clinical-epidemiological characteristics of patients diagnosed with SLE with ILD in a third level hospital and analyze the possible relationship between them.

Methods: Descriptive observational study of patients diagnosed with SLE (SLICC criteria) with ILD in our hospital between 1973 and 2020. The following clinical-epidemiological characteristics were evaluated such as sex, mean age at diagnosis, presence of cardiovascular risk factors (CVRF), smoking, baseline cardiac and respiratory comorbidities, laboratory markers (autoimmunity, CRP and vitamin D), baseline SLEDAI, manifestations of SLE, interstitial pattern on HRCT, correlation with conventional radiology (Rx), respiratory function tests, clinical and physical examination at diagnosis.

Results: 455 patients diagnosed with SLE were included, of whom 20 had ILD (4.4%). 65% were women with a mean age at diagnosis of 63 ± 16.23 years. 30% presented ILD as the first clinical data for the diagnosis of SLE. 30% had jobs with exposure to chemicals. 25% were ex-smokers and 10% were active smokers. 10% had associated CVRF, highlighting HT (35%). 30% had valve disease on echocardiography such as mitral regurgitation (30%) and tricuspid regurgitation (20%). Only 10% had associated bronchopathy. 35% and 25% associated, respectively, pleural serositis and secondary Sjogren's syndrome. Arthritis and skin involvement were documented in 60% for both clinical domains. 40% had SLEDAI> 6.

At the diagnosis of ILD, 90% had symptoms such as dyspnea (75%) and cough (60%). 80% had crackles on examination. 85% had alterations in the X-ray and 100% in the CT scan with the NINE patterns as the main one (65%) with progression at 2 years despite treatment in 25%. Spirometry differentiated an obstructive pattern (25%), restrictive (20%) and normal (55%) with a tendency to stability at one year (40%) with the prescribed treatment. 90% had a decrease in diffusion, the majority being mild (67%). Analytically, 67% had elevated levels of CRP and hypovitaminosis D; 40% elevated DNA titers, 50% hypocomplementemia and 60% ENAS positive, highlighting Ro (45%); La (15%) and RNP (15%). Leukopenia and thrombopenia (30% and 10% respectively) were also observed.

In our study, we did not find any statistical significance between the variables analyzed, due to the small sample size.

Conclusion: 1)ILD is an infrequent manifestation in SLE, it usually associates respiratory symptoms and pulmonary functional repercussions with the diagnosis. The most characteristic radiological pattern is the NINE.

2)In our study, ILD was more frequently associated with women and joint or skin symptoms, as well as with data on immunological activity, without statistical significance.

POS0753 SUBSPECIALTY LUPUS CLINIC CARE IS ASSOCIATED WITH HIGHER QUALITY FOR PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Sreedharan[1,2], A. Hoi[1,2], N. Li[2], G. Littlejohn[2], R. Buchanan[3], M. Nikpour[4], E. F. Morand[1,2], V. Golder[1,2]. [1]*Monash Health, Department of Rheumatology, Melbourne, Australia*; [2]*Monash University, School of Clinical Sciences, Melbourne, Australia*; [3]*Austin Hospital, Department of Rheumatology, Heidelberg, Australia*; [4]*St. Vincent's Hospital Melbourne, Department of Rheumatology, Fitzroy, Australia*

Background: Healthcare quality for systemic lupus erythematosus (SLE) is a modifiable target for improving patient outcomes. Disease-specific subspecialty clinics offer experienced healthcare professionals, collaborative multidisciplinary teams and streamlined care processes. A single centre study in the USA has suggested superior performance of the subspecialty lupus clinic in the provision of quality care (1), but this has not been examined outside the USA where access to care may be influential.

Objectives: To assess the quality of SLE care provided in a subspecialty lupus clinic compared with hospital general rheumatology and private rheumatology clinics in a non-US, universal healthcare setting.

Methods: Lupus patients (n = 258) were recruited in 2016 from various clinic settings in Australia, including a subspecialty lupus clinic (n = 147), two hospital general rheumatology clinics (n = 56) and two private clinics (n = 55). Quality of care was assessed using 31 validated SLE quality indicators (QI) encompassing diagnostic work-up, disease and comorbidities assessment, drug monitoring, preventative care and reproductive health (2,3). Data were collected from medical records and patient questionnaires. Overall and individual QI performance was calculated and compared between the three clinic settings, and multivariable regression was performed to adjust for sociodemographic, disease and healthcare factors.

Results: Median [IQR] overall performance on eligible QIs was higher in the lupus clinic (66.7% [16.9]) than the hospital general rheumatology (52.7% [10.6]) and private rheumatology (50.00% [18.0]) clinics ($p < 0.01$), and remained significant with multivariable adjustment. This trend was still observed when the overall performance was reassessed to include patient self-report (73.1% [14.8] vs 68.1% [11.5] vs 63.2% [13.4], $p < 0.01$). This difference may be due to consistent formal assessments of disease activity (100% vs 0% vs 0%, $p < 0.01$) and disease damage (95.9% vs 0% vs 0%, $p < 0.01$) at the lupus clinic. Performance was high across all clinic settings for diagnostic work-up, comorbidity assessment, drug monitoring, prednisolone taper, osteoporosis management, lupus nephritis and pregnancy quality indicators. However, the lupus clinic significantly outperformed the other clinic settings on eligible quality indicators for new medication counselling, pre-immunosuppression hepatitis and tuberculosis screening, drug toxicity assessment, sun avoidance education, vaccinations, cardiovascular risk factor assessment and contraception counselling.

Conclusion: SLE patients managed in a subspecialty lupus clinic received higher overall quality of care when compared to hospital general rheumatology and private rheumatology clinics. Regular assessment of QI performance can improve quality of care for patients in all clinic settings.

Background: Patients with systemic lupus erythematosus (SLE) have a substantially increased risk of venous thromboembolism (VTE). An individual VTE risk assessment is important to ensure that all patients are assessed and given adequate thromboprophylaxis.

Objectives: We conducted this study to develop a risk score for VTE in patients with SLE.

Methods: Patients with SLE who participated in the Chinese SLE Treatment and Research group were enrolled in this study. Patient baseline information and clinical laboratory indicators were obtained, and VTE events were recorded every 3-6 months during follow-up visits. The risk prediction model was created and internally validated using the bootstrap methods, and a scoring system was established (Figure 1).

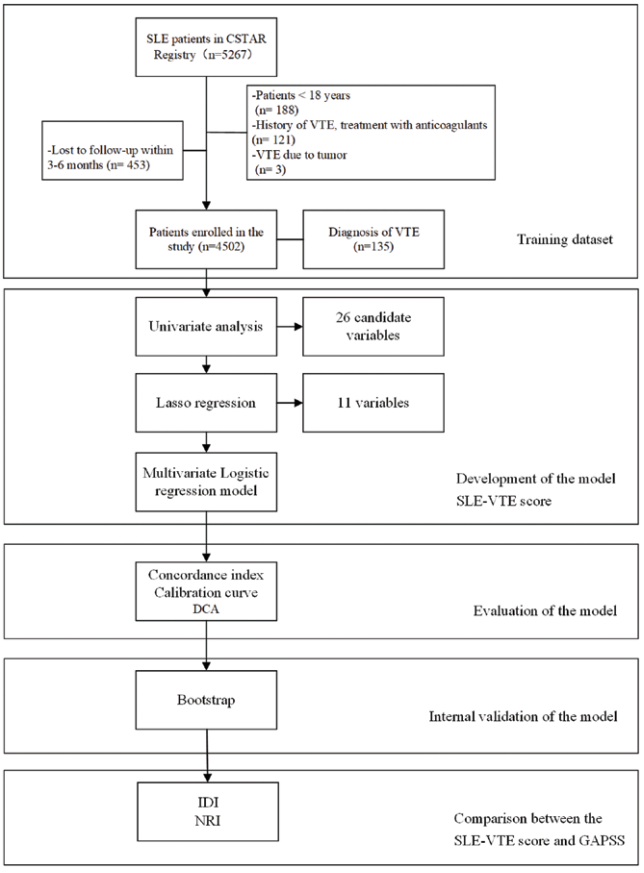

Figure 1. Flow chart of study design.

Results: Out of 4,502 patients included in this study, 135 had a VTE event. After univariate analysis and Lasso regression, the following 11 variables were identified and included in the risk prediction model: male sex, age, BMI ≥25 kg/m2, hyperlipidemia, hypoalbuminemia, hsCRP>3 mg/L, renal involvement, nervous system involvement, anti-β2-glycoprotein I antibody positivity, lupus anticoagulant positivity, and no use of hydroxychloroquine. The AUC for the SLE-VTE score (Table 1) was 0.947 (95% CI, 0.9249-0.9694). The SLE-VTE score's sensitivity and specificity with the optimal cutoff value of 13 were 0.919 and 0.881, respectively. The SLE-VTE score was superior to the GAPSS system in predicting the risk of VTE in patients with SLE (AUC= 0.947 vs. 0.680, P< 0.001; integrated discrimination improvement (IDI)= 0.6652, P< 0.001; net reclassification improvement (NRI)= 0.6652, P< 0.001).

Table 1. Final multivariable analysis for venous thromboembolism risk in patients with SLE

	β coefficients	Odds ratio* (95% CI)	P-value	Points in scoring system
Male	0.621	1.86 (0.953-3.503)	0.061	2
Age at study entry(≥50)	0.837	2.308 (1.339-3.915)	**0.002**	3
BMI02(kg/m^2	0.792	2.209 (1.333-3.627)	**0.002**	3
Hyperlipemia	0.838	2.313 (1.246-4.166)	**0.006**	3
Hypoalbuminemia	2.163	8.697 (5.185-14.794)	**< 0.001**	7
hsCRP>3 mg/L	1.452	4.272 (2.618-6.968)	**< 0.001**	5
Anti β2GPI	1.013	2.754 (1.543-4.853)	**0.001**	3
LA	1.559	4.752 (2.799-8.072)	**< 0.001**	5
Nervous system	2.382	10.832 (6.163-18.998)	**< 0.001**	8
Lupus nephritis	0.835	2.305 (1.414-3.756)	**0.001**	3
No use of hydroxychloroquine	1.771	5.876 (3.722-9.401)	**< 0.001**	6

BMI: body mass index; hsCRP: Hypersensitive c-reactive protein; ACL: anticardiolipin, antiβ2GPI: anti-β2-glycoprotein I, LA: lupus anticoagulantm;Values in bold are statistically significant at p <0.05.

Conclusion: Various factors are related to the occurrence of VTE in patients with SLE. The proposed SLE-VTE risk score can accurately predict the risk of VTE and help identify SLE patients with a high risk of VTE who may benefit from thromboprophylaxis.

POS0755 PREVALENCE AND RELEVANCE OF ANTIBODIES AGAINST CITRULLINATED ALPHA ENOLASE (ANTI-CEP1) IN CONNECTIVE TISSUE DISEASES

A. Alunno[1], O. Bistoni[1], F. Carubbi[2], M. Antonucci[1], S. Calvacchi[1], E. Bartoloni Bocci[1], M. Zen[3], A. Ghirardello[3], R. Depascale[3], A. Doria[3], R. Gerli[1]. *[1]Rheumatology Unit, University of Perugia, Department of Medicine, Perugia, Italy; [2]Internal Medicine and Nephrology Unit, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy; [3]Division of Rheumatology, University of Padua, Department of Medicine DIMED, Padua, Italy*

Background: Anti-citrullinated alpha enolase antibodies have been investigated in rheumatoid arthritis and associated with bone erosion and interstitial lung disease but little is known about their prevalence and role in connective tissue diseases (CTDs).

Objectives: The aim of this study was to investigate the prevalence and relevance of anti-CEP1 antibodies in CTDs.

Methods: Serum samples from five independent patient cohorts were assessed: 1) established (est) primary Sjogren's syndrome (pSS) N=78, 2) est-systemic lupus erythematosus (SLE) N=52, 3) est-systemic sclerosis (SSc) N=71, 4) pSS at disease onset N=30, 5) SLE at disease onset N=46 (cohorts 4 and 5 had at least 3 years of follow-up). Samples from ninety sex and age matched healthy donors (HD) and 200 patients with est-RA (disease controls) were also tested. Anti-CEP1 IgG antibodies were measured with a commercially available ELISA kit (Euroimmun, Luebeck, Germany).

Results: Anti-CEP1 titer was significantly higher in est-pSS, est-SLE and est-SSc compared to HD, significantly lower in est-pSS and est-SSc compared to est-RA and comparable in est-SLE versus est-RA. We divided patients in every CTD group based on whether their anti-CEP1 titer was below or above the 25th, 50th and 75th percentile. In est-SLE anti-CEP1 values over the 25th percentile were associated with articular involvement (odds ratio, OR (95% confidence interval, CI)=11.5; 1.9-70.6, p=0.008). In est-pSS, no relationship between anti-CEP1>25th percentile and articular involvement was found but rather an association with rheumatoid factor positivity (OR (95% CI)=4.8, 1.6-14.1, p=0.004) and salivary gland swelling (OR (95% CI)=6.2, 1.3-29.1, p=0.021). In est-SSc no difference could be detected across the 3 groups. Anti-CEP-1 titers in pSS and SLE at onset did not differ from each other, were comparable also to those of HD and significantly lower than those of est-pSS, est-SLE and est-RA patients (all p<0.0001).). Of interest, we could retrieve a serum sample collected at the time of diagnosis for 5 patients from the cohort of established pSS and we observed that anti-CEP1 titers were significantly lower at pSS onset than during follow up (at least 12 months after the diagnosis, p=0.0024). No difference was observed in the clinical presentation at disease onset according to different anti-CEP1 titer and they did not predict the development of new clinical manifestations during follow-up.

Conclusion: Anti-CEP-1 antibodies can be detected in CTDs at different title during the disease course and may increase overtime, at least in pSS. Although anti-CEP1 antibodies are associated with specific clinical manifestation in est-CTDs, such as articular involvement in est-SLE, they seem to lack a predictive value for future manifestations when measured at disease onset.

POS0756 HOW HAS OUR MANAGEMENT OF SLE CHANGED OVER THE LAST THREE DECADES? REAL LIFE DATA FROM A MONOCENTRIC COHORT

V. Signorini[1], C. Tani[2], E. Elefante[2], D. Zucchi[2], C. Stagnaro[2], F. Ferro[2], L. Carli[2], M. Mosca[2]. *[1]University of Pisa, Rheumatology Unit, Pisa, Italy; [2]University of Pisa, Rheumatology Unit, Pisa, Italy*

Background: Over the last decades new therapies have been approved and new treatment strategies have been proposed in the treatment of SLE. In particular, recently, EULAR recommendations[1] and the Treat to Target[2] approach established a new paradigm for the treatment of SLE based on the early introduction of immunosuppressive treatment and glucocorticoids (GC) minimization.

Objectives: to evaluate changes in therapeutic approach and outcomes over the last three decades in a monocentric cohort of SLE patients.
Methods: This is a retrospective analysis of prospectively collected data from a monocentric cohort of patients with SLE with disease diagnosis between 1990 and 2020. Based on the year of diagnosis, patients were divided in three groups, each of them corresponding to a decade: group 1: decade 1990-1999; group 2: decade 2000-2009; group 3: decade 2010-2020. For each patient, epidemiological and demographic characteristics, cumulative organ involvement and serology, previous and ongoing therapies, comorbidities were collected and compared among the 3 groups. Organ damage was evaluated by the SLICC-DI (SDI)[3] at 1 and 5 years from diagnosis, as comorbidities we considered hypertension, diabetes, osteoporosis and cardiovascular (CV) events occurred during the follow-up.
Results: A total of 262 SLE patients were enrolled in the study (97% Caucasian, 90.5% females): 69 patients in group 1, 100 in group 2 and 93 in group 3. Demographic and clinical characteristics of whole cohort and of the three groups are summarized in table 1. Differences in therapies during the first year from diagnosis among the groups are summarized in table 1. In group 3 the use of Micophenolate Mofetil was significantly more common with respect to the group 1 (25% *vs* 1.4%, p= 0.001) and similar to group 2 (25% vs 25.5%, p=ns); on the contrary, in group 3, Azathioprine (AZA) and Cyclosporine (Cya) were less used (13.2% *vs* 27.5%, p=0.003 and 3.3% vs 14.3%, p= 0.019 respectively). As Cyclophosphamide (CYC) is concerned, it was used with the same frequency in the three decades, but in group 1, the total dose of CYC was significantly higher than second and third group (4.8 g *vs* 2.3 and 0.9, p=0.02 and p=0.001 respectively). In group 2 and 3, during the first year of disease, biological drugs (Rituximab or Belimumab) have been used more frequently (2% and 2.2% *vs* 0%, p=0.04). Any differences have not been showed for GC among the groups. However, in group 3 a significantly higher proportion of patients stopped GC therapy within 5 years from diagnosis (34.5% *vs* 8.8% and 12.5%, p=0.001) and in the same group the duration of GC therapy was significantly shorter with respect to previous two decades (3.1 years *vs* 16.8 and 10.5 respectively, p=0.001). As regard damage accrual, at 1 and 5 years from diagnosis, no significant differences among groups were observed; however, hypertension resulted significantly less common in group 3 (10% vs 26% and 37.3%, p=0.001), even adjusting for age (OR=0.2); less CV events were recorded in group 3, but significance is lost adjusting for age.

Table 1.

	Whole cohort	Group 1	Group 2	Group 3	p
Patients (n)	262	69	100	93	
Caucasian (%)	97%	99%	98%	94.6%.	n.s.
Females (%)	90.5%	94.2%	95%	92.5%	n.s.
Median age at	29	27	28.5	34	**0.001**
diagnosis IQR)	(20-36)	(20-32)	(20-36)	(23-44)	
Cumulative organ involvement					
Renal	48.1%	52.2%	57%	35.5%	**0.007**
Articular	74.4%	75.3%	66%	82.8%	n.s.
Serositic	19.5%	20.3%	22%	16.1%	n.s.
Neuropsychiatric	8%	11.6%	6%	7.5%	n.s.
Cutaneous	63%	70%	60%	61.3%	n.s.
Hematological	58.4%	51.5%	61%	61.3%	n.s.
Therapies 1st year					
AZA	17.2%	8.7%	27.5%	13.2%	**0.003**
MMF	18.7%	1.4%	25.5%	25.3%	**0.001**
CYC	22.5%	21.7%	27%	17%	n.s.
Cya	9.9%	13%	14.3%	3.3	**0.019**
Biologicals	1.5%	0%	2%	2.2%	n.s

Conclusion: These data show that new therapies and new treatment strategies have actually been implemented in clinical practice over the past 30 years; further studies with a longer follow-up are necessary to appreciate the impact of these advancement on clinical outcomes.

POS0757

SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) DIAGNOSED DURING HOSPITALIZATION: CLINICAL PHENOTYPE AND PERFORMANCE OF THE SLE RISK PROBABILITY INDEX (SLERPI)

N. Kapsala[1], D. Nikolopoulos[1], S. Flouda[1], K. Chavatza[1], A. Pieta[1], A. Grivas[1], A. Ntourou[1], K. Togia[1], P. Rapsomaniki[1], T. Gerogianni[1], D. Tseronis[1], M. Aggelakos[1], T. Karageorgas[1], P. Katsimpri[1], G. Bertsias[2], A. Fanouriakis[1,3], D. Boumpas[1]. *[1]"Attikon" University Hospital of Athens, Rheumatology and Clinical Immunology, Medical School, National and Kapodistrian University of Athens, Athens, Greece*; *[2]University of Crete, Rheumatology, Clinical Immunology and Allergy, Heraklion, Greece*; *[3]"Asklepieion" General Hospital, Department of Rheumatology, Voula, Athens, Greece*

Background: Systemic Lupus Erythematosus (SLE) can first present with severe or critical disease leading to hospitalization. Prompt recognition of the disease in hospitalized patients may lead to early institution of treatment and improve outcomes. We have recently developed a clinician-friendly algorithm for SLE diagnosis based on classical clinical and serological SLE features [SLE Risk Probability Index (SLERPI)][1].
Objectives: To determine the clinical phenotype of SLE patients first diagnosed during hospitalization, the interval between hospitalization and SLE diagnosis and the potential impact of SLERPI on early diagnosis.
Methods: Mixed prospective (from June 2020 to January 2021) and retrospective study of SLE patients from "Attikon" cohort (n=820)[2]. Clinical phenotype was divided into 10 core domains (neuropsychiatric, thrombosis, nephritis, serosal, haematologic, pulmonary, cardiovascular, gastrointestinal, skin-joints, other). Chart review and patient interview was performed to assess the lag time between 1) the onset of symptoms and 2) the hospitalization and the final diagnosis. Demographic and clinical characteristics, SLERPI and SLICC damage index were recorded for each patient at the time of diagnosis. SLE diagnosis was based on at least one of the three existing classification criteria.
Results: Out of 820 SLE patients, 202 (24.6%) diagnosed during hospitalization were included. Among them, 185 patients (91.5%) were hospitalized because of a lupus related feature, while in the remaining 17 SLE patients, hospitalization was due to non-lupus related manifestations. The most common lupus-related clinical phenotype leading to hospital admission was neuropsychiatric lupus (n=51, 25.2%) with cerebrovascular events constituting the dominant clinical syndrome (n=8/51). Thrombotic events (n=32, 15.8%), mainly pulmonary embolism (n=20/32), cytopenias (n=32, 15.8%), lupus nephritis (n=30, 14.8%), skin-joint disease (n=26, 12.8%) and serositis (n=24, 11.8%) were also common as dominant manifestations. Pulmonary disease (n=16, 7.9%), heart disease (n= 4, 1.9%) and gastrointestinal disease (n=2, 0.9%) were less common. On admission, 11.3% of patients (n=23) had symptoms from at least 2 clinical domains as defined. Most patients (93.5%) had multisystem disease while only 6.5% had organ-dominant disease. Early diagnosis (within 3 months from hospitalization) was established in 86.6% while 27 patients had their SLE diagnosis more than 3 months from hospitalization. The mean lag time between the hospitalization and the diagnosis was approximately 14 months (SD 19.9). Overall, the mean interval between the onset of symptoms and the diagnosis was 48.2 months (SD 73.2). Importantly, a SLERPI >7 (suggesting probable SLE) at hospitalization was present in 92.5% of SLE patients with delayed diagnosis.
Conclusion: One out of four SLE patients first present with moderate to severe disease necessitating hospitalization, while in approximately 15% of such patients, diagnosis is initially missed. Application of the SLERPI may facilitate early SLE diagnosis.

POS0758

DOES EXPERIENCE IN SYSTEMIC LUPUS ERYTHEMATOSUS INFLUENCE THE PHYSICIAN GLOBAL ASSESSMENT SCORING? A CROSS-SECTIONAL STUDY ON TWO EUROPEAN COHORTS

E. Chessa[1], M. Piga[1], F. Sagez[2], R. Felten[2], A. Floris[1], A. Cauli[1], L. Arnaud[2]. *[1]Rheumatology Unit, AOU and University of Cagliari, Department of Medical Sciences and Public Health, Cagliari, Italy*; *[2]Hôpitaux Universitaires de Strasbourg, Université de Strasbourg, Service de Rhumatologie, Centre National de Référence des Maladies Systemiques et Autoimmunes Rares Est Sud-Ouest (RESO), Strasbourg, France*

Background: The Physician Global Assessment (PGA) is an outcome instrument based on physician judgement of disease activity in patients with Systemic Lupus Erythematosus (SLE). Due to the subjectivity of the score and lack of standardization, the PGA could represent a source of heterogeneity, because the same manifestations could be rated differently by physicians with different backgrounds (1).

Objectives: The purpose of this study was to evaluate the inter-rater reliability of PGA between a rheumatology trainee and rheumatologists expert in SLE from 2 european countries.

Methods: SLE patients classified according to SLICC 2012 criteria were enrolled between May 2019 and December 2019 during a SLEuro traineeship program. Demographic, clinical (SLEDAI-2k, PGA), serological and ongoing medication data were collected. PGA was evaluated before (pre-lab) and after (post-lab) knowledge of laboratory exams, using a Visual Analogue Scale (VAS) ranging from 0 to 3, anchored at point 1 (mild), 2 (moderate) and 3 (severe activity). A trainee in Rheumatology (EC) and three rheumatologists experts in SLE (LA, MP, FS) independently scored the PGA for each patient.

The trainee preliminarily received a standardization training with her tutor (MP), consisting of a shared discussion about 10 consecutive SLE outpatients to increase reliability in PGA scoring.

Inter-rater reliability was analysed using the intraclass correlation coefficient (ICC) with a two-way single-rating model (2,1); 95% confidence interval (CI) was calculated.

Results: Fifty-seven patients (86% female) affected from SLE (29 belonging to a French cohort and 28 to an Italian cohort) with a mean (SD) age 43.2 (15.9) years and a median [IQR] disease duration 6.4 [2.0-15.4] years were enrolled. Clinical features are presented in table 1. Pre-lab PGA scores were obtained from all patients and ranged from 0 to 2.3; post-lab PGA scores were obtained from 51 patients and ranged from 0 to 2.9. Inter-rater reliability of the PGA among the trainee was good to excellent for each lupus expert comparison: a) pre-lab PGA ICC 0.94, 95% CI 0.87-0.97; post-lab PGA ICC 0.94, 95% CI 0.87-0.97 (MP); b) pre-lab PGA ICC 0.84, 95% CI 0.63-0.93; post-lab PGA ICC 0.96 CI 0.88-0.99 (LA); c) pre-lab PGA ICC 0.91, 95% CI 0.65-0.98; post-lab PGA ICC 0.91, 95% CI 0.65-0.98 (FS).

Conclusion: After an adequate standardization, PGA scoring reaches good to excellent reliability between trainee and experts.

POS0759

THE JOURNEY OF PATIENTS FROM FIRST SYMPTOMS TO DIAGNOSIS OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): AN OBSERVATIONAL STUDY

N. Kapsala[1], S. Flouda[1], D. Nikolopoulos[1], K. Chavatza[1], A. Pieta[1], A. Grivas[1], A. Ntourou[1], K. Togia[1], P. Rapsomaniki[1], T. Gerogianni[1], D. Tseronis[1], M. Aggelakos[1], T. Karageorgas[1], P. Katsimpri[1], G. Bertsias[2], A. Fanouriakis[1,3], D. Boumpas[1]. *[1]"Attikon" University Hospital of Athens, Rheumatology and Clinical Immunology, Medical School, National and Kapodistrian University of Athens, Athens, Greece*; *[2]University of Crete, Rheumatology, Clinical Immunology and Allergy, Heraklion, Greece*; *[3] "Asklepieion" General Hospital, Department of Rheumatology, Voula, Athens, Greece*

Background: The lack of pathognomonic features poses a considerable challenge in SLE diagnosis. The time from symptom onset to diagnosis has been reported to range from two to six years[1].

Objectives: To document the initial symptoms of the disease and the time lapse until its diagnosis.

Methods: We examined 438 patients from the "Attikon" SLE cohort[2]. For diagnosis, we used the classification criteria (ACR, SLICC, EULAR-ACR) or in few cases clinical diagnosis (n=32, 7.3%). Data were collected using patient interviews, in-person clinical visits and medical charts review. Initial symptoms were recorded and determined chronologically using prespecified forms with a list of typical manifestations (skin, joints, renal, nervous system, pleuropulmonary, cardiovascular, anti-phospholipid syndrome) as well as characteristic disease features (Raynaud's phenomenon, fatigue, fever, sicca symptoms). Questions also included the time between symptom onset and initial physician visit, the time from first medical consultation until first rheumatologist assessment, the time from rheumatologist assessment to SLE definite diagnosis, the number of physicians seen before SLE diagnosis, the specialty of first physician and of diagnosing physician. Information on demographic and clinical characteristics, disease activity and disease damage, was collected both at enrolment and at last follow-up visit.

Results: 88.5% of patients were females, mean (±SD) age at diagnosis was 41.9 years ± 15.4 and disease duration was 6.7 ± 7 years. Most common systems involved were joints (94.5%), skin (73.7%), blood (39.2%) and renal (17.5%). At diagnosis, 9.8% of patients were ANA negative. The most common initial symptoms at disease onset were arthritis/arthralgia (74.4%), followed by fatigue (53.1%) and photosensitive rash (50.9%) (Table 1). Among non-criteria features, Raynaud's phenomenon was reported by 146 patients (33.3%) prior the diagnosis. The median interval between symptoms onset and the SLE diagnosis was 16 months (IQR 5-60). SLE was diagnosed earlier in ANA-positive than -negative patients [median time 14 months (IQR 5-60) vs 36 months (IQR 10.5-84); P=0.1, t-test]. Approximately half of the patients (52.5%) were diagnosed after 12 months from disease onset with only 15.9% diagnosed within 3 months of symptoms presentation. The median lag time between onset of symptoms and the first medical consultation was 2 months (IQR 1-12). Internists were the most common first consultants (27.8%) followed by orthopedists (15.9%), dermatologists (13.6%) and rheumatologists (13.4%). The median interval between the first medical assessment and first rheumatologist evaluation was 3 months (IQR 0-11.5) while the median time from rheumatologist assessment to definite diagnosis was 0 months (IQR 0-4). SLE patients consulted an average of 3 different physicians before the definite diagnosis, which in 95.8% was established by rheumatologists.

Conclusion: Approximately 50% of patients were diagnosed with SLE after 12 months from symptom onset with a mean time from symptoms to definite diagnosis almost 4 years. Increasing awareness of internists to SLE and avoidance of strict adherence to ANA as a requirement for diagnosis may improve early diagnosis.

Table 1. Initial symptoms prior to diagnosis

Symptoms	*N=438 (%)*	*Duration* (mean months ±SD)*
Arthralgias	326 (74.4)	37.5 ±69.4
Photosensitive rash	223 (50.9)	30.6 ±70.2
Malar rash	168 (38.3)	22.6 ±62
Alopecia	167 (38.1)	19.6 ±54.6
Ulcers	106 (24.2)	16.8 ±54.4
Fever	103 (23.5)	9.3 ±43.8
Raynaud's phenomenon	146 (33.3)	22.3 ±68.5
Fatigue	233 (53.1)	19.7 ±45.7

*Mean time from symptom onset to established diagnosis

MONITORING C3 AND C4 VARIATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS PREGNANCIES IS USEFUL TO RECOGNIZE COMPLICATIONS. DATA FROM 2 ITALIAN CENTERS

F. Crisafulli[1], R. Reggia[2], M. Filippini[1], M. Fredi[1], M. C. Gerardi[1], R. Gorla[1], M. G. Lazzaroni[1], D. Lini[1], C. Nalli[1], M. Taglietti[1], A. Lojacono[3], S. Zatti[3], C. Zanardini[3], C. Tani[4], D. Zucchi[4], M. Mosca[4], F. Franceschini[1], L. Andreoli[1], A. Tincani[1]. *[1]ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy*; *[2]Casa di Cura San Camillo, Internal Medicine, Cremona, Italy*; *[3]ASST Spedali Civili and University of Brescia, Obstetrics and Gynecology Unit, Brescia, Italy*; *[4]University of Pisa, Rheumatology Unit, Pisa, Italy*

Background: In SLE pregnancies adverse pregnancy outcomes (APO) are more frequent than in general obstetric population (GOP). In clinical practice, low C3 and C4 levels are associated with active disease and, during pregnancy, complement activation products are shown to be associated with APO.
Objectives: To analyse complement variations during SLE pregnancies, focusing on disease flares and APO.
Methods: Data on SLE pregnancies prospectively-followed by multidisciplinary team in 2 Italian Centers from 1987 to 2018 were retrospectively analysed. C3 and C4 normal levels were calculated in general obstetric population (GOP) as previously described[1], and related to maternal and fetal outcome. Non categorical variables were compared using Mann-Whitney test or Wilcoxon test when appropriate.
Results: Two hundred forty-six pregnancies in 172 SLE patients were analysed (mean age at conception 31.3 ±4.9 years; mean disease duration 8.3 ±7.1). Anti-Ro antibodies were positive in 64 patients (37%) and anti-phospholipid antibodies (aPL) were positive in 84 (48%), with single positivity in 54%, double in 24% and triple in 21%; 9 patients (5%) had also a diagnosis of obstetric-antiphospholipid syndrome (APS) and 8 (4%) had thrombotic-APS. Seventy-one patients (41%) had history of Lupus Nephritis.
Thirty-five flares were recorded in 30 pregnancies (12%). APO occurred in 47 pregnancies (19%) and were: 27 fetal loss (20 early miscarriage <10th week and 7 intrauterine fetal death), 11 severe preterm birth (<34th week) and 15 hypertensive disorder (11 pre-eclampsia and 5 pre-eclampsia+HELLP syndrome).

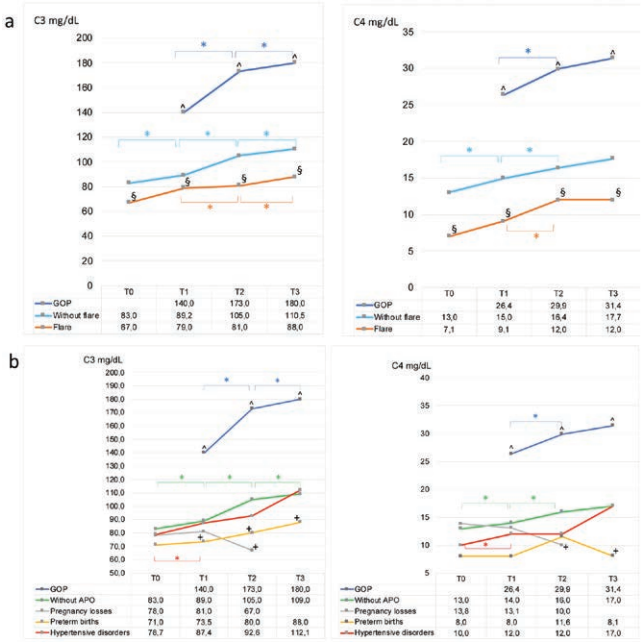

Figure 1. Variations of C3 and C4 median levels (mg/dL) throughout pregnancy in GOP[1] and in SLE pregnancies without and with flare (a) and without and with APO (b).

In GOP, C3 progressively increased throughout pregnancy and C4 increase from the 1st trimester to the 2nd trimester, as well as in SLE pregnancies without flares and without APO, from preconception (Fig 1). In the other SLE groups, C3 and C4 showed a different trend: in pregnancies with flares, they did not increase from preconception to the 1st trimester; in fetal losses and severe pre-term births, they remained stable throughout pregnancy; in hypertensive disorders they increased only between preconception and the 1st trimester.
C3 and C4 levels were higher in GOP than in all SLE pregnancies groups (including those without flares and without APO) in each trimester. SLE pregnancies without flares showed higher C3 and C4 levels than pregnancies with flares, at preconception and in each trimester. SLE pregnancies without APO had higher C3 and C4 levels than pregnancies with fetal death at 2nd trimester, higher C3 levels than severe pre-term births in each trimester and higher C4 at 3rd trimester (Fig.1).
At preconception, pregnancies with flares showed a higher frequency of low C3 and of low C4 than in pregnancies without flares (76% vs 42%, p=0.01; 76% vs 26%, p<0.001, respectively). Using the normality range previously calculated in GOP, SLE pregnancies with flares had higher frequency of low C4 in every trimester as compared with pregnancies without flares (1st: 82% vs 48%, p=0.003; 2nd: 82% vs 64%, p=0.01; 3rd: 64% vs 30%, p=0.002). At multivariate analysis, low C4 at preconception was associated with flare (OR [95% CI]: 10.34 [2.52-42.39]; p=0.001).
** p <0.05*
^as compared with SLE groups: p<0.05; § as compared with SLE pregnancies without flare: p<0.05; + as compared with SLE pregnancies without APO: p<0.05
Conclusion: In SLE pregnancies, monitoring of C3 and C4 is important: its failure to increase can be useful to recognize potential risk situations which deserve particular monitoring.

INVESTIGATION ON THE EFFECT AND MECHANISM OF ABNORMALLY ACTIVATED CD8+ T CELLS FROM BONE MARROW ON HEMATOPOIETIC STEM CELLS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

T. Fu[1], Y. Yang[1], X. Gu[2], C. Dong[2], R. Zhao[1], J. Ji[2], Z. Xue[1], X. Zhang[3], Z. Gu[2]. [1]*Affiliated Hospital of Nantong University, Research Center of Clinical Medicine, Nantong, China*; [2]*Affiliated Hospital of Nantong University, Department of Rheumatology, Nantong, China*; [3]*Institute Pasteur of Shanghai Chinese Academy of Sciences, Key Laboratory of Molecular Virology & Immunology, Shanghai, China*

Background: SLE is an autoimmune disease characterized by the abnormal function of lymphocytes. The impairment of hematopoietic function of bone marrow participates in its pathogenesis, in which T cells play an important role. However, study on bone marrow T cells in SLE patients is very limited.
Objectives: This study aims to characterize the phenotype and molecular characteristics of abnormally activated CD8+T cells in bone marrow of SLE patients and explore the mechanism of hematopoietic stem cells (HSCs) reduction caused by the abnormally activated CD8+T cells in bone marrow of patients with SLE.
Methods: A total of 8 SLE patients and 5 age- and sex-matched controls were recruited in our study. Among them, 3 SLE patients and 4 donors were collected bone marrow and peripheral blood samples for Single-cell RNA sequencing (scRNA-seq) and functional studies. BM and peripheral T cell subsets were measured by flow cytometry. Plasma cytokines and secreted immunoglobulins were detected by Luminex. Disease activity of SLE patients was measured using the SLE Disease Activity Index (SLEDAI). All analyses were performed using R language and Flowjo 9.
Results: In the present study, SLE patients had increased CD8+T%αβT cells and decreased CD4+T%αβT cells in bone marrow of SLE, compared to healthy controls. A large number of CD38+HLADR+CD8+T cells existed in the bone marrow and peripheral blood of SLE patients. Those patients also showed reduced number of HSCs, and with a downward trend of the numbers of peripheral red blood cells, white blood cells, neutrophils, hemoglobin, and platelets. By scRNA-seq, the CD38+HLADR+CD8+T cells contained high levels of GZMK, GZMA, PRF1, IFNG, and TNF in the bone marrow of SLE patients. the CD38+HLADR+CD8+T cells exhibited significant relationship with HSCs, white blood cells, neutrophils, and platelets.
Conclusion: These findings demonstrated that the abnormally activated CD8+T cells in bone marrow can reduce the number of HSCs by the expression of killer molecules, which contributes to the impairment of hematopoietic function and the development of SLE. This project focuses on the specific bone marrow T cell subset in SLE. The completement of this project provides information for exploring the mechanism of hematopoiesis involvement.

CAN THE SLE-DAS SUBSTITUTE BILAG TO MEASURE LUPUS DISEASE ACTIVITY IN CLINICAL TRIALS? POST-HOC ANALYSIS OF THE BLISS-76 TRIAL

D. Jesus[1,2], A. Matos[3,4], C. Henriques[3,5], A. Doria[6], L. Inês[2,7]. [1]*Centro Hospitalar de Leiria, Rheumatology Department, Leiria, Portugal*; [2]*University of Beira Interior, Faculty of Health Sciences, Covilhã, Portugal*; [3]*Institute of Viseu, Technology and Management, Viseu, Portugal*; [4]*Research Centre in Digital Services, CISeD, Viseu, Portugal*; [5]*University of Coimbra, Centre for Mathematics, Coimbra, Portugal*; [6]*University of Padova, Division of Rheumatology, Padova, Italy*; [7]*Centro Hospitalar e Universitário de Coimbra, CHUC Lupus Clinic, Rheumatology Department, Coimbra, Portugal*

Background: The primary endpoint for randomized clinical trials (RCT) in Systemic lupus erythematosus (SLE) is usually defined as proportion of responders in a composite index. The most widely used are British Isles Lupus Assessment Group (BILAG)-based Composite Lupus Assessment (BICLA) and Systemic Lupus Responder Index (SRI). Both comprise BILAG along with SLE Disease Activity Index (SLEDAI). BICLA and SRI are complex and time-consuming to assess.
The SLE Disease Activity Score (SLE-DAS) is an easy to apply, validated, continuous disease activity measure, highly correlated with SLEDAI, with higher accuracy and sensitivity-to-change as compared to SLEDAI[1].
We hypothesize that SLE-DAS can also identify the SLE disease activity information from BILAG, thus dispensing the use of composite indexes for RCT.
Objectives: To compare the ability of the SLE-DAS and the Safety of Estrogen in Lupus National Assessment (SELENA)-SLEDAI to discriminate between BILAG classification of mild *vs.* moderate *vs.* severe disease activity.
Methods: Post-hoc analysis of all intention-to-treat patients in the BLISS-76 (NCT00410384) RCT at the baseline study visit. SELENA-SLEDAI and BILAG were assessed at time of the study visits and SLE-DAS was retrospectively scored from the study database. Patients' disease activity was classified as: (i) mild (no BILAG B or A scores in any organ domain); (ii) moderate (1 BILAG B, no A scores); (iii) severe (≥2 BILAG B and/or ≥1 BILAG A). Ability of the SLE-DAS and SELENA-SLEDAI to differentiate between: (i) mild *vs.* moderate/severe disease activity; (ii) mild/moderate *vs.* severe disease activity (according to BILAG), were evaluated using receiver operating characteristic (ROC) analysis. The area under the ROC curves (AUCs) with 95% confidence intervals (95%CI) as a measure of discriminatory ability of the SLE-DAS and SELENA-SLEDAI were compared using Delong's test for two correlated curves. Because AUC measurements might have restricted accuracy for imbalanced datasets, precision-recall (PR) curves and area under PR curves (AUC-PR) were also performed. Statistical significance was set at 0.05.
Results: We included 819 patients, classified by BILAG as presenting mild (7.7%), moderate (28.8%) or severe (63.5%) disease activity. To differentiate mild *vs.* moderate/severe disease activity, the discriminatory ability of SLE-DAS was outstanding (AUC 0.948; 95%CI 0.923-0.973), while that of SELENA-SLEDAI was acceptable (AUC 0.729; 95%CI 0.657-0.801) (p<0.005) (figure 1A). To differentiate mild/moderate *vs.* severe disease activity, the discriminatory ability of SLE-DAS was excellent (AUC 0.873; 95%CI 9.846-0.899), while that of SELENA-SLEDAI was acceptable (AUC 0.707; 95%CI 0.670-0.744) (p<0.005) (figure 1B). The AUC-PR confirmed the higher performance of SLE-DAS over SELENA-SLEDAI to differentiate mild *vs.* moderate/severe disease activity (0.995 *vs.* 0.965, respectively) (figure 1C) and mild/moderate *vs.* severe disease activity (0.902 *vs.* 0.794, respectively) (figure 1D).

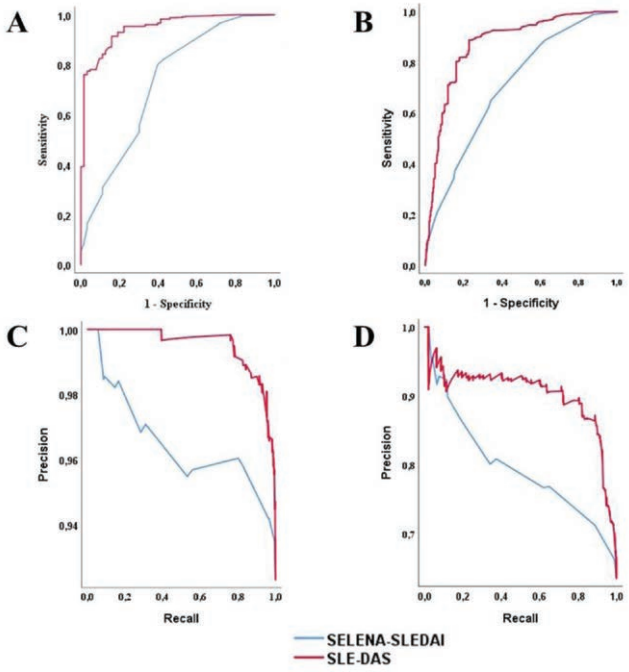

Figure 1. Receiver operating characteristics (ROC) curves comparing the ability of the SLE-DAS and SELENA-SLEDAI to differentiate (A) mild *vs.* moderate/severe disease activity and (B) mild/moderate *vs.* severe disease activity, as assessed by BILAG; and Precision-recall (PR) curves comparing the performance of the SLE-DAS and SELENA-SLEDAI to differentiate (C) mild *vs.* moderate/severe disease activity and (D) mild/moderate *vs.* severe disease activity.

Conclusion: The SLE-DAS presents excellent performance in assessing SLE disease activity categorized by BILAG scores, which is not the case for SELENA-SLEDAI. Further studies will aim to better define ability of SLE-DAS to substitute composite responder indices.

San Martín de La Plata, Servicio de Reumatología, La Plata, Argentina*; *[6]Hospital Provincial de Rosario, Servicio de Reumatología, BZL, Argentina*; *[7]Instituto de Investigaciones Médicas Alfredo Lanari, Servicio de Reumatología, Buenos Aires, Argentina*

Background: In 2019 ACR and EULAR published in joint collaboration the new classification criteria for Systemic Lupus Erythematosus (SLE). Compared to the previous ones, these criteria have shown higher sensitivity and specificity in multiple cohorts. To our knowledge, its performance has not been evaluated in a cohort of patients with rheumatological diseases living in Argentina.
Objectives: The aim of this study was to evaluate the sensitivity and specificity of the ACR/ EULAR 2019 criteria in a cohort of patients with connective tissue diseases residing in Argentina. Secondary objectives were to determine the Likelihood Ratio (LR) of these criteria and the correlation of their global score with activity and damage indexes of the disease.
Methods: Multicentre, retrospective and analytical study. Patients ≥ 18 years old with diagnosis of SLE (ACR 1997/SLICC 2012) without other associated collagen diseases (case group), and patients with other non-SLE connective tissue diseases (control group) were included. Those with active infectious disease, oncohematological disease, drug-induced lupus and overlap syndrome were excluded. Sociodemographic data, characteristics of the disease and treatment were recorded. In addition, activity and damage indexes were recorded in the group with SLE.
Three SLE experts, blinded to the diagnosis determined, for every individual if the patient had SLE or another rheumatological disease. An interrater agreement of 100% (including the 3 evaluators) was considered "defined SLE" and used as gold standard. In all cases, ACR 1997/SLICC 2012/ACR / EULAR 2019 criteria were applied and compared with the gold standard. Statistical analysis: Descriptive statistics was estimated. Sensitivity, specificity, positive and negative LR of the criteria were determined. The association between the final score of the ACR-EULAR 2019 criteria and the disease activity and damage indexes were estimated with Spearman correlation test. STATA 15.0 was used for data analysis.
Results: A total of 365 patients from 7 centres in Argentina were included. A One hundred and eighty-three belonged to the SLE group: 92.3% women, mean age 39 years (SD 13.3), median disease duration 92 months (IQR 37-150). The most frequent manifestations of the disease were mucocutaneous (94%), musculoskeletal (82.5%) and haematological (69%). All patients presented ANA +, 88% hypocomplementemia, 69.4% Anti-DNA and 19.5% antiphospholipid antibodies. Median SLEDAI and SLICC were 2 (IQR 0-6) and 0 (IQR 0-1), respectively.
In the control group, 182 patients were recruited: 84% women, mean age 53.6 years (SD 14.2) and median disease duration 82.5 months (IQR 38-151). The most frequent diseases were Rheumatoid Arthritis (46.1%), Scleroderma (18.1%) and Sjögren's Syndrome (16.5%) and most common manifestations were musculoskeletal (81.9%), immunological (73.6%) and constitutional (25.3%). A total of 62.6% of patients presented ANA+, 8.6% hypocomplementemia, and 1.3% Antiphospholipid antibodies.
Ninety-one percent of patients in the case group were classified as defined SLE and 3.8% in the control group.
The ACR / EULAR 2019 Criteria showed a 99.4% sensitivity and an 89.1% specificity, with a LR+ of 9.1 and a LR- of 0.007. The sensitivity and specificity of SLICC 2012 criteria were 98.3% and 88%, respectively with a LR+ of 8.2 and a LR- of 0.02; and the ACR 1997 criteria showed a 93.96% sensitivity and 90.1% specificity, with LR + of 8.21 and LR - of 0.07.
The correlations between the ACR/EULAR 2019 Criteria global score, and activity and damage indexes were 0.19 and -0.006, respectively.
Conclusion: The new ACR / EULAR 2019 criteria have shown high sensitivity, a specificity comparable to its predecessors, and a higher ability to distinguish SLE from other diseases and to exclude it in non-SLE patients. No correlation was observed between the criteria scores and activity and damage indexes.

Background: Targets of therapy and quality of care are receiving increased attention in systemic lupus erythematosus (SLE).
Objectives: To develop Quality Indicators (QIs) for the care of SLE patients based on the EULAR recommendations, and assess their performance.
Methods: Using the published EULAR recommendations for SLE, we developed 44 candidate QIs. These were independently rated for validity and feasibility by 12 experts, analysed by a modified RAND/UCLA model and further scrutinized based on the scorings and expert opinion. (Fig.1) Adherence to the final set of QIs was tested in a cohort of 220 SLE patients combined with an assessment on its impact on disease outcomes such as flares, hospitalizations and organ damage.
Results: The panel rated 18 QIs as valid and feasible. These involve diagnosis; disease and damage assessment; monitoring for lupus nephritis and drug toxicity; therapy and targets of therapy; fertility and pregnancy; and adjunct therapy (preventive measures for osteoporosis, vaccination, cardiovascular disease). On average, SLE patients received 54% (95%CI 52–56%) of the indicated care with adherence ranging from 41% for QIs related to monitoring to 88% for treatment-related QIs. Regarding targets of therapy, sustained remission or low disease activity were achieved in 27%, while 94% of patients received low-dose glucocorticoids, and 92% the recommended hydroxychloroquine dose. Dependent upon individual QI tested, adherence for lupus nephritis-related QIs was 88% for receiving appropriate adjunct therapy (ACE inhibitors) to 100% for being treated with the indicated immunosuppressive treatment. In contrast, adherence to QIs related to preventive measures and other adjunct therapies was moderate to low. Notably, patients who were eligible for cardiovascular risk modification, vaccination, and osteoporosis management received lower quality of care (40.5%, 47.7% and 45.5% respectively) while 91.4% had sunscreen protection. In reference to laboratory work-up and monitoring, complete laboratory work-up at diagnosis was performed in 48%, while disease activity and damage, were fully assessed only in 14.1% (in three consecutive visits) and 28.6% (annually) respectively, Similarly, reproductive health and pregnancy counselling adherence rates were modest estimated at 50% and 62% respectively. Higher adherence to the indicated care during follow-up (monitoring QIs) was associated with reduced risk for adverse outcomes during the last year of observation (OR 0.97, 95%CI 0.96-0.99). Patients who achieved sustained remission or LLDAS, exhibited fewer flares (OR=0.15, p-value<0.001) and damage accrual (OR=0.35, p-value<0.001). Of interest, patients who received low-dose of GCs or were appropriately vaccinated, had a lower risk of experiencing a flare (OR=0.23 and 0.46 respectively).

Conclusion: A set of 18 QIs based on the EULAR recommendations for SLE was developed to be used towards improving care in SLE. Initial real-life data suggest variable degree of adherence with higher adherence resulting in reduced adverse outcomes.

POS0765 LABORATORY RATIOS: A SUBROGATE BIOMARKER FOR DETECTION OF INFECTION IN SLE PATIENTS

Y. Santamaria-Alza[1], J. Sanchez-Bautista[2], T. Urrego Callejas[1], J. Moreno[2], F. Jaimes[2], J. Rodello[3], D. Fernández[4], L. A. González[1], G. Vásquez[1].

[1]Universidad de Antioquia, Rheumatology, Medellín, Colombia; *[2]Universidad de Antioquia, Internal Medicine, Medellín, Colombia*; *[3]Universidad de Antioquia, Nephrology, Medellín, Colombia*; *[4]Polytechnic University of Catalonia-BarcelonaTech, Statistics and Operations Research, Medellín, Colombia*

Background: The most common complication in patients with SLE is infection, and its clinical presentation is often indistinguishable from SLE flares. Therefore, laboratory ratios have been evaluated to differentiate between those events. Among them, ESR/CRP[1], neutrophil/lymphocyte (NLR)[2], and platelet/lymphocyte (PLR)[3] ratios have been previously assessed with acceptable performance; however, there is no validation of those ratios in our SLE population.

Objectives: To examine the predictive capacity of infection of the lymphocyte/C4 (LC4R), lymphocyte/C3 (LC3R), and ferritin/ESR (FER) ratios in SLE patients, and to evaluate the performance of ESR/CRP, NLR, AND PLR ratios in our SLE population.

Methods: We conducted a cross-sectional study of SLE patients admitted to the emergency service at Hospital San Vicente Fundación (HSVF). The HSVF ethics committee approved the execution of the project.

Patients were categorized into four groups according to the main cause of hospitalization: (1) infection, (2) flare, (3) infection and flare and, (4) neither infection nor flare. We calculated the median values of the ratios and their respective interquartile ranges for each group. Then, we compared those summary measures using the Kruskal-Wallis test. Subsequently, we assessed the predictive capacity of infection of each ratio using ROC curve. Finally, we carried out a logistic regression model.

Results: A total of 246 patients were included, among them 90.7% were women. The median age was 28 years (IQR: 20-35 years). Regarding the outcomes, 37.0% of the patients had flares, 30.9% had neither infection nor flare, 16.7% had an infection and, 15.5% had simultaneously infection and flare. When compared the four groups, statistical significance ($p<0.05$) was observed. Area under the ROC curve (AUC) for infection prediction was as follows: 0.752 (sensitivity 60.5%, specificity 80.5%) for LC4R, 0.740 (sensitivity 73.2%, specificity 68.3%) for FER, 0.731 (sensitivity 77.6%, specificity 80.5%) for LC3R.

In the logistic regression modeling, we observed that an increase in the risk of infection was associated with an LC4R below 66.7 (OR: 6.3, CI: 2.7 – 14.3, $p<0.0001$), a FER greater than 13.6 (OR: 5.9, CI: 2.8 – 12.1, $p<0.0001$) and an LC3R below 11.2 (OR: 4.9, CI: 2.4 – 9.8, $p<0.0001$).

The ESR/CRP and PLR performed poorly with an AUC of 0.580 and 0.655, respectively. In contrast, the NLR showed better performance (AUC of 0.709, with a sensitivity of 80.2% and specificity of 55.7%).

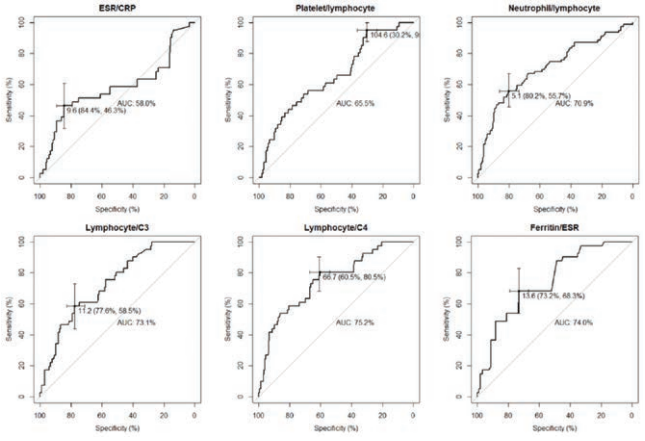

Figure 1. ROC curves of the evaluated ratios

Conclusion: These laboratory ratios could be easy to assay and inexpensive biomarkers to differentiate between infection and activity in SLE patients. The LC4R, FER, and LC3R have a significant diagnostic performance for detecting infection among SLE patients. Of the ratios previously evaluated, ESR/CRP, LPR, NLR, only the latest has an adequate performance in our population.

POS0766 CLUSTER ANALYSIS AND COMPARISON OF CUMULATIVE DAMAGE BY DIAPS IN A SINGLE CENTER COHORT OF APS PATIENTS

O. Uludag[1], E. Gurel[1], C. Cetin[1], E. Cene[2], Y. Yalçınkaya[1], A. Gül[1], M. Inanc[1], B. Artim-Esen[1]. *[1]Istanbul Faculty of Medicine, Division of Rheumatology, Department of Internal Medicine, İstanbul, Turkey*; *[2]Faculty of Arts and Science, Yıldız Technical University, Department of Statistics, Istanbul, Turkey*

Background: Antiphospholipid syndrome (APS) is a chronic autoimmune disease with significant morbidity and mortality. The recently developed damage index for APS (DIAPS) considers thrombotic APS specific damage.
Objectives: Herein we aimed to identify disease clusters based on clinical characteristics and compare DIAPS between these clusters in a single center cohort of patients with APS ± systemic lupus erythematosus (SLE).
Methods: This retrospective study included 237 consecutive patients with APS [114 primary APS (PAPS) and 123 SLE+APS]. Data regarding demographics, clinical and laboratory characteristics and cardiovascular risk factors were retrieved from the existing database and revised. Two-step cluster analysis was performed. Cumulative damage was calculated for all patients by applying DIAPS as described previously.
Results: 237 patients were classified into 4 subgroups by cluster analysis. Cluster 1 (*n*=74) consisted of older patients with arterial-predominant VT, livedo reticularis and increased cardiovascular risk, cluster 2 (*n*=70) of SLE+APS patients with thrombocytopenia and heart valve disease, cluster 3 (*n*=59) of patients with venous-predominant VT, less extra-criteria manifestations and cluster 4 (*n*=34) of patients with only PM with a lower frequency of extra-criteria features and cardiovascular risk (table 1).

Table 1. Demographic, clinical and laboratory characteristics of clusters

	All (*n*=237)	Cluster 1 (*n*=74)	Cluster 2 (*n*=70)	Cluster 3 (*n*=59)	Cluster 4 (*n*=34)	*P*
Age (years), median (range)	43 (20-81)	51 (20-81)	40 (27-72)	42 (24-69)	40.5 (26-65)	<0.001
Duration of disease (years), median (range)	9.5 (1-37.7)	13.1 (1-37.7)	10.4 (1-28.7)	8.5 (1-32.8)	7 (1-22.4)	0.028
Female, *n* (%)	198 (83.5)	56 (75.7)	61 (87.1)	47 (79.7)	34 (100)	<0.05
SLE, *n* (%)	123 (51.9)	31 (41.9)	46 (65.7)	32 (54.2)	14 (41.2)	<0.05
Vascular thrombosis, *n* (%)	191 (80.6)	73 (98.6)	59 (84.3)	59 (100)	0 (0)	<0.001
Arterial thrombosis, *n* (%)	109 (46)	50 (67.6)	31 (44.3)	28 (47.5)	0 (0)	<0.001
Venous thrombosis, *n* (%)	112 (47.3)	36 (48.6)	37 (52.9)	39 (66.1)	0 (0)	<0.001
Pregnancy morbidity, *n* (%)	117 (49.4)	22 (29.7)	46 (65.7)	15 (25.4)	34 (100)	<0.001
Livedo reticularis, *n* (%)	38 (16)	21 (28.4)	10 (14.3)	5 (8.5)	2 (5.9)	<0.01
Thrombocytopenia, *n* (%)	81 (34.2)	4 (5.4)	65 (92.9)	4 (6.8)	8 (23.5)	<0.001
Heart valve disease, *n* (%)	92 (38.8)	32 (43.2)	46 (65.7)	8 (13.6)	6 (17.6)	<0.001
Arterial hypertension, *n* (%)	101 (42.6)	49 (66.2)	34 (48.6)	18 (30.5)	0 (0)	<0.001
Hyperlipidemia, *n* (%)	103 (43.5)	69 (93.2)	26 (37.1)	0 (0)	8 (23.5)	<0.001
Smoking, *n* (%)	58 (24.5)	31 (41.9)	7 (10)	17 (28.8)	3 (8.8)	<0.001
Lupus anticoagulant, *n* (%)	156 (65.8)	53 (71.6)	48 (68.6)	35 (59.3)	20 (58.8)	0.36
Anticardiolipin IgG/IgM, *n* (%)	155 (65.4)	46 (62.2)	46 (65.7)	38 (64.4)	25 (73.5)	0.71
Anti-β2-glycoprotein I IgG/IgM, *n* (%)	93 (39.2)	25 (33.8)	33 (47.1)	26 (44.1)	9 (26.5)	0.13
Triple aPL positivity, *n* (%)	45 (19)	12 (16.2)	16 (22.9)	13 (22)	4 (11.8)	0.46

Cluster 2 had the highest cumulative damage (mean DIAPS 2.48 ± 1.67) followed by cluster 1 (2.24 ± 1.44), cluster 3 (1.69 ± 1.27) and cluster 4 (0.32 ± 0.68). Comparison of DIAPS (total and major domains) between the clusters is shown in figure 1.
Patients with SLE+APS had a higher mean DIAPS compared to those with PAPS (2.10 ± 1.61 vs 1.69 ± 1.47, *P*=0.046). Cardiovascular domain was the most frequently affected DIAPS domain in both groups. Proteinuria and avascular necrosis were significantly more frequent in SLE+APS (9.8% vs 2.2%, *P*=0.02 and 5.7% vs 0%, *P*=0.009, respectively). DIAPS was positively correlated with disease duration (r=0.192, *P*=0.003).
Conclusion: Elder APS patients with arterial thrombosis and increased cardiovascular risk and SLE+APS patients with extra-criteria manifestations had higher cumulative DIAPS. Longer disease duration, higher frequency of major organ involvement and higher immunosuppressive usage may have contributed to this difference. Therefore, control of cardiovascular risk factors, prevention and effective treatment of SLE flares may help to reduce damage in these subgroups.

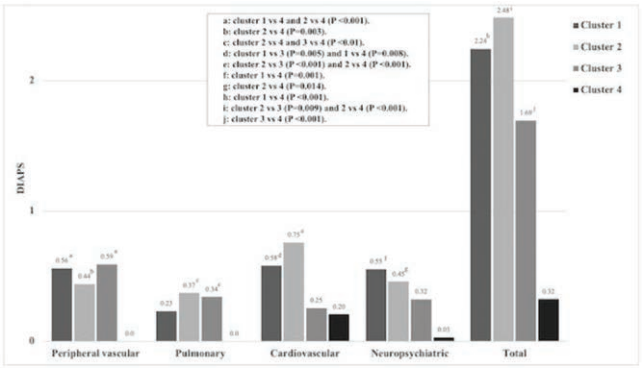

Figure 1. Comparison of mean DIAPS (total and major domains) between the clusters

CLINICAL MANIFESTATIONS, TREATMENT, AND OUTCOMES OF "NON-CRITERIA" ANTIPHOSPHOLIPID SYNDROME IN COMPARISON WITH DEFINITE ANTIPHOSPHOLIPID SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS

G. Pires Da Rosa[1,2], E. Ferreira[2,3], B. Sousa-Pinto[4,5], I. Rodriguez-Pubto[6], P. Bettencourt[2,7], R. Cervera[1], G. Espinosa[1]. [1]*Hospital Clínic, Institut d'Investigacions Biomèdiques August Pi I Sunyer (IDIBAPS), University of Barcelona, Department of Autoimmune Diseases, Barcelona, Catalonia, Spain*; [2]*University of Porto, Faculty of Medicine, Porto, Portugal*; [3]*Centro Hospitalar Universitário de São João, Department of Internal Medicine, Porto, Portugal*; [4]*CINTESIS – Center for Health Technology and Services Research, Porto, Portugal*; [5]*Faculty of Medicine, University of Porto, MEDCIDS – Department of Community Medicine, Information and Health Decision Sciences, Porto, Portugal*; [6]*Hospital Universitari Mútua de Terrassa, Autoimmune Diseases Unit, Terrassa, Catalonia, Spain*; [7]*Hospital CUF, Department of Internal Medicine, Porto, Portugal*

Background: Patients with laboratorial or clinical manifestations suggestive of antiphospholipid syndrome (APS) but not fulfilling the classification criteria [1] constitute a challenge in clinical practice.
Objectives: To establish a comparison between patients with "non-criteria" versus those with definite APS on the frequency of clinical manifestations, prescribed therapies and reported outcomes.
Methods: A systematic review of observational studies comparing "non-criteria" with definite APS patients was performed searching 4 electronic databases. Data was extracted on clinical manifestations, therapies and outcomes. Studies were analyzed globally and, where possible, grouped under four potential "non-criteria" APS subsets. Random-effects meta-analyses were performed.
Results: Fourteen studies were included, assessing a total of 3,238 participants (Table 1). In the meta-analysis, no difference was detected in the frequency of arterial events or thrombosis recurrence between "non-criteria" and definite APS. However, a lower frequency of venous events was observed in "non-criteria" patients (risk ratio [RR]=0.9; 95%CI 0.7-1.0; p-value=0.047, I^2=0%; Q Cochran p-value=0.226). Regarding obstetric morbidity, no difference was observed in most outcomes, but previous history of intrauterine growth restriction was less frequent (RR=0.7; 95%CI=0.6-0.9; p-value=0.003, I^2=0%; Q Cochran p-value=0.228) and the risk of prematurity in followed pregnancies lower in "non-criteria" patients. There was no significant difference in treatment frequency between groups, except for less use of hydroxychloroquine in "non-criteria" APS (RR=0.7; 95%CI=0.5-0.9; p-value=0.007, I^2=46.5%; Q Cochran p-value=0.642). There was no significant difference in the risk of fetal loss between groups either with or without treatment (Figure 1). It should be noted that significant heterogeneity was observed in some outcomes across the studied categories. Most studies focused on "seronegative" and "incomplete laboratory" APS.

Table 1. Description of studies included in the systematic review.

	Number of Patients

Omar, 2018 [7]	30	30
Signorelli, 2017 [8]	77	13
Fredi, 2018 [9]	85	81
Litvinova, 2018 [10]	41	17
Alijotas-Reig, 2019 [11]	1000	640
Ferreira, 2020 [12]	15	21
Liu, 2020 [13]	192	90
Li, 2020 [14]	34	94
Lo, 2020 [15]	12	24

Abbreviations – APS: Antiphospholipid Syndrome; NC-APS: Non-criteria antiphospholipid syndrome.

Conclusion: This review suggests an absence of marked differences in most of the evaluated variables regarding clinical manifestations, treatment and outcomes between "non-criteria" and definite APS. These results should be interpreted with caution in light of the low-quality evidence available and heterogeneity observed in some outcomes.

POS0768 THE IMPACT OF ANTI-RO ANTIBODIES IN PREGNANT PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND SJÖGREN'S SYNDROME

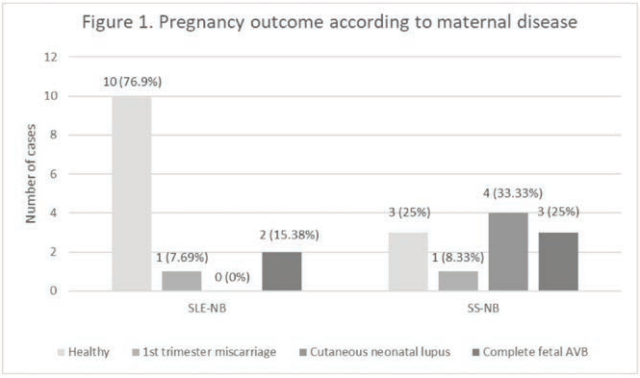
D. A. Vaida-Voevod[1,2], L. E. Mera[3], S. C. Vesa[4], M. M. Tamas[1,2], I. Felea[2], L. Muntean[1,2], I. Filipescu[1,2], C. Pamfil[1], L. Damian[2], S. P. Simon[1,2], S. Rednic[1,2]. *[1]Iuliu Hatieganu University of Medicine and Pharmacy, Rheumatology, Cluj-Napoca, Romania*; *[2]Emergency Clinical County Hospital, Rheumatology, Cluj-Napoca, Romania*; *[3]University Hospital C.F.R, ENT, Cluj-Napoca, Romania*; *[4]Iuliu Hatieganu University of Medicine and Pharmacy, Pharmacology, Toxicology and Clinical Pharmacology, Cluj-Napoca, Romania*

Background: The presence of anti-Ro antibodies in female patients diagnosed with systemic lupus erythematosus (SLE) and primary Sjögren syndrome (SS) in their fertile years raises concern among the medical team due to the risk of neonatal lupus in their newborns (NB).(1)
Objectives: The aim of this study was to determine whether there are differences between the outcome of anti-Ro positive pregnancies in SLE and SS.
Methods: This is a retrospective observational study carried out in a Rheumatology tertiary center. We included anti-Ro positive female SLE and SS patients, who were diagnosed before or during pregnancy and followed in our clinic between 2003-2020. The diagnosis of SLE or SS was established according to the 2012 SLICC criteria and the 2016 EULAR/ACR criteria, respectively. Clinical, immunological and pregnancy parameters were recorded before (where available), during and after pregnancy, as well as maternal risk factors (smoking, BMI, disease and medication history). Statistical analysis for continuous variables were performed with T-student test and categorical variables with Person Chi-square test, using IBM SPSS Statistics version 20.
Results: Eleven out of 65 anti-Ro positive SLE patients and 10 out of 153 anti Ro-positive SS patients met the inclusion criteria and had 13 and 12 pregnancies, respectively. The mean age at diagnosis was 24,75 ± 5,19 years for SLE and 31,92 ± 4,05 years for SS, and the mean pregnancy age was 28,33 ± 4,05 years for SLE and 33,17 ± 3,63 years for SS. Nine (81,81%) SLE patients were diagnosed before pregnancy, while 6 (60%) of the SS patience were diagnosed during pregnancy. Two (18,18%) SLE and 1 (10%) SS were smokers, median BMI was 21 for both SLE and SS (1 SS patient was obese), 2 (18,18%) had a history of lupus nephritis, 6 (54.54%) LES patients had secondary antiphospholipid syndrome, out of which 1 had a previous miscarriage. In the SS group there were 3 previous miscarriages, one patient had a history of parotid lymphoma. The majority of both SLE and SS patients had moderate anti-Ro antibody titers (<200 U/ml) before as well as during pregnancy: 6 (46.5%) and 8 (61.53%) in SLE, 5 (41.6%) and 7 (58.3%) in SS. More preterm NB and stillbirths were encountered in SLE mothers, possibly due to the association of secondary antiphospholipid syndrome, both groups encountered 1 pregnancy loss, and cesarean delivery outweighed vaginal ones in both SLE and SS patients. (Table 1)

Table 1. Gestational age and delivery type according to maternal disease

		SLE number (%)	SS number (%)
Gestational age			
	Full-term pregnancy	4 (30.76%)	10 (83.33%)
	Late preterm births	4 (30.76%)	1 (8.33%)
	Very preterm births	2 (15.38%)	0
	Stillbirth	2 (15.38%)	0
	Pregnancy loss	1 (7.69%)	1 (8.33%)
Delivery type			
	Vaginal	3 (25%)	4 (36.36%)
	Cesarean	9 (75%)	7 (63.63%)

Distribution of pregnancy outcome is exhibited in figure 1. There were 4 (33.33%) NB with cutaneous neonatal lupus all from SS mothers, 3 of whom used HCQ before and/or during pregnancy; and there were 5 NB with complete fetal atrioventricular block (AVB), 3 (25%) from SS mothers and 2 (15.38%) from SLE mothers. A history of HCQ usage was recorded in 3 out of these 5 mothers, and all 5 NB with complete fetal AVB were treated with dexamethasone, without success. Two NB died (both from SLE mothers) and 3 NB (all from SS mothers) needed pacemaker implantation. From the latter, 1 developed pacemaker cardiomyopathy and 1 developed sepsis.



Conclusion: Neonatal lupus seems to be more prevalent in anti-Ro positive SS patients than SLE patients, even though no difference was seen in anti-Ro titer between the two diseases. Fetal cardiac arrhythmia may lead to SS diagnosis. Dexamethasone did not improve the outcome of the fetal AVB.

POS0769 VALIDATION OF THE SIMPLE INDEX FOR DISEASE ACTIVITY OF SYSTEMIC LUPUS ERYTHEMATOSUS IN CHINESE PATIENTS

C. C. Mok[1], L. Y. Ho[1], K. L. Chan[1], J. Meenakshi[2]. *[1]Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[2]Rush University, Medicine, New York, United States of America*

Objectives: To validate the SIMPLE index for systemic lupus erythematosus (SLE) disease activity assessment in Chinese patients.
Methods: Adult patients (age ≥18 years) who fulfilled the 2013 SLICC criteria for SLE and were followed in the Rheumatology clinics of Tuen Mun Hospital, Hong Kong were recruited in a cross-sectional study. Participants were invited to complete the SIMPLE questionnaire before seeing doctors on the same day. The two laboratory results were supplemented by research nurses. Physicians, who were blinded to the SIMPLE results, were asked to complete disease activity assessment by the SELENA-SLEDAI and physicians' global assessment (PGA) after consultation. Correlation was made between the SIMPLE score and the SLEDAI/PGA scores by Spearman's rank correlation test. Receiver operating characteristic (ROC) analysis was performed to find the best cut-off SIMPLE score that predicted a clinical SLEDAI score of 1-6 (mild SLE activity) and ≥7 (moderate/severe activity).
Results: 364 SLE patients were studied (94% women; age 45.4±13.4 years; disease duration 13.2±8.0 years). The proportion of patients having a history of neuropsychiatric and renal disease that required immunosuppressive therapies was 9.3% and 56%, respectively. At the time of questionnaire completion, 69 (19%) patients had SLEDAI ≥6 and 192 (53%) had SLEDAI 1-5. The mean SLEDAI was 3.04±2.85 and PGA score was 0.62±0.55. A total of 161 (44%) had SDI score ≥1. The mean SIMPLE index was 26.0±12.9. SIMPLE index correlated significantly with SLEDAI (ρ=0.76; p<0.001) and PGA score (ρ=0.48; p<0.001). ROC analysis showed that a SIMPLE index of >27 points best predicted a clinical SLEDAI score of 1-6 (area under the curve [AUC] 0.78[0.73-0.84]; sensitivity 0.75; specificity 0.71), and >36.8 points best predicted a clinical SLEDAI score of ≥7 (AUC 0.87[0.69-1.00]; sensitivity 0.88, specificity 0.85).
Conclusion: SIMPLE shows a good correlation with SELENA-SLEDAI and PGA. It is a simple tool that enables patients to self-report disease activity and communicate with the health care team more efficiently.

POS0770 DIFFERENTIAL CLINICAL PRESENTATION BETWEEN SLE RUPHUS PATIENTS AND SLE NON-RHUPUS PATIENTS: A CASE-CONTROL STUDY

J. Sanchez-Bautista[1], Y. Santamaria-Alza[2], C. Quintero[2], M. Muñoz[2], A. Ramírez[1], C. Muñoz[2,3], A. L. Vanegas-García[2,3], G. Vásquez[2], L. A. González[2]. [1]*Universidad de Antioquia, Internal Medicine, Medellín, Colombia*; [2]*Universidad de Antioquia, Rheumatology, Medellín, Colombia*; [3]*Hospital San Vicente Fundación, Rheumatology, Medellín, Colombia*

Background: Rhupus is a term that describe the coexistence of systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). Rhupus patients have symmetrical, erosive arthritis, characteristic SLE manifestations and an array of autoantibodies including rheumatoid factor (RF), anti-cyclic citrullinated peptides (anti-CCP), anti-dsDNA, and anti-Sm.[1] Joint involvement is common in SLE patients (90%), but only 1% to 9,7% have rhupus.[2] Due to its low prevalence, there is still a lack of evidence on its presentation and differences with other SLE patients without rhupus.
Objectives: To examine the rhupus prevalence and to compare the clinical and serological characteristics between rhupus, and non-rhupus SLE patients (SLE with arthritis (SLEa), and SLE without arthritis (SLEwa)).
Methods: We performed a case-control study. Rhupus patients (cases) were matched 1:1 with non-rhupus SLE patients (controls). Descriptive statistics were calculated and rhupus, SLEa, and SLEwa were compared.
Results: A total of 72 patients were included, 24 patients in each group; most were female (87.5%). The median age at rhupus onset was 36.5 years (IQR 30-42.5). RA preceded rhupus in half of the patients, 29% were initially diagnosed as SLE, and 21% were initially diagnosed as rhupus. The median duration of RA was 66 months (IQR 30-144).
In the descriptive analysis of rhupus patients, the most affected joints were the proximal interphalangeal and metacarpophalangeal joints (87.5%), followed by the wrists (79.1%). Regarding immunological findings, RF and anti-CCP were positive in 87.5% and 50% of the patients, respectively. As to radiographic findings, the median number of erosions in the hands and wrists was 2 (IQR 0-5) and the median number of joints with narrowed joint space was 7 (IQR: 1.5 - 13.5). In terms of treatment, 95.8% received corticosteroids (median 10 mg/day), 91.6% antimalarials, 79.1% methotrexate, 41.6% leflunomide, and 25.0% rituximab.
Patients with rhupus were older and had less renal and hematological involvement than patients with SLEa and SLEwa. SLEa patients had higher seropositivity for anti-RNP and anti-Sm, higher neurological involvement, and higher SLEDAI-2K scores than rhupus patients. Comparisons of other clinical and serological variables between SLE rhupus and non-ruphus patients are shown in table 1 and figure 1.

Table 1. Clinical and serological manifestations in rhupus, articular SLE, and non-articular SLE

Variables	RHUPUS M (IQR)	SLE with arthritis M (IQR)	SLE without arthritis M (IQR)	P value RHUPUS vs. SLE with arthritis	p value RHUPUS vs. SLE without arthritis
Age (years) M (IQR)	40 (31.5 – 49)	29 (21.5 – 45)	33 (19.5 – 37.5)	0.043	0.013
CPR M (IQR)	2.3 (1– 8.5)	1.6 (0.3– 3.6)	0.9 (0.2– 2.5)	0.337	0.032
Positive anti-RNP N (%)	7 (29.1%)	14 (58.3%)	7 (29.1%)	0.042	1.000
Positive anti-Sm N (%)	5 (20.8%)	15 (62.5%)	6 (25%)	0.003	0.500
SLEDAI – 2K score M (IQR)	4.5 (1 – 7)	9 (2 – 18)	7 (3.5 – 15)	0.045	0.082

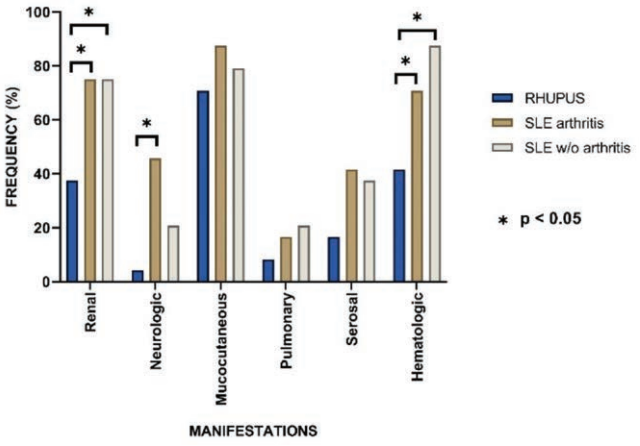

Figure 1. Differences in the frequencies of organic alterations. w/o: without.

Conclusion: Patients with rhupus were older and had lower SLEDAI-2K scores compared with those non-rhupus. Furthermore, renal, neurological, and hematological manifestations were more common in non-rhupus patients than in rhupus patients.

POS0771 VALIDATION OF THE 2019 EUROPEAN LEAGUE AGAINST RHEUMATISM/AMERICAN COLLEGE OF RHEUMATOLOGY (EULAR/ACR) CLASSIFICATION CRITERIA FOR SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN HONG KONG CHINESE

C. C. Mok[1], Y. K. Chung[2], C. Lee[2], L. Y. Ho[1], C. H. To[2]. [1]*Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; [2]*Pok Oi Hospital, Medicine, Hong Kong, Hong Kong (SAR)*

Objectives: To validate the 2019 EULAR/ACR classification criteria for SLE in Hong Kong Chinese patients and compare its performance with the 2012 Systemic Lupus International Collaborating Clinics (SLICC) and 1997 American college of rheumatology (ACR) criteria.
Methods: We retrospectively reviewed the medical records of consecutive patients who attended the Rheumatology clinics in Tuen Mun and Pok Oi hospitals between May and September 2019. Patients with anti-nuclear antibody (ANA) ≥1:80 were included and patients with ANA <1:80 or no ANA results were excluded. Patients were evaluated and cross-checked for the fulfilment of the 1997 ACR, 2012 SLICC and 2019 EULAR/ACR criteria by two investigators (YKC,CL). Medical records were then reviewed by an expert panel consisting of 3 senior rheumatologists, who were blinded for the results of the criteria evaluation, for a diagnosis of SLE based on the clinical judgement and therapeutic decisions. Teleconferences were arranged by the panel to discuss the discrepancies of the final diagnosis and agreement was made by voting. The three SLE criteria

were evaluated against the clinical diagnosis of SLE as judged by the expert panel on the sensitivity and specificity, which was calculated by 2x2 contingency tables ("condition positive" = clinical diagnosis of SLE; "test positive" = criteria positive for SLE) with standard formulas (sensitivity = true positive/[true positive + false negative]; specificity = true negative / [true negative + false positive]). Receiver operating characteristic (ROC) curve was used to study the optimal cut-off points from the EULAR/ACR criteria for the highest summation of specificity and sensitivity.

Results: 3967 patients were screened; 1542 patients who were positive for ANA (≥1:80) were included (88.3% women). The mean age of these patients at first rheumatology clinic attendance was 45.6±15.0 years and the duration of follow-up was 7.5±7.0 years. A total of 567 patients were judged to have SLE by the expert panel (discrepancy of clinical diagnosis in 135 patients resolved with voting). The sensitivity and specificity of the three SLE classification criteria in our patients are listed in Table 1. ROC analysis showed that the best cut-off for a clinical diagnosis of SLE using the EULAR/ACR criteria was 10 points (area under the curve [AUC] 0.977; sensitivity 89.2% and specificity 89.6%). Similar figures were obtained for subgroups of patients stratified by gender and different age ranges.

Conclusion: In our cohort of Hong Kong Chinese patients, the 2019 EULAR/ACR criteria is more sensitive but less specific when compared with 1997 ACR criteria for classifying SLE. On the other hand, the EULAR/ACR criteria is less sensitive but more specific than the 2012 SLICC criteria. The specificity of the EULAR/ACR criteria for SLE is higher in male than female patients. In our patients older than 50 years, the EULAR/ACR criteria is less sensitive but more specific for a classification of SLE. Overall, the performance of the EULAR/ACR criteria for a diagnosis of SLE in our study is similar to that reported in recent Asian studies although the sensitivity is lower, which may be related to the inclusion of ANA+ patients only.

POS0772 PREVALENCE AND RISK FACTORS FOR HERPES ZOSTER REACTIVATION IN 1542 PATIENTS WITH RHEUMATIC DISEASES

C. C. Mok[1], L. Y. Ho[1], S. M. Tse[1], K. L. Chan[1], C. H. To[2]. *[1]Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[2]Pok Oi Hospital, Medicine, Hong Kong, Hong Kong (SAR)*

Objectives: To study the prevalence and risk factors of herpes zoster (HZ) infection in patients with rheumatic diseases.

Methods: Medical records of patients with rheumatic diseases who attended our out-patient rheumatology clinics between 2019 March and 2019 August were retrospectively reviewed. Patients who were using biological or targeted DMARDs were excluded. Episodes of HZ infection since disease diagnosis were identified and the prevalence over time was calculated. Laboratory parameters (total white cell count, neutrophil-to-lymphocyte ratio, serum albumin, globulin & creatinine), history of diabetes mellitus and the highest doses of immunosuppressive medications within 6 months of the first episode of HZ infection were compared with those within 6 months of last follow-up in patients who did not have HZ infection. Cox regression analysis was performed to identify factors associated with the first HZ infection in all patients.

Results: 1542 patients were studied (88% women, age 46.4±15.0 years). The underlying diseases were systemic lupus erythematosus (SLE) (38%), rheumatoid arthritis (26%) and other rheumatic diseases (36%). After a total follow-up of 11,515 patient-years since diagnosis (7.5±7.0 years), 122 (7.9%) patients developed 146 episodes of HZ infection, giving an overall prevalence of 1.27/100-patient years. The prevalence rates of HZ in SLE, RA and non-SLE/RA patients were 1.70, 0.64 and 0.76 per 100 patient-years, respectively. Patients who experienced HZ reactivation were younger (41.6±14.7 vs 46.8±15.0 years; p<0.001), more likely to have SLE (74% vs 35%; p<0.001) and diabetes mellitus (17% vs 7.3%; p=0.01), and had a significantly lower albumin (38.6±5.6 vs 41.3±3.5; p<0.001) and higher neutrophil-to-lymphocyte ratio (4.9±6.2 vs 2.8±2.6; p<0.001). More patients with HZ reactivation were treated with prednisolone (54% vs 22%; p<0.001), azathioprine (20% vs 8%; p<0.001), mycophenolate mofetil [MMF] (21% vs 12%; p=0.006), cyclophosphamide [CYC] (4.9% vs 0.1%; p<0.001) and hydroxychloroquine (48% vs 34%; p=0.002) in the preceding 6 months compared with those who did not have HZ infection. Among those using immunosuppressive drugs, the doses of MMF (1.42±0.64 vs 1.02±0.31g; p=0.005) and prednisolone (15.6±15.9 vs 5.5±4.5mg; p<0.001) were significantly higher in those with HZ infection. The cumulative risk of having HZ reactivation in SLE patients at 24 and 48 months since diagnosis was 5.9% and 8.6%, respectively, which was significantly higher than that in non-SLE patients (1.9% and 2.5%, respectively; p<0.001 by log rank test). Cox regression analysis revealed that having a diagnosis of SLE (HR 1.97 [1.17-3.31]), albumin level (HR 0.93 [0.90-0.97] per g/L; p=0.001), serum creatinine (HR 0.995 [0.990-1.00] per umol/L), higher neutrophil/lymphocyte ratio (HR 1.08 [1.05-1.11]) and the use of CYC (HR 6.69 [2.56-17.5]) and prednisolone (HR 1.61 [1.02-2.45]) in the preceding 6 months were independently associated with the development of HZ infection.

Conclusion: Reactivation of HZ is fairly common in patients with rheumatic diseases. Underlying SLE, prednisolone/cyclophosphamide therapy and the neutrophil/lymphocyte ratio, but not age, sex or other laboratory parameters, are the major risk factors for HZ reactivation.

POS0773 CLINICAL PRESENTATION AND OUTCOMES OF THE ANTIPHOSPHOLIPID SYNDROME (APS) IN SOUTHERN CHINESE PATIENTS: THE HONG KONG APS REGISTRY

C. C. Mok[1], C. Lee[2], M. C. Leung[3], Y. K. Tang[4], C. Ho[5], S. Woo[6], M. L. Lee[7], M. C. Wan[6], M. Y. Lee[8]on behalf of Hong Kong APS registry working group. *[1]Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[2]Pok Oi Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[3]United Christian Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[4]Kwong Wah Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[5]Queen Mary Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[6]Rutonjee Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[7]Yan Chai Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; *[8]Tai Po Hospital, Medicine, Hong Kong, Hong Kong (SAR)*

Objectives: To report the clinical presentation and outcomes of the APS in Hong Kong Chinese patients.

Methods: The HKAPS registry was established in early 2020 by the Hong Kong Society of Rheumatology to study the outcomes of Chinese patients with APS treated in public hospitals in Hong Kong. Patients aged ≥18 years were identified by the Hospital Authority Clinical Data retrieval system using the ICD-10 diagnostic code of APS. The medical history and APS diagnosis was verified by sub-investigators in different hospitals using the 2006 modified consensus criteria for the APS. Eligible patients were classified into definite APS or probable APS, which was further categorized into primary (without underlying rheumatic diseases) and secondary types. The presentation, treatment and outcomes of these patients were summarized.

Results: 232 APS patients (76.3% women) were identified. All were ethnic Chinese. A total of 160 patients fulfilled the 2006 criteria for APS (definite APS) while 72 patients had probable APS (anti-phospholipid [aPL] antibodies positive once or with non-criteria manifestations). In those with definite APS, the mean age at diagnosis was 44.9±15.8 years and the female to male ratio was 3.1:1. APS was primary in 82 patients while 78 patients had concomitant rheumatic diseases (SLE in 95% of patients). 130(81%) patients had thromboembolic manifestations, 20(13%) had obstetric morbidities and 10(6%) had both. In patients with secondary APS, 23% thrombotic or obstetric manifestations occurred before diagnosis of the rheumatic diseases (ie. evolved from primary APS). Lupus anticoagulant was present in 81(51%) patients, moderate/high titers of anti-cardiolipin were present in 90(56%) patients and anti-$\beta_2$glycoprotein-1 was present in 6(4%) patients. Sixteen (10%) patients were double positive while 1 patient was triple positive for these aPL antibodies. Among the thromboembolic manifestations, arterial thrombosis (n=84) (ischemic stroke 77%, myocardial infarction 4.8%, peripheral vascular disease with limb/digital gangrene 2.4%, retinal artery 2.4%, splenic artery 1.2%, bowel infarct 1.2%) was more common than venous thrombosis (n=73) (calf vein thrombosis ± pulmonary embolism 86%, cerebral veins 2.7%, inferior vena cava/iliac veins 6.8%, retinal vein 2.7%, splenic vein 1.4%). The following treatment regimens were used in our APS patients: warfarin (71%), aspirin plus subcutaneous heparin (4%), aspirin + warfarin (3.1%), aspirin alone (17%) and the direct oral anticoagulant (DOAC) (5%). Bleeding complications developed in 35(22%) patients. Over a mean follow-up of 9.9±7.0years, recurrence of thromboembolic or obstetric manifestations recurred in 39(24%) and 6(4%) patients, respectively. A total of 29(18%) patients succumbed (median time to death: 6.4 years) and the causes of death were: pneumonia (24%), septicemia (17%), intracranial hemorrhage (14%), myocardial infarction (10%), ischemic stroke (3%), bowel infarct (3%), pulmonary hypertension (6.9%) and sudden death with unknown causes (14%).

Conclusion: APS in southern Chinese is relatively uncommon and most cases were associated with SLE. In contrast with the Caucasians, venous thrombosis related to APS is less frequent than arterial thrombosis in Chinese patients. With long-term anticoagulation treatment, the outcome is satisfactory with relatively low rates of recurrence and mortality. Expansion of the sample size to study factors associated with recurrence and mortality by involving more hospitals is in progress.

POS0774 INFLUENZA INFECTION AS A TRIGGER FOR SYSTEMIC LUPUS ERYTHEMATOSUS FLARES RESULTING IN HOSPITALIZATION

Y. B. Joo[1], Y. J. Park[2]. [1]*Hanyang University Guri Hospital, Rheumatology, Guri, Korea, Rep. of (South Korea)*; [2]*St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Rheumatology, Seoul, Korea, Rep. of (South Korea)*

Background: Infections have been associated with a higher risk of systemic lupus erythematosus (SLE) flares, but the impact of influenza infection on SLE flares has not been evaluated.
Objectives: We evaluated the association between influenza infection and SLE flares resulting in hospitalization.
Methods: SLE flares resulting in hospitalization and influenza cases were ascertained from the Korean national healthcare insurance database (2014-2018). We used a self-controlled case series design. We defined the risk interval as the first 7 days after the influenza index date and the control interval was defined as all other times during the observation period of each year. We estimated the incidence rates of SLE flares resulting in hospitalization during the risk interval and control interval and compared them using a Poisson regression model.
Results: We identified 1,624 influenza infections among the 1,455 patients with SLE. Among those, there were 98 flares in 79 patients with SLE. The incidence ratio (IR) for flares during the risk interval as compared with the control interval was 25.75 (95% confidence interval 17.63 – 37.59). This significantly increased the IRs for flares during the risk interval in both women (IR 27.65) and men (IR 15.30), all age groups (IR 17.00 – 37.84), with and without immunosuppressive agent (IR 24.29 and 28.45, respectively), and with and without prior respiratory diseases (IR 21.86 and 26.82, respectively).
Conclusion: We found significant association between influenza infection and SLE flares resulting in hospitalization. Influenza infection has to be considered as a risk factor for flares in all SLE patients regardless of age, sex, medications, and comorbidities.

POS0775 APLS-ASSOCIATED RETINAL VASCULOPATHY AS A PRESENTATION OF THROMBOTIC MICROANGIOPATHY

W. Qi[1], Z. Xie[1], J. L. Zhao[1], X. Tian[1], M. Li[1], X. Zeng[1]. [1]*Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China*

Background: Persistent antiphospholipid antibodies (aPL) positivity was a recognized risk factor for thrombotic events, obstetric morbidity and a variety of manifestations beyond thrombosis. The presence of some non-criteria manifestations including thrombocytopenia, hemolytic anemia, and APS nephropathy should prompt consideration for thrombotic microangiopathy (TMA).[1] Patients with APS can also present with a variety of ocular and neuro-ophthalmic manifestations, such as retinal artery/vein occlusion, retinal arteritis, optic neuritis and ischemic optic neuropathy, with underlying mechanisms remained elusive. Retinal vasculopathy including retinal artery occlusion (RAO) or retinal vein occlusion (RVO) was recently found occurred more frequently in APS patients with thrombocytopenia[2], suggested other possible mechanisms besides thromboembolism.
Objectives: To explore risk factors and possible mechanisms of retinal vasculopathy among APS patients.
Methods: In this single-center case-control study among APS patients, we evaluated patients who fulfilled 2006 Sapporo APS Classification Criteria[3] with or without retinal vasculopathy during 2018-2020 at Peking Union Medical College Hospital. Demographic data, aPL-related manifestations, cardiovascular risk factors and antibodies profile were compared and a logistical regression model was built. Hierarchical cluster analysis with the Euclidean distance and the Ward method was applied to identify clusters of variables.
Results: A total of 310 APS patients (67.4% female, mean age 38.1 years) were included, of whom 18 patients were diagnosed with retinal vasculopathy (9 with RVO and 9 with RAO). No significant differences was found among most demographic characteristics, clinical manifestations, or antibody profile. However, APS-related heart valve disease (OR 13.66, 95% confidence interval [CI] 4.55-40.98), APS nephropathy (OR 12.77, 95% CI 4.04-40.35), thrombocytopenia (OR 2.63, 95% CI 1.01-6.89) and high serum IgM (OR 3.67, 95% CI 1.30-10.40) were predictive of retinal vasculopathy (Figure 1 A). APS-related heart valve disease and nephropathy were also found statistical significant in multivariate logistical regression (Figure 1 B). They and other non-criteria manfestations were aggregated with retinal vasculopathy from cluster analysis of variables (Figure 1 C).
Conclusion: Patients with APS-related heart valve disease and nephropathy suffered a higher risk of retinal vasculopathy including RAO and RVO. The underlying mechanisms of aPLs-associated retinal vasculopathy may involve TMA, leading to a poor prognosis and therapeutic changes.

POS0776 CORRELATION OF PERIPHERAL CD4+GRANZB+CTLS WITH DISEASE SEVERITY IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

Q. Wang[1], L. Gu[2], M. Zhang[1]. [1]*The First Affiliated Hospital of Nanjing Medical University, Department of Rheumatology, Nanjing, China*; [2]*The First Affiliated Hospital of Nanjing Medical University, Department of Rheumatology, Nanjing, China*

Background: Sjögren's syndrome (SS) is a chronic autoimmune disorder. The major histopathologic lesion of it is a focal lymphocytic infiltrate around ductal and acinar epithelial cells, which include a majority of CD4+T. Several studies have shown that the epithelial cells in SS present diverse phenomena, such as MHC class II overexpression. CD4+T cells with cytotoxic activity (CD4 CTL) have been detected in various immune responses. They are characterized by their ability to secrete perforin and granzyme B to kill the target cells in an MHC class II-restricted fashion.
Objectives: So this study was to investigate the correlation of peripheral CD4+GranzB+CTLs with disease severity and organ involvement in patients with primary Sjögren's syndrome.
Methods: We recruited 116 pSS patients and 46 healthy controls using flow cytometry to examine proportion of CD4+GranzB+CTLs in their peripheral blood, and immunofluorescence to test the expression of CD4+GranzB+CTLs in labial gland. The correlations of CD4+GranzB+CTLs and the relevant clinical data were analyzed.

Results: We analyzed the percentage of CD4+GranzB+cytotoxic T cells in peripheral blood mononuclear cells (PBMCs) by flow cytometry. Frequency of peripheral CD4+GranzB+CTLs were measured in 116 patients with pSS and 46 healthy controls matched for age and sex. The percentage of CD4+GranzB+CTLs were significantly up-regulated in pSS patients than healthy controls (7.1%±4.9% vs 3.1%±1.9%, p <0.0001) and positive correlation with ESSDAI in pSS patients(r = 0.6332, p<0.001). The percentage of CD4+GranzB+CTLs were markedly higher in pSS patients with extraglandular manifestations. Moreover, CD4+GranzB+CTLs were observed in the lymphocytic foci and periductal areas of the LSGs and were elevated with increased foci index (FI). After excluding the other risk factors associated with pSS, CD4+GranzB+CTLs were still related to ESSDIA and extraglandular manifestations independently(p<0.05). ROC curve analysis indicated that the area under the curve (AUC) of CD4+GranzB+CTLs was 0.796 to predict the activity of pSS, and 0.851 to presume extraglandular manifestations. The best diagnostic cut-off point was 4.865 for pSS patients.
Conclusion: In this study, We provide new evidence indicating involvement of CD4+GranzB+CTLs over activation in the disease pathophysiology of pSS, which may serve as a new biomarker to evaluate the activity and severity of pSS.

POS0777

ANTIPHOSPHOLIPID RELATED LARGE VESSEL LESIONS: NOT ONLY THROMBOSIS

H. Jiang[1], W. Qi[1], J. Zhao[1], Y. Zhao[1]. [1]*Peking Union Medical College Hospital, Department of Rheumatology, National Clinical Research Center for Dermatologic and Immunologic Diseases, Beijing, China*

Background: Antiphospholipid syndrome (APS) is demonstrated as recurrent venous/arterial thromboses or obstetric morbidities with persistent antiphospholipid antibodies(aPLs). Recently, several cases reported that non-thrombotic lesions of large vessels may exist in APS, while less report described the characteristics of these patients.
Objectives: The study investigated patients with chronic large vessel lesions (stenosis or occlusion) (LVL) in APS, to detect the features of non-thrombotic arterial vasculopathy in APS (VAPS) by comparing with thrombotic APS (TAPS).
Methods: This is a single-center study involved the APS database from Peking Union Medical College Hospital (PUMCH) from 2013 to 2020. The study analyzed demography and laboratory index of 18 patients with LVL by comparing with 216 patients with thrombotic APS. Patients with LVL presented no specific vasculitis or in situ thrombosis at the lesion.
Results: Radiographic analysis in patients with LVL showed widespread thickening/enhancement of vessel wall or multiple segments stenoses, without intraluminal thrombus or atherosclerosis. In comparing with 216 patients with TAPS, the 18 patients with LVL complicated no other autoimmune diseases, had more cardiovascular risks (72.22% vs. 30.09%, $P < 0.01$), lower inflammatory index such as erythrocyte sedimentation rate (ESR) (6 vs. 11, p<0.05), increased cerebrovascular symptoms which maybe related to cerebral/carotid vessel occlusions (55.56%vs. 25.93%, p=0.01). Population characteristics, complications and antibody profiles in VAPS are similar to TAPS.
Conclusion: Large vessel lesions in APS could present non-thrombotic and non-inflammatory manifestations which is different from TAPS.

ULTRA HIGH-RESOLUTION ULTRASOUND (UHFUS) OF LABIAL GLANDS IS A STRONG PREDICTOR OF SALIVARY GLAND HISTOPATHOLOGY IN SJÖGREN'S SYNDROME (PSS)

G. Fulvio[1], F. Ferro[1], R. Izzetti[2], S. Fonzetti[1], G. La Rocca[1], G. Governato[1], G. Aringhieri[3], D. Caramella[3], M. Mosca[1], V. Donati[4], C. Baldini[1]. [1]*University of Pisa, Rheumatology Unit, Clinical and Experimental Medicine, Pisa, Italy*; [2]*University of Pisa, Unit of Dentistry and Oral Surgery, Surgical, Medical and Molecular Pathology and Critical Care Medicine, Pisa, Italy*; [3]*University of Pisa, Diagnostic and Interventional Radiology, Translational Research and of New Technologies in Medicine and Surgery, Pisa, Italy*; [4]*Unit of Pathological Anatomy 2, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy*

Background: Last-generation ultra high-resolution ultrasound (UHFUS) transducers, producing frequencies up to 70 MHz and achieving tissue resolution up to 30 µm, are opening up new possibilities for the study of labial salivary glands (LSG) in patients clinically suspected with primary Sjögren's syndrome (pSS).
Objectives: To explore the value of LSG-UHFUS as a predictor of the intensity of the histological inflammation in LSG biopsy in an inception cohort of patients with sicca symptoms derived from daily clinical practice.

Methods: Consecutive patients undergoing a LSG for clinically suspected pSS were included in this study from January 2018 to October 2020. UHFUS of LSG was performed by using VEVO MD, equipped with a 70 MHz probe, scanning first the central compartment of the inferior lip, and then both peripheral compartments. Parenchymal homogeneity was graded on a scale of 0 (normal) to 3 (evident). UHFUS imaging was used to locate the LSG for the US-guided biopsy. For each of the LSG specimens the area of the glandular tissue, the presence and number of foci and the focus score (FS) were assessed. Immunostaining for CD21 was performed to evaluate the presence of follicular dendritic cells (FDC) in foci.

Results: We included a total of 171 patients with suspected pSS: out of them, 83 (48.5%) received a diagnosis of pSS (ACR 2016 criteria) and 88 (51.5 %) were diagnosed as no-SS sicca controls. Out of the 171 LSG biopsies, 73/171 (42.7%) were characterized by a nonspecific chronic sialadenitis (NSCS) whereas a focal lymphocytic sialadenitis (FLS) was described in the remaining 98/171 (57.3%). UHFUS-LSG scores were differently distributed in pSS patients with respect to no-SS sicca controls: a score 0 was detected in 16/88 no-SS sicca controls and in none of the 83 pSS patients, whereas a score 3 was detected in 12/83 pSS and in none of no-SS sicca controls. (p<0.001). The higher was the UHFUS grading, the higher was the number of foci (from a mean (S.D) = 0.38 (0.72) in UHFUS-score 0 to 4.58 (3.11) in UHFUS-score 3, p<0.001) and the focus score (from 0.17 (0.32) in UHFUS-score 0 to 1.88 (0.90) in UHFUS-score 3, p<0.001) of the samples. Overall, out of the 16 no-SS controls with LSG-UHFUS score 0, only 4/16 showed histological features of focal lymphocytic infiltrate; however, the mean FS of those 4/16 samples was 0.17 (0.32). In fact, considering a FS≥1, negative UHFUS-LSG was highly predictive of a negative histology (100 %). By contrast, out of the 12 pSS patients with the highest score at LSG-UHFUS (score 3), 10/12 presented FDC networks in their biopsies, with a positive predictive value of 83% of the severity of the infiltrate.

Conclusion: UHFUS of LSG appeared feasible and sensitive in pSS; due to its striking negative predictive value this novel tool can help to identify negative patients on subsequent lip biopsy, thus avoiding invasive procedures in selected cases. Besides its diagnostic role, considering the association with the presence of FDC networks, UHFUS-LGS may also have a role in patients prognostic stratification.

POS0779 MYOCARDIAL INFARCTIONS, SUBTYPES, LOCATIONS AND CORONARY ATHEROSCLEROSIS IN SLE - A COMPARATIVE STUDY WITH MATCHED CONTROLS

I. Samuelsson[1], I. Parodis[1,2], I. Gunnarsson[1,2], A. Zickert[1,2], C. Hofman-Bang[3,4], H. Wallén[3,4], E. Svenungsson[1,2]. *[1]Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden*; *[2]Karolinska University Hospital, Unit of Rheumatology, Stockholm, Sweden*; *[3]Karolinska Institutet, Department of Clinical Sciences, Danderyd Hospital, Stockholm, Sweden*; *[4]Danderyd Hospital, Unit of Cardiology, Stockholm, Sweden*

Background: Myocardial infarction (MI) is estimated to be 2- to 3-fold elevated in systemic lupus erythematosus (SLE) as compared to gender- and age-matched controls (1-2). Even though some risk factors have been purposed, mechanisms of increased MI incidence remains to be determined.

Objectives: To explore underlying mechanisms, we compared MI characteristics and risk factors between SLE patients with MI (MI-SLE), MI patients without SLE (MI-nonSLE) and SLE patients without MI (nonMI-SLE).

Methods: We performed retrospective medical file review including angiography and echocardiography reports in 34 MI-SLE patients, 34 MI-nonSLE patients and 34 nonMI-SLE patients – all individually matched for gender and age in a ratio of 1:1:1.

Results: Median age was 61 years and 88% were females. MI-SLE patients had more coronary arteries involved (table 1; p=0.038), and ≥50% coronary atherosclerosis/occlusion at MI was numerically more common compared to MI-nonSLE controls (88% versus 66%; p=0.065). The left anterior descending artery was most frequently involved in both MI groups (73% versus 59%; p=0.11). Decreased (<50%) left ventricular ejection fraction occurred with similar frequency (45% versus 36%; p=0.79) in MI-SLE patients compared to MI-non-SLE patients. Cardiovascular disease (CVD) (44%, 5.9%, 12%; p<0.001) and coronary artery disease excluding MI (CAD, 32%, 2.9%, 0%; p<0.001) preceded MI/inclusion more commonly in MI-SLE than in MI-nonSLE and nonMI-SLE patients, respectively. MI-SLE patients differed from nonMI-SLE patients through lower plasma albumin levels (35 (29-37) versus 40 (37-42) g/L; p=0.002) and longer disease duration (22 (14-32) versus 14 (6.3-24) years; p=0.038).

Conclusion: We demonstrate that non-procedural MIs in SLE are in 88% of cases associated with significant coronary atherosclerosis. Increased prevalence of CAD prior MI and higher number of coronary arteries involved at MI, suggest accelerated coronary atherosclerosis in SLE patients. This calls for attentive surveillance of CVD and early atheroprotective treatment in this patients group.

POS0780 SKIN LESIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME

A. Shumilova[1], F. Cheldieva[2,3], T. Reshetnyak[2,3], A. Lila[3,4]. *[1]V.A. Nasonova Research Institute of Rheumatology, 4th Department of Rheumatology, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Vascular Rheumatology Department, Moscow, Russian Federation*; *[3]Russian Medical Academy of Continuing Professional Education, Department of Rheumatology, Moscow, Russian Federation*; *[4]V.A. Nasonova Research Institute of Rheumatology, Head of the Institute, Moscow, Russian Federation*

Background: In more than 40% of cases, systemic lupus erythematosus (SLE) is associated with the presence of highly positive antiphospholipid antibodies, with 50-70% of patients developing antiphospholipid syndrome (APS) over the next 10 years of the disease. Both diseases have similar and different clinical manifestations of skin lesions. The variety of skin lesions in SLE and APS requires a differential diagnosis and can make it difficult to diagnose a systemic autoimmune disease in a timely manner.

Objectives: To study the frequency of skin manifestations in SLE and APS, depending on the positivity of aPL.

Methods: The study included 116 patients with SLE (104 women and 12 men), mean age 37.9±12.9, disease duration 8.5 [1.15-13.0]; 40 patients with APS (33 women and 7 men), mean age 36.2±9.39. All patients were evaluated for skin lesions, and patients with APS were determined by IgG/IgM-aCL and IgG/IgM-aß2HP1 by enzyme immunoassay (ELISA), 19 of them were determined by IgA-aCL, IgA-aß2HP1 and IgG-aß2HP1-D1 chemiluminescence analysis (CMA).

Results: Acute skin lesions in past history were noted in 58 (50%) patients, chronic lesions -I n 21 (18.1%) patients; photosensivity and alopecia were indicated in 46 (39.6%) patients, mucosal lesions were noted in 36 (31%) of 116 patients, which corresponds to the literature data on the frequency of skin lesions and its appendages in SLE. At the time of inclusion in the study, skin lesions were detected in 20 patients. Score according to the CLASI index in patients with skin lesions: activity index=1.55 [0-22]; damage index=1.81 [0-36].

Skin lesions are the second most common signs of SLE onset (debut in 26 (22.4%) patients), second only to arthritis (38 (32.5%) patients), while the

detection of immunological disorders (highly positive ab to dsDNA) was observed in 7 patients (6%) with reliable APS and probable SLE, who may not have had time to develop a clinic for reliable SLE.
Livedo, as one of the most frequent skin manifestations of APS, was detected in 60 patients and was significantly associated with IgM-aCL and IgM-aß2HP1 positivity (p<0.0001). Significantly, positivity for IgG-aCL, IgG-aß2HP1 and IgG-aß2HP1-D1 (p=0.0001) and IgA-aCL (p=0.008) was associated with the development of comminuted hemorrhages, which occurred in 7 patients with APS and was associated with positivity of IgG-aCL, IgG-aß2HP1, IgG-aß2HP1-D1 (p=0.0001) and IgA-aCL (p=0.008).
The development of ulcerative-necrotic vasculitis with deep skin necrosis was observed in 3 patients, 2 of them were highly positive for IgG-aCL, IgG-aß2HP1, IgG-aß2HP1-D1. Melanoma was detected in the past history in 2 patients with highly positive for IgG-aCL, which is not a manifestation of the underlying disease, but confirms an increased risk of malignancy with aPL-positivity.
Conclusion: More than half of the patients had acute skin lesions, and about a quarter of the cases had skin lesions at the onset of the disease. The presence of comminuted hemorrhages was associated with positivity of IgG-aCL, IgG-aß2HP1, IgG-aß2HP1-D1) and IgA-aCL. Assessment of skin activity and damage (in particular, according to the CLASI index) is necessary for a comprehensive analysis of the dynamics of the disease and the response to therapy. The detection of aPL is necessary not only for the purpose of predicting thrombotic catastrophes, but also for the development of skin manifestations of APS.

POS0781 PERFORMANCE OF MAJOR SALIVARY GLAND ULTRASOUND FOR THE DIAGNOSIS OF SJÖGREN'S SYNDROME IN CLINICAL PRACTICE

M. C. Tenazinha[1,2], V. C. Romão[1,2,3], J. Polido-Pereira[1,2,4], N. Khmelinskii[1,2], R. Barros[1], F. M. Diamantino Saraiva[1,2], J. E. Fonseca[1,2,3,4]. *[1]Hospital de Santa Maria, Rheumatology and Metabolic Bone Diseases, Lisboa, Portugal*; *[2]Instituto de Medicina Molecular (IMM), João Eurico Fonseca Lab, Lisboa, Portugal*; *[3]Faculty of Medicine, University of Lisbon, Clinical Semiotics Institute, Lisboa, Portugal*; *[4]Faculty of Medicine, University of Lisbon, Rheumatology, Lisboa, Portugal*

Background: There is no specific test to diagnose Sjögren's Syndrome (SS) although available classification criteria intended for research purposes help guide the diagnosis. Major salivary gland ultrasound (MSGUS) may contribute to SS diagnosis.
Objectives: To study the performance of MSGUS for the clinical diagnosis of SS and its relationship with other relevant markers of disease.
Methods: We included patients with a clinical suspicion of SS that underwent MSGUS evaluation at our Department. Parotid and submandibular glands were classified bedside on a 0-4 scale, based on tissue inhomogeneity. The score of the highest graded gland was considered and a score ≥2 was defined as a positive MSGUS. Minor salivary gland biopsy (mSGB) was considered positive if a focus score ≥1 was reported. We compared MSGUS findings across diagnoses and against mSGB result and anti-SSA status. Categorical variables were compared using the chi-square test. Continuous variables were compared using Student's t-test, Mann-Whitney U test, or ANOVA. P-value was considered significant at <0.05.
Results: A total of 219 patients were included (Table 1). MSGUS was positive in a higher proportion of patients with primary and secondary SS, in comparison to non-Sjögren's sicca syndrome (nSSS) and undifferentiated connective tissue disease (UCTD; p<0.001). Mean MSGUS score was higher in SS patients in comparison to nSSS and UCTD (p<0.001). A positive MSGUS was associated with anti-SSA positivity (61.4% vs 38.6% in anti-SSA negative patients; p<0,001). Patients positive for anti-SSA had a higher mean MSGUS score (2.12 ± 1.03) in comparison with anti-SSA negative patients (1.31 ± 0.97, p<0.001). While MSGUS and mSGB were not significantly associated (p=0.237), the mean MSGUS score was higher in patients with a positive mSGB (1.95 ± 1.17) in comparison with those with a negative mSGB (1.61 ± 0.99; p=0.027).

Table 1. General sample characteristics

	Overall (n=219)	pSS (n=131)	sSS (n=17)	nSSS (n=62)	UCTD (n=9)	p-value
Age, years (mean ± sd)	60 ± 14	58 ± 17	56 ± 19	60 ± 13	48 ± 16	0.07
Female, n (%)	210 (95.9)	127 (97.0)	15 (88.2)	59 (95.2)	9 (100)	<0.001
Anti-SSA positive, n (%)	105 (47.9)	91 (69.5)	10 (5.8)	3 (4.8)	1 (11.1)	<0.001
Positive mSGB, n (%)	85 (46.4)	69 (63.3)	7 (46.7)	8 (15.7)	1 (12.5)	<0.001
MSGUS score, mean ± sd	1.70 ± 1.09	1.98 ± 1.09	1.76 ± 1.11	1.13 ± 1.09	1.44 ± 1.12	<0.001
Grade 0, n (%)	35 (16.0)	17 (13.0)	3 (17.7)	15 (24.2)	0 (0.0)	<0.001
Grade 1, n (%)	62 (28.3)	25 (19.1)	4 (23.5)	27 (43.6)	6 (66.7)	
Grade 2, n (%)	62 (28.3)	39 (29.8)	4 (23.5)	17 (27.5)	2 (22.2)	
Grade 3, n (%)	54 (24.7)	44 (33.6)	6 (35.3)	3 (4.9)	1 (11.1)	
Grade 4, n (%)	6 (2.7)	6 (4.6)	0 (0.0)	0 (0.0)	0 (0.0)	
MSGUS score ≥ 2, n (%)	122 (55.7)	89 (67.9)	10 (58.8)	20 (32.3)	3 (33.3)	<0.001

Conclusion: MSGUS is a valuable resource in the investigation of SS. It is associated with clinical diagnosis, anti-SSA and MSGB findings. Together with these other complementary exams, it can be used to assist in the diagnosis of patients presenting with sicca features suggestive of SS.

POS0782 FOLLICULAR DENDRITIC CELL NETWORKS IN MINOR SALIVARY GLAND BIOPSIES: A MARKER OF DISEASE ACTIVITY AT BASELINE AND DURING THE FOLLOW-UP IN SJÖGREN'S SYNDROME

C. Baldini[1], F. Ferro[1], G. Fulvio[1], G. La Rocca[1], S. Fonzetti[1], G. Governato[1], M. De Francesco[1], M. Mosca[1], R. Izzetti[2], V. Donati[3]. *[1]University of Pisa, Rheumatology Unit, Clinical and Experimental Medicine, Pisa, Italy*; *[2]University of Pisa, Unit of Dentistry and Oral surgery, Surgical, Medical and Molecular Pathology and Critical Care Medicine, Pisa, Italy*; *[3]Unit of Pathological Anatomy 2, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy*

Background: Minor salivary gland biopsy (MSGB) has been increasingly recognized as an important tool for the stratification of patients with primary Sjögren's syndrome (pSS). Recently, the presence of follicular dendritic cell (FDC) networks in the inflammatory infiltrate has been associated with more severe biological and serological abnormalities compared with less organized infiltrates.
Objectives: To investigate the associations between the presence and number of FDC networks in foci and pSS glandular and extra-glandular disease activity at baseline and during the follow-up.
Methods: Consecutive MSGBs performed in daily practice for clinically suspected pSS from January 2017 to October 2020 were reviewed. Patients' demographic, clinical, biological and serological data were obtained from medical records. The ESSDAI was used to measure disease activity at baseline and at the end of the follow-up in pSS patients. For histopathology, 3 µm sections were cut from each formalin-fixed paraffin-embedded block of MSGBs and stained with haematoxylin and eosin (H&E). Immunohistochemical stainings were performed on additional 3 µm sections in order to detect T lymphocytes (CD3), B lymphocytes (CD20) and follicular dendritic cells (CD21). Glandular tissue areas, number of foci, focus score (FS) and the presence and number of FDC networks were assessed.
Results: We reviewed 330 consecutive MSGBs from patients with suspected pSS: out of them 146/330 (44%) were classified as nonspecific chronic sialadenitis (NSCS) whereas 184/330 (56%) as focal lymphocytic sialadenitis (FLS). According to the ACR/EULAR criteria the diagnosis of pSS was confirmed in 130 patients (117 F:13 M, age 56±13 yrs). The mean (S.D) surface area of the MSGBs was 7.8 (3.9) mm^2. The number of foci in the FLS samples ranged from 1 to 12 (mean (S.D)=3.1 (2.6)), whereas the FS ranged from 0.3 to 9.0 (mean (S.D) = 1.4 (1.2)).The presence of FDC networks was documented in 106/330 (32%) of the samples; in 54/106 (51%) of these MSGBs the number of FDC networks ranged from 2 to 8 (mean (S.D)=3.1 (1.4)). The number of FDC networks significantly correlated with the number of foci (r=0.721**) and FS (r=0.707**). Patients with FDC networks in the inflammatory infiltrate presented more serological abnormalities (i.e anti-Ro/SSA, anti-LA/SSB, Rheumatoid factor) and elevated IgG levels (p<0.001). In pSS patients, the number of FDC networks slightly correlated also with C4 levels (r=-0.216*), peripheral lymphocyte count (r=-0.274**) and with glandular (r=0.213*), and biological (r=0.230**) domains of the ESSDAI at baseline. After a mean (S.D) follow-up of 21(13) months, the number of FDC networks still correlated with the final total ESSDAI (r=0.312**).
Conclusion: The presence and number of FDC networks in foci represent a useful histopathological parameter able to reflect disease activity at baseline and during the follow-up, thus allowing more personalized interventions.

POS0783

LUPUS NEPHRITIS: HISTOLOGICAL FEATURES AND LONG TERM OUTCOMES IN A LARGE SINGLE-CENTRE COHORT

A. I. Celia[1], F. R. Spinelli[1], C. Garufi[1], S. Truglia[1], V. A. Pacucci[1], F. Ceccarelli[1], C. Pirone[1], F. Natalucci[1], M. Speziali[1], C. Alessandri[1], F. Conti[1]. [1]*Department of Clinical Internal, Anaesthesiological and Cardiovascular Sciences, Sapienza University, Rome, Italy*

Background: In Systemic Lupus Erythematosus (SLE) patients the incidence of lupus nephritis (LN) is about 40% [(1)]. The rate of progression to end stage renal disease (ESRD) is 4.3-10.1% [(2)] and renal involvement is a strong predictor of morbidity and mortality.
Objectives: To describe clinical, histological features and renal outcomes of LN patients included in our single-center registry reporting data from more than 30 years. Moreover, we examined the correlation between clinical features at LN diagnosis and therapeutic lines used during the course of a 24 years follow-up.
Methods: A total of 71 patients were diagnosed with LN from 1989 to 2020. Demographic features and laboratory abnormalities (serum creatinine, 24 hours urine protein, urinary sediment, ds-DNA) at the time of LN diagnosis and at last available follow-up, were evaluated. We also examined renal biopsy performed and the histological classes (proliferative vs non-proliferative). We considered the increase number of therapeutic lines adopted as a negative prognostic factor in response to therapy.
Mean (SD) or median (IQR) were used according the variable distribution. T-test and Chi square and Mann-Whitney were used and p-value <0.05 were considered significant.
Results: Among 71 patients with LN, 63 (88.7%) were females and 8 (11.3%) males, with a F/M ratio of 6. Median SLE duration was 180 (162) months. The median age at the onset of nephritis was 28 (19.5) years and occurred in median after 12 (60) months from SLE diagnosis.
Sixty patients underwent a biopsy: the histology showed class III or IV proliferative glomerulonephritis in 49 patients (81.6%) and a non-proliferative class in 11 (18.3%) (p< 0.0001). Median serum creatinine value, 24 hours urine protein, urinary sediment, anti-ds-DNA at LN onset are reported in Table 1. Induction therapy was performed with cyclofosfamide in 14.5% of cases, mycophenolate in 21.1%, rituximab in 1.3%, cyclosporine A in 1.9% and azathioprine in 4.6%. The lines of therapies adopted during the follow-up ranged between a minimum of 0 and a maximum of 6 lines with a median value of 1.
Overall, the median follow-up was 180 (111) months and 30 (21.3%) patients had at least 120 months of follow-up. Median serum creatinine value, 24 hours urine protein, urinary sediment and eGFR last available follow-up are reported in Table 1. Three patients underwent dialysis and 3 kidney transplantation.
Eight patients underwent a re-biopsy: 7 (87.5%) had a proliferative class and 1 (12.5%) had a membranous class (p=0.01). Median serum creatinine value, 24 hours urine protein, urinary sediment at re-biopsy are reported in Table 1. In re-bioptized subgroup patients, induction therapies were cyclofosfamide in 50% of cases, mycophenolate in 12.5%, cyclosporine A in 25% and azathioprine in 12.5%. There were not statistically significant differences among the age on LN onset, the time from renal onset to the onset of the disease and the number of therapeutic lines adopted (Figure 1).
Conclusion: Among patients with LN the proliferative classes are the most common. At the 15-year follow-up 2,1% had renal transplantation and 2,1% dyalisis. We did not detect any association between age at diagnosis, time from renal impairment and the number of therapeutic lines.

AUDIOLOGIC EVALUATION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS AND IMPACT OF HYDROXYCHLOROQUINE THERAPY

S. Tharwat[1], W. Elshawaf[2], M. K. Nassar[3]. [1]*Mansoura University, Internal Medicine, Rheumatology & Immunology, Mansoura, Egypt*; [2]*Mansoura University, Audiology Unit, ORL Department, Mansoura, Egypt*; [3]*Mansoura University, Mansoura University Nephrology and Dialysis Unit, Internal Medicine Department, Mansoura, Egypt*

Background: Hydroxychloroquine (HCQ) is a commonly used agent in the treatment of rheumatic diseases including systemic lupus erythematosus (SLE). **[1]**
Objectives: The aim of this study was to evaluate the hearing function in SLE patients and assess the impact of chronic HCQ.
Methods: This study was carried out on 60 individuals (48 SLE and 12 healthy controls). The SLE patients were divided into HCQ group (n=36) and non-HCQ group (n=12) according to the chronic administration of HCQ. All participants were assessed by full audiological history and extended high frequency audiometry at frequencies 9, 10, 11, 2, 12.5, 14, 16,18 and 20 KHz.
Results: When comparing the study SLE patients with healthy controls,there was a statistically significant difference regarding patient reported otological manifestations such as tinnitus (p=.021), vertigo (p=.002) and hearing impairment (p=.042) while there was no significant difference regarding deafness or ear buzzing in one or both ears. HCQ group showed more hearing impairment at frequency 9000 and 20000 Hz than non-HCQ group (p=.004, <.001 respectively).
Conclusion: Otological symptoms and sensorineural hearing loss are prevalent among SLE patients. Chronic administration of HCQ may have an ototoxic effect.

CHANGING EXPRESSION PROFILES OF LONG NONCODING RNAS, MIRNAS, MRNAS AND CIRCULAR RNAS IN LABIAL SALIVARY GLANDS OF PRIMARY SJÖGREN'S SYNDROME (PSS)

G. Feng[1], L. Huang[2], J. Ji[3], C. Dong[3], Y. Xia[3], C. Cheng[4], Z. Gu[3]. [1]*Affiliated Hospital of Nantong University, Department of Stomatology, Nantong, China*; [2]*Affiliated Hospital of Nantong University, Department of Critical Care Medicine, Nantong, China*; [3]*Affiliated Hospital of Nantong University, Department of Rheumatology, Nantong, China*; [4]*Nantong University, Jiangsu Province Key Laboratory for Inflammation and Molecular Drug Target, Nantong, China*

Background: Primary Sjögren's syndrome (pSS) is a relatively common autoimmune disease characterized by oral and ocular dryness. An increasing number of studies have revealed that long non-coding RNA (lncRNA), miRNA, mRNA and circular RNA (circRNA) contributes to the pathogenesis of autoimmune diseases.
Objectives: To explore lncRNA, miRNA, mRNA and circRNA expression profiles in labial salivary glands (LSGs) in pSS patients and their biological functions in the regulation of pSS.
Methods: The expression of 75,550 lncRNAs, 2,318 miRNA, 20,292 mRNAs and 6,877 circRNAs were determined in the LSG of six pSS patients and six healthy controls using microarray experiments. Validation was performed in pSS patients and controls using real-time PCR. LncRNA-mRNA co-expression and gene-pathway networks were constructed using bioinformatics software.
Results: A total of 599 lncRNAs (upregulated: 279, downregulated: 320), 78 miRNAs (upregulated: 26, downregulated: 52), 615 mRNAs (upregulated: 590, downregulated: 25) and 160 mRNAs (upregulated: 110, downregulated: 50) were differentially expressed in the LSGs of pSS patients. Five of these lncRNAs were validated using real-time PCR. lncRNA HCP5, lncRNA SNHG5, lncRNA IFI44L, lncRNA CMPK2 were significantly upregulated and lncRNA TTYH1 were downregulated in pSS. GO

and KEGG biological pathway analysis were performed to predict the functions of differentially expressed lncRNAs and co-expressed potential targeting genes. Subsequently, a ceRNA (lncRNA-miRNA-mRNA) network including 2320 ceRNA pairs was constructed based on predicted miRNAs shared by lncRNAs and mRNAs.
Conclusion: The expression profile provided a systematic perspective on the potential functions of lncRNAs miRNAs, mRNAs and circRNAs in the pathogenesis of pSS. Therefore, this study will aid in the development of new diagnostic biomarkers and drug therapies.

POS0786 UNMET TREATMENT NEEDS IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): A CROSS-SECTIONAL ASSESSMENT OF DISEASE ACTIVITY IN SLE PATIENTS DURING THEIR LAST VISIT

O. Gioti[1], K. Chavatza[2], G. Belevonis[1], S. Koutsoviti[1], C. Katsimpari[1], I. Sofianos[1], A. Tatsi[1], P. Tzanis[1], A. Lazarini[1], K. Klavdianou[1], I. Giannakopoulou[1], E. Kalavri[1], E. Theotikos[1], A. Elezoglou[1], D. Boumpas[2], A. Fanouriakis[1,2]. [1]*"Asklepieio" General Hospital, Department of Rheumatology, Athens, Greece*; [2]*"Attikon" University Hospital, Rheumatology and Clinical Immunology Unit, Athens, Greece*

Background: The current goal of treatment in SLE is remission or low disease activity (LDA) and prevention of flares, achieved with the lowest possible dose of glucocorticoids. Nevertheless, in current clinical practice a significant number of patients still has active disease.[1,2]
Objectives: To assess the current disease activity state of SLE patients during their most recent visit in two centers (Department of Rheumatology in "Asklepieio" Hospital and Rheumatology Unit in "Attikon" Hospital, both in Athens, Greece).
Methods: Cross-sectional study of patients with a diagnosis of SLE for at least one year. Patients were divided into four groups: 1) *Remission off-therapy*: SLE Disease Activity Index (SLEDAI)=0 without prednisone or immunosuppressive drugs (IS), 2) *Remission on-therapy:* SLEDAI=0, prednisone dose ≤5mg/day and/or IS (conventional and biologic, maintenance phase), 3) *LDA*: SLEDAI ≤4, prednisone dose ≤7.5mg/day and/or IS (maintenance phase), 4) *Active disease*: SLEDAI >4 and/or prednisone dose >7.5mg/day and/or IS (induction phase).[2] Hydroxychloroquine was allowed in all groups.
Results: 205 patients were included [95.1% female, mean (SD) age 48.4 (14.9) years and median disease duration (IQR) 6.2 (12.6) years]. A history of lupus nephritis and neuropsychiatric SLE was present in 16.6% and 17.1% of our patients, respectively, and 39% of patients had SLICC/ACR damage index (SDI) > 0. At last visit, remission off-therapy and remission on-therapy was present in 8.3% (n=17) and 15.1% (n=31) of our patients, respectively. Seventy-five patients (36.6%) had LDA, whereas 82 patients (40%) had active disease. More than 85% (86.3%) of patients were in treatment with hydroxychloroquine and 64.4% were receiving immunosuppressive drugs. Regarding glucocorticoids, 50.2% (n=103) were treated with prednisone dose ≤7.5mg/day and over 40% (42.4%, n=87) did not receive prednisone at all. A SLEDAI score 0 and 1-4 was achieved in 24.4% and 42.9% of patients, respectively, but only 3.9% had a SLEDAI > 8, indicative of high disease activity.
Conclusion: Although the majority of our patients were treated with hydroxychloroquine and glucocorticoids in acceptable levels of daily dose, four out of ten patients in our practice have active disease during their last visit. Achieving treatment goals in SLE patients remains a challenge for future novel therapies.

POS0787 BERBERINE MODULATE LUPUS SYNDROME VIA THE REGULATION OF GUT MICROBIOTA IN MRL/LPR MICE

Y. Bao[1], J. Ji[1], Z. Xue[2], Z. Gu[1]. [1]*Affiliated Hospital of Nantong University, Department of Rheumatology, Nantong, China*; [2]*Affiliated Hospital of Nantong University, Research Center of Clinical Medicine, Nantong, China*

Background: Intestinal flora disorder and immune abnormalities have been reported in systemic lupus erythematosus (SLE) patients[1,2]. Berberine (BBR) showed significant effects in regulating the intestinal flora, repairing gut barriers and regulating immune cells[3,4]. While few reports mentioned the abnormal gut microbiota and metabolites in Chinese SLE patients.
Objectives: Our investigation tried to illustrate the relationship between gut microbiota, intestinal metabolites and disease activity in Chinese SLE patients. And the effect of BBR to intestinal dysbacteriosis, multiple organ damages and over-activated immune system in MRL/Lpr mice.
Methods: 16S high-throughput (16S rRNA) sequence, qRT-PCR and gas chromatography technology were used to determine the gut microbiota and metabolites in 104 SLE patients from Affiliated Hospital of Nantong University, China. BBR was orally treated to the MRL/Lpr mice in low, medium and high doses. After 6 weeks treatment, mice were sacrificed. Serum, faeces and organs were collected for further studies.
Results: Chinese SLE patients showed higher abundance of *Bacteroidetes* and lower abundance of *Firmcutes*. The results of qRT-PCR showed high *Firmcutes*/*Bacteroidetes* (F/B) ratio of SLE patients. The F/B ratio was negative correlated with SLE disease activity index (SLEDA) score. Almost all the tested short-chain fatty acids (SCFAs) found statistically significant results in SLE and LN (lupus nephritis) patients, especially the propanoic acid and butyric. BBR altered the relative abundance of *Bacteroides* and *Verrucomicrobia* and the butyric acid content in colon of MRL/Lpr mice. The increase of tight junction protein also indicated the gut barrier was repaired by BBR. Treg and Tfr cells in spleen and mesenteric lymph node (MLN) were increased. These results revealed a positive therapeutic effect of berberine on SLE from gut microbiota to immune status.
Conclusion: Our study highlights current status of intestinal dysbacteriosis in Chinese patients with SLE and differences in intestinal metabolites among patients with different disease states. The regulation of intestinal flora and the repairment of gut barrier by intestinal metabolites in BBR treated mice seemed to be the factor that directed the immune responses and disease outcomes. The ultimate goal of our study was to determine the beneficial effects of regulating the gut microbiota on the treatment of SLE. The application of berberine is a relatively safe and convenient way. In the coming investigations, we plan to focus on the study of berberine and its metabolites on intestinal function and systemic immunity.

POS0788 CIRCULATING EXOSOMES PROMOTE LUPUS NEPHRITIS IN MRL-LPR MICE

X. Sha[1], X. Ge[1], Y. Jin[1], T. Chen[1], X. Ni[1], W. Zheng[2], J. Ji[1], Z. Gu[1]. [1]*Affiliated Hospital of Nantong University, Department of Rheumatology, Nantong, China*; [2]*Affiliated Hospital of Nantong University, Research Center of Clinical Medicine, Nantong, China*

Background: Systemic Lupus Erythematosus (SLE) is a prototypic autoimmune disease that characterized by the loss of self-tolerance and the production of autoantibodies (autoAbs) [1, 2]. Lupus nephritis (LN), the severe organ-threatening manifestations of SLE, could cause massive damage to patients[3, 4]. Currently, some exosomal microRNAs (miRNAs) are considered as potential biomarkers in SLE. However, the role of exosomal miRNAs in Lupus Nephritis (LN) remains unclear.
Objectives: The purpose of this study was to investigate molecular mechanism of plasma exosomal miRNAs in the development of Lupus Nephritis.
Methods: Circulating exosomes were isolated from plasma of patients with LN, SLE without LN (NLN). Plasma exosomes were authenticated by Western Blot, Nanosight Tracking Analysis (NTA) and transmission electron microscopy (TEM). Fluorescence microscopy of co-cultured plasma exosomes and podocytes demonstrated that exosomes were uptaken into podocytes. Moreover, cell apoptosis and the inflammation factors was assessed using Western Blot. We analyzed the expression profiles of miRNAs in LN and NLN exosomes and the expression profiles of mRNAs of podocytes stimulated with LN and NLN exosomes with the help of next generation sequencing (NGS).
Results: We demonstrate that exosomes derived from LN plasma could be taken by neighboring podocytes and promote the apoptosis of podocytes and the expression of inflammation factors. In addition, the sequencing found that miRNAs were differentially expressed in LN and NLN exosomes and mRNAs were differentially expressed in podocytes stimulated with LN and NLN exosomes.
Conclusion: LN plasma exosomes have a potency to stimulate the apoptosis of podocytes and the expression of inflammation factors. Moreover, differentially expressed miRNAs in exosomes play a potential role in the development of LN.

APPLICATION OF THE NEW ACR/EULAR 2019 CLASSIFICATION CRITERIA OF SYSTEMIC LUPUS ERYTHEMATOSUS TO A INCEPTION, MONOCENTRIC COHORT OF UNDIFFERENTIATED CONNECTIVE TISSUE DISEASES POPULATION AT ONSET OF THE DISEASE

E. Elefante[1,2], A. Parma[1], V. Nannipieri[1], V. Signorini[3], C. Stagnaro[3], D. Zucchi[3], L. Carli[3], F. Ferro[3], C. Tani[3], M. Mosca[3]. *[1]University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*; *[2] University of Siena, Department of Medical Biotechnology, Siena, Italy*; *[1]University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: undifferentiated connective tissue diseases (UCTDs) are a group of systemic autoimmune diseases that share clinical and serological manifestations with definite connective tissue diseases (CTDs), but do not satisfy existing classification criteria[1]. Within this group, it is possible to identify very heterogeneous conditions: transitory and self-limiting forms, stable conditions over time and forms that will evolve towards definite CTDs, in particular Systemic Lupus Erythematosus (SLE). The availability of new classification criteria for CTDs could be useful in identifying major CTDs from their onset and help in the differentiation from stable UCTDs, which will maintain their undifferentiated profile over time.
Objectives: the aim of this study was to apply the new ACR/EULAR 2019 classification criteria of SLE[2] to patients included, at the onset of UCTD, to evaluate how many patients could be re-classified as SLE.
Methods: this is a retrospective observational study that enrolls patients who received the diagnosis of UCTD at the Rheumatology Unit of Pisa, according to the classification criteria proposed by Mosca et al[1], and were then regularly followed in the same clinic (inception cohort). For each patient, demographics, comorbidities, treatment, clinical and serological data were collected, at baseline and during follow-up. The new ACR/EULAR 2019 classification criteria of SLE were applied to the inception cohort at the onset of the disease. The characteristics of patients re-classified as SLE according to the new classification criteria and those of patients who "remained" classified as UCTD were compared.
Results: we enrolled 202 patients with a diagnosis of UCTD, mainly female (F:M 193:9) and of Caucasian ethnicity (97.5%), mean age at the diagnosis 38,5 ± 13,2 years and a median follow-up of 5 years (IQR 2-10).
During the follow-up, 10 patients (4.9%) in our cohort developed clinical and serological characteristics that led to a diagnosis of a definite CTD, in particular: 7 SLE, 2 Mixed Connective Tissue Disease (MCTD) and 1 Sjogren's syndrome.
Applying the ACR/EULAR 2019 classification criteria of SLE to patients enrolled at the onset of the disease, 38/202 (18.8%) would have been classified as SLE (with a median score of 12 (IQR 11-15)) on the basis of the presenting clinical and serological manifestations. Interestingly, 6/7 patients who received a diagnosis of SLE during the follow-up were among these 38 patients.
Among the items of the new classification criteria of SLE, the most frequently satisfied by patients "re-classified" were arthritis (63.2%), hematological (44.7%) and skin (23.7%) manifestations; as for the "immunological" items, hypocomplementemia (71%), SLE-specific (52.6%) and antiphospholipid (35.1%) autoantibodies.
Comparing the subgroup of patients "re-classified" as SLE with that of patients who "remained" UCTD, we found that the first group presented more frequently hematological manifestations, hypocomplementemia and anti-dsDNA, anti-Sm, anti-RNP, anti-beta2GPI positivity at the onset of the disease ($p<0.01$). Moreover, during the follow-up, the subgroup of patients "re-classified" as SLE developed more frequently malar ($p<0.05$) and discoid rash and arthritis ($p<0.01$) compared to patients who "remained" UCTD.
Conclusion: The development of increasingly sensible and specific classification criteria for definite CTDs may guide in the identification of stable UCTDs since their early stages and consequently in better definition of these conditions that can be considered as a distinct clinical entity.
The early identification of stable UCTD is of great importance not only for clinical management (follow-up schedules as well as therapeutic protocols) but also for scientific implications.

RELATIONSHIPS BETWEEN SALIVA IMMUNOGLOBULINS FREE LIGHT CHAINS CONCENTRATION AND CLINICAL, IMMUNOLOGICAL, HISTOLOGICAL PARAMETERS IN PATIENT WITH PRIMARY SJOGREN'S SYNDROME

E. Kuvardin[1], I. Kholopova[2], E. Belyakova[3], I. Grigor'eva[1], I. Bekhtereva[3], A. Maslyanskiy[1], Y. Krivolapov[3], S. Lapin[2]. *[1]Almazov National Medical Research Centre, Rheumatology Department, Saint - Petersburg, Russian Federation*; *[2]Pavlov First Saint - Petersburg State Medical University, Center for Molecular Medicine, Laboratory of Autoimmune Diagnostics, Saint - Petersburg, Russian Federation*; *[3]North-Western State Medical University named after I.I. Mechnikov, Pathological Department of Clinical Molecular Morphology, Clinic named after E.E. Eichwald, Saint - Petersburg, Russian Federation*

Background: Patients with primary Sjogren's syndrome (pSS) exhibit biological signs of B cell activation such as serum polyclonal hypergammaglobulinaemia, increased levels of free light chains (FLC) and positivity for autoantibodies. B-cells may comprise up to 50% cells of lymphocytic infiltrates in salivary glands of patents with the disease. For that reasons measuring saliva B-cells products might have diagnostic value in pSS.
Objectives: To evaluate relationships between saliva free light chains concentration and clinical, immunological, histological parameters in patient with pSS.
Methods: Saliva and blood FLC concentrations were measured in patient with pSS (n = 24) and healthy volunteers (n = 11). Patients fulfilled the ACR/EULAR 2016 criteria of pSS. Saliva collected during assessment unstimulated salivary flow was used for analysis. Quantitative assessment of $CD3^+$, $CD4^+$, $CD8^+$, $CD20^+$, $CD21^+$, $CD68^+$, $CD138^+$ cells was performed in minor salivary glands of 9 patient by immunohistochemistry. Cells quantity was calculated in 4 mm^2 (area of section).
Results: FLC concentration in saliva of pSS patients was higher than in healthy volunteers ($p<0,01$). Medians of saliva κ - and λ – free light chains concentrations in patients and healthy persons were 1,08 mg/L [25-;75- percentiles 0,58;1,91], 1,038 mg/L [0,55;2,03] and 0,36 mg/L [0,32; 0,54], 0,35 mg/L [0,21; 0,52] respectively. Median of saliva κ: λ chains ratio in pSS patient was 0,94 [0,6;1,5]. The ratio didn't differ from healthy persons ($p=0,24$). Saliva κ – and λ – free light chain concentrations in patient with pSS correlated with patients age ($r_s = 0,51$, $p=0,033$ and $r_s=0,43$, $p= 0,011$, respectively) and unstimulated salivary flow ($r_s = -0,48$, $p=0,02$ and $r_s=-0,49$, $p= 0,017$, respectively). Concentration of κ – free light chain correlated with number of $CD138^+$-cells ($r_s = 0,733$, $p=0,025$). Interesting that saliva λ – free light chain concentration didn't correlate with quantity of plasmatic cells.
Conclusion: Measuring saliva FLC concentration might be offered as diagnostic marker of pSS. Concentration κ – free light chain can directly mirror the glands quantity of plasmatic cells.

DOSE-DEPENDENT RELATIONSHIP BETWEEN HISTORY OF DENTAL CARIES AND INCREASED RISK OF NEWLY-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: A NATIONWIDE POPULATION-BASED COHORT STUDY

K. S. K. Ma[1]. [1]*National Taiwan University, Taipei, Taiwan, ROC, Department of Life Science, Taipei, Taiwan, Republic of China*

Background: The relationship between oral bacterial invasion caused by periodontal pathogens and risk of systemic lupus erythematosus (SLE) has been identified. However, there is a lack of knowledge on the relationship between carious lesions and risk of SLE, as well as longitudinal studies on the effect of restorative materials on SLE.
Objectives: This study investigated whether patients with history of dental caries are associated with an increased risk of newly-onset systemic lupus erythematosus (SLE).
Methods: A total of 541,461 carious patients and 258,918 controls without carious teeth were enrolled between 1997 and 2013 from the National Health Insurance Research Database. Subgroup analyses were conducted based on restorative materials included amalgam, resins or both. Cumulative incidences and hazard ratios (HRs) of developing SLE were derived after adjusting for age, gender, comorbidities and co-medications in a multivariable model.
Results: The risk of SLE was significantly higher in carious patients (HR = 1.984, 95% = 1.652-2.382) compared to controls. Dose-dependent relationship between caries and risk of SLE was identified. The risks of SLE were higher among those who had over 11 dental visits (HR = 2.525, 95% C.I = 1.859-3.429), followed by those with 3-10 dental visits (HR = 1.863, 95% C.I= 1.356-2.543), then those with 1-2 visits, and were higher among those who had over 5 carious teeth extractions (HR = 1.877, 95% C.I= 1.186-2.970), followed by those with 1-4 carious teeth extractions (HR = 1.363, 95% CI = 1.167-1.593), then those without extraction. The risk of SLE among different restorative materials, including amalgam or resins, for caries management, were not significantly different.
Conclusion: Patients with caries were associated with higher SLE risks. The relationship between caries and risk of SLE was dose-dependent, regardless of used restorative materials.

BASELINE FACTORS ASSOCIATED WITH LUPUS FLARES: A POST-HOC ANALYSIS OF PATIENTS WITH MODERATE TO SEVERE ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS ENROLLED IN A 48 WEEK PHASE II RANDOMIZED CLINICAL TRIAL

L. Lindsay[1], H. A. Mao[2], J. E. Cheng[2], C. Y. Chuo[3], N. Jones[4], M. D. Cascino[4], K. Tuckwell[4]. [1]*Genentech, Inc., Personalized Healthcare Data Science, South San Francisco, United States of America*; [2]*Hoffmann-La Roche Limited, Product Development Biometrics, Mississauga, Canada*; [3]*Genentech, Inc., Personalized Healthcare Analytics, South San Francisco, United States of America*; [4]*Genentech, Inc., Product Development Clinical Science, South San Francisco, United States of America*

Background: Systemic lupus erythematosus (SLE) is a chronic disease characterized by periodic flares associated with poor outcomes and subsequent organ damage (1-2). Flare prevention is important for optimal patient management and development of effective therapies.
Objectives: To identify patient-level factors associated with flares among patients with moderate/severe SLE.
Methods: We conducted a post-hoc analysis of 260 patients with active, autoantibody+ SLE enrolled in a phase II randomized clinical trial (Fenebrutinib) (3). The relationship between baseline demographic (age, gender, ethnicity, BMI), region (US/EU, outside US/EU), disease severity (PGA, SLEDAI-2K, BILAG domain involvement), disease duration, serologic markers (C3, C4, ANA, anti-dsDNA Ab, anti-Smith Ab), treatment arm, standard of care (SOC) and flares (BILAG and SFI) over 48 wks was assessed by survival analysis and multiple Cox Proportional Hazard models. We examined concordance between BILAG and SFI flares using Cohen's Kappa Index.
Results: The overall rate of flare was low (n=37 SFI flare, n=25 BILAG flare). Median time to first flare was 8 wks for SFI flares compared to 12 wks for BILAG flares. There was no difference in flare rate by treatment arm. Cumulative flare hazard increased over time. Concordance between SFI and BILAG flares was 0.14. Multivariable analyses identified a higher flare rate for both SFI and BILAG-defined flares in patients with severe disease at baseline (PGA >1.7, SLEDAI-2K ≥10) and <7 y disease duration.
Flares were more common in patients ANA, anti-dsDNA and anti-Smith+ at baseline compared to patients with <3 + markers (p<.001). Furthermore, anti-dsDNA (p = .03) and/or anti-Smith (p = .001) positivity at baseline were better indicators of higher flare rate compared to ANA (p = 0.5). Low baseline complement level (C3 and C4) was associated with a higher flare rate (p = .03 and p = .03 respectively).
Patients from non-US/EU regions had a higher flare rate compared to patients from the US/EU, despite receiving more frequent SOC therapy and higher baseline corticosteroid doses (≥10 mg/d). Overall, flare-free probability was comparable at 48 wks regardless of baseline corticosteroid dose but patients receiving <10 mg/d had a median time to flare of 4 vs 24 wks for those receiving ≥10 mg/d (p = .004).
Conclusion: In this study, flares were more common among patients with more severe disease, shorter disease duration, multiple serologic markers, were from outside the US/EU, and received lower steroid doses at baseline.

PREDICTORS OF END STAGE RENAL DISEASE IN THE RENAL BIOPSY PROVEN LUPUS NEPHRITIS

E. Duran[1], T. Yıldırım[2], U. Kalyoncu[1], A. Taghiyeva[3], E. Arzu Sağlam[4], M. Üner[4], E. Bilgin[1], J. Jabrayilov[2], E. C. Bolek[1], C. Önal[2], B. Farisoğulları[1], N. S. Koç[2], G. K. Yardımcı[1], S. Girgin[2], G. Ayan[1], Z. Özsoy[1], G. Sandal Uzun[1], L. Kılıç[1], Ş. R. Yılmaz[2], A. Akdoğan[1], Ş. A. Bilgen[1], O. Karadag[1], S. Kiraz[1], B. Altun[2],

A. İ. Ertenli[1], M. Arıcı[2], Y. Erdem[2]. *[1]Hacettepe University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[2]Hacettepe University School of Medicine, Department of Internal Medicine, Division of Nephrology, Ankara, Turkey*; *[3]Hacettepe University School of Medicine, Department of Internal Medicine, Ankara, Turkey*; *[4]Hacettepe University School of Medicine, Department of Department of Pathology, Ankara, Turkey*

Background: Although focusing on the proliferative form of lupus nephritis (LN), recent reports also highlight the importance of recognizing and treating non-proliferative forms of LN.

Objectives: In this study, we aimed to compare the clinical features and outcomes between proliferative and non-proliferative LN and to investigate the predictor factors of end stage renal disease (ESRD).

Methods: This retrospective study included 139 SLE patients who had at least one kidney biopsy between 2001 and 2020. 116 patients were diagnosed as LN. Biopsy findings had been classified according to the International Society of Nephrology and the Renal Pathology Society (ISN/RPS) classification. Demographics, disease involvements, laboratory values, treatment regimens, and outcomes in LN course were compared according to the proliferative and non-proliferative LN. Complete renal response within first 24 months was defined as ACR response criteria. Factors predicting the ESRD were analysed by the logistic regression analysis.

Results: A total of 116 lupus nephritis patients were categorised class 3 (n=17, 14.7%) or 4 (n=77, 66.4%) as proliferative LN and class 2 (n=9, 7.8%) or 5 (n=13, 11.2%) as non-proliferative LN. Of these patients, 80.2% was female. Mean age at the SLE diagnosis and SLE manifestations were similar for both group. ANA (+) ≥ 1:320, ds-DNA level, APS antibodies, anti-Sm (+) were similar for proliferative and non-proliferative LN, but ds DNA positivity and low level of C3 and C4 were more frequent in proliferative LN. LN duration was similar. Median renal SLEDAI scores were higher in proliferative LN group. Induction treatment regimens included pulse steroid 72.3%, CyC 51.8%, MMF 24.6%, Rtx 6.1%, CsA 4.4%, and plasma exchange 12.9%. ESRD, renal transplantation and exitus were major complications of LN. Predictors of ESRD were duration of lupus nephritis (OR 1.32 [1.09-1.61]; 95% CI), decrease in GFR at the biopsy time (OR 0.97 [0.95-0.99]; 95% CI), and being in complete renal response within 24 months (OR 21.07 [2.28-194.36]; 95% CI).

Conclusion: Unfortunately, LN patients still have worse outcomes, such as high ESRD rate, regarding to current effective immunosuppressive treatment regimens. Although patients' number were not enough for conclusion, interestingly, worse outcomes were not related with proliferative or non-proliferative LN. Complete remission within 24 months was most relevant good prognostic factor, and clinicians should be kept in mind to these windows of opportunity period.

Table 1. Demographic, clinical characteristics, and outcomes of the patients with lupus nephritis

Variables*	All patients (n=116)	Class 3 or 4 LN (n=94)	Class 2 or 5 LN (n=22)	p
Age at the SLE diagnosis, years	22.5±13.1	23±13.3	20.3±14	0.32

POS0794 INCIDENCE AND PHENOTYPE OF ANTIPHOSPHOLIPID SYNDROME (APS) AFTER PREECLAMPSIA

S. Amylidi-Mohr[1], M. Karakitsiou[1], R. Braun[1], F. Förger[2], E. Rexhaj[3], L. Raio[1]. *[1]Inselspital, Obstetrics, Bern, Switzerland*; *[2]Inselspital, Rheumatology, Bern, Switzerland*; *[3]Inselspital, Cardiology, Bern, Switzerland*

Background: Obstetric Antiphospholipid syndrom (oAPS) is induced by antiphospholipid antibodies (aPL) and associated with specific pregnancy complications. oAPS requires the combination of at least one obstetrical and one laboratory criteria (in 2 or more occasions at least 12 weeks apart). Multiple aPL positivity, lupus anticoagulant (LA) or persistently high aPL titers is defined as high risk aPL profile. *"Non-criteria" oAPS* are cases not fulfilling the clinical criteria.

Objectives: To investigate the incidence of aPL after preeclampsia and the association of phenotypes of oAPS and pregnancy outcome.

Methods: The present retrospective cohort analysis included women followed up after preeclampsia. Anti-PL (LA, aCL, anti-β2GBI of IgG and IgM isotype) are assessed 8 to 12 weeks after PE and if positive, again at least 12 weeks apart. According to the ISSHP PE is classified as severe if the blood pressure exceeds 160/110mmHg, or is associated with HELLP syndrome, or eclampsia. FGR is defined as estimated fetal weight <5th, and birth weight <10th percentile, and/or pathologic fetal Doppler.

Results: Complete clinical and laboratory data were available for 99 women over a period of 6 years. 38.4% delivered <34+0 weeks. PE was severe in 63.6% of cases, and the incidence of FGR was 58.9%. HELLP syndrome was diagnosed in 34.3% and in 4 cases it was isolated. The prevalence of aPL was 35 (35.4%) at first evaluation, and 23 (23.2%) were still positive 12 weeks apart. 14/99 (14.1%) cases fulfilled the definition of classical oAPS, and 9/99 (9.1%) delivered >34 weeks ("non-criteria oAPS"). Of interest, the incidende og high risk aPL profiles was similar in both groups (64.3% vs. 77.8%; p=NS). The incidence of HELLP syndrome was higher in the presence of APS (APS: 9/23 [39.1%] vs. 21/76 [27.6%]; p=NS). 3 out of 4 cases with isolated HELLP syndrome were associated with high risk aPL profiles. Overall, aCL IgG was the dominant aPL. 32/35 (91.4%) and 22/23 (95.7%) had positive aCL at first and second investigation, respectively (p=NS). An aCL IgG titer >32.8CU at first assessment yield a LR of 10 for persistent aCL with a sensitivity and specificity of 91.3% and 90.9%, respectively.

Conclusion: Classical and "non-criteria" obstetrical APS show a similar aPL pattern and distribution of aPL phenotypes regardless of gestational age at delivery. aCL IgG is the dominant aPL antibody and is highly predictive for aPL persistence at follow up. HELLP syndrome may be an additional feature of oAPS, in particular the isolated form. However, more studies are necessary to explore this possible association.

POS0795 ULTRASOUND-GUIDED CORE NEEDLE BIOPSY: AN EFFECTIVE AND SAFE TOOL TO DIAGNOSE SJÖGREN`S SYNDROME AND LYMPHOMA OF THE MAJOR SALIVARY GLANDS

U. Borner[1], L. Nisa Hernandez[1], A. C. Sarbu[2], L. Christ[2], Y. Banz[3], B. Maurer[2], M. D. Caversaccio[1], F. Kollert[2]. *[1]Inselspital, University Hospital Bern, University of Bern, Otorhinolaryngology, Head and Neck Surgery, Bern, Switzerland*; *[2]Inselspital, University Hospital Bern, University of Bern, Rheumatology & Immunology, Bern, Switzerland*; *[3]Pathology, University of Bern, Bern, Switzerland*

Background: Histopathology is a cornerstone of diagnostics in Sjögren`s syndrome (SjS). The current widely accepted standard, minor salivary gland (lip) biopsy, is a surgical procedure with several disadvantages including permanent sensory loss of the lips as a well-known complication (reviewed in 1). Moreover, lymphoma of salivary glands cannot be excluded. Ultrasound-guided core needle biopsy (CNB) is an excellent diagnostic tool with good safety (2) and encouraging results as compared to open biopsy (3).

Objectives: To retrospectively analyze safety and diagnostic outcome of ultrasound-guided CNB in patients with known or suspected SjS.

Methods: A retrospective analysis of a case series of four patients with known or suspected SjS. All patients were treated at the outpatient clinic of the Department of Rheumatology & Immunology, and the Department of Otorhinolaryngology. All patients underwent ultrasound-guided CNB: We clean and disinfect the ultrasound transducer and the skin of the patient before and after the procedure. We use a sterile probe cover and gloves. Only sterile ultrasound gel or ultrasound compatible disinfectant should be used. Core-needle biopsy was

performed using a 20 g needle (Bard). A Logiq S8 GE ultrasound device with a 6-15 MHz matrix linear transducer was used. We performed a local anesthesia at the entry point and a 2mm skin incision. The sampling length was set on 20mm. The CNB was performed at the most suspicious focal sonographic lesion. 2-3 needle passes were carried out through the same skin access.

Results: Representative histopathological samples were obtained from all patients. In patient 1 (62y) with known SjS and parotid swelling, mucosa-associated lymphoid tissue (MALT) lymphoma was diagnosed (previous lip biopsy with no proof of malignancy). Also in patient 2 (35y) with known SjS and a 20-years history of parotid swelling, MALT lymphoma was diagnosed. In this patient a lip biopsy was performed in the previous year supporting the diagnosis of SjS, but without proof of malignancy. In patient 3 (64y) with SSc, anti-Ro/SSA positivity and dry eyes and mouth, the biopsy established the diagnosis of SjS. In patient 4 (59y) with SSc, negative anti-Ro/SSA antibodies and dry eyes/mouths, SjS could be excluded. In the corresponding ultrasound, all patients showed hypoechogenic lesions and inhomogeneous parenchyma of major salivary glands reflecting OMERACT grade II-III SjS ultrasound score (4). No safety signals were observed. Patients with prior lip biopsies perceived ultrasound-guided CNB as preferable.

Conclusion: This pilot study suggests that ultrasound-guided CNB in SjS is a safe procedure with an excellent diagnostic yield allowing the diagnosis of lymphoma of the salivary glands, which is superior to lip biopsy. Given these encouraging results, we will now increase patient numbers for further validation.

Vasculitis – large vessel vasculitis

POS0796 SURVIVAL OF GIANT CELL ARTERITIS PATIENTS IN SLOVENIA

A. Hočevar[1,2], A. Viršček[3], R. Jese[1], M. Tomsic[1,2], Z. Rotar[1,2]. [1]*University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia*; [2]*Medical Faculty, University of Ljubljana, Internal Medicine, Ljubljana, Slovenia*; [3]*Statistical Office of the Republic of Slovenia, Ljubljana, Slovenia*

Background: Recent meta-analysis reported no difference in the long-term mortality of GCA patients at a population level, but an increased mortality in hospital-based cohorts[1].

Objectives: The aim of our study was to evaluate for the first time the survival of GCA patients in Slovenia.

Methods: We included patients with clinical diagnosis of GCA supported by histology or imaging diagnosed between September 2011 and December 2019 and prospectively followed at our secondary/tertiary rheumatology center. To evaluate mortality the censor date of 24. June 2020 was used. Kaplan–Meier analysis was used to analyze mortality. Standardized mortality ratio (SMR) was calculated using data of age matched Slovenian population as the reference.

Results: Between September 2011 and December 2019 we identified 309 new GCA patients (203 (65.7%) females, median (IQR) age 74.9 (67.7–80.1.7), range 53.7 to 97.5 years). Patients were followed (until death or censor date) of a median (IQR) 33.3 (17.5-60.8) months. Until the censor date 51 (16.5%) GCA patients died (24 females, 27 males). We found no significant sex related differences in the net survival estimates during the first five years of follow up (p=0.68).

Figure 1 shows the survival curve of GCA patients and general population as a comparator according to Kaplan–Meier analysis. In the first year following GCA diagnosis the mortality rate was 1.9 times higher compared to general Slovenian population (95% CI 1.19 - 2.88, p=0.03). For patients who survived the first year after diagnosis the mortality was comparable to the general population (Table 1).

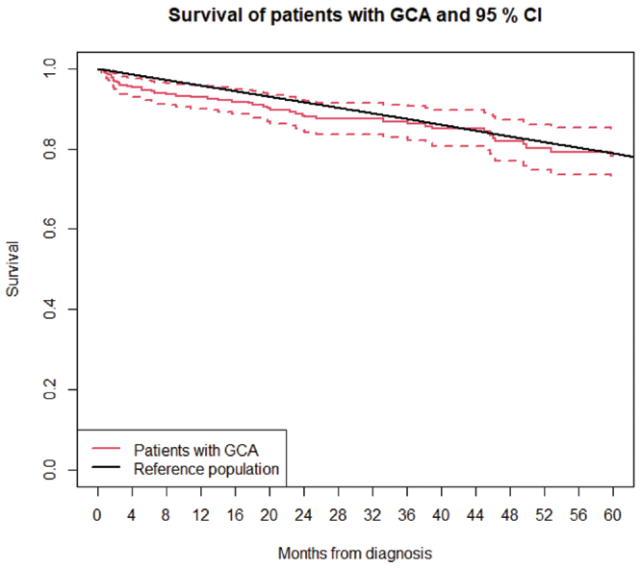

Figure 1. Survival curve according to Kaplan–Meier analysis in GCA

Table 1. Standardized mortality ratios of patients who survived the first year after diagnosing GCA (ie. were followed at least one year) compared to the general population

Years of FU	Observed deaths	Expected deaths	SMR (95%CI)	P-value
2	11	9.7	1.14 (0.57-2.03)	0.753
3	14	16.5	0.85 (0.46-1.43)	0.626
4	21	21.6	0.97 (0.60-1.49)	0.987
5	25	25.0	1.00 (0.65-1.48)	0.921
6	26	27.6	0.94 (0.61-1.38)	0.831

Legend: FU follow up; SMR Standardized mortality ratios; CI confidence interval

Conclusion: GCA patients had an increased risk of death in the first year from the GCA diagnosis.

POS0797 LARGE VESSEL-GCA: A DIAGNOSTIC CHALLENGE

F. Regola[1], F. Franceschini[1], G. Bosio[2], P. Toniati[1]. [1]*ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy*; [2]*ASST Spedali Civili, Nuclear Medicine Unit, Brescia, Italy*

Background: GCA is the most frequent systemic vasculitis in patients older than 50 years involving medium-sized and large arteries. Inflammation of the extracranial branches of the carotid artery gives rise to the classic symptoms of GCA. However, in almost two-thirds of patients GCA involves also the aorta and its major branches (1,2). Large vessel involvement leads to a different atypical clinical picture which can be challenging to diagnose (3,4). More information on clinical presentation and vessel involvement in large-vessel GCA are needed to better diagnose it.

Objectives: To analyze clinical presentation of large-vessel GCA compared to classical cranial disease.

Methods: 100 consecutive patients with a clinical diagnosis of GCA were enrolled in this retrospective study. All patients were older than 50 years of age, met the ACR criteria for GCA or had a positive biopsy of the temporal artery or evidence of large vessel vasculitis at FDG-PET/CT scan.

Results: Based on vascular involvement, patients were classified into three group: 61 patients with only cranial arteritis (C-GCA), 16 patients with only extracranial large vessel vasculitis (LV-GCA) and 23 patients with both cranial and large vessel involvement (LV-C-GCA).

Compared to C-GCA, patients with large vessel involvement (LV-GCA and LV-C-GCA) were younger and more frequently women, and the difference was further significant for patients with isolated LV-GCA. Patients with isolated LV-GCA had also the longer duration of symptoms at GCA diagnosis [LV-GCA 20(16-82) *vs* LV-C-GCA 12(4-16) *vs* C-GCA 4(3-12) weeks; p<0.001]. Systemic symptoms, as fever and fatigue, were associated with large vessel involvement, both in LV-GCA and LV-C-GCA groups. Polymyalgia rheumatica was equally reported in all three cohorts of patients and no significant differences were found in inflammatory markers levels according to vessel involvement.

In patients with large vessels involvement (LV-GCA and LV-C-GCA) thoracic aorta, subclavian arteries and abdominal aorta were the most frequently involved arteries.

Conclusion: GCA is not a single entity but includes several patterns of disease. Female gender, younger age and systemic symptoms are associated with large vessel involvement, regardless the presence or absence of cranial symptoms. The different clinical manifestations of large vessel GCA lead to a longer time to diagnosis if compared to C-GCA. For these reasons, in patients with the aforementioned characteristics, a large vessel involvement should be considered in order to reduce the time to diagnosis.

POS0798 GIANT CELL ARTERITIS TREATMENT PATTERNS AND RATES OF SERIOUS INFECTIONS

S. Tedeschi[1], Y. Jin[2], S. Vine[2], H. Lee[2], A. Pethoe-Schramm[3], V. Yau[4], S. Kim[1,2]. *[1]Brigham and Women's Hospital, Rheumatology, Inflammation and Immunity, Boston, United States of America*; *[2]Brigham and Women's Hospital, Pharmacoepidemiology and Pharmacoeconomics, Boston, United States of America*; *[3]F. Hoffmann-La Roche Ltd., Global Medical Affairs - Immunology, Basel, Switzerland*; *[4]Genentech, Personalized Healthcare Data Science, South San Francisco, United States of America*

Background: Giant cell arteritis (GCA) afflicts older adults, who may have age- and comorbidity-related risks for infection, and is treated with glucocorticoids and other immunosuppressants that might increase the risk of serious infections.

Objectives: To examine GCA treatment patterns and rates of serious infections in two real-world cohorts in the U.S.

Methods: Using claims data from two U.S. health insurance databases, Medicare (public, 2007-2017) and MarketScan (commercial, 2015-2019), we selected a cohort of patients with GCA based on a validated claims-based algorithm requiring ≥2 diagnosis codes for GCA plus dispensing of high-dose oral glucocorticoid (PPV 84.8%) [1]. The Medicare cohort included Medicare enrollees aged ≥65 years with GCA who were treated at a large Massachusetts-based healthcare system; the MarketScan cohort included a nationwide sample of GCA patients aged ≥50 years. GCA index date was the date of 1st glucocorticoid prescription. We assessed baseline comorbidities in the year prior to index date. Immunosuppressants and prophylactic antibiotics dispensed within 30 days of index date were recorded. Influenza vaccine administration in the year after index date was identified. We calculated the incidence rate of serious infections, defined as infections requiring hospitalization, after index date through end of cohort follow-up (12/31/17 in Medicare; 12/31/2019 in MarketScan), disenrollment, or death.

Results: The Medicare cohort included 734 patients, 28% male, mean age 77.1 (SD 7.4); the MarketScan cohort included 1022 patients, 30% male, mean age 68.4 (SD 10.9). The most common comorbidity was hypertension (80% Medicare; 72% MarketScan) followed by hyperlipidemia, cancer, coronary artery disease, and diabetes (Table 1). High-dose prednisone was the most common initial treatment; a small percentage received tocilizumab within 30 days of index date. Prophylaxis against pneumocystis pneumonia was similar in Medicare (13%) and MarketScan cohorts (10%). Influenza vaccination was more common in the Medicare (56%) than MarketScan (22%) cohort in the year after GCA index date. During the mean follow-up time of 2.6 (SD 2.5) years in Medicare and 1.5 (SD 0.9) years in MarketScan, 27.9% of the Medicare and 7.2% of MarketScan patients developed serious infections: incidence rate per 100 person-years = 10.7 (95% CI 9.3, 12.2) in Medicare and 6.3 (95% CI 5.0, 7.9) in MarketScan.

Conclusion: In these 2 real-world GCA cohorts in the US, over 25% of Medicare and 7% of MarketScan patients developed serious infection during follow-up. The incidence rate of serious infection was similar to ANCA-associated vasculitis [2]. Use of prophylactic antibiotics and influenza vaccination was suboptimal among GCA patients.

POS0799 THE EFFICACY AND SAFETY OF TOCILIZUMAB IN PATIENTS WITH GIANT CELL ARTERITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Koster[1], K. J. Warrington[1], J. Han[2], S. Mohan[3]. *[1]Mayo Clinic, Division of Rheumatology, Rochester, United States of America*; *[2]Genentech, Inc., Biometrics, South San Francisco, United States of America*; *[3]Genentech, Inc., Immunology, South San Francisco, United States of America*

Background: Tocilizumab (TCZ) has been proven to be safe and effective for the treatment of giant cell arteritis (GCA) in 2 randomized controlled trials; however, data from additional types of studies provide valuable information related to the treatment of GCA with TCZ.

Objectives: To review and analyze efficacy and safety data for TCZ in GCA based on peer-reviewed publications to date.

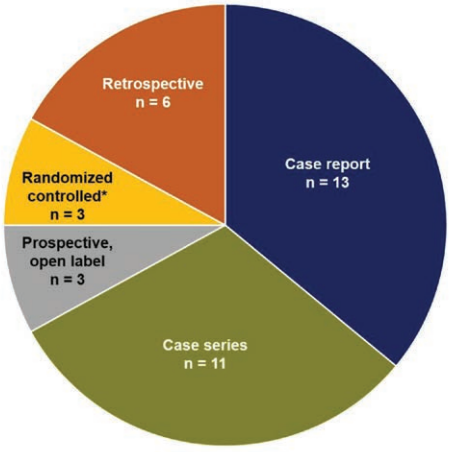
Methods: A systematic literature review was conducted according to the PRISMA guidelines. Publications were retrieved from the MEDLINE, Embase, Cochrane, Scopus and Web of Science databases. Publications of clinical trials and retrospective or prospective observational studies (April 11, 2005-October 8, 2019) including patients with GCA (classified based on ACR criteria and/or positive biopsy vs imaging) treated with TCZ and reporting a measure of efficacy were eligible for inclusion. Extracted data included year of publication, year(s) when the study was conducted, number of patients with GCA, method of GCA diagnosis, age and sex, TCZ treatment details (dose, route of administration, frequency, duration), clinical outcome (remission, relapse), serious adverse events

(SAEs) following treatment with TCZ, corticosteroid dose before and following TCZ initiation and imaging data following TCZ treatment. Results are presented for the studies (unweighted) and as the weighted population mean. Unweighted mean proportions were calculated as the average of the proportions reported from each study; unweighted means were calculated by computing the mean of individual reported study means. The weighted population proportion was estimated by calculating the total number of patients achieving an outcome and dividing by the total number of patients in all of the studies. The weighted population mean was equivalent to the sum of the individual patient's outcome values divided by the total number of patients in all of the studies.

Results: The search retrieved 664 references; 55 full-text articles were reviewed for eligibility, and 36 studies were included in the meta-analysis (Figure 1); the once-weekly and every-2-weeks subcutaneous (SC) TCZ arms of the GiACTA trial were counted as separate studies. A total of 519 patients were included. The median (IQR) duration of treatment with intravenous and SC TCZ was 26.0 (20.0-37.3) and 52.0 (26.0-52.0) weeks, respectively, across all studies in the unweighted analysis and 25.8 (20.8-41.9) and 38.9 (32.4-45.5) weeks in the weighted analysis. The mean (SE) proportion of patients achieving investigator-defined remission at the end of the study was 86.3% (4.3%) and 79.3% (6.0%) in the unweighted and weighted analyses, respectively (Table 1). The mean (SE) proportion of patients who relapsed while receiving TCZ was 2.6% (1.3%) and 12.0% (4.5%) in the unweighted and weighted analyses, respectively. The median prednisone dose at the end of the study was < 5 mg/day, and the mean proportion of patients with SAEs after TCZ initiation was ≈ 14.0%.

Conclusion: A high proportion of patients with GCA treated with TCZ were in investigator-defined remission at the end of the study across all studies analyzed. These meta-analysis findings add to the evidence of the efficacy and safety of TCZ in GCA.

Figure 1. Study Types Included in Meta-Analysis



*The subcutaneous TCZ once-weekly and every-2-weeks treatment arms of the GiACTA trial were counted as separate studies.

Table 1. Summary of Remission, Relapse and Adverse Events

Mean (SE) [95% CI]	Across GCA Studies; Unweighted (n = 36 studies)	Weighted Population Mean (n = 519 patients)
Percentage of patients in investigator-defined remission at the end of the study	n=35	n=411
	86.3 (4.3) [77.6 to 94.9]	79.3 (6.0) [67.2 to 91.4]
Percentage of patients who relapsed while receiving TCZ	n=31	n=39
	2.6 (1.3) [–0.18 to 5.3]	12.0 (4.5) [2.8 to 21.2]
Percentage of patients who relapsed after TCZ discontinuation	n=20	n=41
	26.4 (7.8) [10.1 to 42.7]	14.8 (5.8) [2.7 to 26.9]
Percentage of patients receiving no steroids at the end of follow-up	n=31	n=170
	41.8 (6.8) [27.8 to 55.8]	49.4 (8.1) [32.8 to 66.0]
Percentage of patients with SAEs after TCZ initiation	n=35	n=72
	14.0 (4.1) [5.5 to 22.4]	14.3 (1.3) [11.7 to 17.0]

POS0800 VISUAL ISCHEMIA DURING RELAPSE AND FOLLOW-UP OF GIANT CELL ARTERITIS: A SYSTEMATIC REVIEW

K. Bugdayli[1], P. Ungprasert[2], K. J. Warrington[3], M. Koster[3]. [1]*Case Western Reserve University School of Medicine, Internal Medicine, Cleveland, United States of America*; [2]*Cleveland Clinic Main Campus, Rheumatology, Cleveland, United States of America*; [3]*Mayo Clinic College of Medicine and Science, Rheumatology, Rochester, United States of America*

Background: Visual ischemia (VI) is one of the most feared complications in giant cell arteritis (GCA). While the frequencies of VI development at or near diagnosis are better studied, limited information is available regarding the frequency of VI during relapse.

Objectives: The purpose of this study was to characterize the frequency of visual ischemia (VI) as a manifestation of relapse or during follow-up in patients with GCA through performance of a systematic literature review.

Methods: Potentially eligible studies were identified from Medline and EMBASE databases from inception to November 31, 2019 using a search strategy that comprised of terms for "giant cell arteritis," "temporal arteritis," or "Horton's disease," with "relapse," "recurrence," "flare," "outcome," "follow-up," or "prognosis." VI was defined as transient or permanent, full or partial, monocular or binocular visual field loss. VI occurring within 4 wks of GCA diagnosis was considered due to active disease and not included as a relapse event. Inclusion criteria used: (1) original research reported in English, (2) GCA definition provided, (3) VI outcome described as one of the following: (a) relapse rate/frequency denoting the presence or absence of VI, or (b) absolute number of VI events (> 4 weeks after GCA diagnosis) even if total cohort relapse rate/frequency was not provided. In order to reduce bias from under-reporting of negative results, studies that reported relapse rates/frequencies with accompanying relapse characteristics but did not provide initial detail regarding the presence/absence of VI were also identified. In such circumstances, the primary authors were directly contacted for patient-level data regarding VI and these studies were included in the final analysis if such data were available and provided.

Results: A total of 913 unique articles were identified and underwent screening. Among these, 148 articles underwent independent full-text review by two physicians (K.B. and M.J.K). 33 articles met full inclusion criteria and an additional 21 articles included data on relapse but did not report VI patient data in the publication. Responses were received from authors of 11 of these 21 studies allowing for inclusion. 44 studies accounting for 3,649 patients with GCA were identified. Average percentage of baseline VI was 19% (range 0-66%). The average length of follow-up was 3.4 years (range 0.4 to 8.7). VI developing > 4 weeks after GCA diagnosis was recorded in a total of 53 patients (1.5%).

Study-defined relapses were reported in 36 studies. A total of 1,215 patients with at least one or more relapses were recorded among 2,592 patients under observation (47%). Among these 36 studies, VI occurred in 37 patients (3.0%) with at least one study defined relapse event.

Comparing trial design, retrospective studies (n=25) reported 27 of 2,718 (1%) patients developed VI during follow-up whereas 19 of 541 (3.5%) patients in randomized controlled trials (n=8) developed VI during the trial or post-trial follow-up.

Conclusion: This report outlines the first systematic review evaluating VI as a manifestation of relapse and during follow-up in GCA. Overall, VI > 4 weeks after GCA diagnosis is uncommon (1.5%) but is noted in up to 3% of patients with at least one relapse event. Frequencies of reported VI were 3.5 times higher in randomized controlled trials compared to retrospective studies.

POS0801 VASCULITIS IN PATIENTS WITH SARCOIDOSIS: A SINGLE-INSTITUTION CASE SERIES OF 17 PATIENTS

A. Kimbrough[1], K. J. Warrington[2], H. Langenfeld[3], C. S. Crowson[2,3], E. Carmona[4], A. Virata[5], M. Koster[2]. [1]*Mayo Clinic College of Medicine and Science, Internal Medicine, Rochester, United States of America*; [2]*Mayo Clinic College of Medicine and Science, Rheumatology, Rochester, United States of America*; [3]*Mayo Clinic School of Health Sciences, Bioinformatics and Statistics, Rochester, United States of America*; [4]*Mayo Clinic College of Medicine and Science, Pulmonology and Critical Care Medicine, Rochester, United States of America*; [5]*Mayo Clinic College of Medicine and Science, Pathology, Rochester, United States of America*

Background: Vasculitis in patients with sarcoidosis is rare and can affect blood vessels of any size. Limited information describing this association is available.
Objectives: To describe a large, single-institution case-series of patients with sarcoidosis and vasculitis.
Methods: A single-institution retrospective study was performed reviewing all patients with a diagnosis code for sarcoidosis and vasculitis between January 1, 1998 and December 31, 2019. Medical records were individually reviewed, and data regarding diagnosis, treatment, and outcomes were abstracted. Sarcoidosis was diagnosed based on histologic, radiographic, and clinical data with exclusion of alternative diagnoses. Diagnosis for small vessel vasculitis (SVV) required biopsy confirmation. Patients with large or medium-vessel vasculitis (L/MVV) required biopsy and/or arterial imaging. Comparison between patients presenting with L/MVV versus patients with only SVV was performed.
Results: Seventeen patients were identified during the study period. Nine patients (56% female) had L/MVV and 8 (50% female) had SVV. Sarcoidosis preceded the diagnosis of vasculitis in 4 (44%) patients in the L/MVV group compared to 3 (38%) patients in the SVV group. Mean±SD age at sarcoidosis diagnosis was 53.2±17.8 and 51.9±11.4 years and mean±SD age at vasculitis diagnosis was 57.4±19.6 and 59.0±13.4 years in L/MVV and SVV groups, respectively. Number of organ systems involved by sarcoidosis was similar [median (IQR) 3 (1,4) L/MVV vs. 2.5 (1.75, 3.25) SVV]. Sarcoid organ involvement and vasculitis vessel distributions are noted in Table 1. Mean length of follow-up was 11.5±12.8 years in L/MVV and 13.1±14.3 years in SVV. All patients were treated with glucocorticoids for vasculitis. More patients with L/MVV were treated with at least one DMARD/biologic (8/9, 89%) compared to SVV (3/8, 38%, p=0.05). Complete response to therapy for vasculitis was observed in 8/9 L/MVV and 7/8 in SVV. Four patients in SVV group were able to stop all immunosuppression but only one patient with L/MVV was off all therapy at last follow-up.

POS0802

18F-FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY AS A PREDICTOR OF ANGIOGRAPHIC PROGRESSION OF DISEASE IN LARGE-VESSEL VASCULITIS

K. A. Quinn[1], M. Ahlman[2], H. Alessi[1], A. Malayeri[2], J. Marko[2], E. Novakovich[1], P. Grayson[1]. [1]*National Institutes of Health, NIAMS, Bethesda, United States of America*; [2]*National Institutes of Health, Clinical Center, Radiology and Imaging Sciences, Bethesda, United States of America*

Background: Giant cell arteritis (GCA) and Takayasu's arteritis (TAK) are the two main forms of large-vessel vasculitis (LVV). Although angiography is essential to detect vascular disease in patients with LVV, there is limited prospective data characterizing change in arterial lesions over time, and factors that predict angiographic change remain unknown.
Objectives: The objectives of this study were to: 1) describe longitudinal change in angiographic studies in patients with GCA and TAK and 2) determine whether FDG-PET activity predicts angiographic progression of disease.
Methods: Patients with GCA or TAK were recruited into a prospective, observational cohort. All patients underwent baseline magnetic resonance (MR) or computed tomography (CT) angiography and a follow-up study (same modality) ≥6 months after baseline per a standardized imaging protocol. For patients who had multiple angiograms, the baseline and most recent images were compared. Arterial lesions, defined as stenosis, occlusion, or aneurysm, were evaluated by visual inspection in 4 segments of the aorta and 13 branch arteries by a single reader blinded to clinical status. On follow up angiography, the development of new lesions in these same territories was recorded, and existing lesions were characterized as improved, worsened, or unchanged by visual inspection, with confirmation by an independent reader.
All patients underwent FDG-PET on the same date as angiography. Qualitative assessment of FDG uptake was performed in each corresponding arterial territory evaluated by angiography. Active vasculitis was defined as greater FDG uptake in the arterial wall compared to the liver by visual inspection.
Results: At the baseline visit, there were 248 arterial lesions (21%) out of 1162 arterial territories evaluated from 70 patients with LVV (TAK=38; GCA=32). Baseline characteristics were as follows: Age [TAK=29.5 years (18.4-39.5), GCA=69.6 years (60.7-75.5)], Female gender [TAK=30 patients (79%), GCA=23 patients (72%)], Disease duration [TAK=2.2 years (0.6-5.5), GCA=0.7 years (0.1-2.6)], Active clinical disease [TAK=17 patients (45%), GCA=20 patients (63%)].
Over 1.6 years (1.0-2.7) of median follow-up, no angiographic change was observed in 1,132 (97%) arterial territories. New lesions developed in 8 arterial territories, exclusively in 5 patients with TAK. Arterial lesions improved in 16 territories (GCA = 7, TAK = 9) and worsened in 6 territories (GCA = 1, TAK = 5). Patients with angiographic improvement were initially imaged earlier in the disease course compared to patients with new/worsening lesions (median 1.1 vs 16.4 months, p=0.09). Patients with angiographic improvement had significantly lower acute phase reactants at follow-up compared to patients with new/worsening arterial lesions [median ESR 3.0 (2.0-15.0) vs. 27.0 (7.3-39) mm/h, p<0.01; median CRP 0.7 (0.3-1.4) vs. 6.1 (3.1-19.6) mg/L, p<0.01]. Seventy-nine percent of patients with new/worsening arterial lesions had received increased treatment over the follow-up interval compared to 100% patients with improved arterial lesions, p=0.09. FDG-PET activity was evaluated in 1091/1162 (94%) of corresponding arterial territories. PET activity in an arterial territory at baseline was significantly associated with change in that arterial territory (either new/worsening or improvement) on follow-up angiography (p<0.01) (FIGURE 1). PET activity had a sensitivity of 80% and specificity of 74% for predicting change in arterial lesions. Most arterial territories without PET activity at baseline remained unchanged over time by angiography, yielding a negative predictive value of 99%. (FIGURE 1).
Conclusion: Development of new arterial lesions is infrequent in LVV. Change in arterial lesions is dynamic, and improvement can occur. FDG-PET activity predicts change in angiographic lesions, and lack of PET activity is strongly associated with stable angiographic disease. These data may inform guideline recommendations for imaging monitoring in LVV.

POS0803 TRENDS IN THE INCIDENCE OF GIANT CELL ARTERITIS ACROSS SEVEN DECADES AND CHANGES IN DIAGNOSTIC MODALITIES: A POPULATION-BASED STUDY

T. Garvey[1], C. S. Crowson[1], M. Koster[1], K. J. Warrington[1]. [1]*Mayo Clinic, Rheumatology, Rochester, United States of America*

Background: Diagnostic methods for giant cell arteritis (GCA) have evolved over recent decades, and large vessel imaging plays an increasing role in disease detection.
Objectives: This study aims to estimate the incidence of GCA over the past 10 years in a population and compare it to preceding incidence estimates. It also explores trends in the diagnostic modalities used to identify GCA.
Methods: A pre-existing population-based cohort of patients diagnosed with GCA between 1950 and 2009 was extended with incident cases from 2010 to 2019. The diagnosis of GCA was confirmed by review of medical records of patients with ICD9/10 codes for GCA between 1/1/2010 and 12/31/2019. Incident cases that met either one of the following sets of inclusion criteria were added to the cohort: one, American College of Rheumatology 1990 GCA classification criteria; or two, patients aged ≥50 years with elevation of erythrocyte sedimentation rate or C-reactive protein and radiographic evidence of large vessel vasculitis attributed to GCA. Incident cases were classified into one of three groups: group 1, temporal artery biopsy (TAB) positive; group 2, TAB negative or not done with positive large-vessel imaging; or group 3, clinical diagnosis of GCA.
Results: The study cohort included 305 patients diagnosed with GCA from 1950 until 2019. Fifty-five incident cases were diagnosed between 2010 and 2019; 37 females (67%) and 18 males (33%). The age and sex adjusted incidence rates (95% CI) per 100,000 between 2010 and 2019 for females, males, and the total population were 13.0 (8.8, 17.3), 8.6 (4.6, 12.7), and 10.8 (8.0, 13.7), respectively. The corresponding incidence rates from 2000-2009 were 28.0 (21.0, 35.1), 10.2 (5.0, 15.5), and 20.5 (15.9, 25.1), respectively. This represents a significant decline in the incidence rates in females (p<0.001) and the total group (p<0.001) between the 2000-2009 and 2010-2019 cohorts but no change in males (p=0.64). Of the 55 patients diagnosed between 2010 and 2019, there were 37 (67%) in group 1, 10 (18%) in group 2, and 8 (15%) in group 3. In contrast, of the 250 patients diagnosed between 1950 and 2009 there were 209 (84%) in group 1, 4 (2%) in group 2, and 37 (15%) in group 3. There was a significant difference between the 1950-2009 and 2010-2019 cohorts in the composition of these groups (p<0.001).
Conclusion: In this population-based cohort of patients with GCA diagnosed over a 70-year period, the incidence of GCA has declined in recent years. The total decline is driven by a decline in females but not in males. The reasons for this are unclear but should be followed over time and investigated in other population-based cohorts. There has also been a shift in the diagnostic modalities for GCA. In recent years, there are fewer TAB positive patients, and more patients diagnosed with large vessel imaging. This is the first population-based incidence cohort demonstrating a trend towards increased use of large vessel imaging for the diagnosis of GCA.

POS0804 OUTCOMES OF SURGICALLY RESECTED THORACIC AORTITIS: RESULTS FROM A PROSPECTIVE MULTI-CENTRE REGISTRY

H. Caterson[1], A. Li[2], L. March[3], P. Bannon[4], J. Kench[5], T. Davidson[6], H. C. Soh[7], A. Sammel[8]. [1]*Royal Prince Alfred Hospital, Rheumatology, Camperdown, Australia*; [2]*The University of Sydney, Charles Perkins Centre and Boden Institute, Camperdown, Australia*; [3]*Royal North Shore Hospital, Rheumatology, St Leonards, Australia*; [4]*Royal Prince Alfred Hospital, Cardiothoracic Surgery, Camperdown, Australia*; [5]*Royal Prince Alfred Hospital, Anatomical Pathology, Camperdown, Australia*; [6]*Prince of Wales Hospital, Anatomical Pathology, Randwick, Australia*; [7]*Royal North Shore Hospital, Anatomical Pathology, St Leonards, Australia*; [8]*Prince of Wales Hospital, Rheumatology, Randwick, Australia*

Background: Inflammatory thoracic aortitis is a cause of aneurysm and is often diagnosed incidentally following aortic replacement surgery. It may be due to systemic diseases such as giant cell arteritis (GCA) and Takayasu arteritis (TAK) or a topographically isolated variant termed clinically isolated aortitis (CIA). While CIA is identified in 2-12% of thoracic aortic surgical pathology,[1] its short-term post-operative outcome is unknown.
Objectives: This study was undertaken to examine the short-term post-operative mortality and morbidity of patients with surgically resected thoracic aortitis compared to those with non-inflammatory thoracic aortic aneurysms and assess if outcomes varied based on post-operative corticosteroid therapy.
Methods: The study was based at three tertiary referral hospitals in Sydney, Australia, for the years 2004-2018. Prospectively collected data was accessed from a national surgical registry for all patients who underwent thoracic aortic aneurysm replacement. Aortitis patients were identified from histopathology records.
Inpatient medical records were reviewed to categorise aortitis cases as CIA, GCA, TAK or other aortitis and to audit the use of corticosteroids. Outcomes were compared between aortitis cases and the non-inflammatory cohort using logistic regressions, controlling for age, sex, year of procedure, and hospital.
Results: 41 aortitis cases were identified from the cohort of 1119 surgical patients (3.7%). 27 (66%) met criteria for CIA, 11 (27%) for GCA, 2 (5%) for TAK, and 1 (2%) for Other. 8 (20%) received corticosteroid therapy for aortitis.
Compared with non-inflammatory patients, the aortitis cohort was predominantly female (54% vs 28%, p < 0.01), older (mean 70 vs 62 years, p < 0.01), and had higher rates of hypertension (83% vs 67%, p = 0.03) and pre-operative immunosuppression (10% vs 1%, p < 0.01).
There was no difference (p > 0.05) between the aortitis and the non-aortitis groups for 30-day mortality (7% vs 7%), composite significant morbidity (15% vs 22%), composite infection (10% vs 6%), return to theatre for bleeding (7% vs 13%), stroke (5% vs 5%) or readmission (12% vs 10%). Similar results were also seen for CIA and the aortitis subgroup who did not receive corticoid steroid therapy when compared to the non-aortitis group (table 1).

Table 1. 30-day mortality and morbidity

	Non-aortitis		All aortitis		Aortitis, not treated for aortitis		CIA	
	n=1078		n=41		n=33		n=27	
	%	n	%	n	%	n	%	n
Mortality	7	70	7	3	6	2	4	1
Stroke	5	57	5	2	6	2	4	1
Return to theatre bleed	13	137	7	3	6	2	4	1
Composite morbidity	22	241	15	6	15	5	11	3
Composite infection	6	69	10	4	9	3	11	3
Readmission	10	108	12	5	12	4	11	3

Note: Differences in outcomes between the aortitis groups and the no aortitis group were modelled using logistic regression, controlling for age, sex, year of procedure, and hospital. There were no statistically significant differences in outcomes (p > 0.05).
CIA; clinically isolated aortitis. Composite morbidity; an outcome comprised of return to theatre for bleeding, stroke, new renal failure, acute myocardial infarction or aortic dissection. Composite infection; an outcome comprised of 30-day pneumonia, septicaemia, deep sternal wound infection or deep thoracotomy infection.

Conclusion: The finding of thoracic aortitis following aortic replacement surgery does not affect short-term post-operative mortality or morbidity. Corticosteroid therapy in the immediate post-operative period did not impact upon short-term outcomes.

POS0805 TREATMENT OF GIANT CELL ARTERITIS WITH TOCILIZUMAB: A RETROSPECTIVE COHORT STUDY OF 119 PATIENTS

J. Rakholiya[1], M. Koster[1], H. Langenfeld[2], C. S. Crowson[1,2], A. Abril[3], P. Bansal[4], L. Mertz[5], A. Rodriguez-Pla[5], R. Sehgal[4], B. Wang[3], K. J. Warrington[1]. *[1]Mayo Clinic, Rheumatology, Rochester, United States of America*; *[2]Mayo Clinic School of Health Sciences, Biomedical Statistics and Informatics, Rochester, United States of America*; *[3]Mayo Clinic, Rheumatology, Jacksonville, United States of America*; *[4]Mayo Clinic Health System, Rheumatology, Eau Claire, United States of America*; *[5]Mayo Clinic, Rheumatology, Scottsdale, United States of America*

Background: Giant cell arteritis (GCA) is an inflammatory condition of medium- and large-sized arteries. Prospective clinical trials have demonstrated the efficacy of tocilizumab (TCZ) for treatment of patients with GCA (1). However, there is a limited data on the use of TCZ in routine clinical practice.

Objectives: To evaluate the efficacy and safety of TCZ in a retrospective cohort study of patients with GCA treated with TCZ.

Methods: Patients with GCA treated with TCZ at 4 clinical centers of a single tertiary care institution (2000-2020) were identified. The diagnosis of GCA was confirmed by at least one of the following modalities: 1. Arterial biopsy 2. Large vessel imaging 3. Clinical diagnosis of GCA meeting ACR classification criteria and established by a rheumatologist. Patient demographics, clinical presentation, laboratory studies, treatment course and adverse events were abstracted from the medical record; only patients with at least 6 months of follow-up after TCZ initiation were included. Kaplan-Meier methods were used to estimate time to TCZ discontinuation and time to first relapse after TCZ discontinuation. Poisson regression models were used to compare relapse rates before and after TCZ initiation.

Results: The study cohort included 119 patients [61% female; mean (SD) age at GCA diagnosis 70.3 (8.2) years]. The majority of patients (89%) had a biopsy-proven and/or imaging-based diagnosis of GCA, while 13 (11%) had a clinical diagnosis of GCA. In addition to glucocorticoids, 40 (34%) patients received other immunosuppressive agents prior to TCZ. The method of initial TCZ administration was subcutaneous (162mg/ml) weekly in 48 (41%), subcutaneous every other week in 20 (17%), monthly 4mg/kg infusions in 34 (29%), monthly 8mg/kg infusions in 14 (12%) and non-standard dosing in 3 remaining patients. The median (IQR) duration from GCA diagnosis to TCZ initiation was 4.8 (1.2-22.0) months and the median (IQR) duration of TCZ treatment was 18 (11-28) months. The mean (SD) dose of prednisone at TCZ initiation was 31 (19) mg/day and was reduced to a mean (SD) dose of 3.9 (6.7) mg/day at TCZ discontinuation/last follow-up visit. The relapse rate per year decreased 43% from 0.77 to 0.44 after the initiation of TCZ (RR=0.57; 95% CI: 0.44-0.75; p<0.001). The mean (SD) ESR and CRP decreased from 22 (20) mm/hour to 6 (9.2) mm/hour and from 19.1 (25) mg/L to 5.4 (16.6) mg/L, respectively from TCZ initiation to TCZ discontinuation/last follow-up visit. At 2 years of follow-up, 67% of patients had discontinued glucocorticoids. At last follow up, 46 patients had discontinued TCZ, only 14 of which were due to adverse events. The median time to TCZ discontinuation was 2.9 years. Only 17% (95%CI: 10-24%) had discontinued by 1 year after TCZ initiation and 38% (95% CI: 26-47%) had discontinued by 2 years. The most common adverse events were infections and cytopenias. While on TCZ, 1 patient developed new onset vision loss related to GCA and 1 patient, without history of diverticulitis, had bowel perforation. Among those discontinuing TCZ, 61% had relapsed at least once by 1 year after TCZ discontinuation.

Conclusion: In this large single institution cohort of patients with GCA, TCZ use resulted in a significantly reduced relapse rate and reduction in glucocorticoid dosage. Overall, patients tolerated long-term use with only 12% discontinuing due to adverse events. However, over half of patients stopping TCZ had a subsequent flare; highlighting ongoing use may be required beyond two years in several patients with GCA to maintain remission.

Background: GCA is characterized by cranial symptoms but imaging techniques show that patients with non-specific symptoms such as systemic inflammation or PMR may have undiagnosed large vessel (LV) GCA[1]. Although silent GCA in patients with clinically isolated PMR may have consequences for patients' outcome, little is known about its prevalence and characteristics of affected patients.

Objectives: To review data on the prevalence of silent GCA in newly diagnosed PMR patients without cranial GCA symptoms and to analyze which characteristics are associated with vascular involvement among PMR patients.

Methods: We systematically screened PubMed, Embase and Web of Science databases and included studies screening for GCA in steroid naïve PMR patients without cranial symptoms consistent with GCA. Authors of the publications that used PET for vasculitis screening were invited to share their individual patient data (IPD) for a meta-analysis. We sought to define patient characteristics that were associated with vasculitis using univariable mixed effects logistic regression models with vascular involvement as the outcome, missing values were imputed using multilevel joint modeling multiple imputation. To fit a multivariable model with the candidate predictors we excluded variables that were hypothesized to have less medical relevance for the outcome and highly correlated inflammation markers (ESR, Lc).

Results: Out of the 3047 studies screened independently by 2 authors (DG and TD), 13 fulfilled the inclusion criteria. These studies (published 1963-2019) reported on 543 PMR patients examined by temporal artery biopsy (n=175), ultrasound (n=110), PET or PET-CT (n=258). 115 PMR patients were diagnosed with GCA (21.2%), with prevalence ranging from 0-92%.

We collected IPD for 243 patients from 4 cohorts using PET and 3 using PET/CT for GCA diagnosis. The overall median age of patients was 72.3 years (IQR 66.4-78.0) and vasculitis was found in 65 patients (26.7%) (table 1).

Table 1.

	Overall	PMR	PMR+GCA
n (%)	243	178 (73.3)	65 (26.7)
Female sex (%)	146 (60.1)	98 (55.1)	48 (73.8)
Shoulder girdle pain (%)	236 (97.1)	174 (97.8)	62 (95.4)
Pelvic girdle pain (%)	174 (71.6)	127 (71.3)	47 (72.3)
Inflammatory back pain (%)			
No	107 (44.0)	83 (46.6)	24 (36.9)
Yes	106 (43.6)	70 (39.3)	36 (55.4)
Lower limb pain (%)			
No	87 (35.8)	61 (34.3)	26 (40.0)
Yes	81 (33.3)	68 (38.2)	13 (20.0)
Weight loss (%)	112 (46.1)	78 (43.8)	34 (52.3)
CRP (mg/l) (median [IQR])	46.0 [19.0, 77.7]	44.0 [16.9, 74.2]	52.0 [27.9, 85.0]
ESR (mm/h) (mean (SD))	65.2 (30.3)	62.7 (30.2)	72.3 (29.7)
Hemoglobin (g/dl) (mean (SD))	12.1 (1.5)	12.2 (1.5)	11.7 (1.6)
Thrombocytes (1e+09/ml) (mean (SD))	341.9 (106.3)	323.9 (103.2)	375.8 (104.6)

In the univariable analyses the following factors were most strongly associated with vasculitic PET findings: female sex (OR 2.31, CI 1.17-4.58), inflammatory back pain (OR 2.73, CI 1.32-5.64), temperature >37° (OR 1.83, CI 0.90-3.7), weight loss (OR 1.83, CI 0.96-3.51), thrombocytosis (i.e., patients with a thrombocyte count 1 SD above mean have an OR of 1.51, CI 1.05-2.18), anemia (i.e., 1 g/dl decrease in Hb below mean corresponds to an OR of 1.25, CI 1.00-1.56). Patients with lower limb pain were less likely to have vasculitis (OR 0.43, CI 0.19–0.95). The estimated ORs were very similar in the multivariable model although the 95%CIs became wider.

Conclusion: Although the prevalence across published studies showed substantial variation, 6 out of 13 studies reported a prevalence of silent GCA in 18-40% of all PMR patients. The exploratory analysis of the collected IPD identified female sex, inflammatory back pain, fever, weight loss, absence of lower leg pain, thrombocytosis and anemia as factors associated with LV-GCA. These findings should be validated in future prospective cohort studies. The presence or absence of these factors may further aid in diagnosing LV-GCA in PMR patients.

POS0807 RETINAL VESSEL CALIBERS AS A NON-INVASIVE BIOMARKER OF INFLAMMATORY BURDEN IN PRIMARY SYSTEMIC VASCULITIS

O. Argyropoulou[1], E. Aissopou[1], A. Argyris[1], A. Goules[1], C. Mavragani[2], N. Tentolouris[3], P. Sfikakis[3], P. Vlachoyiannopoulos[1], A. Tzioufas[1], A. Protogerou[1]. [1]*School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece*; [2]*School of Medicine, National and Kapodistrian University of Athens, Physiology, Athens, Greece*; [3]*Medical School, National and Kapodistrian University of Athens, Athens, First Department of Propaedeutic Internal Medicine, Athens, Greece*

Background: Primary Systemic Vasculitides (PSV) constitute a heterogeneous group of rare and potentially life-threatening autoimmune diseases, characterized by a varying degree of inflammatory response, leading to local or generalized vascular disease. Vessel involvement accounts for the micro- and macrovascular complications of the disease, along with the classic risk factors including, among others age and chronic use of steroids (1). Early identification of high-risk patients for cardiovascular disease (CVD) development and the contribution of inflammation towards this adverse outcome are still unmet needs. Alterations of retinal microcirculation have been independently associated with increased CVD risk in the general population (2). The potential changes of retinal vasculature and their association with disease activity and the magnitude of inflammation have not been studied in PSV so far.

Objectives: To explore the effect of disease activity and inflammation on retinal microcirculation in PSV, classified according to vessel size as large, medium or small vessel vasculitides (LVV, MVV or SVV respectively), and polymyalgia rheumatica (PMR) without vasculitis.

Methods: Fifty-nine patients, 43 with active disease [30 active vasculitis (12 LVV, 4 MVV, 14 SVV) and 13 PMR] and 16 with chronic inactive disease (13 vasculitis, 3 PMR) were studied. All patients were matched at 1:1 ratio with 59 controls, without underlying autoimmune/autoinflammatory disorder, neoplasia or infection, according to age, gender, CVD history, BMI, smoking, arterial hypertension, dyslipidemia, diabetes mellitus and treatment related to comorbidities. A total of 32 rheumatoid arthritis (RA) patients with mild to moderate inflammatory component as defined by standard of care acute phase reactants (ESR and CRP) and 16 chronic RA patients with normal ESR and CRP levels, matched 1:1 according to all the above parameters with 32 active and 16 inactive vasculitis/PMR patients respectively, served as disease controls. Digital retinal images were obtained and retinal vessel calibers were measured with a validated software to determine central retinal arteriolar and venular equivalents ratio (CRAE and CRVE respectively). For 16 patients with active vasculitis/PMR, retinal examination was performed in two time points (baseline and ≤ 6 months later).

Results: In the overall population, patients with active Vasculitis/PMR had increased CRVE (213.8±21.7 vs 201.3±17.1, p<0.001) and CRAE (180.0±19.2 vs 164.1±17.5 p<0.001) compared to healthy controls. Separating patients according to disease type, we found that in LVV, MVV and PMR, CRAE (p≤0.05) and CRVE (p<0.05) were increased compared to control group, while in SVV only CRAE was increased (p<0.001). Interestingly, chronic patients with disease in remission displayed higher CRAE compared to matched controls (179.8±17.2 vs 169.1±11.1, p=0.006). After immunosuppressive treatment for ≤ 6 months CRVE and to a lesser extent CRAE were reduced (p=0.048 and 0.149 respectively) with a stronger statistical significance found in the Vasculitis group (p=0.026 and 0.069 respectively). Pearson's linear correlation coefficient in active disease state (at baseline examination) revealed positive bivariate correlation only between CRVE with ESR and CRP. Patients with Vasculitis/PMR had also increased CRAE when compared to RA patients in both active and inactive disease status (182.8±19.4 vs 170.1±18.4, p<0.001 and 179.8±17.2 vs 166.3±17.9, p=0.005 respectively).

Conclusion: Systemic inflammation alters retinal microcirculation in both a reversible (venules) and irreversible (arterioles) way, independently of PSV form. Thus, common disease specific pathogenetic mechanisms related to inflammation may be implicated in vascular remodeling. Sequential follow-up of PSV patients will address whether retinal vessel calibers may serve as a biomarker of disease activity and CVD development.

POS0808 CHARACTERISTICS OF GIANT CELL ARTERITIS FLARES AFTER SUCCESSFUL TREATMENT WITH TOCILIZUMAB: RESULTS FROM THE LONG-TERM EXTENSION OF A RANDOMIZED CONTROLLED PHASE 3 TRIAL

S. Unizony[1], S. Mohan[2], J. Han[2], J. H. Stone[1]. [1]*Harvard Medical School, Massachusetts General Hospital Rheumatology Unit, Boston, United States of America*; [2]*Genentech, US Medical Affairs, South San Francisco, United States of America*

Background: GiACTA investigated tocilizumab (TCZ) for the treatment of giant cell arteritis (GCA).

Objectives: To investigate disease flare characteristics after successful treatment with TCZ in GiACTA.

Methods: We report a post hoc analysis from part 2 of GiACTA. Part 1 was a 52-week, double-blind, randomized controlled period and part 2 was a 2-year open-label follow-up. In part 1, patients received TCZ 162 mg subcutaneously every week or every other week with a 26-week prednisone taper or placebo plus a 26- or 52-week prednisone taper. Patients who were in remission at week 52 were to enter part 2 on no TCZ treatment. Part 2 treatment was at the investigator's discretion. We report characteristics of first disease flare in patients assigned to TCZ in part 1 who were in sustained remission at week 52 and experienced flare in part 2. Flare was defined as reappearance of cranial symptoms (headaches, jaw claudication, visual manifestations, scalp tenderness) or polymyalgia rheumatica (PMR) symptoms or elevation of erythrocyte sedimentation rate (ESR) ≥30 mm/h attributable to GCA that required treatment.

Results: Of 149 patients assigned to TCZ in part 1, 81 (54%) were in sustained remission on entering part 2. Of these 81 patients, 37 (46%) experienced at least one flare in part 2, including 17 with new-onset GCA and 20 with relapsing GCA at baseline. Median time to flare was 26.6 weeks. In patients with new-onset GCA, flares included cranial (53%) more often than PMR symptoms (18%). Cranial and PMR symptoms were balanced (both 60%) at the time of flare in patients with relapsing GCA. Visual manifestations occurred in two patients (5%) (Table 1). ESR and CRP were elevated in 65% and 36% of patients, respectively, at the time of flare. Three (8%) flares occurred with elevated ESR without clinical symptoms.

Table 1. Clinical manifestations during flare in part 2

	Part 1 Treatment[a]		
	TCZ QW+Pred	TCZ Q2W+Pred	All TCZ
New-onset disease			
Patients, n	28	14	42
Patients with ≥1 flare, n (%)[b]	9 (32.1)	8 (57.1)	17 (40.5)
Patients with ESR ≥30 mm/h during flare, n (%)[b]	6 (66.7)	6 (75.0)	12 (70.6)
Patients with CRP ≥10 mg/L during flare, n (%)[b]	4 (44.4)	2 (25.0)	6 (35.3)
Patients with GCA signs or symptoms during flare, n (%)[c]	7 (77.8)	7 (87.5)	14 (82.4)
PMR symptoms	1 (11.1)	2 (25.0)	3 (17.6)
Cranial symptoms[d]	4 (44.4)	5 (62.5)	9 (52.9)
Amaurosis fugax	0	0	0
Blurred vision	1 (11.1)	0	1 (5.9)
Diplopia	0	0	0
Blindness	0	0	0
Ischemic optic neuropathy	0	0	0
Fever	1 (11.1)	0	1 (5.9)
Other[e]	3 (33.3)	2 (25.0)	5 (29.4)
Relapsing disease			
Patients, n	28	11	39
Patients with ≥1 flare, n (%)[b]	14 (50.0)	6 (54.5)	20 (51.3)
Patients with ESR ≥30 mm/h during flare, n (%)[b]	8 (57.1)	4 (66.7)	12 (60.0)
Patients with CRP ≥10 mg/L during flare, n (%)[b]	5 (35.7)	3 (50.0)	8 (40.0)
Patients with GCA signs or symptoms during flare, n (%)[c]	14 (100)	6 (100)	20 (100)
PMR symptoms	8 (57.1)	4 (66.7)	12 (60.0)
Cranial symptoms[d]	8 (57.1)	4 (66.7)	12 (60.0)
Amaurosis fugax	1 (7.1)	0	1 (5.0)
Blurred vision	0	0	0
Diplopia	0	0	0
Blindness	0	0	0
Ischemic optic neuropathy	1 (7.1)	0	1 (5.0)
Fever	0	0	0
Other[e]	6 (4.3)	1 (16.7)	7 (35.0)

[a]Patients from part 1 TCZ+Pred groups who were in sustained remission at week 52 entered part 2 on no treatment.
[b]Percentage based on N in disease-onset group.
[c]Percentage based on number of flare patients in disease-onset group. Individual signs or symptoms are shown as number of patients with each symptom; patients could have ≥1 sign or symptom at the time of flare.
[d]New-onset localized headache, scalp tenderness, temporal artery tenderness or decreased pulsation, ischemia-related vision loss, or jaw pain claudication.
[e]Includes fatigue, malaise, subjective weakness, and night sweats.

Conclusion: Overall, 46% of GCA patients successfully treated with TCZ for 1 year experienced disease flare within the next 2 years. Flares in patients with new-onset disease occurred more often with cranial than PMR symptoms. Visual manifestations were rare, and no blindness occurred. ESR and CRP were normal in a sizable percentage of patients experiencing flare.

POS0809 A BIOMARKER PROFILE AIDING AN EARLY DIAGNOSIS OF GIANT CELL ARTERITIS

Y. Van Sleen[1], P. Therkildsen[2], A. Boots[1], B. Dalsgaard Nielsen[2], K. Van der Geest[1], P. Heeringa[3], M. G. Huitema[1], M. D. Posthumus[4], M. Sandovici[1], E. Toonen[5], J. Zijlstra[1], E. M. Hauge[2], E. Brouwer[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]Aarhus University Hospital, Rheumatology, Aarhus N, Denmark*; *[3]University Medical Center Groningen, Pathology and Clinical Immunology, Groningen, Netherlands*; *[4]Martini Ziekenhuis Groningen, Rheumatology, Groningen, Netherlands*; *[5]Hycult Biotech, R&D Department, Uden, Netherlands*

Background: Diagnosing patients with giant cell arteritis (GCA) remains difficult. Due to its non-specific symptoms, it is challenging to identify GCA in patients presenting with polymyalgia rheumatica (PMR), which is a more common disease (1). In addition, commonly used acute-phase markers fail to discriminate between GCA patients and (infectious) mimicry patients.
Objectives: To investigate a selection of biomarkers for their utility in the accurate diagnosis of GCA in two cohorts.
Methods: Treatment-naïve GCA patients participated in the Aarhus GCA/PMR cohort (N=52) and the Groningen GPS cohort (N=48). Symptoms and biomarker levels were compared to patients presenting phenotypically as isolated PMR, disease controls and healthy controls (HCs). Diagnosis or exclusion of diagnosis of GCA was based on clinical assessment and in the majority of cases aided by imaging. Serum/plasma levels of 12 biomarkers were measured by ELISA or Luminex.
Results: In both the Aarhus and the GPS cohort, we found that weight loss, elevated erythrocyte sedimentation rate (ESR) and higher angiopoietin-2/-1 ratios but lower matrix metalloproteinase (MMP)-3 levels identify concomitant GCA in PMR patients (Figure 1). In addition, we confirmed (1) that elevated platelet counts are characteristic of GCA but not of GCA look-alikes, and that low MMP-3 and proteinase 3 (PR3) levels may help to discriminate GCA from other diseases (Figure 1). Multiple biomarkers of inflammation were found elevated in patient and disease control groups when compared to HCs.
Conclusion: This study, performed in two independent cohorts, consistently shows the potential of angiopoietin-2/-1 ratios and MMP-3 levels to identify GCA in patients presenting with PMR. These biomarkers may be used to select which PMR patients require further diagnostic workup. Platelet counts may be used to discriminate GCA from GCA look-alike patients.

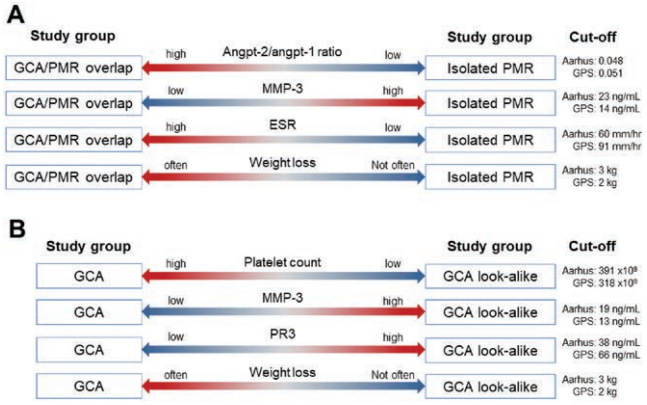

Figure 1. Summary of the most important and consistent findings in both cohorts. A shows the four factors that perform best in discriminating GCA/PMR patients overlap from isolated PMR patients in both cohorts. B shows the four factors that perform best in discriminate GCA patients from GCA look-alike patients in both cohorts. Cut-off values for the biomarkers are calculated by the Youden index.

POS0810 PULMONARY FINDINGS ON HIGH-RESOLUTION COMPUTED TOMOGRAPHY IN TAKAYASU ARTERITIS

X. Kong[1], J. Zhang[2], J. Lin[3], P. LV[3], H. Chen[1], Z. Ji[1], X. Dai[1], X. Jin[4], L. Ma[1], L. Jiang[1]. *[1]Zhongshan Hospital Fudan University, Department of Rheumatology, Shanghai, China*; *[2]Zhongshan Hospital Fudan University, Department of Pulmonary Medicine, Shanghai, China*; *[3]Zhongshan Hospital Fudan University, Department of Radiology, Shanghai, China*; *[4]Zhongshan Hospital Fudan University, Department of Clinical Epidemiology Center, Shanghai, China*

Background: Takayasu arteritis (TA) is a chronic granulomatous large-vessel vasculitis most commonly seen in women under 50 years of age[1]. The pulmonary arteries are less often involved, with the frequency of involvement varying widely between countries (from 4% to >50%) [2–5]. Respiratory symptoms or signs and pulmonary imaging findings in TA have not been fully investigated [6–7].
Objectives: This study aimed to describe pulmonary high-resolution computed tomography (HRCT) findings in TA and to determine possible causes.
Methods: A total of 243 TA patients were enrolled from a prospective cohort after excluding 260 patients with other pulmonary disorders or incomplete data. Clinical data including symptoms, lab results, imaging information were collected. Pulmonary HRCT were interpreted by two radiologist who were blinded to patients' clinical information. Abnormal pulmonary features were recorded as nodules, stripe opacity (linear opacity), patchy opacity, ground-glass opacity, pleural thickening, pleural effusion, pulmonary infarction, mosaic attenuation, pulmonary bronchiectasis, pulmonary oedema. After evaluation, patients were divided into two groups: those with normal lung HRCT and those with abnormal lung HRCT. Clinical characteristics were compared between groups and binary logistic regression analysis was applied to identify potential risk factors for the lung lesions. Follow-up HRCT (obtained in 64 patients) was analysed to study changes in pulmonary lesions after at least 6 months' treatment.
Results: Of the 243 patients, 107 (44.0%) had normal lung HRCT while 136 (56.0%) had abnormal lung HRCT, including stripe opacity (60.3%), nodules (44.9%), patchy opacity (25.0%), pleural thickening (15.4%), pleural effusion (10.3%), ground-glass opacity (8.1%), pulmonary infarction (6.6%), mosaic attenuation (4.4%), bronchiectasis (3.7%), and pulmonary oedema (2.2%). Patients with abnormal HRCT were significantly more likely to have type II arterial involvement (25% vs. 12.2%, P = 0.04), pulmonary arterial involvement (PAI; 21.3% vs. 5.6%, P < 0.001), pulmonary hypertension (20.6% vs. 8.4%, P = 0.01), and abnormal heart function (27.9% vs. 7.6%, P < 0.001). Logistic regression analysis demonstrated that PAI (OR = 3.0, 95% CI= 1.1-8.4, P=0.03), worsened heart function (OR = 2.7, 95% CI = 1.1-6.6, P=0.03), and age (OR = 1.1, 95% CI = 1.0-1.1, P<0.01) were associated with presence of pulmonary lesions. Pulmonary infarction, pleural effusion, and patchy opacities improved partially after treatment.
Conclusion: Pulmonary lesions are not rare in patients with TA. Age, PAI, and worsened heart function are potential risk factors for presence of pulmonary lesions in TA.

POS0811 EULAR RECOMMENDATIONS ON GIANT CELL ARTERITIS IN REAL LIFE

F. Regola[1], F. Franceschini[1], G. Bosio[2], P. Toniati[1]. [1]*ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy*; [2]*ASST Spedali Civili of Brescia, Nuclear Medicine Unit, Bresica, Italy*

Background: GCA is the most frequent systemic vasculitis in patients older than 50 years involving medium-sized and large arteries. On July 2019 EULAR published its updated recommendations for the management of large vessel vasculitis, including GCA.
Objectives: To analyze how the application of the updated EULAR recommendations changed clinical practice in GCA patients in our Hospital.
Methods: All patients with a new diagnosis of GCA between January 1st, 2018 and December 31st, 2020 were enrolled in this study. Two cohorts were analyzed: patients who received GCA diagnosis in the eighteen months before EULAR recommendations publication (between January 1st, 2018 and June 30th, 2019: cohort A) and patients who received GCA diagnosis in the following eighteen months (between July 1st, 2019 and December 31st, 2020: cohort B). Data are expressed as median (IQR).
Results: 70 patients were enrolled in the study (F: 47, M: 23, age: 76 (69-79) years): 39 patients in cohort A, 31 in cohort B. Table 1 summarize main clinical features and treatment of patients. Sixteen patients of cohort A (41%) and eleven patients of cohort B (35%) presented large vessel involvement demonstrated by FDG-PET/CT. Thirty-one patients in cohort A (79%) and twenty-seven in cohort B (87%) presented cranial symptoms and were studied with temporal arteries ultrasound (US) and/or biopsy (TAB). More specifically, in cohort A US was performed in 42% of patients with cranial symptoms and TAB in 58% of them. After EULAR recommendations publication (cohort B) the percentage of patients with cranial symptoms who performed US increased to 56% and the percentage of TAB decreased to 52%.
After EULAR recommendations publication, time between symptoms onset and first rheumatologic evaluation was reduced by 30% (from 61 (23-131) to 43 (22-92) days).
No difference in treatment regiments were found between groups, whether in glucocorticoid initial dose or DMARDs adjunctive therapy.
Conclusion: After EULAR recommendations publication, two major improvement were achieved in our cohort. EULAR suggests GCA patients should be urgently referred to a specialist team. Consistently with this recommendation, time between symptoms onset and first rheumatologic evaluation was markedly reduced. Moreover, EULAR suggests always confirming GCA diagnosis by imaging or TAB, with US as first choice. In line with these recommendations, in our cohort US became more and more frequently performed and progressively preferred over TAB. On the other hand, no differences in treatment regiments were found over time, with EULAR recommendations satisfied both before and after their publication.

POS0812 SUBCLAVIAN ARTERIES INVOLVEMENT IN PATIENTS WITH GIANT CELL ARTERITIS: DO WE NEED A MODIFIED HALO SCORE?

J. Molina Collada[1], J. Martínez-Barrio[1], B. Serrano-Benavente[1], I. Castrejon[1], J. C. Nieto González[1], L. R. Caballero Motta[1], L. Trives Folguera[1], J. M. Alvaro-Gracia[1]. [1]*Hospital General Universitario Gregorio Marañón, Rheumatology, Madrid, Spain*

Background: EULAR recommendations propose temporal and axillary arteries ultrasound (US) as first-line investigation when predominantly cranial giant cell arteritis (GCA) is suspected. Recently, two novel US scoring systems, the halo count and the Southend Halo Score, have been developed to quantify the extent of inflammation by US in GCA.
Objectives: To assess whether adding the subclavian arteries examination into the ultrasound (US) Southend Halo Score, as proposed in the modified Halo Score, improves the diagnostic accuracy of GCA and its relationship with systemic inflammation.
Methods: Retrospective observational study of patients referred to a GCA fast track pathway (FTP) over a 1-year period. Patients underwent US exam of temporal and large vessel (LV) (carotid, subclavian and axillary) arteries. The extent of inflammation was measured by the halo count, the Southend Halo Score and the modified Halo Score (Image 1). The gold standard for GCA diagnosis was clinical confirmation after 6 months follow-up.
Results: 64 patients were evaluated in the FTP, 17(26.5%) had GCA. Subclavian arteries involvement was present only in patients with GCA (29.4% versus 0%,p<0.001) (Table 1). Overall, the three scores showed excellent diagnostic accuracy for GCA (ROC AUC 0.906, 0.930 and 0.928, respectively) and moderate correlations with acute phase reactants (0.35-0.51, p<0.01). However, in the subgroup of patients presenting LV involvement, moderate correlations were

found between the modified Halo Score and ESR (rho 0.712, p<0.05), haemoglobin (rho 0.703, p<0.05) and platelets (rho 0.734, p<0.05), but not with the other two US scores.

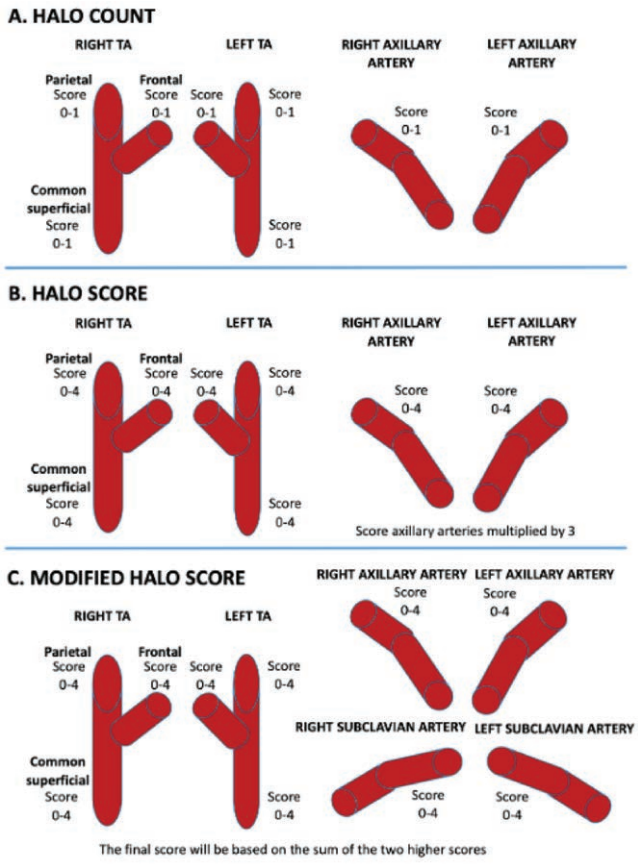

Figure 1. Proposed scores to quantify the extent of vascular inflammation by ultrasound in giant cell arteritis. A. Halo count, B. Halo Score, C: Modified Halo Score

Table 1. Clinical, laboratory and ultrasound findings of patients included in the fast track pathway with or without GCA clinical confirmation.

	Total n=64	Patients with GCA n=17	Patients without GCA n=47	p
Age, median (IQR)	78 (69.3-83)	78 (72.5-83)	78 (66-83)	0.5
Female, n (%)	42 (65.6%)	10 (58.8%)	32 (68.1%)	0.491
Temporal artery biopsy positive n=13, no. of patients	5 (38.5%)	5 (50%)	0 (0%)	0.231
^{18}F-FDG-PET/CT positive n=14, no. of patients	7 (50%)	5 (62.5%)	2 (33.3%)	0.592
Fulfilling 1990 GCA criteria, no. of patients	16 (25%)	8 (47.1%)	8 (17%)	0.022
PMR diagnosis before US examination, no. of patients	21 (32.8%)	4 (23,5%)	17 (36,2%)	0.386
Headache, no. of patients	31 (48.4%)	12 (70.6%)	19 (40.4%)	0.033
Jaw claudication, no. of patients	12 (18.8%)	9 (52.9%)	3 (6.4%)	<0.001
Ocular ischaemia, no. of patients	4 (6.3%)	2 (11.8%)	2 (4.3%)	0.285
Abnormal TA clinical examination, no. of patients	5 (7.8%)	3 (17.6%)	2 (4.3%)	0.112
CRP (mg/dL), median (IQR)	1.7(0-6.5)	7 (2.1-14)	1.1 (0-5.1)	0.001
ESR (mm/h), mean (SD)	52.8 (34.6)	68.3 (33.3)	46.8 (33.3)	0.044
Haemoglobin (g/dL), mean (SD)	12.5 (1.7)	11.8 (1.6)	12.7 (1.7)	0.059
Platelets 10^9/L, mean (SD)	276.1 (105.8)	323.4 (116.3)	258.7 (97.3)	0.52
Positive US findings, no. of patients	17 (26.6%)	15 (88.2%)	2 (4.3%)	<0.001
Temporal artery positive US findings, no. of patients	13 (20.3%)	12 (70.6%)	1 (2.1%)	<0.001
Axillary positive US findings, no. of patients	9 (14.1%)	8 (47.1%)	1 (2.1%)	<0.001
Subclavian positive US findings, no. of patients	5 (7.8%)	5 (29.4%)	0 (0%)	<0.001
Temporal artery + axillary or subclavian positive US findings, no. of patients	5 (7.9%)	5 (29.4%)	0 (0%)	0.003
Halo Count, median (IQR)	0 (0-0.75)	2 (1-4.5)	0 (0-0)	<0.001
Halo Score, median (IQR)	0 (0-4.5)	18 (7-22.5))	0 (0-0)	<0.001
Modified Halo Score, median (IQR)	0 (0-2.75)	8 (3-13.5)	0 (0-0)	<0.001

Conclusion: The inclusion of subclavian arteries examination in the modified Halo Score does not improve the diagnostic accuracy of GCA. Nevertheless, it correlates better with markers of systemic inflammation in LV-GCA

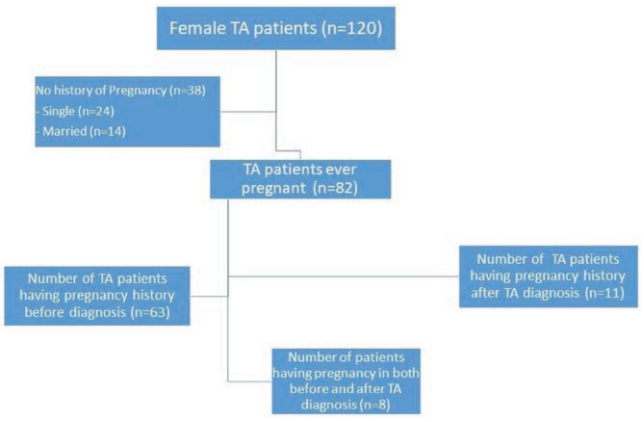
POS0813 FERTILITY AND PREGNANCY OUTCOMES IN TAKAYASU'S ARTERITIS

A. Taghiyeva[1], L. Kılıç[2], M. Cagan[3], E. C. Bolek[2], G. K. Yardımcı[2], O. Karadag[2], O. Ozyuncu[3], Ş. A. Bilgen[2]. [1]*Hacettepe University Faculty of Medicine, İnternal Medicine, Ankara, Turkey*; [2]*Hacettepe University Faculty of Medicine, Department of Internal Diseases Rheumatology, Ankara, Turkey*; [3]*Hacettepe University Faculty of Medicine, Department of Obstetrics and Gynecology, Ankara, Turkey*

Background: Takayasu's arteritis (TA) is commonly seen in women of childbearing ages; therefore, reproductive health of TA patients is an important issue.
Objectives: We aimed to evaluate the fertility and pregnancy (PG) outcomes of TA patients before and after diagnosis.
Methods: In the prospective database of the Hacettepe University Vasculitis Research Centre (HUVAC), 202 TA patients (female =184) meeting the 1990 ACR criteria were registered by the end of February 2020. 120 patients who could be reached out gynaecological records and marriage status, were included in the study. We identified 233 PG in 82 of included these 120 TA patients (Figure 1). Demographic and clinical features, comorbidities, distribution of vascular involvement, obstetrical histories and outcomes were retrospectively evaluated. Patients were classified according to a novel proposed disease clusters (C1: Abdominal Predominant, C2: Aortic Arch Predominant, C3: Focal Disease) using the defined decision tree.
Results: 12 of 96 (12.5%) married TA patients had infertility being defined as not being able to get pregnant after one year (or longer) of unprotected sex. 20 (16.7%) women had menopause before the age of 45, being defined as early menopause (EM). Compared to normal population, infertility (12.5% vs. 8.1%) and EM ratios (16.7% vs. 7.6%) seem to be increased in TA patients. (1, 2)
200 PG had occurred before TA diagnosis (bTA) in 71 women, and 33 PG were observed after TA diagnosis (aTA) diagnosis in 19 women (two patients diagnosed during PG). According to novel disease subsets, aTA patients classified into C1 (n=3; 15.7%), C2 (n=9; 47.3%) and C3 (n=6; 31.5%). One patient could not be classified.
GHT was seen in 4 (12.1%) patients being the most frequent maternal complication in aTA group. Most common fetal complications were prematurity, IUGR and LBW in both groups (Table 1). Even fetal complications were more frequent in aTA group, it was not statistically significant [11 (33.3%) vs. 43 (21.5%), p=0.18 respectively]. However, maternal complications were significantly more common in aTA group [22 (11.0%) vs. 8 (24.2%), p=0.048]. There was no difference for the obstetrical outcomes in terms of novel TA classification.



Conclusion: This study showed increased infertility and EM ratios in TA patients. PG of aTA had more complications in terms of maternal complications. Fetal complications were more frequent in PG of aTA but not statistically significant. Larger cohort data is required.

POS0814

DRUG RETENTION RATE, REASONS FOR DISCONTINUATION AND OUTCOME OF INFLIXIMAB USE IN BEHÇET SYNDROME

S. N. Esatoglu[1,2], B. Tukek[3], S. S. Taflan[3], Y. Ozyazgan[4], D. Ucar[4], V. Hamuryudan[1,2], Y. Ozguler[1,2], E. Seyahi[1,2], M. Melikoglu[1,2], U. Uygunoglu[5], A. Siva[5], Z. Kutlubay[6], I. Fresko[1,2], S. Yurdakul[1], H. Yazici[1,2], G. Hatemi[1,2].
[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; *[2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behcet Disease Center, Istanbul, Turkey*; *[3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey*; *[4]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophthalmology, Istanbul, Turkey*; *[5]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Neurology, Istanbul, Turkey*; *[6]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Dermatology, Istanbul, Turkey*

Background: Infliximab (IFX) plays a key role in the management of severe and refractory manifestations of Behçet syndrome (BS). However we had previously shown that its sustained use may be limited due to adverse events and lack of patient compliance (1).
Objectives: To assess the retention rate of IFX, adverse events, causes of discontinuation and outcome after cessation of IFX in a larger group of BS patients who were followed in a tertiary center.
Methods: The charts of BS patients who were prescribed IFX between 2004 and 2020 were reviewed to determine demographic features, reasons for IFX use, previous and concomitant drugs, IFX duration, reasons for cessation of IFX and time to flare following cessation of IFX. Follow-up was censored on March 2020.
Results: A total of 252 patients (195 men, mean age 40±10 years) received IFX for uveitis (n=122), vascular involvement (n=82), parenchymal neurologic involvement (n=32), gastrointestinal involvement (n=11), arthritis (n=10), mucocutaneous involvement (n=4), and secondary amyloidosis (n=1). Ten patients had more than 1 involvement requiring IFX.
During a median follow-up of 52 (IQR: 30-88) months, 122 (48%) patients were still receiving IFX for a median period of 33 (IQR: 15-56) months while 130 (52%) patients had discontinued IFX after a median follow-up of 17 (IQR: 7-31) months. Reasons for discontinuation were remission in 25 (19%) patients, adverse events in 39 (30%), lack of efficacy in 23 (18%) (4 primary and 19 secondary), lack of patient compliance in 36 (28%), pregnancy in 4, and preparation for surgery in 3 patients.
Adverse events (n=39) that required the cessation of IFX were infusion reaction (n=17), infection (n=7), hepatotoxicity (n=4), malignancy (n=4), palmoplantar psoriasis (n=3), lichen planus (n=1), drug induced lupus (n=1), splenic infarction (n=1), and a decrease in left ventricular ejection fraction (n=1).
Among the 25 patients who discontinued IFX due to remission, 5 (20%) had a relapse after 4, 21, 26, 29, 38 and 46 months. The remaining patients did not experience a relapse during a median follow-up of 35 (IQR: 24-68) months.

Reasons for infliximab treatment	No of patients	No (%) of patients who were still receiving infliximab	Number (%) of patients who discontinued infliximab	Reasons for discontinuation	Duration of infliximab use (median (IQR) months)
Eye involvement	122	59 (48)	63 (52)	Remission (n=17) Inefficacy (n=10) Lack of patient compliance (n=19) Adverse event (n=12) Others (n)=5)	28 (12.5-52)
Vascular involvement	82	40 (49)	42 (51)	Remission (n=10) Inefficacy (n=7) Lack of patient compliance (n=12) Adverse event (n=12) Others (n=4)	18.5 (9-33.5)
Parenchymal neurologic involvement	32	21 (66)	11 (34)	Adverse event (n=8) Inefficacy (n=2) Lack of patient compliance (n=1)	25 (14.5-50)
Gastrointestinal involvement	11	4 (36)	7 (64)	Remission (n=1) Inefficacy (n=1) Adverse event (n=2) Lack of patient compliance (n=4)	7 (2-17)
Joint involvement	10	2 (20)	8 (80)	Inefficacy (n=1) Adverse event (n=5) Lack of patient compliance (n=2)	20 (4-35)
Mucocutaneous involvement	4	3	1	Inefficacy (n=1)	6, 10, 12, 104 months
AA amyloidosis	1	0	1	Inefficacy (n=1)	6 years

At the end of the follow-up, 2 patients had died due to lung adenocarcinoma during IFX treatment and 3 patients had died 1 year, 3 and 8 years after IFX discontinuation. The causes of death were with right heart failure due to pulmonary hypertension in 1, and severe nervous system involvement in 2 of the patients.

Conclusion: Despite its successful use for the management of potentially organ and life-threatening manifestations in more than half of our patients with BS, long term maintenance was not possible in 42%, mainly due to adverse events, lack of patient compliance and inefficacy.

POS0815 CLINICAL CHARACTERISTICS, IMAGING PHENOTYPE, AND LONG-TERM OUTCOMES OF TAKAYASU ARTERITIS PATIENTS WITH HYPERTENSION

Y. Sun[1], L. Ma[1], H. Chen[1,2], C. Rongyi[2], L. Jiang[2]. [1]*Zhonngshan Hospital, Fudan University, Rheumatology, Shanghai, China*; [2]*Zhonngshan Hospital, Fudan University, Rheumatology, Shanghai, China*

Background: Hypertension occurred in 30-80% of TAK patients around the world. The occurrence of hypertension might severely worsen TAK prognosis. Nevertheless, data describing the specific imaging features in hypertensive TAK patients and the associations between hypertensive severity, blood pressure control status and long-term outcome were still lacking.

Objectives: To investigate the characteristics and associations of hypertensive characteristics with adverse events-free survival in Takayasu arteritis (TAK) patients with hypertension.

Methods: This research was based on a prospectively on-going observational cohort-East China Takayasu Arteritis (ECTA) cohort. In all, 618 TAK patients, who registered in the ECTA cohort up to December 2019, were enrolled. The main outcome was the adverse-events-free survival among hypertensive TAK patients during the follow-up ended on August 2020.

Results: Totally, 204 (33.0%) patients suffered from hypertension, with 48 (23.5%), 62 (30.4%), and 94 (46.1%) mild, moderate, and severe hypertension, respectively. Cluster analysis indicated three imaging phenotypes for hypertensive TAK patients: Cluster 1: involvement of the abdominal aorta and/or renal artery (n=56, 27.5%); Cluster 2: involvement of the ascending aorta, thoracic aorta, and the aortic arch and its branches (n=38, 18.6%); Cluster 3: combined involvement of Cluster 1 and Cluster 2 (n=111, 54.4%). By the end of the follow-up, the blood pressure control rate was 50.8%, while the adverse-events-free survival was 67.9% in the entire hypertensive population. Multivariate Cox regression analysis indicated that well-controlled blood pressure (HR=2.13, 95%CI 1.32–3.78, p=0.047), co-existence of severe aortic valve regurgitation (HR=0.87, 95%CI 0.64–0.95, p=0.043), Cluster 1 (HR=0.69, 95%CI 0.48–0.92, p=0.017) and Cluster 3 (HR=0.72, 95%CI 0.43–0.94, p=0.048) imaging phenotype was associated with the adverse-events-free survival.

Conclusion: Patients with controlled hypertension showed better adverse-events-free survival, while those with the Cluster 1 imaging phenotype were more likely to suffer from worse adverse-events-free survival. Hypertension occurred in 30-80% of TAK patients around the world. The occurrence of hypertension might severely worsen TAK prognosis.

POS0816 PROGNOSTIC FACTORS FOR AGGRAVATED VASCULAR DAMAGE IN TAKAYASU ARTERITIS

R. Chen[1,1], L. Ma[1], Y. Liu[1], L. Ma[1], L. Jiang[1]. [1]*Zhongshan Hospital Fudan University, Rheumatology, Shanghai, China*

Background: Takayasu arteritis is a rare disease characterized by inflammation in the aorta and its branches. Some patients were discovered to suffer the aggravated vascular damage (AVD), monitored by imaging techniques, even with the effective anti-inflammation treatment. But the general characteristics and the related prognostic factors of AVD in TA were unclear yet.

Objectives: We aimed to describe the characteristics of the AVD and identify its prognostic factors in TA.

Methods: From the living East China Takayasu arteritis cohort, patients who underwent at least two magnetic resonance angiography (MRA) examinations at Zhongshan Hospital from April 2009 to April 2019 were enrolled as the derivation cohort to explore the prognostic factors of AVD in MRA. An independent group of patients from May 2019 to July 2020 comprising the validation cohort were used to validate the nomogram formed by these prognostic factors.

Results: Among 235 enrolled patients, 69 patients (29.3%) suffered AVD with the median follow-up of 14 months. The limb arteries were the most vulnerable and the aggravated vascular stenosis were the most commonly seen in AVD. Patients with AVD were younger, had higher complement 4 levels at baseline, and lower disease remission rate at 6 months. Multivariate cox regression analysis revealed that younger age (HR: 0.25-0.42, 95%CI: 0.09-0.91), higher CRP levels (HR = 2.57, 95%CI: 1.51–4.36) at baseline, and lower remission rate at 6 months (HR = 0.36, 95%CI: 0.21–0.64) were significant predictors. In the validation cohort of 65 patients, 19 cases had AVD. The predictive nomogram based on these factors achieved C-indices of 0.745 and 0.641 in the derivation and validation cohort respectively.

Conclusion: Totally, 29.3% of patients suffered AVD, among which the aggravated vascular stenosis and limb arteries involvement were most commonly seen. Younger age, higher CRP at baseline, and lower disease remission rate at 6 months were prognostic factors for AVD.

POS0817 A NOVEL MODEL TO ASSESS DISEASE ACTIVITY IN TAKAYASU ARTERITIS BASED ON 18F-FDG-PET/CT: A CHINESE COHORT STUDY

L. Ma[1], B. Wu[2], X. Jin[3], Y. Sun[1], X. Kong[1], Z. Ji[1], R. Chen[1], X. Cui[1], H. Shi[2], L. Jiang[1]. [1]*Zhongshan Hospital, Fudan University, Department of Rheumatology, Shanghai, China*; [2]*Zhongshan Hospital, Fudan University, Department of Nuclear Medicine, Shanghai, China*; [3]*Zhongshan Hospital, Fudan University, Department of Medical Statistics, Shanghai, China*

Background: Takayasu arteritis (TA) is a condition characterized by major large-vessel vasculitis (LVV), and is most commonly found in young women (age <40 years) of East Asia countries. 18F-FDG-PET/CT has been widely used in the diagnosis and follow-up of cancers to gather functional information based on metabolic activity. In the present study, we evaluated the value of different parameters in 18F-FDG-PET/CT for assessing active TA disease, and we establish a simple, quantifiable, and effective disease activity evaluation model based on 18F-FDG-PET/CT. A comparison in the ability to identify active disease was performed between the established Kerr score and the new 18F-FDG-PET/CT was also performed.

Objectives: To investigate the utility of 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG-PET/CT) in assessing disease activity in TA.

Methods: Ninety-one patients with TA, were recruited from a Chinese cohort from October 2017 to January 2019. Clinical data, acute-phase reactants (APRs), and 18F-FDG-PET/CT findings were simultaneously recorded. The Physician Global Assessment was used as the gold standard to assess TA disease activity. The value of using 18F-FDG-PET/CT to identify active disease

was evaluated, using erythrocyte sedimentation rate (ESR) as a reference. Disease activity assessment models were constructed and concordance index (C-index), net reclassification index (NRI), and integrated discrimination index (IDI) were evaluated to compare the benefits of the new modes with ESR and Kerr score.

Results: In total, 64 (70.3%) cases showed active disease. Higher levels of ESR and CRP, and lower interleukin (IL)-2R levels, were observed in active cases. 18F-FDG-PET/CT parameters, including SUVmean, SUVratio1, SUVratio2, sum of SUVmean, and sum of SUVmax, were significantly higher in active disease groups. The C index threshold of ESR to indicate active disease was 0.78 (95% CI: 0.69-0.88). The new activity assessment model combining ESR, sum of SUVmean, and IL-2R showed significant improvement in C index over the ESR method (0.96 vs. 0.78, P < 0.01; NRI 1.63, P < 0.01; and IDI 0.48, P < 0.01). The new model also demonstrated modest superiority to Kerr score assessment (0.96 vs. 0.87, P = 0.03; NRI 1.19, P < 0.01; and IDI 0.33 P < 0.01).

Conclusion: A novel 18F-FDG-PET/CT-based method that involves combining the sum of SUVmean with ESR score and IL-2R levels demonstrated superiority in identifying active TA compared to conventional methods.

POS0818 TREATMENT OF POLYMYALGIA RHEUMATICA WITH TOCILIZUMAB: RESULTS OF AN OBSERVATIONAL RETROSPECTIVE MULTICENTER STUDY

M. Assaraf[1], B. Chevet[2], P. Philippe[1], J. Avouac[3], M. Delacour[4], E. Houvenagel[5], T. Pascart[5], J. Henry[6], C. Roux[7], D. Wendling[8], J. Paccou[1], B. Cortet[1], V. Devauchelle-Pensec[2], R. M. Flipo[1]. *[1]Lille University Hospital, Rheumatology, Lille, France*; *[2]Brest University Hospital, Rheumatology, Brest, France*; *[3]Cochin University Hospital, Rheumatology, Paris, France*; *[4]Arras Hospital Medical Center, Rheumatology, Arras, France*; *[5]Saint Philibert University Hospital, Rheumatology, Lomme, France*; *[6]Kremlin Bicêtre Univeristy Hospital, Rheumatology, Paris, France*; *[7]Nice University Hospital, Rheumatology, Nice, France*; *[8]Besançon University Hospital, Rheumatology, Besançon, France*

Background: In 2017, TOCILIZUMAB (TCZ) obtained marketing authorization for treatment of giant cell arteritis (GCA); however, this doesn't extend to polymyalgia rheumatica (PMR) therapy. Based on efficacy data for TCZ in GCA, TCZ is sometimes used as a glucocorticoid (GC) sparing agent when PMR is GC dependent or when a rapid steroid withdraw is needed. Currently, there are no available recommendations on the use of this therapeutic class in for this particular indication.

Objectives: Here, we present the results of an observational French multicentric study of patients with PMR treated with TCZ.

Methods: Thirteen medical centers were included in this study. The data was collected retrospectively between 2015 and 2020. The minimum duration of treatment was 3 months. Patients were included when receiving TCZ for isolated PMR or associated with a non-active GCA (asymptomatic, no vascular fixation on PET scanner).

Results: Overall, 34 patients were included (24 women; mean age 70.1 years (+/-10.3)). At TCZ introduction, patients had been treated with GC for a mean duration of 27,9 months (+/-25.9) and the mean GC dose was 16,8mg/d (+/-10). Fifteen patients (44%) had one or more complications from GC therapy. Another immunosuppressant was added before TCZ treatment for 25 (74%); mostly METHOTREXATE (24/25).

TCZ was initiated intravenously at 8mg/kg every 4 weeks for 27 patients (79%) and subcutaneously at 162mg/week for 7 patients (21%).

The reasons for TCZ introduction included GC dependence (n=30, 88%), and necessity of quick GC sparing (n=4 patients,12%).

Of all patients, 76% (26 patients) had stopped GC treatment definitively, with a mean time of 9,4 (0-32) months.

The mean TCZ treatment period was 19,2 months (3-66). Fifteen patients (44%) permanently stopped TCZ at the end of the observation period (8 prolonged remissions;1 myocardial infarction; 1 cutaneous lymphoma; 1 primary failure, 3 lost to follow up).

Eighteen patients (60%) benefited from an attempted tapering of TCZ (infusion spacing or dose reduction), 6 attempts (1/3) led to a relapse. 1/2 patients had side effects mostly benign (cytopenia n=6, infections n=5).

Conclusion: This is the largest cohort presenting results of the use of TCZ in PMR. Despite the small number of participants, our study suggests TCZ is effective as a GC sparing agent in PMR. As there are no official recommendations of use, indications for TCZ use within this population are no defined. Randomized Controlled Trial would be beneficial to validate these first results.

POS0819 EMERGENCE OF DE NOVO MANIFESTATIONS DURING INFLIXIMAB TREATMENT IN BEHÇET SYNDROME

B. Tukek[1], S. N. Esatoglu[2,3], G. Hatemi[2,3], E. B. Caliskan[1], Y. Ozyazgan[4], D. Ucar[4], Y. Ozguler[2,3], E. Seyahi[2,3], M. Melikoglu[2,3], U. Uygunoglu[5], A. Siva[5], Z. Kutlubay[6], I. Fresko[2,3], S. Yurdakul[2,3], H. Yazici[2,3], V. Hamuryudan[2,3]. *[1]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul,Turkey*; *[2]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul,Turkey*; *[3]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Behcet Disease Center, Istanbul,Turkey*; *[4]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophthalmology, Istanbul,Turkey*; *[5]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Neurology, Istanbul,Turkey*; *[6]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Dermatology, Istanbul,Turkey*

Background: Infliximab (IFX) is increasingly used in the management of severe, relapsing or refractory manifestations of Behçet Syndrome (BS). Emergence of de novo manifestations have been reported during IFX treatment, despite efficacy for the initial manifestation that required IFX use[1].

Objectives: We aimed to survey a sizeable cohort of BS patients treated with IFX for the development of de novo manifestations during treatment.

Methods: A chart review was conducted to identify all BS patients who were given IFX in our Behçet Disease Research Center between 2004 and 2020. Demographic data, indications for IFX initiation, concomitant drugs, prior treatments, and outcomes were recorded. De novo manifestations were defined as new BS manifestations that had not occurred before IFX treatment.

Results: A total of 252 patients used IFX with the main indications being uveitis in 122, vascular involvement in 82, parenchymal central nervous system involvement in 32, gastrointestinal involvement in 11, arthritis in 10, mucocutaneous involvement in 4, and secondary amyloidosis in 1. Of these patients, 17 (6%) had developed a total of 21 de-novo manifestations during a mean follow-up of 38.4 ± 92 (SD) months (Table 1). Vascular involvement was the main indication for IFX in the majority (n=12; 71%) of these 17 patients followed by eye involvement (n=3; 18%), central nervous system involvement (n=1), and joint involvement (n=1). Concomitant medications were prednisolone in 14 patients, azathioprine in 6 patients, mycophenolate mofetil, cyclosporine-A and methotrexate in 1 patient each. Thirteen patients (76%) were in remission for the main indication when de-novo manifestations emerged. In 10 patients IFX treatment was intensified either by increasing the dose to

10 mg/kg (2 patients) or by shortening the infusion intervals to 4 weeks (2 patients) along with the addition of corticosteroids or immunosuppressives. In the remaining 7 patients IFX was switched to another agent (cyclophosphamide in 5, adalimumab in 1 and anakinra in 1). At the time of this survey 8/17 patients were still on IFX for a mean follow-up of 32.5 ± 24.6 (SD) months, with concomitant low dose prednisolone in 5, azathioprine in 3 and mycophenolate mofetil in 3. In addition to the 7 patients who discontinued IFX at the time of de-novo manifestations, 2 more patients had discontinued IFX due to allergic reactions.

Conclusion: De novo manifestations developed during IFX treatment in 6% of BS patients, despite efficacy for the initial manifestation. Appearance of de novo manifestations mostly in patients with vascular involvement is noteworthy. Intensification of IFX treatment was efficacious in managing de novo manifestations in more than half of these patients.

POS0820 INFLIXIMAB FOR VASCULAR INVOLVEMENT IN BEHÇET SYNDROME

G. Hatemi[1,2], B. Tukek[3], S. N. Esatoglu[1,2], Y. Ozguler[1,2], M. Melikoglu[1,2], E. B. Caliskan[3], S. Ugurlu[1,2], I. Fresko[1,2], S. Yurdakul[1,2], H. Yazici[1,2], V. Hamuryudan[1,2]. *[1]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; *[2]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Behcet Disease Center, Istanbul, Turkey*; *[3]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey*

Background: Vascular involvement is an important cause of morbidity and mortality in patients with Behçet syndrome (BS). TNF inhibitors have been reported to be effective for almost all serious manifestations of BS but data on vascular involvement is still limited.

Objectives: To survey the efficacy and safety of infliximab (IFX) in BS patients with vascular involvement followed in a dedicated tertiary center.

Methods: We reviewed the charts of all BS patients who used IFX and identified those who used this drug for vascular involvement. A standard form was used for extracting data on demographic and clinical features, type of vascular involvement, concomitant immunosuppressives, duration of IFX use, relapses, adverse events and outcome.

Results: 83 patients (67 men, 16 women, mean age 39.5 ± 8.4 SD years) had used IFX for vascular involvement. The number of patients with each type of vascular involvement as the main indication for IFX, and previous treatment modalities right before IFX are presented in the Table 1. 33 patients had more than 1 type of vascular lesion. Additional organ manifestations were eye involvement in 32, central nervous system involvement in 4 and gastrointestinal involvement in 3 patients. All but one patient used IFX at a dose of 5 mg/kg every 6-8 weeks. All patients used concomitant prednisolone and 51 received pulse methylprednisolone during induction. Other concomitant medications were azathioprine in 21 and mycophenolate mofetil in 4 patients. Outcome of IFX treatment at the end of a mean follow-up of 25.9 months (range 1-103) is tabulated according to arterial and venous involvement (Table 1). Overall, 57/83 (68%) patients obtained remission with no further relapses and IFX could be stopped in 12 (14%) of them. IFX was discontinued due to adverse events in 15 patients. These were allergic reactions in 8, tuberculosis, disseminated zona, lung adenocarcinoma, fibromyxoid sarcoma, heart failure, systemic lupus erythematosus, and palmoplantar pustulosis in 1 patient each. Three patients had died. Causes of death were lung adenocarcinoma in one patient and pulmonary hypertension related right heart failure due to pulmonary artery thrombosis in 2 patients.

Conclusion: Infliximab seems to be beneficial in Behçet syndrome patients with vascular involvement, even in those who are refractory to immunosuppressives and corticosteroids. No further relapses occurred in 68% of the patients, and adverse events leading to discontinuation were observed in 18%.

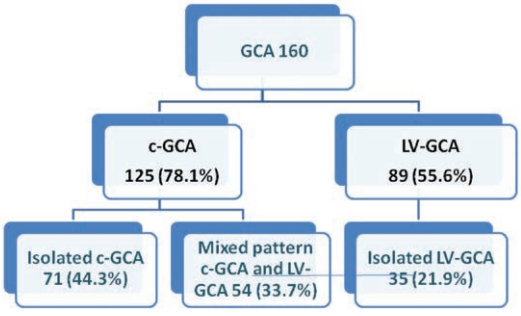
POS0821

THE DIFFERENT SUBTYPES OF GIANT CELL ARTERITIS BY ULTRASOUND: RESULTS FROM A FAST-TRACK CLINIC

I. Monjo[1], E. Fernández-Fernández[1], J. Ortega[2], E. De Miguel[1]. [1]*La Paz University Hospital, Rheumatology, Madrid, Spain*; [2]*Universidad Autónoma de Madrid, School of Medicine, Madrid, Spain*

Background: Giant cell arteritis (GCA) is a vasculitis that affects the medium and large vessels (LV). Although cranial artery involvement is better known, awareness of the importance of LV involvement is increasing. Imaging techniques currently constitute the basis for the diagnosis of LV-GCA and have improved its diagnosis and prevalence. In recent years, differences in clinical patterns and different inflammatory and etiopathogenic mechanisms of the disease have been suggested. Therefore, improving sensitivity to diagnosis is essential to improve the knowledge and care of our population.
Objectives: The aim of this study was to know the prevalence of the different ultrasound patterns of GCA in our area.
Methods: Retrospective records of available data were collected from all patients referred to our ACG fast track clinic in the past three years. The clinical and laboratory characteristics were evaluated at the time of referral. All patients underwent an ultrasound scan of cranial vessels (superficial temporal arteries (TA) and their frontal and parietal branches) and large vessels (axillary, subclavian and carotid arteries). The doctor confirmed the GCA diagnosis after at least six months of follow-up. The OMERACT definitions of halo sign with a hypoechoic wall thickness ≥ 0.34 mm were used for TA pathology for the ultrasound diagnosis of GCA and for axillary, subclavian and carotid arteries and homogeneous hypoechoic thicknesses ≥ 1 mm of the arterial wall were applied. Atherosclerosis lesions were evaluated to detect this disease as a possible false positive halo sign. An Esaote Mylab Twice with a 13 MHz probe in BT and 22 MHz for cranial vessels in 2017-2019 and an Esaote Mylab X8plus with a 15 MHz probe for BT and a 24 MHz probe for cranial arteries in 2019-2020 were used by two rheumatologist with long experience in ACG ultrasound.
Results: A total of 261 patients (180 women / 81 men) with suspected GCA were evaluated in our fast track clinic. The mean age (± SD) was 76 ± 9.2 years and CRP at diagnosis was 75.7 ± 68.6 mg/L. The time elapsed since the first symptoms was less than 6, 6-12, 12-24 or >24 weeks in 37.5%, 19.9%, 12.3% and 15.7% respectively. Of the 261 cases explored, 160 had GCA, of which 102 were women and 58 men, and had a mean age of 77.21 ± 7.9 years. The ultrasound patterns of GCA were: 71 patients had exclusive involvement of the TA (cranial-GCA), 54 had a mixed pattern with involvement of both TA and LV (mixed-CGA), and 35 had isolated involvement of the LV (LV-GCA). That is, 125 patients had cranial involvement with or without LV involvement and 89 had LV-GCA associated or not with cranial involvement (Figure 1).



GCA= Giant Cell Arteritis; c-GCA= Cranial Giant Celll Arteritis; LV-GCA= Large Vessell Giant Cell Arteritis

Figure 1. Ultrasound patters of GCA

Conclusion: Ultrasound is a useful tool for the screening of GCA and its different subtypes of vascular involvement. The isolated cranial subtype or associated with LV-GCA is the most common (78% of cases), but LV-GCA is also very common (55.6% of cases of GCA) and 21.9% presents as an isolated LV-GCA standard. The LV arteries should be included in the ultrasound examination for suspected GCA.

Vasculitis – small vessel vasculitis

POS0822

NEW FACES OF POLYARTERITIS NODOSA: 18F-FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY FINDINGS IN A SERIES OF 10 PATIENTS

C. Rousselin[1], T. Machet[1], G. Collet[2], T. Quéméneur[1], R. Ben Ticha[2], M. Verstraete[2], N. Le Gouellec[1], F. Demailly[2], A. Fagart[2]. [1]*Hôpital de Valenciennes, Internal Medicine and Nephrology, Valenciennes, France*; [2]*Hôpital de Valenciennes, Nuclear Medicine, Valenciennes, France*

Background: ^{18}F-fluorodeoxyglucose positron emission tomography with computed tomography (FDG-PET/CT) is widely used in patients with large-vessel vasculitis (1). The benefits of FDG-PET/CT in polyarteritis nodosa (PAN) has only been assessed in a few case reports (2-3).
Objectives: Our aim was to describe FDG-PET/CT findings in 10 patients with newly diagnosed PAN.
Methods: This was a retrospective study of patients with PAN who underwent FDG-PET/CT at the time of diagnosis, between 2017 and 2020. The FDG-PET/CT data were analysed retrospectively and compared with clinical, biological, histological and conventional imaging data.
Results: Ten patients were included: 9 men and 1 woman, median age of 67 (43–78) years. PAN was diagnosed according to ACR criteria (6) in 9 patients, and histologically in the remaining patient. The clinical manifestations were: systemic (n=10), muscular (n=6), joint (n=3), skin (n=3), peripheral nervous system (n=3), and gastrointestinal (n=2). All patients had high C-reactive protein levels (median, 223 mg/L). One patient had incomplete FDG-PET exploration. Three patients had begun corticosteroid therapy before their FDG-PET/CT scan. The main FDG-PET/CT abnormality was increased tracer uptake in the muscles, particularly in the connective tissue (perimysium, epimysium) (n=7), in linear (n=5) or focal (n=2) patterns. Increased FDG uptake in large-diameter vessels was observed in 4 patients, in the humeral (n=4), femoral (n=1) and the common interosseous (n=1) arteries. Nine patients had bone-marrow FDG uptake, six had splenic FDG uptake. Three patients had synovitis. Three had lymph-node uptake. One patient had subcutaneous FDG uptake, with a "leopard skin" appearance.
Conclusion: FDG-PET/CT seems to be a useful non-invasive imaging technique for diagnosing PAN, particularly in patients with non-specific systemic features. Tracer uptake in muscular connective tissue seems to be a recurrent sign in patients with PAN.

POS0823

ARTHRITIS IN ADULT IGA VASCULITIS

A. Hočevar[1,2], V. Jurčić[3], M. Tomsic[1,2], Z. Rotar[1,2]. [1]*University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia*; [2]*Medical Faculty, University of Ljubljana, Internal Medicine, Ljubljana, Slovenia*; [3]*Medical Faculty, University of Ljubljana, Institute of Pathology, Ljubljana, Slovenia*

Background: Arthritis is one of the main clinical features of IgA vasculitis (IgAV). Joint involvement represents the second most common manifestation in childhood IgAV with the predilection for the knees and ankles.
Objectives: We aimed to describe the characteristics of arthritis in adult IgAV cohort.
Methods: We analysed medical records of histologically proven adult IgAV cases, diagnosed between January 2010 and December 2020 at our secondary/

tertiary rheumatology centre. The frequency, temporal occurrence and the localization of arthritis was recorded. In addition, we searched for potential differences in other IgAV features between patients with and without arthritis.

Results: During the 132-month observation period we identified 328 new IgAV cases (59.5% males, median (IQR) age 64.3 (45.1; 76.1) years). Forty-eight (14.6%) patients developed arthritis. Arthritis was the first IgAV manifestation in 16 (4.9%) patients. Arthritis was mono-, oligo- and poly- articular (involving up to 15 joints) in 13 (4.0%), 25 (7.6%) and 10 (3.0%) patients, respectively. Arthritis was most common in wrists and ankles (each in 18 (37.5%) patients); metacarpophalangeal joints and knees (each in 11 (22.9%)); proximal interphalangeal joints (9 (18.8%)); elbows (8 (16.7%)) and metatarsophalangeal joints (4 (8.3%)). Clinical differences between IgAV patients with and without arthritis are presented in table 1. Patients with arthritis were significantly younger, more commonly developed gastrointestinal tract involvement compared to those without arthritis. Arthritis remitted in all with immunomodulatory treatment (given predominantly for necrotic skin purpura or visceral involvement). Follow up (FU) data accessible for 42/48 (87.5%) patients with arthritis showed that IgAV relapsed in 10 (23.8%) patients during a median (IQR) 24.5 (12.9; 40.7) month FU. Relapses were limited to skin and/or kidneys, there were no relapses of arthritis.

Table 1. Clinical characteristics of IgA vasculitis patients with and without arthritis

Clinical characteristics	Arthritis IgAV (48)	Non-arthritis IgAV (280)	P value
Male gender (%)	56.3	60.0	0.636
Age (years)*	49.9 (36.1-66.9)	65.4 (48.4;77.5)	<0.001
Ever smoker (%)	50.0	43.6	0.435
Prior infection (%)	43.8	30.4	0.094
Generalized purpura	50.0	50.0	1.0
Skin necroses (%)	35.4	49.6	0.085
GI involvement (%)	47.9	25.0	0.002
Renal involvement (%)	47.9	46.8	1.0
Elevated serum IgA (%)	33.3 (11/33)	52.0 (115/221)	0.061

Legend: * median and IQR; GI gastrointestinal;

Conclusion: Arthritis in adult IgAV was frequently oligoarticular, involved large and small joints of both upper and lower extremities, and was not prone to chronic course and recurrence. In addition, we found an association between arthritis and gastrointestinal tract involvement.

POS0824 THE LONG-TERM CLINICAL COURSE OF MUSCULAR VASCULITIS DEPENDING ON THE ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY STATUS: A RETROSPECTIVE OBSERVATIONAL STUDY

T. Yoshida[1], K. Nishimura[1], D. Waki[1], K. Mizukawa[1], N. Tanaka[1], H. Murabe[1], T. Yokota[1]. [1]*Kurashiki Central Hospital, Department of Endocrinology and Rheumatology, Kurashiki, Okayama, Japan*

Background: Skeletal muscle is known as one of the organ involvements of primary systemic vasculitis.[1,2] Muscle inflammation is detected by magnetic resonance imaging, and necrotizing vasculitis is proved by muscle biopsy.[3] As with systemic vasculitis or single organ vasculitis, glucocorticoid (GC) and immunosuppressants are used in its treatment.[4] There are not many reports about muscular vasculitis, and its long-term clinical course after initial treatment, including the rates of relapse and mortality, remains unclear.

Objectives: To identify the predictors of relapse and mortality in patients with muscular vasculitis, especially focusing on the status of anti-neutrophil cytoplasmic antibody (ANCA).

Methods: We retrospectively reviewed patients diagnosed with necrotizing vasculitis with muscle involvements in our hospital between 2004 and 2020. In all cases, muscular vasculitis was identified by muscle biopsy or magnetic resonance imaging. To focus on the clinical features of muscular vasculitis, we excluded patients with such severe organ involvements as cardiovascular, abdominal, cerebral, severe renal, and severe pulmonary involvements. We compared the 5-year cumulative incidence of relapse, the overall survival rate, and the dose of GC over 5 years between the ANCA-positive and ANCA-negative groups. A relapse was defined as any new or worsened state of disease activity requiring an escalation of GC dose. Gray's method was used for assessing the cumulative incidence of relapse. The log-rank test was used for assessing overall survival. The Mann-Whitney U test was used for assessing the dose of GC. The possible factors for relapse in 5 years in a univariate analysis were selected for a multivariate analysis using the Cox proportional hazards model.

Results: Forty-nine patients were enrolled. The median age of onset was 77 (69-82) years and 71.4% were women. There were 30 ANCA-positive patients (90.0% with anti-myeloperoxidase) and 19 ANCA-negative patients. The median age and the number of patients with renal involvements were higher in the ANCA-positive group than in the ANCA-negative group (73.0 ± 9.29 years vs. 79.5 ± 20.28 years, p=0.0062 and 7/30 [23.3%] vs. 0/19 [0.0%], p=0.034, respectively). The Birmingham Vasculitis Activity Score (ver. 3), the induction dose of GC, and the rate of immunosuppressants use were not significantly different between the two groups. During the observational period, 24 patients relapsed. The 5-year cumulative incidence of relapse was significantly higher in the ANCA-positive group than in the ANCA-negative group (p=0.026) (Figure 1). The Cox proportional hazards model revealed that the presence of ANCA was an independent risk factor for relapse (hazard ratio: 3.15; 95% confidence interval 1.06–9.38; p=0.040). During the observational period, 9 patients died (3 died from cancer, 1 from interstitial pneumonia, 1 from cerebral hemorrhage, 1 from infection, and 3 from unknown reasons). The ANCA-positive group exhibited a higher mortality rate than the ANCA-negative group without a statistical significance (p=0.12). The 5-year cumulative dose of GC was larger in the ANCA-positive group than in the ANCA-negative group without a statistical significance (14786 [11246–19138] mg vs. 10088 [7129–12634] mg, p=0.12).

Conclusion: In muscular vasculitis, the presence of ANCA is an independent risk factor for long-term relapse. Stratified treatment depending on the ANCA status may reduce the relapse rate and the occurrence of side effects of GC in patients with muscular vasculitis.

POS0825 DEVELOPMENT OF A NEW AND SIMPLIFIED FORMULA TO PREDICT MORTALITY IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS ADMITTED TO THE INTENSIVE CARE UNIT

P. Korsten[1], F. Kück[2], K. Tejiozem Donfack[1], R. Vasko[1], A. Lena[2], B. Tampe[1]. [1]*Universitätsmedizin Göttingen, Department of Nephrology and Rheumatology, GÖTTINGEN, Germany*; [2]*Universitätsmedizin Göttingen, Department of Medical Statistics, Göttingen, Germany*

Background: ANCA-associated vasculitis (AAV) can present with a wide range of symptoms, including acute kidney injury (AKI) requiring renal replacement therapy or diffuse alveolar hemorrhage (1). These two manifestations often require admission to an intensive care unit (ICU) and are associated with increased mortality. To predict ICU mortality, the Simplified Acute Physiology Score version 2 (SAPS2) is often used but has not been formally tested in AAV patients (2). In addition, it is cumbersome to assess.

Objectives: To develop a novel, simplified formula to predict ICU mortality in an AAV ICU population from an academic tertiary care center.

Methods: We retrospectively recorded clinical and laboratory parameters in patients admitted to our ICU from 2000-2018. We performed risk factor analysis using univariate and multivariate logistic regression. In the multivariate case we applied the least absolute shrinkage and selection operator (lasso) method for variable selection. We considered average marginal effects and partial dependence plots in order to describe the influence of various independent variables on the probability of death more specifically. We evaluated our new score by comparing the corresponding area under the curve (AUC) to the AUC corresponding to the established SAPS2 score.
Results: We analyzed 58 patients with AAV (39 granulomatosis with polyangiitis, 19 with microscopic polyangiitis) with a mean age of 74±14 (GPA) and 73±12 (MPA). 19/39 (48.7%) of GPA and 9/19 (47.4%) were female. Reasons for admission included disease manifestations or infectious complications from treatment (e. g. pneumonia, urinary tract infection). In total, 13/58 (22.4%) patients died throughout the study (10 GPA, 3 MPA patients). Using a cut-off threshold of 40 for SAPS2, sensitivity and specificity for mortality were 0.92 and 0.60, respectively. Confidence interval for the AUC was [0.68,0.95]. In the fitted multivariate logistic regression model, lasso was applied for variable selection. The identified variables included: disease duration, pH, procalcitonin, hemoglobin, leukocytes on admission, coronary heart disease, and pneumonia on admission. The estimated mortality is given by the formula $f(\beta 0 + \beta 1\chi 1 + \ldots + \beta 7\chi 7)$, where $f(u)=1/(1+\exp(-u))$. Table 1 shows the estimated mortality for various values of the new score.

Table 1. Example scores predicting mortality using the novel formula.

Score	Predicted mortality
-2.2	0.1
-1.1	0.25
0	0.5
1.1	0.75
2.2	0.9

Testing if the AUC corresponding to the new model is significantly larger than the one corresponding to the SAPS2 score as independent variable resulted in p-value of 0.037. To identify possible overfitting, a 5-fold cross validation was performed. This resulted in a CI for the AUC of [0.64,0.96], suggesting that the new score allows for simpler prediction of mortality.
Conclusion: We developed a novel formula corresponding to a score which is able to simpler predict mortality in patients with AAV admitted to the ICU. We will test our formula in the available ICU database MIMIC III, which comprises a large dataset of ICU patients.

POS0826 SKIN LIMITED IGA VASCULITIS IN ADULTS

A. Hočevar[1,2], J. Ostrovrsnik[1], K. Perdan-Pirkmajer[1], M. Tomsic[1,2], Z. Rotar[1,2]. [1]*University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia*; [2]*Medical Faculty, University of Ljubljana, Internal Medicine, Ljubljana, Slovenia*

Background: IgA vasculitis (IgAV) could be limited to skin or evolve into a systemic disease, affecting characteristically joints, gastrointestinal tract and/or kidneys.
Objectives: We aimed to look for differences between adult IgAV patients with disease limited to skin compared to systemic IgAV.
Methods: Medical records of histologically proven adult IgAV cases, diagnosed between January 2010 and December 2020 at our secondary/tertiary rheumatology centre were analyzed.
Results: During the 132-month observation period we identified 328 new IgAV cases (59.5% males, median (IQR) age 64.3 (45.1; 76.1) years). Ninety-four (40.2%) patients had skin limited disease, and the rest systemic IgAV.

Clinical differences between skin limited and systemic adult IgAV are presented in table 1. Adults with IgAV limited to skin were significantly older, had less commonly skin lesions above the waistline and a lower level of C reactive protein compared to patients with a systemic disease. There were no differences in the frequency of skin necroses between the compared IgAV subgroups. The frequency of potential vasculitis triggers (prior infections, new medications, malignancy) was similar between the compared subgroups.

Table 1. Clinical characteristics of IgA vasculitis patients with skin limited and systemic disease

Clinical characteristics	Skin limited IgAV (94)	Systemic IgAV (234)	P value
Male gender (%)	54.3	61.5	0.263
Age (years)*	68.0 (55.0-80.5)	61.5 (41.7-75.8)	0.007
Current smoker (%)	13.8	21.8	0.123
Antecedent infection (%)	28.7	33.8	0.434
New medication	23.4	23.5	1.0
History of cancer	12.8	10.7	0.569
Symptom duration (days)*	7 (5-21)	8 (5-14)	0.756
Purpura above waistline	36.2	55.6	0.002
Skin necroses (%)	52.1	45.7	0.329
ESR /mm/h) *	32 (18-52)	34 (17-53)	0.873
CRP (g/l) *	13.5 (1-32)	30 (11-68)	<0.001
Elevated serum IgA (%)	50.6	49.1	0.892

Legend: * median and IQR;

Follow up data were available for 250 (76.2%) patients. During the follow up of median (IQR) 12.5 (6.8 – 22.4) months 35 patients relapsed (13/70 (18.6%) with skin limited IgAV and 22/180 (12.2%) with systemic IgAV, p= 0.224).
Conclusion: Skin limited IgAV was associated with older age and less extensive skin puprura in adults. However, relapses of purpura were as common as in systemic IgAV.

POS0827 HEPATOTROPIC VIRUSES WITH HIGHER RHEUMATOID FACTOR, BUT NOT RHEUMATIC DISEASES LINK TO PREVALENT CRYOGLOBULINEMIA. CORRELATION OF CLINICAL AND SEROLOGICAL MARKERS WITH ETIOLOGICAL CAUSES

S. Jeria Navarro[1], T. Franco[2], L. Alserawan[2], D. Lobo Prat[1], A. García-Guillén[1], L. Sainz Comas[1], H. Park[1], A. M. Millán Arciniegas[1], P. Moya[1], B. Magallares[1], C. Díaz-Torné[1], E. Moga[2], C. Juarez[2], H. Corominas[1]. [1]*Hospital Universitari de la Santa Creu i Sant Pau & Dos de Maig, Rheumatology Unit, Barcelona, Spain*; [2]*Hospital Universitari de la Santa Creu i Sant Pau, Immunology Unit, Barcelona, Spain*

Background: Cryoglobulinemia (CG) is a rare phenomenon, which is defined as the persistent presence in serum of abnormal immunoglobulins (Igs) that precipitate in vitro at less than 37ºC and dissolve when the temperature rises again. Is related to hematological disorders, infections and autoimmunes diseases.
Objectives: To describe the differential clinical features, serological and demographics in a cohort of patients diagnosed with CG.
Methods: We describe a retrospective cohort of 252 cryoglobulin (Cg) positive samples, obtained from a database from the immunology laboratory of a tertiary hospital (November 2018-November 2019). We obtained 182 patients with CG, classified according to their etiology into 4 groups: 1)Rheumatic diseases (RD) that includes rheumatoid arthritis, Systemic lupus erythematosus, Sjögren´s syndrome and Systemic scleroderma, 2)Hepatotropic viruses (HV) with patients diagnosed with Hepatitis C virus, B virus and both, 3)Hematological diseases (HD) and 4)Essential cryoglobulinemia (CGE). Demographic variables, clinical and serological data were collected. A comparative analysis was performed with the Mann-Whitney U test and the multivariate Kruskal-Wallis test, nonparametric variables were compared using a Wilcoxon test. Ten patients, with more than one disease from 4 groups, were excluded from the study.
Results: Out of 182 reviewed patients, 172 were included in the study. Mean age at diagnosis was 59.7(±14.0). Demographic, clinical and laboratory characteristics are described in table 1. Mixed CG was the predominant subtype, in 116 (67.4%) patients. The most prevalent CG-associated diseases were HV infection with 91(53%) patients. CGE mostly presented with cutaneous manifestations (p=0.0001), particularly purpura. In RD group the presence of Raynaud and non-erosive arthritis (p=0.0001) was relevant. Laboratory findings showed that CG titration varies according to the etiology, being HD the one with the highest values with 292.2 (±546.2). There is significant difference in

terms of the average of rheumatoid factor (RF) being higher in the group by CGE. On other hand, the group HV presented more consumption of complement, and showed the lowest average p=0.0001, without more severe clinical manifestations.

Table 1.

	RD (n=47)	HV (n=91)	HD (n=17)	CGE (n=17)	
Gender,n(%) F	42 (89.4)	57 (62.6)	7 (41.2)	11 (64.7)

ESR (mm/h) p50	40.0 (±28.5)	20.3 (±20.2)	35.4 (±35.1)	24.5 (±25.0)	p= 0.0003
RF + (>20UI/mL), n (%)	19/46 (41.3)	44/86 (51.2)	5/11 (45.5)	7/17 (41.2)	p= 0.09
p50	90.6 (±175.9)	161.0 (±219.5)	94.8 (±135.6)	284.5 (±619.3)	p<0.001
C3 (<85mg/dL), n %)	20 (42.6)	47 (51.6)	3 (17.6)	3 (17.6)	p= 0.13
x̄ (± SD)	90.1 (±28.6)	68.5 (±10.8)	99.1 (±29.0)	114.8 (±12.7)	p<0.001
C4 (<12mg/dL), n (%)	17 (36.2)	36 (39.6)	-	3 (17.6)	p= 0.02
x̄ (± SD)	15.6 (±9.0)	7.6 (±3.5)	20.4 (±7.4)	21.1 (±9.5)	p<0.001

Conclusion: In our cohort, not all patients with CG presented clinical manifestations being those associated with CGE and RD those with the highest skin and joint expression. The most prevalent association of CG continues to be the HV and we confirmed the characteristic decrease in C3 and C4 complement levels, together with the positivity for RF.

POS0828

CONSISTENT EFFICACY WITH APREMILAST IN MEN AND WOMEN TO TREAT ORAL ULCERS ASSOCIATED WITH BEHÇET'S SYNDROME: PHASE 3 RELIEF STUDY RESULTS

G. Hatemi[1], A. Mahr[2], M. Takeno[3], D. Kim[4], M. Melikoglu[1], S. Cheng[5], S. Richter[5], S. Jardon[5], M. Paris[5], M. Chen[5], Y. Yazici[6]. [1]*Istanbul University-Cerrahpaşa, Cerrahpaşa Medical School and Behçet's Disease Research Center, Division of Rheumatology, Department of Internal Medicine, Istanbul, Turkey*; [2]*Cantonal Hospital St. Gallen, Department of Rheumatology, St. Gallen, Switzerland*; [3]*Nippon Medical School, Rheumatology, Kawasaki, Japan*; [4]*Yonsei University College of Medicine and Severance Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; [5]*Amgen Inc., Global Medical Affairs, Thousand Oaks, United States of America*; [6]*New York University School of Medicine, Department of Medicine, New York, United States of America*

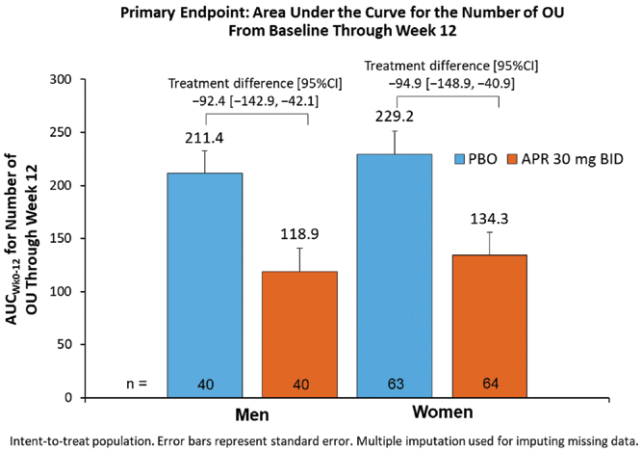
Background: Painful, recurring oral ulcers (OU) associated with Behçet's syndrome negatively affect quality of life (QoL). Differences across sexes were reported in the frequency of disease manifestations, disease course, and response to colchicine. The phase 3, randomized, double-blind, placebo (PBO)-controlled RELIEF study showed overall efficacy of apremilast (APR) for OU associated with Behçet's syndrome, including improvements in OU pain, disease activity, and QoL.

Objectives: To evaluate the consistency of efficacy with APR in men and women with Behçet's syndrome.

Methods: Adults with active Behçet's syndrome and ≥3 OU at randomization or ≥2 OU at screening and randomization, without active major organ involvement, were randomized to APR 30 mg BID or PBO during the 12-wk PBO-controlled phase. Randomization was stratified by sex. The primary endpoint was area under the curve for the number of OU through Wk 12 (AUC_{Wk0-12}) to assess continued efficacy over the time period in a symptom that waxed and waned. Key secondary endpoints included OU pain, complete response (OU-free), maintenance of complete response, and QoL at Wk 12. Disease activity was also assessed using Behçet's Syndrome Activity Score (BSAS) and Behçet's Disease Current Activity Index Form (BDCAF). QoL was assessed using Behçet's Disease QoL (BDQoL). Prespecified subgroup analyses in men and women were performed to assess treatment effect in primary and secondary endpoints.

Results: Eighty men and 127 women were randomized and received ≥1 dose of study medication. Mean age was 38.7 yrs (men) and 40.8 yrs (women). Mean (SD) OU count at baseline was 3.4 (1.4) (PBO) and 3.7 (1.5) (APR) for men and 4.3 (3.2) (PBO) and 4.5 (4.5) (APR) for women. Greater improvements in favor of APR vs PBO were observed in AUC_{Wk0-12} in men and women (Figure 1). Consistency in efficacy with APR was observed between men and women, with greater reduction in pain and achievement of OU complete response (OU-free) and maintenance of response at Wk 12 vs PBO (Table 1). In men and women, consistent treatment effects in favor of APR vs PBO were observed for disease activity and QoL measures, although moderate treatment differences were observed in BDCAI (men/women) and BDQoL (men) (Table 1).

Conclusion: Consistent treatment effects in favor of APR vs PBO in clinically relevant outcomes, including OU number and pain, OU complete response, and disease activity measures, were observed in men and women with OU associated with Behçet's syndrome.



Intent-to-treat population. Error bars represent standard error. Multiple imputation used for imputing missing data.

Key Secondary Efficacy Outcomes at Wk 12

	Men			Women		
	PBO (n = 40)	APR (n = 40)	Tx Difference [95% CI]	PBO (n = 63)	APR (n = 64)	Tx Difference [95% CI]

POS0829 SPECIFICITY OF PANCA AUTOANTIBODIES IN AUTOIMMUNE DISEASES

O. Argyropoulou[1], A. Tsirogianni[2], C. Sfontouris[3], G. Boutzios[1], P. Vlachoyiannopoulos[1], A. Tzioufas[1], E. Kapsogeorgou[1]. [1]*School of Medicine, National and Kapodistrian University of Athens, Pathophysiology, Athens, Greece*; [2]*Evangelismos General Hospital, Immunology and Histocompatibility, Athens, Greece*; [3]*Evangelismos General Hospital, Rheumatology, Athens, Greece*

Background: The clinical significance of pANCA by indirect immunofluorescence is well-established. However, their clinical utility is sometimes hindered by the fact that pANCA are also detected in various autoimmune diseases. Myeloperoxidase (MPO) is considered as the major autoantigen recognized by pANCA in ANCA-associated vasculitides (AAV) and predominantly in microscopic polyangiitis (MPA). However, information regarding the targets of pANCA in other autoimmune diseases is still elusive.
Objectives: To investigate the specific autoantigens recognized by pANCA in autoimmune diseases.
Methods: Sera from all patients that were found positive for pANCA in the diagnostic laboratories of the Department of Pathophysiology, School of Medicine, National and Kapodistrian University of Athens and the Department of Immunology and Histocompatibility, Evangelismos General Hospital, Athens, Greece during the last two years were studied. The pANCA+ sera were evaluated for reactivity with the major antigens that are recognized by pANCA [MPO, lactoferrin, neutrophil elastase, cathepsin G and bactericidal/permeability increasing protein (BPI)] by a commercially available multiplex ELISA (ANCA profile ELISA, Euroimmun, Lubeck, Germany).
Results: A total of 82 patients were included in the study. All patients had positive pANCA by indirect immunofluorescence with a title ranging from 1/160 to 1/640. According to respective classification criteria, 21 patients had systemic vasculitides (15 MPA, 1 granulomatosis with polyangiitis; GPA, 1 Behcet's disease; BD, 1 aortitis, 2 Henoch-Schonlein purpura; HSP and 1 cryoglobulinemic vasculitis; CV), 29 had systemic lupus erythematosus (SLE), 6 antiphospholipid syndrome (APS), 8 Sjögren's syndrome (SS), 2 rheumatoid arthritis (RA), 1 systemic scleroderma (SScl), 14 Hashimoto thyroiditis and 1 sarcoidosis. The specificities of pANCA in each entity are shown in the following table.

Autoimmune Diseases		Antigens recognized by pANCA+ sera				
		MPO	**Elastase**	**Cathepsin G**	**BPI**	**Lactoferrin**
Vasculitides	MPA	66.7 (10/15)	0 (0/15)	0 (0/15)	0 (0/15)	0 (0/15)
	GPA	100 (1/1)	0 (0/1)	0 (0/1)	0 (0/1)	0 (0/1)
	BD	100 (1/1)	0 (0/1)	0 (0/1)	0 (0/1)	0 (0/1)
	Aortitis	0 (0/1)	0 (0/1)	0 (0/1)	0 (0/1)	0 (0/1)
	HSP	0 (0/2)	0 (0/2)	0 (0/2)	0 (0/2)	0 (0/2)
	CV	0 (0/1)	0 (0/1)	0 (0/1)	0(0/1)	100 (1/1)
SLE		6.9 (2/29)	0 (0/29)	0 (0/29)	0 (0/29)	6.9 (2/29)
APS		16.6 (1/6)	16.6 (1/6)	0 (0/6)	0 (0/6)	0 (0/6)
SS		0 (0/8)	12.5 (1/8)	0 (0/8)	12.5 (1/8)	0 (0/8)
RA		50 (1/2)	0 (0/2)	0 (0/2)	0 (0/2)	0 (0/2)
SScl		100 (1/1)	0 (0/1)	0 (0/1)	0 (0/1)	0 (0/1)
Hashimoto		0 (0/14)	0 (0/14)	0 (0/14)	0 (0/14)	0 (0/14)
Sarcoidosis		0 (0/1)	0 (0/1)	0 (0/1)	0 (0/1)	0 (0/1)

Conclusion: pANCA positive staining in AAVs is highly restricted to MPO specificity. On the contrary, pANCA staining pattern in other autoimmune diseases, involves unknown autoantigens that are under investigation in our laboratory.

POS0830 FACTORS INFLUENCING PATIENT-REPORTED OUTCOMES IN ANCA-ASSOCIATED VASCULITIS

S. Monti[1,2], P. Delvino[1,2], C. Klersy[3], G. Coppa[4], A. Milanesi[1], C. Montecucco[1]. [1]*Pavia, Rheumatology, IRCCS Policlinico S. Matteo Fondazione, Pavia, Italy*; [2]*Pavia, PhD in Experimental Medicine, University of Pavia, Pavia, Italy*; [3]*Pavia, Biometry and Clinical Epidemiology, IRCCS Policlinico S. Matteo Fondazione, Pavia, Italy*; [4]*Pavia, University of Pavia, School of Medicine and Surgery, Pavia, Italy*

Background: Patient-reported outcomes (PROs) are currently poorly integrated in the clinical evaluation of disease activity in patients with ANCA-associated vasculitis (AAV).
Objectives: To assess the distribution of the Patient Global Assessment (PtGA) in patients with AAV in stable remission, and to identify correlates of PtGA; to assess the discordance between PtGA score and PhGA.
Methods: Patients with a diagnosis of AAV [eosinophilic granulomatosis with polyangiitis, granulomatosis with polyangiitis, microscopic polyangiitis] in stable, complete remission (defined by a BVAS=0) and with a Physician Global Assessment (PhGA)=0 were included. A questionnaire including several aspects of disease captured by PROs was collected. PtGA on a 0-100 mm visual analogue scale (VAS) was assessed, with higher scores representing higher/worse levels of disease activity. Similarly, VAS for pain, chronic damage according to the patient's opinion, general health (GH), fatigue, and sleep quality were collected. The worst symptom in the patient's opinion affecting the overall assessment of disease activity was recorded. The Cragg Hurdle model was used to assess the predictors of PtGA.
Results: 65 patients were included, female 57%, mean age 61±12 years. Mean disease duration at enrollment was 8±6 years. Mean vasculitis damage index (VDI) was 4.4 ±2.3, with 45% of patients having a VDI ≥ 5. Despite having been classified as being in remission, PtGA was elevated in 37% of patients. We explored several correlates of PtGA. Higher degree of damage accrual (VDI) did not influence the patient's evaluation of current disease activity. Similarly, we did not identify a correlation between older age, educational level, number of organ-systems involved, number of comorbidities, the number of previous major or minor relapses, higher disease duration, nor the type of AAV diagnosis (figure 1, panel A). Only sex significantly correlated with PtGA scores: 19 (51%) of female patients reported an elevated PtGA compared to only 5 (18%) of male (p=0.009). PtGA resulted to be significantly correlated with other (mostly modifiable) PROs including VAS pain, perception of the level of chronic damage accrual, GH, and fatigue (figure 1, panel B). The agreement between patients' and physicians' assessments of disease activity was 63%. Patients reported pain, followed by chronic respiratory symptoms to be the worst-experienced ongoing manifestations affecting their evaluation of disease activity.
Conclusion: A significant proportion of patients with AAV considered to be in remission by the physician still declares to have persistent aspects of uncontrolled disease. PtGA is significantly influenced by persistent pain and fatigue, which warrant better assessment in the future.

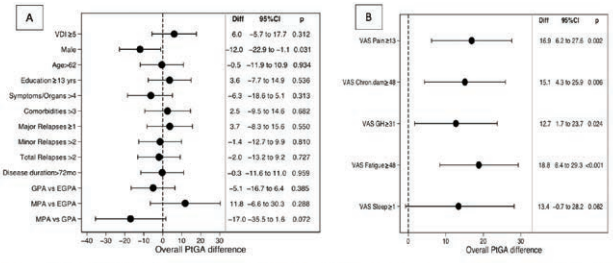

Figure 1. Forrest plots of correlates of the Patient Global Assessment (PtGA): patient- and disease-related items (Panel A); influence of other patient-reported outcomes (Panel B). Cut-off values were identified based on the median value of the population.

POS0831

EARLY INFECTIOUS RISK IN PATIENTS WITH NEWLY-DIAGNOSED ANTI-NEUTROPHILCYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS ACCORDING TO THE REMISSION-INDUCTIONTHERAPY: A FRENCH MONOCENTRIC RETROSPECTIVE STUDY INCLUDING 145 PATIENTS

M. Gérard[1], H. De Boysson[1], R. Morello[1], N. M. Silva[1], A. C. Leroux[2], A. Dumont[1], G. Maigné[1], J. Boutemy[1], K. Khoy[1], D. Mariotte[1], T. Lobbedez[1], A. Aouba[1], S. Deshayes[1]. [1]*Centre Hospitalier et Universitaire de Caen, Calvados, Caen, France*; [2]*Centre Hospitalier et Universitaire de Caen, Manche, Saint-Lô, France*

Background: Few comparative data exist on early infections secondary to remission-induction therapy (RIT) with rituximab versus cyclophosphamide in newly-diagnosed ANCA-associated vasculitis (AAV) patients.
Objectives: We compared and analyzed the rate and predictors of severe infections in such patients within the first six months following RIT.

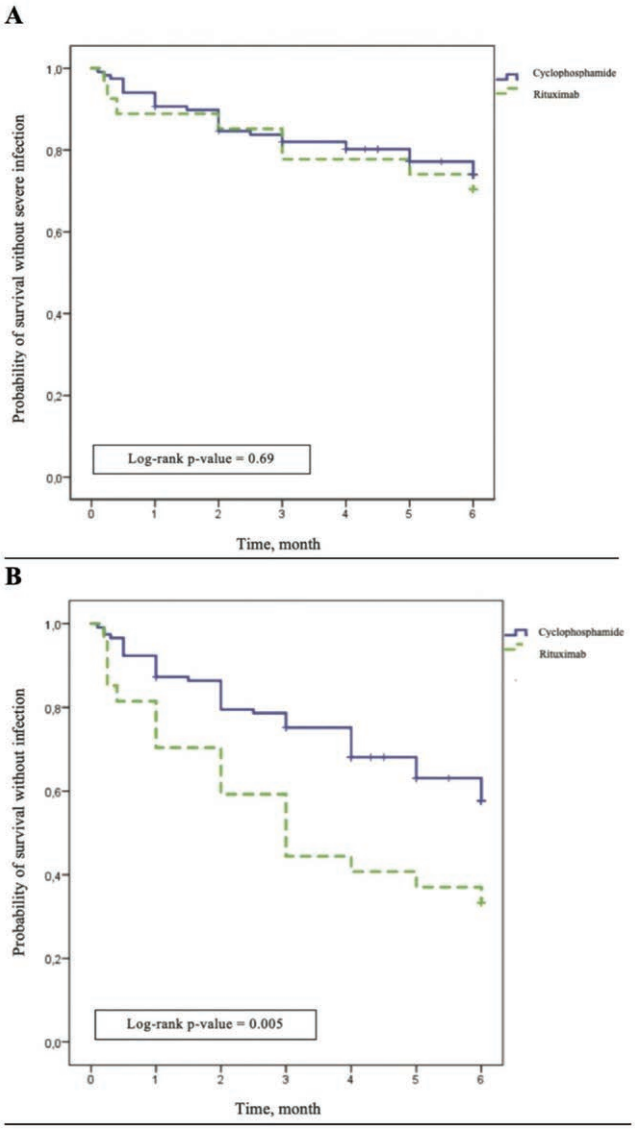

Figure 1. Comparison of the 6-month survival without severe infection (A) or without infection of any severity (B) in patients with newly-diagnosed ANCA-associated vasculitis treated by rituximab or cyclophosphamide

Methods: We included, from the databases of Caen University Hospital, all consecutive adults newly-diagnosed with granulomatosis with polyangiitis or microscopic polyangiitis between January 2006 and December 2019. We compared the survival without severe infections (WSI) and the survival without infection of any severity (WIOAS) within 6 months from the RIT, and used a multivariate cox analysis to identify predictors of infection.
Results: We included 145 patients, 27 in rituximab group and 118 in cyclophosphamide group. Patients in the rituximab group more frequently had pneumococcal vaccination ($p<0.01$) and creatinine level <150 µmol/L, while other characteristics, including Birmingham Vasculitis Activity Score, were comparable between both groups.
Overall, 37 severe infections and 65 infections of any severity were recorded. The survival WSI was similar in both groups ($p=0.69$), but survival WIOAS was lower in rituximab group ($p=0.005$).
In multivariate analysis, risk factors at diagnosis for severe infections were chronic urinary tract disease, dialysis and absence of prophylaxis with trimethoprim-sulfamethoxazole ($p<0.01$ each).
Conclusion: The survival WIS within the 6 months following RIT was similar in patients with newly-diagnosed AAV treated by rituximab or cyclophosphamide, but survival WIOAS appeared to be lower within the 6 months following rituximab despite a better pneumococcal vaccination coverage.

POS0832

A NOVEL GREY SCALE AND POWER DOPPLER ULTRASONOGRAPHIC SCORE FOR IDIOPATHIC INFLAMMATORY MYOPATHIES: SIENA MYOSITIS ULTRASOUND GRADING SCALE

E. Conticini[1], P. Falsetti[1], S. G. Al Khayyat[1], C. Baldi[1], F. Bellisai[1], M. Bardelli[1], L. Cantarini[1], B. Frediani[1]. [1]*University of Siena, Rheumatology Unit, Siena, Italy*

Background: No clear-cut guidelines exist about the use of diagnostic procedures for idiopathic inflammatory myopathies (IIM) and only scanty and conflicting data report the use of ultrasound (US).
Objectives: We aimed to assess if grey-scale (GS) and Power Doppler (PD) US, graded with a 0-3-points-scale, may be a reliable tool in a cohort of patients affected by IIM.
Methods: We prospectively collected, since July to October 2020, all patients referred to Vasculitis and Myositis clinic, Rheumatology Unit, University of Siena, for suspected IIM, as well as patients with a previous, definite diagnosis of IIM and evaluated during follow-up or referred from other centers for a second opinion. All patients underwent US examination of both thighs in axial and longitudinal scans. Edema and atrophy, both assessed in GS, and PD, were graded with a 0-3-points-scale. Spearman test was used to identify the correlations between US and clinical and serological variables.
Results: A total of 18 patients was included. Four of them were evaluated twice, at baseline and within 3 months of therapy. Muscle edema was found to be directly correlated with physician global assessment (PhGA), serum myoglobin and PD and negatively with disease duration. PD score was positively correlated to PhGA and negatively to disease duration. Muscle atrophy directly correlated with Myositis Damage Index and patients' age. The single-thigh sub-analysis evidenced a direct correlation between PD score and Manual Muscle Test.
Conclusion: In our cohort, we found that edema and PD are strictly related to early, active myositis, suggesting that an inflamed muscle should appear swollen, thickened and with Doppler signal. Conversely, muscle atrophy reflects the age of the patient and the overall severity of the disease. Such findings shed a new, promising, light in the role of US in diagnosis and monitoring of IIMs.

Table 1. Siena Myositis Ultrasound Grading Scale (SMUGS).

	Grey-scale edema	Grey-scale atrophy	Power Doppler
0	Normal muscle echotexture with hyperechoic septa and hypoechoic muscle fibers, conserved thickness.	Normal muscle echotexture, with hyperechoic septa and hypoechoic muscle fibers, conserved thickness.	No PD signal.
1	Focal hypoechoic areas, where septa are less evident. Conserved thickness.	Focal heterogeneously hyperechoic areas, where septa are thicker and more evident, and muscle fibers are thinner. Conserved muscle thickness.	One or two PD signals in at least one muscle (PD vascular spots, small vessels of homogenous diameters, vessel diameters approximately not superior to fibrous intramuscular septa)
2	Diffuse and heterogeneous hypo echogenicity (rectus femoris as hypoechoic or more than vastus intermedius), septa diffusely less evident. Conserved thickness.	Diffuse and heterogeneously hyperechoic muscle, with thicker septa and thinner muscle fibers. Conserved muscle thickness.	More than 2 PD signals for each muscle (as vascular spots, small vessels of homogenous diameters, vessel diameters approximately not superior to fibrous intramuscular septa).
3	Diffuse and heterogeneous hypo echogenicity (rectus femoris as hypoechoic or more than vastus intermedius), septa diffusely less evident. Increased thickness (rectus femoris became thicker than vastus intermedius).	Diffuse and heterogeneously hyperechoic muscle, with thicker septa and thinner muscle fibers. Reduced muscle thickness.	More than 2 PD signals for each muscle with larger diameter of the vessel (at least superior to fibrous intramuscular septa), or vessels with different diameters or branched vessels.

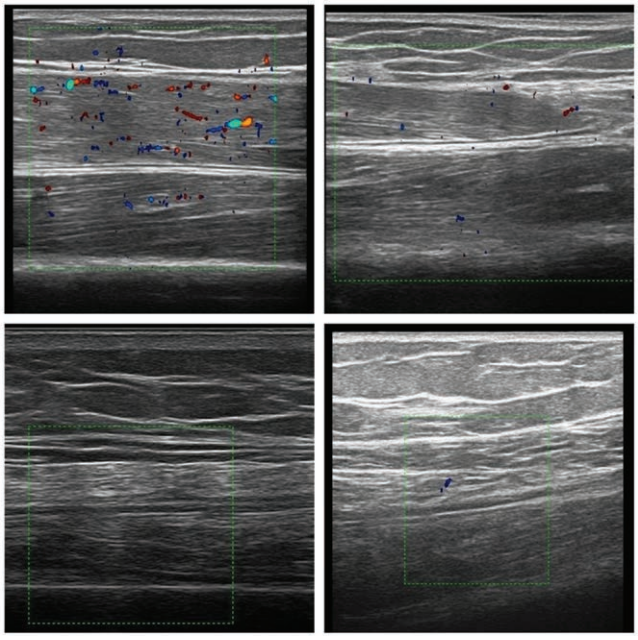

Figure 1. Different PD findings (clockwise) in longitudinal anterior scans of the thigh: PD 3 in a patient with a recent diagnosis of anti-Mi2 DM; PD 2 in the same patient after one month of treatment with steroids and Methotrexate; PD 1 in a patient affected by anti-SAE DM, with a suspected disease flare; PD 0 in a patient affected by an advanced polymyositis diagnosed in 2000, currently not in treatment.

POS0833 A RETROSPECTIVE COHORT STUDY IN CHINESE PATIENTS WITH ADULT POLYMYOSITIS AND DERMATOMYOSITIS: RISK OF COMORBIDITIES AND SUBCLASSIFICATION USING MACHINE LEARNING

J. Zhu[1], L. Wu[2], Y. Zhou[3], R. Wang[1], S. Chen[1], S. Yu[4], S. Zheng[1], F. Xiao[1], J. Li[1]. [1]*Nanfang Hospital, Southern Medical University, Department of Rheumatic & TCM Medical Center, Guangzhou, China*; [2]*School of Traditional Chinese Medicine, Southern Medical University, Department of Internal Medicine of Traditional Chinese Medicine, Guangzhou, China*; [3]*Guangdong Women and Children Hospital, Department of Obstetrics, Guangzhou, China*; [4]*Nanfang Hospital, Southern Medical University, Department of Rheumatology, Guangzhou, China*

Background: Idiopathic inflammatory myopathy (IIM), also known as myositis, refers to a group of heterogeneous disorders including polymyositis (PM), dermatomyositis (DM), inclusion body myositis and immune-mediated necrotising myopathy. Phenotype, pathogenesis, and prognosis vary due to multi-organ involvement and comorbidities. With the clinical application of MSAs, a new classification system for myositis was explored to reduce confusion between subgroups. But it is far from showing the full picture of myositis due to high heterogeneity. Therefore, it is necessary to systematically evaluate the relevant risk factors of myositis for ILD, other rheumatic diseases, and malignancy for better clinical vigilance. And further exploring the subclassification of myositis is critical.
Objectives: To identify the risk factors in Chinese patients with adult polymyositis and dermatomyositis for their comorbidities and explore a subclassification system.
Methods: Clinical records of 397 patients with idiopathic inflammatory myopathies were retrospectively reviewed. Logistic regression was used to identify potential risk factors for interstitial lung disease (ILD), other rheumatic diseases, and malignancy after bivariate analysis. Hierarchical clustering and decisional tree were utilized to identify subgroups and explore a subclassification system.
Results: A total of 119 polymyositis and 191 dermatomyositis patients were included. Anti-PM/Scl, anti-Ro52, anti-aminoacyl-tRNA synthetase and anti-MDA5 (adjusted odds ratios (AOR)=4.779, 1.917, 5.092 and 7.714 respectively) antibodies were risks (p<0.05), whereas overlapping malignancy was protective (AOR=0.107; p=0.002) for ILD across polymyositis, dermatomyositis and the total group. In subgroup models, Raynaud's phenomenon, arthralgia and semi-quantitative anti-nuclear antibody (AOR=51.233, 4.261, 3.047 respectively) were risks for other overlapping rheumatic diseases (p<0.05). For overlapping malignancy, male and anti-TIF1γ antibodies (AOR=2.533, 16.949) were risks (p<0.05), whereas disease duration and combination of ILD (AOR=0.954, 0.106) were protective in the total group (p<0.05); while anti-NXP2 antibodies were identified as risk factors (AOR=73.152; p=0.038) in polymyositis. Hierarchical clustering suggested a subclassification with 6 subgroups: malignancy overlapping dermatomyositis, classical dermatomyositis, polymyositis with severe muscle involvement, dermatomyositis with ILD, polymyositis with ILD, and overlapping of myositis with other rheumatic diseases according to the characteristics of grouped patients. Accuracy of the classification and regression trees model was 0.768 (95% CI 0.711 to 0.819) on training set and 0.633 (95%CI 0.499 to 0.754) on test set.
Conclusion: Accompanying ILD, other rheumatic diseases and malignancy are strongly associated with clinical manifestation and myositis-specific or myositis-associated autoantibodies among Chinese polymyositis and dermatomyositis patients. The subclassification system proposed a more precise phenotype defining toward stratified treatments.

Background: Gastroesophageal reflux disease (GERD) occurs frequently in patients with systemic sclerosis (SSc) and SSc-associated interstitial lung disease (SSc-ILD). PPI use has to been shown to improve survival in patients with idiopathic pulmonary fibrosis, whereas to date there are no data on the use of PPI in SSc-ILD.

Objectives: This study was aimed to assess whether use of PPI is associated with progression of SSc-ILD and survival.

Methods: We retrospectively analysed 1931 patients with SSc and SSc-ILD from the German Network for Systemic Sclerosis (DNSS) database (2003 onwards). Kaplan–Meier analysis compared overall survival (OS) and progression-free survival (PFS) in patients with vs. without GERD (SSc and SSc-ILD), and PPI vs. no PPI use (SSc-ILD only). Progression was defined as a decrease in either % predicted forced vital capacity ≥10% or single-breath diffusing capacity for carbon monoxide ≥15%, or death.

Results: GERD was not associated with decreased OS or PFS in patients with either SSc or SSc-ILD. In patients with SSc-ILD, PPI use was associated with improved OS vs. no PPI use after 1 year (98.4% [95% confidence interval: 97.6–99.3]; n=760 vs. 90.8% [87.9–93.8]; n=290) and after 5 years (91.4% [89.2–93.8]; n=357 vs. 70.9% [65.2–77.1]; n=106; p<0.0001). PPI use was also associated with improved PFS vs. no PPI use after 1 year (95.9% [94.6–97.3]; n=745 vs. 86.4% [82.9–90.1]; n=278) and after 5 years (66.8% [63.0–70.8]; n=286 vs. 45.9% [39.6–53.2]; n=69; p<0.0001).

Conclusion: GERD had no effect on survival in SSc or SSc-ILD. PPIs improved survival in patients with SSc-ILD; however, controlled, prospective trials are needed to confirm this finding.

Background: In the randomized SENSCIS trial in subjects with SSc-ILD, nintedanib reduced the rate of decline in FVC over 52 weeks (mL/year) by 44% compared to placebo. Healthy individuals have varied FVC depending on age, sex, ethnicity and height; expected values can be determined using internationally recognised reference equations.

Objectives: To provide further context to the FVC declines observed in the SENSCIS trial, we compared the decline in FVC observed in subjects with SSc-ILD in the SENSCIS trial with the decline in FVC that would be expected in hypothetical subjects without ILD matched for age, sex, ethnicity and height.

Methods: The SENSCIS trial enrolled subjects with SSc-ILD aged ≥18 years with first non-Raynaud symptom ≤7 years before screening, extent of fibrotic ILD ≥10% on HRCT, FVC ≥40% predicted and DLco 30–89% predicted. Baseline FVC (mL) and changes in FVC (mL) at week 52 were assessed in the nintedanib and placebo groups, with missing values at week 52 imputed using predictions from the primary analysis model (random slope and intercept model). Changes in FVC in the SENSCIS trial were compared to values in hypothetical healthy reference subjects matched to the SENSCIS subjects for age, sex, ethnicity and height. FVC values in these healthy reference subjects were derived from the equations published by the European Respiratory Society Global Lung Function Initiative in 2012, which were derived from data from over 70,000 subjects.[1]

Results: In the nintedanib and placebo groups of the SENSCIS trial, respectively, mean (SD) time since onset of first non-Raynaud symptom was 3.5 (1.6) and 3.5 (1.8) years. In the nintedanib group, mean (SD) FVC at baseline was 2460 (737) mL, compared with 3403 (787) mL in the healthy reference subjects. In the placebo group, mean (SD) FVC at baseline was 2544 (817) mL compared with 3516 (887) mL in the healthy reference subjects. The difference in the change from baseline in FVC at week 52 between the nintedanib-treated subjects in the SENSCIS trial (n=287) and the healthy reference subjects was 26.6 mL ([95% CI: 1.2, 52.0]; p=0.04). The difference in the change from baseline in FVC at week 52 between the placebo-treated subjects in the SENSCIS trial (n=286) and the reference subjects was 77.5 mL ([95% CI: 51.4, 103.7]; p<0.001) (Figure 1).

Conclusion: Subjects with SSc-ILD who participated in the SENSCIS trial had marked lung function impairment at baseline compared with healthy matched reference subjects, despite a mean duration of SSc of 3.5 years. Over 52 weeks, the decline in FVC in subjects with SSc-ILD who received placebo was 4-fold greater than in healthy reference subjects. Subjects with SSc-ILD who were treated with nintedanib had a decline in FVC that was only slightly greater than the decline observed in the matched healthy subjects. These data support the clinical relevance of the reduction in the rate of FVC decline provided by nintedanib in patients with SSc-ILD.

POS0836 CONDUCTION AND RHYTHM DISORDERS AMONG PATIENTS WITH SYSTEMIC SCLEROSIS: A US POPULATION BASED STUDY

Y. Radwan[1,2], R. Kurmann[3], E. El-Am[3], A. Sandhu[2], C. S. Crowson[2,4], E. Matteson[2], T. G. Osborn[2], K. J. Warrington[2], R. Mankad[3], A. Makol[2]. *[1]Michigan State University, Department of Internal Medicine, Lansing, United States of America*; *[2]Mayo Clinic, Division of Rheumatology, Rochester, United States of America*; *[3]Mayo Clinic, Department of Cardiovascular Disease, Rochester, United States of America*; *[4]Mayo Clinic, Department of Health Sciences Research, Rochester, United States of America*

Background: Systemic sclerosis (SSc) can impact multiple areas of the heart through fibrotic and vascular processes; leading to variable cardiac involvement including electrocardiogram (ECG) abnormalities. Conduction and rhythm disorders are associated with worse prognosis in patients with SSc. (1, 2)

Objectives: To study the incidence, risk factors and outcomes of conduction and rhythm disorders in a US population-based cohort of patients with SSc and non-SSc comparators from the same geographic area.

Methods: A previously identified incident cohort of SSc patients (1980-2016) in a well-defined geographic area was compared to a randomly selected 2:1 cohort of age- and sex-matched non-SSc subjects from the same population base. Demographics, disease characteristics, cardiovascular risk factors and laboratory tests were abstracted by manual record review. ECGs and Holter ECGs were reviewed to determine the occurrence of any conduction or rhythm abnormalities. The need for cardiac interventions was also abstracted.

Results: 78 incident SSc cases and 156 non-SSc comparators were identified [age 56 years± 15.7, 91% female]. Prevalence of any conduction disorders before SSc diagnosis compared to non-SSc comparators was 15% vs. 7% (p=0.06), and any rhythm disorder was 18% vs. 13% (p=0.33). During a median follow up of 10.5 years in patients with SSc and 13.0 years in non-SSc comparators, conduction disorders developed in 25 SSc patients with a cumulative incidence (ci) of 20.5% (95% CI: 12.4-34.1%) compared to 28 non-SSc patients with ci of 10.4% (95% CI: 6.2-17.4%) (HR: 2.57; 95% CI: 1.48-4.45), while rhythm disorders developed in 27 SSc patients with ci of 27.3% (95% CI: 17.9-41.6%) vs 43 non-SSc patients with ci of 18.0% (95% CI: 12.3-26.4%) (HR: 1.62; 95% CI: 1.00-2.64). (Figure 1).

Conduction disorders in patients with SSc during follow up included: 1st-degree atrioventricular block (AVB) (n=12), 2nd-degree AVB (n=1), 3rd-degree AVB (n=1), right bundle branch block (n=10), left bundle branch block (n=4), bifascicular block (n=6), and prolonged-QT (n=13). Rhythm disorders included: atrial fibrillation (n=10), atrial flutter (n=4), supraventricular tachycardia (n=4), ventricular tachycardia (n=1), and premature ventricular contractions (n=16).

Pulmonary hypertension (PHT) was the only significant risk factor identified for development of both conduction and rhythm disorders (HR=8.38, 95% CI: 1.32-53.40 and HR=8.07, 95% CI: 1.60-40.74, respectively). Current smoking significantly increased the risk for development of rhythm disorders (HR=2.91, 95% CI: 1.19-7.12). Conduction and rhythm disorders were associated with increased mortality among patients with SSc (HR=7.60, 95% CI: 3.49-16.55 and HR=4.87, 95% CI: 2.28-10.42, respectively, after adjusting for age, sex and calendar year of diagnosis).

Conclusion: Patients with SSc have a significantly higher prevalence of conduction disorders at disease onset than non-SSc comparators. During the course of their disease, their risk of developing conduction disorders is 2.6-fold, and risk of rhythm disorders is 1.6-fold increased, compared to non-SSc subjects.

PHT was significantly associated with increased risk of developing conduction and rhythm disorders among patients with SSc, a finding that should warrant increased vigilance and screening for ECG abnormalities in this population.

POS0837 THE USE OF CANNABIDIOL IN THE TREATMENT OF PAIN RELATED TO SCLERODERMA DIGITAL ULCERS

D. Giuggioli[1], M. De Pinto[1], L. Parenti[1], L. Magnani[2], P. Castrignanò[1], C. Salvarani[1,2], A. Spinella[1]. *[1]University of Modena and Reggio Emilia, Scleroderma Unit, Rheumatology Unit, Modena, Italy*; *[2]AUSL-IRCCS of Reggio Emilia, Italy, Rheumatolgy, Reggio Emilia, Italy*

Background: Systemic Sclerosis-SSc is an autoimmune disease, characterized by fibrosis due to immune-mediated microangiopathy. Digital ulcers-DUs represent frequent complications, they are recurrent, painful and often resistant to traditional treatments. Standard therapy, in particular oral opioids, is often

inadequate or limited by side effect. Cannabidiol-CBD, is the major non-psychotropic component of the Cannabis sativa, recent studies on its effectiveness as an anxiolytic, anti-inflammatory, and antipsychotic drug showed promising results, in the setting of chronic pain too.

Objectives: We evaluated the efficacy of CBD drop in pain management in a cohort of SSc patients using standard rating scale VAS, PSQI and HAQ. We further assessed the safety profile and the potential use as opioid-sparing.

Methods: From January to November 2019 we consecutively enrolled 31 SSc patients (F/M 26/5, mean age 53.0±14.6SD-years) referred to our Scleroderma Unit. All patients satisfied the EULAR/ACR SSc classification criteria. All cases were complicated by painful DUs resistant to analgesics and pain was classified as severe, according to WHO guidelines. CBD drops consist of cannabis sativa seed in olive oil, 10% CBD, laboratory tested to confirm a tetrahydrocannabinol-THC level<0.3%. The CBD oil was administrated sublingually twice-a-day. All patients started with CBD 3 drops twice-a-day, and progressively increased to the maximum dosage of 6 drops twice-a-day (from 27.6 g to 55.2 g dose/day). All patients continued local/systemic treatments for SSc: 24/31 subjects performed calcium-channel blockers, 31/31 prostanoids infusion, 24/31 anti-endothelin drugs. All subjects were provided with a daily diary to record self-evaluation of pain using VAS, PSQI, hours of sleep per night, use of other analgesics, eventual side effects. HAQ-DI was also administrated. These indicators were assessed baseline and during follow-up. Safety of CBD was evaluated by patient's records of side effects. All data were analyzed by paired t-test. This investigation was a monocentric, prospective study. Ethical approval was obtained from the Competent Ethics Committee (protocol n. 282/15) and all participants gave written consent.

Results: CBD was administered for a mean period of 5.9±3.2SD-months. After the first month, VAS decreased from 94.80±8.72SD to 54.70±9.40SD ($p<0.0001$), PSQI decreased from 9.27±2.9SD to 4.47±1.06SD ($p<0.001$), total hours of sleep increased from 2.56±1.28 SD to 5.67±0.85SD ($p< 0.0001$). The additional analgesic therapy was necessary in 22/31 patients: 6/22 only paracetamol, 12/22 paracetamol+oxycodone reducing the dosage of oxycodone at the minimum, 2/22 oxycodone 20 mg twice-a-day, 2/22 need fentanyl transdermal patch. After 3 months, VAS further reduced to 40.90±12.90, PSQI decreased to 3.1±1.4SD, the mean total hours of sleep per night was 6.10±0.79SD and the HAQ-DI decreased from 2.19±0.67SD (baseline) to 0.79±0.46SD at the last patients' evaluation. At the end of the observation, 18/31 patients (58%) showed DUs healing. We also interestingly reported improvement of dysphagia and appetite in 70%, and an improvement in constipation related to opiods in 48%. No patients experienced severe side effects in particular no psychoactive aspects. Mild side effects, namely dry mouth was referred by 9/31 (29%), mild abdominal pain and changes in appetite by 10/31 (32%). No interaction with other drugs was observed.

Conclusion: Our study suggests that oral CBD is effective and safe in maintaining analgesia in SSc patients with DUs. Furthermore, CBD could be helpful in opioids tapering and to treat dysphagia, even if these observations need focused investigations. In conclusion, CBD might be a useful tool to manage chronic pain in SSc-DUs. These data provide a compelling rationale for further research to clarify the therapeutic potential of CBD in SSc.

POS0838 EPIDEMIOLOGY AND TRENDS IN SURVIVAL OF SYSTEMIC SCLEROSIS IN OLMSTED COUNTY: A POPULATION-BASED STUDY (1980-2018)

C. Coffey[1], Y. Radwan[2], A. Sandhu[3], C. S. Crowson[1,4], P. Bauer[5], E. Matteson[1,4], A. Makol[1]. [1]*Mayo Clinic, Division of Rheumatology, Rochester, MN, United States of America*; [2]*Michigan State University, Internal Medicine, Lansing, MI, United States of America*; [3]*Kettering Health, Internal Medicine, Kettering, OH, United States of America*; [4]*Mayo Clinic, Health Sciences Research, Rochester, MN, United States of America*; [5]*Mayo Clinic, Division of Pulmonary and Critical Care, Rochester, MN, United States of America*

Background: Systemic sclerosis (SSc) is a complex immune-mediated disease with heterogeneous manifestations, which is characterized by vasculopathy and fibrosis of the skin and visceral organs. Mortality associated with SSc exceeds that of other rheumatic diseases, though population-based studies assessing recent trends in survival are lacking.

Objectives: We aimed to determine the incidence and prevalence of physician-diagnosed SSc in a population-based cohort over a 39-year time period, and assess for trends in survival over time.

Methods: Medical records of patients with a diagnosis or suspicion of SSc in a geographically well-defined area from Jan 1, 1980 to Dec 31, 2018 were reviewed to identify incident cases of SSc. Cases were defined by physician diagnosis of SSc, and fulfillment of the 2013 ACR/EULAR classification criteria was ascertained. Prevalent cases of SSc on Jan 1, 2015 were also identified. Incidence and prevalence rates were age- and sex-adjusted to the 2010 U.S. white population. Survival rates were compared with expected rates in the general population.

Results: 85 incident cases of SSc (91% female, mean age 55.4 ± 16 y) and 49 prevalent cases on Jan 1, 2015 were identified. Patients had a mean 11.7 (SD 9.4) years of follow-up available. The overall age and sex adjusted annual incidence for 1980-2018 was 2.5 (95% CI: 2.0-3.1) per 100,000 population, with no change in incidence over time (p=0.32). The age-adjusted incidence was 4.4 (95% CI: 3.4-5.4) for females, and 0.56 (95% CI: 0.16-0.96) for males per 100,000 population. The age- and sex-adjusted prevalence on Jan 1, 2015 was 43.6 (95% CI: 31.3-55.8) per 100,000 population.

77 (91%) patients fulfilled the 2013 classification criteria; 38 (45%) fulfilled 1980 criteria. 70 (82%) had limited cutaneous involvement, 12 (14%) had diffuse cutaneous involvement, and 3 (4%) had sine scleroderma. At SSc diagnosis, 80 (94%) patients had Raynaud's, 43 (51%) had sclerodactyly, 39 (46%) had telangiectasias, 14/48 (29%) had abnormal nailfold capillaries, 16/35 (46%) had digital ulcers or fingertip scarring, 8 (9%) had interstitial lung disease (ILD), and 7 (8%) had pulmonary arterial hypertension (PAH). 77/82 patients (91%) had a positive antinuclear antibody. 44 (52%) had a known SSc-related autoantibody: 32 (73%) with anti-centromere, 9 (20%) with anti-Scl-70, and 4 (9%) with anti-RNA-polymerase III.

Survival was 77% (95% CI: 69-87) at 5 years, 66% (95% CI: 56-78) at 10 years, and 42% (95% CI: 30-57) at 20 years, with no evidence of improved survival over time (p=0.46). Age (Hazard ratio [HR]: 1.49 per 10 year increase; 95% CI 1.19-1.88), smoking at time of diagnosis (HR: 2.37; 95% CI: 1.05-5.34), digital ischemia (HR: 2.54; 95% CI: 1.33-4.87), ILD (HR: 4.00; 95% CI: 2.11-7.59), and PAH (HR: 4.30; 95% CI: 2.24-8.25) had significant associations with mortality. Survival of patients with SSc was poorer than the general population (standardized mortality ratio: 2.48; 95% CI: 1.76-3.39).

Conclusion: The average incidence of SSc in this population-based cohort spanning 39 years was 2.5 per 100,000 population, with no change in incidence over time. Age, smoking, digital ischemia, ILD and PAH were risk factors for poorer survival. Overall survival for patients with SSc is worse than that of the general population and shows no improvement over time, suggesting continued need for improved diagnostic and treatment measures.

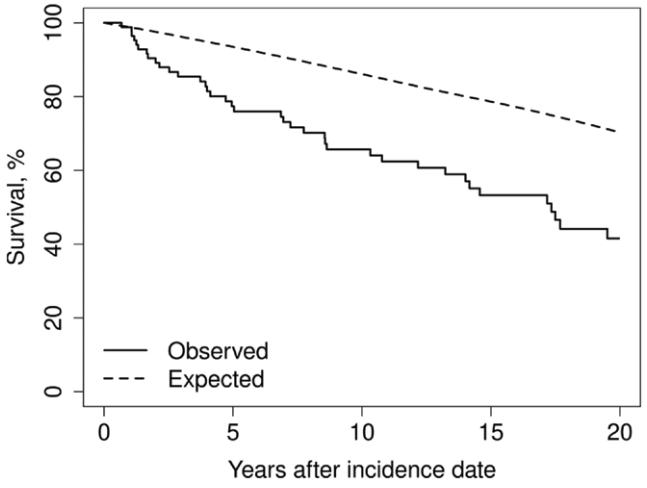

Figure 1. Survival of 85 Olmsted County residents with SSc compared with expected survival rates from Minnesota lifetables (observed: solid line, expected: dashed line).

POS0839 BODY COMPOSITION AND FREQUENCY OF SARCOPENIA IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Efremova[1], O. Nikitinskaya[1], N. Toroptsova[1], O. Dobrovolskaya[1], N. Demin[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation*

Background: Sarcopenia can be age associated (primary form) or secondary to chronic disorders, including rheumatic inflammatory disorders. Systemic sclerosis (SSc) is a chronic autoimmune rheumatic disease characterized by widespread vasculopathy, progressive fibrosis of the skin and other internal organs, such as lung, kidneys, gastrointestinal tract, cardiovascular system. Different from the other chronic rheumatic inflammatory disorders, sarcopenia has not been well evaluated in SSc patients.

Objectives: To assess the body composition (BC) and to identify the frequency of sarcopenia (SP) in SSc patients.
Methods: A total of 44 women who met the ACR/EULAR 2013 classification criteria were included. Mean age was 53,2 + 8,8 years. The median disease duration was 7,0 [4,0;12,0] years. 26 (59,1%) patients had limited and 18 (40,9%) - diffuse cutaneous subtype. Body composition was measured using Dual-energy X-ray absorptiometry (DXA) of whole body. The appendicular lean mass index (ALMI) was calculated as the ratio of appendicular lean mass (ALM) to height (kg/m2). Handgrip measurement and chair stand test were performed. Physical function was measured with the Short Physical Performance Battery (SPPB). SP was diagnosed in agreement with the 2019 revised consensus on definition and diagnosis of SP of the European Working Group on Sarcopenia in Older People 2 (EWGSOP2): handgrip <16kg, chair stand test > 15 seconds for 5 rises, ALM <15 kg or ALMI <5.5 kg/m2. Severe SP was detected if the patient additionally had gait speed ≤0.8 m/s or SPPB ≤ 8-point score. Overfat was defined as body fat percentage >35%.
Results: The median bone mineral content was 2.0 [1.8; 2.2] kg, total lean mass - 39,5 [35,7; 45,5] kg, ALM - 16,3 [14,5;19,4] kg, ALMI – 6,5 [5,7; 7,2] kg/m2, trunk fat mass – 13,5 [9,1; 16,7] kg and total fat mass - 26,6 [20,1; 34,5] kg. Body fat percentage was 38,8% [34,2; 42,7].
9 (20,5%) women had low ALM and low ALMI, 6 (13,6%) – only low ALM. Healthy BC was found in 5 (11,3%), low ALM or low ALMI – in 7 (15,9%), overfat – in 24 (54,5%), low ALM + overfat – in 8 (18,2%) patients. We found no differences in BC between SSc patients with limited and diffuse cutaneous subtype.
Low muscle strength (SP probable) was found in 21 (47,7%) women, meanwhile confirmed SP (low muscle strength and muscle mass) was diagnosed in 10 (22,7%) patients, among them 5 (11,4%) persons had severe SP. No significant difference in SP frequency among patients with limited and diffuse cutaneous SSc 4 (15,4%) and 6 (33,3%), respectively, (p=0,27). Osteoporosis was found in 6 (60%) patients with SP without differences in SSc subtypes.
Conclusion: Healthy BC was found only in 11,3% cases, while overfat - in 72,7% and low ALM – in 34,1% SSc patients. SP was detected in 22.7% of women, among them in half of cases - severe SP, without any differences between the limited and diffuse subtypes of the disease.

POS0840 RISK OF MALNUTRITION IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE (SSC-ILD): FURTHER ANALYSES OF THE SENSCIS TRIAL

E. Volkmann[1], Z. Mcmahan[2], S. Johnson[3], V. Smith[4], S. Jouneau[5], C. Miede[6], M. Alves[7], A. Herrick[8]on behalf of the SENSCIS trial investigators.. *[1]University of California, David Geffen School of Medicine, Department of Medicine, Division of Rheumatology, Los Angeles, United States of America*; *[2]Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, United States of America*; *[3]Toronto Western and Mount Sinai Hospitals, University of Toronto, Toronto Scleroderma Program, Department of Medicine, Toronto, Canada*; *[4]Ghent University Hospital, Department of Rheumatology and Internal Medicine, Ghent, Belgium*; *[5]Competences Centre for Rare Pulmonary Diseases, University of Rennes, CHU Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) - UMR_S 1085, Department of Respiratory Medicine, F-35000 Rennes, France*; *[6]mainanalytics GmbH, Statistics, Sulzbach (Taunus), Germany*; *[7]Boehringer Ingelheim International GmbH, TA Inflammation Med, Ingelheim am Rhein, Germany*; *[8]The University of Manchester, Salford Royal NHS Foundation Trust, Centre for Musculoskeletal Research, Manchester, United Kingdom*

Background: Gastrointestinal (GI) involvement is common in patients with SSc and may lead to weight loss and malnutrition. In the SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) (mL/year) over 52 weeks, with mainly GI adverse events. The Malnutrition Universal Screening Tool (MUST) was developed to identify adults who are at risk of malnutrition and has been used in studies of patients with SSc.
Objectives: To evaluate nutritional status over 52 weeks in the SENSCIS trial based on a modified MUST score.
Methods: The SENSCIS trial enrolled patients with SSc-ILD with first non-Raynaud symptom ≤7 years before screening, extent of fibrotic ILD ≥10% on HRCT and FVC ≥40% predicted. Patients who had taken a stable dose of mycophenolate for ≥6 months were eligible to participate. Patients were randomised to receive nintedanib 150 mg bid or placebo. Dose reductions to 100 mg bid and treatment interruptions were allowed to manage adverse events and specific recommendations were provided for the management of diarrhoea. We calculated a modified MUST score at baseline and weeks 12, 24, 36 and 52 based on (A) BMI, (B) weight loss (week 12 vs baseline; week 24 vs week 12; week 36 vs week 24; week 52 vs week 36), and (C) a surrogate for acute disease effect (if the patient had any serious adverse event that led to hospitalisation between weight assessments and received ≥1 medication from the WHO classification code for "solutions for parenteral nutrition" for ≥5 days). MUST score at baseline was based solely on BMI. With scores ranging from 0 to 6, the risk of malnutrition is defined as low (score = 0), medium (score = 1) or high (score ≥2).
Results: Among 576 patients who received nintedanib (n=288) or placebo (n=288), mean (SD) age at baseline was 54.0 (12.2) years, weight was 69.7 (15.9) kg and BMI was 25.9 (5.0) kg/m^2; median time since onset of first non-Raynaud symptom was 3.4 years; and 75.2% of patients were female. In the nintedanib and placebo groups, respectively, MUST scores suggested that 74.0% and 78.1% of patients were at low risk of malnutrition at baseline and remained at low risk at their last measurement (Table 1). At weeks 12 and 52, respectively, mean (SD) MUST scores were 0.3 (0.6) and 0.4 (0.7) in the nintedanib group and 0.2 (0.5) and 0.2 (0.6) in the placebo group. At weeks 12, 24, 36 and 52, respectively, the proportions of patients at low risk of malnutrition were 81.8%, 80.9%, 72.9% and 76.5% in the nintedanib group and 86.6%, 86.4%, 88.3% and 80.8% in the placebo group; the proportions at medium risk were 12.1%, 13.1%, 18.0% and 13.5% in the nintedanib group and 8.5%, 8.6%, 5.8% and 13.1% in the placebo group; and the proportions of patients at high risk were 6.1%, 5.6%, 8.3% and 9.6% in the nintedanib group and 4.9%, 4.3%, 4.7% and 5.4% in the placebo group.

Table 1. Risk of malnutrition at baseline and at last assessment over 52 weeks in the SENSCIS trial.

Last assessment of risk	Nintedanib (n=288)				Placebo (n=288)			
	Baseline risk				Baseline risk			
	Low	Medium	High	Total	Low	Medium	High	Total
Low	213 (74.0)	1 (0.3)	0	214 (74.3)	225 (78.1)	7 (2.4)	0	232 (80.6)
Medium	31 (10.8)	8 (2.8)	0	39 (13.5)	20 (6.9)	14 (4.9)	4 (1.4)	38 (13.2)
High	13 (4.5)	8 (2.8)	7 (2.4)	28 (9.7)	3 (1.0)	2 (0.7)	10 (3.5)	15 (5.2)
Missing	7 (2.4)	0	0	7 (2.4)	3 (1.0)	0	0	3 (1.0)
Total	264 (91.7)	17 (5.9)	7 (2.4)	288 (100)	251 (87.2)	23 (8.0)	14 (4.9)	288 (100)

MUST score ranges from 0 to 6. Score of 0 = low risk: score of 1 = medium risk; score of ≥2 = high risk. Baseline MUST score was based solely on BMI.

Conclusion: In the SENSCIS trial, scores based on a modified MUST indicated that most patients treated with nintedanib were at low risk of malnutrition at baseline and remained at low risk over 52 weeks. The proportions of patients at high risk of malnutrition were low but were numerically greater in patients who received nintedanib than placebo. Management of disease manifestations and gastrointestinal adverse events that may be associated with weight loss is important to reduce the risk of malnutrition in patients with SSc-ILD treated with nintedanib.

POS0841 RISK FACTORS OF LOW BONE MINERAL DENSITY IN WOMEN WITH SYSTEMIC SCLEROSIS

A. Efremova[1], N. Toroptsova[2], N. Demin[2], O. Dobrovolskaya[2], O. Nikitinskaya[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation*; *[2]V.A. Nasonova Research Institute of Rheumatology, Department of Osteoporosis, Moscow, Russian Federation*

Background: Chronic inflammatory rheumatic diseases are risk factors of bone loss and fractures. Systemic sclerosis (SSc) has been recognized to be another potential inflammatory joint disease that may affect bone tissue.
Objectives: to evaluate bone mineral density (BMD) and risk factors of low BMD in women with SSc.
Methods: 173 women, among them 110 postmenopausal (median age 60[55,63] years) and 63 premenopausal (median age 35[31,44] years). BMD was measured at lumbar spine (LS), femoral neck (FN) and total hip (TH) by dual energy X-ray absorptiometry (DXA, Hologic 4500A). Low BMD was diagnosed if the T-score was < -1.0 standard deviation (SD) in postmenopausal women and if the Z-score was < -2.0 SD in premenopausal women. The relationship between BMD and SSc patients' characteristics was evaluated using univariate linear regression analysis.
Results: Low BMD was found in 66% patients: 79% - in postmenopausal and 18% - in premenopausal women. Among postmenopausal persons osteoporosis was discovered in 47% and osteopenia – in 32% cases. In postmenopausal woman BMD of LS, FN and TH were associated with body mass index (BMI) (β=0.27, p=0.010; β=0.47, p<0,001 and β=0.45, p<0,001, respectively), duration of glucocorticoids (GCs) using (β=-0.31, p=0.008; β=-0.34, p=0.003 and β=-0.27, p=0.022, respectively); BMD of FN and TH with C-reactive protein (β= -0.32, p=0.016 and β= -0.29, p=0.029, respectively) and LS BMD with current and cumulative GCs dose (β= -0.24, p=0.039 and β= -0.29, p=0.014, respectively). In premenopausal women BMD of LS, FN and TH were associated with BMI (β=0.51, p<0,001; β=0.45, p=0.003 and β=0.47, p=0.002, respectively), duration of GCs using (β= -0.45, p=0.004; β= -0.47, p=0.003 and β= -0.48, p=0.002, respectively) and GCs cumulative dose (β= -0.48, p=0.002; β= -0.51, p=0.001 and β= -0.46, p=0.004, respectively); BMD of FN and TH with 25(OH)D level (β=0.52, p=0.008 and β=0.54, p=0.005, respectively), and LS BMD with SSc duration (β= -0.44, p=0.004).
Conclusion: Low BMD was diagnosed in 66% of women with SSc. Low BMI, GCs cumulative dose and duration of GCs using were independent risk factors for low BMD in both premenopausal and postmenopausal persons. Additional factors as SSc duration and low vitamin D level were found out for premenopausal and current GCs dose and C-reactive protein level for postmenopausal women.

POS0842 LUNG ULTRASOUND TO ASSESS THE SEVERITY OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS

C. Bruni[1], L. Mattolini[1], L. Tofani[1], L. Gargani[2], N. Landini[3,4], G. Lepri[1], M. Orlandi[1], S. Guiducci[1], S. Bellando Randone[1], M. Matucci-Cerinic[1].
[1]Careggi University Hospital, Experimental and Clinical Medicine, Division of Rheumatology, Firenze, Italy; *[2]National Research Council (CNR) PISA, Institute of Clinical Physiology, Pisa, Italy*; *[3]Cà Foncello General Hospital, Radiology, Treviso, Italy*; *[4]University of Florence, Experimental and Clinical Biomedical Sciences, Division of Radiology, Firenze, Italy*

Background: Interstitial lung disease (ILD) is one of the most common complications and one of the main causes of morbidity and mortality in Systemic Sclerosis (SSc). High-resolution computed tomography (HRCT) is the gold standard for the diagnosis of ILD and it allows its quantification. Among semi-quantitative methods, Goh et al proposed a semi-quantitative scoring system to visually quantify ILD extent, with categorical cut-off of 20% to distinguish limited and extensive parenchymal involvement with prognostic implications. More recently, the use of radiomics has allowed the objective quantification of ILD through the use of dedicated software, which calculate different parameters of lung density. Given the exposure to ionizing radiation that the procedure entails, other methods of ILD evaluation are being studied, among which lung ultrasound (LUS) identifies the B-lines as a main feature of ILD. So far, different evidences have proposed the use of LUS for the screening of ILD, even in the early phases of the disease and in subclinical lung involvement.
Objectives: the aim of this study is to test the role of LUS in quantifying the severity of SSc-ILD, evaluated with both semi-quantitative visual radiological and quantitative radiomic scores.
Methods: Adult SSc patients classified according to the ACR/EULAR 2013 criteria patients were assessed with pulmonary function test (PFTs), lung ultrasound and HRCT over 60 days. CT images were analysed qualitatively (by presence/absence of ILD), semi-quantitatively (categorical Goh score <20% vs> 20% of extent and the continuous extent Goh score made from 5 levels' assessment– 0 to 100%) and quantitatively [with the densitometric radiomic data obtained through the Horos software - Mean lung attenuation (MLA), Standard Deviation (SD), Kurtosis, Skewness and Lung volume (LV)]. LUS was used to quantify the B-lines detected in each patient by scanning a total of 13 intercostal spaces, on both anterior and posterior chest wall.
Results: Among 59 SSc patients (81% women, mean age 48±14 years, 45% anti-Scl70 positive), 23 (39%) presented ILD on HRCT, of which 14 limited and 9 extensive. The mean visual semi-quantitative score was 6%, ranging from 0 to 66%. Our data showed a significantly different number of B-Lines in ILD vs non-ILD patients (median 38 vs 9, p <.005), a result which was further confirmed among non-ILD vs ILD> 20% (median 47 vs 9, p=.001) and ILD <20% (median 36 vs 9, p=.001) patients. Conversely, the number of B-lines was not statistically different between patients with ILD <20% and >20% (median 47 vs 36, p=.78). We observed a significant negative correlation between the number of B-lines and FVC (r=-.472, p<.05) TLC (r=-.436, p=.003), DLco (r=-.515, p<.001), DLCO/VA (r=.-306, p=.03). Finally, the number of B-lines showed a statistically significant correlation with the Goh score on 5 levels (r=.437, p=.001), MLA (r=.571, p<.001), kurtosis (r=-.285, p=.028), skewness (r=-.370, p = .004) and LV (r=-.277, p=.033). All data were confirmed analysing anterior and posterior B-Lines separately.
Conclusion: Our study confirms that LUS represents a useful tool for the identification of SSc-ILD. In addition, we showed that LUS may be useful also for the quantification of the severity of SSc-ILD, by correlating with PFT parameters, radiomics parameters and visual radiological evaluation. Together with the PFTs, LUS could be used to increase the accuracy of the screening and, potentially, of the follow-up of SSc-ILD patients.

POS0843 A NEW RISK MODEL IS ABLE TO IDENTIFY SYSTEMIC SCLEROSIS PATIENTS WITH A LOW RISK OF DISEASE PROGRESSION

N. Van Leeuwen[1], M. Maurits[1], S. Liem[1], J. Ciaffi[1], N. Ajmone-Marsan[2], M. Ninaber[3], C. Allaart[1], H. Gillet-van Dongen[4], R. Goekoop[5], T. Huizinga[1], R. Knevel[1], J. De Vries-Bouwstra[1]. *[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; *[2]Leiden University Medical Center, Cardiology, Leiden, Netherlands*; *[3]Leiden University Medical Center, Pulmonology, Leiden, Netherlands*; *[4]Haaglanden Medisch Centrum, Rheumatology, Den Haag, Netherlands*; *[5]HagaZiekenhuis, Rheumatology, Den Haag, Netherlands*

Background: Disease course in Systemic Sclerosis (SSc) ranges from mild, to severe with progressive organ involvement within months. Guidelines for follow-up are mainly based on expert consensus, and advocate annual assessment. So far, no data driven guidelines exist that describe tailormade systematic assessments for individual patients in line with individual disease course.
Objectives: To develop a prediction model to guide annual assessment of SSc patients tailored in accordance to disease activity.
Methods: A machine learning approach was used to develop a model that can identify patients without disease progression. SSc patients included in the prospective Leiden SSc cohort and fulfilling the ACR/EULAR 2013 criteria were included. The primary endpoint in the prediction model was disease progression which was defined as progression in ≥1 organ system, and/or start of immunosuppression or death between the two most recent visits. Using elastic-net-regularization, and including 90 independent clinical variables (100% complete), we trained the model on 75% and validated it on 25% of the patients in order to perform internal validation of the final model. We optimized the model on negative predictive value (NPV) to minimize the likelihood of missing progression. By expert assessment of the test characteristics, including swarm plots of the probability scores, cut-offs were identified for low, intermediate and high risk for disease progression.
Results: Of the 492 SSc patients (range of follow-up: 2-10yrs), disease progression during follow-up was observed in 52% (median time 4.9yrs), including myocardial progression in 29%, lung progression in 23%, skin progression in 16%,

Baseline characteristics	Total n=492	Non-Progressors N=235	Progressors N=257
Demographics			
Female, n (%)	389 (79)	193 (82)	196 (76)
Age, mean (SD)	55 (14)	55 (15)	55 (13)

RP=raynaud phenomenon, dcSSc= diffuse cutaneous systemic sclerosis, mRSS=modified rodnan skin score, DU=digital ulcera, DLCO= single-breath diffusing capacity for carbon monoxide, FVC= forced vital capacity, ILD=interstitial lung disease, HRCT= high resolution computed tomography, PAH= pulmonary arterial hypertension, GAVE= gastric antral vascular extasia.

and death in 12%. Performance of the model in the test set showed an AUC-ROC of 0.66. Probability score cutoffs were defined: low risk for disease progression (<0.197, NPV:1.0; 29% of patients), intermediate risk (0.197-0.223, NPV:0.82; 27%) and high risk (>0.223, NPV:0.78; 44%). The predictive variables included in the model were: previous use of cyclophosphamide or corticosteroids, start with immunosuppressive drugs, previous gastrointestinal progression, previous cardiovascular event, pulmonary arterial hypertension, modified Rodnan Skin Score, creatinine kinase, and diffusing capacity for carbon monoxide.
Conclusion: Our machine-learning-assisted model for disease progression enabled us to classify 29% of SSc patients as 'low risk'. In this group annual assessment programs could be less extensive than indicated by international guidelines.

POS0844 EFFECTS OF SERIAL LOCALLY APPLIED WATER-FILTERED INFRARED A RADIATION IN PATIENTS WITH SYSTEMIC SCLEROSIS WITH SEVERE RAYNAUD'S SYNDROME RECEIVING PROSTAGLANDINE TREATMENT – A RANDOMIZED CONTROLLED TRIAL

P. Klemm[1], J. Bär[1], I. Aykara[1], K. Frommer[1], E. Neumann[1], U. Müller-Ladner[1], U. Lange[1]. [1]*Justus Liebig University Giessen, Campus Kerckhoff, Rheumatology, Clinical Immunology, Osteology and Physical Medicine, Bad Nauheim, Germany*

Background: More than 95% of patients with systemic sclerosis (SSc) suffer from Raynaud's syndrome (RS) leading to digital ulcerations (DU). In severe RS, intravenous application of prostaglandins is required. Moreover, these patients profit from an additional non-pharmacological treatment using hyperthermia to increase vasodilatation and perfusion, and to reduce pain.
Serial locally applied water-filtered infrared A radiation (sl-wIRAR) is a hyperthermia treatment modality using infrared heat radiation in the range of 780-1400nm with high tissue penetration and low thermal load on the skin surface [1]. wIRAR has both, temperature-dependent and non-dependent effects, which do not inherit thermal energy transfer and/or relevant temperature changes [1]. It is therefore not only used in acute and chronic wound healing as it promotes perfusion, alleviates pain and has anti-infectious effects [2], but is also used in oncology [3] and rheumatology [4].
Objectives: We conducted a randomized controlled trial with a follow-up visit after 2 weeks to evaluate the value of a high-frequent hyperthermia treatment using sl-wIRAR in comparison to a low-frequent hyperthermia treatment (our standard) in SSc patients with severe RS receiving Iloprost treatment.
Methods: Eligible patients had SSc according to the 2013 ACR/EULAR classification criteria, were 18 to 80 years old and had RS requiring treatment with Iloprost in an in-patient setting. Key exclusion criteria were contraindications to any hyperthermia treatment such as infection or heat insensitivity. The trial was conducted at Campus Kerckhoff of Justus-Liebig University Giessen. Eligible patients were equally randomized to the intervention group (IG) receiving additional sl-wIRAR treatment (2 treatments for 30 min per day for 8 days) plus the standard of care (Iloprost treatment over 8 days plus daily carbon dioxide hand baths of 20 min) and the control group (CG) receiving only the standard of care. Primary outcome was the between-group difference in pain measured on a numeric rating scale (NRS) after intervention. Key secondary outcomes included a change in RS frequency, RS duration, and a change in Interleukin (IL) -6 and VEGF levels.
Results: From 01.03.2020 to 31.12.2020 49 SSc patients met the inclusion criteria. 42 patients were enrolled (IG: 21, CG: 21). 38 patients (IG:19, CG: 19) completed the full trial period and were analyzed. There was no statistically significant between-group difference in pain levels (NRS) (p=0.284, Z -1.082 (Mann-Whitney U Test)) and thus the primary outcome was not met. Therefore, all p values for secondary outcomes are nominal. Intensity (Visual analogue scale 0-100mm) and duration (min) of RS were reduced in the IG (mean ± standard error) -14.579 ± 7.214 mm (p=0.058) and -2.917 ± 1.510 min (p=0.08), respectively. Intra- and inter-group comparison of IL-6 and VEGF levels showed no relevant change.
Conclusion: The additive and frequent use of sl-wIRAR in the treatment of SSc patients with RS requiring Iloprost treatment does not improve outcomes regarding pain levels, RS intensity or frequency nor IL-6 and VEGF levels when compared to Iloprost treatment and low-frequent hyperthermia application.

POS0845 SCLERODERMIC HAND SENSOR: SMART TECHNOLOGY APPLIED TO RHEUMATOLOGY

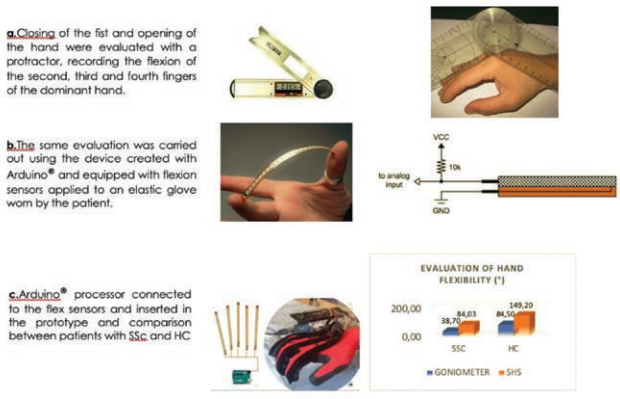
S. Parisi[1], M. C. Ditto[1], C. L. Peroni[1], A. Laganà[1], E. Fusaro[1]. [1]*AOU Città della Salute e della Scienza di Torino, Rheumatology Unit, Turin, Italy*

Background: Systemic Sclerosis (SSc) is an autoimmune rheumatic disease characterized by excessive production and accumulation of collagen in the skin and internal organs and by injuries to small arteries.
Impairment of the musculoskeletal system is one of the main causes of disability in SSc, indeed, about 90% of these patients have a loss of hand function. To date, the degree of skin involvement is evaluated through a semi-quantitative method called Rodnan Skin Score (RSS) or Modified-RSS (MRSS). However, MRSS is a method that has limitations related to the operator and his experience and does not provide information on joint mobility.
Arduino® is an open source integrated online platform based on easy to use hardware and software. It is a system for creating interactive projects by inserting a special configuration code, using the Arduino® development environment. Through this platform it is possible to create electronic devices with specific purposes to lead the possibility of integrating different kits (eg types of sensors) in relation to the object of study.
Objectives: We have therefore created an electronic instrument (Sclerodermic Hand Sensor - SHS) independent operator and easily reproducible in order to measure the degree of mobility (flexion) of the hand in patients with SSc (Fig.1). The aim was to evaluate whether the SHS was able to highlight significant differences between patients with SSc and healthy patients.
Methods: We recruited 20 female patients with SSc according to ACR criteria with a mean age of 50.8 ± 15.5 years and 20 healthy (HC) patients with a mean age of 44.3 ± 10.8 years (Tab.1), in order to test the effectiveness and sensitivity of the SHS tool.
Results: The results showed a significant difference between the two groups of patients (SSc vs HC) independent of the measurement method used as expected (Goniometer SSc / HC: Δ45.80 ° p: 0.003 SHS SSc / HC: Δ65.17 ° p: 0.002, Fig.1c), however the device created with Arduino® proved to be more sensitive than the goniometric measurement in detecting the degree of joint flexion (p: 0.002). The flexion sensor, indeed, unlike the goniometer, evaluates the simultaneous articular excursion of the entire finger (MCF, IFP and IFD) and not just one segment (Fig.1).
Conclusion: This technology application, thanks to the creation of dedicated electronic devices, allows the physicians to be supported in clinical practice with independent operating tools.

Table 1. SSc Patients Characteristics

Chararcteristics	SSc
Patients (n°, subset D=Diffuse; L=Limited)	20 (9D/11L)
Age, mean ± SD years	50.8 ± 15.5
Duration of Raynaud's Phenomenon (mean ± SD years)	12.8 ± 4.4
Duration of SSc (mead ± SD years)	8.4 ± 3.6
MRSS (mean ± SD years)	15.9 ± 5.3

Fig.1. Comparison between the use of the goniometer and SHS in SSc patients



The tool we propose could be a valid support in accurately assessing the joint and indirectly skin involvement of sclerodactyly in this type of patient, especially in the context of a clinical trial to evaluate the efficacy of a treatment.
Further studies are needed to compare with other methods to assess hand disability in SSc such as the use of HAMIS (Hand Mobility in Scleroderma) test.

Background: Systemic sclerosis (SSc) is a multisystem, connective tissue disorder characterized by fibrosis of the skin and internal organ involvement, which can influence all aspects of life, including sexual life.
Objectives: This study aimed to compare sexual function in patients with SSc to age-/sex-matched healthy controls (HC) and determine the potential impact of clinical features on sexual function.
Methods: In total, 90 women with SSc (mean age: 49.1, disease duration: 6.1 years, lcSSc/dcSSc: 62/28, mRSS: 9.3, ESSG activity index: 2.1), who fulfilled the ACR/EULAR 2013 criteria, and 90 healthy controls (mean age: 49.1) without rheumatic diseases filled in 12 well-established and validated questionnaires assessing sexual function (FSFI, BISF-W, SFQ-28, SQoL-F), pelvic floor function (PISQ-12, PFIQ-7), fatigue (FIS, Fatigue Impact Scale), physical activity (HAP, Human Activity Profile), disability (HAQ, Health Assessment Questionnaire), depression (BDI-II, Beck's Depression Inventory-II) and quality of life (SF-36, Medical outcomes study Short Form 36 – PCS, Physical Component Summary; MCS, Mental Component Summary). A routine laboratory testing was performed. Data are presented as median (IQR).
Results: Patients with SSc reported significantly greater prevalence and severity of sexual dysfunction (FSFI, BISF-W, SFQ28 – in all subscales as well as total scores), worse sexual quality of life (SQoL-F) and pelvic floor dysfunction (PISQ-12, PFIQ-7) compared to HC (table 1). The prevalence of sexual dysfunction in patients with SSc according to the FSFI cut-off score was 77%. Worse scores in SSc patients were associated with longer disease duration [BISF-W-total (r=-0.243,p=0.026), FSFI-lubrication (r=-0.229,p=0.035)], higher disease activity [ESSG activity index: BISF-W-total (r=-0.291,p=0.010), FSFI-arousal (r=-0.299,p=0.007)], increased inflammation [CRP: BISF-W-receptivity/initiation (r=-0.301,p=0.007)], more pronounced fatigue [FIS-total: BISF-W-total (r=-0.412,p<0.0001)], more severe depression [BDI-II: FSFI-total (r=-0.506,p<0.0001), SQoL-F (r=-0.369, p<0.0001)], worse functional disability [HAQ: FSFI-total (r=-0.394,p<0.0001)], reduced physical activity [HAP: FSFI-total (r=0.535,p<0.0001)], and decreased overall quality of life [SF-36 PCS: FSFI-total (r=0.428,p<0.0001), SF-36 MCS: SQoL-F (r=0.472, p<0.0001)].

Table 1. Sexual function and pelvic floor function in women with SSc and healthy controls

Questionnaire: score range (meaning)	SSc (n=90)	HC (n=90)	p-value
FSFI: Female sexual function index: 2 (worst) - 36 (best)	19.4 (3.9-26.8)	30.1 (23.1-32.9)	**p<0.0001**
BISF-W: Brief Index of Sexual Function for Women: -16 (worst) - 75 (best)	14.3 (2.1-35.1)	38.2 (19.3-46.2)	**p<0.0001**
SQoL-F: Sexual Quality of Life Questionnaire-Female: 0 (worst) - 100 (best)	61.1 (34.4-81.1)	91.1 (70.0-96.7)	**p<0.0001**
PISQ-12: Pelvic Organ Prolapse/Urinary Incontinence Sexual Questionnaire short form: 0 (best) - 48 (worst)	13.0 (9.0-17.0)	7.0 (5.0-12.0)	**p<0.0001**
PFIQ-7: Pelvic Floor Distress Inventory Questionnaire: 0 (best) - 300 (worst)	9.5 (0.0-48.8)	0.0 (0.0-8.3)	**p<0.0001**
SFQ-28: Sexual Functioning Questionnaire-28 desire: 5 (worst) - 31 (best)	17.0 (12.0-20.0)	21.0 (17.0-23.0)	**p<0.0001**
SFQ-28 arousal sensation: 4 (worst) - 20 (best)	10.0 (8.0-13.0)	12.0 (9.0-15.0)	**p=0.0031**
SFQ-28 arousal lubrication: 2 (worst) - 10 (best)	5.0 (4.0-7.0)	8.0 (5.2-9.0)	**p<0.0001**
SFQ-28 arousal cognitive: 2 (worst) - 10 (best)	5.0 (4.0-6.0)	7.0 (5.0-8.0)	**p<0.0001**
SFQ-28 orgasm: 1 (worst) - 15 (best)	10.0 (6.5-12.0)	12.0 (10.0-13.0)	**p<0.0001**
SFQ-28 pain: 2 (worst) - 15 (best)	12.0 (9.5-15.0)	15.0 (13.0-15.0)	**p<0.0001**
SFQ-28 enjoyment: 6 (worst) - 30 (best)	19.0 (12.5-24.0)	24.0 (20.0-25.8)	**p<0.0001**
SFQ-28 partner: 2 (worst) - 10 (best)	9.0 (8.0-10.0)	10. (9.0-10.0)	**p=0.0182**

Conclusion: Women with SSc reported significantly impaired sexual function and pelvic floor function compared to age-/sex-matched healthy controls. Worse scores in SSc were associated with disease-related features.

POS0847 IDENTIFICATION OF MOLECULAR PHENOTYPES IN SYSTEMIC SCLEROSIS BY INTEGRATIVE SYSTEMS ANALYSIS

M. J. Chang[1,2,3], S. X. Zhang[1,2,3], Q. Wang[4,5], J. Qiao[1,2,3], R. Zhao[1,2,3], S. Song[1,2,3], Y. Zhang[1,2,3], Q. Yu[6], P. F. He[5], X. Li[1,2,3]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; *[2]Shanxi Li Xiaofeng Medical Groups, Department of Rheumatology, Taiyuan, China*; *[3]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; *[4]Shanxi Medical University, Basic Medical College, Taiyuan, China*; *[5]Shanxi Medical University, Medical Data Sciences, Taiyuan, China*; *[6]Shanxi Medical University, Medical Data Sciences/School of Management, Taiyuan, China*

Background: Systemic sclerosis (scleroderma, SSc) is a systemic autoimmune disease characterized by inflammation, fibrosis and vasculopathy and associated with high mortality and high morbidity[1]. Stratification based on whole-genome gene expression data could provide a new basis for clinical diagnosis from a micro perspective[2].
Objectives: The objective of this study is to stratify patients with SSc, combine with clinical skin scores and clinical features, and provide a preliminary assessment and novel insights for assessing disease severity, and treatment design.
Methods: The original data mRNA expression profiles of GSE95065 (including 18 SSc patients and 4 healthy controls) and GSE130955 (including 58 SSc patients and 33 healthy controls) were downloaded from the public Gene Expression Omnibus (GEO) database. After batch correction, background adjustment, and other pre-processing, a large gene matrix was obtained to identify the differently expressed genes (DEGs) of SSc compared with healthy controls. Then the gene expression matrix decomposition was used to identify SSc subtypes by NMF algorithm. The cluster-based signature genes were applied to pathway enrichment analysis by Metascape[3]. Immune infiltrating cells and clinical skin scores were evaluated in all SSc subtypes.
Results: Total 325 DEGs were imputed to NMF unsupervised machine learning algorithm. Patients were divided into 2 subtypes (Figure 1A), one of which (sub1) was mostly enriched in the defense response to bacterium and cellular response to lipopolysaccharide pathway and another subtype (sub2) was enriched in the PPAR signaling and alcohol metabolic process pathway (Figure 1B-C). According to immune infiltration, sub1 had higher level of immune cells such as B cells, CD4+T cells, DC cells, Th2 cells and Tregs compared with sub2 ($P < 0.01$). Sub2 had more skin-related cells, including Epithelial cells, Fibroblasts and Sebocytes ($P < 0.05$). Interestingly, combined with clinical information, sub1 showed a severe clinical skin score over those of Sub2 patients ($P < 0.05$)(Figure 1D-E).
Conclusion: Our findings indicated that SSc patients could be stratified into 2 subtypes which had different molecular profiles of disease progression and

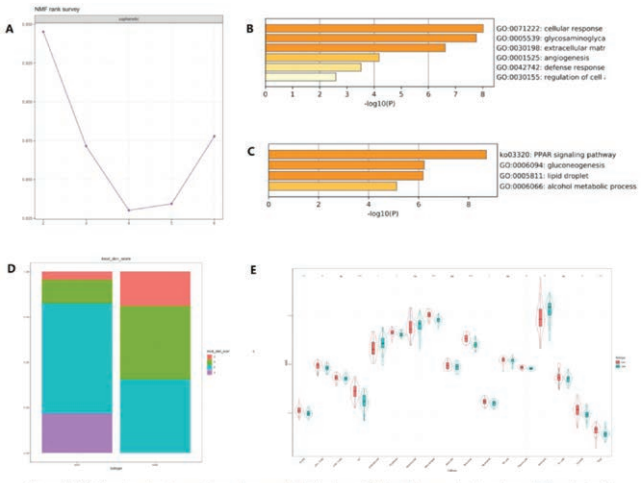

Figure 1 NMF clustering function enrichment, immune cells infiltration and clinical skin scores in SSc patients. **(A)**The relationship between cophenetic with respect to number of clusters. **(B-C)** Genetic functional enrichment for sub1 and sub2. **(D)** The box plot shows the difference in the clinical skin scores between the two subtypes. **(E)**Violin plot visualizing the differently infiltrated immune cells and skin cells (red represents sub1 and blue represents sub2) (ns, no significant;P> 0.05; *P< 0.05; **p< 0.01; **P< 0.001.)

clinical disease activities. This result could serve as a template for future studies to design stratified approaches for SSc patients.

POS0848 IDENTIFICATION OF POTENTIAL CRUCIAL GENES AND KEY PATHWAYS IN PULMONARY ARTERIAL HYPERTENSION WITH SYSTEMIC SCLEROSIS BY BIOINFORMATIC ANALYSIS

S. Feng[1], S. X. Zhang[2,3,4], R. Zhao[2,3,4], C. Zheng[5], L. Cheng[5], T. Kong[5], X. Sun[5], Q. Wang[6], X. Li[2,3,4], Q. Yu[5,7], P. F. He[7]. *[1]Shanxi Medical University, School of Humanities and Social Sciences, Taiyuan, China*; *[2]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; *[3]Shanxi Li Xiaofeng Medical Groups, Department of Rheumatology, Taiyuan, China*; *[4]Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; *[5]Shanxi Medical University, School of Management, Taiyuan, China*; *[6]Shanxi Medical University, Basic Medical College, Taiyuan, China*; *[7]Shanxi Medical University, Medical Data Sciences, Taiyuan, China*

Background: Pulmonary arterial hypertension with systemic sclerosis (SSc-PAH) is the main cause of death in patients with SSc. Early diagnosis and timely treatment are very important to reduce the mortality of patients with SSc-PAH[1]. At present, there are not many sensitive markers for the diagnosis of SSc-PAH. Therefore, it is necessary to mine more sensitive markers as more accurate and practical predictors, which is of great significance for the diagnosis and treatment of SSc-PAH.

Objectives: To discover the differentially expressed genes (DEGs) and activated signaling pathways in SSc-PAH.

Methods: Fifty-five samples (27 SSc-PAH v.s 28 normal controls) in GSE33463 chip data obtained from Gene Expression Omnibus (GEO) were included in this study. DEGs in SSc-PAH patients were screened by R, key pathways and hub genes were discoved by Metascape[2], STRING[3] and Cytoscape.

Results: Total 431 genes with large differences were identified, including 238 up-regulated genes and 193 down-regulated genes, after standardizing the data ($|logFC| > 1$; $P < 0.05$). GO analysis showed that the upregulated genes were mainly involved in defense response to virus, hemoglobin complex, platelet alpha granule membrane and cytokine binding. The downregulated genes were mainly characterized by positive regulation of cell death, regulation of MAPK cascade, regulation of DNA-binding transcription factor activity and transcription factor AP-1 complex. Several significant enriched pathways obtained in the KEGG pathway analysis were Influenza A, Hepatitis C, IL-17 signaling pathway, MAPK signaling pathway, Toll-like receptor signaling pathway. Finally, after the selected differential genes were introduced into STRING online software, the data information of protein interaction network was derived, and 12 core genes in the network were identified, they were CXCL8, PPBP, LPAR1, FPR2, GNG11, CXCL10, LPAR5, JUN, C3AR1, CCR2, CCR3, IRF2.

Conclusion: The genes and signal pathways related to SSc-PAH discovered by bioinformatics methods could not only provided new molecular markers for its diagnosis and treatment, but also provided new ideas for its related biological research.

POS0849 SEXUAL FUNCTION IS IMPAIRED IN WOMEN WITH IDIOPATHIC INFLAMMATORY MYOPATHIES COMPARED TO HEALTHY CONTROLS

B. Heřmánková[1,2], M. Špiritović[1,2], S. Oreska[2,3], H. Štorkánová[2,3], H. Smucrova[2], M. Komarc[4], M. Klein[2,3], K. Pavelka[2,3], L. Šenolt[2,3], H. Mann[2,3], J. Vencovský[2,3], M. Tomčík[2,3]. *[1]Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Prague, Czech Republic*;

[2]*Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic*; [3]*First Faculty of Medicine, Charles University, Department of Rheumatology, Prague, Czech Republic*; [4]*Faculty of Physical Education and Sport, Charles University, Department of Methodology, Prague, Czech Republic*

Background: Idiopathic inflammatory myopathies (IIM) are rare diseases characterized by chronic muscle inflammation and multiple organ involvement. These serious clinical manifestations can be associated with significant impairment of quality of life, including sexual life.

Objectives: This study aimed to compare sexual function in patients with IIM to age-/sex-matched healthy controls (HC) and determine the potential impact of clinical features on sexual function.

Methods: In total, 62 women with IIM [mean age: 53.1, disease duration: 5.2 years, dermatomyositis (DM, 29)/ polymyositis (PM, 27)/ necrotizing myopathy (IMNM, 5)/ inclusion body myositis (IBM, 1)], who fulfilled the Bohan/ Peter 1975 criteria for DM/PM, or ENMC criteria for IMNM or IBM, and 62 healthy controls (HC) (mean age: 53.1) without rheumatic diseases filled in 11 well-established and validated questionnaires assessing sexual function (FSFI, SFQ28, BISF-W, SQoL-F), pelvic floor function (PFIQ-7, PISQ-12), fatigue (FIS, Fatigue Impact Scale), physical activity (HAP, Human Activity Profile), disability (HAQ, Health Assessment Questionnaire), depression (BDI-II, Beck's Depression Inventory-II), and quality of life (SF-36, Medical outcomes study Short Form 36 – PCS, Physical Component Summary; MCS, Mental Component Summary). A routine laboratory testing was performed. Data are presented as median (IQR).

Results: Patients with IIM reported significantly greater prevalence and severity of sexual dysfunction (FSFI, BISF-W, SFQ28, SQoL-F) and pelvic floor dysfunction (PISQ-12, PFIQ-7) compared to HC (Table 1). The prevalence of sexual dysfunction in patients with IIM according to the FSFI cut-off score was 59%. Worse scores in IIM patients were associated with greater muscle weakness of m. gluteus maximus [MMT: FSFI (r=0.289, p=0.035), PFIQ-7 (r=-0.407, p=0.003)], m. gluteus medius [MMT: PFIQ-7 (r=-0.381, p=0.005)], more pronounced fatigue [FIF: SQoL-F (r=-0.412, p=0.003)], severer depression [BDI-II: SQoL-F (r=-0.459, p=0.0007)], worse functional disability [HAQ: FSFI (r=-0.436, p=0.005)], reduced physical activity [HAP: FSFI (r=0.403, p=0.001), SQoL-F (r=0.368, p=0.007)], and decreased quality of life [SF-36 PCS: FSFI-total (r=0.381,p=0.002), SF-36 MCS: SQoL-F (r=0.407, p=0.002)]. We did not observe any associations with disease duration, the current prednisone dose, or serum levels of muscle enzymes.

Conclusion: Women with IIM reported significantly impaired sexual function and pelvic floor function compared to age-/sex-matched healthy controls. Worse scores in IIM were associated with disease-related features.

Table 1. Sexual function and pelvic floor function in women with IIM and healthy controls

Questionnaire: score range (meaning)	IIM (n=62)	HC (n=62)	p-value
FSFI: Female Sexual Function Index: 2 (worst) - 36 (best)	18.2 (3.2-28.5)	28.4 (14.4-32.1)	**p=0.006**
BISF-W: Brief Index of Sexual Function for Women: -16 (worst) - 75 (best)	18.6 (2.7-32.3)	34.0 (8.0-44.7)	**p=0.004**
SQoL-F: Sexual Quality of Life Questionnaire – Female: 0 (worst) - 100 (best)	60.0 (41.4-83.6)	86.7 (70.8-95.6)	**p<0.0001**
PISQ–12: Pelvic Organ Prolapse/Urinary Incontinence Sexual Questionnaire short form: 0 (best) - 48 (worst)	14.5 (9.0-18.0)	8.0 (5.0-12.0)	**p<0.0001**
PFIQ7: Pelvic Floor Impact Questionnaire – short form 7: 0 (best) - 300 (worst)	4.8 (0.0-23.8)	0.0 (0.0-4.8)	**p=0.052**
SFQ-28: Sexual Functioning Questionnaire-28 desire: 5 (worst) - 31 (best)	18.0 (13.3-20.0)	19.0 (17.0-22.0)	**p=0.042**
SFQ-28 arousal sensation: 4 (worst) - 20 (best)	9.5 (7.0-11.0)	12.0 (9.0-14.3)	p=0.082
SFQ-28 arousal lubrication: 2 (worst) - 10 (best)	6.0 (4.0-8.0)	7.0 (5.0-9.0)	p=0.112
SFQ-28 arousal cognitive: 2 (worst) - 10 (best)	6.0 (4.3-7.0)	6.0 (5.0-7.3)	p=0.235
SFQ-28 orgasm: 1 (worst) - 15 (best)	11.0 (8.0-13.0)	12.0 (9.8-13.0)	p=0.279
SFQ-28 pain: 2 (worst) - 15 (best)	12.0 (10.0-15.0)	15.0 (13.0-15.0)	**p=0.004**
SFQ-28 enjoyment: 6 (worst) - 30 (best)	19.0 (14.3-24.3)	23.0 (19.0-25.0)	**p=0.027**
SFQ-28 partner: 2 (worst) - 10 (best)	9.0 (8.0-10.0)	10.0 (9.0-10.0)	**p=0.012**

POS0850 NAILFOLD CAPILLARY DILATIONS IN RAYNAUD'S PHENOMENON: QUANTIFYING A PREDICTIVE THRESHOLD FOR THE 'SCLERODERMA PATTERN'

G. Pacini[1], M. Pendolino[1], C. Pizzorni[1], E. Gotelli[1], A. Sulli[1], L. Carmisciano[2], S. Paolino[1], V. Smith[3,4], M. Cutolo[1]. [1]*IRCCS Polyclinic San Martino, University of Genova, Laboratory of Experimental Rheumatology and Academic Division of Rheumatology, Postgraduate School of Rheumatology, Department of Internal Medicine and Specialties, Genova, Italy*; [2]*University of Genova, Biostatistics Unit, Department of Health Sciences, Genova, Italy*; [3]*Ghent University Hospital, Department of Internal Medicine, Department of Rheumatology, Gent, Belgium*; [4]*VIB-UGent Center for Inflammation Research, Unit for Molecular Immunology and Inflammation, Gent, Belgium*

Background: Non-specific abnormalities could be detected by nailfold videocapillaroscopy (NVC) in subject with primary Raynaud's Phenomenon (RP) several years before the clinical onset of connective tissue diseases (CTD)s [1]. Previous findings from our group proved that ≤30 µm capillary dilations in RP patients have a negative predictive value for developing the 'scleroderma pattern' during follow-up [2].

Objectives: To investigate the role of NVC >30 µm capillary dilations as positive predictive factors of the 'scleroderma pattern' in RP patients later developing systemic sclerosis (SSc)-related RP.

Methods: A 10-year retrospective NVC-based investigation evaluated the dataset of sequential NVCs of 18 RP patients later developing SSc (cases) and 19 sex- and age-matched RP patients later developing other CTDs (controls). Both cases and controls had ≥1 NVC performed before the 'scleroderma pattern'/CTD diagnosis (basal NVC) showing >30 µm dilated capillaries. Each NVC was qualitatively and semi-quantitatively assessed, recording number of total capillaries, number and average/site-specific diameters (arterial, apical, venous) of >30 µm dilated capillaries [3]. Statistical analysis was performed to stratify the risk of developing the 'scleroderma pattern'.

Results: Significant differences of capillary diameters were observed between cases and controls both at basal NVC and during follow-up (p<0.001). The proportion of >30 µm dilated capillaries in basal NVC was the strongest predictor of 'scleroderma pattern' in a median 3-year time, with a 27% cut-off (PPV 0.79, 95%CI 0.54,0.94; p<0.001). Additional "Higher risk" NVC hallmarks for 'scleroderma pattern' development were apical diameter >40 µm (p<0.001), venous diameter >25 µm (p<0.05) and average diameter ≥35 µm (p<0.005). Conversely, CTDs patients showed a stable NVC 'non-scleroderma pattern' over a median 10-year time.

Conclusion: This is the first study to show that NVC-detected homogeneous and progressive capillary loop dilations in RP patients significantly contribute to predict the 'scleroderma pattern' evolution within a median 3-year time, possibly providing a "very early" window of opportunity in SSc pre-clinical stages.

POS0851 IDENTIFICATION OF HUB GENES AND PATHWAYS IN DERMATOMYOSITIS BY BIOINFORMATICS ANALYSIS

C. Zheng[1], S. X. Zhang[2,3,4], R. Zhao[2,3,4], L. Cheng[1], T. Kong[1], X. Sun[1], S. Feng[5], Q. Wang[6], X. Li[2,3,4], Q. Yu[7], P. F. He[8]. *[1]Shanxi Medical University, School of Management, Taiyuan, China*; *[2]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; *[3]Shanxi Li Xiaofeng Medical Groups, Department of Rheumatology, Taiyuan, China*; *[4]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; *[5]Shanxi Medical University, School of Humanities and Social Sciences, Taiyuan, China*; *[6]Shanxi Medical University, Basic Medical College, Taiyuan, China*; *[7]Shanxi Medical University, Medical Data Sciences/School of Management, Taiyuan, China*; *[8]Shanxi Medical University, Medical Data Sciences, Taiyuan, China*

Background: Dermatomyositis (DM) is a chronic systemic autoimmune disease characterized by inflammatory infiltrates in the skin and muscle[1]. The genes and pathways in the inflamed myopathies in patients with DM are poorly understood[2].
Objectives: To identify the key genes and pathways associated with DM and further discover its pathogenesis.
Methods: Muscle tissue gene expression profile (GSE143323) were acquired from the GEO database, which included 39 DM samples and 20 normal samples. The differentially expressed genes (DEGs) in DM muscle tissue were screened by adopting the R software. Gene ontology (GO) and Kyoto Encyclopedia of Genome (KEGG) pathway enrichment analysis was performed by Metascape online analysis tool. A protein-protein interaction (PPI) network was then constructed by STRING software using the genes in significantly different pathways. Network of DEGs was analyzed by Cytoscape software. And degree of nodes was used to screen key genes.
Results: Totally, 126 DEGs were obtained, which contained 122 up-regulated and 4 down-regulated. GO analysis revealed that most of the DEGs were significantly enriched in type I interferon signaling pathway, response to interferon-gamma, collagen-containing extracellular matrix, response to interferon-alpha and bacterium, positive regulation of cell death, leukocyte chemotaxis. KEGG pathway analysis showed that upregulated DEGs enhanced pathways associated with the hepatitis C, complement and coagulation cascades, p53 signaling pathway, RIG-I-like receptor signaling, Osteoclast differentiation, and AGE-RAGE signaling pathway. Ten hub genes were identified in DM, they were ISG15, IRF7, STAT1, MX1, OASL, OAS2, OAS1, OAS3, GBP1, and IRF9 according to the Cytoscape software and cytoHubba plugin.
Conclusion: The findings from this bioinformatics network analysis study identified the key hub genes that might provide new molecular markers for its diagnosis and treatment.

POS0852 HIGH DOSE INTRAVENOUS PULSE METHOTREXATE IN REFRACTORY EOSINOPHILIC FASCIITIS: WHAT ARE THE ADVERSE EVENTS?

G. Geurts[1], J. Mertens[2], N. Van Herwaarden[1], E. De Jong[3], R. M. Thurlings[1]. *[1]Radboudumc, Rheumatology, Nijmegen, Netherlands*; *[2]Jeroen Bosch Ziekenhuis, Internal Medicine, Nijmegen, Netherlands*; *[3]Radboudumc, Dermatology, Nijmegen, Netherlands*

Background: Eosinophilic Fasciitis (EF) is a disease of unknown origin initially characterized by limb or trunk edema, and collagenous thickening of the subcutaneous fascia in later stages. Eosinophilia in peripheral blood is commonly observed. Being a rare disease, evidence regarding treatment is mainly based on case series and anecdotal evidence. The mainstay systemic treatment is prednisone, and Methotrexate (MTX) up to doses of 25 mg/week is the leading prednisone-sparing agent. Mycophenolate can be considered in refractory cases. As an alternative we explored the use of intravenous (i.v.) pulse MTX. We already showed this to be a potentially effective and safe treatment option in a prospective single-arm study[1], but more data on adverse events (AEs) are needed.
Objectives: To present an overview of AEs of high dose i.v. pulse MTX in refractory EF.
Methods: Adult patients with EF based on clinical appearance combined with histology and/or MRI, who were unresponsive to prednisone combined with low-dose MTX or presenting with severe disease, were selected for this retrospective cohort study. Patients received 6-9 monthly infusions of 4 mg/kg MTX followed by oral folinic acid rescue therapy, which is comparable to treatment schedules for trophoblast disease. An additional number of six pulses could be administered in case of a partial effect or flare. Safety data were monitored during each visit and classified according to the Common Terminology Criteria for Adverse Events (CTCAE) from the National Institute of Health (2009).
Results: Twenty-seven patients (26 with EF, one with deep linear morphea) were included in this study (five males), with a mean age of 59 (sd 11.5) years, based on clinical presentation and histology and/or MRI. Previous treatment data were available for 22 patients of which 21 received oral prednisone (20-60 mg) whether or not combined with low dose MTX and/or UVA1 therapy. All patients reported ≥ 1 AEs at some stage, exactly 100 in total. '*Gastro-intestinal disorders*' (n=36) and '*General disorders and administration site conditions*' (n=15) were most common; especially nausea (n=6) and fatigue (n=11). One patient was hospitalized for blood transfusion. In four cases, treatment was discontinued due to AEs (acute kidney injury (AKI), depression, nausea/vomiting, and leukopenia resp.). Each reported AE appeared reversible. The patient with AKI had an MTX level in the toxic range; methotrexate-induced crystal nephropathy seemed the most likely explanation, probably due to a combination of high body weight (and thus high absolute dosage of MTX) and the concomitant use of omeprazole. Oral folinic acid rescue therapy was prolonged, together with 500 cc i.v. fluid, after which kidney function normalized.

Organ system	AE	Frequency
Gastro-intestinal disorders	Nausea, oral mucositis, diarrhea, vomiting, abdominal pain, anorexia	36
General disorders, administration site conditions	Malaise, fatigue	15
Respiratory, thoracic, mediastinal disorders	Cough and dyspnea	10
Skin and subcutaneous tissue disorders	Skin hyperpigmentation, hair loss, alopecia, other	9
Nervous system	Headache, nerve abducens disorder	7
Infections and infestinations	Skin, urinary tract, upper respiratory tract, other	6
Blood, lymphatic system disorders	Anemia, leukopenia, pancytopenia	4
Psychiatric conditions	Depression	3
Renal, urinary disorders	Acute Kidney Injury	1
Other systems		9
		100

Conclusion: AEs were common among patients receiving high dose i.v. pulse MTX, especially nausea and fatigue, but were generally mild and reversible in all cases. This is in line with studies performed with patients with trophoblast disease. One episode of reversible AKI occurred that seemed to be related to high body weight and the use of concomitant medication. The safety profile of i.v. pulse MTX thus seems auspicious, but the case of AKI illustrates that further data on safety is needed.

POS0853 DECREASE IN ANTI-TOPOISOMERASE-1 ANTIBODY TITER IN PATIENTS WITH SYSTEMIC SCLEROSIS DURING LONG-TERM RITUXIMAB THERAPY

L. Garzanova[1], L. P. Ananyeva[1], O. Koneva[1], O. Desinova[1], O. Ovsyannikova[1], M. Starovoytova[1], R. Shayakhmetova[1], S. Glukhova[2], M. Cherkasova[3]. *[1]VA Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, MOSCOW, Russian Federation*; *[2]VA Nasonova Research Institute of Rheumatology, Educational and Methodical Department, Moscow, Russian Federation*; *[3]VA Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology, Moscow, Russian Federation*

Background: Rituximab (RTX) is a new option in the treatment of systemic sclerosis (SSc) [1]. There is not enough data on changes in the level of autoantibodies and their clinical significance during RTM therapy. There are only a few reports on the higher efficiency of RTX in patients (pts) with SSc positive for anti-topoisomerase-1 antibodies (a-Topo-1), therefore the study of this issue might be interested.
Objectives: To compare clinical parameters and B-lymphocytes (B-lymph) level in SSc pts depending on the presence or absence of a-Topo-1 during RTX therapy with prospective long-term follow-up.
Methods: This study included 88 pts with SSc. The mean follow-up period was 26,3±10,7 months. The mean age was 47years (17-71), female-73 pts (83%), the diffuse cutaneous subset of the disease had 50 pts (57%). Symptoms of the interstitial lung disease (ILD) were observed in 70 pts (80%). The mean disease duration was 5,9±4,8 years. The cumulative mean dose of RTX was 2,9±1,1 grams. All patients received prednisone at a dose of 11,7±4,4 mg, immunosuppressants received 42% of them. There were 63 pts positive for a-Topo-1 and 25 pts - negative. The pts of the compared groups did not differ in the main demographic and clinical parameters, excepting lung involvement. In a-Topo-1 positive group 55 (87%) pts had ILD and only 15 (60%) – in a-Topo-1-negative group (p=0,02). The results at baseline and at the end of the follow up are presented in the form of mean values and changes in parameters (delta).
Results: Considering the entire cohort, an improvement of almost all outcome parameters was found. When a-Topo-1 positive and a-Topo-1-negative pts were analyzed separately, we observed a significantly higher decrease in the activity score, depletion of B-lymph, an increase in forced vital capacity (FVC) and diffusion capacity for carbon monoxide (DLCO) in a-Topo-1 positive group of pts (table 1).

Table 1. Changes of the main outcome parameters depending on the presence of a-Topo-1 on RTX therapy.

Parameters	a-Topo-1 positive pts	a-Topo-1 negative pts	P
Delta Activity score (EScSG-AI)	1,79	0,9	0,001
Delta Rodnan skin score (mRSS)	4,9	5,2	NS
Delta B-lymphocytes (absolute count)	0,212	0,193	0,001
Delta FVC*, %	8,64	6,46	0,001
Delta DLCO**, %	2,86	0,032	0,001

*FVC - forced vital capacity % predicted, **DLCO - diffusion capacity for carbon monoxide % predicted

The a-Topo-1 level decreased from 174,2±50,1 to 148,1±66,1 units/ml (p=0,0009). In this group, a-Topo-1 became negative in 5 pts (7,9%). The disappearance of a-Topo-1 positivity was accompanied by a more pronounced decrease in mRSS (delta mRSS=7,4) and a higher depletion of B-lymph. There was a higher cumulative dose of RTX (4±1,4grams) in this 5 pts compared with the pts who sustained a-Topo-1 positivity. There was a moderate negative statistically significant correlation between the a-Topo-1 and the total dose of RTX (r=-0,298, p=0,017). A moderate negative statistically significant correlation was found between the a-Topo-1 and FVC (r=-0,322, p=0,009).
Conclusion: In our study, the a-Topo-1 level significantly decreased during RTX therapy in Russian pts. The decrease in a-Topo-1 titers correlated with the total dose of RTX and was accompanied by a decrease in mRSS, disease activity index and an increase in FVC and DLCO. A higher efficacy of RTX in the a-Topo-1 positive group with prevalence of ILD was revealed, therefore a-Topo-1 positivity could be considered as a predictor of a better response to RTX therapy.

POS0854 SEX DIFFERENCES IN SYSTEMIC SCLEROSIS PATIENTS IN A SINGLE CENTER IN EASTERN EUROPE

A. Petre[1], L. Groseanu[1,2], A. Balanescu[1,2], V. Bojinca[1,2], D. Opris-Belinski[1,2], F. Berghea[1,1], I. Saulescu[1,2], D. Mazilu[1,2], S. Daia[1,1], A. Borangiu[1,2], C. L. Constantinescu[1,2], M. Abobului[1,2], M. M. Negru[1,2], C. Cobilinschi[1,2], D. Predeteanu[1], R. Ionescu[1,2]. *[1]Sf Maria Clinical Hospital, Bucharest, Romania, Department of Internal Medicine and Rheumatology, Bucharest, Romania*; *[2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, Department of Internal Medicine and Rheumatology, Bucharest, Romania*

Background: The low overall prevalence of systemic sclerosis (SSc) and the low proportion of male patients have resulted in a scarcity of studies assessing sex differences in SSc patients, and contradictory results have often been observed.
Objectives: The aim of the study was to assess differences in disease manifestations in a cohort of SSc patients according to gender.
Methods: We performed a retrospective observational study using data extract from the EULAR scleroderma trials and research (EUSTAR) cohort 096.We looked at sex influence on disease characteristics at baseline and then focused on patients with at least 2 years of follow-up to estimate the effects of sex on disease progression and survival.
Results: 173 patients with SSc were available for the baseline analyses. Males were older (52,96 vs 45,88, p=0.009), were more likely to smoke (73% vs 7%, p<0,001), had more frequent diffuse skin involvement (73,1% vs 56,5%,p<0.01), higher modified Rodnan skin score (34,61% vs 17%, p=0.01) and activity score(84,62% vs 46,26%,p<0.001) and were more often associed with positive acute phase reactants (65,38% vs 38,77%, p=0.01). Severe interstitial lung disease was more common in males (59,09% vs 27,53%, p=0.003), also the presence of tendon friction rubs was more frequent in this sex group (23,07% vs 8,84%, p=0.032).
In the longitudinal analysis after a mean follow-up of 3,5(±0,65) years, male sex was associated with a higher risk of scleroderma renal crisis (OR:9.45 (1.49 to 59.69); p=0.004), digital contractures (OR:8,2 (3,1 to 21,9); p<0,001), arrhythmias (OR:3,37 (1.36 to 8,34); p=0.006), pulmonary fibrosis (OR: 3.56, (1.51 to 8.41); p=0.003), pulmonary hypertension (OR: 3.01 (1.19 to 7,59); p=0.016), severe vascular involvement (OR:2,86, (1,22 to 6,73); p=0.013) and low ventricular ejection fraction (OR: 2,84, (1.2 to 6,73); p=0.014). Males had significantly reduced survival time after diagnosis (p=0,004). The most frequent causes of death were scleroderma renal crisis in males and pulmonary hypertension in females.
Conclusion: Although more common in women, SSc appears as strikingly more severe in men. Our results demonstrate a higher risk of severe organ involvement and poor prognosis in men. These results raise the point of including sex in the management and the decision-making process.

Background: Current treatments for systemic sclerosis-associated interstitial lung disease (SSc-ILD) are characterised by different attributes such as mode of administration, adverse events (AE) and efficacy. Physicians and patients often have different perspectives on treatments, thus shared decision-making between patients and physicians is essential. An understanding of patients' decision processes when weighing treatment attributes and the trade-offs they are willing to make is important for shared decision-making.
Objectives: The study aimed to 1) identify relevant treatment attributes, 2) elicit patient preferences for these attributes and 3) quantify preference as relative attribute importance (RAI; a higher RAI indicates that more of the variability in patients' responses may be explained by changes in the attribute); and maximum acceptable risk (MAR) of diarrhoea, nausea and/or vomiting (MAR is a trade-off measure that evaluates attributes in risk-equivalences as a unit of measurement).
Methods: A discrete choice experiment (DCE) was created, based on a literature review, a patient advisory board, qualitative patient interviews, and a workshop involving SSc-ILD expert physicians. Seven SSc-ILD treatment attributes were identified: 1) mode of administration; 2) shortness of breath; 3) skin tightness; 4) cough; 5) tiredness; 6) risk of gastrointestinal tract (GIT) AEs; and 7) risk of serious and non-serious infections. The levels of AE risk were informed by frequencies observed in clinical trials and patient input during the interviews. The DCE was integrated into an online survey, which asked patients to make repeated choices between two alternatives described by varying levels of included attributes. Patients with SSc-ILD were recruited by physician referral from Switzerland, Norway, France, Germany and the USA. DCE data were analysed using a logit model, and RAI and MAR measures were calculated.
Results: A total of 231 patients with physician-confirmed SSc-ILD (mean age 52.6±13.2 years; 54% diagnosed for >5 years) completed the survey. Patients with SSc-ILD mostly preferred twice-daily oral treatments ($p<0.001$) and infusion every 6–12 months ($p<0.001$) over monthly infusions. Patients' choices were mostly affected by the risk of GIT AEs (RAI=25%; 95% CI 22–28%) and risk of infections (RAI=20%; 95% CI 16–24%). Improvements in shortness of breath and type and severity of cough were jointly more important than improvement in skin tightness ($p<0.001$).
Patients accepted an additional 21% risk (95% CI 13–29%) of GIT AEs if they could reduce the frequency of infusions from monthly to 6–12 monthly, or accepted an extra 15% (95% CI 7–23%) increase in risk if changing to an oral treatment twice daily. Among symptoms, an additional 28% (95% CI 20–36%) risk of GIT AEs was considered acceptable if the severity of patients' persistent cough was reduced to a level that was easier to tolerate, even if it remained persistent. Similarly, a 37% (95% CI 28–46%) increase in the risk of GIT AEs was acceptable if it resulted in breathlessness during routine activities rather than breathlessness at rest. Finally, patients were willing to accept an additional 36% risk (95% CI 27–45%) of GIT AEs if it reduced their risk of non-serious infections from 30% to 15% and of serious infections from 10% to 5%.
Conclusion: This is the first study to quantitatively elicit patients' preferences for attributes of SSc-ILD treatments. Preferences were driven by safety, efficacy and technical considerations. Patients showed willingness to make trade-offs, providing a firm basis for shared decision-making in routine clinical practice.

POS0856 CLINICAL UTILITY OF BREATH-HOLDING TEST FOR MEASURING CARDIOPULMONARY FUNCTION IN PATIENTS WITH SYSTEMIC SCLEROSIS

J. Yeo[1], M. H. Kim[2], J. W. Park[2], J. K. Park[2,3], E. B. Lee[2,3,4]. *[1]Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[2]Seoul National University Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[3]Seoul National University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[4]Seoul National University, Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul, Korea, Rep. of (South Korea)*

Background: Interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH) are major causes of death in systemic sclerosis (SSc). Six-minute-walk test (6MWT) is a standard outcome measure for exercise capacity in cardiopulmonary diseases. However, the results of 6MWT may not reflect real cardiopulmonary function of SSc patients in whom musculoskeletal system is frequently inflicted.
Objectives: This study aimed to evaluate the clinical utility of breath-holding test (BHT) in evaluating cardiopulmonary function in SSc patients, as compared with 6MWT.
Methods: Seventy-two patients with SSc were prospectively enrolled and underwent BHT and 6MWT with measurement of Borg score and Scleroderma Health Assessment Questionnaire (SHAQ). Data on diffusing capacity for carbon monoxide (DLCO, %), forced vital capacity (FVC, % and liters), and ejection fraction and pulmonary arterial systolic pressure (PASP) measured by transthoracic echocardiography (TTE), were also collected. For BHT, participants were required to make a maximum expiration followed by a maximum inspiration and to hold the breath as long as possible at maximum inspiratory level. This procedure was repeated three times, with 5-minute intervals. 6MWT was performed according to the American Thoracic Society guidelines. Pearson's correlation test was applied to demonstrate the relationship between BHT results and each clinical parameter.

Results: Among 72 (66 female) patients, mean (SD) age was 57.1 (11.1) years, modified Rodnan skin score 10.6 (10.5), SHAQ 0.64 (0.61) and 6MWT distance 473.5 (95.5) m. Mean BHT time was 35.05 (14.90) sec at the first time, 38.92 (16.14) sec at the second time, and 41.11 (17.71) sec at the third time. The BHT time showed a statistically significant negative correlation with Borg scale (pre-test, r = -0.336, p = 0.002; post-test, r = -0.252, p = 0.034; Figure 1 and Table 1), while 6MWT showed a negative correlation with only post-test Borg scale (pre-test, r = -0.113 p = 0.343; post-test, r = -0.351 p = 0.002; Table 1). The BHT time was positively correlated with DLCO (%, r = 0.409, p < 0.001) and FVC (liters, r = 0.402, p < 0.001) (Table 1). We also found a statistically significant correlation between BHT time and SHAQ score (r = -0.451, p < 0.001; Table 1). However, EF and PASP by TTE showed no significant relationship with BHT time (EF, r = -0.108, p = 0.374; PASP, r = -0.246, p = 0.054; Table 1).

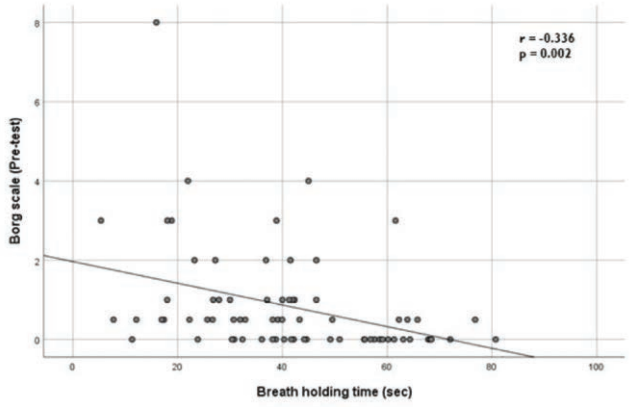

Figure 1. Association of Borg dyspnea scale with breath-holding time.

Table 1. Pearson's correlation coefficients (r) for the relation between BHT and clinical parameters in comparison to 6MWT.

	Pre-test Borg scale	Post-test Borg scale	DLCO (%)	FVC (L)	FVC (%)	FVC /DLCO	EF (%)	PSAP (mm Hg)	SHAQ (score)
BHT (sec)	-0.366**	-0.252*	0.409***	0.402**	0.191	-0.244***	-0.108	-0.246	-0.451***
6MWT (m)	-0.113	-0.351**	0.297*	0.321**	0.063	-0.250*	0.137	-0.354**	-0.531***

BHT, breath-holding test; 6MWT, 6-minute-walk test; DLCO, diffusing capacity for carbon monoxide; FVC, forced vital capacity; EF, ejection fraction estimated by transthoracic echocardiography; SHAQ, Scleroderma Health Assessment Questionnaire.
* p < 0.05, ** p < 0.01, *** p < 0.001

Conclusion: The BHT is a simple, safe, and less time-consuming test, reflective of pulmonary parameters and SHAQ, as compared with 6MWT. Our results suggest that the BHT might be a useful surrogate marker of cardiopulmonary capacity in SSc patients.

POS0857 IMMUNOSUPPRESSANTS (CYCLOPHOSPHAMIDE AND MYCOPHENOLATE MOFETIL) VERSUS RITUXIMAB A SINGLE-AGENT THERAPY IN SCLERODERMA-RELATED INTERSTITIAL LUNG DISEASE: REAL CLINICAL PRACTICE

O. Koneva[1], L. P. Ananyeva[1], L. Garzanova[1], O. Desinova[1], O. Ovsyannikova[1], M. Starovoytova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation*

Background: Although interstitial lung disease (ILD) occurs in the majority of patients with systemic sclerosis (SSc), treatment options for this manifestation is empirical and at present consists of Cyclophosphamide (CyP) or Mycophenolate Mofetil (MMF). However, the immunosuppressants (IS) use leads to rather limited improvement of ILD and is associated with many adverse reactions. The search for novel, more efficacious agents has been continued, such as attracting much attention RTM. However, the limited number of RTM-treated patients, considerably different dose regimens, cumulative doses, and observation periods does not allow univocal conclusions on RTM efficacy or definitive recommendations on RTM use in the patients with SSc.

Objectives: To compare the impact of IS and RTM a single-agent therapy on SSc clinical manifestation and activity, and the safety of these agents in the open-label prospective non-randomized study.

Methods: 116 patients with the confirmed SSc diagnosis and ILD evidence based on MSCT findings were enrolled into the study. All patients received low and moderate-dose glucocorticoids regimens. Group A(n=35) received RTM as a single therapy agent for 13.3±2.3 months at total dose 1.35±0,5g (the patient's average age was 45.0±15 years, with female proportion 80%; SSc duration 6.3±2.3 years; diffused/localized forms 1.3/1). Group B (n=36) received parenteral CyP for 12±6 months at total dose 10.6±5 g (the average age 47±12 years, females 92%, SSc duration 5.0±4.8 years, diffused/localized forms 1.6/1). Group C (n=45) received MMF for 12±6 months at a dose of 2 grams per day (the average age 49±13 years, females 91%, SSc duration 7.1±5 years, diffused/localized forms 1/1.3). The time courses of FVC, modified skin count (mRss, points), activity index (EScSG, points) were assessed into the study.

Results: In Groups A, B and C the therapy was associated with significant decrease in mRss (p=0.02, 0.008, 0.007, respectively) and EScSG (p=0.00017, 0.000165, 0.01, respectively).

Evaluation of FVC time course revealed significant FVC increase only in Groups A (p= 0.002) and B (p=0.034), with median increment about 5%.

In Groups A and B 10% FVC increase was found in the third of the patients thus exceeding respective parameter twice in Group C (p=0.15 and 0.008, respectively). The patient percentage with FVC decrease by ≥10% did not differ significantly between groups.

The therapy was better tolerated in RTM-treated group: during RTM therapy adverse reactions emerged in lower proportion of the patients (4/11%) compared with CyP (19/53%, p=0.0000) and MMF-treated group (12/27%, p=0,5).

Parameters	Group A	Group B	Group C
Activity Index 1 *M ± SD*	2.8±1.4*	3.2±1.9*	1.9±1.5*
Activity Index 2 *M ± SD*	1.4±1.2*	1.4±1.2*	1.2±0.9*
Skin count 1 *M ± SD*	11.5±9.5 *	11.2±7.9 *	7.5±6.9 *
Skin count 2 *M ± SD*	8.2±6.2 *	7.9±6.8 *	4.8±3.9 *
FVC 1 *M ± SD*	78.7±20.0 *	80.5±20.1*	90.3±20.8
FVC 2 *M ± SD*	84.2±20.0*	85.8±20.4*	92.2±21.0
Δ FVC %	5.3 [0.8; 11.1]	5.7 [0; 11.2]	1.9 [-3.5; 6.0]
FVC increment by ≥10%, n/%	9/26	14/31	6/13.3
FVC decrement by ≥10% n/%	2/5.7	2/4.4	4/8.9

Notes: *in Parameters column 1 = before treatment, 2 = after treatment; M ± SD = mean value and standard deviation; * = significant difference between the vales measured before and after the treatment*

Conclusion: All agents effectively alleviated skin induration and EScSG, but only RTM and CyP significantly improved FVC. The RTM single therapy was better tolerated compared to IS. The study findings substantiate potential use an RTM single therapy both as a first-line agent for ILD treatment in the patients with a progressive course of ILD damage SSc, and in the event of CyP inefficacy of poor tolerability. The MMF use is more preferable in patients with less pronounced ILD.

POS0858 POTENTIAL EFFICACY PREDICTORS OF ANTI-B-CELL THERAPY IN THE PATIENTS WITH SYSTEMIC SCLEROSIS ASSOCIATED WITH INTERSTITIAL LUNG DISEASE

O. Koneva[1], L. P. Ananyeva[1], L. Garzanova[1], O. Desinova[1], O. Ovsyannikova[1], M. Starovoytova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation*

Background: Rituximab (RTM) is considered as a promising therapeutic agent for treatment of With Interstitial Lung Disease (ILD) in the patients with systemic sclerosis (SSc). However, the limited number of RTM-treated patients, considerably

varying dose regimens, cumulative doses and observation periods, lack of data on potential predictors of RTM therapy response do not allow univocal conclusions on RTM efficacy or definitive recommendations on RTM use in the patients with SSc.
Objectives: The study of potential efficacy predictors of anti-B-cell therapy in the patients with SSc associated with ILD.
Methods: 90 patients with SSc-ILD verified by multispiral computed tomography were enrolled to the study and received RTM therapy for 12-42 months at cumulative dose 2.9±1.1 grams (disease duration 5.9±4.8 years, diffused/limited SSc 1.3/1, average age 47 ± 13.6 years, females 83%). All patients received low or moderate dose glucocorticoids. 45 patients received RTM in addition to immunosuppressive therapy (cyclophosphamide and mycophenolate mofetil) because of inadequate efficacy of immunosuppressants. After evaluation of FVC trends in the patients receiving RTM the overall study population was divided into two patient groups for the analysis: group A (n=35) comprised the patients with ≥10% FVC increase (disease duration 6.1±5.8 years, diffused/limited SSc 1,3/1, average age 50±12 years, females 86%, cumulative RTM dose 3.2±1.24 grams), and group B (n=11) comprised the patients with ≥5% FVC decrease (disease duration 5.2±4, diffused/limited SSc 0.8/1, average age 43±16, females 72%, cumulative RTM dose 2.5±0.99 grams). Subsequently correlation analysis was made to clarify the association between delta FVC and a number of clinical (age, gender, duration and form of SSc, modified skin count, presence of gastroesophageal reflux, mPAP, SSc activity (EScSG, points), cumulative RTM dose, immunosuppressive therapy) and laboratory parameters (ESR, ANA-HEP-2, a-Scl-70, CRP, B cell count).
Results: In the overall patient population RTM therapy was associated with significant FVC increase from 77.0±19.9 % to 84.7±20.9% (p=0.000000), with median FVC increment 6.6% [0;14.1].
In group A FVC increased from 75.3±19.9 to 94.3±20.4) (p=0.000000), with median FVC increment 16.3 [12.6; 24.7].
In group B FVC decreased from 82.5 ±23.2 to 72,3±19.4 (p=0,000176), with median FVC decrement 10.4% [-13.4; -6].
Correlation analysis in groups A and B showed significant association of between delta FVC and the patient age (R=0.36), cumulative RTM dose (R=0.34) and EScSG during the last examination (1.2±.,0 and 3.1±1.4 in groups A and B, respectively; R=-0.42).
No significant correlation between delta FVC and any other tested parameters was found.
Conclusion: Therefore, older patients who received the cumulative rituximab dose more than 3 grams with suppressed SSc activity achieved greater FVC increase at the background of therapy. These data allow to consider the above parameters as potential predictors of response to anti-B-cell therapy in the patients with SSc-ILD.

POS0859 DEEP PHENOTYPING OF DERMATOMYOSITIS BASED ON LIPID FERROPTOSIS-RELATED GENES BY MACHINE LEARNING

J. Q. Zhang[1,2,3], S. X. Zhang[1,2,3], R. Zhao[1,2,3], J. Qiao[1,2,3], M. T. Qiu[1,2,3], S. Song[1,2,3], M. J. Chang[1,2,3], Y. Zhang[1,2,3], G. Y. Liu[1], P. F. He[4], X. Li[1,2,3]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*Shanxi Li Xiaofeng Medical Groups, Department of Rheumatology, Taiyuan, China*; [3]*Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; [4]*Shanxi Medical University, Medical Data Sciences, Taiyuan, China*

Background: Dermatomyositis (DM) is an idiopathic inflammatory myopathy with heterogeneous clinical manifestation that raise challenges regarding diagnosis and therapy[1]. Ferroptosis is a newly discovered form of regulated cell death that is the nexus between metabolism, redox biology, and rheumatic immune diseases[2]. However, how ferroptosis maintains the balance of lymphocyte T cells and affect disease activity in DM is unclear.
Objectives: To investigate an ferroptosis-related multiple gene expression signature for classification by assessing the global gene expression profile, and calculate the lymphocyte T cells status in the different subsets.
Methods: Gene expression profiles of skeletal muscle from DM samples were acquired from GEO database. GSE143323 (30 patients and 20 HCs) was selected as the training set. The GSE3307 contained 21 DM patients and was selected as the validation set. The 60 ferroptosis genes were obtained from previous literature[3]. The intersection of the global gene and ferroptosis genes was considered the set of significant G-Ferroptosis genes for further analysis. The "NMF" (R-package) was applied as an unsupervised clustering method for sample classification by using G-Ferroptosis genes expression microarray data from the training datasets. An ferroptosis score model was constructed. The performance of the ferroptosis genes-based risk score model constructed by the DM training set was validated in the batch-1 and batch-2 DM sets. Normalized ferroptosis genes training data was used to compare the ssGSEA scores of gene sets between the high risk and low risk group. The statistical software package R (version 4.0.3) was used for all analyses. *P* value < 0.05 were considered statistically significant.
Results: We selected 54 significant G-Ferroptosis genes for further analysis in training set. There were 2 distinct subtypes (high-ferroptosis-score groups and low-ferroptosis-score groups) identified in G-Ferroptosis genes cohort which were also identified in validation datasets (Fig.1A, C, D). Metallothionein 1G (MT1G) was a characteristic gene of low-ferroptosis-score group. The characteristic genes of high-ferroptosis-score group were acyl-CoA synthetase family member 2(ACSF2) and aconitase 1(ACO1) (Fig.1B). Patients in high-ferroptosis-score group had a lower level of Tregs compared with that of low-ferroptosis-score patients in both training and validation set (*P* <0.05, Fig.1E).
Conclusion: The biological process of ferroptosis is associated with the lever of Tregs, suggesting the process of ferroptosis may be involved in the disease progression of DM. Identificating ferroptosis-related features for DM might provide a new idea for clinical treatment.

POS0860 EFFICACY AND SAFETY OF TWO COURSES OF RITUXIMAB BIOSIMILAR ACELLBIA IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS: A PROSPECTIVE OBSERVATIONAL STUDY

L. P. Ananyeva[1], L. Garzanova[1], O. Desinova[1], M. Starovoytova[1], O. Koneva[1], O. Ovsyannikova[1], R. Shayakhmetova[1]. [1]*VA Nasonova Research Institute of Rheumatology, Laboratory of Microcirculation and Inflammation, Moscow, Russian Federation*

Background: Interstitial lung disease associated with systemic sclerosis (ILD-SSc) is a frequent manifestation of the disease, impairing the quality of life and the prognosis of the disease. The efficacy of rituximab (RTX) in patients (pts) with ILD-SSC have been shown [1]. The "biosimilar" versions of RTX might reduce the cost of therapy and increase pts accessibility to this treatment option. The RTX biosimilar Acellbia (ACB), "BIOCAD", has received approval in Russian Federation in 2014 for all indications held by reference RTX.
Objectives: to investigate the efficacy and safety of ACB in naive to biological therapy pts with ILD-SSc during at least 12 month of follow-up.
Methods: Twenty pts were included in prospective observational study. The pts were aged 49,7 (s.d.14) years, 14 (70%) were females, mean disease duration was 3,5±2,7years, with diffuse subset in 11 (55%), 13 (65%) were anti-topoisomerase positive, all pts has NSIP-pattern by HRCT. All pts were naive to ACB, received glucocorticoids in low doses, 10 (50%) pts were previously treated with immunosuppressants and 4(20%) of them continued to take mycophenolate mofetil as a concomitant therapy. Pts received two courses of ABC with the same scheme: 1 g repeated 1 week apart (4 g ACB in total). An assessment of basic measurements was obtained at baseline (Point 0), before the second course (after 7,2±1,7 mo, Point 1) and at the end of follow-up (13,4±1,6 mo, Point 2). The results are presented in the form of mean values and standard deviations.
Results: We observed a gradual improvement in the main parameters from Point 0 to Point 2 (table). Importantly, that at Point 1 there were no differences in most parameters, except for Rodnan skin score (mRSS) and the absolute number of B-lymphocytes (B-lymph), but at Point 2 there were significant differences between most basic outcome measures.

Table 1. Follow-up data of ACB treatment in ILD-SSC pts

Parameters	Point 0 (n=20)	Point 1 (n=20)	Point 2 (n=18)#	P 1-2	P 1-3
mRSS	12,75±11,1	8,25±7,72	6,16±5,65	0,002	0,002
FVC*, % pred	89,1±18,2	92,31±19,21	98,26±16,13	NS	0,0002
DLCO, % pred**	56,67±15,7	58,11±17,71	61,86±17,16	NS	0,019
SHAQ	1,13±0,628	0,98±0,678	0,61±0,495	NS	0,00001
IgG, g/l	12,61±2,348	11,5±1,61	10,19±2,18	NS	0,002
a-Topo-1, unit/ml	109,68±86,92	96,46±81,72	72,46±69,46	NS	0,004
B-lymph, absolute count	0,329±0,34	0,0016±0,003	0,00189±0,003	0,0004	0,001
Glucocorticoids, mg/day	11,0±2,7	10,75±2,0	9,4±2,3	NS	0,03

**FVC - forced vital capacity % predicted, **DLCO - diffusion capacity for carbon monoxide % predicted.# Of the 20 patients who received the second course, 2 (10%) dropped out the follow-up due to pregnancy (1) and lung cancer (1).*

The frequency and spectrum of adverse events (AE) corresponds to the known in the treatment of RTX, most AEs were classified as mild ones.There were 11 (55%) of AE in 9 (45 %) pts. Infections were observed in 7 (35%) pts: 4 cases of acute respiratory tract infections, 2 cases of positivity in interferon-gamma release assayand one case each of otitis, cystitis, cholecystitis (9 AE in total). One pts developed low limb vein thrombosis and one - lung cancer. There were no infusion-related reactions.
Conclusion: The data from this prospective pilot study showed the effectiveness of the ACB in ILD-SSc. The clinical effect of ACB arises gradually and the baseline outcome measures reliably improve by the end of the first year. Our study have demonstrated a well-tolerated safety profile. We believe that ACB can be prescribed at SSc-ILD as a first-line drug and/or in the form of monotherapy.

Background: Tocilizumab (TCZ) showed trends for improving skin fibrosis and prevented progression of lung fibrosis in patients with systemic sclerosis (SSc) in placebo-controlled randomised clinical trials (RCTs). However, safety and effectiveness of TCZ beyond these selected and enriched clinical trial populations in SSc is still unknown.
Objectives: To assess safety and effectiveness of TCZ treatment compared to standard of care in SSc patients from the large, multicentre, observational, real-life EUSTAR network/database using propensity score matching.
Methods: SSc patients from the EUSTAR network/database, who fulfilled the ACR/EULAR 2013 classification criteria, with a baseline and a follow-up visit at 12±3 months, receiving TCZ or standard of care (controls), were selected. The following variables were used for the propensity score matching (1:1): age at diagnosis, gender, disease subtype, baseline modified Rodnan skin score (mRSS), forced vital capacity (FVC), and diffusing capacity for carbon monoxide (DLCO), co-therapy with immunosuppressives, disease duration, and year of treatment. Primary endpoints were mRSS and FVC at 12±3 months follow-up compared between the groups, using paired t-tests. Secondary endpoints were the percentage of progressive/regressive patients for skin and lung at 12±3 months follow-up according to standard definitions (1,2). Sensitivity analyses assessed pre-processing decisions (selection of most recent vs. random observation for control patients with multiple suitable time intervals), as well as the matching method (optimal vs. exact matching). Missing values were addressed with 100-fold multiple imputation using chained equations. Safety data were analysed in all patients. The study including the statistical analysis plan was pre-registered at www.drks.de (DRKS-ID: DRKS00015537).
Results: We identified 93 SSc patients treated with TCZ and 2370 SSc patients with standard of care who fulfilled the inclusion criteria. Forty nine (57.7%) of the TCZ treated patients were diffuse, eight patients were not classified, disease duration was (mean±SD) 6.35±5.40 years, their baseline mRSS was 15.05±10.85, and 76 (81.7%) received immunosuppressive therapy in addition to TCZ.Through multiple imputation and propensity score matching, 100 imputed

sets of 93 pairs of TCZ/controls were generated. Comparison between groups showed consistent effects of TCZ across all pre-defined primary and secondary endpoints: mRSS was lower in the TCZ group (mean difference (95% confidence interval (CI)) -1.8 (-4.79 to 1.19), p=0.24, Figure 1A). Similarly, FVC % predicted was higher in the TCZ group mean difference (2.25, 95% CI -4.57 to 9.06), p=0.51, Figure 1B). Considering secondary endpoints, the percentage of skin progressors as well as lung progressors at follow up was lower in the TCZ group (odds ratio OR 0.67 (95% CI 0.07 to 6.41), p=0.74 and OR 0.53 (95% CI 0.16 to 1.7); p=0.2, respectively. Consistently, the percentage of regressors for skin (OR 1.6 (95% CI 0.56 to 4.54), p=0.38) and for lung (OR 1.74 (95% CI 0.66 to 4.58), p=0.26) was higher in TCZ. These results were robust regarding the sensitivity analyses. Safety analysis confirmed previously reported adverse event profiles.

Conclusion: In this large, observational, controlled, real-life EUSTAR study, effectiveness of TCZ did not reach statistical significance compared to standard of care treatment but showed consistent positive effects of TCZ on skin and lung fibrosis across all pre-defined primary and secondary endpoints confirming data from recent RCTs.

POS0862 NAILFOLD CAPILLAROSCOPY IN UNDIFFERENTIATED AND MIXED CONNECTIVE TISSUE DISEASES

C. Pizzorni[1], G. Ferrari[1], C. Schenone[1], E. Gotelli[1], S. Paolino[1], A. Sulli[1], G. Pacini[1], E. Alessandri[1], V. Smith[2], M. Cutolo[1]. *[1]Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic, Genoa, Italy*; *[2]Department of Rheumatology – Department of Internal Medicine – Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Ghent University Hospital, Ghent, Belgium*

Background: Microvascular damage is a frequent feature in connective tissue diseases (CTDs) and can be easily detected trough nailfold videocapillaroscopy (NVC) (1,2). Mixed and Undifferentiated connective tissue diseases (MCTD and UCTD) do not show a specific and unique NVC pattern (3). However, a variety of microvascular abnormalities can occur in these two CTDs, both non-specific or specific for the scleroderma like-pattern (3-5).

Objectives: To retrospectively assess and compare nailfold microangiopathy observed by NVC in MCTD and stable UCTD versus primary Raynaud's phenomenon (PRP) (6). In addition, the aim was to correlate NVC findings with serum levels of autoantibodies (Abs) against extractable nuclear antigen (ENA) detected in UCTD.

Methods: Files of fourty-six MCTD patients (Kasukawa's criteria) (mean age 42.8±16 SD years), fourty-seven UCTD patients (mean age 47.7±16.1 SD years), fifty-one PRP (mean age 45.9±17.3 SD years) were retrospectively evaluated in the study. Among UCTD and MCTD patients 95% of both showed Raynaud's phenomenon. Main NVC parameters (i.e. dilated capillaries, giant capillaries, microhemorrhages, abnormal shapes and number of capillaries) and related semiquantitative scale (score 0–3 for every parameter), were analyzed and compared between the two distinct CTD groups and PRP. Furthermore, ENA Abs (in particular, Ro/SSA, La/SSB, Scl70 and Jo1) were evaluated. The CTD patients were receiving different immunosuppressive treatments. Statistical analysis was performed by non-parametric tests.

Results: Among UCTD group, 36% of patients showed a normal NVC pattern, 53% had non-specific NVC abnormalities and 11% had a scleroderma like-pattern. The latter was significantly more frequent in MCTD than in UCTD ($p<0.001$), in fact 22 out of 46 (48%) MCTD patients presented a scleroderma-like pattern. On the other hand, normal pattern or non-specific NVC abnormalities were respectively found in 9% and 43% MCTD patients. Therefore, CTD patients showing giant capillaries, abnormal shapes (i.e. angiogenesis) and lower capillary density were significantly more affected by MCTD than UCTD ($p<0.001$). Finally, the absolute number of capillaries was found significantly lower in MCTD versus UCTD patients (mean 7±1.7 SD vs mean 9.2±1 SD, respectively, $p<0.001$). Not any statistical correlation was observed between NVC parameters and specific Abs ENA in UCTD. PRP showed a normal NVC pattern in 2% and non-specific capillary abnormalities in 98%, (including dilated capillaries and microhemorrhages).

Conclusion: NVC features in UCTD patients seem very close to the pattern observed in PRP (mostly non-specific capillary abnormalities), conversely in MCTD the scleroderma-like pattern was found significantly prevalent together with a significant capillary number reduction. The transition from the scleroderma-like to the scleroderma pattern (mean systemic sclerosis) is matter of actual investigation.
